Product Notes

Chapter 1
What’s New in SAS Scalable Performance (SPD) Server 5.2 . . . . . . . 3
What's New in SAS Scalable Performance (SPD) Server 5.2

What's New in SPD Server 5.2?

SAS Scalable Performance Data Server 5.2 on SAS 9.4 offers the following new features and enhancements:

- SPD Server 5.2 can read, write and update tables in the Hadoop environment. SPD Server support for Hadoop is enabled by the SPD Server administrator. Changes to the SPD Server configuration must be made in the SPD Server LIBNAME parameter file and the SPD Server server parameter file. New SPD Server Hadoop options have also been introduced to specify Hadoop operational parameters. Hadoop access is supported only on SPD Server 5.2 running on Linux. For more information about SPD Server and Hadoop, see “Using SPD Server with Hadoop” on page 111.

- SPD Server 5.2 supports WHERE-processing optimization in the Hadoop cluster using MapReduce. SPD Server WHERE processing enables you to conditionally select a subset of observations, so the software processes only the observations that meet specified conditions. To optimize the performance of WHERE processing, you can request that data subsetting be performed in the Hadoop cluster. SPD Server instantiates the WHERE expression as a Java class and submits the Java class to the Hadoop cluster as a component in a MapReduce program. By subsetting the data in the Hadoop cluster, performance might be improved by the filtering and ordering capabilities of the MapReduce framework. For more information, see “Configure SPD Server for Hadoop WHERE Processing Optimization with MapReduce” on page 124.

- When accessing a Hadoop domain, parallel reads are supported without requiring a WHERE clause. For more information, see “SPDSHPRD=” in Chapter 9 of SAS Scalable Performance Data Server: User’s Guide.

- In order to support enterprise computing environments that have existing authentication processes and password management systems, SPD Server 5.2 provides support for performing non-native user authentication via the SAS Metadata Server. When user authentication is requested via the SAS Metadata Server, the back-end server that is specified in the SAS Metadata Server configuration will perform the user authentication.

Performing authentication through the SAS Metadata Server can provide enhanced LDAP support over the LDAP support provided natively by the SPD Server. Using SAS Metadata Server to integrate SPD Server user IDs and passwords with the
framework of the platform’s authentication provider allows the SPD Server administrator to maintain only one set of user IDs and passwords. For more information, see “Configuring SPD Server for SAS Metadata Server Authentication” on page 175.

• The SPD Server PROC SPDO CLUSTER LIST command supports an OUT= option with the SPD Server 5.2 release. The new CLUSTER LIST OUT= option enables you to specify the name of a destination file to be created with the contents of the CLUSTER LIST output.

• The SPD Server PROC SPDO CLUSTER LIST command now enables the SAS ODSDEST= option. The SAS ODSDEST= option configures the default output display system content formatting. This is favorable because the default ODSDEST= setting is HTML, which produces easy-to-read HTML output with embedded style sheets. This makes it easier to read and share CLUSTER LIST results. For more information about the CLUSTER LIST command, see “Querying and Reading Member Tables in a Dynamic Cluster” in Chapter 6 of SAS Scalable Performance Data Server: User’s Guide.

• Additional protection is provided against intrusion from unknown clients. SPD Server processes communicate with one another and clients via TCP/IP sockets. Improvements in TCP/IP socket monitoring allow SPD Server to identify and handle these unknown client requests in a secure and consistent manner.

• SPD Server 5.2 supports the sharing of SPD Server user proxy processes with different credentials in the same SAS session. Sharing proxy processes mitigates some of the resource and performance issues that can occur when redundant proxy processes are created.

Chapter 2
SAS Scalable Performance Data (SPD) Server Pre-Installation and System Requirements Guide

Operating System Requirements and Tuning for 64-Bit SPD Server

SPD Server Operating System Resource Configuration

Operating System Requirements and Tuning for 64-Bit SPD Server

The operating system level requirements for SPD Server 5.1 on a given platform are the same requirements needed for SAS 9.4. For complete information about platform requirements for SAS SPD Server on SAS 9.4, see the information available in Usage Note 42197, via the online SAS Knowledge Base Samples and SAS Notes web page: http://support.sas.com/kb/42/197.html. The technical papers on this page are useful for troubleshooting system performance problems.

Some operating system owners provide white papers that help to tune SAS and SPD server for best results on their platform. For example, IBM provides information at http://www.sas.com/en_us/partners/find-a-partner/alliance-partners/ibm.html#white-papers. You can find a list of SAS Alliance Partners such as IBM here: http://www.sas.com/en_us/partners/find-a-partner.html#alliance-partners.

SPD Server Operating System Resource Configuration

Some systems limit either the number of concurrent processes a user can own at one time. Some systems limit the number of concurrent files a user can have open at one time. If you are using an operating system that enforces one or more of these limits, you should consider the following configuration updates:

Number of Processes per Operating System User ID

SPD Server installation requires eight concurrent processes. Furthermore, each SPD Server user ID creates another process when the SPD Server client connects to the SPD Server host. Therefore, the maximum number of processes that SPD Server requires is the number of concurrent active SPD Server users plus 8.

Number of Open Files per Process

During SPD Server queries, all tables that the query requires are fully opened, including the table metadata file, index files, and data partition files. Therefore, the...
maximum number of open files would be as follows:

\[ \text{SPD Server Max Open Files per Process} = (1 + \text{the maximum number of partitions in a queried SPD Server table}) + (2 \times \text{the maximum number of indexes in a queried SPD Server table}). \]

To calculate the maximum number of open files per process for an SPD Server dynamic cluster, the calculated number of open files per process for a single table is multiplied by the number of members in the dynamic cluster table.

For queries that involve more than one table, the maximum number of open files per process is the sum of the open files for each table (or dynamic cluster member) involved in the query. A general practice for SPD Server resource management is to configure the number of SPD Server open files per process that are available to the user who owns the SPD Server executables to the system maximum value. If SPD Server reaches a system-imposed limit for the number of processes per user, or number of open files per user, the query fails and an error is printed to the SPD Server log.
Chapter 3
Installing SAS Scalable Performance Data (SPD) Server on UNIX

Before You Install: Precautions and Required Permissions
Review the following precautions and required permissions:

- Use a UNIX user ID other than root to run your production SPD Server environment. The UNIX user ID of the SPD Server installation should be the UNIX user ID of the
SPD Server administrator. For more information and a list of options to use when you are configuring SPD Server, see “Notes for SPD Server Administrators” on page 15.

• Install SPD Server in a location that is adequately mirrored and backed up to assure reliability.

• General familiarity with UNIX is required to install SPD Server. At a minimum, you should be familiar with basic UNIX shell entities (such as sh, csh, and ksh), Bourne shell scripts, and modifying files using a UNIX text editor.

• To create the installation directory for SPD Server, you need appropriate access permissions on the file system on which you install the server software. The owner of the SPD Server installation directory should be the UNIX user ID of the SPD Server administrator.

• If you want SPD Server clients to connect to the SPD Server host using name services instead of specifying port numbers at invocation, you need Write access to your server machine's /etc/inet/services or /etc/services file. Name services require you to define registered ports that use the services file appropriate to your machine.

• If your SPD Server clients access the SPD Server host using name services instead of specifying port numbers, you need Write access to the services files on the clients, in the path /etc/services or /etc/inet/services.

---

SPD Server UNIX Installation Packing List

Directory names in the packing list are subdirectories of your SPD Server host installation directory, whose path is represented by InstallDir/.

Note: InstallDir/ represents the root directory in which SPD Server is installed.

The InstallDir/bin/ subdirectory contains the SAS SPD Server executable files.

The InstallDir/lib/ subdirectory contains libraries that facilitate third-party access to SPD Server (other than via the SAS SPD Server LIBNAME engine).

The InstallDir/samples/ directory contains sample start-up scripts and SAS programs that provide example uses of SPD Server.

The InstallDir/site/ directory is a storage directory for a user's site-specific customization of the sample SPD Server start-up and configuration files. The spdsclen clean utility script is located in the InstallDir/site/ directory of your SPD Server 5.2 installation.

---

SPD Server Quick UNIX Installation Guide

This section outlines a quick installation of SPD Server to validate and test your installation.

Follow the instructions on your SAS software order. Use SAS Download Manager to download your order, and then use SAS Deployment Wizard to install your order.

While in SAS Deployment Wizard, be sure to select the SAS Scalable Performance Data Server product for installation. You also need to include the SAS Scalable Performance
Data Client, the SAS Management Console, and the SAS Scalable Performance Data Server Plug-in for SAS Management Console in your product install selection.

Configuring SPD Server Host Software for Your Site

During installation of SAS Scalable Performance Data Server, you will be prompted to configure the SPD Server connection port, as well as the SPD Server SNET server connection port. The SPD Server Data server connection port connects the SPD Server LIBNAME client engine to the SPD Server Data server. The SPD Server SNET connection connects a JDBC client to the SPD Server SNET server. You use the SPD Server data port to make connections from the SAS SPD Server LIBNAME engine to the SPD Server host, as well as to the SPD Server SNET server port. The SPD Server SNET server port is required in order to connect to SPD Server from a JDBC client.

The default SPD Server port assignments are 5400 and 5401. You can change the default port assignments to port numbers that are available on your system. If you are running within a firewall, see “How do I know which ports must be surfaced through an Internet firewall?” in Appendix 2 of SAS Scalable Performance Data Server: User’s Guide or see “Using SAS Scalable Performance Data (SPD) Server with an Internet Firewall” on page 195 for more detailed information.

Completing the Quick Start Configuration

After you install SPD Server, navigate to the /site subdirectory (relative to the directory where you installed SPD Server), and do the following to complete the quick installation of your server:

1. Verify that the WORKPATH statement in your spdsserv.parm file is valid. If the WORKPATH statement is incorrect, edit your spdsserv.parm file.
2. Verify that the pathname for libname=tmp in the libnames.parm file is valid. If the pathname is not correct, edit the libnames.parm file.
3. Initialize the SPD Server Password Manager Database by invoking the pwdb script by doing the following:
   a. At the Enter command> prompt, enter groupdef.
   b. At the Enter group name to define> prompt, enter admingrp.
   c. At the Enter command> prompt, enter add to add yourself as an administrator.
   d. Choose a user name of up to eight alphanumeric characters, and choose a temporary password of six to eight alphanumeric characters that uses at least one numeral.
   e. Assign yourself an authorization level of 7 for maximum permissions, and then assign yourself to the admingrp group. Press Enter to use default settings for the remaining prompts.
   f. To change your password to a permanent password, enter chgpass at the command> prompt and follow the instructions.
   g. To exit the password manager utility, enter quit at the Enter command> prompt.
4. Start SPD Server by executing the rc.spds script. Use the UNIX `ps` command to verify that SPD Server is running.

   If SPD Server is running, you should see the following processes:
   
   - `spdsserv`
   - `spdsbase`
   - `spdssnet`
   - `spdsnsrv`

   You should also see several spdslog processes.

   If SPD Server is not running, review the SPD Server log at `InstallDir/log/spdsserv*spdslog` for any errors.

   After you correct any start-up errors, end all running SPD Server processes, and then restart the software by using the `rc.spds` script.

---

### Testing the SPD Server Quickstart Installation

Use SAS to connect to SPD Server and to verify your installation.

In the SAS Program Editor, submit and run the following code:

```sas
%let spdshost=<hostname where SPD Server is running>;
%let spdsport=<your SPD Data Server port>;

libname test sasspds 'tmp'
    host="&spdshost"
    serv="&spdsport"
    user="anonymous";

libname testrl sasspds 'tmp'
    host="&spdshost"
    serv="&spdsport"
    user="anonymous"
    locking=yes;

/* include "Installdir"/samples/verify.sas" */
/* to verify dataset access to SPD Server.*/
%inc "Installdir"/samples/verify.sas"

/* include "Installdir"/samples/verptsql.sas */
/* to verify SQL access to SPD Server. */
%inc "Installdir"/samples/verptsql.sas";
endsdas;
```
Potential Problems with Test Verification

Your LIBNAME statement to SPD server can fail with the following errors.

ERROR: The SASSPDS Engine cannot be found
This error indicates that your SAS installation did not include the SAS Scalable Performance Data Server client. Review your SAS installation.

ERROR: Unable to connect to SPD Name Server
This error indicates that SAS SPD Server is not running, or that your SPDSHOST and SPDSPORT connection variable settings are not correctly configured. Verify your connection variables and ensure that your SPD Server is running on the specified host using the specified port.

ERROR: Protocol version mismatch. Proxy version is 5.1 while engine version is <version-number>
This error indicates that you are trying to connect to an SPD Server host with an old client. For SPD Server 5.1, verify that you are running SAS 9.4 with the SAS Scalable Performance Data Server client.

Customizing Your SPD Server Installation

After you complete the SPD Server quick start, you can customize the installation for your site. Shut down SPD Server by using the `Installdir/site/killrc` script to begin updating your installation.

Logging

The `rc.spds` script assumes that you want to keep the logs from messages that are written to STDOUT or STDERR of the `spdsnsrv` (SPD Server name server) and `spdsserv` (SPD Server host) processes. The `rc.spds` script variable LOGDIR= defines the directory where these logs are stored.

If you do not want to keep these logs, change the value for LOGDIR=, and the `rc.spds` script uses `/dev/null`. If you want to keep the logs in another location besides "InstallDir"/log, change the value of LOGDIR=.

SPD Server log files can grow very large if there is considerable activity. The log files can be configured to recycle at a given time each day and start a new logfile. The older log files can then be removed or archived.

The DSRVFILE= and DSRVTIME= spdsserv options, NSRVFILE= and NSRVTIME= spdsnsrv options, and SNSFILE= and SNSTIME= spdssnet options have the following default values in the `rc.spds` script to define the log name and recycle time:

DSRVFILE=spdsserv
specifies the spdsserv process log file prefix

DSRVTIME=00:00
specifies a recycle time of midnight

NSRVFILE=spdsnsrv
specifies the spdsnsrv process log file prefix
NSRVTIME=00:00
    specifies a recycle time of midnight
SNSFILE=spdsnet
    specifies the prefix of the spdssnet process log file
SNSTIME=00:00
    specifies the time of midnight

If you want SPD Server to disable automatic log filename generation and cycling, change those settings to empty pointers.

Audit File Facility

The `rc.spds` script enables you to use the SPD Server audit file facility. The audit file facility is not enabled by default. Use the following script variables to configure the SPD Server audit file facility:

```plaintext
AUDDIR=
    specifies the directory for the audit log files
AUDFILE=
    specifies the prefix for audit log files
AUDFILESQL=
    specifies the prefix for SQL audit log files
AUDTIME=
    specifies the time of day (HH:MM) to cycle the audit log file.
```

*Note:* When AUDDIR= and AUDFILE= are set, proxy audit file creation is enabled. When AUDDIR= and AUDFILESQL= are set, SQL audit file creation is enabled. If AUDTIME= is set, automatic audit file cycling occurs at the specified time of day.

For more information about SPD Server auditing, see “SAS Scalable Performance Data (SPD) Server Auditing” on page 199.

User Password and Parameter Files

The `rc.spds` script assumes that you keep your spdsserv.parm parameter file and your SPD Server user password file in the `"InstallDir"/site` directory. If you do not keep the files in this location, you need to change your ACLDIR= and PARMDIR= assignments.

Accessing SPD Server through a Registered Port

If you want to access SPD Server through a registered port (name service), add the following service to your `/etc/inet/services` or `/etc/services` file (if this service is not already present):

```
spdsname 5400/tcp # SPDS Name Service
```

This service defines the port number for the SPD Server name server process. Make sure that this port number matches the port number that you used when you installed SPD Server. If you are running SAS on an existing SPD Server installation, this service name is probably already defined. You can either define another service name for the SAS client to use (for example, `sp45name`), or you can directly include the SPD Server port number in your SAS statements.
**SPD SNET Server**

The `rc.spds` script assumes that you want the spdssnet process running for clients that are accessing SPD Server data via a JDBC client. If you do not support this access, use the `-nosnet` option with the `rc.spds` script to disable start-up of the SPD SNET server.

**Adding Users to the SPD Server psmgr Database**

See the section Chapter 17, “Managing SAS Scalable Performance Data (SPD) Server Passwords and Users,” on page 172 for more information about adding users to the SPD Server psmgr database.

**Authenticating SPD Server User Passwords**

SPD Server user passwords can be authenticated by the SPD Server psmgr utility, or by an LDAP server (such as Microsoft Active Directory, Sun Java System Directory Server, or OpenLDAP).

LDAP authentication integrates with the SPD Server password facility and provides a centralized approach to user ID and password management. SPD Server clients that use LDAP authentication should have user accounts that are managed by the authenticating LDAP server. The user ID and password information must be stored on an LDAP server that the SPD Server can access. The user ID must be entered into the SPD Server password database through the psmgr utility or via the SAS Management Console utility. These user ID requirements exist in order to ensure that all SPD Server user information is recorded and properly propagated.

When a client uses LDAP authentication to connect to SPD Server, the LDAP server that is configured in the SPD Server's parameter file performs the authentication. After the client is verified, SPD Server uses the client's password database record for all other SPD Server operations.

For more information about SPD Server LDAP authentication, see “Overview of LDAP Authentication” on page 177.

**Customizing SPD Server Configuration**

To customize configuration of the "Installdir/site/spdsserv.parm" parameter file and the "Installdir/site/libnames.parm" LIBNAME file for your installation, see Part 4, Chapters 6–13, in SAS Scalable Performance Data Server: Administrator’s Guide.

---

**Notes for SPD Server Administrators**

The SPD Server administrator performs the maintenance and configuration functions for SPD Server. The following sections contain guidelines for administrators.

**UNIX User IDs**

The SPD Server administrator requires a UNIX login ID on the machine where SPD Server will be installed and administered. Other SPD Server users do not need UNIX
login IDs. Other users’ access to SPD Server data resources is controlled via SPD Server user IDs via the SPD Server password facility.

Administrate your SPD Server environment by using the same UNIX user ID that was used to install SPD Server on the host machine. The user ID should also be the SPD Server administrator's user ID. The common user ID minimizes potential problems with file ownership and system access permissions on the server machine. You add SPD Server access controls to the resources that were created with SPD Server by using SPD Server user IDs and SPD Server ACLs. The SPD Server user IDs and ACLs provide fine-grained access controls for SPD Server data resources.

Regardless of how the SPD Server run-time environment is configured, SPD Server processes always run using the UNIX user ID that started the SPD Server session. That UNIX user ID owns all of the files that the SPD Server process creates. The UNIX user ID is governed by UNIX file access permissions. Remember this when you start SPD Server processes and run SPD Server administrator utilities. Otherwise, it is possible to create files that have ownership and permissions that deny access to required SPD Server processes. If you perform all SPD Server installation and administration tasks from the same UNIX user ID, subsequent use of SPD Server is much easier.

SPD Server User IDs

The SPD Server administrator needs to be familiar with the SPD Server psmgr utility. The SPD Server system uses its own layer of access controls that overlay UNIX access permissions. SPD Server processes run in the context of a UNIX user ID, and that user owns all of the resulting SPD Server file resources that are created.

Each SPD User is given their own SPD Server user ID and password. The user ID and password are needed to complete the LIBNAME connection to SPD Server. All resources that a user creates are owned by the user. An SPD Server user can access only resources that that user created, or resources that another SPD Server user grants them access to via SPD ACLs. There also exists an "anonymous" user account that any SPD Server user can access with no password, and where all resources that are created by the anonymous user are accessible to any other SPD Server user.

Troubleshooting

Key information for SPD Server troubleshooting can be found in the SPD Server name server log and in the SPD Server host process log files. Those two log files enable you to reconstruct SAS interactions with SPD Server components. Entries in the log files are time-stamped for reference. You should be able to correlate activities between the two logs by using the time-stamp information. The logs are formatted as plain text files.

Name Server Start-Up Failed

Check the name server log file. The log should contain information about the problem. Some common things to look for include:

- The -LICENSEFILE file specification is not valid
- -LICENSEFILE specifies a file with invalid contents.
- The name server port is in use by another process.

Determine whether another name server process is already running on the same node by issuing the following command:
ps -ef | grep i spdsnsrv

**SPD Server Host Start-Up Failed**

Check the SPD Server host log file for information. Some common things to look for include:

- The -NAMESERVER node name is incorrect.
- -NAMESERVERPORT specifies the wrong port number if the SPD Server name server is running with a nonstandard port assignment.
- The -PARMFILE file specification is invalid, or the specified file does not exist.
- The -LIBNAMEFILE file specification is invalid, or the specified file does not exist.
- The contents of the specified -LIBNAMEFILE does not conform to expected syntax. Check the SPD Server host log file for messages about invalid entries.
- The -ACLDIR option was omitted from the command line.
- The -ACLDIR option specifies an invalid directory path for the SPD Server password file, or the specified directory path does not contain a valid SPD Server password file.

**SAS LIBNAME Assignment Failed**

If the SAS LIBNAME assignment fails, first check the error messages from the SPD Server LIBNAME engine through the SAS log output. In most circumstances, you can diagnose the reason for the failure from these messages. Some common problems include:

**ERROR:** The SASSPDS engine cannot be found.
   This error indicates your SAS installation did not include the SAS Scalable Performance Data Server client. Review your SAS installation.

**ERROR:** Unable to connect to SPD Name Server.
   This error indicates that SAS SPD Server is not running, or your LIBNAME HOST= or SERV= values are not correct. Verify your LIBNAME statement and that SPD Server is running on the correct host with the correct port.

**ERROR:** Protocol version mismatch. Proxy version is 5.1 while engine version is <version>.
   This error indicates you are trying to connect to SPD Server with an old client. Verify that you are running SAS 9.4 with the SAS Scalable Performance Data Server client.

**ERROR:** SPD Server has rejected login from user <username>
   This error indicates you are trying to connect to SPD Server with an invalid user ID or password. Verify your LIBNAME statement.

---

**Renewing Your SPD Server License**

When you receive SPD Server, licensing information is pre-initialized. When you renew the license, you receive a new license to replace your existing license. You must restart SPD Server to use the new license. You must edit your `rc.spds` LICFILE= variable name so that it reads the name of the new license file.
Upgrading and Reinstalling SPD Server

If you need to reinstall SPD Server, or if you install a newer release of SPD Server, the installation process does not alter any files that have been modified in the "InstallDir/site" directory. Any custom modifications that were made to installation files are retained when you upgrade SPD Server to a subsequent release.
Before You Install: Precautions and Required Permissions

Review the following precautions and required permissions:

- If you want SPD Server clients to connect to the SPD Server host using name services instead of specifying port numbers at invocation, you need Write access to
your server machine's \etc\services directory. Name services require you to define registered ports that use the services file appropriate to your machine.

- If your SPD Server clients access the SPD Server host by using name services instead of by specifying port numbers, you need write access to the services files on the clients, in the path \etc\services.

### SPD Server Windows Installation Packing List

Directory names in the packing list are subdirectories of your SPD Server host installation directory, whose path is represented by InstallDir\

*Note:* InstallDir\ represents the root directory in which SPD Server is installed.

The InstallDir\bin\ subdirectory contains the SAS SPD Server executable files.

The InstallDir\lib\ subdirectory contains libraries that facilitate third-party access to SPD Server (other than via the SAS SPD Server LIBNAME engine).

The InstallDir\samples\ directory contains sample start-up scripts and SAS programs that provide example uses of SPD Server.

The InstallDir\site\ directory is a storage directory for a user's site-specific customization of the sample SPD Server start-up and configuration files. No SPD Server files are delivered in this directory; it is for customer use only.

### SPD Server Quick Windows Installation Guide

This section outlines a quick installation of SPD Server to validate and test your installation.

Follow the instructions on your SAS software order. Use SAS Download Manager to download your order, and then use SAS Deployment Wizard to install your order.

While in SAS Deployment Wizard, be sure to select the SAS Scalable Performance Data Server product for installation. You also need to include the SAS Scalable Performance Data Client, the SAS Management Console, and the SAS Scalable Performance Data Server Plug-in for SAS Management Console in your product installation selection.

### Configuring SPD Server Host Software for Your Site

During installation of SAS Scalable Performance Data Server, you will be prompted to configure the SPD Server connection port, as well as the SPD Server SNET server connection port. The SPD Server Data server connection port connects the SPD Server LIBNAME client engine to the SPD Server Data server. The SPD Server SNET connection connects a JDBC client to the SPD Server SNET server. You use the SPD Server data port to make connections from the SAS SPD Server LIBNAME engine to the SPD Server host, as well as to the SPD Server SNET server port. The SPD Server SNET server port is required in order to connect to SPD Server from a JDBC client.
The default SPD Server port assignments are 5400 and 5401. You can change the default port assignments to port numbers that are available on your system. If you are running within a firewall, see “How do I know which ports must be surfaced through an Internet firewall?” in Appendix 2 of SAS Scalable Performance Data Server: User’s Guide or see “Using SAS Scalable Performance Data (SPD) Server with an Internet Firewall” on page 195 for more detailed information.

Completing the Quick Start Configuration

After you install SPD Server, navigate to the \site subdirectory (relative to the directory where you installed SPD Server), and do the following to complete the quick installation of your server:

1. Verify that the WORKPATH statement in your spdsserv.parm file is valid. If the WORKPATH statement is incorrect, edit your spdsserv.parm file.
2. Verify that the pathname for libname=tmp in the libnames.parm file is valid. If the pathname is not correct, edit the libnames.parm file.
3. Initialize the SPD Server Password Manager Database:
   a. Click the Windows Start button and select All Programs ⇒ SAS ⇒ SAS SPD Server 5.1 ⇒ Account Manager. The SPD Server Account Manager is launched in a command window.
   b. At the Enter command> prompt, enter groupdef.
   c. At the Enter group name to define> prompt, enter admingrp.
   d. To add yourself as an administrator, enter add at the Enter command> prompt.
   e. Choose a user name of up to eight alphanumeric characters, and choose a temporary password of six to eight alphanumeric characters that uses at least one numeral.
   f. Assign yourself an authorization level of 7 for maximum permissions, and then assign yourself to the admingrp group. Press Enter to use default settings for the remaining prompts.
   g. To change your password to a permanent password, enter chgpass at the command> prompt and follow the instructions.
   h. To exit the password manager utility, enter quit at the Enter command> prompt.
4. Start the SPD Server name server. Click the Windows Start button and select All Programs ⇒ SAS ⇒ SAS SPD 5.1 Name Server.
5. Start the SPD Server data server. Click the Windows Start button and select All Programs ⇒ SAS ⇒ SAS SPD 5.1 Data Server.
6. Use the Windows Task Manager to verify that SPD Server is running. You should see the following processes running:
   • spdsserv
   • spdsbase
   • spdsnssrv
   If SPD Server is not running, review the SPD Server log at InstallDir\log \spdsserv*spdslog for any errors.
After you correct any start-up errors, end all running SPD Server processes, and then restart your server.

---

## Testing the SPD Server Quickstart Installation

Use SAS to connect to SPD Server and to verify your installation.

In the SAS Program Editor, submit and run the following:

```sas
%let spdshost=<hostname where SPD Server is running>;
%let spdsport=<your SPD Data Server port>;

libname test sasspds 'tmp'
  host="&spdshost"
  serv="&spdsport"
  user="anonymous";

libname testrl sasspds 'tmp'
  host="&spdshost"
  serv="&spdsport"
  user="anonymous"
  locking=yes;

/* Submit the LIBNAME statements */

/* Open the program verify.sas */
/* from InstallDir\samples\ dir */
/* and submit it to verify data */
/* set access to SPD Server. */

/* Open the program verptsql.sas */
/* from InstallDir\samples\ dir */
/* and submit it to verify SQL */
/* access to SPD Server. */

```

---

## Potential Problems with Test Verification

Your LIBNAME statement to SPD server can fail with the following errors:

**ERROR: The SASSPDS Engine cannot be found**

This error indicates that your SAS installation did not include the SAS Scalable Performance Data Server client. Review your SAS installation.

**ERROR: Unable to connect to SPD Name Server**

This error indicates that SAS SPD Server is not running, or that your SPDSHOST and SPDSPORT connection variable settings are not correctly configured. Verify your connection variables and ensure that your SPD Server is running on the specified host using the specified port.
Customizing Your SPD Server Installation

After you complete the SPD Server quick start, you can customize the installation for your site. Shut down SPD Server using the Windows Task Manager.

Logging

The `InstallDir\site\*.bat` files for the spdsnsrv, spdsserv, and spdssnet assume that you want to keep the logs from messages that are written to STDOUT or STDERR by the SPD Server name server (spdsnsrv), the SPD Server host (spdsserv), or the SPD Server SNET server (spdssnet). These processes are logged to the `InstallDir\log\` directory.

SPD Server log files can grow very large if there is considerable activity. The log files can be configured to recycle at a given time each day and start a new log file. The older log files can then be removed or archived.

To alter the name, location, or cycle time to generate a new logfile, modify the following start-up parameters for the spdsserv, spdsnsrv, or spdssnet processes in their respective batch files:

- `logfile fileSpec`
  specifies that the logger process automatically creates a server log file. fileSpec specifies a partial pathname or filename specification that is used to generate the complete log file path.

  For example, if you specify fileSpec as `c:\logs\spdsnsrv`, the name `c:\logs\spdsnsrv_mmddyyyy_hh:mm:ss.spdslog` is generated. The values `mmddyyyy` and `hh:mm:ss` indicate the time at which the system created the log file.

- `logtime hh:mm`
  specifies the time of day at which to cycle a new generation of the name server log file. At this time each day, the previous log file is closed and a new log file is opened. For example, `-logtime 00:00` cycles the log at midnight.

Audit File Facility

The "Installdir\site\spdsserv.bat` file enables you to use the SPD Server audit file facility. The audit file facility is not enabled by default. Use the following start-up parameters to the spdsserv process to configure the SPD Server audit file facility:

- `auditfile fileSpec`
  enables proxy audit logging for the server, and enables automatic audit log file creation by the audit process. The parameter fileSpec specifies a path or filename that is used to generate the complete audit file path.

  For example, if you specify fileSpec as `\audit\spds`, the generated name will be `\audit\spds_mmddyyyy_hh:mm:ss.spdsaudit`, where `mmddyyyy` is the system date when the log file was created.
-sqlauditfile fileSpec
  enables SQL audit logging for the server, and enables automatic audit log file creation by the audit process. The parameter fileSpec specifies a path or filename that is used to generate the complete SQL audit file path. For example, if you specify fileSpec as \audit\spdssql, the generated name will be \audit \spdssql_mmddyyyy_hh:mm:ss.spdsaudit, where mmddyyyy is the system date when the log file was created.

-audittime hh:mm
  specifies the time of day to cycle a new generation of the audit log file or SQL audit log file. At this time each day, the previous log file is closed and a new log file is opened. For example, -audittime 00:00 cycles the logs at midnight. For more information about SPD Server auditing, see “SAS Scalable Performance Data (SPD) Server Auditing” on page 199.

User Password and Parameter Files

The spdsserv.bat file assumes that you keep your spdsserv.parm parameter file and your SPD Server user password file in the "InstallDir\site" directory. If you do not keep the files in this location, you need to change the following start-up parameters:

-parmfile file-spec
  specifies an explicit file path for the SPD Server host's parameter file. This file is mandatory and contains any SPD Server options. If this option is omitted, the SPD Server host assumes that a parameter file named spdsserv.parm is in the process's current working directory.

-libnamefile file-spec
  specifies the name of the file that contains the logical LIBNAME domain definitions that the SPD Server host supports.

Accessing SPD Server through a Registered Port

If you want to access SPD Server through a registered port (name service), add the following service to your \etc\inet\services or \etc\services file (if this service is not already present):

spdsname 5400\tcp # SPDS Name Service

This service defines the port number for the SPD Server name server process. Make sure that this port number matches the port number that you used when you installed SPD Server. If you are running SAS on an existing SPD Server installation, this service name is probably already defined. You can either define another service name for the SAS client to use (for example, sp45name) or you can directly include the SPD Server port number in your SAS statements.

Adding Users to the SPD Server psmgr Database

See the section Chapter 17, “Managing SAS Scalable Performance Data (SPD) Server Passwords and Users,” on page 172 for more information about adding users to the SPD Server psmgr database.
**Authenticating SPD Server User Passwords**

SPD Server user passwords can be authenticated by the SPD Server psmgr utility, or by an LDAP server (such as Microsoft Active Directory, Sun Java System Directory Server, or OpenLDAP).

LDAP authentication integrates with the SPD Server password facility and provides a centralized approach to user ID and password management. SPD Server clients that use LDAP authentication should have user accounts that are managed by the authenticating LDAP server. The user ID and password information must be stored on an LDAP server that the SPD Server can access. The user ID must be entered into the SPD Server password database through the psmgr utility or via the SAS Management Console utility. These user ID requirements exist in order to ensure that all SPD Server user information is recorded and properly propagated.

When a client uses LDAP authentication to connect to SPD Server, the LDAP server that is configured in the SPD Server's parameter file performs the authentication. After the client is verified, SPD Server uses the client's password database record for all other SPD Server operations.

For more information about SPD Server LDAP authentication, see “Overview of LDAP Authentication” on page 177.

**Customizing SPD Server Configuration**

To customize configuration of the "Installdir\site\spdsserv.parm" parameter file and the "Installdir\site\libnames.parm" LIBNAME file for your installation, see Part 4, Chapters 6–13, in *SAS Scalable Performance Data Server: Administrator’s Guide*.

**Install SPD Server as a Service**

You can use Windows Services to start SPD Server. To install the services that start the SPD Server name server, the SPD Server Data Server, and the SPD Server SNET server, select **Start ➔ All Programs ➔ SAS ➔ Utilities ➔ Install SPD 5.1 as a Service**.

Select **Start ➔ All Programs ➔ SAS ➔ Utilities ➔ Start SPD 5.1 as a Service** to manually start the SPD Server service.

Select **Start ➔ All Programs ➔ SAS ➔ Utilities ➔ Stop SPD 5.1 as a Service** to manually stop the SPD Server service.

After you install SPD Server as a service, you can verify SPD Server services via Windows Services. To open the Windows Services window, select **Start ➔ Control Panel ➔ Administrative Tools ➔ Services**.

The main panel of Windows Services contains a sortable list of Windows services. Scroll down the **Services** list to find entries for the SPD Server 5.1 services.

Most users want to configure SPD Server to automatically start and stop when they start and stop Windows. The **Automatic** setting starts the name server, data server, and SNET server without prompting. The same setting also stops the services without prompting when you close Windows.

Here is how to configure SPD Server to automatically start and stop when users start and stop Windows:
1. In the Window Services window, scroll down the Services list to find the entry for SPD Server 5.1 Name Server.

2. Select the name server service in the list, right-click on it, and select Properties. The Properties window appears.

3. Select Automatic from the Start-up type list. This setting configures the SPD Server Name server service to automatically start and stop with the Windows operating environment. Click OK to apply the changes and close the window.

4. Repeat this process to change the Start-up type setting for the SPD Server data server and the SPD Server SNET Server. At this point, your name server, data server, and SNET Server services are configured to automatically start and stop with the Windows operating environment.

Note: The first time you set your SPD Server services to Automatic, you need to manually start them by selecting Start → All Programs → SAS → Utilities → Start SPD Server 5.1 Services. After you manually start the services, they will automatically start and stop with Windows.

Notes for SPD Server Administrators

The SPD Server administrator performs the maintenance and configuration functions for SPD Server. The following sections contain guidelines for administrators.

SPD Server User IDs

The SPD Server administrator needs to be familiar with the SPD Server psmgr utility. The SPD Server system uses its own layer of access controls that overlay Windows access permissions. SPD Server processes run in the context of a Windows user ID, and that user owns all of the resulting SPD Server file resources that are created.

Each SPD User is given their own SPD Server user ID and password. The user ID and password are needed to complete the LIBNAME connection to SPD Server. All resources that a user creates are owned by the user. An SPD Server user can access only resources that that user created, or resources that another SPD Server user grants them access to via SPD ACLs. There also exists an "anonymous" user account that any SPD Server user can access with no password, and where all resources that are created by the anonymous user are accessible to any other SPD Server user.

Troubleshooting

Key information for SPD Server troubleshooting can be found in the SPD Server name server log and in the SPD Server host process log files. Those two log files enable you to reconstruct SAS interactions with SPD Server components. Entries in the log files are time-stamped for reference. You should be able to correlate activities between the two logs by using the time-stamp information. The logs are formatted as plain text files.

Name Server Start-Up Failed

Check the name server log file. The log should contain information about the problem. Some common things to look for include:
• The -LICENSEFILE file specification is not valid
• -LICENSEFILE specifies a file with invalid contents.
• The name server port is in use by another process.

**SPD Server Host Start-Up Failed**

Check the SPD Server host log file for information. Some common things to look for include:

• The -NAMESERVER node name is incorrect.
• -NAMESERVERPORT specifies the wrong port number if the SPD Server name server is running with a nonstandard port assignment.
• The -PARMFILE file specification is invalid, or the specified file does not exist.
• The -LIBNAMEFILE file specification is invalid, or the specified file does not exist.
• The contents of the specified -LIBNAMEFILE does not conform to expected syntax. Check the SPD Server host log file for messages about invalid entries.
• The -ACLDIR option was omitted from the command line.
• The -ACLDIR option specifies an invalid directory path for the SPD Server password file, or the specified directory path does not contain a valid SPD Server password file.

**SAS LIBNAME Assignment Failed**

If the SAS LIBNAME assignment fails, first check the error messages from the SPD Server LIBNAME engine through the SAS log output. In most circumstances, you can diagnose the reason for the failure from these messages. Some common problems include:

ERROR: The SASSPDS engine cannot be found.
   This error indicates your SAS installation did not include the SAS Scalable Performance Data Server client. Review your SAS installation.

ERROR: Unable to connect to SPD Name Server.
   This error indicates that SAS SPD Server is not running, or your LIBNAME HOST= or SERV= values are not correct. Verify your LIBNAME statement and that SPD Server is running on the correct host with the correct port.

ERROR: Protocol version mismatch. Proxy version is 5.1 while engine version is <version>.
   This error indicates you are trying to connect to SPD Server with an old client. Verify that you are running SAS 9.4 with the SAS Scalable Performance Data Server client.

ERROR: SPD Server has rejected login from user <username>
   This error indicates you are trying to connect to SPD Server with an invalid user ID or password. Verify your LIBNAME statement.
Renewing Your SPD Server License

When you receive SPD Server, licensing information is pre-initialized. When you renew the license, you receive a new license to replace your existing license. You must restart SPD Server to use the new license. You must edit your rc.spds LICFILE= variable name so that it reads the name of the new license file.

Upgrading and Reinstalling SPD Server

If you need to reinstall SPD Server, or if you install a newer release of SPD Server, the installation process does not alter any files that have been modified in the "InstallDir\site" directory. Any custom modifications that were made to installation files are retained when you upgrade SPD Server to a subsequent release.
Part 3

Migration

Chapter 5

Using Earlier Version Tables with SAS Scalable Performance Data (SPD) Server 5.2 ........................................ 31
Chapter 5
Using Earlier Version Tables with SAS Scalable Performance Data (SPD) Server 5.2

Introduction

SPD Server 5.2 uses architectures that enable features like the ability to support data tables that contain more than 2 G of observations. The new architectures provide functionality that today's data marts need, but the current generation of SPD Server tables use metadata architectures that are not backward compatible with SPD Server 3.x software.

SPD Server 4.x tables use architectures that use SAS 9.4 metadata. SPD Server 3.x tables use architectures that use SAS 8 metadata. These two metadata architectures are not compatible. However, SPD Server 5.2 provides a conversion utility SPDSCONV that SPD Server 3.x customers can use to convert existing tables into SPD Server 4.x format, which SPD Server 5.2 can read and open. If SPD Server 5.2 modifies an SPD Server 4.x table, the table will be saved in SPD Server 5.2 format. The SPDSCONV utility is designed to be run by the SPD Server Administrator.

To summarize:

- SPD Server 5.2 can read SPD Server 5.2 and SPD Server 4.x tables.
- SPD Server 4.x tables that are modified by SPD Server 5.2 become SPD Server 5.2 tables.
- SPD Server 3.x and SPD Server 4.x cannot read SPD Server 5.2 tables. If you have SPD Server 3.x tables, you must convert them to SPD Server 4.x tables before SPD Server 5.2 can read or open the tables.

Note: Before you begin the SPDSCONV conversion process, back up all images of the SPD Server 3.x data sets that are to be converted.
Converting SPD Server 3.x Tables to SPD Server 4.x Tables

Before You Convert

The SPDSCONV utility changes the format of SPD Server 3.x tables to the format used by SPD Server 4.x tables. The conversion is not reversible. After you convert a table for use with SPD Server 4.x, the table can no longer be read by SPD Server 3.x. Before you start converting SPD Server tables, back up all your existing SPD Server 3.x tables. If you ever need to revert to your SPD Server 3.x tables, you can restore them.

If you need to temporarily use your tables with both SPD Server 3.x and SPD Server 4.x, you can use PROC COPY to make copies of the tables before you convert them. You can use SPDSCONV on the copied versions to convert them for use with SPD Server 4.x (and, by extension, SPD Server 5.2) and maintain archival versions of the older SPD Server tables.

Overview of the SPDSCONV Utility

The SPDSCONV utility converts SPD Server 3.x metadata files for use with SPD Server 4.x. The conversion process updates the physical structure of the metadata files and renames them. The SPDSCONV utility also updates the data partition files if the SPD Server 3.x tables that are being converted contain compressed data.

You can identify SPD Server 3.x table files by their filename extension. SPD Server 3.x table files end with the filename extension .spds8. SPD Server 4.x and SPD Server 5.2 table files end with the filename extension .spds9. All tables that are upgraded to be compatible with SPD Server 4.x or SPD Server 5.2 have the filename extension .spds9.

SPD Server 4.x and SPD Server 5.2 index files differ from SPD Server 3.x index files. SPD Server 4.x and SPD Server 5.2 index files permit greater numbers of observations than SPD Server 3.x index files did. SPD Server 3.x index files are not compatible with the SPD Server 4.x or SPD Server 5.2 environment.

The SPDSCONV table conversion utility does not re-create index files. When you use the SPDSCONV utility to convert tables from SPD Server 3.x to SPD Server 4.x and SPD Server 5.2 format, the utility automatically deletes physical files that were associated with the old 3.x indexes and that are now obsolete. The SPDSCONV utility does offer an option to create a SAS job file that you can run in the SPD Server 4.x or SPD Server 5.2 environment to re-create the SPD Server 3.x index files for use with SPD Server 5.2.

If you choose to create the SAS job file to re-create SPD Server 3.x indexes for use in SPD Server 4.x and SPD Server 5.2, the code resembles the following example:

```%let SPDSIASY=YES;
PROC DATASETS
  lib=<spdsv4 LIBNAME>;
modify MYTABLE;
  index create X1 [/Options];
  index create X2 [/Options];
...```
You can specify the destination directory for the SAS job file that you create, but the SPDSCONV utility names the job file that you create. The utility generates SAS job filenames by adding the text string _v4ix.sas to the table name.

**TIP** You should defer re-creating an index because the process can require intensive computing. In busy computing environments, consider performing this task as an off-peak batch job.

After you convert the indexes, you might notice that SPD Server 4.x metadata files are slightly larger than the SPD Server 3.x metadata files were. The increase in file size is related to the new structures that enable SPD Server 4.x and SPD Server 5.2 to use tables that contain more than 2,000,000 rows of data.

How does SPDSCONV work? When the SPDSCONV utility converts a table, it reads the original SPD Server 3.x metadata file and creates a new SPD Server 4.x and SPD Server 5.2 metadata file. Both these files are locked during the conversion process. The lock prevents other users from accessing the files while changes are being made. If the conversion process encounters problems, the SPD Server 4.x and SPD Server 5.2 metadata file is deleted, and the original SPD Server 3.x table remains intact.

SPDSCONV reads the SPD Server 3.x metadata file one section at a time, and re-creates each structure in the SPD Server 4.x and SPD Server 5.2 metadata file as it is read. After the SPD Server 4.x and SPD Server 5.2 metadata file is fully populated, the utility checks the data partition file component to determine whether updates are required.

If SPDSCONV detects the presence of compression block headers, then the data partition file contains SAS 8 compression information that is not compatible in SPD Server 4.x and SPD Server 5.2, and SPDSCONV must update the data partition files. SPDSCONV updates the file by overwriting the compression block headers.

SPDSCONV does not change the size of the data partition file, of any file components, or of any data that is contained in the files. The increase in metadata file size is modest and represents only a small percentage of storage space when compared to its corresponding data partition file component.

After SPDSCONV updates the data partition file, you cannot restore or re-create the original SPD Server 3.x data partition file. Ensure that you have complete backup images of the SPD Server 3.x data sets that you intend to convert before you run the conversion.

After the SAS job file re-creates the SPD Server 3.x indexes for use with SPD Server 4.x and SPD Server 5.2, all remnants of the SPD Server 3.x table are deleted. The SPDSCONV utility does not perform ACL checks during the conversion process. You cannot browse the contents of table rows from within the utility. During the metadata file conversion, no table rows are accessed, and there are no options to expose table row contents as part of logging or index job creation. The SPD Server 4.x and SPD Server 5.2 table retains the same SPD Server owner as the SPD Server 3.x table.

### Using SPDSCONV

The SPDSCONV program is a command-line utility. You use a set of command-line options and parameters to specify the name and location of tables that you want to convert. Then you specify the options that you want for your conversion. If your SPD Server software is installed on a UNIX platform, see Chapter 3, “Installing SAS Scalable Performance Data (SPD) Server on UNIX,” on page 9 for information about setting up your environment before you run SPDSCONV.

The command-line syntax is as follows:

```
SPDSCONV <Options> [-a | table1 [table2]]
```
The order of options and table names on the command line does not matter. All of the currently available options are global options. Placing a global option before or after a table does not change the option setting for that table alone. Global options are always applied globally.

The SPDSCONV command has the following options:

- **-d pathname**
  the directory path that corresponds to an existing SPD Server LIBNAME domain. This pathname should be the same as the PATHNAME= directory path in the libnames.parm file.

- **-l logpath**
  the directory path where SAS job files that are created during the conversion process should be stored. The default logpath setting is the directory from which the SPDSCONV command is issued.

- **-a**
  converts all SPD Server 3.x compatible tables in the -d pathname directory to tables that are compatible with SPD Server 4.x and SPD Server 5.2.

- **-j**
  creates a SAS job in the log directory for each SPD Server 3.x table that contains an index. When you use the -j option, the SAS job re-creates the indexes on the SPD Server 5.2 table. You must run the SAS job after the SPDSCONV utility completes the conversion process. Because re-creating an index recreation can be computation-intensive, you should schedule SAS index re-creation jobs as a SAS batch job during off-peak hours. The utility generates the name of the SAS job file, which has the following format:

  TableName_v4ix.sas

In the name, TableName is the name of the table that is compatible with SPD Server 4.x and SPD Server 5.2. The SAS job file contains the SAS language statements that are required for re-creating the indexes that the SPD Server 3.x table used. You need to edit the job file before the job executes. Editing the file ensures that the correct SPD Server 4.x and SPD Server 5.2 LIBNAME is used with the PROC DATASETS statement.

- **-v**
  creates verbose output for the conversion process.

### SPDSCONV Utility Examples

#### Example LIBNAME Parameter File

These examples assume that you use the following LIBNAME parameter file for your SPD Server installation:

```plaintext
LIBNAME=usmkt pathname=/mdat1/usmkt
  roptions="data path=('/dat11/usmkt'
                  '/dat12/usmkt'
                  '/dat13/usmkt'
                  '/dat14/usmkt')"
index path=('/ix11/usmkt'
              '/ix12/usmkt')"
LIBNAME=sales pathname=/mdat1/sales
```

34 Chapter 5 • Using Earlier Version Tables with SAS Scalable Performance Data (SPD) Server 5.2
Converting SPD Server 4.x 32-Bit Windows Tables to SPD Server 5.2 64-Bit Windows Tables

Tables that were created with SPD Server 4.x running in Windows 32-bit mode are not compatible with SPD Server 5.2 tables in 64-bit mode. SPD Server 5.2 for 64-bit Windows does not recognize SPD Server 4.x components. If you submit a PROC CONTENTS command to SPD Server 5.2 on a Windows 64-bit server, SPD Server 5.2 does not recognize SPD Server 4.x tables, views, or clusters, even if they exist in a valid SPD Server domain. There are two ways that you can convert SPD Server 4.x tables from a 32-bit Windows environment to SPD Server 5.2 tables for use in a 64-bit Windows environment:

**Convert SPD Server 4.x Tables to SAS Tables, Then to SPD Server 5.2 Tables**

You can convert SPD Server 4.x tables into SAS 9.2 or SAS 9.3 tables by making a LIBNAME connection to your SPD Server 4.x server, and then making a LIBNAME connection to SAS. After both LIBNAME connections are established, you can use PROC COPY to copy the tables from your SPD Server domain to your SAS domain.

```
LIBNAME spd44 saspds "<SPD-Server-4.x-domain-name>"
   host=localhost
c   serv=<SPD-Server-4.x-server-port>
   user=<user-ID> ;
```
After you copy your SPD Server 4.x tables into SAS 9.2 or SAS 9.3 tables and store them in a SAS location, you can install SAS 9.4 and SPD Server 5.2 on your Windows 64-bit platform. Next, you use the 64-bit Windows environment to create a SAS 9.4 LIBNAME connection to the directory location where you stored your copied SPD Server 4.x tables, and a SAS 9.4 LIBNAME connection to your SPD Server 5.2 domain. Now you are able to use the SAS 9.4 PROC COPY command to restore the former SPD Server 4.x tables to your SPD Server 5.2 domain in SPD Server 5.2 format.

LIBNAME spd52 sasspds "<SPD-Server-5.2-domain-name>"
        host=localhost
        serv=<SPD-Server-5.2-server-port>
        user=<user-ID> ;

LIBNAME SAS94 "<path-to-SAS9.4-directory>";
PROC COPY in=SAS94 out=spd52;

SPD Server 5.2 will be able to recognize and use the copied tables in the new SAS 9.4 and SPD Server 5.2 domain space.

Convert Directly from SPD Server 4.x Tables to SPD Server 5.2 Tables

You can convert directly from SPD Server 4.x tables to SPD Server 5.2 tables by using SAS 9.4 with an SPD Server 4.x and an SPD Server 5.2 server. You must be able to operate both versions of SPD Server in your computing environment in order to use this conversion approach.

First, you make two LIBNAME connections using SAS 9.4. You make the first LIBNAME connection to your SPD Server 4.x server, and then you make the second LIBNAME connection to your SPD Server 5.2 server. After you establish a LIBNAME connection between the SPD Server 4.x host and the SPD Server 5.2 host, you can use a PROC COPY statement to copy your SPD Server tables directly from your 4.x host to your SPD Server 5.2 host.

LIBNAME spd44 sasspds "<SPD-Server-4.x-domain-name>"
        host=localhost
        serv=<SPD-Server-4.x-server-port>
        user=<user-ID> ;

LIBNAME spd52 sasspds "<SPD-Server-5.2-domain-name>"
        host=localhost
        serv=<SPD-Server-5.2-server-port>
        user=<user-ID> ;

PROC COPY in=spd44 out=spd52;

Using PROC COPY with SPD Server Clusters

If you use the PROC COPY command to move tables from one SPD Server domain to another SPD Server domain or SAS location, and if your source domain contains tables that use SPD Server clusters, the output file that is produced by the PROC COPY
command will be either a SAS table, or an SPD Server table. The output file will not be a clustered table.

To migrate formerly clustered tables from SPD Server 4.x to SPD Server 5.2, you must first undo the table cluster in the source (SPD Server 4.x) location before copying the component tables to the destination (SPD Server 5.2) location.

After the tables are unclustered, you can use PROC COPY to copy the files from the source domain to the destination domain. After you successfully copy your tables to the destination domain, use SPD Server 5.2 CLUSTER TABLE commands to reform the clustered table structures.

Using the SAS Scalable Performance Data (SPD) Server Name Server to Manage Resources

Managing SPD Server Computing Resources with a Name Server

The SPD Server name server gives you the ability to manage computing resources without disturbing system users. The SPD Server name server maps logical names that are referenced in SAS programs to the physical location of SPD Server tables. A name server enables you to add, remove, or reallocate disk space and computing power without needing to change SAS source code. You also do not need to inform others about changes in resource allocation as long the name of the machine that hosts the name service remains the same.

The following example demonstrates how to configure SPD Server to spread the processing load across multiple machines in a network.

Configuring SPD Server on a Corporate Network

Example Scenario

The corporation in this example maintains a network of computers. The corporate network contains a mix of computers and processing power: machines with multiple processors and large amounts of available disk space, smaller machines that are used for servers, and desktop machines for client users. The dedicated servers have the following names:

worldcpu
  a data store for the company's worldwide operations
asiacpu
   a data store for the company's Asia department, which uses the data to generate
   reports, analysis, and so on
namecpu
   the machine that runs the name server

Because data for worldwide operations is stored in an SPD Server table on worldcpu, the Asia department must periodically access that server. The Asia users want to extract worldcpu data to create SPD Server tables that will reside on their own departmental server, asiacpu. The Asia users can then access tables that contain only Asia data, and transfer that information to their desktops for further analysis.

The SPD Server system administrator runs the name server on the namecpu machine. Consequently, namecpu must be accessible by every machine in the network that wants to locate an SPD Server table. The administrator must also run a data server on the worldcpu and asiacpu machines. The following section describes how to configure the servers in order to distribute the processing load.

Run the Name Server on the namecpu Machine

Invoke the name server by using the -listenport option. Specify a valid TCP/IP port number. Use the same port number when you invoke SPD Server on the worldcpu and asiacpu servers.

Configure SPD Server on the worldcpu Server

The libname.parm file that resides on the worldcpu server contains the following line:

```
LIBNAME=world pathname=/spds;
```

This code instructs SPD Server to register the combination (world, worldcpu, /spds) with the name server. Thereafter, when a SAS LIBNAME statement contains the domain name world in combination with the appropriate name server, it will locate SPD Server tables in the directory /spds on the worldcpu server. The following SAS LIBNAME statement invokes the SPD Server engine and makes this association:

```
LIBNAME worldlib sasspds 'world'
   server= namecpu.spdsname;
```

When your network uses an SPD Server name server, the users do not have to remember which machine houses a particular domain. Users need to remember only that the SAS domain named world contains the tables that they need. Even if the machine that stores the domain changes without the users' knowledge, the users' SAS programs continue to run as before.

Specify namecpu as the value for the -nameserver option and invoke SPD Server. The value for the name server port must match the port number that you used to start the name server on that machine.

Set Up asiacpu, the Asia Departmental Server

The libname.parm file that resides on asiacpu contains the following line of code:

```
LIBNAME=asia pathname=/spds;
```

This code instructs the SPD Server that is running on asiacpu to register the combination (asia, asiacpu, /spds) with the name server. When a SAS LIBNAME statement contains the domain name asia in combination with the
appropriate name server, it will locate SPD Server tables in the directory `/spds` on machine `asiacpu`. The following SAS LIBNAME statement invokes the SPD Server engine and makes this association:

```
LIBNAME asialib sasspds 'asia'
   server=namecpu.spdsname;
```

The value that follows the LIBNAME server specification is the same in all these LIBNAME statements because both SPD Servers use a common name service. Asia departmental users do not need to know the name of the machine that provides storage for their domain.

Which SAS Program Statement Runs Where?

Assume that a user in the Asia department needs to create an SPD Server table on the departmental server `asiacpu`. This task requires data to be extracted from an SPD Server table named `alldata`. The user knows that the `alldata` table resides in the domain `world`. The user submits the following SAS code on a desktop SPD Server client:

```
LIBNAME worldlib sasspds 'world'
   server=namecpu.spdsname;
LIBNAME asialib sasspds 'asia'
   server=namecpu.spdsname;

data asialib.mydata;
set worldlib.alldata;
where region='Asia';
   if country='Japan' then
      subreg=1;
run;
```

This code extracts records from an SPD Server table named `alldata` that resides in the domain `world`. The `world` domain is stored on machine `worldcpu` in the directory `/spds`. Because the `alldata` table resides on `worldcpu`, and SPD Server processes certain SAS WHERE clauses, the search for the value `Asia` is performed on `worldcpu`.

The SAS program runs on the Asia user's desktop machine. The desktop machine scans each row in the `alldata` table, looking for the string `Japan`. If the string is found, the desktop client forwards the row to the machine on which the output table resides, which is `asiacpu` in this example.

Disk space for the output table `mydata` is allocated in the `/spds` directory on `asiacpu`. The processing work (transferring data received from the user's desktop machine to the SPD Server table) is also performed by `asiacpu`.

The processing that was required to create the output SPD Server table was distributed across three machines. However, the user's desktop machine requires no permanent disk space, because SAS WHERE clauses execute on the machine that stores the source table. Only the selected rows that match the submitted WHERE clause are sent over the network to the desktop client. This strategy significantly reduces both network traffic and the time that is needed to complete a SAS program.
Chapter 7
Administering and Configuring SAS Scalable Performance Data (SPD) Server Using the SAS Management Console

Overview of SAS Management Console

Overview of SAS Management Console is a Java application that provides a single point of control for managing multiple SAS application resources. Rather than using a separate administrative interface for each application in your enterprise intelligence environment, you can use the SAS Management Console interface to perform the administrative tasks required to create and maintain an integrated environment.

SAS Management Console manages resources and controls by creating and maintaining metadata definitions for entities such as:
Metadata definitions that are created through SAS Management Console are stored in a repository or on a SAS Metadata Server where they are available for other applications to use. For example, you can use SAS Management Console to create a metadata definition for a SAS library that specifies information such as the libref, path, and engine type (such as sasospd). After SAS Management Console stores the metadata definition for the library in the repository on the SAS Metadata Server, any other application can access the definition to access the specified library.

The SAS Management Console application is a framework. The metadata definitions are created using Java plug-ins, which are application modules that create metadata for a specific type of resource.

For example, administrators can use SAS Management Console to configure SPD Server user and group passwords and ACLs instead of using the traditional SPD Server psmgr utility and SPDO procedure statements.

SAS Management Console for SPD Server 5.1 is installed with SAS 9.4 Management Console.

Accessing SPD Server Services in SAS Management Console

The left portion of SAS Management Console contains a navigation tree of available management tools. Click the SPD Manager folder to access SPD Server services. The SPDS Manager folder contains the SPD Server Password Manager, ACL Manager, Server Manager, Process Profiler, and Proxy Manager.

Before you can access any of the SPD Server Management utilities, you must connect to an SPD Server. For more information, see “Connect to an SPD Server” on page 46.

Connect to an SPD Server

On the Users tab in the SAS Management Console window, click Connect to open the Connect to SPD Server window:
The Connect to SPD Server window contains input fields for the following components. The components in the window follow the same usage rules as the components that you would use in a LIBNAME statement to connect to an SPD Server host.

**Server**
- name of the SPD Server host

**Port**
- SPD Name Server listen port

**Domain**
- the SPD Server domain

**User**
- user name that is designated as ACL special

**Password**
- password associated with the user name

**Group**
- optional group name

**ACL Special**
- select this box to enable ACL special privileges

Complete the required information, and then click **Connect**. After you connect to an SPD Server host, you can use the SPD Server Management utilities. The status bar at the bottom of the active tab indicates that a connection exists.

*Note:* Do not confuse the SAS Management Console status indicator in the lower right corner of the SAS Management Console window with the SPD Server connection status at the bottom of the active tab.
Password Manager

Overview of Password Manager

You can use Password Manager in the SAS Management Console window to configure SPD Server user and group passwords. Use the Users and Groups tabs of the Password Manager to access the configuration information for individual users or for user groups.

If you open Password Manager in the SAS Management Console window when no server connection exists, the display resembles the following:

When no server connection exists, no data is displayed. To display data, you must connect to an SPD Server. For more information, see “Connect to an SPD Server” on page 46.

Managing Users with Password Manager

Users Tab

On the Users tab in the SAS Management Console window, click List Users to display the defined users and groups.
The window contains the following components:

**User Name**
name of the user. You cannot change this field directly. To change a user name, delete the user and then add a new user. For more information, see “Delete a User” on page 50 and “Add a User” on page 50.

**Auth Level**
umeric authorization level, in the range 0–7. To change the value, select the field and edit it.

**Perf Level**
this setting is not yet implemented in SPD Server. In the future, this field will be used to indicate to the server how to manage resources for the associated user.

**IP Address**
IP address of the workstation that the individuals listed in the User Name column are using.

**Def Group**
default group for a user. Use the drop-down list to change the currently defined group.

**Group 2 - Group 5**
shows the numbered groups 2–5 that are assigned to each user. Use the drop-down list to change the currently defined groups.

**Expires**
number of days remaining until the current password expires. The value 0 indicates that the password never expires.

**PW Last Modified**
date and time when a user's password was last modified.

**Last Login**
date and time of the last user login.

**Time-out**
number of idle days since the user's last login. When the number of days since a user's last login equals the Time-out value, the user's access is disabled. For example, if the Time-out value is 7, and if a given user does not log on at least every seven days, then the user's access is disabled. The value 0 indicates that the user account never times out.
Allowed Login Failures
number of consecutive login failures that is allowed before the user's access is
disabled. The value 0 indicates that unlimited login failures are allowed.

Accrued Login Failures
current number of consecutive failed login attempts by this user.

Add a User
To add a user, click Add Users. Complete the values for User, Password, Verify
Password, Auth Level, Performance Level, IP Address, PW Expire, Def Group,
Login Timeout, and Failed Logins. The Verify Password field is a check that requires
you to re-enter the password to ensure that the two items match and that you did not
make any keyboard errors when you entered the password string. Performance Level
reflects the performance class of the user and should be Low, Medium, or High. For
more information about performance levels, see “Server Performance Levels” on page
73.

Delete a User
To delete a user, select the user from the list and click Delete. The user is deleted and the
list is updated.

Change a Password
To change a user's password, select the user and click Chg Pass User. Enter the user's
old password and new password in the Change User Password dialog box, and click
Change.
Reset a Password

To reset the password for a selected user, click Reset Pass. Specify the user's new password and click Change. You do not need to know the user's current password to change it. The user must change the password before he can connect to the server.

You use Reset Pass to reset a user's password after that user has been disabled. Users can be disabled for excessive login failures or for a login time-out.

Managing Groups with Password Manager

Groups Tab

On the Groups tab in the SAS Management Console window, click List to display the existing defined groups. When you first connect to the Password Manager or after you make changes to a group, the window lists the existing defined groups by default.
Add a Group
To add a group, click Add. Enter a group name in the Add Group window and click Add. The group name is added and the list is updated.

Delete a Group
To delete a group, select the group from the list and click Delete. The group is deleted and the list is updated.

ACL Manager

Overview of ACL Manager
Click the ACL Manager folder in the SAS Management Console window to manage ACL resources. The ACL Manager panel resembles the following display.

You must connect to an SPD Server host machine before you can use the SPD Management utilities. For information about connecting to an SPD Server host, see “Connect to an SPD Server” on page 46.

List ACL Resources
To display the ACL resources that have been defined, click List ACL in the ACL Manager panel of the SAS Management Console window.
The ACL Manager display contains the following components:

**Owner**
- resource owner. You cannot change this field directly. To change a resource owner, delete the resource, and then add a new one.

**Resource**
- resource name. You cannot change this field directly. To change a resource name, delete the resource, and then add a new one.

**Type**
- type of resource (for example, DATA, CATALOG, VIEW, or MDDB). You cannot change this field directly. To change the type of a resource, delete the current resource, and then add a new one.

**Column**
- column name, if the resource is limited by a column constraint. You cannot change the column name directly. To change the column name, delete the existing resource and then add a new one.

**Persist**
- a Boolean flag. When this value is set to *Yes*, the ACL resource definition continues to exist if the referenced resource is deleted. If the **Persist** setting is blank, the ACL resource definition is deleted when the referenced resource is deleted.

**Name**
- name of a user or group to which the Read, Write, Alter, and Control permissions are applied for this resource. **Universal** is the default setting for all unnamed groups or users.

**Read**
- if this check box is selected, the user or group has permission to read this resource.

**Write**
- if this check box is selected, the user or group has permission to write to this resource.

**Alter**
- if this check box is selected, the user or group has permission to alter this resource.

**Control**
- if this check box is selected, the user or group has permission to modify the permissions of other users and groups that are associated with this resource.
Add an ACL Resource

To add an ACL resource, click Add ACL in the ACL Manager panel of the SAS Management Console window.

Specify the following values in the Add ACL window.

**Resource**
- name of the resource that you are adding.

**Column**
- column restrictions for the resource that you are adding. If there are no restrictions, leave this field blank.

**Type**
- type of the resource (for example, DATA, CATALOG, VIEW, or MDDB).

**Persist**
- a Boolean flag. If you select this check box, the ACL resource definition continues to exist if the referenced resource is deleted. If you do not select this check box, the ACL resource definition is deleted when the referenced resource is deleted.

**Generic**
- select this check box if the resource name is a generic name.

**LIBNAME**
- select this check box if the resource is a LIBNAME resource.

**R, W, A, C**
- select the appropriate default and group permissions to grant Read, Write, Alter, and Control permission to the resource.

**Model**
- specify the name of an existing ACL resource to use as a model for this ACL resource.
Delete an ACL Resource

To delete an ACL resource, select the appropriate row in the ACL resource table and click **Delete ACL**. The ACL resource is removed, and the list is automatically updated.

Add a User or Group to an ACL Resource

To add a user or group to an ACL resource, click **Add ACL User** in the ACL Manager panel. In the Add Acl User window, enter the user or group name in the **User** field. Select the boxes that correspond to the default Read, Write, Alter, and Control permissions that you want to grant. Then click **Add**.

![Add Acl User](image)

The user is added and the ACL listing is automatically updated. You cannot delete an individual user or group from an ACL resource. To delete a user, you must delete the entire ACL resource, and then add it, omitting that user.

Change Resource Permissions

Each ACL resource has at least one set of permissions called universal permissions. Universal permissions are the default permissions for the ACL resource if no other permissions are applied. If any group names or user names have permissions for the ACL resource, they are displayed.

Each set of permissions has four attributes: Read, Write, Alter, and Control. To enable a default and group permission for each resource, select the appropriate check box.

Server Manager

Overview of Server Manager

Click the **Server Manager** folder in the SAS Management Console window to refresh the SPD Server configuration and to run selected SPD Server utilities. The Server Manager panel resembles the following display when no server connection exists.
You must connect to an SPD Server host machine before you can use the SPD Server Management utilities. For information about connecting to an SPD Server host, see “Connect to an SPD Server” on page 46.

**Refresh Domains**

To reload the current libnames.parm file, click **Refresh Domains** in the Server Manage panel of the SAS Management Console window. The libnames.parm file describes the list of available domains.
**Refresh Configuration Information**

To reload the current spdsserv.parm file, click **Refresh Parms** in the SPD Server Manager panel. The spdsserv.parm file controls the server configuration and options.

![Server Manager panel](image1.png)

**Run Commands**

To run an SPD Server operator command or utility function, click **Perform Command** in the Server Manager panel. Enter the command or utility in the Perform Operator Command window, and then click **Perform**.

![Perform Operator Command](image2.png)

The following example shows the Server Manager panel after the `spdsbkup` command was issued:
Process Profiler

Click the **Process Profiler** folder in the SAS Management Console window to view server resources that are monitored by the Performance Server.

*Note:* The SPD Server Process Profile Manager is not supported on Windows or on Linux on X64.
The Performance Server gathers SPD Server process performance information and distributes it across the SPD Management section of SAS Management Console. This information consists of memory and resource allocations that are attributable to users and SPD Server processes that are spawned by an SPD Server name server. All SPD Server users must connect to an SPD Server name server before their SPD Server session can be spawned. Each SPD Server name server owns a dynamic family of subordinate SPD Server processes. SPD Server users and jobs create and terminate these processes.

To access a server's process performance information, the Performance Server application spdsperf must be running for the targeted SPD Server name server. SAS Management Console must be able to connect to the listening port of the SPD Server Performance Server.

You must first connect the Process Profiler to the Performance Server. Click Connect in the Process Profiler panel to open the Connect to SPD Profile Server dialog box.

Enter your host name or server name, and the Performance Server's listening port, and then click Connect. (You specify the Performance Server's listening port number when you start the Performance Server application.)

After SAS Management Console is connected to the Performance Server, the information that the Performance Server captures is displayed.
Note: Some host systems provide varying amounts of available resource information. Performance and resource information can vary from host to host.

The host performance profile information is automatically updated whenever the Performance Server performs another capture. You specify the frequency with which the Performance Server captures information using the -c option when you start the Performance Server. More information about Performance Server start-up settings is available in Chapter 12, “Setting Up SAS Scalable Performance Data (SPD) Server Performance Server,” on page 105.

If the SAS Management Console user also connects to the same SPD Server name server through ACL Manager, Password Manager, or Server Manager, the user information that is displayed is the SPD Server user name that was used to connect with the LIBNAME statement. Otherwise, the user name of the user that started SPD Server and the component SPD Server processes is displayed.

Proxy Manager

Overview of Proxy Manager

Click the Proxy Manager folder in the SAS Management Console window to display tables that list all users that access a specific SPD Server host. The current libref allocations are displayed for each user, as well as information about the proxy that serves each libref. Available proxy information includes the process ID, the port number, the library path, and, if the libref was established with record locking, the thread ID. For each allocated libref, you can view every data set that is accessible to or open in the libref. If a libref was established with ACL special privileges, then all data sets in the specified domain are visible and accessible to that libref, regardless of any connection settings that are established through the SPD Management utilities in SAS Management Console.

Before you can perform any operations in the Proxy Manager, you must be connected to an SPD Server host. For more information about connecting to a host, see “Connect to an SPD Server” on page 46. After you connect to an SPD Server host, click Refresh Data in the Proxy Manager to update the table data.
You can filter, sort, reorder, and hide Proxy Manager table columns to display proxies of interest. Click on the column headings and select the appropriate choice from the menu.

You can apply filters to any number of columns. The following filter options are available:

- Show all values in the column.
- Show only the highlighted value or values in the column.
- Exclude the highlighted value or values in the column and show all others.

You can drag column headings to a new place in the table to reorder columns. To hide or reveal a column, use the blue down arrow that is above the vertical scroll bar on the right side of the Proxy Manager.

**Refresh Proxies**

Click **Refresh Data** to show the most current proxy data. You must refresh the data after an initial connection or after a proxy state has been manipulated. Because a proxy's state is dynamic, each refresh provides only a current snapshot of the proxies. The status of the data might change immediately after you refresh the data. If no users are currently logged on to the server, a window displays a message to that effect.

**Interrupt Proxies**

Click **Interrupt** to interrupt the proxies for a selected libref. The proxy's activity is halted the next time it attempts to process data from its socket. The frequency with which the proxy accesses its socket is unpredictable and can vary depending on many variables. However, the proxy interrupt operation is typically the first method that you use to halt a proxy from accessing a given data set or domain.

**Cancel Proxies**

Click **Cancel** to cancel all proxies in the selected libref. The proxy's activity is immediately halted, and any open data connections are immediately closed. Use this
method to stop a proxy from accessing a data set or a given domain if a previous interrupt operation is unacceptably delayed.
Chapter 8
SAS Scalable Performance Data (SPD) Server SQL Query Rewrite Facility

Overview of the SQL Query Rewrite Facility

The SQL Query Rewrite Facility in SPD Server examines SQL queries in order to optimize processing performance. Some SQL queries contain SQL statements and sub-queries that can be more rapidly evaluated in a separate space, as opposed to sequentially evaluating large blocks of SQL statements. When SPD Server detects and processes SQL statements or sub-queries in a separate space, intermediate result tables are produced. The original SQL query is dynamically rewritten, using intermediate results tables to replace the SQL code that was evaluated separately. The result is a dynamic process that evaluates and processes SQL queries more efficiently.

Inserting the derived intermediate data into the original SQL query does not change the quantitative results. Rather, the processing that is required to calculate them is expedited. The SQL Query Rewrite Facility does not change the content of the query's answer row set. However, the order of the rows in the query answer set might vary if you compare the optimized query answer set with the query answer set that SPD Server generates when the SQL Query Rewrite Facility is disabled.

Configuring Storage Space for the SQL Query Rewrite Facility

The SQL Query Rewrite Facility uses intermediate results tables to expedite original SQL queries. You must provide adequate space in order for the intermediate results tables to be generated and stored. The intermediate results tables are formatted as SPD Server tables. Optional indexes are permitted.

Intermediate results tables are stored in a common SPD Server LIBNAME domain that you specify. One dedicated SQL Rewrite Facility LIBNAME domain is sufficient to provide adequate intermediate results table storage for many concurrent SPD Server
users. Why is only one domain enough? The SQL Query Rewrite Facility uses the SPD Server TEMP=YES option setting when it accesses the LIBNAME domain for intermediate result tables. The TEMP=YES option creates a processing environment in which multiple users can concurrently create tables without name or resource contention issues. The TEMP=YES option also automatically cleans up the contents of the working storage area when users close their SPD Server session in a normal fashion.

SPD Server administrators and users can specify LIBNAME domains for SQL Query Rewrite Facility intermediate results storage. Administrators can use the TMPDOMAIN= parameter in the spdsserv.parm file to specify the SQL Query Rewrite Facility intermediate results storage domain:

```
TMPDOMAIN=\<Domain-Name>;
```

The `<Domain-Name>` value is the name of a LIBNAME domain that is defined in the libnames.parm file that is associated with SPD Server.

SPD Server users can override the primary TMPDOMAIN= location by specifying their own LIBNAME domain for SQL Query Rewrite Facility intermediate results storage. Users specify their own LIBNAME domain by using the pass-through SQL RESET command with the TMPDOMAIN= option. For example, if an individual SPD Server user wants to use the EMATMP LIBNAME domain for SQL Rewrite Facility intermediate results, the user submits the following RESET command in his or her SQL job stream:

```
execute(reset tmpdomain=ematmp) by sasspds;
```

TMPDOMAIN=EMATMP causes the EMATMP domain to take precedence over the TMPDOMAIN= setting that was specified in the spdsserv.parm file. Any LIBNAME domain that an individual user submits as an SQL Query Rewrite storage location must be defined in the libnames.parm file of the SPD server that runs the pass-through SQL code.

Reassigning the location of the SQL Query Rewrite Facility intermediate results storage does not affect the TMP=YES environment setting that permits concurrent access to tables in the domain by multiple SPD Server users. Multiple SPD Server users can specify and share remapped TMPDOMAIN= locations without experiencing table handling or contention issues.

**Note:** If the SPD Server parameter TMPDOMAIN is not configured and the SQL query rewrite is enabled, the query rewrite fails with the following error:

```
SPDS_ERROR: Error materializing RWE context.
```

---

**SQL Query Rewrite Facility Options**

The SQL Query Rewrite Facility is enabled by default in SPD Server. When an SPD Server user submits SQL statements that contain sub-expressions that SPD Server can handle more efficiently by using the SQL Query Rewrite Facility, the software optimizes the SQL query. RESET options provide control over the SQL Query Rewrite Facility.

**_QRWENABLE Option**

Use the _QRWENABLE reset option to disable the SQL Query Rewrite Facility. You might use this option if you suspect that the SQL Query Rewrite Facility is not enhancing the performance of the SQL query execution. The SQL Query Rewrite Facility is enabled by default.
Examples:

Disable SQL Query Rewrite Facility:

```
execute(reset no_qrwenable) by sasspds; /* Disable query rewrite */
execute(reset _qrwenable=0) by sasspds; /* Another way to disable */
```

Re-enable SQL Query Rewrite Facility:

```
execute(reset _qrwenable) by sasspds; /* Re-enable query rewrite */
execute(reset _qrwenable=1) by sasspds; /* Another way to enable */
```

_QRW Option

Use the _QRW reset option to enable diagnostic debugging and tracing outputs from the SQL Query Rewrite Facility in the log. The diagnostic debugging option is disabled by default.

Examples:

Enable diagnostic debugging function:

```
execute(reset _qrw) by sasspds; /* Enable diagnostics */
execute(reset _qrw=1) by sasspds; /* Another way to enable */
```

Disable diagnostic debugging function:

```
execute(reset no_qrw) by sasspds; /* Disable diagnostics */
execute(reset _qrw=0) by sasspds; /* Another way to disable */
```
Chapter 9
Configuring Disk Storage for SAS Scalable Performance Data (SPD) Server

Introduction

This section discusses how to manage large SPD Server data stores that can consume terabytes of disk storage.

How you configure SPD Server disk storage is important, whether you have many SPD Server users or a just a few large-scale users. To effectively configure SPD Server disk storage for your installation, you need to understand the four types of component files that SPD Server creates, the relative sizes of these files, and when these files are created.

SPD Server Component File Types and Sizes

SPD Server uses four types of component files. Component files are physical file entities that SPD Server uses to track table and index metadata. When component files are combined, they form a logical structure that SPD Server understands and interprets as a single table. The following table lists the relative sizes of the four types of SPD Server component files.

<table>
<thead>
<tr>
<th>File Type</th>
<th>File Extension</th>
<th>Relative Size</th>
<th>Number of Component Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table metadata</td>
<td>.mdf</td>
<td>Very small</td>
<td>1</td>
</tr>
<tr>
<td>Table data</td>
<td>.dpf</td>
<td>Large</td>
<td>1-to-many</td>
</tr>
</tbody>
</table>

Example 1: Primary File System Storage for All Component Files
Example 2: Using ROPTIONS= to Store SPD Server Table Data and Index Component Files in Other File Systems
Example 3: Adding More File Systems to a Path Option When Its File System Is Full
<table>
<thead>
<tr>
<th>File Type</th>
<th>File Extension</th>
<th>Relative Size</th>
<th>Number of Component Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index</td>
<td>.idx</td>
<td>Medium-to-large</td>
<td>1 or more per index</td>
</tr>
<tr>
<td>Index</td>
<td>.hbx</td>
<td>Medium-to-large</td>
<td>1 or more per index</td>
</tr>
</tbody>
</table>

At a minimum, an SPD Server table consists of two component files, the metadata .mdf file and the data .dpf file. The size of the data file component depends on two factors: the size of a table column and the number of columns. The data .dpf component file can be many gigabytes in size. A single table can consist of many .dpf files. SPD Server is not constrained by an operating system file system size limit (such as the 2-gigabyte limit on file size that some UNIX systems impose).

The SPD Server index uses two index component files: the .hbx file and the .idx file. The .hbx file maintains a global view of the index and contains an entry for each key that exists in the index. The .idx file contains the row identifiers for each value in the .hbx file.

The size of the .hbx file depends on the cardinality of the index keys. The higher the cardinality of the index keys, the larger the .hbx file. The size of the .idx file is more difficult to determine because it depends on how the data is distributed.

The best-case scenario for creating an optimally sized .idx file occurs when the table is sorted by the indexed columns. The worst-case scenario for creating an optimally sized .idx file occurs when the index keys are distributed throughout the table.

### Configuring LIBNAME Domain Disk Space

You define the primary file system for each LIBNAME domain for the SPD Server user base. You can define initial and overflow storage locations for the .dpf data component files, as well as for the two index component (.hbx and .idx) files.

#### Example 1: Primary File System Storage for All Component Files

The primary file system is the base directory that you assign to the LIBNAME domain by issuing a PATHNAME= statement in the SPD Server LIBNAME parameter file, libnames.parm. Here is an example of a libnames.parm parameter file entry:

```bash
spdsserv -acl
-acldir InstallDir/site
-nameserver samson
-libnamefile libnames.parm
```

Sample libnames.parm file entry for a UNIX system:

```
LIBNAME=all_users
 pathname=/disk1/peruser_tables;
```

Sample libnames.parm file entry for Windows:

```
LIBNAME=all_users
 pathname=d:\peruser_tables;
```
When SPD Server users create new tables in a LIBNAME domain, you must keep in mind that the metadata component (.mdf) must start in the primary file system. If all the available space in the primary file system is consumed, SPD Server cannot create new tables until disk space becomes available.

Example 1 stores all the component files (metadata, data, and index data) in the primary file system. This arrangement can cause problems if you use large tables. Large tables can quickly fill up the primary file system. To avoid this problem, you should store the data and index components separately from the primary file system. Example 2 shows how to do this using ROPTIONS= with your LIBNAME statement in your libnames.parm file.

**Example 2: Using ROPTIONS= to Store SPD Server Table Data and Index Component Files in Other File Systems**

The following SPD Server code invokes the libnames.parm file:

```bash
spdsserv -acl
   -acldir InstallDir/site
   -nameserver samson
   -libnamefile libnames.parm
```

Sample libnames.parm for a UNIX system:

```
LIBNAME=all_users pathname=/disk1/peruser_tables
    roptions="datapath=('/disk2/userdata' '/disk3/userdata'
                     '/disk12/userdata' '/disk13/userdata')
            indexpath=('/disk4/userindexes' '/disk5/userindexes'
                     '/disk14/userindexes' '/disk15/userindexes')";
```

Sample libnames.parm for a Windows system:

```
LIBNAME=all_users pathname=d:\peruser_tables
    roptions="datapath=('e:\userdata' 'f:\userdata')
            indexpath=('g:\userindexes' 'h:\userindexes')";
```

In Example 2, the PATHNAME= directory stores metadata files for SPD Server tables in the **all_users** LIBNAME domain. The initial and overflow stores for the data and index files are directed to other file systems. In Example 2, users who create large tables will not quickly exhaust the primary file system; the primary file system is reserved for only small metadata files. The larger data and index files are stored in the other file systems specified with the DATAPATH= and INDEXPATH= options in the LIBNAME parameter file.

**Example 3: Adding More File Systems to a Path Option When Its File System Is Full**

If you need to add file systems to your path because an existing file system is running out of space, see the following:

```bash
spdsserv -acl
   -acldir InstallDir/site
   -nameserver samson
   -libnamefile libnames.parm
```

Configuring LIBNAME Domain Disk Space
Sample libnames.parm for a UNIX system:

LIBNAME=all_users pathname=/disk1/peruser_tables
   roptions="datapath=('disk2/userdata' 'disk3/userdata' 'disk12/userdata' 'disk13/userdata')
            indexpath=('disk4/userindexes' 'disk5/userindexes' 'disk14/userindexes' 'disk15/userindexes')";

Sample libnames.parm for a Windows system:

LIBNAME=all_users
pathname=d:\peruser_tables
   roptions="datapath=('e:\userdata' 'f:\userdata' 'i:\userdata')
            indexpath=('g:\userindexes' 'h:\userindexes' 'j:\userindexes')";

In Example 3, SAS users can continue to create more SPD Server tables, as long as space is available for the metadata files in the primary file system. When the primary file system is exhausted, you must create a new LIBNAME domain. You cannot expand storage for the .mdf components by adding the METAPATH= specification to your ROPTIONS= value in your LIBNAME parameter file. Remember the SPD Server restriction: the initial partition file for all .mdf components must be created in the primary file system (the directory that was first specified by the PATHNAME= option for the LIBNAME domain).

Overview of the Server Parameter File

The spdssrv process requires a parameter file at start-up. You specify the name of the parameter file using the -parmfile command-line option.

Syntax for the -parmfile Option

The syntax for the spdsserv -parmfile option is:

```
-parmfile file-spec
```

`file-spec` is an explicit file path for the SPD Server parameter file. The parameter file is required because it maintains options that control the SPD Server processing behavior and use of server resources. If you do not specify your SPD Server parameter file with the -parmfile option, SPD Server assumes that a file with the default name of spdsserv.parm is located in the current working directory.

Syntax for the spdsserv.parm Options

The syntax for spdsserv.parm file options is:

```
Option[ = Value] ;
```

The value is option dependent. Option keywords are not case sensitive. Comments are allowed in the SPD Server parameter file. Any value that is a memory size is stated in bytes. These values can support an "m" or "M" suffix to specify megabytes, or a "g" or "G" suffix to specify gigabytes.

Examples of SPD Server parameter files are in `InstallDir/samples/spdsserv.parm`. `InstallDir` is a placeholder for the path to the root directory of your SPD Server installation.
You can specify different SPD Server performance-level parameters based on the performance class of the user, or based on whether the user is assigned the SPD Server locking proxy specified by the LOCKING=YES LIBNAME option. Every SPD Server user in the SPD Server Password Manager database is assigned a performance class attribute. For more information about user performance classes, see “The Password Manager Utility psmgr” on page 179. Each performance class can be associated with server parameters that use the performance class to control how user resources are allocated.

You enter users into the Password Manager database as either low, medium, or high-performance users. Low users get the LOW (or default) values that are specified in the spdsserv.parm file. Medium users inherit the LOW values plus any values redefined in the MED section of the spdsserv.parm file. High users inherit the LOW values plus any values redefined in the HIGH section of the spdsserv.parm file. LOCKING=YES is a special user class that is activated by a LOCKING=YES LIBNAME assignment for the user. LOCKING=YES users inherit the LOW values plus any values redefined in the LOCKING section of the spdsserv.parm file.

When you use the following keywords in the spdsserv.parm file, they associate a user with the performance-level parameter settings:

**MED**
Parameters defined in this section are applied to medium performance class users.

**HIGH**
Parameters defined in this section are applied to high-performance class users.

**LOCKING**
Parameters defined in this section are applied to LOCKING=YES users.

Consider the following example:
User Bob belongs to the low-performance class. User Tom belongs to the medium performance class. User Mary belongs to the high-performance class. If you wanted to assign different server values to low, medium, and high users, you would define the following entities in the spdsserv.parm file:

```
SORTSIZE=256M;
BINBUFSIZE=32K;
MAXWHTHREADS=4;
WORKPATH="/var/tmp";
---MED---
SORTSIZE=512M;
MAXWHTHREADS=6;
---HIGH---
SORTSIZE=1G;
MAXWHTHREADS=6;
WORKPATH="/var/hightmp";
```

In the spdsserv.parm file, all low users receive the initial LOW (default) values for SORTSIZE=, BINBUFSIZE=, MAXWHTHREADS=, and WORKPATH=. Medium users inherit the LOW values, with the exceptions of the SORTSIZE= setting, which has a value of 256 MB, and the MAXWHTHREADS= setting, which has a value of 6. High users inherit the LOW values, with the following exceptions: the SORTSIZE= setting,
which has a value of 1 GB, the MAXWHTHREADS= setting, which has a value of 6, and the WORKPATH= setting, which has a value of /var/hightmp. All initial values are inherited from the LOW setting. Users who are set to HIGH do not inherit any parameter settings from MEDIUM users. Therefore, you must specify MAXWHTHREADS=6 for users who are set to HIGH or MED.

The LOCKING=YES value is a special user case. All users share the same SPD Server locking proxy. For LOCKING=YES, all users inherit the LOW values in the spdsserv.parm file, regardless of performance class. You can use the following code to override the parameter values for all users of the locking proxy.

```
SORTSIZE=256M;
BINBUFSIZE=32K;
MAXWHTHREADS=4;
WORKPATH="/var/tmp";
---MED---
SORTSIZE=512M;
MAXWHTHREADS=6;
---HIGH---
SORTSIZE=1G;
MAXWHTHREADS=8;
WORKPATH="/var/hightmp";
---LOCKING---
MAXWHTHREADS=2;
```

In this example, all LOCKING=YES users inherit the initial default parameter values, with the exception of the initial MAXWHTHREADS=4 setting, which changes to MAXWHTHREADS=2.

### SPD Server Parameter File Options

#### BINBUFSIZE=

BINBUFSIZE= specifies the amount of memory to allocate for each bin buffer during a sort operation. During the sorting process, SPD Server writes blocks of sorted rows (called spill bins) to disk. The final step of the process reads the contents of the spill bins to perform final row ordering. BINBUFSIZE= specifies the amount of memory that is allocated to each spill bin during final row ordering. The spill bins use the memory buffer to read rows back into memory during interleaving.

The number of spill bins depends on the size of the table, the amount of memory specified on SORTSIZE=, and the number of threads that SPD Server uses to perform sorting. For example, if you sort a 10 GB table using two concurrent threads, and SORTSIZE=2 GB, the SORTSIZE= value is divided between the two concurrent threads. Each thread reads 1 GB of row data from the table into memory. In this case, each 1 GB block of row data comprises a spill bin. The rows in the spill bin are sorted and then written to disk. After all of the rows in the table have been sorted and written to disk, the sorting process reads the spill bins back into memory for final processing. In the example, a total of 10 spill bins and 10 buffer areas interleave the sorted rows.

#### Usage:

```
BINBUFSIZE= <bin-buffer-size> ;
```
**Note:** If you specify a value that is smaller than the record length of the spill bin, a bin buffer large enough to hold one record is created automatically.

**FMTDOMAIN=**

FMTDOMAIN= specifies the domain where the user-defined format is stored. To use formats that are user-defined, create a domain that is named FORMATS. Use FMTDOMAIN= with FMTNAMENODE= and FMTNAMEPORT=.

**Usage:**

```
FMTDOMAIN=FORMATS ;
```

**FMTNAMENODE=**

specifies the server on which the user-defined formats are stored. Use FMTNAMENODE= with FMTDOMAIN= and FMTNAMEPORT=.

**Usage:**

```
FMTNAMENODE=d8488 ;
```

**FMTNAMEPORT=**

specifies the port number of the server on which the user-defined formats are stored. Use FMTNAMEPORT= with FMTDOMAIN= and FMTNAMENODE=.

**Usage:**

```
FMTNAMEPORT=5400 ;
```

**GRPBYROWCACHE=**

specifies the maximum number of memory threads that are used during parallel group aggregations. The parallel group SELECT statement uses multiple threads up to the MAXWHTHREADS= limit to perform parallel group aggregations. The threads equally share the memory that is specified on GRPBYROWCACHE to cache groups in memory; each thread receives 1/MAXWHTHREADS= of the cache.

When a thread accumulates enough distinct groups to fill its cache, the groups are moved to secondary bins. At the completion of the parallel BY-group processing, the parallel group aggregations in memory and in secondary bins are merged to produce the final sorted results. If you omit the GRPBYROWCACHE option, the default value is a 2-megabyte cache per thread. You can improve aggregation performance with large numbers of groups by increasing the default value. However, you can potentially allocate more memory than is needed for caching, which diminishes the resources that are available for processing by the excess amount of assigned memory.

**Usage:**

```
GRPBYROWCACHE= <memory-cache-size> ;
```
**IDLE_TIMEOUT=**

specifies the interval of idle time that lapses before the SPD Server client process automatically terminates the client connection. When IDLE_TIMEOUT= is greater than 0, the option is enabled. If the value is less than or equal to 0, SPD Server does not enable idle timeouts. The default value is 0.

Usage:

```
IDLE_TIMEOUT= <timeout_seconds> ;
```

**INDEX_MAXMEMORY=**

restricts the amount of memory that is allocated for each open index. This option affects Read operations on SPD Server tables.

Usage:

```
INDEX_MAXMEMORY= <maximum-allocated-index-memory> ;
```

**INDEX_SORTSIZE=**

controls the amount of memory that is allocated for creating asynchronous (parallel) sort indexes or appends. This value is divided by the number \( n \) of indexes that are to be created or appended in parallel; each index receives \( 1/n \)th of the allocated memory.

Usage:

```
INDEX_SORTSIZE= <allocated-async-sort-index-memory> ;
```

**LDAPSERVER=**

specifies the network IP address or the host machine for the LDAP server. This value is usually the same as the IP address of the SPD Server host, which is the default value.

Usage:

```
LDAPSERVER= <ldap_server_host_ip> <LDAP-Server-IP-address-or-LDAP-Server-name> ;
```

**LDAPPORT=**

specifies the TCP/IP port that is used to communicate with the LDAP server. The default value is LOCAL_HOST or port 389.

Usage:

```
LDAPPORT= <ldap_server_tcpi_port_number> <port-number-or-port-name> ;
```

**LDAPBINDMETH=**

indicates the LDAP authentication security level. The default value is LDAP_AUTH_SASL. The Simple Authentication and Security Layer (SASL) performs LDAP_AUTH_SASL and SPD Server user authentication using Digest-MD5.

Usage:
LDAPBINDMETH=LDAP_SERVER_BINDMETH_STRING <LDAP-bind-method-string> ;

**LDAPBINDDN=**

specifies the relative distinguished name (RDN) or the location in the LDAP server database where the information for the connecting client is stored. You can obtain RDN strings from the LDAP server administrator when you are configuring the SPD Server to use LDAP authentication.

**Usage:**

LDAPBINDDN=ldap_server_binddn_string <RDN-string> ;

**MAXGENNUM=**

specifies the maximum number of member tables that can be created in an SPD Server cluster table.

**Usage:**

MAXGENNUM= <maximum-number-of-member-tables> ;

**MAXMEMORYSIZE=**

specifies the maximum amount of memory that can be used by an SPDSBASE process. All server parameter memory size options are constrained by MAXMEMORYSIZE=.

**Usage:**

MAXMEMORYSIZE= <memory-size> ;

**Default:**

If MAXMEMORYSIZE= is not defined in the server parameter file, the default setting is an unlimited size.

**Example:**

The following statement specifies that a maximum of 4 gigabytes of memory can be dedicated to an SPDSBASE process.

MAXMEMORYSIZE= 4G ;

**MAXSEGRATIO=**

controls segment candidate pre-evaluation for WHERE clause predicates with a hybrid index. The WHERE clause planner pre-evaluates the segment candidates for the predicate. Only the segment candidates are searched to resolve the WHERE clause. Some queries can benefit from not performing pre-evaluation, based on the ratio of the number of segments that contain candidates to the total number of segments in the file. If the percentage of possible segments exceeds MAXSEGRATIO=, pre-evaluation is not performed and all of the segments are searched to resolve the WHERE clause. If you omit this value, the default value is 75%.

**Usage:**

MAXSEGRATIO= <maximum-ratio-of-segment-candidates-to-segments> ;
**MAXSORTTHREADS=**
specifies the number of parallel threads to create for a parallel sort operation. Threading for sorting data in parallel is a resource-intensive process that behaves differently from threaded processing. Use caution when you assign a value for MAXSORTTHREADS=.
If a parallel sort uses one thread for every CPU on the server, the sort job might starve other jobs of resources. For better performance during parallel sort operations, configure values for SORTSIZE= (in MB) and MAXSORTTHREADS= (in number of threads) so that the ratio of SORTSIZE= to MAXSORTTHREADS= is between 256 MB per thread and 1 GB per thread.

Use MAXSORTTHREADS= with MAXWHTHREADS= to balance your system load. Parallel sorting can be a resource-intensive process, and parallel WHERE processing tends to be more I/O intensive. In most cases, parallel WHERE processing tasks require more threads than parallel sorting tasks. If you omit this value, SPD Server assigns the value of MAXWHTHREADS= to MAXSORTTHREADS=.

**Usage:**

```
MAXSORTTHREADS= <maximum-number-of-parallel-sort-threads> ;
```

**MAXWHTHREADS=**
specifies the number of parallel threads to launch for a WHERE clause evaluation.

**Usage:**

```
MAXWHTHREADS= <maximum-number-of-parallel-threads> ;
```

**MINPARTSIZE=**
ensures that large SPD Server tables cannot be created with an arbitrarily small partition size. Large SPD Server tables with small partition sizes create an excessive number of physical files, which increases clutter and degrades I/O performance. The default MINPARTSIZE= value is 16 MB, unless you are creating tables in a HADOOP=YES LIBNAME. If you are using a Hadoop domain, the minimum MINPARTSIZE= is 128 MB. The most common values for the MINPARTSIZE parameter are in the range 128 MB–256 MB.

The MINPARTSIZE= server option does not affect Hadoop tables unless the value is greater than or equal to 128 MB.

**Usage:**

```
MINPARTSIZE= <minimum-partition-size> ;
```

**MINPORTNO= and MAXPORTNO=**
specifies a range of port numbers that can the SPD Server user proxy processes can use to communicate with the client. You must set both the MINPORTNO= and the MAXPORTNO= option. This option supports the use of SPD Server ports through an Internet firewall, in order to limit the range of ports that are used by the server. If you omit MINPORTNO= and MAXPORTNO=, then the SPD Server user proxy processes use any port that is available to communicate with the client.

**Usage:**

```
MINPORTNO= and MAXPORTNO= ;
```
MINPORTNO=<lower-port-range-number> ;
MAXPORTNO= <upper-port-range-number> ;

[NO]BYINDEX

controls whether to use an index for a BY sort. The default value is NOBYINDEX, which indicates that an index is not used. The [NO]BYINDEX server parameter is used only when the SPDSNBIX= macro is set to NO (the default value).

Usage:
BYINDEX ; NOBYINDEX ;

[NO]COREFILE

controls whether the LIBNAME proxy creates a core file when an unexpected process trap occurs. The default value is NOCOREFILE.

Usage:
COREFILE ; NOCOREFILE ;

[NO]LDAP

turns SPD Server LDAP user authentication on or off. If the LDAP option is found or set during SPD Server start-up, then the SPD Server host creates a context for LDAP user authentication.

Usage:
LDAP ; NOLDAP;

RANDOMPLACEDPF

invokes random placement of the initial data partition for all tables in a domain. The random placement strategy manages large tables efficiently and balances data loads without losing disk space. RANDOMPLACEDPF is enabled by default. To disable RANDOMPLACEDPF in SPD Server 5.1, include a NORANDOMPLACEDPF statement in your spdsserv.parm file.

Usage:
RANDOMPLACEDPF;

RANIOBUFMIN=

specifies the minimum random I/O buffer size. This value becomes the minimum I/O buffer size that is used by the proxy when it performs random I/O and table requests.

Usage:
RANIOBUFMIN= <minimum-random-i/o-buffer-size> ;
[NO]REVNUMUPDATE

controls whether the revision number is updated on SPD Server table component files. The default value is NOREVNUMUPDATE. The default setting suppresses revision number updates to component files when a table is modified so that the DPF and INDEX file components of an SPD Server table will not change the component filenames. There is a performance benefit in not updating revision numbers, particularly if the table contains a large number of DPF partitions, or if dynamic locking is used while performing table updates. There is also a benefit for backup and restore: the DPF partitions do not change names, and the last modified date on the file changes only if the DPF file was physically modified. Previous versions of SPD Server used REVNUMUPDATE as a default setting. If an SPD Server user has been using the revision number to track backup and restore versions, the REVNUMUPDATE setting can still be used.

Usage:

REVNUMUPDATE ;NOREVNUMUPDATE ;

SEQIOBUFMIN=

specifies the minimum sequential I/O buffer size. This value becomes the minimum I/O buffer size that is used by the proxy when it performs sequential I/O and table requests.

Usage:

SEQIOBUFMIN= <minimum-sequential-i/o-buffer-size> ;

SHRUSRPRXY=

enables enhanced sharing of user proxies. Enhanced SPD Server proxy sharing enables users with different SPD Server user and group credentials to use the same proxy. Enhanced user proxy sharing keeps the number of concurrent SPDSBASE process resources from growing too large. A large number of concurrent SPDSBASE processes can create system resource allocation issues in some SPD Server environments.

The SHRUSRPRXY= server parameter file option defines the default behavior for enhanced user proxy sharing. This option setting can be overridden by the SHARE= sasspds engine LIBNAME option.

Syntax

SHRUSRPRXY=[YES|NO]

Default

The default setting for the SHRUSRPRXY= parameter file option is YES.

SORTSIZE=

controls the amount of memory to allocate for sort operations. During parallel sort operations, the memory that SORTSIZE= allocates is divided evenly among the sort threads. For best results, specify SORTSIZE= values in the range 256 MB–1 GB per parallel sort thread, or between 256 * MAXSORTTHREADS= and 1 GB * MAXSORTTHREADS=.

Usage:
SORTSIZE= <memory-allocated-for-sort-operations> ;

**STARSIZE=**

controls the amount of memory to allocate for STARJOIN operations. During STARJOIN operations, the temporary results of Phase 1 of the IN-SET STARJOIN strategy are cached in memory for use by Phase 2 if there is sufficient STARSIZE= memory. Caching Phase 1 temporary results can result in significant performance improvements for STARJOIN. If you omit STARSIZE=, STARJOIN uses the SORTSIZE= option to determine the memory to use for Phase 1 caching.

**Usage:**

STARSIZE= <memory-allocated-for-STARPJOIN-operations> ;

SQLOPTS= overrides SQL default options for each SQL connect when you use the SQLOPTS= statement with an SQL RESET command. If you omit SQLOPTS=, SQL default options apply. See the For more information about SPD Server SQL RESET options, see “Specifying SPD Server SQL Planner Options” in Chapter 7 of SAS Scalable Performance Data Server: User's Guide.

**Usage:**

SQLOPTS= "RESET <SQL-option> [ <SQL-option>]" ;

**TMPDOMAIN=**

specifies an SPD Server domain that is defined in the SPD Server LIBNAME parameter file. The SQL Query Rewrite facility uses the domain specified in TMPDOMAIN= to store intermediate tables.

SPD Server administrators and users can specify LIBNAME domains for SQL Query Rewrite facility intermediate results storage. Administrators can use the TMPDOMAIN= parameter in the spdsserv.parm file to specify the SQL Query Rewrite facility intermediate results storage domain.

For more detailed information about TMPDOMAIN= and the SQL query rewrite facility, see “Configuring Storage Space for the SQL Query Rewrite Facility” on page 63.

**Usage:**

TMPDOMAIN=<Domain-Name>;

**Example:**

... LIBNAME=qrw pathname=/IDX1/spdsmgr/spds45_sasdqh/qrw ;
...
TMPDOMAIN=qrw ;

**Note:** If the SPD Server parameter TMPDOMAIN is not configured and the SQL query rewrite is enabled, the query rewrite fails with the following error: SPDS_ERROR: Error materializing RWE context.
**[NO]WHERECOSTING**

controls whether to use dynamic WHERE costing. The default value is NOWHERECOSTING. When dynamic WHERE costing is not enabled, SPD Server uses the rules-based heuristic WHINIT.

**Usage:**

```
WHERECOSTING ;
NOWHERECOSTING ;
```

**WORKPATH=**

specifies the LIBNAME proxy path for work files. If you think that the work files might overflow a single file system, you can specify multiple paths. When you specify multiple paths, enclose the complete path statement in double quotation marks.

**Usage:**

```
WORKPATH= "('DirPath1' 'DirPath2' ...)";
```

---

**SPD Server Parameter File Configurations for SAS Metadata Server Authentication**

SPD Server 5.2 features several new options for performing user authentication through the SAS Metadata Server. For more detailed information about nonnative authentication strategies, see “Configuring SPD Server for SAS Metadata Server Authentication” on page 175.

**[NO]METAAUTHENTIC**

Specifies whether SPD Server should use the SAS Metadata Server to provide user authentication. The back-end authentication provider is whatever the SAS Metadata Server was configured for. NOMETAAUTHENTIC is the default setting.

**Syntax**

```
METAAUTHENTIC ;
```

**Description**

When in the default setting of NOMETAAUTHENTIC, an internal account (native to SPD Server) is used for authentication. When METAAUTHENTIC is specified, SAS Metadata Server will provide user authentication via the back-end authentication provider that it was configured to use.

**Note:** If you specify any META* option in your SPD Server server parameter file, then SPD Server assumes an authentication setting of METAAUTHENTIC.

**METASERVER=**

Specifies the name of the host that the SAS Metadata Server is running on.

**Syntax**
METASERVER=SAS-Metadata-Server-hostname

**Description**
Provides the name of the host that the SAS Metadata Server resides on. If SAS Metadata Server authentication is configured, but METASERVER= is not specified, then SPD Server assigns a default value of METASERVER=localhost. An option value of localhost indicates that the SAS Metadata Server is running on the same host as the SPD Server.

**METAPORT=**

Specifies the port number of the SAS Metadata Server.

**Syntax**
METAPORT=SAS-Metadata-Server-port-number

**Description**
Identifies the port number of the SAS Metadata Server. If SAS Metadata Server authentication is configured, but no METAPORT= value is specified, then SPD Server assigns a default value of METAPORT=8561.

**METADOMAIN=**

Specifies the domain where the back-end authenticator resides.

**Syntax**
METADOMAIN=domain-name

**Description**
The domain name, if needed, for the back-end authenticator used by the SAS Metadata Server. No domain will be used if this option is not specified.

**Examples of SPD Server Authentication Options**
The simplest way to use SAS Metadata Server authentication is to add METAAUTHENTIC to the server parameter file. The value for METASERVER= will default to localhost and the value for METAPORT= will default to 8561. localhost selects the host that SPD Server server runs on.

Both examples below will configure SPD Server to use SAS Metadata Server for authentication:

**Example using default values for METASERVER= and METAPORT=**
METAAUTHENTIC;

**Example using option values for METASERVER= and METAPORT=**
METASERVER=lax94d01;
METAPORT=8561;

Either of the options declared above implies METAAUTHENTIC to SPD Server.
SPD Server Parameter File Configurations for LDAP

There are five possible SPD Server parameter file configurations for LDAP:

- **Configuration 1**: LDAP Server that is running on an SPD Server host

  For this configuration, assume that all other LDAP settings use the default configuration. To run an LDAP server on the SPD Server host, add the LDAP option to your SPD Server parameter file. User authentication is performed by the LDAP server, which is running on the port LOCAL_HOST on the SPD Server host.

- **Configuration 2**: LDAP Server that is running on an SPD Server Host using a port other than LOCAL_HOST

  For this configuration, assume that all other LDAP settings use the default configuration. Also assume that you want to perform LDAP user authentication on the LDAP server. To run an LDAP server on the SPD Server host by using a port assignment other than LOCAL_HOST, add the LDAP option and the LDAPPORT= port specification to your SPD Server parameter file.

- **Configuration 3**: LDAP Server and SPD Server host that are running on different machines

  For this configuration, assume that you want to perform LDAP user authentication, but the LDAP server and the SPD Server hosts are on different machines. To run an LDAP server and the SPD Server hosts on different machines, add the LDAP option and the LDAPSERVER= specification (such as `<host.domain.company.com>`) to your SPD Server parameter file. An LDAP user is authenticated when the LDAP server is running at port LOCAL_HOST on host.domain.company.com.

- **Configuration 4**: SPD Server user IDs and passwords that are not in their default location in the LDAP database

  For this configuration, assume that you want to perform LDAP user authentication, but the SPD Server user IDs and passwords are not in their default locations in the LDAP database. Assume that all other LDAP settings use the default configuration. Add the LDAP option and the LDAPBINDDN= specification. The LDAPBINDDN= property setting is ou=people, dc=domain, dc=company, dc=com. An LDAP user is authenticated when the LDAP server is running at port LOCAL_HOST on the SPD Server host machine. The LDAP server looks for SPD Server users at the location that corresponds to ou=people, dc=domain, dc=company, dc=com in its database.

- **Configuration 5**: SPD Server user IDs and passwords that are not in their default location in the LDAP database and in the LDAP Server that is using TCPIP_PORT

  For this configuration, assume the following: You want to perform LDAP user authentication. The SPD Server user IDs and passwords are located at ou=people, dc=domain, dc=company, dc=com in the LDAP database, and the LDAP server is using the port TCPIP_PORT. Add the LDAP option and set the LDAPPORT= port specification to TCPIP_PORT in your SPD Server parameter file. Next, add the LDAPBINDDN= specification. The LDAPBINDDN= property setting is ou=people, dc=domain, dc=company, dc=com. A user is authenticated when the LDAP server is running at port TCPIP_PORT on the SPD Server host machine. The LDAP server looks for SPD Server users at the location that corresponds to ou=people, dc=domain, dc=company, dc=com in its database.
SPD Server Parameter File Validation

The SPD Server parameter file is validated during a system start-up, and when refreshed by the PROC SPDO REFRESH PARMS command. For more information about the REFRESH PARMS command, see REFRESH PARMS “Overview of the REFRESH Command” on page 215. Any errors in the server parameter file at start-up will cause the SPD Server program start to fail. Errors are reported in the SPD Server log file.

Errors that occur during the server parameter file refresh will cause the refresh to fail, and the server will maintain the most recent parameter file settings. PROC SPDO refresh parameter errors are reported in the SAS log and in the SPD Server log file.

Pathname Substitution

You can use the keyword @HOSTNAME@ in your SPD Server parameter file WORKPATH= option to substitute the short host name in the workpath.

Usage:

workpath= /work/@HOSTNAME@ ;

Pathname substitution enables you to use the same parameter file on different hosts, when each host requires its own workspace area.

SPD Server Parameter File Configurations for Auditing

[NO]WHEREAUDIT

Enables audit logs for WHERE clauses that are submitted to SPD Server. Specify the WHEREAUDIT option in the spdsserv.parm file to enable the audit logs. The spdslog message logger logs messages, and the spdsaud audit logger logs audits. If you use the WHEREAUDIT option, both the spdslog log file and the spdsaud log file contain WHERE statement information.

Usage:

WHEREAUDIT;

NOWHEREAUDIT;

The WHEREAUDIT option enables audit logging for the server. It also enables automatic audit log file creation by spdsaud. The file specification is a partial pathname or filename that is used to generate the complete audit filename. For example, if your file specification is /audit/spds, the generated filename is /audit/spds_mmddyyyy.spdsaudit. In the output, mmddyyyy is the system date when the audit log file was created.
SQLAUDLEN=

Specifies the maximum size of the SQL statement in the audit log when the following conditions are both true: proxy auditing is enabled in SPD Server, and the WHEREAUDIT option is specified.

Usage:

SQLAUDLEN=<maximum-number-of-characters-in-SQL-statement>

The default value for SQLAUDLEN is 1,024 characters. The maximum value is 4,096 characters.

WHAUDLEN=

Specifies the maximum size of the WHERE clause in the audit log when the following conditions are both true: proxy auditing is enabled in SPD Server and the WHEREAUDIT option is specified.

Usage:

WHAUDLEN=<maximum-number-of-characters-in-WHERE-clause>

The default value for WHAUDLEN is 512 characters. The maximum value is 4,096 characters.
Overview of the LIBNAME Parameter File

When SPD Server starts, it reads the information stored in the LIBNAME parameter (libnames.parm) file. The LIBNAME parameter file establishes the names and file storage locations of SPD Server domains during the server session. SPD Server
administrators can use the LIBNAME parameter file as a central tool to control SPD Server domain resources and user access to SPD Server domains.

Domain Naming Syntax for LIBNAME Parameter Files

To define an SPD Server domain in the LIBNAME parameter file, you must define the domain as a LIBNAME and define the path that points to the directory in which data files for the domain are stored.

```
LIBNAME=domain-name PATHNAME=primary-metadata-path
   <optional specifications>
       OWNER=owner-id
       LIBACLINHERIT=<YES/NO>
       DYNLOCK=<YES/NO>
       BACKUP=<YES/NO> ;
```

The domain name that is associated with the LIBNAME must follow standard SAS LIBNAME nomenclature rules. The PATHNAME= specification defines the computing path that contains the metadata tables that are associated with the domain. By default, the PATHNAME= specification also contains the data tables, index tables, and intermediate tables that the domain creates. SPD Server administrators and users can use the options described in “LIBNAME Domain Path Options” on page 88 to enhance computational performance by specifying separate paths for domain data, index, and work tables. All SPD Server domain names must be unique. Different SPD Server domains should never share the same domain path.

Here are some examples of simple LIBNAME parameter file domain declarations:

```
LIBNAME=spds123 PATHNAME=c:\data\spds123;
LIBNAME=123spds PATHNAME=c:\data\123spds;
LIBNAME=_under PATHNAME=c:\data\_under;
LIBNAME=under_ PATHNAME=c:\data\under_;
```

The LIBNAME parameter file is the preferred method to declare domains for use in SPD Server. Users can connect to domains by submitting SAS code to SPD Server after a session has started. The following example SAS code connects to the first domain in the previous example:

```
LIBNAME spds123 sasspds 'spds123'
server=d8488.5200
user='anonymous';
```

LIBNAME Domain Path Options

You can specify optional path parameters for a domain in LIBNAME parameter libref statements. You specify these optional path parameters using either standard option statements or using reserved option statements. The difference between non-reserved
and reserved option statements is that non-reserved option statements can be altered by subsequent libref statements that are submitted to SPD Server with SAS code.

Use the following syntax to specify optional path parameters in the LIBNAME parameter file for ROPTIONS:

```
LIBNAME=domain-name
PATHNAME=primary-metadata-path
ROPTIONS="DATAPATH=('data-path_1' 'data-path_2' ... 'data-path_n')
INDEXPATH=('index-path_1' 'index-path_2' ... 'data-path_n')
WORKPATH=('work-path_1' 'work-path_2' ... 'work-path_n')
METAPATH=('meta-path_1' 'meta-path_2' ... 'meta-path_n')";
```

**DATAPATH=** specifies a list of paths that contain SPD Server data tables that are associated with the declared domain. You use ROPTIONS to specify DATAPATH=.

**Usage:**

```
DATAPATH=('/data1/spds123' 
  '/data2/spds123' 
  '/data3/spds123' 
  '/data4/spds123')
```

**INDEXPATH=** specifies a list of paths that contain SPD Server index tables that are associated with the declared domain. You use ROPTIONS to specify INDEXPATH=.

**Usage:**

```
INDEXPATH=('/idx1/spds123' 
  '/idx2/spds123' 
  '/idx3/spds123' 
  '/idx4/spds123')
```

**WORKPATH=** specifies a list of paths that contain temporary SPD Server work tables and temporary SPD Server intermediate files that are associated with the declared domain. You use ROPTIONS to specify WORKPATH=.

**Usage:**

```
WORKPATH=('/work1/spds123' 
  '/work2/spds123' 
  '/work3/spds123' 
  '/work4/spds123')
```

**METAPATH=** specifies a list of paths that are allocated to contain overflow SPD Server metadata if the designated metadata space that is allocated in the PATHNAME= option statement becomes full. The additional metapaths provide a buffer space that can be used for Update and Append operations to existing SPD Server tables.

When the primary metadata space that is defined by the PATHNAME= option is full, new tables cannot be added to the domain. Put the primary path on a file system that is expandable and mirrored. As a conservative estimate for space, plan for 20 gigabytes of metadata for every terabyte of compressed physical data.

You can use OPTIONS or ROPTIONS to specify METAPATH=.

**Usage:**
Path Substitution

You can use the keyword @HOSTNAME@ in your LIBNAME parameter primary path or OPTIONS= path to substitute the short host name in the path. Path substitution is useful when SPD Server is installed on a shared file system, accessible by multiple hosts, in which each host is running its own image of SPD Server. Path substitution enables each host to share the same LIBNAME parameter file, but substitutes the unique pathnames that each host requires.

LIBNAME host_specific= /data/@HOSTNAME@;

Verification of LIBNAME Parameter Files

The LIBNAME parameter file is verified on system start-up and when the system is refreshed. The validation includes syntax checking and path validation. LIBNAME parameter file syntax error messages are displayed in the SPD Server log.

Path validation verifies that the specified path exists. Path validation errors are reported in the SPD Server log.

If errors are detected in the LIBNAME parameter file during SPD Server start-up, the session is not launched. If errors are detected in the LIBNAME parameter file during a refresh, the refresh is canceled and the previous LIBNAME parameter definitions are used.

Domain Access Options

A domain is an SPD Server resource that enables you to access and manipulate SPD Server tables, views, and so on. When you issue a libref statement to create a domain for SPD Server, you can use the following optional specifications to control the accessibility of resources among other SPD Server users.

LIBNAME access to the OWNER= domain controls Read or Write access to the domain. LIBNAME access to the OWNER= domain does not grant access to the objects in the domain. Once the LIBNAME is established, normal SPD Server ACL access rules are used to grant or deny access to the objects in the domain.

OWNER=

specifies the owner of a domain. The SPD Server owner controls LIBNAME access to the domain. The domain owner can create a LIBNAME ACL on the domain to grant or deny LIBNAME access to other SPD Server users. When the domain is specified with an owner, only the owner can use the TEMP=YES LIBNAME option with the domain.

Note: The owner can use LIBNAME ACL to grant the following access levels:
Read access to allow a user or group to get a LIBNAME to the domain to read SPD Server tables that the user or group has access to

Write access to allow a user or group to create new objects in the domain

Control access to allow a user or group to modify the owner’s LIBNAME ACL

**Usage:**

**OWNER=**<owner-id>

**LIBACLINHERIT=** controls the ACL precedence of permission checks. For more information about the LIBACLINHERIT= domain access option and its use, see “Controlling the Precedence of Permission Checks with the LIBACLINHERIT= Option and the OWNER= Option” on page 91.

**DYNLOCK=** specifies whether dynamic locking is enabled. If you omit the DYNLOCK= option, the default SPD Server setting is NO. For more information about dynamic locking, see “Dynamic Locking” on page 94.

**Usage:**

**DYNLOCK=**<YES/NO>

**BACKUP=** controls whether the objects in the domain can be backed up or restored using the SPD Server Backup and Restore utilities. For more information about back up and restore utilities, see Chapter 25, “SAS Scalable Performance Data (SPD) Server Backup and Restore Utilities ,” on page 234.

**Usage:**

**BACKUP=**<YES/NO>

---

**Controlling the Precedence of Permission Checks with the LIBACLINHERIT= Option and the OWNER= Option**

Precedence of permission checks for a LIBACLINHERIT=YES OWNER= domain can include inheriting the permissions of the LIBNAME ACL of the user for resources that are owned by the domain owner. This allows the domain owner to create domain resources that other users can access via LIBNAME ACLs, without having to create user or group ACLs for those resources.

When a user attempts to access resources in a LIBACLINHERIT=YES OWNER=<domain-name>, the following ACL precedence of permission checks are made on the resource:

1. If user-specific ACLs are defined on the object for the user, the user gets these permissions.

2. If group-specific ACLs are defined on the object for the user’s group, the user gets these permissions.
3. If LIBNAME ACL permissions are defined for the user and the resource belongs to the OWNER= of the domain, then the user gets the domain LIBNAME ACL permissions on the object.

4. If LIBNAME ACL permissions are defined for the user’s group and the user is a member of the OWNER= group of the domain, then the user gets the LIBNAME ACL group permissions on the object.

5. If universal ACLs are defined on the object for the user, the user gets the universal ACL permissions.

An OWNER=<owner-name> LIBACLINHERIT=YES domain statement uses a slightly different methodology. When the owner specifies the OWNER= parameter with LIBACLINHERIT=YES, the owner can grant the following access levels:

- Read access to allow a user or group to get a LIBNAME to the domain
- Alter access to allow a user or group to create new objects in the domain
- Control access to allow a user or group to modify the owner's LIBNAME ACL

The owner can use Alter access with OWNER= and LIBACLINHERIT=YES to allow a user or group to create a new resource in the domain. Alter access is sometimes preferable to Write access for an OWNER= domain. Alter access prevents users or groups that inherit Write access from writing to, updating, or deleting resources that were created by the domain owner. When the owner uses LIBNAME Alter access with OWNER= and LIBACLINHERIT=YES, the owner can grant privileges to users to create objects in the domain. The owner can use Write access to inherit Write access to the owner's resources.

The following example shows SAS code submitted to SPD Server using LIBACLINHERIT. The example begins with information in the LIBNAME parameter file where domain names and paths are declared.

Contents of the LIBNAME parameter file:

```
LIBNAME=libinher
PATHNAME=/IDX1/spdsmgr/spds45test/libinher
LIBACLINHERIT=YES
OWNER=admin ;

LIBNAME=noinher
PATHNAME=/IDX1/spdsmgr/spds45test/noinher
OWNER=admin ;
```

SAS code submitted to SPD Server by the user:

```
LIBNAME libinher saspsds 'libinher'
   server=gomez.5129
   user='admin'
   password='spds123' ;

LIBNAME noinher saspsds 'noinher'
   server=gomez.5129
   user='admin'
   password='spds123' ;

data libinher.admins_table
   noinher.admins_table ;
   do i = 1 to 10 ;
     output ;
```
Controlling the Precedence of Permission Checks with the LIBACLINHERIT= Option and the OWNER= Option

LIBNAME a_inher sasspds 'libinher'  
server=gomez.5129  
user='anonymous' ;

LIBNAME a_noher sasspds 'noinher'  
server=gomez.5129  
user='anonymous' ;
PROC PRINT data=a_inher.admins_table;
  title 'with libaclinher';
run;

PROC PRINT data=a_noher.admins_table;
  title 'without libaclinher'
run;

Dynamic Locking

Overview of Dynamic Locking

Dynamic locking is an SPD Server feature that gives multiple users concurrent access to SPD Server tables. Multiple users can perform read and write functions (insert, append, delete, and update), and the integrity of the table contents is preserved.

Dynamic locking is enabled or disabled at the domain level. All tables that are stored within the domain are subject to the setting of the dynamic locking feature. The DYNLOCK= statement should be used in LIBNAME parameter file domain declarations.

Dynamic locking is different from SPD Server record-level locking. Clients that use dynamic locking connect to a separate SPD user proxy process for each LIBNAME connection in the domain. In SPD Server record-level locking, all clients share the same record-level locking proxy process.

Benefits of Using Dynamic Locking

SPD Server uses the dynamic locking feature to alleviate some of the problems and limitations that occur with record-level locking. The dynamic locking method of using separate proxy processes instead of a single record-level proxy distributes resource allocations, which decreases the probability of a single proxy process reaching resource limits. Dynamic locking also removes a single record-level locking point of failure for the record-level proxy. If there is a failure in an SPD Server user proxy when dynamic locking is being used, only the client that is connected to that proxy is affected. If there is a failure in an SPD Server record-level proxy, then all client connections are affected.

Dynamic locking can also provide better performance than record-level locking. Dynamic locking has performance advantages over record-level locking when concurrent READ and WRITE access to a table is required. This advantage is due to the more distributed processing and parallelism that occurs when multiple SPD Server user proxies are used. The performance benefit depends on the opportunities for parallelism, and you should quantify the benefit on a case-by-case basis.

How Dynamic Locking Works

To use dynamic locking, SPD Server tables must be part of a named SPD Server domain. When dynamic locking is enabled for a domain, all of the SPD Server users that access tables in that domain automatically use dynamic locking. The SPD Server clients do not need to set any additional parameters to take advantage of the benefits of dynamic locking.
When SPD Server proxy processes receive concurrent Update, Append, Insert, and Delete commands, the commands are sequentially queued and then executed in order of arrival. Only one Update operation is performed on a table at any one time. Read requests can be executed at any point during an Update operation. Read requests get the most recent information that is available in the table, based on the last physical update to disk.

Dynamic locking is not a replacement for using record-level locking when the user requires SAS record-level integrity across multiple clients. Reading a record using dynamic locking does not guarantee that the record will not change before a subsequent read or update is executed. If a client needs a true record-level lock, then the record-level locking protocol should be used.

Note: A domain that has dynamic locking enabled cannot also use record-level locking.

Organizing Domains for Scalability

Overview of Organizing Domains

SPD Server performance is based on scalable I/O. To exploit scalable I/O, you can use the LIBNAME parameter file to optimize how SPD Server stores files. “Domain Access Options” on page 90 describes how to specify named paths for the three data components of SPD Server tables (observation data tables, index data tables, and metadata tables), and how to specify paths for temporary intermediate calculation tables. LIBNAME domain declaration statements can specify the system paths that are associated with each table space component. However, you must allocate the correct amount of disk space and I/O redundancy to the various paths.

This section provides functional information about the table spaces that are defined by the DATAPATH=, INDEXPATH=, WORKPATH=, and METAPATH= options of the LIBNAME domain declaration statements. Use this information to determine the best sizing, I/O, and redundancy requirements to optimize performance and scalability for named SPD Server domain paths.

Data Table Space

When you declare a domain in a LIBNAME statement, data tables are stored in the space that is defined in the PATHNAME= specification, unless you specify the DATAPATH= option. The PATHNAME= space contains metadata tables for a domain, but it can also contain data tables. As the size and complexity of a domain increase, so do the benefits of organizing data tables into their own DATAPATH= space.

Organizing your data table space significantly impacts I/O scalability. The disk space that is allocated to data tables stores permanent warehouse tables that users will access. This disk space should support scalable I/O because it facilitates both parallel processing and real-time multi-user access to the data. In a large warehouse, this disk space probably has the greatest proportion of Read and Write I/O.

Typically, you load and refresh tables in the data table space using batch processes during evenings or off-peak hours. You can restrict access to data table space to Read-Only access for all users except administrators who perform the load and refresh processes.
To ensure reliability, organize data table space into RAID 1+0 or RAID-5 disk configurations. For large warehouses, consider a RAID-5 configuration with a second storage array to mirror the data.

**Index Table Space**

When you declare a domain in a LIBNAME statement, index tables are stored in the space that is defined in the PATHNAME= specification, unless you specify the INDEXPATH= option. The PATHNAME= space contains metadata tables for a domain, but it can also contain index tables. As the size and complexity of a domain increase, so do the benefits of organizing index tables into their own INDEXPATH= space.

Index space typically does not require the high-level scalability that data space, temporary table space, or workspace needs for I/O performance. When a process is using an index, the Read access pattern is different from a parallel I/O Read access pattern of data, or multiple user Read access patterns against data.

Typically, you configure index space as a large striped file system across a large number of disks and I/O channels. A typical configuration such as RAID 1+0 or RAID 5 supports some redundancy to ensure the availability of index space.

**Metadata Table Space**

When you declare a domain in a LIBNAME statement, metadata tables are stored in the space that is defined in the PATHNAME= specification. If the space configured in PATHNAME= is full, SPD Server stores overflow metadata for existing tables in the space that is defined in the METAPATH= specification, if it is declared. The PATHNAME= and METAPATH= spaces contain metadata tables for a domain.

Compared to the other space categories, metadata space is relatively small and usually does not require scalability. If compressed data in a given warehouse uses 10 terabytes of disk space, then there are approximately 10 gigabytes of metadata. When you are setting up metadata space, plan to allot 20 gigabytes of metadata space for every 10 terabytes of physical data disk space. When new data paths are added to expand a server, you should add more metadata space within the primary path of the server. Even though the metadata requires only a small amount of space, the disk space must be expandable and mirrored. You also need to back up the metadata.

The metadata for a table becomes larger when rows in the table are marked as deleted. Bitmaps are stored in the metadata that is used to filter the deleted rows. The space required depends on the number of rows that were deleted and on their distribution within the table.

**SPD Server Workspaces**

You reserve a space for intermediate calculations and temporary files in statements that are in the body of the spdsserv.parm file. The workspace that you configure in spdsserv.parm is shared by all SPD Server users.

Some users have data needs that might be constrained by using the common intermediate calculation and file space that is reserved for all users. Use the LIBNAME parameter file to create and reserve a workspace that is specifically associated with a single domain and its approved users. Doing so can improve both security and performance. As the size and complexity of a domain increase, so do the benefits of organizing temporary and intermediate tables into their own workspace, defined by WORKPATH=.
A workspace is an area on disk that SPD Server software uses to store required files when the available CPU memory cannot contain the entire set of calculations. When sufficient memory is not available, some utility files are written to disk. Workspaces are important to scalability. Tasks such as large sorts, index creation, parallel group-by operations, and SQL joins can require dedicated workspace to store temporary utility files.

You typically configure a workspace as part of a large striped file system that spans as many disks and I/O channels as possible. Workspace I/O can critically impact the performance behavior of an SPD Server host.

Workspace on disk is typically a RAID 0 configuration or a hardware-redundant RAID design. RAID 0 configurations are risky because if the RAID 0 disk goes down, the system is also affected; any process that was running at the time of failure is also likely to be affected.

---

**Domains and Data Spaces**

**Overview of Domains and Data Spaces**

You can configure SPD Server to meet different data requirements. If you need different types of SPD Server domain space, you can use domain declarations in the LIBNAME parameter file to configure spaces that balance processing speed, space, and growth needs with data security requirements. Typically, SPD Server users use most or all of the types of table spaces. The type of queries and reports that the user makes can indicate the types of data space that the user needs. The following figure shows the three basic types of domain space.

<table>
<thead>
<tr>
<th>Production / Sales / Inventory Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shared Benchmark Data</td>
</tr>
</tbody>
</table>

**Permanent Table Space**

(Admin Controlled)

<table>
<thead>
<tr>
<th>Project-Based Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Development and Test Space</td>
</tr>
</tbody>
</table>

**Semi-Permanent Table Space**

<table>
<thead>
<tr>
<th>Intermediate Calculation Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Ad-Hoc Reporting</td>
</tr>
<tr>
<td>SQL Optimization Tables</td>
</tr>
</tbody>
</table>

**Temporary Space**

(User Session Controlled)

---

**Permanent Table Space**

In SPD Server, large production, inventory, and sales data storage areas work best using permanent table space. A rolling 5-year sales data table organized by division and
company is an example of an SPD Server structure that is most suitable for permanently allocated space on the enterprise computers. If you have this type of table, large quantities of production, inventory, or sales data can be updated on a day-to-day, or even shift-to-shift, basis. These data repositories require permanent, secure processing space that can be accessed only by a select group of users. When you allocate permanent space for the data, you ensure that disk space that is required for combining and manipulating large amounts of data from multiple large warehouse tables is always available.

For example, an organization might call such a tightly controlled, permanently defined area the production data space. Data analysts in organizations typically manipulate production-type data to produce smaller, more focused reports. Analyst reports often benchmark specific areas of performance or interest. Regular analyst reports are frequently distributed across the organization. The distributed analyst reports (although not as critical as the production, inventory, or sales data) should also use permanently defined data spaces that are separate from the permanent table spaces devoted to production reporting. In this situation, permanent table space should be accessible to a specific group (such as analysts) of regular SPD Server users.

You can use the LIBNAME parameter file to configure paths that map to an area of reserved disk space on a host computer. This disk space is a safe place to store permanent tables, with limited user access. To reserve permanent table space, use the optional DATAPATH=, INDEXPATH=, and OWNER= statements on the LIBNAME domain statement in the LIBNAME parameter file to specify unique, appropriately sized disk areas for data tables and index tables. The OWNER= statement configures ownership and access. You must ensure that the paths named in domain declarations have access to sufficient disk space.

You can grant user access to permanent table spaces by using individual user account access privileges, or by establishing an ACL group of approved users through the owner of the domain. LIBNAME domain statements create permanent table space by default.

**Semi-Permanent Table Space**

Organizations often have short-term data mining projects that rely on production, inventory, or sales data. Sometimes the organization changes how the data is processed, or augments the production, inventory, or sales data with additional information. These projects should be conducted in a test data space, isolated from the permanent space that is dedicated to critical production, inventory, or sales data. This design lets development trials be conducted without the risk of corrupting mission-critical data.

For example, the test data space that is used for a month-long development project could be considered a semi-permanent space. You need to grant access to an area where data can safely exist, isolated from production, sales, or inventory data, for a period of time that is longer than a single SPD Server user session. The test environment should persist long enough for works-in-progress to mature to production-quality. After the project is completed, the data, metadata, and work tables that are associated with the development phase should be cleaned up and deleted from the test environment.

SPD Server administrators and SPD Server users can configure semi-permanent table space. However, administrators should allocate semi-permanent spaces using the LIBNAME parameter file.

**Temporary Table Space**

Managers in an organization often ask analysts to query data warehouses for various types of information. Such ad hoc requests might be as important as standard reports, but ad hoc reporting has different data space needs. Ad hoc reports usually have a lower
frequency of repetition and a broader query scope than standard daily reporting does. Ad hoc reports are usually suitable for temporary table space. The life span of temporary table spaces begin and end with the user's SPD Server sessions.

You can use temporary table space for more than ad hoc user reporting. Even data warehouse queries and reports that use permanent table space use intermediate tables and calculation metadata to process queries. For example, the SPD Server SQL optimization process requires significant temporary table space while it heuristically finds the most efficient SQL strategy to resolve a query. Intermediate SPD Server tables and calculation metadata are usually deleted when the job terminates.

Any report might require temporary table space for intermediate calculation tables. SPD Server users can configure temporary table space with the LIBNAME domain statements that they submit during an SPD Server session. To create temporary table space, users specify the optional TEMP=YES option when they issue the LIBNAME domain statement in the SPD Server job code. All tables in temporary table space are lost at the end of the SPD Server user session, when temporary table space is automatically deleted.

---

**Example LIBNAME Parameter File Configurations**

The following SPD Server code examples show the range of LIBNAME domains that you can create using the LIBNAME parameter file. The code examples begin with the simplest form of LIBNAME domain declaration and increase in complexity.

**Example 1: Minimum Configuration for Domain Declaration**

This example contains the syntax that is required for the simplest form of LIBNAME domain configuration:

```
LIBNAME=SKULIST PATHNAME=c:\data\skulist;
```

This statement creates the SPD Server LIBNAME domain SKULIST. All SPD Server tables that are associated with the SKULIST domain (table data, metadata, index data, and intermediate data) reside in the single directory that is referenced in the path specification `c:\data\skulist`.

**Example 2: Specify Domain Paths for Data, Index, and Workspace Tables**

This example contains the syntax that is required to declare a LIBNAME domain with separate paths allocated for the domain data tables, index tables, and intermediate data files. The domain metadata continues to be stored in the location specified by the PATHNAME= specification.

```
LIBNAME=SKULIST PATHNAME=/metadata/skulist
roptions="
    DATAPATH=('/data01/skulist'
        '/data02/skulist'
        '/data03/skulist'
        '/data04/skulist'
        '/data05/skulist'
        '/data06/skulist')
    INDEXPATH=('/idx01/skulist'
        '/idx02/skulist'
```
This example uses the domain path options DATAPATH=, INDEXPATH=, and WORKPATH=. You can achieve optimal performance with this configuration when each domain path resides on a separate disk or on network components that can take advantage of parallelism.

The INDEXPATH= option takes advantage of multiple file systems. In SPD Server 5.1, index components can take advantage of the SPD Server RANDOMPLACEDPF feature. You can configure smaller disk partitions for index space with the RANDOMPLACEDPF feature, which benefits SPD Server backup and recovery operations.

The WORKPATH= specified for the SKULIST domain enables domain users to override a default workpath that is specified in the spdsserv.parm file.

**Example 3: Query-Rewrite Domain Configuration**

This example shows how to use temporary tables to configure a LIBNAME domain for optimal performance when you are using the SPD Server SQL query rewrite facility.

The SPD Server SQL query rewrite facility finds the most processor-efficient method to evaluate SQL statements. The SQL query rewrite facility uses numerous temporary tables that are distributed across a parallelized environment to rapidly evaluate and process the SQL statements.

At the end of the SPD Server session, temporary tables are automatically deleted. Some SPD Server users might use the QRW domain for its temporary table space, even if they are not submitting code for an SPD Server SQL query rewrite job.

This example creates a query rewrite domain named QRW that uses distributed temporary SPD Server tables. To use SPD Server QRW:

- **Create a specific domain for the query rewrite operations in the LIBNAME parameter file.** This example names the query rewrite domain **QRW**.
- **In the spdsserv.parm file, include a TMPDOMAIN=<QRW-domain-name> statement that references the QRW domain that you created in the LIBNAME parameter file.**

The LIBNAME parameter file code (the LIBNAME=QRW statement creates a specific domain for the query rewrite tables):

```plaintext
LIBNAME=QRW PATHNAME=/metadata/qrw
         roptions="
         DATAPATH=('/data01/qrw'
                      '/data02/qrw'
                      '/data03/qrw'
                      '/data04/qrw'
                      '/data05/qrw'
                      '/data06/qrw'
                      '/data07/qrw'
                      '/data08/qrw'
                      '/data09/qrw')
         INDEXPATH=('/idx01/qrw'
```

This example uses the domain path options DATAPATH=, INDEXPATH=, and WORKPATH=. You can achieve optimal performance with this configuration when each domain path resides on a separate disk or on network components that can take advantage of parallelism.

The INDEXPATH= option takes advantage of multiple file systems. In SPD Server 5.1, index components can take advantage of the SPD Server RANDOMPLACEDPF feature. You can configure smaller disk partitions for index space with the RANDOMPLACEDPF feature, which benefits SPD Server backup and recovery operations.

The WORKPATH= specified for the SKULIST domain enables domain users to override a default workpath that is specified in the spdsserv.parm file.

**Example 3: Query-Rewrite Domain Configuration**

This example shows how to use temporary tables to configure a LIBNAME domain for optimal performance when you are using the SPD Server SQL query rewrite facility.

The SPD Server SQL query rewrite facility finds the most processor-efficient method to evaluate SQL statements. The SQL query rewrite facility uses numerous temporary tables that are distributed across a parallelized environment to rapidly evaluate and process the SQL statements.

At the end of the SPD Server session, temporary tables are automatically deleted. Some SPD Server users might use the QRW domain for its temporary table space, even if they are not submitting code for an SPD Server SQL query rewrite job.

This example creates a query rewrite domain named QRW that uses distributed temporary SPD Server tables. To use SPD Server QRW:

- **Create a specific domain for the query rewrite operations in the LIBNAME parameter file.** This example names the query rewrite domain **QRW**.
- **In the spdsserv.parm file, include a TMPDOMAIN=<QRW-domain-name> statement that references the QRW domain that you created in the LIBNAME parameter file.**

The LIBNAME parameter file code (the LIBNAME=QRW statement creates a specific domain for the query rewrite tables):

```plaintext
LIBNAME=QRW PATHNAME=/metadata/qrw
         roptions="
         DATAPATH=('/data01/qrw'
                      '/data02/qrw'
                      '/data03/qrw'
                      '/data04/qrw'
                      '/data05/qrw'
                      '/data06/qrw'
                      '/data07/qrw'
                      '/data08/qrw'
                      '/data09/qrw')
         INDEXPATH=('/idx01/qrw'
```
The spdsserv.parm file code (the TMPDOMAIN=QRW statement references the domain created for query rewrite tables):

```
TMPDOMAIN=QRW;
```

### Example 4: Multiple Domain Types and Paths Configuration

This example uses a combination of LIBNAME parameter file settings, server parameter file settings, and user-issued SAS code that is submitted to SPD Server to create multiple domains that store the following items:

- permanent production tables
- permanent to semi-permanent user tables
- temporary tables for intermediate calculations

In this environment, users can access information from permanent production-type tables, manipulate the information, and save and delete the results in a semi-permanent user space. At the same time, they can use temporary tables with sufficient disk space to perform large or optimized intermediate table calculations. The code specifies data and index paths to take advantage of RAID-configured disk arrays.

The LIBNAME parameter file code defines the domain named PROD, which contains permanent production and historical data tables.

```
LIBNAME=PROD PATHNAME=/metadata/prod
  roptions="
    DATAPATH=('/data01/prod'
      '/data02/prod'
      '/data03/prod'
      '/data04/prod'
      '/data05/prod'
      '/data06/prod'
      '/data07/prod'
      '/data08/prod'
      '/data09/prod')

    INDEXPATH=('/idx01/prod'
      '/idx02/prod'
      '/idx03/prod'
      '/idx04/prod'
      '/idx05/prod')"
```

Additional LIBNAME parameter file code defines the domain named USERTBLS, which contains semi-permanent tables for user projects. SPD Server users can save and delete content in USERTBLS.

```
LIBNAME=USERTBLS PATHNAME=/metadata/usertbls
  roptions="
    DATAPATH=('/data01/usertbls'
      '/data02/usertbls'
      '/data03/usertbls'
      '/data04/usertbls'
      '/data05/usertbls')"
```
Finally, more LIBNAME parameter file code defines the domain named SPDTEMP, which contains temporary table space that is automatically deleted at the end of the SPD Server session.

LIBNAME=SPDTEMP PATHNAME=/metadata/spdtemp
  roptions="
    DATAPATH=('/data01/spdtemp'
      '/data02/spdtemp'
      '/data03/spdtemp'
      '/data04/spdtemp'
      '/data05/spdtemp'
      '/data06/spdtemp')
    INDEXPATH=('/idx01/spdtemp'
      '/idx02/spdtemp'
      '/idx03/spdtemp'
      '/idx04/spdtemp'
      '/idx05/spdtemp')"

The spdsserv.parm file code uses the TMPDOMAIN=SPDTEMP statement to reference the domain that was created for temporary tables. This code also uses the WORKPATH= statement to identify an array of RAID-enabled disk paths for temporary SPD Server work tables and temporary SPD Server intermediate files.

SORTSIZE=128M;
INDEX_SORTSIZE=128M;
GRPBYROWCACHE=128M;
BINBUFSIZE=32K;
INDEX_MAXMEMORY=8M;
NOCOREFILE;
SEQIOBUFMIN=64K;
RANIOBUFMIN=4K;
MAXWHTHREADS=8;
WHERECOSTING;
RANDOMPLACEDPF;
MINPARTSIZE=128M;
TMPDOMAIN=SPDTEMP;
WORKPATH="('/work1/spdswork'
  '/work2/spdswork'
  '/work3/spdswork'
  '/work4/spdswork'
  '/work5/spdswork')";
temporary domain space. Tables in the SPDTEMP domain are automatically deleted at
the end of the SPD Server session.

LIBNAME PROD sasspds "PROD"
    server=hostname.hostport
    user="user-id"
    password="password"
    IP=YES;

LIBNAME USERTBLS sasspds "USERTBLS"
    server=hostname.hostport
    user="user-id"
    password="password"
    IP=YES;

LIBNAME SPDTEMP sasspds "SPDTEMP"
    server=hostname.hostport
    user="user-id"
    password="password"
    IP=YES
    TEMP=YES;
Overview of SPD Server Performance Server

SAS SPD Server 5.1 provides a performance monitoring server called spdsperf. SPD Server Performance Server is an optional component and is not required for the normal operation of SPD Server.

Note: SPD Server Performance Server is currently not available for the Windows or Linux X64 platforms.

SPD Server Performance Server gathers SPD Server process performance information and posts it to the SPD Server Management section of the SAS Management Console application. The information consists of memory and resource allocations by users, and SPD Server processes that were spawned by an SPD Server name server. All SPD Server users must connect to an SPD Server name server before their SPD Server session is spawned. Each SPD Server name server owns a dynamic family of subordinate SPD Server processes that SPD Server users and jobs create and terminate.

The information that is gathered by SPD Server Performance Server is stored in the SAS Management Console. The SAS Management Console has a folder that is reserved for SPD Server management. The SPD Management folder is a child of the Environmental Management folder in the SAS Management Console. When you expand the SPD Management folder, the next to last utility is SPD Process Profiler. Highlight the SPD Process Profiler utility to display the process information table, which contains performance summary statistics. Each row in the table provides information about a single SPD Server process that was spawned on the SPD Server name server that resides on the specified port ID (PID).
The SPD Process Profiler displays information about memory and resource allocations. For this reason, you can use the SAS Management Console to review which SPD Server processes are occupying host computing resources, how the resources are distributed across users and processes at a given point in time, and whether the resource uses and distributions are appropriate for your computing environment.

Not only can you display performance summary statistics in the SAS Management Console application. You can also configure the SPD Server Performance Server when you launch it, to create text log files that can be saved locally on the SPD Server host machine. SPD Server is shipped with a PERL utility called process_perf_log that can parse the log that SPD Server Performance Server created.

Starting SPD Server Performance Server

Overview of Starting the Performance Server

You can start SPD Server Performance Server in two ways. You can invoke the Performance Server on the command line, or you can launch it by calling the rc.perf script that is configured for your location's SPD Server installation.

By default, the SPD Server Performance Server process displays the captured performance data on the user's screen. To disable the user screen display, redirect stdout and stderr to /dev/null. If you redirect the screen output, it is easier to run spdsperf in the background, or as an orphan.
Start Performance Server from the Command Line

You can start the SPD Server Performance Server from a UNIX command line. SPD Server and the SAS Management Console applications must be running before you start the Performance Server. If you need to restart SPD Server, you must also shut down and restart the SPD Server Performance Server after SPD Server is restarted. The Performance Server utility is not compatible with SPD Server releases earlier than SPD Server 4.4.

Use the following command to start Performance Server:

```
spdsperf -g SMID -n NSP -s SNP -p PLP -l LOG [-i SEC] [-c CNT]
```

**SMID**

SMID is the shared memory ID that is passed to the spdsbase user proxy when it is started by SPD Server. SMID contains information that spdsperf requires. You can find the shared memory ID by issuing a UNIX process status report command for all processes and then grep for ‘spdsbase’, using a form similar to `ps -eo args | grep spdsbase`. The shared memory ID should be the first parameter (after the process name) that is passed to the process.

**NSP**

the process-ID number of the SPD Server name server whose family of spawned processes you want to monitor.

**SNP**

the process-ID number of the SPD Server SNET Server.

**PLP**

the listening port number that the SAS Management Console uses to contact the Performance Server.

**LOG**

the path to which you want to write the profile log.

**SEC**

an optional property that specifies the number of seconds that transpire between instances of performance monitoring data captures. Valid values are integers that are greater than or equal to 1 and less than or equal to the SPD Server MAXINT value.

**CNT**

an optional property that specifies the number of performance monitoring data captures that you want the Performance Server to take. Valid values are integers that are greater than or equal to 0 and less than or equal to the SPD Server MAXINT value. The value 0 specifies an infinite number of data captures.

Start Performance Server by Using the rc.perf Script

You can also start SPD Server Performance Server by calling the rc.perf script during start-up. See “Sample rc.perf Script” on page 108 for a sample rc.perf script that you can cut and paste into an editor of your choice, and customize for your use. SPD Server 5.1 is also shipped with a sample rc.perf script that you can modify. The sample rc.perf script is in your SPD Server installation folders at `./samples/perfmon/rc.perf`. You can use either example file to create a custom rc.perf script.

Make the following changes when you customize your version of the rc.perf script:

1. If your SPD Server installation uses a custom SPD Server installation path, modify the INSTDIR path setting to specify your installation path.
2. Modify the UNIX environment setting for DISPLAY. This environmental variable tells the X server where to display the window for the Performance Server program.

3. If your SPD Server installation uses custom NSPORT and SNPORT assignments, modify the NSPORT and SNPORT settings in the sample script to specify the port addresses that your SPD Server installation uses.

4. The script uses the -PARGS setting to specify how many times the Performance Server should capture performance information snapshots before shutting down. The sample rc.spds script specifies 0, which indicates an infinite number of performance information captures. If you do not change the default number of information captures from 0 (infinity), consider modifying your rc.killspds script to shut down the rc.perf process when you shut down SPD Server.

Sample rc.perf Script

The following sample code is a typical rc.perf script that you can modify for use at your own site. Follow the instructions in “Start Performance Server by Using the rc.perf Script” on page 107 to customize the script for your SPD Server installation. Copy and paste the example code into a text editor. Make your changes, and then save the file to your SPD Server installation in a location where the script can be called for execution.

```
#!/bin/ksh
#
# PURPOSE: Start the SPD Performance Profiler for the specified servers.
#
# PARAMETERS: version - Version of SPDS to build and run (e.g., dev, 403).
#
# NOTES: Common optional parameters:
#   -nsport overrides NSPORT for server.
#   -snport overrides SNPORT for server.
#   -debug use alternate port numbers for development.
#
# The default repetition count for spdsperf is 3. This script over-rides the default to run indefinitely. Supplying a -c option to this script will over-ride this new default.
#

---

Performance Server Log File

You can configure SPD Server Performance Server to save the process performance information to a text log file. Your SPD Server installation includes a PERL utility called process_perf_log that is in the .../samples/perfmon directory of your SPD Server installation. When you use the process_perf_log PERL script with your SPD Server Name Server log files, the files are parsed and formatted for SAS processing.

A sample SAS script for importing the parsed log file data is in the .../samples/perfmon/PerfDataSample.sas directory in your SPD Server installation.
Using SPD Server with Hadoop

Overview

Hadoop is an open-source software framework under the Apache Software Foundation. You use Hadoop to store and process big data in a distributed fashion on large clusters of commodity hardware. Hadoop is an attractive technology for a number of reasons:

- Cost-effective alternative for data storage
- Scalable architecture through distributed data across multiple machines
- Data replication provides failure resiliency

Beginning with SPD Server 5.2, SPD Server can read, write and update tables in the Hadoop environment. SPD Server support for Hadoop is enabled by the SPD Server administrator. Changes to the SPD Server configuration must be made in the LIBNAME
parameter file and the server parameter file. New SPD Server Hadoop options have also been introduced to specify Hadoop operational parameters. SPD Server 5.2 supports Hadoop access only on the Linux platform.

**Pre-installation Checklist for Interfacing with Hadoop**

A good understanding of your Hadoop environment is critical to a successful installation of an SPD Server that interfaces with Hadoop. Before you install SPD Server software that interfaces with Hadoop, it is recommended that you verify your Hadoop environment by becoming familiar with the following items:

- Gain working knowledge of the Hadoop distribution that you are using (for example, Cloudera). You will also need working knowledge of the Hadoop Distributed File System (HDFS), and services for MapReduce 1, MapReduce 2, and YARN services. For more information, see the Apache website or the vendor’s website.
- Ensure that the HDFS, MapReduce, and YARN services are running on the Hadoop cluster.
- Know the location of the MapReduce home.
- Know the host name of the NameNode.
- Determine where the HDFS server is running.
- Understand and verify your Hadoop user authentication.
- Understand and verify your security setup. It is highly recommended that you enable Kerberos for data security.
- Verify that you can connect to your Hadoop cluster (HDFS) from your client machine outside of the SPD Server environment with your defined security protocol.

**Steps to Configure SPD Server for Use with Hadoop**

Verify that all SPD Server Hadoop prerequisites have been satisfied. This step ensures that you understand your Hadoop environment. For more information, see “Hadoop Prerequisites for SPD Server” on page 112.

Make Hadoop JAR files available to the SPD Server machine by using the SPD Server HADOOPJAR= option in the LIBNAME parameter file to specify the location of the files. This step involves copying a set of JAR files to the SPD Server machine that accesses Hadoop. For more information, see “Make Required Hadoop JAR Files Available to SPD Server” on page 113.

Make Hadoop configuration files available to the SPD Server machine. For more information, see “Make Required Hadoop Cluster Configuration Files Available to SPD Server” on page 114.

Run basic tests to confirm that your Hadoop connections are working. For more information, see “Validating the SPD Server to Hadoop Connection” on page 116.

**Hadoop Prerequisites for SPD Server**

**Install SPD Server 5.2**
Install SPD Server 5.2 by following the instructions. For more information about installing SPD Server, see Chapter 3, “Installing SAS Scalable Performance Data (SPD) Server on UNIX,” on page 9.
**Supported Hadoop Distributions for SPD Server**

SPD Server 5.2 supports the following distributions:

- Cloudera CDH 5.2.

**Hadoop Configuration File and JRE Requirements**

The Hadoop configuration file must include the properties to run MapReduce (MR1) or MapReduce 2 (MR2) and YARN. The JRE version for the Hadoop cluster must be either 1.6, which is the default configuration, or 1.7. If the JRE version for the Hadoop cluster is 1.7, use the HADOOPACCELJVER= server parameter file setting use the HADOOPACCELJVER= server parameter file setting “HADOOPACCELJVER=” on page 119 to specify the updated JRE version.

**Make Required Hadoop JAR Files Available to SPD Server**

In order to interoperate with a Hadoop environment, you must make certain Hadoop JAR files available to the SPD Server machine. In the context of Hadoop, SPD Server is a client to the Hadoop cluster. To make the required JAR files available, you must define the HADOOPJAR= option in the SPD Server parameter file and specify HADOOP=YES for each domain definition in the LIBNAME parameter file that you want to be a Hadoop domain.

Alternatively, you can use a HADOOPJAR= statement in your LIBNAME parameter file. If you specify any HADOOP option within a domain definition, SPD Server automatically assumes the setting HADOOP=YES for that domain.

To specify the location of the required Hadoop JAR files:

1. Create a directory that is accessible to the SPD Server machine.
2. From the Hadoop cluster, copy the required JAR files for the particular Hadoop distribution to the directory that you created in Step 1.
3. Use the SPD Server HADOOPJAR= server parameter file option to specify the path to the Hadoop JAR files.

For example, if the JAR files are copied to the location /u/hadoop/hdist/cdh/cdh52, then the following syntax sets the option appropriately.

```
HADOOPJAR=/u/hadoop/hdist/cdh/cdh52;
```

If multiple paths are required, you can use the colon operator : to concatenate pathnames:

```
HADOOPJAR=/u/hadoop/hdist/cdh/cdh52:/u/myjars/cdh/cdh52;
```

The Java version of the JAR files in your HADOOPJAR folder is important. The Java version of all Hadoop JAR files must exactly match the Java version that the corresponding Hadoop environment is using. If you have multiple Hadoop servers that are running different Java versions, then you must create a different SPD Server HADOOPJAR= folder for each unique Java version that you use in your Hadoop environments.

SPD Server 5.2 requires the following JAR files for Hadoop domains:

- commons-beanutils-1.7.0.jar
- commons-cli-1.2.jar
- commons-codec-1.4.jar
- commons-configuration-1.6.jar
Before you can connect SPD Server to a Hadoop server, you must first make the Hadoop cluster configuration files available to the SPD Server machine. To make the Hadoop cluster configuration files available, you must define the HADOOPCFG= option in your SPD Server parameter file, and then specify HADOOP=YES for each Hadoop domain definition.

If you specify any Hadoop option (such as HADOOPCFG= or HADOOPJAR=) as part of a domain definition, SPD Server automatically assumes a default option setting of HADOOP=YES.

To specify the location of your Hadoop configuration files:

1. Create a directory that is accessible to the SPD Server machine.

Make Required Hadoop Cluster Configuration Files Available to SPD Server
2. From the specific Hadoop cluster, copy the following configuration files to the directory that you created in step 1:
   - core-site.xml
   - hdfs-site.xml
   - mapred-site.xml
   - yarn-site.xml.

3. Use the HADOOPCFG= server parameter file option to specify the path to the directory containing the Hadoop configuration files.

   For example, if the cluster configuration files are copied to the location /u/hadoop/hdist/cdh/confdir, then the following syntax sets the option appropriately:

   HADOOPCFG=/u/hadoop/hdist/cdh/confdir;

Kerberos Security

To access Hadoop clusters that are secured with Kerberos, you must provide HADOOPREALM= and HADOOPKEYTAB= option values in the SPD Server parameter file. Specifying these options in the server parameter file means that any Hadoop domain that is defined in the LIBNAME parameter file is treated as a domain that is secured with Kerberos. If you have a Hadoop LIBNAME domain definition that you do not want to be treated as a domain that is secured with Kerberos, you can include the option HADOOPKERBEROS=NO as part of the Hadoop LIBNAME domain definition in the parameter file.

Alternatively, you can use the HADOOPREALM= and/or HADOOPKEYTAB= options on individual Hadoop domain definitions in the LIBNAME parameter file to specify that you want those domains to be treated as domains that are secured with Kerberos.

For example, if your Kerberos realm name is FOO.ORG, and your keytab file is in /<keytab-path>/userid.keytab, then the following LIBNAME parameter file syntax sets the HADOOPREALM= and HADOOPKEYTAB= options appropriately:

   HADOOPREALM=FOO.ORG;
   HADOOPKEYTAB=<keytab_path/userid.keytab>;

SPD Server ACLs for Hadoop Domains

SPD Server ACLs for SPD Server resources are typically created in the root pathname of each SPD Server domain. Storing SPD Server ACLs in this location does not work for domains defined by Hadoop, for the following reasons:

- SPD Server ACLs are small, and are updated frequently. Updating data in the Hadoop Distributed File System (HDFS) is very slow. This would represent a significant performance degradation if the SPD Server ACLs were stored in HDFS.

- HDFS does not support the type of locking required for SPD Server ACL processing.

Because of the above restrictions, SPD Server ACLs for Hadoop domains must be stored in the local file system. The SPD Server parameter file option, HADOOPACLPATH=, specifies a local file system directory where ACLs for the Hadoop environment will be created and stored.

If the HADOOPACLPATH= option is not defined, the default location for SPD Server Hadoop ACLs is the location that is specified as the location provided by the ACLDIR= SPD Server start up option in the rc.spds file. If you define an SPD Server LIBNAME
domain that contains a HADOOP=YES setting, SPD Server creates a directory using the following schema:

\(<\text{HADOOPACLPATH}>\)/HADOOPACLS/\(<\text{domain}\_\text{name}\\>).

The \(<\text{HADOOPACLPATH}>\) value is either the HADOOPACLPATH= parameter option, or the ACLDIR= start up option in the \text{rc.spds} file. The specified location contains the ACLs for the declared libref.

**SPD Server User Password File**

By default, the SPD Server user password file is located in the InstallDir/site directory. If you do not keep the file in this location, you need to specify the location using the ACLDIR start up option. This location must be on the local file system, not HDFS. This restriction exists for the following reasons:

- SPD Server password files are small, and are updated frequently. Updating data in HDFS is very slow. This would represent a significant performance degradation if the SPD Server password files were stored in HDFS.
- HDFS does not support the type of locking required for SPD Server password file processing.

**Validating the SPD Server to Hadoop Connection**

To validate that your SPD Server is correctly configured to access Hadoop files:

- Ensure that you specified values for HADOOPCFG= and HADOOPJAR= option settings in either your SPD Server parameter file, or within specific LIBNAME definitions in your LIBNAME parameter file.
- If you want one or more of your Hadoop domains to access Hadoop files that are secured with Kerberos, make sure that you specified values for HADOOPREALM= and HADOOPKEYTAB= option settings for the domains in the SPD Server parameter file (or within specific LIBNAME definitions in the LIBNAME parameter file.)
- After you start your SPD Server session, check the SPD Server log file to verify that your Hadoop domains were added to the SPD Name Server. Hadoop option information is logged when each Hadoop domain is added to the SPD Server Name Server. The SPD Server log entry should resemble the following:

```
Libname MYDOMAIN added to Name Server (HADOOP=yes)
HADOOPCFG=/u/hadoop/hdist/cdh/confdir;
HADOOPJAR=/u/hadoop/hdist/cdh/cdh52;
HADOOPACLPATH=/u/mylocal/acls/HADOOPACLS/MYDOMAIN;
```

- Submit a LIBNAME assignment to a Hadoop SPD Server domain that resembles the following:

```
LIBNAME foo sasspds 'public' server=myhost.5400 user="anonymous";
```

If the LIBNAME assignment is successful, then your Hadoop connection has been made.

- Add MYDOMAIN to your LIBNAME parameter file as a HADOOP=YES libref with a path located in your Hadoop file system.
Example of Using a LIBNAME Statement to Validate a Hadoop Environment

The example code below shows how to issue a LIBNAME statement and two PROC steps that will validate whether your Hadoop environment is set up correctly.

LIBNAME foo sasspds 'mydomain' server=myhost.5400 user="anonymous";

NOTE: This is a SPD 5.2 Engine
executing SAS (r) 9.4 (TS1M2) on the Linux platform.
NOTE: User anonymous(ACL Group) connected to SPD(LAX) 5.2 server at 10.24.7.79.
NOTE: Libref FOO was successfully assigned as follows:
Engine: SASSPDS
Physical Name: :23107/my_Hadoop_domain_path/

data foo.atable;
x=1;
run;

NOTE: The data set FOO.TABLE has 1 observations and 1 variables.
NOTE: DATA statement used (Total process time):

SPD Server Hadoop LIBNAME Parameter and Server Parameter File Options

You can specify the Hadoop options in either the LIBNAME parameter file (as part of an individual domain definition) or in the SPD Server parameter file. Hadoop options that you specify in the LIBNAME parameter file take precedence over the Hadoop options that you specify in the SPD Server parameter file. This allows the SPD Server administrator to define common Hadoop options in the SPD Server parameter file, and
to use LIBNAME parameter file options to override server parameter file settings when required.

The required options to access Hadoop are HADOOPCFG= and HADOOPJAR= in either parameter file, and the HADOOP=YES option in the LIBNAME parameter file.

When you specify HADOOPCFG= and HADOOPJAR= option settings in the SPD Server parameter file, these settings become the default settings for any domain that specifies HADOOP=YES.

**HADOOP= YES|NO**

specifies whether a domain can access data in the Hadoop file system.

**YES**
specifies that a domain can access data in the Hadoop file system.

**NO**
specifies that a domain cannot access data in a Hadoop file system.

Valid in LIBNAME parameter file

Default NO

**HADOOPACCELJVER=**
specifies the Java version used in the Hadoop environment when performing SPD Server WHERE processing optimization with MapReduce.

Valid in SPD Server parameter file

**Interactions**
The HADOOPACCELJVER= option affects only domains that specify HADOOP=YES or domains that specify any other SPD Server HADOOP* option.

The SPD engine submits the Java class to the Hadoop cluster as a component in a MapReduce program. By requesting that data subsetting be performed in the Hadoop cluster, performance might be improved by taking advantage of the filtering and ordering capabilities of the MapReduce framework. As a result, only the subset of the data is returned to the SAS client. Performance is often improved with large data sets when the WHERE expression qualifies only a relatively small subset. The default value is 1.6.

**See**
For more information about SPD Server and WHERE optimization with MapReduce, see “SPD Server Hadoop WHERE Processing Optimization Data Set and SAS Code Requirements” on page 125

**Example**
HADOOPACCELJVER= <Java-version> ;

**HADOOPACCELWH=**
specifies whether to perform SPD Server WHERE processing optimization with MapReduce by performing data subsetting in the Hadoop cluster.

Valid in SPD Server parameter file

**Interactions**
The HADOOPACCELWH= option affects only domains that specify HADOOP=YES or domains that specify any other SPD Server HADOOP* option.

By requesting that data subsetting be performed in the Hadoop cluster, performance might be improved by taking advantage of the filtering
and ordering capabilities of the MapReduce framework. As a result, only the subset of the data is returned to the SPD Server client. Performance is often improved with large data sets when the WHERE expression qualifies only a relatively small subset.

See
For more information about SPD Server and WHERE optimization with MapReduce, see “SPD Server Hadoop WHERE Processing Optimization Data Set and SAS Code Requirements” on page 125.

Example
HADOOPACCELWH= YES | NO ;

HADOOPACLPATH= local-file-system-directory-for-Hadoop-ACL-files
specifies the local file system directory to store Hadoop ACL files.

Valid in
SPD Server parameter file

Default
The ACL files are created in the location identified in the \_acldir
spdserv process start-up parameter. This is the same location as the psmgr database.

Interaction
If you specify a value for the \_hadoopaclpath option with the
SPDSCLEAN utility, that value overrides any other
HADOOPACLPATH= settings that are specified in the SPD Server
parameter file.

HADOOPCFG=local-path-to-Hadoop-configuration-file-directory
specifies the local path to the Hadoop configuration files.

Valid in
LIBNAME parameter file

SPD Server parameter file

Interactions
When you specify this option in the SPD parameter file, this option
affects only domains that specify HADOOP=YES or domains that
have other SPD Server HADOOP* option specified.

If you specify any SPD Server HADOOP* domain option, the SPD
Server assumes that the HADOOP=YES option is set for that domain.

Example
HADOOPCFG=/u/hadoop/hdist/cdh/confdir;

HADOOPJAR=local-path-to-Hadoop-JAR-file-directory
specifies the local path to the Hadoop JAR files.

Valid in
LIBNAME parameter file

SPD Server parameter file

Interactions
When you specify this option in the SPD Server parameter file, this option
affects only domains that specify HADOOP=YES or domains that
have other SPD Server HADOOP* option specified.

If you specify any SPD Server HADOOP* domain option, the SPD
Server assumes that the HADOOP=YES option is set for that domain.

Example
HADOOPJAR=/u/hadoop/hdist/cdh/cdh52;
HADOOPKERBEROS= YES|NO
specifies whether a Hadoop cluster requires authentication using Kerberos.

YES
specifies that a Hadoop cluster requires authentication using Kerberos.

NO
specifies that a Hadoop cluster does not require authentication using Kerberos.

Valid in LIBNAME parameter file

Interactions To access a Hadoop cluster that is secured with Kerberos, the
HADOOPREALM= and the HADOOPKEYTAB= options must be
specified in either the LIBNAME parameter file or the SPD Server
parameter file.

If either the HADOOPREALM= HADOOPKEYTAB= option is
specified in the SPD Server parameter file, then a domain that has
HADOOP=YES specified is secured by Kerberos unless
HADOOPKERBEROS=NO.

HADOOPKEYTAB= path-to-Kerberos-keytab-file
specifies the path to a Kerberos keytab file when accessing a Hadoop cluster that is
secured with Kerberos. If you specify any SPD Server HADOOP* domain option,
then SPD Server assumes that HADOOP=YES is set for that domain.

Valid in LIBNAME parameter file

SPD Server parameter file

Interactions When you specify this option in the SPD Server parameter file, this
option affects only domains that specify HADOOP=YES or domains
that have other SPD Server HADOOP* option specified.

If you specify any SPD Server HADOOP* domain option, the SPD
Server assumes that the HADOOP=YES option is set for that domain.

HADOOPREALM= Kerberos-realm
specifies the Kerberos realm to use to access a Hadoop cluster that is secured with
Kerberos.

Valid in LIBNAME parameter file

SPD Server parameter file

Interactions When you specify this option in the SPD Server parameter file, this
option affects only domains that specify HADOOP=YES or domains
that have other SPD Server HADOOP* option specified.

If you specify any SPD Server HADOOP* domain option, the SPD
Server assumes that the HADOOP=YES option is set for that domain.

HADOOPWORKPATH= path-to temporary MapReduce output
specifies the path to the directory in the Hadoop Distributetd File System that stores
the temporary results of the MapReduce output.

Valid in SPD Server parameter file
The Interaction option affects only domains that specify HADOOP=YES or domains that specify any other SPD Server HADOOP* option.

Using SPDSCLEAN with Hadoop

You can use the SPD Server SPDSCLEAN utility to clean Hadoop domains. There are a few considerations when using spdsclean on Hadoop domains. You must first provide Hadoop with configuration and JAR resource information for the target domain. The spdsclean utility is located in the /site directory of your SPD Server installation location.

Hadoop SPDSCLEAN Configuration Information

To use the SPDSCLEAN functionality within a Hadoop domain, you must provide the Hadoop configuration path and the Hadoop JAR information, in the same way that you must configure SPD Server to access Hadoop environments. SPD Server provides several methods that you can use to invoke the SPDSCLEAN function within a Hadoop domain.

You can use the SPDSCLEAN utility to invoke SPDSCLEAN for a Hadoop domain. Use the \texttt{-hadoopaclpath} option of the SPDSCLEAN command to specify the location of the Hadoop ACL files that you want to clean. If you specify a value for the \texttt{-hadoopaclpath} option, that value overrides any other HADOOPACLPATH= settings declared in the SPD Server parameter file. The Hadoop ACL path is needed for SPDSCLEAN to access and clean the SPD Server ACL files in the specified Hadoop domain. You must also specify the SPDSCLEAN \texttt{-acl} or \texttt{-all} options in order for SPDSCLEAN to clean up any SPD Server ACL files.

Configure Hadoop SPDSCLEAN via Environment Variables

You can use environment variables to specify Hadoop CONFIG_PATH and JAR_PATH configuration parameters for SPDSCLEAN. You specify values for the parameters via UNIX command prompt, before submitting the \texttt{spdsclean} script, or you can incorporate the parameter value statements within the \texttt{spdsclean} script itself.

```
export SAS_HADOOP_CONFIG_PATH=/u/fedadmin/hadoopcfg/cdh52p1
export SAS_HADOOP_JAR_PATH=/u/fedadmin/hadoopjars/cdh52
```

Configure Hadoop SPDSCLEAN via SPDSCLEAN Options

You can modify your \texttt{spdsclean} script to use the \texttt{-hadoopcfg} and \texttt{-hadoopjar} option settings to specify the values for your Hadoop config path and JAR path.

```
spdsclean -hadoopcfg /u/fedadmin/hadoopcfg/cdh52p1
           -hadoopjar /u/fedadmin/hadoopjars/cdh52
           other-options;
```

Configure Hadoop for SPDSCLEAN via \texttt{–libnamefile} and \texttt{–parmfile} Options in spdsclean Script

You can modify your \texttt{spdsclean} script to reference Hadoop configuration information that is defined in your LIBNAME parameter file, your SPD Server parameter file, or both.

Typical content for the \texttt{spdsclean} script:
Typical content for the LIBNAME parameter file:

libname=Stuff1
pathname=/user/userlname
hadoopcfg=/u/fedadmin/hadoopcfg/cdh52p1
hadoopjar=/u/fedadmin/hadoopjars/cdh52
hadoop=yes;

Note: It is not necessary to specify Hadoop configuration information in both the LIBNAME parameter file and the SPD Server parameter file. You can choose either method. Examples of both methods are provided for convenience.

Specify Hadoop SPDSCLEAN Configuration Information for Domains Secured with Kerberos

To use the SPDSCLEAN utility on Hadoop domains that are secured via Kerberos, submit the following kinit command before invoking SPDSCLEAN: $ kinit -kt <full—path—to—keytab—file><UserID>;

SPD Server Hadoop Configuration Examples

The following sections document different methods that you can use to configure SPD Server to access Hadoop clusters.

Configure SPD Server for Hadoop Access via LIBNAME Domain Statements

One way to set up access to a Hadoop cluster (without Kerberos) is to specify a domain in the SPD Server LIBNAME parameter file, and then add the HADOOPCFG= and HADOOPJAR= options.

In the libnames.parm file:

libname=foo
pathname=/user/userlname/mydomain
hadoopcfg=/u/hadoop/hdist/cdh/confdir/hdp20p1
hadoopjar=/u/hadoop/hdist/cdh/sas_cdh20u;

Configure SPD Server for Hadoop Access via spdsserv.parm Global Options

Another simple way to access a Hadoop cluster (without Kerberos) is to specify HADOOPCFG= and HADOOPJAR= options in your SPD Server parameter file. Then, you can specify multiple Hadoop domains in your LIBNAME parameter file. Each of those domains will get their Hadoop configuration and JAR file information from the global options that are specified in the SPD Server parameter file.

In the SPD Server parameter file:

HADOOPCFG=/u/hadoop/hdist/cdh/confdir/hdp20p1;
HADOOPJAR=/u/hadoop/hdist/cdh/sas_cdh20u;

In the LIBNAME parameter file, you only need to specify the Hadoop libname and pathname, and HADOOP=YES.

libname=Stuff1 pathname=/user/userlname/mydomain1 hadoop=yes;
libname=Stuff2 pathname=/user/userlname/mydomain2 hadoop=yes;

To use the Hadoop domains defined in the LIBNAME parameter file, specify them in the same way as any other SPD Server domain in client code:

libname Stuff1 saspds `Stuff1` server=lax94d01.14526 user="anonymous";

**Configure SPD Server for Hadoop WHERE Processing Optimization with MapReduce**

SPD Server WHERE processing enables you to conditionally select a subset of observations, so the software processes only the observations that meet specified conditions. To optimize the performance of WHERE processing, you can request that data subsetting be performed in the Hadoop cluster. Then, when you submit SPD Server code that includes a WHERE expression (that defines the condition that selected observations must satisfy), SPD Server instantiates the WHERE expression as a Java class. The software submits the Java class to the Hadoop cluster as a component in a MapReduce program. By requesting that data subsetting be performed in the Hadoop cluster, performance might be improved by taking advantage of the filtering and ordering capabilities of the MapReduce framework. As a result, only the subset of the data is returned to the SPD Server client. Performance is often improved with large data sets when the WHERE expression qualifies only a relatively small subset.

The action of pushing WHERE-based data subsetting to the Hadoop cluster is sometimes called a WHERE pushdown.

If you want additional details about an SPD Server MapReduce job, you can include the macro SPDSWEB=YES in your code to determine whether the optimization occurred.

**SPD Server Hadoop WHERE Pushdown Server Parameter Options**

By default, data subsetting is performed by SPD Server on the SPD Server host. To request that data subsetting be performed in the Hadoop cluster, you must specify the following in your SPD Server parameter file:

- Specify HADOOPACCELWH=YES to enable the Java MapReduce data subsetting. If not specified, HADOOPACCELWH= defaults to NO. Users can override an unspecified HADOOPACCELWH= setting via the SPDSACWH macro variable or the ACCELWHERE= table option.
- Use the SPD Server parameter file option HADOOPACCELJVER=Java-version to specify the Java version running on the HDFS cluster. If not specified, the Java version defaults to 1.6.
- Use the SPD Server parameter file option HADOOPWORKPATH=Hadoop-file-system-path to specify the path to the directory that will contain the temporary results of the MapReduce output. If the Hadoop workpath parameter is not specified, by default the files are written to /tmp. The Hadoop workpath that you specify must be an existing path structure. If you specify a HADOOPWORKPATH= parameter that does not exist, the map reduce job fails.

**SPD Server Hadoop WHERE Processing Optimization Overrides**

SPD Servers users might want to experiment with SPD Server WHERE processing optimization when the SPD Server site administrator has not yet specified a setting for the HADOOPACCELWH= server parameter file option. SPD Server provides user
override settings so that users can try WHERE processing optimization in select cases when the feature is not globally enabled.

- If HADOOPACCELWH= is set to NO in the server parameter file by the SPD Server administrator, no WHERE processing optimization is allowed. User overrides are not available.

- If HADOOPACCELWH= is set to YES in the server parameter file by the SPD Server administrator, SPD Server users can override and disable WHERE processing optimization by setting the SPDSACWH macro to NO or by issuing the ACCELWHERE=NO table option.

- If no HADOOPACCELWH= setting is defined in your installation’s server parameter file, WHERE processing optimization is disabled by default. However, SPD Server users can override and enable WHERE processing optimization by either setting the SPDSACWH macro to YES or by issuing the ACCELWHERE=YES table option in a statement.

For more information about the SPDSACWH= macro variable, see “Variables to Enhance Performance” in Chapter 9 of SAS Scalable Performance Data Server: User's Guide. For more detailed information about the ACCELWHERE= table option, see “Options to Enhance Performance” in Chapter 11 of SAS Scalable Performance Data Server: User's Guide.

**SPD Server Hadoop WHERE Processing Optimization Data Set and SAS Code Requirements**

To perform the data subsetting in the Hadoop cluster for WHERE processing optimization, the following data set and SAS code requirements must be met. If any of these requirements are not met, data subsetting is not performed by MapReduce in the Hadoop cluster.

- The data set cannot be encrypted.
- The data set cannot be compressed.
- The data set must be larger than the HDFS block size.
- The submitted SAS code cannot request BY-group processing.
- The submitted SAS code cannot include the STARTOBS= or ENDOBS= options.
- The data set must not be an SPD Server cluster.

To perform data subsetting in the Hadoop cluster for WHERE processing optimization, the submitted WHERE expression cannot include any of the following syntax:

- a variable as an operand, such as WHERE lastname;
- variable-to-variable comparison
- SAS functions such as SUBSTR, TODAY, UPCASE, and PUT
- arithmetic operators *, /, +, -, and **
- IS NULL or IS MISSING and IS NOT NULL or IS NOT MISSING operators
- concatenation operators, such as || (two OR symbols) or !! (two exclamation marks)
- negative prefix operator, such as WHERE z = -(x+y);
- pattern matching operators LIKE and CONTAINS
- sounds-like operator SOUNDEX (=*)
• truncated comparison operator using the colon modifier, such as `WHERE lastname=: 'S';`

**SPD Server Hadoop Restrictions**

**Pass-Through LOAD and COPY Commands**
Some SPD Server commands require local direct access to the source and destination tables from the machine that the server is running on. These commands do not work if the tables are in a Hadoop environment. The Hadoop environment currently does not support the direct open method for tables.

As a result, the SPD Server pass-through SQL commands for COPY and LOAD are not available for tables that reside in a Hadoop domain.

**Implicit Pass-Through and Hadoop Tables**
A Hadoop table cannot be replaced by using implicit pass-through.

An implicit pass-through using the CREATE TABLE AS SELECT statement to SPD Server does not support creating a Hadoop table that already exists. A best practice is to drop a table before creating the table. If a table already exists, SPD Server fails the query with a Member Lock error. This results in PROC SQL planning and executing the `create table as select ...` query, causing the selected rows to be read from SPD Server to SAS. The selected rows are returned to SPD Server to create the table.

**SPD Server User-Defined Formats**
SPD Server does not support user-defined formats in Hadoop. User-defined formats require a record-level locking proxy, but the Hadoop file system locking mechanisms do not support this operation. As a result, the SPD Server formats domain does not support the HADOOP=YES option.

**Librefs with BACKUP=YES and DYNLOCK=YES Options**
SPD Server does not support the use of any LIBNAME in a Hadoop environment that has BACKUP=YES or DYNLOCK=YES option settings. The Hadoop file system locking mechanisms do not support these operations. If these are found together, the server does not start, and an error is displayed in the SAS log.

**Librefs with LOCKING=YES Options**
SPD Server does not support the LOCKING=YES LIBNAME option for a HADOOP=YES domain.
Chapter 14
Configuring and Managing
SPDSBASE Processes

About SPD Server SPDSBASE Processes

The SPDSBASE process is responsible for accessing or creating SPD resources for SPD Server users. Several SPDSBASE processes can be active simultaneously in an SPD Server installation, handling work requests for different users or different SAS sessions. The SPDSBASE process can take on the role of either an SPD Server user proxy, an SPD Server SQL proxy, or an SPD Server SQL user proxy.

SPD Server User Proxy

The SPD Server user proxy is created by the SPD Server client, via the sasspds engine LIBNAME statement. The user proxy has the credentials of the LIBNAME statement, which include:

- the user’s SPD Server User ID
- the user’s SPD Server group name
- the user’s SPD Server ACLSPECIAL privileges

If there are multiple librefs in the same SAS session that have the same LIBNAME credentials, the librefs share the same user proxy. Any SPD Server resources (such as tables and views) that are accessed by the user proxy on behalf of a SAS procedure are granted access based on the credentials of the user proxy.
**SPD Server SQL Proxy**

The SPD Server SQL proxy plans and executes SQL queries from SAS PROC SQL for implicit or explicit SQL statements. The sasspds engine can respond in two ways. The sasspds engine can request that the SPD Server host create an SQL proxy, or the sasspds engine can use an existing user proxy as the SQL proxy. (The user credentials of the SQL connection must be same as the credentials for the user proxy for this to happen.) The sasspds engine then sends implicit or explicit SQL statements to the SQL proxy on behalf of PROC SQL.

**SPD Server SQL User Proxy**

SQL queries given to the SQL proxy can either create or query SPD resources. Complex SQL queries can query resources from multiple librefs that have different user credentials. As a result, the SQL proxy creates its own user proxy, called the SQL user proxy, to access resources for the SQL query.

SQL user proxies have either credentials for IP=YES librefs for implicit SQL, or credentials for LIBGEN=YES librefs for explicit SQL. The credentials include the following:

- the user’s SPD Server User ID
- the user’s SPD Server group name
- the user’s SPD Server ACLSPECIAL privileges

If there are multiple IP=YES or LIBGEN=YES librefs that have the same user credentials, the librefs share the same SQL user proxy. Any SPD Server resources (such as tables and views) that are accessed by the SQL proxy are authorized access based on the credentials of the SQL user proxy that is currently servicing that LIBNAME.

**Restrictions for Sharing an SPDSBASE in Hadoop Environments**

SPD Server 5.2 and later provides support for SPD Server tables in Hadoop domains. The Hadoop environment requires additional restrictions if you want to share SPDSBASE processes.

To access the Hadoop cluster, the SPD Server user proxy forks and executes the SAS Java proxy (JProxy) process. The SAS Java proxy process provides the Java Virtual Machine (JVM) environment that is required to communicate with the Hadoop cluster. A Java proxy is configured to access only one Hadoop cluster.

In order for Hadoop LIBNAME domains to share the same user proxy, the LIBNAME domains must have the same values for the following options:

- HADOOPCFG= and HADOOPJAR= must have the same values
- HADOOPUSER= and HADOOPREALM= options must have the same values
Enhanced SPDSBASE Sharing

Configuring Enhanced SPDSBASE Sharing

You specify SPDSBASE enhanced user proxy sharing settings via the SHARE= SPD Server LIBNAME option, or via the SHRUSRPRXY= SPD Server server parameter file option.

SHRUSRPRXY= Server Parameter File Option

You can enable enhanced sharing of user proxies via the SPD Server SHRUSRPRXY= parameter file option. The SPD Server SHRUSRPRXY= server parameter file option defines the default behavior for enhanced user proxy sharing. The SHRUSRPRXY= parameter file option setting can be overridden by the SHARE= saspds engine LIBNAME option.

Syntax

SHRUSRPRXY=[YES|NO]

Default

The default setting for the SHRUSRPRXY= parameter file option is **YES**.

SHARE= LIBNAME Option

You can enable enhanced sharing of user proxies via the SHARE= saspds engine LIBNAME option. Enhanced sharing enables librefs with different user credentials in the same SAS session to share the same SPDSBASE user proxy.

Syntax

SHARE=[YES|NO]

Default

If the SHARE= LIBNAME option is not specified, SPD Server enhanced user proxy sharing settings default to the configuration defined by the SHRUSRPRXY= setting in the server parameter file.

Managing Concurrent SPDSBASE Process Resources

The following situations can cause a large number of SPDSBASE processes to be created during a SAS session:

- Jobs that use multiple LIBNAME statements with different user credentials.
- A user who is a member of multiple groups requires a separate LIBNAME statement for each group credentials. The result is a separate user proxy for each LIBNAME. SPD Server supports up to 32 groups for each user, but you cannot specify more than one group in a LIBNAME statement.
- Librefs with different credentials require their own SQL user proxy. The SQL proxy assigns all librefs that have LIBGEN=YES options for explicit SQL, or librefs that are configured via the IP=YES option setting for implicit pass-through SQL to an SQL user proxy.
When you use the SAS Java proxy to access the Hadoop cluster, it requires additional SPD Server process resources, as well as additional start-up requirements for the user proxy.

You can address resource allocation issues by enabling enhanced sharing of SPD Server user proxies. Enhanced SPD Server proxy sharing does not require the following matching credentials:

- matching SPD Server User ID credentials
- matching SPD Server Group credentials
- matching SPD Server ACLSPECIAL credentials

This means that almost all librefs in the same SAS session are able to share the same user proxy. The same is also true for any IP=YES or LIBGEN=YES librefs that are generated by the SQL proxy. Almost all of those librefs can share the same SQL user proxy. Shared proxies contain a control thread for each LIBNAME assigned to the user proxy. The control thread contains the user attributes of the LIBNAME, which are used to authenticate any resources accessed by that LIBNAME.

Enhanced proxy sharing is recommended if you are experiencing resource allocation issues due to a large number of concurrent spdsbase processes. However, turning the feature off is beneficial in the following situations:

You might want to turn off the enhanced user proxy sharing feature for the following reasons:

- If the user proxy terminates unexpectedly due to a failure, turning it off reduces the number of librefs affected.
- Turning it off enables you to kill the user proxies for a given job.

For example, if a user submits a job that is consuming too many computing resources and enhanced user proxy sharing is not enabled, you could kill the user proxies for only that user job. However, killing all the user proxies for the SAS session, rather than for that particular job, is easier if enhanced user proxy sharing is enabled.
Chapter 15
ACL Security Overview

SPD Server ACL Security Overview

SPD Server uses access control lists (ACLs) and SPD Server user IDs to secure domain resources. Users obtain their user ID and password from the SPD Server administrator.
SPD Server also supports ACL groups, which are similar to UNIX groups. You can associate an SPD Server user as many as five ACL groups.

ACL permissions affect all SPD Server resources, including domains, tables, table columns, catalogs, catalog entries, and utility files. SPD Server grants access rights only to the owner (creator) of an SPD Server resource. Resource owners can use PROC SPDO to grant Read, Write, and Alter ACL permissions to a specific group (called an ACL group) or to all SPD Server users.

The resource owner can use the following properties to grant ACL permissions to all SPD Server users:

READ
   grants universal Read access to the resource (read or query)

WRITE
   grants universal Write access to the resource (append to or update)

ALTER
   grants universal Alter access to the resource (add, rename, delete, or replace a resource, and add or delete indexes associated with a table)

The resource owner can use the following properties to grant ACL permissions to a named ACL group:

GROUPREAD
   grants group Read access to the resource (read or query)

GROUPWRITE
   grants group Write access to the resource (append to or update)

GROUPALTER
   grants group Alter access to the resource (rename, delete, or replace a resource, and add or delete indexes associated with a table)

---

SPD Server ACL Security Model

Overview of the ACL Security Model

SPD Server provides a security system that is based on Access Control Lists, or ACLs.

SPD Server comes bundled with SAS Management Console. SAS Management Console is a GUI utility that you can use to manage passwords and ACLs. SAS Management Console manages passwords using the same capabilities that the psmgr utility provides, and it also manages ACLs using the same capabilities provided by PROC SPDO.

ACL Security

UNIX File-Level Protection with ACL Security

Each session of SPD Server is attached to a user with a UNIX or Windows user ID. If SPD Server runs on UNIX, all files that the software creates are protected according to the permissions for creating UNIX files that are associated with that UNIX user's ID. SPD Server can read or write only files that have the appropriate file and directory access permissions to the SPD Server's user's ID. Use the UNIX umask command to restrict the permissions for creating files.
Validating User IDs and Passwords
SAS users must issue a user ID and password with the LIBNAME statement to connect to SPD Server. The user ID and password are verified against an SPD Server user ID table that is set up by the system administrator. You can enforce the expiration of passwords by using the psmgr administration tool for the user ID table or by using SAS Management Console, if it is installed and configured for SPD Server. Whether you are in a Windows or UNIX environment, you can prevent logins under the anonymous user ID by placing user anonymous in the user ID table with a password that is unknown to the SAS users.

Controlling LIBNAME Domains with ACL Security
You define the valid LIBNAME domains by adding entries in the LIBNAME parameter file for each SPD Server. The PATHNAME= specification defines the file system for the LIBNAME. LIBNAME= specifications provide the access route to the file system. Restricting knowledge of the LIBNAME= specification information restricts access to the corresponding file systems.

User Ownership of LIBNAME Domains and Tables
In the LIBNAME parameter file, you can attach the OWNER= specification to any defined LIBNAME domain. Only the system user whose user ID matches the OWNER= specification can create tables in this domain. (However, that user can grant other users Read or Write access rights through ACLs that were issued from the SAS LIBNAME statement.)

Each table created is tagged with the SPD server user ID (referred to as the owner) of the user who created it. Only the owner or ACLSPECIAL users can access a table. (However, the owner can grant access to other users through ACLs by adding a LIBNAME ACL with PROC SPDO.)

Granting Permissions with ACLs
An SPD Server ACL permits three distinct levels of permission on a resource. First, you can grant Universal permissions to SPD Server users who are not in the same ACL group as the resource owner. Second, you can grant Group permissions to SPD Server users who are in the same ACL group as the resource owner. Third, you can grant User permissions to a specific SPD Server user ID. The precedence of permission checks is as follows:

1. Check user-specific permissions first. If permissions are defined, the accessor is granted these permissions.
2. If a resource is owned by the same ACL group as the accessor, the accessor is granted the resource's Group permissions.
3. If the resource is owned by a different ACL group than the accessor, the accessor is granted the resource's Universal permissions.

ACL Concepts

ACL Groups
ACL groups are similar to UNIX groups. Each SPD Server user ID can belong to one or more ACL groups.

You can associate a given SPD Server user ID with up to five ACL groups. When a user connects to an SPD Server using a LIBNAME assignment, the user specifies a specific
ACL group by using the ACLGRP= option. The ACLGRP= value in the user’s LIBNAME assignment must match one of the five groups that you defined for that user. If the user does not specify ACLGRP= in the LIBNAME assignment, the SPD Server affiliates the user with his or her default ACL group (which is the first group in the list).

When you define user-specific ACL permissions, you can use an ACL group wherever you can use an explicit SPD Server user ACL. Using an ACL group grants permissions to the ACL group instead of to only a specific SPD Server user.

**Column Security**

You can control access to table contents at the column level by using ACLs. You can apply column-level security ACLs to individual users at the user level, or to collections of users at the group level. SPD Server enforces precedence for user and group ACL permissions: first, user ACL permissions are applied, then group ACL restrictions are applied. SPD Server user permissions override SPD Server group permissions.

When you use an ACL statement to create a protected column in a table, all individual users or groups are automatically denied access to the protected column until you explicitly grant them ACL permission to access it. When you issue an ACL statement to grant or deny the contents of a table column to a single user or to a user group, the protected column automatically becomes unavailable to all individual users and user groups, unless you specifically give them access to the protected column.

Consider a scenario in which a testing department hires a new member, Joe. Joe has applied for classified security clearance, but his security clearance level will not be certified for several weeks. All members of the department use an SPD Server table called Testing that contains a column of classified information. Joe needs access to all of the Testing table except the protected column, and the rest of his group needs access to the whole Testing table. Here are steps to give Joe and the other members of the department the correct permissions:

1. You submit a user-level ACL statement to restrict the secure column in table Testing from Joe.
   
   Joe is explicitly denied access, but because the column is now a protected entity, all other users who access the Testing table are also denied access to the column by default.

2. Instead of issuing user-level column ACL permissions to the rest of the testing group individually, you issue a group-level ACL column permission to the user group Testgroup. The permission must explicitly grant access to the protected column.
   
   After a column is protected with ACL security, you must grant explicit permissions in order for any user (or groups of users) to be able to access the column content.

3. SPD Server reads the user-level ACL permissions first, and gives Joe access to the table Testing, but restricts him from the secure column.

4. SPD Server reads the group ACL permissions and grants all of the Testgroup members access to the full table, including the secure column.

   Joe is a member of Testgroup, but the user-level ACL permissions maintain precedence over group-level ACL permissions. All the members of Testgroup have full table access, except Joe. Joe's user-level ACL column security restriction prevents him from accessing the classified column.

Now consider another scenario, in which John manages a group Devgroup whose members record their billable project hours and codes in an SPD Server table. In that table, manager John keeps billing-rate information based on employee salaries in a protected column Rate. Only John should be able to see the entire table, and the rest of
the Devgroup should be able to see the table minus the Rate column. In this case, you create column security by protecting the Rate column with a user-level ACL permission statement for John. The Devgroup members can have full table permissions at the group level, but cannot see the protected column because John's user-level column security ACLs override any group-level ACLs for the Devgroup table. For example code that implements column-level security, see “Column-Level Security Example” on page 164.

**Generic ACL**

You can use generic ACL names for a class of resources that have a common prefix. You can use an asterisk (*) as a wildcard character to make a single ACL entry instead of making explicit entries for each resource. For example, if you have tables named Salesne, Salesse, Salesmw, Salessw, Salespw, and Salesnw, you could use the wildcard character to create the generic ACL name, Sales*, to include all of them. You then would define your ACL permissions on the Sales* generic ACL.

When you are using the SPDO procedure, use the /GENERIC command option to identify a generic ACL. (See “Controlling SPD Server Resources with PROC SPDO” on page 139.)

*Note:* If you specify /GENERIC when you define a table-column ACL, the /GENERIC option applies to the table name, not to the column name. You cannot use wildcard characters with column names.

**LIBNAME ACL**

You can control access permissions to an entire LIBNAME domain by using the SPD Server ACL facility. When you are using PROC SPDO, use the /LIBNAME option to identify the LIBNAME domain ACL.

**Persistent ACL**

A persistent ACL entry is an ACL that is not removed from the ACL tables when the resource itself is deleted. When you are using PROC SPDO, use the /PERSIST command option to identify a persistent ACL.

**Resource**

A PROC SPDO resource can be one of the following items:

- a table (data set)
- a table column (data set variable)
- a catalog
- a catalog entry
- a utility file (for example, a VIEW, an MDDB, and so on)
- a LIBNAME domain

**Two-Part Resource Name**

Two-part names identify a column entry in a table. Use the SAS convention `table.column` when you specify the table and column that you want to secure.

When you issue SPDO commands, you can use two-part names in any context that defines, modifies, lists, or deletes table-related ACLs. You can also specify the reserved word _ALL_ as the column name when you issue SPDO commands that support the _ALL_ resource name.
Giving Control to Others
You can permit other SPD Server users to alter your own ACL entry by granting a specific user or group access to that ACL entry. See “MODIFY ACL and MODIFY ACL _ALL_ ” on page 141 for more information about user-specific ACL entries.

Securing SPD Server Against Unknown Client Attacks

Overview of SPD Server Security for Unknown Client Attacks
SPD Server is a client-server-based architecture that allows outside clients to connect to SPD Server processes on well-known published ports. SPD server also uses ephemeral (unpublished) ports for internal communication between SPD Server processes and clients.

SPD Server provides protection against attacks from unknown clients in the following ways:

• SPD Server uses a proprietary communication protocol. All messages that are received are examined to determine whether they are valid. Any invalid message is discarded.

• SPD Server provides the option of logging any unknown communications in the SPD Server log files. Unknown communications can be logged from the spdsnsrv process, the spdserv process, the spdssnet process, and the spdsbase process. The log messages include the IP address of the client that sent the message.

• SPD Server processes effectively handle an invalid message by continuing to function properly for subsequent valid messages.

In some cases, third-party port checking software can cause unexpected growth in SPD Server logs. If this is the case, set the SPDSLOGBADCONNECT= SPD Server environment variable in your rc.spds start-up script to control how port access attempts are logged.

SPDSLOGBADCONNECT= Environment Variable
To enable logging of invalid messages, export the SPDSLOGBADCONNECT=Y environment variable in your rc.spds start-up script. You must export the variable value before any SPD Server processes are started. All SPD Server processes that communicate will check the status of the environment variable on start-up, and log accordingly.

Usage:
Specify the SPDSLOGBADCONNECT=Y environment variable in your SPD Server rc.spds start-up script.

export SPDSLOGBADCONNECT= [Y|N]

Default:
The default value of SPDSLOGBADCONNECT= is N, which configures SPD Server processes to not log failed connections.
Controlling SPD Server Resources with PROC SPDO

Overview of PROC SPDO

PROC SPDO is the SAS procedure for the SPD Server operator interface. This procedure runs only on systems where the SAS is installed.

PROC SPDO Command Set

To invoke PROC SPDO, submit the following command:

```
PROC SPDO LIB=libref ;
```

In this command, `libref` is a LIBNAME that was previously allocated to the sasspds engine.

PROC SPDO commands are divided into two classes:
- ACL commands
- LIBNAME proxy commands

The ACL commands are described in “Using the ACL Command Set” on page 139 with some simple examples that demonstrate their syntax and usage. For more information about LIBNAME proxy commands, see Chapter 22, “SAS Scalable Performance Data (SPD) Server Operator Interface Procedure (PROC SPDO),” on page 209.

Using the ACL Command Set

Overview of the ACL Command Set

This section describes PROC SPDO commands that you use to create and maintain ACLs on SPD Server resources.

To issue an ACL-related command, you must first specify an ACL user ID to define the scope of your access. You might also want to set up a scoping member type to access ACLs for resource types other than DATA. Then you can add, modify, list, or delete ACLs within the scope that you set up. You can switch the scope of a user type, a member type, or both at any point in a command sequence. Then you can continue with additional ACL commands in the new scope.

```
SET ACLTYPE memtype;
```

sets the member type for subsequent ACL operations. Valid values are DATA, CATALOG, VIEW, and MDDB. The default is DATA.
**SET ACLUSER [name]:**

sets the SPD Server user scope for subsequent ACL operations. The user scope restricts the user’s view to only those ACL records that have the specified user name as the owner of the ACL entry. If you omit the *name* value, the default name is the user who assigns the libref.

To perform an ACL operation on a resource entry, one of the following statements must be true:

- the user is the owner of the ACL entry
- the user has Control access to the ACL entry
- ACLSPECIAL=YES is enabled on the user’s PROC SPDO LIBNAME connection

*Note:* You must first issue a SET ACLUSER command before you issue any ADD ACL commands that are described in the following section.

**ADD ACL Command**

**ADD ACL acl1 acl2... [C=cat T=type] [/options]**

creates new ACL entries acl1 acl2, and so on. All the ACL entries that you create can be one-part resource names or two-part (table.column) names.

Specify one or more of the following ADD ACL options:

- **READ**
  grants universal Read access to the resource.

- **WRITE**
  grants universal Write access to the resource.

- **ALTER**
  grants universal Alter access to the resource.

- **GROUPREAD**
  grants group Read access to the resource.

- **GROUPWRITE**
  grants group Write access to the resource.

- **GROUPALTER**
  grants group Alter access to the resource.

- **GENERIC**
  indicates that the specified ACLs are generic ACLs.

- **PERSIST**
  indicates that the specified ACLs are persistent ACLs.

- **LIBNAME**
  identifies the special LIBNAME domain resource.

- **MODEL=acl-name**
  specifies the name of another ACL. This option requests SPD Server to copy all the access permissions and access list entries from this ACL.

- **C=cat**
  identifies the specified ACL names as the names of catalog entries in the catalog *cat*. Pair this value with the *T* = option.
T=type
identifies the catalog entry type that is used to qualify the specified ACLs when the
C=cat option is specified.

**ADD ACL Command Examples**

**Add a LIBNAME Domain ACL**
This ACL grants universal Read and group Write access.

```
add acl/LIBNAME
    read
    groupwrite;
```

**Add a Resource ACL**
This ACL for the resource MINE_JAN1999 grants universal Read and Write access.

```
add acl mine_jan1999/read write;
```

**Add a Generic ACL**
This generic ACL for MINE* grants universal Read access.

```
add acl mine/generic read;
```

**Add a Column ACL**
This ACL for the column MINE_JAN2006.SALARY grants group Read access and
denies access to all others.

```
add acl mine_jan2006.salary/groupread;
```

**Add a Generic Column ACL**
This ACL for the column MINE*.SALARY grants group Read access and denies
access to all others.

```
add acl mine.salary/generic groupread;
```

**Add a Catalog ACL**
This ACL for the MYCAT catalog grants universal Read and group Read / Write
access.

```
set acltype catalog;
add acl mycat/read
groupread
```

**Add a Generic ACL for Catalog Entries**
This ACL for catalog entries, MYCAT.MY*.CATAMS, grants universal Read and
group Read access.

```
set acltype catalog;
add acl my
c=mycat
t=catams/generic
    read
    groupread;
```

**MODIFY ACL and MODIFY ACL _ALL_**

```
MODIFY ACL acl1 acl2... [C=cat T=type] /options Group List;
```
**MODIFY ACL _ALL_ /options Group List;**

modifies existing ACLs (acl1, acl2, and so on) for the specified resources. The ACL entries can be one-part resource names or two-part (table.column) names. Specify _ALL_ to modify all existing ACLs for which you have Control access. If you specify _ALL_ as the table identifier in a two-part name, you modify all tables for which the given column is matched. If you specify _ALL_ as the column identifier in a two-part name, you modify all columns for which the given table is matched. Specify the characteristics that you want to modify by specifying one or more of the following options, or by specifying *group list* or *user*.

Specify one or more of the MODIFY ACL options:

- **READ**
  - grants universal Read access.

- **NOREAD**
  - removes universal Read access.

- **WRITE**
  - grants universal Write access.

- **NOWRITE**
  - removes universal Write access.

- **ALTER**
  - grants universal Alter access.

- **NOALTER**
  - removes universal Alter access.

- **GROUPREAD**
  - grants group Read access.

- **NOGROUPREAD**
  - removes group Read access.

- **GROUPWRITE**
  - grants group Write access.

- **NOGROUPWRITE**
  - removes group Write access.

- **GROUPALTER**
  - grants group Alter access.

- **NOGROUPALTER**
  - removes group Alter access.

- **GENERIC**
  - indicates that the specified ACLs are generic ACLs.

- **LIBNAME**
  - identifies the special LIBNAME domain ACL.

- **C=cat**
  - identifies the specified ACLs as names of catalog entries from the catalog *cat*. Pair this value with the *T=* option.

- **T=type**
  - identifies the catalog entry type that is used to qualify the specified ACLs when the C=cat option is specified.

*Group List |User*

a list of the following form: *group list* = (Y/N,Y/N,Y/N,Y/N) where each comma-delimited Y or N represents, in order, group settings for Read, Write, Alter, and
Control privileges, or \textit{user name} = (Y/N,Y/N,Y/N,Y/N) where each comma-delimited Y or N represents, in order, user settings for Read, Write, Alter, and Control privileges.

\textbf{MODIFY ACL Command Examples}

\textbf{Modify a LIBNAME Domain ACL}
This command modifies a LIBNAME domain to set Read and Write access for a given user.

\begin{verbatim}
modify acl/LIBNAME
  ralph=(y,y,n,n);
\end{verbatim}

\textbf{Modify the ACL MINE}
This command modifies the ACL MINE\_JAN2003 to deny universal Write access and to add user-specific permissions.

\begin{verbatim}
modify acl mine\_jan2003/nowrite
  bolick=(y,n,n,n)
  johndoe=(n,n,n,n);
\end{verbatim}

\textbf{Modify a Generic ACL}
This command modifies the generic ACL MINE* to add user-specific permissions.

\begin{verbatim}
modify acl mine/generic
  tom=(y,y,y,n);
\end{verbatim}

\textbf{Modify All ACLs}
This command modifies all ACLs to grant Read access to a given user.

\begin{verbatim}
modify acl _all_/gene=(y,,);
\end{verbatim}

\textbf{Modify a Column ACL}
This command modifies the column ACL MINE\_JAN2006.SALARY to add explicit Read and Write access for a given user.

\begin{verbatim}
modify acl mine\_jan2006.salary/ralph=(y,y,n,n);
\end{verbatim}

\textbf{Modify a Generic Column ACL}
This command modifies the generic column ACL MINE*.SALARY to add explicit Read and Write access for a given user.

\begin{verbatim}
modify acl mine.salary/generic
  debby=(y,y,n,n);
\end{verbatim}

\textbf{Modify an ACL for a Catalog}
This command modifies the catalog MYCAT to remove universal Read and group Write access.

\begin{verbatim}
set acltype catalog;
modify acl mycat/noread nogroupwrite;
\end{verbatim}

\textbf{Modify a Generic ACL for Catalog Entries}
This command modifies the generic ACL for catalog entries MYCAT.MY*.CATAMS to remove universal Read access.

\begin{verbatim}
set acltype catalog;
modify acl my
c=mycat
t=catams/generic noread;
\end{verbatim}
LIST ACL and LIST ACL _ALL_

LIST ACL acl1 acl2... [/options];

LIST ACL _ALL_ [/options];
lists information about the specified ACLs (acl1, acl2, and so on). The ACL entries can
be one-part resource names or two-part (table.column) names. Specify _ALL_ to list all
existing resource ACLs for which you have Control access. Specify _ALL_ as the table
identifier in a two-part name to list all tables for which the given column is matched.
Specify _ALL_ as the column identifier in a two-part name to list all columns for which
the given table is matched.

Specify one or more of the LIST ACL options:

- GENERIC
  indicates that the specified ACLs are generic ACLs.

- LIBNAME
  identifies the special LIBNAME domain ACL.

- C=cat
  identifies the specified ACLs as names of catalog entries from the catalog cat. Pair
  this value with the T= option.

- T=type
  identifies the catalog entry type that is used to qualify the selected ACLs when the
  C=cat option is specified.

- VERBOSE
  performs the requested table ACL listing, followed by the column ACLs for one or
  more specified tables. This option is equivalent to specifying a LIST ACL table
  command followed by a LIST ACL table._ALL_ command.

LIST ACL Command Examples

List All ACL Entries
  This command lists all ACL entries for the current ACL type setting.
  
  list acl _all_;

List a Generic ACL
  This command lists a generic ACL entry for MINE*.
  
  list acl mine/generic;

List All Column ACLS for a Table
  This command lists all column ACLs for table MINE_JAN2003.
  
  list acl mine_jan2003._all_;

List All Column ACLs for All Tables
  This command lists all column ACLs for all tables.
  
  list acl _all._all_;

List a Specific Column
  This command lists the column ACL for MINE_JAN2006.SALARY.
  
  list acl
  mine_jan2006.salary;
List All ACL Data for a Table
This command provides all ACL information for table MINE_JAN2006.

```
list acl
mine_jan2006/verbose;
```

List All ACLs for Catalogs
This command lists all ACLs for the ACL type catalog.

```
set acltype catalog;
list acl _all_;  
```

List All ACLs for a Catalog
This command lists all ACLs for catalog MYCAT?.CATAMS.

```
set acltype catalog;
list acl _all_ c=mycat t=catams;
```

DELETE ACL and DELETE ACL _ALL_

DELETE ACL acl1 acl2... [C=cat T=type] /options

DELETE _ALL_ [C=cat T=type] /options;
deletes existing ACLs for the specified resources (acl1 acl2, and so on). The ACL entries can be one-part resource names or two-part table.column names. Specify _ALL_ to delete all existing resource ACLs for which you have Control access. Specify _ALL_ as the table identifier in a two-part name to delete all tables for which the given column is matched. If you specify _ALL_ as the column identifier in a two-part name, you delete all columns for which the given table is matched.

Specify one or more of the DELETE ACL options:

**GENERIC**
indicates that the specified ACLs are generic ACLs.

**LIBNAME**
identifies the special LIBNAME domain ACL.

**C=cat**
identifies the specified ACLs as names of catalog entries from the catalog cat. Pair this value with the T= option.

**T=type**
identifies the catalog entry type that is used to qualify the specified ACLs when the C=cat option is specified.

DELETE ACL Examples

Delete a LIBNAME ACL
This command deletes a LIBNAME ACL.

```
delete acl/LIBNAME;
```

Delete All ACLs for the Current ACL Type
This command deletes all the ACLs for the current ACL type.

```
delete acl _all_;  
```

Delete a Resource ACL
This command deletes the ACL MINE_JAN2003.

```
delete acl MINE_JAN2003;
```
Delete a Generic ACL
This command deletes the generic ACL MINE*.

```sql
delete acl mine/generic;
```

Delete a Column ACL
This command deletes a column ACL on MINE_JAN2003.SALARY.

```sql
delete acl mine_jan2003.salary;
```

Delete All Column ACLs on a Table
This command deletes all column ACLs on the table KBIKE.

```sql
delete acl kbike._all_;
```

Delete All Column ACLs on All Tables
This command deletes all column ACLs on all tables.

```sql
delete acl _all_.all_;
```

Delete a Catalog ACL
This command deletes an ACL on the catalog RBIKE.

```sql
set acltype catalog;
delete acl rbike;
```

Delete a Generic ACL on Catalog Entries
This command deletes a generic ACL on the catalog entries MYCAT.MY*.CATAMS.

```sql
set acltype catalog;
delete acl my
c=mycat
t=catams/generic;
```

---

**ACL Security Examples**

**Overview of Security Examples**

Precedence of permission checks includes inheriting the permissions of the LIBNAME ACL for resources owned by the domain owner. The LIBNAME ACL is used first to grant LIBNAME access to the domain, and then to inherit ACLs to resources that belong to the domain owner. When a user attempts to access resources in a domain in which the domain owner specifies LIBACLINHERIT=YES, the following ACL precedence of permissions checks are made on the resource:

1. If user-specific ACLs are defined on the object for the user, the user gets these permissions.
2. If group-specific ACLs are defined on the object for the user’s group, the user gets these permissions.
3. If LIBNAME ACL permissions are defined for the user and the resource belongs to the OWNER= of the domain, then the user gets the domain LIBNAME ACL permissions on the object.
4. If LIBNAME ACL permissions are defined for the user’s group and the user is a member of the OWNER= group of the domain, then the user gets the LIBNAME ACL group permissions on the object.

5. Otherwise, the user gets UNIVERSAL ACLs on the resource.

The following listing contains the libnames.parm files that are used in the code examples, and a list of users and groups in the password database.

libnames.parm:

```
----------------------------------
LIBNAME=d1
   pathname=/IDX1/spdsmgr/d1
   owner=admin ;
LIBNAME=d2
   pathname=/IDX1/spdsmgr/d2
   owner=prod1 ;
LIBNAME=colsec
   pathname=/IDX1/spdsmgr/colsec
   owner=boss ;
LIBNAME=onepath
   pathname=/IDX1/spdsmgr/onepath ;
```

**Domain Security Examples**

When you specify the libname.parm option OWNER=, no other user can access the domain unless the user is given permissions by the domain owner. Permissions to access a domain are given using a LIBNAME ACL statement.

The following code example uses a LIBNAME ACL statement to give access permissions to different groups.
The ID `prod2` is in the group that has permissions to control the LIBNAME ACL. Any ID in that group can modify the LIBNAME ACL.

Because the ACL was created by user `prod1`, the user `prod2` must use the user ID `prod1` to modify the LIBNAME ACL. This is allowed because the group was given control. User `prod1` still remains the owner of the LIBNAME ACL.
A user who has ACL special privileges can also change the LIBNAME ACLs. In the following example, the user `admin1` uses the ACLSPECIAL= statement to modify the LIBNAME ACL. As in the previous example, the user `admin1` must use the user ID `prod1`.

```
LIBNAME admin1d2 sasspds 'd2'
   server=zztop.5162
   user='admin1'
   password='spds123'
   ACLSPECIAL=YES
   IP=YES ;
PROC SPDO library=admin1d2 ;
/* The ACLSPECIAL= statement allows */
/* the user 'admin1' to operate under */
/* the user ID 'prod1', allowing the */
/* ACLs to be modified. */
set acluser prod1 ;
modify ACL /
   LIBNAME admingrp=(y,n,n,n) ;
list ACL _all_ ;
quit ;
```

**LIBACLINHERIT Example**

If the LIBACLINHERIT domain option is turned on for a domain in the libnames.parm file, the ACL precedence of permission checks changes for resources that belong to the domain owner. Turning on LIBACLINHERIT creates a LIBNAME ACL on the specified LIBNAME domain. For information about LIBACLINHERIT permissions and how they affect ACL precedence of permission checks, see “Controlling the Precedence of Permission Checks with the LIBACLINHERIT= Option and the OWNER= Option” on page 91.

The following example uses LIBACLINHERIT:

```
/* information from libnames.parm */
/* */
/* LIBNAME=LIBINHER */
/* pathname=/IDX1/spdsmgr/spds41test/libinher */
/* LIBACLINHERIT=YES */
/* owner=admin; */
/* LIBNAME=noinher */
/* pathname=/IDX1/spdsmgr/spds41test/noinher */
/* owner=admin; */

LIBNAME libinher sasspds 'libinher'
   server=zztop.5129
   user='admin'
   password='spds123';

LIBNAME noinher sasspds 'noinher'
   server=zztop.5129
```
user='admin'
password='spds123';

data libinher.admins_table
    noinher.admins_table;
        do i = 1 to 10;
            output;
        end;
run;

/* Set up LIBNAME access for user anonymous */
PROC SPDO library=libinher;

/* set who will own these ACLs */
set acluser admin;

/* Add a LIBNAME ACL to d1 */
add acl / LIBNAME;

/* Modify LIBNAME ACL Domain d1 */
/* Allow users in Group 1 read-only */
/* access to the domain */
modify acl / LIBNAME read;
    list acl _all_;
    quit;

/* Set up LIBNAME access for user anonymous */
PROC SPDO library=noinher;

/* Specify who owns these ACLs */
set acluser admin;

/* add a LIBNAME ACL to d1 */
add acl / LIBNAME;

/* Modify LIBNAME ACL Domain d1 */
/* Allow users in Group 1 read-only */
/* access to the domain */
modify acl / LIBNAME read;
list acl _all_; quit;

LIBNAME a_inher sasspds 'libinher'
  server=zztop.5129
  user='anonymous';
LIBNAME a_noher sasspds 'noinher'
  server=zztop.5129
  user='anonymous';

PROC PRINT data=a_inher.admins_table;
  title 'with libaclinher';
run;

PROC PRINT data=a_noher.admins_table;
  title 'without libaclinher';
run;

**Anonymous User Account Example**

The SPD Server uses a general ID that is called anonymous. Any person who can connect to the server can do so using the anonymous user ID. The anonymous ID cannot be removed from the password database using the psmgr utility and the `delete` command. If you want to prevent anonymous user ID access, use the psmgr utility to add a user called *anonymous* to the password database and keep the password secret.

Any table that is created by the anonymous user ID can be viewed by all users who have access to that table's domain. The anonymous ID can place ACLs on the table to limit access.

/* John logs in using the anonymous */
/* user ID and creates a table */

LIBNAME john sasspds 'onepath'
  server=zztop.5162
  user='anonymous'
  password='anonymous'
  IP=YES ;

data john.anonymous_table ;
  do i = 1 to 100 ;
    output ;
  end ;
run ;

/* Mary can also log in as anonymous */
/* and read the table that John */
/* created. */

LIBNAME mary sasspds 'onepath'
  server=zztop.5162
  user='anonymous'
  IP=YES ;

PROC PRINT data=mary.anonymous_table
/* user1 can log in and read the table */
/* that John created */

LIBNAME user1 sasspds 'onepath'
server=zztop.5162
user='user1'
password='spds123'
IP=YES;

PROC PRINT data=user1.anonymous_table
(obs=10);
title
mary reading anonymous_table;
run;

PROC SPDO library=john;
/* assign who owns the ACL */
set acluser anonymous;

/* The MODIFY statement sets an ACL so */
/* only user ID 'anonymous' can read */
/* the table */
add ACL anonymous_table;
modify ACL anonymous_table /
anonymous=(y,n,n,n);
list ACL _all_
quit;

/* Now, only user ID 'anonymous' can */
/* read the table */

LIBNAME user1 sasspds 'onepath'
server=zztop.5162
user='user1'
password='spds123'
IP=YES;

PROC PRINT data=user1.anonymous_table
(obs=10);
title
user1 trying to read anonymous_table;
run;

LIBNAME mary sasspds 'onepath'
Read-Only Tables Examples

A common security measure in SPD Server assigns an SPD Server ID to act as the owner of a domain and to provide control over it.

Typically, one or two user IDs administer table loads and refreshes. These user IDs can perform all the jobs that are required to create, load, refresh, update, and administer SPD Server security. Using one or two user IDs centralizes the data administration on the server. More than one ID for data administration spreads responsibility and still provides backup. The following example demonstrates how to grant different groups access to the domain and tables, and how different groups can control resources in the domain.

LIBNAME d1 sasspds 'd1'
server=zztop.5162
user='admin1'
password='spds123'
IP=YES ;

PROC SPDO library=d1 ;
/* assign who owns the ACLs */
set acluser admin1 ;
/* add a LIBNAME ACL to d1 */
add ACL / LIBNAME ;

The MODIFY statement in the following code enables the following actions:

- Any user who is in the same group as admin can read, write, or alter tables and can modify the LIBNAME access to the domain.
- Users in group1 and group2 are granted Read access to the domain.
- Users in group3 and group4 are granted Read and Write access to the domain.

modify ACL / LIBNAME
admingrp=(y,y,y,y)
group1=(y,n,n,n)
group2=(y,n,n,n)
group3=(y,y,n,n)
group4=(y,y,n,n) ;

list ACL _all_
quit ;

/* create two tables */

data d1.admin1_table1 ;
do i = 1 to 100 ;
output ;
end ;
run ;

/* admin1 has write privileges to */
/* the domain */

data d1.admin1_table2 ;
do i = 1 to 100 ;
output ;
end ;
run ;

/* Generic ACLs allow all users to */
/* read tables created by admin1 */
/* unless a specific ACL is placed */
/* on a resource */

PROC SPDO library=d1 ;

/* Assign who owns the ACLs */

set acluser admin1 ;

The two ACL commands in the following code give Read privileges to members of the ACL group ADMIN1 for any table that is created by the user admin1. The user admin1 has Read access to the domain.

This ACL is a good example for data marts and warehouses that do not contain sensitive data. A generic ACL gives broad access to tables in a domain. You must use generic ACLs correctly (or not at all) if you need to restrict access to sensitive data to specific users or groups of users. If a table in a domain with generic ACLs is not specifically protected by its own ACL, there is a risk of allowing access by any user to sensitive data.

add ACL / generic
read ;
modify ACL / generic read
admingrp=(y,n,n,y) ;
list ACL _all_
quit ;

/* Test access for a user in group1 */

LIBNAME userid1 saswpds 'd1'
When any ACL is placed on a specific table, that ACL takes precedence over the generic ACL. The ACL in the following code provides the following access:

- gives group1 Read access to admin1_table2.
- gives admingrp Read and Control access to admin1_table2.
- prevents users who are not granted specific access to admin1_table2 from reading, writing, altering, or controlling the table. The ACL in the code takes precedence over the generic Read ACL.
add ACL admin1_table2 ;
modify ACL admin1_table2 /
group1=(y,n,n,n)
  admingrp=(y,n,n,y) ;
list ACL _all_;
quit ;

/* Test access for a user in group1 */
LIBNAME user1d1 sasspds 'd1'
  server=zztop.5162
  user='user1'
  password='spds123'
  IP=YES ;
PROC PRINT data=user1d1.admin1_table2
   (obs=10) ;
title
   'read admin1_table2 by user1' ;
run ;

/* Test access for a user in group2 */
LIBNAME user2d1 sasspds 'd1'
  server=zztop.5162
  user='user2'
  password='spds123'
  IP=YES ;
PROC PRINT data=user2d1.admin1_table2
   (obs=10) ;
title
   'read admin1_table2 by user2' ;
run ;

Domain Security and Group Access Example

This section of code provides an overview of SPD Server domain security and group access using PROC SPDO.

Permissions are often granted to a group of users rather than to individual users. This example shows how to grant access to different groups of users access to the domain owned by the user ID admin, and then extends the access to the tables. Granting permissions in this way makes administration both simpler and more secure. Admin1 is the owner of the domain and can determine access to the resources. In the following example, PROC SPDO grants the following user access:

- Any user ID in admingrp is granted Read/Write/Alter access to the domain.
- Any user ID in group1 or group2 is granted Read access to the domain.
- Any user ID in group3 or group4 is granted Read/Write access to the domain.

LIBNAME d1 sasspds 'd1'
  server=zztop.5162
  user='admin'
password='spds123
IP=YES

PROC SPDO library=d1;

/* assign who owns the ACLs */
set acluser admin;

/* add a LIBNAME ACL to d1 */
add ACL / LIBNAME;

/* Allow any user in same group */
/* as admin to read, write, or */
/* alter tables in the domain */
modify ACL / LIBNAME
   admingrp=(y,y,y,n)
   group1=(y,n,n,n)
   group2=(y,n,n,n)
   group3=(y,y,n,n)
   group4=(y,y,n,n);

list ACL _all_
run;

/* admin1 has write privileges to */
/* the domain */
data d1.admin1_table1;
   do i = 1 to 100;
      output;
   end;
run;

/* Generic ACL allows all users to */
/* read tables created by admin1 */

PROC SPDO library=d1;

/* assign who owns the ACLs */
set acluser admin1;

/* Modify LIBNAME for groupread */
/* and groupwrite. The ACL MUST */
/* include groupread if other */
/* users in the same group as */
/* admin2 need to be able to read */
/* tables that were created by */
/* admin2. */
add ACL admin1_table1 /
   generic
read
groupread
groupalter;

list ACL _all_; run;

/* admin1 has write privileges to */
/* the domain */
data d1.admin1_table2 ;
do i = 1 to 100 ;
output ;
end ;
run ;

/* generic ACL allows all users to */
/* read the tables */
PROC SPDO library=d1 ;

/* assign who owns the ACLs */
set acluser admin1 ;

/* Add a table and modify LIBNAME ACL */
/* for groupread and groupwrite. The */
/* ACL MUST include groupread to give */
/* users in the same group as admin2 */
/* the ability to read tables created */
/* by admin2 */

add ACL admin1_table2 /
group1=(y,n,n,n)
admingrp=(y,n,n,y) ;
list ACL _all_; run;

/* admin2 has write privileges to the */
/* domain */
data admin2d1.admin2_table ;
do i = 1 to 100 ;
output ;
end ;
run ;

/* Admin2 must use PROC SPDO to allow */
/* users read access to the table. */
/* The PROC SPDO example below uses */
/* generic syntax with a read. This */
/* provides any user outside of the */
/* admingrp read access to tables */
/* that were created by admingrp. The */
/* groupread and groupalter allow */
/* access by users within admingrp. */
PROC SPDO library=admin2d1 ;

/* Assign who owns the ACLs */

set acluser admin2 ;

/* Modify LIBNAME ACL for groupread */
/* and groupwrite. The ACL MUST */
/* include groupread if other users */
/* in the same group as admin2 need */
/* to read tables created by admin2. */

add ACL / generic
read
groupread
groupalter ;

list ACL _all_;

/* admin (same group) can read the */
/* table */

PROC PRINT data=d1.admin2_table
  (obs=10) ;
  title 'read by admin' ;
  run ;

/* Admin has been given the ability to */
/* modify or replace tables created by */
/* admin2 with 'groupalter' */

data d1.admin2_table ;
do i = 1 to 100 ;
  output ;
end ;
run ;

/* Provide other users in same group */
/* read access to the table */

PROC SPDO library=admin2d1 ;

/* assign who owns the ACLs */

set acluser user3 ;

/* Modify LIBNAME ACL for groupread */
/* and groupwrite. The ACL MUST */
/* include groupread if other users in */
/* the same group as admin2 are to be */
/* able to read tables that were */
/* created by admin2 */

add ACL user3_table /
groupread ;
Bring a Table Offline to Refresh

The following scenario explains how to bring a table offline and refresh it:

1. Revoke Read access to all user IDs, except the ID that will perform the refresh.

   ```
   LIBNAME d2 saspds 'd2'
   server=zztop.5162
   user='prod1'
   password='spds123'
   IP=YES ;
   ```

   This example assumes that the table prod1_table is already loaded in the domain and that the groups who use the table have access.

   ```
   PROC SPDO library=d2 ;
   /* assign who will owns these ACLs */
   set acluser prod1 ;
   ```

2. Modify the table ACL:
   a. Revoke Read and Control access by user IDs that are in the same group. This step prevents locks during table refreshes.
   b. Revoke Read access by users that are in group1 through group4 to prevent locks during the refresh process.

   *Note:* If a user is actively accessing a data table when the ACLs for that table are modified, the user continues to have access. This situation can create a table lock that prevents the table refresh from occurring. By revoking the table's Read privileges before the refresh occurs, new SPD Server jobs cannot access the table.

   Existing jobs continue to run and can finish under the lock.

   **Tip** You can also use the special PROC SPDO operator commands to identify any users that might be running unattended jobs, and disconnect them so that the refresh can take place.

   ```
   modify ACL prod1_table /
   prodgrp=(n,n,n,n)
   group1=(n,n,n,n)
   group2=(n,n,n,n)
   group3=(n,n,n,n)
   group4=(n,n,n,n) ;
   ```

3. Modify table ACLs to allow the user ID prod1 to perform table refreshes. Because user ID prod1 is part of the group prodgrp, that ID loses access to the table when the permissions are changed. Prod1, the domain and table owner, can still modify ACLs to gain access.

   ```
   modify ACL prod1_table /
   prod1=(y,y,y,y) ;
   list ACL _all_;
   quit;
   ```

   Now user ID prod1 has full access to refresh the table.
After the table has been refreshed, modify the ACL to allow Read access again.

```plaintext
modify ACL prod1_table /
prodg=(y,n,n,y)
group1=(y,n,n,n)
group2=(y,n,n,n)
group3=(y,n,n,n)
group4=(y,n,n,n)
list ACL _all_
run;
```

You do not need to issue an ADD ACL command for prod1_table. When you delete or replace a table, you do not delete the ACLs. The ACL for that table remains until one of the following actions has occurred:

- the table ACL is deleted using PROC SPDO delete syntax
- the table is deleted and another user creates a table with the same name

If one of these actions occurs, the ACLs have not been deleted. Deleting the table releases any rights that owner has on the table. The exception is when persistent ACLs are used.

### Bring a Domain Offline in Order to Refresh Tables

You can approach this type of table refresh in two ways.

You can minimize contention and table locking by revoking privileges of users and groups who will not be involved in the refresh process.

This example assumes that the tables are already loaded in the domain and that the groups that use them have access to the domain.

```plaintext
LIBNAME d2 sasspds 'd2'
   server=zztop.5162
   user='prod1'
   password='spds123'
   IP=YES;
PROC SPDO library=d2;
/* Assign who owns the ACLs */
   set acluser prod1;
```
resources in the domain. This example turns off all Read access to the domain, except for IDs that are in the production group (prodgrp). This approach allows the production IDs to have full control over the tables and resources.

Note: Any user who is currently accessing the domain continues to have access until they are disconnected. This situation can cause a lock to occur. You can use the PROC SPDO special operator commands to identify the user and disconnect the process so that the refresh can occur.

modify ACL / LIBNAME
prodgrp=(y,y,y,y)
group1=(n,n,n,n)
group2=(n,n,n,n)
group3=(n,n,n,n)
group4=(n,n,n,n);
list ACL _all_;
run;

/* Modify ACL for tables to be refreshed */
PROC SPDO library=d2;

/* set who owns the ACLs */
set acluser prod1;

/* Modify table ACL to revoke read and */
/* control by user IDs in same group, */
/* which prevents locks during table */
/* refreshes. */
modify ACL prod1_table /
prodgrp=(n,n,n,n); 
/* Modify table ACL to allow the */
/* 'prod1' user ID to refresh the */
/* table. */
modify ACL prod1_table /
prod1=(y,y,y,y);
list ACL _all_; 
/* refresh warehouse table(s) */
data d2.prod1_table;
do i = 1 to 100;
  output;
end;
run;

PROC SPDO library=d2;

/* Assign who owns the ACLs */
set ACLUSER prod1;

/* Allow users and groups access to */
ACL Security Examples

ACL Special Users Example

SPD Server user IDs are divided into two levels, 0 through 3 and 4 through 7. Level 4 through level 7 user IDs can log on as an SPD Server super user who can do the following tasks:

• access any table
• change table ACLs
• disconnect users
• perform administrative functions when necessary

SPD Server super users can perform database administrator functions. SPD Server super users cannot change the ownership of a table, but they can assume the identity of the table owner to do required work. This type of situation occurs when a user needs access and the table owner or domain owner is out of the office.

Before you give a user SPD Server super user status, consider the following questions:

• Do you trust this user? SPD Server super users can access any data in any domain.
• How many SPD Server super users do you want? Limit the number in order to maintain Control access.
• Is this user knowledgeable about the data and the database users' needs?

Assume that the table user1_table1 is loaded, and that users in group1 have Read permissions to that table. User4 is a member of group4, and group4 does not have Read access to the table. User1 is the owner of table user1_table1 in domain d2. User1 is on vacation and user4 has been given an assignment that requires Read access to the table user1_table1 to create a report for management.

Management has approved user4 for access to the table. The super user prod1 uses the ACLSPECIAL= option to modify the ACLs and to give user4 Read access to the table.

LIBNAME prod1d2 sasspds 'd2'
server=zztop.5162
user='prod1'
password='spds123'
acispecial=YES
IP=YES ;

PROC SPDO library=prod1d2 ;
/* assign to the user to who owns */
/* the ACL that will be modified */
Column-Level Security Example

The goal of column-level security is to allow only privileged users to access sensitive columns of tables that other users are not permitted to access.

LIBNAME user1 sasspds 'onepath' server=zztop.5161 user='user1' password='spds123';
LIBNAME user2 sasspds 'onepath' server=zztop.5161 user='user2' password='spds123' aclgrp='group2';
LIBNAME user6 sasspds 'onepath' server=zztop.5161 user='user3' password='spds123' aclgrp='group2';

/* generate some dummy data */
data user1.t;
id=1;
salary=2000;
run;

/* Example of only user2 in group2 */
/* being allowed to read column */
/* salary */
PROC SPDO library=user1;
/* Assign who owns the ACLs */
set acluser;

/* Clean Up */
delete ACL t;
delete ACL t.salary;

/* Create an ACL on table t to */
/* allow members of group2 to read */
/* table */
add ACL t;
modify ACL t / group2=(y,n,n,n);

/* Create an ACL on column t.salary */
/* to only allow user2 of group2 to */
/* read the column */
add ACL t.salary;
modify ACL t.salary / group2=(y,n,n,n);
quit;
/* Let both users print the table */
/* Only user2 can access column salary */
proc print data=user2.t;
run;

proc print data=user6.t;
run;

/* Example of every BUT user2 in group2 being allowed to read column salary */
PROC SPDO library=user1;
/* Assign who owns the ACLs */
set acluser;
/* Clean Up Column ACL */
delete ACL t.salary;
/* Create an ACL on column t.salary to only allow members of group2 to read the column */
add ACL t.salary;
modify ACL t.salary / user2=(y,n,n,n);
/* User permissions have priority over group permissions. So now deny user2 access to column salary */
modify ACL t.salary / user2=(n,n,n,n);
quit;

/* Let both users print the table */
/* Only user6 can access column salary */
proc print data=user2.t;
run;

proc print data=user6.t;
run;
quit;
Chapter 16
Symbolic Substitution

SAS Scalable Performance Data (SPD) Server SQL Symbolic Substitution

Overview of Symbolic Substitution

SPD Server SQL supports symbolic substitution of the following items in SQL queries:

- a user ID, which is substituted by @SPDSUSR
- a group, which is substituted by @SPDSGRP
- a user who has ACL Special privileges, which is substituted by @SPDSSPEC

The right-hand side of symbolic substitution statement must be in all uppercase text (for example, @SPDSUSR=SOMEUSER).

Symbolic Substitution and Row-Level Security

A powerful use of symbolic substitution is to deploy row-level security on sensitive tables that use views. Suppose that only certain users or groups can access a sensitive table. You can use symbolic substitution to create a single view to the table that provides restricted access based on user ID or groups. You can grant Universal access to the view, but only users or groups that meet the symbolic substitution constraints can see the rows.

For another example, imagine a table that contains sensitive information has a column that contains group names or user IDs. You can use symbolic substitution to create a single view that allows users to access only the rows that contain their user ID or group. You can grant Universal access to the view, but each user or group is allowed to see only their user or group rows.

CAUTION:

SPD Server SQL symbolic substitution uses an 8-byte literal string (blank padded if necessary) to replace SPD Server user and SPD Server group names. Symbolic substitution will not match a column that is less than 8 characters wide. If the table column that contains user IDs or group names is not at least 8
characters wide, symbolic substitution will evaluate the WHERE- predicate on that column to be FALSE, which can result in incorrect results.

Symbolic Substitution Example

PROC SQL;
   connect to sappds
       (dbq="path1"
        server=host.port
        user='anonymous');

   /* queries comparing literal rows are */
   /* only selected if the symbolic      */
   /* substitution evaluates as 'true'   */

   select *
      from connection
      to sappds{
         select *
            from mytable
            where "@SPDSUSR" = "SOMEUSER"};

   select *
      from connection
      to sappds{
         select *
            from mytable
            where "@SPDSGRP" = "SOMEGROUP"};

   select *
      from connection
      to sappds{
         select *
            from mytable
            where "@SPDSSPEC" = "TRUE"};

   /* queries based on column values will only */
   /* select appropriate columns            */

   select *
      from connection
      to sappds{
         select *
            from mytable
            where usercol = "@SPDSUSR"};

   select *
      from connection
      to sappds{
         select *
            from mytable
            where grpcol = "@SPDSGRP"};

   /* Create a view to worktable that allows */
   /* users FRED or BOB, groups BCD or ACD, or */
execute(create view workview as
    select *
    from worktable
    where 
        "@SPDSUSR" in ("FRED", "BOB") or
        "@SPDSGRP" in ("BCD", "ACD") or
        "@SPDSSPEC" = "TRUE")
    by sasspds;

execute(create view workview as
    select *
    from worktable
    where usergrp = "@SPDSGRP" and
        ("@SPDSUSR" = "BOSS" or userid != "BOSS")
    by sasspds;
    disconnect from sasspds;
quit;

Overview of SPD Server Authentication

SAS encourages SPD Server users to consolidate the storage and management of user information through industry standard authenticators. Examples of SAS authenticators include the legacy LDAP (Lightweight Directory Access Protocol), Active Directory, and as of 2015, SAS SAS Metadata Repository.

Starting with SPD Server 5.2, support for user authentication through SAS Metadata Server is provided. SAS Metadata Server authentication provides improved integration with other SAS products, and can be configured to use the authentication provider of choice (such as LDAP).

The legacy LDAP authentication support is retained in SPD Server, but customers are encouraged to migrate to the newer, more flexible SAS Metadata Server implementation. The newer SAS Metadata Server version provides higher levels of encryption, better integration, support, and documentation.

By default, SPD Server uses a native method of user authentication that accesses user ID and password information stored in the password database.

**Psmgr** is an internal stand-alone SPD Server command-line utility that you can use to create and modify the password database. The SAS Management Console and the SpdsMgr plug-in provide alternative ways of modifying the password database. (The SpdsMgr plug-in is a GUI interface that provides the same functionality as the command-line interface of the SPD Server psmgr.)

Native Authentication

**Overview**

Native authentication refers to an internal SPD Server user authentication process that accesses the SPD Server password database, either via psmgr commands, or via a GUI application such as the SAS Management console. SPD Server 5.2 still supports native authentication.

By default, whenever SPD Server needs to authenticate a user's identity, it accesses the SPD Server password database. This database contains relevant information about SPD Server users, such as the following:

- SPD Server user ID
- SPD Server password
- SPD Server Groups
- SPD Server Group Members
- Special user privileges
- date and time of last login
- number of consecutive failed login attempts
- account expiration information.
In default configuration, SPD Server validates the user by passing the user ID via a
LIBNAME statement to the password database. This database contains all information
pertaining to the user, including permissions and account management information.
After validation, SPD Server allows access to the tables, groups, and rights that are
appropriate for each user. Starting with version 5.2, SPD Server will be providing more
flexible methods for user authentication.

To use native SPD Server authentication, do not include any authentication configuration
options in the server parameter file.

**How SPD Server Performs Native Authentication**

The following describes how SPD Server performs native authentication:

1. SPD Server user issues a LIBNAME statement from SAS.
2. The SPD Server client passes the LIBNAME request to the SPD Server host,
   including user name and password information provided in the body of the
   LIBNAME statement.
3. SPD Server looks up the user in the password database, and verifies that the user ID
   and password are valid, and that the user account is in good standing.
4. Following authentication, SPD Server allows the user access and rights as indicated
   by the information contained in the password database.

**Overview**

An enterprise computing environment usually contains a collection of business software
solutions that are sold as a platform, and applied across an organization and further
customized to specific areas. Platform services come with their own authentication
processes and password management systems. When SPD Server is added to such an
environment, it brings its own authentication process and password management system,
which means the administrator has to maintain two sets of user IDs, one for SPD Server
and another for the platform services. Additionally, disparate user ID and password
management tools can have incongruous requirements. For example, SPD Server
password lengths must be 6–8 characters in length, whereas the password length
requirements for a given enterprise platform can range anywhere from 6 characters to 64
or more characters, allowing for stronger passwords.

One solution is to leave all SPD Server authentication to the enterprise platform. By
integrating SPD Server user IDs and passwords with the framework of the platform's
authenticator, the SPD Server administrator must maintain only one set of user IDs and
passwords.

**How SPD Server Performs Alternative Authentication**

SPD Server performs alternative authentication in the following way:

1. SPD Server user issues a LIBNAME statement from SAS.
2. The SPD Server client passes the LIBNAME request to the SPD Server host, including user name and password information provided in the body of the LIBNAME statement.

3. SPD Server forwards the request to the external or alternative authenticator. The alternative authenticator (for example, SAS Metadata Server or LDAP) verifies whether the user account is in good standing, and ensures that all authentication policies (such as a password expiration date) are in force.

4. If the alternative authenticator finds the user account is in good standing, the SPD Server host is signaled. The SPD Server host then looks up the user in the SPD Server password manager database to apply SPD Server-specific attributes (such as SPD Server access rights, groups and group membership) to the user’s permissions.

5. Following authentication, SPD Server allows the user access and rights as indicated by the information contained in the password manager database.

---

### SAS Metadata Server Authentication

**Overview of SAS Metadata Server Authentication**

To use nonnative authentication, you should configure authentication through the SAS Metadata Server. SAS Metadata Server uses the authentication provider specified in its configuration to perform the authentication. In this case, SPD Server passes the authentication request to back-end authenticator via the SAS Metadata Server.

The SAS Metadata Server parameter options configure SPD Server to use the SAS Metadata Server to perform user authentication. SPD Server passes the user ID and password to the SAS Metadata Server for validation. After SAS Metadata Server validates the user account, SPD Server then accesses its internal password database file to determine other attributes belonging to the user, such as group and permissions information. For more information, about the SAS Metadata Server parameter options, see “SPD Server Parameter File Configurations for SAS Metadata Server Authentication” on page 82.

When using SAS Metadata Server to perform user authentication, an entry is still required for each user in the SPD Server password database. The SPD Server password database is managed by the psmgr utility. Each user entry in the database provides non-authentication information, such as SPD Server group memberships, user performance levels, ACL privileges, and so on.

The benefits of using SAS Metadata Server include the ability to use longer passwords than supported by the native SPD Server authentication, or by SPD Server authentication performed via LDAP. SPD Server has a native password length limit of 8 characters. However, the password length limit when using a non-native authenticator via SAS Metadata Server is defined by the back-end authenticator. This often provides access to longer and more secure passwords. SAS Metadata Server also provides better support for using LDAP as a back-end authentication provider.

**LDAP through SAS Metadata Server**

If you want to use LDAP as the default authenticator for SAS Metadata Server, SPD Server can use this configuration by sending user IDs through SAS Metadata Server to LDAP for validation. In this scenario, the SPD Server user IDs must exist in LDAP, and the METAAUTHENTIC option must be specified in the SPD Server server parameter.
file. You can also specify values for the METASERVER=, METAPORT=, and METADOMAIN= server parameter options as needed. For more information about configuring SAS Metadata Server authentication options in SPD Server, see “SPD Server Parameter File Configurations for SAS Metadata Server Authentication” on page 82.

The SPD Server host passes the user ID to SAS Metadata Server for authentication. SAS Metadata Server routes the authentication requests to LDAP, which performs the authentication and passes the results via SAS Metadata Server back to the SPD Server host.

Both LDAP and the SPD Server psmgr password database require user IDs and passwords to operate. Some administrative planning is required: user IDs for LDAP and the SPD Server psmgr accounts must be exact matches. However, the passwords for the LDAP and psmgr user IDs do not have to match. Only the LDAP password is used to perform authentication. The psmgr password is not part of authentication transactions. The psmgr password is used only when SPD Server administrators add a new user to the psmgr password database.

For example, in the following LIBNAME statement, the password ripsnert9 for the user coretest must exist in the authentication provider configured in SAS Metadata Server, but not in the SPD Server password database accessed via psmgr.

```sas
LIBNAME region_data sasspds "spds_domain"
  host="s658d01.unx.sas.com"
  service="14567"
  user="coretest"
  password="ripsnert9";
```

**Configuring SPD Server for SAS Metadata Server Authentication**

An SPD Server host can use only one configured authenticator. For example, an SPD Server host cannot use both native SPD Server authentication and either legacy LDAP authentication or SAS Metadata Server authentication.

If either legacy LDAP or SAS Metadata Server authentication is configured, native authentication is disabled.

If both legacy LDAP and SAS Metadata Server are configured, only LDAP is used.

However, if SAS Metadata Server authentication is used, SAS Metadata Server can use multiple authenticators based on its configuration.

One feature of these non-native authenticators is their support for large password lengths. These lengths are defined by each authenticator, but usually support a maximum length of 64 characters.

**SPD Server Parameter File Options for Configuring SAS Metadata Server Authentications**

SPD Server 5.2 features several new options for performing user authentication through the SAS Metadata Server. Although most server parameters can be changed and refreshed while the SPD Server host is running, the collection of server parameter options that begin with LDAP* and META* should not be changed or modified while the host is running. Changing LDAP* and META* property settings without first shutting down the server can cause unpredictable results. To modify LDAP* and META* options in the SPD Server server parameter file, you must first shut down the
server, make your parameter file configuration changes, and then restart the SPD Server host. The following options can be specified only in the SPD Server server parameter file.

**[NO]METAAUTHENTIC**
Specifies whether SPD Server should use the SAS Metadata Server to perform user authentication. The back-end authentication provider is whatever the SAS Metadata Server was configured with. NOMETAAUTHENTIC is the default setting.

**Syntax**

```plaintext
METAAUTHENTIC;
```

**Description**
When in the default setting of NOMETAAUTHENTIC, an internal account (native to SPD Server) is used for authentication. When METAAUTHENTIC is specified, SAS Metadata Server performs user authentication via the authentication provider that is specified in the SPD Server server parameter file.

**Note:** If you specify any META* option in your SPD Server server parameter file, then SPD Server assumes an authentication setting of METAAUTHENTIC.

**METASERVER=**
Specifies the name of the host that the SAS Metadata Server is running on.

**Syntax**

```plaintext
METASERVER=SAS-Metadata-Server-hostname
```

**Description**
Provides the name of the host that the SAS Metadata Server resides on. If SAS Metadata Server authentication is configured but METASERVER= is not specified, then SPD Server assigns a default value of METASERVER=localhost.

**METAPORT=**
Specifies the port number of the SAS Metadata Server.

**Syntax**

```plaintext
METAPORT=SAS-Metadata-Server-port-number
```

**Description**
Identifies the port number of the SAS Metadata Server. If SAS Metadata Server authentication is configured but no METAPORT= value is specified, then SPD Server assigns a default value of METAPORT=8561.

**METADOMAIN=**
Specifies the domain where the back-end authenticator resides.

**Syntax**

```plaintext
METADOMAIN=domain-name
```

**Description**
The domain name, if needed, for the back-end authenticator used by the SAS Metadata Server. No domain is used if this option is not specified.
Examples of SPD Server Authentication Options

The simplest way to use SAS Metadata Server authentication is to add METAAUTHENTIC to the server parm file. The value for METASERVER= defaults to localhost and the value for METAPORT= defaults to 8561. localhost selects the host that SPD Server server runs on.

The following examples configure SPD Server to use SAS Metadata Server for authentication:

Example using default values for METASERVER= and METAPORT=

METAAUTHENTIC;

Example using option values for METASERVER= and METAPORT=

METASERVER=lax94d01;
METAPORT=8561;

Either of these options imply METAAUTHENTIC to SPD Server.

Note: The METADOMAIN= option is required only by some authentication providers when configured with SAS Metadata Server.

LDAP Authentication

Overview of LDAP Authentication

Prior to SPD Server 5.2, the only alternative to native SPD Server authentication was LDAP (Lightweight Directory Access Protocol). (For more information about alternative authentication methods, such as using SAS Metadata Server to configure back-end authenticators, see “Overview of SAS Metadata Server Authentication” on page 174.) An LDAP server that runs on the SPD Server machine performs LDAP authentication. When you use LDAP authentication, the operating system handles password maintenance. LDAP authentication has the added benefit of operating-system-level security and convenience.

On start up, an LDAP configuration in the server parameter file signals the SPD Server host to use LDAP Authentication. SPD Server sends the LDAP server a DN (Distinguished Name) which consists of the user ID. LDAP begins the process of validation and setting access accordingly. LDAP authentication levels can range from anonymous authentication, which gives the least amount of access to information, to administrator authentication, which gives a user complete access. After LDAP settings are accessed, SPD Server grants user access according to the protocols set in the password database.

When you use an LDAP server to perform SPD Server user authentication, keep the following facts in mind:

- SPD Server users can be authenticated by an LDAP server, or by SPD Server via the psmgr password database, but not by both. The type of authentication to be performed is specified in the server parameter file, which is read when SPD Server is invoked.
- If you are changing from using the LDAP server to using SPD Server via the psmgr password database for authentication, you must remove all LDAP parameters from the SPD Server server parameter file. In order for the changes to the server parameter file to be read, you must restart SPD Server.
When you configure SPD Server to perform user authentication using the LDAP server, you still need the `psmgr` utility. When you use the LDAP server, a password database record is required for each SPD Server user. SPD Server uses the `psmgr` utility's password database to perform user access control tasks and other tasks that are not related to user password authentication.

Users that connect to an SPD Server must have corresponding logon information about the LDAP server. The LDAP server user ID and the SPD Server user ID formats are the same. The logon password format is the host-operating-system format.

You must enter the initial password in the `psmgr` table when you are adding a new user. This password is never used, and simply enables you to add the new user. The user is not required to use the `NEWPASSWD=` or `CHANGEPASS=YES` LIBNAME option to use the LDAP password.

Some LDAP server products might require users to enter host logon information. In these cases, confirm with your LDAP server administrator that the host logon information exists in the LDAP database.

If you are using LDAP user authentication, and you create a user connection that uses the `NEWPASSWD=` LIBNAME option, the user password is not changed. If you want to change a user password, follow the operating system procedures to change a user password, and check with your LDAP server administrator to ensure that the LDAP database records the password changes. The same process information applies to other non-native authenticators as well.

### Configuring LDAP Authentication

To set up LDAP authentication, add the following parameters to the SPD Server's server parameter configuration file:

- **(NO)LDAP**
  - turns on LDAP authentication. If the LDAP parameter is found during start-up, SPD Server creates a context for LDAP authentication. The default setting is `NOLDAP`.

- **LDAPSERVER**=
  - specifies a valid IP address or the host machine for the LDAP server. This address is usually the same as the IP address of the SPD Server host. The default value is the IP address of the SPD Server host.

- **LDAPPORT**=
  - specifies the TCP/IP port that is used to communicate with the LDAP server. This value is usually the default `LOCAL_HOST` value, or port 389. Valid values are in the range 0–65,536. The default setting is the `LDAP_PORT` value.

- **LDAPBINDMETH**=
  - controls how SPD Server clients are authenticated by the LDAP server. If this parameter is found in the SPD Server parameter file, `LDAPBINDMETH` is a character string whose value must be `LDAP_AUTH_SASL`. The default setting is null.

- **LDAPBINDDDN**=
  - the distinguished name (DN) of the LDAP database entry, or the location in the LDAP Server database where the client information is stored. `LDAPBINDDDN` is a Lightweight Directory Access Protocol (LDAP) term. `LDAPBINDDDN` is the combination of the user name and the network domain in which the user operates. The form of this string is `ID=, rdn1=RDN1, rdn2=RDN2, ...`, where `ID` is the identifier for the relative distinguished name (RDN) of a user ID that exists in the...
LDAP server database. The default value of the DN is `uid= , dc=DOM1, dc=DOM2, dc=DOM3`. The default value of the LDAPPBINDDN parameter is null.

If no distinguished name is specified in the SPD Server server parameter file, SPD Server uses the LDAP Server host's domain name to generate values for DOM1, DOM2, and DOM3. The SPD Server user ID becomes the value for the user ID. The resulting value becomes the default user location for LDAP database members.

For example, suppose the LDAP host machine is sunhost.unx.sun.com, and the user ID is sunjws. The resulting default DN is `uid=sunjws, dc=unx, dc=sun, dc=com`. The distinguished name is used to locate the user sunjws. Then the sunjws user password is compared to the password that is stored in the LDAP database. If SPD Server users are located in a specific location in your LDAP database, be sure to specify that location using LDAPPBINDDN.

See the LDAP Server administrator for your site if you need more information about LDAP parameters for your server parameter file. To use the default value for any LDAP parameter, omit the parameter specification from the server parameter file. Undeclared parameters automatically assume default values.

*Note:* Entering the LDAP_HOST value for LDAPSERVER can cause SPD Server to fail during start-up.

---

**The Password Manager Utility psmgr**

**Overview of the psmgr Utility**

The psmgr utility manages the password manager database that enables access to the SPD Server host. When you start SPD Server, the command line option `-ACLDIR` specifies the location (directory path) of the password manager database. The owner of the password manager database, typically the SPD Server administrator, can update the database.

The password manager database contains the following attributes and capabilities for each system user:

- a user ID
- a password
- an access privilege
- an optional IP address
- an optional password expiration time
- an optional ACL group name
- an optional time limit between successful logins
- an optional number of login failures that can occur before the user ID is disabled
- an optional user performance class

A user ID is restricted to 8 characters and does not need to correspond to any system user ID. A password is also restricted to 8 characters. All alphanumeric characters and the underscore symbol are acceptable for use in user IDs and passwords.

A password for the psmgr table must contain a minimum of 6 characters. At least one character must be numeric, and at least one character must be alphabetic. A new
password must be different from the last six passwords for that user. The password cannot contain the user ID.

If a user has three consecutive failed attempts to connect to the SPD Server host, that user ID is no longer enabled. That user cannot connect to the SPD Server host until an administrator resets the user ID.

If you are upgrading to SPD Server 5.1 from SPD Server 3.x, you must repopulate the SPD Server 5.1 psmgr utility from the SPD Server 3.x password table.

**Invoking the psmgr Utility**

You invoke the psmgr utility by entering the psmgr command and specifying the directory path where the password manager database is located. (Or you can specify a path for a password table that has not yet been created.)

Use the following command:

```
psmgr <full-path-specification-to-password-table>
```

This command invokes the psmgr utility and specifies the directory path for the password manager database.

**Migrating a psmgr Database from a Previous SPD Server Installation**

You can use the psmgr EXPORT and IMPORT commands to migrate psmgr data from a previous installation.

To convert your SPD Server password file to SPD Server 4.x or SPD Server 5.1 format from SPD Server 3.x format, do the following:

1. Start the SPD Server psmgr utility using your previous SPD Server installation.
2. Export your SPD Server password table to a file.
3. Start your new installation of the SPD Server psmgr utility with a new password table.
4. In your new installation of SPD Server, import the file from the previous installation into the new password table.

**Example:**

The following example creates a psmgr table from an old format psmgr table that exists at /installdir3_0/site.

```
/Installdir3_0/bin/psmgr /Installdir3_0/site

Enter Command > export /Installdir3_0/site/oldtable
Enter Command > quit

/Installdir4_0/bin/psmgr /Installdir4_0/site

Enter Command > import /Installdir3_0/site/oldtable
```
psmgr Commands

The psmgr utility is an interactive program. It reads commands and operands from your computer, and prompts you for input when necessary. You can also send a file of commands to the utility and structure each command so that no input is required.

The commands and operands are positional, and they must be separated by blank spaces. If you specify an insufficient number of operands, the utility prompts you for the remaining operands. Password operands, which are obtained with a prompt, are not echoed back to the computer.

You can enter default values for a command in two ways. If you are entering a single operand, a carriage return in place of the operand value causes SPD Server to populate the operand with its default value. If you are entering multiple operands, entering a hyphen or minus “-” symbol for each operand value causes SPD Server to populate each operand with its default value.

psmgr Commands

**ADD**

adds a new user to the password manager database.

Syntax

```
add username passwd passwd privilege
    [ip_addr|-] [expiretime|-] [group|-]
    [timeout|-] [failures|-] [class|-]
```

Arguments

user name

the user ID of an SPD Server user. The user ID is restricted to 8 characters. All characters must be alphanumeric or underscores. The SPD Server user ID does not have to correspond to any system user ID.

passwd

the user's password, which is restricted to 8 characters. The psmgr table requires a password with a minimum of 6 characters—at least one character must be numeric, and at least one character must be alphabetic. The argument is repeated to verify the password.

*Note:* This password expires after the first logon to SPD Server. The user must change the password by using either the NEWPASSWD= or the CHANGEPASS= LIBNAME option. Password changing techniques do not apply to users who rely on LDAP Authentication for SPD Server access.

privilege

an authorization level number in the range 0 to 7. The authorization level number assigns access privileges to the user.

The numbers 0–3 are equivalent. Use the numbers 0–3 to specify a normal, non-privileged user.

The numbers 4–7 are equivalent. Use the numbers 4–7 to specify a special user. Special users can update the password manager database and override any ACL restrictions on SPD Server tables. You should grant special privileges to the SPD Server user ID and password for yourself only.
ip_addr
   a numerical IP address. A hyphen (-) indicates that no IP address is specified. This argument restricts the user's access to SPD Server to the specified IP address.

   Note: The IP address is not verified.

expiretime
   the length of time, in days, after which the user must change his password. A hyphen (-) indicates that no password expiration time is being specified. The time is measured from the day that you add the user.

group
   the default group for the user. A hyphen (-) indicates that no default group is being specified. If specified, the group definition must have been created by a previous GROUPDEF command. You can change group affiliation by using a GROUPMEM command.

timeout
   the maximum amount of time that is allowed between successful logins before the account is no longer enabled. A hyphen (-) indicates that no time-out is being specified.

failures
   the number of password failures. A hyphen (-) indicates that no failure limit is being specified. The value specifies the number of login failures allowed before the user is disabled. A disabled can be re-enabled by the psmgr administrator using the RESET command.

class
   the performance class of the user. Valid values are in the range 1–3. The value specifies whether the user is in a Low (1), Medium (2), or High (3) performance class. The SPD Server server can be configured to provide different server parameters, based on the user's performance class setting.

**AUTHORIZE**
   authorizes a user to modify the password manager database.

**Syntax**

authorize username userspasswd

**Arguments**

username
   the user ID of an SPD Server user.

userspasswd
   a valid user's password.

**Description**

The password manager database is owned by the operating system ID of the psmgr executable. The owner of the psmgr database is normally the only person with authorized access to the database.

The following conditions must apply if you want to allow another system user to update the psmgr database using the psmgr utility:

- The user must have operating system rights to run the psmgr executable utility.
- The user must have operating system Read and Write access to the psmgr database.
- The user must have operating system AUTHORIZE access to update the psmgr database. This requires an spdsuser ID that has a special privilege level of 4 - 7.
Example
For example, assume that you are an operating system user and your user account meets
the preconditions of operating system rights to run the psmgr executable utility, and you
also have operating system Read and Write access to the psmgr database. Your SPD
Server administrator has given you a special spdsuser ID of user=auxadmin,
password=admin2. To be authorized to update the psmgr database, use the following
command:
authorize auxadmin admin2

CHGAUTH
changes the authorization level for a user.

Syntax
chgauth username authlevel

Arguments
user name
the user ID of an SPD Server user.
authlevel
an authorization level for the user, in the range 1–7. The authorization level number
assigns access privileges to the user.
The numbers 0–3 are equivalent. Use the numbers 0–3 to specify a normal, non-
privileged user.
The numbers 4–7 are equivalent. Use the numbers 4–7 to specify a special user.
Special users can update the password manager database and override any ACL
restrictions on SPD Server tables. You should grant special privileges to the SPD
Server user ID and password for yourself only.

CHGEXPIRE
changes the expiration date for the specified user's password. By default, a new user ID
is created with an expired password.

Syntax
chgexpire username exptime

Arguments
user name
the user ID of an SPD Server user. The user ID is restricted to 8 characters. All
characters must be alphanumeric or underscores. The SPD Server user ID does not
have to correspond to any system user ID.
exptime
the length of time, in days, after which the user must change his password. A hyphen
(-) indicates that no password expiration time is being specified. The time is
measured from the day that you add the user.

CHGIP
changes the IP address from which the user must connect to the SPD Server. The IP
address on which the SAS, ODBC, JDBC, or SQL client software is running must match
the IP address that is entered in the password manager database.

Syntax
chgip username "New IP Address"

**Arguments**

user name
   the name (user ID) of an SPD Server user. This name must already exist in the password manager database.

ip_addr
   the new IP address from which the user must connect to the SPD Server host. The IP address must be specified numerically using the format `xxx.xxx.xxx.xxx`. The IP address is not verified. Invalid and incorrect IP addresses are noted as errors in the SPD Server log and will cause that user's future logon attempts to fail. The default value is blank.

**CHGTIMEOUT**

changes the logon time-out date for a user's password.

**Syntax**

chgtimeout username timeoutperiod

**Arguments**

user name
   the user ID of an SPD Server user.

timeoutperiod
   a password logon time-out period, specified in days. The time-out period requires the user to successfully log on before the specified number of days has expired. The value is the number of days from the last successful logon that the password is valid.

**CHGPASS**

changes the password for a user to a permanent password.

**Syntax**

chgpass username oldpwd newpwd newpwd

**Arguments**

user name
   the user ID of an SPD Server user.

oldpwd
   the user's old password.

newpwd
   the new password for the user. If you are prompted for the new password, you are prompted again to re-enter it for accuracy. The new password must be different from the last six passwords. The new password must also contain at least 6 characters, with at least one numeric character and with at least one alphabetic character. The password cannot contain the user ID.

**CHGPERFCLASS**

changes the performance class of a user.

**Syntax**

chgperfclass class

**Arguments**
user name
  the user ID of an SPD Server user.

class
  a performance class for the user, in the range 1–3. The value specifies whether the
  user is in a Low (1), Medium (2), or High (3) performance class. The SPD Server
  server can be configured to provide different server parameters, based on the user's
  performance class setting.

**DELETE**
deletes a user ID.

**Syntax**
delete username !

**Arguments**

user name
  the user ID of an SPD Server user.

! verifies that you intend to delete the user ID from the password manager database. If
  you do not specify !, you are prompted to verify the deletion.

**EXPORT**
exports the current password manager database into a flat file.

**Syntax**
export textfile

**Arguments**

textfile
  name of the flat file to create that will contain the contents of the current password
  manager database.

**Description**
The EXPORT command generates a single line in the flat file for each record in the
password manager database. User passwords are encrypted in the table.

The contents of the flat file is a representation of what is stored in the password manager
database. When you are making changes that affect many users, it might be easier to edit
the flat file than to use the `psmgr` utility. After you make the changes in the file, you can
use the IMPORT command to construct a new, modified password manager database.

**GROUPDEF**
defines a new ACL group entry.

**Syntax**
groupdef groupname

**Arguments**

groupname
  the name of a group. The name must be unique and is restricted to 8 characters. All
  characters must be alphanumeric or underscores. This argument verifies that the
  groups that are specified on the GROUPMEM command are valid.
GROUPDEL

deletes an ACL group entry.

Syntax

groupdel groupname !

Arguments

groupname
    the name of a group.

! 
    verifies that you intend to delete the group from the password manager database. If you do not specify !, you are prompted to verify the deletion.

GROUPMEM

updates the ACL group list for a user ID. You can specify up to 32 groups for a user.

Syntax

groupmem username groupname [groupname|"] [groupname|"] !

Arguments

user name
    the user ID of an SPD Server user.

groupname
    the name of an ACL group. The name must be unique and is restricted to 8 characters. Separate each ACL group name with a space. The first ACL group name that you specify becomes the default ACL group for the user. You can specify up to 32 groups.

Note: If you specify fewer than 32 ACL groups, the utility prompts you for additional ACL groups (up to 32). Enter an exclamation point (!) to indicate to SPD Server that there are no more groups in your groupname declaration.

Note: If you use the groupmem command in batch mode, the syntax enables you to submit 32 groupname arguments. If you want to update the user ID with less than 32 ACL group members, use an exclamation point (!) to indicate to SPD Server that there are no more groups in your groupname declaration.

GROUPS

lists all the ACL groups that are in the password manager database.

Syntax

groups

HELP

displays general or command-specific help for the psmgr utility.

Syntax

help [command]

Arguments
command
   a psmgr command. If you specify a command, a short description of the command is
displayed. If you issue a HELP command without an operand, a list of all available
psmgr commands is displayed.

IMPORT
imports user information from a flat file to the password manager database. The flat file
was created with the EXPORT command.
Syntax
import textfile
Arguments
textfile
   the name of the flat file to import. This flat file contains the user definitions to add to
   the password manager database.
Description
The IMPORT command reads the flat file, interpreting each single line as a record in the
password manager database. Typically, the flat file is output from a submitted EXPORT
command that was issued on the same password manager database or another password
manager database.

If the psmgr utility encounters an identical user name (SPD Server user ID) in the
password manager database during the import process, it skips the line. The psmgr
utility displays a message that states that the line was skipped.

LIST
lists the contents of the password manager database or a specific user.
Syntax
list [username]
Arguments
user name
   the user ID of an SPD Server user. If you do not specify a user ID, the entire
   password manager database is listed.
Example
list bar
This example might produce the following listing:

USER AUTHORIZATION IP ADDRESS
---- ------------- -----------
bar       7

RESET
resets a password for a user to a new temporary, one-time password. The RESET
command can be used to reset a user’s password after three consecutive failed attempts
to connect to a server. After the third failed attempt, the user ID is no longer enabled.
After the password has been reset, the user must change the password before connecting
to a server, using either the NEWPASSWD= or the CHANGEPASSWD= LIBNAME
option.
Syntax

reset username newpwd newpwd

Arguments

user name
the name (user ID) of an SPD Server user.

newpwd
a new password for the user. The new password can be up to 8 characters in length. The new password must contain at least six characters. At least one character must be numeric, and at least one character must be alphabetic. The argument is repeated to verify the password for accuracy.

Example

reset tom abc123 abc123

This example resets the password for tom.

QUIT
ends the session and exits from psmgr.

Syntax

quit

Using a File as Input to psmgr

You can create and then send a file of commands to the psmgr utility.

Here is a command file named pscmds:

groupdef group1
add newuser newpwd1 newpwd1 0 - - group1 - - -
list
quit

The command file contains the group group1 and puts newuser in group1.

To run the psmgr utility using the command file named pscmds as input, use the appropriate syntax.

For UNIX:

psmgr /usr/local/SPDS/site < pscmds

For Windows:

psmgr d:\spds\site < pscmds

SAS Management Console

Overview of SAS Management Console

SPD Server supports SAS Management Console. SAS Management Console is an application that a privileged user can use to manage passwords and ACLs.
For more information about using SPD Server with SAS Management Console, see Chapter 7, “Administering and Configuring SAS Scalable Performance Data (SPD) Server Using the SAS Management Console,” on page 45.

## Enabling 32 Groups for Selected SPD Server Users

SPD Server versions 4.x and earlier limited SPD Server users to membership in five or fewer SPD Server user groups. SPD Server 5.1 and later supports SPD Server user membership in up to 32 SPD Server groups. The default user limitation remains at five groups per SPD Server user ID, which suits the majority of SPD Server users, but you can grant users the ability to belong to as many as 32 groups. Users requiring the larger group membership ceiling need to convert their SPD Server group password data sets to SPD Server 5.1 password data sets.

### Converting SPD Server 4.x Password Tables to SPD Server 5.x Password Tables

Default SPD Server user account configurations for SPD Server 5.1 have a default limitation of five SPD Server group memberships per user. This ceiling does not affect most SPD Server users. When power SPD Server users to belong to more than five groups, you can raise the ceiling raised to a maximum of 32 memberships to SPD Server user groups.

To raise the maximum to 32 groups per user, you must change the user’s password table data sets. Users that need the higher group membership must use the SPD Server 5.x formatted password table data set.

The SPD Server `psmgr` utility manages both SPD Server 4.x (and earlier), and SPD Server 5.x password tables. Psmgr independently recognizes both types of table formats and handles all transactions appropriately.

**Note:** SPD Server 5.x password table data sets are not backward compatible with earlier versions of SPD Server.

To convert an SPD Server 4.x password Table to an SPD Server 5.x password table:

1. Export existing password table data sets to EXPORT-FILE.
2. Back up old password table data sets.
3. Create a new target directory for new password table data sets.
4. Run the `psmgr` utility and make the new table an SPD Server Version 5 table by including the `-ver 5` switch in the command:
   ```
   psmgr <target-directory-name> -ver 5
   ```
5. Import the old passwords from the export file that you created in Step 1.
6. Quit the `psmgr` utility.
7. Verify that the SPD Server start-up scripts point to the newly created password table data sets.
**SPD Server psmgr GROUPMEM Updates**

The SPD Server 5.x psmgr utility accommodates greater flexibility in group membership and password management. Updates required the following minor changes in the GROUPMEM command.

- In SPD Server 4.x and earlier, if the user specifies fewer than five groups by using the GROUPMEM command, SPD Server prompts the user to supply additional group names until five group names are provided. In SPD Server 5.x, you can specify an exclamation point (!) as a GROUPMEM group name list argument to terminate the group list without further interactive user prompting.

- Specify a hyphen (-) as a group list argument to serve as a place holder for a group name that cannot be changed.

- Specify an empty quoted argument (" ") as a group list argument to clear the group in that position.

**SPD Server 5.x GROUPMEM Example**

The following example uses the SPD Server GROUPMEM command to change the groups for user dswider such that the user’s previously assigned groups in the first, second, and fourth positions remain the same, the group in the user’s third position is to be deleted, and the fifth group position is assigned to the group fondo. The exclamation mark indicates to psmgr that no additional group memberships are to be declared for this user.

```
GROUPMEM dswider - - "" -FONDO !
```

**Using SPD Server SAS Management Console Plug-in with SPD Server Groups**

The SPD Server plug-in for SAS Management Console enables viewing and editing of up to five SPD Server groups, the utility opens an informational window that states this particular user is a member of more than five groups, and that the SPD Server psmgr utility should be used to view and edit SPD Server groups for that user.
Overview of Dictionaries

In addition to providing dictionary information for tables and columns, SPD Server provides information about the users in the password database and the ACL objects that are available. The following listing shows the column definitions for DICTIONARY.PWDB and DICTIONARY.ACLS:

```sql
DICTIONARY.PWDB {user char(8) Label = 'User'
 auth_lvl char(5) Label = 'Authorization Level'
 ip_addr char(16) Label = 'IP Address'
 defgrp char(8) Label = 'Default Group'
 othgrps char(40) Label = 'Other Groups'
 expire char(6) Label = 'Expire Period'
 mod_date char(32) Label = 'Password Last Modified'
 log_date char(32) Label = 'Last Login'
 timeout char(6) Label = 'Timeout Period'
 strikes char(6) Label = 'Failed Login Attempts'}

DICTIONARY.ACLS {owner char(8) Label = 'Owner'
 group char(8) Label = 'Group'
 defacs char(56) Label = 'Default Access'
 grpacs char(56) Label = 'Group Access'}
```

Example: Listing the Users in the Password Database Using SQL Pass-Through

To use SQL pass-through, you must first establish an SQL pass-through connection to SPD Server using ACLSPECIAL=YES.
proc sql;
connect to sasspds (dbq='tmp' server=localhost.5400
user='admin'
password='spds123'
ACLSPECIAL=YES);

Note: Without ACLSPECIAL=YES, you get the result set only for the users who are making a pass-through connection and not for all users.

To list all the users in the password database, submit the following command:

```sql
select *
from connection
to sasspds
(select *
from dictionary.pwdb)
```

To select only the user name and last log in date, submit the following command:

```sql
select *
from connection
to sasspds
(select user, log_date
from dictionary.pwdb);
```

**Example: Listing ACL Objects Using SQL Pass-Through**

To list all ACL objects for a user by using a pass-through connection, first establish an SQL pass-through connection to SPD Server using ACLSPECIAL=YES.

```sql
proc sql;
connect to sasspds (dbq='tmp' server=localhost.5400
user='admin'
password='spds123'
ACLSPECIAL=YES);

Note: Without ACLSPECIAL=YES, you get the result set only for the users who are making a pass-through connection and not for all users.

Then, submit the following command:

```sql
select *
from connection
to sasspds
(select *
from dictionary.acls);
```

To find any ACL objects that specify Jones as the owner, submit the following command:

```sql
select *
from connection
to sasspds
```
(select *
from dictionary.acls
where owner = "Jones");
Chapter 19

Using SAS Scalable Performance Data (SPD) Server with an Internet Firewall

Overview of Using SPD Server with a Firewall

SPD Server and its clients communicate through ports that permit requests to be sent to the server and that send and receive data (such as table rows) between client and server. If the server is running with an Internet firewall, the ports that the client and server use must be configured so that the firewall allows the communication. This section describes the SPD Server server and client ports, as well as how to assign and configure them for use with an Internet firewall.

SPD Server clients communicate with the SPD Server name server via the SPD Server name server listen port. The name server listen port is used by clients (such as Base SAS) when LIBNAME and SQL CONNECT statements are issued. The LIBNAME and SQL CONNECT statements must be able to pass through a firewall. The name server listen port is also used by ODBC data sources that need to communicate with the SPD Server name server.

SPD Server clients communicate with the SPD Server host whenever a client needs to complete a LIBNAME connection, or whenever a client needs to issue SPD Server operator commands. LIBNAME connections and operator commands must be able to access the SPD Server listen port and the SPD Server operator port through existing firewalls.

When an SPD Server server completes a client request for a LIBNAME connection, it creates an SPD Server base user proxy process. The user proxy handles all of the client data requests. The proxy process requires multiple ports: a port to receive data commands from the client, a port to receive operator commands from the client, and a port for each open table to send and receive data between client and server. Therefore, the SPD Server Base user proxy requires a range of port numbers that must be accessible through the firewall.
Assigning SPD Server Ports That Require Firewall Access

**SPD Server Name Server Listen Port**

You can specify the SPD Server name server listen port by using well-known port definitions that are declared in the operating system's services file. You can also use the SPD Server command-line interface to specify the listen port. In the services file, the `spdsname` specification corresponds to the listen port. For UNIX installations, you can define the SPD name server listen port in the `rc.spds` start-up script. The `NSPORT` parameter in the `rc.spds` start-up script defines the SPD Server name server listen port. If `NSPORT` is not defined in the `rc.spds` start-up script, the SPD name server uses the `spdsname` service entry.

**SPD Server Listen Port and SPD Server Operator Port**

You can specify the SPD Server listen and operator ports by using well-known port definitions that are declared in the operating system's services file. You can also use the SPD Server command-line interface. In the operating system's services file, the `spdsserv_sas` specification corresponds to the SPD Server listen port. The `spdsserv_oper` specification corresponds to the SPD Server operator port. For UNIX installations, you can also define the SPD Server listen and operator ports in the `rc.spds` start-up script for UNIX installations. In an `rc.spds` start-up script, the `SRVLPORT` parameter defines the listen port, and the `SRVOPORT` parameter defines the operator port. If the listen and operator ports are not defined, or are defined as zero values, the SPD Server uses `spdsserv_sas` and `spdsserv_oper` in the operating system's services file. If there are no listen or operator ports defined in the operating system's services file, then SPD Server chooses any available ports for listen and operator port functions by default. This is the normal mode of operation when SPD Server clients and servers run in environments that do not have firewalls.

**SPD Server Base Proxy Ports**

You must use the SPD Server MINPORTNO= and MAXPORTNO= server parameter specifications to define the available range of ports for the SPD Server Base Proxy processes. You must specify both the MINPORTNO= and MAXPORTNO= parameters when you define the range of port numbers that are available to communicate with SPD Server clients that might be outside of a firewall. If the SPD Server parameters for MINPORTNO= and MAXPORTNO= are not specified, an SPD Server Base proxy process uses any port that is available to communicate with its SPD Server client. This is the normal mode of operation when SPD Server clients and servers run in environments that do not have firewalls.

How many port numbers do you need to reserve for SPD Server Base user proxy processes? Each SPD Server Base user proxy process produces its own command port. You can access the command port via command-line specifications that are issued by an SPD Server client. You can access the operator port for a command port by using PROC SPDO operator commands.

Each SPD Server host table that is opened also creates its own port. Each SPD Server table port becomes a dedicated data transfer connection that is used to stream data transfers to and from the SPD Server client. SPD Server host table ports are normally assigned dynamically, unless MINPORTNO= and MAXPORTNO= parameters have been specified.

If MINPORTNO= and MAXPORTNO= parameters have been specified, then SPD Server host table ports are assigned from within the port range that is defined by the minimum and maximum port parameter statements. The port range that is specified by
the MINPORTNO= and MAXPORTNO= parameters must be able to accommodate the maximum number of concurrent LIBNAME connections required at the server, as well as the I/O data streams that travel between the SPD Server Base processes on the host and the SPD Server clients.
Overview of SPD Server Auditing

SPD Server supports SQL audit logging of submitted SQL queries and proxy auditing of access to SPD Server resources. SPD Server proxy auditing and SQL audit logging (spdsaud) are enabled when the server is started using the -AUDITFILE or -SQLAUDITFILE parameters. You can enable proxy auditing, SQL audit logging, or both.

SPD Server auditing logs access to SPD Server resources. Auditing also logs implicit or explicit SQL pass-through queries that are submitted to SPD Server. Separate audit logs are created for proxy auditing and SQL audit logging. SPD Server includes three SAS programs (auditwithwhere.sas, auditraw.sas, and auditsql.sas) in the /samples directory of your SPD Server installation. You can use these programs to input the audit logs in to SAS tables. You can then query the SAS tables to determine access to SPD Server tables and resources.

Proxy Auditing

Proxy auditing helps you determine access to SPD Server resources. The audit record contains the following information:

- the activity timestamp
- the primary path of the domain that contains the resource
- the LIBNAME of the domain
- the user ID of the SPD Server user that is accessing the resource
- the resource name
- the resource type
WHERE Clause Auditing

WHERE clause auditing provides an audit record that contains the following information:

- the length of the WHERE clause
- the contents of the WHERE clause

You enable WHERE clause auditing by using the WHEREAUDIT option. The maximum size that can be allocated to WHERE clauses is controlled by the WHAUDLEN option. For more information, see “SPD Server Parameter File Configurations for Auditing” on page 85.
SQL Query Auditing

SQL audit logging provides a record of the SQL queries that were submitted to the SPD Server server. The SQL audit record contains the following information:

- the SQL query timestamp
- the type of the SQL query
  - 1=SELECT
  - 2=DROP
  - 3=ALTER
  - 4=CREATE
  - 5=DESCRIBE
  - 6=UPDATE
  - 7=DELETE
  - 18=RESET
  - 19=BEGIN ASYNC
  - 20=END ASYNC
- the number of rows that were returned for an SQL SELECT statement
- the elapsed time, in seconds, required to process the SQL query
- the user ID of the SPD Server user that submitted the query
- the group ID of the SPD Server user that submitted the query
- the default LIBNAME for the query, used for any table that is not referenced by a two-part name
- the number of characters in the query
- the text of the submitted SQL query

You control the maximum size that can be allocated in the SQL log for an SQL statement by using the SQLAUDLEN option. For more information, see “SPD Server Parameter File Configurations for Auditing” on page 85.
Chapter 21
SAS Scalable Performance Data (SPD) Server Table WHERE Constraints

Overview of Table WHERE Constraints
SPD Server table WHERE constraints enable SPD Server table owners to associate a WHERE clause with a table. This association means that the WHERE clause is applied when a user accesses the table. As a result, the user sees only the table rows that remain after the table owner's WHERE clause filter has been processed. The filtering is applied any time the table is accessed by a DATA step or by an SQL query. You can use SPD Server table WHERE constraints with SPD Server symbolic substitutions to create row-level security that filters table rows based on the values for user ID, group ID, or ACLSPECIAL privileges. SPD Server table WHERE constraints do not effect normal SPD table ACL settings, such as Read, Write, and Column access.

Table constraints are not applied to a table that is opened for Update access. The table owner should grant Update access only to users who can modify any row of the table, delete any row of the table, or append new rows to the table.

Creating and Controlling Table WHERE Constraint
To create a table WHERE constraint, you must be the table owner. Use PROC SPDO commands to define, delete, and describe table WHERE constraints.

To add a table WHERE constraint:
constraint add <table-name>;
where <where-clause-expression>;

To describe a table WHERE constraint:
constraint describe <table-name>;
To remove a table WHERE constraint:

```
constraint remove <table-name>;
```

### Table Constraint WHERE Clauses

A table constraint WHERE clause can be any WHERE clause that SPD Server can parse and interpret. The WHERE clause can use any function that SPD Server supports. Generally, the WHERE clause uses SPD Server symbolic substitution to create row-level security that is based on the values for user ID, group, or ACLSPECIAL privileges. For more information, see “SAS Scalable Performance Data (SPD) Server SQL Symbolic Substitution” on page 167.

The table constraint WHERE clause is applied when a user accesses the table. If the WHERE clause specifies the table owner, then the WHERE clause is also applied when the owner access the table. Table owners should be careful to construct WHERE clause constraints that allow only the table owner to see all of the table rows.

### Table Constraint Restrictions and Limitations

The SPD Server SQL COPY TABLE and UPDATE TABLE extensions do not function on a table that has a table constraint WHERE clause. You must use a different method (such as PROC COPY or SQL CREATE TABLE as SELECT) to copy the table. If you try to use COPY TABLE or UPDATE TABLE, the destination table contains rows that were filtered by the WHERE constraints on the source table only. The destination table does not inherit the WHERE constraints of the source table.

### Example Table Constraint WHERE Clauses

Assume that the following SPD Server users exist:

<table>
<thead>
<tr>
<th>User</th>
<th>Password</th>
<th>Group</th>
<th>ACLSPECIAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>William</td>
<td>worker1</td>
<td>group1</td>
<td>no</td>
</tr>
<tr>
<td>Guy</td>
<td>worker2</td>
<td>group1</td>
<td>no</td>
</tr>
<tr>
<td>Frank</td>
<td>worker3</td>
<td>group2</td>
<td>no</td>
</tr>
<tr>
<td>Ed</td>
<td>worker4</td>
<td>group2</td>
<td>no</td>
</tr>
<tr>
<td>Bossman</td>
<td>worker5</td>
<td>group2</td>
<td>no</td>
</tr>
<tr>
<td>Aclspec</td>
<td>worker6</td>
<td>group3</td>
<td>yes</td>
</tr>
</tbody>
</table>

The user **Bossman** creates a table that contains sensitive data. Only some users or user groups are authorized to see certain rows in the table. **Bossman** uses WHERE constraints to control which table rows are available to different users or user groups.

```
LIBNAME foo sasspds 'tmp' ... user="bossman";
DATA foo.employees;
input user $ grp $ salary $ position $ state $ region $;
cards;
WILLIAM GROUP1 70000 Engr1 CA W
GUY GROUP1 60000 Engr1 CA W
ED GROUP1 50000 Engr2 NJ E
FRANK GROUP2 80000 Engr2 TX S
TOM GROUP2 65000 Engr3 WA W
BOSSMAN GROUP2 80000 Mgr NJ E;
```
The following code provides Read access for all users. The code uses table WHERE constraints to determine which table rows a user or user group can read:

```
PROC SPDO lib=foo;
SET ACLUSER;
ADD ACL employees;
MODIFY ACL employees / read;
quit;
```

The user *Bossman* can create table WHERE constraints to control access to the table in the following ways:

- **Bossman** can read any row of the table. Any other user can read only rows where the value in the User column matches the user's user ID.

```
PROC SPDO lib=foo;
SET ACLUSER;
constraint add employees;
  WHERE (User = "@SPDSUSR")
  or ("@SPDSUSR" = "BOSSMAN");
constraint describe employees;
quit;
```

- **Bossman** or an ACLSPECIAL user can read any row of the table; any other user can read only rows where the value in the User column matches the user's group ID.

```
PROC SPDO lib=foo;
SET ACLUSER;
constraint remove employees;
constraint add employees;
  WHERE (grp= "@SPDSGRP")
  or ("@SPDSUSR" = "BOSSMAN")
  or ("@SPDSSPEC" = "TRUE");
constraint describe employees;
quit;
```

- **Bossman** can read all rows. Other users can read only rows where the value in the User column matches the user's user ID, except for user *Guy*. User *Guy* can also read rows for employees from the state of California.

```
PROC SPDO lib=foo;
SET ACLUSER;
constraint remove employees;
constraint add employees;
  WHERE (User = "@SPDSUSR")
  or ("@SPDSUSR" = "BOSSMAN")
  or ("@SPDSUSR" = "GUY" and state = "CA");
constraint describe employees;
quit;
```

- **Bossman** can read all rows. Other users can read only rows where the value in the User column matches the user's user ID, or rows where the value in the Salary column is less than or equal to $6,000 per month (rounded down to the nearest dollar).

```
PROC SPDO lib=foo;
SET ACLUSER;
constraint remove employees;
constraint add employees;
  WHERE (User = "@SPDSUSR")
  or ("@SPDSUSR" = "BOSSMAN")
  or ("@SPDSUSR" = "GUY" and state = "CA");
constraint describe employees;
quit;
```
or (@SPDSUSR = "BOSSMAN")
or (floor(salary/12) <= 6000);
constraint describe employees;
quit;

- **Bossman** can read all rows. User **William** can read rows for employees who belong to the West region. User **Ed** can read rows for employees who belong to the East region. User **Frank** can read rows for employees who belong to the South region.

PROC SPDO lib=foo;
SET ACLUSER;
constraint remove employees;
constraint add employees;
WHERE (@SPDSUSR = "BOSSMAN")
or (@SPDSUSR = "WILLIAM" and REGION = "W")
or (@SPDSUSR = "ED" and REGION = "E")
or (@SPDSUSR = "FRANK" and REGION = "S");
constraint describe employees;
quit;

PROC SPDO SPDSCMD Statement

The SPDO commands described in this section require that ACLSPECIAL= is enabled for your SPDO LIBNAME connection.

To enable ACLSPECIAL=, you must first grant the SPD Server user ID ACLSPECIAL= access rights. Next, the user must request access for a specific connection. To request access, the user adds the ACLSPECIAL=YES option to the LIBNAME statement. The user can now submit SPDO commands:

SPDSCMD 'command'

The PROC SPDO SPDSCMD statement sends SPD Server a command to run. SPD Server uses the host system() call to run the command. The command is executed according to the user ID rights of the individual or administrator that started the SPD Server session. SPD Server returns the system() call value to PROC SPDO. PROC SPDO echoes the exit status of the command that was run on the host.

No restrictions are placed on commands that are executed in this manner. Therefore, you must carefully consider which SPD Server users need ACLSPECIAL access rights.
Note: For additional information about using PROC SPDO, see “Controlling SPD Server Resources with PROC SPDO” on page 139.

**SPDSCMD= Statement Examples**

List the WORKPATH directory:

```
spdscmd 'ls /spdswork/*.spds';
spdscmd 'dir d:\spdswork\*.spds';
```

Clean up WORKPATH files:

```
spdscmd 'rm /spdswork/*.spds';
spdscmd 'del d:\spdswork\*.spds';
```

**Validating PROC SPDO SPDSCMD Statement Execution**

**PROC SPDO SPDSCMD Statement**

When you use the PROC SPDO SPDSCMD statement to perform a system command, PROC SPDO sets the SAS SYSRC macro variable to the value that was returned by the system command.

Note: System commands executed on Linux do not reliably return the status of the command being executed. Therefore, PROC SPDO cannot set the SYSRC macro variable.

If the SPD Server cannot run the system command for any reason, PROC SPDO sets the SAS SYSERR macro to 1012.

**LIBNAME Proxy Commands**

**Overview of Proxy Commands**

To issue proxy commands, you must first select the SPD Server user proxy.

```
LIST USERS;
```

lists the proxy processes that are accessible to the PROC SPDO lib=<LIBNAME> statement that was dispatched from the SPD Server host. Accessible proxies are anonymous proxies and proxies that are owned by the LIBNAME owner. If the LIBNAME owner has ACLSPECIAL privileges, then all user proxies are listed.

```
SET USER user-ID [port-number];
```

enables you to use the port number to distinguish between two proxies that share the same user ID.

```
LIST USERS/LOCKING;
```

lists the user-locking proxy threads that are accessible by the PROC SPDO lib=<LIBNAME> statement that was dispatched from the SPD Server host and that were created with the LOCKING=YES LIBNAME option. Accessible proxies are anonymous proxies and proxies that are owned by the LIBNAME owner. If the LIBNAME owner has ACLSPECIAL privileges, then all user-locking proxies are listed. For each user-locking proxy thread, SPD Server returns the SPD Server user ID, the client login, and the thread ID. You can select a user-locking proxy thread from the LIST USERS list by submitting a command in the following form:
SET USER/LOCKING [user-ID threadID=\#];
After a user-locking proxy is selected, you can get LIBNAME information by submitting the following commands:

SHOWLIBNAME libref | _ALL_;
SHOWLIBNAME libref / DATA=[ _ALL_ ] dsname;
SHOWLIBNAME libref / DUMP=[ _ALL_ ] dsname;

The value for libref is an explicit SPD Server LIBNAME name. Specify _ALL_ to see every currently assigned LIBNAME for the proxy.

If the /DATA= option is used with _ALL_, information about all of the open tables in the proxy for the given LIBNAME is displayed. If the /DATA= option is used with a data set name dsname, detailed information about the specified data set table is displayed.

If the /DUMP= option is used with _ALL_, information about all of the accessible tables in the proxy for the given LIBNAME is displayed. If the /DATA= option is used with a data set name dsname, detailed information about the specified data set table is displayed.

**LIBNAME Proxy Command Examples**

The following are examples of LIBNAME proxy commands that an administrator might use. They are presented in an order that would be typical of an administrator who is gathering user proxy information before issuing proxy commands on a user’s behalf.

1. List all of the users for the server **sunburn.6100**:

   LIBNAME example sasspds
   host='sunburn'
   serv='6100'
   user='sassyl'
   passwd='abc123'
   aclspecial=YES;

   PROC SPDO lib=example;
   list users;

   Users Currently Connected to SPD Server
   UserName    Pid   Portno
   -------------------------------
   SASSYL      17704 58382
   SASSYL      17614 58298
   SASSYL      17613 58293
   ANONYMOU    17611 58288
   ANONYMOU    17610 58283

2. Set the user to ANONYMOU and specify process ID (PID) 17610:

   set user anonymou 17610;

   NOTE: User ANONYMOU connected to proxy operator port with pid=17610.

3. Show every LIBNAME for user ANONYMOU for this proxy:

   showlibname _all_;
   LIBREF(FOO):Pathname assigned=/bigdisk/test/qabigl_dev/
   LIBREF(FOO):ACL Owner=
   LIBREF(FOO):ACL Defaults(R,W,A,C)=(Y,Y,Y,Y)
4. Show all of the open tables in LIBNAME FOO:
   
   `showlibname FOO/data=_all_;`

   NOTE: No data sets currently opened for LIBREF FOO.

5. Show all of the accessible tables in LIBNAME FOO:
   
   `showlibname FOO/dump=_all_;`

   LIBREF(FOO): Dataset name=BIGX
   LIBREF(FOO): ACL Owner=ANONYMOU
   LIBREF(FOO): ACL Defaults (R,W,A,C) = (N,N,N,N)
   LIBREF(FOO): Dataset name=X
   LIBREF(FOO): ACL Owner=ANONYMOU
   LIBREF(FOO): ACL Defaults (R,W,A,C) = (N,N,N,N)

6. The user ANONYMOU issues a WHERE clause on the table BIGX. Show all of the open tables in LIBNAME FOO:
   
   `showlibname FOO/data=_all_;`

   LIBREF(FOO): Dataset name=BIGX
   LIBREF(FOO): ACL Owner=ANONYMOU
   LIBREF(FOO): ACL Defaults (R,W,A,C) = (N,N,N,N)
   LIBREF(FOO): WHERE clause read thread active

7. User ANONYMOU performs a WHERE clause on the table BIGX and displays detailed information about the table BIGX:
   
   `showlibname FOO/data=bigx;`

   LIBREF(FOO): Dataset name=BIGX
   LIBREF(FOO): ACL Owner=ANONYMOU
   LIBREF(FOO): ACL Defaults (R,W,A,C) = (N,N,N,N)
   LIBREF(FOO): WHERE clause read thread active
   LIBREF(FOO): Type=  
   LIBREF(FOO): Label=  
   LIBREF(FOO): Number observations=5000000  
   LIBREF(FOO): Observation length=41  
   LIBREF(FOO): Wire blocksize=32718  
   LIBREF(FOO): Wire block factor=798  
   LIBREF(FOO): Data port number=58392  
   LIBREF(FOO): Active data socket=33  
   LIBREF(FOO): Metafile/bigdisk/test/qabig1_dev/bigx.mdf.0.0.0.spds9  
   LIBREF(FOO): Metafile size=31  
   LIBREF(FOO): Datafile=  
      /spds02/test/qabig1_dev/bigx.dpf._bigdisk_test_qabig1_dev.0.1.spds9:  
      /spds04/test/qabig1_dev/bigx.dpf._bigdisk_test_qabig1_dev.2.1.spds9:  
      /spds01/test/qabig1_dev/bigx.dpf._bigdisk_test_qabig1_dev.3.1.spds9:  
      /spds04/test/qabig1_dev/bigx.dpf._bigdisk_test_qabig1_dev.4.1.spds9:  
      /spds01/test/qabig1_dev/bigx.dpf._bigdisk_test_qabig1_dev.5.1.spds9:  
      /spds04/test/qabig1_dev/bigx.dpf._bigdisk_test_qabig1_dev.6.1.spds9:  
      /spds01/test/qabig1_dev/bigx.dpf._bigdisk_test_qabig1_dev.7.1.spds9:  
      /spds02/test/qabig1_dev/bigx.dpf._bigdisk_test_qabig1_dev.8.1.spds9:  
      /spds04/test/qabig1_dev/bigx.dpf._bigdisk_test_qabig1_dev.9.1.spds9:  
      /spds04/test/qabig1_dev/bigx.dpf._bigdisk_test_qabig1_dev.10.1.spds9:  
      /spds01/test/qabig1_dev/bigx.dpf._bigdisk_test_qabig1_dev.11.1.spds9:
8. List all locking users for the server sunburn.6100:

```
list users/locking;
```

Users Currently Connected to the Record Level Proxy

<table>
<thead>
<tr>
<th>SPDUserName</th>
<th>Client Login</th>
<th>Thread Id</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANONYMOU</td>
<td>SASTEST</td>
<td>7</td>
</tr>
<tr>
<td>TEST</td>
<td>SASTEST</td>
<td>8</td>
</tr>
</tbody>
</table>

9. Set the user to ANONYMOU and specify thread ID 7:

```
set user/locking anonymou threadid 7;
```

NOTE: User ANONYMOU connected to record level proxy operator port with thread=7.

10. Show every LIBNAME for locking user ANONYMOU:

```
showlibname _all_;
```

LIBREF(LOCKING):Pathname assigned=/bigdisk/test/qabig1/
LIBREF(LOCKING):ACL Owner=
LIBREF(LOCKING):ACL Defaults(R,W,A,C)=(Y,Y,Y,Y)

11. Show all of the open tables in LIBNAME LOCKING:

```
showlibname LOCKING/data=_all_;
```

NOTE: No data sets currently opened for LIBREF LOCKING.

---

### Privileged OPER Commands

You must have ACLSPECIAL access rights (LIBNAME option ACLSPECIAL=YES) to run privileged OPER commands. To use privileged OPER commands, submit the following command to set yourself as the proxy operator:

```
SET MODE OPER;
```

The SET MODE OPER command sets you as the operator of the user proxy that you are currently set to. A user proxy can have only one operator at any time. If you submit the SET MODE OPER command when someone is already established as operator of the user proxy, you get the following message:

ERROR: Operator mode owned by another connection.
Cannot grant this request.

After you have successfully set yourself as the operator, you can submit the following commands:

```
OPER CANCEL [/DUMP];
```

cancels and exits the user proxy. If you specify the /DUMP option for a nonlocking user proxy, the proxy exits with an abort() call, which produces a core file. If you are the operator of a locking user proxy, the /DUMP option is ignored. The OPER CANCEL command initiates a hard exit of the user proxy. Hard exits might leave
tables opened for UPDATE access, which is an inconsistent and unusable state. In this case, you can submit the PROC DATASETS REPAIR command to restore the tables to a usable state.

**OPER DISCONNECT;**
drops the control socket from the user proxy to the client. This action causes the user proxy to terminate the next time it tries to communicate with the client. This termination initiates a hard exit of the user proxy. Hard exits might leave tables opened for UPDATE access, which is an inconsistent and unusable state. In this case, you can submit the PROC DATASETS REPAIR command to restore the tables to a usable state.

The **OPER DISCONNECT** command differs from the **OPER CANCEL** command. When the **OPER DISCONNECT** command is submitted, the user proxy continues until it detects that the control socket connection has been dropped. As a result, the **OPER DISCONNECT** command has the potential to complete. However, the point at which the user proxy detects that the control socket has been disconnected varies, which produces different results.

**OPER INTERRUPT;**
sets a soft interrupt flag in any open tables that belong to the user proxy. During certain long-running operations such as large table sorts, table scans with a WHERE clause, or index creations, the user proxy periodically checks for an interrupt flag in all of the open tables that are involved in the operation. If the user proxy detects an interrupt flag, it terminates the operation and any previously opened tables are closed.

Unlike the **OPER CANCEL** command or the **OPER DISCONNECT** command, the **OPER INTERRUPT** command initiates a soft exit of the user proxy. The user receives a message in the SAS log that states that the job has been interrupted. If the job did not finish, then the results might be incomplete. However, the user LIBNAME is intact, and the user proxy is still viable. You cannot determine whether a job will be interrupted; it depends on the job that is currently running. To determine whether a job can be interrupted, submit a SHOWLIBNAME libref / DATA=_ALL_ command before you submit the **OPER INTERRUPT** command to see all of the open tables. You can also submit the SHOWLIBNAME libref / DATA=_ALL_ command after you submit the **OPER INTERRUPT** command to see whether all of the open tables were closed. If the tables are still open after you submitted the **OPER INTERRUPT** command, you can wait and check again later. If the tables need to be closed immediately, you can issue **OPER CANCEL** to cancel the user proxy.

---

**TRUNCATE Command and Example**

The **TRUNCATE** command is a **PROC SPDO** command that enables you to delete all of the rows in a table without deleting the table structure or metadata.

```sas
%let host=kaboom;
%let port=5191;
%let domain=path2;

LIBNAME &domain sasspds "&domain"
server=&host&port
user='anonymous'
ip=YES;
```

---
/* create a table */

DATA &domain..staceys_table;

d o i = 1 t o 100;
  output;
  end;
  run;

/* verify the contents of the created table */

PROC CONTENTS data=&domain..staceys_table ;
  run;

/* SPDO Truncate command deletes the table */
/* data but leaves the table structure in */
/* place so new data can be appended */

PROC SPDO lib=&domain;
  SET acluser;
  TRUNCATE staceys_table;

  quit;

/* verify that no rows or data remain in */
/* the structure of staceys_table */

PROC CONTENTS data=&domain..staceys_table;
  run;

---

**REFRESH Command**

**Overview of the REFRESH Command**

You can use PROC SPDO to dynamically refresh SPD Server parameter and LIBNAME files. If you make changes to your spdsserv.parm file or to your LIBNAME parameter file environment file for SPD Server, you can use the REFRESH command to avoid restarting the server. Submitting the REFRESH command refreshes the specified SPD Server file without restarting the server.

When you submit the REFRESH command, SPD Server refreshes the operating parameter file.

Use the following syntax for the REFRESH command:

- To refresh the libnames.parm file:

  `REFRESH DOMAINS`

- To refresh the spdsserv.parm file:

  `REFRESH PARMS`

Each REFRESH operation completely refreshes and replaces the contents of the previous libnames.parm file or spdsserv.parm file in the SPD Server environment.
REFRESH Command Examples

Add a new LIBNAME domain to your current libnames.parm file and use it without restarting the server:

LIBNAME spds45 sasspds 'spds45'
    server=estore.5180
    user='admin'
    password='spds123'
    aclspecial=YES
    prompt=YES;

PROC SPDO library=spds44;
SET acluser admin;
REFRESH PARMS;
REFRESH DOMAINS;
quit;

Here is a more detailed version of the example above:

/* Domain reftest is a pre-existing domain. */
/* Add domain reftest2 to libnames.parm and */
/* specify owner=admin */
LIBNAME=tmp pathname=c:\temp;
LIBNAME=formats pathname=c:\data\formats;
LIBNAME=reftest pathname=c:\data\reftest
    owner=admin;
LIBNAME=reftest2 pathname=c:\data\reftest2
    owner=admin;

/* Run refresh job using admin with ACLSPECIAL */
/* The SPD Server user must have ACLSPECIAL */
/* privileges to refresh domains. */
LIBNAME reftest sasspds 'reftest'
    server=d8488.5180
    user='admin'
    password='spds123'
    aclspecial=YES;

PROC SPDO library=reftest;
SET acluser admin;
REFRESH DOMAINS;
quit;

/* Domains that have an owner= option such as */
/* reftest2 (owner=admin) must be reconnected */
/* to the domain again. */
LIBNAME reftest2 sasspds 'reftest2'
    server=d8488.5180
    user='admin'
    password='spds123';
In SPD Server, you can submit operator commands to a user after you select the user with the SET USER or SET USER/LOCKING command. However, user sessions are finite. The user that you select with SET USER or SET USER/LOCKING might be unavailable when the user ends the SAS session or disconnects from a LIBNAME and the user proxy. If you submit an OPER command to a user that is no longer in session, or to a user that has ended a locking user proxy, you get the following message:

ERROR: Specified locking user no longer exists.

If the disconnected user used a nonlocking user proxy, and you submit an OPER command, you get the following message:

ERROR: Specified user <userID> with pid <Process-ID> no longer exists.

Both of these messages indicate that the user that was selected is no longer valid. In this case, you must use SET USER or SET USER/RECORD to select a different user.
Chapter 23
SAS Scalable Performance Data (SPD) Server Index Utility Ixutil

The Index Utility ixutil
The ixutil utility enables you to reorganize an SPD Server hybrid index to improve query performance and minimize disk space. The utility also prints the disk usage statistics and the contents of indexes.

ixutil Usage
Note: Index names are case sensitive. You must specify them exactly as they are listed in the PROC CONTENTS output.

 ixutil -crejidx <data set1,column1> <data set2,column2> ... <data set_n,column_n> -libpath <physical path> -joinparts <number of parallel join work units> ;
Create a join index for a pair of data sets that are in the same domain. The join index can be used by the SPD Server to optimize parallel range joins. The columns must already be indexed. The recommended number of parallel join work units is two times the number of processors.

 ixutil -deljidx <data set1,column1> <data set2,column2> ... <data set_n,column_n> -libpath <physical path> ;
Delete a join index.

 ixutil -lstjidx -libpath <physical path> [-verbose] ;
List the join indexes that are in a domain.
ixutil -statjidx <data set1,column1> <data set2,column2> ... <data set_n,column_n> -libpath <physical path> ;
Gather statistics about the join index parts. The average join row percentage indicates the average number of rows that a parallel join work unit reads. For example, a row percentage of 75 indicates that the parallel join work unit uses 75% of the rows that it must read. The closer the percentage is to 100, the better performance will be. The percentage increases as the distribution of the data for the join column becomes more sorted.

ixutil -stats <indx1,indx2,...> -dsn<data set> -libpath <physical path> [-dist] ;
Print the disk usage statistics and segment list fragmentation statistics for the specified set of indexes that belong to a given table. Each value in the index has a segment list. A value's segment list can become fragmented when the index is updated. An index that is highly fragmented can degrade query performance and waste disk space. To improve performance and reclaim the wasted disk space, the index should be reorganized using the ixutil option -reorg.

ixutil -runstats <indx1,indx2,...> -dsn <data set name> -libpath <physical path> [-maxruns <number>] ;
Print the run statistics for each index for the specified set of indexes that belong to a given table. Run statistics provide an indication of how the values of a particular index are sorted in relation to their observation numbers. By default, ixutil run statistics display the ten longest runs in the data set. A run is defined as the number of successive observations that contain the same index value. Use the optional [-maxruns <number>] argument to change the default setting of 10 runs to any integer in the range 1–100. You can use ixutil run statistics to construct more efficient BY and WHERE clause constructs for the data set.

ixutil -reorg <index1,index2,...> -dsn <data set name> -libpath <physical path> ;
Reorganize the specified set of indexes in a table to reclaim wasted disk space and to aggregate the per-value segment lists. Reorganizing an index results in optimal disk usage and query performance.

ixutil -help
Print the Help menu.

**Invoking Ixutil as a Stand-alone Utility**

The following environment variables must be established in order to invoke this utility as a stand-alone utility. These environment variables are not needed if the utility is invoked in PROC SPDO via the spdscmd interface.

For UNIX:

```
INSTDIR=<!replace with SPD Server 5.2 Installation Directory!>
SASVER=9.4
SASHOME=<!replace with SPD Server 5.2 Installation Directory!>
LD_LIBRARY_PATH=$INSTDIR/bin:$SASHOME/SASFoundation/$SASVER/sasexe
export LD_LIBRARY_PATH
LIBPATH=$INSTDIR/bin:$SASHOME/SASFoundation/$SASVER/sasexe
export LIBPATH
TKPATH=$INSTDIR/bin:$SASHOME/SASFoundation/$SASVER/sasexe:$SASHOME/SASFoundation
/$SASVER/utilities/bin
export TKPATH
MSGPATH=$SASHOME/SASFoundation/$SASVER/misc/tkspddrv
export MSGPATH
```
For Windows:

SET SASROOT=\!replace with SPD Server 5.2 Installation Directory!\
SET INSTALLDIR=\!replace with SPD Server 5.2 Installation Directory!\
SET MSGPATH=@SASROOT@\tkspddrv\sasmisc
SET TKPATH=@INSTALLDIR@\bin;@SASROOT@\core\sasext

Ixutil Options

-crejidx <data set1,column1> <data set2,column2> ... <data set_n,column_n>
  Create a join index for the SPD Server parallel join utility to use.

-deljidx <data set1,column1> <data set2,column2> ... <data set_n,column_n>
  Delete a join index.

-dist
  Include the distribution statistics with the index statistics.

-lstjidx -libpath <library path>
  List the join indexes for a domain.

-statjidx <data set1,column1> <data set2,column2> ... <data set_n,column_n>
  Get statistics about a join index.

-stats <index,index...>
  For each specified index, print the index disk usage statistics and value segment list statistics.

-runstats <index,index...>
  For each specified index, print the run statistics. Runs are defined as successive observations in a table that contain the same index value.

-reorg <index,index...>
  For each index, reorganize the index to reclaim any unused disk space and coalesce any fragmented value segment lists.

-joinparts <number of parallel join work units>
  The number of parallel join work units for a join index. Parallel join threads join the work units concurrently and then merge their partial results into the final result.

-dsn <data set name>
  The SPD Server table that contains the index.

-libpath <physical path>
  The physical path of the domain that contains the table.

-help
  Print the ixutil help menu.
Ixutil Examples

Create an Index

Assume that an SPD Server domain named *my domain* is assigned to the directory `/spds` on a machine named *spot*. A user has created a table with the following SAS program:

```sas
LIBNAME my_data sasspds 'mydomain'
    server=spot.spdsnname
    user='anonymous';

data my_data.test(index=(x));
    do i = 1 to 30000;
        x = mod(i,3);
        output;
    end;
run;

data my_data.test1;
    do i = 1 to 10000;
        x = mod(i,2);
        output;
    end;
run;

PROC APPEND
    base=my_data.test
    data=my_data.test1;
run;

PROC SQL;
    delete from my_data.test
    where x=1;
quit;
```

This SAS program creates an index for column X of the table named *test*, on the machine named *spot*, in the directory named `/spds`.

Retrieve Disk Usage and Fragmentation Statistics

Use the `-stats` option of `ixutil` to get the disk usage and segment list fragmentation statistics for the index:

```
> ixutil -stats test -dsn test -libpath /spds
```

SAS Scalable Performance Data Server 5.1(TS M0)
Build(Apr 26 2013, 11:50:08)
Index File Utility
Copyright (c) 1996-2013 by SAS Institute Inc, Cary NC 27513 USA

Statistics for Index X:
Ixutil Examples

Ixutil completed successfully

The statistics include the following information:

• the segment size of the index.
• the number of segments in the table.
• the number of distinct values for the index.
• the number of virtually deleted values (values that are no longer recognized by query indexes).
• the percentage of virtually deleted values.
• the number of values that require segment lists (a value that is in only one segment does not require a segment list).
• the number of segment list chunks for all values of the index.
• the average number of chunks for any value in the index.
• the size of the .idx file for the index. The .idx file maintains the value segment lists and bitmaps.
• the number of garbage bytes in the .idx file. Garbage bytes are the space in the file that was thrown away and cannot be reclaimed. Garbage bytes can result from deleting values, updating values, or appending values.
• the percentage of garbage bytes in the .idx file.

The average number of chunks for a segment list is a good indicator of the fragmentation level of the index. As this value increases, query performance can degrade when SPD Server must retrieve per-value information by making multiple reads of the index. If the average number of chunks exceeds 10, you should consider reorganizing the index to consolidate the segment lists.

The number of garbage bytes and the percentage of garbage bytes indicate the amount of unused disk space that is being consumed by the index. To conserve and consolidate disk space, consider reorganizing the index. Reorganizing the index frees up disk space when the garbage content is high.

Retrieve Index Distribution Statistics

Use the -dist option of \texttt{ixutil -stats} to get the index distribution for the index:

\texttt{ixutil -stats x -dsn test -libpath /spds -dist}

SAS Scalable Performance Data Server
Statistics for Index X:
---------------------------------------------------
+--segment_size         = 8192
+--n_segments_in_tbl    = 5
+--n_values_in_index    = 2
+--n_vdeleted_values    = 1
+--percent_vdeleted     = 33.33
+--n_seglist_values     = 2
+--n_seglist_chunks     = 3
+--avg_chunks_per_list  = 1.00
+--idx_file_bytes       = 13304
+--idx_garbage_bytes    = 4272
+--percent_idx_garbage  = 32.11

+--Distribution Stats for Non Unique Values
+----minimum segments for all values = 4
+----maximum segments for all values = 5
+----average segments of any value = 4
+----average percentage of segments of any value = 90.00

Ixutil completed successfully

The distribution statistics include the following information:
• the number of unique values in the index
• the number of nonunique values in the index
• the minimum number of segments that any value is divided into
• the maximum number of segments that any value is divided into
• the average number of segments that all values are divided into
• the average percentage of segments that all values are divided into

You can use the distribution statistics to determine the effectiveness of the index. The index performs better if the distribution of the index values is clustered in a minimum number of segments. In general, the lower the average percentage of segments that all values are divided into, the better the index performs.

Reorganize the Index

Use the -reorg option to reorganize the index to consolidate segment lists and retrieve unused disk space:

> ixutil -reorg x -dsn test -libpath /spds
SAS Scalable Performance Data Server
Ixutil completed successfully

Reorg for Index x:
Reorg successfully completed
Ixutil completed successfully
If you run the index utility program again to get the statistics, you will find that the segment lists for all of the values have been aggregated (the avg_chunks_per_list is 1.0) and that the unused disk space has been freed (the idx_garbage_bytes is 0). This outcome results in a proportional decrease in the size of the index file.

Aggregating the segment lists and compacting the index file minimizes the reads on the index for a query. The locality of segment data for an index key also increases. The combination of these process results in the best query performance for the index.

Review Disk Usage Statistics

Use the -stats option to review the index and segment list data, in order to view the improved performance statistics.

> ixutil -stats x -dsn test -libpath /spds
SAS Scalable Performance Data Server

Create a Join Index

Assume that SPD Server tables are in a domain in the directory /tmp. A user has created two tables, Table1 and Table2 that can be joined on the column ID. An SPD Server index exists on the column ID for both tables. A join index is created on the tables to allow a parallel range join on column ID.

Use the -crejidx option of the SPD Server ixutil command to create the join index.

> ixutil -crejidx Table1,ID Table2,ID
   -libpath /tmp
   -joinparts 4

Ixutil completed successfully.
Generate Join Index Statistics

Obtain statistics on the join index that you created by using the -statjidx option of the ixutil command. The statistics are printed for each join range of the index and for the overall index. The range statistics identify each range (sobs=starting observation, eobs=ending observation), the number of unique join keys that exist in the range, and the number of keys that are joined in the range for each table.

```bash
> ixutil -statjidx Table1,ID Table2,ID
-libpath /tmp

Ixutil completed successfully
Delete the Join Index

Use the -deljidx option of the ixutil command to delete the join index.

> ixutil -deljidx Table1,ID Table2,ID
   -libpath /tmp

Ixutil completed successfully

Parallel join work units are based on the ranges of the join keys. For example, range 0 joins ranges 1 through 100, range 1 can join range 101 to 200, and so on. Ranges can overlap observations if the tables are not sorted by the join key. Join keys result in table sorting. The nature of the join key determines how much sorting is performed on the table. The more extensive the table sorting performed on behalf of the join key, the fewer rows a range work unit needs to read in order to gather all of the rows in its range. The overall performance of the parallel join index depends on how well the table is sorted by the join key. The stronger the join key sort, the better the performance. If a range work unit has a range percentage of 0 for either table, then there are no rows in the table for that range, and that range is discarded by a parallel work thread.

SAS Scalable Performance Data (SPD) Server Table List Utility spdsls

Description
The spdsls utility lists the contents of an SPD Server domain directory, or lists all other component files for a given SPD Server table component file. The list utility has three purposes:

• furnish a complete list of tables for each SPD Server domain that you want to include in a backup
• for a specified damaged or questionable component file, provide a list of all other component files for the table that might be affected
• provide information about the size of SPD Server tables

Invoking Spdsls as a Standalone Utility

The following environment variables must be established for this utility to be invoked as a standalone utility. Note that these environmental variables are not needed if the utility is invoked in PROC SPDO via the spdscmd interface.

For UNIX:

INSTDIR=<!replace with SPD Server 5.2 Installation Directory!>
SASVER=9.4
SASHOME=<!replace with SPD Server 5.2 Installation Directory!>
LD_LIBRARY_PATH=$INSTDIR/bin:$SASHOME/SASFoundation/$SASVER/sasexe
export LD_LIBRARY_PATH
LIBPATH=$INSTDIR/bin:$SASHOME/SASFoundation/$SASVER/sasexe
export LIBPATH
TKPATH=$INSTDIR/bin:$SASHOME/SASFoundation/$SASVER/sasexe:$SASHOME/SASFoundation/\utilities/bin
export TKPATH
MSGPATH=$SASHOME/SASFoundation/$SASVER/misc/tkspddrv
export MSGPATH

For Windows:

SET SASROOT=<!replace with SPD Server 5.2 Installation Directory!>
SET INSTALLDIR=<!replace with SPD Server 5.2 Installation Directory!>
SET MSGPATH=@SASROOT@\tkspddrv\sasmisc
SET TKPATH=@INSTALLDIR@\bin;@SASROOT@\core\sasext

Usage

spdsls -l
lists all component files for a specified SPD Server table in the LIBNAME domain.
If no table is specified, all tables in the LIBNAME domain are listed. You can use the output list with any system full backup utility.

spdsls -c
For a specified component file (which is identified by a complete path), lists all other component files for the table that contains the specified file. If you have an SPD Server table file that is corrupted or that has been deleted, use this option to find all related component files that might be affected.

spdsls -info
lists information about a specified SPD Server table in the LIBNAME domain. This option provides one line of information about the table as a whole rather than a listing for each component of the table.

Options

-a
includes the domain ACL files in the listing. The files contain the access control lists (ACLs) for any SPD Server table in the domain.
-aonly
includes only the domain ACL files in the listing.
-c
For a specified component file (identified with a complete path), lists all other component files for the table. If you have an SPD Server table file that is corrupted or that has been deleted, use this option to find all related component files that might be affected.
-help
prints a list containing the command-line usage and option switches for the spdsls utility.
lists the index files.

For a specified SPD Server table in the LIBNAME domain, lists all component files for the table. If there is no table specified, lists all tables in the LIBNAME domain. The output list can be used with any system full backup utility.

lists the number of component files.

lists the file owner.

lists the size of the component file, in bytes. When you use this option with `spdsls -info`, the size of the accumulated component file is listed, in bytes.

includes the version number in the listing.

when specified with `spdsls -info`, the `-verbose` option includes detailed information about an SPD Server table. The information includes the number of observations in the table, the length of the observation, the size of the index segment, the partition size, and whether the table is compressed, encrypted, or is a cluster member.

lists only SAS 6.x data sets.

lists only SAS 8.x or SAS 9.x data sets.

complete path of an SPD Server LIBNAME directory.

complete path of a specified table component file.

specifies one or more tables to list. (If no table is specified, all tables in the LIBNAME domain are listed.)

When `spdsls` exits, it generates a return value. If the return value is 0, the utility was successful. If the return value is 1, the utility completed normally.

**spdsls Examples**

**Use spdsls to List All Components in a Domain**

You can use the `-l` option of the `spdsls` command to display index, owner, and size information for component files in the domain `/bigdisk/sas/data/public`. 
Use `spdsls` to List Sizing Information and Table Information for a Domain

You can use the `-info` option of the `spdsls` command to get size and verbose descriptive information about tables in the domain `/bigdisk/sas/data/public`.

```
spdsls -info -s -verbose /bigdisk/sas/data/public
```

Overview of the SPD Server Backup and Restore Utilities

The SPD Server backup and restore utilities provide you with the following advantages:

- You can back up an SPD Server table that remains open for query access.
- Each utility has a detailed Help menu.
- An enhanced user interface and user messages are available.

The standard file system backup and restore facilities that native operating systems provide are generally inadequate for backing up and restoring SPD Server tables. SPD Server tables can be enormous in size, surpassing the file size limits maintained by some operating environments. SPD Server is also dependent on the operation environment's ability to detect a modification to a table, such as adding, deleting, or modifying a record. A change in a table is typically a signal to ensure that the newly modified file is backed up.

When a standard utility subsequently performs an incremental backup, it processes the file change by backing up the entire table. If the table is very large, the backup time can be lengthy. In addition, the processing can consume considerable resources. Administrators frequently struggle with a dilemma: are incremental backups of large tables worth the resources that they consume?

The SPD Server backup and restore utilities alleviate these problems because they perform their functions incrementally. Instead of backing up an entire table, the backup utility backs up only the records that changed after the previous backup date. If a subsequent restore of the table becomes necessary, the restore utility can incrementally restore the table to its last backup state.

By backing up only the changed records, SPD Server conserves valuable system resources. This, in turn, encourages more frequent backups. By performing backups more frequently, you minimize the possible loss or corruption of an SPD Server table. The software also gives you the option to perform periodic full backups. You can use the SPD Server full backup and restore capabilities or you can use your system's full backup and restore facilities.

The SPD Server provides the following backup and restore utilities:

- **spdsbkup**
  - performs incremental or full backups of SPD Server tables, storing the information in an SPD Server backup data file

- **spdsrstr**
  - performs incremental or full restores of SPD Server tables using the SPD Server backup data file that is created by the utility.
Path Requirements for SPD Server Utilities

SPD Server provides National Language Support (NLS) for multiple languages and character sets in database operations. As a result, all SPD Server utilities require access to the `InstallDir/bin` directory. You must ensure that the `InstallDir/bin` directory is included in your SPD Server library path specification.

Here is an example of a statement that specifies the necessary path:

```
LD_LIBRARY_PATH=$LD_LIBRARY_PATH:InstallDir/bin
export LD_LIBRARY_PATH
```

Compatibility with Previous Versions

SPD Server 5.1 backup and restore utilities are not compatible with SPD Server 3.x and earlier releases. You cannot restore SPD Server 3.x backup files using SPD Server 5.1 utilities. You must use your SPD Server 3.x utilities to restore SPD Server 3.x backup files, and then archive the restored files using the SPD Server 5.1 utilities.

Privileged Access Protection

Running the SPD Server backup and restore utilities is a privileged operation. For a user to have access to SPD Server backup and restore utilities, one of the following statements must be true:

- The user ID that starts the SPD Server session must be identical to the user ID that performs the SPD Server backup and restore utilities (by definition, the user ID that starts the SPD Server session is a privileged user).

- The user has ACLSPECIAL=YES privileges.

To run the backup and restore utilities remotely, use SAS PROC SPDO `spdscmd`. The PROC SPDO `spdscmd` command requires the same access rights as backup and restore: either identical user IDs or ACLSPECIAL=YES user privileges.

Access to the backup and restore utilities is granted to the special user SPDSBKUP. You can use the optional user and password options for the utilities to give a specific privileged user access to the utilities.
The SPD Server Table Backup Utility spdsbkup

Description

The backup utility spdsbkup performs a full or incremental backup of an SPD Server table or LIBNAME domain. It also creates a backup file that contains full backups of newly created SPD Server tables or incremental backups of tables that have been backed up before.

During the backup process, the spdsbkup utility performs the following tasks:

• connects to a specified SPD Server
• uses the SPD Server pass-through facility to generate SQL queries on SPD Server domain tables
• backs up the records that the query returned
• compresses the record data
• stores the data in a flat data file so that the restore utility can use it later when it restores the tables

Performing a Full Backup

When you do a full backup of an SPD Server table, all of the table rows and attributes (indexes, partition size, compression, sorted) are backed up. When you restore a full backup, the table is created with those attributes, and then all the rows are added. Any changes that were made to the table attributes since the last full backup was performed are not restored.

ACL files must be in the same physical directory as the domain. If any ACL file does not meet this requirement, the ACLs are not backed up, and a warning message is sent to the log. The spdsbkup utility continues to back up all specified tables.

Performing an Incremental Backup

When you perform an incremental backup of an SPD Server table, only changes that were made to the table rows since the last full backup are included in the backup. Changes to the table attributes are not backed up. When you restore an SPD Server incremental backup, the incremental changes to the rows are applied. Only attributes that were associated the table at the time of the last full backup (indexes, partition size, compression, sorted) are applied to the restored rows.

Return Values

When spdsbkup exits, it generates a return value. If the return value is 0, the utility was successful. If the return value is 1, one or more data sets were not backed up. In that case, examine your SAS log for warning messages. If the return value is 2, a critical error caused the process to terminate early. Examine your SAS log for warning and error messages.
Backup Requirements

Client Access to an SPD Server Domain

The client that performs the backup does not have to execute on the same machine as the SPD Server. However, the client must be able to access the physical path of the SPD Server domain that is being backed up. The client can access the physical path of the domain directly or through a network connection.

Creating the LIBNAME Domain

Before a table is eligible for backup, you must create the SPD Server LIBNAME domain by using the BACKUP=YES option in the parameter file. The following two example LIBNAME entries from a data server's LIBNAME parameter file, libnames.parm, show how domains are processed with and without the BACKUP= option:

Consider the following two entries:

LIBNAME=nobackup pathname=/usr/foo/test;

LIBNAME=canbackup pathname=/usr/foo/test BACKUP=YES;

The entry for the LIBNAME domain called nobackup creates tables in the directory /usr/foo/test, but no BACKUP= option is specified. For this reason, tables that are created through this domain definition are ineligible for backup. In contrast, the entry for the LIBNAME domain canbackup, which also creates tables in the directory /usr/foo/test, specifies the BACKUP=YES option. As a consequence, tables that are created through this domain are eligible for backup.

When spdsbkup performs a backup, it checks every table in /usr/foo/test. However, based on the parameter file entries in this example, spdsbkup backs up only the eligible tables in canbackup. When you create client connections using pass-through or LIBNAME statements, you can use the BACKUP=NO LIBNAME option to override default backup settings.

Incremental Backups Require a Prior Full Backup

Before you can do an incremental backup of an SPD Server table, you must do a full backup of the table. You can perform the full backup in two ways:

- Use the system's full backup utility, and then inform spdsbkup of the system's last full backup date.
- If a full backup has not been done before, use spdsbkup to perform a full backup.

After you have performed a full backup on an SPD Server table, you can then proceed with an incremental backup strategy. The first incremental backup saves all table changes that were made after the last full backup date. Each successive incremental backup saves the changes that were made after the previous incremental backup.
spdsbkup Usage

spdsbkup -d <dom> -f <file> -h <host> [-hash] [-s <serv>] [-u <user>]
[-fibfact <n>] [-p <passwd>] [-t <mm/dd/yy:hh:mm:ss>] [-r <count>]
[-a | -aonly] [-n] [-q] [-v] [-nv6warn] [-proj <dir>] [Table ...]

spdsbkup -inc -d <dom> -f <file> -h <host> [-hash] [-s <serv>] [-u <user>]
[-fibfact <n>] [-p <passwd>] [-t <mm/dd/yy:hh:mm:ss>] [-r <count>]
[-a | -aonly] [-n] [-q] [-v] [-nv6warn] [-proj <dir>] [Table ...]

spdsbkup -full -d <dom> -f <file> -h <host> [-hash] [-s <serv>] [-u <user>]
[-fibfact <n>] [-p <passwd>] [-t <mm/dd/yy:hh:mm:ss>] [-r <count>]
[-a | -aonly] [-n] [-q] [-v] [-nv6warn] [-proj <dir>] [Table ...]

spdsbkup
performs an incremental backup or full backup of SPD Server tables

• If a table does not have a pre-existing full backup, **spdsbkup** performs a full
  backup of the table and sets the last full backup date.

• If the table does have a pre-existing full backup, **spdsbkup** performs an
  incremental backup. The incremental backup uses the latest full or incremental
  backup date as the beginning point for the incremental content change for the
  table.

spdsbkup -inc
performs only incremental backups of SPD Server tables.

• If a full backup (required for an incremental) is unavailable, **spdsbkup -inc**
  prints a warning message and the table is not backed up.

• If a full backup is available, **spdsbkup -inc** performs an incremental backup of
  the table using the later of the two dates: the date of the last full backup or of the
  last SPD Server incremental backup for the table.

• Attribute changes to the table are not backed up in an incremental backup. Only
  the incremental changes for the rows since the last backup are backed up.

  **Note:** When an incremental backup is restored, only the incremental changes to
  the rows are applied. Any indexes defined for the table are updated accordingly.

spdsbkup -full
performs only full backups of SPD Server tables. All of the table observations and
attributes (indexes, definitions, partition size, compression, and sorted) are backed
up. After each full table backup, **spdsbkup -inc** resets the last full backup date for
the table. See the **-n** option for dependencies.

  **Note:** When a full backup is restored, the table is created with those attributes and
  then all of the rows are added.

Invoking spdsbkup as a Standalone Utility

The following environment variables must be established for this utility to be invoked as
a standalone utility. Note that these are not needed if the utility is invoked in PROC
SPDO via the spdscmd interface.
For UNIX:

```
INSTDIR=<replace with SPD Server 5.2 Installation Directory!>
SASVER=9.4
SASHOME=<replace with SPD Server 5.2 Installation Directory!>
LD_LIBRARY_PATH=$INSTDIR/bin:$SASHOME/SASFoundation/$SASVER/sasexe
export LD_LIBRARY_PATH
LIBPATH=$INSTDIR/bin:$SASHOME/SASFoundation/$SASVER/sasexe
export LIBPATH
TKPATH=$INSTDIR/bin:$SASHOME/SASFoundation/$SASVER/sasexe:$SASHOME/SASFoundation/
$SASVER/utilities/bin
export TKPATH
MSGPATH=$SASHOME/SASFoundation/$SASVER/misc/tkspddrv
export MSGPATH
```

For Windows:

```
SET SASROOT=<replace with SPD Server 5.2 Installation Directory!>
SET INSTALLDIR=<replace with SPD Server 5.2 Installation Directory!>
SET MSGPATH=@SASROOT@\tkspddrv\sasmisc
SET TKPATH=@INSTALLDIR@\bin;@SASROOT@\core\sasext
```

### spdsbkup Options

- `-a`
  includes the domain ACL files in the backup.
- `-aonly`
  includes only the domain ACL files in the backup. No tables are backed up.
- `-d <domain>`
  the LIBNAME domain of SPD Server.
  
  **Note:** The system that performs the backup must be able to access the physical path for the domain locally or through a network connection.

- `-f`
  prefix filename for the backup data file. This filename is concatenated with `_BK_ ddmmmyyy hhmmss.0.0.0.spds`. The complete name identifies the file as an SPD Server backup file. If the backup file exceeds the system's file size limit, `spdsbkup` automatically extends the file and separates it into multiple backup files. Each file has a unique SPD Server filename extension (the 0.0.0 portion of the filenames is different).

- `-fibfact <n>`
  increases the File Information Block (FIB) metadata space by a factor of n, where n is greater than or equal to 2. The `-fibfact` option is necessary only if a backup fails due to insufficient FIB metadata space (fibspace). FIB metadata space shortages occur when the domain that is being backed up contains an unusually large number of data sets.

- `-full`
  performs only full backups of SPD Server tables. All of the table observations and attributes (indexes, definitions, partition size, compression, and sorted) are backed
After each full table backup, -full resets the last full backup date for the table. See the -n option for dependencies.

-h
the SPD Server host to use for the backup.

-hash
prints the hash sign (#) to stdout for each 256K block that is compressed and written to the backup file.

-help
prints the command-line usage syntax and option switch list for the spdsbkup utility.

-inc
performs incremental backups of the SPD Server tables.

-n
specifies that index information for SPD Server tables should not be saved when performing full backups. When the table is restored, the restore utility does not create indexes. The index itself is not backed up; only the definition of the index is backed up.

-nv6warn
suppresses the warning Cannot back up v6 data set. spdsbkup 5.1 can back up only SPD Server and SPD Server data sets. If you try to back up earlier versions of SPD Server data sets, a warning message is issued unless you specify the -nv6warn option.

-p
the user password.

-proj <directory>
the domain project directory.

-q
runs spdsbkup in quiet mode, which includes only error messages and warning messages in the output during a backup operation.

-r
number of times spdsbkup retries accessing a table that is not available because it is being updated. A table that is being updated cannot be backed up. The spdsbkup utility pauses 5 seconds, and then retries the table if it was unavailable during the previous access attempt. The default retry count is 1.

-s
the port number of the name server. If you do not specify this option, the default value is spdsname.

-t
The date/time of the last full system backup for the table that is to be backed up.

When you specify the -t option with spdsbkup, the utility performs a full backup only if the table was created after the specified date/time. Otherwise, the utility sets the last full backup date for the table to the specified date/time and performs an incremental backup from the last full system backup date.

When you specify the -t option with spdsbkup -inc, the utility prints a warning message if it encounters a table that was created after the specified date/time. The message states that the table will not be backed up until a full backup of the table is completed. If spdsbkup encounters a table that was created before the specified date/time (that is, the table is in the last full system backup), spdsbkup sets the last full backup date for the table to the specified time and performs an incremental backup of the table using the last full system backup date.
You cannot use the -t option with `spdsbkup -full`.

- `u`
  the user name.

- `v`
  includes the full name of the backup file and the backup's table of contents file as part of a `spdsbkup` note.

Note: The list of tables to be backed up must be the last option that you specify.

---

**Backup Data File**

**Backup Data File Nomenclature**

The `spdsbkup` utility stores backup data in a file named file_BK_ddmmmyyyy_hhmmss.0.0.0.spds. The suffix, which is added to the filename, generates a unique backup file that indicates when the backup was performed. Because the suffix is unique, you can use the same filename for successive backups of a domain or a table, without overwriting an existing file.

**Backup Data File Extensions**

If the backup file exceeds the system file size limit, `spdsbkup` automatically extends the file and stores the excess data in additional files. The software identifies these files with a file extension that follows the date/time. (The SPD Server file extension is the 0.0.0 portion of the filename.) Although the extensions for the files vary, the date/time is the same on all the files.

You must have a backup file complete with filename extension before you can begin a restore session.

---

**Backup Table of Contents File**

In addition to the backup file, `spdsbkup` creates a table of contents file using the name file_TC_ddmmmyyyy_hhmmss. The TC in the filename identifies it as a table of contents file. If the table of contents file is created in the same SPD Server operation, the timestamp for the backup file and the table of contents file are identical. The table of contents file does not have an SPD Server file extension. Unlike the backup file, the table of contents file is a regular system file and cannot be extended. The table of contents file size is constrained only by the native operating system's file size limit.

The table of contents file contains the following information for each table that is backed up:

- Columns 1–32 contain the table name. If the file is a domain ACL file, these columns contain the ACL name.
Columns 33–232 contain the backup filename.

Columns 233–250 contain the last full backup date, using the SAS datetime18 format.

Columns 251–258 contain the incremental backup sequence number, since the last full backup. For example, the value 2 indicates that this is the second incremental backup since the last full backup.

Columns 259–268 contain the number of rows that were backed up.

Column 269 contains F for a full SPD Server backup, or I for an incremental backup.

Columns 270–277 contain the number of indexes that were backed up during a full SPD Server backup. This field contains the value 0 if an incremental backup is being performed.

Column 278 is a Boolean ACL file indicator. Column 278 contains a T if a domain ACL file is being backed up, or an F if a table is being backed up. If the ACL file indicator is set to T, columns 1–32 are configured for ACL names.

The table of contents file is formatted so that it can be used as a table of contents for a SAS backup file. The table of contents file uses the following SAS format:

```sas
format lastfull datetime18.;
input @1 table $32. @33 bk_file $200.
@233 lastfull datetime18. @251 inc_seq 8.
@259 rows 10. @269 bk_type $1.
@270 num_idx 8.,
@278 acls $1.;
```

After you perform each SPD Server backup, you should append the resulting table of contents file to the SAS table of contents backup file. This step saves the backup history and will assist you when you restore the tables.

For example, if you want to determine which backup files you need to restore a specific table, you could create the following SQL query, using the date of the last full backup:

```sql
select bk_file from foo.bkup_toc
where table = "dset"
and datepart(lastfull) >= 'ddmmmyyyy'd;
```

### spdsbkup User Messages

Three basic types of SPD Server spdsbkup backup user messages can appear in your SAS log:

- **Successful Backup**

  If spdsbkup successfully backs up a table, it writes notes to stdout, unless the -q option is specified. The notes include summary information such as the name of the table that was backed up, the number of observations that were backed up, and whether a full backup or an incremental backup was performed.

- **Warning: Table Cannot Be Backed Up**

  If spdsbkup cannot back up a table, it prints a warning message that states why the table could not be backed up.

- **Failed Backup: Error and Program Aborts**
If the `spdsbkup` utility detects a serious failure condition, it stops the backup process and prints an error message that states the reason for the failure.

---

The SPD Server Table Restore Utility `spdsrstr`

**spdsrstr Description**

The restore utility `spdsrstr` uses a backup file to restore a specified set of SPD Server tables. Tables must meet restore requirements or the `spdsrstr` utility bypasses them. The `spdsrstr` utility can also provide a list of the tables in the backup file that are eligible for restoration.

The restore process is different depending on the type of backup that is being restored:

- When an incremental backup is restored, only the incremental changes to the observations are applied.
- When a full backup is restored, the table is created with the attribute settings that existed when the full backup was performed, and then all of the rows are added.

**spdsrstr Requirements**

You must meet the following requirements when you use the `spdsrstr` utility to restore a table:

- The table to be restored must be identical to the table that was backed up. The name and creation date of the table to be restored must match the name and creation date of the backed up table.
- You must perform incremental table restores in the same order as the incremental backups were performed.
- The table must not have been modified between the incremental restore dates, which assures that the table is returned to the exact state at time of backup.
- The backup file (regardless of its file extension type) must be available.

If a table does not meet all of the criteria, `spdsrstr` prints a warning message to `stdout` and does not restore the table. If `spdsrstr` is restoring multiple tables, it restores only the tables that meet the restore criteria.

**spdsrstr Syntax**

```

spdsrstr -v -d <dom> -h <host> {-f <fullfile> | -e <extfile>} [-s <serv>] [-u <user>] [-p <passwd>] [-proj <dir>] [table ...]

spdsrstr -t {-f <fullfile> | -e <extfile>} [table...]

spdsrstr -help
```
spdsrstr
restores all or selected tables from a backup file.

spdsrstr -t
prints a table of contents for a backup file. This file indicates when the backup file
was created and the type of backup that was performed. If a full backup was
performed, the file includes the number of indexes. For each table that was backed
up, the file specifies the name, backup sequence, and the number of columns and
records that are in the table.

spdsrstr -v
verifies that all or selected tables from a backup file can be restored, but does not do
the actual restore.

**spdsrstr Options**

-a
restores the backed up domain ACL (access control list) files if they do not already
exist.

-aforce
restores the backed up domain ACL files if they do not exist or overwrites the
current files if they do exist.

*Note:* To ensure that the domain ACL files are consistent with the last file that was
restored, use this option when you are restoring multiple files with the -e option.

-aonly
restores only the domain ACL files, and nothing else.

-d
the SPD Server LIBNAME domain.

*Note:* The system that performs the restore must be able to access the physical path
for the domain locally or through a network connection.

-e <extfile>
the backup filename prefix as specified in **spdsbkup** that you use to restore all
backup files in the directory with the name `<extfile>_BK_ddmmmyyy_hhmmss`.0.0.0.spds. The backup files are restored in order from oldest to newest as
determined by the `ddmmmyyy_hhmmss` component of the filename.

-f <fullfile>
the name of the backup file that contains the tables to restore.

*Note:* The filename must be the full filename (including its extension) that was
created by the SPD Server backup utility.

-h
the host SPD Server to use for the backup.

-hash
prints a hash sign (#) to stdout for each 256K compressed block that is read from the
backup file.

-n
specifies that indexes should not be created for a full restore of a table that was
backed up with index information.

-p
the user password.
-proj <dir>
  the domain project directory.

-q
  Runs spdsrstr in quiet mode, which includes only error and warning messages in the output during a backup operation.

-r
  Specifies the number of times spdsrstr retries accessing tables that are not available during a restore operation because they were in Query or Update mode. The spdsrstr utility cannot restore a table if that table is in Query or Update mode when spdsrstr accesses it. The utility pauses 5 seconds, and then retries the table if it was in Query or Update mode. The default retry count is 1.

-s
  the port number of the name server. If you do not specify this option, the default value is spdsname.

-u
  the user name.

-v
  verifies which tables in the backup file can be restored, but do not actually perform the restore operations.

[Table ...]
  the list of tables to restore from the backup file. If you do not specify any tables, all the tables in the file are restored.

  Note: The list of tables must be the last option that you specify in your spdsrstr command.

spdsrstr Return Values

When spdsrstr exits, it generates a return value. If the return value is 0, the utility was successful. If the return value is 1, one or more data sets could not be restored. In that case, examine your SAS log for warning information. If the return value is 2, a critical error caused the process to terminate early. Examine your SAS log for warning and error information.

spdsrstr User Messages

Three basic types of SPD Server spdsrstr backup user messages can appear in your SAS log:

• Successful Restore
  If spdsrstr successfully restores a table, it writes notes to stdout, unless the -q option is specified. The notes include summary information such as the name of the table that was restored, the number of observations that were restored, and whether the restore that was performed was a full restore or an incremental restore.

• Warning: Table Cannot Be Restored
  If spdsrstr cannot restore a table, it prints a warning message that states why the table could not be restored. No tables are restored after the failure.

• Failed Restore
  If the spdsrstr utility detects a serious failure condition, it stops the restore process and prints an error message that states the reason for the failure.
spdsbkup and spdsrstr Usage Examples

Backup and Restore Utility Example Scenario

The backup and restore examples in this scenario use Sunday, February 3, 2008 as the starting date for the backup cycle. The weekly schedule includes the following backup schedule:

- a full backup of the SPD Server domain test every Sunday at 23:30
- an incremental backup of the domain at 23:30 on the remaining days of the week

The scenario includes the following examples:

- Perform Exclusive SPD Server Full and Incremental Backups on page 246
- Perform SPD Server Incremental and Full Backups, and System Full Backups on page 247
- Restore a Single SPD Server Table on page 248
- Restore an SPD Server Domain on page 248

Example 1: Perform Exclusive SPD Server Full and Incremental Backups

You can use the SPD Server backup and restore utilities exclusively to perform full and incremental table backups and restores.

This example outlines the steps that you use to perform a full backup of your domain once a week, and to perform incremental backups the rest of the week. The incremental backups also fully back up any newly created tables.

1. On Sunday, February 3, 2008 at 23:30, run the SPD Server backup utility to do a full backup of the domain *test*:

```
spdsbkup -full -a -d test -h host -s serv -f backup
```

The backup creates the backup data file backup_BK_05Feb2006_233000.0.0.0.spds and the backup table of contents file backup_TC_03Feb2008_233000. The backup file contains the full SPD Server backup for each table and for any ACL files in the domain. The table of contents file contains information about each table that was backed up.

2. Archive the SPD Server backup file and the source that are in the table of contents file into a SAS table of contents table.

3. On Monday night through Saturday night, use the SPD Server backup facility to perform incremental backups:

```
spdsbkup -a -d test -h host -s serv -f backup
```

This statement performs incremental SPD Server backups of tables that were previously backed up, performs a full backup of tables that were created after the previous night's backup, and backs up any ACL files that are in the domain.
Example 2: Perform SPD Server Incremental and Full Backups, and System Full Backups

You can use SPD Server utilities to perform incremental backups on data sets that you have previously archived, and to perform full backups on new data sets that have never been backed up. You can also back up your SPD Server data sets by using a system utility from your native operating environment. Which one should you use? The advantage to using system full backups is that a system utility does not parse the data set. Therefore, this type of backup usually runs faster than the SPD Server utility when you are doing a full backup. For example, system utilities often write directly to tape storage media. In contrast, the SPD Server utility first writes backup data to a file on the hard drive, and then the backup file is usually backed up to tape.

This example outlines the steps that you use to perform a full system backup of the domain test by using operating system utilities once a week, and then to use SPD Server to perform a domain back up on the remaining nights.

1. On Sunday, February 3, 2008 at 23:30, run the SPD Server list utility spdsls -l to produce a listing of the tables that belong to the domain test in preparation for a full backup.

   spdsls -l -a <physical_path_of_domain>

2. On Monday, February 4, 2008 at 23:30, run the SPD Server backup utility spdsbkup and set the last full backup date to the previous night for the test tables. The utility performs an incremental backup of tables that have changed since the last full system backup, and it performs a full backup of tables that were created after the last full system backup was performed.

   spdsbkup -d test -h host -s serv -t 02/04/08:23:30:00 -f backup

   The utility creates the backup data file backup_BK_04Feb2008_233000.0.0.0.spds and a backup table of contents file backup_TC_04Feb2008_233000.

   The backup file contains incremental changes for tables that were modified after 23:30:00 on February 3, 2008, and full backups of tables created after 23:30:00 on February 4, 2008. Only the tables that were modified or created since the last full backup date are included in the backup file. The table of contents file contains information about each table that was either incrementally or fully backed up.

3. Archive the SPD Server backup file and source in the table of contents file into a SAS table of contents table.

4. On Tuesday night through Saturday night, use the SPD Server backup facility to do incremental backups of previously backed up tables and full backups of the newly created tables:

   spdsbkup -d test -h host -s serv -f backup

   A last full backup date is not specified for the remaining week's incremental backups. The SPD Server backup utility performs incremental backups of tables that were previously backed up and full backups of tables that were created since the previous night's backup. Although the same filename prefix is specified each night, spdsbkup saves each night's backup to a different file and appends the date and time of the backup to the filename.

5. Archive the incremental data file and source in the table of contents file into a SAS table of contents table.
Example 3: Restore a Single SPD Server Table

Use the following steps to restore a table that was accidentally deleted from the domain test on Friday, February 8, 2008.

1. If the table was backed up fully by the operating system backup utility, use the system restore utility to restore the table. (Restore the table to its last full backup image, which was taken on February 3, 2008.) If the table was backed up fully by the SPD Server backup utility, skip this step.

2. Run a SAS query on the backup table of contents table bkup.toc.

   ```sql
   select bk_file from foo.bkup_toc
   where domain = "test"
   and table = "results"
   and dttime >= '03Feb2008:23:30:00'd;
   ``

   The query results indicate which SPD Server backup files are required to restore the table to its last full backup state.

3. Restore the archived SPD Server backup files and any extensions that are required to restore the table.

4. Run `spdsrstr` on each sequential SPD Server backup file to restore the table. The order runs from the oldest backup date to the most recent backup date. The example table was backed up fully using the SPD Server backup utility on Sunday, February 3, 2008. The table was then backed up incrementally on Tuesday, February 5, and on Thursday, February 7. The following order of the statements is required to restore the table:

   ```
   spdsrstr -d test -h host -s serv -f backup_BK_03Feb2008_233000.0.0.0.spds results
   spdsrstr -d test -h host -s serv -f backup_BK_05Feb2008_233000.0.0.0.spds results
   spdsrstr -d test -h host -s serv -f backup_BK_07Feb2008_233000.0.0.0.spds results
   ```

   **Tip** You can also use the -e option of `spdsrstr` and restore all of the files with one command:

   ```
   spdsrstr -d test -h hostname -s serv -e backup results
   ```

   **Note:** When you restore a single table, you do not need to restore the ACL files, because they were not deleted.

Example 4: Restore an SPD Server Domain

Use the following steps to restore an SPD Server domain named test. This domain was lost due to a system media failure that occurred on Friday, February 15, 2008.

1. If the domain was backed up fully using the system backup utility, use the system restore utility to restore the domain test to its state at the last full backup date of February 10, 2008. If the domain was backed up fully using the SPD Server utility, then skip this step.

2. Use SAS to run a query on the backup table of contents table bkup_toc.

   ```sql
   select bk_file from foo.bkup_toc
   where domain = "test"
   and dttime >= '10FEB2008:23:30:00'd;
   ```
The query results identify which SPD Server backup files are required to restore the domain.

3. Restore the archived SPD Server backup files required to restore the domain.

4. Use the SPD Server restore utility to restore the domain `test`:
   
   ```bash
   spdsrstr -aforce -d test -h host -s serv -e backup
   ```
   
   The `-aforce` option causes the domain ACLs to be updated for each restore file. Therefore, the latest backup of the ACLs is restored.

---

**Use PROC SPDO to Back Up and Restore SPD Server Tables**

You can use the SAS PROC SPDO `spdscmd` command to run the SPD Server backup and restore utilities. In order to use this command, you must submit the command using an SPD Server LIBNAME that has special privileges. Backup and restore utilities require privileged access. To grant special privileges, you must specify the LIBNAME option ACLSPECIAL=YES.

When you execute commands using the PROC SPDO `spdscmd` command, the current working directory is the root directory of SPD Server. Messages generated by the commands are echoed to the SAS log. In the next example, the SPD Server incremental backup and restore utilities reside in the SPD Server directory. The incremental backup and restore files are saved in the server directory `/spdsadm/bkup`.

**Note:** There is a limitation when you use the `-aforce` option with PROC SPDO to restore data on Windows. The `-aforce` option fails if ACLs exist and there are active connections to the domain that were specified by using the `-d` option during the restore process. ACLSPECIAL= connections to a libref must specify a domain that is separate from the domain in which you are attempting to restore the ACLs (if the ACLs currently exist). If you make ACLSPECIAL= libref connections that specify the domain in which you are attempting to restore the ACLs, then the ACL restore operation fails.

Use the following steps to use PROC SPDO to execute SPD Server backup and restore utilities:

1. Create an SPD Server LIBNAME, and specify special privileges.
   
   ```sql
   LIBNAME backup sasspds 'test'
   host='sunny'
   serv='5150'
   user='admin'
   passwd='admin'
   ACLSPECIAL=YES;
   ```
   
   This example creates the LIBNAME backup for the domain `test` on the host machine `sunny`. The port number of the name server is 5150, and `admin` is the SPD Server user ID and password.

2. Invoke PROC SPDO for the LIBNAME:
   
   ```bash
   PROC SPDO lib=backup;
   ```
3. Use PROC SPDO remote system commands to issue backup and restore statements on the server. The following example performs a full SPD Server backup of the domain `tstdomn` at 23:30 on February 3, 2008.

   `spdsadm 'spdsbkup -a -full -d tstdomn -h sunny -s 5150 -f /spdsadm/bkup/test';`

   The example statement creates the backup file `/spdsadm/bkup/test_BK_03Feb2008_233000.0.0.spds` and the table of contents file `/spdsadm/bkup/test_TC_03Feb2008_233000` on the server.

4. If a later restore operation is necessary, run the SPD Server restore utility to restore the domain to its last full backup state:

   `spdsadm 'spdsrstr -aforce -d tstdomn -h sunny -s 5150 -e /spdsadm/bkup/test'`

---

**Back Up and Restore Table Indexes Using SPD Server Full Backups**

When you perform an SPD Server full backup of a table, by default the utility saves information to re-create the indexes. This information is subsequently used to re-create the indexes if the table is fully restored.

The SPD Server full backup utility does not save the index data. The utility saves only the information necessary to re-create the indexes when the table is restored. Therefore, when you back up table indexes, the information that is saved does not require additional overhead or a lot of additional space.

If you must fully restore a table later, you can use one of the following two methods to restore the indexes:

- The SPD Server restore utility can re-create the indexes when the table is created. In this method, the index is updated dynamically as each observation is added to the table.
- Use the `-n` option on the SPD Server restore utility. The `-n` option suppresses the creation of an index. After the table is fully restored, you can use PROC DATASETS or PROC SQL to re-create the indexes.

---

**Back Up and Restore SPD Server Table Indexes Using System Full Backups**

**Overview of Backing Up and Restoring SPD Server Table Indexes Using System Full Backups**

Restoring indexes from system full backups and restores is not as clean as restoring indexes from SPD Server full backups and restores. To understand why, consider the two methods that you can use to restore indexes from a system full backup:

- **restore the index dynamically as the table is restored**
- **recreate the index after the table is restored**
How do you decide which method to use? You must balance the time and resources that are needed to back up the index against the time needed to re-create the index when the table is restored.

**Restoring the Index Dynamically**

To restore the index dynamically, you must include the table index files in the full backup and restore of the table. To determine which index files to include, use `spdsls` with the `-i` index option. The output lists component files for each table in the domain that is to be fully backed up.

When you restore a table, you must first restore the table metadata, data, and index files from the last full backup archive. Then use `spdsrstr` to perform incremental restores. As the tables are restored, the indexes are dynamically updated to include any new or modified records.

This method trades the additional resources that are required for full backup of the table index files, which can be very large, against the potentially short time that might be required to restore them. You can restore indexes for a table that has not had any incremental changes after the system full backup by using a system full restore.

**Re-creating the Index After the Table Is Restored**

If you use this method, you do not need to include the index files in the full backup of the table. When you run `spdsls` to list the component files for each table in the domain that you intend to back up, omit the `-i` index option. The `spdsls` utility includes a list in the output that excludes index files.

*Note:* If you do not save index information, you can experience problems when you attempt to fully restore the table. The table's metadata contains information about the index files that might be missing or out of date. As a result, the metadata no longer mirrors the contents of the table.

Before you can perform an incremental restore of the table, you must first repair the table metadata. To repair the metadata, use PROC DATASETS to modify the table and delete all of the indexes, and then run `spdsrstr` to restore the table. After the table is restored, use PROC DATASETS again to modify the table and create the indexes.

This method trades the resources that you save by not fully backing up the index files against the greater amount of time it can take to re-create the indexes fully if the table must be restored.
Overview of the SPD Server Directory Cleanup Utility spdsclean

The spdsclean utility script is located in the InstallDir/site/ directory of your SPD Server 5.2 installation. You use the SPD Server cleanup utility spdsclean to perform routine maintenance functions on the following types of directories:

- directories that you use to configure SPD Server storage
- directories that SPD Server uses for working storage
- various system-specific directories that are designated for temporary files

The spdsclean utility uses a simple command-line interface. You can control the level of cleanup performed and control the behavior of elements that are used in the utility.
CAUTION:
Use the spdsclen command line utility only when SPD Server is not running. Do not run spdsclen when the SPD Server host is running. The directory cleanup utility does not ensure that files in the SPD Server cleanup area are not in use by others. Some cleanup actions can violate SPD Server file integrity, which permits concurrent access to file structures that were not designed to support concurrent access.

Using the Directory Cleanup Utility spdsclen

The spdsclen program is a command-line utility. It supports a set of command-line options and parameters that you use to specify the location and names of tables to convert, and to specify behaviors that you want to control during the conversion process.

Here is the command-line syntax:

```bash
spdsclen <-options>
```

You can specify options in any order. All options are global in scope.

spdsclen Wildcards and Pattern Matching

Some spdsclen options, such as -domains, use wildcards and pattern matching functions. The spdsclen utility uses the following wildcard and pattern matching rules:

- Character strings must match the LIBNAME domain name from the LIBNAME file. The match is not case sensitive.
- In the search pattern, the period (.) and question mark (?) characters find a wildcard match to any single character in a LIBNAME domain name in the LIBNAME file.
- The asterisk (*) character terminates the pattern and finds wildcard matches to all remaining characters in the LIBNAME domain name in the LIBNAME file.

For example, the -domains pattern ?test* matches the domains ATEST1, ATEST123, ATESTXYZ, CTEST1, and so on, from a LIBNAME file. The -domains pattern test* matches only the domain name TEST from the LIBNAME file.

Note: When you use wildcard characters in a -domains pattern, follow the rules for your command shell (such as ksh) to ensure that these characters are passed to the spdsclen command. For example, a ksh command shell user needs to enclose the wildcard pattern in double quotation marks. The double quotation marks ensure that the wildcard pattern matching occurs relative to the spdsclen command. For example:

```bash
spdsclen -domains "*?test*"
```

You can also disable command shell globbing for the execution of the spdsclen command.
spdsClean Options

Options That Define Actions

The spdsClean utility uses the following option settings to define specific actions:

-.hadoopaclpath path-to-directory-containing-ACL-files-for-Hadoop-domain
  specifies the path to the directory containing ACL files for a Hadoop domain. These
  ACL files are cleaned up when -all or -acl options are used. For more
  information about ACL file options -all and -acl, see “Options That Modify
  Behavior” on page 255.

  Note: If you specify a value for the -hadoopaclpath path-to-directory-containing-
  ACL-files-for-Hadoop-domain option with the SPDSCLEAN utility, that value
  overrides any other HADOOPACLPATH= settings declared in the SPD Server
  server parameter file.

-libnamefile full-path-specification-to-SPD-Server-libname-parameter-file
  runs a cleanup on the SPD Server environment that is specified by libnameFile (the
  LIBNAME parameter file). The cleanup process empties directory resources that are
  defined in LIBNAME statements in the LIBNAME parameter file. Cleaning up
  directory resources removes files and file types that you specify in the spdsClean
  action. The spdsClean utility always deletes residual lock files that were left behind
  in the domain directory. The cleanup process removes any temporary (TEMP=yes)
  directories and files. Residual temporary files in the allocated domain directories are
  deleted by default. You can include ACL files and the LIBNAME state file in the
  files to be deleted, and you can suppress the default deletion of residual temporary
  files. Use the -domains option with pattern matching to filter the domains that you
  want to clean in the LIBNAME parameter file. For more information, see the
  description for the -domains option.

-parmfile full-path-specification-to-SPD-Server-parameter-file
  runs cleanup on the specified SPD Server environment, which is defined in the SPD
  Server parameter file in the provided path. The cleanup action empties all directory
  resources that are defined in the SPD Server parameter file. All files in the
  WORKPATH= path list are deleted. Options that modify -parmfile cleanup actions
  are described in “Options That Modify Behavior” on page 255

-logdir path-to-directory-containing-.spdslog-file
  specifies the path for SPD Server to use when cleaning server log files. SPD Server
  searches the specified log path directories for .spdslog files. When .spdslog files are
  found, SPD Server checks them for aging criteria. You specify the aging criteria,
  which tells SPD Server how long to keep the log files using the -logage option.
  When spdsClean finds server log files that have a creation date that is older than
  -logage days, spdsClean deletes the files. Files that are equal to or less than the
  specified age are retained. For more information, see the -logage option under
  “Options That Modify Behavior” on page 255.

Options That Modify Behavior

The spdsClean utility uses the following option settings to modify specific behaviors:
-all
equivalent to specifying the following options:
- tmp - acl - lib11
-
-tmp
enables deletion of residual temporary files in the LIBNAME domain path list.
Deletion is enabled by default.
+tmp
disables the deletion of residual temporary files in the LIBNAME domain path list.
-acl
enables the deletion of ACL files in the LIBNAME domain path list. Enabling the - acl setting deletes .spres11* and .sppro11* files from the LIBNAME domains that are specified by the -libnamefile option. The -acl option applies to all of the LIBNAME domains that you specify on the -libnamefile option. Deleting the ACL files does not grant broader access to a given resource. Deleting the ACL files restricts the access to the resource owner.
+acl
disables the deletion of ACL files in the LIBNAME domain path list.
-lib11
enables the deletion of the domain state file, .spdslib11. The default setting is +lib11.
+lib11
disables the deletion of the domain state file. This setting is the default setting for the lib11 variable.
-verbose
enables logging of the resource cleanup process from WORKPATH, system workspace directories, and LIBNAME domain directories. Specifying -verbose is equivalent to specifying -vwork and -vdomain.
+verbose
disables logging of the resource cleanup process from WORKPATH, system workspace directories, and LIBNAME domain directories. Specifying +verbose is equivalent to specifying +vwork and +vdomain.
-vwork
enables logging of the resource cleanup process from WORKPATH and system workspace directories.
+vwork
disables logging of the resource cleanup process for WORKPATH and system workspace directories. This setting is the default setting.
-vdomain
enables logging of the resource cleanup process from LIBNAME domain directories.
+vdomain
disables logging of the resource cleanup process from LIBNAME domain directories. This setting is the default setting.
-domains dompat1, [dompat2,
 specifies a list of domains. The list is a comma-separated list of domain names and wildcard matching patterns. The list builds the LIBNAME domains from the LIBNAME file when it is processed. Standard pattern matching rules and wildcards apply.
-logage ageDays
sets the age threshold, in days, for keeping .spdslog files in the SPD Server log
directory when the -logdir option is specified. If the -logdir option is specified and
the .spdslog files in the SPD Server log directory are older than the threshold value,
the files are deleted. The default value for ageDays is 7.

spdsclean Examples

For the following examples, assume that the InstallDir/ value for your SPD Server
is the directory /opt/spds45.

Cleaning WORKPATH Files on Your Server

The following spdsclean command cleans all of the files in the WORKPATH directory list
that is designated by /opt/spds45/site/spdsserv.parm.

spdsclean -parmfile /opt/spds45/site/spdsserv.parm

If you want spdsclean to log the files that it deletes, add the -verbose option to the
command.

spdsclean -parmfile /opt/spds45/site/spdsserv.parm -verbose

Cleaning Residual Temporary LIBNAME Domain Files

The following spdsclean command cleans all of the residual temporary files from all of
the LIBNAME domains that are defined in the specified LIBNAME file.

spdsclean -libnamefile /opt/spds45/site/libnames.parm

If you want spdsclean to log the files that it deletes, add the -verbose option to the
command.

spds_clean -libnamefile /opt/spds45/site/libnames.parm -verbose

Cleaning Specific LIBNAME Domains

The following spds_clean command cleans all residual temporary files from the
LIBNAME domain TRIAL99.

spds_clean -libnamefile /opt/spds45/site/libnames.parm -domains trial99

To add domain UJOE04 to be cleaned also, use the following command:

spds_clean -libnamefile /opt/spds45/site/libnames.parm -domains trial99, ujoe04

To clean all TRIAL9x domains and all domains that begin with UJOE from the specified
LIBNAME file, use the following command:

spds_clean -libnamefile /opt/spds45/site/libnames.parm -domains trial9?, ujoe*

To log the domains that spds_clean processed and the files that were deleted from each
domain, add the -verbose option to any of these spds_clean commands.
Cleaning Other LIBNAME Domain File Classes

The following `spdscclean` command cleans only the ACL files from LIBNAME domains that begin with UJOE that are defined in the specified LIBNAME file. Because this command specifies the `+tmp` option, the deletion of residual temporary files is suppressed. To log the LIBNAME domains that were cleaned and the ACL files that were deleted, add the `-verbose` option.

```
spdscclean -libnamefile /opt/spds45/site/libnames.parm +tmp -acl -domains ujoe*
```

To clean domain state files from domains TRIAL9x for the specified LIBNAME file, issue the following command:

```
spdscclean -libnamefile /opt/spds45/site/libnames.parm -domains trial9* -lib11 +tmp
```

To log the LIBNAME domains that were cleaned and the files that were deleted, add the `-verbose` option.

Cleaning WORKPATH and LIBNAME Combinations

The following `spdscclean` command cleans all of the WORKPATH files from the directory list specified by the `-parmfile` option. This command also cleans residual temporary files from domain directories specified by the `-libnamefile` option.

```
spdscclean -parmfile /opt/spds45/site/spdsserv.parm -libnamefile /opt/spds45/site/libnames.parm -verbose
```

Logging is enabled for the WORKPATH and LIBNAME domain directories and for the files that were deleted from each directory.

Cleaning Log Files

The following `spdscclean` command cleans the .spdslog files that are more than 7 days old from the specified log path directory.

```
spdscclean -logdir /opt/spds45/log
```

To keep log files that are older than 10 days from the date of creation, use the following command:

```
spdscclean -logdir /opt/spds45/log -logage 10
```

If you want to see the files that were deleted, add the `-verbose` option to the `spdscclean` command.

Cleaning WORKPATH, LIBNAME Domain, and Log Files

The following `spdscclean` command cleans WORKPATH files from the directory list specified by the `-parmfile` option, residual temporary files from domain directories in the LIBNAME file specified by `-libnamefile`, and .spdslog files that are older than 7 days from the specified log path directory.

```
spdscclean -parmfile /opt/spds45/site/spdsserv.parm -libnamefile /opt/spds45/site/libnames.parm -logdir /opt/spds45/log -verbose
```
Glossary of spdsclen Term

ACL files
When you create SPD Server access control lists (ACLs), hidden ACL files are created in the primary directory of the LIBNAME domain. The hidden files are named .spres11* and .sppro11*. The hidden ACL files retain the state of the ACLs that were defined for the LIBNAME domain resources. Typically, you should not delete ACL files.

domain state file
The domain state file is also known as .spdslib11. The domain state file retains the set of directory paths that are configured for the LIBNAME domain. The directory path information is stored as an ordered list for each of the following SPD Server domain storage classes:

- METAPATH=
- DATAPATH=
- INDEXPATH=

As you make LIBNAME assignments over the life of the domain, the new directories are appended to the end of the ordered lists for METAPATH=, DATAPATH=, and INDEXPATH= storage classes. The order of directories listed in the .spdslib11 file defines the order of data cycling and overflow sequencing for each of the respective classes.

libnames.parm file
The libnames.parm file defines the SPD Server LIBNAME domains for the SPD Server environment. The libnames.parm file is a collection of LIBNAME statements. Each LIBNAME statement defines a storage domain that SPD Server uses with clients. You modify the libnames.parm file by using the -libnamefile option with the spdsserv command.

residual lock file
When SPD Server accesses a data resource or table that is within a LIBNAME domain, it creates a lock file. The local operating environment uses the locking mechanism to ensure that proper member-level locking is observed by all SPD Server processes that access the named data resource. If a LIBNAME proxy process terminates unexpectedly, the residual lock files remain in the LIBNAME domain. Residual lock files do not cause problems when the files are accessed again because the lock belongs to the operating environment. The lock is cleared when the process terminates and does not depend on the presence of the file itself. However, unused residual lock files can accumulate and create clutter in your primary domain directory.

residual temporary file
SPD Server creates temporary files when you create a new resource in a LIBNAME domain. If the SPD Server LIBNAME proxy process terminates unexpectedly while you are creating a new file, the residual temporary files remain in the LIBNAME domain directories. These temporary files contain a leading dollar sign character ($) in the name, which prevents the residual temporary files from appearing in a PROC DATASETS directory listing. You should periodically remove old or abandoned residual temporary files that unexpected proxy process terminations created.

spdsserv.parm file
The spdsserv.parm file defines the SPD Server operating parameters. The WORKPATH= statement in this file lists the directories that SPD Server uses for...
transient or working disk storage. To specify the spdsserv.parm file, use the `spdsserv` command with the `-parmfile` option.

system-specific temporary files
SPD Server uses pre-assigned directories (which vary by operating environment) that are designated for temporary files. The pre-assigned directories hold files, logs, and other temporary entities that SPD Server creates while it is running. SPD Server usually cleans up these temporary files when it exits. If SPD Server terminates abnormally, these temporary files might be left in the temporary directory. In UNIX operating environments, the temporary files usually appear in directories such as `/tmp` or `/var/tmp`. In Windows operating environments, the temporary files are usually stored in `C:/TEMP` (or wherever the user profile is configured to store temporary files).

Using SPDSCLEAN with Hadoop

SPD Server 5.2 uses a script called `spdsclean_Hadoop` to invoke the SPDSCLEAN functionality within a Hadoop domain. The SPDSCLEAN command for domains that are not Hadoop domains continues in force without any modifications. The `spdsclean_Hadoop` script accepts the same arguments as the standard SPDSCLEAN command, with the addition of some Hadoop operational parameters that must be specified. The script defines parameter values for SPD Server environment variables such as `PATH`, `LD_LIBRARY_PATH`, `TKPATH`, and `JREOPTIONS`.

Hadoop SPDSCLEAN Configuration Information
To use the SPDSCLEAN (or SPDSCLEAN2) functionality within a Hadoop domain, you must provide Hadoop config path configuration and Hadoop JAR information, in the same way that you must configure SPD Server to access Hadoop environments. You can choose from several methods to invoke the SPDSCLEAN function within a Hadoop domain.

Configure Hadoop SPDSCLEAN via Environment Variables
You can use environment variables to specify Hadoop `CONFIG_PATH` and `JAR_PATH` configuration parameters for SPDSCLEAN. You specify values for the parameters via UNIX command prompt, before submitting the `spdsclean_Hadoop` script, or you can incorporate the parameter value statements within the `spdsclean_Hadoop` script itself.

```
export SAS_HADOOP_CONFIG_PATH=/u/fedadmin/hadoopcfg/cdh52p1
export SAS_HADOOP_JAR_PATH=/u/fedadmin/hadoopjars/cdh52
```

Configure Hadoop SPDSCLEAN via SPDSCLEAN Options
You can modify your `spdsclean_Hadoop` script to use the `-hadoopcfg` and `-hadoopjar` option settings to specify the values for your Hadoop config path and JAR path.

```
spdsclean -hadoopcfg /u/fedadmin/hadoopcfg/cdh52p1
         -hadoopjar /u/fedadmin/hadoopjars/cdh52
         other-options;
```
Specify Hadoop Configuration Information for SPDSCLEAN via -libnamefile and -parmfile Options in spdsclean_Hadoop Script

You can modify your `spdsclean_Hadoop` script to reference Hadoop configuration information that is defined in your SPD Server libnames.parm file or in your spdsserv.parm file.

Typical content for the `spdsclean_Hadoop` script:

```
spdsclean -libnamefile libnames.parm -parmfile spdsserv.parm
```

Typical content for the libnames.parm file:

```
libname=Stuff1
  pathname=/user/userlname
  hadoopcfg=/u/fedadmin/hadoopcfg/cdh52p1
  hadoopjar=/u/fedadmin/hadoopjars/cdh52
  hadoop=yes;
```

*Note:* You do not need to specify Hadoop configuration information in both the libnames.parm file and in the spdsserv.parm file. Examples of both methods are provided for convenience.
Overview of SPD Server Debugging Tools

SPD Server includes debugging tools that are useful for system administrators. The debugging tools allow SPD Server system administrators to create debug images and to evaluate test images that do not interfere with a pre-existing production SPD Server environment. The debugging tools are organized into LIBNAME statement options and server parameter file options.

SPD Server 5.2 LIBNAME Statement Debug Option

When you issue a LIBNAME statement in SPD Server, the following debug option is available:

**ALTPATH=**

The ALTPATH= option enables the use of an alternate binary path, which is defined by the ALTBINPATH= option in the file. The ALTPATH= option does not search entities in the PATH environment variable. If ALTPATH= does not find the ALTBINPATH= option specified in the file, a login failure error is issued. The ALTPATH= option is useful if you want to load a non-production copy of SPD Server (for example, testing a fix) without replacing the production copy of SPD Server on a user basis.

**Syntax**

```
ALTPATH= YES | NO
```

**Arguments**
YES
   enables use of the alternate binary path that is defined on the ALTBINPATH=
   parameter file debug option.

NO
   disables the alternate binary path for the specified proxy if a binary path is present.

ALTPATH= Example

Issue a LIBNAME proxy that uses the alternate binary path that is defined on the
ALTBINPATH= parameter file debug option:

LIBNAME mylib sasspds ’spdsdata'
   user=’denettee' altpath=yes;
