In some situations, a count (frequency) is available for each category, or you can compress a large data set by creating a frequency variable for the categories before applying the PARETO procedure. *See PARETO5 in the SAS/QC Sample Library*

For example, you can use the FREQ procedure to obtain the compressed data set Failure2 from the data set Failure1.

```
proc freq data=Failure1;
  tables Cause / noprint out=Failure2;
run;
```

A listing of Failure2 is shown in Figure 15.8.

Figure 15.8 The Data Set Failure2 Created Using PROC FREQ

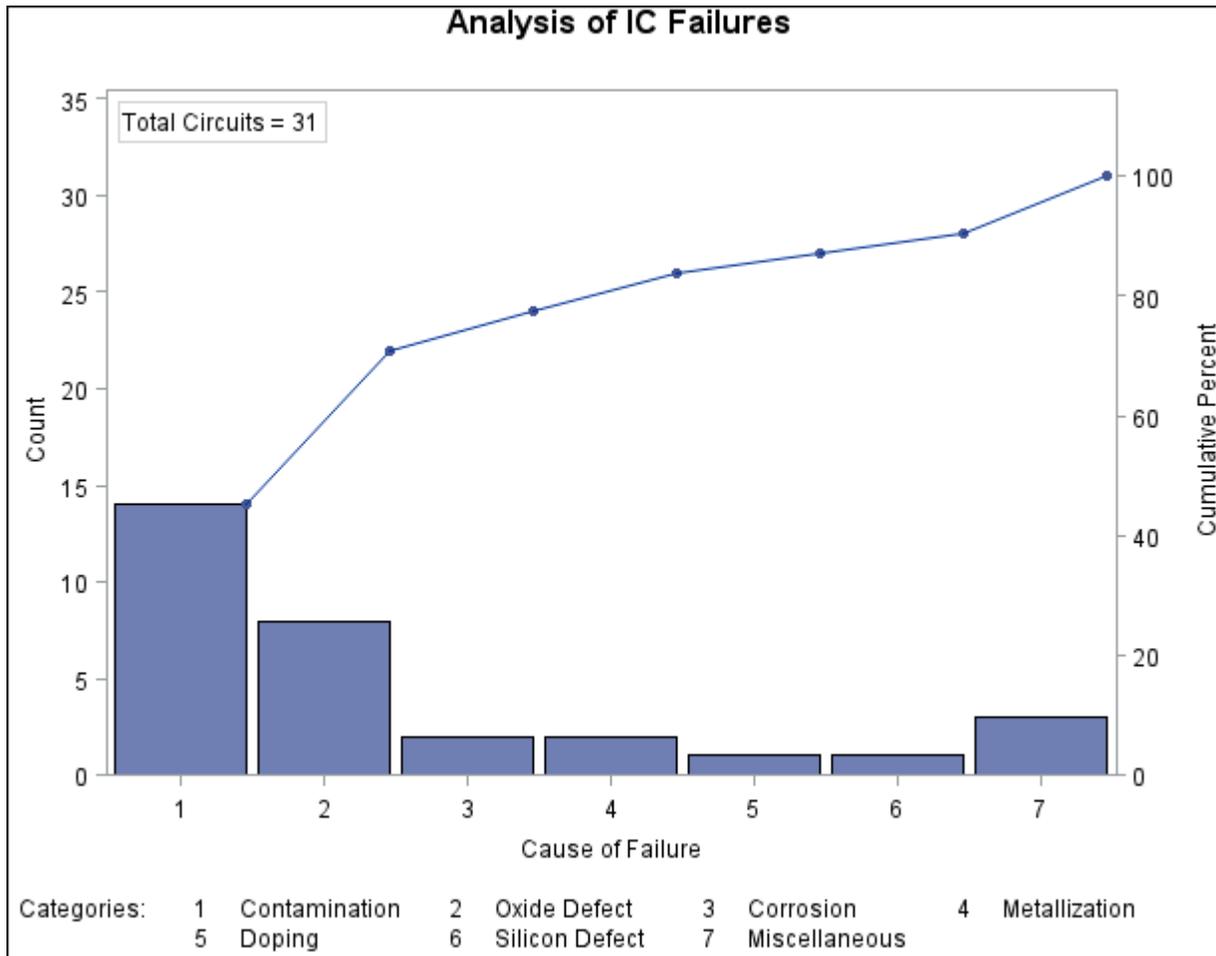

IC Manufacturing Problems				
Obs	Cause	COUNT	PERCENT	
1	Contamination	14	45.1613	
2	Corrosion	2	6.4516	
3	Doping	1	3.2258	
4	Metallization	2	6.4516	
5	Miscellaneous	3	9.6774	
6	Oxide Defect	8	25.8065	
7	Silicon Defect	1	3.2258	

The following statements produce a Pareto chart for the data in Failure2:

```
title 'Analysis of IC Failures';
symbol v=dot;
proc pareto data=Failure2;
  vbar Cause / freq      = Count
  scale      = count
  interbar  = 1.0
  last      = 'Miscellaneous'
  nlegend   = 'Total Circuits'
  cframenleg;
run;
```

The chart is displayed in Figure 15.9.

Figure 15.9 Pareto Chart with Frequency Scale

A slash (/) is used to separate the process variable Cause from the options specified in the VBAR statement. The frequency variable Count is specified with the FREQ= option. Specifying the keyword COUNT with the SCALE= option requests a frequency scale for the vertical axis.

The INTERBAR= option inserts a small space between the bars, and specifying LAST='Miscellaneous' causes the category *Miscellaneous* to be displayed last regardless of its frequency. The NLEGEND= option adds a sample size legend labeled *Total Circuits*, and the CFRAMENLEG option frames the legend. The SYMBOL statement marks points on the curve with dots.

There are two sets of tied categories in this example; *Corrosion* and *Metallization* each occur twice, and *Doping* and *Silicon Defect* each occur once. The procedure displays tied categories in alphabetical order of their formatted values. Thus, *Corrosion* appears before *Metallization*, and *Doping* appears before *Silicon Defect* in Figure 15.9. This is simply a convention, and no practical significance should be attached to the order in which tied categories are arranged.

Restricting the Number of Pareto Categories

See *PARETO2* in the *SAS/QC Sample Library*. Unlike the previous examples, some applications involve too many categories to display on a chart. The solution presented here is to create a restricted Pareto chart that displays only the most frequently occurring categories.

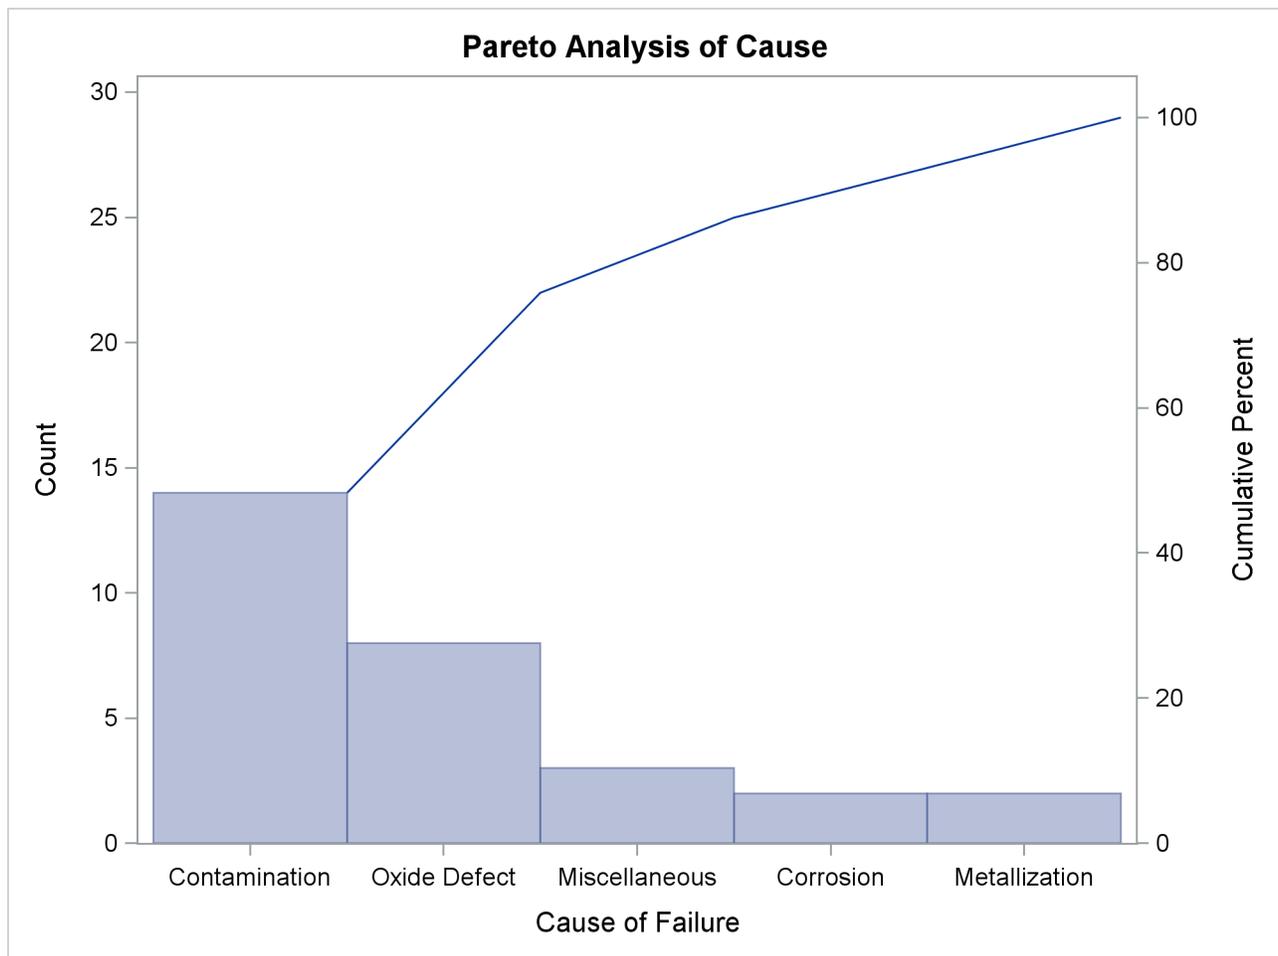

The following statements create a Pareto chart for the five most frequently occurring levels of Cause in the data set Failure2, which is listed in [Figure 15.8](#):

```
ods graphics on;
proc pareto data=Failure2;
  vbar Cause / freq      = Count
                scale    = count
                maxncat  = 5;
run;
```

The ODS GRAPHICS ON statement specified before the PROC PARETO statement enables ODS Graphics, so the Pareto chart is created using ODS Graphics instead of traditional graphics.

The MAXNCAT= option specifies the number of categories to be displayed. The chart, shown in [Figure 15.10](#), does not display the categories *Doping* and *Silicon Defect*.

Figure 15.10 Restricted Pareto Chart

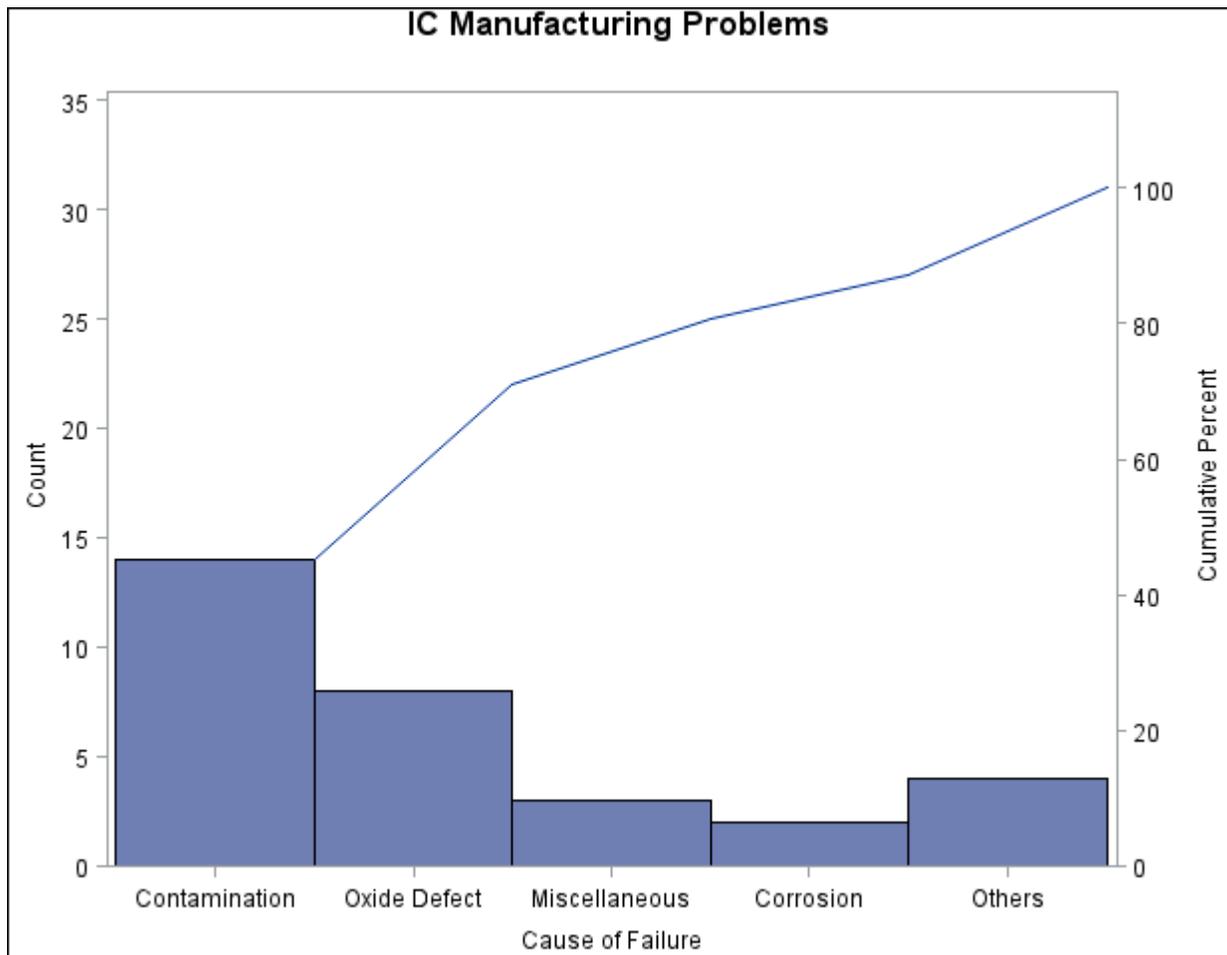

You can also display the most frequently occurring categories and merge the remaining categories into a single *other* category that is represented by a bar. You can specify the name for the new category with the OTHER= option. If, in addition, you specify the name with the LAST= option, the category is positioned at the far right of the chart. The following statements illustrate both options:

```
ods graphics off;
title 'IC Manufacturing Problems';
proc pareto data=Failure2;
  vbar Cause / freq      = Count
                    scale = count
                    maxncat = 5
                    other  = 'Others'
                    last   = 'Others';
run;
```

The chart is shown in Figure 15.11.

Figure 15.11 Restricted Pareto Chart with *Other* Category

The number of categories displayed is five, which is the number specified with the MAXNCAT= option. The first four categories are the four most frequently occurring problems in Failure2, and the fifth category merges the remaining problems.

Note that *Corrosion* and *Metallization* both have a frequency of two. When the MAXNCAT= option is applied to categories with tied frequencies, the procedure breaks the tie by using the order of the formatted values. Thus *Corrosion* is displayed, whereas *Metallization* is merged into the *Other* category. The MAXNCAT= and related options are described in “[Restricted Pareto Charts](#)” on page 1176.

Syntax: VBAR Statement

The syntax for the VBAR statement is as follows:

```
VBAR (variable-list) </ options > ;
```

You can use any number of VBAR statements in the PARETO procedure. If you specify two or more *variables* in the VBAR statement, they must be enclosed in parentheses. The components of the VBAR statement are described as follows.

options

specify the layout and features of the chart, and they are listed after a slash (/) that follows the variables to be analyzed.

The section “[Summary of Options](#)”, which follows, provides summary tables of options organized by function. The “[Dictionary of Options](#)” on page 1138 describes the *options* in detail.

variable-list

specifies the process variables to be analyzed. A chart is created for each *variable*, and the values of each *variable* determine the Pareto categories for that chart. A list of two or more *variables* must be enclosed in parentheses.

The *variables* can be numeric or character, and the maximum length of a character *variable* is 64. Formatted values are used to determine the categories and are displayed in labels and legends. The maximum format length is 64.

Summary of Options

Table 15.3 lists the VBAR statement options by function. For complete descriptions, see “[Dictionary of Options](#)” on page 1138.

Table 15.3 VBAR Statement Options

Option	Description
Options for ODS Graphics Output	
CATLEGEND=	displays Pareto categories legend
CHARTTYPE=	specifies type of Pareto chart produced
MARKERS	requests markers on the cumulative percent curve
ODSFOOTNOTE=	specifies footnote displayed on chart
ODSFOOTNOTE2=	specifies secondary footnote displayed on chart
ODSTITLE=	specifies title displayed on chart
ODSTITLE2=	specifies secondary title displayed on chart

Table 15.3 (continued)

Option	Description
URL=	specifies a variable whose values are URLs to be associated with bars
Options for the Cumulative Percent Curve	
ANCHOR=	specifies corner of leftmost bar to which curve is anchored
CCONNECT=	specifies color for curve
CMPCTLABEL	labels curve points with their values
NOCURVE	suppresses curve
NOVLABEL2	suppresses secondary vertical axis label
NOVTICK2	suppresses secondary vertical axis tick marks and tick mark labels
Data Processing Options	
FREQ=	specifies frequency variable
MISSING	specifies that missing values of the process variable be treated as a Pareto category
MISSING1	specifies that missing values of the first CLASS= variable be analyzed as a level
MISSING2	specifies that missing values of the second CLASS= variable be analyzed as a level
OUT=	creates output data set that saves information displayed in the Pareto chart
WEIGHT=	specifies weight variables used to weight frequencies
Options for Restricting the Number of Categories	
COTHER=	specifies color for OTHER= bar
LOTHER=	specifies label for OTHER= bar
MAXCMPCT=	displays only the categories with cumulative percentage less than the <i>percent</i> specified
MAXNCAT=	displays only the categories with the <i>n</i> highest values
MINPCT=	displays only the categories with percents greater than the <i>percent</i> specified
OTHER=	merges all categories not displayed
OTHERCVAL=	specifies an OUT= data set character variable value for the OTHER= category
OTHERNVAL=	specifies an OUT= data set numeric variable value for the OTHER= category
POTHER=	specifies pattern for OTHER= bar
Options to Enhance Graphical Output	
ANNOTATE=	specifies annotate data set with primary vertical axis data units
ANNOTATE2=	specifies annotate data set with secondary vertical axis data units
CTEXT=	specifies color for text
CTEXTSIDE=	specifies color for row labels
CTEXTTOP=	specifies color for column labels
DESCRIPTION=	specifies description of Pareto chart's GRSEG catalog entry
FONT=	specifies font for text

Table 15.3 (continued)

Option	Description
HEIGHT=	specifies text height in percent screen units
HTML=	specifies a variable whose values create links associated with bars in traditional graphics output
INFONT=	specifies font for text inside frame
INHEIGHT=	specifies text height in percent screen units for text inside frame
NAME=	specifies name of Pareto chart's GRSEG catalog entry
Options for Reference Lines	
CHREF=	specifies color for HREF= lines
CLIPREF	draws reference lines behind bars
CVREF=	specifies color for VREF= and VREF2= lines
FRONTREF	draws reference lines in front of bars
HREF=	requests reference lines perpendicular to horizontal axis
HREFLABELS=	specifies labels for HREF= lines
HREFLABPOS=	specifies position of HREFLABELS= labels
LHREF=	specifies line type for HREF= lines
LVREF=	specifies line type for VREF= and VREF2= lines
VREF=	requests reference lines perpendicular to primary vertical axis
VREF2=	requests reference lines perpendicular to secondary vertical axis
VREFLABELS=	specifies labels for VREF= lines
VREF2LABELS=	specifies labels for VREF2= lines
VREFLABPOS=	specifies position of VREFLABELS= and VREF2LABELS= labels
Options for Comparative Pareto Charts	
ANNOKEY	applies annotation only to the key cell
CFRAMESIDE=	specifies frame color for row labels
CFRAMETOP=	specifies frame color for column labels
CLASS=	specifies classification variables
CLASSKEY=	specifies the key cell
CPROP=	requests proportion-of-frequency bars
CTILES=	specifies colors for tile backgrounds
INTERTILE=	specifies distance in percent screen units between tiles
MISSING1	specifies that missing values of the first CLASS= variable be analyzed as a level
MISSING2	specifies that missing values of the second CLASS= variable be analyzed as a level
NCOLS=	specifies number of columns
NOKEYMOVE	suppresses the placement of the key cell in the top left corner
NROWS=	specifies number of rows
ORDER1=	specifies the order in which values of the first CLASS= variable are displayed
ORDER2=	specifies the order in which values of the second CLASS= variable are displayed

Table 15.3 (continued)

Option	Description
Options for Grids	
CGRID=	specifies color for GRID lines
CGRID2=	specifies color for GRID2 lines
GRID	adds grid corresponding to primary vertical axis
GRID2	adds grid corresponding to secondary vertical axis
LGRID=	specifies line type for GRID lines
LGRID2=	specifies line type for GRID2 lines
WGRID=	specifies width of GRID lines
WGRID2=	specifies width of GRID2 lines
Options for Controlling Axes	
ANGLE=	rotates horizontal axis tick mark labels
AXISFACTOR=	specifies distance factor between the tallest bar and the upper frame
CAXIS=	specifies axis color
CAXIS2=	specifies color for secondary vertical axis and tick marks
CFRAME=	specifies color for area enclosed by axes and frame
HOFFSET=	specifies horizontal axis offset in percent screen units
NOCHART	suppresses Pareto chart
NOFRAME	suppresses axis frame
NOHLABEL	suppresses horizontal axis label
NOVLABEL	suppresses primary vertical axis label
NOVLABEL2	suppresses secondary vertical axis label
NOVTICK	suppresses tick marks and tick mark labels for primary vertical axis
NOVTICK2	suppresses tick marks and tick mark labels for secondary vertical axis
SCALE=	specifies units in which primary vertical axis is scaled
TURNVLABEL	turns and strings vertically the characters in the primary and secondary vertical axis labels
VAXIS=	specifies tick mark values for primary vertical axis
VAXISLABEL=	labels primary vertical axis
VAXIS2=	specifies tick mark values for secondary vertical axis
VAXIS2LABEL=	labels secondary vertical axis
VOFFSET=	specifies vertical axis offset in percent screen units
WAXIS=	specifies width in pixels for the axes and frame
Options for Displaying Legends	
BARLEGEND=	displays legend for CBARS= colors or PBARS= patterns
BARLEGLABEL=	displays label for BARLEGEND= legend
CATLEGLABEL=	specifies label for Pareto categories legend
CFRAMENLEG=	frames the sample size legend
HLLEGLABEL=	displays label for the legend that describes colors and patterns of highest or lowest bars
NLEGEND=	requests sample size legend

Table 15.3 (continued)

Option	Description
NOHLLEG	suppresses legend describing colors and patterns of highest or lowest bars
TILELEGEND=	specifies legend for CTILES= colors
TILELEGLABEL=	specifies label for TILELEGEND= legend
Options for Displaying Bars	
BARLABEL=	displays labels for bars
BARLABPOS=	specifies position of BARLABEL= labels
BARS=	specifies variable that groups bars for display using ODS style colors
BARWIDTH=	specifies width (horizontal dimension) in percent screen units of the bars
CBARLINE=	specifies color for bar outlines
CBARS=	specifies color for bars
CHIGH(<i>n</i>)=	specifies color for bars with the <i>n</i> highest values
CLOW(<i>n</i>)=	specifies color for bars with the <i>n</i> lowest values
INTERBAR=	specifies distance between bars in percent screen units
LABOTHER=	specifies BARLABEL= label for 'other' category
LAST=	specifies bottommost category
PBARS=	specifies pattern for the bars
PHIGH(<i>n</i>)=	specifies pattern for bars with the <i>n</i> highest values
PLOW(<i>n</i>)=	specifies pattern for bars with the <i>n</i> lowest values
WBARLINE=	specifies width for bar outlines
Options for Line Printer Charts	
CONNECTCHAR=	specifies plot character for cumulative percent curve segments
HREFCHAR=	specifies plot character for HREF= lines
VREFCHAR=	specifies plot character for VREF= and VREF2= lines
SYMBOLCHAR=	specifies plot character for points on cumulative percent curve

Dictionary of Options

The following entries provide detailed descriptions of options you can specify after the slash (/) in the VBAR statement. For example, to request that the bars of your Pareto chart be colored red, use the CBARS= option, as follows:

```
proc pareto data=failure;
  vbar cause / cbars = red;
run;
```

The marginal notes *Traditional Graphics*, *ODS Graphics*, and *Line Printer* identify options that apply to traditional graphics, ODS Graphics output, and line printer charts, respectively.

ANCHOR=BC | BL | TC | TR

specifies where the Pareto curve is anchored to the leftmost bar on the chart. The following table lists the possible positions.

Keyword	Anchoring position
BC	bottom center
BL	bottom left corner
TC	top center
TR	top right corner

See [Output 15.2.1](#) for an illustration. The default is TR.

Note: The ANCHOR= option is not supported for ODS Graphics output. The curve is anchored at the top center of the leftmost bar.

ANGLE=*value*

specifies an angle in degrees for rotating the Pareto category labels on the horizontal axis. The *value* is the angle between the baseline of the label and the horizontal axis. See [Output 15.1.1](#) and [Output 15.1.2](#) for an illustration. The *value* must be greater than or equal to -90 and less than 90 . If you are producing a line printer chart, only ANGLE=0 and ANGLE= -90 are applicable. The default *value* is zero. *Traditional Graphics
Line Printer*

ANNOKEY

specifies that annotation requested with the ANNOTATE= and ANNOTATE2= options is to be applied only to the key cell in a comparative Pareto chart. By default, annotation is applied to all of the cells. *Traditional Graphics*

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an input data set that contains annotate variables as described in *SAS/GRAPH: Reference*. You can use this data set to customize traditional graphics. This data set is associated with the primary vertical axis. If the annotation is based on data coordinates, you must use the same units as the primary vertical axis. Features provided in the ANNOTATE= data set are added to every chart produced with the VBAR statement. *Traditional Graphics*

ANNOTATE2=*SAS-data-set*

ANNO2=*SAS-data-set*

specifies an input data set that contains annotate variables as described in *SAS/GRAPH: Reference*. You can use this data set to customize traditional graphics. This data set is associated with the secondary vertical axis. If the annotation is based on data coordinates, you must use the same units as the secondary vertical axis. Features provided in the ANNOTATE2= data set are added to every chart produced with the VBAR statement. *Traditional Graphics*

AXISFACTOR=*value*

specifies a factor used in scaling the primary vertical axis. This factor determines (approximately) the ratio of the length of the axis to the length of the tallest bar, and it is used to provide space for the cumulative percent curve. The *value* must be greater than one.

By default, the factor is chosen so that the curve will be anchored at the top right corner of the leftmost bar (see also the ANCHOR= option). If this causes the bars to be flattened excessively, however, a smaller default factor is used.

The AXISFACTOR= option is not applicable if the curve is suppressed with the NOCURVE option.

BARLABEL = VALUE | COUNT | CMPCT | (*variable-list*)

specifies that a label is to be displayed above each bar. If you specify `BARLABEL=VALUE`, the label indicates the height of the bar in the units used by the primary vertical axis. See [Example 15.8](#) for an illustration.

If you specify `BARLABEL=COUNT`, the label displays the count for the bar.

If you specify `BARLABEL=CMPT`, the label indicates the cumulative percent associated with that bar. An alternative to `BARLABEL=CMPT` is the `CMPTLABEL` option, which labels points on the cumulative percent curve with the cumulative percents.

If you specify `BARLABEL= (variable-list)`, the label displays the values of a variable from the input data set. The variable can have a formatted length less than or equal to 32. If a format is associated with the variable, then the formatted value is displayed. The values must be consistent within observations corresponding to a particular Pareto category. The variable is saved in the `OUT=` data set. If you specify more than one process variable in the chart statement, you can specify more than one `BARLABEL=` variable. The `BARLABEL=` and process variables are matched by their positions in the variable lists.

BARLABPOS=VFIT | HCENTER | VBAR | HLJUST

Traditional Graphics

specifies the position for labels requested with the `BARLABEL=` option.

- `BARLABPOS=VFIT` displays the labels vertically on or above the bars, depending on the available space (the labels are truncated if necessary).
- `BARLABPOS=HCENTER` centers the labels horizontally above the bars.
- `BARLABPOS=VBAR` displays the labels vertically on the bars (the labels are truncated if necessary).
- `BARLABPOS=HLJUST` left-justifies the labels horizontally above the bars.

By default, the labels are horizontally centered above the bars, with a reduction in text height if necessary. Reduction is not applied with the `BARLABPOS=` options.

BARLEGEND=(*variable-list*)

Traditional Graphics

ODS Graphics

specifies that a legend is to be added to the chart to explain colors for bars specified with the `BARS=` or `CBARS=(variable-list)` options, or patterns for bars specified with the `PBARS=(variable-list)` option. The *variable-list* must be enclosed in parentheses even if only one *variable* is specified. See [Output 15.4.1](#) for an illustration.

The values of the `BARLEGEND=` variable provide the explanatory labels used in the legend. The variable can have a formatted length that does not exceed 32. If a format is associated with the variable, then the formatted value is displayed.

The `BARLEGEND=` option is not applicable unless you specify `BARS=`, `CBARS=(variable-list)`, or `PBARS=(variable-list)`. In the `DATA=` data set, the values of the `BARLEGEND=` variable must be identical in observations for which the value of the `BARS=`, `CBARS=`, or `PBARS=` variable (or the combination of the `CBARS=` and `PBARS=` values) is the same. This ensures that the legend derived from the `BARLEGEND=` variable is consistent.

If you specify more than one process variable in the chart statement and a corresponding list of `BARS=`, `CBARS=`, or `PBARS=` variables, you can specify a list of `BARLEGEND=` variables. The number of `BARLEGEND=` variables should be less than or equal to the number of

process variables. The lists of variables are matched so that the first BARLEGEND= variable is applied to the first process variable and the first BARS=, CBARS=, or PBARS= variable, the second BARLEGEND= variable is applied to the second process variable and the second BARS=, CBARS=, or PBARS= variable, and so forth. If the list of process variables is longer than the *variable-list* in the BARLEGEND= option, the charts for the extra process variables will not display a bar legend.

BARLEGLABEL='label'

specifies the label displayed to the left of the legend created with the BARLEGEND= option. *Traditional Graphics*
See [Output 15.4.1](#) for an illustration. *ODS Graphics*

The BARLEGLABEL= option is applicable only in conjunction with BARS=, CBARS=, or PBARS= variables. The label can be up to 16 characters and must be enclosed in quotes.

If no label is specified with the BARLEGLABEL= option, the label associated with the BARLEGEND= variable is displayed (unless the label is longer than 16 characters, in which case the variable name is displayed). If the BARLEGLABEL= option is not specified and no label is associated with the BARLEGEND= variable, no legend label is displayed. If both labels are specified, the BARLEGLABEL= label takes precedence over the variable label.

BARS=(variable-list)

groups bars of the Pareto chart for display using colors from the current ODS style. The BARS= option should not be used when the NOGSTYLE option is in effect, and you cannot specify the BARS= option in conjunction with the CHIGH or CLOW options. Bars corresponding to the same value of the BARS= variable are filled with the same color from the ODS style. *Traditional Graphics*
ODS Graphics

If you specify more than one process variable, you can specify more than one BARS= variable. The number of BARS= variables should be less than or equal to the number of process variables. The two lists of variables are paired in order of specification. If a BARS= variable is not provided for a process variable, the bars for that chart are filled with the default color from the ODS style.

BARWIDTH=value

specifies the width of the bars in percent screen units. By default, the bars are as wide as possible. *Traditional Graphics*

CATLEGEND=ON | OFF | AUTO

specifies whether a category legend is created for ODS Graphics output. The default value is AUTO, which creates a category legend only when the category labels would be too crowded on the horizontal axis. This option is ignored if ODS Graphics is not enabled. *ODS Graphics*

CATLEGLABEL='label'

specifies a label for the category legend that is added when there is insufficient space to label the categories along the horizontal axis. The *label* can be up to 16 characters and must be enclosed in quotes. The default label is *Categories:*. See [Example 15.3](#) for an illustration. The CATLEGLABEL= option is ignored if it is unnecessary to add the legend.

CAXIS=*color***CAXES=***color***CA=***color**Traditional Graphics*

specifies the color for the axis line and tick marks on the chart. If the NOGSTYLE option is in effect, this color is also used for bar outlines and grid lines, unless overridden by the CBARLINE=, CGRID=, or CGRID2= options.

CAXIS2=*color**Traditional Graphics*

specifies the color for the tick mark labels and axis label associated with the secondary axis. By default, the color specified with the CTEXT= option (or its default) is used.

CBARLINE=*color**Traditional Graphics*

specifies the color for bar outlines.

CBARS=*color***CBARS=**(*variable-list*)*Traditional Graphics*

specifies how the bars of the Pareto chart are to be colored. You can use one of the following approaches:

- You can specify a single color to be used for all the bars with **CBARS=***color*. You can use this option in conjunction with the CHIGH and CLOW options. See [Output 15.2.1](#) for an illustration.
- You can specify a distinct color for each bar (or combination of bars) by providing the colors as values of a **CBARS=** variable. This variable must be a character variable of length eight. You can use the special value 'EMPTY' to indicate that a bar is not to be colored. Note that the variable name must be enclosed in parentheses. You cannot specify a **CBARS=** variable in conjunction with the CHIGH and CLOW options. See [Output 15.3.1](#) and [Output 15.4.1](#) for examples.

If you specify more than one process variable, you can specify more than one **CBARS=** variable. The number of **CBARS=** variables should be less than or equal to the number of process variables. The two lists of variables are paired in order of specification. If a **CBARS=** variable is not provided for a process variable, the bars for that chart are not colored.

If you specify one or more **CBARS=** variables, you can also use the **BARLEGEND=** option to add a legend to the chart that explains the significance of each color. Furthermore, you can use the **PBARS=** option to specify patterns in conjunction with the **CBARS=** option. See [Output 15.4.1](#) and [Output 15.5.1](#) for examples.

CCONNECT=*color**Traditional Graphics*

specifies the color for the line segments connecting the points on the cumulative percent curve. You can specify the color for the points themselves with the **COLOR=** option in the **SYMBOL** statement; this is the default color.

CFRAME=*color**Traditional Graphics*

specifies the color for filling the area enclosed by the axes and the frame. The **CFRAME=** option cannot be used in conjunction with the **NOFRAME** option or the **CTILES=** option.

CFRAMENLEG=*color*

CFRAMENLEG

specifies that the legend requested with the NLEGEND option be framed and that the frame be filled with the color indicated. If you specify CFRAMENLEG=EMPTY, a frame is drawn but is not filled with a color. Specify CFRAMENLEG without an argument to fill the frame with a color from the ODS style. See [Figure 15.9](#) for an illustrations. *Traditional Graphics*

CFRAMESIDE=*color*

specifies the color for filling the frame area for the row labels displayed along the left side of a comparative Pareto chart requested with the CLASS= option. If a label is associated with the classification variable, this color is also used to fill the frame area for this label. *Traditional Graphics*

CFRAMETOP=*color*

specifies the color for filling the frame area for the column labels displayed across the top of a comparative Pareto chart requested with the CLASS= option. If a label is associated with the classification variable, this color is also used to fill the frame area for this label. *Traditional Graphics*

CGRID=*color*

specifies the color for grid lines requested with the GRID option. If you specify the CGRID= option, you do not need to specify the GRID option. *Traditional Graphics*

CGRID2=*color*

specifies the color for grid lines requested with the GRID2 option. If you specify the CGRID2= option, you do not need to specify the GRID2 option. *Traditional Graphics*

CHARTTYPE=CUMULATIVE | INTERVALS*<(intervals-options)>* | **STANDARD**

specifies the type of Pareto chart to be produced. You can specify CUMULATIVE to create a cumulative Pareto bar chart and INTERVALS to create a Pareto dot plot with acceptance intervals. Wilkinson (2006) describes the advantages of these variations on the traditional Pareto chart. Specifying CHARTTYPE=STANDARD produces a traditional Pareto chart, which is the default. *ODS Graphics*

When you specify CHARTTYPE=INTERVALS, acceptance intervals for the categories are computed using simulation. You can specify the following *intervals-options* for computing acceptance intervals:

ALPHA=*value*

specifies the significance level for the acceptance intervals. The default value is 0.05.

NSAMPLES=*n*

specifies the number of random samples used in the simulation. The default value is 2000.

SEED=*n*

specifies the seed value for the random number generator used in the simulation. By default, or when you specify $n \leq 0$, a seed value is generated by using the system clock.

See [Example 15.9](#) for examples of these alternative Pareto charts.

CHIGH(*n*)=color**CHIGH(*n*)**

Traditional Graphics
ODS Graphics

specifies the color used to fill the bars with the *n* highest values. You cannot use the CHIGH(*n*)= option in conjunction with a CBARS= variable, but you can use the CHIGH(*n*)= option together with the CLOW(*n*)= and CBARS=*color* options. Use the CHIGH(*n*) option without specifying a color to fill the *n* highest bars with a color from the ODS style. See [Output 15.3.1](#) for an illustration.

CHREF=*color*

Traditional Graphics

specifies the color for lines requested with the HREF= option.

CLASS=*variable***CLASS=(*variable1 variable2*)**

creates a comparative Pareto chart using the levels of the *variables*. You must enclose two *variables* in parentheses. See [Example 15.1](#) and [Example 15.2](#).

If you specify a single CLASS= *variable*, the observations in the input data set are classified by the formatted values (levels) of the *variable*. A Pareto chart is created for the process variable values in each level, and these component charts (referred to as cells) are arranged in an array. The cells are labeled with the levels, and uniform horizontal and vertical axes are used to facilitate comparisons.

If you specify two CLASS= *variables*, the observations in the input data set are cross-classified by the values (levels) of the *variables*. A Pareto chart is created for the process variable values in each cell of the cross-classification, and these charts are arranged in a *matrix*. The levels of the first CLASS= *variable* label the rows, and the levels of the second CLASS= *variable* label the columns. Uniform horizontal and vertical axes are used to facilitate comparisons.

Note that the array or matrix comparative Pareto chart is displayed only if you produce traditional graphics or ODS Graphics output. If you produce a line printer chart, the cells are printed separately.

The CLASS= *variables* can be numeric or character. The maximum length of a character *variable* is 32. If a format is associated with a CLASS= *variable*, the formatted values determine the levels. Only the first 32 characters of the formatted value are used to determine the levels. You can specify whether missing values are to be treated as a level with the MISSING1 and MISSING2 options.

If a label is associated with a CLASS= *variable*, the label is displayed on the chart. In traditional graphics output, the *variable* label is displayed parallel to the column (or row) labels. On line printer charts the *variable* label is displayed at the top of the chart.

CLASSKEY=*'value'***CLASSKEY=(*'value1' 'value2'*)**

specifies the *key cell* in a comparative Pareto chart requested with the CLASS= option. The key cell is defined as the cell in which the Pareto bars are arranged in decreasing order. This order then determines the uniform horizontal axis used for all the cells.

If you specify CLASS=*variable*, you can specify CLASSKEY=*'value'* to identify the key cell as the level for which *variable* is equal to *value*. The *value* can have up to 32 characters, and

you must specify a formatted *value*. By default, the levels are sorted in the order determined by the ORDER1= option, and the key cell is the level that occurs first in this order. The cells are displayed in this order from top to bottom (or left to right), and consequently the key cell is displayed at the top or at the left. If you specify a different key cell with the CLASSKEY= option, this cell is displayed at the top or at the left unless you also specify the NOKEYMOVE option.

If you specify CLASS=(*variable1 variable2*), you can specify CLASSKEY=('value1' 'value2') to identify the key cell as the level for which *variable1* is equal to *value1* and *variable2* is equal to *value2*. Here, *value1* and *value2* must be formatted values, and they must be enclosed in quotes. By default, the levels of *variable1* are sorted in the order determined by the ORDER1= option, and then within each of these levels, the levels of *variable2* are sorted in the order determined by the ORDER2= option. The default key cell is the combination of levels of *variable1* and *variable2* that occurs first in this order. The cells are displayed in order of *variable1* from top to bottom and in order of *variable2* from left to right. Consequently, the default key cell is displayed in the upper left corner. If you specify a different key cell with the CLASSKEY= option, this cell is displayed in the upper left corner unless you also specify the NOKEYMOVE option.

For an example of the use of the CLASSKEY= option, see [Output 15.1.3](#).

CLIPREF

draws reference lines requested with the HREF= and VREF= options behind the bars on the Pareto chart. When the GSTYLE option is in effect, reference lines are drawn in front of the bars by default. *Traditional Graphics*

CLOW(*n*)=*color*

CLOW(*n*)

specifies the color used to fill the bars with the *n* lowest values. You cannot use the CLOW(*n*)= option in conjunction with a CBARS=*variable*, but you can use the CLOW(*n*)= option together with the CBARS=*color* and CHIGH options. See [Output 15.3.1](#) for an illustration of the CHIGH(*n*)= option. Use the CLOW(*n*) option without specifying a color to fill the *n* lowest bars with a color from the ODS style. *Traditional Graphics*
ODS Graphics

CMPCTLABEL

labels points on the cumulative percent curve with their values. By default, the points are not labeled.

CONNECTCHAR='character'

CCHAR='character'

specifies the plot character for line segments that connect points on the cumulative percent curve. The default character is a plus sign ('+'). *Line Printer*

COTHER=*color*

specifies the color for the bar defined by the OTHER= option. The COTHER= option is not applicable unless a CBARS=*variable* is specified. *Traditional Graphics*

CPROP=*color***CPROP***Traditional Graphics*

requests a proportion-of-frequency bar of the specified color displayed horizontally across the top of each tile in a comparative Pareto chart. Specify CPROP without an argument to create bars filled with a color from the ODS style. The length of the bar relative to the width of the tile indicates the proportion of the total frequency count in the chart that is represented by the tile. You can use the bars to visualize the distribution of frequency count by tile. See [Output 15.1.4](#) for an illustration.

The CPROP= option provides a graphical alternative to the NLEGEND options, which display the actual count. The CPROP= option is applicable only with comparative Pareto charts. Empty bars are displayed if you specify CPROP=EMPTY. Bars are not displayed if the CPROP= option is not specified.

CTEXT=*color***CT=***color**Traditional Graphics*

specifies the color for text, such as tick mark labels, axis labels, and legends. The default is the value specified for the CTEXT= option in the GOPTIONS statement.

CTEXTSIDE=*color**Traditional Graphics*

specifies the color for row labels displayed along the left side of a comparative Pareto chart requested with the CLASS= option. The default color is the color specified with the CTEXT= option in the VBAR statement or the CTEXT= option in the GOPTIONS statement.

CTEXTTOP=*color**Traditional Graphics*

specifies the color for column labels displayed across the top of a comparative Pareto chart requested with the CLASS= option. The default color is the color specified with the CTEXT= option in the VBAR statement or the CTEXT= option in the GOPTIONS statement.

CTILES=(*variable*)*Traditional Graphics*

specifies a character variable of length eight whose values are the fill colors for the tiles in a comparative Pareto chart. The CTILES= option generalizes the CFRAME= option, which provides a single color for all of the tiles. The *variable* must be enclosed in parentheses. The values of the *variable* must be identical for all observations with the same level of the CLASS= variables. You can use the same color to fill more than one tile. You can use the special value 'EMPTY' to indicate that a tile is not to be filled.

The CTILES= option cannot be used in conjunction with the NOFRAME option or the CFRAME= option. You can use the TILELEGEND= option in conjunction with the CTILES= option to add an explanatory legend for the CTILES= colors at the bottom of the chart. See [Output 15.5.1](#) for an illustration. By default, the tiles are not filled.

CVREF=*color**Traditional Graphics*

specifies the color for lines requested with the VREF= and VREF2= options.

DESCRIPTION='*string*'**DES=**'*string*'*Traditional Graphics*

specifies a description, up to 256 characters long, for the GRSEG catalog entry for a traditional graphics chart.

FONT=font

specifies a software font for text used in labels and legends. The FONT= option takes precedence over the FTEXT= option in the GOPTIONS statement. *Traditional Graphics*

FREQ=variable

specifies a frequency variable whose value provides the counts (numbers of occurrences) of the values of the process variable. Specifying a FREQ= variable is equivalent to replicating the observations in the input data set. The FREQ= variable must be a numeric variable with nonnegative integer values. See “[Creating a Pareto Chart Using Frequency Data](#)” on page 1129 for an illustration. If you specify more than one process variable in the chart statement, the FREQ= variable values are used with each process variable. If you do not specify a FREQ= variable, each value of the process variable is counted exactly once.

FRONTREF

draws reference lines requested with the HREF= and VREF= options in front of the bars on the Pareto chart. When the NOGSTYLE option is in effect, reference lines are drawn behind the bars by default and can be obscured by them. *Traditional Graphics*

GRID

adds a grid to the Pareto chart corresponding to the primary vertical axis. Grid lines are horizontal lines positioned at tick marks on the primary vertical axis. The lines are useful for comparing the heights of the bars.

GRID2

adds a grid to the Pareto chart corresponding to the secondary vertical axis. Grid lines are horizontal lines positioned at tick marks on the secondary vertical axis. The lines are useful for reading the cumulative percent curve.

HEIGHT=value

specifies the height in percent screen units of text for labels and legends. This option should be used only in conjunction with the FONT= option. The HEIGHT= option takes precedence over the HTEXT= option in a GOPTIONS statement. *Traditional Graphics*

HLLEGLABEL='label'

specifies a label displayed to the left of the legend that is automatically created when you use a combination of the CHIGH, CLOW, PHIGH, and PLOW options. See [Output 15.3.1](#) for an illustration. The *label* can be up to 16 characters and must be enclosed in quotes. The default *label* is *Bars:*. *Traditional Graphics*
ODS Graphics

HOFFSET=value

specifies the length in percent screen units of the offset at both ends of the horizontal axis. You can eliminate the offset by specifying HOFFSET=0. *Traditional Graphics*

HREF='value-list'

specifies where reference lines perpendicular to the horizontal (Pareto category) axis are to appear on the chart. Character values can be up to 64 characters and must be enclosed in quotes. The values must be values of the process variable even when the bars are numbered and a category legend is introduced.

HREFCHAR=*'character'*

Line Printer specifies the plot character used to form the lines requested with the HREF= option. The default character is a vertical bar (|).

HREFLABELS=*'label1'... 'labeln'*

specifies labels for the lines requested with the HREF= option. The number of labels must equal the number of lines requested. Labels can be up to 16 characters and must be enclosed in quotes.

HREFLABPOS=*n*

specifies the vertical position of HREFLABELS= labels, as described in the following table.

<i>n</i>	Position
1	along top of chart
2	staggered from top to bottom of chart
3	along bottom of chart
4	staggered from bottom to top of chart

By default, HREFLABPOS=1. **Note:** HREFLABPOS=2 and HREFLABPOS=4 are not supported for ODS Graphics output.

HTML=*variable*

Traditional Graphics specifies a variable whose values create links associated with Pareto bars when traditional graphics output is directed into HTML. You can specify a character variable or formatted numeric variable. The value of the HTML= variable should be the same for each observation with a given value of the process variable.

INFONT=*font*

Traditional Graphics specifies a software font for text used inside the frame of the chart, such as sample size legends. The INFONT= option takes precedence over the FONT= option and the FTEXT= option in the GOPTIONS statement.

INHEIGHT=*value*

Traditional Graphics specifies the height in percent screen units of text used inside the frame of the chart, such as sample size legends and bar labels. This option should be used in conjunction with the INFONT= option.

INTERBAR=*value*

Traditional Graphics
Line Printer specifies the distance in percent screen units between bars on the chart. By default, the bars are contiguous. See [Figure 15.9](#) for an illustration.

INTERTILE=*value*

Traditional Graphics
ODS Graphics specifies the distance in horizontal percent screen units between tiles (cells) in a comparative Pareto chart. By default, the tiles are contiguous. See [Output 15.1.3](#) for an illustration.

LABOTHER= *'other-label'*

is used in conjunction with the BARLABEL=(variable) option and specifies a label for the 'other' category that is optionally specified with the OTHER= option.

LAST='category'

specifies that the bar corresponding to the *category* is to be displayed at the right end of the chart regardless of the percent associated with this category. The *category* must be a formatted value of the process variable and must be enclosed in quotes. The *category* can be up to 64 characters. See Figure 15.10 for an illustration.

LGRID=line-type

specifies the line type for the grid requested with the GRID option. If you specify the LGRID= *Traditional Graphics* option, you do not need to specify the GRID option.

LGRID2=line-type

specifies the line type for the grid requested with the GRID2 option. If you specify the *Traditional Graphics* LGRID2= option, you do not need to specify the GRID2 option.

LHREF=line-type**LH=line-type**

specifies the line type for lines requested with the HREF= option. *Traditional Graphics*

LOTHER='label'

specifies a label for the bar defined with the OTHER= option. This label appears in the legend *Traditional Graphics* created with the BARLEGEND= option. The *label* must be enclosed in quotes and can be *ODS Graphics* up to 32 characters. The default *label* is the value specified with the OTHER= option. The LOTHER= option is applicable only when a BARLEGEND= variable is specified.

LVREF=line-type**LV=line-type**

specifies the line type for lines requested with the VREF= and VREF2= options. *Traditional Graphics*

MARKERS

specifies that the points on the cumulative percent curve be plotted with markers in ODS *ODS Graphics* Graphics output. You can use a SYMBOL statement to plot the points in traditional graphics and the SYMBOLCHAR= option to specify the plotting character for a line printer chart.

MAXCMPCT=percent

specifies that only the Pareto categories with the *n* highest frequency counts are to be displayed, where the sum of the *n* corresponding percents is less than or equal to the specified *percent*. For example, if you specify

```
proc pareto data=failure;
  vbar cause / maxcmpct = 90;
```

the chart displays only the *n* most frequently occurring categories that account for no more than 90 percent of the total frequency.

You can use the OTHER= option in conjunction with the MAXCMPCT= option to create and display a new category that combines those categories that are not selected with the MAXCMPCT= option. For example, if you specify

```
proc pareto data=failure;
  vbar cause / maxcmpct = 90
             other      = 'Others';
```

the chart displays the categories that account for no more than 90 percent of the total frequency, together with a category labeled *Others* that merges the remaining categories. The MAXCMPCT= option is an alternative to the MINPCT= and MAXNCAT= options.

MAXNCAT=*n*

specifies that only the Pareto categories with the *n* highest frequencies are to be displayed. For example, if you specify

```
proc pareto data=failure;
  vbar cause / maxncat = 20;
```

the chart displays only the categories with the 20 highest frequencies. If the total number of categories is less than 20, all the categories are displayed.

You can use the OTHER= option in conjunction with the MAXNCAT= option to create and display a new category that combines those categories that are not selected with the MAXNCAT= option. For example, if you specify

```
proc pareto data=failure;
  vbar cause / maxncat = 20
             other= 'Others';
```

the chart displays the categories with the 19 highest frequencies, together with a category labeled *Others* that merges the remaining categories. See [Figure 15.10](#) for another illustration.

The MAXNCAT= option is an alternative to the MINPCT= and MAXCMPCT= options.

MINPCT=*percent*

specifies that only the Pareto categories with frequency percents greater than or equal to the specified *percent* are to be displayed. For example, if you specify

```
proc pareto data=failure;
  vbar cause / minpct = 5;
```

the chart displays only those categories with at least five percent of the total frequency.

You can use the OTHER= option in conjunction with the MINPCT= option to create and display a new category that combines those categories that are not selected with the MINPCT= option. The merged category created by the OTHER= option is displayed even if its total percent is less than the *percent* specified with the MINPCT= option. For example, if you specify

```
proc pareto data=failure;
  vbar cause / minpct = 5
             other = 'Others';
```

the chart displays the categories with percents greater than or equal to five percent, together with a category labeled *Others* that merges the remaining categories.

The MINPCT= option is an alternative to the MAXNCAT= and MAXCMPCT= options.

MISSING

specifies that missing values of the process variable are to be treated as a Pareto category represented with a bar on the chart. If the process variable is a character variable, a missing value is defined as a blank internal (unformatted) value. If the process variable is numeric, a missing value is defined as any of the SAS missing values. If you do not specify the MISSING option, missing values are excluded from the analysis.

MISSING1

specifies that missing values of the first CLASS= variable are to be treated as a level of the CLASS= variable. If the first CLASS= variable is a character variable, a missing value is defined as a blank internal (unformatted) value. If the first CLASS= variable is numeric, a missing value is defined as any of the SAS missing values. If you do not specify MISSING1, observations in the DATA= data set for which the first CLASS= variable is missing are excluded from the analysis.

MISSING2

specifies that missing values of the second CLASS= variable are to be treated as a level of the CLASS= variable. If the second CLASS= variable is a character variable, a missing value is defined as a blank internal (unformatted) value. If the second CLASS= variable is numeric, a missing value is defined as any of the SAS missing values. If you do not specify MISSING2, observations in the DATA= data set for which the second CLASS= variable is missing are excluded from the analysis.

NAME='string'

specifies the name of the GRSEG catalog entry for a traditional graphics chart, and the name of the graphics output file if one is created. The name can be up to 256 characters long, but the GRSEG name is truncated to eight characters. The default name is 'PARETO'. *Traditional Graphics*

NCOLS=*n***NCOL=*n***

specifies the number of columns in a comparative Pareto chart. You can use the NCOLS= option in conjunction with the NROWS= option. See [Output 15.2.3](#) and [Output 15.2.4](#) for an illustration. By default, NCOLS=1 and NROWS=2 if one CLASS= variable is specified, and NCOLS=2 and NROWS=2 if two CLASS= variables are specified. *Traditional Graphics*
ODS Graphics

NLEGEND**NLEGEND='label'****NLEGEND=(*variable*)**

requests a sample size legend and specifies its form as follows:

- If you specify the NLEGEND option, the form is $N=n$, where n is the total count for the Pareto categories. In a comparative Pareto chart, a legend is displayed in each tile, and n is the total count for that particular cell. See [Output 15.2.1](#) for an illustration.
- If you specify the NLEGEND='label' option, the form is $label=n$, where n is the total count for the Pareto categories. The label can be up to 32 characters and must be enclosed in quotes. For an illustration, see [Figure 15.9](#) or [Output 15.1.4](#).
- If you specify the NLEGEND=(*variable*) option, the legend is the value of the *variable*, which must be a variable in the DATA= data set whose formatted length does not exceed

32. If a format is associated with the variable, then the formatted value is displayed. This option is intended for use with comparative Pareto charts and enables you to display a customized legend inside each tile (this legend need not provide total count). It is assumed that the values of the *variable* are identical for all observations in a particular class.

By default, the legend is placed in the upper-left corner of the chart. If the NOCURVE option is specified, the legend is placed in the upper-right corner of the chart. You can use the CFRAMENLEG= option to frame the sample size legend. No legend is displayed if you do not specify an NLEGEND option.

NOCHART

suppresses the creation of a Pareto chart. This option is useful when you are simply creating an output data set.

NOCURVE

suppresses the display of the cumulative percent curve and the secondary vertical axis. Compare [Output 15.2.1](#) and [Output 15.2.2](#) for an illustration.

NOFRAME

Traditional Graphics
Line Printer

suppresses the frame that is drawn around the chart by default. The NOFRAME option cannot be specified in conjunction with the CFRAME= or CTILES= options.

NOHLABEL

suppresses the label for the horizontal axis. This is useful for avoiding clutter in situations where the meaning of the horizontal axis is apparent from the labels for the Pareto categories. See [Output 15.2.2](#) for an illustration.

NOHLLEG

suppresses the legend generated by the CHIGH(n)=, CLOW(n)=, PHIGH(n)=, and PLOW(n)= options.

NOKEYMOVE

Traditional Graphics
ODS Graphics

suppresses the rearrangement of cells within a comparative Pareto chart that occurs when you use the CLASSKEY= option. The key cell appears in the top left corner of a comparative Pareto chart unless you use the CLASSKEY= option together with the NOKEYMOVE option.

NOVLABEL

suppresses the label for the primary vertical axis.

NOVLABEL2

suppresses the label for the secondary vertical axis. This is useful for avoiding clutter on comparative Pareto charts.

NOVTICK

suppresses the primary vertical axis label, tick marks, and tick mark labels.

NOVTICK2

suppresses the secondary vertical axis label, tick marks, and tick mark labels.

NROWS=*n***NROW=*n***

specifies the number of rows in a comparative Pareto chart. You can use the NROWS= option in conjunction with the NCOLS= option. See [Output 15.2.3](#) and [Output 15.2.4](#) for an illustration. By default, NROWS=2. *Traditional Graphics*
ODS Graphics

ODSFOOTNOTE=FOOTNOTE | FOOTNOTE1 | 'string'

adds a footnote to ODS Graphics output. If you specify the FOOTNOTE (or FOOTNOTE1) keyword, the value of the SAS FOOTNOTE statement is used as the graph footnote. If you specify a quoted string, that is used as the footnote. The quoted string can contain either of the following escaped characters, which are replaced with the appropriate values from the analysis: *ODS Graphics*

\n is replaced by the analysis variable name.

\l is replaced by the analysis variable label (or name if the analysis variable has no label).

ODSFOOTNOTE2=FOOTNOTE2 | 'string'

adds a secondary footnote to ODS Graphics output. If you specify the FOOTNOTE2 keyword, the value of the SAS FOOTNOTE2 statement is used as the secondary graph footnote. If you specify a quoted string, that is used as the secondary footnote. The quoted string can contain any of the following escaped characters, which are replaced with the appropriate values from the analysis: *ODS Graphics*

\n is replaced by the analysis variable name.

\l is replaced by the analysis variable label (or name if the analysis variable has no label).

ODSTITLE=TITLE | TITLE1 | NONE | DEFAULT | LABELFMT | 'string'

specifies a title for ODS Graphics output. You can specify the following values: *ODS Graphics*

TITLE (or TITLE1) uses the value of the SAS TITLE statement as the graph title.

NONE suppresses all titles from the graph.

DEFAULT uses the default ODS Graphics title (a descriptive title consisting of the plot type and the analysis variable name).

LABELFMT uses the default ODS Graphics title with the variable label instead of the variable name.

If you specify a quoted string, that is used as the graph title. The quoted string can contain the following escaped characters, which are replaced with the appropriate values from the analysis:

\n is replaced by the analysis variable name.
 \l is replaced by the analysis variable label (or name if the analysis variable has no label).

ODSTITLE2=TITLE2 | 'string'*ODS Graphics*

specifies a secondary title for ODS Graphics output. If you specify the TITLE2 keyword, the value of the SAS TITLE2 statement is used as the secondary graph title. If you specify a quoted string, that is used as the secondary title. The quoted string can contain the following escaped characters, which are replaced with the appropriate values from the analysis:

\n is replaced by the analysis variable name.
 \l is replaced by the analysis variable label (or name if the analysis variable has no label).

ORDER1=INTERNAL | FORMATTED | DATA | FREQ

specifies the display order for the values of the first CLASS= variable. The levels of the first CLASS= variable are always constructed using the formatted values of the variable, and the formatted values are always used to label the rows (columns) of a comparative Pareto chart.

If you specify ORDER1=INTERNAL, the rows (columns) are displayed from top to bottom (left to right) in increasing order of the internal, or unformatted, values of the first CLASS= variable. If there are two or more distinct internal values with the same formatted value, the order is determined by the internal value that occurs first in the input data set. For example, suppose that you use a numeric CLASS= variable called DAY (with values 1, 2, and 3) to create a one-way comparative Pareto chart. Suppose also that you use the FORMAT procedure to associate the formatted values 1 = 'Wednesday', 2 = 'Thursday', and 3 = 'Friday' with the variable DAY. If you specify ORDER1=INTERNAL, the rows of the comparative chart will appear in chronological order (*Wednesday, Thursday, Friday*) from top to bottom.

If you specify ORDER1=FORMATTED, the rows (columns) are displayed from top to bottom (left to right) in increasing order of the formatted values of the first CLASS= variable. For instance, in the previous illustration, if you specify ORDER1=FORMATTED, the rows will appear in alphabetical order (*Friday, Thursday, Wednesday*) from top to bottom.

If you specify ORDER1=DATA, the rows (columns) are displayed from top to bottom (left to right) in the order in which the values of the first CLASS= variable first appear in the input data set.

If you specify ORDER1=FREQ, the rows (columns) are displayed from top to bottom (left to right) in order of *decreasing* frequency count. If two or more classes have the same frequency count, the order is determined by the formatted values.

By default, ORDER1=INTERNAL.

ORDER2=INTERNAL | FORMATTED | DATA | FREQ

specifies the display order for the values of the second CLASS= variable. The levels of the second CLASS= variable are always constructed using the formatted values of the variable, and the formatted values are always used to label the columns of a two-way comparative Pareto chart.

The PARETO procedure determines the layout of a two-way comparative Pareto chart by first using the ORDER1= option to obtain the order of the rows from top to bottom (recall that ORDER1=INTERNAL by default). Then the ORDER2= option is applied to the observations corresponding to the first row to obtain the order of the columns from left to right. If any columns remain unordered (that is, the categories are unbalanced), the ORDER2= option is applied to the observations in the second row, and so on until all the columns have been ordered.

The values of the ORDER2= option are interpreted as described for the ORDER1= option. By default, ORDER2=INTERNAL.

OTHER='category'

specifies a new category that merges all categories not selected with the MAXNCAT=, MINPCT=, or MAXCMPCT= options. See [Figure 15.10](#) for an illustration.

The *category* should be specified as a formatted value of the process variable. The *category* can be up to 32 characters and must be enclosed in quotes. If you specify an OUT= data set, you should also specify an internal value corresponding to the *category* with the OTHERCVAL= option or the OTHERNVAL= option.

The OTHER= option is not applicable unless you specify the MAXNCAT=, MINPCT=, or MAXCMPCT= option. You can use the COTHER=, LOTHER=, POTHER=, OTHERCVAL=, and OTHERNVAL= options with the OTHER= option.

OTHERCVAL='value'

specifies the internal (unformatted) value for a character process variable in the OUT= data set that corresponds to the category created with the OTHER= option. The *category* can be up to 64 characters and must be enclosed in quotes.

The OTHERCVAL= option is not applicable unless you specify the OTHER= and OUT= options. If you specify the OTHER= option but not the OTHERCVAL= option, the default *value* is the *value* specified with the OTHER= option.

OTHERNVAL=value

specifies the internal (unformatted) value for a numeric process variable in the OUT= data set that corresponds to the category created with the OTHER= option. The OTHERNVAL= option is not applicable unless you specify the OTHER= and OUT= options. If you specify the OTHER= option but not the OTHERNVAL= option, *value* is assigned a missing value.

OUT=SAS-data-set

creates an output data set that contains the information displayed in the Pareto chart. This is useful if you want to create a report to accompany your chart. See [Example 15.8](#) for an illustration.

PBARS=pattern

PBARS=(variable-list)

specifies pattern fills for the bars. You can use one of two approaches:

- You can specify a single pattern to be used for all the bars with the PBARS=*pattern* option. You can use this option in conjunction with the PHIGH and PLOW options.

- You can specify a distinct pattern for *each* bar (or combination of bars) by providing the patterns as values of a PBARS= variable. For example, you might use the solid pattern ('S') to indicate severe problems and the empty pattern ('E') for all other problems. The variable must be a character variable of length eight, and the variable name must be enclosed in parentheses. You cannot specify a PBARS= variable in conjunction with the PHIGH and PLOW options.

If you specify more than one process variable in the chart statement, you can provide more than one PBARS= variable. The number of PBARS= variables should be less than or equal to the number of process variables. The two lists of variables are paired in order of specification. If a PBARS= variable is not provided for a process variable, the bars for that chart are not filled.

If you specify one or more variables with the PBARS= option, you can also use the BAR-LEGEND= option to add a legend to the chart that explains the significance of each pattern. Furthermore, you can use the CBARS= option to specify colors in conjunction with the PBARS= option.

PHIGH(*n*)=*pattern*

Traditional Graphics

specifies the pattern used to fill the bars with the *n* highest values. You cannot specify the PHIGH option in conjunction with a PBARS= variable, but you can specify the PHIGH(*n*)= option together with the PLOW(*n*)= and PBARS=*pattern* options.

PLOW(*n*)=*pattern*

Traditional Graphics

specifies the pattern used to fill the bars with the *n* lowest values. You cannot specify the PLOW option in conjunction with a PBARS= variable, but you can use the PLOW(*n*)= option together with the PHIGH(*n*)= and PBARS=*pattern* options.

POTHER=*pattern*

Traditional Graphics

specifies the pattern used for the bar defined by the OTHER= option. The POTHER= option is not applicable unless a PBARS= variable is specified.

SCALE=PERCENT | COUNT | WEIGHT

specifies the scale for the primary vertical axis.

If you specify SCALE=PERCENT, the scale is percent of total frequency. If a WEIGHT= variable is used, the scale is percent of total weight.

If you specify SCALE=COUNT, the scale is counts. See [Output 15.1.4](#) for an illustration. This option is not applicable if a WEIGHT= variable is used. You can specify SCALE=FREQUENCY instead of SCALE=COUNT.

If you specify SCALE=WEIGHT, the vertical axis is scaled in the same units as the WEIGHT= variable. This option is not applicable unless you use a WEIGHT= variable.

By default, SCALE=PERCENT. See [Output 15.8.1](#) for an example. Regardless of how SCALE= is specified, the secondary axis is scaled in cumulative percent units.

SYMBOLCHAR='character'

Line Printer

specifies the plot character for points on the cumulative percent curve. The default character is an asterisk (*).

TILELEGEND=(*variable*)

specifies a variable used to add a legend for CTILES= colors. The variable can have a formatted length less than or equal to 32. If a format is associated with the variable, then the formatted value is displayed. The TILELEGEND= option must be used in conjunction with the CTILES= option for filling the tiles in a comparative Pareto chart. If CTILES= is specified and TILELEGEND= is not specified, a color legend is not displayed. *Traditional Graphics*

The values of the CTILES= and TILELEGEND= variables should be consistent for all observations with the same level of the CLASS= variables. The value of the TILELEGEND= variable is used to identify the corresponding color value of the CTILES= variable in the legend. See [Output 15.5.1](#) for an illustration.

TILELEGLABEL='label'

specifies a label displayed to the left of the legend that is created when you specify a TILELEGEND= variable. The *label* can be up to 16 characters and must be enclosed in quotes. The default *label* is *Tiles:*. See [Output 15.5.1](#) for an illustration. *Traditional Graphics*

TURNVLABEL**TURNVLABELS**

turns and strings out vertically the characters in the labels for the primary and secondary vertical axes. *Traditional Graphics*

URL=*variable*

specifies URLs as values of the specified character variable (or formatted values of a numeric variable). These URLs are associated with bars on the Pareto chart when ODS Graphics output is directed into HTML. The value of the HTML= variable should be the same for each observation with a given value of the process variable. *ODS Graphics*

VAXIS=*value-list*

specifies tick mark values for the primary vertical axis. The values must be equally spaced and in increasing order, and the first *value* must be zero. You must scale the values in the same units as the bars (see the SCALE= option), and the last *value* must be greater than or equal to the height of the largest bar.

VAXISLABEL='label'

specifies a label, up to 40 characters, for the primary vertical axis. The default label depends on the value of the SCALE= option, or it is the label associated with the WEIGHT= variable.

VAXIS2=*value-list*

specifies tick mark values for the secondary vertical axis. The values must be equally spaced and in increasing order, and the first *value* must be zero. You must scale the values in percent units, and the last *value* must be greater than or equal to 100.

VAXIS2LABEL='label'

specifies a label, up to 40 characters, for the secondary vertical axis. The default label is *Cumulative Percent* or *Cm Pct*, depending on the space available.

VOFFSET=*value*

specifies the length in percent screen units of the offset at the upper end of the primary vertical axis.

VREF=*value-list*

specifies where reference lines perpendicular to the primary vertical axis are to appear on the chart. You must specify the values in the same units used to scale the primary axis. By default, the primary axis is scaled in percent units, but you can specify other units with the SCALE= option. See [Output 15.2.3](#) for an illustration.

VREF2=*value-list*

specifies where reference lines perpendicular to the secondary vertical axis are to appear on the chart. You must specify the values in cumulative percent units.

VREFCHAR=*'character'**Line Printer*

specifies the character used to form the lines requested with the VREF= and VREF2= options. The default character is a dash (-).

VREFLABELS=*'label1'... 'labeln'*

specifies labels for the lines requested with the VREF= option. The number of labels must equal the number of lines requested. Enclose the labels in quotes. Labels can be up to 16 characters.

VREF2LABELS=*'label1'... 'labeln'*

specifies labels for the lines requested with the VREF2= option. The number of labels must equal the number of lines requested. Enclose the labels in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the vertical positioning of the VREFLABELS= and VREF2LABELS= labels. If you specify VREFLABPOS=1, the labels are positioned at the left of the chart, and if you specify VREFLABPOS=2, the labels are positioned at the right. By default, $n = 1$.

WAXIS=*n**Traditional Graphics*

specifies the line thickness (in pixels) for the axes and frame. This thickness is also used for bar outlines and grid lines, unless overridden by the WBARLINE=, WGRID=, or WGRID2= options.

WBARLINE=*n**Traditional Graphics*

specifies the width for bar outlines.

WEIGHT=*variable-list*

specifies weight variables used to construct weighted Pareto charts. The WEIGHT= variables are paired with the process variables in order of specification. The WEIGHT= variables must be numeric, and their values must be nonnegative (noninteger values are permitted). If a WEIGHT= variable is not provided for a process variable, the weights applied to that process variable are assumed to be one. See “[Weighted Pareto Charts](#)” on page 1176 for computational details.

A WEIGHT= variable is particularly useful for carrying out a Pareto analysis based on *cost* rather than frequency of occurrence. See [Example 15.8](#) for an illustration.

WGRID=*n*

specifies the width of the primary chart grid lines. If the WGRID= option is specified the *Traditional Graphics* GRID option is not required.

WGRID2=*n*

specifies the width of the secondary chart grid lines. If the WGRID2= option is specified the *Traditional Graphics* GRID2 option is not required.

INSET Statement: PARETO Procedure

Overview: INSET Statement

The INSET statement enables you to enhance a Pareto chart by adding a box or table (referred to as an *inset*) of summary statistics directly to the graph. An inset can display statistics calculated by the PARETO procedure or arbitrary values provided in a SAS data set.

Note that an INSET statement by itself does not produce a display but must be used in conjunction with a chart statement. Insets are not available with line printer charts, so the INSET statement is not applicable when the LINEPRINTER option is specified in the PROC PARETO statement.

You can use options in the INSET statement to

- specify the position of the inset
- specify a header for the inset table
- specify graphical enhancements, such as background colors, text colors, text height, text font, and drop shadows

When an INSET statement is associated with a chart statement producing a comparative Pareto chart, an inset is produced in each cell of the comparative chart.

Getting Started: INSET Statement

This section introduces the INSET statement with examples that illustrate commonly used options. Complete syntax for the INSET statement is presented in the section “Syntax: INSET Statement” on page 1165.

Displaying Summary Statistics on a Pareto Chart

During the manufacture of a metal-oxide semiconductor (MOS) capacitor, causes of failures were recorded before and after a tube in the diffusion furnace was cleaned. This information was saved in a SAS data set named Failure3. *See PARETO7 in the SAS/QC Sample Library*

```

data Failure3;
  length Cause $ 16 Stage $ 16;
  label Cause = 'Cause of Failure';
  input Stage & $ Cause & $ Counts;
datalines;
Before Cleaning   Contamination   14
Before Cleaning   Corrosion         2
Before Cleaning   Doping           1
Before Cleaning   Metallization     2
Before Cleaning   Miscellaneous     3
Before Cleaning   Oxide Defect      8
Before Cleaning   Silicon Defect    1
After Cleaning    Doping           0
After Cleaning    Corrosion         2
After Cleaning    Metallization     4
After Cleaning    Miscellaneous     2
After Cleaning    Oxide Defect      1
After Cleaning    Contamination   12
After Cleaning    Silicon Defect    2
;

```

The following statements generate a Pareto chart from the Failure3 data. The MAXNCAT= option is specified to limit the number of Pareto categories to five. An INSET statement is used to display the total count for the categories displayed and the total count for the categories excluded by the MAXNCAT= option.

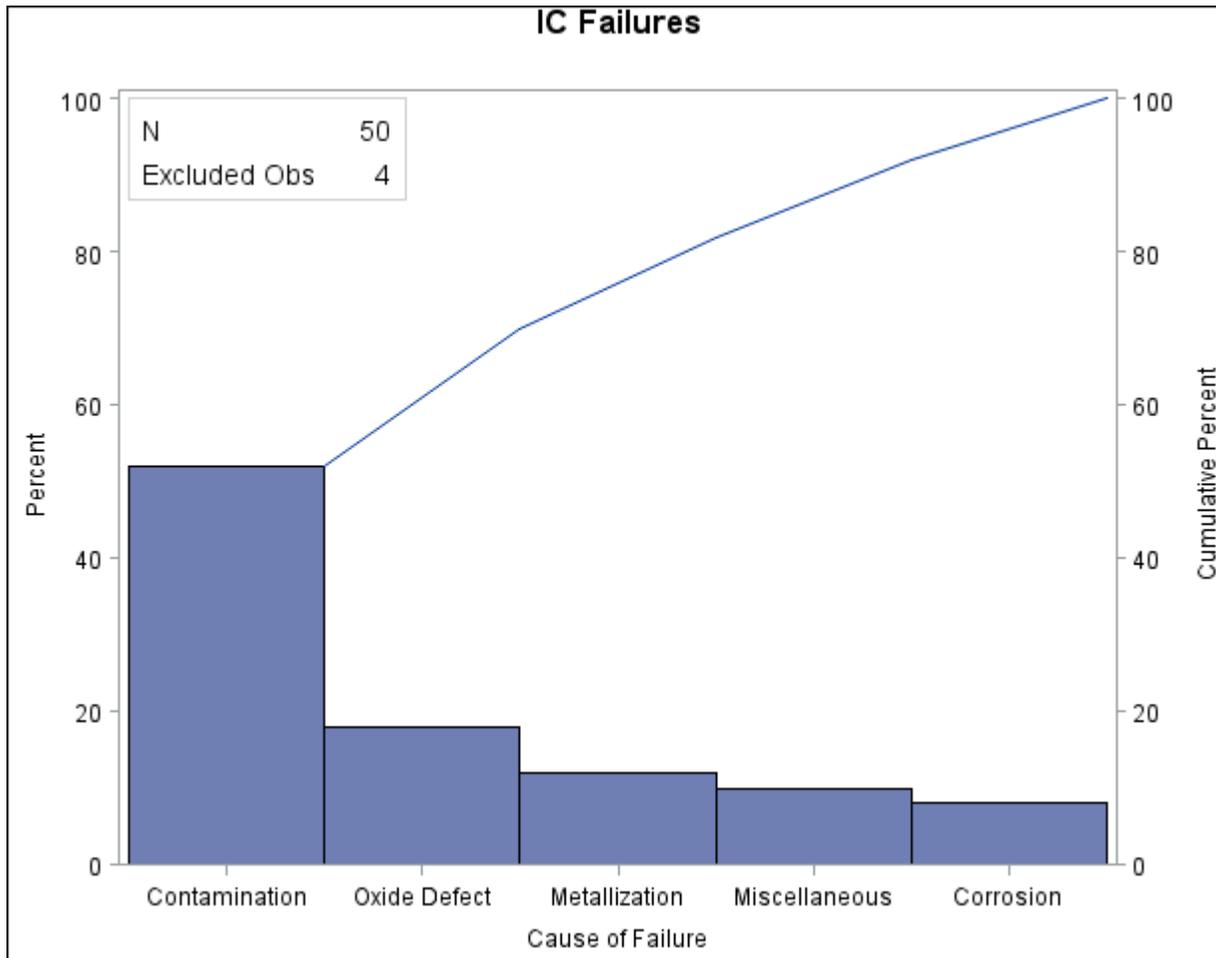

```

ods graphics off;
title 'IC Failures';
proc pareto data=Failure3;
  vbar Cause /
    freq      = Counts
    maxncat   = 5;
  inset n nexcl / height = 3;
run;

```

The resulting chart is displayed in [Figure 15.12](#). The INSET statement immediately follows the chart statement that creates the graphical display (in this case, the VBAR statement). Specify the keywords for inset statistics (such as N and NEXCL) immediately after the word INSET. The inset statistics appear in the order in which you specify the keywords. The HEIGHT= option in the INSET statement specifies the text height used to display the statistics in the inset.

A complete list of keywords that you can use with the INSET statement is provided in [“Summary of INSET Keywords”](#) on page 1166.

Figure 15.12 A Pareto Chart with an Inset

The following examples illustrate options commonly used for enhancing the appearance of an inset.

Customizing Labels and Formatting Values

By default, each inset statistic is identified with an appropriate label, and each numeric value is printed using an appropriate format. However, you may want to provide your own labels and formats. For example, in [Figure 15.12](#) the default label used for the NEXCL statistic is rather long. The following statements produce a comparative Pareto chart with insets using a shorter label for the number of excluded observations. A format with one decimal place is also specified for each statistic. (These are integer values—the decimals are added only to demonstrate this feature.) Note that a single INSET statement produces an inset in each cell of the comparative Pareto chart.

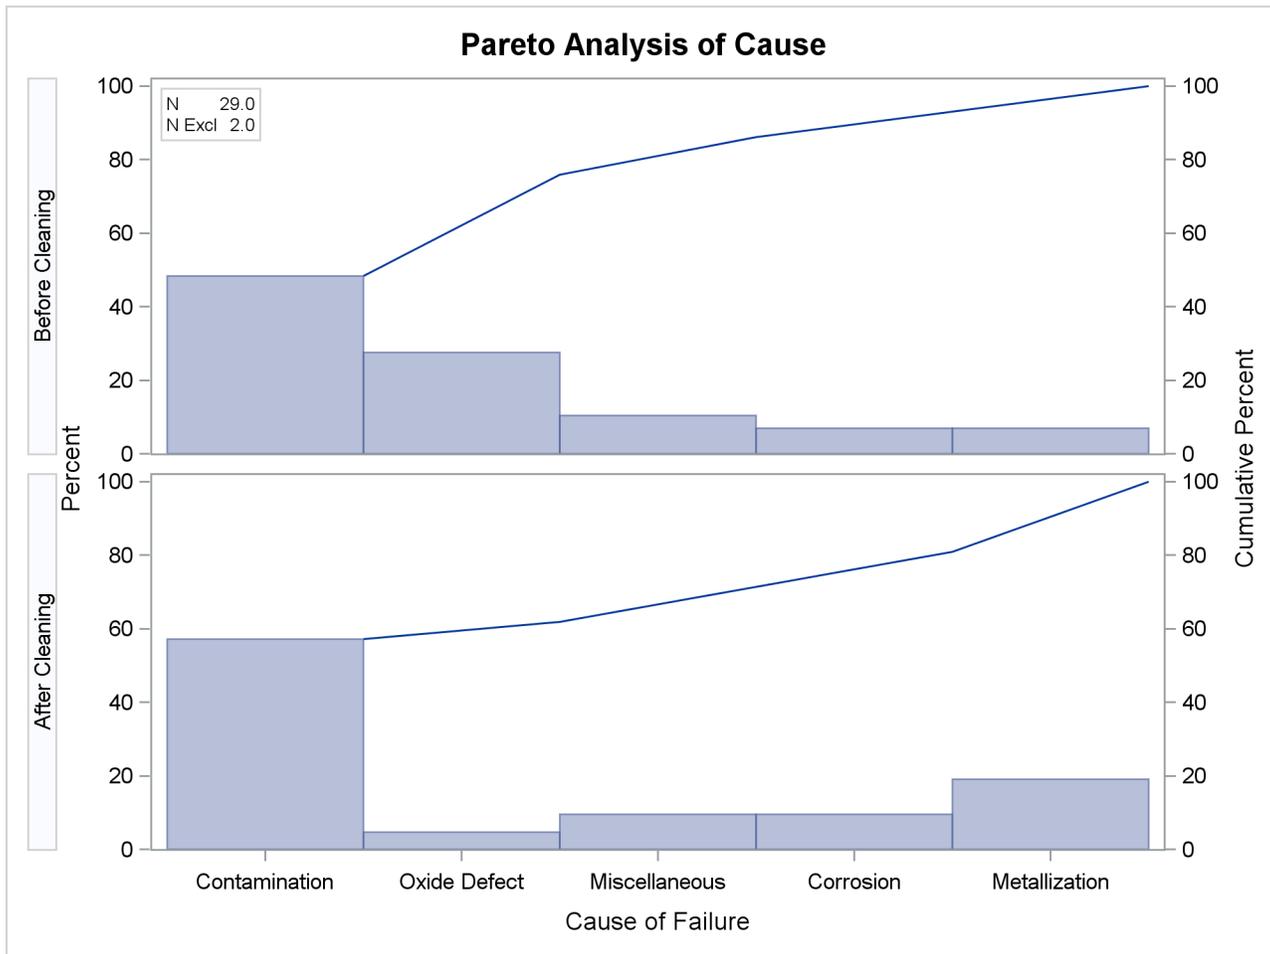

```
ods graphics on;
proc pareto data=Failure3;
  vbar Cause /
    class      = Stage
    freq       = Counts
    maxncat    = 5
    classkey   = 'Before Cleaning';
  inset n (4.1) nexcl='N Excl' (3.1);
run;
```

The ODS GRAPHICS ON statement specified before the PROC PARETO statement enables ODS Graphics, so the Pareto chart is created using ODS Graphics instead of traditional graphics.

The resulting chart is displayed in [Figure 15.13](#). You can provide your own label by specifying the keyword for that statistic followed by an equal sign (=) and the label in quotes. The label can have up to 24 characters.

The format 4.1 specified in parentheses after the N keyword displays the statistics with a field width of four and one decimal place. In general, you can specify any numeric SAS format in parentheses after an inset keyword. You can also specify a format to be used for all the statistics in the INSET statement with the FORMAT= option. For more information about SAS formats, refer to *SAS Formats and Informats: Reference*.

Note that if you specify both a label and a format for a statistic, the label must appear before the format.

Figure 15.13 Customizing Labels and Formatting Values in an Inset

Adding a Header and Positioning the Inset

In the previous examples, the insets are displayed in the upper left corners of the plots, which is the default position for insets added to Pareto charts. You can control the inset position with the `POSITION=` option. In addition, you can display a header at the top of the inset with the `HEADER=` option. The following statements create a data set to be used with the `INSET DATA=` keyword and produce the horizontal Pareto chart shown in Figure 15.14:

```
data location;
  length _LABEL_ $ 10 _VALUE_ $ 12;
  input _LABEL_ _VALUE_ &;
datalines;
Plant      Santa Clara
Line      1
;

ods graphics off;
title 'IC Failures';
proc pareto data=Failure3;
```

```

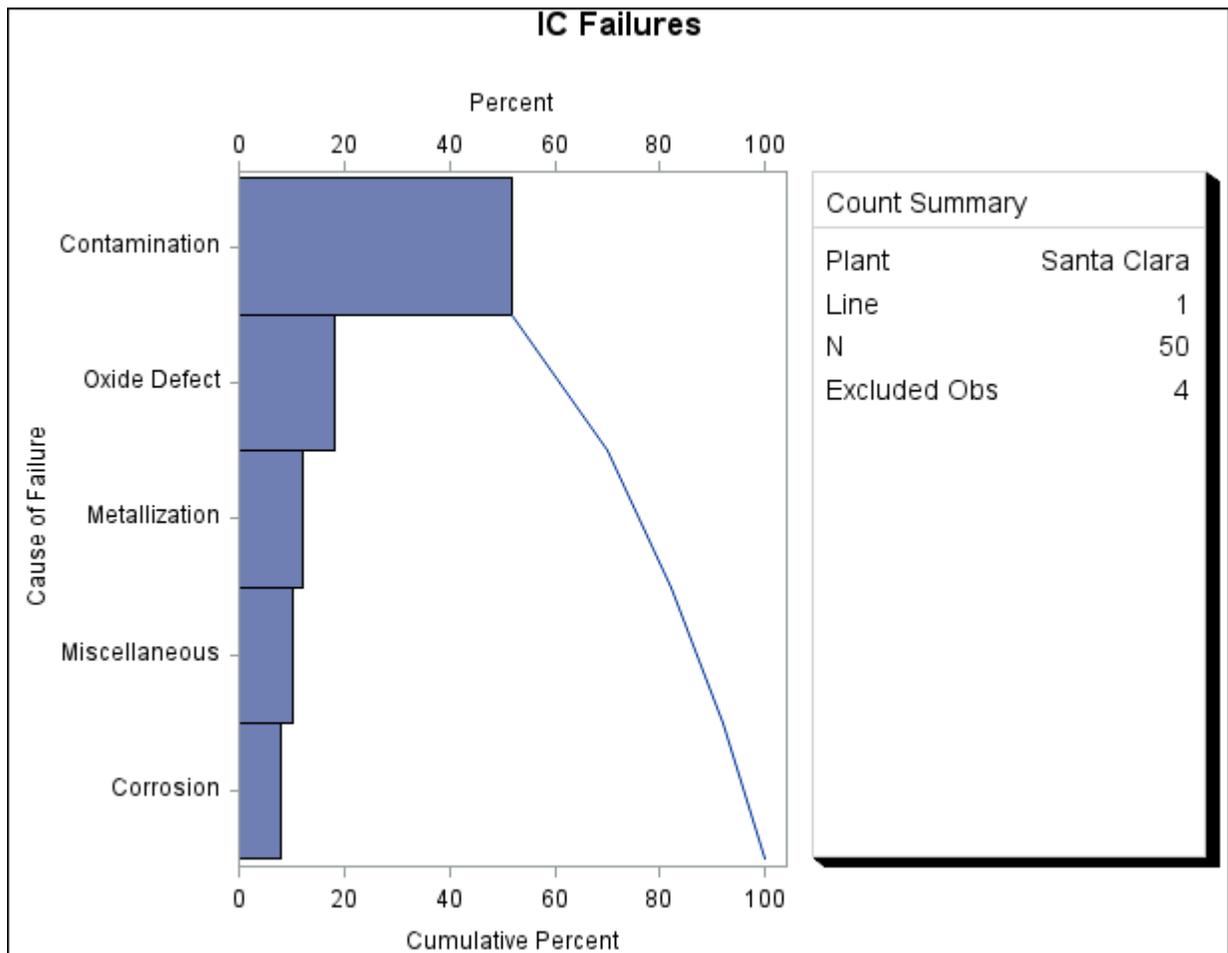

hbar Cause /
  freq      = Counts
  maxncat   = 5;
inset data = location n nexcl /
  height    = 3
  position  = rm
  cshadow   = black
  header    = 'Count Summary';
run;

```

The header (in this case, *Count Summary*) can be up to 40 characters. Note that a longer list of inset statistics is requested. Consequently, POSITION=RM is specified to position the inset in the right margin so that it does not interfere with features of the chart. For more information about positioning, see “[Details: INSET Statement](#)” on page 1169. The CSHADOW= option is used to display a drop shadow on this inset. The *options*, such as [HEADER=](#), [POSITION=](#), and [CSHADOW=](#), are specified after the slash (/) in the INSET statement. For more details on INSET statement options, see “[Dictionary of Options](#)” on page 1167.

Note that the contents of the data set location appear before other statistics in the inset. The position of the DATA= keyword in the keyword list determines the position of the data set’s contents in the inset.

Figure 15.14 Adding a Header and Repositioning the Inset

Syntax: INSET Statement

The syntax for the INSET statement is as follows:

```
INSET keyword-list </ options > ;
```

You can use any number of INSET statements in the PARETO procedure. Each INSET statement produces a separate inset and must follow one of the chart statements. When the chart statement produces a comparative Pareto chart, an inset appears in every cell produced by the chart statement. The statistics are displayed in the order in which they are specified. The following statements produce a vertical Pareto chart with insets in the upper left and upper right corners, and a horizontal comparative Pareto chart with insets in each cell.

```
proc pareto data=Failure3;
  vbar Cause / maxncat = 5 other = 'Others';
    inset nothercat / pos = nw;
    inset nother / pos = ne;
  hbar Cause / class = stage classkey = 'Before Cleaning';
    inset n / pos = ne;
run;
```

The statistics displayed in an inset are computed for a specific process variable using observations for the current BY group and CLASS= variable level, if applicable. For example, in the following statements there are two process variables (Tomato and Squash), a BY variable (Year), and two CLASS= variables (Fert and Pest). If there are three different years (levels of Year), then a total of six comparative Pareto charts are produced: three for each process variable. In addition, if there are two different levels of Fert and three of Pest, each comparative Pareto chart contains six cells. Each cell contains an inset with statistics computed for a particular process variable, year, and combination of Fert and Pest values.

```
proc pareto data=Plants;
  by Year;
  vbar (Tomato Squash) / class = (Fert Pest);
  inset n;
run;
```

The components of the INSET statement are described as follows.

keyword-list

can include any of the *keywords* listed in “[Summary of INSET Keywords](#)” on page 1166. The DATA= *keyword* requires an operand specified immediately after it, naming the data set containing data to be displayed.

The NOTHERCAT and NOTHER statistics are zero if the OTHER= option is not specified. The NEXCL statistic is zero if the OTHER= option *is* specified.

By default, inset statistics are identified with appropriate labels, and numeric values are printed using appropriate formats. However, you can provide customized labels and formats. You provide the customized label by specifying the *keyword* for that statistic followed by an equal sign (=) and the label in quotes. Labels can have up to 24 characters. You provide the numeric format in parentheses after the *keyword*. Note that if you specify both a label and a format for a statistic, the label must appear before the format. For an example, see the section “[Customizing Labels and Formatting Values](#)” on page 1162.

options

appear after the slash (/) and control the appearance of the inset. For example, the following INSET statement uses two appearance *options* (POSITION= and CTEXT=):

```
inset n nothercat nother / position=ne ctext=yellow;
```

The POSITION= option determines the location of the inset, and the CTEXT= option specifies the color of the text of the inset.

See the section “Summary of Options” on page 1166 for a list of all available *options* and “Dictionary of Options” on page 1167 for detailed descriptions. Note the difference between *keywords* and *options*; *keywords* specify the information to be displayed in an inset, whereas *options* control the appearance of the inset.

Summary of INSET Keywords

All keywords available with the PARETO procedure’s INSET statement request a single statistic in an inset, except for the DATA= keyword.

The DATA= keyword specifies a SAS data set containing (label, value) pairs to be displayed in an inset. The data set must contain the variables _LABEL_ and _VALUE_. _LABEL_ is a character variable whose values provide labels for inset entries. _VALUE_ can be character or numeric, and it provides values displayed in the inset. The label and value from each observation in the DATA= data set occupy one line in the inset. Figure 15.14 shows an inset containing entries from a DATA= data set.

Table 15.4 Summary Statistics

Keyword	Description
N	sample size
NOTHERCAT	number of categories merged to form OTHER= category in restricted Pareto chart
NOTHER	number of observations in OTHER= category
NEXCL	observations excluded in restricted Pareto chart
SUMWGTS	sum across all categories of weighted frequencies
DATA=	(label, value) pairs from <i>SAS-data-set</i>

Summary of Options

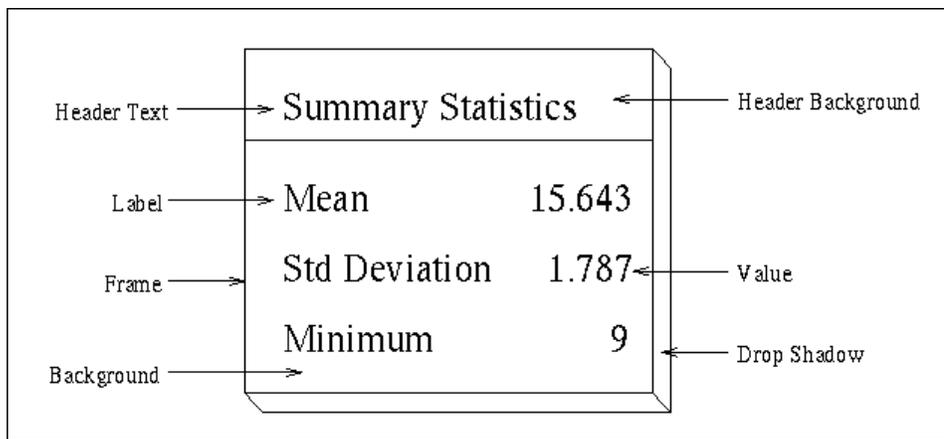

The following table lists the INSET statement options. For complete descriptions, see “Dictionary of Options” on page 1167 which follows this section.

Table 15.5 INSET Options

Keyword	Description
CFILL=	specifies color of inset background
CFILLH=	specifies color of header background
CFRAME=	specifies color of frame
CHEADER=	specifies color of header text
CSHADOW=	specifies color of drop shadow
CTEXT=	specifies color of inset text
DATA	specifies data units for POSITION=(<i>x</i> , <i>y</i>) coordinates
FONT=	specifies font of text
FORMAT=	specifies format of values in inset
GUTTER=	specifies gutter width for inset in top or bottom margin
HEADER=	specifies header text
HEIGHT=	specifies height of inset text
NCOLS=	specifies number of columns for inset in top or bottom margin
NOFRAME	suppresses frame around inset
POSITION=	specifies position of inset
REFPOINT=	specifies reference point of inset positioned with POSITION=(<i>x</i> , <i>y</i>) coordinates

Dictionary of Options

The following entries provide detailed descriptions of options for the INSET statement. The marginal notes *Traditional Graphics* and *ODS Graphics* identify options that apply only to traditional graphics and ODS Graphics output, respectively. Terms used in this section are illustrated in Figure 15.15.

Figure 15.15 The Inset

CFILL=*color* | BLANK*Traditional Graphics*

specifies the color of the background (including the header background if you do not specify the CFILLH= option).

If you do not specify the CFILL= option, then, by default, the background is empty. This means that items that overlap the inset (such as Pareto bars or the cumulative percent curve) show through the inset. If you specify any value for the CFILL= option, then overlapping items no longer show through the inset. Specify CFILL=BLANK to leave the background uncolored and also to prevent items from showing through the inset.

CFILLH=*color**Traditional Graphics*

specifies the color of the header background. By default, if you do not specify a CFILLH= color, the CFILL= color is used.

CFRAME=*color**Traditional Graphics*

specifies the color of the frame. By default, the frame is the same color as the axis of the plot.

CHEADER=*color**Traditional Graphics*

specifies the color of the header text. By default, if you do not specify a CHEADER= color, the CTEXT= color is used.

CSHADOW=*color***CS=*color****Traditional Graphics*

specifies the color of the drop shadow. See [Figure 15.14](#) for an example. By default, if you do not specify the CSHADOW= option, a drop shadow is not displayed.

CTEXT=*color***CT=*color****Traditional Graphics*

specifies the color of the text. By default, the inset text color is the same as the other text on the plot.

DATA

specifies that data coordinates are to be used in positioning the inset with the POSITION= option. The DATA option is available only when you specify POSITION= (*x*, *y*), and it must be placed immediately after the coordinates (*x*, *y*). For details, see the entry for the POSITION= option or “Positioning the Inset Using Coordinates” on page 1172. See [Figure 15.18](#) for an example.

FONT=*font**Traditional Graphics*

specifies the font of the text. By default, the font is SIMPLEX if the inset is located in the interior of the plot, and the font is the same as the other text displayed on the plot if the inset is located in the exterior of the plot.

FORMAT=*format*

specifies a format for all the values displayed in an inset. If you specify a format for a particular statistic, then this format overrides the format you specified with the FORMAT= option.

GUTTER=*value*

specifies the gutter width in percent screen units for an inset located in the top or bottom margin. The gutter is the space between columns of values in an inset. *ODS Graphics*

HEADER= *'string'*

specifies the header text. The *string* cannot exceed 40 characters. If you do not specify the HEADER= option, no header line appears in the inset.

HEIGHT=*value*

specifies the height of the text. *Traditional Graphics*

NCOLS=*n*

specifies the number of columns of (label, value) pairs displayed in an inset located in the top or bottom margin. *ODS Graphics*

NOFRAME

suppresses the frame drawn around the text.

POSITION=*position***POS=***position*

determines the position of the inset. The *position* can be a compass point keyword, a margin keyword, or a pair of coordinates (*x*, *y*). You can specify coordinates in axis percent units or axis data units. For more information, see “[Details: INSET Statement](#)” on page 1169. By default, POSITION=NW, which positions the inset in the upper left (northwest) corner of the display.

NOTE: In this release of the PARETO procedure, you cannot specify coordinates with the POSITION= option when producing ODS Graphics output.

REFPOINT=BR | BL | TR | TL**RP=**BR | BL | TR | TL

specifies the reference point for an inset that is positioned by a pair of coordinates with the POSITION= option. Use the REFPOINT= option with POSITION= coordinates. The REFPOINT= option specifies which corner of the inset frame you want positioned at coordinates (*x*, *y*). The keywords BL, BR, TL, and TR represent bottom left, bottom right, top left, and top right, respectively. See [Figure 15.19](#) for an example. The default is REFPOINT=BL. *Traditional Graphics*

If you specify the position of the inset as a compass point or margin keyword, the REFPOINT= option is ignored. For more information, see “[Positioning the Inset Using Coordinates](#)” on page 1172.

Details: INSET Statement

This section provides details on three different methods of positioning the inset using the POSITION= option. With the POSITION= option, you can specify

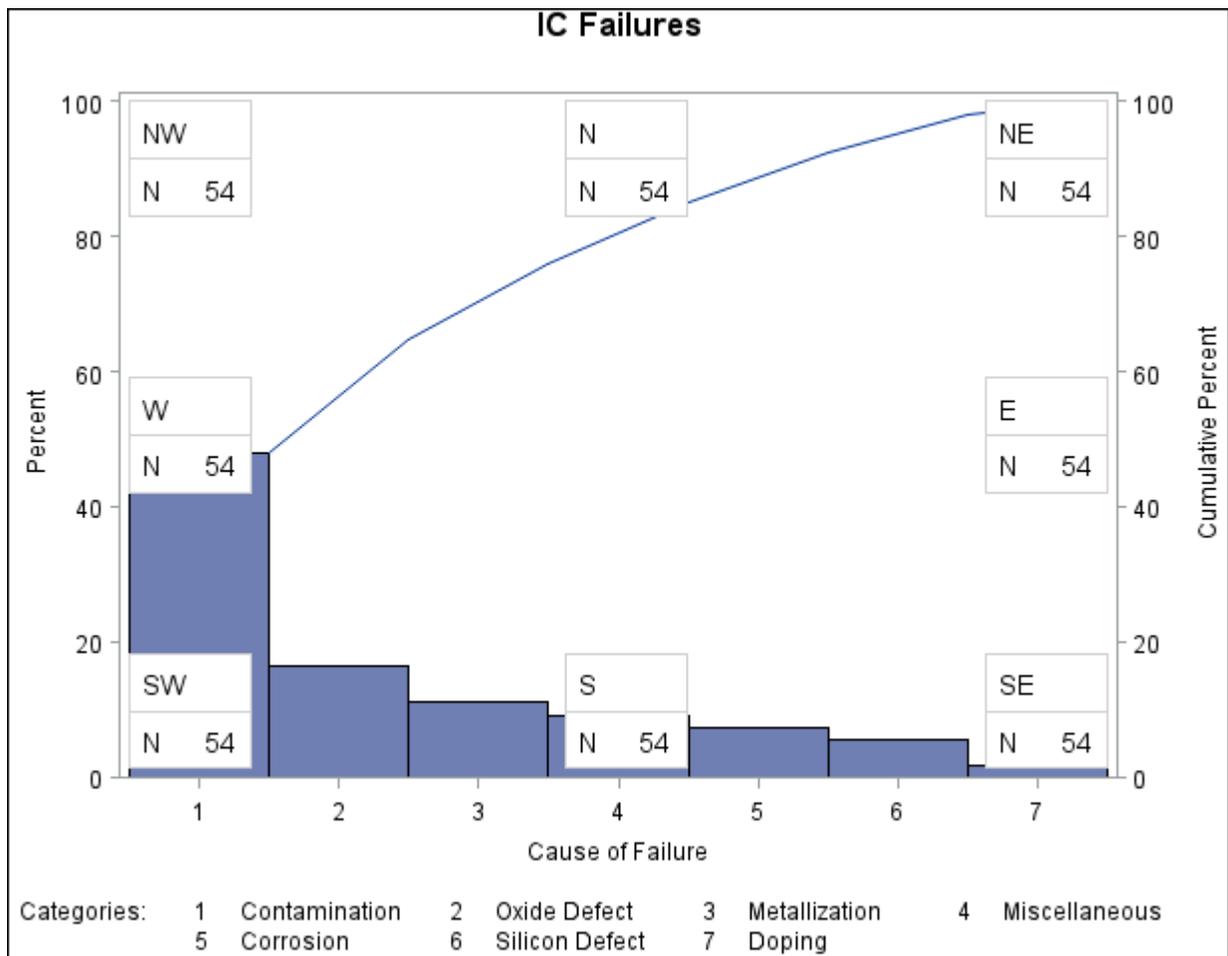

- compass points
- keywords for margin positions
- coordinates in data units or percent axis units

Positioning the Inset Using Compass Points

See *SHWINS2* in the *SAS/QC Sample Library*. You can specify the eight compass points N, NE, E, SE, S, SW, W, and NW as keywords for the POSITION= option. The following statements create the display in Figure 15.16, which demonstrates all eight compass positions. The default is NW.

```
ods graphics off;
proc pareto data=Failure3;
  vbar Cause / freq = Counts;
  inset n / height=3 cfill=blank header='NW' pos=nw;
  inset n / height=3 cfill=blank header='N ' pos=n ;
  inset n / height=3 cfill=blank header='NE' pos=ne;
  inset n / height=3 cfill=blank header='E ' pos=e ;
  inset n / height=3 cfill=blank header='SE' pos=se;
  inset n / height=3 cfill=blank header='S ' pos=s ;
  inset n / height=3 cfill=blank header='SW' pos=sw;
  inset n / height=3 cfill=blank header='W ' pos=w ;
run;
```

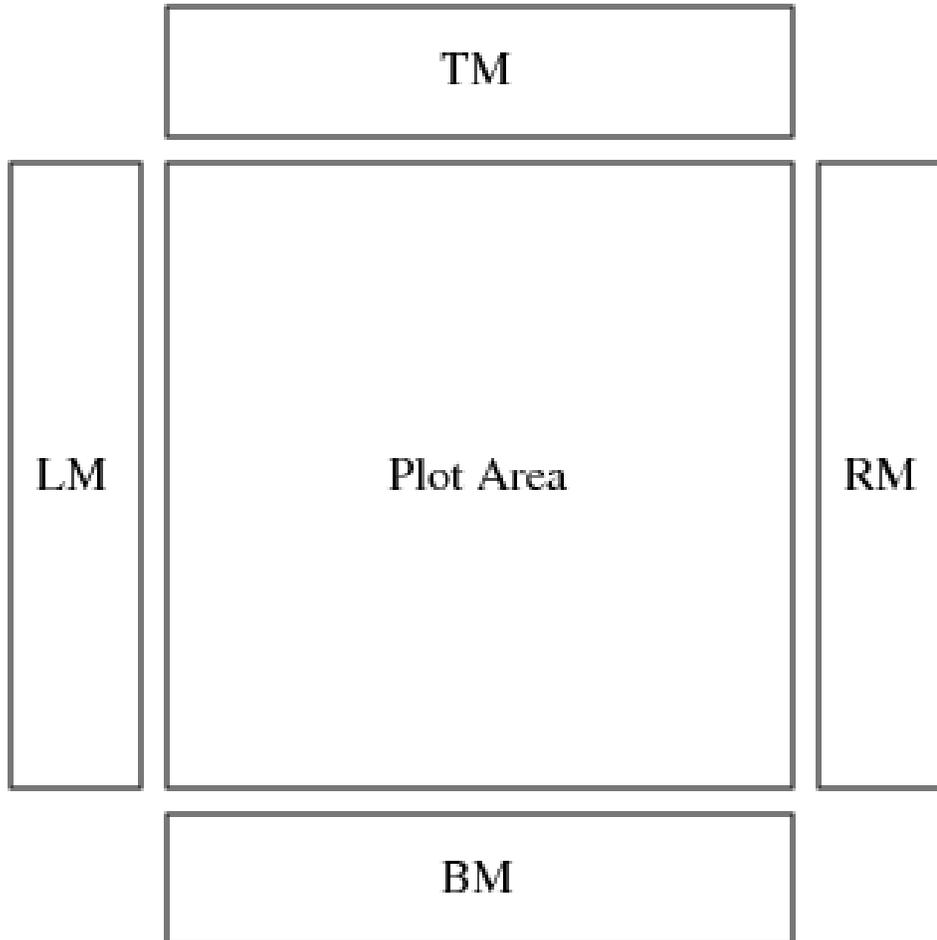

Figure 15.16 Insets Positioned Using Compass Points

Positioning the Inset in the Margins

Using the INSET statement you can also position an inset in one of the four margins surrounding the plot area using the margin keyword LM, RM, TM, or BM, as illustrated in [Figure 15.17](#).

Figure 15.17 Positioning Insets in the Margins

For an example of an inset placed in the right margin, see [Figure 15.14](#). Margin positions are recommended if a large number of statistics are listed in the INSET statement. If you attempt to display a lengthy inset in the interior of the plot, it is likely that the inset will collide with the data display.

Insets associated with a comparative Pareto chart cannot be positioned in the margins.

Positioning the Inset Using Coordinates

You can also specify the position of the inset with coordinates: POSITION= (*x*, *y*). The coordinates can be given in axis percent units (the default) or in axis data units.

NOTE: In this release of the PARETO procedure, you cannot position insets by using coordinates when producing ODS Graphics output.

Data Unit Coordinates

If you specify the DATA option immediately following the coordinates, the inset is positioned using axis data units. Data units along the category axis (the horizontal axis on a vertical bar chart or the vertical axis on a horizontal bar chart) are based on category numbers. Categories are numbered from left to right (vertical bar chart) or top to bottom (horizontal bar chart), starting with 1.

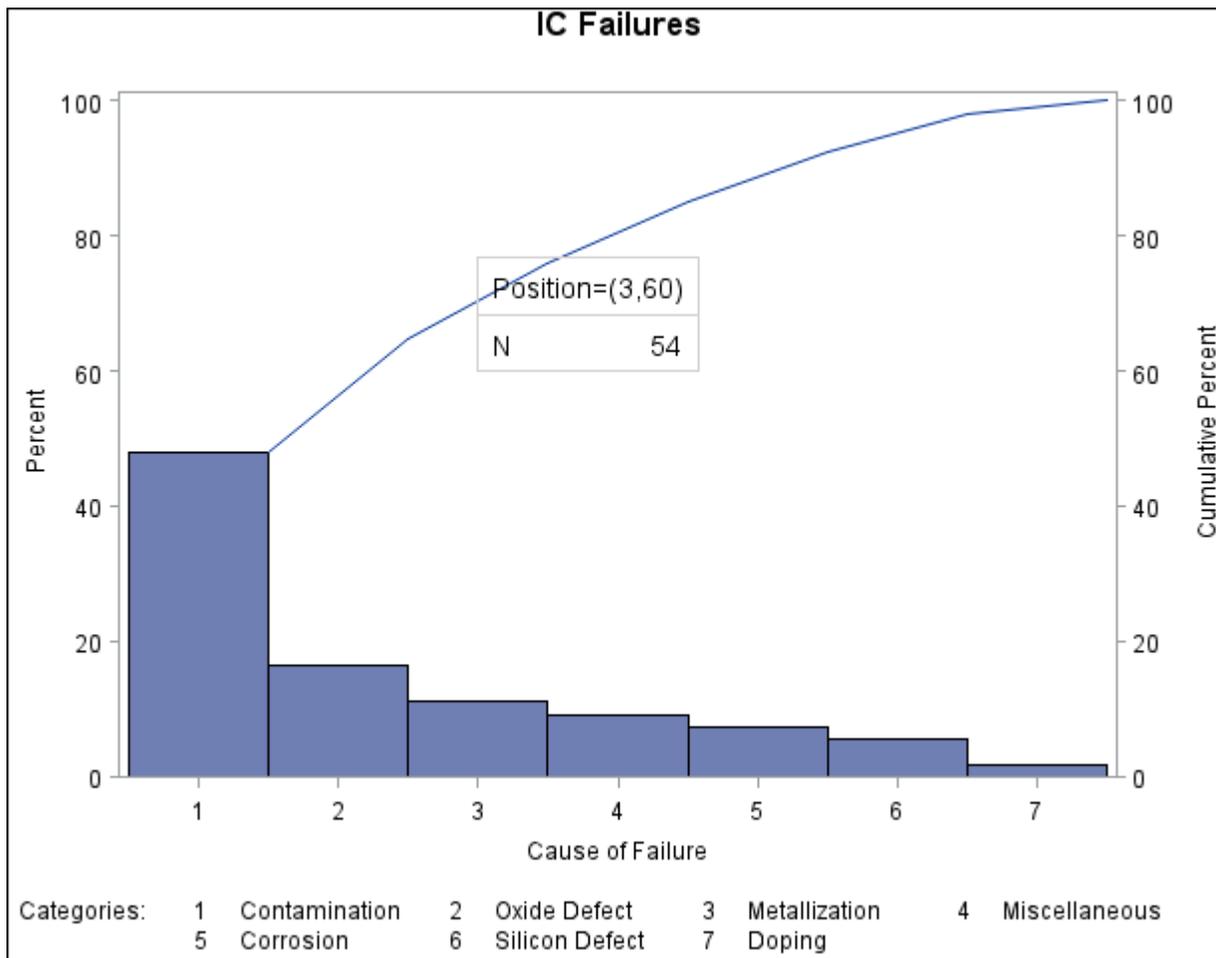

For example, the following statements produce the Pareto chart displayed in [Figure 15.18](#):

See SHWINS2 in the SAS/QC Sample Library

```
ods graphics off;
proc pareto data=Failure3;
  vbar Cause / freq = Counts;
  inset n / header   = 'Position=(3,60)'
           position = (3,60) data
           height    = 3;
run;
```

The bottom left corner of the inset is lined up with the tick mark for the third category on the horizontal axis and at 60 on the vertical axis. By default, the specified coordinates determine the position of the bottom left corner of the inset. You can change this reference point with the REFPOINT= option, as in the next example.

Figure 15.18 Inset Positioned Using Data Unit Coordinates

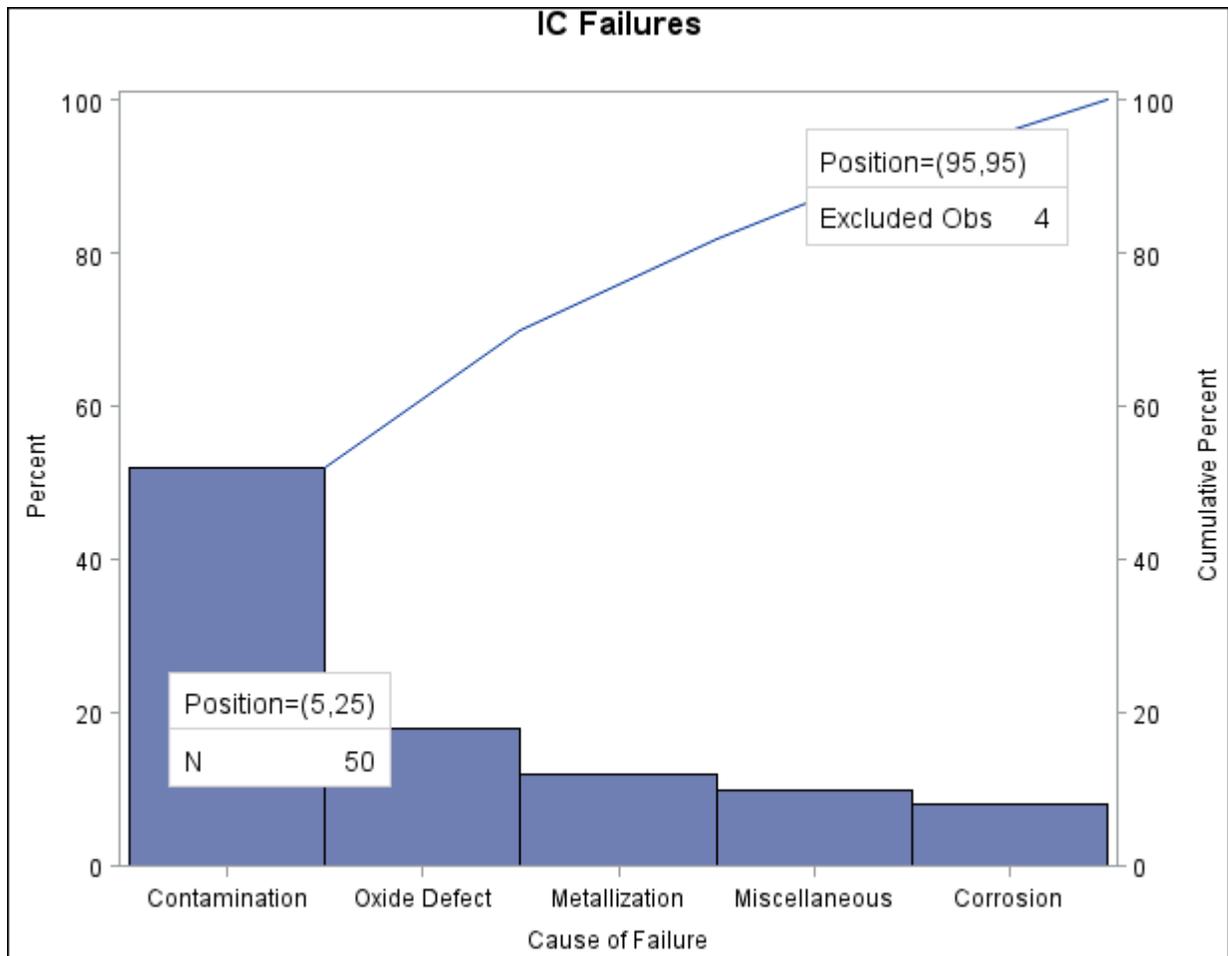

Axis Percent Unit Coordinates

If you do not use the DATA option, the inset is positioned using axis percent units. The coordinates of the bottom left corner of the display are (0, 0), while the upper right corner is (100, 100). For example, the following statements create a horizontal Pareto chart with two insets, both positioned using coordinates in axis percent units. *See SHWINS2 in the SAS/QC Sample Library*

```
ods graphics off;
proc pareto data=Failure3;
  vbar Cause / freq      = Counts
              maxncat   = 5;
  inset n / position = (5,25)
        header   = 'Position=(5,25) '
        height   = 3
        cfill    = blank
        refpoint = tl;
  inset nexcl / position = (95,95)
        header   = 'Position=(95,95) '
        height   = 3
        cfill    = blank
        refpoint = tr;
run;
```

The display is shown in Figure 15.19. Notice that the REFPOINT= option is used to determine which corner of the inset is to be placed at the coordinates specified with the POSITION= option. The first inset has REFPOINT=TL, so the top left corner of the inset is positioned 5% of the way across the horizontal axis and 25% of the way up the vertical axis. The second inset has REFPOINT=TR, so the top right corner of the inset is positioned 95% of the way across the horizontal axis and 95% of the way up the vertical axis. Note also that coordinates in axis percent units must be *between* 0 and 100.

Figure 15.19 Inset Positioned Using Axis Percent Unit Coordinates

Details and Examples: PARETO Procedure

Details: PARETO Procedure

This chapter provides details on the following topics:

- terminology
- labels for chart features
- scaling the cumulative percent curve
- creating output data sets
- constructing effective Pareto charts
- missing values
- the role of variable formats
- large data sets

The section “Examples: PARETO Procedure” on page 1182 illustrates these topics with several detailed examples.

Terminology

Basic Pareto Charts

A basic Pareto chart (see [Figure 15.6](#)) analyzes the unique values of a *process variable*, which are referred to as *Pareto categories* or *levels*. These values typically represent problems encountered during some phase of a manufacturing or service activity.

A basic vertical Pareto chart (as produced by the PARETO procedure’s VBAR statement) has one horizontal and two vertical axes. The horizontal (or *category*) axis is displayed at the bottom of the chart and lists the Pareto categories. The *primary vertical axis* (or *frequency axis*) is displayed on the left. The relative frequency of each Pareto category is represented by a vertical bar whose height is measured on the primary vertical axis. You can use the SCALE= option to scale this axis in percent, count, or weight units. The *secondary vertical axis* (or *cumulative percent axis*) is displayed on the right. This axis is scaled in cumulative percent units and is used to read the *cumulative percent curve*. The height of each point on the curve represents the percent of the total frequency accounted for by the Pareto categories to the left of the point.

In a horizontal Pareto chart (as produced by the HBAR statement), the category axis is displayed vertically on the left. Categories appear in order of decreasing relative frequency from top to bottom. The frequency axis appears at the top of the chart and the cumulative percent axis is at the bottom. The relative frequencies of the Pareto categories are represented by horizontal bars. A point on the cumulative percent curve represents the percent of the total frequency accounted for by the Pareto categories above that point.

NOTE: For the sake of brevity, in this chapter the term *height* is used to refer to the size of a bar as measured along the frequency axis, whether the Pareto chart is oriented vertically or horizontally.

Restricted Pareto Charts

A *restricted Pareto chart* (see Figure 15.10) displays only the n most frequently occurring categories in a data set that contains N categories, where $N > n$. The remaining $N - n$ categories are dropped or are merged into a single “other” category created with the OTHER= option. The MAXCMPCT=, MAXNCAT=, and MINPCT= options provide alternative methods for specifying n . See the entries for these options in the section “Dictionary of Options” on page 1138.

Weighted Pareto Charts

A *weighted Pareto chart* (see Example 15.8) displays bars whose heights represent the weighted frequencies of the categories. Typical weights are the cost of repair or the loss incurred by the customer.

The weight W_i for the i th Pareto category is computed as

$$W_i = \sum_{u \in C_i} w(u) f(u)$$

where C_i is the set of observations that make up the i th category, $w(u)$ is the value of the weight variable in the u th observation, and $f(u)$ is the value of the frequency variable in the u th observation (taking $f(u) \equiv 1$ if a FREQ= variable is not specified). If SCALE=WEIGHT is specified, the height of the bar for the i th category is W_i . If SCALE=PERCENT is specified, the height of this bar is

$$\frac{100W_i}{\sum_{j=1}^N W_j}$$

where N is the total number of categories.

Comparative Pareto Charts

A *comparative Pareto chart* combines two or more Pareto charts for the same process variable. The component charts are displayed with uniform axes to facilitate comparison. The observations represented by a components chart are referred to as a *cell*. The framed areas for the component charts are referred to as *tiles*.

In a *one-way comparative Pareto chart*, each component chart corresponds to a different level of a single classification variable specified with the CLASS= option. The component charts are arranged in a stack or a row, as illustrated in Output 15.1.3, Output 15.2.2, and Output 15.2.3. In a *two-way comparative Pareto chart*, each component chart corresponds to a different combination of levels of two classification variables specified with the CLASS= option. The component charts are arranged in a matrix, as illustrated in Output 15.2.4.

In any comparative Pareto chart there is a *key cell*, in which the bars are in decreasing order and whose order is imposed on all the other cells to achieve a uniform category axis. By default, the key cell is the cell in the upper left corner, but you can use the CLASSKEY= option to designate any other cell as the key cell. In this case, the rows and columns of the comparative chart will be rearranged so that the key cell appears in the upper left. However, if you require the rows and columns in a particular order, you can specify the NOKEYMOVE option in conjunction with the CLASSKEY= option to suppress the rearrangement.

If you are creating traditional graphics or ODS Graphics output, you can use the NROWS= and NCOLS= options to specify the numbers of rows and columns in a comparative Pareto chart. By default, NROWS=2 and NCOLS=1 for a one-way comparison and NROWS=2 and NCOLS=2 for a two-way comparison. There is no upper limit to the number of rows or columns that you can specify, but in practice the limit is determined by the area of the graphical display. If the numbers of classification variable levels exceed the NROWS= and NCOLS= values, the chart is created on multiple screens or pages.

If the same set of Pareto categories does not occur in each cell of a comparative Pareto chart, the categories are said to be *unbalanced*. In this case, the procedure uses the following convention to construct the uniform category axis. First, the categories that occur in the key cell are arranged on the category axis from left to right (top to bottom for a horizontal chart), sorted in decreasing order of frequency, with tied levels arranged in order of their formatted values. The categories not in the key cell are assigned frequencies of zero in the key cell, and they are arranged at the right (bottom) of the category axis, where they are ordered by their formatted values. This arrangement is simply a convention of the procedure and should not be interpreted to mean that one category is more important than another.

Whether the categories in the input data set are balanced or not, the categories in the OUT= data set are always balanced. The procedure balances this data set by assigning values of zero to the _COUNT_ and _PCT_ variables as necessary.

Unbalanced categories present a special problem when the MAXNCAT= option is used to restrict the number of categories displayed on the chart. For instance, suppose that you specify MAXNCAT=12 and there are 15 categories in all, 10 of which occur in the key cell. Since there is no unambiguous method for selecting two of the remaining five categories to complete the restricted list, the procedure reduces the restricted list to the categories that occur in the key cell and displays only those 10 categories. A warning message is issued in the SAS log.

Labels for Chart Features

The following table summarizes methods for labeling the features of Pareto charts.

Table 15.6 Labeling Features of Pareto Charts

Feature	Method for Specifying Label
titles	TITLE n statements
footnotes	FOOTNOTE n statements
category axis	<i>process variable</i> label
primary vertical axis (VBAR only)	VAXISLABEL= option
secondary vertical axis (VBAR only)	VAXIS2LABEL= option
primary horizontal axis (HBAR only)	HAXISLABEL= option
secondary horizontal axis (HBAR only)	HAXIS2LABEL= option
bars	BARLABEL= option
points on cumulative percent curve	CMPCTLABEL= option
rows and columns	CLASS= variable labels
cells	NLEGEND option or NLEGEND= variable
category legend	CATLEGLABEL= option
high/low bar legend	HLLEGLABEL= option
bar color legend	BARLEGLABEL= option
tile legend	TILELEGLABEL= option
annotation	ANNOTATE= and ANNOTATE2= data sets

Scaling the Cumulative Percent Curve

Pareto charts shown in textbooks typically scale the cumulative percent curve so that it is anchored at the top right corner of the leftmost bar. The upper end of the primary vertical axis is then extended to accommodate the curve. For an illustration, see [Output 15.2.1](#). By default, the PARETO procedure uses the top right corner as the anchor position on a vertical chart and the bottom right corner of the topmost bar as the anchor position on a horizontal chart. You can override the default with the ANCHOR= option.

This method of scaling is not feasible if the number of categories is very large and if the Pareto distribution is uniform. In this case, the bars are excessively compressed relative to the curve. Conversely, this method excessively compresses the curve relative to the bars when you use a count scale for the frequency axis in a comparative Pareto chart and the tallest bar does not occur in the key cell. In either situation, the procedure overrides the textbook scaling method and balances the scales of the bars and the curve.

You can use the AXISFACTOR= option to specify the extent to which the frequency axis should be extended. Alternatively, you can extend the frequency axis by using the VBAR statement VAXIS= option or HBAR statement HAXIS= option to specify the tick mark values for the axis.

Another scaling anomaly is illustrated by the comparative Pareto chart in [Output 15.1.4](#). Here, the cumulative percent curve in the bottom chart is not anchored due to the combination of a uniform count scale and different sample sizes in the two cells.

Output Data Sets

The OUT= data set saves the information displayed on a Pareto chart. If you specify CLASS= variables, the OUT= data set contains one block of observations for each combination of levels of the CLASS= variables, and within each block there is an observation. The observations are sorted in the order in which the categories are displayed on the chart. The following variables read from a DATA= data set are saved in an OUT= data set:

- process variables
- CLASS= variables
- BY variables
- WEIGHT= variables
- the CTILES= variable
- the TILELEGEND= variable
- the NLEGEND= variable
- CBARS= variables
- PBARS= variables
- BARLEGEND= variables

In addition, the OUT= data set contains the following variables that are created during the analysis:

- `_COUNT_`, which saves the frequency count for each Pareto category
- `_WCOUNT_`, which saves the weighted count for each category. This variable is created only when you specify the WEIGHT= option.
- `_PCT_`, which saves the percent of the total count for each category. If you specify the WEIGHT= option, the variable `_PCT_` saves the percent of the total weighted count.
- `_CMPCT_`, which saves the cumulative percent for each category

See [Output 15.8.2](#) for an example of an OUT= data set.

If you specify the MAXNCAT=, MAXCMPCT=, or MINPCT= option, the OUT= data set saves only the categories displayed on the chart. If you create an OTHER= category that merges the remaining categories, an additional observation is saved with the new category. Since the OTHER= value is defined as a formatted value of the process variable, you should also specify a corresponding internal value, as follows:

- If the process variable is a character variable, specify the internal value with the OTHERCVAL= option. If you do not specify this value, the OTHER= value is saved as the internal value.
- If the process variable is a numeric variable, specify the internal value with the OTHERNVAL= option. If you do not specify this value, an internal missing value is saved.

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*).

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. HBAR and VBAR statement options used to control the appearance of traditional graphics are ignored for ODS Graphics output.

When ODS Graphics is in effect, the PARETO procedure assigns a name to graphs it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 15.7](#).

Table 15.7 ODS Graphics Produced by the PARETO Procedure

ODS Graph Name	Plot Description
ParetoChart	Pareto chart

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Constructing Effective Pareto Charts

The following are recommendations for improving the visual clarity of Pareto charts:

- Decide carefully how the bars should be scaled. The default percent scale is not always the best choice. For instance, a count scale may be more appropriate in a comparative Pareto chart where the total count per cell varies widely from cell to cell and where you want to compare Pareto distributions on an *absolute* scale rather than a *relative* scale. You can request a count scale by specifying SCALE=COUNT. In other situations, it may be more appropriate to use a weighted percent scale or a weighted count scale (specify a WEIGHT= variable and either SCALE=PERCENT or SCALE=WEIGHT).
- Use a weight variable if the counts are dependent on a factor such as exposure or opportunity that varies from one category to another. For instance, suppose that you are creating a Pareto chart for the number of medical claims submitted by company employees categorized by job title. The counts can be weighted to adjust for the fact that there are more individuals in some jobs than in others and for the fact that some jobs may be associated with greater health risks than others.
- Use the NOCURVE option to eliminate the cumulative percent curve in situations where the curve reveals little information about the data. In general, the bars should be more prominent than the curve.
- Maximize the space used for the bars by eliminating unnecessary labels and visual clutter. This is particularly important for comparative Pareto charts. The NOHLABEL and NOVLABEL options are useful for this purpose. You can also use the NOVLABEL2, NOVTICK, and NOVTICK2 options with a VBAR statement or the NOHLABEL2, NOHTICK, and NOHTICK2 options with an HBAR statement.

- Make legends more informative by specifying legend labels.
- Avoid filling bars with multiple types of cross-hatched patterns; solid color fills are less distracting. Use color sparingly to emphasize important features (such as the “vital few” categories), and choose bar colors that provide good visual discrimination.
- If you are working with a large data set involving many categories, limit the number displayed to achieve visual clarity.
- If your application involves classification effects, construct more than one Pareto chart for the data using various combinations of classification variables (this approach is illustrated in [Example 15.2](#)).
- Provide reference lines on comparative Pareto charts to aid visual comparison.

Refer to Chapter 2 of Cleveland (1985) for a general discussion of the principles of statistical graphics.

Missing Values

By default, observations with missing values of a process variable are not processed. If you specify the MISSING option, then missing values are treated as a Pareto category.

Likewise, observations with missing values of the CLASS= variables are not processed by default. Missing values of the first CLASS= variable are treated as a level if the MISSING1 option is specified, and missing values of the second CLASS= variable are treated as a level if the MISSING2 option is specified.

Role of Variable Formats

The categories of a Pareto chart are always determined using formatted values of the process variable, and the format is used to label the categories.

On the chart, the categories are displayed in decreasing order of frequency. If there are multiple categories with the same count, the tied categories are displayed in order of their formatted values.

When you create a comparative Pareto chart, the formatted levels of the CLASS= variables are used to group the data into cells. There is a cell for each level of the CLASS= variable in a one-way comparative chart, and there is a cell for each combination of levels of the CLASS= variables in a two-way comparative chart.

You can specify the order of the rows and columns corresponding to the classification levels with the ORDER1= and ORDER2= options. The default value of these options is INTERNAL, which means that the order is determined by the internal values of the CLASS= variables. It is possible for a particular formatted value to correspond to more than one internal value. To resolve this ambiguity, the internal value that determines the position of the row or column is the value that occurs first in the input data set.

Other values that you can specify for the ORDER1= and ORDER2= options are FORMATTED, FREQ, and DATA.

Large Data Sets

While there is no limit to the number of observations that can be read from an input data set, the maximum number of Pareto categories that can be read is 32,767. This limit is a practical issue only if you are creating a restricted Pareto chart from a large data set, because the number of categories that can be displayed is limited by the resolution of your graphical display. The number of categories that can be read is limited by the amount of memory available, since the levels are stored in memory. If you run out of memory, you should first reduce the data with the FREQ procedure.

Examples: PARETO Procedure

Example 15.1: Creating Before-and-After Pareto Charts

See PARETO7 in the SAS/QC Sample Library During the manufacture of a metal-oxide semiconductor (MOS) capacitor, causes of failures were recorded before and after a tube in the diffusion furnace was cleaned. This information was saved in a SAS data set named Failure3.

```
data Failure3;
  length Cause $ 16 Stage $ 16;
  label Cause = 'Cause of Failure';
  input Stage & $ Cause & $ Counts;
  datalines;
Before Cleaning   Contamination    14
Before Cleaning   Corrosion          2
Before Cleaning   Doping            1
Before Cleaning   Metallization     2
Before Cleaning   Miscellaneous     3
Before Cleaning   Oxide Defect      8
Before Cleaning   Silicon Defect    1
After Cleaning    Doping            0
After Cleaning    Corrosion          2
After Cleaning    Metallization     4
After Cleaning    Miscellaneous     2
After Cleaning    Oxide Defect      1
After Cleaning    Contamination    12
After Cleaning    Silicon Defect    2
;
```

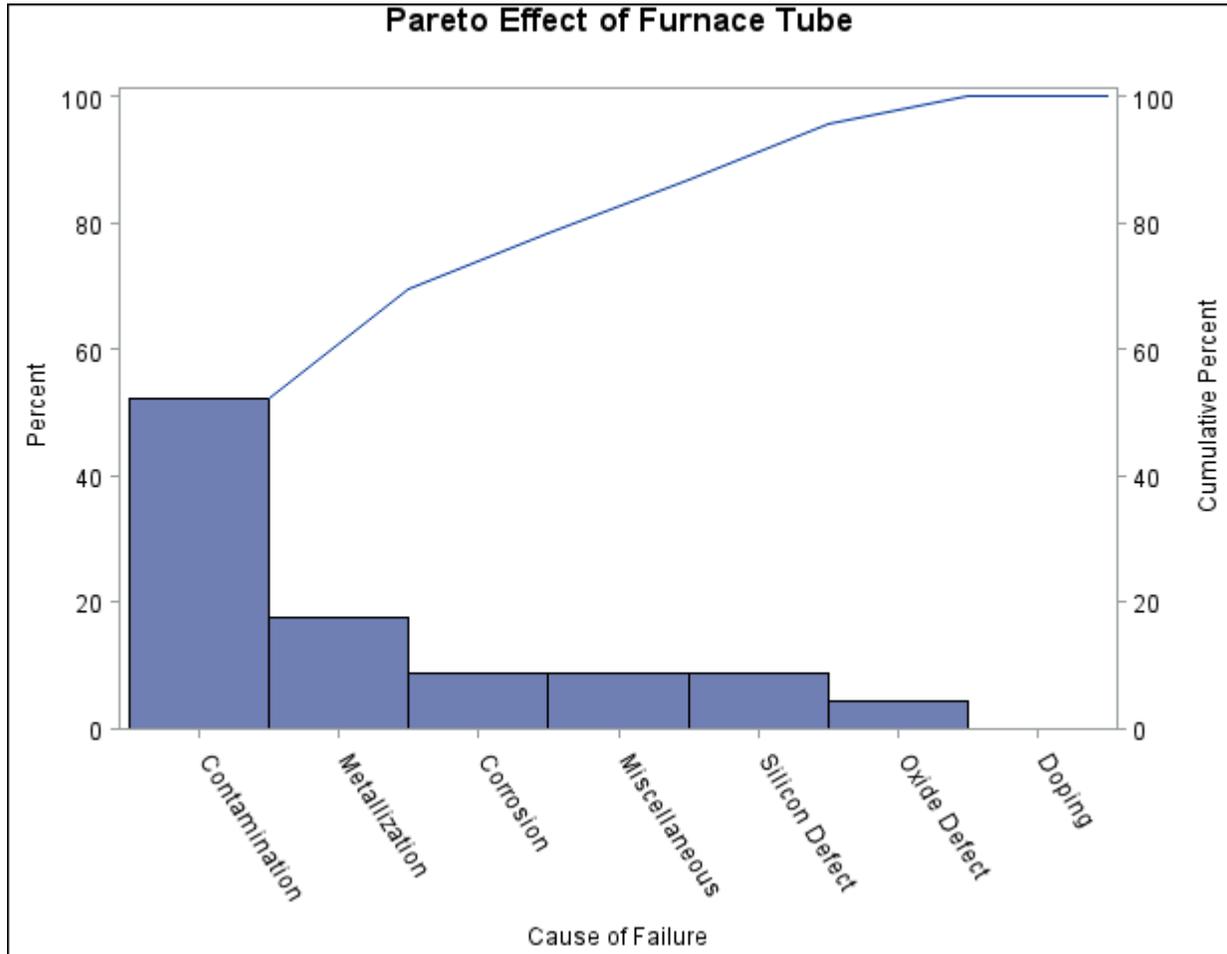

To compare distribution of failures before and after cleaning, you can create two separate Pareto charts, one for the observations in which Stage is equal to 'Before Cleaning' and one for the observations in which Stage is equal to 'After Cleaning'. You can do this with the BY statement.

```
proc sort data=Failure3;
  by Stage;
run;

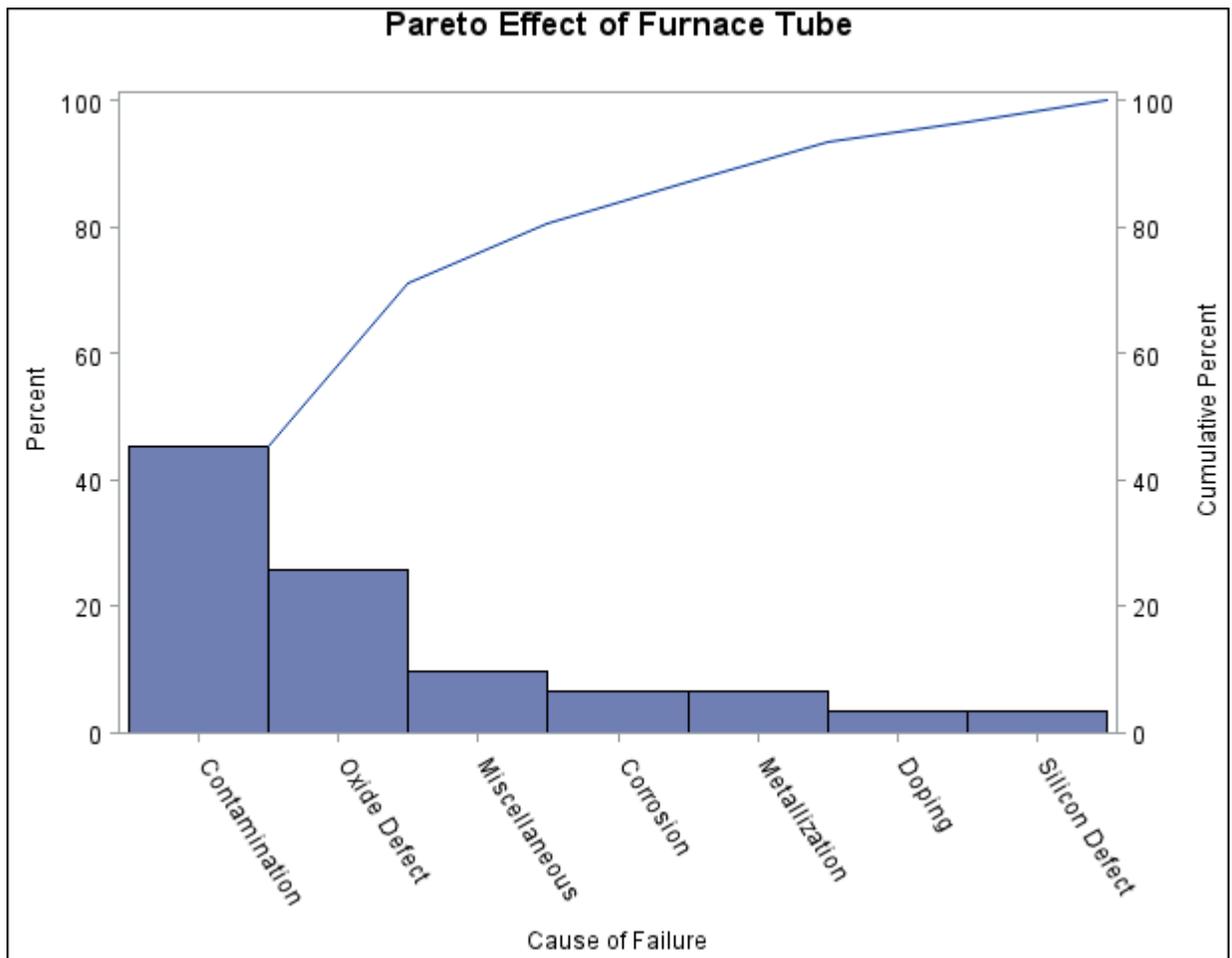

ods graphics off;
title 'Pareto Effect of Furnace Tube';
proc pareto data=Failure3;
  vbar Cause / freq = Counts
             angle = -60;
  by Stage;
run;
```

The SORT procedure sorts the observations in order of the values of Stage. It is not necessary to sort by the values of Cause since this is done by the PARETO procedure. The two charts, displayed in Output 15.1.1 and Output 15.1.2, reveal a reduction in oxide defects after the tube was cleaned. This is a relative reduction, since the primary axes are scaled in percent units.

Output 15.1.1 “After” Analysis Using Stage as a BY Variable

Output 15.1.2 “Before” Analysis Using Stage as a BY Variable

In general, it is difficult to compare Pareto charts created with BY processing because their axes are not necessarily uniform. A better approach is to construct a comparative Pareto chart, as illustrated by the following statements:

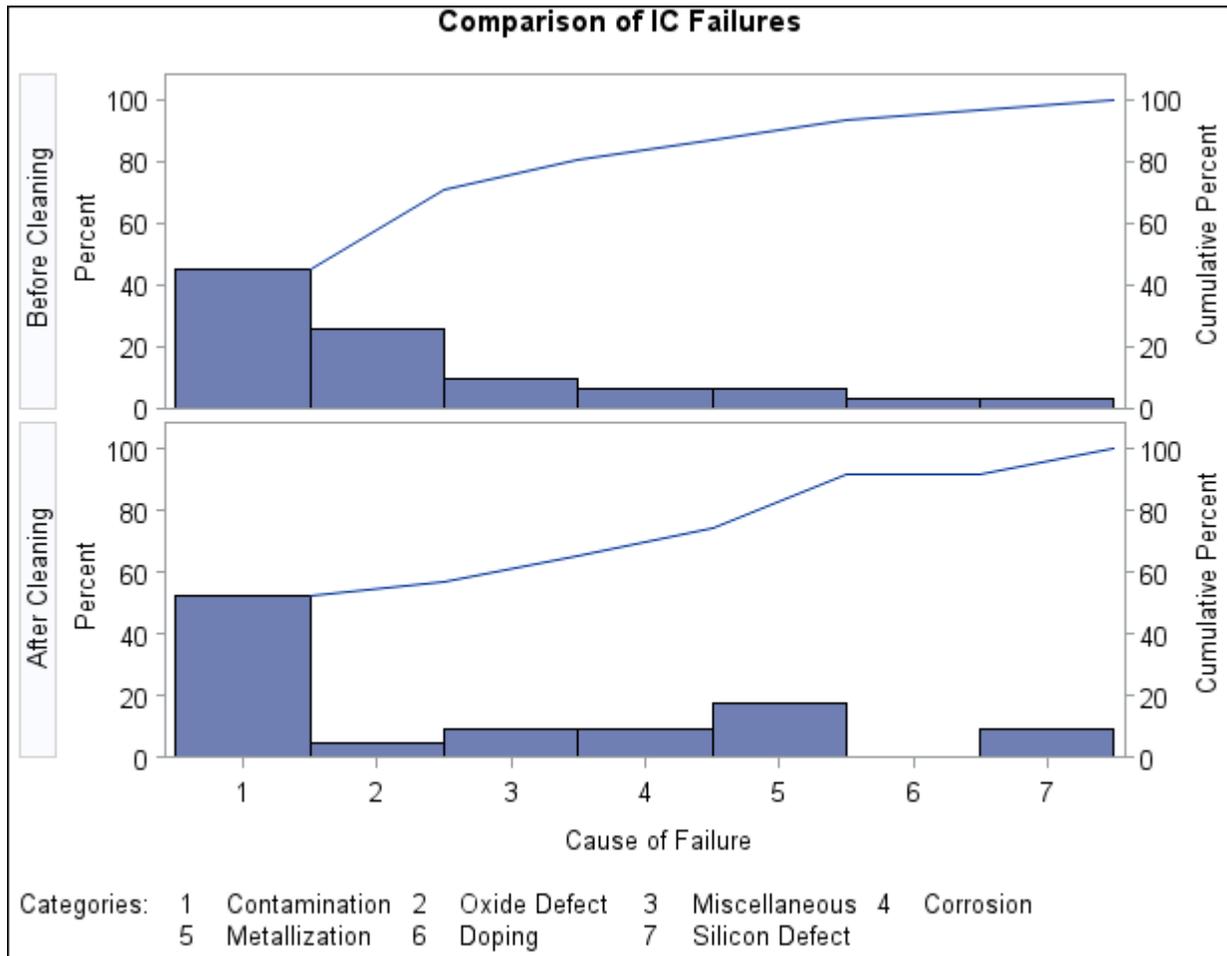

```

options vsize=4.25 in htext=2.8 pct htitle=3.2 pct;
title 'Comparison of IC Failures';
proc pareto data=Failure3;
  vbar Cause / class      = Stage
                      freq  = Counts
                      scale  = percent
                      intertile = 1.0
                      classkey = 'Before Cleaning';
run;

```

See PARETO8 in the SAS/QC Sample Library

The CLASS= option designates Stage as a classification variable, and this directs the procedure to create the one-way comparative Pareto chart, shown in Output 15.1.3, that displays a component chart for each level of Stage.

Output 15.1.3 Before-and-After Analysis Using Comparative Pareto Chart

In a comparative Pareto chart, there is always one special cell, called the *key cell*, in which the bars are displayed in decreasing order, and whose order determines the uniform horizontal axis used for all the cells. The key cell is positioned at the top of the chart. Here, the key cell is the set of observations for which Stage equals 'Before Cleaning', as specified by the CLASSKEY= option. By default, the levels are sorted in the order determined by the ORDER1= option, and the key cell is the level that occurs first in this order.

In many applications, it may be more revealing to base comparisons on counts rather than percents. The following statements construct a chart with a frequency scale:

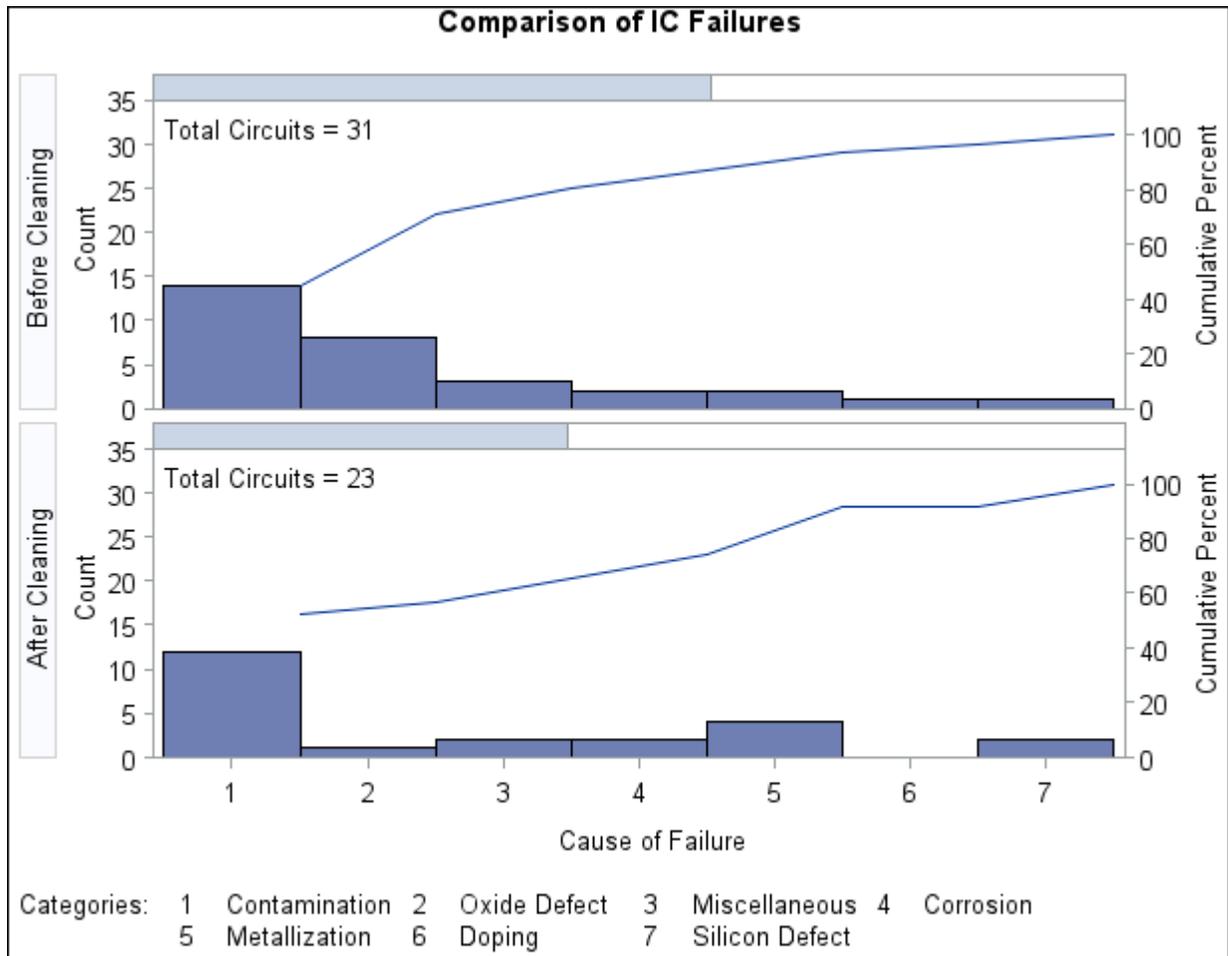

```

title 'Comparison of IC Failures';
proc pareto data=Failure3;
  vbar Cause / class      = Stage
                      freq      = Counts
                      scale     = count
                      intertile = 1.0
                      nlegend   = 'Total Circuits'
                      classkey  = 'Before Cleaning'
                      cprop;
run;

```

The chart is shown in [Output 15.1.4](#).

Output 15.1.4 Before-and-After Analysis Using Comparative Pareto Chart

Specifying `SCALE=COUNT` scales the primary vertical axis in frequency units. The `NLEGEND=` option adds a sample size legend, and the `CFRAMENLEG` option frames the legend. The `CPROP` option adds bars that indicate the proportion of total frequency represented by each cell. The `INTERTILE=` option separates the tiles with a small offset.

Note that the lower cumulative percent curve in [Output 15.1.4](#) is not anchored to the first bar. This is a consequence of the uniform frequency scale and of the fact that the number of observations in each cell is not the same.

Example 15.2: Creating Two-Way Comparative Pareto Charts

See `PARETO9` in the `SAS/QC Sample Library`

During the manufacture of a MOS capacitor, different cleaning processes were used by two manufacturing systems operating in parallel. Process A used a standard cleaning solution, while Process B used a different cleaning mixture that contained less particulate matter. The failure causes ob-

served with each process for five consecutive days were recorded and saved in a SAS data set called Failure4.

```

data Failure4;
  length Process $ 9 Cause $ 16;
  label Cause = 'Cause of Failure';
  input Process & $ Day & $ Cause & $ Counts;
  datalines;
Process A   March 1   Contamination   15
Process A   March 1   Corrosion       2
Process A   March 1   Doping          1
Process A   March 1   Metallization   2
Process A   March 1   Miscellaneous    3
Process A   March 1   Oxide Defect    8
Process A   March 1   Silicon Defect  1
Process A   March 2   Contamination   16
Process A   March 2   Corrosion       3
Process A   March 2   Doping          1
Process A   March 2   Metallization   3
Process A   March 2   Miscellaneous    1
Process A   March 2   Oxide Defect    9
Process A   March 2   Silicon Defect  2
Process A   March 3   Contamination   20
Process A   March 3   Corrosion       1
Process A   March 3   Doping          1
Process A   March 3   Metallization   0
Process A   March 3   Miscellaneous    3
Process A   March 3   Oxide Defect    7
Process A   March 3   Silicon Defect  2
Process A   March 4   Contamination   12
Process A   March 4   Corrosion       1
Process A   March 4   Doping          1
Process A   March 4   Metallization   0
Process A   March 4   Miscellaneous    0
Process A   March 4   Oxide Defect   10
Process A   March 4   Silicon Defect  1
Process A   March 5   Contamination   23
Process A   March 5   Corrosion       1
Process A   March 5   Doping          1
Process A   March 5   Metallization   0
Process A   March 5   Miscellaneous    1
Process A   March 5   Oxide Defect    8
Process A   March 5   Silicon Defect  2
Process B   March 1   Contamination   8
Process B   March 1   Corrosion       2
Process B   March 1   Doping          1
Process B   March 1   Metallization   4
Process B   March 1   Miscellaneous    2
Process B   March 1   Oxide Defect   10
Process B   March 1   Silicon Defect  3
Process B   March 2   Contamination   9
Process B   March 2   Corrosion       0
Process B   March 2   Doping          1
Process B   March 2   Metallization   2

```

```

Process B   March 2   Miscellaneous   4
Process B   March 2   Oxide Defect   9
Process B   March 2   Silicon Defect  2
Process B   March 3   Contamination  4
Process B   March 3   Corrosion      1
Process B   March 3   Doping         1
Process B   March 3   Metallization  0
Process B   March 3   Miscellaneous   0
Process B   March 3   Oxide Defect   10
Process B   March 3   Silicon Defect  1
Process B   March 4   Contamination  2
Process B   March 4   Corrosion      2
Process B   March 4   Doping         1
Process B   March 4   Metallization  0
Process B   March 4   Miscellaneous   3
Process B   March 4   Oxide Defect   7
Process B   March 4   Silicon Defect  1
Process B   March 5   Contamination  1
Process B   March 5   Corrosion      3
Process B   March 5   Doping         1
Process B   March 5   Metallization  0
Process B   March 5   Miscellaneous   1
Process B   March 5   Oxide Defect   8
Process B   March 5   Silicon Defect  2
;

```

In addition to the process variable Cause, there are two classification variables in this data set: Process and Day. The variable Counts is a frequency variable.

This example creates a series of displays that progressively use more of the classification information.

Basic Pareto Chart

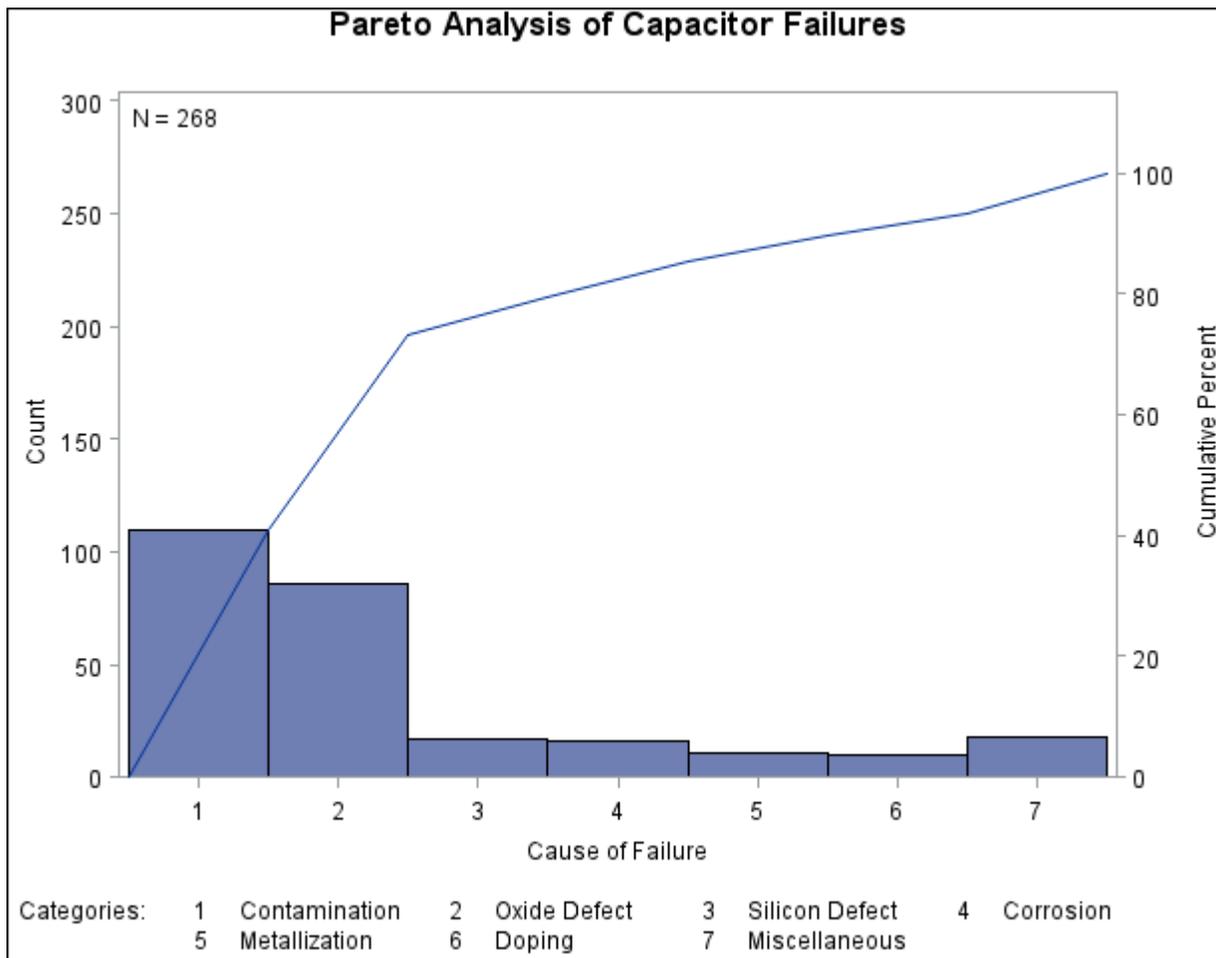

The first display, created with the following statements, analyzes the process variable without taking into account the classification variables.

```

ods graphics off;
title 'Pareto Analysis of Capacitor Failures';
proc pareto data=Failure4;
  vbar Cause / freq          = Counts
                    last      = 'Miscellaneous'
                    scale     = count
                    anchor    = b1
                    nlegend;
run;

```

The chart, shown in [Output 15.2.1](#), indicates that contamination is the most frequently occurring problem.

Output 15.2.1 Pareto Analysis without Classification Variables

The color and pattern for the bars are specified with the CBARS= and PBARS= options. The pattern M5X45 is a particular type of crosshatching (refer to *SAS/GRAPH: Reference* for a pattern selection guide). If you specify a color but not a pattern, the bars are filled with a solid color.

The option ANCHOR=BL anchors the cumulative percent curve at the bottom left (BL) of the first bar. The NLEGEND option adds a sample size legend.

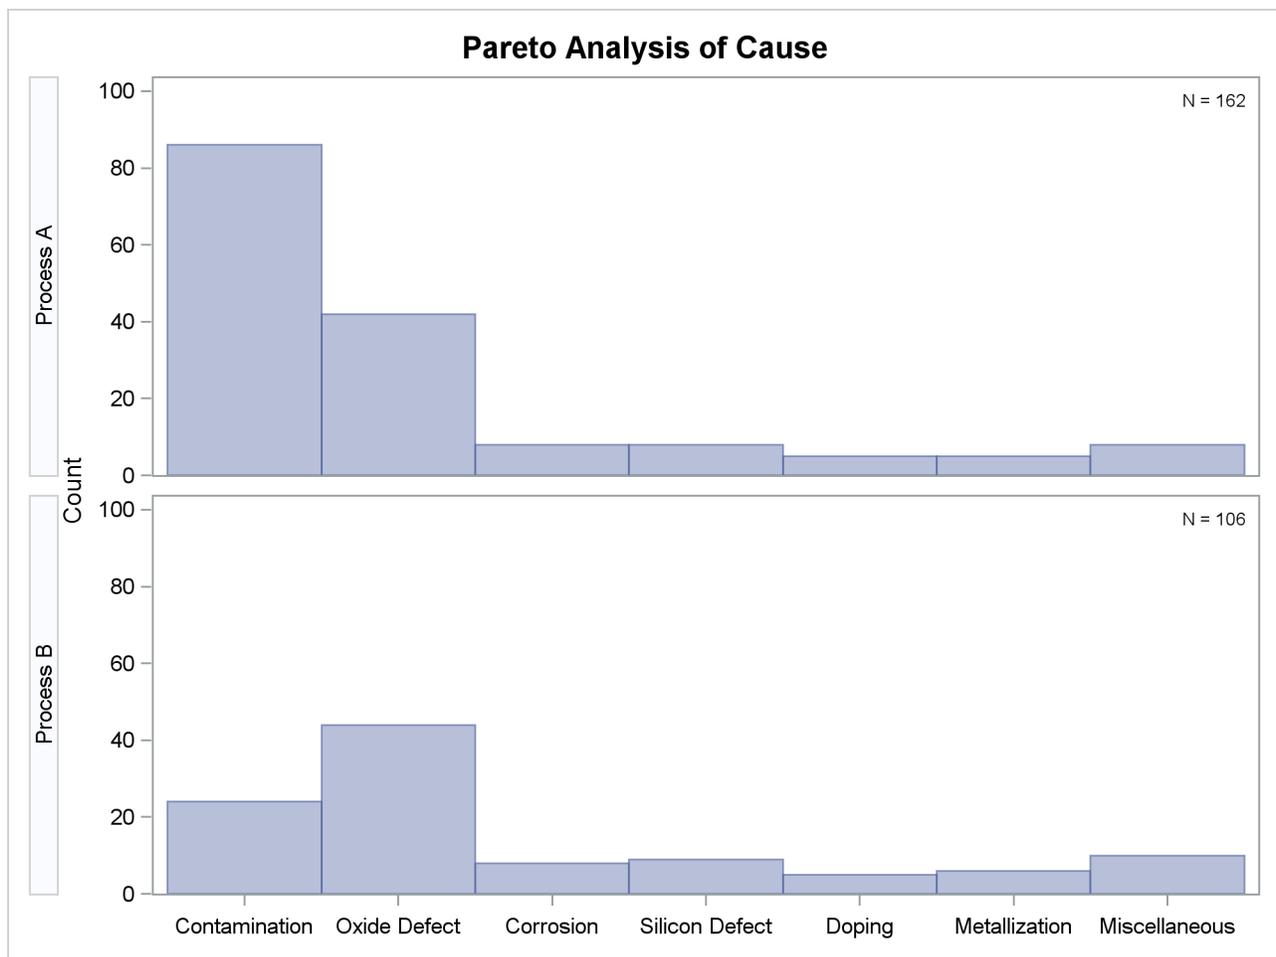

One-Way Comparative Pareto Chart for Process

The following statements specify Process as a classification variable to create the comparative Pareto chart displayed in [Output 15.2.2](#):

```
ods graphics on;
proc pareto data=Failure4;
  vbar Cause / class      = Process
                    freq  = Counts
                    last   = 'Miscellaneous'
                    scale  = count
                    catleglabel = 'Failure Causes:'
                    nohlabel
                    nocurve
                    nlegend;
run;
```

The ODS GRAPHICS ON statement specified before the PROC PARETO statement enables ODS Graphics, so the Pareto chart is created using ODS Graphics instead of traditional graphics.

Output 15.2.2 One-Way Comparative Pareto Analysis with CLASS=Process

Each cell corresponds to a level of the CLASS= variable (Process). By default, the cells are arranged from top to bottom in alphabetical order of the formatted values of Process, and the key cell is the top cell. The main difference in the two cells is a drop in contamination using Process B.

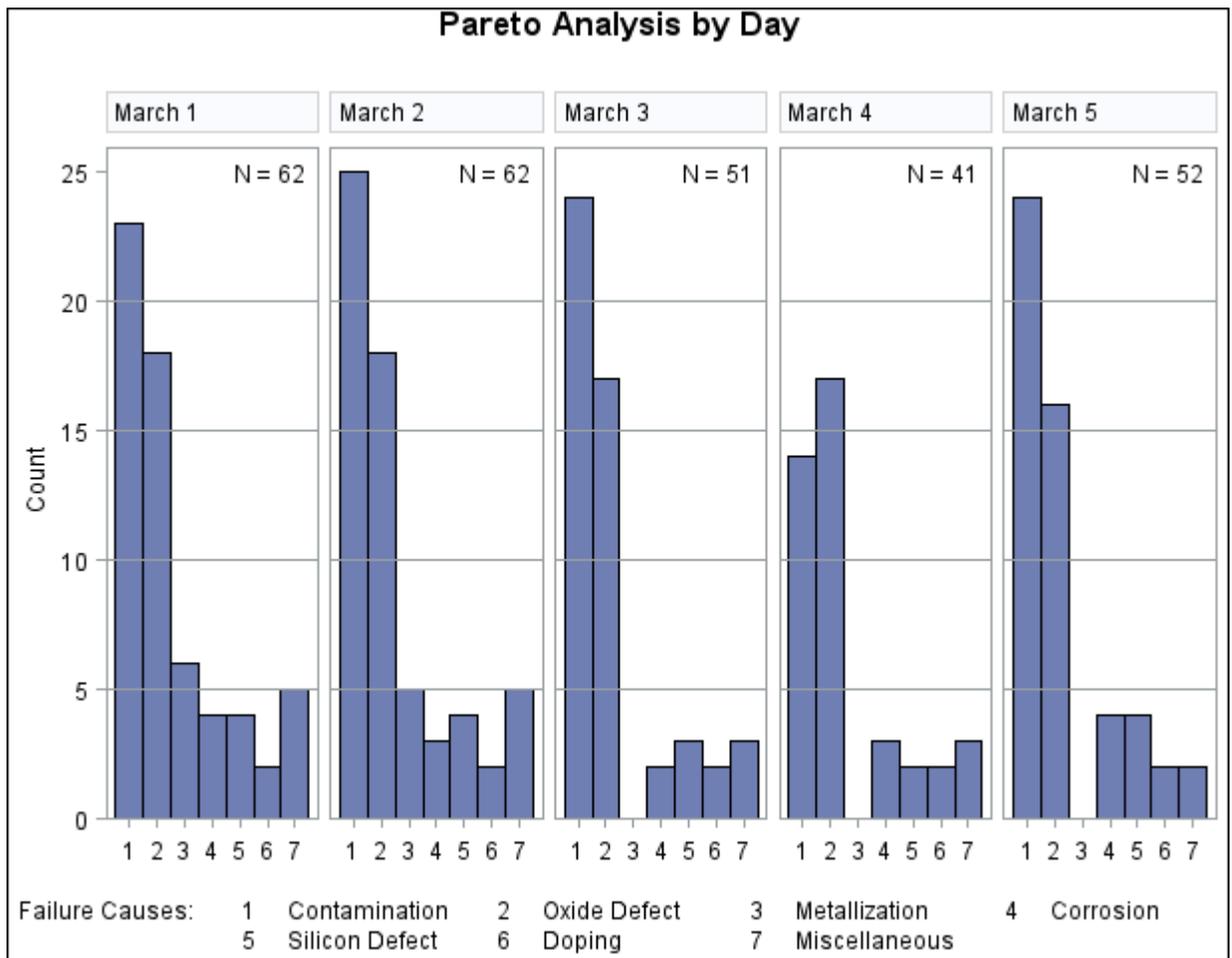

The CATLEGLABEL= option specifies the category legend label *Failure Causes:*. The NOHLABEL option suppresses the horizontal axis labels. The NOCURVE option suppresses the cumulative percent curve.

One-way Comparative Pareto Chart for Day

The following statements specify Day as a classification variable:

```
ods graphics off;
title 'Pareto Analysis by Day';
proc pareto data=Failure4;
  vbar Cause / class      = Day
                    freq  = Counts
                    last   = 'Miscellaneous'
                    scale  = count
                    catlelabel = 'Failure Causes:'
                    intertile = 1.0
                    nrows  = 1
                    ncols  = 5
                    vref   = 5 10 15 20
                    nohlabel
                    nocurve
                    nlegend;
run;
```

The NROWS= and NCOLS= options display the cells in a side-by-side arrangement. The VREF= and LVREF= options add reference lines. The chart is displayed in [Output 15.2.3](#).

Output 15.2.3 One-Way Comparative Pareto Analysis with CLASS=Day

By default, the key cell is the leftmost cell. There were no failures due to Metallization starting on March 3 (in fact, process controls to reduce this problem were introduced on this day).

Two-way Comparative Pareto Chart for Process and Day

The following statements specify both Process and Day as CLASS= variables to create a two-way comparative Pareto chart:

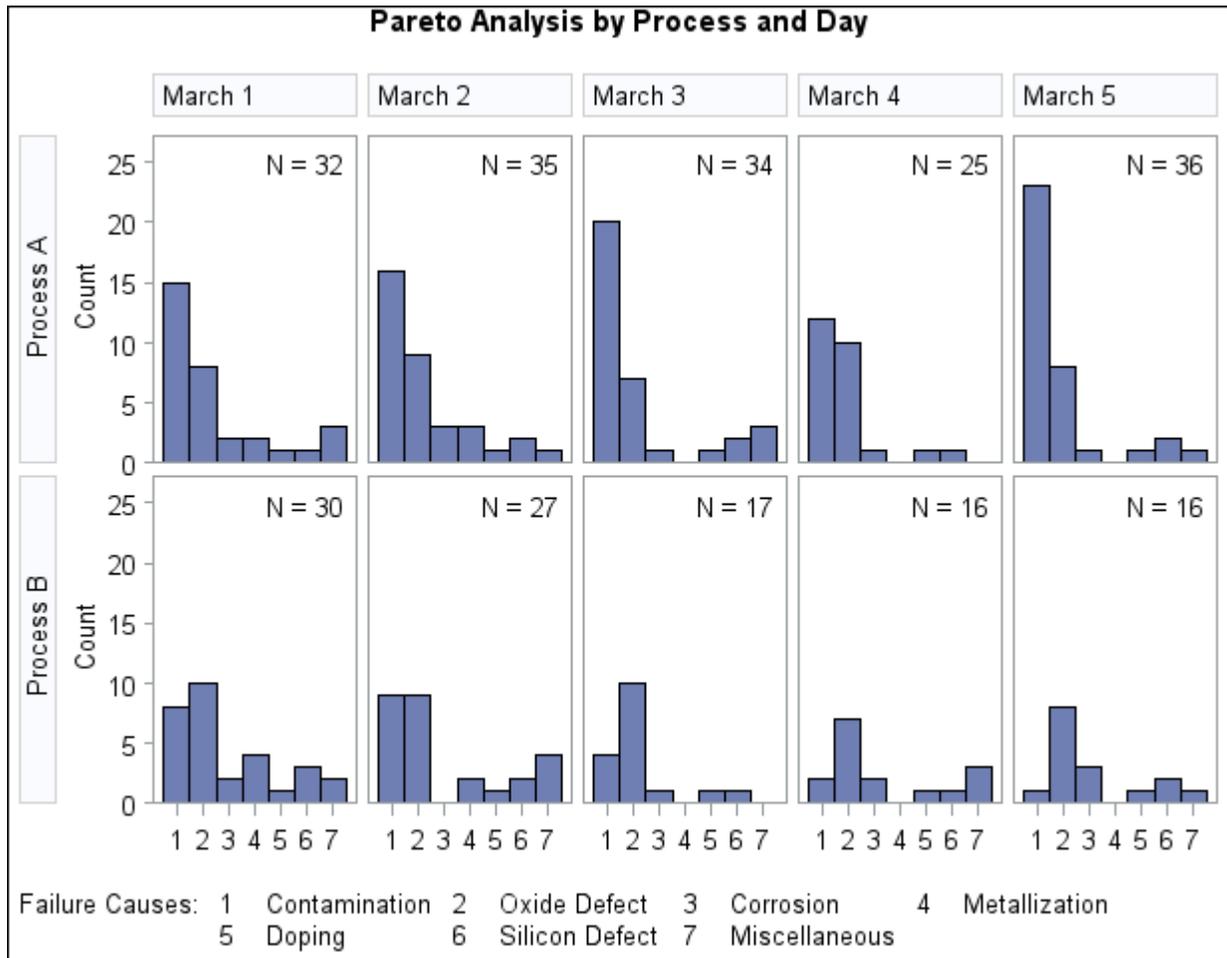

```

options vsize=4.25 in htext=2.8 pct htitle=3.2 pct;
title 'Pareto Analysis by Process and Day';
proc pareto data=Failure4;
  vbar Cause / class      = ( Process Day )
    freq                 = Counts
    nrows                 = 2
    ncols                  = 5
    last                   = 'Miscellaneous'
    scale                  = count
    catleglabel            = 'Failure Causes:'
    intertile              = 1.0
    nohlabel
    nocurve
    nlegend;
run;

```

The chart is displayed in [Output 15.2.4](#).

Output 15.2.4 Two-Way Comparative Pareto Analysis for Process and Day

The cells are arranged in a matrix whose rows correspond to levels of the first CLASS= variable (Process) and whose columns correspond to levels of the second CLASS= variable (Day). The dimensions of the matrix are specified with the NROWS= and NCOLS= options. The key cell is in the upper left corner.

The chart reveals continuous improvement with Process B.

Example 15.3: Highlighting the “Vital Few”

See PARETO10 in the SAS/QC Sample Library

This example is a continuation of Example 15.2.

In some applications you may want to use colors and patterns to highlight the bars corresponding to the most frequently occurring categories, which are referred to as the “vital few.”

The following statements highlight the two most frequently occurring categories in each cell of the comparative Pareto chart shown in Output 15.2.4:

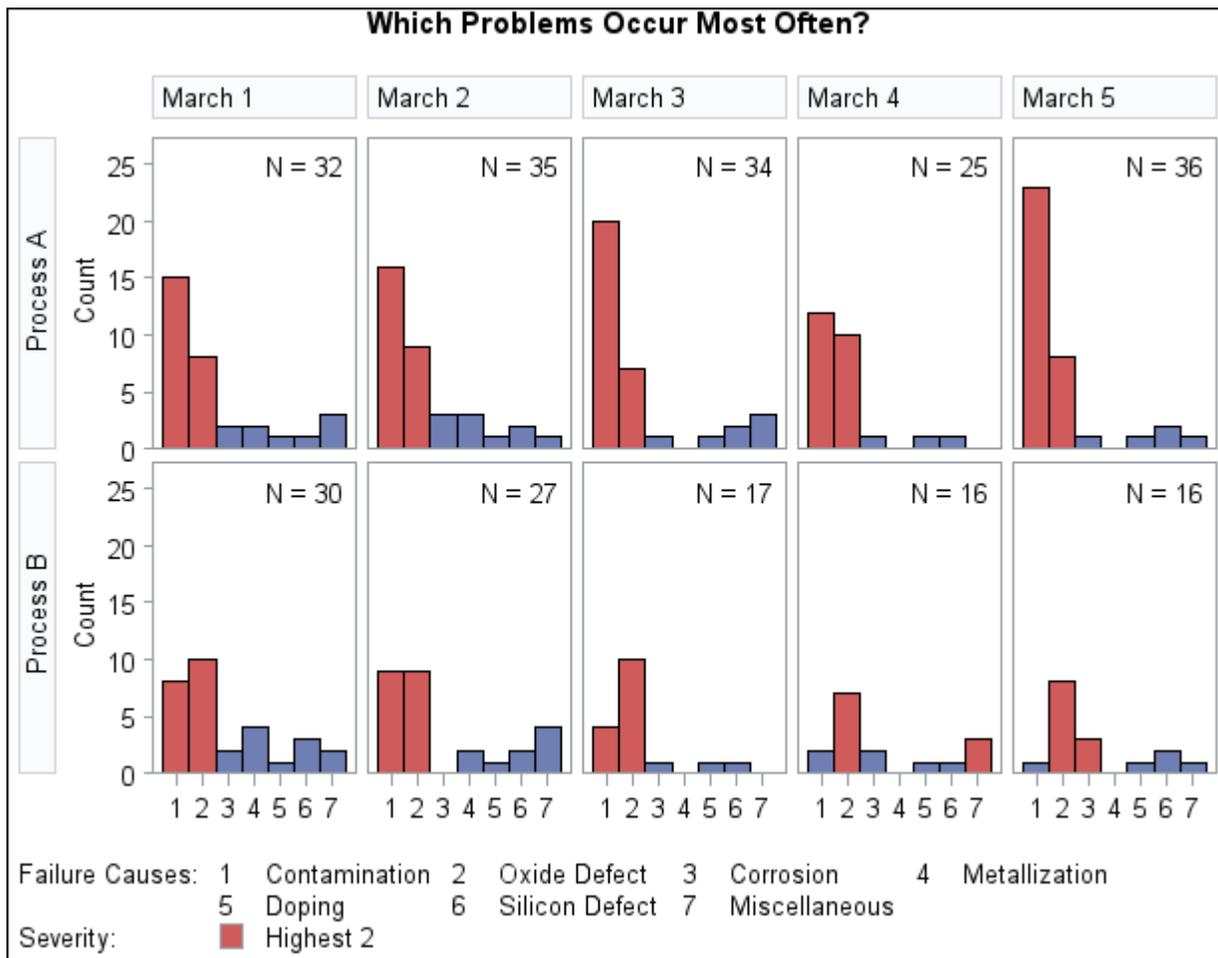

```
ods graphics off;
options vsize=4.25 in htext=2.8 pct htitle=3.2 pct;
title 'Which Problems Occur Most Often?';
proc pareto data=Failure4;
  vbar Cause / class      = ( Process Day )
                freq      = Counts
                nrows     = 2
                ncols     = 5
                last      = 'Miscellaneous'
                scale     = count
                chigh(2)
                hlleglabel = 'Severity:'
                catleglabel = 'Failure Causes:'
                intertile = 1.0
                nohlabel
                nocurve
                nlegend;
run;
```

Specifying CHIGH(2)=GREEN and PHIGH(2)=M5X45 causes the two highest bars in each cell to be filled in green with the pattern M5X45 (refer to *SAS/GRAPH: Reference* for a pattern selection guide). If you omit the PHIGH(2)= option, a solid green fill is used.

The new chart is displayed in Output 15.3.1. In all but two of the cells, the two vital problems are Contamination and Oxide Defect.

You can also highlight the “trivial many” categories (also referred to as the “useful many”) with the CLOW(*m*)= and PLOW(*m*)= options. You can use these options in conjunction with the CHIGH(*n*)=, PHIGH(*n*)=, CBARS=, and PBARS= options. For further details, see the entries for these options in the “Dictionary of Options” on page 1138.

Output 15.3.1 Emphasizing the “Vital Few”

Example 15.4: Highlighting Combinations of Categories

In some applications, it is useful to classify the categories into groups that are not necessarily related to frequency. This example, which is a continuation of [Example 15.2](#), shows how you can display this classification with a bar legend. *See PARETO11 in the SAS/QC Sample Library*

Suppose that Contamination and Metallization are high priority problems, Oxide Defect is a medium priority problem, and all other categories are low priority problems. Begin by adding this information to the data set Failure4.

```

data Failure4;
  length priority $ 16;
  set Failure4;
  if Cause = 'Contamination' or
     Cause = 'Metallization'
  then do;
    priority = 'High';
  end;
  else
  if Cause = 'Oxide Defect'
  then do;
    priority = 'Medium';
  end;
  else do;
    priority = 'Low';
  end;
run;

```

The variable `PRIORITY` indicates the priority, and the variables `COLOR` and `PATTERN` (character variables of length eight) provide colors and patterns corresponding to the levels of `PRIORITY`. The pattern values 'S' and 'M5X45' correspond to a solid fill and a crosshatched fill, respectively.

The following statements specify `PRIORITY` as a `BARLEGEND=` variable, `COLOR` as a `CBARS=` variable, and `PATTERN` as a `PBARS=` variable:

```

ods graphics off;
options vsize=4.25 in htext=2.8 pct htitle=3.2 pct;
title 'Which Problems Take Priority?';
proc pareto data=Failure4;
  vbar Cause / class      = ( Process Day )
                freq      = Counts
                nrows     = 2
                ncols     = 5
                last      = 'Miscellaneous'
                scale     = count
                bars      = ( priority )
                barlegend = ( priority )
                barleglabel = 'Priority:'
                catleglabel = 'Failure Causes:'
                intertile  = 1.0
                nohlabel
                nocurve
                nlegend;
run;

```

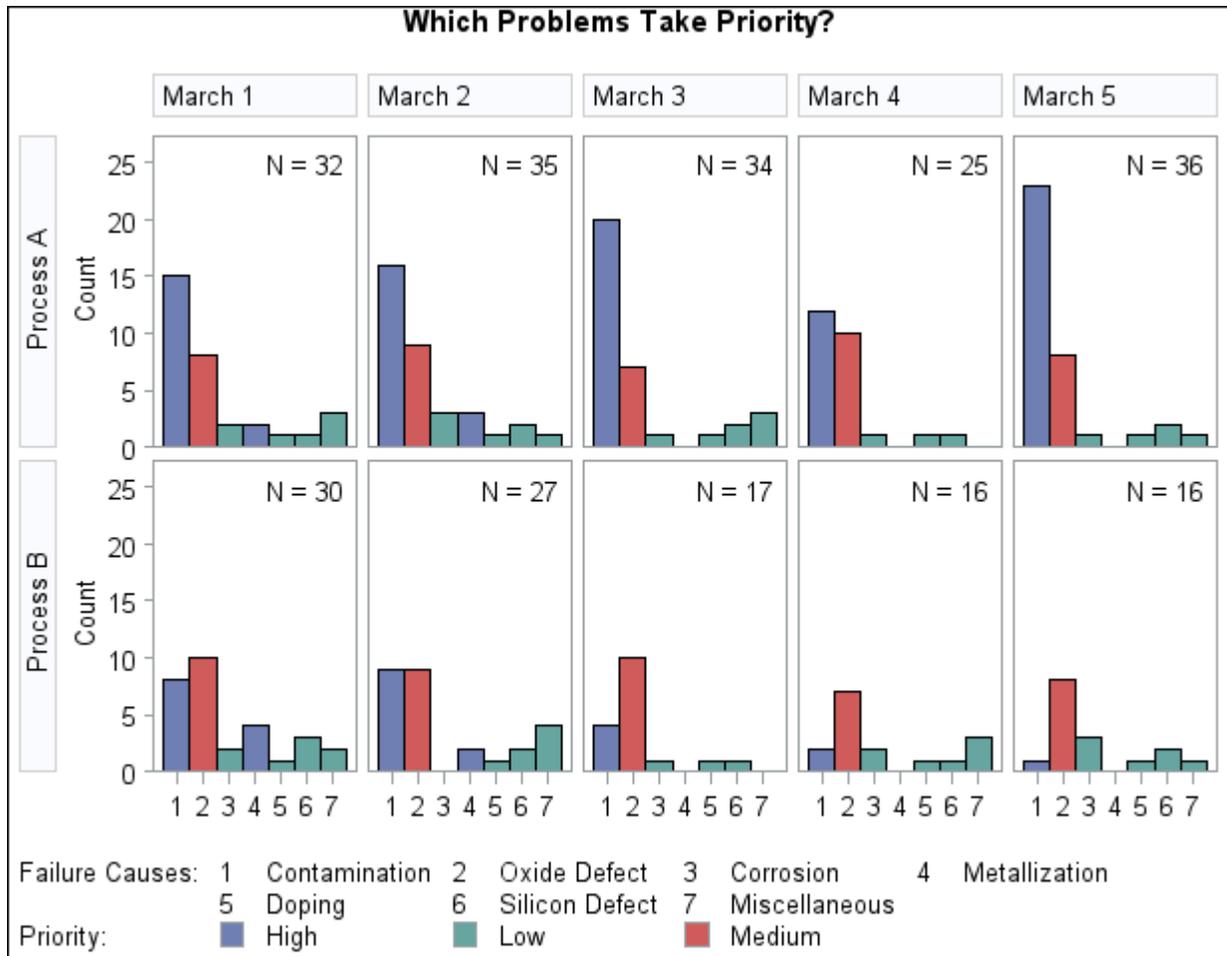

Note that the `BARLEGEND=`, `CBARS=`, and `PBARS=` variable names are enclosed in parentheses. (Parentheses are not used when you specify fixed colors and patterns with the `CBARS=` and `PBARS=` options, as in [Example 15.2](#).)

The chart is displayed in [Output 15.4.1](#). The levels of the `BARLEGEND=` variable are the values displayed in the legend labeled *Priority:* at the bottom of the chart.

In general, when you create CBARS=, PBARS=, and BARLEGEND= variables, their values must be consistent and unambiguous. You must assign distinct color and pattern values to the CBARS= and PBARS= variables for each level of the BARLEGEND= variable. It is not necessary to specify a PBARS= variable to accompany a BARLEGEND= variable, and if a PBARS= variable is omitted, the bars are filled with solid colors.

For further details, see the entries for the BARLEGEND=, CBARS=, and PBARS= options in “Dictionary of Options” on page 1138.

Output 15.4.1 Highlighting Selected Subsets of Categories

Example 15.5: Highlighting Combinations of Cells

This example is a continuation of Example 15.4.

In some applications involving comparative Pareto charts, it is useful to classify the cells into groups. This example shows how you can display this type of classification by coloring the tiles and adding a legend. *See PARETO1 in the SAS/QC Sample Library*

Suppose that you want to enhance [Output 15.4.1](#) by highlighting the two cells for which Process='Process B' and Day='March 4' and 'March 5' to emphasize the improvement displayed in those cells. Begin by adding a tile color variable (TILECOL) and a tile legend variable (TILELEG) to the data set Failure4.

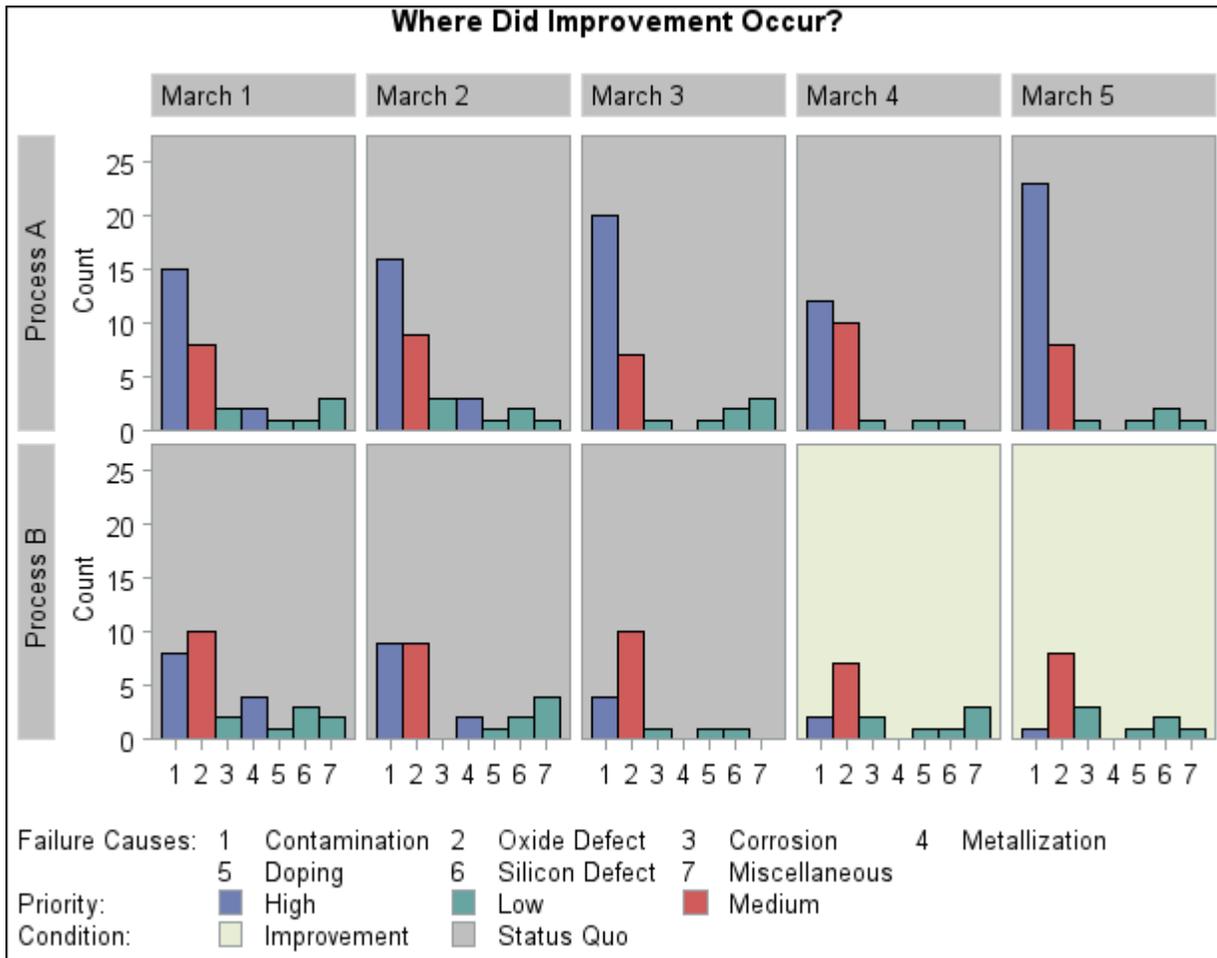

```
data Failure4;
  length tilecol $ 8 tileleg $ 16;
  set Failure4;
  if (Process='Process B') and (Day='March 4' or Day='March 5')
  then do; tilecol='ywh'; tileleg = 'Improvement'; end;
  else do; tilecol='ligr'; tileleg = 'Status Quo'; end;
run;
```

The following statements specify TILECOL as a CTILES= variable and TILELEG as a TILELEGEND= variable. Note that the variable names are enclosed in parentheses.

```
ods graphics off;
title 'Where Did Improvement Occur?';
proc pareto data=Failure4;
  vbar Cause / class      = ( Process Day )
                freq      = Counts
                nrows     = 2
                ncols     = 5
                last      = 'Miscellaneous'
                scale     = count
                catleglabel = 'Failure Causes:'
  /* options for highlighting bars: */
  bars          = ( priority )
  barlegend     = ( priority )
  barleglabel   = 'Priority:'
  /* options for highlighting tiles: */
  ctiles        = ( tilecol )
  tilelegend    = ( tileleg )
  tileleglabel  = 'Condition:'
  intertile    = 1.0
  cframeside   = ligr
  cframetop    = ligr
  nohlabel
  nocurve;
run;
```

In the chart, shown in [Output 15.5.1](#), the values displayed in the legend labeled *Condition:* are the levels of the TILELEGEND= variable.

Output 15.5.1 Highlighting Specific Tiles

Example 15.6: Ordering Rows and Columns in a Comparative Pareto Chart

See PARETO13 in the SAS/QC Sample Library. This example illustrates methods for controlling the order of rows and columns in a comparative Pareto chart.

The following statements create a data set named Failure7:

```
proc format;
  value procfmt    1    = 'Process A'
                  2    = 'Process B';
  value dayfmt     1    = 'Monday'
                  2    = 'Tuesday'
                  3    = 'Wednesday'
                  4    = 'Thursday'
                  5    = 'Friday';
run;

data Failure7;
  length Cause $16;
  format Process procfmt. Day dayfmt.;
  label Cause = 'Cause of Failure'
        Process = 'Cleaning Method'
        Day = 'Day of Manufacture';
  input Process Day Cause $16. Counts @@;
  datalines;
1 1 Contamination 15 1 1 Corrosion 2
1 1 Doping 1 1 1 Metallization 2
1 1 Miscellaneous 3 1 1 Oxide Defect 8
1 1 Silicon Defect 1 1 2 Contamination 16
1 2 Corrosion 3 1 2 Doping 1
1 2 Metallization 3 1 2 Miscellaneous 1
1 2 Oxide Defect 9 1 2 Silicon Defect 2
1 3 Contamination 20 1 3 Corrosion 1
1 3 Doping 1 1 3 Metallization 0
1 3 Miscellaneous 3 1 3 Oxide Defect 7
1 3 Silicon Defect 2 1 4 Contamination 12
1 4 Corrosion 1 1 4 Doping 1
1 4 Metallization 0 1 4 Miscellaneous 0
1 4 Oxide Defect 10 1 4 Silicon Defect 1
1 5 Contamination 23 1 5 Corrosion 1
1 5 Doping 1 1 5 Metallization 0
1 5 Miscellaneous 1 1 5 Oxide Defect 8
1 5 Silicon Defect 2 2 1 Contamination 8
2 1 Corrosion 2 2 1 Doping 1
2 1 Metallization 4 2 1 Miscellaneous 2
2 1 Oxide Defect 10 2 1 Silicon Defect 3
2 2 Contamination 9 2 2 Corrosion 0
2 2 Doping 1 2 2 Metallization 2
2 2 Miscellaneous 4 2 2 Oxide Defect 9
2 2 Silicon Defect 2 2 3 Contamination 4
2 3 Corrosion 1 2 3 Doping 1
```

```

2 3 Metallization 0 2 3 Miscellaneous 0
2 3 Oxide Defect 10 2 3 Silicon Defect 1
2 4 Contamination 2 2 4 Corrosion 2
2 4 Doping 1 2 4 Metallization 0
2 4 Miscellaneous 3 2 4 Oxide Defect 7
2 4 Silicon Defect 1 2 5 Contamination 1
2 5 Corrosion 3 2 5 Doping 1
2 5 Metallization 0 2 5 Miscellaneous 1
2 5 Oxide Defect 8 2 5 Silicon Defect 2
;

```

Note that Failure7 is similar to the data set Failure4 created in [Example 15.2](#). Here, the classification variables Process and Day are numeric formatted variables, and the formatted values of Day are ‘Monday’ through ‘Friday’. In [Example 15.2](#), Process and Day are character variables, and the values of Day are ‘March 1’ through ‘March 5’.

The following statements create a two-way comparative Pareto chart for Cause in which the rows represent levels of Process and the columns represent levels of Day:

```

ods graphics off;
title 'Pareto Analysis by Process and Day';
proc pareto data=Failure7;
  vbar Cause / class      = ( Process Day )
                freq      = Counts
                nrows     = 2
                ncols     = 5
                last      = 'Miscellaneous'
                scale     = count
                catleglabel = 'Failure Causes:'
                intertile = 1.0
                nohlabel
                nocurve
                nlegend;
run;

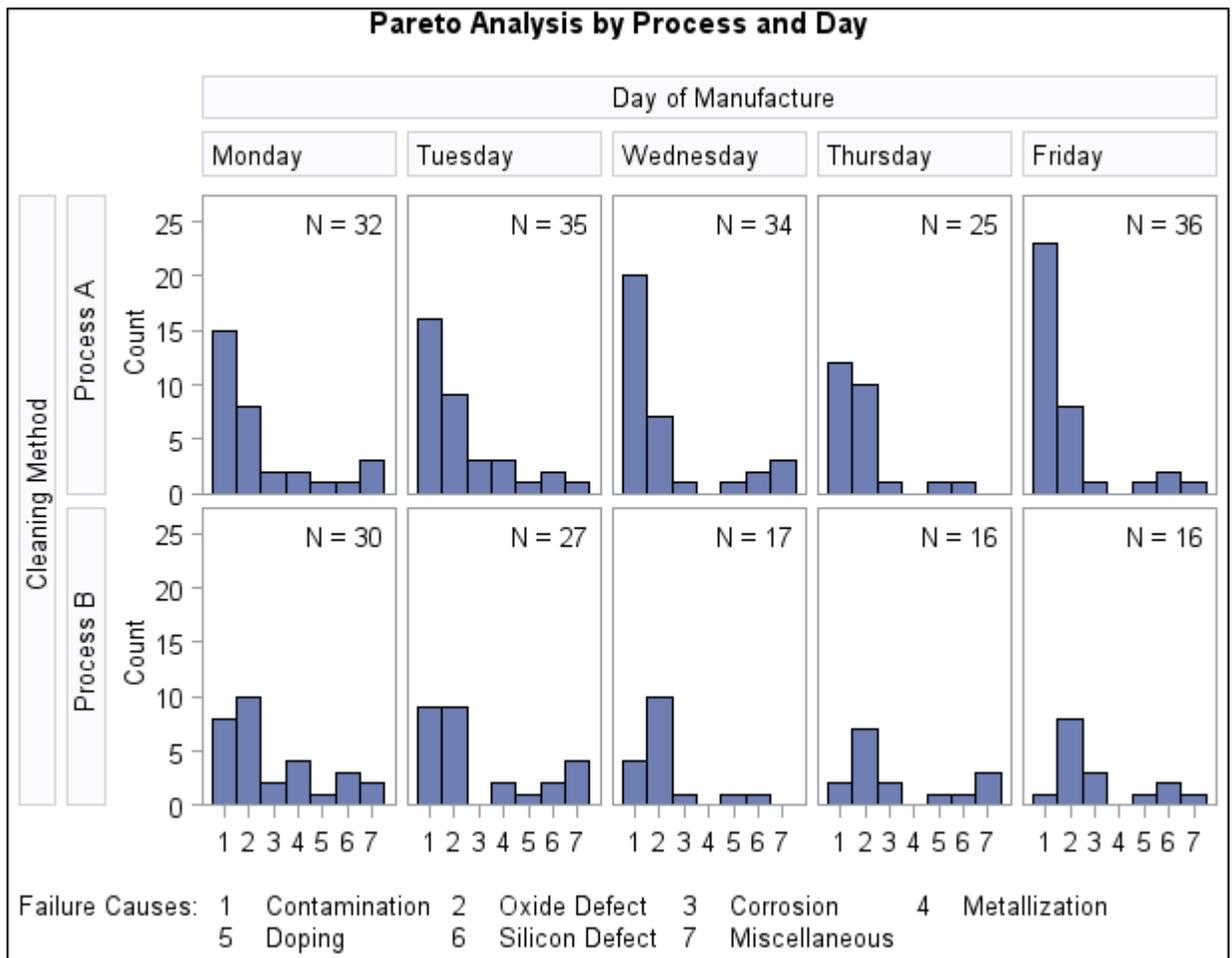

```

The chart is shown in [Output 15.6.1](#). The levels of the classification variables are determined by their formatted values. The default order in which the rows and columns are displayed is determined by the internal values of the classification variables, and, consequently, the columns appear in the order of the days of the week.

If Day had been defined as a character variable with values ‘Monday’ through ‘Friday’, the columns in [Output 15.6.1](#) would have appeared in alphabetical order.

You can override the default order with the `ORDER1=` and `ORDER2=` options.

Output 15.6.1 Controlling Row and Column Order

Example 15.7: Merging Columns in a Comparative Pareto Chart

See PARETO14 in the SAS/QC Sample Library This example is a continuation of Example 15.4 and illustrates a method for merging the columns in a comparative Pareto chart.

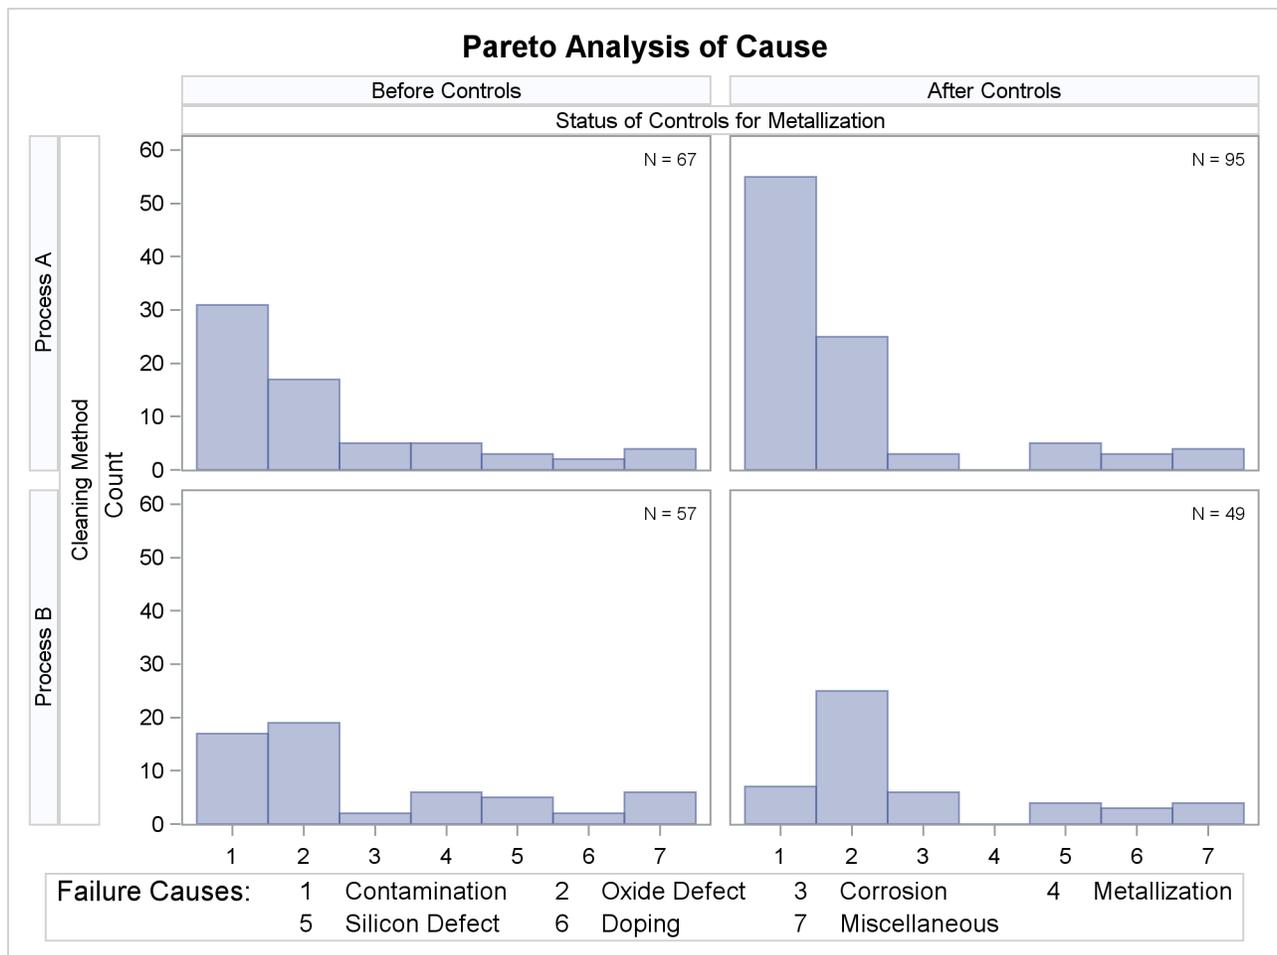

Suppose that controls for metallization were introduced on Wednesday. To show the effect of the controls, the columns for *Monday* and *Tuesday* are to be merged into a column labeled *Before Controls*, and the remaining columns are to be merged into a column labeled *After Controls*. The following statements introduce a format named CNTLFMT that merges the levels of Day:

```
proc format;
  value cntlfmt  1-2 = 'Before Controls'
                3-5 = 'After Controls';
```

The following statements create the chart shown in [Output 15.7.1](#):

```
ods graphics on;
proc pareto data=Failure7;
  vbar Cause / class      = ( Process Day )
                    freq  = Counts
                    last   = 'Miscellaneous'
                    scale  = count
                    catleglabel = 'Failure Causes:'
                    nohlabel
                    nocurve
                    nlegend;
  format Day cntlfmt.;
  label Day = 'Status of Controls for Metallization';
run;
```

Output 15.7.1 Merging Classification Levels

The levels of Day are determined by its formatted values, 'Before Controls' and 'After Controls'. By default, the order in which the columns are displayed is determined by the internal values. In this example, there are multiple distinct internal values for each level, and the procedure uses the internal value that occurs first in the input data set.

Example 15.8: Creating Weighted Pareto Charts

See PARETO12 in the SAS/QC Sample Library

In many applications, you can quantify the priority or severity of a problem with a measure such as the cost of repair or the loss to the customer expressed in man-hours. This example shows how to analyze such data with a weighted Pareto chart that incorporates the cost.

Suppose that the cost associated with each of the problems in data set Failure7 (see Example 15.6) has been determined and that the costs have been converted to a relative scale. The following statements add the cost information to the data set:

```
data Failure7;
  length Analysis $ 16;
  label Analysis = 'Basis for Analysis';
  set Failure7;
  Analysis = 'Cost';
  if      Cause = 'Contamination' then Cost = 3.0;
  else if Cause = 'Metallization' then Cost = 8.5;
  else if Cause = 'Oxide Defect'  then Cost = 9.5;
  else if Cause = 'Corrosion'     then Cost = 2.5;
  else if Cause = 'Doping'        then Cost = 3.6;
  else if Cause = 'Silicon Defect' then Cost = 3.4;
  else                             Cost = 1.0;
  output;
  Analysis = 'Frequency';
  Cost = 1.0;
  output;
run;
```

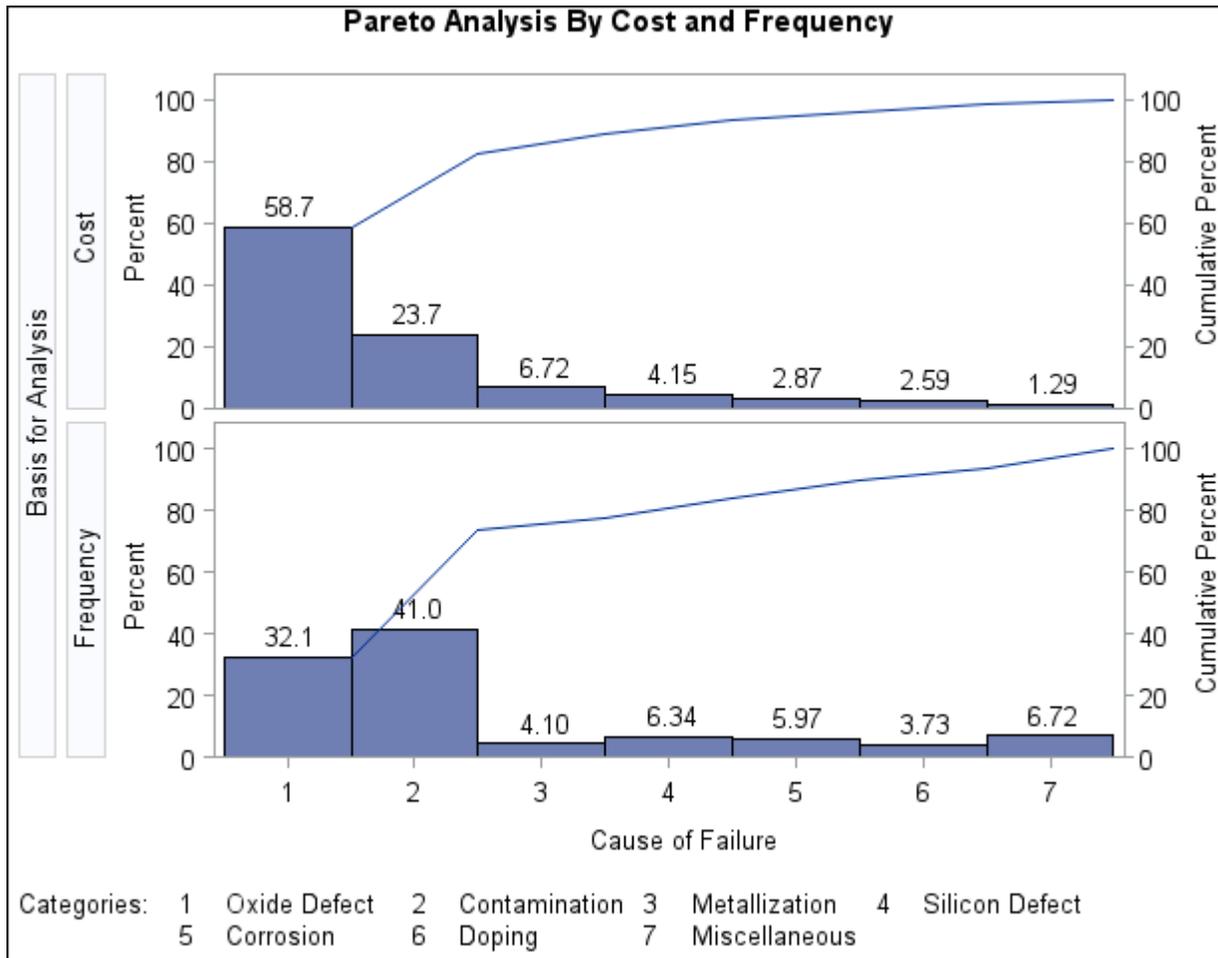

The classification variable Analysis has two levels, 'Cost' and 'Frequency'. For Analysis='Cost', the value of Cost is the relative cost, and for Analysis='Frequency', the value of Cost is one.

The following statements create a one-way comparative Pareto chart with Analysis as the classification variable, in which the cells are weighted Pareto charts with Cost as the weight variable:

```
ods graphics off;
goptions vsize=4.25 in htext=2.8 pct htitle=3.2 pct;
title 'Pareto Analysis By Cost and Frequency';
proc pareto data=Failure7;
  vbar Cause / class      = ( Analysis )
                freq      = Counts
                weight     = Cost
                barlabel   = value
                out        = summary
                intertile  = 1.0;
run;
```

The display is shown in Output 15.8.1.

Output 15.8.1 Taking Cost into Account

Within each cell, the height of a bar is the frequency of the category multiplied by the value of Cost, expressed as a percent of the total across all categories. Thus, for the cell in which Analysis is equal to 'Frequency', the bars simply indicate the frequencies expressed in percent units. This display shows that the most commonly occurring problem (Contamination) is not the most expensive problem (Oxide Defect). The output data set summary is listed in [Output 15.8.2](#).

Output 15.8.2 The Output Data Set SUMMARY

Pareto Analysis By Cost and Frequency							
Obs	Analysis	Cause	Cost	_COUNT_	_WCOUNT_	_PCT_	_CMPCT_
1	Cost	Oxide Defect	9.5	86	817.0	58.6799	58.680
2	Cost	Contamination	3.0	110	330.0	23.7018	82.382
3	Cost	Metallization	8.5	11	93.5	6.7155	89.097
4	Cost	Silicon Defect	3.4	17	57.8	4.1514	93.249
5	Cost	Corrosion	2.5	16	40.0	2.8729	96.122
6	Cost	Doping	3.6	10	36.0	2.5856	98.707
7	Cost	Miscellaneous	1.0	18	18.0	1.2928	100.000
8	Frequency	Oxide Defect	1.0	86	86.0	32.0896	32.090
9	Frequency	Contamination	1.0	110	110.0	41.0448	73.134
10	Frequency	Metallization	1.0	11	11.0	4.1045	77.239
11	Frequency	Silicon Defect	1.0	17	17.0	6.3433	83.582
12	Frequency	Corrosion	1.0	16	16.0	5.9701	89.552
13	Frequency	Doping	1.0	10	10.0	3.7313	93.284
14	Frequency	Miscellaneous	1.0	18	18.0	6.7164	100.000

Example 15.9: Alternative Pareto Charts

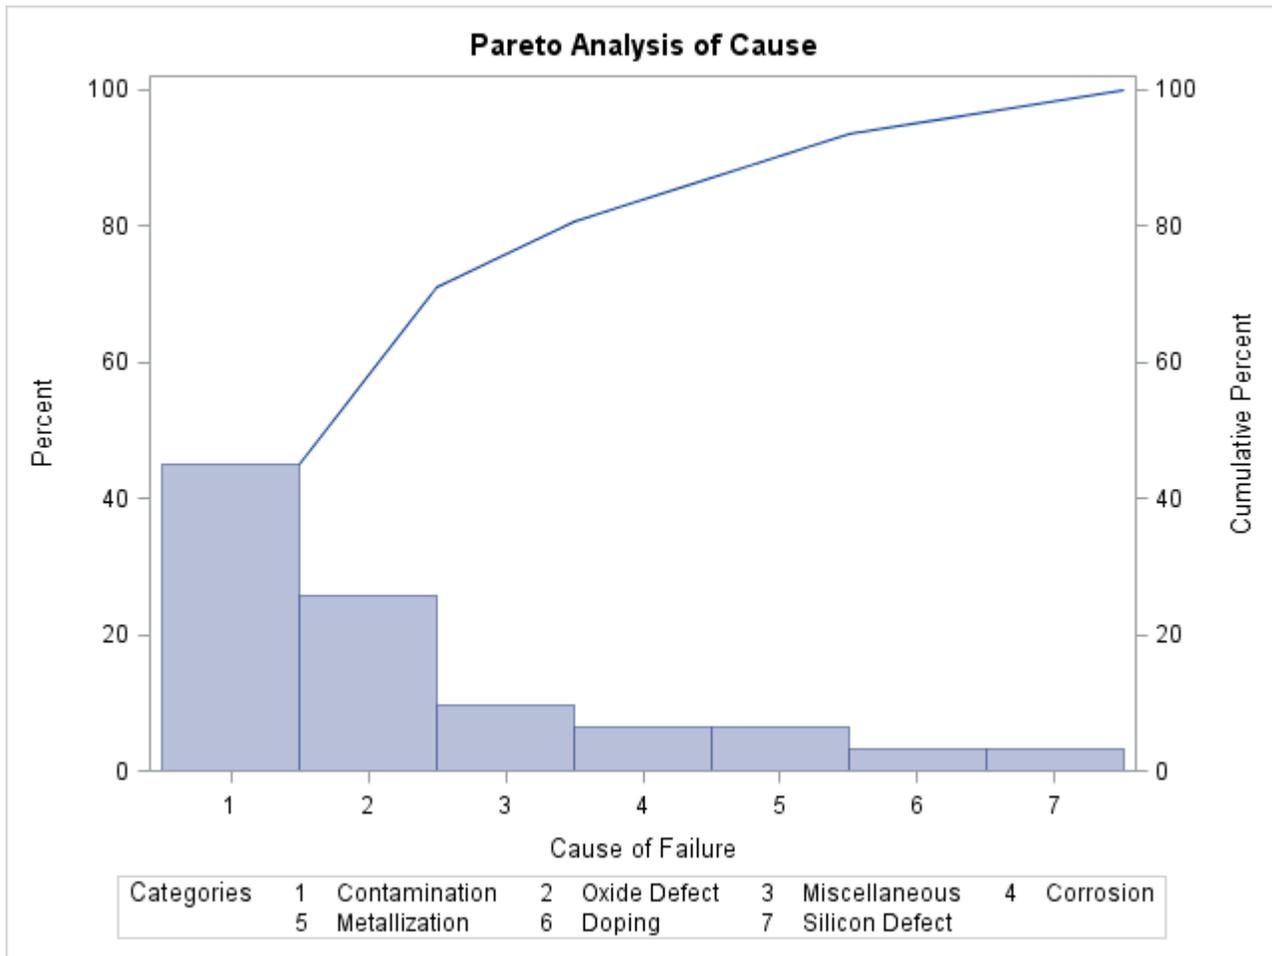

This example uses the Failure1 data set of integrated circuit fabrication failures from the section “Getting Started: VBAR Statement” on page 1126. The following statements produce a standard Pareto chart, a cumulative Pareto bar chart, and a Pareto dot plot with acceptance intervals of the data: `CHARTTYPE=` option.

```
ods graphics on;
proc pareto data=Failure1;
  vbar Cause;
  vbar Cause / charttype=cumulative;
  vbar Cause / charttype=intervals;
run;
```

Note that ODS Graphics must be enabled for you to use the `CHARTTYPE=` option.

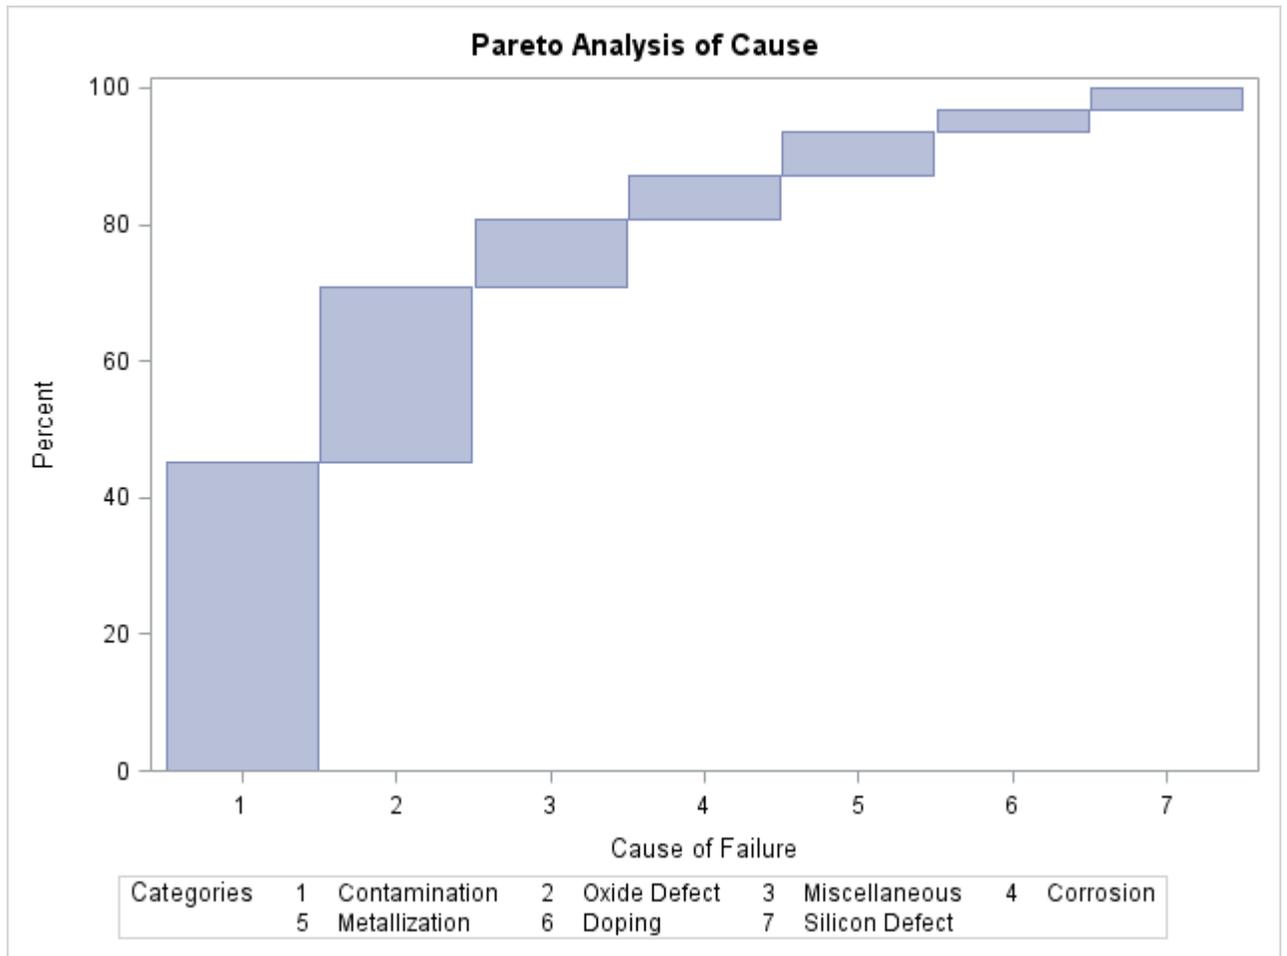

Output 15.9.1 shows the standard Pareto chart.

Output 15.9.1 Standard Pareto Chart

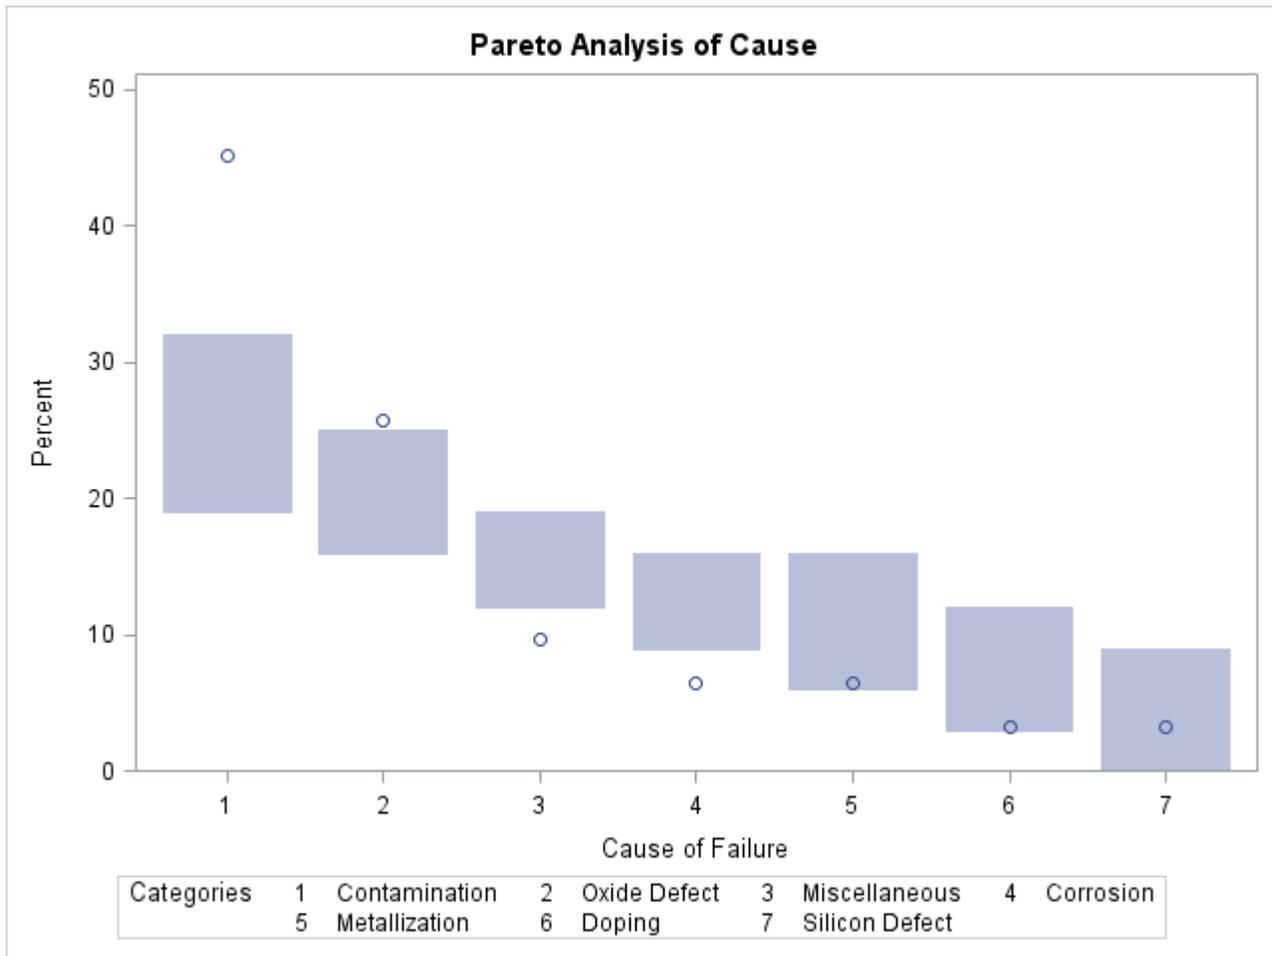

Output 15.9.2 shows the cumulative Pareto bar chart.

Output 15.9.2 Cumulative Pareto Bar Chart

Output 15.9.3 shows the Pareto dot plot with acceptance intervals.

Output 15.9.3 Pareto Dot Plot with Acceptance Intervals

The chart shows that the most frequently occurring problem, *Contamination*, does occur more frequently than the first-ranked cause from a random sample of seven uniformly distributed causes. This indicates that addressing contamination problems should be given a high priority.

Overview: RELIABILITY Procedure

The RELIABILITY procedure provides tools for reliability and survival data analysis and for recurrent events data analysis. You can use this procedure to

- construct probability plots and fitted life distributions with left-censored, right-censored, and interval-censored lifetime data
- fit regression models, including accelerated life test models, to combinations of left-censored, right-censored, and interval-censored data
- analyze recurrence data from repairable systems

These tools benefit reliability engineers and industrial statisticians working with product life data and system repair data. They also aid workers in other fields, such as medical research, pharmaceuticals, social sciences, and business, where survival and recurrence data are analyzed.

Most practical problems in reliability data analysis involve right-censored, left-censored, or interval-censored data. The RELIABILITY procedure provides probability plots of uncensored, right-censored, interval-censored, and arbitrarily censored data.

Features of the RELIABILITY procedure include

- probability plotting and parameter estimation for the common life distributions: Weibull, three-parameter Weibull, exponential, extreme value, normal, lognormal, logistic, and log-logistic. The data can be complete, right censored, or interval censored.
- maximum likelihood estimates of distribution parameters, percentiles, and reliability functions
- both asymptotic normal and likelihood ratio confidence intervals for distribution parameters and percentiles. Asymptotic normal confidence intervals for the reliability function are also available.
- estimation of distribution parameters by least squares fitting to the probability plot
- Weibayes analysis, where there are no failures and where the data analyst specifies a value for the Weibull shape parameter
- estimates of the resulting distribution when specified failure modes are eliminated
- plots of the data and the fitted relation for life versus stress in the analysis of accelerated life test data
- fitting of regression models to life data, where the life distribution location parameter is a linear function of covariates. The fitting yields maximum likelihood estimates of parameters of a regression model with a Weibull, exponential, extreme value, normal, lognormal, logistic and log-logistic, or generalized gamma distribution. The data can be complete, right censored, left censored, or interval censored. For example, accelerated life test data can be modeled with such a regression model.
- nonparametric estimates and plots of the mean cumulative function for cost or number of recurrences and associated confidence intervals from data with exact or interval recurrence ages
- maximum likelihood estimation of the parameters of parametric models for recurrent events data

Some of the features provided in the RELIABILITY procedure are available in other SAS procedures.

- You can construct probability plots of life data with the CAPABILITY procedure; however, the CAPABILITY procedure is intended for process capability analysis rather than reliability analysis, and the data must be complete (that is, uncensored).
- The LIFEREG procedure fits regression models with life distributions such as the Weibull, lognormal, and log-logistic to left-, right-, and interval-censored data. The RELIABILITY procedure fits the same distributions and regression models as the LIFEREG procedure and, in addition, provides a graphical display of life data in probability plots.

Lawless (2003), Meeker and Escobar (1998), Nelson (1982, 1990), Abernethy (2006), and Tobias and Trindade (1995) provide many examples taken from diverse fields and describe the analyses provided by the RELIABILITY procedure.

The features of the procedure that deal with the nonparametric analysis of recurrent events data from repairable systems are based on the work of Doganaksoy and Nelson (1998), Nelson (1988, 1995, 2002), and Nelson and Doganaksoy (1989), who provide examples of repair data analysis. Meeker and Escobar (1998), Rigdon and Basu (2000), Cook and Lawless (2007), Abernethy (2006), Tobias and Trindade (1995), Crowder et al. (1991), and U.S. Army (2000) provide details of parametric models for recurrent events data.

Getting Started: RELIABILITY Procedure

This section introduces the RELIABILITY procedure with examples that illustrate some of the analyses that it performs.

Analysis of Right-Censored Data from a Single Population

The Weibull distribution is used in a wide variety of reliability analysis applications. This example illustrates the use of the Weibull distribution to model product life data from a single population. The following statements create a SAS data set containing observed and right-censored lifetimes of 70 diesel engine fans (Nelson 1982, p. 318):

```
data fan;
  input Lifetime censor @@;
  Lifetime = Lifetime/1000;
  label lifetime='Fan Life (1000s of Hours)';
  datalines;
  450 0    460 1    1150 0    1150 0    1560 1
  1600 0   1660 1   1850 1    1850 1    1850 1
  1850 1   1850 1   2030 1    2030 1    2030 1
  2070 0   2070 0   2080 0    2200 1    3000 1
  3000 1   3000 1   3000 1    3100 0    3200 1
  3450 0   3750 1   3750 1    4150 1    4150 1
  4150 1   4150 1   4300 1    4300 1    4300 1
  4300 1   4600 0   4850 1    4850 1    4850 1
  4850 1   5000 1   5000 1    5000 1    6100 1
  6100 0   6100 1   6100 1    6300 1    6450 1
  6450 1   6700 1   7450 1    7800 1    7800 1
  8100 1   8100 1   8200 1    8500 1    8500 1
  8500 1   8750 1   8750 0    8750 1    9400 1
  9900 1  10100 1  10100 1  10100 1  11500 1
  ;
```

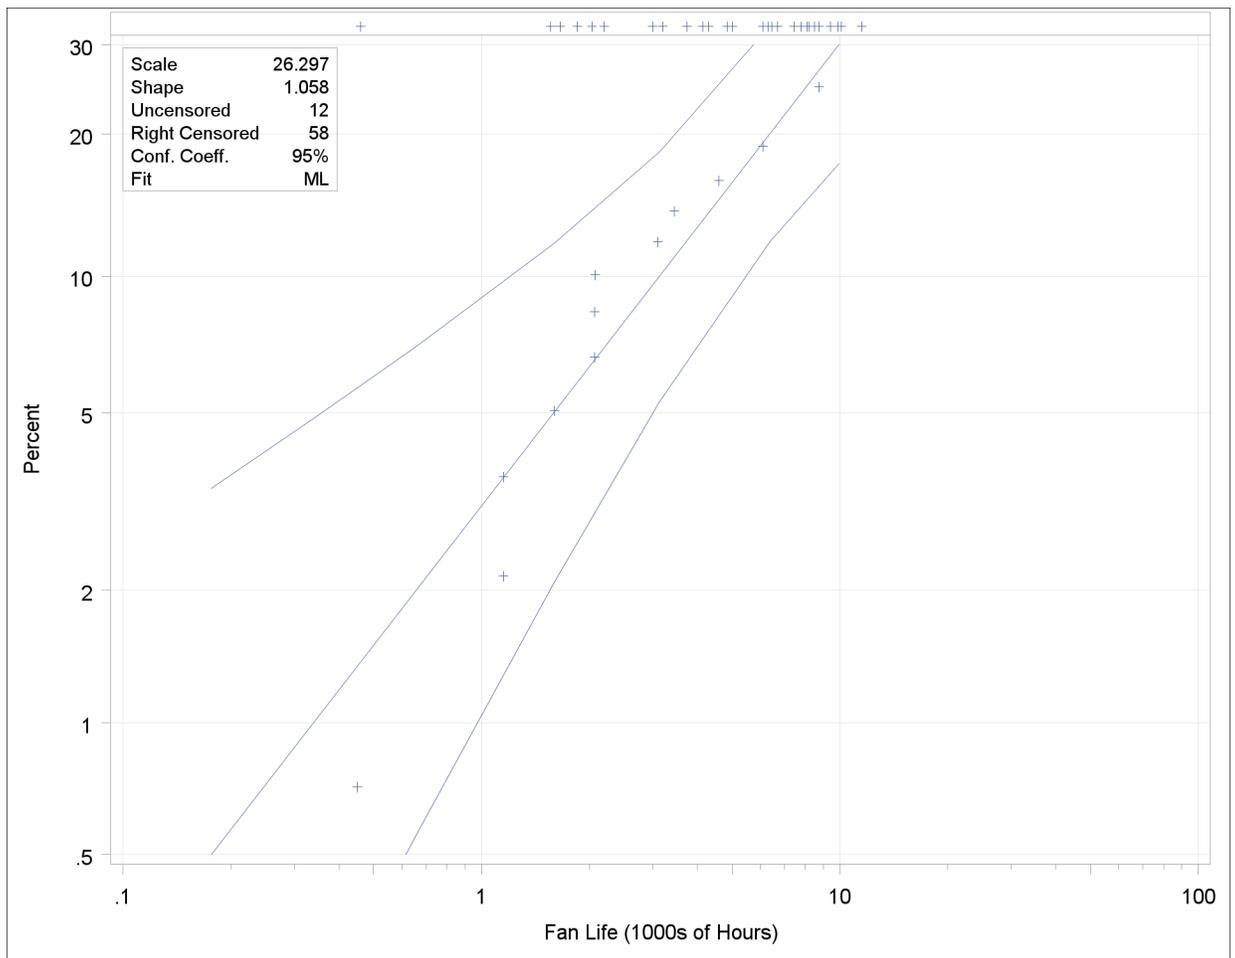

Some of the fans had not failed at the time the data were collected, and the unfailed units have right-censored lifetimes. The variable Lifetime represents either a failure time or a censoring time in thousands of hours. The variable Censor is equal to 0 if the value of Lifetime is a failure time, and it is equal to 1 if the value is a censoring time.

If ODS Graphics is disabled, graphical output is created using traditional graphics; otherwise, ODS Graphics is used. The following statements use the RELIABILITY procedure to produce the traditional graphical output shown in [Figure 16.1](#):

```
ODS Graphics OFF;
proc reliability data=fan;
  distribution Weibull;
  pplot lifetime*censor( 1 ) / covb ;
run;
ODS Graphics ON;
```

The DISTRIBUTION statement specifies the Weibull distribution for probability plotting and maximum likelihood (ML) parameter estimation. The PROBLOT statement produces a probability plot for the variable Lifetime and specifies that the value of 1 for the variable Censor denotes censored observations. You can specify any value, or group of values, for the *censor-variable* (in this case, Censor) to indicate censoring times. The option COVB requests the ML parameter estimate covariance matrix.

The graphical output, displayed in [Figure 16.1](#), consists of a probability plot of the data, an ML fitted distribution line, and confidence intervals for the percentile (lifetime) values. An *inset* box containing summary statistics, Weibull scale and shape estimates, and other information is displayed on the plot by default. The locations of the right-censored data values are plotted in an area at the top of the plot.

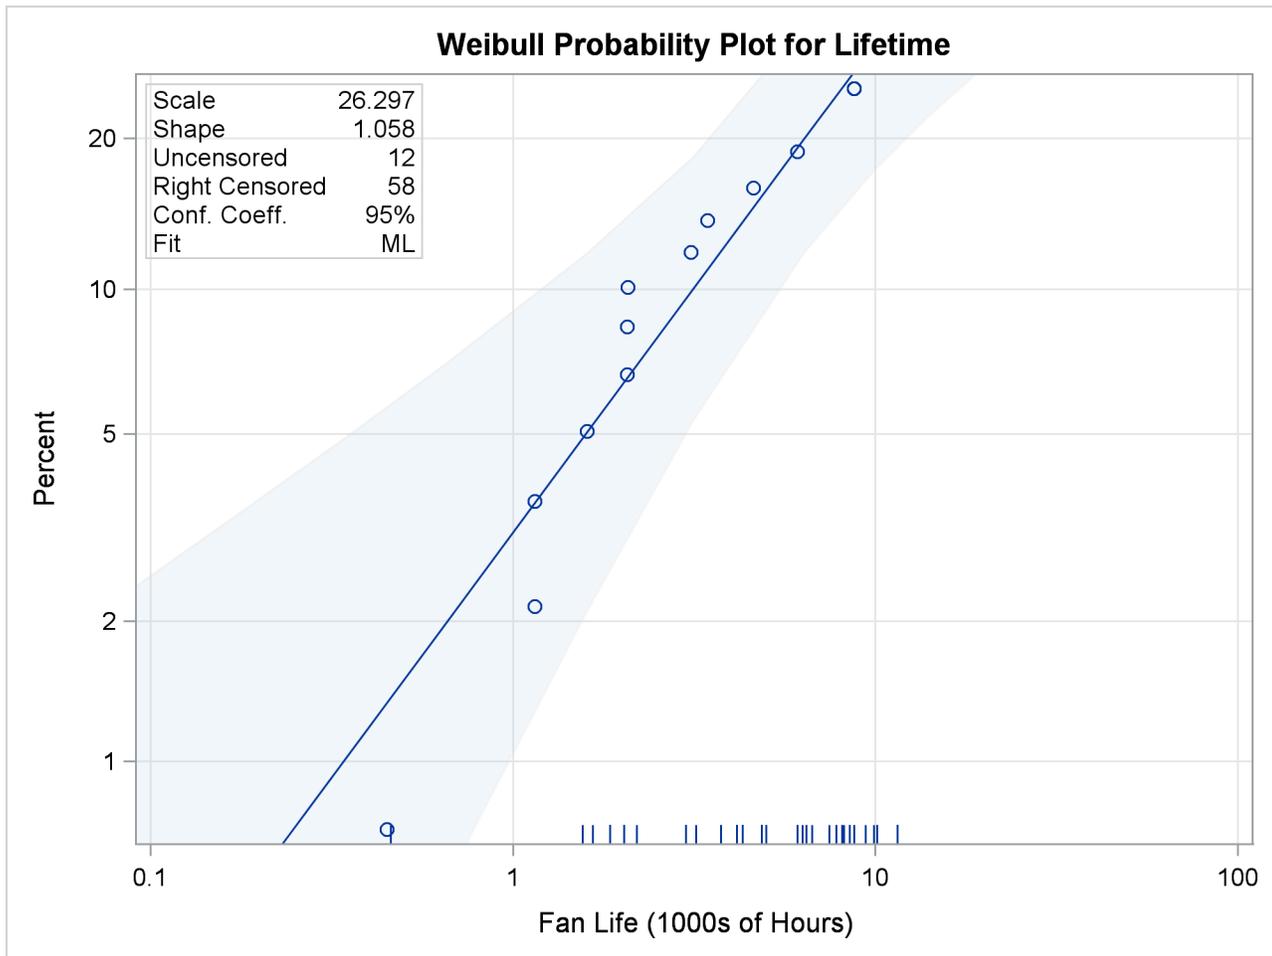

Figure 16.1 Weibull Probability Plot for Engine Fan Data (Traditional Graphics)

If ODS Graphics is enabled, you can create the probability plot by using [ODS Graphics](#). The following SAS statements use ODS Graphics to create the probability plot shown in [Figure 16.1](#):

```
proc reliability data=fan;
  distribution Weibull;
  pplot lifetime*censor( 1 ) / covb;
run;
```

The plot is shown in [Figure 16.2](#).

Figure 16.2 Weibull Probability Plot for Engine Fan Data (ODS Graphics)

The tabular output produced by the preceding SAS statements is shown in Figure 16.3 and Figure 16.4. This consists of summary data, fit information, parameter estimates, distribution percentile estimates, standard errors, and confidence intervals for all estimated quantities.

Weibull Analysis Comparing Groups of Data

This example illustrates probability plotting and distribution fitting for data grouped by the levels of a special *group-variable*. The data are from an accelerated life test of an insulating fluid and are the times to electrical breakdown of the fluid under different high voltage levels. Each voltage level defines a subset of data for which a separate analysis and Weibull plot are produced. These data are the 26kV, 30kV, 34kV, and 38kV groups of the data provided by Nelson (1990, p. 129). The following statements create a SAS data set containing the lifetimes and voltages:

```

data fluid;
  input Time voltage $ @@;
  datalines;
5.79    26kv    1579.52 26kv
2323.7  26kv    7.74   30kv
17.05   30kv    20.46  30kv
21.02   30kv    22.66  30kv
43.4    30kv    47.3   30kv
139.07  30kv    144.12 30kv
175.88  30kv    194.90 30kv
0.19    34kv    .78    34kv
0.96    34kv    1.31   34kv
2.78    34kv    3.16   34kv
4.15    34kv    4.67   34kv
4.85    34kv    6.50   34kv
7.35    34kv    8.01   34kv

```

```

8.27    34kv    12.06    34kv
31.75   34kv    32.52    34kv
33.91   34kv    36.71    34kv
72.89   34kv     .09     38kv
0.39    38kv     .47     38kv
0.73    38kv     .74     38kv
1.13    38kv     1.40    38kv
2.38    38kv
;

```

The variable `Time` provides the time to breakdown in minutes, and the variable `Voltage` provides the voltage level at which the test was conducted. These data are not censored.

The RELIABILITY procedure plots the data for the different voltage levels on the same Weibull probability plot, fits a separate distribution to the data at each voltage level, and superimposes distribution lines on the plot.

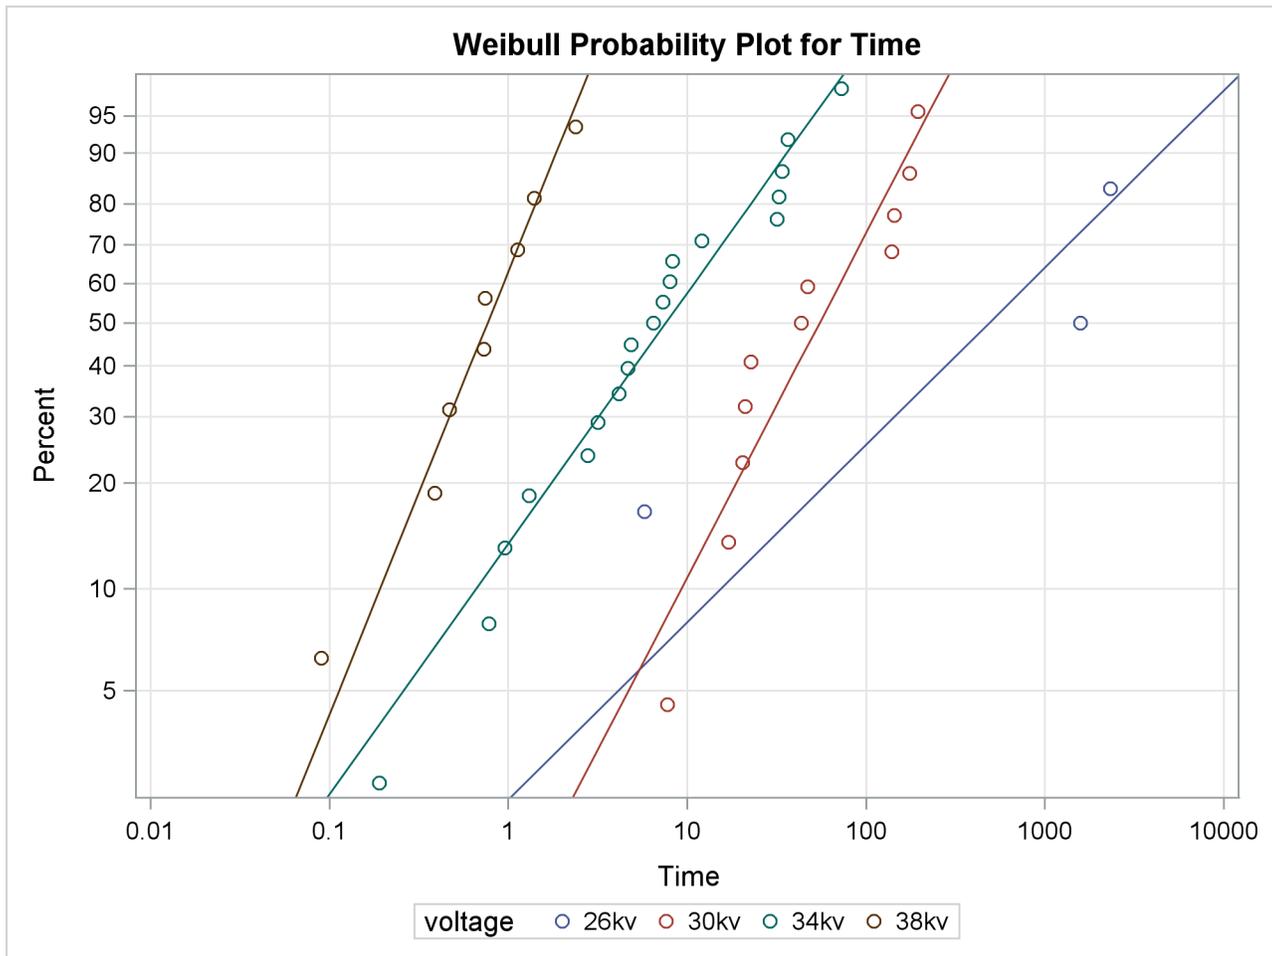

The following statements produce the probability plot shown in [Figure 16.5](#) for the variable `Time` at each level of the *group-variable* `Voltage`:

```

proc reliability data=fluid;
  distribution Weibull;
  pplot time=voltage / overlay
                        noconf;
run;

```

The input data set FLUID is specified by the `DATA=` option in the PROC RELIABILITY statement. The PROBLOT statement option OVERLAY specifies that plots for the groups are to be overlaid rather than displayed separately. The option NOCONF specifies that no confidence bands are to be plotted, since these can interfere with one another on overlaid plots; confidence bands are displayed by default.

Figure 16.5 Weibull Probability Plot for the Insulating Fluid Data

A summary table that contains information for all groups is displayed. In addition, information identical to that shown in Figure 16.3 is tabulated for each level of voltage. The summary table for all groups and the tables for the 26kV group are shown in Figure 16.6 and Figure 16.7.

Analysis of Accelerated Life Test Data

The following example illustrates the analysis of an accelerated life test for Class B electrical motor insulation. The data are provided by Nelson (1990, p. 243). Forty insulation specimens were tested at four temperatures: 150°, 170°, 190°, and 220°C. The purpose of the test is to estimate the median life of the insulation at the design operating temperature of 130°C.

The following SAS program creates the data listed in Figure 16.8. Ten specimens of the insulation were tested at each test temperature. The variable `Time` provides a specimen time to failure or a censoring time, in hours. The variable `Censor` is equal to 1 if the value of the variable `Time` is a right-censoring time and is equal to 0 if the value is a failure time. Some censor times and failure times are identical at some of the temperatures. Rather than repeating identical observations in the input data set, the variable `Count` provides the number of specimens with identical times and temperatures. The variable `Temp` provides the test temperature in degrees centigrade. The variable `Cntrl` is a control variable specifying that percentiles are to be computed only for the first value of `Temp` (130°C). The value of `Temp` in the first observation (130°C) does not correspond to a test temperature. The missing values in the first observation cause the observation to be excluded from the model fit, and the value of 1 for the variable `Cntrl` causes percentiles corresponding to a temperature of 130°C to be computed.

17	528	220	5	1	0

An Arrhenius-lognormal model is fitted to the data in this example. In other words, the fitted model has the lognormal (base 10) distribution, and its location parameter μ depends on the centigrade temperature Temp through the Arrhenius relationship

$$\mu(x) = \beta_0 + \beta_1 x$$

where

$$x = \frac{1000}{\text{Temp} + 273.15}$$

is 1000 times the reciprocal absolute temperature. The lognormal (base e) distribution is also available.

The following SAS statements fit the Arrhenius-lognormal model, and they display the fitted model distributions side-by-side on the probability and the relation plots shown in [Figure 16.9](#):

```
proc reliability;
  distribution lognormal10;
  freq count;
  model hours*censor(1) = temp /
    relation=arr
    obstats( q=.1 .5 .9 control=cntrl );
  rplot hours*censor(1) = temp /
    pplot
    fit=model
    noconf
    relation = arr
    plotdata
    plotfit 10 50 90
    lupper = 1.e5
    slower=120;
run;
```

The PROC RELIABILITY statement invokes the procedure and specifies CLASSB as the input data set. The DISTRIBUTION statement specifies that the lognormal (base 10) distribution is to be used for maximum likelihood parameter estimation and probability plotting. The FREQ statement specifies that the variable Count is to be used as a frequency variable; that is, if Count= n , then there are n specimens with the time and temperature specified in the observation.

The MODEL statement fits a linear regression equation for the distribution location parameter as a function of independent variables. In this case, the MODEL statement also transforms the independent variable through the Arrhenius relationship. The dependent variable is specified as Time. A value of 1 for the variable Censor indicates that the corresponding value of Time is a right-censored observation; otherwise, the value is a failure time. The temperature variable Temp is specified as the independent variable in the model. The MODEL statement option RELATION=ARR specifies the Arrhenius relationship.

The option OBSTATS requests statistics computed for each observation in the input data set. The options in parentheses following OBSTATS indicate which statistics are to be computed. In this case, QUANTILE=.1 .5 .9 specifies that quantiles of the fitted distribution are to be computed for the value of the variable Temp at each observation. The CONTROL= option requests quantiles only for those observations in which the variable Cntrl has a value of 1. This eliminates unnecessary quantiles in the OBSTATS table since, in this case, only the quantiles at the design temperature of 130°C are of interest.

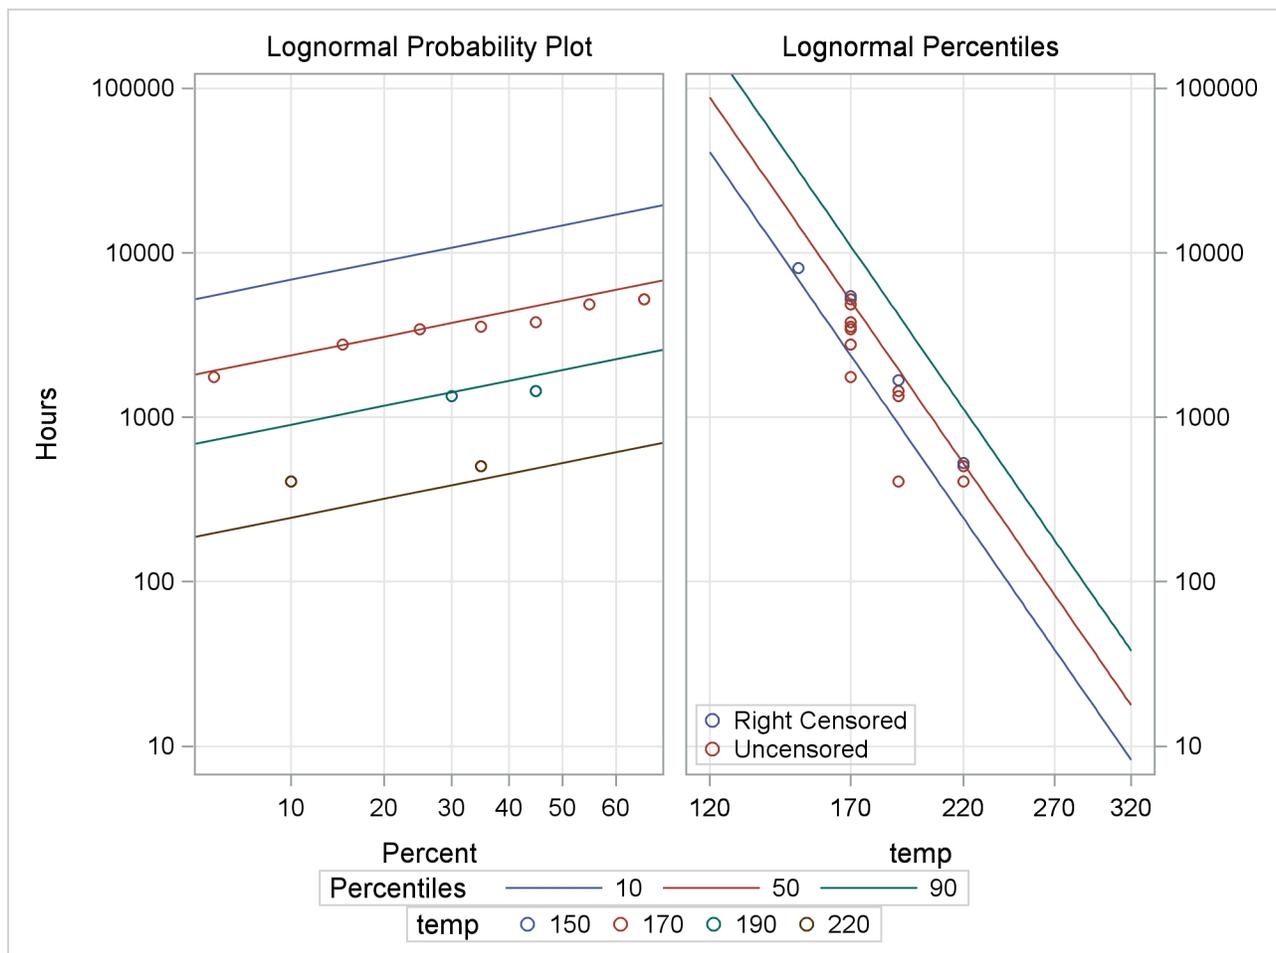

The RPLOT, or RELATIONPLOT, statement displays a plot of the lifetime data and the fitted model. The dependent variable Time, the independent variable Temp, and the censoring indicator Censor are the same as in the MODEL statement. The option FIT=MODEL specifies that the model fitted

with the preceding MODEL statement is to be used for probability plotting and in the relation plot. The option RELATION=ARR specifies an Arrhenius scale for the horizontal axis of the relation plot. The PLOT option specifies that a probability plot is to be displayed alongside the relation plot. The type of probability plot is determined by the distribution named in the DISTRIBUTION statement, in this case, a lognormal (base 10) distribution. Weibull, extreme value, lognormal (base e), normal, log-logistic, and logistic distributions are also available. The NOCONF option suppresses the default percentile confidence bands on the probability plot. The PLOTDATA option specifies that the failure times are to be plotted on the relation plot. The PLOTFIT option specifies that the 10th, 50th, and 90th percentiles of the fitted relationship are to be plotted on the relation plot. The options LUPPER and SLOWER specify an upper limit on the life axis scale and a lower limit on the stress (temperature) axis scale in the plots.

The plots produced by the preceding statements are shown in Figure 16.9. The plot on the left is an overlaid lognormal probability plot of the data and the fitted model. The plot on the right is a relation plot showing the data and the fitted relation. The fitted straight lines are percentiles of the fitted distribution at each temperature. An Arrhenius relation fitted to the data, plotted on an Arrhenius plot, yields straight percentile lines.

Since all the data at 150°C are right censored, there are no failures corresponding to 150°C on the probability plot. However, the fitted distribution at 150°C is plotted on the probability plot.

Figure 16.9 Probability and Relation Plots for the Class B Insulation Data

The tabular output requested with the MODEL statement is shown in Figure 16.10. The “Model Information” table provides general information about the data and model. The “Summary of Fit” table shows the number of observations used, the number of failures and of censored values (accounting for the frequency count), and the maximum log likelihood for the fitted model.

The “Lognormal Parameter Estimates” table contains the Arrhenius-lognormal model parameter estimates, their standard errors, and confidence interval estimates. In this table, INTERCEPT is the maximum likelihood estimate of β_0 , TEMP is the estimate of β_1 , and Scale is the estimate of the lognormal scale parameter, σ .

Observation Statistics					
Hours	censor	temp	count	Prob	Pcntl
.	.	130	.	0.1000	21937.658
.	.	130	.	0.5000	47135.132
.	.	130	.	0.9000	101274.29
Observation Statistics					
Hours	Stderr	Lower	Upper		
.	6959.151	11780.636	40851.857		
.	16125.548	24106.685	92162.016		
.	42061.1	44872.401	228569.92		

The “Observation Statistics” table provides the estimates of the fitted distribution quantiles, their standard errors, and the confidence limits. These are given only for the value of 130°C, as specified with the CONTROL= option in the MODEL statement. The predicted median life at 130°C corresponds to a quantile of 0.5, and it is approximately 47,134 hours.

In addition to the MODEL statement output in Figure 16.10, the RELIABILITY procedure produces tabular output for each temperature that is identical to the output produced with the PROBLOT statement. This output is not shown.

Weibull Analysis of Interval Data with Common Inspection Schedule

Table 16.1 shows data for 167 identical turbine parts provided by Nelson (1982, p. 415). The parts were inspected at certain times to determine which parts had cracked since the last inspection. The times at which parts develop cracks are to be fitted with a Weibull distribution.

Table 16.1 Turbine Part Cracking Data

Inspection (Months)		Number	
Start	End	Cracked	Cumulative
0	6.12	5	5
6.12	19.92	16	21
19.92	29.64	12	33
29.64	35.40	18	51
35.40	39.72	18	69
39.72	45.24	2	71
45.24	52.32	6	77
52.32	63.48	17	94
63.48	Survived	73	167

Table 16.1 shows the time in months of each inspection period and the number of cracked parts found in each period. These data are said to be interval censored since only the time interval in

which failures occurred is known, not the exact failure times. Seventy-three parts had not cracked at the last inspection, which took place at 63.48 months. These 73 lifetimes are right censored, since the lifetimes are known only to be greater than 63.48 months.

The interval data in this example are read from a SAS data set with a special structure. All units must have a common inspection schedule. This type of interval data is called readout data. The following SAS program creates the SAS data set named CRACKS, shown in Figure 16.11, and provides the data in Table 16.1 with this structure:

```
data cracks;
  input Time units fail;
  datalines;
6.12 167 5
19.92 162 16
29.64 146 12
35.4 134 18
39.72 116 18
45.24 98 2
52.32 96 6
63.48 90 17
;
```

The variable Time is the inspection time—that is, the upper endpoint of each interval. The variable Units is the number of unfailed units at the beginning of each interval, and the variable Fail is the number of units with cracks at the inspection time.

Figure 16.11 Listing of the Turbine Part Cracking Data

Obs	Time	units	fail
1	6.12	167	5
2	19.92	162	16
3	29.64	146	12
4	35.40	134	18
5	39.72	116	18
6	45.24	98	2
7	52.32	96	6
8	63.48	90	17

The following statements use the RELIABILITY procedure to produce the probability plot in Figure 16.12 for the data in the data set CRACKS:

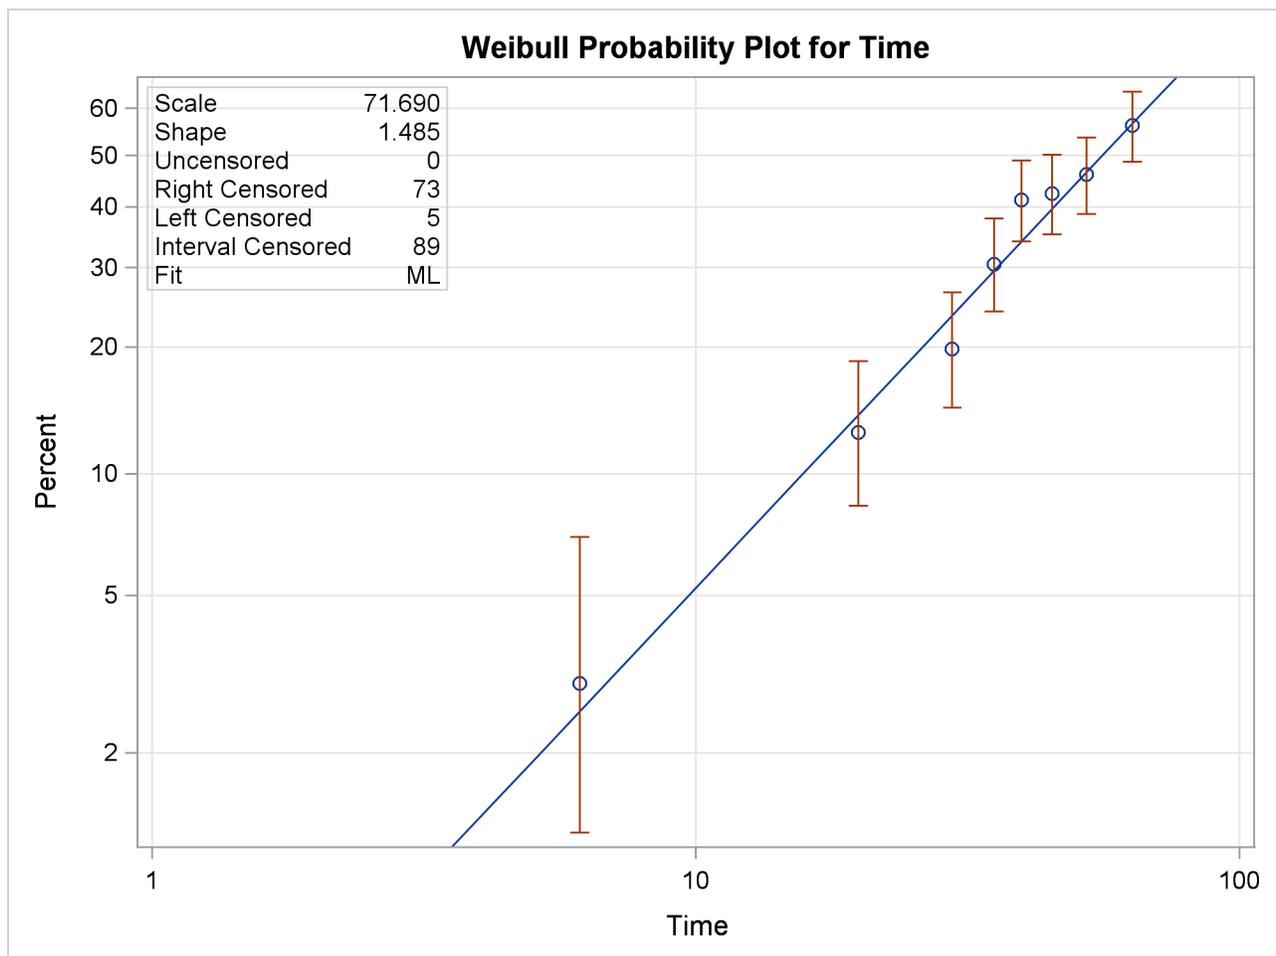

```
proc reliability data=cracks;
  freq fail;
  nenter units;
  distribution Weibull;
  probplot time / readout
  ppout
  pconfplt
  noconf;
run;
```

The FREQ statement specifies that the variable Fail provides the number of failures in each interval. The NENTER statement specifies that the variable Units provides the number of unfailed units at the beginning of each interval. The DISTRIBUTION statement specifies that the Weibull distribution be used for parameter estimation and probability plotting. The PROBPLOT statement requests a probability plot of the data.

The PROBPLOT statement option READOUT indicates that the data in the CRACKS data set are readout (or interval) data. The option PCONFPLT specifies that confidence intervals for the cumulative probability of failure be plotted. The confidence intervals for the cumulative probability are based on the binomial distribution for time intervals until right censoring occurs. For time intervals after right censoring occurs, the binomial distribution is not valid, and a normal approximation is used to compute confidence intervals.

The option NOCONF suppresses the display of confidence intervals for distribution percentiles in the probability plot.

Figure 16.12 Weibull Probability Plot for the Part Cracking Data

A listing of the tabular output produced by the preceding SAS statements is shown in Figure 16.13 and Figure 16.14. By default, the specified Weibull distribution is fitted by maximum likelihood. The line plotted on the probability plot and the tabular output summarize this fit. For interval data, the estimated cumulative probabilities and associated confidence intervals are tabulated. In addition, general fit information, parameter estimates, percentile estimates, standard errors, and confidence intervals are tabulated.

99.9	263.348102	44.7205513	188.791789	367.347666

In this example, the number of unfailed units at the beginning of an interval minus the number failing in the interval is equal to the number of unfailed units entering the next interval. This is not always the case since some unfailed units might be removed from the test at the end of an interval; that is, they might be right censored. The special structure of the input SAS data set required for interval data enables the RELIABILITY procedure to analyze this more general case.

Lognormal Analysis with Arbitrary Censoring

This example illustrates analyzing data that have more general censoring than in the previous example. The data can be a combination of exact failure times, left censored, right censored, and interval censored data. The intervals can be overlapping, unlike in the previous example, where the interval endpoints had to be the same for all units.

Table 16.2 shows data from Nelson (1982, p. 409), analyzed by Meeker and Escobar (1998, p. 135). Each of 435 turbine wheels was inspected once to determine whether a crack had developed in the wheel or not. The inspection time (in 100s of hours), the number inspected at the time that had cracked, and the number not cracked are shown in the table. The quantity of interest is the time for a crack to develop.

Table 16.2 Turbine Wheel Cracking Data

Inspection Time (100 hours)	Number Cracked	Number Not Cracked
4	0	39
10	4	49
14	2	31
18	7	66
22	5	25
26	9	30
30	9	33
34	6	7
38	22	12
42	21	19
46	21	15

These data consist only of left and right censored lifetimes. If a unit has developed a crack at an inspection time, the unit is left censored at the time; if a unit has not developed a crack, it is right censored at the time. For example, there are 4 left-censored lifetimes and 49 right-censored lifetimes at 1000 hours.

The following statements create a SAS data set named TURBINE that contains the data in the format necessary for analysis by the RELIABILITY procedure:

```
data turbine;
  label t1 = 'Time of Cracking (Hours x 100)';
  input t1 t2 f;
  datalines;
.   4  0
4   .  39
.  10  4
10  .  49
.  14  2
14  .  31
.  18  7
18  .  66
.  22  5
```

```

22 . 25
. 26 9
26 . 30
. 30 9
30 . 33
. 34 6
34 . 7
. 38 22
38 . 12
. 42 21
42 . 19
. 46 21
46 . 15
;

```

The variables T1 and T2 represent the inspection times and determine whether the observation is right or left censored. If T1 is missing (.), then T2 represents a left-censoring time; if T2 is missing, T1 represents a right-censoring time. The variable F is the number of units that were found to be cracked for left-censored observations, or not cracked for right-censored observations at an inspection time.

The following statements use the RELIABILITY procedure to produce the probability plot in [Figure 16.15](#) for the data in the data set TURBINE:

```

proc reliability data = turbine;
  distribution lognormal;
  freq f;
  pplot ( t1 t2 ) / maxitem = 5000
          ppout;
run;

```

The DISTRIBUTION statement specifies that a lognormal probability plot be created. The FREQ statement identifies the frequency variable F. The option MAXITEM=5000 specifies that the iterative algorithm that computes the points on the probability plot takes a maximum of 5000 iterations. The algorithm does not converge for these data in the default 1000 iterations, so the maximum number of iterations needs to be increased for convergence. The option PPOUT specifies that a table of the cumulative probabilities plotted on the probability plot be printed, along with standard errors and confidence limits.

The tabular output for the maximum likelihood lognormal fit for these data is shown in [Figure 16.16](#). [Figure 16.15](#) shows the resulting lognormal probability plot with the computed cumulative probability estimates and the lognormal fit line.

Regression Modeling

This example is an illustration of a Weibull regression model that uses a load accelerated life test of rolling bearings, with data provided by Nelson (1990, p. 305). Bearings are tested at four different loads, and lifetimes in 10^6 of revolutions are measured. The data are shown in Table 16.3. An outlier identified by Nelson (1990) is omitted.

Table 16.3 Bearing Lifetime Data

Load		Life (10^6 Revolutions)								
0.87	1.67	2.2	2.51	3.00	3.90	4.70	7.53	14.7	27.76	37.4
0.99	0.80	1.0	1.37	2.25	2.95	3.70	6.07	6.65	7.05	7.37
1.09	0.18	0.2	0.24	0.26	0.32	0.32	0.42	0.44	0.88	
1.18	0.073	0.098	0.117	0.135	0.175	0.262	0.270	0.350	0.386	0.456

These data are modeled with a Weibull regression model in which the independent variable is the logarithm of the load. The model is

$$\mu_i = \beta_0 + \beta_1 x_i$$

where μ_i is the location parameter of the extreme value distribution and

$$x_i = \log(\text{load})$$

for the i th bearing. The following statements create a SAS data set containing the loads, log loads, and bearing lifetimes:

```
data bearing;
  input load Life @@;
  lload = log(load);
  datalines;
.87 1.67      .87 2.2      .87 2.51      .87 3.0      .87 3.9
.87 4.7      .87 7.53     .87 14.7     .87 27.76   .87 37.4
.99 .8      .99 1.0      .99 1.37     .99 2.25    .99 2.95
.99 3.7      .99 6.07     .99 6.65     .99 7.05    .99 7.37
1.09 .18     1.09 .2      1.09 .24     1.09 .26    1.09 .32
1.09 .32     1.09 .42     1.09 .44     1.09 .88    1.18 .073
1.18 .098    1.18 .117    1.18 .135    1.18 .175   1.18 .262
1.18 .270    1.18 .350    1.18 .386    1.18 .456
;
```

Figure 16.17 shows a listing of the bearing data.

The PROC RELIABILITY statement invokes the procedure and identifies BEARING as the input data set. The DISTRIBUTION statement specifies the Weibull distribution for model fitting. The MODEL statement specifies the regression model, identifying Life as the variable that provides the response values (the lifetimes) and Lload as the independent variable (the log loads). The MODEL statement option COVB requests the regression parameter covariance matrix, and the CORRB option requests the correlation matrix. The option OBSTATS requests a table that contains residuals, predicted values, and other statistics. The ODS OUTPUT statement creates a SAS data set named RESIDUAL that contains the table created by the OBSTATS option.

Figure 16.18 shows the tabular output produced by the RELIABILITY procedure. The “Weibull Parameter Estimates” table contains parameter estimates, their standard errors, and 95% confidence intervals. In this table, INTERCEPT corresponds to β_0 , LLOAD corresponds to β_1 , and SHAPE corresponds to the Weibull shape parameter. Figure 16.19 shows a listing of the output data set RESIDUAL.

The value of the lifetime Life and the log load Lload are included in this data set, as well as statistics computed from the fitted model. The variable Xbeta is the value of the linear predictor

$$\mathbf{x}'\hat{\boldsymbol{\beta}} = \hat{\beta}_0 + \text{Lload}\hat{\beta}_1$$

for each observation. The variable Surv contains the value of the reliability function, the variable Sresid contains the standardized residual, and the variable Aresid contains a residual adjusted for right-censored observations. Since there are no censored values in these data, Sresid is equal to Aresid for all the bearings. See Table 16.32 and Table 16.33 for other statistics that are available in

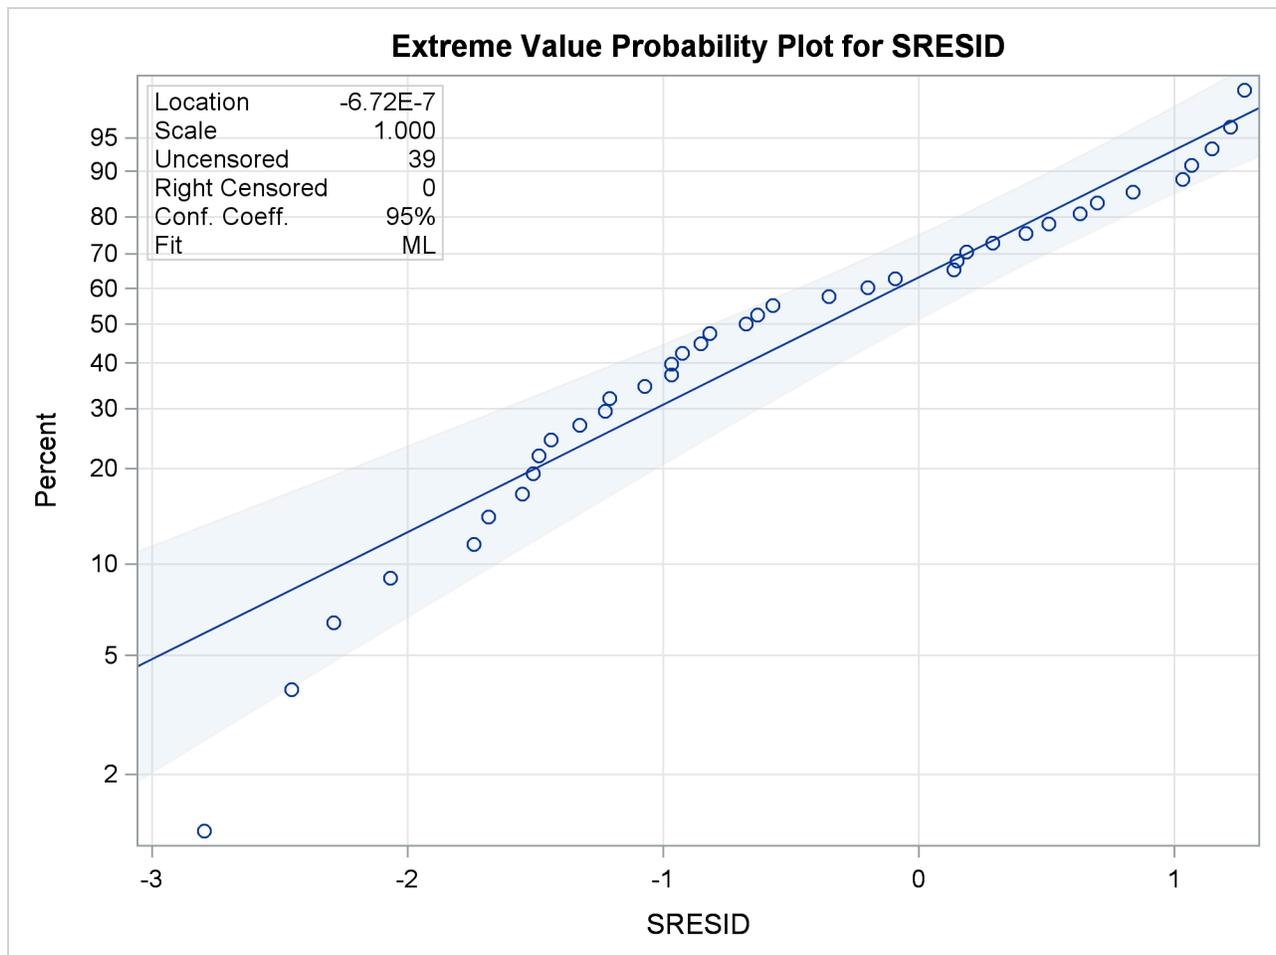

the OBSTATS table and data set. See the section “Regression Model Statistics Computed for Each Observation for Lifetime Data” on page 1377 for a description of the residuals and other statistics.

If the fitted regression model is adequate, the standardized residuals have a standard extreme value distribution. You can check the residuals by using the RELIABILITY procedure and the RESIDUAL data set to create an extreme value probability plot of the residuals.

The following statements create the plot in Figure 16.20:

```
proc reliability data=residual;
  distribution ev;
  probplot sresid;
run;
```

Figure 16.20 Extreme Value Probability Plot for the Standardized Residuals

Although the estimated location is near zero and the estimated scale is near one, the plot reveals systematic curvature, indicating that the Weibull regression model might be inadequate.

Regression Model with Nonconstant Scale

Nelson (1990, p. 272) and Meeker and Escobar (1998, p. 439) analyzed data from a strain-controlled fatigue test on 26 specimens of a type of superalloy. The following SAS statements create a SAS data set containing for each specimen the level of pseudo-stress (Pstress), the number of cycles (in thousands) (Kcycles) until failure or removal from the test, and a variable to indicate whether a specimen failed (F) or was right censored (C) (Status):

```
data alloy;
  input pstress kCycles status$ @@;
  cen = ( status = 'C' );
  datalines;
80.3 211.629 F 99.8 43.331 F
80.6 200.027 F 100.1 12.076 F
80.8 57.923 C 100.5 13.181 F
84.3 155.000 F 113.0 18.067 F
85.2 13.949 F 114.8 21.300 F
85.6 112.968 C 116.4 15.616 F
85.8 152.680 F 118.0 13.030 F
86.4 156.725 F 118.4 8.489 F
86.7 138.114 C 118.6 12.434 F
87.2 56.723 F 120.4 9.750 F
87.3 121.075 F 142.5 11.865 F
89.7 122.372 C 144.5 6.705 F
91.3 112.002 F 145.9 5.733 F
;
```

The following statements fit a Weibull regression model with the number of cycles to failure as the response variable:

```
ods output ModObstats = Resids;
proc reliability data = alloy;
  distribution Weibull;
  model kcycles*cen(1) = pstress pstress*pstress / Relation = Pow Obstats;
  logscale pstress;
  rplot kcycles*cen(1) = pstress / fit=regression
    relation = pow
    plotfit 10 50 90
    slower=60 supper=160
    lupper=500;

  label pstress = "Pseudo-Stress";
  label kcycles = "Thousands of Cycles";
run;
```

The data set RESIDS contains standardized residuals created with the ODS OUTPUT statement. The MODEL statement specifies a model quadratic in the log of pseudo-stress for the extreme value location parameter. The quadratic model in pseudo-stress PSTRESS is specified in the MODEL statement, and the RELATION=POW option specifies that the log transformation be applied to Pstress in the MODEL statement and the LOGSCALE statement. The LOGSCALE statement specifies the log of the scale parameter as a linear function of the log of Pstress. The RPLOT statement specifies a plot of the data and the fitted regression model versus the variable Pstress.

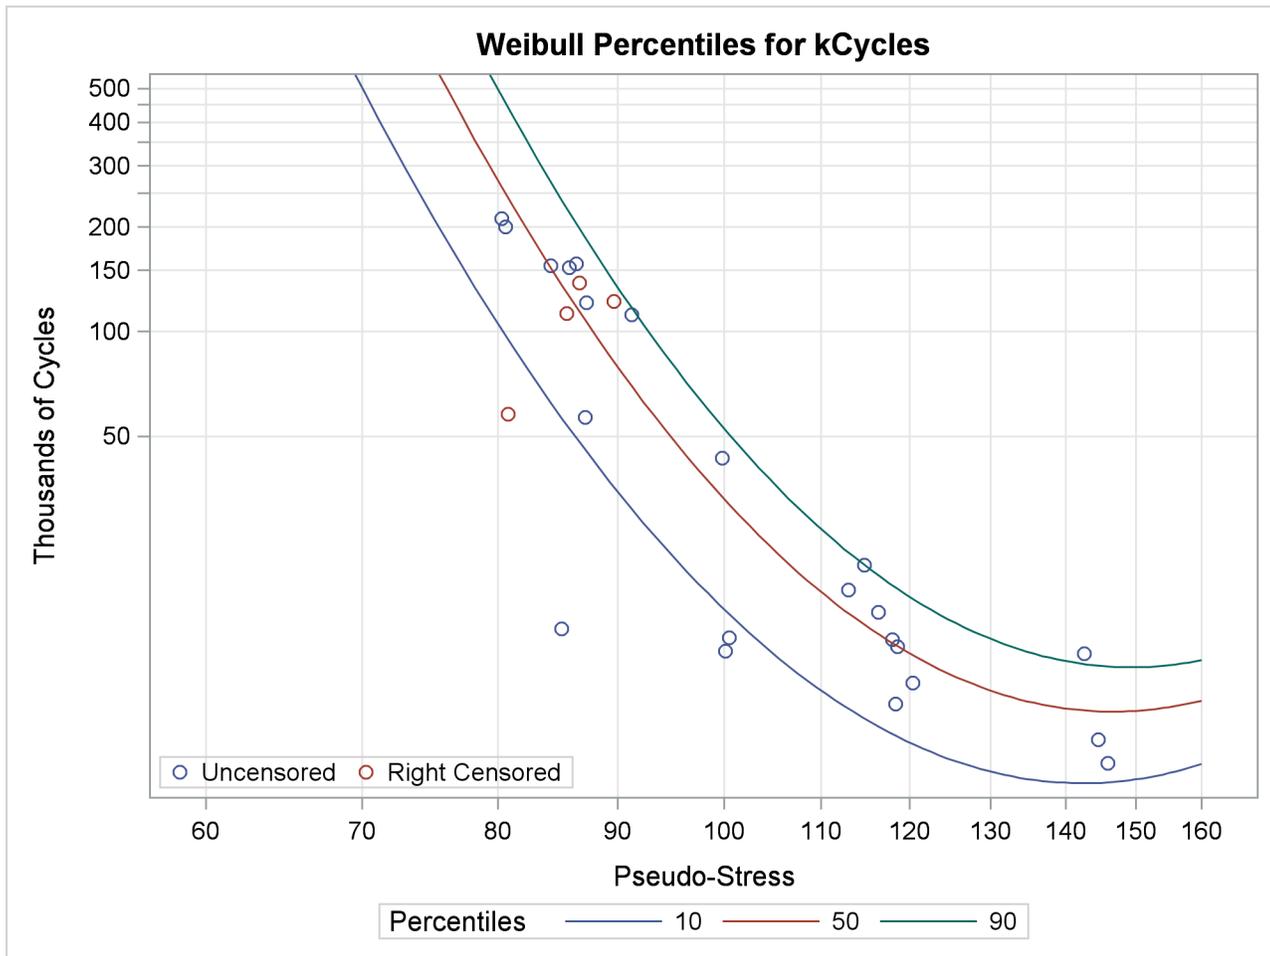

The FIT=REGRESSION option specifies plotting the regression model fitted with the preceding MODEL statement. The RELATION=POW option specifies a log stress axis. The PLOTFIT option specifies plotting the 10th, 50th, and 90th percentiles of the regression model at each stress level. The SLOWER, SUPPER, and LUPPER options control limits on the stress and lifetime axes.

Figure 16.21 displays the parameter estimates from the fitted regression model. Parameter estimates for both the model for the location parameter and the scale parameter models are shown. Standard errors and confidence limits for all parameter estimates are included.

Figure 16.21 Parameter Estimates for Fitted Regression Model

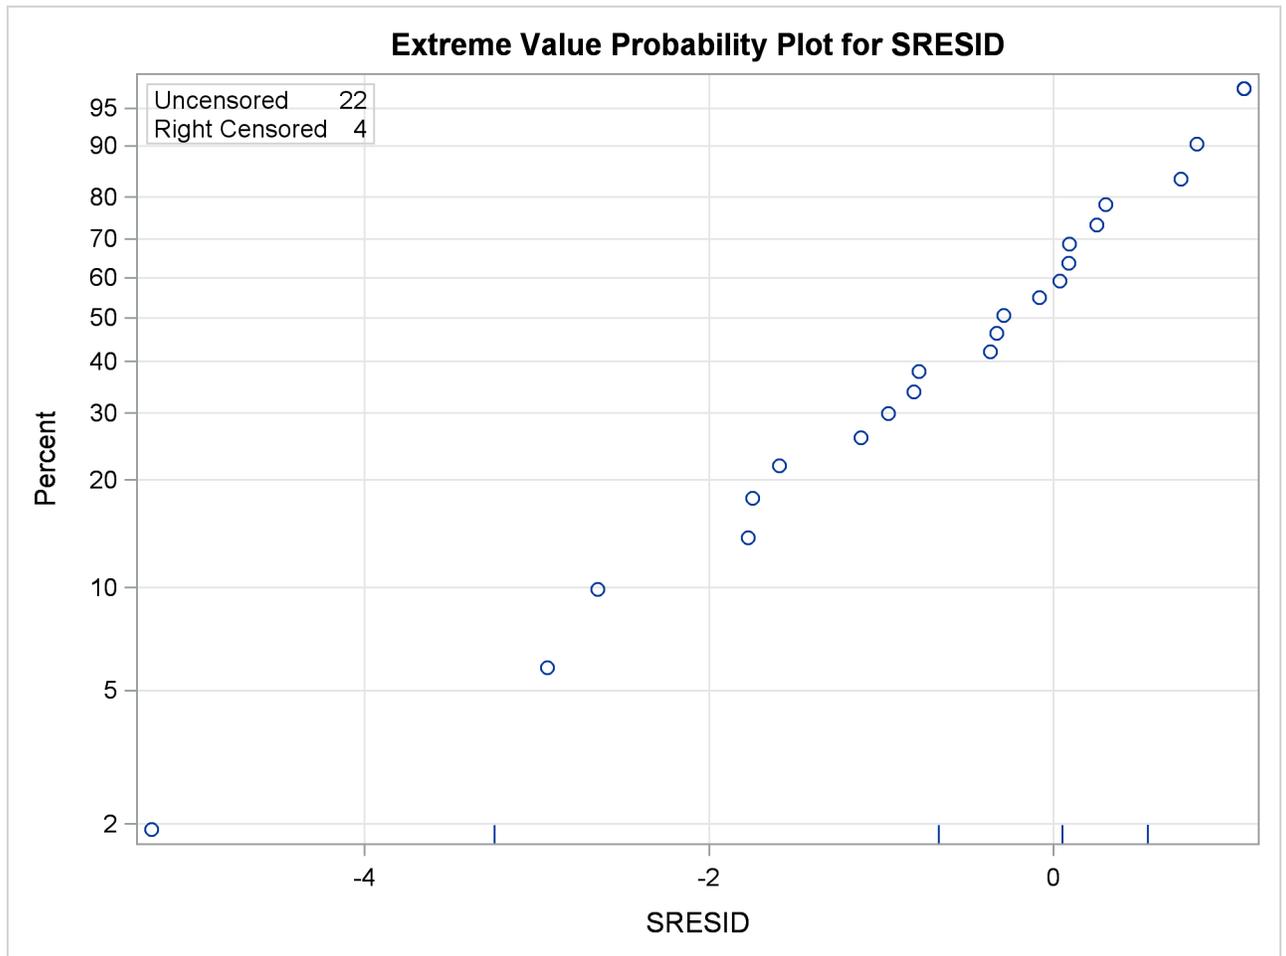

The RELIABILITY Procedure

Figure 16.22 displays the plot of the data and fitted regression model.

Figure 16.22 Superalloy Fatigue Data with Fitted Regression Model

The following SAS statements create an extreme values probability plot of standardized residuals from the regression model shown in Figure 16.23:

```
proc reliability data = Resids;
  distribution ev;
  pplot sresid*cen(1) / nofit
  ;
run;
```

Figure 16.23 Residuals for Superalloy Fatigue Data Regression Model

Regression Model with Two Independent Variables

Meeker and Escobar (1998, p. 447) analyzed data from an accelerated test on the lifetimes of glass capacitors as a function of operating voltage and temperature. The following SAS statements create a SAS data set containing the data. There are four lifetimes for each of eight combinations and four censored observations after the fourth failure for each combination:

```

data glass;
  input Temp Voltage @;
  do i = 1 to 4;
    cen = 0;
    input Hours @; output;
  end;
  do i = 1 to 4;
    cen = 1;
    output;
  end;
datalines;

```

```

170 200 439 904 1092 1105
170 250 572 690 904 1090
170 300 315 315 439 628
170 350 258 258 347 588
180 200 959 1065 1065 1087
180 250 216 315 455 473
180 300 241 315 332 380
180 350 241 241 435 455
;

```

The following statements analyze the capacitor data. The MODEL statement fits a regression model with Temp and Voltage as independent variables. Parameter estimates from the fitted regression model are shown in Figure 16.24. An interaction term between Temp and Voltage is included. The PPLOT statement creates a Weibull probability plot shown in Figure 16.25 with all temperature-voltage combinations overlaid on the same plot. The regression model fit is also plotted. The RPLOT statement creates the plot shown in Figure 16.26 of the data and Weibull distribution percentiles from the regression model as a function of voltage for values of temperature of 150, 170, and 180:

```

proc reliability data = glass;
  distribution Weibull;
  model Hours*cen(1) = temp voltage temp * voltage;
  pplot Hours*cen(1) = ( temp voltage ) / fit = model
                        overlay
                        noconf
                        lupper = 2000;

run;

proc reliability data = glass;
  distribution Weibull;
  model Hours*cen(1) = temp voltage temp * voltage;
  rplot Hours*cen(1) = voltage / fit = regression(temp = 150, 170, 180)
                    plotfit;

run;

```

Figure 16.24 Parameter Estimates for Fitted Regression Model

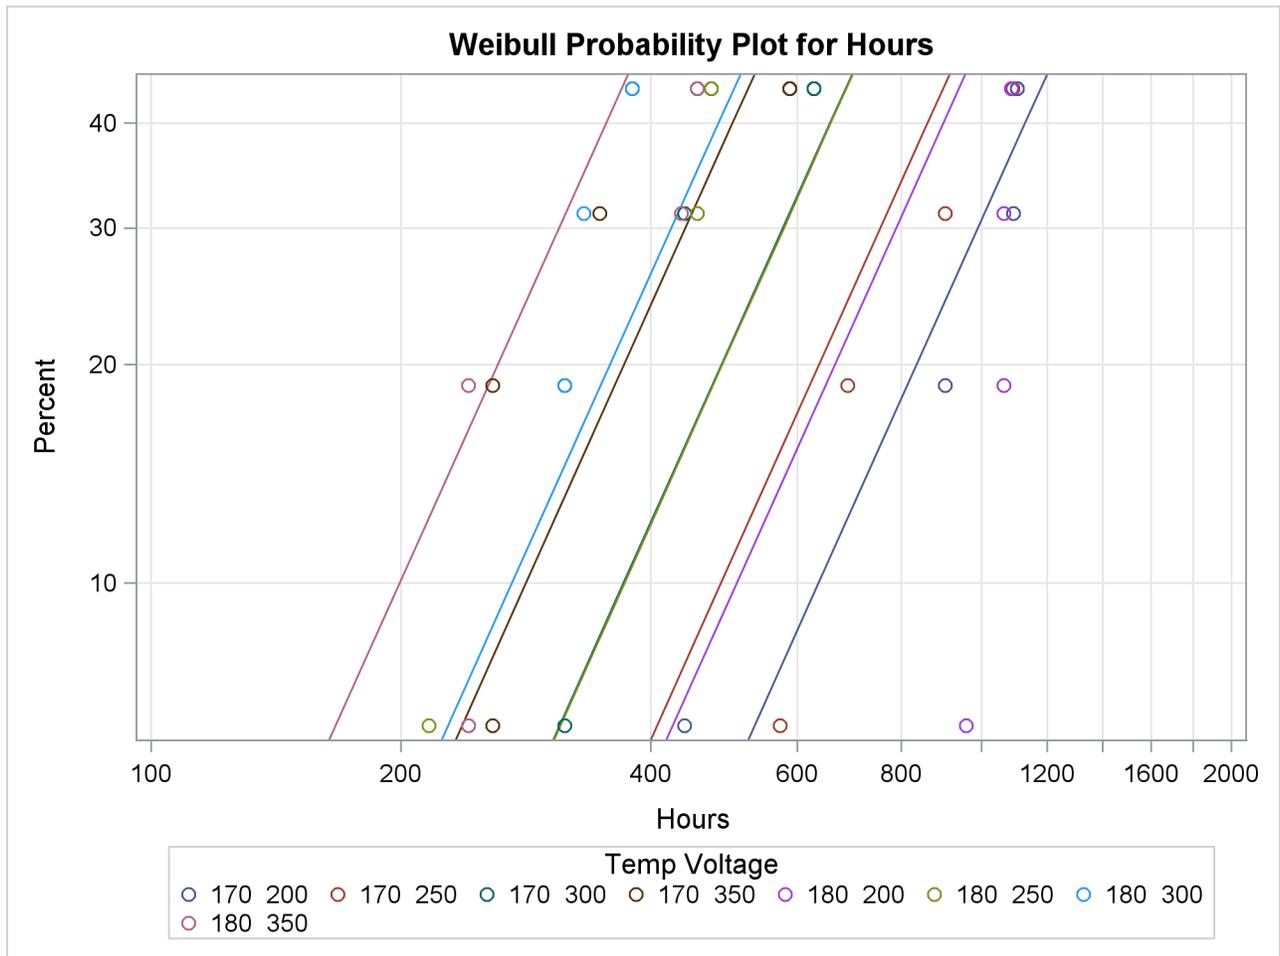

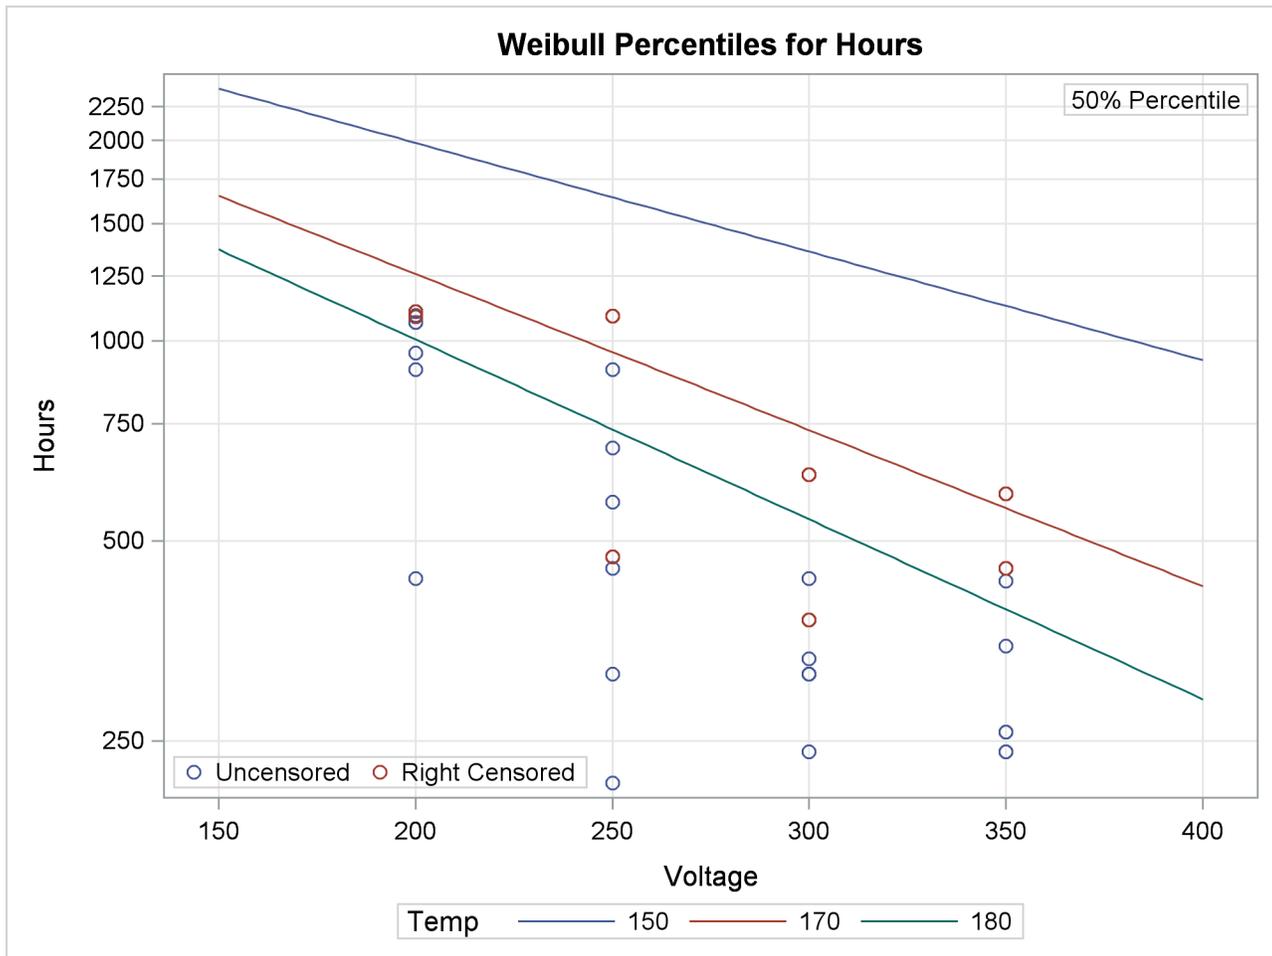

Figure 16.26 Plot of Data and Fitted Weibull Percentiles for Glass Capacitor Regression Model

Weibull Probability Plot for Two Combined Failure Modes

Doganaksoy, Hahn, and Meeker (2002) analyzed failure data for the dielectric insulation of generator armature bars. A sample of 58 segments of bars were subjected to a high voltage stress test. Based on examination of the sample after the test, failures were attributed to one of two modes:

- Mode D (degradation failure): degradation of the organic material. Such failures usually occur later in life.
- Mode E (early failure): insulation defects due to a processing problem. These failures tend to occur early in life.

The following SAS statements create a SAS data set that contains the failure data:

```
data Voltage;
  input Hours Mode$ @@;
  if Mode = 'Cen' then Status = 1;
  else Status = 0;
  datalines;
2   E   3   E   5   E   8   E   13  Cen 21  E
28  E   31  E   31  Cen 52  Cen 53  Cen 64  E
67  Cen 69  E   76  E   78  Cen 104 E   113 Cen
119 E   135 Cen 144 E   157 Cen 160 E   168 D
179 Cen 191 D   203 D   211 D   221 E   226 D
236 E   241 Cen 257 Cen 261 D   264 D   278 D
282 E   284 D   286 D   298 D   303 E   314 D
317 D   318 D   320 D   327 D   328 D   328 D
348 D   348 Cen 350 D   360 D   369 D   377 D
387 D   392 D   412 D   446 D
;
```

The variable Hours represents the number of hours until a failure, or the number of hours on test if the sample unit did not fail. The variable Mode represents the failure mode: D for degradation failure, E for early failures, or Cen if the unit did not fail (i.e., is right-censored). The computed variable Status is a numeric indicator for censored observations.

The following statements fit a Weibull distribution to the individual failure modes (D and E), and compute the failure distribution with both modes acting:

```
proc reliability data=Voltage;
  distribution Weibull;
  pplot Hours*Status(1) / vref(intersect) = 10
                        vreflabel = ('10% Percentile')
                        survtime = 100 200 300 400 500 1000
                        lupper = 500;
  fmode combine = Mode( 'D' 'E' );
run;
```

Figure 16.27 contains estimates of the combined failure mode survival function at the times specified with the SURVTIME= option in the PLOT statement.

Figure 16.27 Survival Function Estimates for Combined Failure Modes

100.00	0.1898	0.1172	0.2926	0.8102	0.7074	0.8828
200.00	0.3115	0.2139	0.4292	0.6885	0.5708	0.7861
300.00	0.5866	0.4621	0.7010	0.4134	0.2990	0.5379
400.00	0.9405	0.8476	0.9782	0.0595	0.0218	0.1524
500.00	0.9998	0.9711	1.0000	0.0002	0.0000	0.0289
1000.00	1.0000	0.0000	1.0000	0.0000	0.0000	1.0000

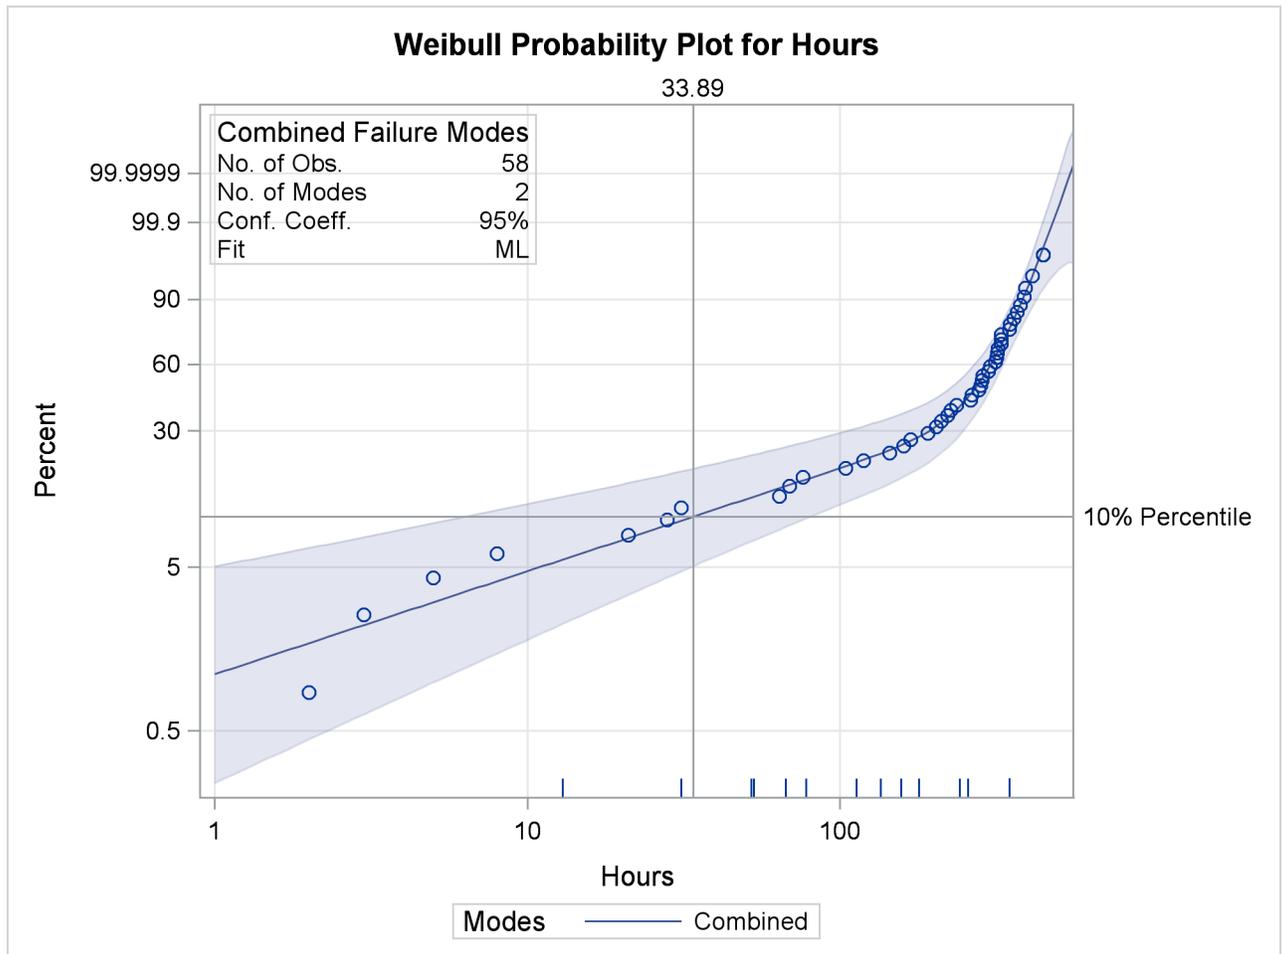

Figure 16.28 shows Weibull parameter estimates for the two individual failure modes.

Figure 16.28 Parameter Estimates for Individual Failure Modes

Individual Failure Mode					
Weibull Parameter Estimates					
Parameter	Estimate	Standard Error	Asymptotic Normal		Mode
			95% Confidence Limits		
			Lower	Upper	
EV Location	5.8415	0.0350	5.7730	5.9100	D
EV Scale	0.1785	0.0254	0.1350	0.2360	D
Weibull Scale	344.2966	12.0394	321.4903	368.7208	D
Weibull Shape	5.6020	0.7985	4.2365	7.4076	D
EV Location	7.0649	0.5109	6.0637	8.0662	E
EV Scale	1.5739	0.3415	1.0287	2.4080	E
Weibull Scale	1170.1832	597.7903	429.9480	3184.8703	E
Weibull Shape	0.6354	0.1379	0.4153	0.9721	E

Figure 16.29 is a Weibull probability plot of the failure probability distribution with the two failure modes combined, along with approximate pointwise 95% confidence limits. A reference line at the 10% point on the vertical axis intersecting the distribution curve shows the 10% percentile of lifetimes when both modes act to be about 34 hours.

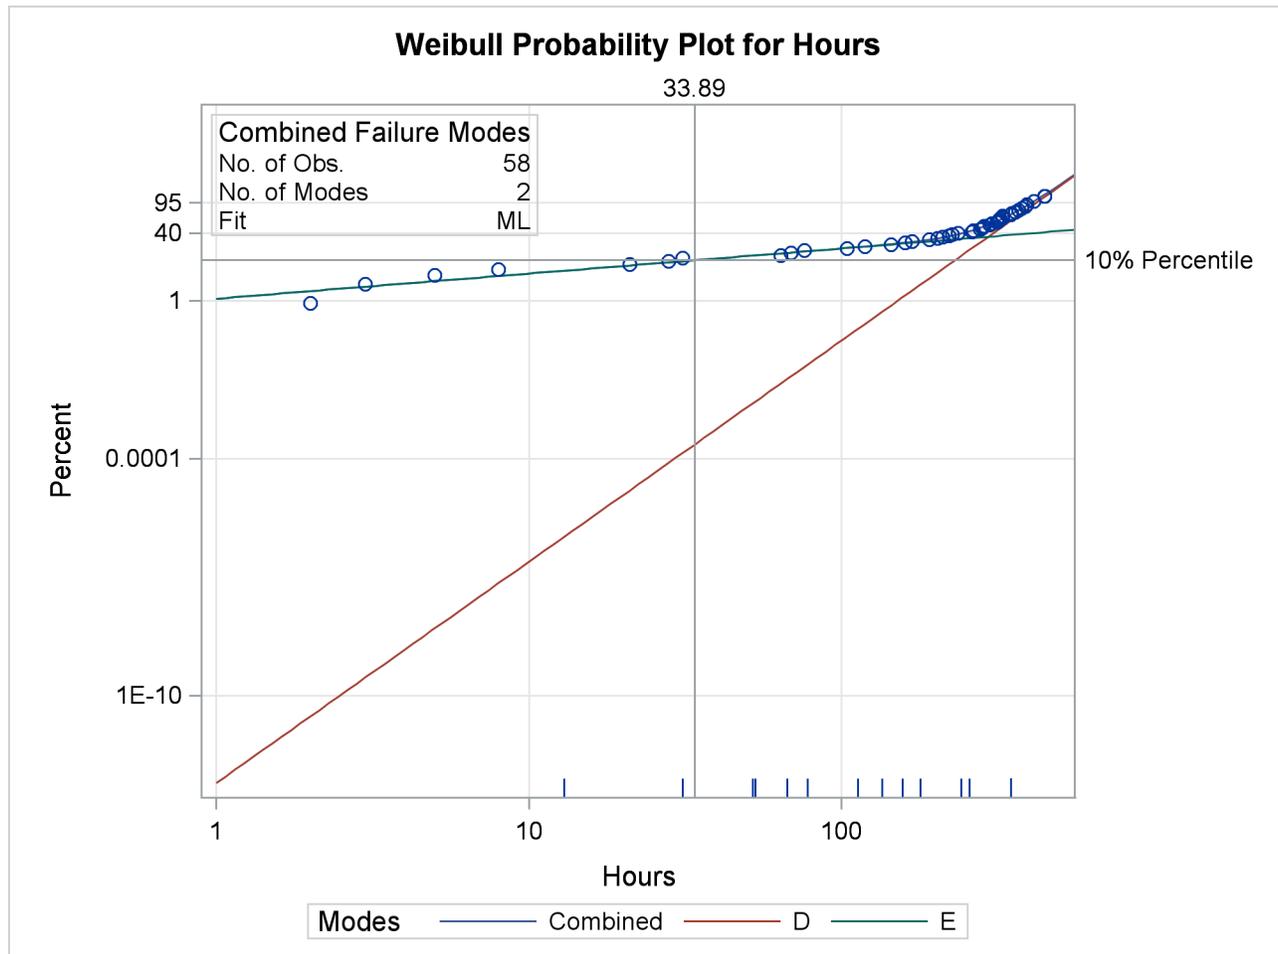

Figure 16.29 Weibull Plot for Failure Modes D and E

The following SAS statements create the Weibull probability plot in Figure 16.30:

```
proc reliability data=Voltage;
  distribution Weibull;
  pplot Hours*Status(1) / vref(intersect) = 10
                        vreflabel = ('10% Percentile')
                        survtime = 100 200 300 400 500 1000
                        noconf
                        lupper = 500;
  fmode combine = Mode( 'D' 'E' ) / plotmodes;
run;
```

The PLOTMODES option in the FMODE statement cause the Weibull fits for the individual failure modes to be included on the probability plot. The combined failure mode curve is almost the same as the fit curve for mode E for lifetimes less than 100 hours, and slightly greater than the fit curve for mode D for lifetimes greater than 100 hours.

Figure 16.30 Weibull Plot for Failure Modes D and E with Individual Modes

Analysis of Recurrence Data on Repairs

This example illustrates analysis of recurrence data from repairable systems. Repair data analysis differs from life data analysis, where units fail only once. As a repairable system ages, it accumulates repairs and costs of repairs. The RELIABILITY procedure provides a nonparametric estimate and plot of the *mean cumulative function* (MCF) for the number or cost of repairs for a population of repairable systems.

The nonparametric estimate of the MCF, the variance of the MCF estimate, and confidence limits for the MCF estimate are based on the work of Nelson (1995). The MCF, also written as $M(t)$, is defined by Nelson (1995) to be the *population mean* of the distribution of the cumulative number or cost of repairs at age t . The method does not assume any underlying structure for the repair process.

The SAS statements that follow create the listing of the SAS data set VALVE shown in Figure 16.31, which contains repair histories of 41 diesel engines in a fleet (Nelson 1995). The valve seats in these engines wear out and must be replaced. The variable `Id` is a unique identifier for individual engines. The variable `Days` provides the engine age in days. The value of the variable `Value` is 1 if the age is a valve seat replacement age or -1 if the age is the end of history, or censoring age, for the engine.

```

The following statements produce the graphical display in [Figure 16.32](#).

```
proc reliability;
  unitid id;
  mcfplot Days*value(-1) / nocenprint;
run;
```

The UNITID statement specifies that the variable `id` uniquely identifies each system. The MCFPLOT statement requests a plot of the MCF estimates as a function of the age variable `Days`, and it specifies -1 as the value of the variable `Value`, which identifies the end of history for each engine (system). The option NOCENPRINT specifies that only failure times, and not censoring times, be printed in the tabular output.

In [Figure 16.32](#), the MCF estimates and confidence limits are plotted versus system age in days. The end-of-history ages are plotted in an area at the top of the plot. Except for the last few points, the plot is essentially a straight line, suggesting a constant replacement rate. Consequently, the prediction of future replacements of valve seats can be based on a fitted line in this case.

Figure 16.32 Mean Cumulative Function for the Number of Repairs

A partial listing of the tabular output is shown in Figure 16.33 and Figure 16.34. It contains a summary of the repair data, estimates of the MCF, the Nelson (1995) standard errors, and confidence intervals for the MCF.

Parametric modeling of the repair process requires more assumptions than nonparametric modeling, and considerable work has been done in this area. Ascher and Feingold (1984), Tobias and Trindade (1995), Crowder et al. (1991), Meeker and Escobar (1998), Cook and Lawless (2007), Abernethy (2006), and Rigdon and Basu (2000) describe parametric models for repair processes. Repairs are sometimes modeled as a nonhomogeneous Poisson process, and the RELIABILITY procedure provides several forms of Poisson process models for recurrent events data. See the section “[Parametric Models for Recurrent Events Data](#)” on page 1388 for details about the Poisson process models that the RELIABILITY procedure provides.

A nonparametric MCF plot might be a first step in modeling a repair process, and, in many cases, provide the required answers without further analysis. An estimate of the MCF for a sample of systems aids engineers in determining the repair rate at any age and the increase or decrease of repair rate with population age. The estimate is also useful for predicting the number of future repairs.

Comparison of Two Samples of Repair Data

Nelson (2002) and Doganaksoy and Nelson (1998) show how the difference of MCFs from two samples can be used to compare the populations from which they are drawn. The RELIABILITY procedure provides Doganaksoy and Nelson’s confidence intervals for the pointwise difference of the two MCFs, which can be used to assess whether the difference is statistically significant.

Doganaksoy and Nelson (1998) give an example of two samples of locomotives with braking grids from two different production batches. [Figure 16.35](#) contains a listing of the data. The variable ID is a unique identifier for individual locomotives. The variable Days provides the locomotive age in days. The variable Value is 1 if the age corresponds to a valve seat replacement or -1 if the age corresponds to the locomotive’s latest age (the current end of its history). The variable Sample is a group variable that identifies the grid production batch.

20	Sample1	S1-07	625	1

The following statements request the Nelson (1995) nonparametric estimate and confidence limits for the difference of the MCF functions shown in [Figure 16.36](#) for the braking grids:

```

proc reliability data=Grids;
  unitid ID;
  mcfplot Days*Value(-1) = Sample / mcfdiff;
run;

```

The MCFPLOT statement requests a plot of each MCF estimate as a function of age (provided by Days), and it specifies that the end of history for each system is identified by Value equal to -1. The variable Sample identifies the two samples of braking grids. The option MCFDIFF requests that the difference between the MCFs of the two groups given in the variable Sample be computed and plotted. Confidence limits for the MCF difference are also computed and plotted. The UNITID statement specifies that the variable Id uniquely identify each system.

[Figure 16.36](#) shows the plot of the MCF difference function and pointwise 95% confidence intervals. Since the pointwise confidence limits do not include zero for some system ages, the difference between the two populations is statistically significant. A listing of the tabular output is shown in [Figure 16.37](#). It contains a summary of the repair data for the two samples, estimates, standard errors, and confidence intervals for the MCF difference. A statistical test for different MCFs is

also computed and is displayed in the table “Tests for Equality of Mean Functions.” The tests also indicate a significant difference between the two samples.

Linear	-4.435032	1.424770	13.805393	1	0.0002

You can fit a parametric model that uses *Sample* as a classification variable. This results in a model with a common shape parameter for the two groups but with different scale parameters. Suppose you want estimates of the parametric mean and intensity functions at values of the time variable 500, 600, 700, 800, 900, and 1,000 days for each of the two groups. The following statements create a new input data set that has observations for the desired prediction times appended to it. The additional observations are not used in the analysis, because the censoring variable *Value* is set to missing for those observations. Values of the mean and intensity function are computed, however, in the table that is produced by specifying the *OBSTATS* option in the *MODEL* statement.

The following statements create the new data set by appending observations to the original *Grids* data set:

```
data Predict;
  Control=1;
  if _N_ < 7 then Sample = 'Sample1';
  else Sample = 'Sample2';

  input ID$ Days Value;
  cards;
9999 500 .
9999 600 .
9999 700 .
9999 800 .
9999 900 .
9999 1000 .
9999 500 .
9999 600 .
9999 700 .
9999 800 .
9999 900 .
9999 1000 .
;

data Grids;
  set Predict Grids;
run;
```

The following statements fit a nonhomogeneous Poisson process with a power law mean function that uses `Sample` as a two-level covariate. The `OBSTATS` option requests that predicted values be computed for values of the variable `Control` equal to 1. The `MCFPLOT` statement plots the fitted model as well as the nonparametric estimates of the MCF. Parametric confidence limits are displayed by default.

```
proc reliability data=Grids;
  unitid ID;
  distribution nhpp(pow);
  class Sample;
  model Days*Value(-1) = Sample /obstats(control=Control);
  mcfplot Days*Value(-1) = Sample /fit=model overlay;
run;
```

Figure 16.39 Fitted Model

The predicted values of the mean and intensity functions at the desired values of Days, with standard errors and confidence limits, are shown in Figure 16.38.

A plot of the fitted mean function, along with nonparametric estimates for the two samples, is shown in Figure 16.39.

Analysis of Interval Age Recurrence Data

You can analyze recurrence data when the recurrence ages are grouped into intervals, instead of being exact ages. Figure 16.40 shows a listing of a SAS data set containing field data on replacements of defrost controls in 22,914 refrigerators, whose ages are grouped by months in service. Nelson (2002, problem 5.2, chapter 5) presents these data. Grouping the control data on the 22,914 refrigerators into age intervals enables you to represent the data by 29 data records, instead of requiring a single data record for each refrigerator, as required for exact recurrence data.

The variables Lower and Upper are the lower and upper monthly interval endpoints, Recurrences is the number of defrost control replacements in each month, and Censored is the number of refriger-

ator histories censored in each month—that is, the number with current age in the monthly interval. Data are entered as shown in Figure 16.40.

Figure 16.40 Listing of the Defrost Controls Data

Obs	Lower	Upper	Recurrences	Censored
1	0	1	83	0
2	1	2	35	0
3	2	3	23	0
4	3	4	15	0
5	4	5	22	0
6	5	6	16	3
7	6	7	13	36
8	7	8	12	24
9	8	9	15	29
10	9	10	15	37
11	10	11	24	40
12	11	12	12	20041
13	12	13	7	14
14	13	14	11	17
15	14	15	15	13
16	15	16	6	28
17	16	17	8	22
18	17	18	9	27
19	18	19	9	64
20	19	20	5	94
21	20	21	6	119
22	21	22	6	118
23	22	23	6	138
24	23	24	5	1188
25	24	25	7	17
26	25	26	5	28
27	26	27	5	99
28	27	28	6	128
29	28	29	3	590

The following SAS statements create the plot of the sample MCF of defrost control replacement shown in Figure 16.41 and the tabular listing in Figure 16.42:

```
proc reliability data=defrost;
  mcfplot ( interval      = Lower Upper
            recurrences  = Recurrences
            censor        = Censored ) / plotsymbol = X
            vaxis = 0 to .12 by .04
            interpolate = join;
run;
```

Pointwise confidence limits are included on the plot and in the tabular listing. These limits are approximate, and are usually shorter than the correct limits, which have not been developed for interval data.

Here, INTERVAL = LOWER UPPER specifies the input data set variables Lower and Upper as the age interval endpoints. The variable Recurrences identifies the number of recurrences (defrost

control replacements) in each time interval, and Censored identifies the number of units censored in each interval (number in an age interval or removed from the sample in an age interval).

27.00	28.00	0.081	0.007	0.066	0.096
* 28.00	29.00	0.091	0.010	0.072	0.110

* The estimate and limits for this interval may not be appropriate.

The last interval is always marked with a footnote indicating that estimates for the last interval may be biased since censoring ages often are not uniformly spread over that interval.

Analysis of Binomial Data

This example illustrates the analysis of binomial proportions of capacitor failures from nine circuit boards. The data are given by Nelson (1982, p. 451). The following statements create and list a SAS data set named BINEX containing the data:

```
data binex;
  input board sample fail;
  datalines;
1 84 2
```

```

2 72 3
3 72 5
4 119 19
5 538 21
6 51 2
7 517 9
8 462 18
9 143 2
;

```

Figure 16.43 displays a listing of the data. The variable Board identifies the circuit board, the variable Sample provides the number of capacitors on the boards, and the variable Fail provides the number of capacitors failing on the boards.

Figure 16.43 Listing of the Capacitor Data

	Obs	board	sample	fail
	1	1	84	2
	2	2	72	3
	3	3	72	5
	4	4	119	19
	5	5	538	21
	6	6	51	2
	7	7	517	9
	8	8	462	18
	9	9	143	2

The following statements analyze the proportion of capacitors failing:

```

proc reliability data=Binex;
  distribution binomial;
  analyze fail(sample) = board / predict(1000)
                                tolerance(.05);
run;

```

The DISTRIBUTION statement specifies the binomial distribution. The analysis requested with the ANALYZE statement consists of tabular output only. Graphical output is not available for the binomial distribution. The variable Fail provides the number of capacitors failing on each board, the variable Sample provides the sample size (number of capacitors) for each board, and the variable Board identifies the individual boards. The statement option PREDICT(1000) requests the predicted number of capacitors failing and prediction limits in a future sample of size 1000. The option TOLERANCE(.05) requests the sample size required to estimate the binomial proportion to within 0.05. Figure 16.44 displays the results of the analysis.

The “Pooled Data Analysis” table displays the estimated binomial probability and exact binomial confidence limits when data from all boards are pooled. The chi-square value and p -value for a test of equality of the binomial probabilities for all of the boards are also shown. In this case, the p -value is less than 0.05, so you reject the test of equality at the 0.05 level.

The “Predicted Values and Limits” table provides the predicted failure count and prediction limits for the number of capacitors that would fail in a future sample of size 1000 for the pooled data,

as requested with the PREDICT(1000) option. The “Sample Size for Estimation” table gives the sample size required to estimate the binomial probability to within 0.05 for the pooled data, as requested with the TOLERANCE(.05) option.

The “Estimates by Group” table supplies the estimated binomial probability, confidence limits, and the contribution to the total chi-square for each board. The pooled values are shown in the last line of the table.

The “Predicted Values by Group” table gives the predicted counts in a future sample of size 1000, prediction limits, and the sample size required to estimate the binomial probability to within the tolerance of 0.05 for each board. Values for the pooled data are shown in the last line of the table.

Three-Parameter Weibull

Meeker and Escobar (1998) give an example of the number of cycles to fatigue failure of specimens of a certain alloy. The first 67 specimens experienced failure, and the last five specimens had no failure at 300,000 cycles. The following statements create a SAS data set named Alloy that contains the number of cycles (in thousands) to failure or end of test for the specimens:

```

data Alloy;
  input kCycles@@;
  Cen = _n_ > 67;
  label kCycles = 'Fatigue Life in Thousands of Cycles';
  datalines;
94 96 99 99 104 108 112 114 117 117
118 121 121 123 129 131 133 135 136 139
139 140 141 141 143 144 149 149 152 153
159 159 159 159 162 168 168 169 170 170
171 172 173 176 177 180 180 184 187 188
189 190 196 197 203 205 211 213 224 226
227 256 257 269 271 274 291 300 300 300

```

```
300 300
;
```

The following SAS statements fit a three-parameter Weibull distribution to the specimen lifetimes, in thousands of cycles. The PROFILE option requests a profile likelihood plot for the threshold parameter. ODS Graphics must be enabled to create a profile likelihood plot with the PROFILE option.

```
proc Reliability data=Alloy;
  distribution Weibull13;
  Pplot kCycles*Cen(1) / Profile(noconf range=(50,100)) LifeUpper=500;
run;
```

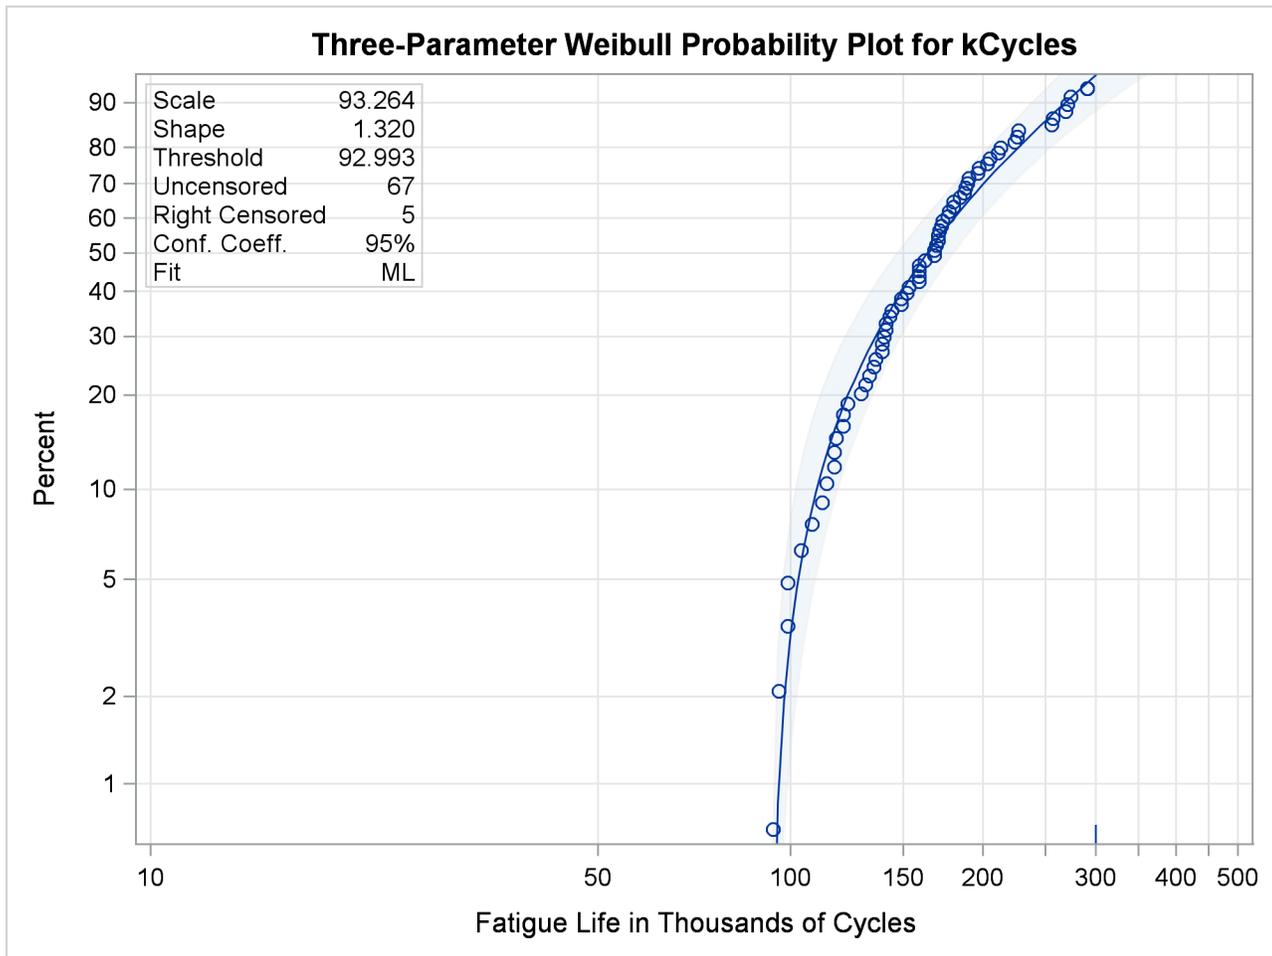

Figure 16.45 shows the maximum likelihood estimates of the Weibull threshold, shape and scale parameters, and the corresponding extreme value location and scale parameter estimates.

Figure 16.45 Three-Parameter Weibull Parameter Estimates

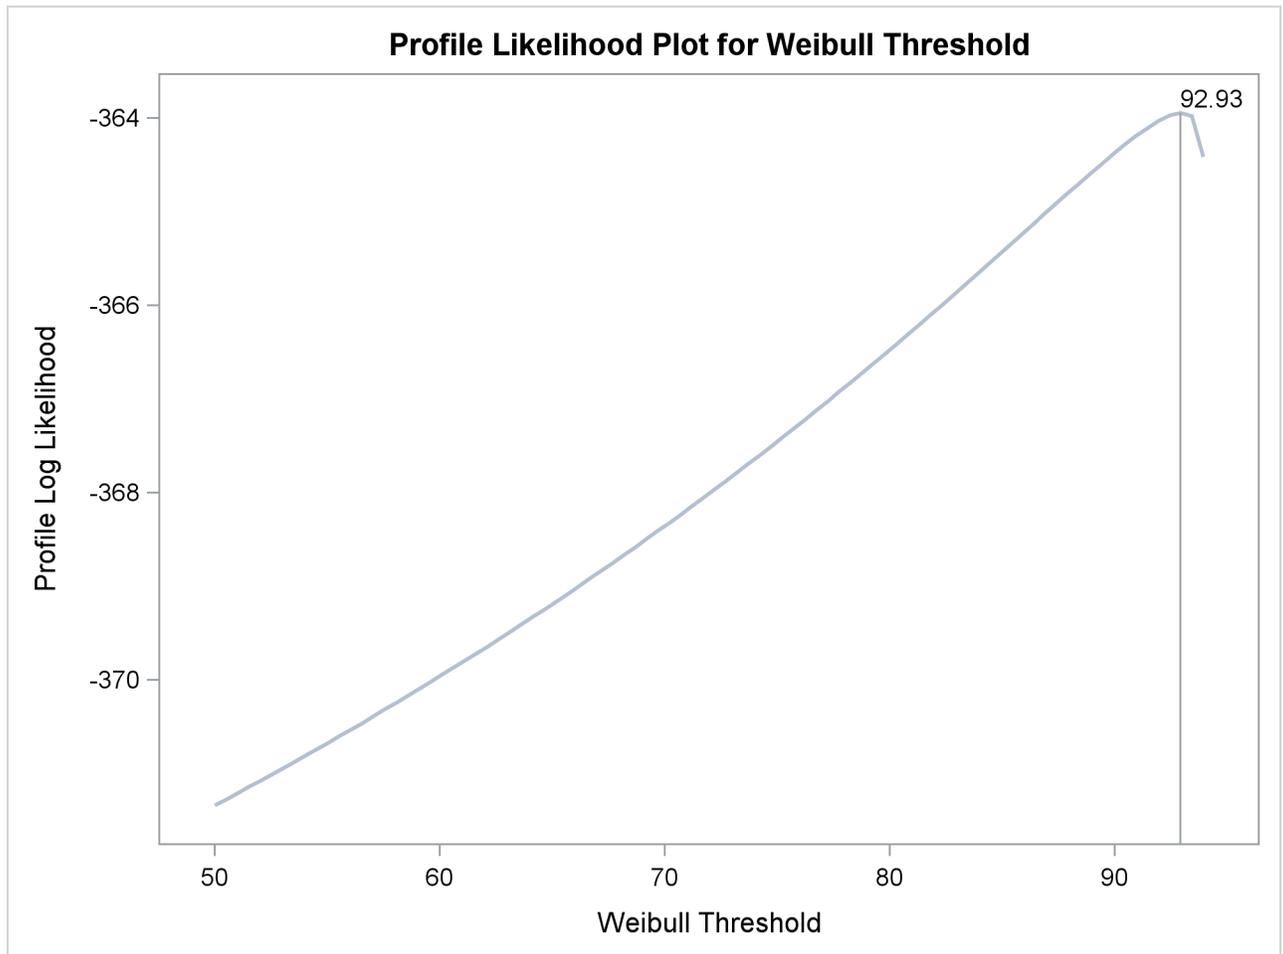

The RELIABILITY Procedure				
Three-Parameter Weibull Parameter Estimates				
Parameter	Estimate	Standard Error	Asymptotic Normal 95% Confidence Limits	
			Lower	Upper
EV Location	4.5354	0.1009	4.3377	4.7332
EV Scale	0.7575	0.0898	0.6005	0.9556
Weibull Scale	93.2642	9.4082	76.5329	113.6531
Weibull Shape	1.3202	0.1565	1.0465	1.6654
Weibull Threshold	92.9928	1.9516	89.1676	96.8179

A probability plot of the failure lifetimes and the fitted three-parameter Weibull distribution is shown in Figure 16.46.

Figure 16.46 Three-Parameter Weibull Probability Plot

A profile likelihood plot for the threshold parameter is shown in Figure 16.47. The threshold value at the maximum log likelihood corresponds to the maximum likelihood estimate of the threshold parameter.

Figure 16.47 Profile Likelihood for Three-Parameter Weibull Threshold

Parametric Model for Recurrent Events Data

The following SAS statements fit a non-homogeneous Poisson process with a power intensity function model to the valve seat data described in the section “[Analysis of Recurrence Data on Repairs](#)” on page 1253. The FIT=MODEL option in the MCFPLOT statement requests that the fitted model be plotted on the plot with the nonparametric mean cumulative function estimates.

```
proc reliability data=Valve;
  unitid id;
  distribution Nhpp(Pow);
  model Days*Value(-1);
  mcfplot Days*Value(-1) / Fit=Model Noconf;
run;
```

The model parameter estimates are shown in [Figure 16.48](#).

Figure 16.48 Power Model Parameter Estimates for the Valve Seat Data

The RELIABILITY Procedure				
NHPP-Power Parameter Estimates				
Parameter	Estimate	Standard Error	Asymptotic Normal	
			95% Confidence Limits	
			Lower	Upper
Intercept	553.6430	57.8636	451.0941	679.5048
Shape	1.3996	0.2005	1.0570	1.8533

Figure 16.49 displays a plot of nonparametric estimates of the mean cumulative function and the fitted model mean function. The parametric model matches the data well except at the upper end of the range of repair times, where the parametric model does not capture the rapid increase in the number of replacements of the valve seats. For this reason, the parametric model might not be appropriate for predicting future repairs of the engines.

Figure 16.49 Mean Cumulative Function Plot for the Valve Seat Data

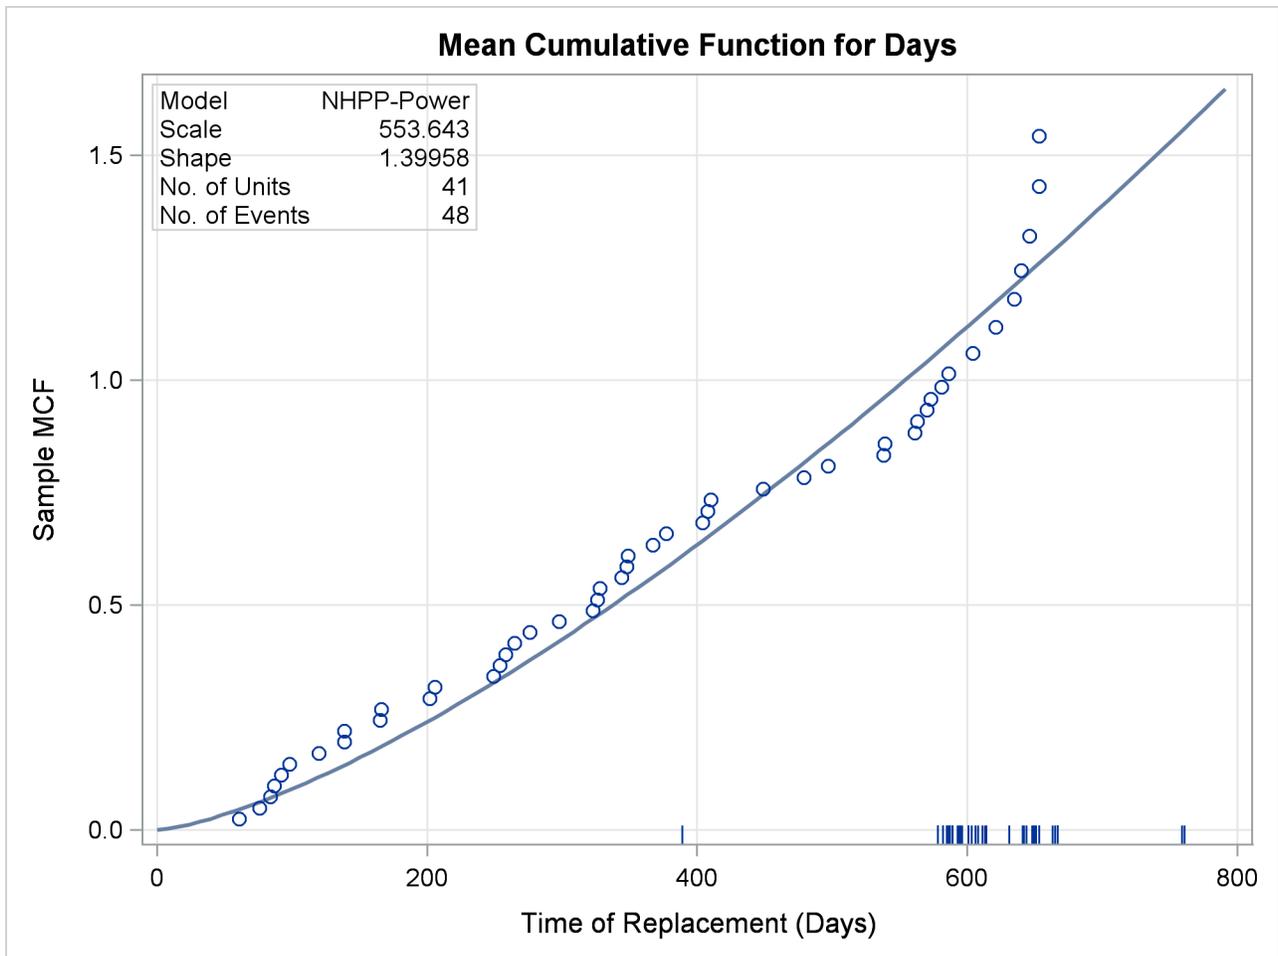

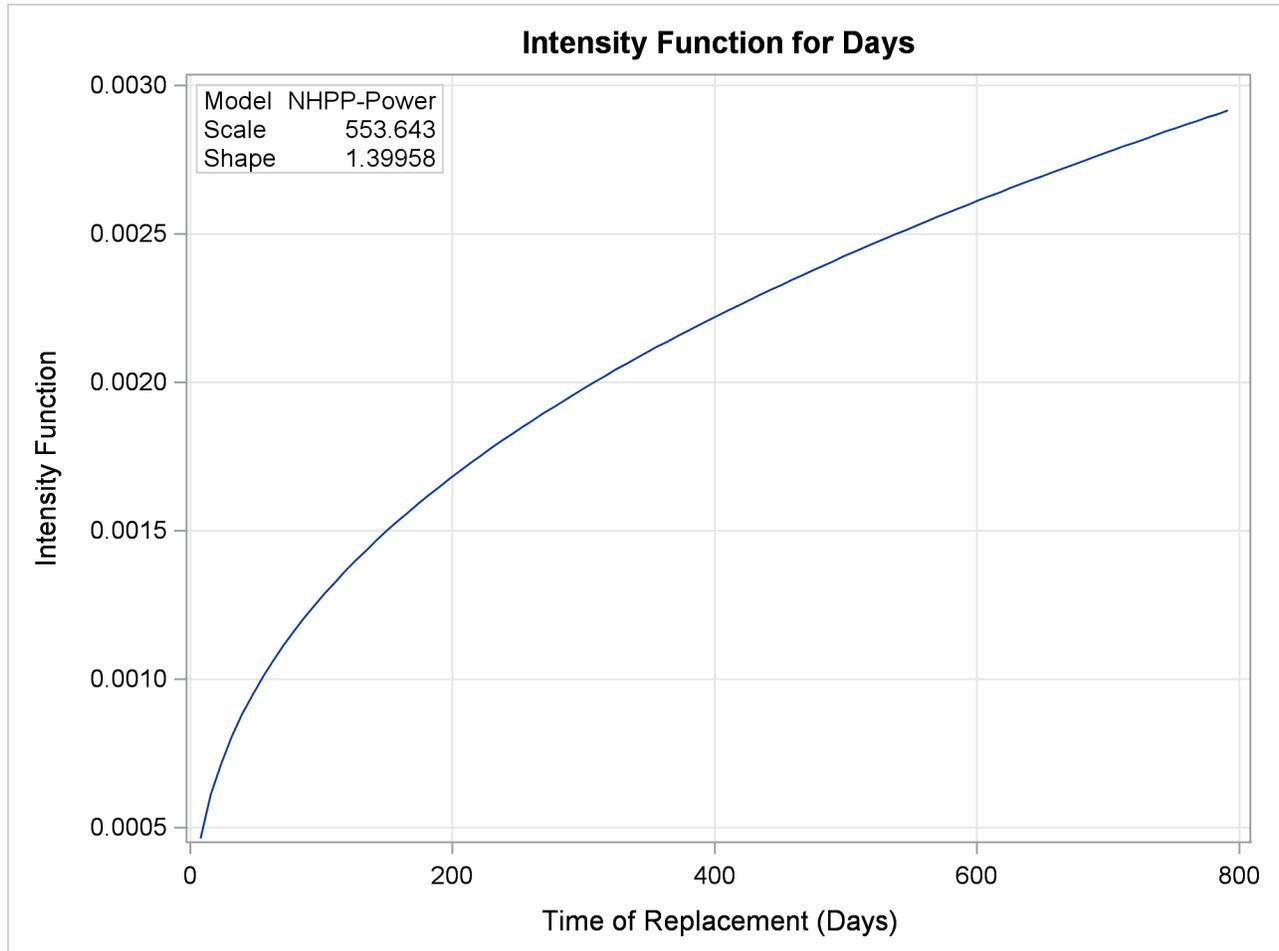

Figure 16.50 shows the parametric model intensity function. The intensity function increases with time, indicating an increasing rate of repairs. This is consistent with the parameter estimates in Figure 16.48, where a shape parameter significantly greater than 1 indicates an increasing failure rate.

Figure 16.50 Intensity Function Plot for the Valve Seat Data

Parametric Model for Interval Recurrent Events Data

Byar (1980) provides data for recurrences of bladder tumors in patients in a clinical trial. Figure 16.51 is a partial listing of data for 86 patients, of which 48 were given a placebo and 38 were treated with the drug Thiotepa. The data are here grouped into one month intervals.

Figure 16.51 Partial Listing of the Bladder Tumor Data

Obs	Group	Age	Age1	N	R
1	Placebo	0	1	48	0
2	Placebo	1	2	47	0
3	Placebo	2	3	46	1
4	Placebo	3	4	46	4
5	Placebo	4	5	46	7
6	Placebo	5	6	45	0
7	Placebo	6	7	45	2
8	Placebo	7	8	45	4
9	Placebo	8	9	44	1
10	Placebo	9	10	44	2
11	Placebo	10	11	44	4
12	Placebo	11	12	42	2
13	Placebo	12	13	42	1
14	Placebo	13	14	42	4
15	Placebo	14	15	42	1
16	Placebo	15	16	41	1
17	Placebo	16	17	41	5
18	Placebo	17	18	41	4
19	Placebo	18	19	41	4
20	Placebo	19	20	38	1

The following SAS statements fit a non-homogeneous Poisson process model with a power intensity function to the interval recurrence data. Some patients were lost to follow-up in each month, so the number of patients observed changes from month to month. The variable N provides the number of patients available at the beginning of each month and assumed to be observed throughout the month. The variable R is the number of recurrences of tumors in each month. Age represents the number of months after randomization into the trial (starting with month 0), and Age1=Age+1 is the end of a month. The variable Group represents the treatment, either Placebo or Thiotepa. The MODEL statement requests a maximum likelihood fit of the model with Group as a classification variable. The MCFPLOT statement requests a plot of the fitted model and nonparametric estimates of the mean cumulative function for each group.

```
proc reliability data=Tumor;
  distribution nhpp(pow);
  freq R;
  nenter N;
  class Group;
  model (Age Age1) = Group;
  mcfplot(Age Age1) = Group / fit=Model;
run;
```

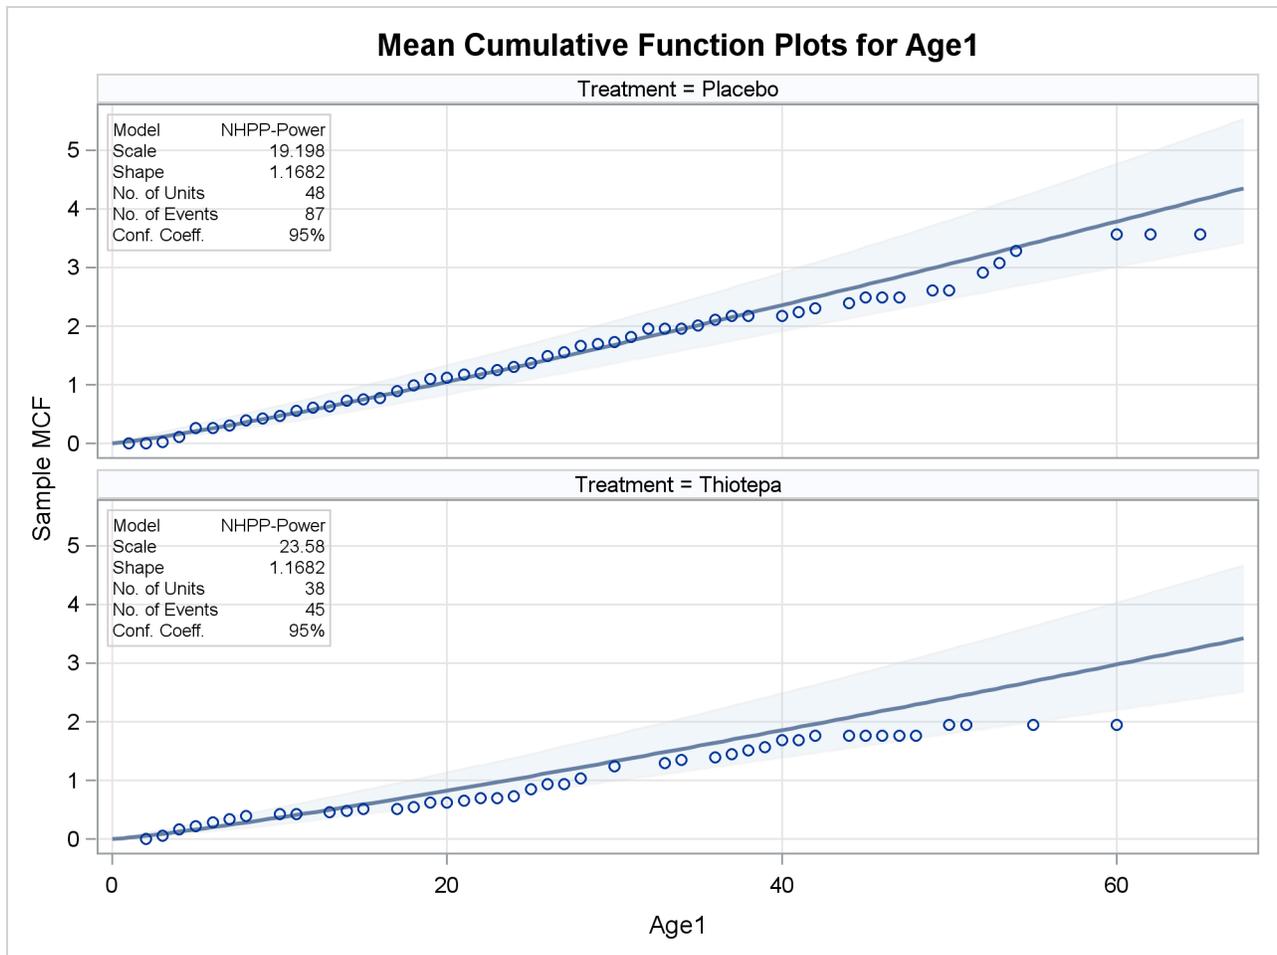

The resulting maximum likelihood parameter estimates are shown in [Figure 16.52](#).

Figure 16.52 Power Model Parameter Estimates for the Bladder Tumor Data

The RELIABILITY Procedure					
NHPP-Power Parameter Estimates					
Parameter		Estimate	Standard Error	Asymptotic Normal 95% Confidence Limits	
				Lower	Upper
Intercept		23.5802	3.1567	17.3932	29.7671
Group	Placebo	-4.3826	3.4873	-11.2175	2.4523

  < label: > PROBPLOT variable < * censor-variable(values) > < =group-variables >
    < / options > ;
  < label: > RELATIONPLOT variable < * censor-variable(values) > < =group-variables >
    < / options > ;

```

The PROC RELIABILITY statement invokes the procedure.

The plot statements (**PROBPLOT**, **RELATIONPLOT**, and **MCFPLOT**) create graphical displays. Each of the plot statements has options that control the content and appearance of the plots they create. The default settings provide the best plots for many purposes; however, if you want to control specific details of the plots, such as axis limits or background colors, then you need to specify the options.

In addition to graphical output, each plot statement provides analysis results in tabular form. The tabular output also can be controlled with statement options.

The **MODEL** and **ANALYZE** statements produce only tabular analysis output, not graphical displays.

You can specify one or more of the plot and **ANALYZE** statements. If you specify more than one **MODEL** statement, only the last one specified is used.

Secondary Statements

You can specify the following statements in conjunction with the primary statements listed previously. These statements are used to modify the behavior of the primary statements or to specify additional variables.

```

BY variables ;
CLASS variables ;
DISTRIBUTION distribution-name ;
EFFECTPLOT < plot-type <(plot-definition-options)>> </ options> ;
ESTIMATE < 'label'> estimate-specification </ options> ;
FMODE keyword = variable('value1' ... 'valuen') ;
FREQ variable ;
INSET keyword-list </ options> ;
LSMEANS < model-effects> </ options> ;
LSMESTIMATE model-effect < 'label'> values < divisor=n> <, ...< 'label'> values
    < divisor=n>> </ options> ;
MAKE 'table' OUT=SAS-data-set < options> ;
NENTER variable ;
NLOPTIONS < options> ;
SLICE model-effect </ options> ;
STORE < OUT=>item-store-name </ LABEL='label'> ;
TEST < model-effects> </ options> ;
UNITID variable ;

```

The **EFFECTPLOT**, **ESTIMATE**, **LSMEANS**, **LSMESTIMATE**, **SLICE**, **STORE**, and **TEST** statements are used to provide further analysis of regression models that are fit by using a **MODEL** statement and are common to many SAS/STAT procedures. Summary descriptions of functionality and syntax for these statements appear after the **PROC RELIABILITY** statement in alphabetical order, and full documentation about them is available in Chapter 19, “Shared Concepts and Topics” (*SAS/STAT User’s Guide*).

You can use the **STORE** statement to store the results of fitting a regression model with a **MODEL** statement for later analysis with the SAS/STAT procedure **PROC PLM**, if you have SAS/STAT software installed at your site.

The **BY** statement specifies variables in the input data set that are used for BY processing. A separate analysis is performed for each group of observations defined by the levels of the BY variables. The input data set must be sorted in order of the BY variables.

The **CLASS** statement specifies variables in the input data set that serve as *indicator*, *dummy*, or *classification* variables in the **MODEL** statement.

The **DISTRIBUTION** statement specifies a probability distribution name for those statements that require a probability distribution for proper operation (the **ANALYZE**, **PROBPLOT**, **MODEL**, and **RELATIONPLOT** statements). If you do not specify a distribution with the **DISTRIBUTION** statement, the normal distribution is used.

The **FMODE** statement specifies what failure-mode data to include in the analysis of data. Use this statement in conjunction with the **ANALYZE**, **MODEL**, **PROBPLOT**, or **RELATIONPLOT** statement.

The **FREQ** statement specifies a variable that provides frequency counts for each observation in the input data set.

The **INSET** statement specifies what information is printed in the inset box created by the **PROBPLOT** or **MCFPLOT** statement. The **INSET** statement also controls the appearance of the inset box.

The **MAKE** statement creates a SAS data set from any of the tables produced by the procedure. You specify a table and a SAS data set name for the data set you want to create. There is a unique table name that identifies each table printed; see the tables in the section “**MAKE Statement**” on page 1298.

The **NENTER** statement specifies interval-censored data having a special structure; these data are called *readout* data. Use the **NENTER** statement in conjunction with the **FREQ** statement.

The **NLOPTIONS** statement enables you to control aspects of the nonlinear optimizations used for maximum likelihood estimation of the parameters of the three-parameter Weibull distribution in the **ANALYZE** and **PROBPLOT** statements, and of parametric models for recurrent events data in the **MODEL** statement.

The **UNITID** statement specifies a variable in the input data set that is used to identify each individual unit in an **MCFPLOT** statement.

Graphical Enhancement Statements

You can use the **TITLE**, **FOOTNOTE**, and **NOTE** statements to enhance printed output. If you are creating plots, you can also use the **LEGEND** and **SYMBOL** statements to enhance your plots. For details, see the SAS/GRAPH documentation and the section for the plot statement that you are using.

PROC RELIABILITY Statement

PROC RELIABILITY *< options >* ;

The **PROC RELIABILITY** statement invokes the procedure. You can specify the following options.

DATA=*SAS-data-set*
specifies an input data set

GOUT=*graphics-catalog*
specifies a catalog for saving graphical output

NAMELEN=*n*
specifies the length of effect names in tables and output data sets to be *n* characters long, where *n* is a value between 20 and 200 characters. The default length is 20 characters.

ANALYZE Statement

*< label: >***ANALYZE** *variable* *< *censor-variable(values) >* *< =group-variables >* *< / options >* ;

*< label: >***ANALYZE** (*variable1 variable2*) *< =group-variables >* *< / options >* ;

*< label: >***ANALYZE** *variable1(variable2)* *< =group-variables >* *< / options >* ;

You use the ANALYZE statement to estimate the parameters of the probability distribution specified in the DISTRIBUTION statement without producing any graphical output. The ANALYZE statement performs the same analysis as the PROBLOT statement, but it does not produce any plots. In addition, you can use the ANALYZE statement to analyze data with the binomial and Poisson distributions. The third format for the preceding ANALYZE statement applies only to Poisson and binomial data. You can use any number of ANALYZE statements after a PROC RELIABILITY statement; each ANALYZE statement produces a separate analysis. You can specify an optional *label* to distinguish between multiple ANALYZE statements in the output.

You must specify one *variable*. If your data are right censored, you must specify a *censor-variable* and, in parentheses, the *values* of the *censor-variable* that correspond to censored data values.

If you are using the binomial or Poisson distributions, you must specify *variable1* to represent a binomial or Poisson count and *variable2* to provide an exposure measure for the Poisson distribution or the binomial sample size for the binomial distribution.

You can optionally specify one or two *group-variables*. The ANALYZE statement produces an analysis for each level combination of the *group-variable* values. The observations in a given level are referred to as a *cell*.

The elements of the ANALYZE statement are described as follows.

variable

represents the data for which an analysis is to be produced. A *variable* must be a numeric variable in the input data set.

censor-variable(values)

indicates which observations in the input data set are right censored. You specify the values of *censor-variable* that represent censored observations by placing those values in parentheses after the variable name. If your data are not right censored, then you omit the specification of *censor-variable*; otherwise, *censor-variable* must be a numeric variable in the input data set.

(variable1 variable2)

is another method of specifying the data. You can use this syntax in a situation where uncensored, interval-censored, left-censored, and right-censored values occur in the same set of data. Table 16.31 shows how you use this syntax to specify different types of censoring by using combinations of missing and nonmissing values. See the section “Lognormal Analysis with Arbitrary Censoring” on page 1233 for an example of using this syntax to create a probability plot.

variable1

represents the count data for which a Poisson or binomial analysis is to be produced. A *variable1* must be a numeric variable in the input data set.

variable2

provides either an exposure measure for a Poisson analysis or a binomial number of trials for a binomial analysis. A *variable2* must be a numeric variable in the input data set.

group-variables

are one or two group variables. If no group variables are specified, a single analysis is produced. The *group-variables* can be numeric or character variables in the input data set.

Note that the parentheses surrounding the `textitgroup`-variables are needed only if two group variables are specified.

options

control the features of the analysis. All *options* are specified after a slash (/) in the ANALYZE statement.

Summary of Options

The following tables summarize the options available in the ANALYZE statement. You can specify one or more of these options to control the parameter estimation and provide optional analyses.

Table 16.4 Analysis Options for Distributions Other Than Poisson or Binomial

Option	Option Description
CONFIDENCE= <i>number</i>	Specifies the confidence coefficient for all confidence intervals. Specify a <i>number</i> between 0 and 1. The default value is 0.95.
CONVERGE= <i>number</i>	Specifies the convergence criterion for maximum likelihood fit. See the section “ Maximum Likelihood Estimation ” on page 1361 for details.
CONVH= <i>number</i>	Specifies the convergence criterion for the relative Hessian convergence criterion. See the section “ Maximum Likelihood Estimation ” on page 1361 for details.
CORRB	Requests the parameter correlation matrix.
COVB	Requests the parameter covariance matrix.
FITTYPE FIT= <i>fit-specification</i>	Specifies the method of estimating distribution parameters. The available <i>fit-specifications</i> and their meanings are shown in the following table.

Table 16.4 Analysis Options for Distributions Other Than Poisson or Binomial (continued)

Option	Option Description														
MAXITEM= <i>number1</i> < , <i>number2</i> >	<i>number1</i> specifies the maximum number of iterations allowed for Turnbull algorithm. Iteration history is printed in increments of <i>number2</i> if requested with ITPRINTEM. See the section “Interval-Censored Data” on page 1354 for details.														
NOPCTILES	Suppresses computation of percentiles.														
NOPOLISH	Suppresses the setting of small interval probabilities to 0 in the Turnbull algorithm. See the section “Interval-Censored Data” on page 1354 for details.														
PCTLIST= <i>number-list</i>	Specifies a list of percentages for which to compute percentile estimates. <i>number-list</i> must be a list of numbers separated by blanks or commas. Each number in the list must be between 0 and 100. If this option is not specified, percentiles are computed for a standard list of percentages.														
PPOS= <i>plotting-position</i>	Specifies the <i>plotting-position</i> type used to compute nonparametric estimates of the probability distribution function. See the section “Probability Plotting” on page 1350 for details. The available <i>plotting-position</i> types are shown in the following table.														
<table border="1"> <thead> <tr> <th>Plotting Position</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>EXPRANK</td> <td>Expected ranks</td> </tr> <tr> <td>MEDRANK</td> <td>Median ranks</td> </tr> <tr> <td>MEDRANK1</td> <td>Median ranks (exact formula)</td> </tr> <tr> <td>KM</td> <td>Kaplan-Meier</td> </tr> <tr> <td>MKM</td> <td>Modified Kaplan-Meier (default)</td> </tr> <tr> <td>NA NELSONAALLEN</td> <td>Nelson-Aalen</td> </tr> </tbody> </table>		Plotting Position	Type	EXPRANK	Expected ranks	MEDRANK	Median ranks	MEDRANK1	Median ranks (exact formula)	KM	Kaplan-Meier	MKM	Modified Kaplan-Meier (default)	NA NELSONAALLEN	Nelson-Aalen
Plotting Position	Type														
EXPRANK	Expected ranks														
MEDRANK	Median ranks														
MEDRANK1	Median ranks (exact formula)														
KM	Kaplan-Meier														
MKM	Modified Kaplan-Meier (default)														
NA NELSONAALLEN	Nelson-Aalen														
PPOUT	Requests a table of cumulative probabilities.														
PRINTPROBS	Print intervals and associated probabilities for the Turnbull algorithm.														
PROBLIST= <i>number-list</i>	Specifies a list of initial values for Turnbull algorithm. See the section “Interval-Censored Data” on page 1354 for details.														
PSTABLE= <i>number</i>	Specifies stable parameterization. The <i>number</i> must be between 0 and 1. See the section “Stable Parameters” on page 1366 for further information.														

Table 16.4 Analysis Options for Distributions Other Than Poisson or Binomial (continued)

Option	Option Description
READOUT	Analyzes readout data.
SCALE= <i>number</i> <SCINIT>	Specifies the fixed or initial value of scale parameter.
SHAPE= <i>number</i> <SHINIT>	Specifies the fixed or initial value of shape parameter.
SINGULAR= <i>number</i>	Specifies the singularity criterion for matrix inversion.
SURVTIME= <i>number-list</i>	Requests that the survival function, cumulative distribution function, and confidence limits be computed for values in <i>number-list</i> . See the section “Reliability Function” on page 1370 for details.
THRESHOLD= <i>number</i>	Specifies a fixed threshold parameter. See Table 16.57 for the distributions with a threshold parameter.
TOLLIKE= <i>number</i>	Specifies the criterion for convergence in the Turnbull algorithm. The default is 10^{-8} . See the section “Interval-Censored Data” on page 1354 for details.
TOLPROB= <i>number</i>	Specifies the criterion for setting interval probability to 0 in the Turnbull algorithm. Default is 10^{-6} . See the section “Interval-Censored Data” on page 1354 for details.

Table 16.5 Analysis Options for Poisson and Binomial Distributions

Option	Option Description
CONFIDENCE= <i>number</i>	Specifies the confidence coefficient for all confidence intervals. Specify a <i>number</i> between 0 and 1. The default value is 0.95.
PREDICT(<i>number</i>)	Requests predicted counts for exposure <i>number</i> for Poisson or sample size <i>number</i> for binomial.
TOLERANCE(<i>number</i>)	Requests exposure for Poisson or sample size for binomial to estimate Poisson rate or binomial probability within <i>number</i> with probability given by the CONFIDENCE= option.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC RELIABILITY to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the RELIABILITY procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variable-names*< / options > ;

The CLASS statement specifies variables in the input data set that serve as *indicator*, *dummy*, or *classification* variables in the MODEL statement. If a CLASS variable is specified as an independent variable in the MODEL statement, the RELIABILITY procedure automatically generates an indicator variable for each level of the CLASS variable. The indicator variables generated are used as independent variables in the regression model specified in the MODEL statement. An indicator variable for a level of a CLASS variable is a variable equal to 1 for those observations corresponding to the level and equal to 0 for all other observations.

You can specify the following option in the CLASS statement.

TRUNCATE< =*n*>

specifies the length *n* of CLASS variable values to use in determining CLASS variable levels. If you specify TRUNCATE without the length *n*, the first 16 characters of the formatted values are used. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases before SAS 9. The default is to use the full formatted length of the CLASS variable.

DISTRIBUTION Statement

DISTRIBUTION *probability distribution-name* ;

The **ANALYZE**, **PROBPLOT**, **RELATIONPLOT**, and **MODEL** statements require you to specify the probability distribution that describes your data. You can specify a probability distribution for lifetime data by using the **DISTRIBUTION** statement anywhere after the **PROC RELIABILITY** statement and before the **RUN** statement. If you do not specify a distribution in a **DISTRIBUTION** statement, the normal distribution is assumed. In addition, you can specify a parametric non-homogeneous Poisson process model for recurrent events data in a **DISTRIBUTION** statement. The probability distribution for lifetime data or the model for recurrent events data specified determines the distribution for which parameters are estimated from your data. The valid distributions and the statements to which they apply are shown in [Table 16.6](#) and [Table 16.7](#).

Table 16.6 Probability Distributions for Lifetime Data

Distribution	Distribution-Name Specified	Statement
Binomial	BINOMIAL	ANALYZE
Exponential	EXPONENTIAL	ANALYZE, PROBPLOT, RELATIONPLOT, MODEL
Extreme value	EXTREME EV	ANALYZE, PROBPLOT, RELATIONPLOT, MODEL
Generalized gamma	GAMMA	MODEL
Logistic	LOGISTIC LOGIT	ANALYZE, PROBPLOT, RELATIONPLOT, MODEL
Log-logistic	LLOGISTIC LLOGIT	ANALYZE, PROBPLOT, RELATIONPLOT, MODEL
Lognormal (base e)	LOGNORMAL LNORM	ANALYZE, PROBPLOT, RELATIONPLOT, MODEL
Lognormal (base 10)	LOGNORMAL10 LNORM10	ANALYZE, PROBPLOT, RELATIONPLOT, MODEL
Normal	NORMAL	ANALYZE, PROBPLOT, RELATIONPLOT, MODEL
Poisson	POISSON	ANALYZE
Weibull	WEIBULL W2	ANALYZE, PROBPLOT, RELATIONPLOT, MODEL
Three-parameter Weibull	WEIBULL3 W3	ANALYZE, PROBPLOT

Table 16.7 Poisson Process Models for Recurrence Data

NHPP Model	Distribution-Name Specified	Statement
Homogeneous	HPP	MODEL
Crow-AMSAA	NHPP(CA) NHPP(CROWAMSAA)	MODEL
Log-linear	NHPP(LOG) NHPP(LOGLINEAR)	MODEL
Power	NHPP(POW) NHPP(POWER)	MODEL
Proportional intensity	NHPP(PROP) NHPP(PROPORTIONAL)	MODEL

EFFECTPLOT Statement

EFFECTPLOT < *plot-type* < (*plot-definition-options*) > > < / *options* > ;

The EFFECTPLOT statement produces a display of the fitted model and provides options for changing and enhancing the displays. Table 16.8 describes the available *plot-types* and their *plot-definition-options*.

Table 16.8 *Plot-Types and Plot-Definition-Options*

Plot-Type and Description	Plot-Definition-Options
<p>BOX Displays a box plot of continuous response data at each level of a CLASS effect, with predicted values superimposed and connected by a line. This is an alternative to the INTERACTION <i>plot-type</i>.</p>	<p>PLOTBY= variable or CLASS effect X= CLASS variable or effect</p>
<p>CONTOUR Displays a contour plot of predicted values against two continuous covariates.</p>	<p>PLOTBY= variable or CLASS effect X= continuous variable Y= continuous variable</p>
<p>FIT Displays a curve of predicted values versus a continuous variable.</p>	<p>PLOTBY= variable or CLASS effect X= continuous variable</p>
<p>INTERACTION Displays a plot of predicted values (possibly with error bars) versus the levels of a CLASS effect. The predicted values are connected with lines and can be grouped by the levels of another CLASS effect.</p>	<p>PLOTBY= variable or CLASS effect SLICEBY= variable or CLASS effect X= CLASS variable or effect</p>
<p>SLICEFIT Displays a curve of predicted values versus a continuous variable grouped by the levels of a CLASS effect.</p>	<p>PLOTBY= variable or CLASS effect SLICEBY= variable or CLASS effect X= continuous variable</p>

For full details about the syntax and options of the EFFECTPLOT statement, see the section “EFFECTPLOT Statement” (Chapter 19, *SAS/STAT User’s Guide*) in Chapter 19, “Shared Concepts and Topics” (*SAS/STAT User’s Guide*).

ESTIMATE Statement

ESTIMATE < '*label*' > *estimate-specification* < (*divisor=n*) >
< , ... < '*label*' > *estimate-specification* < (*divisor=n*) > >
< / *options* > ;

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form $L\beta$. You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 16.9 summarizes the options available in the ESTIMATE statement.

Table 16.9 ESTIMATE Statement Options

Option	Description
Construction and Computation of Estimable Functions	
DIVISOR=	Specifies a list of values to divide the coefficients
NOFILL	Suppresses the automatic fill-in of coefficients for higher-order effects
SINGULAR=	Tunes the estimability checking difference
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple comparison adjustment of estimates
ALPHA= α	Determines the confidence level ($1 - \alpha$)
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiplicity-corrected p -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits
CORR	Displays the correlation matrix of estimates
COV	Displays the covariance matrix of estimates
E	Prints the L matrix
JOINT	Produces a joint F or chi-square test for the estimable functions
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the ESTIMATE statement, see the section “ESTIMATE Statement” (Chapter 19, *SAS/STAT User’s Guide*) in Chapter 19, “Shared Concepts and Topics” (*SAS/STAT User’s Guide*).

FMODE Statement

FMODE keyword=*variable* ('value1' ... 'valuen') < /options > ;

Use the FMODE statement with data that have failures attributable to multiple causes (*failure modes*). You can analyze data by either keeping, eliminating, or combining specific failure modes with the FMODE statement. Use this statement with the KEEP or ELIMINATE keyword in conjunction with the ANALYZE, MODEL, PROBLOT, or RELATIONPLOT statement. Use this

statement with the COMBINE keyword with the [ANALYZE](#) or [PROBPLOT](#) statement. You can place an FMODE statement anywhere after the [PROC RELIABILITY](#) statement and before the RUN statement.

If you specify the keyword KEEP, the life distribution for only the identified failure modes is estimated, with all other failure modes treated as right-censored data. If you specify the keyword ELIMINATE, the life distribution that results if the failure modes identified are completely eliminated is estimated. The keyword ELIMINATE causes the failure modes identified to be treated as right-censored data and causes a single life distribution to be estimated for the remaining data. If you specify the keyword COMBINE, the data are analyzed with all the specified failure modes combined acting. See the section “[Weibull Probability Plot for Two Combined Failure Modes](#)” on page 1250 for an example of a Weibull plot of data with two combined failure modes. The failure mode for an observation in the input data set is identified by the value of *variable*, where *variable* is any numeric or character variable in the input data set. You must identify a failure mode for each observation that is not right-censored. You specify failure modes to keep, eliminate, or combine by listing variable values (*value1* . . . *valuen*) in parentheses after the failure mode variable name. The list of variable values must have entries separated by blanks or commas. You can specify the following *options* after the slash (/). These options will affect the analysis only when you use the COMBINE keyword.

Table 16.10 FMODE Statement Options

Option	Description
LEGEND=	Specifies a LEGEND statement for individual mode fit lines.
NOLEGEND	Suppresses legend for individual mode fit lines.
PLOTMODES	Plots individual failure distribution lines on probability plot.

FREQ Statement

FREQ *variable-name* ;

The FREQ statement specifies a variable that provides frequency counts for each observation in the input data set. If n is the value of the FREQ variable in the input data set for an observation, then that observation is weighted by n . The log-likelihood function for maximum likelihood estimation is multiplied by n . If n is not an integer, the integer part of n is used in creating probability plots.

You can also use the FREQ statement in conjunction with the [NENTER](#) statement to specify interval-censored data having a special structure; these data are called *readout* data. The FREQ statement specifies a variable in the input data set that determines the number of units failing in each interval. See the section “[Weibull Analysis of Interval Data with Common Inspection Schedule](#)” on page 1228 for an example that uses the FREQ statement with readout data.

You can also use the FREQ statement in conjunction with the [NENTER](#) statement to specify recurrent events data when the event times are grouped into intervals, rather than being observed exactly. The FREQ statement specifies a variable in the input data set that determines the number of events in each interval.

You can use the FREQ statement with the [MCFPLOT](#) and [MODEL](#) statements for exact age data to provide frequency counts for entire recurrence histories. If n is the value of the FREQ variable at a censor time, the history of recurrences for the corresponding system is replicated independently n

times. Values of the FREQ variable at times other than censor times are not used; they can be any value or missing without affecting the analysis.

INSET Statement

```
INSET keyword-list < / options > ;
```

The box or table of summary information produced on plots made with the **PROBPLOT** or **MCF-PLOT** statement is called an *inset*. You can use the INSET statement to customize the appearance of the inset box and the information that is printed in the inset box. To supply the information that is displayed in the inset box, you specify a *keyword* that corresponds to the information you want shown. For example, the following statements produce a Weibull plot with the sample size, the number of failures, and the Weibull mean displayed in the inset:

```
proc reliability data=fan;
  distribution Weibull;
  pplot lifetime*censor(1);
  inset n nfail weibull(mean);
run;
```

By default, inset entries are identified with appropriate labels. However, you can provide a customized label by specifying the *keyword* for that entry followed by the equal sign (=) and the label in quotes. For example, the following INSET statement produces an inset that contains the sample size and Weibull mean, labeled “Sample Size” and “Weibull Mean” in the inset:

```
inset n='Sample Size' weibull(mean='Weibull Mean');
```

If you specify a keyword that does not apply to the plot you are creating, then the keyword is ignored.

The *options* control the appearance of the box.

If you specify more than one INSET statement, only the last one is used.

Keywords Used in the INSET Statement

Table 16.11 through Table 16.13 list keywords available in the INSET statement to display summary statistics, distribution parameters, and distribution fitting information.

Table 16.11 Summary Statistics

Keyword	Description
N	Sample size
NFAIL	Number of failures for probability plots.
NEVENTS	Number of events or repairs for MCF plots.
NEVENTS1	Number of events or repairs in the first group for MCF difference plots.
NEVENTS2	Number of events or repairs in the second group for MCF difference plots.

Table 16.11 Summary Statistics (continued)

Keyword	Description
NUNITS	Number of units or systems for MCF plots.
NUNITS1	Number of units or systems in the first group for MCF difference plots.
NUNITS2	Number of units or systems in the second group for MCF difference plots.

Table 16.12 General Information

Keyword	Description
CONFIDENCE	Confidence coefficient for all confidence intervals or for the Weibayes fit
FIT	Method used to estimate distribution parameters for probability plots
RSQUARE	R square for least squares distribution fit to probability plots

Distribution parameters are specified as *distribution-name(distribution-parameters)*. The following table lists the keywords available.

Table 16.13 Distribution Parameters

Keyword	Secondary Keyword	Description
EXPONENTIAL	SCALE	Scale parameter
	THRESHOLD	Threshold parameter
	MEAN	Expected value
EXTREME EV	LOCATION	Location parameter
	SCALE	Dscale parameter
	MEAN	Expected value
LOGISTIC LOGIT	LOCATION	Location parameter
	SCALE	Scale parameter
	MEAN	Expected value
LOGLOGISTIC LLOGIT	LOCATION	Location parameter
	SCALE	Scale parameter
	THRESHOLD	Threshold parameter
	MEAN	Expected value
LOGNORMAL	LOCATION	Location parameter
	SCALE	Scale parameter
	THRESHOLD	Threshold parameter
	MEAN	Expected value

Table 16.13 Distribution Parameters (continued)

Keyword	Secondary Keyword	Description
LOGNORMAL10	LOCATION	Location parameter
	SCALE	Scale parameter
	THRESHOLD	Threshold parameter
	MEAN	Expected value
NORMAL	LOCATION	Location parameter
	SCALE	Scale parameter
	MEAN	Expected value
WEIBULL	SCALE	Scale parameter
	SHAPE	Shape parameter
	THRESHOLD	Threshold parameter
	MEAN	Expected value

Options Used in the INSET Statement

Table 16.14 through Table 16.17 list INSET statement options that control the appearance of the inset box.

Table 16.14 lists options that control the appearance of the box when you use traditional graphics.

Table 16.14 General Appearance Options (Traditional Graphics)

Option	Option Description
HEADER= <i>quoted-string</i>	Specifies text for header or box title.
NOFRAME	Omits frame around box.
POS= <i>value</i> <DATA PERCENT >	Determines the position of the inset. The <i>value</i> can be a compass point (N, NE, E, SE, S, SW, W, NW) or a pair of coordinates (<i>x</i> , <i>y</i>) enclosed in parentheses. The coordinates can be specified in axis percent units or axis data units.
REFPOINT= <i>name</i>	Specifies the reference point for an inset that is positioned by a pair of coordinates with the POS= option. You use the REFPOINT= option in conjunction with the POS= coordinates. <i>name</i> specifies which corner of the inset frame you have specified with coordinates (<i>x</i> , <i>y</i>); it can take the value of BR (bottom right), BL (bottom left), TR (top right), or TL (top left). The default is REFPOINT=BL. If the inset position is specified as a compass point, then the REFPOINT= option is ignored.

Table 16.15 lists options that control the appearance of the box when you use ODS Graphics.

Table 16.15 General Appearance Options (ODS Graphics)

Option	Option Description
HEADER= <i>quoted-string</i>	Specifies text for header or box title.
NOFRAME	Omits frame around box.
POS= <i>value</i>	Determines the position of the inset. The <i>value</i> can be a compass point (N, NE, E, SE, S, SW, W, NW).

Table 16.16 lists options that control the appearance of the text within the box when you use traditional graphics. These options are not available if ODS Graphics is enabled.

Table 16.16 Text Enhancement Options (Traditional Graphics)

Option	Option Description
FONT= <i>font</i>	Software font for text
HEIGHT= <i>value</i>	Height of text

Table 16.17 lists options that control the colors and patterns used in the box when you use traditional graphics. These options are not available if ODS Graphics is enabled.

Table 16.17 Color and Pattern Options (Traditional Graphics)

Option	Option Description
CFILL= <i>color</i>	Color for filling box
CFILLH= <i>color</i>	Color for filling box header
CFRAME= <i>color</i>	Color for frame
CHEADER= <i>color</i>	Color for text in header
CTEXT= <i>color</i>	Color for text

LOGSCALE Statement

LOGSCALE *effect-list* < /options > ;

You use the LOGSCALE statement to model the logarithm of the distribution scale parameter as a function of explanatory variables. A MODEL statement must also be present to specify the model for the distribution location parameter. *effect-list* is a list of variables in the input data set representing the values of the independent variables in the model for each observation, and combinations of variables representing interaction terms. It can contain any variables or combination of variables in the input data set. It can contain the same variables as the MODEL statement, or it can contain different variables. The variables in the *effect-list* can be any combination of indicator variables named in a CLASS statement and continuous variables. The coefficients of the explanatory variables are estimated by maximum likelihood.

Table 16.18 lists the *options* available for the LOGSCALE statement.

Table 16.18 LOGSCALE Statement Options

Option	Option Description
INITIAL= <i>number-list</i>	Specifies initial values for log-scale regression parameters other than the intercept term.
INTERCEPT= <i>number</i> <INTINIT >	Specifies an initial or fixed value of the intercept parameter, depending on whether INTINIT is present.

LSMEANS Statement

LSMEANS < *model-effects* > < / *options* > ;

The LSMEANS statement computes and compares least squares means (LS-means) of fixed effects. LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs.

Table 16.19 summarizes the options available in the LSMEANS statement.

Table 16.19 LSMEANS Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies the covariate value in computing LS-means
BYLEVEL	Computes separate margins
DIFF	Requests differences of LS-means
OM=	Specifies the weighting scheme for LS-means computation as determined by the input data set
SINGULAR=	Tunes estimability checking
Degrees of Freedom and <i>p</i>-values	
ADJUST=	Determines the method for multiple-comparison adjustment of LS-means differences
ALPHA= α	Determines the confidence level $(1 - \alpha)$
STEPDOWN	Adjusts multiple-comparison <i>p</i> -values further in a step-down fashion

Table 16.19 *continued*

Option	Description
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the L matrix
LINES	Produces a “Lines” display for pairwise LS-means differences
MEANS	Prints the LS-means
PLOTS=	Requests graphs of means and mean comparisons
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the LSMEANS statement, see the section “LSMEANS Statement” (Chapter 19, *SAS/STAT User’s Guide*) in Chapter 19, “Shared Concepts and Topics” (*SAS/STAT User’s Guide*).

LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
             < , ... <'label'> values <divisor=n>>
             </options> ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 16.20 summarizes the options available in the LSMESTIMATE statement.

Table 16.20 LSMESTIMATE Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies covariate values in computing LS-means
BYLEVEL	Computes separate margins
DIVISOR=	Specifies a list of values to divide the coefficients
OM=	Specifies the weighting scheme for LS-means computation as determined by a data set
SINGULAR=	Tunes estimability checking

Table 16.20 continued

Option	Description
Degrees of Freedom and p-values	
ADJUST=	Determines the method for multiple-comparison adjustment of LS-means differences
ALPHA= α	Determines the confidence level ($1 - \alpha$)
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiple-comparison p -values further in a step-down fashion
TESTVALUE=	Specifies values under the null hypothesis for tests
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the L matrix
ELSM	Prints the K matrix
JOINT	Produces a joint F or chi-square test for the LS-means and LS-means differences
SEED=	Specifies the seed for computations that depend on random numbers

For details about the syntax of the LSMESTIMATE statement, see the section “LSMESTIMATE Statement” (Chapter 19, *SAS/STAT User’s Guide*) in Chapter 19, “Shared Concepts and Topics” (*SAS/STAT User’s Guide*).

MAKE Statement

MAKE *'table'* **OUT=SAS-data-set** < SAS-data-set options > ;

The MAKE statement creates a SAS data set from any of the tables produced by the RELIABILITY procedure. You can specify SAS data set options in parentheses after the data set name. You can specify one MAKE statement for each table that you want to save to a SAS data set.

The ODS statement also creates SAS data sets from tables, in addition to providing an extensive and flexible method of controlling output created by the RELIABILITY procedure. The ODS statement is the recommended method of controlling procedure output; however, the MAKE statement is provided for compatibility with earlier releases of the SAS System.

The valid values for *table* are shown in the section “ODS Table Names” on page 1395, organized by the RELIABILITY procedure statement that produces the tabular output. The *table* names are not case sensitive, but they must be enclosed in single quotes.

MCFPLOT Statement

```
< label: >MCFPLOT variable*cost/censor-variable(values) <=group-variables> </ options > ;
```

```
< label: >MCFPLOT (< INTERVAL= >variable1 variable2 < RECURRENCES= > variable3
< CENSOR= > variable4 ) <=group-variables> </ options > ;
```

```
< label: >MCFPLOT (variable1 variable2) <=group-variables> </ options > ;
```

You can specify any number of MCFPLOT statements after a **PROC RELIABILITY** statement. Each MCFPLOT statement creates a separate MCF plot and associated analysis. See the section “Analysis of Recurrence Data on Repairs” on page 1253, the section “Comparison of Two Samples of Repair Data” on page 1258, and the section “Analysis of Interval Age Recurrence Data” on page 1265 for examples that use the MCFPLOT statement. You can specify an optional *label* to distinguish between multiple MCFPLOT statements in the output.

To create a plot of the mean cumulative function for cost or number of repairs with exact age data, you specify a *variable* that represents the times of repairs. You must also specify a *cost/censor-variable* and the *values*, in parentheses, of the *cost/censor-variable* that correspond to end-of-history data values (also referred to as *censored* data values).

To create a plot of the mean cumulative function for cost or number of repairs with interval age data, you specify *variable1 variable2* that represents the age intervals. You must also specify either *variable3* that represents the number of recurrences in the intervals and *variable4* that represents the number censored in the intervals, or a **FREQ** statement that represents the number of recurrent events in the intervals and a **NENTER** statement that represents the number of units observed in the intervals.

You can optionally specify one or two *group-variables* (also referred to as *classification variables*). The MCFPLOT statement displays a component plot for each level of the *group-variables*. The observations in a given level are called a *cell*.

For exact data, you must also specify a *unit-identification* variable in conjunction with the MCFPLOT statement to identify the individual unit name for each instance of repair or end of history on the unit. Specify the *unit-identification* variable in the **UNITID** statement.

The elements of the MCFPLOT statement are described as follows.

variable

represents the time of repair. A *variable* must be a numeric variable in the input data set.

variable1 variable2

represents time intervals for grouped data. *variable1* and *variable2* must be numeric variables in the input data set.

variable3

represents the number of recurrences in an interval. A *variable3* must be a numeric variable in the input data set.

variable4

represents the number censored in an interval. A *variable4* must be a numeric variable in the input data set.

cost/censor-variable(values)

indicates the cost of each repair or the number of repairs. This variable also indicates which observations in the input data set are end-of-history (censored) data points. You specify the values of *cost/censor-variable* that represent censored observations by placing those values in parentheses after the variable name. A *cost/censor-variable* must be a numeric variable in the input data set.

group-variables

are one or two group variables. If no group variables are specified, a single plot is produced. The *group-variables* can be any numeric or character variables in the input data set. For exact data, if a single group variable is specified, and the group variable has two levels, then a statistical test for equality of the groups represented by the two levels is computed and displayed in the “Tests for Equality of Mean Functions” table. Refer to “[Comparison of Two Groups of Recurrent Events Data](#)” on page 1388 for more details.

Note that the parentheses surrounding the *group-variables* are needed only if two group variables are specified.

options

control the features of the mean cumulative function plot. All *options* are specified after a slash (/) in the MCFPLOT statement. The “Summary of Options” section, which follows, lists all options by function.

Summary of Options

Table 16.21 lists available analysis options.

Table 16.21 Analysis Options

Option	Option Description
CONFIDENCE= <i>number</i>	Specifies the confidence coefficient for all confidence intervals. Specify a <i>number</i> between 0 and 1. The default value is 0.95.
INDINC	Sequest variance estimates of the MCF using the Nelson (2002) estimator under the independent increments assumption.
LOGINTERVALS	Requests that confidence intervals be computed based on the asymptotic normality of log(MCF). This is appropriate only when the MCF estimate is positive, so does not apply to MCF differences or when negative costs are specified.
MCFDIFF	Requests a plot of differences of MCFS of two groups specified by a single group variable.
NOVARIANCE	Suppresses MCF variance computation.
VARIANCE= <i>variance-specification</i>	Specifies the method of variance calculation. The following methods are available.

Table 16.21 Analysis Options (continued)

Option	Option Description
Method	Definition
INDINC	The method of Nelson (2002) assuming independent increments
LAWLESS VARMETHOD2	The method of Lawless and Nadeau (1995) (the default method)
NELSON	The method of Nelson (2002)
POISSON	Poisson process method

Table 16.22 lists plot layout options that are available when you use traditional graphics.

Table 16.22 Plot Layout Options for Traditional Graphics

Option	Option Description
CENBIN	Plots censored data as frequency counts rather than as individual points.
CENSYMBOL= <i>symbol</i> (<i>symbol-list</i>)	Specifies symbols for censored values. <i>symbol</i> is one of the symbol names (plus, star, square, diamond, triangle, hash, paw, point, dot, circle) or a letter (A–Z). If you are creating overlaid plots for groups of data, you can specify different symbols for the groups with a list of symbols or letters, separated by blanks, enclosed in parentheses. If no CENSYMBOL option is specified, the symbol used for censored values is the same as for repairs.
HOFFSET= <i>value</i>	Specifies offset for horizontal axis.
INBORDER	Requests a border around MCF plots.
INTERPOLATE=JOIN STEP NONE	Requests that symbols in an MCF plot be connected with a straight line, step function, or not connected.
INTERTILE= <i>value</i>	Specifies the distance between tiles.
MCFLEGEND= <i>legend-statement-name</i> NONE	Identifies a legend statement to specify legend for overlaid MCF plots.
MISSING1	Requests that missing values of first GROUP= variable be treated as a level of the variable.
MISSING2	Requests that missing values of second GROUP= variable be treated as a level of the variable.

Table 16.22 Plot Layout Options (continued)

Option	Option Description
NCOLS= <i>n</i>	Specifies the number of columns plotted on a page.
NOCENPLOT	Suppresses plotting of censored data points.
NOCONF	Suppresses plotting of confidence intervals.
NOFRAME	Suppresses the frame around the plotting area.
NOINSET	Suppresses the inset.
NOLEGEND	Suppresses the legend for overlaid MCF plots.
NROWS= <i>n</i>	Specifies the number of rows plotted on a page.
ORDER1=DATA FORMATTED FREQ INTERNAL	Specifies display order for values of the first GROUP= variable.
ORDER2=DATA FORMATTED FREQ INTERNAL	Specifies display order for values of the second GROUP= variable.
OVERLAY	Requests that plots with group variables be overlaid on a single page.
PLOTSYMBOL= <i>symbol</i> (<i>symbol-list</i>)	Specifies symbols that represent events in an MCF plot.
PLOTCOLOR= <i>color</i> (<i>color-list</i>)	Specifies colors of symbols that represent events in an MCF plot.
TURNVLABELS	Vertically strings out characters in labels for vertical axis.
VOFFSET= <i>value</i>	Specifies length of offset at upper end of vertical axis.

Table 16.23 lists plot layout options available when you use ODS Graphics.

Table 16.23 Plot Layout Options for ODS Graphics

Option	Option Description
DUANE	Requests that a Duane plot be created in addition to an MCF plot. If you specify the FIT=MODEL option, the fitted parametric model is included in the Duane plot. See the section “ Duane Plots ” on page 1394 for a description of Duane plots.

Table 16.23 Plot Layout Options (continued)

Option	Option Description
FIT=MODEL	Requests that a parametric cumulative mean function fit with a MODEL statement be plotted on the same plot with nonparametric estimates of the MCF. This option is valid only if the response specification in the MCFPLOT statement matches the response specification in the MODEL statement. If this option is specified, the fit parametric intensity function is plotted on a separate graph.
INTERPOLATE=JOIN STEP NONE	Requests that symbols in an MCF plot be connected with a straight line, step function, or not connected.
MISSING1	Requests that missing values of first GROUP= variable be treated as a level of the variable.
MISSING2	Requests that missing values of second GROUP= variable be treated as a level of the variable.
NCOLS= <i>n</i>	Specifies the number of columns plotted on a page.
NOCENPLOT	Suppresses plotting of censored data points.
NOCONF	Suppresses plotting of confidence intervals.
NOINSET	Suppresses the inset.
NROWS= <i>n</i>	Specifies the number of rows plotted on a page.
ORDER1=DATA FORMATTED FREQ INTERNAL	Specifies the display order for values of the first GROUP= variable.
ORDER2=DATA FORMATTED FREQ INTERNAL	Specifies the display order for values of the second GROUP= variable.
OVERLAY	Requests that plots with group variables be overlaid on a single page.

Table 16.24 lists reference line options that are available when you use traditional graphics.

Table 16.24 Reference Line Options for Traditional Graphics

Option	Option Description
HREF= <i>value-list</i>	Specifies reference lines perpendicular to horizontal axis.
HREFLABELS=(<i>'label1' ... 'labeln'</i>)	Specifies labels for HREF= lines.

Table 16.24 Reference Line Options (continued)

Option	Option Description														
HREFLABPOS= <i>n</i>	Specifies the vertical position of labels for HREF= lines. The valid values for <i>n</i> and the corresponding label placements are shown in the following table: <table border="1"> <thead> <tr> <th><i>n</i></th> <th>Label Placement</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>Top</td> </tr> <tr> <td>2</td> <td>Staggered from top</td> </tr> <tr> <td>3</td> <td>Bottom</td> </tr> <tr> <td>4</td> <td>Staggered from bottom</td> </tr> <tr> <td>5</td> <td>Alternating from top</td> </tr> <tr> <td>6</td> <td>Alternating from bottom</td> </tr> </tbody> </table>	<i>n</i>	Label Placement	1	Top	2	Staggered from top	3	Bottom	4	Staggered from bottom	5	Alternating from top	6	Alternating from bottom
<i>n</i>	Label Placement														
1	Top														
2	Staggered from top														
3	Bottom														
4	Staggered from bottom														
5	Alternating from top														
6	Alternating from bottom														
LHREF= <i>linetype</i>	Specifies the line style for HREF= lines.														
LVREF= <i>linetype</i>	Specifies the line style for VREF= lines.														
VREF= <i>value-list</i>	Specifies reference lines perpendicular to vertical axis.														
VREFLABELS=(<i>'label1' ... 'labeln'</i>)	Specifies labels for VREF= lines.														
VREFLABPOS= <i>n</i>	Specifies the horizontal position of labels for VREF= lines. The valid values for <i>n</i> and the corresponding label placements are shown in the following table: <table border="1"> <thead> <tr> <th><i>n</i></th> <th>Label Placement</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>Left</td> </tr> <tr> <td>2</td> <td>Right</td> </tr> </tbody> </table>	<i>n</i>	Label Placement	1	Left	2	Right								
<i>n</i>	Label Placement														
1	Left														
2	Right														

Table 16.25 lists reference line options that are available when you use ODS Graphics.

Table 16.25 Reference Line Options for ODS Graphics

Option	Option Description
HREF= <i>value-list</i>	Specifies reference lines perpendicular to the horizontal axis.
HREFLABELS=(<i>'label1' ... 'labeln'</i>)	Specifies labels for HREF= lines.
VREF= <i>value-list</i>	Specifies reference lines perpendicular to the vertical axis.
VREFLABELS=(<i>'label1' ... 'labeln'</i>)	Specifies labels for VREF= lines.

Table 16.26 lists the options that control the appearance of the text when you use traditional graphics. These options are not available if ODS Graphics is enabled.

Table 16.26 Text Enhancement Options

Option	Option Description
FONT= <i>font</i>	Software font for text.
HEIGHT= <i>value</i>	Height of text used outside framed areas.
INFONT= <i>font</i>	Software font for text inside framed areas.
INHEIGHT= <i>value</i>	Height of text inside framed areas.

Table 16.27 lists options to control the appearance of the axes when you use traditional graphics.

Table 16.27 Axis Options for Traditional Graphics

Option	Option Description
HAXIS= <i>value1</i> TO <i>value2</i> <BY <i>value3</i> >	Specifies tick mark values for the horizontal axis. <i>value1</i> , <i>value2</i> , and <i>value3</i> must be numeric, and <i>value1</i> must be less than <i>value2</i> . The lower tick mark is <i>value1</i> . Tick marks are drawn at increments of <i>value3</i> . The last tick mark is the greatest value that does not exceed <i>value2</i> . If <i>value3</i> is omitted, a value of 1 is used. This method of specification of tick marks is not valid for logarithmic axes. Examples of HAXIS= lists follow: <p style="margin-left: 40px;"> haxis = 0 to 10 haxis = 2 to 10 by 2 haxis = 0 to 200 by 10 </p>
HLOWER= <i>number</i>	Specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies <i>number</i> as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS option is used.
HUPPER= <i>number</i>	Specifies the upper limit on the horizontal axis scale. The HUPPER= option specifies <i>number</i> as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.
LGRID= <i>number</i>	Specifies a line style for all grid lines. <i>number</i> is between 1 and 46 and specifies a linestyle for grids.
LOGLOG	Requests log scales on both axes.
MINORLOGGRID	Adds a minor grid for log axes.

Table 16.27 Axis Options (continued)

Option	Option Description
NOGRID	Suppresses grid lines.
NOHLABEL	Suppresses label for horizontal axis.
NOVLABEL	Suppresses label for vertical axis.
NOVTICK	Suppresses tick marks and tick mark labels for vertical axis.
NOHTICK	Suppresses tick marks and tick mark labels for horizontal axis.
NHTICK= <i>number</i>	Specifies the number of tick intervals for the horizontal axis. This option has no effect if the HAXIS= option is used.
NVTICK= <i>number</i>	Specifies the number of tick intervals for the vertical axis. This option has no effect if the VAXIS= option is used.
VAXIS= <i>value1</i> TO <i>value2</i> <BY <i>value3</i> >	Specifies tick mark values for the vertical axis. <i>value1</i> , <i>value2</i> , and <i>value3</i> must be numeric, and <i>value1</i> must be less than <i>value2</i> . The lower tick mark is <i>value1</i> . Tick marks are drawn at increments of <i>value3</i> . The last tick mark is the greatest value that does not exceed <i>value2</i> . This method of specification of tick marks is not valid for logarithmic axes. If <i>value3</i> is omitted, a value of 1 is used. <pre> vaxis = 0 to 10 vaxis = 0 to 2 by .1 </pre>
VAXISLABEL= <i>'string'</i>	Specifies a label for the vertical axis
VLOWER= <i>number</i>	Specifies the lower limit on the vertical axis scale. The VLOWER= option specifies <i>number</i> as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.
VUPPER= <i>number</i>	Specifies the upper limit on the vertical axis scale. The VUPPER= option specifies <i>number</i> as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.
WAXIS= <i>n</i>	Specifies the line thickness for axes and frame.

Table 16.28 lists options that control the appearance of the axes when you use ODS Graphics.

Table 16.28 Axis Options for ODS Graphics

Option	Option Description
HLOWER= <i>number</i>	Specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies <i>number</i> as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS option is used.
HUPPER= <i>number</i>	Specifies the upper limit on the horizontal axis scale. The HUPPER= option specifies <i>number</i> as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.
LOGLOG	Requests log scales on both axes.
MINORLOGGRID	Adds a minor grid for log axes.
NOGRID	Suppresses grid lines.
VLOWER= <i>number</i>	Specifies the lower limit on the vertical axis scale. The VLOWER= option specifies <i>number</i> as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.
VUPPER= <i>number</i>	Specifies the upper limit on the vertical axis scale. The VUPPER= option specifies <i>number</i> as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

Table 16.29 lists options that control colors and patterns used in the graph when you use traditional graphics. These options are not available if ODS Graphics is enabled.

Table 16.29 Color and Pattern Options

Option	Option Description
CAXIS= <i>color</i>	Color for axis.
CCENSOR= <i>color</i>	Color for filling censor plot area.
CENCOLOR= <i>color</i>	Color for censor symbol.
CFRAME= <i>color</i>	Color for frame.
CFRAMESIDE= <i>color</i>	Color for filling frame for row labels.
CFRAMETOP= <i>color</i>	Color for filling frame for column labels.
CGRID= <i>color</i>	Color for grid lines.
CHREF= <i>color</i>	Color for HREF= lines.

Table 16.29 Color and Pattern Options (continued)

Option	Option Description
CTEXT= <i>color</i>	Color for text.
CVREF= <i>color</i>	Color for VREF= lines.

Table 16.30 lists options that control the use of a graphics catalog to store graphs if you use traditional graphics. These options are not available if ODS Graphics is enabled.

Table 16.30 Graphics Catalog Options

Option	Option Description
DESCRIPTION= <i>'string'</i>	Description for graphics catalog member.
NAME= <i>'string'</i>	Name for plot in graphics catalog.

MODEL Statement

MODEL *variable* < * *censor-variable(values)* > < =*effect-list* > < / *options* > ;

MODEL (*variable1 variable2*) < =*effect-list* > < / *options* > ;

You use the MODEL statement to fit regression models, where life is modeled as a function of explanatory variables.

You can use only one MODEL statement after a PROC RELIABILITY statement. If you specify more than one MODEL statement, only the last is used.

The MODEL statement does not produce any plots, but it enables you to analyze more complicated regression models than the ANALYZE, PROBLOT, or RELATIONPLOT statement does. The probability distribution specified in the DISTRIBUTION statement is used in the analysis. The following are examples of MODEL statements:

```
model time = temp voltage;
model life*censor(1) = voltage width;
```

See the section “Analysis of Accelerated Life Test Data” on page 1223 and the section “Regression Modeling” on page 1237 for examples that use the MODEL statement to fit regression models.

If your data are right censored lifetime data, you must specify a *censor-variable* and, in parentheses, the *values* of the *censor-variable* that correspond to censored data values.

If your data are recurrent events data with exact event times, you must specify a *censor-variable* and, in parentheses, the *values* of the *censor-variable* that correspond to the end-of-service times for each unit under observation. In this case, you must also specify a UNITID statement to identify the specific unit that corresponds to each observation.

If your lifetime data contain any interval-censored or left-censored values, you must specify *variable1* and *variable2* in parentheses to provide the endpoints of the interval for each observation.

If your data are recurrent events data, and event times are not known exactly, but are known only to have occurred in intervals, you must specify *variable1* and *variable2* in parentheses to provide the endpoints of the interval for each observation. In this case, you must also specify a variable that determines the number of events observed in each interval with a **FREQ** statement, and a variable that determines the number of units under observation in each interval with a **NENTER** statement.

The independent variables in your regression model are specified in the *effect-list*. The *effect-list* is any combination of continuous variables, classification variables, and interaction effects.

See the section “**Regression Models**” on page 1364 for further information on specifying the independent variables.

The elements of the **MODEL** statement are described as follows.

variable

is the dependent, or response, variable. The *variable* must be a numeric variable in the input data set.

sensor-variable(values)

for lifetime data, indicates which observations in the input data set are right censored. You specify the values of *sensor-variable* that represent censored observations by placing those values in parentheses after the variable name. If your data are not right censored, then you can omit the specification of a *sensor-variable*; otherwise, *sensor-variable* must be a numeric variable in the input data set.

If your data are recurrent events data and exact event times are known, then you must specify *sensor-variable*. If *sensor-variable* is equal to one of the *values*, then the value of *variable* is the end of observation time for a unit. Otherwise, you use *sensor-variable* to assign a cost to the event that occurs at the value of *variable*. If all events have unit cost, then *sensor-variable* should be set to one for all observations that do not correspond to end of observation times. The *sensor-variable* plays the same role as the *cost/censor-variable* in the **MCFPLOT** statement in this case.

(variable1 variable2)

is another method of specifying the dependent variable in a regression model for lifetime data. You can use this syntax in a situation where uncensored, interval-censored, left-censored, and right-censored values occur in the same set of data. [Table 16.31](#) shows how you use this syntax to specify different types of censoring by using combinations of missing and nonmissing values.

Table 16.31 Specifying Censored Values

Variable1	Variable2	Type of Censoring
Nonmissing	Nonmissing	Uncensored if <i>variable1</i> = <i>variable2</i>
Nonmissing	Nonmissing	Interval censored if <i>variable1</i> < <i>variable2</i>
Nonmissing	Missing	Right censored at <i>variable1</i>
Missing	Nonmissing	Left censored at <i>variable2</i>

For example, if T1 and T2 represent time in hours in the input data set

OBS	T1	T2
1	.	6
2	6	12
3	12	24
4	24	.
5	24	24

then the statement

```
model (t1 t2);
```

specifies a model in which observation 1 is left censored at 6 hours, observation 2 is interval censored in the interval (6, 12), observation 3 is interval censored in (12,24), observation 4 is right censored at 24 hours, and observation 5 is an uncensored lifetime of 24 hours.

You can also use this method to specify a model for recurrent events data when exact recurrence times are not known. In this case, events are observed to have occurred in intervals specified by (*variable1 variable2*). The values of the variable specified in a FREQ statement determine the number of events that occurred in each interval, and the values of the variable specified in a NENTER statement determine the number of units under observation in each interval.

effect-list

is a list of variables in the input data set representing the values of the independent variables in the model for each observation, and combinations of variables representing interaction terms. If a variable in the *effect-list* is also listed in a CLASS statement, an indicator variable is generated for each level of the variable. An indicator variable for a particular level is equal to 1 for observations with that level, and equal to 0 for all other observations. This type of variable is called a *classification* variable. Classification variables can be either character or numeric. If a variable is not listed in a CLASS statement, it is assumed to be a continuous variable, and it must be numeric.

options

control how the model is fit and what output is produced. All *options* are specified after a slash (/) in the MODEL statement. The “Summary of Options” section, which follows, lists all options by function.

Summary of Options

Table 16.32 Model Statement Options

Option	Option Description
CONFIDENCE= <i>number</i>	Specifies the confidence coefficient for all confidence intervals. Specify a <i>number</i> between 0 and 1. The default value is 0.95.

Table 16.32 Model Statement Options (continued)

Option	Option Description
CONVERGE= <i>number</i>	Specifies the convergence criterion for maximum likelihood fit. See the section “ Maximum Likelihood Estimation ” on page 1361 for details.
CONVH= <i>number</i>	Specifies the convergence criterion for the relative Hessian convergence criterion. See the section “ Maximum Likelihood Estimation ” on page 1361 for details.
CORRB	Requests parameter correlation matrix.
COVB	Requests parameter covariance matrix.
HPPTEST	Applies only to models for recurrent events data. This option requests a likelihood ratio test for a homogeneous Poisson process.
INEST IN= <i>SAS-data-set</i>	Applies only to models for recurrent events data. This option specifies a SAS data set that can contain initial values, equality constraints, upper bounds, or lower bounds for the intercept and shape parameters in a model for recurrent events data. See the section “ IN-EST Data Set for Recurrent Events Models ” on page 1393 for details.
INITIAL= <i>number list</i>	Specifies initial values for regression parameters other than the location (intercept) term.
ITPRINT	Requests the iteration history for maximum likelihood fit.
LRCL	Requests likelihood ratio confidence intervals for distribution parameters.
LOCATION= <i>number</i> <LINIT >	Specifies the fixed or initial value of the location, or intercept parameter.
MAXIT= <i>number</i>	Specifies the maximum number of iterations allowed for maximum likelihood fit.

Table 16.32 Model Statement Options (continued)

Option	Option Description
OBSTATS	Requests a table that contains the XBETA, SURV, SRESID, and ADJRESID statistics in Table 16.33 or the XBETA, MCF, and INTENSITY statistics in Table 16.34. The table also contains the dependent and independent variables in the model. You can use this option to compute statistics such as survival function estimates for lifetime data or mean function estimates for recurrent events data for dependent variable values not included in the analysis. Refer to “Comparison of Two Samples of Repair Data” on page 1258 for an example of computing predicted values for recurrent events data.
OBSTATS(<i>statistics</i>)	Requests a table that contains the model variables and the statistics in the specified list of <i>statistics</i> . Available statistics are shown in Table 16.33.
ORDER=DATA FORMATTED FREQ INTERNAL	Specifies the sort order for values of the classification variables in the <i>effect-list</i> .
PSTABLE= <i>number</i>	Specifies stable parameterization. The <i>number</i> must be between zero and one. See the section “Stable Parameters” on page 1366 for further information.
READOUT	Analyzes data in readout structure. The FREQ statement must be used to specify the number of units that fail in each interval, and the NENTER statement must be used to specify the number of unfailed units that enter each interval.
RELATION= <i>transformation-keyword</i>	

Table 16.32 Model Statement Options (continued)

Option	Option Description												
RELATION=(<i>transformation-keyword1</i> < , > <i>transformation-keyword2</i>)	Specifies the type of relationship between independent and dependent variables. In the first form, the transformation specified is applied to the first continuous independent variable in the model. In the second form, the transformations specified within parentheses are applied to the first two continuous independent variables in the model, in the order listed. <i>transformation-keyword</i> , <i>transformation-keyword1</i> , and <i>transformation-keyword2</i> can be any of the transformations listed in the following table. See Table 16.67 for definitions of the transformations.												
<table border="1"> <thead> <tr> <th>Transformation Keyword</th> <th>Type of Transformation</th> </tr> </thead> <tbody> <tr> <td>ARRHENIUS</td> <td>Arrhenius (Nelson parameterization)</td> </tr> <tr> <td>ARRHENIUS2</td> <td>Arrhenius (activation energy)</td> </tr> <tr> <td>POWER</td> <td>Logarithmic</td> </tr> <tr> <td>LINEAR</td> <td>Linear</td> </tr> <tr> <td>LOGISTIC</td> <td>Logistic</td> </tr> </tbody> </table>		Transformation Keyword	Type of Transformation	ARRHENIUS	Arrhenius (Nelson parameterization)	ARRHENIUS2	Arrhenius (activation energy)	POWER	Logarithmic	LINEAR	Linear	LOGISTIC	Logistic
Transformation Keyword	Type of Transformation												
ARRHENIUS	Arrhenius (Nelson parameterization)												
ARRHENIUS2	Arrhenius (activation energy)												
POWER	Logarithmic												
LINEAR	Linear												
LOGISTIC	Logistic												
SCALE= <i>number</i> < SCINIT >	Specifies a fixed or initial value of scale parameter.												
SHAPE= <i>number</i> < SHINIT >	Specifies a fixed or initial value of shape parameter.												
SINGULAR= <i>number</i>	Specifies the singularity criterion for matrix inversion.												
THRESHOLD= <i>number</i>	Specifies a fixed threshold parameter. See Table 16.57 for the distributions with a threshold parameter.												
TREND= <i>trend-test keyword</i> (<i>trend-test keywords</i>)	Applies only to models for recurrent events data. This option requests one or more tests of trend for a Poisson process. TREND=LRHPP is equivalent to the HPPTTEST option. See the section “Tests of Trend” on page 1392 for more information about the tests. The available tests are shown in the following table.												

Table 16.32 Model Statement Options (continued)

Option	Option Description												
	<table border="1"> <thead> <tr> <th>Trend-Test Keyword</th> <th>Description of Test</th> </tr> </thead> <tbody> <tr> <td>MH HDBK MIL-HDBK</td> <td>Military handbook test</td> </tr> <tr> <td>LA LAPLACE</td> <td>Laplace's test</td> </tr> <tr> <td>LR LEWIS-ROBINSON</td> <td>Lewis-Robinson test</td> </tr> <tr> <td>LRHPP LIKELIHOOD</td> <td>Likelihood ratio test</td> </tr> <tr> <td>ALL</td> <td>All available tests</td> </tr> </tbody> </table>	Trend-Test Keyword	Description of Test	MH HDBK MIL-HDBK	Military handbook test	LA LAPLACE	Laplace's test	LR LEWIS-ROBINSON	Lewis-Robinson test	LRHPP LIKELIHOOD	Likelihood ratio test	ALL	All available tests
Trend-Test Keyword	Description of Test												
MH HDBK MIL-HDBK	Military handbook test												
LA LAPLACE	Laplace's test												
LR LEWIS-ROBINSON	Lewis-Robinson test												
LRHPP LIKELIHOOD	Likelihood ratio test												
ALL	All available tests												
WALDCL NORMALCL	Requests Wald type confidence intervals for distribution parameters. See Table 16.68 and Table 16.74 for details about the computation of Wald confidence intervals. This is the default option used if likelihood ratio confidence intervals are not requested by using the LRCL option.												

Table 16.33 Available Statistics Computed for Each Observation with the OBSTATS Option for Lifetime Data

Option	Option Description										
CENSOR	Is a variable that indicates the type of censoring for each observation in the input data set. The possible values for CENSOR and their interpretations are listed in the following table. <table border="1"> <thead> <tr> <th>Type of Response</th> <th>CENSOR Variable Value</th> </tr> </thead> <tbody> <tr> <td>Uncensored</td> <td>0</td> </tr> <tr> <td>Right-censored</td> <td>1</td> </tr> <tr> <td>Left-censored</td> <td>2</td> </tr> <tr> <td>Interval-censored</td> <td>3</td> </tr> </tbody> </table>	Type of Response	CENSOR Variable Value	Uncensored	0	Right-censored	1	Left-censored	2	Interval-censored	3
Type of Response	CENSOR Variable Value										
Uncensored	0										
Right-censored	1										
Left-censored	2										
Interval-censored	3										
CONTROL= <i>variable</i>	Specifies a control variable in the input data set that allows the computation of statistics for a subset of observations in the input data set. If the value of <i>variable</i> is 1, the statistics are computed for that observation. If the value of the control variable is not equal to 1, the statistics are not computed for that observation.										
QUANTILES QUANTILE Q= <i>number-list</i>	Requests distribution quantiles for each number in <i>number-list</i> for each observation. The numbers must be between 0 and 1. Estimated quantile standard errors, and upper and lower confidence limits are also tabulated.										

Table 16.33 Available Statistics Computed for Each Observation with the OBSTATS Option (continued)

Option	Option Description
XBETA	Specifies the linear predictor.
SURVIVAL SURV	Specifies the fitted survival function, evaluated at the value of the dependent variable.
RESID	Specifies the raw residual.
SRESID	Specifies the standardized residual.
GRESID	Specifies the modified Cox-Snell residual.
DRESID	Specifies the deviance residual.
ADJRESID	Specifies the adjusted standardized residuals. These are adjusted for right-censored observations by adding the median of the lifetime greater than the right-censored values to the residuals.
RESIDADJ= <i>number</i>	Specifies the adjustment to be added to Cox-Snell residual for right-censored data values. The default of <i>number</i> is 1.0, the mean of the standard exponential distribution.
RESIDALPHA RALPHA= <i>number</i>	Specifies that the <i>number</i> ×100% percentile residual lifetime be used to adjust right-censored standardized residuals. The <i>number</i> must be between 0 and 1. The default value is 0.5, which corresponds to the median.

Table 16.34 Available Statistics Computed for Each Observation with the OBSTATS Option for Recurrent Events Data

Option	Option Description
CONTROL= <i>variable</i>	Specifies a control variable in the input data set that allows the computation of statistics for a subset of observations in the input data set. If the value of <i>variable</i> is 1, the statistics are computed for that observation. If the value of <i>variable</i> is not equal to 1, the statistics are not computed for that observation.
MCF	Specifies the mean function, which is evaluated at the value of time for each observation. Standard errors and confidence limits are also computed.
INTENSITY	Specifies the intensity function, which is evaluated at the value of time for each observation. Standard errors and confidence limits are also computed.

Table 16.34 Available Statistics Computed for Each Observation with the OBSTATS Option (continued)

Option	Option Description
XBETA	Specifies the linear predictor.

NENTER Statement

NENTER *variable* ;

Use the NENTER statement in conjunction with the **FREQ** statement to specify interval-censored lifetime data having a special structure; these data are called *readout* data. The NENTER statement specifies a *variable* in the input data set that determines the number of unfailed units entering each interval. See the section “[Weibull Analysis of Interval Data with Common Inspection Schedule](#)” on page 1228 for an example that uses the NENTER statement with readout data.

You can also use the NENTER statement in conjunction with the **FREQ** statement to specify recurrent events data when the event times are grouped into intervals, rather than being observed exactly. The NENTER statement specifies a variable in the input data set that determines the number of units observed in each interval.

NLOPTIONS Statement

NLOPTIONS < *options* > ;

You use the NLOPTIONS statement to control aspects of the optimization system that is used to compute maximum likelihood estimates of the parameters of the three-parameter Weibull distribution with an **ANALYZE** or **PROBPLOT** statement, and of the parameters of models for recurrent events data with a **MODEL** statement. The syntax and options of the NLOPTIONS statement are described in Chapter 19, “Shared Concepts and Topics” (*SAS/STAT User’s Guide*).

PROBPLOT Statement

< *label* : > **PROBPLOT** *variable* < **censor-variable*(*values*) > < =*group-variables* > < / *options* > ;

< *label* : > **PROBPLOT** (*variable1 variable2*) < =*group-variables* > < / *options* > ;

You use the **PROBPLOT** statement to create a probability plot from complete, left-censored, right-censored, or interval-censored data.

You can specify the keyword **PLOT** as an alias for **PROBPLOT**. You can specify any number of **PROBPLOT** statements after a **PROC RELIABILITY** statement. Each **PROBPLOT** statement creates a probability plot and an associated analysis. The probability distribution used in creating the probability plot and performing the analysis is determined by the **DISTRIBUTION** statement. You can specify an optional *label* to distinguish between multiple **PROBPLOT** statements in the output.

See the section “Analysis of Right-Censored Data from a Single Population” on page 1214 and the section “Weibull Analysis Comparing Groups of Data” on page 1219 for examples that create probability plots with the PROBPLOT statement.

To create a probability plot, you must specify one *variable*. If your data are right censored, you must specify a *sensor-variable* and, in parentheses, the *values* of the *sensor-variable* that correspond to censored data values.

You can optionally specify one or two *group-variables* (also referred to as *classification variables*). The PROBPLOT statement displays a probability plot for each level of the *group-variables*. The observations in a given level are called a *cell*.

The elements of the PROBPLOT statement are described as follows.

variable

represents the data for which a probability plot is to be produced. The *variable* must be a numeric variable in the input data set.

sensor-variable(values)

indicates which observations in the input data set are right censored. You specify the values of *sensor-variable* that represent censored observations by placing those values in parentheses after the variable name. If your data are not right censored, then you can omit the specification of *sensor-variable*; otherwise, *sensor-variable* must be a numeric variable in the input data set.

(variable1 variable2)

is another method of specifying the data for which a probability plot is to be produced. You can use this syntax in a situation where uncensored, interval-censored, left-censored, and right-censored values occur in the same set of data. Table 16.31 shows how you use this syntax to specify different types of censoring by using combinations of missing and nonmissing values. See the section “Lognormal Analysis with Arbitrary Censoring” on page 1233 for an example that uses this syntax to create a probability plot.

group-variables

are one or two group variables. If no group variables are specified, a single probability plot is produced. The *group-variables* can be numeric or character variables in the input data set.

Note that the parentheses surrounding the *group-variables* are needed only if two group variables are specified.

options

control the features of the probability plot. All *options* are specified after the slash (/) in the PROBPLOT statement. See the section “Summary of Options” on page 1317, which follows, for a list of all options by function.

Summary of Options

Table 16.35 lists analysis options that are available when you use either traditional graphics or ODS Graphics.

Table 16.35 Analysis Options

Option	Option Description														
CONFIDENCE= <i>number</i>	Specifies the confidence coefficient for all confidence intervals. The <i>number</i> must be between 0 and 1. The default value is 0.95														
CONVERGE= <i>number</i>	Specifies the convergence criterion for maximum likelihood fit. See the section “ Maximum Likelihood Estimation ” on page 1361 for details.														
CONVH= <i>number</i>	Specifies the convergence criterion for the relative Hessian convergence criterion. See the section “ Maximum Likelihood Estimation ” on page 1361 for details.														
CORRB	Requests the parameter correlation matrix.														
COVB	Requests the parameter covariance matrix.														
FITTYPE FIT= <i>fit-specification</i>	Specifies the method of estimating distribution parameters. The available <i>fit-specifications</i> and their meanings are shown in the following table.														
<table border="1"> <thead> <tr> <th>Fit Specification</th> <th>Definition</th> </tr> </thead> <tbody> <tr> <td>LSYX</td> <td>Least squares fit to the probability plot. The probability axis is the dependent variable.</td> </tr> <tr> <td>LSXY</td> <td>Least squares fit to the probability plot. The lifetime axis is the dependent variable.</td> </tr> <tr> <td>MLE</td> <td>Maximum likelihood (default).</td> </tr> <tr> <td>MODEL</td> <td>Use the fit from the preceding MODEL statement.</td> </tr> <tr> <td>NONE</td> <td>No fit is computed.</td> </tr> <tr> <td>WEIBAYES <(CONFIDENCE CONF=<i>number</i>)></td> <td>Weibayes fit. <i>number</i> is the confidence coefficient for the Weibayes fit and is between 0 and 1. The default is 0.95.</td> </tr> </tbody> </table>		Fit Specification	Definition	LSYX	Least squares fit to the probability plot. The probability axis is the dependent variable.	LSXY	Least squares fit to the probability plot. The lifetime axis is the dependent variable.	MLE	Maximum likelihood (default).	MODEL	Use the fit from the preceding MODEL statement.	NONE	No fit is computed.	WEIBAYES <(CONFIDENCE CONF= <i>number</i>)>	Weibayes fit. <i>number</i> is the confidence coefficient for the Weibayes fit and is between 0 and 1. The default is 0.95.
Fit Specification	Definition														
LSYX	Least squares fit to the probability plot. The probability axis is the dependent variable.														
LSXY	Least squares fit to the probability plot. The lifetime axis is the dependent variable.														
MLE	Maximum likelihood (default).														
MODEL	Use the fit from the preceding MODEL statement.														
NONE	No fit is computed.														
WEIBAYES <(CONFIDENCE CONF= <i>number</i>)>	Weibayes fit. <i>number</i> is the confidence coefficient for the Weibayes fit and is between 0 and 1. The default is 0.95.														
INEST IN= <i>SAS-data-set</i>	Specifies a SAS data set that can contain initial values, equality constraints, upper bounds, or lower bounds for the scale, shape, and threshold parameters in a three-parameter Weibull model for lifetime data, and applies only to three-parameter Weibull models. See the section “ INEST Data Set for the Three-Parameter Weibull ” on page 1363 for details.														
ITPRINT	Requests the iteration history for maximum likelihood fit.														

Table 16.35 Analysis Options (continued)

Option	Option Description
ITPRINTEM	Requests the iteration history for the Turnbull algorithm.
LRCL	Requests likelihood ratio confidence intervals for distribution parameters.
LRCLPER	Requests likelihood ratio confidence intervals for distribution percentiles.
LRCLSURV	Requests likelihood ratio confidence intervals for survival and cumulative distribution functions at times specified with the SURVTIME= <i>number-list</i> option.
LOCATION= <i>number</i> <LINIT >	Specifies a fixed or initial value of location parameter.
MAXIT= <i>number</i>	Specifies the maximum number of iterations allowed for a maximum likelihood fit.
MAXITEM= <i>number1</i> < , <i>number2</i> >	<i>number1</i> Specifies the maximum number of iterations allowed for the Turnbull algorithm. Iteration history will be printed in increments of <i>number2</i> if an iteration history is requested with ITPRINTEM. See the section “Interval-Censored Data” on page 1354 for details.
NOPCTILES	Suppresses computation of percentiles for standard list of percentage points.
NOPOLISH	Suppresses the setting of small interval probabilities to 0 in the Turnbull algorithm. See the section “Interval-Censored Data” on page 1354 for details.
NPINTERVALS= <i>interval-type</i>	Specifies the type of nonparametric confidence interval displayed in a probability plot. The available types of intervals are listed in the following table.

Table 16.35 Analysis Options (continued)

Option	Option Description
Interval Type POINTWISE POINT	Definition Pointwise confidence intervals for the CDF. See the section “ Pointwise Confidence Intervals ” on page 1360 for details.
SIMULTANEOUS SIMUL< <i>number1</i> , <i>number2</i> >	Simultaneous confidence intervals for the CDF. <i>number1</i> and <i>number2</i> are constants that control the time interval for which simultaneous intervals are computed. The default time intervals are the lowest and highest times corresponding to failures in the case of right-censored data, or to the lowest and highest intervals for which probabilities are computed for interval-censored data. See the section “ Simultaneous Confidence Intervals ” on page 1360 for details.
PCTLIST= <i>number-list</i>	Specifies a list of percentages for which to compute percentile estimates. The <i>number-list</i> must be a list of numbers separated by blanks or commas. Each number in the list must be between 0 and 100. If this option is not specified, percentiles are computed for a standard list of percentages.
PINTERVALS= <i>interval-type</i>	Specifies the type of parametric pointwise confidence interval displayed in a probability plot. The available types of intervals are listed in the following table. The default type is PROBABILITY, pointwise confidence intervals on cumulative failure probability.

Table 16.35 Analysis Options (continued)

Option	Option Description														
	<table border="1"> <thead> <tr> <th>Interval Type</th> <th>Definition</th> </tr> </thead> <tbody> <tr> <td>LIKELIHOOD LRCI</td> <td>Likelihood ratio confidence intervals</td> </tr> <tr> <td>PERCENTILES PER</td> <td>Pointwise parametric confidence intervals for the percentiles of the fitted CDF</td> </tr> <tr> <td>PROBABILITY CDF</td> <td>Pointwise parametric confidence intervals for the cumulative failure probabilities. See the section “Reliability Function” on page 1370 for details.</td> </tr> </tbody> </table>	Interval Type	Definition	LIKELIHOOD LRCI	Likelihood ratio confidence intervals	PERCENTILES PER	Pointwise parametric confidence intervals for the percentiles of the fitted CDF	PROBABILITY CDF	Pointwise parametric confidence intervals for the cumulative failure probabilities. See the section “ Reliability Function ” on page 1370 for details.						
Interval Type	Definition														
LIKELIHOOD LRCI	Likelihood ratio confidence intervals														
PERCENTILES PER	Pointwise parametric confidence intervals for the percentiles of the fitted CDF														
PROBABILITY CDF	Pointwise parametric confidence intervals for the cumulative failure probabilities. See the section “ Reliability Function ” on page 1370 for details.														
PPOS= <i>plotting-position</i>	Specifies the <i>plotting-position</i> type used to compute nonparametric estimates of the probability distribution function. See the section “ Probability Plotting ” on page 1350 for details. The plotting position types available are shown in the following table.														
	<table border="1"> <thead> <tr> <th>Plotting Position</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>EXPRANK</td> <td>Expected ranks</td> </tr> <tr> <td>MEDRANK</td> <td>Median ranks</td> </tr> <tr> <td>MEDRANK1</td> <td>Median ranks (exact formula)</td> </tr> <tr> <td>KM</td> <td>Kaplan-Meier</td> </tr> <tr> <td>MKM</td> <td>Modified Kaplan-Meier (default)</td> </tr> <tr> <td>NA NELSONAALEN</td> <td>Nelson-Aalen</td> </tr> </tbody> </table>	Plotting Position	Type	EXPRANK	Expected ranks	MEDRANK	Median ranks	MEDRANK1	Median ranks (exact formula)	KM	Kaplan-Meier	MKM	Modified Kaplan-Meier (default)	NA NELSONAALEN	Nelson-Aalen
Plotting Position	Type														
EXPRANK	Expected ranks														
MEDRANK	Median ranks														
MEDRANK1	Median ranks (exact formula)														
KM	Kaplan-Meier														
MKM	Modified Kaplan-Meier (default)														
NA NELSONAALEN	Nelson-Aalen														
PPOUT	Requests a table of nonparametric cumulative probabilities in the printed output.														
PRINTPROBS	Specifies that intervals and associated probabilities for the Turnbull algorithm be printed.														
PROBLIST= <i>number-list</i>	Specifies a list of initial values for Turnbull algorithm. See the section “ Interval-Censored Data ” on page 1354 for details.														
PSTABLE= <i>number</i>	Specifies a stable parameterization. The <i>number</i> must be between 0 and 1. See the section “ Stable Parameters ” on page 1366 for further information.														
READOUT	Specifies the data have the readout structure.														
SCALE= <i>number</i> <SCINIT>	Specifies a fixed or initial value of the scale parameter.														
SHAPE= <i>number</i> <SHINIT>	Specifies a fixed or initial value of the shape parameter.														

Table 16.35 Analysis Options (continued)

Option	Option Description
SINGULAR= <i>number</i>	Specifies the singularity criterion for matrix inversion.
SURVTIME= <i>number-list</i>	Requests that the survival function, cumulative distribution function, and confidence limits be computed for values in <i>number-list</i> . See the section “ Reliability Function ” on page 1370 for details.
THRESHOLD= <i>number</i>	Specifies a fixed threshold parameter. See Table 16.57 for the distributions with a threshold parameter.
TOLLIKE= <i>number</i>	Specifies the criterion for convergence in the Turnbull algorithm. The default is 10^{-8} . See the section “ Interval-Censored Data ” on page 1354 for details.
TOLPROB= <i>number</i>	Specifies the criterion for setting interval probabilities to 0 in the Turnbull algorithm. The default is 10^{-6} . See the section “ Interval-Censored Data ” on page 1354 for details.

Table 16.36 lists analysis options that are available when ODS Graphics is enabled.

Table 16.36 Analysis Options for ODS Graphics

Option	Option Description
PROFILE<(options)>	Requests a profile log-likelihood plot of the threshold parameter for a three-parameter Weibull distribution. The <i>options</i> listed in the following table are available; they are specified by enclosing them in parentheses after the PROFILE option.

Table 16.36 Analysis Options (continued)

Option	Option Description
Profile Option	Option Description
NOCONF	Specifies that a reference line on the vertical, log-likelihood axis not be drawn. If this option is not specified, a reference line is drawn at a log-likelihood value that corresponds to the profile likelihood confidence limits on the horizontal axis.
NPROFILE= <i>n</i>	Specifies that the profile log likelihood be computed and plotted at <i>n</i> threshold points. If this option is not specified, the profile log likelihood is computed and plotted at 100 points.
RANGE=(<i>value1</i> , <i>value2</i>)	Specifies the range of threshold values for which the profile log likelihood is computed and plotted as (<i>value1</i> , <i>value2</i>). If this option is not specified, the range of threshold values for which the profile log likelihood is computed is from 0 to the minimum failure time.

Table 16.37 lists plot layout options that are available when you use traditional graphics.

Table 16.37 Probability Plot Layout Options for Traditional Graphics

Option	Option Description
CENBIN	Specifies that censored data be plotted as frequency counts rather than as individual points.
CENSYMBOL= <i>symbol</i> (<i>symbol-list</i>)	Specifies symbols for censored values. The <i>symbol</i> is one of the symbol names (plus, star, square, diamond, triangle, hash, paw, point, dot, circle) or a letter (A–Z). For overlaid plots for groups of data, you can specify different symbols for the groups with a list of symbols or letters, separated by blanks, enclosed in parentheses. If no CENSYMBOL option is specified, the symbol used for censored values is the same as the symbol used for failures.

Table 16.37 Probability Plot Layout Options (continued)

Option	Option Description
HOFFSET= <i>value</i>	Specifies the offset for the horizontal axis.
INBORDER	Requests a border around probability plots.
INTERTILE= <i>value</i>	Specifies the distance between tiles.
LFIT= <i>linetype</i> (<i>linetype list</i>)	Specifies line styles for fit lines and confidence curves in a probability plot. The <i>linetype list</i> is a list of numbers from 1 to 46 representing different line-types; they can be separated by blanks or commas or can be a list in the form n_1 to n_2 < by n_3 >.
MISSING1	Requests that missing values of the first GROUP= variable be treated as a level of the variable.
MISSING2	Requests that missing values of the second GROUP= variable be treated as a level of the variable.
NCOLS= <i>n</i>	Specifies that <i>n</i> columns be plotted on a page.
NOCENPLOT	Suppresses the plotting of censored data points.
NOCONF	Suppresses the plotting of percentile confidence curves.
NOFIT	Suppresses the plotting of fit line and percentile confidence curves.
NOFRAME	Suppresses the frame around the plotting area.
NOINSET	Suppresses the inset.
NOPPLEGEND	Suppresses the legend for overlaid probability plots
NOPPOS	Suppresses plotting of symbols for failures in a probability plot.
NROWS= <i>n</i>	Specifies that <i>n</i> rows be plotted on a page.
ORDER1=DATA FORMATTED FREQ INTERNAL	Specifies display order for values of the first GROUP= variable.
ORDER2=DATA FORMATTED FREQ INTERNAL	Specifies the display order for values of the second GROUP= variable.
OVERLAY	Requests overlaid plots for group variables.
PCONFPLT	Plots confidence intervals on probabilities for readout data.
PPLEGEND = <i>legend-statement- name</i> NONE	Identifies LEGEND n statement to specify a legend for overlaid probability plots.
PPOSSYMBOL= <i>symbol</i> (<i>symbol- list</i>)	Specifies symbols to represent failures on a probability plot.
ROTATE	Requests probability plots with the probability scale on the horizontal axis.
SHOWMULTIPLES	Requests that the count be displayed for multiple overlaying symbols.

Table 16.37 Probability Plot Layout Options (continued)

Option	Option Description
TURNVLABELS	Vertically strings out characters in labels for the vertical axis.
VOFFSET= <i>value</i>	Specifies <i>value</i> as the length of the offset at the upper end of the vertical axis.
WFIT= <i>n</i>	Specifies the line width for the fit line and confidence curves.

Table 16.38 lists plot layout options that are available when you use ODS graphics.

Table 16.38 Probability Plot Layout Options for ODS Graphics

Option	Option Description
MISSING1	Requests that missing values of first GROUP= variable be treated as a level of the variable.
MISSING2	Requests that missing values of second GROUP= variable be treated as a level of the variable.
NCOLS= <i>n</i>	Specifies that <i>n</i> columns be plotted on a page.
NOCENPLOT	Suppresses plotting of censored data points.
NOCONF	Suppresses plotting of percentile confidence curves.
NOFIT	Suppresses plotting of the fit line and percentile confidence curves.
NOINSET	Suppresses the inset.
NOPPLEGEND	Suppresses the legend for overlaid probability plots.
NOPPOS	Suppresses plotting of symbols for failures in a probability plot.
NROWS= <i>n</i>	Specifies that <i>n</i> rows be plotted on a page.
ORDER1=DATA FORMATTED FREQ INTERNAL	Specifies the display order for values of the first GROUP= variable.
ORDER2=DATA FORMATTED FREQ INTERNAL	Specifies the display order for values of the second GROUP= variable.
OVERLAY	Requests overlaid plots for group variables.
PCONFPLT	Plots confidence intervals on probabilities for readout data.
ROTATE	Requests probability plots with the probability scale on the horizontal axis.

Table 16.39 lists reference line options that are available when you use traditional graphics.

Table 16.39 Reference Line Options for Traditional Graphics

Option	Option Description														
HREF < (INTERSECT) >= <i>value-list</i>	Requests reference lines perpendicular to horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value.														
HREFLABELS=(<i>'label1' ... 'labeln'</i>)	Specifies labels for HREF= lines.														
HREFLABPOS= <i>n</i>	Specifies vertical position of labels for HREF= lines. The valid values for <i>n</i> and the corresponding label placements are shown in the following table:														
	<table border="1"> <thead> <tr> <th><i>n</i></th> <th>Label Placement</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>Top</td> </tr> <tr> <td>2</td> <td>Staggered from top</td> </tr> <tr> <td>3</td> <td>Bottom</td> </tr> <tr> <td>4</td> <td>Staggered from bottom</td> </tr> <tr> <td>5</td> <td>Alternating from top</td> </tr> <tr> <td>6</td> <td>Alternating from bottom</td> </tr> </tbody> </table>	<i>n</i>	Label Placement	1	Top	2	Staggered from top	3	Bottom	4	Staggered from bottom	5	Alternating from top	6	Alternating from bottom
<i>n</i>	Label Placement														
1	Top														
2	Staggered from top														
3	Bottom														
4	Staggered from bottom														
5	Alternating from top														
6	Alternating from bottom														
LHREF= <i>linetype</i>	Specifies the line style for HREF= lines.														
LVREF= <i>linetype</i>	Specifies the line style for VREF= lines.														
VREF < (INTERSECT) >= <i>value-list</i>	Specifies reference lines perpendicular to vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value.														
VREFLABELS=(<i>'label1' ... 'labeln'</i>)	Specifies labels for VREF= lines.														
VREFLABPOS= <i>n</i>	Specifies horizontal position of labels for VREF= lines. The valid values for <i>n</i> and the corresponding label placements are shown in the following table:														
	<table border="1"> <thead> <tr> <th><i>n</i></th> <th>Label Placement</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>Left</td> </tr> <tr> <td>2</td> <td>Right</td> </tr> </tbody> </table>	<i>n</i>	Label Placement	1	Left	2	Right								
<i>n</i>	Label Placement														
1	Left														
2	Right														

Table 16.40 lists reference line options that are available when you use ODS graphics.

Table 16.40 Reference Line Options for ODS Graphics

Option	Option Description
HREF LREF <(INTERSECT)>= <i>value-list</i>	Requests reference lines perpendicular to horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value.
HREFLABELS LREFLABELS=(<i>'label1' ... 'labeln'</i>)	Specifies labels for HREF= lines.
VREF PREF <(INTERSECT)>= <i>value-list</i>	Specifies reference lines perpendicular to vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value.
VREFLABELS PREFLABELS=(<i>'label1' ... 'labeln'</i>)	Specifies labels for VREF= lines.

Table 16.41 lists options that control the appearance of the text when you use traditional graphics. These options are not available if ODS Graphics is enabled.

Table 16.41 Text Enhancement Options

Option	Option Description
FONT= <i>font</i>	Specifies a software font for text.
HEIGHT= <i>value</i>	Specifies the height of text used outside framed areas.
INFONT= <i>font</i>	Specifies a software font for text inside framed areas.
INHEIGHT= <i>value</i>	Specifies the height of text inside framed areas.

Table 16.42 lists options that control the appearance of the axes when you use traditional graphics.

Table 16.42 Axis Options for Traditional Graphics

Option	Option Description
LAXIS= <i>value1 to value2 < by value3 ></i>	<p>Specifies tick mark values for the lifetime axis. <i>value1</i>, <i>value2</i>, and <i>value3</i> must be numeric, and <i>value1</i> must be less than <i>value2</i>. The lower tick mark is <i>value1</i>. Tick marks are drawn at increments of <i>value3</i>. The last tick mark is the greatest value that does not exceed <i>value2</i>. If <i>value3</i> is omitted, a value of 1 is used. This method of specification of tick marks is not valid for logarithmic axes. Examples of LAXIS= lists are</p> <pre data-bbox="883 695 1211 747"> laxis = -1 to 10 laxis = 0 to 200 by 10 </pre>
LGRID= <i>number</i>	<p>Specifies a line style for all grid lines. The <i>number</i> is between 1 and 46 and specifies a linestyle for grids.</p>
LIFELOWER LLOWER= <i>number</i>	<p>Specifies the lower limit on the lifetime axis scale. The LLOWER option specifies <i>number</i> as the lower lifetime axis tick mark. The tick interval and the upper lifetime axis limit are determined automatically. This option has no effect if the LAXIS option is used.</p>
LIFEUPPER LUPPER= <i>number</i>	<p>Specifies the upper limit on the lifetime axis scale. The LUPPER option specifies <i>number</i> as the upper lifetime axis tick mark. The tick interval and the lower lifetime axis limit are determined automatically. This option has no effect if the LAXIS option is used.</p>
MPGRID	<p>Adds a minor grid for the probability axis.</p>
MINORLOGGRID	<p>Adds a minor grid for log axes.</p>
NOGRID	<p>Suppresses grid lines.</p>
NOLLABEL	<p>Suppresses label for life, or analysis variable, axis.</p>
NOLTICK	<p>Suppresses tick marks and tick mark labels for lifetime or analysis variable axis.</p>
NOPLABEL	<p>Suppresses label for probability axis.</p>
NOPTICK	<p>Suppresses tick marks and tick mark labels for the probability axis.</p>
NTICK= <i>number</i>	<p>Specifies the number of tick intervals for the lifetime axis. This option has no effect if the LAXIS option is used.</p>

Table 16.42 Axis Options (continued)

Option	Option Description
PCTLOWER PLOWER= <i>number</i>	Specifies the lower limit on probability axis scale.
PCTUPPER PUPPER= <i>number</i>	Specifies the upper limit on probability axis scale.
PAXISLABEL='string'	Specifies a label for the probability axis.
WAXIS= <i>n</i>	Specifies the line thickness for axes and frame.

Table 16.43 lists options that control the appearance of the axes when you use ODS Graphics.

Table 16.43 Axis Options for ODS Graphics

Option	Option Description
LAXIS= <i>value1 to value2 < by value3 ></i>	Specifies tick mark values for the lifetime axis. <i>value1</i> , <i>value2</i> , and <i>value3</i> must be numeric, and <i>value1</i> must be less than <i>value2</i> . The lower tick mark is <i>value1</i> . Tick marks are drawn at increments of <i>value3</i> . The last tick mark is the greatest value that does not exceed <i>value2</i> . If <i>value3</i> is omitted, a value of 1 is used. This method of specification of tick marks is not valid for logarithmic axes. Examples of LAXIS= lists are <p style="margin-left: 40px;"> laxis = -1 to 10 laxis = 0 to 200 by 10 </p>
LIFELOWER LLOWER= <i>number</i>	Specifies the lower limit on the lifetime axis scale. The LLOWER option specifies <i>number</i> as the lower lifetime axis tick mark. The tick interval and the upper lifetime axis limit are determined automatically. This option has no effect if the LAXIS option is used.
LIFEUPPER LUPPER= <i>number</i>	Specifies the upper limit on the lifetime axis scale. The LUPPER option specifies <i>number</i> as the upper lifetime axis tick mark. The tick interval and the lower lifetime axis limit are determined automatically. This option has no effect if the LAXIS option is used.
MINORLOGGRID	Adds a minor grid for log axes.
NOGRID	Suppresses grid lines.
PCTLOWER PLOWER= <i>number</i>	Specifies the lower limit on probability axis scale.

Table 16.43 Axis Options (continued)

Option	Option Description
PCTUPPER PUPPER= <i>number</i>	Specifies the upper limit on probability axis scale.
PAXISLABEL= <i>'string'</i>	Specifies a label for the probability axis.

Table 16.44 lists options that control colors and patterns used in the graph when you use traditional graphics. These options are not available if ODS Graphics is enabled.

Table 16.44 Color and Pattern Options

Option	Option Description
CAXIS= <i>color</i>	Color for axis
CCENSOR= <i>color</i>	Color for filling censor plot area
CENCOLOR= <i>color</i>	Color for censor symbol
CFIT= <i>color</i> (<i>color list</i>)	color for fit lines and confidence curves in a probability plot
CFRAME= <i>color</i>	Color for frame
CFRAMESIDE= <i>color</i>	Color for filling frame for row labels
CFRAMETOP= <i>color</i>	Color for filling frame for column labels
CGRID= <i>color</i>	Color for grid lines
CHREF= <i>color</i>	Color for HREF= lines
CTEXT= <i>color</i>	Color for text
CVREF= <i>color</i>	Color for VREF= lines
PPOSCOLOR= <i>color</i> (<i>color list</i>)	Colors of symbols that represent failures on a probability plot

Table 16.45 lists options that control the use of a graphics catalog to store graphs if you use traditional graphics. These options are not available if ODS Graphics is enabled.

Table 16.45 Graphics Catalog Options

Option	Option Description
DESCRIPTION= <i>'string'</i>	Description for graphics catalog member
NAME= <i>'string'</i>	Name for plot in graphics catalog

RELATIONPLOT Statement

```
< label: >RELATIONPLOT variable < *censor-variable(values) > < =group-variable >
< / options > ;
```

```
< label: >RELATIONPLOT (variable1 variable2) < =group-variable > < / options > ;
```

You use the RELATIONPLOT statement to create life-stress relation plots. A life-stress relation plot is a graphical tool for the analysis of data from accelerated life tests. The plot is a display of the relationship between life and *stress*, such as temperature or voltage. You can also use the RELATIONPLOT statement to display a probability plot alongside the relation plot. See [Figure 16.9](#) for an example of a relation plot.

You can specify the keyword RPLOT as an alias for RELATIONPLOT. You can use any number of RELATIONPLOT statements after a **PROC RELIABILITY** statement. You can specify an optional *label* to distinguish between multiple RELATIONPLOT statements in the output.

See the section “[Analysis of Accelerated Life Test Data](#)” on page 1223 for an example that uses the RELATIONPLOT statement.

To create a life-stress relation plot, you must specify one *variable*. If your data are right censored, you must specify a *censor-variable* and, in parentheses, the *values* of the *censor-variable* that correspond to censored data values. You must specify one *group-variable* to represent the values of stress. The *group-variable* must be a numeric variable.

The RELATIONPLOT statement plots the uncensored values of your data given by *variable* versus the values of the *group-variable*. You can optionally display a boxplot of the values of the data. You can also plot percentiles of the distribution fitted to the data. The RELATIONPLOT statement produces the same tabular output as the PROBLOT statement, and all the analysis options are the same as for the PROBLOT statement.

The elements of the RELATIONPLOT statement are described as follows.

variable

represents the data for which a plot is to be produced. The *variable* must be a numeric variable in the input data set.

censor-variable(values)

indicates which observations in the input data set are right censored. You specify the values of *censor-variable* that represent censored observations by placing those values in parentheses after the variable name. If your data are not right censored, then you omit the specification of *censor-variable*; otherwise, *censor-variable* must be a numeric variable in the input data set.

(variable1 variable2)

is another method of specifying the data for which a life-stress plot is to be produced. You can use this syntax in a situation where uncensored, interval-censored, left-censored, and right-censored values occur in the same set of data. [Table 16.31](#) shows how you use this syntax to specify different types of censoring by using combinations of missing and nonmissing values. See the section “[Lognormal Analysis with Arbitrary Censoring](#)” on page 1233 for an example that uses this syntax to create a probability plot.

group-variable

is a group variable. The *group-variable* must be a numeric variable in the input data set.

options

control the features of the relation plot. All *options* are specified after the slash (/) in the RELATIONPLOT statement. The “Summary of Options” section, which follows, lists all options by function.

The only type of relation plot currently available for interval data is the type in which percentiles of the fitted distribution are plotted at each stress level.

Summary of Options

Table 16.46 Analysis Options

Option	Option Description
CONFIDENCE= <i>number</i>	Specifies the confidence coefficient for all confidence intervals. The <i>number</i> must be between 0 and 1. The default value is 0.95.
CONVERGE= <i>number</i>	Specifies the convergence criterion for maximum likelihood fit. See the section “ Maximum Likelihood Estimation ” on page 1361 for details.
CONVH= <i>number</i>	Specifies the convergence criterion for the relative Hessian convergence criterion. See the section “ Maximum Likelihood Estimation ” on page 1361 for details.
CORRB	Requests the parameter correlation matrix.
COVB	Requests the parameter covariance matrix.
FITTYPE FIT= <i>fit-specification</i>	Specifies the method of estimating distribution parameters. The available <i>fit-specifications</i> and their meanings are shown in the following table.

Table 16.46 Analysis Options (continued)

Option	Option Description														
PCTLIST= <i>number-list</i>	Specifies a list of percentages for which to compute percentile estimates. The <i>number-list</i> must be a list of numbers separated by blanks or commas. Each number in the list must be between 0 and 100. If this option is not specified, percentiles are computed for a standard list of percentages.														
PPOS= <i>plotting-position</i>	Specifies the <i>plotting-position</i> type used to compute nonparametric estimates of the probability distribution function. See the section “ Probability Plotting ” on page 1350 for details. The plotting position types available are shown in the following table.														
	<table border="1"> <thead> <tr> <th>Plotting Position</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>EXPRANK</td> <td>Expected ranks</td> </tr> <tr> <td>MEDRANK</td> <td>Median ranks</td> </tr> <tr> <td>MEDRANK1</td> <td>Median ranks (exact formula)</td> </tr> <tr> <td>KM</td> <td>Kaplan-Meier</td> </tr> <tr> <td>MKM</td> <td>Modified Kaplan-Meier (default)</td> </tr> <tr> <td>NA NELSONAALLEN</td> <td>Nelson-Aalen</td> </tr> </tbody> </table>	Plotting Position	Type	EXPRANK	Expected ranks	MEDRANK	Median ranks	MEDRANK1	Median ranks (exact formula)	KM	Kaplan-Meier	MKM	Modified Kaplan-Meier (default)	NA NELSONAALLEN	Nelson-Aalen
Plotting Position	Type														
EXPRANK	Expected ranks														
MEDRANK	Median ranks														
MEDRANK1	Median ranks (exact formula)														
KM	Kaplan-Meier														
MKM	Modified Kaplan-Meier (default)														
NA NELSONAALLEN	Nelson-Aalen														
PPOUT	Requests a table of nonparametric cumulative probabilities in the printed output.														
PSTABLE= <i>number</i>	Specifies a stable parameterization. The <i>number</i> must be between zero and one. See the section “ Stable Parameters ” on page 1366 for further information.														
RELATION= <i>transformation-keyword</i>	Specifies the type of relationship between independent (stress) and dependent (lifetime) variables. The transformation specified is applied to the independent (stress) variable in the model. This determines the horizontal scale used in the relation plot. <i>transformation-keyword</i> can be any of the transformations listed in the following table. See Table 16.67 for definitions of the transformations.														

Table 16.46 Analysis Options (continued)

Option	Option Description												
	<table border="1"> <thead> <tr> <th>Transformation Keyword</th> <th>Type of Transformation</th> </tr> </thead> <tbody> <tr> <td>ARRHENIUS</td> <td>Arrhenius (Nelson parameterization)</td> </tr> <tr> <td>ARRHENIUS2</td> <td>Arrhenius (activation energy)</td> </tr> <tr> <td>POWER</td> <td>Logarithmic</td> </tr> <tr> <td>LINEAR</td> <td>Linear</td> </tr> <tr> <td>LOGISTIC</td> <td>Logistic</td> </tr> </tbody> </table>	Transformation Keyword	Type of Transformation	ARRHENIUS	Arrhenius (Nelson parameterization)	ARRHENIUS2	Arrhenius (activation energy)	POWER	Logarithmic	LINEAR	Linear	LOGISTIC	Logistic
Transformation Keyword	Type of Transformation												
ARRHENIUS	Arrhenius (Nelson parameterization)												
ARRHENIUS2	Arrhenius (activation energy)												
POWER	Logarithmic												
LINEAR	Linear												
LOGISTIC	Logistic												
READOUT	Specifies the data has the readout structure.												
SCALE= <i>number</i> <SCINIT>	Specifies a fixed or initial value of scale parameter.												
SHAPE= <i>number</i> <SHINIT>	Specifies a fixed or initial value of shape parameter.												
SINGULAR= <i>number</i>	Specifies the singularity criterion for matrix inversion.												
SURVTIME= <i>number-list</i>	Requests that survival function be computed for values in <i>number-list</i> . See the section “ Reliability Function ” on page 1370 for details.												
THRESHOLD= <i>number</i>	Specifies a fixed threshold parameter. See Table 16.57 for the distributions with a threshold parameter.												
<i>variable=number-list</i>	Enables creation of plots of percentiles from a regression model when two independent variables are used in a MODEL statement <i>effect-list</i> . The FIT=REGRESSION option must be used with this option. Percentile plots are created for each value of the independent <i>variable</i> in the <i>number-list</i> . <i>number-list</i> is a list of numeric values separated by blanks or commas, or in the form of a list n_1 to n_2 <by n_3 >.												

Table 16.47 lists plot layout options that are available when you use traditional graphics.

Table 16.47 Plot Layout Options for Traditional Graphics

Option	Option Description
CENSYMBOL= <i>symbol</i> (<i>symbol-list</i>)	Specifies symbols for censored values. The <i>symbol</i> is one of the symbol names (plus, star, square, diamond, triangle, hash, paw, point, dot, circle) or a letter (A–Z). If you are creating overlaid plots for groups of data, you can specify different symbols for the groups with a list of symbols or letters, separated by blanks, enclosed in parentheses. If no CENSYMBOL option is specified, the symbol used for censored values is the same as for failures.
HOFFSET= <i>value</i>	Specifies an offset for horizontal axis.
INBORDER	Requests a border around plots.
LBOXES= <i>number</i>	Specifies a line style for boxplots.
LFIT= <i>linetype</i> (<i>linetype-list</i>)	Specifies line styles for fit lines and confidence curves in a probability plot. The <i>linetype-list</i> is a list of numbers from 1 to 46 representing different linetypes; the numbers can be separated by blanks or commas or can be a list in the form n_1 to n_2 <by n_3 >.
LPLOTFIT= <i>linetype</i> (<i>linetype-list</i>)	Specifies line styles for percentile lines. <i>linetype-list</i> is a list of numbers that represent different linetypes; the numbers can be separated by blanks or commas or can be a list in the form n_1 to n_2 <by n_3 >.
NOCENPLOT	Suppresses plotting of censored data points.
NOCONF	Suppresses plotting of percentile confidence curves.
NOFIT	Suppresses plotting of fit line and percentile confidence curves.
NOFRAME	Suppresses the frame around the plotting area.
NOPPLEND	Suppresses the legend for overlaid probability plots.
NOPPOS	Suppresses plotting of symbols for failures in a probability plot.
NORPLEND	Suppresses the legend for the relation plot.
PINTERVALS= <i>interval-type</i>	Specifies the type of parametric pointwise confidence interval displayed in a probability plot. The available types of intervals are listed in the following table. The default type is PROBABILITY, pointwise confidence intervals on cumulative failure probability.

Table 16.47 Plot Layout Options (continued)

Option	Option Description
Interval Type	Definition
LIKELIHOOD LRCI	Likelihood ratio confidence intervals
PERCENTILES PER	Pointwise parametric confidence intervals for the percentiles of the fitted CDF
PROBABILITY CDF	Pointwise parametric confidence intervals for the cumulative failure probabilities. See the section “ Reliability Function ” on page 1370 for details.
PLOTDATA <DATA MEDIAN BOXES >	Requests that the data be plotted on the relationplot and specifies the representation of the data populations to be plotted.
PLOTFIT <number-list >	Specifies that percentiles of the fitted distribution be plotted on the relation plot. The optional <i>number-list</i> is a list of percentiles (between 0 and 100); if not specified, the 50th percentile (median) is plotted.
PPLEGEND = <i>legend-statement-name</i> NONE	Identifies a LEGEND n statement to specify legend for overlaid probability plots.
PPLOT	Places a probability plot on the same page as the relation plot.
RCENSYMBOL= <i>symbol</i> (<i>symbol-list</i>)	Specifies symbols that represent right-censored and left-censored observations in a relation plot. The <i>symbol</i> is one of the symbol names (plus, star, square, diamond, triangle, hash, paw, point, dot, circle) or a letter (A–Z).
RPLEGEND = <i>legend-statement-name</i> NONE	Identifies a LEGEND n statement to specify legend for the relation plot.
SHOWMULTIPLES	Displays the count for multiple overlaying symbols.
TURNVLABELS	Vertically strings out characters in labels for vertical axis.
VOFFSET= <i>value</i>	Specifies length of offset at upper end of vertical axis.
WFIT= <i>linetype</i>	Specifies line width for fit line and confidence curves.

Table 16.48 lists plot layout options that are available when you use ODS graphics.

Table 16.48 Plot Layout Options for ODS Graphics

Option	Option Description								
NOCENPLOT	Suppresses plotting of censored data points.								
NOCONF	Suppresses plotting of percentile confidence curves.								
NOFIT	Suppresses plotting of fit line and percentile confidence curves.								
NOPPOS	Suppresses plotting of symbols for failures in a probability plot.								
PINTERVALS= <i>interval-type</i>	Specifies the type of parametric pointwise confidence interval displayed in a probability plot. The available types of intervals are listed in the following table. The default type is PROBABILITY, pointwise confidence intervals on cumulative failure probability.								
<table border="1"> <thead> <tr> <th>Interval Type</th> <th>Definition</th> </tr> </thead> <tbody> <tr> <td>LIKELIHOOD LRCI</td> <td>Likelihood ratio confidence intervals</td> </tr> <tr> <td>PERCENTILES PER</td> <td>Pointwise parametric confidence intervals for the percentiles of the fitted CDF</td> </tr> <tr> <td>PROBABILITY CDF</td> <td>Pointwise parametric confidence intervals for the cumulative failure probabilities. See the section “Reliability Function” on page 1370 for details.</td> </tr> </tbody> </table>		Interval Type	Definition	LIKELIHOOD LRCI	Likelihood ratio confidence intervals	PERCENTILES PER	Pointwise parametric confidence intervals for the percentiles of the fitted CDF	PROBABILITY CDF	Pointwise parametric confidence intervals for the cumulative failure probabilities. See the section “Reliability Function” on page 1370 for details.
Interval Type	Definition								
LIKELIHOOD LRCI	Likelihood ratio confidence intervals								
PERCENTILES PER	Pointwise parametric confidence intervals for the percentiles of the fitted CDF								
PROBABILITY CDF	Pointwise parametric confidence intervals for the cumulative failure probabilities. See the section “Reliability Function” on page 1370 for details.								
PLOTDATA	Requests that the data be plotted on the relationplot.								
PLOTFIT < <i>number-list</i> >	Specifies that percentiles of the fitted distribution be plotted on the relation plot. The optional <i>number-list</i> is a list of percentiles (between 0 and 100); if not specified, the 50th percentile (median) is plotted.								
P PLOT	Places a probability plot on the same page as the relation plot.								

Table 16.49 lists reference line options that are available when you use traditional graphics.

Table 16.49 Reference Line Options for Traditional Graphics

Option	Option Description														
HREF <(INTERSECT) >= <i>value-list</i>	Requests reference lines perpendicular to horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value.														
HREFLABELS=(<i>'label1' ... 'labeln'</i>)	Specifies labels for HREF= lines.														
HREFLABPOS= <i>n</i>	Specifies the vertical position of labels for HREF= lines. The valid values for <i>n</i> and the corresponding label placements are shown in the following table:														
	<table border="1"> <thead> <tr> <th><i>n</i></th> <th>Label Placement</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>Top</td> </tr> <tr> <td>2</td> <td>Staggered from top</td> </tr> <tr> <td>3</td> <td>Bottom</td> </tr> <tr> <td>4</td> <td>Staggered from bottom</td> </tr> <tr> <td>5</td> <td>Alternating from top</td> </tr> <tr> <td>6</td> <td>Alternating from bottom</td> </tr> </tbody> </table>	<i>n</i>	Label Placement	1	Top	2	Staggered from top	3	Bottom	4	Staggered from bottom	5	Alternating from top	6	Alternating from bottom

Table 16.49 Reference Line Options (continued)

Option	Option Description						
VREF <(INTERSECT) >= <i>value-list</i>	Requests reference lines perpendicular to vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value.						
VREFLABELS=(<i>'label1' ... 'labeln'</i>)	Specifies labels for VREF= lines.						
VREFLABPOS= <i>n</i>	Specifies the horizontal position of labels for VREF= lines. The valid values for <i>n</i> and the corresponding label placements are shown in the following table:						
	<table border="1"> <thead> <tr> <th><i>n</i></th> <th>Label Placement</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>Left</td> </tr> <tr> <td>2</td> <td>Right</td> </tr> </tbody> </table>	<i>n</i>	Label Placement	1	Left	2	Right
<i>n</i>	Label Placement						
1	Left						
2	Right						

Table 16.50 lists reference line options that are available when you use ODS graphics.

Table 16.50 Reference Line Options for ODS Graphics

Option	Option Description
PREF <(INTERSECT) >= <i>value-list</i>	Requests reference lines perpendicular to probability axis, if a probability plot is specified with the PLOT option. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value.
PREFLABELS=(<i>'label1' ... 'labeln'</i>)	Specifies labels for PREF= lines.
SREF= <i>value-list</i>	Specifies reference lines perpendicular to horizontal stress axis.
SREFLABELS=(<i>'label1' ... 'labeln'</i>)	Specifies labels for SREF= lines.

Table 16.50 Reference Line Options (continued)

Option	Option Description
LREF < (INTERSECT) >= <i>value-list</i>	Requests reference lines perpendicular to vertical (lifetime) axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value.
LREFLABELS=(<i>'label1' ... 'labeln'</i>)	Specifies labels for LREF= lines.

Table 16.51 lists options that control the appearance of the text when you use traditional graphics. These options are not available if ODS Graphics is enabled.

Table 16.51 Text Enhancement Options

Option	Option Description
FONT= <i>font</i>	Specifies a software font for text.
HEIGHT= <i>value</i>	Specifies the height of text used outside framed areas.
INFONT= <i>font</i>	Specifies a software font for text inside framed areas.
INHEIGHT= <i>value</i>	Specifies the height of text inside framed areas.

Table 16.52 lists options that control the appearance of the axes when you use traditional graphics.

Table 16.52 Axis Options for Traditional Graphics

Option	Option Description
LAXIS= <i>value1</i> TO <i>value2</i> < BY <i>value3</i> >	<p>Specifies tick mark values for the lifetime axis. <i>value1</i>, <i>value2</i>, and <i>value3</i> must be numeric, and <i>value1</i> must be less than <i>value2</i>. The lower tick mark is <i>value1</i>. Tick marks are drawn at increments of <i>value3</i>. The last tick mark is the greatest value that does not exceed <i>value2</i>. If <i>value3</i> is omitted, a value of 1 is used. This method of specification of tick marks is not valid for logarithmic axes. Examples of LAXIS= lists are</p> <pre data-bbox="883 695 1214 747"> laxis = -1 to 10 laxis = 0 to 200 by 10 </pre>
LGRID= <i>number</i>	<p>Specifies a line style for all grid lines. The <i>number</i> is between 1 and 46 and specifies a linestyle for grids.</p>
LIFELOWER LLOWER= <i>number</i>	<p>Specifies the lower limit on the lifetime axis scale. The LLOWER option specifies <i>number</i> as the lower lifetime axis tick mark. The tick interval and the upper lifetime axis limit are determined automatically. This option has no effect if the LAXIS option is used.</p>
LIFEUPPER LUPPER= <i>number</i>	<p>Specifies the upper limit on the lifetime axis scale. The LUPPER option specifies <i>number</i> as the upper lifetime axis tick mark. The tick interval and the lower lifetime axis limit are determined automatically. This option has no effect if the LAXIS option is used.</p>
MPGRID	<p>Adds a minor grid for the probability axis.</p>
MINORLOGGRID	<p>Adds a minor grid for log axes.</p>
NOGRID	<p>Suppresses grid lines.</p>
NOLLABEL	<p>Suppresses the label for the lifetime axis.</p>
NOLTICK	<p>Suppresses tick marks and tick mark labels for lifetime or analysis variable axis.</p>
NOPLABEL	<p>Suppresses the label for the probability axis.</p>
NOPTICK	<p>Suppresses tick marks and tick mark labels for probability axis.</p>
NOSLABEL	<p>Suppresses the label for the stress axis.</p>
NOSTICK	<p>Suppresses tick marks and tick mark labels for stress axis.</p>

Table 16.52 Axis Options (continued)

Option	Option Description
NSTRESSTICK= <i>number</i>	Specifies the number of tick intervals for stress axis for relation plot.
NTICK= <i>number</i>	Specifies the number of tick intervals for the lifetime axis. This option has no effect if the LAXIS option is used.
PCTLOWER PLOWER= <i>number</i>	Specifies the lower limit on the probability axis scale.
PCTUPPER PUPPER= <i>number</i>	Specifies the upper limit on the probability axis scale.
STRESSLOWER SLOWER= <i>number</i>	Specifies the lower limit on the stress axis scale.
STRESSUPPER SUPPER= <i>number</i>	Specifies the upper limit on the stress axis scale.
PAXISLABEL='string'	Specifies a label for the probability axis.
WAXIS= <i>n</i>	Specifies the line thickness for axes and frame.

Table 16.53 lists options that control the appearance of the axes when you use ODS Graphics.

Table 16.53 Axis Options for ODS Graphics

Option	Option Description
LIFELOWER LLOWER= <i>number</i>	Specifies the lower limit on the lifetime axis scale. The LLOWER option specifies <i>number</i> as the lower lifetime axis tick mark. The tick interval and the upper lifetime axis limit are determined automatically. This option has no effect if the LAXIS option is used.
LIFEUPPER LUPPER= <i>number</i>	Specifies the upper limit on the lifetime axis scale. The LUPPER option specifies <i>number</i> as the upper lifetime axis tick mark. The tick interval and the lower lifetime axis limit are determined automatically. This option has no effect if the LAXIS option is used.
NOGRID	Suppresses grid lines.
PCTLOWER PLOWER= <i>number</i>	Specifies lower the limit on the probability axis scale.
PCTUPPER PUPPER= <i>number</i>	Specifies upper the limit on the probability axis scale.
STRESSLOWER SLOWER= <i>number</i>	Specifies the lower limit on the stress axis scale.
STRESSUPPER SUPPER= <i>number</i>	Specifies the upper limit on the stress axis scale.

Table 16.53 Axis Options (continued)

Option	Option Description
PAXISLABEL= <i>'string'</i>	Specifies a label for the probability axis.

Table 16.54 lists options that control the use of a graphics catalog to store graphs if you use traditional graphics. These options are not available if ODS Graphics is enabled.

Table 16.54 Graphics Catalog Options

Option	Option Description
DESCRIPTION= <i>'string'</i>	Description for graphics catalog member
NAME= <i>'string'</i>	Name for plot in graphics catalog

Table 16.55 lists options that control colors and patterns used in the graph when you use traditional graphics. These options are not available if ODS Graphics is enabled.

Table 16.55 Color and Pattern Options

Option	Option Description
CAXIS= <i>color</i>	Color for axis
CBOXES= <i>color</i>	Color for box frame for boxplots
CBOXFILL= <i>color</i>	Color for filling boxes for boxplots
CCENSOR= <i>color</i>	Color for filling censor plot area
CENCOLOR= <i>color</i>	Color for censor symbol
CFIT= <i>color</i> (<i>color-list</i>)	color for fit lines and confidence curves in a probability plot
CFRAME= <i>color</i>	Color for frame
CGRID= <i>color</i>	Color for grid lines
CHREF= <i>color</i>	Color for HREF= lines
CPLOTFIT= <i>color</i> (<i>color-list</i>)	colors for percentile lines
CSREF= <i>color</i>	Color for SREF= lines
CTEXT= <i>color</i>	Color for text
CVREF= <i>color</i>	Color for VREF= lines
RCENCOLOR= <i>color</i> (<i>color-list</i>)	Colors for the symbols representing uncensored, right-censored, and left-censored observations in a relation plot

SLICE Statement

```
SLICE model-effect </ options > ;
```

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the LSMEANS statement, which are summarized in Table 19.21 (*SAS/STAT User's Guide*). For details about the syntax of the SLICE statement, see the section “SLICE Statement” (Chapter 19, *SAS/STAT User's Guide*) in Chapter 19, “Shared Concepts and Topics” (*SAS/STAT User's Guide*).

STORE Statement

STORE <OUT= >item-store-name </ LABEL='label'> ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “STORE Statement” (Chapter 19, *SAS/STAT User's Guide*) in Chapter 19, “Shared Concepts and Topics” (*SAS/STAT User's Guide*).

TEST Statement

TEST <model-effects> </ options> ;

The TEST statement enables you to perform F tests for model effects that test Type I, Type II, or Type III hypotheses. See Chapter 15, “The Four Types of Estimable Functions” (*SAS/STAT User's Guide*), for details about the construction of Type I, II, and III estimable functions.

Table 16.56 summarizes the options available in the TEST statement.

Table 16.56 TEST Statement Options

Option	Description
CHISQ	Requests chi-square tests
DDF=	Specifies denominator degrees of freedom for fixed effects
E	Requests Type I, Type II, and Type III coefficients
E1	Requests Type I coefficients
E2	Requests Type II coefficients
E3	Requests Type III coefficients
HTYPE=	Indicates the type of hypothesis test to perform
INTERCEPT	Adds a row that corresponds to the overall intercept

For details about the syntax of the TEST statement, see the section “TEST Statement” (Chapter 19, *SAS/STAT User's Guide*) in Chapter 19, “Shared Concepts and Topics” (*SAS/STAT User's Guide*).

UNITID Statement

UNITID *variable* ;

The UNITID statement names a *variable* in the input data set that is used to identify each individual unit in an MCFPLOT statement. The value of the UNITID variable for an observation corresponds to the name of the unit in the study for which a repair or end of history has occurred. See the section “Analysis of Recurrence Data on Repairs” on page 1253 for an example that uses the UNITID statement with the MCFPLOT statement.

Details: RELIABILITY Procedure

Abbreviations and Notation

The following abbreviations and notation are used in this section:

CDF	Cumulative distribution function: $F(x) = Pr\{X \leq x\}$
log	Base e logarithm
\log_{10}	Base 10 logarithm
Reliability or survivor function	$R(x) = Pr\{X > x\}$
x_p	$p \times 100\%$ percentile: $Pr\{X \leq x_p\} = p$

Types of Lifetime Data

This section describes various types of data that you can analyze with the RELIABILITY procedure.

Lifetime data for which the values of all sample units are observed are called *complete* data. This means that the failure times are observed for all units.

Many practical problems in life data analysis involve data for which some units are unfailed. The failure time for an unfailed unit is known only to be greater than the last running time. This type of data is said to be *right censored*, and the censoring time is used in the analysis of the data. Data for which censoring times are intermixed with failure times are sometimes called *multiply censored* or *progressively censored*.

Failure times may be known only to be less than some value. This type of data is called *left censored*.

Another common situation is where the failure times of units are not known exactly, but time intervals that contain the failure times are known. This type of data is called *interval censored*.

Interval-censored data for which all units share common interval endpoints are called *readout*, *inspection*, or *grouped* data.

Arbitrarily censored data can contain a combination of failures, right-, left-, and interval-censored data.

Probability Distributions

This section describes the probability distributions available in the RELIABILITY procedure for probability plotting and parameter estimation.

PROBPLOT and RELATIONPLOT Statements

Probability plots can be constructed for each of the probability distributions in Table 16.57. For all distributions other than the three-parameter Weibull, estimates of two distribution parameters (*location* and *scale* or *scale* and *shape*) are computed by maximum likelihood or by least squares fitted to points on the probability plot. If one of the parameters is specified as fixed, the other is estimated. In addition, you can specify a fixed *threshold*, or *shift*, parameter for those distributions for which a threshold parameter is indicated in Table 16.57. If you do not specify a threshold parameter, the threshold is set to 0.

For the three-parameter Weibull distribution described in Table 16.57, the scale, shape, and threshold parameters are estimated by maximum likelihood.

You should not interpret the parameters μ and σ as representing the means and standard deviations for all of the distributions in Table 16.57. The normal is the only distribution in Table 16.57 for which this is the case.

Table 16.57 Distributions and Parameters for PROBPLOT and RELATIONPLOT Statements

Distribution	Density Function	Location	Parameters		
			Scale	Shape	Threshold
Normal	$\frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$	μ	σ		
Lognormal	$\frac{1}{\sqrt{2\pi}\sigma(x-\theta)} \exp\left(-\frac{(\log(x-\theta)-\mu)^2}{2\sigma^2}\right)$	μ	σ		θ
Lognormal (base 10)	$\frac{\log(10)}{\sqrt{2\pi}\sigma(x-\theta)} \exp\left(-\frac{(\log_{10}(x-\theta)-\mu)^2}{2\sigma^2}\right)$	μ	σ		θ
Extreme value	$\frac{1}{\sigma} \exp\left(\frac{x-\mu}{\sigma}\right) \exp\left(-\exp\left(\frac{x-\mu}{\sigma}\right)\right)$	μ	σ		
Weibull	$\frac{\beta}{\alpha^\beta} (x-\theta)^{\beta-1} \exp\left(-\left(\frac{x-\theta}{\alpha}\right)^\beta\right)$		α	β	θ
Exponential	$\frac{1}{\alpha} \exp\left(-\left(\frac{x-\theta}{\alpha}\right)\right)$		α		θ
Logistic	$\frac{\exp\left(\frac{x-\mu}{\sigma}\right)}{\sigma\left[1+\exp\left(\frac{x-\mu}{\sigma}\right)\right]^2}$	μ	σ		
Log-logistic	$\frac{\exp\left(\frac{\log(x-\theta)-\mu}{\sigma}\right)}{(x-\theta)\sigma\left[1+\exp\left(\frac{\log(x-\theta)-\mu}{\sigma}\right)\right]^2}$	μ	σ		θ
Three-parameter Weibull	$\frac{\beta}{\alpha^\beta} (x-\theta)^{\beta-1} \exp\left(-\left(\frac{x-\theta}{\alpha}\right)^\beta\right)$		α	β	θ

The exponential distribution shown in Table 16.57 is a special case of the Weibull distribution with $\beta = 1$. The remaining distributions in Table 16.57 are related to one another as shown in Table 16.58. The threshold parameter, θ , is assumed to be 0 in Table 16.58.

Table 16.58 Relationship among Life Distributions

Distribution of T	Parameters	Distribution of Y=logT	Parameters
Lognormal	$\mu \quad \sigma$	Normal	$\mu \quad \sigma$
Weibull	$\alpha \quad \beta$	Extreme value	$\mu = \log \alpha \quad \sigma = \frac{1}{\beta}$
Log-logistic	$\mu \quad \sigma$	Logistic	$\mu \quad \sigma$

MODEL Statement

All of the distributions in [Table 16.57](#) except the three-parameter Weibull are available for regression model estimation by using the MODEL statement. In addition, you can fit regression models with the generalized gamma distribution with the following probability density function $f(t)$:

$$f(t) = \frac{|\lambda|}{t\sigma\Gamma(\lambda^{-2})}(\lambda^{-2})^{(\lambda^{-2})} \exp \left[\lambda^{-2} \left(\lambda \left(\frac{\log(t) - \mu}{\sigma} \right) - \exp \left(\lambda \left(\frac{\log(t) - \mu}{\sigma} \right) \right) \right) \right]$$

If a lifetime T has the generalized gamma distribution, then the logarithm of the lifetime $X = \log(T)$ has the generalized log-gamma distribution, with the following probability density function $g(x)$. When the gamma distribution is specified, the logarithms of the lifetimes are used as responses, and the generalized log-gamma distribution is used to estimate the parameters by maximum likelihood.

$$g(x) = \frac{|\lambda|}{\sigma\Gamma(\lambda^{-2})}(\lambda^{-2})^{(\lambda^{-2})} \exp \left[\lambda^{-2} \left(\lambda \left(\frac{x - \mu}{\sigma} \right) - \exp \left(\lambda \left(\frac{x - \mu}{\sigma} \right) \right) \right) \right]$$

See Lawless (2003) and Meeker and Escobar (1998) for a description of the generalized gamma and generalized log-gamma distributions.

When $\lambda = 1$, the generalized log-gamma distribution reduces to the extreme value distribution with parameters μ and σ . In this case, the log lifetimes have the extreme value distribution, or, equivalently, the lifetimes have the Weibull distribution with parameters $\alpha = \exp(\mu)$ and $\beta = 1/\sigma$. When $\lambda = 0$, the generalized log-gamma reduces to the normal distribution with parameters μ and σ . In this case, the (unlogged) lifetimes have the lognormal distribution with parameters μ and σ . This chapter uses the notation μ for the *location*, σ for the *scale*, and λ for the *shape* parameters for the generalized log-gamma distribution.

ANALYZE Statement

You can use the ANALYZE statement to compute parameter estimates and other statistics for the distributions in [Table 16.57](#). In addition, you can compute estimates for the binomial and Poisson distributions. The forms of these distributions are shown in [Table 16.59](#).

Table 16.59 Binomial and Poisson Distributions

Distribution	$\Pr\{Y=y\}$	Parameter	Parameter Name
Binomial	$\binom{n}{y} p^y (1-p)^{n-y}$	p	binomial probability
Poisson	$\frac{\mu^y}{y!} \exp(-\mu)$	μ	Poisson mean

Probability Plotting

Probability plots are useful tools for the display and analysis of lifetime data. See Abernethy (2006) for examples that use probability plots in the analysis of reliability data. Probability plots use a special scale so that a cumulative distribution function (CDF) plots as a straight line. Thus, if lifetime data are a sample from a distribution, the CDF estimated from the data plots approximately as a straight line on a probability plot for the distribution.

You can use the RELIABILITY procedure to construct probability plots for data that are complete, right censored, or interval censored (in readout form) for each of the probability distributions in Table 16.57.

A random variable Y belongs to a *location-scale* family of distributions if its CDF F is of the form

$$Pr\{Y \leq y\} = F(y) = G\left(\frac{y - \mu}{\sigma}\right)$$

where μ is the location parameter, and σ is the scale parameter. Here, G is a CDF that cannot depend on any unknown parameters, and G is the CDF of Y if $\mu = 0$ and $\sigma = 1$. For example, if Y is a normal random variable with mean μ and standard deviation σ ,

$$G(u) = \Phi(u) = \int_{-\infty}^u \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{u^2}{2}\right) du$$

and

$$F(y) = \Phi\left(\frac{y - \mu}{\sigma}\right)$$

Of the distributions in Table 16.57, the normal, extreme value, and logistic distributions are location-scale models. As shown in Table 16.58, if T has a lognormal, Weibull, or log-logistic distribution, then $\log(T)$ has a distribution that is a location-scale model. Probability plots are constructed for lognormal, Weibull, and log-logistic distributions by using $\log(T)$ instead of T in the plots.

Let $y_{(1)} \leq y_{(2)} \leq \dots \leq y_{(n)}$ be ordered observations of a random sample with distribution function $F(y)$. A probability plot is a plot of the points $y_{(i)}$ against $m_i = G^{-1}(a_i)$, where $a_i = \hat{F}(y_i)$ is an estimate of the CDF $F(y_{(i)}) = G\left(\frac{y_{(i)} - \mu}{\sigma}\right)$. The points a_i are called *plotting positions*. The axis on which the points m_i s are plotted is usually labeled with a probability scale (the scale of a_i).

If F is one of the location-scale distributions, then y is the lifetime; otherwise, the log of the lifetime is used to transform the distribution to a location-scale model.

If the data actually have the stated distribution, then $\hat{F} \approx F$,

$$m_i = G^{-1}(\hat{F}(y_i)) \approx G^{-1}\left(G\left(\frac{y_{(i)} - \mu}{\sigma}\right)\right) = \frac{y_{(i)} - \mu}{\sigma}$$

and points $(y_{(i)}, m_i)$ should fall approximately on a straight line.

There are several ways to compute plotting positions from failure data. These are discussed in the next two sections.

Complete and Right-Censored Data

The censoring times must be taken into account when you compute plotting positions for right-censored data. The RELIABILITY procedure provides several methods for computing plotting positions. These are specified with the PPOS= option in the ANALYZE, PROBLOT, and RELATIONPLOT statements. All of the methods give similar results, as illustrated in the section “Expected Ranks, Kaplan-Meier, and Modified Kaplan-Meier Methods” on page 1351, the section “Nelson-Aalen” on page 1353, and the section “Median Ranks” on page 1353.

Expected Ranks, Kaplan-Meier, and Modified Kaplan-Meier Methods

Let $y_{(1)} \leq y_{(2)} \leq \dots \leq y_{(n)}$ be ordered observations of a random sample including failure times and censor times. Order the data in increasing order. Label all the data with reverse ranks r_i , with $r_1 = n, \dots, r_n = 1$. For the failure corresponding to reverse rank r_i , compute the reliability, or survivor function estimate

$$R_i = \left[\frac{r_i}{r_i + 1} \right] R_{i-1}$$

with $R_0 = 1$. The expected rank plotting position is computed as $a_i = 1 - R_i$. The option PPOS=EXPRANK specifies the expected rank plotting position.

For the Kaplan-Meier method,

$$R_i = \left[\frac{r_i - 1}{r_i} \right] R_{i-1}$$

The Kaplan-Meier plotting position is then computed as $a'_i = 1 - R_i$. The option PPOS=KM specifies the Kaplan-Meier plotting position.

For the modified Kaplan-Meier method, use

$$R'_i = \frac{R_i + R_{i-1}}{2}$$

where R_i is computed from the Kaplan-Meier formula with $R_0 = 1$. The plotting position is then computed as $a''_i = 1 - R'_i$. The option PPOS=MKM specifies the modified Kaplan-Meier plotting position. If the PPOS option is not specified, the modified Kaplan-Meier plotting position is used as the default method.

For complete samples, $a_i = i/(n+1)$ for the expected rank method, $a'_i = i/n$ for the Kaplan-Meier method, and $a''_i = (i - .5)/n$ for the modified Kaplan-Meier method. If the largest observation is a failure for the Kaplan-Meier estimator, then $F_n = 1$ and the point is not plotted. These three methods are shown for the field winding data in Table 16.60 and Table 16.61.

Nelson-Aalen

Estimate the cumulative hazard function by

$$H_i = \frac{1}{r_i} + H_{i-1}$$

with $H_0 = 0$. The reliability is $R_i = \exp(-H_i)$, and the plotting position, or CDF, is $a_i''' = 1 - R_i$. You can show that $R_{KM} < R_{NA}$ for all ages. The Nelson-Aalen method is shown for the field winding data in Table 16.62.

Median Ranks

See Abernethy (2006) for a discussion of the methods described in this section. Let $y_{(1)} \leq y_{(2)} \leq \dots \leq y_{(n)}$ be ordered observations of a random sample including failure times and censor times. A failure order number j_i is assigned to the i th failure: $j_i = j_{i-1} + \Delta$, where $j_0 = 0$. The increment Δ is initially 1 and is modified when a censoring time is encountered in the ordered sample. The new increment is computed as

$$\Delta = \frac{(n + 1) - \text{previous failure order number}}{1 + \text{number of items beyond previous censored item}}$$

The plotting position is computed for the i th failure time as

$$a_i = \frac{j_i - .3}{n + .4}$$

For complete samples, the failure order number j_i is equal to i , the order of the failure in the sample. In this case, the preceding equation for a_i is an approximation to the median plotting position computed as the median of the i th-order statistic from the uniform distribution on (0, 1). In the censored case, j_i is not necessarily an integer, but the preceding equation still provides an approximation to the median plotting position. The PPOS=MEDRANK option specifies the median rank plotting position.

For complete data, an alternative method of computing the median rank plotting position for failure i is to compute the exact median of the distribution of the i th order statistic of a sample of size n from the uniform distribution on (0,1). If the data are right censored, the adjusted rank j_i , as defined in the preceding paragraph, is used in place of i in the computation of the median rank. The PPOS=MEDRANK1 option specifies this type of plotting position.

Nelson (1982, p. 148) provides the following example of multiply right-censored failure data for field windings in electrical generators. Table 16.63 shows the data, the intermediate calculations, and the plotting positions calculated by exact (a'_i) and approximate (a_i) median ranks.

Table 16.63 Median Rank Plotting Position Calculations

Interval-Censored Data

Readout Data

The RELIABILITY procedure can create probability plots for interval-censored data when all units share common interval endpoints. This type of data is called *readout* data in the RELIABILITY procedure. Estimates of the cumulative distribution function are computed at times corresponding to the interval endpoints. Right censoring can also be accommodated if the censor times correspond to interval endpoints. See the section “Weibull Analysis of Interval Data with Common Inspection Schedule” on page 1228 for an example of a Weibull plot and analysis for interval data.

Table 16.64 illustrates the computational scheme used to compute the CDF estimates. The data are failure data for microprocessors (Nelson 1990, p. 147). In Table 16.64, t_i are the interval upper endpoints, in hours, f_i is the number of units failing in interval i , and n_i is the number of unfailed units at the beginning of interval i .

Note that there is right censoring as well as interval censoring in these data. For example, two units fail in the interval (24, 48) hours, and there are 1414 unfailed units at the beginning of the interval, 24 hours. At the beginning of the next interval, (48, 168) hours, there are 573 unfailed units. The number of unfailed units that are removed from the test at 48 hours is $1414 - 2 - 573 = 839$ units. These are right-censored units.

The reliability at the end of interval i is computed recursively as

$$R_i = (1 - (f_i/n_i))R_{i-1}$$

with $R_0 = 1$. The plotting position is $a_i = 1 - R_i$.

Table 16.64 Interval-Censored Plotting Position Calculations

Interval i	Interval Endpoint t_i	f_i/n_i	$R'_i =$ $1 - (f_i/n_i)$	$R_i =$ $R'_i R_{i-1}$	$a_i = 1 - R_i$
1	6	6/1423	0.99578	0.99578	.00421
2	12	2/1417	0.99859	0.99438	.00562

4	48	2/1414	0.99859	0.99297	.00703
5	168	1/573	0.99825	0.99124	.00876
6	500	1/422	0.99763	0.98889	.01111
7	1000	2/272	0.99265	0.98162	.01838
8	2000	1/123	0.99187	0.97364	.02636

Arbitrarily Censored Data

The RELIABILITY procedure can create probability plots for data that consists of combinations of exact, left-censored, right-censored, and interval-censored lifetimes. Unlike the method in the previous section, failure intervals need not share common endpoints, although if the intervals share common endpoints, the two methods give the same results. The RELIABILITY procedure uses an iterative algorithm developed by Turnbull (1976) to compute a nonparametric maximum likelihood estimate of the cumulative distribution function for the data. Since the technique is maximum likelihood, standard errors of the cumulative probability estimates are computed from the inverse of the associated Fisher information matrix. A technique developed by Gentleman and Geyer (1994) is used to check for convergence to the maximum likelihood estimate. Also see Meeker and Escobar (1998, chap. 3) for more information.

Although this method applies to more general situations, where the intervals may be overlapping, the example of the previous section will be used to illustrate the method. Table 16.65 contains the microprocessor data of the previous section, arranged in intervals. A missing (.) lower endpoint

indicates left censoring, and a missing upper endpoint indicates right censoring. These can be thought of as semi-infinite intervals with lower (upper) endpoint of negative (positive) infinity for left (right) censoring.

The nonparametric maximum likelihood estimate of the CDF can only increase on certain intervals, and must remain constant between the intervals. The Turnbull algorithm first computes the intervals on which the nonparametric maximum likelihood estimate of the CDF can increase. The algorithm then iteratively estimates the probability associated with each interval. The ITPRINTEM option along with the PRINTPROBS option instructs the procedure to print the intervals on which probability increases can occur and the iterative history of the estimates of the interval probabilities. The PPOUT option requests tabular output of the estimated CDF, standard errors, and confidence limits for each cumulative probability.

Figure 16.54 shows every 25th iteration and the last iteration for the Turnbull estimate of the CDF for the microprocessor data. The initial estimate assigns equal probabilities to each interval. You can specify different initial values with the PROBLIST= option. The algorithm converges in 130 iterations for this data. Convergence is determined if the change in the loglikelihood between two successive iterations less than Δ , where the default value is $\Delta = 10^{-8}$. You can specify a different value for delta with the TOLLIKE= option. This algorithm is an example of an expectation-maximization (EM) algorithm. EM algorithms are known to converge slowly, but the computations within each iteration for the Turnbull algorithm are moderate. Iterations will be terminated if the algorithm does not converge after a fixed number of iterations. The default maximum number of iterations is 1000. Some data may require more iterations for convergence. You can specify the maximum allowed number of iterations with the MAXITEM= option in the PROBPLOT, ANALYZE, or RPLOT statement.

If an interval probability is smaller than a tolerance (10^{-6} by default) after convergence, the probability is set to zero, the interval probabilities are renormalized so that they add to one, and iterations

are restarted. Usually the algorithm converges in just a few more iterations. You can change the default value of the tolerance with the TOLPROB= option. You can specify the NOPOLISH option to avoid setting small probabilities to zero and restarting the algorithm.

If you specify the ITPRINTEM option, the table in Figure 16.55 summarizing the Turnbull estimate of the interval probabilities is printed. The columns labeled 'Reduced Gradient' and 'Lagrange Multiplier' are used in checking final convergence to the maximum likelihood estimate. The Lagrange multipliers must all be greater than or equal to zero, or the solution is not maximum likelihood. See Gentleman and Geyer (1994) for more details of the convergence checking.

Nonparametric Confidence Intervals for Cumulative Failure Probabilities

The method used in the RELIABILITY procedure for computation of approximate pointwise and simultaneous confidence intervals for cumulative failure probabilities relies on the Kaplan-Meier estimator of the cumulative distribution function of failure time and approximate standard deviation of the Kaplan-Meier estimator. For the case of arbitrarily censored data, the Turnbull algorithm, discussed previously, provides an extension of the Kaplan-Meier estimator.

For multiply censored data, the Kaplan-Meier estimator of the cumulative distribution function at failure time t_i is $\hat{F}(t_i) = 1 - \hat{S}(t_i)$, where

$$\hat{S}(t_i) = \prod_{j=1}^i (1 - \hat{p}_j),$$

$$\hat{p}_i = \frac{d_i}{n_i},$$

d_i is the number of failures in the interval (t_{i-1}, t_i) , and n_i is the number of unfailed units at the beginning of the interval. This definition of the Kaplan-Meier estimator is equivalent to the one previously given.

An estimator of the variance v_i of the Kaplan-Meier estimator $\hat{F}(t_i)$ is given by

$$\hat{v}_i = [\hat{S}(t_i)]^2 \sum_{j=1}^i \frac{\hat{p}_j}{n_j(1 - \hat{p}_j)}$$

An estimator of the standard deviation of $\hat{F}(t_i)$ is $se_{\hat{F}} = \sqrt{\hat{v}_i}$.

For arbitrarily censored data, the Kaplan-Meier estimator is replaced by the nonparametric maximum likelihood estimator computed with the Turnbull algorithm, and the approximate variance of the estimator of $F(t_i)$ is computed from the inverse of the Fisher information matrix.

Pointwise Confidence Intervals

Approximate $(1 - \alpha)100\%$ pointwise confidence intervals are computed as in Meeker and Escobar (1998, section 3.6) as

$$[F_L, F_U] = \left[\frac{\hat{F}}{\hat{F} + (1 - \hat{F})w}, \frac{\hat{F}}{\hat{F} + (1 - \hat{F})/w} \right]$$

where

$$w = \exp \left[\frac{z_{1-\alpha/2} se_{\hat{F}}}{(\hat{F}(1 - \hat{F}))} \right]$$

where z_p is the p th quantile of the standard normal distribution.

Simultaneous Confidence Intervals

Approximate $(1 - \alpha)100\%$ simultaneous confidence bands valid over the lifetime interval (t_a, t_b) are computed as the “Equal Precision” case of Nair (1984) and Meeker and Escobar (1998, section 3.8)

$$[F_L, F_U] = \left[\frac{\hat{F}}{\hat{F} + (1 - \hat{F})w}, \frac{\hat{F}}{\hat{F} + (1 - \hat{F})/w} \right]$$

where

$$w = \exp \left[\frac{e_{a,b,1-\alpha/2} \widehat{F}}{(\widehat{F}(1-\widehat{F}))} \right]$$

where the factor $x = e_{a,b,1-\alpha/2}$ is the solution of

$$x \exp(-x^2/2) \log \left[\frac{(1-a)b}{(1-b)a} \right] / \sqrt{8\pi} = \alpha/2$$

The time interval (t_a, t_b) over which the bands are valid depends in a complicated way on the constants a and b defined in Nair (1984), $0 < a < b < 1$. a and b are chosen by default, so that the confidence bands are valid between the lowest and highest times corresponding to failures in the case of multiply censored data, or, to the lowest and highest intervals for which probabilities are computed for arbitrarily censored data. You can optionally specify a and b directly with the NPINTERVALS=SIMULTANEOUS(a,b) option in the PROBPLOT statement.

Parameter Estimation and Confidence Intervals

Maximum Likelihood Estimation

Maximum likelihood estimation of the parameters of a statistical model involves maximizing the likelihood or, equivalently, the log likelihood with respect to the parameters. The parameter values at which the maximum occurs are the maximum likelihood estimates of the model parameters. The likelihood is a function of the parameters and of the data.

Let x_1, x_2, \dots, x_n be the observations in a random sample, including the failures and censoring times (if the data are censored). Let $f(\boldsymbol{\theta}; x)$ be the probability density of failure time, $S(\boldsymbol{\theta}; x) = Pr\{X \geq x\}$ be the reliability function, and $F(\boldsymbol{\theta}; x) = Pr\{X \leq x\}$ be the cumulative distribution function, where $\boldsymbol{\theta}$ is the vector of parameters to be estimated, $\boldsymbol{\theta} = (\theta_1, \theta_2, \dots, \theta_p)$. The probability density, reliability function, and CDF are determined by the specific distribution selected as a model for the data. The log likelihood is defined as

$$L(\cdot) = \sum_i \log(f(\boldsymbol{\theta}; x_i)) + \sum_i' \log(S(\boldsymbol{\theta}; x_i)) + \sum_i'' \log(F(\boldsymbol{\theta}; x_i)) + \sum_i''' [\log(F(\boldsymbol{\theta}; x_{ui}) - F(\boldsymbol{\theta}; x_{li}))]$$

where

- \sum is the sum over failed units
- \sum' is the sum over right-censored units
- \sum'' is the sum over left-censored units

- \sum''' is the sum over interval-censored units

and (x_{li}, x_{ui}) is the interval in which the i th unit is interval censored. Only the sums appropriate to the type of censoring in the data are included when the preceding equation is used.

The RELIABILITY procedure maximizes the log likelihood with respect to the parameters θ by using a Newton-Raphson algorithm. The Newton-Raphson algorithm is a recursive method for computing the maximum of a function. On the r th iteration, the algorithm updates the parameter vector θ_r with

$$\theta_{r+1} = \theta_r - \mathbf{H}^{-1}\mathbf{g}$$

where \mathbf{H} is the Hessian (second derivative) matrix, and \mathbf{g} is the gradient (first derivative) vector of the log-likelihood function, both evaluated at the current value of the parameter vector. That is,

$$\mathbf{g} = [g_j] = \left[\frac{\partial L}{\partial \theta_j} \right] \Big|_{\theta = \theta_r}$$

and

$$\mathbf{H} = [h_{ij}] = \left[\frac{\partial^2 L}{\partial \theta_i \partial \theta_j} \right] \Big|_{\theta = \theta_r}$$

Iteration continues until the parameter estimates converge. The convergence criterion is

$$|\theta_i^{r+1} - \theta_i^r| \leq c \quad \text{if } |\theta_i^{r+1}| < 0.01$$

$$\left| \frac{\theta_i^{r+1} - \theta_i^r}{\theta_i^{r+1}} \right| \leq c \quad \text{if } |\theta_i^{r+1}| \geq 0.01$$

for all $i = 1, 2, \dots, p$ where c is the convergence criterion. The default value of c is 0.001, and it can be specified with the CONVERGE= option in the MODEL, PROBLOT, RELATIONPLOT, and ANALYZE statements.

After convergence by the preceding criterion, the quantity

$$tc = \frac{\mathbf{g}\mathbf{H}^{-1}\mathbf{g}}{L}$$

is computed. If $tc > d$ then a warning is printed that the algorithm did not converge. tc is called the *relative Hessian* convergence criterion. The default value of d is 0.0001. You can specify other values for d with the CONVH= option. The relative Hessian criterion is useful in detecting the occasional case where no progress can be made in increasing the log likelihood, yet the gradient \mathbf{g} is not zero.

A location-scale model has a CDF of the form

$$F(x) = G\left(\frac{x - \mu}{\sigma}\right)$$

where μ is the location parameter, σ is the scale parameter, and G is a standardized form ($\mu = 0, \sigma = 1$) of the cumulative distribution function. The parameter vector is $\theta = (\mu \ \sigma)$. It is more convenient computationally to maximize log likelihoods that arise from location-scale models. If you specify a distribution from [Table 16.57](#) that is not a location-scale model, it is transformed to a location-scale model by taking the natural (base e) logarithm of the response. If you specify the lognormal base 10 distribution, the logarithm (base 10) of the response is used. The Weibull, lognormal, and log-logistic distributions in [Table 16.57](#) are not location-scale models. [Table 16.58](#) shows the corresponding location-scale models that result from taking the logarithm of the response.

Maximum likelihood is the default method of estimating the location and scale parameters in the MODEL, PROBLOT, RELATIONPLOT, and ANALYZE statements. If the Weibull distribution is specified, the logarithms of the responses are used to obtain maximum likelihood estimates ($\hat{\mu}$, $\hat{\sigma}$) of the location and scale parameters of the extreme value distribution. The maximum likelihood estimates ($\hat{\alpha}$, $\hat{\beta}$) of the Weibull scale and shape parameters are computed as $\hat{\alpha} = \exp(\hat{\mu})$ and $\hat{\beta} = 1/\hat{\sigma}$.

Three-Parameter Weibull

The parameters of the three-parameter Weibull distribution are estimated by maximizing the log likelihood function. The threshold parameter θ must be less than the minimum failure time t_0 , unless $\beta = 1$, in which case, θ can be equal to t_0 . The RELIABILITY procedure sets a default upper bound of $t_0 - 0.001$ for the threshold in the iterative estimation computations and a default lower bound of 0.0. You can set different bounds by specifying an INEST data set as described in the section “[INEST Data Set for the Three-Parameter Weibull](#)” on page 1363.

If the shape parameter β is less than one, then the density function in [Table 16.57](#) has a singularity at $t = \theta$, and the log likelihood is unbounded above as the threshold parameter approaches the minimum failure time t_0 . For any fixed $\theta < t_0$, maximum likelihood estimates of the scale and shape parameters α and β exist. If $\hat{\beta} < 1$ in the iterative estimation procedure, the estimate of the threshold θ is set to the upper bound and maximum likelihood estimates of α and β are computed.

INEST Data Set for the Three-Parameter Weibull

You can specify a SAS data set to set lower bounds, upper bounds, equality constraints, or initial values for estimating the parameters of a three-parameter Weibull distribution by using the INEST= option in the ANALYZE or PROBLOT statement. The data set must contain a variable named `_TYPE_` that specifies the action that you want to take in the iterative estimation process, and some combination of variables named `_SCALE_`, `_SHAPE_`, and `_THRESHOLD_` that represent the distribution parameters. If BY processing is used, the INEST= data set should also include the BY variables, and there must be at least one observation for each BY group.

The possible values of `_TYPE_` and corresponding actions are summarized in [Table 16.66](#).

Table 16.66 _TYPE_ Variable Values

Value of _TYPE_	Action
LB	Lower bound
UB	Upper bound
EQ	Equality
PARMS	Initial value

For example, you can use the INEST data set In created by using the following SAS statements to specify bounds for data that contain the BY variable Group with three BY groups: A, B, and D. The data set In specifies a lower bound for the threshold parameter of -100 for groups A, B, and D, and an upper bound of 3 for the threshold parameter for group D. Since the variables _Scale_ and _Shape_ are set to missing, no action is taken for them, and these variables could be omitted from the data set.

```
data In;
  input Group$1 _Type_ $ 2-11 _Scale_ _Shape_ _Threshold_;
  datalines;
A    lb    . . -100
B    lb    . . -100
D    lb    . . -100
D    ub    . . 3
;
```

Regression Models

You can specify a regression model by using the MODEL statement. For example, if you want to relate the lifetimes of electronic parts in a test to Arrhenius-transformed operating temperature, then an appropriate model might be

$$\mu_i = \beta_0 + x_i \beta_1$$

where $x_i = 1000/(T_i + 273.15)$, and T_i is the centigrade temperature at which the i th unit is tested. Here, $\mathbf{x}'_i = [1 \ x_i]$.

There are two types of explanatory variables: *continuous* variables and *classification* variables. Continuous variables represent physical quantities, such as temperature or voltage, and they must be numeric. Continuous explanatory variables are sometimes called *covariates*.

Classification variables identify classification levels and are declared in the CLASS statement. These are also referred to as *categorical*, *dummy*, *qualitative*, *discrete*, or *nominal* variables. Classification variables can be either character or numeric. The values of classification variables are called *levels*. For example, the classification variable Batch could have levels 'batch1' and 'batch2' to identify items from two production batches. An indicator (0-1) variable is generated for each level of a classification variable and is used as an explanatory variable. See Nelson (1990, p. 277) for an example that uses an indicator variable in the analysis of accelerated life test data. In a model, an explanatory variable that is not declared in a CLASS statement is assumed to be continuous.

By default, all regression models automatically contain an intercept term; that is, the model is of the form

$$\mu_i = \beta_0 + \beta_1 x_{i1} + \dots$$

where β_0 does not have an explanatory variable multiplier. The intercept term can be excluded from the model by specifying INTERCEPT=0 as a MODEL statement option.

For numerical stability, continuous explanatory variables are centered and scaled internally to the procedure. This transforms the parameters β in the original model to a new set of parameters. The parameter estimates β and covariances are transformed back to the original scale before reporting, so that the parameters should be interpreted in terms of the originally specified model. Covariates that are indicator variables—that is, those specified in a CLASS statement—are not centered and scaled.

Initial values of the regression parameters used in the Newton-Raphson method are computed by ordinary least squares. The parameters β and the scale parameter σ are jointly estimated by maximum likelihood, taking a logarithmic transformation of the responses, if necessary, to get a location-scale model.

The generalized gamma distribution is fit using log lifetime as the response variable. The regression parameters β , the scale parameter σ , and the shape parameter λ are jointly estimated.

The Weibull distribution shape parameter estimate is computed as $\hat{\beta} = 1/\hat{\sigma}$, where σ is the scale parameter from the corresponding extreme value distribution. The Weibull scale parameter $\hat{\alpha}_i = \exp(\mathbf{x}'\hat{\beta})$ is not computed by the procedure. Instead, the regression parameters β and the shape β are reported.

In a model with one to three continuous explanatory variables x , you can use the RELATION= option in the MODEL statement to specify a transformation that is applied to the variables before model fitting. Table 16.67 shows the available transformations.

Table 16.67 Variable Transformations

Relation	Transformed variable
ARRHENIUS (Nelson parameterization)	$1000/(x + 273.15)$
ARRHENIUS2 (activation energy parameterization)	$11605/(x + 273.15)$
POWER	$\log(x)$, $x > 0$
LINEAR	x
LOGISTIC	$\log\left(\frac{x}{1-x}\right)$, $0 < x < 1$

Nonconstant Scale Parameter

In some situations, it is desirable for the scale parameter to change with the values of explanatory variables. For example, Meeker and Escobar (1998, section 17.5) present an analysis of accelerated life test data where the spread of the data is greater at lower levels of the stress. You can use the LOGSCALE statement to specify the scale parameter as a function of explanatory variables. You must also have a MODEL statement to specify the location parameter. Explanatory variables can be continuous variables, indicator variables specified in the CLASS statement, or any interaction

combination. The variables can be the same as specified in the MODEL statement, or they can be different variables. Any transformation specified with the RELATION= MODEL statement option will be applied to the same variable appearing in the LOGSCALE statement. See the section “Regression Model with Nonconstant Scale” on page 1243 for an example of fitting a model with nonconstant scale parameter.

The form of the model for the scale parameter is

$$\log(\sigma_i) = \beta_0 + \beta_1 x_{i1} + \dots + \beta_p x_{ip}$$

where β_0 is the intercept term. The intercept term can be excluded from the model by specifying INTERCEPT=0 as a LOGSCALE statement option.

The parameters $\beta_0, \beta_1, \dots, \beta_p$ are estimated by maximum likelihood jointly with all the other parameters in the model.

Stable Parameters

The location and scale parameters (μ, σ) are estimated by maximizing the likelihood function by numerical methods, as described previously. An alternative parameterization that is likely to have better numerical properties for heavy censoring is (η, σ) , where $\eta = \mu + z_p \sigma$ and z_p is the p th quantile of the standardized distribution. See Meeker and Escobar (1998, p. 90) and Doganaksoy and Schmee (1993) for more details on alternate parameterizations.

By default, RELIABILITY estimates a value of z_p from the data that will improve the numerical properties of the estimation. You can also specify values of p from which the value of z_p will be computed with the PSTABLE= option in the ANALYZE, PROBLOT, RELATIONPLOT, or MODEL statement. Note that a value of $p = 0.632$ for the Weibull and extreme value and $p = 0.5$ for all other distributions will give $z_p = 0$ and the parameterization will then be the usual location-scale parameterization.

All estimates and related statistics are reported in terms of the location and scale parameters (μ, σ) . If you specify the ITPRINT option in the ANALYZE, PROBLOT, or RELATIONPLOT statement, a table showing the values of p , v , σ , and the last evaluation of the gradient and Hessian for these parameters is produced.

Covariance Matrix

An estimate of the covariance matrix of the maximum likelihood estimators (MLEs) of the parameters θ is given by the inverse of the negative of the matrix of second derivatives of the log likelihood, evaluated at the final parameter estimates:

$$\Sigma = [\sigma_{ij}] = -\mathbf{H}^{-1} = - \left[\frac{\partial^2 L}{\partial \theta_i \partial \theta_j} \right]_{\theta = \hat{\theta}}^{-1}$$

The negative of the matrix of second derivatives is called the observed Fisher information matrix. The diagonal term σ_{ii} is an estimate of the variance of $\hat{\theta}_i$. Estimates of standard errors of the MLEs are provided by

$$SE_{\theta_i} = \sqrt{\sigma_{ii}}$$

An estimator of the correlation matrix is

$$\mathbf{R} = \left[\frac{\sigma_{ij}}{\sqrt{\sigma_{ii} \sigma_{jj}}} \right]$$

The covariance matrix for the Weibull distribution parameter estimators is computed by a first-order approximation from the covariance matrix of the estimators of the corresponding extreme value parameters (μ, σ) as

$$\begin{aligned}\text{Var}(\hat{\alpha}) &= [\exp(\hat{\mu})]^2 \text{Var}(\hat{\mu}) \\ \text{Var}(\hat{\beta}) &= \frac{\text{Var}(\hat{\sigma})}{\hat{\sigma}^4} \\ \text{Cov}(\hat{\alpha}, \hat{\beta}) &= -\frac{\exp(\hat{\mu})}{\hat{\sigma}^2} \text{Cov}(\hat{\mu}, \hat{\sigma})\end{aligned}$$

For the regression model, the variance of the Weibull shape parameter estimator $\hat{\beta}$ is computed from the variance of the estimator of the extreme value scale parameter σ as shown previously. The covariance of the regression parameter estimator $\hat{\beta}_i$ and the Weibull shape parameter estimator $\hat{\beta}$ is computed in terms of the covariance between $\hat{\beta}_i$ and $\hat{\sigma}$ as

$$\text{Cov}(\hat{\beta}_i, \hat{\beta}) = -\frac{\text{Cov}(\hat{\beta}_i, \hat{\sigma})}{\hat{\sigma}^2}$$

Confidence Intervals for Distribution Parameters

Table 16.68 shows the method of computation of approximate two-sided $\gamma \times 100\%$ confidence limits for distribution parameters. The default value of confidence is $\gamma = 0.95$. Other values of confidence are specified using the CONFIDENCE= option. In Table 16.68, K_γ represents the $(1 + \gamma)/2 \times 100\%$ percentile of the standard normal distribution, and $\hat{\mu}$ and $\hat{\sigma}$ are the MLEs of the location and scale parameters for the normal, extreme value, and logistic distributions. For the lognormal, Weibull, and log-logistic distributions, $\hat{\mu}$ and $\hat{\sigma}$ represent the MLEs of the corresponding location and scale parameters of the location-scale distribution that results when the logarithm of the lifetime is used as the response. For the Weibull distribution, μ and σ are the location and scale parameters of the extreme value distribution for the logarithm of the lifetime. $SE_{\hat{\theta}}$ denotes the standard error of the MLE of θ , computed as the square root of the appropriate diagonal element of the inverse of the Fisher information matrix.

Table 16.68 Confidence Limit Computation

Distribution	Parameters		
	Location μ or Threshold θ	Scale	Shape
Normal	$\mu_L = \hat{\mu} - K_\gamma(\text{SE}_{\hat{\mu}})$ $\mu_U = \hat{\mu} + K_\gamma(\text{SE}_{\hat{\mu}})$	$\sigma_L = \hat{\sigma} / \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$ $\sigma_U = \hat{\sigma} \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$	
Lognormal	$\mu_L = \hat{\mu} - K_\gamma(\text{SE}_{\hat{\mu}})$ $\mu_U = \hat{\mu} + K_\gamma(\text{SE}_{\hat{\mu}})$	$\sigma_L = \hat{\sigma} / \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$ $\sigma_U = \hat{\sigma} \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$	
Lognormal (base 10)	$\mu_L = \hat{\mu} - K_\gamma(\text{SE}_{\hat{\mu}})$ $\mu_U = \hat{\mu} + K_\gamma(\text{SE}_{\hat{\mu}})$	$\sigma_L = \hat{\sigma} / \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$ $\sigma_U = \hat{\sigma} \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$	
Extreme value	$\mu_L = \hat{\mu} - K_\gamma(\text{SE}_{\hat{\mu}})$ $\mu_U = \hat{\mu} + K_\gamma(\text{SE}_{\hat{\mu}})$	$\sigma_L = \hat{\sigma} / \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$ $\sigma_U = \hat{\sigma} \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$	
Weibull		$\alpha_L = \exp[\hat{\mu} - K_\gamma(\text{SE}_{\hat{\mu}})]$ $\alpha_U = \exp[\hat{\mu} + K_\gamma(\text{SE}_{\hat{\mu}})]$	$\beta_L = \exp[-K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]/\hat{\sigma}$ $\beta_U = \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]/\hat{\sigma}$
Exponential		$\alpha_L = \exp[\hat{\mu} - K_\gamma(\text{SE}_{\hat{\mu}})]$ $\alpha_U = \exp[\hat{\mu} + K_\gamma(\text{SE}_{\hat{\mu}})]$	
Logistic	$\mu_L = \hat{\mu} - K_\gamma(\text{SE}_{\hat{\mu}})$ $\mu_U = \hat{\mu} + K_\gamma(\text{SE}_{\hat{\mu}})$	$\sigma_L = \hat{\sigma} / \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$ $\sigma_U = \hat{\sigma} \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$	
Log-logistic	$\mu_L = \hat{\mu} - K_\gamma(\text{SE}_{\hat{\mu}})$ $\mu_U = \hat{\mu} + K_\gamma(\text{SE}_{\hat{\mu}})$	$\sigma_L = \hat{\sigma} / \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$ $\sigma_U = \hat{\sigma} \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$	
Generalized Gamma		$\sigma_L = \hat{\sigma} / \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$ $\sigma_U = \hat{\sigma} \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$	$\mu_L = \hat{\lambda} - K_\gamma(\text{SE}_{\hat{\lambda}})$ $\mu_U = \hat{\lambda} + K_\gamma(\text{SE}_{\hat{\lambda}})$
Three-parameter Weibull	$\theta_L = \hat{\theta} - K_\gamma(\text{SE}_{\hat{\theta}})$ $\theta_U = \hat{\theta} + K_\gamma(\text{SE}_{\hat{\theta}})$	$\alpha_L = \exp[\hat{\mu} - K_\gamma(\text{SE}_{\hat{\mu}})]$ $\alpha_U = \exp[\hat{\mu} + K_\gamma(\text{SE}_{\hat{\mu}})]$	$\beta_L = \exp[-K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]/\hat{\sigma}$ $\beta_U = \exp[K_\gamma(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]/\hat{\sigma}$

Regression Parameters Approximate $\gamma \times 100\%$ confidence limits for the regression parameter β_i are given by

$$\beta_{iL} = \hat{\beta}_i - K_\gamma(\text{SE}_{\hat{\beta}_i})$$

$$\beta_{iU} = \hat{\beta}_i + K_\gamma(\text{SE}_{\hat{\beta}_i})$$

Percentiles

The maximum likelihood estimate of the $p \times 100\%$ percentile x_p for the extreme value, normal, and logistic distributions is given by

$$\hat{x}_p = \hat{\mu} + z_p \hat{\sigma}$$

where $z_p = G^{-1}(p)$, G is the standardized CDF shown in Table 16.69, and $(\hat{\mu}, \hat{\sigma})$ are the maximum likelihood estimates of the location and scale parameters of the distribution. The maximum likelihood estimate of the percentile t_p for the Weibull, lognormal, and log-logistic distributions is given by

$$\hat{t}_p = \exp[\hat{\mu} + z_p \hat{\sigma}]$$

where $z_p = G^{-1}(p)$, and G is the standardized CDF of the location-scale model corresponding to the logarithm of the response. For the lognormal (base 10) distribution,

$$\hat{t}_p = 10^{[\hat{\mu} + z_p \hat{\sigma}]}$$

The maximum likelihood estimate of the percentile t_p for the three-parameter Weibull distribution is computed by

$$\hat{t}_p = \hat{\theta} + \exp[\hat{\mu} + z_p \hat{\sigma}]$$

where $z_p = G^{-1}(p)$, and G is the standardized CDF of extreme value distribution.

Table 16.69 Standardized Cumulative Distribution Functions

Distribution	Location-Scale Distribution	Location-Scale CDF
Weibull	Extreme value	$1 - \exp[-\exp(z)]$
Lognormal	Normal	$\int_{-\infty}^z \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{u^2}{2}\right) du$
Log-logistic	Logistic	$\frac{\exp(z)}{1 + \exp(z)}$

Confidence Intervals The variance of the MLE of the $p \times 100\%$ percentile for the normal, extreme value, or logistic distribution is

$$\text{Var}(\hat{x}_p) = \text{Var}(\hat{\mu}) + z_p^2 \text{Var}(\hat{\sigma}) + 2z_p \text{Cov}(\hat{\mu}, \hat{\sigma})$$

Two-sided approximate $100\gamma\%$ confidence limits for x_p are

$$\begin{aligned} x_{pL} &= \hat{x}_p - K_\gamma \sqrt{\text{Var}(\hat{x}_p)} \\ x_{pU} &= \hat{x}_p + K_\gamma \sqrt{\text{Var}(\hat{x}_p)} \end{aligned}$$

where K_γ represents the $100(1 + \gamma)/2 \times 100\%$ percentile of the standard normal distribution.

The limits for the lognormal, Weibull, or log-logistic distributions are

$$t_{pL} = \exp\left(\hat{x}_p - K_\gamma \sqrt{\text{Var}(\hat{x}_p)}\right)$$

$$t_{pU} = \exp\left(\hat{x}_p + K_\gamma \sqrt{\text{Var}(\hat{x}_p)}\right)$$

where x_p refers to the percentile of the corresponding location-scale distribution (normal, extreme value, or logistic) for the logarithm of the lifetime. For the lognormal (base 10) distribution,

$$t_{pL} = 10^{(\hat{x}_p - K_\gamma \sqrt{\text{Var}(\hat{x}_p)})}$$

$$t_{pU} = 10^{(\hat{x}_p + K_\gamma \sqrt{\text{Var}(\hat{x}_p)})}$$

Approximate limits for the three-parameter Weibull distribution are computed as

$$t_{pL} = \hat{\theta} + \exp\left(\hat{x}_p - K_\gamma \sqrt{\text{Var}(\hat{x}_p)}\right)$$

$$t_{pU} = \hat{\theta} + \exp\left(\hat{x}_p + K_\gamma \sqrt{\text{Var}(\hat{x}_p)}\right)$$

where x_p refers to the percentile of the standard extreme value distribution.

Reliability Function

For the extreme value, normal, and logistic distributions shown in Table 16.69, the maximum likelihood estimate of the reliability function $R(x) = \Pr\{X > x\}$ is given by

$$\hat{R}(x) = 1 - F\left(\frac{x - \hat{\mu}}{\hat{\sigma}}\right)$$

The MLE of the CDF is $\hat{F}(x) = 1 - \hat{R}(x)$.

Confidence Intervals Let $\hat{u} = \frac{x - \hat{\mu}}{\hat{\sigma}}$. The approximate variance of u is

$$\text{Var}(\hat{u}) \approx \frac{\text{Var}(\hat{\mu}) + \hat{u}^2 \text{Var}(\hat{\sigma}) + 2\hat{u} \text{Cov}(\hat{\mu}, \hat{\sigma})}{\hat{\sigma}^2}$$

Two-sided approximate $\gamma \times 100\%$ confidence intervals for $R(x)$ are computed as

$$R_L(x) = \hat{R}(u_2)$$

$$R_U(x) = \hat{R}(u_1)$$

where

$$u_1 = \hat{u} - K_\gamma \sqrt{\text{Var}(\hat{u})}$$

$$u_2 = \hat{u} + K_\gamma \sqrt{\text{Var}(\hat{u})}$$

and K_γ represents the $(1 + \gamma)/2 \times 100\%$ percentile of the standard normal distribution. The corresponding limits for the CDF are

$$F_L(x) = 1 - R_U(x)$$

$$F_U(x) = 1 - R_L(x)$$

As an alternative, you can request that two-sided $\gamma \times 100\%$ likelihood ratio confidence limits for the reliability function and the CDF be computed by specifying the **LRCLSURV** option in the **ANALYZE** statement or the **LRCLSURV** option in the **PROBPLOT** statement.

Limits for the Weibull, lognormal, and log-logistic reliability function $R(t)$ are the same as those for the corresponding extreme value, normal, or logistic reliability $R(y)$, where $y = \log(t)$. Limits for the three-parameter Weibull use $y = \log(t - \theta)$ and the extreme value CDF.

You can create a table containing estimates of the reliability function, the CDF, and confidence limits computed as described in this section with the **SURVTIME=** option in the **ANALYZE** statement or with the **SURVTIME=** option in the **PROBPLOT** statement. You can plot confidence limits for the CDF on probability plots created with the **PROBPLOT** statement with the **PINTERVALS=CDF** option in the **PROBPLOT** statement. **PINTERVALS=CDF** is the default option for parametric confidence limits on probability plots.

Estimation with the Binomial and Poisson Distributions

In addition to estimating the parameters of the distributions in [Table 16.57](#), you can estimate parameters, compute confidence limits, compute predicted values and prediction limits, and compute chi-square tests for differences in groups for the binomial and Poisson distributions by using the **ANALYZE** statement. Specify either **BINOMIAL** or **POISSON** in the **DISTRIBUTION** statement to use one of these distributions. The **ANALYZE** statement options available for the binomial and Poisson distributions are given in [Table 16.5](#). See the section “[Analysis of Binomial Data](#)” on page 1268 for an example of an analysis of binomial data.

Binomial Distribution

If r is the number of successes and n is the number of trials in a binomial experiment, then the maximum likelihood estimator of the probability p in the binomial distribution in [Table 16.59](#) is computed as

$$\hat{p} = r/n$$

Two-sided $\gamma \times 100\%$ confidence limits for p are computed as in Johnson, Kotz, and Kemp (1992, p. 130):

$$p_L = \frac{v_1 F[(1 - \gamma)/2; v_1, v_2]}{v_2 + v_1 F[(1 - \gamma)/2; v_1, v_2]}$$

with $v_1 = 2r$ and $v_2 = 2(n - r + 1)$ and

$$p_U = \frac{v_1 F[(1 + \gamma)/2; v_1, v_2]}{v_2 + v_1 F[(1 + \gamma)/2; v_1, v_2]}$$

with $\nu_1 = 2(r + 1)$ and $\nu_2 = 2(n - r)$, where $F[\gamma; \nu_1, \nu_2]$ is the $\gamma \times 100\%$ percentile of the F distribution with ν_1 degrees of freedom in the numerator and ν_2 degrees of freedom in the denominator.

You can compute a sample size required to estimate p within a specified tolerance w with probability γ . Nelson (1982, p. 206) gives the following formula for the approximate sample size:

$$n \approx \hat{p}(1 - \hat{p}) \left(\frac{K_\gamma}{w} \right)^2$$

where K_γ is the $(1 + \gamma)/2 \times 100\%$ percentile of the standard normal distribution. The formula is based on the normal approximation for the distribution of \hat{p} . Nelson recommends using this formula if $np > 10$ and $np(1 - p) > 10$. The value of γ used for computing confidence limits is used in the sample size computation. The default value of confidence is $\gamma = 0.95$. Other values of confidence are specified using the CONFIDENCE= option. You specify a tolerance of *number* with the TOLERANCE(*number*) option.

The predicted number of successes X in a future sample of size m , based on the previous estimate of p , is computed as

$$\hat{X} = m(r/n) = m\hat{p}$$

Two-sided approximate $\gamma \times 100\%$ prediction limits are computed as in Nelson (1982, p. 208). The prediction limits are the solutions X_L and X_U of

$$X_U/m = [(r + 1)/n]F[(1 + \gamma)/2; 2(r + 1), 2X_U]$$

$$m/(X_L + 1) = (n/r)F[(1 + \gamma)/2; 2(X_L + 1), 2r]$$

where $F[\gamma; \nu_1, \nu_2]$ is the $\gamma \times 100\%$ percentile of the F distribution with ν_1 degrees of freedom in the numerator and ν_2 degrees of freedom in the denominator. You request predicted values and prediction limits for a future sample of size *number* with the PREDICT(*number*) option.

You can test groups of binomial data for equality of their binomial probability by using the ANALYZE statement. You specify the K groups to be compared with a group variable having K levels.

Nelson (1982, p. 450) discusses a chi-square test statistic for comparing K binomial proportions for equality. Suppose there are r_i successes in n_i trials for $i = 1, 2, \dots, K$. The grouped estimate of the binomial probability is

$$\hat{p} = \frac{r_1 + r_2 + \dots + r_K}{n_1 + n_2 + \dots + n_K}$$

The chi-square test statistic for testing the hypothesis $p_1 = p_2 = \dots = p_K$ against $p_i \neq p_j$ for some i and j is

$$Q = \sum_{i=1}^K \frac{(r_i - n_i \hat{p})^2}{n_i \hat{p}(1 - \hat{p})}$$

The statistic Q has an asymptotic chi-square distribution with $K - 1$ degrees of freedom. The RELIABILITY procedure computes the contribution of each group to Q , the value of Q , and the p -value for Q based on the limiting chi-square distribution with $K - 1$ degrees of freedom. If you

specify the PREDICT option, predicted values and prediction limits are computed for each group, as well as for the pooled group. The p -value is defined as $p_0 = 1 - \chi_{K-1}^2[Q]$, where $\chi_{K-1}^2[x]$ is the chi-square CDF with $K - 1$ degrees of freedom, and Q is the observed value. A test of the hypothesis of equal binomial probabilities among the groups with significance level α is

- $p_0 > \alpha$: do not reject the equality hypothesis
- $p_0 \leq \alpha$: reject the equality hypothesis

Poisson Distribution

You can use the ANALYZE statement to model data by using the Poisson distribution. The data consist of a count Y of occurrences in a “length” of observation T . Observation T is typically an *exposure time*, but it can have other units, such as distance. The ANALYZE statement enables you to compute the rate of occurrences, confidence limits, and prediction limits.

An estimate of the rate λ is computed as

$$\hat{\lambda} = Y/T$$

Two-sided $\gamma \times 100\%$ confidence limits for λ are computed as in Nelson (1982, p. 201):

$$\lambda_L = 0.5\chi^2[(1 - \gamma)/2; 2Y]/T$$

$$\lambda_U = 0.5\chi^2[(1 + \gamma)/2; 2(Y + 1)]/T$$

where $\chi^2[\delta; \nu]$ is the $\delta \times 100\%$ percentile of the chi-square distribution with ν degrees of freedom.

You can compute a length T required to estimate λ within a specified tolerance w with probability γ . Nelson (1982, p. 202) provides the following approximate formula:

$$\hat{T} \approx \hat{\lambda} \left(\frac{K_\gamma}{w} \right)^2$$

where K_γ is the $(1 + \gamma)/2 \times 100\%$ percentile of the standard normal distribution. The formula is based on the normal approximation for $\hat{\lambda}$ and is more accurate for larger values of λT . Nelson recommends using the formula when $\lambda T > 10$. The value of γ used for computing confidence limits is also used in the length computation. The default value of confidence is $\gamma = 0.95$. Other values of confidence are specified using the CONFIDENCE= option. You specify a tolerance of *number* with the TOLERANCE(*number*) option.

The predicted future number of occurrences in a length S is

$$\hat{X} = (Y/T)S = \hat{\lambda}S$$

Two-sided approximate $\gamma \times 100\%$ prediction limits are computed as in Nelson (1982, p. 203). The prediction limits are the solutions X_L and X_U of

$$X_U/S = [(Y + 1)/T]F[(1 + \gamma)/2; 2(Y + 1), 2X_U]$$

$$S/(X_L + 1) = (T/Y)F[(1 + \gamma)/2; 2(X_L + 1), 2Y]$$

where $F[\gamma; \nu_1, \nu_2]$ is the $\gamma \times 100\%$ percentile of the F distribution with ν_1 degrees of freedom in the numerator and ν_2 degrees of freedom in the denominator. You request predicted values and prediction limits for a future exposure *number* with the PREDICT(*number*) option.

You can compute a chi-square test statistic for comparing K Poisson rates for equality. You specify the K groups to be compared with a group variable having K levels.

See Nelson (1982, p. 444) for more information. Suppose that there are Y_i Poisson counts in lengths T_i for $i = 1, 2, \dots, K$ and that the Y_i are independent. The grouped estimate of the Poisson rate is

$$\hat{\lambda} = \frac{Y_1 + Y_2 + \dots + Y_K}{T_1 + T_2 + \dots + T_K}$$

The chi-square test statistic for testing the hypothesis $\lambda_1 = \lambda_2 = \dots = \lambda_K$ against $\lambda_i \neq \lambda_j$ for some i and j is

$$Q = \sum_{i=1}^K \frac{(Y_i - \hat{\lambda}T_i)^2}{\hat{\lambda}T_i}$$

The statistic Q has an asymptotic chi-square distribution with $K - 1$ degrees of freedom. The RELIABILITY procedure computes the contribution of each group to Q , the value of Q , and the p -value for Q based on the limiting chi-square distribution with $K - 1$ degrees of freedom. If you specify the PREDICT option, predicted values and prediction limits are computed for each group, as well as for the pooled group. The p -value is defined as $p_0 = 1 - \chi_{K-1}^2[Q]$, where $\chi_{K-1}^2[x]$ is the chi-square CDF with $K - 1$ degrees of freedom and Q is the observed value. A test of the hypothesis of equal Poisson rates among the groups with significance level α is

- $p_0 > \alpha$: accept the equality hypothesis
- $p_0 \leq \alpha$: reject the equality hypothesis

Least Squares Fit to the Probability Plot

Fitting to the probability plot by least squares is an alternative to maximum likelihood estimation of the parameters of a life distribution. Only the failure times are used. A least squares fit is computed using points $(x_{(i)}, m_i)$, where $m_i = F^{-1}(a_i)$ and a_i are the plotting positions as defined in the section “Probability Plotting” on page 1350. The x_i are either the lifetimes for the normal, extreme value, or logistic distributions or the log lifetimes for the lognormal, Weibull, or log-logistic distributions. The ANALYZE, PROBLOT, or RELATIONPLOT statement option FITTYPE=LSXY specifies the $x_{(i)}$ as the dependent variable (‘y-coordinate’) and the m_i as the independent variable (‘x-coordinate’). You can optionally reverse the quantities used as dependent and independent variables by specifying the FITTYPE=LSYX option.

Weibayes Estimation

Weibayes estimation is a method of performing a Weibull analysis when there are few or no failures. The FITTYPE=WEIBAYES option requests this method. The method of Nelson (1985) is used to compute a one-sided confidence interval for the Weibull scale parameter when the Weibull shape parameter is specified. See Abernethy (2006) for more discussion and examples. The Weibull shape parameter β is assumed to be known and is specified to the procedure with the SHAPE=*number* option. Let T_1, T_2, \dots, T_n be the failure and censoring times, and let $r \geq 0$ be the number of failures in the data. If there are no failures ($r = 0$), a lower $\gamma \times 100\%$ confidence limit for the Weibull scale parameter α is computed as

$$\alpha_L = \left\{ \sum_{i=1}^n T_i^\beta / [-\log(1 - \gamma)] \right\}^{1/\beta}$$

The default value of confidence is $\gamma = 0.95$. Other values of confidence are specified using the CONFIDENCE= option.

If $r \geq 1$, the MLE of α is given by

$$\hat{\alpha} = \left[\sum_{i=1}^n T_i^\beta / r \right]^{1/\beta}$$

and a lower $\gamma \times 100\%$ confidence limit for the Weibull scale parameter α is computed as

$$\alpha_L = \hat{\alpha} [2r / \chi^2(\gamma, 2r + 2)]^{1/\beta}$$

where $\chi^2(\gamma, 2r + 2)$ is the γ percentile of a chi-square distribution with $2r + 2$ degrees of freedom. The procedure uses the specified value of β and the computed value of α_L to compute distribution percentiles and the reliability function.

Estimation With Multiple Failure Modes

In many applications, units can experience multiple causes of failure, or *failure modes*. For example, in the section “Weibull Probability Plot for Two Combined Failure Modes” on page 1250, insulation specimens can experience either early failures due to manufacturing defects or degradation failures due to aging. The FMODE statement is used to analyze this type of data. See the section “FMODE Statement” on page 1290 for the syntax of the FMODE statement. This section describes the analysis of data when units experience multiple failure modes.

The assumptions used in the analysis are

- a cause, or mode, can be identified for each failure
- failure modes follow a series-system model; i.e., a unit fails when a failure due to one of the modes occurs
- each failure mode has the specified lifetime distribution with different parameters
- failure modes act statistically independently

Suppose there are m failure modes, with lifetime distribution functions $F_1(t), F_2(t), \dots, F_m(t)$.

If you wish to estimate the lifetime distribution of a failure mode, say mode i , acting alone, specify the KEEP keyword in the FMODE statement. The failures from all other modes are treated as right-censored observations, and the lifetime distribution is estimated by one of the methods described in other sections, such as maximum likelihood. This lifetime distribution is interpreted as the distribution if the specified failure mode is acting alone, with all other modes eliminated. You can also specify more than one mode to KEEP, but the assumption is that all the specified modes have the same distribution.

If you specify the ELIMINATE keyword, failures due to the specified modes are treated as right censored. The resulting distribution estimate is the failure distribution if the specified modes are eliminated.

If you specify the COMBINE keyword, the failure distribution when all the modes specified in the FMODE statement modes act is estimated. The failure distribution $F_i(t), i = 1, 2, \dots, m$, from each individual mode is first estimated by treating all failures from other modes as right censored. The estimated failure distributions are then combined to get an estimate of the lifetime distribution when all modes act,

$$\hat{F}(t) = 1 - \prod_{i=1}^m [1 - \hat{F}_i(t)]$$

Pointwise approximate asymptotic normal confidence limits for $F(t)$ can be obtained by the delta method. See Meeker and Escobar (1998, appendix B.2). The delta method variance of $\hat{F}(t)$ is, assuming independence of failure modes,

$$\text{Var}(\hat{F}(t)) = \sum_{i=1}^m [S_0(u_1)S_0(u_2) \dots f_0(u_i) \dots S_0(u_m)]^2 \text{Var}(u_i)$$

where $u_i = \frac{y - \hat{\mu}_i}{\hat{\sigma}_i}$, y is t for the extreme value, normal, and logistic distributions or $\log(t)$ for the Weibull, lognormal or log-logistic distributions, $\hat{\mu}_i$ and $\hat{\sigma}_i$ are location and scale parameter estimates for mode i , and S_0 and f_0 are the standard ($\mu = 0, \sigma = 1$) survival function and density function for the specified distribution.

Two-sided approximate $(1 - \alpha)100\%$ pointwise confidence intervals are computed as in Meeker and Escobar (1998, section 3.6) as

$$[F_L, F_U] = \left[\frac{\hat{F}}{\hat{F} + (1 - \hat{F})w}, \frac{\hat{F}}{\hat{F} + (1 - \hat{F})/w} \right]$$

where

$$w = \exp \left[\frac{z_{1-\alpha/2} \text{se}_{\hat{F}}}{(\hat{F}(1 - \hat{F}))} \right]$$

where $\text{se}_{\hat{F}} = \sqrt{\text{Var}(\hat{F}(t))}$ and z_p is the p th quantile of the standard normal distribution.

Regression Model Statistics Computed for Each Observation for Lifetime Data

This section describes statistics that are computed for each observation when you fit a model for lifetime data. For regression models that are fit using the MODEL statement, you can specify a variety of statistics to be computed for each observation in the input data set. This section describes the method of computation for each statistic. See Table 16.32 and Table 16.33 for the syntax to request these statistics.

Predicted Values

The linear predictor is

$$\hat{\mu}_i = \mathbf{x}'_i \hat{\boldsymbol{\beta}}$$

where \mathbf{x}_i is the vector of explanatory variables for the i th observation.

Percentiles

An estimator of the $p \times 100\%$ percentile x_p for the i th observation for the extreme value, normal, and logistic distributions is

$$\hat{x}_{i,p} = \mathbf{x}'_i \hat{\boldsymbol{\beta}} + z_p \hat{\sigma}$$

where $z_p = G^{-1}(p)$, G is the standardized CDF, and σ is the distribution scale parameter.

An estimator of the $p \times 100\%$ percentile t_p for the i th observation for the Weibull, lognormal, and log-logistic distributions is

$$\hat{t}_{i,p} = \exp[\mathbf{x}'_i \hat{\boldsymbol{\beta}} + z_p \hat{\sigma}]$$

where G is the standardized CDF of the extreme value, normal, or logistic distribution that corresponds to the logarithm of the lifetime, and σ is the distribution scale parameter.

The percentile of the lognormal (base 10) distribution is

$$\hat{t}_{i,p} = 10^{[\mathbf{x}'_i \hat{\boldsymbol{\beta}} + z_p \hat{\sigma}]}$$

where G is the CDF of the standard normal distribution.

An estimator of the $p \times 100\%$ percentile t_p for the i th observation for the generalized gamma distribution is

$$\hat{t}_{i,p} = \exp[\mathbf{x}'_i \hat{\boldsymbol{\beta}} + w_{\lambda,p} \hat{\sigma}]$$

where

$$w_{\lambda,p} = \frac{1}{\lambda} \log \left(\frac{\lambda^2}{2} \chi_{(2/\lambda^2),p}^2 \right)$$

and $\chi_{k,p}^2$ is the $p \times 100\%$ percentile of the chi-square distribution with k degrees of freedom.

Standard Errors of Percentile Estimator

For the extreme value, normal, and logistic distributions, the standard error of the estimator of the $p \times 100\%$ percentile is computed as

$$\sigma_{i,p} = \sqrt{\mathbf{z}' \boldsymbol{\Sigma} \mathbf{z}}$$

where

$$\mathbf{z} = \begin{bmatrix} \mathbf{x}_i \\ z_p \end{bmatrix}$$

and $\boldsymbol{\Sigma}$ is the covariance matrix of $(\hat{\boldsymbol{\beta}}, \hat{\sigma})$.

For the Weibull, lognormal, and log-logistic distributions, the standard error is computed as

$$\sigma_{i,p} = \exp(x_{i,p}) \sqrt{\mathbf{z}' \boldsymbol{\Sigma} \mathbf{z}}$$

where $x_{i,p}$ is the percentile computed from the extreme value, normal, or logistic distribution that corresponds to the logarithm of the lifetime. The standard error for the lognormal (base 10) distribution is computed as

$$\sigma_{i,p} = 10^{x_{i,p}} \sqrt{\mathbf{z}' \boldsymbol{\Sigma} \mathbf{z}}$$

The standard error for the generalized gamma distribution percentile is computed as

$$\sigma_{i,p} = \exp[\mathbf{x}' \hat{\boldsymbol{\beta}} + w_{\lambda,p} \hat{\sigma}] \sqrt{\mathbf{z}' \boldsymbol{\Sigma} \mathbf{z}}$$

where

$$\mathbf{z} = \begin{bmatrix} \mathbf{x}_i \\ w_{\lambda,p} \\ \hat{\sigma} \frac{\partial w_{\lambda,p}}{\partial \lambda} \end{bmatrix}$$

$\boldsymbol{\Sigma}$ is the covariance matrix of $(\hat{\boldsymbol{\beta}}, \hat{\sigma}, \hat{\lambda})$, $\boldsymbol{\beta}$ is the vector of regression parameters, σ is the scale parameter, and λ is the shape parameter.

Confidence Limits for Percentiles

Two-sided approximate $100\gamma\%$ confidence limits for $x_{i,p}$ for the extreme value, normal, and logistic distributions are computed as

$$\begin{aligned} x_L &= \hat{x}_{i,p} - K_\gamma \sigma_{i,p} \\ x_U &= \hat{x}_{i,p} + K_\gamma \sigma_{i,p} \end{aligned}$$

where K_γ represents the $100(1 + \gamma)/2 \times 100\%$ percentile of the standard normal distribution.

Limits for the Weibull, lognormal, and log-logistic percentiles are computed as

$$\begin{aligned} t_L &= \exp(x_L) \\ t_U &= \exp(x_U) \end{aligned}$$

where x_L and x_U are computed from the corresponding distributions for the logarithms of the lifetimes. For the lognormal (base 10) distribution,

$$\begin{aligned}t_L &= 10^{x_L} \\t_U &= 10^{x_U}\end{aligned}$$

Limits for the generalized gamma distribution percentiles are computed as

$$\begin{aligned}t_L &= \exp \left[\mathbf{x}'_i \boldsymbol{\beta} + w_{\lambda,p} \hat{\sigma} - K_\gamma \sqrt{\mathbf{z}' \boldsymbol{\Sigma} \mathbf{z}} \right] \\t_U &= \exp \left[\mathbf{x}'_i \boldsymbol{\beta} + w_{\lambda,p} \hat{\sigma} + K_\gamma \sqrt{\mathbf{z}' \boldsymbol{\Sigma} \mathbf{z}} \right]\end{aligned}$$

Reliability Function

For the extreme value, normal, and logistic distributions, an estimate of the reliability function evaluated at the response y_i is computed as

$$R(y_i) = 1 - G \left(\frac{y_i - \mathbf{x}'_i \hat{\boldsymbol{\beta}}}{\hat{\sigma}} \right)$$

where $G(x)$ is the standardized CDF of the distribution from Table 16.69.

Estimates of the reliability function evaluated at the response t_i for the Weibull, lognormal, log-logistic, and generalized gamma distributions are computed as

$$R(t_i) = 1 - G \left(\frac{\log(t_i) - \mathbf{x}'_i \hat{\boldsymbol{\beta}}}{\hat{\sigma}} \right)$$

where $G(x)$ is the standardized CDF of the corresponding extreme value, normal, logistic, or generalized log-gamma distributions.

Residuals

The RELIABILITY procedure computes several different kinds of residuals. In the following equations, y_i represents the i th response value if the extreme value, normal, or logistic distributions are specified. If t_i is the i th response and if the Weibull, lognormal, log-logistic, or generalized gamma distributions are specified, then y_i represents the logarithm of the response $y_i = \log(t_i)$. If the lognormal (base 10) distribution is specified, then $y_i = \log_{10}(t_i)$.

Raw Residuals

The raw residual is computed as

$$r_{Ri} = y_i - \mathbf{x}'_i \hat{\boldsymbol{\beta}}$$

Standardized Residuals

The standardized residual is computed as

$$r_{Si} = \frac{y_i - \mathbf{x}'\hat{\boldsymbol{\beta}}}{\hat{\sigma}}$$

Adjusted Residuals

If an observation is right censored, then the standardized residual for that observation is also right censored. Adjusted residuals adjust censored standardized residuals upward by adding a percentile of the residual lifetime distribution, given that the standardized residual exceeds the censoring value. The default percentile is the median (50th percentile), but you can, optionally, specify a $\gamma \times 100\%$ percentile by using the RESIDALPHA= γ option in the MODEL statement. The $\gamma \times 100$ percentile residual life is computed as in Joe and Proschan (1984). The adjusted residual is computed as

$$r_{Ai} = \begin{cases} G^{-1}[1 - (1 - \gamma)S(u_i)] & \text{for right-censored observations} \\ u_i & \text{for uncensored observations} \end{cases}$$

where G is the standard CDF,

$$S(u) = 1 - G(u)$$

is the reliability function, and

$$u_i = \frac{y_i - \mathbf{x}'\hat{\boldsymbol{\beta}}}{\hat{\sigma}}$$

If the generalized gamma distribution is specified, the standardized CDF and reliability functions include the estimated shape parameter $\hat{\lambda}$.

Modified Cox-Snell Residuals

Let

$$\delta_i = \begin{cases} 1 & \text{for uncensored observations} \\ 0 & \text{for right-censored observations} \end{cases}$$

The Cox-Snell residual is defined as

$$r_{Ci} = -\log(R(y_i))$$

where

$$R(y) = 1 - G\left(\frac{y - \mathbf{x}'\hat{\boldsymbol{\beta}}}{\hat{\sigma}}\right)$$

is the reliability function. The modified Cox-Snell residual is computed as in Collett (1994, p. 152):

$$r'_{Ci} = r_{Ci} + (1 - \delta_i)\alpha$$

where α is an adjustment factor. If the fitted model is correct, the Cox-Snell residual has approximately a standard exponential distribution for uncensored observations. If an observation is censored, the residual evaluated at the censoring time is not as large as the residual evaluated at the (unknown) failure time. The adjustment factor α adjusts the censored residuals upward to account for the censoring. The default is $\alpha = 1.0$, the mean of the standard exponential distribution. You can, optionally, specify any adjustment factor by using the MODEL statement option RESIDADJ= α . Another commonly used value is the median of the standard exponential distribution, $\alpha = 0.693$.

Deviance Residuals

Deviance residuals are a zero-mean, symmetrized version of modified Cox-Snell residuals. Deviance residuals are computed as in Collett (1994, p. 153):

$$r_{Di} = \text{sgn}(\delta_i - r_{Ci}) \{-2[\delta_i - r_{Ci} + \delta_i \log(r_{Ci})]\}^{1/2}$$

where

$$\text{sgn}(u) = \begin{cases} -1 & \text{if } u < 0 \\ 1 & \text{if } u \geq 0 \end{cases}$$

Regression Model Statistics Computed for Each Observation for Recurrent Events Data

This section describes statistics that are computed for each observation when you fit a model for recurrent events data. For regression models that are fit using the MODEL statement, you can specify a variety of statistics to be computed for each observation in the input data set. This section describes the method of computation for each statistic. See Table 16.32 and Table 16.34 for the syntax to request these statistics.

Let t_i be the event time in the i th observation in the input data set. The following statistics use the definitions of the mean function $M(t; \eta, \beta)$ and intensity function $\lambda(t; \eta, \beta)$ in Table 16.72, where η and β are replaced by their maximum likelihood estimates. The shape parameter β is assumed to be constant for all observations. For regression models, the scale parameter η in Table 16.72 for the i th observation is

$$\eta_i = \beta_0 + \beta_1 x_{i1} + \dots$$

where x_{i1}, x_{i2}, \dots are regression coefficients and β_0, β_1, \dots are the maximum likelihood estimates of the regression parameters.

Predicted Values of Scale Parameter

The scale parameter that is predicted by the model for the i th observation is

$$\hat{\eta}_i = \mathbf{x}'_i \hat{\boldsymbol{\beta}}$$

where \mathbf{x}_i is the vector of explanatory variables for the i th observation and $\boldsymbol{\beta}$ is the vector of maximum likelihood estimates of the regression parameters.

Mean Function

The predicted mean function is computed as $M(t_i, \hat{\eta}_i, \hat{\boldsymbol{\beta}})$.

Confidence Limits for the Mean Function

Confidence limits for the estimated $M(t_i)$ are computed as described in the section “NHPP Model Parameter Confidence Limit Computation” on page 1391, using t_i , $\hat{\eta}_i$, and $\hat{\boldsymbol{\beta}}$.

Standard Error of the Mean Function

The standard error of the estimated $M(t_i)$ is computed as described in the section “NHPP Model Parameter Confidence Limit Computation” on page 1391, using t_i , $\hat{\eta}_i$, and $\hat{\beta}$.

Intensity Function

The predicted intensity function is computed as $\lambda(t_i, \hat{\eta}_i, \hat{\beta})$.

Confidence Limits for the Intensity Function

Confidence limits for the estimated $\lambda(t_i)$ are computed as described in the section “NHPP Model Parameter Confidence Limit Computation” on page 1391, using t_i , $\hat{\eta}_i$, and $\hat{\beta}$.

Standard Error of the Intensity Function

The standard error of the estimated $\lambda(t_i)$ is computed as described in the section “NHPP Model Parameter Confidence Limit Computation” on page 1391, using t_i , $\hat{\eta}_i$, and $\hat{\beta}$.

Recurrence Data from Repairable Systems

Failures in a system that can be repaired are sometimes modeled as *recurrence data*, or *recurrent events data*. When a repairable system fails, it is repaired and placed back in service. As a repairable system ages, it accumulates a history of repairs and costs of repairs. The mean cumulative function (MCF) $M(t)$ is defined as the population mean of the cumulative number (or cost) of repairs up until time t . You can use the RELIABILITY procedure to compute and plot nonparametric estimates and plots of the MCF for the number of repairs or the cost of repairs. The Nelson (1995) confidence limits for the MCF are also computed and plotted. You can compute and plot estimates of the difference of two MCFs and confidence intervals. This is useful for comparing the repair performance of two systems.

See Nelson (2002, 1995, 1988), Doganaksoy and Nelson (1998), and Nelson and Doganaksoy (1989) for discussions and examples of nonparametric analysis of recurrence data.

You can also fit a parametric model for recurrent event data and display the resulting model on a plot, along with nonparametric estimates of the MCF.

See Rigdon and Basu (2000), Tobias and Trindade (1995), and Meeker and Escobar (1998) for discussions of parametric models for recurrent events data.

Nonparametric Analysis

Recurrent Events Data with Exact Ages

See the section “Analysis of Recurrence Data on Repairs” on page 1253 and the section “Comparison of Two Samples of Repair Data” on page 1258 for examples of the analysis of recurrence data with exact ages.

Formulas for the MCF estimator $\hat{M}(t)$ and the variance of the estimator $\text{Var}(\hat{M}(t))$ are given in Nelson (1995). Table 16.70 shows a set of artificial repair data from Nelson (1988). For each system, the data consist of the system and cost for each repair. If you want to compute the MCF for

the number of repairs, rather than cost of repairs, then you should set the cost equal to 1 for each repair. A plus sign (+) in place of a cost indicates that the age is a censoring time. The repair history of each system ends with a censoring time.

Table 16.70 System Repair Histories for Artificial Data

Unit	(Age in Months, Cost in \$100)			
6	(5,\$3)	(12,\$1)	(12,+)	
5	(16,+)			
4	(2,\$1)	(8,\$1)	(16,\$2)	(20,+)
3	(18,\$3)	(29,+)		
2	(8,\$2)	(14,\$1)	(26,\$1)	(33,+)
1	(19,\$2)	(39,\$2)	(42,+)	

Table 16.71 illustrates the calculation of the MCF estimate from the data in Table 16.70. The RELIABILITY procedure uses the following rules for computing the MCF estimates.

1. Order all events (repairs and censoring) by age from smallest to largest.
 - If the event ages of the same or different systems are equal, the corresponding data are sorted from the largest repair cost to the smallest. Censoring events always sort as smaller than repair events with equal ages.
 - When event ages and values of more than one system coincide, the corresponding data are sorted from the largest system identifier to the smallest. The system IDs can be numeric or character, but they are always sorted in ASCII order.
2. Compute the number of systems I in service at the current age as the number in service at the last repair time minus the number of censored units in the intervening times.
3. For each repair, compute the mean cost as the cost of the current repair divided by the number in service I .
4. Compute the MCF for each repair as the previous MCF plus the mean cost for the current repair.

Table 16.71 Calculation of MCF for Artificial Data

Event	(Age,Cost)	Number <i>I</i> in Service	Mean Cost	MCF
1	(2,\$1)	6	\$1/6=0.17	0.17
2	(5,\$3)	6	\$3/6=0.50	0.67
3	(8,\$2)	6	\$2/6=0.33	1.00
4	(8,\$1)	6	\$1/6=0.17	1.17
5	(12,\$1)	6	\$1/6=0.17	1.33
6	(12,+)	5		
7	(14,\$1)	5	\$1/5=0.20	1.53
8	(16,\$2)	5	\$2/5=0.40	1.93
9	(16,+)	4		
10	(18,\$3)	4	\$3/4=0.75	2.68
11	(19,\$2)	4	\$2/4=0.50	3.18
12	(20,+)	3		
13	(26,\$1)	3	\$1/3=0.33	3.52
14	(29,+)	2		
15	(33,+)	1		
16	(39,\$2)	1	\$2/1=2.00	5.52
17	(42,+)	0		

If you specify the VARIANCE=NELSON option, the variance of the estimator of the MCF $\text{Var}(\hat{M}(t))$ is computed as in Nelson (1995). If the VARIANCE=LAWLESS or VARMETHOD2 option is specified, the method of Lawless and Nadeau (1995) is used to compute the variance of the estimator of the MCF. This method is recommended if the number of systems or events is large or if a FREQ statement is used to specify a frequency variable. If you do not specify a variance computation method, the method of Lawless and Nadeau (1995) is used.

Default approximate two-sided $\gamma \times 100\%$ pointwise confidence limits for $M(t)$ are computed as

$$M_L(t) = \hat{M}(t) - K_\gamma \sqrt{\text{Var}(\hat{M}(t))}$$

$$M_U(t) = \hat{M}(t) + K_\gamma \sqrt{\text{Var}(\hat{M}(t))}$$

where K_γ represents the $100(1 + \gamma)/2$ percentile of the standard normal distribution.

If you specify the LOGINTERVALS option in the MCFPLOT statement, alternative confidence intervals based on the asymptotic normality of $\log(\hat{M}(t))$, rather than of $\hat{M}(t)$, are computed. Let

$$w = \exp \left[\frac{K_\gamma \sqrt{\text{Var}(\hat{M}(t))}}{\hat{M}(t)} \right]$$

Then the limits are computed as

$$M_L(t) = \frac{\hat{M}(t)}{w}$$

$$M_U(t) = \hat{M}(t) \times w$$

These alternative limits are always positive, and can provide better coverage than the default limits when the MCF is known to be positive, such as for counts or for positive costs. They are not appropriate for MCF differences, and are not computed in this case.

The following SAS statements create the tabular output shown in [Figure 16.58](#) and the plot shown in [Figure 16.59](#):

```

data Art;
  input Sysid $ Time Cost;
  datalines;

Figure 16.59 MCF Plot for the Artificial Data

Recurrent Events Data with Ages Grouped into Intervals

Recurrence data are sometimes grouped into time intervals for convenience, or to reduce the number of data records to be stored and analyzed. Interval recurrence data consist of the number of recurrences and the number of censored units in each time interval.

You can use PROC RELIABILITY to compute and plot MCFs and MCF differences for interval data. Formulas for the MCF estimator $\hat{M}(t)$ and the variance of the estimator $\text{Var}(\hat{M}(t))$ for interval data, as well as examples and interpretations, are given in Nelson (2002, chapter 5). These calculations apply only to the number of recurrences, and not to cost.

Let N_0 be the total number of units, R_i the number of recurrences in interval i , $i = 1, \dots, n$, and C_i the number of units censored into interval i . Then $N_0 = \sum_{i=1}^n C_i$ and the number entering interval i is $N_i = N_{i-1} - C_{i-1}$ with $C_0 = 0$. The MCF estimate for interval i is $M_0 = 0$,

$$M_i = M_{i-1} + \frac{R_i}{N_i - 0.5C_i}$$

The denominator $N_i - 0.5C_i$ approximates the number at risk in interval i , and treats the censored units as if they were censored halfway through the interval. Since no censored units are likely to

have ages lasting through the entire last interval, the MCF estimate for the last interval is likely to be biased. A footnote is printed in the tabular output as a reminder of this bias for the last interval.

See the section “[Analysis of Interval Age Recurrence Data](#)” on page 1265 for an example of interval recurrence data analysis.

Comparison of Two Groups of Recurrent Events Data

If you specify a group variable in an MCFPLOT statement, and the group variable has only two levels representing two groups of data, then there are two ways to compare the MCFs of the two groups for equality.

If you specify the MCFDIFF option in the MCFPLOT statement, estimates of the difference between two MCFs $MDIFF(t) = M_1(t) - M_2(t)$ and the variance of the estimator are computed and plotted as in Doganaksoy and Nelson (1998). Confidence limits for the MCF difference function are computed in the same way as for the MCF, by using the variance of the MCF difference function estimator. If the confidence limits do not enclose zero at any time point, then the statistical hypothesis that the two MCFs are equal at all times is rejected.

Cook and Lawless (2007, section 3.7.5) describe statistical tests based on weighted sums of sample differences in the MCFs of the two groups. These tests, similar to log-rank tests for survival data, are computed and displayed in the “Tests for Equality of Mean Functions” table. Two cases are computed, corresponding to different weight functions in the test statistic. The “constant” case is powerful in cases where the two MCFs are approximately proportional. The “linear” case is more powerful for cases where the MCFs are not proportional, but do not cross.

These methods are not available for grouped data, as described in “[Recurrent Events Data with Ages Grouped into Intervals](#)” on page 1387.

Parametric Models for Recurrent Events Data

The parametric models used for recurrent events data in PROC RELIABILITY are called *Poisson process models*. Some important features of these models are summarized below. See, for example, Rigdon and Basu (2000) and Meeker and Escobar (1998) for a full mathematical description of these models. See Cook and Lawless (2007) for a general discussion of maximum likelihood estimation in Poisson processes. Abernethy (2006) and U.S. Army (2000) provide examples of the application of Poisson process models to system reliability.

Let $N(t)$ be the number of events up to time t , and let $N(a, b)$ be the number of events in the interval $(a, b]$. Then, for a Poisson process,

- $N(0) = 0$.
- $N(a, b)$ and $N(c, d)$ are statistically independent if $a < b \leq c < d$.
- $N(a, b)$ is a Poisson random variable with mean $M(a, b) = M(b) - M(a)$ where $M(t)$ is the mean number of failures up to time t . $M(0) = 0$.

Poisson processes are characterized by their cumulative mean function $M(t)$, or equivalently by their *intensity, rate, or rate of occurrence of failure* (ROCOF) function $\lambda(t) = \frac{d}{dt}M(t)$, so that

$$M(a, b) = M(b) - M(a) = \int_a^b \lambda(t) dt$$

Poisson processes are parameterized through their mean and rate functions. The RELIABILITY procedure provides the Poisson process models shown in Table 16.72.

Table 16.72 Models and Parameters for Recurrent Events Data

Model	Intensity Function	Mean Function
Crow-AMSAA	$\beta\eta t^{\beta-1}$	ηt^β
Homogeneous	$\exp(\eta)$	$\exp(\eta)t$
Log-linear	$\exp(\eta + \beta t)$	$\frac{\exp(\eta)}{\beta} [\exp(\beta t) - 1]$
Power	$\frac{\beta}{\eta} \left(\frac{t}{\eta}\right)^{\beta-1}$	$\left(\frac{t}{\eta}\right)^\beta$
Proportional intensity	$\exp(\eta)\beta t^{\beta-1}$	$\exp(\eta)t^\beta$

For a homogeneous Poisson process, the intensity function is a constant; that is, the rate of failures does not change with time. For the other models, the rate function can change with time, so that a rate of failures that increases or decreases with time can be modeled. These models are called *non-homogeneous* Poisson processes.

In the RELIABILITY procedure, you specify a Poisson model with a DISTRIBUTION statement and a MODEL statement. You must also specify additional statements, depending on whether failure times are observed exactly, or observed to occur in time intervals. These statements are explained in the sections “Recurrent Events Data with Exact Event Ages” on page 1393, “Recurrent Events Data with Interval Event Ages” on page 1394, and “MODEL Statement” on page 1308. The DISTRIBUTION statement specifications for the models described in Table 16.72 are summarized in Table 16.73.

Table 16.73 DISTRIBUTION Statement Specification for Recurrent Events Data Models

Model	DISTRIBUTION Statement Value
Crow-AMSAA	NHPP(CA)
Homogeneous	HPP
Log-linear	NHPP(LOG)
Power	NHPP(POW)
Proportional intensity	NHPP(PROP)

For each of the models, you can specify a regression model for the parameter η in Table 16.72 for the i th observation as

$$\eta_i = \beta_0 + \beta_1 x_{i1} + \dots$$

where x_{i1}, x_{i2}, \dots are regression coefficients specified as described in the section “MODEL Statement” on page 1308. The parameter β_0 is labeled Intercept in the printed output, and the parameter β in Table 16.72 is labeled Shape. If no regression coefficients are specified, Intercept represents the parameter η in Table 16.72.

Model parameters are estimated by maximizing the log-likelihood function, which is equivalent to maximizing the likelihood function. The sections “Recurrent Events Data with Exact Event Ages” on page 1393 and “Recurrent Events Data with Interval Event Ages” on page 1394 contain descriptions of the form of the log likelihoods for the different models. An estimate of the covariance

matrix of the maximum likelihood estimators (MLEs) of the parameters θ is given by the inverse of the negative of the matrix of second derivatives of the log likelihood, evaluated at the final parameter estimates:

$$\Sigma = [\sigma_{ij}] = -\mathbf{H}^{-1} = -\left[\frac{\partial^2 LL}{\partial\theta_i\partial\theta_j}\right]_{\theta=\hat{\theta}}^{-1}$$

The negative of the matrix of second derivatives is called the observed Fisher information matrix. The diagonal term σ_{ii} is an estimate of the variance of $\hat{\theta}_i$. Estimates of standard errors of the MLEs are provided by

$$SE_{\theta_i} = \sqrt{\sigma_{ii}}$$

An estimator of the correlation matrix is

$$\mathbf{R} = \left[\frac{\sigma_{ij}}{\sqrt{\sigma_{ii}\sigma_{jj}}}\right]$$

Wald-type confidence intervals are computed for the model parameters as described in Table 16.74. Wald intervals use asymptotic normality of maximum likelihood estimates to compute approximate confidence intervals. If a parameter must be greater than zero, then an approximation based on the asymptotic normality of the logarithm of the parameter estimate is often more accurate, and the lower endpoint is strictly positive. The intercept term β_0 in an intercept-only power NHPP model with no other regression parameters represents η in Table 16.72, and is a model parameter that must be strictly positive. Also, the shape parameter for the power and proportional intensity models, represented by β in Table 16.72, must be strictly positive. In these cases, formula 7.11 of Meeker and Escobar (1998, p. 163) is used in Table 16.74 to compute confidence limits.

Table 16.74 shows the method of computation of approximate two-sided $\gamma \times 100\%$ confidence limits for model parameters. The default value of confidence is $\gamma = 0.95$. Other values of confidence are specified using the CONFIDENCE= option. In Table 16.74, K_γ represents the $(1 + \gamma)/2 \times 100\%$ percentile of the standard normal distribution, and $w(\hat{\theta}) = \exp[K_\gamma(SE_{\hat{\theta}})/\hat{\theta}]$.

Table 16.74 NHPP Model Parameter Confidence Limit Computation

Model	Parameters

Proportional intensity			
	Lower	$\hat{\beta}_0 - K_\gamma(\text{SE}_{\hat{\beta}_0})$	$\hat{\beta}_i - K_\gamma(\text{SE}_{\hat{\beta}_i})$
	Upper	$\hat{\beta}_0 + K_\gamma(\text{SE}_{\hat{\beta}_0})$	$\hat{\beta}_i + K_\gamma(\text{SE}_{\hat{\beta}_i})$

You can request that profile likelihood confidence intervals for model parameters be computed instead of Wald intervals with the **LRCL** option in the **MODEL** statement.

Confidence limits for the mean and intensity functions for plots that are created with the **MCFPLOT** statement and for the table that is created with the **OBSTATS** option in the **MODEL** statement are computed by using the delta method. See Meeker and Escobar (1998, Appendix B) for a full explanation of this method. If Σ represents the covariance matrix of the estimates of the parameters η and β in Table 16.72, then the variance of the mean or intensity function estimate is given by

$$V = \begin{bmatrix} \frac{\partial g}{\partial \eta} & \frac{\partial g}{\partial \beta} \end{bmatrix} \Sigma \begin{bmatrix} \frac{\partial g}{\partial \eta} \\ \frac{\partial g}{\partial \beta} \end{bmatrix}'$$

where $g = g(t; \eta, \beta)$ represents either the mean function or the intensity function in Table 16.72. Since both of these functions must be positive, formula 7.11 of Meeker and Escobar (1998, p. 163) is used to compute confidence limits, using the standard error $\sigma = \sqrt{V}$. For regression models,

the full covariance matrix of all the regression parameter estimates and the parameter β is used to compute Σ .

Tests of Trend

For the nonhomogeneous models in Table 16.72, you can request a test for a homogeneous Poisson process by specifying the `HPPTEST` option in the `MODEL` statement. In this case the test is a likelihood ratio test for $\beta = 1$ for the power, Crow-AMSAA, and proportional intensity models, and $\beta = 0$ for the log-linear model.

You can request other tests of trend by using the `TREND=` option in the `MODEL` statement. These tests are not available for the kind of grouped data that are described in the section “Recurrent Events Data with Interval Event Ages” on page 1394. See Lindqvist and Doksum (2003), Kvaloy and Lindqvist (1998), and Meeker and Escobar (1998) for a discussion of these kinds of tests.

Let there be m independent systems observed, and let $t_{i1}, t_{i2}, \dots, t_{in_i}$ be the times of observed events for system i . Let the last time of observation of system i be T_i , with $t_{in_i} \leq T_i$. The following test statistics can be computed. These are extended versions of trend tests for a single system, and they allow valid tests for HPP versus NHPP even if the intensities vary from system to system.

- Military Handbook (MH)

$$\text{MH} = 2 \sum_{i=1}^m \sum_{j=1}^{n_i} \log \left(\frac{T_i}{t_{ij}} \right)$$

The asymptotic distribution of MH is the chi-square with $2 \sum_{i=1}^m n_i$ degrees of freedom. This test statistic is powerful for testing HPP versus NHPP in the power law model.

- Laplace (LA)

$$\text{LA} = \frac{\sum_{i=1}^m \sum_{j=1}^{n_i} (t_{ij} - \frac{1}{2}T_i)}{\sqrt{\frac{1}{12} \sum_{i=1}^m n_i T_i^2}}$$

The asymptotic distribution of LA is the standard normal. This test statistic is powerful for testing HPP versus NHPP in a log-linear model.

- Lewis-Robinson (LR)

Let LA_i be the Laplace test statistic for system i ,

$$\text{LA}_i = \frac{\sum_{j=1}^{n_i} (t_{ij} - \frac{1}{2}T_i)}{\sqrt{\frac{1}{12}n_i}}$$

The extended Lewis-Robinson test statistic is defined as

$$\text{LR} = \sum_{i=1}^m \frac{\bar{X}_i}{\sigma_i} \text{LA}_i$$

where \bar{X}_i and σ_i are the estimated mean and standard deviation of the event interarrival times for system i . The asymptotic distribution of LR is the standard normal. This test statistic is powerful for testing HPP versus NHPP in a log-linear model.

INEST Data Set for Recurrent Events Models

You can specify a SAS data set to set lower bounds, upper bounds, equality constraints, or initial values for estimating the intercept and shape parameters of the models in Table 16.72 by using the `INEST=` option in the `MODEL` statement. The data set must contain a variable named `_TYPE_` that specifies the action that you want to take in the iterative estimation process, and some combination of variables named `_INTERCEPT_` and `_SHAPE_` that represent the distribution parameters. If BY processing is used, the `INEST=` data set should also include the BY variables, and there must be at least one observation for each BY group.

The possible values of `_TYPE_` and corresponding actions are summarized in Table 16.75.

Table 16.75 `_TYPE_` Variable Values

Value of <code>_TYPE_</code>	Action
LB	Lower bound
UB	Upper bound
EQ	Equality
PARMS	Initial value

For example, you can use the `INEST` data set `In` created by the following SAS statements to specify an equality constraint for the shape parameter. The data set `In` specifies that the shape parameter be constrained to be 1.5. Since the variable `_Intercept_` is set to missing, no action is taken for it, and this variable could be omitted from the data set.

```
data In ;
  input _Type_ $ 1-5 _Intercept_ _Shape_ ;
  datalines;
eq      . 1.5
;
```

Recurrent Events Data with Exact Event Ages

Let there be m independent systems observed, and let $t_{i1}, t_{i2}, \dots, t_{in_i}$ be the times of observed events for system i . Let the last time of observation of system i be T_i , with $t_{in_i} \leq T_i$.

If there are no regression parameters in the model, or there are regression parameters and they are constant for each system, then the log-likelihood function is

$$LL = \sum_{i=1}^m \left\{ \sum_{j=1}^{n_i} [\log(\lambda(t_{ij}))] - M(T_i) \right\}$$

If there are regression parameters that can change over time for individual systems, the `RELIABILITY` procedure uses the convention that a covariate value specified at a given event time takes effect immediately after the event time; that is, the value of a covariate used at an event time is the value specified at the previous event time. The value used at the first event time is the value specified at that event time. You can establish a different value for the first event time by specifying a zero cost event previous to the first actual event. The zero cost event is not used in the analysis, but it is used to establish a covariate value for the next event time. The covariate value used at the end time T_i is the value established at the last event time.

With these conventions, the log likelihood is

$$LL = \sum_{i=1}^m \left\{ \sum_{j=1}^{n_i} [\log(\lambda(t_{ij})) - (M(t_{ij}) - M(t_{i,j-1}))] - (M(T_i) - M(t_{in_i})) \right\}$$

with $t_{i0} = 0$ for each $i = 1, 2, \dots, m$. Note that this log likelihood reduces to the previous log likelihood if covariate values do not change over time for each system.

In order to specify a parametric model for recurrence data with exact event times, you specify the event times, end of observation times, and regression model, if any, with a **MODEL** statement, as described in the section “**MODEL Statement**” on page 1308. In addition, you specify a variable that uniquely identifies each system with a **UNITID** statement. See the section “**Parametric Model for Recurrent Events Data**” on page 1274 for an example of fitting a parametric recurrent events model to data with exact recurrence times.

Recurrent Events Data with Interval Event Ages

If n independent and statistically identical systems are observed in the time interval $(t_a, t_b]$, then the number r of events that occur in the interval is a Poisson random variable with mean $nM(t_a, t_b) = n[M(t_a) - M(t_b)]$, where $M(t)$ is the cumulative mean function for an individual system.

Let $(t_0, t_1], (t_1, t_2], \dots, (t_{m-1}, t_m]$ be nonoverlapping time intervals for which r_i events are observed among the n_i systems observed in time interval $(t_{i-1}, t_i]$. The parameters in the mean function $M(t)$ are estimated by maximizing the log likelihood

$$LL = \sum_{i=1}^m [r_i \log(n_i) + r_i \log(M(t_{i-1}, t_i)) - n_i M(t_{i-1}, t_i) - \log(r_i!)]$$

The time intervals do not have to be of the same length, and they do not have to be adjacent, although the preceding formula shows them as adjacent.

If you have data from groups of systems to which you are fitting a regression model (for example, to model the effects of different manufacturing lines or different vendors), the time intervals in the different groups do not have to coincide. The only requirement is that the data in the different groups be independent; for example, you cannot have data from the same systems in two different groups.

In order to specify a parametric model for interval recurrence data, you specify the time intervals and regression model, if any, with a **MODEL** statement, as described in the section “**MODEL Statement**” on page 1308. In addition, you specify a variable that contains the number n_i of systems under observation in time interval i with an **NENTER** statement, and the number of events r_i observed with a **FREQ** statement. See the section “**Parametric Model for Interval Recurrent Events Data**” on page 1276 for an example of fitting a parametric recurrent events model to data with interval recurrence times.

Duane Plots

A Duane plot is defined as a graph of the quantity $H(t) = M(t)/t$ versus t , where $M(t)$ is the MCF. The graph axes are usually both on the log scale, so that if $M(t)$ is the power law type in Table 16.72, a linear graph is produced. Duane plots are traditionally used as a visual assessment of the goodness of fit of a power law model. You should exercise caution in using Duane plots, because even if the

underlying model is a power law process, a nonlinear Duane plot can result. See Rigdon and Basu (2000, section 4.1.1) for a discussion of Duane plots. You can create a Duane plot by specifying the **DUANE** option in the **MCFPLOT** statement. A scatter plot of nonparametric estimates of $\hat{H}(t_i) = \hat{M}(t_i)/t_i$ versus t_i is created on a log-log scale, where $\hat{M}(t_i)$ are the nonparametric estimates of the MCF that are described in the section “Nonparametric Analysis” on page 1382. If you specify a parametric model with the **FIT=MODEL** option in the **MCFPLOT** statement, the corresponding parametric estimate of $H(t)$ is plotted on the same graph as the scatter plot.

ODS Table Names

The following tables contain the ODS table names created by the RELIABILITY Procedure, organized by the statements that produce them.

Table 16.76 Tables Produced with the ANALYZE Statement

Table Name	Description
ConvergenceStatus	Convergence status
CorrMat	Parameter correlation matrix
CovMat	Parameter covariance matrix
DatSum	Summary of fit
GradHess	Last evaluation of parameters, gradient, and Hessian
IterEM	Iteration history for Turnbull algorithm
IterLRParm	Iteration history for likelihood ratio confidence intervals for parameters
IterLRPer	Iteration history for likelihood ratio confidence intervals for percentiles
IterParms	Iteration history for parameter estimates
Lagrange	Lagrange multiplier statistics
NObs	Observations summary
PBEst	Poisson/binomial estimates by group
PBPred	Poisson/binomial predicted values
PBPredTol	Poisson/binomial predicted values by group
PBSum	Poisson/binomial analysis summary
PBTol	Poisson/binomial tolerance estimates
PctEst	Percentile estimates
ParmEst	Parameter estimates
ParmOther	Fitted distribution mean, median, mode
PGradHess	Last evaluation of parameters, gradient, and Hessian in terms of stable parameters
ProbabilityEstimates	Nonparametric cumulative distribution function estimates
RelInfo	Model information
SurvEst	Survival function estimates
TurnbullGrad	Interval probabilities, reduced gradient, Lagrange multipliers for Turnbull algorithm
WCorrMat	Parameter correlation matrix for Weibull distribution
WCovMat	Parameter covariance matrix for Weibull distribution

Table 16.77 Tables Produced with the MCFPLOT Statement

Table Name	Description
McfDEst	MCF difference estimates
McfDSum	MCF difference data summary
McfEst	MCF estimates
McfLogRank	Tests of difference between two MCFs
McfSum	MCF data summary

Table 16.78 Tables Produced with the MODEL Statement

Table Name	Description
MConvergenceStatus	Convergence status
ClassLevels	Class level information
ModCorMat	Parameter correlation matrix
ModCovMat	Parameter covariance matrix
ModFitSum	Summary of fit
ModInfo	Model information
ModIterLRparm	Iteration history for likelihood ratio confidence intervals for parameters
ModIterParms	Iteration history for parameter estimates
ModLagr	Lagrange multiplier statistics
ModLastGradHess	Last evaluation of the gradient and Hessian
ModNObs	Observations summary
ModObstats	Observation statistics
ModParmInfo	Parameter information
ModPrmEst	Parameter estimates
RecurGoodFit	Test for homogeneous Poisson process

Table 16.79 Tables Produced with PROBPLOT and RELATIONPLOT Statements

Table Name	Description
ConvergenceStatus	Convergence status
CorrMat	Parameter correlation matrix
CovMat	Parameter covariance matrix
DatSum	Summary of fit
GradHess	Last evaluation of parameters, gradient, and Hessian
IterEM	Iteration history for Turnbull algorithm
IterLRParm	Iteration history for likelihood ratio confidence intervals for parameters
IterLRPer	Iteration history for likelihood ratio confidence intervals for percentiles
IterParms	Iteration history for parameter estimates
Lagrange	Lagrange multiplier statistics
NObs	Observations summary
PctEst	Percentile estimates
ParmEst	Parameter estimates
ParmOther	Fitted distribution mean, median, mode

Table 16.79 Tables Produced with PROBLOT and RELATIONPLOT Statements (continued)

Table Name	Description
PGradHess	Last evaluation of parameters, gradient, and Hessian in terms of stable parameters
ProbabilityEstimates	Nonparametric cumulative distribution function estimates
RelInfo	Model information
SurvEst	Survival function estimates
TurnbullGrad	Interval probabilities, reduced gradient, Lagrange multipliers for Turnbull algorithm
WCorrMat	Parameter correlation matrix for Weibull distribution
WCovMat	Parameter covariance matrix for Weibull distribution

ODS Graphics

SAS/QC procedures use ODS Graphics functionality to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

Before you create graphs, ODS Graphics must be enabled. For example:

```
ods graphics on;

proc reliability;
  probplot y;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

See Chapter 3, “SAS/QC Graphics,” for alternative methods of creating graphics with PROC RELIABILITY. See the section “Analysis of Right-Censored Data from a Single Population” on page 1214 for an example that uses ODS Graphics in PROC RELIABILITY to create a probability plot and the section “ODS Graph Names” on page 1397 for ODS Graphics table names.

ODS Graph Names

If ODS Graphics is enabled (for example, with the ODS GRAPHICS ON statement), PROC RELIABILITY creates graphs by using ODS Graphics. You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC RELIABILITY generates are listed in Table 16.80, along with the required statements and options.

Table 16.80 Graphs Produced by PROC RELIABILITY

ODS Graph Name	Description	Statement	Option
IntensityPlot	Plot of intensity function for NHPP model	MCFPLOT	Fit=MODEL
IntensityPlots	Plot of intensity functions for NHPP model for multiple groups	MCFPLOT	Fit=MODEL
MCFDiffPlot	Plot of mean cumulative function differences	MCFPLOT	MCFDIFF
MCFPlot	Plot of mean cumulative function plot for single population	MCFPLOT	Default
MCFPlotPanel	Plot of mean cumulative function plots for multiple groups	MCFPLOT	Group variable
ProbabilityPlot	Probability plot for single population	PROBPLOT	Default
ProbabilityPlotFM	Probability plot with failure modes	PROBPLOT	FMODE
ProbabilityPlotPanel	Probability plots for multiple groups	PROBPLOT	Group variable
PercentilePlot	Plot of model percentiles	RELATIONPLOT	Default
RelationPlot	Plot of model percentiles with probability plot	RELATIONPLOT	PLOT

Introduction: SHEWHART Procedure

The Shewhart control chart is a graphical and analytical tool for deciding whether a process is in a state of statistical control. You can use the SHEWHART procedure to display many different types of control charts, including all commonly used charts for variables and attributes. In addition, you can use the SHEWHART procedure to

- create charts from either raw data (actual measurements) or summarized data
- analyze multiple process variables
- specify control limits in terms of a multiple of the standard error of the plotted summary statistic or as probability limits
- adjust control limits to compensate for unequal subgroup sizes
- estimate control limits from the data, compute control limits from specified values for population parameters (known standards), or read limits from an input data set
- create historical control charts that display distinct sets of control limits for multiple time phases
- perform tests for special causes based on runs patterns (Western Electric rules)
- estimate the process standard deviation using various methods (variable charts only)
- accept numeric-valued or character-valued subgroup variables
- display subgroups with date and time formats
- save chart statistics and control limits in output data sets
- tabulate chart statistics and control limits

- produce charts as traditional graphics, ODS Graphics output, or legacy line printer charts. Line printer charts can use special formatting characters that improve the appearance of the chart. Traditional graphics can be annotated, saved, and replayed.

Uses of Shewhart Charts

The Shewhart chart is named after Walter A. Shewhart (1891-1967), a physicist at the Bell Telephone Laboratories, who introduced the method in 1924 and elaborated upon it in his book *Economic Control of Quality of Manufactured Product*, (1931). The concepts underlying the control chart are that the natural variability in any manufacturing process can be quantified with a set of control limits and that the variation exceeding these limits signals a change in the process.

In industry, the Shewhart chart is the most commonly applied statistical quality control method for studying the variation in output from a manufacturing process. Shewhart charts are typically used to distinguish variation due to *special causes* from variation due to *common causes*. Special causes, also referred to as *assignable causes*, are local, sporadic problems such as the failure of a particular machine or a mistakenly recorded measurement. Common causes are problems inherent in the manufacturing system as a whole. Examples of common causes are inadequate product design, inherited defective material, and excessive humidity.

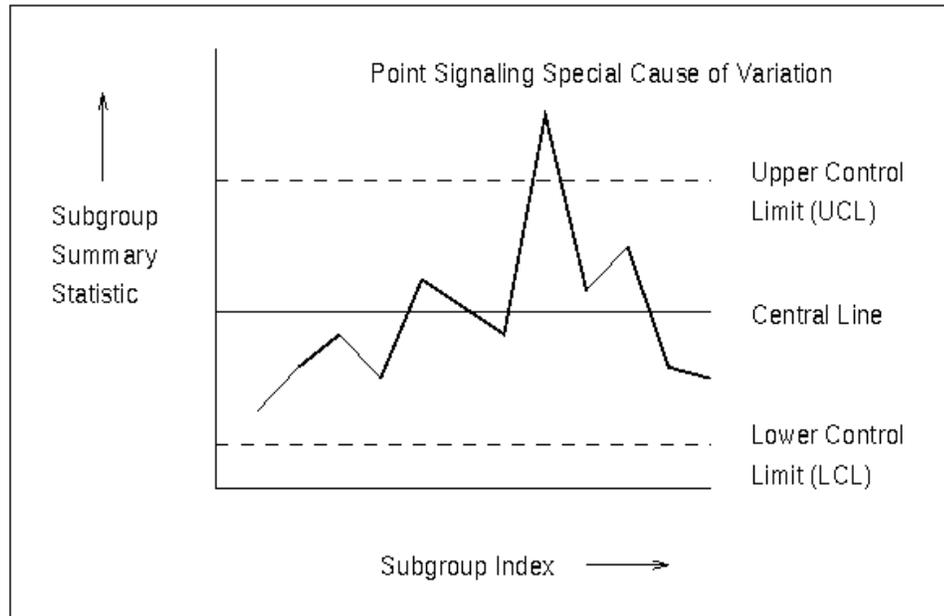

When the special causes have been identified and eliminated, the process is said to be in *statistical control*. Once statistical control has been established, Shewhart charts can be used to monitor the process for the occurrence of future special causes and to measure and reduce the effects of common causes.

Deming (1982) emphasized that the improvement of a process can begin only after statistical control has been established. Deming also noted that control chart techniques are applicable to quality improvement in service industries as well as manufacturing industries.

Characteristics of Shewhart Charts

Figure 17.1 illustrates a typical Shewhart chart.

Figure 17.1 A Shewhart Control Chart

All Shewhart charts have the following characteristics:

- Each point represents a *summary statistic* computed from a sample of measurements of a quality characteristic. For example, the summary statistic might be the average value of a critical dimension of five items selected at random, or it might be the proportion of nonconforming items in a sample of 100 items.
- The *vertical axis* of a Shewhart chart is scaled in the same units as the summary statistic.
- The samples from which the summary statistics are computed are referred to as *rational subgroups* or *subgroup samples*. The organization of the data into subgroups is critical to the interpretation of a Shewhart chart. Shewhart (1931) advocated selecting rational subgroups so that variation within subgroups is minimized and variation among subgroups is maximized; this makes the chart more sensitive to shifts in the process level. Various approaches to subgrouping are discussed by Grant and Leavenworth (1988), Montgomery (1996), and Kume (1985).
- The *horizontal axis* of a Shewhart chart identifies the subgroup samples. Frequently, the samples are indexed according to the order in which they were taken or the time at which they were taken. Subgroup samples can also be assigned labels that indicate some other type of classification (for example, lot number).
- The *central line* on a Shewhart chart indicates the average (expected value) of the summary statistic when the process is in statistical control.

- The *upper and lower control limits*, labeled UCL and LCL, respectively, indicate the range of variation to be expected in the summary statistic when the process is in statistical control. The control limits are commonly computed as 3σ limits¹ representing three standard errors² of variation in the summary statistic above and below the central line. However, the limits can also be determined using a multiple of the standard error other than three, or from a specified probability (α) that a single summary statistic will exceed the limits when the process is in statistical control. Limits determined by the latter method are referred to as *probability limits*.

The control limits are also determined by the subgroup sample size because the standard error of the summary statistic is a function of sample size. If the sample size is constant across subgroups, the control limits are typically horizontal lines, as in Figure 17.1. However, if the sample size varies from subgroup to subgroup, the limits are usually adjusted to compensate for the effect of sample size, resulting in step-like boundaries.

Control limits can be estimated from the data being analyzed, or they can be standard, previously determined values. Estimated limits are often used when statistical control is being established, and standard limits are often used when statistical control is being maintained.

- A *point outside the control limits* signals the presence of a special cause of variation. Additionally, *tests for special causes* (also referred to as *Western Electric rules* and *runs tests*) can signal an out-of-control condition if a statistically unusual pattern of points is observed in the control chart. For example, one pattern used to diagnose the existence of a trend is seven consecutive steadily increasing points.

When the process is in statistical control, a point may fall outside the control limits purely by chance, resulting in a false out-of-control signal. However, when the Shewhart chart correctly signals the presence of a special cause, additional action is needed to determine the nature of the problem and eliminate it.

Classification of Shewhart Charts

Shewhart charts are broadly classified according to the type of data analyzed.

- Shewhart charts for *variables* are used when the quality characteristic of a process is measured on a continuous scale.
- Shewhart charts for *attributes* are used when the quality characteristic of a process is measured by counting the number of nonconformities (defects) in an item or the number of nonconforming (defective) items in a sample.

¹In this context, the symbol σ always stands for the standard error of the subgroup summary statistic that is plotted on the chart. Elsewhere in this section, σ is also used to denote the standard deviation of a process, also referred to as the population standard deviation. This dual usage is standard practice.

²The term *standard deviation* is also used by some authors to refer to this quantity; see, for example, Montgomery (1996). This section uses the term *standard error* for the dispersion of the distribution of a statistic and the term *standard deviation* for the dispersion of a distribution of individual measurements.

Shewhart charts for variables are further classified according to the subgroup summary statistic plotted on the chart.

- \bar{X} and R charts display subgroup means (averages) and ranges. Typically the two charts are presented on the same page, with the \bar{X} chart aligned above the R chart to facilitate the simultaneous analysis of the central tendency and variability of the process.
- \bar{X} and s charts display subgroup means (averages) and standard deviations. Typically the two charts are presented on the same page, with the \bar{X} chart aligned above the s chart.
- Median and range charts display subgroup medians and ranges. Typically the two charts are presented on the same page, with the median chart aligned above the R chart.
- Charts for individual measurements and moving ranges display individual measurements and moving ranges of two or more successive measurements. In this case the subgroup sample consists of a single observation.

Likewise, Shewhart charts for attributes are classified according to the subgroup summary statistic plotted on the chart:

- A p chart displays the proportion of nonconforming (defective) items in a subgroup sample.
- An np chart displays the number of nonconforming (defective) items in a subgroup sample.
- A u chart displays the number of nonconformities (defects) per unit in a subgroup sample consisting of an arbitrary number of units.
- A c chart displays the number of nonconformities (defects) in a unit (here, a subgroup sample typically consists of one unit).

You can create all of the preceding types of Shewhart charts with the SHEWHART procedure. In addition, you can create a wide variety of nonstandard Shewhart charts, including

- a trend chart displaying a time trend plot and an \bar{X} chart (or median chart) that has been created removing the time trend from the data. The trend chart and \bar{X} chart are presented on the same page, with the \bar{X} aligned above the trend chart, to facilitate the detection of special causes after accounting for the time trend effect. Trend charts are applicable when a time trend (for instance, due to tool wear) is observed in a preliminary \bar{X} chart of the original data.
- a box chart displaying a box plot (box-and-whisker plot) for each subgroup and control limits for the subgroup means. This chart facilitates detailed analysis of the subgroup distributions and is applicable with large subgroup sample sizes (ten or more).

Learning to Use the SHEWHART Procedure

Although the SHEWHART procedure provides a large number of options, you can use the procedure to create a basic Shewhart chart with as few as two SAS statements:

- the PROC SHEWHART statement, which starts the procedure and specifies the input SAS data set
- a chart statement, which specifies the type of Shewhart chart you want to create and the variables in the input data set that you want to analyze

For example, you can use the following statements to create \bar{X} and R charts with 3σ limits for measurements read from a SAS data set named Drums:

```
proc shewhart data=Drums;
  xrchart Flangewidth * Hour;
run;
```

The keyword XRCHART in the chart statement specifies that \bar{X} and R charts are to be created. The following SAS variables are specified in the XRCHART statement:

- A SAS variable (Flangewidth), whose values are the process measurements, is specified before the asterisk. This variable is referred to as the *process*.
- A SAS variable (Hour), whose values classify the measurements into subgroups, is specified after the asterisk. This variable is referred to as a *subgroup-variable*.

The same form of specification is used with other chart statements to create different types of Shewhart charts. The following table lists the 13 chart statements that are available with the SHEWHART procedure:

Table 17.1 Chart Statements in the SHEWHART Procedure

Statement	Chart(s) Displayed	“Getting Started” Section
BOXCHART	box chart with optional trend chart	“Getting Started: BOXCHART Statement” on page 1425
CCHART	c chart	“Getting Started: CCHART Statement” on page 1493
IRCHART	individual and moving range charts	“Getting Started: IRCHART Statement” on page 1530
MCHART	median chart with optional trend chart	“Getting Started: MCHART Statement” on page 1572
MRCHART	median and R charts	“Getting Started: MRCHART Statement” on page 1616
NPCHART	np chart	“Getting Started: NPCHART Statement” on page 1659
PCHART	p chart	“Getting Started: PCHART Statement” on page 1701
RCHART	R chart	“Getting Started: RCHART Statement” on page 1745
SCHART	s chart	“Getting Started: SCHART Statement” on page 1783
UCHART	u chart	“Getting Started: UCHART Statement” on page 1818
XCHART	\bar{X} chart with optional trend chart	“Getting Started: XCHART Statement” on page 1857
XRCHART	\bar{X} and R charts	“Getting Started: XRCHART Statement” on page 1903
XSCHART	\bar{X} and s charts	“Getting Started: XSCHART Statement” on page 1957

If you are using the SHEWHART procedure for the first time, you should do the following:

- Read “PROC SHEWHART and General Statements” on page 1416.
- Read the “Getting Started” subsection in the section for the chart statement you need to create your chart. Table 17.1 provides links to these sections.

Once you have learned to use a particular chart statement, you will find it straightforward to use the remaining chart statements since their syntax is nearly the same. A separate, self-contained section is provided for each chart statement.

PROC SHEWHART and General Statements

Overview: SHEWHART Procedure

The PROC SHEWHART statement starts the SHEWHART procedure and it optionally identifies various data sets.

To create a Shewhart chart, you specify a chart statement (after the PROC SHEWHART statement) that specifies the type of Shewhart chart you want to create and the variables in the input data set that you want to analyze. For example, the following statements request \bar{X} and R charts:

```
proc shewhart data=Values;
  xrchart Weight*Lot;
run;
```

Here, the DATA= option specifies an input data set (Values) with the *process* measurement variable (Weight) and the *subgroup-variable* (Lot).³

You can use options in the PROC SHEWHART statement to

- specify input data sets containing variables to be analyzed, control limit information, or annotation information
- specify a graphics catalog for saving traditional graphics
- specify whether charts are to be produced as traditional graphics or line printer charts
- define characters used for features on line printer charts

See Chapter 3, “SAS/QC Graphics,” for a detailed discussion of the alternatives available for producing charts with SAS/QC procedures.

NOTE: If you are learning to use the SHEWHART procedure, you should read both this section and the “Getting Started” subsection in the section for the chart statement that corresponds to the chart you want to create.

³In SAS 6.12 and previous releases of SAS/QC software, the keyword GRAPHICS was required in the PROC SHEWHART statement to specify that the chart be created using traditional graphics. In SAS 7 and later releases, you can specify the LINEPRINTER option to request line printer charts.

Syntax: SHEWHART Procedure

The following are the primary statements that control the SHEWHART procedure:

```

PROC SHEWHART < options > ;
  BOXCHART (processes) * subgroup-variable < (block-variables) >
    < =symbol-variable | = 'character' > < / options > ;
  CCHART (processes) * subgroup-variable < (block-variables) >
    < =symbol-variable | = 'character' > < / options > ;
  IRCHART (processes) * subgroup-variable < (block-variables) >
    < =symbol-variable | = 'character' > < / options > ;
  MCHART (processes) * subgroup-variable < (block-variables) >
    < =symbol-variable | = 'character' > < / options > ;
  MRCHART (processes) * subgroup-variable < (block-variables) >
    < =symbol-variable | = 'character' > < / options > ;
  NPCHART (processes) * subgroup-variable < (block-variables) >
    < =symbol-variable | = 'character' > < / options > ;
  PCHART (processes) * subgroup-variable < (block-variables) >
    < =symbol-variable | = 'character' > < / options > ;
  RCHART (processes) * subgroup-variable < (block-variables) >
    < =symbol-variable | = 'character' > < / options > ;
  SCHART (processes) * subgroup-variable < (block-variables) >
    < =symbol-variable | = 'character' > < / options > ;
  UCHART (processes) * subgroup-variable < (block-variables) >
    < =symbol-variable | = 'character' > < / options > ;
  XCHART (processes) * subgroup-variable < (block-variables) >
    < =symbol-variable | = 'character' > < / options > ;
  XRCHART (processes) * subgroup-variable < (block-variables) >
    < =symbol-variable | = 'character' > < / options > ;
  XSCHART (processes) * subgroup-variable < (block-variables) >
    < =symbol-variable | = 'character' > < / options > ;
  INSET keyword-list < / options > ;
  INSET2 keyword-list < / options > ;

```

The PROC SHEWHART statement invokes the procedure and specifies the input data set. The chart statements create different types of control charts. You can specify one or more of each of the chart statements. For details, read the section on the chart statement that corresponds to the type of control chart you want to produce.

In addition, you can optionally specify one of each of the following statements:

BY Statement

```
BY variables ;
```

You can specify a BY statement with PROC SHEWHART to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the SHEWHART procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

ID Statement

ID variables ;

The ID statement specifies variables used to identify observations. The ID variables must be variables in the DATA= or HISTORY= input data sets.

The ID variables are used in the following ways:

- If you create an OUTHISTORY= or OUTTABLE= data set, the ID variables are included. If the input data set is a DATA= data set, only the values of the ID variables from the first observation in each subgroup are passed to the output data set.
- If you specify the TABLEID or TABLEALL options in a chart statement, the table produced is augmented by a column for each of the ID variables. Only the values of the ID variables from the first observation in each subgroup are tabulated. See the entry for the TABLEID option in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.
- If you specify the BOXSTYLE=SCHEMATICID option or the BOXSTYLE= SCHEMATICIDFAR option in the BOXCHART statement, the value of the first variable listed in the ID statement is used to label each extreme observation. See [Output 17.2.3](#) and [Output 17.2.4](#).

Graphical Enhancement Statements

You can use TITLE, FOOTNOTE, and NOTE statements to enhance graphical and printed output. If you are creating traditional graphics, you can also use AXIS, LEGEND, and SYMBOL statements to enhance your charts. For details, refer to *SAS/GRAPH: Reference* and see the section for the control chart statement that you are using.

PROC SHEWHART Statement

The syntax for the PROC SHEWHART statement is as follows:

```
PROC SHEWHART < options > ;
```

The PROC SHEWHART statement starts the SHEWHART procedure, and it optionally identifies various data sets and requests graphics output. The following section lists all *options*. See “[Dictionary of Options](#)” on page 1419 below for detailed information.

Summary of Options

The following table lists the PROC SHEWHART *options* by function:

Table 17.2 PROC SHEWHART Statement Options

Option	Description
Input Data Sets Options	
ANNOTATE=	specifies input data set containing annotation information for primary chart
ANNOTATE2=	specifies input data set containing annotation information for secondary chart
BOX=	specifies input data set containing summary statistics, control limits, and box chart outlier values
DATA=	specifies input data set containing raw data
HISTORY=	specifies input data set containing summary statistics
LIMITS=	specifies input data set containing control limits
TABLE=	specifies input data set containing summary statistics and control limits
TESTHTML=	specifies input data set defining links to be associated with subgroups with positive tests for special causes
TESTURLS=	specifies input data set containing URLs associated with subgroups with positive tests for special causes
Plotting and Graphics Options	
FORMCHAR(<i>index</i>)=	defines characters used for features on charts
GOUT=	specifies catalog for saving traditional graphics output
LINEPRINTER	requests line printer charts be produced

Dictionary of Options

The following entries provide detailed descriptions of options in the PROC SHEWHART statement. The marginal notes *Traditional Graphics*, *ODS Graphics*, and *Line Printer* identify options that apply to traditional graphics and line printer charts, respectively.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an input data set containing Annotate variables as described in *SAS/GRAPH: Reference*. You can use this data set to add features to traditional graphics. Use this data set only

when creating traditional graphics. It is ignored when the LINEPRINTER option is specified and when ODS Graphics is in effect. Features provided in this data set are displayed on every chart produced in the current run of PROC SHEWHART.

ANNOTATE2=SAS-data-set

ANNO2=SAS-data-set

Traditional Graphics

specifies an input data set that contains annotate variables. You can use this data set to add features to the secondary chart in statements that produce two charts (the IRCHART, MRCHART, XRCHART, and XSCHART statements and, when you specify the TRENDVAR= option, the BOXCHART, MCHART, and XCHART statements). The restrictions and features are the same as those for the ANNOTATE= option.

BOX=SAS-data-set

names an input data set that contains subgroup summary statistics, control limits, and outlier values in “strung out” form, with more than one observation per subgroup. Each observation corresponds to one feature of one subgroup’s box-and-whisker plot. Typically, this data set is created as an OUTBOX= data set in a previous run of PROC SHEWHART with a BOXCHART statement. The BOX= data set is the only kind of summary data set you can use to produce schematic box-and-whisker plots. The BOXCHART statement is the only chart statement you can use with a BOX= input data set.

You cannot use a BOX= data set together with a DATA=, HISTORY=, or TABLE= data set. If you do not specify one of these four input data sets, PROC SHEWHART uses the most recently created data set as a DATA= data set.

DATA=SAS-data-set

names an input data set that contains raw data as observations. Note that the DATA= data set may need sorting. If the values of the *subgroup-variable* are numeric, you must sort the data set so that these values are in increasing order (within BY groups). Use PROC SORT if the data are not already sorted.

The DATA= data set may contain more than one observation for each value of the *subgroup-variable*. This happens, for example, when you produce a control chart for means and ranges with the XRCHART statement.

You cannot use a DATA= data set together with a BOX=, HISTORY=, or TABLE= data set. If you do not specify one of these four input data sets, PROC SHEWHART uses the most recently created data set as a DATA= data set. For more information, see the “DATA= Data Set” subsection in the section for the chart statement you are using.

FORMCHAR(index)='string'

Line Printer

defines characters used for features on line printer charts, where *index* is a list of numbers ranging from 1 to 17, and *string* is a character or hexadecimal string. The *index* identifies which features are controlled with the *string* characters, as discussed in the following table. If you specify the FORMCHAR= option and omit the *index*, the *string* controls all 17 features.

Value of <i>index</i>	Description of Character	Chart Feature
1	vertical bar	frame
2	horizontal bar	frame, central line
3	box character (upper left)	frame
4	box character (upper middle)	serifs, tick (horizontal axis)
5	box character (upper right)	frame
6	box character (middle left)	not used
7	box character (middle middle)	serifs
8	box character (middle right)	tick (vertical axis)
9	box character (lower left)	frame
10	box character (lower middle)	serifs
11	box character (lower right)	frame
12	vertical bar	control limits
13	horizontal bar	control limits
14	box character (upper right)	control limits
15	box character (lower left)	control limits
16	box character (lower right)	control limits
17	box character (upper left)	control limits

Not all printers can produce all the characters in the preceding list. By default, the form character list specified with the SAS system FORMCHAR= option is used; otherwise, the default is FORMCHAR='|—|+|—|====='. If you print to a PC screen or if your device supports the ASCII symbol set (1 or 2), the following is recommended:

```
formchar=' B3 , C4 , DA , C2 , BF , C3 , C5 , B4 , C0 , C1 , D9 , BA , CD , BB , C8 , BC , D9 ' X
```

Note that the FORMCHAR= option in the PROC SHEWHART statement enables you to override temporarily the values of the SAS system option of the same name. The values of the SAS system option are not altered by using the FORMCHAR= option in the PROC SHEWHART statement.

GOUT=*graphics-catalog*

specifies the graphics catalog for traditional graphics output from PROC SHEWHART. This is useful if you want to save the output. The GOUT= option is used only when creating traditional graphics. It is ignored when the LINEPRINTER option is specified and when ODS Graphics is in effect. *Traditional Graphics*

HISTORY=*SAS-data-set*

HIST=*SAS-data-set*

names an input data set that contains subgroup summary statistics. For example, you can read sample sizes, means, and ranges for the subgroups to create \bar{X} and R charts. Typically, this data set is created as an OUTHISTORY= data set in a previous run of PROC SHEWHART, but it can also be created using a SAS summarization procedure such as the MEANS procedure.

Note that the HISTORY= data sets may need sorting. If the values of the *subgroup-variable* are numeric, you need to sort the data set so that these values are in increasing order (within BY groups). Use PROC SORT if the data are not already sorted. The HISTORY= data set can contain only one observation for each value for the *subgroup-variable*.

You cannot use a HISTORY= data set together with a BOX=, DATA=, or TABLE= data set. If you do not specify one of these four input data sets, PROC SHEWHART uses the most recently created data set as a DATA= data set. For more information, see the “HISTORY= Data Set” subsection in the section for the chart statement you are using.

LIMITS=SAS-data-set

names an input data set that contains preestablished control limits or the parameters from which control limits can be computed. Each observation in a LIMITS= data set provides control limit information for a *process*. Typically, this data set is created as an OUTLIMITS= data set in a previous run of PROC SHEWHART.

If you omit the LIMITS= option, then control limits are computed from the data in the DATA= or HISTORY= input data sets or read from the BOX= or TABLE= input data sets. For details about the variables needed in a LIMITS= data set, see the “LIMITS= Data Set” subsection in the section for the chart statement you are using.

LINEPRINTER

Line Printer requests that line printer charts be produced. By default, the procedure creates traditional graphics.

TABLE=SAS-data-set

names an input data set that contains subgroup summary statistics and control limits. Each observation in a TABLE= data set provides information for a particular subgroup and *process*. Typically, this data set is created as an OUTTABLE= data set in a previous run of PROC SHEWHART.

You cannot use a TABLE= data set together with a BOX=, DATA=, or HISTORY= data set. If you do not specify one of these four input data sets, PROC SHEWHART uses the most recently created data set as a DATA= data set. For more information, see the “TABLE= Data Set” subsection in the section for the chart statement that you are using.

TESTHTML=SAS-data-set

Traditional Graphics names an input data set for creating links associated with tests for special causes when traditional graphics output is directed into HTML. A TESTHTML= data set contains variables _TEST_, _CHART_, and _URL_. _TEST_ and _CHART_ are numeric variables identifying a test for special causes (1-8) and the primary or secondary chart (1 or 2). _URL_ is a character variable containing the HTML syntax to create links associated with subgroups for which the given test on the given chart is positive. See the section “[Interactive Control Charts: SHEWHART Procedure](#)” on page 2212 for more information.

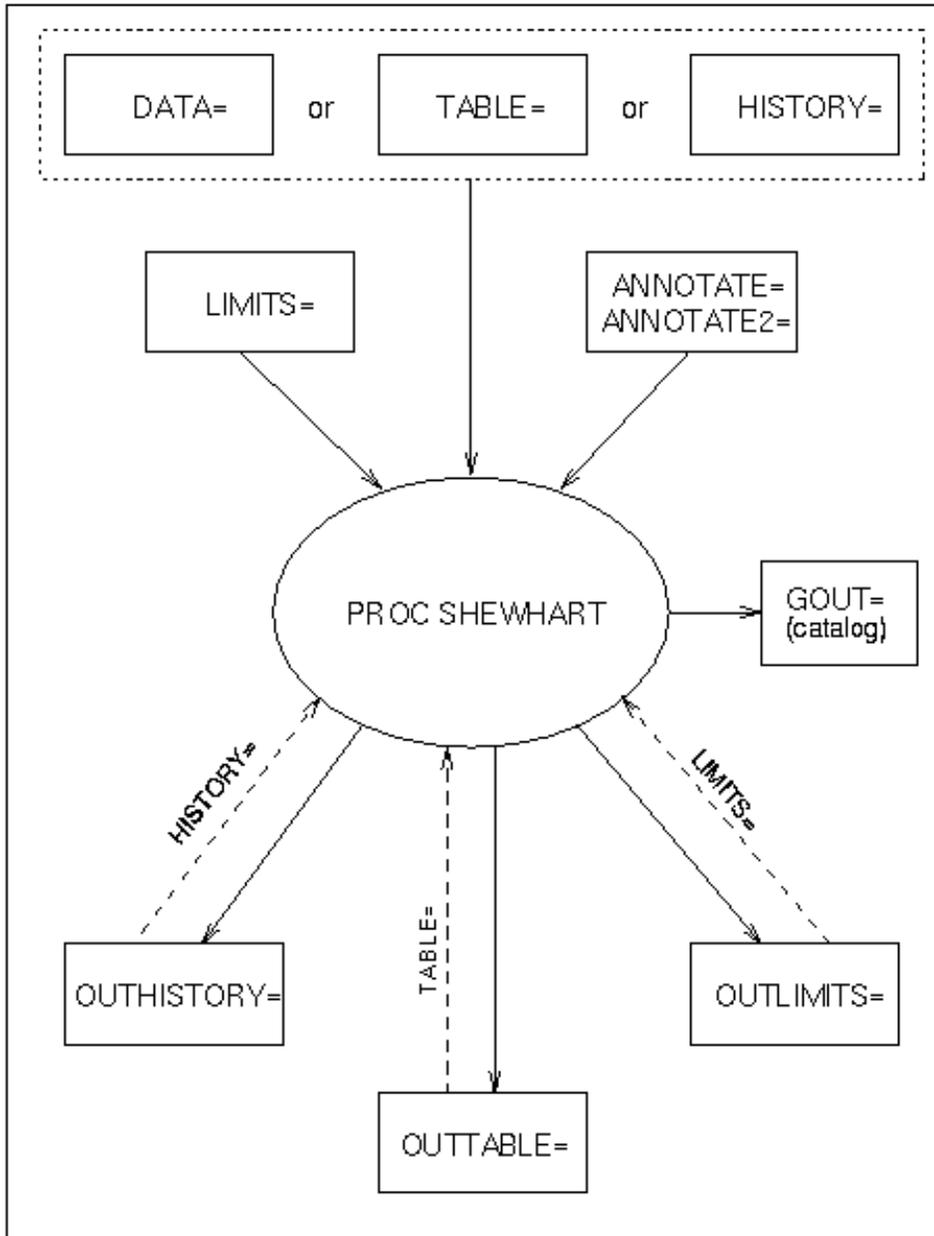

TESTURLS=SAS-data-set

ODS Graphics names an input data set for associating URLs with tests for special causes when ODS Graphics output is directed into HTML. A TESTURLS= data set contains variables _TEST_, _CHART_, and _URL_. _TEST_ and _CHART_ are numeric variables identifying a test for special causes (1-8) and the primary or secondary chart (1 or 2). _URL_ is a character variable containing the URL to be associated with subgroups for which the given test on the given chart is positive. See the section “[Interactive Control Charts: SHEWHART Procedure](#)” on page 2212 for more information.

Input and Output Data Sets: SHEWHART Procedure

Figure 17.2 summarizes the input and output data sets used with the SHEWHART procedure.

Figure 17.2 Input and Output Data Sets in the SHEWHART Procedure

BOXCHART Statement: SHEWHART Procedure

Overview: BOXCHART Statement

The BOXCHART statement creates an \bar{X} chart for subgroup means superimposed with box-and-whisker plots of the measurements in each subgroup. Throughout this chapter, a chart of this type is referred to as a *box chart*. This chart is recommended for large subgroup sample sizes (typically greater than ten). You can also use the BOXCHART statement to create standard side-by-side box-and-whisker plots (see [Example 17.2](#) and [Example 17.3](#)).

You can use options in the BOXCHART statement to

- specify control limits for subgroup means or medians
- compute control limits from the data based on a multiple of the standard error of the means (or medians) or as probability limits
- tabulate subgroup summary statistics and control limits
- save control limits in an output data set
- save subgroup summary statistics in an output data set
- read preestablished control limits from a data set
- apply tests for special causes (also known as runs tests and Western Electric rules)
- specify one of several methods for estimating the process standard deviation
- specify whether subgroup standard deviations or subgroup ranges are used to estimate the process standard deviation
- specify a known (standard) process mean and standard deviation for computing control limits
- create a secondary chart that displays a time trend removed from the data (see “[Displaying Trends in Process Data](#)” on page 2126)
- specify one of several methods for calculating quantile statistics (percentiles)
- control the style of the box-and-whisker plots
- display distinct sets of control limits for data from successive time phases
- add block legends and symbol markers to reveal stratification in process data
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have three alternatives for producing box charts with the BOXCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH® is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: BOXCHART Statement

This section introduces the BOXCHART statement with simple examples that illustrate commonly used options. Complete syntax for the BOXCHART statement is presented in the section “Syntax: BOXCHART Statement” on page 1439, and advanced examples are given in the section “Examples: BOXCHART Statement” on page 1471.

Creating Box Charts from Raw Data

A petroleum company uses a turbine to heat water into steam that is pumped into the ground to make oil less viscous and easier to extract. This process occurs 20 times daily, and the amount of power (in kilowatts) used to heat the water to the desired temperature is recorded. The following statements create a SAS data set that contains the power output measurements for 20 days: *See SHWBOXA in the SAS/QC Sample Library*

```
data Turbine;
  informat Day date7.;
  format Day date5.;
  label KWatts='Average Power Output';
  input Day @;
  do i=1 to 10;
    input KWatts @;
    output;
  end;
  drop i;
  datalines;

```

A partial listing of Turbine is shown in [Figure 17.3](#). This data set is said to be in “strung-out” form since each observation contains the day and power output for a single heating. The first 20 observations contain the outputs for the first day, the second 20 observations contain the outputs for the second day, and so on. Because the variable Day classifies the observations into rational subgroups, it is referred to as the *subgroup-variable*. The variable KWatts contains the output measurements and is referred to as the *process variable* (or *process* for short).

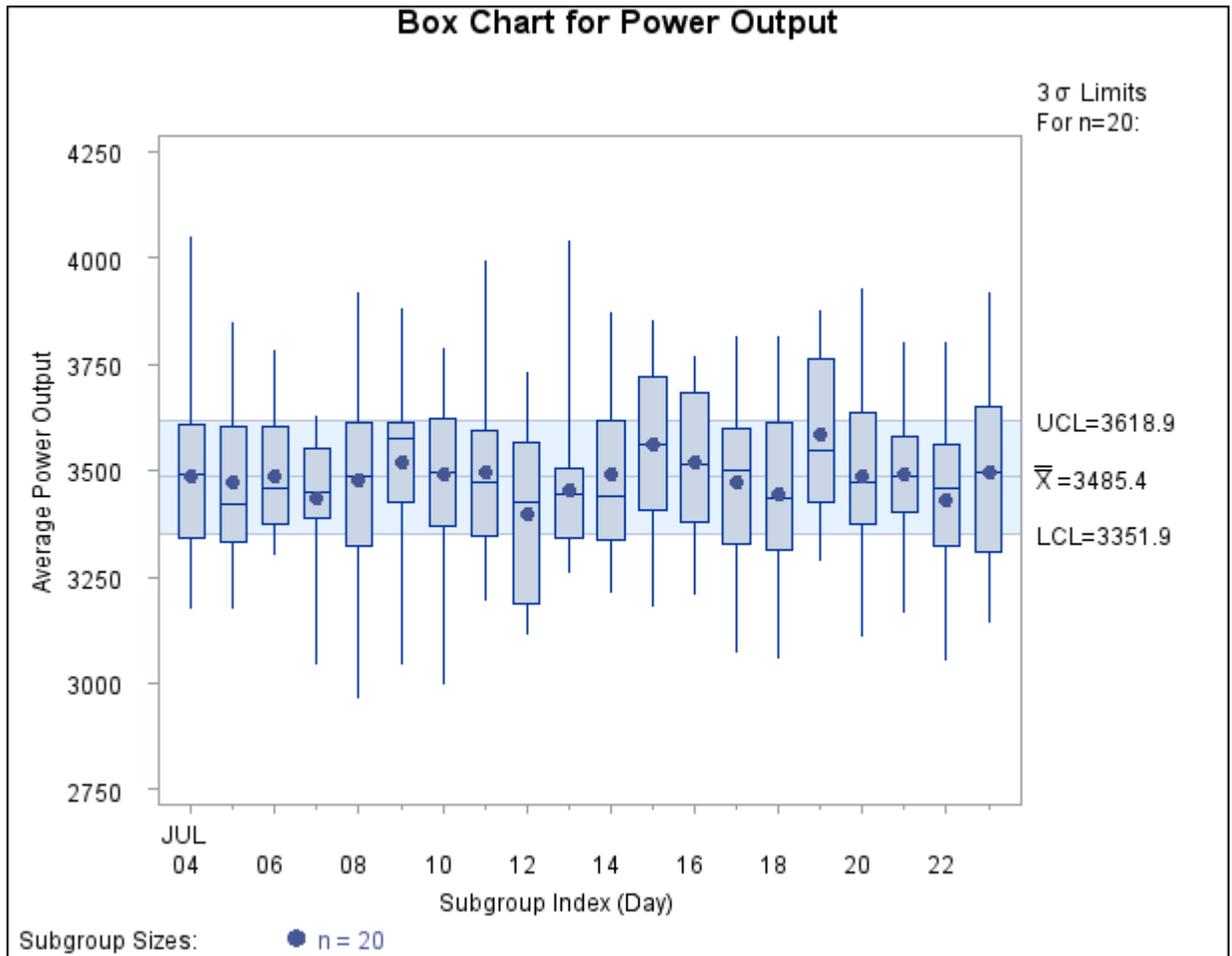

Figure 17.3 Partial Listing of the Data Set Turbine

Kilowatt Power Output Data

25	05JUL	3635

You can use a box chart to examine the distribution of power output for each day and to determine whether the mean level of the heating process is in control. The following statements create the box chart shown in [Figure 17.4](#):

```
ods graphics off;
title 'Box Chart for Power Output';
symbol v=dot;
proc shewhart data=Turbine;
  boxchart KWatts*Day;
run;
```

This example illustrates the basic form of the BOXCHART statement. After the keyword BOXCHART, you specify the *process* to analyze (in this case, KWatts), followed by an asterisk and the *subgroup-variable* (Day).

Figure 17.4 Box Chart for Power Output Data (Traditional Graphics)

The input data set is specified with the DATA= option in the PROC SHEWHART statement.

By default, the BOXCHART statement requests an \bar{X} chart superimposed with box-and-whisker plots for each subgroup. Table 17.3 lists the summary statistics represented by each plot. For details on the computation of percentiles, see “Percentile Definitions” on page 1469.

Table 17.3 Summary Statistics Represented by Box-and-Whisker Plots

Subgroup Summary Statistic	Feature of Box-and-Whisker Plot
Maximum	Endpoint of upper whisker
Third quartile (75th percentile)	Upper edge of box
Median (50th percentile)	Line inside box
Mean	Symbol marker (in this example, a dot)
First quartile (25th percentile)	Lower edge of box
Minimum	Endpoint of lower whisker

The within-subgroup variation in power output is stable, as indicated in Figure 17.4 by the edges of the boxes and the endpoints of the whiskers. Since the subgroup means, indicated by the dots, lie

within the control limits, you can conclude that the heating process is in statistical control.

The skeletal style of the box-and-whisker plots shown in [Figure 17.4](#) is the default. You can request different styles, as illustrated in [Example 17.2](#). By default, the control limits shown are 3σ limits estimated from the data; the formulas for the limits are given in [Table 17.5](#) and [Table 17.6](#).

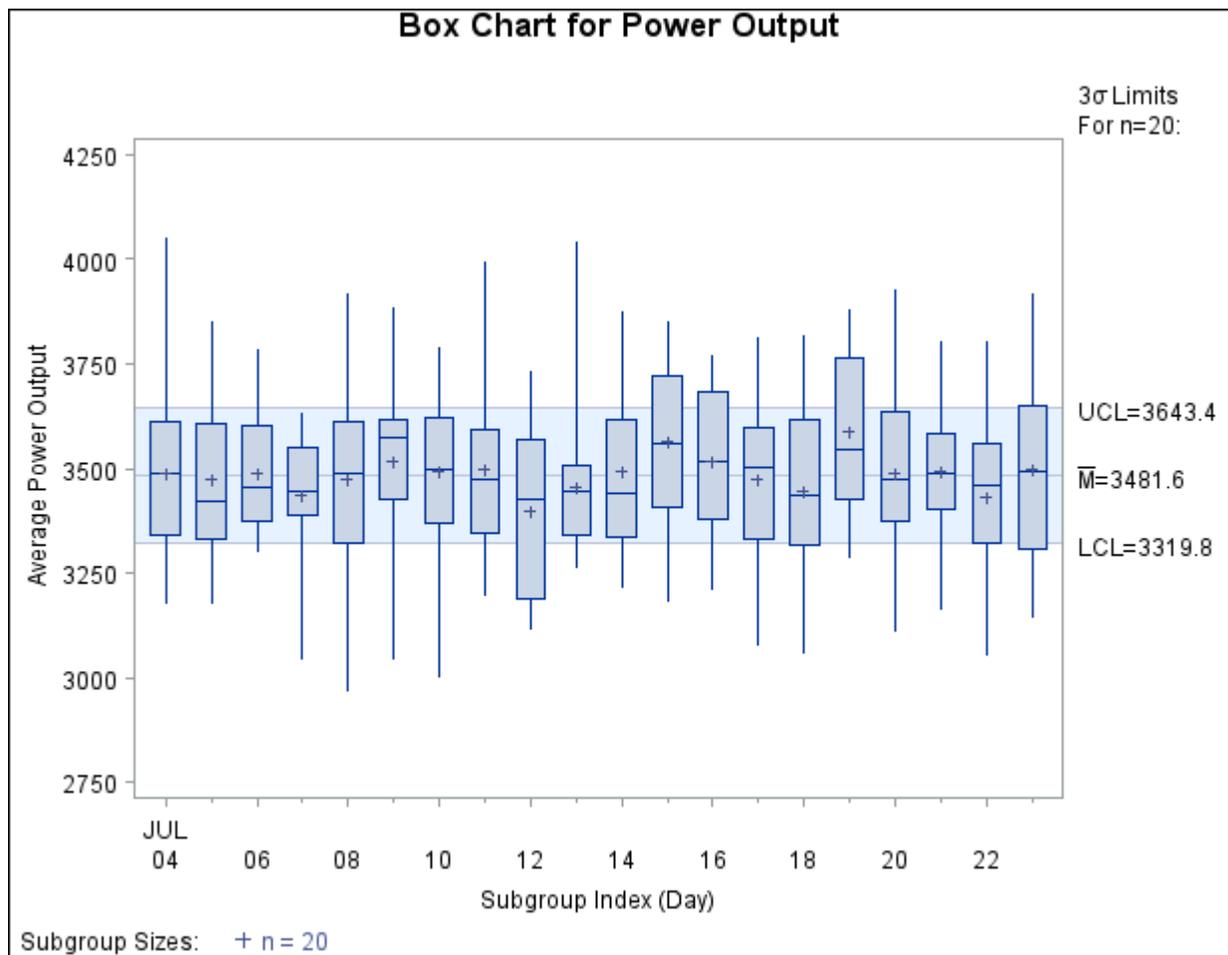

You can also create box charts in which the control limits apply to the subgroup medians. For example, the following statements create the chart shown in [Figure 17.5](#):

```
title 'Box Chart for Power Output';
proc shewhart data=Turbine;
  boxchart KWatts*Day / controlstat = median;
run;
```

The CONTROLSTAT=MEDIAN option requests control limits that apply to the medians. Alternatively, you can specify the NOLIMITS option to suppress the display of control limits and create ordinary side-by-side box-and-whisker plots. See [Example 17.2](#).

Options such as CONTROLSTAT= and NOLIMITS are specified after the slash (/) in the BOXCHART statement. A complete list of options is presented in the section “[Syntax: BOXCHART Statement](#)” on page 1439.

Figure 17.5 Box Chart for Power Output Data (Traditional Graphics)

Creating Box Charts from Subgroup Summary Data

See SHWBOXA in the SAS/QC Sample Library. The previous example illustrates how you can create box charts using raw data (process measurements). However, in many applications the data are provided as subgroup summary statistics. This example illustrates how you can use the BOXCHART statement with data of this type.

The following data set (Oilsum) provides the data from the preceding example in summarized form. There is exactly one observation for each subgroup (note that the subgroups are still indexed by Day).

```
data oilsum;
  input Day KWattsL KWatts1 KWattsX KWattsM
        KWatts3 KWattsH KWattsR KWattsN;
  informat Day date7. ;
  format Day date5. ;
  label Day      = 'Date of Measurement'
        KWattsL = 'Minimum Power Output'
        KWatts1 = '25th Percentile'
        KWattsX = 'Average Power Output'
        KWattsM = 'Median Power Output'
        KWatts3 = '75th Percentile'
        KWattsH = 'Maximum Power Output'
        KWattsR = 'Range of Power Output'
        KWattsN = 'Subgroup Sample Size';
  datalines;

;
```

A partial listing of Oilsum is shown in Figure 17.6.

Figure 17.6 The Summary Data Set Oilsum

Summary Data Set for Power Outputs								
Day	KWatts L	KWatts1	KWattsX	KWatts M	KWatts3	KWatts H	KWatts R	KWatts N
04JUL	3180	3340.0	3487.40	3490.0	3610.0	4050	870	20
05JUL	3179	3333.5	3471.65	3419.5	3605.0	3849	670	20
06JUL	3304	3376.0	3488.30	3456.5	3604.5	3781	477	20
07JUL	3045	3390.5	3434.20	3447.0	3550.0	3629	584	20
08JUL	2968	3321.0	3475.80	3487.0	3611.5	3916	948	20

There are eight summary variables in Oilsum.

- KWattsL contains the subgroup minimums (low values).
- KWatts1 contains the 25th percentile (first quartile) for each subgroup.
- KWattsX contains the subgroup means.
- KWattsM contains the subgroup medians.
- KWatts3 contains the 75th percentile (third quartile) for each subgroup.
- KWattsH contains the subgroup maximums (high values).
- KWattsR contains the subgroup ranges.
- KWattsN contains the subgroup sample sizes.

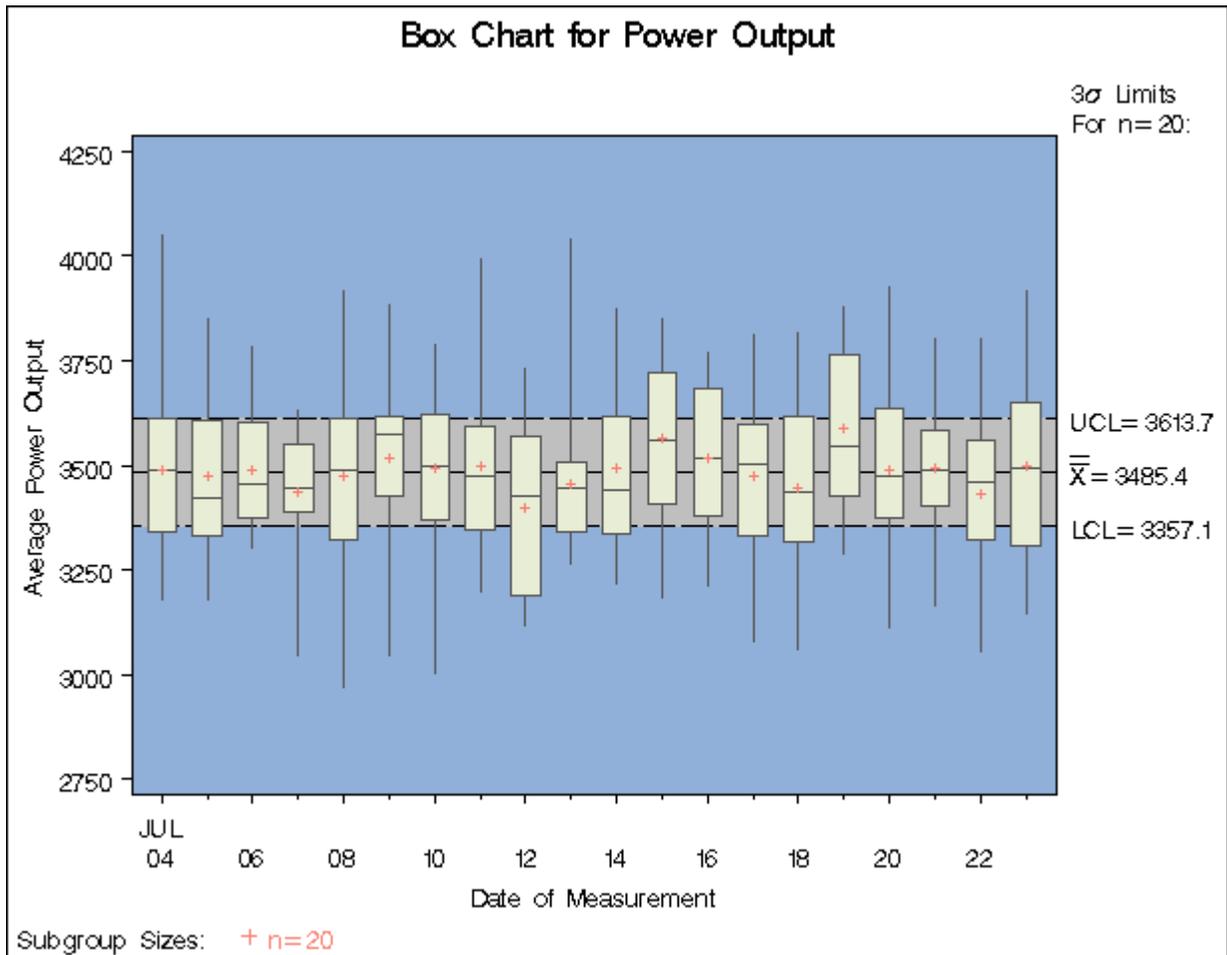

You can read this data set by specifying it as a HISTORY= data set in the PROC SHEWHART statement, as illustrated by the following statements, which create the box chart shown in Figure 17.7:

```
options nogstyle;
goptions ftext=swiss;
symbol color = salmon h = .8;
title 'Box Chart for Power Output';
proc shewhart history=Oilsum;
    boxchart KWatts*Day / cinfill = ligr
                    cboxfill = ywh
                    cboxes = dagr
                    cframe = vligb
                    ranges;
run;
options gstyle;
```

The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the SYMBOL statement and BOXCHART statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently.

Note that the *process* KWatts is *not* the name of a SAS variable in the data set but is, instead, the common prefix for the names of the eight summary variables. The suffix characters *L*, *I*, *X*, *M*, *3*, *H*, *R*, and *N* indicate the contents of the variable. For example, the suffix characters *I* and *3* indicate first and third quartiles. The name *Day* specified after the asterisk is the name of the *subgroup-variable*.

Figure 17.7 Box Chart for Power Output Data (Traditional Graphics with NOGSTYLE)

In general, a HISTORY= input data set used with the BOXCHART statement must contain the following variables:

- subgroup variable
- subgroup minimum variable
- subgroup first quartile variable
- subgroup mean variable
- subgroup median variable
- subgroup third quartile variable

- subgroup maximum variable
- subgroup sample size variable
- either a subgroup standard deviation variable or a subgroup range variable

Furthermore, the names of the summary variables must begin with the *process* name specified in the BOXCHART statement and end with the appropriate suffix character. If the names do not follow this convention, you can use the RENAME option in the PROC SHEWHART statement to rename the variables for the duration of the SHEWHART procedure step (see “Creating Charts for Means and Ranges from Summary Data” on page 1907).

If you specify the RANGES option in the BOXCHART statement, the HISTORY= data set must contain a subgroup range variable; otherwise, the HISTORY= data set must contain a subgroup standard deviation variable. The RANGES option specifies that the estimate of the process standard deviation σ is to be calculated from subgroup ranges rather than subgroup standard deviations. For example, in the following statements, the data set Oilsum2 must contain a subgroup standard deviation variable named KWattsS, because the RANGES option not specified:

```
title 'Box Chart for Power Output';
proc shewhart history=Oilsum2;
    boxchart KWatts*Day;
run;
```

In summary, the interpretation of *process* depends on the input data set.

- If raw data are read using the DATA= option (as in the previous example), *process* is the name of the SAS variable containing the process measurements.
- If summary data are read using the HISTORY= option (as in this example), *process* is the common prefix for the names of the variables containing the summary statistics.

For more information, see “HISTORY= Data Set” on page 1462.

Saving Summary Statistics

In this example, the BOXCHART statement is used to create a summary data set that can be read later by the SHEWHART procedure (as in the preceding example). The following statements read measurements from the data set Turbine and create a summary data set named Turbhist: See SHWBOXA in the SAS/QC Sample Library

```
title 'Summary Data Set for Power Output';
proc shewhart data=Turbine;
    boxchart KWatts*Day / outhistory = Turbhist
                        nochart;
run;
```

The OUTHISTORY= option names the output data set, and the NOCHART option suppresses the display of the chart, which would be identical to the chart in Figure 17.4.

Figure 17.8 contains a partial listing of Turbhist.

Figure 17.8 The Summary Data Set Turbhist

Summary Data Set for Power Output									
Obs	Day	KWatts		KWatts			KWatts		KWatts
		L	KWatts1	KWattsX	M	KWatts3	H	KWattsS	
1	04JUL	3180	3340.0	3487.40	3490.0	3610.0	4050	220.260	20
2	05JUL	3179	3333.5	3471.65	3419.5	3605.0	3849	210.427	20
3	06JUL	3304	3376.0	3488.30	3456.5	3604.5	3781	147.025	20
4	07JUL	3045	3390.5	3434.20	3447.0	3550.0	3629	157.637	20
5	08JUL	2968	3321.0	3475.80	3487.0	3611.5	3916	258.949	20

There are nine variables in the data set Turbhist.

- Day is the subgroup variable.
- KWattsL contains the subgroup minimums.
- KWatts1 contains the first quartiles for each subgroup.
- KWattsX contains the subgroup means.
- KWattsM contains the subgroup medians.
- KWatts3 contains the third quartiles for each subgroup.
- KWattsH contains the subgroup maximums.
- KWattsS contains the subgroup standard deviations.
- KWattsN contains the subgroup sample sizes.

Note that the summary statistic variables are named by adding the suffix characters *L*, *I*, *X*, *M*, *3*, *H*, *S*, and *N* to the *process* KWatts specified in the BOXCHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as that for HISTORY= data sets.

If you specify the RANGES option, the OUTHISTORY= data set includes a subgroup range variable, rather than a subgroup standard deviation variable, as demonstrated by the following statements:

```
proc shewhart data=Turbine;
  boxchart KWatts*Day / outhistory = Turbhist2
                    ranges
                    nochart;
run;
```

Figure 17.9 contains a partial listing of Turbhist2. The variable KWattsR contains the subgroup ranges.

The RANGES option is not recommended when the subgroup sample sizes are greater than 10, nor when you use the NOLIMITS option to create standard side-by-side box-and-whisker plots.

For more information, see “OUTHISTORY= Data Set” on page 1457.

Figure 17.9 The Summary Data Set Turbhist2

Summary Data Set for Power Output								
Day	KWatts L	KWatts1	KWattsX	KWatts M	KWatts3	KWatts H	KWatts R	KWatts N
04JUL	3180	3340.0	3487.40	3490.0	3610.0	4050	870	20
05JUL	3179	3333.5	3471.65	3419.5	3605.0	3849	670	20
06JUL	3304	3376.0	3488.30	3456.5	3604.5	3781	477	20
07JUL	3045	3390.5	3434.20	3447.0	3550.0	3629	584	20
08JUL	2968	3321.0	3475.80	3487.0	3611.5	3916	948	20

Saving Control Limits

You can save the control limits for a box chart in a SAS data set; this enables you to apply the control limits to future data (see “[Reading Preestablished Control Limits](#)” on page 1438) or modify the limits with a DATA step program. *See SHWBOXA in the SAS/QC Sample Library*

The following statements read measurements from the data set Turbine (see “[Creating Box Charts from Raw Data](#)” on page 1425) and save the control limits displayed in [Figure 17.4](#) in a data set named TURBLIM:

```
proc shewhart data=Turbine;
  boxchart KWatts*Day / outlimits=Turblim
                nochart;
run;
```

The OUTLIMITS= option names the data set containing the control limits, and the NOCHART option suppresses the display of the chart. The data set Turblim is listed in [Figure 17.10](#).

Figure 17.10 The Data Set Turblim Containing Control Limit Information

Control Limits for Power Output Data						
VAR	_SUBGRP_	_TYPE_	_LIMITN_	_ALPHA_	_SIGMAS_	_LCLX_
KWatts	Day	ESTIMATE	20	.002699796	3	3351.92
MEAN	_UCLX_	_LCLS_	_S_	_UCLS_	_STDDEV_	
3485.41	3618.90	100.207	196.396	292.584	198.996	

The data set Turblim contains one observation with the limits for *process* KWatts. The variables `_LCLX_` and `_UCLX_` contain the lower and upper control limits for the means, and the variable `_MEAN_` contains the central line. The value of `_MEAN_` is an estimate of the process mean, and the value of `_STDDEV_` is an estimate of the process standard deviation σ . The value of `_LIMITN_` is the nominal sample size associated with the control limits, and the value of `_SIGMAS_` is the multiple of σ associated with the control limits. The variables `_VAR_` and `_SUBGRP_` are bookkeeping variables that save the *process* and *subgroup-variable*. The variable `_TYPE_` is a bookkeeping

variable that indicates whether the values of `_MEAN_` and `_STDDEV_` are estimates or standard values.

The variables `_LCLS_`, `_S_`, and `_UCLS_` are not used to create box charts, but they are included so that the data set `Turblim` can be used to create an *s* chart; see “[XSCHART Statement: SHEWHART Procedure](#)” on page 1955. If you specify the `RANGES` option in the `BOXCHART` statement, the variables `_LCLR_`, `_R_`, and `_UCLR_`, rather than the variables `_LCLS_`, `_S_`, and `_UCLS_`, are included in the `OUTLIMITS=` data set. These variables can be used to create an *R* chart; see “[XRCHART Statement: SHEWHART Procedure](#)” on page 1902.

If you specify `CONTROLSTAT=MEDIAN` to request control limits for medians, the variables `_LCLM_` and `_UCLM_`, rather than the variables `_LCLX_` and `_UCLX_`, are included in the `OUTLIMITS=` data set as demonstrated by the following statements:

```
proc shewhart data=Turbine;
  boxchart KWatts*Day / outlimits = Turblim2
              controlstat = median
              nochart;
run;
```

`Turblim2` is listed in [Figure 17.11](#). For more information, see “[OUTLIMITS= Data Set](#)” on page 1454.

Figure 17.11 The Data Set `Turblim2` Containing Control Limit Information

Control Limits for Power Output Data						
<code>_VAR_</code>	<code>_SUBGRP_</code>	<code>_TYPE_</code>	<code>_LIMITN_</code>	<code>_ALPHA_</code>	<code>_SIGMAS_</code>	<code>_LCLM_</code>
KWatts	Day	ESTIMATE	20	.002776264	3	3319.85
<code>_MEAN_</code>	<code>_UCLM_</code>	<code>_LCLS_</code>	<code>_S_</code>	<code>_UCLS_</code>	<code>_STDDEV_</code>	
3481.63	3643.40	100.207	196.396	292.584	198.996	

You can create an output data set containing both control limits and summary statistics with the `OUTTABLE=` option, as illustrated by the following statements:

```
title 'Summary Statistics and Control Limit Information';
proc shewhart data=Turbine;
  boxchart KWatts*Day / outtable=Turbtab
              nochart;
run;
```

The data set `Turbtab` is partially listed in [Figure 17.12](#).

Figure 17.12 The OUTTABLE= Data Set Turbtabs

Summary Statistics and Control Limit Information								
<u>_VAR_</u>	<u>Day</u>	<u>_SIGMAS_</u>	<u>_LIMITN_</u>	<u>_SUBN_</u>	<u>_LCLX_</u>	<u>_SUBX_</u>	<u>_MEAN_</u>	<u>_UCLX_</u>

198.996		3056	3322.0	3460.0	3561.0	3800		
198.996		3145	3308.5	3495.0	3652.0	3917		

This data set contains one observation for each subgroup sample. The variable _SUBMIN_ contains the subgroup minimums, and the variable _SUBQ1_ contains the first quartile for each subgroup. The variable _SUBX_ contains the subgroup means, and the variable _SUBMED_ contains the subgroup medians. The variable _SUBQ3_ contains the third quartiles, and the variable _SUBMAX_ contains the subgroup maximums. The variable _SUBN_ contains the subgroup sample sizes. The

variables `_LCLX_` and `_UCLX_` contain the lower and upper control limits for the means. The variable `_MEAN_` contains the central line. The variables `_VAR_` and `Day` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “[OUTTABLE= Data Set](#)” on page 1459.

An `OUTTABLE=` data set can be read later as a `TABLE=` data set. For example, the following statements read `Turbtab` and display a box chart (not shown here) identical to the chart in [Figure 17.4](#):

```
title 'Box Chart for Power Output';
proc shewhart table=Turbtab;
  boxchart KWatts*Day;
  label _SUBX_ = 'Average Power Output';
run;
```

Because the SHEWHART procedure simply displays the information in a `TABLE=` data set, you can use `TABLE=` data sets to create specialized control charts (see “[Specialized Control Charts: SHEWHART Procedure](#)” on page 2171).

For more information, see “[TABLE= Data Set](#)” on page 1464.

Reading Prestablished Control Limits

See `SHWBOXA` in the *SAS/QC Sample Library*

In the previous example, the `OUTLIMITS=` data set `TURBLIM` saved control limits computed from the measurements in `Turbine`. This example shows how these limits can be applied to new data. The following statements create the box chart in [Figure 17.13](#) using new measurements in a data set named `Turbine2` (not listed here) and the control limits in `TURBLIM`:

```
title 'Box Chart for Power Output';
ods graphics on;
proc shewhart data=Turbine2 limits=Turblim;
  boxchart KWatts*Day / odstitle=title;
run;
```

The `ODS GRAPHICS ON` statement specified before the `PROC SHEWHART` statement enables ODS Graphics, so the box chart is created by using ODS Graphics instead of traditional graphics.

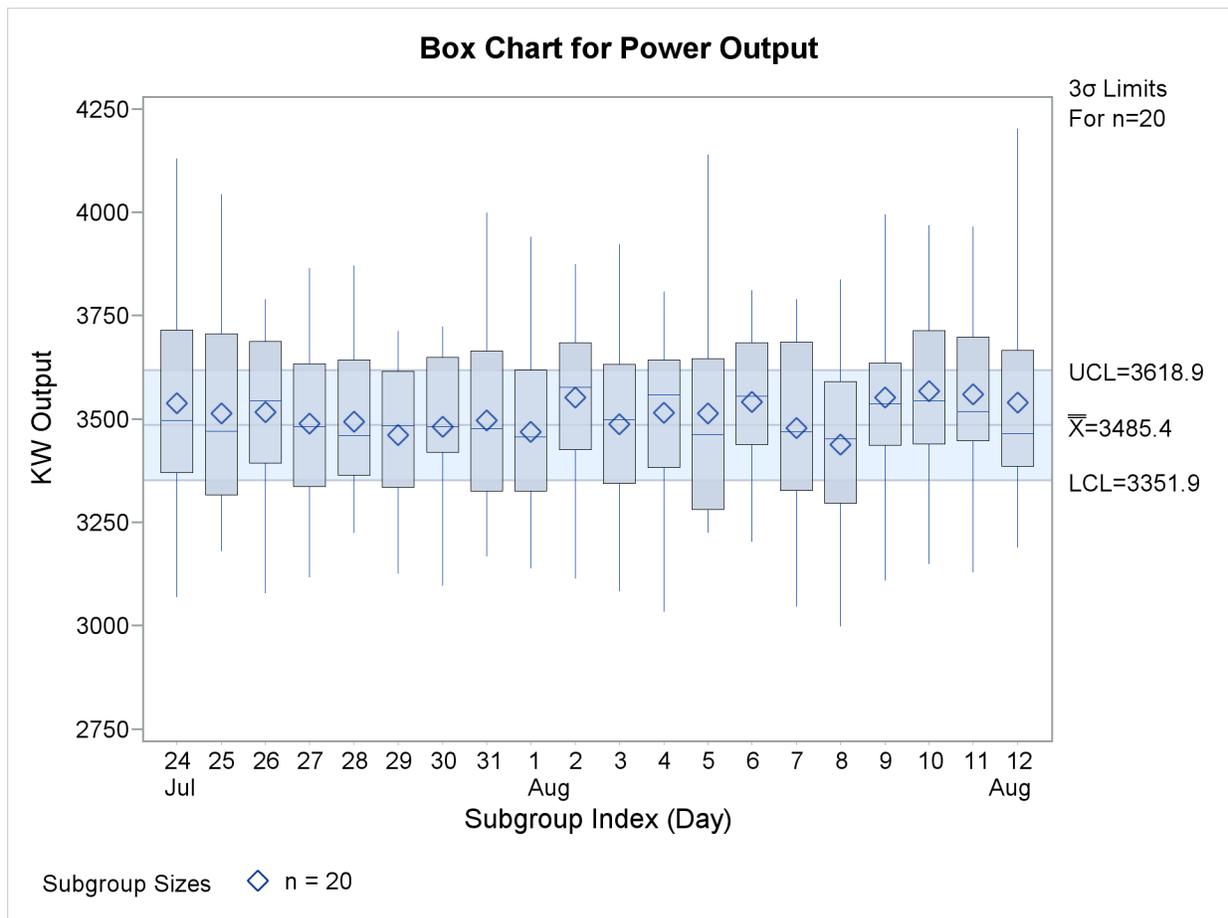

The `LIMITS=` option in the `PROC SHEWHART` statement specifies the data set containing the control limits. By default,⁴ this information is read from the first observation in the `LIMITS=` data set for which

- the value of `_VAR_` matches the *process* name `KWatts`
- the value of `_SUBGRP_` matches the *subgroup-variable* name `Day`

The chart reveals an increase in variability beginning on August 1.

⁴In SAS 6.09 and in earlier releases, it is also necessary to specify the `READLIMITS` option to read control limits from a `LIMITS=` data set.

Figure 17.13 Box Chart for Second Set of Power Outputs (ODS Graphics)

In this example, the LIMITS= data set was created in a previous run of the SHEWHART procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on page 1461 for details concerning the variables that you must provide.

Syntax: BOXCHART Statement

The basic syntax for the BOXCHART statement is as follows:

```
BOXCHART process * subgroup-variable ;
```

The general form of this syntax is as follows:

```
BOXCHART processes * subgroup-variable <(block-variables)>
  <=symbol-variable | = 'character'> / <options> ;
```

You can use any number of BOXCHART statements in the SHEWHART procedure. The components of the BOXCHART statement are described as follows.

process**processes**

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC SHEWHART statement.

- If raw data are read from a DATA= data set, *process* must be the name of the variable containing the raw measurements. For an example, see “[Creating Box Charts from Raw Data](#)” on page 1425.
- If summary data are read from a HISTORY= data set, *process* must be the common prefix of the summary variables in the HISTORY= data set. For an example, see “[Creating Box Charts from Subgroup Summary Data](#)” on page 1430.
- If summary data and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “[Saving Control Limits](#)” on page 1435.

A *process* is required. If you specify more than one *process*, enclose the list in parentheses. For example, the following statements request distinct box charts for Weight, Length, and Width:

```
proc shewhart data=summary;
    boxchart (Weight Length Width)*Day;
run;
```

subgroup-variable

is the variable that identifies subgroups in the data. The *subgroup-variable* is required. In the preceding BOXCHART statement, Day is the subgroup variable. For details, see “[Subgroup Variables](#)” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. These blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or character used to plot the means.

- If you produce a line printer chart, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOL n statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create a box chart using an asterisk (*) to plot the means:

```
proc shewhart data=values lineprinter;
    boxchart weight*day='*';
run;
```

options

enhance the appearance of the box chart, request additional analyses, save results in data sets, and so on. The “Summary of Options” on page 1441 section, which follows, lists all options by function. “Dictionary of Options: SHEWHART Procedure” on page 2018 describes each option in detail.

Summary of Options

The following tables list the BOXCHART statement options by function. For complete descriptions, see “Dictionary of Options: SHEWHART Procedure” on page 2018.

Table 17.4 BOXCHART Statement Options

Option	Description
Options for Specifying Control Limits	
ALPHA=	requests probability limits for control charts
CONTROLSTAT=	specifies whether control limits are computed for subgroup means or subgroup medians
LIMITN=	specifies either nominal sample size for fixed control limits or varying limits
NOREADLIMITS	computes control limits for each <i>process</i> from the data rather than from a LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from a LIMITS= data set
READINDEX=	reads control limits for each <i>process</i> from a LIMITS= data set
READLIMITS	reads single set of control limits for each <i>process</i> from a LIMITS= data set (SAS 6.09 and earlier releases)
SIGMAS=	specifies width of control limits in terms of multiple <i>k</i> of standard error of plotted statistic
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit on box chart
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits

Table 17.4 continued

Option	Description
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line in box chart
NOCTL	suppresses display of central line in box chart
NOLCL	suppresses display of lower control limit in box chart
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit in box chart
UCLLABEL=	specifies label for upper control limit in box chart
WLIMITS=	specifies width for control limits and central line
XSMBOL=	specifies label for central line in box chart
Process Mean and Standard Deviation Options	
MEDCENTRAL=	specifies method for estimating process mean μ
MU0=	specifies known value of μ_0 for process mean μ
RANGES	specifies that estimate of process standard deviation σ is to be calculated from subgroup ranges
SIGMA0=	specifies known value σ_0 for process standard deviation σ
SMETHOD=	specifies method for estimating process standard deviation σ
TYPE=	identifies whether parameters are estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
Options for Controlling Box Appearance	
BOXCONNECT=	connects subgroup means, medians, maximum values, minimum values, or quartiles in box-and-whisker plots
BOXSTYLE=	specifies style of box-and-whisker plots
BOXWIDTH=	specifies width of box-and-whisker plots
BOXWIDTHSCALE=	specifies that widths of box-and-whisker plots vary proportionately to subgroup sample size
CBOXES=	specifies color for outlines of box-and-whisker plots
CBOXFILL=	specifies fill color for interior of box-and-whisker plots
IDCOLOR=	specifies outlier symbol color in schematic box-and-whisker plots
IDCTEXT=	specifies text color to label outliers or process variable values
IDFONT=	specifies text font to label outliers or process variable values
IDHEIGHT=	specifies text height to label outliers or process variable values

Table 17.4 continued

Option	Description
IDSYMBOL=	specifies outlier symbol in schematic box-and-whisker plots
LBOXES=	specifies line types for outlines of box-and-whisker plots
NOTCHES	specifies that box-and-whisker plots are to be notched
PCTLDEF=	specifies percentile definition used for box-and-whisker plots
SERIFS	adds serifs to the whiskers of skeletal box-and-whisker plots
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on box chart
ALLLABEL2=	labels every point on trend chart
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CLABEL=	specifies color for labels
COUT=	specifies color for portions of line segments that connect points outside control limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NOCONNECT	suppresses line segments that connect points on chart
NOTRENDCONNECT	suppresses line segments that connect points on trend chart
OUTLABEL=	labels points outside control limits on box chart
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
Options for Specifying Tests for Special Causes	
INDEPENDENTZONES	computes zone widths independently above and below center line
NO3SIGMACHECK	enables tests to be applied with control limits other than 3σ limits
NOTESTACROSS	suppresses tests across <i>phase</i> boundaries
TESTS=	specifies tests for special causes for the box chart
TEST2RUN=	specifies length of pattern for Test 2
TEST3RUN=	specifies length of pattern for Test 3
TESTACROSS	applies tests across <i>phase</i> boundaries
TESTLABEL=	provides labels for points where test is positive
TESTLABEL n =	specifies label for n th test for special causes
TESTNMETHOD=	applies tests to standardized chart statistics
TESTOVERLAP	performs tests on overlapping patterns of points

Table 17.4 continued

Option	Description
TESTRESET=	enables tests for special causes to be reset for the box chart
ZONES	adds lines to box chart delineating zones A, B, and C
ZONEVALPOS=	specifies position of ZONEVALUES labels
ZONEVALUES	labels zone lines with their values
Options for Displaying Tests for Special Causes	
CTESTLABBOX=	specifies color for boxes enclosing labels indicating points where test is positive
CTESTS=	specifies color for labels indicating points where test is positive
CTESTSYMBOL=	specifies color for symbol used to plot points where test is positive
CZONES=	specifies color for lines and labels delineating zones A, B, and C
LTESTS=	specifies type of line connecting points where test is positive
LZONES=	specifies line type for lines delineating zones A, B, and C
TESTFONT=	specifies software font for labels at points where test is positive
TESTHEIGHT=	specifies height of labels at points where test is positive
TESTLABBOX	requests that labels for points where test is positive be positioned so that do not overlap
TESTSYMBOL=	specifies plot symbol for points where test is positive
TESTSYMBOLHT=	specifies symbol height for points where test is positive
WTESTS=	specifies width of line connecting points where test is positive
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOVANGLE	requests vertical axis labels that are strung out vertically

Table 17.4 *continued*

Option	Description
SKIPHLABELS=	specifies thinning factor for tick mark labels on horizontal axis
SPLIT=	specifies splitting character for axis labels
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis of box chart
VAXIS2=	specifies major tick mark values for vertical axis of trend chart
VFORMAT=	specifies format for primary vertical axis tick mark labels
VFORMAT2=	specifies format for secondary vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis for primary chart
VZERO2	forces origin to be included in vertical axis for secondary chart
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots summary statistics for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process variable only when exceptions occur
INTERVAL=	specifies natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	specifies maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of box chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
TRENDVAR=	specifies list of trend variables

Table 17.4 continued

Option	Description
YPCT1=	specifies length of vertical axis on box chart as a percentage of sum of lengths of vertical axes for box and trend charts
ZEROSTD	displays box chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= and HREF2= options
CVREF=	specifies color for lines requested by VREF= and VREF2= options
HREF=	specifies position of reference lines perpendicular to horizontal axis on box chart
HREF2=	specifies position of reference lines perpendicular to horizontal axis on trend chart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on box chart
HREF2DATA=	specifies position of reference lines perpendicular to horizontal axis on trend chart
HREFLABELS=	specifies labels for HREF= lines
HREF2LABELS=	specifies labels for HREF2= lines
HREFLABPOS=	specifies position of HREFLABELS= and HREF2LABELS= labels
LHREF=	specifies line type for HREF= and HREF2= lines
LVREF=	specifies line type for VREF= and VREF2= lines
NOBYREF	specifies that reference line information in a data set is to be applied uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis on box chart
VREF2=	specifies position of reference lines perpendicular to vertical axis on trend chart
VREFLABELS=	specifies labels for VREF= lines
VREF2LABELS=	specifies labels for VREF2= lines
VREFLABPOS=	specifies position of VREFLABELS= and VREF2LABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points

Table 17.4 continued

Option	Description
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to box chart
ANNOTATE2=	specifies annotate data set that adds features to trend chart
DESCRIPTION=	specifies description of box chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of box chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
WTREND=	specifies width of line segments connecting points on trend chart
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies variables whose values define colors for filling background of <i>block-variable</i> legend
BOXES=	specifies variables whose values define colors box outlines
BOXFILL=	specifies variables whose values define colors for filling boxes
CFRAMELAB	draws a frame around labeled points
CPHASEBOX	requests boxes enclosing all plotted points for a phase
CPHASEBOXCONNECT	requests lines connecting adjacent enclosing boxes
CPHASEBOXFILL	fills boxes enclosing all plotted points for a phase
CPHASEMEANCONNECT	requests lines connecting phase average value points
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
BOXTRANSPARENCY=	specifies the box fill transparency for box-and-whisker charts
INFILLTRANSPARENCY=	specifies the control limit infill transparency
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOBOXFILLLEGEND	suppresses legend for levels of a BOXFILL= variable
NOFILLLEGEND	suppresses legend for levels of a BOXFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills

Table 17.4 continued

Option	Description
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTHIGHURL=	specifies variable whose values are URLs to be associated with outliers above the upper fence on a schematic box chart
OUTLOWURL=	specifies variable whose values are URLs to be associated with outliers below the lower fence on a schematic box chart
OVERLAYURL=	specifies URLs to associate with overlay points
OVERLAY2URL=	specifies URLs to associate with overlay points on secondary chart
PHASEBOXLABELS	draws phase labels as titles along the top of phase boxes
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
POINTSURL=	specifies variable whose values are URLs to be associated with points representing individual observations
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
URL=	specifies a variable whose values are URLs to be associated with subgroups
URL2=	specifies a variable whose values are URLs to be associated with subgroups on secondary chart
WBOXES=	specifies width of box outlines for box-and-whisker charts
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTBOX=	creates output data set containing subgroup summary statistics, control limits, and outlier values for box chart
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits

Table 17.4 *continued*

Option	Description
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup values, subgroup sample sizes, subgroup summary statistics, and control limits
TABLEALL	is equivalent to the options TABLE, TABLEBOX, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUT, and TABLETEST
TABLEBOX	augments basic table with columns for minimum, 25th percentile, median, 75th percentile, and maximum of observations in a subgroup
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLELEGEND	augments basic table with legend for tests for special causes
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
TABLETESTS	augments basic table with a column indicating which tests for special causes are positive
Specification Limit Options	
CIINDICES	specifies α value and type for computing capability index confidence limits
LSL=	specifies list of lower specification limits
TARGET=	specifies list of target values
USL=	specifies list of upper specification limits
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASEBOX=	specifies color for box enclosing all plotted points for a phase
CPHASEBOXCONNECT=	specifies color for line segments connecting adjacent enclosing boxes
CPHASEBOXFILL=	specifies fill color for box enclosing all plotted points for a phase
CPHASELEG=	specifies text color for <i>phase</i> legend
CPHASEMEANCONNECT=	specifies color for line segments connecting average value points within a phase

Table 17.4 continued

Option	Description
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the <code>OUTHISTORY=</code> data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEMEANSYMBOL=	specifies symbol marker for average of values within a phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Overlay Options	
CCOVERLAY=	specifies colors for primary chart overlay line segments
CCOVERLAY2=	specifies colors for secondary chart overlay line segments
COVERLAY=	specifies colors for primary chart overlay plots
COVERLAY2=	specifies colors for secondary chart overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for primary chart overlay line segments
LOVERLAY2=	specifies line types for secondary chart overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on primary chart
OVERLAY2=	specifies variables to overlay on secondary chart
OVERLAY2HTML=	specifies links to associate with secondary chart overlay points
OVERLAY2ID=	specifies labels for secondary chart overlay points
OVERLAY2SYM=	specifies symbols for secondary chart overlays
OVERLAY2SYMHT=	specifies symbol heights for secondary chart overlays
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with primary chart overlay points
OVERLAYID=	specifies labels for primary chart overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for primary chart overlays
OVERLAYSYMHT=	specifies symbol heights for primary chart overlays
WOVERLAY=	specifies widths of primary chart overlay line segments
WOVERLAY2=	specifies widths of secondary chart overlay line segments

Table 17.4 continued

Option	Description
Options for Interactive Control Charts	
HTML=	specifies variable whose values create links to be associated with subgroups on primary chart
HTML2=	specifies variable whose values create links to be associated with subgroups on secondary chart
HTML_LEGEND=	specifies variable whose values create links to be associated with symbols in the symbol legend
OUTHIGHHTML=	specifies variable whose values create links to be associated with outliers above the upper fence on a schematic box chart
OUTLOWHTML=	specifies variable whose values create links to be associated with outliers below the lower fence on a schematic box chart
POINTSHTML=	specifies variable whose values create links to be associated with points representing individual observations
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= and HREF2= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
TESTCHAR=	specifies character for line segments that connect any sequence of points for which a test for special causes is positive
VREFCHAR=	specifies line character for VREF= and VREF2= lines
ZONECHAR=	specifies character for lines that delineate zones for tests for special causes

Details: BOXCHART Statement

Constructing Box Charts

The following notation is used in this section:

μ	process mean (expected value of the population of measurements)
σ	process standard deviation (standard deviation of the population of measurements)
\bar{X}_i	mean of measurements in i th subgroup
n_i	sample size of i th subgroup
N	the number of subgroups
x_{ij}	j th measurement in the i th subgroup, $j = 1, 2, 3, \dots, n_i$
$x_{i(j)}$	j th largest measurement in the i th subgroup:

$$x_{i(1)} \leq x_{i(2)} \leq \dots \leq x_{i(n_i)}$$

$\bar{\bar{X}}$ weighted average of subgroup means

M_i median of the measurements in the i th subgroup:

$$M_i = \begin{cases} x_{i((n_i+1)/2)} & \text{if } n_i \text{ is odd} \\ (x_{i(n_i/2)} + x_{i((n_i/2)+1)})/2 & \text{if } n_i \text{ is even} \end{cases}$$

\bar{M} average of the subgroup medians:

$$\bar{M} = (n_1 M_1 + \dots + n_N M_N) / (n_1 + \dots + n_N)$$

\tilde{M} median of the subgroup medians. Denote the j th largest median by $M_{(j)}$ so that $M_{(1)} \leq M_{(2)} \leq \dots \leq M_{(N)}$.

$$\tilde{M} = \begin{cases} M_{((N+1)/2)} & \text{if } N \text{ is odd} \\ (M_{(N/2)} + M_{(N/2)+1})/2 & \text{if } N \text{ is even} \end{cases}$$

$e_M(n)$ standard error of the median of n independent, normally distributed variables with unit standard deviation (the value of $e_M(n)$ can be calculated with the STD MED function in a DATA step)

$Q_p(n)$ $100 \times p$ th percentile ($0 < p < 1$) of the distribution of the median of n independent observations from a normal population with unit standard deviation

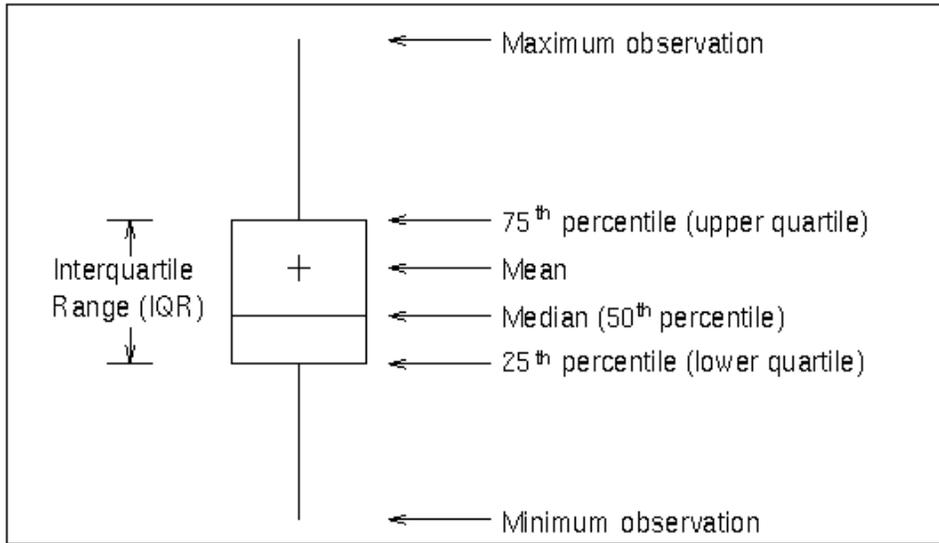

z_p $100 \times p$ th percentile of the standard normal distribution

$D_p(n)$ $100 \times p$ th percentile of the distribution of the range of n independent observations from a normal population with unit standard deviation

Elements of Box-and-Whisker Plots

A box-and-whisker plot is displayed for the measurements in each subgroup on the box chart. Figure 17.14 illustrates the elements of each plot.

Figure 17.14 Box-and-Whisker Plot

The skeletal style of the box-and-whisker plot shown in [Figure 17.14](#) is the default. You can specify alternative styles with the `BOXSTYLE=` option; see [Example 17.2](#) or the entry for `BOXSTYLE=` in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Control Limits and Central Line

You can compute the limits in the following ways:

- as a specified multiple (k) of the standard error of \bar{X}_i (or M_i) above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that \bar{X}_i (or M_i) exceeds the limits

The `CONTROLSTAT=` option specifies whether control limits are computed for subgroup means (the default) or subgroup medians. The following tables provide the formulas for the limits:

Table 17.5 Control Limits and Central Line for Box Charts

CONTROLSTAT=MEAN	CONTROLSTAT=MEDIAN
LCLX = lower limit = $\bar{\bar{X}} - k\hat{\sigma} / \sqrt{n_i}$	LCLM = lower limit = $\bar{M} - k\hat{\sigma}e_M(n_i)$
Central Line = $\bar{\bar{X}}$	Central Line = \bar{M}
UCLX = upper limit = $\bar{\bar{X}} + k\hat{\sigma} / \sqrt{n_i}$	UCLM = upper limit = $\bar{M} + k\hat{\sigma}e_M(n_i)$

Table 17.6 Probability Limits and Central Line for Box Charts

CONTROLSTAT=MEAN	CONTROLSTAT=MEDIAN
LCLX = lower limit = $\bar{\bar{X}} - z_{\alpha/2}(\hat{\sigma}/\sqrt{n_i})$	LCLM = lower limit = $\bar{M} - Q_{\alpha/2}(n_i)\hat{\sigma}$
Central Line = $\bar{\bar{X}}$	Central Line = \bar{M}
UCLX = upper limit = $\bar{\bar{X}} + z_{\alpha/2}(\hat{\sigma}/\sqrt{n_i})$	UCLM = upper limit = $\bar{M} + Q_{1-\alpha/2}(n_i)\hat{\sigma}$

In the preceding tables, replace \bar{M} with $\bar{\bar{X}}$ if you specify MEDCENTRAL=AVGMEAN in addition to CONTROLSTAT=MEDIAN. Likewise, replace \bar{M} with \tilde{M} if you specify MEDCENTRAL=MEDMED in addition to CONTROLSTAT=MEDIAN. If standard values μ_0 and σ_0 are available for μ and σ , replace $\bar{\bar{X}}$ with μ_0 and $\hat{\sigma}$ with σ_0 in Table 17.5 and Table 17.6.

Note that the limits vary with n_i . The formulas for median limits assume that the data are normally distributed.

You can specify parameters for the limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify μ_0 with the MU0= option or with the variable `_MEAN_` in a LIMITS= data set.
- Specify σ_0 with the SIGMA0= option or with the variable `_STDDEV_` in a LIMITS= data set.

NOTE: You can suppress the display of the control limits with the NOLIMITS option. This is useful for creating standard side-by-side box-and-whisker plots.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves control limits and control limit parameters. The following variables can be saved:

Table 17.7 OUTLIMITS= Data Set

Variable	Description
ALPHA	probability (α) of exceeding limits
CP	capability index C_p
CPK	capability index C_{pk}
CPL	capability index C_{PL}
CPM	capability index C_{pm}
CPU	capability index C_{PU}
INDEX	optional identifier for the control limits specified with the OUTINDEX= option
LCLM	lower control limit for subgroup median
LCLR	lower control limit for subgroup range
LCLS	lower control limit for subgroup standard deviation
LCLX	lower control limit for subgroup mean
LIMITN	nominal sample size associated with the control limits
LSL	lower specification limit
MEAN	process mean (value of central line on box chart)
R	value of central line on R chart
S	value of central line on s chart
SIGMAS	multiple (k) of standard error of \bar{X}_i or M_i
STDDEV	process standard deviation ($\hat{\sigma}$ or σ_0)
SUBGRP	<i>subgroup-variable</i> specified in the BOXCHART statement
TARGET	target value
TYPE	type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLM	upper control limit for subgroup median
UCLR	upper control limit for subgroup range
UCLS	upper control limit for subgroup standard deviation
UCLX	upper control limit for subgroup mean
USL	upper specification limit
VAR	<i>process</i> specified in the BOXCHART statement

Notes:

1. The variables _LCLM_ and _UCLM_ are included if you specify CONTROL-STAT=MEDIAN; otherwise, the variables _LCLX_ and _UCLX_ are included.
2. The variables _LCLR_, _R_, and _UCLR_ are included if you specify the RANGES option; otherwise, the variables _LCLS_, _S_, and _UCLS_ are included. These variables are not used to create box charts, but they enable the OUTLIMITS= data set to be used as a LIMITS= data set with the XRCHART, XSCHART, MRCHART, SCHART, and RCHART statements.
3. If the control limits vary with subgroup sample size, the special missing value V is assigned to the variables _LIMITN_, _LCLX_, _UCLX_, _LCLM_, _UCLM_, _LCLR_, _R_, _UCLR_, _LCLS_, _S_, and _UCLS_.

4. If the limits are defined in terms of a multiple k of the standard error of \bar{X}_i , the value of `_ALPHA_` is computed as $\alpha = 2(1 - \Phi(k))$, where $\Phi(\cdot)$ is the standard normal distribution function. If the limits are defined in terms of a multiple k of the standard error of M_i , the value of `_ALPHA_` is computed as $\alpha = 2(1 - F_{med}(k, n))$, where $F_{med}(\cdot, n)$ is the cumulative distribution function of the median of a random sample of n standard normally distributed observations, and n is the value of `_LIMITN_`. If `_LIMITN_` has the special missing value V , this value is assigned to `_ALPHA_`.
5. If the limits for means are probability limits, the value of `_SIGMAS_` is computed as $k = \Phi^{-1}(1 - \alpha/2)$, where Φ^{-1} is the inverse standard normal distribution function. If the limits for medians are probability limits, the value of `_SIGMAS_` is computed as $k = F_{med}^{-1}(1 - \alpha/2, n)$, where $F_{med}^{-1}(\cdot, n)$ is the inverse distribution function of the median of a random sample of n standard normally distributed observations, and n is the value `_LIMITN_`. If `_LIMITN_` has the special missing value V , this value is assigned to `_SIGMAS_`.
6. The variables `_CP_`, `_CPK_`, `_CPL_`, `_CPU_`, `_LSL_`, and `_USL_` are included only if you provide specification limits with the `LSL=` and `USL=` options. The variables `_CPM_` and `_TARGET_` are included if, in addition, you provide a target value with the `TARGET=` option. See “[Capability Indices](#)” on page 1941 for computational details.
7. Optional BY variables are saved in the `OUTLIMITS=` data set.

The `OUTLIMITS=` data set contains one observation for each *process* specified in the `BOXCHART` statement. For an example, see “[Saving Control Limits](#)” on page 1435.

OUTBOX= Data Set

The `OUTBOX=` data set saves subgroup summary statistics, control limits, and outlier values. The following variables can be saved:

- the *subgroup-variable*
- the variable `_VAR_`, containing the process variable name
- the variable `_TYPE_`, identifying features of box-and-whisker plots
- the variable `_VALUE_`, containing values of box-and-whisker plot features
- the variable `_ID_`, containing labels for outliers
- the variable `_HTML_`, containing links associated with box-and-whisker plot features

`_ID_` is included in the `OUTBOX=` data set only if one of the keywords `SCHEMATICID` or `SCHEMATICIDFAR` is specified with the `BOXSTYLE=` option. `_HTML_` is present only if one or more of the `HTML=`, `OUTHIGHHTML=`, `OUTLOWHTML=`, or `POINTSHTML=` options are specified.

Each observation in an `OUTBOX=` data set records the value of a single feature of one subgroup’s box-and-whisker plot, such as its mean. The `_TYPE_` variable identifies the feature whose value is recorded in `_VALUE_`. The following table lists valid `_TYPE_` variable values:

Table 17.8 Valid _TYPE_

Value	Description
N	subgroup size
SIGMAS	multiple (k) of standard error of \bar{X}_i or M_i
ALPHA	probability (α) of exceeding limits
LIMITN	nominal sample size associated with control limits
LCLM	lower control limit for subgroup median
LCLX	lower control limit for subgroup mean
UCLM	upper control limit for subgroup median
UCLX	upper control limit for subgroup mean
PROCMED	process median
PROCMEAN	process mean
EXLIM	control limit exceeded on box chart
TREND	trend variable value
MIN	minimum subgroup value
Q1	subgroup first quartile
MEDIAN	subgroup median
MEAN	subgroup mean
Q3	subgroup third quartile
MAX	subgroup maximum value
LOW	low outlier value
HIGH	high outlier value
LOWHISKR	low whisker value, if different from MIN
HIWHISKR	high whisker value, if different from MAX
FARLOW	low far outlier value
FARHIGH	high far outlier value

Additionally, the following variables, if specified, are included:

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

OUTHISTORY= Data Set

The OUTHISTORY= data set saves subgroup summary statistics. The following variables can be saved:

- the *subgroup-variable*
- a subgroup minimum variable named by the prefix *process* suffixed with *L*
- a subgroup first-quartile variable named by the prefix *process* suffixed with *I*

- a subgroup mean variable named by the prefix *process* suffixed with *X*
- a subgroup median variable named by the prefix *process* suffixed with *M*
- a subgroup third-quartile variable named by the prefix *process* suffixed with *3*
- a subgroup maximum variable named by the prefix *process* suffixed with *H*
- a subgroup sample size variable named by the prefix *process* suffixed with *N*
- a subgroup range variable named by the prefix *process* suffixed with *R* or a subgroup standard deviation variable named by *process* suffixed with *S*

A subgroup range variable is included if you specify the RANGES option; otherwise, a subgroup standard deviation variable is included.

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Subgroup summary variables are created for each *process* specified in the BOXCHART statement. For example, consider the following statements:

```
proc shewhart data=steel;
  boxchart (Width Diameter)*Lot / outhistory=Summary;
run;
```

The data set Summary contains variables named Lot, WidthL, Width1, WidthM, WidthX, Width3, WidthH, WidthS, WidthN, DiameterL, Diameter1, DiameterM, DiameterX, Diameter3, DiameterH, DiameterS, and DiameterN.

The variables WidthS and DiameterS are included since the RANGES option is not specified. If you specified the RANGES option, the data set Summary would contain the variables WidthR and DiameterR rather than WidthS and DiameterS.

Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

For an example of an OUTHISTORY= data set, see “Saving Summary Statistics” on page 1433.

OUTTABLE= Data Set

The OUTTABLE= data set saves subgroup summary statistics, control limits, and related information. The following variables can be saved:

Variable	Description
ALPHA	probability (α) of exceeding control limits
EXLIM	control limit exceeded on box chart
LCLM	lower control limit for median
LCLX	lower control limit for mean
LIMITN	nominal sample size associated with the control limits
MEAN	process mean
SIGMAS	multiple (k) of the standard error associated with control limits
<i>subgroup</i>	values of the subgroup variable
SUBMAX	subgroup maximum
SUBMED	subgroup median
SUBMIN	subgroup minimum
SUBN	subgroup sample size
SUBQ1	subgroup first quartile (25th percentile)
SUBQ3	subgroup third quartile (75th percentile)
SUBX	subgroup mean
TESTS	tests for special causes signaled on box chart
UCLM	upper control limit for median
UCLX	upper control limit for mean
VAR	<i>process</i> specified in the BOXCHART statement

The variables _LCLM_ and _UCLM_ are included if you specify CONTROLSTAT=MEDIAN; otherwise, the variables _LCLX_ and _UCLX_ are included. In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- _PHASE_ (if the READPHASES= option is specified)
- _TREND_ (if the TRENDVAR= option is specified)

Notes:

1. Either the variable _ALPHA_ or the variable _SIGMAS_ is saved depending on how the control limits are defined (with the ALPHA= or SIGMAS= options, respectively, or with the corresponding variables in a LIMITS= data set).
2. The variable _TESTS_ is saved if you specify the TESTS= option. The k th character of a value of _TESTS_ is k if Test k is positive at that subgroup. For example, if you request all

eight tests and Tests 2 and 8 are positive for a given subgroup, the value of `_TESTS_` has a 2 for the second character, an 8 for the eighth character, and blanks for the other six characters.

3. The variables `_EXLIM_` and `_TESTS_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “Saving Control Limits” on page 1435.

ODS Tables

The following table summarizes the ODS tables that you can request with the BOXCHART statement.

Table 17.9 ODS Tables Produced with the BOXCHART Statement

Table Name	Description	Options
BOXCHART	box plot summary statistics	TABLE, TABLEALL, TABLEBOX, TABLEC, TABLEID, TABLELEG, TABLEOUT, TABLETESTS
TestDescriptions	descriptions of tests for special causes requested with the TESTS= option for which at least one positive signal is found	TABLEALL, TABLELEG

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the SHEWHART procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced using ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. BOXCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “Dictionary of Options: SHEWHART Procedure” on page 2018.

When ODS Graphics is in effect, the BOXCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 17.10](#).

Table 17.10 ODS Graphics Produced by the BOXCHART Statement

ODS Graph Name	Plot Description
BoxChart	box chart

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (process measurements) from a DATA= data set specified in the PROC SHEWHART statement. Each *process* specified in the BOXCHART statement must be a SAS variable in the data set. This variable provides measurements which must be grouped into subgroup samples indexed by the *subgroup-variable*. The *subgroup-variable*, specified in the BOXCHART statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a value for each *process* and a value for the *subgroup-variable*. If the *i*th subgroup contains n_i measurements, there should be n_i consecutive observations for which the value of the *subgroup-variable* is the index of the *i*th subgroup. For example, if each subgroup contains 20 items and there are 30 subgroup samples, the DATA= data set should contain 600 observations. Other variables that can be read from a DATA= data set include

- `_PHASE_` (if READPHASES= is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a DATA= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) with the READPHASES= option for an example, see “[Displaying Stratification in Phases](#)” on page 2103.

For an example of a DATA= data set, see “[Creating Box Charts from Raw Data](#)” on page 1425.

LIMITS= Data Set

You can read preestablished control limits (or parameters from which the control limits can be calculated) from a LIMITS= data set specified in the PROC SHEWHART statement. For example, the following statements read control limit information from the data set `Conlims`:⁵

⁵In SAS 6.09 and in earlier releases, it is necessary to specify the READLIMITS option.

```
proc shewhart data=Info limits=Conlims;
  boxchart Weight*Batch;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the SHEWHART procedure. Such data sets always contain the variables required for a LIMITS= data set; see [Table 17.7](#). The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LCLX_`, `_MEAN_`, and `_UCLX_` or (if you specify `CONTROL-STAT=MEDIAN`) the variables `_LCLM_`, `_MEAN_`, and `_UCLM_`. These variables specify the control limits directly.
- the variables `_MEAN_` and `_STDDEV_`, which are used to calculate the control limits according to the equations in [Table 17.5](#) and [Table 17.6](#)

In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables whose lengths are no greater than 32.
- The variable `_INDEX_` is required if you specify the `READINDEX=` option; this must be a character variable whose length is no greater than 48.
- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8; valid values are ‘ESTIMATE’, ‘STANDARD’, ‘STDMU’, and ‘STDSIGMA’.
- BY variables are required if specified with a BY statement.

For an example, see “[Reading Preestablished Control Limits](#)” on page 1438.

HISTORY= Data Set

You can read subgroup summary statistics from a HISTORY= data set specified in the PROC SHEWHART statement. This enables you to reuse OUTHISTORY= data sets that have been created in previous runs of the SHEWHART, CUSUM, or MACONTROL procedures or to read output data sets created with SAS summarization procedures, such as PROC UNIVARIATE.

A HISTORY= data set used with the BOXCHART statement must contain the following:

- the *subgroup-variable*
- a subgroup minimum variable for each *process*
- a subgroup first-quartile variable for each *process*
- a subgroup median variable for each *process*
- a subgroup mean variable for each *process*
- a subgroup third-quartile variable for each *process*
- a subgroup maximum variable for each *process*
- a subgroup sample size variable for each *process*
- either a subgroup range variable or a subgroup standard deviation variable for each *process*

If you specify the RANGES option, the subgroup range variable must be included; otherwise, the subgroup standard deviation variable must be included.

The names of the subgroup summary statistics variables must be the *process* name concatenated with the following special suffix characters:

Subgroup Summary Statistic	Suffix Character
subgroup minimum	L
subgroup first-quartile	1
subgroup median	M
subgroup mean	X
subgroup third-quartile	3
subgroup maximum	H
subgroup sample size	N
subgroup range	R
subgroup standard deviation	S

For example, consider the following statements:

```
proc shewhart history=summary;
  boxchart (weight Yieldstrength)*batch;
run;
```

The data set Summary must include the variables Batch, WeightL, Weight1, WeightM, WeightX, Weight3, WeightH, WeightS, WeightN, YieldstrengthL, Yieldstrength1, YieldstrengthM, YieldstrengthX, Yieldstrength3, YieldstrengthH, YieldstrengthS, and YieldstrengthN.

If the RANGES option were specified in the preceding BOXCHART statement, it would be necessary for Summary to include the variables WeightR and YieldstrengthR rather than WeightS and YieldstrengthS.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a HISTORY= data set include

- `_PHASE_` (if READPHASES= is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a HISTORY= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) with the READPHASES= option (see “[Displaying Stratification in Phases](#)” on page 2103 for an example).

For an example of a HISTORY= data set, see “[Creating Box Charts from Subgroup Summary Data](#)” on page 1430.

TABLE= Data Set

You can read summary statistics and control limits from a TABLE= data set specified in the PROC SHEWHART statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the SHEWHART procedure. Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts. Examples are provided in “[Specialized Control Charts: SHEWHART Procedure](#)” on page 2171.

The following table lists the variables required in a TABLE= data set used with the BOXCHART statement:

Table 17.11 Variables Required in a TABLE= Data Set

Variable	Description
LCLM	lower control limit for median
LCLX	lower control limit for mean
LIMITN	nominal sample size associated with the control limits
MEAN	process mean
<i>subgroup-variable</i>	values of the <i>subgroup-variable</i>
SUBMAX	subgroup maximum
SUBMIN	subgroup minimum
SUBMED	subgroup median
SUBN	subgroup sample size
SUBQ1	subgroup first quartile (25th percentile)
SUBQ3	subgroup third quartile (75th percentile)
SUBX	subgroup mean
UCLM	upper control limit for median
UCLX	upper control limit for mean

Note that if you specify CONTROLSTAT=MEDIAN, the variables _LCLM_, _SUBMED_, and _UCLM_ are required; otherwise, the variables _LCLX_, _SUBX_, and _UCLX_ are required.

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- _PHASE_ (if the READPHASES= option is specified). This variable must be a character variable whose length is no greater than 48.
- _TESTS_ (if the TESTS= option is specified). This variable is used to flag tests for special causes and must be a character variable of length 8.
- _VAR_. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable whose length is no greater than 32.

For an example of a TABLE= data set, see “Saving Control Limits” on page 1435.

BOX= Data Set

You can read summary statistics, control limits, and outlier values from a BOX= data set specified in the PROC SHEWHART statement. This enables you to reuse an OUTBOX= data set created in a previous run of the SHEWHART procedure to display a box chart.

A BOX= data set must contain the following variables:

- the group variable
- `_VAR_`, containing the process variable name
- `_TYPE_`, identifying features of box-and-whisker plots
- `_VALUE_`, containing values of those features

Each observation in a BOX= data set records the value of a single feature of one subgroup's box-and-whisker plot, such as its mean. The `_TYPE_` variable identifies the feature whose value is recorded in a given observation. The following table lists valid `_TYPE_` variable values:

Table 17.12 Valid `_TYPE_` Values in a BOX= Data Set

Value	Description
N	subgroup size
SIGMAS	multiple (k) of standard error of \bar{X}_i or M_i
ALPHA	probability (α) of exceeding limits
LIMITN	nominal sample size associated with control limits
LCLM	lower control limit for subgroup median
LCLX	lower control limit for subgroup mean
UCLM	upper control limit for subgroup median
UCLX	upper control limit for subgroup mean
PROCMED	process median
PROCMEAN	process mean
EXLIM	control limit exceeded on box chart
TREND	trend variable value
MIN	minimum subgroup value
Q1	subgroup first quartile
MEDIAN	subgroup median
MEAN	subgroup mean
Q3	subgroup third quartile
MAX	subgroup maximum value
LOW	low outlier value
HIGH	high outlier value
LOWHISKR	low whisker value, if different from MIN
HIWHISKR	high whisker value, if different from MAX
FARLOW	low far outlier value
FARHIGH	high far outlier value

The features identified by the `_TYPE_` values N, LCLM or LCLX, UCLM or UCLX, PROCMED or PROCMEAN, MIN, Q1, MEDIAN, MEAN, Q3, and MAX are required for each subgroup.

Other variables that can be read from a BOX= data set include:

- the variable `_ID_`, containing labels for outliers
- the variable `_HTML_`, containing links to be associated with features on box plots
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

When you specify one of the keywords SCHEMATICID or SCHEMATICIDFAR with the BOXSTYLE= option, values of `_ID_` are used as outlier labels. If `_ID_` does not exist in the BOX= data set, the values of the first variable listed in the ID statement are used.

Methods for Estimating the Standard Deviation

When control limits are computed from the input data, three methods (referred to as default, MVLUE and RMSDF) are available for estimating the process standard deviation σ . The method depends on whether you specify the RANGES option. If you specify this option, σ is estimated using subgroup ranges; otherwise, σ is estimated using subgroup standard deviations.

Default Method Based on Subgroup Standard Deviations

If you do not specify the RANGES option, the default estimate for σ is

$$\hat{\sigma} = \frac{s_1/c_4(n_1) + \cdots + s_N/c_4(n_N)}{N}$$

where N is the number of subgroups for which $n_i \geq 2$, s_i is the sample standard deviation of the i th subgroup

$$s_i = \sqrt{\frac{1}{n_i - 1} \sum_{j=1}^{n_i} (x_{ij} - \bar{X}_i)^2}$$

and

$$c_4(n_i) = \frac{\Gamma(n_i/2) \sqrt{2/(n_i - 1)}}{\Gamma((n_i - 1)/2)}$$

Here $\Gamma(\cdot)$ denotes the gamma function, and \bar{X}_i denotes the i th subgroup mean. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$. If the observations are normally distributed, the expected value of s_i is $c_4(n_i)\sigma$. Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ . This method is described in the American Society for Testing and Materials (1976).

Default Method Based on Subgroup Ranges

If you specify the RANGES option, the default estimate for σ is

$$\hat{\sigma} = \frac{R_1/d_2(n_1) + \cdots + R_N/d_2(n_N)}{N}$$

where N is the number of subgroups for which $n_i \geq 2$, and R_i is the sample range of the observations x_{i1}, \dots, x_{in_i} in the i th subgroup.

$$R_i = \max_{1 \leq j \leq n_i} (x_{ij}) - \min_{1 \leq j \leq n_i} (x_{ij})$$

A subgroup range R_i is included in the calculation only if $n_i \geq 2$. The unbiasing factor $d_2(n_i)$ is defined so that, if the observations are normally distributed, the expected value of R_i is $d_2(n_i)\sigma$. Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ . This method is described in the American Society for Testing and Materials (1976).

MVLUE Method Based on Subgroup Standard Deviations

If you do not specify the RANGES option and specify SMETHOD=MVLUE, a minimum variance linear unbiased estimate (MVLUE) is computed for σ . Refer to Burr (1969, 1976) and Nelson (1989, 1994). This estimate is a weighted average of N unbiased estimates of σ of the form $s_i/c_4(n_i)$, and it is computed as

$$\hat{\sigma} = \frac{h_1 s_1/c_4(n_1) + \cdots + h_N s_N/c_4(n_N)}{h_1 + \cdots + h_N}$$

where

$$h_i = \frac{[c_4(n_i)]^2}{1 - [c_4(n_i)]^2}$$

A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$. The MVLUE assigns greater weight to estimates of σ from subgroups with larger sample sizes, and it is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the MVLUE reduces to the default estimate.

MVLUE Method Based on Subgroup Ranges

If you specify the RANGES option and SMETHOD=MVLUE, a minimum variance linear unbiased estimate (MVLUE) is computed for σ . Refer to Burr (1969, 1976) and Nelson (1989, 1994). The MVLUE is a weighted average of N unbiased estimates of σ of the form $R_i/d_2(n_i)$, and it is computed as

$$\hat{\sigma} = \frac{f_1 R_1/d_2(n_1) + \cdots + f_N R_N/d_2(n_N)}{f_1 + \cdots + f_N}$$

where

$$f_i = \frac{[d_2(n_i)]^2}{[d_3(n_i)]^2}$$

A subgroup range R_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$. The unbiasing factor $d_3(n_i)$ is defined so that, if the observations are normally distributed, the expected value of σ_{R_i} is $d_3(n_i)\sigma$. The MVLUE assigns greater weight to estimates of σ from subgroups with larger sample sizes, and it is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the MVLUE reduces to the default estimate.

RMSDF Method Based on Subgroup Standard Deviations

If you do not specify the RANGES option and specify SMETHOD=RMSDF, a weighted root-mean-square estimate is computed for σ .

$$\hat{\sigma} = \frac{\sqrt{(n_1 - 1)s_1^2 + \dots + (n_N - 1)s_N^2}}{c_4(n)\sqrt{n_1 + \dots + n_N - N}}$$

The weights are the degrees of freedom $n_i - 1$. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$.

If the unknown standard deviation σ is constant across subgroups, the root-mean-square estimate is more efficient than the minimum variance linear unbiased estimate. However, in process control applications, it is generally not assumed that σ is constant, and if σ varies across subgroups, the root-mean-square estimate tends to be more inflated than the MVLUE.

Percentile Definitions

You can use the PCTLDEF= option to specify one of five definitions for computing quantile statistics (percentiles). Let n equal the number of nonmissing values for a variable, and let x_1, x_2, \dots, x_n represent the ordered values of the process variable. For the t th percentile, set $p = t/100$, and express np as

$$np = j + g$$

where j is the integer part of np , and g is the fractional part of np .

The t th percentile (call it y) can be defined in five ways, as described in the next five sections.

PCTLDEF=1

This uses the weighted average at x_{np}

$$y = (1 - g)x_j + gx_{j+1}$$

where x_0 is taken to be x_1 .

PCTLDEF=2

This uses the observation numbered closest to np

$$y = x_i$$

where i is the integer part of $np + 1/2$.

PCTLDEF=3

This uses the empirical distribution function

$$\begin{aligned} y &= x_j && \text{if } g = 0 \\ y &= x_{j+1} && \text{if } g > 0 \end{aligned}$$

PCTLDEF=4

This uses the weighted average aimed at $x_{p(n+1)}$

$$y = (1 - g)x_j + gx_{j+1}$$

where $(n + 1)p = j + g$, and where x_{n+1} is taken to be x_n .

PCTLDEF=5

This uses the empirical distribution function with averaging

$$\begin{aligned} y &= (x_j + x_{j+1})/2 && \text{if } g = 0 \\ y &= x_{j+1} && \text{if } g > 0 \end{aligned}$$

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical (box chart)	DATA=	<i>process</i>
Vertical (box chart)	HISTORY=	subgroup mean variable
Vertical (box chart)	TABLE=	<code>_SUBX_</code>

Note that if you specify the CONTROLSTAT=MEDIAN option, you should assign the label to the subgroup median variable in a HISTORY= data set or to the variable `_SUBMED_` in an TABLE= data set.

If you specify the TRENDVAR= option, you can provide distinct labels for the vertical axes of the box and trend charts by breaking the vertical axis into two parts with a split character. Specify the split character with the SPLIT= option. The first part labels the vertical axis of the box chart, and the second part labels the vertical axis of the trend chart.

For an example, see “[Labeling Axes](#)” on page 2136.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: BOXCHART Statement

This section provides advanced examples of the BOXCHART statement.

Example 17.1: Using Box Charts to Compare Subgroups

In this example, a box chart is used to compare the delay times for airline flights during the Christmas holidays with the delay times prior to the holiday period. The following statements create a data set named Times with the delay times in minutes for 25 flights each day. When a flight is cancelled, the delay is recorded as a missing value. *See SHWBOX4 in the SAS/QC Sample Library*

```

data Times;
  informat Day date7. ;
  format Day date7. ;
  input Day @ ;
  do Flight=1 to 25;
    input Delay @ ;
    output;
  end;
  datalines;
16DEC88 4 12 2 2 18 5 6 21 0 0
          0 14 3 . 2 3 5 0 6 19
          7 4 9 5 10
17DEC88 1 10 3 3 0 1 5 0 . .
          1 5 7 1 7 2 2 16 2 1
          3 1 31 5 0
18DEC88 7 8 4 2 3 2 7 6 11 3
          2 7 0 1 10 2 3 12 8 6
          2 7 2 4 5
19DEC88 15 6 9 0 15 7 1 1 0 2
          5 6 5 14 7 20 8 1 14 3
          10 0 1 11 7
20DEC88 2 1 0 4 4 6 2 2 1 4
          1 11 . 1 0 6 5 5 4 2
          2 6 6 4 0
21DEC88 2 6 6 2 7 7 5 2 5 0
          9 2 4 2 5 1 4 7 5 6
          5 0 4 36 28
22DEC88 3 7 22 1 11 11 39 46 7 33
          19 21 1 3 43 23 9 0 17 35
          50 0 2 1 0
23DEC88 6 11 8 35 36 19 21 . . 4
          6 63 35 3 12 34 9 0 46 0
          0 36 3 0 14
24DEC88 13 2 10 4 5 22 21 44 66 13
          8 3 4 27 2 12 17 22 19 36
          9 72 2 4 4
25DEC88 4 33 35 0 11 11 10 28 34 3
          24 6 17 0 8 5 7 19 9 7
          21 17 17 2 6

```

```

26DEC88  3  8  8  2  7  7  8  2  5  9
          2  8  2 10 16  9  5 14 15  1
          12 2  2 14 18
;

```

First, the MEANS procedure is used to count the number of cancelled flights for each day. This information is then added to the data set Times.

```

proc means data=Times noprint;
  var Delay;
  by Day ;
  output out=Cancel nmiss=Ncancel;

data Times;
  merge Times cancel;
  by Day;
run;

```

The following statements create a data set named Weather that contains information about possible causes for delays. This data set is merged with the data set Times.

```

data Weather;
  informat Day date7. ;
  format   Day date7. ;
  length Reason $ 16 ;
  input Day Flight Reason & ;
  datalines;
16DEC88  8  Fog
17DEC88 18  Snow Storm
17DEC88 23  Sleet
21DEC88 24  Rain
21DEC88 25  Rain
22DEC88  7  Mechanical
22DEC88 15  Late Arrival
24DEC88  9  Late Arrival
24DEC88 22  Late Arrival
;

data Times;
  merge Times Weather;
  by Day Flight;
run;

```

Next, control limits are established using the delays prior to the holiday period.

```
proc shewhart data=Times;
  where Day <= '21DEC88'D;
  boxchart Delay * Day /
    nochart
    outlimits=Timelim;
run;
```

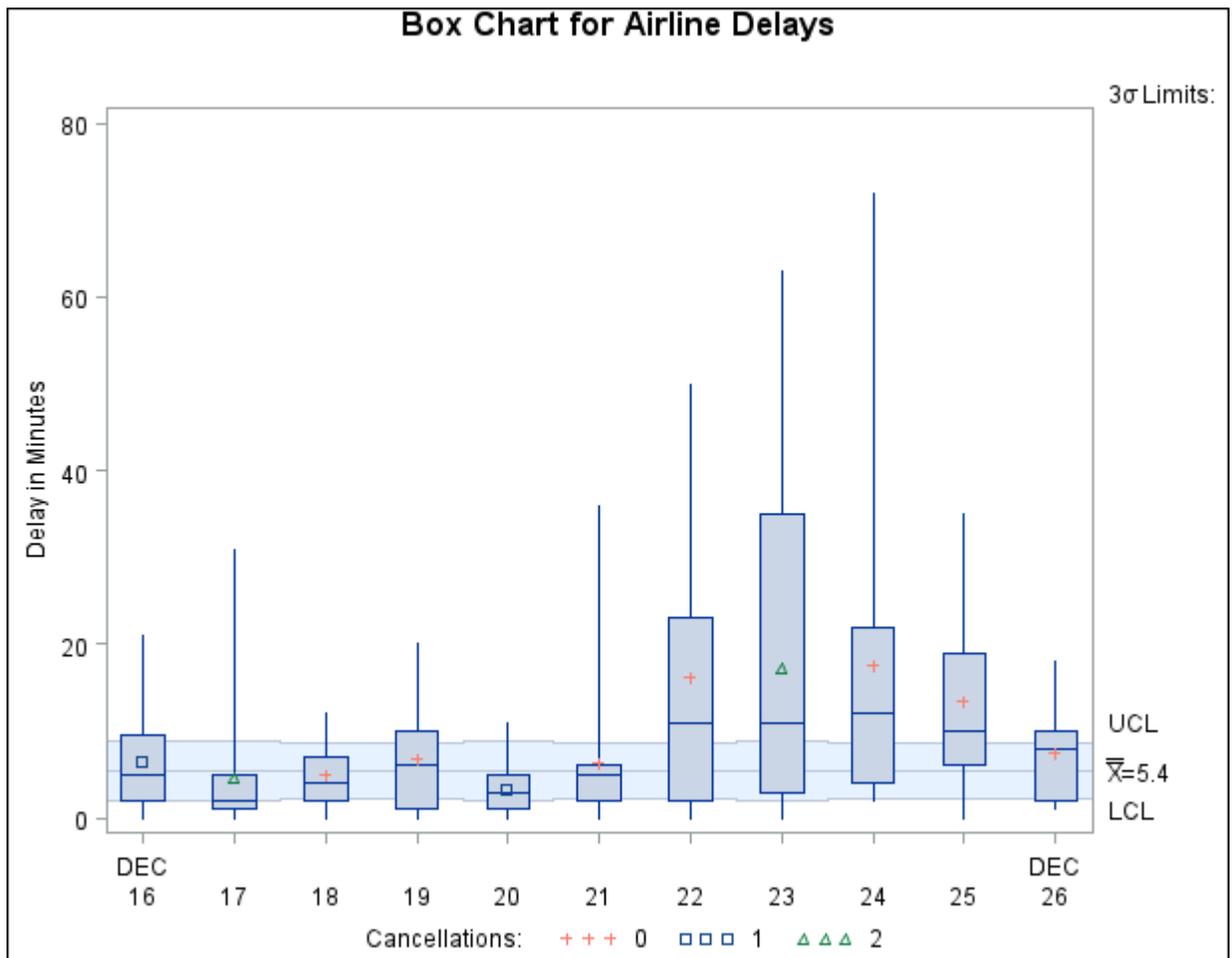

The OUTLIMITS= option names a data set (Timelim) that saves the control limits. The NOCHART option suppresses the display of the chart.

The following statements create a box chart for the complete set of data using the control limits in Timelim:

```
ods graphics off;
symbol1 v=plus      c=salmon;
symbol2 v=square    c=vigb;
symbol3 v=triangle  c=vig;
title 'Box Chart for Airline Delays';
proc shewhart data=Times limits=Timelim ;
  boxchart Delay * Day = Ncancel /
    readlimits
    nohlabel
    nolegend
    symbollegend = legend1;
  legend1 label=('Cancellations: ');
  label Delay = 'Delay in Minutes';
run;
```

The box chart is shown in [Output 17.1.1](#). The level of the *symbol-variable* Ncancel determines the symbol marker for each subgroup mean, and the SYMBOLLEGEND= option controls the appearance of the legend for the symbols. The NOHLABEL option suppresses the label for the horizontal axis, and the NOLEGEND option suppresses the default legend for subgroup sample sizes.

Output 17.1.1 Box Chart for Airline Data

The delay distributions from December 22 through December 25 are drastically different from the delay distributions during the pre-holiday period. Both the mean delay and the variability of the delays are much greater during the holiday period.

Example 17.2: Creating Various Styles of Box-and-Whisker Plots

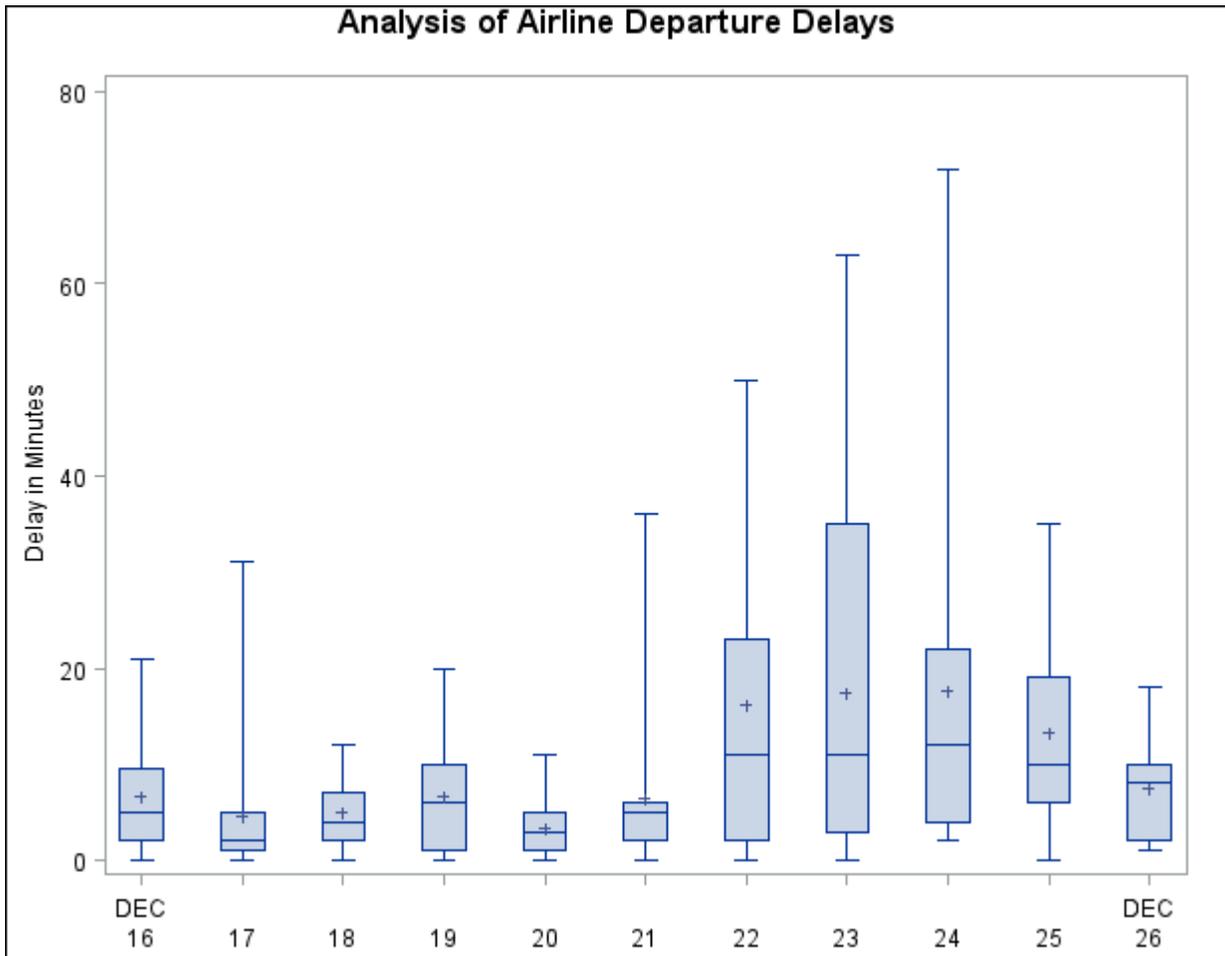

See *SHWBOX5* in the *SAS/QC Sample Library*

This example uses the flight delay data of the preceding example to illustrate how you can create box charts with various styles of box-and-whisker plots. For simplicity, the control limits are suppressed. The following statements create a chart, shown in [Output 17.2.1](#), that displays *skeletal box-and-whisker plots*:

```
ods graphics off;
title 'Analysis of Airline Departure Delays';
proc shewhart data=Times limits=Timelim ;
  boxchart Delay * Day /
    boxstyle = skeletal
    serifs
    nolimits
    nohlabel
    nolegend;
  label Delay = 'Delay in Minutes';
run;
```

In a skeletal box-and-whisker plot, the whiskers are drawn from the quartiles to the extreme values of the subgroup sample. You can also request this style by omitting the BOXSTYLE= option, since this style is the default. The SERIFS option adds serifs to the whiskers (by default, serifs are omitted with the skeletal style). The NOLIMITS option suppresses the display of the control limits.

Output 17.2.1 BOXSTYLE=SKELETAL with Serifs

The following statements request a box chart with *schematic box-and-whisker plots*:

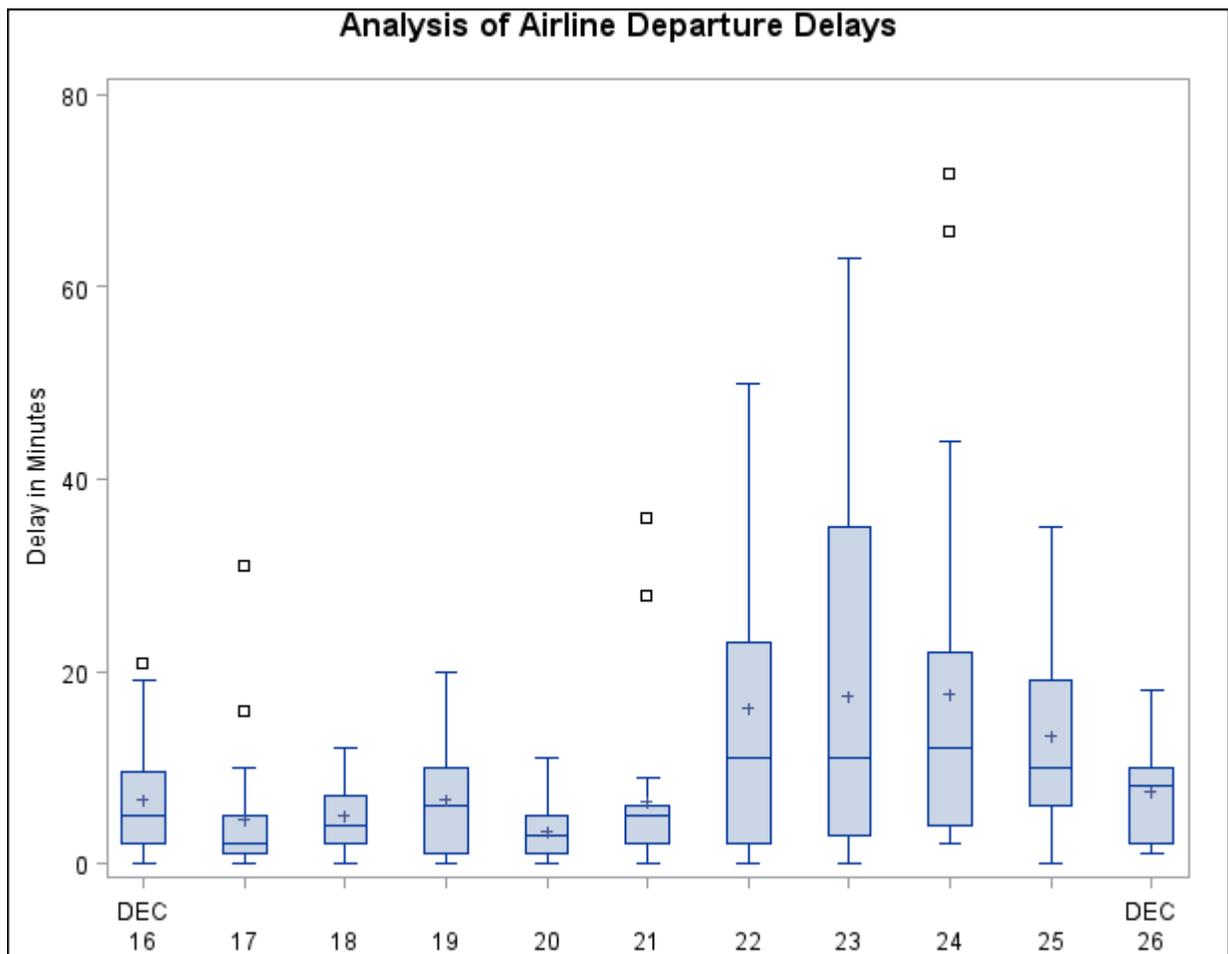

```

title 'Analysis of Airline Departure Delays';
proc shewhart data=Times limits=Timelim ;
  boxchart Delay * Day /
    boxstyle = schematic
    nolimits
    nohlabel
    nolegend;
  label Delay = 'Delay in Minutes';
run;

```

The chart is shown in [Output 17.2.2](#). When `BOXSTYLE=SCHEMATIC` is specified, the whiskers are drawn to the most extreme points in the subgroup sample that lie within so-called “fences.” The *upper fence* is defined as the third quartile (represented by the upper edge of the box) plus 1.5 times the interquartile range (IQR). The *lower fence* is defined as the first quartile (represented by the lower edge of the box) minus 1.5 times the interquartile range. Observations outside the fences are identified with a special symbol. The default symbol is a square, and you can specify the shape and color for this symbol with the `IDSYMBOL=` and `IDCOLOR=` options. Serifs are added to the whiskers by default. For further details, see the entry for `BOXSTYLE=` in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Output 17.2.2 BOXSTYLE=SCHEMATIC

The following statements create a box chart with schematic box-and-whisker plots in which the observations outside the fences are labeled:

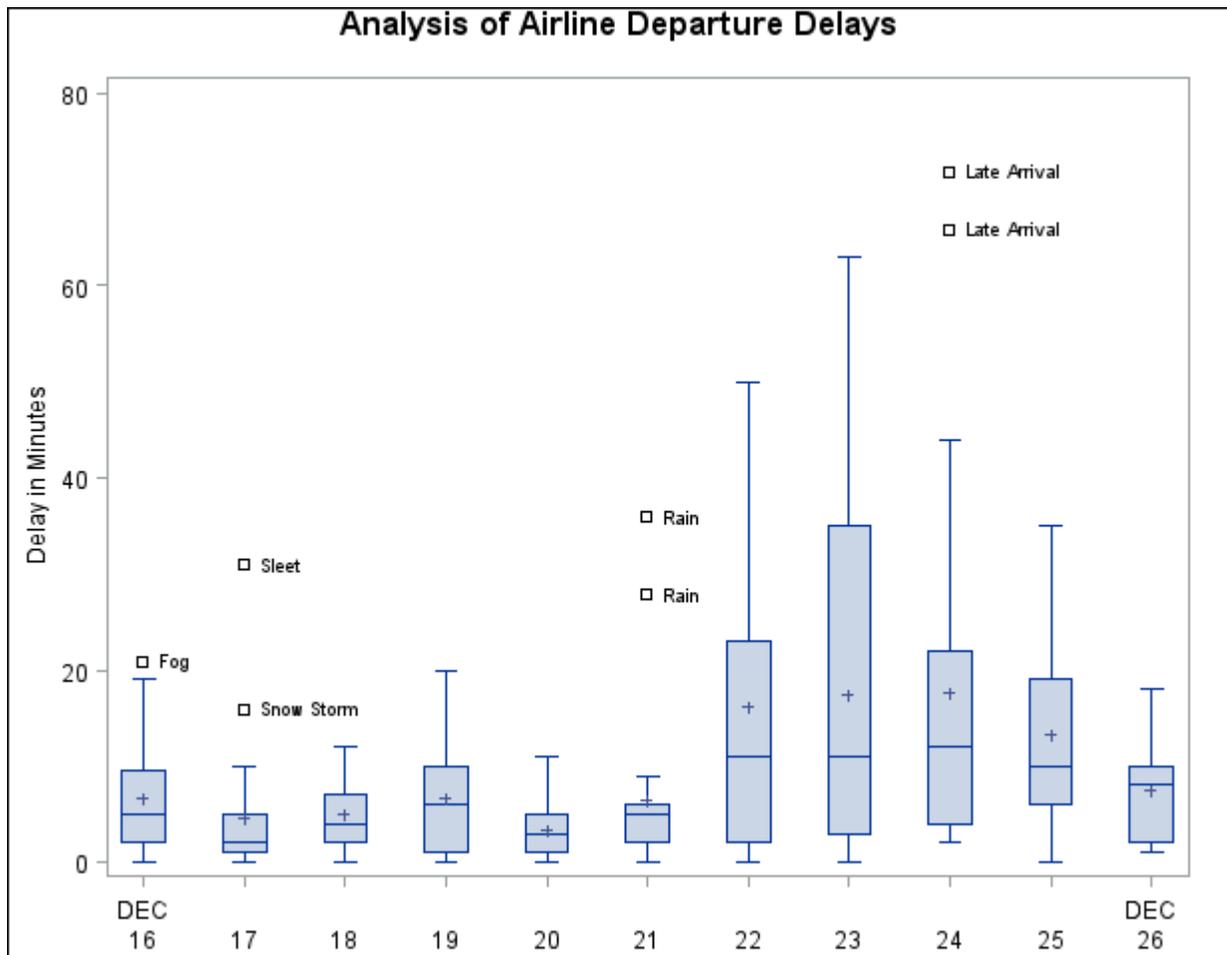

```

title 'Analysis of Airline Departure Delays';
proc shewhart data=Times limits=Timelim ;
  boxchart Delay * Day /
    boxstyle = schematicid
    llimits = 20
    nolimits
    nohlabel
    nolegend;
  id Reason;
  label Delay = 'Delay in Minutes';
run;

```

The chart is shown in [Output 17.2.3](#). If you specify BOXSTYLE=SCHEMATICID, schematic box-and-whisker plots are displayed in which the value of the first ID variable (in this case, Reason) is used to label each observation outside the fences.

Output 17.2.3 BOXSTYLE=SCHEMATICID

The following statements create a box chart with schematic box-and-whisker plots in which only the extreme observations outside the fences are labeled:

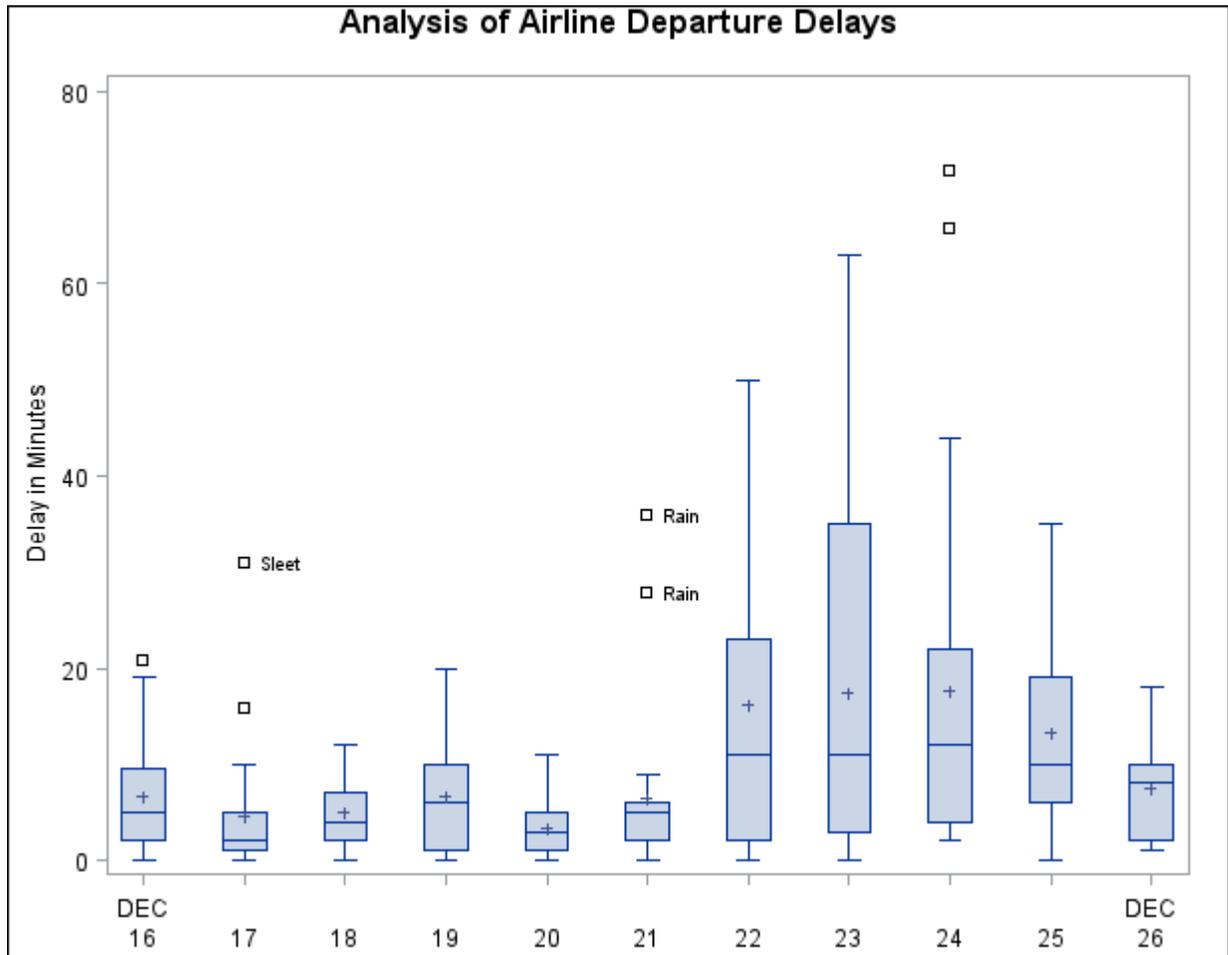

```

title 'Analysis of Airline Departure Delays';
proc shewhart data=Times limits=Timelim ;
  boxchart Delay * Day /
    boxstyle = schematicidfar
    nolimits
    nohlabel
    nolegend;
  id Reason;
  label Delay = 'Delay in Minutes';
run;

```

The chart is shown in [Output 17.2.4](#). If you specify `BOXSTYLE=SCHEMATICIDFAR`, schematic box-and-whisker plots are displayed in which the value of the first ID variable is used to label each observation outside the *lower* and *upper far fences*. The *lower* and *upper far fences* are located $3 \times \text{IQR}$ below the 25th percentile and above the 75th percentile, respectively. Observations between the fences and the far fences are identified with a symbol but are not labeled.

Output 17.2.4 BOXSTYLE=SCHEMATICIDFAR

Other options for controlling the display of box-and-whisker plots include the BOXWIDTH=, BOXWIDTHSCALE=, CBOXES=, CBOXFILL=, and LBOXES= options. For details, see the corresponding entries in “Dictionary of Options: SHEWHART Procedure” on page 2018.

Example 17.3: Creating Notched Box-and-Whisker Plots

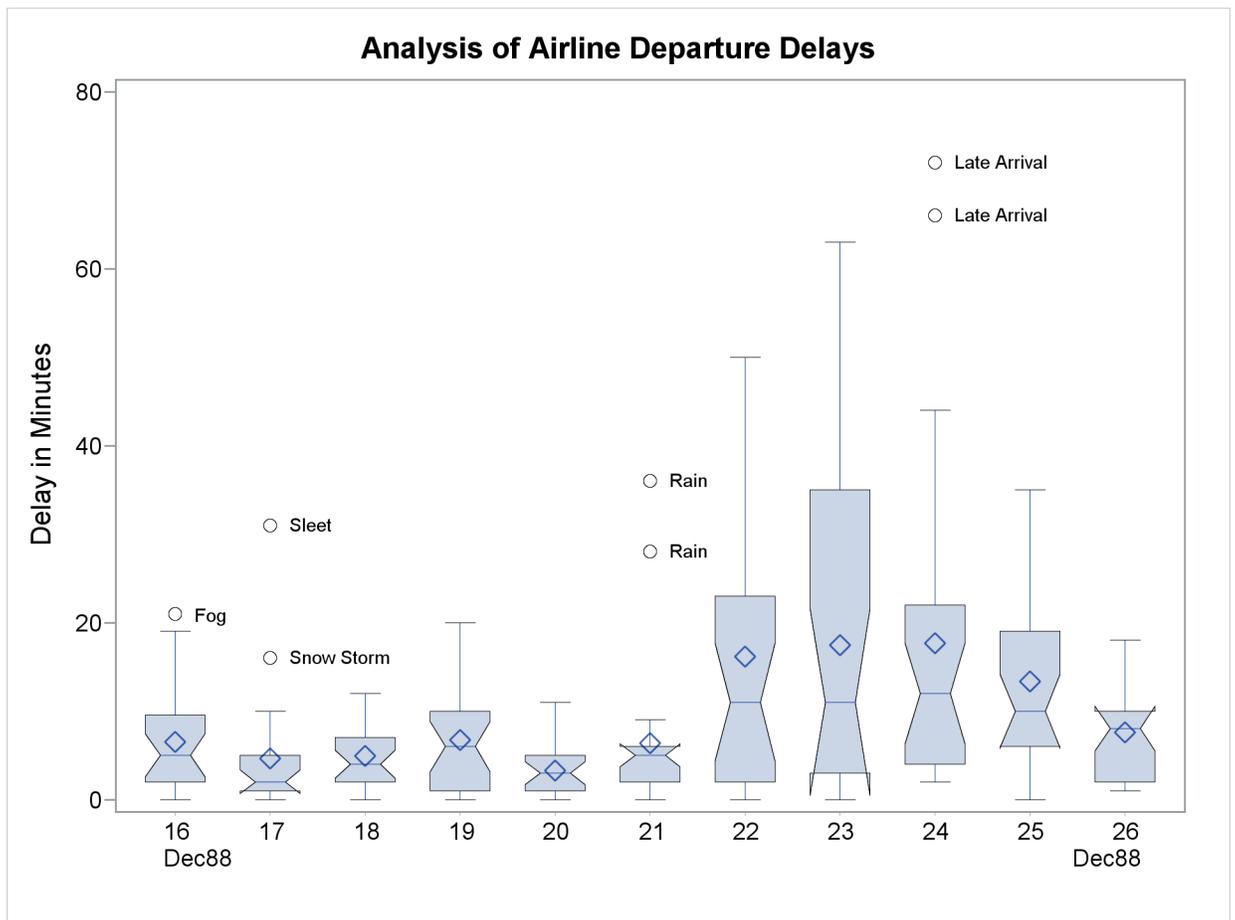

The following statements use the flight delay data of Example 17.1 to illustrate how to create side-by-side box-and-whisker plots with notches: *See SHWBOX4 in the SAS/QC Sample Library*

```

title 'Analysis of Airline Departure Delays';
ods graphics on;
proc shewhart data=Times limits=Timelim ;
  boxchart Delay * Day /
    boxstyle = schematicid
    odstitle = title
    nolimits
    nohlabel
    nolegend
    notches;
  id Reason;
  label Delay = 'Delay in Minutes';
run;

```

The control limits are suppressed with the NOLIMITS option. The notches, requested with the NOTCHES option, measure the significance of the difference between two medians. The medians are significantly different at approximately the 95% level if the notches do not overlap. For details, see the entry for NOTCHES in “Dictionary of Options: SHEWHART Procedure” on page 2018.

Output 17.3.1 Notched Side-by-Side Box-and-Whisker Plots

Example 17.4: Creating Box-and-Whisker Plots with Varying Widths

See *SHWBOX7* in the *SAS/QC Sample Library*. This example shows how to create a box chart with box-and-whisker plots whose widths vary proportionately with the subgroup sample size. The following statements create a SAS data set named *Times2* that contains flight departure delays (in minutes) recorded daily for eight consecutive days:

```
data Times2;
  label Delay = 'Delay in Minutes';
  informat Day date7. ;
  format Day date7. ;
  input Day @ ;
  do Flight=1 to 25;
    input Delay @ ;
    output;
  end;
  datalines;
01MAR90 12 4 2 2 15 8 0 11 0 0
          0 12 3 . 2 3 5 0 6 25
          7 4 9 5 10
02MAR90 1 . 3 . 0 1 5 0 . .
```

```

      1  5  7  .  7  2  2  16  2  1
      3  1 31  .  0
03MAR90  6  8  4  2  3  2  7  6 11  3
      2  7  0  1 10  2  5 12  8  6
      2  7  2  4  5
04MAR90 12  6  9  0 15  7  1  1  0  2
      5  6  5 14  7 21  8  1 14  3
     11  0  1 11  7
05MAR90  2  1  0  4  .  6  2  2  1  4
      1 11  .  1  0  .  5  5  .  2
      3  6  6  4  0
06MAR90  8  6  5  2  9  7  4  2  5  1
      2  2  4  2  5  1  3  9  7  8
      1  0  4 26 27
07MAR90  9  6  6  2  7  8  .  . 10  8
      0  2  4  3  .  .  .  7  .  6
      4  0  .  .  .
08MAR90  1  6  6  2  8  8  5  3  5  0
      8  2  4  2  5  1  6  4  5 10
      2  0  4  1  1
;

```

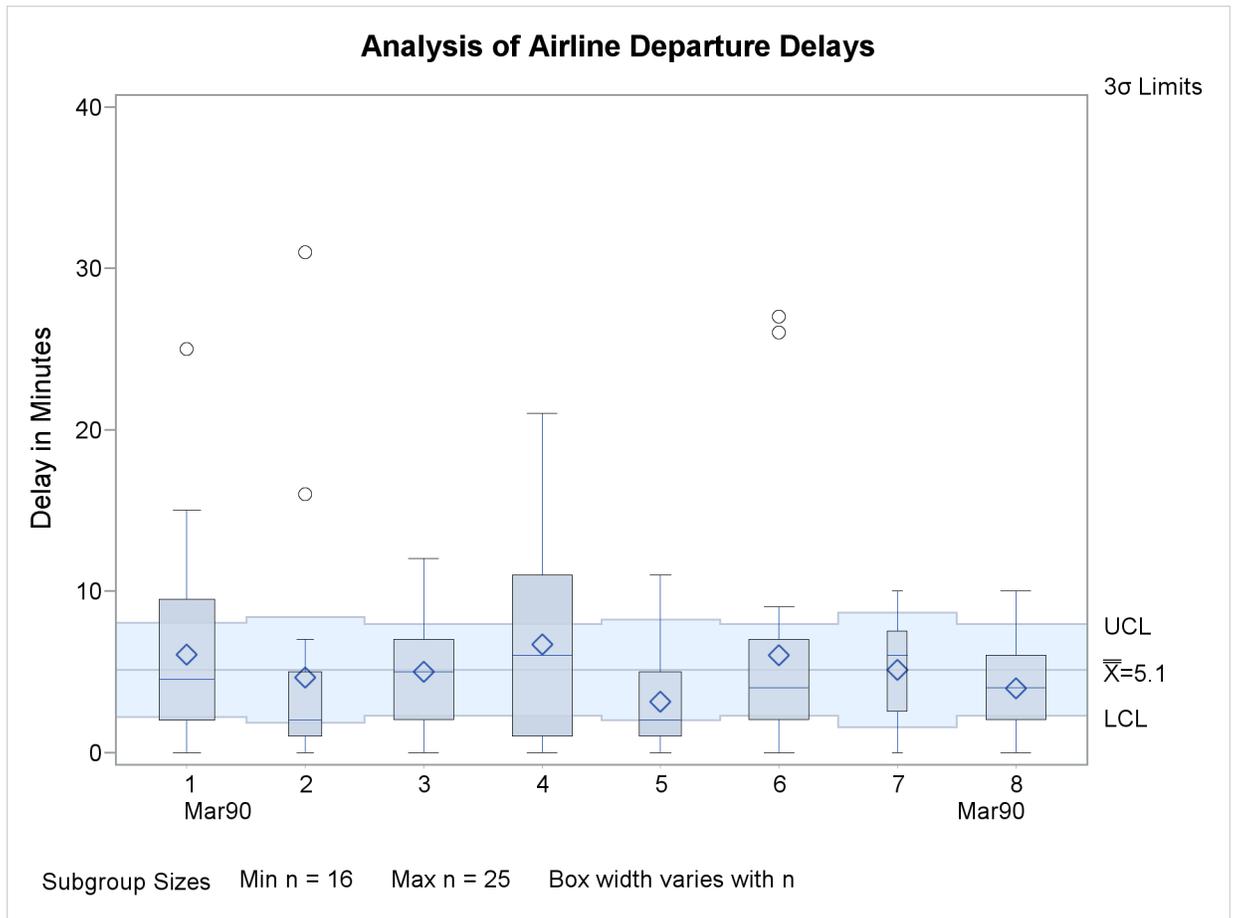

The following statements create the box chart shown in [Output 17.4.1](#):

```

title 'Analysis of Airline Departure Delays';
proc shewhart data=Times2;
  boxchart Delay * Day /
    nohlabel
    boxstyle      = schematic
    odstitle      = title
    boxwidthscale = 1 ;
run;

```

The `BOXWIDTHSCALE=1` option specifies that the widths of the box-and-whisker plots are to vary proportionately to the subgroup sample size n . This option is useful in situations where the sample size varies widely across subgroups. For further details, see the entry for `BOXWIDTHSCALE=` in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Output 17.4.1 Box Chart with Box-and-Whisker Plots of Varying Widths

Example 17.5: Creating Box-and-Whisker Plots with Different Line Styles and Colors

See SHWBOX7 in the SAS/QC Sample Library

The control limits in Output 17.4.1 apply to the subgroup means. This example illustrates how you can modify the chart to indicate whether the variability of the process is in control. The following statements create a box chart for Delay in which a dashed outline and a light gray fill color are used for a box-and-whisker plot if the corresponding subgroup standard deviation exceeds its 3σ limits.

First, the SHEWHART procedure is used to create an OUTTABLE= data set (Delaytab) that contains a variable (_EXLIMS_) that records which standard deviations exceed their 3σ limits.

```
proc shewhart data=Times2;
  xschart Delay * Day / nochart
                    outtable = Delaytab;
run;
```

Then, this information is used to set the line styles and fill colors as follows:

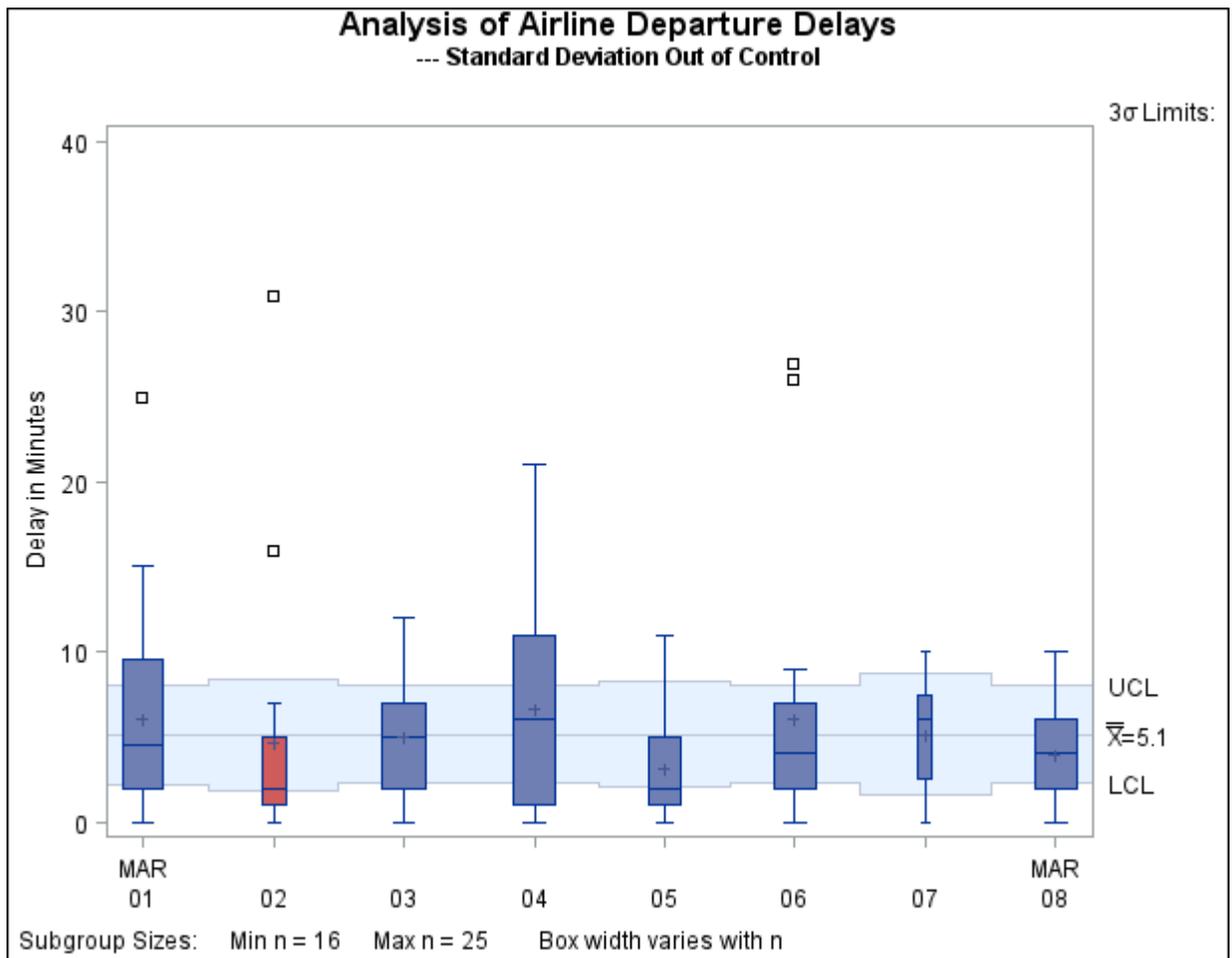

```
data Delaytab;
  length Boxcolor $ 8 ;
  set Delaytab;
  keep Day Boxcolor;
  if _exlims_ = 'UPPER' or _exlims_ = 'LOWER' then do;
    Boxcolor = 'Outside' ;
  end;
  else do;
    Boxcolor = 'Inside' ;
  end;
run;

data Times2;
  merge Times2 Delaytab;
  by Day;
run;
```

The following statements create the modified box chart:

```
ods graphics off;
title 'Analysis of Airline Departure Delays' ;
title2 '--- Standard Deviation Out of Control';
proc shewhart data=Times2;
  boxchart Delay * Day /
    nohlabel
    boxstyle      = schematic
    boxfill       = ( Boxcolor )
    boxwidthscale = 1
    odstitle     = title;
run;
```

The chart is shown in [Output 17.5.1](#). The values of the variable `Linestyle` specified with the `LBOXES=` option determine the outline styles for the box-and-whisker plots. The values of the variable `Boxcolor` specified with the `CBOXFILL=` option determines the fill colors. For further details, see the entries for these options in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018. The chart indicates that the large variability for March 2 should be checked.

Output 17.5.1 Box Chart Displaying Out-of-Control Subgroup Standard Deviations

Example 17.6: Computing the Control Limits for Subgroup Maximums

See SHWBOX3 in the SAS/QC Sample Library

This example illustrates how to compute and display control limits for the *maximum* of a subgroup sample. Subgroup samples of 20 metal braces are collected daily, and the lengths of the braces are measured in centimeters. These data are analyzed extensively in Example 17.43. The box chart for LogLength (the log of length) shown in Output 17.43.3 indicates that the subgroup mean is in control and that the subgroup distributions of LogLength are approximately normal. The following statements save the control limits for the mean of the LogLength in a data set named LOGLLIMS:

```
data lengdata;
  set lengdata;
  LogLength=log (Length-105);
run;

proc shewhart data=lengdata;
  xchart LogLength*Day /
  nochart
  outlimits=logllims;
run;
```

The next statements replace the control limits for the mean of LogLength with control limits for the maximum of LogLength:

```
data maxlim;
  set lengdata;
  set logllims;
  drop expmax stdmax;
  label _lclx_ = 'Lower Limit for Maximum of 20'
        _uclx_ = 'Upper Limit for Maximum of 20'
        _mean_ = 'Central Line for Maximum of 20';
  expmax = _stddev_*1.86748 + _mean_;
  stdmax = _stddev_*0.52507;
  _lclx_ = expmax - _sigmas_*stdmax;
  _uclx_ = expmax + _sigmas_*stdmax;
  _mean_ = expmax;
  call symput ('avgmax', left (put (expmax, 8.1)));
run;
```

The control limits are computed using the fact that the maximum of a sample of size 20 from a normal population with zero mean and unit standard deviation has an expected value of 1.86747 and a standard deviation of 0.52509; refer to Teichroew (1962) and see [Table 17.13](#). Finally, the following statements create a box chart for LogLength that displays control limits for the subgroup maximum:

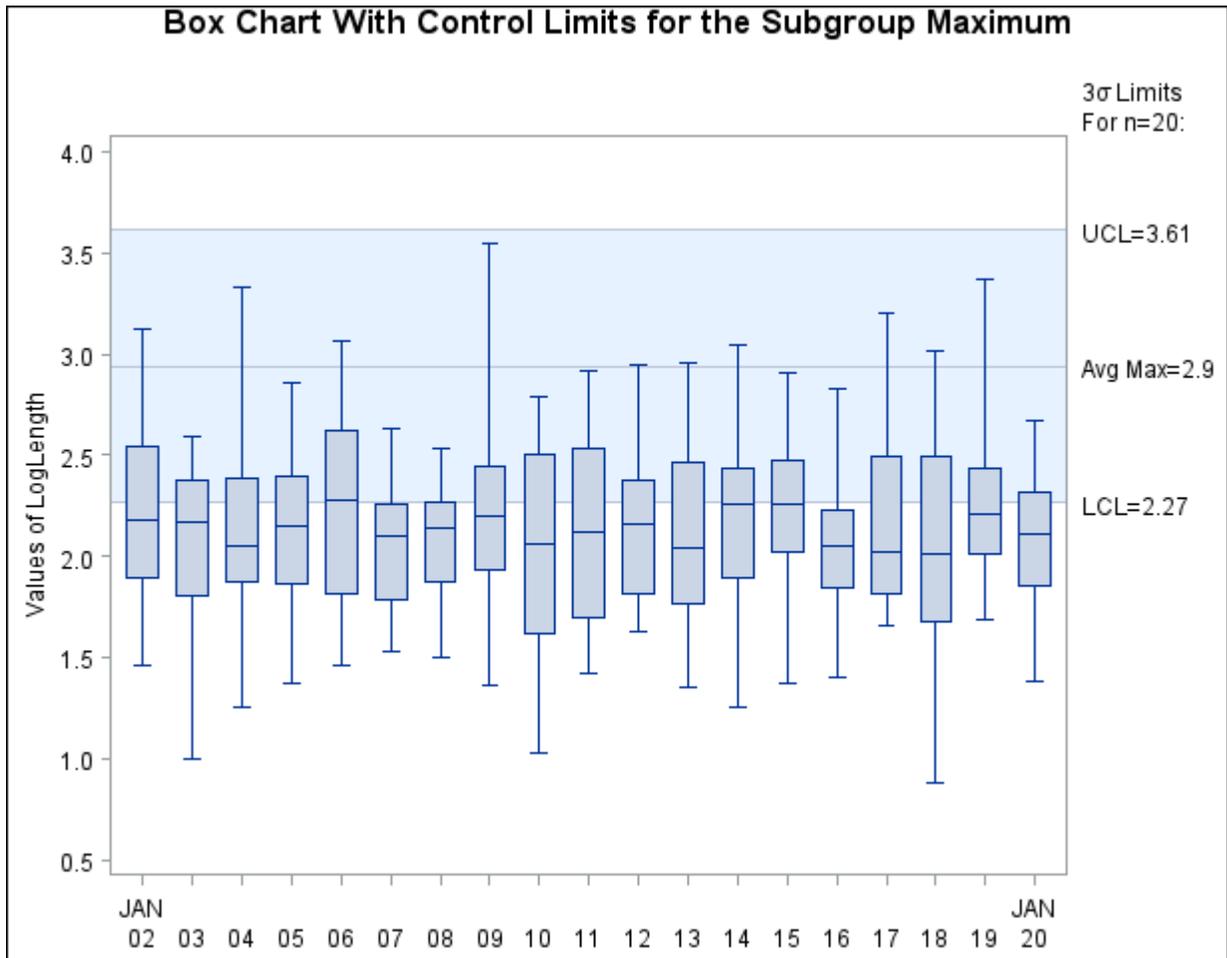

```
ods graphics off;
title 'Box Chart With Control Limits for the Subgroup Maximum';
symbol v=none;
proc shewhart data=lengdata limits=maxlim;
  boxchart LogLength*Day /
    ranges
    serifs
    nohlabel
    nolegend
    xsymbol="Avg Max=&AVGMAX" ;
  label LogLength='Values of LogLength';
run;
```

The box chart, shown in [Output 17.6.1](#), indicates that the maximum is in control since the tips of the upper whiskers fall within the control limits.

The SYMPUT call is used to pass the value of `_MEAN_` in a macro variable to the SHEWHART procedure so that this value can be used to label the central line.

You can apply the variable replacement method shown here to data with sample sizes other than 20 by replacing the constants 1.86747 and 0.52509 with the appropriate values from [Table 17.13](#). Austin (1973) describes a method for approximating these values. You can also use the preceding statements to display control limits for the subgroup minimum by changing the sign of the expected values in [Table 17.13](#).

Output 17.6.1 Box Chart for Subgroup Maximum

The variable replacement method can also be used to create a variety of box charts, including the modifications suggested by Iglewicz and Hoaglin (1987) and Rocke (1989).

Table 17.13 Expected Values and Standard Deviations of Maximum of a Normal Sample

n	Expected Value	Standard Deviation
2	0.56418	0.82565
3	0.84628	0.74798
4	1.02937	0.70123
5	1.16296	0.66899
6	1.26720	0.64494
7	1.35217	0.62605
8	1.42360	0.61065
9	1.48501	0.59780
10	1.53875	0.58681
11	1.58643	0.57730
12	1.62922	0.56891
13	1.66799	0.56144
14	1.70338	0.55474
15	1.73591	0.54869
16	1.76599	0.54316
17	1.79394	0.53809
18	1.82003	0.53342
19	1.84448	0.52910
20	1.86747	0.52509

Example 17.7: Constructing Multi-Vari Charts

“Multi-vari” charts⁶ are used in a variety of industries to analyze process data with nested (hierarchical) patterns of variation

- within-sample variation (for example, position within wafer)
- sample-to-sample variation within batches of samples (for example, wafer within lot)
- batch-to-batch variation (for example, across lots)

This example illustrates the construction of a “multi-vari” display. The following statements create a SAS data set named `Parm` that contains the value of a measured parameter (`Measure`) recorded at each of five positions on wafers produced in lots.

```
data Parm;
  length _phase_ $ 5 Wafer $ 2 position $ 1;
  input _phase_ $ & Wafer $ & position $ Measure ;
  datalines;
  Lot A      01          L          2.42435
  Lot A      01          B          2.44150
  Lot A      01          C          2.42143
```

⁶Multi-vari charts should not be confused with multivariate control charts.

```

Lot A      01      T      2.44960
Lot A      01      R      2.50050
Lot A      02      L      2.68188
Lot A      02      B      2.57195
Lot A      02      C      2.54678
Lot A      02      T      2.65978
Lot A      02      R      2.69208
Lot A      03      L      2.18005
Lot A      03      B      2.13593
Lot A      03      C      2.44303
Lot A      03      T      2.29052
Lot A      03      R      2.25963
Lot B      01      L      2.46573
Lot B      01      B      2.44898
Lot B      01      C      2.52365

... more lines ...

Lot G      03      C      2.66303
Lot G      03      T      2.65913
Lot G      03      R      2.84378
;

```

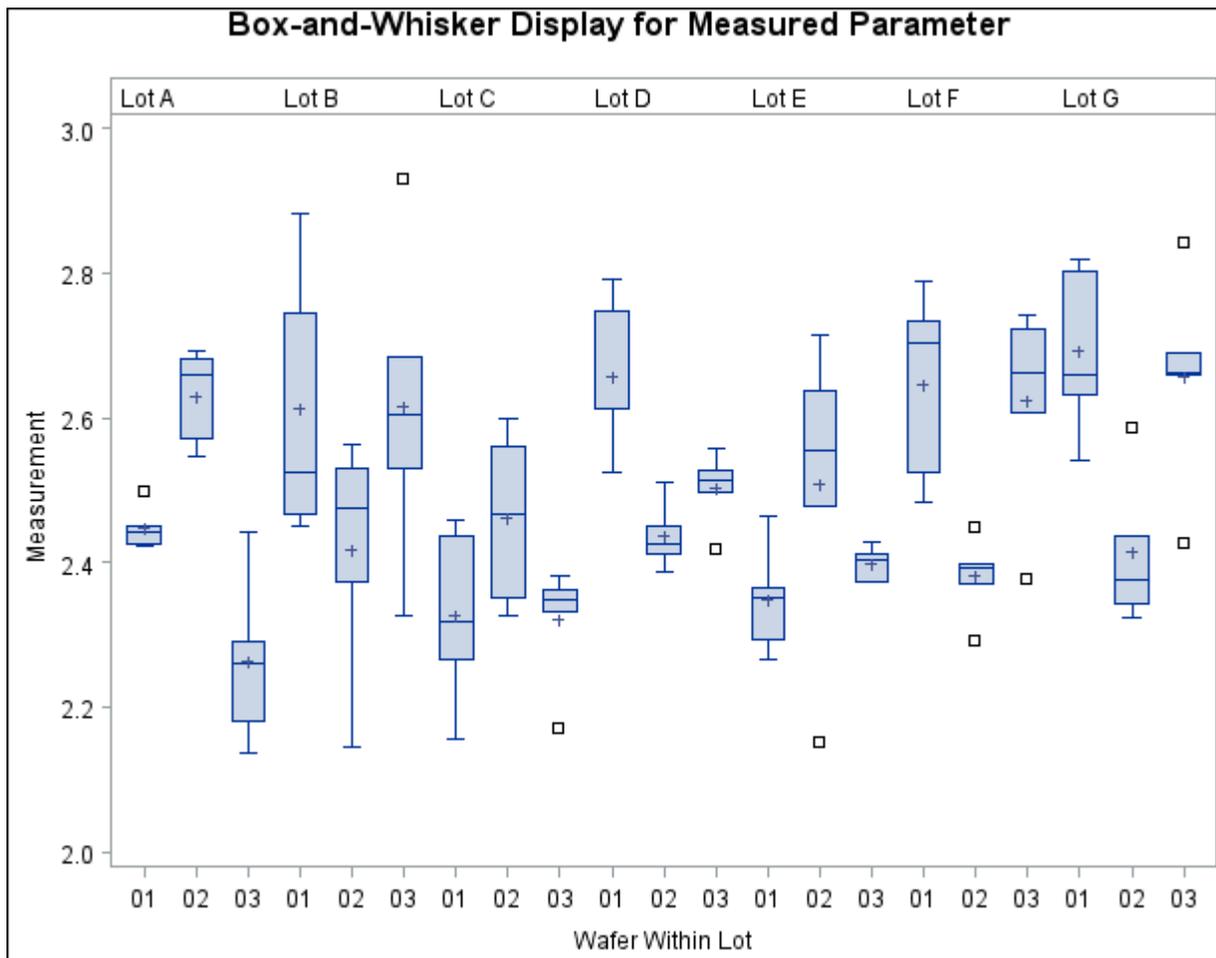

The following statements create an ordinary side-by-side box-and-whisker display for the measurements.

```

ods graphics off;
title 'Box-and-Whisker Display for Measured Parameter';
proc shewhart data=Parm;
  boxchart Measure*Wafer /
    nolimits
    boxstyle = schematic
    idsymbol = square
    readphase = all
    phaselegend
    nolegend;
  label Measure = 'Measurement'
         Wafer   = 'Wafer Within Lot';
run;

```

The display is shown in [Output 17.7.1](#). Here, the *subgroup-variable* is *Wafer*, and the option `BOXSTYLE=SCHEMATIC` is specified to request schematic box-and-whisker plots for the measurements in each subgroup (wafer) sample. The lot values are provided as the values of the special variable `_PHASE_`, which is read when the option `READPHASE=ALL` is specified. The option `PHASELEGEND` requests the legend for phase (lot) values at the top of the chart, and the `NOLEGEND` option suppresses the default legend for sample sizes. The `NOLIMITS` option suppresses the display of control limits. This option is recommended whenever you are using the `BOXCHART` statement to create side-by-side box-and-whisker plots.

Output 17.7.1 Box-and-Whisker Plot Using BOXSTYLE=SCHEMATIC

The box-and-whisker display in [Output 17.7.1](#) is not particularly appropriate for these data since there are only five measurements in each wafer and since the variation within each wafer may depend on the position, which is not indicated. The next statements use the `BOXCHART` statement to produce a multi-vari chart for the same data.

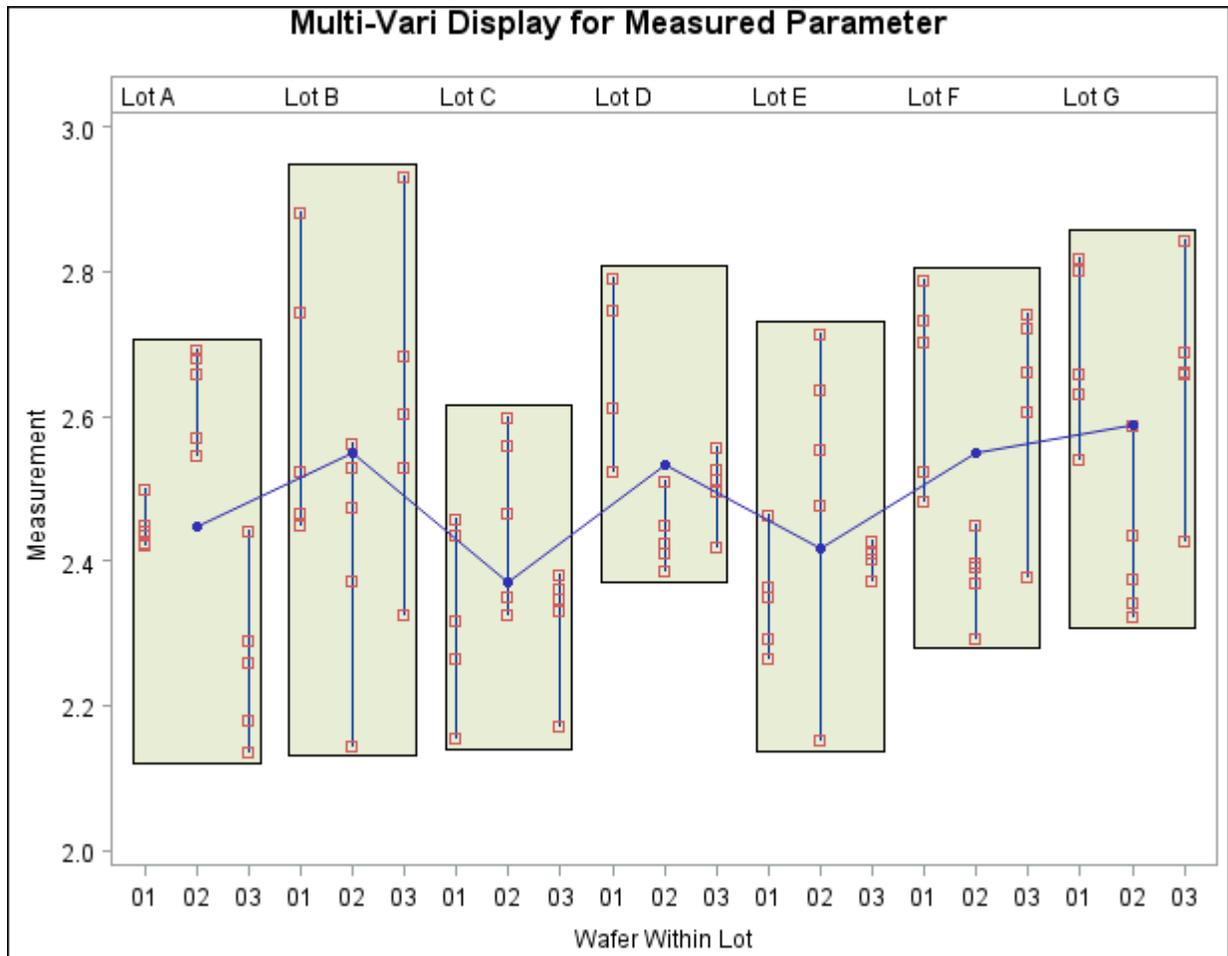

```

symbol v=none;
title 'Multi-Vari Display for Measured Parameter';
proc shewhart data=Parm;
  boxchart Measure*Wafer /
    nolimits
    boxstyle          = pointsjoin
    idsymbol          = square
    cphaseboxfill    = ywh
    cphasebox        = black
    cphasemeanconnect = bib
    phasemeanconnect = dot
    readphase        = all
    phaselegend
    nolegend;
  label Measure = 'Measurement'
        Wafer   = 'Wafer Within Lot';
run;

```

The display is shown in [Output 17.7.2](#).

Output 17.7.2 Multi-Vari Chart Using BOXSTYLE=POINTSJOIN

The option `BOXSTYLE=POINTSJOIN` specifies that the values for each wafer are to be displayed as points joined by a vertical line. The `IDSYMBOL=` option specifies the symbol marker for the points. The option `V=NONE` in the `SYMBOL` statement is specified to suppress the symbol for the wafer averages shown in [Output 17.7.1](#). The option `CPHASEBOX=BLACK` specifies that the points for each lot are to be enclosed in a black box, and the `CPHASEBOXFILL=` option specifies the fill color for the box. The option `CPHASEMEANCONNECT=BLACK` specifies that the means of the lots are to be connected with black lines, and the `PHASEMEANSYMBOL=` option specifies the symbol marker for the lot means.

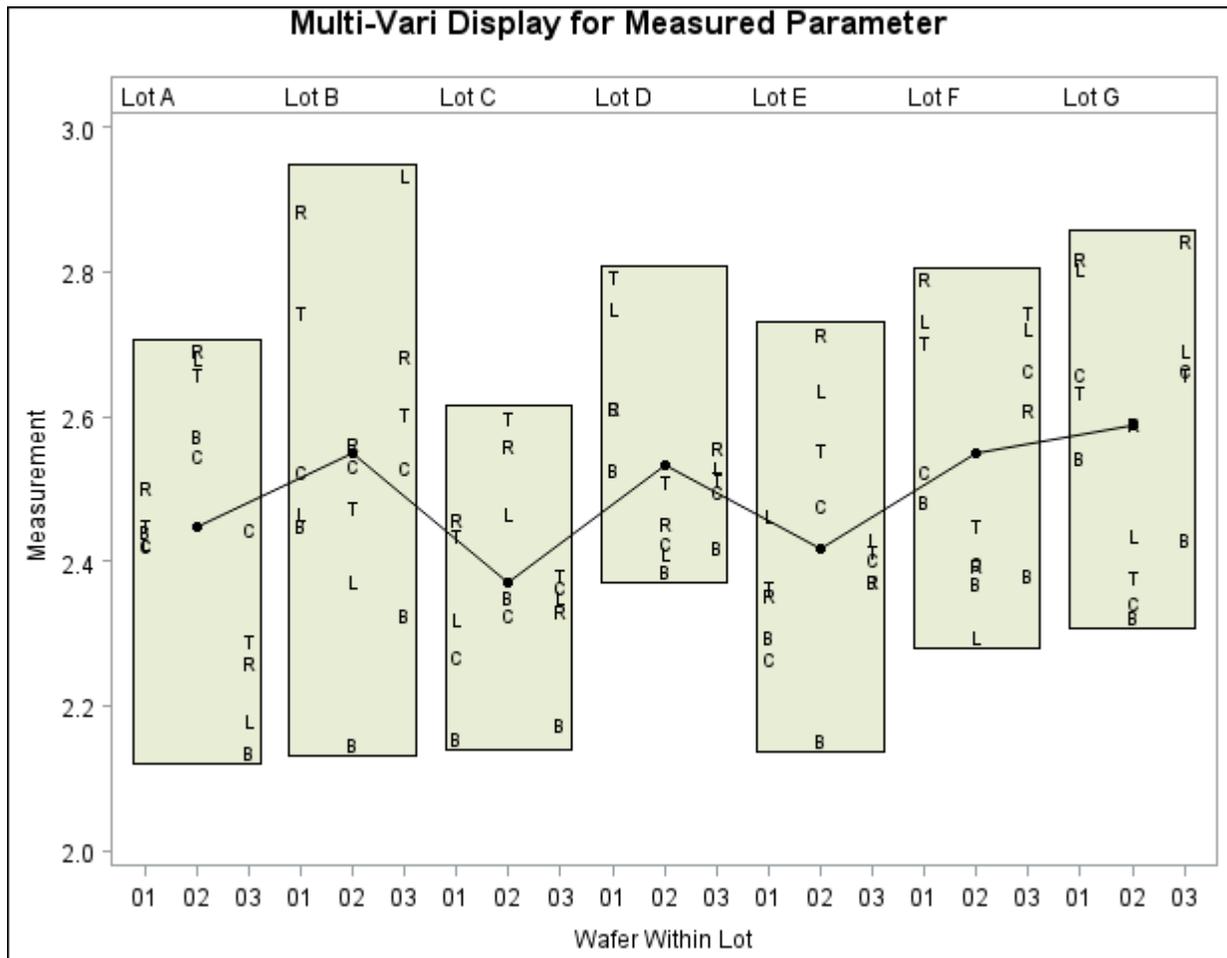

The following statements create a slightly different multi-vari chart using the values of the variable `POSITION` to identify the measurements for each wafer. Note that the option `BOXSTYLE=POINTS` is specified and that `POSITION` is specified as the ID variable. The display is shown in [Output 17.7.3](#).

```

symbol v=none;
title 'Multi-Vari Display for Measured Parameter';
proc shewhart data=Parm;
  boxchart Measure*Wafer /
    nolimits
    cphaseboxfill      = ywh
    cphasemeanconnect = black
    boxstyle           = pointsid
    phasemeansymbol   = dot
    readphase         = all
    phaselegend
    nolegend;
  label Measure = 'Measurement'
        Wafer   = 'Wafer Within Lot';
  id position;
run;

```

Output 17.7.3 Multi-Vari Chart Using BOXSTYLE=POINTSID

CCHART Statement: SHEWHART Procedure

Overview: CCHART Statement

The CCHART statement creates c charts for the numbers of nonconformities (defects) in subgroup samples.

You can use options in the CCHART statement to

- specify the number of inspection units per subgroup. Typically (but not necessarily), each subgroup consists of a single unit.
- compute control limits from the data based on a multiple of the standard error of the counts or as probability limits
- tabulate subgroup summary statistics and control limits
- save control limits in an output data set
- save subgroup summary statistics in an output data set
- read preestablished control limits from a data set
- apply tests for special causes (also known as runs tests and Western Electric rules)
- specify a known (standard) value for the average number of nonconformities per inspection unit
- display distinct sets of control limits for data from successive time phases
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control the layout and appearance of the chart

You have three alternatives for producing c charts with the CCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: CCHART Statement

This section introduces the CCHART statement with simple examples that illustrate commonly used options. Complete syntax for the CCHART statement is presented in the section “Syntax: CCHART Statement” on page 1502, and advanced examples are given in the section “Examples: CCHART Statement” on page 1522.

Creating c Charts from Defect Count Data

A *c* chart is used to monitor the number of paint defects on new trucks. Twenty trucks of the same model are inspected, and the number of paint defects per truck is recorded. The following statements create a SAS data set named Trucks, which contains the defect counts: *See SHWCCHRT1 in the SAS/QC Sample Library*

```
data Trucks;
  input TruckID $ Defects @@;
  label TruckID='Truck Identification Number'
        Defects='Number of Paint Defects';
  datalines;
C1  5  C2  4  C3  4  C4  8  C5  7
C6 12  C7  3  C8 11  E4  8  E9  4
E7  9  E6 13  A3  5  A4  4  A7  9
Q1 15  Q2  8  Q3  9  Q9 10  Q4  8
;
```

A partial listing of Trucks is shown in Figure 17.15.

Figure 17.15 The Data Set Trucks

Paint Defects on New Trucks	
Truck ID	Defects
C1	5
C2	4
C3	4
C4	8
C5	7

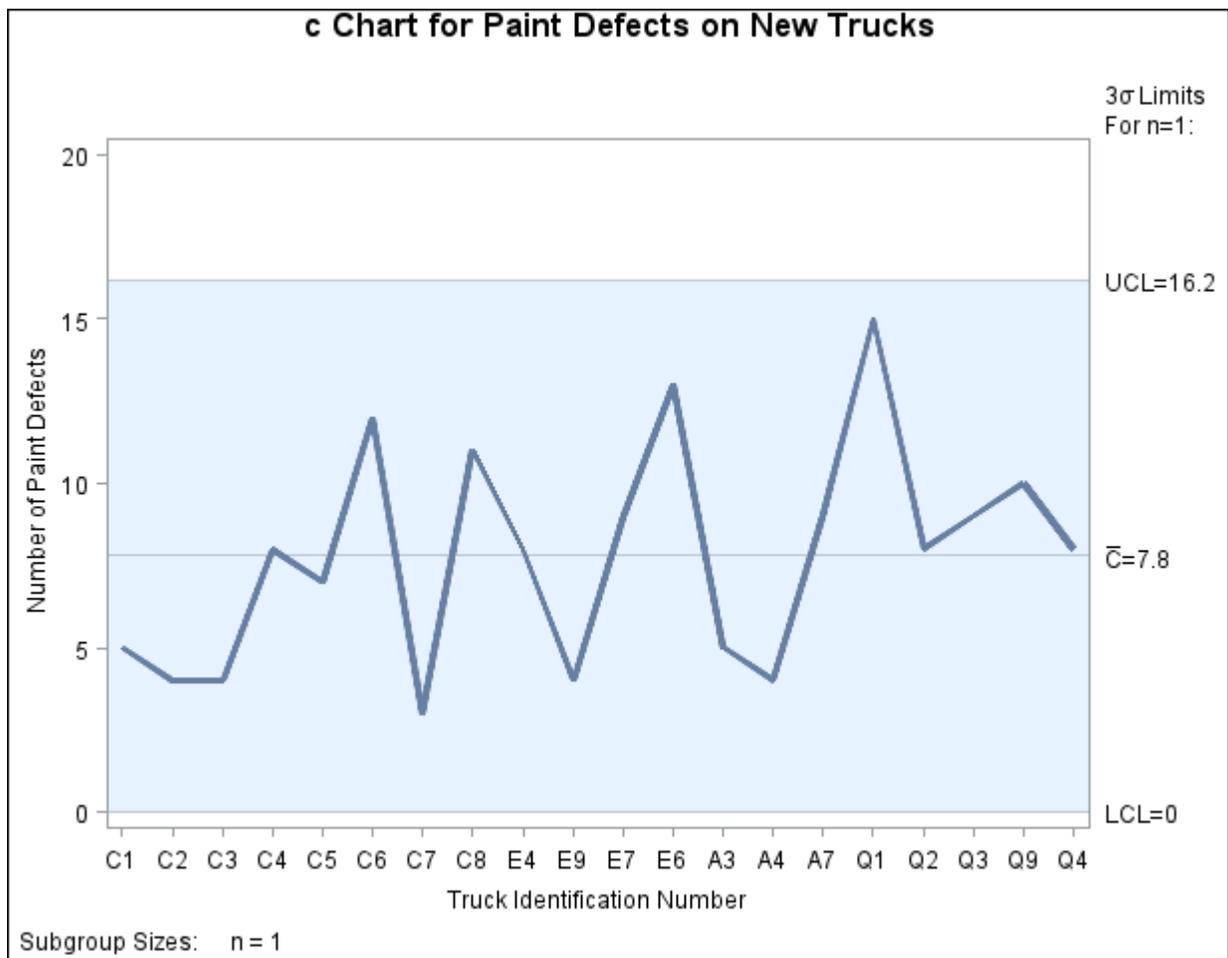

There is a single observation per truck. The variable `TruckID` identifies the subgroup sample and is referred to as the *subgroup-variable*. The variable `Defects` contains the number of nonconformities in each subgroup sample and is referred to as the *process variable* (or *process* for short).

The following statements create the *c* chart shown in Figure 17.16:

```
ods graphics off;
title 'c Chart for Paint Defects on New Trucks';
proc shewhart data=Trucks;
  cchart Defects*TruckID;
run;
```

This example illustrates the basic form of the `CCHART` statement. After the keyword `CCHART`, you specify the *process* to analyze (in this case, `Defects`) followed by an asterisk and the *subgroup-variable* (`TruckID`).

Figure 17.16 *c* Chart of Paint Defects (Traditional Graphics)

Each point on the *c* chart represents the number of nonconformities for a particular subgroup. For instance, the value plotted for the first subgroup is 5 (since there are five paint defects on the first truck). By default, the control limits shown are 3σ limits estimated from the data; the formulas are given in “Control Limits” on page 1513. Since none of the points exceed the 3σ limits, the *c* chart indicates that the painting process is in statistical control.

See “Constructing Charts for Numbers of Nonconformities (c Charts)” on page 1512 for details concerning *c* charts. For more details on reading raw data, see “DATA= Data Set” on page 1518.

Saving Control Limits

You can save the control limits for a *c* chart in a SAS data set; this enables you to apply the control limits to future data (see the section “Reading Preestablished Control Limits” on page 1497) or subsequently modify the limits with a DATA step program. *See SHWCCHRI in the SAS/QC Sample Library*

The following statements read the data set Trucks introduced in “Creating *c* Charts from Defect Count Data” on page 1493 and saves the control limit information displayed in Figure 17.16 in a data set named Deflim:

```
proc shewhart data=Trucks;
  cchart Defects*TruckID / outlimits=Deflim
                        nochart;
run;
```

The OUTLIMITS= option names the data set containing the control limits, and the NOCHART option suppresses the display of the chart. Options such as OUTLIMITS= and NOCHART are specified after the slash (/) in the CCHART statement. A complete list of options is presented in the section “Syntax: CCHART Statement” on page 1502. The data set Deflim is listed in Figure 17.17.

Figure 17.17 The Data Set Deflim Containing Control Limit Information

Control Limits Data Set Deflim									
VAR	_SUBGRP_	_TYPE_	_LIMITN_	_ALPHA_	_SIGMAS_	_U_	_LCLC_	_C_	_UCLC_
Defects	TruckID	ESTIMATE	1	.002902622	3	7.8	0	7.8	16.1785

The data set Deflim contains one observation with the limits for the *process* Defects. The variables _LCLC_, and _UCLC_ contain the lower and upper control limits. The variable _C_ contains the central line, and the variable _U_ contains the average number of nonconformities per inspection unit. Since all the subgroups contain a single inspection unit, the values of _C_ and _U_ are the same. The value of _LIMITN_ is the nominal sample size associated with the control limits, and the value of _SIGMAS_ is the multiple of σ associated with the control limits. The variables _VAR_ and _SUBGRP_ are bookkeeping variables that save the *process* and *subgroup-variable*. The variable _TYPE_ is a bookkeeping variable that indicates whether the value of _U_ is an estimate or standard value. For more information, see the section “OUTLIMITS= Data Set” on page 1515.

Alternatively, you can use the OUTTABLE= option to create an output data set that saves both the control limits and the subgroup statistics, as illustrated by the following statements:

```
title 'Number of Nonconformities and Control Limit Information';
proc shewhart data=Trucks;
  cchart Defects*TruckID / outtable=Trucktab
                        nochart;
run;
```

The OUTTABLE= data set Trucktab is listed in Figure 17.18.

Figure 17.18 The Data Set Trucktab

Number of Nonconformities and Control Limit Information									
Truck									
VAR	ID	_SIGMAS_	_LIMITN_	_SUBN_	_LCLC_	_SUBC_	_C_	_UCLC_	_EXLIM_
Defects	C1	3	1	1	0	5	7.8	16.1785	
Defects	C2	3	1	1	0	4	7.8	16.1785	
Defects	C3	3	1	1	0	4	7.8	16.1785	
Defects	C4	3	1	1	0	8	7.8	16.1785	
Defects	C5	3	1	1	0	7	7.8	16.1785	
Defects	C6	3	1	1	0	12	7.8	16.1785	
Defects	C7	3	1	1	0	3	7.8	16.1785	
Defects	C8	3	1	1	0	11	7.8	16.1785	
Defects	E4	3	1	1	0	8	7.8	16.1785	
Defects	E9	3	1	1	0	4	7.8	16.1785	
Defects	E7	3	1	1	0	9	7.8	16.1785	
Defects	E6	3	1	1	0	13	7.8	16.1785	
Defects	A3	3	1	1	0	5	7.8	16.1785	
Defects	A4	3	1	1	0	4	7.8	16.1785	
Defects	A7	3	1	1	0	9	7.8	16.1785	
Defects	Q1	3	1	1	0	15	7.8	16.1785	
Defects	Q2	3	1	1	0	8	7.8	16.1785	
Defects	Q3	3	1	1	0	9	7.8	16.1785	
Defects	Q9	3	1	1	0	10	7.8	16.1785	
Defects	Q4	3	1	1	0	8	7.8	16.1785	

This data set contains one observation for each subgroup sample. The variables `_SUBC_` and `_SUBN_` contain the number of nonconformities per subgroup and the number of inspection units per subgroup. The variables `_LCLC_` and `_UCLC_` contain the lower and upper control limits, and the variable `_C_` contains the central line. The variables `_VAR_` and `TruckID` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “[OUTTABLE= Data Set](#)” on page 1516.

An `OUTTABLE=` data set can be read later as a `TABLE=` data set in the SHEWHART procedure. For example, the following statements read `Trucktab` and display a *c* chart (not shown here) identical to the chart in [Figure 17.16](#):

```

title 'c Chart for Paint Defects in New Trucks';
proc shewhart table=Trucktab;
  cchart Defects*Truckid;
  label _SUBC_ = 'Number of Paint Defects';
run;

```

Because the SHEWHART procedure simply displays the information in a `TABLE=` data set, you can use `TABLE=` data sets to create specialized control charts (see “[Specialized Control Charts: SHEWHART Procedure](#)” on page 2171). For more information, see “[TABLE= Data Set](#)” on page 1520.

Reading Preestablished Control Limits

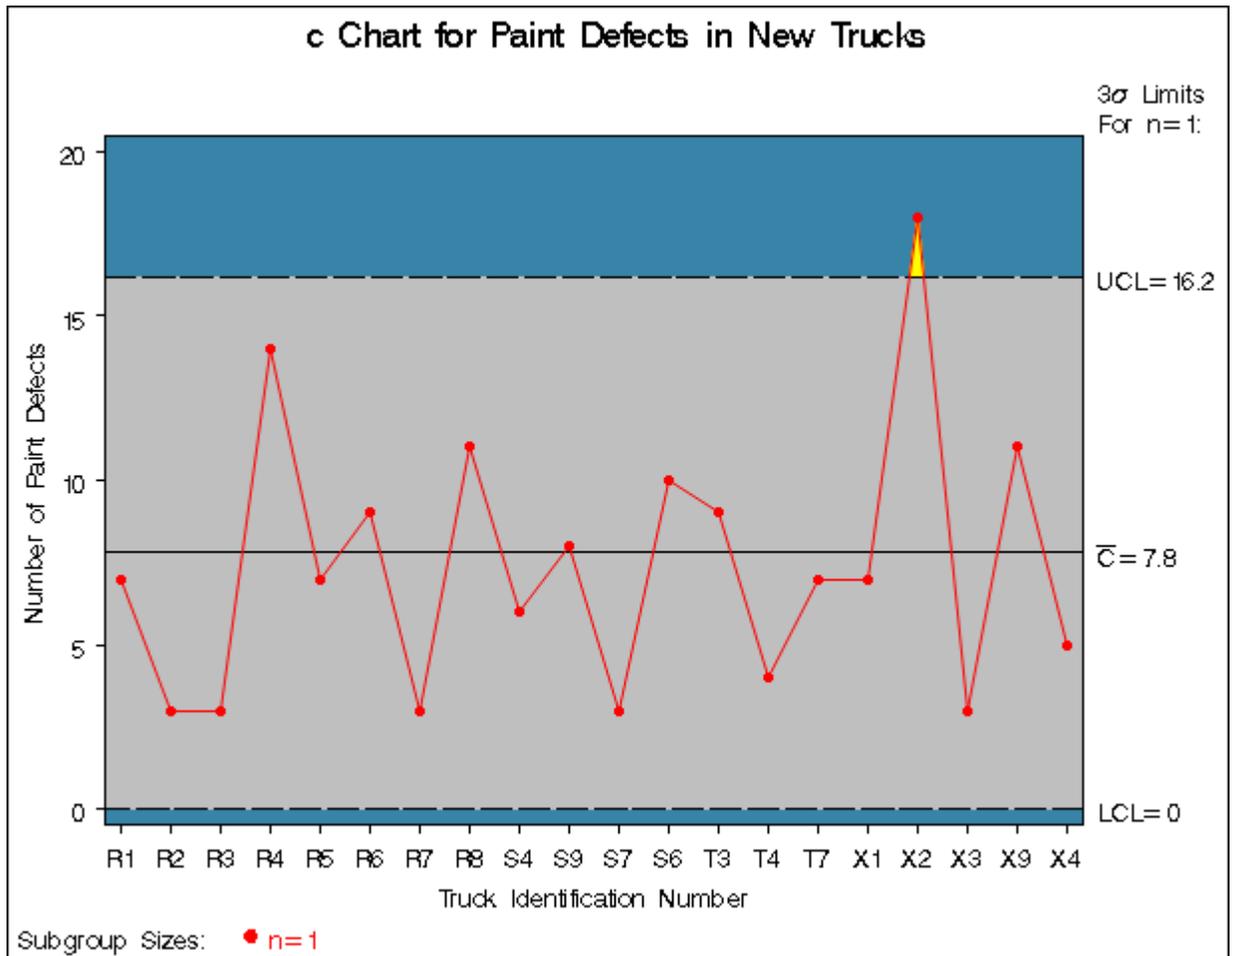

In the previous example, control limits were saved in a SAS data set named Deflim. This example shows how these limits can be applied to defect data for a second group of trucks, which are provided in the following data set: *See SHWCCHRI in the SAS/QC Sample Library*

```
data Trucks2;
  input TruckID $ Defects @@;
  label TruckID='Truck Identification Number'
        Defects='Number of Paint Defects';
  datalines;
R1 7  R2 3  R3 3  R4 14  R5 7
R6 9  R7 3  R8 11  S4 6  S9 8
S7 3  S6 10  T3 9  T4 4  T7 7
X1 7  X2 18  X3 3  X9 11  X4 5
;
```

The following statements plot the number of paint defects for the second group of trucks on a *c* chart using the control limits in Deflim. The chart is shown in [Figure 17.19](#).

```
options nogstyle;
options ftext=swiss;
symbol v=dot color=red height=.8;
title 'c Chart for Paint Defects in New Trucks';
proc shewhart data=Trucks2 limits=Deflim;
  cchart Defects*TruckID / cframe = steel
                        cconnect = red
                        cinfill = ligr
                        coutfill = yellow ;
run;
options gstyle;
```

The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the SYMBOL statement and CCHART statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently.

Figure 17.19 *c* Chart for Second Set of Trucks (Traditional Graphics with NOGSTYLE)

Note that the number of defects on the truck with identification number X2 exceeds the upper control limit, indicating that the process is out-of-control. The LIMITS= option in the PROC SHEWHART statement specifies the data set containing the control limits. By default,⁷ this information is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches the *process* name Defects
- the value of `_SUBGRP_` matches the *subgroup-variable* name TruckID

In this example, the LIMITS= data set was created in a previous run of the SHEWHART procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on page 1519 for details concerning the variables that you must provide.

⁷In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

Creating c Charts from Nonconformities per Unit

In the previous example, the input data set provided the number of nonconformities per subgroup. However, in some applications, as illustrated here, the data may be provided as the number of nonconformities *per inspection unit* for each subgroup. *See SHWCCHRI in the SAS/QC Sample Library*

A clothing manufacturer ships shirts in boxes of ten. Prior to shipment, each shirt is inspected for flaws. Since the manufacturer is interested in the average number of flaws per shirt, the number of flaws found in each box is divided by ten and then recorded. The following statements create a SAS data set named Shirts, which contains the average number of flaws per shirt for 25 boxes:

```
data Shirts;
  input Box avgdefu @@;
  avgdefn=10;
  datalines;
  1 0.4 2 0.7 3 0.5 4 1.0 5 0.3
  6 0.2 7 0.0 8 0.4 9 0.4 10 0.6
  11 0.2 12 0.7 13 0.3 14 0.1 15 0.3
  16 0.6 17 0.6 18 0.3 19 0.7 20 0.3
  21 0.0 22 0.1 23 0.5 24 0.6 25 0.4
  ;
```

A partial listing of Shirts is shown in Figure 17.20.

Figure 17.20 The Data Set Shirts

Average Number of Shirt Flaws		
Box	avgdefu	avgdefn
1	0.4	10
2	0.7	10
3	0.5	10
4	1.0	10
5	0.3	10

The data set Shirts contains three variables: the box number (Box), the average number of flaws per shirt (avgdefu), and the number of shirts per box (avgdefn). Here, a *subgroup* is a box of shirts, and an *inspection unit* is an individual shirt. Note that each subgroup consists of ten inspection units.

To create a *c* chart plotting the total number of flaws per box (instead of per shirt), you can specify Shirts as a HISTORY= data set.

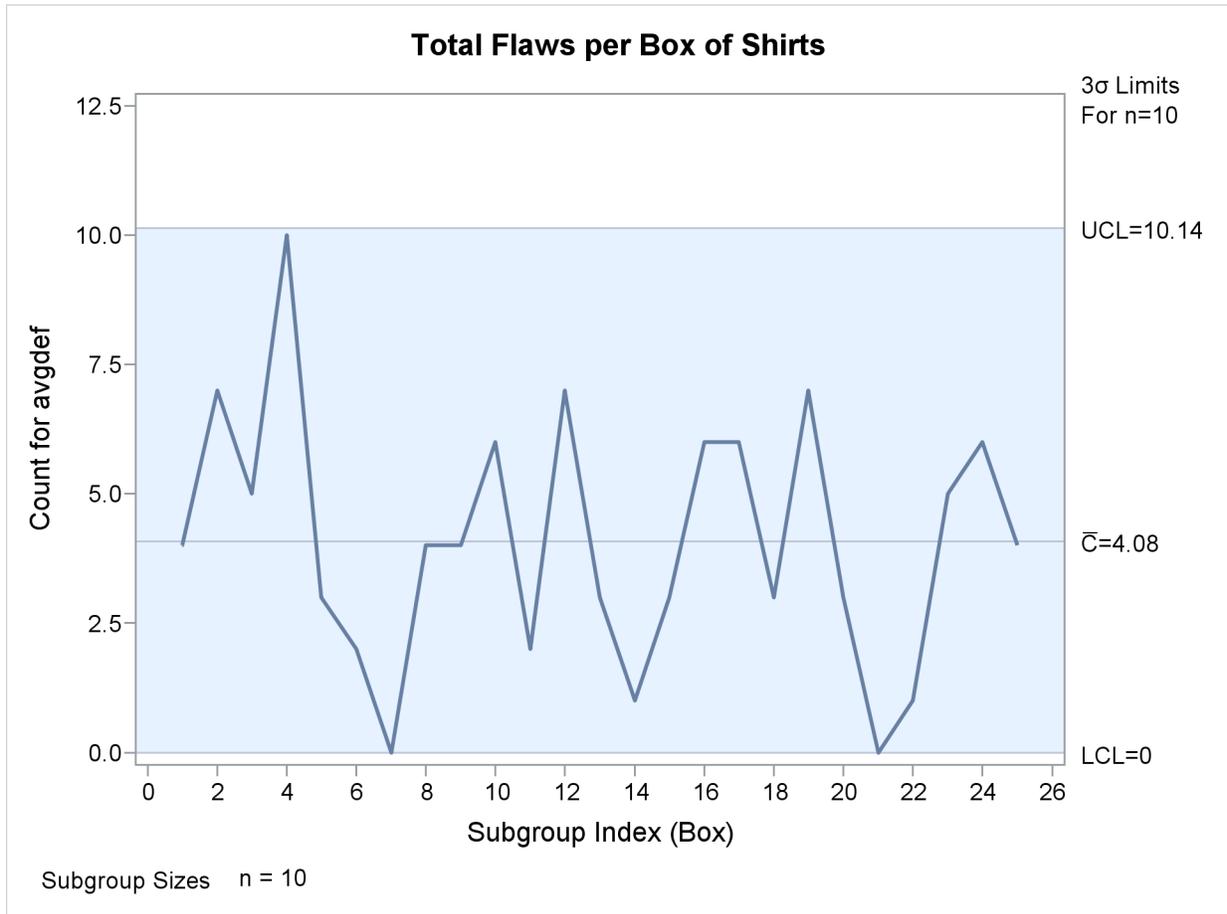

```
ods graphics on;
title 'Total Flaws per Box of Shirts';
proc shewhart history=Shirts;
  cchart avgdef*Box / odstitle=title;
run;
```

The ODS GRAPHICS ON statement specified before the PROC SHEWHART statement enables ODS Graphics, so the *c* chart is created using ODS Graphics instead of traditional graphics.

Note that avgdef is *not* the name of a SAS variable in the data set but is instead the common prefix

for the SAS variable names `avgdefu` and `avgdefn`. The suffix characters *U* and *N* indicate *number of nonconformities per unit* and *sample size*, respectively. This naming convention enables you to specify two variables in the `HISTORY=` data set with a single name referred to as the *process*. The name `Box` specified after the asterisk is the name of the *subgroup-variable*. The *c* chart is shown in Figure 17.21.

Figure 17.21 *c* Chart for Boxes of Shirts (ODS Graphics)

In general, a `HISTORY=` input data set used with the `CCHART` statement must contain the following variables:

- subgroup variable
- subgroup number of nonconformities per unit variable
- subgroup sample size variable

Furthermore, the names of the nonconformities per unit and sample size variables must begin with the *process* name specified in the `CCHART` statement and end with the special suffix characters *U* and *N*, respectively. If the names do not follow this convention, you can use the `RENAME` option to rename the variables for the duration of the `SHEWHART` procedure step. Suppose that, instead of the variables `avgdefu` and `avgdefn`, the data set `Shirts` contained the variables `Shirtdef` and `Sizes`. The following statements would temporarily rename `Shirtdef` and `Sizes` to `avgdefu` and `avgdefn`:

```

proc shewhart
  history=Shirts (rename=(Shirtdef = AvgdefU
                        Sizes      = AvgdefN ));
  cchart Avgdef*Box;
run;

```

For more information, see “HISTORY= Data Set” on page 1519.

Saving Nonconformities per Unit

A department store receives boxes of shirts containing 10, 25, or 50 shirts. Each box is inspected, and the total number of defects per box is recorded. The following statements create a SAS data set named Shirts2, which contains the total defects per box for 20 boxes: *See SHWCCHRI in the SAS/QC Sample Library*

```

data Shirts2;
  input Box Flaws Nshirts @@;
  datalines;
  1 3 10 2 8 10 3 15 25 4 20 25
  5 9 25 6 1 10 7 1 10 8 21 50
  9 3 10 10 7 10 11 1 10 12 21 25
  13 9 25 14 3 25 15 12 50 16 18 50
  17 7 10 18 4 10 19 8 10 20 4 10
;

```

A partial listing of Shirts2 is shown in Figure 17.22.

Figure 17.22 The Data Set Shirts2

Number of Shirt Flaws per Box		
Box	Flaws	Nshirts
1	3	10
2	8	10
3	15	25
4	20	25
5	9	25

The variable Box contains the box number, the variable Flaws contains the number of flaws in each box, and the variable Nshirts contains the number of shirts in each box. To evaluate the quality of the shirts, you should report the average number of defects per shirt. The following statements create a data set containing the number of flaws per shirt and the number of shirts per box:

```

proc shewhart data=Shirts2;
  cchart Flaws*Box / subgroupn = Nshirts
    outhistory = shirthist
  nochart ;
run;

```

The SUBGROUPN= option names the variable in the DATA= data set whose values specify the number of inspection units per subgroup. The OUTHISTORY= option names an output data set containing the number of nonconformities per inspection unit and the number of inspection units

per subgroup. A partial listing of Shirthist is shown in Figure 17.23.

Figure 17.23 The Data Set Shirthist

Average Defects Per Shirt		
Box	Flaws	Flaws
	U	N
1	0.30	10
2	0.80	10
3	0.60	25
4	0.80	25
5	0.36	25

There are three variables in the data set Shirthist.

- Box contains the subgroup index.
- FlawsU contains the numbers of nonconformities per inspection unit.
- FlawsN contains the subgroup sample sizes.

Note that the variables containing the numbers of nonconformities per inspection unit and subgroup sample sizes are named by adding the suffix characters *U* and *N* to the *process* Defects specified in the CCHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as that for HISTORY= data sets.

For more information, see “OUTHISTORY= Data Set” on page 1515.

Syntax: CCHART Statement

The basic syntax for the CCHART statement is as follows:

```
CCHART process * subgroup-variable ;
```

The general form of this syntax is as follows:

```
CCHART processes * subgroup-variable <(block-variables)>
  <=symbol-variable | 'character'> / <options> ;
```

You can use any number of CCHART statements in the SHEWHART procedure. The components of the CCHART statement are described as follows.

process

processes

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC SHEWHART statement.

- If numbers of nonconformities per subgroup are read from a DATA= data set, *process* must be the name of the variable containing the numbers of nonconformities.
For an example, see “[Creating c Charts from Defect Count Data](#)” on page 1493.
- If numbers of nonconformities per unit and numbers of inspection units per subgroup are read from a HISTORY= data set, *process* must be the common prefix of the appropriate variables in the HISTORY= data set.
For an example, see “[Creating c Charts from Nonconformities per Unit](#)” on page 1499.
- If numbers of nonconformities per subgroup, numbers of inspection units per subgroup, and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set.
For an example, see “[Saving Control Limits](#)” on page 1495.

A *process* is required. If you specify more than one process, enclose the list in parentheses. For example, the following statements request distinct *c* charts for Defects and Flaws:

```
proc shewhart data=Info;
    cchart (Defects Flaws)*Sample;
run;
```

subgroup-variable

is the variable that identifies subgroups in the data. The *subgroup-variable* is required. In the preceding CCHART statement, SAMPLE is the subgroup variable. For details, see “[Subgroup Variables](#)” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. These blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or character used to plot the number of nonconformities.

- If you produce a line printer chart, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOL*n* statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create a *c* chart using an asterisk (*) to plot the points:

```
proc shewhart data=Info lineprinter;
  cchart Defects*Sample='*';
run;
```

options

enhance the appearance of the chart, request additional analyses, save results in data sets, and so on. The section “Summary of Options”, which follows, lists all options by function. “Dictionary of Options: SHEWHART Procedure” on page 2018 describes each option in detail.

Summary of Options

The following tables list the CCHART statement options by function. For complete descriptions, see “Dictionary of Options: SHEWHART Procedure” on page 2018.

Table 17.14 CCHART Statement Options

Option	Description
Options for Specifying Control Limits	
ALPHA=	requests probability limits for chart
LIMITN=	specifies either nominal sample size for fixed control limits or varying limits
NOREADLIMITS	computes control limits for each <i>process</i> from the data rather than a LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from a LIMITS= data set
READINDEX=	reads control limits for each <i>process</i> from a LIMITS= data set
READLIMITS	reads single set of control limits for each <i>process</i> from a LIMITS= data set (SAS 6.09 and earlier releases)
SIGMAS=	specifies width of control limits in terms of multiple <i>k</i> of standard error of plotted means
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
CSYMBOL=	specifies label for central line
LCLLABEL=	specifies label for lower control limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line
NOCTL	suppresses display of central line
NOLCL	suppresses display of lower control limit

Table 17.14 *continued*

Option	Description
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit
UCLLABEL=	specifies label for upper control limit
WLIMITS=	specifies width for control limits and central line
Standard Value Options	
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
U0=	specifies known average number of nonconformities per unit
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on <i>c</i> chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
OUTLABEL=	labels points outside control limits
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles
Options for Specifying Tests for Special Causes	
INDEPENDENTZONES	computes zone widths independently above and below center line
NO3SIGMACHECK	enables tests to be applied with control limits other than 3σ limits

Table 17.14 continued

Option	Description
NOTEACROSS	suppresses tests across <i>phase</i> boundaries
TESTS=	specifies tests for special causes
TEST2RUN=	specifies length of pattern for Test 2
TEST3RUN=	specifies length of pattern for Test 3
TESTACROSS	applies tests across <i>phase</i> boundaries
TESTLABEL=	provides labels for points where test is positive
TESTLABEL n =	specifies label for n th test for special causes
TESTNMETHOD=	applies tests to standardized chart statistics
TESTOVERLAP	performs tests on overlapping patterns of points
TESTRESET=	enables tests for special causes to be reset
ZONELABELS	adds labels A, B, and C to zone lines
ZONES	adds lines delineating zones A, B, and C
ZONEVALPOS=	specifies position of ZONEVALUES labels
ZONEVALUES	labels zone lines with their values
Options for Displaying Tests for Special Causes	
CTESTLABBOX=	specifies color for boxes enclosing labels indicating points where test is positive
CTESTS=	specifies color for labels indicating points where test is positive
CTESTSYMBOL=	specifies color for symbol used to plot points where test is positive
CZONES=	specifies color for lines and labels delineating zones A, B, and C
LTESTS=	specifies type of line connecting points where test is positive
LZONES=	specifies line type for lines delineating zones A, B, and C
TESTFONT=	specifies software font for labels at points where test is positive
TESTHEIGHT=	specifies height of labels at points where test is positive
TESTLABBOX	requests that labels for points where test is positive be positioned so that do not overlap
TESTSYMBOL=	specifies plot symbol for points where test is positive
TESTSYMBOLHT=	specifies symbol height for points where test is positive
WTESTS=	specifies width of line connecting points where test is positive
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text

Table 17.14 *continued*

Option	Description
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOTRUNC	suppresses vertical axis truncation at zero applied by default
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPLABELS=	specifies thinning factor for tick mark labels on horizontal axis
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis
VFORMAT=	specifies format for vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
ZEROSTD	displays c chart regardless of whether $\hat{\sigma} = 0$

Table 17.14 *continued*

Option	Description
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= options
CVREF=	specifies color for lines requested by VREF= options
HREF=	specifies position of reference lines perpendicular to horizontal axis
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis
HREFLABELS=	specifies labels for HREF= lines
HREFLABPOS=	specifies position of HREFLABELS= labels
LHREF=	specifies line type for HREF= lines
LVREF=	specifies line type for VREF= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis
VREFLABELS=	specifies labels for VREF= lines
VREFLABPOS=	position of VREFLABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features chart
DESCRIPTION=	specifies description of <i>c</i> chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of <i>c</i> chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option

Table 17.14 continued

Option	Description
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency

Table 17.14 continued

Option	Description
URL=	specifies a variable whose values are URLs to be associated with subgroups
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
SUBGROUPN	specifies subgroup sample sizes as constant number <i>n</i> or as values of variable in a DATA= data set
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the OUTLIMITS= data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLELEGEND	augments basic table with legend for tests for special causes
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
TABLETESTS	augments basic table with a column indicating which tests for special causes are positive
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set

Table 17.14 continued

Option	Description
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for overlay line segments
COVERLAY=	specifies colors for overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on chart
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with overlay points
OVERLAYID=	specifies labels for overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for overlays
OVERLAYSYMHT=	specifies symbol heights for overlays
WOVERLAY=	specifies widths of overlay line segments

Table 17.14 continued

Option	Description
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
TESTCHAR=	specifies character for line segments that connect any sequence of points for which a test for special causes is positive
VREFCHAR=	specifies line character for VREF= lines
ZONECHAR=	specifies character for lines that delineate zones for tests for special causes

Details: CCHART Statement

Constructing Charts for Numbers of Nonconformities (c Charts)

The following notation is used in this section:

u	expected number of nonconformities per unit produced by the process
u_i	number of nonconformities per unit in the i th subgroup
c_i	total number of nonconformities in the i th subgroup
n_i	number of inspection units in the i th subgroup. Typically, $n_i = 1$ and $u_i = c_i$ for c charts. In general, $u_i = c_i/n_i$.
\bar{u}	average number of nonconformities per unit taken across subgroups. The quantity \bar{u} is computed as a weighted average:

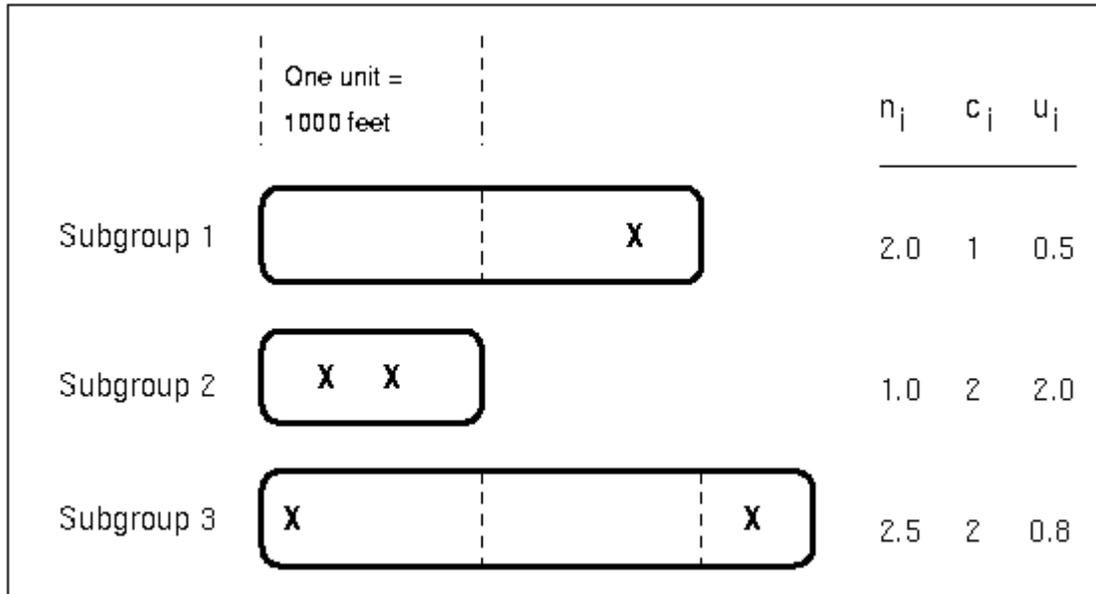

$$\bar{u} = \frac{n_1 u_1 + \cdots + n_N u_N}{n_1 + \cdots + n_N} = \frac{c_1 + \cdots + c_N}{n_1 + \cdots + n_N}$$

N	number of subgroups
χ_v^2	has a central χ^2 distribution with ν degrees of freedom

Plotted Points

Each point on a c chart represents the total number of nonconformities (c_i) in a subgroup. For example, Figure 17.24 displays three sections of pipeline that are inspected for defective welds (indicated by an X). Each section represents a *subgroup* composed of a number of *inspection units*, which are 1000-foot-long sections. The number of units in the i th subgroup is denoted by n_i , which is the subgroup sample size. The value of n_i can be fractional; Figure 17.24 shows $n_3 = 2.5$ units in the third subgroup.

Figure 17.24 Terminology for c Charts and u Charts

The number of nonconformities in the i th subgroup is denoted by c_i . The number of nonconformities per unit in the i th subgroup is denoted by $u_i = c_i/n_i$. In Figure 17.24, the number of welds per inspection unit in the third subgroup is $u_3 = 2/2.5 = 0.8$.

A u chart created with the UCHART statement plots the quantity u_i for the i th subgroup (see “UCHART Statement: SHEWHART Procedure” on page 1817). An advantage of a u chart is that the value of the central line at the i th subgroup does not depend on n_i . This is not the case for a c chart, and consequently, a u chart is often preferred when the number of units n_i is not constant across subgroups.

Central Line

On a c chart, the central line indicates an estimate for $n_i u$, which is computed as $n_i \bar{u}$. If you specify a known value (u_0) for u , the central line indicates the value of $n_i u_0$.

Note that the central line varies with subgroup sample size n_i . When $n_i = 1$ for all subgroups, the central line has the constant value $\bar{c} = (c_1 + \dots + c_N)/N$.

Control Limits

You can compute the limits in the following ways:

- as a specified multiple (k) of the standard error of c_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that c_i exceeds the limits

The lower and upper control limits, LCLC and UCLC respectively, are given by

$$\begin{aligned} \text{LCLC} &= \max\left(n_i\bar{u} - k\sqrt{n_i\bar{u}}, 0\right) \\ \text{UCLC} &= n_i\bar{u} + k\sqrt{n_i\bar{u}} \end{aligned}$$

The upper and lower control limits vary with the number of inspection units per subgroup n_i . If $n_i = 1$ for all subgroups, the control limits have constant values.

$$\begin{aligned} \text{LCLC} &= \max\left(\bar{c} - k\sqrt{\bar{c}}, 0\right) \\ \text{UCLC} &= \bar{c} + k\sqrt{\bar{c}} \end{aligned}$$

An upper probability limit UCLC for c_i can be determined using the fact that

$$\begin{aligned} P\{c_i > \text{UCLC}\} &= 1 - P\{c_i \leq \text{UCLC}\} \\ &= 1 - P\{\chi_{2(\text{UCLC}+1)}^2 \geq 2n_i\bar{u}\} \end{aligned}$$

The upper probability limit UCLC is then calculated by setting

$$1 - P\{\chi_{2(\text{UCLC}+1)}^2 \geq 2n_i\bar{u}\} = \alpha/2$$

and solving for UCLC.

A similar approach is used to calculate the lower probability limit LCLC, using the fact that

$$P\{c_i < \text{LCLC}\} = P\{\chi_{2(\text{LCLC}+1)}^2 > 2n_i\bar{u}\}$$

The lower probability limit LCLC is then calculated by setting

$$P\{\chi_{2(\text{LCLC}+1)}^2 > 2n_i\bar{u}\} = \alpha/2$$

and solving for LCLC. This assumes that the process is in statistical control and that c_i has a Poisson distribution. For more information, refer to Johnson, Kotz, and Kemp (1992). Note that the probability limits vary with the number of inspection units per subgroup (n_i) and are asymmetric about the central line.

If a standard value u_0 is available for u , replace \bar{u} with u_0 in the formulas for the control limits. You can specify parameters for the limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify u_0 with the U0= option or with the variable `_U_` in a LIMITS= data set.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves control limits and control limit parameters. The following variables can be saved:

Table 17.15 OUTLIMITS= Data Set

Variable	Description
ALPHA	probability (α) of exceeding limits
C	value of central line on c chart ($n_i\bar{u}$ or n_iu_0)
INDEX	optional identifier for the control limits specified with the OUTINDEX= option
LCLC	lower control limit for number of nonconformities
LIMITN	sample size associated with the control limits
SIGMAS	multiple (k) of standard error of c_i
SUBGRP	<i>subgroup-variable</i> specified in the CCHART statement
TYPE	type (estimate or standard value) of _U_
U	average number of nonconformities per unit (\bar{u} or u_0)
UCLC	upper control limit for number of nonconformities
VAR	<i>process</i> specified in the CCHART statement

Notes:

1. If the control limits vary with subgroup sample size, the special missing value V is assigned to the variables _C_, _LCLC_, _UCLC_, and _LIMITN_.
2. If the limits are defined in terms of a multiple k of the standard error of c_i , the value of _ALPHA_ is computed as $P\{c_i < _LCLC_\} + P\{c_i > _UCLC_\}$. If control limits vary with subgroup sample size and are determined in terms of k , _ALPHA_ is assigned the special missing value V .
3. If the limits are probability limits, the value of _SIGMAS_ is computed as $(_UCLC_ - _C_)/\sqrt{_C_}$. If probability limits vary with subgroup sample size, _SIGMAS_ is assigned the special missing value V .
4. Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *process* specified in the CCHART statement. For an example, see “Saving Control Limits” on page 1495.

OUTHISTORY= Data Set

The OUTHISTORY= data set saves subgroup statistics. The following variables are saved:

- the *subgroup-variable*
- a subgroup sample size variable named by *process* suffixed with N

- a subgroup number of nonconformities per unit variable named by *process* suffixed with *U*

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Subgroup summary variables are created for each *process* specified in the CCHART statement. For example, consider the following statements:

```
proc shewhart data=Fabric;
  cchart (Flaws Ndefects)*lot / outhistory=Summary;
run;
```

The data set SUMMARY contains variables named LOT, FlawsU, FlawsN, NDEFCTSU, and NDEFCTSN. Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

For an example that creates an OUTHISTORY= data set, see “Saving Nonconformities per Unit” on page 1501. Note that an OUTHISTORY= data set created with the CCHART statement can be used as a HISTORY= data set by either the CCHART statement or the UCHART statement.

OUTTABLE= Data Set

The OUTTABLE= data set saves subgroup summary statistics, control limits, and related information. The following variables are saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_C_</code>	average number of nonconformities
<code>_EXLIM_</code>	control limit exceeded on <i>c</i> chart
<code>_LCLC_</code>	lower control limit for number of nonconformities
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_SIGMAS_</code>	multiple (<i>k</i>) of the standard error associated with control limits
<code>subgroup</code>	values of the subgroup variable
<code>_SUBC_</code>	subgroup number of nonconformities
<code>_SUBN_</code>	subgroup sample size
<code>_TESTS_</code>	tests for special causes signaled on <i>c</i> chart
<code>_UCLC_</code>	upper control limit for number of nonconformities
<code>_VAR_</code>	<i>process</i> specified in the CCHART statement

In addition, the following variables, if specified, are included:

- BY variables

- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the `READPHASES=` option is specified)

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved depending on how the control limits are defined (with the `ALPHA=` or `SIGMAS=` options, respectively, or with the corresponding variables in a `LIMITS=` data set).
2. The variable `_TESTS_` is saved if you specify the `TESTS=` option. The *k*th character of a value of `_TESTS_` is *k* if Test *k* is positive at that subgroup. For example, if you request the first four tests (the ones appropriate for *c* charts) and Tests 2 and 4 are positive for a given subgroup, the value of `_TESTS_` has a 2 for the second character, a 4 for the fourth character, and blanks for the other six characters.
3. The variables `_EXLIM_` and `_TESTS_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “Saving Control Limits” on page 1495.

ODS Tables

The following table summarizes the ODS tables that you can request with the CCHART statement.

Table 17.16 ODS Tables Produced with the CCHART Statement

Table Name	Description	Options
CCHART	<i>c</i> chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLELEG, TABLEOUT, TABLETESTS
TestDescriptions	descriptions of tests for special causes requested with the <code>TESTS=</code> option for which at least one positive signal is found	TABLEALL, TABLELEG

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the `ODS GRAPHICS ON` statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s*

Guide). **NOTE:** In SAS/QC 12.1 the SHEWHART procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. CCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the CCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 17.17](#).

Table 17.17 ODS Graphics Produced by the CCHART Statement

ODS Graph Name	Plot Description
CChart	<i>c</i> chart

See Chapter 3, “[SAS/QC Graphics](#),” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read the number of nonconformities in subgroup samples from a DATA= data set specified in the PROC SHEWHART statement. Each *process* specified in the CCHART statement must be a SAS variable in the data set. This variable provides the number of nonconformities in subgroup samples indexed by the *subgroup-variable*. Typically (but not necessarily), the subgroup consists of a single inspection unit. The *subgroup-variable*, specified in the CCHART statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a value for each *process* and a value for the *subgroup-variable*. The data set must contain one observation per subgroup. Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a DATA= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) with the READPHASES= option (for an example, see “[Displaying Stratification in Phases](#)” on page 2103).

For an example of a DATA= data set, see “[Creating c Charts from Defect Count Data](#)” on page 1493.

LIMITS= Data Set

You can read preestablished control limits (or parameters from which the control limits can be calculated) from a LIMITS= data set specified in the PROC SHEWHART statement. For example, the following statements read control limit information from the data set Conlims:⁸

```
proc shewhart data=Info limits=Conlims;
  cchart Defects*Lot;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the SHEWHART procedure. Such data sets always contain the variables required for a LIMITS= data set. The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LCLC_`, `_C_`, and `_UCLC_`, which specify the control limits
- the variable `_U_`, which is used to calculate the control limits (see “Control Limits” on page 1513)

In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables whose lengths are no greater than 32.
- The variable `_INDEX_` is required if you specify the `READINDEX=` option; this must be a character variable whose length is no greater than 48.
- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8; valid values are ‘ESTIMATE’ and ‘STANDARD’.
- BY variables are required if specified with a BY statement.

For an example, see “Reading Preestablished Control Limits” on page 1497.

HISTORY= Data Set

You can read subgroup summary statistics from a HISTORY= data set specified in the PROC SHEWHART statement. This enables you to reuse OUTHISTORY= data sets that have been created in previous runs of the SHEWHART procedure or to create your own HISTORY= data set. A HISTORY= data set used with the CCHART statement must contain the following variables:

- *subgroup-variable*
- subgroup number of nonconformities per unit variable for each *process*
- subgroup sample size variable (number of units per subgroup) for each *process*

The names of the subgroup number of nonconformities per unit and subgroup sample size variables must be the *process* name concatenated with the special suffix characters *U* and *N*, respectively. For example, consider the following statements:

⁸In SAS 6.09 and in earlier releases, it is necessary to specify the READLIMITS option.

```
proc shewhart history=summary;
  cchart (flaws ndefects)*lot;
run;
```

The data set SUMMARY must include the variables LOT, FlawsU, FlawsN, NDEFCTSU, and NDEFCTSN.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character. Other variables that can be read from a HISTORY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all the observations in a HISTORY= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) with the READPHASES= option (see “[Displaying Stratification in Phases](#)” on page 2103 for an example).

For an example of a HISTORY= data set, see “[Creating c Charts from Nonconformities per Unit](#)” on page 1499.

TABLE= Data Set

You can read summary statistics and control limits from a TABLE= data set specified in the PROC SHEWHART statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the SHEWHART procedure or to create your own TABLE= data set. Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts. Examples are provided in “[Specialized Control Charts: SHEWHART Procedure](#)” on page 2171.

The following table lists the variables required in a TABLE= data set used with the CCHART statement:

Table 17.18 Variables Required in a TABLE= Data Set

Variable	Description
<code>_C_</code>	average number of nonconformities
<code>_LCLC_</code>	lower control limit for nonconformities
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>subgroup-variable</code>	values of the <i>subgroup-variable</i>
<code>_SUBC_</code>	subgroup number of nonconformities
<code>_SUBN_</code>	subgroup sample size
<code>_UCLC_</code>	upper control limit for nonconformities

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- `_PHASE_` (if the READPHASES= option is specified). This variable must be a character variable whose length is no greater than 48.
- `_TESTS_` (if the TESTS= option is specified). This variable is used to flag tests for special causes and must be a character variable of length 8.
- `_VAR_`. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable whose length is no greater than 32.

For an example of a TABLE= data set, see “[Saving Control Limits](#)” on page 1495.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical	DATA=	<i>process</i>
Vertical	HISTORY=	subgroup defect counts variable
Vertical	TABLE=	<code>_SUBC_</code>

For an example, see “[Labeling Axes](#)” on page 2136.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: CCHART Statement

This section provides advanced examples of the CCHART statement.

Example 17.8: Applying Tests for Special Causes

See SHWCEX1 in the SAS/QC Sample Library

This example illustrates how you can apply tests for special causes to make *c* charts more sensitive to special causes of variation. Twenty trucks of the same model are inspected, and the number of paint defects per truck is recorded. The following statements create a SAS data set named Trucks3:

```
data Trucks3;
  input TruckID $ Defects @@;
  label TruckID='Truck Identification Number'
        Defects='Number of Paint Defects';
  datalines;
B1 12   B2 4    B3 4    B4 3
B5 4    D1 2    D2 3    D3 3
D4 2    D9 4    M2 9    M6 13
L3 5    L4 4    L7 6    Z1 15
Z2 8    Z3 9    Z7 6    Z9 8
;
```

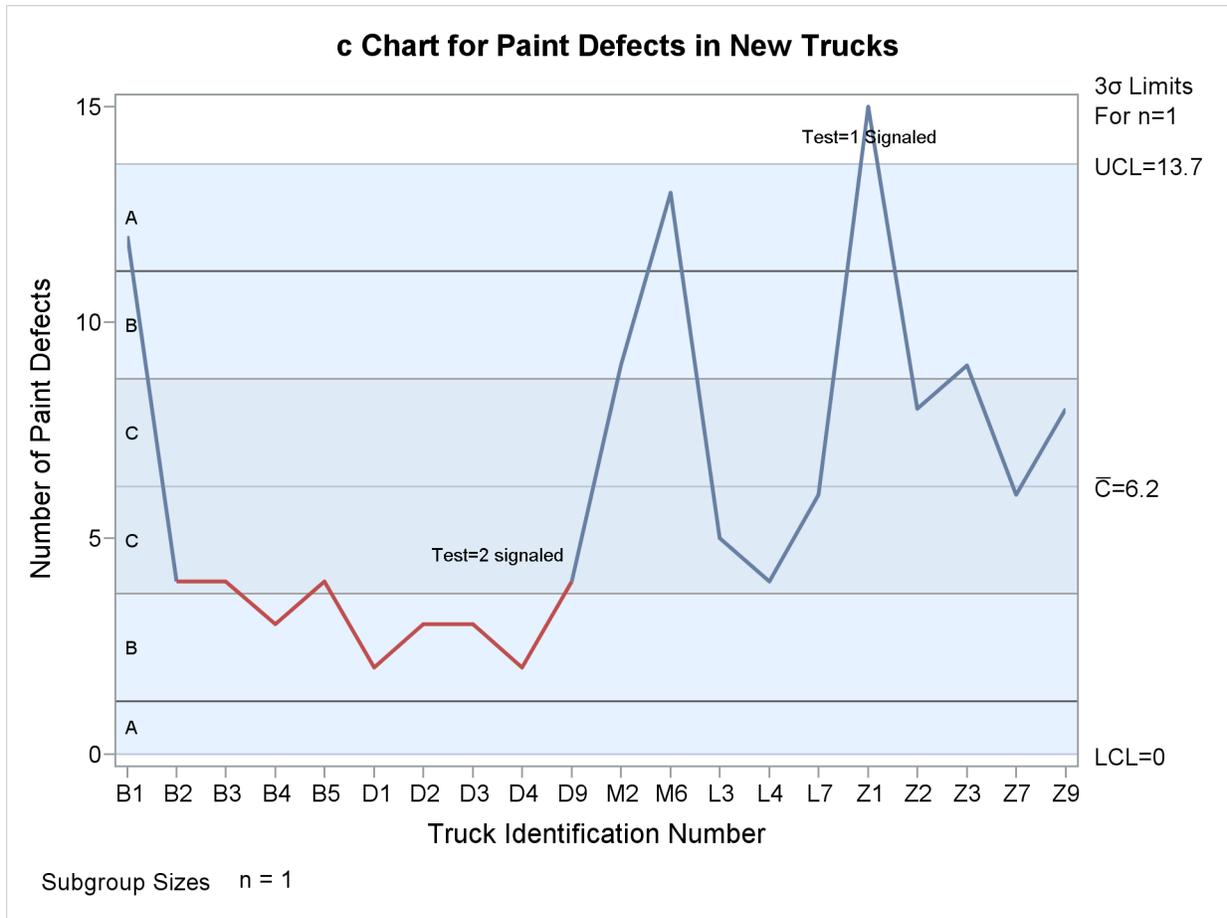

The following statements create a *c* chart and tabulate the information on the chart. The chart and table are shown in [Output 17.8.1](#) and [Output 17.8.2](#).

```
ods graphics on;
title1 'c Chart for Paint Defects in New Trucks';
title2 'Tests=1 to 4';
proc shewhart data=Trucks3;
  cchart Defects*TruckID / tests      = 1 to 4
                        testlabel1 = 'Test=1 Signaled'
                        testlabel2 = 'Test=2 signaled'
                        odstitle   = title
                        zonelabels
                        tabletests
                        tablelegend;
run;
```

The TESTS= option requests Tests 1, 2, 3, and 4, which are described in “[Tests for Special Causes: SHEWHART Procedure](#)” on page 2146. Only Tests 1, 2, 3, and 4 are recommended for *c* charts. The TESTLABEL1= and TESTLABEL2= options specify the labels for points where Tests 1 and

2 are positive. The TESTFONT= option specifies the font for the labels indicating points at which the tests are positive.

Output 17.8.1 Tests for Special Causes Displayed on *c* Chart

Output 17.8.2 Tabular Form of *c* Chart

c Chart for Paint Defects in New Trucks					
Tests=1 to 4					
The SHEWHART Procedure					
c Chart Summary for Defects					
TruckID	Subgroup Sample Size	-3 Sigma Lower Limit	Limits with n=1 for Subgroup Count	Count- Upper Limit	Special Tests Signaled

Z9	1.00000	0	8.000000	13.669940	

Test Descriptions	
Test 1	One point beyond Zone A (outside control limits)
Test 2	Nine points in a row on one side of center line

The ZONELABELS option requests zone lines and displays zone labels on the chart. The zones are used to define the tests. The TABLETESTS option requests a table of counts of nonconformities, subgroup sample sizes, and control limits, together with a column indicating the subgroups at which the tests are positive. The TABLELEGEND option adds a legend describing the tests that are positive.

Output 17.8.1 and Output 17.8.2 indicate that Test 1 is positive at Truck Z1 and Test 2 is positive at Truck D9.

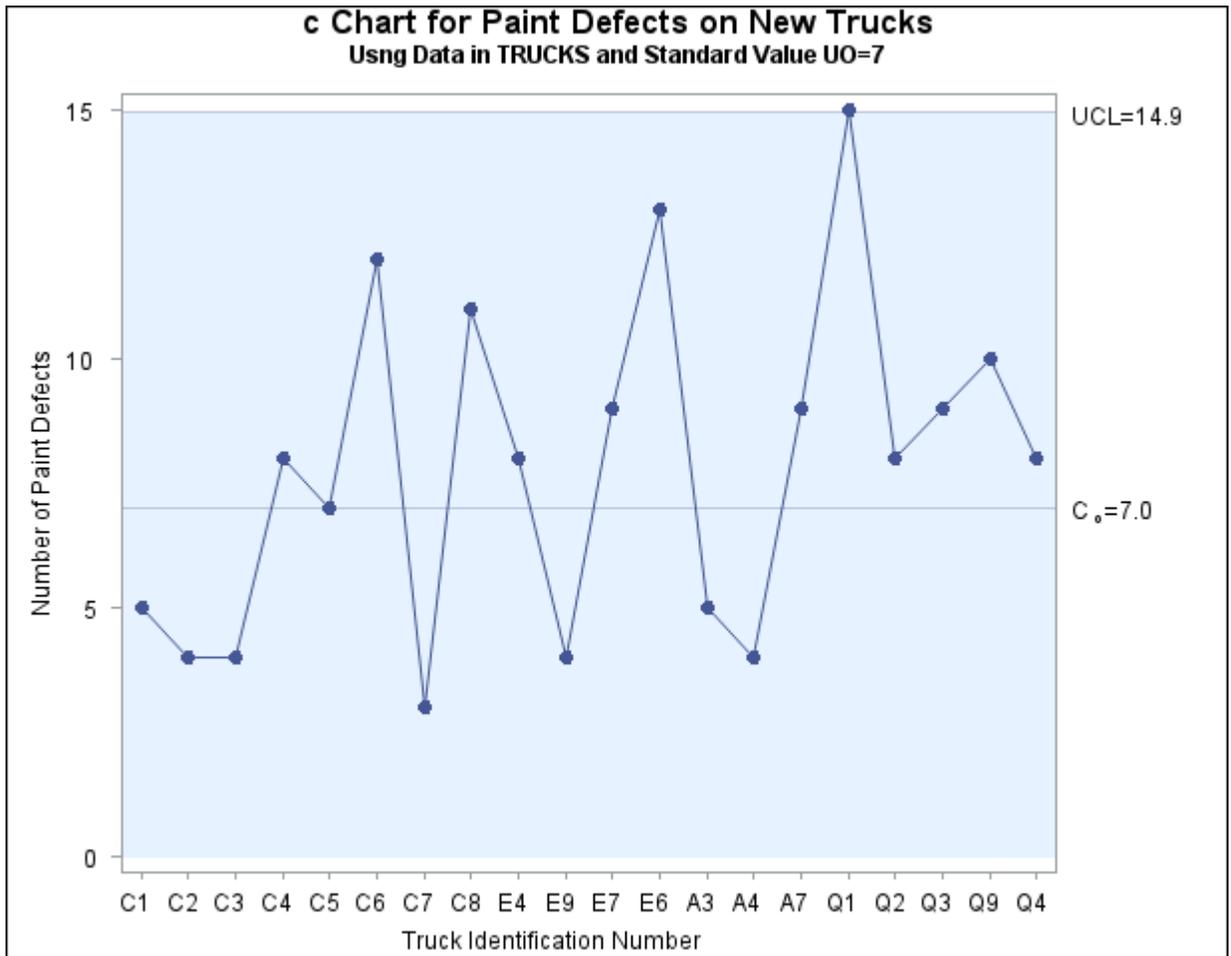

Example 17.9: Specifying a Known Expected Number of Nonconformities

This example illustrates how you can create a c chart based on a known (standard) value u_0 for the expected number of nonconformities per unit. *See SHWCX2 in the SAS/QC Sample Library*

A c chart is used to monitor the number of paint defects per truck. The defect counts are provided as values of the variable Defects in the data set Trucks given in “Creating c Charts from Defect Count Data” on page 1493. Based on previous testing, it is known that $u_0 = 7$. The following statements create a c chart with control limits derived from this value:

```
ods graphics off;
symbol v=dot;
title 'c Chart for Paint Defects on New Trucks';
title2 'Usng Data in TRUCKS and Standard Value U0=7';
proc shewhart data=Trucks;
    cchart Defects*TruckID / u0          = 7
                        csymbol = c0
                        nolegend
                        nolimitslegend
                        nolimit0;
run;
```

The chart is shown in [Output 17.9.1](#). The U0= option specifies u_0 , and the CSYMBOL= option requests a label for the central line indicating that the line represents a standard value. The NOLEGEN option suppresses the legend for the subgroup sample size, and the NOLIMITSLEGEND option suppresses the legend for the control limits that appears by default in the upper right corner of the chart. The NOLIMIT0 option suppresses the display of the lower limit when it is equal to zero.

Output 17.9.1 A c Chart with Standard Value u_0 

The number of paint defects on Truck Q1 exceeds the upper control limit, indicating that the process is out of control.

Alternatively, you can specify u_0 as the value of the variable `_U_` in a `LIMITS=` data set, as follows:

```
data tlimits;
  length _subgrp_ _var_ _type_ $8;
  _U_    = 7;
  _subgrp_ = 'truckid';
  _var_   = 'defects';
  _limitn_ = 1;
  _type_  = 'STANDARD';

proc shewhart data=trucks limits=tlimits;
  cchart defects*truckid / csymbol=c0
                    nolegend
                    nolimitslegend
                    nolimit0;

run;
```

The chart produced by these statements is identical to the one in [Output 17.9.1](#).

For further details, see “LIMITS= Data Set” on page 1519.

Example 17.10: Creating *c* Charts for Varying Numbers of Units

In applications where the number of inspection units per subgroup is not equal to one, a *u* chart is typically used to analyze the number of nonconformities *per unit* (see “[UCHART Statement: SHEWHART Procedure](#)” on page 1817). However, as shown in this example, you can use the CCHART statement to create a *c* chart for this type of data. See SHWCX3 in the SAS/QC Sample Library

Figure 17.25 Difference between *c* Charts and *u* Charts

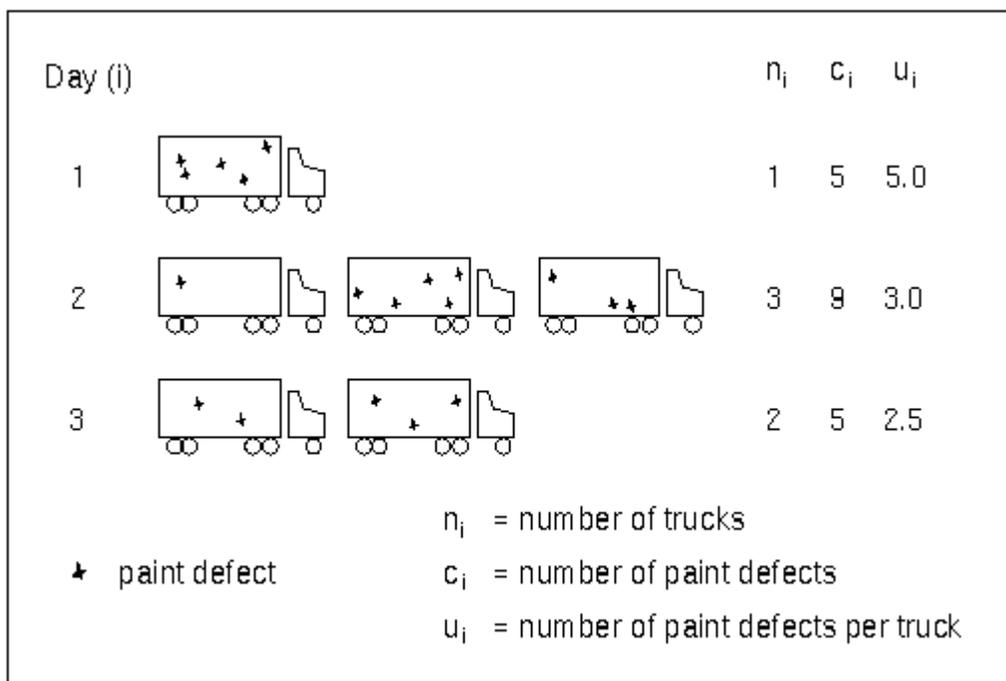

Figure 17.25 illustrates a situation in which varying numbers of trucks are painted each day. Trucks painted on the same day are regarded as *subgroups*, and each truck is regarded as an *inspection unit*. The following statements create a SAS data set named Trucks4, which contains paint defects for trucks painted on 26 days:

```

data Trucks4;
  input Day Defects Ntrucks @@;
  label Day='Day'
        Defects='Number of Paint Defects';
  datalines;
1   5  1   2   9  3
3   5  2   4   9  2
5  24  4   6  10  2
7  15  3   8  17  3
9  16  3  10  13  2
11 28  4  12  18  5
13  8  2  14   7  2
15  5  1  16  17  3
17  2  1  18  17  3
19 15  4  20  19  5
21  6  3  22  23  5
23 27  4  24   6  2
25 12  2  26  12  3
;

```

The variable Defects provides the defect count (c_i) for the i th day, and the variable Ntrucks provides the number of inspection units (n_i). The following statements create a c chart for this data:

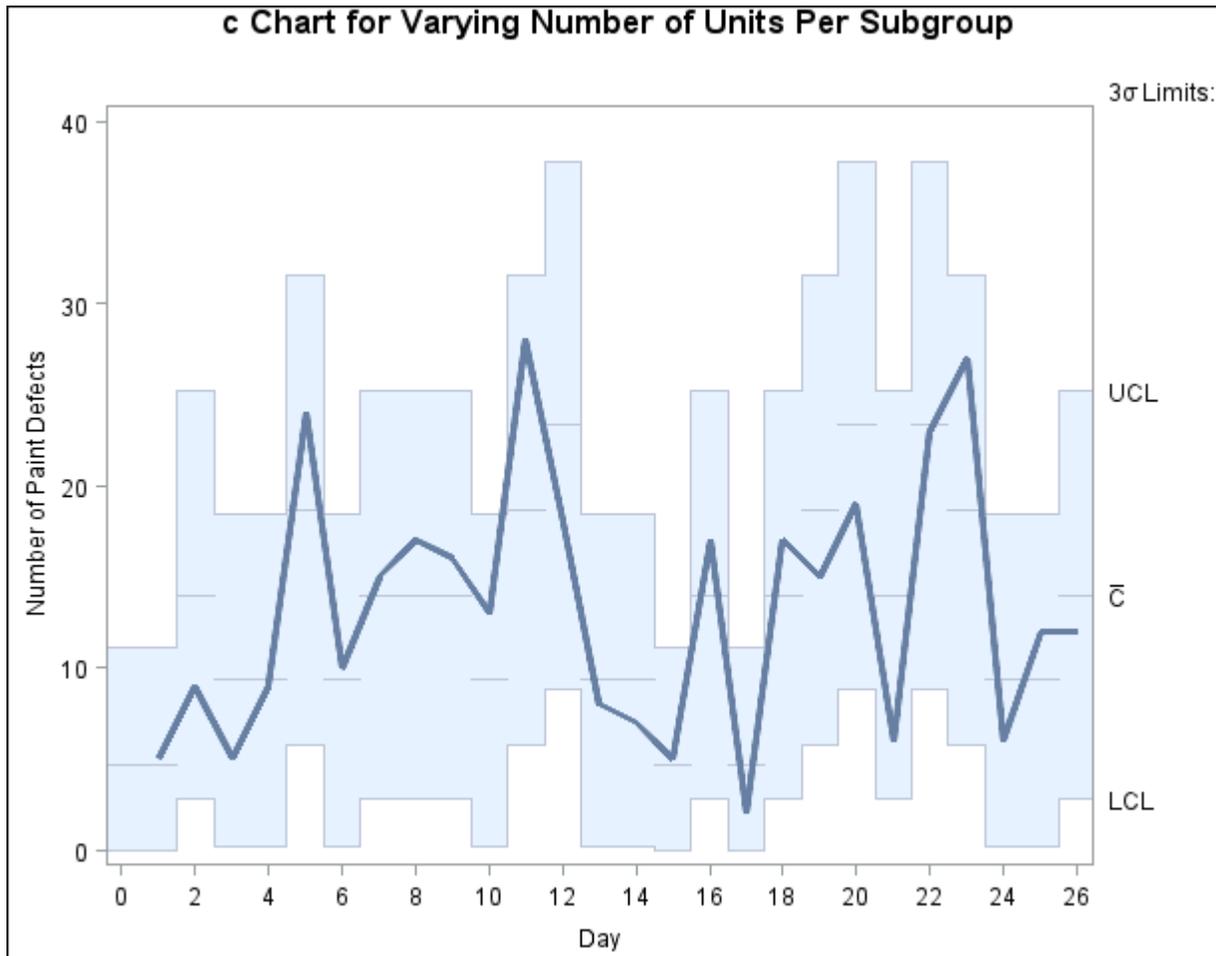

```

ods graphics off;
title 'c Chart for Varying Number of Units Per Subgroup';
proc shewhart data=Trucks4;
  cchart Defects*Day / subgroupn = Ntrucks
        nolegend;
run;

```

The SUBGROUPN= option specifies the subgroup sample size variable Ntrucks (in general, the values of this variable need not be integers). Alternatively, you can specify a fixed value with the SUBGROUPN= option. When this option is not specified, it is assumed that $n_i = 1$.

The chart is shown in [Output 17.10.1](#). Note that the central line and the control limits vary with the number of inspection units.

Output 17.10.1 *c* Chart for Varying Number of Units

IRCHART Statement: SHEWHART Procedure

Overview: IRCHART Statement

The IRCHART statement creates control charts for individual measurements and moving ranges. These charts are appropriate when only one measurement is available for each subgroup sample and when the measurements are independently and normally distributed.

You can use options in the IRCHART statement to

- compute control limits from the data based on a multiple of the standard error of the individual measurements and moving ranges or as probability limits
- tabulate individual measurements, moving ranges, and control limits
- save control limits in an output data set

- save individual measurements and moving ranges in an output data set
- read preestablished control limits from a data set
- apply tests for special causes (also known as runs tests and Western Electric rules)
- specify a known (standard) process mean and standard deviation for computing control limits
- specify the number of consecutive measurements to use when computing the moving ranges
- display distinct sets of control limits for data from successive time phases
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have three alternatives for producing charts of individual measurements and moving ranges with the IRCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: IRCHART Statement

This section introduces the IRCHART statement with simple examples that illustrate commonly used options. Complete syntax for the IRCHART statement is presented in the section “Syntax: IRCHART Statement” on page 1539, and advanced examples are given in the section “Examples: IRCHART Statement” on page 1563.

Creating Individual Measurements and Moving Range Charts

An aeronautics company manufacturing jet engines measures the inner diameter of the forward face of each engine (in centimeters). The following statements create a SAS data set that contains the diameter measurements for 20 engines: *See SHWIRI in the SAS/QC Sample Library*

```
data Jets;
  input Engine Diam @@;
  label Engine = "Engine Number";
  datalines;
  1 78.4  2 80.1  3 84.4  4 79.1  5 80.4
  6 83.5  7 73.8  8 83.5  9 75.0 10 76.8
 11 70.5 12 80.3 13 82.4 14 79.4 15 86.4
 16 90.5 17 77.7 18 82.5 19 79.9 20 83.2
  ;
```

A partial listing of Jets is shown in Figure 17.26.

Figure 17.26 Partial Listing of the Data Set Jets

The Data Set JETS	
Engine	Diam
1	78.4
2	80.1
3	84.4
4	79.1
5	80.4

Each observation contains the diameter measurement and identification number for a particular engine. The variable Engine identifies the sequence of engines and is referred to as the *subgroup-variable*.⁹ The variable Diam contains the measurements and is referred to as the *process variable* (or *process* for short).

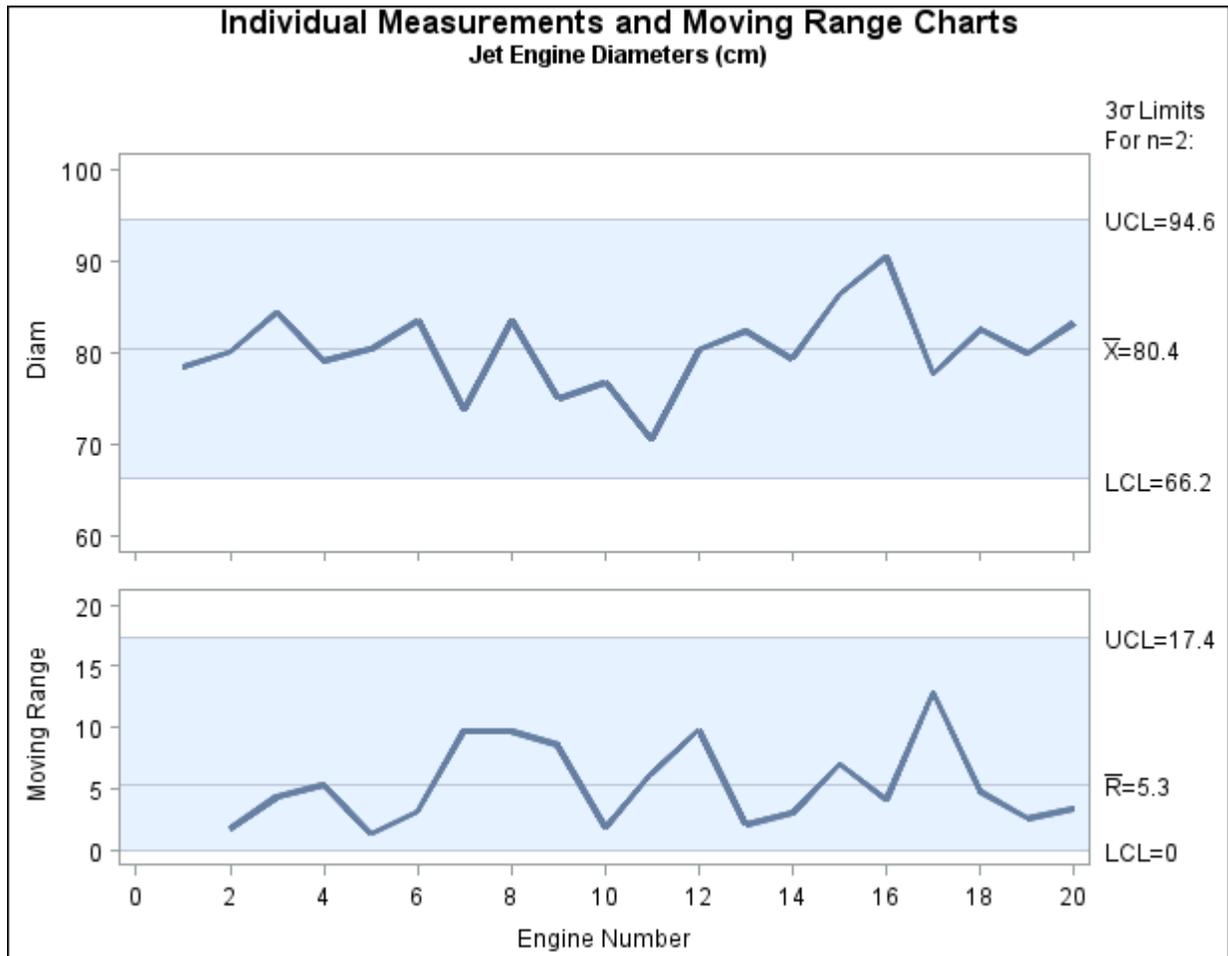

Since the production rate is low, individual measurements and moving range charts are used to monitor the process. The following statements create the charts shown in Figure 17.27:

```
ods graphics off;
title 'Individual Measurements and Moving Range Charts';
title2 'Jet Engine Diameters (cm)';
proc shewhart data=Jets;
  irchart Diam*Engine;
run;
```

This example illustrates the basic form of the IRCHART statement. After the keyword IRCHART, you specify the *process* to analyze (in this case, Diam), followed by an asterisk and the *subgroup-variable* (Engine).

The input data set is specified with the DATA= option in the PROC SHEWHART statement.

⁹Technically, the data for individual measurements and moving range charts are not arranged in rational subgroups. The term *subgroup-variable* is used for consistency with other chart statements in the SHEWHART procedure, and it is convenient to think of the “subgroups” as consisting of single measurements.

Figure 17.27 Individual Measurements and Moving Range Charts (Traditional Graphics)

Each point on the individual measurements chart indicates the inner diameter of a particular engine. Each point on the moving range chart indicates the range of the two most recent measurements. For instance, the moving range plotted for the second engine is $|78.4 - 80.1| = 1.7$. No moving range is plotted for the first engine. Since all of the individual measurements and moving ranges lie within the control limits, it can be concluded that the process is in statistical control.

By default, the control limits shown are 3σ limits estimated from the data; the formulas for the limits are given in section “Limits for Individual Measurements and Moving Range Charts” on page 1553. You can also read control limits from an input data set; see “Reading Prestablished Control Limits” on page 1537.

Saving Individual Measurements and Moving Ranges

See *SHWIR1* in the *SAS/QC Sample Library*

In this example, the IRCHART statement is used to create an output data set containing individual measurements and moving ranges. The following statements read the diameter measurements from the data set Jets (see “Creating Individual Measurements and Moving Range Charts” on page 1531) and create a data set named Jetinfo:

```
proc shewhart data=Jets;
  irchart Diam*Engine / outhistory = Jetinfo
                      nochart;
run;
```

The OUTHISTORY= option names the output data set, and the NOCHART option suppresses the display of the charts, which would be identical to those in Figure 17.27. Options such as OUTHISTORY= and NOCHART are specified after the slash (/) in the IRCHART statement. A complete list of options is presented in the section “Syntax: IRCHART Statement” on page 1539.

Figure 17.28 contains a partial listing of Jetinfo.

Figure 17.28 The Data Set Jetinfo

Individual Measurements and Moving Ranges for Diameters			
Engine	Diam	Diam R	
1	78.4	.	
2	80.1	1.7	
3	84.4	4.3	
4	79.1	5.3	
5	80.4	1.3	

The data set Jetinfo contains one observation for each engine, and it includes three variables.

- Engine contains the subgroup index.
- Diam contains the individual measurements.
- DiamR contains the moving ranges.

Note that the variable containing the moving ranges is named by adding the suffix character *R* to the *process* Diam specified in the IRCHART statement.

For more information, see “OUTHISTORY= Data Set” on page 1555.

Reading Individual Measurements and Moving Ranges

In some applications, both individual measurements and moving ranges may be provided. You can read this type of data set by specifying it with the HISTORY= option in the PROC SHEWHART statement. For example, the following statements read the data set Jetinfo (see Figure 17.28) and create the charts shown in Figure 17.29:

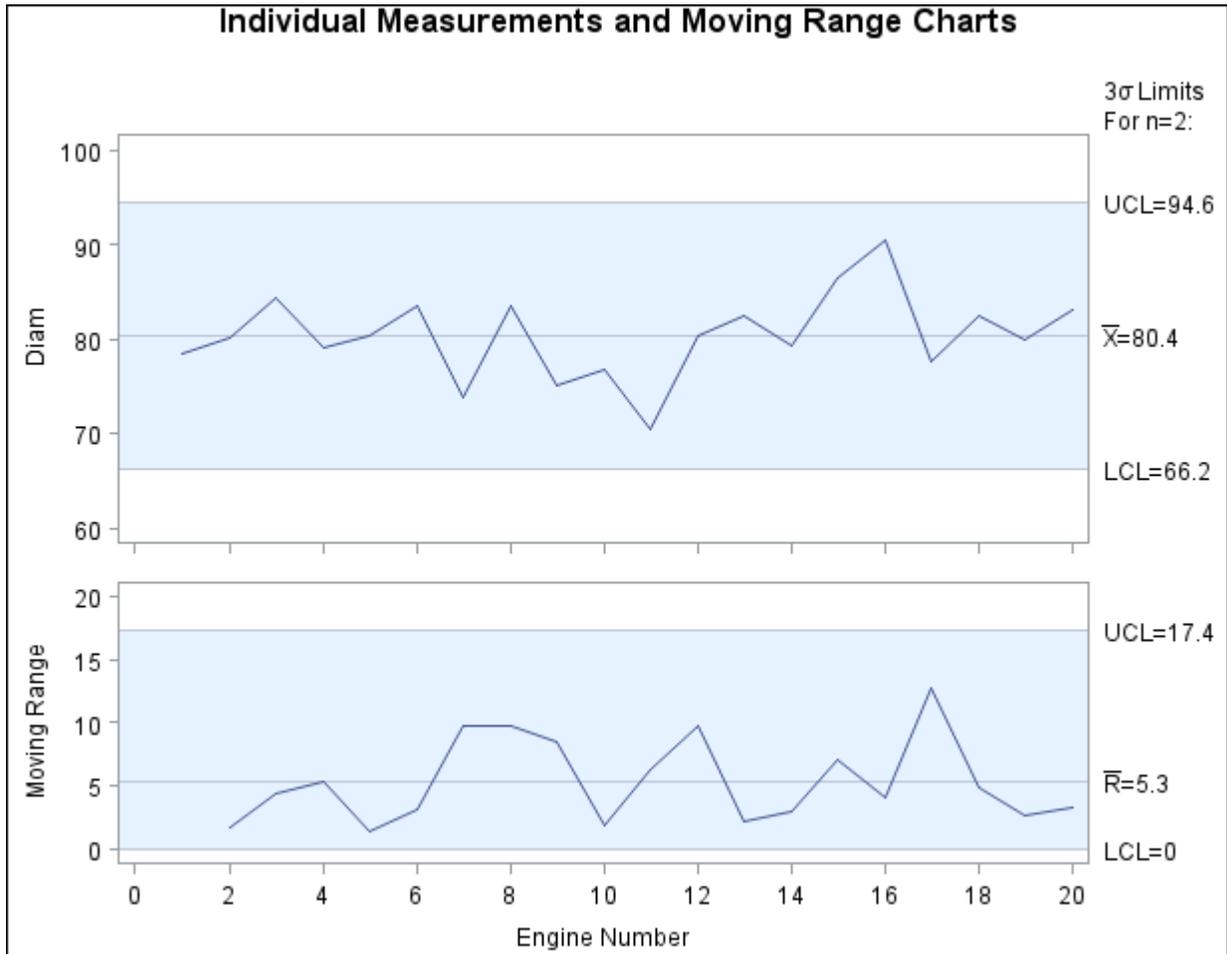

See SHWIRI in the SAS/QC Sample Library

```

symbol h = .8;
title 'Individual Measurements and Moving Range Charts';
proc shewhart history=Jetinfo;
    irchart Diam*Engine;
run;

```

Figure 17.29 Charts Produced from Summary Data Set Jetinfo

A HISTORY= data set used with the IRCHART statement must contain the following variables:

- subgroup variable
- individual measurements variable
- moving range variable

Furthermore, the name of the moving range variable must begin with the *process* name specified in the IRCHART statement and end with the special suffix character *R*. If the name does not follow this convention, you can use the RENAME option in the PROC SHEWHART statement to rename this variable for the duration of the procedure step (see “Creating Charts for Means and Ranges from Summary Data” on page 1907). For more information, see “HISTORY= Data Set” on page 1559.

Saving Control Limits

You can save the control limits for individual measurements and moving range charts in a SAS data set; this enables you to apply the control limits to future data (see “[Reading Preestablished Control Limits](#)” on page 1537) or modify the limits with a DATA step program. *See SHWIRI in the SAS/QC Sample Library*

The following statements read the diameter measurements from the data set `Jets` (see “[Creating Individual Measurements and Moving Range Charts](#)” on page 1531) and save the control limits displayed in [Figure 17.27](#) in a data set named `Jetlim`:

```
proc shewhart data=Jets;
  irchart Diam*Engine / outlimits = Jetlim
                    nochart;
run;
```

The `OUTLIMITS=` option names the data set containing the control limits, and the `NOCHART` option suppresses the display of the charts. The data set `Jetlim` is listed in [Figure 17.30](#).

Figure 17.30 The Data Set `Jetlim` Containing Control Limit Information

Control Limits for Diameters						
<u>_VAR_</u>	<u>_SUBGRP_</u>	<u>_TYPE_</u>	<u>_LIMITN_</u>	<u>_ALPHA_</u>	<u>_SIGMAS_</u>	<u>_LCLI_</u>
Diam	Engine	ESTIMATE	2	.002699796	3	66.2290
<u>_MEAN_</u>	<u>_UCLI_</u>	<u>_LCLR_</u>	<u>_R_</u>	<u>_UCLR_</u>	<u>_STDDEV_</u>	
80.39	94.5510	0	5.32632	17.3986	4.72032	

The data set `Jetlim` contains one observation with the limits for *process* `Diam`. The variables `_LCLI_` and `_UCLI_` contain the control limits for the individual measurements, and the variable `_MEAN_` contains the central line. The variables `_LCLR_` and `_UCLR_` contain the control limits for the moving ranges, and the variable `_R_` contains the central line. The value of `_MEAN_` is an estimate of the process mean, and the value of `_STDDEV_` is an estimate of the process standard deviation σ . The value of `_LIMITN_` is the number of consecutive measurements used to compute the moving ranges, and the value of `_SIGMAS_` is the multiple of σ associated with the control limits. The variables `_VAR_` and `_SUBGRP_` are bookkeeping variables that save the *process* and *subgroup-variable*. The variable `_TYPE_` is a bookkeeping variable that indicates whether the values of `_MEAN_` and `_STDDEV_` are estimates or standard values. For more information, see “[OUTLIMITS= Data Set](#)” on page 1554.

You can create an output data set containing both control limits and summary statistics with the `OUTTABLE=` option, as illustrated by the following statements:

```
proc shewhart data=Jets;
  irchart Diam*Engine / outtable=Jtable
                    nochart;
run;
```

The data set `Jtable` is listed in [Figure 17.31](#).

Figure 17.31 The Data Set Jtable

Summary Statistics and Control Limit Information													
	S L					S					E

Diam 7	3	2	66.2290	73.8	80.39	94.5510	4.72032	0	9.7	5.32632	17.3986		
Diam 8	3	2	66.2290	83.5	80.39	94.5510	4.72032	0	9.7	5.32632	17.3986		
Diam 9	3	2	66.2290	75.0	80.39	94.5510	4.72032	0	8.5	5.32632	17.3986		
Diam 10	3	2	66.2290	76.8	80.39	94.5510	4.72032	0	1.8	5.32632	17.3986		
Diam 11	3	2	66.2290	70.5	80.39	94.5510	4.72032	0	6.3	5.32632	17.3986		
Diam 12	3	2	66.2290	80.3	80.39	94.5510	4.72032	0	9.8	5.32632	17.3986		
Diam 13	3	2	66.2290	82.4	80.39	94.5510	4.72032	0	2.1	5.32632	17.3986		
Diam 14	3	2	66.2290	79.4	80.39	94.5510	4.72032	0	3.0	5.32632	17.3986		
Diam 15	3	2	66.2290	86.4	80.39	94.5510	4.72032	0	7.0	5.32632	17.3986		
Diam 16	3	2	66.2290	90.5	80.39	94.5510	4.72032	0	4.1	5.32632	17.3986		
Diam 17	3	2	66.2290	77.7	80.39	94.5510	4.72032	0	12.8	5.32632	17.3986		
Diam 18	3	2	66.2290	82.5	80.39	94.5510	4.72032	0	4.8	5.32632	17.3986		
Diam 19	3	2	66.2290	79.9	80.39	94.5510	4.72032	0	2.6	5.32632	17.3986		
Diam 20	3	2	66.2290	83.2	80.39	94.5510	4.72032	0	3.3	5.32632	17.3986		

This data set contains one observation for each subgroup. The variables `_SUBI_` and `_SUBR_` contain the individual measurements and moving ranges. The variables `_LCLI_` and `_UCLI_` contain the lower and upper control limits for the individual measurements chart, and the variables `_LCLR_` and `_UCLR_` contain the lower and upper control limits for the moving range chart. The variable `_MEAN_` contains the central line of the individual measurements chart, and the variable `_R_` contains the central line of the moving range chart. The variables `_VAR_` and `Engine` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “`OUTTABLE= Data Set`” on page 1556.

An `OUTTABLE=` data set can be read later as a `TABLE=` data set. For example, the following statements read `Jtable` and display charts (not shown here) identical to those in Figure 17.27:

```

title 'Individual Measurements and Moving Range Control Charts';
title2 'Jet Engine Diameters (cm)';
proc shewhart table=Jtable;
    irchart Diam*Engine;
run;

```

Because the SHEWHART procedure simply displays the information in a `TABLE=` data set, you can use `TABLE=` data sets to create specialized control charts (see “`Specialized Control Charts`”:

SHEWHART Procedure” on page 2171).

For more information, see “TABLE= Data Set” on page 1560.

Reading Prestablished Control Limits

In the previous example, the OUTLIMITS= data set Jetlim saved control limits computed from the measurements in Jets. This example shows how these limits can be applied to data for an additional 20 jet engines provided in the following data set: *See SHWIRI in the SAS/QC Sample Library*

```
data Jets2;
  input Engine Diam @@;
  label Diam = "Inner Diameter (cm)"
         Engine = "Engine Number";
  datalines;
21 81.8 22 87.5 23 80.0 24 89.3 25 83.9
26 76.3 27 75.8 28 82.4 29 82.6 30 77.7
31 79.3 32 81.4 33 76.8 34 75.9 35 86.3
36 77.4 37 80.9 38 87.1 39 85.7 40 73.3
;
```

The following statements create individual measurements and moving range charts for the data in Jets2 using the control limits in Jetlim:

```
options nogstyle;
goptions ftext=swiss;
title 'Individual Measurements and Moving Range Control Charts';
proc shewhart data=Jets2 limits=Jetlim;
  irchart Diam*Engine / cframe = vrgb
                   cconnect = yellow
                   coutfill = red
                   cinfill = vlib;
run;
options gstyle;
```

The charts are shown in [Figure 17.32](#). The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the IRCHART statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently.

The LIMITS= option in the PROC SHEWHART statement specifies the data set containing the control limits. By default,¹⁰ this information is read from the first observation in the LIMITS= data set for which

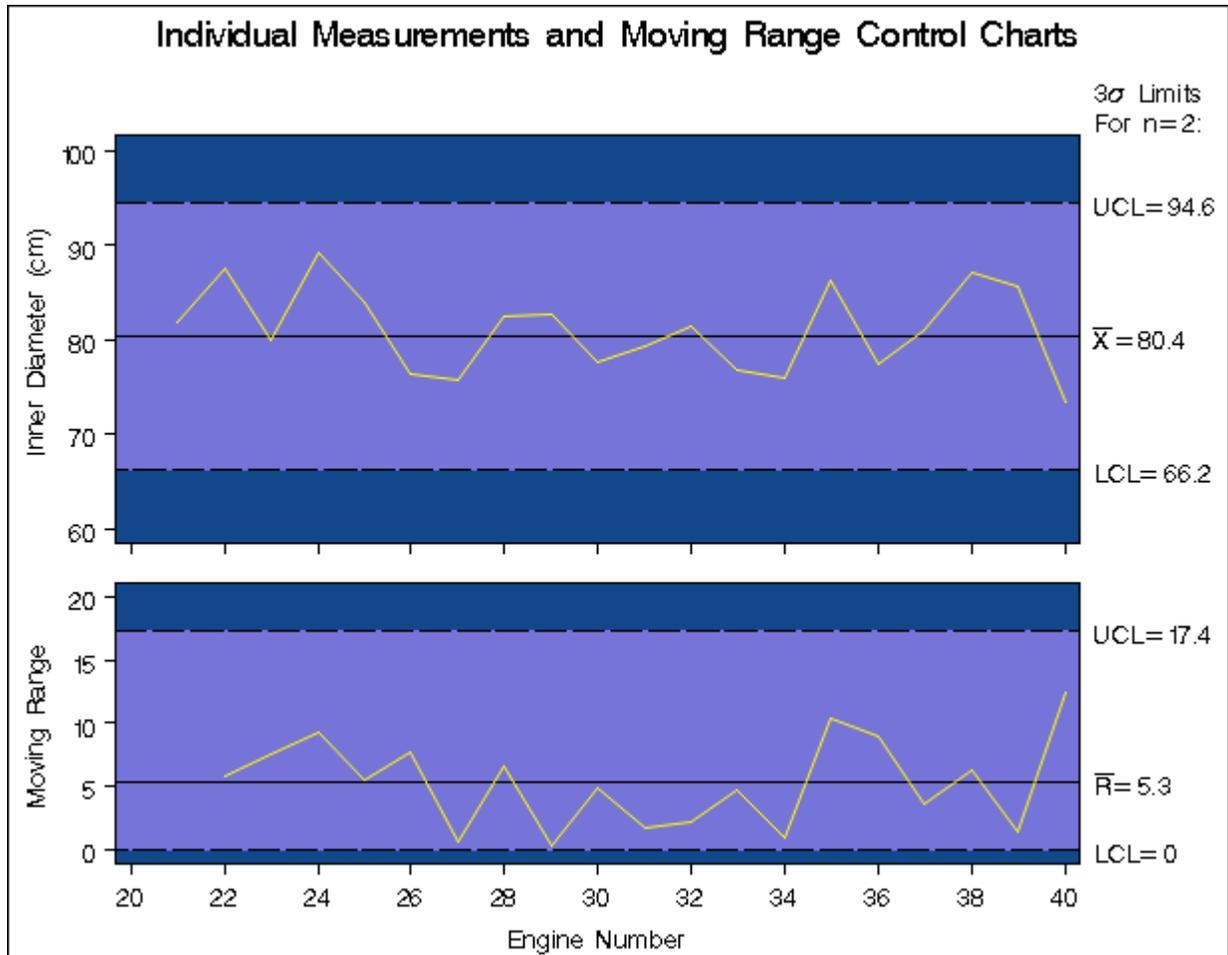

- the value of `_VAR_` matches the *process* name Diam
- the value of `_SUBGRP_` matches the *subgroup-variable* name Engine

The charts indicate that the process is in control, since all the individual measurements and moving ranges lie within their respective control limits.

¹⁰In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

In this example, the LIMITS= data set was created in a previous run of the SHEWHART procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on page 1558 for details concerning the variables that you must provide.

Figure 17.32 Charts for Second Set of Engine Noise Levels (Traditional Graphics with NOGSTYLE)

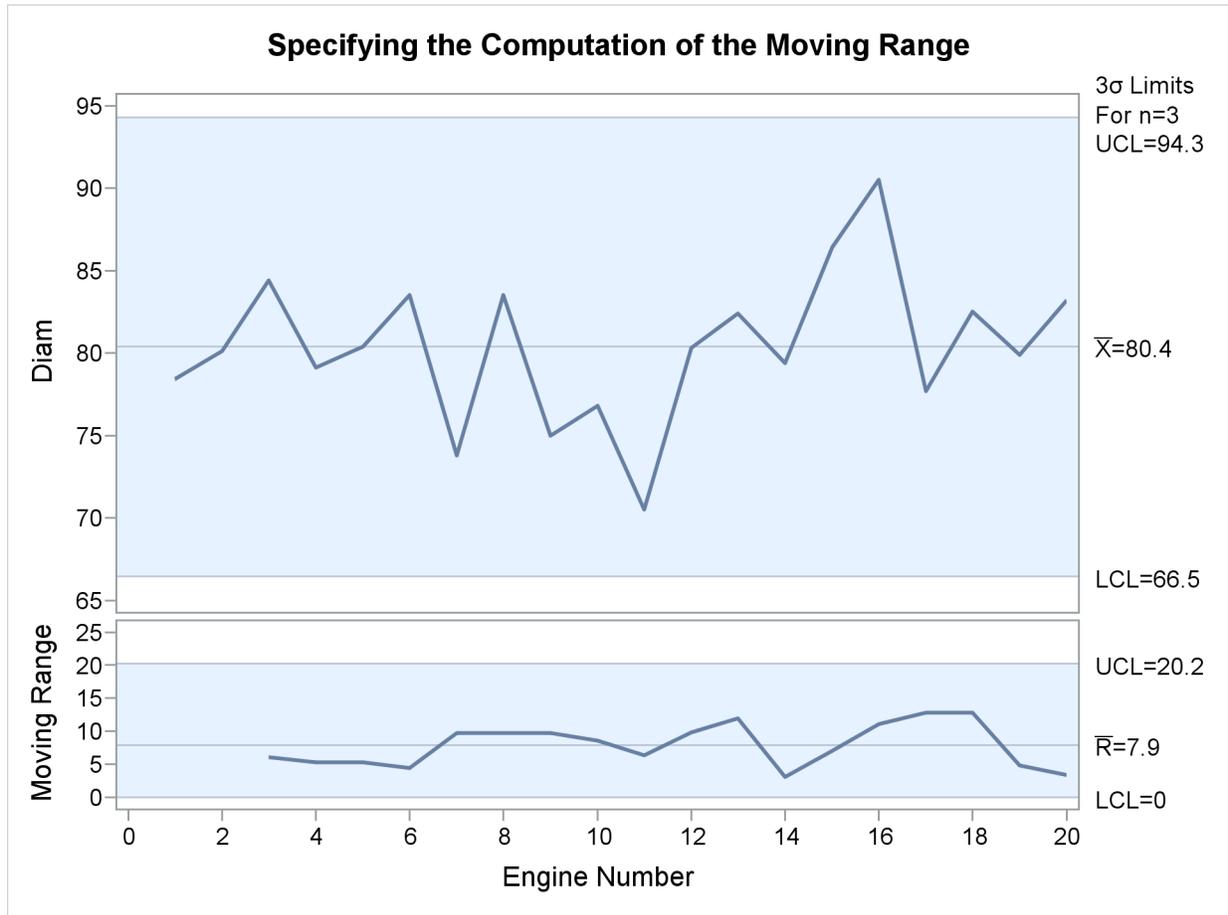

Specifying the Computation of the Moving Range

See *SHWIR1* in the *SAS/QC Sample Library*. By default, the IRCHART statement uses two consecutive measurements to calculate moving ranges. However, you can specify a different number of measurements to use, as illustrated by the following statements:

```
ods graphics on;
title 'Specifying the Computation of the Moving Range';
proc shewhart data=Jets;
  irchart Diam*Engine / limitn=3 odstitle=title;
run;
```

The ODS GRAPHICS ON statement specified before the PROC SHEWHART statement enables ODS Graphics, so the charts are created by using ODS Graphics instead of traditional graphics. The LIMITN= option specifies the number of consecutive measurements used to compute the moving ranges. The resulting charts are shown in Figure 17.33.

Figure 17.33 Computing Moving Ranges from Three Consecutive Measurements (ODS Graphics)

Note that the LIMITN= value is displayed in the legend above the control limit labels. The charts indicate that the process is in control, since all the points lie within the control limits.

Syntax: IRCHART Statement

The basic syntax for the IRCHART statement is as follows:

```
IRCHART process * subgroup-variable ;
```

The general form of this syntax is as follows:

```
IRCHART processes * subgroup-variable <(block-variables)>
    <=symbol-variable | ='character'> / <options> ;
```

You can use any number of IRCHART statements in the SHEWHART procedure. The components of the IRCHART statement are described as follows.

process**processes**

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC SHEWHART statement.

- If raw data are read from a DATA= data set, *process* must be the name of the variable containing the individual measurements. For an example, see “[Creating Individual Measurements and Moving Range Charts](#)” on page 1531.
- If individual measurements and moving ranges are read from a HISTORY= data set, *process* must be the name of the variable containing the individual measurements as well as the prefix of the variable containing the moving ranges in the HISTORY= data set. For an example, see “[Saving Individual Measurements and Moving Ranges](#)” on page 1532.
- If individual measurements, moving ranges, and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “[Saving Control Limits](#)” on page 1535.

A *process* is required. If you specify more than one *process*, enclose the list in parentheses. For example, the following statements request distinct individual measurements and moving range charts for Weight, Length, and Width:

```
proc shewhart data=Measures;
    irchart (Weight Length Width)*Day;
run;
```

subgroup-variable

is the variable that identifies subgroups in the data. The *subgroup-variable* is required. In the preceding IRCHART statement, Day is the subgroup variable. Note that each “subgroup” consists of a single observation. For details, see “[Subgroup Variables](#)” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or character used to plot the individual measurements and moving ranges.

- If you produce a line printer chart, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOL*n* statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create charts using an asterisk (*) to plot the points:

```
proc shewhart data=Values lineprinter;
  irchart Weight*Day='*';
run;
```

options

enhance the appearance of the charts, request additional analyses, save results in data sets, and so on. The section “[Summary of Options](#)”, which follows, lists all options by function. “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018 describes each option in detail.

Summary of Options

The following tables list the IRCHART statement options by function. For complete descriptions, see “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 17.19 IRCHART Statement Options

Option	Description
Options for Specifying Control Limits	
ALPHA=	requests probability limits for chart
LIMITN=	specifies either nominal sample size for fixed control limits or varying limits
MRRESTART	restarts the moving range computation at missing values
NOREADLIMITS	computes control limits for each <i>process</i> from the data rather than a LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from a LIMITS= data set
READINDEX=	reads control limits for each <i>process</i> from a LIMITS= data set
READLIMITS	reads single set of control limits for each <i>process</i> from a LIMITS= data set (SAS 6.09 and earlier releases)
SIGMAS=	specifies width of control limits in terms of multiple <i>k</i> of standard error of plotted means
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit on individual measurements chart
LCLLABEL2=	specifies label for lower control limit on moving range chart

Table 17.19 *continued*

Option	Description
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line on individual measurements chart
NDECIMAL2=	specifies number of digits to right of decimal place in default labels for control limits and central line on moving range chart
NOCTL	suppresses display of central line on individual measurements chart
NOCTL2	suppresses display of central line on moving range chart
NOLCL	suppresses display of lower control limit on individual measurements chart
NOLCL2	suppresses display of lower control limit on moving range chart
NOLIMIT0	suppresses display of zero lower control limit on moving range chart
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit on individual measurements chart
NOUCL2	suppresses display of upper control limit on moving range chart
RSYMBOL=	specifies label for central line on moving range chart
UCLLABEL=	specifies label for upper control limit on individual measurements chart
UCLLABEL2=	specifies label for upper control limit on moving range chart
WLIMITS=	specifies width for control limits and central line
XSYMBOL=	specifies label for central line on individual measurements chart
Process Mean and Standard Deviation Options	
MU0=	specifies known value of μ_0 for process mean μ
SIGMA0=	specifies known value σ_0 for process standard deviation σ
SMETHOD=	specifies method for estimating process standard deviation σ
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set

Table 17.19 *continued*

Option	Description
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on individual measurements chart
ALLLABEL2=	labels every point on moving range chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
OUTLABEL=	labels points outside control limits on individual measurements chart
OUTLABEL2=	labels points outside control limits on moving range chart
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles
Options for Specifying Tests for Special Causes	
INDEPENDENTZONES	computes zone widths independently above and below center line
NO3SIGMACHECK	enables tests to be applied with control limits other than 3σ limits
NOTESTACROSS	suppresses tests across <i>phase</i> boundaries
TESTS=	specifies tests for special causes for the individual measurements chart
TEST2RUN=	specifies length of pattern for Test 2
TEST3RUN=	specifies length of pattern for Test 3
TESTACROSS	applies tests across <i>phase</i> boundaries
TESTLABEL=	provides labels for points where test is positive
TESTLABEL n =	specifies label for n th test for special causes
TESTNMETHOD=	applies tests to standardized chart statistics
TESTOVERLAP	performs tests on overlapping patterns of points

Table 17.19 *continued*

Option	Description
TESTRESET= ZONELABELS	enables tests for special causes to be reset adds labels A, B, and C to zone lines for individual measurements chart
ZONES	adds lines to individual measurements chart delineating zones A, B, and C
ZONEVALPOS= ZONEVALUES	specifies position of ZONEVALUES labels labels individual measurements chart zone lines with their values
Options for Displaying Tests for Special Causes	
CTESTLABBOX=	specifies color for boxes enclosing labels indicating points where test is positive
CTESTS=	specifies color for labels indicating points where test is positive
CTESTSYMBOL=	specifies color for symbol used to plot points where test is positive
CZONES=	specifies color for lines and labels delineating zones A, B, and C
LTESTS=	specifies type of line connecting points where test is positive
LZONES=	specifies line type for lines delineating zones A, B, and C
TESTFONT=	specifies software font for labels at points where test is positive
TESTHEIGHT= TESTLABBOX	specifies height of labels at points where test is positive requests that labels for points where test is positive be positioned so that do not overlap
TESTSYMBOL= TESTSYMBOLHT= WTESTS=	specifies plot symbol for points where test is positive specifies symbol height for points where test is positive specifies width of line connecting points where test is positive
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis

Table 17.19 *continued*

Option	Description
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOTRUNC	suppresses vertical axis truncation at zero applied by default to moving range chart
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPHLABELS=	specifies thinning factor for tick mark labels on horizontal axis
SPLIT=	specifies splitting character for axis labels
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis of individual measurements chart
VAXIS2=	specifies major tick mark values for vertical axis of moving range chart
VFORMAT=	specifies format for primary vertical axis tick mark labels
VFORMAT2=	specifies format for secondary vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis for primary chart
VZERO2	forces origin to be included in vertical axis for secondary chart
WAXIS=	specifies width of axis lines
Plot Layout Options	
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NOCHART	suppresses creation of charts
NOCHART2	suppresses creation of moving range chart
NOFRAME	suppresses frame for plot area
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
SEPARATE	displays individual measurements and moving range charts on separate screens or pages
TOTPANELS=	specifies number of pages or screens to be used to display chart

Table 17.19 *continued*

Option	Description
YPCT1=	specifies length of vertical axis on individual measurements chart as a percentage of sum of lengths of vertical axes for individual measurements and moving range charts
ZEROSTD	displays individual measurements chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= and HREF2= options
CVREF=	specifies color for lines requested by VREF= and VREF2= options
HREF=	specifies position of reference lines perpendicular to horizontal axis on individual measurements chart
HREF2=	specifies position of reference lines perpendicular to horizontal axis on moving range chart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on individual measurements chart
HREF2DATA=	specifies position of reference lines perpendicular to horizontal axis on moving range chart
HREFLABELS=	specifies labels for HREF= lines
HREF2LABELS=	specifies labels for HREF2= lines
HREFLABPOS=	specifies position of HREFLABELS= and HREF2LABELS= labels
LHREF=	specifies line type for HREF= and HREF2= lines
LVREF=	specifies line type for VREF= and VREF2= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis on individual measurements chart
VREF2=	specifies position of reference lines perpendicular to vertical axis on moving range chart
VREFLABELS=	specifies labels for VREF= lines
VREF2LABELS=	specifies labels for VREF2= lines
VREFLABPOS=	position of VREFLABELS= and VREF2LABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines

Table 17.19 *continued*

Option	Description
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to individual measurements chart
ANNOTATE2=	specifies annotate data set that adds features to moving range chart
DESCRIPTION=	specifies description of individual measurements chart's GRSEG catalog entry
DESCRIPTION2=	specifies description of moving range chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
LTMARGIN=	specifies width of left margin area for plot requested with LTMPLLOT= option
LTMPLLOT=	requests univariate plot in left margin
NAME=	specifies name of individual measurements chart's GRSEG catalog entry
NAME2=	specifies name of moving range chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
RTMARGIN=	specifies width of right margin area for plot requested with LTMPLLOT= option
RTMPLLOT=	requests univariate plot in right margin
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors

Table 17.19 *continued*

Option	Description
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
OVERLAY2URL=	specifies URLs to associate with overlay points on secondary chart
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
URL2=	specifies a variable whose values are URLs to be associated with subgroups on secondary chart
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set

Table 17.19 *continued*

Option	Description
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLELEGEND	augments basic table with legend for tests for special causes
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
TABLETESTS	augments basic table with a column indicating which tests for special causes are positive
Specification Limit Options	
CIINDICES	specifies α value and type for computing capability index confidence limits
LSL=	specifies list of lower specification limits
TARGET=	specifies list of target values
USL=	specifies list of upper specification limits
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase

Table 17.19 *continued*

Option	Description
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on individual measurements chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for primary chart overlay line segments
CCOVERLAY2=	specifies colors for secondary chart overlay line segments
COVERLAY=	specifies colors for primary chart overlay plots
COVERLAY2=	specifies colors for secondary chart overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for primary chart overlay line segments
LOVERLAY2=	specifies line types for secondary chart overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on primary chart
OVERLAY2=	specifies variables to overlay on secondary chart
OVERLAY2HTML=	specifies links to associate with secondary chart overlay points
OVERLAY2ID=	specifies labels for secondary chart overlay points
OVERLAY2SYM=	specifies symbols for secondary chart overlays
OVERLAY2SYMHT=	specifies symbol heights for secondary chart overlays
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays

Table 17.19 *continued*

Option	Description
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with primary chart overlay points
OVERLAYID=	specifies labels for primary chart overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for primary chart overlays
OVERLAYSYMHT=	specifies symbol heights for primary chart overlays
WOVERLAY=	specifies widths of primary chart overlay line segments
WOVERLAY2=	specifies widths of secondary chart overlay line segments
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML2=	specifies variable whose values create links to be associated with subgroups on secondary chart
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= and HREF2= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
TESTCHAR=	specifies character for line segments that connect any sequence of points for which a test for special causes is positive
VREFCHAR=	specifies line character for VREF= and VREF2= lines
ZONECHAR=	specifies character for lines that delineate zones for tests for special causes

Details: IRCHART Statement

Constructing Charts for Individual Measurements and Moving Ranges

The following notation is used in this section:

μ	process mean (expected value of the population of measurements)
σ	process standard deviation (standard deviation of the population of measurements)
X_i	the i th individual measurement
\bar{X}	mean of the individual measurements, computed as $(X_1 + \cdots + X_N)/N$, where N is the number of individual measurements
n	number of consecutive measurements used to calculate the moving ranges (by default, $n = 2$)
R_i	moving range computed for the i th subgroup (corresponding to the i th individual measurement). If $i < n$, then R_i is assigned a missing value. Otherwise,
	$R_i = \max(X_i, X_{i-1}, \dots, X_{i-n+1}) - \min(X_i, X_{i-1}, \dots, X_{i-n+1})$
	This formula assumes that $X_i, X_{i-1}, \dots, X_{i-n+1}$ are nonmissing.
\bar{R}	average of the nonmissing moving ranges, computed as
	$\frac{R_n + R_{n+1} \cdots + R_N}{N + 1 - n}$
$d_2(n)$	expected value of the range of n independent normally distributed variables with unit standard deviation
$d_3(n)$	standard error of the range of n independent observations from a normal population with unit standard deviation
z_p	100 p th percentile ($0 < p < 1$) of the standard normal distribution
$D_p(n)$	100 p th percentile ($0 < p < 1$) of the distribution of the range of n independent observations from a normal population with unit standard deviation

Plotted Points

Each point on an individual measurements chart, indicates the value of a measurement (X_i).

Each point on a moving range chart indicates the value of a moving range (R_i). With $n = 2$, for example, if the first three measurements are 3.4, 3.7, and 3.6, the first moving range is missing, the second moving range is $|3.7 - 3.4| = 0.3$, and the third moving range is $|3.6 - 3.7| = 0.1$.

Central Lines

By default, the central line on an individual measurements chart indicates an estimate for μ , which is computed as \bar{X} . If you specify a known value (μ_0) for μ , the central line indicates the value of μ_0 .

The central line on a moving range chart indicates an estimate for the expected moving range, computed as $d_2(n)\hat{\sigma}$ where $\hat{\sigma} = \bar{R}/d_2(n)$. If you specify a known value ($\hat{\sigma}_0$) for σ , the central line indicates the value of $d_2(n)\sigma_0$.

Control Limits

You can compute the limits

- as a specified multiple (k) of the standard errors of X_i and R_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that X_i or R_i exceeds the limits

The following table provides the formulas for the limits:

Table 17.20 Limits for Individual Measurements and Moving Range Charts

Control Limits	
Individual Measurements Chart	LCL = lower control limit = $\bar{X} - k\hat{\sigma}$ UCL = upper control limit = $\bar{X} + k\hat{\sigma}$
Moving Range Chart	LCL = lower control limit = $\max(d_2(n)\hat{\sigma} - kd_3(n)\hat{\sigma}, 0)$ UCL = upper control limit = $d_2(n)\hat{\sigma} + kd_3(n)\hat{\sigma}$
Probability Limits	
Individual Measurements Chart	LCL = lower control limit = $\bar{X} - z_{\alpha/2}\hat{\sigma}$ UCL = upper control limit = $\bar{X} + z_{\alpha/2}\hat{\sigma}$
Moving Range Chart	LCL = lower control limit = $D_{\alpha/2}(n)\hat{\sigma}$ UCL = upper control limit = $D_{1-\alpha/2}(n)\hat{\sigma}$

The formulas assume that the measurements are normally distributed. Note that the probability limits for the moving range are asymmetric about the central line. If standard values μ_0 and σ_0 are available for μ and σ , replace \bar{X} with μ_0 and $\hat{\sigma}$ with σ_0 in Table 17.20.

You can specify parameters for the limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify n with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify μ_0 with the MU0= option or with the variable `_MEAN_` in the LIMITS= data set.
- Specify σ_0 with the SIGMA0= option or with the variable `_STDDEV_` in the LIMITS= data set.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves control limits and control limit parameters. The following variables can be saved:

Table 17.21 OUTLIMITS= Data Set

Variable	Description
ALPHA	probability (α) of exceeding limits
CP	capability index C_p
CPK	capability index C_{pk}
CPL	capability index CPL
CPM	capability index C_{pm}
CPU	capability index CPU
INDEX	optional identifier for the control limits specified with the OUTINDEX= option
LCLI	lower control limit for individual measurements
LCLR	lower control limit for moving ranges
LIMITN	number of consecutive measurements used to compute moving ranges
LSL	lower specification limit
MEAN	process mean
R	value of central line on moving range chart
SIGMAS	multiple (k) of standard error of individual measurement or moving range
STDDEV	process standard deviation ($\hat{\sigma}$ or σ_0)
SUBGRP	<i>subgroup-variable</i> specified in the IRCHART statement
TARGET	target value
TYPE	type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLI	upper control limit for individual measurements
UCLR	upper control limit for moving ranges range
USL	upper specification limit
VAR	<i>process</i> specified in the IRCHART statement

Notes:

1. If the limits are defined in terms of a multiple k of the standard errors of X_i and R_i , the value of _ALPHA_ is computed as $\alpha = 2(1 - \Phi(k))$, where $\Phi(\cdot)$ is the standard normal distribution function.
2. If the limits are probability limits, the value of _SIGMAS_ is computed as $k = \Phi^{-1}(1 - \alpha/2)$, where Φ^{-1} is the inverse standard normal distribution function.
3. The variables _CP_, _CPK_, _CPL_, _CPU_, _LSL_, and _USL_ are included only if you provide specification limits with the LSL= and USL= options. The variables _CPM_ and

`_TARGET_` are included if, in addition, you provide a target value with the `TARGET=` option. See “[Capability Indices](#)” on page 1941 for computational details.

4. Optional BY variables are saved in the `OUTLIMITS=` data set.

The `OUTLIMITS=` data set contains one observation for each *process* specified in the IRCHART statement. For an example, see “[Saving Control Limits](#)” on page 1535.

OUTHISTORY= Data Set

The `OUTHISTORY=` data set saves individual measurements and moving ranges. The following variables are saved:

- the *subgroup-variable*
- an individual measurements variable named by *process*
- a moving range variable named by *process* suffixed with *R*

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

A variable containing the moving ranges is created for each *process* specified in the IRCHART statement. For example, consider the following statements:

```
proc shewhart data=Steel;
  irchart (Width Diameter)*Lot / outhistory=Summary;
run;
```

The data set `Summary` contains variables named `Lot`, `Width`, `WidthR`, `Diameter`, and `DiameterR`.

Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the `OUTPHASE=` option is specified)

For an example of an `OUTHISTORY=` data set, see “[Saving Individual Measurements and Moving Ranges](#)” on page 1532.

OUTTABLE= Data Set

The OUTTABLE= data set saves individual measurements, moving ranges, control limits, and related information. The following variables are saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_EXLIM_</code>	control limit exceeded on individual measurements chart
<code>_EXLIMR_</code>	control limit exceeded on moving range chart
<code>_LCLI_</code>	lower control limit for individual measurements
<code>_LCLR_</code>	lower control limit for moving range
<code>_LIMITN_</code>	number of consecutive measurements used to compute moving ranges
<code>_MEAN_</code>	process mean
<code>_R_</code>	average range
<code>_SIGMAS_</code>	multiple (k) of the standard error associated with control limits
<code>subgroup</code>	values of the subgroup variable
<code>_SUBI_</code>	individual measurement
<code>_SUBR_</code>	moving range
<code>_TESTS_</code>	tests for special causes signaled on individual measurements chart
<code>_UCLI_</code>	upper control limit for individual measurements
<code>_UCLR_</code>	upper control limit for moving range
<code>_VAR_</code>	<i>process</i> specified in the IRCHART statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the READPHASES= option is specified)

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved, depending on how the control limits are defined (with the ALPHA= or SIGMAS= options, respectively, or with the corresponding variables in a LIMITS= data set).
2. The variable `_TESTS_` is saved if you specify the TESTS= option. The k th character of a value of `_TESTS_` is k if Test k is positive at that subgroup. For example, if you request all eight tests and Tests 2 and 8 are positive for a given subgroup, the value of `_TESTS_` has a 2 for the second character, an 8 for the eighth character, and blanks for the other six characters.
3. The variables `_EXLIM_`, `_EXLIMR_`, and `_TESTS_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “Saving Control Limits” on page 1535.

ODS Tables

The following table summarizes the ODS tables that you can request with the IRCHART statement.

Table 17.22 ODS Tables Produced with the IRCHART Statement

Table Name	Description	Options
IRCHART	individual measurement and moving range chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLELEG, TABLEOUT, TABLETESTS
TestDescriptions	descriptions of tests for special causes requested with the TESTS= option for which at least one positive signal is found	TABLEALL, TABLELEG

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the SHEWHART procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. IRCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the IRCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 17.23](#).

Table 17.23 ODS Graphics Produced by the IRCHART Statement

ODS Graph Name	Plot Description
IRChart	individual measurements and moving range chart

See Chapter 3, “[SAS/QC Graphics](#),” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read individual measurements from a DATA= data set specified in the PROC SHEWHART statement. Each *process* specified in the IRCHART statement must be a SAS variable in the data set. This variable provides measurements of items indexed by the *subgroup-variable*. The *subgroup-variable*, which is specified in the IRCHART statement, must also be a SAS variable in the data set. Each observation in a DATA= data set must contain a measurement for each *process* and a value for the *subgroup-variable*. Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a DATA= data set. However, if the DATA= data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option in the IRCHART statement (for an example, see “[Displaying Stratification in Phases](#)” on page 2103).

For an example of a DATA= data set, see “[Creating Individual Measurements and Moving Range Charts](#)” on page 1531.

LIMITS= Data Set

You can read preestablished control limits (or parameters from which the control limits can be calculated) from a LIMITS= data set specified in the PROC SHEWHART statement. For example, the following statements read control limit information from the data set `Conlims`:¹¹

```
proc shewhart data=info limits=Conlims;
  irchart Weight*ID;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the SHEWHART procedure. Such data sets always contain the variables required for a LIMITS= data set; see [Table 17.20](#). The LIMITS= data set can also be created directly using a DATA step.

When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LCL_`, `_MEAN_`, `_UCL_`, `_LCLR_`, `_R_`, and `_UCLR_`, which specify the control limits directly
- the variables `_MEAN_` and `_STDDEV_`, which are used to calculate the control limits according to the equations in [Table 17.20](#)

¹¹In SAS 6.09 and in earlier releases, it is necessary to specify the READLIMITS option.

In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables whose lengths are no greater than 32.
- The variable `_INDEX_` is required if you specify the `READINDEX=` option; this must be a character variable whose length is no greater than 48.
- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8; valid values are 'ESTIMATE', 'STANDARD', 'STDMU', and 'STDSIGMA'. See [Example 17.12](#) for an illustration.
- BY variables are required if specified with a BY statement.

For an example, see “[Reading Prestablished Control Limits](#)” on page 1537.

HISTORY= Data Set

You can read individual measurements and moving ranges from a `HISTORY=` data set specified in the `PROC SHEWHART` statement. This enables you to reuse `OUTHISTORY=` data sets that have been created in previous runs of the `SHEWHART` procedure.

A `HISTORY=` data set used with the `IRCHART` statement must contain the following:

- the *subgroup-variable*
- an individual measurements variable for each *process*
- a moving range variable for each *process*

The name of the individual measurements variable must be the *process* specified in the `IRCHART` statement. The name of the moving range variable must be the prefix *process* concatenated with the special suffix character *R*. For example, consider the following statements:

```
proc shewhart history=Summary;
  irchart (Weight Yieldstrength) * ID;
run;
```

The data set `Summary` must include the variables `ID`, `Weight`, `WeightR`, `YieldstrengthN`, and `YieldstrengthR`.

Note that if you specify a *process* name that contains 32 characters, the name of the moving range variable must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with *R*.

Other variables that can be read from a HISTORY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a HISTORY= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (see “Displaying Stratification in Phases” on page 2103 for an example).

For an example of a HISTORY= data set, see “Reading Individual Measurements and Moving Ranges” on page 1533.

TABLE= Data Set

You can read individual measurements, moving ranges, and control limits from a TABLE= data set specified in the PROC SHEWHART statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the SHEWHART procedure. Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts. Examples are provided in “Specialized Control Charts: SHEWHART Procedure” on page 2171.

The following table lists the variables required in a TABLE= data set used with the IRCHART statement:

Table 17.24 Variables Required in a TABLE= Data Set

Variable	Description
<code>_LCLI_</code>	lower control limit for individual measurements
<code>_LCLR_</code>	lower control limit for moving range
<code>_LIMITN_</code>	number of consecutive measurements used to calculate moving ranges
<code>_MEAN_</code>	process mean
<code>_R_</code>	average moving range
<i>subgroup-variable</i>	values of the <i>subgroup-variable</i>
<code>_SUBI_</code>	individual measurements
<code>_SUBR_</code>	moving ranges
<code>_UCLI_</code>	upper control limit for individual measurements
<code>_UCLR_</code>	upper control limit for moving range

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- `_PHASE_` (if the READPHASES= option is specified). This variable must be a character variable whose length is no greater than 48.
- `_TESTS_` (if the TESTS= option is specified). This variable is used to flag tests for special causes and must be a character variable of length 8.
- `_VAR_`. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable whose length is no greater than 32.

For an example of a TABLE= data set, see “[Saving Control Limits](#)” on page 1535.

Methods for Estimating the Standard Deviation

When control limits are computed from the input data, three methods (referred to as default, MAD and MMR) are available for estimating the process standard deviation σ .

Default Method

The default estimate for σ is

$$\hat{\sigma} = \bar{R}/d_2(n)$$

where \bar{R} is the average of the moving ranges, n is the number of consecutive individual measurements used to compute each moving range, and the unbiasing factor $d_2(n)$ is defined so that if the observations are normally distributed, the expected value of R_i is

$$E(R_i) = d_2(n_i)\sigma$$

This method is described in the American Society for Testing and Materials (1976).

MAD Method

If you specify SMETHOD=MAD, a median absolute deviation estimator is computed for σ , as described by Boyles (1997). It is computed as

$$\hat{\sigma} = \text{median}\{|X_i - \tilde{X}|, 1 \leq i \leq N\}/0.6745$$

where \tilde{X} is the sample median.

MMR Method

If you specify SMETHOD=MMR, a median moving range estimator is computed for σ . This estimator is described by Boyles (1997). It is computed as

$$\hat{\sigma} = \tilde{R}/0.954$$

where \tilde{R} is the median of the nonmissing moving ranges.

Interpreting Charts for Individual Measurements and Moving Ranges

Montgomery (1996) points out that a moving range chart should be interpreted with care because “the moving ranges are correlated, and this correlation may often induce a pattern or runs or cycles on the chart.” For this reason Nelson (1982) recommends against plotting the moving ranges. Nelson notes that the assumption of normality is more critical for an individual measurements chart than for an \bar{X} chart. You can use the NOCHART2 option in the IRCHART statement to specify that only the individual measurements chart is to be displayed. See [Example 17.13](#) for an illustration. If, instead, you specify the SEPARATE option, the charts for individual measurements and moving ranges are displayed on separate screens.

An alternative method for creating an individual measurements chart is to use the XCHART statement, which uses an estimate of σ based on moving ranges of two consecutive measurements when the subgroup sample sizes are all equal to one. Note that the XCHART statement displays the control limit legend $n = 1$ to indicate the common subgroup sample size, whereas the IRCHART statement displays a legend that indicates the number of consecutive measurements used to compute the moving ranges (the “pseudo subgroup sample size”).

Nelson (1982) explains that the reason for estimating the process standard deviation σ from moving ranges of two consecutive measurements rather than the sample standard deviation of the measurements is that “the moving range of two minimizes inflationary effects on the variability which are caused by trends and oscillations that may be present.” Nelson suggests that any moving range that exceeds 3.5 times the average moving range should be removed from the calculation of the average moving range.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical (Individual measurements chart)	DATA=	<i>process</i>
Vertical (Individual measurements chart)	HISTORY=	subgroup measurement variable
Vertical (Individual measurements chart)	TABLE=	<i>_SUBI_</i>

You can specify distinct labels for the vertical axes of the individual measurements and moving range charts by breaking the vertical axis into two parts with a split character. Specify the split character with the SPLIT= option. The first part labels the vertical axis of the individual measurements chart, and the second part labels the vertical axis of the moving range chart.

For example, the following sets of statements specify the label *Avg gap in mm* for the vertical axis of the individual measurements chart and the label *Range in mm* for the vertical axis of the moving range chart:

```
proc shewhart data=Doors;
  irchart Gap*Hour / split = '/' ;
  label Gap = 'Avg gap in mm/Range in mm';
run;

proc shewhart history=Doorhist;
```

```

    irchart Gap*Hour / split = '/' ;
    label Gap = 'Avg gap in mm/Range in mm';
run;

proc shewhart table=Doortab;
    irchart Gap*Hour / split = '/' ;
    label _SUBI_ = 'Avg gap in mm/Range in mm';
run;

```

In this example, the label assignments are in effect only for the duration of the procedure step, and they temporarily override any permanent labels associated with the variables.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: IRCHART Statement

This section provides advanced examples of the IRCHART statement.

Example 17.11: Applying Tests for Special Causes

This example illustrates how you can apply tests for special causes to make an individual measurements chart more sensitive to special causes of variation. The following statements create a data set named Engines, which contains the weights for 25 jet engines: *See SHWIREX1 in the SAS/QC Sample Library*

```

data Engines;
    input ID Weight @@;
    label Weight='Engine Weight (lbs)'
           ID    ='Engine ID Number';
    datalines;
1711 1270   1712 1258   1713 1248   1714 1260
1715 1263   1716 1260   1717 1259   1718 1240
1719 1260   1720 1246   1721 1238   1722 1253
1723 1249   1724 1245   1725 1251   1726 1252
1727 1249   1728 1274   1729 1258   1730 1268
1731 1248   1732 1295   1733 1243   1734 1253
1735 1258
;

```

Individual measurements and moving range charts are used to monitor the weights. The following statements produce the tables shown in [Output 17.11.1](#) and create the charts shown in [Output 17.11.2](#):

```

title 'Tests for Special Causes Applied to Jet Engine Weights';
ods graphics on;
proc shewhart data=Engines;
  irchart Weight*ID /
    tests      = 1 to 8
    test2run   = 7
    odstitle   = title
    tabletest
    zonelabels
    markers;
run;

```

The TESTS= option applies eight tests for special causes, which are described in “Tests for Special Causes: SHEWHART Procedure” on page 2146. The TEST2RUN= option specifies the length of the pattern for Test 2. The TABLETESTS option requests a table of individual measurements, moving ranges, and control limits, and it adds a column indicating which measurements tested positive for special causes.

The ZONELABELS option displays zone lines and zone labels on the individual measurements chart. The zones are used to define the tests.

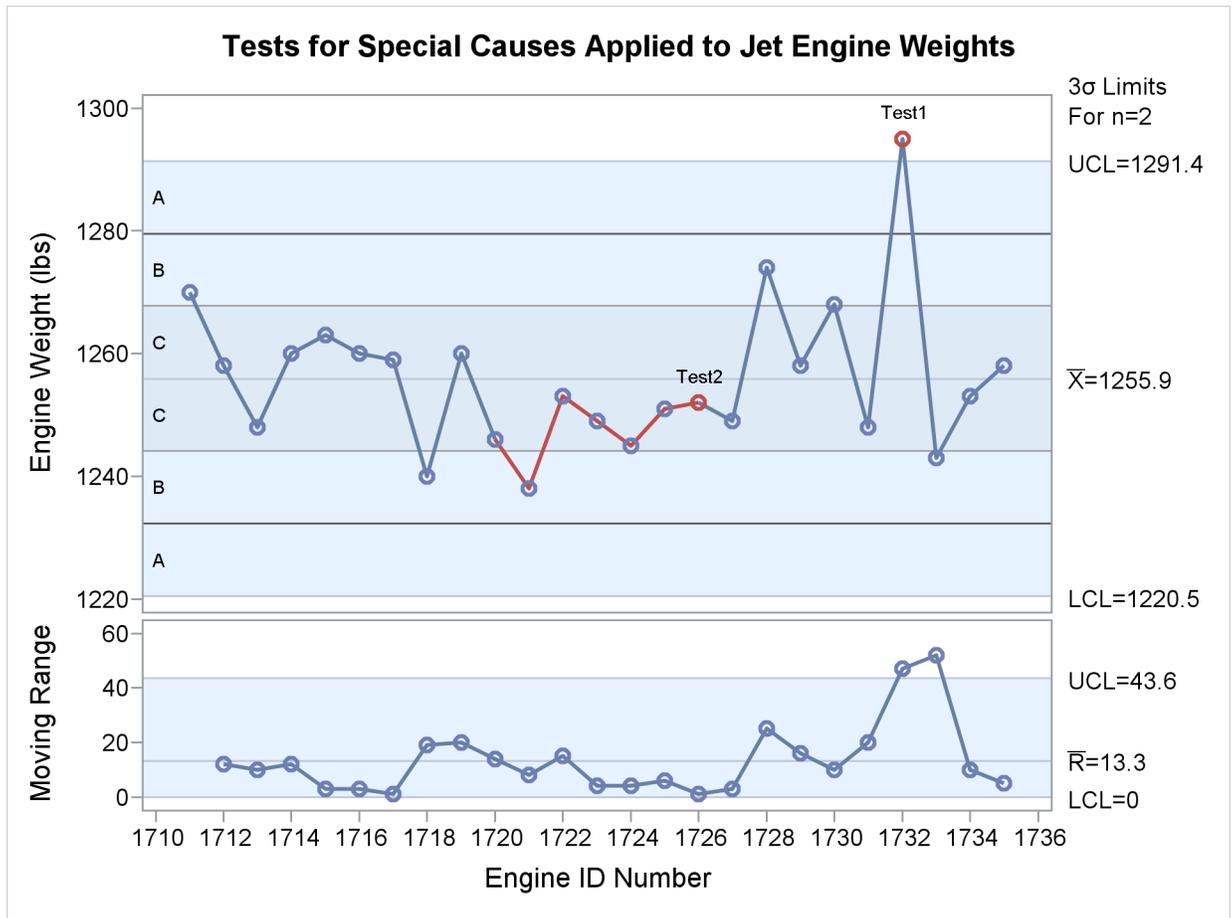

Output 17.11.1 Tabular Form of Individual Measurements and Moving Range Chart

Individual Measurements Chart Summary for Weight

1735	0	5.000000	43.553759

Output 17.11.2 Tests for Special Causes

Output 17.11.1 and Output 17.11.2 indicate that Test 1 was positive for engine 1732 and Test 2 was positive for engine 1726. Test 1 detects one point beyond Zone A (outside the control limits) and Test 2 detects seven points (TEST2RUN=7) in a row on one side of the central line.

Example 17.12: Specifying Standard Values for the Process Mean and Standard Deviation

See SHWIREX2 in the SAS/QC Sample Library

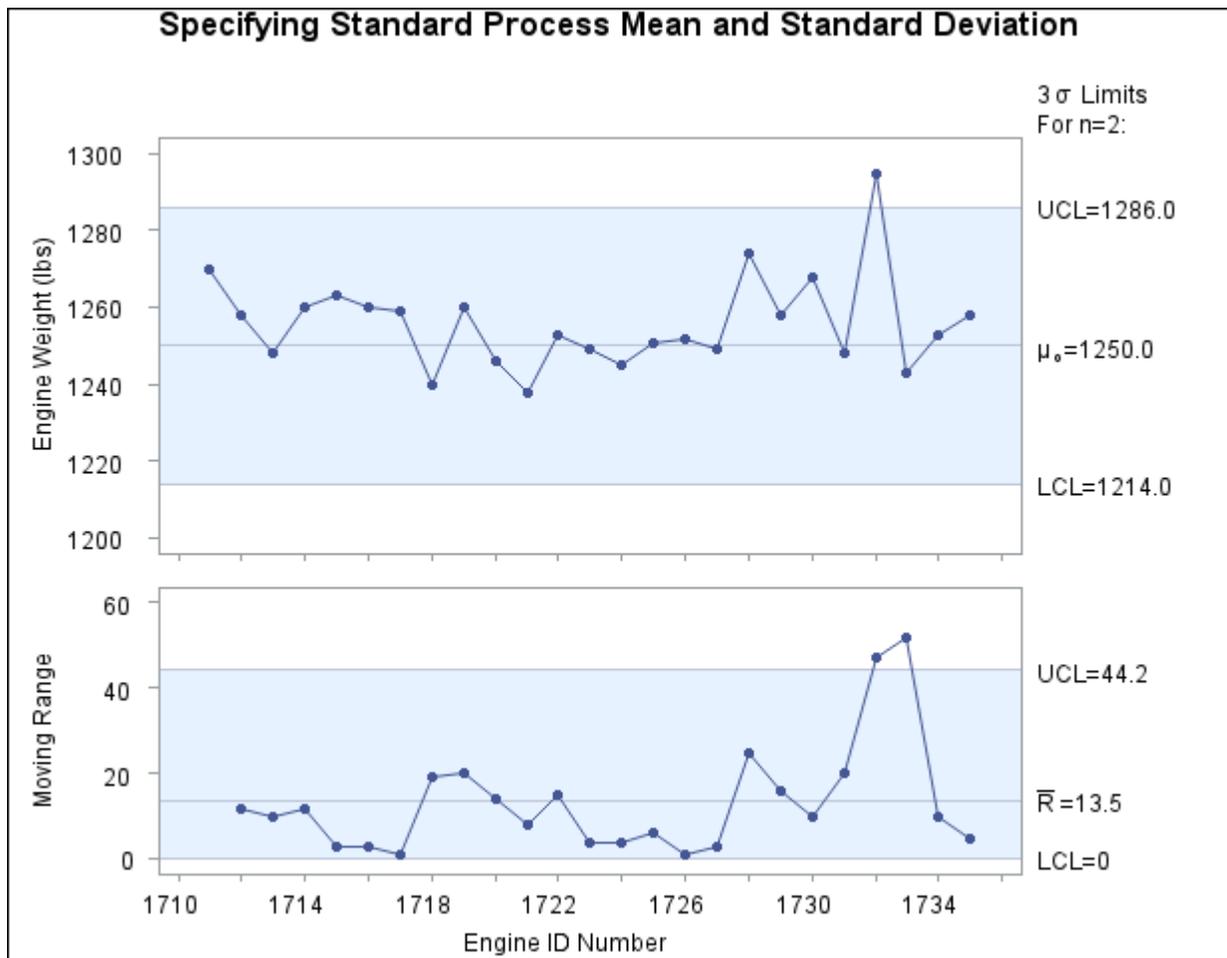

By default, the IRCHART statement estimates the process mean (μ) and standard deviation (σ) from the data, as in the previous example. However, there are applications in which known (standard) values μ_0 and σ_0 are available for these parameters based on previous experience or extensive sampling.

For example, suppose that the manufacturing process described in the previous example produces engines whose weights are normally distributed with a mean of 1250 and a standard deviation of 12. The following statements create individual measurements and moving range charts based on these values:

```
ods graphics off;
symbol v = dot h = .8;
title 'Specifying Standard Process Mean and Standard Deviation';
proc shewhart data=Engines;
  irchart Weight*ID /
    mu0      = 1250
    sigma0   = 12
    xsymbol  = mu0;
run;
```

The charts are shown in [Output 17.12.1](#). The MU0= option and SIGMA0= option specify μ_0 and σ_0 . The XSYMBOL= option specifies the label for the central line on the individual measurements chart, and the keyword MU0 requests a label indicating that the central line is based on a standard value.

Output 17.12.1 Specifying Standard Values with MU0= and SIGMA0=

You can also specify μ_0 and σ_0 as the values of the variables `_MEAN_` and `_STDDEV_` in a LIMITS= data set. For example, the following statements create a LIMITS= data set with the standard values specified in the preceding IRCHART statement:

```

data Enginelimits;
  length _var_ _subgrp_ _type_ $8;
  _var_   = 'Weight';
  _subgrp_ = 'id';
  _limitn_ = 2;
  _type_   = 'STANDARD';
  _mean_   = 1250;
  _stddev_ = 12;
run;

```

The variables `_VAR_` and `_SUBGRP_` are required, and their values must match the *process* and *subgroup-variable*, respectively, specified in the `IRCHART` statement. The bookkeeping variable `_TYPE_` is not required, but it is recommended to indicate that the variables `_MEAN_` and `_STDDEV_` provide standard values rather than estimated values. See “`LIMITS= Data Set`” on page 1558 for details.

The following statements read `Enginelimits` as a `LIMITS=` data set:

```

proc shewhart data=Engines limits=Enginelimits;
  irchart Weight*ID / xsymbol=mu0;
run;

```

The resulting charts (not shown here) are identical to those shown in [Output 17.12.1](#).

Example 17.13: Displaying Distributional Plots in the Margin

See *SHWIREX3* in the *SAS/QC Sample Library*

You can augment a chart for individual measurements with one of several graphical displays, such as a histogram or a box-and-whisker plot. These displays summarize the measurements plotted on the chart, and, if the process is in statistical control, they provide a view of the process distribution.

For example, the following statements create an individual measurements chart for the engine weight measurements in the data set `Engines` (see [Example 17.11](#)) augmented with a histogram of the weights:

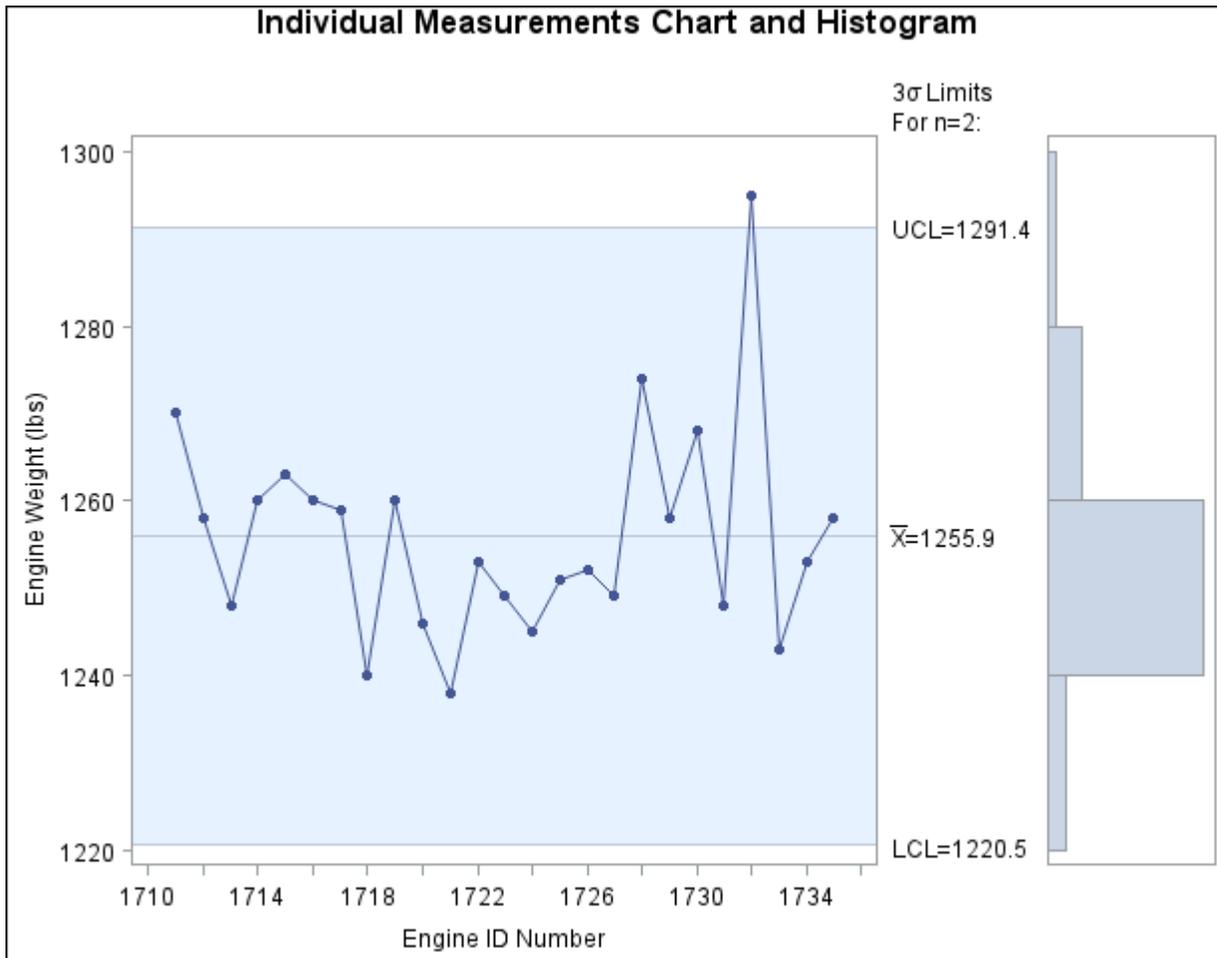

```

ods graphics off;
title 'Individual Measurements Chart and Histogram';
proc shewhart data=Engines;
  irchart Weight*ID /
    rtmplot = histogram
    nochart2;
run;

```

The chart is shown in [Output 17.13.1](#). The `RTMPLOT=` option requests a histogram in the right margin. The `NOCHART2` option suppresses the display of the moving range chart.

Output 17.13.1 Histogram in Right Margin

The following *keywords*, requesting different types of plots, are available with the RTMPLOT= option:

Keyword	Marginal Plot
HISTOGRAM	histogram
DIGIDOT	digidot plot
SKELETAL	skeletal box-and-whisker plot
SCHEMATIC	schematic box-and-whisker plot
SCHEMATICID	schematic box-and-whisker plot with outliers labeled
SCHEMATICIDFAR	schematic box-and-whisker plot with far outliers labeled

See the entry for the BOXSTYLE= option in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018 for a description of the various box-and-whisker plots.

You can also use the LTMPLOT= option to request univariate plots in the left margin. The following statements request an individual measurements chart with a box-and-whisker plot in the left margin:

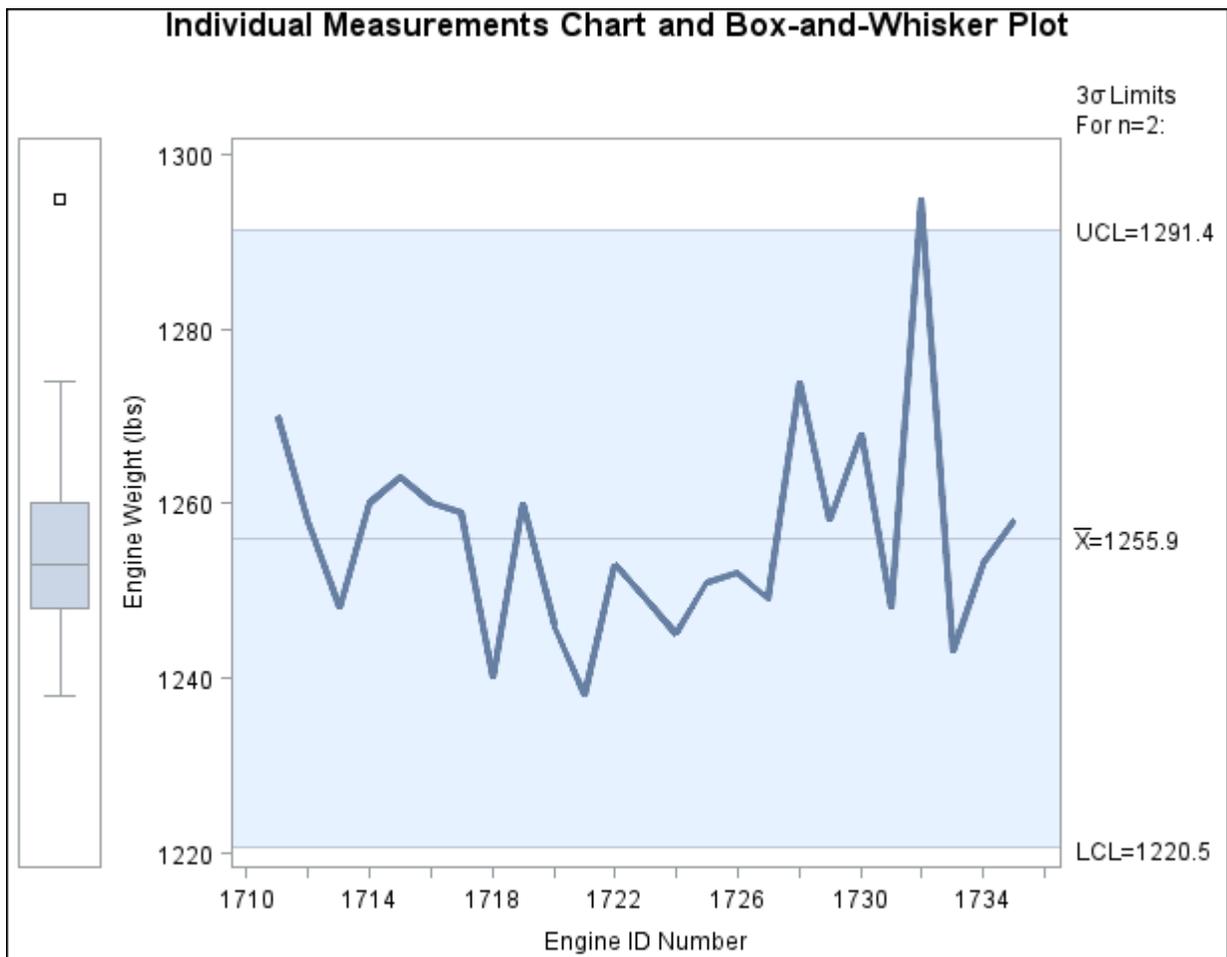

```

title 'Individual Measurements Chart and Box-and-Whisker Plot';
proc shewhart data=Engines;
  irchart Weight*ID /
    ltmplot = schematic
    ltmargin = 8
    nochart2;
run;

```

The chart is shown in [Output 17.13.2](#). The same *keywords* that are available with the RTMPLOT= option can be specified with the LTMPLLOT= option. The LTMARGIN= option specifies the width (in horizontal percent screen units) of the left margin.

Output 17.13.2 Box-and-Whisker Plot in Left Margin

MCHART Statement: SHEWHART Procedure

Overview: MCHART Statement

The MCHART statement creates a chart for subgroup medians, which is used to monitor the central tendency of a process.

You can use options in the MCHART statement to

- compute control limits from the data based on a multiple of the standard error of the plotted medians or as probability limits
- tabulate subgroup sample sizes, subgroup medians, control limits, and other information
- save control limits in an output data set
- save subgroup sample sizes and subgroup medians in an output data set
- read preestablished control limits from a data set
- apply tests for special causes (also known as runs tests and Western Electric rules)
- specify one of several methods for estimating the process standard deviation
- specify whether subgroup standard deviations or subgroup ranges are used to estimate the process standard deviation
- specify a known (standard) process mean and standard deviation for computing control limits
- create a secondary chart that displays a time trend removed from the data (see “[Displaying Trends in Process Data](#)” on page 2126)
- display distinct sets of control limits for data from successive time phases
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the charts more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have three alternatives for producing medians charts with the MCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

NOTE: When analyzing variables data, you should examine the variability of the process as well as the mean level. You can use the MRCHART statement in the SHEWHART procedure to monitor both the mean level and variability.

Getting Started: MCHART Statement

This section introduces the MCHART statement with simple examples that illustrate commonly used options. Complete syntax for the MCHART statement is presented in the section “Syntax: MCHART Statement” on page 1585.

Creating Charts for Medians from Raw Data

See SHWMCHR in the SAS/QC Sample Library

A consumer products company weighs detergent boxes (in pounds) to determine whether the fill process is in control. The following statements create a SAS data set named Detergent, which contains the weights for five boxes in each of 28 lots. A lot is considered a rational subgroup.

```
data Detergent;
  input Lot @;
  do i=1 to 5;
    input Weight @;
    output;
  end;
  drop i;
  datalines;
1 17.39 26.93 19.34 22.56 24.49
2 23.63 23.57 23.54 20.56 22.17
3 24.35 24.58 23.79 26.20 21.55
4 25.52 28.02 28.44 25.07 23.39
5 23.25 21.76 29.80 23.09 23.70
6 23.01 22.67 24.70 20.02 26.35
7 23.86 24.19 24.61 26.05 24.18
8 26.00 26.82 28.03 26.27 25.85
9 21.58 22.31 25.03 20.86 26.94
10 22.64 21.05 22.66 29.26 25.02
11 26.38 27.50 23.91 26.80 22.53
12 23.01 23.71 25.26 20.21 22.38
13 23.15 23.53 22.98 21.62 26.99
14 26.83 23.14 24.73 24.57 28.09
15 26.15 26.13 20.57 25.86 24.70
16 25.81 23.22 23.99 23.91 27.57
```

```

17 25.53 22.87 25.22 24.30 20.29
18 24.88 24.15 25.29 29.02 24.46
19 22.32 25.96 29.54 25.92 23.44
20 25.63 26.83 20.95 24.80 27.25
21 21.68 21.11 26.07 25.17 27.63
22 26.72 27.05 24.90 30.08 25.22
23 31.58 22.41 23.67 23.47 24.90
24 28.06 23.44 24.92 24.64 27.42
25 21.10 22.34 24.96 26.50 24.51
26 23.80 24.03 24.75 24.82 27.21
27 25.10 26.09 27.21 24.28 22.45
28 25.53 22.79 26.26 25.85 25.64
;

```

A partial listing of Detergent is shown in [Figure 17.34](#).

Figure 17.34 Partial Listing of the Data Set Detergent

The Data Set DETERGENT	
Lot	Weight
1	17.39
1	26.93
1	19.34
1	22.56
1	24.49
2	23.63
2	23.57
2	23.54
2	20.56
2	22.17
3	24.35
3	24.58
3	23.79
3	26.20
3	21.55
4	25.52

The data set Detergent is said to be in “strung-out” form, since each observation contains the lot number and weight of a single box. The first five observations contain the weights for the first lot, the second five observations contain the weights for the second lot, and so on. Because the variable Lot classifies the observations into rational subgroups, it is referred to as the *subgroup-variable*. The variable Weight contains the weights and is referred to as the *process variable* (or *process* for short).

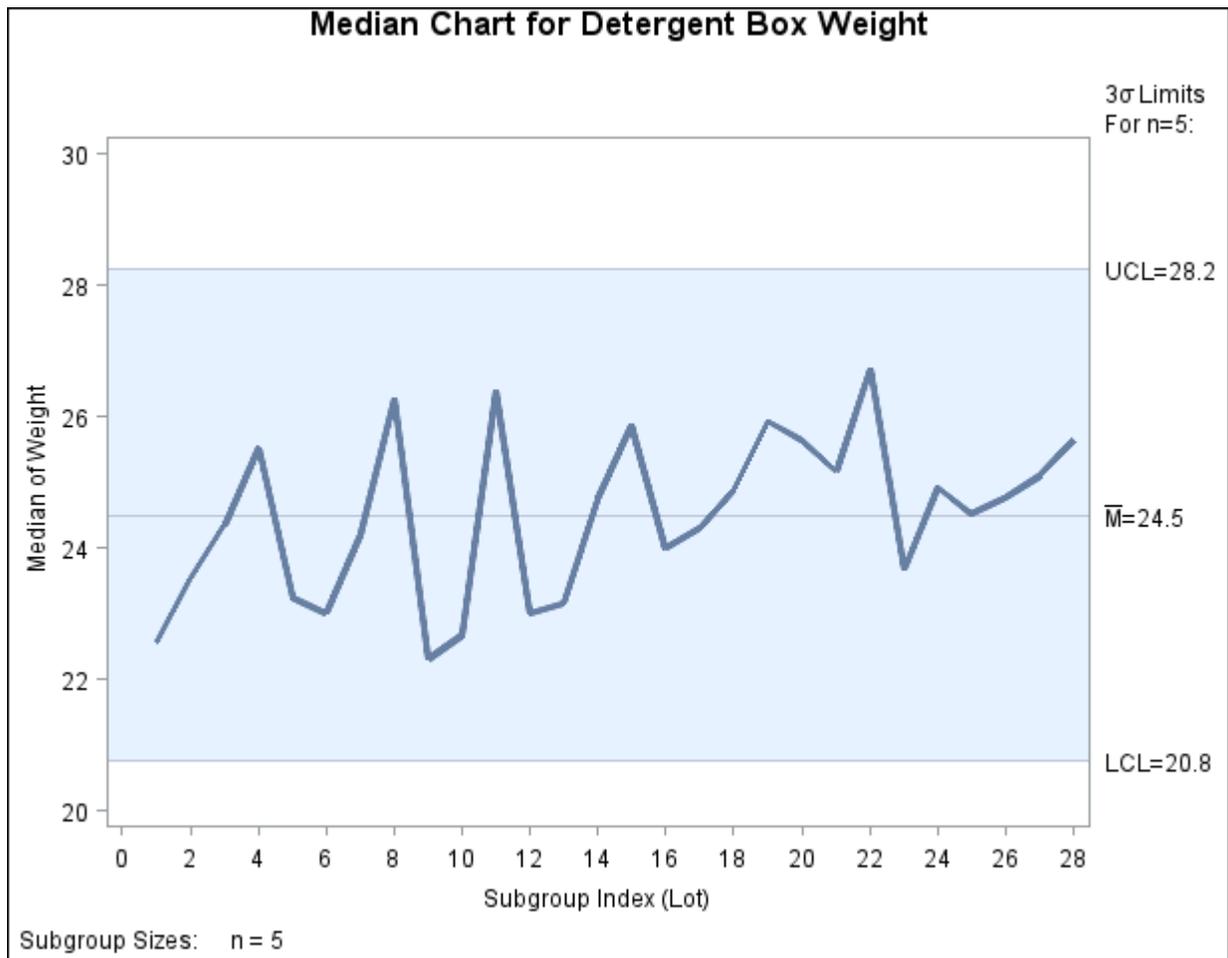

The within-subgroup variability of the weights is known to be stable. You can use a median chart to determine whether the mean level of the weights is in control. The following statements create the median chart shown in [Figure 17.35](#):

```
ods graphics off;
title 'Median Chart for Detergent Box Weight';
proc shewhart data=Detergent;
  mchart Weight*Lot;
run;
```

This example illustrates the basic form of the MCHART statement. After the keyword MCHART, you specify the *process* to analyze (in this case, Weight) followed by an asterisk and the *subgroup-variable* (Lot).

The input data set is specified with the DATA= option in the PROC SHEWHART statement.

Figure 17.35 Median Chart for Detergent Box Weight Data (Traditional Graphics)

Each point on the chart represents the median of the weights for a particular lot. For instance, the weights for the first lot are 17.39, 19.34, 22.56, 24.49, and 26.93, and consequently, the median plotted for this lot is 22.56.

Since all of the subgroup medians lie within the control limits, you can conclude that the process is in statistical control. By default, the control limits shown are 3 σ limits estimated from the data; the formulas for the limits are given in Table 17.26. You can also read control limits from an input data set; see “Reading Prestablished Control Limits” on page 1583.

For computational details, see “Constructing Median Charts” on page 1596. For more details on reading raw measurements, see “DATA= Data Set” on page 1603.

Creating Charts for Medians from Subgroup Summary Data

The previous example illustrates how you can create median charts using raw data (process measurements). However, in many applications the data are provided as subgroup summary statistics. This example illustrates how you can use the MCHART statement with data of this type. *See SHWMCHR in the SAS/QC Sample Library*

The following data set (Detsum) provides the data from the preceding example in summarized form. There is exactly one observation for each subgroup (note that the subgroups are still indexed by Lot). The variable WeightM contains the subgroup medians, the variable WeightR contains the subgroup ranges, and the variable WeightN contains the subgroup sample sizes (these are all five).

```
data Detsum;
  input Lot WeightM WeightR;
  WeightN = 5;
  datalines;
1  22.56  9.54
2  23.54  3.07
3  24.35  4.65
4  25.52  5.05
5  23.25  8.04
6  23.01  6.33
7  24.19  2.19
8  26.27  2.18
9  22.31  6.08
10 22.66  8.21
11 26.38  4.97
12 23.01  5.05
13 23.15  5.37
14 24.73  4.95
15 25.86  5.58
16 23.99  4.35
17 24.30  5.24
18 24.88  4.87
19 25.92  7.22
20 25.63  6.30
21 25.17  6.52
22 26.72  5.18
23 23.67  9.17
24 24.92  4.62
25 24.51  5.40
26 24.75  3.41
27 25.10  4.76
28 25.64  3.47
;
```

A partial listing of Detsum is shown in Figure 17.36.

Figure 17.36 The Summary Data Set Detsum

Summary Data Set for Detergent Box Weights			
Lot	Weight M	Weight R	Weight N
1	22.56	9.54	5
2	23.54	3.07	5
3	24.35	4.65	5
4	25.52	5.05	5
5	23.25	8.04	5
6	23.01	6.33	5
7	24.19	2.19	5
8	26.27	2.18	5
9	22.31	6.08	5
10	22.66	8.21	5
11	26.38	4.97	5
12	23.01	5.05	5
13	23.15	5.37	5
14	24.73	4.95	5
15	25.86	5.58	5
16	23.99	4.35	5
17	24.30	5.24	5
18	24.88	4.87	5
19	25.92	7.22	5
20	25.63	6.30	5
21	25.17	6.52	5
22	26.72	5.18	5
23	23.67	9.17	5
24	24.92	4.62	5
25	24.51	5.40	5
26	24.75	3.41	5
27	25.10	4.76	5
28	25.64	3.47	5

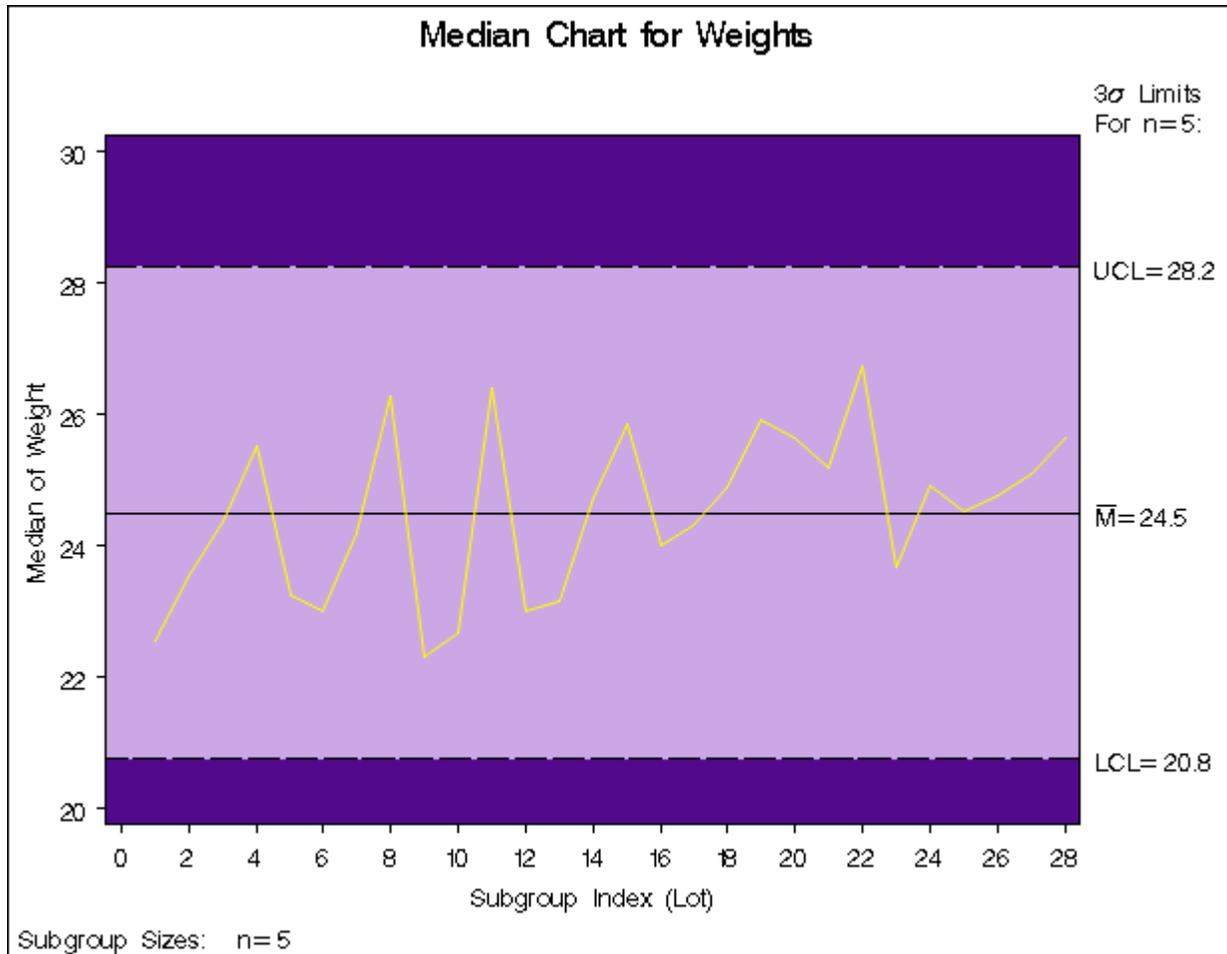

You can read this data set by specifying it as a HISTORY= data set in the PROC SHEWHART statement, as follows:

```
options nogstyle;
goptions ftext=swiss;
title 'Median Chart for Weights';
proc shewhart history=Detsum;
    mchart Weight*Lot / cframe = viv
                    cinfill = vpav
                    cconnect = yellow;
run;
options gstyle;
```

The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the MCHART statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently. The resulting median chart is shown in [Figure 17.37](#).

Note that *Weight* is *not* the name of a SAS variable in the data set *Detsum* but is, instead, the common prefix for the names of the three SAS variables *WeightM*, *WeightR*, and *WeightN*. The suffix characters *M*, *R*, and *N* indicate *median*, *range*, and *sample size*, respectively. Thus, you can specify three subgroup summary variables in the *HISTORY=* data set with a single name (*Weight*), which is referred to as the *process*. The name *Lot* specified after the asterisk is the name of the *subgroup-variable*.

Figure 17.37 Median Chart from Summary Data Set *Detsum* (Traditional Graphics with *NOGSTYLE*)

In general, a *HISTORY=* input data set used with the *MCHART* statement must contain the following variables:

- subgroup variable
- subgroup median variable
- either a subgroup range variable or a subgroup standard deviation variable
- subgroup sample size variable

Furthermore, the names of the subgroup median, range (or standard deviation), and sample size variables must begin with the *process* name specified in the MCHART statement and end with the special suffix characters *M*, *R* (or *S*), and *N*, respectively. If the names do not follow this convention, you can use the RENAME option in the PROC SHEWHART statement to rename the variables for the duration of the SHEWHART procedure step (see “Creating Charts for Medians and Ranges from Summary Data” on page 1619).

If you specify the STDDEVIATIONS option in the MCHART statement, the HISTORY= data set must contain a subgroup standard deviation variable; otherwise, the HISTORY= data set must contain a subgroup range variable. The STDDEVIATIONS option specifies that the estimate of the process standard deviation σ is to be calculated from subgroup standard deviations rather than subgroup ranges. For example, in the following statements, the data set Detsum2 must contain a subgroup standard deviation variable named WeightS:

```
title 'Median Chart for Weights';
symbol v=dot;
proc shewhart history=Detsum2;
    mchart Weight*Lot / stddeviations;
run;
```

Options such as STDDEVIATIONS are specified after the slash (/) in the MCHART statement. A complete list of options is presented in the section “Syntax: MCHART Statement” on page 1585.

In summary, the interpretation of *process* depends on the input data set.

- If raw data are read using the DATA= option (as in the previous example), *process* is the name of the SAS variable containing the process measurements.
- If summary data are read using the HISTORY= option (as in this example), *process* is the common prefix for the names of the variables containing the summary statistics.

For more information, see “HISTORY= Data Set” on page 1604.

Saving Summary Statistics

See SHWMCHR in the SAS/QC Sample Library In this example, the MCHART statement is used to create a summary data set that can be read later by the SHEWHART procedure (as in the preceding example). The following statements read measurements from the data set Detergent and create a summary data set named Dethist:

```
proc shewhart data=Detergent;
    mchart Weight*Lot / outhistory = Dethist
                        nochart;
run;
```

The OUTHISTORY= option names the output data set, and the NOCHART option suppresses the display of the chart, which would be identical to the chart in Figure 17.35. Figure 17.38 contains a partial listing of Dethist.

Figure 17.38 The Summary Data Set Dethist

Summary Data Set DETHIST for Detergent Box Weights				
Lot	Weight M	Weight R	Weight N	
1	22.56	9.54	5	
2	23.54	3.07	5	
3	24.35	4.65	5	
4	25.52	5.05	5	
5	23.25	8.04	5	
6	23.01	6.33	5	
7	24.19	2.19	5	
8	26.27	2.18	5	
9	22.31	6.08	5	
10	22.66	8.21	5	
11	26.38	4.97	5	
12	23.01	5.05	5	
13	23.15	5.37	5	
14	24.73	4.95	5	
15	25.86	5.58	5	
16	23.99	4.35	5	
17	24.30	5.24	5	
18	24.88	4.87	5	
19	25.92	7.22	5	
20	25.63	6.30	5	
21	25.17	6.52	5	
22	26.72	5.18	5	
23	23.67	9.17	5	
24	24.92	4.62	5	
25	24.51	5.40	5	
26	24.75	3.41	5	
27	25.10	4.76	5	
28	25.64	3.47	5	

There are four variables in the data set Dethist.

- Lot contains the subgroup index.
- WeightM contains the subgroup medians.
- WeightR contains the subgroup ranges.
- WeightN contains the subgroup sample sizes.

Note that the summary statistic variables are named by adding the suffix characters *M*, *R*, and *N* to the *process* Weight specified in the MCHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as that for HISTORY= data sets.

If you specify the STDDEVIATIONS option, the OUTHISTORY= data set includes a subgroup standard deviation variable instead of a subgroup range variable, as demonstrated by the following statements:

```

proc shewhart data=Detergent;
  mchart Weight*Lot / outhistory = Dethist2
                    stddeviations
                    nochart;
run;

```

Figure 17.39 contains a partial listing of Dethist2.

Figure 17.39 The Summary Data Set Dethist2

Summary Data Set with Subgroup Standard Deviations				
Lot	Weight M	WeightS	Weight N	
1	22.56	3.84205	5	
2	23.54	1.34050	5	
3	24.35	1.68087	5	
4	25.52	2.11558	5	
5	23.25	3.14747	5	
6	23.01	2.37115	5	
7	24.19	0.86491	5	
8	26.27	0.88382	5	
9	22.31	2.55563	5	
10	22.66	3.20064	5	
11	26.38	2.10858	5	
12	23.01	1.85360	5	
13	23.15	1.99936	5	
14	24.73	1.96853	5	
15	25.86	2.37425	5	
16	23.99	1.77395	5	
17	24.30	2.14006	5	
18	24.88	1.98148	5	
19	25.92	2.78591	5	
20	25.63	2.51040	5	
21	25.17	2.82905	5	
22	26.72	2.05752	5	
23	23.67	3.67124	5	
24	24.92	1.96007	5	
25	24.51	2.15219	5	
26	24.75	1.35365	5	
27	25.10	1.80968	5	
28	25.64	1.38345	5	

The variable WeightS, which contains the subgroup standard deviations, is named by adding the suffix character *S* to the *process* Weight.

For more information, see “OUTHISTORY= Data Set” on page 1599.

Saving Control Limits

You can save the control limits for a median chart in a SAS data set; this enables you to apply the control limits to future data (see “[Reading Prestablished Control Limits](#)” on page 1583) or modify the limits with a DATA step program. *See SHWMCHR in the SAS/QC Sample Library*

The following statements read measurements from the data set Detergent (see “[Creating Charts for Medians from Raw Data](#)” on page 1572) and save the control limits displayed in [Figure 17.35](#) in a data set named Detlim:

```
proc shewhart data=Detergent;
  mchart Weight*Lot / outlimits=Detlim
                    nochart;
run;
```

The OUTLIMITS= option names the data set containing the control limits, and the NOCHART option suppresses the display of the charts. The data set Detlim is listed in [Figure 17.40](#).

Figure 17.40 The Data Set Detlim Containing Control Limit Information

Control Limits for Detergent Box Weights						
<u>_VAR_</u>	<u>_SUBGRP_</u>	<u>_TYPE_</u>	<u>_LIMITN_</u>	<u>_ALPHA_</u>	<u>_SIGMAS_</u>	<u>_LCLM_</u>
Weight	Lot	ESTIMATE	5	.002909021	3	20.7554
<u>_MEAN_</u>	<u>_UCLM_</u>	<u>_LCLR_</u>	<u>_R_</u>	<u>_UCLR_</u>	<u>_STDDEV_</u>	
24.4996	28.2439	0	5.42036	11.4613	2.33041	

The data set Detlim contains one observation with the limits for the *process* Weight. The variables _LCLM_ and _UCLM_ contain the lower and upper control limits for the medians, and the variable _MEAN_ contains the central line. The value of _MEAN_ is an estimate of the process mean, and the value of _STDDEV_ is an estimate of the process standard deviation σ . The value of _LIMITN_ is the nominal sample size associated with the control limits, and the value of _SIGMAS_ is the multiple of σ associated with the control limits. The variables _VAR_ and _SUBGRP_ are bookkeeping variables that save the *process* and *subgroup-variable*. The variable _TYPE_ is a bookkeeping variable that indicates whether the values of _MEAN_ and _STDDEV_ are estimates or standard values.

The variables _LCLR_, _R_, and _UCLR_ are not used to create median charts, but they are included so the data set Detlim can be used to create an *R* chart; see “[MRCHART Statement: SHEWHART Procedure](#)” on page 1615 and “[RCHART Statement: SHEWHART Procedure](#)” on page 1744. If you specify the STDDEVIATIONS option in the MCHART statement, the variables _LCLS_, _S_, and _UCLS_ are included in the OUTLIMITS= data set. These variables can be used to create an *s* chart; see “[SCHART Statement: SHEWHART Procedure](#)” on page 1782. For more information, see “[OUTLIMITS= Data Set](#)” on page 1598.

You can create an output data set containing both control limits and summary statistics with the OUTTABLE= option, as illustrated by the following statements:

```
proc shewhart data=Detergent;
  mchart Weight*Lot / outtable=Dtable
                    nochart;
run;
```

The data set Dtable is listed in Figure 17.41.

Figure 17.41 The Data Set Dtable

Weight	14	3	5	5	20.7554	24.73	24.4996	28.2439	2.33041	
Weight	15	3	5	5	20.7554	25.86	24.4996	28.2439	2.33041	
Weight	16	3	5	5	20.7554	23.99	24.4996	28.2439	2.33041	
Weight	17	3	5	5	20.7554	24.30	24.4996	28.2439	2.33041	
Weight	18	3	5	5	20.7554	24.88	24.4996	28.2439	2.33041	
Weight	19	3	5	5	20.7554	25.92	24.4996	28.2439	2.33041	
Weight	20	3	5	5	20.7554	25.63	24.4996	28.2439	2.33041	
Weight	21	3	5	5	20.7554	25.17	24.4996	28.2439	2.33041	
Weight	22	3	5	5	20.7554	26.72	24.4996	28.2439	2.33041	
Weight	23	3	5	5	20.7554	23.67	24.4996	28.2439	2.33041	
Weight	24	3	5	5	20.7554	24.92	24.4996	28.2439	2.33041	
Weight	25	3	5	5	20.7554	24.51	24.4996	28.2439	2.33041	
Weight	26	3	5	5	20.7554	24.75	24.4996	28.2439	2.33041	
Weight	27	3	5	5	20.7554	25.10	24.4996	28.2439	2.33041	
Weight	28	3	5	5	20.7554	25.64	24.4996	28.2439	2.33041	

This data set contains one observation for each subgroup sample. The variables `_SUBMED_` and `_SUBN_` contain the subgroup medians and subgroup sample sizes. The variables `_LCLM_` and `_UCLM_` contain the lower and upper control limits, and the variable `_MEAN_` contains the central line. The variables `_VAR_` and `Lot` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “`OUTTABLE= Data Set`” on page 1600.

An OUTTABLE= data set can be read later as a TABLE= data set. For example, the following statements read Dtable and display a median chart (not shown here) identical to the chart in Figure 17.35:

```
title 'Median Chart for Detergent Box Weight';
proc shewhart table=Dtable;
  mchart Weight*Lot;
run;
```

Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts (see “Specialized Control Charts: SHEWHART Procedure” on page 2171). For more information, see “TABLE= Data Set” on page 1605.

Reading Prestablished Control Limits

In the previous example, the OUTLIMITS= data set Detlim saved control limits computed from the measurements in Detergent. This example shows how these limits can be applied to new data provided in the following data set: *See SHWMCHR in the SAS/QC Sample Library*

```
data Detergent2;
  input Lot @;
  do i=1 to 5;
    input Weight @;
    output;
  end;
  drop i;
  datalines;
29 16.66 27.49 18.87 22.53 24.72
30 23.74 23.67 23.64 20.26 22.09
31 24.56 24.82 23.92 26.67 21.38
32 25.89 28.73 29.21 25.38 23.47
33 23.32 21.61 30.75 23.13 23.82
34 23.04 22.65 24.96 19.64 26.84
35 24.01 24.38 24.86 26.50 24.37
36 26.43 27.36 28.74 26.74 26.27
37 21.41 22.24 25.34 20.59 27.51
38 22.62 20.81 22.64 30.15 25.32
39 26.86 28.14 24.06 27.35 22.49
40 23.03 23.83 25.59 19.85 22.33
41 23.19 23.63 23.00 21.46 27.57
42 27.38 23.18 24.99 24.81 28.82
43 26.60 26.58 20.26 26.27 24.96

45 25.90 22.88 25.55 24.50 19.95
46 16.66 27.49 18.87 22.53 24.72
47 23.74 23.67 23.64 20.26 22.09
48 24.56 24.82 23.92 26.67 21.38
49 25.89 28.73 29.21 25.38 23.47
50 23.32 21.61 30.75 23.13 23.82
;
```

The following statements create a median chart for the data in Detergent2 using the control limits in Detlim:

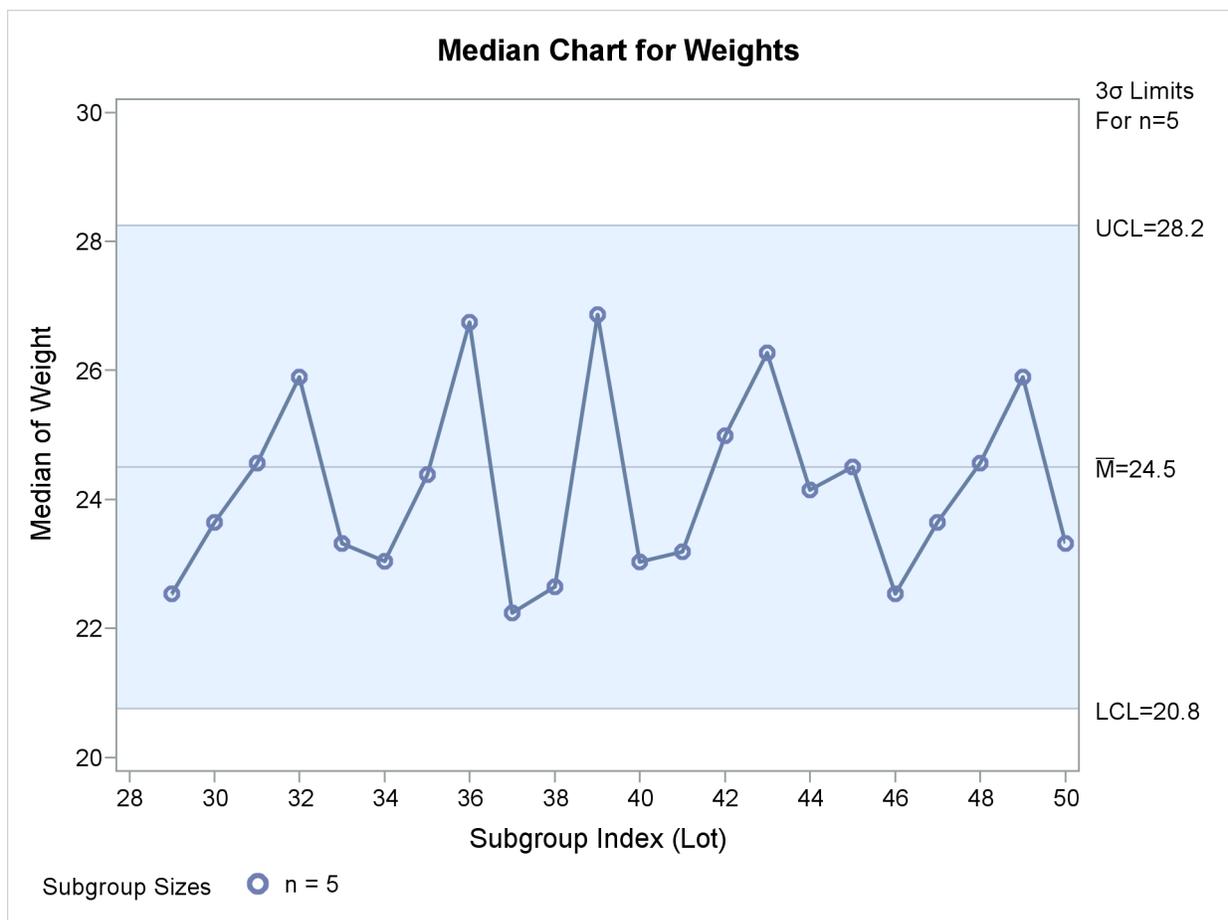

```
ods graphics on;
title 'Median Chart for Weights';
proc shewhart data=Detergent2 limits=Detlim;
  mchart Weight*Lot / odstitle=title markers;
run;
ods graphics off;
```

The ODS GRAPHICS ON statement specified before the PROC SHEWHART statement enables ODS Graphics, so the median chart is created using ODS Graphics instead of traditional graphics. The chart is shown in Figure 17.42.

The LIMITS= option in the PROC SHEWHART statement specifies the data set containing the control limits. By default,¹² this information is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches the *process* name Weight
- the value of `_SUBGRP_` matches the *subgroup-variable* name Lot

Figure 17.42 Median Chart for Second Set of Detergent Box Weight Data (ODS Graphics)

¹²In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

The chart indicates that the process is in control, since all the medians lie within the control limits.

In this example, the LIMITS= data set was created in a previous run of the SHEWHART procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on page 1603 for details concerning the variables that you must provide.

Syntax: MCHART Statement

The basic syntax for the MCHART statement is as follows:

```
MCHART process * subgroup-variable ;
```

The general form of this syntax is as follows:

```
MCHART processes * subgroup-variable <( block-variables ) >  
    <=symbol-variable | ='character'> /< options > ;
```

You can use any number of MCHART statements in the SHEWHART procedure. The components of the MCHART statement are described as follows.

process

processes

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC SHEWHART statement.

- If raw data are read from a DATA= data set, *process* must be the name of the variable containing the raw measurements. For an example, see “Creating Charts for Medians from Raw Data” on page 1572.
- If summary data are read from a HISTORY= data set, *process* must be the common prefix of the summary variables in the HISTORY= data set. For an example, see “Creating Charts for Medians from Subgroup Summary Data” on page 1575.
- If summary data and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “Saving Control Limits” on page 1581.

A *process* is required. If you specify more than one process, enclose the list in parentheses. For example, the following statements request distinct median charts for Weight, Length, and Width:

```
proc shewhart data=Measures;  
    mchart (Weight Length Width)*Day;  
run;
```

subgroup-variable

is the variable that identifies subgroups in the data. The *subgroup-variable* is required. In the preceding MCHART statement, Day is the subgroup variable. For details, see “Subgroup Variables” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or character used to plot the medians.

- If you produce a line printer chart, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOLn statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create a median chart using an asterisk (*) to plot the points:

```
proc shewhart data=Values lineprinter;
  mchart Weight*Day='*';
run;
```

options

enhance the appearance of the charts, request additional analyses, save results in data sets, and so on. The section “[Summary of Options](#)”, which follows, lists all options by function. “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018 describes each option in detail.

Summary of Options

The following tables list the MCHART statement options by function. For complete descriptions, see “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 17.25 MCHART Statement Options

Option	Description
Options for Specifying Control Limits	
ALPHA=	requests probability limits for chart
LIMITN=	specifies either nominal sample size for fixed control limits or varying limits
NOREADLIMITS	computes control limits for each <i>process</i> from the data rather than a LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from a LIMITS= data set

Table 17.25 *continued*

Option	Description
READINDEX=	reads control limits for each <i>process</i> from a LIMITS= data set
READLIMITS	reads single set of control limits for each <i>process</i> from a LIMITS= data set (SAS 6.09 and earlier releases)
SIGMAS=	specifies width of control limits in terms of multiple <i>k</i> of standard error of plotted means
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line
NOCTL	suppresses display of central line
NOLCL	suppresses display of lower control limit
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit
UCLLABEL=	specifies label for upper control limit
WLIMITS=	specifies width for control limits and central line
XSMBOL=	specifies label for central line
Process Mean and Standard Deviation Options	
MEDCENTRAL=	specifies method for estimating process mean μ
MU0=	specifies known value of μ_0 for process mean μ
SIGMA0=	specifies known value σ_0 for process standard deviation σ
SMETHOD=	specifies method for estimating process standard deviation σ
STDDEVIATIONS	specifies that estimate of process standard deviation σ is to be calculated from subgroup standard deviations
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on median chart
ALLLABEL2=	labels every point on trend chart
CLABEL=	specifies color for labels

Table 17.25 *continued*

Option	Description
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
NOTRENDCONNECT	suppresses line segments that connect points on trend chart
OUTLABEL=	labels points outside control limits
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles
Options for Specifying Tests for Special Causes	
INDEPENDENTZONES	computes zone widths independently above and below center line
NO3SIGMACHECK	enables tests to be applied with control limits other than 3σ limits
NOTESTACROSS	suppresses tests across <i>phase</i> boundaries
TESTS=	specifies tests for special causes
TEST2RUN=	specifies length of pattern for Test 2
TEST3RUN=	specifies length of pattern for Test 3
TESTACROSS	applies tests across <i>phase</i> boundaries
TESTLABEL=	provides labels for points where test is positive
TESTLABEL n =	specifies label for n th test for special causes
TESTNMETHOD=	applies tests to standardized chart statistics
TESTOVERLAP	performs tests on overlapping patterns of points
TESTRESET=	enables tests for special causes to be reset
ZONELABELS	adds labels A, B, and C to zone lines
ZONES	adds lines delineating zones A, B, and C
ZONEVALPOS=	specifies position of ZONEVALUES labels
ZONEVALUES	labels zone lines with their values

Table 17.25 *continued*

Option	Description
Options for Displaying Tests for Special Causes	
CTESTLABBOX=	specifies color for boxes enclosing labels indicating points where test is positive
CTESTS=	specifies color for labels indicating points where test is positive
CTESTSYMBOL=	specifies color for symbol used to plot points where test is positive
CZONES=	specifies color for lines and labels delineating zones A, B, and C
LTESTS=	specifies type of line connecting points where test is positive
LZONES=	specifies line type for lines delineating zones A, B, and C
TESTFONT=	specifies software font for labels at points where test is positive
TESTHEIGHT= TESTLABBOX	specifies height of labels at points where test is positive requests that labels for points where test is positive be positioned so that do not overlap
TESTSYMBOL=	specifies plot symbol for points where test is positive
TESTSYMBOLHT=	specifies symbol height for points where test is positive
WTESTS=	specifies width of line connecting points where test is positive
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPHLABELS=	specifies thinning factor for tick mark labels on horizontal axis
SPLIT=	specifies splitting character for axis labels
TURNHLABELS	requests horizontal axis labels that are strung out vertically

Table 17.25 *continued*

Option	Description
VAXIS=	specifies major tick mark values for vertical axis of median chart
VAXIS2=	specifies major tick mark values for vertical axis of trend chart
VFORMAT=	specifies format for primary vertical axis tick mark labels
VFORMAT2=	specifies format for secondary vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis for primary chart
VZERO2	forces origin to be included in vertical axis for secondary chart
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
TRENDVAR=	specifies list of trend variables
YPCT1=	specifies length of vertical axis on median chart as a percentage of sum of lengths of vertical axes for median and trend charts
ZEROSTD	displays median chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= and HREF2= options

Table 17.25 *continued*

Option	Description
CVREF=	specifies color for lines requested by VREF= and VREF2= options
HREF=	specifies position of reference lines perpendicular to horizontal axis on median chart
HREF2=	specifies position of reference lines perpendicular to horizontal axis on trend chart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on median chart
HREF2DATA=	specifies position of reference lines perpendicular to horizontal axis on trend chart
HREFLABELS=	specifies labels for HREF= lines
HREF2LABELS=	specifies labels for HREF2= lines
HREFLABPOS=	specifies position of HREFLABELS= and HREF2LABELS= labels
LHREF=	specifies line type for HREF= and HREF2= lines
LVREF=	specifies line type for VREF= and VREF2= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis on median chart
VREF2=	specifies position of reference lines perpendicular to vertical axis on trend chart
VREFLABELS=	specifies labels for VREF= lines
VREF2LABELS=	specifies labels for VREF2= lines
VREFLABPOS=	position of VREFLABELS= and VREF2LABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points

Table 17.25 continued

Option	Description
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to median chart
ANNOTATE2=	specifies annotate data set that adds features to trend chart
DESCRIPTION=	specifies description of median chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of median chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
WTREND=	specifies width of line segments connecting points on trend chart
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB COUT	draws a frame around labeled points draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote

Table 17.25 *continued*

Option	Description
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
OVERLAY2URL=	specifies URLs to associate with overlay points on secondary chart
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
URL2=	specifies a variable whose values are URLs to be associated with subgroups on secondary chart
Input Data Set Options	
MISSSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLELEGEND	augments basic table with legend for tests for special causes
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
TABLETESTS	augments basic table with a column indicating which tests for special causes are positive

Table 17.25 *continued*

Option	Description
Specification Limit Options	
CIINDICES	specifies α value and type for computing capability index confidence limits
LSL=	specifies list of lower specification limits
TARGET=	specifies list of target values
USL=	specifies list of upper specification limits
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars

Table 17.25 *continued*

Option	Description
STARSPCE=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on median chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for primary chart overlay line segments
CCOVERLAY2=	specifies colors for secondary chart overlay line segments
COVERLAY=	specifies colors for primary chart overlay plots
COVERLAY2=	specifies colors for secondary chart overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for primary chart overlay line segments
LOVERLAY2=	specifies line types for secondary chart overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on primary chart
OVERLAY2=	specifies variables to overlay on secondary chart
OVERLAY2HTML=	specifies links to associate with secondary chart overlay points
OVERLAY2ID=	specifies labels for secondary chart overlay points
OVERLAY2SYM=	specifies symbols for secondary chart overlays
OVERLAY2SYMHT=	specifies symbol heights for secondary chart overlays
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with primary chart overlay points
OVERLAYID=	specifies labels for primary chart overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for primary chart overlays
OVERLAYSYMHT=	specifies symbol heights for primary chart overlays
WOVERLAY=	specifies widths of primary chart overlay line segments
WOVERLAY2=	specifies widths of secondary chart overlay line segments
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML2=	specifies variable whose values create links to be associated with subgroups on secondary chart
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data

Table 17.25 continued

Option	Description
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= and HREF2= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
TESTCHAR=	specifies character for line segments that connect any sequence of points for which a test for special causes is positive
VREFCHAR=	specifies line character for VREF= and VREF2= lines
ZONECHAR=	specifies character for lines that delineate zones for tests for special causes

Details: MCHART Statement

Constructing Median Charts

The following notation is used in this section:

μ	process mean (expected value of the population of measurements)
σ	process standard deviation (standard deviation of the population of measurements)
\bar{X}_i	mean of measurements in i th subgroup
n_i	sample size of i th subgroup
N	the number of subgroups
x_{ij}	j th measurement in the i th subgroup, $j = 1, 2, 3, \dots, n_i$
$x_{i(j)}$	j th largest measurement in the i th subgroup. Then

$$x_{i(1)} \leq x_{i(2)} \leq \dots \leq x_{i(n_i)}$$

$\bar{\bar{X}}$	weighted average of subgroup means
M_i	median of the measurements in the i th subgroup:

$$M_i = \begin{cases} x_{i((n_i+1)/2)} & \text{if } n_i \text{ is odd} \\ (x_{i(n_i/2)} + x_{i((n_i/2)+1)})/2 & \text{if } n_i \text{ is even} \end{cases}$$

\bar{M}	average of the subgroup medians:
-----------	----------------------------------

$$\bar{M} = (n_1 M_1 + \dots + n_N M_N) / (n_1 + \dots + n_N)$$

\tilde{M}	median of the subgroup medians. Denote the j th largest median by $M_{(j)}$ so that $M_{(1)} \leq M_{(2)} \leq \dots \leq M_{(N)}$. Then
-------------	---

$$\tilde{M} = \begin{cases} M_{((N+1)/2)} & \text{if } N \text{ is odd} \\ (M_{(N/2)} + M_{(N/2)+1})/2 & \text{if } N \text{ is even} \end{cases}$$

- $e_M(n)$ standard error of the median of n independent, normally distributed variables with unit standard deviation (the value of $e_M(n)$ can be calculated with the `STDMED` function in a `DATA` step)
- $Q_p(n)$ 100 p th percentile ($0 < p < 1$) of the distribution of the median of n independent observations from a normal population with unit standard deviation
- z_p 100 p th percentile of the standard normal distribution
- $D_p(n)$ 100 p th percentile of the distribution of the range of n independent observations from a normal population with unit standard deviation

Plotted Points

Each point on a median chart indicates the value of a subgroup median (M_i). For example, if the tenth subgroup contains the values 12, 15, 19, 16, and 14, the value plotted for this subgroup is $M_{10} = 15$.

Central Line

The value of the central line indicates an estimate for μ , which is computed as

- \bar{M} by default
- $\bar{\bar{X}}$ when you specify `MEDCENTRAL=AVGMEAN`
- \tilde{M} when you specify `MEDCENTRAL=MEDMED`
- μ_0 when you specify μ_0 with the `MU0=` option

Control Limits

You can compute the limits

- as a specified multiple (k) of the standard error of M_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that M_i exceeds the limits

The following table provides the formulas for the limits:

Table 17.26 Limits for Median Charts

Control Limits
LCLM = lower limit = $\bar{M} - k\hat{\sigma}e_M(n_i)$
UCLM = upper limit = $\bar{M} + k\hat{\sigma}e_M(n_i)$
Probability Limits
LCLM = lower limit = $\bar{M} - Q_{\alpha/2}(n_i)\hat{\sigma}$
UCLM = upper limit = $\bar{M} + Q_{1-\alpha/2}(n_i)\hat{\sigma}$

Note that the limits vary with n_i . In Table 17.26, replace \bar{M} with $\bar{\bar{X}}$ if you specify MEDCENTRAL=AVGMEAN, and replace \bar{M} with \tilde{M} if you specify MEDCENTRAL=MEDMED. Replace \bar{M} with μ_0 if you specify μ_0 with the MU0= option, and replace $\hat{\sigma}$ with σ_0 if you specify σ_0 with the SIGMA0= option. The formulas assume that the data are normally distributed.

You can specify parameters for the limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify μ_0 with the MU0= option or with the variable `_MEAN_` in the LIMITS= data set.
- Specify σ_0 with the SIGMA0= option or with the variable `_STDDEV_` in the LIMITS= data set.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves control limits and control limit parameters. The following variables can be saved:

Table 17.27 OUTLIMITS= Data Set

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding limits
<code>_CP_</code>	capability index C_p
<code>_CPK_</code>	capability index C_{pk}
<code>_CPL_</code>	capability index C_{PL}
<code>_CPM_</code>	capability index C_{pm}
<code>_CPU_</code>	capability index C_{PU}
<code>_INDEX_</code>	optional identifier for the control limits specified with the OUTINDEX= option
<code>_LCLM_</code>	lower control limit for subgroup median
<code>_LCLR_</code>	lower control limit for subgroup range
<code>_LCLS_</code>	lower control limit for subgroup standard deviation
<code>_LIMITN_</code>	sample size associated with the control limits
<code>_LSL_</code>	lower specification limit
<code>_MEAN_</code>	value of central line on median chart (\bar{M} , \tilde{M} , $\bar{\bar{X}}$, or μ_0)
<code>_R_</code>	value of central line on R chart
<code>_S_</code>	value of central line on s chart
<code>_SIGMAS_</code>	multiple (k) of standard error of M_i
<code>_STDDEV_</code>	process standard deviation ($\hat{\sigma}$ or σ_0)
<code>_SUBGRP_</code>	<i>subgroup-variable</i> specified in the MCHART statement
<code>_TARGET_</code>	target value

Table 17.27 continued

Option	Description
TYPE	type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLM	upper control limit for subgroup median
UCLR	upper control limit for subgroup range
UCLS	upper control limit for subgroup standard deviation
USL	upper specification limit
VAR	<i>process</i> specified in the MCHART statement

Notes:

1. The variables _LCLS_, _S_, and _UCLS_ are included if you specify the STDDEVIATIONS option; otherwise, the variables _LCLR_, _R_, and _UCLR_ are included. These variables are not used to create median charts, but they enable the OUTLIMITS= data set to be used as a LIMITS= data set with the BOXCHART, XRCHART, XSCHART, and MRCHART statements.
2. If the control limits vary with subgroup sample size, the special missing value V is assigned to the variables _LIMITN_, _LCLM_, _UCLM_, _LCLR_, _R_, _UCLR_, _LCLS_, _S_, and _UCLS_.
3. If the limits are defined in terms of a multiple k of the standard error of M_i , the value of _ALPHA_ is computed as $\alpha = 2(1 - F_{med}(k, n))$, where $F_{med}(\cdot, n)$ is the cumulative distribution function of the median of a random sample of n standard normally distributed observations, and n is the value of _LIMITN_. If _LIMITN_ has the special missing value V , this value is assigned to _ALPHA_.
4. If the limits are probability limits, the value of _SIGMAS_ is computed as $k = F_{med}^{-1}(1 - \alpha/2, n)$, where $F_{med}^{-1}(\cdot, n)$ is the inverse distribution function of the median of a random sample of n standard normally distributed observations, and n is the value of _LIMITN_. If _LIMITN_ has the special missing value V , this value is assigned to _SIGMAS_.
5. The variables _CP_, _CPK_, _CPL_, _CPU_, _LSL_, and _USL_ are included only if you provide specification limits with the LSL= and USL= options. The variables _CPM_ and _TARGET_ are included if, in addition, you provide a target value with the TARGET= option. See “[Capability Indices](#)” on page 1941 for computational details.
6. Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *process* specified in the MCHART statement. For an example, see “[Saving Control Limits](#)” on page 1581.

OUTHISTORY= Data Set

The OUTHISTORY= option saves subgroup summary statistics. The following variables can be saved:

- the *subgroup-variable*

- a subgroup median variable named by *process* suffixed with *M*
- a subgroup range variable named by *process* suffixed with *R*
- a subgroup standard deviation variable named by *process* suffixed with *S*
- a subgroup sample size variable named by *process* suffixed with *N*

A subgroup standard deviation variable is included if you specify the STDDEVIATIONS option; otherwise, a subgroup range variable is included.

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Variables containing subgroup summary statistics are created for each *process* specified in the MCHART statement. For example, consider the following statements:

```
proc shewhart data=Steel;
  mchart (Width Diameter)*Lot / outhistory=Summary;
run;
```

The data set Summary contains variables named Lot, WidthM, WidthR, WidthN, DiameterM, DiameterR, and DiameterN. The variables WidthR and DiameterR are included, since the STDDEVIATIONS option is not specified. If you specified the STDDEVIATIONS option, the data set Summary would contain WidthS and DiameterS rather than WidthR and DiameterR.

Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

For an example of an OUTHISTORY= data set, see “Saving Summary Statistics” on page 1578.

OUTTABLE= Data Set

The OUTTABLE= data set saves subgroup summary statistics, control limits, and related information. The following variables are saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_EXLIM_</code>	control limit exceeded on median chart
<code>_LCLM_</code>	lower control limit for median
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_MEAN_</code>	estimate of process mean (\bar{M} , \tilde{M} , \bar{X} , or μ_0)
<code>_SIGMAS_</code>	multiple (k) of the standard error associated with control limits
<code>subgroup</code>	values of the subgroup variable
<code>_SUBMED_</code>	subgroup median
<code>_SUBN_</code>	subgroup sample size
<code>_TESTS_</code>	tests for special causes signaled on median chart
<code>_UCLM_</code>	upper control limit for median
<code>_VAR_</code>	<i>process</i> specified in the MCHART statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the READPHASES= option is specified)
- `_TREND_` (if the TRENDVAR= option is specified)

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved depending on how the control limits are defined (with the ALPHA= or SIGMAS= options, respectively, or with the corresponding variables in a LIMITS= data set).
2. The variable `_TESTS_` is saved if you specify the TESTS= option. The k th character of a value of `_TESTS_` is k if Test k is positive at that subgroup. For example, if you request all eight tests and Tests 2 and 8 are positive for a given subgroup, the value of `_TESTS_` has a 2 for the second character, an 8 for the eighth character, and blanks for the other six characters.
3. The variables `_EXLIM_` and `_TESTS_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “Saving Control Limits” on page 1581.

ODS Tables

The following table summarizes the ODS tables that you can request with the MCHART statement.

Table 17.28 ODS Tables Produced with the MCHART Statement

Table Name	Description	Options
MCHART	median chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLELEG, TABLEOUT, TABLETESTS
TestDescriptions	descriptions of tests for special causes requested with the TESTS= option for which at least one positive signal is found	TABLEALL, TABLELEG

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the SHEWHART procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. MCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the MCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 17.29](#).

Table 17.29 ODS Graphics Produced by the MCHART Statement

ODS Graph Name	Plot Description
MChart	median chart

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (process measurements) from a DATA= data set specified in the PROC SHEWHART statement. Each *process* specified in the MCHART statement must be a SAS variable in the DATA= data set. This variable provides measurements that must be grouped into subgroup samples indexed by the values of the *subgroup-variable*. The *subgroup-variable*, which is specified in the MCHART statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a value for each *process* and a value for the *subgroup-variable*. If the *i*th subgroup contains n_i items, there should be n_i consecutive observations for which the value of the *subgroup-variable* is the index of the *i*th subgroup. For example, if each subgroup contains five items and there are 30 subgroup samples, the DATA= data set should contain 150 observations.

Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a DATA= data set. However, if the DATA= data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (for an example, see “[Displaying Stratification in Phases](#)” on page 2103).

For an example of a DATA= data set, see “[Creating Charts for Medians from Raw Data](#)” on page 1572.

LIMITS= Data Set

You can read preestablished control limits (or parameters from which the control limits can be calculated) from a LIMITS= data set specified in the PROC SHEWHART statement. For example, the following statements read control limit information from the data set `Conlims`:¹³

```
proc shewhart data=Info limits=Conlims;
    mchart Weight*Batch;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the SHEWHART procedure. Such data sets always contain the variables required for a LIMITS= data set. The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LCLM_`, `_MEAN_`, and `_UCLM_`, which specify the control limits directly

¹³In SAS 6.09 and in earlier releases, it is necessary to specify the READLIMITS option.

- the variables `_MEAN_` and `_STDDEV_`, which are used to calculate the control limits according to the equations in [Table 17.26](#)

In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables whose lengths are no greater than 32.
- The variable `_INDEX_` is required if you specify the `READINDEX=` option; this must be a character variable whose length is no greater than 48.
- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8; valid values are ‘ESTIMATE’, ‘STANDARD’, ‘STDMU’, and ‘STDSIGMA’.
- BY variables are required if specified with a BY statement.

For an example, see the section “[Reading Preestablished Control Limits](#)” on page 1583.

HISTORY= Data Set

You can read subgroup summary statistics from a `HISTORY=` data set specified in the `PROC SHEWHART` statement. This enables you to reuse `OUTHISTORY=` data sets that have been created in previous runs of the `SHEWHART` procedure or to read output data sets created with SAS summarization procedures, such as `PROC UNIVARIATE`.

A `HISTORY=` data set used with the `MCHART` statement must contain the following:

- the *subgroup-variable*
- a subgroup mean variable for each *process*
- a subgroup median variable for each *process*
- a subgroup sample size variable for each *process*
- either a subgroup range variable or a subgroup standard deviation variable for each *process*

The names of the subgroup summary statistics variables must be the *process* name concatenated with the following special suffix characters:

Subgroup Summary Statistic	Suffix Character
subgroup median	M
subgroup mean	X
subgroup sample size	N
subgroup range	R
subgroup standard deviation	S

You must provide the subgroup mean variable only if you specify the `MEDCENTRAL=AVGMEAN` option. If you specify the `STDDEVIATIONS` option, the subgroup standard deviation variable must be included; otherwise, the subgroup range variable must be included.

For example, consider the following statements:

```
proc shewhart history=Summary;
  mchart (Weight Yieldstrength)*Batch / medcentral=avgmean;
run;
```

The data set Summary must include the variables Batch, WeightX, WeightM, WeightR, WeightN, YieldstrengthX, YieldstrengthM, YieldstrengthR, and YieldstrengthN. If the STDDEVIATIONS option were specified in the preceding MCHART statement, it would be necessary for Summary to include the variables Batch, WeightX, WeightM, WeightS, WeightN, YieldstrengthX, YieldstrengthM, YieldstrengthS, and YieldstrengthN.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a HISTORY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all the observations in a HISTORY= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (see “[Displaying Stratification in Phases](#)” on page 2103 for an example).

For an example of a HISTORY= data set, see “[Creating Charts for Medians from Subgroup Summary Data](#)” on page 1575.

TABLE= Data Set

You can read summary statistics and control limits from a TABLE= data set specified in the PROC SHEWHART statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the SHEWHART procedure. Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts. Examples are provided in “[Specialized Control Charts: SHEWHART Procedure](#)” on page 2171.

The following table lists the variables required in a TABLE= data set used with the MCHART statement:

Table 17.30 Variables Required in a TABLE= Data Set

Variable	Description
LCLM	lower control limit for median
LIMITN	nominal sample size associated with the control limits
MEAN	process mean
<i>subgroup-variable</i>	values of the <i>subgroup-variable</i>
SUBMED	subgroup median
SUBN	subgroup sample size
UCLM	upper control limit for median

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- _PHASE_ (if the READPHASES= option is specified). This variable must be a character variable whose length is no greater than 48.
- _TESTS_ (if the TESTS= option is specified). This variable is used to flag tests for special causes and must be a character variable of length 8.
- _VAR_. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable whose length is no greater than 32.

For an example of a TABLE= data set, see “Saving Control Limits” on page 1581.

Methods for Estimating the Standard Deviation

When control limits are determined from the input data, three methods (referred to as default, MVLUE, and RMSDF) are available with the MCHART statement for estimating the process standard deviation σ . The method used to calculate σ depends on whether you specify the STDDEVIACTIONS option in the MCHART statement. If this option is specified, σ is estimated using subgroup standard deviations; otherwise, σ is estimated using subgroup ranges. For further details and formulas, see “Methods for Estimating the Standard Deviation” on page 1890.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical	DATA=	<i>process</i>
Vertical	HISTORY=	subgroup median variable
Vertical	TABLE=	<code>_SUBMED_</code>

If you specify the TRENDVAR= option, you can provide distinct labels for the vertical axes of the median and trend charts by breaking the vertical axis into two parts with a split character. Specify the split character with the SPLIT= option. The first part labels the vertical axis of the median chart, and the second part labels the vertical axis of the trend chart.

For an example, see “[Labeling Axes](#)” on page 2136.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: MCHART Statement

This section provides more advanced examples of the MCHART statement.

Example 17.14: Controlling Value of Central Line

You can specify options in the MCHART statement to request one of the following values for the central line on median charts:

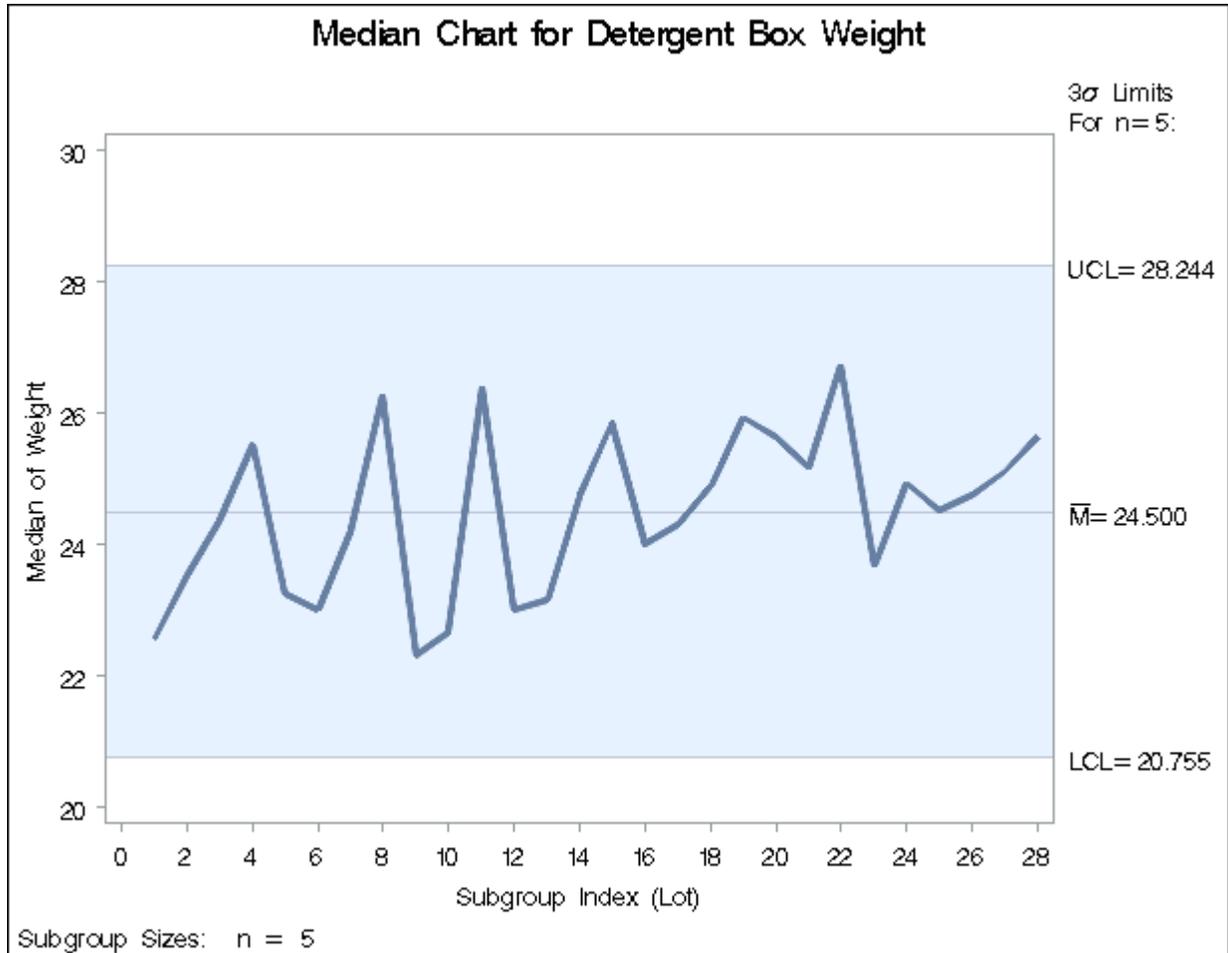

- the average of the subgroup medians
- the average of the subgroup means
- the median of the subgroup medians
- a standard value of the process mean

By default, the value of the central line is the average of the subgroup medians. The following statements create a median chart for the detergent box weights stored in the data set Detergent (see “[Creating Charts for Medians from Raw Data](#)” on page 1572) with the average of the subgroup medians as the central line. The resulting chart is shown in [Output 17.14.1](#).

```
ods graphics off;
title 'Median Chart for Detergent Box Weight';
proc shewhart data=Detergent;
  mchart Weight*Lot / ndecimal = 3;
run;
```

The NDECIMAL= option specifies the number of decimal digits in the default labels for the control limits and central line.

Output 17.14.1 Central Line is Average of Subgroup Medians

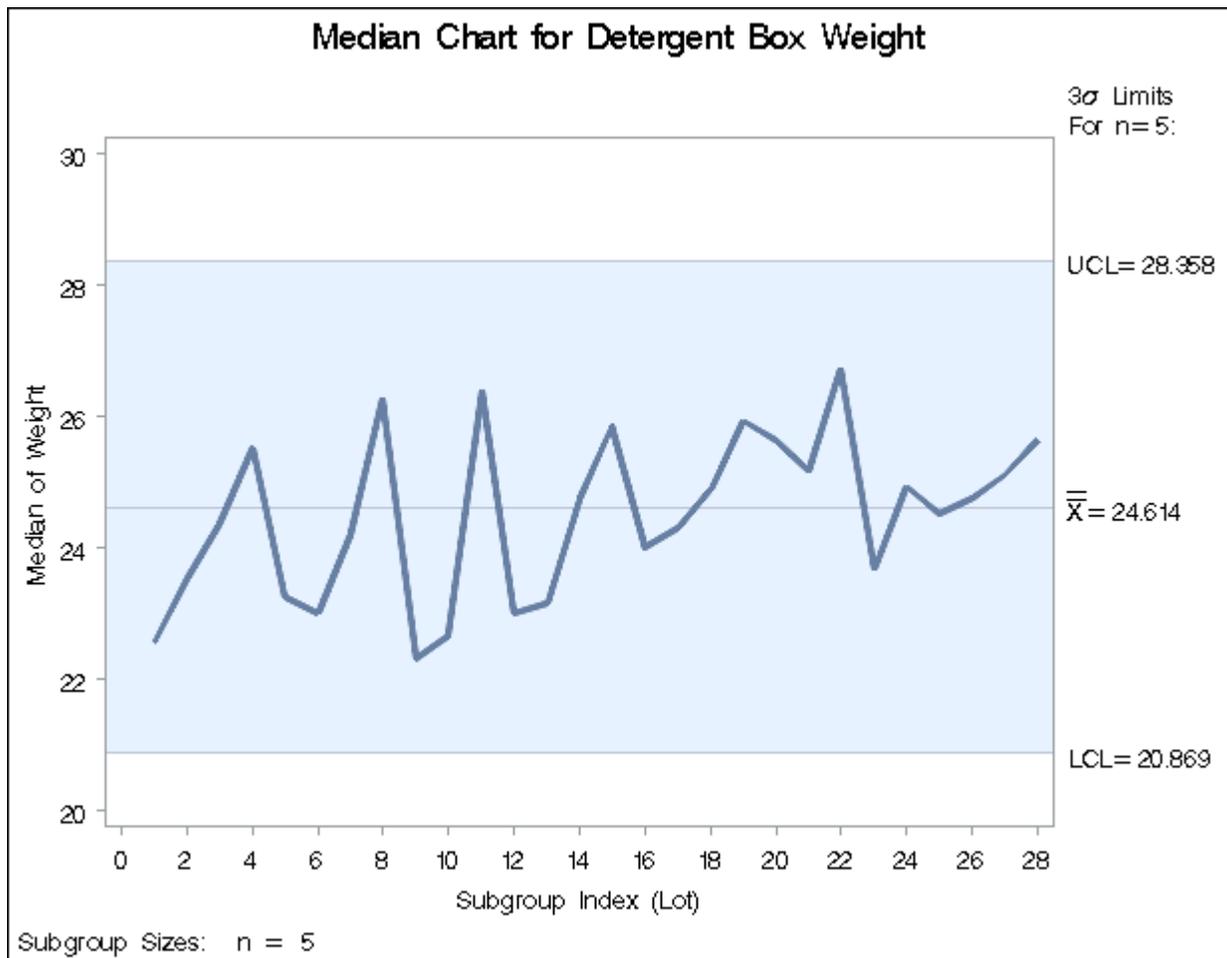

You can also request that the central line indicate the average of the subgroup means. The following statements create a median chart with this value for the central line:

```
title 'Median Chart for Detergent Box Weight';
proc shewhart data=Detergent;
  mchart Weight*Lot / ndecimal = 3
                    medcentral = avgmean;
run;
```

The MEDCENTRAL= option specifies the value used for the central line. In this case, MEDCENTRAL=AVGMEAN is specified to request a central line indicating the average of the subgroup

means. The resulting chart is shown in [Output 17.14.2](#).

Output 17.14.2 Central Line is Average of Subgroup Means

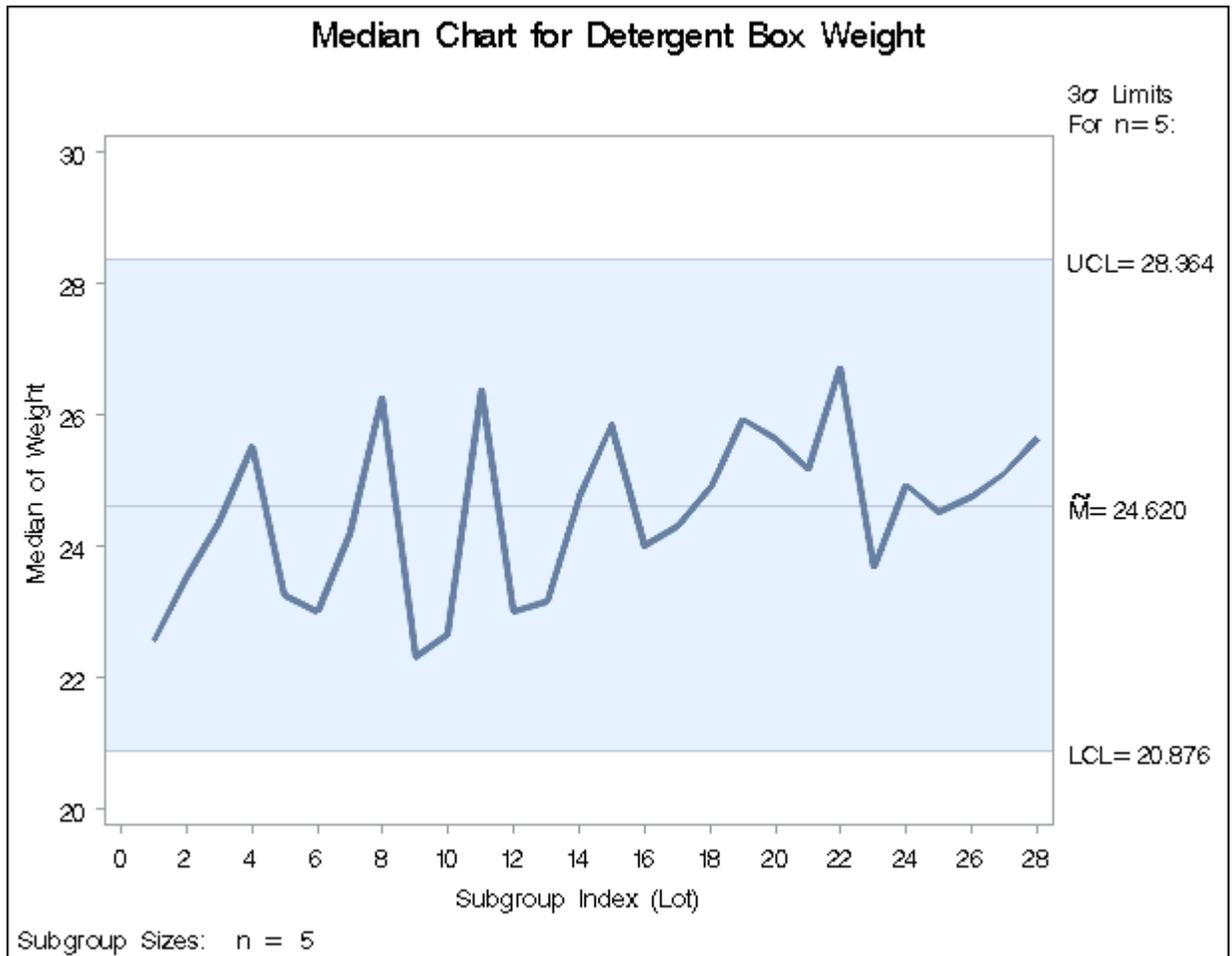

If you specify MEDCENTRAL=MEDMED, the median of the subgroup medians is used for the central line, as demonstrated by the following statements:

```

title 'Median Chart for Detergent Box Weight';
proc shewhart data=Detergent;
  mchart Weight*Lot / ndecimal = 3
                    medcentral = medmed;
run;

```

The resulting chart is shown in [Output 17.14.3](#).

Output 17.14.3 Central Line is Median of Subgroup Medians

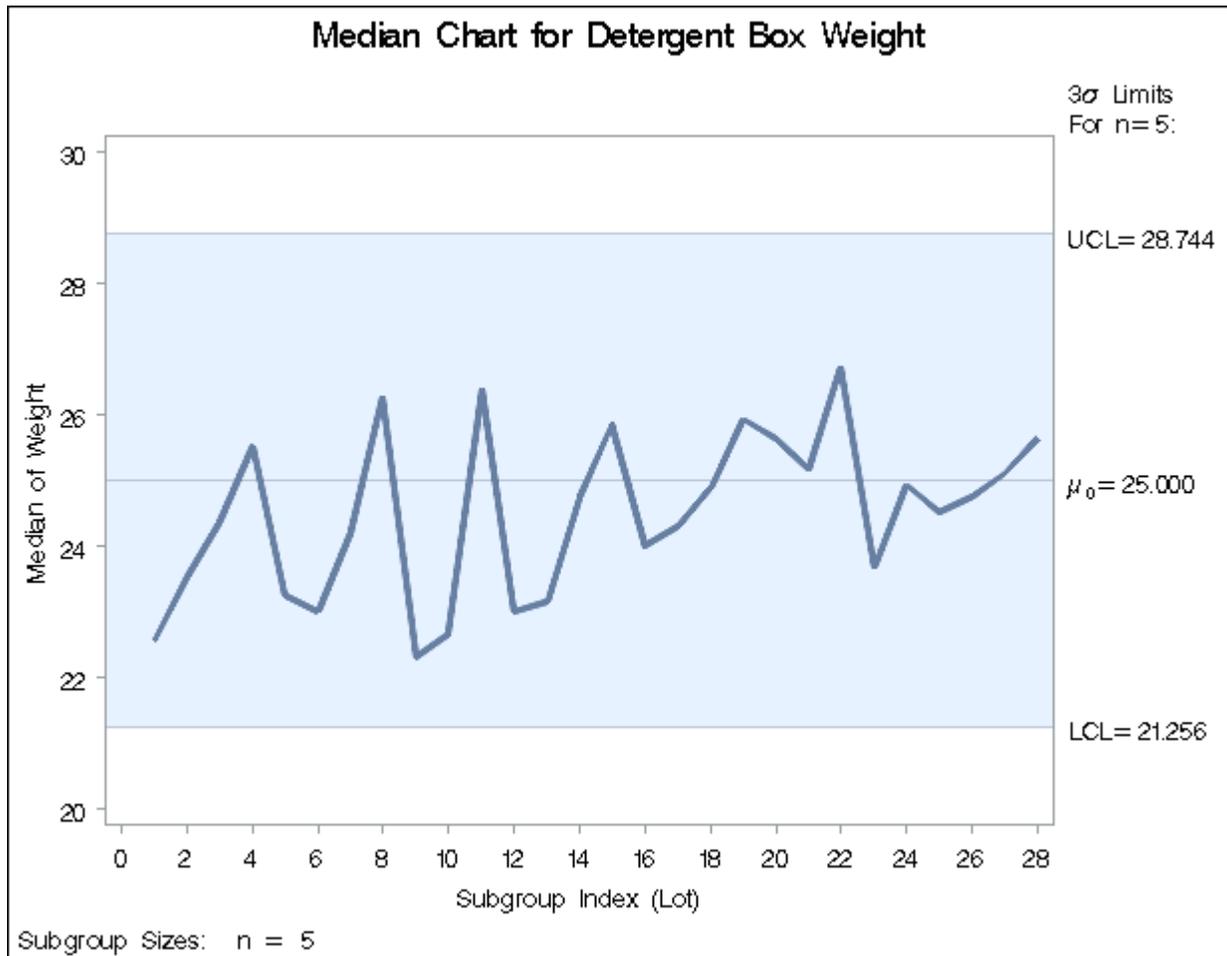

In some situations a standard value for the process mean (μ_0) is available. For instance, extensive startup testing provides an estimate of the process mean. If specified, this value is used for the central line. The following statements create a median chart for the detergent box weights with $\mu_0 = 25$:

```

title 'Median Chart for Detergent Box Weight';
proc shewhart data=Detergent;
  mchart Weight*Lot / ndecimal = 3
                    mu0      = 25
                    xsymbol  = mu0;
run;

```

The MU0= option specifies the standard value for the process mean, and the XSYMBOL= option specifies the label for the central line. In this case, XSYMBOL=MU0 is specified to indicate that the central line represents a standard value. The resulting chart is shown in [Output 17.14.4](#).

Output 17.14.4 Median Chart for Detergent Box Weight Data

Note that you can also provide μ_0 with the `_MEAN_` variable in a `LIMITS=` data set. For example, the following DATA step creates a data set (Dlims) which contains the same standard value specified in the preceding MCHART statement:

```
data Dlims;
  _var_   = "Weight ";
  _subgrp_ = "Lot   ";
  _mean_  = 25;
run;
```

The `_VAR_` and `_SUBGRP_` variables are required if this data set is to be read as a `LIMITS=` data set in the PROC SHEWHART statement. These values must match the names of the *process* and *subgroup-variable* specified in the MCHART statement. The following statements specify the data set Dlims as a `LIMITS=` data set and create a median chart (not shown here) identical to the one in Output 17.14.4:

```

title 'Median Chart for Detergent Box Weight';
symbol v=dot;
proc shewhart data=Detergent limits=Dlims;
  mchart Weight*Lot / xsymbol =mu0
                    ndecimal=3;
run;

```

For more information, see “Constructing Median Charts” on page 1596.

Example 17.15: Estimating the Process Standard Deviation

The following data set (Wire) contains breaking strength measurements recorded in pounds per inch for 25 samples from a metal wire manufacturing process. The subgroup sample sizes vary between 3 and 7.

```

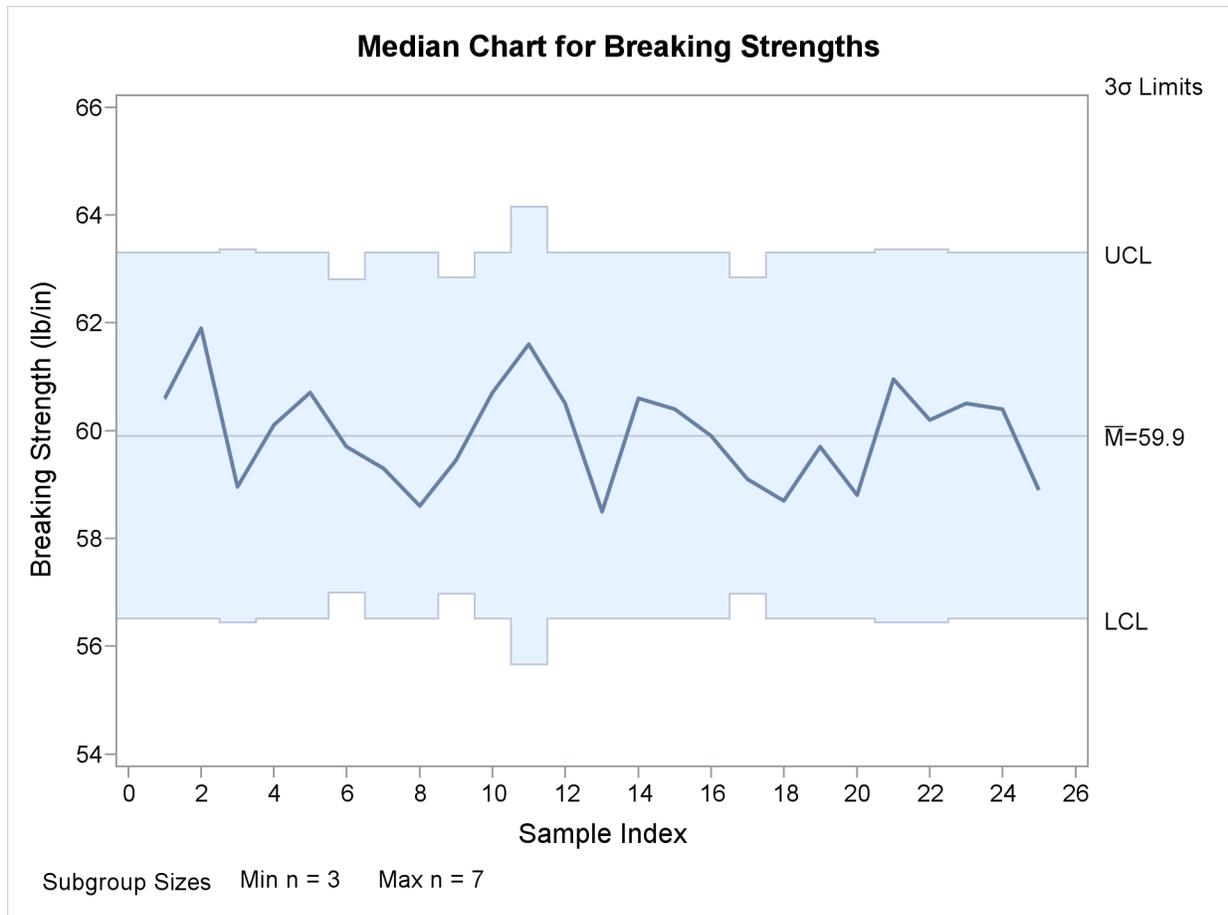

data Wire;
  input Sample Size @;
  do i=1 to Size;
    input Breakstrength @@;
    output;
  end;
  drop i size;
  label Breakstrength = 'Breaking Strength (lb/in)'
        Sample = 'Sample Index';
  datalines;
1  5 60.6 62.3 62.0 60.4 59.9
2  5 61.9 62.1 60.6 58.9 65.3
3  4 57.8 60.5 60.1 57.7
4  5 56.8 62.5 60.1 62.9 58.9
5  5 63.0 60.7 57.2 61.0 53.5

;

```

The following statements request a median chart, shown in [Output 17.15.1](#), for the wire breaking strength measurements:

```
title 'Median Chart for Breaking Strengths';
ods graphics on;
proc shewhart data=Wire;
  mchart Breakstrength*Sample / odstitle=title;
run;
```

Output 17.15.1 Median Chart with Varying Sample Sizes

Note that the control limits vary with the subgroup sample size. The sample size legend in the lower left corner displays the minimum and maximum subgroup sample sizes.

By default, the control limits shown in [Output 17.15.1](#) are 3σ limits estimated from the data. You can use the `STDDEVIATIONS` option and the `SMETHOD=` option in the `MCHART` statement to control how the estimate of the process standard deviation σ is calculated. The `STDDEVIATIONS` option specifies that the estimate of σ is to be calculated from subgroup standard deviations rather than subgroup ranges, the default. The `SMETHOD=` option specifies the method for estimating σ . You can specify the following methods:

- NOWEIGHT
- MVLUE
- RMSDF

The NOWEIGHT method, which is the default, requests an unweighted average of subgroup estimates, the MVLUE method requests a minimum variance linear unbiased estimate, and the RMSDF method requests a weighted root-mean-square estimate. Note that the RMSDF method is only available if, in addition, you specify the STDDEVIATIONS option. For details, see “[Methods for Estimating the Standard Deviation](#)” on page 1606.

The following statements contain five MCHART statements, which calculate five different estimates for σ by specifying different combinations of options:

```

title 'Estimates of the Process Standard Deviation';
proc shewhart data=Wire;
  mchart Breakstrength*Sample / outlimits=Wirelim1
        nochart outindex = 'NOWEIGHT-Ranges';
  mchart Breakstrength*Sample / outlimits=Wirelim2
        stddeviations
        nochart outindex = 'NOWEIGHT-Stds';
  mchart Breakstrength*Sample / outlimits=Wirelim3
        smethod =mvlue
        nochart outindex = 'MVLUE -Ranges';
  mchart Breakstrength*Sample / outlimits=Wirelim4
        stddeviations
        smethod =mvlue
        nochart outindex = 'MVLUE -Stds';
  mchart Breakstrength*Sample / outlimits=Wirelim5
        stddeviations
        smethod =rmsdf
        nochart outindex = 'RMSDF -Stds';

run;

```

The OUTLIMITS= option names the data set containing the control limit information. The _STDDEV_ variable in the OUTLIMITS= data set contains the estimate of the process standard deviation. The OUTINDEX= option specifies the value of the _INDEX_ variable in the OUTLIMITS= data set and is used in this example to identify the estimation method. The following statements create a data set named Wlimits, which contains the five different estimates. This data set is listed in [Output 17.15.2](#).

```

data Wlimits;
  set Wirelim1 Wirelim2 Wirelim3 Wirelim4 Wirelim5;
  keep _index_ _stddev_;
run;

```

Output 17.15.2 The Data Set Wlimits

The Wlimits Data Set		
<u>INDEX</u>		<u>STDDEV</u>
	NOWEIGHT-Ranges	2.11146
	NOWEIGHT-Stds	2.15453
	MVLUE -Ranges	2.11240
	MVLUE -Stds	2.14790
	RMSDF -Stds	2.17479

The median chart shown in [Output 17.14.1](#) uses the estimate listed first in [Output 17.15.2](#) ($\sigma = 2.11146$), since the MCHART statement used to create this chart omitted the STDDEVIATIONS option and the SMETHOD= option.

MRCHART Statement: SHEWHART Procedure

Overview: MRCHART Statement

The MRCHART statement creates charts for subgroup medians and ranges, which are used to analyze the central tendency and variability of a process.

You can use options in the MRCHART statement to

- compute control limits from the data based on a multiple of the standard error of the plotted medians and ranges or as probability limits
- tabulate subgroup sample sizes, subgroup medians, subgroup ranges, control limits, and other information
- save control limits in an output data set
- save subgroup sample sizes, subgroup medians, and subgroup ranges in an output data set
- read preestablished control limits from a data set
- apply tests for special causes (also known as runs tests and Western Electric rules)
- specify the method for estimating the process standard deviation
- specify a known (standard) process mean and standard deviation for computing control limits
- display distinct sets of control limits for data from successive time phases
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors

- clip extreme points to make the charts more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have three alternatives for producing charts of medians and ranges with the MRCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: MRCHART Statement

This section introduces the MRCHART statement with simple examples that illustrate commonly used options. Complete syntax for the MRCHART statement is presented in the section “Syntax: MRCHART Statement” on page 1628, and advanced examples are given in the section “Examples: MRCHART Statement” on page 1651.

Creating Charts for Medians and Ranges from Raw Data

See SHWMR1 in the SAS/QC Sample Library A consumer products company weighs detergent boxes (in pounds) to determine whether the fill process is in control. The following statements create a SAS data set named Detergent, which contains the weights for five boxes in each of 28 lots. A lot is considered a rational subgroup.

```
data Detergent;
  input Lot @;
  do i=1 to 5;
    input Weight @;
    output;
  end;
  drop i;
  datalines;
1 17.39 26.93 19.34 22.56 24.49
2 23.63 23.57 23.54 20.56 22.17
3 24.35 24.58 23.79 26.20 21.55
4 25.52 28.02 28.44 25.07 23.39
5 23.25 21.76 29.80 23.09 23.70
6 23.01 22.67 24.70 20.02 26.35
7 23.86 24.19 24.61 26.05 24.18
```

```

8 26.00 26.82 28.03 26.27 25.85
9 21.58 22.31 25.03 20.86 26.94
10 22.64 21.05 22.66 29.26 25.02
11 26.38 27.50 23.91 26.80 22.53
12 23.01 23.71 25.26 20.21 22.38
13 23.15 23.53 22.98 21.62 26.99
14 26.83 23.14 24.73 24.57 28.09
15 26.15 26.13 20.57 25.86 24.70
16 25.81 23.22 23.99 23.91 27.57
17 25.53 22.87 25.22 24.30 20.29
18 24.88 24.15 25.29 29.02 24.46

26 23.80 24.03 24.75 24.82 27.21
27 25.10 26.09 27.21 24.28 22.45
28 25.53 22.79 26.26 25.85 25.64
;

```

A partial listing of Detergent is shown in [Figure 17.43](#).

Figure 17.43 Partial Listing of the Data Set Detergent

The Data Set DETERGENT	
Lot	Weight
1	17.39
1	26.93
1	19.34
1	22.56
1	24.49
2	23.63
2	23.57
2	23.54
2	20.56
2	22.17
3	24.35
3	24.58
3	23.79
3	26.20
3	21.55
4	25.52

The data set Detergent is said to be in “strung-out” form, since each observation contains the lot number and weight of a single box. The first five observations contain the weights for the first lot, the second five observations contain the weights for the second lot, and so on. Because the variable Lot classifies the observations into rational subgroups, it is referred to as the *subgroup-variable*. The variable Weight contains the weights and is referred to as the *process variable* (or *process* for

short).

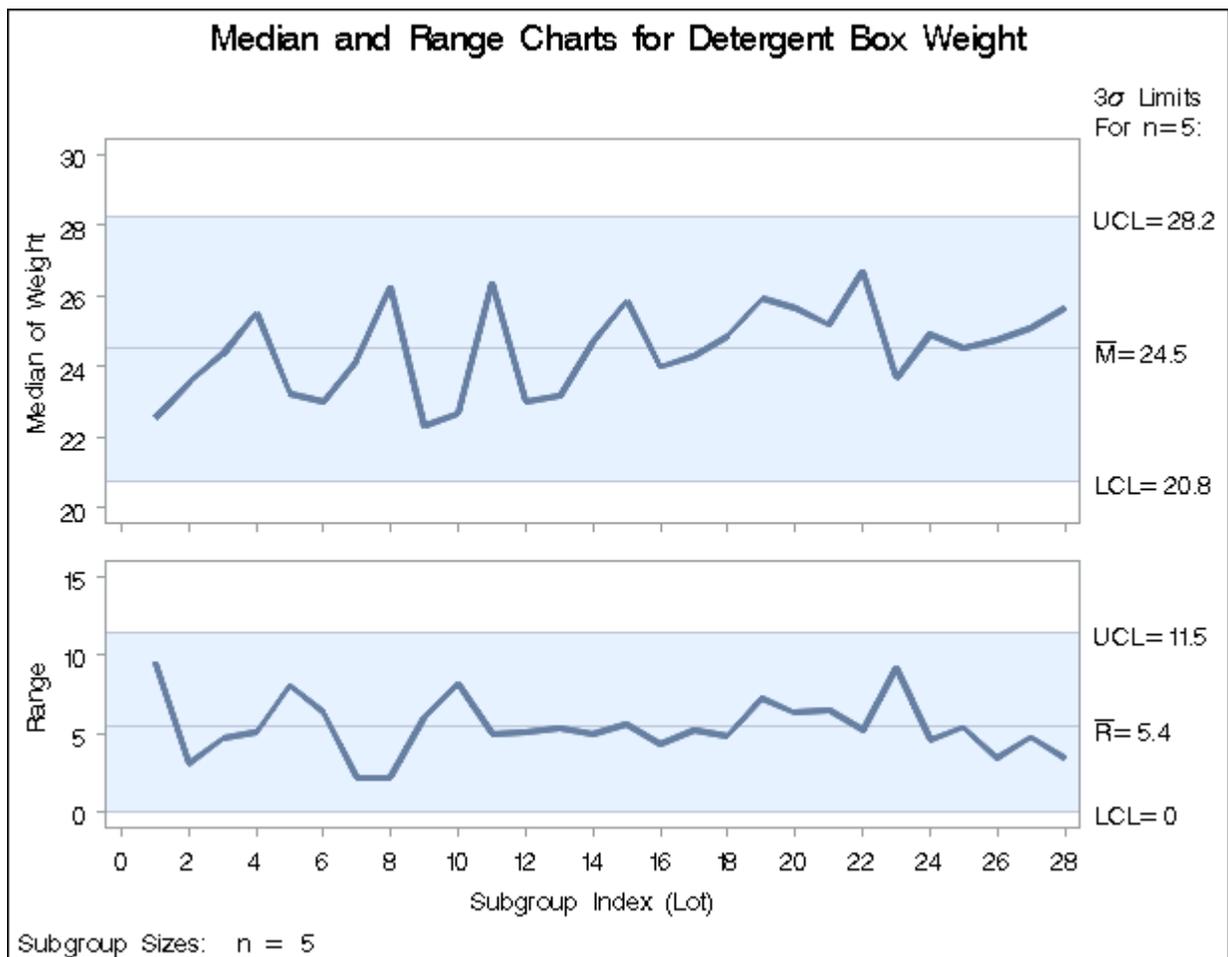

You can use median and range charts to determine whether the fill process is in control. The following statements create the charts shown in Figure 17.44:

```
ods graphics off;
title 'Median and Range Charts for Detergent Box Weight';
proc shewhart data=Detergent;
  mrchart Weight*Lot ;
run;
```

This example illustrates the basic form of the MRCHART statement. After the keyword MRCHART, you specify the *process* to analyze (in this case, Weight) followed by an asterisk and the *subgroup-variable* (Lot).

The input data set is specified with the DATA= option in the PROC SHEWHART statement.

Figure 17.44 Median and Range Charts (Traditional Graphics)

Each point on the median chart represents the median of the measurements for a particular lot. For instance, the weights for the first lot are 17.39, 19.34, 22.56, 24.49, and 26.93, and consequently, the median plotted for this lot is 22.56. Each point on the range chart represents the range of the measurements for a particular batch. For instance, the range plotted for the first lot is 26.93 – 17.39

= 9.54. Since all of the points lie within the control limits, you can conclude that the process is in statistical control.

By default, the control limits shown are 3σ limits estimated from the data; the formulas for the limits are given in Table 17.32. You can also read control limits from an input data set; see “Reading Preestablished Control Limits” on page 1626.

For computational details, see “Constructing Charts for Medians and Ranges” on page 1640. For more details on reading raw data, see “DATA= Data Set” on page 1646.

Creating Charts for Medians and Ranges from Summary Data

The previous example illustrates how you can create median and range charts using raw data (process measurements). However, in many applications, the data are provided as subgroup summary statistics. This example illustrates how you can use the MRCHART statement with data of this type. *See SHWMR1 in the SAS/QC Sample Library*

The following data set (Detsum) provides the data from the preceding example in summarized form. There is exactly one observation for each subgroup (note that the subgroups are still indexed by Lot). The variable WeightM contains the subgroup medians, the variable WeightR contains the subgroup ranges, and the variable WeightN contains the subgroup sample sizes (these are all five).

```
data Detsum;
  input Lot WeightM WeightR;
  WeightN = 5;
  datalines;
1  22.56  9.54
2  23.54  3.07
3  24.35  4.65
4  25.52  5.05
5  23.25  8.04
6  23.01  6.33
7  24.19  2.19
8  26.27  2.18
9  22.31  6.08
10 22.66  8.21
11 26.38  4.97
12 23.01  5.05
13 23.15  5.37
14 24.73  4.95
15 25.86  5.58
16 23.99  4.35
17 24.30  5.24
18 24.88  4.87
19 25.92  7.22
20 25.63  6.30
21 25.17  6.52
22 26.72  5.18
23 23.67  9.17
24 24.92  4.62
25 24.51  5.40
26 24.75  3.41
27 25.10  4.76
28 25.64  3.47
;
```

A partial listing of Detsum is shown in [Figure 17.45](#).

Figure 17.45 The Summary Data Set Detsum

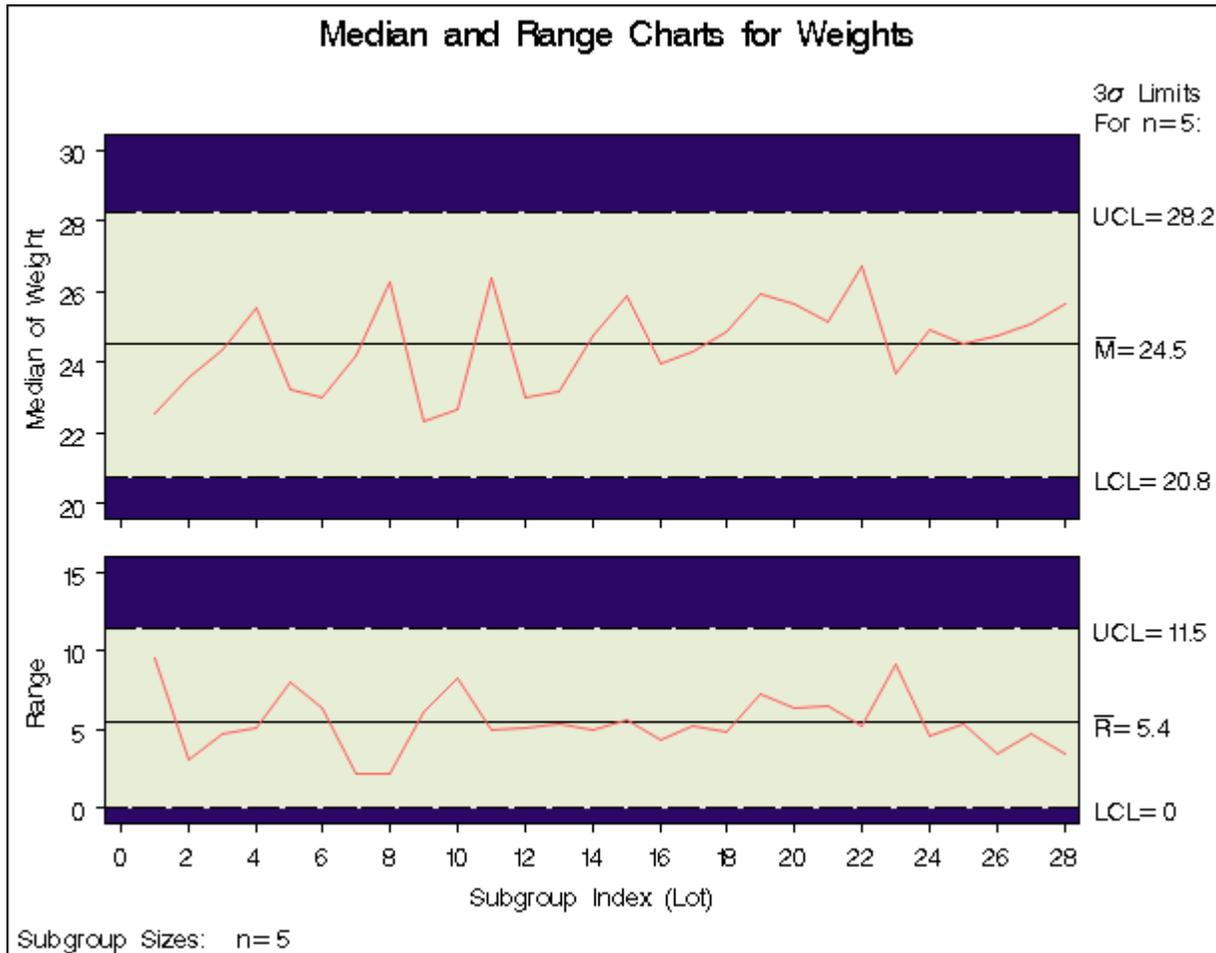

Summary Data for Detergent Box Weights			
Lot	Weight M	Weight R	Weight N
1	22.56	9.54	5
2	23.54	3.07	5
3	24.35	4.65	5
4	25.52	5.05	5
5	23.25	8.04	5

You can read this data set by specifying it as a HISTORY= data set in the PROC SHEWHART statement, as follows:

```
options nogstyle;
options ftext=swiss;
symbol color = rose h = .8;
title 'Median and Range Charts for Weights';
proc shewhart history=Detsum;
    mrchart Weight*Lot / cframe    = vipb
                        cinfll    = ywh
                        cconnect  = rose
                        coutfill  = salmon;
run;
options gstyle;
```

The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the SYMBOL statement and MRCHART statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently. The charts are shown in [Figure 17.46](#).

Figure 17.46 Median and Range Charts from Summary Data Set Detsum (Traditional Graphics with NOGSTYLE)

Note that *Weight* is *not* the name of a SAS variable in the data set *Detsum* but is, instead, the common prefix for the names of the three SAS variables *WeightM*, *WeightR*, and *WeightN*. The suffix characters *M*, *R*, and *N* indicate *median*, *range*, and *sample size*, respectively. This naming convention enables you to specify three subgroup summary variables in the *HISTORY=* data set with a single name (*Weight*), referred to as the *process*. The name *Lot* specified after the asterisk is the name of the *subgroup-variable*.

In general, a *HISTORY=* input data set used with the *MRCHART* statement must contain the following variables:

- subgroup variable
- subgroup median variable
- subgroup range variable
- subgroup sample size variable

Furthermore, the names of the subgroup median, range, and sample size variables must begin with the prefix *process* specified in the MRCHART statement and end with the special suffix characters *M*, *R*, and *N*, respectively. If the names do not follow this convention, you can use the RENAME option to rename the variables for the duration of the SHEWHART procedure step. Suppose that, instead of the variables WeightM, WeightR, and WeightN, the data set Detsum contained summary variables named medians, ranges, and sizes. The following statements would temporarily rename medians, ranges, and sizes to WeightM, WeightR, and WeightN, respectively:

```
proc shewhart
  history=Detsum (rename=(medians = WeightM
                        ranges   = WeightR
                        sizes    = WeightN ));
  mrchart Weight*Lot;
run;
```

In summary, the interpretation of *process* depends on the input data set:

- If raw data are read using the DATA= option (as in the previous example), *process* is the name of the SAS variable containing the process measurements.
- If summary data are read using the HISTORY= option (as in this example), *process* is the common prefix for the names containing the summary statistics.

For more information, see “[HISTORY= Data Set](#)” on page 1648.

Saving Summary Statistics

See SHWMR1 in the SAS/QC Sample Library

In this example, the MRCHART statement is used to create a summary data set that can be read later by the SHEWHART procedure (as in the preceding example). The following statements read measurements from the data set Detergent and create a summary data set named Dethist:

```
proc shewhart data=Detergent;
  mrchart Weight*Lot / outhistory = Dethist
                    nochart;
run;
```

The OUTHISTORY= option names the output data set, and the NOCHART option suppresses the display of the charts, which would be identical to the charts in [Figure 17.44](#). Options such as OUTHISTORY= and NOCHART are specified after the slash (/) in the MRCHART statement. A complete list of options is presented in the section “[Syntax: MRCHART Statement](#)” on page 1628.

[Figure 17.47](#) contains a partial listing of Dethist.

Figure 17.47 The Summary Data Set Dethist

Summary Data Set DETHIST for Detergent Box Weights				
Lot	Weight M	Weight R	Weight N	
1	22.56	9.54	5	
2	23.54	3.07	5	
3	24.35	4.65	5	
4	25.52	5.05	5	
5	23.25	8.04	5	

There are four variables in the data set Dethist.

- Lot contains the subgroup index.
- WeightM contains the subgroup medians.
- WeightR contains the subgroup ranges.
- WeightN contains the subgroup sample sizes.

Note that the summary statistic variables are named by adding the suffix characters *M*, *R*, and *N* to the *process* Weight specified in the MRCHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as that for HISTORY= data sets.

For more information, see “OUTHISTORY= Data Set” on page 1643.

Saving Control Limits

You can save the control limits for median and range charts in a SAS data set; this enables you to apply the control limits to future data (see “Reading Preestablished Control Limits” on page 1626) or modify the limits with a DATA step program. *See SHWMR1 in the SAS/QC Sample Library*

The following statements read measurements from the data set Detergent (see “Creating Charts for Medians and Ranges from Raw Data” on page 1616) and save the control limits displayed in Figure 17.44 in a data set named Detlim:

```
proc shewhart data=Detergent;
  mrchart Weight*Lot / outlimits=Detlim
                    nochart;
run;
```

The OUTLIMITS= option names the data set containing the control limits, and the NOCHART option suppresses the display of the charts. The data set Detlim is listed in Figure 17.48.

Figure 17.48 The Data Set Detlim Containing Control Limit Information

Control Limits for Detergent Box Weights						
<u>_VAR_</u>	<u>_SUBGRP_</u>	<u>_TYPE_</u>	<u>_LIMITN_</u>	<u>_ALPHA_</u>	<u>_SIGMAS_</u>	<u>_LCLM_</u>
Weight	Lot	ESTIMATE	5	.002909021	3	20.7554
<u>_MEAN_</u>	<u>_UCLM_</u>	<u>_LCLR_</u>	<u>_R_</u>	<u>_UCLR_</u>	<u>_STDDEV_</u>	
24.4996	28.2439	0	5.42036	11.4613	2.33041	

The data set Detlim contains one observation with the limits for *process* Weight. The variables _LCLM_ and _UCLM_ contain the control limits for the medians, and the variable _MEAN_ contains the central line. The variables _LCLR_ and _UCLR_ contain the control limits for the ranges, and the variable _R_ contains the central line. The values of _MEAN_ and _STDDEV_ are estimates of the process mean and process standard deviation σ . The value of _LIMITN_ is the nominal sample size associated with the control limits, and the value of _SIGMAS_ is the multiple of σ associated with the control limits. The variables _VAR_ and _SUBGRP_ are bookkeeping variables that save the *process* and *subgroup-variable*. The variable _TYPE_ is a bookkeeping variable that indicates whether the values of _MEAN_ and _STDDEV_ are estimates or standard values. For more information, see “OUTLIMITS= Data Set” on page 1642.

You can create an output data set containing both control limits and summary statistics with the OUTTABLE= option, as illustrated by the following statements:

```
proc shewhart data=Detergent;
  mrchart Weight*Lot / outtable=Dtable
                    nochart;
run;
```

This data set contains one observation for each subgroup sample. The variables _SUBMED_, _SUBR_, and _SUBN_ contain the subgroup medians, subgroup ranges, and subgroup sample sizes. The variables _LCLM_ and _UCLM_ contain the control limits for the median chart, and the variables _LCLR_ and _UCLR_ contain the control limits for the range chart. The variable _MEAN_ contains the central line for the median chart, and the variable _R_ contains the central line for the range chart. The variables _VAR_ and Batch contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “OUTTABLE= Data Set” on page 1644.

The data set Dtable is listed in Figure 17.49.

Figure 17.49 The Data Set Dtable

An OUTTABLE= data set can be read later as a TABLE= data set. For example, the following statements read Dtable and display charts (not shown here) identical to those in Figure 17.44:

```

title 'Median and Range Charts for Detergent Box Weight';
proc shewhart table=Dtable;
    mrchart Weight*Lot;
run;

```

Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts (see “Specialized Control Charts: SHEWHART Procedure” on page 2171). For more information, see “TABLE= Data Set” on page 1649.

Reading Prestablished Control Limits

See *SHWMRI* in the *SAS/QC Sample Library*. In the previous example, the OUTLIMITS= data set Detlim saved control limits computed from the measurements in Detergent. This example shows how these limits can be applied to new data provided in the following data set:

```

data Detergent2;
  input Lot @;
  do i=1 to 5;
    input Weight @;
    output;
  end;
  drop i;
  datalines;
29 16.66 27.49 18.87 22.53 24.72
30 23.74 23.67 23.64 20.26 22.09
31 24.56 24.82 23.92 26.67 21.38
32 25.89 28.73 29.21 25.38 23.47
33 23.32 21.61 30.75 23.13 23.82
34 23.04 22.65 24.96 19.64 26.84
35 24.01 24.38 24.86 26.50 24.37
36 26.43 27.36 28.74 26.74 26.27
37 21.41 22.24 25.34 20.59 27.51
38 22.62 20.81 22.64 30.15 25.32
39 26.86 28.14 24.06 27.35 22.49
40 23.03 23.83 25.59 19.85 22.33
41 23.19 23.63 23.00 21.46 27.57
42 27.38 23.18 24.99 24.81 28.82
43 26.60 26.58 20.26 26.27 24.96
44 26.22 23.28 24.15 24.06 28.23
45 25.90 22.88 25.55 24.50 19.95
46 16.66 27.49 18.87 22.53 24.72
47 23.74 23.67 23.64 20.26 22.09
48 24.56 24.82 23.92 26.67 21.38
49 25.89 28.73 29.21 25.38 23.47
50 23.32 21.61 30.75 23.13 23.82
;

```

The following statements create median and range charts for the data in Detergent2 using the control limits in Detlim:

```

ods graphics on;
title 'Median and Range Charts for Weights';
proc shewhart data=Detergent2 limits=Detlim;
  mrchart Weight*Lot / odstitle=title;
run;

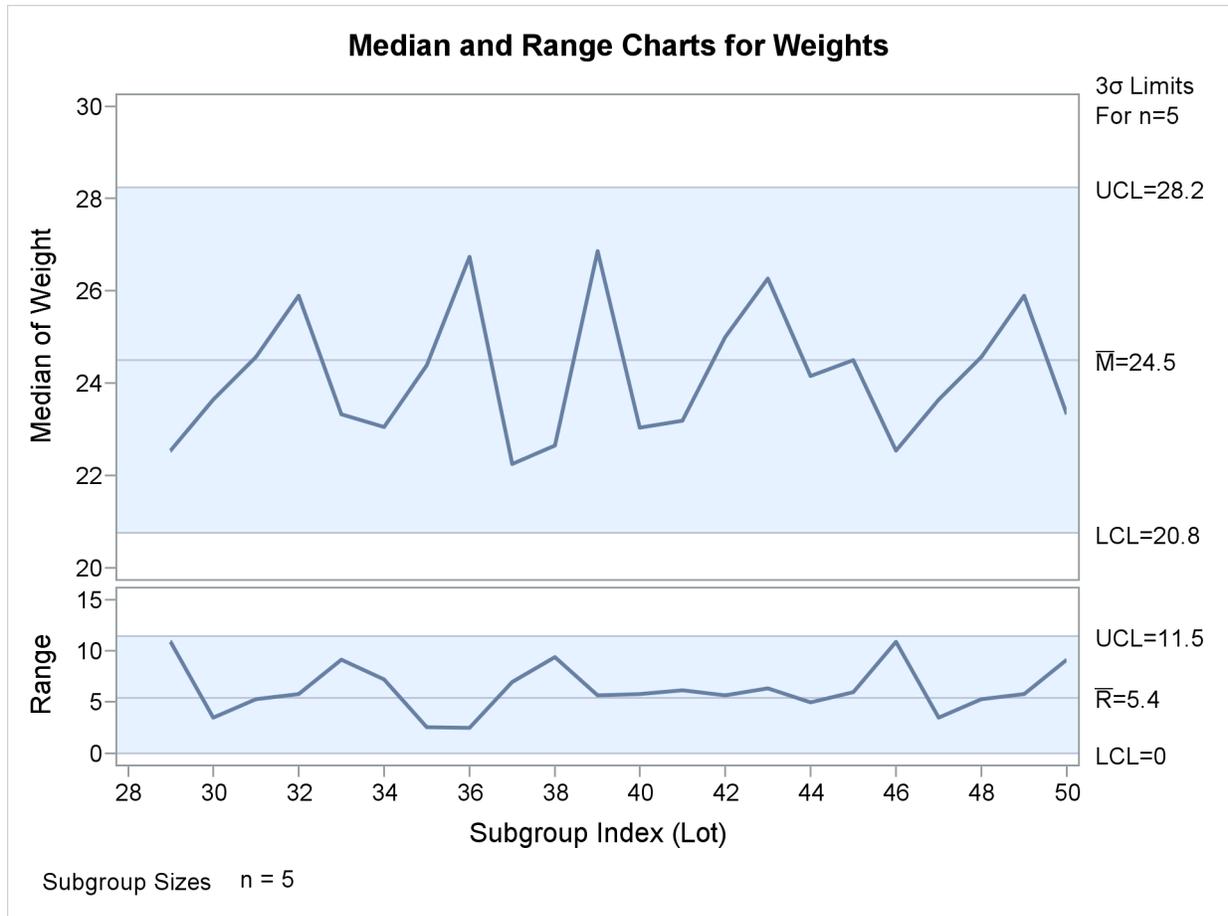

```

The ODS GRAPHICS ON statement specified before the PROC SHEWHART statement enables ODS Graphics, so the median and range charts are created using ODS Graphics instead of traditional graphics. The charts are shown in [Figure 17.50](#).

The LIMITS= option in the PROC SHEWHART statement specifies the data set containing the control limits. By default,¹⁴ this information is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches the *process* name Weight
- the value of `_SUBGRP_` matches the *subgroup-variable* name Lot

Figure 17.50 Median and Range Charts for Second Set of Detergent Box Weights (ODS Graphics)

The charts indicate that the process is in control, since all the medians and ranges lie within the control limits.

In this example, the LIMITS= data set was created in a previous run of the SHEWHART procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on page 1647 for details concerning the variables that you must provide.

¹⁴In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

Syntax: MRCHART Statement

The basic syntax for the MRCHART statement is as follows:

```
MRCHART process * subgroup-variable ;
```

The general form of this syntax is as follows:

```
MRCHART processes * subgroup-variable <(block-variables)>  
      <=symbol-variable | =‘character’> / <options> ;
```

You can use any number of MRCHART statements in the SHEWHART procedure. The components of the MRCHART statement are described as follows.

process

processes

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC SHEWHART statement.

- If raw data are read from a DATA= data set, *process* must be the name of the variable containing the raw measurements. For an example, see “[Creating Charts for Medians and Ranges from Raw Data](#)” on page 1616.
- If summary data are read from a HISTORY= data set, *process* must be the common prefix of the summary variables in the HISTORY= data set. For an example, see “[Creating Charts for Medians and Ranges from Summary Data](#)” on page 1619.
- If summary data and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “[Saving Control Limits](#)” on page 1623.

A *process* is required. If you specify more than one *process*, enclose the list in parentheses. For example, the following statements request distinct median and range charts for Weight, LENGTH, and Width:

```
proc shewhart data=Measures;  
      mrchart (Weight Length Width)*Day;  
run;
```

subgroup-variable

is the variable that identifies subgroups in the data. The *subgroup-variable* is required. In the preceding MRCHART statement, DAY is the subgroup variable. For details, see “[Subgroup Variables](#)” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or character used to plot the medians and ranges.

- If you produce a line printer chart, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOln statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create median and range charts using an asterisk (*) to plot the points:

```
proc shewhart data=Values lineprinter;
  mrchart Weight*Day='*';
run;
```

options

enhance the appearance of the charts, request additional analyses, save results in data sets, and so on. The section “[Summary of Options](#)”, which follows, lists all options by function. “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018 describes each option in detail.

Summary of Options

The following tables list the MRCHART statement options by function. For complete descriptions, see “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 17.31 MRCHART Statement Options

Option	Description
Options for Specifying Control Limits	
ALPHA=	requests probability limits for chart
LIMITN=	specifies either nominal sample size for fixed control limits or varying limits
NOREADLIMITS	computes control limits for each <i>process</i> from the data rather than a LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from a LIMITS= data set
READINDEX=	reads control limits for each <i>process</i> from a LIMITS= data set
READLIMITS	reads single set of control limits for each <i>process</i> from a LIMITS= data set (SAS 6.09 and earlier releases)

Table 17.31 *continued*

Option	Description
SIGMAS=	specifies width of control limits in terms of multiple k of standard error of plotted means
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit on median chart
LCLLABEL2=	specifies label for lower control limit on R chart
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line on median chart
NDECIMAL2=	specifies number of digits to right of decimal place in default labels for control limits and central line on R chart
NOCTL	suppresses display of central line on median chart
NOCTL2	suppresses display of central line on R chart
NOLCL	suppresses display of lower control limit on median chart
NOLCL2	suppresses display of lower control limit on R chart
NOLIMIT0	suppresses display of zero lower control limit on R chart
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit on median chart
NOUCL2	suppresses display of upper control limit on R chart
RSYMBOL=	specifies label for central line on R chart
UCLLABEL=	specifies label for upper control limit on median chart
UCLLABEL2=	specifies label for upper control limit on R chart
WLIMITS=	specifies width for control limits and central line
XSYPMBOL=	specifies label for central line on median chart
Process Mean and Standard Deviation Options	
MEDCENTRAL=	specifies method for estimating process mean μ
MU0=	specifies known value of μ_0 for process mean μ
SIGMA0=	specifies known value σ_0 for process standard deviation σ
SMETHOD=	specifies method for estimating process standard deviation σ
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set

Table 17.31 *continued*

Option	Description
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on median chart
ALLLABEL2=	labels every point on <i>R</i> chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
OUTLABEL=	labels points outside control limits on median chart
OUTLABEL2=	labels points outside control limits on <i>R</i> chart
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles
Options for Specifying Tests for Special Causes	
INDEPENDENTZONES	computes zone widths independently above and below center line
NO3SIGMACHECK	enables tests to be applied with control limits other than 3σ limits
NOTESTACROSS	suppresses tests across <i>phase</i> boundaries
TESTS=	specifies tests for special causes for the median chart
TESTS2=	specifies tests for special causes for the <i>R</i> chart
TEST2RESET=	enables tests for special causes to be reset for the <i>R</i> chart
TEST2RUN=	specifies length of pattern for Test 2
TEST3RUN=	specifies length of pattern for Test 3
TESTACROSS	applies tests across <i>phase</i> boundaries
TESTLABEL=	provides labels for points where test is positive
TESTLABEL n =	specifies label for n th test for special causes
TESTNMETHOD=	applies tests to standardized chart statistics
TESTOVERLAP	performs tests on overlapping patterns of points
TESTRESET=	enables tests for special causes to be reset

Table 17.31 *continued*

Option	Description
ZONELABELS	adds labels A, B, and C to zone lines for median chart
ZONE2LABELS	adds labels A, B, and C to zone lines for <i>R</i> chart
ZONES	adds lines to median chart delineating zones A, B, and C
ZONES2	adds lines to <i>R</i> chart delineating zones A, B, and C
ZONEVALPOS=	specifies position of ZONEVALUES labels
ZONEVALUES	labels median chart zone lines with their values
ZONE2VALUES	labels <i>R</i> zone lines with their values
Options for Displaying Tests for Special Causes	
CTESTLABBOX=	specifies color for boxes enclosing labels indicating points where test is positive
CTESTS=	specifies color for labels indicating points where test is positive
CTESTSYMBOL=	specifies color for symbol used to plot points where test is positive
CZONES=	specifies color for lines and labels delineating zones A, B, and C
LTESTS=	specifies type of line connecting points where test is positive
LZONES=	specifies line type for lines delineating zones A, B, and C
TESTFONT=	specifies software font for labels at points where test is positive
TESTHEIGHT=	specifies height of labels at points where test is positive
TESTLABBOX	requests that labels for points where test is positive be positioned so that do not overlap
TESTSYMBOL=	specifies plot symbol for points where test is positive
TESTSYMBOLHT=	specifies symbol height for points where test is positive
WTESTS=	specifies width of line connecting points where test is positive
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis

Table 17.31 *continued*

Option	Description
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOTRUNC	suppresses vertical axis truncation at zero applied by default to <i>R</i> chart
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPHLABELS=	specifies thinning factor for tick mark labels on horizontal axis
SPLIT=	specifies splitting character for axis labels
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis of median chart
VAXIS2=	specifies major tick mark values for vertical axis of <i>R</i> chart
VFORMAT=	specifies format for primary vertical axis tick mark labels
VFORMAT2=	specifies format for secondary vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis for primary chart
VZERO2	forces origin to be included in vertical axis for secondary chart
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of charts
NOCHART2	suppresses creation of <i>R</i> chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes
NPANELPOS=	specifies number of subgroup positions per panel on each chart

Table 17.31 *continued*

Option	Description
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
SEPARATE	displays median and R charts on separate screens or pages
TOTPANELS=	specifies number of pages or screens to be used to display chart
YPCT1=	specifies length of vertical axis on median chart as a percentage of sum of lengths of vertical axes for median and R charts
ZEROSTD	displays median chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= and HREF2= options
CVREF=	specifies color for lines requested by VREF= and VREF2= options
HREF=	specifies position of reference lines perpendicular to horizontal axis on median chart
HREF2=	specifies position of reference lines perpendicular to horizontal axis on R chart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on median chart
HREF2DATA=	specifies position of reference lines perpendicular to horizontal axis on R chart
HREFLABELS=	specifies labels for HREF= lines
HREF2LABELS=	specifies labels for HREF2= lines
HREFLABPOS=	specifies position of HREFLABELS= and HREF2LABELS= labels
LHREF=	specifies line type for HREF= and HREF2= lines
LVREF=	specifies line type for VREF= and VREF2= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis on median chart
VREF2=	specifies position of reference lines perpendicular to vertical axis on R chart
VREFLABELS=	specifies labels for VREF= lines
VREF2LABELS=	specifies labels for VREF2= lines
VREFLABPOS=	position of VREFLABELS= and VREF2LABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart

Table 17.31 *continued*

Option	Description
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to median chart
ANNOTATE2=	specifies annotate data set that adds features to <i>R</i> chart
DESCRIPTION=	specifies description of median chart's GRSEG catalog entry
DESCRIPTION2=	specifies description of <i>R</i> chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of median chart's GRSEG catalog entry
NAME2=	specifies name of <i>R</i> chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency

Table 17.31 *continued*

Option	Description
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
OVERLAY2URL=	specifies URLs to associate with overlay points on secondary chart
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
URL2=	specifies a variable whose values are URLs to be associated with subgroups on secondary chart
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the OUTLIMITS= data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits

Table 17.31 continued

Option	Description
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLELEGEND	augments basic table with legend for tests for special causes
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
TABLETESTS	augments basic table with a column indicating which tests for special causes are positive
Specification Limit Options	
CIINDICES	specifies α value and type for computing capability index confidence limits
LSL=	specifies list of lower specification limits
TARGET=	specifies list of target values
USL=	specifies list of upper specification limits
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set

Table 17.31 *continued*

Option	Description
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on median chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for primary chart overlay line segments
CCOVERLAY2=	specifies colors for secondary chart overlay line segments
COVERLAY=	specifies colors for primary chart overlay plots
COVERLAY2=	specifies colors for secondary chart overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for primary chart overlay line segments
LOVERLAY2=	specifies line types for secondary chart overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on primary chart
OVERLAY2=	specifies variables to overlay on secondary chart
OVERLAY2HTML=	specifies links to associate with secondary chart overlay points
OVERLAY2ID=	specifies labels for secondary chart overlay points
OVERLAY2SYM=	specifies symbols for secondary chart overlays
OVERLAY2SYMHT=	specifies symbol heights for secondary chart overlays
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with primary chart overlay points

Table 17.31 *continued*

Option	Description
OVERLAYID=	specifies labels for primary chart overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for primary chart overlays
OVERLAYSYMHT=	specifies symbol heights for primary chart overlays
WOVERLAY=	specifies widths of primary chart overlay line segments
WOVERLAY2=	specifies widths of secondary chart overlay line segments
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML2=	specifies variable whose values create links to be associated with subgroups on secondary chart
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= and HREF2= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
TESTCHAR=	specifies character for line segments that connect any sequence of points for which a test for special causes is positive
VREFCHAR=	specifies line character for VREF= and VREF2= lines
ZONECHAR=	specifies character for lines that delineate zones for tests for special causes

Details: MRCHART Statement

Constructing Charts for Medians and Ranges

The following notation is used in this section:

μ	process mean (expected value of the population of measurements)
σ	process standard deviation (standard deviation of the population of measurements)
\bar{X}_i	mean of measurements in i th subgroup
R_i	range of measurements in i th subgroup
n_i	sample size of i th subgroup
N	the number of subgroups
x_{ij}	j th measurement in the i th subgroup, $j = 1, 2, 3, \dots, n_i$
$x_{i(j)}$	j th largest measurement in the i th subgroup. Then

$$x_{i(1)} \leq x_{i(2)} \leq \dots \leq x_{i(n_i)}$$

$\bar{\bar{X}}$	weighted average of subgroup means
M_i	median of the measurements in the i th subgroup:

$$M_i = \begin{cases} x_{i((n_i+1)/2)} & \text{if } n_i \text{ is odd} \\ (x_{i(n_i/2)} + x_{i((n_i/2)+1)})/2 & \text{if } n_i \text{ is even} \end{cases}$$

\bar{M}	average of the subgroup medians:
-----------	----------------------------------

$$\bar{M} = (n_1 M_1 + \dots + n_N M_N) / (n_1 + \dots + n_N)$$

\tilde{M}	median of the subgroup medians. Denote the j th largest median by $M_{(j)}$ so that $M_{(1)} \leq M_{(2)} \leq \dots \leq M_{(N)}$.
-------------	--

$$\tilde{M} = \begin{cases} M_{((N+1)/2)} & \text{if } N \text{ is odd} \\ (M_{(N/2)} + M_{(N/2)+1})/2 & \text{if } N \text{ is even} \end{cases}$$

$e_M(n)$	standard error of the median of n independent, normally distributed variables with unit standard deviation (the value of $e_M(n)$ can be calculated with the STD MED function in a DATA step)
$Q_p(n)$	100 p th percentile ($0 < p < 1$) of the distribution of the median of n independent observations from a normal population with unit standard deviation
$d_2(n)$	expected value of the range of n independent normally distributed variables with unit standard deviation
$d_3(n)$	standard error of the range of n independent observations from a normal population with unit standard deviation
z_p	100 p th percentile of the standard normal distribution
$D_p(n)$	100 p th percentile of the distribution of the range of n independent observations from a normal population with unit standard deviation

Plotted Points

Each point on a median chart indicates the value of a subgroup median (M_i). For example, if the tenth subgroup contains the values 12, 15, 19, 16, and 14, the value plotted for this subgroup is $M_{10} = 15$. Each point on a range chart indicates the value of a subgroup range (R_i). For example, the value plotted for the tenth subgroup is $R_{10} = 19 - 12 = 7$.

Central Lines

On a median chart, the value of the central line indicates an estimate for μ , which is computed as

- \bar{M} by default
- $\bar{\bar{X}}$ when you specify MEDCENTRAL=AVGMEAN
- \tilde{M} when you specify MEDCENTRAL=MEDMED
- μ_0 when you specify μ_0 with the MU0= option

On the range chart, by default, the central line for the i th subgroup indicates an estimate for the expected value of R_i , which is computed as $d_2(n_i)\hat{\sigma}$, where $\hat{\sigma}$ is an estimate of σ . If you specify a known value (σ_0) for σ , the central line indicates the value of $d_2(n_i)\sigma_0$. The central line on the range chart varies with n_i .

Control Limits

You can compute the limits

- as a specified multiple (k) of the standard errors of M_i and R_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that M_i or R_i exceeds its limits

The following table provides the formulas for the limits:

Table 17.32 Limits for Median and Range Charts

Control Limits	
Median Chart	LCL = lower limit = $\bar{M} - k\hat{\sigma}e_M(n_i)$ UCL = upper limit = $\bar{M} + k\hat{\sigma}e_M(n_i)$
Range Chart	LCL = lower control limit = $\max(d_2(n_i)\hat{\sigma} - kd_3(n_i)\hat{\sigma}, 0)$ UCL = upper control limit = $d_2(n_i)\hat{\sigma} + kd_3(n_i)\hat{\sigma}$
Probability Limits	
Median Chart	LCL = lower limit = $\bar{M} - Q_{\alpha/2}(n_i)\hat{\sigma}$ UCL = upper limit = $\bar{M} + Q_{1-\alpha/2}(n_i)\hat{\sigma}$
Range Chart	LCL = lower limit = $D_{\alpha/2}\hat{\sigma}$ UCL = upper limit = $D_{1-\alpha/2}\hat{\sigma}$

In Table 17.32, replace \bar{M} with $\bar{\bar{X}}$ if you specify MEDCENTRAL=AVGMEAN, and replace \bar{M} with \tilde{M} if you specify MEDCENTRAL=MEDMED. Replace \bar{M} with μ_0 if you specify μ_0 with the MU0= option, and replace $\hat{\sigma}$ with σ_0 if you specify σ_0 with the SIGMA0= option.

The formulas assume that the data are normally distributed. Note that the limits for both charts vary with n_i and that the probability limits for R_i are asymmetric around the central line.

You can specify parameters for the limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify μ_0 with the MU0= option or with the variable `_MEAN_` in the LIMITS= data set.
- Specify σ_0 with the SIGMA0= option or with the variable `_STDDEV_` in the LIMITS= data set.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves control limits and control limit parameters. The following variables can be saved:

Table 17.33 OUTLIMITS= Data Set

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding limits
<code>_CP_</code>	capability index C_p
<code>_CPK_</code>	capability index C_{pk}
<code>_CPL_</code>	capability index C_{PL}
<code>_CPM_</code>	capability index C_{pm}
<code>_CPU_</code>	capability index C_{PU}
<code>_INDEX_</code>	optional identifier for the control limits specified with the OUTINDEX= option
<code>_LCLM_</code>	lower control limit for subgroup median
<code>_LCLR_</code>	lower control limit for subgroup range
<code>_LIMITN_</code>	sample size associated with the control limits
<code>_LSL_</code>	lower specification limit
<code>_MEAN_</code>	estimate of process mean (\bar{M} , \tilde{M} , $\bar{\bar{X}}$, or μ_0)
<code>_R_</code>	value of central line on range chart
<code>_SIGMAS_</code>	multiple (k) of standard error of M_i or R_i
<code>_STDDEV_</code>	process standard deviation ($\hat{\sigma}$ or σ_0)
<code>_SUBGRP_</code>	<i>subgroup-variable</i> specified in the MRCHART statement
<code>_TARGET_</code>	target value

Table 17.33 (continued)

Variable	Description
TYPE	type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLM	upper control limit for subgroup median
UCLR	upper control limit for subgroup range
USL	upper specification limit
VAR	<i>process</i> specified in the MRCHART statement

Notes:

1. If the control limits vary with subgroup sample size, the special missing value V is assigned to the variables _LIMITN_, _LCLM_, _UCLM_, _LCLR_, _R_, and _UCLR_.
2. If the limits are defined in terms of a multiple k of the standard errors of M_i and R_i , the value of _ALPHA_ is computed as $\alpha = 2(1 - F_{med}(k, n))$, where $F_{med}(\cdot, n)$ is the cumulative distribution function of the median of a random sample of n standard normally distributed observations, and n is the value of _LIMITN_. If _LIMITN_ has the special missing value V , this value is assigned to _ALPHA_.
3. If the limits are probability limits, the value of _SIGMAS_ is computed as $k = F_{med}^{-1}(1 - \alpha/2, n)$, where $F_{med}^{-1}(\cdot, n)$ is the inverse distribution function of the median of a random sample of n standard normally distributed observations, and n is the value of _LIMITN_. If _LIMITN_ has the special missing value V , this value is assigned to _SIGMAS_.
4. The variables _CP_, _CPK_, _CPL_, _CPU_, _LSL_, and _USL_ are included only if you provide specification limits with the LSL= and USL= options. The variables _CPM_ and _TARGET_ are included if, in addition, you provide a target value with the TARGET= option. See “[Capability Indices](#)” on page 1941 for computational details.
5. Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *process* specified in the MRCHART statement. For an example of an OUTLIMITS= data set, see “[Saving Control Limits](#)” on page 1623.

OUTHISTORY= Data Set

The OUTHISTORY= option saves subgroup summary statistics. The following variables are saved:

- the *subgroup-variable*
- a subgroup median variable named by *process* suffixed with M
- a subgroup range variable named by *process* suffixed with R
- a subgroup sample size variable named by *process* suffixed with N

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Variables containing subgroup medians, ranges, and sample sizes are created for each *process* specified in the MRCHART statement. For example, consider the following statements:

```
proc shewhart data=Steel;
  mrchart (Width Diameter)*lot / outhistory=Summary;
run;
```

The data set Summary contains variables named Lot, WidthM, WidthR, WidthN, DiameterM, DiameterR, and DiameterN.

Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

For an example of an OUTHISTORY= data set, see “[Saving Summary Statistics](#)” on page 1622.

OUTTABLE= Data Set

The OUTTABLE= data set saves subgroup summary statistics, control limits, and related information. The following variables are saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_EXLIM_</code>	control limit exceeded on median chart
<code>_EXLIMR_</code>	control limit exceeded on range chart
<code>_LCLM_</code>	lower control limit for median
<code>_LCLR_</code>	lower control limit for range
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_MEAN_</code>	estimate of process mean (\bar{M} , \tilde{M} , \bar{X} , or μ_0)
<code>_R_</code>	average range
<code>_SIGMAS_</code>	multiple (k) of the standard error associated with control limits
<code>subgroup</code>	values of the subgroup variable
<code>_SUBM_</code>	subgroup median
<code>_SUBN_</code>	subgroup sample size
<code>_SUBR_</code>	subgroup range
<code>_TESTS_</code>	tests for special causes signaled on median chart
<code>_TESTS2_</code>	tests for special causes signaled on range chart
<code>_UCLM_</code>	upper control limit for mean
<code>_UCLR_</code>	upper control limit for range
<code>_VAR_</code>	<i>process</i> specified in the MRCHART statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the `READPHASES=` option is specified)

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved depending on how the control limits are defined (with the `ALPHA=` or `SIGMAS=` options, respectively, or with the corresponding variables in a `LIMITS=` data set).
2. The variable `_TESTS_` is saved if you specify the `TESTS=` option. The *k*th character of a value of `_TESTS_` is *k* if Test *k* is positive at that subgroup. For example, if you request all eight tests and Tests 2 and 8 are positive for a given subgroup, the value of `_TESTS_` has a 2 for the second character, an 8 for the eighth character, and blanks for the other six characters.
3. The variable `_TESTS2_` is saved if you specify the `TESTS2=` option. The *k*th character of a value of `_TESTS2_` is *k* if Test *k* is positive at that subgroup.
4. The variables `_EXLIM_`, `_EXLIMR_`, `_TESTS_`, and `_TESTS2_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example of an `OUTTABLE=` data set, see “[Saving Control Limits](#)” on page 1623.

ODS Tables

The following table summarizes the ODS tables that you can request with the MRCHART statement.

Table 17.34 ODS Tables Produced with the MRCHART Statement

Table Name	Description	Options
MRCHART	median and <i>R</i> chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLELEG, TABLEOUT, TABLETESTS
TestDescriptions	descriptions of tests for special causes requested with the <code>TESTS=</code> option for which at least one positive signal is found	TABLEALL, TABLELEG

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the SHEWHART procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. MRCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the MRCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 17.35](#).

Table 17.35 ODS Graphics Produced by the MRCHART Statement

ODS Graph Name	Plot Description
MRChart	median and <i>R</i> chart

See Chapter 3, “[SAS/QC Graphics](#),” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (process measurements) from a DATA= data set specified in the PROC SHEWHART statement. Each *process* specified in the MRCHART statement must be a SAS variable in the DATA= data set. This variable provides measurements that must be grouped into subgroup samples indexed by the values of the *subgroup-variable*. The *subgroup-variable*, which is specified in the MRCHART statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a value for each *process* and a value for the *subgroup-variable*. If the *i*th subgroup contains n_i items, there should be n_i consecutive observations for which the value of the *subgroup-variable* is the index of the *i*th subgroup. For example, if each subgroup contains five items and there are 30 subgroup samples, the DATA= data set should contain 150 observations.

Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables

- ID variables

By default, the SHEWHART procedure reads all of the observations in a DATA= data set. However, if the DATA= data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (for an example, see “[Displaying Stratification in Phases](#)” on page 2103).

For an example of a DATA= data set, see “[Creating Charts for Medians and Ranges from Raw Data](#)” on page 1616.

LIMITS= Data Set

You can read preestablished control limits (or parameters from which the control limits can be calculated) from a LIMITS= data set specified in the PROC SHEWHART statement. For example, the following statements read control limit information from the data set Conlims:¹⁵

```
proc shewhart data=Info limits=Conlims;
  mrchart Weight*Batch;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the SHEWHART procedure. Such data sets always contain the variables required for a LIMITS= data set. The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LCLM_`, `_MEAN_`, `_UCLM_`, `_LCLR_`, `_R_`, and `_UCLR_`, which specify the control limits directly
- the variables `_MEAN_` and `_STDDEV_`, which are used to calculate the control limits according to the equations in [Table 17.32](#)

In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables whose lengths are no greater than 32.
- The variable `_INDEX_` is required if you specify the READINDEX= option; this must be a character variable whose length is no greater than 48.
- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8; valid values are ‘ESTIMATE’, ‘STANDARD’, ‘STDMU’, and ‘STDSIGMA’.
- BY variables are required if specified with a BY statement.

For an example, see “[Reading Preestablished Control Limits](#)” on page 1626.

¹⁵In SAS 6.09 and in earlier releases, it is necessary to specify the READLIMITS option.

HISTORY= Data Set

You can read subgroup summary statistics from a HISTORY= data set specified in the PROC SHEWHART statement. This enables you to reuse OUTHISTORY= data sets that have been created in previous runs of the SHEWHART procedures or to read output data sets created with SAS summarization procedures, such as PROC UNIVARIATE.

A HISTORY= data set used with the MRCHART statement must contain the following variables:

- the *subgroup-variable*
- a subgroup mean variable for each *process*
- a subgroup median variable for each *process*
- a subgroup range variable for each *process*
- a subgroup sample size variable for each *process*

The names of the subgroup mean, subgroup median, subgroup range, and subgroup sample size variables must be the *process* name concatenated with the special suffix characters *X*, *M*, *R*, and *N*, respectively. You must provide the subgroup mean variable only if you specify the MEDCENTRAL=AVGMEAN option.

For example, consider the following statements:

```
proc shewhart history=Summary;
  mrchart (Weight Yieldstrength)*Batch / medcentral=avgmean;
run;
```

The data set Summary must include the variables Batch, WeightX, WeightM, WeightR, WeightN, YieldstrengthX, YieldstrengthM, YieldstrengthR, and YieldstrengthN.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a HISTORY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all the observations in a HISTORY= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (see “Displaying Stratification in Phases” on page 2103 for an example).

For an example of a HISTORY= data set, see “Creating Charts for Medians and Ranges from Summary Data” on page 1619.

TABLE= Data Set

You can read summary statistics and control limits from a TABLE= data set specified in the PROC SHEWHART statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the SHEWHART procedure or to read data sets created by other SAS procedures. Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts. Examples are provided in “Specialized Control Charts: SHEWHART Procedure” on page 2171.

The following table lists the variables required in a TABLE= data set used with the MRCHART statement:

Table 17.36 Variables Required in a TABLE= Data Set

Variable	Description
LCLM	lower control limit for median
LCLR	lower control limit for range
LIMITN	nominal sample size associated with the control limits
MEAN	process mean
R	average range
<i>subgroup-variable</i>	values of the <i>subgroup-variable</i>
SUBM	subgroup median
SUBN	subgroup sample size
SUBR	subgroup range
UCLM	upper control limit for median
UCLR	upper control limit for range

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- _PHASE_ (if the READPHASES= option is specified). This variable must be a character variable whose length is no greater than 48.
- _TESTS_ (if the TESTS= option is specified). This variable is used to flag tests for special causes for subgroup medians and must be a character variable of length 8.
- _TESTS2_ (if the TESTS2= option is specified). This variable is used to flag tests for special causes for subgroup ranges and must be a character variable of length 8.
- _VAR_. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable whose length is no greater than 32.

For an example of a TABLE= data set, see “Saving Control Limits” on page 1623.

Methods for Estimating the Standard Deviation

When control limits are determined from the input data, two methods are available for estimating the process standard deviation σ .

Default Method

The default estimate for σ is

$$\hat{\sigma} = \frac{R_1/d_2(n_1) + \cdots + R_N/d_2(n_N)}{N}$$

where N is the number of subgroups for which $n_i \geq 2$, and R_i is the sample range of the observations x_{i1}, \dots, x_{in_i} in the i th subgroup.

A subgroup range R_i is included in the calculation only if $n_i \geq 2$. The unbiasing factor $d_2(n_i)$ is defined so that, if the observations are normally distributed, the expected value of R_i is equal to $d_2(n_i)\sigma$. Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ . This method is described in the American Society for Testing and Materials (1976).

MVLUE Method

If you specify `SMETHOD=MVLUE`, a minimum variance linear unbiased estimate (MVLUE) is computed for σ . Refer to Burr (1969, 1976) and Nelson (1989, 1994). The MVLUE is a weighted average of N unbiased estimates of σ of the form $R_i/d_2(n_i)$, and it is computed as

$$\hat{\sigma} = \frac{f_1 R_1/d_2(n_1) + \cdots + f_N R_N/d_2(n_N)}{f_1 + \cdots + f_N}$$

where

$$f_i = \frac{[d_2(n_i)]^2}{[d_3(n_i)]^2}$$

A subgroup range R_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$. The MVLUE assigns greater weight to estimates of σ from subgroups with larger sample sizes, and it is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the MVLUE reduces to the default estimate.

See [Example 17.16](#) for illustrations of the default and MVLUE methods.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical (median chart)	DATA=	<i>process</i>
Vertical (median chart)	HISTORY=	subgroup median variable
Vertical (median chart)	TABLE=	<code>_SUBMED_</code>

You can specify distinct labels for the vertical axes of the median and R charts by breaking the vertical axis into two parts with a split character. Specify the split character with the `SPLIT=`

option. The first part labels the vertical axis of the median chart, and the second part labels the vertical axis of the *R* chart.

For an example, see [Example 17.17](#).

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: MRCHART Statement

This section provides advanced examples of the MRCHART statement.

Example 17.16: Working with Unequal Subgroup Sample Sizes

A brewery monitors its bottling process to ensure that each bottle is filled with the proper amount of beer. The following data set contains the amount of beer recorded in fluid ounces for 23 batches: *See SHWMR2 in the SAS/QC Sample Library*

```
data Beer;
  input Batch size @;
  do i=1 to size;
    input Amount @@;
    output;
  end;
  drop i size;
  label Batch = 'Batch Number';
  datalines;
1 5 12.01 11.97 11.93 11.98 12.00
2 5 11.88 11.98 11.93 12.03 11.92
3 5 11.93 11.99 12.00 12.03 11.95
4 5 11.98 11.94 12.02 11.90 11.97
5 5 12.02 12.02 11.98 12.04 11.90

;

```

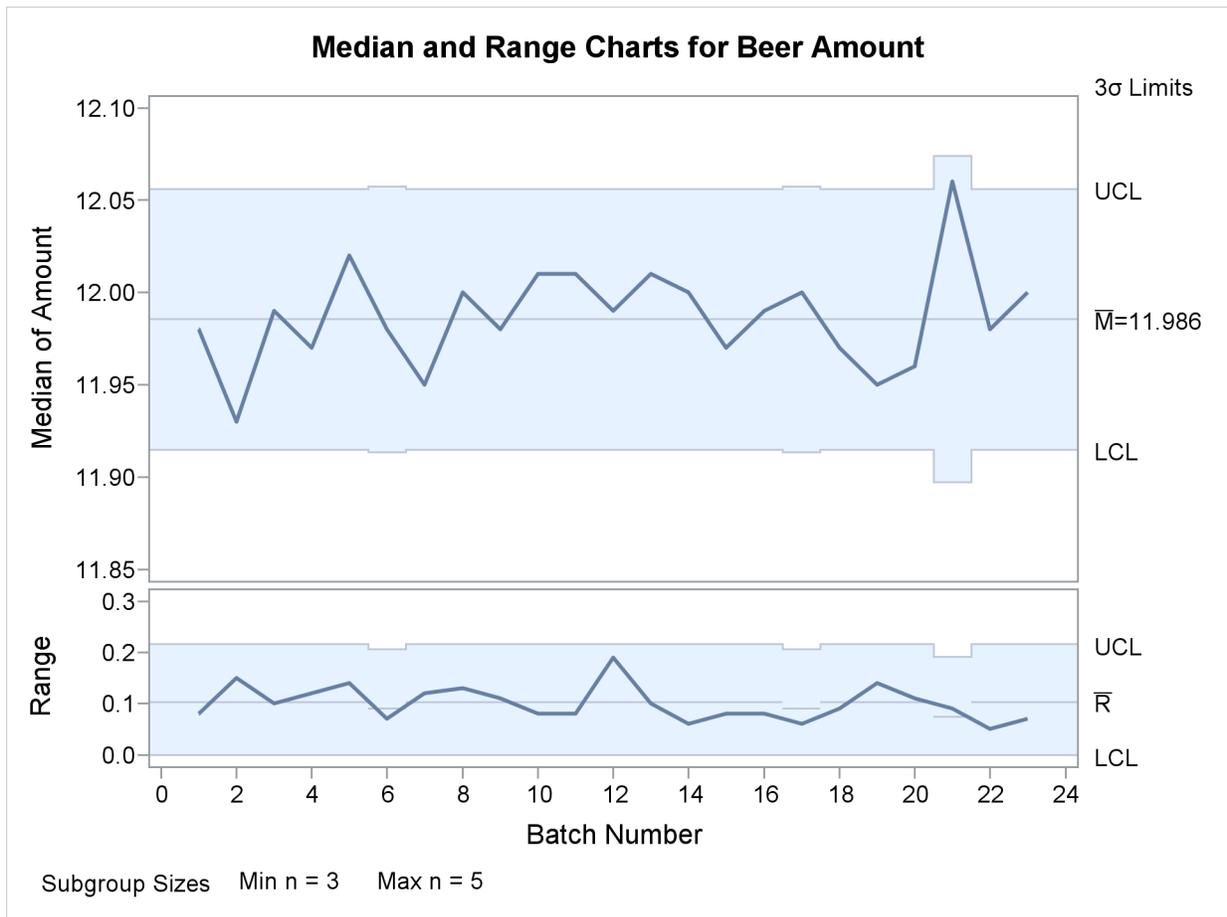

A batch is regarded as a rational subgroup. Five bottles of beer are supposed to be tested in each batch. However, in batch 6 and batch 17 only four bottles are tested, and in batch 21 only three bottles are tested. The following statements request median and range charts, shown in [Output 17.16.1](#), for the beer amounts:

```

ods graphics on;
title 'Median and Range Charts for Beer Amount';
proc shewhart data=Beer;
  mrchart Amount*Batch / odstitle=title;
run;

```

Output 17.16.1 Median and Range Charts with Varying Sample Sizes

Since none of the subgroup medians or subgroup ranges fall outside their respective control limits, you can conclude that the process is in control.

Note that the central line on the range chart and the control limits on both charts vary with the subgroup sample size. The subgroup sample size legend displays the minimum and maximum subgroup sample sizes.

The SHEWHART procedure provides various options for working with unequal subgroup sample sizes. For example, you can use the LIMITN= option to specify a fixed (nominal) sample size for the control limits, as illustrated by the following statements:

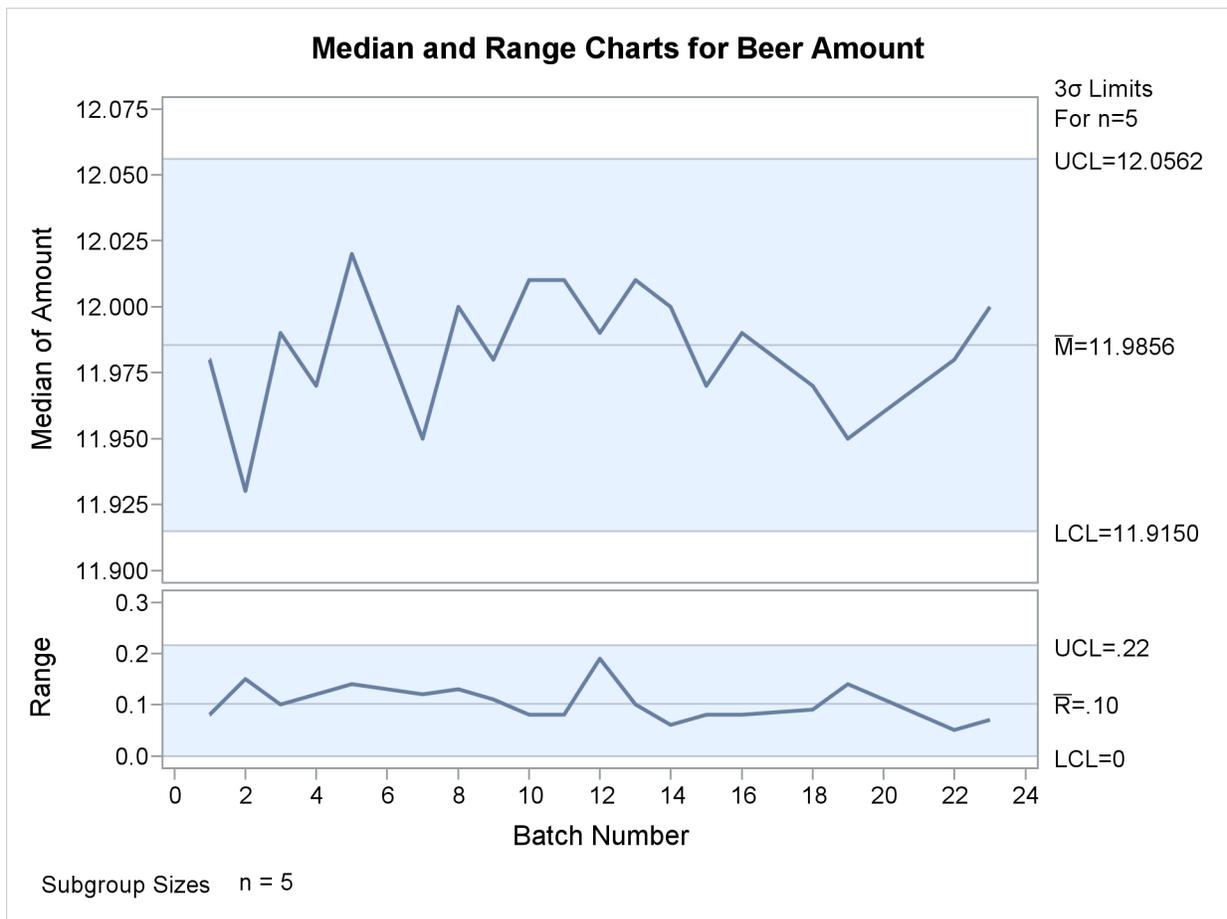

```

title 'Median and Range Charts for Beer Amount';
proc shewhart data=Beer;
  mrchart Amount*Batch / limitn=5 odstitle=title;
run;

```

The resulting charts are shown in [Output 17.16.2](#).

Output 17.16.2 Control Limits Based on Fixed Sample Size

Note that the points displayed on the chart are those corresponding to subgroups whose sample size matches the nominal sample size (five) specified with the LIMITN= option. Points are not plotted for batches 6, 17, and 21. To display points for all subgroups (regardless of subgroup sample size), specify the ALLN option. The following statements produce the charts shown in [Output 17.16.3](#):

```

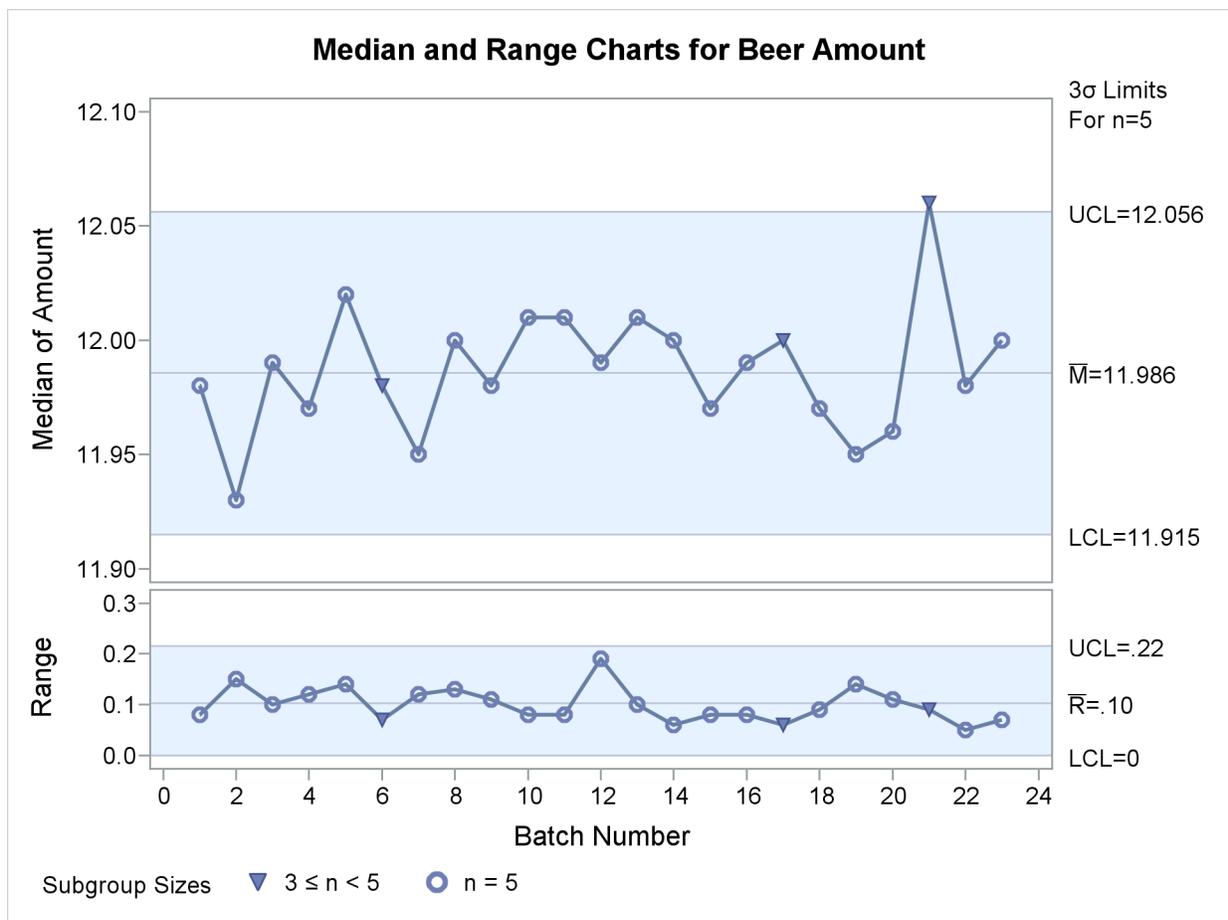

title 'Median and Range Charts for Beer Amount';
proc shewhart data=Beer;
  mrchart Amount*Batch / limitn = 5
              odstitle = title
              alln
              nmarkers;

run;

```

The NMARKERS option requests special symbols that identify points for which the subgroup sample size differs from the nominal sample size. In [Output 17.16.3](#), the median amount for batch 21 exceeds the upper control limits, indicating that the process is not in control. This illustrates the approximate nature of fixed control limits used with subgroup samples of varying sizes.

Output 17.16.3 Displaying All Subgroups Regardless of Sample Size

You can use the SMETHOD= option to determine how the process standard deviation σ is to be estimated when the subgroup sample sizes vary. The default method computes σ as an unweighted average of subgroup estimates of σ . The MVLUE method assigns greater weight to estimates of σ from subgroups with larger sample sizes. If the subgroup sample sizes are constant, the MVLUE method reduces to the NOWEIGHT method.

For details, see “Methods for Estimating the Standard Deviation” on page 1650. The following statements estimate σ using both methods:

```
proc shewhart data=Beer;
  mrchart Amount*Batch / outindex = 'Default'
                        outlimits = Blim1
                        nochart;
  mrchart Amount*Batch / smethod = mvlue
                        outindex = 'MVLUE'
                        outlimits = Blim2
                        nochart;

run;

data Blimits;
  set Blim1 Blim2;
run;
```

The estimates are saved as values of the variable `_STDDEV_` in the data set `Blimits`, which is listed in [Output 17.16.4](#). The bookkeeping variable `_INDEX_` identifies the estimate.

Output 17.16.4 The Data Set `Blimits`

The Data Set Blimits												
	S			L		S						S
	U	I		I	A	I						T
	B	N	T	M	L	G	L	M	U	L	U	D
V	G	D	Y	I	P	M	C	E	C	C	C	D
A	R	E	P	T	H	A	L	A	L	L	L	E
R	P	X	E	N	A	S	M	N	M	R	R	V
Amount	Batch	Default	ESTIMATE	V	V	3	V	11.9856	V	V	V	0.043938
Amount	Batch	MVLUE	ESTIMATE	V	V	3	V	11.9856	V	V	V	0.044004

In the data set `Blimits`, the variables `_LIMITN_`, `_ALPHA_`, `_LCLM_`, `_UCLM_`, `_LCLR_`, `_R_`, and `_UCLR_` have been assigned the special missing value `V`. This indicates that the quantities represented by these variables vary with the subgroup sample size.

Example 17.17: Specifying Axis Labels

This example illustrates various methods for specifying axis labels and other axis features for median and range charts. For further details, see “Labeling Axes” on page 2136.

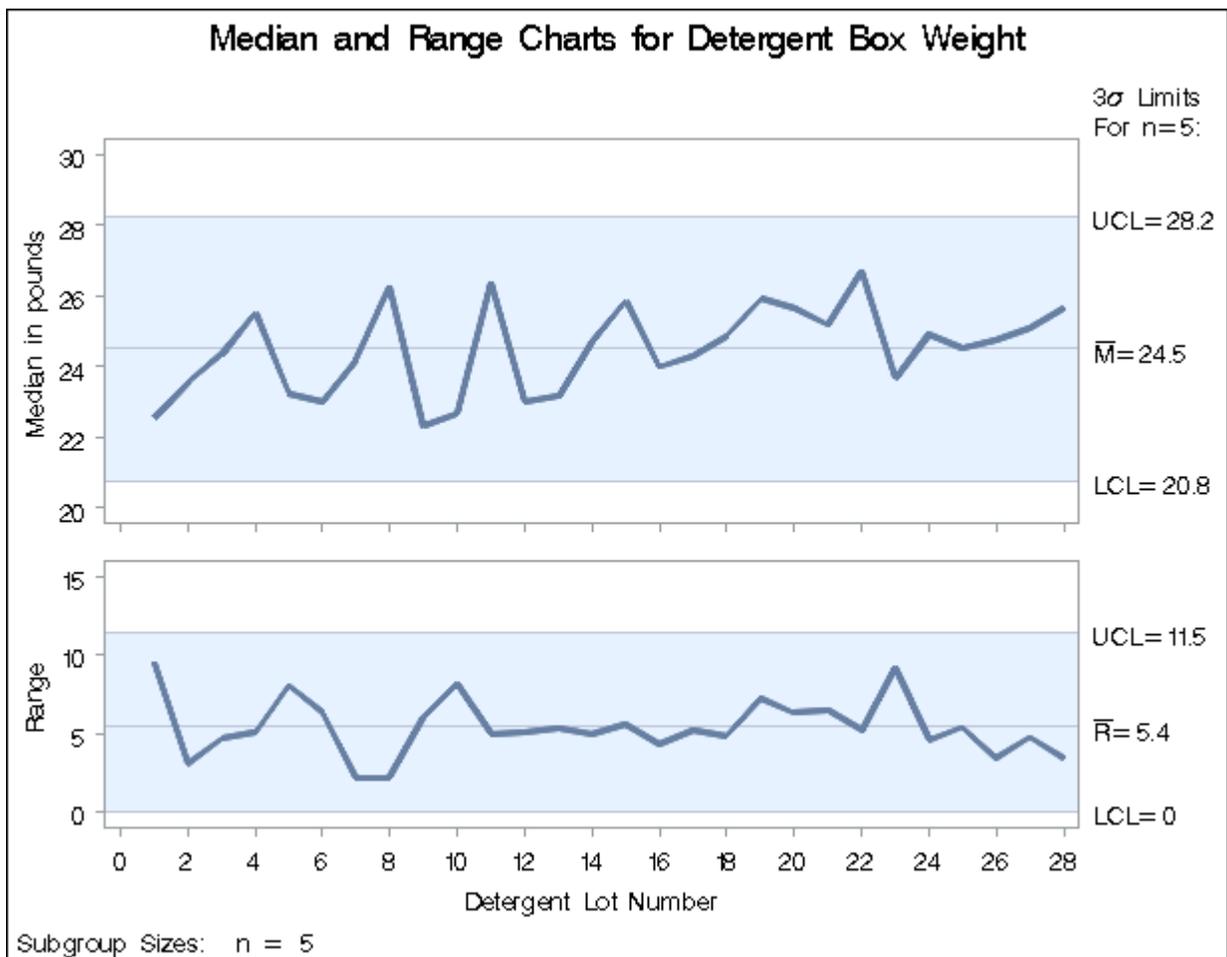

See SHWMR3 in the SAS/QC Sample Library

The charts in [Figure 17.44](#), which are based on the data set `Detergent` introduced in the section “Getting Started: MRCHART Statement” on page 1616, display default labels for the horizontal and vertical axes. You can specify axis labels by associating labels with the *process* and *subgroup* variables as illustrated by the following statements:

```
ods graphics off;
title 'Median and Range Charts for Detergent Box Weight';
proc shewhart data=Detergent;
  mrchart Weight*Lot / split = '/';
  label Lot = 'Detergent Lot Number'
        Weight = 'Median in pounds/Range';
run;
```

The charts are shown in [Output 17.17.1](#). The horizontal axis label is the label associated with the *subgroup-variable* Lot. The vertical axis label for the median chart, referred to as the primary vertical axis label, is the first portion of the label associated with the *process* variable Weight, up to but not including the split character, which is specified with the SPLIT= option. The vertical axis label for the range chart, referred to as the secondary vertical axis label, is the second portion of the label associated with Weight.

Output 17.17.1 Customized Axis Labels Using Variable Labels

When the input data set is a HISTORY= data set, the vertical axis labels are determined by the label associated with the subgroup median variable. This is illustrated by the following statements, which use the data set DETSUM introduced in “Creating Charts for Medians and Ranges from Summary Data” on page 1619:

```

title 'Median and Range Charts for Detergent Box Weight';
proc shewhart history=Detsum;
  mrchart Weight*Lot / split = '/';
  label Lot      = 'Detergent Lot Number'
        WeightM = 'Median (pounds)/Range';
run;

```

The charts are identical to those in [Output 17.17.1](#).

When the input data set is a TABLE= data set, the vertical axis labels are determined by the label associated with the subgroup median variable `_SUBMED_`. This is illustrated by the following statements, which use the data set Dtable introduced in [Figure 17.49](#):

```

title 'Median and Range Charts for Detergent Box Weight';
proc shewhart table=Dtable;
  mrchart Weight*Lot / split = '/';
  label Lot      = 'Detergent Lot Number'
        _submed_ = 'Median (pounds)/Range';
run;

```

The charts are identical to those in [Output 17.17.1](#).

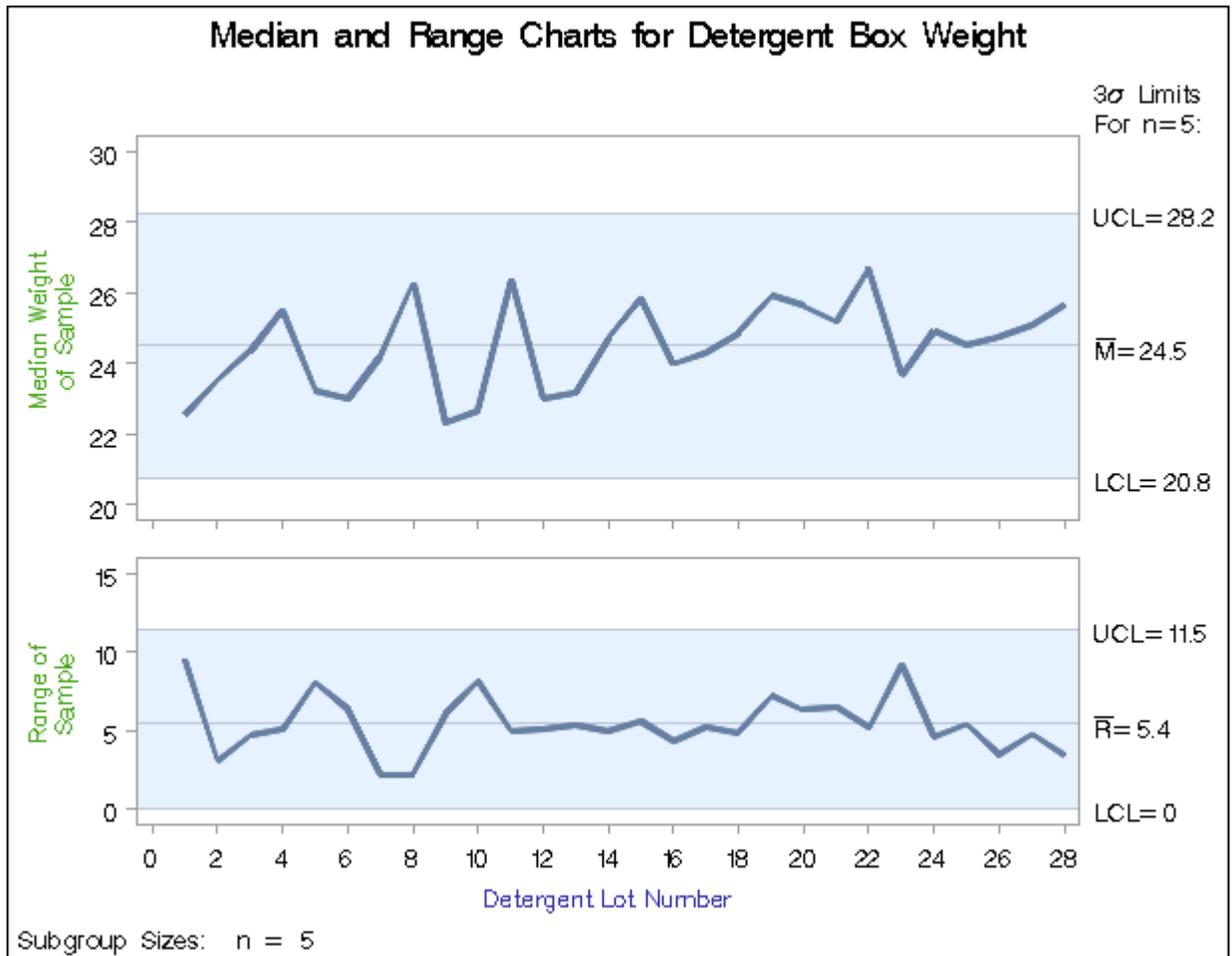

When you are creating traditional graphics, you can use AXIS statements to enhance the appearance of the axes. This method is illustrated by the following statements:

```

title 'Median and Range Charts for Detergent Box Weight';
proc shewhart data=Detergent;
  mrchart Weight*Lot / haxis  = axis1
                        vaxis  = axis2
                        vaxis2 = axis3;
axis1 label=(c=bib f=simplex 'Detergent Lot Number'      );
axis2 label=(c=vilg f=simplex 'Median Weight' j=c 'of Sample' );
axis3 label=(c=vilg f=simplex 'Range of' j=c 'Sample'      );
run;

```

The charts are shown in [Output 17.17.2](#).

Output 17.17.2 Customized Axis Labels Using AXIS Statements

You can use AXIS statements to customize a variety of axis features. For details, see *SAS/GRAPH: Reference*.

NPCHART Statement: SHEWHART Procedure

Overview: NPCHART Statement

The NPCHART statement creates np charts for the numbers of nonconforming (defective) items in subgroup samples.

You can use options in the NPCHART statement to

- compute control limits from the data based on a multiple of the standard error of the numbers of nonconforming items or as probability limits
- tabulate subgroup sample sizes, numbers of nonconforming items, control limits, and other information

- save control limits in an output data set
- save subgroup sample sizes and proportions of nonconforming items in an output data set
- read preestablished control limits from a data set
- apply tests for special causes (also known as runs tests and Western Electric rules)
- specify a known (standard) proportion of nonconforming items for computing control limits
- specify the data as counts, proportions, or percentages of nonconforming items
- display distinct sets of control limits for data from successive time phases
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have three alternatives for producing np charts with the NPCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: NPCHART Statement

This section introduces the NPCHART statement with simple examples that illustrate commonly used options. Complete syntax for the NPCHART statement is presented in the section “Syntax: NPCHART Statement” on page 1669, and advanced examples are given in the section “Examples: NPCHART Statement” on page 1689.

Creating np Charts from Count Data

See SHWNPI in the SAS/QC Sample Library

An electronics company manufactures circuits in batches of 500 and uses an *np* chart to monitor the number of failing circuits. Thirty batches are examined, and the failures in each batch are counted. The following statements create a SAS data set named Circuits,¹⁶ which contains the failure counts:

```
data Circuits;
  input Batch Fail @@;
  datalines;
1   5  2  6  3 11  4  6  5  4
6   9  7 17  8 10  9 12 10  9
11  8 12  7 13  7 14 15 15  8
16 18 17 12 18 16 19  4 20  7
21 17 22 12 23  8 24  7 25 15
26  6 27  8 28 12 29  7 30  9
;
```

A partial listing of Circuits is shown in Figure 17.51.

Figure 17.51 The Data Set Circuits

Number of Failing Circuits	
Batch	Fail
1	5
2	6
3	11
4	6
5	4

There is a single observation for each batch. The variable Batch identifies the subgroup sample and is referred to as the *subgroup-variable*. The variable Fail contains the number of nonconforming items in each subgroup sample and is referred to as the *process variable* (or *process* for short).

The following statements create the *np* chart shown in Figure 17.52:

```
ods graphics off;
title 'np Chart for the Number of Failing Circuits';
proc shewhart data=Circuits;
  npchart Fail*Batch / subgroupn = 500;
run;
```

This example illustrates the basic form of the NPCHART statement. After the keyword NPCHART, you specify the *process* to analyze (in this case, Fail), followed by an asterisk and the *subgroup-variable* (Batch).

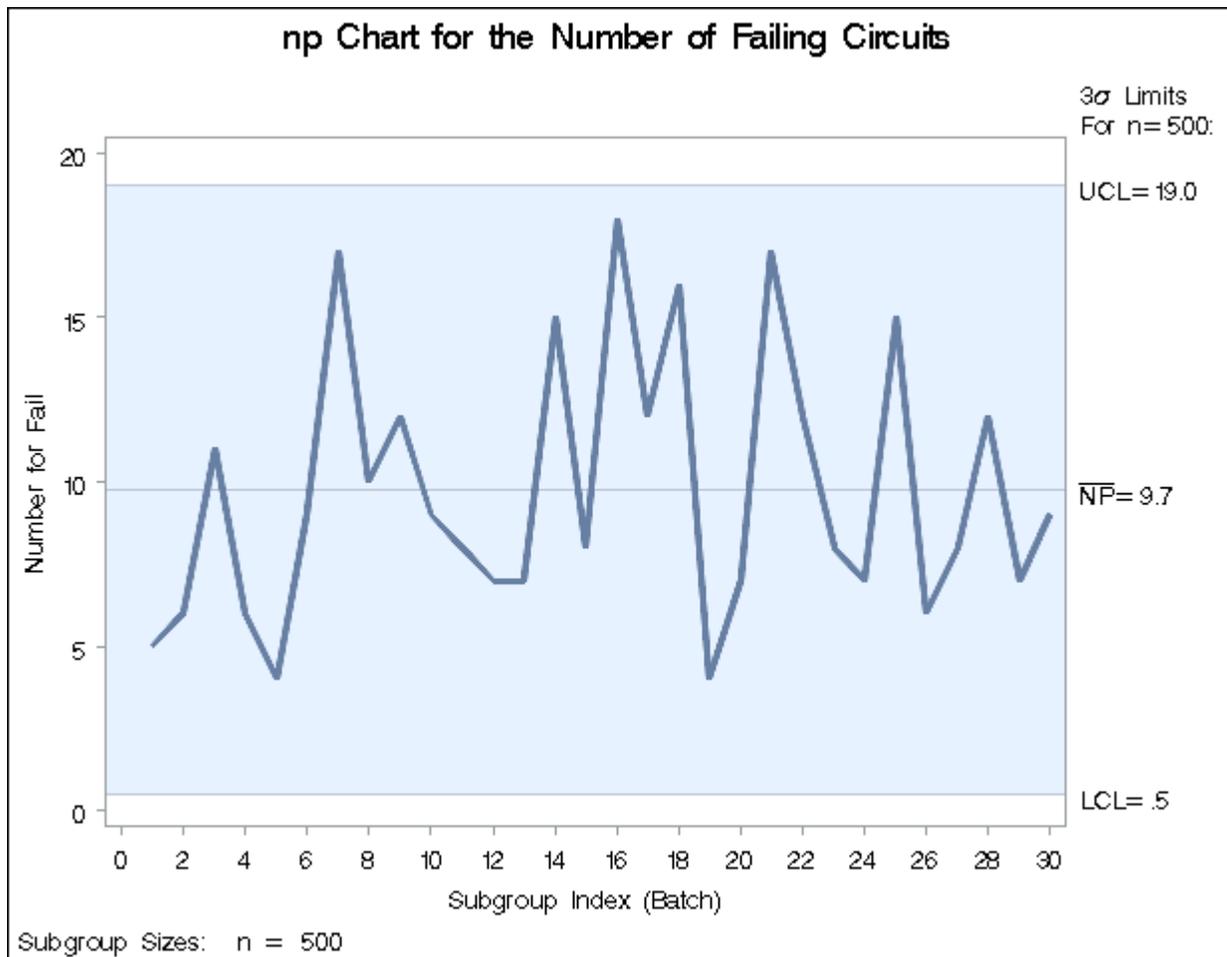

¹⁶This data set is also used in the “Getting Started” section of “PCHART Statement: SHEWHART Procedure” on page 1700

The input data set is specified with the DATA= option in the PROC SHEWHART statement. The SUBGROUPN= option specifies the number of items in each subgroup sample and is required with a DATA= input data set. The SUBGROUPN= option specifies one of the following:

- a constant subgroup sample size (in this case)
- a variable in the input data set whose values provide the subgroup sample sizes (see the next example)

Options such as SUBGROUPN= are specified after the slash (/) in the NPCHART statement. A complete list of options is presented in the section “Syntax: NPCHART Statement” on page 1669.

Figure 17.52 *np* Chart for Circuit Failures (Traditional Graphics)

Each point on the *np* chart represents the number of nonconforming items for a particular subgroup. For instance, the value plotted for the first batch is 5.

Since all the points fall within the control limits, it can be concluded that the process is in statistical control.

By default, the control limits shown are 3σ limits estimated from the data; the formulas for the limits are given in “Control Limits” on page 1681. You can also read control limits from an input data set; see “Reading Preestablished Control Limits” on page 1668. For computational details, see “Constructing Charts for Number Nonconforming (np Charts)” on page 1680. For more details on reading raw data, see “DATA= Data Set” on page 1685.

Creating np Charts from Summary Data

See *SHWNPI* in the *SAS/QC Sample Library*

The previous example illustrates how you can create np charts using raw data (counts of nonconforming items). However, in many applications, the data are provided in summarized form as proportions or percentages of nonconforming items. This example illustrates how you can use the NPCHART statement with data of this type.

The following data set provides the data from the preceding example in summarized form:

```
data Cirprop;
  input Batch pFailed @@;
  sizes=500;
  datalines;
  1 0.010 2 0.012 3 0.022 4 0.012 5 0.008
  6 0.018 7 0.034 8 0.020 9 0.024 10 0.018
  11 0.016 12 0.014 13 0.014 14 0.030 15 0.016
  16 0.036 17 0.024 18 0.032 19 0.008 20 0.014
  21 0.034 22 0.024 23 0.016 24 0.014 25 0.030
  26 0.012 27 0.016 28 0.024 29 0.014 30 0.018
  ;
```

A partial listing of Cirprop is shown in Figure 17.53. The subgroups are still indexed by Batch. The variable pFailed contains the proportions of nonconforming items, and the variable Sampsize contains the subgroup sample sizes.

Figure 17.53 The Data Set Cirprop

Subgroup Proportions of Nonconforming Items		
Batch	P Failed	sizes
1	0.010	500
2	0.012	500
3	0.022	500
4	0.012	500
5	0.008	500

The following statements create an *np* chart identical to the one in [Figure 17.52](#):

```

title 'np Chart for the Number of Failing Circuits';
symbol v=dot;
proc shewhart data=Cirprop;
  npchart pFailed*Batch / subgroupn=Sampsize
          dataunit =proportion;
label pFailed = 'Number of FAIL';
run;

```

The DATAUNIT= option specifies that the values of the *process* (pFailed) are proportions of nonconforming items. By default, the values of the *process* are assumed to be counts of nonconforming items (see the previous example).

Alternatively, you can read the data set Cirprop by specifying it as a HISTORY= data set in the PROC SHEWHART statement. A HISTORY= data set used with the NPCHART statement must contain the following variables:

- subgroup variable
- subgroup proportion of nonconforming items variable
- subgroup sample size variable

Furthermore, the names of the subgroup proportion and sample size variables must begin with the *process* name specified in the NPCHART statement and end with the special suffix characters *P* and *N*, respectively.

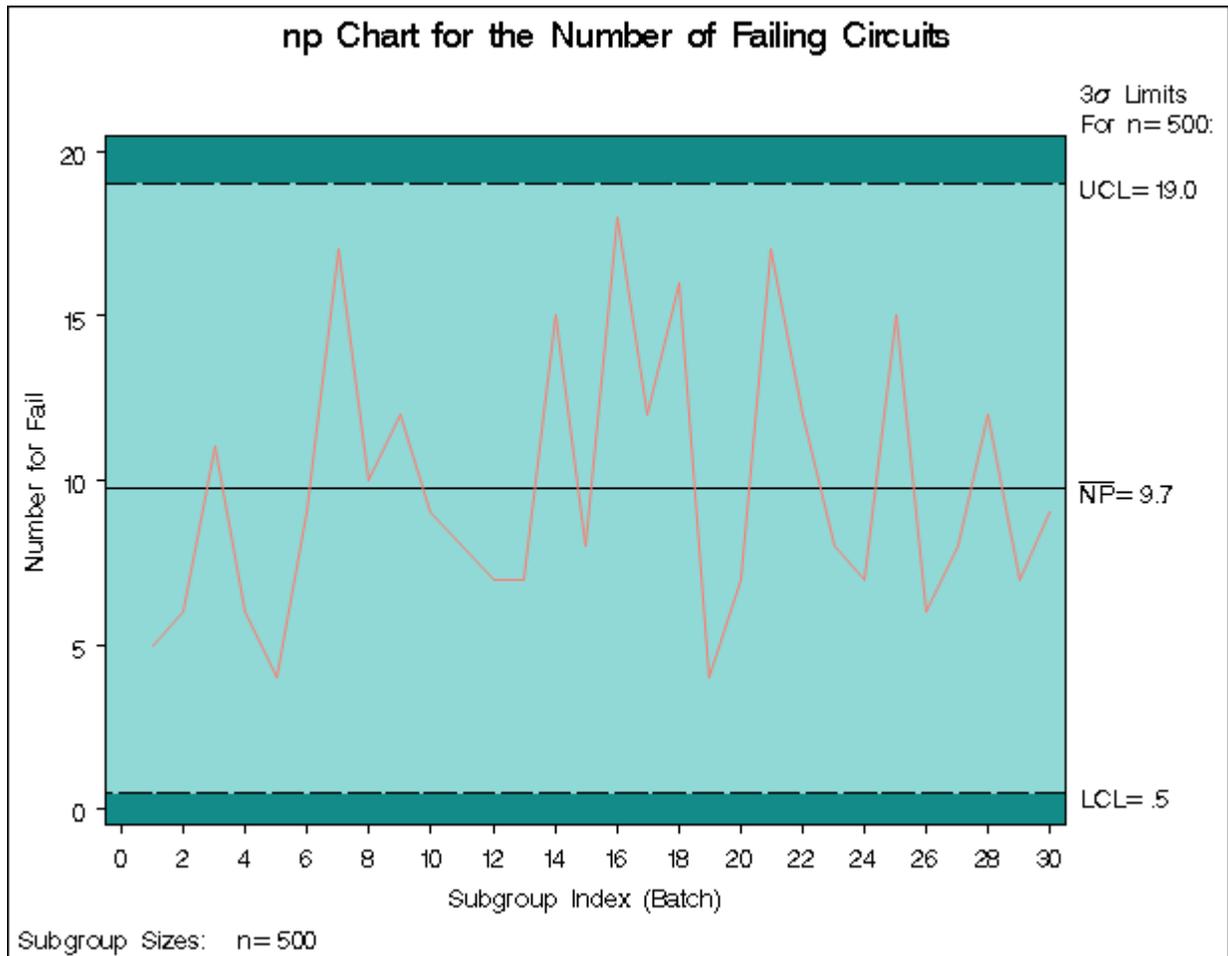

To specify Cirprop as a HISTORY= data set and Fail as the *process*, you must rename the variables pFailed and Sampsize to FailP and FailN, respectively. The following statements temporarily rename pFailed and Sampsize for the duration of the procedure step:

```

options nogstyle;
options ftext=swiss;
title 'np Chart for the Number of Failing Circuits';
proc shewhart history=Cirprop(rename=(pFailed =FailP
                                   sizes=FailN ));
  npchart Fail*Batch / cframe    = vibg
                    cinfill    = vlibg
                    coutfill   = salmon
                    cconnect   = salmon;
run;
options gstyle;

```

The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the NPCHART statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently. The resulting *np* chart is shown in [Figure 17.54](#).

Figure 17.54 *np* Chart for Circuit Failures (Traditional Graphics with NOGSTYLE)

In this example, it is more convenient to use Cirprop as a DATA= data set than as a HISTORY= data set. As illustrated in the next example, it is generally more convenient to use the HISTORY= option for input data sets that have been created previously by the SHEWHART procedure as OUTHISTORY= data sets.

For more information, see “HISTORY= Data Set” on page 1687.

Saving Proportions of Nonconforming Items

See SHWNPI in the SAS/QC Sample Library In this example, the NPCHART statement is used to create a data set that can be read later by the SHEWHART procedure (as in the preceding example). The following statements read the number of nonconforming items from the data set Circuits (see “Creating *np* Charts from Count Data” on page 1660) and create a summary data set named Cirhist:

```

proc shewhart data=Circuits;
  npchart Fail*Batch / subgroupn = 500
                    outhistory = Cirhist
                    nochart;
run;

```

The OUTHISTORY= option names the output data set, and the NOCHART option suppresses the display of the chart, which would be identical to the chart in Figure 17.52. Figure 17.55 contains a partial listing of Cirhist.

Figure 17.55 The Data Set Cirhist

Subgroup Proportions of Failing Circuits			
Batch	FailP	Fail N	
1	0.010	500	
2	0.012	500	
3	0.022	500	
4	0.012	500	
5	0.008	500	

There are three variables in the data set Cirhist.

- Batch contains the subgroup index.
- FailP contains the subgroup proportion of nonconforming items.
- FailN contains the subgroup sample size.

Note that the variables containing the subgroup proportions of nonconforming items and subgroup sample sizes are named by adding the suffix characters *P* and *N* to the *process* Fail specified in the NPCHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as that for HISTORY= data sets.

For more information, see “OUTHISTORY= Data Set” on page 1683.

Saving Control Limits

You can save the control limits for an *np* chart in a SAS data set; this enables you to apply the control limits to future data (see “Reading Prestablished Control Limits” on page 1668) or modify the limits with a DATA step program. *See SHWNPI in the SAS/QC Sample Library*

The following statements read the number of nonconforming items per subgroup from the data set Circuits (see “Creating *np* Charts from Count Data” on page 1660) and save the control limits displayed in Figure 17.52 in a data set named Cirlim:

```

proc shewhart data=Circuits;
  npchart Fail*Batch / subgroupn=500
                    outlimits=Cirlim
                    nochart;
run;

```

The OUTLIMITS= option names the data set containing the control limits, and the NOCHART option suppresses the display of the chart. The data set Cirlim is listed in [Figure 17.56](#).

Figure 17.56 The Data Set Cirlim Containing Control Limit Information

Control Limits for the Number of Failing Circuits									
Fail	Batch	ESTIMATE	500	.005040334	3	0.019467	0.46539	9.73333	19.00
—	—	—	—	—	—	—	—	—	—
S	U	B	T	M	L	G	C	L	U
—	—	—	—	—	—	—	—	—	—
V	G	Y	I	P	M	L	L	—	L
A	R	P	T	H	A	—	N	N	N
R	P	E	N	A	S	P	P	P	P
—	—	—	—	—	—	—	—	—	—

The data set Cirlim contains one observation with the limits for *process* Fail. The variables `_LCLNP_` and `_UCLNP_` contain the lower and upper control limits, and the variable `_NP_` contains the central line. The variable `_P_` contains the average proportion of nonconforming items. The value of `_LIMITN_` is the nominal sample size associated with the control limits, and the value of `_SIGMAS_` is the multiple of σ associated with the control limits. The variables `_VAR_` and `_SUBGRP_` are bookkeeping variables that save the *process* and *subgroup-variable*. The variable `_TYPE_` is a bookkeeping variable that indicates whether the value of `_P_` is an estimate or a standard value.

For more information, see “OUTLIMITS= Data Set” on page 1682.

You can create an output data set containing both control limits and summary statistics with the OUTTABLE= option, as illustrated by the following statements:

```

proc shewhart data=Circuits;
  npchart Fail*Batch / subgroupn=500
                    outtable=Cirtable
                    nochart;
run;

```

The Cirtable data set contains one observation for each subgroup sample. The variables `_SUBNP_` and `_SUBN_` contain the subgroup numbers of nonconforming items and subgroup sample sizes, respectively. The variables `_LCLNP_` and `_UCLNP_` contain the lower and upper control limits, and the variable `_NP_` contains the central line. The variables `_VAR_` and `Batch` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “OUTTABLE= Data Set” on page 1683.

The data set Cirtable is listed in Figure 17.57.

Figure 17.57 The Data Set Cirtable

Number Nonconforming and Control Limit Information									
VAR	Batch	_SIGMAS_	_LIMITN_	_SUBN_	_LCLNP_	_SUBNP_	_NP_	_UCLNP_	_EXLIM
Fail	1	3	500	500	0.46539	5	9.73333	19.0013	
Fail	2	3	500	500	0.46539	6	9.73333	19.0013	
Fail	3	3	500	500	0.46539	11	9.73333	19.0013	
Fail	4	3	500	500	0.46539	6	9.73333	19.0013	
Fail	5	3	500	500	0.46539	4	9.73333	19.0013	
Fail	6	3	500	500	0.46539	9	9.73333	19.0013	
Fail	7	3	500	500	0.46539	17	9.73333	19.0013	
Fail	8	3	500	500	0.46539	10	9.73333	19.0013	
Fail	9	3	500	500	0.46539	12	9.73333	19.0013	
Fail	10	3	500	500	0.46539	9	9.73333	19.0013	
Fail	11	3	500	500	0.46539	8	9.73333	19.0013	
Fail	12	3	500	500	0.46539	7	9.73333	19.0013	
Fail	13	3	500	500	0.46539	7	9.73333	19.0013	
Fail	14	3	500	500	0.46539	15	9.73333	19.0013	
Fail	15	3	500	500	0.46539	8	9.73333	19.0013	
Fail	16	3	500	500	0.46539	18	9.73333	19.0013	
Fail	17	3	500	500	0.46539	12	9.73333	19.0013	
Fail	18	3	500	500	0.46539	16	9.73333	19.0013	
Fail	19	3	500	500	0.46539	4	9.73333	19.0013	
Fail	20	3	500	500	0.46539	7	9.73333	19.0013	
Fail	21	3	500	500	0.46539	17	9.73333	19.0013	
Fail	22	3	500	500	0.46539	12	9.73333	19.0013	
Fail	23	3	500	500	0.46539	8	9.73333	19.0013	
Fail	24	3	500	500	0.46539	7	9.73333	19.0013	
Fail	25	3	500	500	0.46539	15	9.73333	19.0013	
Fail	26	3	500	500	0.46539	6	9.73333	19.0013	
Fail	27	3	500	500	0.46539	8	9.73333	19.0013	
Fail	28	3	500	500	0.46539	12	9.73333	19.0013	
Fail	29	3	500	500	0.46539	7	9.73333	19.0013	
Fail	30	3	500	500	0.46539	9	9.73333	19.0013	

An OUTTABLE= data set can be read later as a TABLE= data set. For example, the following statements read Cirtable and display an *np* chart (not shown here) identical to the chart in Figure 17.52:

```

title 'np Chart for the Number of Failing Circuits';
proc shewhart table=Cirtable;
  npchart Fail*Batch;
run;

```

Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts (see “Specialized Control Charts: SHEWHART Procedure” on page 2171). For more information, see “TABLE= Data Set” on page 1688.

Reading Prestablished Control Limits

See *SHWNPI* in the *SAS/QC Sample Library*

In the previous example, the OUTLIMITS= data set Cirlim saved control limits computed from the data in Circuits. This example shows how these limits can be applied to new data provided in the following data set:

```
data Circuit2;
  input Batch Fail;
  datalines;
31 12 32 9 33 16 34 9
35 3 36 8 37 20 38 4
39 8 40 6 41 12 42 16
43 9 44 2 45 10 46 8
47 14 48 10 49 11 50 9
;
```

The following statements create an *np* chart for the data in Circuit2 using the control limits in Cirlim:

```
ods graphics on;
title 'np Chart for the Proportion of Failing Circuits';
proc shewhart data=Circuit2 limits=Cirlim;
  npchart Fail*Batch / subgroupn = 500
                    odstitle = title;
run;
```

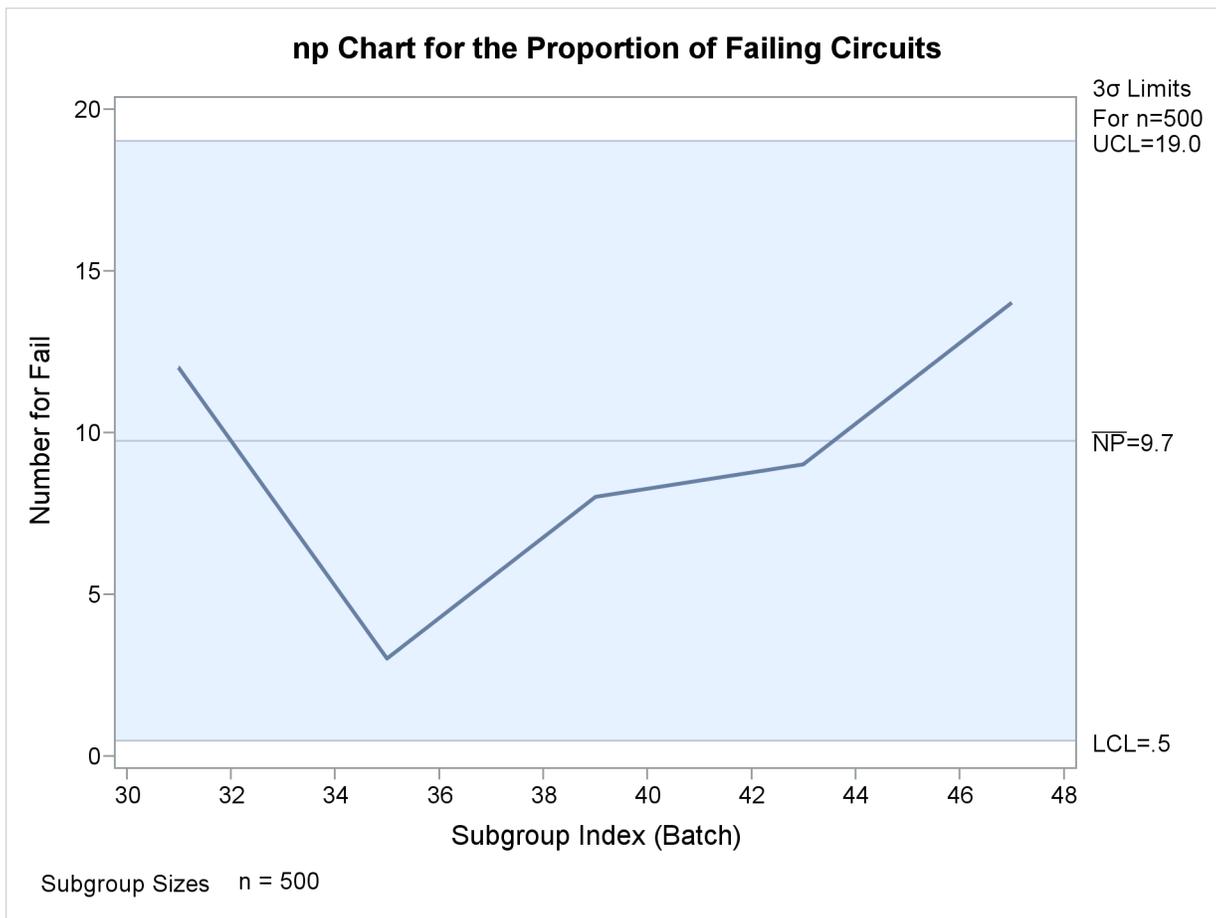

The ODS GRAPHICS ON statement specified before the PROC SHEWHART statement enables ODS Graphics, so the *np* chart is created using ODS Graphics instead of traditional graphics.

The LIMITS= option in the PROC SHEWHART statement specifies the data set containing the control limits. By default,¹⁷ this information is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches the *process* name Fail
- the value of `_SUBGRP_` matches the *subgroup-variable* name Batch

The resulting *np* chart is shown in [Figure 17.58](#).

¹⁷In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

Figure 17.58 *np* Chart for Second Set of Circuit Failures (ODS Graphics)

The number of nonconforming items in the 37th batch exceeds the upper control limit, signaling that the process is out of control.

In this example, the LIMITS= data set was created in a previous run of the SHEWHART procedure. You can also create a LIMITS= data set with the DATA step; see [Example 17.21](#) for an example. See “LIMITS= Data Set” on page 1686 for details concerning the variables that you must provide.

Syntax: NPCHART Statement

The basic syntax for the NPCHART statement is as follows:

```
NPCHART process * subgroup-variable ;
```

The general form of this syntax is as follows:

```
NPCHART processes * subgroup-variable <(block-variables)>  
          <=symbol-variable | =character'> / <options> ;
```

You can use any number of NPCHART statements in the SHEWHART procedure. The components of the NPCHART statement are described as follows.

process**processes**

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC SHEWHART statement.

- If numbers of nonconforming items are read from a DATA= data set, *process* must be the name of the variable containing the numbers. For an example, see “[Creating np Charts from Count Data](#)” on page 1660.
- If proportions of nonconforming items are read from a HISTORY= data set, *process* must be the common prefix of the summary variables in the HISTORY= data set. For an example, see “[Creating np Charts from Summary Data](#)” on page 1662.
- If numbers of nonconforming items and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “[Saving Control Limits](#)” on page 1665.

A *process* is required. If you specify more than one process, enclose the list in parentheses. For example, the following statements request distinct *np* charts for Rejects and Reworks:

```
proc shewhart data=Measures;
  npchart (Rejects Reworks)*Sample / subgroupn=100;
run;
```

Note that when data are read from a DATA= data set, the SUBGROUPN= option, which specifies subgroup sample sizes, is required.

subgroup-variable

is the variable that identifies subgroups in the data. The *subgroup-variable* is required. In the preceding NPCHART statement, `Sample` is the subgroup variable. For details, see “[Subgroup Variables](#)” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or character used to plot numbers of nonconforming items.

- If you produce a line printer chart, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOLn statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create an *np* chart using an asterisk (*) to plot the points:

```
proc shewhart data=Values lineprinter;
  npchart Rejects*Day='*' / subgroupn=100;
run;
```

options

enhance the appearance of the chart, request additional analyses, save results in data sets, and so on. The “[Summary of Options](#)” on page 1671 section, which follows, lists all options by function. “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018 describes each option in detail.

Summary of Options

The following tables list the NPCHART statement options by function. For complete descriptions, see “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 17.37 NPCHART Statement Options

Option	Description
Options for Specifying Control Limits	
ALPHA=	requests probability limits for chart
LIMITN=	specifies either nominal sample size for fixed control limits or varying limits
NOREADLIMITS	computes control limits for each <i>process</i> from the data rather than a LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from a LIMITS= data set
READINDEX=	reads control limits for each <i>process</i> from a LIMITS= data set
READLIMITS	reads single set of control limits for each <i>process</i> from a LIMITS= data set (SAS 6.09 and earlier releases)
SIGMAS=	specifies width of control limits in terms of multiple <i>k</i> of standard error of plotted means
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line

Table 17.37 continued

Option	Description
NOCTL	suppresses display of central line
NOLCL	suppresses display of lower control limit
NOLIMIT0	suppresses display of lower control limit if it is 0
NOLIMIT1	suppresses display of upper control limit if it is 1 (100%)
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit
NPSYMBOL=	specifies label for central line
UCLLABEL=	specifies label for upper control limit
WLIMITS=	specifies width for control limits and central line
Standard Value Options	
P0=	specifies known (standard) value p_0 for proportion of nonconforming items
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on np chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
OUTLABEL=	labels points outside control limits
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles

Table 17.37 continued

Option	Description
Options for Specifying Tests for Special Causes	
INDEPENDENTZONES	computes zone widths independently above and below center line
NO3SIGMACHECK	enables tests to be applied with control limits other than 3σ limits
NOTESTACROSS	suppresses tests across <i>phase</i> boundaries
TESTS=	specifies tests for special causes
TEST2RUN=	specifies length of pattern for Test 2
TEST3RUN=	specifies length of pattern for Test 3
TESTACROSS	applies tests across <i>phase</i> boundaries
TESTLABEL=	provides labels for points where test is positive
TESTLABEL n =	specifies label for n th test for special causes
TESTNMETHOD=	applies tests to standardized chart statistics
TESTOVERLAP	performs tests on overlapping patterns of points
TESTRESET=	enables tests for special causes to be reset
ZONELABELS	adds labels A, B, and C to zone lines
ZONES	adds lines delineating zones A, B, and C
ZONEVALPOS=	specifies position of ZONEVALUES labels
ZONEVALUES	labels zone lines with their values
Options for Displaying Tests for Special Causes	
CTESTLABBOX=	specifies color for boxes enclosing labels indicating points where test is positive
CTESTS=	specifies color for labels indicating points where test is positive
CTESTSYMBOL=	specifies color for symbol used to plot points where test is positive
CZONES=	specifies color for lines and labels delineating zones A, B, and C
LTESTS=	specifies type of line connecting points where test is positive
LZONES=	specifies line type for lines delineating zones A, B, and C
TESTFONT=	specifies software font for labels at points where test is positive
TESTHEIGHT=	specifies height of labels at points where test is positive
TESTLABBOX	requests that labels for points where test is positive be positioned so that do not overlap
TESTSYMBOL=	specifies plot symbol for points where test is positive
TESTSYMBOLHT=	specifies symbol height for points where test is positive
WTESTS=	specifies width of line connecting points where test is positive
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels

Table 17.37 *continued*

Option	Description
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOTRUNC	suppresses vertical axis truncation at zero applied by default
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPLABELS=	specifies thinning factor for tick mark labels on horizontal axis
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis
VFORMAT=	specifies format for vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes
NPANELPOS=	specifies number of subgroup positions per panel on each chart

Table 17.37 continued

Option	Description
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
ZEROSTD	displays np chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= options
CVREF=	specifies color for lines requested by VREF= options
HREF=	specifies position of reference lines perpendicular to horizontal axis
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis
HREFLABELS=	specifies labels for HREF= lines
HREFLABPOS=	specifies position of HREFLABELS= labels
LHREF=	specifies line type for HREF= lines
LVREF=	specifies line type for VREF= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis
VREFLABELS=	specifies labels for VREF= lines
VREFLABPOS=	position of VREFLABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features chart
DESCRIPTION=	specifies description of np chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of np chart's GRSEG catalog entry

Table 17.37 continued

Option	Description
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases

Table 17.37 *continued*

Option	Description
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
Input Data Set Options	
DATAUNIT	specifies that input values are proportions or percentages (rather than counts) of nonconforming items
MISSBREAK	specifies that observations with missing values are not to be processed
SUBGROUPN	specifies subgroup sample sizes as constant number <i>n</i> or as values of variable in a DATA= data set
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the OUTLIMITS= data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLELEGEND	augments basic table with legend for tests for special causes
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
TABLETESTS	augments basic table with a column indicating which tests for special causes are positive
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend

Table 17.37 continued

Option	Description
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for overlay line segments
COVERLAY=	specifies colors for overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on chart
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with overlay points

Table 17.37 *continued*

Option	Description
OVERLAYID=	specifies labels for overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for overlays
OVERLAYSYMHT=	specifies symbol heights for overlays
WOVERLAY=	specifies widths of overlay line segments
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
TESTCHAR=	specifies character for line segments that connect any sequence of points for which a test for special causes is positive
VREFCHAR=	specifies line character for VREF= lines
ZONECHAR=	specifies character for lines that delineate zones for tests for special causes

Details: NPCHART Statement

Constructing Charts for Number Nonconforming (np Charts)

The following notation is used in this section:

p	expected proportion of nonconforming items produced by the process
p_i	proportion of nonconforming items in the i th subgroup
X_i	number of nonconforming items in the i th subgroup
n_i	number of items in the i th subgroup
\bar{p}	average proportion of nonconforming items taken across subgroups:

$$\bar{p} = \frac{n_1 p_1 + \cdots + n_N p_N}{n_1 + \cdots + n_N} = \frac{X_1 + \cdots + X_N}{n_1 + \cdots + n_N}$$

N	number of subgroups
$I_T(\alpha, \beta)$	incomplete beta function:

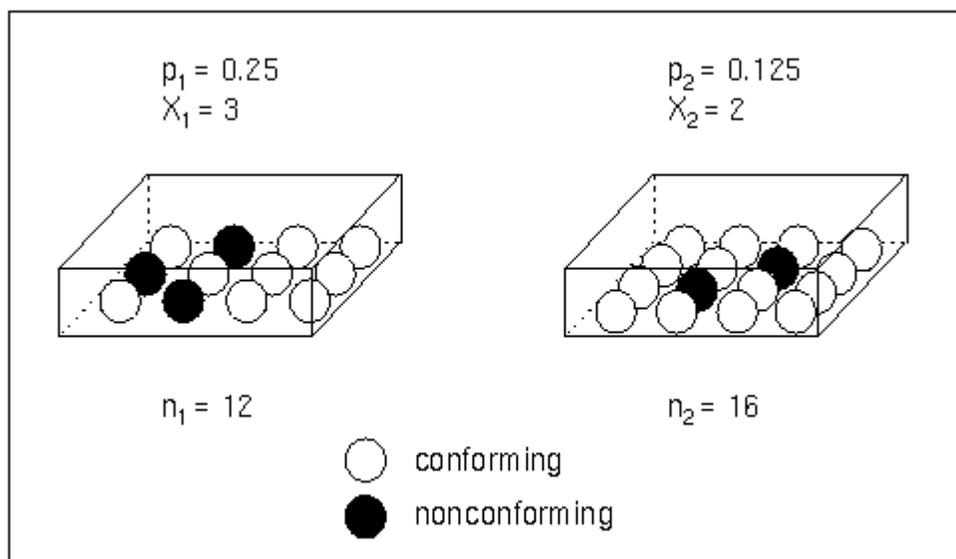

$$I_T(\alpha, \beta) = (\Gamma(\alpha + \beta) / \Gamma(\alpha)\Gamma(\beta)) \int_0^T t^{\alpha-1} (1-t)^{\beta-1} dt$$

for $0 < T < 1$, $\alpha > 0$, and $\beta > 0$, where $\Gamma(\cdot)$ is the gamma function

Plotted Points

Each point on an np chart represents the observed number (X_i) of nonconforming items in a subgroup. For example, suppose the first subgroup (see Figure 17.59) contains 12 items, of which three are nonconforming. The point plotted for the first subgroup is $X_1 = 3$.

Figure 17.59 Proportions Versus Counts

Note that a p chart displays the proportion of nonconforming items p_i . You can use the PCHART statement to create p charts; see “PCHART Statement: SHEWHART Procedure” on page 1700.

Central Line

By default, the central line on an np chart indicates an estimate for $n_i p$, which is computed as $n_i \bar{p}$. If you specify a known value (p_0) for p , the central line indicates the value of $n_i p_0$. Note that the central line varies with n_i .

Control Limits

You can compute the limits in the following ways:

- as a specified multiple (k) of the standard error of X_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that X_i exceeds the limits

The lower and upper control limits, LCL and UCL respectively, are computed as

$$\begin{aligned} \text{LCL} &= \max \left(n_i \bar{p} - k \sqrt{n_i \bar{p}(1 - \bar{p})}, 0 \right) \\ \text{UCL} &= \min \left(n_i \bar{p} + k \sqrt{n_i \bar{p}(1 - \bar{p})}, n_i \right) \end{aligned}$$

A lower probability limit for X_i can be determined using the fact that

$$\begin{aligned} P\{X_i < \text{LCL}\} &= 1 - P\{X_i \geq \text{LCL}\} \\ &= 1 - I_{\bar{p}}(\text{LCL}, n_i + 1 - \text{LCL}) \\ &= I_{1-\bar{p}}(n_i + 1 - \text{LCL}, \text{LCL}) \end{aligned}$$

Refer to Johnson, Kotz, and Kemp (1992). This assumes that the process is in statistical control and that X_i is binomially distributed. The lower probability limit LCL is then calculated by setting

$$I_{1-\bar{p}}(n_i + 1 - \text{LCL}, \text{LCL}) = \alpha/2$$

and solving for LCL. Similarly, the upper probability limit for X_i can be determined using the fact that

$$\begin{aligned} P\{X_i > \text{UCL}\} &= P\{X_i > \text{UCL}\} \\ &= I_{\bar{p}}(\text{UCL}, n_i + 1 - \text{UCL}) \end{aligned}$$

The upper probability limit UCL is then calculated by setting

$$I_{\bar{p}}(\text{UCL}, n_i + 1 - \text{UCL}) = \alpha/2$$

and solving for UCL. The probability limits are asymmetric about the central line. Note that both the control limits and probability limits vary with n_i .

You can specify parameters for the limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify p_0 with the P0= option or with the variable `_P_` in the LIMITS= data set.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves control limits and control limit parameters. The following variables can be saved:

Table 17.38 OUTLIMITS= Data Set

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding limits
<code>_INDEX_</code>	optional identifier for the control limits specified with the OUTINDEX= option
<code>_LCLNP_</code>	lower control limit for number of nonconforming items
<code>_LIMITN_</code>	sample size associated with the control limits
<code>_NP_</code>	average number of nonconforming items ($n_i \bar{p}$ or $n_i p_0$)
<code>_P_</code>	average proportion of nonconforming items (\bar{p} or p_0)
<code>_SIGMAS_</code>	multiple (k) of standard error of X_i
<code>_SUBGRP_</code>	<i>subgroup-variable</i> specified in the NPCHART statement
<code>_TYPE_</code>	type (standard or estimate) of <code>_NP_</code>
<code>_UCLNP_</code>	upper control limit for number of nonconforming items
<code>_VAR_</code>	<i>process</i> specified in the NPCHART statement

Notes:

1. If the control limits vary with subgroup sample size, the special missing value V is assigned to the variables `_LIMITN_`, `_LCLNP_`, `_UCLNP_`, `_NP_`, and `_SIGMAS_`.
2. If the limits are defined in terms of a multiple k of the standard error of X_i , the value of `_ALPHA_` is computed as $\alpha = P\{X_i < \text{_LCLNP_}\} + P\{X_i > \text{_UCLNP_}\}$, using the incomplete beta function.
3. If the limits are probability limits, the value of `_SIGMAS_` is computed as $k = (\text{_UCLNP_} - \text{_NP_}) / \sqrt{\text{_NP_}(1 - \text{_NP_}) / \text{_LIMITN_}}$. If `_LIMITN_` has the special missing value V , this value is assigned to `_SIGMAS_`.
4. Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *process* specified in the NPCHART statement. For an example, see “[Saving Control Limits](#)” on page 1665.

OUTHISTORY= Data Set

The OUTHISTORY= data set saves subgroup summary statistics. The following variables are saved:

- the *subgroup-variable*
- the subgroup proportion of nonconforming items variable named by the *process* suffixed with *P*
- a subgroup sample size variable named by the *process* suffixed with *N*

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Subgroup summary variables are created for each *process* specified in the NPCHART statement. For example, consider the following statements:

```
proc shewhart data=Input;
  npchart (Rework Rejected)*Batch / outhistory=Summary
      subgroupn =30;
run;
```

The data set Summary contains variables named Batch, ReworkP, ReworkN, RejectedP, and RejectedN.

Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

For an example of an OUTHISTORY= data set, see “Saving Proportions of Nonconforming Items” on page 1664.

OUTTABLE= Data Set

The OUTTABLE= data set saves subgroup summary statistics, control limits, and related information. The following variables are saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_EXLIM_</code>	control limit exceeded on np chart
<code>_LCLNP_</code>	lower control limit for number of nonconforming items
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_NP_</code>	average number of nonconforming items
<code>_SIGMAS_</code>	multiple (k) of the standard error of X_i associated with the control limits
<code>subgroup</code>	values of the subgroup variable
<code>_SUBNP_</code>	subgroup number of nonconforming items
<code>_SUBN_</code>	subgroup sample size
<code>_TESTS_</code>	tests for special causes signaled on np chart
<code>_UCLNP_</code>	upper control limit for number of nonconforming items
<code>_VAR_</code>	<i>process</i> specified in the NPCHART statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the READPHASES= option is specified)

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved depending on how the control limits are defined (with the ALPHA= or SIGMAS= options, respectively, or with the corresponding variables in a LIMITS= data set).
2. The variable `_TESTS_` is saved if you specify the TESTS= option. The k th character of a value of `_TESTS_` is k if Test k is positive at that subgroup. For example, if you request the first four tests (the tests appropriate for np charts) and Tests 2 and 4 are positive for a given subgroup, the value of `_TESTS_` has a 2 for the second character, a 4 for the fourth character, and blanks for the other six characters.
3. The variables `_EXLIM_` and `_TESTS_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “Saving Control Limits” on page 1665.

ODS Tables

The following table summarizes the ODS tables that you can request with the NPCHART statement.

Table 17.39 ODS Tables Produced with the NPCHART Statement

Table Name	Description	Options
NPCHART	<i>np</i> chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLELEG, TABLEOUT, TABLETESTS
TestDescriptions	descriptions of tests for special causes requested with the TESTS= option for which at least one positive signal is found	TABLEALL, TABLELEG

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the SHEWHART procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. NPCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the NPCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 17.40](#).

Table 17.40 ODS Graphics Produced by the NPCHART Statement

ODS Graph Name	Plot Description
NPChart	<i>np</i> chart

See Chapter 3, “[SAS/QC Graphics](#),” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (counts of nonconforming items) from a DATA= data set specified in the PROC SHEWHART statement. Each *process* specified in the NPCHART statement must be a SAS variable in the DATA= data set. This variable provides counts for subgroup samples indexed by the values of the *subgroup-variable*. The *subgroup-variable*, which is specified in the NPCHART

statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a count for each *process* and a value for the *subgroup-variable*. The data set must contain one observation for each subgroup. Note that you can specify the DATAUNIT= option in the NPCHART statement to read proportions or percentages of nonconforming items instead of counts. Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

When you use a DATA= data set with the NPCHART statement, the SUBGROUPN= option (which specifies the subgroup sample size) is required. By default, the SHEWHART procedure reads all of the observations in a DATA= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (for an example, see “[Displaying Stratification in Phases](#)” on page 2103).

For an example of a DATA= data set, see “[Creating np Charts from Count Data](#)” on page 1660.

LIMITS= Data Set

You can read preestablished control limits (or parameters from which the control limits can be calculated) from a LIMITS= data set specified in the PROC SHEWHART statement. For example, the following statements read control limit information from the data set `Conlims`:¹⁸

```
proc shewhart data=Info limits=Conlims;
  npchart Rejects*Batch / subgroupn=100;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the SHEWHART procedure. Such data sets always contain the variables required for a LIMITS= data set. The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LCLNP_`, `_NP_`, and `_UCLNP_`, which specify the control limits directly
- the variable `_P_`, which is used to calculate the control limits according to the equations in the section “[Control Limits](#)” on page 1681

In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables whose lengths are no greater than 32.
- The variable `_INDEX_` is required if you specify the READINDEX= option; this must be a character variable whose length is no greater than 48.

¹⁸In SAS 6.09 and in earlier releases, it is necessary to specify the READLIMITS option.

- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8; valid values are 'ESTIMATE' and 'STANDARD'.
- BY variables are required if specified with a BY statement.

For an example, see “[Reading Preestablished Control Limits](#)” on page 1668.

HISTORY= Data Set

You can read subgroup summary statistics from a HISTORY= data set specified in the PROC SHEWHART statement. This enables you to reuse OUTHISTORY= data sets that have been created in previous runs of the SHEWHART procedure or to create your own HISTORY= data set.

A HISTORY= data set used with the NPCHART statement must contain

- the *subgroup-variable*
- a subgroup proportion of nonconforming items variable for each *process*
- a subgroup sample size variable for each *process*

The names of the proportion sample size variables must be the *process* name concatenated with the special suffix characters *P* and *N*, respectively.

For example, consider the following statements:

```
proc shewhart history=Summary;
  npchart ( Rework Rejected)*Batch / subgroupn=50;
run;
```

The data set Summary must include the variables Batch, ReworkP, ReworkN, RejectedP, and RejectedN.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a HISTORY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a HISTORY= data set. However, if the data set includes the variable _PHASE_, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (see “Displaying Stratification in Phases” on page 2103 for an example).

For an example of a HISTORY= data set, see “Creating np Charts from Summary Data” on page 1662.

TABLE= Data Set

You can read summary statistics and control limits from a TABLE= data set specified in the PROC SHEWHART statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the SHEWHART procedure. Because the SHEWHART procedure simply displays the information read from a TABLE= data set, you can use TABLE= data sets to create specialized control charts. Examples are provided in “Specialized Control Charts: SHEWHART Procedure” on page 2171.

The following table lists the variables required in a TABLE= data set used with the NPCHART statement:

Table 17.41 Variables Required in a TABLE= Data Set

Variable	Description
LCLNP	lower control limit for number of nonconforming items
LIMITN	nominal sample size associated with the control limits
NP	average number of nonconforming items
<i>subgroup-variable</i>	values of the <i>subgroup-variable</i>
SUBN	subgroup sample size
SUBNP	subgroup number of nonconforming items
UCLNP	upper control limit for number of nonconforming items

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- _PHASE_ (if the READPHASES= option is specified). This variable must be a character variable whose length is no greater than 48.
- _TESTS_ (if the TESTS= option is specified). This variable is used to flag tests for special causes and must be a character variable of length 8.
- _VAR_. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable whose length is no greater than 32.

For an example of a TABLE= data set, see “Saving Control Limits” on page 1665.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical	DATA=	<i>process</i>
Vertical	HISTORY=	subgroup number nonconforming variable
Vertical	TABLE=	<code>_SUBNP_</code>

For an example, see “Labeling Axes” on page 2136.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: NPCHART Statement

This section provides advanced examples of the NPCHART statement.

Example 17.18: Applying Tests for Special Causes

This example shows how you can apply tests for special causes to make *np* charts more sensitive to special causes of variation. The following statements create a SAS data set named Circuit3, which contains the number of failing circuits for 20 batches from the circuit manufacturing process introduced in the section “Creating *np* Charts from Count Data” on page 1660: *See SHWNP2 in the SAS/QC Sample Library*

```
data Circuit3;
  input Batch Fail @@;
  datalines;
  1 12    2 21    3 16    4  9
  5  3    6  4    7  6    8  9
  9 11   10 13   11 12   12  7
 13  2   14 14   15  9   16  8
 17 14   18 10   19 11   20  9
  ;
```

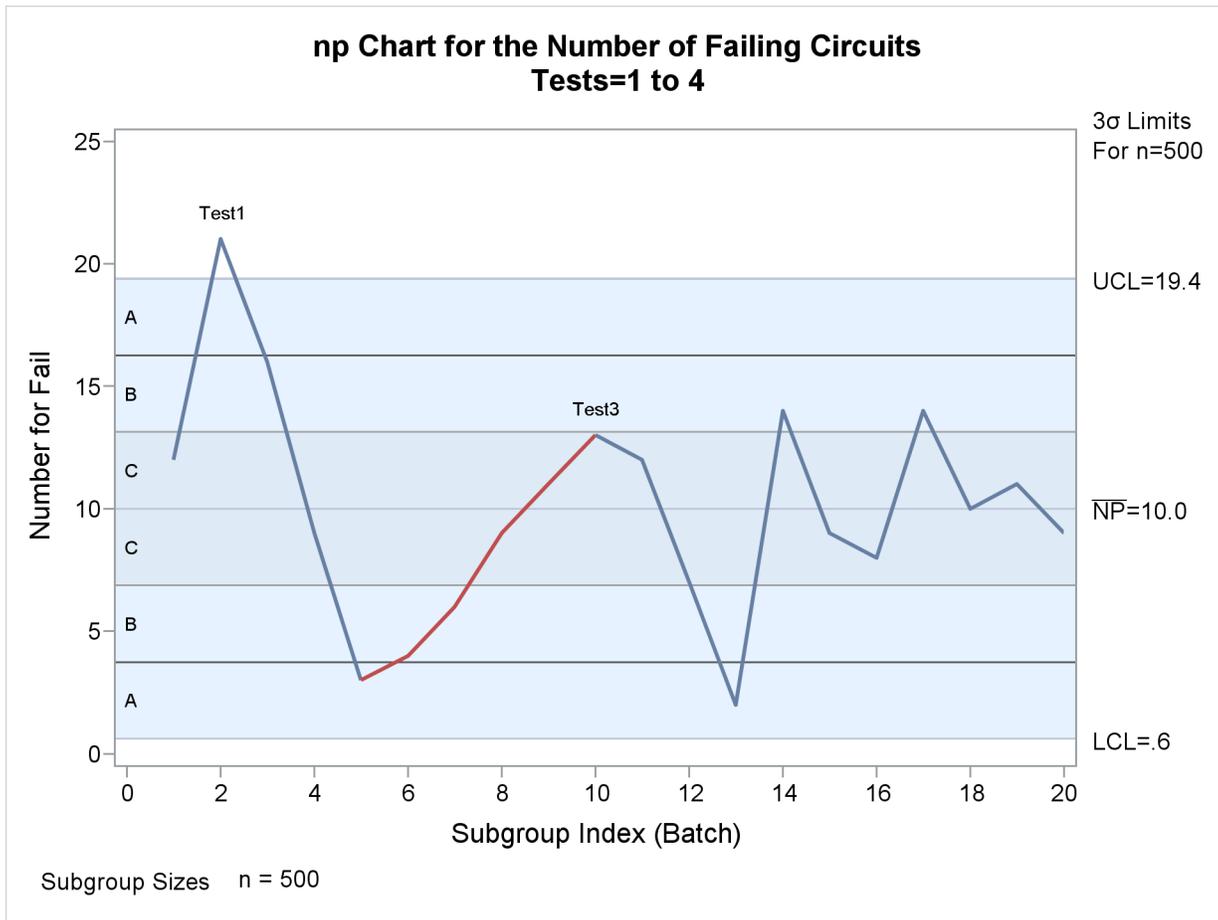

The following statements create the np chart, apply several tests to the chart, and tabulate the results:

```
ods graphics on;
title1 'np Chart for the Number of Failing Circuits';
title2 'Tests=1 to 4';
proc shewhart data=Circuit3;
  npchart Fail*Batch / subgroupn = 500
                    tests=1 to 4
                    table
                    tabletest
                    tablelegend
                    zones
                    zonelabels
                    odstitle = title
                    odstitle2 = title2;
run;
```

The chart is shown in [Output 17.18.1](#), and the printed output is shown in [Output 17.18.2](#). The TESTS= option requests Tests 1, 2, 3, and 4, which are described in “Tests for Special Causes: SHEWHART Procedure” on page 2146. The TABLETESTS option requests a table of counts of nonconforming items and control limits, with a column indicating which subgroups tested positive for special causes. The TABLELEGEND option adds a legend describing the tests. The ZONELABELS option displays zone lines and zone labels on the chart. The zones are used to define the tests.

[Output 17.18.1](#) and [Output 17.18.2](#) indicate that Test 1 is positive at batch 2 and Test 3 is positive at batch 10.

Output 17.18.1 Tests for Special Causes Displayed on np Chart

Output 17.18.2 Tabular Form of np Chart

np Chart for the Number of Failing Circuits Tests=1 to 4					
The SHEWHART Procedure					
np Chart Summary for Fail					
Batch	Subgroup Sample Size	-3 Sigma Limits Lower Limit	with n=500 for Number- Subgroup Number	Upper Limit	Special Tests Signaled

8	500	0.60851449	9.000000	19.391486	
9	500	0.60851449	11.000000	19.391486	
10	500	0.60851449	13.000000	19.391486	3
11	500	0.60851449	12.000000	19.391486	
12	500	0.60851449	7.000000	19.391486	
13	500	0.60851449	2.000000	19.391486	
14	500	0.60851449	14.000000	19.391486	
15	500	0.60851449	9.000000	19.391486	
16	500	0.60851449	8.000000	19.391486	
17	500	0.60851449	14.000000	19.391486	
18	500	0.60851449	10.000000	19.391486	
19	500	0.60851449	11.000000	19.391486	
20	500	0.60851449	9.000000	19.391486	

Test Descriptions	
Test 1	One point beyond Zone A (outside control limits)
Test 3	Six points in a row steadily increasing or decreasing

Example 17.19: Specifying Standard Average Proportion

See SHWNP3 in the SAS/QC Sample Library. In some situations, a standard (known) value (p_0) is available for the expected proportion of non-conforming items, based on extensive testing or previous sampling. This example illustrates how you can specify p_0 to create an np chart.

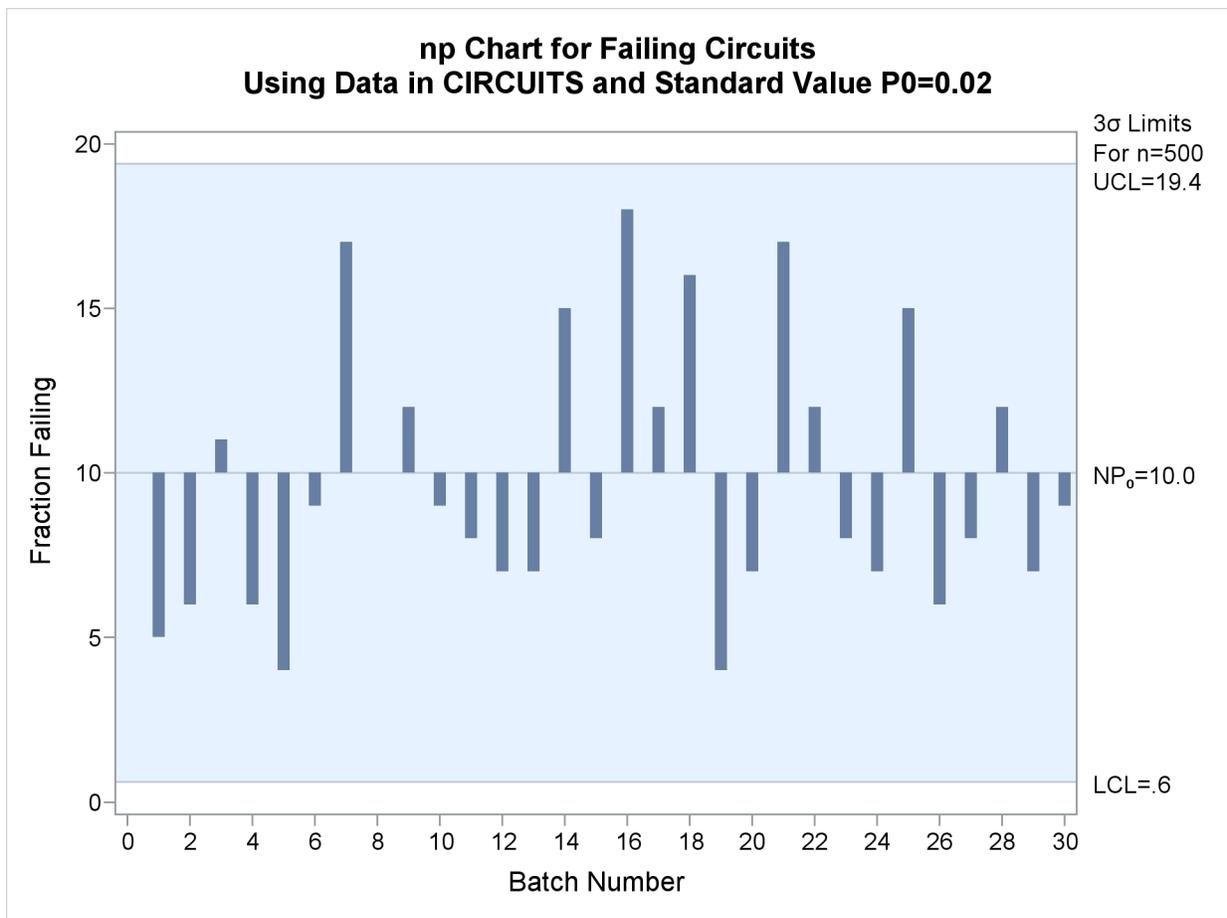

An np chart is used to monitor the number of failing circuits in the data set Circuits, which is introduced in “Creating np Charts from Count Data” on page 1660. The expected proportion of failing circuits is known to be $p_0 = 0.02$. The following statements create an np chart, shown in Output 17.19.1, using p_0 to compute the control limits:

```

title1 'np Chart for Failing Circuits';
title2 'Using Data in CIRCUITS and Standard Value P0=0.02';
proc shewhart data=Circuits;
  npchart Fail*Batch / subgroupn = 500
                    p0          = 0.02
                    npsymbol   = np0
                    nolegend
                    needles
                    odstitle    = title
                    odstitle2   = title2;
  label Batch = 'Batch Number'
        Fail  = 'Fraction Failing';
run;

```

Output 17.19.1 An np Chart with Standard Value of p_0

The chart indicates that the process is in control. The $P_0=$ option specifies p_0 . The $NPSYMBOL=$ option specifies a label for the central line indicating that the line represents a standard value. The $NEEDLES$ option connects points to the central line with vertical needles. The $NOLEGEND$ option suppresses the default legend for subgroup sample sizes. Labels for the vertical and horizontal axes are provided with the $LABEL$ statement. For details concerning axis labeling, see “[Axis Labels](#)” on page 1689.

Alternatively, you can specify p_0 using the variable `_P_` in a `LIMITS=` data set, as follows:

```
data Climits;
  length _var_ _subgrp_ _type_ $8;
  _p_      = 0.02;
  _subgrp_ = 'Batch';
  _var_    = 'Fail';
  _type_   = 'STANDARD';
  _limitn_ = 500;

proc shewhart data=Circuits limits=Climits;
  npchart Fail*Batch / subgroupn = 500
                    npsymbol  = np0
                    nolegend
                    needles;
  label Batch = 'Batch Number'
        Fail  = 'Fraction Failing';
run;
```

The bookkeeping variable `_TYPE_` indicates that `_P_` has a standard value. The chart produced by these statements is identical to the chart in [Output 17.19.1](#).

Example 17.20: Working with Unequal Subgroup Sample Sizes

See SHWNP4 in the SAS/QC Sample Library The following statements create a SAS data set named `Battery`, which contains the number of alkaline batteries per lot failing an acceptance test. The number of batteries tested in each lot varies but is approximately 150.

```
data Battery;
  length Lot $3;
  input Lot nFailed Sampsize @@;
  label nFailed = 'Number Failed'
        Lot      = 'Lot Number'
        Sampsize = 'Number Sampled';
  datalines;
AE3  6  151    AE4  5  142    AE9  6  145
BR3  9  149    BR7  3  150    BR8  0  156
BR9  4  150    DB1  9  158    DB2  4  152
DB3  0  162    DB5  9  140    DB6  7  161
DS4  6  154    DS6  1  144    DS8  5  154
JG1  3  151    MC3  8  148    MC4  2  143
MK6  4  150    MM1  4  147    MM2  0  150
RT5  2  154    RT9  8  149    SP1  3  160
SP3  9  153
;
```

The variable `nFailed` contains the number of battery failures, the variable `Lot` contains the lot number, and the variable `Sampsize` contains the lot sample size. The following statements request an *np* chart for this data:

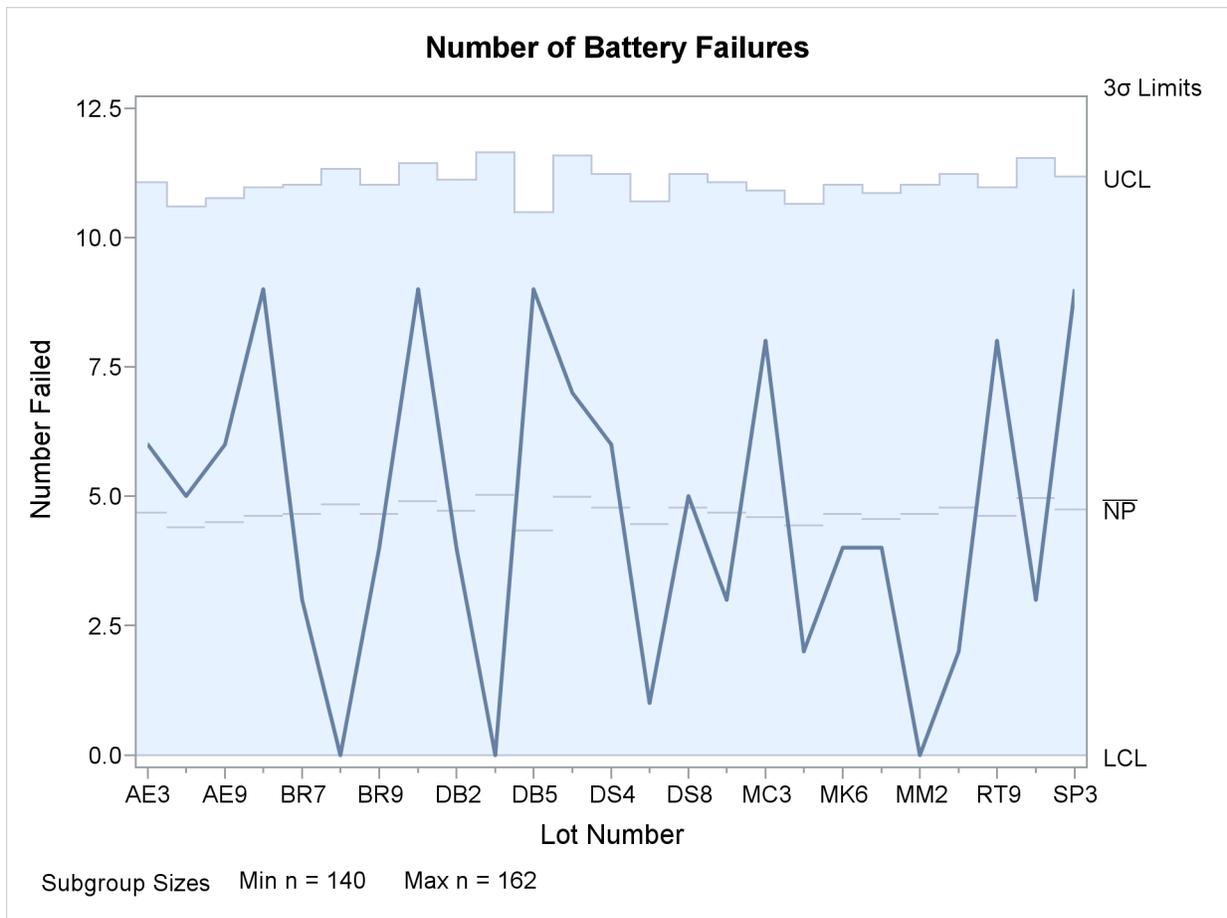

```

title 'Number of Battery Failures';
proc shewhart data=Battery;
  npchart nFailed*Lot / subgroupn = Sampsize
           outlimits = Batlim
           odstitle = title;
  label nFailed='Number Failed';
run;

```

The chart is shown in [Output 17.20.1](#), and the `OUTLIMITS=` data set `Batlim` is listed in [Output 17.20.2](#).

Output 17.20.1 An *np* Chart with Varying Subgroup Sample Sizes

Note that the upper control limit and central line on the np chart vary with the subgroup sample size. The lower control limit is truncated at zero. The sample size legend indicates the minimum and maximum subgroup sample sizes.

Output 17.20.2 The Control Limits Data Set Batlim

Control Limits for Battery Failures									
	—		—		—				
	S		L		S				
	U		I	A	I		L		U
	B	—	M	L	G		C		C
V	G	Y	I	P	M		L	—	L
A	R	P	T	H	A		N	N	N
R	P	E	N	A	S	P	P	P	P
—	—	—	—	—	—	—	—	—	—
nFailed	Lot	ESTIMATE	V	V	3	0.031010	V	V	V

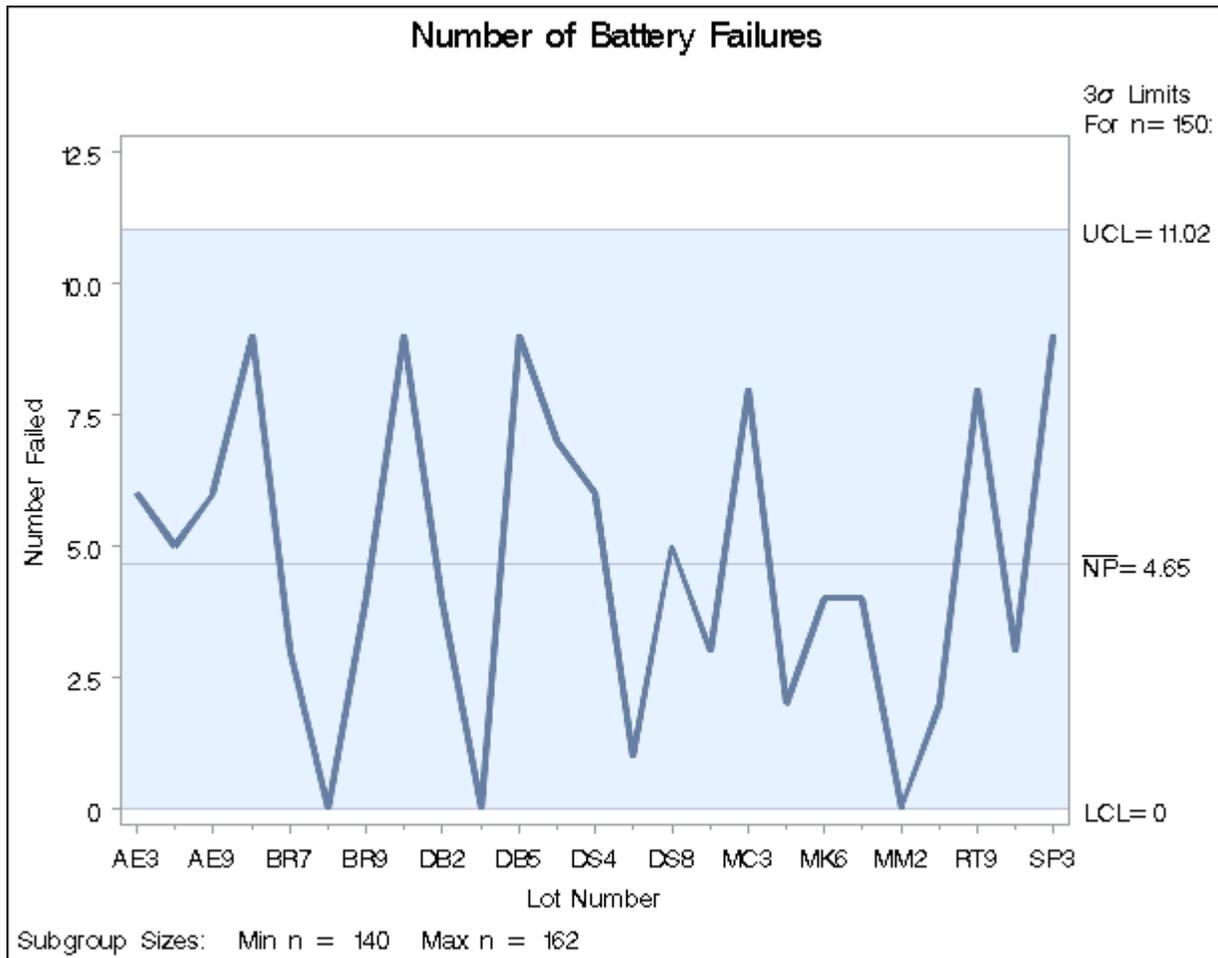

The variables in Batlim whose values vary with subgroup sample size are assigned the special missing value V .

The SHEWHART procedure provides various options for working with unequal subgroup sample sizes. For example, you can use the LIMITN= option to specify a fixed (nominal) sample size for computing the control limits, as illustrated by the following statements:

```
ods graphics off;
title 'Number of Battery Failures';
proc shewhart data=Battery;
  npchart nFailed*Lot / subgroupn = Sampsize
           limitn      = 150
           alln;
  label nFailed='Number Failed';
run;
```

The ALLN option specifies that all points (regardless of subgroup sample size) are to be displayed. By default, only points for subgroups whose sample size matches the LIMITN= value are displayed. The chart is shown in [Output 17.20.3](#).

Output 17.20.3 Control Limits Based on Fixed Subgroup Sample Size

All the points are inside the control limits, indicating that the process is in statistical control. Since there is relatively little variation in the sample sizes, the control limits in [Output 17.20.3](#) provide a close approximation to the exact control limits in [Output 17.20.1](#), and the same conclusions can be drawn from both charts. In general, you should be careful when interpreting charts that use a nominal sample size to compute control limits, since these limits are only approximate when the sample sizes vary.

Example 17.21: Specifying Control Limit Information

See SHWNP5 in the SAS/QC Sample Library

This example shows how to use the DATA step to create LIMITS= data sets for use with the NPCHART statement. The variables `_VAR_` and `_SUBGRP_` are required. These variables must be character variables whose lengths are no greater than 32, and their values must match the *process* and *subgroup-variable* specified in the NPCHART statement. In addition, you must provide one of the following:

- the variables `_LCLNP_`, `_NP_`, and `_UCLNP_`
- the variable `_P_`

The following DATA step creates a data set named `Climits1`, which provides a complete set of control limits for an *np* chart:

```
data Climits1;
  length _var_ _subgrp_ _type_ $8;
  _var_   = 'Fail';
  _subgrp_ = 'Batch';
  _limitn_ = 500;
  _type_   = 'STANDARD';
  _lclnp_  = 0;
  _np_     = 10;
  _uclnp_  = 20;
run;
```

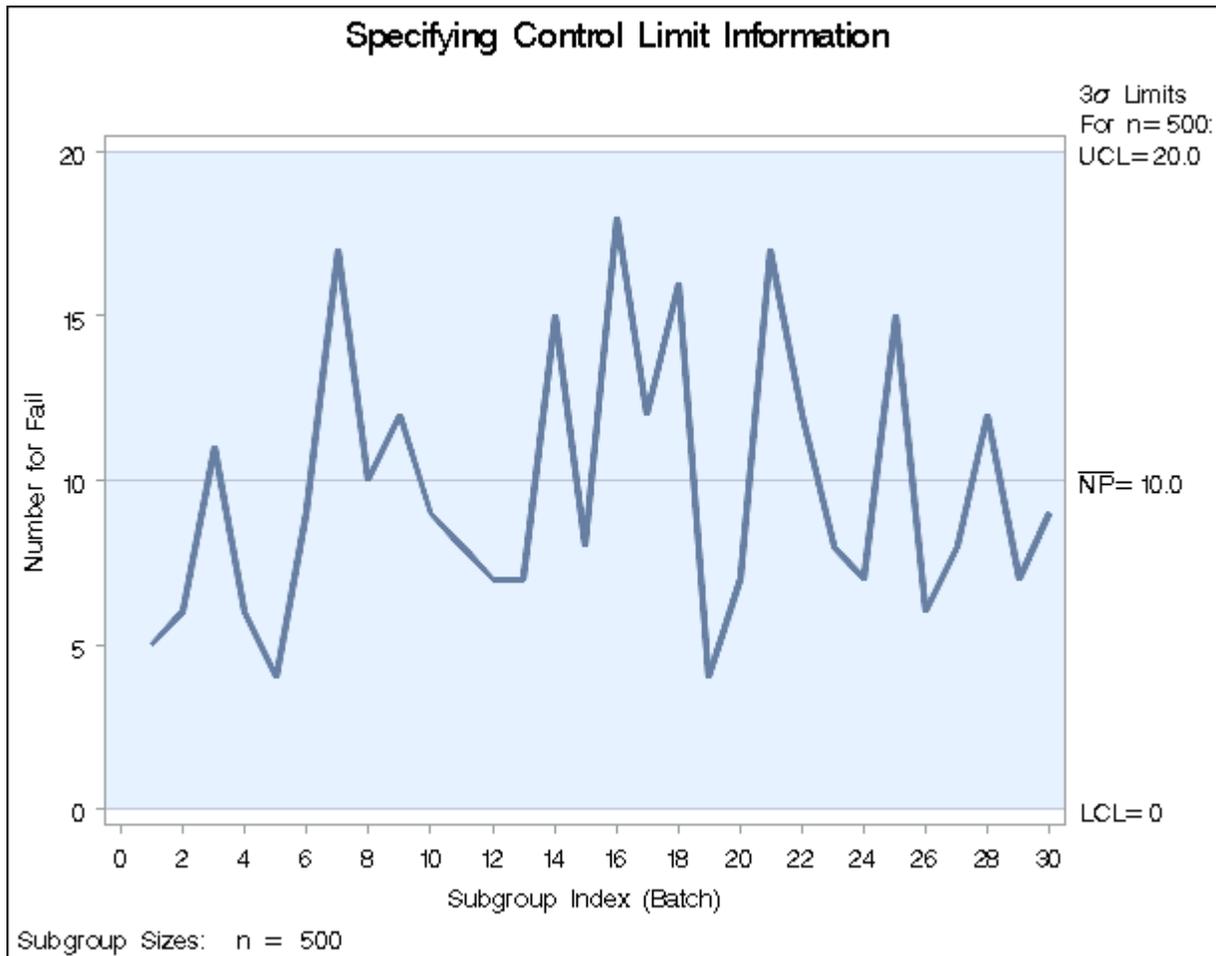

The following statements read the control limits¹⁹ from the data set `Climits1` and apply them to the count data in the data set `Circuits`, which is introduced in “Creating np Charts from Count Data” on page 1660:

```
ods graphics off;
title 'Specifying Control Limit Information';
proc shewhart data=Circuits limits=Climits1;
  npchart Fail*Batch / subgroupn = 500;
run;
```

The chart is shown in [Output 17.21.1](#).

¹⁹In SAS 6.09 and in earlier releases, you must also specify the READLIMITS option.

Output 17.21.1 Control Limit Information Read from Climits1

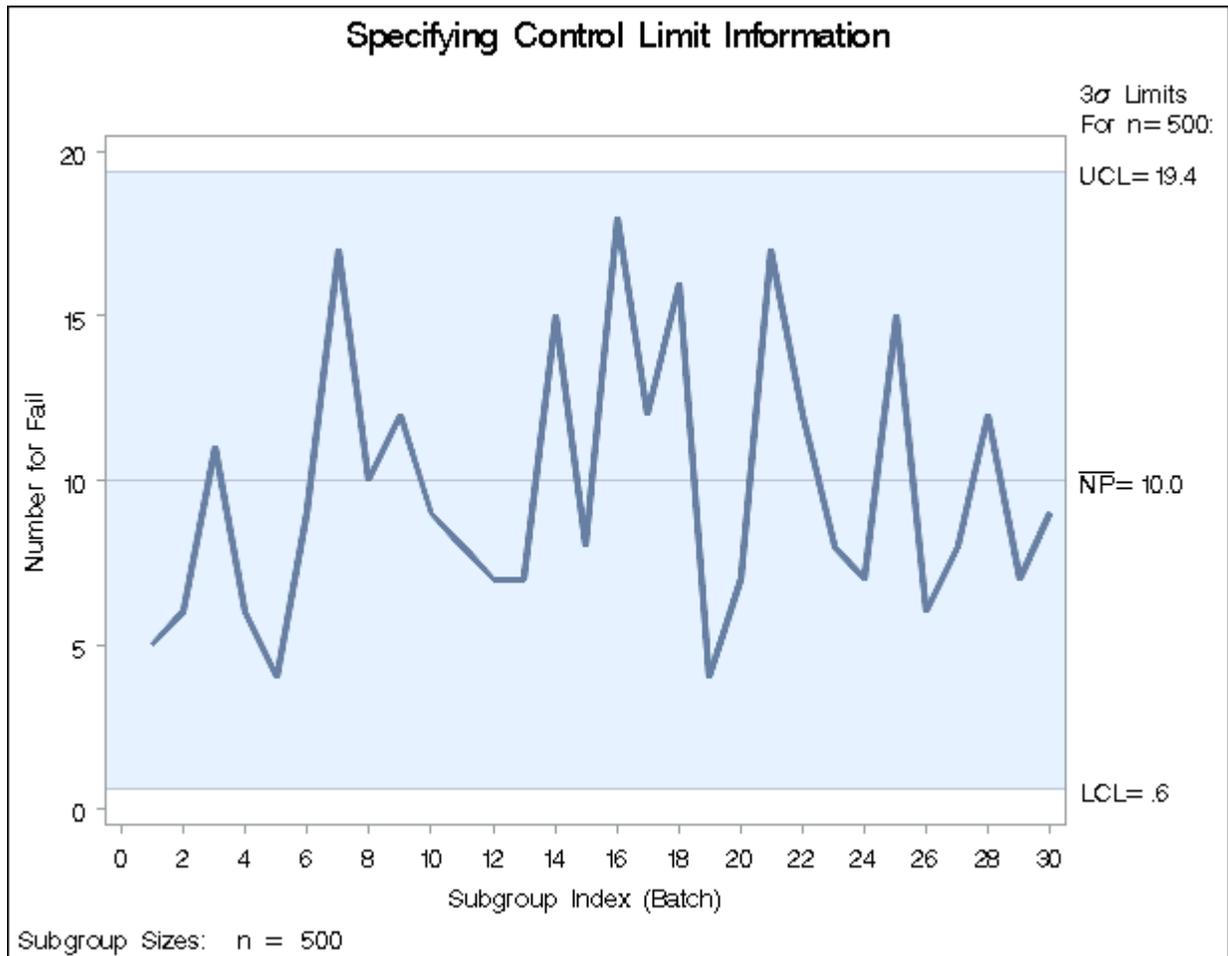

The following DATA step creates a data set named Climits2, which provides a value for the expected proportion of nonconforming items (\bar{P}). This parameter is then used to compute the control limits for the data in Circuits according to the equations in “Control Limits” on page 1681.

```
data Climits2;
  length _var_ _subgrp_ _type_ $8;
  _var_   = 'Fail';
  _subgrp_ = 'Batch';
  _limitn_ = 500;
  _type_   = 'STANDARD';
  _p_     = .02;
run;

title 'Specifying Control Limit Information';
proc shewhart data=Circuits limits=Climits2;
  npchart Fail*Batch / subgroupn = 500;
run;
```

The chart is shown in Output 17.21.2. Note that the control limits are not the same as those shown in Output 17.21.1.

Output 17.21.2 Control Limit Information Read from Climits2

PCHART Statement: SHEWHART Procedure

Overview: PCHART Statement

The PCHART statement creates p charts for the proportions of nonconforming (defective) items in subgroup samples.

You can use options in the PCHART statement to

- compute control limits from the data based on a multiple of the standard error of the proportions or as probability limits
- tabulate subgroup sample sizes, proportions of nonconforming items, control limits, and other information
- save control limits in an output data set

- save subgroup sample sizes and proportions of nonconforming items in an output data set
- read preestablished control limits from a data set
- apply tests for special causes (also known as runs tests and Western Electric rules)
- specify a known (standard) proportion of nonconforming items for computing control limits
- specify the data as counts, proportions, or percentages of nonconforming items
- display distinct sets of control limits for data from successive time phases
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have three alternatives for producing p charts with the PCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: PCHART Statement

This section introduces the PCHART statement with simple examples that illustrate commonly used options. Complete syntax for the PCHART statement is presented in the section “Syntax: PCHART Statement” on page 1711, and advanced examples are given in the section “Examples: PCHART Statement” on page 1732.

Creating p Charts from Count Data

See SHWPCHR in the SAS/QC Sample Library. An electronics company manufactures circuits in batches of 500 and uses a p chart to monitor the proportion of failing circuits. Thirty batches are examined, and the failures in each batch are counted. The following statements create a SAS data set named Circuits,²⁰ which contains the failure counts:

```
data Circuits;
  input Batch Fail @@;
  datalines;
1   5   2   6   3  11   4   6   5   4
6   9   7  17   8  10   9  12  10   9
11  8  12   7  13   7  14  15  15   8
16 18  17  12  18  16  19   4  20   7
21 17  22  12  23   8  24   7  25  15
26  6  27   8  28  12  29   7  30   9
;
```

A partial listing of Circuits is shown in Figure 17.60.

Figure 17.60 The Data Set Circuits

Number of Failing Circuits	
Batch	Fail
1	5
2	6
3	11
4	6
5	4

There is a single observation for each batch. The variable Batch identifies the subgroup sample and is referred to as the *subgroup-variable*. The variable Fail contains the number of nonconforming items in each subgroup sample and is referred to as the *process variable* (or *process* for short).

The following statements create the p chart shown in Figure 17.61:

```
ods graphics off;
title 'p Chart for the Proportion of Failing Circuits';
proc shewhart data=Circuits;
  pchart Fail*Batch / subgroupn = 500;
run;
```

This example illustrates the basic form of the PCHART statement. After the keyword PCHART, you specify the *process* to analyze (in this case, Fail), followed by an asterisk and the *subgroup-variable* (Batch).

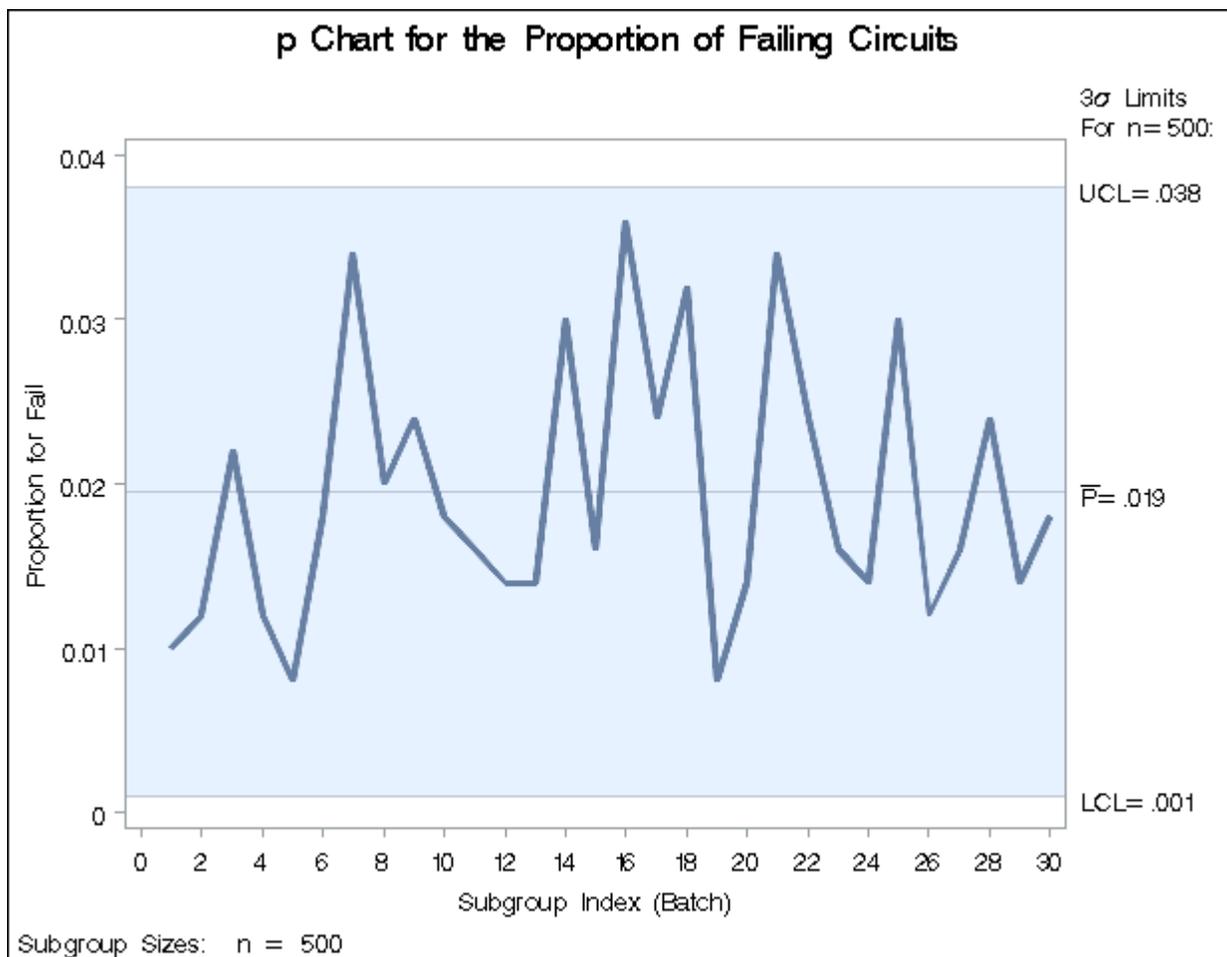

²⁰This data set is also used in the “Getting Started” section of “NPCHART Statement: SHEWHART Procedure” on page 1658.

The input data set is specified with the DATA= option in the PROC SHEWHART statement. The SUBGROUPN= option specifies the number of items in each subgroup sample and is required with a DATA= input data set. The SUBGROUPN= option specifies one of the following:

- a constant subgroup sample size (as in this case)
- a variable in the input data set whose values provide the subgroup sample sizes (see the next example)

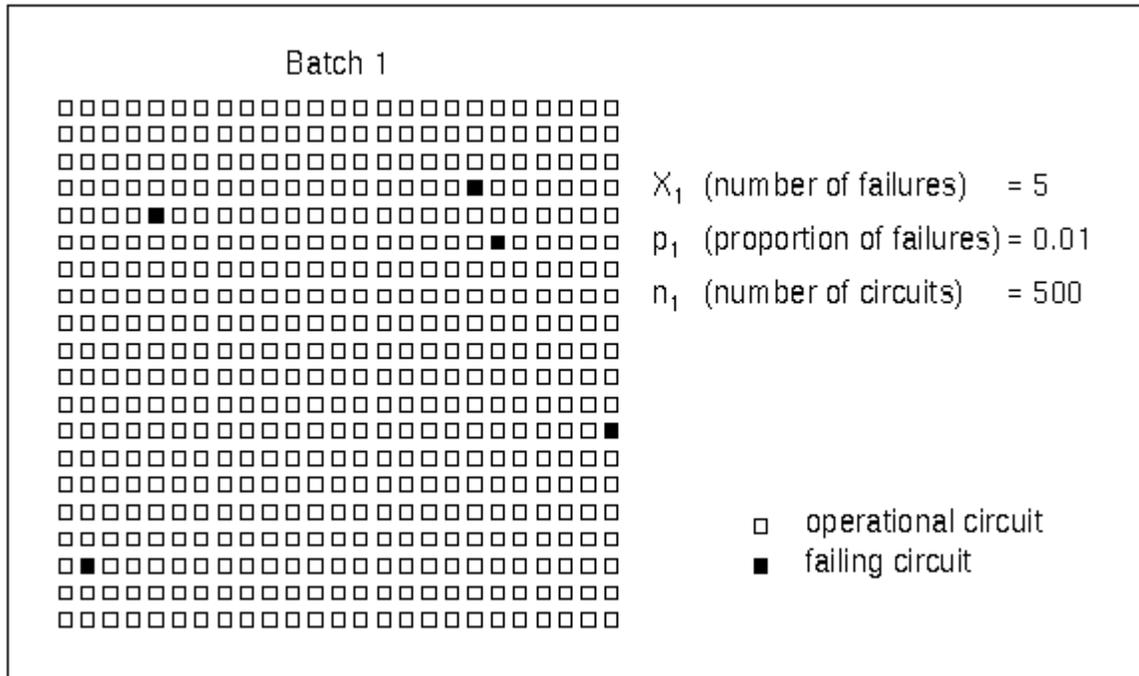

Options such as SUBGROUPN= are specified after the slash (/) in the PCHART statement. A complete list of options is presented in the section “Syntax: PCHART Statement” on page 1711.

Figure 17.61 p Chart for Circuit Failures (Traditional Graphics)

Each point on the p chart represents the proportion of nonconforming items for a particular subgroup. For instance, the value plotted for the first batch is $5/500 = 0.01$, as illustrated in Figure 17.62.

Figure 17.62 Proportions Versus Counts

Since all the points fall within the control limits, it can be concluded that the process is in statistical control.

By default, the control limits shown are 3σ limits estimated from the data; the formulas for the limits are given in “Control Limits” on page 1723. You can also read control limits from an input data set; see “Reading Preestablished Control Limits” on page 1710. For computational details, see “Constructing Charts for Proportion Nonconforming (p Charts)” on page 1722. For more details on reading counts of nonconforming items, see “DATA= Data Set” on page 1727.

Creating p Charts from Summary Data

See SHWPCHR in the SAS/QC Sample Library The previous example illustrates how you can create p charts using raw data (counts of nonconforming items). However, in many applications, the data are provided in summarized form as proportions or percentages of nonconforming items. This example illustrates how you can use the PCHART statement with data of this type.

The following data set provides the data from the preceding example in summarized form:

```
data Cirprop;
  input Batch pFailed @@;
  Sampsiz=500;
  datalines;
  1 0.010 2 0.012 3 0.022 4 0.012 5 0.008
  6 0.018 7 0.034 8 0.020 9 0.024 10 0.018
  11 0.016 12 0.014 13 0.014 14 0.030 15 0.016
  16 0.036 17 0.024 18 0.032 19 0.008 20 0.014
  21 0.034 22 0.024 23 0.016 24 0.014 25 0.030
  26 0.012 27 0.016 28 0.024 29 0.014 30 0.018
  ;
```

A partial listing of Cirprop is shown in [Figure 17.63](#). The subgroups are still indexed by Batch. The variable `pFailed` contains the proportions of nonconforming items, and the variable `Sampsize` contains the subgroup sample sizes.

Figure 17.63 The Data Set Cirprop

Subgroup Proportions of Nonconforming Items		
Batch	p Failed	Sampsize
1	0.010	500
2	0.012	500
3	0.022	500
4	0.012	500
5	0.008	500

The following statements create a p chart identical to the one in [Figure 17.61](#):

```

title 'p Chart for the Proportion of Failing Circuits';
symbol v=dot;
proc shewhart data=Cirprop;
    pchart pFailed*Batch / subgroupn=Sampsize
            dataunit =proportion;
label pfailed = 'Proportion for Fail';
run;

```

The `DATAUNIT=` option specifies that the values of the *process* (`pFailed`) are proportions of nonconforming items. By default, the values of the *process* are assumed to be counts of nonconforming items (see the previous example).

Alternatively, you can read the data set Cirprop by specifying it as a `HISTORY=` data set in the `PROC SHEWHART` statement. A `HISTORY=` data set used with the `PCHART` statement must contain the following variables:

- subgroup variable
- subgroup proportion of nonconforming items variable
- subgroup sample size variable

Furthermore, the names of the subgroup proportion and sample size variables must begin with the *process* name specified in the `PCHART` statement and end with the special suffix characters *P* and *N*, respectively.

To specify Cirprop as a `HISTORY=` data set and Fail as the *process*, you must rename the variables `pFailed` and `Sampsize` to `FailP` and `FailN`, respectively. The following statements temporarily rename `pFailed` and `Sampsize` for the duration of the procedure step:

```

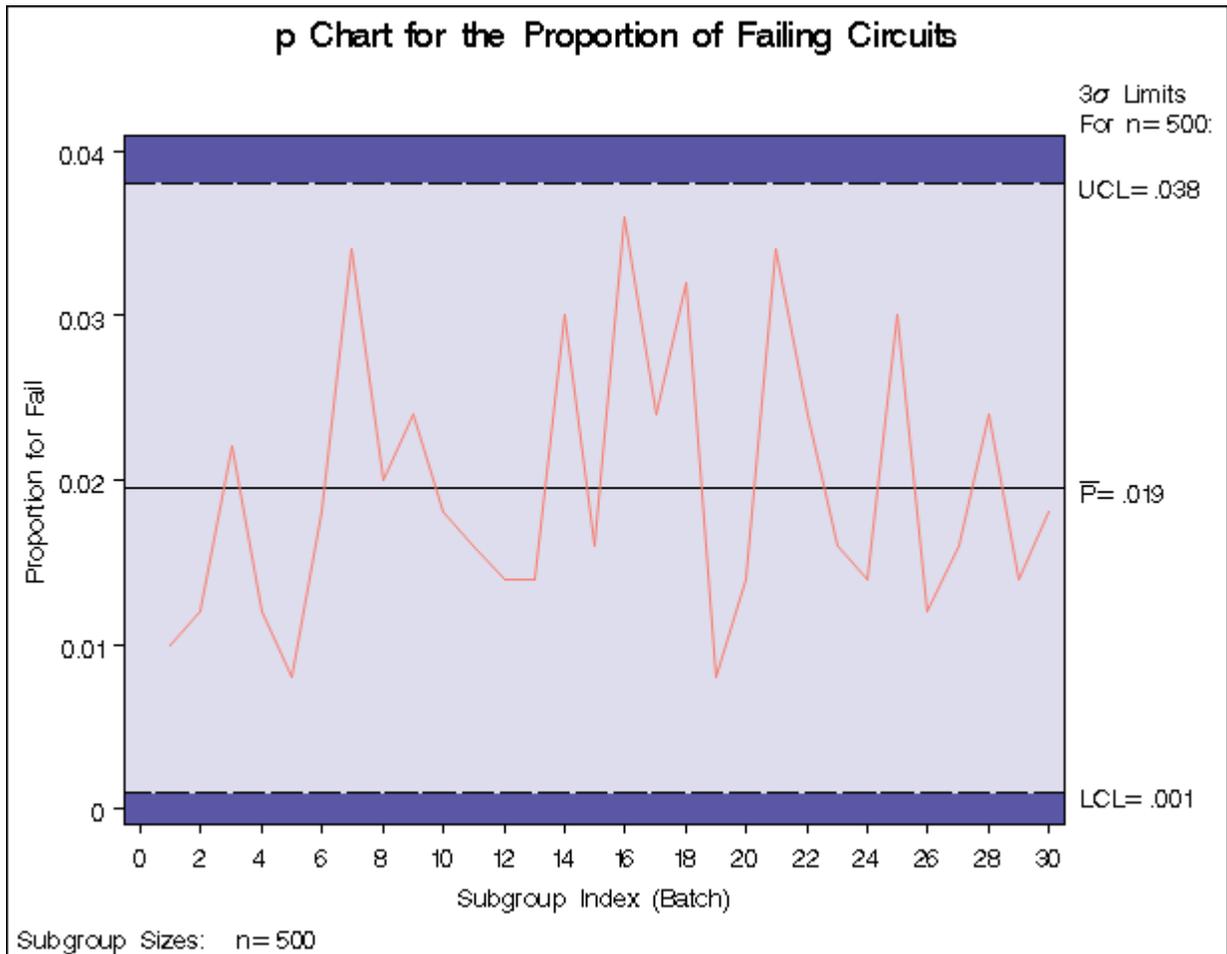

options nogstyle;
goptions ftext=swiss;
title 'p Chart for the Proportion of Failing Circuits';
proc shewhart history=Cirprop(rename=(pFailed=FailP
                               Sampsiz=FailN ));
    pchart Fail*Batch / cframe    = lib
                       cinfill   = bwh
                       coutfill  = yellow
                       cconnect   = salmon;

run;
options gstyle;

```

The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the PCHART statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently. The resulting p chart is shown in Figure 17.64.

Figure 17.64 p Chart from Subgroup Proportions (Traditional Graphics with NOGSTYLE)

In this example, it is more convenient to use Cirprop as a DATA= data set than as a HISTORY= data set. In general, it is more convenient to use the HISTORY= option for input data sets that have

been previously created by the SHEWHART procedure as OUTHISTORY= data sets, as illustrated in the next example. For more information, see “[HISTORY= Data Set](#)” on page 1729.

Saving Proportions of Nonconforming Items

In this example, the PCHART statement is used to create a data set that can later be read by the SHEWHART procedure (as in the preceding example). The following statements read the number of nonconforming items from the data set Circuits (see “[Creating p Charts from Count Data](#)” on page 1702) and create a summary data set named Cirhist: *See SHWPCHR in the SAS/QC Sample Library*

```
proc shewhart data=Circuits;
  pchart Fail*Batch / subgroupn = 500
                    outhistory = Cirhist
                    nochart ;
run;
```

The OUTHISTORY= option names the output data set, and the NOCHART option suppresses the display of the chart, which would be identical to the chart in [Figure 17.61](#). [Figure 17.65](#) contains a partial listing of Cirhist.

Figure 17.65 The Data Set Cirhist

Subgroup Proportions and Control Limit Information			
Batch	FailP	Fail N	
1	0.010	500	
2	0.012	500	
3	0.022	500	
4	0.012	500	
5	0.008	500	

There are three variables in the data set Cirhist.

- Batch contains the subgroup index.
- FailP contains the subgroup proportion of nonconforming items.
- FailN contains the subgroup sample size.

Note that the variables containing the subgroup proportions of nonconforming items and subgroup sample sizes are named by adding the suffix characters *P* and *N* to the *process* Fail specified in the PCHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as that for HISTORY= data sets. For more information, see “[OUTHISTORY= Data Set](#)” on page 1725.

The data set Cirtable is listed in Figure 17.67.

Figure 17.67 The Data Set Cirtable

Subgroup Proportions and Control Limit Information									
<u>_VAR_</u>	<u>Batch</u>	<u>_SIGMAS_</u>	<u>_LIMITN_</u>	<u>_SUBN_</u>	<u>_LCLP_</u>	<u>_SUBP_</u>	<u>_P_</u>	<u>_UCLP_</u>	<u>_EXL</u>
Fail	1	3	500	500	.000930786	0.010	0.019467	0.038003	
Fail	2	3	500	500	.000930786	0.012	0.019467	0.038003	
Fail	3	3	500	500	.000930786	0.022	0.019467	0.038003	
Fail	4	3	500	500	.000930786	0.012	0.019467	0.038003	
Fail	5	3	500	500	.000930786	0.008	0.019467	0.038003	
Fail	6	3	500	500	.000930786	0.018	0.019467	0.038003	
Fail	7	3	500	500	.000930786	0.034	0.019467	0.038003	
Fail	8	3	500	500	.000930786	0.020	0.019467	0.038003	
Fail	9	3	500	500	.000930786	0.024	0.019467	0.038003	
Fail	10	3	500	500	.000930786	0.018	0.019467	0.038003	
Fail	11	3	500	500	.000930786	0.016	0.019467	0.038003	
Fail	12	3	500	500	.000930786	0.014	0.019467	0.038003	
Fail	13	3	500	500	.000930786	0.014	0.019467	0.038003	
Fail	14	3	500	500	.000930786	0.030	0.019467	0.038003	
Fail	15	3	500	500	.000930786	0.016	0.019467	0.038003	
Fail	16	3	500	500	.000930786	0.036	0.019467	0.038003	
Fail	17	3	500	500	.000930786	0.024	0.019467	0.038003	
Fail	18	3	500	500	.000930786	0.032	0.019467	0.038003	
Fail	19	3	500	500	.000930786	0.008	0.019467	0.038003	
Fail	20	3	500	500	.000930786	0.014	0.019467	0.038003	
Fail	21	3	500	500	.000930786	0.034	0.019467	0.038003	
Fail	22	3	500	500	.000930786	0.024	0.019467	0.038003	
Fail	23	3	500	500	.000930786	0.016	0.019467	0.038003	
Fail	24	3	500	500	.000930786	0.014	0.019467	0.038003	
Fail	25	3	500	500	.000930786	0.030	0.019467	0.038003	
Fail	26	3	500	500	.000930786	0.012	0.019467	0.038003	
Fail	27	3	500	500	.000930786	0.016	0.019467	0.038003	
Fail	28	3	500	500	.000930786	0.024	0.019467	0.038003	
Fail	29	3	500	500	.000930786	0.014	0.019467	0.038003	
Fail	30	3	500	500	.000930786	0.018	0.019467	0.038003	

This data set contains one observation for each subgroup sample. The variables `_SUBP_` and `_SUBN_` contain the subgroup proportions of nonconforming items and subgroup sample sizes. The variables `_LCLP_` and `_UCLP_` contain the lower and upper control limits, and the variable `_P_` contains the central line. The variables `_VAR_` and `Batch` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “`OUTTABLE= Data Set`” on page 1725.

An `OUTTABLE=` data set can be read later as a `TABLE=` data set. For example, the following statements read the information in Cirtable and display a *p* chart (not shown here) identical to the chart in Figure 17.61:

```
title 'p Chart for the Proportion of Failing Circuits';
proc shewhart table=Cirtable;
  pchart Fail*Batch;
run;
```

Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts (see “Specialized Control Charts: SHEWHART Procedure” on page 2171). For more information, see “TABLE= Data Set” on page 1730.

Reading Preestablished Control Limits

See SHWPCHR in the SAS/QC Sample Library

In the previous example, the OUTLIMITS= data set Cirlim saved control limits computed from the data in Circuits. This example shows how these limits can be applied to new data provided in the following data set:

```
data Circuit2;
  input Batch Fail @@;
  datalines;
31 12 32 9 33 16 34 9
35 3 36 8 37 20 38 4
39 8 40 6 41 12 42 16
43 9 44 2 45 10 46 8
47 14 48 10 49 11 50 9
;
```

The following statements create a p chart for the data in Circuit2 using the control limits in Cirlim:

```
title 'p Chart for the Proportion of Failing Circuits';
proc shewhart data=Circuit2 limits=Cirlim;
  pchart Fail*Batch / subgroupn = 500
                    odstitle = title;
run;
```

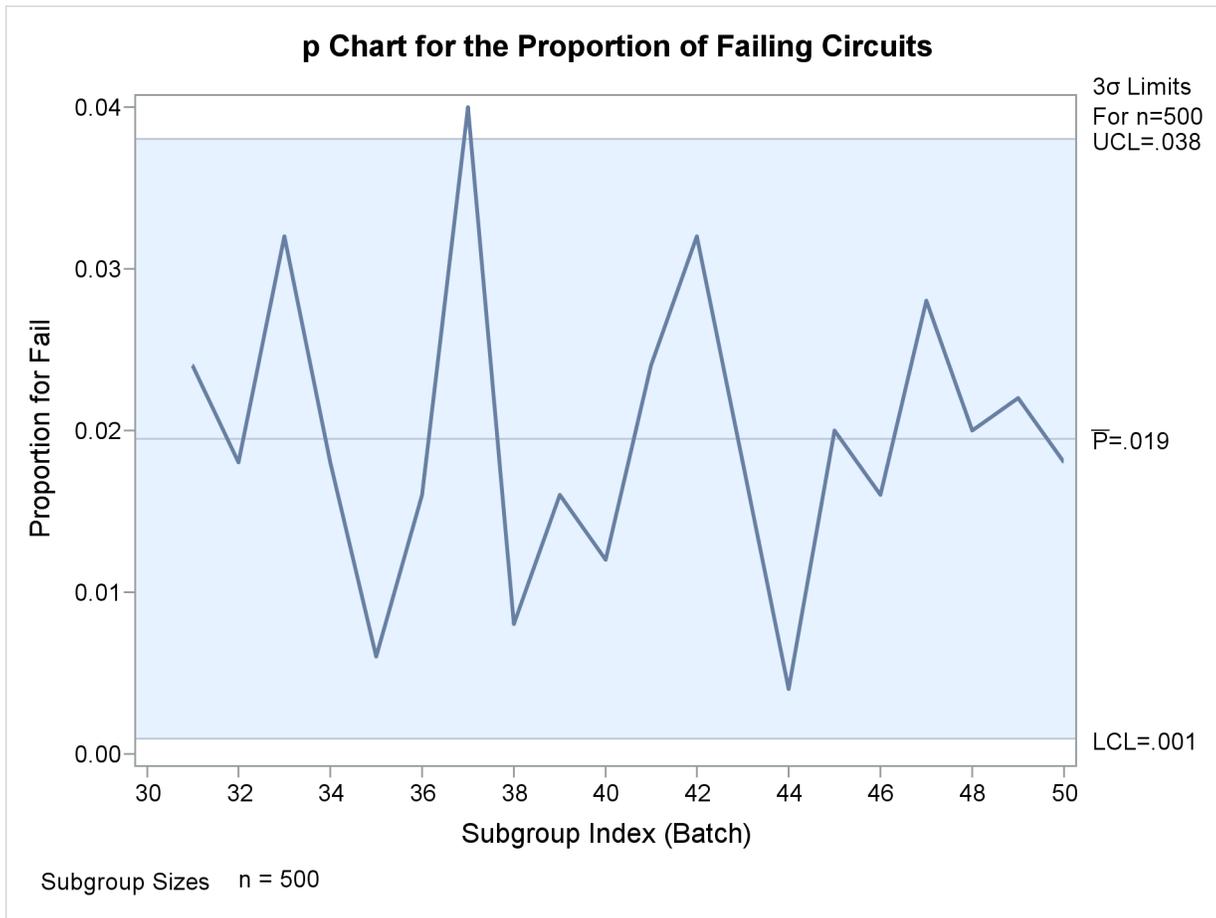

The ODS GRAPHICS ON statement specified before the PROC SHEWHART statement enables ODS Graphics, so the p chart is created by using ODS Graphics instead of traditional graphics.

The LIMITS= option in the PROC SHEWHART statement specifies the data set containing the control limits. By default,²¹ this information is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches the *process* name Fail
- the value of `_SUBGRP_` matches the *subgroup-variable* name Batch

The resulting p chart is shown in Figure 17.68.

²¹In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

Figure 17.68 *p* Chart for Second Set of Circuit Failures (ODS Graphics)

The proportion of nonconforming items in the 37th batch exceeds the upper control limit, signaling that the process is out of control.

In this example, the LIMITS= data set was created in a previous run of the SHEWHART procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on page 1728 for details concerning the variables that you must provide.

Syntax: PCHART Statement

The basic syntax for the PCHART statement is as follows:

```
PCHART process * subgroup-variable ;
```

The general form of this syntax is as follows:

```
PCHART processes * subgroup-variable <(block-variables)>
  <=symbol-variable | =character'> / <options> ;
```

You can use any number of PCHART statements in the SHEWHART procedure. The components of the PCHART statement are described as follows.

process**processes**

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC SHEWHART statement.

- If numbers of nonconforming items are read from a DATA= data set, *process* must be the name of the variable containing the numbers. For an example, see “[Creating p Charts from Summary Data](#)” on page 1704.
- If proportions of nonconforming items are read from a HISTORY= data set, *process* must be the common prefix of the summary variables in the HISTORY= data set. For an example, see “[Creating p Charts from Summary Data](#)” on page 1704.
- If proportions of nonconforming items and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “[Saving Control Limits](#)” on page 1708.

A *process* is required. If you specify more than one process, enclose the list in parentheses. For example, the following statements request distinct *p* charts for Rejects and Reworks:

```
proc shewhart data=Measures;
    pchart (Rejects Reworks)*Sample / subgroupn=100;
run;
```

Note that when data are read from a DATA= data set, the SUBGROUPN= option, which specifies subgroup sample sizes, is required.

subgroup-variable

is the variable that identifies subgroups in the data. The *subgroup-variable* is required. In the preceding PCHART statement, Sample is the subgroup variable. For details, see “[Subgroup Variables](#)” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or character used to plot proportions of nonconforming items.

- If you produce a line printer chart, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOL n statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create a p chart using an asterisk (*) to plot the points:

```
proc shewhart data=Values lineprinter;
  pchart Rejects*Day='*' / subgroupn=100;
run;
```

options

enhance the appearance of the chart, request additional analyses, save results in data sets, and so on. The section “[Summary of Options](#)”, which follows, lists all options by function. “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018 describes each option in detail.

Summary of Options

The following tables list the PCHART statement options by function. For complete descriptions, see “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 17.42 PCHART Statement Options

Option	Description
Options for Specifying Control Limits	
ALPHA=	requests probability limits for chart
LIMITN=	specifies either nominal sample size for fixed control limits or varying limits
NOREADLIMITS	computes control limits for each <i>process</i> from the data rather than a LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from a LIMITS= data set
READINDEX=	reads control limits for each <i>process</i> from a LIMITS= data set
READLIMITS	reads single set of control limits for each <i>process</i> from a LIMITS= data set (SAS 6.09 and earlier releases)
SIGMAS=	specifies width of control limits in terms of multiple k of standard error of plotted means
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line

Table 17.42 *continued*

Option	Description
NOCTL	suppresses display of central line
NOLCL	suppresses display of lower control limit
NOLIMIT0	suppresses display of lower control limit if it is 0
NOLIMIT1	suppresses display of upper control limit if it is 1 (100%)
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit
PSYMBOL=	specifies label for central line
UCLLABEL=	specifies label for upper control limit
WLIMITS=	specifies width for control limits and central line
Standard Value Options	
P0=	specifies known (standard) value p_0 for proportion of nonconforming items p
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on p chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
OUTLABEL=	labels points outside control limits
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles

Table 17.42 continued

Option	Description
Options for Specifying Tests for Special Causes	
INDEPENDENTZONES	computes zone widths independently above and below center line
NO3SIGMACHECK	enables tests to be applied with control limits other than 3σ limits
NOTESTACROSS	suppresses tests across <i>phase</i> boundaries
TESTS=	specifies tests for special causes
TEST2RUN=	specifies length of pattern for Test 2
TEST3RUN=	specifies length of pattern for Test 3
TESTACROSS	applies tests across <i>phase</i> boundaries
TESTLABEL=	provides labels for points where test is positive
TESTLABEL n =	specifies label for n th test for special causes
TESTNMETHOD=	applies tests to standardized chart statistics
TESTOVERLAP	performs tests on overlapping patterns of points
TESTRESET=	enables tests for special causes to be reset
ZONELABELS	adds labels A, B, and C to zone lines
ZONES	adds lines delineating zones A, B, and C
ZONEVALPOS=	specifies position of ZONEVALUES labels
ZONEVALUES	labels zone lines with their values
Options for Displaying Tests for Special Causes	
CTESTLABBOX=	specifies color for boxes enclosing labels indicating points where test is positive
CTESTS=	specifies color for labels indicating points where test is positive
CTESTSYMBOL=	specifies color for symbol used to plot points where test is positive
CZONES=	specifies color for lines and labels delineating zones A, B, and C
LTESTS=	specifies type of line connecting points where test is positive
LZONES=	specifies line type for lines delineating zones A, B, and C
TESTFONT=	specifies software font for labels at points where test is positive
TESTHEIGHT=	specifies height of labels at points where test is positive
TESTLABBOX	requests that labels for points where test is positive be positioned so that do not overlap
TESTSYMBOL=	specifies plot symbol for points where test is positive
TESTSYMBOLHT=	specifies symbol height for points where test is positive
WTESTS=	specifies width of line connecting points where test is positive
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels

Table 17.42 *continued*

Option	Description
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOTRUNC	suppresses vertical axis truncation at zero applied by default
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPLABELS=	specifies thinning factor for tick mark labels on horizontal axis
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis
VFORMAT=	specifies format for vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis
WAXIS=	specifies width of axis lines
YSCALE=	scales vertical axis in percent units (rather than proportions)
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes

Table 17.42 continued

Option	Description
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
ZEROSTD	displays p chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= options
CVREF=	specifies color for lines requested by VREF= options
HREF=	specifies position of reference lines perpendicular to horizontal axis
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis
HREFLABELS=	specifies labels for HREF= lines
HREFLABPOS=	specifies position of HREFLABELS= labels
LHREF=	specifies line type for HREF= lines
LVREF=	specifies line type for VREF= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis
VREFLABELS=	specifies labels for VREF= lines
VREFLABPOS=	position of VREFLABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features chart
DESCRIPTION=	specifies description of p chart's GRSEG catalog entry

Table 17.42 *continued*

Option	Description
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of p chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level

Table 17.42 *continued*

Option	Description
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
Input Data Set Options	
DATAUNIT	specifies that input values are proportions or percentages (rather than counts) of nonconforming items
MISSBREAK	specifies that observations with missing values are not to be processed
SUBGROUPN	specifies subgroup sample sizes as constant number <i>n</i> or as values of variable in a DATA= data set
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the OUTLIMITS= data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLELEGEND	augments basic table with legend for tests for special causes
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
TABLETESTS	augments basic table with a column indicating which tests for special causes are positive
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend

Table 17.42 continued

Option	Description
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for overlay line segments
COVERLAY=	specifies colors for overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on chart
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays

Table 17.42 *continued*

Option	Description
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with overlay points
OVERLAYID=	specifies labels for overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for overlays
OVERLAYSYMHT=	specifies symbol heights for overlays
WOVERLAY=	specifies widths of overlay line segments
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
TESTCHAR=	specifies character for line segments that connect any sequence of points for which a test for special causes is positive
VREFCHAR=	specifies line character for VREF= lines
ZONECHAR=	specifies character for lines that delineate zones for tests for special causes

Details: PCHART Statement

Constructing Charts for Proportion Nonconforming (p Charts)

The following notation is used in this section:

p	expected proportion of nonconforming items produced by the process
p_i	proportion of nonconforming items in the i th subgroup
X_i	number of nonconforming items in the i th subgroup
n_i	number of items in the i th subgroup
\bar{p}	average proportion of nonconforming items taken across subgroups:

$$\bar{p} = \frac{n_1 p_1 + \cdots + n_N p_N}{n_1 + \cdots + n_N} = \frac{X_1 + \cdots + X_N}{n_1 + \cdots + n_N}$$

N	number of subgroups
$I_T(\alpha, \beta)$	incomplete beta function:

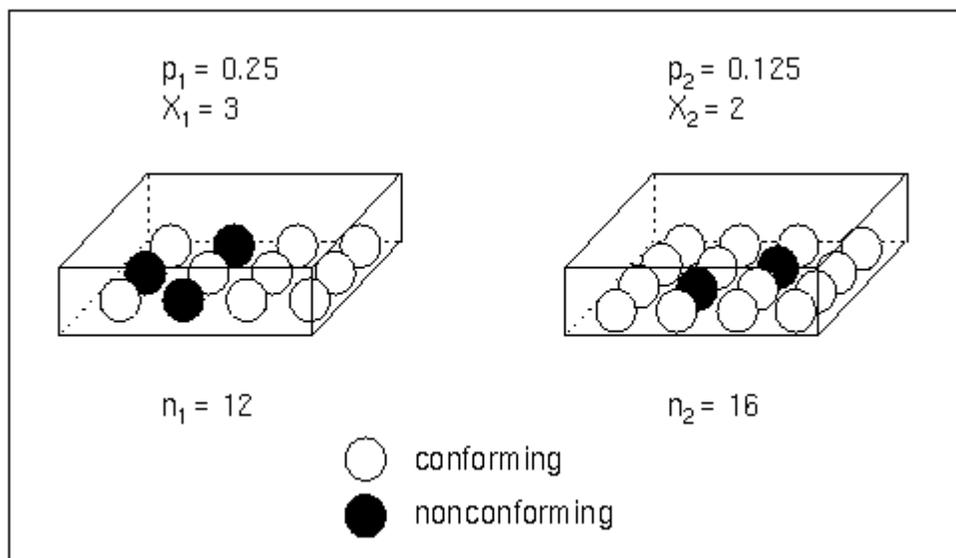

$$I_T(\alpha, \beta) = (\Gamma(\alpha + \beta) / \Gamma(\alpha)\Gamma(\beta)) \int_0^T t^{\alpha-1} (1-t)^{\beta-1} dt$$

for $0 < T < 1$, $\alpha > 0$, and $\beta > 0$, where $\Gamma(\cdot)$ is the gamma function

Plotted Points

Each point on a p chart represents the observed proportion ($p_i = X_i/n_i$) of nonconforming items in a subgroup. For example, suppose the second subgroup (see Figure 17.69) contains 16 items, of which two are nonconforming. The point plotted for the second subgroup is $p_2 = 2/16 = 0.125$.

Figure 17.69 Proportions Versus Counts

Note that an np chart displays the number (count) of nonconforming items X_i . You can use the NPCHART statement to create np charts; see “NPCHART Statement: SHEWHART Procedure” on page 1658.

Central Line

By default, the central line on a p chart indicates an estimate of p that is computed as \bar{p} . If you specify a known value (p_0) for p , the central line indicates the value of p_0 .

Control Limits

You can compute the limits in the following ways:

- as a specified multiple (k) of the standard error of p_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that p_i exceeds the limits

The lower and upper control limits, LCL and UCL, respectively, are computed as

$$\begin{aligned} \text{LCL} &= \max\left(\bar{p} - k\sqrt{\bar{p}(1-\bar{p})/n_i}, 0\right) \\ \text{UCL} &= \min\left(\bar{p} + k\sqrt{\bar{p}(1-\bar{p})/n_i}, 1\right) \end{aligned}$$

A lower probability limit for p_i can be determined using the fact that

$$\begin{aligned} P\{p_i < \text{LCL}\} &= 1 - P\{p_i \geq \text{LCL}\} \\ &= 1 - P\{X_i \geq n_i \text{LCL}\} \\ &= 1 - I_{\bar{p}}(n_i \text{LCL}, n_i + 1 - n_i \text{LCL}) \\ &= I_{1-\bar{p}}(n_i + 1 - n_i \text{LCL}, n_i \text{LCL}) \end{aligned}$$

Refer to Johnson, Kotz, and Kemp (1992). This assumes that the process is in statistical control and that X_i is binomially distributed. The lower probability limit LCL is then calculated by setting

$$I_{1-\bar{p}}(n_i + 1 - n_i \text{LCL}, n_i \text{LCL}) = \alpha/2$$

and solving for LCL. Similarly, the upper probability limit for p_i can be determined using the fact that

$$\begin{aligned} P\{p_i > \text{UCL}\} &= P\{p_i > \text{UCL}\} \\ &= P\{X_i > n_i \text{UCL}\} \\ &= I_{\bar{p}}(n_i \text{UCL}, n_i + 1 - n_i \text{UCL}) \end{aligned}$$

The upper probability limit UCL is then calculated by setting

$$I_{\bar{p}}(n_i \text{UCL}, n_i + 1 - n_i \text{UCL}) = \alpha/2$$

and solving for UCL. The probability limits are asymmetric around the central line. Note that both the control limits and probability limits vary with n_i .

You can specify parameters for the limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify p_0 with the P0= option or with the variable `_P_` in a LIMITS= data set.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves control limits and control limit parameters. The following variables can be saved:

Table 17.43 OUTLIMITS= Data Set

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding limits
<code>_INDEX_</code>	optional identifier for the control limits specified with the OUTINDEX= option
<code>_LCLP_</code>	lower control limit for proportion of nonconforming items
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_P_</code>	average proportion of nonconforming items (\bar{p} or p_0)
<code>_SIGMAS_</code>	multiple (k) of standard error of p_i
<code>_SUBGRP_</code>	<i>subgroup-variable</i> specified in the PCHART statement
<code>_TYPE_</code>	type (standard or estimate) of <code>_P_</code>
<code>_UCLP_</code>	upper control limit for proportion of nonconforming items
<code>_VAR_</code>	<i>process</i> specified in the PCHART statement

Notes:

1. If the control limits vary with subgroup sample size, the special missing value V is assigned to the variables `_LIMITN_`, `_LCLP_`, `_UCLP_`, and `_SIGMAS_`.
2. If the limits are defined in terms of a multiple k of the standard error of p_i , the value of `_ALPHA_` is computed as $\alpha = P\{p_i < _LCLP_ \} + P\{p_i > _UCLP_ \}$, using the incomplete beta function.
3. If the limits are probability limits, the value of `_SIGMAS_` is computed as $k = (_UCLP_ - _P_)/\sqrt{_P_(1 - _P_)/_LIMITN_}$. If `_LIMITN_` has the special missing value V , this value is assigned to `_SIGMAS_`.
4. Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *process* specified in the PCHART statement. For an example, see “Saving Control Limits” on page 1708.

OUTHISTORY= Data Set

The OUTHISTORY= data set saves subgroup summary statistics. The following variables are saved:

- the *subgroup-variable*
- a subgroup proportion of nonconforming items variable named by *process* suffixed with *P*
- a subgroup sample size variable named by *process* suffixed with *N*

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Subgroup summary variables are created for each *process* specified in the PCHART statement. For example, consider the following statements:

```
proc shewhart data=Input;
  pchart (Rework Rejected)*Batch / outhistory=Summary
      subgroupn =30;
run;
```

The data set Summary contains variables named Batch, ReworkP, ReworkN, RejectedP, and RejectedN.

Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

For an example of an OUTHISTORY= data set, see “Saving Proportions of Nonconforming Items” on page 1707.

Note that an OUTHISTORY= data set created with the PCHART statement can be reused as a HISTORY= data set by either the PCHART statement or the NPCHART statement.

OUTTABLE= Data Set

The OUTTABLE= data set saves subgroup summary statistics, control limits, and related information. The variables shown in the following table are saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_EXLIM_</code>	control limit exceeded on p chart
<code>_LCLP_</code>	lower control limit for proportion of nonconforming items
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_P_</code>	average proportion of nonconforming items
<code>_SIGMAS_</code>	multiple (k) of the standard error of p_i associated with the control limits
<code>subgroup</code>	values of the subgroup variable
<code>_SUBP_</code>	subgroup proportion of nonconforming items
<code>_SUBN_</code>	subgroup sample size
<code>_TESTS_</code>	tests for special causes signaled on p chart
<code>_UCLP_</code>	upper control limit for proportion of nonconforming items
<code>_VAR_</code>	<i>process</i> specified in the PCHART statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the READPHASES= option is specified)

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved depending on how the control limits are defined (with the ALPHA= or SIGMAS= options, respectively, or with the corresponding variables in a LIMITS= data set).
2. The variable `_TESTS_` is saved if you specify the TESTS= option. The k th character of a value of `_TESTS_` is k if Test k is positive at that subgroup. For example, if you request the first four tests (the tests appropriate for p charts) and Tests 2 and 4 are positive for a given subgroup, the value of `_TESTS_` has a 2 for the second character, a 4 for the fourth character, and blanks for the other six characters.
3. The variables `_EXLIM_` and `_TESTS_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “Saving Control Limits” on page 1708.

ODS Tables

The following table summarizes the ODS tables that you can request with the PCHART statement.

Table 17.44 ODS Tables Produced with the PCHART Statement

Table Name	Description	Options
PCHART	p chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLELEG, TABLEOUT, TABLETESTS
TestDescriptions	descriptions of tests for special causes requested with the TESTS= option for which at least one positive signal is found	TABLEALL, TABLELEG

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the SHEWHART procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. PCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the PCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 17.45](#).

Table 17.45 ODS Graphics Produced by the PCHART Statement

ODS Graph Name	Plot Description
PChart	p chart

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (counts of nonconforming items) from a DATA= data set specified in the PROC SHEWHART statement. Each *process* specified in the PCHART statement must be a SAS variable in the DATA= data set. This variable provides counts for subgroup samples indexed by the values of the *subgroup-variable*. The *subgroup-variable*, which is specified in the PCHART

statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a count for each *process* and a value for the *subgroup-variable*. The data set must contain one observation for each subgroup. Note that you can specify the DATAUNIT= option in the PCHART statement to read proportions or percentages of nonconforming items instead of counts. Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

When you use a DATA= data set with the PCHART statement, the SUBGROUPN= option (which specifies the subgroup sample size) is required. By default, the SHEWHART procedure reads all of the observations in a DATA= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (for an example, see “[Displaying Stratification in Phases](#)” on page 2103).

For an example of a DATA= data set, see “[Creating p Charts from Count Data](#)” on page 1702.

LIMITS= Data Set

You can read preestablished control limits (or parameters from which the control limits can be calculated) from a LIMITS= data set specified in the PROC SHEWHART statement. For example, the following statements read control limit information from the data set `Conlims`:²²

```
proc shewhart data=Info limits=Conlims;
  pchart Rejects*Batch / subgroupn= 100;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the SHEWHART procedure. Such data sets always contain the variables required for a LIMITS= data set. The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LCLP_`, `_P_`, and `_UCLP_`, which specify the control limits directly
- the variable `_P_`, without providing `_LCLP_` and `_UCLP_`. The value of `_P_` is used to calculate the control limits according to the equations in “[Control Limits](#)” on page 1723.

In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables whose lengths are no greater than 32.
- The variable `_INDEX_` is required if you specify the READINDEX= option; this must be a character variable whose length is no greater than 48.

²²In SAS 6.09 and in earlier releases, it is necessary to specify the READLIMITS option.

- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8; valid values are 'ESTIMATE' and 'STANDARD'.
- BY variables are required if specified with a BY statement.

For an example, see “[Reading Preestablished Control Limits](#)” on page 1710.

HISTORY= Data Set

You can read subgroup summary statistics from a HISTORY= data set specified in the PROC SHEWHART statement. This enables you to reuse OUTHISTORY= data sets that have been created in previous runs of the SHEWHART procedure or to create your own HISTORY= data set.

A HISTORY= data set used with the PCHART statement must contain the following:

- the *subgroup-variable*
- a subgroup proportion of nonconforming items variable for each *process*
- a subgroup sample size variable for each *process*

The names of the proportion sample size variables must be the *process* name concatenated with the special suffix characters *P* and *N*, respectively.

For example, consider the following statements:

```
proc shewhart history=Summary;
  pchart (Rework Rejected)*Batch / subgroupn=50;
run;
```

The data set Summary must include the variables Batch, ReworkP, ReworkN, RejectedP, and RejectedN.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a HISTORY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a HISTORY= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations

(referred to as *phases*) by specifying the READPHASES= option (see “Displaying Stratification in Phases” on page 2103 for an example).

For an example of a HISTORY= data set, see “Creating p Charts from Summary Data” on page 1704.

TABLE= Data Set

You can read summary statistics and control limits from a TABLE= data set specified in the PROC SHEWHART statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the SHEWHART procedure. Because the SHEWHART procedure simply displays the information read from a TABLE= data set, you can use TABLE= data sets to create specialized control charts. Examples are provided in “Specialized Control Charts: SHEWHART Procedure” on page 2171.

The following table lists the variables required in a TABLE= data set used with the PCHART statement:

Table 17.46 Variables Required in a TABLE= Data Set

Variable	Description
<code>_LCLP_</code>	lower control limit for proportion of nonconforming items
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_P_</code>	average proportion of nonconforming items
<i>subgroup-variable</i>	values of the <i>subgroup-variable</i>
<code>_SUBN_</code>	subgroup sample size
<code>_SUBP_</code>	subgroup proportion of nonconforming items
<code>_UCLP_</code>	upper control limit for proportion of nonconforming items

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- `_PHASE_` (if the READPHASES= option is specified). This variable must be a character variable whose length is no greater than 48.
- `_TESTS_` (if the TESTS= option is specified). This variable is used to flag tests for special causes and must be a character variable of length 8.
- `_VAR_`. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable whose length is no greater than 32.

For an example of a TABLE= data set, see “Saving Control Limits” on page 1708.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical	DATA=	<i>process</i>
Vertical	HISTORY=	subgroup proportion nonconforming variable
Vertical	TABLE=	<code>_SUBP_</code>

For example, the following sets of statements specify the label *Proportion Nonconforming* for the vertical axis of the *p* chart:

```
proc shewhart data=Circuits;
  pchart Fail*Batch / subgroupn=500;
  label Fail = 'Proportion Nonconforming';
run;

proc shewhart history=Cirhist;
  pchart Fail*Batch ;
  label FailP = 'Proportion Nonconforming';
run;

proc shewhart table=Cirtable;
  pchart Fail*Batch ;
  label _SUBP_ = 'Proportion Nonconforming';
run;
```

In this example, the label assignments are in effect only for the duration of the procedure step, and they temporarily override any permanent labels associated with the variables.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: PCHART Statement

This section provides advanced examples of the PCHART statement.

Example 17.22: Applying Tests for Special Causes

See SHWPEX1 in the SAS/QC Sample Library

This example shows how you can apply tests for special causes to make p charts more sensitive to special causes of variation. The following statements create a SAS data set named Circuit3, which contains the number of failing circuits for 20 batches from the circuit manufacturing process introduced in “Creating p Charts from Count Data” on page 1702:

```
data Circuit3;
  input Batch Fail @@;
  datalines;
  1 12    2 21    3 16    4 9
  5 3     6 4     7 6     8 9
  9 11    10 13    11 12    12 7
  13 2    14 14    15 9    16 8
  17 14   18 10   19 11   20 9
  ;
```

The following statements create the p chart, apply several tests to the chart, and tabulate the results:

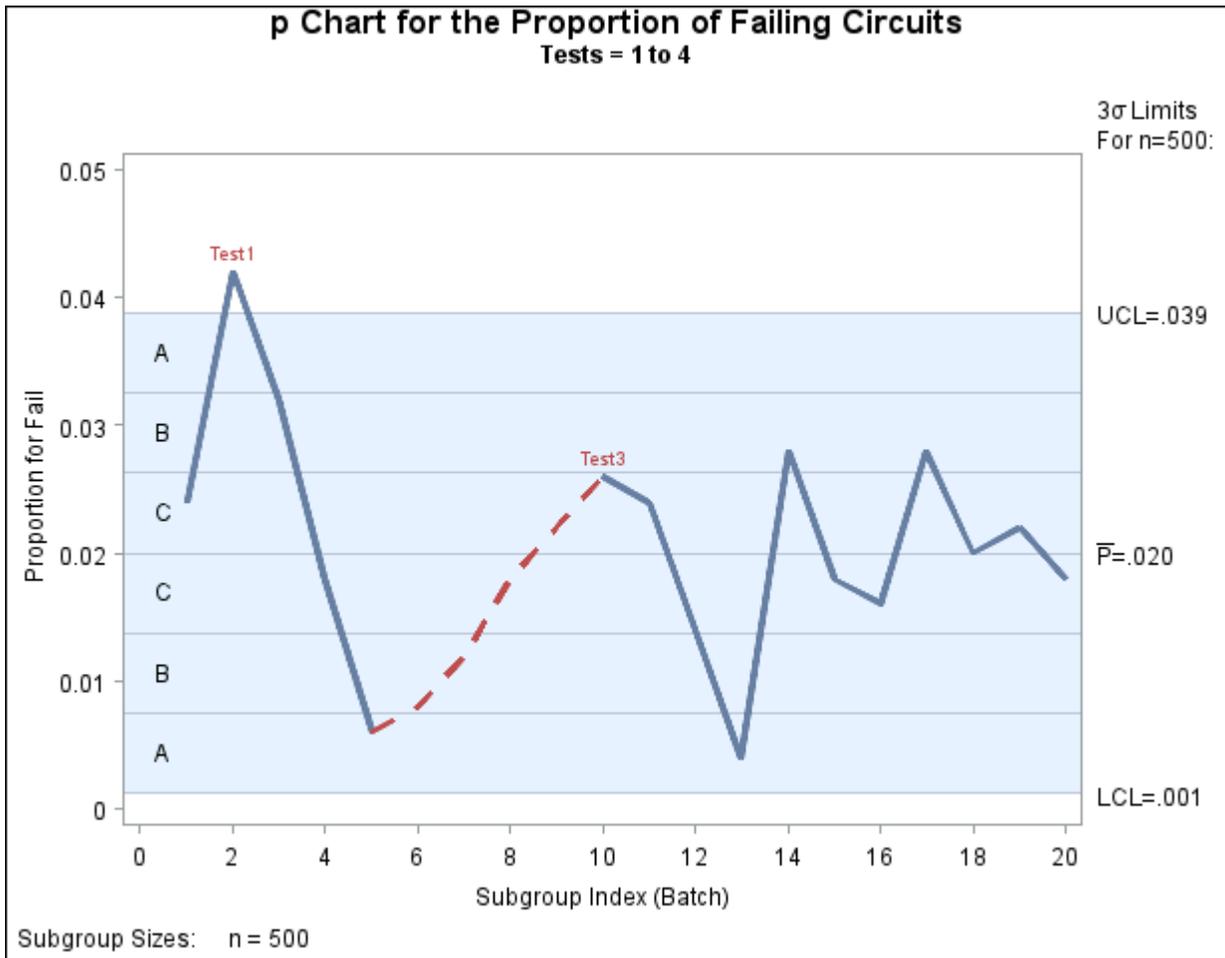

```
ods graphics off;
title1 'p Chart for the Proportion of Failing Circuits';
title2 'Tests = 1 to 4';
proc shewhart data=Circuit3;
  pchart Fail*Batch / subgroupn = 500
                    tests      = 1 to 4
                    zones
                    zonelabels
                    ltests     = 20
                    table
                    tabletest
                    tablelegend;
run;
```

The chart is shown in [Output 17.22.1](#), and the printed output is shown in [Output 17.22.2](#). The TESTS= option requests Tests 1, 2, 3, and 4, which are described in “Tests for Special Causes: SHEWHART Procedure” on page 2146. The TABLETESTS option requests a table of proportions of nonconforming items and control limits, with a column indicating which subgroups tested positive for special causes. The TABLELEGEND option adds a legend describing the tests that are positive.

The ZONELABELS option displays zone lines and zone labels on the chart. The zones are used to define the tests. The LTESTS= option specifies the line type used to connect the points in a pattern for a test that is signaled.

[Output 17.22.1](#) and [Output 17.22.2](#) indicate that Test 1 is positive at batch 2 and Test 3 is positive at batch 10.

Output 17.22.1 Tests for Special Causes Displayed on p Chart

Output 17.22.2 Tabular Form of p Chart

p Chart for the Proportion of Failing Circuits					
Tests = 1 to 4

19	500	0.00121703	0.02200000	0.03878297	
20	500	0.00121703	0.01800000	0.03878297	

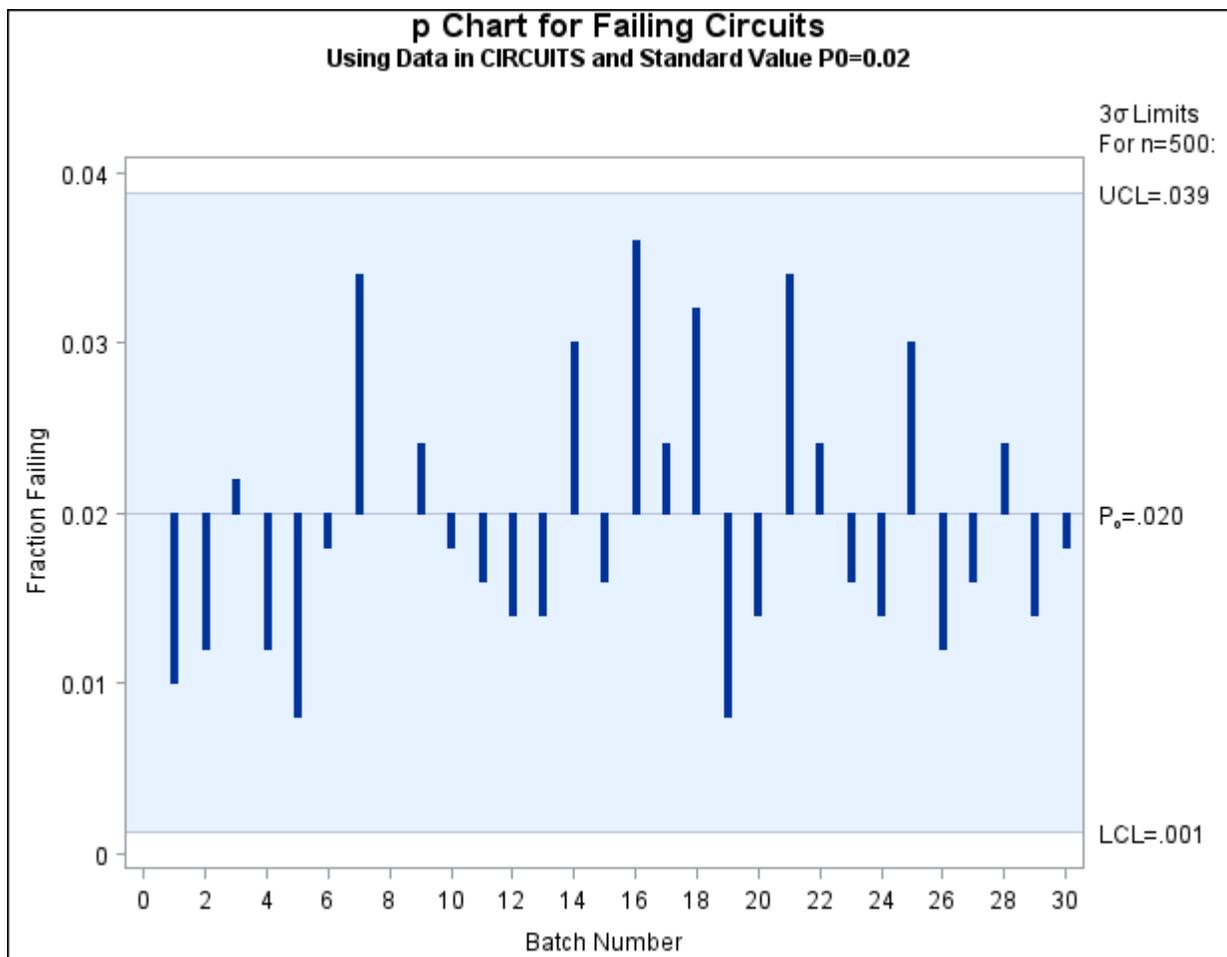

Test Descriptions	
Test 1	One point beyond Zone A (outside control limits)
Test 3	Six points in a row steadily increasing or decreasing

Example 17.23: Specifying Standard Average Proportion

See SHWPEX2 in the SAS/QC Sample Library In some situations, a standard (known) value (p_0) is available for the expected proportion of non-conforming items, based on extensive testing or previous sampling. This example illustrates how you can specify p_0 to create a p chart.

A p chart is used to monitor the proportion of failing circuits in the data set Circuits, which is introduced in “Creating p Charts from Count Data” on page 1702. The expected proportion is known to be $p_0 = 0.02$. The following statements create a p chart, shown in [Output 17.23.1](#), using p_0 to compute the control limits:

```
ods graphics off;
title1 'p Chart for Failing Circuits';
title2 'Using Data in CIRCUITS and Standard Value P0=0.02';
proc shewhart data=Circuits;
  pchart Fail*Batch / subgroupn = 500
                    p0          = 0.02
                    psymbol    = p0
                    wneedles   = 3
                    nolegend;
  label Batch = 'Batch Number'
        Fail  = 'Fraction Failing';
run;
```

Output 17.23.1 A p Chart with Standard Value p_0 

The chart indicates that the process is in control. The P0= option specifies p_0 . The PSYMBOL= option specifies a label for the central line indicating that the line represents a standard value. The NEEDLES option connects points to the central line with vertical needles. The NOLEGEND option suppresses the default legend for subgroup sample sizes. Labels for the vertical and horizontal axes are provided with the LABEL statement. For details concerning axis labeling, see “Axis Labels” on page 1731.

Alternatively, you can specify p_0 using the variable `_P_` in a LIMITS= data set,²³ as follows:

```
data Climits;
  length _var_ _subgrp_ _type_ $8;
  _p_      = 0.02;
  _subgrp_ = 'Batch';
  _var_    = 'Fail';
  _type_   = 'STANDARD';
  _limitn_ = 500;
run;

proc shewhart data=Circuits limits=Climits;
  pchart Fail*Batch / subgroupn = 500
                    psymbol    = p0
                    nolegend
                    needles;
  label batch = 'Batch Number'
        fail  = 'Fraction Failing';
run;
```

The bookkeeping variable `_TYPE_` indicates that `_P_` has a standard value. The chart produced by these statements is identical to the chart in [Output 17.23.1](#).

Example 17.24: Working with Unequal Subgroup Sample Sizes

See SHWPEX3 in the SAS/QC Sample Library The following statements create a SAS data set named Battery, which contains the number of alkaline batteries per lot failing an acceptance test. The number of batteries tested in each lot varies but is approximately 150.

```
data Battery;
  length lot $3;
  input lot nFailed Sampsize @@;
  label nFailed = 'Number Failed'
        lot      = 'Lot Number'
        Sampsize = 'Number Sampled';
  datalines;
AE3 6 151    AE4 5 142    AE9 6 145
BR3 9 149    BR7 3 150    BR8 0 156
BR9 4 150    DB1 9 158    DB2 4 152
DB3 0 162    DB5 9 140    DB6 7 161
DS4 6 154    DS6 1 144    DS8 5 154
JG1 3 151    MC3 8 148    MC4 2 143
MK6 4 150    MM1 4 147    MM2 0 150
RT5 2 154    RT9 8 149    SP1 3 160
SP3 9 153
;
```

The variable `nFailed` contains the number of battery failures, the variable `Lot` contains the lot number, and the variable `Sampsize` contains the lot sample size. The following statements request a p chart for this data:

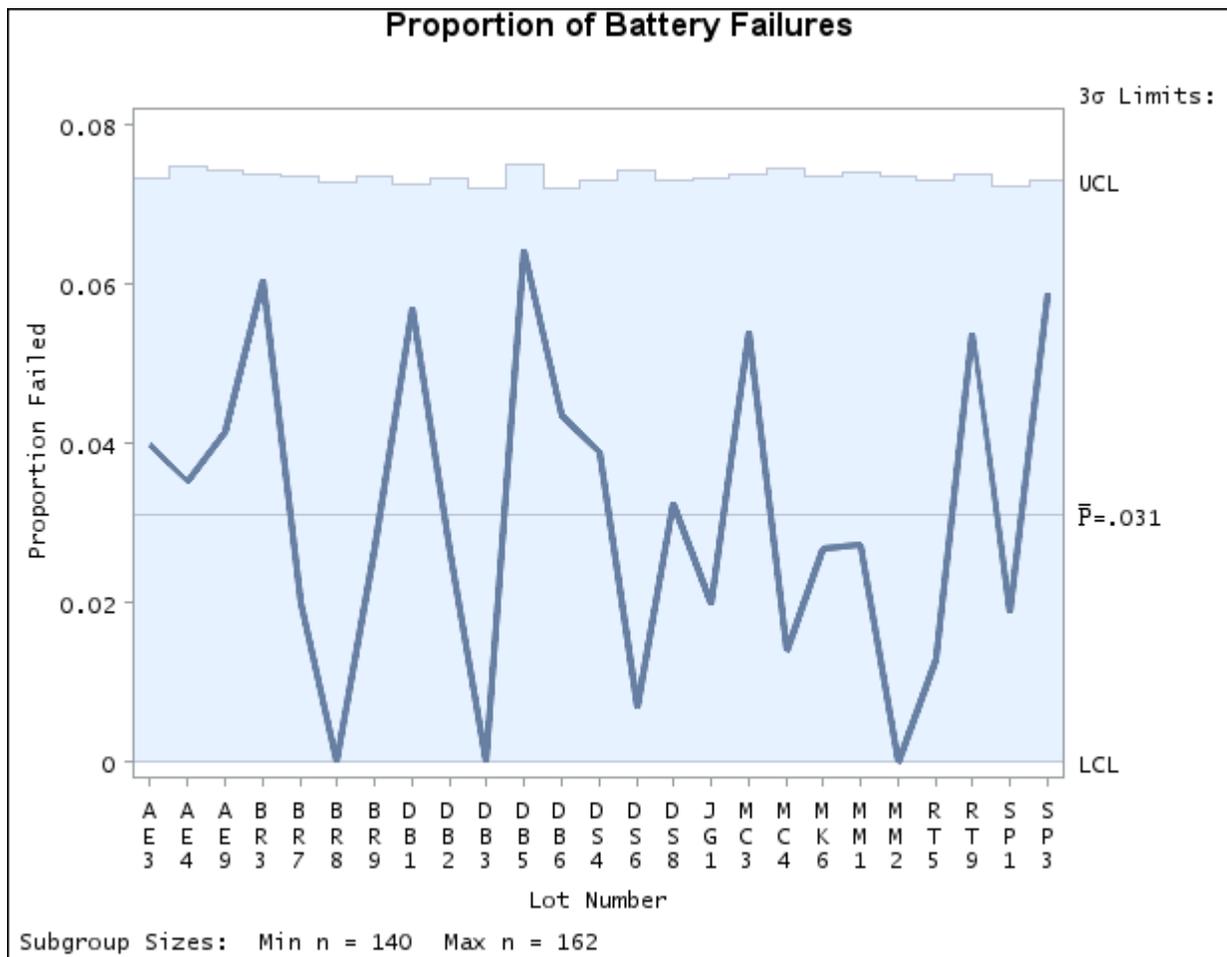

²³In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option

```
ods graphics off;
title 'Proportion of Battery Failures';
proc shewhart data=Battery;
  pchart nFailed*Lot / subgroupn = Sampsize
    turnhlabels
    font      = 'Lucida Console'
    outlimits = Batlim;
  label nFailed = 'Proportion Failed';
run;
```

Here the FONT= option is used to specify the name of a hardware font to be used for the *p* chart. In this case the requested font is Lucida Console, a Windows TrueType font. See *SAS/GRAPH: Reference* and *SAS Companion for Microsoft Windows* for more information about hardware and TrueType fonts.

The chart is shown in [Output 17.24.1](#) and the OUTLIMITS= data set Batlim is listed in [Output 17.24.2](#).

Output 17.24.1 A *p* Chart with Varying Subgroup Sample Sizes

Note that the upper control limit varies with the subgroup sample size. The lower control limit is truncated at zero. The sample size legend indicates the minimum and maximum subgroup sample

sizes.

Output 17.24.2 Listing of the Control Limits Data Set Batlim

Control Limits for Battery Failures								
<u>_VAR_</u>	<u>_SUBGRP_</u>	<u>_TYPE_</u>	<u>_LIMITN_</u>	<u>_ALPHA_</u>	<u>_SIGMAS_</u>	<u>_LCLP_</u>	<u>_P_</u>	<u>_UCLP_</u>
nFailed	lot	ESTIMATE	V	V	3	V	0.031010	V

The variables in Batlim whose values vary with subgroup sample size are assigned the special missing value *V*.

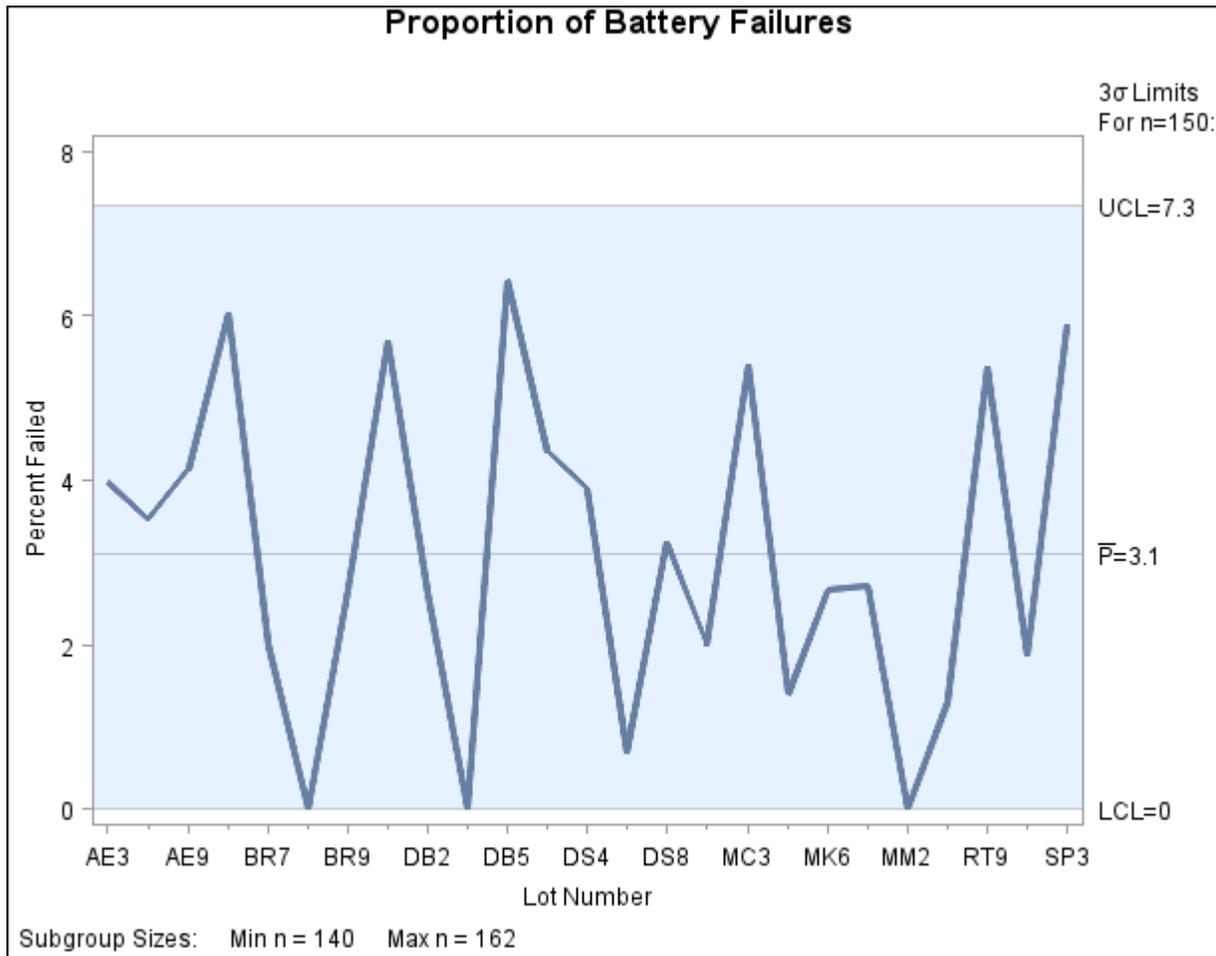

The SHEWHART procedure provides various options for working with unequal subgroup sample sizes. For example, you can use the LIMITN= option to specify a fixed (nominal) sample size for computing the control limits, as illustrated by the following statements:

```

title 'Proportion of Battery Failures';
proc shewhart data=Battery;
  pchart nFailed*Lot / subgroupn = Sampsize
                    limitn    = 150
                    alln
                    outlimits = clim2
                    yscale    = percent;
  label nFailed = 'Percent Failed';
run;

```

The ALLN option specifies that all points (regardless of subgroup sample size) are to be displayed. By default, only points for subgroups whose sample size matches the LIMITN= value are displayed. The YSCALE= option specifies that the vertical axis is to be scaled in percentages rather than proportions. The chart is shown in [Output 17.24.3](#).

Output 17.24.3 Control Limits Based on Fixed Subgroup Sample Size

All the points are inside the control limits, indicating that the process is in statistical control. Since there is relatively little variation in the sample sizes, the control limits in [Output 17.24.3](#) provide a close approximation to the exact control limits in [Output 17.24.1](#), and the same conclusions can be drawn from both charts. In general, care should be taken when interpreting charts that use a nominal sample size to compute control limits, since these limits are only approximate when the sample sizes vary.

Example 17.25: Creating a Chart with Revised Control Limits

The following statements create a SAS data set named `CircOne`, which contains the number of failing circuits for 30 batches produced by the circuit manufacturing process introduced in the section *See SHWPEX4 in the SAS/QC Sample Library* “Getting Started: PCHART Statement” on page 1701:

```
data CircOne;
  input Batch Fail @@;
  datalines;
  1 7 2 6 3 6 4 9 5 2
  6 11 7 8 8 8 9 6 10 19
```

```

11  7 12  5 13  7 14  5 15  8
16 13 17  7 18 14 19 19 20  5
21  7 22  5 23  7 24  5 25 11
26  4 27  6 28  3 29 11 30  3
;

```

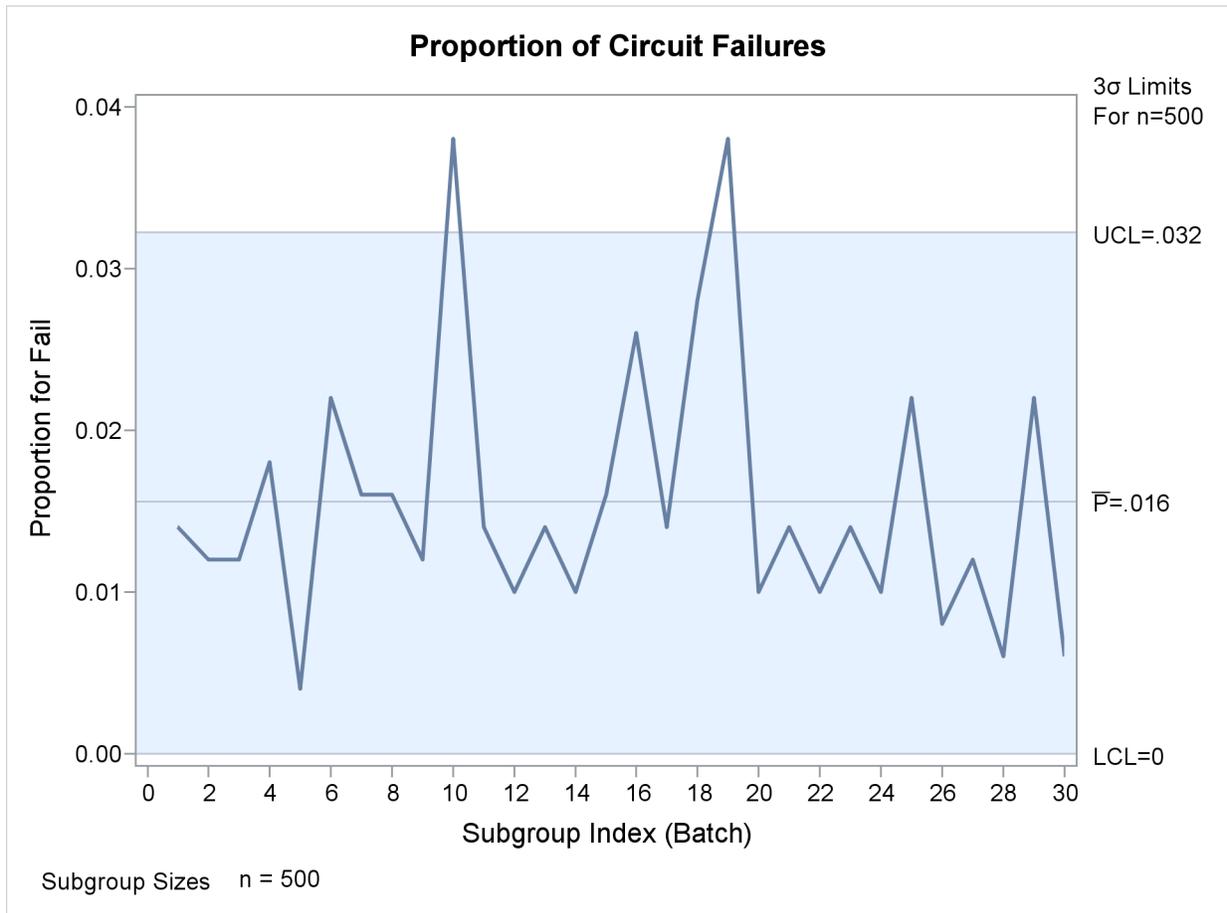

A p chart is used to monitor the proportion of failing circuits. The following statements create the chart shown in [Output 17.25.1](#):

```

ods graphics on;
title 'Proportion of Circuit Failures';
proc shewhart data=CircOne;
  pchart Fail*Batch / subgroupn = 500
                    outindex = 'Trial Limits'
                    outlimits = Faillim1
                    odstitle = title;
run;

```

Output 17.25.1 A p Chart for Circuit Failures

Batches 10 and 19 have unusually high proportions of failing circuits. Subsequent investigation identifies special causes for both batches, and it is decided to eliminate these batches from the data set and recompute the control limits. The following statements create a data set named `Faillim2` that contains the revised control limits:

```
proc shewhart data=CircOne;
  where Batch ^= 10 and Batch ^= 19;
  pchart Fail*Batch / subgroupn = 500
    nochart
    outindex = 'Revised Limits'
    outlimits = Faillim2;
run;

data Faillims;
  set Faillim1 Faillim2;
run;
```

The data set Faillims, which contains the true and revised control limits, is listed in [Output 17.25.2](#).

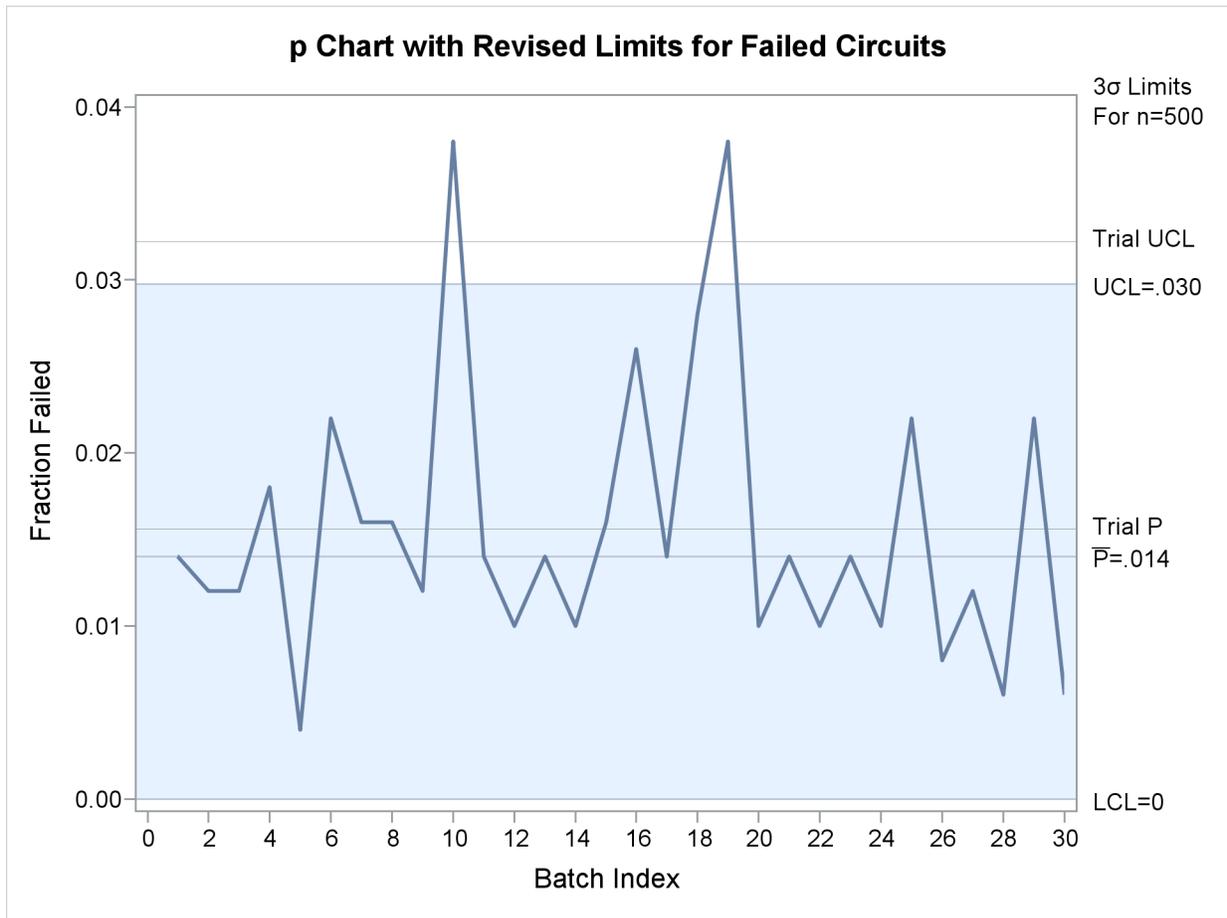

Output 17.25.2 Listing of the Data Set Faillims

Proportion of Circuit Failures								
—	S	—	—	L	—	S	—	—
—	U	I	—	I	A	I	—	—
—	B	N	T	M	L	G L	—	U
V	G	D	Y	I	P	M C	—	C
A	R	E	P	T	H	A L	—	L
R	P	X	E	N	A	S P	P	P
—	—	—	—	—	—	—	—	—
Fail Batch Trial Limits	ESTIMATE	500	.005620297	3	0	0.0156	0.032226	
Fail Batch Revised Limits	ESTIMATE	500	.005942336	3	0	0.0140	0.029763	

The following statements create a *p* chart displaying both sets of control limits:

```
title 'p Chart with Revised Limits for Failed Circuits';
proc shewhart data=CircOne limits=Faillims;
  pchart Fail*Batch / subgroupn = 500
    readindex = 'Revised Limits'
    vref       = 0.0156 0.032226
    vreflabels = ('Trial P' 'Trial UCL')
    vreflabpos = 3
    odstitle  = title
    nolegend;
  label Fail = 'Fraction Failed'
        Batch = 'Batch Index';
run;
ods graphics off;
```

The READINDEX= option is used to select the revised limits displayed on the *p* chart in [Output 17.25.3](#). See “[Displaying Multiple Sets of Control Limits](#)” on page 2105. The VREF=, VREFLABELS=, and VREFLABPOS= options are used to display and label the trial limits. You can also pass in the values of the trial limits with macro variables. For an illustration of this technique, see [Example 17.6](#).

Output 17.25.3 p Chart with Revised Limits

Example 17.26: OC Curve for Chart

See SHWPOC in the SAS/QC Sample Library This example uses the GPLOT procedure and the OUTLIMITS= data set Faillim2 from the previous example to plot an OC curve for the p chart shown in [Output 17.25.3](#).

The OC curve displays β (the probability that p_i lies within the control limits) as a function of p (the true proportion nonconforming). The computations are exact, assuming that the process is in control and that the number of nonconforming items (X_i) has a binomial distribution.

The value of β is computed as follows:

$$\begin{aligned}
 \beta &= P(p_i \leq \text{UCL}) - P(p_i < \text{LCL}) \\
 &= P(X_i \leq n\text{UCL}) - P(X_i < n\text{LCL}) \\
 &= P(X_i < n\text{UCL}) + P(X_i = n\text{UCL}) - P(X_i < n\text{LCL}) \\
 &= I_{1-p}(n+1-n\text{UCL}, n\text{UCL}) + P(X_i = n\text{UCL}) - I_{1-p}(n+1-n\text{LCL}, n\text{LCL}) \\
 &= I_p(n\text{LCL}, n+1-n\text{LCL}) + P(X_i = n\text{UCL}) - I_p(n\text{UCL}, n+1-n\text{UCL})
 \end{aligned}$$

Here, $I_p(\cdot, \cdot)$ denotes the incomplete beta function. The following DATA step computes β (the variable BETA) as a function of p (the variable P):

```

data ocpchart;
  set Faillim2;
  keep beta fraction _lclp_ _p_ _uclp_;
  nucl=_limitn*_uclp_;
  nlcl=_limitn*_lclp_;
  do p=0 to 500;
    fraction=p/1000;
    if nucl=floor(nucl) then
      adjust=probbnml(fraction,_limitn_,nucl) -
        probbnml(fraction,_limitn_,nucl-1);
    else adjust=0;
    if nlcl=0 then
      beta=1 - probbeta(fraction,nucl,_limitn_-nucl+1) + adjust;
    else beta=probbeta(fraction,nlcl,_limitn_-nlcl+1) -
      probbeta(fraction,nucl,_limitn_-nucl+1) +
      adjust;
    if beta >= 0.001 then output;
  end;
  call symput('lcl', put(_lclp_,5.3));
  call symput('mean',put(_p_, 5.3));
  call symput('ucl', put(_uclp_,5.3));
run;

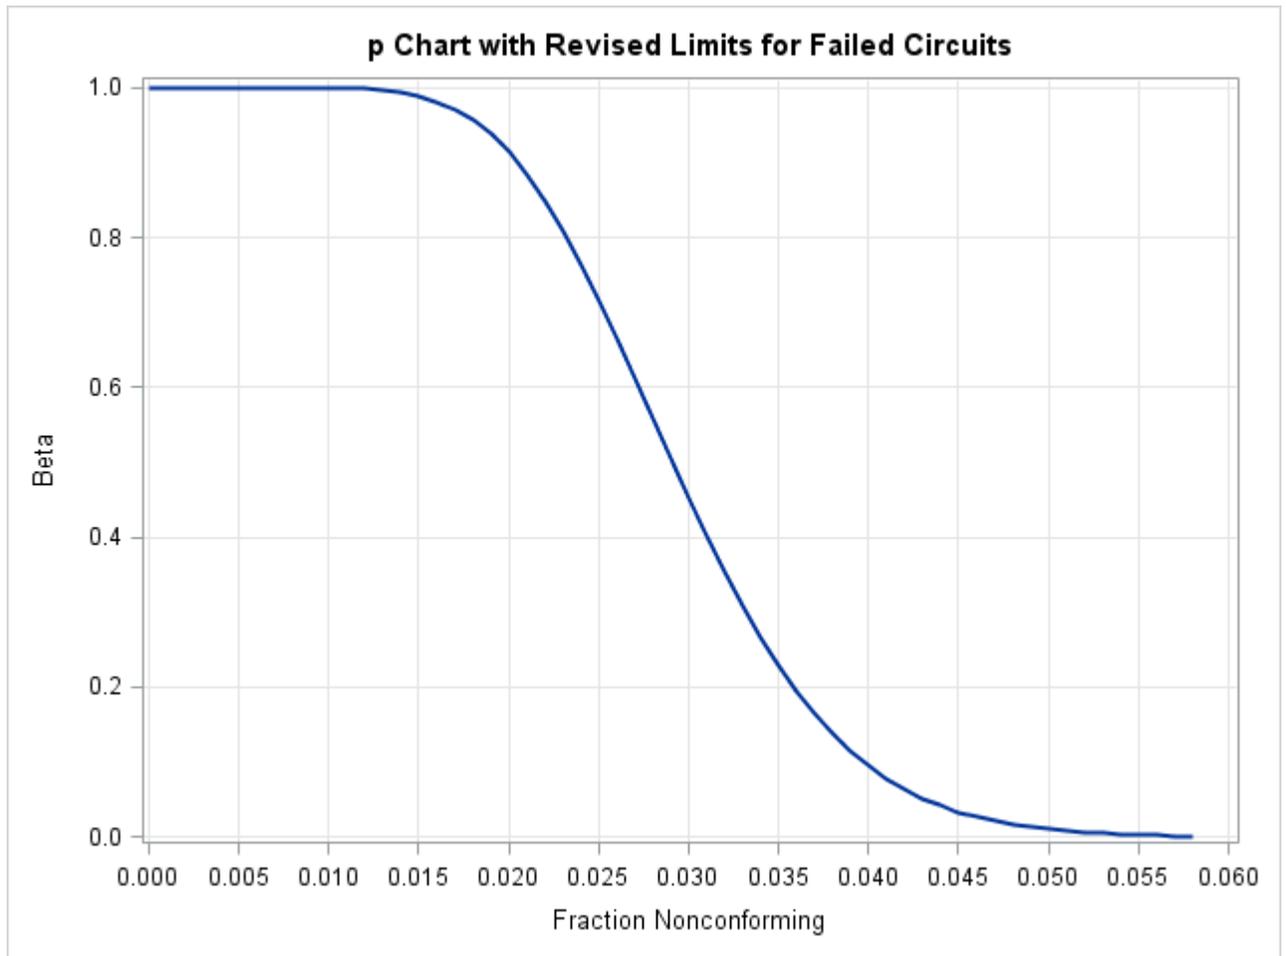

```

The following statements display the OC curve shown in [Output 17.26.1](#):

```

proc sgplot data=ocpchart;
  series x=fraction y=beta / lineattrs=(thickness=2);
  xaxis values=(0 to 0.06 by 0.005) grid;
  yaxis grid;
  label fraction = 'Fraction Nonconforming'
        beta      = 'Beta';
run;

```

Output 17.26.1 OC Curve for p Chart

RCHART Statement: SHEWHART Procedure

Overview: RCHART Statement

The RCHART statement creates an R chart for subgroup ranges, which is used to analyze the variability of a process.²⁴

You can use options in the RCHART statement to

- compute control limits from the data based on a multiple of the standard error of the plotted ranges or as probability limits
- tabulate subgroup sample sizes, subgroup ranges, control limits, and other information

²⁴You can also use s charts for this purpose; see “SCHART Statement: SHEWHART Procedure” on page 1782. In general, s charts are recommended with large subgroup sample sizes ($n_i \geq 10$).

- save control limits in an output data set
- save subgroup sample sizes, subgroup means, and subgroup ranges in an output data set
- read preestablished control limits from a data set
- specify the method for estimating the process standard deviation
- specify a known (standard) process standard deviation for computing control limits
- display distinct sets of control limits for data from successive time phases
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have three alternatives for producing *R* charts with the RCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: RCHART Statement

This section introduces the RCHART statement with simple examples that illustrate the most commonly used options. Complete syntax for the RCHART statement is presented in the section “Syntax: RCHART Statement” on page 1757, and advanced examples are given in the section “Examples: RCHART Statement” on page 1777.

Creating Range Charts from Raw Data

See *SHWRCHR* in the *SAS/QC Sample Library* A disk drive manufacturer performs a battery of tests to evaluate its drives. The following statements create a data set named *Disks*, which contains the time (in milliseconds) required to complete one of these tests for six drives in each of 25 lots:

```

data Disks;
  input Lot @;
  do i=1 to 6;
    input Time @;
    output;
  end;
  drop i;
  datalines;
1 8.05 7.90 8.04 8.06 8.01 7.99
2 8.03 8.06 8.02 8.02 7.97 8.03
3 8.00 7.94 7.97 7.95 8.00 8.01
4 8.00 8.06 8.06 7.99 7.97 7.96
5 7.93 8.01 8.00 8.09 8.06 8.02
6 7.98 7.99 8.01 8.09 8.00 7.97
7 8.00 7.94 7.93 8.03 7.93 8.08
8 8.01 7.98 7.98 8.07 8.05 8.09
9 7.97 7.96 8.01 8.11 8.06 8.07
10 7.93 8.03 8.03 8.00 7.93 8.03
11 8.00 8.00 8.02 7.92 7.98 8.01
12 7.98 7.93 8.01 7.97 8.02 8.00
13 8.06 7.93 7.98 7.98 8.02 7.96
14 8.05 7.98 8.05 7.99 7.95 7.99

A partial listing of *Disks* is shown in [Figure 17.70](#).

Figure 17.70 Partial Listing of the Data Set Disks

The Data Set DISKS	
Lot	Time
1	8.05
1	7.90
1	8.04
1	8.06
1	8.01
1	7.99
2	8.03
2	8.06
2	8.02
2	8.02
2	7.97
2	8.03
3	8.00
3	7.94
3	7.97
3	7.95
3	8.00
3	8.01

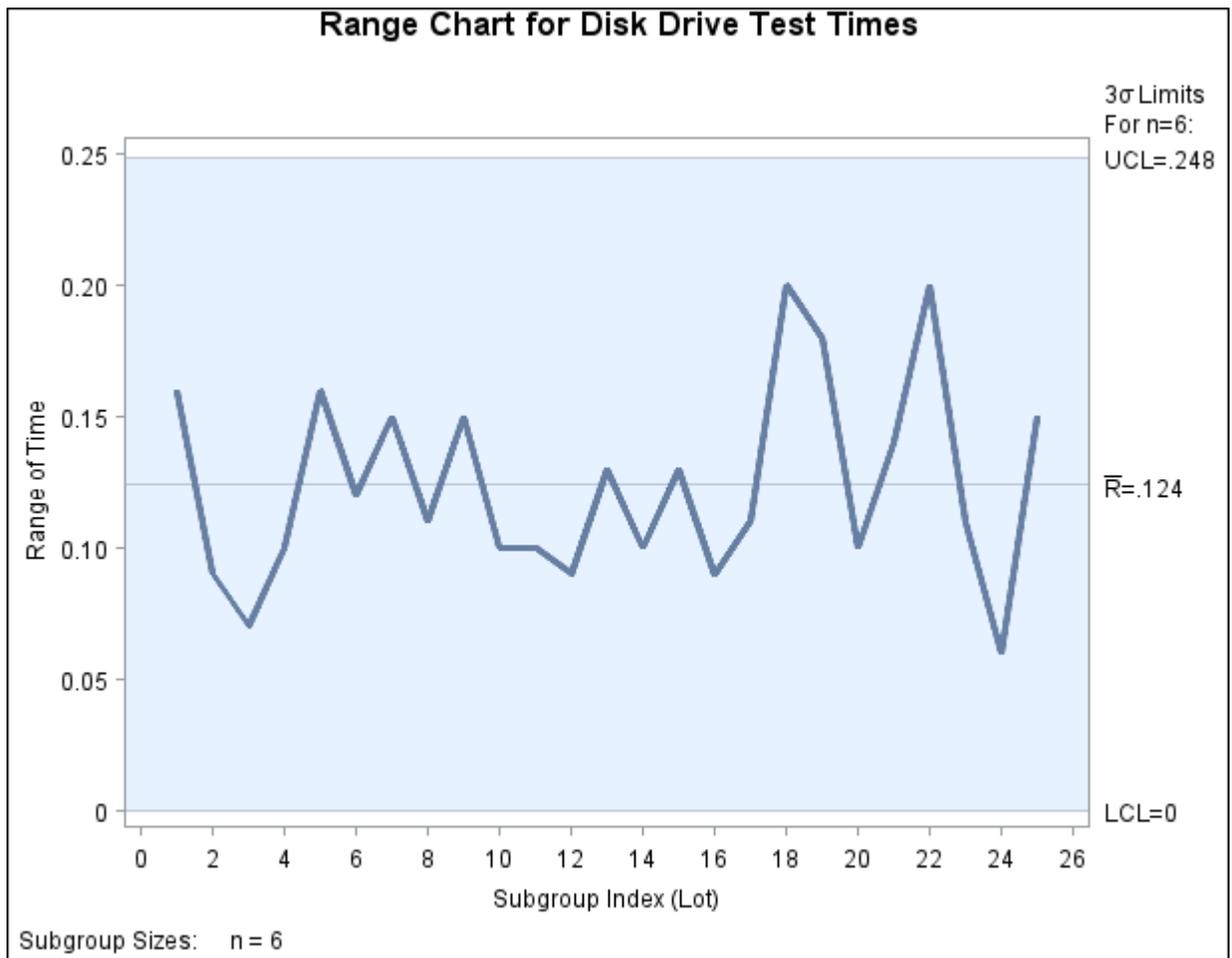

The data set Disks is said to be in “strung-out” form since each observation contains the lot number and test time for a single disk drive. The first five observations contain the times for the first lot, the second five observations contain the times for the second lot, and so on. Because the variable Lot classifies the observations into rational subgroups, it is referred to as the *subgroup-variable*. The variable Time contains the time measurements and is referred to as the *process variable* (or *process* for short).

You can use an *R* chart to determine whether the variability in the performance of the disk drives is in control. The following statements create the *R* chart shown in Figure 17.71:

```
ods graphics off;
title 'Range Chart for Disk Drive Test Times';
proc shewhart data=Disks;
  rchart Time*Lot;
run;
```

This example illustrates the basic form of the RCHART statement. After the keyword RCHART, you specify the *process* to analyze (in this case, Time), followed by an asterisk and the *subgroup-variable* (Lot).

The input data set is specified with the DATA= option in the PROC SHEWHART statement.

Figure 17.71 *R* Chart for the Data Set Disks (Traditional Graphics)

Each point on the *R* chart represents the range of the measurements for a particular lot. For instance, the range plotted for the first lot is $8.06 - 7.90 = 0.16$. Since all of the subgroup ranges lie within the control limits, you can conclude that the variability in the performance of the disk drives is in statistical control.

By default, the control limits shown are 3σ limits estimated from the data; the formulas for the limits are given in Table 17.48. You can also read control limits from an input data set; see “Reading Preestablished Control Limits” on page 1755.

For computational details, see “Constructing Range Charts” on page 1767. For more details on reading raw data, see “DATA= Data Set” on page 1773.

Creating Range Charts from Summary Data

See SHWRCHR in the SAS/QC Sample Library

The previous example illustrates how you can create *R* charts using raw data (process measurements). However, in many applications the data are provided as subgroup summary statistics. This example illustrates how you can use the RCHART statement with data of this type.

The following data set (Disksum) provides the data from the preceding example in summarized form:

```

data Disksum;
  input Lot TimeX TimeR;
  TimeN=6;
  datalines;
1  8.00833  0.16
2  8.02167  0.09
3  7.97833  0.07
4  8.00667  0.10
5  8.01833  0.16
6  8.00667  0.12
7  7.98500  0.15
8  8.03000  0.11
9  8.03000  0.15
10 7.99167  0.10
11 7.98833  0.10
12 7.98500  0.09
13 7.98833  0.13
14 8.00167  0.10
15 7.98333  0.13
16 8.01833  0.09
17 8.00833  0.11
18 7.98667  0.20
19 7.98667  0.18
20 8.01500  0.10
21 7.99000  0.14
22 8.01833  0.20
23 8.00833  0.11
24 7.98500  0.06
25 8.03667  0.15
;

```

A partial listing of Disksum is shown in Figure 17.72. There is exactly one observation for each subgroup (note that the subgroups are still indexed by Lot). The variable TimeX contains the subgroup means, the variable TimeR contains the subgroup ranges, and the variable TimeN contains the subgroup sample sizes (these are all six).

Figure 17.72 The Summary Data Set Disksum

The Summary Data Set of Disk Drive Test Times				
Lot	TimeX	Time R	Time N	
1	8.00833	0.16	6	
2	8.02167	0.09	6	
3	7.97833	0.07	6	
4	8.00667	0.10	6	
5	8.01833	0.16	6	

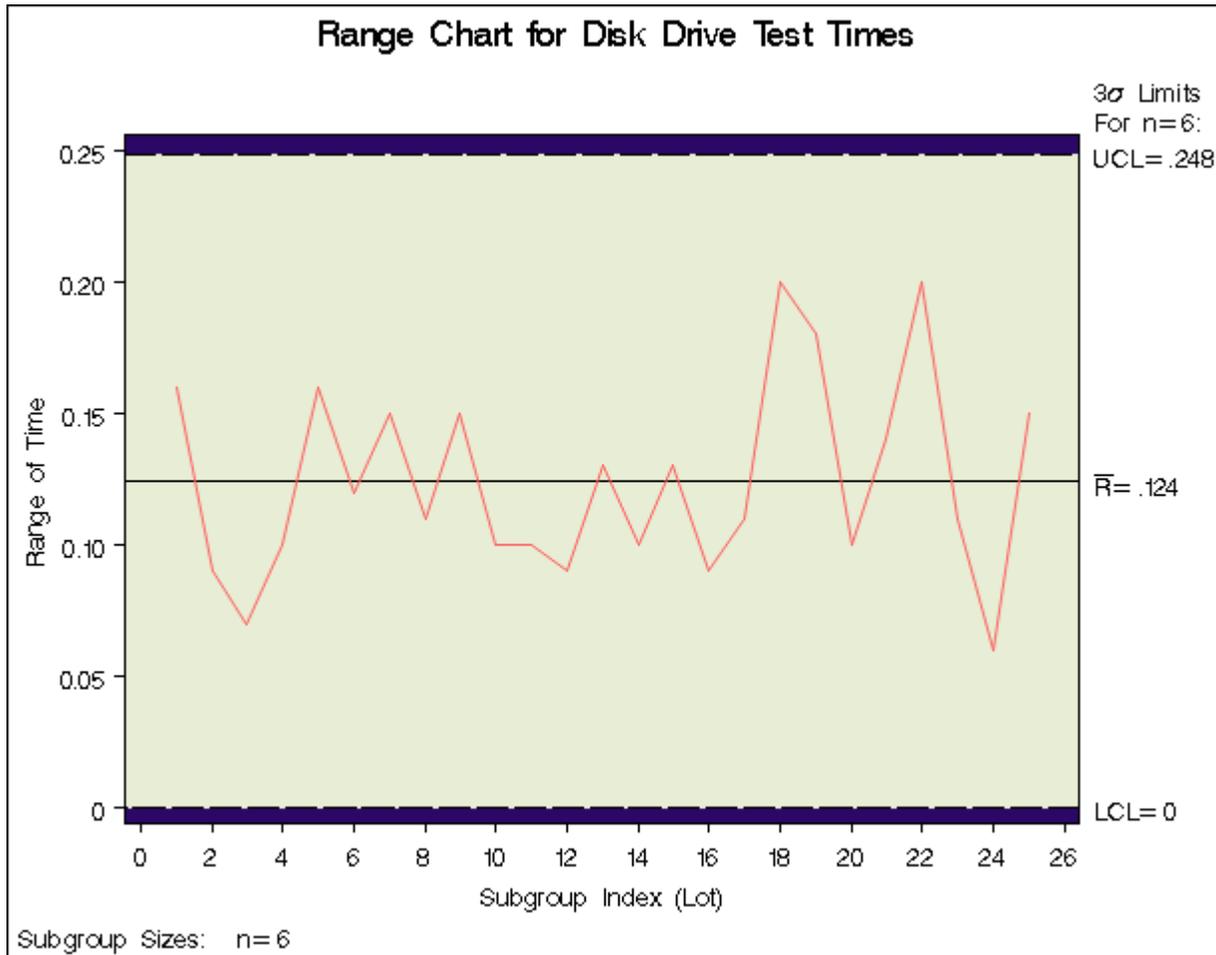

You can read this data set by specifying it as a HISTORY= data set in the PROC SHEWHART statement, as follows:

```
options nogstyle;
options ftext=swiss;
symbol color = rose h = .8;
title 'Range Chart for Disk Drive Test Times';
proc shewhart history=Disksum;
    rchart Time*Lot / cframe    = vipb
                   cinfll    = ywh
                   cconnect   = rose;
run;
options gstyle;
```

The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the SYMBOL statement and RCHART statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently. The resulting *R* chart is shown in [Figure 17.73](#).

Note that Time is *not* the name of a SAS variable in the data set Disksum but is, instead, the common prefix for the names of the SAS variables TimeR and TimeN. The suffix characters *R* and *N* indicate *range* and *sample size*, respectively. Thus, you can specify two subgroup summary variables in the HISTORY= data set with a single name (Time), which is referred to as the *process*. The name Lot specified after the asterisk is the name of the *subgroup-variable*.

Figure 17.73 *R* Chart from the Summary Data Set Disksum (Traditional Graphics with NOGSTYLE)

In general, a HISTORY= input data set used with the RCHART statement must contain the following variables:

- subgroup variable
- subgroup range variable
- subgroup sample size variable

Furthermore, the names of the subgroup range and sample size variables must begin with the *process* name specified in the RCHART statement and end with the special suffix characters *R* and *N*, respectively. If the names do not follow this convention, you can use the **RENAME** option in the PROC SHEWHART statement to rename the variables for the duration of the SHEWHART procedure step (see page 1909).

In summary, the interpretation of *process* depends on the input data set.

- If raw data are read using the DATA= option (as in the previous example), *process* is the name of the SAS variable containing the process measurements.
- If summary data are read using the HISTORY= option (as in this example), *process* is the common prefix for the names of the variables containing the summary statistics.

For more information, see “HISTORY= Data Set” on page 1774.

Saving Summary Statistics

See SHWRCHR in the SAS/QC Sample Library

In this example, the RCHART statement procedure is used to create a summary data set that can be read later by the SHEWHART procedure (as in the preceding example). The following statements read measurements from the data set Disks and create a summary data set named Diskhist:

```
proc shewhart data=Disks;
  rchart Time*Lot / outhistory = Diskhist
  nochart;
run;
```

The OUTHISTORY= option names the output data set, and the NOCHART option suppresses the display of the chart, which would be identical to the chart in Figure 17.71. Options such as OUTHISTORY= and NOCHART are specified after the slash (/) in the RCHART statement. A complete list of options is presented in the section “Syntax: RCHART Statement” on page 1757.

Figure 17.74 contains a partial listing of Diskhist.

Figure 17.74 The Summary Data Set Diskhist

Summary Data Set for Disk Times				
Lot	TimeX	Time R	Time N	
1	8.00833	0.16	6	
2	8.02167	0.09	6	
3	7.97833	0.07	6	
4	8.00667	0.10	6	
5	8.01833	0.16	6	

There are four variables in the data set Diskhist.

- Lot contains the subgroup index.
- TimeX contains the subgroup means.
- TimeR contains the subgroup ranges.
- TimeN contains the subgroup sample sizes.

The subgroup mean variable is included in the OUTHISTORY= data set even though it is not required by the RCHART statement. This enables the data set to be used as a HISTORY= data set

with the BOXCHART, XCHART, and XRCHART statements, as well as with the RCHART statement. Note that the summary statistic variables are named by adding the suffix characters *X*, *R*, and *N* to the *process* Time specified in the RCHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as that for HISTORY= data sets.

For more information, see “OUTHISTORY= Data Set” on page 1770.

Saving Control Limits

You can save the control limits for an *R* chart in a SAS data set; this enables you to apply the control limits to future data (see “Reading Preestablished Control Limits” on page 1755) or modify the limits with a DATA step program. *See SHWRCHR in the SAS/QC Sample Library*

The following statements read measurements from the data set Disks (see “Creating Range Charts from Raw Data” on page 1746) and save the control limits displayed in Figure 17.71 in a data set named Disklim:

```
title 'Control Limits for Disk Times';
proc shewhart data=Disks;
    rchart Time*Lot / outlimits = Disklim
                    nochart;
run;
```

The OUTLIMITS= option names the data set containing the control limits, and the NOCHART option suppresses the display of the chart. The data set Disklim is listed in Figure 17.75.

Figure 17.75 The Data Set Disklim Containing Control Limit Information

Control Limits for Disk Times						
VAR	_SUBGRP_	_TYPE_	_LIMITN_	_ALPHA_	_SIGMAS_	
Time	Lot	ESTIMATE	6	.004447667	3	
LCLX	_MEAN_	_UCLX_	_LCLR_	_R_	_UCLR_	_STDDEV_
7.94314	8.00307	8.06299	0	0.124	0.24847	0.048927

The data set Disklim contains one observation with the limits for *process* Time. The variables LCLR and UCLR contain the lower and upper control limits, and the variable R contains the central line. The value of MEAN is an estimate of the process mean, and the value of STDDEV is an estimate of the process standard deviation σ . The value of LIMITN is the nominal sample size associated with the control limits, and the value of SIGMAS is the multiple of σ associated with the control limits. The variables VAR and SUBGRP are bookkeeping variables that save the *process* and *subgroup-variable*. The variable TYPE is a bookkeeping variable that indicates whether the values of MEAN and STDDEV are estimates or standard values. The variables LCLX and UCLX, which contain the lower and upper control limits for subgroup means, are included so that the data set Disklim can be used to create an \bar{X} chart (see “XRCHART Statement: SHEWHART Procedure” on page 1902). For more information, see “OUTLIMITS= Data Set” on page 1768.

You can create an output data set containing both control limits and summary statistics with the `OUTTABLE=` option, as illustrated by the following statements:

```

title 'Summary Statistics and Control Limit Information';
proc shewhart data=Disks;
  rchart Time*Lot / outtable=Disktab
                    nochart;
run;

```

The data set `Disktab` is listed in [Figure 17.76](#).

Figure 17.76 The Data Set `Disktab`

Summary Statistics and Control Limit Information										
		S	L						S	
		I	I						T	E

Time	15	3	6	6	0	0.13	0.124	0.24847	0.048927	
Time	16	3	6	6	0	0.09	0.124	0.24847	0.048927	
Time	17	3	6	6	0	0.11	0.124	0.24847	0.048927	
Time	18	3	6	6	0	0.20	0.124	0.24847	0.048927	
Time	19	3	6	6	0	0.18	0.124	0.24847	0.048927	
Time	20	3	6	6	0	0.10	0.124	0.24847	0.048927	
Time	21	3	6	6	0	0.14	0.124	0.24847	0.048927	
Time	22	3	6	6	0	0.20	0.124	0.24847	0.048927	
Time	23	3	6	6	0	0.11	0.124	0.24847	0.048927	
Time	24	3	6	6	0	0.06	0.124	0.24847	0.048927	
Time	25	3	6	6	0	0.15	0.124	0.24847	0.048927	

This data set contains one observation for each subgroup sample. The variables `_SUBR_` and `_SUBN_` contain the subgroup ranges and subgroup sample sizes. The variables `_LCLR_` and `_UCLR_` contain the lower and upper control limits, and the variable `_R_` contains the central line. The variables `_VAR_` and `Batch` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “[OUTTABLE= Data Set](#)” on page 1771. An `OUTTABLE=` data set can be read later as a `TABLE=` data set. For example, the following statements read `Disktab` and display an *R* chart (not shown here) identical to the chart in [Figure 17.71](#):

```
title 'Range Chart for Disk Drive Test Times';
proc shewhart table=Disktab;
  rchart Time*Lot;
run;
```

Because the `SHEWHART` procedure simply displays the information in a `TABLE=` data set, you can use `TABLE=` data sets to create specialized control charts (see “[Specialized Control Charts: SHEWHART Procedure](#)” on page 2171). For more information, see “[TABLE= Data Set](#)” on page 1775.

Reading Prestablished Control Limits

In the previous example, the `OUTLIMITS=` data set `Disklim` saved control limits computed from the measurements in `Disks`. This example shows how these limits can be applied to new data provided in the following data set: *See SHWRCHR in the SAS/QC Sample Library*

```
data Disks2;
  input Lot @;
  do i=1 to 6;
    input Time @;
    output;
  end;
  drop i;
  datalines;
26 7.93 7.97 7.89 7.81 7.88 7.92
27 7.86 7.91 7.87 7.89 7.83 7.87
28 7.93 7.95 7.90 7.89 7.88 7.90
29 7.97 8.00 7.86 7.89 7.84 7.78
30 7.91 7.93 7.98 7.93 7.83 7.88
31 7.85 7.94 7.88 7.98 7.96 7.84
32 7.86 8.01 7.88 7.95 7.90 7.89
33 7.87 7.93 7.96 7.89 7.81 8.00
34 7.87 7.97 7.95 7.89 7.92 7.84
35 7.92 7.97 7.90 7.88 7.89 7.86
36 7.96 7.90 7.90 7.84 7.90 8.00
37 7.92 7.90 7.98 7.92 7.94 7.94
38 7.88 7.99 8.02 7.98 7.88 7.92
39 7.89 7.91 7.92 7.90 7.94 7.94
40 7.84 7.88 7.91 7.98 7.87 7.93
41 7.91 7.87 7.96 7.91 7.89 7.92
42 7.96 7.93 7.86 7.93 7.86 7.94
43 7.84 7.82 7.87 7.91 7.91 8.01
44 7.93 7.91 7.92 7.88 7.91 7.86
45 7.95 7.92 7.93 7.90 7.86 8.00
;
```

The following statements create an *R* chart using the control limits in `Disklim`:

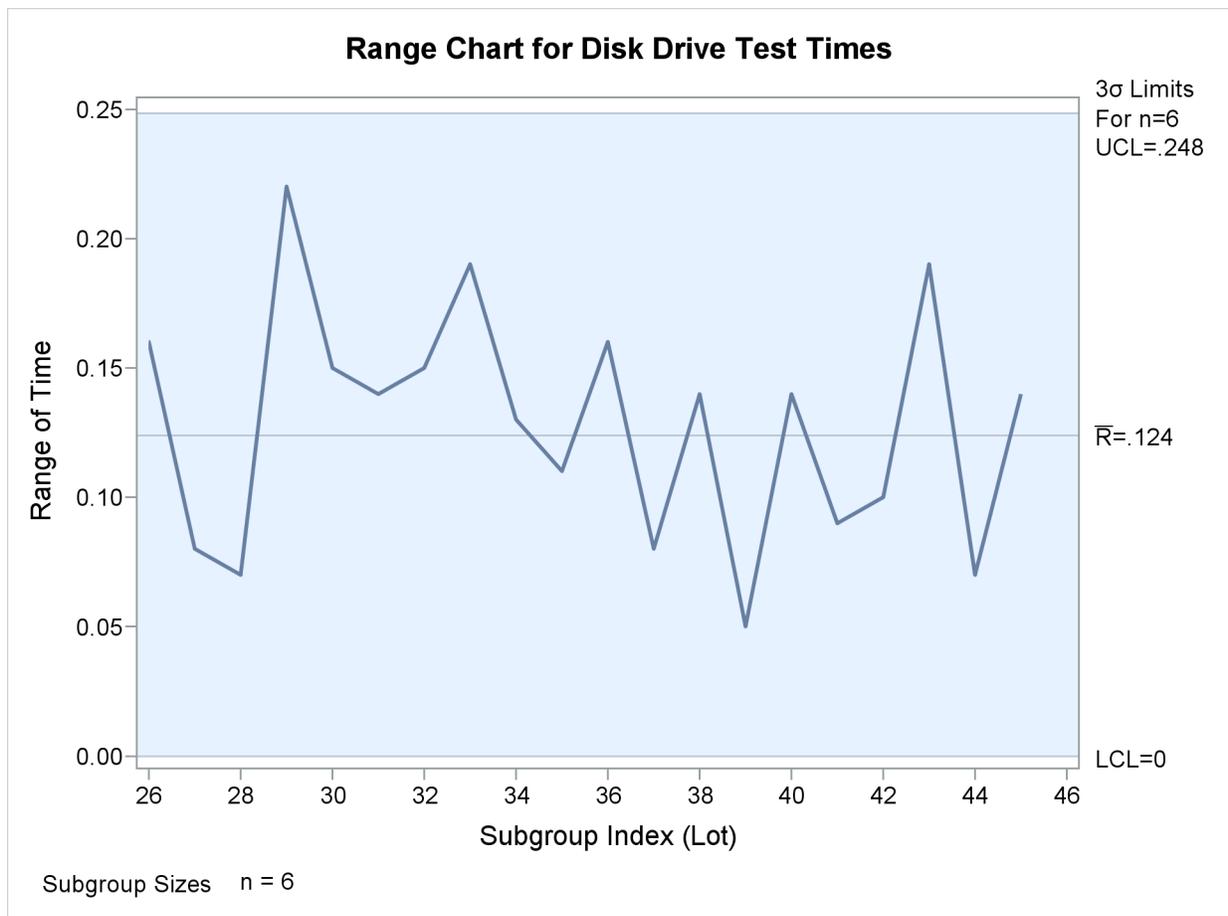

```
ods graphics on;
title 'Range Chart for Disk Drive Test Times';
proc shewhart data=Disks2 limits=Disklim;
  rchart Time*Lot / odstitle=title;
run;
```

The ODS GRAPHICS ON statement specified before the PROC SHEWHART statement enables ODS Graphics, so the *R* chart is created using ODS Graphics instead of traditional graphics. The chart is shown in Figure 17.77.

The LIMITS= option in the PROC SHEWHART statement specifies the data set containing the control limits. By default,²⁵ this information is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches the *process* name Time
- the value of `_SUBGRP_` matches the *subgroup-variable* name Lot

Figure 17.77 *R* Chart for Second Set of Disk Drive Test Times (ODS Graphics)

²⁵In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

All the ranges lie within the control limits, indicating that the variability in disk drive performance is still in statistical control.

In this example, the LIMITS= data set was created in a previous run of the SHEWHART procedure. You can also create a LIMITS= data set with the DATA step. See [Example 17.28](#) and “LIMITS= Data Set” on page 1773 for details concerning the variables that you must provide.

Syntax: RCHART Statement

The basic syntax for the RCHART statement is as follows:

```
RCHART process * subgroup-variable ;
```

The general form of this syntax is as follows:

```
RCHART processes * subgroup-variable <(block-variables)>  
    <=symbol-variable | ='character'> / <options> ;
```

You can use any number of RCHART statements in the SHEWHART procedure. The components of the RCHART statement are described as follows.

process

processes

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC SHEWHART statement.

- If raw data are read from a DATA= data set, *process* must be the name of the variable containing the raw measurements. For an example, see “[Creating Range Charts from Raw Data](#)” on page 1746.
- If summary data are read from a HISTORY= data set, *process* must be the common prefix of the summary variables in the HISTORY= data set. For an example, see “[Creating Range Charts from Summary Data](#)” on page 1748.
- If summary data and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “[Saving Control Limits](#)” on page 1753.

A *process* is required. If you specify more than one *process*, enclose the list in parentheses. For example, the following statements request distinct *R* charts for Weight, Length, and Width:

```
proc shewhart data=Measures;  
    rchart (Weight Length Width)*Day;  
run;
```

subgroup-variable

is the variable that identifies subgroups in the data. The *subgroup-variable* is required. In the preceding RCHART statement, Day is the subgroup variable. For details, see “[Subgroup Variables](#)” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or character used to plot the ranges.

- If you produce a line printer chart, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOL*n* statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create an *R* chart using an asterisk (*) to plot the points:

```
proc shewhart data=Values lineprinter;
  rchart Weight*Day='*';
run;
```

options

enhance the appearance of the chart, request additional analyses, save results in data sets, and so on. The section “[Summary of Options](#)”, which follows, lists all options by function. “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018 describes each option in detail.

Summary of Options

The following tables list the RCHART statement options by function. For complete descriptions, see “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 17.47 RCHART Statement Options

Option	Description
Options for Specifying Control Limits	
ALPHA=	requests probability limits for chart
LIMITN=	specifies either nominal sample size for fixed control limits or varying limits
NOREADLIMITS	computes control limits for each <i>process</i> from the data rather than a LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from a LIMITS= data set

Table 17.47 continued

Option	Description
READINDEX=	reads control limits for each <i>process</i> from a LIMITS= data set
READLIMITS	reads single set of control limits for each <i>process</i> from a LIMITS= data set (SAS 6.09 and earlier releases)
SIGMAS=	specifies width of control limits in terms of multiple <i>k</i> of standard error of plotted means
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line
NOCTL	suppresses display of central line
NOLCL	suppresses display of lower control limit
NOLIMITO	suppresses display of zero lower control limit on <i>R</i> chart
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit
RSYMBOL=	specifies label for central line on <i>R</i> chart
UCLLABEL=	specifies label for upper control limit
WLIMITS=	specifies width for control limits and central line
Process Mean and Standard Deviation Options	
SIGMA0=	specifies known value σ_0 for process standard deviation σ
SMETHOD=	specifies method for estimating process standard deviation σ
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
Options for Plotting and Labeling Points	
ALLLABEL2=	labels every point on <i>R</i> chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line

Table 17.47 continued

Option	Description
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
OUTLABEL2=	labels points outside control limits on <i>R</i> chart
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles
Options for Specifying Tests for Special Causes	
INDEPENDENTZONES	computes zone widths independently above and below center line
NO3SIGMACHECK	enables tests to be applied with control limits other than 3σ limits
NOTESTACROSS	suppresses tests across <i>phase</i> boundaries
TESTS2=	specifies tests for special causes for the <i>R</i> chart
TEST2RESET=	enables tests for special causes to be reset for the <i>R</i> chart
TEST2RUN=	specifies length of pattern for Test 2
TEST3RUN=	specifies length of pattern for Test 3
TESTACROSS	applies tests across <i>phase</i> boundaries
TESTLABEL=	provides labels for points where test is positive
TESTLABEL n =	specifies label for n th test for special causes
TESTNMETHOD=	applies tests to standardized chart statistics
TESTOVERLAP	performs tests on overlapping patterns of points
TESTRESET=	enables tests for special causes to be reset
ZONE2LABELS	adds labels A, B, and C to zone lines for <i>R</i> chart
ZONES2	adds lines to <i>R</i> chart delineating zones A, B, and C
ZONEVALPOS=	specifies position of ZONEVALUES labels
ZONE2VALUES	labels <i>R</i> zone lines with their values

Table 17.47 *continued*

Option	Description
Options for Displaying Tests for Special Causes	
CTESTLABBOX=	specifies color for boxes enclosing labels indicating points where test is positive
CTESTS=	specifies color for labels indicating points where test is positive
CTESTSYMBOL=	specifies color for symbol used to plot points where test is positive
CZONES=	specifies color for lines and labels delineating zones A, B, and C
LTESTS=	specifies type of line connecting points where test is positive
LZONES=	specifies line type for lines delineating zones A, B, and C
TESTFONT=	specifies software font for labels at points where test is positive
TESTHEIGHT=	specifies height of labels at points where test is positive
TESTLABBOX	requests that labels for points where test is positive be positioned so that do not overlap
TESTSYMBOL=	specifies plot symbol for points where test is positive
TESTSYMBOLHT=	specifies symbol height for points where test is positive
WTESTS=	specifies width of line connecting points where test is positive
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOTRUNC	suppresses vertical axis truncation at zero applied by default to <i>R</i> chart
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPHLABELS=	specifies thinning factor for tick mark labels on horizontal axis
SPLIT=	specifies splitting character for axis labels

Table 17.47 *continued*

Option	Description
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis
VFORMAT=	specifies format for vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
ZEROSTD	displays R chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= options
CVREF=	specifies color for lines requested by VREF= options
HREF=	specifies position of reference lines perpendicular to horizontal axis
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis
HREFLABELS=	specifies labels for HREF= lines
HREFLABPOS=	specifies position of HREFLABELS= labels
LHREF=	specifies line type for HREF= lines
LVREF=	specifies line type for VREF= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups

Table 17.47 *continued*

Option	Description
VREF=	specifies position of reference lines perpendicular to vertical axis
VREFLABELS=	specifies labels for VREF= lines
VREFLABPOS=	position of VREFLABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to chart
DESCRIPTION=	specifies description of R chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of R chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors

Table 17.47 *continued*

Option	Description
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits

Table 17.47 continued

Option	Description
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLELEGEND	augments basic table with legend for tests for special causes
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
TABLETESTS	augments basic table with a column indicating which tests for special causes are positive
Specification Limit Options	
CIINDICES	specifies α value and type for computing capability index confidence limits
LSL=	specifies list of lower specification limits
TARGET=	specifies list of target values
USL=	specifies list of upper specification limits
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set

Table 17.47 *continued*

Option	Description
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for overlay line segments
COVERLAY=	specifies colors for overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on chart
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with overlay points
OVERLAYID=	specifies labels for overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for overlays
OVERLAYSYMHT=	specifies symbol heights for overlays
WOVERLAY=	specifies widths of overlay line segments
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data

Table 17.47 continued

Option	Description
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= and HREF2= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
TESTCHAR=	specifies character for line segments that connect any sequence of points for which a test for special causes is positive
VREFCHAR=	specifies line character for VREF= and VREF2= lines
ZONECHAR=	specifies character for lines that delineate zones for tests for special causes

Details: RCHART Statement

Constructing Range Charts

The following notation is used in this section:

σ	process standard deviation (standard deviation of the population of measurements)
R_i	range of measurements in i th subgroup
n_i	sample size of i th subgroup
$d_2(n)$	expected value of the range of n independent normally distributed variables with unit standard deviation
$d_3(n)$	standard error of the range of n independent observations from a normal population with unit standard deviation
$D_p(n)$	100 p th percentile of the distribution of the range of n independent observations from a normal population with unit standard deviation

Plotted Points

Each point on an R chart indicates the value of a subgroup range (R_i). For example, if the tenth subgroup contains the values 12, 15, 19, 16, and 14, the value plotted for this subgroup is $R_{10} = 19 - 12 = 7$.

Central Line

By default, the central line for the i th subgroup indicates an estimate of the expected value of R_i , which is computed as $d_2(n_i)\hat{\sigma}$, where $\hat{\sigma}$ is an estimate of σ . If you specify a known value (σ_0) for σ , the central line indicates the value of $d_2(n_i)\sigma_0$. Note that the central line varies with n_i .

Control Limits

You can compute the limits in the following ways:

- as a specified multiple (k) of the standard error of R_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that R_i exceeds the limits

The following table provides the formulas for the limits:

Table 17.48 Limits for R Charts

Control Limits
LCL = lower limit = $\max(d_2(n_i)\hat{\sigma} - kd_3(n_i)\hat{\sigma}, 0)$
UCL = upper limit = $d_2(n_i)\hat{\sigma} + kd_3(n_i)\hat{\sigma}$

Probability Limits
LCL = lower limit = $D_{\alpha/2}\hat{\sigma}$
UCL = upper limit = $D_{1-\alpha/2}\hat{\sigma}$

The formulas assume that the data are normally distributed. Note that the control limits vary with n_i and that the probability limits for R_i are asymmetric around the central line. If a standard value σ_0 is available for σ , replace $\hat{\sigma}$ with σ_0 in Table 17.48.

You can specify parameters for the limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify σ_0 with the SIGMA0= option or with the variable `_STDDEV_` in a LIMITS= data set.

Output Data Sets**OUTLIMITS= Data Set**

The OUTLIMITS= data set saves control limits and control limit parameters. The following variables are saved:

Table 17.49 OUTLIMITS= Data Set

Variable	Description
ALPHA	probability (α) of exceeding limits
CP	capability index C_p
CPK	capability index C_{pk}
CPL	capability index C_{PL}
CPM	capability index C_{pm}
CPU	capability index C_{PU}
INDEX	optional identifier for the control limits with the OUTINDEX= option
LCLR	lower control limit for subgroup range
LCLX	lower control limit for subgroup mean
LIMITN	sample size associated with the control limits
LSL	lower specification limit
MEAN	process mean (\bar{X})
R	value of central line on R chart
SIGMAS	multiple (k) of standard error of R_i
STDDEV	process standard deviation ($\hat{\sigma}$ or σ_0)
SUBGRP	<i>subgroup-variable</i> specified in the RCHART statement
TARGET	target value
TYPE	type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLR	upper control limit for subgroup range
UCLX	upper control limit for subgroup mean
USL	upper specification limit
VAR	<i>process</i> specified in the RCHART statement

Notes:

1. The variables _LCLX_, _MEAN_, and _UCLX_ are saved to enable the OUTLIMITS= data set to be used as a LIMITS= data set with the BOXCHART, XCHART, and XRCHART statements.
2. If the control limits vary with subgroup sample size, the special missing value V is assigned to the variables _LIMITN_, _LCLX_, _UCLX_, _LCLR_, _R_, and _UCLR_.
3. If the limits are defined in terms of a multiple k of the standard error of R_i , the value of _ALPHA_ is computed as

$$F_R(\text{_LCLR_}/\text{_STDDEV_}) + 1 - F_R(\text{_UCLR_}/\text{_STDDEV_})$$

where $F_R(\cdot)$ is the cumulative distribution function of the range of a sample of n observations from a normal population with unit standard deviation, and n is the value of _LIMITN_. If _LIMITN_ has the special missing value V , this value is assigned to _ALPHA_.

4. If the limits are probability limits, the value of _SIGMAS_ is computed as $(\text{_UCLR_} - \text{_R_})/e$, where e is the standard error of the range of n observations from a normal population with unit standard deviation. If _LIMITN_ has the special missing value V , this value is assigned to _SIGMAS_.

5. The variables `_CP_`, `_CPK_`, `_CPL_`, `_CPU_`, `_LSL_`, and `_USL_` are included only if you provide specification limits with the `LSL=` and `USL=` options. The variables `_CPM_` and `_TARGET_` are included if, in addition, you provide a target value with the `TARGET=` option. See “[Capability Indices](#)” on page 1941 for computational details.
6. Optional BY variables are saved in the `OUTLIMITS=` data set.

The `OUTLIMITS=` data set contains one observation for each *process* specified in the `RCHART` statement. For an example, see “[Saving Control Limits](#)” on page 1753.

OUTHISTORY= Data Set

The `OUTHISTORY=` data set saves subgroup summary statistics. The following variables are saved:

- the *subgroup-variable*
- a subgroup mean variable named by *process* suffixed with *X*
- a subgroup range variable named by *process* suffixed with *R*
- a subgroup sample size variable named by *process* suffixed with *N*

The subgroup mean variable is saved so that the data set can be reused as a `HISTORY=` data set with the `BOXCHART`, `XCHART`, and `XRCHART` statements, as well as the `RCHART` statement.

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Subgroup summary variables are created for each *process* specified in the `RCHART` statement. For example, consider the following statements:

```
proc shewhart data=Steel;
    rchart (Width Diameter)*Lot / outhistory=Summary;
run;
```

The data set `Summary` contains variables named `Lot`, `WidthX`, `WidthR`, `WidthN`, `DiameterX`, `DiameterR`, and `DiameterN`. Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the `OUTPHASE=` option is specified)

For an example of an `OUTHISTORY=` data set, see “[Saving Summary Statistics](#)” on page 1752.

OUTTABLE= Data Set

The OUTTABLE= data set saves subgroup summary statistics, control limits, and related information. The following variables are saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_EXLIM_</code>	control limit exceeded on <i>R</i> chart
<code>_LCLR_</code>	lower control limit for range
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_R_</code>	average range
<code>_SIGMAS_</code>	multiple (k) of the standard error associated with control limits
<code>subgroup</code>	values of the subgroup variable
<code>_SUBN_</code>	subgroup sample sizes
<code>_SUBR_</code>	subgroup range
<code>_TESTS2_</code>	tests for special causes signaled on <i>R</i> chart
<code>_UCLR_</code>	upper control limit for range
<code>_VAR_</code>	<i>process</i> specified in the RCHART statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the READPHASES= option is specified)

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved, depending on how the control limits are defined (with the ALPHA= or SIGMAS= option, respectively, or with the corresponding variables in a LIMITS= data set).
2. The variable `_TESTS2_` is saved if you specify the TESTS2= option.
3. The variables `_EXLIM_` and `_TESTS2_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “Saving Control Limits” on page 1753.

ODS Tables

The following table summarizes the ODS tables that you can request with the RCHART statement.

Table 17.50 ODS Tables Produced with the RCHART Statement

Table Name	Description	Options
RCHART	<i>R</i> chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLELEG, TABLEOUT, TABLETESTS
TestDescriptions	descriptions of tests for special causes requested with the TESTS= option for which at least one positive signal is found	TABLEALL, TABLELEG

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the SHEWHART procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. RCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the RCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 17.51](#).

Table 17.51 ODS Graphics Produced by the RCHART Statement

ODS Graph Name	Plot Description
RChart	<i>R</i> chart

See Chapter 3, “[SAS/QC Graphics](#),” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (process measurements) from a DATA= data set specified in the PROC SHEWHART statement. Each *process* specified in the RCHART statement must be a SAS variable in the DATA= data set. This variable provides measurements that must be grouped in subgroup samples indexed by the *subgroup-variable*. The *subgroup-variable*, which is specified in the RCHART statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a raw measurement for each *process* and a value for the *subgroup-variable*. If the *i*th subgroup contains n_i items, there should be n_i consecutive observations for which the value of the subgroup variable is the index of the *i*th subgroup. For example, if each subgroup contains five items and there are 30 subgroup samples, the DATA= data set should contain 150 observations.

Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a DATA= data set. However, if the DATA= data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (for an example, see “[Displaying Stratification in Phases](#)” on page 2103).

For an example of a DATA= data set, see “[Creating Range Charts from Raw Data](#)” on page 1746.

LIMITS= Data Set

You can read preestablished control limits (or parameters from which the control limits can be calculated) from a LIMITS= data set specified in the PROC SHEWHART statement. For example, the following statements read control limit information from the data set `Conlims`.²⁶

```
proc shewhart data=Info limits=Conlims;
  rchart Weight*Batch;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the SHEWHART procedure. Such data sets always contain the variables required for a LIMITS= data set; see [Table 17.49](#). The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LCLR_`, `_R_`, and `_UCLR_`, which specify the control limits directly
- the variable `_STDDEV_`, which is used to calculate the control limits according to the equations in [Table 17.48](#)

²⁶In SAS 6.09 and in earlier releases, it is necessary to specify the READLIMITS option.

In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables whose lengths are no greater than 32.
- The variable `_INDEX_` is required if you specify the `READINDEX=` option; this must be a character variable whose length is no greater than 48.
- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8; valid values are 'ESTIMATE', 'STANDARD', 'STDMU', and 'STDSIGMA'.
- BY variables are required if specified with a BY statement.

For an example, see “[Reading Preestablished Control Limits](#)” on page 1755.

HISTORY= Data Set

You can read subgroup summary statistics from a `HISTORY=` data set specified in the PROC SHEWHART statement. This enables you to reuse `OUTHISTORY=` data sets that have been created in previous runs of the SHEWHART procedure or to read output data sets created with SAS summarization procedures, such as the MEANS procedure.

A `HISTORY=` data set used with the RCHART statement must contain the following:

- the *subgroup-variable*
- a subgroup range variable for each *process*
- a subgroup sample size variable for each *process*

The names of the subgroup range and subgroup sample size variables must be the prefix *process* concatenated with the special suffix characters *R* and *N*, respectively.

For example, consider the following statements:

```
proc shewhart history=Summary;
    rchart (Weight Yieldstrength) *Batch;
run;
```

The data set Summary must include the variables Batch, WeightR, WeightN, YieldstrengthR, and YieldstrengthN.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a `HISTORY=` data set include

- `_PHASE_` (if the `READPHASES=` option is specified)
- *block-variables*

- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a HISTORY= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as phases) by specifying the READPHASES= option (see “Displaying Stratification in Phases” on page 2103 for an example).

For an example of a HISTORY= data set, see “Creating Range Charts from Summary Data” on page 1748.

TABLE= Data Set

You can read summary statistics and control limits from a TABLE= data set specified in the PROC SHEWHART statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the SHEWHART procedure. Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts. Examples are provided in “Specialized Control Charts: SHEWHART Procedure” on page 2171.

The following table lists the variables required in a TABLE= data set used with the RCHART statement:

Table 17.52 Variables Required in a TABLE= Data Set

Variable	Description
<code>_LCLR_</code>	lower control limit for range
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_R_</code>	average range
<i>subgroup-variable</i>	values of the <i>subgroup-variable</i>
<code>_SUBN_</code>	subgroup sample size
<code>_SUBR_</code>	subgroup range
<code>_UCLR_</code>	upper control limit for range

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- `_PHASE_` (if the READPHASES= option is specified). This variable must be a character variable whose length is no greater than 48.
- `_TESTS2_` (if the TESTS2= option is specified). This variable is used to flag tests for special causes and must be a character variable of length 8.

- `_VAR_`. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable whose length is no greater than 32.

For an example of a TABLE= data set, see “Saving Control Limits” on page 1753.

Methods for Estimating the Standard Deviation

When control limits are determined from the input data, two methods (referred to as default and MVLUE) are available for estimating σ .

Default Method

The default estimate for σ is

$$\hat{\sigma} = \frac{R_1/d_2(n_1) + \cdots + R_N/d_2(n_N)}{N}$$

where N is the number of subgroups for which $n_i \geq 2$, and R_i is the sample range of the observations x_{i1}, \dots, x_{in_i} in the i th subgroup.

$$R_i = \max_{1 \leq j \leq n_i} (x_{ij}) - \min_{1 \leq j \leq n_i} (x_{ij})$$

A subgroup range R_i is included in the calculation only if $n_i \geq 2$. The unbiasing factor $d_2(n_i)$ is defined so that, if the observations are normally distributed, the expected value of R_i is $d_2(n_i)\sigma$. Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ . This method is described in the American Society for Testing and Materials (1976).

MVLUE Method

If you specify SMETHOD=MVLUE, a minimum variance linear unbiased estimate (MVLUE) is computed for σ . Refer to Burr (1969, 1976) and Nelson (1989, 1994). The MVLUE is a weighted average of N unbiased estimates of σ of the form $R_i/d_2(n_i)$, and it is computed as

$$\hat{\sigma} = \frac{f_1 R_1/d_2(n_1) + \cdots + f_N R_N/d_2(n_N)}{f_1 + \cdots + f_N}$$

where

$$f_i = \frac{[d_2(n_i)]^2}{[d_3(n_i)]^2}$$

A subgroup range R_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$. The unbiasing factor $d_3(n_i)$ is defined so that, if the observations are normally distributed, the expected value of σ_{R_i} is $d_3(n_i)\sigma$. The MVLUE assigns greater weight to estimates of σ from subgroups with larger sample sizes, and it is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the MVLUE reduces to the default estimate.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical	DATA=	<i>process</i>
Vertical	HISTORY=	subgroup range variable
Vertical	TABLE=	<code>_SUBR_</code>

For an example, see “Labeling Axes” on page 2136.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: RCHART Statement

This section provides advanced examples of the RCHART statement.

Example 17.27: Computing Probability Limits

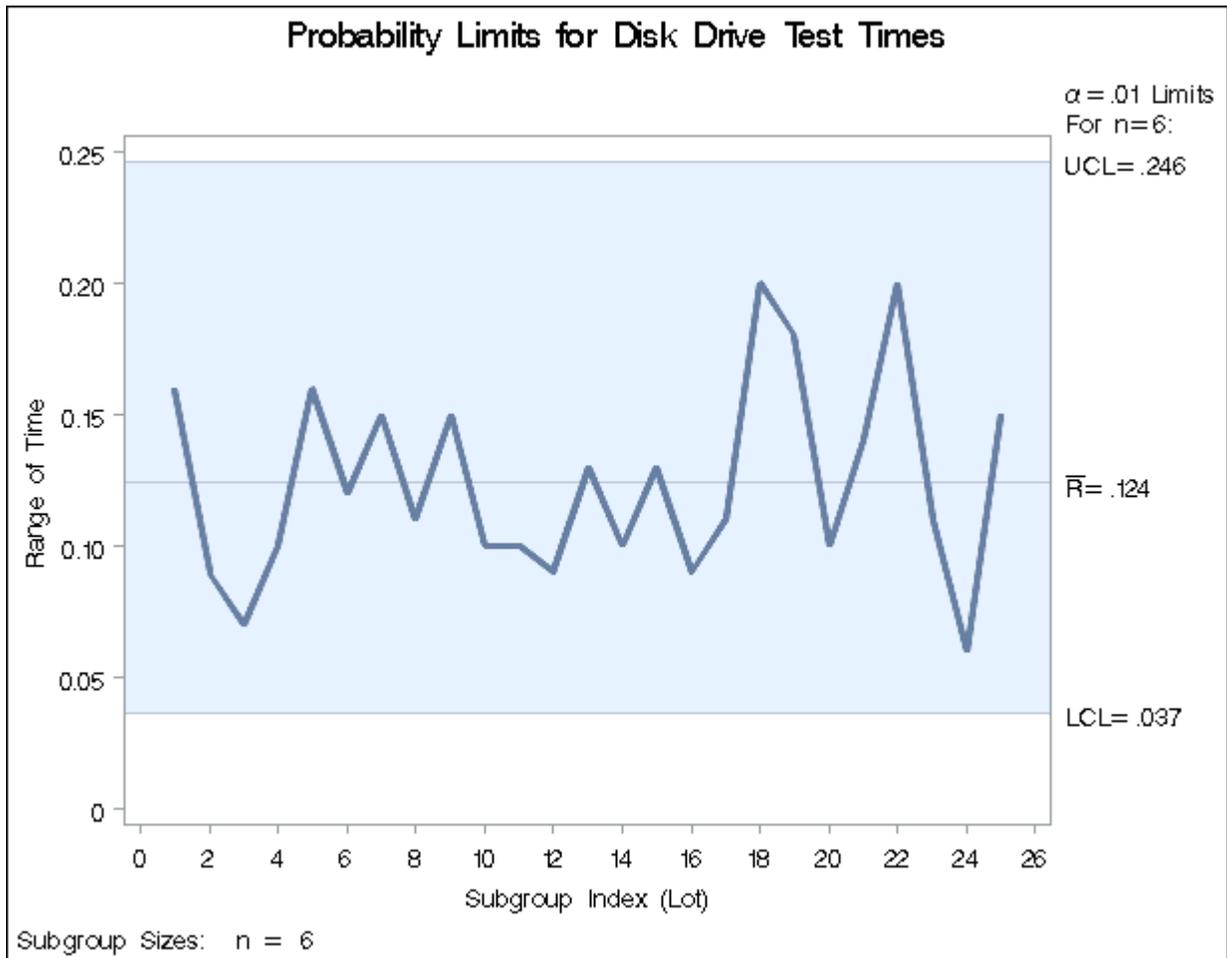

This example demonstrates how to create *R* charts with probability limits. The following statements read the disk drive test times from the data set `Disks` (see “Creating Range Charts from Raw Data” on page 1746) and create the *R* chart shown in [Output 17.27.1](#): See SHWREX1 in the SAS/QC Sample Library

```
ods graphics off;
title 'Probability Limits for Disk Drive Test Times';
proc shewhart data=Disks;
  rchart Time*Lot / alpha      = .01
                    outlimits = Dlimits;
run;
```

The ALPHA= option specifies the probability (α) that a subgroup range exceeds its limits. Here, the limits are computed so that the probability that a range is less than the lower limit is $\alpha/2 = 0.005$, and the probability that a range is greater than the upper limit is $\alpha/2 = 0.005$. This assumes that the measurements are normally distributed. The OUTLIMITS= option names an output data set that saves the probability limits. A listing of Dlimits is shown in [Output 17.27.2](#).

The variable `_ALPHA_` saves the value of α . Note that, in this case, the upper probability limit is equivalent to an upper 2.95σ limit.

Output 17.27.1 R Chart with Probability Limits

Output 17.27.2 Probability Limits Data Set

Probability Limits for Disk Drive Test Times						
<u>_VAR_</u>	<u>_SUBGRP_</u>	<u>_TYPE_</u>	<u>_LIMITN_</u>	<u>_ALPHA_</u>	<u>_SIGMAS_</u>	<u>_LCLX_</u>
Time	Lot	ESTIMATE	6	0.01	2.94688	7.95162
<u>_MEAN_</u>	<u>_UCLX_</u>	<u>_LCLR_</u>	<u>_R_</u>	<u>_UCLR_</u>	<u>_STDDEV_</u>	
8.00307	8.05452	0.036645	0.124	0.24627	0.048927	

Since all the points fall within the probability limits, it can be concluded that the variability in the disk drive performance is in statistical control.

The following statements apply the limits in Dlimits to the times in the data set DISKS2 (see “Reading Preestablished Control Limits” on page 1755):

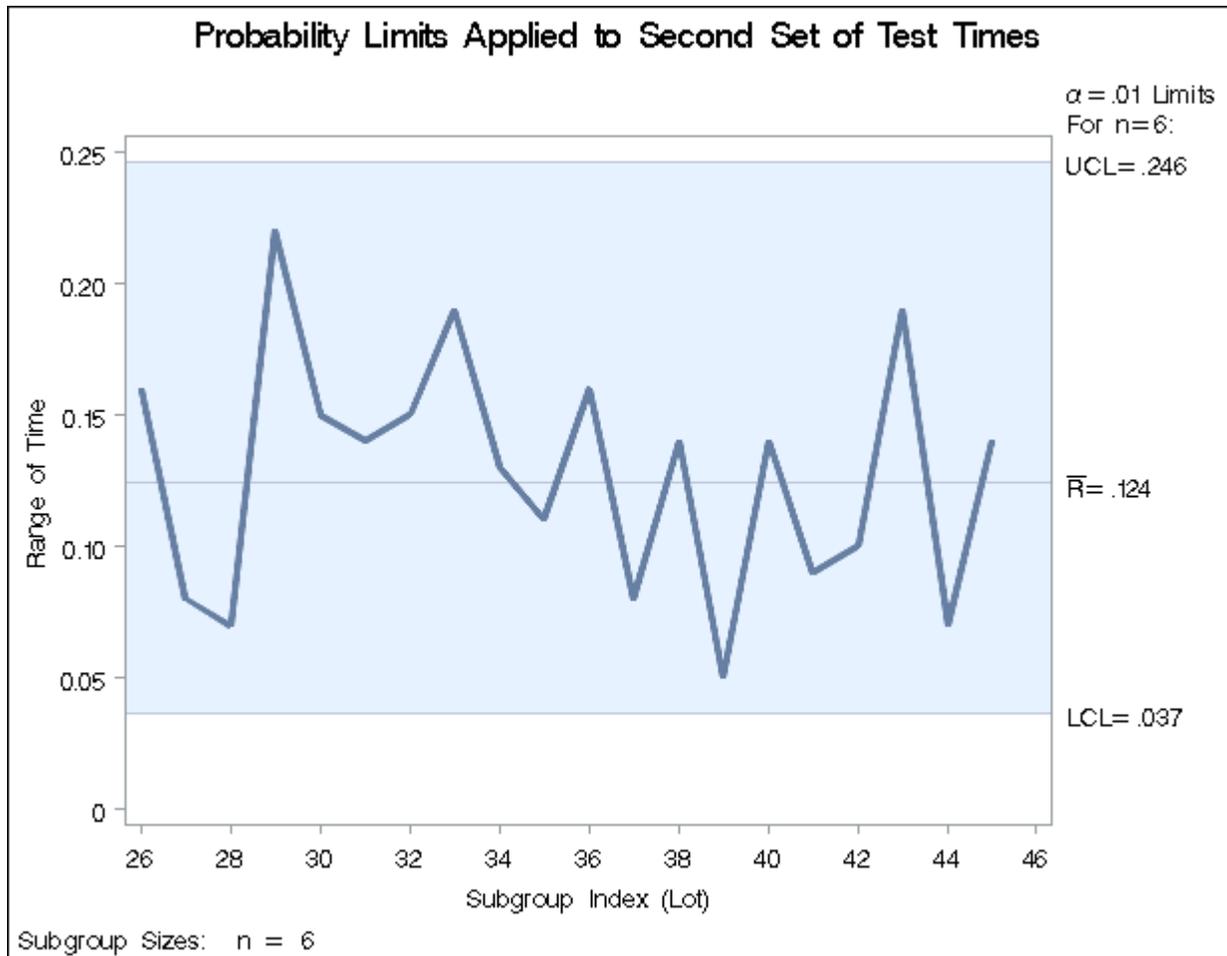

```

title 'Probability Limits Applied to Second Set of Test Times';
proc shewhart data=Disks2 limits=Dlimits;
  rchart Time*Lot / readalpha;
run;

```

The READALPHA option²⁷ specifies that the variable `_ALPHA_`, rather than the variable `_SIGMAS_`, is to be read from the `LIMITS=` data set. Thus the limits displayed in the chart, shown in Output 17.27.3, are probability limits.

Output 17.27.3 Reading Probability Limits from a `LIMITS=` Data Set

Example 17.28: Specifying Control Limit Information

This example illustrates how you can use a `DATA` step program to create a `LIMITS=` data set. You can provide previously established values for the limits and central line with the variables `_LCLR_`, `_R_`, and `_UCLR_`, as in the following statements: *See SHWREX2 in the SAS/QC Sample Library*

²⁷In SAS 6.09 and in earlier releases, it is also necessary to specify the `READLIMITS` option.

```

data Dlimits2;
  length _var_ _subgrp_ _type_ $8;
  _var_   = 'Time';
  _subgrp_ = 'Lot';
  _type_  = 'STANDARD';
  _limitn_ = 6;
  _lclr_  = .03;
  _r_     = .12;
  _uclr_  = .25;
run;

```

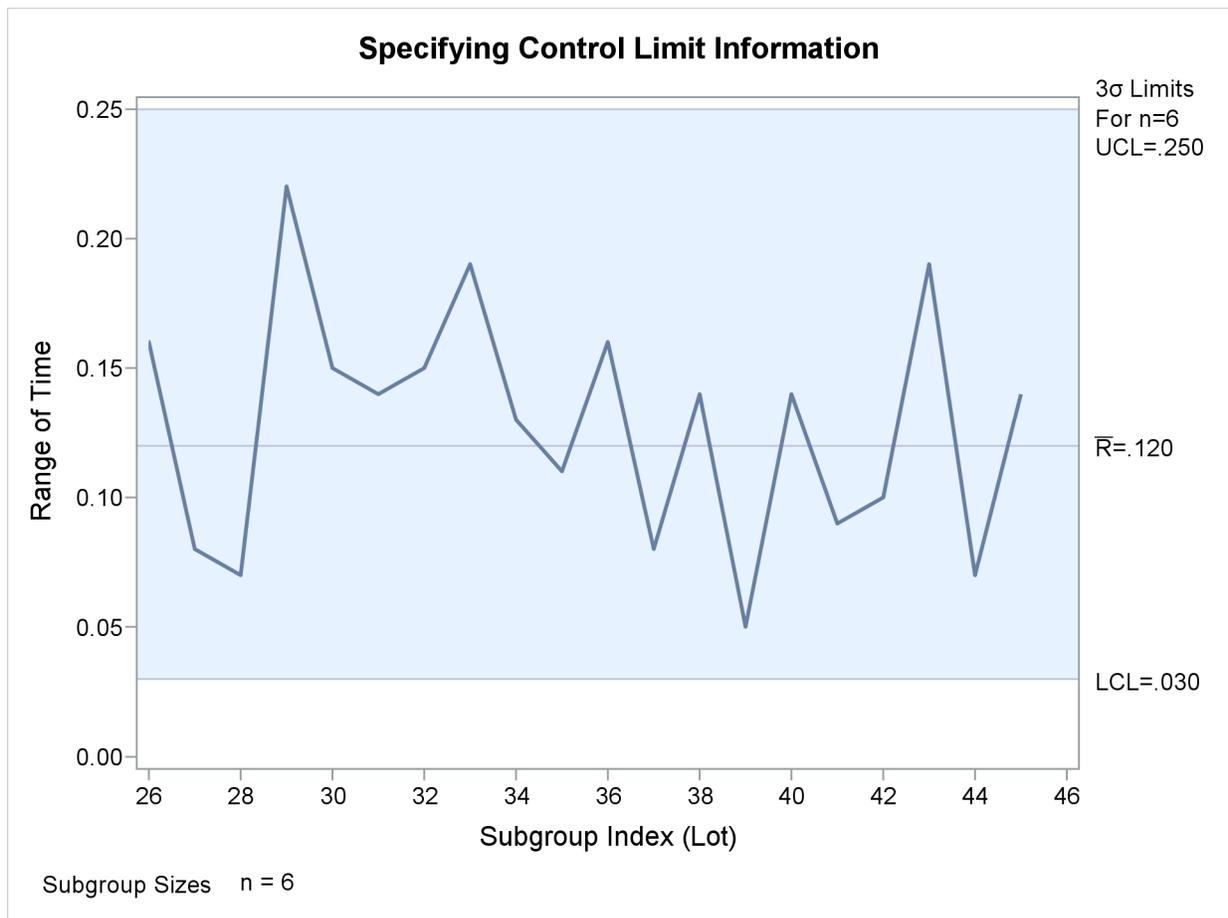

The following statements²⁸ apply the control limits in Dlimits2 to the measurements in DISKS2 (see “Reading Preestablished Control Limits” on page 1755) and create the *R* chart shown in Output 17.28.1:

```

ods graphics on;
title 'Specifying Control Limit Information';
proc shewhart data=Disks2 limits=Dlimits2;
  rchart Time*Lot / odstitle=title;
run;

```

Output 17.28.1 Reading Control Limits from Dlimits2

²⁸In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option.

In some cases, a standard value (σ_0) may be available for the process standard deviation. The following DATA step creates a data set named Dlimits3 that provides this value:

```
data Dlimits3;
  length _var_ _subgrp_ _type_ $8;
  _var_   = 'Time';
  _subgrp_ = 'Lot';
  _stddev_ = .045;
  _limitn_ = 6;
  _type_   = 'STDSIGMA';
run;
```

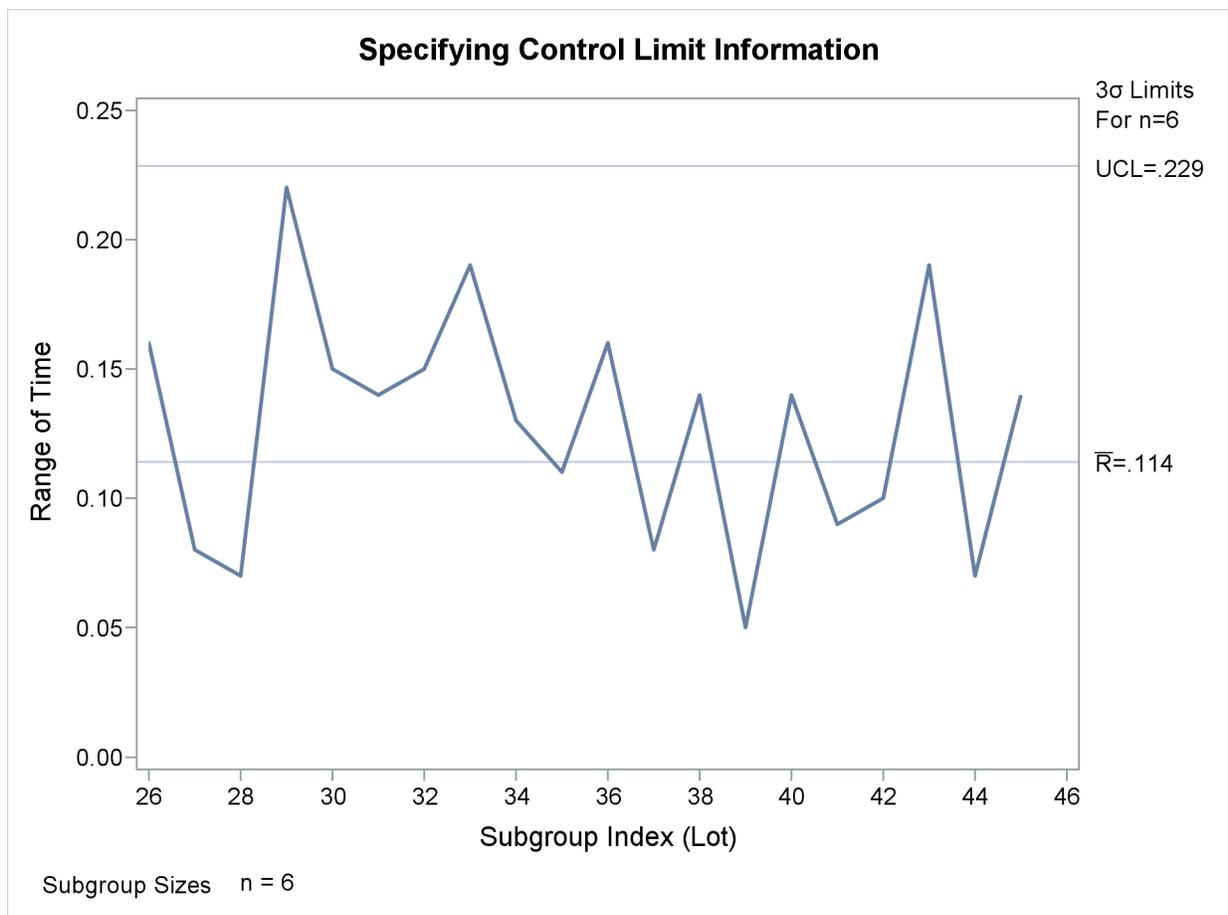

The variable `_TYPE_` is a bookkeeping variable whose value indicates that the value of `_STDDEV_` is a standard value rather than an estimate.

The following statements read the value of σ_0 from Dlimits3 and create the *R* chart shown in Output 17.28.2:

```
title 'Specifying Control Limit Information';
proc shewhart data=Disks2 limits=Dlimits3;
  rchart Time*Lot / nolimit0 odstitle=title;
run;
```

The NOLIMIT0 option suppresses the display of a fixed lower control limit if the value of the limit is zero (which is the case in this example).

Output 17.28.2 Reading in Standard Value for Process Standard Deviation

Instead of specifying σ_0 with the variable `_STDDEV_` in a `LIMITS=` data set, you can use the `SIGMA0=` option in the `RCHART` statement. The following statements create an R chart identical to the chart shown in [Output 17.28.2](#):

```
proc shewhart data=Disks;
    rchart Time*Lot / sigma0=.045 nolimit0;
run;
```

For more information, see “[LIMITS= Data Set](#)” on page 1773.

SCHART Statement: SHEWHART Procedure

Overview: SCHART Statement

The `SCHART` statement creates an s chart for subgroup standard deviations, which is used to analyze the variability of a process.²⁹

You can use options in the `SCHART` statement to

- compute control limits from the data based on a multiple of the standard error of the plotted standard deviations or as probability limits
- tabulate subgroup sample sizes, subgroup standard deviations, control limits, and other information
- save control limits in an output data set
- save subgroup sample sizes, subgroup means, and subgroup standard deviations in an output data set
- read preestablished control limits from a data set
- specify a method for estimating the process standard deviation
- specify a known (standard) process standard deviation for computing control limits
- display distinct sets of control limits for data from successive time phases
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels

²⁹You can also use R charts for this purpose; see “[RCHART Statement: SHEWHART Procedure](#)” on page 1744. In general, s charts are recommended with large subgroup sample sizes ($n_i \geq 10$).

- control layout and appearance of the chart

You have three alternatives for producing *s* charts with the SCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: SCHART Statement

This section introduces the SCHART statement with simple examples that illustrate commonly used options. Complete syntax for the SCHART statement is presented in the section “Syntax: SCHART Statement” on page 1793, and advanced examples are given in the section “Examples: SCHART Statement” on page 1814.

Creating Standard Deviation Charts from Raw Data

A petroleum company uses a turbine to heat water into steam, which is then pumped into the ground to make oil less viscous and easier to extract. This heating process occurs 20 times daily, and the amount of power (in kilowatts) used to heat the water to the desired temperature is recorded. The following statements create a SAS data set named Turbine, which contains the power output measurements for 20 days. *See SHWSCHR in the SAS/QC Sample Library*

```
data Turbine;
  informat Day date7.;
  format Day date5.;
  input Day @;
  do i=1 to 10;
    input KWatts @;
    output;
  end;
  drop i;
  datalines;

;

```

A partial listing of Turbine is shown in [Figure 17.78](#).

Figure 17.78 Partial Listing of the Data Set Turbine

Kilowatt Power Output Data		
Obs	Day	KWatts
1	04JUL	3196
2	04JUL	3507
3	04JUL	4050
4	04JUL	3215
5	04JUL	3583
6	04JUL	3617
7	04JUL	3789
8	04JUL	3180
9	04JUL	3505
10	04JUL	3454
11	04JUL	3417
12	04JUL	3199
13	04JUL	3613
14	04JUL	3384
15	04JUL	3475
16	04JUL	3316
17	04JUL	3556
18	04JUL	3607
19	04JUL	3364
20	04JUL	3721
21	05JUL	3390
22	05JUL	3562
23	05JUL	3413
24	05JUL	3193
25	05JUL	3635

The data set Turbine is said to be in “strung-out” form, since each observation contains the day and power output for a single heating. The first 20 observations contain the power outputs for the first day, the second 20 observations contain the power outputs for the second day, and so on. Because the variable Day classifies the observations into rational subgroups, it is referred to as the *subgroup-variable*. The variable KWatts contains the power output measurements and is referred to as the *process variable* (or *process* for short).

You can use an *s* chart to determine whether the variability in the heating process is in control. The following statements create the *s* chart shown in [Figure 17.79](#):

```

ods graphics off;
symbol v=dot h=.8;
title 'Chart for Standard Deviations of Power Output';
proc shewhart data=Turbine;

```

```

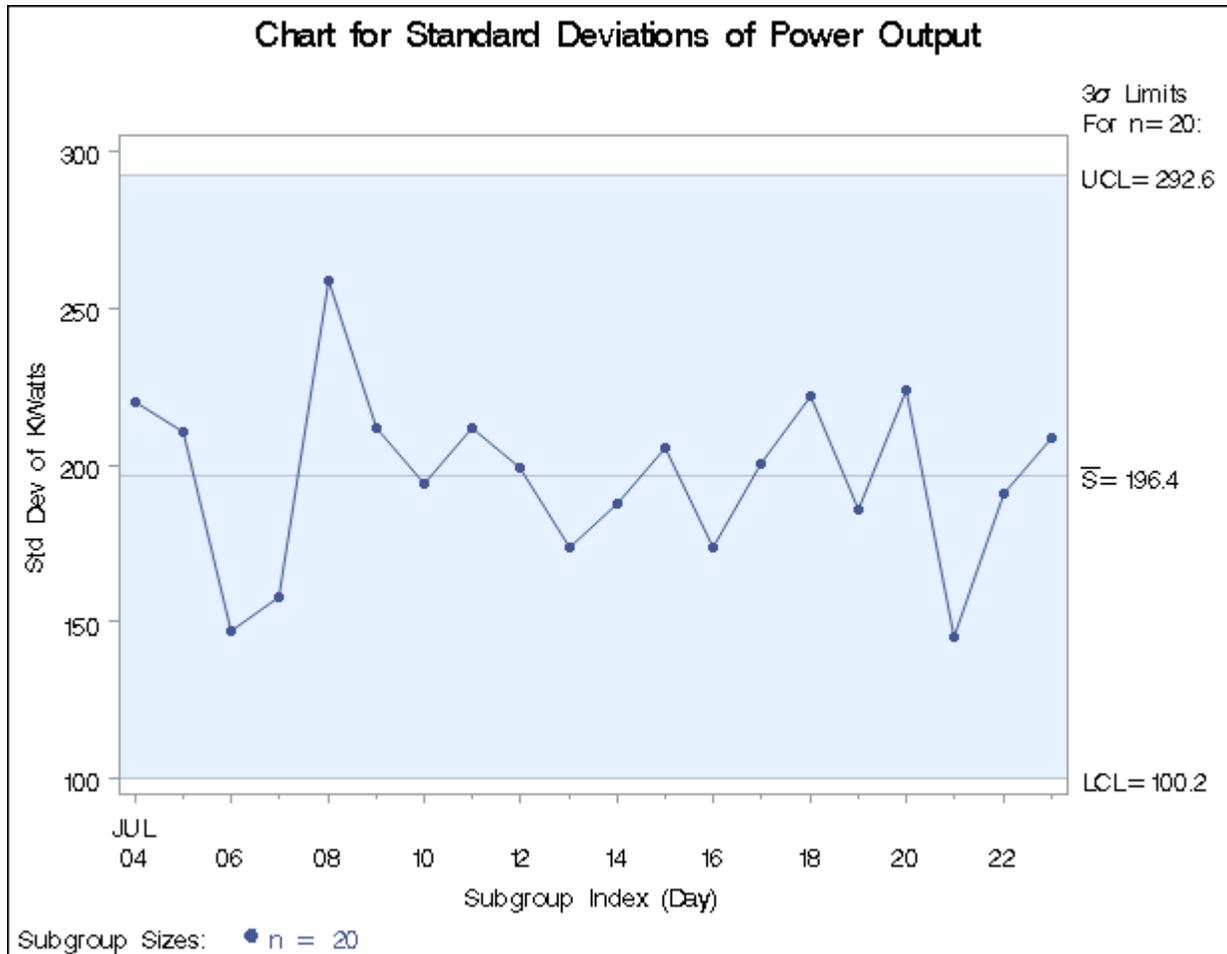

schart KWatts*Day;
run;

```

This example illustrates the basic form of the SCHAT statement. After the keyword SCHAT, you specify the *process* to analyze (in this case, KWatts), followed by an asterisk and the *subgroup-variable* (Day).

The input data set is specified with the DATA= option in the PROC SHEWHART statement.

Figure 17.79 *s* Chart for Power Output Data (Traditional Graphics)

Each point on the chart represents the standard deviation of the measurements for a particular day. For instance, the standard deviation plotted for the first day is

$$\sqrt{\frac{(3196 - 3487.4)^2 + (3507 - 3487.4)^2 + \dots + (3721 - 3487.4)^2}{19}} = 220.26$$

Since all of the subgroup standard deviations lie within the control limits, you can conclude that the variability of the process is in statistical control.

By default, the control limits shown are 3 σ limits estimated from the data; the formulas for the limits are given in Table 17.54. You can also read control limits from an input data set; see “Reading Preestablished Control Limits” on page 1792.

For computational details, see “Constructing Charts for Standard Deviations” on page 1804. For more details on reading raw data, see “DATA= Data Set” on page 1809.

Creating Standard Deviation Charts from Subgroup Summary Data

See SHWSCHR in the SAS/QC Sample Library

The previous example illustrates how you can create s charts using raw data (process measurements). However, in many applications, the data are provided as subgroup summary statistics. This example illustrates how you can use the SCHART statement with data of this type.

The following data set (Oilsum) provides the data from the preceding example in summarized form:

```
data Oilsum;
  input Day KWattsX KWattsS KWattsN;
  informat Day date7. ;
  format Day date5. ;
  label Day   ='Date of Measurement';
  datalines;
04JUL94 3487.40 220.260 20
05JUL94 3471.65 210.427 20
06JUL94 3488.30 147.025 20
07JUL94 3434.20 157.637 20
08JUL94 3475.80 258.949 20
09JUL94 3518.10 211.566 20
10JUL94 3492.65 193.779 20
11JUL94 3496.40 212.024 20
12JUL94 3398.50 199.201 20
13JUL94 3456.05 173.455 20
14JUL94 3493.60 187.465 20
15JUL94 3563.30 205.472 20
16JUL94 3519.05 173.676 20
17JUL94 3474.20 200.576 20
18JUL94 3443.60 222.084 20
19JUL94 3586.35 185.724 20
20JUL94 3486.45 223.474 20
21JUL94 3492.90 145.267 20
22JUL94 3432.80 190.994 20
23JUL94 3496.90 208.858 20
;
```

A partial listing of Oilsum is shown in [Figure 17.80](#). There is exactly one observation for each subgroup (note that the subgroups are still indexed by Day). The variable KWattsX contains the subgroup means, the variable KWattsS contains the subgroup standard deviations, and the variable KWattsN contains the subgroup sample sizes (these are all 20).

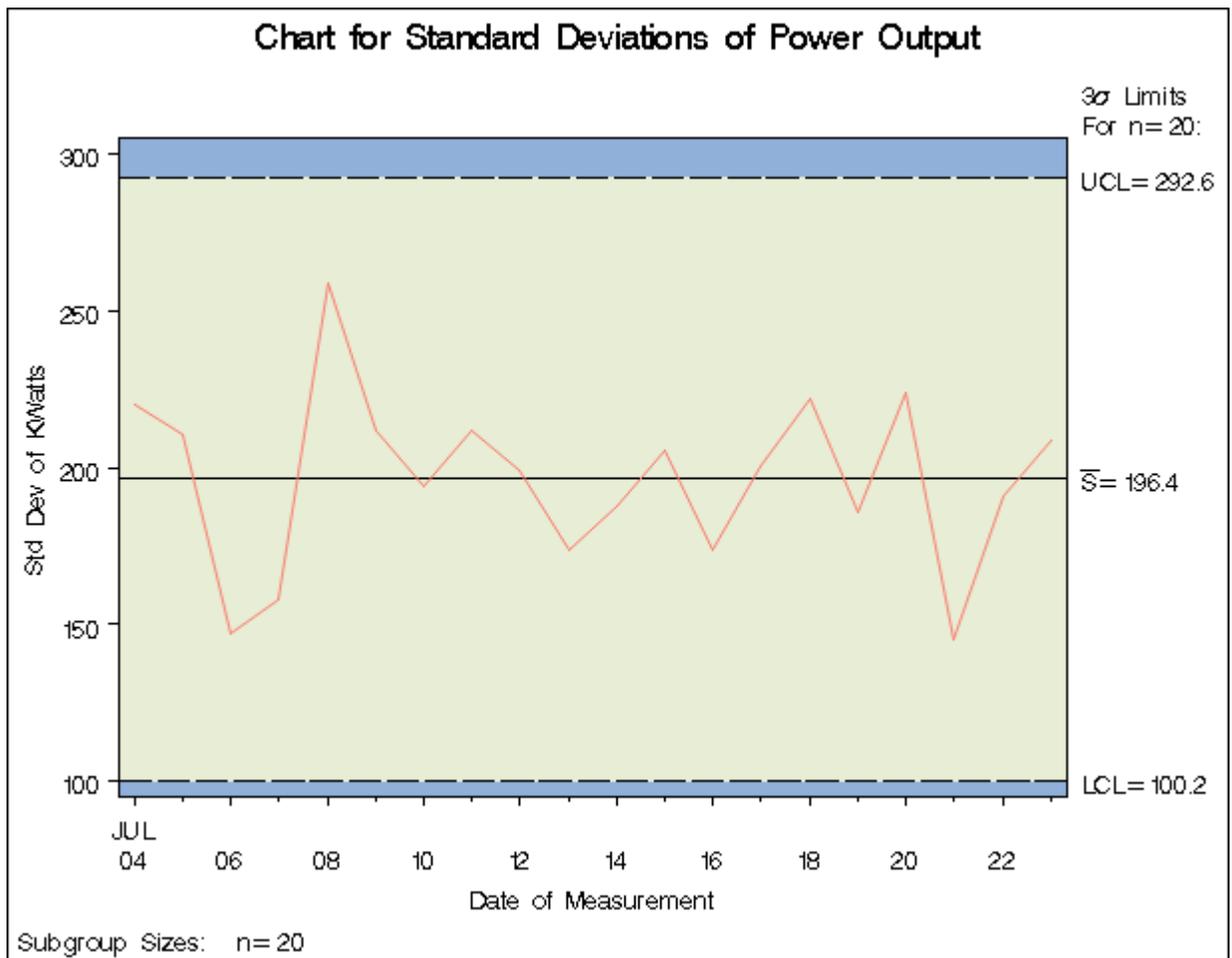

Figure 17.80 The Summary Data Set Oilsum

Summary Data Set for Power Outputs			
Day	KWattsX	KWattsS	KWatts N
04JUL	3487.40	220.260	20
05JUL	3471.65	210.427	20
06JUL	3488.30	147.025	20
07JUL	3434.20	157.637	20
08JUL	3475.80	258.949	20

You can read this data set by specifying it as a HISTORY= data set in the PROC SHEWHART statement, as follows:

```
options nogstyle;
goptions ftext=swiss;
title 'Chart for Standard Deviations of Power Output';
proc shewhart history=Oilsum;
    schart KWatts*Day / cframe = vligb
                    cinfill = ywh
                    cconnect = salmon;
run;
options gstyle;
```

The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the SChart statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently. The resulting s chart is shown in [Figure 17.81](#).

Figure 17.81 s Chart for Power Output Data (Traditional Graphics with NOGSTYLE)

Note that KWatts is *not* the name of a SAS variable in the data set Oilsum but is, instead, the common prefix for the names of the SAS variables KWattsS and KWattsN. The suffix characters *S* and *N* indicate *standard deviation* and *sample size*, respectively. Thus, you can specify two subgroup summary variables in the HISTORY= data set with a single name (KWatts), which is referred to as the *process*. The name Day, specified after the asterisk, is the name of the *subgroup-variable*.

In general, a HISTORY= input data set used with the SCHART statement must contain the following variables:

- subgroup variable
- subgroup standard deviation variable
- subgroup sample size variable

Furthermore, the names of the subgroup standard deviation and sample size variables must begin with the *process* name specified in the SCHART statement and end with the special suffix characters *S* and *N*, respectively. If the names do not follow this convention, you can use the RENAME option

in the PROC SHEWHART statement to rename the variables for the duration of the SHEWHART procedure step (see “Creating Charts for Means and Ranges from Summary Data” on page 1907).

In summary, the interpretation of *process* depends on the input data set.

- If raw data are read using the DATA= option (as in the previous example), *process* is the name of the SAS variable containing the process measurements.
- If summary data are read using the HISTORY= option (as in this example), *process* is the common prefix for the names of the variables containing the summary statistics.

For more information, see “HISTORY= Data Set” on page 1811.

Saving Summary Statistics

In this example, the SCHART statement is used to create a summary data set that can be read later by the SHEWHART procedure (as in the preceding example). The following statements read measurements from the data set Turbine and create a summary data set named Turbhist: *See SHWSCHR in the SAS/QC Sample Library*

```
proc shewhart data=Turbine;
    schart KWatts*Day / outhistory = Turbhist
                    nochart;
run;
```

The OUTHISTORY= option names the output data set, and the NOCHART option suppresses the display of the chart, which would be identical to the chart in Figure 17.79. Options such as OUTHISTORY= and NOCHART are specified after the slash (/) in the SCHART statement. A complete list of options is presented in the section “Syntax: SCHART Statement” on page 1793.

Figure 17.82 contains a partial listing of Turbhist.

Figure 17.82 The Summary Data Set Turbhist

Summary Data Set for Power Output			
Day	KWattsX	KWattsS	KWatts
			N
04JUL	3487.40	220.260	20
05JUL	3471.65	210.427	20
06JUL	3488.30	147.025	20
07JUL	3434.20	157.637	20
08JUL	3475.80	258.949	20

There are four variables in the data set Turbhist.

- Day contains the subgroup index.
- KWattsX contains the subgroup means.
- KWattsS contains the subgroup standard deviations.

- KWattsN contains the subgroup sample sizes.

The subgroup mean variable is included even though it is not required by the SCHART statement. This enables the data set to be used as a HISTORY= data set with the BOXCHART, XCHART, and XSCHART statements, as well as with the SCHART statement. Note that the summary statistic variables are named by adding the suffix characters *X*, *S*, and *N* to the *process* KWatts specified in the SCHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as that for HISTORY= data sets.

For more information, see “OUTHISTORY= Data Set” on page 1807.

Saving Control Limits

See SHWSCHR in the SAS/QC Sample Library You can save the control limits for an *s* chart in a SAS data set; this enables you to apply the control limits to future data (see “Reading Preestablished Control Limits” on page 1792) or modify the limits with a DATA step program.

The following statements read measurements from the data set Turbine (see “Creating Standard Deviation Charts from Raw Data” on page 1783) and save the control limits displayed in Figure 17.79 in a data set named Turblim:

```
proc shewhart data=Turbine;
    schart KWatts*Day / outlimits=Turblim
        nochart;
run;
```

The OUTLIMITS= option names the data set containing the control limits, and the NOCHART option suppresses the display of the chart. The data set Turblim is listed in Figure 17.83.

Figure 17.83 The Data Set Turblim Containing Control Limit Information

Control Limits for Power Output Data						
<u>_VAR_</u>	<u>_SUBGRP_</u>	<u>_TYPE_</u>	<u>_LIMITN_</u>	<u>_ALPHA_</u>	<u>_SIGMAS_</u>	<u>_LCLX_</u>
KWatts	Day	ESTIMATE	20	.002792725	3	3351.92
<u>_MEAN_</u>	<u>_UCLX_</u>	<u>_LCLS_</u>	<u>_S_</u>	<u>_UCLS_</u>	<u>_STDDEV_</u>	
3485.41	3618.90	100.207	196.396	292.584	198.996	

The data set Turblim contains one observation with the limits for *process* KWatts. The variables _LCLS_ and _UCLS_ contain the lower and upper control limits, and the variable _S_ contains the central line. The value of _MEAN_ is an estimate of the process mean, and the value of _STDDEV_ is an estimate of the process standard deviation σ . The value of _LIMITN_ is the nominal sample size associated with the control limits, and the value of _SIGMAS_ is the multiple of σ associated with the control limits. The variables _VAR_ and _SUBGRP_ are bookkeeping variables that save the *process* and *subgroup-variable*. The variable _TYPE_ is a bookkeeping variable that indicates whether the values of _MEAN_ and _STDDEV_ are estimates or standard values. The variables _LCLX_ and _UCLX_, which contain the lower and upper control limits for subgroup means, are

included so that the data set Turblim can be used to create an \bar{X} chart (see “XSCHART Statement: SHEWHART Procedure” on page 1955). For more information, see “OUTLIMITS= Data Set” on page 1805.

You can create an output data set containing both control limits and summary statistics with the OUTTABLE= option, as illustrated by the following statements:

```
proc shewhart data=Turbine;
  schart KWatts*Day / outtable=Turbtab
                    nochart;
run;
```

The data set Turbtabs is listed in Figure 17.84.

Figure 17.84 The OUTTABLE= Data Set Turbtabs

Summary Statistics and Control Limit Information										
		S	L					S

KWatts	12JUL	3	20	20	100.207	199.201	196.396	292.584	198.996	
KWatts	13JUL	3	20	20	100.207	173.455	196.396	292.584	198.996	
KWatts	14JUL	3	20	20	100.207	187.465	196.396	292.584	198.996	
KWatts	15JUL	3	20	20	100.207	205.472	196.396	292.584	198.996	
KWatts	16JUL	3	20	20	100.207	173.676	196.396	292.584	198.996	
KWatts	17JUL	3	20	20	100.207	200.576	196.396	292.584	198.996	
KWatts	18JUL	3	20	20	100.207	222.084	196.396	292.584	198.996	
KWatts	19JUL	3	20	20	100.207	185.724	196.396	292.584	198.996	
KWatts	20JUL	3	20	20	100.207	223.474	196.396	292.584	198.996	
KWatts	21JUL	3	20	20	100.207	145.267	196.396	292.584	198.996	
KWatts	22JUL	3	20	20	100.207	190.994	196.396	292.584	198.996	
KWatts	23JUL	3	20	20	100.207	208.858	196.396	292.584	198.996	

This data set contains one observation for each subgroup sample. The variables `_SUBS_` and `_SUBN_` contain the subgroup standard deviations and subgroup sample sizes. The variables `_LCLS_` and `_UCLS_` contain the lower and upper control limits, and the variable `_S_` contains the central line. The variables `_VAR_` and `Batch` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “OUTTABLE= Data Set” on page 1807.

An OUTTABLE= data set can be read later as a TABLE= data set. For example, the following statements read Turbtab and display an *s* chart (not shown here) identical to the chart in [Figure 17.79](#):

```
title 'Chart for Standard Deviations of Power Output';
symbol v=dot;
proc shewhart table=Turbtab;
    schart KWatts*Day;
run;
```

Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts (see “[Specialized Control Charts: SHEWHART Procedure](#)” on page 2171). For more information, see “[TABLE= Data Set](#)” on page 1812.

Reading Prestablished Control Limits

See SHWSCHR in the SAS/QC Sample Library

In the previous example, the OUTLIMITS= data set Turblim saved control limits computed from the measurements in Turbine. This example shows how these limits can be applied to new data.

The following statements create an *s* chart for new measurements in the data set Turbine2 (not listed here) using the control limits in Turblim:

```
ods graphics on;
title 'Chart for Standard Deviations of Power Output';
proc shewhart data=Turbine2 limits=Turblim;
    schart KWatts*Day / odstitle=title;
run;
```

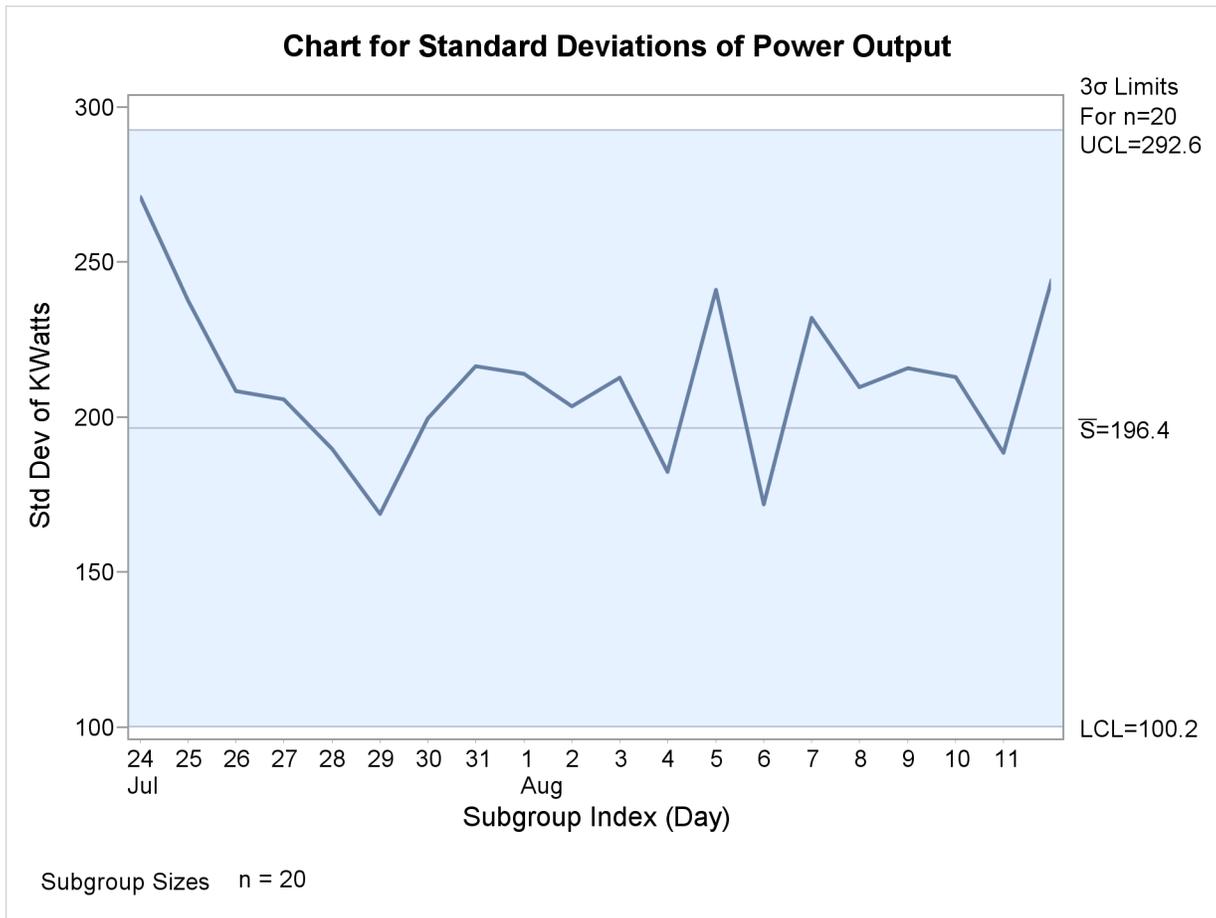

The ODS GRAPHICS ON statement specified before the PROC SHEWHART statement enables ODS Graphics, so the *s* chart is created by using ODS Graphics instead of traditional graphics. The chart is shown in [Figure 17.85](#).

The LIMITS= option in the PROC SHEWHART statement specifies the data set containing the control limits. By default,³⁰ this information is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches the *process* name KWatts
- the value of `_SUBGRP_` matches the *subgroup-variable* name Day

³⁰In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

Figure 17.85 s Chart for Second Set of Power Output Data (ODS Graphics)

All the standard deviations lie within the control limits, indicating that the variability of the heating process is still in statistical control.

In this example, the LIMITS= data set was created in a previous run of the SHEWHART procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on page 1810 for details concerning the variables that you must provide.

Syntax: SCHAT Statement

The basic syntax for the SCHAT statement is as follows:

```
SCHAT process * subgroup-variable ;
```

The general form of this syntax is as follows:

```
SCHAT processes * subgroup-variable <(block-variables)>  
      <=symbol-variable | =‘character’> / <options> ;
```

You can use any number of SCHAT statements in the SHEWHART procedure. The components of the SCHAT statement are described as follows.

process**processes**

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC SHEWHART statement.

- If raw data are read from a DATA= data set, *process* must be the name of the variable containing the raw measurements. For an example, see “[Creating Standard Deviation Charts from Raw Data](#)” on page 1783.
- If summary data are read from a HISTORY= data set, *process* must be the common prefix of the summary variables in the HISTORY= data set. For an example, see “[Creating Standard Deviation Charts from Subgroup Summary Data](#)” on page 1786.
- If summary data and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “[Saving Control Limits](#)” on page 1790.

A *process* is required. If you specify more than one *process*, enclose the list in parentheses. For example, the following statements request distinct *s* charts for Weight, Length, and Width:

```
proc shewhart data=Measures;
    schart (Weight Length Width)*Day;
run;
```

subgroup-variable

is the variable that identifies subgroups in the data. The *subgroup-variable* is required. In the preceding SCHART statement, Day is the subgroup variable. For details, see “[Subgroup Variables](#)” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or character used to plot the subgroup standard deviations.

- If you produce a line printer chart, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOL n statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create an *s* chart using an asterisk (*) to plot the points:

```
proc shewhart data=Values lineprinter;
  schart Weight*Day='*';
run;
```

options

enhance the appearance of the chart, request additional analyses, save results in data sets, and so on. The section “Summary of Options”, which follows, lists all options by function. “Dictionary of Options: SHEWHART Procedure” on page 2018 describes each option in detail.

Summary of Options

The following tables list the SCHAT statement options by function. For complete descriptions, see “Dictionary of Options: SHEWHART Procedure” on page 2018.

Table 17.53 SCHAT Statement Options

Option	Description
Options for Specifying Control Limits	
ALPHA=	requests probability limits for chart
LIMITN=	specifies either nominal sample size for fixed control limits or varying limits
NOREADLIMITS	computes control limits for each <i>process</i> from the data rather than a LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from a LIMITS= data set
READINDEX=	reads control limits for each <i>process</i> from a LIMITS= data set
READLIMITS	reads single set of control limits for each <i>process</i> from a LIMITS= data set (SAS 6.09 and earlier releases)
SIGMAS=	specifies width of control limits in terms of multiple <i>k</i> of standard error of plotted means
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line
NOCTL	suppresses display of central line
NOLCL	suppresses display of lower control limit
NOLIMITO	suppresses display of zero lower control limit on <i>s</i> chart

Table 17.53 *continued*

Option	Description
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit
SSYMBOL=	specifies label for central line on <i>s</i> chart
UCLLABEL=	specifies label for upper control limit
WLIMITS=	specifies width for control limits and central line
Process Mean and Standard Deviation Options	
SIGMA0=	specifies known value σ_0 for process standard deviation σ
SMETHOD=	specifies method for estimating process standard deviation σ
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
Options for Plotting and Labeling Points	
ALLLABEL2=	labels every point on <i>s</i> chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
OUTLABEL2=	labels points outside control limits on <i>s</i> chart
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles

Table 17.53 continued

Option	Description
Options for Specifying Tests for Special Causes	
INDEPENDENTZONES	computes zone widths independently above and below center line
NO3SIGMACHECK	enables tests to be applied with control limits other than 3σ limits
NOTESTACROSS	suppresses tests across <i>phase</i> boundaries
TESTS2=	specifies tests for special causes for the <i>s</i> chart
TEST2RESET=	enables tests for special causes to be reset for the <i>s</i> chart
TEST2RUN=	specifies length of pattern for Test 2
TEST3RUN=	specifies length of pattern for Test 3
TESTACROSS	applies tests across <i>phase</i> boundaries
TESTLABEL=	provides labels for points where test is positive
TESTLABEL _{<i>n</i>} =	specifies label for <i>n</i> th test for special causes
TESTNMETHOD=	applies tests to standardized chart statistics
TESTOVERLAP	performs tests on overlapping patterns of points
TESTRESET=	enables tests for special causes to be reset
ZONE2LABELS	adds labels A, B, and C to zone lines for <i>s</i> chart
ZONES2	adds lines to <i>s</i> chart delineating zones A, B, and C
ZONEVALPOS=	specifies position of ZONEVALUES labels
ZONE2VALUES	labels <i>s</i> zone lines with their values
Options for Displaying Tests for Special Causes	
CTESTLABBOX=	specifies color for boxes enclosing labels indicating points where test is positive
CTESTS=	specifies color for labels indicating points where test is positive
CTESTSYMBOL=	specifies color for symbol used to plot points where test is positive
CZONES=	specifies color for lines and labels delineating zones A, B, and C
LTESTS=	specifies type of line connecting points where test is positive
LZONES=	specifies line type for lines delineating zones A, B, and C
TESTFONT=	specifies software font for labels at points where test is positive
TESTHEIGHT=	specifies height of labels at points where test is positive
TESTLABBOX	requests that labels for points where test is positive be positioned so that do not overlap
TESTSYMBOL=	specifies plot symbol for points where test is positive
TESTSYMBOLHT=	specifies symbol height for points where test is positive
WTESTS=	specifies width of line connecting points where test is positive
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area

Table 17.53 *continued*

Option	Description
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOTRUNC	suppresses vertical axis truncation at zero applied by default to <i>s</i> chart
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPLABELS=	specifies thinning factor for tick mark labels on horizontal axis
SPLIT=	specifies splitting character for axis labels
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis
VFORMAT=	specifies format for vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes

Table 17.53 *continued*

Option	Description
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
ZEROSTD	displays s chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= options
CVREF=	specifies color for lines requested by VREF= options
HREF=	specifies position of reference lines perpendicular to horizontal axis
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis
HREFLABELS=	specifies labels for HREF= lines
HREFLABPOS=	specifies position of HREFLABELS= labels
LHREF=	specifies line type for HREF= lines
LVREF=	specifies line type for VREF= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis
VREFLABELS=	specifies labels for VREF= lines
VREFLABPOS=	position of VREFLABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to chart
DESCRIPTION=	specifies description of s chart's GRSEG catalog entry

Table 17.53 *continued*

Option	Description
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of <i>s</i> chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level

Table 17.53 *continued*

Option	Description
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLELEGEND	augments basic table with legend for tests for special causes
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
TABLETESTS	augments basic table with a column indicating which tests for special causes are positive
Specification Limit Options	
CIINDICES	specifies α value and type for computing capability index confidence limits
LSL=	specifies list of lower specification limits
TARGET=	specifies list of target values
USL=	specifies list of upper specification limits

Table 17.53 continued

Option	Description
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars

Table 17.53 *continued*

Option	Description
Overlay Options	
CCOVERLAY=	specifies colors for overlay line segments
COVERLAY=	specifies colors for overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on chart
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with overlay points
OVERLAYID=	specifies labels for overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for overlays
OVERLAYSYMHT=	specifies symbol heights for overlays
WOVERLAY=	specifies widths of overlay line segments
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= and HREF2= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
TESTCHAR=	specifies character for line segments that connect any sequence of points for which a test for special causes is positive
VREFCHAR=	specifies line character for VREF= and VREF2= lines
ZONECHAR=	specifies character for lines that delineate zones for tests for special causes

Details: SChart Statement

Constructing Charts for Standard Deviations

The following notation is used in this section:

σ	process standard deviation (standard deviation of the population of measurements)
s_i	standard deviation of measurements in i th subgroup

$$s_i = \sqrt{(1/(n_i - 1))((x_{i1} - \bar{X}_i)^2 + \cdots + (x_{in_i} - \bar{X}_i)^2)}$$

n_i	sample size of i th subgroup
$c_4(n)$	expected value of the standard deviation of n independent normally distributed variables with unit standard deviation
$c_5(n)$	standard error of the standard deviation of n independent observations from a normal population with unit standard deviation
$\chi_p^2(n)$	100 p th percentile ($0 < p < 1$) of the χ^2 distribution with n degrees of freedom

Plotted Points

Each point on an s chart indicates the value of a subgroup standard deviation (s_i). For example, if the tenth subgroup contains the values 12, 15, 19, 16, and 13, the value plotted for this subgroup is

$$s_{10} = \sqrt{((12 - 15)^2 + (15 - 15)^2 + (19 - 15)^2 + (16 - 15)^2 + (13 - 15)^2)/4} = 2.739$$

Central Line

By default, the central line for the i th subgroup indicates an estimate for the expected value of s_i , which is computed as $c_4(n_i)\hat{\sigma}$, where $\hat{\sigma}$ is an estimate of σ . If you specify a known value (σ_0) for σ , the central line indicates the value of $c_4(n_i)\sigma_0$. Note that the central line varies with n_i .

Control Limits

You can compute the limits in the following ways:

- as a specified multiple (k) of the standard error of s_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that s_i exceeds the limits

The following table provides the formulas for the limits:

Table 17.54 Limits for *s* Charts

Control Limits
LCL = lower limit = $\max(c_4(n_i)\hat{\sigma} - kc_5(n_i)\hat{\sigma}, 0)$
UCL = upper limit = $c_4(n_i)\hat{\sigma} + kc_5(n_i)\hat{\sigma}$
Probability Limits
LCL = lower limit = $\hat{\sigma} \sqrt{\chi_{\alpha/2}^2(n_i - 1)/(n_i - 1)}$
UCL = upper limit = $\hat{\sigma} \sqrt{\chi_{1-\alpha/2}^2(n_i - 1)/(n_i - 1)}$

The formulas assume that the data are normally distributed. If a standard value σ_0 is available for σ , replace $\hat{\sigma}$ with σ_0 in Table 17.54. Note that the upper and lower limits vary with n_i and that the probability limits are asymmetric around the central line.

You can specify parameters for the limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify σ_0 with the SIGMA0= option or with the variable `_STDDEV_` in a LIMITS= data set.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves control limits and control limit parameters. The following variables are saved:

Table 17.55 OUTLIMITS= Data Set

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding limits
<code>_CP_</code>	capability index C_p
<code>_CPK_</code>	capability index C_{pk}
<code>_CPL_</code>	capability index C_{PL}
<code>_CPM_</code>	capability index C_{pm}
<code>_CPU_</code>	capability index C_{PU}
<code>_INDEX_</code>	optional identifier for the control limits specified with the OUTINDEX= option
<code>_LCLS_</code>	lower control limit for subgroup standard deviation
<code>_LCLX_</code>	lower control limit for subgroup mean
<code>_LIMITN_</code>	sample size associated with the control limits

Table 17.55 continued

Option	Description
<code>_LSL_</code>	lower specification limit
<code>_MEAN_</code>	process mean (\bar{X} or μ_0)
<code>_S_</code>	value of central line on <i>s</i> chart
<code>_SIGMAS_</code>	multiple (<i>k</i>) of standard error of \bar{X}_i or s_i
<code>_STDDEV_</code>	process standard deviation ($\hat{\sigma}$ or σ_0)
<code>_SUBGRP_</code>	<i>subgroup-variable</i> specified in the SCHART statement
<code>_TARGET_</code>	target value
<code>_TYPE_</code>	type (estimate or standard value) of <code>_MEAN_</code> and <code>_STDDEV_</code>
<code>_UCLS_</code>	upper control limit for subgroup standard deviation
<code>_UCLX_</code>	upper control limit for subgroup mean
<code>_USL_</code>	upper specification limit
<code>_VAR_</code>	<i>process</i> specified in the SCHART statement

Notes:

1. The variables `_LCLX_`, `_MEAN_`, and `_UCLX_` are saved to enable the OUTLIMITS= data set to be used as a LIMITS= data set with the BOXCHART, XCHART, and XSCHART statements.
2. If the control limits vary with subgroup sample size, the special missing value *V* is assigned to the variables `_LIMITN_`, `_LCLX_`, `_UCLX_`, `_LCLS_`, `_S_`, and `_UCLS_`.
3. If the limits are defined in terms of a multiple *k* of the standard error of s_i , the value of `_ALPHA_` is computed as

$$F_S(\text{_LCLS_}/\text{_STDDEV_}) + 1 - F_S(\text{_UCLS_}/\text{_STDDEV_})$$

where $F_S(\cdot)$ is the cumulative distribution function of the standard deviation of a sample of n observations from a normal population with unit standard deviation, and n is the value of `_LIMITN_`. If `_LIMITN_` has the special missing value *V*, this value is assigned to `_ALPHA_`.

4. If the limits are probability limits, the value of `_SIGMAS_` is computed as $(\text{_UCLS_} - \text{_S_})/e$, where e is the standard error of the standard deviation of n observations from a normal population with unit standard deviation. If `_LIMITN_` has the special missing value *V*, this value is assigned to `_SIGMAS_`.
5. The variables `_CP_`, `_CPK_`, `_CPL_`, `_CPU_`, `_LSL_`, and `_USL_` are included only if you provide specification limits with the LSL= and USL= options. The variables `_CPM_` and `_TARGET_` are included if, in addition, you provide a target value with the TARGET= option. See “[Capability Indices](#)” on page 1941 for computational details.
6. Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *process* specified in the SCHART statement. For an example, see “[Saving Control Limits](#)” on page 1790.

OUTHISTORY= Data Set

The OUTHISTORY= data set saves subgroup summary statistics. The following variables are saved:

- the *subgroup-variable*
- a subgroup mean variable named by *process* suffixed with *X*
- a subgroup standard deviation variable named by *process* suffixed with *S*
- a subgroup sample size variable named by *process* suffixed with *N*

The subgroup mean variable is included so that the data set can be reused as a HISTORY= data set with the BOXCHART, XCHART, and XSCHART statements, as well as the SCHART statement.

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Subgroup summary variables are created for each *process* specified in the SCHART statement. For example, consider the following statements:

```
proc shewhart data=Steel;
  schart (Width Diameter)*Lot / outhistory=Summary;
run;
```

The data set Summary contains variables named Lot, WidthX, WidthS, WidthN, DiameterX, DiameterS, and DiameterN.

Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

For an example of an OUTHISTORY= data set, see “Saving Summary Statistics” on page 1789.

OUTTABLE= Data Set

The OUTTABLE= data set saves subgroup summary statistics, control limits, and related information. The following variables are saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_EXLIM_</code>	control limit exceeded on <i>s</i> chart
<code>_LCLS_</code>	lower control limit for standard deviation
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_S_</code>	average standard deviation
<code>_SIGMAS_</code>	multiple (<i>k</i>) of the standard error associated with control limits

Table 17.55 continued

Option	Description
<i>subgroup</i>	values of the subgroup variable
<code>_SUBN_</code>	subgroup sample size
<code>_SUBS_</code>	subgroup standard deviation
<code>_TESTS2_</code>	tests for special causes signaled on <i>s</i> chart
<code>_UCLS_</code>	upper control limit for standard deviation
<code>_VAR_</code>	<i>process</i> specified in the SCHART statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the READPHASES= option is specified)

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved depending on how the control limits are defined (with the ALPHA= or SIGMAS= option, respectively, or with the corresponding variables in a LIMITS= data set).
2. The variable `_TESTS2_` is saved if you specify the TESTS2= option.
3. The variables `_EXLIM_` and `_TESTS2_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “Saving Control Limits” on page 1790.

ODS Tables

The following table summarizes the ODS tables that you can request with the SCHART statement.

Table 17.56 ODS Tables Produced with the SCHAT Statement

Table Name	Description	Options
SCHAT	<i>s</i> chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLELEG, TABLEOUT, TABLETESTS
TestDescriptions	descriptions of tests for special causes requested with the TESTS= option for which at least one positive signal is found	TABLEALL, TABLELEG

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the SHEWHART procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. SCHAT options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the SCHAT statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 17.57](#).

Table 17.57 ODS Graphics Produced by the SCHAT Statement

ODS Graph Name	Plot Description
SChart	<i>s</i> chart

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (process measurements) from a DATA= data set specified in the PROC SHEWHART statement. Each *process* specified in the SCHAT statement must be a SAS variable in the DATA= data set. This variable provides measurements, which must be grouped into subgroup samples indexed by the values of the *subgroup-variable*. The *subgroup-variable*, which is specified in the SCHAT statement, must also be a SAS variable in the DATA= data set.

Each observation in a DATA= data set must contain a value for each *process* and a value for the *subgroup-variable*. If the *i*th subgroup contains n_i items, there should be n_i consecutive observations for which the value of the *subgroup-variable* is the index of the *i*th subgroup. For example, if each subgroup contains five items and there are 30 subgroup samples, the DATA= data set should contain 150 observations. Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a DATA= data set. However, if the DATA= data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) with the READPHASES= option (for an example, see “[Displaying Stratification in Phases](#)” on page 2103).

For an example of a DATA= data set, see “[Creating Standard Deviation Charts from Raw Data](#)” on page 1783.

LIMITS= Data Set

You can read preestablished control limits (or parameters from which the control limits can be calculated) from a LIMITS= data set specified in the PROC SHEWHART statement. For example, the following statements read control limit information from the data set `Conlims`:³¹

```
proc shewhart data=Info limits=Conlims;
    schart Weight*Batch;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the SHEWHART procedure. Such data sets always contain the variables required for a LIMITS= data set; see [Table 17.55](#). The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LCLS_`, `_S_`, and `_UCLS_`, which specify the control limits directly
- the variable `_STDDEV_`, which is used to calculate the control limits according to the equations in [Table 17.54](#)

In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables whose lengths are no greater than 32.

³¹In SAS 6.09 and in earlier releases, it is necessary to specify the READLIMITS option.

- The variable `_INDEX_` is required if you specify the `READINDEX=` option. This must be a character variable whose length is no greater than 48.
- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8; valid values are 'ESTIMATE', 'ESTIMATE', 'STDMU', and 'STDSIGMA'.
- BY variables are required if specified with a BY statement.

For an example, see “[Reading Preestablished Control Limits](#)” on page 1792.

HISTORY= Data Set

You can read subgroup summary statistics from a `HISTORY=` data set specified in the PROC SHEWHART statement. This enables you to reuse OUTHISTORY= data sets that have been created in previous runs of the SHEWHART, CUSUM, or MACONTROL procedures or to read output data sets created with SAS summarization procedures, such as the MEANS procedure.

A `HISTORY=` data set used with the SCHART statement must contain the following:

- the *subgroup-variable*
- a subgroup standard deviation variable for each *process*
- a subgroup sample size variable for each *process*

The names of the subgroup standard deviation and subgroup sample size variables must be the *process* name concatenated with the special suffix characters *S* and *N*, respectively. For example, consider the following statements:

```
proc shewhart history=Summary;
    schart (Weight Yieldstrength)*Batch;
run;
```

The data set Summary must include the variables Batch, WeightS, WeightN, YieldstrengthS, and YieldstrengthN.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a `HISTORY=` data set include

- `_PHASE_` (if the `READPHASES=` option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all the observations in a HISTORY= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (see “Displaying Stratification in Phases” on page 2103 for an example).

For an example of a HISTORY= data set, see “Creating Standard Deviation Charts from Subgroup Summary Data” on page 1786.

TABLE= Data Set

You can read summary statistics and control limits from a TABLE= data set specified in the PROC SHEWHART statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the SHEWHART procedure. Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts. Examples are provided in “Specialized Control Charts: SHEWHART Procedure” on page 2171.

The following table lists the variables required in a TABLE= data set used with the SChart statement:

Table 17.58 Variables Required in a TABLE= Data Set

Variable	Description
<code>_LCLS_</code>	lower control limit for standard deviation
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_S_</code>	average standard deviation
<i>subgroup-variable</i>	values of the <i>subgroup-variable</i>
<code>_SUBN_</code>	subgroup sample size
<code>_SUBS_</code>	subgroup standard deviation
<code>_UCLS_</code>	upper control limit for standard deviation

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- `_PHASE_` (if the READPHASES= option is specified). This variable must be a character variable whose length is no greater than 48.
- `_TESTS2_` (if the TESTS2= option is specified). This variable is used to flag tests for special causes and must be a character variable of length 8.
- `_VAR_`. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable whose length is no greater than 32.

For an example of a TABLE= data set, see “Saving Control Limits” on page 1790.

Methods for Estimating the Standard Deviation

When control limits are determined from the input data, three methods (referred to as default, MVLUE, and RMSDF) are available for estimating σ .

Default Method

The default estimate for σ is

$$\hat{\sigma} = \frac{s_1/c_4(n_1) + \cdots + s_N/c_4(n_N)}{N}$$

where N is the number of subgroups for which $n_i \geq 2$, s_i is the sample standard deviation of the i th subgroup

$$s_i = \sqrt{\frac{1}{n_i - 1} \sum_{j=1}^{n_i} (x_{ij} - \bar{X}_i)^2}$$

and

$$c_4(n_i) = \frac{\Gamma(n_i/2)\sqrt{2/(n_i - 1)}}{\Gamma((n_i - 1)/2)}$$

Here $\Gamma(\cdot)$ denotes the gamma function, and \bar{X}_i denotes the i th subgroup mean. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$. If the observations are normally distributed, then the expected value of s_i is $c_4(n_i)\sigma$. Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ . This method is described in the American Society for Testing and Materials (1976).

MVLUE Method

If you specify SMETHOD=MVLUE, a minimum variance linear unbiased estimate (MVLUE) is computed for σ . Refer to Burr (1969, 1976) and Nelson (1989, 1994). This estimate is a weighted average of N unbiased estimates of σ of the form $s_i/c_4(n_i)$, and it is computed as

$$\hat{\sigma} = \frac{h_1 s_1/c_4(n_1) + \cdots + h_N s_N/c_4(n_N)}{h_1 + \cdots + h_N}$$

where

$$h_i = \frac{[c_4(n_i)]^2}{1 - [c_4(n_i)]^2}$$

A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$. The MVLUE assigns greater weight to estimates of σ from subgroups with larger sample sizes, and it is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the MVLUE reduces to the default estimate.

RMSDF Method

If you specify SMETHOD=RMSDF, a weighted root-mean-square estimate is computed for σ .

$$\hat{\sigma} = \frac{\sqrt{(n_1 - 1)s_1^2 + \cdots + (n_N - 1)s_N^2}}{c_4(n)\sqrt{n_1 + \cdots + n_N - N}}$$

The weights are the degrees of freedom $n_i - 1$. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$.

If the unknown standard deviation σ is constant across subgroups, the root-mean-square estimate is more efficient than the minimum variance linear unbiased estimate. However, in process control applications, it is generally not assumed that σ is constant, and if σ varies across subgroups, the root-mean-square estimate tends to be more inflated than the MVLUE.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical	DATA=	<i>process</i>
Vertical	HISTORY=	subgroup standard deviation variable
Vertical	TABLE=	<code>_SUBS_</code>

For an example, see “Labeling Axes” on page 2136.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: SChart Statement

This section provides advanced examples of the SChart statement.

Example 17.29: Specifying a Known Standard Deviation

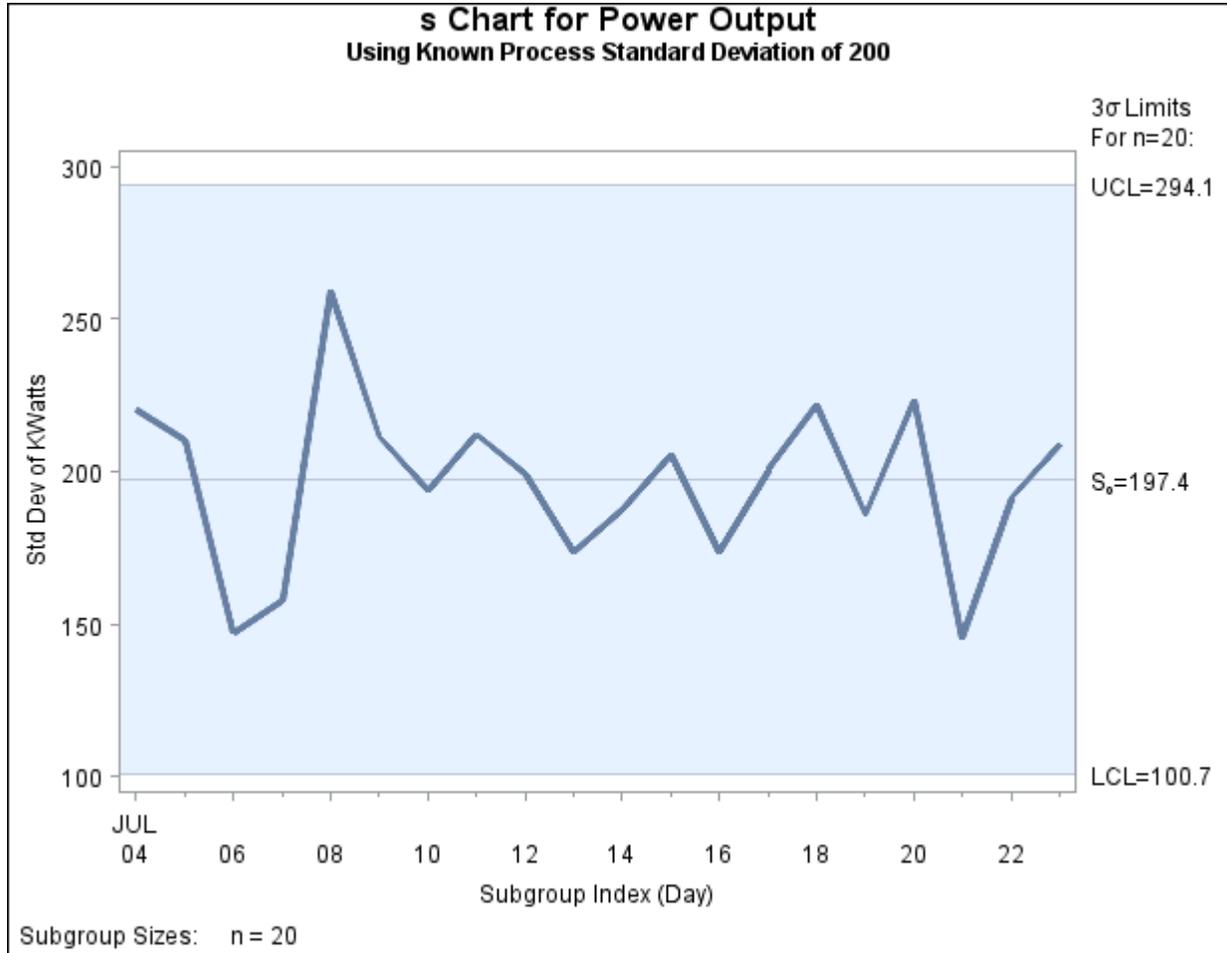

See SHWSEX1 in the SAS/QC Sample Library In some applications, a standard value σ_0 may be available for the process standard deviation σ . This example shows how you can specify σ_0 to compute the control limits.

Suppose that the amount of power needed to heat water in the heating process described in “Creating Standard Deviation Charts from Raw Data” on page 1783 has a known standard deviation of 200. The following statements specify this known value and create an *s* chart, shown in Output 17.29.1, for the power output measurements in the data set Turbine:

```
ods graphics off;
title 's Chart for Power Output';
title2 'Using Known Process Standard Deviation of 200';
proc shewhart data=Turbine;
    schart KWatts*Day / sigma0 = 200
                    ssymbol = s0;
run;
```

The SIGMA0= option specifies σ_0 , and the SSYMBOL= option specifies a label for the central line indicating that the central line is computed from σ_0 . Since all the points lie within the limits, you can conclude that the variability of the process is stable.

Output 17.29.1 Reading in Standard Value for Process Standard Deviation

You can also specify σ_0 as the value of the variable `_STDDEV_` in a `LIMITS=` data set, as illustrated by the following statements:³²

```
data Plimits;
  length _var_ _subgrp_ _type_ $8;
  _var_   = 'KWatts';
  _subgrp_ = 'Day';
  _type_  = 'STDSIGMA';
  _limitn_ = 20;
  _stddev_ = 200;
run;

title 'Chart Using Known Process Standard Deviation';
proc shewhart data=Turbine limits=Plimits;
```

³²In SAS 6.09 and in earlier releases, it is necessary to specify the READLIMITS option.

```

schart KWatts*Day / ssymbol=s0;
run;

```

The resulting s chart (not shown here) is identical to the one shown in Output 17.29.1. For more information, see “LIMITS= Data Set” on page 1810.

Example 17.30: Computing Average Run Lengths for s Charts

See SHWSARL in the SAS/QC Sample Library

This example illustrates how you can compute the average run length of an s chart. The data used here are the power measurements in the data set Turbine, which is introduced in “Creating Standard Deviation Charts from Raw Data” on page 1783.

The in-control average run length of a Shewhart chart is $ARL = \frac{1}{p}$, where p is the probability that a single point exceeds its control limits. Since this probability is saved as the value of the variable `_ALPHA_` in an OUTLIMITS= data set, you can compute ARL for an s chart as follows:

```

title 'Average In-Control Run Length';
proc shewhart data=Turbine;
  schart KWatts*Day / outlimits=Turblim nochart;

data ARLcomp;
  keep _var_ _sigmas_ _alpha_ arl;
  set Turblim;
  arl = 1 / _alpha_;
run;

```

The data set ARLcomp is listed in Output 17.30.1, which shows that the ARL is equal to 358.

Output 17.30.1 The Data Set ARLcomp

Average In-Control Run Length			
<code>_VAR_</code>	<code>_ALPHA_</code>	<code>_SIGMAS_</code>	<code>arl</code>
KWatts	.002792725	3	358.073

To compute out-of-control average run lengths, define f as the slippage factor for the process standard deviation σ , where $f > 1$. In other words, the “shifted” standard deviation to be detected by the chart is $f\sigma$. The following statements compute the ARL as a function of f :

```

data ARLshift;
  keep f f_std p arl_f;
  set Turblim;
  df = _limitn_ - 1;
  do f = 1 to 1.5 by 0.05;
    f_std = f * _stddev_;
    low  = df * ( _lcls_ / f_std )**2;
    upp  = df * ( _ucls_ / f_std )**2;
    p    = probchi( low, df ) + 1 - probchi( upp, df );
    arl_f = 1 / p;
  end;
run;

```

```

output;
end;
run;

```

The data set ARLshift is listed in [Output 17.30.2](#). For example, on average, 53 samples are required to detect a ten percent increase in σ (a shifted standard deviation of approximately 219). The computations use the fact that $(n_i - 1)s_i^2/\sigma^2$ has a χ^2 distribution with $n_i - 1$ degrees of freedom, assuming that the measurements are normally distributed.

Output 17.30.2 The Data Set ARLshift

Average Run Length Analysis			
f	f_std	p	arl_f
1.00	198.996	0.00279	358.073
1.05	208.945	0.00758	131.922
1.10	218.895	0.01875	53.322
1.15	228.845	0.03984	25.102

1.50	298.494	0.50546	1.978

UCHART Statement: SHEWHART Procedure

Overview: UCHART Statement

The UCHART statement creates u charts for the numbers of nonconformities (defects) per inspection unit in subgroup samples containing arbitrary numbers of units.

You can use options in the UCHART statement to

- specify the number of inspection units per subgroup
- compute control limits from the data based on a multiple of the standard error of the plotted values or as probability limits
- tabulate subgroup summary statistics and control limits
- save control limits in an output data set
- save subgroup summary statistics in an output data set
- read preestablished control limits from a data set

- apply tests for special causes (also known as runs tests and Western Electric rules)
- specify a known (standard) value for the average number of nonconformities per inspection unit
- display distinct sets of control limits for data from successive time phases
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have three alternatives for producing u charts with the UCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: UCHART Statement

This section introduces the UCHART statement with simple examples that illustrate commonly used options. Complete syntax for the UCHART statement is presented in the section “Syntax: UCHART Statement” on page 1829, and advanced examples are given in the section “Examples: UCHART Statement” on page 1849.

Creating u Charts from Defect Count Data

See SHWUCHR in the SAS/QC Sample Library A textile company uses a u chart to monitor the number of defects per square meter of fabric. The fabric is spooled onto rolls as it is inspected for defects. Each piece of fabric is one meter wide and 30 meters in length. The following statements create a SAS data set named Fabric, which contains the defect counts for 20 rolls:

```

data Fabric;
  input Roll Defects @@;
  datalines;
1 12    2 11    3 9    4 15
5 7     6 6     7 5     8 10
9 8     10 8    11 14    12 5
13 9    14 13    15 7     16 5
17 8    18 11    19 7     20 12
;

```

A partial listing of Fabric is shown in Figure 17.86.

Figure 17.86 The Data Set Fabric

Number of Fabric Defects	
Roll	Defects
1	12
2	11
3	9
4	15
5	7

There is a single observation per roll. The variable Roll identifies the subgroup sample and is referred to as the *subgroup-variable*. The variable Defects contains the number of nonconformities (defect count) for each subgroup sample and is referred to as the *process variable* (or *process* for short).

The following statements create the *u* chart shown in Figure 17.87:

```

ods graphics off;
title 'u Chart for Fabric Defects';
proc shewhart data=Fabric;
  uchart Defects*Roll / subgroupn = 30;
run;

```

This example illustrates the basic form of the UCHART statement. After the keyword UCHART, you specify the *process* to analyze (in this case, Defects), followed by an asterisk and the *subgroup-variable* (Roll).

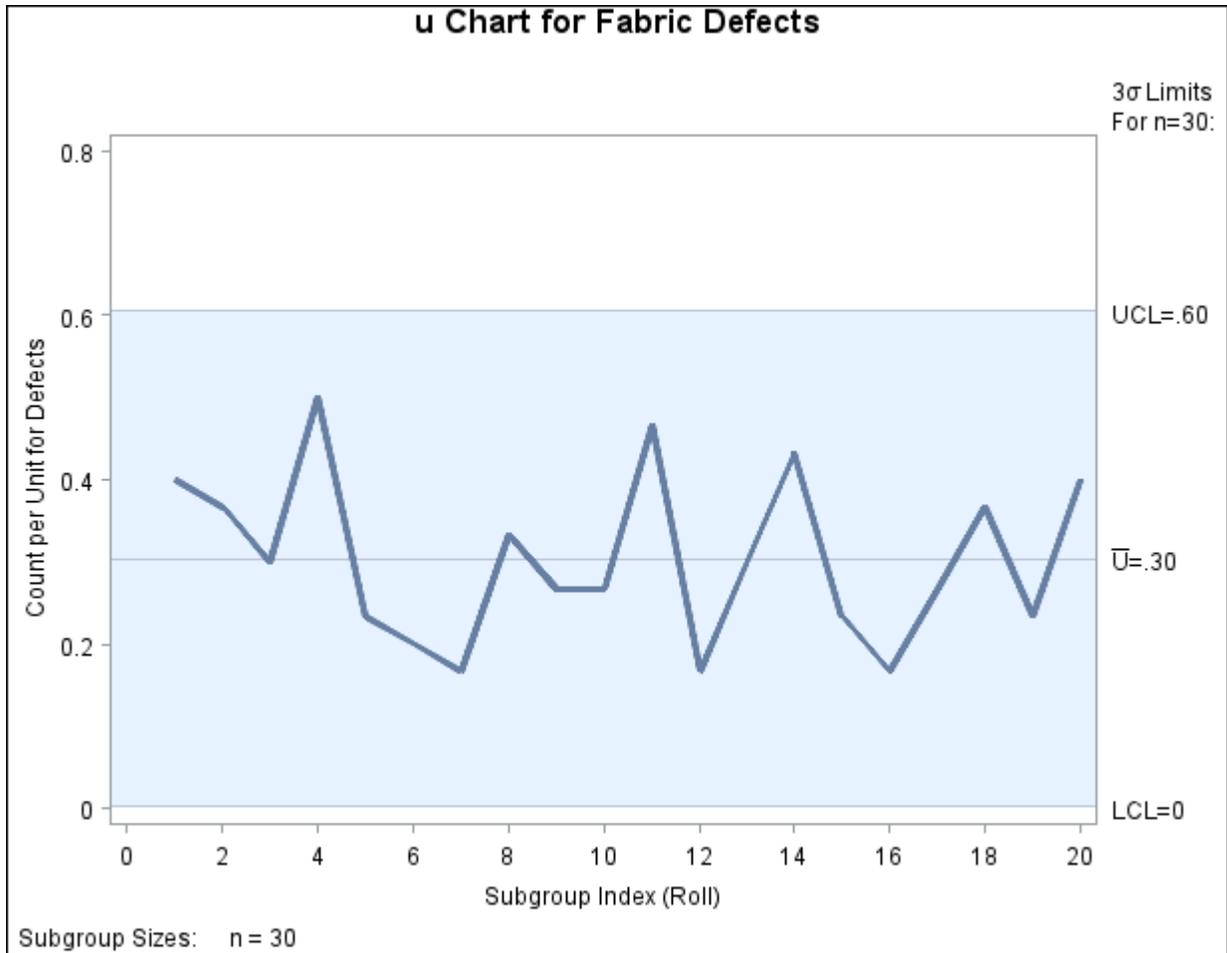

The SUBGROUPN= option specifies the number of inspection units in each subgroup sample and is required if the input data set is a DATA= data set. In this example, each square meter of fabric is an inspection unit, and each roll is a subgroup sample. The number of inspection units per subgroup can be thought of as the subgroup sample size.

You can use the SUBGROUPN= option to specify one of the following:

- a constant subgroup sample size (as in this example)
- an input variable name whose values contain the subgroup sample sizes (for an example, see “Saving Nonconformities per Unit” on page 1827)

Options such as `SUBGROUPN=` are specified after the slash (/) in the `UCHART` statement. A complete list of options is presented in the section “Syntax: `UCHART` Statement” on page 1829.

Figure 17.87 u Chart Example (Traditional Graphics)

The input data set is specified with the `DATA=` option in the `PROC SHEWHART` statement.

Each point on the u chart represents the number of nonconformities per inspection unit for a particular subgroup. For instance, the value plotted for the first subgroup is $12/30 = 0.4$ (since there are 12 defects on the first roll and this roll contains 30 square meters of fabric). By default, the control limits shown are 3σ limits estimated from the data; the formulas for the limits are given in “Control Limits” on page 1840. Since none of the points exceed the 3σ limits, the u chart indicates that the fabric manufacturing process is in statistical control.

See “Constructing Charts for Nonconformities per Unit (u Charts)” on page 1839 for details concerning u charts. For more details on reading defect count data, see “`DATA=` Data Set” on page 1845.

Saving Control Limits

You can save the control limits for a u chart in a SAS data set; this enables you to apply the control limits to future data (see “[Reading Preestablished Control Limits](#)” on page 1823) or modify the limits with a DATA step program. *See SHWUCHR in the SAS/QC Sample Library*

The following statements read defect counts from the data set Fabric (see “[Creating \$u\$ Charts from Defect Count Data](#)” on page 1818) and save the control limits displayed in [Figure 17.87](#) in a data set named Fablim:

```
proc shewhart data=Fabric;
  uchart Defects*Roll / subgroupn = 30
                    outlimits = Fablim
                    nochart;
run;
```

The SUBGROUPN= option specifies the number of inspection units in each subgroup sample. The OUTLIMITS= option names the data set containing the control limits, and the NOCHART option suppresses the display of the chart. The data set Fablim is listed in [Figure 17.88](#).

Figure 17.88 The Data Set Fablim Containing Control Limit Information

Control Limits Data Set FABLIM								
—	S	—	L	—	S	—	—	—
—	U	—	I	A	I	—	—	—
V	B	T	M	L	G	L	—	U
A	G	Y	I	P	M	C	—	C
R	R	P	T	H	A	L	—	L
—	P	E	N	A	S	U	U	U
—	—	—	—	—	—	—	—	—
Defects	Roll	ESTIMATE	30	.002550178	3	.001671271	0.30333	0.60

The data set Fablim contains one observation with the limits for *process* Defects. The variables `_LCLU_` and `_UCLU_` contain the lower and upper control limits, and the variable `_U_` contains the central line. The value of `_LIMITN_` is the nominal sample size associated with the control limits, and the value of `_SIGMAS_` is the multiple of σ associated with the control limits. The variables `_VAR_` and `_SUBGRP_` are bookkeeping variables that save the *process* and *subgroup-variable*. The variable `_TYPE_` is a bookkeeping variable that indicates whether the value of `_U_` is an estimate or standard value. For more information, see “[OUTLIMITS= Data Set](#)” on page 1841.

Alternatively, you can use the OUTTABLE= option to create an output data set that saves both the control limits and the subgroup statistics, as illustrated by the following statements:

```
proc shewhart data=Fabric;
  uchart Defects*Roll / subgroupn = 30
                    outtable = Fabtab
                    nochart;
run;
```

The data set Fabtab is listed in [Figure 17.89](#).

Figure 17.89 The Data Set Fabtab

Number of Defects Per Square Meter and Control Limits									
		S	L						
		I	I						E

Defects	2	3	30	30	.001671271	0.36667	0.30333	0.60500	
Defects	3	3	30	30	.001671271	0.30000	0.30333	0.60500	
Defects	4	3	30	30	.001671271	0.50000	0.30333	0.60500	
Defects	5	3	30	30	.001671271	0.23333	0.30333	0.60500	
Defects	6	3	30	30	.001671271	0.20000	0.30333	0.60500	
Defects	7	3	30	30	.001671271	0.16667	0.30333	0.60500	
Defects	8	3	30	30	.001671271	0.33333	0.30333	0.60500	
Defects	9	3	30	30	.001671271	0.26667	0.30333	0.60500	
Defects	10	3	30	30	.001671271	0.26667	0.30333	0.60500	
Defects	11	3	30	30	.001671271	0.46667	0.30333	0.60500	
Defects	12	3	30	30	.001671271	0.16667	0.30333	0.60500	
Defects	13	3	30	30	.001671271	0.30000	0.30333	0.60500	
Defects	14	3	30	30	.001671271	0.43333	0.30333	0.60500	
Defects	15	3	30	30	.001671271	0.23333	0.30333	0.60500	
Defects	16	3	30	30	.001671271	0.16667	0.30333	0.60500	
Defects	17	3	30	30	.001671271	0.26667	0.30333	0.60500	
Defects	18	3	30	30	.001671271	0.36667	0.30333	0.60500	
Defects	19	3	30	30	.001671271	0.23333	0.30333	0.60500	
Defects	20	3	30	30	.001671271	0.40000	0.30333	0.60500	

This data set contains one observation for each subgroup sample. The variables `_SUBU_` and `_SUBN_` contain the number of nonconformities per unit in each subgroup and the number of inspection units per subgroup. The variables `_LCLU_` and `_UCLU_` contain the lower and upper control limits, and the variable `_U_` contains the central line. The variables `_VAR_` and `Roll` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “`OUTTABLE= Data Set`” on page 1843.

An `OUTTABLE=` data set can be read later as a `TABLE=` data set by the SHEWHART procedure. For example, the following statements read `Fabtab` and display a *u* chart (not shown here) identical to the chart in Figure 17.87:

```

title 'u Chart for Fabric Defects';
proc shewhart Table=Fabtab;
    uchart Defects*Roll / subgroupn=30;
run;

```

Because the SHEWHART procedure simply displays the information in a `TABLE=` data set, you can use `TABLE=` data sets to create specialized control charts (see “`Specialized Control Charts: SHEWHART Procedure`” on page 2171). For more information, see “`TABLE= Data Set`” on page 1847.

Reading Prestablished Control Limits

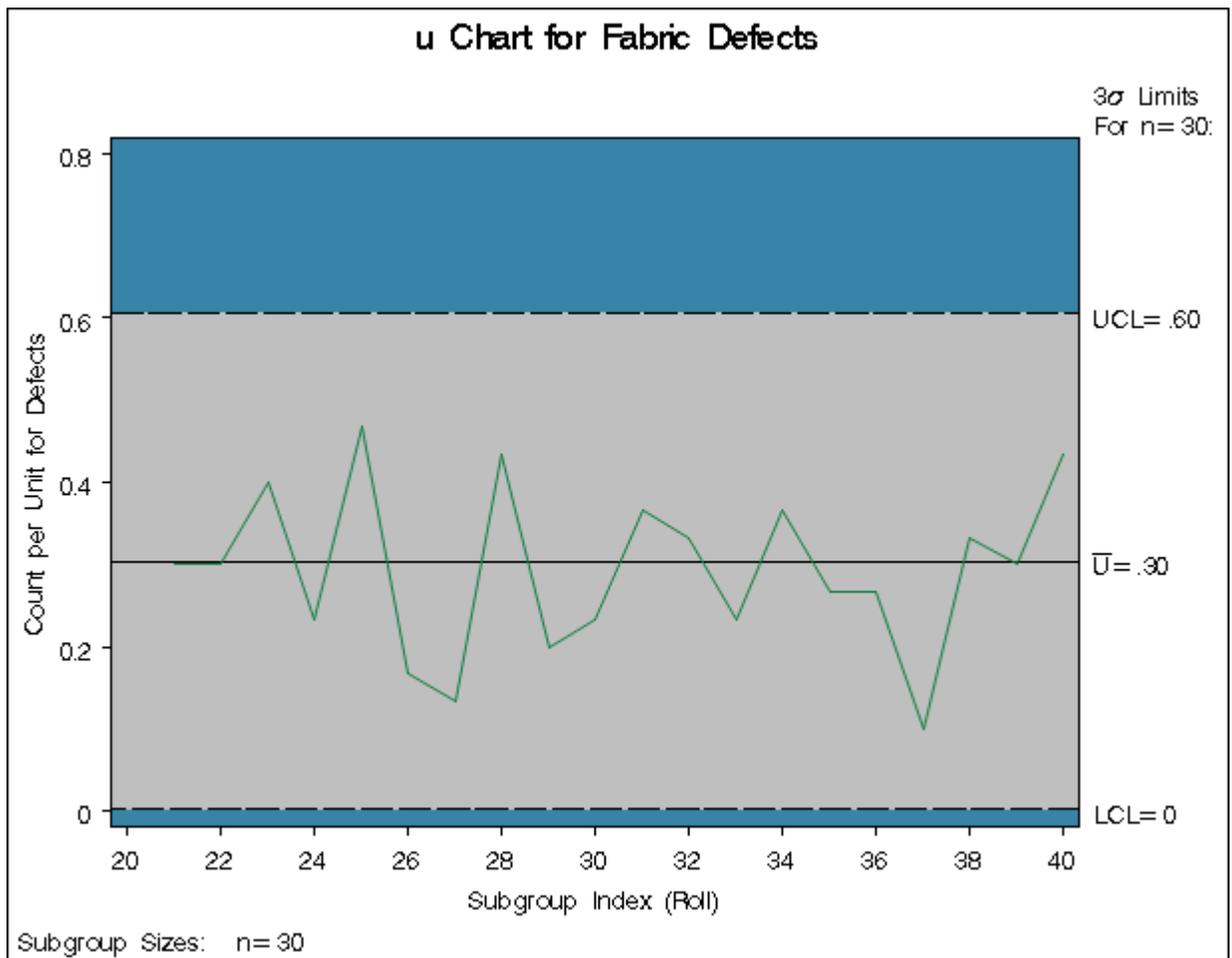

In the previous example, control limits were saved in a SAS data set named `Fablim`. This example *See SHWUCHR in the SAS/QC Sample Library* shows how these limits can be applied to defect counts for an additional 20 rolls of fabric, which are provided in the following data set:

```
data Fabric2;
  input Roll Defects @@;
  datalines;
21 9    22 9    23 12   24 7    25 14
26 5    27 4    28 13   29 6    30 7
31 11   32 10   33 7    34 11   35 8
36 8    37 3    38 10   39 9    40 13
;
```

The following statements create a *u* chart for the second group of rolls using the control limits in `Fablim`:

```
options nogstyle;
goptions ftext=swiss;
symbol color = vig h = .8;
title 'u Chart for Fabric Defects';
proc shewhart data=Fabric2 limits=Fablim;
  uchart Defects*Roll / subgroupn = 30
                    cframe      = steel
                    cinfill     = ligr
                    cconnect    = vig
                    coutfill    = yellow;
run;
options gstyle;
```

The `NOGSTYLE` system option causes ODS styles not to affect traditional graphics. Instead, the `SYMBOL` statement and `UCHART` statement options control the appearance of the graph. The `GSTYLE` system option restores the use of ODS styles for traditional graphics produced subsequently. The chart is shown in [Figure 17.90](#) and indicates that the process is in control.

Figure 17.90 A u Chart for Second Set of Fabric Rolls (Traditional Graphics with NOGSTYLE)

The LIMITS= option in the PROC SHEWHART statement specifies the data set containing the control limits. By default,³³ this information is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches the *process* Defects
- the value of `_SUBGRP_` matches the *subgroup-variable* name Roll

In this example, the LIMITS= data set was created in a previous run of the SHEWHART procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on page 1845 for details concerning the variables that you must provide.

³³In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

Creating *u* Charts from Nonconformities per Unit

In the previous example, the input data set provided the number of nonconformities for each subgroup sample. However, in some applications, as illustrated here, the data provide the number of nonconformities *per inspection unit* for each subgroup. *See SHWUCHR in the SAS/QC Sample Library*

A clothing manufacturer ships shirts in boxes of ten. Prior to shipment, each shirt is inspected for flaws. Since the manufacturer is interested in the average number of flaws per shirt, the number of flaws found in each box is divided by ten and then recorded. The following statements create a SAS data set named *Shirts*, which contains the average number of flaws per shirt for 25 boxes:

```
data Shirts;
  input Box AvgdefU @@;
  AvgdefN=10;
  datalines;
  1 0.4    2 0.7    3 0.5    4 1.0    5 0.3
  6 0.2    7 0.0    8 0.4    9 0.4   10 0.6
 11 0.2   12 0.7   13 0.3   14 0.1   15 0.3
 16 0.6   17 0.6   18 0.3   19 0.7   20 0.3
 21 0.0   22 0.1   23 0.5   24 0.6   25 0.4
;
```

Note that this is the same data set used in “Getting Started: CCHART Statement” on page 1493 of “CCHART Statement: SHEWHART Procedure” on page 1492. A partial listing of *Shirts* is shown in Figure 17.91.

Figure 17.91 The Data Set *Shirts*

Average Number of Shirt Flaws		
Box	Avgdef U	Avgdef N
1	0.4	10
2	0.7	10
3	0.5	10
4	1.0	10
5	0.3	10

The data set *Shirts* contains three variables: the box number (*Box*), the average number of flaws per shirt (*AvgdefU*), and the number of shirts per box (*AvgdefN*). Here, a *subgroup* is a box of shirts, and an *inspection unit* is an individual shirt. Note that each subgroup contains ten inspection units.

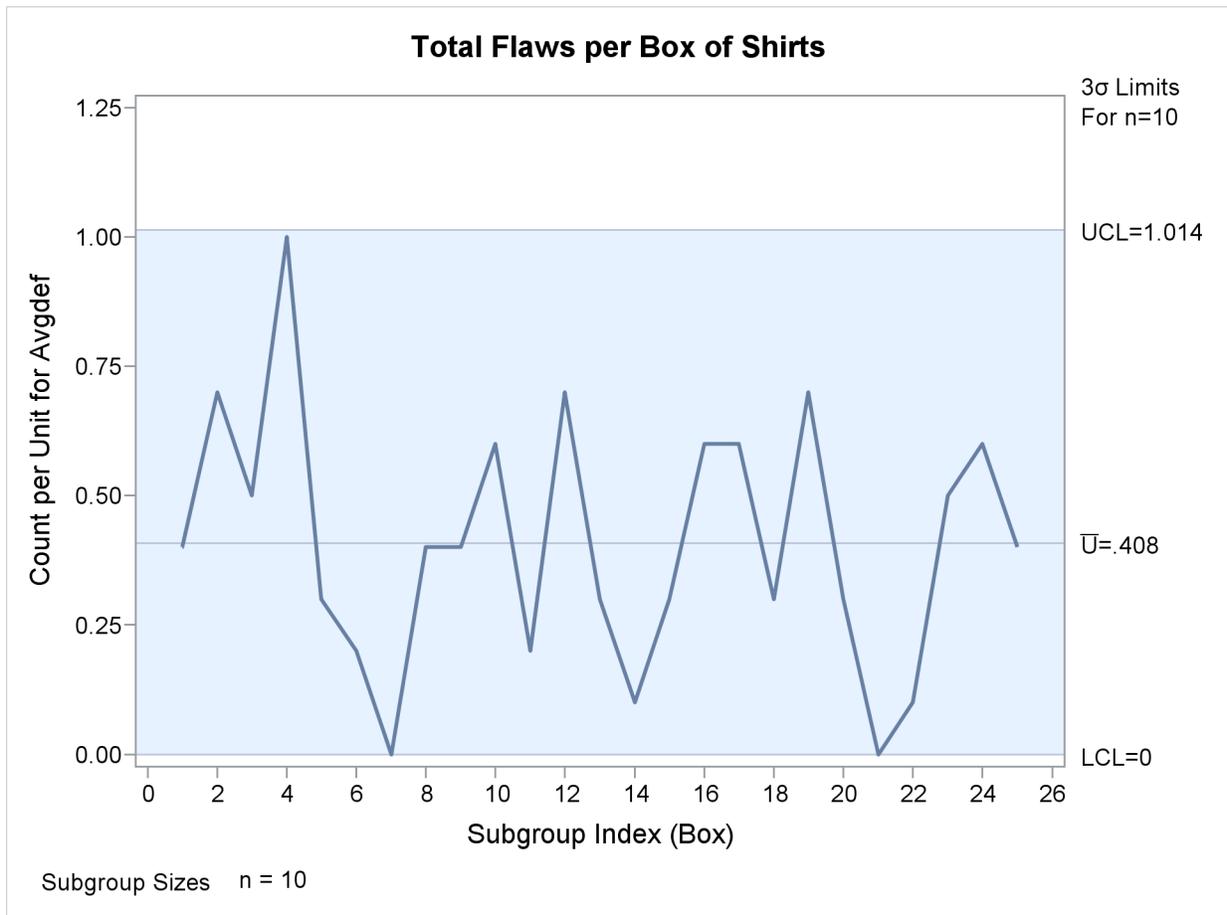

To create a *u* chart for the average number of flaws per shirt in each box, you can specify *Shirts* as a *HISTORY=* data set.

```
ods graphics on;
title 'Total Flaws per Box of Shirts';
proc shewhart history=Shirts;
  uchart Avgdef*Box / odstitle=title;
run;
```

The ODS GRAPHICS ON statement specified before the PROC SHEWHART statement enables ODS Graphics, so the *u* chart is created by using ODS Graphics instead of traditional graphics.

Note that `Avgdef` is *not* the name of a SAS variable in the data set but is, instead, the common prefix for the names of the SAS variables `AvgdefU` and `AvgdefN`. The suffix characters *U* and *N* indicate *number of nonconformities per unit* and *sample size*, respectively. This naming convention enables you to specify two variables in the `HISTORY=` data set with a single name, which is referred to as the *process*. The name `Box`, specified after the asterisk, is the name of the *subgroup-variable*. The *u* chart is shown in Figure 17.92.

Figure 17.92 *u* Chart for Boxes of Shirts (ODS Graphics)

In general, a `HISTORY=` input data set used with the `UCHART` statement must contain the following variables:

- subgroup variable
- subgroup number of nonconformities per unit variable
- subgroup sample size variable

Furthermore, the names of the nonconformities per unit and sample size variables must begin with the *process* name specified in the `UCHART` statement and end with the special suffix characters *U* and *N*, respectively. If the names do not follow this convention, you can use the `RENAME` option to rename the variables for the duration of the `SHEWHART` procedure step. Suppose that, instead of

the variables AvgdefU and AvgdefN, the data set Shirts contained the variables Shirtdef and Sizes. The following statements temporarily rename Shirtdef and Sizes to AvgdefU and AvgdefN:

```
proc shewhart
  history=Shirts (rename=(Shirtdef = AvgdefU
                        Sizes      = AvgdefN ));
  uchart Avgdef*Box;
run;
```

For more information, see “HISTORY= Data Set” on page 1846.

Saving Nonconformities per Unit

In this example, the UCHART statement is used to create a summary data set containing the number of nonconformities per unit. This data set can be read later by the SHEWHART procedure (as in the preceding example). *See SHWUCHR in the SAS/QC Sample Library*

A department store receives boxes of shirts containing 10, 25, or 50 shirts. Each box is inspected, and the total number of defects per box is recorded. The following statements create a SAS data set named Shirts2, which contains the total defects per box for 20 boxes:

```
data Shirts2;
  input Box Flaws nShirts @@;
  datalines;
  1 3 10 2 8 10 3 15 25 4 20 25
  5 9 25 6 1 10 7 1 10 8 21 50
  9 3 10 10 7 10 11 1 10 12 21 25
  13 9 25 14 3 25 15 12 50 16 18 50
  17 7 10 18 4 10 19 8 10 20 4 10
  ;
```

A partial listing of Shirts2 is shown in Figure 17.93.

Figure 17.93 The Data Set Shirts2

Number of Shirt Flaws per Box		
Box	Avgdef U	Avgdef N
1	0.4	10
2	0.7	10
3	0.5	10
4	1.0	10
5	0.3	10

The variable `Box` contains the box number, the variable `Flaws` contains the number of flaws in each box, and the variable `nShirts` contains the number of shirts in each box. To evaluate the quality of the shirts, you should report the average number of defects per shirt. The following statements create a data set containing the number of flaws per shirt and the number of shirts per box:

```
proc shewhart data=Shirts2;
  uchart Flaws*Box / subgroupn = nShirts
          outhistory = Shirthist
          nochart;
run;
```

The `SUBGROUPN=` option names the variable in the `DATA=` data set whose values specify the number of inspection units per subgroup. The `OUTHISTORY=` option names an output data set containing the number of nonconformities per inspection unit and the number of inspection units per subgroup. A partial listing of `Shirthist` is shown in [Figure 17.94](#).

Figure 17.94 The Data Set `Shirthist`

Average Defects Per Tee Shirt		
Box	Flaws	Flaws
	U	N
1	0.30	10
2	0.80	10
3	0.60	25
4	0.80	25
5	0.36	25

There are three variables in the data set `Shirthist`.

- `Box` contains the subgroup index.
- `FlawsU` contains the numbers of nonconformities per inspection unit.
- `FlawsN` contains the subgroup sample sizes.

Note that the variables containing the numbers of nonconformities per inspection unit and subgroup sample sizes are named by adding the suffix characters *U* and *N* to the *process* `Flaws` specified in the `UCHART` statement. In other words, the variable naming convention for `OUTHISTORY=` data sets is the same as that for `HISTORY=` data sets.

For more information, see “[OUTHISTORY= Data Set](#)” on page 1842.

Syntax: UCHART Statement

The basic syntax for the UCHART statement is as follows:

```
UCHART process * subgroup-variable ;
```

The general form of this syntax is as follows:

```
UCHART processes * subgroup-variable <(block-variables)>
  <=symbol-variable | =‘character’> / <options> ;
```

You can use any number of UCHART statements in the SHEWHART procedure. The components of the UCHART statement are described as follows.

process

processes

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC SHEWHART statement.

- If numbers of nonconformities per subgroup are read from a DATA= data set, *process* must be the name of the variable containing the numbers of nonconformities. For an example, see “[Creating u Charts from Defect Count Data](#)” on page 1818.
- If numbers of nonconformities per unit and numbers of inspection units per subgroup are read from a HISTORY= data set, *process* must be the common prefix of the appropriate variables in the HISTORY= data set. For an example, see “[Creating u Charts from Nonconformities per Unit](#)” on page 1825.
- If numbers of nonconformities per item, numbers of inspection units per subgroup, and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “[Saving Control Limits](#)” on page 1821.

A *process* is required. If you specify more than one process, enclose the list in parentheses. For example, the following statements request distinct *u* charts for Defects and Flaws:

```
proc shewhart data=Measures;
  uchart (Defects Flaws)*Sample / subgroupn=50;
run;
```

Note that when data are read from a DATA= data set with the UCHART statement, the SUBGROUPN= option (which specifies the number of inspection units per subgroup) is required.

subgroup-variable

is the variable that identifies subgroups in the data. The *subgroup-variable* is required. In the preceding UCHART statement, `Sample` is the subgroup variable. For details, see “[Subgroup Variables](#)” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or character used to plot the number of nonconformities per unit.

- If you produce a line printer chart, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOln statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create a *u* chart using an asterisk (*) to plot the points:

```
proc shewhart data=Values lineprinter;
    uchart Defects*Sample='*' / subgroupn=100;
run;
```

options

enhance the appearance of the chart, request additional analyses, save results in data sets, and so on. The section “[Summary of Options](#)”, which follows, lists all options by function. “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018 describes each option in detail.

Summary of Options

The following tables list the UCHART statement options by function. For complete descriptions, see “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 17.59 UCHART Statement Options

Option	Description
Options for Specifying Control Limits	
ALPHA=	requests probability limits for chart
LIMITN=	specifies either nominal sample size for fixed control limits or varying limits
NOREADLIMITS	computes control limits for each <i>process</i> from the data rather than a LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from a LIMITS= data set
READINDEX=	reads control limits for each <i>process</i> from a LIMITS= data set
READLIMITS	reads single set of control limits for each <i>process</i> from a LIMITS= data set (SAS 6.09 and earlier releases)

Table 17.59 *continued*

Option	Description
SIGMAS=	specifies width of control limits in terms of multiple k of standard error of plotted means
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line
NOCTL	suppresses display of central line
NOLCL	suppresses display of lower control limit
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit
UCLLABEL=	specifies label for upper control limit
USYMBOL=	specifies label for central line
WLIMITS=	specifies width for control limits and central line
Standard Value Options	
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
U0=	specifies known average number of nonconformities per unit
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on u chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TEST-FONT= option)

Table 17.59 *continued*

Option	Description
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
OUTLABEL=	labels points outside control limits
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles
Options for Specifying Tests for Special Causes	
INDEPENDENTZONES	computes zone widths independently above and below center line
NO3SIGMACHECK	enables tests to be applied with control limits other than 3σ limits
NOTESTACROSS	suppresses tests across <i>phase</i> boundaries
TESTS=	specifies tests for special causes
TEST2RUN=	specifies length of pattern for Test 2
TEST3RUN=	specifies length of pattern for Test 3
TESTACROSS	applies tests across <i>phase</i> boundaries
TESTLABEL=	provides labels for points where test is positive
TESTLABEL n =	specifies label for n th test for special causes
TESTNMETHOD=	applies tests to standardized chart statistics
TESTOVERLAP	performs tests on overlapping patterns of points
TESTRESET=	enables tests for special causes to be reset
ZONELABELS	adds labels A, B, and C to zone lines
ZONES	adds lines delineating zones A, B, and C
ZONEVALPOS=	specifies position of ZONEVALUES labels
ZONEVALUES	labels zone lines with their values
Options for Displaying Tests for Special Causes	
CTESTLABBOX=	specifies color for boxes enclosing labels indicating points where test is positive
CTESTS=	specifies color for labels indicating points where test is positive
CTESTSYMBOL=	specifies color for symbol used to plot points where test is positive
CZONES=	specifies color for lines and labels delineating zones A, B, and C
LTESTS=	specifies type of line connecting points where test is positive
LZONES=	specifies line type for lines delineating zones A, B, and C
TESTFONT=	specifies software font for labels at points where test is positive

Table 17.59 *continued*

Option	Description
TESTHEIGHT= TESTLABBOX	specifies height of labels at points where test is positive requests that labels for points where test is positive be positioned so that do not overlap
TESTSYMBOL= TESTSYMBOLHT= WTESTS=	specifies plot symbol for points where test is positive specifies symbol height for points where test is positive specifies width of line connecting points where test is positive
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOTRUNC	suppresses vertical axis truncation at zero applied by default
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPHLABELS=	specifies thinning factor for tick mark labels on horizontal axis
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis
VFORMAT=	specifies format for vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis
WAXIS=	specifies width of axis lines

Table 17.59 *continued*

Option	Description
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
ZEROSTD	displays u chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= options
CVREF=	specifies color for lines requested by VREF= options
HREF=	specifies position of reference lines perpendicular to horizontal axis
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis
HREFLABELS=	specifies labels for HREF= lines
HREFLABPOS=	specifies position of HREFLABELS= labels
LHREF=	specifies line type for HREF= lines
LVREF=	specifies line type for VREF= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis
VREFLABELS=	specifies labels for VREF= lines
VREFLABPOS=	position of VREFLABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart

Table 17.59 *continued*

Option	Description
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features chart
DESCRIPTION=	specifies description of <i>u</i> chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of <i>u</i> chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines

Table 17.59 *continued*

Option	Description
NOPHASEREFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
SUBGROUPN	specifies subgroup sample sizes as constant number n or as values of variable in a DATA= data set
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the OUTLIMITS= data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables

Table 17.59 *continued*

Option	Description
TABLELEGEND	augments basic table with legend for tests for special causes
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
TABLETESTS	augments basic table with a column indicating which tests for special causes are positive
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars

Table 17.59 *continued*

Option	Description
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for overlay line segments
COVERLAY=	specifies colors for overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on chart
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with overlay points
OVERLAYID=	specifies labels for overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for overlays
OVERLAYSYMHT=	specifies symbol heights for overlays
WOVERLAY=	specifies widths of overlay line segments
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
TESTCHAR=	specifies character for line segments that connect any sequence of points for which a test for special causes is positive
VREFCHAR=	specifies line character for VREF= lines
ZONECHAR=	specifies character for lines that delineate zones for tests for special causes

Details: UCHART Statement

Constructing Charts for Nonconformities per Unit (u Charts)

The following notation is used in this section:

- u expected number of nonconformities per unit produced by process
- u_i number of nonconformities per unit in the i th subgroup. In general, $u_i = c_i/n_i$.
- c_i total number of nonconformities in the i th subgroup
- n_i number of inspection units in the i th subgroup
- \bar{u} average number of nonconformities per unit taken across subgroups. The quantity \bar{u} is computed as a weighted average:

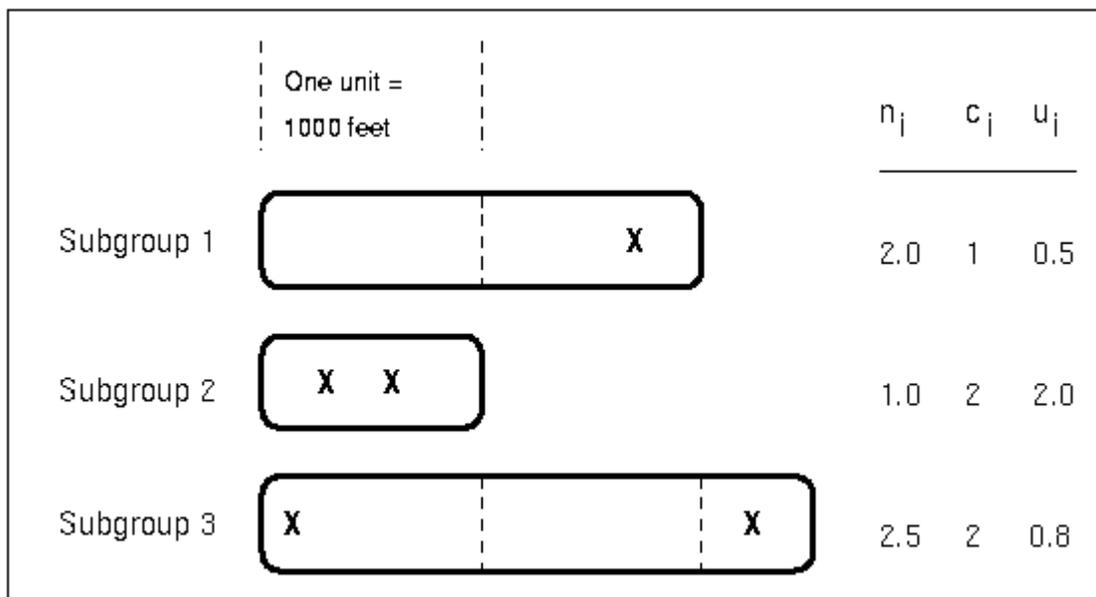

$$\bar{u} = \frac{n_1 u_1 + \cdots + n_N u_N}{n_1 + \cdots + n_N} = \frac{c_1 + \cdots + c_N}{n_1 + \cdots + n_N}$$

- N number of subgroups
- χ^2_ν has a central χ^2 distribution with ν degrees of freedom

Plotted Points

Each point on a u chart indicates the number of nonconformities per unit (u_i) in a subgroup. For example, Figure 17.95 displays three sections of pipeline that are inspected for defective welds (indicated by an X). Each section represents a *subgroup* composed of a number of *inspection units*, which are 1000-foot-long sections. The number of units in the i th subgroup is denoted by n_i , which is the subgroup sample size.

Figure 17.95 Terminology for c Charts and u Charts

The number of nonconformities in the i th subgroup is denoted by c_i . The number of nonconformities

per unit in the i th subgroup is denoted by $u_i = c_i/n_i$. In Figure 17.95, the number of defective welds per unit in the third subgroup is $u_3 = 2/2.5 = 0.8$.

A u chart plots the quantity u_i for the i th subgroup. A c chart plots the quantity c_i for the i th subgroup (see “CCHART Statement: SHEWHART Procedure” on page 1492). An advantage of a u chart is that the value of the central line at the i th subgroup does not depend on n_i . This is not the case for a c chart, and consequently, a u chart is often preferred when the number of units n_i is not constant across subgroups.

Central Line

On a u chart, the central line indicates an estimate of u , which is computed as \bar{u} by default. If you specify a known value (u_0) for u , the central line indicates the value of u_0 .

Control Limits

You can compute the limits in the following ways:

- as a specified multiple (k) of the standard error of u_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that u_i exceeds the limits

The lower and upper control limits, LCLU and UCLU, respectively, are given by

$$\begin{aligned} \text{LCLU} &= \max\left(\bar{u} - k\sqrt{\bar{u}/n_i}, 0\right) \\ \text{UCLU} &= \bar{u} + k\sqrt{\bar{u}/n_i} \end{aligned}$$

The limits vary with n_i .

The upper probability limit UCLU for u_i can be determined using the fact that

$$\begin{aligned} P\{u_i > \text{UCLU}\} &= 1 - P\{u_i \leq \text{UCLU}\} \\ &= 1 - P\{c_i \leq n_i \text{UCLU}\} \\ &= 1 - P\{\chi_{2(n_i(\text{UCLU}+1))}^2 \geq 2n_i\bar{u}\} \end{aligned}$$

The limit UCLU is then calculated by setting

$$1 - P\{\chi_{2(n_i(\text{UCLU}+1))}^2 \geq 2n_i\bar{u}\} = \alpha/2$$

and solving for UCLU.

Likewise, the lower probability limit LCLC for u_i can be determined using the fact that

$$\begin{aligned} P\{u_i < \text{LCLC}\} &= P\{c_i < n_i \text{LCLC}\} \\ &= P\{\chi_{2(n_i(\text{LCLC}+1))}^2 > 2n_i\bar{u}\} \end{aligned}$$

The limit LCLC is then calculated by setting

$$P\{\chi_{2(n_i(\text{LCLC}+1))}^2 > 2n_i\bar{u}\} = \alpha/2$$

and solving for LCLC. For more information, refer to Johnson, Kotz, and Kemp (1992). This assumes that the process is in statistical control and that c_i has a Poisson distribution. Note that the probability limits vary with n_i and are asymmetric around the central line. If a standard value u_0 is available for u , replace \bar{u} with u_0 in the formulas for the control limits.

You can specify parameters for the limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify u_0 with the U0= option or with the variable `_U_` in a LIMITS= data set.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves control limits and control limit parameters. The following variables can be saved:

Table 17.60 OUTLIMITS= Data Set

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding limits
<code>_INDEX_</code>	optional identifier for the control limits specified with the OUTINDEX= option
<code>_LCLU_</code>	lower control limit for number of nonconformities per unit
<code>_LIMITN_</code>	sample size associated with the control limits
<code>_SIGMAS_</code>	multiple (k) of standard error of u_i
<code>_SUBGRP_</code>	<i>subgroup-variable</i> specified in the UCHART statement
<code>_TYPE_</code>	type (estimate or standard value) of <code>_U_</code>
<code>_U_</code>	value of central line of u chart (\bar{u} or u_0)
<code>_UCLU_</code>	upper control limit for number of nonconformities per unit
<code>_VAR_</code>	<i>process</i> specified in the UCHART statement

Notes:

1. If the control limits vary with subgroup sample size, the special missing value 'V' is assigned to the variables `_LCLU_`, `_UCLU_`, and `_LIMITN_`.
2. If the limits are defined in terms of a multiple k of the standard error of u_i , the value of `_ALPHA_` is computed as $P\{u_i < _LCLU_\} + P\{u_i > _UCLU_\}$, provided that n_i is a constant. Otherwise, `_ALPHA_` is assigned the special missing value 'V'.
3. If the limits are probability limits, the value of `_SIGMAS_` is computed as $(_UCLU_ - _U_)/\sqrt{_U_/_LIMITN_}$, provided that n_i is a constant. Otherwise, `_SIGMAS_` is assigned the special missing value V.

- Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *process* specified in the UCHART statement. For an example, see “[Saving Control Limits](#)” on page 1821.

OUTHISTORY= Data Set

The OUTHISTORY= data set saves subgroup summary statistics. The following variables are saved:

- the *subgroup-variable*
- a subgroup number of nonconformities per unit variable named by *process* suffixed with *U*
- a subgroup sample size variable named by *process* suffixed with *N*

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Subgroup summary variables are created for each *process* specified in the UCHART statement. For example, consider the following statements:

```
proc shewhart data=Fabric;
    uchart (Flaws nDefects)*lot / outhistory=Summary
        subgroupn = 10;
run;
```

The data set Summary contains the variables Lot, FlawsU, FlawsN, nDefectsU, and nDefectsN.

Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

For an example of an OUTHISTORY= data set, see “[Saving Nonconformities per Unit](#)” on page 1827. Note that an OUTHISTORY= data set created with the UCHART statement can be used as a HISTORY= data set by either the CCHART statement or the UCHART statement.

OUTTABLE= Data Set

The OUTTABLE= data set saves subgroup summary statistics, control limits, and related information. The following variables are saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_EXLIM_</code>	control limit exceeded on u chart
<code>_LCLU_</code>	lower control limit for number of nonconformities per unit
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_SIGMAS_</code>	multiple (k) of the standard error associated with the control limits
<code>subgroup</code>	values of the subgroup variable
<code>_SUBU_</code>	subgroup number of nonconformities per unit
<code>_SUBN_</code>	subgroup sample size
<code>_TESTS_</code>	tests for special causes signaled on u chart
<code>_U_</code>	average number of nonconformities per unit
<code>_UCLU_</code>	upper control limit for number of nonconformities per unit
<code>_VAR_</code>	<i>process</i> specified in the UCHART statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the READPHASES= option is specified)

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved, depending on how the control limits are defined (with the ALPHA= or SIGMAS= option, respectively, or with the corresponding variables in a LIMITS= data set).
2. The variable `_TESTS_` is saved if you specify the TESTS= option. The k th character of a value of `_TESTS_` is k if Test k is positive at that subgroup. For example, if you request the first four tests (the ones appropriate for u charts) and Tests 2 and 4 are positive for a given subgroup, the value of `_TESTS_` has a 2 for the second character, a 4 for the fourth character, and blanks for the other six characters.
3. The variables `_EXLIM_` and `_TESTS_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “Saving Control Limits” on page 1821.

ODS Tables

The following table summarizes the ODS tables that you can request with the UCHART statement.

Table 17.61 ODS Tables Produced with the UCHART Statement

Table Name	Description	Options
UCHART	<i>u</i> chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLELEG, TABLEOUT, TABLETESTS
TestDescriptions	descriptions of tests for special causes requested with the TESTS= option for which at least one positive signal is found	TABLEALL, TABLELEG

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the SHEWHART procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. UCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the UCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 17.62](#).

Table 17.62 ODS Graphics Produced by the UCHART Statement

ODS Graph Name	Plot Description
UChart	<i>u</i> chart

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read defect counts for subgroup samples from a DATA= data set specified in the PROC SHEWHART statement. Each *process* specified in the UCHART statement must be a SAS variable in the data set. This variable provides the defect count (number of nonconformities) for subgroup samples indexed by the *subgroup-variable*. The *subgroup-variable*, specified in the UCHART statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a value for each *process* and a value for the *subgroup-variable*. The data set should contain one observation per subgroup. When you use a DATA= data set with the UCHART statement, the SUBGROUPN= option (which specifies the number of inspection units per subgroup) is required. Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a DATA= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) with the READPHASES= option (for an example, see “Displaying Stratification in Phases” on page 2103).

For an example of a DATA= data set, see “Creating u Charts from Defect Count Data” on page 1818.

LIMITS= Data Set

You can read preestablished control limits (or parameters from which the control limits can be calculated) from a LIMITS= data set specified in the PROC SHEWHART statement. For example, the following statements read control limit information from the data set `Conlims`:³⁴

```
proc shewhart data=Info limits=Conlims;
  uchart Defects*Lot / subgroupn = 10;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the SHEWHART procedure. Such data sets always contain the variables required for a LIMITS= data set. The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LCLU_`, `_U_`, and `_UCLU_`, which specify the control limits
- the variable `_U_`, which is used to calculate the control limits (see “Control Limits” on page 1840)

In addition, note the following:

³⁴In SAS 6.09 and in earlier releases, it is necessary to specify the READLIMITS option.

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables whose lengths are no greater than 32.
- The variable `_INDEX_` is required if you specify the `READINDEX=` option; this must be a character variable whose length is no greater than 48.
- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8; valid values are 'ESTIMATE' and 'STANDARD'.
- BY variables are required if specified with a BY statement.

For an example, see “[Reading Preestablished Control Limits](#)” on page 1823.

HISTORY= Data Set

You can read subgroup summary statistics from a `HISTORY=` data set specified in the PROC SHEWHART statement. This enables you to reuse `OUTHISTORY=` data sets that have been created in previous runs of the SHEWHART procedure or to read output data sets created with SAS summarization procedures.

A `HISTORY=` data set used with the UCHART statement must contain the following variables:

- *subgroup-variable*
- subgroup number of nonconformities per unit variable for each *process*
- subgroup sample size variable (number of units per subgroup) for each *process*

The names of the variables containing the number of nonconformities per unit and subgroup sample sizes must be the *process* name concatenated with the special suffix characters *U* and *N*, respectively. For example, consider the following statements:

```
proc shewhart history=Summary;
  uchart (Flaws nDefects)*Lot;
run;
```

The data set Summary must include the variables Lot, FlawsU, FlawsN, nDefectsU, and nDefectsN.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a `HISTORY=` data set include

- `_PHASE_` (if the `READPHASES=` option is specified)
- *block-variables*
- *symbol-variable*
- BY variables

- ID variables

By default, the SHEWHART procedure reads all the observations in a HISTORY= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) with the READPHASES= option (see “[Displaying Stratification in Phases](#)” on page 2103 for an example).

For an example of a HISTORY= data set, see “[Creating u Charts from Nonconformities per Unit](#)” on page 1825.

TABLE= Data Set

You can read summary statistics and control limits from a TABLE= data set specified in the PROC SHEWHART statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the SHEWHART procedure or to create your own TABLE= data set. Because the SHEWHART procedure simply displays the information read from a TABLE= data set, you can use TABLE= data sets to create specialized control charts. Examples are provided in “[Specialized Control Charts: SHEWHART Procedure](#)” on page 2171.

The following table lists the variables required in a TABLE= data set used with the UCHART statement:

Table 17.63 Variables Required in a TABLE= Data Set

Variable	Description
<code>_LCLU_</code>	lower control limit for nonconformities per unit
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>subgroup-variable</code>	values of the <i>subgroup-variable</i>
<code>_SUBN_</code>	subgroup sample size
<code>_SUBU_</code>	subgroup number of nonconformities per unit
<code>_U_</code>	average number of nonconformities per unit
<code>_UCLU_</code>	upper control limit for nonconformities per unit

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- `_PHASE_` (if the READPHASES= option is specified). This variable must be a character variable whose length is no greater than 48.
- `_TESTS_` (if the TESTS= option is specified). This variable is used to flag tests for special causes and must be a character variable of length 8.

- `_VAR_`. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable whose length is no greater than 32.

For an example of a TABLE= data set, see “[Saving Control Limits](#)” on page 1821.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical	DATA=	<i>process</i>
Vertical	HISTORY=	subgroup defects per unit variable
Vertical	TABLE=	<code>_SUBU_</code>

For an example, see “[Labeling Axes](#)” on page 2136.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: UCHART Statement

This section provides advanced examples of the UCHART statement.

Example 17.31: Applying Tests for Special Causes

This example illustrates how you can apply tests for special causes to make u charts more sensitive to special causes of variation. *See SHWUEX1 in the SAS/QC Sample Library*

A textile company inspects rolls of fabric for defects. The rolls are one meter wide and 30 meters long. The following statements create a SAS data set named Fabric3, which contains the number of fabric defects for 20 rolls of fabric:

```
data Fabric3;
  input Roll Defects @@;
  datalines;
  1 6 2 9 3 14 4 17
  5 3 6 8 7 9 8 2
  9 14 10 1 11 3 12 5
  13 6 14 9 15 10 16 12
  17 11 18 4 19 9 20 4
  ;
```

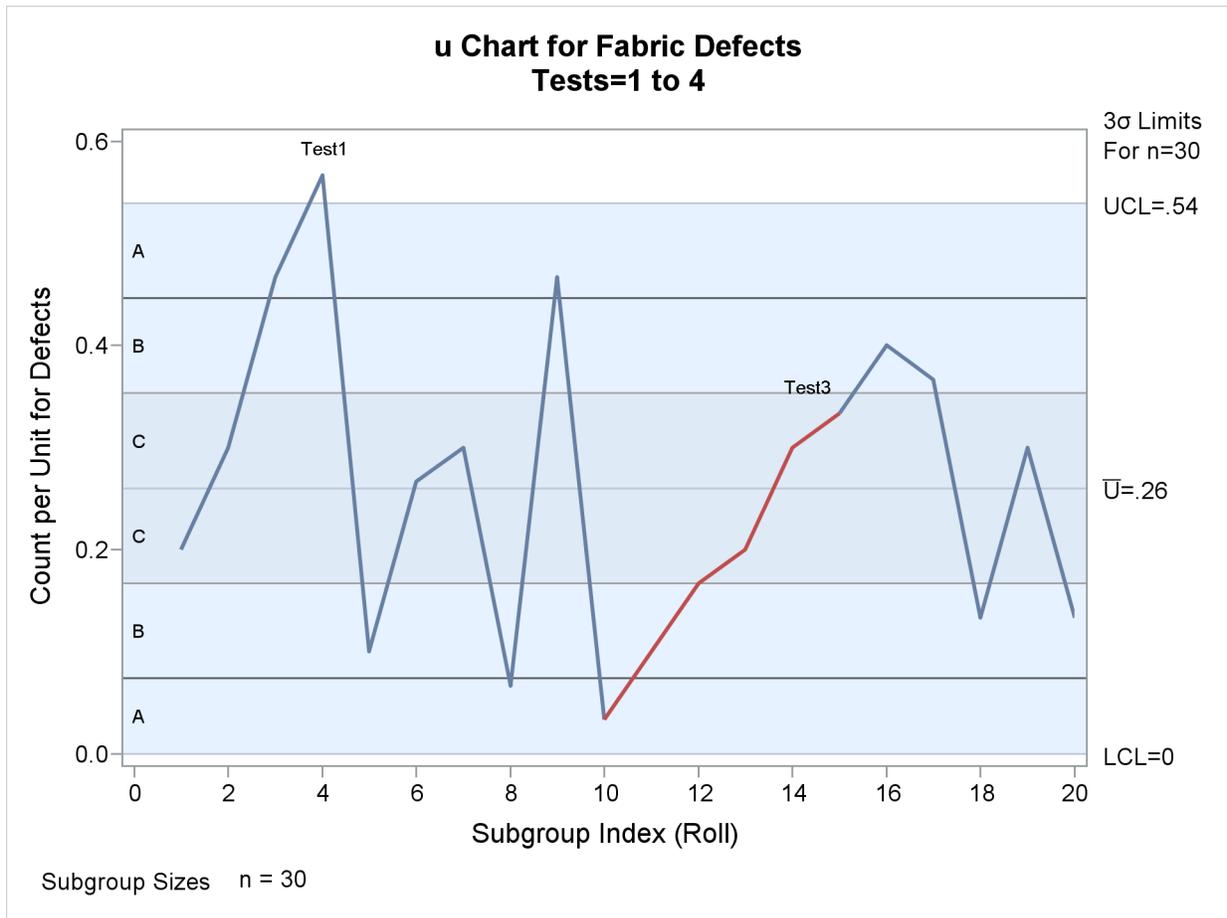

The following statements create a u chart and tabulate the information on the chart. The chart and tables are shown in [Output 17.31.1](#) and [Output 17.31.2](#).

```
ods graphics on;
title1 'u Chart for Fabric Defects';
title2 'Tests=1 to 4';
proc shewhart data=Fabric3;
  uchart Defects*Roll / subgroupn = 30
                    tests      = 1 to 4
                    odstitle   = title
                    odstitle2  = title2
                    tabletests
                    zonelabels;
run;
```

The TESTS= option requests Tests 1, 2, 3, and 4, which are described in “[Tests for Special Causes: SHEWHART Procedure](#)” on page 2146. Only Tests 1, 2, 3, and 4 are recommended for u charts. The ZONELABELS option requests the zone lines, which are used to define the tests, and displays labels for the zones. The TABLETESTS option requests a table of the values of u_i and the control limits, together with a column indicating the subgroups at which the tests are positive.

[Output 17.31.1](#) and [Output 17.31.2](#) indicate that Test 1 is positive for Roll 4 and Test 3 is positive at Roll 15.

Output 17.31.1 Tests for Special Causes Displayed on u Chart

Output 17.31.2 Tabular Form of u Chart

Example 17.32: Specifying a Known Expected Number of Nonconformities

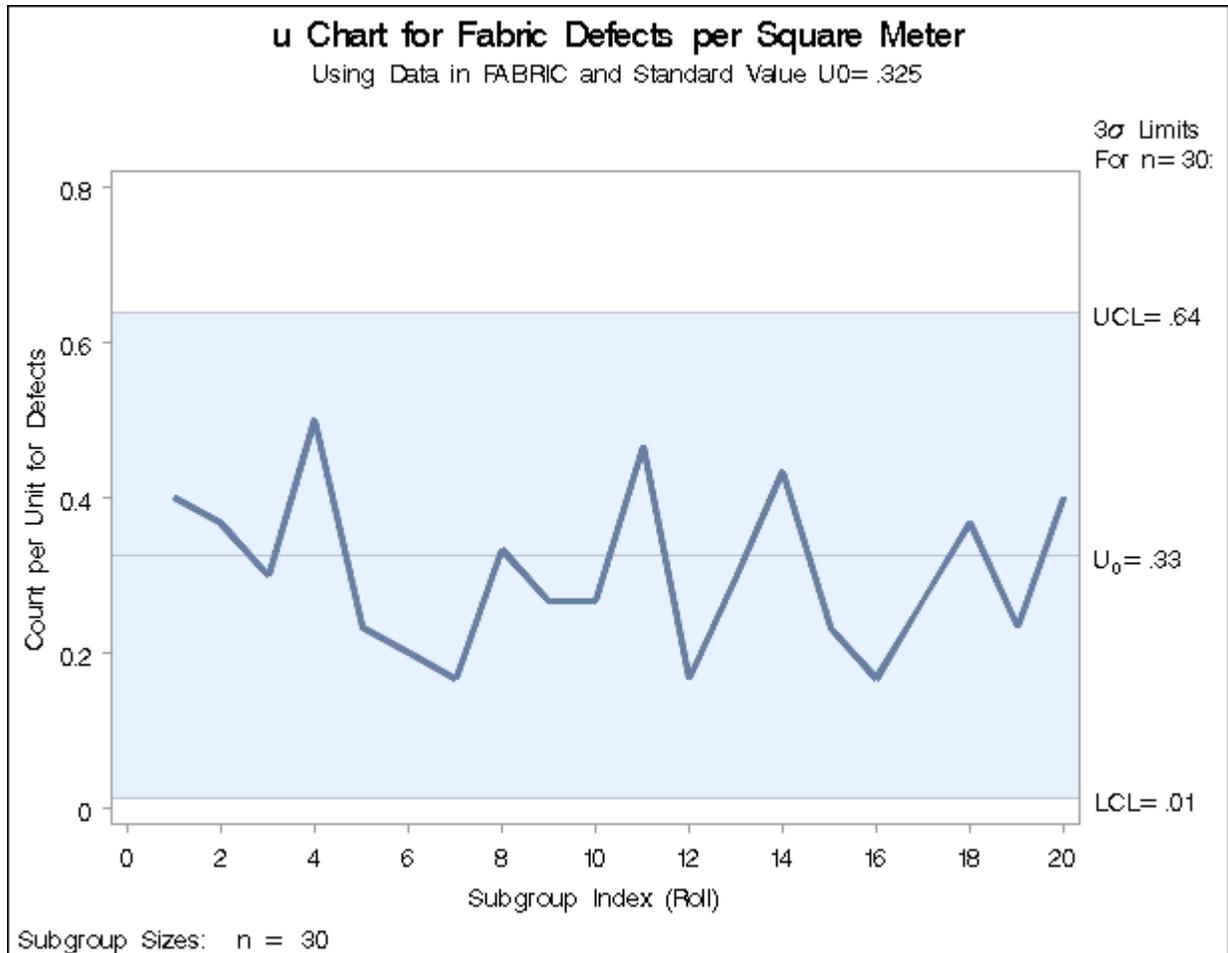

This example illustrates how you can create a u chart based on a known (standard) value u_0 for the expected number of nonconformities per unit. *See SHWUEX2 in the SAS/QC Sample Library*

A u chart is used to monitor the number of defects per square meter of fabric. The defect counts are provided as values of the variable Defects in the data set Fabric (see “Creating u Charts from Defect Count Data” on page 1818). Based on previous testing, it is known that $u_0 = 0.325$. The following statements create a u chart with control limits derived from this value:

```
ods graphics off;
title 'u Chart for Fabric Defects per Square Meter';
title2 'Using Data in FABRIC and Standard Value U0=.325';
proc shewhart data=Fabric;
    uchart Defects*Roll / subgroupn = 30
                u0          = 0.325
                usymbol    = u0;
run;
```

The chart is shown in [Output 17.32.1](#). The `U0=` option specifies u_0 , and the `USYMBOL=` option requests a label for the central line indicating that the line represents a standard value.

Output 17.32.1 A u Chart with Standard Value u_0

Since all the points lie within the control limits, the process is in statistical control.

Alternatively, you can specify u_0 as the value of the variable `_U_` in a `LIMITS=` data set, as follows:

```
data Tlimits;
  length _subgrp_ _var_ _type_ $8;
  _u_     = .325;
  _limitn_ = 30;
  _type_  = 'STANDARD';
  _subgrp_ = 'Roll';
  _var_   = 'Defects';

proc shewhart data=Fabric limits=Tlimits;
  uchart Defects*Roll / subgroupn=30
          usymbol =u0;
run;
```

The chart produced by these statements is identical to the one in [Output 17.32.1](#). For further details, see “LIMITS= Data Set” on page 1845.

Example 17.33: Creating *u* Charts for Varying Numbers of Units

In the fabric manufacturing process described in “Creating *u* Charts from Defect Count Data” on page 1818, each roll of fabric is 30 meters long, and an inspection unit is defined as one square meter. Thus, there are 30 inspection units in each subgroup sample. Suppose now that the length of each piece of fabric varies. The following statements create a SAS data set (Fabrics2) that contains the number of fabric defects and size (in square meters) of 25 pieces of fabric: *See SHWUEX3 in the SAS/QC Sample Library*

```
data Fabrics2;
  input Roll Defects Squaremeters @@;
  datalines;
  1 7 30.0  2 11 27.6  3 15 30.4  4 6 34.8  5 11 26.0
  6 15 28.6  7 5 28.0  8 10 30.2  9 8 28.2  10 3 31.4
  11 3 30.3  12 14 27.8  13 3 27.0  14 9 30.0  15 7 32.1
  16 6 34.8  17 7 26.5  18 5 30.0  19 14 31.3  20 13 31.6
  21 11 29.4  22 6 28.6  23 6 27.5  24 9 32.6  25 11 31.7
  ;
```

A partial listing of Fabrics2 is shown in [Output 17.33.1](#).

Output 17.33.1 The Data Set Fabrics2

Number of Fabric Defects		
Roll	Defects	Squaremeters
1	7	30.0
2	11	27.6
3	15	30.4
4	6	34.8
5	11	26.0

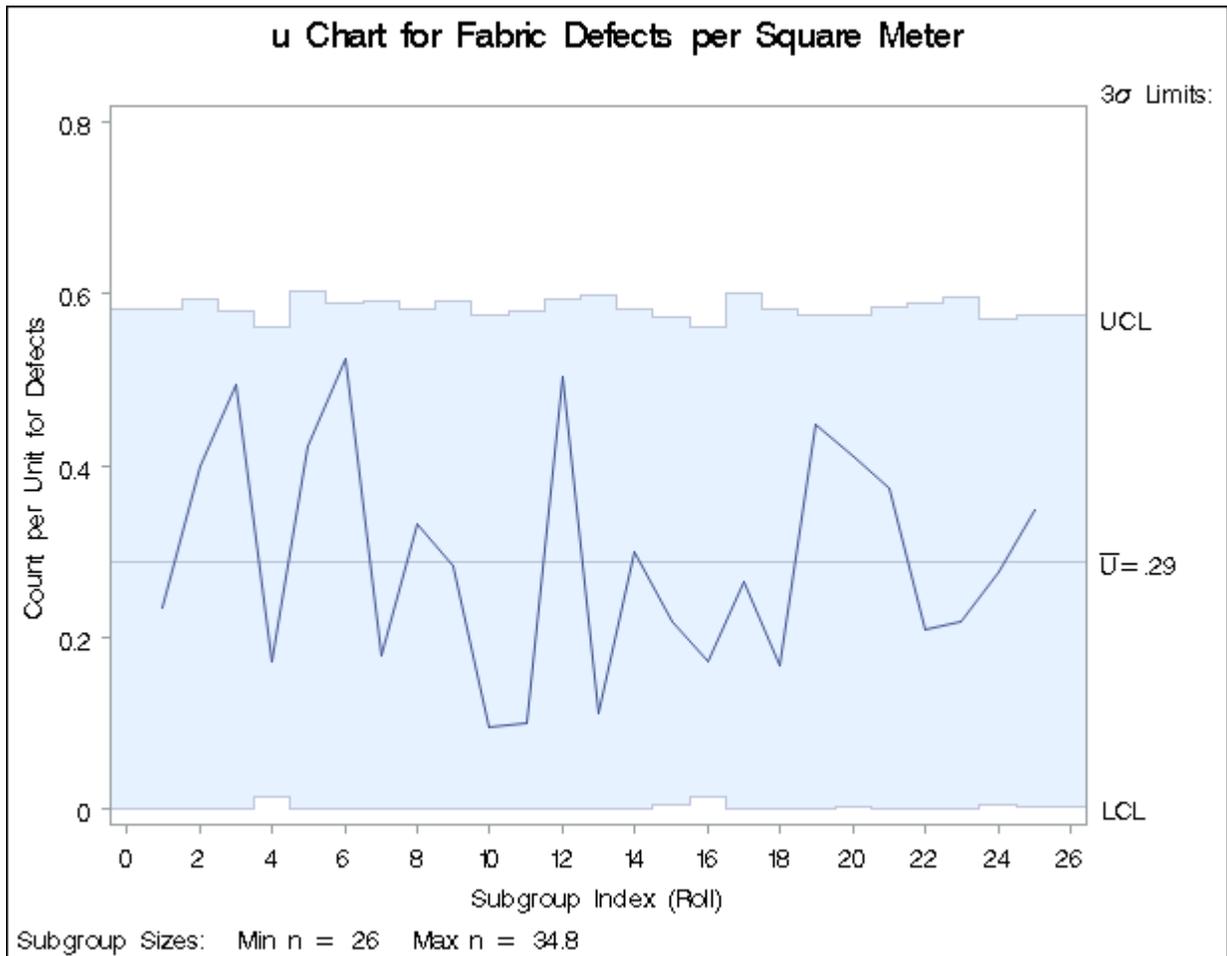

The variable Roll contains the roll number, the variable Defects contains the number of defects in each piece of fabric, and the variable Squaremeters contains the size of each piece.

The following statements request a *u* chart for the number of defects per square meter:

```
ods graphics off;
symbol h=1;
title 'u Chart for Fabric Defects per Square Meter';
proc shewhart data=Fabrics2;
  uchart Defects*Roll / subgroupn = Squaremeters
          outlimits = Fablimits;
run;
```

The *u* chart is shown in [Output 17.33.2](#), and the data set Fablimits is listed in [Output 17.33.3](#).

Output 17.33.2 A u Chart with Varying Number of Units per Subgroup

Note that the control limits vary with the number of units per subgroup (subgroup sample size). The legend in the lower left corner indicates the minimum and maximum subgroup sample sizes.

Output 17.33.3 The Control Limits Data Set Fablimits

Control Limits for Fabric Defects								
VAR	_SUBGRP_	_TYPE_	_LIMITN_	_ALPHA_	_SIGMAS_	_LCLU_	_U_	_UCLU_
Defects	Roll	ESTIMATE	V	V	3	V	0.28805	V

Output 17.33.3 shows that the variables `_LIMITN_`, `_ALPHA_`, `_LCLU_`, and `_UCLU_` have the special missing value `V`, indicating that these variables vary with the sample size.

The following statements request a u chart with a fixed sample size of 30.0 for the control limits. In other words, the control limits are computed as if each piece of fabric were 30 meters long.

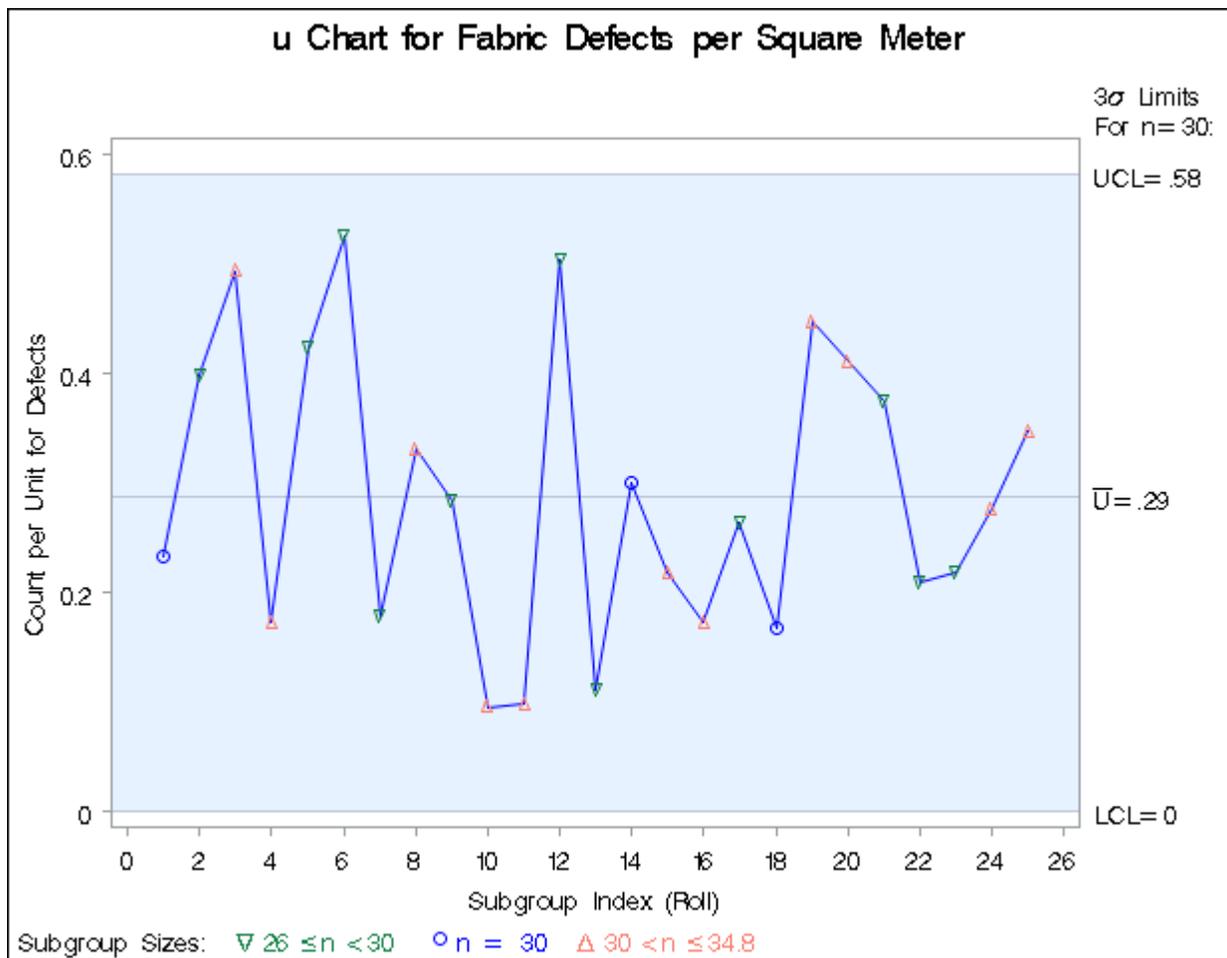

```

symbol1 c=blue v=circle;
symbol2 c=vig;
symbol3 c=salmon;
title 'u Chart for Fabric Defects per Square Meter';
proc shewhart data=Fabrics2;
    uchart Defects*Roll / subgroupn = Squaremeters
                    outlimits = Fablimits2
                    limitn    = 30
                    alln
                    nmarkers;
run;

```

The ALLN option specifies that points are to be displayed for all subgroups, regardless of their sample size. By default, when you specify the LIMITN= option, only points for subgroups whose sample size matches the LIMITN= value are displayed. The NMARKERS option requests special symbols that identify points for which the subgroup sample size differs from the nominal sample size of 30. The chart is shown in [Output 17.33.4](#).

Output 17.33.4 Control Limits Based on Fixed Subgroup Sample Size

In [Output 17.33.4](#), no points lie outside the control limits, indicating that the process is in control. However, you should be careful when interpreting charts that use a nominal sample size, since the fixed control limits based on this value are only an approximation. [Output 17.33.5](#) lists the data set `Fablimits2`, which contains the fixed control limits displayed in [Output 17.33.4](#).

Output 17.33.5 The Fixed Control Limits Data Set `Fablimits2`

Fixed Control Limits for Fabric Defects								
	S		L		S			
	U		I	A	I			
	B	T	M	L	G	L		U
V	G	Y	I	P	M	C		C
A	R	P	T	H	A	L		L
R	P	E	N	A	S	U	U	U
Defects	Roll	ESTIMATE	30	.002621618	3	0	0.28805	0.58201

XCHART Statement: SHEWHART Procedure

Overview: XCHART Statement

The XCHART statement creates an \bar{X} chart for subgroup means, which is used to analyze the central tendency of a process.

You can use options in the XCHART statement to

- compute control limits from the data based on a multiple of the standard error of the plotted means or as probability limits
- tabulate subgroup sample sizes, subgroup means, control limits, and other information
- save control limits in an output data set
- save subgroup sample sizes and subgroup means in an output data set
- read preestablished control limits from a data set
- apply tests for special causes (also known as runs tests and Western Electric rules)
- specify one of several methods for estimating the process standard deviation
- specify whether subgroup standard deviations or subgroup ranges are used to estimate the process standard deviation
- specify a known (standard) process mean and standard deviation for computing control limits

- create a secondary chart that displays a time trend removed from the data (see “[Displaying Trends in Process Data](#)” on page 2126)
- display distinct sets of control limits for data from successive time phases
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the chart more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have three alternatives for producing \bar{X} charts with the XCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “[SAS/QC Graphics](#),” for more information about producing these different kinds of graphs.

NOTE: When working with variables data, you should analyze the variability of the process as well as its central tendency. You can use the XRCHART statement or the XSCHART statement in the SHEWHART procedure for this purpose.

Getting Started: XCHART Statement

This section introduces the XCHART statement with simple examples that illustrate the most commonly used options. Complete syntax for the XCHART statement is presented in the section “[Syntax: XCHART Statement](#)” on page 1870, and advanced examples are given in the section “[Examples: XCHART Statement](#)” on page 1894.

Creating Charts for Means from Raw Data

Subgroup samples of five parts are taken from the manufacturing process at regular intervals, and the width of a critical gap in each part is measured in millimeters. The following statements create a SAS data set named Partgaps, which contains the gap width measurements for 21 samples: *See SHWXCHR in the SAS/QC Sample Library*

```

data Partgaps;
  input Sample @;
  do i=1 to 5;
    input Partgap @;
    output;
  end;
  drop i;
  label Partgap='Gap Width'
        Sample='Sample Index';
  datalines;
1 255 270 268 290 267
2 260 240 265 262 263
3 238 236 260 250 256
4 260 242 281 254 263
5 268 260 279 289 269
6 270 249 265 253 263
7 280 260 256 256 243
8 229 266 250 243 252
9 250 270 245 273 262
10 248 258 247 266 256
11 280 251 252 270 287
12 245 253 243 279 245
13 268 260 289 275 273
14 264 286 275 271 279
15 271 257 263 247 247
16 291 250 273 265 266
17 228 253 240 260 264
18 270 260 269 245 276
19 259 257 246 271 257
20 252 244 230 266 248
21 254 251 239 233 263
;

```

A partial listing of Partgaps is shown in [Figure 17.96](#).

Figure 17.96 Partial Listing of the Data Set Partgaps

The Data Set PARTGAPS	
Sample	Partgap
1	255
1	270
1	268
1	290
1	267
2	260
2	240
2	265
2	262
2	263

The data set `Partgaps` is said to be in “strung-out” form, since each observation contains the sample number and gap width measurement for a single part. The first five observations contain the gap widths for the first sample, the second five observations contain the gap widths for the second sample, and so on. Because the variable `Sample` classifies the observations into rational subgroups, it is referred to as the *subgroup-variable*. The variable `Partgap` contains the gap width measurements and is referred to as the *process variable* (or *process* for short).

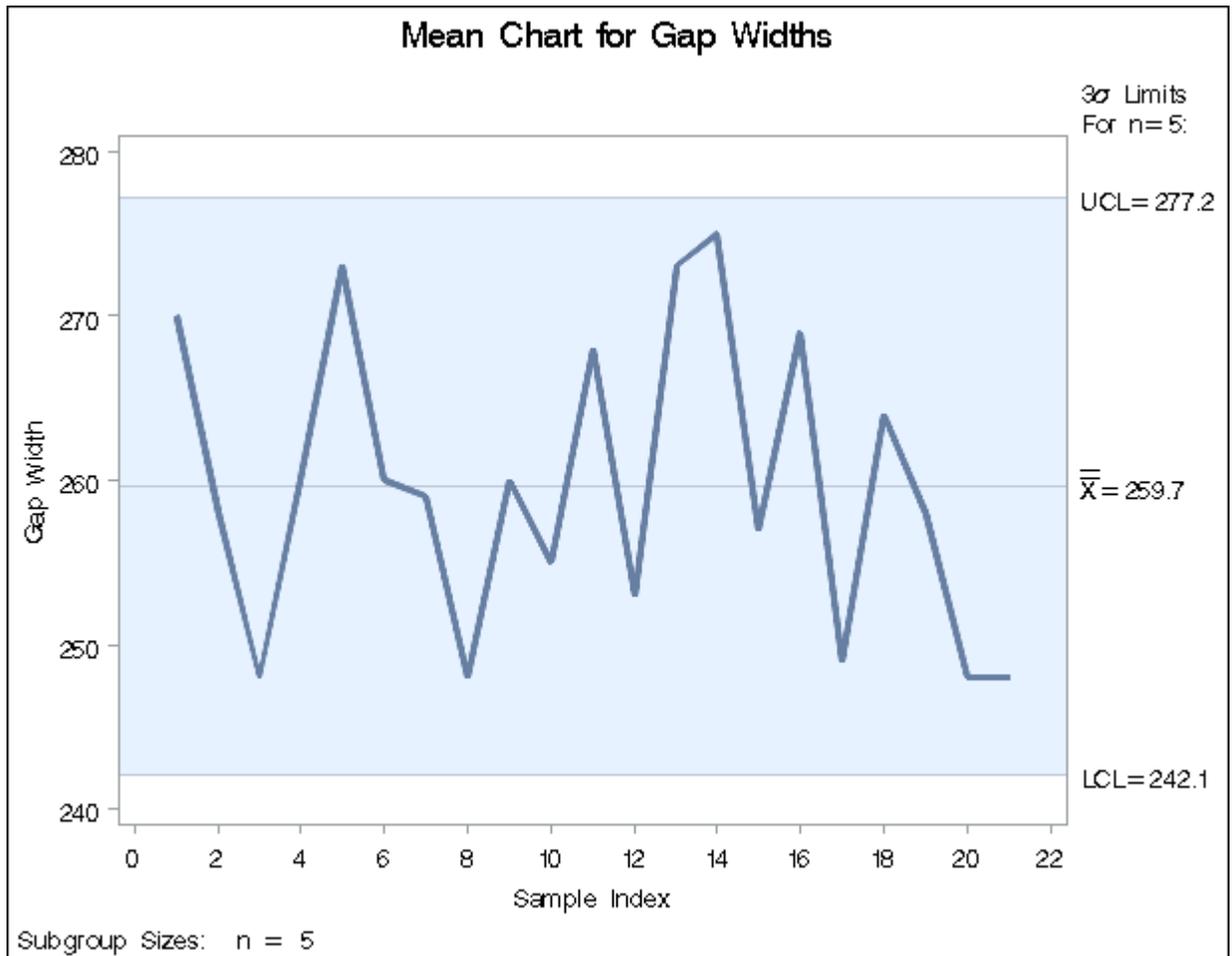

The within-subgroup variability of the gap widths is known to be stable. You can use an \bar{X} chart to determine whether their mean level is in control. The following statements create the \bar{X} chart shown in [Figure 17.97](#):

```
ods graphics off;
title 'Mean Chart for Gap Widths';
proc shewhart data=Partgaps;
  xchart Partgap*Sample;
run;
```

This example illustrates the basic form of the XCHART statement. After the keyword XCHART, you specify the *process* to analyze (in this case, `Partgap`) followed by an asterisk and the *subgroup-variable* (`Sample`). The input data set is specified with the `DATA=` option in the PROC SHEWHART statement.

Each point on the \bar{X} chart represents the average (mean) of the measurements for a particular sample. For instance, the mean plotted for the first sample is

$$\frac{255 + 270 + 268 + 290 + 267}{5} = 270$$

Figure 17.97 \bar{X} Chart for Gap Width Data (Traditional Graphics)

Since all of the subgroup means lie within the control limits, it can be concluded that the mean level of the process is in statistical control.

By default, the control limits shown are 3σ limits estimated from the data; the formulas for the limits are given in Table 17.65. You can also read control limits from an input data set; see “Reading Preestablished Control Limits” on page 1868.

For computational details, see “Constructing Charts for Means” on page 1881. For details on reading raw measurements, see “DATA= Data Set” on page 1887.

Creating Charts for Means from Subgroup Summary Data

See SHWXCHR in the SAS/QC Sample Library

The previous example illustrates how you can create \bar{X} charts using raw data (process measurements). However, in many applications, the data are provided as subgroup summary statistics. This example illustrates how you can use the XCHART statement with data of this type.

The following data set (Parts) provides the data from the preceding example in summarized form:

```

data Parts;
  input Sample PartgapX PartgapR;
  PartgapN=5;
  label PartgapX='Mean of Gap Width'
        Sample  ='Sample Index';
  datalines;
1  270  35
2  258  25
3  248  24
4  260  39
5  273  29
6  260  21
7  259  37
8  248  37
9  260  28
10 255  19
11 268  36
12 253  36
13 273  29
14 275  22
15 257  24
16 269  41
17 249  36
18 264  31
19 258  25
20 248  36
21 248  30
;

```

A partial listing of Parts is shown in [Figure 17.98](#). There is exactly one observation for each subgroup (note that the subgroups are still indexed by Sample). The variable PartgapX contains the subgroup means, the variable PartgapR contains the subgroup ranges, and the variable PartgapN contains the subgroup sample sizes (these are all five).

Figure 17.98 The Summary Data Set Parts

The Data Set PARTS			
Sample	Partgap X	Partgap R	Partgap N
1	270	35	5
2	258	25	5
3	248	24	5
4	260	39	5
5	273	29	5

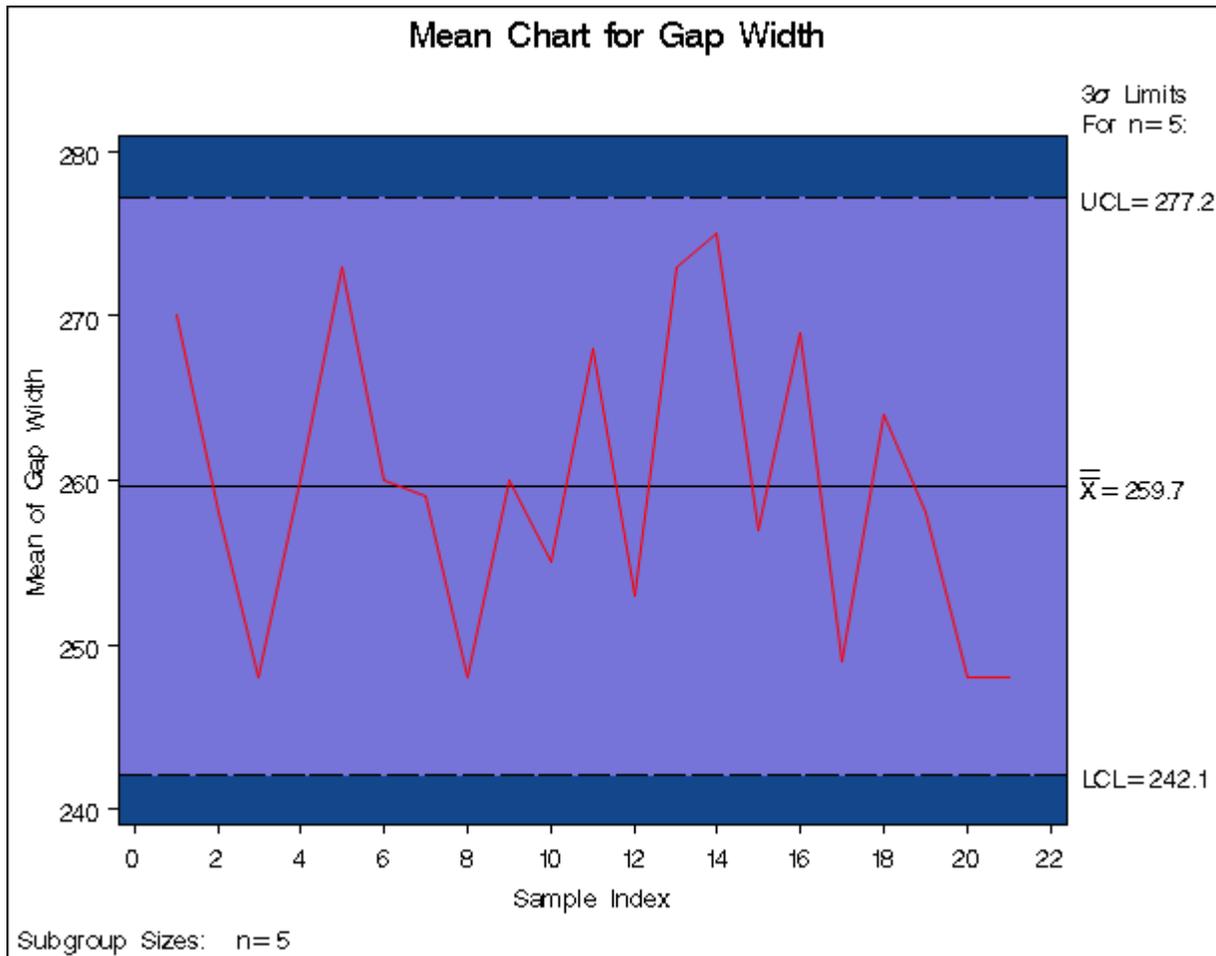

You can read this data set by specifying it as a HISTORY= data set in the PROC SHEWHART statement, as follows:

```
options nogstyle;
options ftext=swiss;
title 'Mean Chart for Gap Width';
proc shewhart history=Parts;
    xchart Partgap*Sample / cframe    = vlgb
                          cinfill   = vlib
                          cconnect  = red;
run;
options gstyle;
```

The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the XCHART statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently. The resulting \bar{X} chart is shown in [Figure 17.99](#).

Note that Partgap is *not* the name of a SAS variable in the data set but is, instead, the common prefix for the names of the three SAS variables PartgapX, PartgapR, and PartgapN. The suffix characters *X*, *R*, and *N* indicate *mean*, *range*, and *sample size*, respectively. Thus, you can specify three subgroup summary variables in a HISTORY= data set with a single name (Partgap), which is referred to as the *process*. The name Sample specified after the asterisk is the name of the *subgroup-variable*.

Figure 17.99 \bar{X} Chart from the Summary Data Set Parts (Traditional Graphics with NOGSTYLE)

In general, a HISTORY= input data set used with the XCHART statement must contain the following variables:

- subgroup variable
- subgroup mean variable
- either a subgroup range variable or a subgroup standard deviation variable
- subgroup sample size variable

Furthermore, the names of the subgroup mean, range (or standard deviation), and sample size variables must begin with the *process* name specified in the XCHART statement and end with the special suffix characters *X*, *R* (or *S*), and *N*, respectively. If the names do not follow this convention, you can use the RENAME option in the PROC SHEWHART statement to rename the variables for the duration of the SHEWHART procedure step (see “Creating Charts for Means and Ranges from Summary Data” on page 1907).

If you specify the STDDEVIATIONS option in the XCHART statement, the HISTORY= data set must contain a subgroup standard deviation variable; otherwise, the HISTORY= data set must contain a subgroup range variable. The STDDEVIATIONS option specifies that the estimate of the process standard deviation σ is to be calculated from subgroup standard deviations rather than subgroup ranges. For example, in the following statements, the data set Parts2 must contain a subgroup standard deviation variable named PartgapS:

```
title 'Mean Chart for Gap Width';
proc shewhart history=Parts2;
  xchart Partgap*Sample='*' / stddeviations;
run;
```

Options such as STDDEVIATIONS are specified after the slash (/) in the XCHART statement. A complete list of options is presented in the section “Syntax: XCHART Statement” on page 1870.

In summary, the interpretation of *process* depends on the input data set.

- If raw data are read using the DATA= option (as in the previous example), *process* is the name of the SAS variable containing the process measurements.
- If summary data are read using the HISTORY= option (as in this example), *process* is the common prefix for the names of the variables containing the summary statistics.

For more information, see “HISTORY= Data Set” on page 1888.

Saving Summary Statistics

See SHWXCHR in the SAS/QC Sample Library

In this example, the XCHART statement is used to create a summary data set that can be read later by the SHEWHART procedure (as in the preceding example). The following statements read measurements from the data set Partgaps and create a summary data set named Gaphist:

```
proc shewhart data=Partgaps;
  xchart Partgap*Sample / outhistory = Gaphist
                        nochart;
run;
```

The OUTHISTORY= option names the output data set, and the NOCHART option suppresses the display of the chart, which would be identical to the chart in Figure 17.97.

Figure 17.100 contains a partial listing of Gaphist.

Figure 17.100 The Summary Data Set Gaphist

Summary Data Set for Gap Widths			
Sample	Partgap X	Partgap R	Partgap N
1	270	35	5
2	258	25	5
3	248	24	5
4	260	39	5
5	273	29	5

There are four variables in the data set Gaphist.

- Sample contains the subgroup index.
- PartgapX contains the subgroup means.
- PartgapR contains the subgroup ranges.
- PartgapN contains the subgroup sample sizes.

Note that the summary statistic variables are named by adding the suffix characters *X*, *R*, and *N* to the *process* Partgap specified in the XCHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as that for HISTORY= data sets.

If you specify the STDDEVIATIONS option, the OUTHISTORY= data set includes a subgroup standard deviation variable rather than a subgroup range variable, as demonstrated by the following statements:

```
proc shewhart data=Partgaps;
  xchart Partgap*Sample / outhistory = Gaphist2
                        stddeviations
                        nochart;
run;
```

Figure 17.101 contains a partial listing of Gaphist2.

Figure 17.101 The Summary Data Set Gaphist2

Summary Data Set with Subgroup Standard Deviations			
Sample	Partgap X	Partgap S	Partgap N
1	270	12.6293	5
2	258	10.2225	5
3	248	10.6771	5
4	260	14.2302	5
5	273	11.2027	5

The variable PartgapS, which contains the subgroup standard deviations, is named by adding the suffix character *S* to the *process* Partgap.

For more information, see “OUTHISTORY= Data Set” on page 1884.

Saving Control Limits

See SHWXCHR in the SAS/QC Sample Library You can save the control limits for an \bar{X} chart in a SAS data set; this enables you to apply the control limits to future data (see “Reading Prestablished Control Limits” on page 1868) or modify the limits with a DATA step program.

The following statements read measurements from the data set Partgaps (see “Creating Charts for Means from Raw Data” on page 1857) and save the control limits displayed in Figure 17.97 in a data set named Gaplim:

```
proc shewhart data=Partgaps;
  xchart Partgap*Sample / outlimits = Gaplim
                        nochart;
run;
```

The OUTLIMITS= option names the data set containing the control limits, and the NOCHART option suppresses the display of the chart. The data set Gaplim is listed in Figure 17.102.

Figure 17.102 The Data Set Gaplim Containing Control Limit Information

Control Limits for Gap Width Measurements						
<u>_VAR_</u>	<u>_SUBGRP_</u>	<u>_TYPE_</u>	<u>_LIMITN_</u>	<u>_ALPHA_</u>	<u>_SIGMAS_</u>	
Partgap	Sample	ESTIMATE	5	.002699796	3	
<u>_LCLX_</u>	<u>_MEAN_</u>	<u>_UCLX_</u>	<u>_LCLR_</u>	<u>_R_</u>	<u>_UCLR_</u>	<u>_STDDEV_</u>
242.087	259.667	277.246	0	30.4762	64.4419	13.1028

The data set Gaplim contains one observation with the limits for *process* Partgap. The variables _LCLX_ and _UCLX_ contain the lower and upper control limits for the means, and the variable _MEAN_ contains the central line. The value of _MEAN_ is an estimate of the process mean, and the value of _STDDEV_ is an estimate of the process standard deviation σ . The value of _LIMITN_ is the nominal sample size associated with the control limits, and the value of _SIGMAS_ is the multiple of σ associated with the control limits. The variables _VAR_ and _SUBGRP_ are bookkeeping variables that save the *process* and *subgroup-variable*. The variable _TYPE_ is a bookkeeping variable that indicates whether the values of _MEAN_ and _STDDEV_ are estimates or standard values.

The variables _LCLR_, _R_, and _UCLR_ are not used to create \bar{X} charts, but they are included so the data set Gaplim can be used to create an *R* chart; see “XRCHART Statement: SHEWHART Procedure” on page 1902. If you specify the STDDEVIATIONS option in the XCHART statement, the variables _LCLS_, _S_, and _UCLS_ are included in the OUTLIMITS= data set. These variables can be used to create an *s* chart; see “XSCHART Statement: SHEWHART Procedure” on page 1955. For more information, see “OUTHISTORY= Data Set” on page 1882.

You can create an output data set containing both control limits and summary statistics with the `OUTTABLE=` option, as illustrated by the following statements:

```
proc shewhart data=Partgaps;
  xchart Partgap*Sample / outtable=Gaptable
    nochart;
run;
```

The data set `Gaptable` is listed in [Figure 17.103](#).

Figure 17.103 The Data Set `Gaptable`

Summary Statistics and Control Limit Information

Partgap	13	3	5	5	242.087	273	259.667	277.246	13.1028	
Partgap	14	3	5	5	242.087	275	259.667	277.246	13.1028	
Partgap	15	3	5	5	242.087	257	259.667	277.246	13.1028	
Partgap	16	3	5	5	242.087	269	259.667	277.246	13.1028	
Partgap	17	3	5	5	242.087	249	259.667	277.246	13.1028	
Partgap	18	3	5	5	242.087	264	259.667	277.246	13.1028	
Partgap	19	3	5	5	242.087	258	259.667	277.246	13.1028	
Partgap	20	3	5	5	242.087	248	259.667	277.246	13.1028	
Partgap	21	3	5	5	242.087	248	259.667	277.246	13.1028	

This data set contains one observation for each subgroup sample. The variables `_SUBX_` and `_SUBN_` contain the subgroup means and sample sizes. The variables `_LCLX_` and `_UCLX_` contain the lower and upper control limits, and the variable `_MEAN_` contains the central line. The variables `_VAR_` and `Sample` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “`OUTTABLE= Data Set`” on page 1885.

An OUTTABLE= data set can be read later as a TABLE= data set. For example, the following statements read Gaptable and display an \bar{X} chart (not shown here) identical to the chart in [Figure 17.97](#):

```
title 'Mean Chart for Gap Widths';
proc shewhart table=Gaptable;
  xchart Partgap*Sample;
  label _SUBX_ = 'Gap Width';
run;
```

Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts (see “[Specialized Control Charts: SHEWHART Procedure](#)” on page 2171).

For more information, see “[TABLE= Data Set](#)” on page 1889.

Reading Prestablished Control Limits

See SHWXCHR in the SAS/QC Sample Library

In the previous example, the OUTLIMITS= data set Gaplim saved control limits computed from the measurements in Partgaps. This example shows how these limits can be applied to new data provided in the following data set:

```
data gaps2;
  input Sample @;
  do i=1 to 5;
    input Partgap @;
    output;
  end;
  drop i;
  datalines;
22 287 265 248 263 271
23 267 253 285 251 271
24 249 252 277 269 241
25 243 248 263 282 261
26 287 266 256 278 242
27 251 262 243 274 245
28 256 245 244 243 272
29 262 247 252 277 266
30 244 269 263 278 261
31 245 264 246 242 273
32 272 257 277 265 241
33 251 249 240 260 261
34 289 277 275 273 261
35 267 286 275 261 272
36 266 256 247 255 241
37 291 267 267 252 262
38 258 245 264 245 281
39 277 267 241 272 244
40 252 267 272 245 252
41 243 241 245 263 248
;
```

The following statements create an \bar{X} chart for the data in GAPS2 using the control limits in Gaplim:

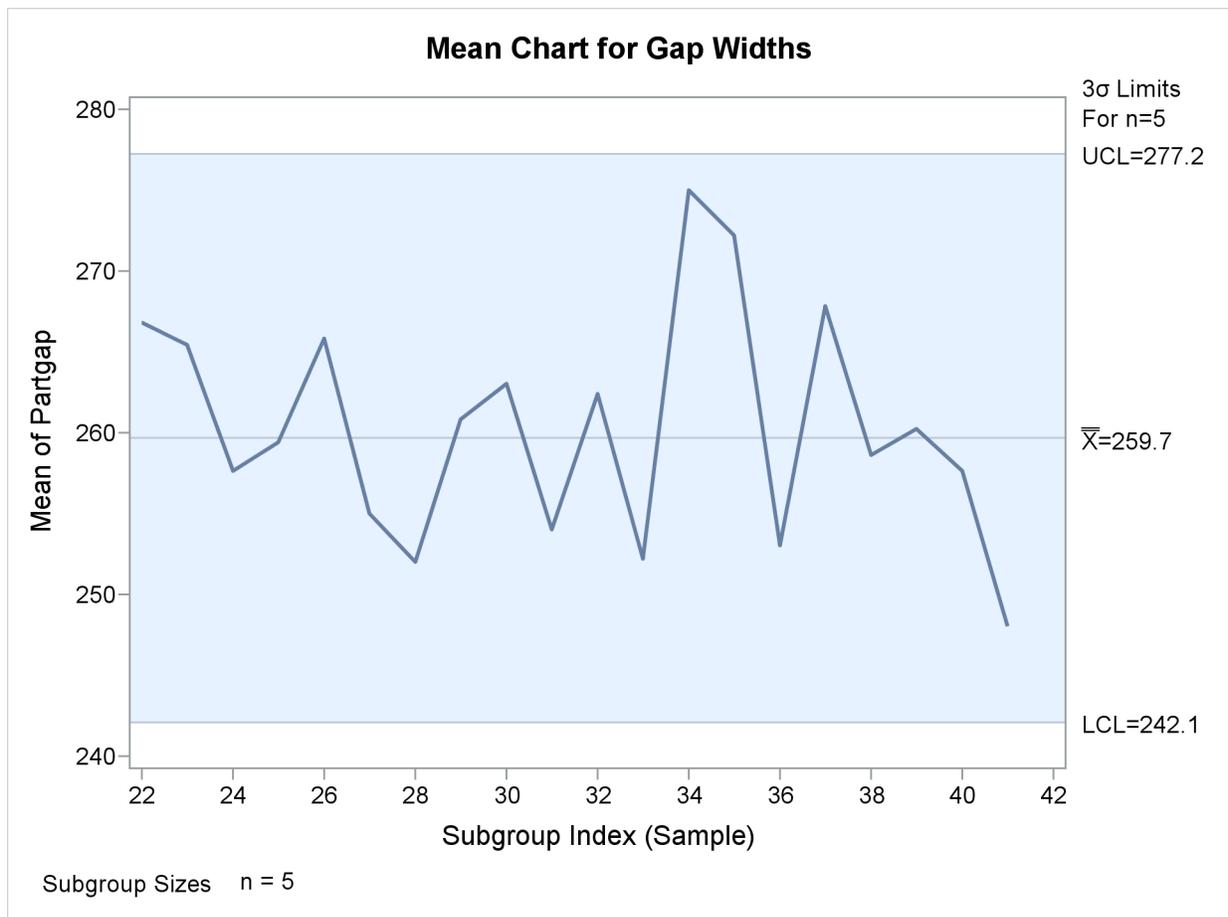

```
ods graphics on;
title 'Mean Chart for Gap Widths';
proc shewhart data=gaps2 limits=Gaplim;
  xchart Partgap*Sample / odstitle=title;
run;
```

The ODS GRAPHICS ON statement specified before the PROC SHEWHART statement enables ODS Graphics, so the \bar{X} chart is created using ODS Graphics instead of traditional graphics. The chart is shown in Figure 17.104.

The LIMITS= option in the PROC SHEWHART statement specifies the data set containing the control limits. By default,³⁵ this information is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches the *process* name Partgap
- the value of `_SUBGRP_` matches the *subgroup-variable* name Sample

Figure 17.104 \bar{X} Chart for Second Set of Gap Width Data (ODS Graphics)

³⁵In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

The chart indicates that the process is in control, since all the means lie within the control limits.

In this example, the LIMITS= data set was created in a previous run of the SHEWHART procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on page 1887 for details concerning the variables that you must provide.

Syntax: XCHART Statement

The basic syntax for the XCHART statement is as follows:

```
XCHART process * subgroup-variable ;
```

The general form of this syntax is as follows:

```
XCHART processes * subgroup-variable <(block-variables)>  
      <=symbol-variable | 'character'> / <options> ;
```

You can use any number of XCHART statements in the SHEWHART procedure. The components of the XCHART statement are described as follows.

process

processes

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC SHEWHART statement.

- If raw data are read from a DATA= data set, *process* must be the name of the variable containing the raw measurements. For an example, see “Creating Charts for Means from Raw Data” on page 1857.
- If summary data are read from a HISTORY= data set, *process* must be the common prefix of the summary variables in the HISTORY= data set. For an example, see “Creating Charts for Means from Subgroup Summary Data” on page 1860.
- If summary data and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “Saving Control Limits” on page 1866.

A *process* is required. If you specify more than one process, enclose the list in parentheses. For example, the following statements request distinct \bar{X} charts for Weight, Length, and Width:

```
proc shewhart data=Measures;  
      xchart (Weight Length Width)*Day;  
run;
```

subgroup-variable

is the variable that identifies subgroups in the data. The *subgroup-variable* is required. In the preceding XCHART statement, Day is the subgroup variable. For details, see “Subgroup Variables” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See the section “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or character used to plot the means.

- If you produce a line printer chart, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOL*n* statements. See the section “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create an \bar{X} chart using an asterisk (*) to plot the points:

```
proc shewhart data=Values lineprinter;
  xchart Weight*Day='*';
run;
```

options

enhance the appearance of the chart, request additional analyses, save results in data sets, and so on. The section “[Summary of Options](#)”, which follows, lists all options by function. “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018 describes each option in detail.

Summary of Options

The following table lists the XCHART statement options by function. For complete descriptions, see “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 17.64 XCHART Statement Options

Option	Description
Options for Specifying Control Limits	
ALPHA=	requests probability limits for chart
LIMITN=	specifies either nominal sample size for fixed control limits or varying limits
NOREADLIMITS	computes control limits for each <i>process</i> from the data rather than a LIMITS= data set (SAS 6.10 and later releases)

Table 17.64 continued

Option	Description
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from a <code>LIMITS=</code> data set
READINDEX=	reads control limits for each <i>process</i> from a <code>LIMITS=</code> data set
READLIMITS	reads single set of control limits for each <i>process</i> from a <code>LIMITS=</code> data set (SAS 6.09 and earlier releases)
SIGMAS=	specifies width of control limits in terms of multiple <i>k</i> of standard error of plotted means
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line
NOCTL	suppresses display of central line
NOLCL	suppresses display of lower control limit
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a <code>LIMITS=</code> data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit
UCLLABEL=	specifies label for upper control limit
WLIMITS=	specifies width for control limits and central line
XSMBOL=	specifies label for central line
Process Mean and Standard Deviation Options	
MU0=	specifies known value of μ_0 for process mean μ
SIGMA0=	specifies known value σ_0 for process standard deviation σ
SMETHOD=	specifies method for estimating process standard deviation σ
STDDEVIATIONS	specifies that estimate of process standard deviation σ is to be calculated from subgroup standard deviations
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the <code>OUTLIMITS=</code> data set
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on \bar{X} chart
ALLLABEL2=	labels every point on trend chart

Table 17.64 *continued*

Option	Description
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
NOTRENDCONNECT	suppresses line segments that connect points on trend chart
OUTLABEL=	labels points outside control limits
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles
Options for Specifying Tests for Special Causes	
INDEPENDENTZONES	computes zone widths independently above and below center line
NO3SIGMACHECK	enables tests to be applied with control limits other than 3σ limits
NOTESTACROSS	suppresses tests across <i>phase</i> boundaries
TESTS=	specifies tests for special causes
TEST2RUN=	specifies length of pattern for Test 2
TEST3RUN=	specifies length of pattern for Test 3
TESTACROSS	applies tests across <i>phase</i> boundaries
TESTLABEL=	provides labels for points where test is positive
TESTLABEL n =	specifies label for n th test for special causes
TESTNMETHOD=	applies tests to standardized chart statistics
TESTOVERLAP	performs tests on overlapping patterns of points
TESTRESET=	enables tests for special causes to be reset
ZONELABELS	adds labels A, B, and C to zone lines
ZONES	adds lines delineating zones A, B, and C
ZONEVALPOS=	specifies position of ZONEVALUES labels
ZONEVALUES	labels zone lines with their values

Table 17.64 *continued*

Option	Description
Options for Displaying Tests for Special Causes	
CTESTLABBOX=	specifies color for boxes enclosing labels indicating points where test is positive
CTESTS=	specifies color for labels indicating points where test is positive
CTESTSYMBOL=	specifies color for symbol used to plot points where test is positive
CZONES=	specifies color for lines and labels delineating zones A, B, and C
LTESTS=	specifies type of line connecting points where test is positive
LZONES=	specifies line type for lines delineating zones A, B, and C
TESTFONT=	specifies software font for labels at points where test is positive
TESTHEIGHT=	specifies height of labels at points where test is positive
TESTLABBOX	requests that labels for points where test is positive be positioned so that do not overlap
TESTSYMBOL=	specifies plot symbol for points where test is positive
TESTSYMBOLHT=	specifies symbol height for points where test is positive
WTESTS=	specifies width of line connecting points where test is positive
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPHLABELS=	specifies thinning factor for tick mark labels on horizontal axis
SPLIT=	specifies splitting character for axis labels
TURNHLABELS	requests horizontal axis labels that are strung out vertically

Table 17.64 *continued*

Option	Description
VAXIS=	specifies major tick mark values for vertical axis of \bar{X} chart
VAXIS2=	specifies major tick mark values for vertical axis of trend chart
VFORMAT=	specifies format for primary vertical axis tick mark labels
VFORMAT2=	specifies format for secondary vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis for primary chart
VZERO2	forces origin to be included in vertical axis for secondary chart
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
TOTPANELS=	specifies number of pages or screens to be used to display chart
TRENDVAR=	specifies list of trend variables
YPCT1=	specifies length of vertical axis on \bar{X} chart as a percentage of sum of lengths of vertical axes for \bar{X} and trend charts
ZEROSTD	displays \bar{X} chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= and HREF2= options

Table 17.64 *continued*

Option	Description
CVREF=	specifies color for lines requested by VREF= and VREF2= options
HREF=	specifies position of reference lines perpendicular to horizontal axis on \bar{X} chart
HREF2=	specifies position of reference lines perpendicular to horizontal axis on trend chart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on \bar{X} chart
HREF2DATA=	specifies position of reference lines perpendicular to horizontal axis on trend chart
HREFLABELS=	specifies labels for HREF= lines
HREF2LABELS=	specifies labels for HREF2= lines
HREFLABPOS=	specifies position of HREFLABELS= and HREF2LABELS= labels
LHREF=	specifies line type for HREF= and HREF2= lines
LVREF=	specifies line type for VREF= and VREF2= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis on \bar{X} chart
VREF2=	specifies position of reference lines perpendicular to vertical axis on trend chart
VREFLABELS=	specifies labels for VREF= lines
VREF2LABELS=	specifies labels for VREF2= lines
VREFLABPOS=	position of VREFLABELS= and VREF2LABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points

Table 17.64 *continued*

Option	Description
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to \bar{X} chart
ANNOTATE2=	specifies annotate data set that adds features to trend chart
DESCRIPTION=	specifies description of \bar{X} chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of \bar{X} chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
WTREND=	specifies width of line segments connecting points on trend chart
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data

Table 17.64 *continued*

Option	Description
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
OVERLAY2URL=	specifies URLs to associate with overlay points on secondary chart
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
URL2=	specifies a variable whose values are URLs to be associated with subgroups on secondary chart
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLELEGEND	augments basic table with legend for tests for special causes
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
TABLETESTS	augments basic table with a column indicating which tests for special causes are positive

Table 17.64 *continued*

Option	Description
Specification Limit Options	
CIINDICES	specifies α value and type for computing capability index confidence limits
LSL=	specifies list of lower specification limits
TARGET=	specifies list of target values
USL=	specifies list of upper specification limits
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars

Table 17.64 *continued*

Option	Description
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star
STARVERTICES=	superimposes star at each point on \bar{X} chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for primary chart overlay line segments
CCOVERLAY2=	specifies colors for secondary chart overlay line segments
COVERLAY=	specifies colors for primary chart overlay plots
COVERLAY2=	specifies colors for secondary chart overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for primary chart overlay line segments
LOVERLAY2=	specifies line types for secondary chart overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on primary chart
OVERLAY2=	specifies variables to overlay on secondary chart
OVERLAY2HTML=	specifies links to associate with secondary chart overlay points
OVERLAY2ID=	specifies labels for secondary chart overlay points
OVERLAY2SYM=	specifies symbols for secondary chart overlays
OVERLAY2SYMHT=	specifies symbol heights for secondary chart overlays
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with primary chart overlay points
OVERLAYID=	specifies labels for primary chart overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for primary chart overlays
OVERLAYSYMHT=	specifies symbol heights for primary chart overlays
WCOVERLAY=	specifies widths of primary chart overlay line segments
WCOVERLAY2=	specifies widths of secondary chart overlay line segments
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML2=	specifies variable whose values create links to be associated with subgroups on secondary chart
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data

Table 17.64 *continued*

Option	Description
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= and HREF2= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
TESTCHAR=	specifies character for line segments that connect any sequence of points for which a test for special causes is positive
VREFCHAR=	specifies line character for VREF= and VREF2= lines
ZONECHAR=	specifies character for lines that delineate zones for tests for special causes

Details: XCHART Statement

Constructing Charts for Means

The following notation is used in this section:

μ	process mean (expected value of the population of measurements)
σ	process standard deviation (standard deviation of the population of measurements)
\bar{X}_i	mean of measurements in <i>i</i> th subgroup
R_i	range of measurements in <i>i</i> th subgroup
n_i	sample size of <i>i</i> th subgroup
N	number of subgroups
$\bar{\bar{X}}$	weighted average of subgroup means
z_p	100 <i>p</i> th percentile of the standard normal distribution

Plotted Points

Each point on an \bar{X} chart indicates the value of a subgroup mean (\bar{X}_i). For example, if the tenth subgroup contains the values 12, 15, 19, 16, and 14, the value plotted for this subgroup is

$$\bar{X}_{10} = \frac{12 + 15 + 19 + 16 + 14}{5} = 15.2$$

Central Line

By default, the central line on an \bar{X} chart indicates an estimate for μ , which is computed as

$$\hat{\mu} = \bar{\bar{X}} = \frac{n_1 \bar{X}_1 + \cdots + n_N \bar{X}_N}{n_1 + \cdots + n_N}$$

If you specify a known value (μ_0) for μ , the central line indicates the value of μ_0 .

Control Limits

You can compute the limits in the following ways:

- as a specified multiple (k) of the standard error of \bar{X}_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that \bar{X}_i exceeds the limits

The following table provides the formulas for the limits:

Table 17.65 Limits for \bar{X} Charts

Control Limits
$\text{LCL} = \text{lower limit} = \bar{\bar{X}} - k\hat{\sigma} / \sqrt{n_i}$ $\text{UCL} = \text{upper limit} = \bar{\bar{X}} + k\hat{\sigma} / \sqrt{n_i}$
Probability Limits
$\text{LCL} = \text{lower limit} = \bar{\bar{X}} - z_{\alpha/2}(\hat{\sigma} / \sqrt{n_i})$ $\text{UCL} = \text{upper limit} = \bar{\bar{X}} + z_{\alpha/2}(\hat{\sigma} / \sqrt{n_i})$

Note that the limits vary with n_i . If standard values μ_0 and σ_0 are available for μ and σ , respectively, replace $\bar{\bar{X}}$ with μ_0 and $\hat{\sigma}$ with σ_0 in Table 17.65.

You can specify parameters for the limits as follows:

- Specify k with the SIGMAS= option or with the variable _SIGMAS_ in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable _ALPHA_ in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable _LIMITN_ in a LIMITS= data set.
- Specify μ_0 with the MU0= option or with the variable _MEAN_ in a LIMITS= data set.
- Specify σ_0 with the SIGMA0= option or with the variable _STDDEV_ in a LIMITS= data set.

Output Data Sets**OUTLIMITS= Data Set**

The OUTLIMITS= data set saves control limits and control limit parameters. The following variables can be saved:

Table 17.66 OUTLIMITS= Data Set

Variable	Description
ALPHA	probability (α) of exceeding limits
CP	capability index C_p
CPK	capability index C_{pk}
CPL	capability index C_{PL}
CPM	capability index C_{pm}
CPU	capability index C_{PU}
INDEX	optional identifier for the control limits specified with the OUTIN- DEX= option
LCLR	lower control limit for subgroup range
LCLS	lower control limit for subgroup standard deviation
LCLX	lower control limit for subgroup mean
LIMITN	sample size associated with the control limits
LSL	lower specification limit
MEAN	process mean (\bar{X} or μ_0)
R	value of central line on R chart
S	value of central line on s chart
SIGMAS	multiple (k) of standard error of \bar{X}_i
STDDEV	process standard deviation ($\hat{\sigma}$ or σ_0)
SUBGRP	<i>subgroup-variable</i> specified in the XCHART statement
TARGET	target value
TYPE	type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLR	upper control limit for subgroup range
UCLS	upper control limit for subgroup standard deviation
UCLX	upper control limit for subgroup mean
USL	upper specification limit
VAR	<i>process</i> specified in the XCHART statement

Notes:

1. The variables _LCLS_, _S_, and _UCLS_ are included if you specify the STDDEVIATIONS option; otherwise, the variables _LCLR_, _R_, and _UCLR_ are included. These variables are not used to create \bar{X} charts, but they enable the OUTLIMITS= data set to be used as a LIMITS= data set with the BOXCHART, MRCHART, RCHART, SCHART, XRCHART, and XSCHART statements.
2. If the control limits vary with subgroup sample size, the special missing value 'V' is assigned to the variables _LIMITN_, _LCLX_, _UCLX_, _LCLR_, _R_, _UCLR_, _LCLS_, _S_, and _UCLS_.
3. If the limits are defined in terms of a multiple k of the standard error of \bar{X}_i , the value of _ALPHA_ is computed as $\alpha = 2(1 - \Phi(k))$, where $\Phi(\cdot)$ is the standard normal distribution function.
4. If the limits are probability limits, the value of _SIGMAS_ is computed as $k = \Phi^{-1}(1 - \alpha/2)$, where Φ^{-1} is the inverse standard normal distribution function.

5. The variables `_CP_`, `_CPK_`, `_CPL_`, `_CPU_`, `_LSL_`, and `_USL_` are included only if you provide specification limits with the `LSL=` and `USL=` options. The variables `_CPM_` and `_TARGET_` are included if, in addition, you provide a target value with the `TARGET=` option. See “[Capability Indices](#)” on page 1941 for computational details.
6. Optional BY variables are saved in the `OUTLIMITS=` data set.

The `OUTLIMITS=` data set contains one observation for each *process* specified in the `XCHART` statement. For an example, see “[Saving Control Limits](#)” on page 1866.

OUTHISTORY= Data Set

The `OUTHISTORY=` data set saves subgroup summary statistics. The following variables can be saved:

- the *subgroup-variable*
- a subgroup mean variable named by *process* suffixed with *X*
- a subgroup sample size variable named by *process* suffixed with *N*
- a subgroup range variable named by *process* suffixed with *R*
- a subgroup standard deviation variable named by *process* suffixed with *S*

A subgroup standard deviation variable is included if you specify the `STDDEVIATIONS` option; otherwise, a subgroup range variable is included.

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Subgroup summary variables are created for each *process* specified in the `XCHART` statement. For example, consider the following statements:

```
proc shewhart data=Steel;
  xchart (Width Diameter)*Lot / outhistory=Summary;
run;
```

The data set `Summary` contains variables named `Lot`, `WidthX`, `WidthR`, `WidthN`, `DiameterX`, `DiameterR`, and `DiameterN`. The variables `WidthR` and `DiameterR` are included, since the `STDDEVIATIONS` option is not specified. If you specified the `STDDEVIATIONS` option, the data set `Summary` would contain the variables `WidthS` and `DiameterS` rather than `WidthR` and `DiameterR`.

Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the `OUTPHASE=` option is specified)

For an example of an `OUTHISTORY=` data set, see “Saving Summary Statistics” on page 1864.

OUTTABLE= Data Set

The `OUTTABLE=` data set saves subgroup summary statistics, control limits, and related information. The following variables can be saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_EXLIM_</code>	control limit exceeded on \bar{X} chart
<code>_LCLX_</code>	lower control limit for mean
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_MEAN_</code>	process mean
<code>_SIGMAS_</code>	multiple (k) of the standard error associated with control limits
<code>subgroup</code>	values of the subgroup variable
<code>_SUBN_</code>	subgroup sample size
<code>_SUBX_</code>	subgroup mean
<code>_TESTS_</code>	tests for special causes signaled on \bar{X} chart
<code>_UCLX_</code>	upper control limit for mean
<code>_VAR_</code>	<i>process</i> specified in the XCHART statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the `READPHASES=` option is specified)
- `_TREND_` (if the `TRENDVAR=` option is specified)

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved, depending on how the control limits are defined (with the `ALPHA=` or `SIGMAS=` option, respectively, or with the corresponding variables in a `LIMITS=` data set).
2. The variable `_TESTS_` is saved if you specify the `TESTS=` option. The k th character of a value of `_TESTS_` is k if Test k is positive at that subgroup. For example, if you request all eight tests and Tests 2 and 8 are positive for a given subgroup, the value of `_TESTS_` has a 2 for the second character, an 8 for the eighth character, and blanks for the other six characters.
3. The variables `_EXLIM_` and `_TESTS_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “[Saving Control Limits](#)” on page 1866.

ODS Tables

The following table summarizes the ODS tables that you can request with the XCHART statement.

Table 17.67 ODS Tables Produced with the XCHART Statement

Table Name	Description	Options
XCHART	\bar{X} chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLELEG, TABLEOUT, TABLETESTS
TestDescriptions	descriptions of tests for special causes requested with the <code>TESTS=</code> option for which at least one positive signal is found	TABLEALL, TABLELEG

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the `ODS GRAPHICS ON` statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the SHEWHART procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. XCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the XCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 17.68](#).

Table 17.68 ODS Graphics Produced by the XCHART Statement

ODS Graph Name	Plot Description
XChart	\bar{X} chart

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (process measurements) from a DATA= data set specified in the PROC SHEWHART statement. Each *process* specified in the XCHART statement must be a SAS variable in the DATA= data set. This variable provides measurements that must be grouped into subgroup samples indexed by the *subgroup-variable*. The *subgroup-variable*, which is specified in the XCHART statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a value for each *process* and a value for the *subgroup-variable*. If the *i*th subgroup contains n_i items, there should be n_i consecutive observations for which the value of the *subgroup-variable* is the index of the *i*th subgroup. For example, if each subgroup contains five items and there are 30 subgroup samples, the DATA= data set should contain 150 observations.

Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a DATA= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) with the READPHASES= option (for an example, see the section “[Displaying Stratification in Phases](#)” on page 2103).

For an example of a DATA= data set, see “[Creating Charts for Means from Raw Data](#)” on page 1857.

LIMITS= Data Set

You can read preestablished control limits (or parameters from which the control limits can be calculated) from a LIMITS= data set specified in the PROC SHEWHART statement. For example, the following statements read control limit information from the data set `Conlims`:³⁶

³⁶In SAS 6.09 and in earlier releases, it is necessary to specify the READLIMITS option.

```
proc shewhart data=Info limits=Conlims;
  xchart Weight*Batch;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the SHEWHART procedure. Such data sets always contain the variables required for a LIMITS= data set; see Table 17.66. The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LCLX_`, `_MEAN_`, and `_UCLX_`, which specify the control limits directly
- the variables `_MEAN_` and `_STDDEV_`, which are used to calculate the control limits according to the equations in Table 17.65

In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables whose lengths are no greater than 32.
- The variable `_INDEX_` is required if you specify the `READINDEX=` option; this must be a character variable whose length is no greater than 48.
- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8; valid values are 'ESTIMATE', 'STANDARD', 'STDMU', and 'STDSIGMA'.
- BY variables are required if specified with a BY statement.

For an example, see “Reading Preestablished Control Limits” on page 1868.

HISTORY= Data Set

You can read subgroup summary statistics from a HISTORY= data set specified in the PROC SHEWHART statement. This enables you to reuse OUTHISTORY= data sets that have been created in previous runs of the SHEWHART, CUSUM, or MACONTROL procedures or to read output data sets created with SAS summarization procedures, such as the MEANS procedure.

A HISTORY= data set used with the XCHART statement must contain the following:

- the *subgroup-variable*
- a subgroup mean variable for each *process*
- a subgroup sample size variable for each *process*
- either a subgroup range variable or subgroup standard deviation variable for each *process*

If you specify the STDDEVIATIONS option, the subgroup standard deviation variable must be included; otherwise, the subgroup range variable must be included.

The names of the subgroup mean, subgroup range or subgroup standard deviation, and subgroup sample size variables must be the *process* name concatenated with the suffix characters *X*, *R* or *S*, and *N*, respectively.

For example, consider the following statements:

```
proc shewhart history=Summary;
    xchart (Weight Yieldstrength)*Batch;
run;
```

The data set Summary must include the variables Batch, WeightX, WeightR, WeightN, YieldstrengthX, YieldstrengthR, and YieldstrengthN. If the STDDEVIATIONS option were specified in the preceding XCHART statement, it would be necessary for Summary to include the variables Batch, WeightX, WeightS, WeightN, YieldstrengthX, YieldstrengthS, and YieldstrengthN.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a HISTORY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a HISTORY= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (see the section “[Displaying Stratification in Phases](#)” on page 2103 for an example).

For an example of a HISTORY= data set, see “[Creating Charts for Means from Subgroup Summary Data](#)” on page 1860.

TABLE= Data Set

You can read summary statistics and control limits from a TABLE= data set specified in the PROC SHEWHART statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the SHEWHART procedure. Because the SHEWHART procedure simply displays the information in a TABLE= data set, you can use TABLE= data sets to create specialized control charts. Examples are provided in “[Specialized Control Charts: SHEWHART Procedure](#)” on page 2171.

The following table lists the variables required in a TABLE= data set used with the XCHART statement:

Table 17.69 Variables Required in a TABLE= Data Set

Variable	Description
LCLX	lower control limit for mean
LIMITN	nominal sample size associated with the control limits
MEAN	process mean
<i>subgroup-variable</i>	values of the <i>subgroup-variable</i>
SUBN	subgroup sample size
SUBX	subgroup mean
UCLX	upper control limit for mean

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- _PHASE_ (if the READPHASES= option is specified). This variable must be a character variable whose length is no greater than 48.
- _TESTS_ (if the TESTS= option is specified). This variable is used to flag tests for special causes and must be a character variable of length 8.
- _VAR_. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable whose length is no greater than 32.

For an example of a TABLE= data set, see “Saving Control Limits” on page 1866.

Methods for Estimating the Standard Deviation

When control limits are computed from the input data, three methods (referred to as default, MVLUE, and RMSDF) are available for estimating the process standard deviation σ . The method depends on whether you specify the STDDEVIATIONS option. If you specify this option, σ is estimated using subgroup standard deviations; otherwise, σ is estimated using subgroup ranges.

For an illustration of the methods, see [Example 17.35](#).

Default Method Based on Subgroup Ranges

If you do not specify the STDDEVIATIONS option, the default estimate for σ is

$$\hat{\sigma} = \frac{R_1/d_2(n_1) + \cdots + R_N/d_2(n_N)}{N}$$

where N is the number of subgroups for which $n_i \geq 2$, and R_i is the sample range of the observations x_{i1}, \dots, x_{in_i} in the i th subgroup.

$$R_i = \max_{1 \leq j \leq n_i} (x_{ij}) - \min_{1 \leq j \leq n_i} (x_{ij})$$

A subgroup range R_i is included in the calculation only if $n_i \geq 2$. The unbiasing factor $d_2(n_i)$ is defined so that, if the observations are normally distributed, the expected value of R_i is $d_2(n_i)\sigma$. Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ . This method is described in the American Society for Testing and Materials (1976).

Default Method Based on Subgroup Standard Deviations

If you specify the STDDEVIATIONS option, the default estimate for σ is

$$\hat{\sigma} = \frac{s_1/c_4(n_1) + \dots + s_N/c_4(n_N)}{N}$$

where N is the number of subgroups for which $n_i \geq 2$, s_i is the sample standard deviation of the i th subgroup

$$s_i = \sqrt{\frac{1}{n_i - 1} \sum_{j=1}^{n_i} (x_{ij} - \bar{X}_i)^2}$$

and

$$c_4(n_i) = \frac{\Gamma(n_i/2)\sqrt{2/(n_i - 1)}}{\Gamma((n_i - 1)/2)}$$

Here $\Gamma(\cdot)$ denotes the gamma function, and \bar{X}_i denotes the i th subgroup mean. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$. If the observations are normally distributed, the expected value of s_i is $c_4(n_i)\sigma$. Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ . This method is described in the American Society for Testing and Materials (1976).

MVLUE Method Based on Subgroup Ranges

If you do not specify the STDDEVIATIONS option and you specify SMETHOD=MVLUE, a minimum variance linear unbiased estimate (MVLUE) is computed for σ . Refer to Burr (1969, 1976) and Nelson (1989, 1994). The MVLUE is a weighted average of N unbiased estimates of σ of the form $R_i/d_2(n_i)$, and it is computed as

$$\hat{\sigma} = \frac{f_1 R_1/d_2(n_1) + \dots + f_N R_N/d_2(n_N)}{f_1 + \dots + f_N}$$

where

$$f_i = \frac{[d_2(n_i)]^2}{[d_3(n_i)]^2}$$

A subgroup range R_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$. The unbiasing factor $d_3(n_i)$ is defined so that, if the observations are normally distributed, the expected value of σ_{R_i} is $d_3(n_i)\sigma$. The MVLUE assigns greater weight to estimates of σ from subgroups with larger sample sizes, and it is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the MVLUE reduces to the default estimate.

MVLUE Method Based on Subgroup Standard Deviations

If you specify the STDDEVIATIONS option and SMETHOD=MVLUE, a minimum variance linear unbiased estimate (MVLUE) is computed for σ . Refer to Burr (1969, 1976) and Nelson (1989, 1994). This estimate is a weighted average of N unbiased estimates of σ of the form $s_i/c_4(n_i)$, and it is computed as

$$\hat{\sigma} = \frac{h_1 s_1 / c_4(n_1) + \cdots + h_N s_N / c_4(n_N)}{h_1 + \cdots + h_N}$$

where

$$h_i = \frac{[c_4(n_i)]^2}{1 - [c_4(n_i)]^2}$$

A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$. The MVLUE assigns greater weight to estimates of σ from subgroups with larger sample sizes, and it is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the MVLUE reduces to the default estimate.

RMSDF Method Based on Subgroup Standard Deviations

If you specify the STDDEVIATIONS option and SMETHOD=RMSDF, a weighted root-mean-square estimate is computed for σ .

$$\hat{\sigma} = \frac{\sqrt{(n_1 - 1)s_1^2 + \cdots + (n_N - 1)s_N^2}}{c_4(n) \sqrt{n_1 + \cdots + n_N - N}}$$

The weights are the degrees of freedom $n_i - 1$. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$.

If the unknown standard deviation σ is constant across subgroups, the root-mean-square estimate is more efficient than the minimum variance linear unbiased estimate. However, in process control applications, it is generally not assumed that σ is constant, and if σ varies across subgroups, the root-mean-square estimate tends to be more inflated than the MVLUE.

Default Method Based on Individual Measurements

When each subgroup sample contains a single observation ($n_i \equiv 1$), the process standard deviation σ is estimated as $\hat{\sigma} = \bar{R}/d_2(2)$, where \bar{R} is the average of the moving ranges of consecutive measurements taken in pairs. This is the method used to estimate σ for individual measurements and moving range charts. See “Methods for Estimating the Standard Deviation” on page 1561.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical	DATA=	<i>process</i>
Vertical	HISTORY=	subgroup mean variable
Vertical	TABLE=	<u>SUBX</u>

If you specify the TRENDVAR= option, you can provide distinct labels for the vertical axes of the \bar{X} and trend charts by breaking the vertical axis into two parts with a split character. Specify the split character with the SPLIT= option. The first part labels the vertical axis of the \bar{X} chart, and the second part labels the vertical axis of the trend chart.

For example, the following sets of statements specify the label *Residual Mean* for the vertical axis of the \bar{X} chart and the label *Fitted Mean* for the vertical axis of the trend chart:

```
proc shewhart data=Toolwear;
  xchart Diameter*Hour / split    = '/'
                        trendvar = Fitted ;
  label Diameter = 'Residual Mean/Fitted Mean';
run;

proc shewhart history=Regdata;
  xchart Diameter*Hour / split    = '/'
                        trendvar = Fitted;
  label DiameterX = 'Residual Mean/Fitted Mean';
run;
```

In this example, the label assignments are in effect only for the duration of the procedure step, and they temporarily override any permanent labels associated with the variables.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: XCHART Statement

This section provides advanced examples of the XCHART statement.

Example 17.34: Applying Tests for Special Causes

See SHWTEST in the SAS/QC Sample Library

This example illustrates how you can apply tests for special causes to make \bar{X} charts more sensitive to special causes of variation.

The following statements create an \bar{X} chart for the gap width measurements in the data set Parts in “Creating Charts for Means from Subgroup Summary Data” on page 1860 and tabulate the results:

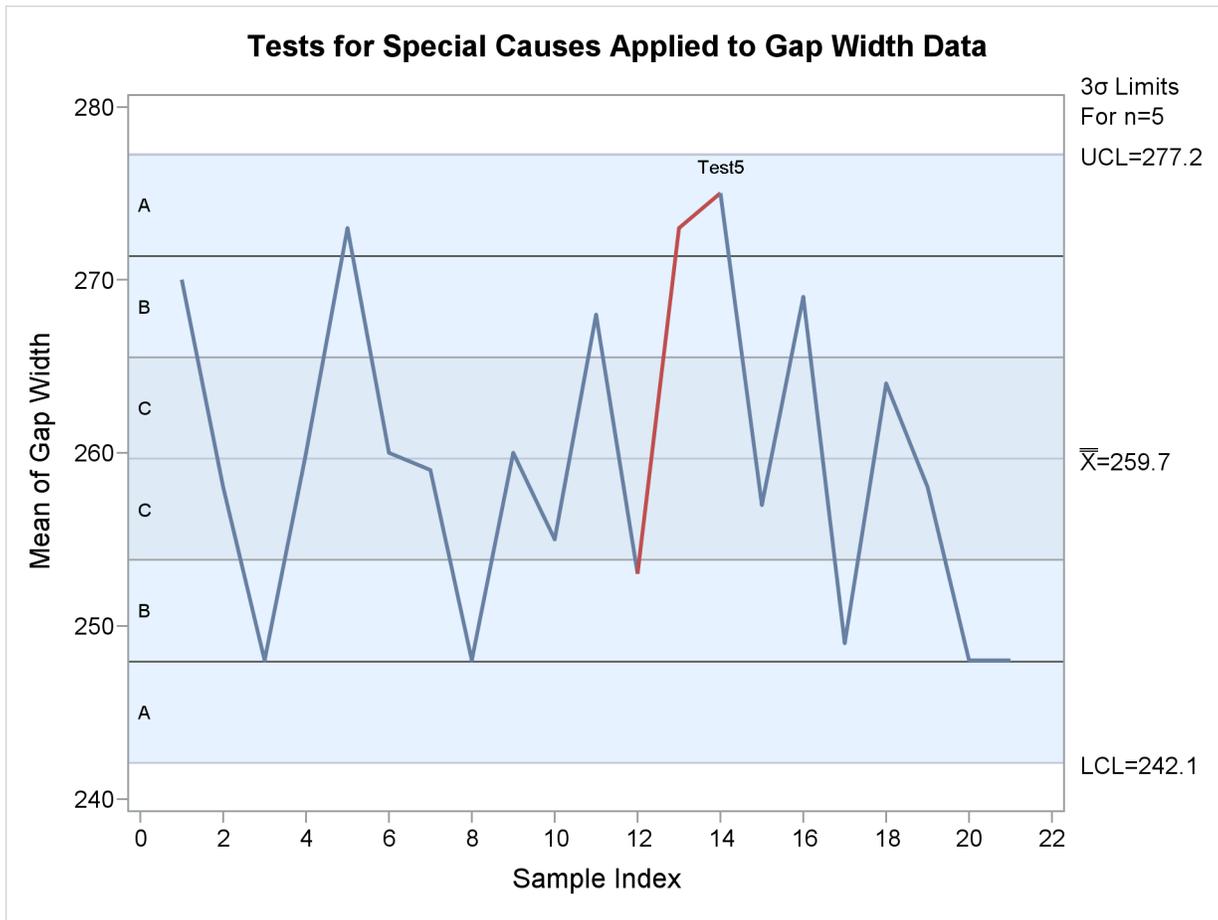

```
ods graphics on;
title 'Tests for Special Causes Applied to Gap Width Data';
proc shewhart history=Parts;
  xchart Partgap*Sample/ tests      = 1 to 5
                        odstitle = title
                        tabletests
                        nolegend
                        tablecentral
                        tablelegend
                        zonelabels;
run;
```

The \bar{X} chart is shown in [Output 17.34.1](#) and the printed output is shown in [Output 17.34.2](#). The TESTS= requests Tests 1, 2, 3, 4, and 5, which are described in “Tests for Special Causes: SHEWHART Procedure” on page 2146. The TABLECENTRAL option requests a table of the subgroup means, control limits, and central line. The TABLETESTS option adds a column indicating which subgroups tested positive for special causes, and the TABLELEGEND option adds a legend describing the tests that were signaled.

The ZONELABELS option displays zone lines and zone labels on the chart. The zones are used to define the tests. The NOLEGEND option suppresses the subgroup sample size legend that is displayed by default in the lower left corner of the chart.

[Output 17.34.1](#) and [Output 17.34.2](#) indicate that Test 5 was positive at sample 14, signaling a possible shift in the mean of the process.

Output 17.34.1 Tests for Special Causes Displayed on an \bar{X} Chart

Output 17.34.2 Tabular Form of \bar{X} Chart

Example 17.35: Estimating the Process Standard Deviation

The following data set (Wire) contains breaking strength measurements recorded in pounds per inch for 25 samples from a metal wire manufacturing process. The subgroup sample sizes vary between 3 and 7. *See SHWXEX2 in the SAS/QC Sample Library*

```

data Wire;
  input Sample size @;
  do i=1 to size;
    input Breakstrength @@;
    output;
  end;
  drop i size;
  label Breakstrength = 'Breaking Strength (lb/in)'
        Sample = 'Sample Index';
  datalines;
1  5 60.6 62.3 62.0 60.4 59.9
2  5 61.9 62.1 60.6 58.9 65.3
3  4 57.8 60.5 60.1 57.7
4  5 56.8 62.5 60.1 62.9 58.9
5  5 63.0 60.7 57.2 61.0 53.5
6  7 58.7 60.1 59.7 60.1 59.1 57.3 60.9
7  5 59.3 61.7 59.1 58.1 60.3
8  5 61.3 58.5 57.8 61.0 58.6
9  6 59.5 58.3 57.5 59.4 61.5 59.6
10 5 61.7 60.7 57.2 56.5 61.5
11 3 63.9 61.6 60.9
12 5 58.7 61.4 62.4 57.3 60.5
13 5 56.8 58.5 55.7 63.0 62.7
14 5 62.1 60.6 62.1 58.7 58.3
15 5 59.1 60.4 60.4 59.0 64.1
16 5 59.9 58.8 59.2 63.0 64.9
17 6 58.8 62.4 59.4 57.1 61.2 58.6
18 5 60.3 58.7 60.5 58.6 56.2
19 5 59.2 59.8 59.7 59.3 60.0
20 5 62.3 56.0 57.0 61.8 58.8
21 4 60.5 62.0 61.4 57.7
22 4 59.3 62.4 60.4 60.0
23 5 62.4 61.3 60.5 57.7 60.2
24 5 61.2 55.5 60.2 60.4 62.4
25 5 59.0 66.1 57.7 58.5 58.9
;

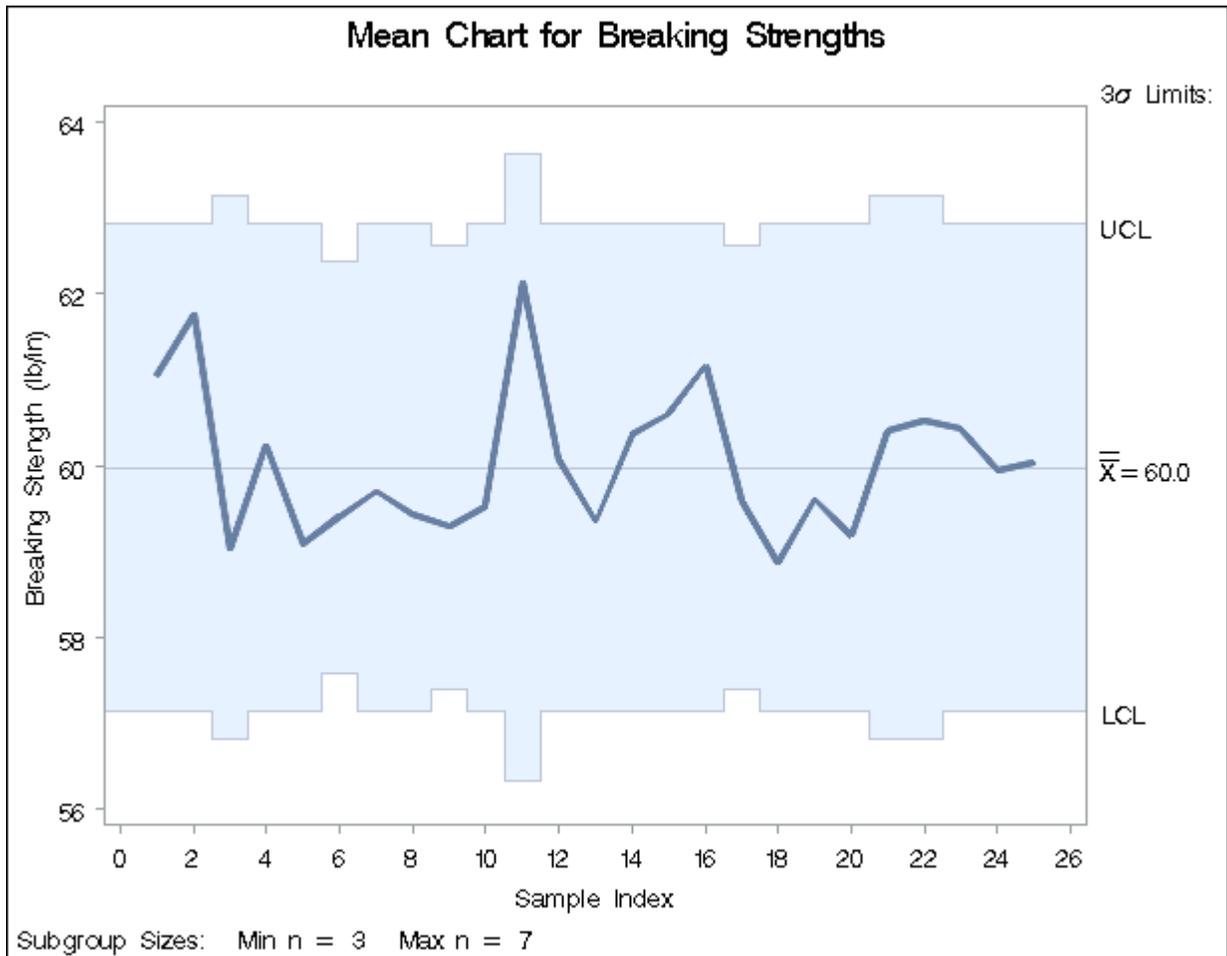

```

The following statements request an \bar{X} chart, shown in [Output 17.35.1](#), for the breaking strength measurements:

```

ods graphics off;
title 'Mean Chart for Breaking Strengths';
proc shewhart data=Wire;
  xchart Breakstrength*Sample;
run;

```

Output 17.35.1 \bar{X} Chart with Varying Subgroup Sample Sizes

Note that the control limits vary with the subgroup sample size. The sample size legend in the lower left corner displays the minimum and maximum subgroup sample sizes.

By default, the control limits are 3σ limits estimated from the data. You can use the `STDDEVIATIONS` option and the `SMETHOD=` option to specify how the estimate of the process standard deviation σ is to be computed, as illustrated by the following statements:

```
proc shewhart data=Wire;
  xchart Breakstrength*Sample / outlimits=Wirelim1
    outindex = 'Default-Ranges'
    nochart;
  xchart Breakstrength*Sample / outlimits=Wirelim2
    stddeviations
    outindex = 'Default-Stds'
    nochart;
  xchart Breakstrength*Sample / outlimits=Wirelim3
    smethod =mvlue
    outindex = 'MVLUE -Ranges'
    nochart;
  xchart Breakstrength*Sample / outlimits=Wirelim4
    stddeviations
```

```

        smethod =mvlue
        outindex = 'MVLUE  -Stds'
        nochart;
xchart Breakstrength*Sample / outlimits=Wirelim5
        stddeviations
        smethod =rmsdf
        outindex = 'RMSDF  -Stds'
        nochart;

run;

```

The STDDEVIATIONS option specifies that the estimate is to be calculated from subgroup standard deviations rather than subgroup ranges, the default. The SMETHOD= option specifies the method for estimating σ . The default method estimates σ as an unweighted average of subgroup estimates of σ . Specifying SMETHOD=MVLUE requests a minimum variance linear unbiased estimate, and specifying SMETHOD=RMSDF requests a weighted root-mean-square estimate. For details, see “Methods for Estimating the Standard Deviation” on page 1890.

The variable `_STDDEV_` in each OUTLIMITS= data set contains the estimate of σ . The OUTINDEX= option specifies the value of the variable `_INDEX_` in the OUTLIMITS= data set and is used here to identify the estimation method.

The following statements merge the five OUTLIMITS= data sets into a single data set, which is listed in [Output 17.35.2](#):

```

data wlimits;
    set Wirelim1 Wirelim2 Wirelim3 Wirelim4 Wirelim5;
    keep _index_ _stddev_;
run;

```

Output 17.35.2 The Data Set WLIMITS

Estimates of the Process Standard Deviation	
<code>_INDEX_</code>	<code>_STDDEV_</code>
Default-Ranges	2.11146
Default-Stds	2.15453
MVLUE -Ranges	2.11240
MVLUE -Stds	2.14790
RMSDF -Stds	2.17479

The \bar{X} chart shown in [Output 17.35.1](#) uses the default estimate listed first in [Output 17.35.2](#) ($\sigma = 2.11146$). In this case, there is very little difference in the five estimates, since the sample sizes do not differ greatly. In general, the MVLUE's are recommended with large sample sizes ($n_i \geq 10$).

Example 17.36: Plotting OC Curves for Mean Charts

This example uses the GLOT procedure and the DATA step function PROBNOORM to plot operating characteristic (OC) curves for \bar{X} charts with 3σ limits. An OC curve is plotted for each of the subgroup samples sizes 1, 2, 3, 4, and 16. Refer to page 226 in Montgomery (1996). Each curve

See SHWOC1 in the SAS/QC Sample Library

plots the probability β of not detecting a shift of magnitude $\nu\sigma$ in the process mean as a function of ν . The value of β is computed using the following formula:

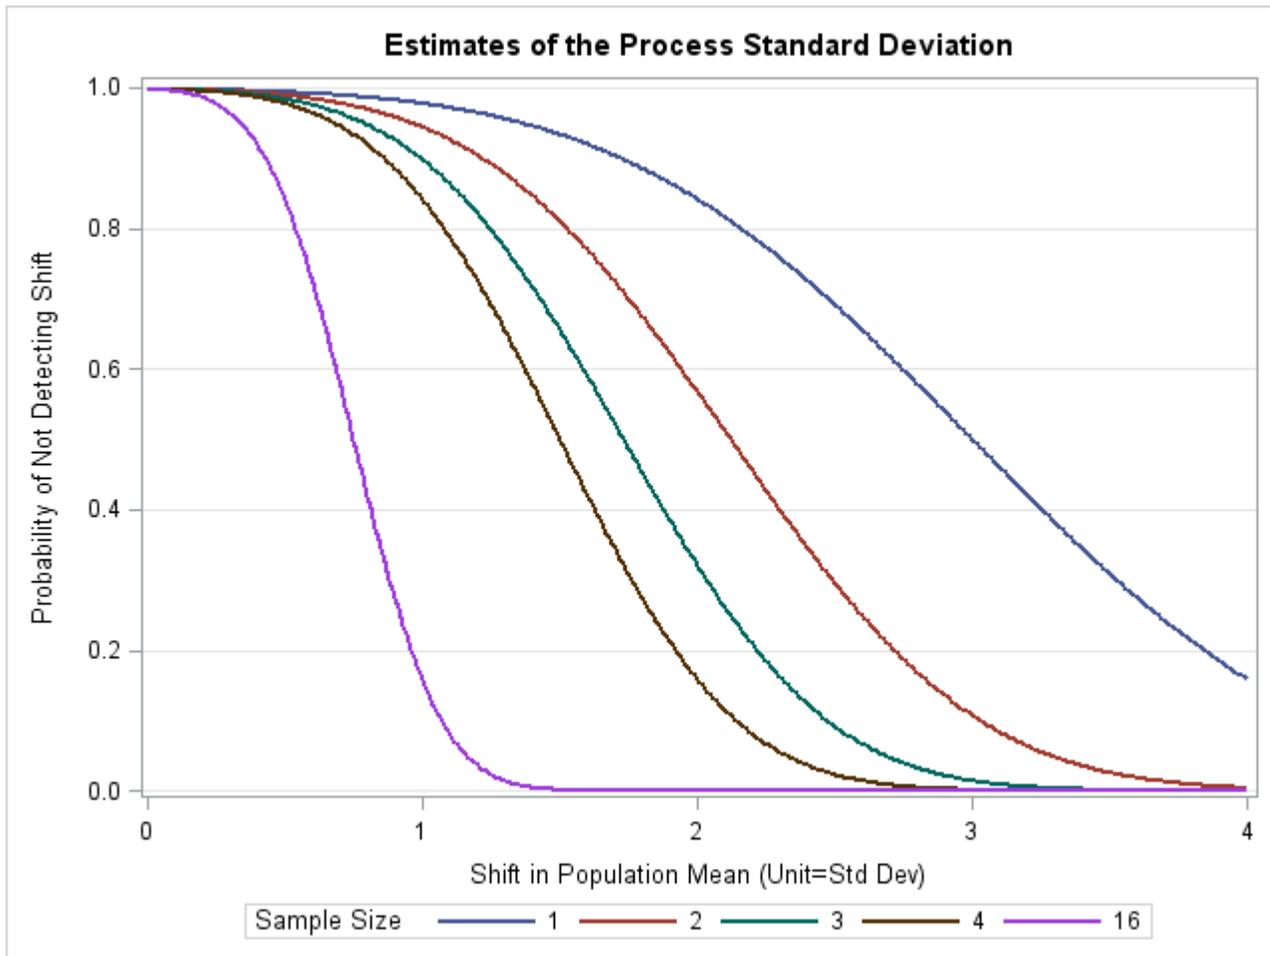

$$\begin{aligned}\beta &= P\{LCL \leq \bar{X}_i \leq UCL\} \\ &= \Phi(3 - \nu\sqrt{n}) - \Phi(-3 - \nu\sqrt{n})\end{aligned}$$

The following statements compute β (the variable BETA) as a function of ν (the variable NU). The variable nSample contains the sample size.

```
data oc;
  keep prob nSample t plot2;
  plot2=.;
  do nSample=1, 2, 3, 4, 16;
    do j=0 to 400;
      t=j/100;
      prob=probnorm( 3-t*sqrt(nSample)) -
            probnorm(-3-t*sqrt(nSample));
      output;
    end;
  end;
  label t      ='Shift in Population Mean (Unit=Std Dev)'
        prob='Probability of Not Detecting Shift';
run;
```

The following statements use the GPLOT procedure to display the OC curves shown in [Output 17.36.1](#):

```
proc sgplot data=oc;
  series x=t y=prob /
    group=nSample lineattrs=(pattern=solid thickness=2);
  yaxis grid;
  label nSample='Sample Size';
run;
```

Output 17.36.1 OC Curves for Different Subgroup Sample Sizes

Example 17.37: Computing Process Capability Indices

You can save process capability indices in an OUTLIMITS= data set if you provide specification limits with the LSL= and USL= options. This is illustrated by the following statements:

```

title 'Control Limits and Capability Indices';
proc shewhart data=Partgaps;
  xchart Partgap*Sample / outlimits = Gaplim2
    usl      = 270
    lsl      = 240
  nochart;
run;

```

The data set Gaplim22 is listed in [Output 17.37.1](#).

Output 17.37.1 Data Set Gaplim2 Containing Control Limit Information

Control Limits with Capability Indices for Gap Width Measurements									
Partgap	Sample	ESTIMATE	5	.002699796	3	242.087	259.667	277.246	0
30.4762	64.4419	13.1028	240	270	0.38160	0.50032	0.26288	0.26288	

The variables `_CP_`, `_CPL_`, `_CPU_`, and `_CPK_` contain the process capability indices. It is reasonable to compute capability indices in this case, since [Figure 17.97](#) indicates that the process is in statistical control. For more information, see the section “`OUTLIMITS= Data Set`” on page 1882.

XRCHART Statement: SHEWHART Procedure

Overview: XRCHART Statement

The XRCHART statement creates \bar{X} and R charts for subgroup means and ranges, which are used to analyze the central tendency and variability of a process.

You can use options in the XRCHART statement to

- compute control limits from the data based on a multiple of the standard error of the plotted means and ranges or as probability limits
- tabulate subgroup sample sizes, subgroup means, subgroup ranges, control limits, and other information
- save control limits in an output data set
- save subgroup sample sizes, subgroup means, and subgroup ranges in an output data set

- read preestablished control limits from a data set
- apply tests for special causes (also known as runs tests and Western Electric rules)
- specify a method for estimating the process standard deviation
- specify a known (standard) process mean and standard deviation for computing control limits
- display distinct sets of control limits for data from successive time phases
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the charts more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have three alternatives for producing \bar{X} and R charts with the XRCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “SAS/QC Graphics,” for more information about producing these different kinds of graphs.

Getting Started: XRCHART Statement

This section introduces the XRCHART statement with simple examples illustrating commonly used options. Complete syntax for the XRCHART statement is presented in the section “Syntax: XRCHART Statement” on page 1917, and advanced examples are given in the section “Examples: XRCHART Statement” on page 1945.

Creating Charts for Means and Ranges from Raw Data

See *SHWXRI* in the *SAS/QC Sample Library*. In the manufacture of silicon wafers, batches of five wafers are sampled, and their diameters are measured in millimeters. The following statements create a SAS data set named *Wafers*, which contains the measurements for 25 batches:

```

data Wafers;
  input Batch @;
  do i=1 to 5;
    input Diameter @;
    output;
  end;
  drop i;
  datalines;
1  35.00 34.99 34.99 34.98 35.00
2  35.01 34.99 34.99 34.98 35.00
3  34.99 35.00 35.00 35.00 35.00
4  35.01 35.00 34.99 34.99 35.00
5  35.00 34.99 34.98 34.99 35.00
6  34.99 34.99 35.00 35.00 35.00
7  35.01 34.98 35.00 35.00 34.99
8  35.00 35.00 34.99 34.98 34.99
9  34.99 34.98 34.98 35.01 35.00
10 34.99 35.00 35.01 34.99 35.01
11 35.01 35.00 35.00 34.98 34.99
12 34.99 34.99 35.00 34.98 35.01
13 35.01 34.99 34.98 34.99 34.99
14 35.00 35.00 34.99 35.01 34.99
15 34.98 34.99 34.99 34.98 35.00
16 34.99 35.00 35.00 35.01 35.00
17 34.98 34.98 34.99 34.99 34.98
18 35.01 35.02 35.00 34.98 35.00
19 34.99 34.98 35.00 34.99 34.98
20 34.99 35.00 35.00 34.99 34.99
21 35.00 34.99 34.99 34.98 35.00
22 35.00 35.00 35.01 35.00 35.00
23 35.02 35.00 34.98 35.02 35.00
24 35.00 35.00 34.99 35.01 34.98
25 34.99 34.99 34.99 35.00 35.00
;

```

The following statements use the PRINT procedure to list the data set *Wafers*. A portion of this listing is shown in [Figure 17.105](#).

```

title 'The Data Set Wafers';
proc print data=Wafers noobs;
run;

```

Figure 17.105 Partial Listing of the Data Set Wafers

The Data Set Wafers	
Batch	Diameter
1	35.00
1	34.99
1	34.99
1	34.98
1	35.00
2	35.01
2	34.99
2	34.99
2	34.98
2	35.00
3	34.99
3	35.00
3	35.00
3	35.00
3	35.00

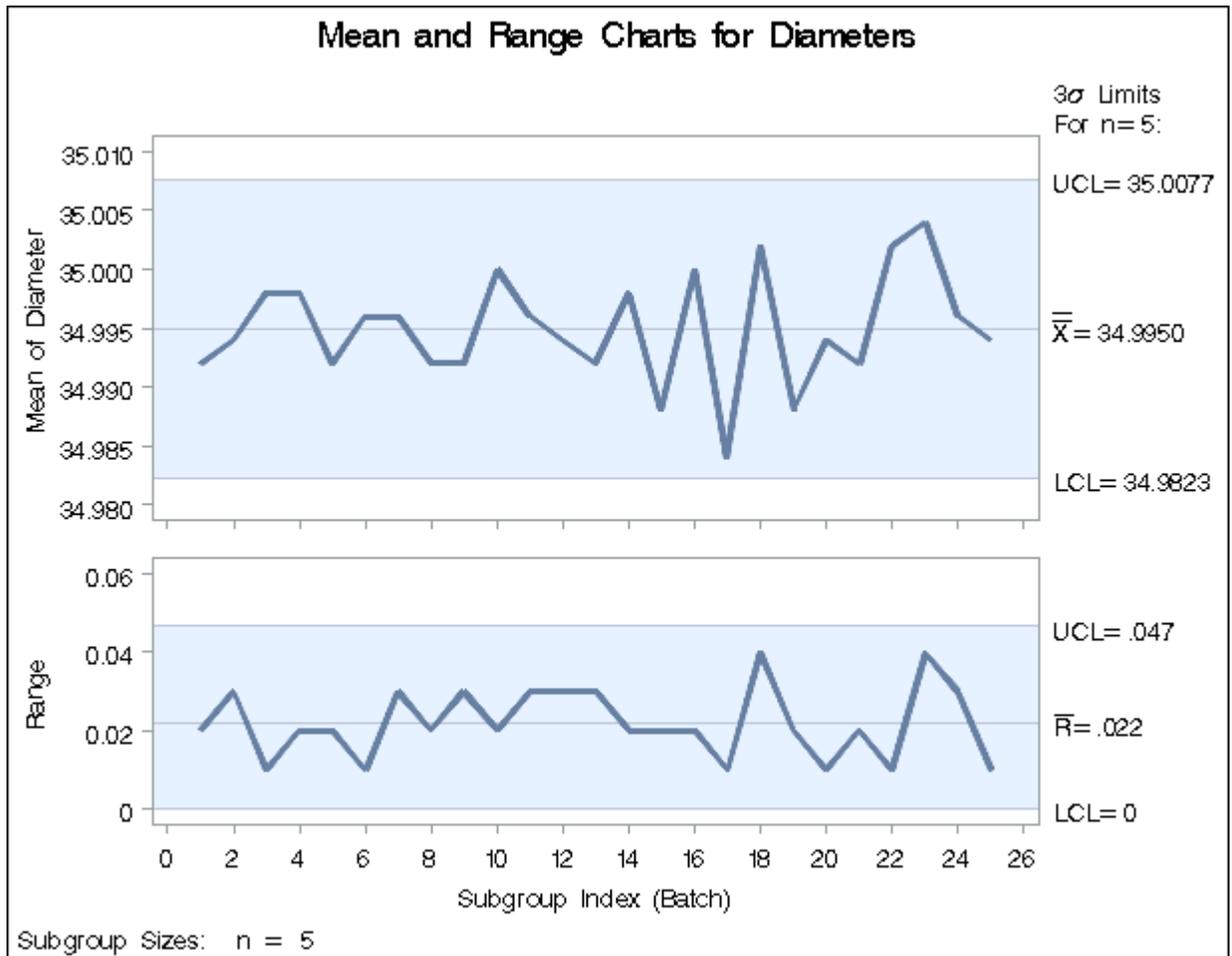

The data set *Wafers* is said to be in “strung-out” form since each observation contains the batch number and diameter measurement for a single wafer. The first five observations contain the diameters for the first batch, the second five observations contain the diameters for the second batch, and so on. Because the variable *Batch* classifies the observations into rational subgroups, it is referred to as the *subgroup-variable*. The variable *Diameter* contains the wafer diameter measurements and is referred to as the *process variable* (or *process* for short).

You can use \bar{X} and *R* charts to determine whether the manufacturing process is in control. The following statements create the \bar{X} and *R* charts shown in Figure 17.106:

```
ods graphics off;
title 'Mean and Range Charts for Diameters';
proc shewhart data=Wafers;
  xrchart Diameter*Batch;
run;
```

This example illustrates the basic form of the XRCHART statement. After the keyword XRCHART, which specifies the type of control chart to display, you specify the *process* to analyze (in this case, *Diameter*) followed by an asterisk and the *subgroup-variable* (*Batch*).

The input data set is specified with the DATA= option in the PROC SHEWHART statement. By default, traditional graphics output is produced, and its appearance is governed by the style in effect for any given ODS destination. Note that the STATISTICAL style is used throughout this book. See Chapter 3, “SAS/QC Graphics,” for a discussion of alternatives for producing graphics with SAS/QC procedures.

Figure 17.106 \bar{X} and R Charts for Wafer Diameter Data (Traditional Graphics)

Each point on the \bar{X} chart represents the average (mean) of the measurements for a particular batch. For instance, the mean plotted for the first batch is

$$\frac{35.00 + 34.99 + 34.99 + 34.98 + 35.00}{5} = 34.992$$

Each point on the R chart represents the range of the measurements for a particular batch. For instance, the range plotted for the first batch is $35.00 - 34.98 = 0.02$.

By default, the control limits shown are 3σ limits estimated from the data; the formulas for the limits are given in Table 17.71. You can also read control limits from an input data set; see “Reading Preestablished Control Limits” on page 1915.

Since all the points lie within the control limits, it can be concluded that the process is in statistical control. For computational details, see “Constructing Charts for Means and Ranges” on page 1929. For more details on reading raw data, see “DATA= Data Set” on page 1935.

Creating Charts for Means and Ranges from Summary Data

The previous example illustrates how you can create \bar{X} and R charts based on raw data (process measurements). However, in many applications, the data are provided as subgroup means and ranges. This example illustrates how you can use the XRCHART statement with data of this type. *See SHWXRI in the SAS/QC Sample Library*

The following data set (Wafersum) provides the data from the preceding example in summarized form:

```
data Wafersum;
  input Batch DiameterX DiameterR;
  DiameterN = 5;
  datalines;
1  34.992  0.02
2  34.994  0.03
3  34.998  0.01
4  34.998  0.02
5  34.992  0.02
6  34.996  0.01
7  34.996  0.03
8  34.992  0.02
9  34.992  0.03
10 35.000  0.02
11 34.996  0.03
12 34.994  0.03
13 34.992  0.03
14 34.998  0.02
15 34.988  0.02
16 35.000  0.02

25 34.994  0.01
;
```

A partial listing of the data set Wafersum is shown in [Figure 17.107](#).

Figure 17.107 Partial Listing of the Summary Data Set Wafersum

Summary Data Set for Wafer Diameters			
Batch	Diameter X	Diameter R	Diameter N
1	34.992	0.02	5
2	34.994	0.03	5
3	34.998	0.01	5
4	34.998	0.02	5
5	34.992	0.02	5

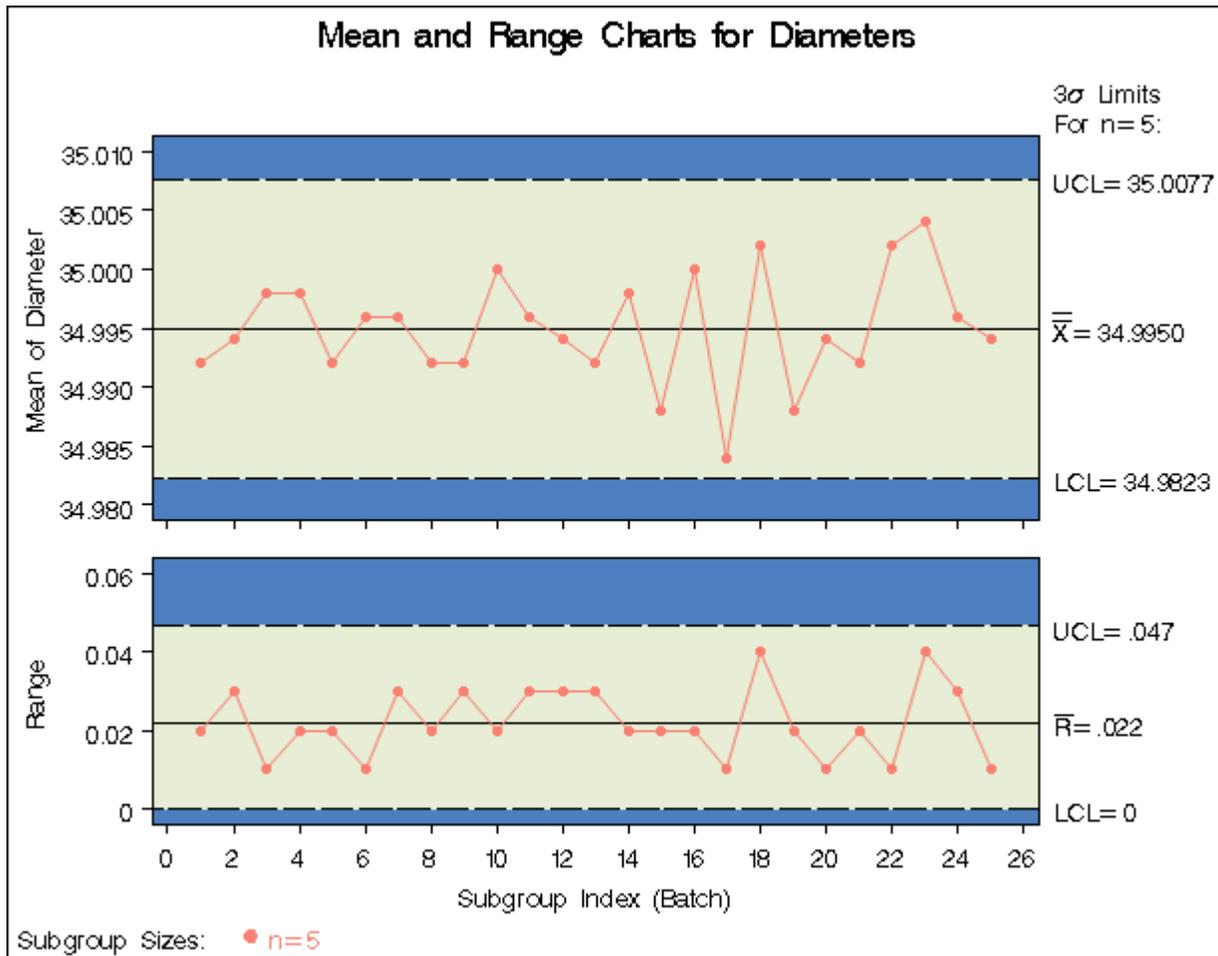

In this data set, there is exactly one observation for each subgroup (note that the subgroups are still indexed by Batch). The variable DiameterX contains the subgroup means, the variable DiameterR contains the subgroup ranges, and the variable DiameterN contains the subgroup sample sizes (these are all equal to five).

You can read this data set by specifying it as a HISTORY= data set in the PROC SHEWHART statement, as follows:

```
options nogstyle;
options ftext=swiss;
title 'Mean and Range Charts for Diameters';
symbol value = dot color = salmon;
proc shewhart history=Wafersum;
    xrchart Diameter*Batch / cframe    = bigb
                          cinfill    = ywh
                          cconnect   = salmon
                          coutfill   = yellow;
run;
options gstyle;
```

Note that Diameter is *not* the name of a SAS variable in the data set Wafersum but is, instead, the common prefix for the names of the three SAS variables DiameterX, DiameterR, and DiameterN. The suffix characters *X*, *R*, and *N* indicate *mean*, *range*, and *sample size*, respectively. Thus, you can specify three subgroup summary variables in the HISTORY= data set with a single name (Diameter), which is referred to as the *process*. The name Batch specified after the asterisk is the name of the *subgroup-variable*.

The NOGSTYLE system option causes the XRCHART statement to ignore ODS styles when producing traditional graphics. Instead, global statements (such as GOPTIONS, SYMBOL, and AXIS statements) and XRCHART options, specified after the slash (/) in the XRCHART statement, control the appearance of the charts. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently. A complete list of options is presented in the section “Syntax: XRCHART Statement” on page 1917. For more information about the GOPTIONS and SYMBOL statements, see *SAS/GRAPH: Reference*. The resulting charts are shown in Figure 17.108.

Figure 17.108 \bar{X} and R Charts from Summary Data (Traditional Graphics with NOGSTYLE)

In general, a HISTORY= input data set used with the XRCHART statement must contain the following variables:

- subgroup variable
- subgroup mean variable
- subgroup range variable
- subgroup sample size variable

Furthermore, the names of the subgroup mean, range, and sample size variables must begin with the *process* name specified in the XRCHART statement and end with the special suffix characters X, R, and N, respectively. If the names do not follow this convention, you can use the RENAME option to rename the variables for the duration of the SHEWHART procedure step. Suppose that, instead of the variables DiameterX, DiameterR, and DiameterN, the data set Wafersum contained summary variables named means, ranges, and sizes. The following statements would temporarily rename means, ranges, and sizes to DiameterX, DiameterR, and DiameterN, respectively:

```

proc shewhart
  history=Wafersum (rename=(means = DiameterX
                           ranges = DiameterR
                           sizes  = DiameterN ));
  xrchart Diameter*Batch=;
run;

```

In summary, the interpretation of *process* depends on the input data set:

- If raw data are read by using the DATA= option (as in the previous example), *process* is the name of the SAS variable containing the process measurements.
- If summary data are read by using the HISTORY= option (as in this example), *process* is the common prefix for the names of the variables containing the summary statistics.

For more information, see “[HISTORY= Data Set](#)” on page 1936.

Saving Summary Statistics

See SHWXR1 in the SAS/QC Sample Library In this example, the XRCHART statement is used to create a summary data set that can be read later by the SHEWHART procedure (as in the preceding example). The following statements read measurements from the data set *Wafers* and create a summary data set named *Waferhist*:

```

proc shewhart data=Wafers;
  xrchart Diameter*Batch / outhistory = Waferhist
                           nochart;
run;

```

The OUTHISTORY= option names the output data set, and the NOCHART option suppresses the display of charts. [Figure 17.109](#) contains a partial listing of *Waferhist*.

Figure 17.109 Partial Listing of the Summary Data Set *Waferhist*

Summary Data Set for Wafer Diameters			
Batch	Diameter X	Diameter R	Diameter N
1	34.992	0.02	5
2	34.994	0.03	5
3	34.998	0.01	5
4	34.998	0.02	5
5	34.992	0.02	5

There are four variables in the data set Waferhist:

- Batch contains the subgroup index.
- DiameterX contains the subgroup means.
- DiameterR contains the subgroup ranges.
- DiameterN contains the subgroup sample sizes.

Note that the summary statistic variables are named by adding the suffix characters X , R , and N to the *process* Diameter specified in the XRCHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as that for HISTORY= data sets.

For more information, see “OUTHISTORY= Data Set” on page 1932.

Saving Control Limits

You can save the control limits for \bar{X} and R charts in a SAS data set; this enables you to apply the control limits to future data (see “Reading Prestablished Control Limits” on page 1915) or modify the limits with a DATA step program. *See SHWXRI in the SAS/QC Sample Library*

The following statements read measurements from the data set Wafers (see “Creating Charts for Means and Ranges from Raw Data” on page 1904) and save the control limits displayed in Figure 17.106 in Waferlim:

```
proc shewhart data=Wafers;
  xrchart Diameter*Batch / outlimits = Waferlim
                        nochart;
run;
```

The OUTLIMITS= option names the data set containing the control limits, and the NOCHART option suppresses the display of the charts. The data set Waferlim is listed in Figure 17.110.

Figure 17.110 The Data Set Waferlim Containing Control Limit Information

Control Limits for Wafer Diameters						
VAR	_SUBGRP_	_TYPE_	_LIMITN_	_ALPHA_	_SIGMAS_	
Diameter	Batch	ESTIMATE	5	.002699796	3	
LCLX	_MEAN_	_UCLX_	_LCLR_	_R_	_UCLR_	_STDDEV_
34.9823	34.9950	35.0077	0	0.022	0.046519	.009458586

The data set Waferlim contains one observation with the limits for *process* Diameter. The variables LCLX and UCLX contain the lower and upper control limits for the \bar{X} chart. The variables LCLR and UCLR contain the lower and upper control limits for the R chart. The variable MEAN contains the central line for the \bar{X} chart, and the variable R contains the central line for the R chart. The value of MEAN is an estimate of the process mean, and the value of STDDEV

is an estimate of the process standard deviation σ . The value of `_LIMITN_` is the nominal sample size associated with the control limits, and the value of `_SIGMAS_` is the multiple of σ associated with the control limits. The variables `_VAR_` and `_SUBGRP_` are bookkeeping variables that save the *process* and *subgroup-variable* names. The variable `_TYPE_` is a bookkeeping variable that indicates whether the values of `_MEAN_` and `_STDDEV_` are estimates or standard values.

You can save process capability indices in an `OUTLIMITS=` data set if you provide specification limits with the `LSL=` and `USL=` options. This is illustrated by the following statements:

```
proc shewhart data=Wafers;
  xrchart Diameter*Batch / outlimits = Waferlim2
                        usl      = 35.03
                        lsl      = 34.97
                        nochart;
run;
```

The data set `Waferlim2` is listed in Figure 17.111.

Figure 17.111 The Data Set `Waferlim2` Containing Process Capability Indices

Control Limits and Capability Indices										
	S	L	A	S						
	U	I	A	I						
	B	M	L	G	L	M	U	L		
V	G	I	P	M	C	E	C	C		
A	R	T	H	A	L	A	L	L		
R	P	E	N	A	S	X	N	X	R	
Diameter	Batch	ESTIMATE	5	.002699796	3	34.9823	34.9950	35.0077	0	0.022
	S									
	T									
U	D									
C	D	L	U			C	C	C		
L	E	S	S	C		P	P	P		
R	V	L	L	P		L	U	K		
0.046519	.009458586	34.97	35.03	1.05724	0.87962	1.23486	0.87962			

The variables `_CP_`, `_CPL_`, `_CPU_`, and `_CPK_` contain the process capability indices. It is reasonable to compute capability indices, since [Figure 17.106](#) indicates that the wafer process is in statistical control. However, it is recommended that you also check for normality of the data. You can use the CAPABILITY procedure for this purpose.

For more information, see “[OUTLIMITS= Data Set](#)” on page 1931.

You can create an output data set containing both control limits and summary statistics with the `OUTTABLE=` option, as illustrated by the following statements:

```
proc shewhart data=Wafers;  
  xrchart Diameter*Batch / outtable=Wafertab  
                           nochart;  
run;
```

The data set Wafertab is listed in [Figure 17.112](#).

Figure 17.112 The Data Set Wafertab

Summary Statistics and Control Limit Information								
<u>VAR</u>	<u>Batch</u>	<u>SIGMAS</u>	<u>LIMITN</u>	<u>SUBN</u>	<u>LCLX</u>	<u>SUBX</u>	<u>MEAN</u>	<u>UCLX</u>

.009458586		0	0.01	0.022	0.046519			

This data set contains one observation for each subgroup sample. The variables `_SUBX_`, `_SUBR_`, and `_SUBN_` contain the subgroup means, subgroup ranges, and subgroup sample sizes. The variables `_LCLX_` and `_UCLX_` contain the lower and upper control limits for the \bar{X} chart. The variables `_LCLR_` and `_UCLR_` contain the lower and upper control limits for the R chart. The variable `_MEAN_` contains the central line of the \bar{X} chart, and the variable `_R_` contains the central line of the R chart. The variables `_VAR_` and `Batch` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “[OUTTABLE= Data Set](#)” on page 1933.

An `OUTTABLE=` data set can be read later as a `TABLE=` data set. For example, the following statements read `Wafertab` and display \bar{X} and R charts identical to those in [Figure 17.106](#):

```
title 'Mean and Range Charts for Diameters';
proc shewhart table=Wafertab;
  xrchart Diameter*Batch;
run;
```

Because the `SHEWHART` procedure simply displays the information read from a `TABLE=` data set, you can use `TABLE=` data sets to create specialized control charts (see “[Specialized Control Charts: SHEWHART Procedure](#)” on page 2171).

For more information, see “[TABLE= Data Set](#)” on page 1937.

Reading Prestablished Control Limits

In a previous example, the `OUTLIMITS=` data set saved control limits computed from the measurements in `Wafers`. This example shows how these limits can be applied to new data provided in the following data set: *See SHWXR1 in the SAS/QC Sample Library*

```
data Wafers2;
  input Batch @;
  do i=1 to 5;
    input Diameter @;
    output;
  end;
  drop i;
  datalines;
26 34.99 34.99 35.00 34.99 35.00
27 34.99 35.01 34.98 34.98 34.97
28 35.00 34.99 34.99 34.99 35.01
29 34.98 34.96 34.98 34.98 34.99
30 34.98 35.00 34.98 34.98 34.99
31 35.00 35.00 34.99 35.01 35.01
32 35.00 34.99 34.98 34.98 35.00
33 34.98 35.00 34.99 35.00 35.01
34 35.00 34.97 35.00 34.99 35.01
35 34.99 34.99 34.98 34.99 34.98
36 35.01 34.98 34.99 34.99 35.00
37 35.01 34.99 34.97 34.98 35.00
38 34.98 34.99 35.00 34.98 35.00
39 34.99 34.99 34.99 34.99 35.01
40 34.99 35.01 35.00 35.01 34.99
41 34.99 35.00 34.99 34.98 34.99
42 35.00 34.99 34.98 34.99 35.00
```

```

43 34.99 34.98 34.98 34.99 34.99
44 35.00 35.00 34.98 35.00 34.99
45 34.99 34.99 35.00 34.99 34.99
;

```

The following statements use the control limits in `Waferlim` to create \bar{X} and R charts for the data in `Wafers2`:

```

ods graphics on;
proc shewhart data=Wafers2 limits=Waferlim;
  xrchart Diameter*Batch;
run;

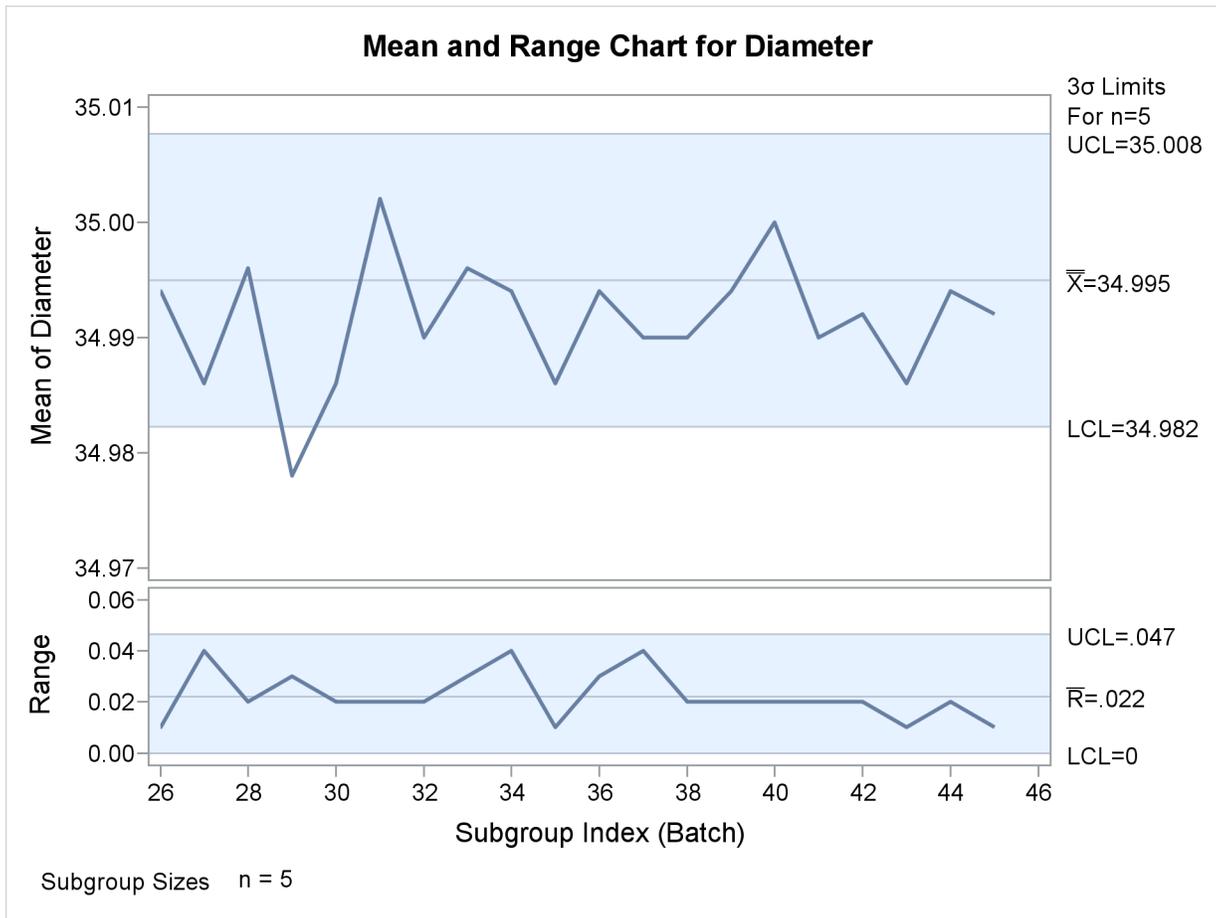

```

The ODS GRAPHICS ON statement specifies that the \bar{X} and R charts are produced using ODS Graphics. The LIMITS= option in the PROC SHEWHART statement specifies the data set containing the control limits. By default,³⁷ this information is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches the *process* name `Diameter`
- the value of `_SUBGRP_` matches the *subgroup-variable* name `Batch`

The charts are shown in [Figure 17.113](#).

³⁷In SAS 6.09 and earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

Figure 17.113 \bar{X} and R Charts for Second Set of Wafer Data (ODS Graphics)

Note that the mean diameter of the 29th batch lies below the lower control limit in the \bar{X} chart, signaling a special cause of variation.

In this example, the LIMITS= data set was created in a previous run of the SHEWHART procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on page 1936 for details concerning the variables that you must provide.

Syntax: XRCHART Statement

The basic syntax for the XRCHART statement is as follows:

```
XRCHART process * subgroup-variable ;
```

The general form of this syntax is as follows:

```
XRCHART processes * subgroup-variable <(block-variables)>  
=<symbol-variable | = 'character'> / <options> ;
```

You can use any number of XRCHART statements in the SHEWHART procedure. The components of the XRCHART statement are described as follows.

process**processes**

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC SHEWHART statement.

- If raw data are read from a DATA= data set, *process* must be the name of the variable containing the raw measurements. For an example, see “[Creating Charts for Means and Ranges from Raw Data](#)” on page 1904.
- If summary data are read from a HISTORY= data set, *process* must be the common prefix of the summary variables in the HISTORY= data set. For an example, see “[Creating Charts for Means and Ranges from Summary Data](#)” on page 1907.
- If summary data and control limits are read from a TABLE= data set, *process* must be a value of the variable `_VAR_` in the TABLE= data set. For an example, see “[Saving Control Limits](#)” on page 1911.

A *process* is required. If you specify more than one *process*, enclose the list in parentheses. For example, the following statements request distinct \bar{X} and *R* charts for Weight, Length, and Width:

```
proc shewhart data=Measures;
    xrchart (Weight Length Width)*Day;
run;
```

subgroup-variable

is the variable that identifies subgroups in the data. The *subgroup-variable* is required. In the preceding XRCHART statement, Day is the subgroup variable. For details, see “[Subgroup Variables](#)” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or character used to plot the means and ranges.

- Distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOL n statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.
- If you specify the LINEPRINTER option in the PROC SHEWHART statement, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.

character

specifies a plotting character for charts produced with the LINEPRINTER option. For example, the following statements use an asterisk (*) to plot the points on the \bar{X} and R charts:

```
proc shewhart data=Values lineprinter;
  xrchart Weight*Day='*';
run;
```

options

enhance the appearance of the charts, request additional analyses, save results in data sets, and so on. The section “[Summary of Options](#)”, which follows, lists all options by function. “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018 describes each option in detail.

Summary of Options

The following tables list the XRCHART statement options by function. For complete descriptions, see “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 17.70 XRCHART Statement Options

Option	Description
Options for Specifying Control Limits	
ALPHA=	requests probability limits for chart
LIMITN=	specifies either nominal sample size for fixed control limits or varying limits
NOREADLIMITS	computes control limits for each <i>process</i> from the data rather than a LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from a LIMITS= data set
READINDEX=	reads control limits for each <i>process</i> from a LIMITS= data set
READLIMITS	reads single set of control limits for each <i>process</i> from a LIMITS= data set (SAS 6.09 and earlier releases)
SIGMAS=	specifies width of control limits in terms of multiple k of standard error of plotted means
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit on \bar{X} chart
LCLLABEL2=	specifies label for lower control limit on R chart
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits

Table 17.70 *continued*

Option	Description
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line on \bar{X} chart
NDECIMAL2=	specifies number of digits to right of decimal place in default labels for control limits and central line on R chart
NOCTL	suppresses display of central line on \bar{X} chart
NOCTL2	suppresses display of central line on R chart
NOLCL	suppresses display of lower control limit on \bar{X} chart
NOLCL2	suppresses display of lower control limit on R chart
NOLIMIT0	suppresses display of zero lower control limit on R chart
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit on \bar{X} chart
NOUCL2	suppresses display of upper control limit on R chart
RSYMBOL=	specifies label for central line on R chart
UCLLABEL=	specifies label for upper control limit on \bar{X} chart
UCLLABEL2=	specifies label for upper control limit on R chart
WLIMITS=	specifies width for control limits and central line
XSYPMBOL=	specifies label for central line on \bar{X} chart
Process Mean and Standard Deviation Options	
MU0=	specifies known value of μ_0 for process mean μ
SIGMA0=	specifies known value σ_0 for process standard deviation σ
SMETHOD=	specifies method for estimating process standard deviation σ
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on \bar{X} chart
ALLLABEL2=	labels every point on R chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits

Table 17.70 *continued*

Option	Description
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
OUTLABEL=	labels points outside control limits on \bar{X} chart
OUTLABEL2=	labels points outside control limits on R chart
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles
Options for Specifying Tests for Special Causes	
INDEPENDENTZONES	computes zone widths independently above and below center line
NO3SIGMACHECK	enables tests to be applied with control limits other than 3σ limits
NOTESTACROSS	suppresses tests across <i>phase</i> boundaries
TESTS=	specifies tests for special causes for the \bar{X} chart
TESTS2=	specifies tests for special causes for the R chart
TEST2RESET=	enables tests for special causes to be reset for the R chart
TEST2RUN=	specifies length of pattern for Test 2
TEST3RUN=	specifies length of pattern for Test 3
TESTACROSS	applies tests across <i>phase</i> boundaries
TESTLABEL=	provides labels for points where test is positive
TESTLABEL $_n$ =	specifies label for n th test for special causes
TESTNMETHOD=	applies tests to standardized chart statistics
TESTOVERLAP	performs tests on overlapping patterns of points
TESTRESET=	enables tests for special causes to be reset
ZONELABELS	adds labels A, B, and C to zone lines for \bar{X} chart
ZONE2LABELS	adds labels A, B, and C to zone lines for R chart
ZONES	adds lines to \bar{X} chart delineating zones A, B, and C
ZONES2	adds lines to R chart delineating zones A, B, and C
ZONEVALPOS=	specifies position of ZONEVALUES labels
ZONEVALUES	labels \bar{X} chart zone lines with their values
ZONE2VALUES	labels R zone lines with their values
Options for Displaying Tests for Special Causes	
CTESTLABBOX=	specifies color for boxes enclosing labels indicating points where test is positive
CTESTS=	specifies color for labels indicating points where test is positive

Table 17.70 *continued*

Option	Description
CTESTSYMBOL=	specifies color for symbol used to plot points where test is positive
CZONES=	specifies color for lines and labels delineating zones A, B, and C
LTESTS=	specifies type of line connecting points where test is positive
LZONES=	specifies line type for lines delineating zones A, B, and C
TESTFONT=	specifies software font for labels at points where test is positive
TESTHEIGHT=	specifies height of labels at points where test is positive
TESTLABBOX	requests that labels for points where test is positive be positioned so that do not overlap
TESTSYMBOL=	specifies plot symbol for points where test is positive
TESTSYMBOLHT=	specifies symbol height for points where test is positive
WTESTS=	specifies width of line connecting points where test is positive
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOTRUNC	suppresses vertical axis truncation at zero applied by default to R chart
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPLABELS=	specifies thinning factor for tick mark labels on horizontal axis
SPLIT=	specifies splitting character for axis labels
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis of \bar{X} chart

Table 17.70 continued

Option	Description
VAXIS2=	specifies major tick mark values for vertical axis of <i>R</i> chart
VFORMAT=	specifies format for primary vertical axis tick mark labels
VFORMAT2=	specifies format for secondary vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis for primary chart
VZERO2	forces origin to be included in vertical axis for secondary chart
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of charts
NOCHART2	suppresses creation of <i>R</i> chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
SEPARATE	displays \bar{X} and <i>R</i> charts on separate screens or pages
TOTPANELS=	specifies number of pages or screens to be used to display chart
YPCT1=	specifies length of vertical axis on \bar{X} chart as a percentage of sum of lengths of vertical axes for \bar{X} and <i>R</i> charts
ZEROSTD	displays \bar{X} chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= and HREF2= options
CVREF=	specifies color for lines requested by VREF= and VREF2= options

Table 17.70 *continued*

Option	Description
HREF=	specifies position of reference lines perpendicular to horizontal axis on \bar{X} chart
HREF2=	specifies position of reference lines perpendicular to horizontal axis on R chart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on \bar{X} chart
HREF2DATA=	specifies position of reference lines perpendicular to horizontal axis on R chart
HREFLABELS=	specifies labels for HREF= lines
HREF2LABELS=	specifies labels for HREF2= lines
HREFLABPOS=	specifies position of HREFLABELS= and HREF2LABELS= labels
LHREF=	specifies line type for HREF= and HREF2= lines
LVREF=	specifies line type for VREF= and VREF2= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis on \bar{X} chart
VREF2=	specifies position of reference lines perpendicular to vertical axis on R chart
VREFLABELS=	specifies labels for VREF= lines
VREF2LABELS=	specifies labels for VREF2= lines
VREFLABPOS=	position of VREFLABELS= and VREF2LABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to \bar{X} chart

Table 17.70 *continued*

Option	Description
ANNOTATE2=	specifies annotate data set that adds features to <i>R</i> chart
DESCRIPTION=	specifies description of \bar{X} chart's GRSEG catalog entry
DESCRIPTION2=	specifies description of <i>R</i> chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of \bar{X} chart's GRSEG catalog entry
NAME2=	specifies name of <i>R</i> chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title

Table 17.70 *continued*

Option	Description
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
OVERLAY2URL=	specifies URLs to associate with overlay points on secondary chart
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
URL2=	specifies a variable whose values are URLs to be associated with subgroups on secondary chart
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options <code>TABLE</code> , <code>TABLECENTRAL</code> , <code>TABLEID</code> , <code>TABLELEGEND</code> , <code>TABLEOUTLIM</code> , and <code>TABLETESTS</code>
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLELEGEND	augments basic table with legend for tests for special causes
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
TABLETESTS	augments basic table with a column indicating which tests for special causes are positive
Specification Limit Options	
CIINDICES	specifies α value and type for computing capability index confidence limits
LSL=	specifies list of lower specification limits

Table 17.70 *continued*

Option	Description
TARGET=	specifies list of target values
USL=	specifies list of upper specification limits
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the OUTHISTORY= data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPecs=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star

Table 17.70 *continued*

Option	Description
STARVERTICES=	superimposes star at each point on \bar{X} chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for primary chart overlay line segments
CCOVERLAY2=	specifies colors for secondary chart overlay line segments
COVERLAY=	specifies colors for primary chart overlay plots
COVERLAY2=	specifies colors for secondary chart overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for primary chart overlay line segments
LOVERLAY2=	specifies line types for secondary chart overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on primary chart
OVERLAY2=	specifies variables to overlay on secondary chart
OVERLAY2HTML=	specifies links to associate with secondary chart overlay points
OVERLAY2ID=	specifies labels for secondary chart overlay points
OVERLAY2SYM=	specifies symbols for secondary chart overlays
OVERLAY2SYMHT=	specifies symbol heights for secondary chart overlays
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with primary chart overlay points
OVERLAYID=	specifies labels for primary chart overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for primary chart overlays
OVERLAYSYMHT=	specifies symbol heights for primary chart overlays
WCOVERLAY=	specifies widths of primary chart overlay line segments
WCOVERLAY2=	specifies widths of secondary chart overlay line segments
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML2=	specifies variable whose values create links to be associated with subgroups on secondary chart
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points

Table 17.70 continued

Option	Description
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= and HREF2= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
TESTCHAR=	specifies character for line segments that connect any sequence of points for which a test for special causes is positive
VREFCHAR=	specifies line character for VREF= and VREF2= lines
ZONECHAR=	specifies character for lines that delineate zones for tests for special causes

Details: XRCHART Statement

Constructing Charts for Means and Ranges

The following notation is used in this section:

μ	process mean (expected value of the population of measurements)
σ	process standard deviation (standard deviation of the population of measurements)
\bar{X}_i	mean of measurements in i th subgroup
R_i	range of measurements in i th subgroup
n_i	sample size of i th subgroup
N	number of subgroups
$\bar{\bar{X}}$	weighted average of subgroup means
$d_2(n)$	expected value of the range of n independent normally distributed variables with unit standard deviation
$d_3(n)$	standard error of the range of n independent observations from a normal population with unit standard deviation
z_p	$100 \times p$ th percentile of the standard normal distribution
$D_p(n)$	$100 \times p$ th percentile of the distribution of the range of n independent observations from a normal population with unit standard deviation

Plotted Points

Each point on the \bar{X} chart indicates the value of a subgroup mean (\bar{X}_i). For example, if the tenth subgroup contains the values 12, 15, 19, 16, and 14, the mean plotted for this subgroup is

$$\bar{X}_{10} = \frac{12 + 15 + 19 + 16 + 14}{5} = 15.2$$

Each point on the R chart indicates the value of a subgroup range (R_i). For example, the range plotted for the tenth subgroup is $R_{10} = 19 - 12 = 7$.

Central Lines

On an \bar{X} chart, by default, the central line indicates an estimate of μ , which is computed as

$$\hat{\mu} = \bar{\bar{X}} = \frac{n_1 \bar{X}_1 + \cdots + n_N \bar{X}_N}{n_1 + \cdots + n_N}$$

If you specify a known value (μ_0) for μ , the central line indicates the value of μ_0 .

On an R chart, by default, the central line for the i th subgroup indicates an estimate for the expected value of R_i , which is computed as $d_2(n_i)\hat{\sigma}$, where $\hat{\sigma}$ is an estimate of σ . If you specify a known value (σ_0) for σ , the central line indicates the value of $d_2(n_i)\sigma_0$. Note that the central line varies with n_i .

Control Limits

You can compute the limits in the following ways:

- as a specified multiple (k) of the standard errors of \bar{X}_i and R_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that \bar{X}_i or R_i exceeds the limits

The following table provides the formulas for the limits.

Table 17.71 Limits for \bar{X} and R Charts

Control Limits	
\bar{X} Chart	LCL = lower limit = $\bar{\bar{X}} - k\hat{\sigma}/\sqrt{n_i}$ UCL = upper limit = $\bar{\bar{X}} + k\hat{\sigma}/\sqrt{n_i}$
R Chart	LCL = lower limit = $\max(d_2(n_i)\hat{\sigma} - kd_3(n_i)\hat{\sigma}, 0)$ UCL = upper limit = $d_2(n_i)\hat{\sigma} + kd_3(n_i)\hat{\sigma}$
Probability Limits	
\bar{X} Chart	LCL = lower limit = $\bar{\bar{X}} - z_{\alpha/2}(\hat{\sigma}/\sqrt{n_i})$ UCL = upper limit = $\bar{\bar{X}} + z_{\alpha/2}(\hat{\sigma}/\sqrt{n_i})$
R Chart	LCL = lower limit = $D_{\alpha/2}\hat{\sigma}$ UCL = upper limit = $D_{1-\alpha/2}\hat{\sigma}$

The formulas for R charts assume that the data are normally distributed. If standard values μ_0 and σ_0 are available for μ and σ , respectively, replace $\bar{\bar{X}}$ with μ_0 and $\hat{\sigma}$ with σ_0 in Table 17.71. Note that the limits vary with n_i and that the probability limits for R_i are asymmetric around the central line.

You can specify parameters for the limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify μ_0 with the MU0= option or with the variable `_MEAN_` in a LIMITS= data set.
- Specify σ_0 with the SIGMA0= option or with the variable `_STDDEV_` in a LIMITS= data set.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves control limits and control limit parameters. The following variables are saved.

Table 17.72 OUTLIMITS= Data Set

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding limits
<code>_CP_</code>	capability index C_p
<code>_CPK_</code>	capability index C_{pk}
<code>_CPL_</code>	capability index C_{PL}
<code>_CPM_</code>	capability index C_{pm}
<code>_CPU_</code>	capability index C_{PU}
<code>_INDEX_</code>	optional identifier for the control limits specified with the OUTINDEX= option
<code>_LCLR_</code>	lower control limit for subgroup range
<code>_LCLX_</code>	lower control limit for subgroup mean
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_LSL_</code>	lower specification limit
<code>_MEAN_</code>	process mean (\bar{X} or μ_0)
<code>_R_</code>	value of central line on R chart
<code>_SIGMAS_</code>	multiple (k) of standard error of \bar{X}_i or R_i
<code>_STDDEV_</code>	process standard deviation ($\hat{\sigma}$ or σ_0)
<code>_SUBGRP_</code>	<i>subgroup-variable</i> specified in the XRCHART statement
<code>_TARGET_</code>	target value
<code>_TYPE_</code>	type (estimate or standard value) of <code>_MEAN_</code> and <code>_STDDEV_</code>
<code>_UCLR_</code>	upper control limit for subgroup range
<code>_UCLX_</code>	upper control limit for subgroup mean
<code>_USL_</code>	upper specification limit
<code>_VAR_</code>	<i>process</i> specified in the XRCHART statement

Notes:

1. If the control limits vary with subgroup sample size, the special missing value v is assigned to the variables `_LIMITN_`, `_LCLX_`, `_UCLX_`, `_LCLR_`, `_R_`, and `_UCLR_`.
2. If the limits are defined in terms of a multiple k of the standard errors of \bar{X}_i and R_i , the value of `_ALPHA_` is computed as $\alpha = 2(1 - \Phi(k))$, where $\Phi(\cdot)$ is the standard normal distribution function.
3. If the limits are probability limits, the value of `_SIGMAS_` is computed as $k = \Phi^{-1}(1 - \alpha/2)$, where Φ^{-1} is the inverse standard normal distribution function.
4. The variables `_CP_`, `_CPK_`, `_CPL_`, `_CPU_`, `_LSL_`, and `_USL_` are included only if you provide specification limits with the `LSL=` and `USL=` options. The variables `_CPM_` and `_TARGET_` are included if, in addition, you provide a target value with the `TARGET=` option. See “[Capability Indices](#)” on page 1941 for computational details.
5. Optional BY variables are saved in the `OUTLIMITS=` data set.

The `OUTLIMITS=` data set contains one observation for each *process* specified in the `XRCHART` statement. For an example, see “[Saving Control Limits](#)” on page 1911.

OUTHISTORY= Data Set

The `OUTHISTORY=` data set saves subgroup summary statistics. The following variables are saved:

- the *subgroup-variable*
- a subgroup mean variable named by *process* suffixed with X
- a subgroup range variable named by *process* suffixed with R
- a subgroup sample size variable named by *process* suffixed with N

Given a *process* name containing 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Variables containing subgroup means, ranges, and sample sizes are created for each *process* specified in the `XRCHART` statement. For example, consider the following statements:

```
proc shewhart data=Steel;
  xrchart (Width Diameter)*Lot / outhistory=Summary;
run;
```

The data set `Summary` contains variables named `Lot`, `WidthX`, `WidthR`, `WidthN`, `DiameterX`, `DiameterR`, and `DiameterN`.

Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the `OUTPHASE=` option is specified)

For an example of an `OUTHISTORY=` data set, see “Saving Summary Statistics” on page 1910.

OUTTABLE= Data Set

The `OUTTABLE=` data set saves subgroup summary statistics, control limits, and related information. The following variables are saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_EXLIM_</code>	control limit exceeded on \bar{X} chart
<code>_EXLIMR_</code>	control limit exceeded on R chart
<code>_LCLR_</code>	lower control limit for range
<code>_LCLX_</code>	lower control limit for mean
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_MEAN_</code>	process mean
<code>_R_</code>	average range
<code>_SIGMAS_</code>	multiple (k) of the standard error associated with control limits
<code>subgroup</code>	values of the subgroup variable
<code>_SUBN_</code>	subgroup sample size
<code>_SUBR_</code>	subgroup range
<code>_SUBX_</code>	subgroup mean
<code>_TESTS_</code>	tests for special causes signaled on \bar{X} chart
<code>_TESTS2_</code>	tests for special causes signaled on R chart
<code>_UCLR_</code>	upper control limit for range
<code>_UCLX_</code>	upper control limit for mean
<code>_VAR_</code>	<i>process</i> specified in the <code>XRCHART</code> statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the `READPHASES=` option is specified)

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved, depending on how the control limits are defined (with the `ALPHA=` or `SIGMAS=` options, respectively, or with the corresponding variables in a `LIMITS=` data set).
2. The variable `_TESTS_` is saved if you specify the `TESTS=` option. The k th character of a value of `_TESTS_` is k if Test k is positive at that subgroup. For example, if you request all eight tests and Tests 2 and 8 are positive for a given subgroup, the value of `_TESTS_` has a 2 for the second character, an 8 for the eighth character, and blanks for the other six characters.
3. The variable `_TESTS2_` is saved if you specify the `TESTS2=` option.
4. The variables `_EXLIM_`, `_EXLIMR_`, `_TESTS_`, and `_TESTS2_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “[Saving Control Limits](#)” on page 1911.

ODS Tables

The following table summarizes the ODS tables that you can request with the `XRCHART` statement.

Table 17.73 ODS Tables Produced with the `XRCHART` Statement

Table Name	Description	Options
<code>XRCHART</code>	\bar{X} and R chart summary statistics	<code>TABLE</code> , <code>TABLEALL</code> , <code>TABLEC</code> , <code>TABLEID</code> , <code>TABLELEG</code> , <code>TABLEOUT</code> , <code>TABLETESTS</code>
<code>TestDescriptions</code>	descriptions of tests for special causes requested with the <code>TESTS=</code> option for which at least one positive signal is found	<code>TABLEALL</code> , <code>TABLELEG</code>

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the `ODS GRAPHICS ON` statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” (Chapter 21, *SAS/STAT User's Guide*). **NOTE:** In SAS/QC 12.1 the SHEWHART procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. `XRCHART` options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics and traditional graphics with ODS styles. [Options for ODS Graphics](#) lists options

to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the XRCHART statement assigns a name to the graph it creates. You can use this name to reference the graph with ODS statements. The name is listed in [Table 17.74](#).

Table 17.74 ODS Graphics Produced by the XRCHART Statement

ODS Graph Name	Plot Description
XRChart	\bar{X} and R chart

See Chapter 3, “[SAS/QC Graphics](#),” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (process measurements) from a DATA= data set specified in the PROC SHEWHART statement. Each *process* specified in the XRCHART statement must be a SAS variable in the DATA= data set. This variable provides measurements that must be grouped into subgroup samples indexed by the *subgroup-variable*. The *subgroup-variable*, which is specified in the XRCHART statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a value for each *process* and a value for the *subgroup-variable*. If the *i*th subgroup contains n_i items, there should be n_i consecutive observations for which the value of the subgroup variable is the index of the *i*th subgroup. For example, if each subgroup contains five items and there are 30 subgroup samples, the DATA= data set should contain 150 observations.

Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all the observations in a DATA= data set. However, if the DATA= data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (for an example, see “[Displaying Stratification in Phases](#)” on page 2103).

For an example of a DATA= data set, see “[Creating Charts for Means and Ranges from Raw Data](#)” on page 1904.

LIMITS= Data Set

You can read preestablished control limits (or parameters from which the control limits can be calculated) from a LIMITS= data set specified in the PROC SHEWHART statement. For example, the following statements read control limit information from the data set Conlims:³⁸

```
proc shewhart data=Info limits=Conlims;
  xrchart Weight*Batch;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the SHEWHART procedure. Such data sets always contain the variables required for a LIMITS= data set. The LIMITS= data set can also be created directly by using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LCLX_`, `_MEAN_`, `_UCLX_`, `_LCLR_`, `_R_`, and `_UCLR_`, which specify the control limits directly
- the variables `_MEAN_` and `_STDDEV_`, which are used to calculate the control limits according to the equations in [Table 17.71](#)

In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables whose lengths are no greater than 32.
- The variable `_INDEX_` is required if you specify the `READINDEX=` option; this must be a character variable whose length is no greater than 48.
- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8; valid values are 'ESTIMATE', 'STANDARD', 'STDMU', and 'STDSIGMA'.
- BY variables are required if specified with a BY statement.

For an example, see “[Reading Preestablished Control Limits](#)” on page 1915.

HISTORY= Data Set

You can read subgroup summary statistics from a HISTORY= data set specified in the PROC SHEWHART statement. This enables you to reuse OUTHISTORY= data sets that have been created in previous runs of the SHEWHART, CUSUM, or MACONTROL procedure or to read output data sets created with SAS summarization procedures, such as the MEANS procedure.

A HISTORY= data set used with the XRCHART statement must contain the following variables:

- the *subgroup-variable*
- a subgroup mean variable for each *process*

³⁸In SAS 6.09 and in earlier releases, it is necessary to specify the READLIMITS option.

- a subgroup range variable for each *process*
- a subgroup sample size variable for each *process*

The names of the subgroup mean, subgroup range, and subgroup sample size variables must be the *process* name concatenated with the special suffix characters X, R, and N, respectively.

For example, consider the following statements:

```
proc shewhart history=Summary;
  xrchart (Weight Yieldstrength)*Batch;
run;
```

The data set Summary must include the variables Batch, WeightX, WeightR, WeightN, YieldstrengthX, YieldstrengthR, and YieldstrengthN.

Note that if you specify a *process* name that contains 32 characters, the names of the summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a HISTORY= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all the observations in a HISTORY= data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (see “[Displaying Stratification in Phases](#)” on page 2103 for an example).

For an example of a HISTORY= data set, see “[Creating Charts for Means and Ranges from Summary Data](#)” on page 1907.

TABLE= Data Set

You can read summary statistics and control limits from a TABLE= data set specified in the PROC SHEWHART statement. This enables you to reuse an OUTTABLE= data set created in a previous run of the SHEWHART procedure or to read data sets created by other SAS procedures. Because the SHEWHART procedure simply displays the information read from a TABLE= data set, you can use TABLE= data sets to create specialized control charts. Examples are provided in “[Specialized Control Charts: SHEWHART Procedure](#)” on page 2171.

Table 17.75 lists the variables required in a TABLE= data set used with the XRCHART statement.

Table 17.75 Variables Required in a TABLE= Data Set

Variable	Description
LCLR	lower control limit for range
LCLX	lower control limit for mean
LIMITN	nominal sample size associated with the control limits
MEAN	process mean
R	average range
<i>subgroup-variable</i>	values of the <i>subgroup-variable</i>
SUBN	subgroup sample size
SUBR	subgroup range
SUBX	subgroup mean
UCLR	upper control limit for range
UCLX	upper control limit for mean

Other variables that can be read from a TABLE= data set include

- *block-variables*
- *symbol-variable*
- BY variables
- ID variables
- _PHASE_ (if the READPHASES= option is specified). This variable must be a character variable whose length is no greater than 48.
- _TESTS_ (if the TESTS= option is specified). This variable is used to flag tests for special causes for subgroup means and must be a character variable of length 8.
- _TESTS2_ (if the TESTS2= option is specified). This variable is used to flag tests for special causes for subgroup ranges and must be a character variable of length 8.
- _VAR_. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable whose length is no greater than 32.

For an example of a TABLE= data set, see “Saving Control Limits” on page 1911.

Subgroup Variables

The values of the *subgroup-variable*, which is specified in the chart statement, indicate how the observations in the input data set (a DATA=, HISTORY=, or TABLE= data set) are arranged into rational subgroups.³⁹ Typically, the values of the *subgroup-variable* are one of the following:

³⁹This discussion also applies to the use of *subgroup-variables* in the CUSUM procedure and the MACONTROL procedure.

- *indices* that give the order in which subgroup samples were collected (for example, 1, 2, 3, . . .). An unformatted numeric *subgroup-variable* is appropriate for this situation. For an example that uses this type of *subgroup-variable*, see “[Creating Charts for Means and Ranges from Raw Data](#)” on page 1904.
- the *dates* or *times* at which subgroup samples were collected (for example, 01JUN, 02JUN, 03JUN, . . .). A numeric *subgroup-variable* with a SAS date, time, or datetime format is appropriate for this situation. You can optionally associate a format with the *subgroup-variable* by using a FORMAT statement; refer to *SAS Formats and Informats: Reference* for details. For an example that uses this type of *subgroup-variable*, see [Example 17.40](#).
- *labels* that uniquely identify subgroup samples (for example, LOT39, LOTX12, LOT43A). A character *subgroup-variable* (with or without a format) is appropriate for this situation. For an example that uses this type of *subgroup-variable*, see [Example 17.38](#).

The values of the *subgroup-variable* also determine how the horizontal axis of the control chart is scaled and labeled.

The notion of a rational subgroup is fundamental to the application of a Shewhart chart. You should select your subgroups so that if special causes of variation are present, the opportunity for variation within subgroups is minimized while the opportunity for variation between subgroups is maximized. In other words, the conditions within a subgroup should be homogeneous. The reason for this requirement is that the construction of the control limits is based on within-subgroup variability. Refer to Montgomery (1996) and Wheeler and Chambers (1986) for approaches to rational subgrouping.

The selection of subgroups is both a practical and a statistical issue that requires knowledge of the process and the sampling or measurement procedure. The values of the subgroup-variable should reflect the selection of subgroups and should not be assigned arbitrarily. Incorrect subgrouping or assignment of subgroup-variable values can result in control limits that are too tight or too wide.

If the input data set is a HISTORY= or TABLE= data set, each observation represents a distinct subgroup, and, consequently, the observations within each BY group must have distinct subgroup variable values. Similarly, if the input data set is a DATA= data set and you are using the CCHART, IRCHART, NPCHART, PCHART, or UCHART statement, each observation represents a distinct subgroup, and, consequently, the observations within each BY group must have distinct subgroup variable values. However, if the input data set is a DATA= data set and you are using the BOXCHART, MCHART, MRCHART, RCHART, SCHAT, XCHART, XRCHART, or XSCHAT statement, subgroups are identified by groups of consecutive observations with identical values of the subgroup-variable.

The order of the observations in the input data set and the scaling of the horizontal axis depend on the type of the subgroup-variable, which can be numeric or character.

Numeric Subgroup Variables

If the subgroup-variable is numeric, the observations must be sorted in increasing order of the values of the subgroup variable. If you use a BY statement, first sort by the BY variables and then by the subgroup variable.

The unformatted values of the subgroup-variable are used to scale the horizontal axis of the control chart, and the formatted values are used to label the major tick marks on the horizontal axis.

As a result, the horizontal distance between two points corresponding to consecutive subgroups is proportional to the difference between their unformatted subgroup values.

If a DATE, DATETIME, WEEKDATE, or WORDDATE format is associated with the subgroup variable, the major tick mark labels are split and displayed in two levels to save space. You can override this default with the TURNHLABELS option (which turns the labels vertically) or with tick label options in an AXIS n statement specified with the HAXIS= option.

Character Subgroup Variables

If the subgroup-variable is numeric, the order of the observations is not checked. The horizontal axis is scaled so that the subgroups are spaced uniformly. Formatted subgroup variable values are used to label the major tick marks.

You can use a character subgroup variable to avoid gaps between groups of points or time values on a control chart. You can also use a character subgroup variable to create a chart in which the order of the points depends only on the order in which the subgroups are arranged in the input data set.

You should verify the order of the observations in the input data set before you use a character subgroup variable in conjunction with the TESTS= option. With the exception of Test 1, the tests for special causes are applicable only if the subgroups are provided in chronological order. See “Tests for Special Causes: SHEWHART Procedure” on page 2146 for details.

To avoid collision of adjacent tick labels on the horizontal axis, the labels are thinned by default. You can override this default with the TURNHLABELS option or with tick label options in an AXIS n statement specified with the HAXIS= option.

Methods for Estimating the Standard Deviation

When control limits are determined from the input data, three methods (referred to as default, MVLUE, and MVGRANGE) are available for estimating σ .

Default Method

The default estimate for σ is

$$\hat{\sigma} = \frac{R_1/d_2(n_1) + \cdots + R_N/d_2(n_N)}{N}$$

where N is the number of subgroups for which $n_i \geq 2$, and R_i is the sample range of the observations x_{i1}, \dots, x_{in_i} in the i th subgroup.

$$R_i = \max_{1 \leq j \leq n_i} (x_{ij}) - \min_{1 \leq j \leq n_i} (x_{ij})$$

A subgroup range R_i is included in the calculation only if $n_i \geq 2$. The unbiasing factor $d_2(n_i)$ is defined so that, if the observations are normally distributed, the expected value of R_i is $d_2(n_i)\sigma$. Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ . This method is described in the American Society for Testing and Materials (1976).

MVLUE Method

If you specify SMETHOD=MVLUE, a minimum variance linear unbiased estimate (MVLUE) is computed for σ . Refer to Burr (1969, 1976) and Nelson (1989, 1994). The MVLUE is a weighted

average of N unbiased estimates of σ of the form $R_i/d_2(n_i)$, and it is computed as

$$\hat{\sigma} = \frac{f_1 R_1/d_2(n_1) + \cdots + f_N R_N/d_2(n_N)}{f_1 + \cdots + f_N}$$

where

$$f_i = \frac{[d_2(n_i)]^2}{[d_3(n_i)]^2}$$

A subgroup range R_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$. The unbiasing factor $d_3(n_i)$ is defined so that, if the observations are normally distributed, the expected value of σ_{R_i} is $d_3(n_i)\sigma$. The MVLUE assigns greater weight to estimates of σ from subgroups with larger sample sizes, and it is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the MVLUE reduces to the default estimate.

MVGRANGE Method

If you specify `SMETHOD=MVGRANGE`, σ is estimated by using a moving range of subgroup averages. This is appropriate for constructing control charts for means when the j th measurement in the i th subgroup can be modeled as $x_{ij} = \sigma_B \omega_i + \sigma_W \epsilon_{ij}$, where σ_B^2 is the between-subgroup variance, σ_W^2 is the within-subgroup variance, the ω_i are independent with zero mean and unit variance, and the ω_i are independent of the ϵ_{ij} .

The estimate for σ is

$$\hat{\sigma} = \bar{R}/d_2(n)$$

where \bar{R} is the average of the moving ranges, n is the number of consecutive subgroup averages used to compute each moving range, and the unbiasing factor $d_2(n)$ is defined so that if the subgroup averages are normally distributed, the expected value of R_i is

$$E(R_i) = d_2(n_i)\sigma$$

This method is appropriate for constructing the three-way control chart that is advocated for this situation by Wheeler (1995). A three-way control chart is useful when sampling, or *within-group* variation is not the only source of variation, as discussed in “[Multiple Components of Variation](#)” on page 2181. A three-way control chart comprises a chart of subgroup means, a moving range chart of the subgroup means, and a chart of subgroup ranges. When you specify the `SMETHOD=MVGRANGE` option, the XRCHART statement produces the appropriate charts of subgroup means and subgroup ranges.

Capability Indices

This section provides formulas for process capability indices, which are saved in the `OUTLIMITS=` data set when you use the `LSL=` and `USL=` options to provide lower and upper specification limits (`LSL` and `USL`, respectively) for the *process*. The estimate $\hat{\sigma}$ is computed as described in the previous section, “[Methods for Estimating the Standard Deviation](#)” on page 1940

The Index C_p

The process capability index C_p is computed as

$$C_p = (USL - LSL)/6\hat{\sigma}$$

If you do not specify both LSL and USL, the variable `_CP_` is assigned a missing value.

The Index CPL

The process capability index CPL is computed as

$$CPL = (\bar{\bar{X}} - LSL)/3\hat{\sigma}$$

If you do not specify LSL, the variable `_CPL_` is assigned a missing value.

The Index CPU

The process capability index CPU is computed as

$$CPU = (USL - \bar{\bar{X}})/3\hat{\sigma}$$

If you do not specify USL, the variable `_CPU_` is assigned a missing value.

The Index C_{pk}

The process capability index C_{pk} is computed as

$$C_{pk} = \min(USL - \bar{\bar{X}}, \bar{\bar{X}} - LSL)/3\hat{\sigma}$$

If you specify only USL, the index C_{pk} is computed as

$$C_{pk} = (USL - \bar{\bar{X}})/3\hat{\sigma}$$

and if you specify only LSL, the index C_{pk} is computed as

$$C_{pk} = (\bar{\bar{X}} - LSL)/3\hat{\sigma}$$

The Index C_{pm}

The process capability index C_{pm} is computed as

$$C_{pm} = \frac{\min(T - LSL, USL - T)}{3\sqrt{\hat{\sigma}^2 + (\bar{\bar{X}} - T)^2}}$$

where T is the target value specified with the TARGET= option.

When a single specification limit (SL) and target are specified, C_{pm} is computed as

$$C_{pm} = \frac{|T - SL|}{3\sqrt{\hat{\sigma}^2 + (\bar{\bar{X}} - T)^2}}$$

You can also use the CAPABILITY procedure to compute a variety of capability indices. The SHEWHART procedure and the CAPABILITY procedure use the same formulas to calculate the indices, but they use different estimates for the process standard deviation σ .

- The SHEWHART procedure calculates $\hat{\sigma}$ from subgroup estimates of σ . For details, see the previous section, “Methods for Estimating the Standard Deviation.”
- The CAPABILITY procedure calculates $\hat{\sigma}$ as the sample standard deviation of the entire sample. For details, see the section “Standard Deviation” on page 235.

Regardless of which method you use, you should verify that the process is in statistical control before interpreting the indices, and you should verify that the data are normally distributed. The CAPABILITY procedure provides a variety of statistical and graphical tests for checking normality.

Some references use different notation and names for capability indices. For example, the manual Division/AIAG (1990) uses the term “process capability indices” for the indices listed in this section, and it uses the term “process performance indices” for the indices computed by the CAPABILITY procedure.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical (\bar{X} chart)	DATA=	<i>process</i>
Vertical (\bar{X} chart)	HISTORY=	subgroup mean variable
Vertical (\bar{X} chart)	TABLE=	<code>_SUBX_</code>

You can specify distinct labels for the vertical axes of the \bar{X} and R charts by breaking the vertical axis into two parts with a split character. Specify the split character with the SPLIT= option. The

first part labels the vertical axis of the \bar{X} chart, and the second part labels the vertical axis of the R chart.

For example, the following sets of statements specify the label “Avg Diameter in mm” for the vertical axis of the \bar{X} chart and the label “Range in mm” for the vertical axis of the R chart:

```
proc shewhart data=Wafers;
  xrchart Diameter*Batch / split = '/' ;
  label Diameter = 'Avg Diameter in mm/Range in mm';
run;

proc shewhart history=Wafersum;
  xrchart Diameter*Batch / split = '/' ;
  label DiameterX = 'Avg Diameter in mm/Range in mm';
run;

proc shewhart table=Wafertab;
  xrchart Diameter*Batch / split = '/' ;
  label _SUBX_ = 'Avg Diameter in mm/Range in mm';
run;
```

In this example, the label assignments are in effect only for the duration of the procedure step, and they temporarily override any permanent labels associated with the variables.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: XRCHART Statement

This section provides advanced examples that use the XRCHART statement.

Example 17.38: Applying Tests for Special Causes

This example illustrates how you can apply tests for special causes to make \bar{X} and R charts more sensitive to special causes of variation. *See SHWXR2 in the SAS/QC Sample Library*

The weight of a roll of tape is measured before and after an adhesive is applied. The difference in weight represents the amount of adhesive applied to the tape during the coating process. The following data set contains the average and the range of the adhesive amounts for 21 samples of five rolls:

```
data Tape;
  input Sample $ WeightX WeightR;
  WeightN=5;
  label WeightX = 'Average Adhesive Amount'
        Sample = 'Sample Code';
  datalines;
C9 1270 35
C4 1258 25
A7 1248 24
A1 1260 39
A5 1273 29
D3 1260 21
D6 1259 37
D1 1240 37
R4 1260 28
H7 1255 19
H2 1268 36
H6 1253 36
P4 1273 29
P9 1275 22
J7 1257 24
J2 1269 41
J3 1249 36
B2 1264 31
G4 1258 25
G6 1248 36
G3 1248 30
;
```

The following statements create \bar{X} and R charts, apply several tests to the \bar{X} chart, and tabulate the results:

```

title 'Tests for Special Causes Applied to Adhesive Tape Data';
ods graphics on;
proc shewhart history=Tape;
  xrchart Weight*Sample / tests    = 1 to 5
                        odstitle = title
                        tabletests
                        zonelabels;
run;

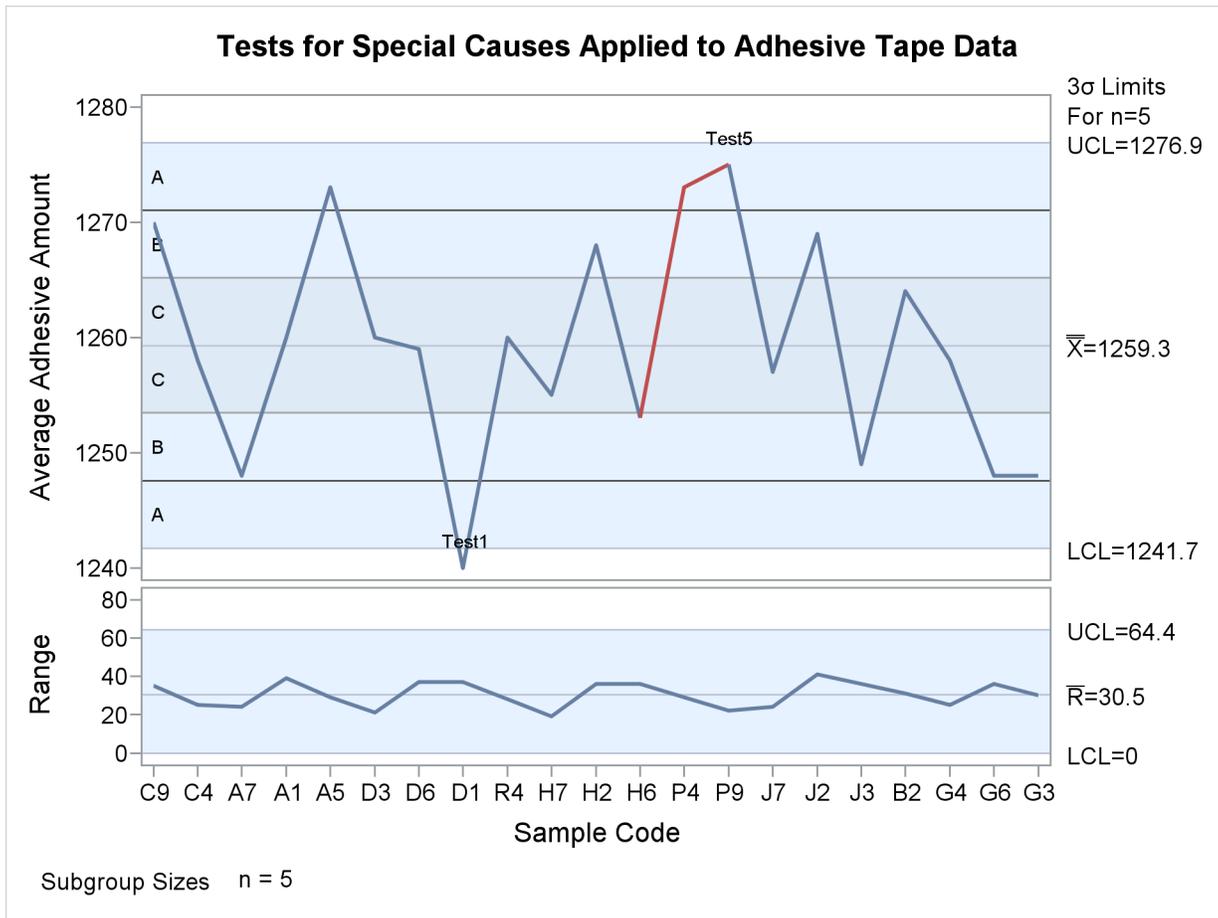

title 'Tests for Special Causes Applied to Adhesive Tape Data';
proc shewhart history=Tape;
  xrchart Weight*Sample / tests    = 1 to 5
                        odstitle = title
                        tabletests
                        nochart
                        zonelabels;
run;

```

The charts are shown in [Output 17.38.1](#), and the table is shown in [Output 17.38.2](#). The TESTS= option requests Tests 1, 2, 3, 4, and 5, which are described in “[Tests for Special Causes: SHEWHART Procedure](#)” on page 2146. The TABLETESTS option requests a basic table of subgroup statistics and control limits with a column indicating which subgroups tested positive for special causes.

The ZONELABELS option displays zone lines and zone labels on the \bar{X} chart. The zones are used to define the tests.

Output 17.38.1 Tests for Special Causes Displayed on \bar{X} and R Charts

Output 17.38.1 and Output 17.38.2 indicate that Test 1 is positive at sample D1 and Test 5 is positive at sample P9. Test 1 detects one point beyond Zone A (outside the control limits), and Test 5 detects two out of three points in a row in Zone A or beyond.

Output 17.38.2 Tabular Form of \bar{X} and R Charts

Example 17.39: Specifying Standard Values for the Process Mean and Standard Deviation

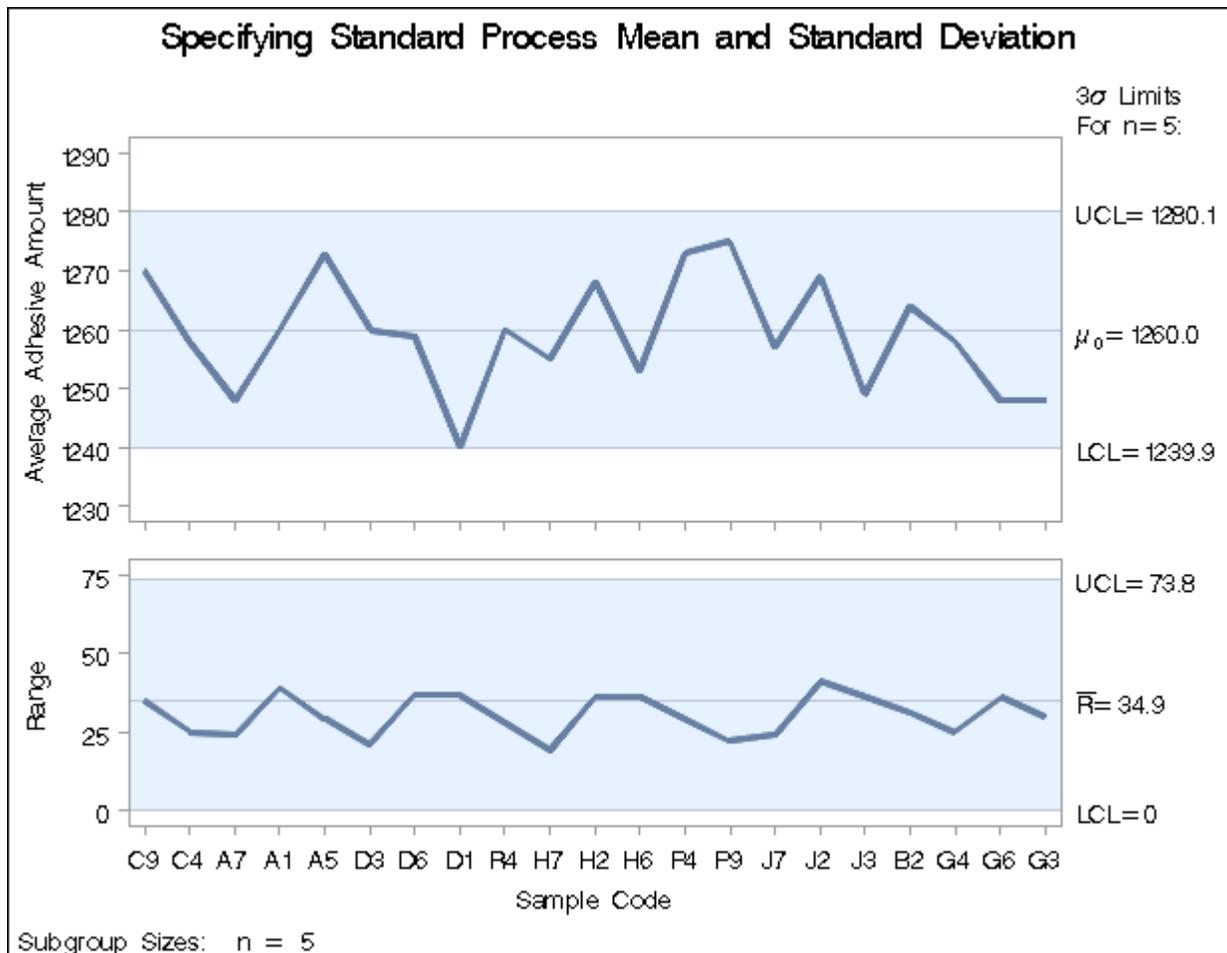

By default, the XRCHART statement estimates the process mean (μ) and standard deviation (σ) from the data, as in the previous example. However, there are applications in which standard values (μ_0 and σ_0) are available based, for instance, on previous experience or extensive sampling. You can specify these values with the MU0= and SIGMA0= options. *See SHWXR3 in the SAS/QC Sample Library*

For example, suppose it is known that the adhesive coating process introduced in the previous example has a mean of 1260 and standard deviation of 15. The following statements specify these standard values:

```
ods graphics off;
title 'Specifying Standard Process Mean and Standard Deviation';
proc shewhart history=Tape;
  xrchart Weight*Sample / mu0      = 1260
                        sigma0    = 15
                        xsymbol   = mu0;
run;
```

The XSYMBOL= option specifies the label for the central line on the \bar{X} chart. The resulting \bar{X} and R charts are shown in Output 17.39.1.

Output 17.39.1 Specifying Standard Values with MU0= and SIGMA0=

The central lines and control limits for both charts are determined by using μ_0 and σ_0 (see the equations in Table 17.71). Output 17.39.1 indicates that the process is in statistical control.

You can also specify μ_0 and σ_0 with the variables `_MEAN_` and `_STDDEV_` in a `LIMITS=` data set, as illustrated by the following statements:

```
data Tapelim;
  length _var_ _subgrp_ _type_ $8;
  _var_   = 'Weight';
  _subgrp_ = 'Sample';
  _type_  = 'STANDARD';
  _limitn_ = 5;
  _mean_  = 1260;
  _stddev_ = 15;

proc shewhart history=Tape limits=Tapelim;
  xrchart Weight*Sample / xsymbol=mu0;
run;
```

The variables `_VAR_` and `_SUBGRP_` are required, and their values must match the *process* and *subgroup-variable*, respectively, specified in the `XRCHART` statement. The bookkeeping variable `_TYPE_` is not required, but it is recommended to indicate that the variables `_MEAN_` and `_STDDEV_` provide standard values rather than estimated values.

The resulting charts (not shown here) are identical to those shown in Output 17.39.1.

Example 17.40: Working with Unequal Subgroup Sample Sizes

See SHWXR4 in the SAS/QC Sample Library The following data set (Wire) contains breaking strength measurements recorded in pounds per inch for 25 samples from a metal wire manufacturing process. The subgroup sample sizes vary between 3 and 7.

```

data Wire;
  input Day size @;
  informat Day date7.;
  format Day date7.;
  do i=1 to size;
    input Breakstrength @@;
    output;
  end;
  drop i size;
  label Breakstrength = 'Breaking Strength';
  datalines;
20JUN94 5 60.6 62.3 62.0 60.4 59.9
21JUN94 5 61.9 62.1 60.6 58.9 65.3
22JUN94 4 57.8 60.5 60.1 57.7
23JUN94 5 56.8 62.5 60.1 62.9 58.9
24JUN94 5 63.0 60.7 57.2 61.0 53.5

11JUL94 4 59.3 62.4 60.4 60.0
12JUL94 5 62.4 61.3 60.5 57.7 60.2
13JUL94 5 61.2 55.5 60.2 60.4 62.4
14JUL94 5 59.0 66.1 57.7 58.5 58.9
;

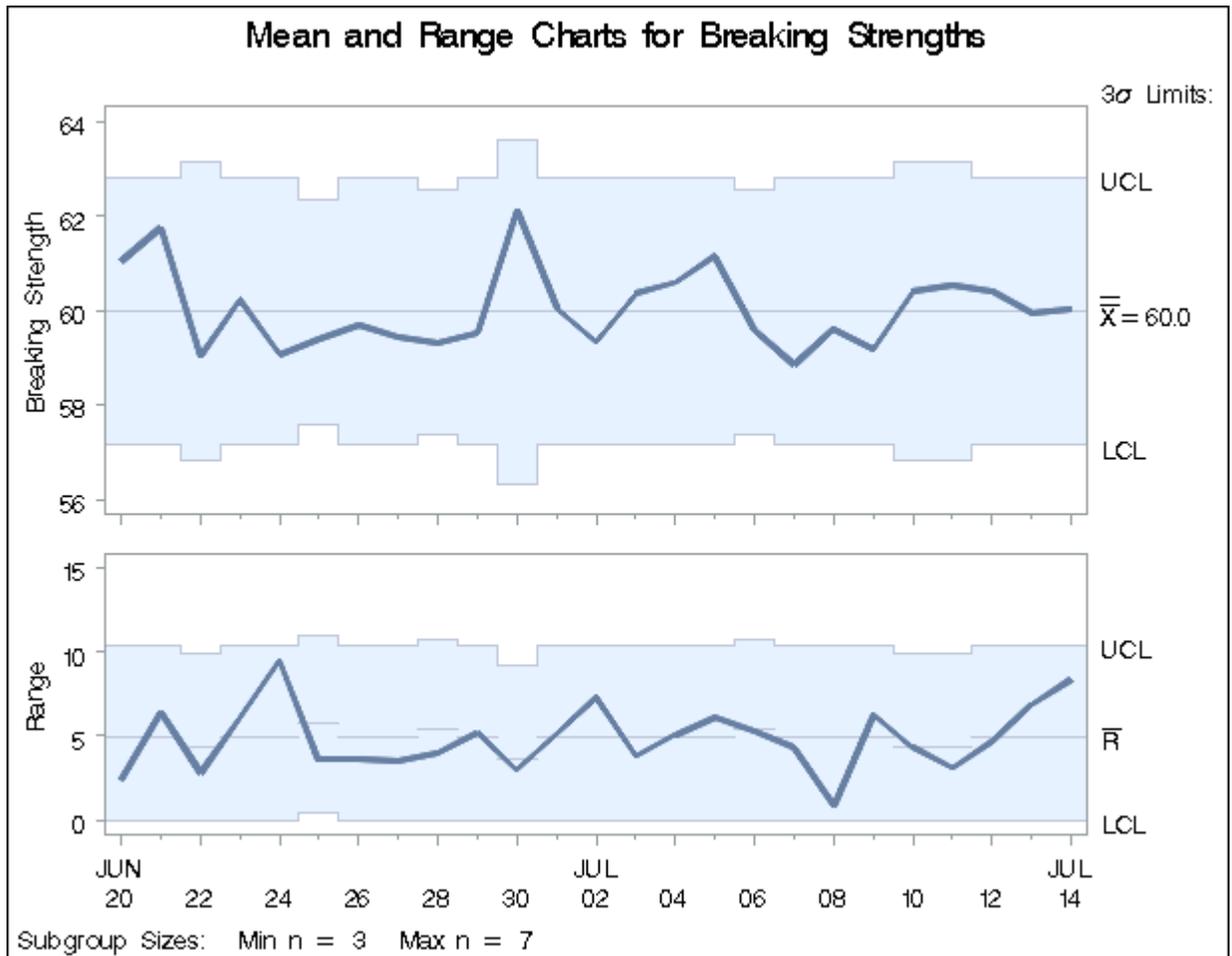

```

The following statements request \bar{X} and R charts, shown in Output 17.40.1, for the strength measurements:

```

ods graphics off;
title 'Mean and Range Charts for Breaking Strengths';
proc shewhart data=Wire;
  xrchart Breakstrength*Day / nohlabel;
run;

```

Output 17.40.1 \bar{X} and R Charts with Varying Subgroup Sample Sizes

Note that the central line on the R chart and the control limits on both charts vary with the subgroup sample size. The sample size legend in the lower-left corner displays the minimum and maximum subgroup sample sizes.

The XRCHART statement provides various options for working with unequal subgroup sample sizes. For example, you can use the LIMITN= option to specify a fixed (nominal) sample size for computing control limits, as illustrated by the following statements:

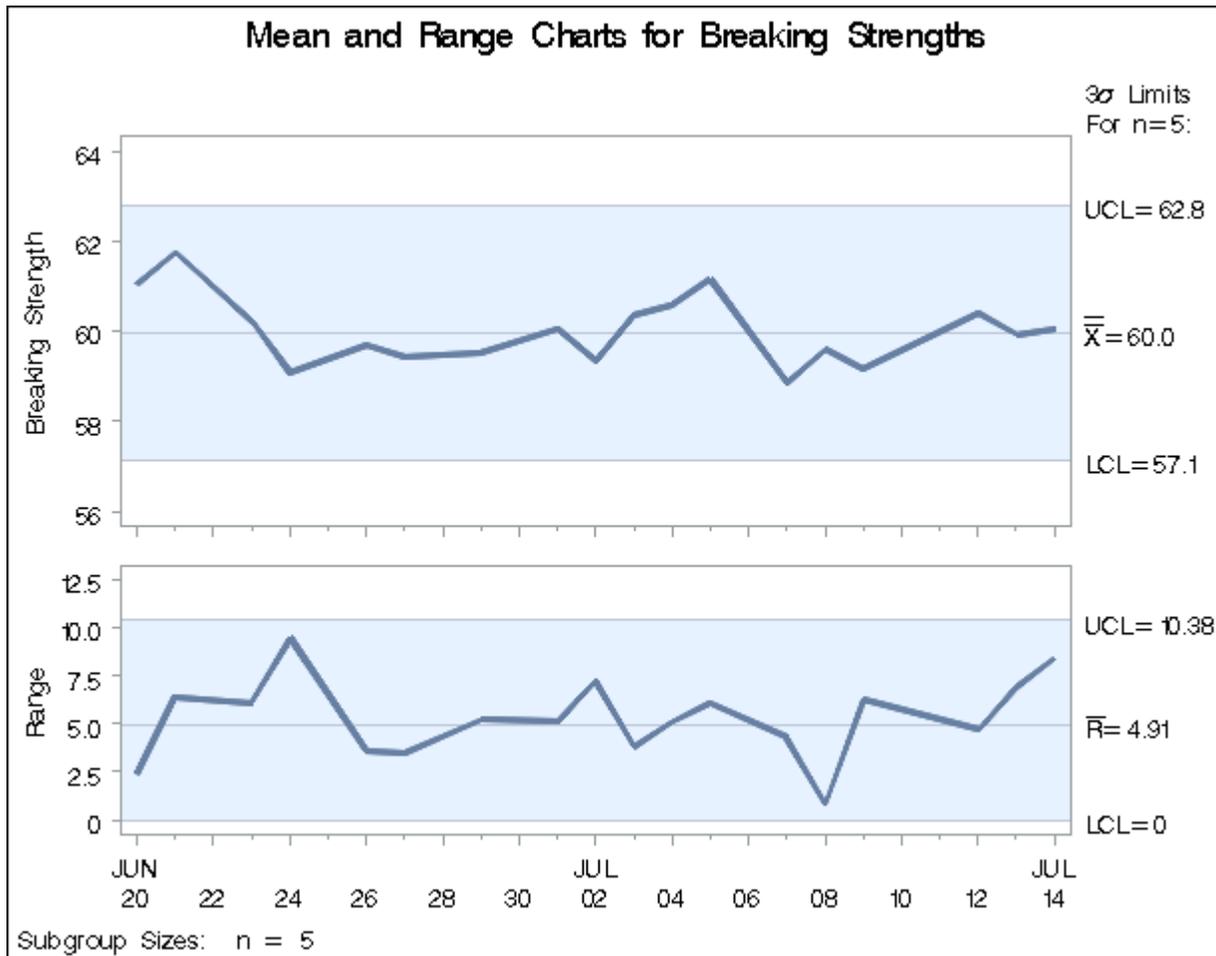

```

title 'Mean and Range Charts for Breaking Strengths';
proc shewhart data=Wire;
  xrchart Breakstrength*Day / nohlabel
    limitn = 5;
run;

```

The resulting charts are shown in [Output 17.40.2](#).

Output 17.40.2 Control Limits Based on Fixed Sample Size

Note that the only points displayed on the chart are those corresponding to subgroups whose sample sizes match the nominal sample size of five. To plot points for all subgroups (regardless of subgroup sample size), you can specify the ALLN option, as follows:

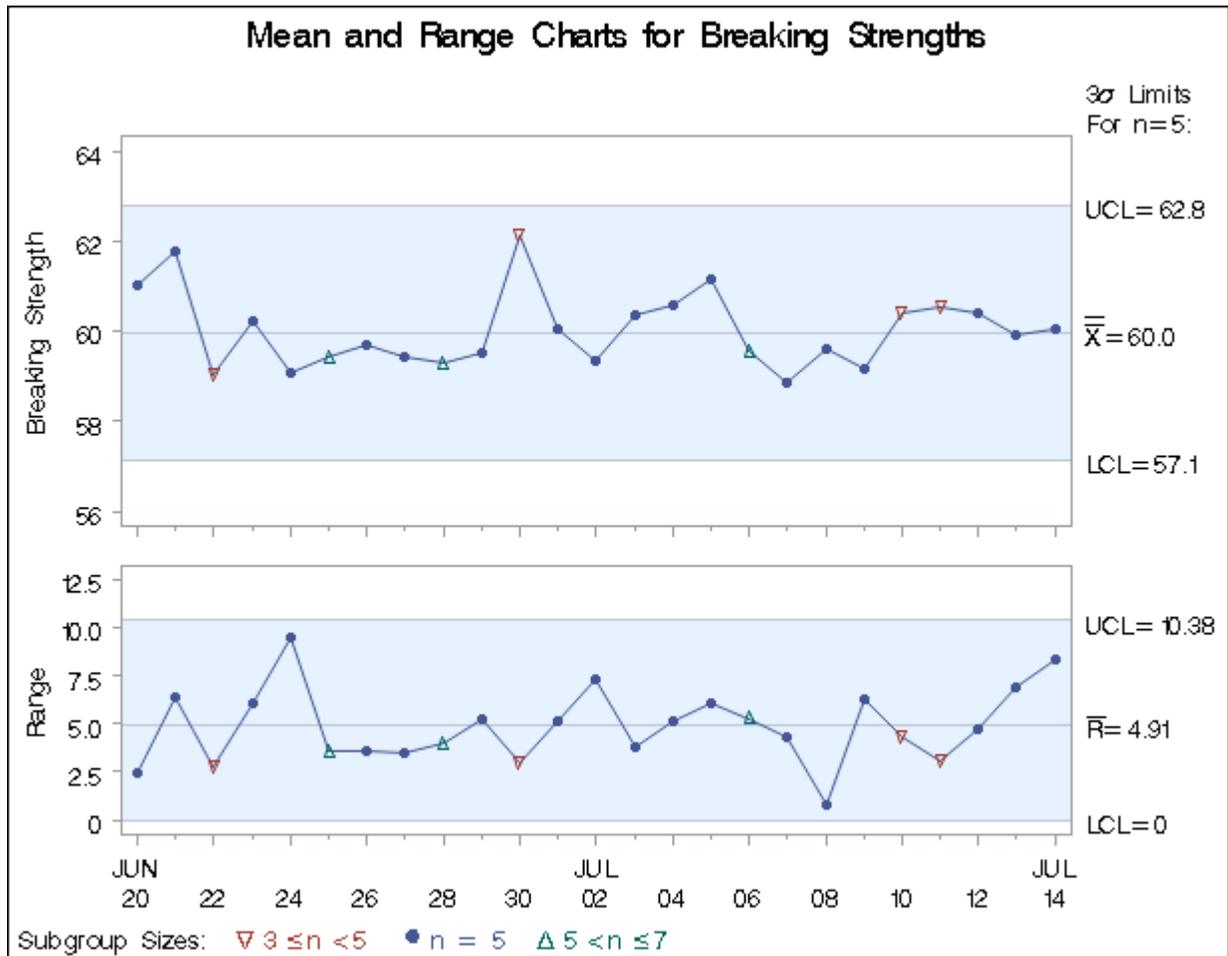

```

symbol1 v=dot;
title 'Mean and Range Charts for Breaking Strengths';
proc shewhart data=Wire;
    xrchart Breakstrength*Day / nohlabel
        limitn = 5
        alln
        nmarkers;
run;

```

The charts are shown in [Output 17.40.3](#). The NMARKERS option requests special symbols to identify points for which the subgroup sample size differs from the nominal sample size.

Output 17.40.3 Displaying All Subgroups Regardless of Sample Size

You can use the SMETHOD= option to determine how the process standard deviation σ is to be estimated when the subgroup sample sizes vary. The default method computes $\hat{\sigma}$ as an unweighted average of subgroup estimates of σ . Specifying SMETHOD=MVLUE requests an estimate that assigns greater weight to estimates of σ from subgroups with larger sample sizes. For more information, see “Methods for Estimating the Standard Deviation” on page 1940.

The following statements apply both methods:

```
proc shewhart data=Wire;
  xrchart Breakstrength*Day / outlimits = Wlim1
                             outindex  = 'Default'
                             nochart;
  xrchart Breakstrength*Day / smethod   = mvlue
                             outlimits  = Wlim2
                             outindex   = 'MVLUE'
                             nochart;

run;

data Wlimits;
  set Wlim1 Wlim2;

run;
```

- specify a known (standard) process mean and standard deviation for computing control limits
- display distinct sets of control limits for data from successive time phases
- add block legends and symbol markers to reveal stratification in process data
- superimpose stars at points to represent related multivariate factors
- clip extreme points to make the charts more readable
- display vertical and horizontal reference lines
- control axis values and labels
- control layout and appearance of the chart

You have three alternatives for producing \bar{X} and s charts with the XSCHART statement:

- ODS Graphics output is produced if ODS Graphics is enabled, for example by specifying the ODS GRAPHICS ON statement prior to the PROC statement.
- Otherwise, traditional graphics are produced by default if SAS/GRAPH[®] is licensed.
- Legacy line printer charts are produced when you specify the LINEPRINTER option in the PROC statement.

See Chapter 3, “[SAS/QC Graphics](#),” for more information about producing these different kinds of graphs.

Getting Started: XSCHART Statement

This section introduces the XSCHART statement with simple examples that illustrate commonly used options. Complete syntax for the XSCHART statement is presented in the section “Syntax: XSCHART Statement” on page 1967, and advanced examples are given in the section “Examples: XSCHART Statement” on page 1992.

Creating Charts for Means and Standard Deviations from Raw Data

A petroleum company uses a turbine to heat water into steam, which is then pumped into the ground to make oil less viscous and easier to extract. This process occurs 20 times daily, and the amount of power (in kilowatts) used to heat the water to the desired temperature is recorded. The following statements create a SAS data set named Turbine, which contains the power output measurements for 20 days:

See SHWXS1 in the SAS/QC Sample Library

```
data Turbine;
  informat Day date7.;
  format Day date5.;
  input Day @;
  do i=1 to 10;
    input KWatts @;
    output;
  end;
  drop i;
  datalines;

11	04JUL	3417
12	04JUL	3199
13	04JUL	3613
14	04JUL	3384
15	04JUL	3475
16	04JUL	3316
17	04JUL	3556
18	04JUL	3607
19	04JUL	3364
20	04JUL	3721
21	05JUL	3390
22	05JUL	3562
23	05JUL	3413
24	05JUL	3193
25	05JUL	3635

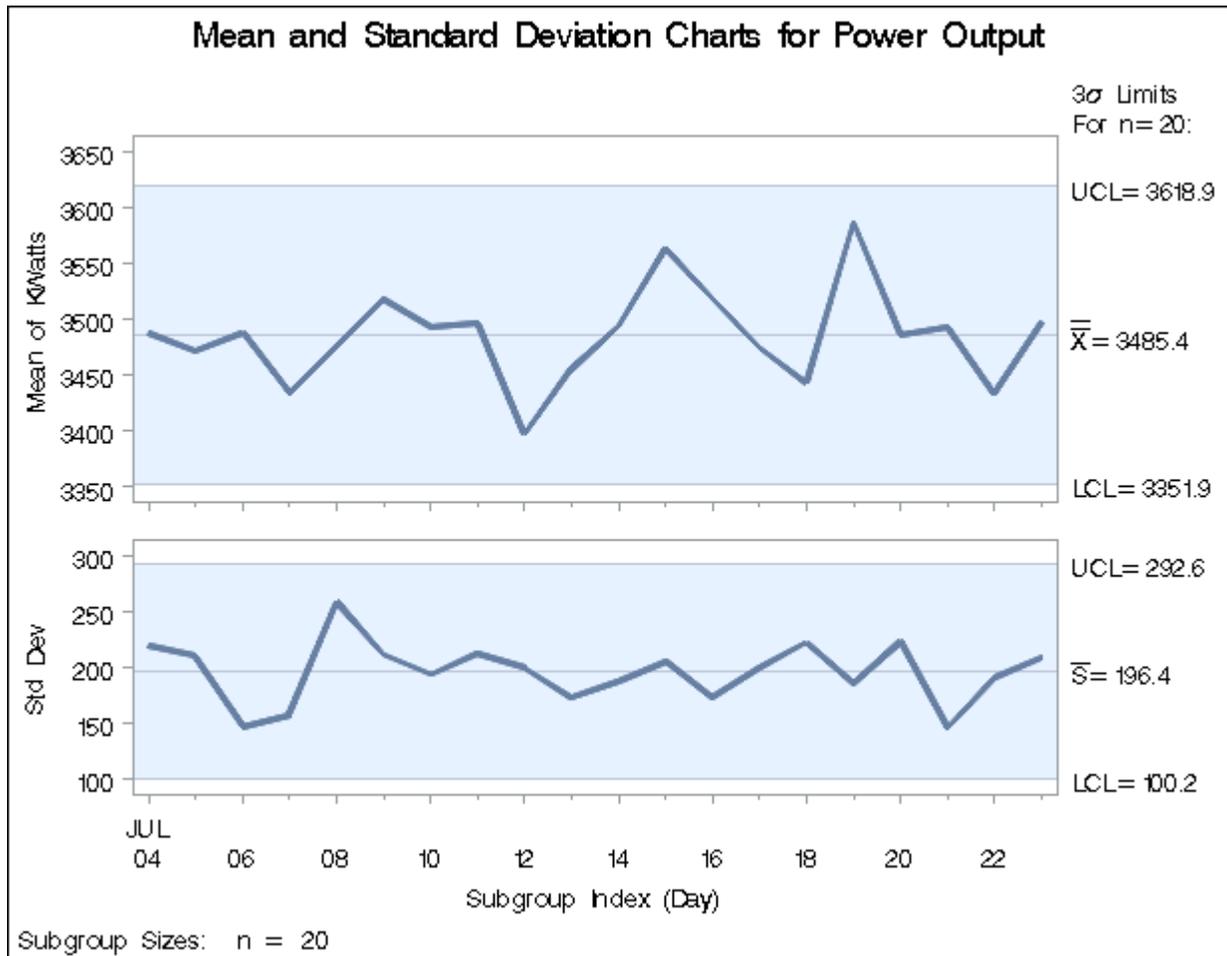

The data set is said to be in “strung-out” form since each observation contains the day and power output for a single heating. The first 20 observations contain the power outputs for the first day, the second 20 observations contain the power outputs for the second day, and so on. Because the variable Day classifies the observations into rational subgroups, it is referred to as the *subgroup-variable*. The variable KWatts contains the power output measurements and is referred to as the *process variable* (or *process* for short).

You can use \bar{X} and s charts to determine whether the heating process is in control. The following statements create the \bar{X} and s charts shown in Figure 17.115:

```
ods graphics off;
title 'Mean and Standard Deviation Charts for Power Output';
proc shewhart data=Turbine;
  xschart KWatts*Day ;
run;
```

This example illustrates the basic form of the XSCHART statement. After the keyword XSCHART, you specify the *process* to analyze (in this case KWatts), followed by an asterisk and the *subgroup-variable* (Day).

The input data set is specified with the DATA= option in the PROC SHEWHART statement.

Figure 17.115 \bar{X} and s Charts for Power Output Data (Traditional Graphics)

Each point on the \bar{X} chart represents the mean of the measurements for a particular day. For instance, the mean plotted for the first day is $(3196 + 3507 + \dots + 3721)/20 = 3487.4$.

Each point on the s chart represents the standard deviation of the measurements for a particular day. For instance, the standard deviation plotted for the first day is

$$\sqrt{\frac{(3196 - 3487.4)^2 + (3507 - 3487.4)^2 + \dots + (3721 - 3487.4)^2}{19}} = 220.26$$

Since all the points lie within the control limits, it can be concluded that the process is in statistical control.

By default, the control limits shown are 3 σ limits estimated from the data; the formulas for the limits are given in Table 17.77. You can also read control limits from an input data set; see “Reading Preestablished Control Limits” on page 1966.

For computational details, see “Constructing Charts for Means and Standard Deviations” on page 1979. For more details on reading raw data, see “DATA= Data Set” on page 1986.

Creating Charts for Means and Standard Deviations from Summary Data

See SHWXS1 in the
SAS/QC Sample Library

The previous example illustrates how you can create \bar{X} and s charts using raw data (process measurements). However, in many applications the data are provided as subgroup summary statistics. This example illustrates how you can use the XSCHEM statement with data of this type.

The following data set (Oilsum) provides the data from the preceding example in summarized form:

```
data Oilsum;
  input Day KWattsX KWattsS KWattsN;
  informat Day date7. ;
  format Day date5. ;
  label Day='Date of Measurement';
  datalines;
04JUL94 3487.40 220.260 20
05JUL94 3471.65 210.427 20
06JUL94 3488.30 147.025 20
07JUL94 3434.20 157.637 20
08JUL94 3475.80 258.949 20
09JUL94 3518.10 211.566 20
10JUL94 3492.65 193.779 20
11JUL94 3496.40 212.024 20
12JUL94 3398.50 199.201 20
13JUL94 3456.05 173.455 20
14JUL94 3493.60 187.465 20
15JUL94 3563.30 205.472 20
16JUL94 3519.05 173.676 20
17JUL94 3474.20 200.576 20
18JUL94 3443.60 222.084 20
19JUL94 3586.35 185.724 20
20JUL94 3486.45 223.474 20
21JUL94 3492.90 145.267 20
22JUL94 3432.80 190.994 20
23JUL94 3496.90 208.858 20
;
```

A partial listing of Oilsum is shown in Figure 17.116.

Figure 17.116 The Summary Data Set Oilsum

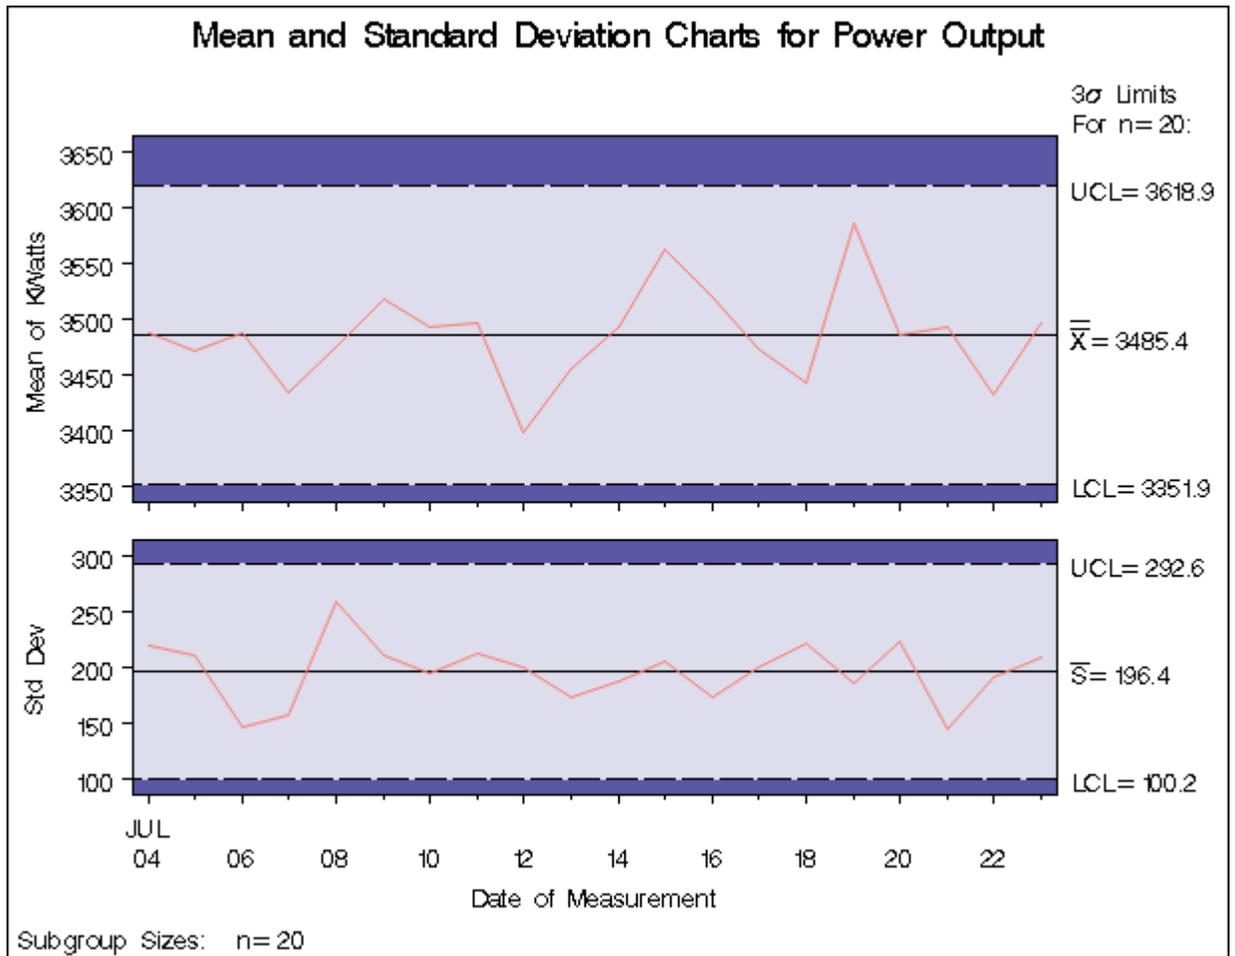

Summary Data Set for Power Output			
Day	KWattsX	KWattsS	KWatts N
04JUL	3487.40	220.260	20
05JUL	3471.65	210.427	20
06JUL	3488.30	147.025	20
07JUL	3434.20	157.637	20
08JUL	3475.80	258.949	20

There is exactly one observation for each subgroup (note that the subgroups are still indexed by Day). The variable KWattsX contains the subgroup means, the variable KWattsS contains the subgroup standard deviations, and the variable KWattsN contains the subgroup sample sizes (which are all 20). You can read this data set by specifying it as a HISTORY= data set in the PROC SHEWHART statement, as follows:

```
options nogstyle;
goptions ftext=swiss;
symbol color = salmon h = .8;
title 'Mean and Standard Deviation Charts for Power Output';
proc shewhart history=Oilsum;
    xschart KWatts*Day / cframe = lib
                    cinfill = bwh
                    cconnect = salmon;
run;
options gstyle;
```

The NOGSTYLE system option causes ODS styles not to affect traditional graphics. Instead, the SYMBOL statement and XSCHART statement options control the appearance of the graph. The GSTYLE system option restores the use of ODS styles for traditional graphics produced subsequently. The resulting \bar{X} and s charts are shown in Figure 17.117.

Note that KWatts is *not* the name of a SAS variable in the data set Oilsum but is, instead, the common prefix for the names of the three SAS variables KWattsX, KWattsS, and KWattsN. The suffix characters X, S, and N indicate *mean*, *standard deviation*, and *sample size*, respectively. Thus, you can specify three subgroup summary variables in the HISTORY= data set with a single name (KWatts), which is referred to as the *process*. The name Day specified after the asterisk is the name of the *subgroup-variable*.

Figure 17.117 \bar{X} and s Charts for Power Output Data (Traditional Graphics with NOGSTYLE)

In general, a HISTORY= input data set used with the XSCHART statement must contain the following variables:

- subgroup variable
- subgroup mean variable
- subgroup standard deviation variable
- subgroup sample size variable

Furthermore, the names of the subgroup mean, standard deviation, and sample size variables must begin with the *process* name specified in the XSCHART statement and end with the special suffix characters X, S, and N, respectively. If the names do not follow this convention, you can use the RENAME option to rename the variables for the duration of the SHEWHART procedure step. For an illustration, see [Example 17.42](#).

In summary, the interpretation of *process* depends on the input data set:

- If raw data are read using the DATA= option (as in the previous example), *process* is the name of the SAS variable containing the process measurements.
- If summary data are read using the HISTORY= option (as in this example), *process* is the common prefix for the names of the variables containing the summary statistics.

For more information, see “HISTORY= Data Set” on page 1987.

Saving Summary Statistics

In this example, the XSCHART statement is used to create a summary data set that can be read later by the SHEWHART procedure (as in the preceding example). The following statements read measurements from the data set Turbine (see “Creating Charts for Means and Standard Deviations from Raw Data” on page 1957) and create a summary data set named Turbhist: *See SHWXS1 in the SAS/QC Sample Library*

```
proc shewhart data=Turbine;
  xschart KWatts*Day / outhistory = Turbhist
                    nochart;
run;
```

The OUTHISTORY= option names the output data set, and the NOCHART option suppresses the display of the charts, which would be identical to those in Figure 17.115. Options such as OUTHISTORY= and NOCHART are specified after the slash (/) in the XSCHART statement. A complete list of options is presented in the section “Syntax: XSCHART Statement” on page 1967.

Figure 17.118 contains a partial listing of Turbhist.

Figure 17.118 The Summary Data Set Turbhist

Summary Data Set for Power Output			
Day	KWattsX	KWattsS	KWatts N
04JUL	3487.40	220.260	20
05JUL	3471.65	210.427	20
06JUL	3488.30	147.025	20
07JUL	3434.20	157.637	20
08JUL	3475.80	258.949	20

There are four variables in the data set Turbhist.

- Day contains the subgroup index.
- KWattsX contains the subgroup means.
- KWattsS contains the subgroup standard deviations.
- KWattsN contains the subgroup sample sizes.

Note that the summary statistic variables are named by adding the suffix characters X , S , and N to the *process* KWatts specified in the XSCHART statement. In other words, the variable naming convention for OUTHISTORY= data sets is the same as that for HISTORY= data sets.

For more information, see “OUTHISTORY= Data Set” on page 1983.

Saving Control Limits

See SHWXS1 in the SAS/QC Sample Library

You can save the control limits for \bar{X} and s charts in a SAS data set; this enables you to apply the control limits to future data (see “Reading Prestablished Control Limits” on page 1966) or modify the limits with a DATA step program.

The following statements read measurements from the data set Turbine (see “Creating Charts for Means and Standard Deviations from Raw Data” on page 1957) and save the control limits displayed in Figure 17.115 in a data set named Turblim:

```
proc shewhart data=Turbine;
  xschart KWatts*Day / outlimits=Turblim
  nochart;
run;
```

The OUTLIMITS= option names the data set containing the control limits, and the NOCHART option suppresses the display of the charts. The data set Turblim is listed in Figure 17.119.

Figure 17.119 The Data Set Turblim Containing Control Limit Information

Control Limits for Power Output Data						
VAR	_SUBGRP_	_TYPE_	_LIMITN_	_ALPHA_	_SIGMAS_	_LCLX_
KWatts	Day	ESTIMATE	20	.002699796	3	3351.92
MEAN	_UCLX_	_LCLS_	_S_	_UCLS_	_STDDEV_	
3485.41	3618.90	100.207	196.396	292.584	198.996	

The data set Turblim contains one observation with the limits for *process* KWatts. The variables _LCLX_ and _UCLX_ contain the lower and upper control limits for the \bar{X} chart, and the variables _LCLS_ and _UCLS_ contain the lower and upper control limits for the s chart. The variable _MEAN_ contains the central line for the \bar{X} chart, and the variable _S_ contains the central line for the s chart. The value of _MEAN_ is an estimate of the process mean, and the value of _STDDEV_ is an estimate of the process standard deviation σ . The value of _LIMITN_ is the nominal sample size associated with the control limits, and the value of _SIGMAS_ is the multiple of σ associated with the control limits. The variables _VAR_ and _SUBGRP_ are bookkeeping variables that save the *process* and *subgroup-variable*. The variable _TYPE_ is a bookkeeping variable that indicates whether the values of _MEAN_ and _STDDEV_ are estimates or standard values. For more information, see “OUTLIMITS= Data Set” on page 1981.

You can create an output data set containing both control limits and summary statistics with the OUTTABLE= option, as illustrated by the following statements:

```

proc shewhart data=Turbine;
  xschart KWatts*Day / outtable=Turbtab
  nochart;
run;

```

The data set Turbtab is listed in Figure 17.120.

Figure 17.120 The OUTTABLE= Data Set Turbtab

Summary Statistics and Control Limit Information								
<u>VAR</u>	<u>Day</u>	<u>SIGMAS</u>	<u>LIMITN</u>	<u>SUBN</u>	<u>LCLX</u>	<u>SUBX</u>	<u>MEAN</u>	<u>UCLX</u>
KWatts	04JUL	3	20	20	3351.92	3487.40	3485.41	3618.90
KWatts	05JUL	3	20	20	3351.92	3471.65	3485.41	3618.90
KWatts	06JUL	3	20	20	3351.92	3488.30	3485.41	3618.90
KWatts	07JUL	3	20	20	3351.92	3434.20	3485.41	3618.90
KWatts	08JUL	3	20	20	3351.92	3475.80	3485.41	3618.90
KWatts	09JUL	3	20	20	3351.92	3518.10	3485.41	3618.90
KWatts	10JUL	3	20	20	3351.92	3492.65	3485.41	3618.90
KWatts	11JUL	3	20	20	3351.92	3496.40	3485.41	3618.90

198.996		100.207	208.858	196.396	292.584			

The data set Turbtab contains one observation for each subgroup sample. The variables `_SUBX_`, `_SUBS_`, and `_SUBN_` contain the subgroup means, subgroup standard deviations, and subgroup sample sizes. The variables `_LCLX_` and `_UCLX_` contain the lower and upper control limits for the \bar{X} chart. The variables `_LCLS_` and `_UCLS_` contain the lower and upper control limits for the s chart. The variable `_MEAN_` contains the central line for the \bar{X} chart. The variable `_S_` contains the central line for the s chart. The variables `_VAR_` and `Batch` contain the *process* name and values of the *subgroup-variable*, respectively. For more information, see “OUTTABLE= Data Set” on page 1983.

A data set created with the `OUTTABLE=` option can be read later as a `TABLE=` data set. For example, the following statements read Turbtab and display charts (not shown here) identical to those in Figure 17.115:

```
title 'Mean and Standard Deviation Charts for Power Output';
proc shewhart table=Turbtab;
  xschart KWatts*Day;
run;
```

Because the SHEWHART procedure simply displays the information in a `TABLE=` data set, you can use `TABLE=` data sets to create specialized control charts (see “Specialized Control Charts: SHEWHART Procedure” on page 2171). For more information, see “TABLE= Data Set” on page 1988.

Reading Preestablished Control Limits

See SHWXS1 in the SAS/QC Sample Library

In the previous example, the `OUTLIMITS=` data set Turblim saved control limits computed from the measurements in Turbine. This example shows how these limits can be applied to new data. The following statements create \bar{X} and s charts for new measurements in a data set named Turbine2 (not listed here) using the control limits in Turblim:

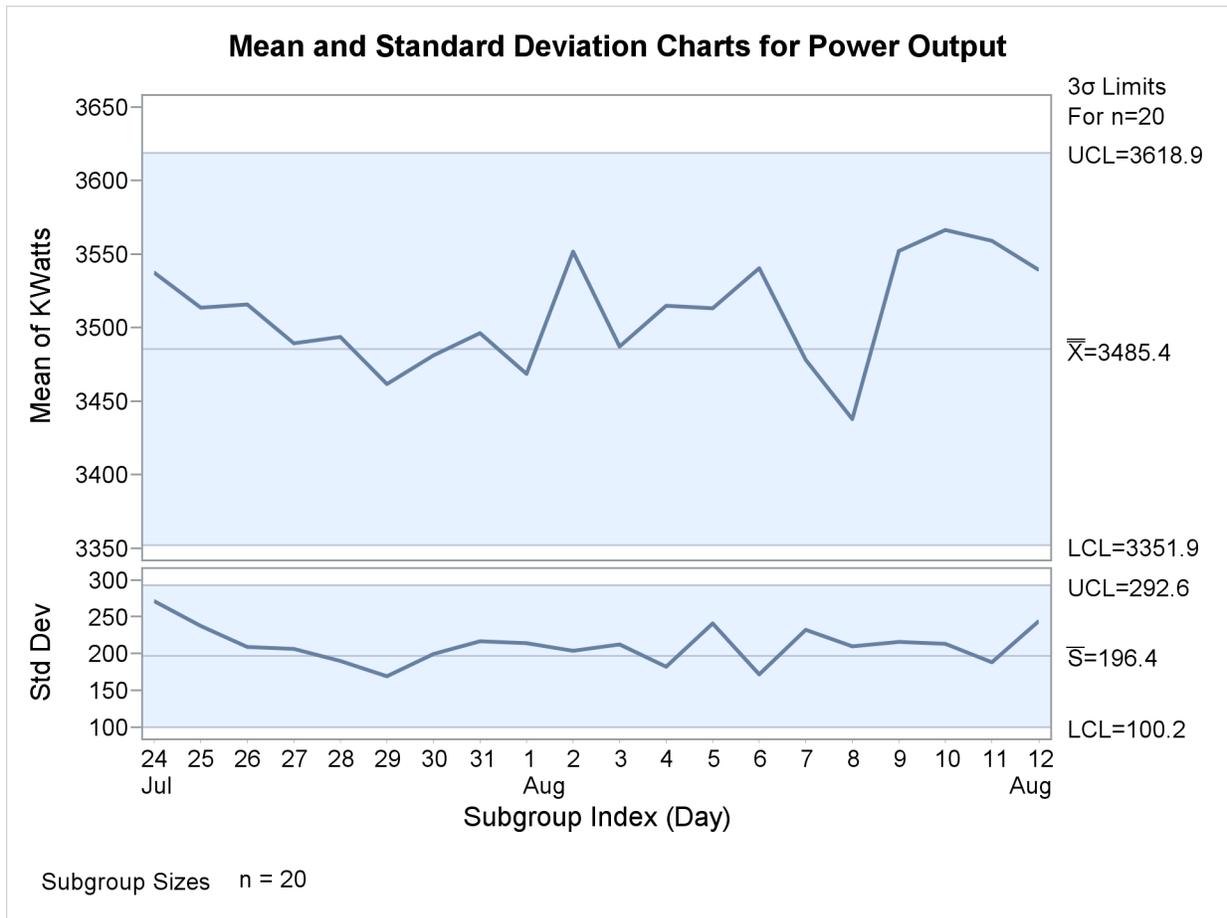

```
ods graphics on;
title 'Mean and Standard Deviation Charts for Power Output';
proc shewhart data=Turbine2 limits=Turblim;
  xschart KWatts*Day / odstitle = title;
run;
```

The `ODS GRAPHICS ON` statement specified before the `PROC SHEWHART` statement enables ODS Graphics, so the \bar{X} and s charts are created by using ODS Graphics instead of traditional graphics. The charts are shown in Figure 17.121.

The `LIMITS=` option in the `PROC SHEWHART` statement specifies the data set containing preestablished control limit information. By default,⁴⁰ this information is read from the first observation in the `LIMITS=` data set for which

- the value of `_VAR_` matches the *process* name KWatts
- the value of `_SUBGRP_` matches the *subgroup-variable* name Day

⁴⁰In SAS 6.09 and in earlier releases, it is also necessary to specify the `READLIMITS` option to read control limits from a `LIMITS=` data set.

Figure 17.121 \bar{X} and s Charts for Second Set of Power Outputs (ODS Graphics)

The means and standard deviations lie within the control limits, indicating that the heating process is still in statistical control.

In this example, the LIMITS= data set was created in a previous run of the SHEWHART procedure. You can also create a LIMITS= data set with the DATA step. See “LIMITS= Data Set” on page 1986 for details concerning the variables that you must provide.

Syntax: XSCHART Statement

The basic syntax for the XSCHART statement is as follows:

```
XSCHART process * subgroup-variable ;
```

The general form of this syntax is as follows:

```
XSCHART processes * subgroup-variable <(block-variables | = 'character') / <options> ;
```

You can use any number of XSCHART statements in the SHEWHART procedure. The components of the XSCHART statement are described as follows.

process**processes**

identify one or more processes to be analyzed. The specification of *process* depends on the input data set specified in the PROC SHEWHART statement.

- If the raw data are read using a DATA= data set, *process* must be the name of the variable containing the raw measurements. For an example, see “[Creating Charts for Means and Standard Deviations from Raw Data](#)” on page 1957.
- If summary data are read from a HISTORY= data set, *process* must be the common prefix of the summary variables in the HISTORY= data set. For an example, see “[Creating Charts for Means and Standard Deviations from Summary Data](#)” on page 1960.
- If summary data and control limits are read from a TABLE= data set, *process* must be the value of the variable `_VAR_` in the TABLE= data set. For an example, see “[Saving Control Limits](#)” on page 1964.

A *process* is required. If more than one *process* is specified, enclose the list in parentheses. For example, the following statements request distinct \bar{X} and *s* charts for Weight, Length, and Width:

```
proc shewhart data=Measures;
    xschart (Weight Length Width)*Day;
run;
```

subgroup-variable

is the variable that identifies subgroups in the data. The *subgroup-variable* is required. In the preceding XSCHEM statement, Day is the subgroup variable. For details, see “[Subgroup Variables](#)” on page 1938.

block-variables

are optional variables that group the data into blocks of consecutive subgroups. The blocks are labeled in a legend, and each *block-variable* provides one level of labels in the legend. See “[Displaying Stratification in Blocks of Observations](#)” on page 2098 for an example.

symbol-variable

is an optional variable whose levels (unique values) determine the symbol marker or character used to plot the means and standard deviations.

- If you produce a line printer chart, an ‘A’ is displayed for the points corresponding to the first level of the *symbol-variable*, a ‘B’ is displayed for the points corresponding to the second level, and so on.
- If you produce traditional graphics, distinct symbol markers are displayed for points corresponding to the various levels of the *symbol-variable*. You can specify the symbol markers with SYMBOL n statements. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097 for an example.

character

specifies a plotting character for line printer charts. For example, the following statements create \bar{X} and s charts using an asterisk (*) to plot the points:

```
proc shewhart data=Values lineprinter;
  xschart Weight*Day='*';
run;
```

options

enhance the appearance of the charts, request additional analyses, save results in data sets, and so on. The “[Summary of Options](#)” on page 1969 section, which follows, lists all options by function. “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018 describes each option in detail.

Summary of Options

The following tables list the XSCHART statement options by function. For complete descriptions, see “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Table 17.76 XSCHART Statement Options

Option	Description
Options for Specifying Control Limits	
ALPHA=	requests probability limits for chart
LIMITN=	specifies either nominal sample size for fixed control limits or varying limits
NOREADLIMITS	computes control limits for each <i>process</i> from the data rather than a LIMITS= data set (SAS 6.10 and later releases)
READALPHA	reads <code>_ALPHA_</code> instead of <code>_SIGMAS_</code> from a LIMITS= data set
READINDEX=	reads control limits for each <i>process</i> from a LIMITS= data set
READLIMITS	reads single set of control limits for each <i>process</i> from a LIMITS= data set (SAS 6.09 and earlier releases)
SIGMAS=	specifies width of control limits in terms of multiple k of standard error of plotted means
Options for Displaying Control Limits	
CINFILL=	specifies color for area inside control limits
CLIMITS=	specifies color of control limits, central line, and related labels
LCLLABEL=	specifies label for lower control limit on \bar{X} chart
LCLLABEL2=	specifies label for lower control limit on s chart
LIMLABSUBCHAR=	specifies a substitution character for labels provided as quoted strings; the character is replaced with the value of the control limit
LLIMITS=	specifies line type for control limits

Table 17.76 *continued*

Option	Description
NDECIMAL=	specifies number of digits to right of decimal place in default labels for control limits and central line on \bar{X} chart
NDECIMAL2=	specifies number of digits to right of decimal place in default labels for control limits and central line on s chart
NOCTL	suppresses display of central line on \bar{X} chart
NOCTL2	suppresses display of central line on s chart
NOLCL	suppresses display of lower control limit on \bar{X} chart
NOLCL2	suppresses display of lower control limit on s chart
NOLIMIT0	suppresses display of zero lower control limit on s chart
NOLIMITLABEL	suppresses labels for control limits and central line
NOLIMITS	suppresses display of control limits
NOLIMITSFRAME	suppresses default frame around control limit information when multiple sets of control limits are read from a LIMITS= data set
NOLIMITSLEGEND	suppresses legend for control limits
NOUCL	suppresses display of upper control limit on \bar{X} chart
NOUCL2	suppresses display of upper control limit on s chart
SSYMBOL=	specifies label for central line on s chart
UCLLABEL=	specifies label for upper control limit on \bar{X} chart
UCLLABEL2=	specifies label for upper control limit on s chart
WLIMITS=	specifies width for control limits and central line
XSYMBOL=	specifies label for central line on \bar{X} chart
Process Mean and Standard Deviation Options	
MU0=	specifies known value of μ_0 for process mean μ
SIGMA0=	specifies known value σ_0 for process standard deviation σ
SMETHOD=	specifies method for estimating process standard deviation σ
TYPE=	identifies parameters as estimates or standard values and specifies value of <code>_TYPE_</code> in the OUTLIMITS= data set
Options for Plotting and Labeling Points	
ALLLABEL=	labels every point on \bar{X} chart
ALLLABEL2=	labels every point on s chart
CLABEL=	specifies color for labels
CCONNECT=	specifies color for line segments that connect points on chart
CFRAMELAB=	specifies fill color for frame around labeled points
CNEEDLES=	specifies color for needles that connect points to central line
COUT=	specifies color for portions of line segments that connect points outside control limits
COUTFILL=	specifies color for shading areas between the connected points and control limits outside the limits

Table 17.76 *continued*

Option	Description
LABELANGLE=	specifies angle at which labels are drawn
LABELFONT=	specifies software font for labels (alias for the TESTFONT= option)
LABELHEIGHT=	specifies height of labels (alias for the TESTHEIGHT= option)
NEEDLES	connects points to central line with vertical needles
NOCONNECT	suppresses line segments that connect points on chart
OUTLABEL=	labels points outside control limits on \bar{X} chart
OUTLABEL2=	labels points outside control limits on s chart
SYMBOLLEGEND=	specifies LEGEND statement for levels of <i>symbol-variable</i>
SYMBOLORDER=	specifies order in which symbols are assigned for levels of <i>symbol-variable</i>
TURNALL/TURNOUT	turns point labels so that they are strung out vertically
WNEEDLES=	specifies width of needles
Options for Specifying Tests for Special Causes	
INDEPENDENTZONES	computes zone widths independently above and below center line
NO3SIGMACHECK	enables tests to be applied with control limits other than 3σ limits
NOTESTACROSS	suppresses tests across <i>phase</i> boundaries
TESTS=	specifies tests for special causes for the \bar{X} chart
TESTS2=	specifies tests for special causes for the s chart
TEST2RESET=	enables tests for special causes to be reset for the s chart
TEST2RUN=	specifies length of pattern for Test 2
TEST3RUN=	specifies length of pattern for Test 3
TESTACROSS	applies tests across <i>phase</i> boundaries
TESTLABEL=	provides labels for points where test is positive
TESTLABEL n =	specifies label for n th test for special causes
TESTNMETHOD=	applies tests to standardized chart statistics
TESTOVERLAP	performs tests on overlapping patterns of points
TESTRESET=	enables tests for special causes to be reset
ZONELABELS	adds labels A, B, and C to zone lines for \bar{X} chart
ZONE2LABELS	adds labels A, B, and C to zone lines for s chart
ZONES	adds lines to \bar{X} chart delineating zones A, B, and C
ZONES2	adds lines to s chart delineating zones A, B, and C
ZONEVALPOS=	specifies position of ZONEVALUES labels
ZONEVALUES	labels \bar{X} chart zone lines with their values
ZONE2VALUES	labels s zone lines with their values
Options for Displaying Tests for Special Causes	
CTESTLABBOX=	specifies color for boxes enclosing labels indicating points where test is positive
CTESTS=	specifies color for labels indicating points where test is positive

Table 17.76 *continued*

Option	Description
CTESTSYMBOL=	specifies color for symbol used to plot points where test is positive
CZONES=	specifies color for lines and labels delineating zones A, B, and C
LTESTS=	specifies type of line connecting points where test is positive
LZONES=	specifies line type for lines delineating zones A, B, and C
TESTFONT=	specifies software font for labels at points where test is positive
TESTHEIGHT=	specifies height of labels at points where test is positive
TESTLABBOX	requests that labels for points where test is positive be positioned so that do not overlap
TESTSYMBOL=	specifies plot symbol for points where test is positive
TESTSYMBOLHT=	specifies symbol height for points where test is positive
WTESTS=	specifies width of line connecting points where test is positive
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill colors for frame for plot area
CTEXT=	specifies color for tick mark values and axis labels
DISCRETE	produces horizontal axis for discrete numeric group values
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
INTSTART=	specifies first major tick mark value on horizontal axis when a date, time, or datetime format is associated with numeric subgroup variable
NOHLABEL	suppresses label for horizontal axis
NOTICKREP	specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on horizontal axis
NOTRUNC	suppresses vertical axis truncation at zero applied by default to <i>s</i> chart
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPLABELS=	specifies thinning factor for tick mark labels on horizontal axis
SPLIT=	specifies splitting character for axis labels
TURNHLABELS	requests horizontal axis labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis of \bar{X} chart

Table 17.76 *continued*

Option	Description
VAXIS2=	specifies major tick mark values for vertical axis of <i>s</i> chart
VFORMAT=	specifies format for primary vertical axis tick mark labels
VFORMAT2=	specifies format for secondary vertical axis tick mark labels
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis for primary chart
VZERO2	forces origin to be included in vertical axis for secondary chart
WAXIS=	specifies width of axis lines
Plot Layout Options	
ALLN	plots means for all subgroups
BILEVEL	creates control charts using half-screens and half-pages
EXCHART	creates control charts for a process only when exceptions occur
INTERVAL=	natural time interval between consecutive subgroup positions when time, date, or datetime format is associated with a numeric subgroup variable
MAXPANELS=	maximum number of pages or screens for chart
NMARKERS	requests special markers for points corresponding to sample sizes not equal to nominal sample size for fixed control limits
NOCHART	suppresses creation of charts
NOCHART2	suppresses creation of <i>s</i> chart
NOFRAME	suppresses frame for plot area
NOLEGEND	suppresses legend for subgroup sample sizes
NPANELPOS=	specifies number of subgroup positions per panel on each chart
REPEAT	repeats last subgroup position on panel as first subgroup position of next panel
SEPARATE	displays \bar{X} and <i>s</i> charts on separate screens or pages
TOTPANELS=	specifies number of pages or screens to be used to display chart
YPCT1=	specifies length of vertical axis on \bar{X} chart as a percentage of sum of lengths of vertical axes for \bar{X} and <i>s</i> charts
ZEROSTD	displays \bar{X} chart regardless of whether $\hat{\sigma} = 0$
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= and HREF2= options
CVREF=	specifies color for lines requested by VREF= and VREF2= options

Table 17.76 *continued*

Option	Description
HREF=	specifies position of reference lines perpendicular to horizontal axis on \bar{X} chart
HREF2=	specifies position of reference lines perpendicular to horizontal axis on s chart
HREFDATA=	specifies position of reference lines perpendicular to horizontal axis on \bar{X} chart
HREF2DATA=	specifies position of reference lines perpendicular to horizontal axis on s chart
HREFLABELS=	specifies labels for HREF= lines
HREF2LABELS=	specifies labels for HREF2= lines
HREFLABPOS=	specifies position of HREFLABELS= and HREF2LABELS= labels
LHREF=	specifies line type for HREF= and HREF2= lines
LVREF=	specifies line type for VREF= and VREF2= lines
NOBYREF	specifies that reference line information in a data set applies uniformly to charts created for all BY groups
VREF=	specifies position of reference lines perpendicular to vertical axis on \bar{X} chart
VREF2=	specifies position of reference lines perpendicular to vertical axis on s chart
VREFLABELS=	specifies labels for VREF= lines
VREF2LABELS=	specifies labels for VREF2= lines
VREFLABPOS=	position of VREFLABELS= and VREF2LABELS= labels
Grid Options	
CGRID=	specifies color for grid requested with GRID or ENDGRID option
ENDGRID	adds grid after last plotted point
GRID	adds grid to control chart
LENDGRID=	specifies line type for grid requested with the ENDGRID option
LGRID=	specifies line type for grid requested with the GRID option
WGRID=	specifies width of grid lines
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme points are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR=	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to \bar{X} chart

Table 17.76 *continued*

Option	Description
ANNOTATE2=	specifies annotate data set that adds features to <i>s</i> chart
DESCRIPTION=	specifies description of \bar{X} chart's GRSEG catalog entry
DESCRIPTION2=	specifies description of <i>s</i> chart's GRSEG catalog entry
FONT=	specifies software font for labels and legends on charts
NAME=	specifies name of \bar{X} chart's GRSEG catalog entry
NAME2=	specifies name of <i>s</i> chart's GRSEG catalog entry
PAGENUM=	specifies the form of the label used in pagination
PAGENUMPOS=	specifies the position of the page number requested with the PAGENUM= option
Options for Producing Graphs Using ODS Styles	
BLOCKVAR=	specifies one or more variables whose values define colors for filling background of <i>block-variable</i> legend
CFRAMELAB	draws a frame around labeled points
COUT	draw portions of line segments that connect points outside control limits in a contrasting color
CSTAROUT	specifies that portions of stars exceeding inner or outer circles are drawn using a different color
OUTFILL	shades areas between control limits and connected points lying outside the limits
STARFILL=	specifies a variable identifying groups of stars filled with different colors
STARS=	specifies a variable identifying groups of stars whose outlines are drawn with different colors
Options for ODS Graphics	
BLOCKREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
INFILLTRANSPARENCY=	specifies the control limit infill transparency
MARKERS	plots subgroup points with markers
NOBLOCKREF	suppresses block and phase reference lines
NOBLOCKREFFILL	suppresses block and phase wall fills
NOFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOPHASEREF	suppresses block and phase reference lines
NOPHASEREFFILL	suppresses block and phase wall fills
NOREF	suppresses block and phase reference lines
NOREFFILL	suppresses block and phase wall fills
NOSTARFILLLEGEND	suppresses legend for levels of a STARFILL= variable
NOTRANSPARENCY	disables transparency in ODS Graphics output
ODSFOOTNOTE=	specifies a graph footnote
ODSFOOTNOTE2=	specifies a secondary graph footnote
ODSLEGENDEXPAND	specifies that legend entries contain all levels observed in the data
ODSTITLE=	specifies a graph title
ODSTITLE2=	specifies a secondary graph title

Table 17.76 *continued*

Option	Description
OUTFILLTRANSPARENCY=	specifies control limit outfill transparency
OVERLAYURL=	specifies URLs to associate with overlay points
OVERLAY2URL=	specifies URLs to associate with overlay points on secondary chart
PHASEPOS=	specifies vertical position of phase legend
PHASEREFLEVEL=	associates phase and block reference lines with either innermost or the outermost level
PHASEREFTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
REFFILLTRANSPARENCY=	specifies the wall fill transparency for blocks and phases
SIMULATEQCFONT	draws central line labels using a simulated software font
STARTRANSPARENCY=	specifies star fill transparency
URL=	specifies a variable whose values are URLs to be associated with subgroups
URL2=	specifies a variable whose values are URLs to be associated with subgroups on secondary chart
Input Data Set Options	
MISSBREAK	specifies that observations with missing values are not to be processed
Output Data Set Options	
OUTHISTORY=	creates output data set containing subgroup summary statistics
OUTINDEX=	specifies value of <code>_INDEX_</code> in the <code>OUTLIMITS=</code> data set
OUTLIMITS=	creates output data set containing control limits
OUTTABLE=	creates output data set containing subgroup summary statistics and control limits
Tabulation Options	
NOTE: specifying (EXCEPTIONS) after a tabulation option creates a table for exceptional points only.	
TABLE	creates a basic table of subgroup means, subgroup sample sizes, and control limits
TABLEALL	is equivalent to the options TABLE, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS
TABLECENTRAL	augments basic table with values of central lines
TABLEID	augments basic table with columns for ID variables
TABLELEGEND	augments basic table with legend for tests for special causes
TABLEOUTLIM	augments basic table with columns indicating control limits exceeded
TABLETESTS	augments basic table with a column indicating which tests for special causes are positive
Specification Limit Options	
CIINDICES	specifies α value and type for computing capability index confidence limits
LSL=	specifies list of lower specification limits

Table 17.76 *continued*

Option	Description
TARGET=	specifies list of target values
USL=	specifies list of upper specification limits
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for <i>block-variable</i> legend
BLOCKLABTYPE=	specifies text size of <i>block-variable</i> legend
BLOCKPOS=	specifies vertical position of <i>block-variable</i> legend
BLOCKREP	repeats identical consecutive labels in <i>block-variable</i> legend
CBLOCKLAB=	specifies fill colors for frames enclosing variable labels in <i>block-variable</i> legend
CBLOCKVAR=	specifies one or more variables whose values are colors for filling background of <i>block-variable</i> legend
Phase Options	
CPHASELEG=	specifies text color for <i>phase</i> legend
NOPHASEFRAME	suppresses default frame for <i>phase</i> legend
OUTPHASE=	specifies value of <code>_PHASE_</code> in the <code>OUTHISTORY=</code> data set
PHASEBREAK	disconnects last point in a <i>phase</i> from first point in next <i>phase</i>
PHASELABTYPE=	specifies text size of <i>phase</i> legend
PHASELEGEND	displays <i>phase</i> labels in a legend across top of chart
PHASELIMITS	labels control limits for each phase, provided they are constant within that phase
PHASEREF	delineates <i>phases</i> with vertical reference lines
READPHASES=	specifies <i>phases</i> to be read from an input data set
Star Options	
CSTARCIRCLES=	specifies color for STARCIRCLES= circles
CSTARFILL=	specifies color for filling stars
CSTAROUT=	specifies outline color for stars exceeding inner or outer circles
CSTARS=	specifies color for outlines of stars
LSTARCIRCLES=	specifies line types for STARCIRCLES= circles
LSTARS=	specifies line types for outlines of STARVERTICES= stars
STARBDRADIUS=	specifies radius of outer bound circle for vertices of stars
STARCIRCLES=	specifies reference circles for stars
STARINRADIUS=	specifies inner radius of stars
STARLABEL=	specifies vertices to be labeled
STARLEGEND=	specifies style of legend for star vertices
STARLEGENDLAB=	specifies label for STARLEGEND= legend
STAROUTRADIUS=	specifies outer radius of stars
STARSPECS=	specifies method used to standardize vertex variables
STARSTART=	specifies angle for first vertex
STARTYPE=	specifies graphical style of star

Table 17.76 *continued*

Option	Description
STARVERTICES=	superimposes star at each point on \bar{X} chart
WSTARCIRCLES=	specifies width of STARCIRCLES= circles
WSTARS=	specifies width of STARVERTICES= stars
Overlay Options	
CCOVERLAY=	specifies colors for primary chart overlay line segments
CCOVERLAY2=	specifies colors for secondary chart overlay line segments
COVERLAY=	specifies colors for primary chart overlay plots
COVERLAY2=	specifies colors for secondary chart overlay plots
COVERLAYCLIP=	specifies color for clipped points on overlays
LOVERLAY=	specifies line types for primary chart overlay line segments
LOVERLAY2=	specifies line types for secondary chart overlay line segments
NOOVERLAYLEGEND	suppresses legend for overlay plots
OVERLAY=	specifies variables to overlay on primary chart
OVERLAY2=	specifies variables to overlay on secondary chart
OVERLAY2HTML=	specifies links to associate with secondary chart overlay points
OVERLAY2ID=	specifies labels for secondary chart overlay points
OVERLAY2SYM=	specifies symbols for secondary chart overlays
OVERLAY2SYMHT=	specifies symbol heights for secondary chart overlays
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
OVERLAYHTML=	specifies links to associate with primary chart overlay points
OVERLAYID=	specifies labels for primary chart overlay points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols for primary chart overlays
OVERLAYSYMHT=	specifies symbol heights for primary chart overlays
WCOVERLAY=	specifies widths of primary chart overlay line segments
WCOVERLAY2=	specifies widths of secondary chart overlay line segments
Options for Interactive Control Charts	
HTML=	specifies a variable whose values create links to be associated with subgroups
HTML2=	specifies variable whose values create links to be associated with subgroups on secondary chart
HTML_LEGEND=	specifies a variable whose values create links to be associated with symbols in the symbol legend
WEBOUT=	creates an OUTTABLE= data set with additional graphics coordinate data
Options for Line Printer Charts	
CLIPCHAR=	specifies plot character for clipped points

Table 17.76 continued

Option	Description
CONNECTCHAR=	specifies character used to form line segments that connect points on chart
HREFCHAR=	specifies line character for HREF= and HREF2= lines
SYMBOLCHARS=	specifies characters indicating <i>symbol-variable</i>
TESTCHAR=	specifies character for line segments that connect any sequence of points for which a test for special causes is positive
VREFCHAR=	specifies line character for VREF= and VREF2= lines
ZONECHAR=	specifies character for lines that delineate zones for tests for special causes

Details: XSCHART Statement

Constructing Charts for Means and Standard Deviations

The following notation is used in this section:

μ	process mean (expected value of the population of measurements)
σ	process standard deviation (standard deviation of the population of measurements)
\bar{X}_i	mean of measurements in i th subgroup
s_i	standard deviation of the measurements x_{i1}, \dots, x_{in_i} in the i th subgroup
$s_i = \sqrt{((x_{i1} - \bar{X}_i)^2 + \dots + (x_{in_i} - \bar{X}_i)^2)/(n_i - 1)}$	
n_i	sample size of i th subgroup
N	number of subgroups
$\bar{\bar{X}}$	weighted average of subgroup means
z_p	100 p th percentile of the standard normal distribution
$c_4(n)$	expected value of the standard deviation of n independent normally distributed variables with unit standard deviation
$c_5(n)$	standard error of the standard deviation of n independent observations from a normal population with unit standard deviation
$\chi_p^2(n)$	100 p th percentile ($0 < p < 1$) of the χ^2 distribution with n degrees of freedom

Plotted Points

Each point on an \bar{X} chart indicates the value of a subgroup mean (\bar{X}_i). For example, if the tenth subgroup contains the values 12, 15, 19, 16, and 13, the mean plotted for this subgroup is

$$\bar{X}_{10} = \frac{12 + 15 + 19 + 16 + 13}{5} = 15$$

Each point on an s chart indicates the value of a subgroup standard deviation (s_i). For example, the standard deviation plotted for the tenth subgroup is

$$s_{10} = \sqrt{((12 - 15)^2 + (15 - 15)^2 + (19 - 15)^2 + (16 - 15)^2 + (13 - 15)^2)/4} = 2.739$$

Central Lines

On an \bar{X} chart, by default, the central line indicates an estimate of μ , which is computed as

$$\hat{\mu} = \bar{\bar{X}} = \frac{n_1 \bar{X}_1 + \dots + n_N \bar{X}_N}{n_1 + \dots + n_N}$$

If you specify a known value (μ_0) for μ , the central line indicates the value of μ_0 .

On the s chart, by default, the central line for the i th subgroup indicates an estimate for the expected value of s_i , which is computed as $c_4(n_i)\hat{\sigma}$, where $\hat{\sigma}$ is an estimate of σ . If you specify a known value (σ_0) for σ , the central line indicates the value of $c_4(n_i)\sigma_0$. Note that the central line varies with n_i .

Control Limits

You can compute the limits in the following ways:

- as a specified multiple (k) of the standard errors of \bar{X}_i and s_i above and below the central line. The default limits are computed with $k = 3$ (these are referred to as 3σ limits).
- as probability limits defined in terms of α , a specified probability that \bar{X}_i or s_i exceeds the limits

The following table provides the formulas for the limits:

Table 17.77 Limits for \bar{X} and s Charts

Control Limits	
\bar{X} Chart	LCL = lower limit = $\bar{\bar{X}} - k\hat{\sigma}/\sqrt{n_i}$ UCL = upper limit = $\bar{\bar{X}} + k\hat{\sigma}/\sqrt{n_i}$
s Chart	LCL = lower limit = $\max(c_4(n_i)\hat{\sigma} - kc_5(n_i)\hat{\sigma}, 0)$ UCL = upper limit = $c_4(n_i)\hat{\sigma} + kc_5(n_i)\hat{\sigma}$
Probability Limits	
\bar{X} Chart	LCL = lower limit = $\bar{\bar{X}} - z_{\alpha/2}(\hat{\sigma}/\sqrt{n_i})$ UCL = upper limit = $\bar{\bar{X}} + z_{\alpha/2}(\hat{\sigma}/\sqrt{n_i})$
s Chart	LCL = lower limit = $\hat{\sigma} \sqrt{\chi_{\alpha/2}^2(n_i - 1)/(n_i - 1)}$ UCL = upper limit = $\hat{\sigma} \sqrt{\chi_{1-\alpha/2}^2(n_i - 1)/(n_i - 1)}$

The formulas for s charts assume that the data are normally distributed. If standard values μ_0 and σ_0 are available for μ and σ , respectively, replace $\bar{\bar{X}}$ with μ_0 and $\hat{\sigma}$ with σ_0 in Table 17.77. Note that the limits vary with n_i and that the probability limits for s_i are asymmetric about the central line.

You can specify parameters for the limits as follows:

- Specify k with the SIGMAS= option or with the variable `_SIGMAS_` in a LIMITS= data set.
- Specify α with the ALPHA= option or with the variable `_ALPHA_` in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits with the LIMITN= option or with the variable `_LIMITN_` in a LIMITS= data set.
- Specify μ_0 with the MU0= option or with the variable `_MEAN_` in a LIMITS= data set.
- Specify σ_0 with the SIGMA0= option or with the variable `_STDDEV_` in a LIMITS= data set.

Output Data Sets

OUTLIMITS= Data Set

The OUTLIMITS= data set saves control limits and control limit parameters. The following variables are saved:

Table 17.78 OUTLIMITS= Data Set

Variable	Description
ALPHA	probability (α) of exceeding limits
CP	capability index C_p
CPK	capability index C_{pk}
CPL	capability index C_{PL}
CPM	capability index C_{pm}
CPU	capability index C_{PU}
INDEX	optional identifier for the control limits specified with the OUTINDEX= option
LCLS	lower control limit for subgroup standard deviation
LCLX	lower control limit for subgroup mean
LIMITN	nominal sample size associated with the control limits
LSL	lower specification limit
MEAN	process mean (\bar{X} or μ_0)
S	value of central line on s chart
SIGMAS	multiple (k) of standard error of \bar{X}_i or s_i
STDDEV	process standard deviation ($\hat{\sigma}$ or σ_0)
SUBGRP	<i>subgroup-variable</i> specified in the XSCHART statement
TARGET	target value
TYPE	type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLS	upper control limit for subgroup standard deviation
UCLX	upper control limit for subgroup mean
USL	upper specification limit
VAR	<i>process</i> specified in the XSCHART statement

Notes:

1. If the control limits vary with subgroup sample size, the special missing value 'V' is assigned to the variables _LIMITN_, _LCLX_, _UCLX_, _LCLS_, _S_, and _UCLS_.
2. If the limits are defined in terms of a multiple k of the standard errors of \bar{X}_i and s_i , the value of _ALPHA_ is computed as $\alpha = 2(1 - \Phi(k))$, where $\Phi(\cdot)$ is the standard normal distribution function.
3. If the limits are probability limits, the value of _SIGMAS_ is computed as $k = \Phi^{-1}(1 - \alpha/2)$, where Φ^{-1} is the inverse standard normal distribution function.
4. The variables _CP_, _CPK_, _CPL_, _CPU_, _LSL_, and _USL_ are included only if you provide specification limits with the LSL= and USL= options. The variables _CPM_ and _TARGET_ are included if, in addition, you provide a target value with the TARGET= option. See "Capability Indices" on page 1941 for computational details.
5. Optional BY variables are saved in the OUTLIMITS= data set.

The OUTLIMITS= data set contains one observation for each *process* specified in the XSCHART statement. For an example, see “[Saving Control Limits](#)” on page 1964.

OUTHISTORY= Data Set

The OUTHISTORY= data set saves subgroup summary statistics. The following variables are saved:

- the *subgroup-variable*
- a subgroup mean variable named by *process* suffixed with *X*
- a subgroup standard deviation variable named by *process* suffixed with *S*
- a subgroup sample size variable named by *process* suffixed with *N*

Given a *process* name that contains 32 characters, the procedure first shortens the name to its first 16 characters and its last 15 characters, and then it adds the suffix.

Subgroup summary variables are created for each *process* specified in the XSCHART statement. For example, consider the following statements:

```
proc shewhart data=Steel;
  xschart (Width Diameter)*Lot / outhistory=Summary;
run;
```

The data set Summary contains variables named Lot, WidthX, WidthS, WidthN, DiameterX, DiameterS, and DiameterN. Additionally, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the OUTPHASE= option is specified)

For an example of an OUTHISTORY= data set, see “[Saving Summary Statistics](#)” on page 1963.

OUTTABLE= Data Set

The OUTTABLE= data set saves subgroup summary statistics, control limits, and related information. The following variables are saved:

Variable	Description
<code>_ALPHA_</code>	probability (α) of exceeding control limits
<code>_EXLIM_</code>	control limit exceeded on \bar{X} chart
<code>_EXLIMS_</code>	control limit exceeded on s chart
<code>_LCLS_</code>	lower control limit for standard deviation
<code>_LCLX_</code>	lower control limit for mean
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_MEAN_</code>	process mean
<code>_S_</code>	average standard deviation
<code>_SIGMAS_</code>	multiple (k) of the standard error associated with control limits
<code>subgroup</code>	values of the subgroup variable
<code>_SUBN_</code>	subgroup sample size
<code>_SUBS_</code>	subgroup standard deviation
<code>_SUBX_</code>	subgroup mean
<code>_TESTS_</code>	tests for special causes signaled on \bar{X} chart
<code>_TESTS2_</code>	tests for special causes signaled on s chart
<code>_UCLS_</code>	upper control limit for standard deviation
<code>_UCLX_</code>	upper control limit for mean
<code>_VAR_</code>	<i>process</i> specified in the XSCHEM statement

In addition, the following variables, if specified, are included:

- BY variables
- *block-variables*
- *symbol-variable*
- ID variables
- `_PHASE_` (if the READPHASES= option is specified)

Notes:

1. Either the variable `_ALPHA_` or the variable `_SIGMAS_` is saved depending on how the control limits are defined (with the ALPHA= or SIGMAS= options, respectively, or with the corresponding variables in a LIMITS= data set).
2. The variable `_TESTS_` is saved if you specify the TESTS= option. The k th character of a value of `_TESTS_` is k if Test k is positive at that subgroup. For example, if you request all eight tests and Tests 2 and 8 are positive for a given subgroup, the value of `_TESTS_` has a 2 for the second character, an 8 for the eighth character, and blanks for the other six characters.
3. The variable `_TESTS2_` is saved if you specify the TESTS2= option.
4. The variables `_EXLIM_`, `_EXLIMS_`, `_TESTS_`, and `_TESTS2_` are character variables of length 8. The variable `_PHASE_` is a character variable of length 48. The variable `_VAR_` is a character variable whose length is no greater than 32. All other variables are numeric.

For an example, see “Saving Control Limits” on page 1964.

ODS Tables

The following table summarizes the ODS tables that you can request with the XSCHART statement.

Table 17.79 ODS Tables Produced with the XSCHART Statement

Table Name	Description	Options
XSCHART	\bar{X} and s chart summary statistics	TABLE, TABLEALL, TABLEC, TABLEID, TABLELEG, TABLEOUT, TABLETESTS
TestDescriptions	descriptions of tests for special causes requested with the TESTS= option for which at least one positive signal is found	TABLEALL, TABLELEG

ODS Graphics

Before you create ODS Graphics output, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” (Chapter 21, *SAS/STAT User’s Guide*). **NOTE:** In SAS/QC 12.1 the SHEWHART procedure does not support the creation of graphs that are editable with the ODS Graphics Editor.

The appearance of a graph produced with ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. XSCHART options used to control the appearance of traditional graphics are ignored for ODS Graphics output. [Options for Producing Graphs Using ODS Styles](#) lists options that can be used to control the appearance of graphs produced with ODS Graphics or with traditional graphics using ODS styles. [Options for ODS Graphics](#) lists options to be used exclusively with ODS Graphics. Detailed descriptions of these options are provided in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

When ODS Graphics is in effect, the XSCHART statement assigns a name to the graph it creates. You can use this name to reference the graph when using ODS. The name is listed in [Table 17.80](#).

Table 17.80 ODS Graphics Produced by the XSCHART Statement

ODS Graph Name	Plot Description
XSChart	\bar{X} and s chart

See Chapter 3, “SAS/QC Graphics,” for more information about ODS Graphics and other methods for producing charts.

Input Data Sets

DATA= Data Set

You can read raw data (process measurements) from a DATA= data set specified in the PROC SHEWHART statement. Each *process* specified in the XSCHART statement must be a SAS variable in the DATA= data set. This variable provides measurements that must be grouped into subgroup samples indexed by the *subgroup-variable*. The *subgroup-variable*, which is specified in the XSCHART statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a value for each *process* and a value for the *subgroup-variable*. If the *i*th subgroup contains n_i items, there should be n_i consecutive observations for which the value of the subgroup variable is the index of the *i*th subgroup. For example, if each subgroup contains five items and there are 30 subgroup samples, the DATA= data set should contain 150 observations.

Other variables that can be read from a DATA= data set include

- `_PHASE_` (if the READPHASES= option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all the observations in a DATA= data set. However, if the DATA= data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the READPHASES= option (for an example, see “[Displaying Stratification in Phases](#)” on page 2103).

For an example of a DATA= data set, see “[Creating Charts for Means and Standard Deviations from Raw Data](#)” on page 1957.

LIMITS= Data Set

You can read preestablished control limits (or parameters from which the control limits can be calculated) from a LIMITS= data set specified in the PROC SHEWHART statement. For example, the following statements read control limit information from the data set `Conlims`:⁴¹

```
proc shewhart data=Info limits=Conlims;
    xschart Weight*Batch;
run;
```

The LIMITS= data set can be an OUTLIMITS= data set that was created in a previous run of the SHEWHART procedure. Such data sets always contain the variables required for a LIMITS= data set. The LIMITS= data set can also be created directly using a DATA step. When you create a LIMITS= data set, you must provide one of the following:

- the variables `_LCLX_`, `_MEAN_`, `_UCLX_`, `_LCLS_`, `_S_`, and `_UCLS_`, which specify the control limits directly

⁴¹In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option.

- the variables `_MEAN_` and `_STDDEV_`, which are used to calculate the control limits according to the equations in [Table 17.77](#)

In addition, note the following:

- The variables `_VAR_` and `_SUBGRP_` are required. These must be character variables whose lengths are no greater than 32.
- The variable `_INDEX_` is required if you specify the `READINDEX=` option; this must be a character variable whose length is no greater than 48.
- The variables `_LIMITN_`, `_SIGMAS_` (or `_ALPHA_`), and `_TYPE_` are optional, but they are recommended to maintain a complete set of control limit information. The variable `_TYPE_` must be a character variable of length 8; valid values are 'ESTIMATE', 'STANDARD', 'STDMU', and 'STDSIGMA'.
- BY variables are required if specified with a BY statement.

For an example, see “[Reading Preestablished Control Limits](#)” on page 1966.

HISTORY= Data Set

You can read subgroup summary statistics from a `HISTORY=` data set specified in the `PROC SHEWHART` statement. This enables you to reuse `OUTHISTORY=` data sets that have been created in previous runs of the `SHEWHART`, `CUSUM`, or `MACONTROL` procedures or to read output data sets created with SAS summarization procedures, such as the `MEANS` procedure.

A `HISTORY=` data set used with the `XSCHART` statement must contain the following variables:

- the *subgroup-variable*
- a subgroup mean variable for each *process*
- a subgroup standard deviation variable for each *process*
- a subgroup sample size variable for each *process*

The names of the subgroup mean, subgroup standard deviation, and subgroup sample size variables must be the *process* name concatenated with the special suffix characters *X*, *S*, and *N*, respectively. For example, consider the following statements:

```
proc shewhart history=Summary;
  xschart (Weight Yieldstrength)*Batch;
run;
```

The data set `Summary` must include the variables `Batch`, `WeightX`, `WeightS`, `WeightN`, `YieldstrengthX`, `YieldstrengthS`, and `YieldstrengthN`.

Note that if you specify a *process* name that contains 32 characters, the names of summary variables must be formed from the first 16 characters and the last 15 characters of the *process* name, suffixed with the appropriate character.

Other variables that can be read from a `HISTORY=` data set include

- `_PHASE_` (if the `READPHASES=` option is specified)
- *block-variables*
- *symbol-variable*
- BY variables
- ID variables

By default, the SHEWHART procedure reads all of the observations in a `HISTORY=` data set. However, if the data set includes the variable `_PHASE_`, you can read selected groups of observations (referred to as *phases*) by specifying the `READPHASES=` option (see “[Displaying Stratification in Phases](#)” on page 2103 for an example).

For an example of a `HISTORY=` data set, see “[Creating Charts for Means and Standard Deviations from Summary Data](#)” on page 1960.

TABLE= Data Set

You can read summary statistics and control limits from a `TABLE=` data set specified in the PROC SHEWHART statement. This enables you to reuse an `OUTTABLE=` data set created in a previous run of the SHEWHART procedure. Because the SHEWHART procedure simply displays the information read from a `TABLE=` data set, you can use `TABLE=` data sets to create specialized control charts. Examples are provided in “[Specialized Control Charts: SHEWHART Procedure](#)” on page 2171.

The following table lists the variables required in a `TABLE=` data set used with the `XSCHART` statement:

Table 17.81 Variables Required in a `TABLE=` Data Set

Variable	Description
<code>_LCLS_</code>	lower control limit for standard deviation
<code>_LCLX_</code>	lower control limit for mean
<code>_LIMITN_</code>	nominal sample size associated with the control limits
<code>_MEAN_</code>	process mean
<code>_S_</code>	average standard deviation
<i>subgroup-variable</i>	values of the <i>subgroup-variable</i>
<code>_SUBN_</code>	subgroup sample size
<code>_SUBS_</code>	subgroup standard deviation
<code>_SUBX_</code>	subgroup mean
<code>_UCLS_</code>	upper control limit for standard deviation
<code>_UCLX_</code>	upper control limit for mean

Other variables that can be read from a `TABLE=` data set include

- *block-variables*

- *symbol-variable*
- BY variables
- ID variables
- `_PHASE_` (if the `READPHASES=` option is specified). This variable must be a character variable whose length is no greater than 48.
- `_TESTS_` (if the `TESTS=` option is specified). This variable is used to flag tests for special causes for subgroup means and must be a character variable of length 8.
- `_TESTS2_` (if the `TESTS2=` option is specified). This variable is used to flag tests for special causes for subgroup standard deviations and must be a character variable of length 8.
- `_VAR_`. This variable is required if more than one *process* is specified or if the data set contains information for more than one *process*. This variable must be a character variable whose length is no greater than 32.

For an example of a `TABLE=` data set, see “Saving Control Limits” on page 1964.

Methods for Estimating the Standard Deviation

When control limits are determined from the input data, four methods (referred to as default, `MVLUE`, `MVGRANGE`, and `RMSDF`) are available for estimating σ .

Default Method

The default estimate for σ is

$$\hat{\sigma} = \frac{s_1/c_4(n_1) + \cdots + s_N/c_4(n_N)}{N}$$

where N is the number of subgroups for which $n_i \geq 2$, s_i is the sample standard deviation of the i th subgroup

$$s_i = \sqrt{\frac{1}{n_i - 1} \sum_{j=1}^{n_i} (x_{ij} - \bar{X}_i)^2}$$

and

$$c_4(n_i) = \frac{\Gamma(n_i/2) \sqrt{2/(n_i - 1)}}{\Gamma((n_i - 1)/2)}$$

Here, $\Gamma(\cdot)$ denotes the gamma function, and \bar{X}_i denotes the i th subgroup mean. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$. If the observations are normally distributed, then the expected value of s_i is $c_4(n_i)\sigma$. Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ . This method is described in the American Society for Testing and Materials (1976).

MVLUE Method

If you specify SMETHOD=MVLUE, a minimum variance linear unbiased estimate (MVLUE) is computed for σ . Refer to Burr (1969, 1976) and Nelson (1989, 1994). This estimate is a weighted average of N unbiased estimates of σ of the form $s_i/c_4(n_i)$, and it is computed as

$$\hat{\sigma} = \frac{h_1 s_1 / c_4(n_1) + \cdots + h_N s_N / c_4(n_N)}{h_1 + \cdots + h_N}$$

where

$$h_i = \frac{[c_4(n_i)]^2}{1 - [c_4(n_i)]^2}$$

A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$. The MVLUE assigns greater weight to estimates of σ from subgroups with larger sample sizes, and it is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the MVLUE reduces to the default estimate.

MVGRANGE Method

If you specify SMETHOD=MVGRANGE, σ is estimated using a moving range of subgroup averages. This is appropriate for constructing control charts for means when the j th measurement in the i th subgroup can be modeled as $x_{ij} = \sigma_B \omega_i + \sigma_W \epsilon_{ij}$, where σ_B^2 is the between-subgroup variance, σ_W^2 is the within-subgroup variance, the ω_i are independent with zero mean and unit variance, and the ω_i are independent of the ϵ_{ij} .

The estimate for σ is

$$\hat{\sigma} = \bar{R} / d_2(n)$$

where \bar{R} is the average of the moving ranges, n is the number of consecutive subgroup averages used to compute each moving range, and the unbiasing factor $d_2(n)$ is defined so that if the subgroup averages are normally distributed, the expected value of R_i is

$$E(R_i) = d_2(n_i) \sigma$$

This method is appropriate for constructing a variation on the three-way control chart that is advocated for this situation by Wheeler (1995). A three-way control chart is useful when sampling, or *within-group* variation is not the only source of variation, as discussed in “[Multiple Components of Variation](#)” on page 2181. Wheeler’s three-way control chart comprises a chart of subgroup means, a moving range chart of the subgroup means, and a chart of subgroup ranges. This variation substitutes a chart of subgroup standard deviations for the chart of subgroup ranges. When you specify the SMETHOD=MVGRANGE option, the XSCHEM statement produces the appropriate charts of subgroup means and subgroup standard deviations.

RMSDF Method

If you specify SMETHOD=RMSDF, a weighted root-mean-square estimate is computed for σ .

$$\hat{\sigma} = \frac{\sqrt{(n_1 - 1)s_1^2 + \cdots + (n_N - 1)s_N^2}}{c_4(n) \sqrt{n_1 + \cdots + n_N - N}}$$

The weights are the degrees of freedom $n_i - 1$. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$.

If the unknown standard deviation σ is constant across subgroups, the root-mean-square estimate is more efficient than the minimum variance linear unbiased estimate. However, in process control applications it is generally not assumed that σ is constant, and if σ varies across subgroups, the root-mean-square estimate tends to be more inflated than the MVLUE.

Axis Labels

You can specify axis labels by assigning labels to particular variables in the input data set, as summarized in the following table:

Axis	Input Data Set	Variable
Horizontal	all	<i>subgroup-variable</i>
Vertical (\bar{X} chart)	DATA=	<i>process</i>
Vertical (\bar{X} chart)	HISTORY=	subgroup mean variable
Vertical (\bar{X} chart)	TABLE=	<code>_SUBX_</code>

You can specify distinct labels for the vertical axes of the \bar{X} and s charts by breaking the vertical axis into two parts with a split character. Specify the split character with the SPLIT= option. The first part labels the vertical axis of the \bar{X} chart, and the second part labels the vertical axis of the s chart.

For example, the following sets of statements specify the label *Avg Power Output* for the vertical axis of the \bar{X} chart and the label *Std Deviation* for the vertical axis of the s chart:

```
proc shewhart data=Turbine;
  xschart KWatts*Day / split = '/' ;
  label KWatts = 'Avg Power Output/Std Deviation';
run;

proc shewhart history=Turbhist;
  xschart KWatts*Day / split = '/' ;
  label KWattsX = 'Avg Power Output/Std Deviation';
run;

proc shewhart table=Turbtab;
  xschart KWatts*Day / split = '/' ;
  label _SUBX_ = 'Avg Power Output/Std Deviation';
run;
```

In this example, the label assignments are in effect only for the duration of the procedure step, and they temporarily override any permanent labels associated with the variables.

Missing Values

An observation read from a DATA=, HISTORY=, or TABLE= data set is not analyzed if the value of the subgroup variable is missing. For a particular process variable, an observation read from a DATA= data set is not analyzed if the value of the process variable is missing. Missing values of process variables generally lead to unequal subgroup sample sizes. For a particular process variable, an observation read from a HISTORY= or TABLE= data set is not analyzed if the values of any of the corresponding summary variables are missing.

Examples: XSCHART Statement

This section provides advanced examples of the XSCHART statement.

Example 17.41: Specifying Probability Limits

See SHWXS2 in the SAS/QC Sample Library

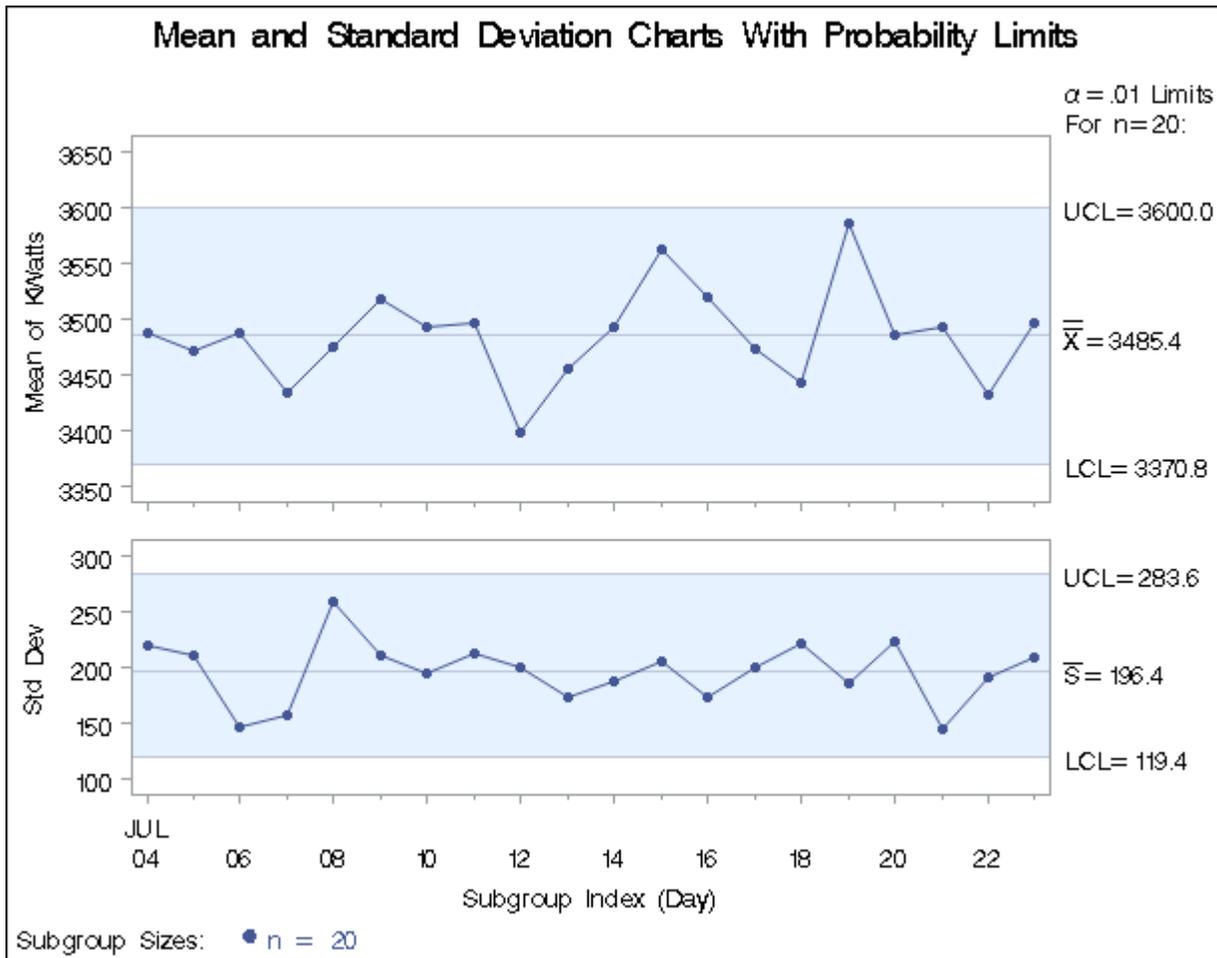

This example illustrates how to create \bar{X} and s charts with probability limits. The following statements read the kilowatt power output measurements from the data set Turbine (see “Creating Charts for Means and Standard Deviations from Raw Data” on page 1957) and create the \bar{X} and s charts shown in Output 17.41.1:

```
ods graphics off;
symbol v=dot h=.8;
title 'Mean and Standard Deviation Charts With Probability Limits';
proc shewhart data=Turbine;
    xschart KWatts*Day / alpha      = 0.01
                        outlimits = Oillim;
run;
```

The ALPHA= option specifies the probability (α) that a subgroup summary statistic is outside the limits. Here, the limits are computed so that the probability that a subgroup mean or standard deviation is less than its lower limit is $\alpha/2 = 0.005$, and the probability that a subgroup mean or standard deviation is greater than its upper limit is $\alpha/2 = 0.005$. This assumes that the measurements are normally distributed.

The OUTLIMITS= option names an output data set (Oillim) that saves the probability limits. The data set Oillim is shown in Output 17.41.2.

Output 17.41.1 Probability Limits on \bar{X} and s Charts

Output 17.41.2 Probability Limit Information

Mean and Standard Deviation Charts with Probability Limits						
<u>VAR</u>	<u>SUBGRP</u>	<u>TYPE</u>	<u>LIMITN</u>	<u>ALPHA</u>	<u>SIGMAS</u>	<u>LCLX</u>
KWatts	Day	ESTIMATE	20	0.01	2.57583	3370.79
<u>MEAN</u>	<u>UCLX</u>	<u>LCLX</u>	<u>S</u>	<u>UCLS</u>	<u>STDDEV</u>	
3485.41	3600.03	119.432	196.396	283.570	198.996	

The variable ALPHA saves the value of α . The value of the variable SIGMAS is computed as $k = \Phi^{-1}(1 - \alpha/2)$, where Φ^{-1} is the inverse standard normal distribution function. Note that, in this case, the probability limits for the mean are equivalent to 2.58σ limits.

Since all the points fall within the probability limits, it can be concluded that the process is in statistical control.

Example 17.42: Computing Subgroup Summary Statistics

See SHWXS3 in the SAS/QC Sample Library

You can use output data sets from a number of SAS procedures as input data sets for the SHEWHART procedure. In this example, the MEANS procedure is used to create a data set containing subgroup summary statistics, which can be read by the SHEWHART procedure as a HISTORY= data set. The following statements create an output data set named Oilsummeans, which contains subgroup means, standard deviations, and sample sizes for the variable KWatts in the data set Turbine (see “Creating Charts for Means and Standard Deviations from Raw Data” on page 1957):

```
proc means data=Turbine noprint;
  var KWatts;
  by Day;
  output out=Oilsummeans mean=means std=stds n=sizes;
run;
```

A listing of Oilsummeans is shown in Output 17.42.1.

Output 17.42.1 The Data Set Oilsummeans

Summary Statistics for Power Output Data					
Day	_TYPE_	_FREQ_	means	stds	sizes
04JUL	0	20	3487.40	220.260	20
05JUL	0	20	3471.65	210.427	20
06JUL	0	20	3488.30	147.025	20
07JUL	0	20	3434.20	157.637	20
08JUL	0	20	3475.80	258.949	20
09JUL	0	20	3518.10	211.566	20
10JUL	0	20	3492.65	193.779	20
11JUL	0	20	3496.40	212.024	20
12JUL	0	20	3398.50	199.201	20
13JUL	0	20	3456.05	173.455	20
14JUL	0	20	3493.60	187.465	20
15JUL	0	20	3563.30	205.472	20
16JUL	0	20	3519.05	173.676	20
17JUL	0	20	3474.20	200.576	20
18JUL	0	20	3443.60	222.084	20
19JUL	0	20	3586.35	185.724	20
20JUL	0	20	3486.45	223.474	20
21JUL	0	20	3492.90	145.267	20
22JUL	0	20	3432.80	190.994	20
23JUL	0	20	3496.90	208.858	20

The variables MEANS, STDS, and SIZES do not follow the naming convention required for HISTORY= data sets (see “HISTORY= Data Set” on page 1987). The following statements temporarily rename these variables to KWattsX, KWattsS, and KWattsN, respectively (the names required when the *process* KWatts is specified in the XSCHART statement):

```

title 'Mean and Standard Deviation Charts for Power Output';
proc shewhart
  history=Oilsummeans (rename=(means = KWattsX
                               stds   = KWattsS
                               sizes  = KWattsN ));
  xschart KWatts*Day;
run;

```

The resulting charts are identical to the charts in Figure 17.115.

Example 17.43: Analyzing Nonnormal Process Data

The standard control limits for s charts (see Table 17.77) are calculated under the assumption that the data are normally distributed. This example illustrates how a transformation to normality can be used in conjunction with \bar{X} and s charts. *See SHWXS4 in the SAS/QC Sample Library*

The length of a metal brace is measured in centimeters for each of 20 braces sampled daily. Subgroup samples are collected for nineteen days, and the data are analyzed to determine if the manufacturing process is in statistical control.

```

data Lengthdata;
  informat Day date7.;
  format Day date5.;
  label Length='Brace Length in cm';
  input Day @;
  do i=1 to 5;
    input Length @;
    output;
  end;
  drop i;
  datalines;
02JAN86 113.64 119.60 111.66 111.88 125.29
02JAN86 114.08 115.28 127.84 109.97 109.34
02JAN86 109.65 121.76 112.17 116.01 111.64
02JAN86 112.70 114.43 110.27 114.76 125.89
03JAN86 115.92 113.62 117.52 114.44 118.08
03JAN86 111.13 118.42 112.16 112.25 107.71
03JAN86 110.46 113.78 109.89 114.59 116.98

... more lines ...

19JAN86 111.90 111.30 112.34 114.20 112.66
20JAN86 112.84 109.01 110.03 114.44 115.21
20JAN86 115.15 112.34 114.99 109.70 111.20
20JAN86 117.81 119.51 109.03 111.61 118.01
20JAN86 113.55 114.78 112.91 111.87 118.54
;

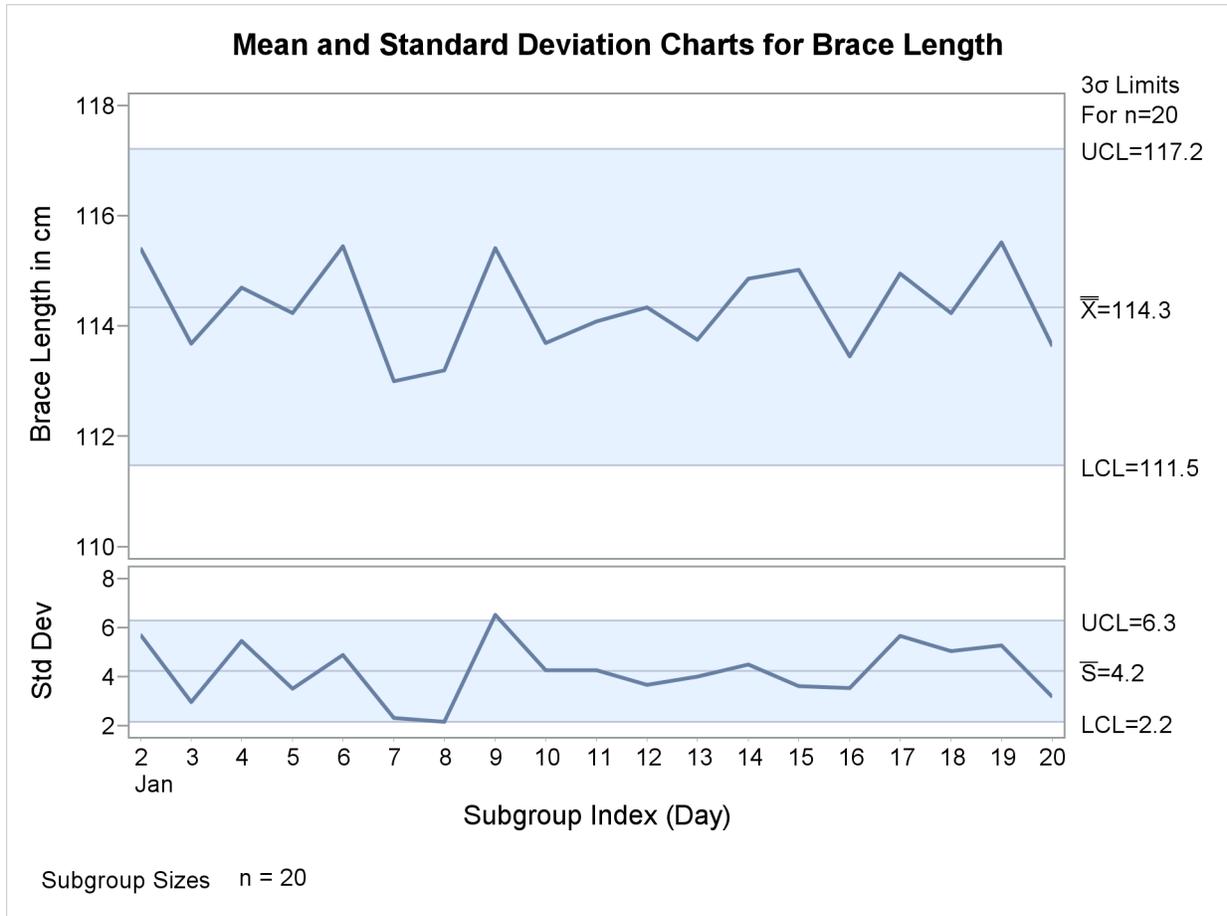

```

The following statements create preliminary \bar{X} and s charts for the lengths:

```
ods graphics on;
title 'Mean and Standard Deviation Charts for Brace Length';
proc shewhart data=lengthdata;
  xschart Length*Day / odstitle = title;
run;
```

The charts are shown in Output 17.43.1.

Output 17.43.1 \bar{X} and s Charts

The s chart suggests that the process is not in control, since the standard deviation of the measurements recorded on January 9 exceeds its upper control limit. In addition, a number of other points on the s chart are close to the control limits.

The following statements create a box chart for the lengths (for more information about box charts, see “[BOXCHART Statement: SHEWHART Procedure](#)” on page 1424).

```

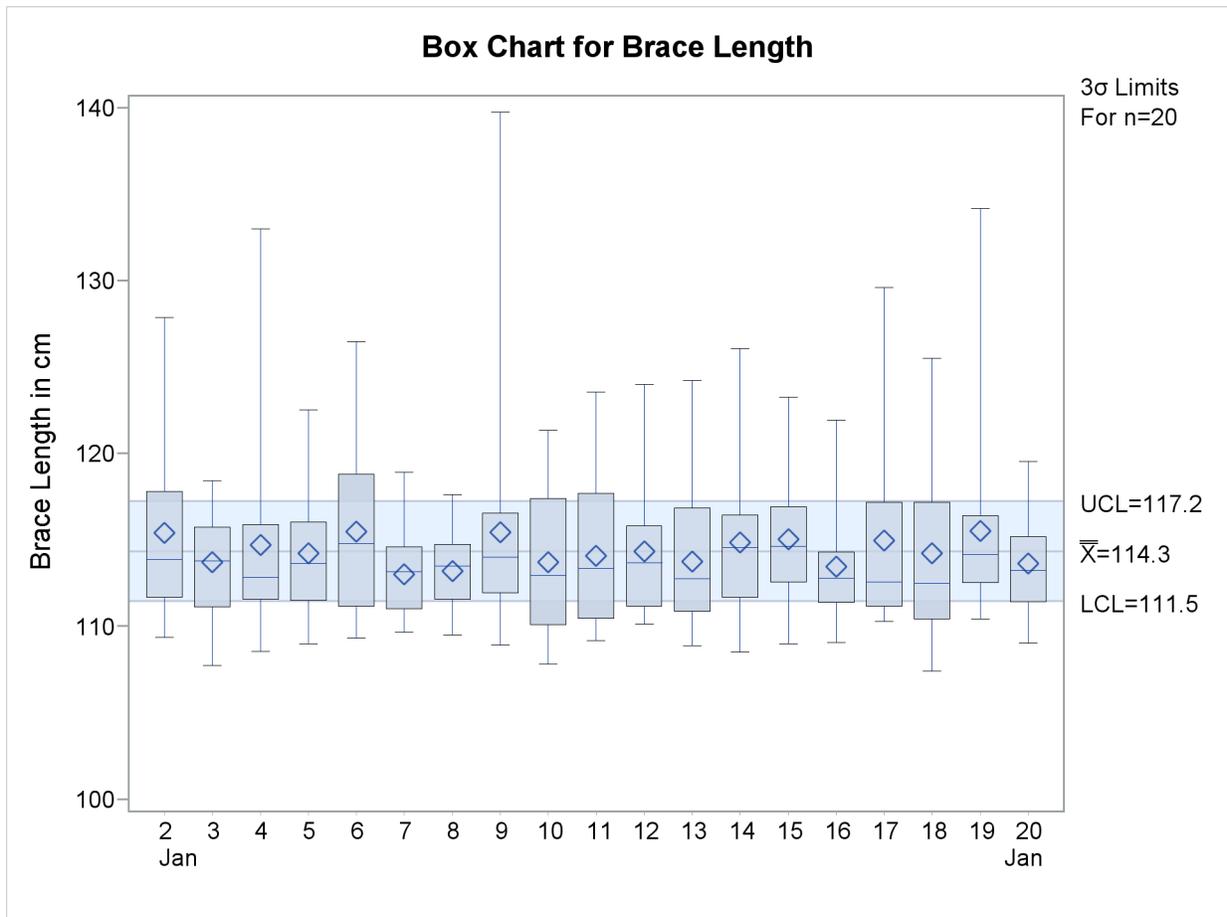

title 'Box Chart for Brace Length';
proc shewhart data=Lengthdata;
  boxchart Length*Day / serifs
           ranges
           nohlabel
           nolegend
           odstitle = title;
run;

```

The chart, shown in [Output 17.43.2](#), reveals that most of the subgroup distributions are skewed to the right. Consequently, the *s* chart shown in [Output 17.43.1](#) should be interpreted with caution, since control limits for *s* charts are based on the assumption that the data are normally distributed.

No special cause for the skewness of the subgroup distributions is discovered. This indicates that the process is in statistical control and that the length distribution is naturally skewed.

Output 17.43.2 Box Chart

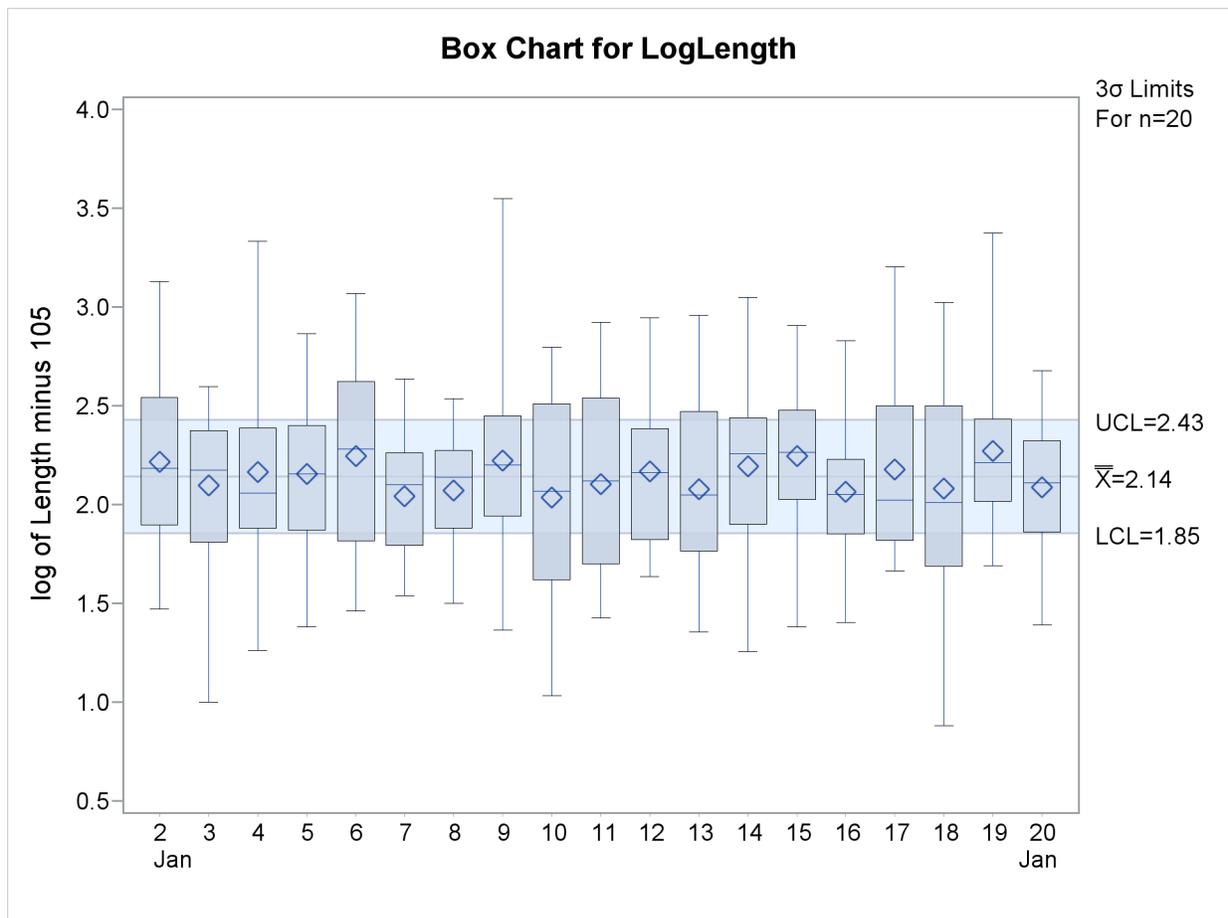

The following statements apply a lognormal transformation to the length measurements and display a box chart for the transformed data:

```
data Lengthdata;
  set Lengthdata;
  LogLength=log(Length-105);
  label LogLength='log of Length minus 105';
run;

title 'Box Chart for log(Length-105)';
proc shewhart data=Lengthdata;
  boxchart LogLength*Day / serifs
           ranges
           nohlabel
           nolegend;
run;
```

The chart, shown in [Output 17.43.3](#), indicates that the subgroup distributions of LogLength are approximately normal (this can be verified with goodness-of-fit tests by using the CAPABILITY procedure).

Output 17.43.3 Box Chart for Transformed Data

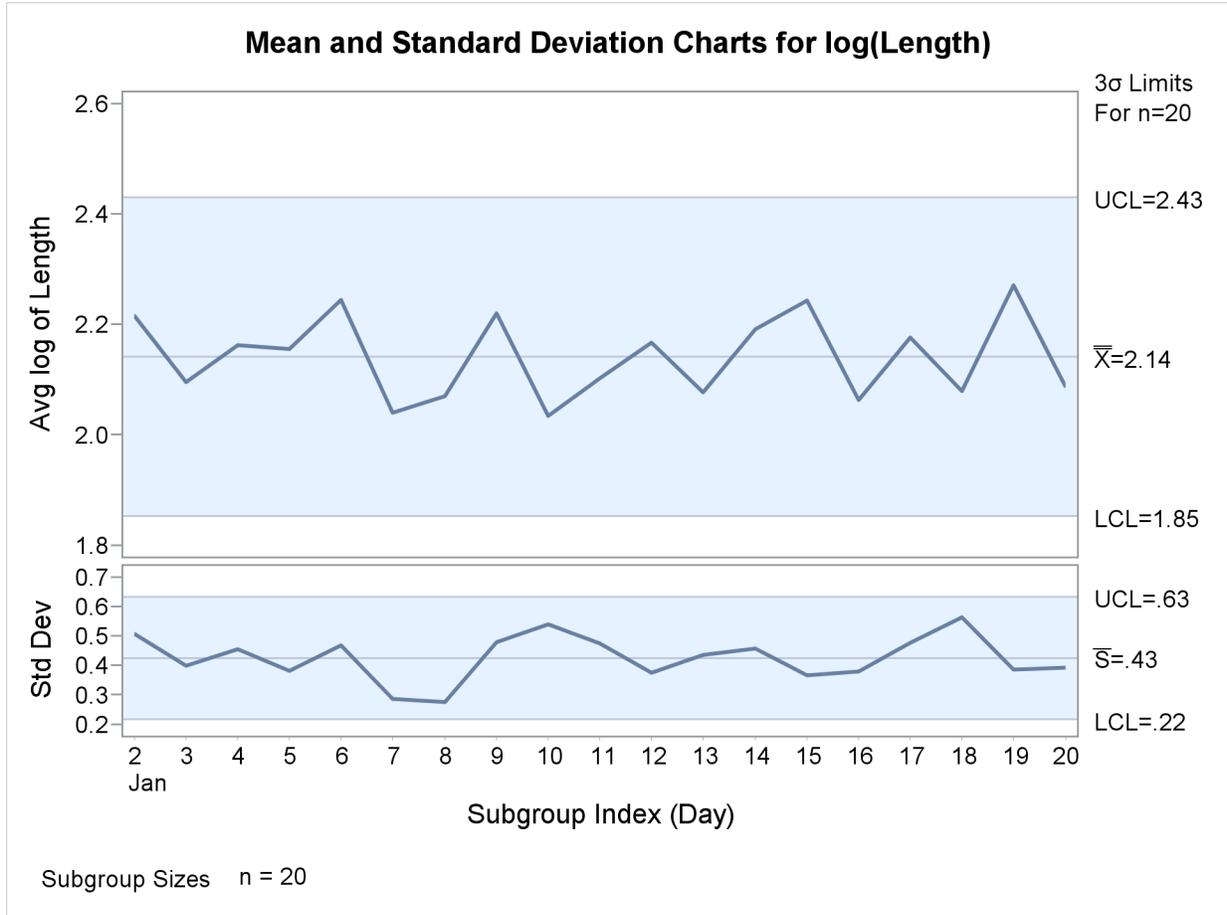

Finally, \bar{X} and s charts, shown in [Output 17.43.4](#), are created for LogLength. They indicate that the

variability and mean level of the transformed lengths are in control.

```

title 'Mean and Standard Deviation Charts for log(Length)';
proc shewhart data=Lengthdata;
  xschart LogLength*Day / split      = '/'
                        odstitle = title;
  label LogLength='Avg log of Length/Std Dev';
run;
    
```

Output 17.43.4 \bar{X} and s Charts for Transformed Length

INSET and INSET2 Statements: SHEWHART Procedure

Overview: INSET and INSET2 Statements

The INSET and INSET2 statements enable you to enhance a Shewhart chart by adding a box or table (referred to as an *inset*) of summary statistics directly to the graph. The INSET statement places an inset in a primary Shewhart chart while the INSET2 statement places one in a secondary Shewhart chart. An inset can display statistics calculated by the SHEWHART procedure or arbitrary values provided in a SAS data set.

Note that an INSET or INSET2 statement by itself does not produce a display but must be used in conjunction with a chart statement. Insets are not available with line printer charts, so the INSET and INSET2 statements are not applicable when the LINEPRINTER option is specified in the PROC SHEWHART statement.

You can use options in the INSET and INSET2 statements to

- specify the position of the inset
- specify a header for the inset table
- specify graphical enhancements, such as background colors, text colors, text height, text font, and drop shadows

The INSET2 statement differs from the INSET statement in only two respects.

1. An INSET2 statement creates an inset within a secondary chart generated by an IRCHART, MRCHART, XRCHART or XSCHART statement or by the TRENDVAR= option. For example, when following an XRCHART statement an INSET statement produces an inset in the \bar{X} chart and an INSET2 statement produces one in the R chart.
2. The INSET statement can be used to place an inset in one of the margins surrounding the plot area, while the INSET2 statement cannot.

Any of the statistics available for display in an inset can be specified with either an INSET or INSET2 statement. Descriptions of the INSET statement in this section also apply to the INSET2 statement except where explicitly noted.

Getting Started: INSET and INSET2 Statements

This section introduces the INSET statement with examples that illustrate commonly used options. Complete syntax for the INSET statement is presented in the section “Syntax: INSET and INSET2 Statements” on page 2006.

Displaying Summary Statistics on a Control Chart

In the manufacture of silicon wafers, batches of five wafers are sampled, and their diameters are measured in millimeters. The following statements create a SAS data set named `Wafers`, which contains the measurements for 25 batches:

```
data Wafers;
  input Batch @;
  do i=1 to 5;
    input Diameter @;
    output;
  end;
  drop i;
  datalines;
1  35.00 34.99 34.99 34.98 35.00
2  35.01 34.99 34.99 34.98 35.00
3  34.99 35.00 35.00 35.00 35.00
4  35.01 35.00 34.99 34.99 35.00
5  35.00 34.99 34.98 34.99 35.00
6  34.99 34.99 35.00 35.00 35.00
7  35.01 34.98 35.00 35.00 34.99
8  35.00 35.00 34.99 34.98 34.99
9  34.99 34.98 34.98 35.01 35.00
10 34.99 35.00 35.01 34.99 35.01
11 35.01 35.00 35.00 34.98 34.99
12 34.99 34.99 35.00 34.98 35.01
13 35.01 34.99 34.98 34.99 34.99
14 35.00 35.00 34.99 35.01 34.99
15 34.98 34.99 34.99 34.98 35.00
16 34.99 35.00 35.00 35.01 35.00
17 34.98 34.98 34.99 34.99 34.98
18 35.01 35.02 35.00 34.98 35.00
19 34.99 34.98 35.00 34.99 34.98
20 34.99 35.00 35.00 34.99 34.99
21 35.00 34.99 34.99 34.98 35.00
22 35.00 35.00 35.01 35.00 35.00
23 35.02 35.00 34.98 35.02 35.00
24 35.00 35.00 34.99 35.01 34.98
25 34.99 34.99 34.99 35.00 35.00
;
```

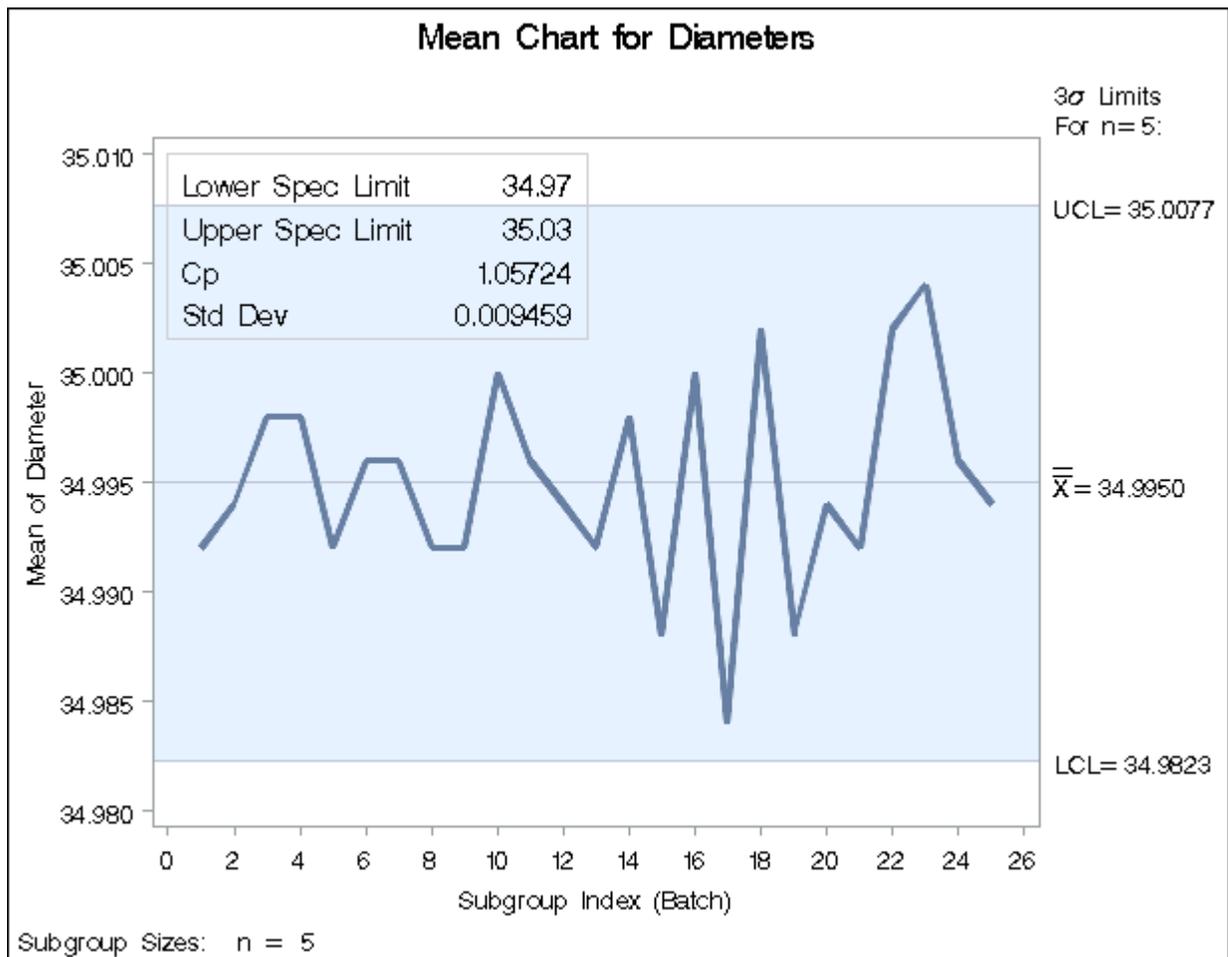

The following statements generate an \bar{X} chart from the `Wafers` data. Lower and upper specification limits for wafer diameters are given and the process capability index C_p is computed. An `INSET` statement is used to display the specification limits, the computed value of C_p and the process standard deviation on the chart:

```
ods graphics off;
title 'Mean Chart for Diameters';
proc shewhart data=Wafers;
  xchart Diameter*Batch /
    lsl = 34.97
    usl = 35.03;
  inset lsl usl cp stddev /
    height = 3;
run;
```

The resulting \bar{X} chart is displayed in Figure 17.122. The INSET statement immediately follows the chart statement that creates the graphical display (in this case, the XCHART statement). Specify the keywords for inset statistics (such as LSL, USL, CP and STDDEV) immediately after the word INSET. The inset statistics appear in the order in which you specify the keywords. The HEIGHT= option on the INSET statement specifies the text height used to display the statistics in the inset.

A complete list of keywords that you can use with the INSET statement is provided in “Summary of INSET Keywords” on page 2007. Note that the set of keywords available for a particular display depends on both the plot statement that precedes the INSET statement and the options that you specify in the plot statement.

Figure 17.122 An \bar{X} Chart with an Inset

The following examples illustrate options commonly used for enhancing the appearance of an inset.

Formatting Values and Customizing Labels

By default, each inset statistic is identified with an appropriate label, and each numeric value is printed using an appropriate format. However, you may want to provide your own labels and formats. For example, in [Figure 17.122](#) the default format used for C_p and the process standard deviation prints an excessive number of decimal places. The following statements produce \bar{X} and R charts, each with its own inset. The unwanted decimal places are eliminated and the default specification limits labels are replaced with abbreviations:

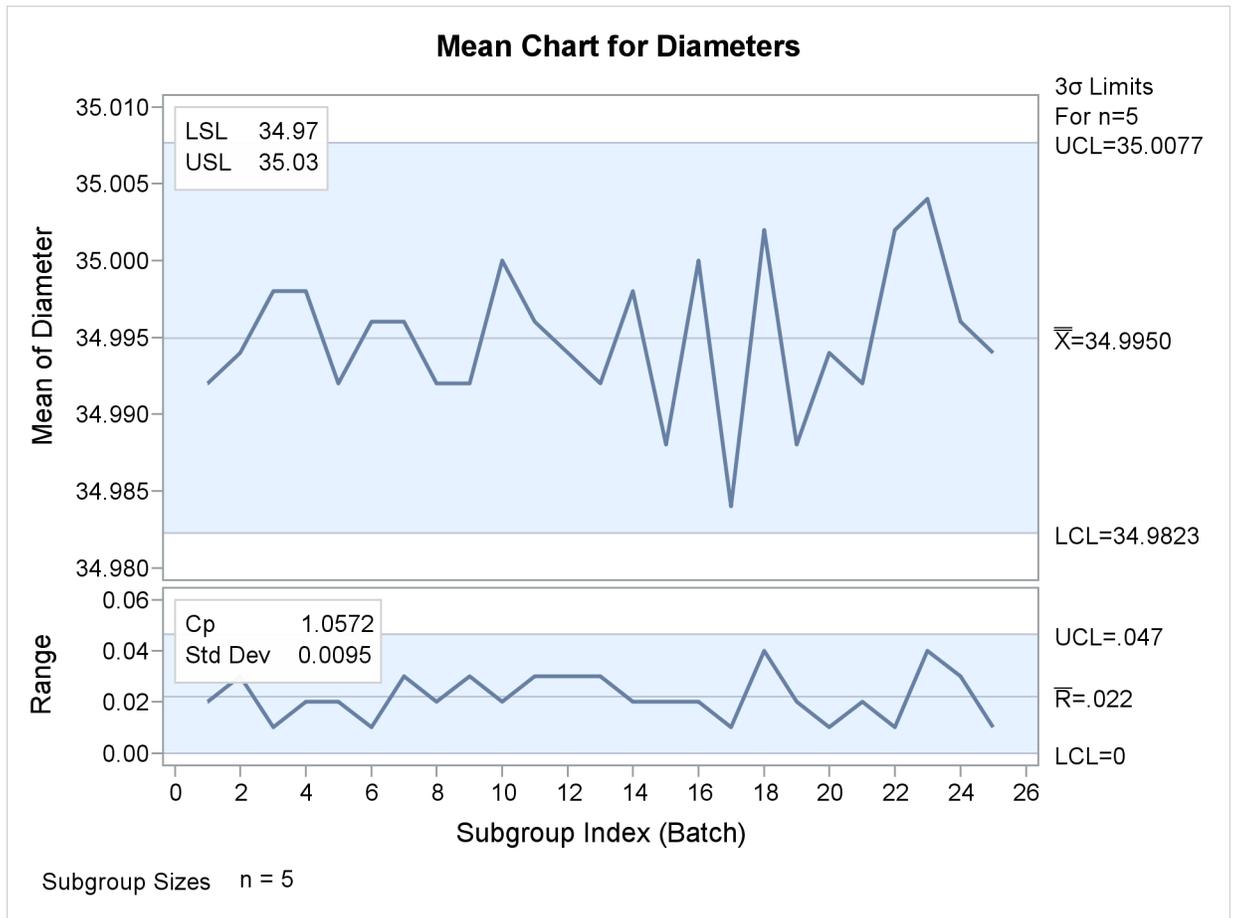

```
ods graphics on;
title 'Mean Chart for Diameters';
proc shewhart data=Wafers;
  xrchart Diameter*Batch /
    lsl      = 34.97
    usl      = 35.03
    odstitle = title;
  inset lsl='LSL' usl='USL' / pos = nw;
  inset2 cp (6.4) stddev (6.4) / pos = nw;
run;
ods graphics off;
```

The ODS GRAPHICS ON statement specified before the PROC SHEWHART statement enables ODS Graphics, so the \bar{X} and R charts are created using ODS Graphics instead of traditional graphics. The resulting charts are displayed in [Figure 17.123](#).

You can provide your own label by specifying the keyword for that statistic followed by an equal sign (=) and the label in quotes. The label can have up to 24 characters.

The format 6.4 specified in parentheses after the CP and STDDEV keywords displays those statistics with a field width of six and four decimal places. In general, you can specify any numeric SAS format in parentheses after an inset keyword. You can also specify a format to be used for all the statistics in the INSET statement with the FORMAT= option. For more information about SAS formats, refer to *SAS Formats and Informats: Reference*.

Note that if you specify both a label and a format for a statistic, the label must appear before the format.

Figure 17.123 Formatting Values and Customizing Labels in an Inset

Adding a Header and Positioning the Inset

In the previous examples, the insets are displayed in the upper left corners of the plots, the default position for insets added to control charts. You can control the inset position with the POSITION= option. In addition, you can display a header at the top of the inset with the HEADER= option. The following statements create a data set to be used with the INSET DATA= keyword and the chart shown in Figure 17.124:

```
data Location;
  length LABEL $ 10 VALUE $ 12;
  input LABEL VALUE &;
  datalines;
Plant      Santa Clara
Line       1
Shift      2
;
```

```

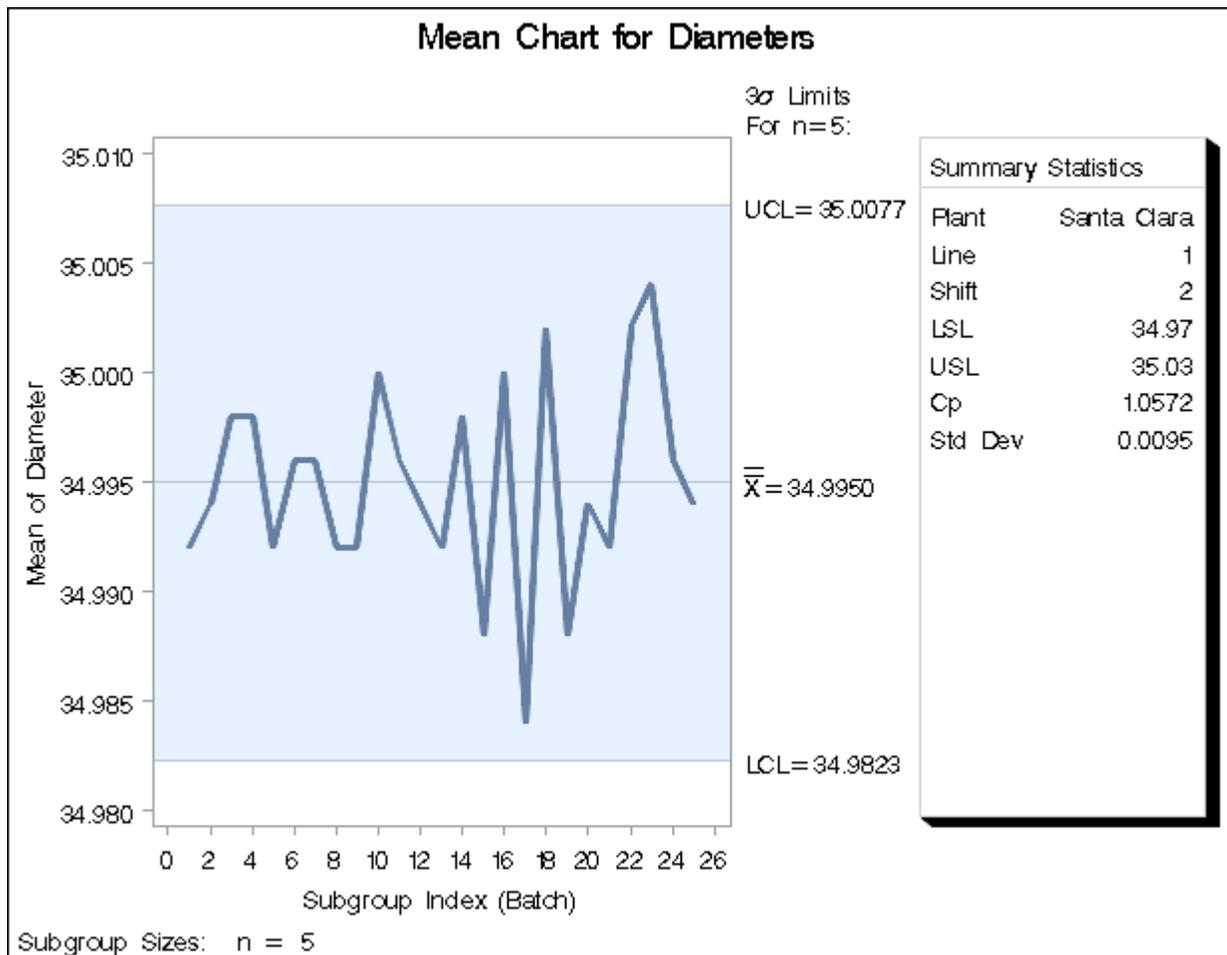

title 'Mean Chart for Diameters';
proc shewhart data=Wafers;
  xchart Diameter*Batch /
    lsl = 34.97
    usl = 35.03;
  inset data= Location lsl='LSL' usl='USL' cp (6.4) stddev (6.4) /
    position = rm
    cshadow = black
    header   = 'Summary Statistics';
run;

```

The header (in this case, *Summary Statistics*) can be up to 40 characters. Note that a relatively long list of inset statistics is requested. Consequently, POSITION=RM is specified to position the inset in the right margin. For more information about positioning, see “[Details: INSET and INSET2 Statements](#)” on page 2013. The CSHADOW= option is used to display a drop shadow on this inset. The *options*, such as HEADER=, POSITION= and CSHADOW= are specified after the slash (/) in the INSET statement. For more details on INSET statement options, see “[Dictionary of Options](#)” on page 2010.

Note that the contents of the data set LOCATION appear before other statistics in the inset. The position of the DATA= keyword in the keyword list determines the position of the data set’s contents in the inset.

Figure 17.124 Adding a Header and Repositioning the Inset

Syntax: INSET and INSET2 Statements

The syntax for the INSET and INSET2 statements is as follows:

```
INSET keyword-list < options > ;
```

```
INSET2 keyword-list < options > ;
```

You can use any number of INSET and INSET2 statements in the SHEWHART procedure. Each INSET or INSET2 statement produces a separate inset and must follow one of the chart statements. The inset appears on every panel (page) produced by the last chart statement preceding it. The statistics are displayed in the order in which they are specified. The following statements produce a boxplot with two insets and an \bar{X} and R chart with one inset in the \bar{X} chart and one in the R chart.

```
proc shewhart data=Wafers;
  boxchart Diameter * Batch / lsl=34.9 target=35 usl=35.1;
    inset lsl target usl;
    inset cp cpk cpm;
  xrchart Diameter * Batch;
    inset nmin nmax nout;
    inset2 nlow2 nhigh2;
run;
```

The statistics displayed in an inset are computed for a specific process variable using observations for the current BY group. For example, in the following statements, there are two process variables (Weight and Diameter) and a BY variable (Location). If there are three different locations (levels of Location), then a total of six \bar{X} charts are produced. The statistics in each inset are computed for a particular variable and location. The labels in the inset are the same for each \bar{X} chart.

```
proc shewhart data=Axles;
  by Location;
  xchart (Weight Diameter) * Batch / tests=1 to 8;
  inset ntests 1 to 8;
run;
```

The components of the INSET and INSET2 statements are described as follows.

keyword-list

can include any of the *keywords* listed in “Summary of INSET Keywords” on page 2007. Some *keywords*, such as NTESTS and DATA=, require operands specified immediately after the *keyword*. Also, some inset statistics are available only if you request chart statements and options for which those statistics are calculated. For example,

- the NHIGH2, NLOW2, NTESTS2, LCL2 and UCL2 keywords are available only when a secondary chart is produced with the IRCHART, MRCHART, XRCHART or XSCHART statements.
- the NTESTS *keyword* requires the TESTS= option;
- the NTESTS2 *keyword* requires the TESTS2= option;
- the capability index *keywords* such as CPK all require one or more of the LSL=, USL= and TARGET= options.

By default, inset statistics are identified with appropriate labels, and numeric values are printed using appropriate formats. However, you can provide customized labels and formats. You provide the customized label by specifying the *keyword* for that statistic followed by an equal sign (=) and the label in quotes. Labels can have up to 24 characters. You provide the numeric format in parentheses after the *keyword*. Note that if you specify both a label and a format for a statistic, the label must appear before the format. For an example, see “[Formatting Values and Customizing Labels](#)” on page 2003.

options

appear after the slash (/) and control the appearance of the inset. For example, the following INSET statement uses two appearance *options* (POSITION= and CTEXT=):

```
inset n nmin nmax / position=ne ctext=yellow;
```

The POSITION= option determines the location of the inset, and the CTEXT= option specifies the color of the text of the inset.

See “[Summary of Options](#)” on page 2010 for a list of all available *options*, and “[Dictionary of Options](#)” on page 2010 for detailed descriptions. Note the difference between *keywords* and *options*; *keywords* specify the information to be displayed in an inset, whereas *options* control the appearance of the inset.

Summary of INSET Keywords

All keywords available with the SHEWHART procedure’s INSET and INSET2 statements request a single statistic in an inset, except for the NTESTS, NTESTS2 and DATA= keywords. The NTESTS and NTESTS2 keywords each require a list of indexes specifying the tests for special causes whose counts of positive results are to be displayed:

```
inset ntests 1 2 3 4;
inset ntests2 1 to 4;
```

For each of the requested tests, the number of positive results for the test is displayed in the inset. So if tests 1 through 4 are requested the results occupy four lines in the inset.

The DATA= keyword specifies a SAS data set containing (label, value) pairs to be displayed in an inset. The data set must contain the variables _LABEL_ and _VALUE_. _LABEL_ is a character variable whose values provide labels for inset entries. _VALUE_ can be character or numeric, and provides values displayed in the inset. The label and value from each observation in the DATA= data set occupy one line in the inset. [Figure 17.124](#) shows an inset containing entries from a DATA= data set.

Table 17.82 Summary Statistics

Keyword	Description
DATA=	(label, value) pairs from <i>SAS-data-set</i>
LCL	primary chart lower control limit
MEAN	estimated or specified process mean
N	nominal subgroup size
NMIN	minimum subgroup size
NMAX	maximum subgroup size
NOUT	number of subgroups outside control limits on primary chart
NLOW	number of subgroups below lower control limit on primary chart
NHIGH	number of subgroups above upper control limit on primary chart
NTESTS	number of positive results of tests for special causes on primary chart
STDDEV	estimated or specified process standard deviation
UCL	primary chart upper control limit

Table 17.83 Secondary Chart Summary Statistics

Keyword	Description
LCL2	secondary chart lower control limit
MEAN2	mean of subgroup ranges or standard deviations
NOUT2	number of subgroups outside control limits on secondary chart
NLOW2	number of subgroups below lower control limit on secondary chart
NHIGH2	number of subgroups above upper control limit on secondary chart
NTESTS2	number of positive results of tests for special causes on secondary chart
UCL2	secondary chart upper control limit

Table 17.84 Specification Limits

Keyword	Description
LSL	lower specification limit
USL	upper specification limit
TARGET	target value

Table 17.85 Capability Indices and Confidence Limits

Keyword	Description
CIALPHA	α value for computing capability index confidence limits
CP	capability index C_p
CPLCL	lower confidence limit for C_p
CPUCL	upper confidence limit for C_p
CPK	capability index C_{pk}
CPKLCL	lower confidence limit for C_{pk}
CPKUCL	upper confidence limit for C_{pk}
CPL	capability index CPL
CPLLCL	lower confidence limit for CPL
CPLUCL	upper confidence limit for CPL
CPM	capability index C_{pm}
CPMLCL	lower confidence limit for C_{pm}
CPMUCL	upper confidence interval for C_{pm}
CPU	capability index CPU
CPULCL	lower confidence limit for CPU
CPUCL	upper confidence limit for CPU

You can use the keywords in [Table 17.86](#) only when producing ODS Graphics output. Greek letters are used in the labels for the statistics requested with the UMU and USIGMA keywords.

Table 17.86 Keywords Specific to ODS Graphics Output

Keyword	Description
TESTLEGEND	requests a legend of positive tests for special causes
UMU	estimated or specified process mean
USIGMA	estimated or specified process standard deviation

Summary of Options

The following table lists the INSET and INSET2 statement options. For complete descriptions, see “Dictionary of Options” on page 2010 which follows this section.

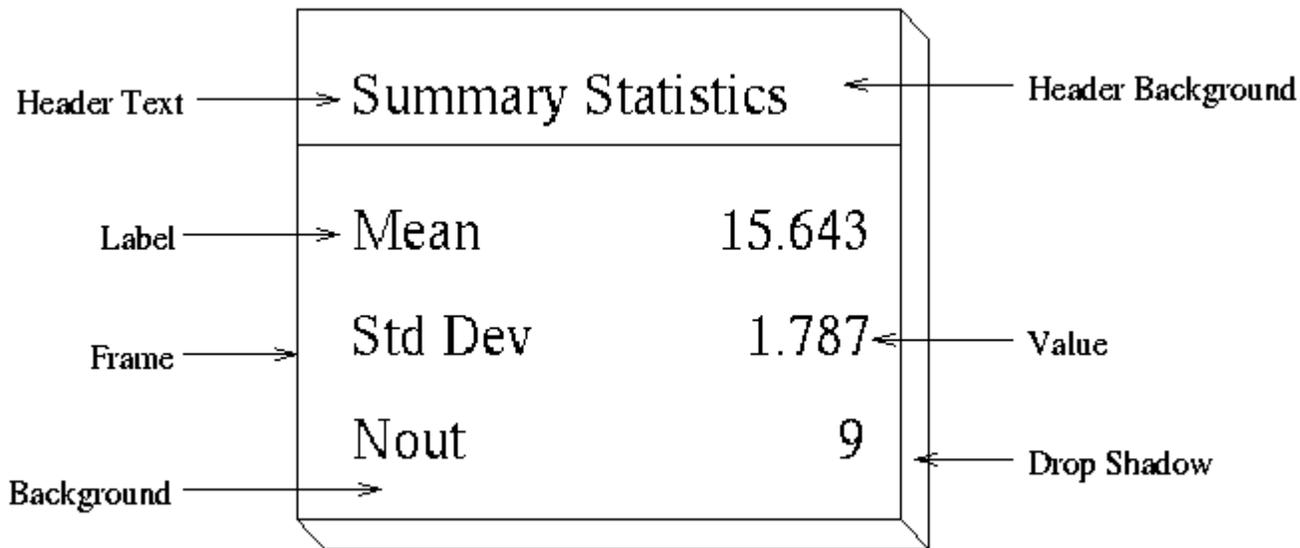

Table 17.87 INSET Options

Option	Description
CFILL=	specifies color of inset background
CFILLH=	specifies color of header background
CFRAME=	specifies color of frame
CHEADER=	specifies color of header text
CSHADOW=	specifies color of drop shadow
CTEXT=	specifies color of inset text
DATA	specifies data units for POSITION=(<i>x</i> , <i>y</i>) coordinates
FONT=	specifies font of text
FORMAT=	specifies format of values in inset
HEADER=	specifies header text
HEIGHT=	specifies height of inset text
HTRANSPARENCY=	specifies transparency of inset header background
NOFRAME	suppresses frame around inset
TRANSPARENCY=	specifies transparency of inset background
POSITION=	specifies position of inset
REFPOINT=	specifies reference point of inset positioned with POSITION=(<i>x</i> , <i>y</i>) coordinates

Dictionary of Options

The following entries provide detailed descriptions of options for the INSET and INSET2 statements. The marginal notes *Traditional Graphics* and *ODS Graphics* identify options that apply only to traditional graphics and ODS Graphics output, respectively. Terms used in this section are illustrated in Figure 17.125.

Figure 17.125 The Inset

**CFILL=*color* | BLANK**

specifies the color of the background (including the header background if you do not specify *Traditional Graphics* the CFILLH= option).

If you do not specify the CFILL= option, then by default, the background is empty. This means that items that overlap the inset (such as subgroup data points or control limits) show through the inset. If you specify any value for the CFILL= option, then overlapping items no longer show through the inset. Specify CFILL=BLANK to leave the background uncolored and also to prevent items from showing through the inset.

CFILLH=*color*

specifies the color of the header background. By default, if you do not specify a CFILLH= *Traditional Graphics* color, the CFILL= color is used.

CFRAME=*color*

specifies the color of the frame. By default, the frame is the same color as the axis of the plot. *Traditional Graphics*

CHEADER=*color*

specifies the color of the header text. By default, if you do not specify a CHEADER= color, *Traditional Graphics* the CTEXT= color is used.

CSHADOW=*color***CS=*color***

specifies the color of the drop shadow. See [Figure 17.124](#) for an example. By default, if you *Traditional Graphics* do not specify the CSHADOW= option, a drop shadow is not displayed.

CTEXT=color*Traditional Graphics***CT=color**

specifies the color of the text. By default, the inset text color is the same as the other text on the plot.

DATA

specifies that data coordinates are to be used in positioning the inset with the POSITION= option. The DATA option is available only when you specify POSITION= (x, y), and it must be placed immediately after the coordinates (x, y). For details, see the entry for the POSITION= option or “Positioning the Inset Using Coordinates” on page 2015. See Figure 17.128 for an example.

FONT=font*Traditional Graphics*

specifies the font of the text. By default, the font is SIMPLEX if the inset is located in the interior of the plot, and the font is the same as the other text displayed on the plot if the inset is located in the exterior of the plot.

FONT=SMALL*ODS Graphics*

changes the fonts used in the inset. By default, the font associated with the GraphLabelText style element is used for inset header and that associated with the GraphValueText style element is used for text in the body of the inset. When you specify FONT=SMALL, the GraphValueText font is used in the header and the GraphDataText font is used in the inset body.

FORMAT=format

specifies a format for all the values displayed in an inset. If you specify a format for a particular statistic, then this format overrides the format you specified with the FORMAT= option.

HEADER= 'string'

specifies the header text. The *string* cannot exceed 40 characters. If you do not specify the HEADER= option, no header line appears in the inset.

HEIGHT=value*Traditional Graphics*

specifies the height of the text in screen percent units.

HEIGHT=SMALL*ODS Graphics*

reduces the size of the text in the inset. By default, the GraphLabelText style element determines the size of inset header text and the GraphValueText style element determines the size of text in the body of the inset. When you specify HEIGHT=SMALL, the GraphValueText size is used for the inset header and the GraphDataText size is used in the inset body.

HTRANSPARENCY=value*ODS Graphics*

specifies the inset header background transparency when transparency is used in ODS Graphics output. The *value* must be between 0 and 1, where 0 is completely opaque and 1 is completely transparent. The default inset header background transparency is 0.65.

NOFRAME

suppresses the frame drawn around the text.

TRANSPARENCY=*value*

specifies the inset background transparency when transparency is used in ODS Graphics output. The *value* must be between 0 and 1, where 0 is completely opaque and 1 is completely transparent. The default inset background transparency is 0.05. *ODS Graphics*

POSITION=*position***POS=*position***

determines the position of the inset. The *position* can be a compass point keyword, a margin keyword, or a pair of coordinates (x, y). You can specify coordinates in axis percent units or axis data units. For more information, see “[Details: INSET and INSET2 Statements](#)” on page 2013. By default, POSITION=NW, which positions the inset in the upper left (northwest) corner of the display.

REFPOINT=BR | BL | TR | TL**RP=BR | BL | TR | TL**

specifies the reference point for an inset that is positioned by a pair of coordinates with the POSITION= option. Use the REFPOINT= option with POSITION= coordinates. The REFPOINT= option specifies which corner of the inset frame you want positioned at coordinates (x, y). The keywords BL, BR, TL, and TR represent bottom left, bottom right, top left, and top right, respectively. See [Figure 17.129](#) for an example. The default is REFPOINT=BL.

If you specify the position of the inset as a compass point or margin keyword, the REFPOINT= option is ignored. For more information, see “[Positioning the Inset Using Coordinates](#)” on page 2015.

Details: INSET and INSET2 Statements

This section provides details on three different methods of positioning the inset using the POSITION= option. With the POSITION= option, you can specify

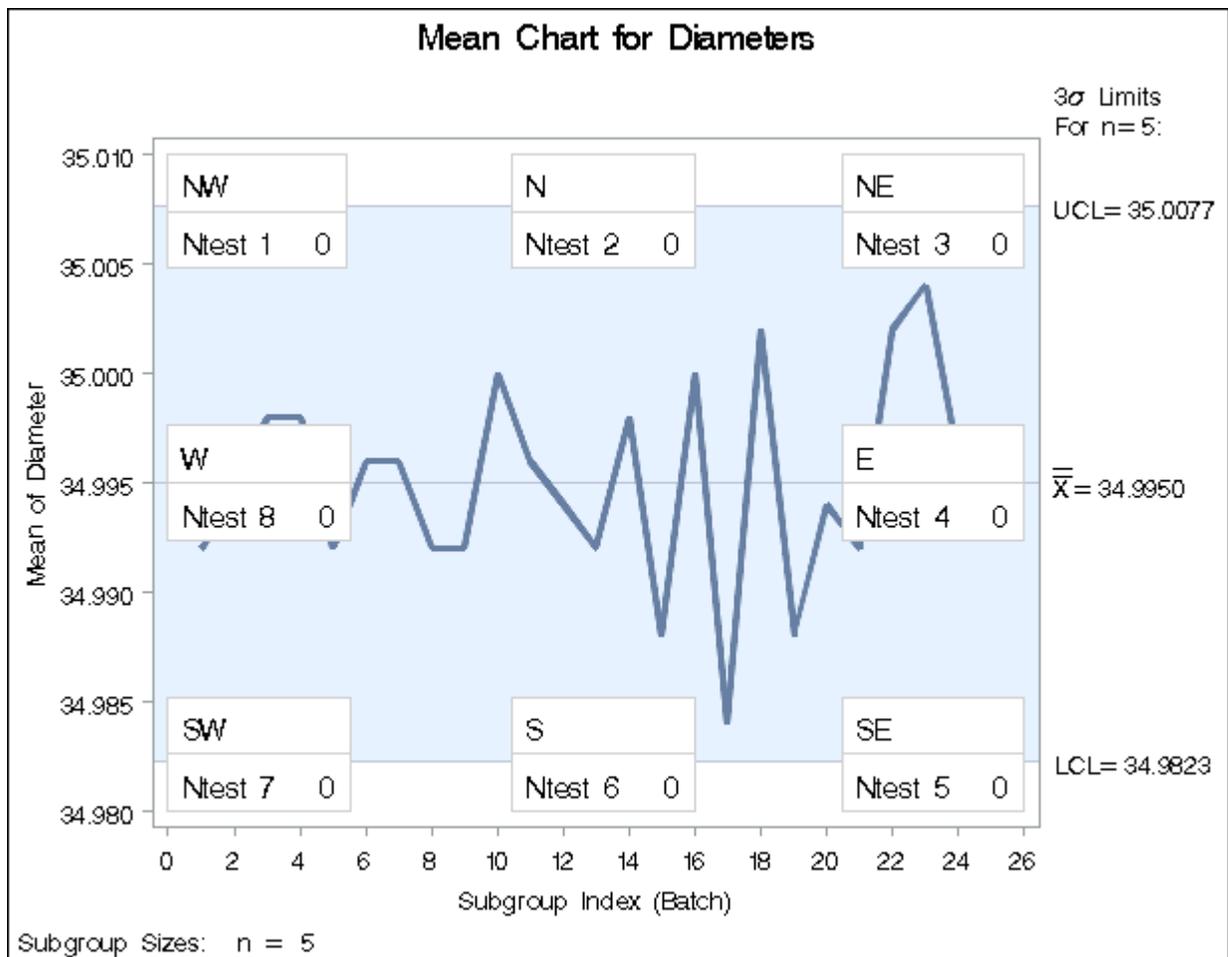

- compass points
- keywords for margin positions
- coordinates in data units or percent axis units

Positioning the Inset Using Compass Points

You can specify the eight compass points N, NE, E, SE, S, SW, W, and NW as keywords for the POSITION= option. The following statements create the display in Figure 17.126, which demonstrates all eight compass positions. The default is NW.

```
ods graphics off;
title 'Mean Chart for Diameters';
proc shewhart data=Wafers;
  xchart Diameter*Batch / tests= 1 to 8;
  inset ntests 1 / height=3 cfill=blank header='NW' pos=nw;
  inset ntests 2 / height=3 cfill=blank header='N ' pos=n ;
  inset ntests 3 / height=3 cfill=blank header='NE' pos=ne;
  inset ntests 4 / height=3 cfill=blank header='E ' pos=e ;
  inset ntests 5 / height=3 cfill=blank header='SE' pos=se;
  inset ntests 6 / height=3 cfill=blank header='S ' pos=s ;
  inset ntests 7 / height=3 cfill=blank header='SW' pos=sw;
  inset ntests 8 / height=3 cfill=blank header='W ' pos=w ;
run;
```

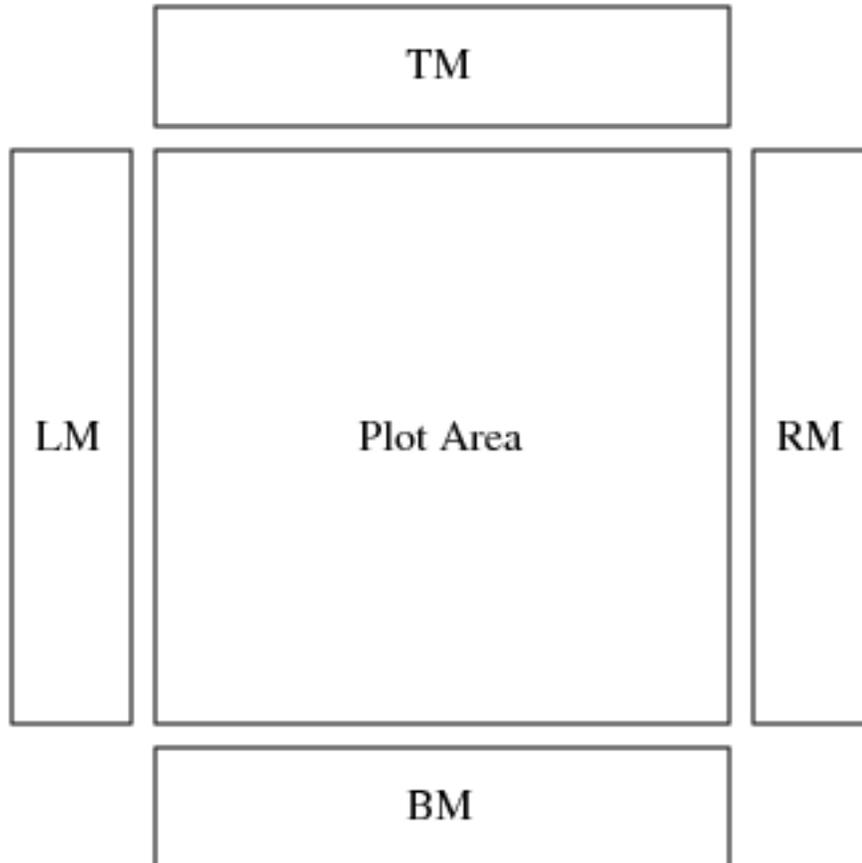

Figure 17.126 Insets Positioned Using Compass Points

Positioning the Inset in the Margins

Using the INSET statement you can also position an inset in one of the four margins surrounding the plot area using the margin keywords LM, RM, TM, or BM, as illustrated in Figure 17.127. The INSET2 statement cannot be used to produce an inset in a margin.

Figure 17.127 Positioning Insets in the Margins

For an example of an inset placed in the right margin, see Figure 17.124. Margin positions are recommended if a large number of statistics are listed in the INSET statement. If you attempt to display a lengthy inset in the interior of the plot, it is likely that the inset will collide with the data display.

Positioning the Inset Using Coordinates

You can also specify the position of the inset with coordinates: POSITION= (x, y). The coordinates can be given in axis percent units (the default) or in axis data units.

Data Unit Coordinates

If you specify the DATA option immediately following the coordinates, the inset is positioned using axis data units. For example, the following statements place the bottom left corner of the inset at 6 on the horizontal axis and 34.985 on the vertical axis:

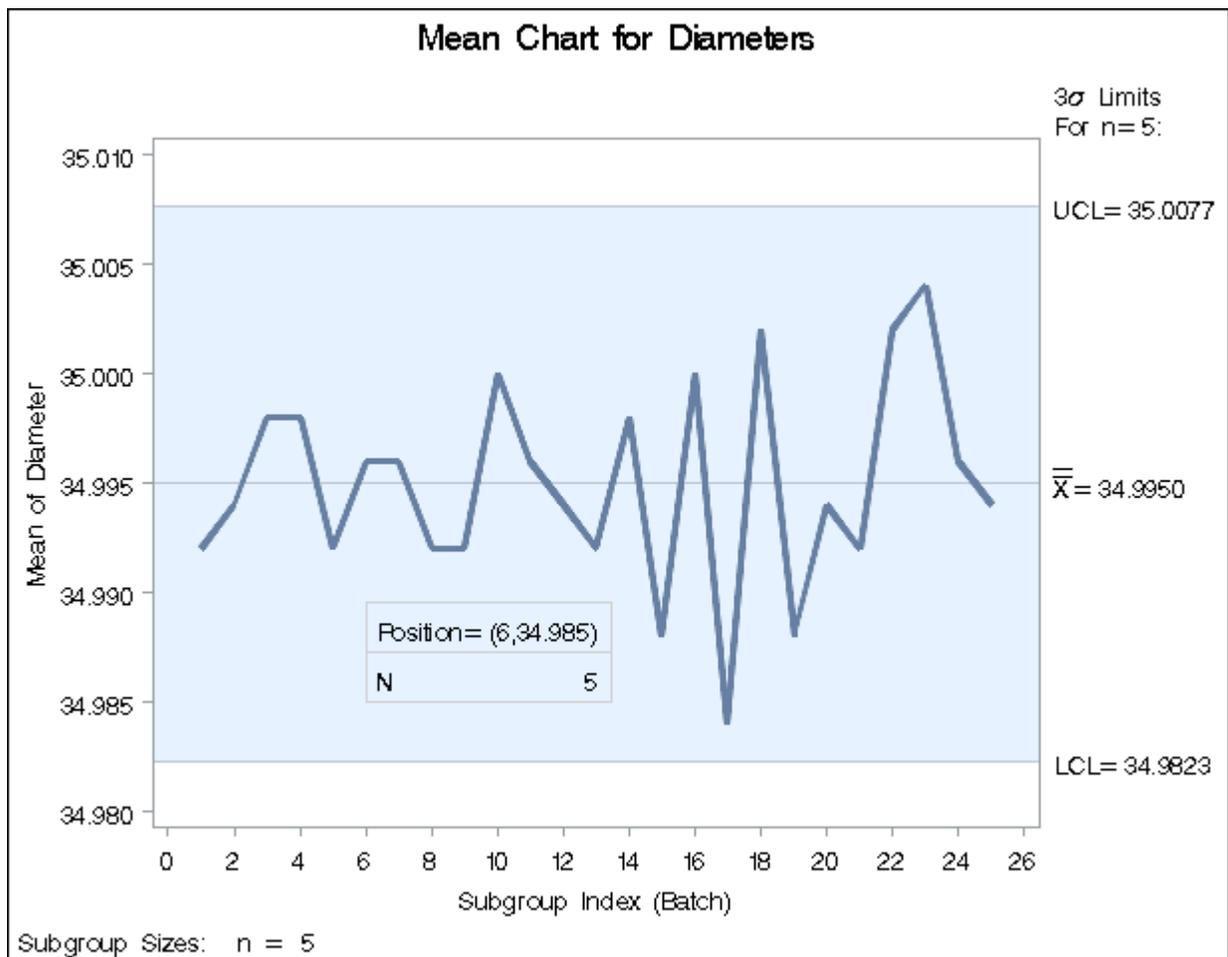

```

title 'Mean Chart for Diameters';
proc shewhart data=Wafers;
  xchart Diameter*Batch;
  inset n /
    header   = 'Position=(6,34.985) '
    position = (6,34.985) data;
run;

```

The control chart is displayed in Figure 17.128. By default, the specified coordinates determine the position of the bottom left corner of the inset. You can change this reference point with the REFPOINT= option, as in the next example.

Figure 17.128 Inset Positioned Using Data Unit Coordinates

Axis Percent Unit Coordinates

If you do not use the DATA option, the inset is positioned using axis percent units. The coordinates of the bottom left corner of the display are (0, 0), while the upper right corner is (100, 100). For example, the following statements create a \bar{X} chart with two insets, both positioned using coordinates in axis percent units:

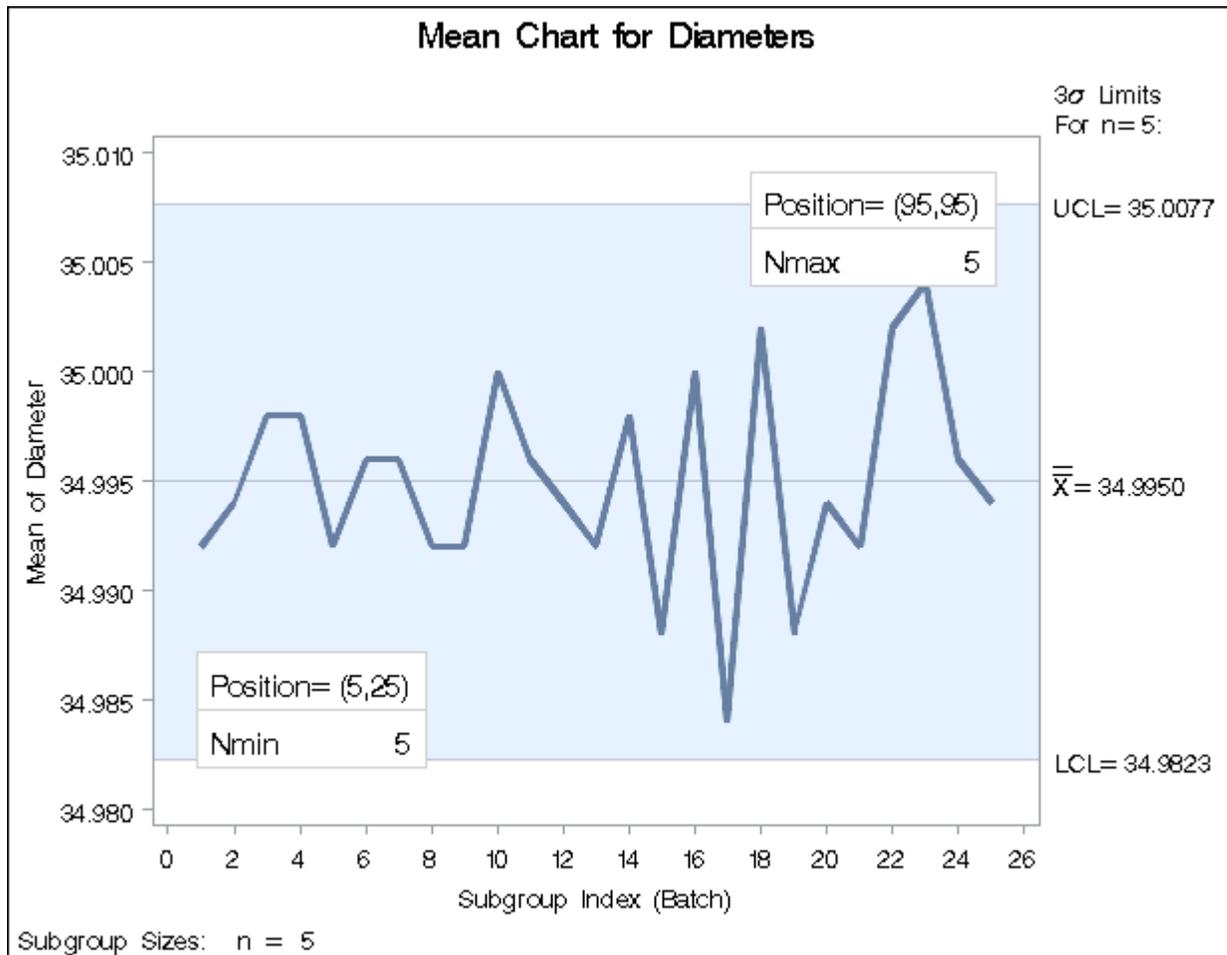

```

title 'Mean Chart for Diameters';
proc shewhart data=Wafers;
  xchart Diameter*Batch;
  inset nmin / position = (5,25)
        header   = 'Position=(5,25) '
        height   = 3
        cfill    = blank
        refpoint = tl;
  inset nmax / position = (95,95)
        header   = 'Position=(95,95) '
        height   = 3
        cfill    = blank
        refpoint = tr;
run;

```

The display is shown in Figure 17.129. Notice that the REFPOINT= option is used to determine which corner of the inset is to be placed at the coordinates specified with the POSITION= option. The first inset has REFPOINT=TL, so the top left corner of the inset is positioned 5% of the way across the horizontal axis and 25% of the way up the vertical axis. The second inset has REFPOINT=TR, so the top right corner of the inset is positioned 95% of the way across the horizontal axis and 95% of the way up the vertical axis. Note also that coordinates in axis percent units must be *between* 0 and 100.

Figure 17.129 Inset Positioned Using Axis Percent Unit Coordinates

Dictionary of Options: SHEWHART Procedure

This section provides detailed descriptions of options that you can specify in the following chart statements:

- BOXCHART
- CCHART
- IRCHART
- MCHART
- MRCHART
- NPCHART
- PCHART
- RCHART
- SCHART
- UCHART
- XCHART
- XRCHART
- XSCHART

Options are specified after the slash (/) in a chart statement. For example, to request tests for special causes with an \bar{X} and R chart, you can use the `TESTS=` option as follows:

```
proc shewhart data=Measures;  
  xrchart Length*Sample / tests=1 to 4 ;  
run;
```

The options described in this section are listed alphabetically. For tables of options organized by function, see the “Summary of Options” tables in the sections for the various chart statements.

Unless indicated otherwise, the options listed here are available with every chart statement. The marginal notes *Traditional Graphics*, *ODS Graphics*, and *Line Printer* identify options that apply to traditional graphics, ODS Graphics output, and line printer charts, respectively. For statements that create two charts, the term *primary chart* refers to the upper chart (for instance, the \bar{X} chart created with the XRCHART statement), and the term *secondary chart* refers to the lower chart (for instance, the R chart created with the XRCHART statement). The term *primary chart* also refers to the single chart created by some statements (for instance, the p chart created with the PCHART statement).

ALLLABEL=VALUE**ALLLABEL=(variable)**

labels every point on the primary chart with the VALUE plotted for that subgroup or with the value of a *variable* in the input data set.

The *variable* provided in the input data set can be numeric or character. If the *variable* is a character variable, its length cannot exceed 16. For each subgroup of observations, the formatted value of the *variable* in the observations is used to label the point representing the subgroup. If you are reading a DATA= data set with multiple observations per subgroup, the values of the *variable* should be identical for observations within a subgroup. You should use this option with care to avoid cluttering the chart. By default, points are not labeled. Related options are CFRAMELAB=, OUTLABEL=, LABELFONT=, LABELHEIGHT=, and TESTLABEL=, but note that the OUTLABEL= option cannot be specified with the ALLLABEL= option.

ALLLABEL2=VALUE**ALLLABEL2=(variable)**

labels every point on an *R*, *s*, or trend chart with the VALUE plotted for that subgroup or with the value of a *variable* in the input data set.

The *variable* provided in the input data set can be numeric or character. If the *variable* is a character variable, its length cannot exceed 16. For each subgroup of observations, the formatted value of the *variable* in the observations is used to label the point representing the subgroup. If you are reading a DATA= data set with multiple observations per subgroup, the values of the *variable* should be identical for observations within a subgroup. You should use this option with care to avoid cluttering the chart. By default, points are not labeled. Related options are CFRAMELAB=, OUTLABEL2=, LABELFONT=, LABELHEIGHT=, and TESTLABEL2=, but note that the OUTLABEL2= option cannot be specified with the ALLLABEL2= option. The option is available in the IRCHART, MRCHART, RCHART, SCHART, XRCHART, and XSCHART statements and in the BOXCHART, MCHART, and XCHART statements with the TRENDVAR= option.

ALLN

plots summary statistics for all subgroups, regardless of whether the subgroup sample size equals the nominal control limit sample size n specified by the LIMITN= option or the variable `_LIMITN_` in the LIMITS= data set. Use the ALLN option in conjunction with the LIMITN= option or the variable `_LIMITN_`.

The ALLN option is useful in applications where almost all of the subgroups have a common sample size n , and you want to display fixed (rather than varying) control limits corresponding to the nominal sample size n . The disadvantage of using the ALLN option with widely differing subgroup sample sizes is that the interpretation of the control limits is meaningful only for those subgroups whose sample size is equal to n . To request special symbol markers indicating that not all the sample sizes are equal to n , use the NMARKERS option in conjunction with the ALLN option.

The ALLN option is not available in the IRCHART statement.

ALPHA=value

requests *probability limits*. If you specify ALPHA= α , the control limits are computed so that the probability is α that a subgroup summary statistic exceeds its control limits. This

assumes that the process is in statistical control and that the data follow a certain theoretical distribution, which depends on the chart statement. The Poisson distribution is assumed for the CCHART and UCHART statements, and the binomial distribution is assumed for the NPCHART and PCHART statements. The normal distribution is assumed for all other chart statements. For the equations used to compute probability limits, see the “Details” subsection in the section for the chart statement that you are using.

The value of α can range between 0 and 1 for most statements. However, for the MCHART statement, the MRCHART statement, and the BOXCHART statement with the CONTROL-STAT=MEDIAN option, the value of α must be one of the following: 0.001, 0.002, 0.01, 0.02, 0.025, 0.04, 0.05, 0.10, or 0.20.

Note the following:

- As an alternative to specifying ALPHA= α , you can read α from the variable `_ALPHA_` in a LIMITS= data set by specifying the READALPHA option. See “Input Data Sets” in the section for the chart statement in which you are interested.
- As an alternative to specifying ALPHA= α (or reading the variable `_ALPHA_` from a LIMITS= data set), you can request “ $k\sigma$ control limits” by specifying SIGMAS= k (or reading the variable `_SIGMAS_` from a LIMITS= data set).

If you specify neither the ALPHA= option nor the SIGMAS= option, the procedure computes 3σ control limits by default.

ANNOTATE=SAS-data-set

ANNO=SAS-data-set

Traditional Graphics

specifies an ANNOTATE= type data set, as described in *SAS/GRAPH: Reference*, that enhances a primary chart. The ANNOTATE= data set specified in a chart statement enhances all charts created by that particular statement. You can also specify an ANNOTATE= data set in the PROC SHEWHART statement to enhance all primary charts created by the procedure.

ANNOTATE2=SAS-data-set

ANNO2=SAS-data-set

Traditional Graphics

specifies an ANNOTATE= type data set, as described in *SAS/GRAPH: Reference*, that enhances a secondary chart. The ANNOTATE2= data set specified in a chart statement enhances all charts created by that particular statement. You can also specify an ANNOTATE2= data set in the PROC SHEWHART statement to enhance all secondary charts created by the procedure.

This option is available in the IRCHART, MRCHART, XRCHART, and XSCHART statements and in the BOXCHART, MCHART, and XCHART statements with the TRENDVAR= option.

BILEVEL

Traditional Graphics

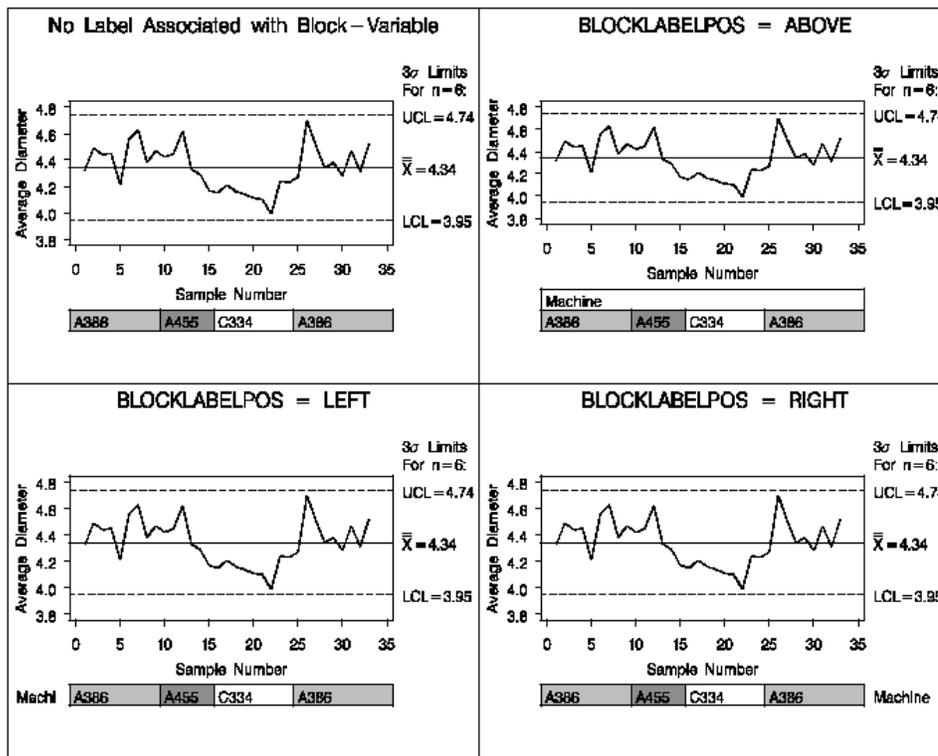

Line Printer

arranges the Shewhart chart in two levels (rather than the default of one level) so that twice as much data can be displayed on a page or screen. The second level is a continuation of the first level, and this arrangement is continued on subsequent pages until all the subgroups are displayed. You use the NPANELPOS= option to control the number of subgroup positions in each level. If you specify the BILEVEL option in a chart statement that produces primary and secondary charts, you must also specify the SEPARATE option.

BLOCKLABELPOS=ABOVE | LEFT | RIGHT

specifies the position of a block-variable label in the block legend. As shown in Figure 17.130, the keyword ABOVE places the label immediately above the legend, LEFT places the label to the left of the legend, and RIGHT places the label to the right of the legend. Use the keywords LEFT and RIGHT with labels that are short enough to fit in the margins on each side of the chart; otherwise, they will be truncated. Use the keyword RIGHT only when the legend is below the control chart (BLOCKPOS=3 or BLOCKPOS=4). The default keyword is ABOVE. Related options are BLOCKLABTYPE=, BLOCKREP, BLOCKPOS=, CBLOCKVAR=, and CBLOCKLAB=.

Figure 17.130 Positions for *block-variable* Labels

BLOCKLABTYPE=SCALED | TRUNCATED | ROTATE | ROTATEALL

BLOCKLABTYPE=height

specifies how lengthy block variable values are to be treated when there is insufficient space to display them in the block legend. By default, lengthy values are not displayed. *Traditional Graphics*
ODS Graphics

If you specify the BLOCKLABTYPE=SCALED option, the values are uniformly reduced in height so that they fit. If you specify the BLOCKLABTYPE=TRUNCATED option, lengthy values are truncated on the right until they fit. When producing traditional graphics, you can also specify a text *height* in vertical percent screen units for the values. For ODS Graphics output, you can specify BLOCKLABTYPE=ROTATE to rotate the values of the block variable displayed closest to the chart by 90 degrees, and BLOCKLABTYPE=ROTATEALL to rotate the values of all block variables. Related options are BLOCKLABELPOS=, BLOCKREP, BLOCKPOS=, CBLOCKVAR=, and CBLOCKLAB=.

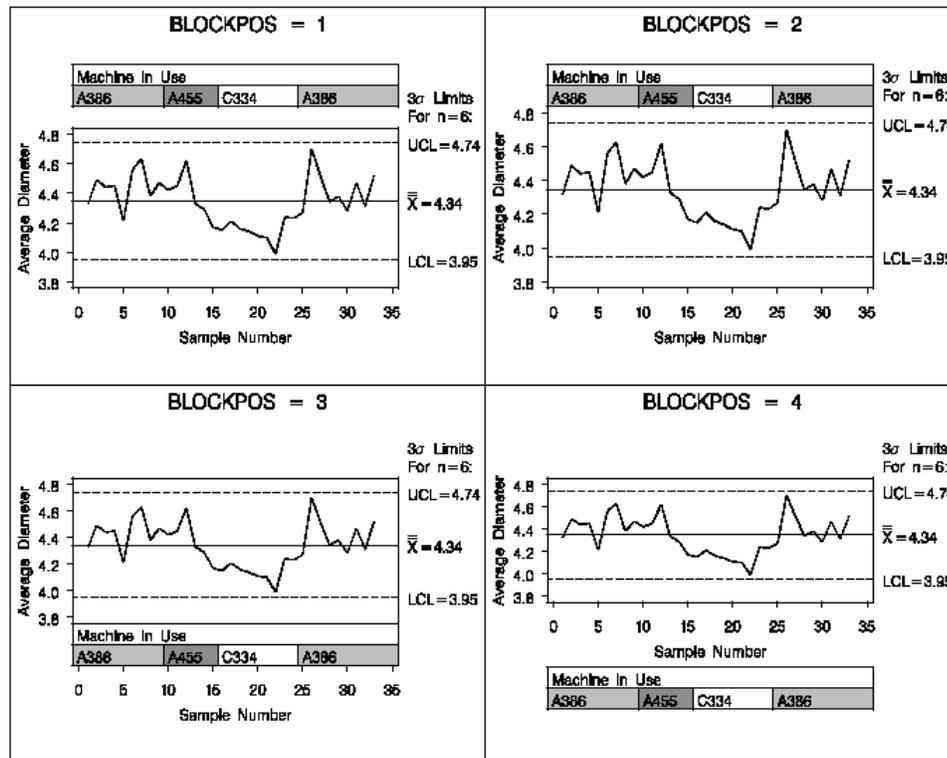

BLOCKPOS=*n*

specifies the vertical position of the legend for the values of the *block-variables* (see “Displaying Stratification in Blocks of Observations” on page 2098). Values of *n* and the corresponding positions are as follows. By default, BLOCKPOS=1.

<i>n</i>	Legend Position
1	Top of chart, offset from axis frame
2	Top of chart, immediately above axis frame
3	Bottom of chart, immediately above horizontal axis
4	Bottom of chart, below horizontal axis label

Figure 17.131 illustrates the various positions that can be specified.

Figure 17.131 Positions for *block-variable* Legends

Related options are BLOCKLABELPOS=, BLOCKLABTYPE=, BLOCKREP, CBLOCKVAR=, and CBLOCKLAB=.

BLOCKREFTRANSPARENCY=*value*

PHASEREFTRANSPARENCY=*value*

REFFILLTRANSPARENCY=*value*

ODS Graphics

specifies the wall fill transparency for blocks and phases when transparency is used in ODS Graphics output. The *value* must be between 0 and 1, where 0 is completely opaque and 1 is completely transparent. The default wall fill transparency is 0.85.

BLOCKREP

specifies that block variable values for all subgroups are to be displayed. By default, only the first block variable value in any block is displayed, and repeated block variable values are not displayed. Related options are BLOCKLABELPOS=, BLOCKLABTYPE=, BLOCKPOS=, CBLOCKVAR=, and CBLOCKLAB=. For more information about block variables, see “Displaying Stratification in Blocks of Observations” on page 2098.

BLOCKVAR=*variable* | (*variable-list*)

specifies variables whose values are used to assign colors for filling the background of the legend associated with block variables. A list of BLOCKVAR= variables must be enclosed in parentheses. BLOCKVAR= variables are matched with block variables by their order in the respective variable lists. While the values of a CBLOCKVAR= variable are color names, values of a BLOCKVAR= variable are used to group block legends for assigning fill colors from the ODS style. Block legends with the same BLOCKVAR= variable value are filled with the same color.

Traditional Graphics
ODS Graphics

BOXCONNECT**BOXCONNECT=**MEAN | MEDIAN | MAX | MIN | Q1 | Q3

specifies that the points representing subgroup means, medians, maximum values, minimum values, first quartiles or third quartiles in box-and-whisker plots created with the BOXCHART statement are to be connected. If BOXCONNECT is specified without a keyword identifying the points to be connected, subgroup means are connected. By default, no points are connected. The BOXCONNECT option is available only in the BOXCHART statement.

BOXES=*variable*

specifies a variable whose values are used to assign colors for the outlines of box-and-whiskers plots. While the values of a CBOXES= variable are color names, values of the BOXES= variable are used to group box-and-whiskers plots for assigning outline colors from the ODS style. The outlines of box-and-whiskers plots of groups with the same BOXES= variable value are drawn using the same color.

Traditional Graphics
ODS Graphics

BOXFILL=*variable* | NONE | EMPTY

specifies how box-and-whisker plots are filled with colors from the ODS style. You can specify a variable whose values are used to group box-and-whiskers plots for assigning fill colors from the ODS style. Boxes associated with groups having the same BOXFILL= variable value are filled with the same color. You can specify the keyword NONE or EMPTY to produce unfilled boxes. When producing traditional graphics, you can use the CBOXFILL= option to select specific colors for filling the boxes. By default, all boxes are filled with a single color from the ODS style.

Traditional Graphics
ODS Graphics

BOXTRANSPARENCY=*value*

specifies the box fill transparency for box-and-whisker charts when transparency is used in ODS Graphics output. The *value* must be between 0 and 1, where 0 is completely opaque and 1 is completely transparent. The default box fill transparency is 0.25.

ODS Graphics

BOXSTYLE=*keyword*

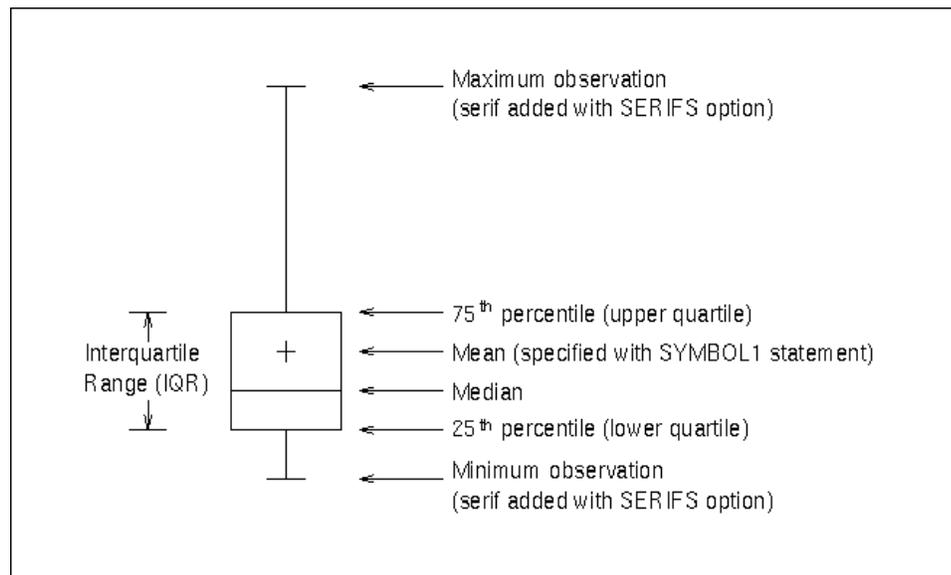

specifies the style of the box-and-whisker plots that are displayed for subgroup samples by the BOXCHART statement.

The SKELETAL, SCHEMATIC, SCHEMATICID, and SCHEMATICIDFAR keywords are useful for creating conventional box-and-whisker displays. The keywords POINTS,

POINTSJOIN, POINTSBOX, POINTSID, and POINTSJOINID are used to generalize the BOXSTYLE= option and, in particular, to facilitate the creation of so-called “multi-vari” charts, as illustrated in [Output 17.7.2](#) and [Output 17.7.3](#). The keyword POINTSSCHEMATIC combines the POINT and SCHEMATIC boxstyles.

If you specify BOXSTYLE=SKELETAL, the whiskers are drawn from the edges of the box to the extreme values of the subgroup sample. This plot is sometimes referred to as a *skeletal box-and-whisker plot*. By default, the whiskers are drawn without serifs, but you can add serifs with the SERIFS option. [Figure 17.132](#) illustrates the elements of a typical skeletal boxplot.

Figure 17.132 BOXSTYLE= SKELETAL

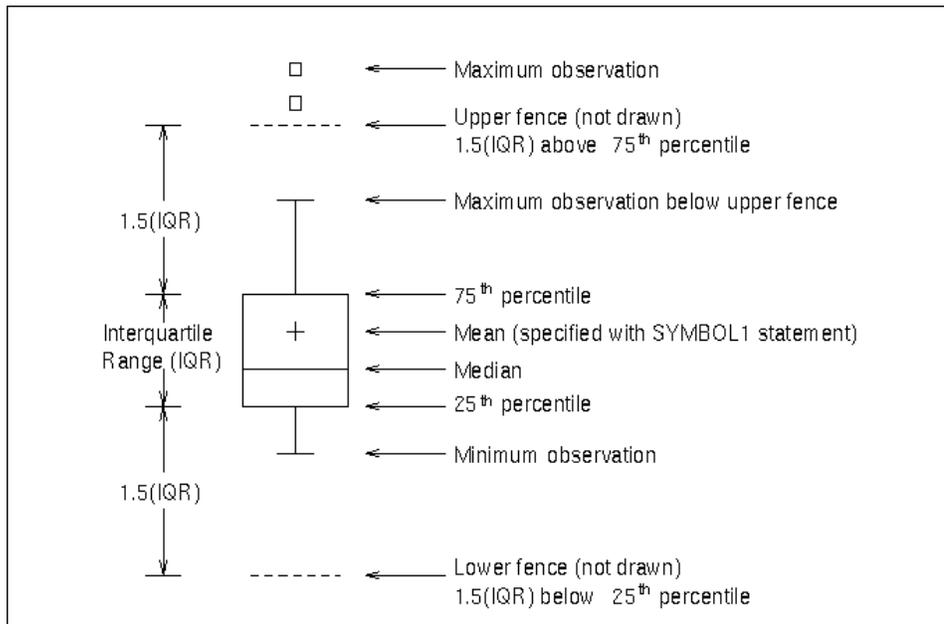

If you specify BOXSTYLE=SCHEMATIC, a whisker is drawn from the upper edge of the box to the largest value within the upper fence and from the lower edge of the box to the smallest value within the lower fence. [Figure 17.133](#) illustrates a typical schematic boxplot and the locations of the fences (which are not displayed in actual output). Serifs are added to the whiskers by default. Observations outside the fences are identified with a special symbol; you can specify the shape and color for this symbol with the IDSYMBOL= and IDCOLOR= options. The default symbol is a square. This type of plot corresponds to the *schematic box-and-whisker plot* described in Chapter 2 of Tukey (1977).

If you specify BOXSTYLE=SCHEMATICID, a schematic box-and-whisker plot is displayed in which the value of the first variable listed in the ID statement is used to label the symbol marking each observation outside the upper and lower fences.

If you specify BOXSTYLE=SCHEMATICIDFAR, a schematic box-and-whisker plot is displayed in which the value of the first variable listed in the ID statement is used to label the symbol marking each observation outside the *lower* and *upper far fences*. The lower and upper far fences are located $3 \times \text{IQR}$ below the 25th percentile and above the 75th percentile, respectively. Observations between the fences and the far fences are identified with a symbol but are not labeled with the ID variable.

Figure 17.133 BOXSTYLE= SCHEMATIC

NOTE: To make side-by-side box charts (as opposed to a control chart with subgroup box plots), you should use the BOXCHART statement with the NOLIMITS option in addition to the BOXSTYLE= option.

If you specify BOXSTYLE=POINTS, all the values in the subgroup sample are plotted as points, and neither a box nor whiskers are drawn. By default, a square plotting symbol is used for the values. You can specify a symbol with the IDSYMBOL= option. You can specify the color of the symbols with the IDCOLOR= option (the default color is the color specified with the CBOXES= option). *Traditional Graphics*

If you specify BOXSTYLE=POINTSJOIN, all the values in the subgroup sample are plotted as points joined with a vertical line. Neither a box nor whiskers are drawn. See [Output 17.7.2](#) for an illustration. By default, a square plotting symbol is used for the values. You can specify a symbol with the IDSYMBOL= option, and you can specify the color of the symbol with the IDCOLOR= option. You can specify the color of the vertical line with the CBOXES= option. *Traditional Graphics*

If you specify BOXSTYLE=POINTSBOX, all the values in the subgroup sample are plotted as points enclosed in a box. By default, a square plotting symbol is used for the values. You can specify a symbol with the IDSYMBOL= option, and you can specify the color of the symbol with the IDCOLOR= option. You can specify the color of the box with the CBOXES= option, the fill color of the box with the CBOXFILL= option, and the line type of the box with the LBOXES= option. *Traditional Graphics*

If you specify BOXSTYLE=POINTSID, all the values in the subgroup sample are plotted using labels specified as the values of the first variable in the ID statement. See [Output 17.7.3](#) for an illustration. It is recommended that you use single-character labels. You can specify a font for the labels with the IDFONT= option. You can specify the height of the labels with the IDHEIGHT= option. You can specify the color of the labels with the IDCTEXT= option. *Traditional Graphics*

Traditional Graphics If you specify `BOXSTYLE=POINTSJOINID`, all the values in the subgroup sample are plotted using labels specified as the values of the first variable in the `ID` statement, and the values are joined by a vertical line. It is recommended that you use single-character labels. You can specify a font for the labels with the `IDFONT=` option. You can specify the height of the labels with the `IDHEIGHT=` option. You can specify the color of the labels with the `IDCTEXT=` option, and you can specify the color of the vertical line with the `CBOXES=` option.

Traditional Graphics If you specify `BOXSTYLE=POINTSSCHEMATIC`, a schematic box chart is overlaid with points plotting all observations in the subgroups.

The `BOXSTYLE=` option is available only in the `BOXCHART` statement; see [Example 17.2](#). The styles `SCHEMATIC`, `SCHEMATICID`, and `SCHEMATICIDFAR` are available only when the input data set is a `DATA=` data set. By default, `BOXSTYLE= SKELETAL`. Related options include `BOXWIDTH=`, `BOXWIDTHSCALE=`, `IDCOLOR=`, and `IDSYMBOL=`.

Note that the keywords `POINTS`, `POINTSJOIN`, `POINTSBOX`, `POINTSID`, and `POINTSJOINID` for the `BOXSTYLE=` option can be used in conjunction with the `CPHASEBOX=`, `CPHASEBOXFILL=`, `CPHASEBOXCONNECT=`, `CPHASEMEANCONNECT=`, and `PHASEMEANSYMBOL=` options to create “multi-vari” displays.

BOXWIDTH=value

Traditional Graphics
ODS Graphics specifies the width of box-and-whisker plots created with the `BOXCHART` statement. For traditional graphics, the width is specified in horizontal percent screen units. For ODS Graphics output, the width is specified in pixels. The default width is chosen so that the boxes are as wide as possible without colliding. You should use the `BOXWIDTH=` option in situations where the number of subgroups per panel is very small and you want to reduce the width. The `BOXWIDTH=` option is available only in the `BOXCHART` statement.

BOXWIDTHSCALE=value

Traditional Graphics
ODS Graphics specifies that the width of box-and-whisker plots created with the `BOXCHART` statement is to vary proportionately to a particular function of the subgroup sample size n . The function is determined by the *value* and is identified on the chart with a legend.

If you specify a positive *value*, the widths are proportional to n^{value} . In particular, if you specify `BOXWIDTHSCALE=1`, the widths are proportional to the sample size. If you specify `BOXWIDTHSCALE=0.5`, the widths are proportional to \sqrt{n} , as described by McGill, Tukey, and Larsen (1978). If you specify `BOXWIDTHSCALE=0`, the widths are proportional to $\log(n)$. See [Example 17.4](#) for an illustration of the `BOXWIDTHSCALE=` option.

By default, the box widths are constant. The `BOXWIDTHSCALE=` option is available only in the `BOXCHART` statement.

CAXIS=color

CAXES=color

CA=color

Traditional Graphics specifies the color for the axes and tick marks. This option overrides any `COLOR=` specifications in an `AXIS` statement.

CBLOCKLAB=*color* | (*color-list*)

specifies fill colors for the frames that enclose the *block-variable* labels in a block legend. *Traditional Graphics*
By default, these areas are not filled. Colors in the CBLOCKLAB= list are matched with *block-variables* in the order in which they appear in the chart statement. Related options are BLOCKLABELPOS=, BLOCKLABTYPE=, BLOCKREP, BLOCKPOS=, and CBLOCKVAR=.

CBLOCKVAR=*variable* | (*variable-list*)

specifies variables whose values are colors for filling the background of the legend associated with *block-variables*. Each CBLOCKVAR= variable must be a character variable of no more than eight characters in the input data set (a DATA=, HISTORY=, or TABLE= data set). A list of CBLOCKVAR= variables must be enclosed in parentheses. You can use the BLOCKVAR= option to specify that the block variable legend be filled with different colors from the ODS style. *Traditional Graphics*

The procedure matches the CBLOCKVAR= variables with *block-variables* in the order specified. That is, each block legend will be filled with the color value of the CBLOCKVAR= variable of the first observation in each block. In general, values of the *i*th CBLOCKVAR= variable are used to fill the block of the legend corresponding to the *i*th *block-variable*. For examples of the CBLOCKVAR= option, see [Figure 17.146](#) and [Figure 17.147](#).

By default, fill colors are not used for the *block-variable* legend. The CBLOCKVAR= option is available only when *block-variables* are used in the chart statement.

CBOXES=*color***CBOXES=**(*variable*)

specifies the colors for the outlines of the box-and-whisker plots created with the BOXCHART statement. You can use one of the following approaches: *Traditional Graphics*

- You can specify CBOXES=*color* to provide a single outline color for all the box-and-whisker plots.
- You can specify CBOXES=(*variable*) to provide a distinct outline color for *each* box-and-whisker plot as the value of the *variable*. The *variable* must be a character variable of length 8 less in the input data set, and its values must be valid SAS/GRAPH color names. The outline color of the plot displayed for a particular subgroup is the value of the *variable* in the observations corresponding to this subgroup. Note that if there are multiple observations per subgroup in the input data set, the values of the *variable* should be identical for all the observations in a given subgroup.

You can use the BOXES= option to group boxes to be drawn with different colors from the ODS style.

The CBOXES= option is available only in the BOXCHART statement.

CBOXFILL=*color***CBOXFILL=**(*variable*)

specifies the interior fill colors for the box-and-whisker plots created with the BOXCHART statement. You can use one of the following approaches: *Traditional Graphics*

- You can specify CBOXFILL=*color* to provide a single color for all of the box-and-whisker plots.

- You can specify `CBOXFILL=(variable)` to provide a distinct color for *each* box-and-whisker plot as the value of the *variable*. The *variable* must be a character variable of length 8 or less in the input data set, and its values must be valid SAS/GRAPH color names (or the value `EMPTY`, which you can use to suppress color filling). The interior color of the plot displayed for a particular subgroup is the value of the *variable* in the observations corresponding to this subgroup. Note that if there are multiple observations per subgroup in the input data set, the values of the *variable* should be identical for all the observations in a given subgroup.

You can use the `BOXFILL=` option to group boxes to be filled with different colors from the ODS style. By default, all boxes are filled with a single color from the ODS style. The `CBOXFILL=` option is available only in the `BOXCHART` statement.

CCLIP=*color**Traditional Graphics*

specifies a color for the plotting symbol that is specified with the `CLIPSYMBOL=` option to mark clipped points. The default color is the color specified in the `COLOR=` option in the `SYMBOL1` statement.

CCONNECT=*color**Traditional Graphics*

specifies the color for the line segments connecting points on the chart. The default color is the color specified in the `COLOR=` option in the `SYMBOL1` statement. This option is not applicable in the `BOXCHART` statement unless you also specify the `BOXCONNECT` option.

CCOVERLAY=(*color-list***)***Traditional Graphics*

specifies the colors for the line segments connecting points on primary chart overlays. Colors in the `CCOVERLAY=` list are matched with variables in the corresponding positions in the `OVERLAY=` list. By default, points are connected by line segments of the same color as the plotted points. You can specify the value `NONE` to suppress the line segments connecting points on an overlay.

CCOVERLAY2=(*color-list***)***Traditional Graphics*

specifies the colors for the line segments connecting points on secondary chart overlays. Colors in the `CCOVERLAY2=` list are matched with variables in the corresponding positions in the `OVERLAY2=` list. By default, points are connected by line segments of the same color as the plotted points. You can specify the value `NONE` to suppress the line segments connecting points on an overlay.

CFRAME=*color***CFRAME=(***color-list***)***Traditional Graphics*

specifies the colors for filling the rectangle enclosed by the axes and the frame. By default, this area is not filled. The `CFRAME=` option cannot be used in conjunction with the `NOFRAME` option.

You can specify a single *color* to fill the entire area. Alternatively, if you are displaying phases (blocks) of data read with the `READPHASES=` option, you can specify a *color-list* with the `CFRAME=` option to fill the sub-rectangles of the framed area corresponding to the phases. The colors, in order of specification, are applied to the sub-rectangles starting from left to right. You can use the value `EMPTY` in the *color-list* to avoid filling a particular sub-rectangle. If the number of colors is less than the number of phases, the colors are applied cyclically. The colors are also used for phase legends requested with the `PHASELEGEND` option.

CFRAMELAB=*color*

CFRAMELAB

specifies the color for filling rectangles that frame the point labels displayed with the ALLLABEL=, ALLLABEL2=, OUTLABEL=, and OUTLABEL2= options. Specify CFRAMELAB with no argument to produced unfilled frames. By default, the points are not framed. *Traditional Graphics*
ODS Graphics

CGRID=*color*

specifies the color for the grid requested by the ENDGRID or GRID option. By default, the grid is the same color as the axes. *Traditional Graphics*

CHREF=*color*

specifies the color for the lines requested by the HREF= and HREF2= options. *Traditional Graphics*

CIINDICES <(< **TYPE**=*keyword* > < **ALPHA**=*value* >)>

requests capability index confidence limits based on subgroup summary data, calculated using “effective degrees of freedom” as described by Bissell (1990). These confidence limits are approximate. When you specify the CIINDICES option, the calculated confidence limits are available for display in an inset and are included in the OUTLIMITS= data set, if one is produced.

TYPE=*keyword*

specifies the type of confidence limit. Valid values are LOWER, UPPER and TWOSIDED. The default value is TWOSIDED.

ALPHA=*value*

specifies the default confidence level to compute confidence limits. The percentage for the confidence limits is $(1 - \textit{value}) * 100$. For example, ALPHA=.05 results in a 95% confidence limit. The default value is .05 and the possible range of values is from 0 to 1.

CINFILL=*color* | **EMPTY** | **NONE**

specifies the color for the area inside the upper and lower control limits. By default, this area filled with an appropriate color from the ODS style. You can specify the keyword EMPTY or NONE to leave the area between the control limits unfilled. See also the COUTFILL= option. *Traditional Graphics*
ODS Graphics

CLABEL=*color*

specifies the color for labels produced by the ALLLABEL=, ALLLABEL2=, OUTLABEL=, and OUTLABEL2= options. *Traditional Graphics*

CLIMITS=*color*

specifies the color for the control limits, the central line, and the labels for these lines. *Traditional Graphics*

CLIPCHAR=*'character'*

specifies a plot character that identifies clipped points, as requested with the CLIPFACTOR= option. Specifying the CLIPCHAR= option is recommended when the CLIPFACTOR= option is used. The default character is an asterisk (*). *Line Printer*

CLIPFACTOR=*factor*

requests clipping of extreme points on the control chart. The *factor* that you specify determines the extent to which these values are clipped, and it must be greater than one (useful values are in the range 1.5 to 2).

For examples of the CLIPFACTOR= option, see [Figure 17.170](#) and [Figure 17.171](#). The CLIPFACTOR= option should not be used in any statement in which the STARVERTICES= option is also used. Related clipping options are CCLIP=, CLIPCHAR=, CLIPLEGEND=, CLIPLEGPOS=, CLIPSUBCHAR=, and CLIPSYMBOL=.

CLIPLEGEND=*label*

specifies the *label* for the legend that indicates the number of clipped points when the CLIPFACTOR= option is used. The *label* must be no more than 16 characters and must be enclosed in quotes. For an example, see [Figure 17.171](#).

CLIPLEGPOS=TOP | BOTTOM

specifies the position for the legend that indicates the number of clipped points when the CLIPFACTOR= option is used. The keywords TOP and BOTTOM position the legend at the top or bottom of the chart, respectively. Do not specify CLIPLEGPOS=TOP together with the PHASELEGEND option or the BLOCKPOS=1 or BLOCKPOS=2 options. By default, CLIPLEGPOS=BOTTOM.

CLIPSUBCHAR=*character*

specifies a substitution character (such as #) for the label provided with the CLIPLEGEND= option. The substitution character is replaced with the number of points that are clipped. For example, suppose that the following statements produce a chart in which three extreme points are clipped:

```
proc shewhart data=Pistons;
  xrchart Diameter*Hour /
    clipfactor = 1.5
    cliplegend = 'Points clipped=#'
    clipsubchar = '#' ;
run;
```

Then the clipping legend displayed on the chart will be

```
Points clipped=3
```

CLIPSYMBOL=*symbol*

Traditional Graphics

specifies a plot symbol used to identify clipped points on the chart and in the legend when the CLIPFACTOR= option is used. You should use this option in conjunction with the CLIPFACTOR= option. The default *symbol* is CLIPSYMBOL=SQUARE.

CLIPSYMBOLHT=*value*

Traditional Graphics

specifies the height for the symbol marker used to identify clipped points on the chart when the CLIPFACTOR= option is used. The default is the height specified with the H= option in the SYMBOL statement.

For general information about clipping options, refer to “[Clipping Extreme Points](#)” on page 2131.

CNEEDLES=*color*

requests that points are to be connected to the central line with vertical line segments (needles) and specifies the color of the needles. You can use needles to visually represent the process as a series of shocks or vertical displacements away from a constant mean. See [Figure 17.168](#) for an example. The CNEEDLES= option is available in all chart statements except the BOXCHART statement. *Traditional Graphics*

CONNECTCHAR=*'character'***CCHAR=***'character'*

specifies the character used to form line segments that connect points on a chart. The default character is a plus (+) sign. *Line Printer*

CONTROLSTAT=MEAN | MEDIAN

specifies whether the control limits displayed in a box chart are to be computed for subgroup means or for subgroup medians. By default, CONTROLSTAT=MEAN. The CONTROLSTAT= option is available only in the BOXCHART statement.

COUT=*color***COUT**

specifies the color for the plotting symbols and the portions of connecting line segments that lie outside the control limits. Specify COUT with no argument to use an appropriate contrasting color from the ODS style. This option is useful for highlighting out-of-control subgroups. *Traditional Graphics*
ODS Graphics

When ODS Graphics is enabled and the BOXCHART statement or STARVERTICES= option is used, COUT highlights the boxes or stars whose subgroup values fall outside the control limits.

COUTFILL=*color*

specifies the fill color for the areas outside the control limits that lie between the connected points and the control limits and are bounded by connecting lines. This option is useful for highlighting out-of-control points. See [Figure 17.202](#) for an example. By default, these areas are not filled. You can use the OUTFILL option to fill this area with an appropriate color from the ODS style. Note that you can use the CINFILL= option to fill the area inside the control limits. *Traditional Graphics*

COVERLAY=(*color-list***)**

specifies the colors used to plot primary chart overlay variables. Colors in the COVERLAY= list are matched with variables in the corresponding positions in the OVERLAY= list. *Traditional Graphics*

COVERLAY2=(*color-list***)**

specifies the colors used to plot secondary chart overlay variables. Colors in the COVERLAY2= list are matched with variables in the corresponding positions in the OVERLAY2= list. *Traditional Graphics*

COVERLAYCLIP=*color**Traditional Graphics*

specifies the color used to plot clipped values on overlay plots when the CLIPFACTOR= option is used.

CPHASEBOX=*color***CPHASEBOX****PHASEBOX***Traditional Graphics**ODS Graphics*

specifies the color for a box that encloses all of the plotted points for a phase (group of consecutive observations that have the same value of the variable `_PHASE_`). Specify CPHASEBOX or PHASEBOX with no argument to request phase boxes drawn using an appropriate color from the ODS style. By default, an enclosing box is not drawn. This option is available only in the BOXCHART statement.

CPHASEBOXCONNECT=*color***CPHASEBOXCONNECT****PHASEBOXCONNECT***Traditional Graphics**ODS Graphics*

specifies the color for line segments that connect the vertical edges of adjacent enclosing boxes requested with the CPHASEBOX= option or the CPHASEBOXFILL= option. The vertical coordinates of the attachment points represent the average of the values plotted inside the box. The CPHASEBOXCONNECT= option is an alternative to the CPHASEMEANCONNECT= option. Specify CPHASEBOXCONNECT or PHASEBOXCONNECT with no argument to connect the phase boxes with lines drawn in an appropriate color from the ODS style. This option is available only in the BOXCHART statement.

CPHASEBOXFILL=*color***CPHASEBOXFILL****PHASEBOXFILL***Traditional Graphics**ODS Graphics*

specifies the fill color for a box that encloses all of the plotted points for a phase. Specify CPHASEBOXFILL or PHASEBOXFILL with no argument to fill the phase boxes with an appropriate color from the ODS style. By default, an enclosing box is not drawn. This option is available only in the BOXCHART statement.

CPHASELEG=*color**Traditional Graphics*

specifies a text color for the phase labels requested with the PHASELEGEND option. By default, if you specify a list of fill colors with the CFRAME= option, these colors are used for the corresponding phase labels, otherwise, the CTEXT= color is used for the phase labels.

CPHASEMEANCONNECT=*color***CPHASEMEANCONNECT****PHASEMEANCONNECT***Traditional Graphics**ODS Graphics*

specifies the color for line segments that connect points representing the average of the values plotted within a phase. This option must be used in conjunction with the CPHASEBOX= or CPHASEBOXFILL= options, and it is an alternative to the CPHASEBOXCONNECT= option. The points are centered horizontally within the enclosing boxes. Specify CPHASEMEANCONNECT or PHASEMEANCONNECT with no argument to connect phase means with lines drawn in an appropriate color from the ODS style. This option is available only in the BOXCHART statement.

CSTARCIRCLES=*color*

specifies a color for the circles requested with the STARCIRCLES= option. See “[Displaying Auxiliary Data with Stars](#)” on page 2114. By default, the color specified with the CSTARTS= option is used. *Traditional Graphics*

CSTARFILL=*color***CSTARFILL=***(variable)*

specifies a color or colors for filling the interior of stars requested with the STARVERTICES= option. You can use one of the following approaches: *Traditional Graphics*

- Specify a single color to be used for all stars with **CSTARFILL=***color*.
- Specify a distinct color for *each* star (or subsets of stars) by providing the colors as values of a variable specified with **CSTARFILL=***(variable)*. The variable must be a character variable of length 8 or less in the input data set, and its values must be valid SAS/GRAPH colors or the value *EMPTY*. The color for the star positioned at the *i*th subgroup on the chart is the value of the **CSTARFILL=** *variable* in the observations corresponding to the *i*th subgroup. Note that if there are multiple observations per subgroup in the input data set (for instance, if you are using the XRCHART statement in the SHEWHART procedure to analyze observations from a DATA= input data set), the values of the **CSTARFILL=** *variable* should be identical for all the observations in a given subgroup.

See “[Displaying Auxiliary Data with Stars](#)” on page 2114.

You can use the STARFILL= option to group stars to be filled with different colors from the ODS style. By default, all stars are filled with a single color from the ODS style.

CSTAROUT=*color***CSTAROUT**

specifies a color for those portions of the outlines of stars (requested with the STARVERTICES= option) that exceed the inner or outer circles. This option applies only with the STARTYPE=RADIAL and STARTYPE=SPOKE options, and it is useful for highlighting extreme values of star vertex variables. Specify **CSTAROUT** with no argument to use an appropriate contrasting color from the ODS style. See “[Displaying Auxiliary Data with Stars](#)” on page 2114. *Traditional Graphics*
ODS Graphics

CSTARTS=*color***CSTARTS=***(variable)*

specifies a color or colors for the outlines of stars requested with the STARVERTICES= option. *Traditional Graphics*

You can use one of the following approaches:

- You can specify a single color to be used for all the stars on the chart with **CSTARTS=***color*.
- You can specify a distinct outline color for *each* star (or subsets of stars) by providing the colors as values of a variable specified with **CSTARTS=***(variable)*. The variable must be a character variable of length 8 or less in the input data set. The outline color for the star positioned at the *i*th subgroup on the chart is the value of the **CSTARTS=***variable*

in the observations corresponding to the i th subgroup. Note that if there are multiple observations per subgroup in the input data set (for instance, if you are using the XRCHART statement in the SHEWHART procedure to analyze observations from a DATA= input data set), the values of the CSTARTS= *variable* should be identical for all the observations in a given subgroup.

See “Displaying Auxiliary Data with Stars” on page 2114.

You can use the STARS= option to group stars to be drawn with different colors from the ODS style. By default, all stars are drawn with a single color from the ODS style.

CSYMBOL='label'

CSYMBOL=C | CBAR | CPM | CPM2 | C0

specifies a label for the central line in a c chart. You can use the option in two ways:

- You can specify a quoted *label* of length 16 or less.
- You can specify one of the keywords listed in the following table. Each keyword requests a label of the form *symbol=value*, where *symbol* is the symbol given in the table, and *value* is the value of the central line. If the central line is not constant, only the symbol is displayed.

Keyword	Symbol Used in	
	Graphics	Line Printer Charts
C	C	C
CBAR	\bar{C}	\bar{C}
CPM	C'	C'
CPM2	C''	C''
C0	C_0	C_0

See [Example 17.9](#) for an example. The default keyword is CBAR. The CSYMBOL= option is available only in the CCHART statement.

CTESTLABBOX=color

Traditional Graphics

specifies the color for boxes enclosing labels for positive tests for special causes requested with the TESTLABBOX option. If you use the CTESTLABBOX= option, you do not need to specify the TESTLABBOX option.

CTESTS=color | test-color-list

Traditional Graphics

CTEST=color | test-color-list

specifies colors for labels indicating points where a test is positive.

- You can specify the *color* for the labels used to identify points at which tests for special causes specified in the TESTS= option are positive. For Tests 2 through 8, this color is also used for the line segments that connect patterns of points for which a test is positive.
- You can specify the *test-color-list* to enable different colors to be used for the labels and highlighted line segments associated with different tests for special causes. Any positive tests for which no specific CTESTS= value is specified are displayed using the general CTESTS= color. A non-default general CTESTS= color can be specified using the CTESTS=*color* syntax.

The following options request the standard tests for special causes 1 through 4 and one user-defined test designated B.

```
TESTS = 1 to 4 M(K=4 DIR=DEC Code=B);
CTESTS = green;
CTESTS = (1 purple 3 yellow B blue);
```

Test 1 will be displayed in purple, Test 3 in yellow, and Test B in blue. Tests 2 and 4 will be displayed in green, the general CTESTS= color.

CTESTSYMBOL=*color*

CTESTSYM=*color*

specifies the color of the symbol used to plot subgroups with positive tests for special causes. *Traditional Graphics*

CTEXT=*color*

specifies the color for tick mark values and axis labels. This color is also used for the sample size legend and for the control limit legend. The default color is the color specified in the CTEXT= option in the most recent GOPTIONS statement. *Traditional Graphics*

CVREF=*color*

CV=*color*

specifies the color for reference lines requested by the VREF= and VREF2= options. *Traditional Graphics*

CZONES=*color*

requests lines marking zones A, B, and C for the tests for special causes (see the TESTS= option) and specifies the *color* for these lines. This color is also used for labels requested with the ZONELABELS option. *Traditional Graphics*

DATAUNIT=PERCENT | PROPORTION

enables you to use percents or proportions as the values for *processes* when you are using the PCHART or NPCHART statements and reading a DATA= input data set. Specify DATAUNIT=PERCENT to indicate that the values are percents of nonconforming items. Specify DATAUNIT=PROPORTION to indicate that the values are proportions of nonconforming items. Values for percents can range from 0 to 100, while values for proportions can range from 0 to 1. By default, the values of *processes* read from a DATA= data set for PCHART and NPCHART statements are assumed to be numbers (counts) of nonconforming items. The DATAUNIT= option is available only in the NPCHART and PCHART statements.

DESCRIPTION='*string*'

DES='*string*'

specifies a description, up to 256 characters long, for the GRSEG catalog entry for the primary chart. The default *string* is the variable name. A related option is NAME=. *Traditional Graphics*

DESCRIPTION2='*string*'

DES2='*string*'

specifies a description, up to 256 characters long, for the GRSEG catalog entry for the secondary chart. The default *string* is the variable name. The DESCRIPTION2= option is available in the IRCHART, MRCHART, XRCHART, and XSCHART statements, and it is used in conjunction with the SEPARATE option. A related option is NAME2=. *Traditional Graphics*

DISCRETE

specifies that numeric subgroup variable values be treated as discrete values, so that each tick value on the default subgroup axis corresponds to a unique subgroup variable value. By default, a *continuous* subgroup axis is created, and if the subgroup variable values are not evenly spaced, the axis contains ticks with no corresponding subgroup data.

ENDGRID

Traditional Graphics
Line Printer

adds a grid to the rightmost portion of the chart, beginning with the first labeled major tick mark position that follows the last plotted point. This grid is useful in situations where you want to add points by hand after the chart is created. You can use the HAXIS= option to force space to be added to the horizontal axis.

EXCHART

creates a control chart only when exceptions occur, specifically, when the control limits are exceeded or when any of the tests requested with the TESTS= option or the TESTS2= option are positive.

FONT=font

Traditional Graphics

specifies a software font for labels and legends. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the GOPTIONS statement. Hardware characters are used by default.

FRONTREF

Traditional Graphics
ODS Graphics

draws reference lines specified with the HREF= and VREF= options in front of box-and-whiskers plots. By default, reference lines are drawn behind the box-and-whiskers plots and can be obscured by filled boxes.

GRID

adds a grid to the control chart. Grid lines are horizontal and vertical lines positioned at labeled major tick marks, and they cover the length and height of the plotting area.

HAXIS=values**HAXIS=AXIS_n**

specifies tick mark values for the horizontal (subgroup) axis. If the subgroup variable is numeric, the *values* must be numeric and equally spaced. Numeric values can be given in an explicit or implicit list. If the subgroup variable is character, *values* must be quoted strings of length 32 or less. If a date, time, or datetime format is associated with a numeric subgroup variable, SAS datetime literals can be used. Examples of HAXIS= lists follow:

```
haxis=0 2 4 6 8 10
haxis=0 to 10 by 2
haxis='LT12A' 'LT12B' 'LT12C' 'LT15A' 'LT15B' 'LT15C'
haxis='20MAY88'D to '20AUG88'D by 7
haxis='01JAN88'D to '31DEC88'D by 30
```

If the subgroup variable is numeric, the HAXIS= list must span the subgroup variable values, and if the subgroup variable is character, the HAXIS= list must include all of the subgroup variable values. You can add subgroup positions to the chart by specifying HAXIS= values that are not subgroup variable values.

If you specify a large number of HAXIS= values, some of these may be thinned to avoid collisions between tick mark labels. To avoid thinning, use one of the following methods:

- Shorten values of the subgroup variable by eliminating redundant characters. For example, if your subgroup variable has values LOT1, LOT2, LOT3, and so on, you can use the SUBSTR function in a DATA step to eliminate “LOT” from each value, and you can modify the horizontal axis label to indicate that the values refer to lots.
- Use the TURNHLABELS option to turn the labels vertically.
- Use the NPANELPOS= option to force fewer subgroup positions per panel.

If you are producing traditional graphics, you can also specify a previously defined AXIS statement with the HAXIS= option.

HEIGHT=*value*

specifies the height (in vertical screen percent units) of the text for axis labels and legends. *Traditional Graphics*
This *value* takes precedence over the HTEXT= value specified in the GOPTIONS statement. This option is recommended for use with software fonts specified with the FONT= option or with the FTEXT= option in the GOPTIONS statement. Related options are LABEL-HEIGHT= and TESTHEIGHT=.

HMINOR=*n*

HM=*n*

specifies the number of minor tick marks between each major tick mark on the horizontal axis. Minor tick marks are not labeled. The default is 0. *Traditional Graphics*

HOFFSET=*value*

specifies the length the offset at both ends of the horizontal axis. For traditional graphics, the offset is specified in percent screen units. For ODS Graphics output, the offset is specified in pixels. You can eliminate the offset by specifying HOFFSET=0. *Traditional Graphics*
ODS Graphics

HREF=*values*

HREF=*SAS-data-set*

draws reference lines perpendicular to the horizontal (subgroup) axis on the primary chart. You can use this option in the following ways:

- You can specify the *values* for the lines with an HREF= list. If the subgroup variable is numeric, the *values* must be numeric. If the subgroup variable is character, the *values* must be quoted strings of up to 32 characters. If the subgroup variable is formatted, the *values* must be given as internal values.

Examples of HREF=*values* follow:

```
href=5
href=5 10 15 20 25 30
href='Shift 1' 'Shift 2' 'Shift 3'
```

- You can specify the values for the lines as the values of a variable named `_REF_` in an HREF= data set. The type and length of `_REF_` must match those of the *subgroup variable* specified in the chart statement. Optionally, you can provide labels for the lines as values of a variable named `_REFLAB_`, which must be a character variable of length

16 or less. If you want distinct reference lines to be displayed in charts for different *processes* specified in the chart statement, you must include a character variable of length 32 or less named `_VAR_`, whose values are the *processes*. If you do not include the variable `_VAR_`, all of the lines are displayed in all of the charts.

Each observation in the HREF= data set corresponds to a reference line. If BY variables are used in the input data set (DATA=, HISTORY=, or TABLE=), the same BY variable structure must be used in the HREF= data set unless you specify the NOBYREF option.

Related options are CHREF=, HREFCHAR=, HREFLABELS=, HREFLABPOS=, LHREF=, and NOBYREF.

HREF2=values

HREF2=SAS-data-set

draws reference lines perpendicular to the horizontal (subgroup) axis on the secondary chart. The conventions for specifying the HREF2= option are identical to those for specifying the HREF= option. Related options are CHREF=, HREFCHAR=, HREF2LABELS=, HREFLABPOS=, LHREF=, and NOBYREF. The HREF2= option is available only in the IRCHART, MRCHART, XRCHART, and XSCHART statements and in the BOXCHART, MCHART, and XCHART statements with the TRENDVAR= option.

HREF2DATA=SAS-data-set

draws reference lines perpendicular to the horizontal (subgroup) axis on the secondary chart. The HREF2DATA= option must be used in place of the HREF2= option to specify a data set using the quoted filename notation.

HREF2LABELS='label1' ... 'labeln'

HREF2LABEL='label1' ... 'labeln'

HREF2LAB='label1' ... 'labeln'

specifies labels for the reference lines requested by the HREF2= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters. The HREF2LABELS= option is available only in the IRCHART, MRCHART, XRCHART, and XSCHART statements and in the BOXCHART, MCHART, and XCHART statements with the TRENDVAR= option.

HREFCHAR='character'

Line Printer

specifies the character used for reference lines requested by the HREF= and HREF2= options on line printer charts. The default is the vertical bar (|).

HREFDATA=SAS-data-set

draws reference lines perpendicular to the horizontal (subgroup) axis on the primary chart. The HREFDATA= option must be used in place of the HREF= option to specify a data set using the quoted filename notation.

HREFLABELS='label1' ... 'labeln'

HREFLABEL='label1' ... 'labeln'

HREFLAB='label1' ... 'labeln'

specifies labels for the reference lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

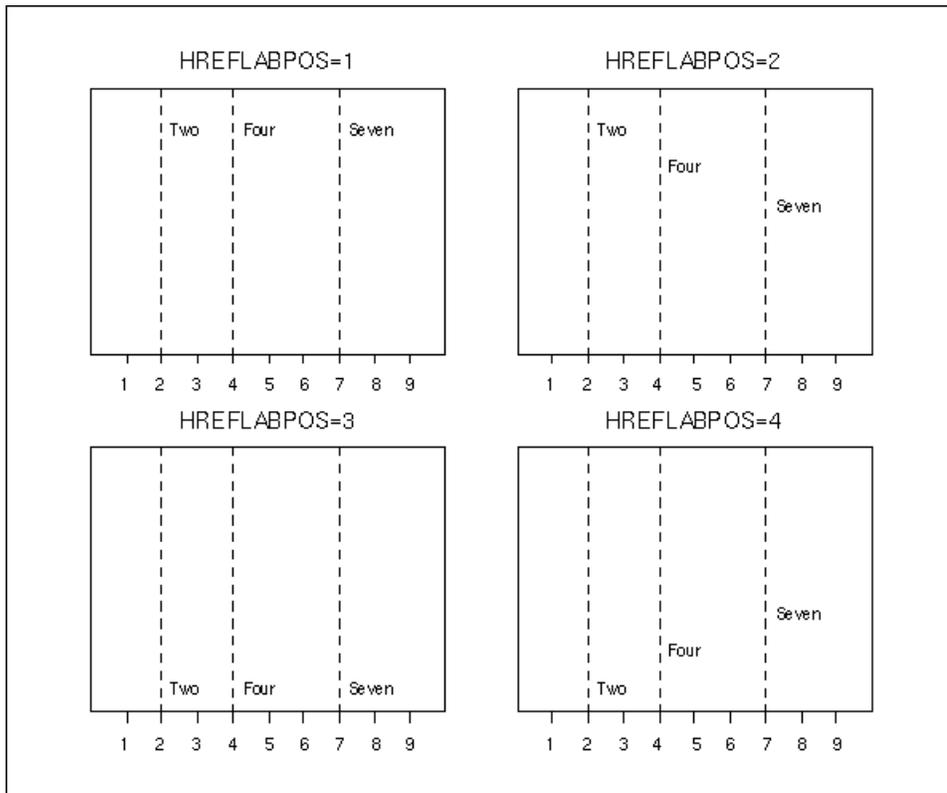

specifies the vertical position of the HREFLABEL= and HREF2LABEL= labels, as described in the following table. By default, *n* = 2.

<i>n</i>	Position
1	along top of subplot area
2	staggered from top to bottom of subplot area
3	along bottom of subplot area
4	staggered from bottom to top of subplot area

Figure 17.134 illustrates label positions for values of the HREFLABPOS= option when the HREF= and HREFLABELS= options are as follows:

```
href          = 2 4 7
hreflabels   = 'Two' 'Four' 'Seven'
```

Figure 17.134 Positions for Reference Line Labels

HTML=*variable*

specifies a variable whose values create links associated with subgroup points on a primary *Traditional Graphics* control chart when traditional graphics output is directed into HTML. You can specify a character variable or formatted numeric variable. The value of the HTML= variable should be the same for each observation with a given value of the subgroup variable. See the section “Interactive Control Charts: SHEWHART Procedure” on page 2212 for more information.

HTML2=variable*Traditional Graphics*

specifies a variable whose values create links associated with subgroup points on a secondary control chart when traditional graphics output is directed into HTML. You can specify a character variable or formatted numeric variable. The value of the HTML2= variable should be the same for each observation with a given value of the subgroup variable. See the section “Interactive Control Charts: SHEWHART Procedure” on page 2212 for more information.

HTML_LEGEND=variable*Traditional Graphics*

specifies HTML links as values of the specified character variable (or formatted values of a numeric variable). These links are associated with symbols in the legend for the levels of a *symbol-variable*. The value of the HTML_LEGEND= variable should be the same for each observation with a given value of *symbol-variable*.

IDCOLOR=color*Traditional Graphics*

specifies the color of the symbol marker used to identify outliers in schematic box-and-whisker plots produced with the BOXCHART statement when you use one of the following options: BOXSTYLE=SCHEMATIC, BOXSTYLE=SCHEMATICID, and BOXSTYLE=SCHEMATICIDFAR. The default *color* is the color specified with the CBOXES= option. The IDCOLOR option is available only in the BOXCHART statement.

IDCTEXT=color*Traditional Graphics*

specifies the color for the text used to label outliers or indicate process variable values when you specify one of the keywords SCHEMATICID, SCHEMATICIDFAR, POINTSID, or POINTSJOINID with the BOXSTYLE= option. The default is the color specified with the CTEXT= option.

IDFONT=font*Traditional Graphics*

specifies the font for the text used to label outliers or indicate process variable values when you specify one of the keywords SCHEMATICID, SCHEMATICIDFAR, POINTSID, or POINTSJOINID with the BOXSTYLE= option. The default *font* is SIMPLEX.

IDHEIGHT=value*Traditional Graphics*

specifies the height for the text used to label outliers or indicate process variable values when you specify one of the keywords SCHEMATICID, SCHEMATICIDFAR, POINTSID, or POINTSJOINID with the BOXSTYLE= option. The default is the height specified with the HTEXT= option in the GOPTIONS statement.

IDSYMBOL=symbol*Traditional Graphics*

specifies the symbol marker used to identify outliers in schematic box-and-whisker plots produced with the BOXCHART statement when you use one of the following options: BOXSTYLE=SCHEMATIC, BOXSTYLE=SCHEMATICID, and BOXSTYLE=SCHEMATICIDFAR. The default *symbol* is SQUARE. The IDSYMBOL= option is available only in the BOXCHART statement.

INDEPENDENTZONES**INDEPZONES**

specifies that the widths of the zones requested with the ZONES option be computed independently above and below the center line of the chart, so that the width of each zone is one-third of the difference between the process mean and the control limit on its side of the

chart. By default, the width of all zones is one-third of the difference between the upper control limits and the process mean, with zones below the center line truncated if necessary. The INDEPENDENTZONES option has no effect when the control limits are symmetric.

INFILLTRANSPARENCY=*value*

specifies the control limit infill transparency when transparency is used in ODS Graphics output. The *value* be between 0 and 1, where 0 is completely opaque and 1 is completely transparent. The default control limit infill transparency is 0.75. *ODS Graphics*

INTERVAL=DAY | DTDAY | HOUR | MINUTE | MONTH | QTR | SECOND

specifies the natural time interval between consecutive subgroup positions when a time, date, or datetime format is associated with a numeric subgroup variable. By default, the INTERVAL= option uses the number of subgroup positions per panel that you specify with the NPANELPOS= option. The default time interval keywords for various time formats are shown in the following table.

Format	Default Keyword	Format	Default Keyword
DATE	DAY	MONYY	MONTH
DATETIME	DTDAY	TIME	SECOND
DDMMYY	DAY	TOD	SECOND
HHMM	HOUR	WEEKDATE	DAY
HOUR	HOUR	WORDDATE	DAY
MMDDYY	DAY	YYMMDD	DAY
MMSS	MINUTE	YYQ	QTR

You can use the INTERVAL= option to modify the effect of the NPANELPOS= option, which specifies the number of subgroup positions per panel (screen or page). The INTERVAL= option enables you to match the scale of the horizontal axis to the scale of the subgroup variable without having to associate a different format with the subgroup variable.

For example, suppose your formatted subgroup values span an overall time interval of 100 days and a DATETIME format is associated with the subgroup variable. Since the default interval for the DATETIME format is DTDAY and since NPANELPOS=50 by default, the chart is displayed with two panels (screens or pages).

Now, suppose your data span an overall time interval of 100 hours and a DATETIME format is associated with the subgroup variable. The chart for these data are created in a single panel, but the data occupy only a small fraction of the chart since the scale of the data (hours) does not match that of the horizontal axis (days). If you specify INTERVAL=HOUR, the horizontal axis is scaled for 50 hours, matching the scale of the data, and the chart is displayed with two panels.

INTSTART=*value*

specifies the starting value for a numeric horizontal axis, when a date, time, or datetime format is associated with the subgroup variable. If the value specified is greater than the first subgroup variable value, this option has no effect.

LABELANGLE=*angle*

Traditional Graphics
ODS Graphics

specifies the angle at which labels requested with the ALLLABEL=, ALLLABEL2=, OUTLABEL=, and OUTLABEL2= options are drawn. A positive angle rotates the labels counterclockwise; a negative angle rotates them clockwise. By default, labels are oriented horizontally.

LABELFONT=*font***TESTFONT=*font***

Traditional Graphics

specifies a software font for labels requested with the ALLLABEL=, ALLLABEL2=, OUTLABEL=, OUTLABEL2=, STARLABEL=, TESTLABEL=, and TESTLABEL n = options. Hardware characters are used by default.

LABELHEIGHT=*value***TESTHEIGHT=*value***

Traditional Graphics

specifies the height (in vertical percent screen units) for labels requested with the ALLLABEL=, ALLLABEL2=, OUTLABEL=, OUTLABEL2=, STARLABEL=, TESTLABEL=, and TESTLABEL n = options. The default height is the height specified with the HEIGHT= option or the HTEXT= option in the GOPTIONS statement.

LBOXES=*linetype***LBOXES=(*variable*)**

Traditional Graphics

specifies the line types for the outlines of the box-and-whisker plots created with the BOXCHART statement. You can use one of the following approaches:

- You can specify LBOXES=*linetype* to provide a single *linetype* for all of the box-and-whisker plots.
- You can specify LBOXES=(*variable*) to provide a distinct line type for *each* box-and-whisker plot. The *variable* must be a numeric variable in the input data set, and its values must be valid SAS/GRAPH *linetype* values (numbers ranging from 1 to 46). The line type for the plot displayed for a particular subgroup is the value of the *variable* in the observations corresponding to this subgroup. Note that if there are multiple observations per subgroup in the input data set, the values of the *variable* should be identical for all of the observations in a given subgroup.

The default value is 1, which produces solid lines. The LBOXES= option is available only in the BOXCHART statement.

LCLLABEL=*'label'*

specifies a label for the lower control limit in the primary chart. The label can be of length 16 or less. Enclose the label in quotes. The default label is of the form $LCL=$ *value* if the control limit has a fixed value; otherwise, the default label is *LCL*. Related options are LCLLABEL2=, UCLLABEL=, and UCLLABEL2=.

LCLLABEL2=*'label'*

specifies a label for the lower control limit in the secondary chart. The label can be of length 16 or less. Enclose the label in quotes. The default label is of the form $LCL=$ *value* if the control limit has a fixed value; otherwise, the default label is *LCL*. The LCLLABEL2= option is available in the IRCHART, MRCHART, XRCHART, and XSCHART statements. Related options are LCLLABEL=, UCLLABEL=, and UCLLABEL2=.

LENDGRID= n

specifies the line type for the grid requested with the ENDGRID option. The default is $n = 1$, *Traditional Graphics* which produces a solid line. If you use the LENDGRID= option, you do not need to specify the ENDGRID option.

LGRID= n

specifies the line type for the grid requested with the GRID option. The default is $n = 1$, *Traditional Graphics* which produces a solid line. If you use the LGRID= option, you do not need to specify the GRID option.

LHREF=*linetype***LH=*linetype***

specifies the line type for reference lines requested with the HREF= and HREF2= options. *Traditional Graphics* The default is 2, which produces a dashed line.

LIMITN= n **LIMITN=VARYING**

specifies either a fixed or varying nominal sample size for the control limits.

If you specify LIMITN= n , the control limits are computed for the fixed value n , and they do not vary with the subgroup sample sizes. Moreover, subgroup summary statistics are plotted *only* for those subgroups with a sample size equal to n . You can specify ALLN in conjunction with LIMITN= n to force all of the statistics to be plotted, regardless of subgroup sample size.

If you do not specify LIMITN= n and the subgroup sample sizes are constant, the default value of n is the constant subgroup sample size.

Depending on the chart statement, there are restrictions on the value of n that you can specify with the LIMITN= option. For the MRCHART, RCHART, and XRCHART statements, $2 \leq n \leq 25$. For the SCHART and XSCHART statements, $n \geq 2$. For the BOXCHART, MCHART, and XCHART statements, $n \geq 1$. If you omit the STDDEVIATIONS option for the MCHART or XCHART statements (or use the RANGES option with the BOXCHART statement) $n < 26$. For the CCHART and UCHART statements, $n > 0$, and n can assume fractional values (for all other chart statements, n must be a whole number). For the PCHART and NPCHART statements, $n \geq 1$.

For the IRCHART statement, n has a somewhat different interpretation; it specifies the number of consecutive measurements from which the moving ranges are to be computed, and $n \geq 2$. You can think of n as a *pseudo* nominal sample size for the control limits, since the data for an individual measurements and moving range chart are not subgrouped.

Note the difference between the LIMITN= option and the SUBGROUPN= option that is available in the CCHART, NPCHART, PCHART, and UCHART statements. The LIMITN= option specifies a nominal sample size for the *control limits*, whereas the SUBGROUPN= option provides the sample sizes for the *data*.

By default, LIMITN=2 in an IRCHART statement. You cannot specify LIMITN= VARYING in an IRCHART statement. For all other chart statements, LIMITN= VARYING is the default.

The following table identifies the chart features that vary when you use LIMITN= VARYING:

Chart Statement	Features Affected by LIMITN=VARYING
BOXCHART	control limits
CCHART	control limits, central line
MCHART	control limits
MRCHART	control limits on both charts, central line on <i>R</i> chart
NPCHART	control limits, central line
PCHART	control limits
RCHART	control limits, central line
SCHART	control limits, central line
UCHART	control limits
XCHART	control limits
XRCHART	control limits on both charts, central line on <i>R</i> chart
XSCHART	control limits on both charts, central line on <i>s</i> chart

NOTE: As an alternative to specifying the LIMITN= option, you can read the nominal control limit sample size from the variable `_LIMITN_` in a LIMITS= data set. See “Input Data Sets” in the section for the chart statement in which you are interested.

LIMLABSUBCHAR=*‘character’*

specifies a substitution character (such as #) for labels provided as quoted strings with the LCLLABEL=, LCLLABEL2=, UCLLABEL=, UCLLABEL2=, CSYMBOL=, NPSYMBOL=, PSYMBOL=, RSYMBOL=, SSYMBOL=, USYMBOL=, and XSYMBOL= options. The substitution character must appear in the label. When the label is displayed on the chart, the character is replaced with the value of the corresponding control limit or center line, provided that this value is constant across subgroups. Otherwise, the default label for a varying control limit or center line is displayed.

LLIMITS=*linetype*

Traditional Graphics specifies the line type for control limits. The default is 4, which produces a dashed line.

LOVERLAY=*(linetypes)*

Traditional Graphics specifies line types for the line segments connecting points on primary chart overlays. Line types in the LOVERLAY= list are matched with variables in the corresponding positions in the OVERLAY= list.

LOVERLAY2=*(linetypes)*

Traditional Graphics specifies line types for the line segments connecting points on secondary chart overlays. Line types in the LOVERLAY2= list are matched with variables in the corresponding positions in the OVERLAY2= list.

LSL=*value-list*

provides lower specification limits used to compute capability indices. If you provide more than one *value*, the number of *values* must match the number of *processes* listed in the chart statement. If you specify only one *value*, it is used for all the *processes*.

The SHEWHART procedure uses the specification limits to compute capability indices, and it saves the limits and indices in the OUTLIMITS= data set. For more information, see “[Capability Indices](#)” on page 1941 and “[Output Data Sets](#)” in the section for the chart statement in which you are interested. Also see the entry for the USL= option. The LSL= option is available in the BOXCHART, IRCHART, MCHART, MRCHART, RCHART, SCHART, XCHART, XRCHART, and XSCHART statements.

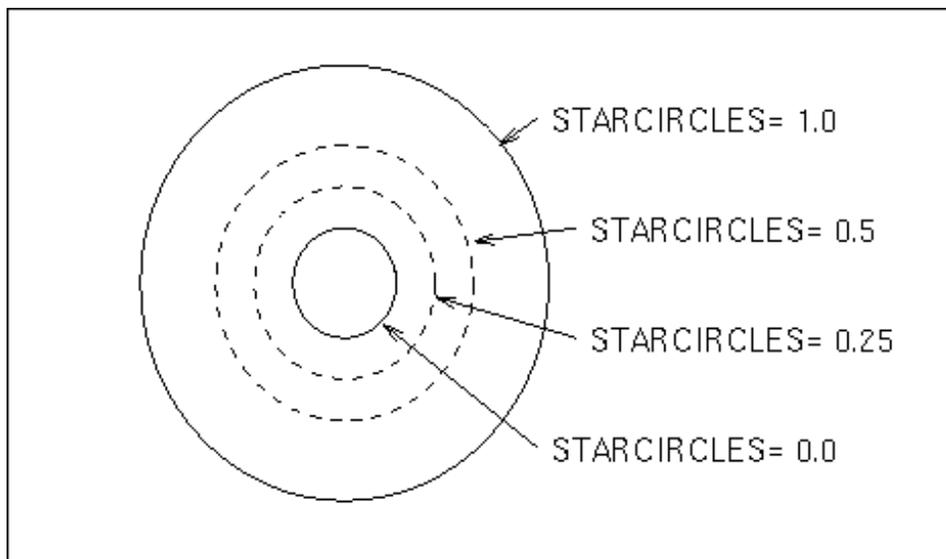

LSTARCIRCLES=*linetypes*

specifies one or more line types for the circles requested with the STARCIRCLES= option. *Traditional Graphics*
The number of line types should match the number of circles requested, and the line types are paired with the circles in the order specified. The default *linetype* is 1, which produces a solid line.

Figure 17.135 illustrates circles displayed by the following LSTARCIRCLES= and STARCIRCLES= options:

```
starcircles = 0.0 1.0 0.25 0.5
lstarcircles = 1 1 2 2
```

Figure 17.135 Line Types for Reference Circles

LSTARS=*linetype*

LSTARS=(*variable*)

specifies the line types for the outlines of stars requested with the STARVERTICES= option. *Traditional Graphics*
You can use one of the following approaches:

- You can specify LSTARS=*linetype* to provide a single line type for all of the stars.
- You can specify LSTARS=(*variable*) to provide a distinct line type for *each* star. The variable must be a numeric variable in the input data set, and its values must be valid SAS/GRAPH line types. The line type for the star positioned at a particular subgroup is the value of the *variable* in the observations corresponding to this subgroup. Note that

if there are multiple observations per subgroup in the input data set, the *variable* values should be identical for all of the observations in a given subgroup.

See “[Displaying Auxiliary Data with Stars](#)” on page 2114. The default *linetype* is 1, which produces a solid line.

LTESTS=linetype

LTEST=linetype

Traditional Graphics specifies the line type for the line segments that connect patterns of points for which a test for special causes (requested with the TESTS= option) is positive. The default is 1, which produces a solid line.

LTMARGIN=value

LTM=value

Traditional Graphics specifies the width of the left marginal area for the plot requested with the LTMPLOT= option.
ODS Graphics For traditional graphics, the width is specified in horizontal percent screen units. For ODS Graphics output, the width is specified in pixels. The LTMARGIN= option is available only in the IRCHART statement.

LTMPLOT=keyword

Traditional Graphics requests a univariate plot of the control chart statistics that is positioned in the left margin of the control chart. The keywords that you can specify and the associated plots are listed in the following table:
ODS Graphics

Keyword	Marginal Plot
HISTOGRAM	histogram
DIGIDOT	digidot plot
SKELETAL	skeletal box-and-whisker plot
SCHEMATIC	schematic box-and-whisker plot
SCHEMATICID	schematic box-and-whisker plot with outliers labeled
SCHEMATICIDFAR	schematic box-and-whisker plot with far outliers labeled

The LTMPLOT= option is available only in the IRCHART statement; see [Example 17.13](#) for an example. Refer to Hunter (1988) for a description of digidot plots, and see the entry for the BOXSTYLE= option for a description of the various box-and-whisker plots. Related options are LTMARGIN=, RTMARGIN=, and RTMPLOT=.

LVREF=linetype

LV=linetype

Traditional Graphics specifies the line type for reference lines requested by the VREF= and VREF2= options. The default is 2, which produces a dashed line.

LZONES=n

Traditional Graphics specifies the line type for lines that delineate zones A, B, and C for standard tests requested with the TESTS= and/or TESTS2= options. The default is $n = 2$, which produces a dashed line.

MARKERS

plots subgroup points with markers. By default, subgroup points are plotted with markers only by the BOXCHART statement. On other types of charts, subgroup points are connected by line segments and are not plotted with markers by default. *ODS Graphics*

MAXPANELS=*n*

specifies the maximum number of pages or screens for a chart. By default, $n = 20$.

MEDCENTRAL=AVGMEAN | AVGMED | MEDMED

identifies a method for estimating the process mean μ , which is represented by the central line on a median chart. The methods corresponding to each keyword are given in the following table:

Keyword	Method for Estimating Process Mean
AVGMEAN	average of subgroup means
AVGMED	average of subgroup medians
MEDMED	median of subgroup medians

The default keyword is AVGMED. The MEDCENTRAL= option is available only in the MCHART and MRCHART statements and in the BOXCHART statement with the CONTROLSTAT=MEDIAN option.

MISSBREAK

determines how subgroups are formed when observations are read from a DATA= data set and a character *subgroup-variable* is provided. When you specify the MISSBREAK option, observations with missing values of the *subgroup variable* are not processed. Furthermore, the next observation with a nonmissing value of the *subgroup-variable* is treated as the beginning observation of a new subgroup even if this value is identical to the most recent nonmissing subgroup value. In other words, by specifying the option MISSBREAK and by inserting an observation with a missing *subgroup-variable* value into a group of consecutive observations with the same *subgroup-variable* value, you can split the group into two distinct subgroups of observations.

By default, if MISSBREAK is not specified, observations with missing values of the *subgroup variable* are not processed, and all remaining observations with the same consecutive value of the *subgroup-variable* are treated as a single subgroup.

MRRESTART**MRRESTART=*value***

causes the moving range computation on the IRCHART to be restarted when a missing value is encountered. Without the MRRESTART option, a missing value is simply skipped, and the moving range for the next non-missing subgroup is computed using the most recent previous non-missing value. MRRESTART restarts the moving range computation, so only the observations after the missing value are used in subsequent moving range computations. MRRESTART restarts the moving range computation on any missing value; you can also specify MRRESTART=*value* to restart only on a particular missing value. For example, MRRESTART=R will restart the computation only when the missing value “.R” is encountered.

MU0=*value*

specifies a known (standard) value μ_0 for the process mean μ . By default, μ is estimated from the data. The MU0= option is available in the BOXCHART, IRCHART, MCHART, MRCHART, XCHART, XRCHART, and XSCHART statements.

NOTE: As an alternative to specifying MU0= μ_0 , you can read a predetermined value for μ_0 from the variable `_MEAN_` in a LIMITS= data set. See “Input Data Sets” in the section for the chart statement in which you are interested.

NAME=*'string'**Traditional Graphics*

specifies the name of the GRSEG catalog entry for the primary chart, and the name of the graphics output file if one is created. The name can be up to 256 characters long, but the GRSEG name is truncated to eight characters. The default name is 'SHEWHART'. A related option is DESCRIPTION=.

NAME2=*'string'**Traditional Graphics*

specifies the name of the GRSEG catalog entry for the secondary chart, and the name of the graphics output file if one is created. The name can be up to 256 characters long, but the GRSEG name is truncated to eight characters. The default name is 'SHEWHART'. The NAME2= option is available in the IRCHART, MRCHART, XRCHART, and XSCHART statements, and it is used in conjunction with the SEPARATE option. A related option is DESCRIPTION2=.

NDECIMAL=*n*

specifies the number of decimal digits in the default labels for the control limits and the central line in the primary chart. The default is one more than the maximum number of decimal digits in the vertical axis tick mark labels. For example, if the vertical axis tick mark label with the largest number of digits after the decimal point is 110.05, the default is $n = 3$.

NDECIMAL2=*n*

specifies the number of decimal digits in the default labels for the control limits and central line in a secondary chart. The default is one more than the maximum number of decimal digits in the vertical axis tick mark labels. The NDECIMAL2= option is available in the IRCHART, MRCHART, XRCHART, and XSCHART statements.

NEEDLES

connects plotted points to the central line with vertical line segments (needles). See [Example 17.19](#) for an example. By default, adjacent points are connected to one another. The NEEDLES option is available in all chart statements except the BOXCHART statement.

NMARKERS

identifies a plotted subgroup summary statistic with a special symbol marker (character) when the corresponding subgroup sample size is not equal to the nominal control limit sample size n . Specify the nominal control limit sample size n with the LIMITN= option or with the variable `_LIMITN_` read from a LIMITS= data set. The following table summarizes the identification:

Sample Size	Graphics Symbol	Line Printer Character
$< n$	▽	L
$> n$	△	G

A legend that explains the symbols is displayed at the bottom of the chart. This legend can be suppressed with the NOLEGEND option.

The NMARKERS option is not available in the IRCHART statement. The NMARKERS option applies only when specified in conjunction with the ALLN option and a fixed nominal control limit sample size provided with the LIMITN= option or the variable _LIMITN_. See [Example 17.40](#) for an illustration.

NO3SIGMACHECK

suppresses the check for 3σ limits when tests for special causes are requested. This enables tests for special causes to be applied when the SIGMAS= option is used to specify control limits other than the default 3σ limits. This option should not be used for standard control chart applications, since the standard tests for special causes assume 3σ limits.

NOBLOCKREF

NOPHASEREF

NOREF

suppresses block and phase reference lines from ODS Graphics output. By default, block and phase reference lines are drawn when ODS Graphics is in effect.

NOBLOCKREFFILL

NOPHASEREFFILL

NOREFFILL

suppresses the block and phase wall fills from ODS Graphics output. By default, block and phase walls are filled when ODS Graphics is in effect.

NOBOXFILLLEGEND

NOFILLLEGEND

NOSTARFILLLEGEND

suppresses the legend for the levels of a BOXFILL= or STARFILL= variable in ODS Graphics output.

NOBYREF

specifies that the reference line information in an HREF=, HREF2=, VREF=, or VREF2= data set is to be applied uniformly to charts created for all the BY groups in the input data set (DATA=, HISTORY=, or TABLE=). If you specify the NOBYREF option, you do not need to provide BY variables in the reference line data set. By default, you must provide BY variables.

NOCHART

suppresses the creation of the chart. You typically specify the NOCHART option when you are using the procedure to compute control limits and save them in an output data set. You can also use the NOCHART option when you are tabulating results with the TABLE and related options.

In the IRCHART, MRCHART, XRCHART, and XSCHART statements, the NOCHART option suppresses the creation of both the primary and secondary charts. If you are producing traditional graphics and specify the NOCHART option, the chart is not saved in a graphics catalog. To save the chart in a graphics catalog while suppressing the display of the chart, specify the NODISPLAY option in a GOPTIONS statement.

NOCHART2

suppresses the creation of a secondary chart. You typically use this option in the IRCHART statement to create a chart for individual measurements and suppress the accompanying chart for moving ranges. The NOCHART2 option is available in the IRCHART, MRCHART, XRCHART, and XSCHART statements.

NOCONNECT

suppresses line segments that connect points on the chart. By default, points are connected except in box charts produced with the BOXCHART statement (see the BOXCONNECT option).

NOCTL

suppresses the display of the central line in a primary chart.

NOCTL2

suppresses the display of the central line in a secondary chart. The NOCTL2 option is available in the IRCHART, MRCHART, XRCHART, and XSCHART statements.

NOFRAME

suppresses the default frame drawn around the chart.

*Traditional Graphics
Line Printer*

NOHLABEL

suppresses the label for the horizontal (subgroup) axis. Use the NOHLABEL option when the meaning of the axis is evident from the tick mark labels, such as when a date format is associated with the subgroup variable.

NOLCL

suppresses the display of the lower control limit in a primary chart.

NOLCL2

suppresses the drawing of the lower control limit in a secondary chart. The NOLCL2 option is available in the IRCHART, MRCHART, XRCHART, and XSCHART statements.

NOLEGEND

suppresses the default legend for subgroup sample sizes, which appears by default below the chart. This option also suppresses the legend displayed by the NMARKERS option. Use the NOLEGEND option when the subgroup sample sizes are constant and equal to the control limit sample size, since the control limit sample size is displayed in the upper right corner of the chart.

NOLIMIT0

suppresses the display of a fixed lower control limit if and only if the value of the limit is zero. This option is useful in situations where a lower limit of zero is considered to be uninformative or visually distracting (for instance, on certain p charts or R charts). The NOLIMIT0 option is available with all chart statements except BOXCHART, MCHART, and XCHART. For the IRCHART, MRCHART, XRCHART, and XSCHART statements, the NOLIMIT0 option applies only to the secondary chart.

NOLIMIT1

suppresses the display of a fixed upper control limit on a p chart if and only if the value of the control limit is 1 (or 100%), or on an np chart if and only if the value of the control limit is n . The NOLIMIT1 option is available only in the NPCHART and PCHART statements.

NOLIMITLABEL

suppresses the default labels for the control limits and central lines.

NOLIMITS

suppresses the display of control limits. This option is particularly useful if you are using the BOXCHART statement to create side by side box-and-whisker plots; in this case, you should also use one of the BOXSTYLE= options.

NOLIMITSFRAME

suppresses the default frame for the control limit information that is displayed across the top of the chart when multiple sets of control limits with distinct multiples of σ and nominal control limit sample sizes are read from a LIMITS= data set. *Traditional Graphics
Line Printer*

NOLIMITSLEGEND

suppresses the legend for the control limits (for example, 3σ Limits For $n=5$), which appears by default in the upper right corner of the chart.

NOOVERLAYLEGEND

suppresses the legend for overlay variables which is displayed by default when the OVERLAY= or OVERLAY2= option is specified. *Traditional Graphics
ODS Graphics*

NOPHASEFRAME

suppresses the default frame for the legend requested by the PHASELEGEND option. *Traditional Graphics
Line Printer*

NOREADLIMITS

specifies that the control limits for each *process* listed in the chart statement are *not* to be read from the LIMITS= data set specified in the PROC SHEWHART statement. There are two basic methods of displaying control limits: calculating control limits from the data and reading control limits from a LIMITS= data set. If you want control limits calculated from the data, you can do one of the following:

1. Do not specify a LIMITS= data set.
2. If you specify a LIMITS= data set, also specify the NOREADLIMITS option.

Otherwise, if you specify a LIMITS= data set in the PROC SHEWHART statement, the procedure reads control limits from that data set.⁴²

The following example illustrates the NOREADLIMITS option:

⁴²This is true for SAS 6.10 and later releases of SAS/QC software. For SAS 6.09 and earlier releases, the procedure calculates control limits from the data unless you specify a LIMITS= data set in the procedure statement **and** you specify either the READLIMITS option or the READINDEXES= option in the chart statement. The NOREADLIMITS option is not available for SAS 6.09 and earlier releases. For more information, see the entry for the READLIMITS option.

```
proc shewhart data=Pistons limits=Diamlim;
  xrchart Diameter*Hour;
  xrchart Diameter*Hour / noreadlimits;
run;
```

The first XRCHART statement reads the control limits from the first observation in the data set DIAMLIM for which the variable `_VAR_` is equal to 'Diameter' and the variable `_SUBGRP_` is equal to 'Hour'. The second XRCHART statement computes the control limits from the measurements in the data set Pistons. Note that the second XRCHART statement is equivalent to the following statements, which are more commonly used:

```
proc shewhart data=Pistons;
  xrchart Diameter*Hour;
run;
```

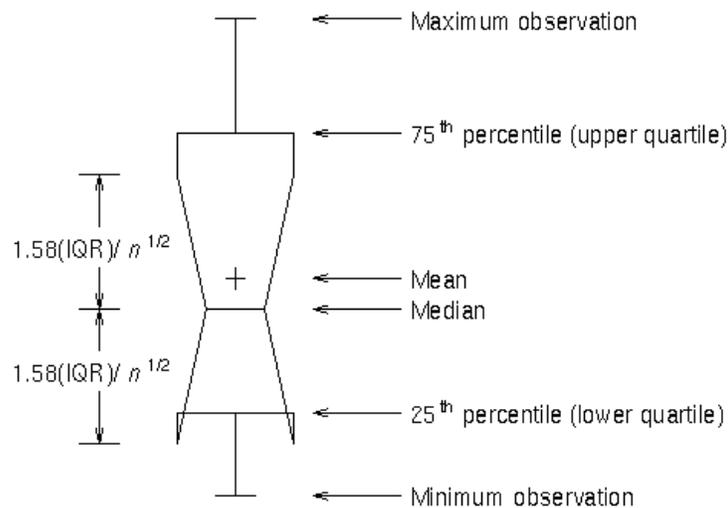

For more information about reading control limits from a LIMITS= data set, see the entry for the READLIMITS option and “[Displaying Multiple Sets of Control Limits](#)” on page 2105.

NOTCHES

Traditional Graphics
ODS Graphics

specifies that box-and-whisker plots created by the BOXCHART statement are to be notched. The endpoints of the notches are located at the median plus and minus $1.58(IQR/\sqrt{n})$, where IQR is the interquartile range and n is the subgroup sample size. The medians (central lines) of two box-and-whisker plots are significantly different at approximately the 0.05 level if the corresponding notches do not overlap. Refer to McGill, Tukey, and Larsen (1978). [Figure 17.136](#) illustrates the NOTCHES option. Notice the folding effect at the bottom, which happens when the endpoint of a notch is beyond its corresponding quartile. This situation occurs typically only when the subgroup sample size is small.

Figure 17.136 NOTCHES Option for Box-and-Whisker Plots

The NOTCHES option is also illustrated in [Output 17.3.1](#) and is available only in the BOXCHART statement.

NOTESTACROSS

specifies that tests for special causes requested with the TESTS= or TESTS2= options not be applied across the boundaries of phases (blocks of consecutive subgroups) determined by the READPHASES= option and the variable `_PHASE_` in the input data set. With constant control limits, if you specify the READPHASES= option but do not specify the NOTESTACROSS option, tests for special causes are applied without regard to phase boundaries. With varying control limits, tests are applied only within phases by default, and you can use the TESTACROSS option to specify that they be applied across phase boundaries. See “[Tests for Special Causes: SHEWHART Procedure](#)” on page 2146.

NOTICKREP

applies to character-valued *subgroup-variables* and specifies that only the first occurrence of repeated, adjacent subgroup values is to be labeled on the horizontal axis.

NOTRANSPARENCY

disables transparency in ODS Graphics output, so that all graph features are opaque. By *ODS Graphics* default, transparency is enabled when ODS Graphics is in effect.

NOTRENDCONNECT

suppresses line segments that connect points on a trend chart. Points are connected by default. The NOTRENDCONNECT option is available only in the BOXCHART, MCHART, and XCHART statements when the TRENDVAR= option is used.

NOTRUNC

overrides the vertical axis truncation at zero, which is applied by default to *c* charts, moving range charts, *np* charts, *p* charts, *R* charts, *s* charts, and *u* charts. This option is useful if you are creating a customized version of one of these charts and want to replace the plotted statistics and control limits with values read from a TABLE= input data set that can be positive or negative. Do not use the NOTRUNC option in standard control chart applications. This option is not available in the BOXCHART, MCHART, and XCHART statements.

NOUCL

suppresses the display of the upper control limit in a primary chart.

NOUCL2

suppresses the display of the upper control limit in a secondary chart. The NOUCL2 option is available in the IRCHART, MRCHART, XRCHART, and XSCHART statements.

NOVANGLE

requests vertical axis labels that are strung out vertically. By default, the labels are drawn at *Traditional Graphics* an angle of 90 degrees if a software font is used.

NPANELPOS=*n*

NPANEL=*n*

specifies the number of subgroup positions per panel on each chart. A *panel* is defined as a screen or page (or a half-screen or half-page if you are also using the BILEVEL option). You typically specify the NPANELPOS= option to display more points on a panel than the default

number, which is $n = 50$ for all chart statements except the BOXCHART statement, for which the default is $n = 20$.

You can specify a positive or negative number for n . The absolute value of n must be at least 5. If n is positive, the number of positions is adjusted so that it is approximately equal to n and so that all panels display approximately the same number of subgroup positions. If n is negative, no balancing is done, and each panel (except possibly the last) displays approximately $|n|$ positions. In this case, the approximation is due only to axis scaling.

You can use the INTERVAL= option to change the effect of the NPANELPOS= option when a date or time format is associated with the *subgroup-variable*. The INTERVAL= option enables you to match the scale of the horizontal axis to the scale of the subgroup variable without having to associate a different format with the subgroup variable.

NPSYMBOL='label'

NPSYMBOL=NP | NPBAR | NPPM | NPPM2 | NP0

specifies a label for the central line in an np chart. You can use the option in the following ways:

- You can specify a quoted *label* up to 16 characters in length.
- You can specify one of the keywords listed in the following table. Each keyword requests a label of the form *symbol=value*, where *symbol* is one of the symbols given in the table, and *value* is the value of the central line. If the central line is not constant, only the symbol is displayed.

Keyword	Symbol Used in	
	Graphics	Line Printer Charts
NP	NP	NP
NPBAR	\overline{NP}	\overline{NP}
NPPM	NP'	NP'
NPPM2	NP''	NP''
NP0	NP ₀	NP0

The default keyword is NPBAR. The NPSYMBOL= option is available only in the NPCHART statement.

ODSFOOTNOTE=FOOTNOTE | FOOTNOTE1 | 'string'

ODS Graphics

adds a footnote to ODS Graphics output. If you specify the FOOTNOTE (or FOOTNOTE1) keyword, the value of SAS FOOTNOTE statement is used as the graph footnote. If you specify a quoted string, that is used as the footnote. The quoted string can contain any of the following escaped characters, which are replaced with the appropriate values from the analysis:

\n	process variable name
\l	process variable label (or name if the process variable has no label)
\x	subgroup variable name
\s	subgroup variable label (or name if the subgroup variable has no label)

ODSFOOTNOTE2=FOOTNOTE2 | *'string'*

adds a secondary footnote to ODS Graphics output. If you specify the FOOTNOTE2 keyword, the value of SAS FOOTNOTE2 statement is used as the secondary graph footnote. If you specify a quoted string, that is used as the secondary footnote. The quoted string can contain any of the following escaped characters, which are replaced with the appropriate values from the analysis: *ODS Graphics*

\n	process variable name
\l	process variable label (or name if the process variable has no label)
\x	subgroup variable name
\s	subgroup variable label (or name if the subgroup variable has no label)

ODSLEGENDEXPAND

specifies that legend entries contain all levels observed in the data. By default, a legend shows only the levels used on the current page. *ODS Graphics*

ODSTITLE=TITLE | **TITLE1** | **NONE** | **DEFAULT** | **LABELFMT** | *'string'*

specifies a title for ODS Graphics output. *ODS Graphics*

TITLE (or TITLE1)	uses the value of SAS TITLE statement as the graph title.
NONE	suppresses all titles from the graph.
DEFAULT	uses the default ODS Graphics title (a descriptive title consisting of the plot type and the process variable name.)
LABELFMT	uses the default ODS Graphics title with the variable label instead of the variable name.

If you specify a quoted string, that is used as the graph title. The quoted string can contain any of the following escaped characters, which are replaced with the appropriate values from the analysis:

\n	process variable name
\l	process variable label (or name if the process variable has no label)
\x	subgroup variable name
\s	subgroup variable label (or name if the subgroup variable has no label)

ODSTITLE2=TITLE2 | *'string'*

specifies a secondary title for ODS Graphics output. If you specify the TITLE2 keyword, the value of SAS TITLE2 statement is used as the secondary graph title. If you specify a quoted string, that is used as the secondary title. The quoted string can contain any of the following escaped characters, which are replaced with the appropriate values from the analysis: *ODS Graphics*

\n	process variable name
\l	process variable label (or name if the process variable has no label)
\x	subgroup variable name
\s	subgroup variable label (or name if the subgroup variable has no label)

OUTBOX=SAS-data-set

creates an output data set that contains subgroup summary statistics, control limits, and outlier values for a box chart. An OUTBOX= data set is the only type of summary data set produced by the SHEWHART procedure from which you can reconstruct a schematic box chart. The OUTBOX= option is available only in the BOXCHART statement. See “OUTBOX= Data Set” on page 1456 for details.

OUTFILL**COUTFILL**

Traditional Graphics
ODS Graphics

fills the areas outside the control limits that lie between the connected points and the control limits and are bounded by connecting lines. The areas are filled with an appropriate contrasting color from the ODS style. This option is useful for highlighting out-of-control points.

OUTFILLTRANSPARENCY=value

ODS Graphics

specifies the control limit outfill transparency when transparency is used in ODS Graphics output. The *value* must be between 0 and 1, where 0 is completely opaque and 1 is completely transparent. The default control limit outfill transparency is 0.75.

OUTHIGHTHTML=variable

Traditional Graphics

specifies a variable whose values create links to be associated with outlier points above the upper fence on a schematic box chart when traditional graphics output is directed into HTML.

OUTHIGHURL=variable

ODS Graphics

specifies a variable whose values are URLs to be associated with outlier points above the upper fence on a schematic box chart when ODS Graphics output is directed into HTML.

OUTHISTORY=SAS-data-set

creates an output data set that contains the subgroup summary statistics. You can use an OUTHISTORY= data set as a HISTORY= input data set in a subsequent run of the procedure. You cannot request an OUTHISTORY= data set if the input data set is a TABLE= data set. See “Output Data Sets” in the section for the chart statement in which you are interested. A related option is OUTPHASE=.

OUTINDEX='label'

specifies the value of the `_INDEX_` variable in the OUTLIMITS= output data set. This is a bookkeeping variable that provides information identifying the control limits saved in the data set. See “Output Data Sets” in the section for the chart statement in which you are interested.

The *label* can be up to 128 characters and should be enclosed in quotes. You should use a label that uniquely identifies the control limits. For example, you might specify OUTINDEX='April 1-15' to indicate that the limits were computed from data collected during the first half of April.

The OUTINDEX= option is intended to be used in conjunction with the OUTLIMITS= option. The `_INDEX_` variable is created only if you specify the OUTINDEX= option. If you specify the OUTINDEX= option and do not specify the name of the OUTLIMITS= data set with the OUTLIMITS= option, the procedure creates an OUTLIMITS= data set whose name is of the form WORK.DATAN.

NOTE: You cannot use the OUTINDEX= and READINDEXES= options in the same chart statement.

OUTLABEL=VALUE**OUTLABEL=(*variable*)**

labels each point that falls outside the control limits on the primary chart with the VALUE plotted for that subgroup or with the value of a *variable* in the input data set.

The *variable* provided in the input data set can be numeric or character. If the *variable* is a character variable, it can be up to 16 characters. For each subgroup of observations whose summary statistic falls outside the control limits, the formatted value of the *variable* in the observations is used to label the point representing the subgroup. If you are reading a DATA= data set with multiple observations per subgroup, the values of the *variable* should be identical for observations within a subgroup. By default, points are not labeled. The OUTLABEL= option takes precedence over the TESTLABEL= option when TESTS=1 is specified. You cannot specify both the OUTLABEL= and ALLLABEL= options.

OUTLABEL2=VALUE**OUTLABEL2=(*variable*)**

labels each point that falls outside the control limits on an *R* or *s* chart with the VALUE plotted for that subgroup or with the value of a *variable* in the input data set.

The *variable* provided in the input data set can be numeric or character. If the *variable* is a character variable, its length cannot exceed 16. For each subgroup of observations whose summary statistic falls outside the control limits, the formatted value of the *variable* in the observations is used to label the point representing the subgroup. If you are reading a DATA= data set with multiple observations per subgroup, the values of the *variable* should be identical for observations within a subgroup. By default, points are not labeled. The OUTLABEL2= option takes precedence over the TESTLABEL2= option when TESTS2=1 is specified. You cannot specify both the OUTLABEL2= and ALLLABEL2= options. The OUTLABEL2= option is available only in the IRCHART, MRCHART, RCHART, SCHART, XRCHART, and XSCHART statements.

OUTLIMITS=SAS-data-set

creates an output data set that saves the control limits. You can use an OUTLIMITS= data set as an input LIMITS= data set in a subsequent run of the procedure. See “Output Data Sets” in the section for the chart statement in which you are interested. A related option is OUTINDEX=.

OUTLOWHTML=*variable*

specifies a variable whose values create links to be associated with outlier points below the lower fence on a schematic box chart when traditional graphics output is directed into HTML. *Traditional Graphics*

OUTLOWURL=*variable*

specifies a variable whose values are URLs to be associated with outlier points below the lower fence on a schematic box chart when ODS Graphics output is directed into HTML. *ODS Graphics*

OUTPHASE='label'

specifies the value of the `_PHASE_` variable in the OUTHISTORY= data set. This is a book-keeping variable that provides information identifying the summary statistics saved in the data set. See “Output Data Sets” in the section for the chart statement in which you are interested.

You should use the OUTPHASE= option if you create OUTHISTORY= data sets at different stages (phases) for the same *processes* and concatenate the data sets to build a master histori-

cal data set. The `_PHASE_` variable then identifies the block of observations that corresponds to each phase.

The *label* can be up to 128 characters and should be enclosed in quotes. You should use a *label* that uniquely identifies the saved data. For example, you might specify `OUTPHASE='April 1-15'` to indicate that the data were collected during the first half of April.

The `_PHASE_` variable is created only if you specify the `OUTPHASE=` option. If you specify the `OUTPHASE=` option and do not specify the name of the `OUTHISTORY=` data set with the `OUTHISTORY=` option, the procedure creates an `OUTHISTORY=` data set whose name is of the form `WORK.DATAn`.

OUTTABLE=SAS-data-set

creates an output SAS data set that saves the information plotted on the chart, including the subgroup variable values and their corresponding summary statistics and control limits.

You can use the `OUTTABLE=` data set to create a customized report with the reporting procedures and methods described in *Base SAS Procedures Guide*. You can also use an `OUTTABLE=` data set as a `TABLE=` input data set in a subsequent run of the procedure. See “Output Data Sets” in the section for the chart statement in which you are interested.

OVERLAY=(variable-list)

Traditional Graphics
ODS Graphics

specifies variables to be overlaid on the primary control chart. A point is plotted for each overlay variable at each subgroup for which it has a non-missing value. The value of a particular overlay variable should be the same for each observation in the input data set with a given value of the subgroup variable. If values differ within a subgroup, the first value appearing in that subgroup is used. The `OVERLAY=` option cannot be specified with the `STARVERTICES=` option.

OVERLAY2=(variable-list)

Traditional Graphics
ODS Graphics

specifies variables to be overlaid on a secondary control chart. A point is plotted for each overlay variable at each subgroup for which it has a non-missing value. The value of a particular overlay variable should be the same for each observation in the input data set with a given value of the subgroup variable. If values differ within a subgroup, the first value appearing in that subgroup is used. The `OVERLAY2=` option cannot be specified with the `STARVERTICES=` option.

OVERLAY2HTML=(variable-list)

Traditional Graphics

specifies variables whose values create links to be associated with points on secondary chart overlays. These links are associated with points on an overlay plot when traditional graphics output is directed into HTML. Variables in the `OVERLAY2HTML=` list are matched with variables in the corresponding positions in the `OVERLAY2=` list. The value of the `OVERLAY2HTML=` variable should be the same for each observation with a given value of the subgroup variable.

OVERLAY2ID=(variable-list)

Traditional Graphics
ODS Graphics

specifies variables whose formatted values are used to label points on secondary chart overlays. Variables in the `OVERLAY2ID=` list are matched with variables in the corresponding positions in the `OVERLAY2=` list. The value of the `OVERLAY2ID=` variable should be the same for each observation with a given value of the subgroup variable.

OVERLAY2SYM=(symbol-list)

specifies symbols used to plot overlays on a secondary control chart. Symbols in the OVERLAY2SYM= list are matched with variables in the corresponding positions in the OVERLAY2= list. *Traditional Graphics*

OVERLAY2SYMHT=(value-list)

specifies the heights of symbols used to plot overlays on a secondary control chart. Heights in the OVERLAY2SYMHT= list are matched with variables in the corresponding positions in the OVERLAY2= list. *Traditional Graphics*

OVERLAY2URL=(variable-list)

specifies variables whose values are URLs to be associated with points on secondary chart overlays. These URLs are associated with points on an overlay plot when ODS Graphics output is directed into HTML. Variables in the OVERLAY2URL= list are matched with variables in the corresponding positions in the OVERLAY2= list. The value of the OVERLAY2URL= variable should be the same for each observation with a given value of the subgroup variable. *ODS Graphics*

OVERLAYCLIPSYM=symbol

specifies the symbol used to plot clipped values on overlay plots when the CLIPFACTOR= option is used. *Traditional Graphics*

OVERLAYCLIPSYMHT=value

specifies the height for the symbol used to plot clipped values on overlay plots when the CLIPFACTOR= option is used. *Traditional Graphics*

OVERLAYHTML=(variable-list)

specifies variables whose values create links to be associated with points on primary chart overlays. These links are associated with points on an overlay plot when traditional graphics output is directed into HTML. Variables in the OVERLAYHTML= list are matched with variables in the corresponding positions in the OVERLAY= list. The value of the OVERLAYHTML= variable should be the same for each observation with a given value of the subgroup variable. *Traditional Graphics*

OVERLAYID=(variable-list)

specifies variables whose formatted values are used to label points on primary chart overlays. Variables in the OVERLAYID= list are matched with variables in the corresponding positions in the OVERLAY= list. The value of the OVERLAYID= variable should be the same for each observation with a given value of the subgroup variable. *Traditional Graphics*
ODS Graphics

OVERLAYLEGLAB='label'

specifies the label displayed to the left of the legend for overlays requested with the OVERLAY= or OVERLAY2= option. The label can be up to 16 characters and must be enclosed in quotes. *Traditional Graphics*
ODS Graphics

OVERLAYSYM=(symbol-list)

specifies symbols used to plot overlays on the primary control chart. Symbols in the OVERLAYSYM= list are matched with variables in the corresponding positions in the OVERLAY= list. *Traditional Graphics*

OVERLAYSYMHT=(value-list)*Traditional Graphics*

specifies the heights of symbols used to plot overlays on the primary control chart. Heights in the OVERLAYSYMHT= list are matched with variables in the corresponding positions in the OVERLAY= list.

OVERLAYURL=(variable-list)*ODS Graphics*

specifies variables whose values are URLs to be associated with points on primary chart overlays. These URLs are associated with points on an overlay plot when ODS Graphics output is directed into HTML. Variables in the OVERLAYURL= list are matched with variables in the corresponding positions in the OVERLAY= list. The value of the OVERLAYURL= variable should be the same for each observation with a given value of the subgroup variable.

P0=value

specifies a known (standard) value p_0 for the proportion of nonconforming items produced by the process. By default, p_0 is estimated from the data. The P0= option is available only in the NPCHART and PCHART statements.

NOTE: As an alternative to specifying $P0=p_0$, you can read a predetermined value for p_0 from the variable `_P_` in a LIMITS= data set. See “Input Data Sets” in the section for the chart statement in which you are interested.

PAGENUM='string'*Traditional Graphics*

specifies the form of the label used for pagination.

ODS Graphics

The *string* must be no longer than 16 characters, and it must include one or two occurrences of the substitution character #. The first # is replaced with the page number, and the optional second # is replaced with the total number of pages.

The PAGENUM= option is useful when you are working with a large number of subgroups, resulting in multiple pages of output. For example, suppose that each of the following XRCHART statements produces multiple pages:

```
proc shewhart data=Pistons;
  xrchart Diameter*Hour / pagenum='Page #';
  xrchart Diameter*Hour / pagenum='Page # of #';
  xrchart Diameter*Hour / pagenum='#/#';
run;
```

The third page produced by the first statement would be labeled *Page 3*. The third page produced by the second statement would be labeled *Page 3 of 5*. The third page produced by the third statement would be labeled *3/5*.

By default, no page number is displayed.

PAGENUMPOS=TL | TR | BL | BR | TL100 | TR100 | BL0 | BR0*Traditional Graphics**ODS Graphics*

specifies where to position the page number requested with the PAGENUM= option. The keywords TL, TR, BL, and BR correspond to the positions top left, top right, bottom left, and bottom right, respectively. You can use the TL100 and TR100 keywords to ensure that the page number appears at the very top of a page when a title is displayed. The BL0 and BR0 keywords ensure that the page number appears at the very bottom of a page when footnotes are displayed. The default keyword is BR.

PCTLDEF=*index*

specifies one of five definitions used to calculate percentiles in the construction of box-and-whisker plots requested with the BOXCHART statement. The *index* can be 1, 2, 3, 4, or 5. The five corresponding percentile definitions are discussed in “[Percentile Definitions](#)” on page 1469. The default *index* is 5. The PCTLDEF= option is available only in the BOXCHART statement.

PHASEBOXLABELS

draws phase labels as titles along the top of phase boxes.

ODS Graphics

PHASEBREAK

specifies that the last point in a phase (defined as a block of consecutive subgroups with the same value of the `_PHASE_` variable) is not to be connected to the first point in the next phase. By default, the points are connected.

PHASELABTYPE=SCALED | TRUNCATED**PHASELABTYPE=*height***

specifies how lengthy `_PHASE_` variable values are to be displayed when there is insufficient space in the legend requested with the PHASELEGEND option. By default, lengthy values are not displayed. *Traditional Graphics*
ODS Graphics

If you specify PHASELABTYPE=SCALED, the values are uniformly reduced in height so that they fit. If you specify PHASELABTYPE=TRUNCATED, lengthy values are truncated on the right until they fit. When producing traditional graphics, you can also specify a text *height* in vertical percent screen units for the values. Related options are PHASELEGEND and PHASEREF.

PHASELEGEND**PHASELEG**

identifies the phases requested with the READPHASES= option in a legend across the top of the chart. Related options are PHASELABTYPE= and PHASEREF.

PHASELIMITS

specifies that the control limits and center line are to be labeled for each phase specified with the READPHASES= option, providing the limits are constant within that phase.

PHASEMEANSYMBOL=*symbol***PHASEMEAN**

specifies a symbol marker for the average of the values plotted within a phase. Specify PHASEMEAN without an argument to plot the phase average in ODS Graphics output. This option is available only in the BOXCHART statement. *Traditional Graphics*
ODS Graphics

PHASEPOS=*n*

specifies the vertical position of the phase legend. Values of *n* and the corresponding positions are as follows. By default, PHASEPOS=1. *ODS Graphics*

***n* Legend Position**

- 1 Top of chart, offset from axis frame
 - 2 Top of chart, immediately above axis frame
 - 3 Bottom of chart, immediately above horizontal axis
 - 4 Bottom of chart, below horizontal axis label
-

PHASEREF

delineates the phases specified with the READPHASES= option with reference lines drawn vertically. Related options are PHASELABTYPE= and PHASELEGEND.

PHASEREFLEVEL=INNER | OUTER | NONE

ODS Graphics enables you to associate phase reference lines (block reference lines) with either the innermost or the outermost level. The default value is INNER.

PHASEVARLABEL

displays the label associated with the variable `_PHASE_` above the phase values in the phase legend. If there is no label associated with `_PHASE_`, or if the PHASELEGEND option is not specified, PHASEVARLABEL has no effect.

PHASEVALSEP

displays vertical lines separating phase values in the phase legend. If the PHASELEGEND option is not specified, PHASEVALSEP has no effect.

POINTSHTML=*variable*

Traditional Graphics specifies a variable whose values create links to be associated with points on a box chart when the BOXSTYLE= value is POINTS, POINTSJOIN, POINTSBOX, POINTSID, or POINTSJOINID. These URLs are associated with points on a box chart when traditional graphics output is directed into HTML.

POINTSURL=*variable*

ODS Graphics specifies a variable whose values are URLs to be associated with points on a box chart when the BOXSTYLE= value is POINTS, POINTSJOIN, POINTSBOX, POINTSID, or POINTSJOINID. These URLs are associated with points on a box chart when ODS Graphics output is directed into HTML.

PSYMBOL='label'**PSYMBOL=P | PBAR | PPM | PPM2 | P0**

specifies a label for the central line in a *p* chart. You can use the option in the following ways:

- Specify a quoted *label* up to 16 characters.
- Specify one of the keywords listed in the following table. Each keyword requests a label of the form *symbol=value*, where *symbol* is the symbol given in the table, and *value* is the value of the central line. If the central line is not constant, only the symbol is displayed.

Keyword	Symbol Used in	
	Graphics	Line Printer Charts
P	P	P
PBAR	\bar{P}	\bar{P}
PPM	P'	P'
PPM2	P''	P''
P0	P ₀	P ₀

The default keyword is PBAR. The PSYMBOL= option is available only in the PCHART statement.

RANGES

estimates the process standard deviation for a boxplot using subgroup ranges. By default, the process standard deviation for a boxplot is estimated from the subgroup standard deviations.

READALPHA

specifies that the variable `_ALPHA_`, rather than the variable `_SIGMAS_`, is to be read from a LIMITS= data set when both variables are available in the data set. Thus, the limits displayed are probability limits. If you do not specify the READALPHA option, then `_SIGMAS_` is read by default. For details, see “Input Data Sets” in the section for the chart statement in which you are interested.

READINDEX=*value-list* | ALL

READINDEXES=*value-list* | ALL

READINDICES=*value-list* | ALL

reads one or more sets of control limits from a LIMITS= data set (specified in the PROC SHEWHART statement) for each *process* listed in the chart statement. The *i*th set of control limits for a particular *process* is read from the first observation in the LIMITS= data set for which

- the value of `_VAR_` matches *process*
- the value of `_SUBGRP_` matches the *subgroup variable*
- the value of `_INDEX_` matches *value*

The *values* can be up to 128 characters and must be enclosed in quotes.

NOTE: You cannot use the READINDEX= and OUTINDEX= options in the same chart statement. Also, the READLIMITS and READINDEX= options are alternatives to each other. If the LIMITS= data set contains more than one set of control limits for the same *process*, you should use the READINDEX= option.

You can display distinct sets of control limits (read from a LIMITS= data set) with data for various *phases* (read from blocks of observations in the input data set) by using the READINDEXES= and READPHASES= options together. See the entry for the READPHASES= option.

For more information about multiple sets of control limits and about the keyword ALL, see “Displaying Multiple Sets of Control Limits” on page 2105.

READLIMITS

specifies that the control limits are to be read from a LIMITS= data set specified in the PROC SHEWHART statement.⁴³ The control limits for each *process* listed in the chart statement are to be read from the first observation in the LIMITS= data set where

- the value of `_VAR_` matches *process*
- the value of `_SUBGRP_` matches the *subgroup variable*

The use of the READLIMITS option depends on the release of SAS/QC software that you are using.

- **In SAS 6.10 and later releases, the READLIMITS option is not necessary.** To read control limits as described previously, you simply specify a LIMITS= data set. However, even though the READLIMITS option is redundant, it continues to function as in earlier releases. Consequently, the following two XRCHART statements are equivalent:

```
proc shewhart data=Pistons limits=Diamlim;
  xrchart Diameter*Hour;
  xrchart Diameter*Hour / readlimits;
run;
```

If the LIMITS= data set contains more than one set of control limits for the same *process*, you should use the READINDEX= option.

- **In SAS 6.09 and earlier releases, you must specify the READLIMITS option to read control limits as described previously.** If you specify a LIMITS= data set without specifying the READLIMITS option (or the READINDEX= option), the control limits are computed from the data. Consequently, the following two XRCHART statements are **not** equivalent:

```
proc shewhart data=Pistons limits=diamlim;
  xrchart Diameter*Hour; /* limits computed from data */
  xrchart Diameter*Hour /
    readlimits;          /* limits read from DIAMLIM */
run;
```

The READLIMITS and READINDEX= options are alternatives to each other.

You can use the READLIMITS and READPHASES= options together. In this case, the control limits are read as described previously, and the data plotted on the chart are those selected by the READPHASES= option.

READPHASES=*value-list* | ALL**READPHASE=***value-list* | ALL

selects blocks of consecutive observations to be read from the input data set. You can use the READPHASES= option only if

- the input data set contains a `_PHASE_` variable
- the `_PHASE_` variable is a character variable of no more than 128 characters

⁴³For details about computing control limits from the data, see the entry for the **NOREADLIMITS** option.

The READPHASES= option selects those observations whose `_PHASE_` value matches one of the *values* specified in the *value-list*. The block of consecutive observations identified by the *ith value* is referred to as the *ith phase*. The *values* can be up to 128 characters and must be enclosed in quotes. List the *values* in the same order that they appear as values of the variable `_PHASE_` in the input data set.

With the READPHASES= option you can

- create control charts that label blocks of data corresponding to multiple time *phases*. See the PHASELEGEND, PHASEREF, and CFRAME= options.
- create *historical control charts* that display distinct sets of control limits for different *phases*. This also requires a LIMITS= data set and the READINDEXES= option.

If the subgroup variable is numeric, the values of the subgroup variable should be contiguous from one block of observations to the next. Otherwise, there may be a gap in the control chart between the last point in one phase and the first point in the next phase. If you read a data set that contains multiple observations for each subgroup, the value of `_PHASE_` must be constant within the subgroup.

You can display distinct sets of control limits (read from a LIMITS= data set) with data for various *phases* by using the READINDEX= and READPHASES= options together. For example, consider the flange width data in the HISTORY= data set Flange and the LIMITS= data set Flangelim. A partial listing of Flange is given in [Figure 17.137](#) (for a complete listing of Flange, see [Figure 17.149](#)). The complete listing of Flangelim is given in [Figure 17.138](#).

```
proc print data=Flange;
  var _phase_ Day Sample FlangewidthX FlangewidthR FlangewidthN;
run;
```

Figure 17.137 Listing of the HISTORY= Data Set Flange

Mean Chart for Diameters						
Obs	_phase_	Day	Sample	Flangewidth X	Flangewidth R	Flangewidth N
1	Production	08FEB90	6	0.97360	0.06247	5

1	Change 1	Flangewidth	Sample	ESTIMATE	5	.0026998	3
2	Production	Flangewidth	Sample	ESTIMATE	5	.0026998	3
3	Start	Flangewidth	Sample	ESTIMATE	5	.0026998	3
Obs	_lclx_	_mean_	_uclx_	_lclr_	_r_	_uclr_	_stddev_
1	0.96167	0.99924	1.03680	0	0.06513	0.13771	0.028000
2	0.93792	0.98827	1.03862	0	0.08729	0.18458	0.037530
3	0.87088	0.96803	1.06517	0	0.16842	0.35612	0.072409

The following statements use the READINDEX= and READPHASES= options to create a historical control chart for the *Production* and *Change 1* phases:

```
ods graphics on;
proc shewhart history=Flange limits=Flangelim;
  xchart Flangewidth*Sample /
    readphases = ('Production' 'Change 1')
    readindexes = ('Production' 'Change 1')
    phaseref
    phaselegend;
run;
ods graphics off;
```

The chart is displayed in Figure 17.139.

Figure 17.139 Multiple Control Limits for Multiple Phases

You can also use the keyword ALL with the READPHASES= option to match control limits to phases. For more information and examples about specifying multiple control limits, including the use of the keyword ALL, see “[Displaying Multiple Sets of Control Limits](#)” on page 2105.

REPEAT**REP**

specifies that the horizontal axis of a chart that spans multiple pages is to be arranged so that the last subgroup position on a page is repeated as the first subgroup position on the next page. The REPEAT option facilitates cutting and pasting panels together. If a SAS DATETIME format is associated with the subgroup variable, REPEAT is used by default.

RSYMBOL='label'

RSYMBOL=R | RBAR | RPM | R0

specifies a label for the central line in an R chart. You can use the option in the following ways:

- You can specify a quoted *label* up to 16 characters.
- You can specify one of the keywords listed in the following table. Each keyword requests a label of the form *symbol=value*, where *symbol* is the symbol given in the table,

and *value* is the value of the central line. If the central line is not constant, only the symbol is displayed.

Keyword	Symbol Used in	
	Graphics	Line Printer Charts
R	R	R
RBAR	\bar{R}	\bar{R}
RPM	R'	R'
R0	R ₀	R ₀

The default keyword is RBAR. The RSYMBOL= option is available only in the IRCHART, MRCHART, RCHART, and XRCHART statements.

RTMARGIN=*value*

RTM=*value*

specifies the width of the right marginal area for the plot requested with the RTMPLOT= *Traditional Graphics* option. For traditional graphics, the width is specified in horizontal percent screen units. For *ODS Graphics* ODS Graphics output, the width is specified in pixels. The RTMARGIN= option is available only in the IRCHART statement.

RTMPLOT=*keyword*

requests a univariate plot of the control chart statistics that is positioned in the right margin *Traditional Graphics* of the control chart. The *keywords* that you can specify and the associated plots are listed in *ODS Graphics* the following table:

Keyword	Marginal Plot
DIGIDOT	digidot plot
HISTOGRAM	histogram
SKELETAL	skeletal box-and-whisker plot
SCHEMATIC	schematic box-and-whisker plot
SCHEMATICID	schematic box-and-whisker plot with outliers labeled
SCHEMATICIDFAR	schematic box-and-whisker plot with far outliers labeled

The RTMPLOT= option is available only in the IRCHART statement; see [Example 17.13](#) for an example. Refer to Hunter (1988) for a description of digidot plots, and see the entry for the BOXSTYLE= option for a description of the various box-and-whisker plots. Related options are LTMARGIN=, LTMPLOT=, and RTMARGIN=.

SEPARATE

displays primary and secondary charts on separate screens or pages. This option is useful if you are displaying line printer charts on a terminal and the number of lines on the screen limits the resolution of the chart. The SEPARATE option is available only in the IRCHART, MRCHART, XRCHART, and XSCHART statements.

SERIFS

adds serifs to the whiskers of *skeletal box-and-whisker charts*. The SERIFS option is available only in the BOXCHART statement.

SIGMA0=value

specifies a known (standard) value σ_0 for the process standard deviation σ . By default, σ_0 is estimated from the data.

The SIGMA0= option is available in the BOXCHART, IRCHART, MCHART, MRCHART, RCHART, SCHAT, XCHART, XRCHART, and XSCHART statements.

NOTE: As an alternative to specifying SIGMA0= σ_0 , you can read a predetermined value for σ_0 from the variable `_STDDEV_` in a LIMITS= data set. For details, see “Input Data Sets” in the section for the chart statement in which you are interested.

SIGMAS=k

specifies the width of the control limits in terms of the multiple k of the standard error of the subgroup summary statistic plotted on the chart. The value of k must be positive. By default, $k = 3$ and the control limits are “ 3σ limits.”

The particular subgroup summary statistic whose standard error is multiplied by k depends on the chart statement, as indicated by the following table:

Statement	Subgroup Summary Statistic
BOXCHART	mean or median
CCHART	number nonconforming
IRCHART	individual measurements and moving ranges
MCHART	median
MRCHART	median and range
NPCHART	number nonconforming
PCHART	proportion nonconforming
RCHART	range
SCHAT	standard deviation
UCHART	number of nonconformities per unit
XCHART	mean
XRCHART	mean and range
XSCHART	mean and standard deviation

For details, see the Options for Specifying Control Limits table and the “Details” subsection in the section for the particular chart statement that you are using.

Note that

- as an alternative to specifying SIGMAS= k , you can read k from the variable `_SIGMAS_` in a LIMITS= data set. For details, see “Input Data Sets” in the section for the chart statement in which you are interested.
- as an alternative to specifying SIGMAS= k (or reading `_SIGMAS_` from a LIMITS= data set), you can request probability limits by specifying ALPHA= α (or reading the variable `_ALPHA_` from a LIMITS= data set by specifying the READALPHA option).

SIMULATEQCFONT

draws the central line labels using a simulated software font rather than a hardware font. *ODS Graphics*

SKIPLABELS=*n*

SKIPLABEL=*n*

specifies the number *n* of consecutive tick mark labels, beginning with the second tick mark label, that are thinned (not displayed) on the horizontal (subgroup) axis. For example, specifying SKIPLABEL=1 causes every other label to be skipped (not displayed). Specifying SKIPLABEL=2 causes the second and third labels to be skipped, the fifth and sixth labels to be skipped, and so forth. *Traditional Graphics
Line Printer*

The default value of the SKIPLABELS= option is the smallest value *n* for which tick mark labels do not collide. A specified *n* will be overridden to avoid collision, unless you specify SKIPLABELS=0, which forces all tick mark labels to be displayed. To avoid both collisions and thinning, you can use the TURNHLABELS option.

SMETHOD=NOWEIGHT | MVLUE | RMSDF | MAD | MMR | MVGRANGE

specifies a method for estimating the process standard deviation, σ , as summarized by the following table:

Keyword	Method for Estimating Standard Deviation
NOWEIGHT	estimates σ as an unweighted average of unbiased subgroup estimates of σ
MVLUE	calculates a minimum variance linear unbiased estimate for σ
RMSDF	calculates a root-mean square estimate for σ
MAD	calculates a median absolute deviation estimate for σ (IR-CHART only)
MMR	calculates a median moving range estimate for σ (IRCHART only)
MVGRANGE	estimates σ based on a moving range of subgroup means (XR-CHART and XSCHART only)

For formulas, see “Methods for Estimating the Process Standard Deviation” in the section for the particular chart statement you are using.

The default keyword is NOWEIGHT. The SMETHOD= option is available in the BOXCHART, IRCHART, MCHART, MRCHART, RCHART, SCHAT, XCHART, XRCHART, and XSCHART statements. You can specify SMETHOD=RMSDF only in the BOXCHART, MCHART, XCHART, SCHAT, and XSCHART statements and only when used with the STDDEVIATIONS option (or only in the absence of the RANGES option with a BOXCHART statement). You can specify SMETHOD=MAD and SMETHOD=MMR only in the IRCHART statement. You can specify SMETHOD=MVGRANGE only in the XRCHART and XSCHART statements.

SPLIT=*'character'*

specifies a special *character* that is inserted into the label of a process variable or summary statistic variable and whose purpose is to split the label into two parts. The first part is used to label the vertical axis of the primary chart, and the second part is used to label the vertical

axis of the secondary chart. The *character* is not displayed in either label. See Figure 17.173 for an example.

The SPLIT= option is available in the IRCHART, MRCHART, XRCHART, and XSCHART statements and in the BOXCHART, MCHART, and XCHART statements with the TREND-VAR= option.

SSYMBOL='label'

SSYMBOL=S | SBAR | SPM | S0

specifies a label for the central line in an *s* chart. You can use the option in the following ways:

- You can specify a quoted *label* up to 16 characters.
- You can specify one of the keywords listed in the following table. Each keyword requests a label of the form *symbol=value*, where *symbol* is the symbol given in the table, and *value* is the value of the central line. If the central line is not constant, only the symbol is displayed.

Keyword	Symbol Used in	
	Graphics	Line Printer Charts
S	S	S
SBAR	\bar{S}	\bar{S}
SPM	S'	S'
S0	S ₀	S0

The default keyword is SBAR. The SSYMBOL= option is available only in the SCHAT and XSCHAT statements.

STARBDRADIUS=value

Traditional Graphics
ODS Graphics

specifies the radius of an imaginary circle that is the outer bound for vertices of stars requested with the STARVERTICES= option. For traditional graphics, the radius is specified in horizontal percent screen units. For ODS Graphics output, the radius is specified in pixels. Vertices that exceed the outer bound are truncated to this value in order to prevent gross distortion of stars due to extreme values in the data. The *value* must be greater than or equal to the value specified with the STAROUTRADIUS= option. See Figure 17.141 or “Displaying Auxiliary Data with Stars” on page 2114.

STARCIRCLES=values

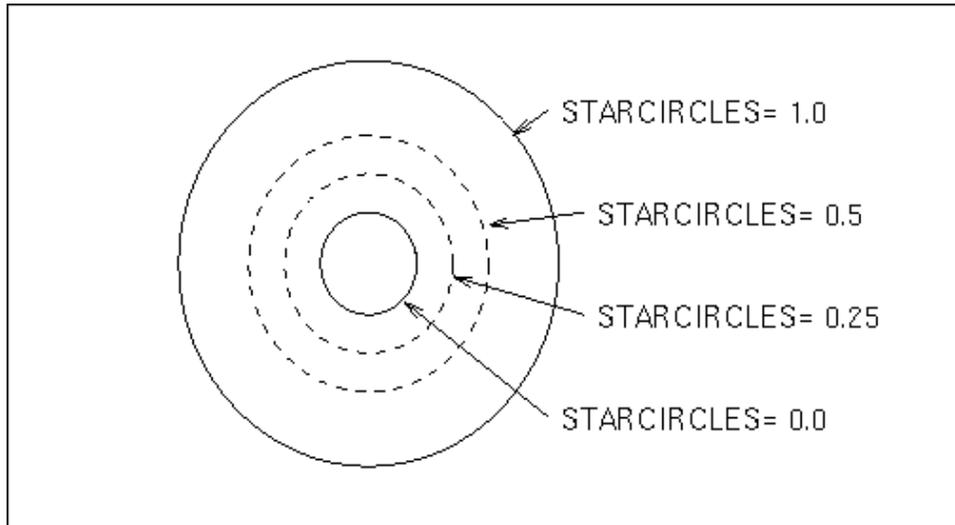

Traditional Graphics

specifies reference circles that are superimposed on the stars requested with the STARVERTICES= option. All of the circles are displayed and centered at each point plotted on the primary chart. The *value* determines the diameter of the circle as follows: a *value* of zero specifies a circle with the *inner radius*, and a value of one specifies a circle with the *outer radius*. In general, a value of *h* specifies a circle with a radius equal to $inradius + h \times (outradius - inradius)$.

Figure 17.140 shows four circles specified with the STARCIRCLES= option. The values 0.0 and 1.0 correspond to the *inner circle* and *outer circle* (see the entries for the STARINRADIUS= and STAROUTRADIUS= options). The value 0.5 specifies a circle with a radius of $inradius + 0.5 \times (outradius - inradius)$ or a circle halfway between the inner circle and

the outer circle. Likewise, the value 0.25 specifies a circle one-fourth of the way from the inner circle to the outer circle. Note also that the line types for the circles are specified with the LSTARCIRCLES= option. For more information, see “[Displaying Auxiliary Data with Stars](#)” on page 2114.

Figure 17.140 Circles Specified by STARCIRCLES=0.0 1.0 0.25 0.5

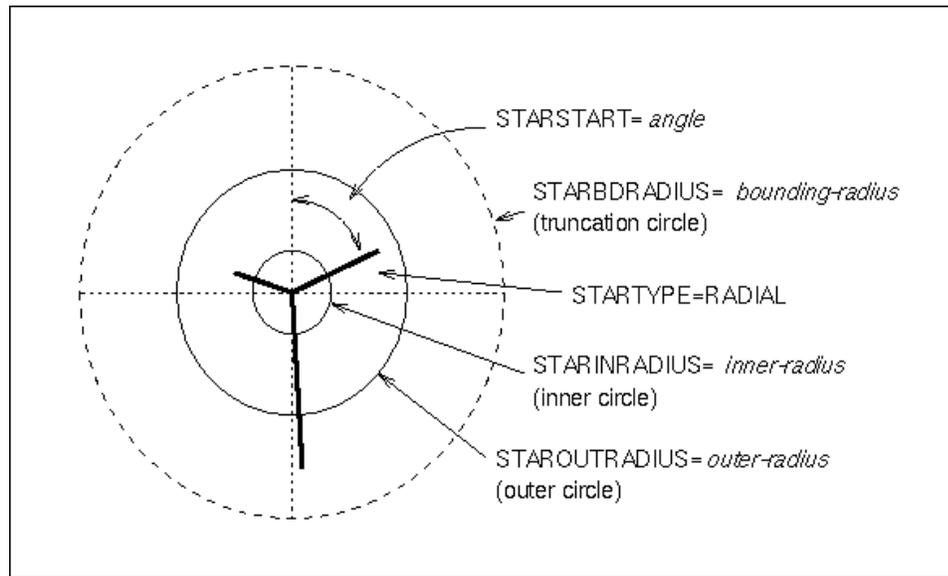

STARINRADIUS=*value*

specifies the inner radius of stars requested with the STARVERTICES= option. For traditional graphics, the radius is specified in horizontal percent screen units. For ODS Graphics output, the radius is specified in pixels. The *value* must be less than the value that is specified with the STAROUTRADIUS= option. The inner radius of a star is the distance from the center of the star to the circle that represents the lower limit of the standardized vertex variables. The lower limit can correspond to the minimum value, a multiple of standard deviations below the mean, or a lower specification limit. The default *value* is one-third of the outer radius.

Traditional Graphics
ODS Graphics

Figure 17.141 illustrates five of the star options. The STARSTART= option determines the angle between the vertical axis and the first vertex. The STARINRADIUS= and STAROUTRADIUS= options specify the radii (in horizontal percent screen units) of the inner and outer circles that are associated with each star. Extremely large vertex values are truncated at the imaginary circle whose radius is specified by the STARBDRADIUS= option. The STAR-TYPE=RADIAL option specifies that the vertices are to be displayed as endpoints of line segments connecting each vertex to the center point. For more information, see the entries for these options or “[Displaying Auxiliary Data with Stars](#)” on page 2114.

Figure 17.141 Illustration of Star Options

**STARFILL=variable**

Traditional Graphics
ODS Graphics

specifies colors for filling the interior of stars requested with the STARVERTICES= option. The STARFILL= option is analogous to the CSTARFILL= option, but the values of the STARFILL= variable are used only to group the stars. Stars in the same group are filled with the same color from the ODS style.

STARLABEL=ALL | FIRST | HIGH | LOW | OUT

Traditional Graphics
ODS Graphics

specifies a method for labeling the vertices of stars requested with the STARVERTICES= option. The following table describes the method corresponding to each keyword:

Keyword	Method for Labeling Star Vertices
ALL	labels all vertices of all stars
FIRST	labels all vertices of the leftmost star
HIGH	labels only vertices that lie outside the outer circle
LOW	labels only vertices that lie inside the inner circle
OUT	labels only vertices that lie inside the inner circle or outside the outer circle

The label used for a particular vertex is the value of the variable `_LABEL_` in the STAR-SPECS= data set. If this data set is not specified, or if the `_LABEL_` variable is not provided, then the name of the vertex variable is used as the label. See “[Displaying Auxiliary Data with Stars](#)” on page 2114. By default, vertices are not labeled.

STARLEGEND=CLOCK | CLOCK0 | DEGREES | NONE

Traditional Graphics
ODS Graphics

specifies the style of the legend used to identify the vertices of stars requested with the STARVERTICES= option. The following table describes the method corresponding to each keyword:

Keyword	Star Vertices Legend Style
CLOCK	identifies the vertex variables by their positions on the clock (starting with 12:00)
CLOCK0	identifies the vertex variables by their positions on the clock (starting with 0:00)
DEGREES	identifies the vertex variables by angles in degrees, with 0 degrees corresponding to 12 o'clock
NONE	suppresses the legend

See “[Displaying Auxiliary Data with Stars](#)” on page 2114. The default keyword is CLOCK.

STARLEGNLAB=‘label’

specifies the label displayed to the left of the legend for stars requested with the STAR- *Traditional Graphics*
LEGNLAB= option. The label can be up to 16 characters and must be enclosed in quotes. See *ODS Graphics*
“[Displaying Auxiliary Data with Stars](#)” on page 2114. The default label is *Vertices:*.

STARTRANSPARENCY=value

specifies the star fill transparency when transparency is used in ODS Graphics output. The *ODS Graphics*
value must be between 0 and 1, where 0 is completely opaque and 1 is completely transparent.
The default star fill transparency is 0.25.

STAROUTRADIUS=value

specifies the outer radius of stars requested with the STARVERTICES= option. For traditional *Traditional Graphics*
graphics, the radius is specified in horizontal percent screen units. For ODS Graphics output, *ODS Graphics*
the radius is specified in pixels. The outer radius of a star is the distance from the center of
the star to the circle that represents the upper limit of the standardized vertex variables. The
upper limit can correspond to the maximum value, a multiple of standard deviations above
the mean, or an upper specification limit.

See [Figure 17.141 “Displaying Auxiliary Data with Stars”](#) on page 2114. For an example,
see [Figure 17.223](#). The default *value* depends on the number of subgroup positions per panel,
and it is as large as possible without causing overlap of adjacent stars.

STARS=variable

specifies colors for the outlines of stars requested with the STARVERTICES= option. The *Traditional Graphics*
STARS= option is analogous to the CSTARTS= option, but the values of the STARS= variable *ODS Graphics*
are used only to group the stars. The outlines of stars in the same group are drawn with the
same color from the ODS style.

STARSPECS=value|SAS-data-set

STARSPEC=value|SAS-data-set

specifies the method used to standardize the star vertex variables listed with the STARVER- *Traditional Graphics*
TICES= option. The method determines how the value of a vertex variable is transformed *ODS Graphics*
to determine the distance between the center of the star and the vertex. The STARSPECS=
option also determines how the inner and outer radii of the star are to be interpreted.

A *value* of zero specifies standardization by the range of the variable. In this case, the distance
between the center and the vertex is proportional to the difference between the variable value
and the minimum variable value (taken across all subgroups). The inner radius of the star

corresponds to the minimum variable value, and the outer radius of the star corresponds to the maximum variable value.

A positive STARSPECS= value requests standardization by a multiple of standard deviations above and below the mean. For example, STARSPECS=3 specifies that the inner radius of the star corresponds to three standard deviations below the mean, and the outer radius corresponds to three standard deviations above the mean. Thus, a vertex variable value exactly equal to the mean is represented by a vertex whose distance to the center of the star is halfway between the inner and outer radii.

You can request a distinct method of standardization for each vertex variable by specifying a STARSPECS= *data set*. Each observation provides standardization and related information for a distinct vertex variable. The variables read from a STARSPECS= *data set* are described in the following table:

Variable	Description
CSPOKE	color of spokes used with STARTYPE=RADIAL and STARTYPE=SPOKE; this must be a character variable of length 8 or less
LABEL	label for identifying the vertex when you specify STARLEGEND=FIRST or STARLEGEND=ALL; this must be a character variable of up to 16 characters
LSL	lower specification limit
LSPOKE	line style for spokes used with STARTYPE=RADIAL, STARTYPE=SPOKE, and STARTYPE=WEDGE
NOMVAL	nominal value substituted for missing values
SIGMAS	multiple of standard deviations above and below the average
UBOUND	upper bound for truncating extremely high values
USL	upper specification limit
VAR	name of vertex variable; this must be a character variable of length 32 or less

Only the variable _VAR_ is mandatory. If you provide the variables _LSL_ and _USL_, standardization is based on the specification limits; in this case, the variable _LSL_ corresponds to the inner radius of the star, and the variable _USL_ corresponds to the outer radius of the star. If you do not provide the variables _LSL_ and _USL_, standardization is based on the value of the variable _SIGMAS_, and if you do not provide the variable _SIGMAS_, standardization is based on the range.

See “[Displaying Auxiliary Data with Stars](#)” on page 2114. If you do not specify the STARSPECS= option, each vertex variable is standardized by its range across subgroups. In other words, the minimum corresponds to the inner radius, and the maximum corresponds to the outer radius.

STARSTART=value

specifies the vertex angle for the first variable in the STARVERTICES= list. Vertex angles for the remaining variables are uniformly spaced clockwise and assigned in the order listed. You can specify the *value* in the following ways:

Traditional Graphics
ODS Graphics

- *Clock position*: If you specify the value as a time literal (between ‘0:00’T and ‘12:00’T), the corresponding clock position is used for the first vertex variable.
- *Degrees*: If you specify the value as a nonpositive number, the absolute value in degrees is used for the first vertex angle. Here, 0 degrees corresponds to 12:00.

The default *value* is zero, so the first vertex variable is positioned at 12:00. See [Figure 17.141](#) or “[Displaying Auxiliary Data with Stars](#)” on page 2114.

STARTYPE=CORONA | POLYGON | RADIAL | SPOKE | WEDGE

specifies the style of the stars requested with the STARVERTICES= option. The following *Traditional Graphics* table describes the method corresponding to each keyword. *ODS Graphics*

Keyword	Star Style
CORONA	polygon with star-vertices emanating from the inner circle
POLYGON	closed polygon
RADIAL	rays emanating from the center
SPOKE	rays emanating from the inner circle
WEDGE	closed polygon with rays from the center to each vertex

See [Figure 17.141](#) or “[Displaying Auxiliary Data with Stars](#)” on page 2114. “[Adding Reference Circles to Stars](#)” on page 2117 describes the inner and outer circles, and “[Specifying the Style of Stars](#)” on page 2119 provides examples of each value of the STARTYPE= option. The default keyword is POLYGON.

STARVERTICES=*variable* | (*variable-list*)

superimposes a star (polygon) at each point on the primary chart. The star is centered at the point, and the distance between the center and each star vertex represents the standardized value of a *variable* in the STARVERTICES= list. The *variables* must be provided in the input data set. *Traditional Graphics* *ODS Graphics*

The star display is suggested as a method for monitoring quantitative variables (such as environmental factors) that are measured simultaneously with the process variable. For examples and details, see “[Displaying Auxiliary Data with Stars](#)” on page 2114. By default, stars are not superimposed on the chart.

STDDEVIATIONS

STDDEVS

specifies that the estimate of the process standard deviation σ is to be calculated from subgroup standard deviations. This, in turn, affects the calculation of control limits; for details, see “[Methods for Estimating the Process Standard Deviation](#)” in the section for the chart statement in which you are interested. By default, the estimate of σ is calculated from subgroup ranges, except with the BOXCHART statement, where subgroup standard deviations are used by default.

If you specify the STDDEVIATIONS option and read summary data from a HISTORY= data set, the data set must contain a subgroup standard deviation variable for each *process*. Conversely, if you omit the STDDEVIATIONS option, the HISTORY= data set must contain a subgroup range variable for each *process* listed in the chart statement.

You should specify `STDDEVIATIONS` when your subgroup sample sizes are large (typically, 15 or greater). The `STDDEVIATIONS` option is available only in the `MCHART` and `XCHART` statements.

SUBGROUPN=value

SUBGROUPN=variable

specifies the subgroup sample sizes as a constant *value* or as the values of a *variable* in the `DATA=` data set. The `SUBGROUPN=` option is available only in the `CCHART`, `NPCHART`, `PCHART`, and `UCHART` statements.

You must specify `SUBGROUPN=` in the `NPCHART`, `PCHART`, and `UCHART` statements when your input data set is a `DATA=` data set. If you are using a `CCHART` statement, the `SUBGROUPN=` option is available only when your input data set is a `DATA=` data set. For the `CCHART` statement, the default value of the `SUBGROUPN=` option is one.

If you specify multiple *processes* in a chart statement, the `SUBGROUPN=` option is used with all of the *processes* listed.

SYMBOLCHARS='character-list'

Line Printer

specifies a list of characters used to mark the points plotted on line printer charts when a *symbol-variable* is used. See “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097.

Each character is associated with a level (unique value) of the *symbol-variable* and is used to mark points associated with that value. For example, consider the following statements:

```
proc shewhart;
  xrchart Gap*Shift=Machine / symbolchars='12345';
run;
```

Here the *symbol-variable* is `Machine`. The \bar{X} and R charts use a ‘1’ to mark points associated with the first unique value of `Machine`, a ‘2’ to mark points associated with the second unique value of `Machine`, and so on.

If the number of levels of the *symbol-variable* exceeds the number of *characters*, the last character listed is used for points associated with the additional values. Thus, in the preceding example, if there are six levels of `Machine`, points with the fifth and six values are indicated by ‘5’.

The default *character-list* is `ABCDEFGHIJKLMNOPQRSTUVWXYZ*`. Thus, the procedure uses ‘A’ for the first unique value of the *symbol-variable*, ‘B’ for the second unique value, and so on. An asterisk is used for points associated with the 27th and subsequent levels when the *symbol-variable* has more than 26 levels.

SYMBOLLEGEND=LEGEND n

SYMBOLLEGEND=NONE

Traditional Graphics
ODS Graphics

controls the legend for the levels of a *symbol-variable* (see “[Displaying Stratification in Levels of a Classification Variable](#)” on page 2097). For traditional graphics, you can specify `SYMBOLLEGEND=LEGEND n` , where n is the number of a `LEGEND` statement defined previously. You can specify `SYMBOLLEGEND=NONE` to suppress the default legend.

SYMBOLORDER=DATA | INTERNAL | FORMATTED**SYMORD=DATA | INTERNAL | FORMATTED**

specifies the order in which symbols are assigned for levels of *symbol-variable*. The DATA keyword assigns symbols to values in the order in which values appear in the input data. This is how symbols were assigned in SAS 6.12 and earlier releases of SAS/QC software. The INTERNAL keyword assigns symbols based on sorted order of internal values of *symbol-variable* and FORMATTED assigns them based on sorted formatted values. The default value is FORMATTED. *Traditional Graphics
Line Printer*

TABLE <(EXCEPTIONS)>**TABLES <(EXCEPTIONS)>**

creates a basic table of the subgroup values, the subgroup sample sizes, the subgroup summary statistics, and the upper and lower control limits. Rows of the table correspond to subgroups. The keyword EXCEPTIONS (enclosed in parentheses) is optional and restricts the tabulation to those subgroups for which the control limits are exceeded or a test for special causes is positive.

You can request extended versions of the basic table by specifying one or more of the following options: TABLEBOX, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUTLIM, and TABLETESTS. Specifying the TABLEALL option is equivalent to specifying all of these options, and it provides the most extensive table.

TABLEALL <(EXCEPTIONS)>

tabulates the information about the control chart and is equivalent to specifying all of the following options: TABLES, TABLECENTRAL, TABLEID, TABLELEGEND, TABLEOUT, and TABLETESTS. If you specify the TABLEALL option in a BOXCHART statement, the TABLEBOX option is also implied. The keyword EXCEPTIONS (enclosed in parentheses) is optional and restricts the tabulation to those subgroups for which the control limits are exceeded or a test for special causes is positive. You can use the OUTTABLE= option to create a data set that saves the information tabulated with the TABLEALL option.

TABLEBOX <(EXCEPTIONS)>

augments the basic table created by the TABLES option with columns for the minimum, 25th percentile, median, 75th percentile, and maximum of the observations in a subgroup. The TABLEBOX option is available only in the BOXCHART statement. The keyword EXCEPTIONS (enclosed in parentheses) is optional and restricts the tabulation to those subgroups for which the control limits are exceeded or a test for special causes is positive.

TABLECENTRAL <(EXCEPTIONS)>**TABLEC <(EXCEPTIONS)>**

augments the basic table created by the TABLES option with columns for the values of the central lines. The keyword EXCEPTIONS (enclosed in parentheses) is optional and restricts the tabulation to those subgroups for which the control limits are exceeded or a test for special causes is positive.

TABLEID <(EXCEPTIONS)>

augments the basic table created by the TABLES option with a column for each of the ID variables. The keyword EXCEPTIONS (enclosed in parentheses) is optional and restricts the tabulation to those subgroups for which the control limits are exceeded or a test for special causes is positive.

TABLELEGEND <(EXCEPTIONS)>**TABLELEG <(EXCEPTIONS)>**

adds a legend to the basic table created by the TABLES option. The legend describes the tests for special causes that were requested with the TESTS= option and for which a positive signal is found for at least one subgroup. The keyword EXCEPTIONS (enclosed in parentheses) is optional and restricts the tabulation to those subgroups for which the control limits are exceeded or a test for special causes is positive.

TABLEOUTLIM <(EXCEPTIONS)>**TABLEOUT <(EXCEPTIONS)>**

augments the basic table created by the TABLES option with columns indicating which control limits (if any) are exceeded. The keyword EXCEPTIONS (enclosed in parentheses) is optional and restricts the tabulation to those subgroups for which the control limits are exceeded or a test for special causes is positive.

TABLETESTS <(EXCEPTIONS)>

augments the basic table created by the TABLES option with a column that indicates which of the tests for special causes (requested with the TESTS= option) are positive. The column contains the numbers of all the tests that are positive at a particular subgroup. The keyword EXCEPTIONS (enclosed in parentheses) is optional and restricts the tabulation to those subgroups for which the control limits are exceeded or a test for special causes is positive.

TARGET=*value-list*

provides target values used to compute the capability index C_{pm} , which is saved in the OUTLIMITS= data set. If you provide more than one *value*, the number of *values* must match the number of *processes* listed in the chart statement. If you specify only one *value*, it is used for all the *processes*.

CAUTION: You can use the TARGET= options only in conjunction with the LSL= and USL= options. For more information, see “[Capability Indices](#)” on page 1941 and “[Output Data Sets](#)” in the section for the chart statement in which you are interested. Also see the entries for the LSL= and USL= options. The TARGET= option is available in the BOXCHART, IRCHART, MCHART, MRCHART, RCHART, SCHAT, XCHART, XRCHART, and XSCHAT statements.

TEST2RESET=*variable***TEST2RESET=*value***

enables tests for special causes to be reset in a secondary chart. The specified variable must be a character variable of length 8, or length 16 if customized tests are requested. The variable values have the same format as those of the `_TESTS_` variable in a TABLE= data set. A test that is flagged by the TEST2RESET= value for a given subgroup is reset starting with that subgroup. That means a positive result for the test can include the given subgroup only if it is the first subgroup in the pattern. For example, the value “12345678” for the TEST2RESET= variable will reset all standard tests for special causes.

TEST2RUN=*run-length*

specifies the length of the pattern for Test 2 requested with the TESTS= and TESTS2= options. The values allowed for the *run-length* are 7, 8, 9, 11, 14, and 20. The form of the test for each *run-length* value is given in the following table. The default *run-length* is 9. See “[Tests for Special Causes: SHEWHART Procedure](#)” on page 2146 for more information.

Run-length	Number of Points on One Side of the Central Line
7	7 in a row
8	8 in a row
9	9 in a row
11	at least 10 out of 11 in a row
14	at least 12 out of 14 in a row
20	at least 16 out of 20 in a row

TEST3RUN=run-length

specifies the length of the pattern for Test 3 requested with the TESTS= and TESTS2= options. Test 3 searches for a pattern of steadily increasing or decreasing values, where the length of the pattern is at least the value given as the *run-length*. The values allowed for the *run-length* are 6, 7, and 8. The default *run-length* is 6. See “Tests for Special Causes: SHEWHART Procedure” on page 2146 for more information.

TESTACROSS

specifies that tests for special causes requested with the TESTS= or TESTS2= options be applied without regard to phases (blocks of consecutive subgroups) determined by the READPHASES= option and the variable `_PHASE_` in the input data set. With varying control limits, if you specify the READPHASES= option but do not specify the TESTACROSS option, tests for special causes are applied within (but not across) phases. With constant control limits, tests are applied across phases by default, and you can use the NOTESTACROSS option to specify that they be applied only within phases. See “Tests for Special Causes: SHEWHART Procedure” on page 2146.

TESTCHAR='character'

specifies the character for the line segments that connect any sequence of points for which a test for special causes (requested with the TESTS= or TESTS2= option) is positive. The default *character* is the number of the test (with values 1 to 8). *Line Printer*

TESTFONT=font**LABELFONT=font**

specifies a software font for labels requested with the ALLLABEL=, ALLLABEL2=, OUTLABEL=, OUTLABEL2=, STARLABEL=, TESTLABEL=, and TESTLABEL n = options. Hardware characters are used by default. *Traditional Graphics*

TESTHEIGHT=value**LABELHEIGHT=value**

specifies the height (in vertical percent screen units) for labels requested with the ALLLABEL=, ALLLABEL2=, OUTLABEL=, OUTLABEL2=, STARLABEL=, TESTLABEL=, and TESTLABEL n = options. The default height is the height specified with the HEIGHT= option or the HTEXT= option in the GOPTIONS statement. *Traditional Graphics*

TESTLABBOX

requests that labels for subgroups with positive tests for special causes are positioned so they do not overlap. The labels are enclosed in boxes that are connected to the associated subgroup points with line segments. *Traditional Graphics*
ODS Graphics

TESTLABEL='label'**TESTLABEL=(variable)****TESTLABEL=TESTINDEX****TESTLABEL=SPACE****TESTLABEL=NONE**

provides labels for points at which one of the tests for special causes (requested with the TESTS= or TESTS2= option) is positive. The values for the TESTLABEL= option are as follows:

- You can specify a *label* of up to 16 characters enclosed in quotes. This label is displayed at all points where a test is signaled.
- You can specify a *variable* (enclosed in parentheses) whose values are used as labels. The *variable* must be provided in the input data set, and it can be numeric or character. If the *variable* is character, its length cannot exceed 16. For each subgroup of observations at which a test is signaled, the formatted value of the *variable* in the observations is used to label the point representing the subgroup. If you are reading a DATA= data set with multiple observations per subgroup, the values of the *variable* should be identical for observations within a subgroup.
- You can specify TESTINDEX to label points with the single-digit *index* that requested the test in a TESTS= or TESTS2= list. If the test was requested with a customized *pattern* in a TESTS= or TESTS2= list, then points are labeled with the letter that you specified using the CODE= option.
- You can specify SPACE to request a label of the form *Test k*. This is slightly more legible than the default label of the form *Testk* (a description of *Testk* follows).
- You can specify NONE to suppress labeling.

If you do not use the TESTLABEL= option, the default label is of the form *Testk*, where *k* is the index of the test as requested with the TESTS= or TESTS2= options, or *k* is the CODE= *character* of the test as requested in a pattern specified with the TESTS= or TESTS2= options.

See “Tests for Special Causes: SHEWHART Procedure” on page 2146. Related options include OUTLABEL=, OUTLABEL2=, TESTFONT=, TESTHEIGHT=, and TESTLABELn=.

TESTLABELn='label'

specifies a *label* for points at which the test for special causes requested with the *index n* in a TESTS= or TESTS2= list is positive. The *index n* can be a number from 1 to 8. The TESTLABELn= option overrides a TESTLABEL= option and the default label *Test n*. The *label* that you specify with the TESTLABELn= option can be up to 16 characters and must be enclosed in quotes.

See “Tests for Special Causes: SHEWHART Procedure” on page 2146. Related options are TESTFONT=, TESTHEIGHT=, and TESTLABEL=.

TESTMETHOD=STANDARDIZE

applies the tests for special causes requested with the TESTS= and TESTS2= options to standardized test statistics when the subgroup sample sizes are not constant. This method was suggested by Nelson (1994). See “Tests for Special Causes: SHEWHART Procedure”

on page 2146. By default, the tests are not applied to data with varying subgroup sample sizes.

TESTOVERLAP

applies tests for special causes (requested with the TESTS= or TESTS2= option) to overlapping patterns of points.

The TESTOVERLAP option modifies the way in which the search for a subsequent pattern is done when a pattern is encountered. If you omit the TESTOVERLAP option, the search begins with the first subgroup after the current pattern ends. If you specify the TESTOVERLAP option, the search begins with the second subgroup in the current pattern.

The following statements illustrate the use of the TESTOVERLAP option:

```
proc shewhart;
  xrchart Width*Hour / test=3;
  xrchart Width*Hour / test=3 testoverlap;
run;
```

Test 3 looks for six subgroup means in a row steadily increasing or decreasing. Suppose that the subgroup means of WIDTH are steadily increasing for HOUR=5, 6, 7, 8, 9, 10, and 11. The first XRCHART statement will signal that Test 3 is positive at HOUR=10 but not at HOUR=11, since the search for the next pattern begins with HOUR=11. The second XRCHART statement will signal that Test 3 is positive at HOUR=10 and HOUR=11, since the search for the next pattern begins with HOUR=6 and thus finds a second pattern ending with HOUR=11. See “Tests for Special Causes: SHEWHART Procedure” on page 2146 for more information.

CAUTION: Specifying TESTOVERLAP affects the interpretation of the standard tests for special causes, because a particular point can contribute to more than one positive test. Typically, this option should not be used.

TESTRESET=*variable*

TESTRESET=*value*

enables tests for special causes to be reset in a primary chart. The specified variable must be a character variable of length 8, or length 16 if customized tests are requested. The variable values have the same format as those of the _TESTS_ variable in a TABLE= data set. A test that is flagged by the TESTRESET= value for a given subgroup is reset starting with that subgroup. That means that a positive result for the test can include the given subgroup only if it is the first subgroup in the pattern. For example, the value “12345678” for the TESTRESET= variable will reset all standard tests for special causes.

TESTS=*index-list*

TESTS=*customized-pattern-list*

requests one or more tests for special causes, which are also known as *runs tests*, *pattern tests*, and *Western Electric rules*. These tests detect particular nonrandom patterns in the points plotted on the primary control chart. The occurrence of a pattern, referred to as a *signal*, suggests the presence of a special cause of variation.

Each pattern is defined in terms of zones A, B, and C, which are constructed by dividing the interval between the control limits into six equally spaced subintervals. Zone A is the union of

the subintervals immediately below the upper control limit and immediately above the lower control limit. Zone C is the union of the subintervals immediately above and below the central line. Zone B is the union of the subintervals between zones A and C. See Figure 17.178 for an illustration of test zones.

You can use the TESTS= option in three ways. First, you can specify an *index-list* to request a combination of standard tests (this is the approach most commonly used). Second, you can specify a *customized-pattern-list* to request a combination of tests based on customized patterns. Third, you can specify a list consisting of both *indexes* and *customized-patterns*. The first two approaches are described as follows.

Standard tests. The following table lists the standard tests that you can request by specifying TEST=*index-list*. The tests are indexed according to the sequence used by Nelson (1984, 1985).

Index	Pattern Description
1	one point beyond Zone A (outside the control limits)
2	nine points in a row in Zone C or beyond on one side of the central line (see the entry for the TEST2RUN option)
3	six points in a row steadily increasing (see the entry for the TEST3RUN option)
4	fourteen points in a row alternating up and down
5	two out of three points in a row in Zone A or beyond
6	four out of five points in a row in Zone B or beyond
7	fifteen points in a row in Zone C on either or both sides of the central line
8	eight points in a row on either or both sides of the central line with no points in Zone C

You can specify any combination of the eight *indexes* with an explicit list or with an implicit list, as in the following example:

```
proc shewhart;
  xrchart Width*Hour / tests=1 2 3 4;
  xrchart Width*Hour / tests=1 to 4;
run;
```

The TESTS= option is available in all but the RCHART and SCHAT statements. Use only tests 1, 2, 3, and 4 in the CCHART, NPCHART, PCHART, and UCHART statements. By default, the TESTS= option is not applied in any chart statement unless the control limits are 3σ limits. You can use the NO3SIGMACHECK option to request tests for special causes when you use the SIGMAS= option to specify control limits other than 3σ limits.

Customized tests. Although the standard tests supported by the TESTS= option are appropriate for the vast majority of control chart applications, there may be situations in which you want to work with customized tests. You can define your own tests by specifying TESTS=*customized-pattern-list*. There are two types of patterns that you can include in this list: *T-patterns* and *M-patterns*.

Use a T-pattern to request a search for k out of m points in a row in the interval (a, b) . The required syntax for a T-pattern is

T(K= k M= m LOWER= a UPPER= b CODE=*character* LABEL=*'label'*)

The default value for SCHEME= is ONESIDED. The options for a T-pattern are summarized in the following table:

Option	Description
K= k	number of points
M= m	number of consecutive points
LOWER= <i>value</i>	lower limit of interval (a, b)
UPPER= <i>value</i>	upper limit of interval (a, b)
SCHEME=ONESIDED	one-sided scheme using (a, b)
SCHEME=TWOSIDED	two-sided scheme using $(a, b) \cup (-b, -a)$
CODE= <i>character</i>	identifier for test (A-H)
LABEL= <i>'label'</i>	label for points if signal
LEGEND= <i>'legend'</i>	legend used with the TABLELEGEND option

Use an M-pattern to request a search for k points in a row increasing or decreasing. The required syntax for an M-pattern is

M(K= k DIR=*direction* CODE=*character* LABEL=*'label'*)

The options for an M-pattern are summarized in the following table:

Option	Description
K= k	number of points
DIR=INC	increasing pattern
DIR=DEC	decreasing pattern
CODE= <i>character</i>	identifier for test (A-H)
LABEL= <i>'label'</i>	label for points if signal
LEGEND= <i>'legend'</i>	legend used with the TABLELEGEND option

For details on the TESTS= option, see “[Tests for Special Causes: SHEWHART Procedure](#)” on page 2146. Related options include CTEST=, CZONES=, LTEST=, TABLETESTS, TABLELEGEND, TEST2RUN=, TEST3RUN=, TESTACROSS, TESTCHAR=, TESTLABEL=, TESTLABEL n =, TESTNMETHOD=, TESTOVERLAP, TESTS2=, ZONES, ZONECHAR=, and ZONELABELS.

TESTS2=*index-list*

TESTS2=*customized-pattern-list*

requests one or more tests for special causes for an R chart or s chart. The syntax for the TESTS2= option is identical to the syntax for the TESTS= option. The TESTS2= option is available in the MRCHART, RCHART, SCHART, XRCHART, and XSCHART statements. For details on the TESTS2= option, see “[Tests for Special Causes: SHEWHART Procedure](#)” on page 2146. Related options include CTEST=, CZONES=, LTEST=, TABLETESTS, TABLELEGEND, TEST2RUN=, TEST3RUN=, TESTACROSS, TESTCHAR=, TESTLABEL=, TESTLABEL n =, TESTNMETHOD=, TESTOVERLAP, TESTS=, ZONES2, ZONECHAR=, and ZONE2LABELS.

TESTSYMBOL=*symbol*

Traditional Graphics **TESTSYM=***symbol*
 specifies the symbol for plotting subgroups with positive tests for special causes.

TESTSYMBOLHT=*value*

Traditional Graphics **TESTSYMHT=***value*
 specifies the height of the symbol used to plot subgroups with positive tests for special causes.

TOTPANELS=*n*

specifies the total number of panels to be used to display the chart. This option overrides the NPANEL= option.

TRENDVAR=*variable* | (*variable-list*)

specifies a list of trend variables, one for each *process* listed in the chart statement. The TRENDVAR= option is available only in the BOXCHART, MCHART, and XCHART statements and only when your input data set is a DATA= or HISTORY= data set.

The values of the trend variables are subtracted from the values of the corresponding process variables (if you read a DATA= data set) or subgroup mean variables (if you read a HISTORY= data set). The chart is then created for the residuals (differences), and the trend values are plotted in a secondary chart. If you specify a single trend variable and two or more *processes*, the trend variable is used with each *process*.

The TRENDVAR= option does not apply if you are reading a TABLE= data set. In this case, the procedure produces a trend chart only if the variable `_TREND_` is included in the TABLE= data set.

For more details, see “[Displaying Trends in Process Data](#)” on page 2126. Related options include NOTRENDCONNECT, SEPARATE, SPLIT=, WTREND=, and YPCT1=.

TURNALL**TURNOUT**

turns the labels produced by the ALLLABEL=, ALLLABEL2=, OUTLABEL= and OUTLABEL2= options so that they are strung out vertically. By default, labels are arranged horizontally.

TURNHLABELS**TURNHLABEL**

Traditional Graphics
Line Printer turns the major tick mark labels for the horizontal (subgroup) axis so that they are strung out vertically. By default, labels are arranged horizontally.

If you are producing traditional graphics with the NOGSTYLE option in effect, you should specify a font (with the FONT= option) in conjunction with the TURNHLABELS option. Otherwise, the labels may be displayed with a mixture of hardware and software fonts.

NOTE: Turning the labels vertically may leave insufficient room on the screen or page for a chart.

TYPE=*value*

specifies the *value* of the `_TYPE_` variable in the `OUTLIMITS=` data set, which in turn indicates whether certain parameter variables in this data set represent estimates or standard (known) values.

If you are using a chart statement that creates a variables chart, `_TYPE_` is a bookkeeping variable that indicates whether the values of the variables `_MEAN_` and `_STDDEV_` in the `OUTLIMITS=` data set are estimates or standard values of the process mean μ and standard deviation σ . The following table summarizes the *values* that you can specify:

Value	<code>_MEAN_</code>	<code>_STDDEV_</code>
ESTIMATE	estimate	estimate
STDMU	standard	estimate
STDSIGMA	estimate	standard
STANDARD	standard	standard

The default *value* is ESTIMATE, unless you specify standard values for μ or σ with the `MU0=` or `SIGMA0=` options.

For `PCHART` and `NPCHART` statements, the *value* you specify for the `TYPE=` option can be either ESTIMATE or STANDARD, indicating that the value of the variable `_P_` in the `OUTLIMITS=` data set is an estimate or standard value of the proportion p of nonconforming items. The default *value* is ESTIMATE, unless you specify a standard value for p with the `P0=` option.

For `UCHART` and `CCHART` statements, the *value* you specify for the `TYPE=` option can be either ESTIMATE or STANDARD, indicating that the value of the variable `_U_` in the `OUTLIMITS=` data set is an estimate or standard value of the average number u of nonconformities per unit. The default *value* is ESTIMATE, unless you specify a standard value for u with the `U0=` option.

U0=*value*

specifies a known (standard) value u_0 for the average number u of nonconformities per unit produced by the process. By default, u_0 is estimated from the data. The `U0=` option is available only in the `CCHART` and `UCHART` statements.

NOTE: As an alternative to specifying the `U0=` option, you can read a predetermined value for u_0 from the variable `_U_` in a `LIMITS=` data set. For details, see “Input Data Sets” in the section for the chart statement in which you are interested.

UCLLABEL=*'label'*

specifies a label for the upper control limit in the primary chart. The label can be up to 16 characters. Enclose the label in quotes. The default label is of the form `UCL=`*value* if the control limit has a fixed value; otherwise, the default label is `UCL`. Related options are `UCLLABEL2=`, `LCLLABEL=`, and `LCLLABEL2=`.

UCLLABEL2=*'label'*

specifies a label for the upper control limit in the secondary chart. The label can be up to 16 characters. Enclose the label in quotes. The default label is of the form `UCL=`*value* if the control limit has a fixed value; otherwise, the default label is `UCL`. This option is available in the `IRCHART`, `MRCHART`, `XRCHART`, and `XSCHART` statements. Related options are `LCLLABEL2=`, `LCLLABEL=`, and `UCLLABEL=`.

URL=variable

ODS Graphics specifies URLs as values of the specified character variable (or formatted values of a numeric variable). These URLs are associated with subgroup points on a primary control chart when ODS Graphics output is directed into HTML. The value of the URL= variable should be the same for each observation with a given value of the subgroup variable.

URL2=variable

ODS Graphics specifies URLs as values of the specified character variable (or formatted values of a numeric variable). These URLs are associated with subgroup points on a secondary control chart when ODS Graphics output is directed into HTML. The value of the URL2= variable should be the same for each observation with a given value of the subgroup variable.

USL=value-list

provides upper specification limits used to compute capability indices. If you provide more than one *value*, the number of *values* must match the number of *processes* listed in the chart statement. If you specify only one *value*, it is used for all the *processes*.

The SHEWHART procedure uses the specification limits to compute capability indices, and it saves the limits and indices in the OUTLIMITS= data set. For more information, see “[Capability Indices](#)” on page 1941 and “[Output Data Sets](#)” in the section for the chart statement in which you are interested. A related option is LSL=. The USL= option is available in the BOXCHART, IRCHART, MCHART, MRCHART, RCHART, SCHART, XCHART, XRCHART, and XSCHART statements.

USYMBOL='label'**USYMBOL=U | UBAR | UPM | UPM2 | U0**

specifies a label for the central line in a *u* chart. You can use the option in the following ways:

- You can specify a quoted *label* up to 16 characters.
- You can specify one of the keywords listed in the following table. Each keyword requests a label of the form *symbol=value*, where *symbol* is the symbol given in the table, and *value* is the value of the central line. If the central line is not constant, only the symbol is displayed.

Keyword	Symbol Used in	
	Graphics	Line Printer Charts
U	U	U
UBAR	\bar{U}	\bar{U}
UPM	U'	U'
UPM2	U''	U''
U0	U ₀	U0

The default keyword is UBAR. The USYMBOL= option is available only in the UCHART statement.

VAXIS=value-list**VAXIS=AXIS_n**

specifies major tick mark values for the vertical axis of a primary chart. The *values* must be listed in increasing order, must be evenly spaced, and must span the range of summary

statistics and control limits displayed in the chart. You can specify the *values* with an explicit list or with an implicit list, as shown in the following example:

```
proc shewhart;
  xrchart Width*Hour / vaxis=0 2 4 6 8;
  xrchart Width*Hour / vaxis=0 to 8 by 2;
run;
```

If you are producing traditional graphics, you can also specify a previously defined AXIS statement with the VAXIS= option. Related options are HAXIS= and VAXIS2=.

VAXIS2=*value-list*

VAXIS2=AXIS*n*

specifies major tick mark values for the vertical axis of a secondary chart. The specifications and restrictions are the same as for the VAXIS= option. The VAXIS2= option is available in the IRCHART, MRCHART, XRCHART, and XSCHART statements and in the BOXCHART, MCHART, and XCHART statements with the TRENDVAR= option. Related options are HAXIS= and VAXIS=.

VFORMAT=*format*

specifies a format to be used for displaying tick mark labels on the vertical axis of a primary chart.

VFORMAT2=*format*

specifies a format to be used for displaying tick mark labels on the vertical axis of a secondary chart.

VMINOR=*n*

VM=*n*

specifies the number of minor tick marks between each major tick mark on the vertical axis. *Traditional Graphics*
No values are printed on the minor tick marks. By default, VMINOR=0.

VOFFSET=*value*

specifies the length of the offset at the ends of the vertical axis. For traditional graphics, the offset is specified in percent screen units. For ODS Graphics output, the offset is specified in pixels. *Traditional Graphics*
ODS Graphics

VREF=*value-list*

VREF=SAS-*data-set*

draws reference lines perpendicular to the vertical axis on the primary chart. Reference line values can be expressed as simple values or as multiples of the standard error of the subgroup summary statistic. You can use this option in the following ways:

- Specify the *values* for the lines with a VREF= list. Examples of the VREF= option follow:

```
vref=20
vref=20 40 80
vref=(2.5 sigma)
vref=20 (1.5 2.0 2.5 sigma) 80
```

Values expressed as multiples of σ must be enclosed in parentheses with the SIGMA keyword.

- Specify the values for the lines as the values of a numeric variable named `_REF_` in a `VREF=` data set. Optionally, you can provide labels for the lines as values of a variable named `_REFLAB_`, which must be a character variable of length 16 or less. If you want distinct reference lines to be displayed in charts for different *processes* specified in the chart statement, you must include a character variable of length 32 or less named `_VAR_`, whose values are the *processes*. If you do not include the variable `_VAR_`, all of the lines are displayed in all of the charts. If you want to display reference lines whose values are multiples of σ , you must include a character variable named `_TYPE_`, whose values are “VALUES” or “SIGMAS.” The value of `_TYPE_` indicates whether the reference line value is expressed as a simple value or as a multiple of σ .

Each observation in the `VREF=` data set corresponds to a reference line. If `BY` variables are used in the input data set (`DATA=`, `HISTORY=`, or `TABLE=`), the same `BY` variable structure must be used in the `VREF=` data set unless you specify the `NOBYREF` option.

This option can be used to add warning limits to be displayed on a chart.

Related options are `CVREF=`, `LVREF=`, `NOBYREF`, `VREFCHAR=`, `VREFLABELS=`, and `VREFLABPOS=`.

VREF2=*value-list*

VREF2=*SAS-data-set*

draws reference lines perpendicular to the vertical axis on the secondary chart. The conventions for specifying the `VREF2=` option are identical to those for specifying the `VREF=` option. Related options are `CVREF=`, `LVREF=`, `NOBYREF`, `VREFCHAR=`, `VREF2LABELS=`, and `VREFLABPOS=`. The `VREF2=` option is available in the `IRCHART`, `MRCHART`, `XRCHART`, and `XSCHART` statements and in the `BOXCHART`, `MCHART`, and `XCHART` statements with the `TRENDVAR=` option.

VREF2LABELS=*'label1' ... 'labeln'*

VREF2LAB=*'label1' ... 'labeln'*

specifies labels for the reference lines requested by the `VREF2=` option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters. The `VREF2LABELS=` option is available in the `IRCHART`, `MRCHART`, `XRCHART`, and `XSCHART` statements and in the `BOXCHART`, `MCHART`, and `XCHART` statements with the `TRENDVAR=` option.

VREFCHAR=*'character'*

Line Printer

specifies the character used for reference lines requested by the `VREF=` and `VREF2=` options on line printer charts. The default is the hyphen (-).

VREFLABELS=*'label1' ... 'labeln'*

specifies labels for the reference lines requested by the `VREF=` option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

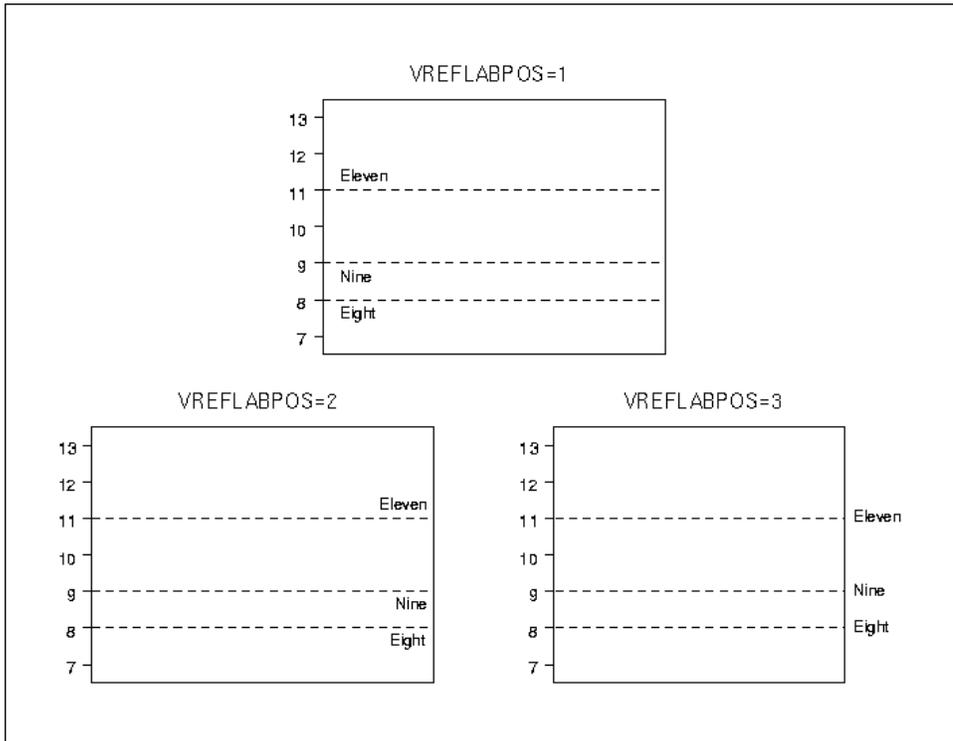

specifies the horizontal position of the VREFLABEL= and VREF2LABEL= labels, as described in the following table. By default, *n* = 1.

<i>n</i>	Label Position
1	left-justified in subplot area
2	right-justified in subplot area
3	left-justified in right margin

Figure 17.142 illustrates label positions for values of the VREFLABPOS= option when the VREF= and VREFLABELS= options are as follows:

```
vref      = 8 9 11
vreflabels = 'Eight' 'Nine' 'Eleven'
```

Figure 17.142 Positions for Reference Line Labels

VZERO

forces the origin to be included in the vertical axis for a primary chart.

VZERO2

forces the origin to be included in the vertical axis for a secondary chart.

WAXIS=*n*

specifies the width in pixels for the axis and frame lines. By default, *n* = 1.

WBOXES=*n*

ODS Graphics specifies the width in pixels for the outlines of the box-and-whisker plots created with the BOXCHART statement in ODS Graphics output.

WEBOUT=*SAS-data-set*

Traditional Graphics produces an output data set containing all the data in an OUTTABLE= data set plus graphics coordinates for points (subgroup summary statistics) that are displayed on a control chart. You can use an WEBOUT= data set to facilitate the development of web-based applications. See “[Interactive Control Charts: SHEWHART Procedure](#)” on page 2212 for details.

WGRID=*n*

Traditional Graphics specifies the width in pixels for grid lines requested with the ENDGRID and GRID options. By default, $n = 1$.

WLIMITS=*n*

Traditional Graphics specifies the width in pixels for the control limits and central line. By default, $n = 1$.

WNEEDLES=*n*

Traditional Graphics specifies the width in pixels of needles connecting plotted points to the central line, as requested with the NEEDLES option. If you use the WNEEDLES= option, you do not need to specify the NEEDLES option. By default, $n = 1$.

WOVERLAY=(*value-list*)

Traditional Graphics specifies the widths in pixels for the line segments connecting points on primary chart overlay plots. Widths in the WOVERLAY= list are matched with variables in the corresponding positions in the OVERLAY= list.

WOVERLAY2=(*value-list*)

Traditional Graphics specifies the widths in pixels for the line segments connecting points on secondary chart overlay plots. Widths in the WOVERLAY2= list are matched with variables in the corresponding positions in the OVERLAY2= list.

WSTARCIRCLES=*n*

Traditional Graphics specifies the width in pixels of the outline of circles requested by the STARCIRCLES= option. See “[Displaying Auxiliary Data with Stars](#)” on page 2114. By default, $n = 1$.

WSTARS=*n*

Traditional Graphics specifies the width in pixels of the outline of stars requested by the STARVERTICES= option. See “[Displaying Auxiliary Data with Stars](#)” on page 2114. By default, $n = 1$.

WTESTS=*n***WTEST=*n***

Traditional Graphics specifies the width in pixels of the line segments that connect patterns of points for which a test for special causes (requested with the TESTS= or TESTS2= option) is positive. By default, $n = 1$.

WTREND=*n*

Traditional Graphics specifies the width in pixels of the line segments that connect points on trend charts requested with the TRENDVAR= option. By default, $n = 1$. The WTREND= option is available in the BOXCHART, MCHART, and XCHART statements.

XSYMBOL=*'label'*

XSYMBOL=*keyword*

specifies a label for the central line in an \bar{X} chart or a median chart. You can use the option in the following ways:

- You can specify a quoted *label* up to 16 characters.
- You can specify one of the *keywords* listed in the following table. Each *keyword* requests a label of the form *symbol=value*, where *symbol* is the symbol given in the table, and *value* is the value of the central line. If the central line is not constant, only the symbol is displayed.

Keyword	Symbol Used in	
	Graphics	Line Printer Charts
MBAR	\bar{M}	\bar{M}
MTIL	\tilde{M}	\tilde{M}
MU	μ	MU
MU0	μ_0	MU0
XBAR	\bar{X}	\bar{X}
XBAR2	$\bar{\bar{X}}$	$\bar{\bar{X}}$
XBARPM	\bar{X}'	\bar{X}'
XBAR0	\bar{X}_0	$\bar{X}0$
XBAR0PM	\bar{X}'_0	$\bar{X}'0$

For the IRCHART statement, the default *keyword* is XBAR. For the MCHART and MRCHART statements, the default *keyword* is MBAR. For all other chart statements, the default *keyword* is XBAR2. The XSYMBOL= option is available in the BOXCHART, IRCHART, MCHART, MRCHART, XCHART, XRCHART, and XSCHART statements.

YPCT1=*value*

specifies a percent (ranging from 0 to 100) that determines the length of the vertical axis for the primary chart in proportion to the sum of the lengths of the vertical axes for the primary and secondary charts. For example, you can specify YPCT1=50 in an XRCHART statement to request that the vertical axes for the \bar{X} and *R* charts have the same length. The default *value* is 60. The YPCT1= option is available in the IRCHART, MRCHART, XRCHART, and XSCHART statements and in the BOXCHART, MCHART, and XCHART statements with the TRENDVAR= option.

YSCALE=PERCENT

scales the vertical axis on a *p* chart in percent units. The YSCALE= option is available only in the PCHART statement.

ZEROSTD

ZEROSTD=NOLIMITS

specifies that a control chart is to be constructed and displayed regardless of whether the estimated process standard deviation $\hat{\sigma}$ is zero. When $\hat{\sigma}$ is zero, the control limits are degenerate (collapsed around the central line), and the chart simply serves as a placeholder, particularly

when a series of charts is to be created. Specify `ZEROSTD=NOLIMITS` to suppress the display of the degenerate limits. By default, a chart is not displayed when $\hat{\sigma}$ is zero.

ZONE2LABELS

adds the labels A, B, and C to zone lines requested with the `ZONES2` or `ZONE2VALUES` options. The `ZONE2LABELS` option is available in the `MRCHART`, `RCHART`, `SCHART`, `XRCHART`, and `XSCHART` statements.

ZONE2VALUES

labels *R* or *s* chart zones lines with their values. If the `ZONE2VALUES` option is specified the `ZONES2` option is not required.

ZONECHAR='character'

Line Printer

specifies the character used to form the zone lines requested by the `ZONES` option. See the entry for the `TESTS=` option for a description of the zones. You do not need to specify the `ZONES` option if you specify the `ZONECHAR=` option. By default, the line between Zone A and Zone B uses the character 'B', and the line between Zone B and Zone C uses the character 'C'. Related options are `TESTS=`, `TESTS2=`, `ZONES`, and `ZONES2`.

ZONELABELS

adds the labels A, B, and C to zone lines requested with the `ZONES` or `ZONEVALUES` options. The `ZONELABELS` option is not available in the `RCHART` or `SCHART` statements.

ZONES

adds lines to a primary chart that delineate zones A, B, and C for standard tests requested with the `TESTS=` option. Related options are `CZONES=` and `ZONELABELS`. The `ZONES` option is not available in the `RCHART` or `SCHART` statements.

ZONES2

adds lines to an *R* or *s* chart that delineate zones A, B, and C for tests requested with the `TESTS2=` option. Related options are `CZONES=` and `ZONE2LABELS`. The `ZONES2` option is available in the `MRCHART`, `RCHART`, `SCHART`, `XRCHART`, and `XSCHART` statements.

ZONEVALPOS=*n*

specifies the horizontal position of the `ZONEVALUES=` and `ZONE2VALUES=` labels, as described in the following table. By default, *n* = 1.

<i>n</i>	Label Position
1	left-justified in subplot area
2	right-justified in subplot area
3	left-justified in right margin

ZONEVALUES

labels the primary chart zones lines with their values. If the `ZONEVALUES` option is specified the `ZONES` option is not required.

Graphical Enhancements: SHEWHART Procedure

Overview: Graphical Enhancements

This section provides details on the following topics:

- displaying process data stratified into levels using a *symbol-variable*
- displaying process data stratified into blocks using *block-variables*
- displaying process data stratified into time phases using the READPHASES= option
- displaying multiple sets of control limits using the READPHASES= and READINDEXES= options
- displaying multivariate process data using star charts
- displaying trends in process data
- clipping extreme points to create more readable charts
- labeling axes
- selecting subgroups for computation and display

The options described in this section can be specified in all the chart statements available in the SHEWHART procedure.

Displaying Stratified Process Data

If the data for a Shewhart chart can be classified by factors relevant to the process (for instance, machines or operators), displaying the classification on the chart can facilitate the identification of special or common causes of variation that are related to the factors. Kume (1985) refers to this type of classification as “stratification” and describes various ways to create stratified control charts.

There are important differences between stratification and subgrouping. The data must always be classified into subgroups before a control chart can be produced. Subgrouping affects how control limits are computed from the data as well as the outcome of tests for special causes (see “[Tests for Special Causes: SHEWHART Procedure](#)” on page 2146). The values of the *subgroup-variable* specified in the chart statement classify the data into subgroups. In contrast, stratification is optional and involves classification variables other than the *subgroup-variable*. Displaying stratification influences how the chart is interpreted, but it does not affect control limits or tests for special causes.

This section describes three types of variables that you can specify to create stratified control charts.

- A *symbol-variable* stratifies data into levels of a classification variable.

- The *block-variables* stratify data into blocks of consecutive observations.
- A *_PHASE_* variable stratifies data into *time phases*.

You can specify any combination of these three variables. You should be careful, however, since it is possible to generate confusing charts by overusing these methods.

The data for the examples in this section consist of diameter measurements for a part produced on one of three different machines. Three subgroups, each consisting of six parts, are sampled each day, corresponding to three shifts worked each day. The data are provided in the data set *Parts*, which is created by the following statements:

```

data Parts;
  length Machine $ 4;
  input Sample Machine $ Day Shift DiamX DiamS;
  DiamN=6;
  datalines;
1  A386  01  1  4.32  0.39
2  A386  01  2  4.49  0.35
3  A386  01  3  4.44  0.44
4  A386  02  1  4.45  0.17
5  A386  02  2  4.21  0.53
6  A386  02  3  4.56  0.26
7  A386  03  1  4.63  0.39
8  A386  03  2  4.38  0.47
9  A386  03  3  4.47  0.40
10 A455  04  1  4.42  0.37
11 A455  04  2  4.45  0.32
12 A455  04  3  4.62  0.36
13 A455  05  1  4.33  0.31
14 A455  05  2  4.29  0.33
15 A455  05  3  4.17  0.25
16 C334  08  1  4.15  0.28
17 C334  08  2  4.21  0.33
18 C334  08  3  4.16  0.19
19 C334  09  1  4.14  0.13
20 C334  09  2  4.11  0.19
21 C334  09  3  4.10  0.27
22 C334  10  1  3.99  0.14
23 C334  10  2  4.24  0.16
24 C334  10  3  4.23  0.14
25 A386  11  1  4.27  0.28
26 A386  11  2  4.70  0.45
27 A386  11  3  4.51  0.45
28 A386  12  1  4.34  0.16
29 A386  12  2  4.38  0.29
30 A386  12  3  4.28  0.24
31 A386  15  1  4.47  0.26
32 A386  15  2  4.31  0.46
33 A386  15  3  4.52  0.33
;

```

Displaying Stratification in Levels of a Classification Variable

To display process data stratified into levels of a classification variable, specify the name of this variable after an equal sign (=) immediately following the *subgroup-variable* in the chart statement. *See SHWSYM1 in the SAS/QC Sample Library* The classification variable, referred to as the *symbol-variable*, must be a variable in the input data set (a DATA=, HISTORY=, or TABLE= data set). The subgroup summary statistics are classified into groups according to the levels of the *symbol-variable* and are identified on the chart with unique plotting symbols.

When you produce traditional graphics output, you can specify the symbols with SYMBOL statements. It is recommended that you place the SYMBOL statements before the PROC SHEWHART statement. If you omit the SYMBOL statements, the procedure uses the default symbol (+) for all levels of the *symbol-variable* but plots the points for each level in a distinct color. The following example illustrates the use of a *symbol-variable* to stratify the points on an \bar{X} chart according to the machine that produced the parts in each subgroup:

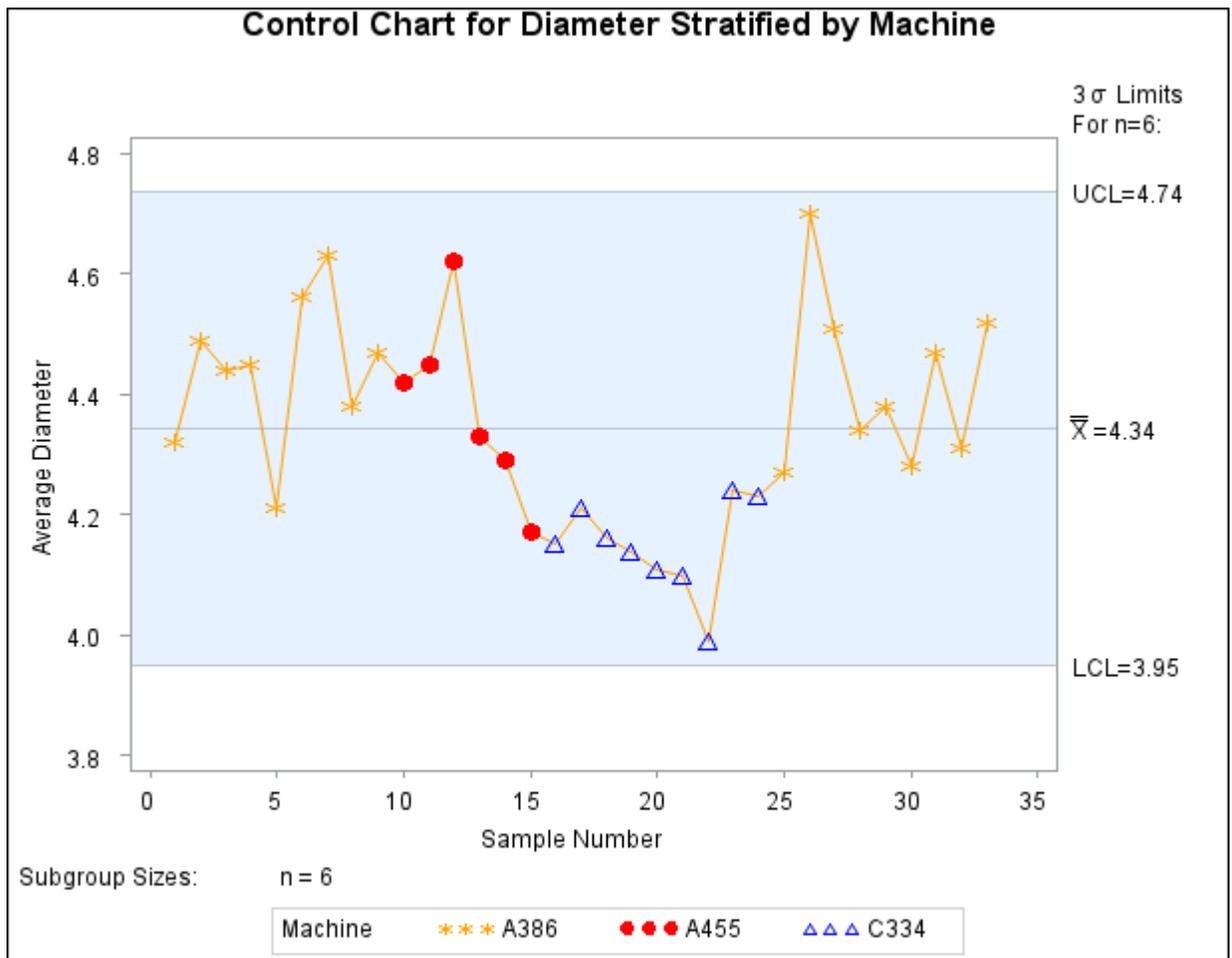

```
ods graphics off;
symbol1 c=orange value=star      h=3.0 pct;
symbol2 c=red    value=dot       h=3.0 pct;
symbol3 c=blue   value=triangle  h=3.0 pct;
title 'Control Chart for Diameter Stratified by Machine';
proc shewhart history=Parts;
    xchart Diam*Sample=Machine / stddeviations
                                symbollegend = legend1;
    label Sample = 'Sample Number'
          DiamX  = 'Average Diameter' ;
    legend1 frame label=('Machine');
run;
```

The symbols are specified with the SYMBOL1, SYMBOL2, and SYMBOL3 statements. The SYMBOLLEGEND= option requests a customized legend for the symbols. For more information about the LEGEND and SYMBOL statements, refer to *SAS/GRAPH: Reference*. The \bar{X} chart, shown in Figure 17.143, reveals an effect due to Machine. In particular, Machine C334 is associated with a run of parts whose diameters are systematically below average, suggesting that this machine may require adjustment.

For line printer charts, you can use the SYMBOLCHARS= option to specify the characters that identify the stratification of the points. For details, see the entry for the SYMBOLCHARS= option in “Dictionary of Options: SHEWHART Procedure” on page 2018.

In this example, Machine A386 is associated with two different blocks of observations that are identified with a common symbol. However, a *symbol-variable* is particularly useful for situations where the stratification is not necessarily chronological or associated with blocks of consecutive groups of observations.

Figure 17.143 Control Chart Stratified into Levels Using Symbols

Displaying Stratification in Blocks of Observations

See SHWBLK in the SAS/QC Sample Library

To display process data stratified into blocks of consecutive observations, specify one or more *block-variables* in parentheses after the *subgroup-variable* in the chart statement. The procedure displays a legend identifying blocks of consecutive observations with identical values of the *block-variables*. The legend displays one track of values for each *block-variable*. The values are the formatted values of the *block-variable*. For example, Figure 17.144 displays a legend with a single track for Machine, while Figure 17.145 displays a legend with two tracks corresponding to Machine and Day. You can label the tracks themselves by using the LABEL statement to associate labels with the corresponding *block-variables*; see Figure 17.146 for an illustration.

By default, the legend is placed above the chart as in Figure 17.144. You can control the position of the legend with the BLOCKPOS= option and the position of the legend labels with the BLOCKLABELPOS= option. See the entries in “Dictionary of Options: SHEWHART Procedure” on page 2018 as well as the following examples.

The *block-variables* must be variables in the input data set (a DATA=, HISTORY=, or TABLE= data set). If the input data set is a DATA= data set that contains multiple observations with the same value of the *subgroup-variable*, the values of a *block-variable* must be the same for all observations

with the same value of the *subgroup-variable*. In other words, subgroups must be nested within groups determined by *block-variables*. The following statements create an \bar{X} chart for the data in Parts stratified by the *block-variable* Machine. The chart is shown in Figure 17.144.

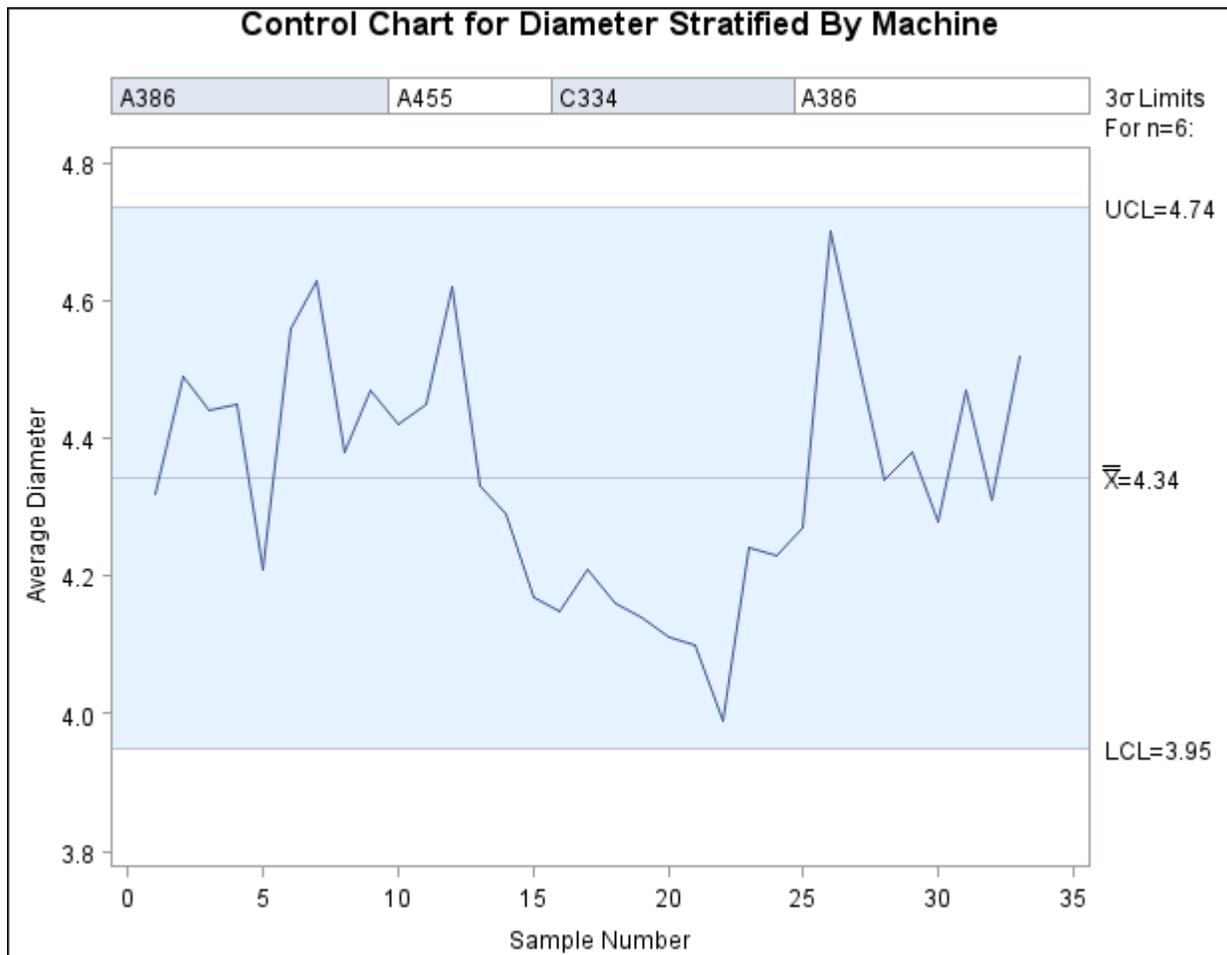

```

symbol h=3.0 pct;
title 'Control Chart for Diameter Stratified By Machine';
proc shewhart history=Parts;
  xchart Diam*Sample (Machine) / stddeviations
                                nolegend ;
  label Sample = 'Sample Number'
        DiamX = 'Average Diameter' ;
run;

```

The unique consecutive values of Machine ('A386', 'A455', 'C334', and 'A386') are displayed in a track above the chart, and they indicate the same relationship between part diameter and machine as the previous example. Note that the track is not labeled (as in Figure 17.146), since no label is associated with Machine. A LABEL statement is used to provide labels for the axes.

Figure 17.144 Stratified Control Chart Using a Single Block Variable

Multiple block variables. You can use multiple *block-variables* to study more than one classification factor with the same chart. The following statements create an \bar{X} chart for the data in Parts,

with Machine and Day as *block-variables*:

```

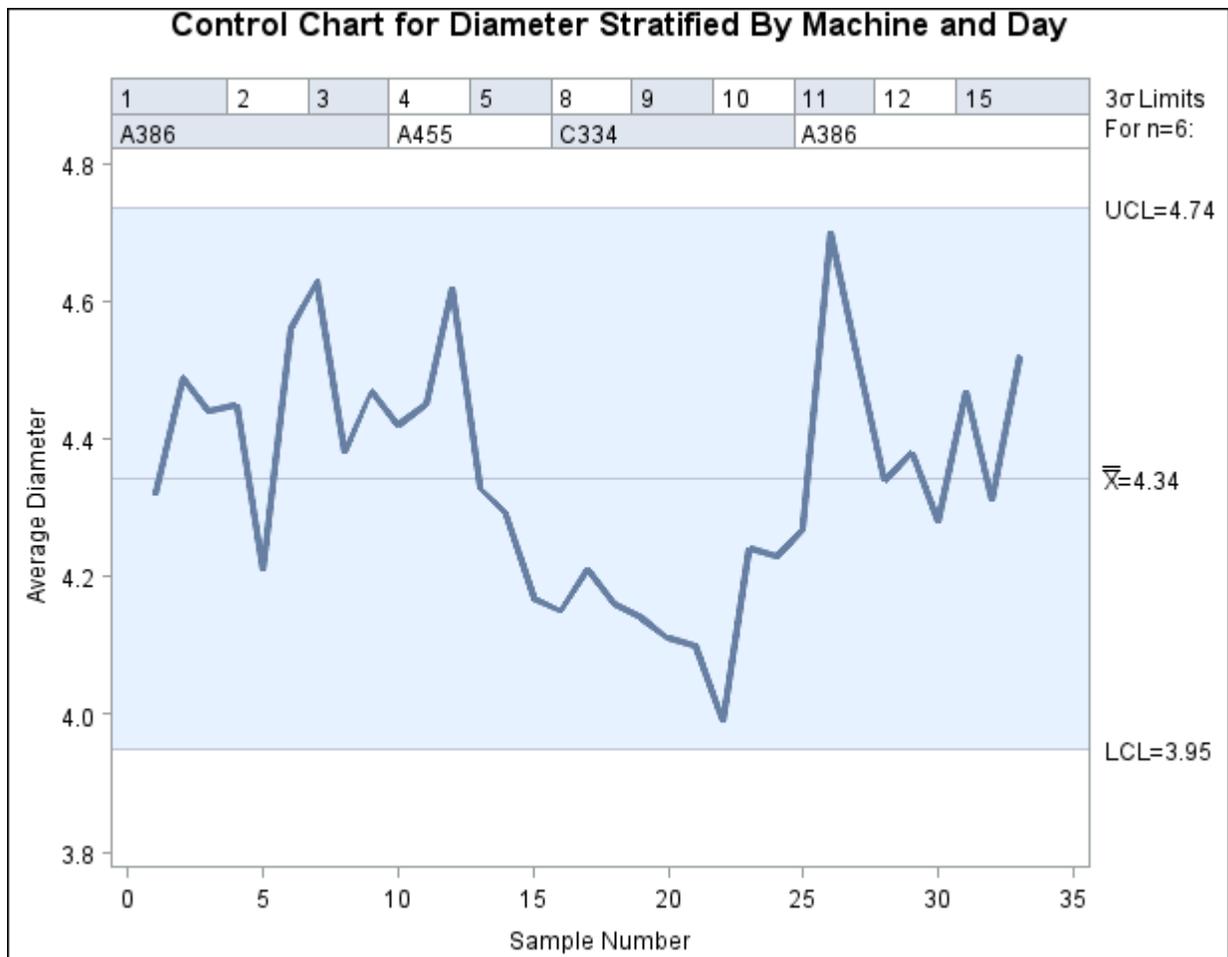

title 'Control Chart for Diameter Stratified By Machine and Day';
proc shewhart history=Parts;
  xchart Diam*Sample (Machine Day) / stddeviations
                                nolegend
                                blockpos = 2;

  label Sample = 'Sample Number'
        DiamX = 'Average Diameter' ;
run;

```

The chart is displayed in Figure 17.145. Specifying BLOCKPOS=2 displays the *block-variable* legend immediately above the chart, without the gap shown in Figure 17.144. The NOLEGEN option suppresses the sample size legend that appears in the lower left of Figure 17.144.

Figure 17.145 Stratified Control Chart Using Multiple Block Variables

Color fills for legend. You can use the CBLOCKVAR= option to fill the legend track sections with colors corresponding to the values of the *block-variables*. Provide the colors as values of variables specified with the CBLOCKVAR= option. The procedure matches the color variables with the *block-variables* in the order specified. Each section is filled with the color for the first observation in the block. For example, the following statements produce an \bar{X} chart using a color variable

named CMachine to fill the legend for the *block-variable* Machine:

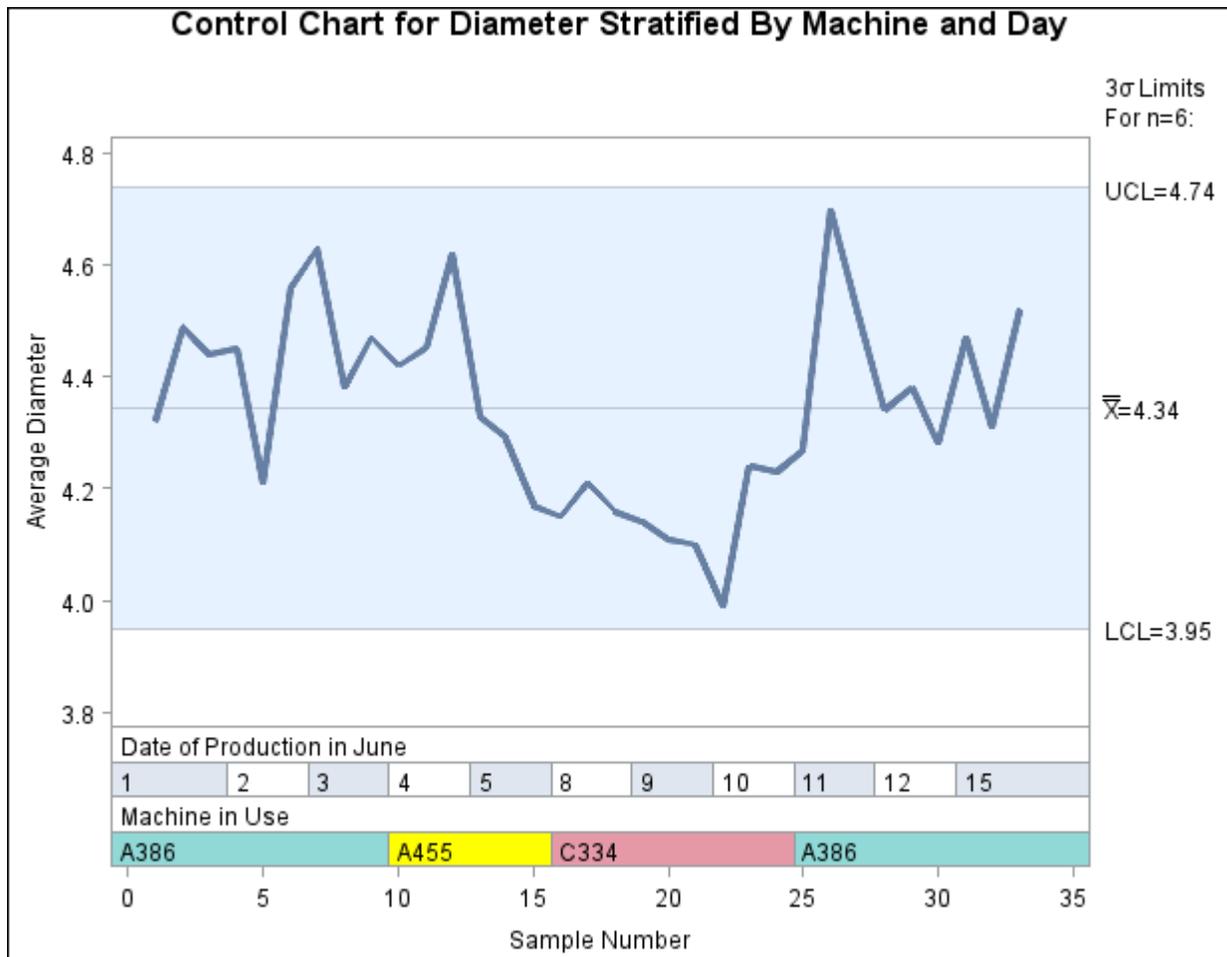

```

title 'Control Chart for Diameter Stratified By Machine and Day';
proc shewhart history=Parts2;
  xchart Diam*Sample (Machine Day) / stddeviations
                                nolegend
                                blockpos = 3
                                cblockvar = CMachine;

  label Sample = 'Sample Number'
        DiamX  = 'Average Diameter'
        Day    = 'Date of Production in June'
        Machine = 'Machine in Use';
run;

```

Figure 17.146 Color Fill for *Block-Variable* Legend

The sections for Machine A386, Machine A455, and Machine C334 are filled with the colors specified as values of CMachine. The legend track for Day is filled with the default alternating colors from the ODS style, because a second color variable was not specified with the CBLOCKVAR= option. Specifying BLOCKPOS=3 positions the legend at the bottom of the chart and facilitates comparison with the subgroup axis. The LABEL statement is used to label the tracks with the labels associated with the *block-variables*.

The following statements produce an \bar{X} chart in which both legend tracks are filled:

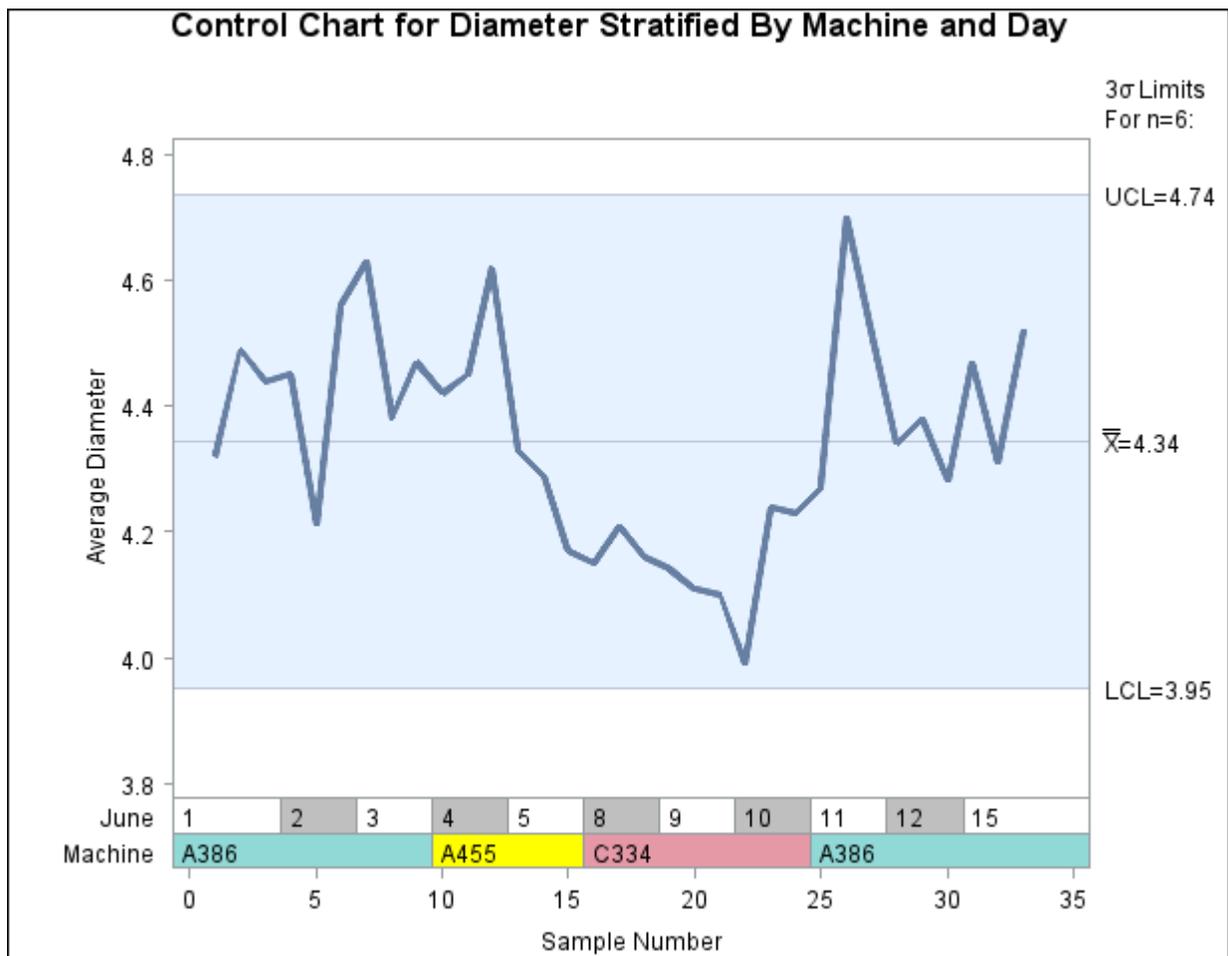

```

title 'Control Chart for Diameter Stratified By Machine and Day';
proc shewhart history=Parts3;
  xchart Diam*Sample (Machine Day) /
    stddeviations
    nolegend
    ltmargin      = 5
    blockpos      = 3
    blocklabelpos = left
    cblockvar     = (CMachine CDay);
  label Sample   = 'Sample Number'
        DiamX    = 'Average Diameter'
        Day      = 'June'
        Machine  = 'Machine';
run;

```

The chart is displayed in Figure 17.147. The color values of CMachine are used to fill the track for Machine, and the color values of CDay are used to fill the track for Day. Specifying BLOCKLABELPOS=LEFT displays the block variable labels to the left of the block legend. The LTMARGIN= option provides extra space in the left margin to accommodate the label *Machine*.

Figure 17.147 Stratified Control Chart Using Multiple Block Variables

Displaying Stratification in Phases

The preceding section describes the use of *block-variables* to display blocks of consecutive observations that correspond to changes in factors such as machines, shifts, and raw materials. This section describes the use of a *_PHASE_ variable* to display phases of consecutive observations (as in Figure 17.148). Although the terms *block* and *phase* have similar meanings, there are differences in the two methods:

- You can provide only one *_PHASE_ variable*, whereas you can specify multiple *block-variables*.
- You can display distinct control limits for each phase (see “Displaying Multiple Sets of Control Limits” on page 2105) but not for each block.
- Different sets of graphical options are available for identifying blocks and phases.

To display phases, your input data set must include a character variable named *_PHASE_* of length 48 or less, and you must specify the *READPHASES=* option in the chart statement. (If your data set does not include a variable named *_PHASE_*, you can temporarily rename another character variable to *_PHASE_*, as illustrated by the following statements.) The procedure classifies the data into phases (groups of consecutive observations with the same value of *_PHASE_*) and reads only those observations whose *_PHASE_* value matches one of the values specified with the *READPHASES=* option.

You can identify and highlight the phases with various options, as illustrated by the following statements, which produce the chart shown in Figure 17.148. The *PHASELEGEND* option displays a legend with the *_PHASE_* values, and the *CPHASELEG=* option specifies the color of the legend text. The *PHASEREF* option delineates the phases with vertical reference lines. The *CFRAME=* option fills the framed areas for the phases with different colors.

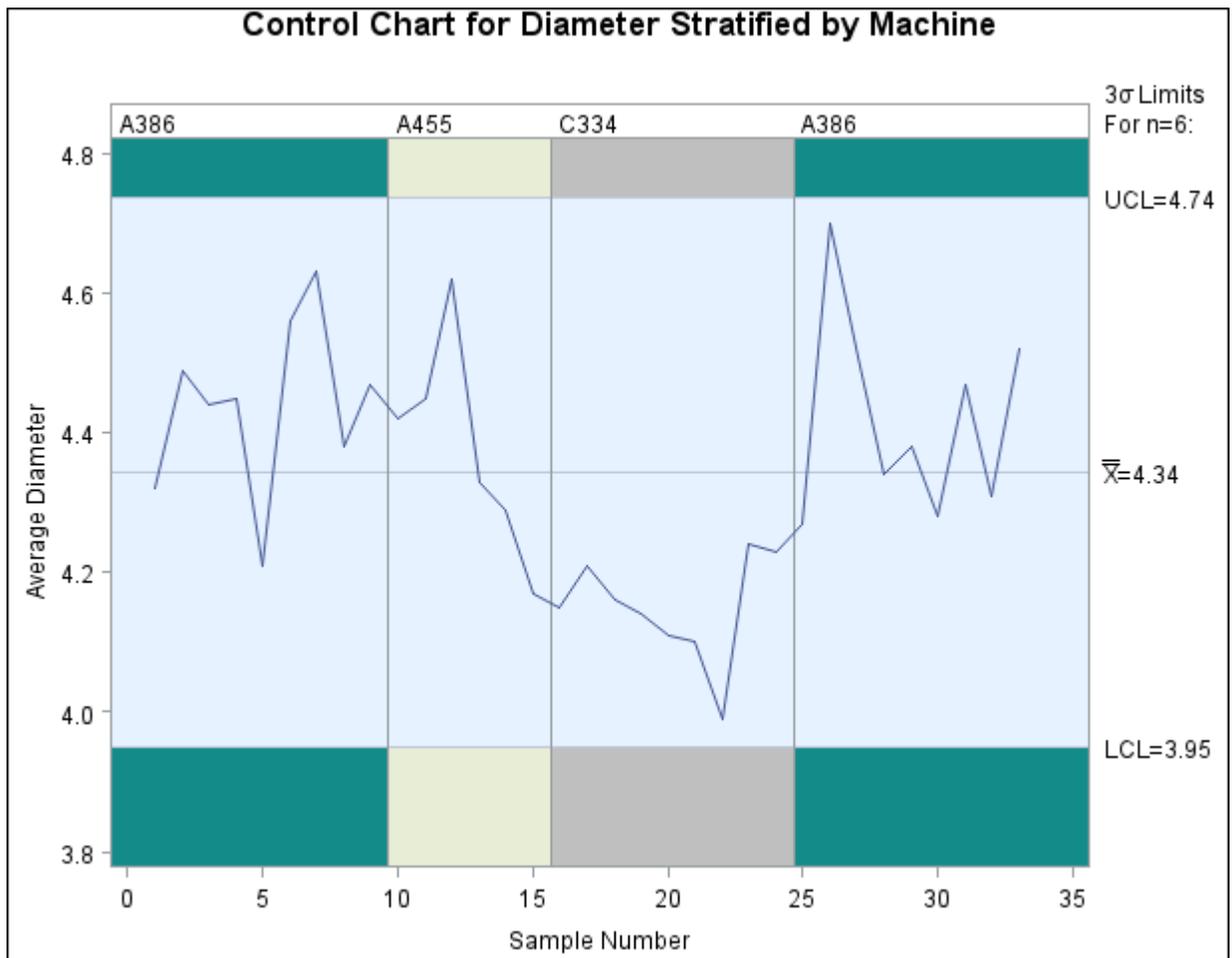

```

title 'Control Chart for Diameter Stratified by Machine';
proc shewhart history=Parts(rename=(Machine=_phase_));
  xchart Diam*Sample /
    stddeviations
    readphases = ('A386' 'A455' 'C334' 'A386')
    cframe      = ( vibg  ywh  ligr  vibg )
    phaselegend
    cphaseleg   = black
    phaseref
    nolegend;
  label Sample = 'Sample Number'
         DiamX  = 'Average Diameter';
run;

```

See *SHWPHASE* in the *SAS/QC Sample Library*

Figure 17.148 Control Chart Stratified by Phases

Note that the data set `Parts` does not contain a variable named `_PHASE_`, so the variable `Machine` is renamed as `_PHASE_` for the duration of the procedure step.

The observations read from `Parts` are those whose value of `Machine` matches one of the values listed with the `READPHASES=` option in that order. Here, the value 'A386' is listed twice; consequently, both groups of observations for which `Machine` equals 'A386' are read.

In this example, the input data set contains a single observation for each subgroup. If your input data set is a `DATA=` data set that contains multiple observations with the same value of the *subgroup-variable*, the value of `_PHASE_` must be the same for all observations with the same value of the *subgroup-variable*. Thus, in general, subgroups must be nested within phases.

Recall that the horizontal axis scale is determined by the *subgroup-variable* (see "Subgroup Variables" on page 1938). If your *subgroup-variable* is numeric, this scale is continuous; consequently, you should select phases that are reasonably contiguous in order to avoid large empty gaps in your chart. For instance, if you were to specify

```
readphases = ('A386' 'A455' 'A386')
```

in the preceding `XCHART` statement, there would be a gap between the 15th and 25th points (these points would be connected unless you specified the `PHASEBREAK` option). You can avoid gaps

by specifying a character *subgroup-variable*⁴⁴ for which a discrete horizontal axis scale will be displayed.

Note that the values listed in the READPHASES= option must be listed in the same order as they occur in the input data set. Thus, in order to display all the observations in the data set Parts, 'A386' must be listed as both the first and last value. An alternative method for selecting all the phases from your input data is to specify READPHASES=ALL, as described in the next section.

The control limits shown in Figure 17.148 are computed from the data and are, therefore, the same across all phases. More generally, you can display a distinct set of control limits for each phase. To do so, you must provide the control limits in a LIMITS= data set and specify the READINDEXES= option in addition to the READPHASES= option, as described in the next section.

Displaying Multiple Sets of Control Limits

This section describes the use of the READPHASES= and READINDEXES= options for creating Shewhart charts that display distinct sets of control limits for multiple phases of observations. The term *phase* refers to a group of consecutive observations in the input data set. For example, the phases might correspond to the time periods during which a new process was brought into production and then put through successive changes. *See SHWCLMS in the SAS/QC Sample Library*

To display phases, your input data must include a character variable named `_PHASE_`, whose length cannot exceed 48. (If your data set does not include a variable named `_PHASE_`, you can temporarily rename another character variable to `_PHASE_`, as illustrated in the statements in the section “Displaying Stratification in Phases” on page 2103.) Each phase consists of a group of consecutive observations with the same value of `_PHASE_`.

To display distinct sets of predetermined control limits for the phases, you must provide the limits in a LIMITS= data set. This data set must include a character variable named `_INDEX_`, whose length cannot exceed 48. This variable identifies the sets of control limits (observations) in the LIMITS= data set that are to be associated with the phases. This data set must also include a number of other variables with reserved names that begin and end with an underscore. The particular structure of a LIMITS= data set depends on the chart statement that you are using; for details, see the sections titled “LIMITS= Data Set” in the sections for the various chart statements. In addition to specifying a LIMITS= data set, you must also specify the READINDEXES= and READPHASES= options in the chart statement.

NOTE: To display a *single* set of predetermined control limits with multiple phases, simply specify a LIMITS= data set in the procedure statement. If you are using SAS 6.09 or an earlier release, you must also specify the READLIMITS option. The control limits are read from the first observation in the LIMITS= data for which the variable `_VAR_` is equal to the name of the *process* and the variable `_SUBGRP_` is equal to the name of the *subgroup-variable*. For an example, see “Reading Preestablished Control Limits” on page 1915.

This section describes the combinations of the READINDEXES= and READPHASES= options that you can specify. The examples that follow use the HISTORY= data set Flange listed in Figure 17.149 and the LIMITS= data set Flangelim listed in Figure 17.150. The data in Flange consist

⁴⁴You can use the PUT function in a DATA step to create a character *subgroup-variable* from a numeric *subgroup-variable*.

of means and ranges of flange width measurements for subgroups of size five. The observations are grouped into three phases determined by the `_PHASE_` values 'Production', 'Change 1', and 'Change 2'. Three sets of control limits are provided in `Flangelim`, corresponding to the `_INDEX_` values 'Start', 'Production', and 'Change 1'.

For each of the READINDEXES= and READPHASES= options, you can specify a single value, a list of values, or the keyword ALL. You can also leave these options unspecified. Thus, there are 16 possible combinations of specifications for the two options, as explained by the following table and notes. The two most commonly encountered combinations are

- reading a single set of limits for one or more phases (see Case 1)
- reading a set of limits matched with a set of phases (see Case 4)

READINDEXES=	READPHASES=			
	Single Value	Multiple Values	Keyword ALL	Not Specified
Single Value	See Case 1	See Case 1	See Case 2	See Case 3
Multiple Values	See Case 9	See Case 4	See Case 2	See Case 2
Keyword ALL	See Case 5	See Case 5	See Case 6	See Case 6
Not Specified	See Case 7	See Case 7	See Case 8	See Case 8

Case 1. READPHASES=*value|value-list* and READINDEXES=*value*

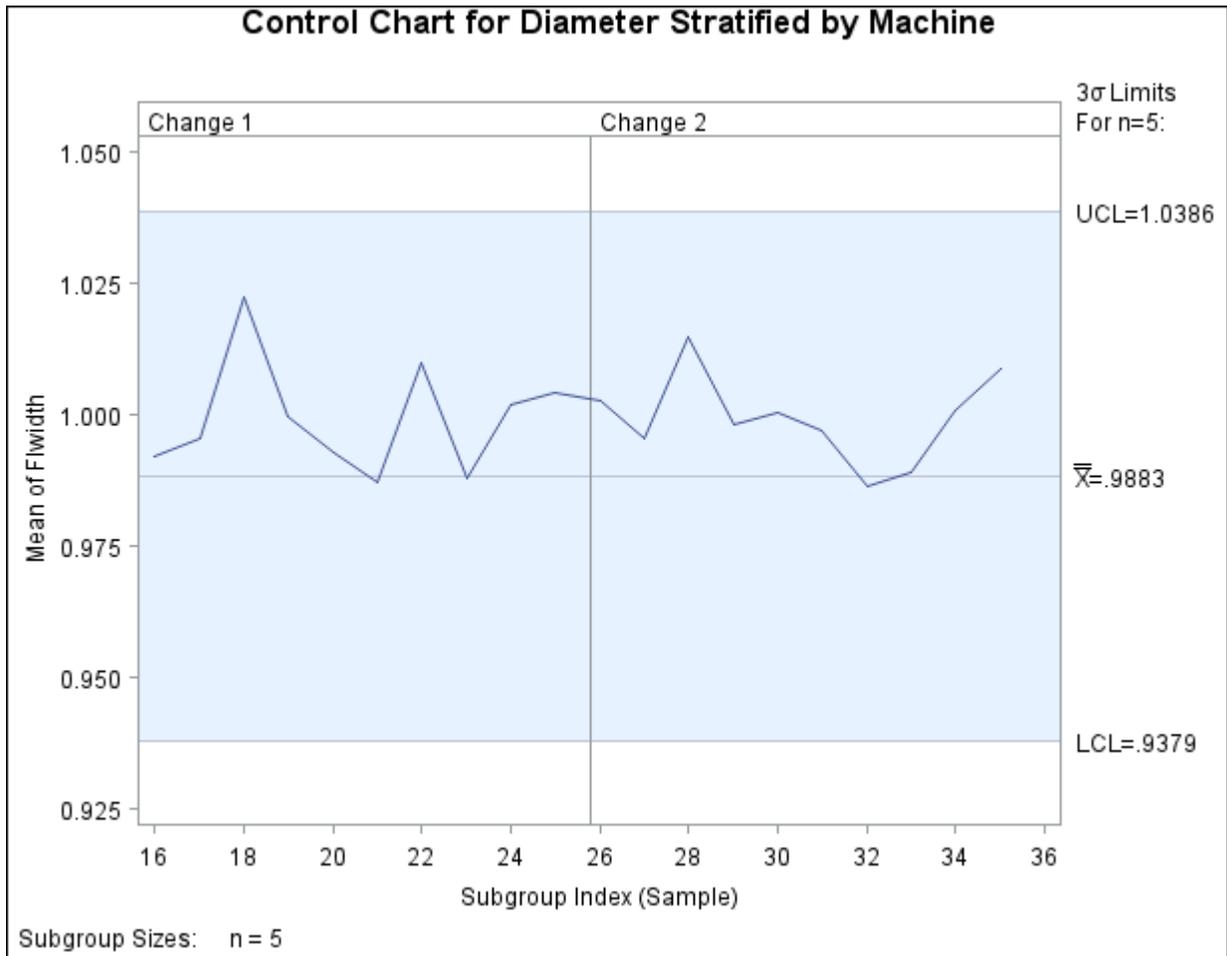

The only phases (groups of observations) read are those for which `_PHASE_` equals one of the *values* specified with the READPHASES= option. The chart displays a single set of control limits given by the first observation in the LIMITS= data set for which `_INDEX_` is equal to the READINDEXES= *value*.

For example, the following statements create a chart for the phases ‘Change 1’ and ‘Change 2’, with control limits read from the second observation in Flangelim. The chart is displayed in Figure 17.151.

```

symbol v = none;
proc shewhart history=Flange limits=Flangelim;
  xchart Flwidth*Sample /
    readphase = ('Change 1' 'Change 2')
    readindex = ('Production')
    phaseref
    phaselegend;
run;

```

Figure 17.151 A Single Set of Control Limits for Multiple Phases

Case 2. READPHASES=ALL and READINDEXES=value|value-list or READPHASES= is omitted and READINDEXES=value-list

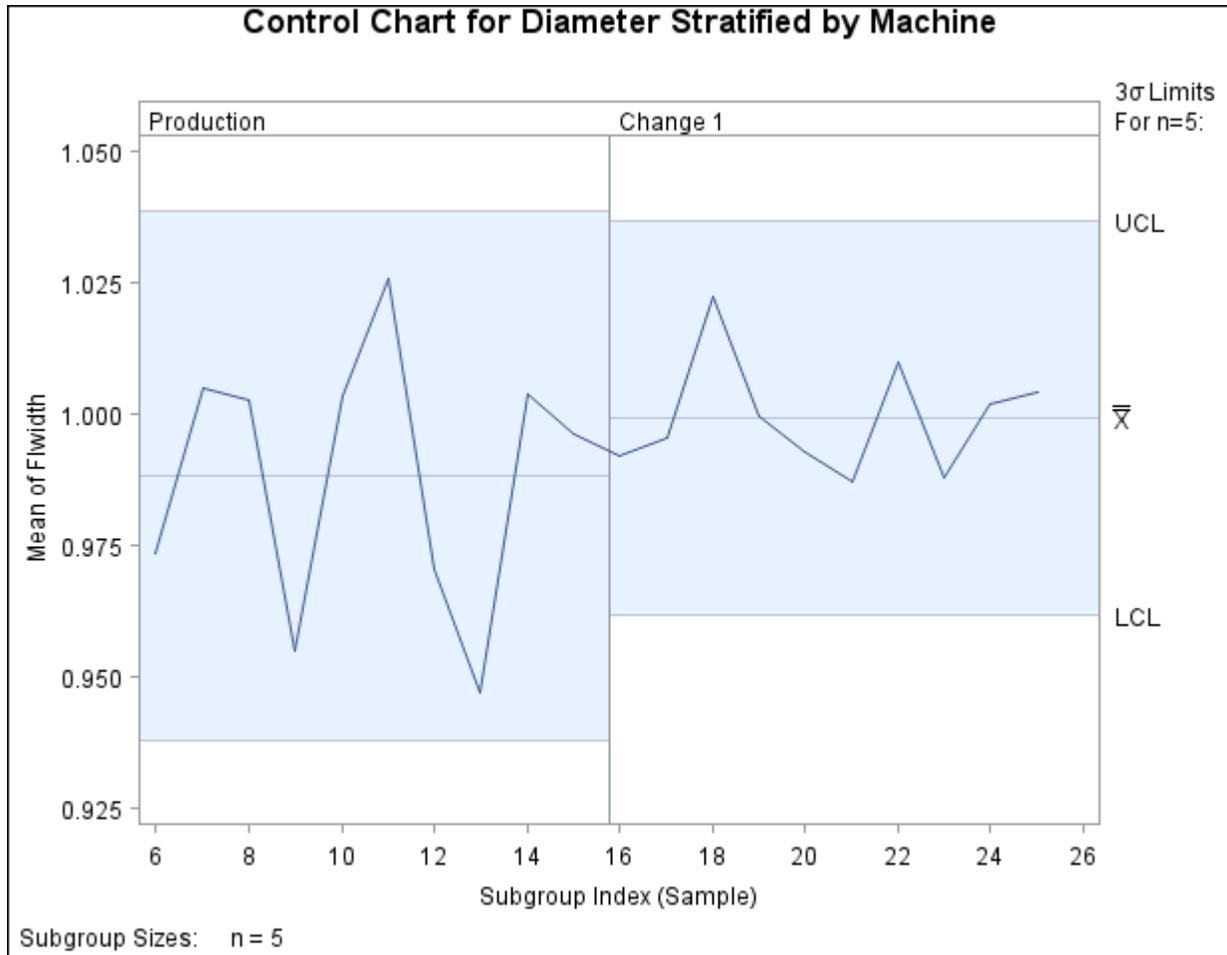

The only phases read are those for which `_PHASE_` equals one of the *values* specified with the `READINDEXES=` option. The chart displays a different set of control limits for each phase, read from the first observation in the `LIMITS=` data set for which `_INDEX_` is equal to the corresponding *value*.

For example, the following statements create a chart for the phases 'Production' and 'Change 1' with control limits read from the second and first observations in `Flangelim`, respectively. The chart is displayed in [Figure 17.152](#).

```
symbol v = none;
proc shewhart history=Flange limits=Flangelim;
  xchart Flwidth*Sample /
    readphase = all
    readindex = ('Production' 'Change 1')
    phaseref
    phaselegend;
run;
```

If you wish to specify a single set of control limits to use with all the phases, use the READINDEXES= option *without* the READPHASES= option (see Case 3).

Figure 17.152 READPHASES=ALL with a List of Values for READINDEXES=

Case 3. READPHASES= is omitted and READINDEXES=value

All observations are read from the input data set. The chart displays a single set of control limits read from the first observation in the LIMITS= data for which _INDEX_ equals the *value*.

Case 4. READPHASES=value-list and READINDEXES=value-list

The only phases read are those for which _PHASE_ equals one of the values specified with the READPHASES= option. The chart displays a different set of control limits for each phase, given by the first observation in the LIMITS= data set for which _INDEX_ equals the READINDEXES=*value*. Control limits are matched with phases in the order listed.

For example, the following statements create a chart for the phases 'Production' and 'Change 1' with control limits read from the first and second observations in Flangelim, respectively. The chart produced by these statements is identical to the chart in Figure 17.152.

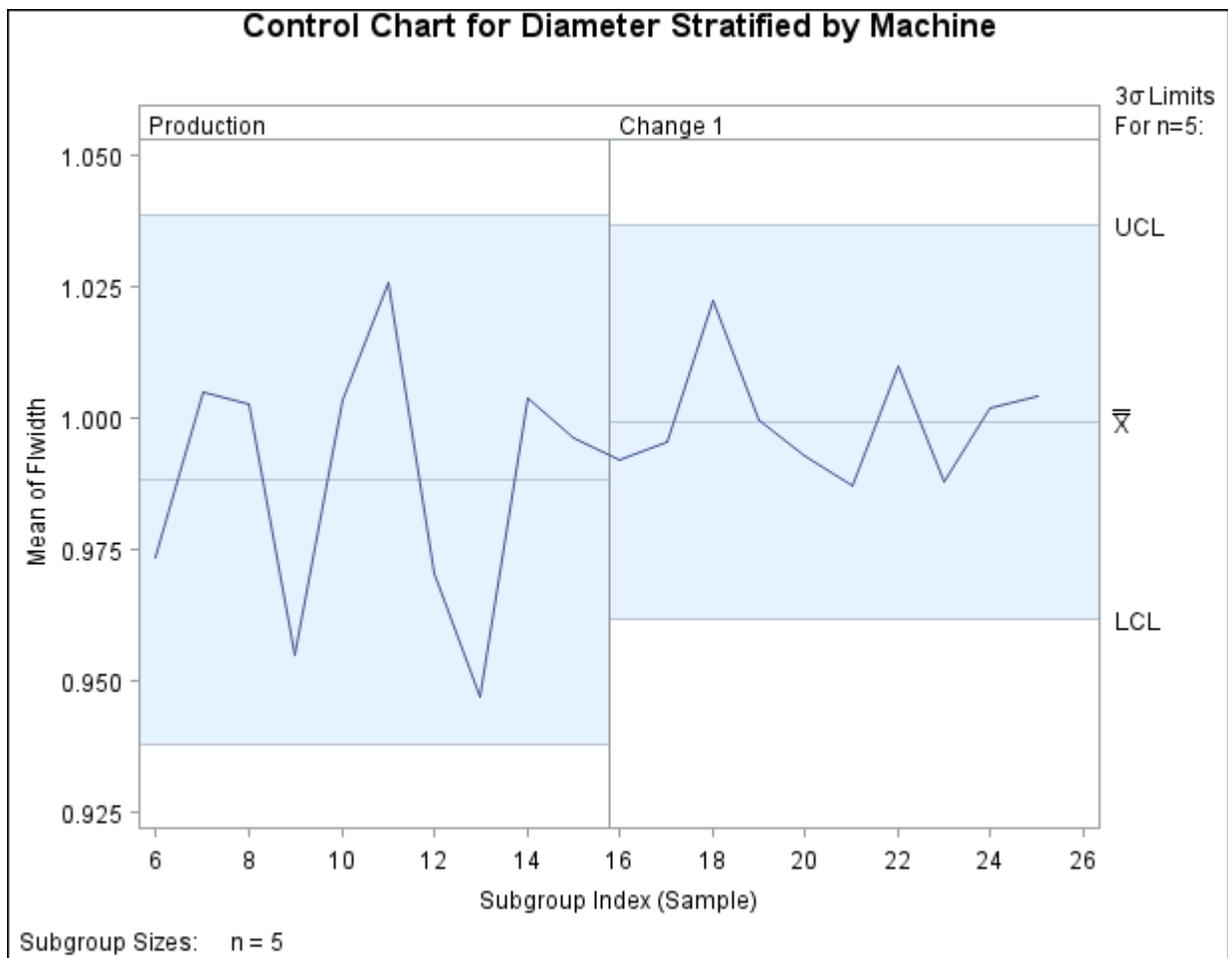

```

symbol v = none;
proc shewhart history=Flange limits=Flangelim;
  xchart Flwidth*Sample /
    readphases = ('Production' 'Change 1')
    readindexes = ('Production' 'Change 1')
    phaseref
    phaselegend;
run;

```

The order of the READINDEX=*value-list* is critical. For instance, the previous statements with READINDEXES=('Change 1' 'Production') create the chart in Figure 17.153, in which the control limits are mismatched with the phases.

Figure 17.153 Multiple Phases with Mismatched Control Limits

Case 5. READPHASES=*value|value-list* and READINDEXES=ALL

The only phases read are those for which `_PHASE_` equals one of the *values* specified with the READPHASES= option. The chart displays a different set of control limits for each phase, read from the first observation in the LIMITS= data set for which `_INDEX_` equals the *value* corresponding to the phase.

For example, the following statements create a chart for the phases ‘Production’ and ‘Change 1’ with the control limits read from the second and first observations in Flangelim, respectively:

```
proc shewhart history=Flange limits=Flangelim;
  xchart Flwidth*Sample /
    readphases = ('Production' 'Change 1')
    readindexes = all
    phaseref
    phaselegend ;
run;
```

The chart is identical to the chart in [Figure 17.152](#). In general, to read a set of phases with identically labeled control limits, you can specify the phases with either the READPHASES= or READINDEXES= option, and you can specify the keyword ALL with the other option.

Case 6. READPHASES=ALL and READINDEXES=ALL or READPHASES= is omitted and READINDEXES=ALL

All phases are read for which `_PHASE_` is a value of `_INDEX_` in the LIMITS= data set. The chart displays a different set of control limits for each phase, read from the first observation in the LIMITS= data set for which `_INDEX_` equals the value of `_PHASE_`.

For example, the following statements create a chart for the phases ‘Production’ and ‘Change 1’ with control limits read from the second and first observations in Flangelim, respectively. These two phases are read because they are the only phases in Flange with matching `_INDEX_` values in Flangelim. The chart is identical to that in [Figure 17.152](#).

```
proc shewhart history=Flange limits=Flangelim;
  xchart Flwidth*Sample /
    readphase = all
    readindex = all
    phaseref
    phaselegend ;
run;
```

Note that an identical chart would be produced if you were to omit the READPHASES= option.

Case 7. READPHASES=value|value-list and READINDEXES= is omitted

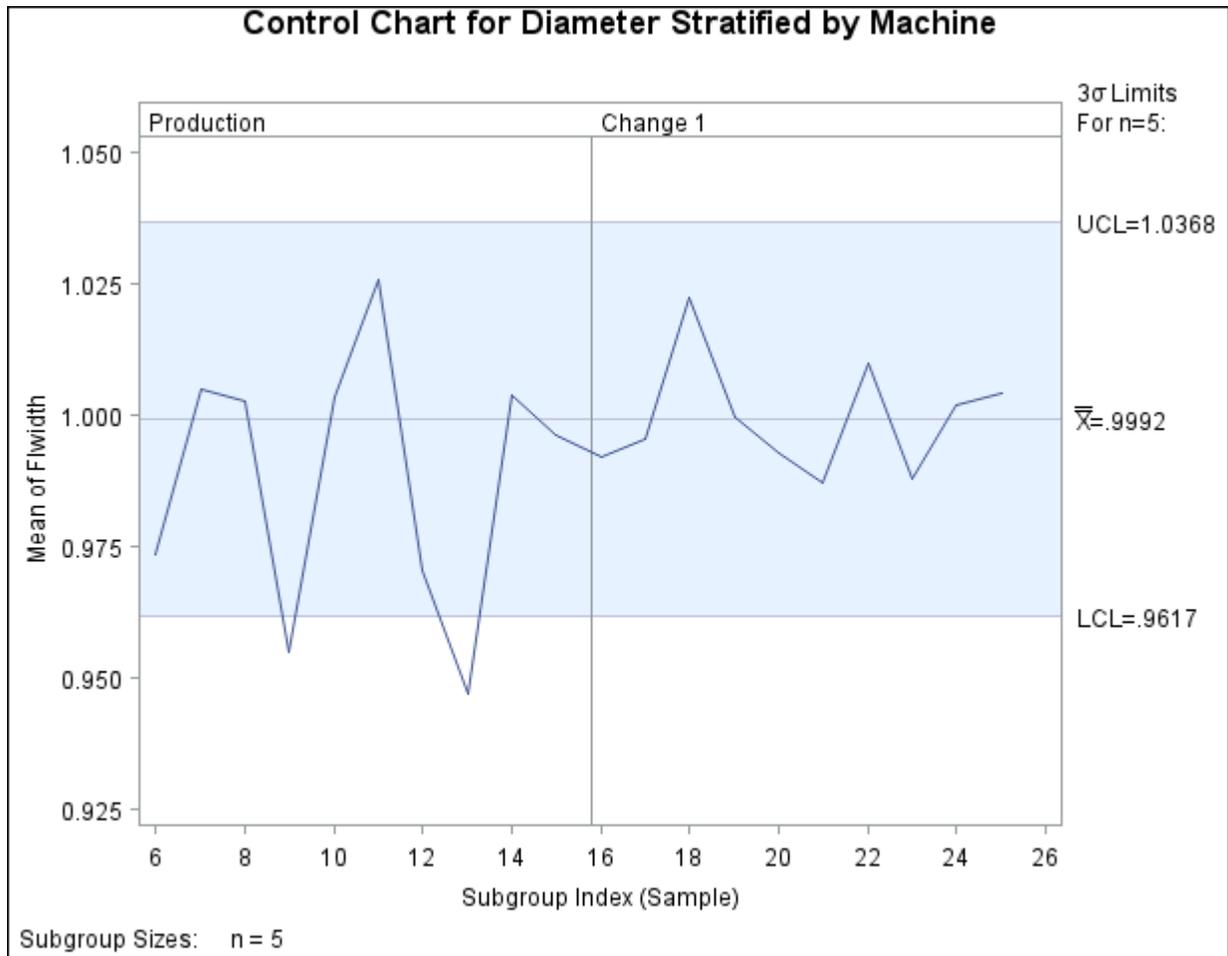

The only phases read are those for which `_PHASE_` equals one of the *values* specified with the READPHASES= option. The chart displays a single set of control limits read from the first observation in the LIMITS= data set for which `_VAR_` equals the *process* and `_SUBGRP_` equals the name of the *subgroup-variable* specified in the chart statement.

For example, the following statements create a chart for the phases ‘Production’ and ‘Change 1’ with control limits read from the first observation in Flangelim, because this is the first observation for which `_VAR_` equals ‘Flwidth’ and `_SUBGRP_` equals ‘Sample’.

```
symbol v = none;
proc shewhart history=Flange limits=Flangelim;
  xchart Flwidth*Sample /
    readphases = ('Production' 'Change 1')
    phaseref
    phaselegend;
run;
```

The chart is displayed in Figure 17.154.

Figure 17.154 Value-list for READPHASES= with READINDEXES= Omitted

Case 8. READPHASES=ALL and READINDEXES= is omitted or READPHASES= is omitted and READINDEXES= is omitted

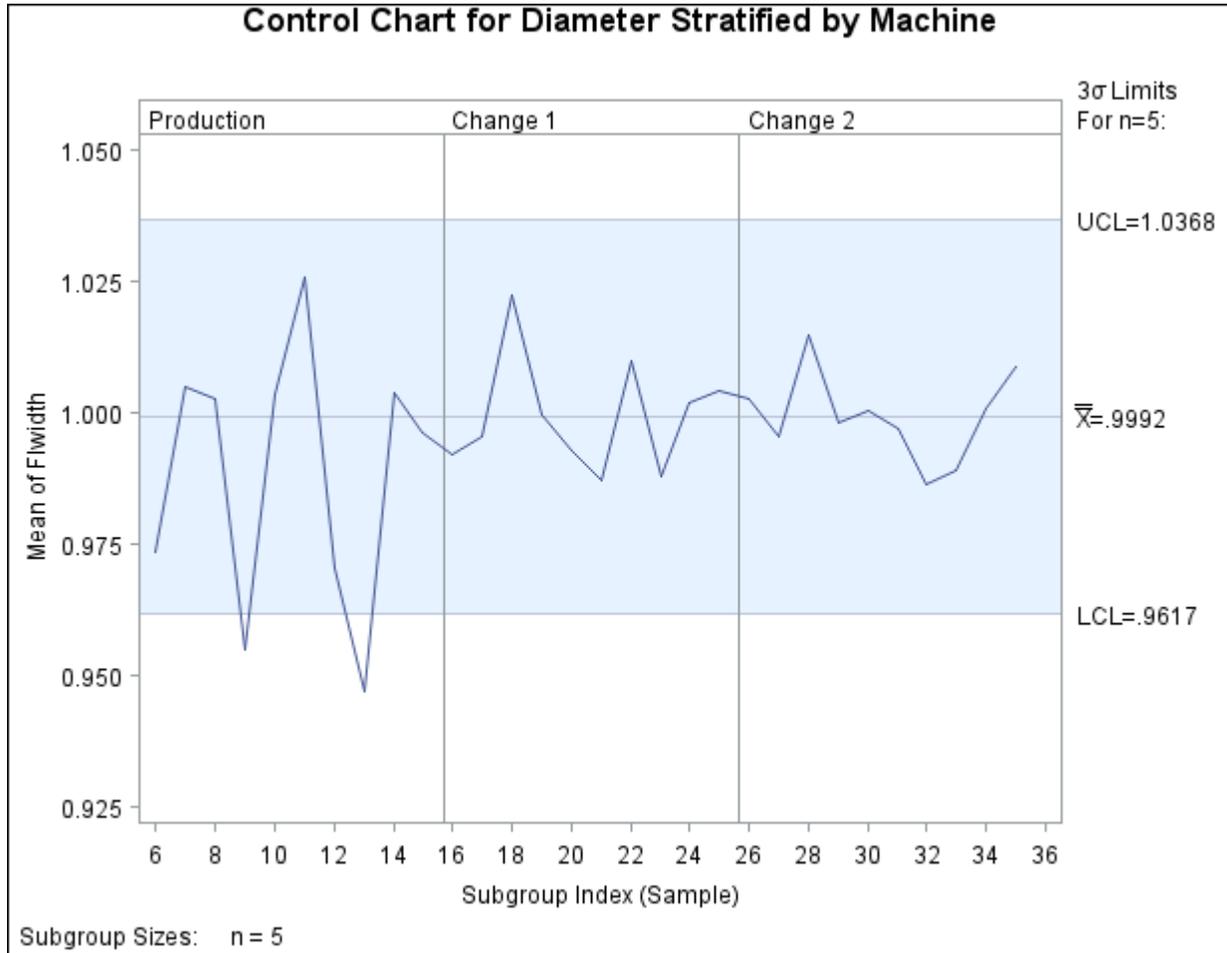

All observations are read from the input data set. The chart displays a single set of control limits read from the first observation in the LIMITS= data set for which `_VAR_` equals the *process* and `_SUBGRP_` equals the name of the *subgroup-variable* specified in the chart statement.

For example, the following statements create a chart for all the phases in Flange with control limits read from the first observation in Flangelim, because this is the first observation for which `_VAR_` equals 'FLWIDTH' and `_SUBGRP_` equals 'SAMPLE':

```
symbol v = none;
proc shewhart history=Flange limits=Flangelim;
  xchart Flwidth*Sample /
    readphase = all
    phaseref
    phaselegend;
run;
```

The chart is shown in Figure 17.155. Note that an identical chart would be produced if you were to omit the READPHASES= option (except that the phase reference lines and phase legends would be omitted).

Figure 17.155 READPHASES=ALL with READINDEXES= Omitted

Case 9. READPHASES=*value* and READINDEXES=*value-list*

The procedure generates an error message.

The following tables summarize the various combinations of the READPHASES= and READINDEXES= options that you can specify.

Table 17.88 READINDEXES=*index-value*

READPHASES=	Phases Displayed	Control Limits Displayed
<i>phase-value</i>	<code>_PHASE_ = <i>phase-value</i></code>	<code>_INDEX_ = <i>index-value</i></code>

Displaying Auxiliary Data with Stars

See SHWSTRI in the SAS/QC Sample Library

In many control chart applications, it is useful to relate the variation of the process to other variables that are being observed simultaneously with the variable that is charted. You can use the features described here to represent auxiliary multivariate data with stars (polygons) that are superimposed on the control chart. See Figure 17.158 for an illustration.

This display, referred to here as a *star chart*, enables you to analyze a process with a control chart while visualizing other quantities such as environmental variables, experimental control variables, or other process variables. The control chart itself can be a standard Shewhart chart, a moving average chart (such as an EWMA chart), or a cumulative sum control chart.

The examples in this section use the HISTORY= input data set paint (listed in Figure 17.156) and the LIMITS= data set paintlim (listed in Figure 17.157). The data in paint consist of the subgroup means, ranges, and sample size (pindexx, pindexr, and pindexn) for an index of paint quality that was monitored on an hourly basis, with six auxiliary variables that were measured simultaneously: thickness, gloss, defects, dust, humidity, and temperature.

Figure 17.156 Listing of the HISTORY= Data Set PAINT

Control Chart for Diameter Stratified by Machine									
hour	pindexx	pindexr	pindexn	thick	gloss	defects	dust	humid	te

Figure 17.157 Listing of the LIMITS= Data Set PAINTLIM

Control Chart for Diameter Stratified by Machine												
	s	l	s								s	
	u	i	i	l	m	u	l		u	t		
	b	t	m	g	l	m	u	l		c	d	
	v	g	y	i	m	c	e	c	c			
O	a	r	p	t	a	l	a	l	l		e	
b	r	p	e	n	s	x	n	x	r	r	v	
s												
1	pindex	hour	estimate	5	3	2.395	3.875	5.355	0	2.5625	5.4184	1.10

The basic variable analyzed with the control chart (in this case, paint index) is referred to as the *process*. The auxiliary variables (in this case, thickness, gloss, defects, dust, humidity, and temperature) are referred to as *vertex variables*, because their values are represented by the vertices of the stars. A star chart can reveal relationships between the process and the vertex variables, and it can reveal relationships among the vertex variables.

You can create star charts for any number of vertex variables. However, the resolution of your graphics device and the number of subgroups per page will limit your ability to distinguish the vertices of the stars. A practical upper limit is twelve vertex variables.

You can specify star options in all chart statements of the SHEWHART procedure except the BOX-CHART statement. You can use these options to

- specify the style of the star

- add reference circles to indicate limits of variation for the stars
- add a legend identifying the relationship between vertices and vertex variables
- label the vertices
- specify colors and line types for individual stars
- specify the size of the stars
- specify different methods of standardization for the vertex variables

The star options do not apply if the LINEPRINTER option is specified.

NOTE: A star chart is *not* the same as a multivariate control chart or a T^2 chart. A star chart is simply a univariate control chart enhanced with stars that represent auxiliary multivariate data. A multivariate control chart displays summary statistics (such as T^2) and control limits determined for a number of processes simultaneously. For an example of a multivariate control chart, see [Figure 17.222](#). [Figure 17.223](#) displays a multivariate control chart in which the principal components of the T^2 statistic are displayed with stars.

Creating a Basic Star Chart

See SHWSTR1 in the SAS/QC Sample Library

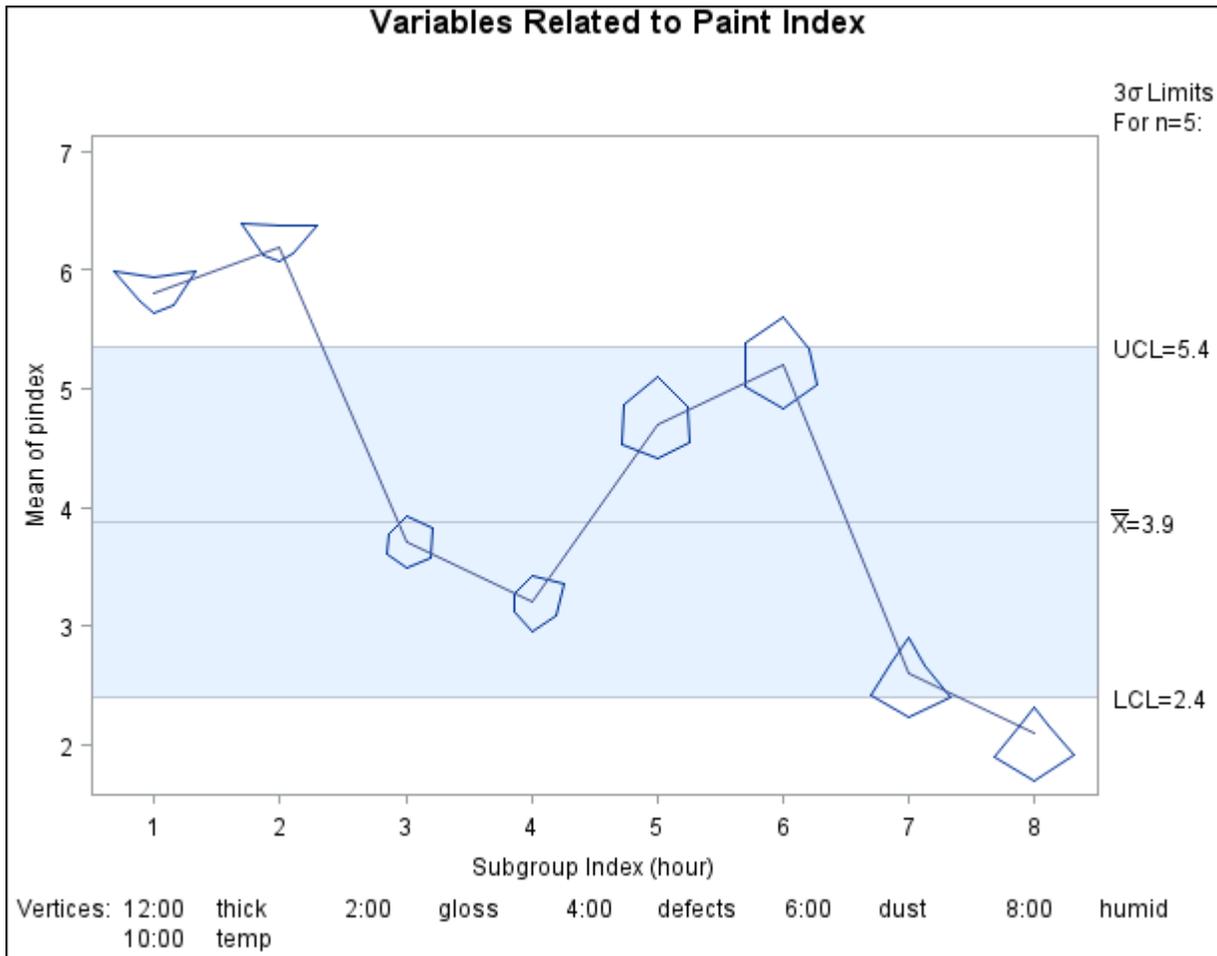

The following statements create the star chart shown in [Figure 17.158](#):

```
symbol v = none;
title 'Variables Related to Paint Index';
proc shewhart history=paint limits=paintlim;
  xchart pindex*hour /
  nolegend
  starvertices = (thick gloss defects dust humid temp);
run;
```

This chart is essentially an \bar{X} chart for paint index. However, the chart also provides information about thickness, gloss, defects, dust, humidity, and temperature. These six variables are represented by the vertices of the stars, as indicated by the legend at the bottom of the chart. By default, the legend uses a clock representation for the vertices; for instance, dust corresponds to the vertex at the six o'clock position.

The stars are centered at the points for average paint index, and the distance from the center to a vertex represents the standardized value of the variable corresponding to the vertex. The star chart reveals that relatively high values of gloss (two o'clock) and temperature (ten o'clock) are associated with high out-of-control averages for paint index. Likewise, relatively high values of defects (four o'clock) and humidity (eight o'clock) are associated with low out-of-control averages for paint index. The star shapes reveal similarities in the data for runs 1 and 2, runs 3 and 4, runs 5 and 6, and runs 7 and 8.

Figure 17.158 A Basic Star Chart

Adding Reference Circles to Stars

You can add reference circles to a star chart to represent limits of variation for the vertex variables. See SHWSTR1 in the SAS/QC Sample Library. The following statements add two special reference circles, called the *inner circle* and the *outer circle*, to the star chart in Figure 17.158:

```

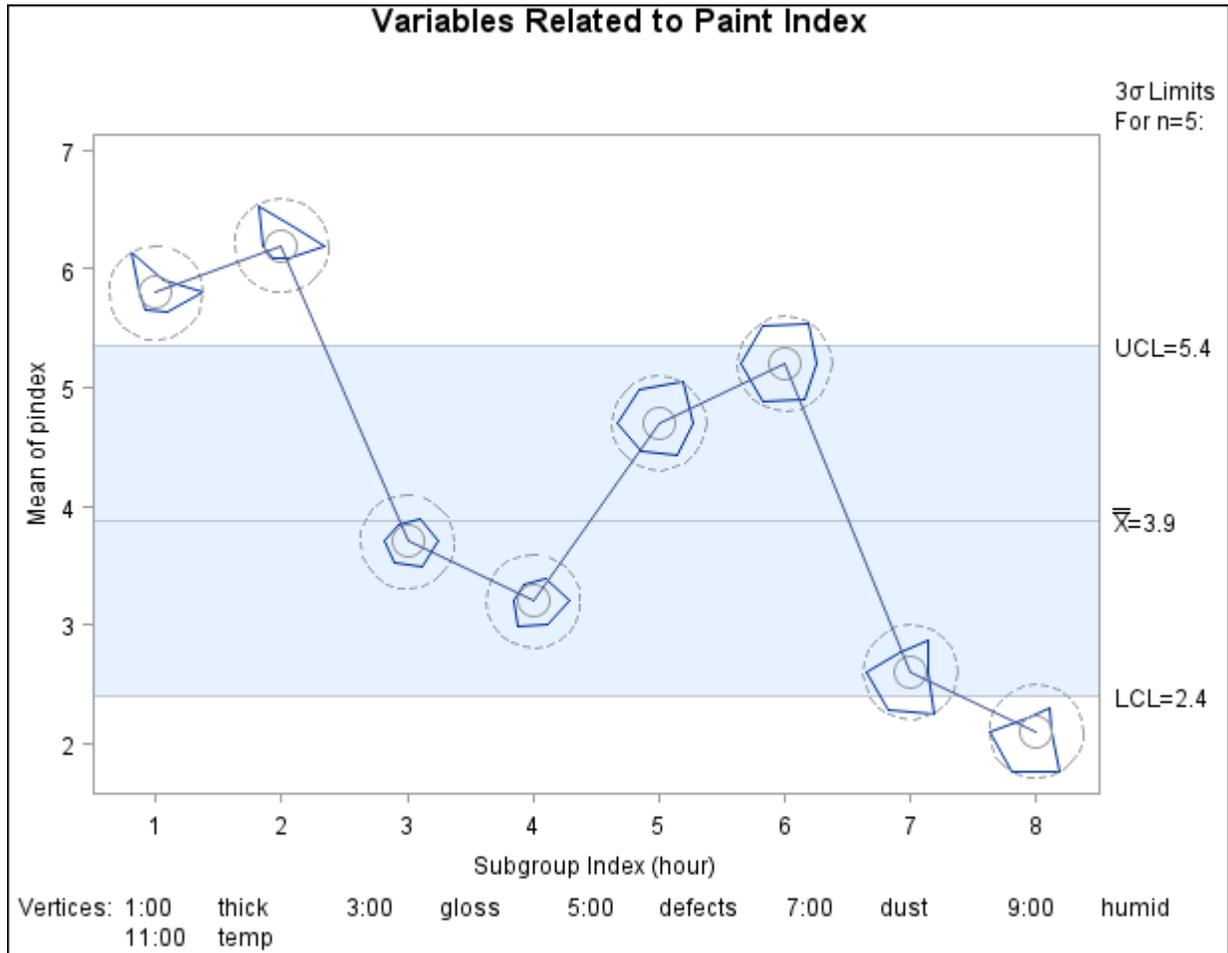

symbol v = none;
title 'Variables Related to Paint Index';
proc shewhart history=paint limits=paintlim;
  xchart pindex*hour /
    nolegend
    starvertices = (thick gloss defects dust humid temp)
    starcircles = 0.0 1.0
    lstarcircles = 1 2
    starstart = '1:00'T ;
run;

```

The star chart shown in Figure 17.159 displays the two reference circles centered about each point. The STARCIRCLES= value 0.0 requests the *inner circle*, and the value 1.0 requests the *outer circle*. Whether or not they are displayed, these circles are always associated with each star.

The interpretation of the inner and outer circles depends on the method used to standardize the vertex variables. By default (as in this example), the data for each vertex variable are standardized by the range of the variable values taken across subgroups. That is, the inner circle represents the minimum value, and the outer circle represents the maximum value. You can specify other methods of standardization (see “Specifying the Method of Standardization” on page 2123).

Figure 17.159 Star Chart with Inner and Outer Circles Added

Note that the STARCIRCLES= option does not specify the physical radius of a reference circle. Instead, this option specifies the radius relative to the radii of the inner and outer circles. Thus, specifying STARCIRCLES=0.0 always displays the inner circle, and specifying STARCIRCLES=1.0 always displays the outer circle. Specifying STARCIRCLES=0.5 displays a reference circle halfway between the inner and outer circles. You can specify the physical radii (in percent screen units) of the inner and outer circles using the STARINRADIUS= and STAROUTRADIUS= options. In the preceding statements, the LSTARCIRCLES= option specifies line types (1=solid and 2=dashed) for the inner and outer circles. You can also use the WSTARCIRCLES= option to control the thickness of the circles.

The STARSTART= option gives the starting position for the first vertex variable listed. In the preceding example, this option specifies that the vertex corresponding to thick is to be positioned at one o'clock. The remaining vertices are uniformly spaced clockwise and correspond to the vertex

variables in the order listed with the STARVERTICES= option.

For more information about the star options, see the appropriate entries in “Dictionary of Options: SHEWHART Procedure” on page 2018.

Specifying the Style of Stars

The following statements create star charts for paint index using different styles for the stars specified with the STARTYPE= option: *See SHWSTR2 in the SAS/QC Sample Library*

```

symbol v = none;
title 'Variables Related to Paint Index';
proc shewhart history=paint limits=paintlim;
  xchart pindex * hour /
    nolegend
    starvertices = ( thick gloss defects dust humid temp )
    starstart    = '1:00'T
    startype     = wedge;
  xchart pindex * hour /
    nolegend
    starvertices = ( thick gloss defects dust humid temp )
    starstart    = '1:00'T
    startype     = radial;
  xchart pindex * hour /
    nolegend
    starvertices = ( thick gloss defects dust humid temp )
    starstart    = '1:00'T
    startype     = spoke;
  xchart pindex * hour /
    nolegend
    starvertices = ( thick gloss defects dust humid temp )
    starstart    = '1:00'T
    startype     = corona;
run;

```

The charts are shown in Figure 17.160, Figure 17.161, Figure 17.162, and Figure 17.163. The default style for the stars is STARTYPE=POLYGON, which is illustrated in Figure 17.158 and Figure 17.159. For more information, see the entry for the STARTYPE= option in “Dictionary of Options: SHEWHART Procedure” on page 2018.

Figure 17.160 Star Chart Using STARTYPE=WEDGE

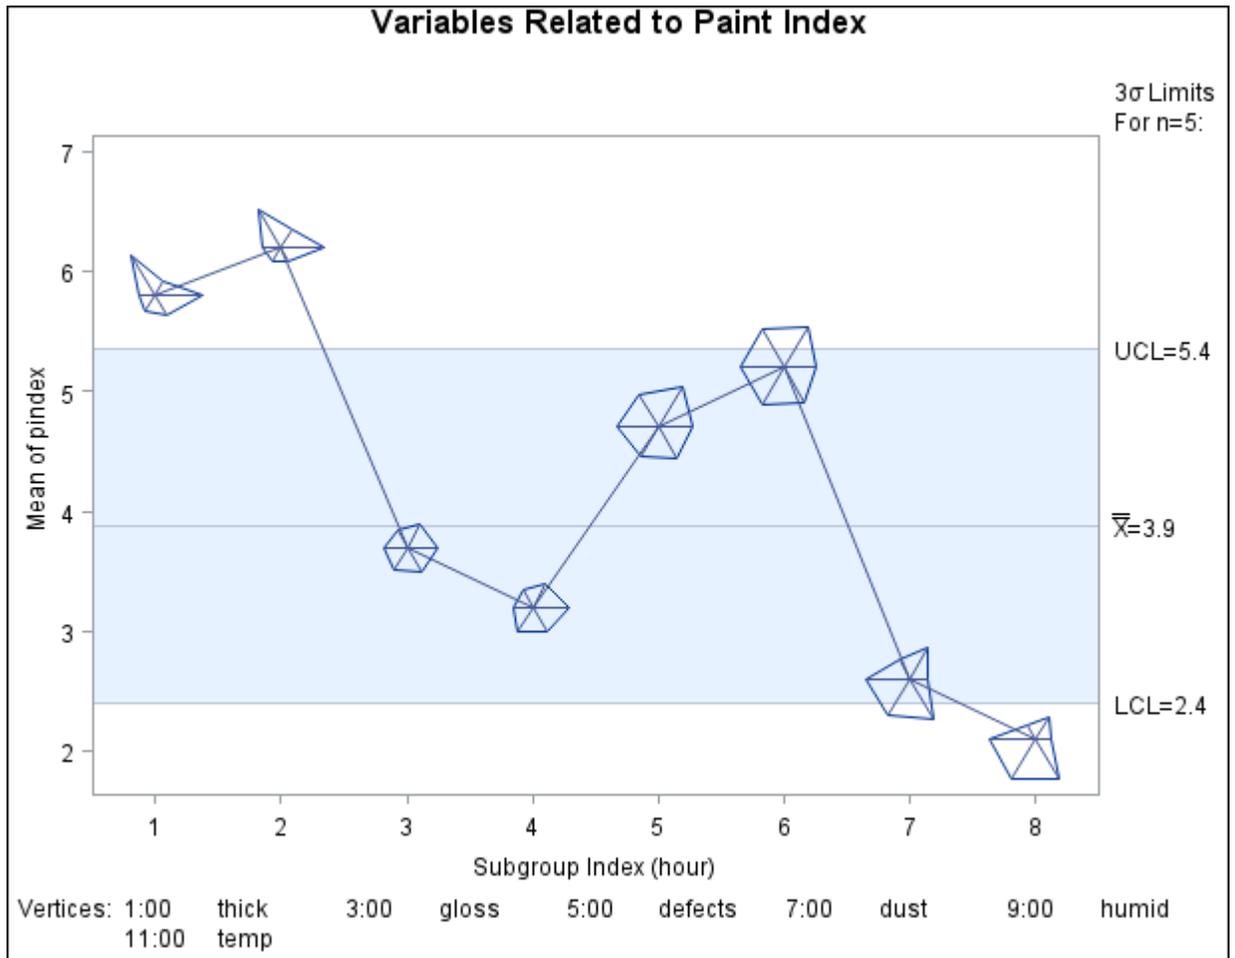

Figure 17.161 Star Chart Using STARTYPE=RADIAL

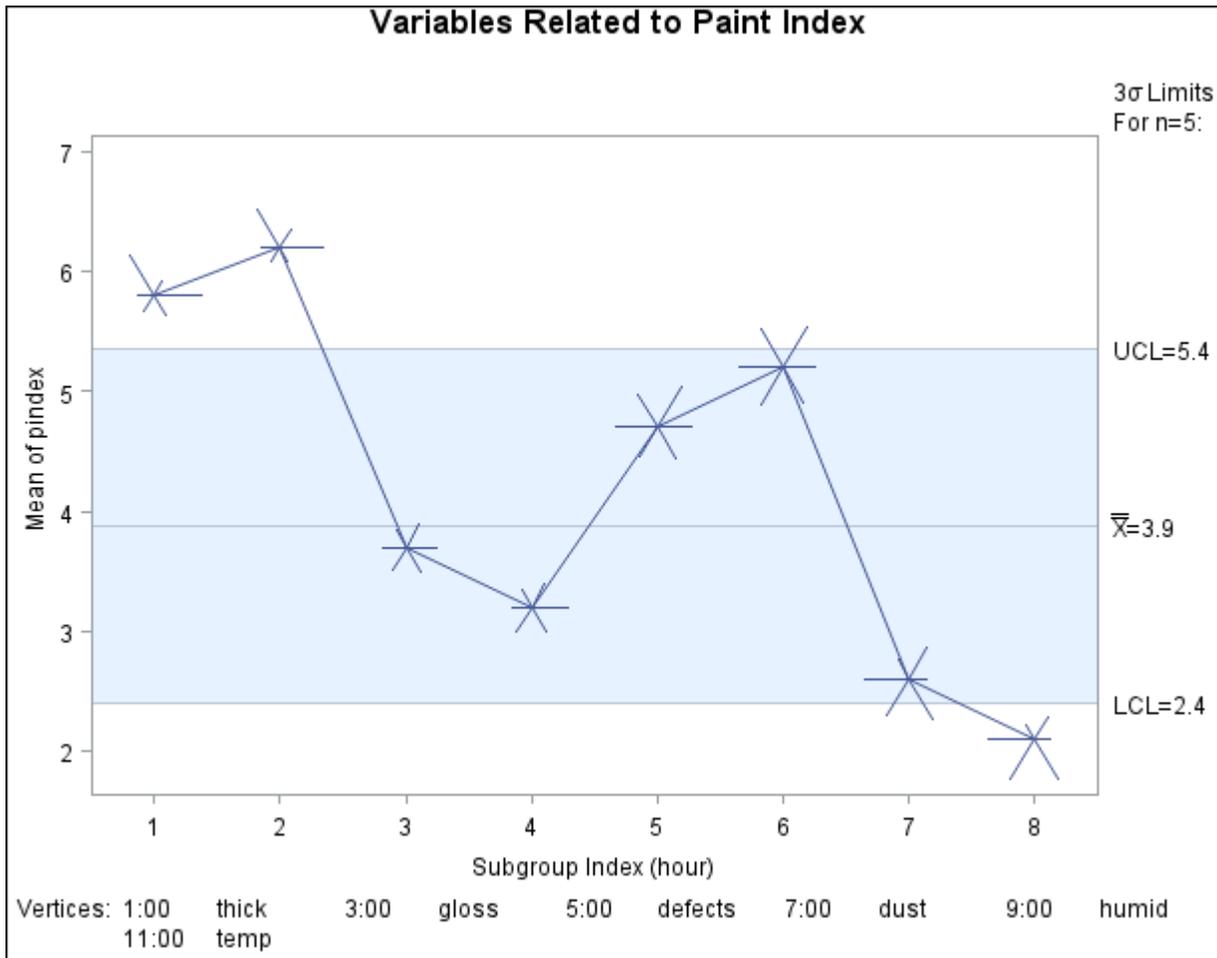

Figure 17.162 Star Chart Using STARTYPE=SPOKE

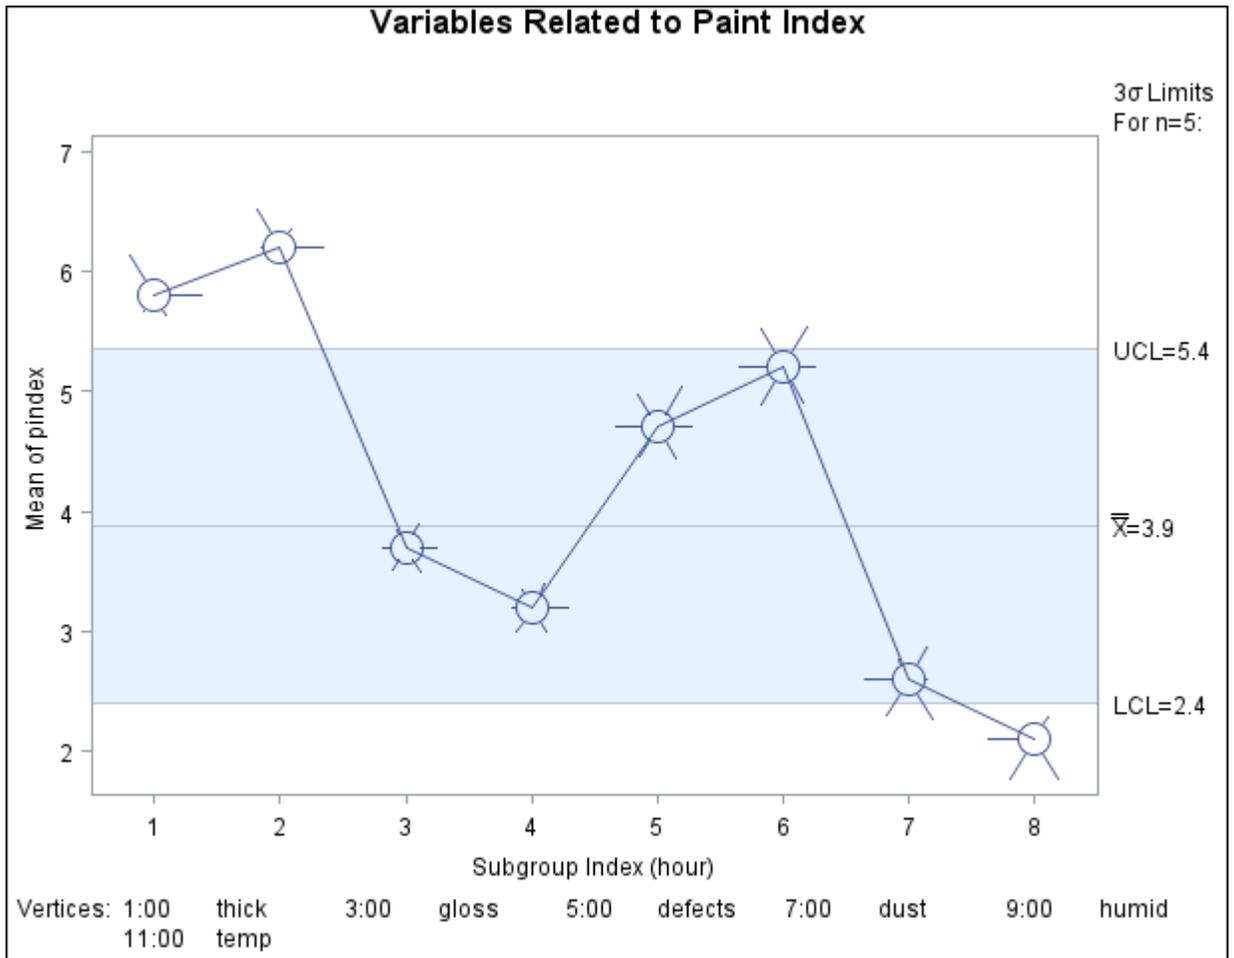

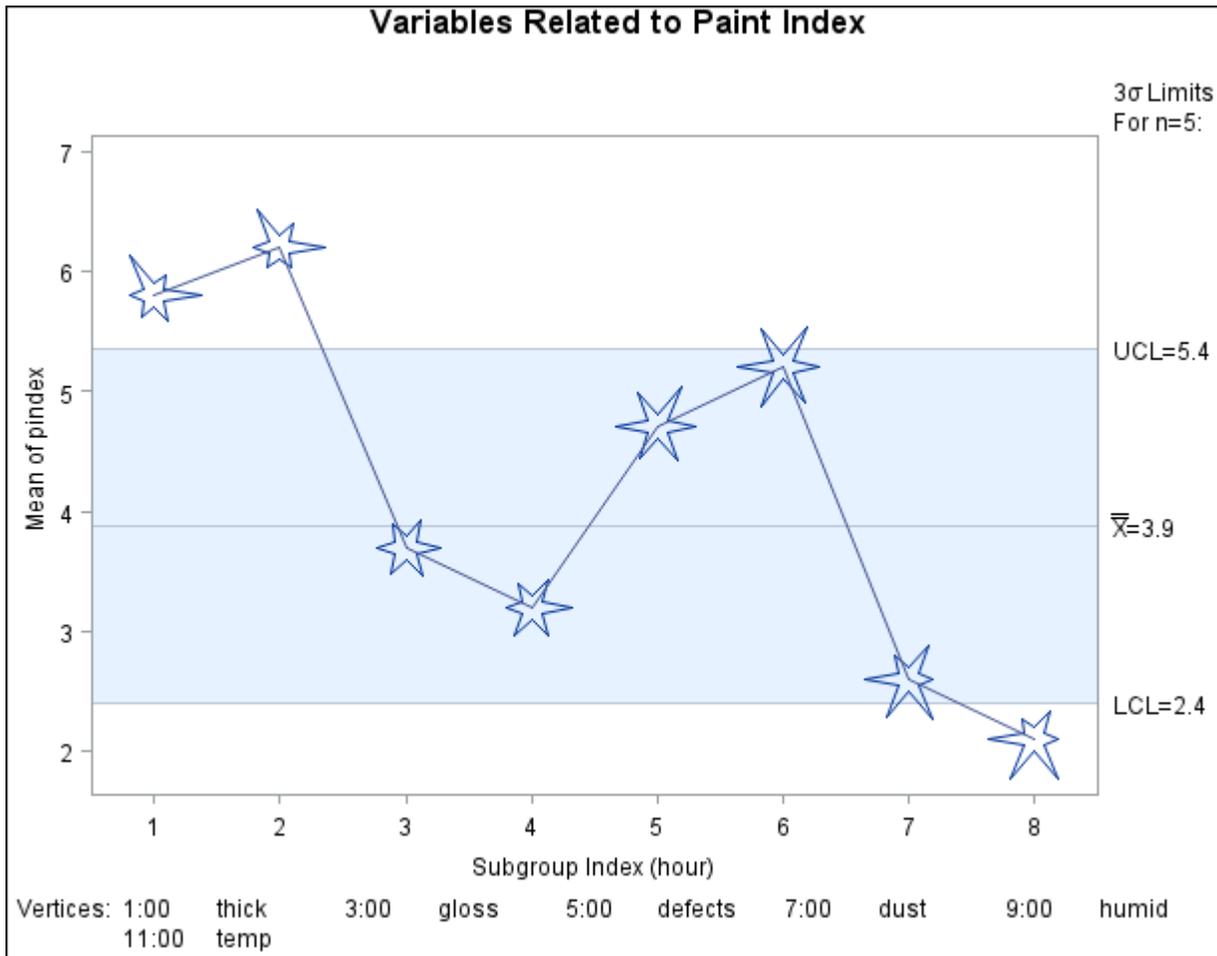

Figure 17.163 Star Chart Using STARTYPE=CORONA

Specifying the Method of Standardization

In the previous examples in this section, the default method of standardization (based on ranges) is used for all six vertex variables. You can specify alternative methods with the STARSPECS= option. For example, specifying STARSPECS=3 standardizes each vertex variable so that the inner circle corresponds to three standard deviations below the mean and the outer circle corresponds to three standard deviations above the mean (that is, the circles represent 3σ limits). Specifying STARSPECS=k requests circles corresponding to kσ limits, and specifying STARSPECS=0 requests the default method. *See SHWSTR3 in the SAS/QC Sample Library*

In some applications, it may be necessary to use distinct methods of standardization for the vertex variables. You can do this by creating an input SAS data set that provides the method for each vertex variable and specifying this data set with the STARSPECS= option.

The following statements create a data set named myspecc that specifies standardization methods for the vertex variables used in the previous examples:

```

data myspecks;
  length _var_      $8
         _label_   $16 ;
  input  _var_ _label_ _lspoke_ _sigmas_ _lsl_ _usl_ ;
  datalines;
thick   Thickness    1      .      0.25  0.50
gloss   Gloss        1      .      0.10  0.60
defects Defects      1      .      0.10  0.60
dust    Dust         2      3.0    .      .
humid   Humidity     2      0.0    .      .
temp    Temperature  2      0.0    .      .
;

```

This data set contains a number of special variables whose names begin and end with an underscore.

Variable Name	Description
<code>_LABEL_</code>	label for identifying the vertex (used in conjunction with the <code>STARLABEL=</code> option). This must be a character variable of length 16 or less.
<code>_LSL_</code>	lower specification limit
<code>_LSPOKE_</code>	line style for spokes used with <code>STARTYPE=RADIAL</code> , <code>STARTYPE=SPOKE</code> , and <code>STARTYPE=WEDGE</code>
<code>_SIGMAS_</code>	multiple of standard deviations above and below the average. A value of zero specifies standardization based on the range.
<code>_USL_</code>	upper specification limit
<code>_VAR_</code>	name of vertex variable. This must be a character variable whose length is no greater than 32.

Standardization is specified with the variables `_SIGMAS_`, `_LSL_`, and `_USL_`, as follows:

- Since nonmissing specification limits (`_LSL_` and `_USL_`) are provided for the variables `thick`, `gloss`, and `defects`, the values of these variables are scaled so that the inner circle represents the lower specification limit and the outer circle represents the upper specification limit.
- Since `_SIGMAS_` is equal to 3 for `dust` (and since both `_LSL_` and `_USL_` are missing), values of `dust` are scaled so that the inner circle represents three standard deviations below the mean, and the outer circle represents three standard deviations above the mean. The mean and standard deviation are calculated across all subgroups.
- Since `_SIGMAS_` is equal to 0 for `humid` and `temp` (and since both `_LSL_` and `_USL_` are missing), values of `humid` and `temp` are scaled so that the inner circle represents the minimum and the outer circle represents the maximum. The minimum and maximum are calculated across all subgroups.

The following statements use the data set `myspecks` to create a star chart for paint index:

```

symbol v = none;
title 'Variables Related to Paint Index';
proc shewhart history=paint limits=paintlim;
  xchart pindex * hour /
    nolegend
    starvertices = ( thick gloss defects dust humid temp )
    startype      = wedge
    starcircles   = 0.0 1.0
    lstarcircles  = 2    2
    starstart     = -30
    labelfont     = simplex
    starlegend    = degrees
    starspecs     = myspecs
    starlabel     = high ;
run;

```

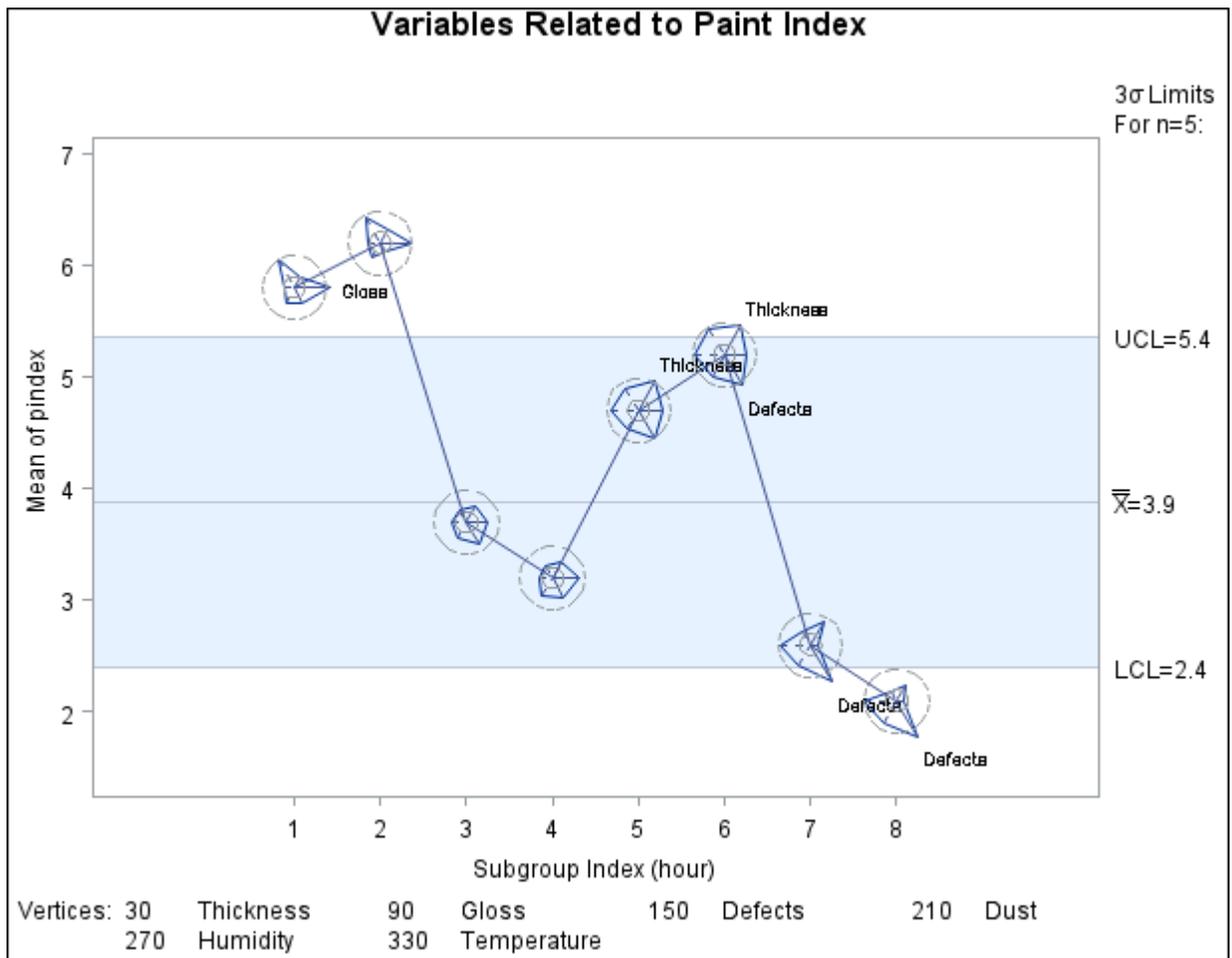

The chart is shown in [Figure 17.164](#). Specifying STARLEGEND=DEGREES requests a legend that identifies the vertex variables by their angles (in degrees) rather than their clock positions. Here, zero degrees corresponds to twelve o'clock, and the degrees are measured clockwise. The first vertex variable is positioned at 30 degrees, as specified with the STARSTART= option. Note that you specify the STARSTART= value as a negative number to indicate that it is in degrees.

In [Figure 17.161](#) the vertices that exceed the outer circle are labeled with the value of the variable `_LABEL_` in the STARSPECS= data set. This type of labeling is requested by specifying STARLABEL=HIGH. A font (SIMPLEX) for the labels is specified with the LABELFONT= option.

The vertices for thick at HOUR=5, 6, and 7 are truncated, as indicated in the SAS log. The truncation value is the physical radius of an imaginary circle referred to as the *bounding circle* that lies outside the outer circle. In general, any vertex that exceeds the bounding circle is truncated to the *bounding radius*. This is done so that unusually large vertex variable values will not result in grossly distorted stars. You can specify a different bounding radius with the STARBDRADIUS= option.

The spokes corresponding to the environmental variables dust, humid, and temp are drawn with a dashed line style to distinguish them from the quality variables thick, gloss, and defects, whose spokes are drawn with a solid line. The styles are specified by the variable `_LSPOKE_`. Refer to *SAS/GRAPH: Reference* for a complete list of line styles. If you are producing charts in color, you can also use the variable `_CSPOKE_` in the STARSPECS= data set to assign colors to the spokes.

Figure 17.164 Star Chart Using STARSPECS= Specifications

For more information about the options used in this example, see the appropriate entries in “Dictionary of Options: SHEWHART Procedure” on page 2018.

Displaying Trends in Process Data

See *SHWTREN* in the *SAS/QC Sample Library*

Time trends due to tool wear, environmental changes, and other gradual process changes are sometimes observed in \bar{X} charts. The presence of a systematic trend makes it difficult to interpret the chart because the control limits are designed to indicate expected variation strictly due to common causes.

You can use the REG procedure (or other modeling procedure) in conjunction with the SHEWHART procedure to determine whether a process with a time trend is in control. With the REG procedure, you can model the trend and save the fitted subgroup means (\hat{X}_t) and the residual subgroup means ($\bar{X}_t - \hat{X}_t$) in an output data set. Then, using this data as input to the SHEWHART procedure, you can create a *trend chart*, which displays a trend plot of the fitted subgroup means together with an \bar{X} chart for the residual subgroup means, thus removing the time-dependent component of the

data from its random component. Having accounted for the time trend, you can decide whether the process is in control by examining the \bar{X} chart.

The following example illustrates the steps used to create a trend chart for a SAS data set named TOOLWEAR that contains diameter measurements for 20 subgroup samples each consisting of eight parts:

```

data toolwear;
  input hour @;
  do i=1 to 8;
    input Diameter @;
    output;
  end;
  drop i;
  datalines;
1   10.0434   9.9427   9.9548   9.8056
   10.0780  10.0302  10.1173  10.0215

   10.3975  10.2714  10.2952  10.6255
20  10.2612  10.3824  10.4240  10.3120
   10.5744  10.4204  10.4073  10.3783
;

```

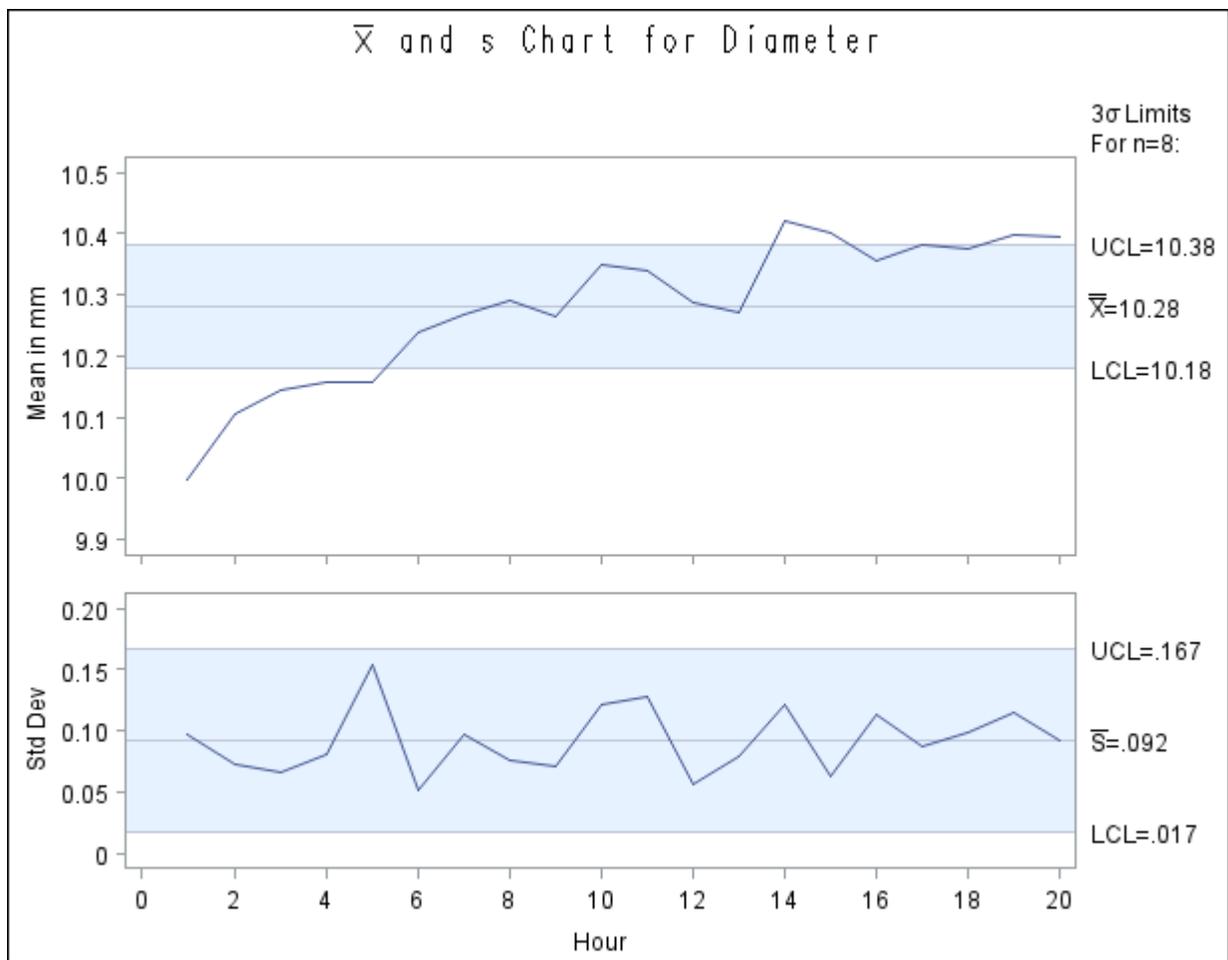

Step 1: Preliminary Mean and Standard Deviation Charts

The following statements create \bar{X} and s charts for the diameter data:

```
symbol h=3.0 pct;
title f=qcfont1 'X ' f=none 'and s Chart for Diameter';
proc shewhart data=toolwear;
  xschart Diameter*hour /
    outhistory = submeans
    nolegend ;
  label Diameter = 'Mean in mm';
  label hour     = 'Hour';
run;
```

The charts are shown in Figure 17.165. The subgroup standard deviations are all within their control limits, indicating the process variability is stable. However, the \bar{X} chart displays a nonlinear trend that makes it difficult to decide if the process is in control. Subsequent investigation reveals that the trend is due to tool wear.

Figure 17.165 \bar{X} and s Charts for TOOLWEAR Data

Note that the symbol \bar{X} is displayed in the title with the special font QCFONT4, which matches the SWISS font used for the remainder of the title. See Chapter D, “Special Fonts in SAS/QC Software,” for a description of the fonts available for displaying \bar{X} and related symbols.

Step 2: Modeling the Trend

The next step is to model the trend as a function of hour. The \bar{X} chart in Figure 17.165 suggests that the mean level of the process (saved as DiameterX in the OUTLIMITS= data set SUBMEANS) grows as the log of HOUR. The following statements fit a simple linear regression model in which DiameterX is the response variable and LOGHOUR (the log transformation of HOUR) is the predictor variable. Part of the printed output produced by PROC REG is shown in Figure 17.166.

```
data submeans;
  set submeans;
  loghour=log(hour);
run;

proc reg data=submeans ;
  model Diameterx=loghour;
  output out=regdata predicted=fitted ;
run;
```

Figure 17.166 Trend Analysis for Diameter from PROC REG

X and s Chart for Diameter						
The REG Procedure						
Model: MODEL1						
Dependent Variable: DiameterX Mean of Diameter						
Parameter Estimates						
Variable	Label	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	Intercept	1	9.99056	0.02185	457.29	<.0001
loghour		1	0.13690	0.00967	14.16	<.0001

Figure 17.166 shows that the fitted equation can be expressed as

$$\widehat{X}_t = 9.99 + 0.14 \times \log(t)$$

where \widehat{X}_t is the fitted subgroup average.⁴⁵ A partial listing of the OUT= data set REGDATA created by the REG procedure is shown in Figure 17.167.

⁴⁵Although this example does not check for the existence of a trend, you should do so by using the hypothesis tests provided by the REG procedure.

Figure 17.167 Partial Listing of the Output Data Set regdata from the REG Procedure

X and s Chart for Diameter					
hour	Diameter X	Diameter S	Diameter N	loghour	fitted
1	9.9992	0.09726	8	0.00000	9.9906
2	10.1060	0.07290	8	0.69315	10.0855
3	10.1428	0.06601	8	1.09861	10.1410
4	10.1565	0.08141	8	1.38629	10.1803
5	10.1583	0.15454	8	1.60944	10.2109

Step 3: Displaying the Trend Chart

The third step is to create a trend chart with the SHEWHART procedure, as follows:

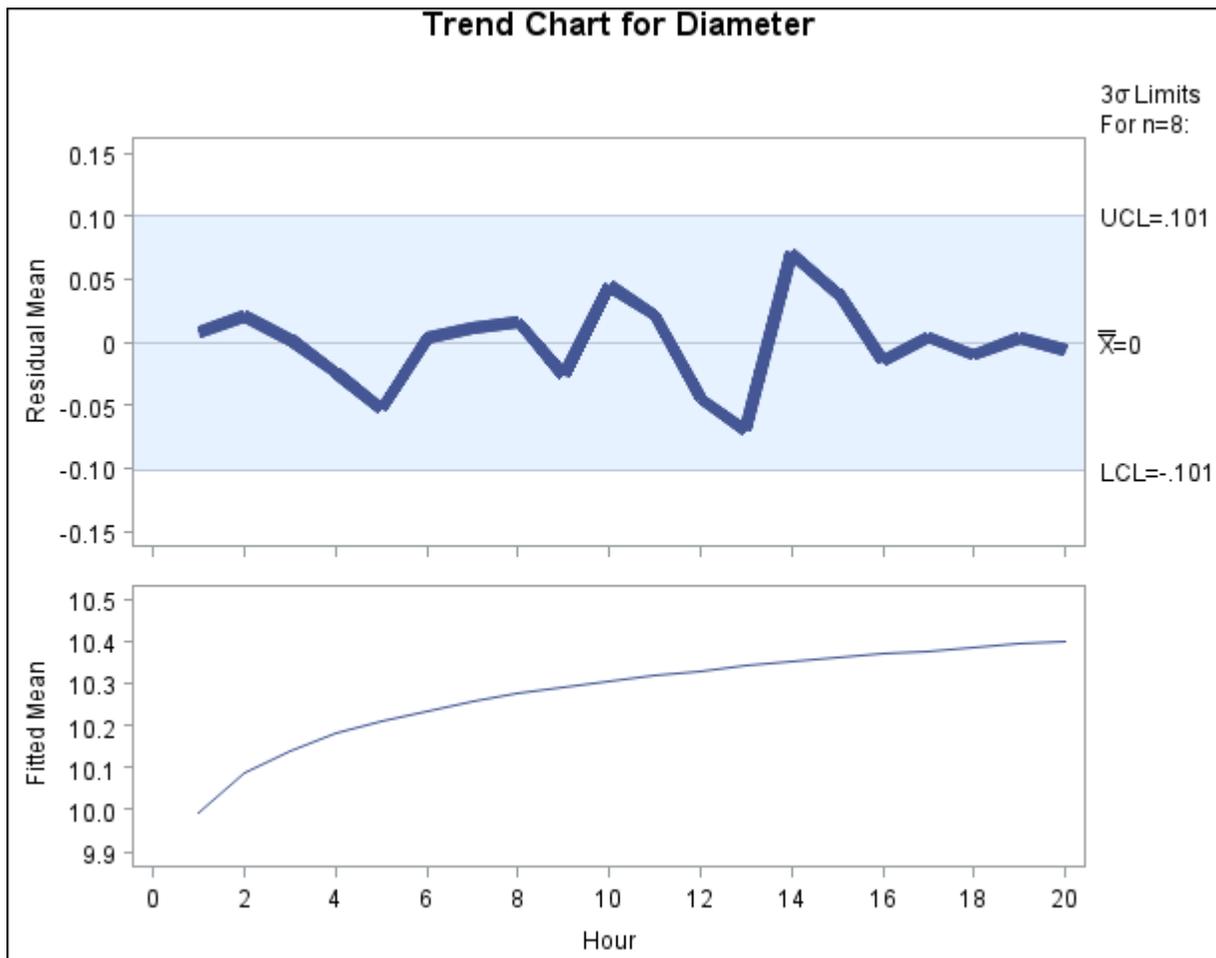

```

symbol v = none w=5;
title 'Trend Chart for Diameter';
proc shewhart history=regdata;
  xchart Diameter*hour /
    wtrend = 1
    trendvar = fitted
    split = '/'
    stddevs
    nolegend;
  label Diameterx = 'Residual Mean/Fitted Mean';
  label hour = 'Hour';
run;

```

The chart is shown in [Figure 17.168](#). The values of FITTED are plotted in the lower half of the trend chart. The upper half of the trend chart is an \bar{X} chart for the residual means (DiameterX – FITTED). The CNEEDLES= option specifies that the residuals are to be represented by vertical bars as deviations from the central line. The \bar{X} chart in [Figure 17.168](#) shows that, after accounting for the trend, the mean level of the process is in control.

Figure 17.168 Trend Chart for Diameter Data

If the data are correlated in time, you can use the ARIMA or AUTOREG procedures in place of the REG procedure to remove autocorrelation structure and display a control chart for the residuals; for an example, see “Autocorrelation in Process Data” on page 2171. Another application of the TRENDVAR= option is the display of nominal values in control charts for short runs; see “Short Run Process Control” on page 2188.

Clipping Extreme Points

In some control chart applications, the out-of-control points can be so extreme that the remaining points are compressed to a scale that is difficult to read. In such cases, you can clip the extreme points so that a more readable chart is displayed, as illustrated in the following example. *See SHWCLIP in the SAS/QC Sample Library*

A company producing copper tubing uses \bar{X} and R charts to monitor the diameter of the tubes. Based on previous production, known values of 70mm and 0.75mm are available for the mean and standard deviation of the diameter. The diameter measurements (in millimeters) for 15 batches of five tubes each are provided in the data set NEWTUBES.

```

data newtubes;
  label Diameter='Diameter in mm';
  do batch = 1 to 15;
    do i = 1 to 5;
      input Diameter @@;
      output;
    end;
  end;
  datalines;
69.13 69.83 70.76 69.13 70.81
85.06 82.82 84.79 84.89 86.53
67.67 70.37 68.80 70.65 68.20
71.71 70.46 71.43 69.53 69.28
71.04 71.04 70.29 70.51 71.29
69.01 68.87 69.87 70.05 69.85
50.72 50.49 49.78 50.49 49.69
69.28 71.80 69.80 70.99 70.50
70.76 69.19 70.51 70.59 70.40
70.16 70.07 71.52 70.72 70.31
68.67 70.54 69.50 69.79 70.76
68.78 68.55 69.72 69.62 71.53
70.61 70.75 70.90 71.01 71.53
74.62 56.95 72.29 82.41 57.64
70.54 69.82 70.71 71.05 69.24
;

```

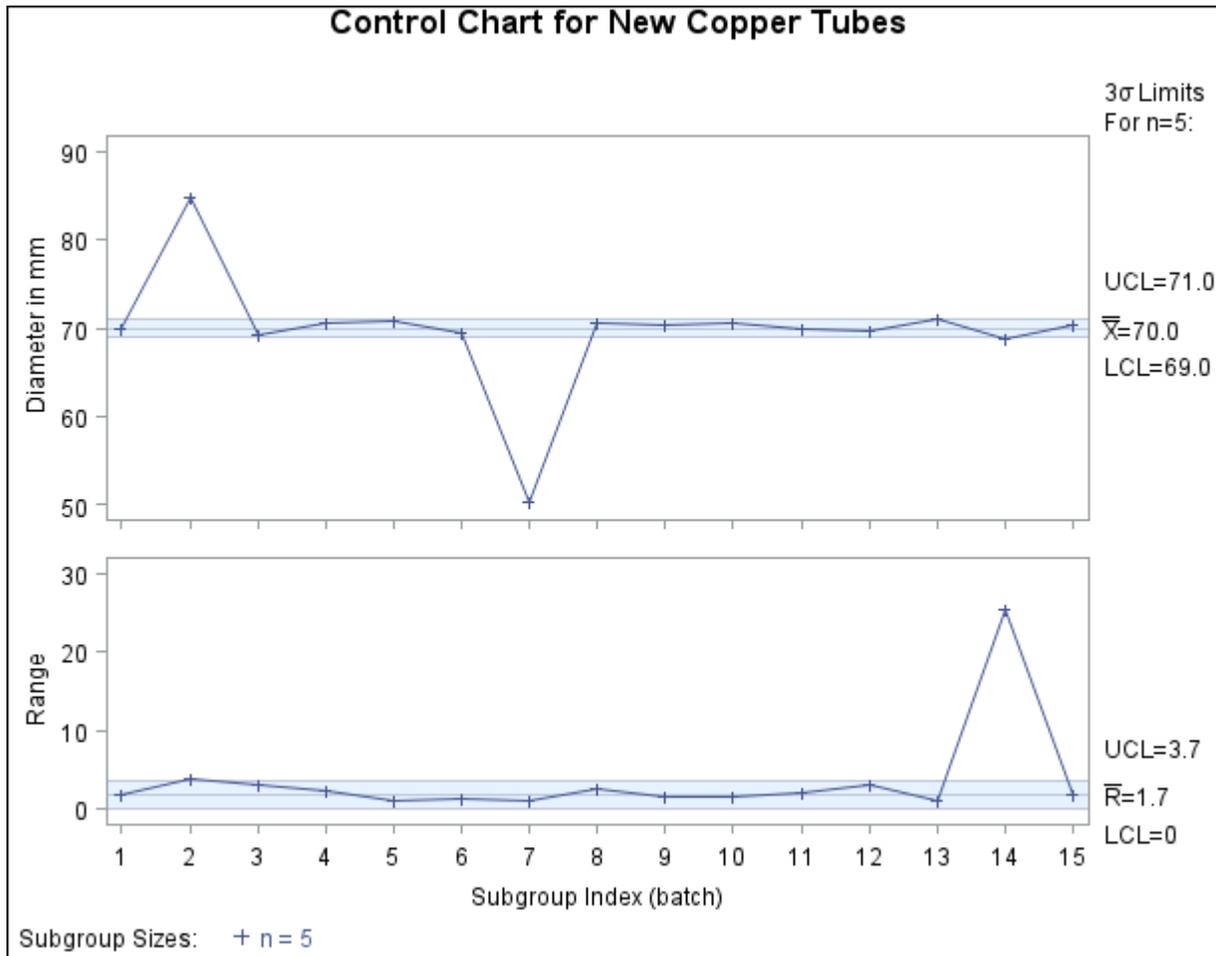

The following statements create the \bar{X} and R charts shown in Figure 17.169 for the tube diameter:

```

symbol value=plus;
title 'Control Chart for New Copper Tubes' ;
proc shewhart data=newtubes;
  xrchart Diameter*batch /
    mu0 = 70
    sigma0 = 0.75;
run;

```

Batches 2 and 7 result in extreme out-of-control points on the mean chart, and batch 14 results in an extreme out-of-control point on the range chart. The vertical axes are scaled to accommodate these extreme out-of-control points, and this in turn forces the control limits to be compressed.

Figure 17.169 \bar{X} and R Charts Without Clipping

You can request clipping by specifying the option `CLIPFACTOR=factor`, where *factor* is a value greater than one (useful values are typically in the range 1.5 to 2). Clipping is applied in two steps, as follows:

1. If a plotted statistic is greater than y_{\max} , it is temporarily set to y_{\max} , where

$$y_{\max} = LCL + (UCL - LCL) \times factor$$

If a plotted statistic is less than y_{\min} , it is temporarily set to y_{\min} , where

$$y_{\min} = UCL - (UCL - LCL) \times factor$$

2. Axis scaling is applied to the clipped statistics. Then the y_{\max} values are reset to the maximum value on the axis and the y_{\min} values are reset to the minimum value on the axis.

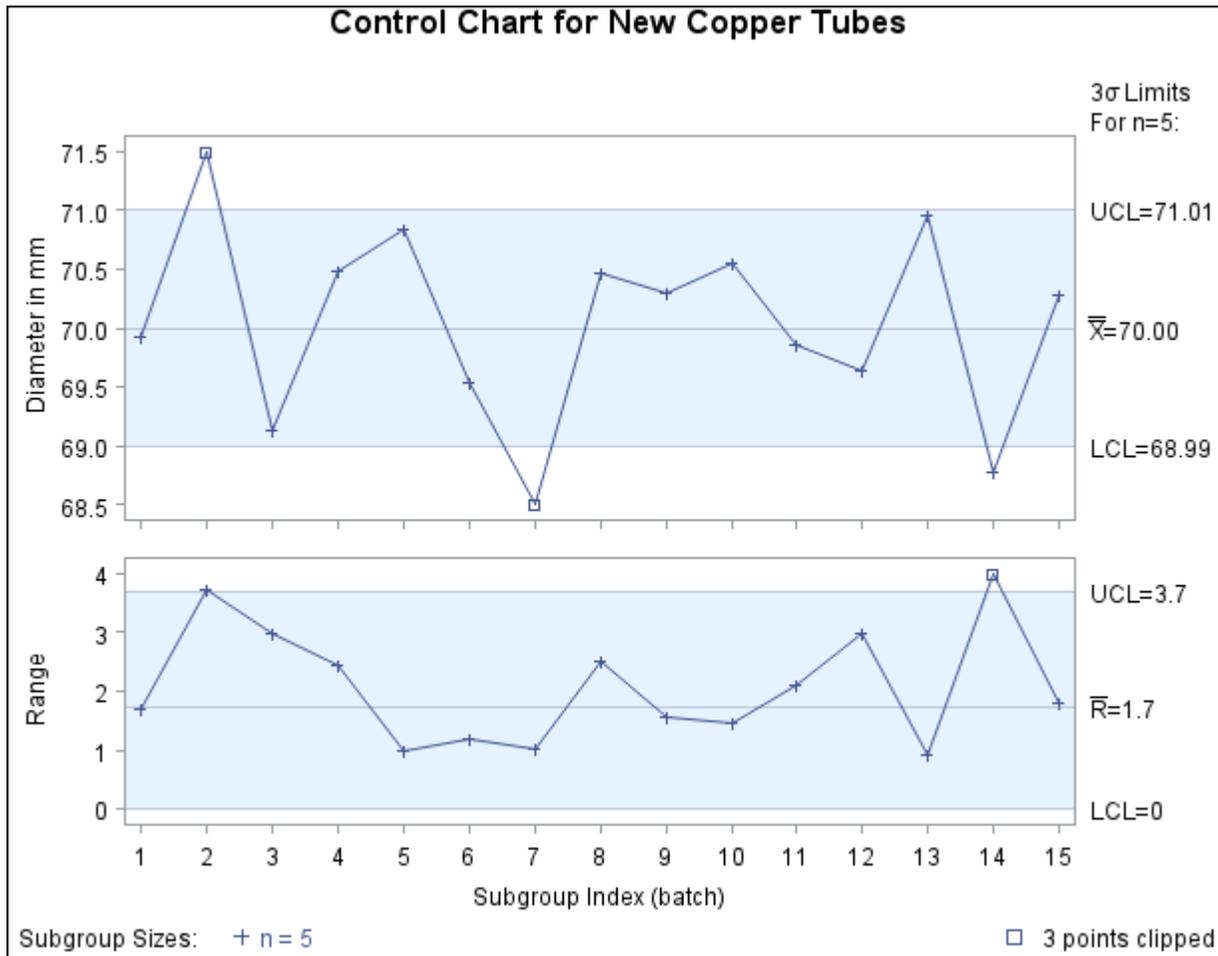

Notes:

- Clipping is applied only to the plotted statistics and not to the statistics tabulated or saved in an output data set.

- Because the *factor* must be greater than one, clipping does not affect whether a plotted statistic is inside or outside the control limits.
- Tests for special causes are applied to the plotted statistics before they are clipped, and clipping does not affect how the tests are flagged on the chart. In some situations, however, clipping can make the patterns associated with the tests less evident on the chart.
- When primary and secondary charts are displayed, the same clipping *factor* is applied to both charts.
- A special symbol is used for clipped points (the default symbol is a square), and a legend is added to the chart indicating the number of points that were clipped.

The following statements create \bar{X} and R charts, shown in [Figure 17.170](#), that use a clipping factor of 1.5:

```
symbol value=plus;
title 'Control Chart for New Copper Tubes' ;
proc shewhart data=newtubes;
  xrchart Diameter*batch /
    mu0          = 70
    sigma0       = 0.75
    clipfactor   = 1.5;
run;
```

Figure 17.170 \bar{X} and R Charts with Clip Factor of 1.5

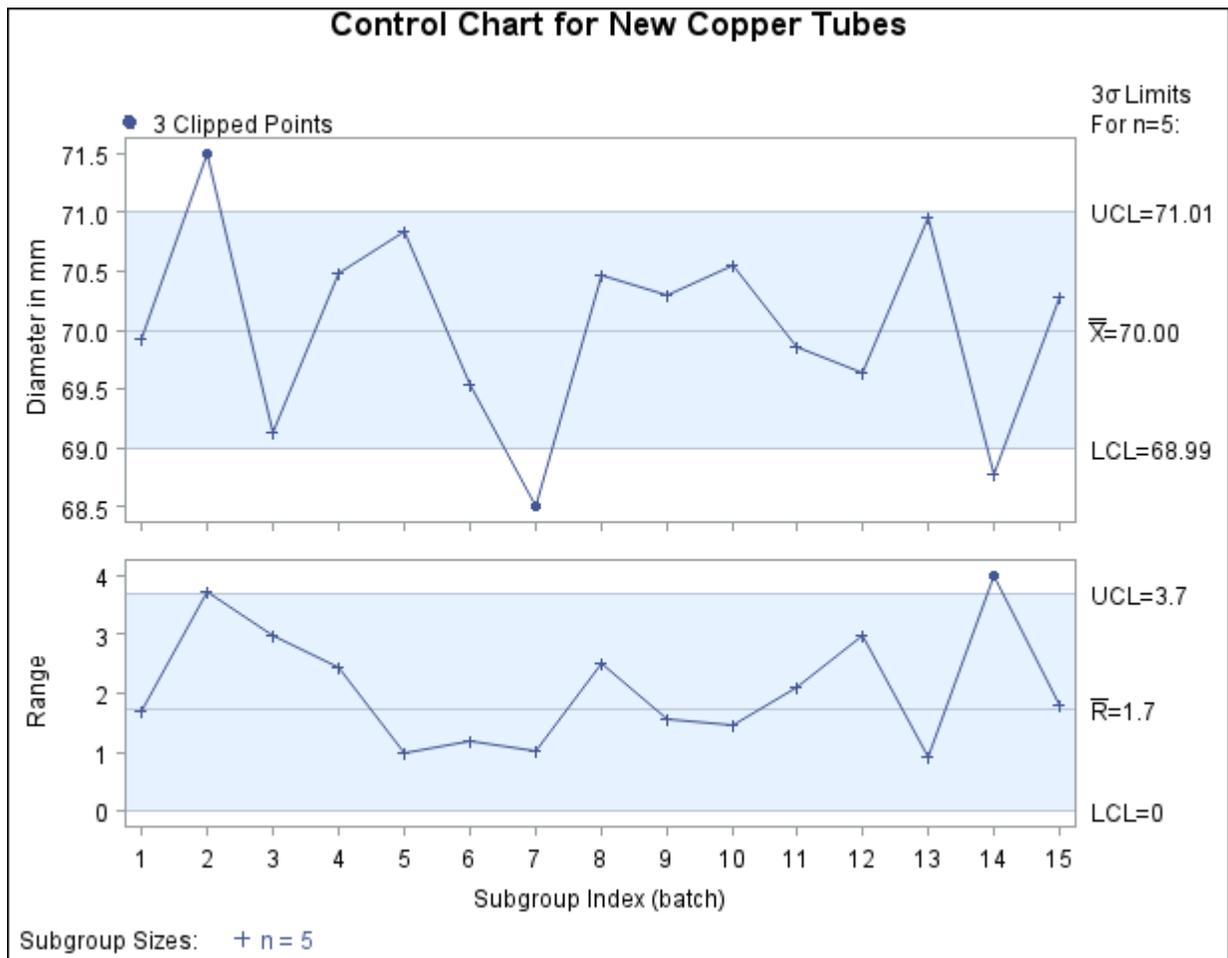

In Figure 17.170, the extreme out-of-control points are clipped making the points plotted within the control limits more readable. The clipped points are marked with a square, and a clipping legend is added at the lower right of the display.

Other clipping options are available, as illustrated by the following statements:

```

symbol value=plus;
title 'Control Chart for New Copper Tubes' ;
proc shewhart data=newtubes;
  xrchart Diameter*batch /
    mu0      = 70
    sigma0   = 0.75
    clipfactor = 1.5
    clipsymbol = dot
    cliplegpos = top
    cliplegend = '# Clipped Points'
    clipsubchar = '#';
run;

```

Figure 17.171 \bar{X} and R Charts Using Clipping Options

Specifying `CLIPSYMBOL=DOT` marks the clipped points with a dot instead of the default square. Specifying `CLIPLEGPOS=TOP` positions the clipping legend at the top of the chart. The options `CLIPLEGEND='# Clipped Points'` and `CLIPSUBCHAR='#'` request the clipping legend *3 Clipped Points*. For more information about the clipping options, see the appropriate entries in “[Dictionary of Options: SHEWHART Procedure](#)” on page 2018.

Labeling Axes

See *SHWLAB* in the *SAS/QC Sample Library*. The SHEWHART procedure provides default labels for the horizontal and vertical axes of control charts. You can specify axis labels by assigning labels to variables, as discussed in the following sections.

Default Labels

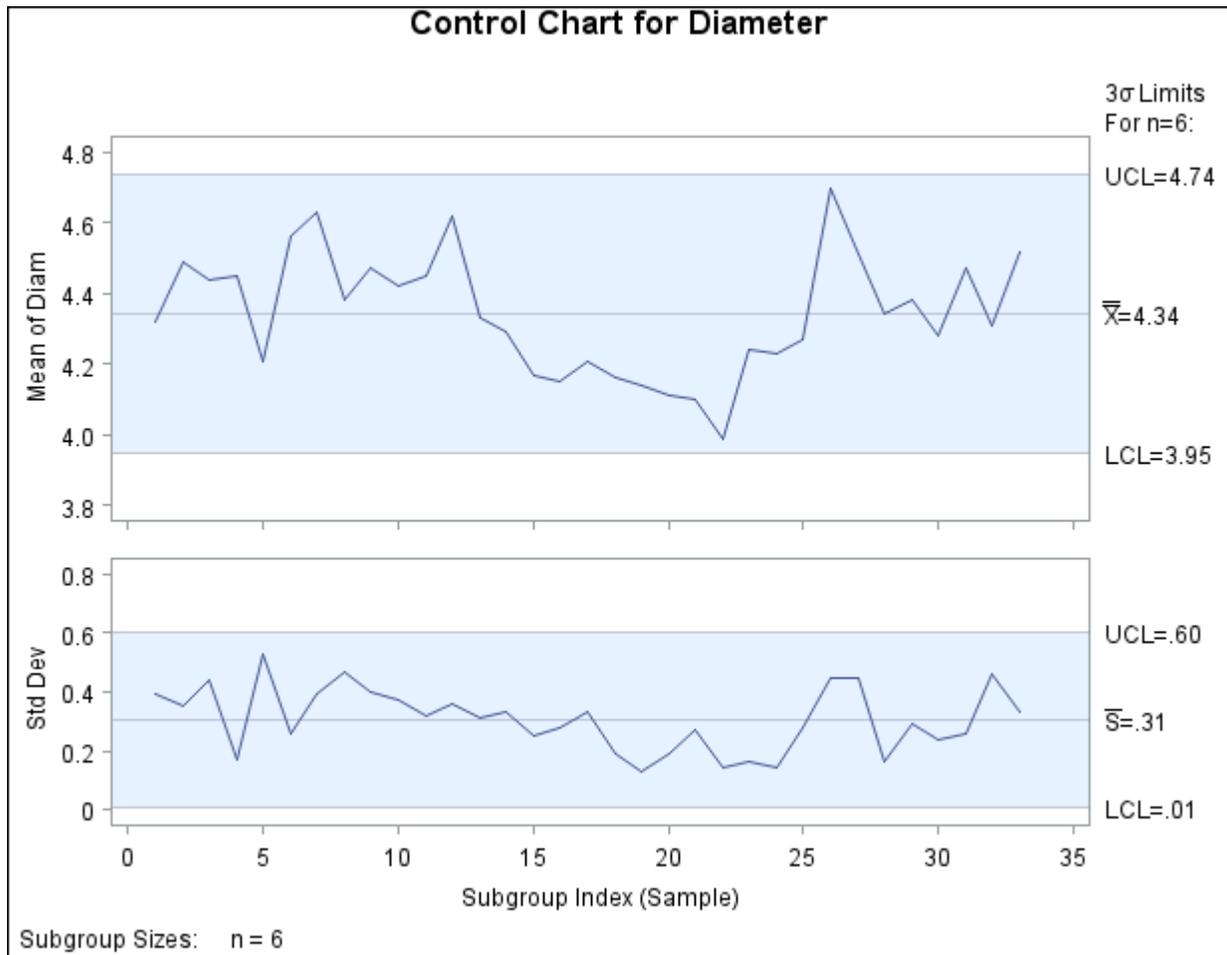

If a label is not associated with the *subgroup-variable*, the default horizontal axis label is “Subgroup Index (*subgroup-variable*).” The default vertical axis label for a primary chart identifies the chart

type and the process variable. The default vertical axis label for a secondary chart identifies the chart type only.

For example, the following statements create \bar{X} and s charts with default labels using the data set `Parts` given in “Displaying Stratified Process Data” on page 2095. The resulting charts are displayed in Figure 17.172.

```
symbol v=none w=1;
title 'Control Chart for Diameter';
proc shewhart history=Parts;
  xschart Diam*Sample;
run;
```

Figure 17.172 Control Charts with Default Labels

Labeling the Horizontal Axis

You can specify a label of up to 40 characters for the horizontal axis by assigning the label to the *subgroup variable* with a `LABEL` statement (refer to *SAS Statements: Reference* for a description of `LABEL` statements). If you use a `LABEL` statement after the `PROC SHEWHART` statement and before the `RUN` statement, the label is associated with the variable only for the duration of the `PROC` step.

For an example, see “Labeling the Vertical Axis” on page 2138, where Figure 17.173 redisplay the \bar{X} and s charts in Figure 17.172 with specified horizontal and vertical axis labels.

Labeling the Vertical Axis

You can specify a label for the vertical axis of a primary chart by using a LABEL statement to assign the label to a particular variable in the input data set. The type of input data set, the chart statement, and the *process* specified in the chart statement determine which variable to use in the LABEL statement.

- If the input data set is a DATA= data set, assign the label to the process variable (*process*) specified in the chart statement.
- If the input data set is a HISTORY= data set, assign the label to the variable specified in the chart statement whose name begins with the prefix *process* and ends with the appropriate suffix given by the following list:

Chart Statement	Suffix
BOXCHART with CONTROLSTAT=MEAN	X
BOXCHART with CONTROLSTAT=MEDIAN	M
CCHART	U
IRCHART	none
MCHART	M
MRCHART	M
NPCHART	P
PCHART	P
RCHART	R
SCHART	S
UCHART	U
XCHART	X
XRCHART	X
XSCHART	X

If the prefix *process* consists of 32 characters, shorten the prefix to its first 16 characters and last 15 characters before adding the suffix.

- If the input data set is a TABLE= data set, assign the label to the predefined variable given by the following table:

Chart Statement	Variable
BOXCHART with CONTROLSTAT=MEAN	_SUBX_
BOXCHART with CONTROLSTAT=MEDIAN	_SUBMED_
CCHART	_SUBC_
IRCHART	_SUBI_
MCHART	_SUBMED_
MRCHART	_SUBMED_
NPCHART	_SUBNP_
PCHART	_SUBP_
RCHART	_SUBR_
SCHART	_SUBS_
UCHART	_SUBU_
XCHART	_SUBX_
XRCHART	_SUBX_
XSCHART	_SUBX_

If the chart statement produces primary and secondary charts, as in the case of the XSCHART statement, you can break the label into two parts by including a split character in the label. The part before the split character labels the vertical axis of the primary chart, and the part after the split character labels the vertical axis of the secondary chart. To specify the split character, use the SPLIT= option in the chart statement.

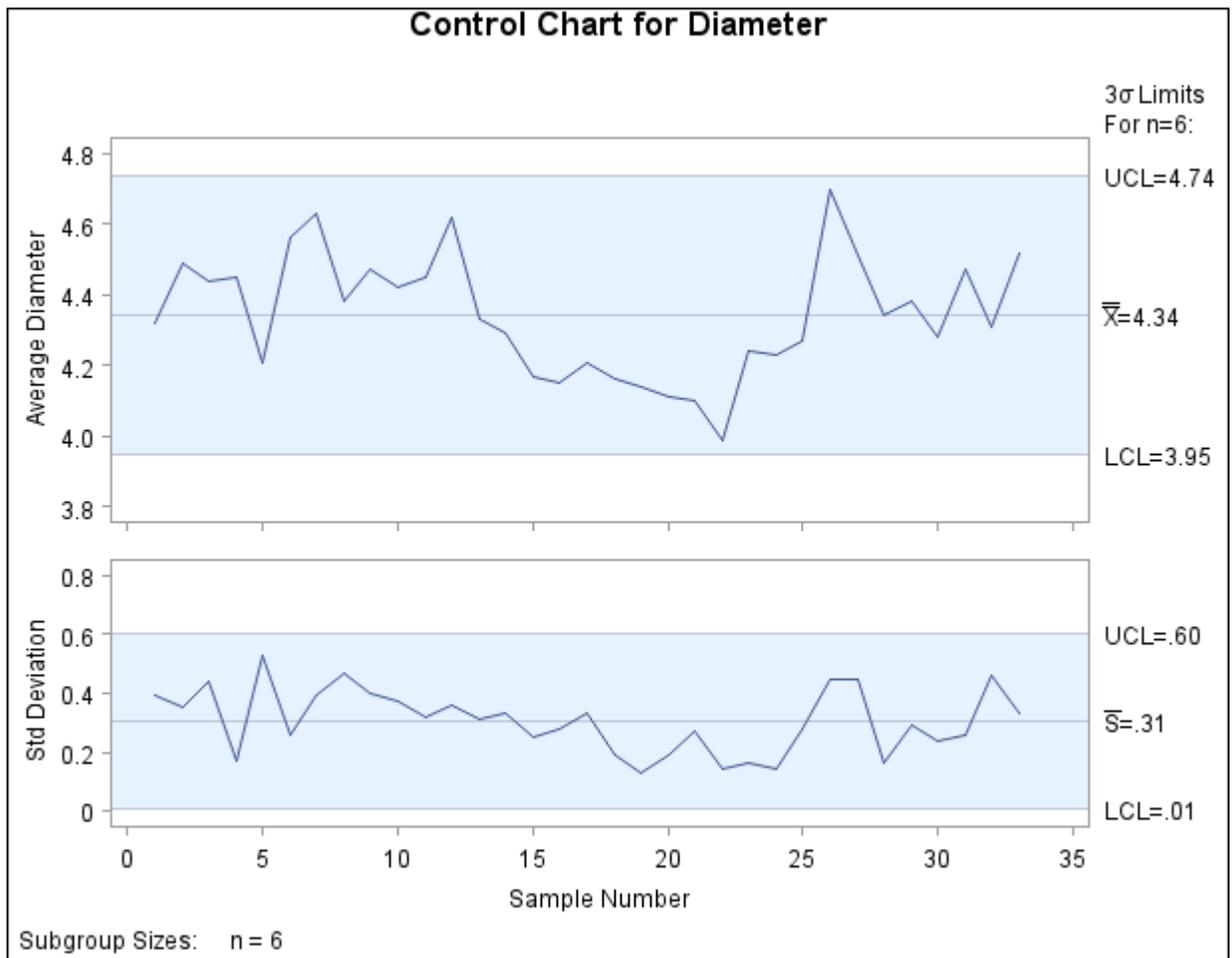

For example, the following statements redisplay the \bar{X} and s charts in Figure 17.172 with specified labels for the horizontal and vertical axes:

```
symbol v=none w=1;
title 'Control Chart for Diameter';
proc shewhart history=Parts;
  xschart Diam*Sample / split = '/';
  label Sample = 'Sample Number'
        DiamX = 'Average Diameter/Std Deviation';
run;
```

The charts are displayed in Figure 17.173. Because the input data set Parts is a HISTORY= data set, the vertical axes are labeled by assigning a label to the subgroup mean variable DiamX (that is, the *process* Diam with the suffix X).⁴⁶ Assigning a label to Diam would result in an error message since Diam is interpreted as a prefix rather than a SAS variable.

⁴⁶If the *process* were Diameter rather than Diam, the label would be assigned to the variable DiameterX.

Figure 17.173 Control Charts with Axis Labels Specified

If the input data set were a DATA= data set rather than a HISTORY= data set, you would associate the label with the variable Diam. If the input data set were a TABLE= data set, you would associate the label with the variable _SUBX_.

For another illustration, see Example 17.17.

Selecting Subgroups for Computation and Display

This section describes methods for specifying which subgroups of observations in an input data set (DATA=, HISTORY=, or TABLE=) are to be used to compute control limits and which subgroups are to be displayed as points on the chart.

Using WHERE Statements

See SHWWHR in the SAS/QC Sample Library The following statements create a data set named BOTTLES that records the number of cracked bottles encountered each day during two months (January and February) of a soft drink bottling operation:

```

data Bottles;
  informat Day date7.;
  format Day date7.;
  nBottles = 3000;
  input Day nCracks @@;
  datalines;
04JAN94 61 05JAN94 56 06JAN94 71 07JAN94 56
10JAN94 51 11JAN94 64 12JAN94 71 13JAN94 91
14JAN94 98 17JAN94 68 18JAN94 63 19JAN94 60
20JAN94 58 21JAN94 55 24JAN94 78 25JAN94 47
26JAN94 54 27JAN94 69 28JAN94 73 31JAN94 66
01FEB94 57 02FEB94 55 03FEB94 63 04FEB94 50
07FEB94 69 08FEB94 54 09FEB94 64 10FEB94 66
11FEB94 70 14FEB94 49 15FEB94 57 16FEB94 56
17FEB94 59 18FEB94 66 21FEB94 60 22FEB94 58
23FEB94 67 24FEB94 60 25FEB94 62 28FEB94 48
;

```

The variable `nBottles` contains the number of bottles sampled each day, and the variable `nCracks` contains the number of cracked bottles in each sample.

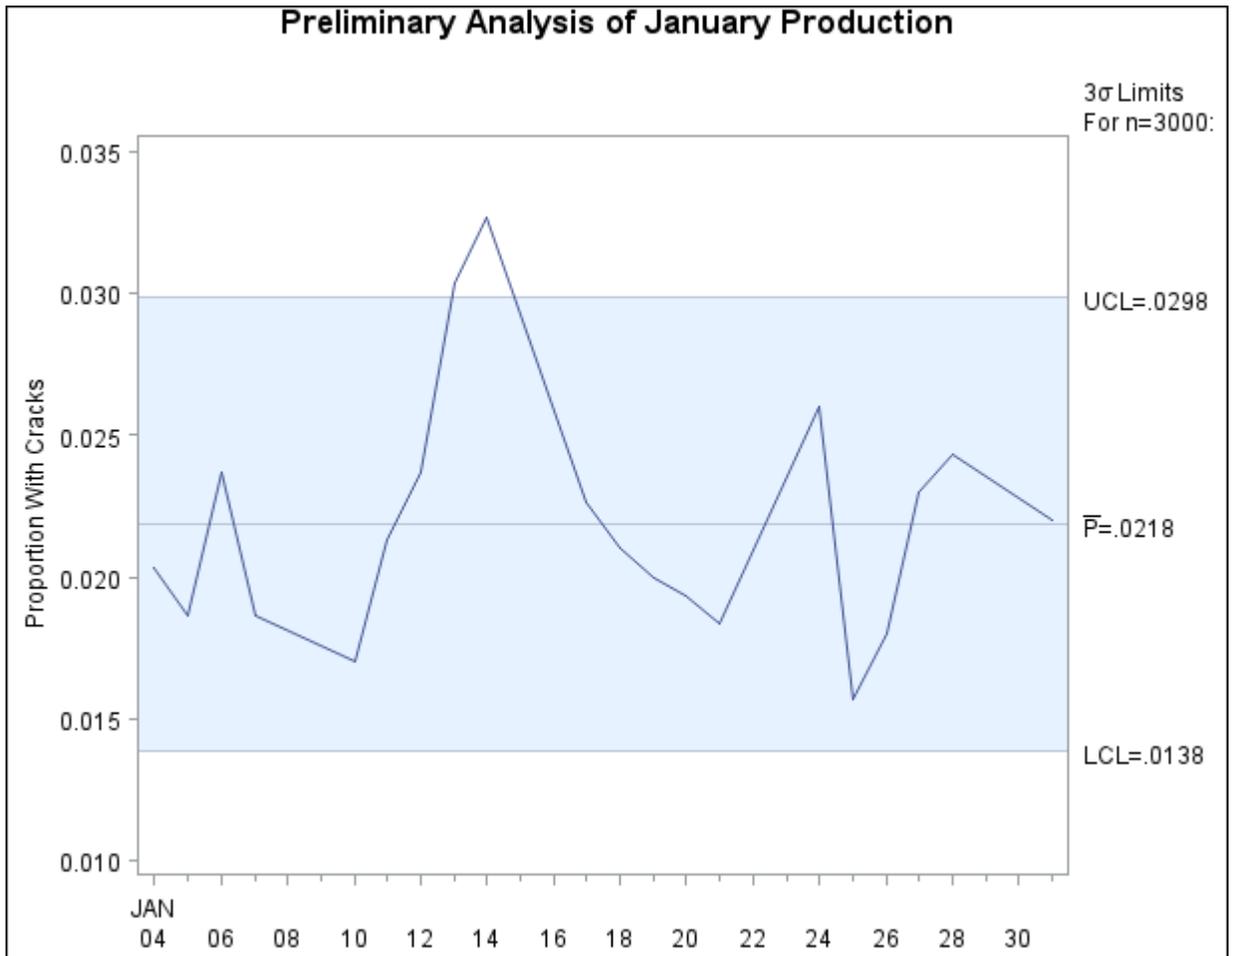

The following statements create a p chart for the number of cracked bottles based on the January production:

```

symbol h=3.0 pct;
title 'Preliminary Analysis of January Production';
proc shewhart data=Bottles;
  where Day <= '31JAN94'D;
  pchart nCracks * Day / subgroupn = nBottles
        nohlabel
        nolegend
        outlimits = mylim;
  label nCracks = 'Proportion With Cracks';
run;

```

The chart is shown in [Figure 17.174](#). The WHERE statement restricts the observations read from BOTTLES so that the control limits are estimated from the January data, and only the January data are displayed on the chart. For details concerning the WHERE statement, refer to *SAS Statements: Reference*.

Figure 17.174 Preliminary p Chart for January Data

In Figure 17.174, a special cause of variation is signaled by the proportions for January 13 and January 14, which exceed the upper control limit. Since the cause, an improper machine setting, was corrected, it is appropriate to recompute the control limits by excluding the data for these two days. Again, this can be done with a WHERE statement, as follows:

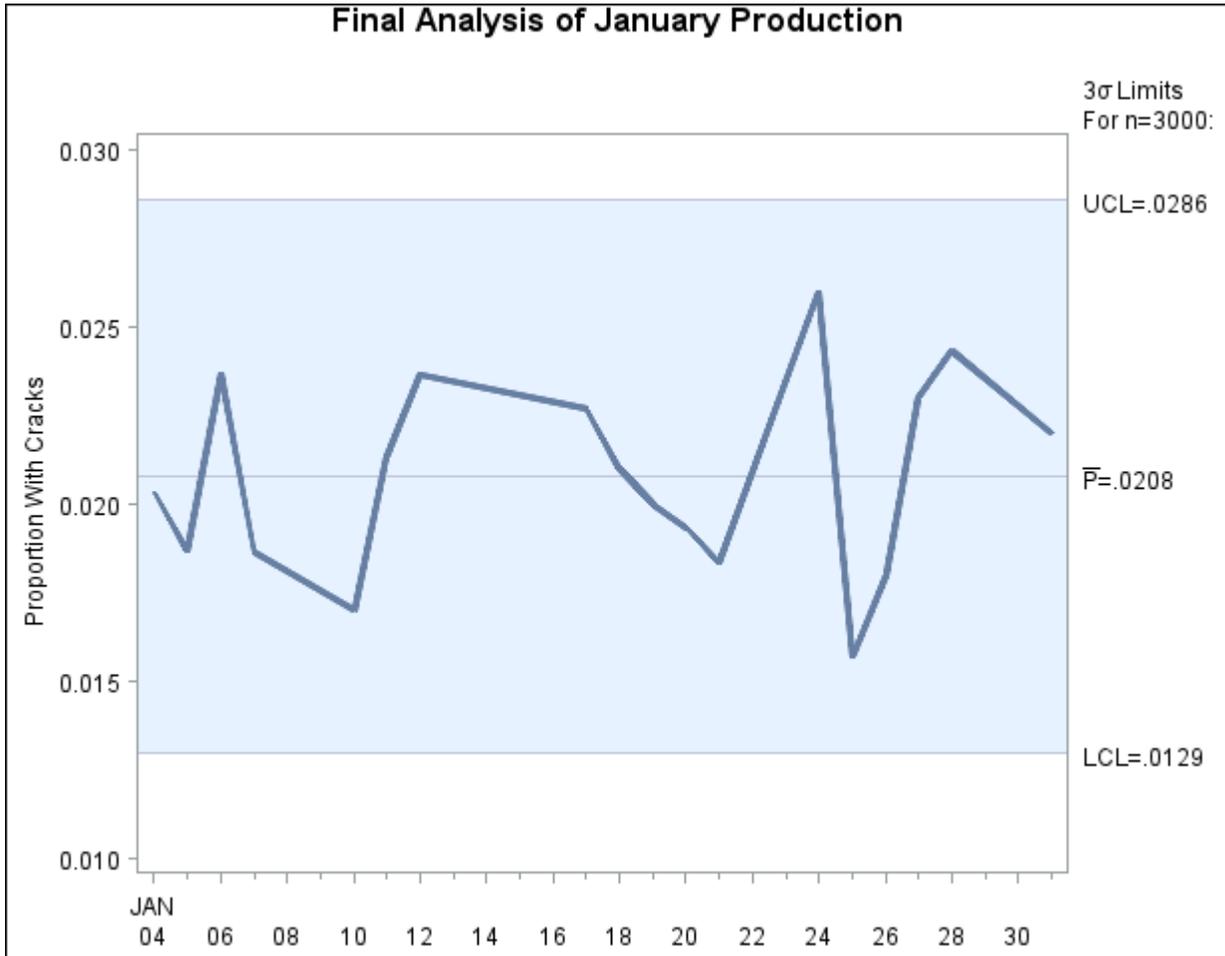

```

title 'Final Analysis of January Production';
proc shewhart data=Bottles;
  where ( Day <= '31JAN94'D ) &
        ( Day ne '13JAN94'D ) &
        ( Day ne '14JAN94'D ) ;
  pchart nCracks * Day / subgroupn = nBottles
        nohlabel
        nolegend
        outlimits = Janlim;
  label nCracks = 'Proportion With Cracks';
run;

```

The chart is shown in Figure 17.175.

Figure 17.175 Final p Chart for January Data

The data set JANLIM, which saves the control limits, is listed in Figure 17.176.

Figure 17.176 Listing of the LIMITS= Data Set JANLIM

Final Analysis of January Production								
	S		L		S			
	U		I	A	I			
	B	T	M	L	G	L		U
V	G	Y	I	P	M	C		C
A	R	P	T	H	A	L		L
R	P	E	N	A	S	P	P	P
nCracks	Day	ESTIMATE	3000	.003072976	3	0.012950	0.020759	0.028569

Now, the control limits based on the January data are to be applied to the February data. Again, this can be done with a WHERE statement, as follows:⁴⁷

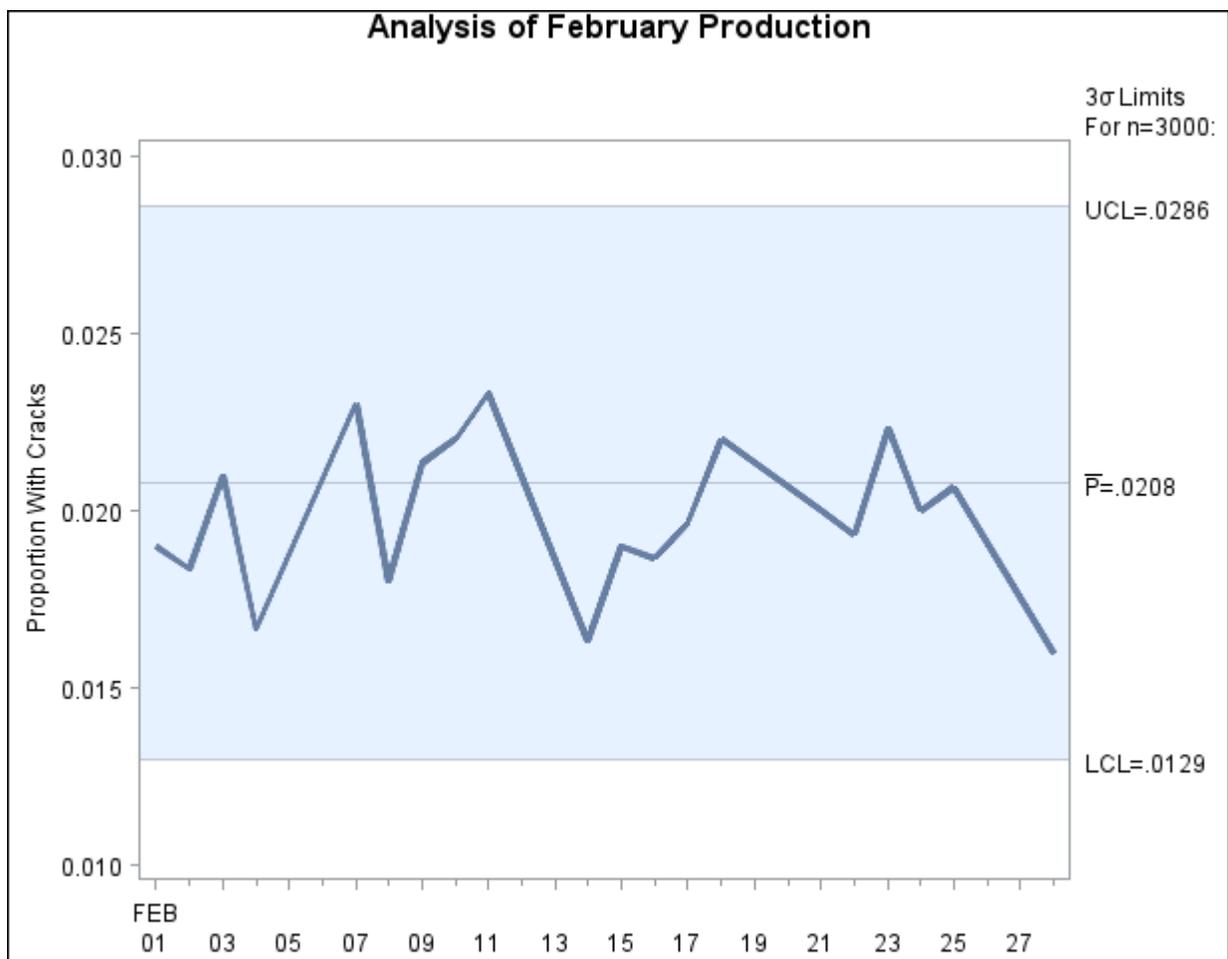

```

title 'Analysis of February Production';
proc shewhart data=Bottles limits=Janlim;
  where Day > '31JAN94'D;
  pchart nCracks * Day / subgroupn = nBottles
          nolegend
          nohlabel;
  label nCracks = 'Proportion With Cracks';
run;

```

The chart is shown in Figure 17.177.

Figure 17.177 *p* Chart for February Data

⁴⁷In SAS 6.09 and in earlier releases, it is also necessary to specify the READLIMITS option to read control limits from a LIMITS= data set.

Using Switch Variables

As an alternative to reading a LIMITS= data set and using a WHERE statement, you can provide two special switch variables named `_COMP_` and `_DISP_` in the input data set. The rules for using these variables are as follows: *See SHWSVAR in the SAS/QC Sample Library*

- Switch variables must be character variables of length one. Valid values for these variables are 'Y' (or 'y') and 'N' (or 'n'). A blank value is treated as 'Y'.
- Subgroups for which `_COMP_` is equal to 'Y' are included in computations of parameter estimates and control limits, and observations for which `_COMP_` is equal to 'N' are excluded.
- Subgroups for which `_DISP_` is equal to 'Y' are displayed on the chart, and subgroups for which `_DISP_` is equal to 'N' are not displayed.
- If the chart statement creates a chart for variables, you can provide two additional switch variables named `_COMP2_` and `_DISP2_`, which are defined similarly to `_COMP_` and `_DISP_`. In this case, the variable `_COMP_` specifies which subgroups are used to estimate the process mean μ , and the variable `_COMP2_` specifies which subgroups are used to estimate the process standard deviation σ . The variable `_DISP_` specifies which subgroups are displayed on the primary chart (\bar{X} chart, median chart, or individual measurements chart), and the variable `_DISP2_` specifies which subgroups are displayed on the secondary chart (R chart or s chart).
- The variables `_COMP_` and `_COMP2_` are not applicable when control limits or control limit parameters are read from a LIMITS= data set.
- The variables `_DISP_` and `_DISP2_` take precedence over the display controlled by the LIMITN= and ALLN options.
- If the input data set is a DATA= data set with multiple observations per subgroup, switch variable values must be constant within a subgroup.
- Switch variables are saved in OUTHISTORY= and OUTTABLE= data sets. Subgroups for which `_DISP_` is equal to 'N' are not saved in an OUTTABLE= data set, and such subgroups are not displayed in tables created with the TABLE and related options.

The following statements illustrate how the switch variables `_COMP_` and `_DISP_` can be used with the bottle production data:

```
data bottles;
  length _comp_ _disp_ $ 1;
  set Bottles;
  if      Day = '13JAN94'D then _comp_ = 'n';
  else if Day = '14JAN94'D then _comp_ = 'n';
  else if Day <= '31JAN94'D then _comp_ = 'y';
  else
    _comp_ = 'n';
  if      Day <= '31JAN94'D then _disp_ = 'n';
  else
    _disp_ = 'y';
run;

title 'Analysis of February Production';
proc shewhart data=Bottles;
```

```

pchart nCracks * day / subgroupn = nBottles
      nolegend
      nohlabel;
label nCracks = 'Proportion With Cracks';
run;

```

The chart is identical to the chart in [Figure 17.177](#).

In general, switch variables are more versatile than WHERE statements in applications where subgroups are simultaneously selected for computation and display. Switch variables also provide a permanent record of which subgroups were selected. The WHERE statement does not alter the input data set; it simply restricts the observations that are read; consequently, the WHERE statement can be more efficient than switch variables for processing large data sets.

Tests for Special Causes: SHEWHART Procedure

This section provides details concerning standard and nonstandard tests for special causes that you can apply with the SHEWHART procedure.

Standard Tests for Special Causes

The SHEWHART procedure provides eight standard *tests for special causes*, also referred to as *rules for lack of control*, *supplementary rules*, *runs tests*, *runs rules*, *pattern tests*, and *Western Electric rules*. These tests improve the sensitivity of the Shewhart chart to small changes in the process.⁴⁸ You can also improve the sensitivity of the chart by increasing the rate of sampling, increasing the subgroup sample size, and using control limits that represent less than three standard errors of variation from the central line. However, increasing the sampling rate and sample size is often impractical, and tightening the control limits increases the chances of falsely signaling an out-of-control condition. By detecting particular nonrandom patterns in the points plotted on the chart, the tests can provide greater sensitivity and useful diagnostic information while incurring a reasonable probability of a false signal.

The patterns detected by the eight standard tests are defined in [Table 17.92](#) and [Table 17.93](#), and they are illustrated in [Figure 17.178](#) and [Figure 17.179](#). All eight tests were developed for use with fixed 3σ limits. The tests are indexed according to the numbering sequence used by Nelson (1984, 1985). You can request any combination of the eight tests by specifying the test *indexes* with the TESTS= option in the BOXCHART, CCHART, IRCHART, MCHART, MRCHART, NPCHART, PCHART, UCHART, XCHART, XRCHART, and XSCHART statements.

The following restrictions apply to the tests:

- Only Tests 1, 2, 3, and 4 are recommended for c charts, np charts, p charts, and u charts created with the CCHART, NPCHART, PCHART, and UCHART statements, respectively. In

⁴⁸Cumulative sum control charts and moving average control charts also detect small shifts more quickly than an ordinary Shewhart chart. See the sections “PROC CUSUM Statement” on page 567 and “PROC MACONTROL Statement” on page 810 for more information.

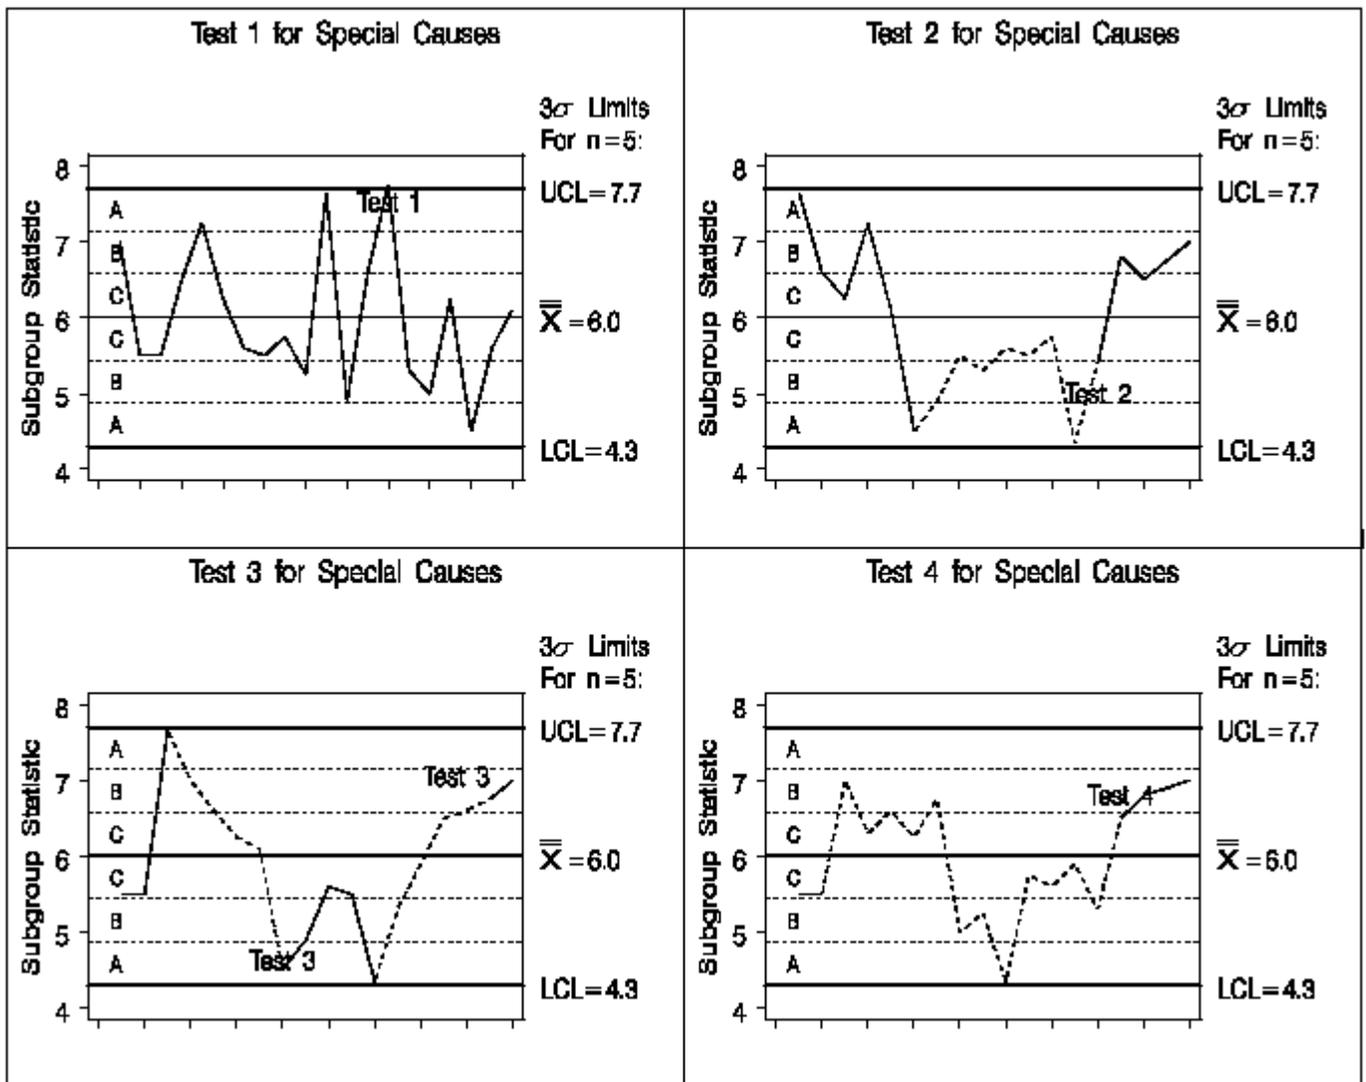

these four cases, Test 2 should not be used unless the process distribution is symmetric or nearly symmetric.

- By default, the TESTS= option is not applied with control limits that are not 3σ limits or that vary with subgroup sample size. You can use the NO3SIGMACHECK option to request tests for special causes when the SIGMAS= option specifies control limits other than 3σ limits. This is not recommended for standard control chart applications, since the standard tests for special causes are based on 3σ limits. You can apply tests for special causes when control limits vary with subgroup sample size by using the LIMITN= or TESTNMETHOD= options (see “Requesting Standard Tests” on page 2150 and “Applying Tests with Varying Subgroup Sample Sizes” on page 2154).

Table 17.92 Definitions of Tests 1 to 4

Test Index	Pattern Description
1	One point beyond Zone A (outside the control limits)
2	Nine points in a row in Zone C or beyond on one side of the central line (see Note 1 below)
3	Six points in a row steadily increasing or steadily decreasing (see Note 2 below)
4	Fourteen points in a row alternating up and down

Figure 17.178 Examples of Tests 1 to 4

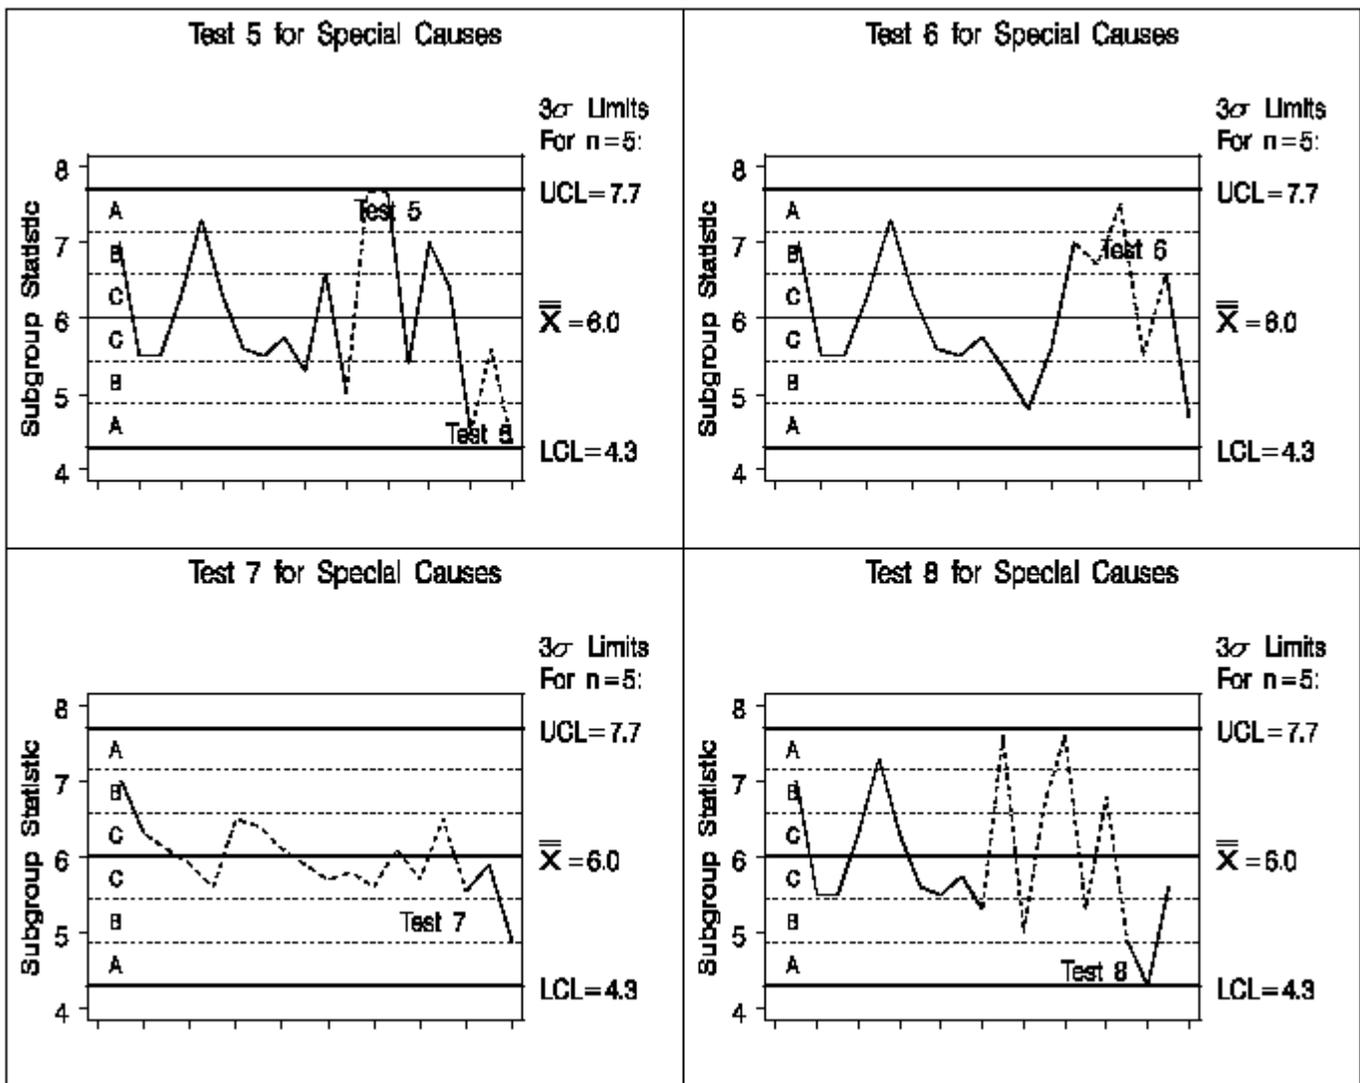

Notes:

1. The number of points in Test 2 can be specified as 7, 8, 9, 11, 14, or 20 with the TEST2RUN= option.
2. The number of points in Test 3 can be specified as 6, 7, or 8 with the TEST3RUN= option.

Table 17.93 Definitions of Tests 5 to 8

Test Index	Pattern Description
5	Two out of three points in a row in Zone A or beyond
6	Four out of five points in a row in Zone B or beyond
7	Fifteen points in a row in Zone C on either or both sides of the central line
8	Eight points in a row on either or both sides of the central line with no points in Zone C

Figure 17.179 Examples of Tests 5 to 8

Requesting Standard Tests

See *SHWTSCI* in the *SAS/QC Sample Library*. The following example illustrates how to request the standard tests for special causes. The tests are applied to an \bar{X} chart for assembly offset measurements whose subgroup means, ranges, and sample sizes are provided by the variables `OffsetX`, `OffsetR`, and `OffsetN`, respectively, in a data set named `Assembly`.⁴⁹

```

data Assembly;
  length System $ 1 comment $ 16;
  label Sample = 'Sample Number';
  input System Sample OffsetX OffsetR OffsetN comment $16. ;
  datalines;
T   1  19.80  3.8  5
T   2  17.16  8.3  5
T   3  20.11  6.7  5
T   4  20.89  5.5  5
T   5  20.83  2.3  5
T   6  18.87  2.6  5
T   7  20.84  2.3  5
T   8  23.33  5.7  5  New Tool
T   9  19.21  3.5  5
T  10  20.48  3.2  5
T  11  22.05  4.7  5
T  12  20.02  6.7  5
T  13  17.58  2.0  5
T  14  19.11  5.7  5
T  15  20.03  4.1  5
R  16  20.56  3.7  5  Changed System
R  17  20.86  3.3  5
R  18  21.10  5.6  5  Reset Tool
R  19  19.05  2.7  5
R  20  21.76  2.8  5
R  21  21.76  6.4  5
R  22  20.54  4.8  5
R  23  20.04  8.2  5
R  24  19.94  8.8  5
R  25  20.70  5.1  5
Q  26  21.40 12.1  7  Bad Reading
Q  27  21.32  3.2  7
Q  28  20.03  5.2  7  New Gauge
Q  29  22.02  5.9  7
Q  30  21.32  4.3  7
;

```

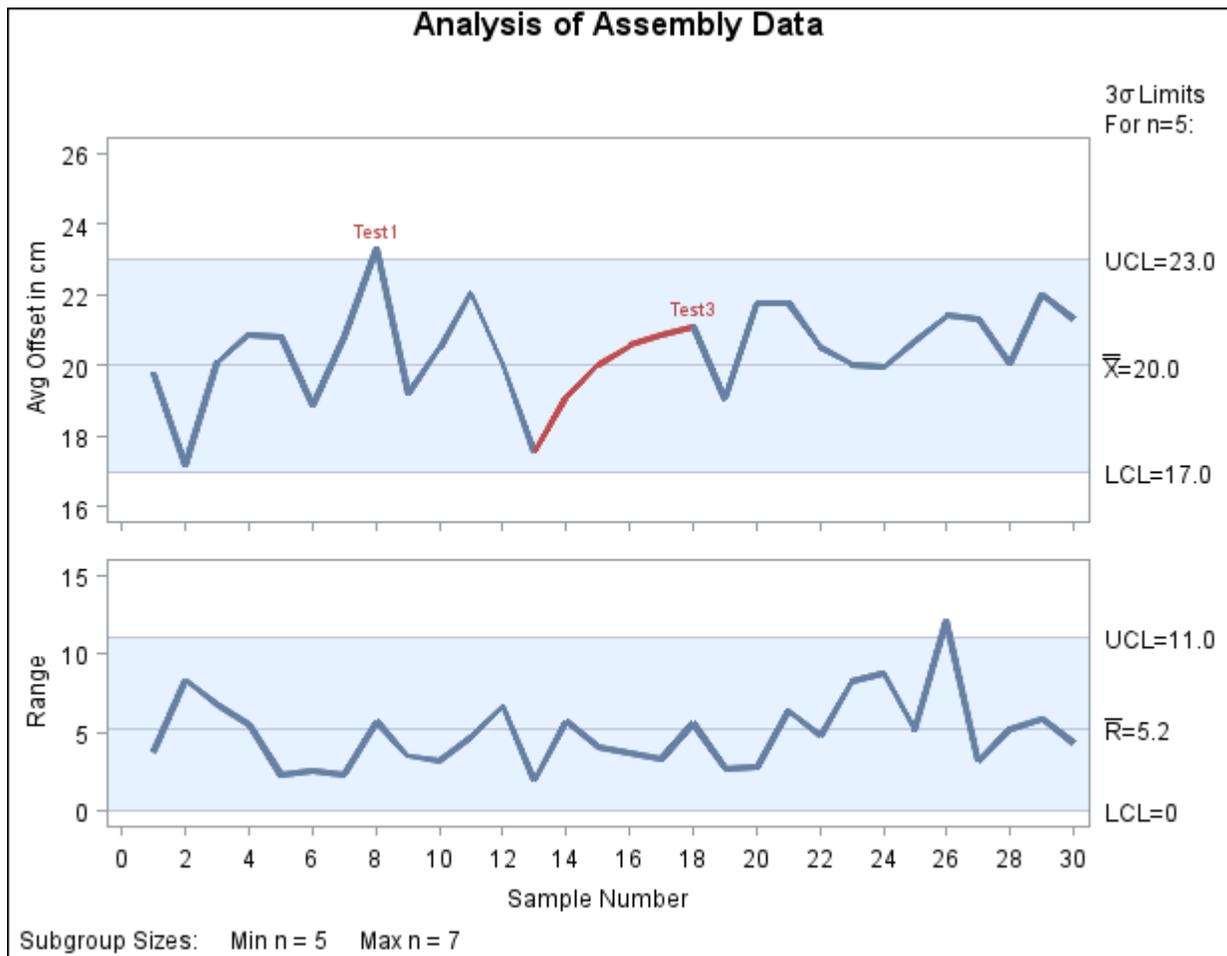

The following statements use the `TESTS=` option to request Tests 1 to 4. Note that the *process* `Offset` is specified in the `XRCHART` statement to indicate that the three summary variables `OffsetX`, `OffsetR`, and `OffsetN` are to be read from the `HISTORY=` data set `Assembly`.

⁴⁹The data set `Assembly` is also used by subsequent examples in this section.

```
ods graphics off;
title 'Analysis of Assembly Data';
proc shewhart history=Assembly;
  xrchart Offset * Sample / mu0      = 20
                                sigma0 = 2.24
                                limitn  = 5
                                alln
                                tests    = 1 to 4
                                vaxis    = 16 to 26 by 2
                                split    = '/';
  label OffsetX = 'Avg Offset in cm/Range';
run;
```

The chart is displayed in Figure 17.180. Test 1 is positive at the 8th subgroup, and Test 3 is positive at the 18th subgroup.

Figure 17.180 Standard Tests Using the TESTS= Option

The control limits in Figure 17.180 are based on standard values for the process mean and standard deviation specified with the MU0= and SIGMA0= options, respectively. Although the subgroup sizes vary, fixed control limits are displayed corresponding to a nominal sample size of five, which is specified with the LIMITN= option. Since ALLN is specified, points are displayed for all subgroups, regardless of sample size.

NOTE: If the LIMITN= option were not specified, the control limits would vary with subgroup sample size, and by default the tests would not be applied. An alternative method for applying the tests with varying subgroup sample sizes is discussed in “Applying Tests with Varying Subgroup Sample Sizes” on page 2154.

Interpreting Standard Tests for Special Causes

Nelson (1984, 1985) makes the following comments concerning the interpretation of the tests:

- When a process is in statistical control, the chance of a false signal for each test is less than five in one thousand.
- Test 1 is positive if there is a shift in the process mean, if there is an increase in the process standard deviation, or if there is a “single aberration in the process such as a mistake in calculation, an error in measurement, bad raw material, a breakdown of equipment, and so on” (Nelson 1985).
- Test 2 signals a shift in the process mean. The use of nine points (rather than seven as in (Grant and Leavenworth 1988) for the pattern that defines Test 2 makes the chance of a false signal comparable to that of Test 1. (To control the number of points for the pattern in test 2, use the TEST2RUN= option in the chart statement.)
- Test 3 signals a drift in the process mean. Nelson (1985) states that causes can include “tool wear, depletion of chemical baths, deteriorating maintenance, improvement in skill, and so on.”
- Test 4 signals “a systematic effect such as produced by two machines, spindles, operators or vendors used alternately” (Nelson 1985).
- Tests 1, 2, 3, and 4 should be applied routinely; the combined chance of a false signal from one or more of these tests is less than one in a hundred. Nelson (1985) describes these tests as “a good set that will react to many commonly occurring special causes.”
- In the case of charts for variables, the first four tests should be augmented by Tests 5 and 6 when earlier warning is desired. The chance of a false signal increases to two in a hundred.
- Tests 7 and 8 indicate stratification (observations in a subgroup have multiple sources with different means). Test 7 is positive when the observations in the subgroup always have multiple sources. Test 8 is positive when the subgroups are taken from one source at a time.

Nelson (1985) also comments that “the probabilities quoted for getting false signals should not be considered to be very accurate” since the probabilities are based on assumptions of normality and independence that may not be satisfied. Consequently, he recommends that the tests “should be viewed as simply practical rules for action rather than tests having specific probabilities associated with them.” Nelson cautions that “it is possible, though unlikely, for a process to be out of control yet not show any signals from these eight tests.”

Modifying Standard Tests for Special Causes

Some textbooks and references present slightly different versions of Tests 2 and 3. You can use the following options to request these modifications:

- TEST2RUN=*run-length* specifies the length of the pattern for Test 2. The form of the test for each *run-length* is given in the following table. The default *run-length* is 9.

Run-length	Number of Points on One Side of Central Line
7	7 in a row
8	8 in a row
9	9 in a row
11	at least 10 out of 11 in a row
14	at least 12 out of 14 in a row
20	at least 16 out of 20 in a row

- TEST3RUN=*run-length* specifies the length of the pattern for Test 3. The *run-length* values allowed are 6, 7, and 8. The default *run-length* is 6.

The Western Electric Company (now AT&T) *Statistical Quality Control Handbook* (1956) and Montgomery (1996) discuss a test that is signaled by eight points in a row in Zone C or beyond (on one side of the central line). You can request this test by specifying TESTS=2 and TEST2RUN=8. The *Handbook* also discusses tests corresponding to Tests 1, 5, 6, 7, and 8.

Kume (1985) recommends a number of tests for special causes that can be regarded as modifications of Tests 2 and 3:

- seven points in a row on one side of the central line. Specify TESTS=2 and TEST2RUN=7.
- at least 10 out of 11 points in a row on one side of the central line. Specify TESTS=2 and TEST2RUN=11.
- at least 12 out of 14 points in a row on one side of the central line. Specify TESTS=2 and TEST2RUN=14.
- at least 16 out of 20 points in a row on one side of the central line. Specify TESTS=2 and TEST2RUN=20.
- seven points in a row steadily increasing or decreasing. Specify TESTS=3 and TEST3RUN=7.

Applying Tests with Varying Subgroup Sample Sizes

See SHWTSCI in the
SAS/QC Sample Library

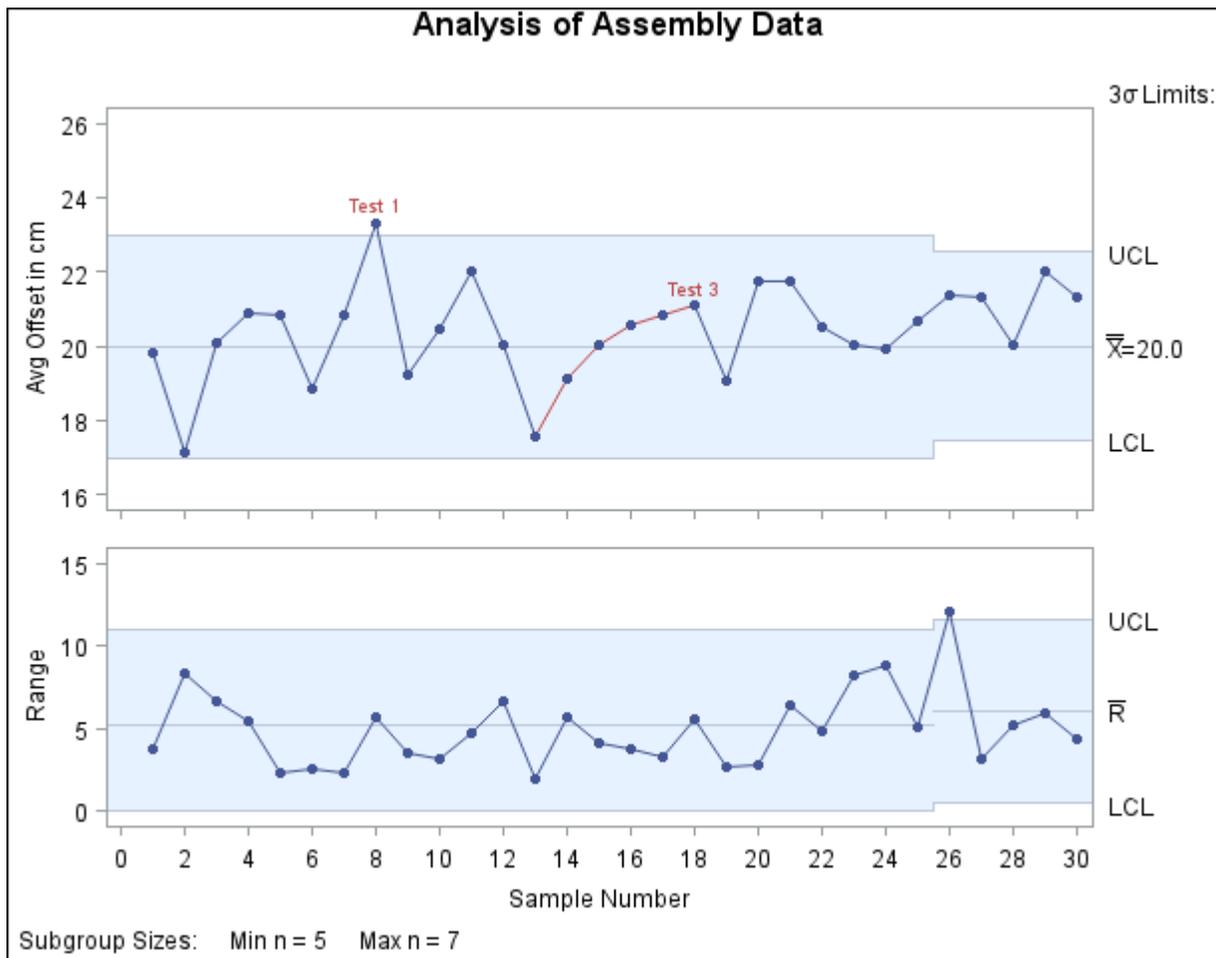

Nelson (1989, 1994) describes the use of standardization to apply the tests for special causes to data involving varying subgroup samples. This approach applies the tests to the standardized subgroup statistics, setting the control limits at ± 3 and the zone boundaries at ± 1 and ± 2 . For instance, for an \bar{X} chart with subgroup means \bar{X}_i and varying subgroup sample sizes n_i , the tests are applied to the standardized values $z_i = (\bar{X}_i - \bar{\bar{X}})/(s/\sqrt{n_i})$, where $\bar{\bar{X}}$ estimates the process mean, and s estimates the process standard deviation. You can request this method with the TESTNMETHOD= option,⁵⁰ as illustrated by the following statements:

```
ods graphics off;
title 'Analysis of Assembly Data';
symbol v=dot;
proc shewhart history=Assembly;
  xrchart Offset * Sample / mu0          = 20
                                sigma0    = 2.24
                                tests      = 1 to 4
                                testnmeth = standardize
                                testlabel  = space
                                vaxis      = 16 to 26 by 2
                                wtests    = 1
                                split     = '/';
  label OffsetX = 'Avg Offset in cm/Range';
run;
```

Here the tests are applied to $z_i = (\bar{X}_i - 20)/(2.24/\sqrt{n_i})$. The chart, shown in [Figure 17.181](#), displays the results of the tests on a plot of the *unstandardized* means.

⁵⁰If the TESTNMETHOD= option were omitted in this example, the tests would not be applied, and a warning message would be displayed in the SAS log.

Figure 17.181 The TESTNMETHOD= Option for Varying Subgroup Sizes

The following statements create an equivalent chart that plots the *standardized* means:

```

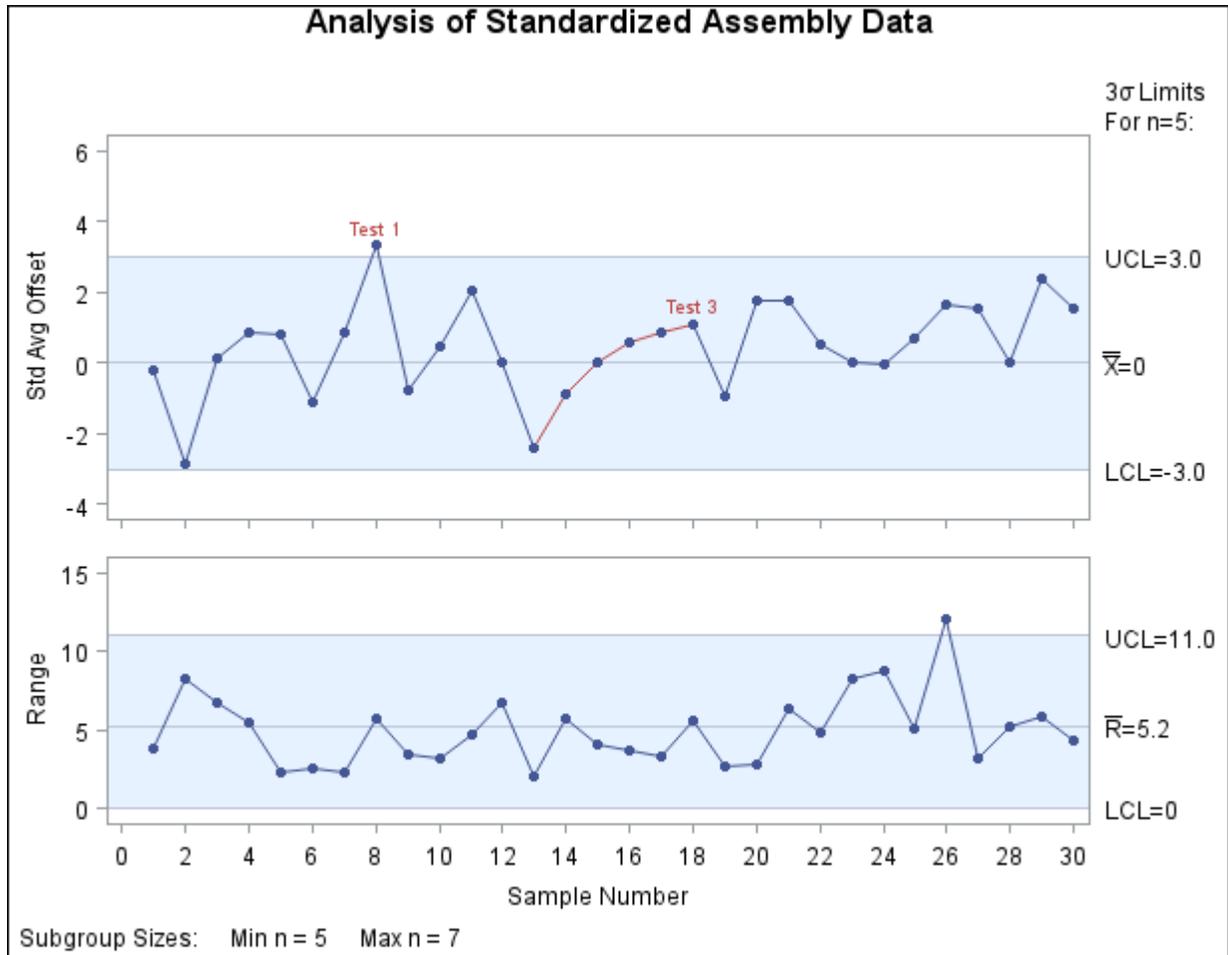

data Assembly;
  set Assembly;
  zx = ( OffsetX - 20 ) / ( 2.24 / sqrt( OffsetN ) );
run;

ods graphics off;
title 'Analysis of Standardized Assembly Data';
symbol v=dot;
proc shewhart
  history=Assembly (rename = (OffsetR=zr OffsetN=zn));
  xrchart z * Sample / mu0          = 0
          sigma0                    = 2.2361 /* sqrt 5 */
          limitn                     = 5
          alln
          tests                      = 1 to 4
          testlabel                   = space
          vaxis                      = -4 to 6 by 2
          wtests                     = 1
          split                       = '/';
  label zx = 'Std Avg Offset/Range';
run;

```

Here, the $SIGMA0=$ value is the square root of the $LIMITN=$ value. The chart is shown in Figure 17.182.

Figure 17.182 Tests with Standardized Means

NOTE: In situations where the standard deviation is estimated from the data and the subgroup sample sizes vary, you can use the $SMETHOD=$ option to request various estimation methods, including the method of Burr (1969).

Labeling Signaled Points with a Variable

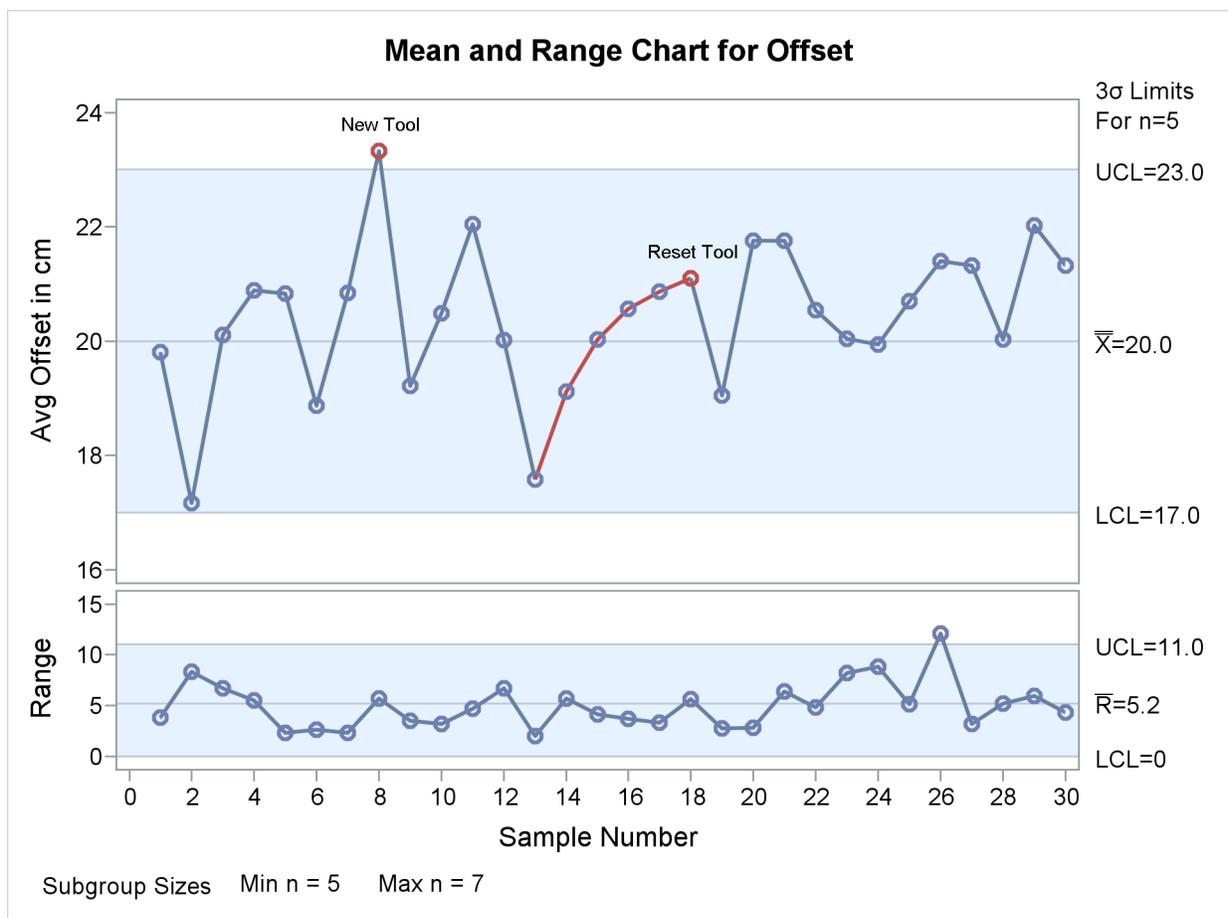

See *SHWTSC1* in the *SAS/QC Sample Library*. If a test is signaled at a particular point, the point is labeled by default with the *index* of the test, as illustrated in Figure 17.180.⁵¹ You can use the $TESTLABEL=$ option to specify a variable in the input data set whose *values* provide the labels, as illustrated by the following statements:

⁵¹If two or more tests are positive at a particular point, the default label identifies the *index* of the test that was specified first with the $TESTS=$ option.

```
ods graphics on;
title 'Analysis of Assembly Data';
proc shewhart history=Assembly;
  xrchart Offset * Sample / mu0      = 20
                                sigma0 = 2.24
                                limitn  = 5
                                alln
                                tests   = 1 to 4
                                testlabel = ( comment )
                                vaxis   = 16 to 24 by 2
                                split   = '/'
                                markers;
  label OffsetX = 'Avg Offset in cm/Range';
run;
```

The labels are shown in Figure 17.183. It is often helpful to specify a variable with the TESTLABEL= option that provides operator comments or other information that can aid in the identification of special causes.

Figure 17.183 Labeling Points with a TESTLABEL= Variable

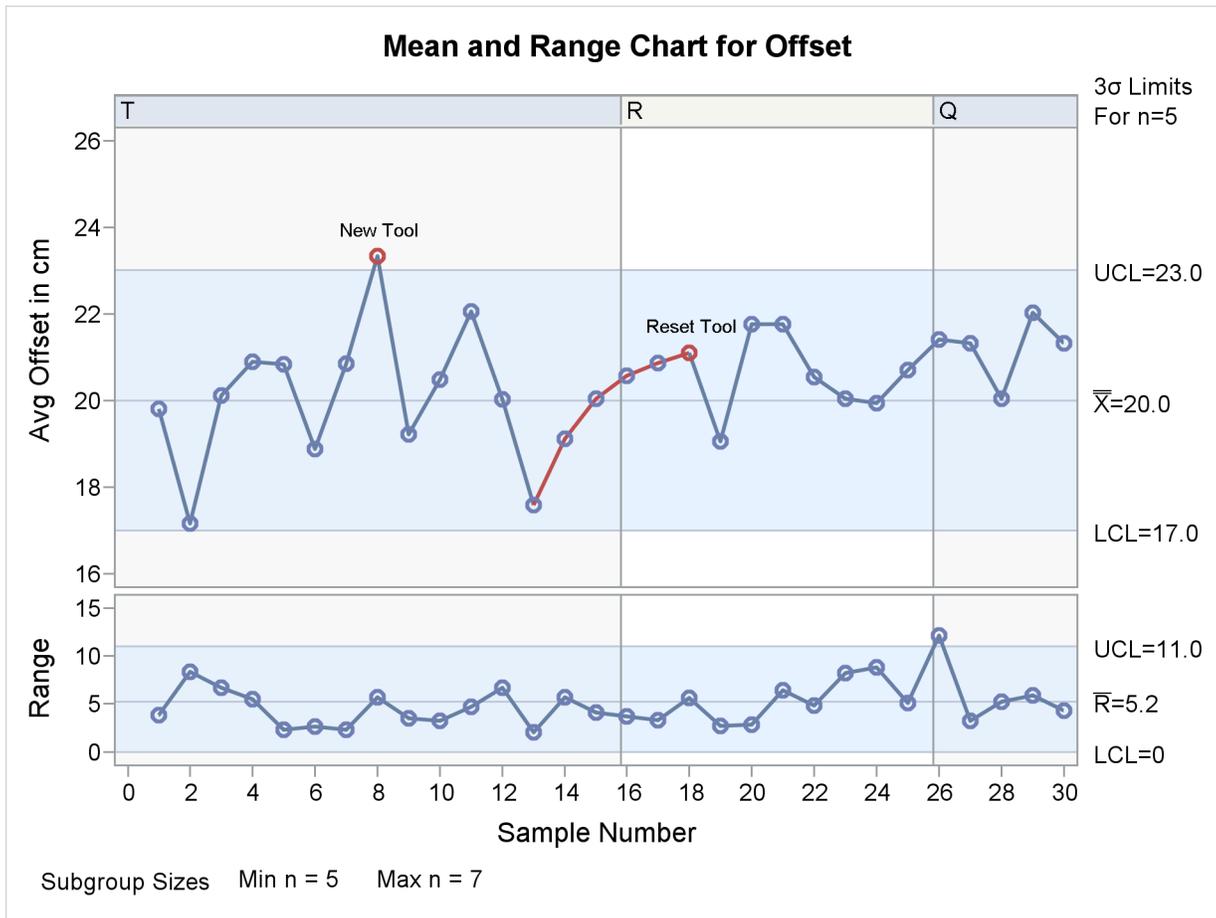

Applying Tests with Multiple Phases

See SHWTSCI in the SAS/QC Sample Library. The data set Assembly includes a variable named System, which indicates the manufacturing system used to produce each assembly. As shown by the following statements, this variable can be temporarily renamed and read as the variable `_PHASE_` to create a control chart that displays the *phases* (groups of consecutive subgroups) for which System is equal to 'T', 'R', and 'Q':

```
ods graphics on;
title 'Manufacturing Systems Used in Assembly';
proc shewhart
  history=Assembly (rename=(System=_phase_));
  xrchart Offset * Sample /
    mu0          = 20
    sigma0       = 2.24
    limitn       = 5
    alln
    tests        = 1 to 4
    testlabel    = ( comment )
    readphases   = ('T' 'R' 'Q')
    phaselegend
    phaseref
    vaxis        = 16 to 26 by 2
    split        = '/'
    markers;
  label OffsetX = 'Avg Offset in cm/Range';
run;
```

The chart is shown in Figure 17.184.

Figure 17.184 Single Set of Limits with Multiple Phases

Note that a single set of fixed 3σ limits is displayed for all three phases because $LIMITN=5$ and $ALLN$ are specified. Consequently, the tests requested with the $TESTS=$ option are applied independently of the phases. In general, however, it is possible to display distinct sets of control limits for different phases, and in such situations, the tests are not applied independently of phases, as discussed in the next example.

Applying Tests with Multiple Sets of Control Limits

See SHWTSC2 in the SAS/QC Sample Library. This example is a continuation of the previous example, except that distinct control limits are displayed for each of the phases determined by the variable System. The control limit parameters (mean, standard deviation, and nominal sample size) for each phase (manufacturing system) are provided in the following data set:

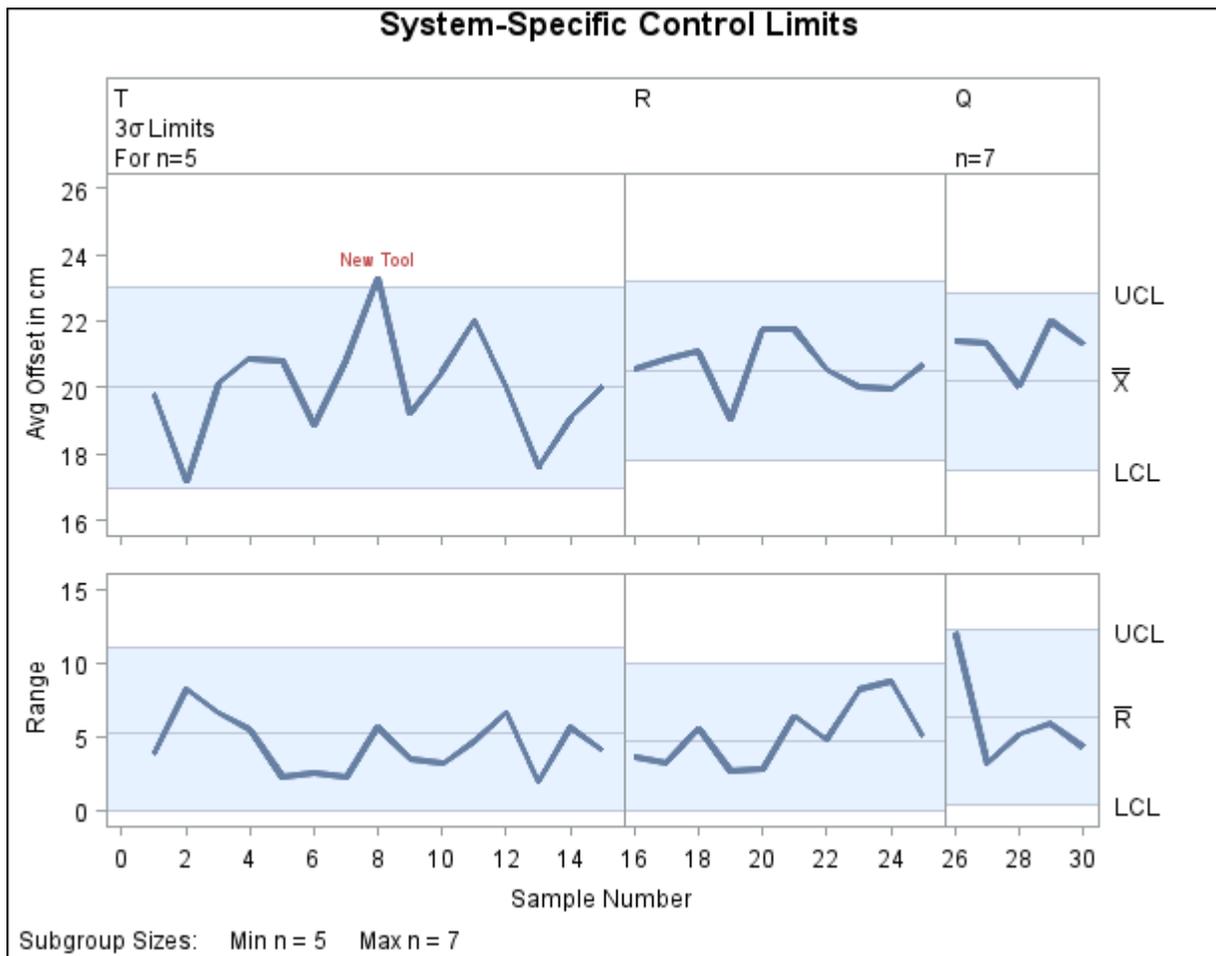

```
data Syslim;
  length _var_ $8 _subgrp_ $8 _type_ $8 _index_ $1;
  input _var_ _subgrp_ _index_ _type_ _mean_ _stddev_
        _limitn_ _sigmas_;
  datalines;
Offset Sample R standard 20.5 2.02 5 3
Offset Sample Q standard 20.2 2.35 7 3
Offset Sample T standard 20.0 2.24 5 3
;
```

The following statements read the control limit parameters from Syslim and use the READPHASES= and READINDEXES= options to display a distinct set of control limits for each phase:

```
ods graphics off;
title 'System-Specific Control Limits';
proc shewhart
  limits=Syslim
  history=Assembly (rename=(System=_phase_));
  xrchart Offset * Sample /
    tests          = 1 to 4
    testlabel      = ( comment )
    readindexes    = ('T' 'R' 'Q')
    readphases    = ('T' 'R' 'Q')
    phaselegend
    phaseref
    phasebreak
    vaxis          = 16 to 26 by 2
    split          = '/' ;
  label OffsetX = 'Avg Offset in cm/Range';
run;
```

The chart is shown in Figure 17.185. The tests requested with the TESTS= option are applied strictly within the phases, since the control limits are not constant across the phases (as in Figure 17.184). In particular, note that the pattern labeled *Reset Tool* in Figure 17.184 is not detected in Figure 17.185.

Figure 17.185 Multiple Sets of Control Limits

In most applications involving multiple control limits, a known change or improvement has occurred at the beginning of each phase; consequently, it is appropriate to restart the tests at the beginning of each phase rather than search for patterns that span the boundaries of consecutive phases. In these situations, the PHASEBREAK option is useful for suppressing the connection of points from one phase to the next. Note that it is not necessary to specify the TESTNMETHOD= option here because the subgroup sample sizes are constant within each phase.

There may be applications in which it is appropriate to apply the tests across phase boundaries. You can use the TESTACROSS option to request this behavior.

```
ods graphics off;
title 'System-Specific Control Limits';
proc shewhart
  limits=Syslim
  history=Assembly (rename=(System=_phase_));
  xrchart Offset * Sample /
    tests      = 1 to 4
    testlabel  = ( comment )
    testnmethod = standardize
    testacross
```

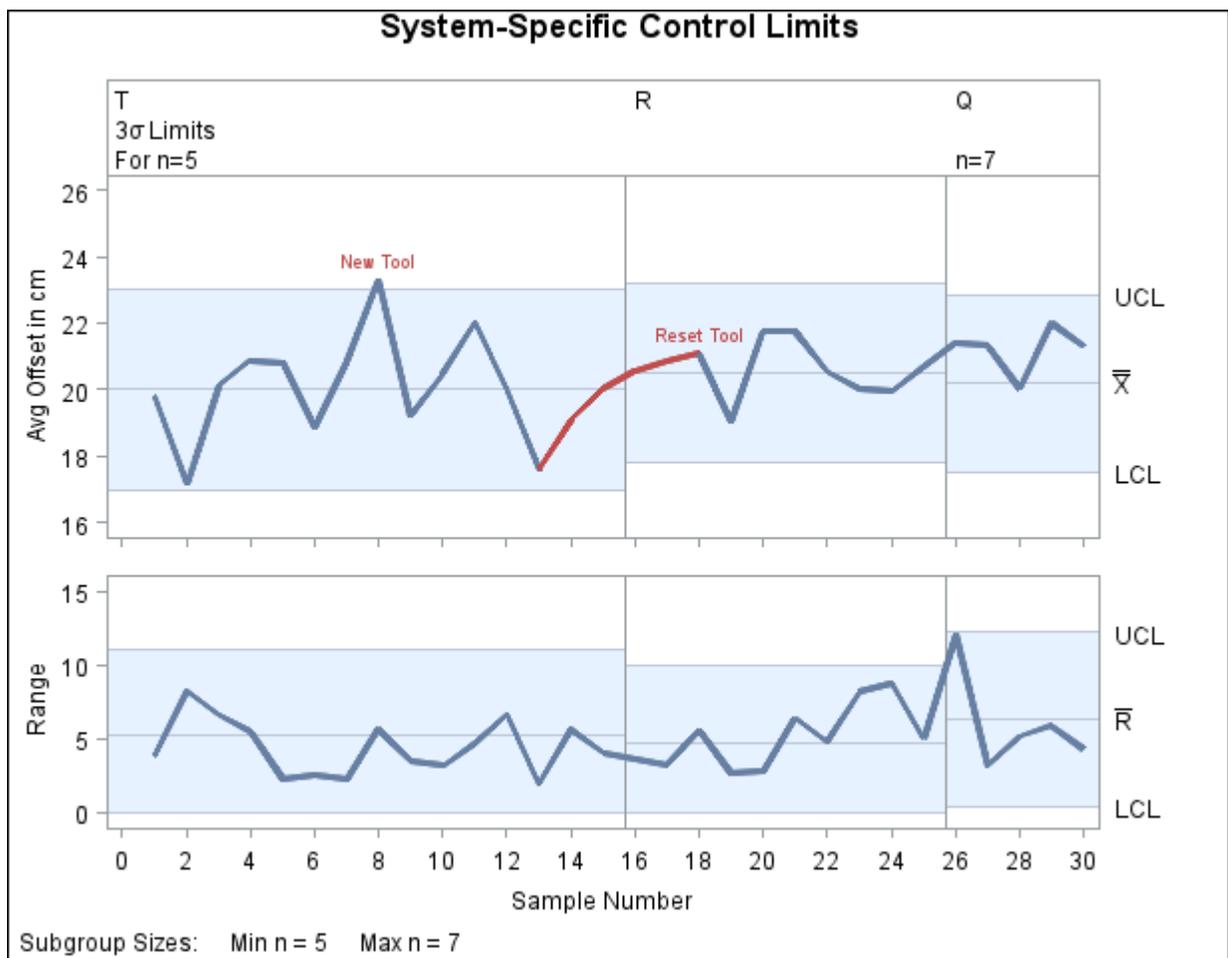

```

readindexes = ('T' 'R' 'Q')
readphases  = ('T' 'R' 'Q')
phaselegend
phaseref
vaxis       = 16 to 26 by 2
split       = '/';
label OffsetX = 'Avg Offset in cm/Range';
run;

```

The chart created with the TESTACROSS option is displayed in Figure 17.186.

Figure 17.186 Multiple Sets of Control Limits with the TESTACROSS Option

Here, it is necessary to specify TESTNMETHOD=STANDARDIZE in conjunction with the TESTACROSS option, since the subgroup sample sizes are not constant across phases.

Although Test 3 is now signaled at sample 18, this result should be interpreted with care since the test is applied to standardized average offsets, and the averages for samples 13, 14, and 15 are standardized differently than the averages for samples 16, 17, and 18. If, for instance, the value of `_MEAN_` for phase 'R' in Syslim were 21.0 rather than 20.5, the standardized mean for sample 16 would be less than the standardized mean for sample 15, and Test 3 would not be signaled at sample 18.

In summary, when working with multiple control limits, you should

- use the TESTACROSS option only if the process is operating in a continuous manner across phases
- use TESTNMETHOD=STANDARDIZE only if it is clearly understood by users that tests signaled on the chart are based on *standardized* statistics rather than the plotted statistics

Enhancing the Display of Signaled Tests

There are various options for labeling points at which a test is signaled.

- The default label for Test *i* is *Testi*. See Figure 17.180 for an example.
- Specify TESTLABEL=SPACE to request labels of the form *Test i*. See Figure 17.181 for an example.
- Specify TESTLABEL_{*i*}=*'label'* to provide a specific *label* for the *i*th test. See Figure 17.190 for an example.
- Specify TESTLABEL=(*variable*) to request labels provided by a *variable* in the input data set. See Figure 17.183 for an example.

If two or more tests are signaled at a particular point, the label displayed corresponds to the test that was specified first in the TESTS= list.

If you are producing traditional graphics, you can specify the color of the label and the connecting line segments for the pattern with the CTESTS= option. You can specify the line type for the line segments with the LTESTS= option. If you are creating line printer charts, you can specify the plot character for the line segments with the TESTCHAR= option.

You can specify the ZONES option to display the zone lines on the chart, and you can specify ZONELABELS to label the zone lines. If you are creating traditional graphics, you can specify the color of the lines with the CZONES= option, and if you are producing line printer charts, you can specify the plot character for the lines with the ZONECHAR= option.

Nonstandard Tests for Special Causes

This section describes options and programming techniques for requesting various nonstandard tests for special causes.

Applying Tests to Range and Standard Deviation Charts

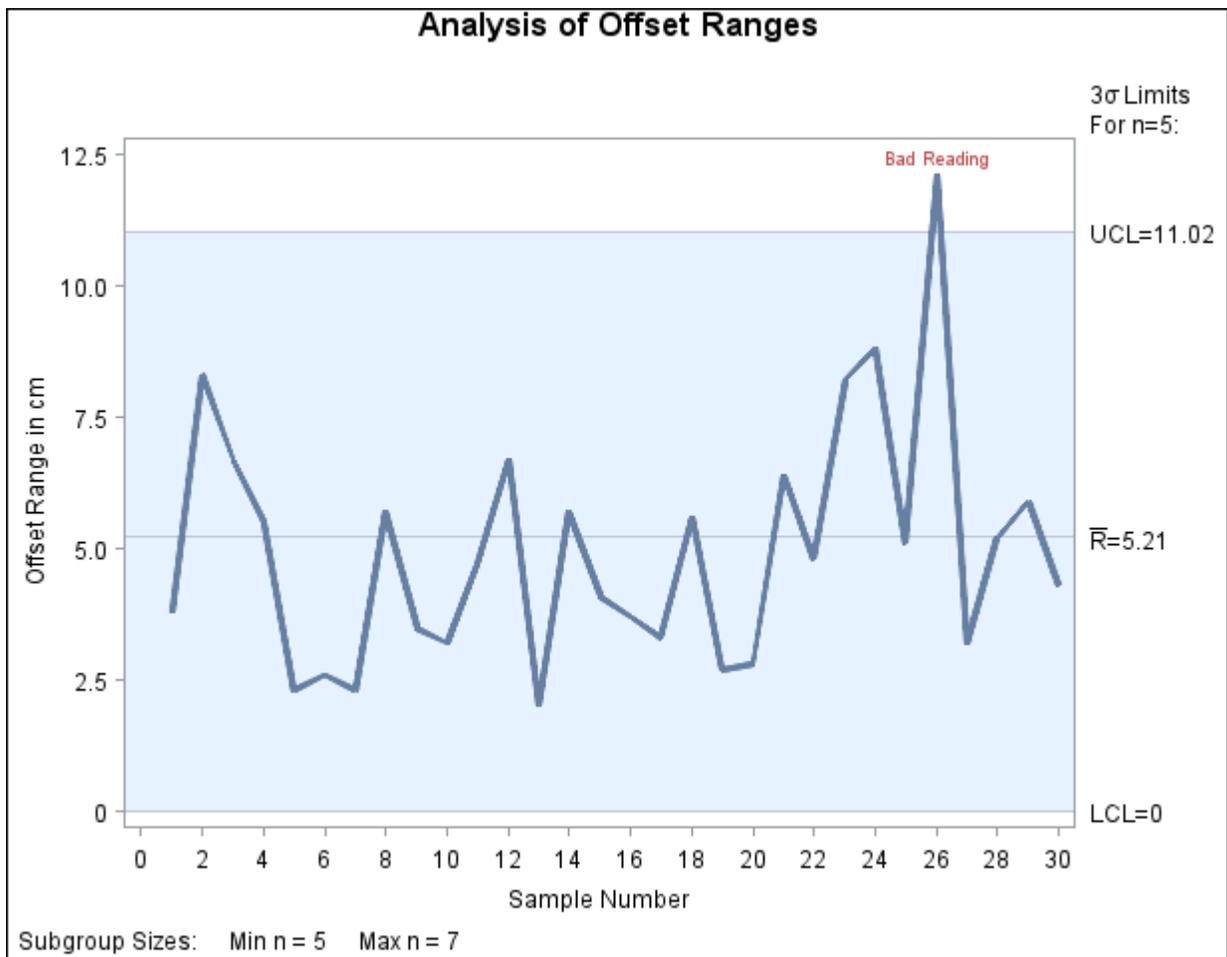

If you are using the MRCHART, RCHART, SCHART, XRCHART, or XSCHART statement, you can use the TESTS2= option to request tests for special causes with an *R* chart or *s* chart. The syntax and test definitions for the TESTS2= option are identical to those for the TESTS= option, and you can use the ZONES2 and ZONE2LABELS options to display the zones on the secondary chart. *See SHWTSC3 in the SAS/QC Sample Library*

The following statements request Test 1 for a range chart of the data in Assembly (see “Requesting Standard Tests” on page 2150):

```
ods graphics off;
title 'Analysis of Offset Ranges';
proc shewhart history=Assembly;
  rchart Offset * Sample / sigma0 = 2.24
                        limitn = 5
                        alln
                        tests2 = 1
                        testlabel = (comment) ;
  label OffsetR = 'Offset Range in cm';
run;
```

The R chart is shown in Figure 17.187.

Figure 17.187 Range Chart with Test 1

CAUTION: Except for requesting Test 1, use of the TESTS2= option is not recommended for general process control work. At the time of this writing, there is insufficient published research supporting the application of the other tests to R charts and s charts. There are no established guidelines for interpreting the other tests, nor are there assessments of their false signal probabilities or average run length characteristics. The TESTS2= option is intended primarily as a research tool.

Applying Tests Based on Generalized Patterns

In addition to *indices* for standard tests, you can specify up to eight *T-patterns* or *M-patterns* with the TESTS= option:

- Specifying a T-pattern requests a search for k out of m points in a row in the interval (a, b) . Tests based on T-patterns are generalizations of Tests 1, 2, 5, and 6. The average run length properties of tests based on T-patterns have been analyzed by Champ and Woodall (1987). Also refer to Chapter 8 of Wetherill and Brown (1991).
- Specifying an M-pattern requests a search for k points in a row increasing or decreasing. Tests based on M-patterns are generalizations of Test 3.

The general syntax for a T-pattern is of the form

**T(K= k M= m LOWER= a UPPER= b SCHEME=*scheme* CODE=*character* LABEL='label'
LEGEND='legend')**

The options for a T-pattern are summarized in the following table:

Table 17.94 Options for T-Patterns

Option	Description
K= k	number of points ($k \leq m$)
M= m	number of consecutive points
LOWER= <i>value</i>	lower limit of interval (a, b)
UPPER= <i>value</i>	upper limit of interval (a, b)
SCHEME=ONESIDED	one-sided scheme using (a, b)
SCHEME=TWOSIDED	two-sided scheme using $(a, b) \cup (-b, -a)$
CODE= <i>character</i>	identifier for test (A-H)
LABEL='label'	label for points that are signaled
LEGEND='legend'	legend used with the TABLELEGEND option

The following rules apply to the T-pattern options:

1. You must specify SCHEME=*scheme*. Specifying SCHEME=ONESIDED requests a one-sided test that searches for k out of m points in a row in the interval (a, b) . Specifying SCHEME=TWOSIDED with positive values for a and b (where $a < b$) requests a two-sided test that searches for k out of m points in a row in the interval (a, b) or k out of m points in a row in the interval $(-b, -a)$.
2. The values a and b must be specified in standardized units, and they must both have the same sign. For instance, specifying LOWER=2 and UPPER=3 with SCHEME=TWOSIDED corresponds to Zone A in Figure 17.178.
3. Specifying a missing value for the LOWER= option and a negative value for b requests a search in the interval $(-\infty, b)$. Specifying a positive value for a and a missing value for the UPPER= option requests a search in the interval (a, ∞) .

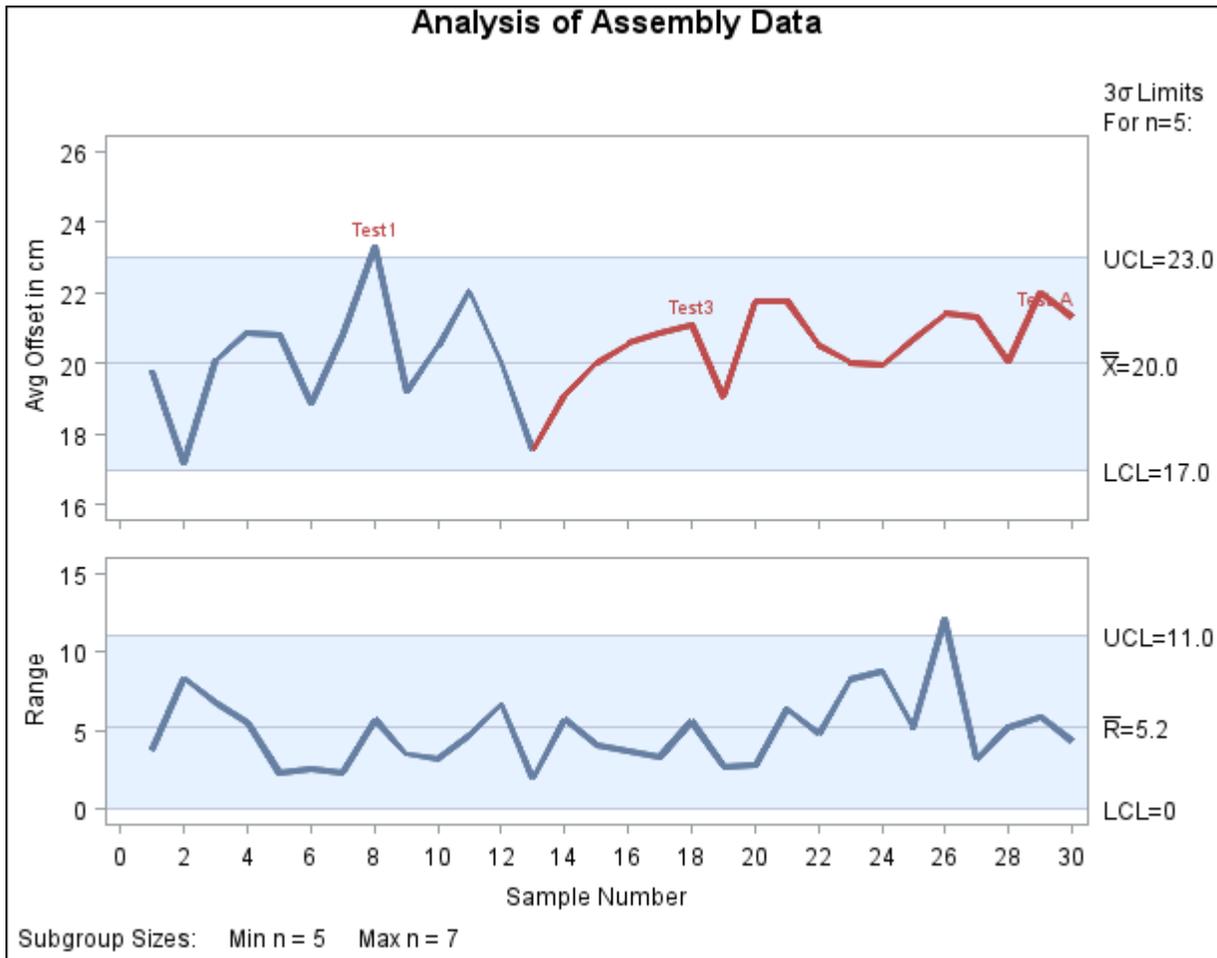

4. You must specify a *CODE= character*, which can be any of the letters A through H. The character identifies the pattern in tables requested with the TABLETESTS and TABLEALL options and in the value of the variable `_TESTS_` in the OUTTABLE= data set. The character is analogous to the indices 1 through 8 that are used to identify the standard tests. If you request multiple T-patterns, you must specify a unique character for each pattern.
5. You can specify a *label* with the LABEL= option. The label must be enclosed in quotes and can be up to 16 characters long. The label is used to label points on the chart at which the test defined by the T-pattern is signaled. The LABEL= option is similar to the TESTLABEL n = options used with the standard tests.
6. You must specify a *legend* with the LEGEND= option if you also specify the TABLELEGEND or TABLEALL option. The legend must be enclosed in quotes and can be up to 40 characters long. The legend is used to describe the test defined by the T-pattern in the table legend requested with the TABLELEGEND and TABLEALL options.

See SHWTSC4 in the SAS/QC Sample Library

An example of a nonstandard test using a T-pattern is the run test based on 14 out of 17 points in a row on the same side of the central line that is suggested by Wheeler and Chambers (1986). The following statements apply this test with Tests 1, 3, and 4. The resulting chart is shown in Figure 17.188.

```
ods graphics off;
title 'Analysis of Assembly Data';
proc shewhart history=Assembly;
  xrchart Offset * Sample /
    mu0      = 20
    sigma0   = 2.24
    limitn   = 5
    alln
    tests    = 1
             t( k=14 m=17
                lower=0 upper=. scheme=twosided
                code=A label='Test A' )
             3 4
    vaxis    = 16 to 26 by 2
    split    = '/' ;
  label OffsetX = 'Avg Offset in cm/Range';
run;
```

Figure 17.188 Generalized T-pattern Applied to Assembly Data

The specified T-pattern is signaled at 30th subgroup. Consequently, this point is labeled *Test A*.

The general syntax for an M-pattern is of the form

M(K=k DIR=direction CODE=character LABEL='label' LEGEND='legend')

The options for an M-pattern are summarized in the following table:

Table 17.95 Options for M-Patterns

Option	Description
K=k	number of points
DIR=INC	increasing pattern
DIR=DEC	decreasing pattern
CODE=character	identifier for test (A-H)
LABEL='label'	label for points that are signaled
LEGEND='legend'	legend used with the TABLELEGEND option

You must specify the direction of the pattern with the DIR= option. The CODE=, LABEL=, and LEGEND= options are used as described on page 2166.

CAUTION: You should not substitute tests based on arbitrarily defined T-patterns and M-patterns for standard tests in general process control applications. The pattern options are intended primarily as a research tool.

See *SHWARL2* in the *SAS/QC Sample Library*

Champ and Woodall (1990) provide a FORTRAN program for assessing the run length distribution of tests based on T-patterns. A version of their algorithm is implemented by a SAS/IML program in the SAS/QC Sample Library.

If you specify either a T-pattern or M-pattern with the TESTS= option and save the results in an OUTTABLE= data set, the length of the variable _TESTS_ is 16 rather than 8 (the default). The ninth character of _TESTS_ is assigned the value 'A' if the test with CODE=A is signaled, the tenth character of _TESTS_ is assigned the value 'B' if the test with CODE=B is signaled, and so on. If you also specify one or more standard tests, the *i*th character of _TESTS_ is assigned the value *i* if Test *i* is signaled.

Customizing Tests with DATA Step Programs

See *SHWTSC5* in the *SAS/QC Sample Library*

Occasionally, you may find it necessary to apply customized tests that cannot be specified with the TESTS= option. You can program your own tests as follows:

1. Run the SHEWHART procedure without the TESTS= option and save the results in an OUTTABLE= data set. Use the NOCHART option to suppress the display of the chart.
2. Use a DATA step program to apply your tests to the subgroup statistics in the OUTTABLE= data set. If tests are signaled at certain subgroups, save these results as values of a flag variable named _TESTS_, which should be a character variable of length 8. Recall that each observation of an OUTTABLE= data set corresponds to a subgroup. Assign the character *i* to the *i*th character of _TESTS_ if the *i*th customized test is signaled at that subgroup (otherwise, assign a blank character).
3. Run the procedure reading the modified data set as a TABLE= data set.

The following example illustrates these steps by creating an \bar{X} chart for the data in Assembly (see “Requesting Standard Tests” on page 2150) that signals a special cause of variation if an average is greater than 2.5 standard errors above the central line. The first step is to compute 2.5σ limits and save both the subgroup statistics and the limits in an OUTTABLE= data set named First.

```
proc shewhart history=Assembly;
  xchart Offset * Sample /
    sigmas    = 2.5
    outtable  = First
    nochart ;
run;

title ;
proc print data=First(obs=10) noobs;
run;
```

A partial listing of the data set First is shown in Figure 17.189.

Figure 17.189 Partial Listing of the Data Set First

	S	I	I	—	—	—	—	—	S	—
	a	G	M	S	L	S	M	U	T	E
V	m	M	I	U	C	U	E	C	D	L
A	p	A	T	B	L	B	A	L	E	I
R	l	S	N	N	X	X	N	X	V	M
	e	—	—	—	—	—	—	—	—	—
Offset	1	2.5	5	5	18.1515	19.80	20.4733	22.7951	2.07665	
Offset	2	2.5	5	5	18.1515	17.16	20.4733	22.7951	2.07665	LOWER
Offset	3	2.5	5	5	18.1515	20.11	20.4733	22.7951	2.07665	
Offset	4	2.5	5	5	18.1515	20.89	20.4733	22.7951	2.07665	
Offset	5	2.5	5	5	18.1515	20.83	20.4733	22.7951	2.07665	
Offset	6	2.5	5	5	18.1515	18.87	20.4733	22.7951	2.07665	
Offset	7	2.5	5	5	18.1515	20.84	20.4733	22.7951	2.07665	
Offset	8	2.5	5	5	18.1515	23.33	20.4733	22.7951	2.07665	UPPER
Offset	9	2.5	5	5	18.1515	19.21	20.4733	22.7951	2.07665	
Offset	10	2.5	5	5	18.1515	20.48	20.4733	22.7951	2.07665	

The second step is to carry out the test and create the flag variable `_TESTS_`.

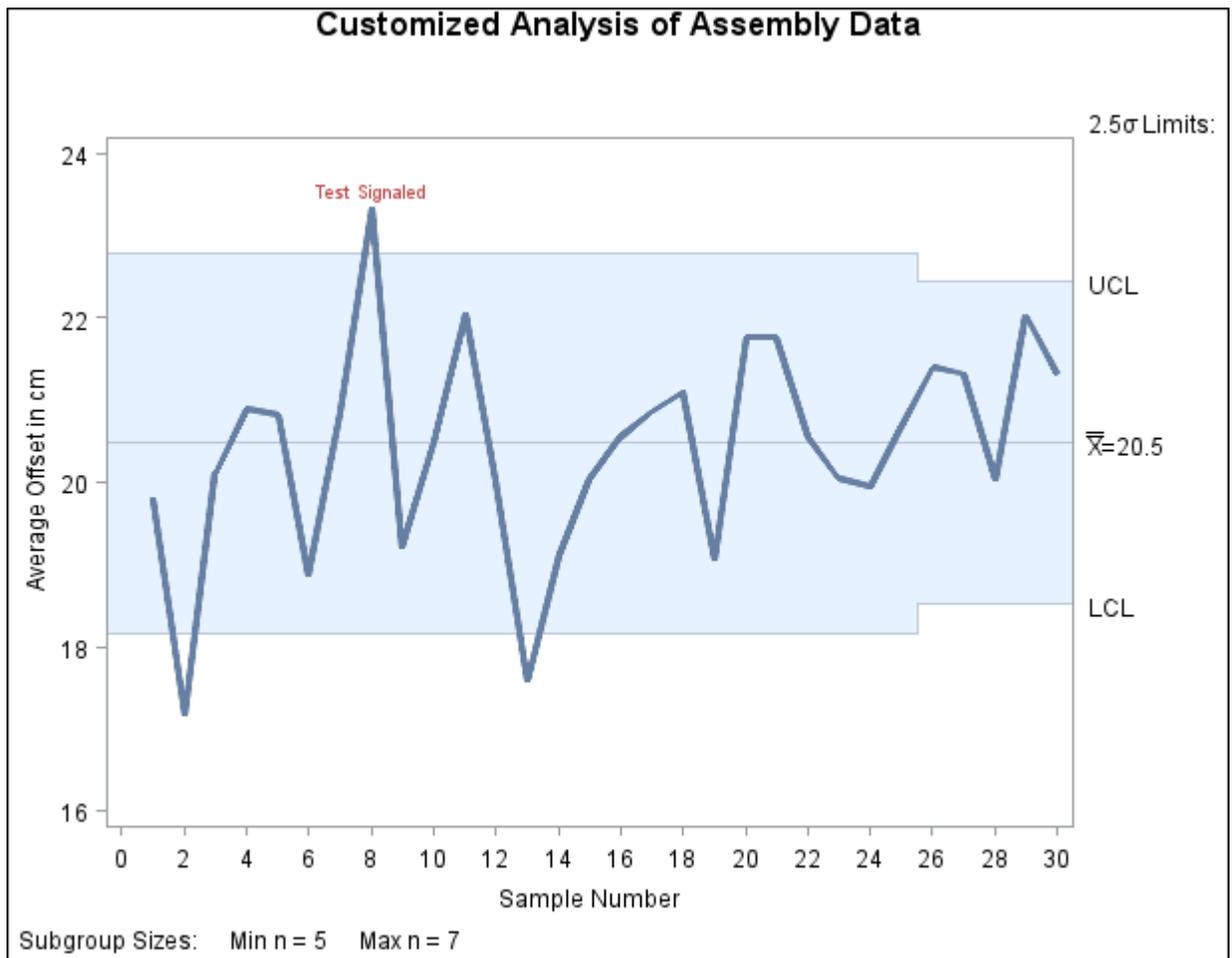

```
data First;
  set First;
  length _tests_ $ 8;
  if _subx_ > _uclx_ then substr( _tests_, 1 ) = '1';
run;
```

Finally, the data set First is read by the SHEWHART procedure as a TABLE= data set.

```
ods graphics off;
title 'Customized Analysis of Assembly Data';
proc shewhart table=First;
  xchart Offset * Sample / tests      = 1
                                testlabell = 'Test Signaled';
  label _subx_ = 'Average Offset in cm';
run;
```

The chart is shown in Figure 17.190. Note that the variable `_TESTS_` is read “as is” to flag points on the chart, and the standard tests are *not* applied to the data. The option TESTS=1 specifies that a point is to be labeled if the first character of `_TESTS_` for the corresponding subgroup is 1. The label is specified by the TESTLABEL1= option (the default would be *Test1*).

Figure 17.190 Customized Test

In general, you can simultaneously apply up to eight customized tests with the variable `_TESTS_`, which is of length 8. If two or more tests are signaled at a particular point, the label that is displayed corresponds to the test that appears first in the `TESTS=` list. In the preceding example, the test involves only the current subgroup. For customized tests involving patterns that span multiple subgroups, you will find it helpful to use the LAG functions described in *SAS Functions and CALL Routines: Reference*.

Notes:

1. If you provide the variable `_TESTS_` in a `TABLE=` data set, you must also use the `TESTS=` option to specify which characters of `_TESTS_` are to be checked.
2. The `CTESTS=` and `LTESTS=` options specify colors and line styles for *standard* patterns and may not be applicable with customized tests.

Specialized Control Charts: SHEWHART Procedure

Overview: Specialized Control Charts

Although the Shewhart chart serves well as the fundamental tool for statistical process control (SPC) applications, its assumptions are challenged by many modern manufacturing environments. For example, when standard control limits are used in applications where the process is sampled frequently, autocorrelation in the measurements can result in too many out-of-control signals. This section also considers process control applications involving multiple components of variation, short production runs, nonnormal process data, and multivariate process data.

These questions are subjects of current research and debate. It is not the goal of this section to provide definitive solutions but rather to illustrate some basic approaches that have been proposed and indicate how they can be implemented with short SAS programs. The examples in this section use the SHEWHART procedure in conjunction with various SAS procedures for statistical modeling, as summarized by the following table:

Process Control Application	Modeling Procedure
Diagnosing and modeling autocorrelation in process data	ARIMA
Developing control limits for processes involving multiple components of variation	MIXED
Establishing control with short production runs and checking for constant variance	GLM
Developing control limits for nonnormal individual measurements	CAPABILITY
Creating control charts for multivariate process data	PRINCOMP

Autocorrelation in Process Data

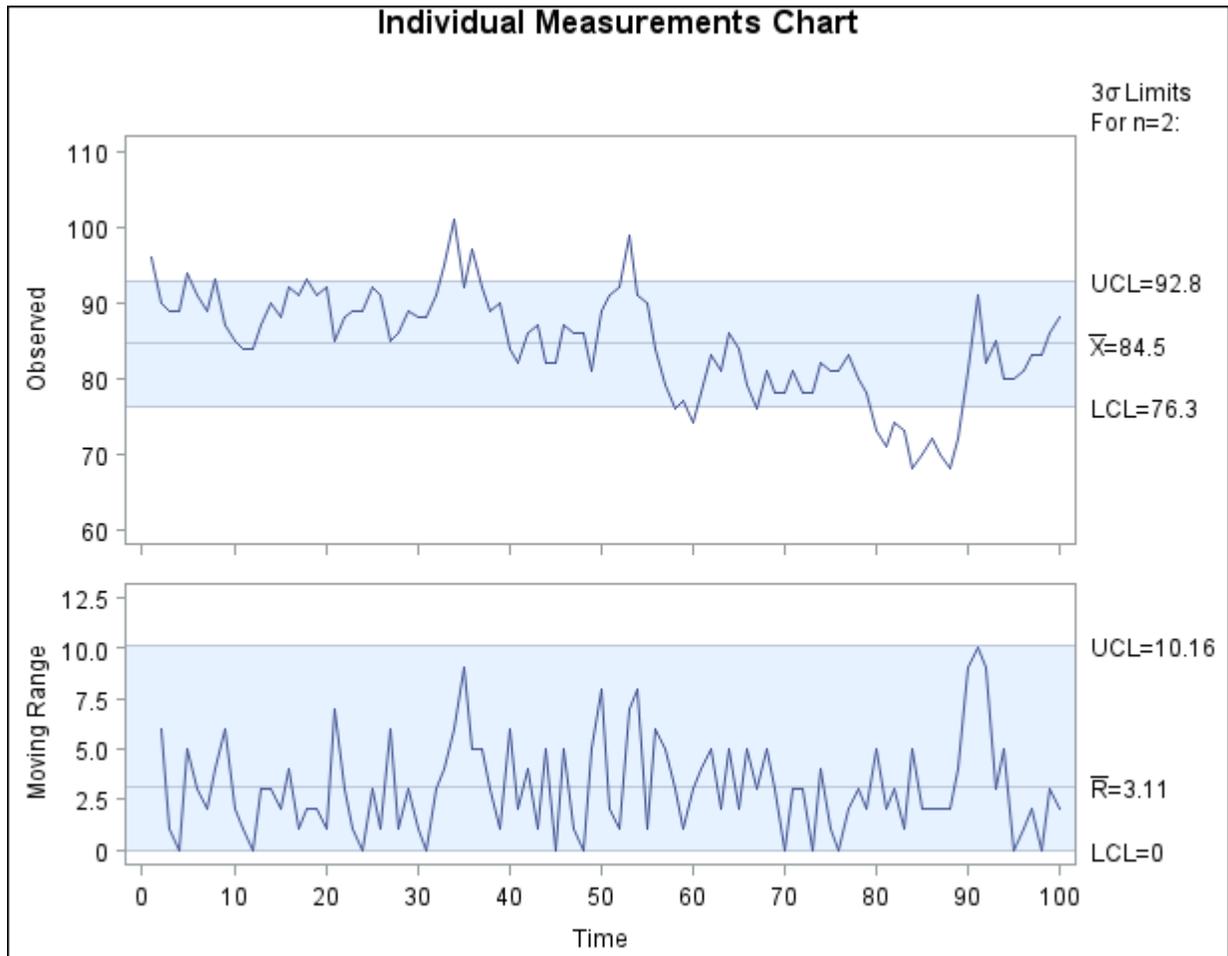

Autocorrelation has long been recognized as a natural phenomenon in process industries, where parameters such as temperature and pressure vary slowly relative to the rate at which they are measured. Only in recent years has autocorrelation become an issue in SPC applications, particularly in parts industries, where autocorrelation is viewed as a problem that can undermine the interpretation of Shewhart charts. One reason for this concern is that, as automated data collection becomes prevalent in parts industries, processes are sampled more frequently and it is possible to recognize autocorrelation that was previously undetected. Another reason, noted by Box and Kramer (1992), is that the distinction between parts and process industries is becoming blurred in areas such as computer chip manufacturing. For two other discussions of this issue, refer to Schneider and Pruett (1994) and Woodall (1993).

See SHWARIEW in the SAS/QC Sample Library

The standard Shewhart analysis of individual measurements assumes that the process operates with a constant mean μ , and that x_t (the measurement at time t) can be represented as $x_t = \mu + \epsilon_t$, where ϵ_t is a random displacement or error from the process mean μ . Typically, the errors are assumed to be statistically independent in the derivation of the control limits displayed at three standard deviations above and below the central line, which represents an estimate for μ .

When Shewhart charts are constructed from autocorrelated measurements, the result can be too many false signals, making the control limits seem too tight. This situation is illustrated in Figure 17.191, which displays an individual measurement and moving range chart for 100 observations of a chemical process.

Figure 17.191 Conventional Shewhart Chart

The measurements are saved in a SAS data set named *Chemical*.⁵² The chart in Figure 17.191 is created with the following statements:

```
symbol h=2.0 pct;
title 'Individual Measurements Chart';
proc shewhart data=Chemical;
  irchart xt*t / npanelpos = 100
             split      = '/';
  label xt = 'Observed/Moving Range'
        t = 'Time';
run;
```

⁵²The measurements are patterned after the values plotted in Figure 1 of Montgomery and Mastrangelo (1991).

Diagnosing and Modeling Autocorrelation

You can diagnose autocorrelation with an autocorrelation plot created with the ARIMA procedure.

```
ods graphics on;
ods select ChiSqAuto SeriesACFPlot SeriesPACFPlot;
proc arima data=Chemical plots(only)=series(acf pacf);
  identify var = xt;
run;
quit;
```

Refer to *SAS/ETS User's Guide* for details on the ARIMA procedure. The output, shown in [Figure 17.192](#) and [Figure 17.193](#), indicates that the data are highly autocorrelated with a lag 1 autocorrelation of 0.83.

Figure 17.192 Autocorrelation Check for Chemical Data

Individual Measurements Chart									
The ARIMA Procedure									
Autocorrelation Check for White Noise

Figure 17.193 Autocorrelation Plots for Chemical Data

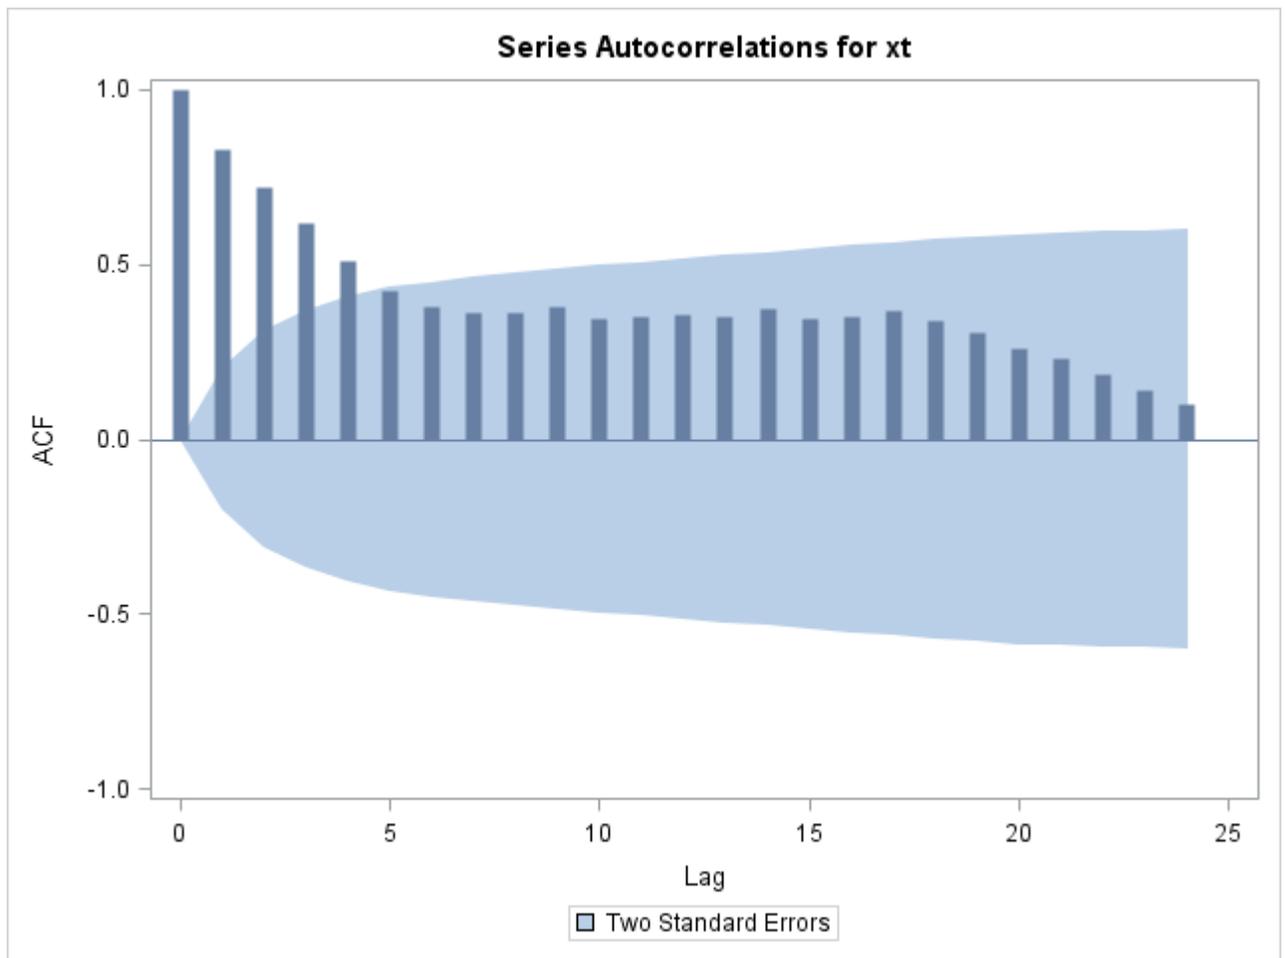

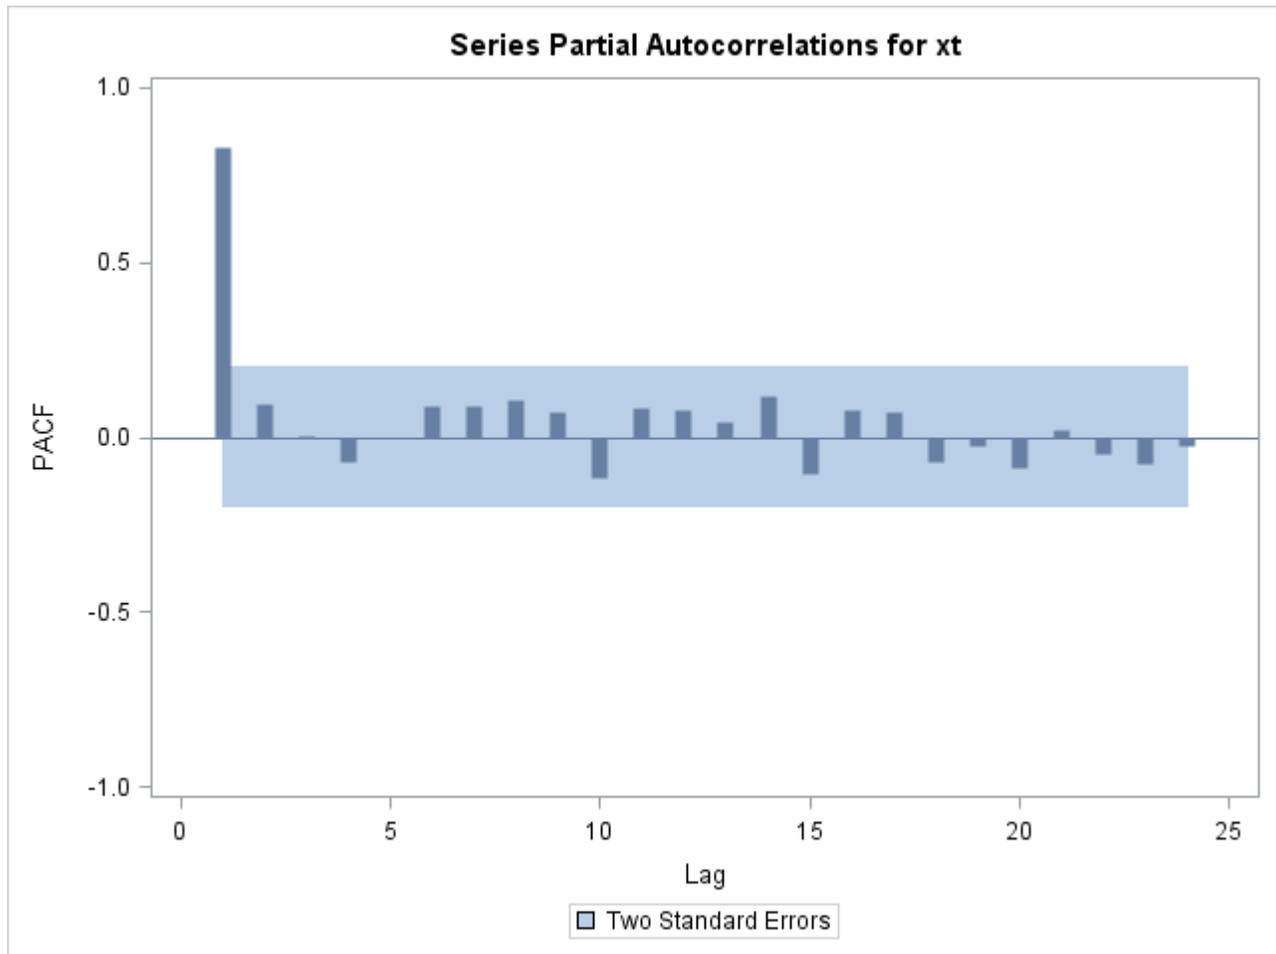

Figure 17.193 continued

The partial autocorrelation plot in Figure 17.193 suggests that the data can be modeled with a first-order autoregressive model, commonly referred to as an AR(1) model.

$$\tilde{x}_t \equiv x_t - \mu = \phi_0 + \phi_1 \tilde{x}_{t-1} + \epsilon_t$$

You can fit this model with the ARIMA procedure. The results in Figure 17.194 show that the equation of the fitted model is $\tilde{x}_t = 13.05 + 0.847\tilde{x}_{t-1}$.

```
ods select ParameterEstimates;
proc arima data=Chemical;
  identify var=xt;
  estimate p=1 method=ml;
run;
```

Figure 17.194 Fitted AR(1) Model

Individual Measurements Chart					
The ARIMA Procedure					
Maximum Likelihood Estimation					
Parameter	Estimate	Standard Error	t Value	Approx Pr > t	Lag
MU	85.28375	2.32973	36.61	<.0001	0
AR1,1	0.84694	0.05221	16.22	<.0001	1

Strategies for Handling Autocorrelation

There is considerable disagreement on how to handle autocorrelation in process data. Consider the following three views:

- At one extreme, Wheeler (1991) argues that the usual control limits are contaminated “only when the autocorrelation becomes excessive (say 0.80 or larger).” He concludes that “one need not be overly concerned about the effects of autocorrelation upon the control chart.”
- At the opposite extreme, automatic process control (APC), also referred to as engineering process control, views autocorrelation as a phenomenon to be exploited. In contrast to SPC, which assumes that the process remains on target unless an unexpected but removable cause occurs, APC assumes that the process is changing dynamically due to known causes that cannot be eliminated. Instead of avoiding “overcontrol” and “tampering,” which have a negative connotation in the SPC framework, APC advocates continuous tuning of the process to achieve minimum variance control. Descriptions of this approach and discussion of the differences between APC and SPC are provided by a number of authors, including Box and Kramer (1992), MacGregor (1987, 1990), MacGregor, Hunter, and Harris (1988), and Montgomery et al. (1994).
- A third strategy advocates removing autocorrelation from the data and constructing a Shewhart chart (or an EWMA chart or a cusum chart) for the residuals; refer, for example, to Alwan and Roberts (1988).

An example of the last approach is presented in the remainder of this section simply to demonstrate the use of the ARIMA procedure in conjunction with the SHEWHART procedure. The ARIMA procedure models the autocorrelation and saves the residuals in an output data set; the SHEWHART procedure creates a control chart using the residuals as input data.

In the chemical data example, the residuals can be computed as forecast errors and saved in an output SAS data set with the FORECAST statement in the ARIMA procedure.

```

proc arima data=Chemical;
  identify var=xt;
  estimate p=1 method=ml;
  forecast out=Results id=t;
run;

```

The output data set (named Results) saves the one-step-ahead forecasts as a variable named FORECAST, and it also contains the original variables xt and t. You can create a Shewhart chart for the residuals by using the data set Results as input to the SHEWHART procedure.

```

title 'Residual Analysis Using AR(1) Model';
symbol h=2.0 pct;
proc shewhart data=Results(firstobs=4 obs=100);
  xchart xt*t / npanelpos = 100
              split      = '/'
              trendvar   = forecast
              xsymbol    = xbar
              ypct1      = 40
              vref2      = 70 to 100 by 10
              lvref      = 2
              nolegend;
  label xt = 'Residual/Forecast'
        t = 'Time';
run;

```

The chart is shown in Figure 17.195. Specifying TRENDVAR=FORECAST plots the values of FORECAST in the lower chart and plots the residuals ($x_t - \text{FORECAST}$) together with their 3σ limits in the upper chart.⁵³

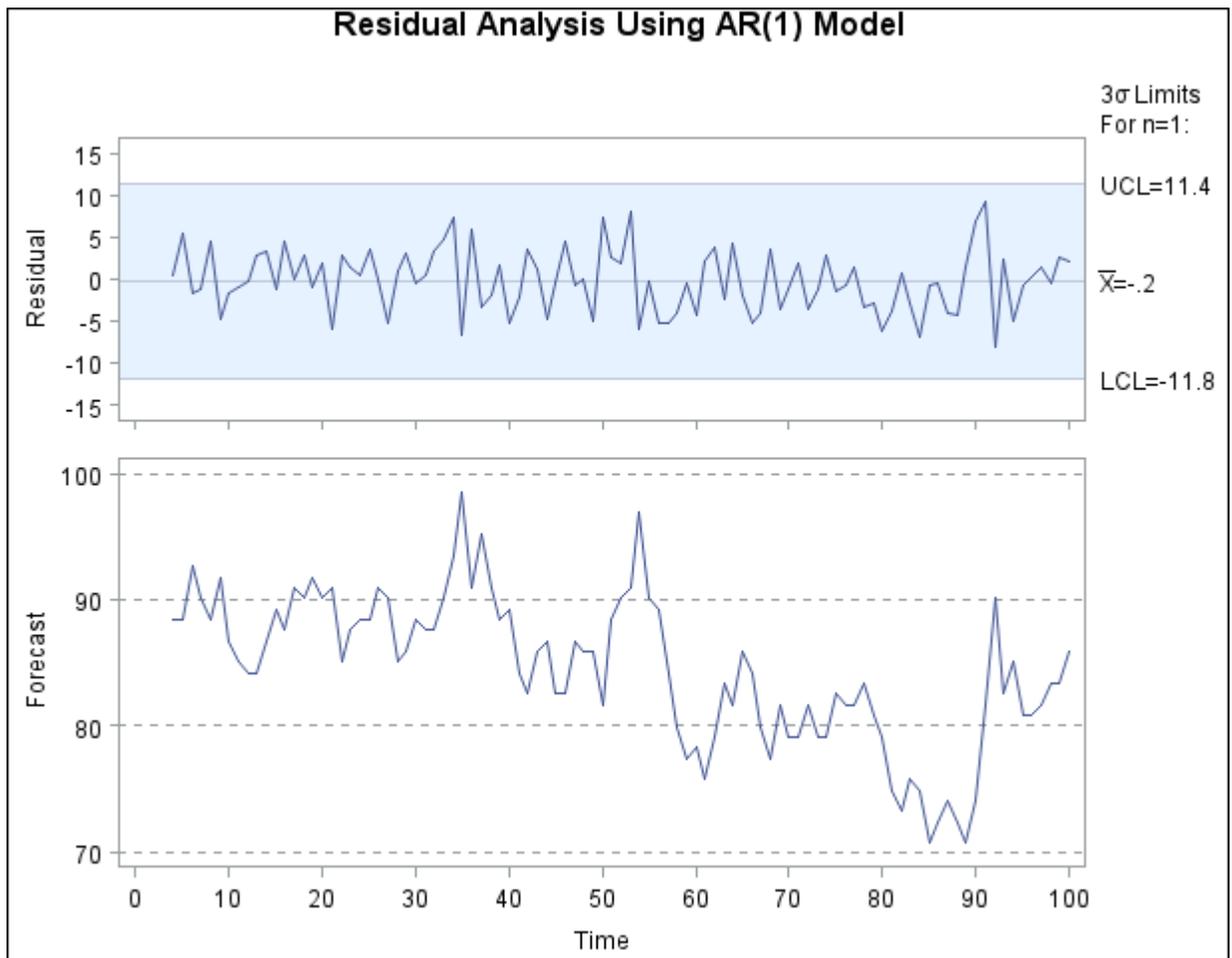

Various other methods can be applied with this data. For example, Montgomery and Mastrangelo (1991) suggest fitting an exponentially weighted moving average (EWMA) model and using this model as the basis for a display that they refer to as an *EWMA central line control chart*.

Before presenting the statements for creating this display, it is helpful to review some terminology. The EWMA *statistic* plotted on a conventional EWMA control chart is defined as

$$z_t = \lambda x_t + (1 - \lambda)z_{t-1}$$

⁵³The upper chart in Figure 17.195 resembles Figure 2 of Montgomery and Mastrangelo (1991), who conclude that the process is in control.

Figure 17.195 Residuals from AR(1) Model

The EWMA chart (which you can construct with the MACONTROL procedure) is based on the assumption that the observations x_t are independent. However, in the context of autocorrelated process data (and more generally in time series analysis), the EWMA statistic z_t plays a different role:⁵⁴ it is the optimal one-step-ahead forecast for a process that can be modeled by an ARIMA(0,1,1) model

$$x_t = x_{t-1} + \epsilon_t - \theta\epsilon_{t-1}$$

provided that the weight parameter λ is chosen as $\lambda = 1 - \theta$. This statistic is also a good predictor when the process can be described by a subset of ARIMA models for which the process is “positively autocorrelated and the process mean does not drift too quickly.”⁵⁵

You can fit an ARIMA(0,1,1) model to the chemical data with the following statements. A summary of the fitted model is shown in Figure 17.196.

⁵⁴For a discussion of these roles, refer to Hunter (1986).

⁵⁵Refer to Montgomery and Mastrangelo (1991) and the discussion that follows their paper.

```

title ;
proc arima data=Chemical;
  identify var=xt(1);
  estimate q=1 method=ml noint;
  forecast out=EWMA id=t;
run;

```

Figure 17.196 Fitted ARIMA(0, 1, 1) Model

The ARIMA Procedure					
Maximum Likelihood Estimation					
Parameter	Estimate	Standard Error	t Value	Approx Pr > t	Lag
MA1,1	0.15041	0.10021	1.50	0.1334	1
	Variance Estimate		14.97024		
	Std Error Estimate		3.86914		
	AIC		549.868		
	SBC		552.4631		
	Number of Residuals		99		

The forecast values and their standard errors (variables FORECAST and STD), together with the original measurements, are saved in a data set named EWMA. The EWMA center line control chart plots the forecasts from the ARIMA(0,1,1) model as the central “line,” and it uses the standard errors of prediction to determine upper and lower control limits. You can construct this chart, shown in Figure 17.197,⁵⁶ with the following statements:

```

data EWMA;
  set EWMA(firstobs=2 obs=100);
run;

data EWMAtab;
  length _var_ $ 8 ;
  set EWMA (rename=(forecast=_mean_ xt=_subx_));
  _var_    = 'xt';
  _sigmas_ = 3;
  _limitn_ = 1;
  _lclx_   = _mean_ - 3 * std;
  _uclx_   = _mean_ + 3 * std;
  _subn_   = 1;
run;

symbol h=2.0 pct;
title 'EWMA Center Line Control Chart';
proc shewhart table=EWMAtab;
  xchart xt*t / npanelpos = 100

```

⁵⁶Figure 17.197 is similar to Figure 5 of Montgomery and Mastrangelo (1991).

```

        xsymbol   = 'Center'
        nolegend;
    label _subx_ = 'Observed'
        t = 'Time' ;
run;

```

Note that EWMA is read by the SHEWHART procedure as a TABLE= input data set, which has a special structure intended for applications in which both the statistics to be plotted and their control limits are pre-computed. The variables in a TABLE= data set have reserved names beginning and ending with the underscore character; for this reason, FORECAST and xt are temporarily renamed as _MEAN_ and _SUBX_, respectively. For more information about TABLE= data sets, see “Input Data Sets” in the section for the chart statement in which you are interested.

Again, the conclusion is that the process is in control. While Figure 17.195 and Figure 17.197 are not the only displays that can be considered for analyzing the chemical data, their construction illustrates the conjunctive use of the ARIMA and SHEWHART procedures in process control applications involving autocorrelated data.

Figure 17.197 EWMA Center Line Chart

Multiple Components of Variation

In the preceding section, the excessive variation in the conventional Shewhart chart in [Figure 17.191](#) is the result of positive autocorrelation in the data. The variation is “excessive” not because it is due to special causes of variation, but because the Shewhart model is inappropriate. This section considers another form of departure from the Shewhart model; here, measurements are *independent* from one subgroup sample to the next, but there are multiple components of variation for each measurement. This is illustrated with an example involving two components.⁵⁷ *See SHWMULTC in the SAS/QC Sample Library*

A company that manufactures polyethylene film monitors the statistical control of an extrusion process that produces a continuous sheet of film. At periodic intervals of time, samples are taken at four locations (referred to as lanes) along a cross section of the sheet, and a test measurement is made of each sample. The test values are saved in a SAS data set named Film. A partial listing of Film is shown in [Figure 17.198](#).

Figure 17.198 Polyethylene Sheet Measurements in the Data Set Film

Sample	Lane	Testval
1	A	93
1	B	87
1	C	92
1	D	78
2	A	87

Preliminary Examination of Variation

As a preliminary step in the analysis, the data are sorted by lane and visually screened for outliers (test values greater than 130) with box plots created as follows:

```
proc sort data=Film;
  by Lane;
run;
symbol h = 2.0 pct;
title 'Outlier Analysis';
proc shewhart data=Film;
  boxchart Testval*Lane / boxstyle = schematicid
    idsymbol = dot
    vref = 130
    vreflab = 'Outlier Cutoff'
    hoffset = 5
    nolegend
    stddevs
    nolimits ;

  id Sample;
run;
```

⁵⁷Also refer to Chapter 5 of Wheeler and Chambers (1986) for an explanation of the effects of subgrouping and sources of variation on control charts.

Specifying `BOXSTYLE=SCHEMATICID` requests schematic box plots with outliers identified by the value of the ID variable `Sample`. The `STDDEVS` option specifies that the estimate of the process standard deviation is to be based on subgroup standard deviations. Although this estimate is not needed here because control limits are not displayed, it is recommended that you specify the `STDDEVS` option whenever you are working with subgroup sample sizes greater than ten. The `NOLEGEND` and `NOLIMITS` options suppress the subgroup sample size legend and control limits for lane means that are displayed by default. The display is shown in Figure 17.199.

Figure 17.199 Outlier Analysis for the Data Set Film

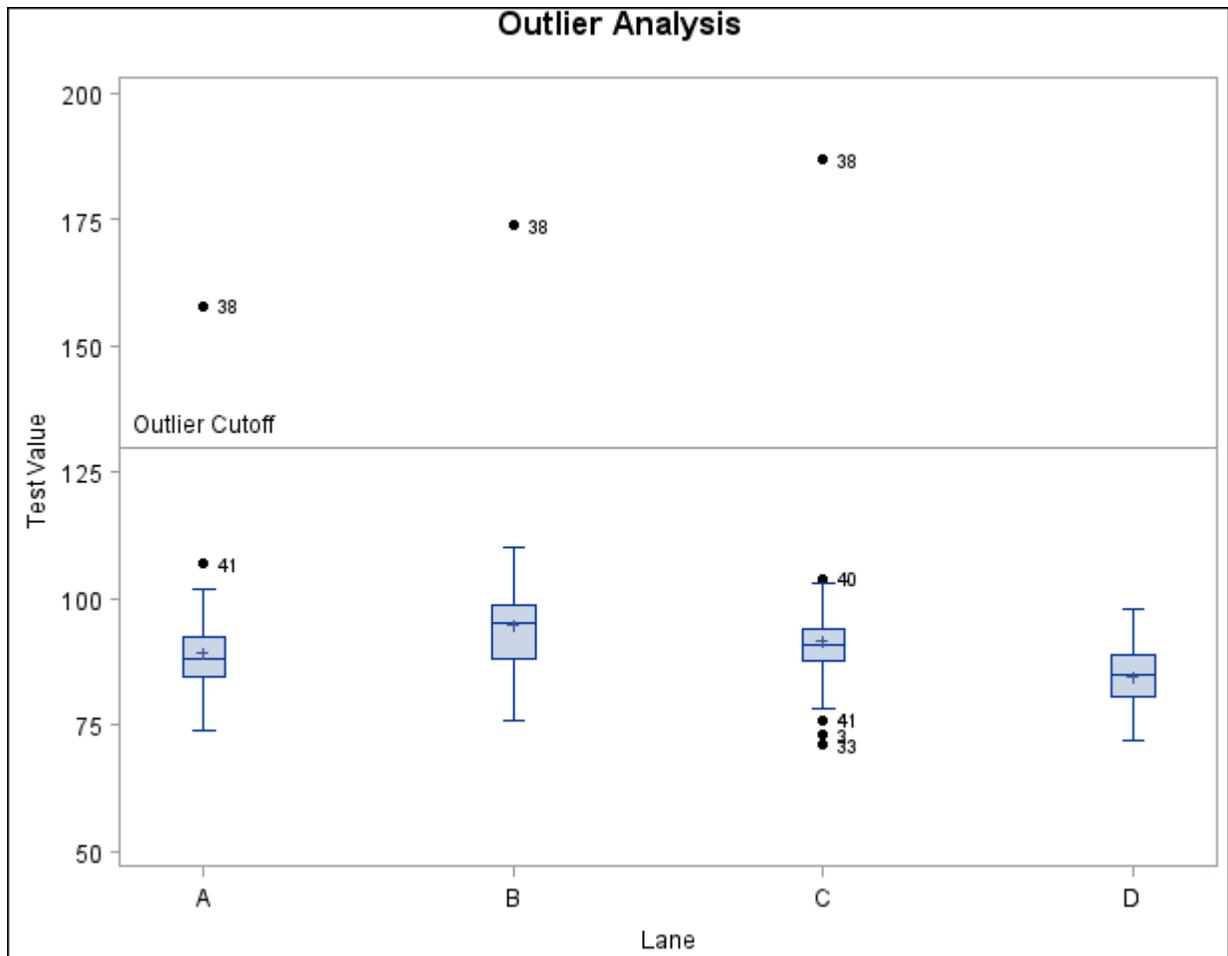

Figure 17.200 shows similarly created box plots for the data in `Film2`, which is created by removing the outliers from the data set `Film`.

```
data Film2;
  set Film;
  if Testval < 130;
symbol h = 2.0 pct;
title 'Variation Within Lane';
proc shewhart data=Film2;
  boxchart Testval*Lane / boxstyle = schematicid
                        boxwidth = 5
                        idsymbol = dot
```

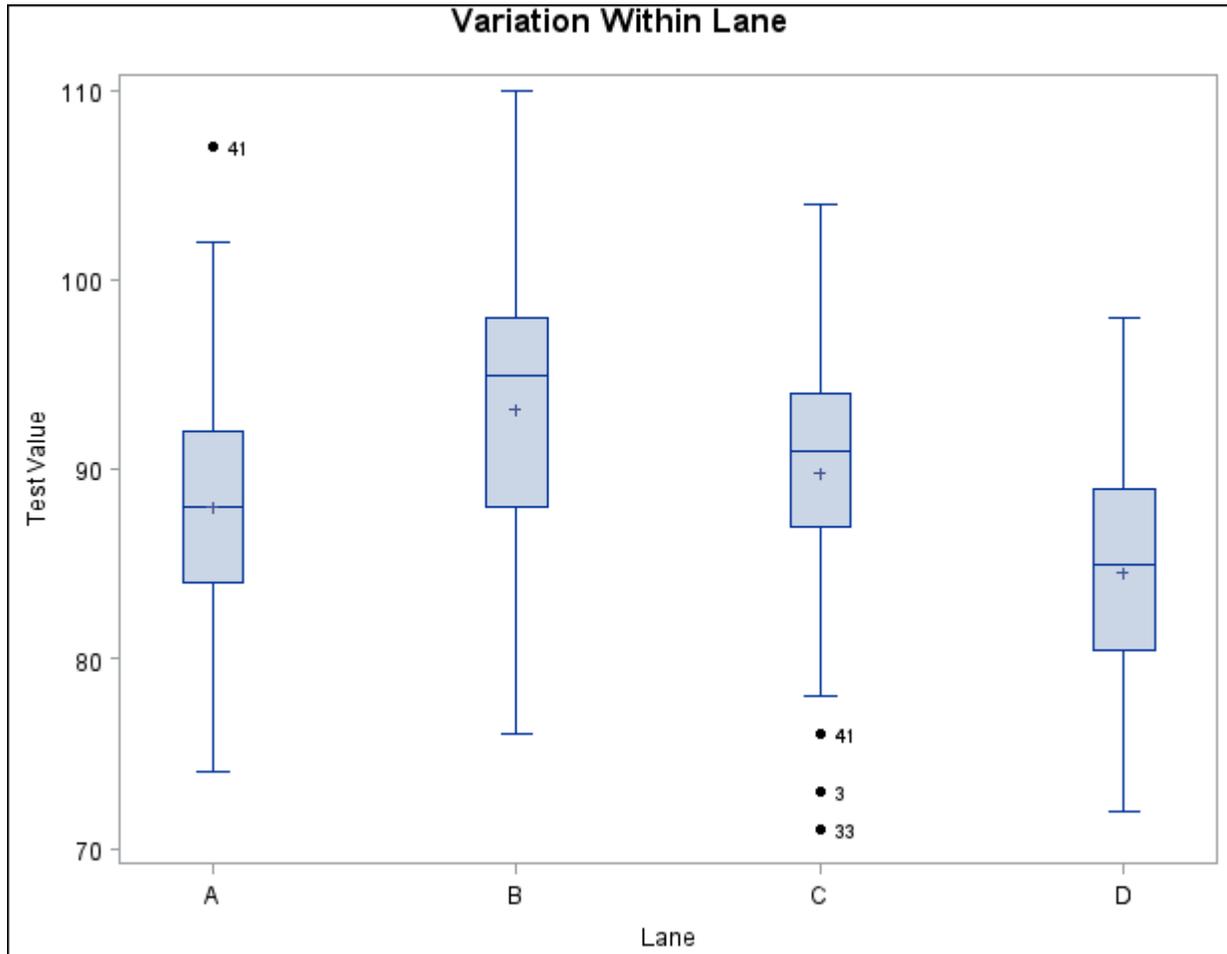

```

                                hoffset = 5
                                nolegend
                                stddevs
                                nolimits ;

id Sample;
run;

```

Figure 17.200 The Data Set Film2 Without Outliers

Since you have no additional information about the process, you may want to create a conventional \bar{X} and R chart for the test values grouped by the variable Sample. This is a straightforward application of the XRCHART statement in the SHEWHART procedure.

```

proc sort data=Film2;
  by Sample;
run;
symbol h=2.0 pct;
title 'Shewhart Chart for Means and Ranges';
proc shewhart data=Film2;
  xrchart Testval*Sample /
    split      = '/'
    npanelpos = 60
    limitn     = 4

```

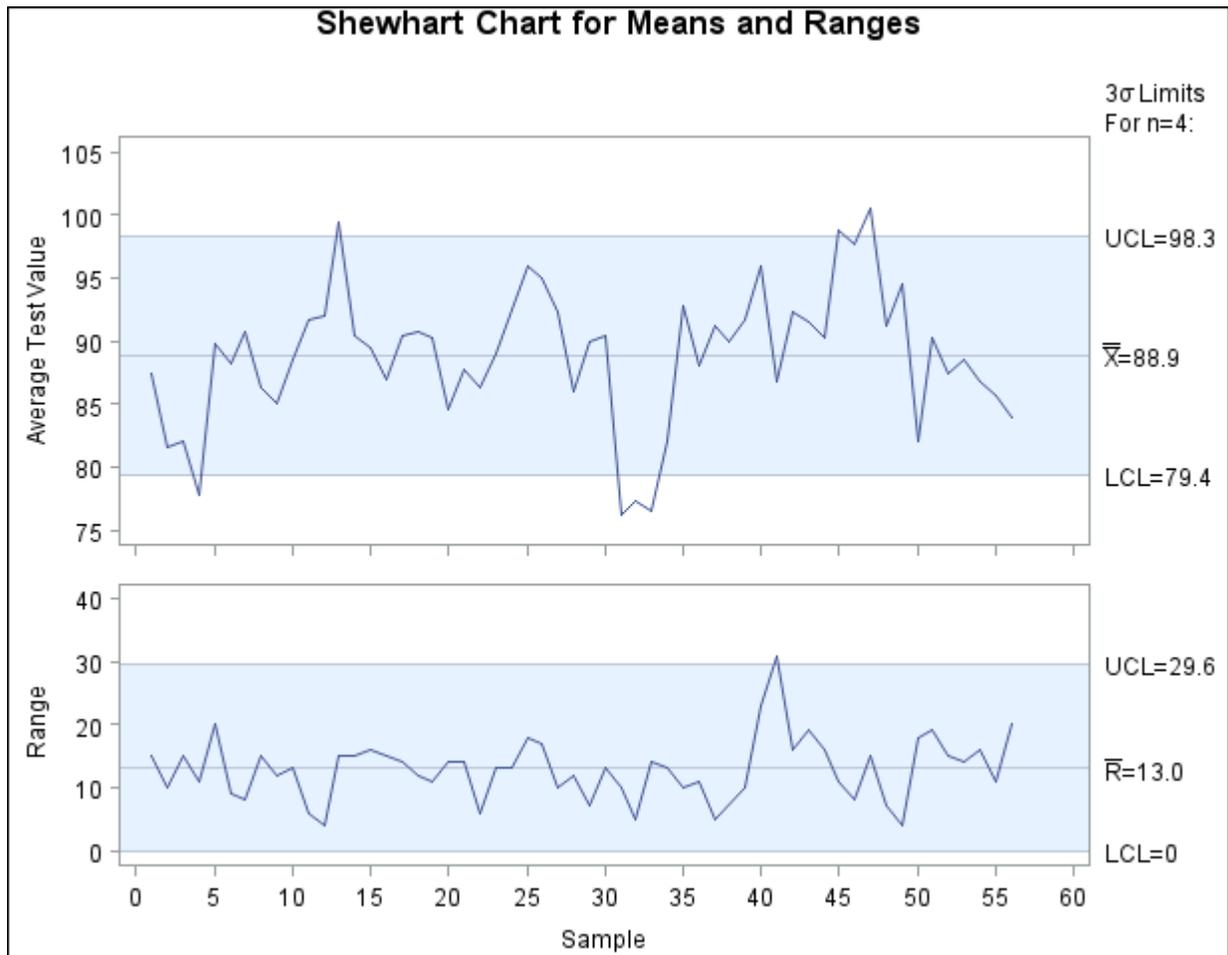

```

outlimits = RLimits
nolegend
alln;
label Testval='Average Test Value/Range';
run;

```

The \bar{X} and R chart is displayed in Figure 17.201. Ordinarily, the out-of-control points in the \bar{X} chart would indicate that the process is not in statistical control. In this situation, however, the process is known to be quite stable, and the data have been screened for outliers. The problem is that the control limits for the average test value were computed from an inappropriate model. This is discussed in the following section.

Figure 17.201 Conventional \bar{X} and R Chart

Determining the Components of Variation

The standard Shewhart analysis assumes that sampling variation, also referred to as *within-group* variation, is the only source of variation. Writing x_{ij} for the j th measurement within the i th subgroup, you can express the model for the conventional \bar{X} and R chart as

$$x_{ij} = \mu + \sigma_W \epsilon_{ij} \quad (1)$$

for $i = 1, 2, \dots, k$ and $j = 1, 2, \dots, n$. The random variables ϵ_{ij} are assumed to be independent with zero mean and unit variance, and σ_W^2 is the within-subgroup variance. The parameter μ denotes the process mean.

In a process such as film manufacturing, this model is not adequate because there is additional variation due to changes in temperature, pressure, raw material, and other factors. A more appropriate model is

$$x_{ij} = \mu + \sigma_B \omega_i + \sigma_W \epsilon_{ij} \quad (2)$$

where σ_B^2 is the *between-subgroup* variance, the random variables ω_i are independent with zero mean and unit variance, and the random variables ω_i are independent of the random variables ϵ_{ij} .⁵⁸

To plot the subgroup averages $\bar{x}_i \equiv \frac{1}{n} \sum_{j=1}^n x_{ij}$ on a control chart, you need expressions for the expectation and variance of \bar{x}_i . These are

$$\begin{aligned} E(\bar{x}_i) &= \mu \\ \text{Var}(\bar{x}_i) &= \sigma_B^2 + \frac{\sigma_W^2}{n} \end{aligned}$$

Thus, the central line should be located at $\hat{\mu}$, and 3σ limits should be located at

$$\hat{\mu} \pm 3\sqrt{\widehat{\sigma_B^2} + \frac{\widehat{\sigma_W^2}}{n}} \quad (3)$$

where $\widehat{\sigma_B^2}$ and $\widehat{\sigma_W^2}$ denote estimates of the variance components. You can use a variety of SAS procedures for fitting linear models to estimate the variance components. The following statements show how this can be done with the MIXED procedure:

```

title;
proc mixed data=Film2;
  class Sample;
  model Testval = / s;
  random Sample;
  ods output solutionf=sf;
  ods output covparms=cp;
run;

```

The results are shown in [Figure 17.202](#). Note that the parameter estimates are $\widehat{\sigma_B^2} = 19.25$, $\widehat{\sigma_W^2} = 39.68$, and $\hat{\mu} = 88.90$.

⁵⁸This notation is used in Chapter 3 of Wetherill and Brown (1991), which discusses this issue.

Figure 17.202 Partial Output from the MIXED Procedure

The Mixed Procedure					
Covariance Parameter Estimates					
Cov Parm	Estimate				
Sample	19.2526				
Residual	39.6825				
Solution for Fixed Effects					
Effect	Estimate	Standard Error	DF	t Value	Pr > t
Intercept	88.8963	0.7250	55	122.61	<.0001

The following statements merge the output data sets from the MIXED procedure into a SAS data set named Newlim that contains the appropriately derived control limit parameters for average test value:

```

data cp;
  set cp sf;
  keep Estimate;
run;

proc transpose data=cp out=Newlim;
run;

data Newlim (keep=_lclx_ _mean_ _uclx_);
  set Newlim;
  _limitn_ = 4;
  _mean_ = col3;
  _stddev_ = sqrt(4*col1 + col2);
  _lclx_ = _mean_ - 3*_stddev_ / sqrt(_limitn_);
  _uclx_ = _mean_ + 3*_stddev_ / sqrt(_limitn_);
  output;
run;

```

Here, the variable `_LIMITN_` is assigned the value of n , the variable `_MEAN_` is assigned the value of $\hat{\mu}$, and the variable `_STDDEV_` is assigned the value of

$$\hat{\sigma}_{\text{adj}} \equiv \sqrt{4\hat{\sigma}_B^2 + \hat{\sigma}_W^2}$$

The 3σ limits (`_LCLX_` and `_UCLX_`) are computed according to (3) using $\hat{\sigma}_{\text{adj}}$. The data set Newlim contains the mean and 3σ limits for the average test value.

The following statements compute appropriate control limits for the \bar{X} and R charts, which are shown in Figure 17.203. First, the data set Newlim2 is created by merging the data set RLimits,

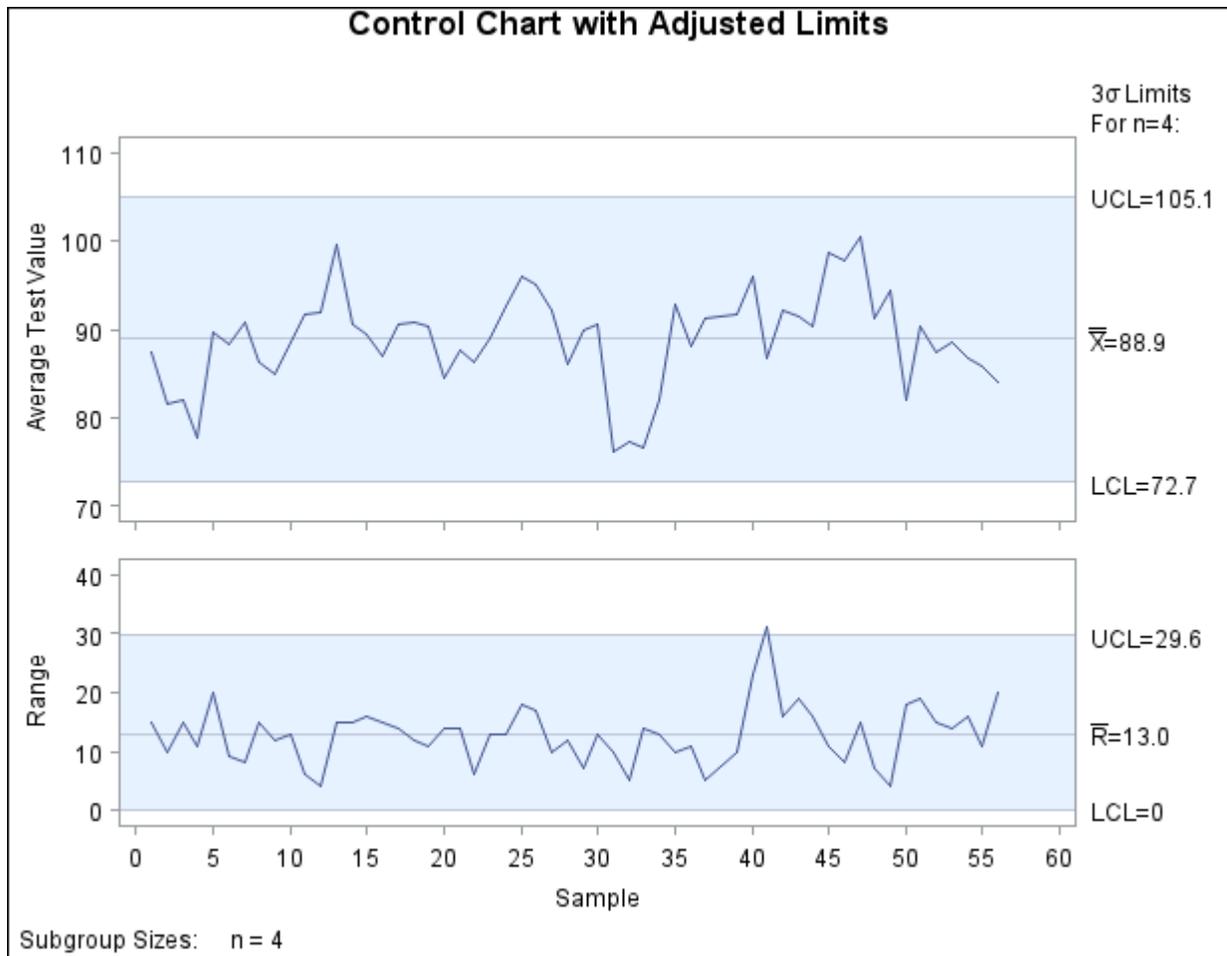

which contains the original R chart limits computed in “Preliminary Examination of Variation” on page 2181, with Newlim, which saved the appropriate \bar{X} chart limits. The original R chart limits are valid because the range in the i th subgroup is $R_i = \sigma_W(\max_j \epsilon_{ij} - \min_j \epsilon_{ij})$, which is the same for models (1) and (2). The LIMITS= option specifies the data set Newlim2 as the source of the control limits for Figure 17.203.

```
data Newlim2;
  merge Newlim RLimits (drop=_lclx_ _mean_ _uclx_);
run;

title 'Control Chart with Adjusted Limits';
symbol h = 2.0 pct;
proc shewhart data=Film2 limits=Newlim2;
  xrchart Testval*Sample / npanelpos = 60;
  label Testval='Average Test Value';
run;
```

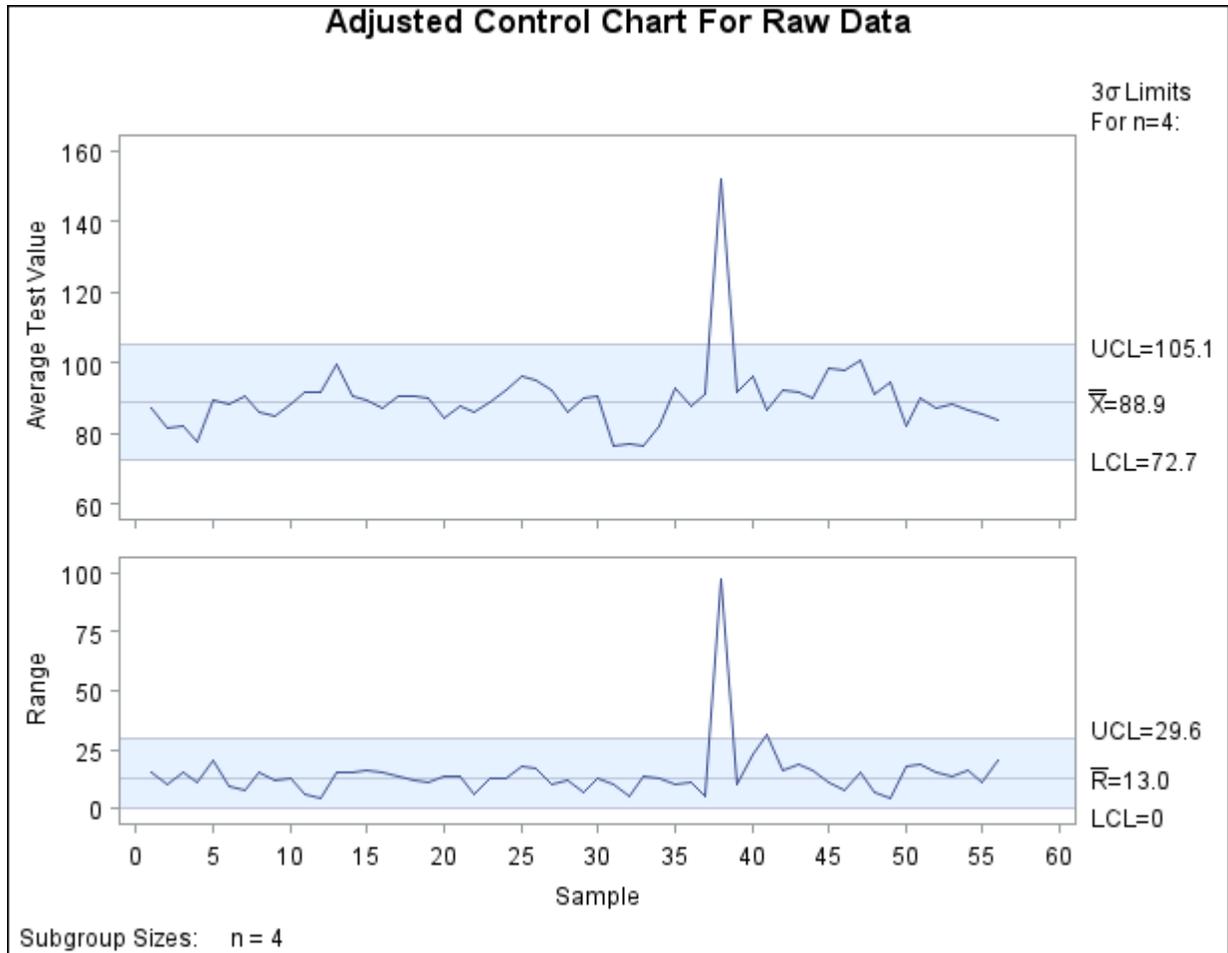

The control limits for the \bar{X} chart in Figure 17.203 are $\hat{\mu} \pm \frac{3}{\sqrt{n}}\hat{\sigma}_{\text{adj}}$. This chart correctly indicates that the variation in the process is due to common causes.

Figure 17.203 \bar{X} and R Chart with Derived Control Limits

You can use a similar set of statements to display the derived control limits in Newlim on an \bar{X} and R chart for the original data (including outliers), as shown in Figure 17.204.

Figure 17.204 \bar{X} and R Chart with Derived Control Limits for Raw Data

A simple alternative to the chart in Figure 17.203 is an “individual measurements” chart for the subgroup means. The advantage of the variance components approach is that it yields separate estimates of the components due to lane and sample, as well as a number of hypothesis tests (these require assumptions of normality). In applying this method, however, you should be careful to use data that represent the process in a state of statistical control.

Short Run Process Control

See SHWSRUN in the SAS/QC Sample Library When conventional Shewhart charts are used to establish statistical control, the initial control limits are typically based on 25 to 30 subgroup samples. Often, however, this amount of data is not available in manufacturing situations where product changeover occurs frequently or production runs are limited.

A variety of methods have been introduced for analyzing data from a process that is alternating between short runs of multiple products. The methods commonly used in the United States are

variations of two basic approaches:⁵⁹

- the *difference from nominal* approach. A product-specific nominal value is subtracted from each measured value, and the differences (together with appropriate control limits) are charted. Here it is assumed that the nominal value represents the central location of the process (ideally estimated with historical data) and that the process variability is constant across products.
- the *standardization* approach. Each measured value is standardized with a product-specific nominal and standard deviation values. This approach is followed when the process variability is not constant across products.

These approaches are highlighted in this section because of their popularity, but two alternatives that are technically more sophisticated are worth noting.

- Hillier (1969) provided a method for modifying the usual control limits for \bar{X} and R charts in startup situations where fewer than 25 subgroup samples are available for estimating the process mean μ and standard deviation σ ; also refer to Quesenberry (1993).
- Quesenberry (1991b, a) introduced the so-called *Q chart* for short (or long) production runs, which standardizes and normalizes the data using probability integral transformations.

SAS examples illustrating these alternatives are provided in the SAS/QC sample library and are described by Rodriguez and Bynum (1992).

Analyzing the Difference from Nominal

The following example⁶⁰ is adapted from an application in aircraft component manufacturing. A metal extrusion process is used to make three slightly different models of the same component. The three product types (labeled M1, M2, and M3) are produced in small quantities because the process is expensive and time-consuming.

Figure 17.205 shows the structure of a SAS data set named *Old*, which contains the diameter measurements for various short runs. Samples 1 to 30 are to be used to estimate the process standard deviation σ for the differences from nominal.

⁵⁹For a review of related methods, refer to Al-Salti and Statham (1994).

⁶⁰Refer to Chapter 1 of Wheeler (1991) for a similar example.

Figure 17.205 Diameter Measurements in the Data Set Old

Sample	Prodtype	Diameter
1	M3	13.99
2	M3	14.69
3	M3	13.86
4	M3	14.32
5	M3	13.23
6	M1	17.55
7	M1	14.26
8	M1	14.62
9	M1	12.97
10	M2	16.18
11	M2	15.29
12	M2	16.20
13	M3	13.89
14	M3	12.71
15	M3	14.32
16	M3	15.35
17	M2	15.08
18	M2	14.72
19	M2	14.79
20	M2	15.27
21	M2	15.95
22	M1	14.78
23	M1	15.19
24	M1	15.41
25	M1	16.26
26	M3	16.68
27	M3	15.60
28	M3	14.86
29	M3	16.67
30	M3	14.35

In short run applications involving many product types, it is common practice to maintain a database for the nominal values for the product types. Here, the nominal values are saved in a SAS data set named *Nomval*, which is listed in [Figure 17.206](#).

Figure 17.206 Nominal Values for Product Types in the Data Set *Nomval*

Prodtype	Nominal
M1	15.0
M2	15.5
M3	14.8
M4	15.2

To compute the differences from nominal, you must merge the data with the nominal values. You can do this with the following SAS statements. Note that an *IN=* variable is used in the *MERGE* statement to allow for the fact that *Nomval* includes nominal values for product types that are not represented in *Old*. [Figure 17.207](#) lists the merged data set *Old*.

```

proc sort data=Old;
  by Prodtype;
run;

data Old;
  format Diff 5.2 ;
  merge Nomval Old(in = a);
  by Prodtype;
  if a;
  Diff = Diameter - Nominal;
run;

proc sort data=Old;
  by Sample;
run;

```

Figure 17.207 Data Merged with Nominal Values

Sample	Prodtype	Diameter	Nominal	Diff
1	M3	13.99	14.8	-0.81
2	M3	14.69	14.8	-0.11
3	M3	13.86	14.8	-0.94

6	M1	17.55	15.0	2.55
7	M1	14.26	15.0	-0.74
8	M1	14.62	15.0	-0.38
9	M1	12.97	15.0	-2.03
10	M2	16.18	15.5	0.68
11	M2	15.29	15.5	-0.21
12	M2	16.20	15.5	0.70
13	M3	13.89	14.8	-0.91
14	M3	12.71	14.8	-2.09
15	M3	14.32	14.8	-0.48
16	M3	15.35	14.8	0.55
17	M2	15.08	15.5	-0.42
18	M2	14.72	15.5	-0.78
19	M2	14.79	15.5	-0.71
20	M2	15.27	15.5	-0.23
21	M2	15.95	15.5	0.45
22	M1	14.78	15.0	-0.22
23	M1	15.19	15.0	0.19
24	M1	15.41	15.0	0.41
25	M1	16.26	15.0	1.26
26	M3	16.68	14.8	1.88
27	M3	15.60	14.8	0.80
28	M3	14.86	14.8	0.06
29	M3	16.67	14.8	1.87
30	M3	14.35	14.8	-0.45

Assume that the variability in the process is constant across product types. To estimate the common process standard deviation σ , you first estimate σ for each product type based on the average of the

moving ranges of the differences from nominal. You can do this in several steps, the first of which is to sort the data and compute the average moving range with the SHEWHART procedure.

```
proc sort data=Old;
  by Prodtype;
run;

proc shewhart data=Old;
  irchart Diff*Sample /
    nochart
    outlimits=Baselim;
  by Prodtype;
run;
```

The purpose of this procedure step is simply to save the average moving range for each product type in the OUTLIMITS= data set Baselim, which is listed in Figure 17.208 (note that Prodtype is specified as a BY variable).

Figure 17.208 Values of \bar{R} by Product Type

Control Limits By Product Type						
Prodtype	_VAR_	_SUBGRP_	_TYPE_	_LIMITN_	_ALPHA_	_SIGMAS_
M1	Diff	Sample	ESTIMATE	2	.002699796	3
M2	Diff	Sample	ESTIMATE	2	.002699796	3
M3	Diff	Sample	ESTIMATE	2	.002699796	3
LCLI	_MEAN_	_UCLI_	_LCLR_	_R_	_UCLR_	_STDDEV_
-3.13258	0.13000	3.39258	0	1.22714	4.00850	1.08753
-1.77795	-0.06500	1.64795	0	0.64429	2.10458	0.57098
-3.22641	-0.19143	2.84356	0	1.14154	3.72887	1.01166

To obtain a combined estimate of σ , you can use the MEANS procedure to average the average ranges in Baselim and then divide by the unbiasing constant d_2 .

```
proc means data=Baselim noprint;
  var _r_;
  output out=Difflim (keep=_r_) mean=_r_;
run;

data Difflim;
  set Difflim;
  drop _r_;
  length _var_ _subgrp_ $ 8;
  _var_ = 'Diff';
  _subgrp_ = 'Sample';
  _mean_ = 0.0;
  _stddev_ = _r_ / d2(2);
  _limitn_ = 2;
  _sigmas_ = 3;
run;
```

The data set Difflim is structured for subsequent use by the SHEWHART procedure as an input LIMITS= data set. The variables in a LIMITS= data set provide pre-computed control limits or—as in this case—the parameters from which control limits are to be computed. These variables have reserved names that begin and end with the underscore character. Here, the variable `_STDDEV_` saves the estimate of σ , and the variable `_MEAN_` saves the mean of the differences from nominal. Recall that this mean is zero, since the nominal values are assumed to represent the process mean for each product type. The identifier variables `_VAR_` and `_SUBGRP_` record the names of the process and subgroup variables (these variables are critical in applications involving many product types). The variable `_LIMITN_` is assigned a value of 2 to specify moving ranges of two consecutive measurements, and the variable `_SIGMAS_` is assigned a value of 3 to specify 3σ limits. The data set Difflim is listed in Figure 17.209.

Figure 17.209 Estimates of Mean and Standard Deviation

Control Limit Parameters For Differences					
<code>_var_</code>	<code>_subgrp_</code>	<code>_mean_</code>	<code>_stddev_</code>	<code>_limitn_</code>	<code>_sigmas_</code>
Diff	Sample	0	0.89006	2	3

Now that the control limit parameters are saved in Difflim, diameters for an additional 30 parts (samples 31 to 60) are measured and saved in a SAS data set named New. You can construct short run control charts for this data by merging the measurements in New with the corresponding nominal values in Nomval, computing the differences from nominal, and then constructing the short run individual measurements and moving range charts.

```
proc sort data=new;
  by Prodtype;
run;

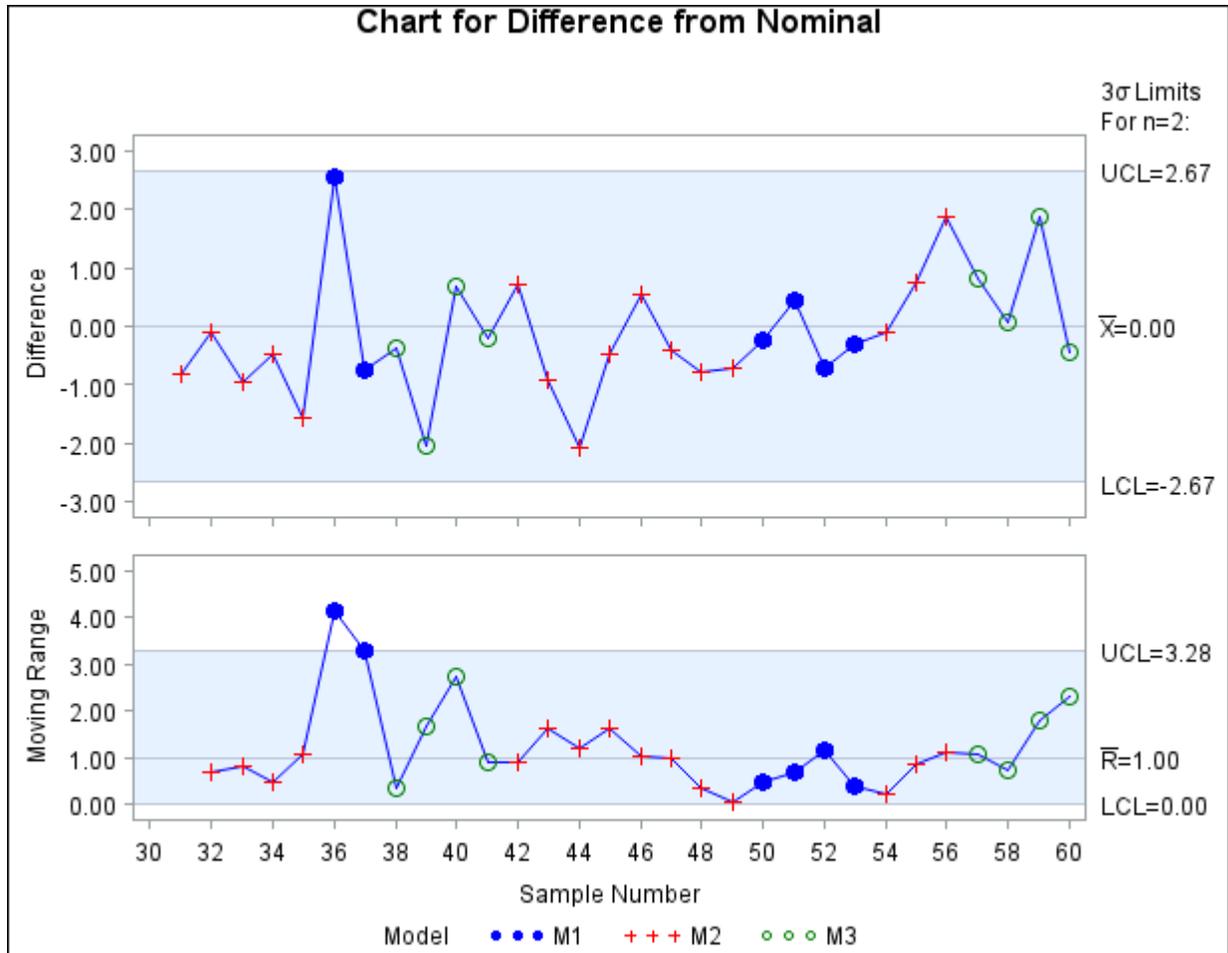

data new;
  format Diff 5.2 ;
  merge Nomval new(in = a);
  by Prodtype;
  if a;
  Diff = Diameter - Nominal;
  label Sample = 'Sample Number'
        Prodtype = 'Model';
run;

proc sort data=new;
  by Sample;
run;

symbol1 v=dot      c=blue;
symbol2 v=plus     c=red;
symbol3 v=circle   c=green;
title 'Chart for Difference from Nominal';
proc shewhart data=new limits=Difflim;
  irchart Diff*Sample=Prodtype / split = '/';
  label Diff = 'Difference/Moving Range';
run;
```

The chart is displayed in Figure 17.210. Note that the product types are identified with symbol markers as requested by specifying `Prodtype` as a *symbol-variable*.

Figure 17.210 Short Run Control Chart

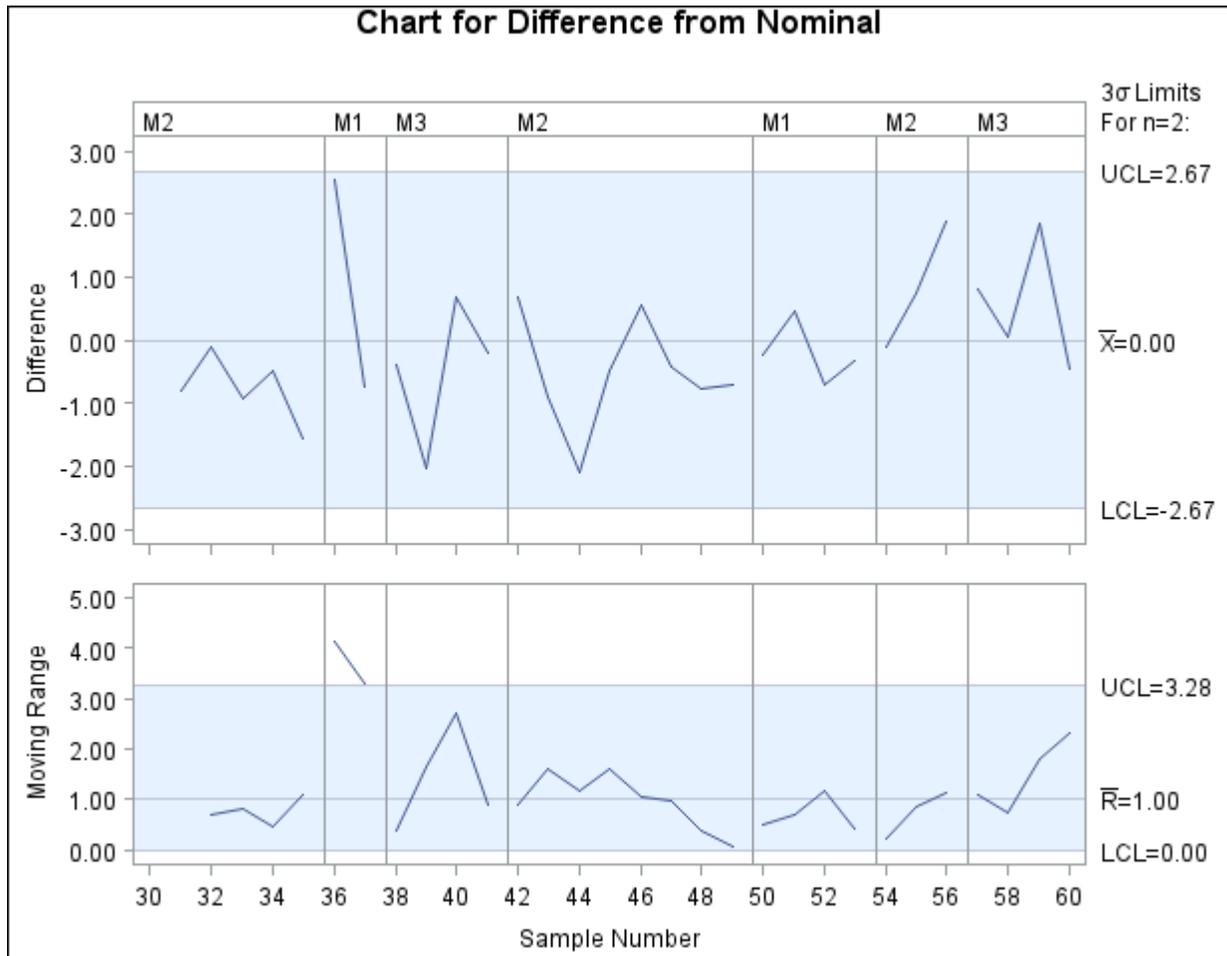

You can also identify the product types with a legend by specifying `Prodtype` as a `_PHASE_` variable.

```
symbol h=3.0 pct;
title 'Chart for Difference from Nominal';
proc shewhart data=new (rename=(Prodtype=_phase_)) limits=Difflim;
  irchart Diff*Sample /
    readphases = all
    phaseref
    phasebreak
    phaselegend
    split      = '/';
  label Diff = 'Difference/Moving Range';
run;
```

The display is shown in Figure 17.211. Note that the `PHASEBREAK` option is used to suppress the connection of adjacent points in different phases (product types).

Figure 17.211 Identification of Product Types

In some applications, it may be useful to replace the moving range chart with a plot of the nominal values. You can do this with the `TRENDVAR=` option in the `XCHART` statement⁶¹ provided that you reset the value of `_LIMITN_` to 1 to specify a subgroup sample of size one.

```

data Difflim;
  set Difflim;
  _var_ = 'Diameter';
  _limitn_ = 1;
run;

title 'Differences and Nominal Values';
proc shewhart data=new limits=Difflim;
  xchart Diameter*Sample (Prodtype) /
    nolimitslegend
    nolegend
    split      = '/'
    blockpos   = 3
    blocklabtype = scaled

```

⁶¹The `TRENDVAR=` option is not available in the `IRCHART` statement.

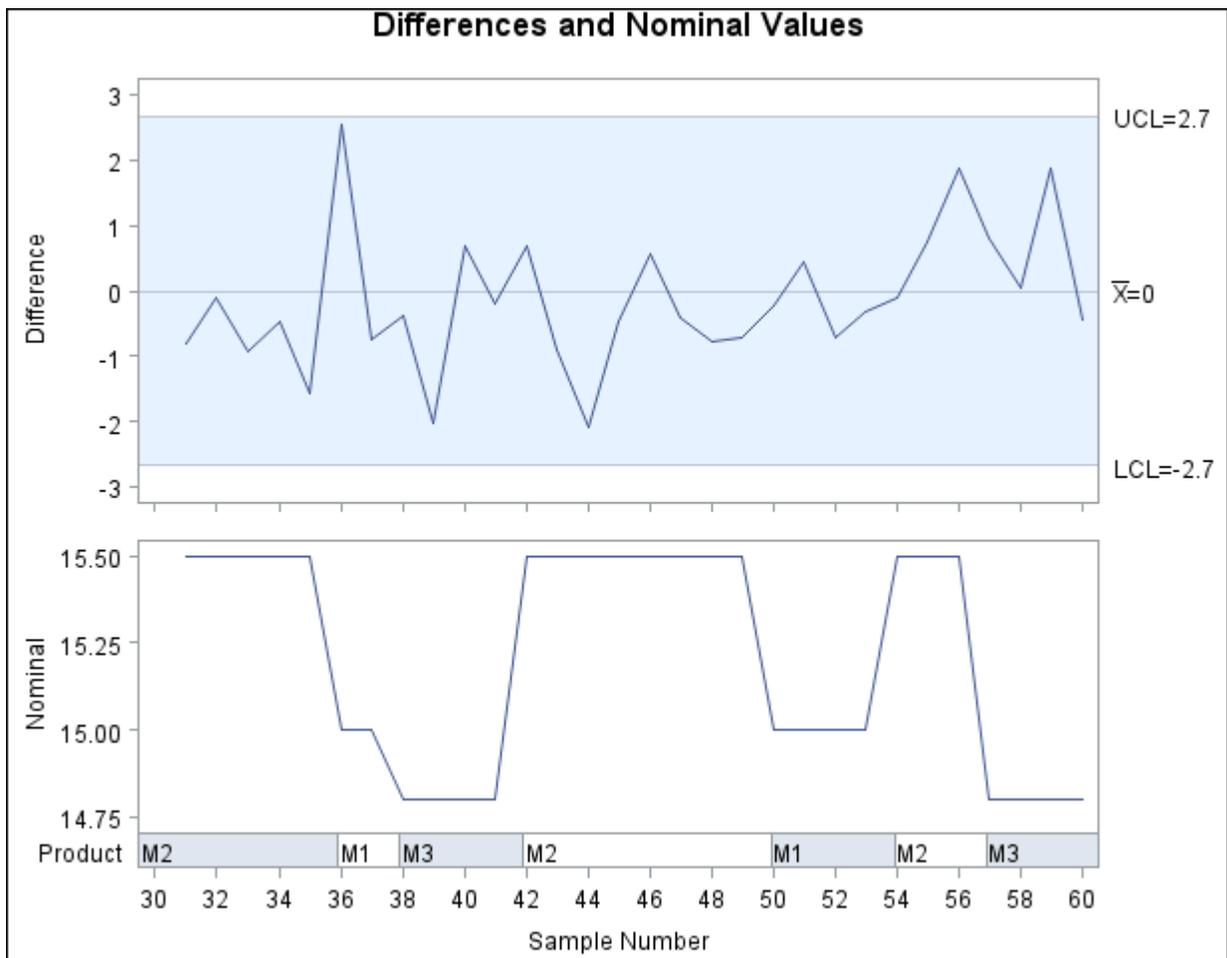

```

blocklabelpos = left
xsymbol       = xbar
trendvar      = Nominal;
label Diameter = 'Difference/Nominal'
Prodtype      = 'Product';
run;

```

The display is shown in Figure 17.212. Note that you identify the product types by specifying Prodtype as a *block variable* enclosed in parentheses after the subgroup variable Sample. The BLOCKLABTYPE= option specifies that values of the block variable are to be scaled (if necessary) to fit the space available in the block legend. The BLOCKLABELPOS= option specifies that the label of the block variable is to be displayed to the left of the block legend.

Figure 17.212 Short Run Control Chart with Nominal Values

Testing for Constant Variances

The difference-from-nominal chart should be accompanied by a test that checks whether the variances for each product type are identical (homogeneous). Levene's test of homogeneity is particularly appropriate for short run applications because it is robust to departures from normality; refer to Snedecor and Cochran (1980). You can implement Levene's method by using the GLM proce-

ture to construct a one-way analysis of variance for the absolute deviations of the diameters from averages within product types.

```
proc sort data=Old;
  by Prodtype;
run;

proc means data=Old noprint;
  var Diameter;
  by Prodtype;
  output out=Oldmean (keep=Prodtype diammean) mean=diammean;
run;

data Old;
  merge Old Oldmean;
  by Prodtype;
  absdev = abs( Diameter - diammean );
run;

proc means data=Old noprint;
  var absdev;
  by Prodtype;
  output out=stats n=n mean=mean css=css std=std;
run;

title;
proc glm data=Old outstat=glmout;
  class Prodtype;
  model absdev = Prodtype;
run;
```

A partial listing of the results is displayed in [Figure 17.213](#). The large p -value (0.3386) indicates that the data do not reject the hypothesis of homogeneity.

Figure 17.213 Levene's Test of Variance Homogeneity

The GLM Procedure					
Dependent Variable: absdev					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	2	1.02901063	0.51450532	1.13	0.3373
Error	27	12.27381243	0.45458565		
Corrected Total	29	13.30282306			

Standardizing Differences from Nominal

When the variances across product types are *not* constant, various authors recommend standardizing the differences from nominal and displaying them on a common chart with control limits at ± 3 .

To illustrate this method, assume that the hypothesis of homogeneity is rejected for the differences in Old. Then you can use the product-specific estimates of σ in `Baselim` to standardize the differences from nominal in New and create the standardized chart as follows:

```
proc sort data=new;
  by Prodtype;
run;

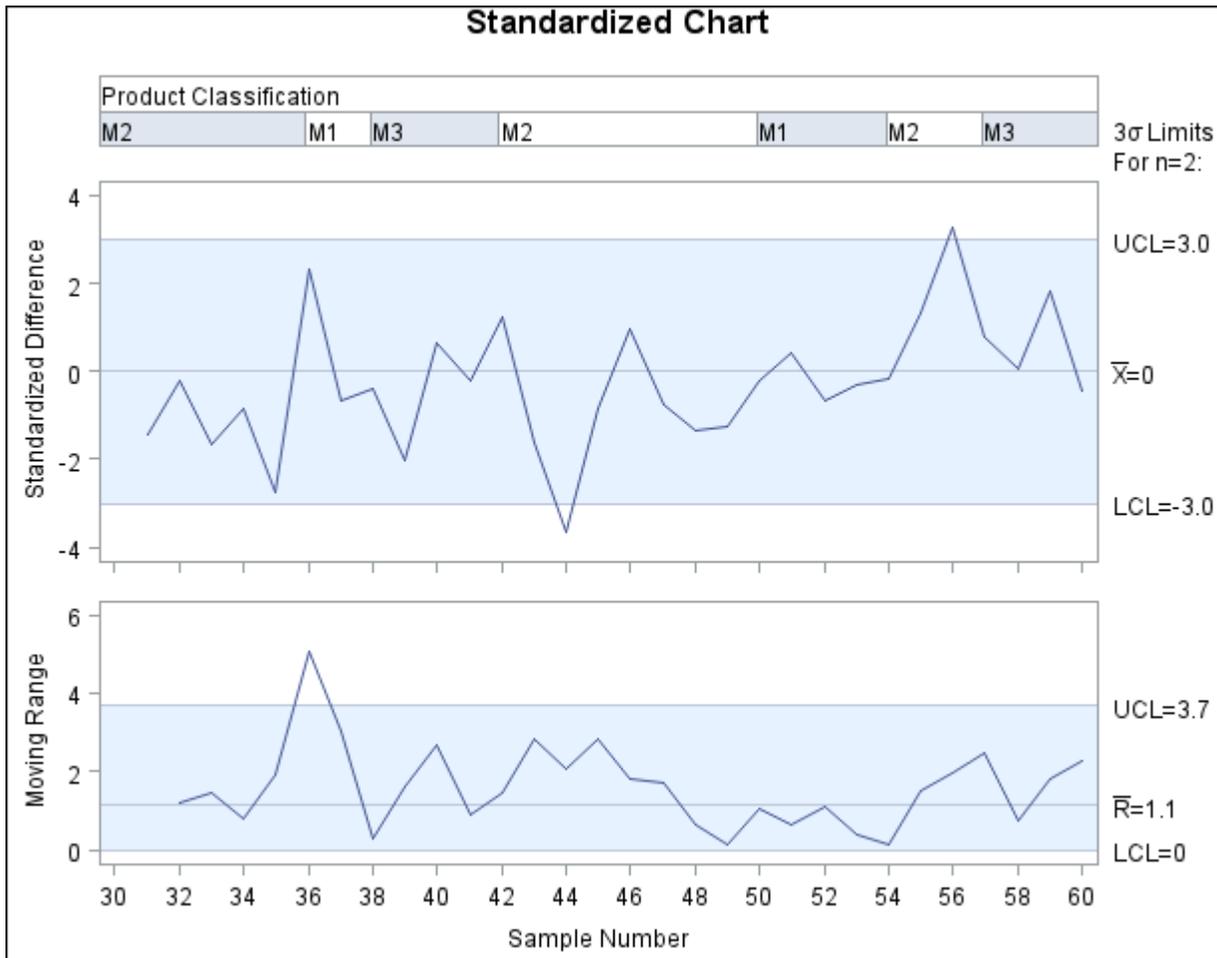

data new;
  keep Sample Prodtype z Diff Diameter Nominal _stddev_;
  label Sample = 'Sample Number';
  format Diff 5.2 ;
  merge Baselim new(in = a);
  by Prodtype;
  if a;
  z = (Diameter - Nominal) / _stddev_ ;
run;

proc sort data=new;
  by Sample;
run;

title 'Standardized Chart';
proc shewhart data=new;
  irchart z*Sample (Prodtype) /
    blocklabtype = scaled
    mu0          = 0
    sigma0       = 1
    split        = '/';
  label Prodtype = 'Product Classification'
        z = 'Standardized Difference/Moving Range';
run;
```

Note that the options `MU0=` and `SIGMA=` specify that the control limits for the standardized differences from nominal are to be based on the parameters $\mu = 0$ and $\sigma = 1$. The chart is displayed in Figure 17.214.

Figure 17.214 Standardized Difference Chart

Nonnormal Process Data

A number of authors have pointed out that Shewhart charts for subgroup means work well whether the measurements are normally distributed or not.⁶² On the other hand, the interpretation of standard control charts for individual measurements (X charts) is affected by departures from normality. *See SHWNONN in the SAS/QC Sample Library*

In situations involving a large number of measurements, it may be possible to subgroup the data and construct an \bar{X} chart instead of an X chart. However, the measurements should not be subgrouped arbitrarily for this purpose.⁶³ If subgrouping is not possible, two alternatives are to transform the data to normality (preferably with a simple transformation such as the log transformation) or modify the usual limits based on a suitable model for the data distribution.

The second of these alternatives is illustrated here with data from a study conducted by a service center. The time taken by staff members to answer the phone was measured, and the delays were saved as values of a variable named Time in a SAS data set named Calls. A partial listing of Calls is shown in Figure 17.215.

⁶²Refer to Schilling and Nelson (1976) and Wheeler (1991).

⁶³Refer to Wheeler and Chambers (1986) for a discussion of subgrouping.

Creating a Preliminary Individual Measurements Chart

As a first step, the delays were analyzed using an X chart created with the following statements. The chart is displayed in Figure 17.216.

```

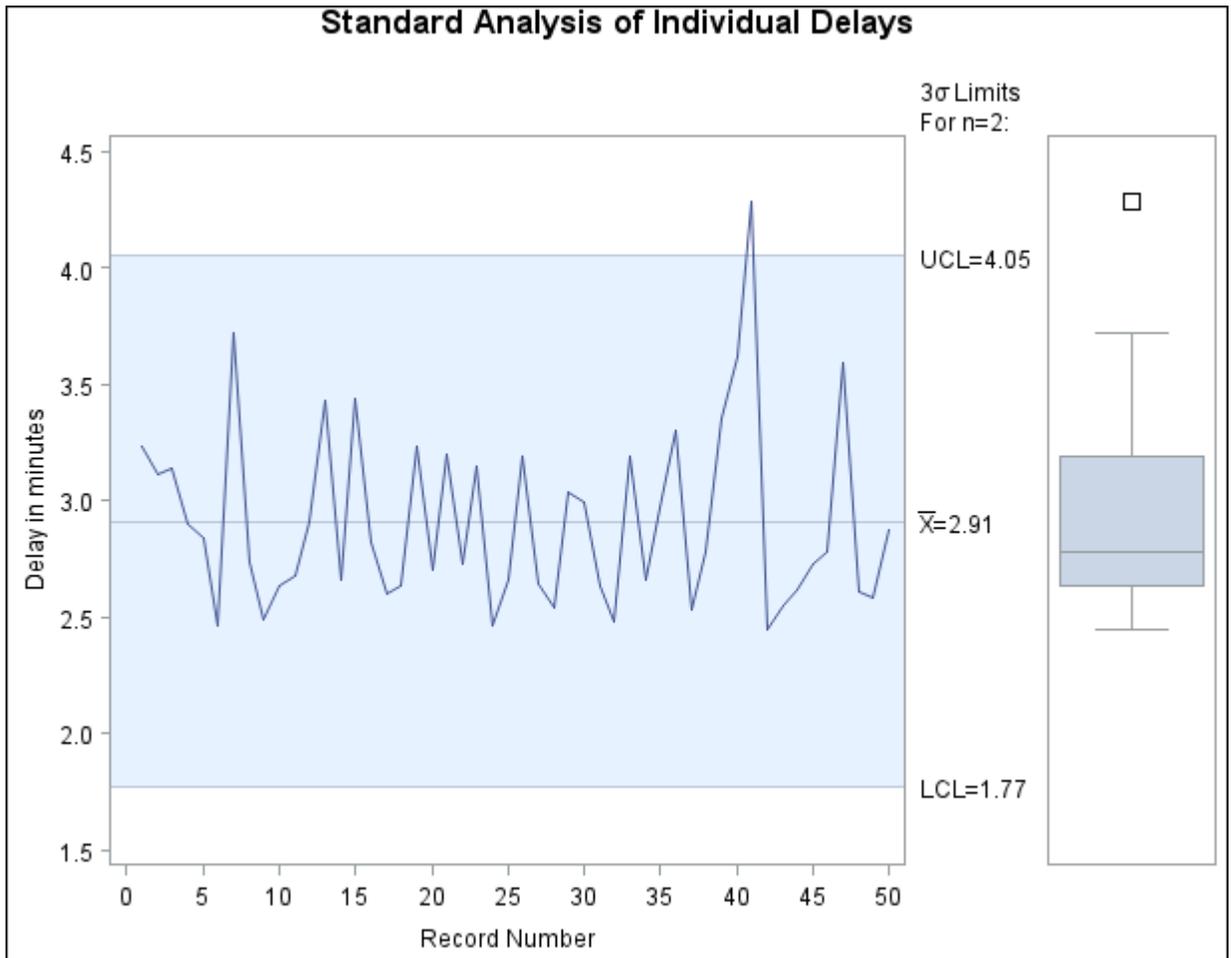

title 'Standard Analysis of Individual Delays';
proc shewhart data=Calls;
  irchart Time * Recnum /
    rtmplot = schematic
    outlimits = delaylim
    nochart2 ;
  label Recnum = 'Record Number'
        Time = 'Delay in minutes' ;
run;

```

You may be inclined to conclude that the 41st point signals a special cause of variation. However, the box plot in the right margin (requested with the `RTMPLOT=` option) indicates that the distribution of delays is skewed. Thus, the reason that the measurements are grouped well within the control limits is that the limits are incorrect and not that the process is too good for the limits.

NOTE: This example assumes the process is in statistical control; otherwise, the box plot could not be interpreted as a representation of the process distribution. You can check the assumption of normality with goodness-of-fit tests by using the `CAPABILITY` procedure, as shown in the statements that follow.

Figure 17.216 Standard Control Limits for Delays

Calculating Probability Limits

The OUTLIMITS= option saves the control limits from the chart in Figure 17.216 in a SAS data set named DELAYLIM, which is listed in Figure 17.217.

Figure 17.217 Control Limits for Standard Chart from the Data Set Calls

	S		L		S				S
	U		I	A	I				T
	B	T	M	L	G	L	M	U	D
V	G	Y	I	P	M	C	E	C	D
A	R	P	T	H	A	L	A	L	E
R	P	E	N	A	S	I	N	I	V
Time	Recnum	ESTIMATE	2	.002699796	3	1.77008	2.91038	4.05068	0.38010

The control limits can be replaced with the corresponding percentiles from a fitted lognormal distribution. The equation for the lognormal density function is

$$f(x) = \frac{1}{x\sqrt{2\pi\sigma}} \exp\left(-\frac{(\log(x)-\zeta)^2}{2\sigma^2}\right) \quad x > 0$$

where σ denotes the shape parameter and ζ denotes the scale parameter.

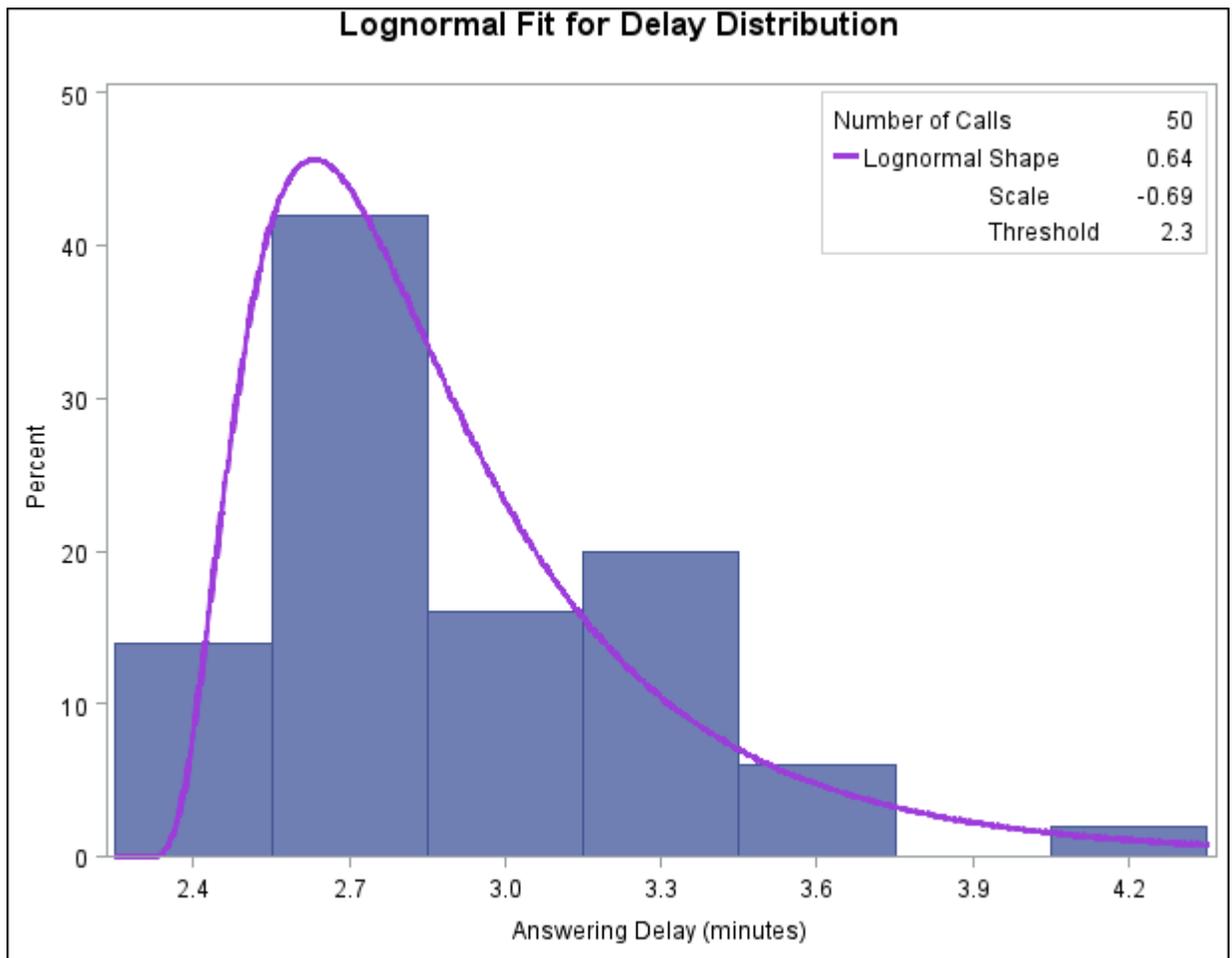

The following statements use the CAPABILITY procedure to fit a lognormal model and superimpose the fitted density on a histogram of the data, shown in [Figure 17.218](#):

```

title 'Lognormal Fit for Delay Distribution';
proc capability data=Calls noprint;
  histogram Time /
    lognormal(threshold=2.3 w=2)
    outfit = Lnfit
    nolegend ;
  inset n = 'Number of Calls'
    lognormal( sigma = 'Shape' (4.2)
              zeta = 'Scale' (5.2)
              theta ) / pos = ne;
  label Time = 'Answering Delay (minutes)';
run;

```

Figure 17.218 Distribution of Delays

Parameters of the fitted distribution and results of goodness-of-fit tests are saved in the data set LNFIT, which is listed in Figure 17.219. The large p -values for the goodness-of-fit tests are evidence that the lognormal model provides a good fit.

Figure 17.219 Parameters of Fitted Lognormal Model in the Data Set LNFIT

<u>_VAR_</u>	<u>_CURVE_</u>	<u>_LOCATN_</u>	<u>_SCALE_</u>	<u>_SHAPE1_</u>	<u>_MIDPTN_</u>
Time	LNORMAL	2.3	-0.68910	0.64110	4.2
<u>_ADASQ_</u>	<u>_ADP_</u>	<u>_CVMWSQ_</u>	<u>_CVMP_</u>	<u>_KSD_</u>	<u>_KSP_</u>
0.34854	0.47465	0.058737	0.40952	0.092223	0.15

The following statements replace the control limits in DELAYLIM with limits computed from percentiles of the fitted lognormal model. The 100α th percentile of the lognormal distribution is $P_\alpha = \exp(\sigma\Phi^{-1}(\alpha) + \zeta)$, where Φ^{-1} denotes the inverse standard normal cumulative distribution function. The SHEWHART procedure constructs an X chart with the modified limits, displayed in

Figure 17.220.

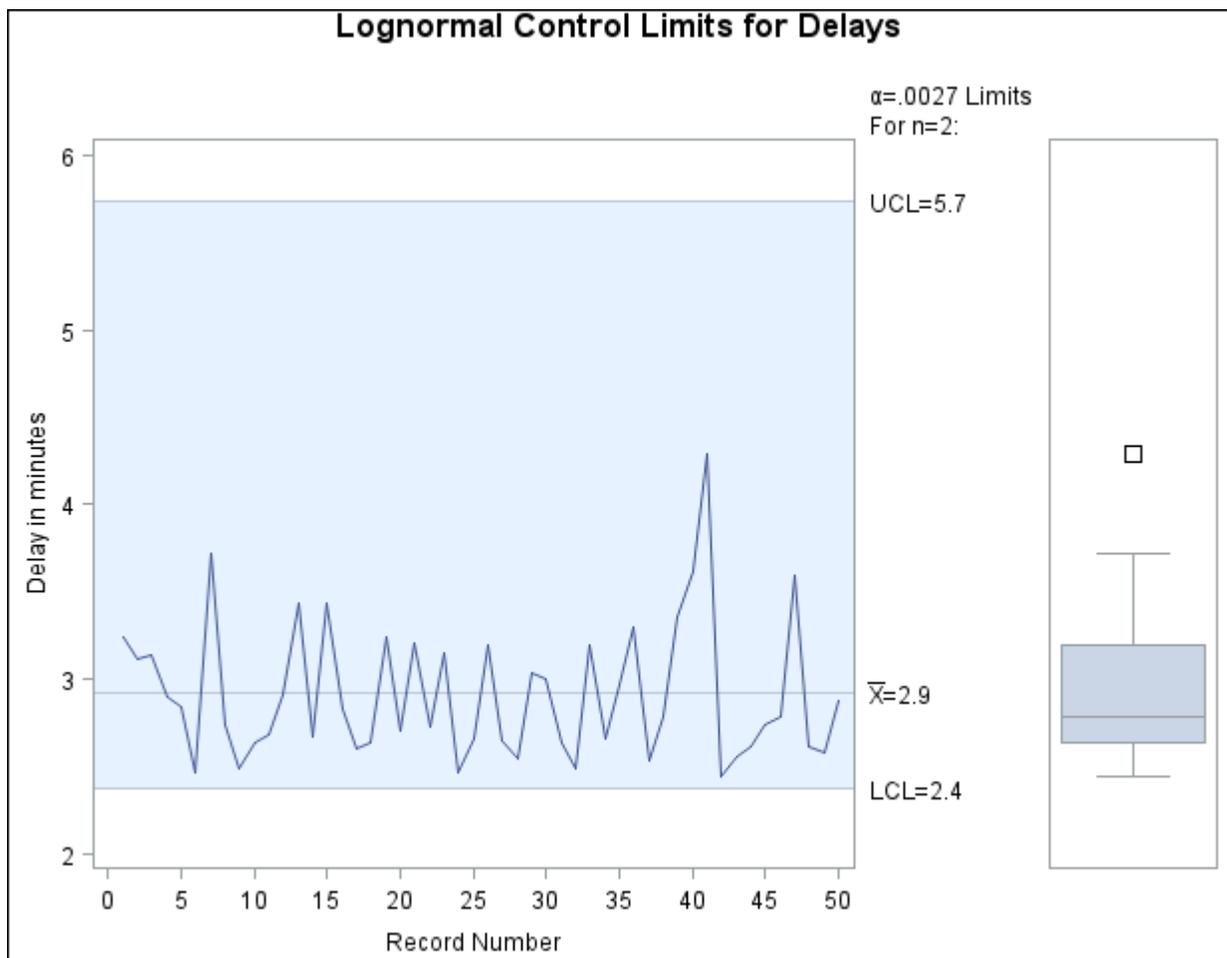

```

data delaylim;
  merge delaylim lnfit;
  drop _sigmas_ ;
  _lcli_ = _locatn_ + exp(_scale_*probit(0.5*_alpha_)*_shapel_);
  _ucli_ = _locatn_ + exp(_scale_*probit(1-.5*_alpha_)*_shapel_);
  _mean_ = _locatn_ + exp(_scale_+0.5*_shapel_*_shapel_);
run;

title 'Lognormal Control Limits for Delays';
proc shewhart data=Calls limits=delaylim;
  irchart Time*Recnum /
    rtmplot = schematic
    nochart2 ;
  label Recnum = 'Record Number'
        Time = 'Delay in minutes' ;
run;

```

Figure 17.220 Adjusted Control Limits for Delays

Clearly the process is in control, and the control limits (particularly the lower limit) are appropriate for the data. The particular probability level $\alpha = 0.0027$ associated with these limits is somewhat

immaterial, and other values of α such as 0.001 or 0.01 could be specified with the ALPHA= option in the original IRCHART statement.

Multivariate Control Charts

See SHWT2 in the SAS/QC Sample Library

In many industrial applications, the output of a process characterized by p variables that are measured simultaneously. Independent variables can be charted individually, but if the variables are correlated, a multivariate chart is needed to determine whether the process is in control.

Many types of multivariate control charts have been proposed; refer to Alt (1985) for an overview. Denote the i th measurement on the j th variable as X_{ij} for $i = 1, 2, \dots, n$, where n is the number of measurements, and $j = 1, 2, \dots, p$. Standard practice is to construct a chart for a statistic T_i^2 of the form

$$T_i^2 = (\mathbf{X}_i - \bar{\mathbf{X}}_n)' \mathbf{S}_n^{-1} (\mathbf{X}_i - \bar{\mathbf{X}}_n)$$

where

$$\bar{X}_j = \frac{1}{n} \sum_{i=1}^n X_{ij}, \quad \mathbf{X}_i = \begin{bmatrix} X_{i1} \\ X_{i2} \\ \vdots \\ X_{ip} \end{bmatrix}, \quad \bar{\mathbf{X}}_n = \begin{bmatrix} \bar{X}_1 \\ \bar{X}_2 \\ \vdots \\ \bar{X}_p \end{bmatrix}$$

and

$$\mathbf{S}_n = \frac{1}{n-1} \sum_{i=1}^n (\mathbf{X}_i - \bar{\mathbf{X}}_n)(\mathbf{X}_i - \bar{\mathbf{X}}_n)'$$

It is assumed that \mathbf{X}_i has a p -dimensional multivariate normal distribution with mean vector $\boldsymbol{\mu} = (\mu_1 \mu_2 \cdots \mu_p)'$ and covariance matrix $\boldsymbol{\Sigma}$ for $i = 1, 2, \dots, n$. Depending on the assumptions made about the parameters, a χ^2 , Hotelling T^2 , or beta distribution is used for T_i^2 , and the percentiles of this distribution yield the control limits for the multivariate chart.

In this example, a multivariate control chart is constructed using a beta distribution for T_i^2 . The beta distribution is appropriate when the data are individual measurements (rather than subgrouped measurements) and when $\boldsymbol{\mu}$ and $\boldsymbol{\Sigma}$ are estimated from the data being charted. In other words, this example illustrates a start-up phase chart where the control limits are determined from the data being charted.

Calculating the Chart Statistic

In this situation, it was shown by Gnanadesikan and Kettenring (1972), using a result of Wilks (1962), that T_i^2 is exactly distributed as a multiple of a variable with a beta distribution. Specifically,

$$T_i^2 \sim \frac{(n-1)^2}{n} B\left(\frac{p}{2}, \frac{n-p-1}{2}\right)$$

Tracy, Young, and Mason (1992) used this result to derive initial control limits for a multivariate chart based on three quality measures from a chemical process in the start-up phase: percent of impurities, temperature, and concentration. The remainder of this section describes the construction of a multivariate control chart using their data, which are given here by the data set Startup.

```

data Startup;
  input Sample Impure Temp Conc;
  label Sample = 'Sample Number'
        Impure = 'Impurities'
        Temp   = 'Temperature'
        Conc   = 'Concentration' ;
  datalines;
1  14.92  85.77  42.26
2  16.90  83.77  43.44
3  17.38  84.46  42.74
4  16.90  86.27  43.60
5  16.92  85.23  43.18
6  16.71  83.81  43.72
7  17.07  86.08  43.33
8  16.93  85.85  43.41
9  16.71  85.73  43.28
10 16.88  86.27  42.59
11 16.73  83.46  44.00
12 17.07  85.81  42.78
13 17.60  85.92  43.11
14 16.90  84.23  43.48
;

```

In preparation for the computation of the control limits, the sample size is calculated and parameter variables are defined.

```

proc means data=Startup noprint ;
  var Impure Temp Conc;
  output out=means n=n;
run;

data Startup;
  if _n_ = 1 then set means;
  set Startup;
  p      = 3;
  _subn_ = 1;
  _limitn_ = 1;
run;

```

Next, the PRINCOMP procedure is used to compute the principal components of the variables and save them in an output data set named Prin.

```

proc princomp data=Startup out=Prin outstat=scores std cov;
  var Impure Temp Conc;
run;

```

The following statements compute T_i^2 and its exact control limits, using the fact that T_i^2 is the sum of squares of the principal components.⁶⁴ Note that these statements create several special SAS variables so that the data set Prin can subsequently be read as a TABLE= input data set by the SHEWHART procedure. These special variables begin and end with an underscore character. The data set Prin is listed in [Figure 17.221](#).

⁶⁴Refer to Jackson (1980).

```
data Prin (rename=(tsquare=_subx_));
  length _var_ $ 8 ;
  drop prin1 prin2 prin3 _type_ _freq_;
  set Prin;
  comp1  = prin1*prin1;
  comp2  = prin2*prin2;
  comp3  = prin3*prin3;
  tsquare = comp1 + comp2 + comp3;
  _var_  = 'tsquare';
  _alpha_ = 0.05;
  _lclx_ = ((n-1)*(n-1)/n)*betainv(_alpha_/2, p/2, (n-p-1)/2);
  _mean_ = ((n-1)*(n-1)/n)*betainv(0.5, p/2, (n-p-1)/2);
  _uclx_ = ((n-1)*(n-1)/n)*betainv(1-_alpha_/2, p/2, (n-p-1)/2);
  label tsquare = 'T Squared'
        comp1   = 'Comp 1'
        comp2   = 'Comp 2'
        comp3   = 'Comp 3';
run;
```

0.0823	0.87976	1.4003	0.05	0.24604	2.44144	7.13966			
1.6153	0.30167	2.3320	0.05	0.24604	2.44144	7.13966			
0.0001	0.00010	0.9032	0.05	0.24604	2.44144	7.13966			

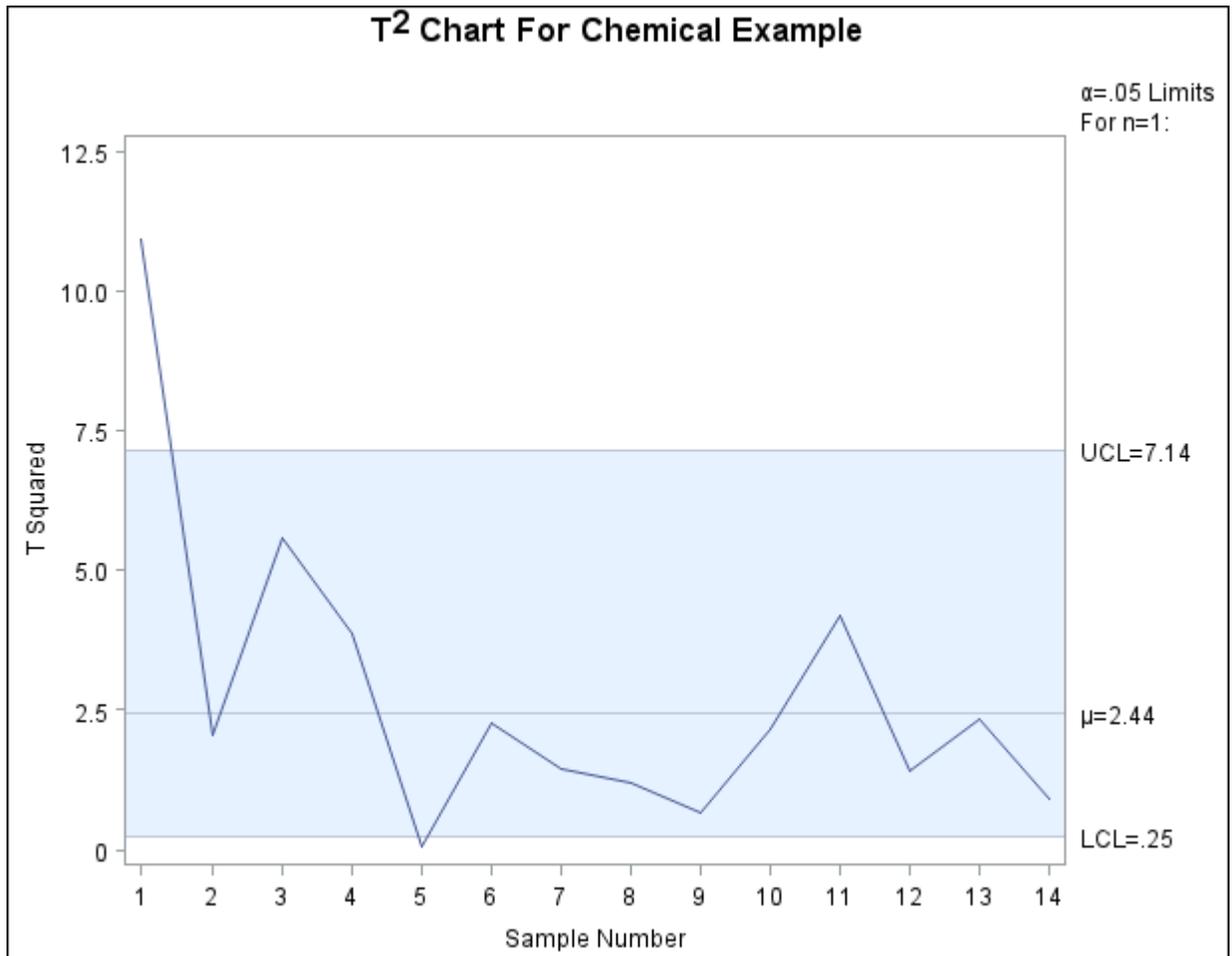

You can now use the data set Prin as input to the SHEWHART procedure to create the multivariate control chart displayed in Figure 17.222.

```

title 'T' m=(+0,+0.5) '2'
      m=(+0,-0.5) ' Chart For Chemical Example';
proc shewhart table=Prin;
  xchart tsquare*Sample /
    xsymbol = mu
    nolegend ;
run;

```

Figure 17.222 Multivariate Control Chart for Chemical Process

The methods used in this example easily generalize to other types of multivariate control charts. You can create charts using the χ^2 and F distributions by using the appropriate CINV or FINV function in place of the BETAINV function. For details, refer to Alt (1985), Jackson (1980, 1991), and Ryan (1989).

Examining the Principal Component Contributions

You can use the *star options* in the SHEWHART procedure to superimpose points on the chart with stars whose vertices represent standardized values of the squares of the three principal components used to determine T_i^2 .

```

title 'T' m=(+0,+0.5) '2'
      m=(+0,-0.5) ' Chart For Chemical Example';
symbol value=none;
proc shewhart table=Prin;
  xchart tsquare*Sample /
    starvertices = (comp1 comp2 comp3)
    startype     = wedge
    starlegend   = none
    starlabel    = first

```

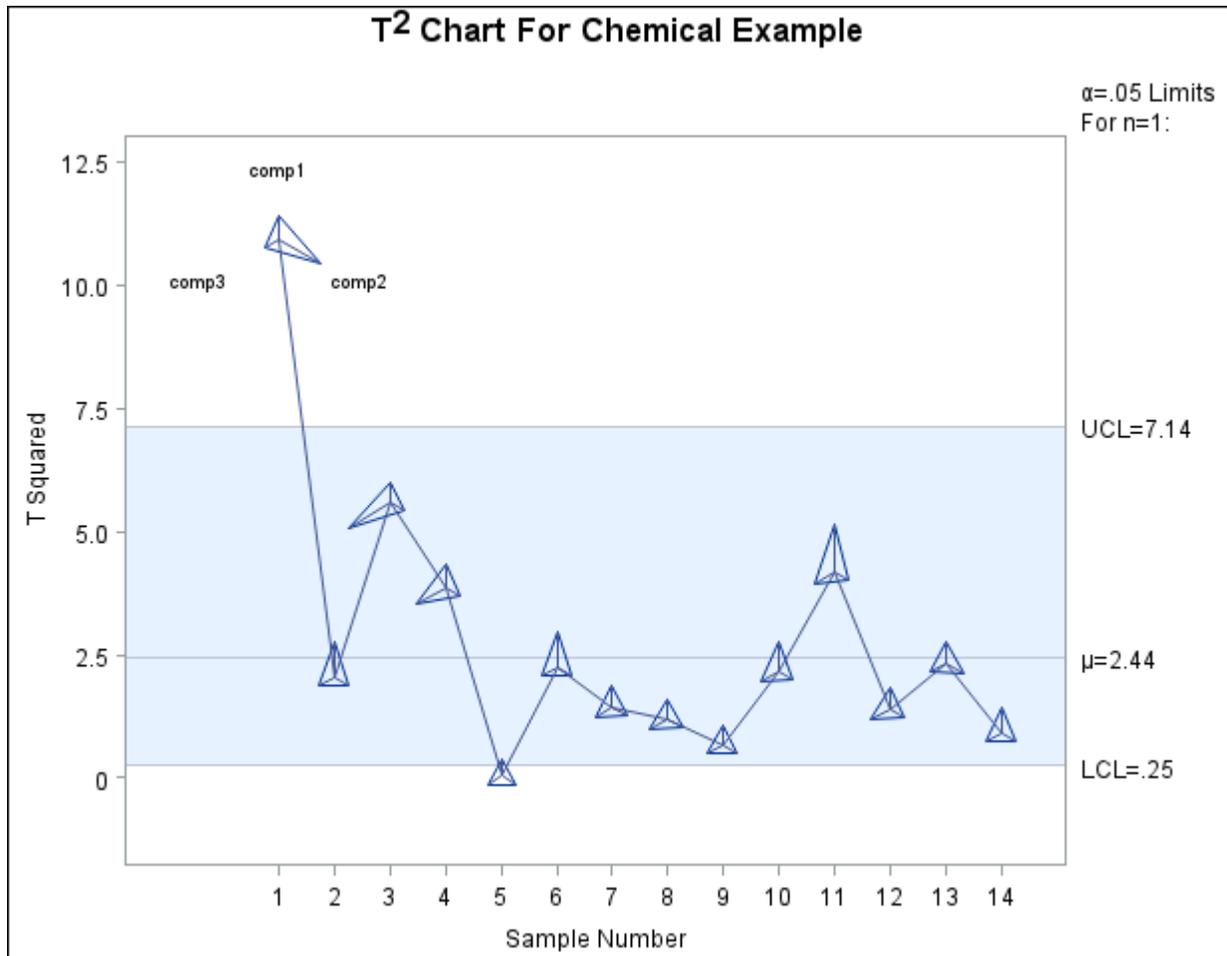

```

staroutradius = 4
npanelpos     = 14
xsymbol       = mu
nolegend      ;
run;

```

The chart is displayed in Figure 17.223. In situations where the principal components have a physical interpretation, the star chart can be a helpful diagnostic for determining the relative contributions of the different components.

Figure 17.223 Multivariate Control Chart Displaying Principal Components

For more information about star charts, see the section “Displaying Auxiliary Data with Stars” on page 2114, or consult the entries for the STARVERTICES= and related options in “Dictionary of Options: SHEWHART Procedure” on page 2018.

Principal components are not the only approach that can be used to interpret multivariate control charts. This problem has recently been studied by a number of authors, including Doganaksoy, Faltin, and Tucker (1991), Hawkins (1991, 1993), and Mason, Tracy, and Young (1993).

Interactive Control Charts: SHEWHART Procedure

Overview: Interactive Control Charts

This section describes two approaches for creating an interactive control chart which enables an end user to “drill down” into subgroup data points and display information not contained in the chart itself. For example, the end user might want to be able to click on a subgroup to

- list the individual measurements in the subgroup
- diagnose an out-of-control point by viewing a Pareto chart of the most common problems affecting the process
- view a list of recommended corrective actions
- trace the raw materials used to manufacture a batch of product

The two approaches for creating interactive control charts are as follows:

- saving graphics coordinate data from control charts for use in creating SAS/AF applications
- associating Uniform Resource Locators (URLs) with subgroups to produce “clickable” control charts in HTML

The options described in this section can be specified in all the chart statements available in the SHEWHART procedure.

Details: Interactive Control Charts

Saving Graphics Coordinates in a Control Chart

You can specify an `WEBOUT=` data set in any chart statement to save graphics coordinate information for a control chart. The `WEBOUT=` data set is an extension of the `OUTTABLE=` data set, which contains the subgroup summary statistics, control limits and related information found in an `OUTTABLE=` data set, as well as coordinate data. The additional coordinate variables are listed in Table 17.96.

Table 17.96 WEBOUT= Data Set

Variable	Description
<code>_X1_</code>	x-coordinate of lower left corner of primary chart subgroup bounding box
<code>_Y1_</code>	y-coordinate of lower left corner of primary chart subgroup bounding box
<code>_X2_</code>	x-coordinate of upper right corner of primary chart subgroup bounding box
<code>_Y2_</code>	y-coordinate of upper right corner of primary chart subgroup bounding box
<code>_Xn_</code>	x-coordinate for point <i>n</i> of the subgroup shape

Table 17.96 (continued)

Variable	Description
<u>_Yn_</u>	y-coordinate for point <i>n</i> of the subgroup shape
<u>_X1_2_</u>	x-coordinate of lower left corner of secondary chart subgroup bounding box
<u>_Y1_2_</u>	y-coordinate of lower left corner of secondary chart subgroup bounding box
<u>_X2_2_</u>	x-coordinate of upper right corner of secondary chart subgroup bounding box
<u>_Y2_2_</u>	y-coordinate of upper right corner of secondary chart subgroup bounding box
<u>_SHAPE_</u>	shape of primary chart subgroup bounding area
<u>_NXY_</u>	number of points defining primary chart subgroup bounding area
<u>_GRAPH_</u>	name of primary chart graphics entry
<u>_GRAPH2_</u>	name of secondary chart graphics entry
<u>_DXMIN_</u>	value of lowest major tick mark on horizontal axis
<u>_DXMAX_</u>	value of highest major tick mark on horizontal axis
<u>_XMIN_</u>	x-coordinate of lowest major tick mark on horizontal axis
<u>_XMAX_</u>	x-coordinate of highest major tick mark on horizontal axis
<u>_DYMIN_</u>	value of lowest major tick mark on vertical axis
<u>_DYMAX_</u>	value of highest major tick mark on vertical axis
<u>_YMIN_</u>	y-coordinate of lowest major tick mark on vertical axis
<u>_YMAX_</u>	y-coordinate of highest major tick mark on vertical axis
<u>_XMIN2_</u>	x-coordinate of lowest major tick mark on secondary chart horizontal axis
<u>_XMAX2_</u>	x-coordinate of highest major tick mark on secondary chart horizontal axis
<u>_DYMIN2_</u>	value of lowest major tick mark on secondary chart vertical axis
<u>_DYMAX2_</u>	value of highest major tick mark on secondary chart vertical axis
<u>_YMIN2_</u>	y-coordinate of lowest major tick mark on secondary chart vertical axis
<u>_YMAX2_</u>	y-coordinate of highest major tick mark on secondary chart vertical axis

You can use the coordinate data saved in the WEBOUT= data set to create a “clickable” control chart in a SAS/AF application. The variables _X1_, _Y1_, _X2_ and _Y2_ contain the coordinates of the lower left and upper right corners of a rectangular *bounding box* associated with each subgroup on the primary chart. This box defines the clickable area associated with the subgroup when the chart is incorporated into a SAS/AF application. It contains the symbol used to plot the subgroup data, or the junction of line segments representing the subgroup if no plotting symbol is used. The variables _X1_2_, _Y1_2_, _X2_2_ and _Y2_2_ contain coordinates of the corners of subgroup bounding boxes for a secondary chart.

If you use the BOXCHART statement, each subgroup is represented by a box-and-whisker plot rather than a single symbol. The subgroup’s bounding box is defined by the sides of the box-and-whisker plot and its lower and upper quartiles, regardless of the BOXSTYLE= value in effect.

If you specify the STARVERTICES= option, each subgroup is represented by a polygon or star with a vertex corresponding to each of the STARVERTICES= variables. The clickable area for a subgroup is the polygon with these vertices, regardless of the STARTYPE= value specified. In the WEBOUT= data set the value of the _SHAPE_ variable is POLY and the _NXY_ variable

contains the number of vertices in the polygon. The variables `_Xn_` and `_Yn_`, where $n = 1$ to the value of `_NXY_`, contain the coordinates of the vertices of a subgroup's polygon. When the `STARVERTICES=` option is not used, the value of `_SHAPE_` is always `RECT` and the value of `_NXY_` is always 2.

When a control chart spans multiple panels (pages), the panels reside in separate SAS graphics entries. The `_GRAPH_` character variable records the name of the graphics entry containing the panel on which a given subgroup is plotted. This is the same name that appears in the `PROC GREPLAY` menu. When the `SEPARATE` option is used, primary and secondary charts are displayed on different graphics entries. The `_GRAPH2_` variable records the name of the graphics entry containing the secondary chart panel where a subgroup appears. When the `SEPARATE` option is not used, the values of `_GRAPH_` and `_GRAPH2_` will be the same for a given subgroup.

The variables `_DXMIN_`, `_DXMAX_`, `_XMIN_` and `_XMAX_` provide the data values and graphics coordinates associated with the lowest and highest major tick marks on the horizontal (subgroup) axis. The variables `_DYMIN_`, `_DYMAX_`, `_YMIN_` and `_YMAX_` provide the analogous values for the vertical axis. Through a simple linear transformation in your SAS/AF application you can use this information to convert from percent screen units to "data" units and vice versa.

The variables `_XMIN2_` and `_XMAX2_` contain the graphics coordinates associated with the lowest and highest major tick marks on the horizontal axis of a secondary chart. No variables for the corresponding data values are required, since they are always identical to those for the primary chart.

The variables `_DYMIN2_`, `_DYMAX2_`, `_YMIN2_` and `_YMAX2_` contain the data and coordinate values for the lowest and highest tick marks on the vertical axis of a secondary chart. A SAS/AF program receives the (x,y) coordinates for the location of the cursor when the user clicks on a subgroup data point. The application can determine whether (x,y) lies within any of the boxes whose coordinates are saved in the `WEBOUT=` data set. If so, the program can determine which subgroup was selected on the primary or secondary chart and can check the `_TESTS_` and `_TESTS2_` variables included in the `WEBOUT=` data set to determine whether an out-of-control condition has been signaled.

Notes:

1. Graphics coordinates are scaled in percent screen units from 0 to 100, where (0,0) represents the lower-left corner of the screen and (100,100) represents the upper-right corner of the screen. Because SAS/AF applications define the origin of the vertical axis at the top of the screen, it will be necessary to subtract the y-coordinates from 100 in your SCL program.
2. The variables `_X1_2_`, `_Y1_2_`, `_X2_2_`, `_Y2_2_`, `_GRAPH2_`, `_XMIN2_`, `_XMAX2_`, `_YMIN2_`, `_YMAX2_`, `_DYMIN2_` and `_DYMAX2_` appear in the `WEBOUT=` data set only when a secondary chart is produced. A secondary chart is produced by the `IRCHART`, `MRCHART`, `XRCHART` and `XSCHART` statements and by the `BOXCHART`, `MCHART` and `XCHART` statements when the `TRENDVAR=` option is specified.
3. When the subgroup variable is a character variable, the value of `_DXMIN_` is zero and the value of `_DXMAX_` is the number of subgroups in the input data set minus one.
4. A bounding box circumscribes a point displayed on a chart and its dimensions depend on the size of the symbol marker used to display the point. If no symbol marker is specified, a small

default size is used for the box. If a large number of subgroups are displayed on a panel, the subgroup symbols may overlap, so it is possible for a user to inadvertently select more than one point.

Associating URLs with Subgroups in HTML

You can use the Output Delivery System (ODS) to produce an HTML file containing a control chart created by the SHEWHART procedure. The HTML= option provides a way to associate Uniform Resource Locators (URLs) with subgroups plotted on a control chart. It specifies a variable in the input data set containing HTML syntax providing the URLs to be associated with different subgroups. The HTML= variable can be a character variable or a numeric variable with an associated character format.

The following statements generate an \bar{X} chart that is saved to a GIF file and included in an HTML file. The formatted values of the numeric HTML= variable Web specify URLs that link subgroups in the input data set to various web pages.

```

goptions target = gif;
ods html body = "example1.html";
proc format;
  value webfmt
    1='href="http://www.sas.com/'
    2='href="http://www.sas.com/service/techsup/faq/qc/shewproc.html"'
    3='href="http://www.sas.com/rnd/app/qc.html"'
    4='href="http://www.sas.com/rnd/app/qc/qcnew.html"'
    5='href="http://www.sas.com/rnd/app/qc/qc.html"'
  ;

data wafers;
  format Web webfmt.;
  input Batch Web @;
  do i=1 to 5;
    input Diameter @;
    output;
  end;
  drop i;
  datalines;
1 1 35.00 34.99 34.99 34.98 35.00
2 1 35.00 34.99 34.99 34.98 35.00
3 1 34.99 34.99 35.00 34.99 35.00
4 1 35.00 35.00 34.99 34.99 35.00
5 2 35.00 34.99 34.98 34.99 35.00
6 2 34.99 34.99 35.00 35.00 35.00
7 2 35.01 34.98 35.00 35.00 34.99
8 2 35.00 35.00 34.99 34.98 34.99
9 3 34.99 34.98 34.99 35.01 35.00
10 3 34.99 35.00 35.00 34.99 35.00
11 3 35.01 35.00 35.00 34.98 34.99
12 3 34.99 34.99 35.00 34.98 35.01
13 4 35.01 34.99 34.98 34.99 34.99
14 4 35.00 35.00 34.99 35.00 34.99
15 4 34.98 35.00 34.99 35.00 34.99

```

```

16  4  34.99 35.00 35.00 35.01 35.00
17  5  34.98 34.98 34.98 34.99 34.98
18  5  35.01 35.02 35.00 34.98 35.00
19  5  34.99 34.98 35.00 34.99 34.98
20  5  34.99 35.00 35.00 34.99 34.99
;

symbol1 v=square;
proc shewhart data=wafers;
    xchart Diameter*Batch / html = ( Web );
run;

ods html close;
run;

```

In this example five different URLs are each associated with a set of four subgroup values. When you view the ODS HTML output with a browser, you can click on a subgroup data point and the browser will bring up the page specified by the subgroup's URL. These URLs happen to point to pages at SAS Institute's web site which may be of interest to SAS/QC users.

NOTE: The value of the HTML= variable must be the same for each observation belonging to a given subgroup.

Links and Tests for Special Causes

The TESTHTML= data set provides a way to associate a link with each subgroup in a control chart for which a given test for special causes is positive:

Table 17.97 Variables Required in a TESTHTML= Data Set

Variable	Type	Description
TEST	character or numeric	test identifier
CHART	numeric	primary (1) or secondary (2) chart
URL	character	HTML specifying URL for subgroups with positive test

The variable _TEST_ identifies a test for special causes (see “Tests for Special Causes: SHEWHART Procedure” on page 2146). A standard test is identified by its number (1 to 8) and a nonstandard test is identified by the CODE= character in its pattern specification. The _TEST_ variable must be a character variable if nonstandard tests are included in the TESTHTML= data set. The value of _CHART_ is 1 or 2, specifying whether the test applies to the primary or secondary chart. The character variable _URL_ contains the HTML syntax for the link to be associated with subgroups for which the test is positive.

The following statements create a TESTHTML= data set and an \bar{X} chart using the same DATA= data set as the previous example:

```

ods html body = "example2.html";

data testlink;
    length _URL_ $ 75;

```

```

input _TEST_ _CHART_ _URL_;
datalines;
1 1 href="http://www.sas.com/"
2 1 href="http://www.sas.com/service/techsup/faq/qc/shewproc.html"
3 1 href="http://www.sas.com/rnd/app/qc.html"
4 1 href="http://www.sas.com/rnd/app/qc/qcnew.html"
5 1 href="http://www.sas.com/products/qc/index.html"
6 1 href="http://www.sas.com/rnd/app/qc/qc/qcspc.html"
7 1 href="http://www.sas.com/software/components/qc.html"
8 1 href="http://www.sas.com/rnd/app/qc/qc.html"
;

symbol1 v=dot;
proc shewhart data=wafers testhtml=testlink;
    xchart Diameter*Batch / tests = 1 to 8;
run;

ods html close;
run;

```

In this example only subgroups triggering tests for special causes have URLs associated with them.

NOTE: If a TESTHTML= data set and an HTML= variable are both specified, the link from the TESTHTML= data set is associated with any subgroup for which the test is positive.

This appendix describes the GAGE application, which is a tool for assessing gage repeatability and reproducibility (R&R). The GAGE application is available with Release 6.10 of the SAS/QC Sample Library.

Introduction

Measurement systems are essential to the quality of a manufacturing process. The gages or instruments that take measurements are subject to variation. Too much variation in the measurement system may mask variation in the process.

One type of measurement variation is caused by conditions inherent in gages. This variation, known as repeatability, is obtained when one person measures the same characteristic several times with the same gage. Another type of measurement variation, known as reproducibility, occurs when different

individuals measure the same characteristic with the same gage. Other sources of measurement variation include part-to-part variation, accuracy, stability, and linearity.

Two graphical methods for evaluating the measurement system are range charts and average charts. Range charts assess repeatability by showing whether the gage variability is consistent. Average charts show consistency of operator variability (reproducibility) and part-to-part variation.

Two statistical approaches to determining gage R&R are the average and range method and the variance components method. The variance components method can provide more information, is more accurate, and is more flexible than the average and range method.

The GAGE application makes it easy for you to enter your data, create range and average charts, and determine gage R&R. Whether you use the average and range method or the more powerful variance components method, the GAGE application reports the results in a standard form. It enables you to save the graphs for later reference, and it enables you to save the reports. You can save the data in a SAS data set for subsequent gage analysis or for more extensive analysis using other components of the SAS System. Because gage R&R techniques are open to local interpretation, this application has been designed so that it can be modified to suit the needs of your company.

Terminology

The following definitions describe the terms used in a gage R&R study.

Gage	any device used to obtain measurements, for example, a micrometer or a gasket thickness gage.
Condition	typically an operator, but can be thought of more generically as any condition affecting the measurements. For example, with an automated process, condition might be a set-up procedure or an environmental condition such as temperature. For the remainder of this appendix, condition is referred to as operator.
Trial	a set of measurements on all parts taken by one operator. Multiple trials help separate the gage variability (repeatability) from the variability contributed by operators (reproducibility).
Part	the item that is measured, for example, a gasket. The parts selected should represent the entire operating range (variability) of the process.
Measurement System	the complete process used to obtain measurements. This includes people, gages, operations, and procedures.
Repeatability	the variation resulting from repeated measurements taken on the same part with the same gage by the same operator. Repeatability is the gage or equipment variation.
Reproducibility	the variation in the average of the measurements resulting when different operators using the same gage take measurements on the same part. Reproducibility is the operator-to-operator variability.

Getting Started

Suppose that ABC Company needs to evaluate a gasket thickness gage. Three operators (George, Jane, and Robert) are selected for this study. Using the same gage, each operator measures ten parts (gaskets) in a random order. Each part is measured by each operator twice (two trials). Table A.1 gives the measurements (gasket thicknesses) collected by each operator and is patterned after an example given in ASQC Automotive Division/AIAG (1990).

Table A.1 Gage Study Data

Part	George		Jane		Robert	
	Trial1	Trial2	Trial1	Trial2	Trial1	Trial2
1	0.65	0.60	0.55	0.55	0.50	0.55
2	1.00	1.00	1.05	0.95	1.05	1.00
3	0.85	0.80	0.80	0.75	0.80	0.80
4	0.85	0.95	0.80	0.75	0.80	0.80
5	0.55	0.45	0.40	0.40	0.45	0.50
6	1.00	1.00	1.00	1.05	1.00	1.05
7	0.95	0.95	0.95	0.90	0.95	0.95
8	0.85	0.80	0.75	0.70	0.80	0.80
9	1.00	1.00	1.00	0.95	1.05	1.05
10	0.60	0.70	0.55	0.50	0.85	0.80

These data are used to illustrate the GAGE application throughout this appendix.

Invoking the GAGE Application

The interface to the GAGE application was implemented using FRAME entries in SAS/AF software. The application is stored in the gage catalog. (File extensions for SAS catalogs differ based on the operating system.)

Assume that you are using the SAS System under Microsoft Windows and that the SAS/QC Sample Library is stored in the `c:\sas\qc\sample` directory. (Check with your SAS site representative for the location of the Sample Library on your system.) You invoke the application as follows:

1. First, for SAS 9.3, you must enter the following statements to ensure proper operation of the GAGE application:

```
ods graphics off;
ods html close;
ods listing;
```

2. Next you must tell the SAS System where the catalog is stored:

```
libname gage 'c:\sas\qc\sample';
```

- You then issue the following command from any SAS display manager window:

```
af c=gage.gage.gage.frame
```

The main window in the application appears, as shown in Figure A.1.

Figure A.1 General Information Window

The screenshot shows a SAS window titled "GAGE: General Information". The window contains the following fields and options:

- Test ID:** [Empty text box]
- Date:** [04/17/02]
- Performed By:** [Empty text box]
- Part No. & Name:** [Empty text box]
- Characteristics:** [Empty text box]
- Specification:** [Empty text box]
- Sigma Multiple:**
 - 4
 - 5.15
 - 6
- Gage Name:** [Empty text box]
- Gage No.:** [Empty text box]
- Gage Type:** [Empty text box]
- Analysis:**
 - %Variation
 - %Tolerance: [Empty text box]

You specify the following general information for your gage study in this window: who performed the study, part number and part name, characteristics, specification, and gage name, number, and type.

The test ID is required for each set of data to be analyzed. It uniquely identifies each gage study. Date is set to the current date and can be changed. You also select either the percent of process variation analysis (%Variation) or the percent of tolerance analysis (%Tolerance). You must specify a tolerance value for the percent of tolerance analysis.

Set the multiple of sigma to whatever level you use for gage studies. This multiple may be a standard level established within your organization. For example, the automotive industry typically uses 5.15σ (ASQC Automotive Division/AIAG 1990), and SEMATECH uses 6σ (SEMATECH, Inc. 1991).

The general information for the gasket thickness gage example is entered, as shown in Figure A.2.

Figure A.2 General Information for Gage Study

The screenshot shows the SAS 'GAGE: General Information' window. The window title is 'SAS' and the menu bar includes 'File', 'Window', and 'Help'. The window content is as follows:

- Test ID: Date:
- Performed By:
- Part No. & Name:
- Characteristics:
- Specification:
- Gage Name:
- Gage No.:
- Gage Type:
- Sigma Multiple: 4, 5.15, 6
- Analysis: %Variation, %Tolerance: 0.4

This study is identified with the test ID *Gasket*. The analysis is based on 5.15σ , and a percent of tolerance analysis based on a tolerance of 0.4mm is requested.

Entering Data

The next step is to enter the data provided in [Table A.1](#). In the General Information window, choose **Edit** from the **File** menu, as shown in [Figure A.3](#).

Figure A.3 Choosing Edit from the File Menu

The screenshot shows the same SAS 'GAGE: General Information' window as in Figure A.2, but with the 'File' menu open. The 'Edit' option is highlighted by the mouse cursor. The menu items are: New, Open..., Edit, Save..., End, and Exit. The window content is identical to Figure A.2.

The Measurements window appears, as shown in Figure A.4.

Figure A.4 Measurements (Data Entry) Window

The screenshot shows the SAS GAGE: Measurements window. The window title is "GAGE: Measurements". The menu bar includes "File", "Window", and "Help". The main area contains a data entry grid with the following structure:

Part	Trial			
	1	2	3	4
1				
2				
3				
4				
5				

On the right side of the window, there is a "Condition" dropdown menu with left and right arrows. Below it are fields for "Test ID" (Gasket) and "Date" (04/17/02). At the bottom right, there is an "Analysis" button.

Enter data for one operator (Condition) in this window only. Only five parts are displayed at one time. Use the scroll bar to move the data region vertically. The first operator is George, whose measurements for parts 1-5 are shown in Figure A.5.

Figure A.5 Measurements for Operator George

The screenshot shows the SAS GAGE: Measurements window with data entered for Operator George. The window title is "GAGE: Measurements". The menu bar includes "File", "Window", and "Help". The main area contains a data entry grid with the following structure:

Part	Trial			
	1	2	3	4
1	0.65	0.6		
2	1	1		
3	0.85	0.8		
4	0.85	0.95		
5	0.55	0.45		

On the right side of the window, there is a "Condition" dropdown menu with left and right arrows, currently set to "George". Below it are fields for "Test ID" (Gasket) and "Date" (04/17/02). At the bottom right, there is an "Analysis" button.

To enter the next operator's measurements, press the arrow \Rightarrow to the right of Condition. An empty Measurements window similar to Figure A.4 appears.

The second operator is Jane. Her measurements for parts 6–10 are shown in Figure A.6.

Data for the third operator are entered similarly. Press the arrow \Leftarrow to the left of Condition to move to the previous operator.

Figure A.6 Measurements for Operator Jane

Part	Trial			
	1	2	3	4
6	1	1.05		
7	0.95	0.9		
8	0.75	0.7		
9	1	0.95		
10	0.55	0.5		

Condition: Jane

Test ID: Gasket

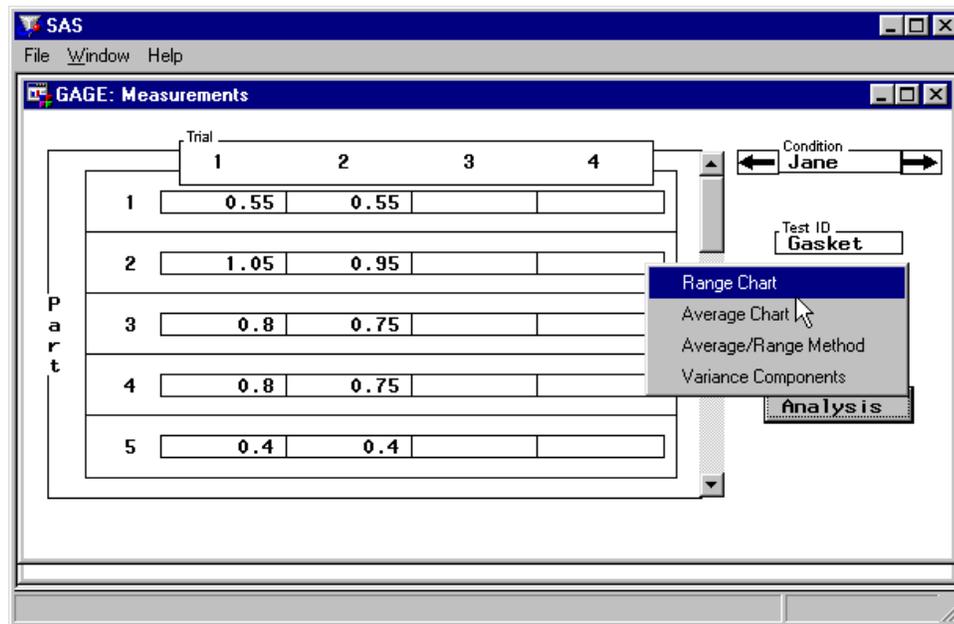

Date: 04/17/02

Analysis

Performing a Range Chart Analysis

Now that the data are entered, the gage variability (repeatability) can be checked for consistency. This is done graphically with a range chart. Press the **Analysis** button in the Measurements window. A menu of analysis options appears, as shown in Figure A.7.

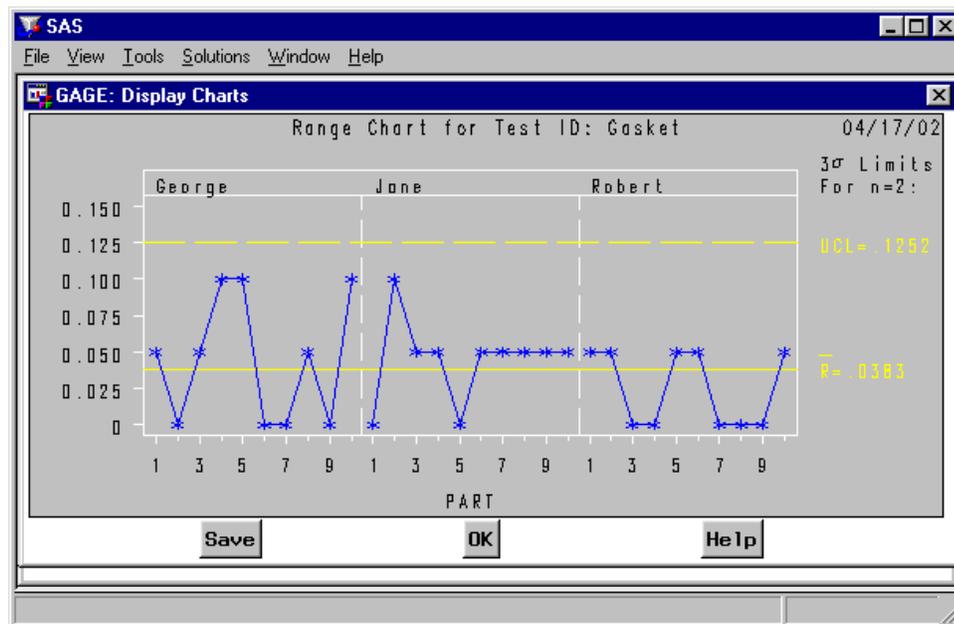

Figure A.7 Analysis Button Options

Select **Range Chart**. The range chart of the data is displayed, as shown in Figure A.8.

No points are out-of-control, and the variability across operators is fairly comparable. This indicates that all operators are using the gage in the same way. If there were any out-of-control points, they should be investigated and dealt with before proceeding.

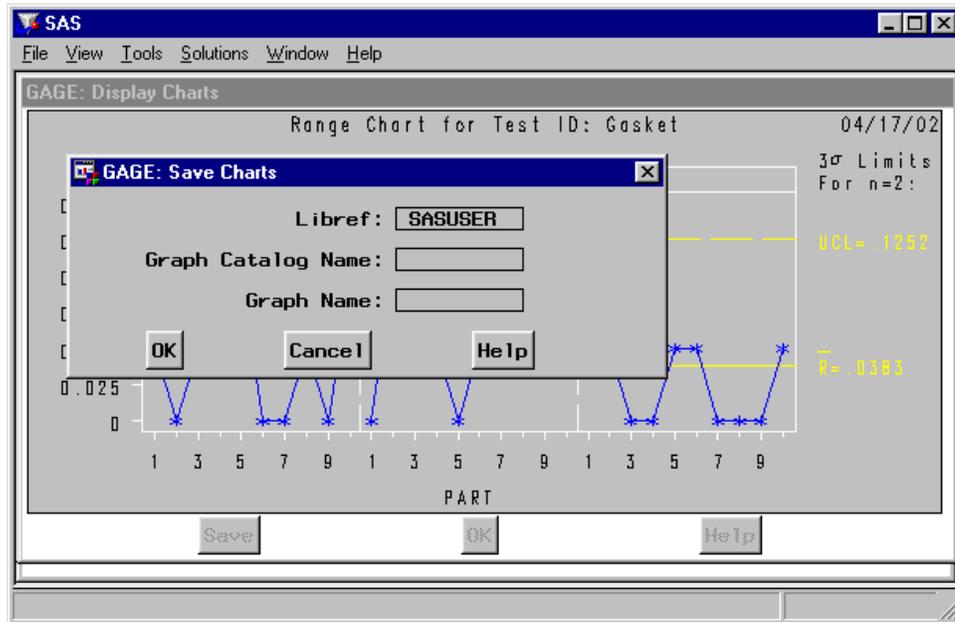

Figure A.8 Range Chart for Gage Study Gasket

You can save this chart in a SAS graphics catalog. Then you can use the GRAPH window or the GREPLAY procedure to view charts stored in the catalog. You also can create hard-copy versions of charts stored in the catalog.

Press the **Save** button to save the range chart. The Save Charts window appears, as shown in Figure A.9.

Figure A.9 Saving the Range Chart

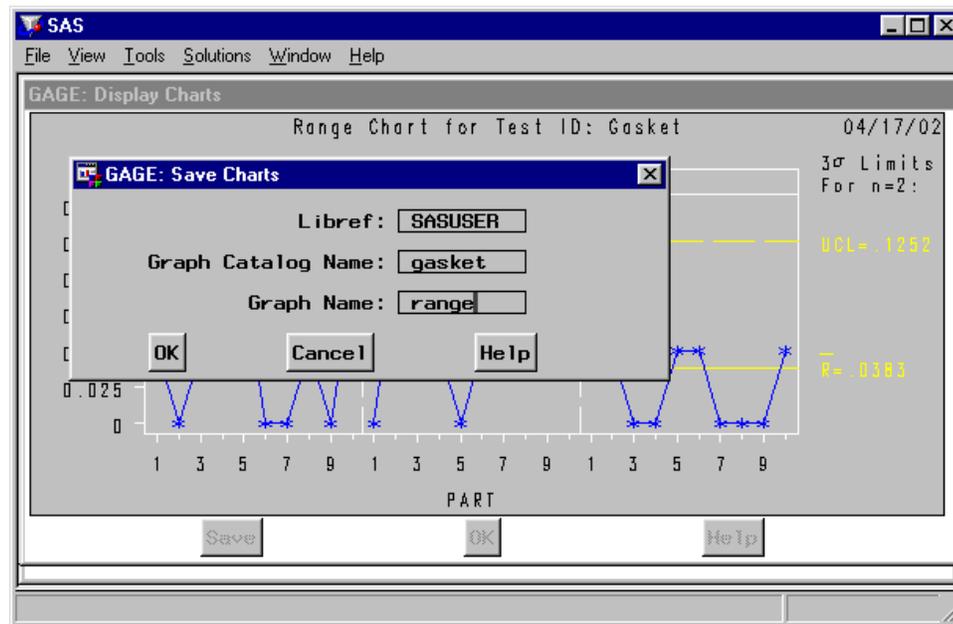

Libref tells the SAS System where to store the SAS graphics catalog. The libref SASUSER stores the catalog in the SASUSER data library, which is created automatically by the SAS System. You must assign other libref locations with the LIBNAME statement.

Graph Catalog Name is the name of the SAS graphics catalog in which to store the chart.

Graph Name is the name of this range chart when stored in the SAS graphics catalog.

Figure A.10 shows that the range chart is to be stored in SASUSER.GASKET.RANGE.

Figure A.10 Saving the Range Chart

Press the **Cancel** button if you decide not to save the chart. Press the **OK** button to save the chart.

You return to the window displaying the range chart. Press the **OK** button to leave the Display Charts window.

Refer to *SAS/GRAPH: Reference* for more information on SAS graphics catalogs, the GRAPH window, and the GREPLAY procedure.

Performing an Average Chart Analysis

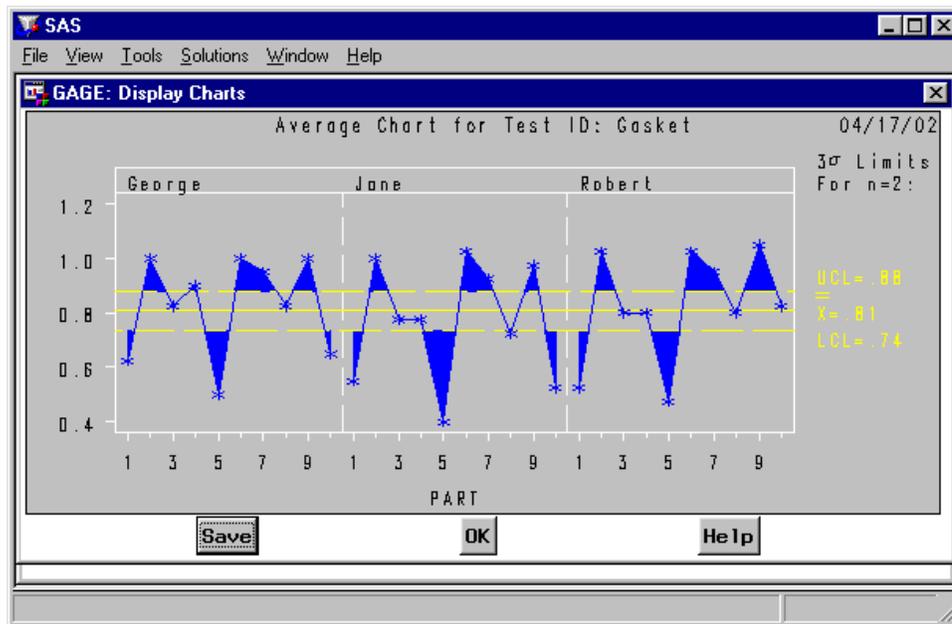

The average chart shows operator variability (reproducibility) and part-to-part variation. Press the **Analysis** button in the Measurements window and select **Average Chart**. The average chart of the data is displayed, as shown in Figure A.11.

Note how most of the averages are beyond the control limits. Also, the out-of-control averages tend to be the same for each operator. This indicates that this study can detect part-to-part variation. If the averages were not outside the control limits, the part-to-part variation would be hidden in the gage variation.

Operator variability can be seen on the average chart by comparing the operator averages for each part. These averages will differ when there is variability.

Note that this is not a standard use of the Shewhart chart. Ordinarily the fact that the points fall outside the control limits would raise concerns that the process is out of control, but here the opposite conclusion is drawn.

Figure A.11 Average Chart for Gage Study Gasket

You can save the average chart by pressing the **Save** button, as described for the range chart. Press the **OK** button to leave this window.

Selecting a Statistical Method

The range chart indicates that the gage variability is consistent. The average chart indicates that the measurement system is adequate to detect part-to-part variation. Now you can perform a statistical analysis. Which analysis method should you choose: average and range, or variance components?

Since the data for this study are balanced (no data points are missing), the average and range method can be used. But it is not as efficient as the variance components method, and it does not provide information about the interaction between operators and parts. Both methods will be shown to illustrate some of these differences.

Performing an Average and Range Analysis

Press the **Analysis** button in the Measurements window and select **Average/Range Method**. The results are displayed, as shown in Figure A.12. You can scroll the report with the vertical scroll bar.

The complete listing of these results is shown in Figure A.24. A percent of tolerance analysis (against a tolerance value of 0.4mm) was requested in the General Information window. This appears on the right side of the report.

As with the charts, you can save this report in a file. Press the **Save** button to save the report. The Save Reports window appears, as shown in Figure A.13.

Figure A.12 Average and Range Analysis of Gage Study Gasket

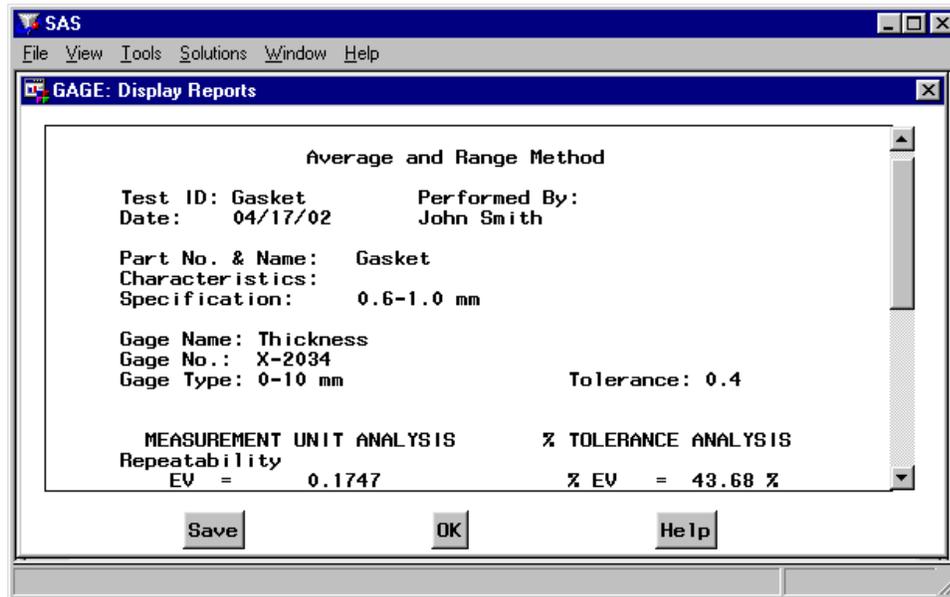

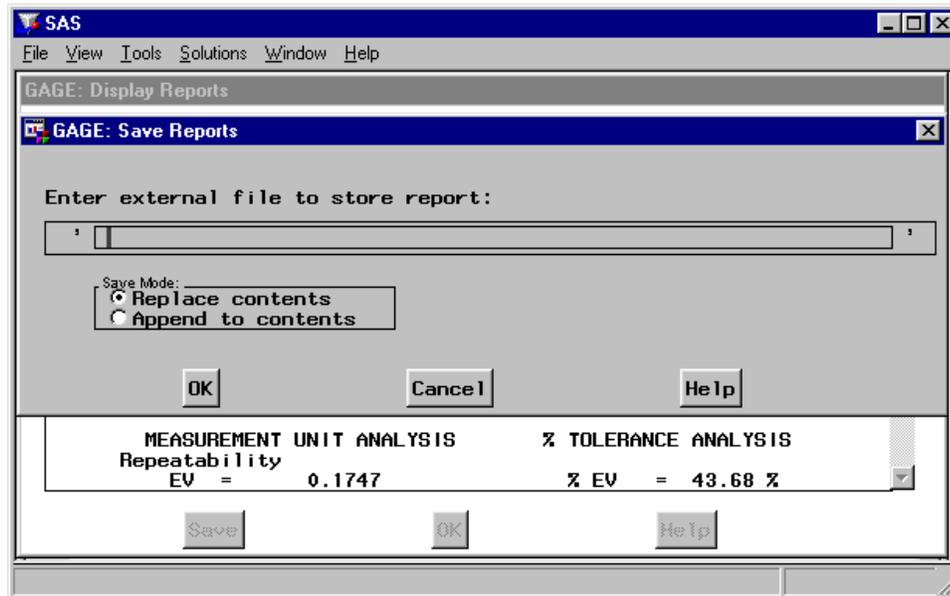

Figure A.13 Saving the Average and Range Report

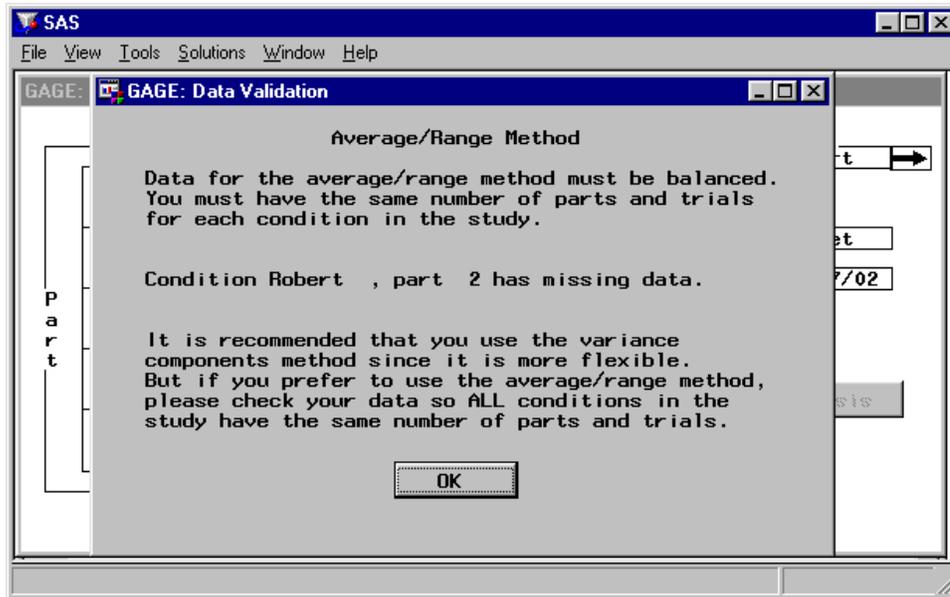

You enter the name of the file in which to store the report. You can select to have this listing replace what is currently in the file (if it exists) or be appended to the information stored in the file.

Press the **Cancel** button if you decide not to save the report. Press the **OK** button to save the report.

You return to the window displaying the average and range report. Press the **OK** button to leave the Display Reports window.

What would happen if you chose this method and there were missing data? Assume that operator Robert was unable to take the second measurement on the second part, and that data point is missing. If you run the average and range method on these data, you receive the message window shown in Figure A.14.

Figure A.14 Average and Range Message Window

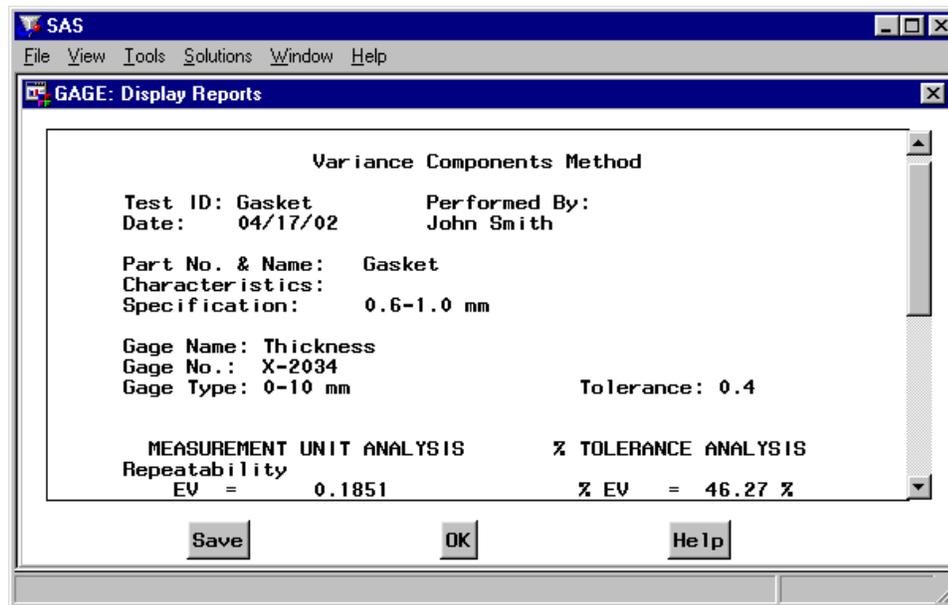

The variance components method can be used for these data.

Performing a Variance Components Analysis

Now perform a variance components analysis on the original data. Press the **Analysis** button in the Measurements window and select **Variance Components**. The results are displayed, as shown in Figure A.15.

Figure A.15 Variance Components Analysis of Gage Study Gasket

The complete listing of these results is shown in [Figure A.25](#). Note that the results you get using the variance components method differ slightly from those you get using the average and range method (see “[Variance Components Method](#)” on page 2243).

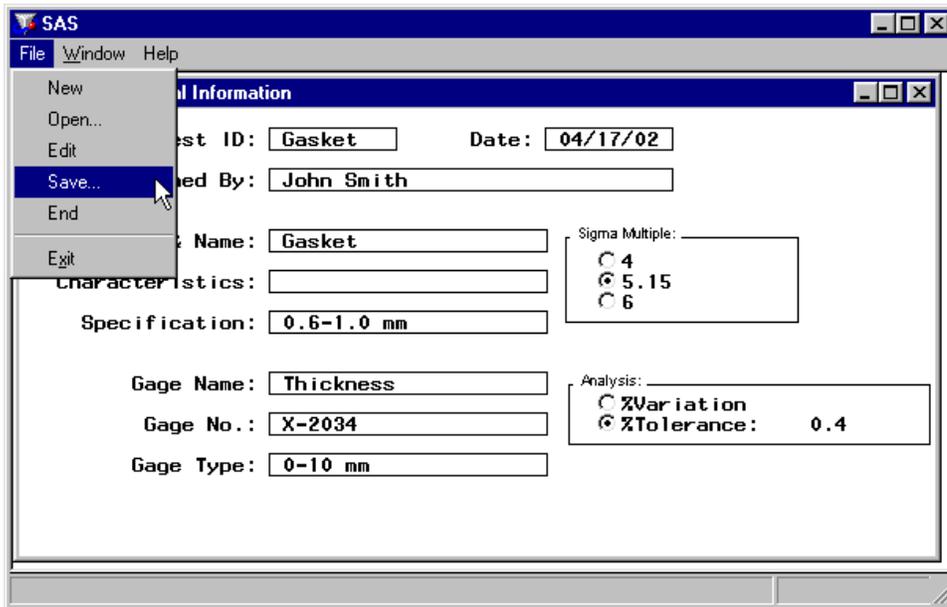

You can save this report by pressing the **Save** button, as described for the average and range analysis. Press the **OK** button to leave this window.

Saving the Data

Now that you have entered the data and performed analyses, you can save the data in a SAS data set for later analysis. You save the data by choosing **Save** from the **File** menu in either the Measurements window or the General Information window.

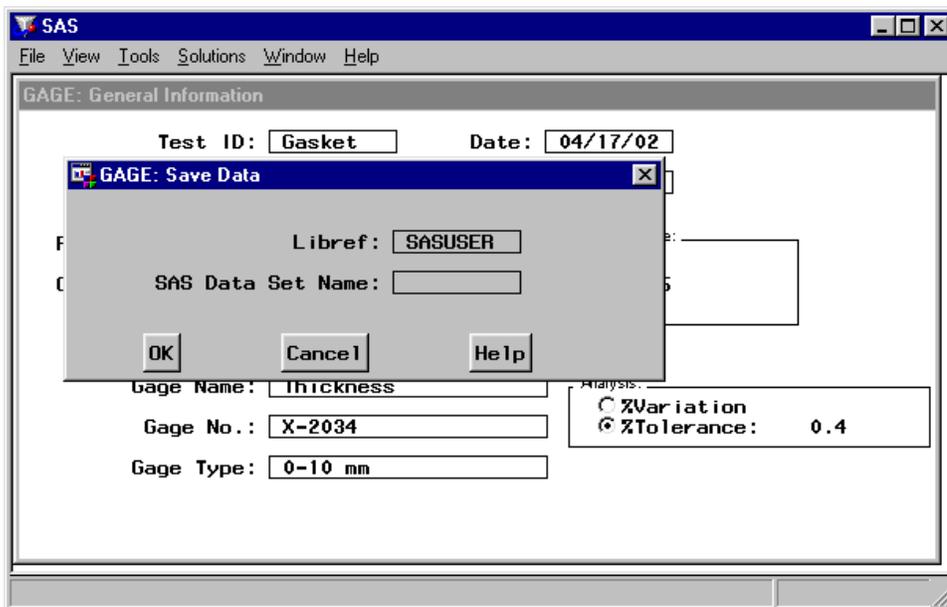

Choose **End** from the **File** menu in the Measurements window to return to the General Information window. Then choose **Save** from the **File** menu, as shown in [Figure A.16](#).

Figure A.16 Choosing Save from the File Menu

The Save Data window appears, as shown in Figure A.17.

Figure A.17 Saving the Data in a SAS Data Set

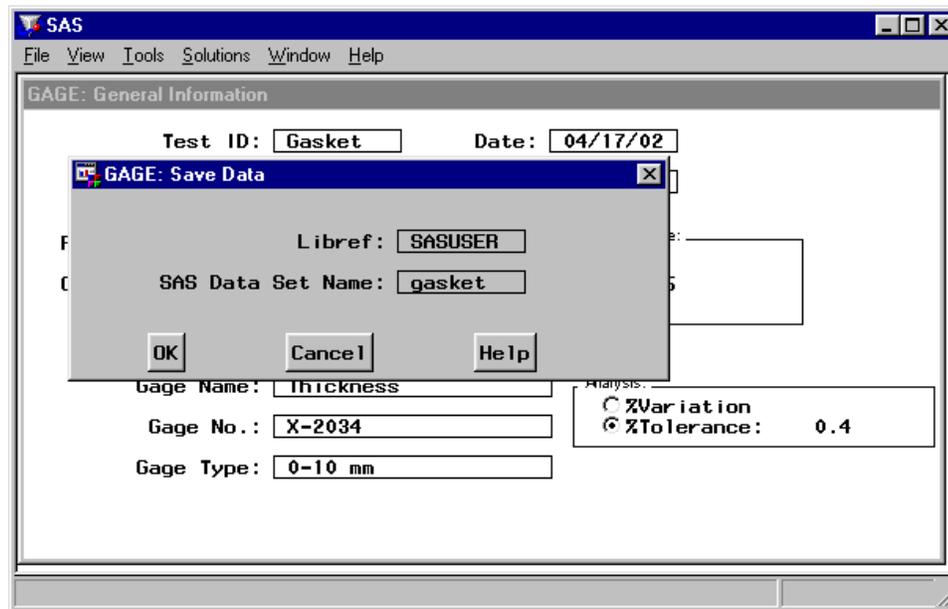

Libref tells the SAS System where to store the SAS data set. The libref SASUSER stores the data set in the SASUSER data library, which is created automatically by the SAS System. You must assign other libref locations with the LIBNAME statement.

SAS Data Set Name is the name of the SAS data set in which to store the data.

Figure A.18 shows that the data are to be stored in SASUSER.GASKET.

Figure A.18 Saving the Data in a SAS Data Set

Press the **Cancel** button if you decide not to save the data. Press the **OK** button to save the data.

You return to the General Information window.

Entering Another Set of Data

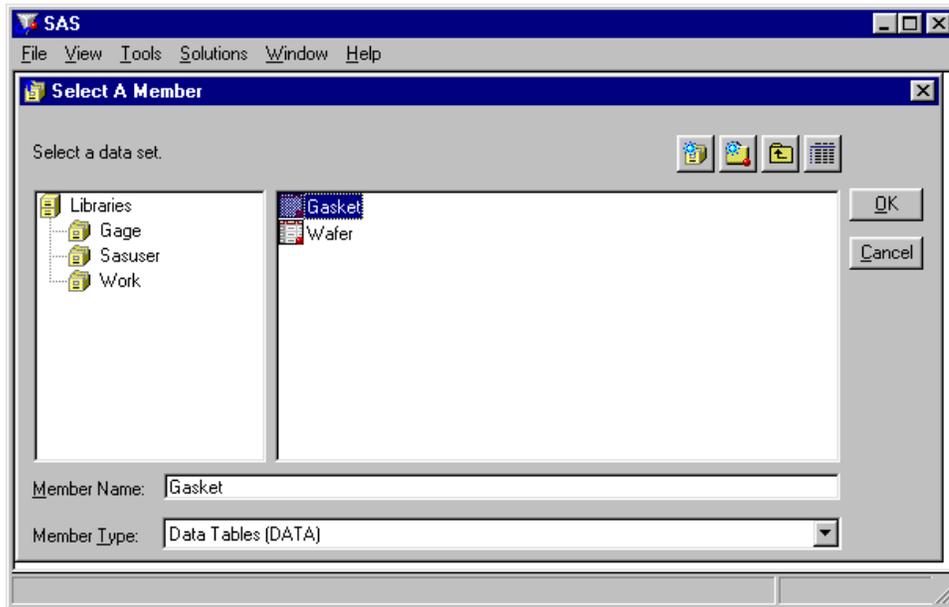

Suppose you have more than one gage study to analyze. You need to clear the current data before entering the new information. You do so by choosing **New** from the **File** menu in the General Information window.

Reading Data from a Data Set

You can save your gage study data in a SAS data set, but how do you bring it back in for further analysis?

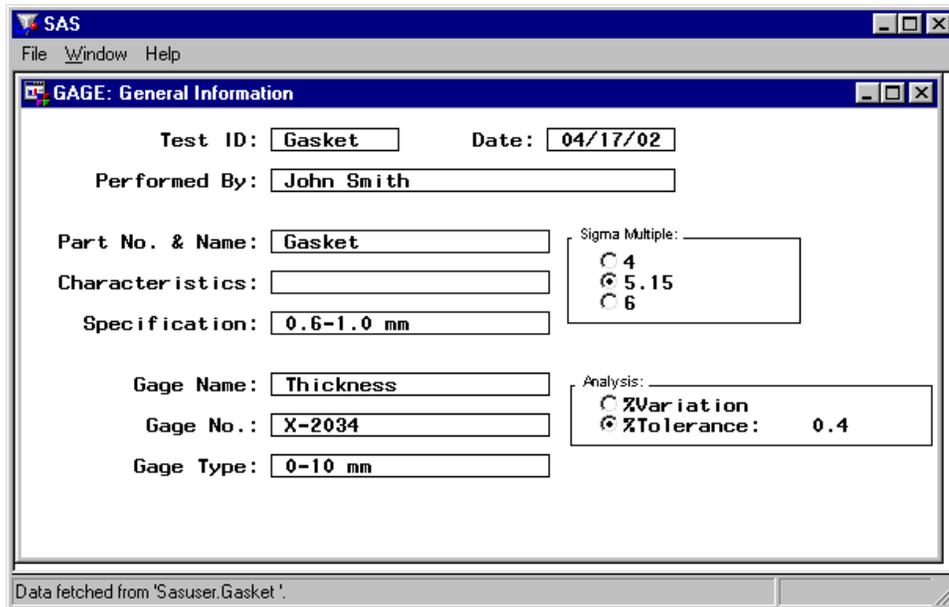

Choose **Open** from the **File** menu in the General Information window to read data into the GAGE application. A directory of available SAS data sets appears, as shown in [Figure A.19](#).

Figure A.19 Selecting a SAS Data Set

Select the data set name from the list. The general information associated with the data is displayed, as shown in Figure A.20.

Figure A.20 Data Read from a SAS Data Set

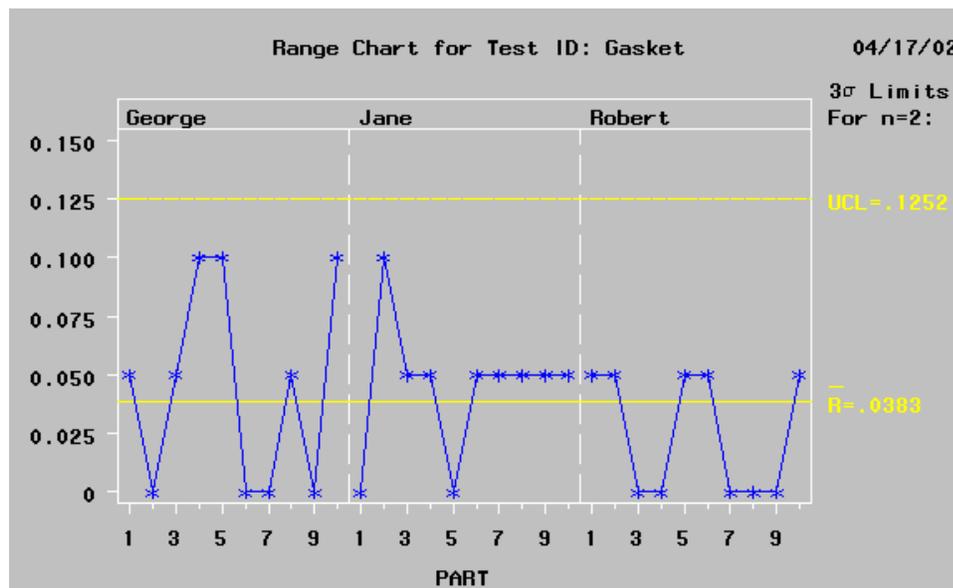

NOTE: The GAGE application reads only SAS data sets that you have previously created using the application.

Details

Range Chart

The range chart is a graphical method for assessing repeatability. It indicates whether the gage variability is consistent. The ranges for each part and each operator are displayed, as shown in Figure A.21.

Figure A.21 Range Chart

For example, in Table A.1 the range for operator George, part 1 is calculated as $0.65 - 0.60 = 0.05$. Similarly computed ranges are displayed for each operator and each part.

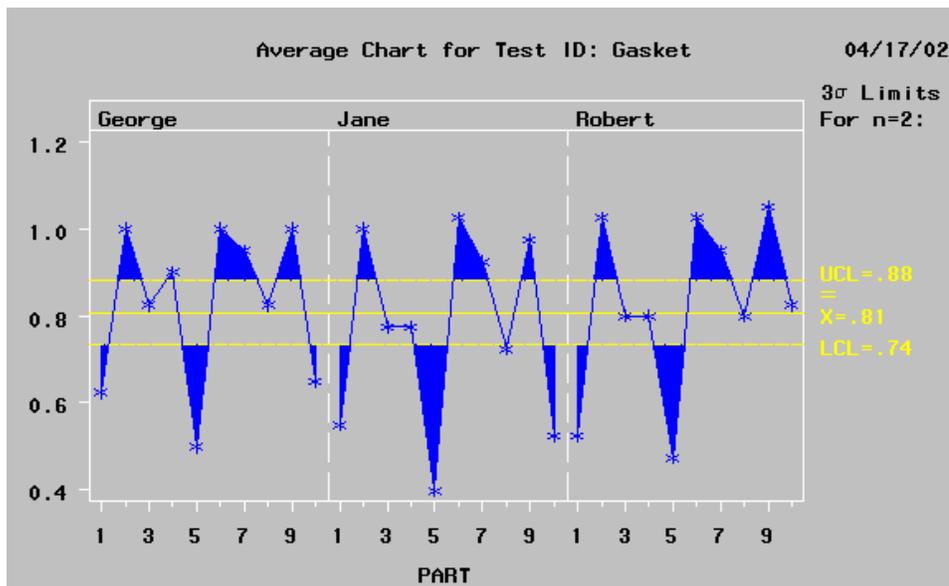

You should investigate out-of-control points and deal with them before proceeding. If you notice that one operator's ranges are out of control, it implies that his technique differs from the others. If all operators have some out-of-control ranges, you might conclude that operator technique is affecting the measurement system and investigate the need for training.

The range chart is created with the RCHART statement of the SHEWHART procedure. For further information, see "RCHART Statement: SHEWHART Procedure" on page 1744.

Average Chart

The average control chart shows both the consistency of operator variability (reproducibility) and part-to-part variation. The averages of the measurements for each part and each operator are displayed, as shown in Figure A.22.

Figure A.22 Average Chart

For example, in Table A.1 the average for operator Jane, part 4 is calculated as $(0.80 + 0.75)/2 = 0.775$. Similarly computed averages are displayed for each operator and each part.

Operator variability can be seen by comparing the operator averages for each part. These averages will differ when there is variation.

The average chart also shows part-to-part differences. The averages should fall outside the control limits since the control limits are based on gage error (repeatability). If the averages do not fall outside the control limits, the part-to-part variation is hidden in the gage variation. The average chart shows the ability of the measurement system to measure parts. The measurement system is generally considered adequate if most of the averages fall outside the limits and if the out-of-control averages tend to be the same for each operator.

Note that this is not a standard use of the Shewhart chart. Ordinarily the fact that the points fall outside the control limits would raise concerns that the process is out of control, but here the opposite conclusion is drawn.

The average chart is created with the XCHART statement of the SHEWHART procedure. For further information, see “XCHART Statement: SHEWHART Procedure” on page 1856.

Average and Range Method

The average and range method is widely used in industry because its calculations can be done by hand. It measures both repeatability and reproducibility for a measurement system.

All calculations described here are based upon a specified multiple of σ , where the multiple ν can be 4, 5.15, or 6. Figure A.23 shows a sample gage report created with the GAGE application using the average and range method.

The measure of repeatability (or equipment variation), denoted by EV , is calculated as

$$EV = \bar{R} \times K_1$$

where \bar{R} is the average range and K_1 is the adjustment factor

$$K_1 = \frac{\nu}{d_2}$$

	MEASUREMENT UNIT ANALYSIS		% PROCESS VARIATION
	Repeatability		
	EV = 0.1747	% EV =	18.70 %
	Reproducibility		
	AV = 0.1570	% AV =	16.80 %
	Gage R&R		
	R&R = 0.2349	% R&R =	25.14 %
	Part Variation		
	PV = 0.9042	% PV =	96.79 %
	Total Variation		
	TV = 0.9342		
Results are based upon predicting 5.15 sigma.			
(99.0% of the area under the normal distribution curve)			

The quantity d_2 (Duncan 1974, Table M) depends on the number of trials used to calculate a single range. In the GAGE application, the number of trials can vary from 2 to 4. Use of d_2 is valid when $\#operators \times \#parts \geq 16$; otherwise, the GAGE application uses d_2^* (Duncan 1974, Table D3), which is based on the number of ranges calculated from $\#operators \times \#parts$ and on the number of trials.

The measure of reproducibility (or appraiser variation), denoted by AV , is calculated as

$$AV = \sqrt{(\bar{X}_{diff} \times K_2)^2 - \frac{(EV)^2}{nr}}$$

where \bar{X}_{diff} is the difference between the maximum operator average and the minimum operator average, K_2 is the adjustment factor

$$K_2 = \frac{v}{d_2^*}$$

n is the number of parts, and r is the number of trials. Reproducibility is contaminated by gage error and is adjusted by subtracting $(EV)^2/nr$. The quantity d_2^* (Duncan 1974, Table D3) depends on the number of operators used to calculate a single range. In the GAGE application, the number of operators can vary from 1 to 4. When there is only one operator, reproducibility is set to zero.

The measure of repeatability and reproducibility, denoted by $R\&R$, is calculated as

$$R\&R = \sqrt{(EV)^2 + (AV)^2}$$

Part-to-part variation, denoted by PV , is calculated as

$$PV = R_p \times K_3$$

where R_p is the range of part averages and K_3 is the adjustment factor

$$K_3 = \frac{v}{d_2^*}$$

Here the quantity d_2^* (Duncan 1974, Table D3) depends on the number of parts used to calculate a single range. In the GAGE application, the number of parts can vary from 2 to 15.

Total variation, denoted by TV , is based on gage R&R and part-to-part variation.

$$TV = \sqrt{(R\&R)^2 + (PV)^2}$$

The measures of repeatability, reproducibility, gage R&R, part variation, and total variation are shown in [Figure A.23](#) under the heading “MEASUREMENT UNIT ANALYSIS.” The right-hand side of the report shows the “% PROCESS VARIATION” analysis, which compares the gage factors to total variation. The percent of total variation accounted for by each factor is calculated as follows:

$$\begin{aligned} \%EV &= 100 \left[\frac{EV}{TV} \right] \\ \%AV &= 100 \left[\frac{AV}{TV} \right] \\ \%R\&R &= 100 \left[\frac{R\&R}{TV} \right] \\ \%PV &= 100 \left[\frac{PV}{TV} \right] \end{aligned}$$

Note that the sum of these percentages does not equal 100%. You can use these percentages to determine whether the measurement system is acceptable for its intended application.

Instead of percent of process variation, your analysis may be based on percent of tolerance. For this you must specify a tolerance value. Then %EV, %AV, %R&R, and %PV are calculated by substituting the tolerance value for TV (the denominator) in the preceding formulas. A sample report with “% TOLERANCE ANALYSIS” is shown in Figure A.24.

What is considered acceptable for %R&R? Barrentine (1991) gives the following guidelines:

10% or less	excellent
11% to 20%	adequate
21% to 30%	marginally acceptable
over 30%	unacceptable

In general, interpretation may be guided by local standards.

Total Variation	
TV = 0.9342	
Results are based upon predicting 5.15 sigma. (99.0% of the area under the normal distribution curve)	

Variance Components Method

As an alternative to the average and range method, you can use the variance components method, which is a more powerful statistical technique for analyzing measurement error and other sources of variation in a gage study. Until recently, this method was underutilized for gage studies because it is computationally more difficult to carry out than the average and range method.

Moreover, the language of variance components analysis is alien to most engineers. To overcome this obstacle, the GAGE report for the variance components method is displayed in the same format as that of the average and range method. This format is a modification of the gage repeatability and reproducibility report given in ASQC Automotive Division/AIAG (1990). [Figure A.25](#) is a sample GAGE report using the variance components method.

As with the average and range method, calculations for the variance components method are based upon a specified multiple of σ , where the multiple ν can be 4, 5.15, or 6.

The advantages of this method versus the average and range method are:

- Variance components are estimated more efficiently in a statistical sense.
- More information can be obtained, such as the interaction between operators and parts (see [Figure A.25](#)).
- There are fewer restrictions on the data.

Figure A.25 Variance Components Method Sample Report

Results are based upon predicting 5.15 sigma. (99.0% of the area under the normal distribution curve)			

The variance components method in the GAGE application uses the MIXED procedure in SAS/STAT[®] software. The MIXED procedure fits mixed linear models, which are a generalization of the standard linear model used in the GLM procedure. Refer to *SAS/STAT User's Guide* for further information on PROC MIXED.

When there is only one operator, PART is a random effect. The MIXED procedure estimates the variance component for PART and for the residual variance (equipment variation) using restricted maximum likelihood (REML).

```
proc mixed;
  class part;
  model meas=;
  random part;
run;
```

When there is more than one operator, there are three random effects: OPERATOR, PART, and OPERATOR*PART. The MIXED procedure uses REML to estimate variance components for these and for the residual variance (equipment variation).

```

proc mixed;
  class operator part;
  model meas=;
  random operator part operator*part;
run;

```

The MIXED procedure creates a table of covariance parameter estimates, including

- σ_{EV}^2 the variance component due to equipment variation
- σ_{AV}^2 the variance component due to operator variation
- σ_{IV}^2 the variance component due to the interaction of operators and parts
- σ_{PV}^2 the variance component due to part variation

From these estimates, repeatability (EV), reproducibility (AV), the interaction of operators and parts (IV), and part variation (PV) are calculated.

$$EV = v \sqrt{\sigma_{EV}^2}$$

$$AV = v \sqrt{\sigma_{AV}^2}$$

$$IV = v \sqrt{\sigma_{IV}^2}$$

$$PV = v \sqrt{\sigma_{PV}^2}$$

When using the variance components method, the measure of gage repeatability and reproducibility has another component, the interaction term.

$$R\&R = \sqrt{(EV)^2 + (AV)^2 + (IV)^2}$$

Total variation is calculated similar to the average and range method.

$$TV = \sqrt{(R\&R)^2 + (PV)^2}$$

The results you get using the variance components method will differ slightly from those you get using the average and range method. This is because the variance components method is more precise, and the variance components method incorporates an interaction term in the measure of gage R&R.

As with the average and range method, the right-hand side of the report can be a percent of process variation or a percent of tolerance. $\%EV$, $\%AV$, $\%IV$, $\%R\&R$, and $\%PV$ are calculated similar to the average and range method.

The variance components method is more flexible than the average and range method in terms of the data that it can handle. Data for the average and range method should be balanced with the same number of parts and trials for each operator in the study. For example, if your study is composed of two operators, two trials, and ten parts, each operator should have 20 measurements. If the

measurement for operator one, trial two, part three is missing, the average and range method cannot compute the gage measures. However, the variance components method can handle such missing data.

The average and range method also requires that a minimum number of parts be collected depending on the number of operators and the number of trials. Otherwise, the estimates will be imprecise. This is another situation where the variance components method can be used.

NOTE: The flexibility of the variance components method does not imply that you should not use locally recommended procedures for setting up and collecting data for gage studies.

Only a subset of the capabilities of PROC MIXED is used in the GAGE application. The procedure is capable of analyzing much more sophisticated statistical models. For example, you could fit an extended model to study the variability among several gages.

Creating a Data Set Outside the GAGE Application

NOTE: This section assumes you have some knowledge of creating SAS data sets.

Suppose your gage study data are stored in an external file, and you want to use the GAGE application but do not want to type in the data. How do you create a SAS data set that can be read by the GAGE application?

Table A.2 lists the SAS variables needed for the general information and the measurements in a GAGE data set.

Table A.2 GAGE Data Set Variables

Description	Variable			
	Name	Type	Length	Values
Test ID	TESTID	character	8	
Date	DATE	numeric	8	
Performed By	WHO	character	30	
Part No. & Name	PART	character	20	
Characteristics	CHAR	character	20	
Specification	SPEC	character	20	
Gage Name	GAGENAME	character	20	
Gage No.	GAGENO	character	20	
Gage Type	GAGETYPE	character	20	
Sigma Multiple	SPREAD	numeric	8	4, 5.15, 6
Analysis	PTYPE	character	1	T, V
Tolerance	TOL	numeric	8	
Operator (condition)	CONDITN	character	8	
Part	SAMPLE	numeric	8	1–15
Trial 1	TRIAL1	numeric	8	
Trial 2	TRIAL2	numeric	8	
Trial 3	TRIAL3	numeric	8	
Trial 4	TRIAL4	numeric	8	

A GAGE data set must have one observation for each combination of values of CONDITN and PART. You can have up to four operators (values of CONDITN), and each must be assigned a unique value. The MMDDYY8. format must be associated with the DATE variable. A PTYPE value of V indicates that you want a percent of process variation analysis. A PTYPE value of T indicates that you want a percent of tolerance analysis. The variable TOL must be assigned a tolerance value when PTYPE = T.

Return to the gasket thickness gage example described in the section “Getting Started” on page 2223. Assume you are using the SAS System under Microsoft Windows, and the gasket thicknesses are stored in the external file `c:\gage\gthick.dat`. A partial listing of the data in `gthick.dat` is as follows:

```
Columns: 0----+----1----+----2----+----3
          George   1   0.65   0.6
          George   2   1.0    1.0
          George   3   0.85   0.8
          George   4   0.85   0.95
          .
          .
          .
          Robert   7   0.95   0.95
          Robert   8   0.8    0.8
          Robert   9   1.05   1.05
          Robert  10  0.85   0.8
```

The following statements read the data into a GAGE SAS data set named SASUSER.GASKET. The LENGTH statement guarantees that each variable is represented in the data set. For the GAGE application to identify the data set as valid, the TYPE and ALTER data set options must be specified as shown.

```
data sasuser.gasket (type=_GRR alter=_GAGE);
  length testid $8 date 8 who $30 part char spec gagename
         gageno gagetype $20 spread 8 ptype $1 tol 8
         conditn $8 sample trial1 trial2 trial3 trial4 8;
  format date mmddyy8.;
  retain testid   'Gasket'          date      '17apr02'd
         who      'John Smith'      part      'Gasket'
         spec     '0.6-1.0 mm'      gagename  'Thickness'
         gageno   'X-2034'          gagetype  '0-10 mm'
         spread   5.15              ptype    'T'
         tol      0.4;
  infile 'c:\gage\gthick.dat';
  input conditn $ 1-8 sample 10-11 trial1 15-18
        trial2 25-28;
run;
```

Figure A.26 is a partial listing of the SAS data set SASUSER.GASKET.

Figure A.26 The SAS Data Set SASUSER.GASKET

Extensibility of the Application

The GAGE application was not designed for any particular industry or company. Because many companies have their own techniques and guidelines for gage studies, the application is designed so that you can tailor it to suit your needs.

The interface to the GAGE application was implemented using FRAME entries in SAS/AF software and the SAS Screen Control Language (SCL). The FRAME entries and SCL source code are available in the gage catalog. FRAME entries provide a flexible environment for building graphical user interfaces. SCL is a programming language that enhances the capabilities of SAS/FSP software and SAS/AF software, including FRAME entries.

For further information on FRAME entries and SCL, refer to *SAS Component Language: Reference* and to *SAS Screen Control Language: Reference*.

Appendix B

The RELIABILITY Graphical Interface

An experimental graphical interface for the RELIABILITY procedure is implemented using FRAME entries in SAS/AF software. The application is available as a SAS/QC sample library program and is stored in the `reliab` catalog. (File extensions for SAS catalogs differ based on the operating system.)

Assume that you are using the SAS System under Microsoft Windows and that the SAS/QC sample library is stored in the `c:\sas\qc\sample` directory. (Check with your SAS site representative for the location of the SAS/QC sample library on your system.) You invoke the RELIABILITY application as follows:

1. First, for SAS 9.3 and later releases, you must enter the following statements to ensure proper operation of the RELIABILITY application:

```
ods graphics off;  
ods html close;  
ods listing;
```

2. Next you must tell the SAS System where the catalog is stored:

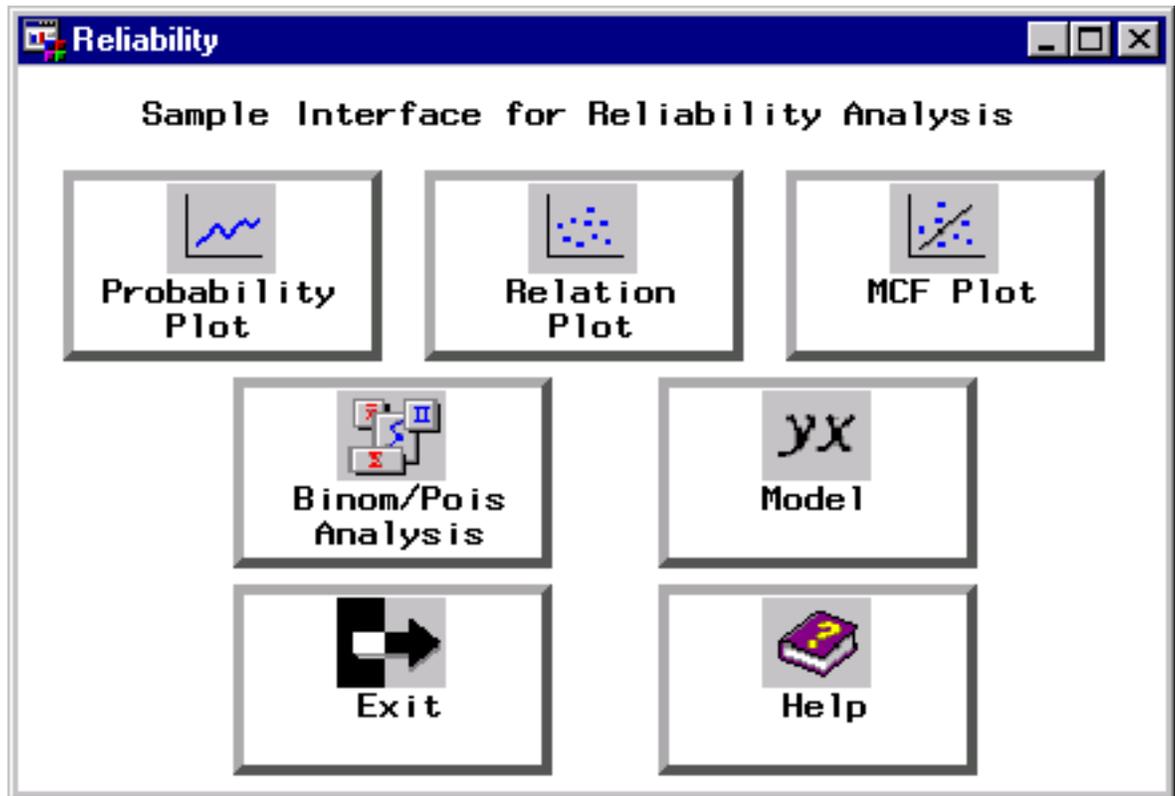

```
libname rel 'c:\sas\qc\sample';
```

3. You then issue the following command from any SAS display manager window:

```
af c=rel.reliab.reliab.frame aws=no
```

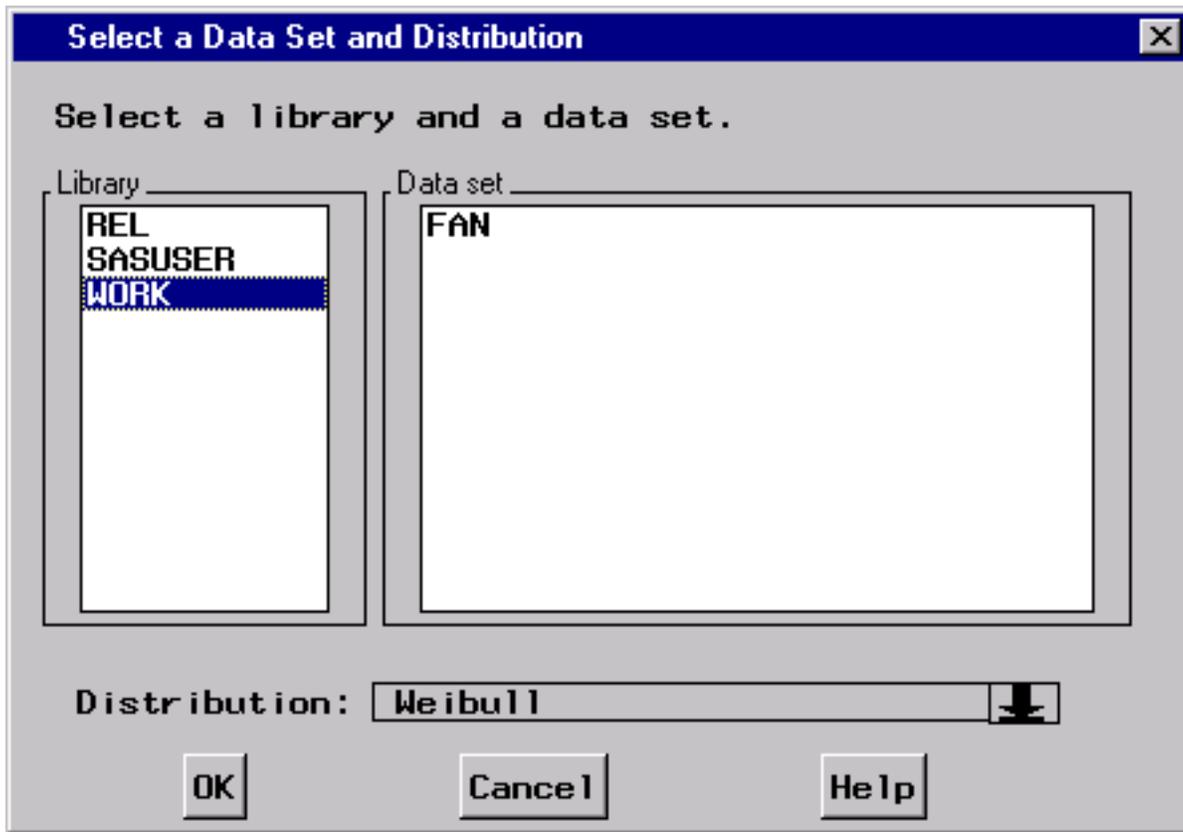

The main application window appears, as shown in [Figure B.1](#). You select a type of analysis from the main window. For example, you can select a probability plot by clicking the Probability Plot button.

Figure B.1 Main Window

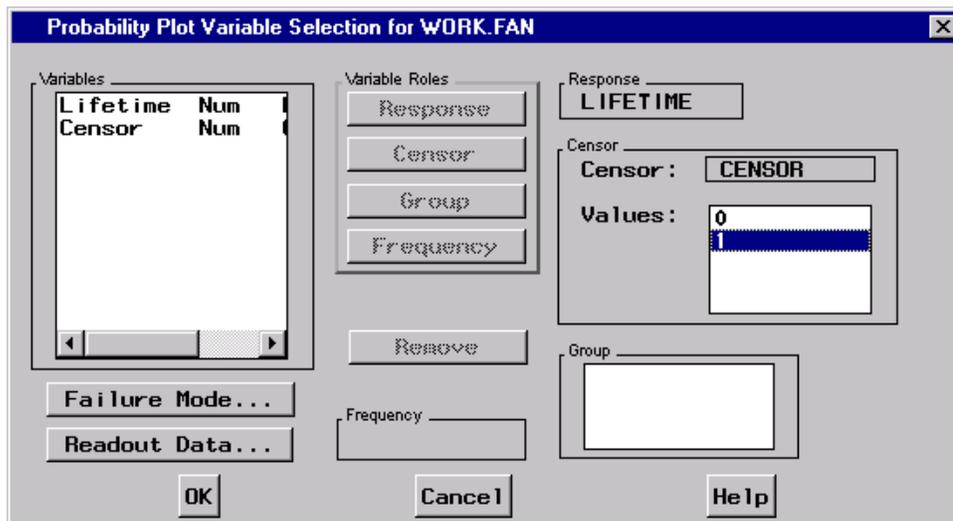

The next window to appear enables you to select the SAS data set that contains your data. You also specify a probability distribution for the probability plot and associated analysis. In Figure B.2, the data set WORK.FAN that contains the data for the engine fan example (see the section “Analysis of Right-Censored Data from a Single Population” on page 1214 in Chapter 16, “The RELIABILITY Procedure,”) is selected, and the Weibull distribution is specified.

Figure B.2 Data Set and Distribution Window

Click the OK button, and the variable selection screen shown in Figure B.3 appears. The variable LIFETIME from the input data set is selected in Figure B.3 as the response variable, and the variable CENSOR is selected as the censoring indicator, with a value of 1 indicating censored lifetimes.

Figure B.3 Variable Selection Window

Clicking the OK button produces the probability plot window shown in Figure B.4. The RESULTS button enables you to view the tabular output from the RELIABILITY procedure.

You can choose procedure options and other analyses by selecting one of the menus at the top of the plot window. For example, you can specify additional plot options by selecting the plot menu, as shown in Figure B.5.

Introduction

SAS/QC software provides specialized DATA step functions for computations related to control chart analysis, for Bayes analysis of screening designs, and for sampling plan evaluation. You can use these functions in DATA step programming statements. The following lists summarize these functions:

Table C.1 Functions for Control Chart Analysis

Function	Description
C4	expected value c_4 of the standard deviation of a sample from a normal population with unit standard deviation
CUSUMARL	average run length for a cumulative sum control chart scheme
D2	expected value d_2 of the range of a sample from a normal population with unit standard deviation
D3	standard deviation d_3 of the range of a sample from a normal population with unit standard deviation
EWMAARL	average run length for an EWMA scheme
PROBMED	cumulative distribution function of sample median
STDMED	standard deviation of median of a standard normal sample

Table C.2 Function for Bayes Analysis of Screening Designs

Function	Description
BAYESACT	posterior probabilities of variance contamination

Table C.3 Functions for Sampling Plan Evaluation

Function	Description
AOQ2	average outgoing quality for double-sampling plan
ASN2	average sample number for double-sampling plan
ATI2	average total inspection for double-sampling plan
PROBACC2	acceptance probability for double-sampling plan

In addition, the PROBBNML and PROBHYPR functions, which are provided in Base SAS software, are useful when evaluating single-sampling plans.

The twelve SAS/QC functions, together with the PROBBNML and PROBHYPR functions, are described in the “[Function Descriptions](#)” section. The section “[Details](#)” on page 2279, summarizes types of sampling plans and gives additional definitions.

Function Descriptions

This section describes the twelve SAS/QC functions and the related functions PROBBNML and PROBHYPR in alphabetical order.

AOQ2 Function

computes average outgoing quality for a double-sampling plan.

Syntax

$AOQ2(replacement, N, a_1, r_1, a_2, n_1, n_2, p)$

where

<i>replacement</i>	has the value ‘REP’ or ‘NOREP’, respectively, depending on whether nonconforming items are replaced with conforming items.
<i>N</i>	is the lot size, where $N \geq 2$.
<i>a</i> ₁	is the acceptance number for the first sample, where $a_1 \geq 0$.
<i>r</i> ₁	is the rejection number for the first sample, where $r_1 > a_1 + 1$.
<i>a</i> ₂	is the acceptance number for the second sample, where $a_2 \geq a_1$.
<i>n</i> ₁	is the size of the first sample, where $n_1 \geq 1$ and $n_1 + n_2 \leq N$.
<i>n</i> ₂	is the size of the second sample, where $n_2 \geq 1$ and $n_1 + n_2 \leq N$.
<i>p</i>	is the proportion of nonconforming items produced by the process, where $0 < p < 1$.

Description

The AOQ2 function returns the average outgoing quality for a Type B double-sampling plan in which nonconforming items are replaced with conforming items (*replacement* is ‘REP’) or not replaced (*replacement* is ‘NOREP’). For details on Type B double-sampling plans, see “Types of Sampling Plans” on page 2279.

For replacement, the average outgoing quality is

$$AOQ = \frac{pP_{a_1}(N - n_1) + pP_{a_2}(N - n_1 - n_2)}{N}$$

and for no replacement, the average outgoing quality is

$$AOQ = \frac{pP_{a_1}(N - n_1)}{N - n_1p} + \frac{pP_{a_2}(N - n_1 - n_2)}{N - n_1p - n_2p}$$

where, in both situations,

$$\begin{aligned}
 P_{a_1} &= \sum_{d=0}^{a_1} f(d|n) \\
 &= \text{probability of acceptance for first sample} \\
 P_{a_2} &= \sum_{d=a_1+1}^{r_1-1} f(d|n_1)F(a_2 - d|n_2) \\
 &= \text{probability of acceptance for second sample}
 \end{aligned}$$

and

$$\begin{aligned}
 f(d|n) &= \binom{n}{d} p^d (1-p)^{n-d} \\
 &= \text{binomial probability that the number of nonconforming items} \\
 &\quad \text{in a sample of size } n \text{ is exactly } d \\
 F(a|n) &= \sum_{d=0}^a f(d|n) \\
 &= \text{probability that the number of nonconforming items is less} \\
 &\quad \text{than or equal to } a
 \end{aligned}$$

Examples

The first set of statements results in a value of 0.0148099904. The second set of statements results in a value of 0.0144743043.

```

data;
  aoq=aoq2('norep',120,0,2,1,13,13,0.18);
put aoq;
run;

```

```

data;
  aoq=aoq2('rep',120,0,2,1,13,13,0.18);
put aoq;
run;

```

ASN2 Function

computes the average sample number for a double-sampling plan.

Syntax

ASN2(*mode*, *a*₁, *r*₁, *a*₂, *n*₁, *n*₂, *p*)

where

<i>mode</i>	identifies whether sampling is under full inspection (<i>mode</i> is 'FULL') or semicurtailed inspection (<i>mode</i> is 'SEMI').
<i>a</i> ₁	is the acceptance number for the first sample, where $a_1 \geq 0$.
<i>r</i> ₁	is the rejection number for the first sample, where $r_1 > a_1 + 1$.
<i>a</i> ₂	is the acceptance number for the second sample, where $a_2 \geq a_1$.
<i>n</i> ₁	is the size of the first sample, where $n_1 \geq 1$.
<i>n</i> ₂	is the size of the second sample, where $n_2 \geq 1$.
<i>p</i>	is the proportion of nonconforming items produced by the process, where $0 < p < 1$.

Description

The ASN2 function returns the average sample number for a Type B double-sampling plan under full inspection (*mode* is 'FULL') or semicurtailed inspection (*mode* is 'SEMI'). For details on Type B double-sampling plans, see “Types of Sampling Plans” on page 2279.

For full inspection, the average sample number is

$$\text{ASN} = n_1 + n_2[F(r_1 - 1|n_1) - F(a_1|n_1)]$$

and for semicurtailed inspection, the average sample number is

$$\text{ASN} = n_1 + \sum_{d=a_1+1}^{r_1-1} f(d|n_1) \left(n_2 F(a_2 - d|n_2) + \frac{r_2 - d}{p} [1 - F(r_2 - d|n_2 + 1)] \right)$$

where

$$\begin{aligned} f(d|n) &= \binom{n}{d} p^d (1-p)^{n-d} \\ &= \text{binomial probability that the number of nonconforming items} \\ &\quad \text{in a sample of size } n \text{ is exactly } d \\ F(a|n) &= \sum_{d=0}^a f(d|n) \\ &= \text{probability that the number of nonconforming items is less} \\ &\quad \text{than or equal to } a \end{aligned}$$

Examples

The first set of statements results in a value of 15.811418112. The second set of statements results in a value of 14.110408695.

```
data;
  asn=asn2('full',0,2,1,13,13,0.18);
  put asn;
run;
```

```
data;
  asn=asn2('semi',0,2,1,13,13,0.18);
  put asn;
run;
```

ATI2 Function

computes the average total inspection for a double-sampling plan.

Syntax

ATI2($N, a_1, r_1, a_2, n_1, n_2, p$)

where

N	is the lot size, where $N \geq 2$.
a_1	is the acceptance number for the first sample, where $a_1 \geq 0$.
r_1	is the rejection number for the first sample, where $r_1 > a_1 + 1$.
a_2	is the acceptance number for the second sample, where $a_2 \geq a_1$.
n_1	is the size of the first sample, where $n_1 \geq 1$ and $n_1 + n_2 \leq N$.
n_2	is the size of the second sample, where $n_2 \geq 1$ and $n_1 + n_2 \leq N$.
p	is the proportion of nonconforming items produced by the process, where $0 < p < 1$.

Description

The ATI2 function returns the average total inspection for a Type B double-sampling plan. For details on Type B double-sampling plans, see “Types of Sampling Plans” on page 2279.

The average total inspection is

$$ATI = n_1 P_{a_1} + (n_1 + n_2) P_{a_2} + N(1 - P_{a_1} - P_{a_2})$$

where

$$\begin{aligned}
 P_{a_1} &= \sum_{d=0}^{a_1} f(d|n) \\
 &= \text{probability of acceptance for first sample} \\
 P_{a_2} &= \sum_{d=a_1+1}^{r_1-1} f(d|n_1) F(a_2 - d|n_2) \\
 &= \text{probability of acceptance for second sample}
 \end{aligned}$$

and

$$\begin{aligned}
 f(d|n) &= \binom{n}{d} p^d (1-p)^{n-d} \\
 &= \text{binomial probability that the number of nonconforming items} \\
 &\quad \text{in a sample of size } n \text{ is exactly } d \\
 F(a|n) &= \sum_{d=0}^a f(d|n) \\
 &= \text{probability that the number of nonconforming items is less} \\
 &\quad \text{than or equal to } a
 \end{aligned}$$

Examples

The following statements result in a value of 110.35046381:

```

data;
  ati=ati2(120,0,2,1,13,13,0.18);
put ati;
run;

```

BAYESACT Call

computes posterior probabilities that observations are contaminated with a larger variance.

Syntax

CALL BAYESACT(*k*, *s*, *df*, $\alpha_1, \dots, \alpha_n$, y_1, \dots, y_n , β_1, \dots, β_n , *p0*);

where

- k* is the contamination coefficient, where $k \geq 1$.
- s* is an independent estimate of σ , where $s \geq 0$.
- df* is the number of degrees of freedom for *s*, where $df \geq 0$.
- α_i is the prior probability of contamination for the *i*th observation in the sample, where $i = 1, \dots, n$ and *n* is the number of observations in the sample. Note that $0 \leq \alpha_i \leq 1$.
- y_i is the *i*th observation in the sample, where $i = 1, \dots, n$ and *n* is the number of observations in the sample. When the BAYESACT call is used to perform a Bayes analysis of designs (see “Description” below), the y_i s are estimates for effects.
- β_i is the variable that contains the returned posterior probability of contamination for the *i*th observation in the sample, where $i = 1, \dots, n$ and *n* is the number of observations in the sample.
- p0* is the variable that contains the posterior probability that the sample is uncontaminated.

Description

The BAYESACT call computes posterior probabilities (β_i) that observations in a sample are *contaminated* with a larger variance than other observations and computes the posterior probability (p_0) that the entire sample is uncontaminated.

Specifically, the BAYESACT call assumes a normal random sample of n independent observations, with a mean of 0 (a centered sample) where some of the observations may have a larger variance than others:

$$\text{Var}(y_i) = \begin{cases} \sigma^2 & \text{with probability } 1 - \alpha_i \\ k^2\sigma^2 & \text{with probability } \alpha_i \end{cases}$$

where $i = 1, \dots, n$. The parameter k is called the *contamination coefficient*. The value of α_i is the *prior probability* of contamination for the i th observation. Based on the prior probability of contamination for each observation, the call gives the posterior probability of contamination for each observation and the posterior probability that the entire sample is uncontaminated.

Box and Meyer (1986) suggest computing posterior probabilities of contamination for the analysis of saturated orthogonal factorial designs. Although these designs give uncorrelated estimates for effects, the significance of effects cannot be tested in an analysis of variance since there are no degrees of freedom for error. Box and Meyer suggest computing posterior probabilities of contamination for the effect estimates. The prior probabilities (α_i) give the likelihood that an effect will be significant, and the contamination coefficient (k) gives a measure of how large the significant effect will be. Box and Meyer recommend using $\alpha = 0.2$ and $k = 10$, implying that about 1 in 5 effects will be about 10 times larger than the remaining effects. To adequately explore posterior probabilities, examine them over a range of values for prior probabilities and a range of contamination coefficients.

If an independent estimate of σ is unavailable (as is the case when the y_i s are effects from a saturated orthogonal design), use 0 for s and df in the BAYESACT call. Otherwise, the call assumes s is proportional to the square root of a χ^2 random variable with df degrees of freedom. For example, if the y_i s are estimated effects from an orthogonal design that is not saturated, then use the BAYESACT call with s equal to the estimated standard error of the estimates and df equal to the degrees of freedom for error.

From Bayes' theorem, the posterior probability that y_i is contaminated is

$$\beta_i(\sigma) = \frac{\alpha_i f(y_i; 0, k^2\sigma^2)}{\alpha_i f(y_i; 0, k^2\sigma^2) + (1 - \alpha_i) f(y_i; 0, \sigma^2)}$$

for a given value of σ , where $f(x; \mu, \sigma)$ is the density of a normal distribution with mean μ and variance σ^2 .

The probability that the sample is uncontaminated is

$$p = \prod_{i=1}^n (1 - \beta_i(\sigma))$$

Posterior probabilities that are independent of σ are derived by integrating $\beta_i(\sigma)$ and p over a noninformative prior for σ . If an estimate of σ is available (when $df > 0$), it is appropriately incorporated. Refer to Box and Meyer (1986) for details.

Examples

The statements

```
data;
  retain post1-post7 postnone;
  call bayesact(10,0,0,
    0.2, 0.2, 0.2, 0.2, 0.2, 0.2, 0.2,
    -5.4375,1.3875,8.2875,0.2625,1.7125,-11.4125,1.5875,
    post1, post2, post3, post4, post5, post6, post7,
    postnone);
run;
```

return the following posterior probabilities:

```
POST1      0.42108
POST2      0.037412
POST3      0.53438
POST4      0.024679
POST5      0.050294
POST6      0.64329
POST7      0.044408
POSTNONE   0.28621
```

The probability that the sample is uncontaminated is 0.28621. A situation where this BAYESACT call would be appropriate is a saturated 2^7 design in 8 runs, where the estimates for main effects are as shown in the function above (-5.4375, 1.3875, . . . , 1.5875).

C4 Function

computes the expected value of the standard deviation of n independent normal random variables.

Syntax

$C4(n)$

where n is the sample size, with $n \geq 2$.

Description

The C4 function returns the expected value of the standard deviation of n independent, normally distributed random variables with the same mean and with standard deviation of 1. This expected value is referred to as the control chart constant c_4 .

The value c_4 is calculated as

$$c_4 = \frac{\Gamma(\frac{n}{2})\sqrt{2/(n-1)}}{\Gamma(\frac{n-1}{2})}$$

where $\Gamma(\cdot)$ is the gamma function. As n grows, c_4 is asymptotically equal to $(4n-4)/(4n-3)$.

For more information, refer to the American Society for Quality Control (1983), the American Society for Testing and Materials (1976), Montgomery (1996), and Wadsworth, Stephens, and Godfrey (1986).

In other chapters, c_4 is written as $c_4(n)$ to emphasize the dependence on n .

You can use the constant c_4 to calculate an unbiased estimate ($\hat{\sigma}$) of the standard deviation σ of a normal distribution from the sample standard deviation of n observations:

$$\hat{\sigma} = (\text{sample standard deviation})/c_4$$

where the sample standard deviation is calculated using $n - 1$ in the denominator. In the SHE-WHART procedure, c_4 is used to calculate control limits for s charts, and it is used in the estimation of the process standard deviation based on subgroup standard deviations.

Examples

The following statements result in a value of 0.939985603:

```
data;
  constant=c4(5);
  put constant;
run;
```

CUSUMARL Function

computes the average run length for a cumulative sum control chart scheme.

Syntax

CUSUMARL(*type*, δ , *h*, *k* <,*headstart*>)

where

- type* indicates a one-sided or two-sided scheme. Valid values are 'ONESIDED' or 'O' for a one-sided scheme, and 'TWO SIDED' or 'T' for a two-sided scheme.
- δ is the shift to be detected, expressed as a multiple of the process standard deviation (σ).
- h* is the decision interval (one-sided scheme) or the vertical distance between the origin and the upper arm of the V-mask (two-sided scheme), each time expressed as a positive value in standard units (a multiple of σ/\sqrt{n} , where n is the subgroup sample size).
- k* is the reference value (one-sided scheme) or the slope of the lower arm of the V-mask (two-sided scheme), each time expressed as a positive value in standard units (a multiple of σ/\sqrt{n} , where n is the subgroup sample size).
- headstart* is the headstart value (optional) expressed in standard units (a multiple of σ/\sqrt{n} , where n is the subgroup sample size). The default *headstart* is zero. For details, refer to Lucas and Crosier (1982).

Description

The CUSUMARL function returns the average run length of one-sided and two-sided cumulative sum schemes with parameters as described above. The notation is consistent with that used in the CUSUM procedure.

For a one-sided scheme, the average run length is calculated using the integral equation method (with 24 Gaussian points) described by Goel and Wu (1971) and Lucas and Crosier (1982).

For a two-sided scheme with no *headstart*, the average run length (ARL) is calculated using the fact that

$$(\text{ARL})^{-1} = (\text{ARL}_+)^{-1} + (\text{ARL}_-)^{-1}$$

where ARL_+ and ARL_- denote the average run lengths of the equivalent one-sided schemes for detecting a shift of the same magnitude in the positive direction and in the negative direction, respectively.

For a two-sided scheme with a nonzero *headstart*, the ARL is calculated by combining average run lengths for one-sided schemes as described in Appendix A.1 of Lucas and Crosier 1982, p. 204.

For a specified shift δ , you can use the CUSUMARL function to design a cusum scheme by first calculating average run lengths for a range of values of h and k and then choosing the combination of h and k that yields a desired average run length.

You can also use the CUSUMARL function to interpolate published tables of average run lengths.

Examples

The following three sets of statements result in the values 4.1500826715, 4.1500836225, and 4.1061588131, respectively.

```
data;
  arl=cusumarl('twosided',2.5,8,0.25);
  put arl;
run;

data;
  arl=cusumarl('onesided',2.5,8,0.25);
  put arl;
run;

data;
  arl=cusumarl('o',2.5,8,0.25,0.1);
  put arl;
run;
```

D2 Function

computes the expected value of the sample range.

Syntax

D2(*n*)

where *n* is the sample size, with $2 \leq n \leq 25$.

Description

The D2 function returns the expected value of the sample range of *n* independent, normally distributed random variables with the same mean and a standard deviation of 1. This expected value is referred to as the control chart constant d_2 . The values returned by the D2 function are accurate to ten decimal places.

The value d_2 can be expressed as

$$d_2 = \int_{-\infty}^{\infty} [1 - (1 - \Phi(x))^n - (\Phi(x))^n] dx$$

where $\Phi(\cdot)$ is the standard normal cumulative distribution function. Refer to Tippett (1925). In other chapters, d_2 is written as $d_2(n)$ to emphasize the dependence on *n*.

In the SHEWHART procedure, d_2 is used to calculate control limits for *r* charts, and it is used in the estimation of the process standard deviation based on subgroup ranges. Also refer to the American Society for Quality Control (1983), the American Society for Testing and Materials (1976), Kume (1985), Montgomery (1996), and Wadsworth, Stephens, and Godfrey (1986).

You can use the constant d_2 to calculate an unbiased estimate ($\hat{\sigma}$) of the standard deviation σ of a normal distribution from the sample range of *n* observations:

$$\hat{\sigma} = (\text{sample range})/d_2$$

Note that the statistical efficiency of this estimate relative to that of the sample standard deviation decreases as *n* increases.

Examples

The following statements result in a value of 2.3259289473:

```
data;
  constant=d2(5);
  put constant;
run;
```

D3 Function

computes the standard deviation of the range of *n* independent normal random variables.

Syntax

D3(*n*)

where *n* is the sample size, with $2 \leq n \leq 25$.

Description

The D3 function returns the standard deviation of the range of *n* independent, normally distributed random variables with the same mean and with unit standard deviation. The standard deviation returned is referred to as the control chart constant d_3 . The values returned by the D3 function are accurate to ten decimal places.

The value d_3 can be expressed as

$$d_3 = \sqrt{2 \int_{-\infty}^{\infty} \int_{-\infty}^y f(x, y) dx dy - d_2^2}$$

where

$$f(x, y) = 1 - (\Phi(y))^n - (1 - \Phi(x))^n + (\Phi(y) - \Phi(x))^n$$

where $\Phi(\cdot)$ is the standard normal cumulative distribution function and d_2 is the expected range. Refer to Tippett (1925).

In other chapters d_3 is written as $d_3(n)$ to emphasize the dependence on *n*.

In the SHEWHART procedure, d_3 is used to calculate control limits for *r* charts, and it is used in the estimation of the process standard deviation based on subgroup ranges.

For more information, refer to the American Society for Quality Control (1983), the American Society for Testing and Materials (1976), Montgomery (1996), and Wadsworth, Stephens, and Godfrey (1986).

You can use the constant d_3 to calculate an unbiased estimate ($\hat{\sigma}$) of the standard deviation σ_R of the range of a sample of *n* normally distributed observations from the sample range of *n* observations:

$$\hat{\sigma}_R = (\text{sample range})(d_3/d_2)$$

You can use the D2 function to calculate d_2 .

Examples

The following statements result in a value of 0.8640819411:

```
data;
  constant=d3(5);
  put constant;
run;
```

EWMAARL Function

computes the average run length for an exponentially weighted moving average.

Syntax

EWMAARL(δ, r, k)

where

- δ is the shift to be detected, expressed as a multiple of the process standard deviation (σ), where $\delta \geq 0$.
- r is the weight factor for the current subgroup mean in the EWMA, where $0 < r \leq 1$. If $r = 1$, the EWMAARL function returns the average run length for a Shewhart chart for means. Refer to Wadsworth, Stephens, and Godfrey (1986). If $r \leq 0.05$, $k \geq 3$, and $\delta < 0.10$, the algorithm used is unstable. However, note that the EWMA behaves like a cusum when $r \rightarrow 0$, and in this case the CUSUMARL function is applicable.
- k is the multiple of σ used to define the control limits, where $k \geq 0$. Typically $k = 3$.

Description

The EWMAARL function computes the average run length for an exponentially weighted moving average (EWMA) scheme using the method of Crowder (1987a, b). The notation used in the preceding list is consistent with that used in the MACONTROL procedure.

For a specified shift δ , you can use the EWMAARL function to design an exponentially weighted moving average scheme by first calculating average run lengths for a range of values of r and k and then choosing the combination of r and k that yields a desired average run length.

Examples

The following statements specify a shift of 1σ , a weight factor of 0.25, and 3σ control limits. The EWMAARL function returns an average run length of 11.154267016.

```
data;
  arl=ewmaarl(1.00,0.25,3.0);
  put arl;
run;
```

PROBACC2 Function

computes the acceptance probability for a double-sampling plan.

Syntax

PROBACC2($a_1, r_1, a_2, n_1, n_2, D, N$)

PROBACC2($a_1, r_1, a_2, n_1, n_2, p$)

where

- a_1 is the acceptance number for the first sample, where $a_1 \geq 0$.
- r_1 is the rejection number for the first sample, where $r_1 > a_1 + 1$.
- a_2 is the acceptance number for the second sample, where $a_2 > a_1$.
- n_1 is the size of the first sample, where $n_1 \geq 1$ and $n_1 + n_2 \leq N$.
- n_2 is the size of the second sample, where $n_2 \geq 1$ and $n_1 + n_2 \leq N$.
- D is the number of nonconforming items in the lot, where $0 \leq D \leq N$.
- N is the lot size, where $N \geq 2$.
- p is the proportion of nonconforming items produced by the process, where $0 < p < 1$.

Description

The PROBACC2 function returns the acceptance probability for a double-sampling plan of Type A if you specify the parameters D and N , and it returns the acceptance probability for a double-sampling plan of Type B if you specify the parameter p . For details on Type A and Type B double-sampling plans, see “Types of Sampling Plans” on page 2279.

For either type of sampling plan, the acceptance probability is calculated as

$$P_{a_1} + P_{a_2}$$

where

$$\begin{aligned}
 P_{a_1} &= \sum_{d=0}^{a_1} f(d|n) \\
 &= \text{probability of acceptance for first sample} \\
 P_{a_2} &= \sum_{d=a_1+1}^{r_1-1} f(d|n_1)F(a_2 - d|n_2) \\
 &= \text{probability of acceptance for second sample}
 \end{aligned}$$

and

$$\begin{aligned}
 f(d|n) &= \binom{n}{d} p^d (1 - p)^{n-d} \\
 &= \text{binomial probability that the number of nonconforming items} \\
 &\quad \text{in a sample of size } n \text{ is exactly } d \\
 F(a|n) &= \sum_{d=0}^a f(d|n) \\
 &= \text{probability that the number of nonconforming items is less} \\
 &\quad \text{than or equal to } a
 \end{aligned}$$

These probabilities are determined from either the hypergeometric distribution (Type A sampling) or the binomial distribution (Type B sampling).

Examples

The first set of statements results in a value of 0.2396723824. The second set of statements results in a value of 0.0921738126.

```
data;
  prob=probacc2(1,4,3,50,100,10,200);
  put prob;
run;
```

```
data;
  prob=probacc2(0,2,1,13,13,0.18);
  put prob;
run;
```

PROBBNML Function

computes the probability that an observation from a binomial(n, p) distribution will be less than or equal to m .

Syntax

PROBBNML(p, n, m)

where

- p is the probability of success for the binomial distribution, where $0 \leq p \leq 1$. In terms of acceptance sampling, p is the probability of selecting a nonconforming item.
- n is the number of independent Bernoulli trials in the binomial distribution, where $n \geq 1$. In terms of acceptance sampling, n is the number of items in the sample.
- m is the number of successes, where $0 \leq m \leq n$. In terms of acceptance sampling, m is the number of nonconforming items.

Description

The PROBBNML function returns the probability that an observation from a binomial distribution (with parameters n and p) is less than or equal to m . To compute the probability that an observation is equal to a given value m , compute the difference of two values for the cumulative binomial distribution.

In terms of acceptance sampling, the function returns the probability of finding m or fewer nonconforming items in a sample of n items, where the probability of a nonconforming item is p . To find the probability that the sample contains exactly m nonconforming items, compute the difference between PROBBNML(p, n, m) and PROBBNML($p, n, m - 1$).

In addition to using the PROBBNML function to return the probability of acceptance, the function can be used in calculations for average sample number, average outgoing quality, and average total inspection in Type B single-sampling. See “Evaluating Single-Sampling Plans” on page 2279 for details.

The PROBBNML function computes

$$\sum_{j=0}^m \binom{n}{j} p^j (1-p)^{n-j}$$

where m , n , and p are defined in the preceding list.

Examples

The following statements compute the probability that an observation from a binomial distribution with $p = 0.05$ and $n = 10$ is less than or equal to 4:

```
data;
  prob=probbnml(0.05,10,4);
  put prob;
run;
```

These statements result in the value 0.9999363102. In terms of acceptance sampling, for a sample of size 10 where the probability of a nonconforming item is 0.05, the probability of finding 4 or fewer nonconforming items is 0.9999363102.

The following statements compute the probability that an observation from a binomial distribution with $p = 0.05$ and $n = 10$ is exactly 4:

```
data;
  p=probbnml(0.05,10,4) - probbnml(0.05,10,3);
  put p;
run;
```

These statements result in the value 0.0009648081.

For additional information on probability functions, refer to *SAS Functions and CALL Routines: Reference*.

PROBHYPYR Function

computes the probability that an observation from a hypergeometric distribution is less than or equal to x .

Syntax

PROBHYPYR($N, K, n, x <, r >$)

where

N	is the population size for a hypergeometric distribution. In terms of acceptance sampling, N is the lot size.
K	is the number of items in the category of interest in the population. In terms of acceptance sampling, K is the number of nonconforming items in a lot.
n	is the sample size for a hypergeometric distribution. In terms of acceptance sampling, n is the sample size.
x	is the number of items from the category of interest in the sample. In terms of acceptance sampling, x is the number of nonconforming items in the sample.
r	is optional and gives the odds ratio for the extended hypergeometric distribution. For the standard hypergeometric distribution, $r = 1$; this value is the default. In acceptance sampling, typically $r = 1$.

Restrictions on items in the syntax are given in the following equations:

$$\begin{aligned}
 1 &\leq N \\
 0 &\leq K \leq N \\
 0 &\leq n \leq N \\
 \max(0, K + n - N) &\leq x \leq \min(K, n) \\
 N, K, n \text{ and } x &\text{ are integers}
 \end{aligned}$$

Description

The PROBHYPR function returns the probability that an observation from an extended hypergeometric distribution with parameters N , K and n and an odds ratio of r is less than or equal to x . The default for r is 1 and leads to the usual hypergeometric distribution.

In terms of acceptance sampling, if $r = 1$, the PROBHYPR function gives the probability of x or fewer nonconforming items in a sample of size n taken from a lot containing N items, K of which are nonconforming, when sampling is done without replacement. Typically $r = 1$ in acceptance sampling.

For example, suppose an urn contains red and white balls, and you are interested in the probability of selecting a white ball. If $r = 1$, the function returns the probability of selecting x white balls when given the population size (number of balls in the urn), sample size (number of balls taken from the urn), and number of white balls in the population (urn).

If, however, the probability of selecting a white ball differs from the probability of selecting a red ball, then $r \neq 1$. Suppose an urn contains one white ball and one red ball, and the probability of choosing the red ball is higher than the probability of choosing the white ball. This might occur if the red ball were larger than the white ball, for example. Given the probabilities of choosing a red ball and a white ball when an urn contains one of each, you calculate r and use the value in the PROBHYPR function. Returning to the case where an urn contains many balls with $r \neq 1$, the function gives the probability of selecting x white balls when given the number of balls in the urn, the number of balls taken from the urn, the number of white balls in the urn, and the relative probability of selecting a white ball or a red ball.

The PROBHYPR function is used to evaluate Type A single-sampling plans. See “[Evaluating Single-Sampling Plans](#)” on page 2279 for details.

If $r = 1$ (the default), the PROBHYPYR function calculates probabilities from the usual hypergeometric distribution:

$$\Pr[X \leq x] = \sum_{i=0}^x P_i$$

where

$$P_i = \begin{cases} \frac{\binom{K}{i} \binom{N-K}{n-i}}{\binom{N}{n}} & \text{if } \max(0, K+n-N) \leq i \leq \min(K, n) \\ 0 & \text{otherwise} \end{cases}$$

The PROBHYPYR function accepts values other than 1 for r , and in these cases, it calculates the probability for the extended hypergeometric distribution:

$$\Pr[X_1 \leq x | X_1 + X_2 = n] = \sum_{i=0}^x P_i$$

where

$$P_i = \begin{cases} \frac{\binom{K}{i} \binom{N-K}{n-i} r^j}{\sum_{j=0}^n \binom{K}{j} \binom{N-K}{n-j} r^j} & \text{if } \max(0, K+n-N) \leq i \leq \min(K, n) \\ 0 & \text{otherwise} \end{cases}$$

where

- X_1 is binomially distributed with parameters K and p_1 .
- X_2 is binomially distributed with parameters $N-K$ and p_2 .
- $q_1 = 1 - p_1$
- $q_2 = 1 - p_2$
- $r = (p_1 q_2) / (p_2 q_1)$

For details on the extended hypergeometric distribution, refer to Johnson and Kotz (1969).

Examples

Suppose you take a sample of size 10 (without replacement) from an urn that contains 200 balls, 50 of which are white. The remaining 150 balls are red. The following statements calculate the probability that your sample contains 2 or fewer white balls:

```

data;
  y=probypr(200,50,10,2);
  put y;
run;

```

These statements result in a value of 0.5236734081. Now, suppose the probability of selecting a red ball does not equal the probability of selecting a white ball. Specifically, suppose the probability of choosing a red ball is $p_2 = 0.4$ and the probability of choosing a white ball is $p_1 = 0.2$. Calculate r as

$$r = \frac{p_1 q_2}{p_2 q_1} = \frac{(0.2)(0.6)}{(0.4)(0.8)} = 0.375$$

With $r = 0.375$, the probability of choosing 2 or fewer white balls from an urn that contains 200 balls, 50 of which are white, is calculated using the following statements:

```

data;
  y=probypr(200,50,10,2,0.375);
  put y;
run;

```

These statements return a value of 0.9053936127. See “Evaluating Single-Sampling Plans” on page 2279 for another example.

For additional information on probability functions, refer to *SAS Functions and CALL Routines: Reference*.

PROBMED Function

computes cumulative probabilities for the sample median.

Syntax

PROBMED(n, x)

where

- n is the sample size.
- x is the point of interest; that is, the PROBMED function calculates the probability that the median is less than or equal to x .

Description

The PROBMED function computes the probability that the sample median is less than or equal to x for a sample of n independent, standard normal random variables (mean 0, variance 1).

Let n represent the sample size and $X_{(i)}$ represent the i th order statistic. Then, when n is odd, the function calculates

$$\Pr[X_{((n+1)/2)} \leq x] = I_{\Phi(x)} \left(\frac{n+1}{2}, \frac{n+1}{2} \right)$$

where

$$I_p(a, b) = \frac{1}{B(a, b)} \int_0^p t^{a-1} (1-t)^{b-1} dt$$

and $B(a, b) = \Gamma(a)\Gamma(b)/\Gamma(a+b)$, where $\Gamma(\cdot)$ is the gamma function. If n is even, the PROBMEDE function calculates

$$\Pr \left[\frac{X_{(n/2)} + X_{((n/2)+1)}}{2} \leq x \right] = \frac{2}{B(\frac{n}{2}, \frac{n}{2})} \int_{-\infty}^x \left\{ [1 - \Phi(u)]^{n/2} - [1 - \Phi(2x - u)]^{n/2} \right\} [\Phi(u)]^{(n/2)-1} \phi(u) du$$

where $B(n/2, n/2) = [\Gamma(n/2)]^2/\Gamma(n)$ and $\Phi(\cdot)$ and $\phi(\cdot)$ are the standard normal cumulative distribution function and density function, respectively.

For more information, refer to David (1981).

Examples

The statements

```
data;
  b=probmed(5, -0.1);
put b;
run;
```

result in a value of 0.4256380897.

STDMED Function

computes the standard deviation of a sample median.

Syntax

STDMED(n)

where n is the sample size.

Description

The STDMED function gives the standard deviation of the median of a normally distributed sample with a mean of 0 and a variance of 1. This function gives the standard error used to determine the width of the control limits for charts produced by the MCHART and MRCHART statements in PROC SHEWHART.

Let n represent the sample size and $X_{(i)}$ represent the i th order statistic. Then, when n is odd, the STD MED function calculates $\sqrt{\text{Var}(X_{((n+1)/2})}$, where

$$\text{Var}(X_{((n+1)/2}) = \frac{1}{B\left(\frac{n+1}{2}, \frac{n+1}{2}\right)} \int_{-\infty}^{\infty} x^2 [\Phi(x)]^{(n-1)/2} [1 - \Phi(x)]^{(n-1)/2} \phi(x) dx$$

where $B(a, b) = \Gamma(a)\Gamma(b)/\Gamma(a + b)$ and $\Gamma(\cdot)$ is the gamma function, $\Phi(\cdot)$ is the standard normal cumulative distribution function, and $\phi(\cdot)$ is the corresponding density function.

If n is even, the function calculates the square root of the following:

$$\begin{aligned} \text{Var} \left[\frac{X_{(n/2)} + X_{((n/2)+1)}}{2} \right] = \\ (1/4) \left[E(X_{(n/2)}^2) + E(X_{((n/2)+1)}^2) + 2E(X_{(n/2)}X_{((n/2)+1)}) \right] \end{aligned}$$

where

$$E(X_{(n/2)}^2) = \frac{2}{B\left(\frac{n}{2}, \frac{n}{2}\right)} \int_{-\infty}^{\infty} x^2 [\Phi(x)]^{(n/2)-1} [1 - \Phi(x)]^{n/2} \phi(x) dx$$

$$E(X_{((n/2)+1)}^2) = \frac{2}{B\left(\frac{n}{2}, \frac{n}{2}\right)} \int_{-\infty}^{\infty} x^2 [\Phi(x)]^{n/2} [1 - \Phi(x)]^{(n/2)-1} \phi(x) dx$$

$$E(X_{(n/2)}X_{((n/2)+1)}) = \frac{n}{B\left(\frac{n}{2}, \frac{n}{2}\right)} \int_{-\infty}^{\infty} \int_{-\infty}^y xy [\Phi(x)]^{(n/2)-1} [1 - \Phi(y)]^{(n/2)-1} \phi(x) \phi(y) dx dy$$

For more details, refer to David (1981), Kendall and Stuart 1977, p. 252, and Sarhan and Greenberg (1962).

Examples

These statements use a loop to calculate the standard deviation of the median for sample sizes from 6 to 12:

```
data;
  do n=6 to 12;
    s=stdmed(n);
    put s;
    output;
  end;
run;
```

The statements produce these values:

0.4634033519
0.4587448763
0.410098592
0.4075552495
0.3719226208
0.3703544701
0.3428063408

Details

Types of Sampling Plans

In single sampling, a random sample of n items is selected from a lot of size N . If the number d of nonconforming (defective) items found in the sample is less than or equal to an acceptance number c , the lot is accepted. Otherwise, the lot is rejected.

In double sampling, a sample of size n_1 is drawn from the lot, and the number d_1 of nonconforming items is counted. If d_1 is less than or equal to an acceptance number a_1 , the lot is accepted, and if d_1 is greater than or equal to a rejection number r_1 , the lot is rejected. Otherwise, if $a_1 < d_1 < r_1$, a second sample of size n_2 is taken, and the number of nonconforming items d_2 is counted. Then if $d_1 + d_2$ is less than or equal to an acceptance number a_2 , the lot is accepted, and if $d_1 + d_2$ is greater than or equal to a rejection number $r_2 = a_2 + 1$, the lot is rejected. This notation follows that of Schilling (1982). Note that some authors, including Montgomery (1996), define the first rejection number using a strict inequality.

In *Type A sampling*, the sample is intended to represent a single, finite-sized lot, and the characteristics of the sampling plan depend on D , the number of nonconforming items in the lot, as well as N , n , and c .

In *Type B sampling*, the sample is intended to represent a series of lots (or the lot size is effectively infinite), and the characteristics of the sampling plan depend on p , the proportion of nonconforming items produced by the process, as well as n and c .

A hypergeometric model is appropriate for Type A sampling, and a binomial model is appropriate for Type B sampling.

Evaluating Single-Sampling Plans

You can use the Base SAS functions PROBBNML and PROBHYPR to evaluate single-sampling plans. Measures of the performance of single-sampling plans include

- the probability of acceptance P_a
- the average sample number ASN
- the average outgoing quality AOQ

- the average total inspection ATI

Probability of Acceptance

Since P_a is the probability of finding c or fewer defectives in the sample, you can calculate the acceptance probability using the function `PROBHYPR(N, D, n, c)` for Type A sampling and the function `PROBBNML(p, n, c)` for Type B sampling.

For example, the following statements calculate P_a for the plan $n = 20, c = 1$ when sampling from a single lot of size $N = 120$ that contains $D = 22$ nonconforming items, resulting in a value of 0.0762970752:

```
data;
  prob=probypr(120,22,20,1);
  put prob;
run;
```

Similarly, the following statements calculate P_a for the plan $n = 20, c = 1$ when sampling from a series of lots for which the proportion of nonconforming items is $p = 0.18$, resulting in a value of 0.1018322793:

```
data;
  prob=probbnml(0.18,20,1);
  put prob;
run;
```

Other Measures of Performance

The measures ASN, AOQ, and ATI are meaningful only for Type B sampling and can be calculated using the `PROBBNML` function. For reference, the following equations are provided.

Average sample number: Following the notation of Schilling (1982), let $F(c|n)$ denote the probability of finding c or fewer nonconforming items in a sample of size n . Note that $F(c|n)$ is equivalent to `PROBBNML(p, n, c)`. Then, depending on the mode of inspection, the average sample number can be expressed as shown in the following table:

Mode of Inspection	ASN
Full	n
Semicurtailed	$nF(c n) + \frac{(c+1)(1-F(c+1 n+1))}{p}$
Fully curtailed	$\frac{(n-c)F(c n+1)}{1-p} + \frac{(c+1)(1-F(c+1 n+1))}{p}$

Average outgoing quality can be expressed as

$$AOQ = \frac{p(N-n)F(c|n)}{N}$$

if the nonconforming items found are replaced with conforming items, and as

$$AOQ = \frac{p(N-n)F(c|n)}{N-np}$$

if the nonconforming items found are not replaced.

Average total inspection can be expressed as

$$ATI = n + (1 - F(c|n))(N - n)$$

Evaluating Double-Sampling Plans

The following list gives some measures for double-sampling plans. The formula for each measure is given in the section describing the corresponding function.

- the probability of acceptance, P_a , calculated with the PROBACC2 function
- the average sample number, ASN, calculated with the ASN2 function
- the average outgoing quality, AOQ, calculated with the AOQ2 function
- the average total inspection, ATI, calculated with the ATI2 function

Deriving Control Chart Constants

You can use the functions D2, D3, and C4 to calculate standard control chart constants that are derived from d_2 , d_3 and c_4 . For reference, the following equations for some of these constants are provided:

$$\begin{aligned} A_2 &= k/(d_2\sqrt{n}) \\ A_3 &= k/(c_4\sqrt{n}) \\ B_3 &= \max(0, 1 - (k/c_4)\sqrt{1 - c_4^2}) \\ B_4 &= 1 + (k/c_4)\sqrt{1 - c_4^2} \\ B_5 &= \max(0, c_4 - k\sqrt{1 - c_4^2}) \\ B_6 &= c_4 + k\sqrt{1 - c_4^2} \\ c_5 &= \sqrt{1 - c_4^2} \\ D_1 &= \max(0, d_2 - kd_3) \\ D_2 &= d_2 + kd_3 \\ D_3 &= \max(0, 1 - kd_3/d_2) \\ D_4 &= 1 + kd_3/d_2 \\ E_2 &= k/d_2 \\ E_3 &= k/c_4 \end{aligned}$$

In the preceding equations, k is the multiple of standard error ($k = 3$ in the case of 3σ limits), and n is the subgroup sample size. The use of these control chart constants is discussed in the American Society for Quality Control (1983), the American Society for Testing and Materials (1976), Montgomery (1996), and Wadsworth, Stephens, and Godfrey (1986).

Although you do not ordinarily need to calculate control chart constants when using the SHEWHART procedure, you may find the D2, D3, and C4 functions useful for creating LIMITS= data sets that contain control limits to be read by the SHEWHART procedure.

Appendix D

Special Fonts in SAS/QC Software

Introduction

Twelve special fonts are provided with SAS/QC software. The SAS/QC procedures use these fonts to display symbols such as \bar{X} and σ , which are commonly encountered in statistical quality improvement applications. The procedure selects the special font that most closely matches the font used to display the other text on the graph. You can also use these fonts to display special symbols in the titles and footnotes of graphs. See the section “[Step 1: Preliminary Mean and Standard Deviation Charts](#)” on page 2128 for an example in which a special font is used to create a title for a control chart.

Font Selection

Each of the four special software fonts matches a particular SAS/GRAPH font, as shown in [Table D.1](#). If you are using a software font for the general text on your graph, choose the special software font corresponding to the SAS/GRAPH font in the table that provides the closest match.

Table D.1 Special Software Fonts

Special Software Font	Matching SAS/GRAPH Font
QCFONT1	SIMPLEX
QCFONT2	DUPLEX
QCFONT3	SWISSE
QCFONT4	SWISS

Eight special TrueType fonts are provided to match a variety of general fonts based on three criteria, as summarized in [Table D.2](#).

Table D.2 Special TrueType Fonts

Serifs	Bold	Italic	Special TrueType Font
no	no	no	Arial Symbol
no	no	yes	Arial Symbol/Italic
