For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option. If your sample design is stratified with different population totals in different strata, then you should name a SAS data set that contains the stratification variables and the stratum totals. See the section "Population Totals and Sampling Rates" on page 6322 for details.

If you do not specify the TOTAL= or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option in the same PROC SURVEYFREQ statement.

VARHEADER=LABEL | NAME | NAMELABEL

specifies the variable identification to use in the displayed output. By default VARHEADER=NAME, which displays variable names in the output. The VARHEADER= option affects the headers of the variable level columns in one-way frequency tables, crosstabulation tables, and the "Stratum Information" table. The VARHEADER= option also controls variable identification in the table headers. The following values are available for the VARHEADER= option:

LABEL	displays the variable label.
NAME	displays the variable name.
NAMELABEL	displays both the variable name and label, with the label in parentheses following the name—that is, *Name (Label)*.

VARMETHOD=BRR < (*method-options***) > | JACKKNIFE < (***method-options***) > | TAYLOR**

specifies the variance estimation method. VARMETHOD=TAYLOR requests the Taylor series method, which is the default if you do not specify the VARMETHOD= option or a REPWEIGHTS statement. VARMETHOD=BRR requests variance estimation by balanced repeated replication (BRR), and VARMETHOD=JACKKNIFE requests variance estimation by the delete-1 jackknife method.

For VARMETHOD=BRR and VARMETHOD=JACKKNIFE, you can specify *method-options* in parentheses following the variance method name. Table 83.1 summarizes the available *method-options*.

Table 83.1 Variance Estimation Options

VARMETHOD=	Variance Estimation Method	*Method-Options*
BRR	Balanced repeated replication	DFADJ FAY <=*value*> HADAMARD=*SAS-data-set* OUTWEIGHTS=*SAS-data-set* PRINTH REPS=*number*
JACKKNIFE	Jackknife	DFADJ OUTJKCOEFS=*SAS-data-set* OUTWEIGHTS=*SAS-data-set*
TAYLOR	Taylor series linearization	*None*

The following values are available for the VARMETHOD= option.

BRR < *method-options* > requests variance estimation by balanced repeated replication (BRR). The BRR method requires a stratified sample design with two primary sampling units (PSUs) in each stratum. If you specify the VARMETHOD=BRR option, you must also specify a STRATA statement unless you provide replicate weights with a REPWEIGHTS statement. See the section "Balanced Repeated Replication (BRR)" on page 6334 for details.

You can specify the following *method-options* in parentheses after the VARMETHOD=BRR option.

DFADJ

computes the degrees of freedom as the number of nonmissing strata for the individual table request. The degrees of freedom for VARMETHOD=BRR equal the number of strata, which by default is based on all valid observations in the data set. But if you specify the DFADJ method-option, PROC SURVEYFREQ excludes from the count any empty strata that occur when observations with missing values of the TABLES variables are removed from the analysis for that table.

See the section "Degrees of Freedom" on page 6340 for more information. See the section "Data Summary Table" on page 6356 for details about valid observations.

The DFADJ method-option has no effect when you specify the MISSING option, which treats missing values as a valid nonmissing level. The DFADJ method-option is not used when you specify the degrees of freedom in the DF= option in the TABLES statement.

The DFADJ method-option cannot be used when you provide replicate weights with a REPWEIGHTS statement. When you use a REPWEIGHTS statement, the degrees of freedom equal the number

of REPWEIGHTS variables (or replicates), unless you specify an alternative value in the DF= option in the REPWEIGHTS or TABLES statement.

FAY < =*value* >
requests Fay's method, which is a modification of the BRR method. See the section "Fay's BRR Method" on page 6335 for details.

You can specify the *value* of the Fay coefficient, which is used in converting the original sampling weights to replicate weights. The Fay coefficient must be a nonnegative number less than 1. By default, the value of the Fay coefficient equals 0.5.

HADAMARD=*SAS-data-set*
H=*SAS-data-set*
names a SAS data set that contains the Hadamard matrix for BRR replicate construction. If you do not provide a Hadamard matrix with the HADAMARD= method-option, PROC SURVEYFREQ generates an appropriate Hadamard matrix for replicate construction. See the sections "Balanced Repeated Replication (BRR)" on page 6334 and "Hadamard Matrix" on page 6336 for details.

If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the HADAMARD=*SAS-data-set* method-option.

In the HADAMARD= input data set, each variable corresponds to a column of the Hadamard matrix, and each observation corresponds to a row of the matrix. You can use any variable names in the HADAMARD= data set. All values in the data set must equal either 1 or –1. You must ensure that the matrix you provide is indeed a Hadamard matrix—that is, $\mathbf{A}'\mathbf{A} = R\mathbf{I}$, where $\mathbf{A}$ is the Hadamard matrix of dimension R and $\mathbf{I}$ is an identity matrix. PROC SURVEYFREQ does not check the validity of the Hadamard matrix that you provide.

The HADAMARD= input data set must contain at least H variables, where H denotes the number of first-stage strata in your design. If the data set contains more than H variables, PROC SURVEYFREQ uses only the first H variables. Similarly, the HADAMARD= input data set must contain at least H observations.

If you do not specify the REPS= method-option, then the number of replicates is taken to be the number of observations in the HADAMARD= input data set. If you specify the number of replicates—for example, REPS=*nreps*—then the first *nreps* observations in the HADAMARD= data set are used to construct the replicates.

You can specify the PRINTH method-option to display the Hadamard matrix that the procedure uses to construct replicates for BRR.

OUTWEIGHTS=*SAS-data-set*

names a SAS data set to store the replicate weights that PROC SURVEYFREQ creates for BRR variance estimation. See the section "Balanced Repeated Replication (BRR)" on page 6334 for information about replicate weights. See the section "Replicate Weights Output Data Set" on page 6355 for details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= method-option is not available when you provide replicate weights with a REPWEIGHTS statement.

PRINTH

displays the Hadamard matrix used to construct replicates for BRR. When you provide the Hadamard matrix in the HADAMARD= method-option, PROC SURVEYFREQ displays only the rows and columns that are actually used to construct replicates. See the sections "Balanced Repeated Replication (BRR)" on page 6334 and "Hadamard Matrix" on page 6336 for more information.

The PRINTH method-option is not available when you provide replicate weights with a REPWEIGHTS statement because the procedure does not use a Hadamard matrix in this case.

REPS=*number*

specifies the number of replicates for BRR variance estimation. The value of *number* must be an integer greater than 1.

If you do not provide a Hadamard matrix with the HADAMARD= method-option, the number of replicates should be greater than the number of strata and should be a multiple of 4. See the section "Balanced Repeated Replication (BRR)" on page 6334 for more information. If a Hadamard matrix cannot be constructed for the REPS= value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the REPS= value that you specify.

If you provide a Hadamard matrix with the HADAMARD= method-option, the value of REPS= must not be less than the number of rows in the Hadamard matrix. If you provide a Hadamard matrix and do not specify the REPS= method-option, the number of replicates equals the number of rows in the Hadamard matrix.

If you do not specify the REPS= or HADAMARD= method-option and do not include a REPWEIGHTS statement, the number of replicates equals the smallest multiple of 4 that is greater than the number of strata.

If you provide replicate weights with a REPWEIGHTS statement, the procedure does not use the REPS= method-option. With a REPWEIGHTS statement, the number of replicates equals the number of REPWEIGHTS variables.

JACKKNIFE | JK < *method-options* > requests variance estimation by the delete-1 jackknife method. See the section "The Jackknife" on page 6337 for details. If you provide replicate weights with a REPWEIGHTS statement, VARMETHOD=JACKKNIFE is the default variance estimation method.

You can specify the following *method-options* in parentheses after the VARMETHOD=JACKKNIFE option:

DFADJ

computes the degrees of freedom by using the number of nonmissing strata and clusters for the individual table request. The degrees of freedom for VARMETHOD=JACKKNIFE equal the number of clusters minus the number of strata, which by default is based on all valid observations in the data set. But if you specify the DFADJ method-option, PROC SURVEYFREQ excludes any empty strata or clusters that occur when observations with missing values of the TABLES variables are removed from the analysis for that table.

See the section "Degrees of Freedom" on page 6340 for more information. See the section "Data Summary Table" on page 6356 for details about valid observations.

The DFADJ method-option has no effect when you specify the MISSING option, which treats missing values as a valid nonmissing level. The DFADJ method-option is not used when you specify the degrees of freedom in the DF= option in the TABLES statement.

The DFADJ method-option cannot be used when you provide replicate weights with a REPWEIGHTS statement. When you include a REPWEIGHTS statement, the degrees of freedom equal the number of REPWEIGHTS variables (or replicates), unless you specify an alternative value in the DF= option in the REPWEIGHTS or TABLES statement.

OUTJKCOEFS=*SAS-data-set*

names a SAS data set to store the jackknife coefficients. See the section "The Jackknife" on page 6337 for information about jackknife coefficients. See the section "Jackknife Coefficients Output Data Set" on page 6355 for details about the contents of the OUTJKCOEFS= data set.

OUTWEIGHTS=*SAS-data-set*

names a SAS data set to store the replicate weights that PROC SURVEYFREQ creates for jackknife variance estimation. See the

section "The Jackknife" on page 6337 for information about replicate weights. See the section "Replicate Weights Output Data Set" on page 6355 for details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= method-option is not available when you provide replicate weights with a REPWEIGHTS statement.

TAYLOR requests Taylor series variance estimation. This is the default method if you do not specify the VARMETHOD= option or a REPWEIGHTS statement. See the section "Taylor Series Variance Estimation" on page 6327 for details.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC SURVEYFREQ to obtain separate analyses of observations in groups defined by the BY variables. The *variables* are one or more variables in the input data set.

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, where the total number of units in the subpopulation is not known with certainty. You should include the domain variable(s) in your TABLES request to obtain domain analysis. See the section "Domain Analysis" on page 6323 for more details.

If you specify more than one BY statement, the procedure uses only the last BY statement and ignores any previous BY statements.

When you use a BY statement, the procedure expects the input data set to be sorted in order of the BY variables. If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the option NOTSORTED or DESCENDING in the BY statement. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the *Base SAS Procedures Guide*.

CLUSTER Statement

CLUSTER *variables* **;**

The CLUSTER statement names variables that identify the first-stage clusters, or primary sampling units (PSUs), in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should specify only the first-stage clusters, or PSUs, in the CLUSTER statement. See the section "Specifying the Sample Design" on page 6320 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with a REPWEIGHTS statement, you do not need to specify a CLUSTER statement.

The CLUSTER *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

You can use multiple CLUSTER statements to specify CLUSTER variables. The procedure uses variables from all CLUSTER statements to create clusters.

REPWEIGHTS Statement

REPWEIGHTS *variables* < */ options* > **;**

The REPWEIGHTS statement names variables that provide replicate weights for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option in the PROC SURVEYFREQ statement. If you do not provide replicate weights for these methods by using a REPWEIGHTS statement, then PROC SURVEYFREQ constructs replicate weights for the analysis. See the sections "Balanced Repeated Replication (BRR)" on page 6334 and "The Jackknife" on page 6337 for information about replicate weights.

Each REPWEIGHTS variable should contain the weights for a single replicate, and the number of replicates equals the number of REPWEIGHTS variables. The REPWEIGHTS variables must be numeric, and the variable values must be nonnegative numbers.

If you provide replicate weights with a REPWEIGHTS statement, you do not need to specify a CLUSTER or STRATA statement. If you use a REPWEIGHTS statement and do not specify the VARMETHOD= option in the PROC SURVEYFREQ statement, the procedure uses VARMETHOD=JACKKNIFE by default.

If you specify a REPWEIGHTS statement but do not include a WEIGHT statement, PROC SURVEYFREQ uses the average of each observation's replicate weights as the observation's weight.

You can specify the following options in the REPWEIGHTS statement after a slash (/):

DF=*df*

specifies the degrees of freedom for the analysis. The value of *df* must be a positive number. By default, the degrees of freedom equals the number of REPWEIGHTS variables. See the section "Degrees of Freedom" on page 6340 for details.

PROC SURVEYFREQ uses the DF= value in computing confidence limits for proportions, totals, and other statistics. See the section "Confidence Limits" on page 6339 for details. PROC SURVEYFREQ also uses the DF= value in computing the denominator degrees of freedom for the *F* statistics in the Rao-Scott and Wald chi-square tests. See the sections "Rao-Scott Chi-Square Test" on page 6346, "Rao-Scott Likelihood Ratio Chi-Square Test" on page 6350, "Wald Chi-Square Test" on page 6352, and "Wald Log-Linear Chi-Square Test" on page 6354 for more information.

JKCOEFS=*value*

specifies the jackknife coefficient for VARMETHOD=JACKKNIFE. The coefficient *value* must be a nonnegative number less than one. See the section "The Jackknife" on page 6337 for details about jackknife coefficients.

You can use this option to specify a single value of the jackknife coefficient, which the procedure uses for all replicates. To specify different coefficients for different replicates, use the JKCOEFS=(*values*) or JKCOEFS=*SAS-data-set* option.

JKCOEFS=(*values***)**

specifies jackknife coefficients for VARMETHOD=JACKKNIFE, where each coefficient corresponds to an individual replicate identified by a REPWEIGHTS variable. You can separate *values* with blanks or commas. The coefficient *values* must be nonnegative numbers less than one. The number of *values* must equal the number of replicate weight variables named in the REPWEIGHTS statement. List these values in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement.

See the section "The Jackknife" on page 6337 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the JKCOEFS=*SAS-data-set* option. To specify a single jackknife coefficient for all replicates, use the JKCOEFS=*value* option.

JKCOEFS=*SAS-data-set*

names a SAS data set that contains the jackknife coefficients for VARMETHOD=JACKKNIFE. You provide the jackknife coefficients in the JKCOEFS= data set variable JKCoefficient. Each coefficient value must be a nonnegative number less than one. The observations in the JKCOEFS= data set should correspond to the replicates that are identified by the REPWEIGHTS variables. Arrange the coefficients or observations in the JKCOEFS= data set in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement. The number of observations in the JKCOEFS= data set must not be less than the number of REPWEIGHTS variables.

See the section "The Jackknife" on page 6337 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the JKCOEFS=*values* option. To specify a single jackknife coefficient for all replicates, use the JKCOEFS=*value* option.

STRATA Statement

STRATA *variables* < / *option* > **;**

The STRATA statement names variables that form the strata in a stratified sample design. The combinations of levels of STRATA variables define the strata in the sample, where strata are nonoverlapping subgroups that were sampled independently.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section "Specifying the Sample Design" on page 6320 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with a REPWEIGHTS statement, you do not need to specify a STRATA statement.

The STRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. The formatted values of the STRATA variables determine the STRATA variable levels. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in Bookreflrdict.

You can specify the following option in the STRATA statement after a slash (/):

LIST

displays a "Stratum Information" table, which lists all strata together with the corresponding values of the STRATA variables. This table provides the number of observations and the number of clusters in each stratum, as well as the sampling fraction if you specify the RATE= or TOTAL= option. See the section "Stratum Information Table" on page 6356 for more information.

TABLES Statement

TABLES *requests* < / *options* > **;**

The TABLES statement requests one-way to *n*-way frequency and crosstabulation tables and statistics for these tables.

If you omit the TABLES statement, PROC SURVEYFREQ generates one-way frequency tables for all DATA= data set variables that are not listed in the other statements.

The following argument is required in the TABLES statement:

requests

specify the frequency and crosstabulation tables to produce. A *request* is composed of one variable name or several variable names separated by asterisks. To request a one-way frequency table, use a single variable. To request a two-way crosstabulation table, use an asterisk between two variables. To request a multiway table (an n-way table, where n>2), separate the desired variables with asterisks. The unique values of these variables form the rows, columns, and layers of the table.

For two-way tables to multiway tables, the values of the last variable form the crosstabulation table columns, while the values of the next-to-last variable form the rows. Each level (or combination of levels) of the other variables forms one layer. PROC SURVEYFREQ produces a separate crosstabulation table for each layer. For example, a specification of A*B*C*D in a TABLES statement produces k tables, where k is the number of different combinations of levels for A and B. Each table lists the levels for D (columns) within each level of C (rows).

You can use multiple TABLES statements in a single PROC SURVEYFREQ step. You can also specify any number of table requests in a single TABLES statement. To specify multiple table requests quickly, use a grouping syntax by placing parentheses around several variables and joining other variables or variable combinations. Table 83.2 shows some examples of grouping syntax.

Table 83.2 Grouping Syntax

Request	Equivalent to
tables A*(B C);	tables A*B A*C;
tables (A B)*(C D);	tables A*C B*C A*D B*D;
tables (A B C)*D;	tables A*D B*D C*D;
tables A – – C;	tables A B C;
tables (A – – C)*D;	tables A*D B*D C*D;

The TABLES statement variables are one or more variables from the DATA= input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. PROC SURVEYFREQ uses the formatted values of the TABLES variable to determine the categorical variable levels. So if you assign a format to a variable with a FORMAT statement, PROC SURVEYFREQ formats the values before dividing observations into the levels of a frequency or crosstabulation table. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

The frequency or crosstabulation table lists the values of both character and numeric variables in ascending order based on internal (unformatted) variable values unless you change the order with the ORDER= option. To list the values in ascending order by formatted value, use ORDER=FORMATTED in the PROC SURVEYFREQ statement.

Without Options

If you request a frequency or crosstabulation table without specifying options, PROC SURVEYFREQ produces the following for each table level or cell:

- frequency, or sample size
- weighted frequency, which estimates the population total
- standard deviation of the weighted frequency
- percentage, which estimates the population proportion
- standard error of the percentage

The table displays weighted frequencies if your analysis includes a WEIGHT statement, or if you specify the WTFREQ option in the TABLES statement. The table also displays the number of observations with missing values. See the sections "One-Way Frequency Tables" on page 6357 and "Crosstabulation Tables" on page 6358 for more information.

Options

Table 83.3 lists the options available in the TABLES statement. Descriptions follow in alphabetical order.

Table 83.3 TABLES Statement Options

Option	Description
Control Statistical Analysis	
ALPHA=	sets the level for confidence limits
CHISQ	requests Rao-Scott chi-square test
CHISQ1	requests Rao-Scott modified chi-square test
DF=	specifies degrees of freedom
LRCHISQ	requests Rao-Scott likelihood ratio test
LRCHISQ1	requests Rao-Scott modified likelihood ratio test
OR	requests odds ratio and relative risks
RISK	requests risks and risk difference
TESTP=	specifies null proportions for one-way chi-square test
WCHISQ	requests Wald chi-square test
WLLCHISQ	requests Wald log-linear chi-square test
Control Additional Table Information	
CL	displays confidence limits for percentages
CLWT	displays confidence limits for weighted frequencies
COL	displays column percentages and standard errors
CV	displays coefficients of variation for percentages
CVWT	displays coefficients of variation for weighted frequencies
DEFF	displays design effects for percentages
EXPECTED	displays expected weighted frequencies (two-way tables)

Table 83.3 *continued*

Option	Description
ROW	displays row percentages and standard errors
VAR	displays variances for percentages
VARWT	displays variances for weighted frequencies
WTFREQ	displays totals and standard errors when there is no WEIGHT statement
Control Displayed Output	
NOCELLPERCENT	suppresses display of overall percentages
NOFREQ	suppresses display of frequency counts
NOPERCENT	suppresses display of all percentages
NOPRINT	suppresses display of tables but displays statistical tests
NOSPARSE	suppresses display of zero rows and columns
NOSTD	suppresses display of standard errors for all estimates
NOTOTAL	suppresses display of row and column totals
NOWT	suppresses display of weighted frequencies

You can specify the following options in a TABLES statement.

ALPHA=α

sets the level for confidence limits. The value of α must be between 0 and 1, and the default is 0.05. A confidence level of α produces $100(1-\alpha)\%$ confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

You request confidence limits for percentages with the CL option, and you request confidence limits for weighted frequencies with the CLWT option. See the section "Confidence Limits" on page 6339 for more information.

The ALPHA= option also applies to confidence limits for the risks and risk difference, which you request with the RISK option, and to confidence limits for the odds ratio and relative risks, which you request with the OR option. See the sections "Risks and Risk Difference" on page 6342 and "Odds Ratio and Relative Risks" on page 6344 for details.

CHISQ

requests the Rao-Scott chi-square test. This test applies a design effect correction to the Pearson chi-square statistic computed from the weighted frequencies. See the section "Rao-Scott Chi-Square Test" on page 6346 for details.

By default for one-way tables, the CHISQ option provides a design-based goodness-of-fit test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the TESTP= option.

The CHISQ option uses proportion estimates to compute the design effect correction. To use null hypothesis proportions instead, specify the CHISQ1 option.

CHISQ1

requests the Rao-Scott modified chi-square test. This test applies a design effect correction to the Pearson chi-square statistic computed from the weighted frequencies, and bases the design

effect correction on null hypothesis proportions. See the section "Rao-Scott Chi-Square Test" on page 6346 for details. To compute the design effect correction from proportion estimates instead of null proportions, specify the CHISQ option.

By default for one-way tables, the CHISQ option provides a design-based goodness-of-fit test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the TESTP= option.

CL

requests confidence limits for the percentages, or proportions, in the crosstabulation table. PROC SURVEYFREQ determines the confidence coefficient from the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits. See the section "Confidence Limits" on page 6339 for more information.

CLWT

requests confidence limits for the weighted frequencies, or totals, in the crosstabulation table. PROC SURVEYFREQ determines the confidence coefficient from the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits. See the section "Confidence Limits" on page 6339 for more information.

COL

displays the column percentage, or estimated proportion of the column total, for each cell in a two-way table. The COL option also provides the standard errors of the column percentages. See the section "Row and Column Proportions" on page 6332 for more information. This option has no effect for one-way tables.

CV

displays the coefficient of variation for each percentage, or proportion estimate, in the crosstabulation table. See the section "Coefficient of Variation" on page 6341 for more information.

CVWT

displays the coefficient of variation for each weighted frequency, or estimated total, in the crosstabulation table. See the section "Coefficient of Variation" on page 6341 for more information.

DEFF

displays the design effect for each overall proportion estimate in the crosstabulation table. See the section "Design Effect" on page 6341 for more information.

DF=*df*

specifies the degrees of freedom for the analysis. The value of *df* must be a nonnegative number. By default, PROC SURVEYFREQ computes the degrees of freedom as described in the section "Degrees of Freedom" on page 6340.

PROC SURVEYFREQ uses the DF= value in computing confidence limits for proportions, totals, and other statistics. See the section "Confidence Limits" on page 6339 for details. PROC SURVEYFREQ also uses the DF= value in computing the denominator degrees of freedom for the *F* statistics in the Rao-Scott and Wald chi-square tests. See the sections

"Rao-Scott Chi-Square Test" on page 6346, "Rao-Scott Likelihood Ratio Chi-Square Test" on page 6350, "Wald Chi-Square Test" on page 6352, and "Wald Log-Linear Chi-Square Test" on page 6354 for more information.

EXPECTED

displays expected weighted frequencies for the table cells in a two-way table. The expected frequencies are computed under the null hypothesis that the row and column variables are independent. See the section "Expected Weighted Frequency" on page 6342 for more information. This option has no effect for one-way tables.

LRCHISQ

requests the Rao-Scott likelihood ratio chi-square test. This test applies a design effect correction to the likelihood ratio chi-square statistic computed from the weighted frequencies. See the section "Rao-Scott Likelihood Ratio Chi-Square Test" on page 6350 for more information.

By default for one-way tables, the LRCHISQ option provides a design-based test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the TESTP= option.

The LRCHISQ option uses proportion estimates to compute the design effect correction. To use null hypothesis proportions instead, specify the LRCHISQ1 option.

LRCHISQ1

requests the Rao-Scott modified likelihood ratio chi-square test. This test applies a design effect correction to the likelihood ratio chi-square statistic computed from the weighted frequencies, and bases the design effect correction on null hypothesis proportions. See the section "Rao-Scott Likelihood Ratio Chi-Square Test" on page 6350 for more information. To compute the design effect correction from proportion estimates instead of null proportions, specify the LRCHISQ option.

By default for one-way tables, the LRCHISQ option provides a design-based test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the TESTP= option.

NOCELLPERCENT

suppresses the display of overall cell percentages in the crosstabulation table, as well as the standard errors of the percentages. The NOCELLPERCENT option does not suppress the display of row or column percentages, which you request with the ROW or COL option.

NOFREQ

suppresses the display of cell frequencies in the crosstabulation table. The NOFREQ option also suppresses the display of row, column, and overall table frequencies.

NOPERCENT

suppresses the display of all percentages in the crosstabulation table. The NOPERCENT option also suppresses the display of standard errors of the percentages. Use the NOCELLPERCENT option to suppress display of overall cell percentages but allow display of row or column percentages.

NOPRINT

suppresses the display of frequency and crosstabulation tables but displays all requested statistical tests. Note that this option disables the Output Delivery System (ODS) for the suppressed tables. For more information, see Chapter 20, "Using the Output Delivery System."

NOSPARSE

suppresses the display of variable levels with zero frequency in two-way tables. By default, the procedure displays all levels of the column variable within each level of the row variable, including any column variable levels with zero frequency for that row. For multiway tables, the procedure displays all levels of the row variable for each layer of the table by default, including any row variable levels with zero frequency for the layer.

NOSTD

suppresses the display of all standard errors in the crosstabulation table.

NOTOTAL

suppresses the display of row totals, column totals, and overall totals in the crosstabulation table.

NOWT

suppresses the display of weighted frequencies in the crosstabulation table. The NOWT option also suppresses the display of standard errors of the weighted frequencies.

OR

requests estimates of the odds ratio, the column 1 relative risk, and the column 2 relative risk for 2×2 tables. The OR option also provides confidence limits for these statistics. See the section "Odds Ratio and Relative Risks" on page 6344 for details.

To compute confidence limits for the odds ratio and relative risks, PROC SURVEYFREQ determines the confidence coefficient from the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits.

RISK

requests risk statistics for 2×2 tables. The RISK option also provides standard errors and confidence limits for these statistics. Risk statistics include the row 1 risk (or proportion), row 2 risk, overall risk, and risk difference. See the section "Risks and Risk Difference" on page 6342 for details.

The RISK option provides both column 1 and column 2 risks. To request only column 1 or column 2 risks, use the RISK1 or RISK2 option.

To compute confidence limits for the risks and risk difference, PROC SURVEYFREQ determines the confidence coefficient from the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits.

RISK1

requests column 1 risk statistics for 2×2 tables, together with their standard errors and confidence limits. Risk statistics include the row 1 risk (or proportion), row 2 risk, overall risk, and risk difference. See the section "Risks and Risk Difference" on page 6342 for details.

To compute confidence limits for the risks and risk difference, PROC SURVEYFREQ determines the confidence coefficient from the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits.

RISK2

requests column 2 risk statistics for 2×2 tables, together with their standard errors and confidence limits. Risk statistics include the row 1 risk (or proportion), row 2 risk, overall risk, and risk difference. See the section "Risks and Risk Difference" on page 6342 for details.

To compute confidence limits for the risks and risk difference, PROC SURVEYFREQ determines the confidence coefficient from the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits.

ROW

displays the row percentage, or estimated proportion of the row total, for each cell in a two-way table. The ROW option also provides the standard errors of the row percentages. See the section "Row and Column Proportions" on page 6332 for more information. This option has no effect for one-way tables.

TESTP=(*values*)

specifies null hypothesis proportions, or test percentages, for one-way chi-square tests. You can separate *values* with blanks or commas. Specify *values* in probability form as numbers between 0 and 1, where the proportions sum to 1. Or specify *values* in percentage form as numbers between 0 and 100, where the percentages sum to 100. PROC SURVEYFREQ treats the value 1 as the percentage form 1%. The number of TESTP= values must equal the number of variable levels in the one-way table. List these values in the same order in which the corresponding variable levels appear in the output.

When you specify the TESTP= option, PROC SURVEYFREQ displays the specified test percentages in the one-way frequency table. The TESTP= option has no effect for two-way tables.

PROC SURVEYFREQ uses the TESTP= values for all one-way chi-square tests you request in the TABLES statement. The available one-way chi-square tests include the Rao-Scott (Pearson) chi-square test and the Rao-Scott likelihood ratio chi-square test and their modified versions, which you request with the CHISQ, CHISQ1, LRCHISQ, and LRCHISQ1 options. See the sections "Rao-Scott Chi-Square Test" on page 6346 and "Rao-Scott Likelihood Ratio Chi-Square Test" on page 6350 for details.

VAR

displays the variance estimate for each percentage in the crosstabulation table. See the section "Proportions" on page 6331 for details. By default, PROC SURVEYFREQ displays the standard errors of the percentages.

VARWT

displays the variance estimate for each weighted frequency, or estimated total, in the crosstabulation table. See the section "Totals" on page 6329 for details. By default, PROC SURVEYFREQ displays the standard deviations of the weighted frequencies.

WCHISQ
requests the Wald chi-square test for two-way tables. See the section "Wald Chi-Square Test" on page 6352 for details.

WLLCHISQ
requests the Wald log-linear chi-square test for two-way tables. See the section "Wald Log-Linear Chi-Square Test" on page 6354 for details.

WTFREQ
displays totals (weighted frequencies) and their standard errors when you do not specify a WEIGHT or REPWEIGHTS statement. PROC SURVEYFREQ displays the weighted frequencies by default when you include a WEIGHT or REPWEIGHTS statement. Without a WEIGHT or REPWEIGHTS statement, PROC SURVEYFREQ assigns all observations a weight of one.

WEIGHT Statement

WEIGHT *variable* **;**

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric, and the sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section "Missing Values" on page 6323 for more information. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

If you do not specify a WEIGHT statement but provide replicate weights with a REPWEIGHTS statement, PROC SURVEYFREQ uses the average of each observation's replicate weights as the observation's weight.

If you do not specify a WEIGHT statement or a REPWEIGHTS statement, PROC SURVEYFREQ assigns all observations a weight of one.

Details: SURVEYFREQ Procedure

Specifying the Sample Design

PROC SURVEYFREQ produces tables and statistics based on the sample design used to obtain the survey data. PROC SURVEYFREQ can be used for single-stage or multistage designs, with or without stratification, and with or without unequal weighting. To analyze your survey data with PROC SURVEYFREQ, you need to provide sample design information for the procedure. This information can include design strata, clusters, and sampling weights. You provide sample de-

sign information with the STRATA, CLUSTER, and WEIGHT statements, and with the RATE= or TOTAL= option in the PROC SURVEYFREQ statement.

If you provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a STRATA or CLUSTER statement. Otherwise, you should specify STRATA and CLUSTER statements whenever your design includes stratification and clustering.

When there are clusters, or PSUs, in the sample design, the procedure estimates variance by using the PSUs, as described in the section "Statistical Computations" on page 6326. For a multistage sample design, the variance estimation depends only on the first stage of the sample design. So, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling.

Stratification

If your sample design is stratified at the first stage of sampling, use the STRATA statement to name the variables that form the strata. The combinations of categories of STRATA variables define the strata in the sample, where strata are nonoverlapping subgroups that were sampled independently. If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement.

If you use a REPWEIGHTS statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a STRATA statement. Otherwise, you should specify a STRATA statement whenever your design includes stratification. If you do not specify a STRATA statement or a REPWEIGHTS statement, then PROC SURVEYFREQ assumes there is no stratification at the first stage.

Clustering

If your sample design selects clusters at the first stage of sampling, use the CLUSTER statement to name the variables that identify the first-stage clusters, or primary sampling units (PSUs). The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata. If your sample design has clustering at multiple stages, you should specify only the first-stage clusters, or PSUs, in the CLUSTER statement. PROC SURVEYFREQ assumes that each cluster defined by the CLUSTER statement variables represents a PSU in the sample, and that each observation belongs to one PSU.

If you use a REPWEIGHTS statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a CLUSTER statement. Otherwise, you should specify a CLUSTER statement whenever your design includes clustering at the first stage of sampling. If you do not specify a CLUSTER statement, then PROC SURVEYFREQ treats each observation as a PSU.

Weighting

If your sample design includes unequal weighting, use the WEIGHT statement to name the variable that contains the sampling weights. Sampling weights must be positive numbers. If an observation

has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section "Missing Values" on page 6323 for more information.

If you do not specify a WEIGHT statement but include a REPWEIGHTS statement, PROC SURVEYFREQ uses the average of each observation's replicate weights as the observation's weight. If you do not specify a WEIGHT statement or a REPWEIGHTS statement, PROC SURVEYFREQ assigns all observations a weight of one.

Population Totals and Sampling Rates

To include a finite population correction (*fpc*) in Taylor series variance estimation, you can input either the sampling rate or the population total by using the RATE= or TOTAL= option in the PROC SURVEYFREQ statement. (You cannot specify both of these options in the same PROC SURVEYFREQ statement.) The RATE= and TOTAL= options apply only to Taylor series variance estimation. The procedure does not use a finite population correction for BRR or jackknife variance estimation.

If you do not specify the RATE= or TOTAL= option, the Taylor series variance estimation does not include a finite population correction. For fairly small sampling fractions, it is appropriate to ignore this correction. See Cochran (1977) and Kish (1965) for more information.

If your design has multiple stages of selection and you are specifying the RATE= option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the TOTAL= option for a multistage design, you should input the total number of PSUs in the study population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you can use the RATE=*value* or TOTAL=*value* option. If your sample design is stratified with different sampling rates or population totals in different strata, use the RATE=*SAS-data-set* or TOTAL=*SAS-data-set* option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the DATA= option.

The secondary data set must contain all the stratification variables listed in the STRATA statement and all the variables in the BY statement. Furthermore, the BY groups must appear in the same order as in the primary data set. If there are formats associated with the STRATA variables and the BY variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the TOTAL=*SAS-data-set* option, the secondary data set must have a variable named _TOTAL_ that contains the stratum population totals. If you specify the RATE=*SAS-data-set* option, the secondary data set must have a variable named _RATE_ that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, the procedure uses the first value of _TOTAL_ or _RATE_ for that stratum and ignores the rest.

The *value* in the RATE= option or the values of _RATE_ in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYFREQ converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the TOTAL=*value* option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

Domain Analysis

PROC SURVEYFREQ provides domain analysis through its multiway table capability. *Domain analysis* refers to the computation of statistics for subpopulations, or domains, in addition to the computation of statistics for the entire study population. Formation of subpopulations can be unrelated to the sample design, and so the domain sample sizes can actually be random variables. Domain analysis takes this variability into account by using the entire sample in estimating the variance of domain estimates. Domain analysis is also known as subgroup analysis, subpopulation analysis, or subdomain analysis. For more information about domain analysis, see Lohr (1999), Cochran (1977), and Fuller et al. (1989).

To request domain analysis with PROC SURVEYFREQ, you should include the domain variable(s) in your TABLES statement request. For example, specifying DOMAIN * A * B in a TABLES statement produces separate two-way tables of A by B for each level of DOMAIN. If your domains are formed by more than one variable, you can specify DomainVariable_1 * DomainVariable_2 * A * B, for example, to obtain two-way tables of A by B for each domain formed by the different combinations of levels for DomainVariable_1 and DomainVariable_2. See Example 83.2 for an example of domain analysis.

If you specify DOMAIN * A in a TABLES statement, the values of the variable DOMAIN form the table rows. The two-way table lists levels of the variable A within each level of the row variable DOMAIN. Specify the ROW option in the TABLES statement to obtain the row percentages and their standard errors. This provides the one-way distribution of A for each domain, or level of the variable DOMAIN.

Including the domain variables in a TABLES statement request gives a different analysis from that obtained by using a BY statement, which provides completely separate analyses of the BY groups. The BY statement can also be used to analyze the data set by subgroups, but it is critical to note that this will *not* produce a valid domain analysis. The BY statement is appropriate only when the number of units in each subgroup is known with certainty; when the subgroup sample size is a random variable, include the domain variables in your TABLES statement request.

Missing Values

WEIGHT Variable

If an observation has a missing value or a nonpositive value for the WEIGHT variable, then PROC SURVEYFREQ excludes that observation from the analysis.

REPWEIGHTS Variables

If you provide replicate weights with a REPWEIGHTS statement for BRR or jackknife variance estimation, all REPWEIGHTS variable values must be nonmissing. Similarly, if you provide jackknife coefficients with the JKCOEFS= option in the REPWEIGHTS statement, all values of the

JKCoefficient variable must be nonmissing. The procedure does not perform the analysis when any replicate weight or jackknife coefficient value is missing.

STRATA and CLUSTER Variables

An observation is excluded from the analysis if it has a missing value for any STRATA or CLUSTER variable, unless you specify the MISSING option in the PROC SURVEYFREQ statement. If you specify the MISSING option, the procedure treats missing values as a valid (nonmissing) category for all categorical variables, which include STRATA variables, CLUSTER variables, and TABLES variables.

TABLES Variables

By default, PROC SURVEYFREQ excludes an observation from a crosstabulation table (and all associated analyses) if the observation has a missing value for any of the variables in the TABLES request, unless you specify the MISSING or NOMCAR option in the PROC SURVEYFREQ statement. When the procedure excludes observations with missing values from a table, it displays the total frequency of missing observations below the table.

If you specify the MISSING option, the procedure treats missing values as a valid (nonmissing) level for each TABLES variable. These levels are displayed in the crosstabulation table and included in computations of totals, percentages, and all other table statistics.

If you specify the NOMCAR option, which is available for Taylor series variance estimation, the procedure includes observations with missing values of TABLES variables in the variance computations. The NOMCAR option does not display missing levels in the crosstabulation table or compute percentages and totals for missing levels.

The NOMCAR Option

The NOMCAR option includes observations with missing values of TABLES variables in the variance computations as *not missing completely at random* (NOMCAR) for Taylor series variance estimation. By default, observations are completely excluded from the analysis if they have missing values for any of the variables in the current TABLES request. This default treatment is based on the assumption that the values are *missing completely at random* (MCAR), and assumes that the analysis results should not be substantially different between the missing and nonmissing groups. See the section "Analysis Considerations" on page 6326 for more information.

When you specify the NOMCAR option, PROC SURVEYFREQ computes variance estimates by analyzing the nonmissing values as a domain or subpopulation, where the entire population includes both nonmissing and missing domains.

Note that the NOMCAR option has no effect when you specify the MISSING option, which treats missing values as a valid nonmissing level. The NOMCAR option does not affect the inclusion of observations with missing values of the WEIGHT, CLUSTER, or STRATA variables. Observations

with missing values of the WEIGHT variable are always excluded from the analysis. Observations with missing values of the CLUSTER or STRATA variables are excluded unless you specify the MISSING option.

The NOMCAR option applies only to Taylor series variance estimation. The replication methods, which you request with the VARMETHOD=BRR and VARMETHOD=JACKKNIFE options, do not use the NOMCAR option.

Degrees of Freedom

PROC SURVEYFREQ computes degrees of freedom to obtain the *t*-percentile for confidence limits for proportions, totals, and other statistics. The procedure also uses degrees of freedom for the *F* statistics in the Rao-Scott and Wald chi-square tests. The degrees of freedom computation depends on the variance estimation method that you request. See the section "Degrees of Freedom" on page 6340 for details. Missing values can affect the degrees of freedom computation.

Taylor Series Variance Estimation

The degrees of freedom can depend on the number of clusters, the number of strata, and the number of observations. For Taylor series variance estimation, these numbers are based on the observations included in the analysis of the individual table. These numbers do not count observations excluded from the table due to missing values. If all values in a stratum are excluded from the analysis of a table as missing values, then that stratum is called an *empty stratum*. Empty strata are not counted in the total number of strata for the table. Similarly, empty clusters and missing observations are not included in the totals counts of cluster and observations use to compute the degrees of freedom for the analysis.

If you specify the MISSING option, missing values are treated as valid nonmissing levels and are included in computing degrees of freedom. If you specify the NOMCAR option for Taylor series variance estimation, observations with missing values of the TABLES variables are included in computing degrees of freedom.

Replicate-Based Variance Estimation

For BRR or jackknife variance estimation, by default PROC SURVEYFREQ computes the degrees of freedom by using all valid observations in the input data set. A valid observation is an observation that has a positive value of the WEIGHT variable and nonmissing values of the STRATA and CLUSTER variables unless you specify the MISSING option. See the section "Data Summary Table" on page 6356 for details about valid observations.

If you specify the DFADJ method-option for VARMETHOD=BRR or VARMETHOD=JACKKNIFE, the procedure computes the degrees of freedom based on the nonmissing observations included in the individual table analysis. This excludes any empty strata or clusters that occur when observations with missing values of the TABLES variables are removed from the analysis for that table.

Table Summary Output Data Set

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS table, "Table Summary," which contains the number of (nonmissing) observations, strata, and clusters that are included in the analysis of the individual table. If there are missing observations, empty strata, or empty clusters excluded from the analysis, the "Table Summary" data set also contains this information. If you request any confidence limits or chi-square tests for the table, which require degrees of freedom, the "Table Summary" data set provides the degrees of freedom.

Due to missing values, the number of observations used for an individual table analysis can differ from the number of valid observations in the input data set, which is reported in the "Data Summary" table. Similarly, a difference can also occur for the number of clusters or strata. See Example 83.3 for more information about the "Table Summary" output data set.

If you specify the NOMCAR option for Taylor series variance estimation, the "Table Summary" data set reflects all observations used for variance estimation, which includes those observations with missing values of the TABLES variables.

Analysis Considerations

If you have missing values in your survey data for any reason (such as nonresponse), this can compromise the quality of your survey results. An observation without missing values is called a *complete respondent*, and an observation with missing values is called an *incomplete respondent*. If the complete respondents are different from the incomplete respondents with regard to a survey effect or outcome, then survey estimates will be biased and will not accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. After data collection is complete, you can use imputation to replace missing values with acceptable values, and you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYFREQ. See Cochran (1977), Kalton and Kaspyzyk (1986), and Brick and Kalton (1996) for more details.

Statistical Computations

Variance Estimation

PROC SURVEYFREQ provides a choice of variance estimation methods for complex survey data. In addition to the Taylor series linearization method, the procedures offer two replication-based or resampling methods—balanced repeated replication (BRR) and the delete-1 jackknife. These variance estimation methods usually give similar, satisfactory results (Lohr 1999; Särndal, Swensson, and Wretman 1992; Wolter 1985). The choice of a variance estimation method can depend on the sample design used, the sample design information available, the parameters to be estimated, and computational issues. See Lohr (1999) for more details.

Taylor Series Variance Estimation

The Taylor series linearization method can be used to estimate standard errors of proportions and other statistics for crosstabulation tables. For sample survey data, the proportion estimator is a ratio estimator formed from estimators of totals. For example, to estimate the proportion in a crosstabulation table cell, the procedure uses the ratio of the estimator of the cell total frequency to the estimator of the overall population total, where these totals are linear statistics computed from the survey data. The Taylor series expansion method obtains a first-order linear approximation for the ratio estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Woodruff 1971; Fuller 1975). For more information about Taylor series variance estimation for sample survey data, see Lohr (1999), Särndal, Swensson, and Wretman (1992), Lee, Forthoffer, and Lorimor (1989), and Wolter (1985).

When there are clusters, or PSUs, in the sample design, the Taylor series method estimates variance from the variance among PSUs. When the design is stratified, the procedure combines stratum variance estimates to compute the overall variance estimate. For a multistage sample design, the variance estimation depends only on the first stage of the sample design. So the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling. This variance estimation method assumes that the first-stage sampling fraction is small, or the first-stage sample is drawn with replacement, as it often is in practice.

See the sections "Proportions" on page 6331, "Row and Column Proportions" on page 6332, "Risks and Risk Difference" on page 6342, and "Odds Ratio and Relative Risks" on page 6344 for details and formulas for Taylor series variance estimates.

Replication-Based Variance Estimation

Replication-based methods for variance estimation draw multiple replicates (or subsamples) from the full sample by following a specific resampling scheme. Commonly used resampling schemes include *balanced repeated replication* (BRR) and the *jackknife*. PROC SURVEYFREQ estimates the parameter of interest (a proportion, total, odds ratio, or other statistic) from each replicate, and then uses the variability among replicate estimates to estimate the overall variance of the parameter estimate. See Wolter (1985) and Lohr (1999) for more information.

The BRR variance estimation method requires a stratified sample design with two PSUs in each stratum. Each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix and adjusting the original weights of the remaining PSUs. The adjusted weights are called *replicate weights*. PROC SURVEYFREQ also provides Fay's method, which is a modification of the BRR method. See the section "Balanced Repeated Replication (BRR)" on page 6334 for details.

The jackknife method deletes one PSU at a time from the full sample to create replicates, and modifies the original weights to obtain replicate weights. The total number of replicates equals the number of PSUs. If the sample design is stratified, each stratum must contain at least two PSUs, and the jackknife is applied separately within each stratum. See the section "The Jackknife" on page 6337 for details.

Instead of having PROC SURVEYFREQ generate replicate weights for the analysis, you can input your own replicate weights with a REPWEIGHTS statement. This can be useful if you need to do multiple analyses with the same set of replicate weights, or if you have access to replicate weights instead of design information. See the section "Replicate Weights Output Data Set" on page 6355 for more information.

Definitions and Notation

For a stratified clustered sample design, define the following:

h	$=$	$1, 2, \ldots, H$	is the stratum number, with a total of H strata
i	$=$	$1, 2, \ldots, n_h$	is the cluster number within stratum h, with a total of n_h sample clusters in stratum h
j	$=$	$1, 2, \ldots, m_{hi}$	is the unit number within cluster i of stratum h, with a total of m_{hi} sample units from cluster i of stratum h
n	$=$	$\sum_{h=1}^{H} \sum_{i=1}^{n_h} m_{hi}$	is the total number of observations in the sample

f_h	$=$	first-stage sampling rate for stratum h
W_{hij}	$=$	sampling weight of unit j in cluster i of stratum h

The sampling rate f_h, which is used in Taylor series variance estimation, is the fraction of first-stage units (PSUs) selected for the sample. You can specify the stratum sampling rates with the RATE= option. Or if you specify population totals with the TOTAL= option, PROC SURVEYFREQ computes f_h as the ratio of stratum sample size to the stratum total, in terms of PSUs. See the section "Population Totals and Sampling Rates" on page 6322 for details. If you do not specify the RATE= option or the TOTAL= option, then the procedure assumes that the stratum sampling rates f_h are negligible and does not use a finite population correction when computing variances.

This notation is also applicable to other sample designs. For example, for a design without stratification, you can let $H = 1$; for a sample design without clustering, you can let $m_{hi} = 1$ for every h and i, which replaces clusters with individual sampling units.

For a two-way table representing the crosstabulation of two variables, define the following, where there are R levels of the row variable and C levels of the column variable:

r	$=$	$1, 2, \ldots, R$	is the row number, with a total of R rows
c	$=$	$1, 2, \ldots, C$	is the column number, with a total of C columns
N_{rc}			is the population total in row r and column c
$N_{r\cdot}$	$=$	$\sum_{c=1}^{C} N_{rc}$	is the total in row r
$N_{\cdot c}$	$=$	$\sum_{r=1}^{R} N_{rc}$	is the total in column c
N	$=$	$\sum_{r=1}^{R} \sum_{c=1}^{C} N_{rc}$	is the overall total

$$
\begin{aligned}
P_{rc} &= N_{rc} \,/\, N && \text{is the population proportion in row } r \text{ and column } c \\
P_{r\cdot} &= N_{r\cdot} \,/\, N && \text{is the proportion in row } r \\
P_{\cdot c} &= N_{\cdot c} \,/\, N && \text{is the proportion in column } c \\
P^{r}_{rc} &= N_{rc} \,/\, N_{r\cdot} && \text{is the row proportion for table cell } (r,c) \\
P^{c}_{rc} &= N_{rc} \,/\, N_{\cdot c} && \text{is the column proportion for table cell } (r,c)
\end{aligned}
$$

For a specified observation (identified by stratum, cluster, and unit number within the cluster), define the following to indicate whether or not that observation belongs to cell (r, c), row r and column c, of the two-way table, for $r = 1, 2, \ldots, R$ and $c = 1, 2, \ldots, C$:

$$
\delta_{hij}(r,c) = \begin{cases} 1 & \text{if observation } (hij) \text{ is in cell } (r,c) \\ 0 & \text{otherwise} \end{cases}
$$

Similarly, define the following functions to indicate the observation's row and column classification:

$$
\delta_{hij}(r\,\cdot) = \begin{cases} 1 & \text{if observation } (hij) \text{ is in row } r \\ 0 & \text{otherwise} \end{cases}
$$

$$
\delta_{hij}(\cdot\, c) = \begin{cases} 1 & \text{if observation } (hij) \text{ is in column } c \\ 0 & \text{otherwise} \end{cases}
$$

Totals

PROC SURVEYFREQ estimates population frequency totals for the specified crosstabulation tables, including totals for two-way table cells, rows, columns, and overall totals. The procedure computes the estimate of the total frequency in table cell (r, c) as the weighted frequency sum,

$$
\widehat{N}_{rc} = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r,c)\; W_{hij}
$$

Similarly, PROC SURVEYFREQ computes estimates of row totals, column totals, and overall totals as

$$
\widehat{N}_{r\cdot} = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r\,\cdot)\; W_{hij}
$$

$$
\widehat{N}_{\cdot c} = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(\cdot\, c)\; W_{hij}
$$

$$
\widehat{N} = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} W_{hij}
$$

PROC SURVEYFREQ estimates the variances of totals by using the variance estimation method that you request. If you request BRR variance estimation (by specifying the VARMETHOD=BRR

option in the PROC SURVEYFREQ statement), the procedure estimates the variances as described in the section "Balanced Repeated Replication (BRR)" on page 6334. If you request jackknife variance estimation (by specifying the VARMETHOD=JACKKNIFE option), the procedure estimates the variances as described in the section "The Jackknife" on page 6337.

If you do not specify the VARMETHOD= option or a REPWEIGHTS statement, the default variance estimation method is Taylor series, which you can also request with the VARMETHOD=TAYLOR option. Since totals are linear statistics, their variances can be estimated directly, without the approximation that is used for proportions and other nonlinear statistics. PROC SURVEYFREQ estimates the variance of the total frequency in table cell (r, c) as

$$\widehat{\mathrm{Var}}(\widehat{N}_{rc}) = \sum_{h=1}^{H} \widehat{\mathrm{Var}}_h(\widehat{N}_{rc})$$

where if $n_h > 1$,

$$\begin{aligned}
\widehat{\mathrm{Var}}_h(\widehat{N}_{rc}) &= \frac{n_h(1-f_h)}{n_h - 1} \sum_{i=1}^{n_h} (n_{rc}^{hi} - \bar{n}_{rc}^{h})^2 \\
n_{rc}^{hi} &= \sum_{j=1}^{m_{hi}} \delta_{hij}(r,c)\, W_{hij} \\
\bar{n}_{rc}^{h} &= \sum_{i=1}^{n_h} n_{rc}^{hi} \,/\, n_h
\end{aligned}$$

and if $n_h = 1$,

$$\widehat{\mathrm{Var}}_h(\widehat{N}_{rc}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \le h' \le H \end{cases}$$

The standard deviation of the total is computed as

$$\mathrm{Std}(\widehat{N}_{rc}) = \sqrt{\widehat{\mathrm{Var}}(\widehat{N}_{rc})}$$

The variances and standard deviations are computed in a similar manner for row totals, column totals, and overall table totals.

Covariance of Totals

The covariance matrix of the table cell totals $\widehat{N}_{rc}$ is an $rc \times rc$ matrix $\widehat{\mathbf{V}}(\widehat{\mathbf{N}})$, which contains the pairwise table cell covariances $\widehat{\mathrm{Cov}}(\widehat{N}_{rc}, \widehat{N}_{ab})$, for $r = 1, \cdots, R$; $c = 1, \cdots, C$; $a = 1, \cdots, R$; and $b = 1, \cdots, C$.

PROC SURVEYFREQ estimates the covariances by using the variance estimation method that you request. If you request BRR variance estimation (by specifying the VARMETHOD=BRR option in the PROC SURVEYFREQ statement), the procedure estimates the covariances by the method described in the section "Balanced Repeated Replication (BRR)" on page 6334. If you request

jackknife variance estimation (by specifying the VARMETHOD=JACKKNIFE option), the procedure uses the method described in the section "The Jackknife" on page 6337.

Otherwise (by default, or if you request the Taylor series method), PROC SURVEYFREQ estimates the covariance between total frequency estimates for table cells (r, c) and (a, b) as

$$\widehat{\mathrm{Cov}}(\widehat{N}_{rc},\ \widehat{N}_{ab}) = \sum_{h=1}^{H} \left(\frac{n_h(1-f_h)}{n_h - 1} \sum_{i=1}^{n_h} (n_{rc}^{hi} - \bar{n}_{rc}^{h})\ (n_{ab}^{hi} - \bar{n}_{ab}^{h}) \right)$$

Proportions

PROC SURVEYFREQ computes the estimate of the proportion in table cell (r, c) as the ratio of the estimated total for the table cell to the estimated overall total,

$$\begin{aligned} \widehat{P}_{rc} &= \widehat{N}_{rc} \ / \ \widehat{N} \\ &= \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r,c)\ W_{hij} \ / \ \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} W_{hij} \end{aligned}$$

If you request BRR variance estimation (by specifying the VARMETHOD=BRR option in the PROC SURVEYFREQ statement), the procedure estimates the variances of proportion estimates as described in the section "Balanced Repeated Replication (BRR)" on page 6334. If you request jackknife variance estimation (by specifying the VARMETHOD=JACKKNIFE option), the procedure estimates the variances as described in the section "The Jackknife" on page 6337.

If you do not specify the VARMETHOD= option or a REPWEIGHTS statement, the default variance estimation method is Taylor series, which you can also request with the VARMETHOD=TAYLOR option. By using Taylor series linearization, the variance of a proportion estimate can be expressed as

$$\widehat{\mathrm{Var}}(\widehat{P}_{rc}) = \sum_{h=1}^{H} \widehat{\mathrm{Var}}_h(\widehat{P}_{rc})$$

where if $n_h > 1$,

$$\begin{aligned} \widehat{\mathrm{Var}}_h(\widehat{P}_{rc}) &= \frac{n_h(1-f_h)}{n_h - 1} \sum_{i=1}^{n_h} (e_{rc}^{hi} - \bar{e}_{rc}^{h})^2 \\ e_{rc}^{hi} &= \left(\sum_{j=1}^{m_{hi}} (\delta_{hij}(r,c) - \widehat{P}_{rc})\ W_{hij} \right) \ / \ \widehat{N} \\ \bar{e}_{rc}^{h} &= \sum_{i=1}^{n_h} e_{rc}^{hi} \ / \ n_h \end{aligned}$$

and if $n_h = 1$,

$$\widehat{\mathrm{Var}}_h(\widehat{P}_{rc}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \le h' \le H \end{cases}$$

The standard error of the proportion is computed as

$$\text{StdErr}(\widehat{P}_{rc}) = \sqrt{\widehat{\text{Var}}(\widehat{P}_{rc})}$$

Similarly, the estimate of the proportion in row r is

$$\widehat{P}_{r\cdot} = \widehat{N}_{r\cdot} \,/\, \widehat{N}$$

And its variance estimate is

$$\widehat{\text{Var}}(\widehat{P}_{r\cdot}) = \sum_{h=1}^{H} \widehat{\text{Var}}_h(\widehat{P}_{r\cdot})$$

where if $n_h > 1$,

$$\begin{aligned}
\widehat{\text{Var}}_h(\widehat{P}_{r\cdot}) &= \frac{n_h(1-f_h)}{n_h - 1} \sum_{i=1}^{n_h} (e_{r\cdot}^{hi} - \bar{e}_{r\cdot}^{h})^2 \\
e_{r\cdot}^{hi} &= \left(\sum_{j=1}^{m_{hi}} (\delta_{hij}(r\,\cdot) - \widehat{P}_{r\cdot})\, W_{hij} \right) \,/\, \widehat{N} \\
\bar{e}_{r\cdot}^{h} &= \sum_{i=1}^{n_h} e_{r\cdot}^{hi} \,/\, n_h
\end{aligned}$$

and if $n_h = 1$,

$$\widehat{\text{Var}}_h(\widehat{P}_{r\cdot}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \le h' \le H \end{cases}$$

The standard error of the proportion in row r is computed as

$$\text{StdErr}(\widehat{P}_{r\cdot}) = \sqrt{\widehat{\text{Var}}(\widehat{P}_{r\cdot})}$$

Computations for the proportion in column c are done in the same way.

Row and Column Proportions

PROC SURVEYFREQ computes the estimate of the row proportion for table cell (r, c) as the ratio of the estimated total for the table cell to the estimated total for row r,

$$\begin{aligned}
\widehat{P}_{rc}^{\,r} &= \widehat{N}_{rc} \,/\, \widehat{N}_{r\cdot} \\
&= \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r,c)\, W_{hij} \;/\; \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r\,\cdot)\, W_{hij}
\end{aligned}$$

Similarly, PROC SURVEYFREQ estimates the column proportion for table cell (r, c) as the ratio of the estimated total for the table cell to the estimated total for column c,

$$\begin{aligned}\widehat{P}_{rc}^{\,c} &= \widehat{N}_{rc} \,/\, \widehat{N}_{\cdot c} \\ &= \sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} \delta_{hij}(r,c)\, W_{hij} \;/\; \sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} \delta_{hij}(\cdot\, c)\, W_{hij}\end{aligned}$$

If you request BRR variance estimation (VARMETHOD=BRR), PROC SURVEYFREQ estimates the variances of the row and column proportions as described in the section "Balanced Repeated Replication (BRR)" on page 6334. If you request jackknife variance estimation (VARMETHOD=JACKKNIFE), the procedure estimates the variances as described in the section "The Jackknife" on page 6337.

If you do not specify the VARMETHOD= option or a REPWEIGHTS statement, the default variance estimation method is Taylor series (VARMETHOD=TAYLOR). By using Taylor series linearization, the variance of the row proportion estimate can be expressed as

$$\widehat{\mathrm{Var}}(\widehat{P}_{rc}^{\,r}) = \sum_{h=1}^{H} \widehat{\mathrm{Var}}_h(\widehat{P}_{rc})$$

where if $n_h > 1$,

$$\begin{aligned}\widehat{\mathrm{Var}}_h(\widehat{P}_{rc}^{\,r}) &= \frac{n_h(1-f_h)}{n_h-1}\sum_{i=1}^{n_h}(g_{rc}^{hi} - \bar{g}_{rc}^{\,h})^2 \\ g_{rc}^{hi} &= \left(\sum_{j=1}^{m_{hi}}(\delta_{hij}(r,c) - \widehat{P}_{rc}^{\,r}\,\delta_{hij}(r\,\cdot))\, W_{hij}\right) \,/\, \widehat{N}_{r\cdot} \\ \bar{g}_{rc}^{\,h} &= \sum_{i=1}^{n_h} g_{rc}^{hi} \,/\, n_h\end{aligned}$$

and if $n_h = 1$,

$$\widehat{\mathrm{Var}}_h(\widehat{P}_{rc}^{\,r}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \le h' \le H \end{cases}$$

The standard error of the row proportion is computed as

$$\mathrm{StdErr}(\widehat{P}_{rc}^{\,r}) = \sqrt{\widehat{\mathrm{Var}}(\widehat{P}_{rc}^{\,r})}$$

The Taylor series variance estimate for the column proportion is computed as described previously for the row proportion, but with

$$g_{rc}^{hi} = \left(\sum_{j=1}^{m_{hi}}(\delta_{hij}(r,c) - \widehat{P}_{rc}^{\,c}\,\delta_{hij}(\cdot\, c))\, W_{hij}\right) \,/\, \widehat{N}_{\cdot c}$$

Balanced Repeated Replication (BRR)

If you specify the VARMETHOD=BRR option, then PROC SURVEYFREQ uses balanced repeated replication (BRR) for variance estimation. The BRR variance estimation method requires a stratified sample design with two PSUs in each stratum. You can provide replicate weights for BRR variance estimation by using a REPWEIGHTS statement, or the procedure can construct replicate weights for the analysis. PROC SURVEYFREQ estimates the parameter of interest (a proportion, total, odds ratio, or other statistic) from each replicate, and then uses the variability among replicate estimates to estimate the overall variance of the parameter estimate. See Wolter (1985) and Lohr (1999) for more information about BRR variance estimation.

If you do not provide replicate weights with a REPWEIGHTS statement, PROC SURVEYFREQ constructs replicates based on the stratified design with two PSUs in each stratum. This section describes replicate construction by the traditional BRR method. If you specify the FAY method-option for VARMETHOD=BRR, the procedure uses Fay's modified BRR method, which is described in the section "Fay's BRR Method" on page 6335.

With the traditional BRR method, each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix of dimension R, where R is the number of replicates. The number of replicates equals the smallest multiple of 4 that is greater than the number of strata H. Alternatively, you can specify the number of replicates with the REPS= method-option. If a Hadamard matrix cannot be constructed for the REPS= value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the REPS= value that you specify.

You can provide a Hadamard matrix for BRR replicate construction by using the HADAMARD= method-option. Otherwise, PROC SURVEYFREQ generates an appropriate Hadamard matrix. See the section "Hadamard Matrix" on page 6336 for more information. You can display the Hadamard matrix by specifying the PRINTH method-option.

PROC SURVEYFREQ constructs replicates by using the first H columns of the $R \times R$ Hadamard matrix, where H denotes the number of strata. The rth replicate ($r = 1, 2, \ldots, R$) is drawn from the full sample according to the rth row of the Hadamard matrix as follows:

- If the (r, h)th element of the Hadamard matrix equals 1, then the first PSU of stratum h is included in the rth replicate, and the second PSU of stratum h is excluded.
- If the (r, h)th element of the Hadamard matrix equals -1, then the second PSU of stratum h is included in the rth replicate, and the first PSU of stratum h is excluded.

For the PSUs included in replicate r, the original weights are doubled to form the replicate r weights. For the PSUs not included in replicate r, the replicate r weights equal zero. You can use the OUTWEIGHTS= method-option to store the replicate weights in a SAS data set. See the section "Replicate Weights Output Data Set" on page 6355 for details about the contents of the OUTWEIGHTS= data set. You can provide these replicate weights to the procedure for subsequent analyses by using a REPWEIGHTS statement.

Let θ denote the population parameter to be estimated—for example, a proportion, total, odds ratio, or other statistic. Let $\hat{\theta}$ denote the estimate of θ from the full sample, and let $\hat{\theta}_r$ denote the estimate

from the rth BRR replicate, which is computed by using the replicate weights. The BRR variance estimate for $\hat{\theta}$ is computed as

$$\widehat{V}(\hat{\theta}) = \frac{1}{R}\sum_{r=1}^{R}\left(\hat{\theta}_r - \hat{\theta}\right)^2$$

where R is the total number of replicates.

If a parameter cannot be estimated from some replicate(s), then the variance estimate is computed by using those replicates from which the parameter can be estimated. For example, suppose the parameter is a column proportion—the proportion of column j for table cell (i, j). If a replicate r contains no observations in column j, then the column j proportion is not estimable from replicate r. In this case, the BRR variance estimate is computed as

$$\widehat{V}(\hat{\theta}) = \frac{1}{R'}\sum_{r=1}^{R'}\left(\hat{\theta}_r - \hat{\theta}\right)^2$$

where the summation is over the replicates where the parameter θ is estimable, and R' is the number of those replicates.

Fay's BRR Method

If you specify the FAY method-option for VARMETHOD=BRR, then PROC SURVEYFREQ uses Fay's BRR method, which is a modification of the traditional BRR variance estimation method. As for traditional BRR, Fay's method requires a stratified sample design with two PSUs in each stratum. You can provide replicate weights by using a REPWEIGHTS statement, or the procedure can construct replicate weights for the analysis. PROC SURVEYFREQ estimates the parameter of interest (a proportion, total, odds ratio, or other statistic) from each replicate, and then uses the variability among replicate estimates to estimate the overall variance of the parameter estimate.

If you do not provide replicate weights with a REPWEIGHTS statement, PROC SURVEYFREQ constructs replicates based on the stratified design with two PSUs in each stratum. As for traditional BRR, the number of replicates R equals the smallest multiple of 4 that is greater than the number of strata H, or you can specify the number of replicates with the REPS= method-option. You can provide a Hadamard matrix for replicate construction by using the HADAMARD= method-option, or PROC SURVEYFREQ generates an appropriate Hadamard matrix.

The traditional BRR method constructs half-sample replicates by deleting one PSU per stratum according to the Hadamard matrix and doubling the original weights to form replicate weights. Fay's BRR method adjusts the original weights by a coefficient ϵ, where $0 \leq \epsilon < 1$. You can specify the value of ϵ with the FAY= method-option. If you do not specify the value of ϵ, PROC SURVEYFREQ uses $\epsilon = 0.5$ by default. See Judkins (1990) and Rao and Shao (1999) for information about the value of the Fay coefficient. When $\epsilon = 0$, Fay's method becomes the traditional BRR method. See Dippo, Fay, and Morganstein (1984), Fay (1989), and Judkins (1990) for more information.

PROC SURVEYFREQ constructs Fay BRR replicates by using the first H columns of the $R \times R$ Hadamard matrix, where H denotes the number of strata. The rth replicate ($r = 1, 2, \ldots, R$) is drawn from the full sample according to the rth row of the Hadamard matrix as follows:

- If the (r, h)th element of the Hadamard matrix equals 1, the sampling weight of the first PSU in stratum h is multiplied by ϵ, and the sampling weight of the second PSU is multiplied by $(2 - \epsilon)$ to form the rth replicate weights.
- If the (r, h)th element of the Hadamard matrix equals -1, then the sampling weight of the second PSU in stratum h is multiplied by ϵ, and the sampling weight of the first PSU is multiplied by $(2 - \epsilon)$ to form the rth replicate weights.

You can use the OUTWEIGHTS= method-option to store the replicate weights in a SAS data set. See the section "Replicate Weights Output Data Set" on page 6355 for details about the contents of the OUTWEIGHTS= data set. You can provide these replicate weights to the procedure for subsequent analyses by using a REPWEIGHTS statement.

Let θ denote the population parameter to be estimated—for example, a proportion, total, odds ratio, or other statistic. Let $\hat{\theta}$ denote the estimate of θ from the full sample, and let $\hat{\theta}_r$ denote the estimate from the rth BRR replicate, which is computed by using the replicate weights. The Fay BRR variance estimate for $\hat{\theta}$ is computed as

$$\widehat{V}(\hat{\theta}) = \frac{1}{R(1-\epsilon)^2} \sum_{r=1}^{R} \left(\hat{\theta}_r - \hat{\theta}\right)^2$$

where R is the total number of replicates and ϵ is the Fay coefficient.

If you request Fay's BRR method and also include a REPWEIGHTS statement, PROC SURVEYFREQ uses the replicate weights that you provide and includes the Fay coefficient ϵ in the denominator of the variance estimate in the preceding expression.

If a parameter cannot be estimated from some replicate(s), then the variance estimate is computed by using those replicates from which the parameter can be estimated. For example, suppose the parameter is a column proportion—the proportion of column j for table cell (i, j). If a replicate r contains no observations in column j, then the column j proportion is not estimable from replicate r. In this case, the BRR variance estimate is computed as

$$\widehat{V}(\hat{\theta}) = \frac{1}{R'(1-\epsilon)^2} \sum_{r=1}^{R'} \left(\hat{\theta}_r - \hat{\theta}\right)^2$$

where the summation is over the replicates where the parameter θ is estimable, and R' is the number of those replicates.

Hadamard Matrix

PROC SURVEYFREQ uses a Hadamard matrix to construct replicates for BRR variance estimation. You can provide a Hadamard matrix for replicate construction by using the HADAMARD= method-option for VARMETHOD=BRR. Otherwise, PROC SURVEYFREQ generates an appropriate Hadamard matrix. You can display the Hadamard matrix by specifying the PRINTH method-option.

A Hadamard matrix $\mathbf{A}$ of dimension R is a square matrix that has all elements equal to 1 or –1. A Hadamard matrix must satisfy the requirement that $\mathbf{A}'\mathbf{A} = R\mathbf{I}$, where $\mathbf{I}$ is an identity matrix. The dimension of a Hadamard matrix must equal 1, 2, or a multiple of 4.

For example, the following matrix is a Hadamard matrix of dimension $k = 8$:

$$\begin{array}{rrrrrrrr} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 & 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 & 1 & -1 & -1 & 1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & -1 & 1 & -1 & -1 & 1 & -1 & 1 \\ 1 & 1 & -1 & -1 & -1 & -1 & 1 & 1 \\ 1 & -1 & -1 & 1 & -1 & 1 & 1 & -1 \end{array}$$

For BRR replicate construction, the dimension of the Hadamard matrix must be at least H, where H denotes the number of first-stage strata in your design. If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the HADAMARD=*SAS-data-set* method-option. You must ensure that the matrix you provide is actually a Hadamard matrix; PROC SURVEYFREQ does not check the validity of your Hadamard matrix.

See the section "Balanced Repeated Replication (BRR)" on page 6334 and "Fay's BRR Method" on page 6335 for details about how the Hadamard matrix is used to construct replicates for BRR variance estimation.

The Jackknife

If you specify the VARMETHOD=JACKKNIFE option, PROC SURVEYFREQ uses the delete-1 jackknife method for variance estimation. The jackknife method can be used for stratified sample designs and for designs with no stratification. If your design is stratified, the jackknife method requires at least two PSUs in each stratum. You can provide replicate weights for jackknife variance estimation by using a REPWEIGHTS statement, or the procedure can construct replicate weights for the analysis. PROC SURVEYFREQ estimates the parameter of interest (a proportion, total, odds ratio, or other statistic) from each replicate, and then uses the variability among replicate estimates to estimate the overall variance of the parameter estimate. See Wolter (1985) and Lohr (1999) for more information about jackknife variance estimation.

If you do not provide replicate weights with a REPWEIGHTS statement, PROC SURVEYFREQ constructs the replicates. The number of replicates R equals the number of PSUs, and the procedure deletes one PSU from the full sample to form each replicate. The sampling weights are modified by the jackknife coefficient for the replicate to create the replicate weights.

If your design is not stratified (no STRATA statement), the jackknife coefficient has the same value for each replicate r. The jackknife coefficient equals

$$\alpha_r = \frac{R-1}{R} \quad \text{for } r = 1, 2, \ldots, R$$

where R is the total number of replicates (or total number of PSUs). For the PSUs included in a replicate, the replicate weights are computed by dividing the original sampling weights by the jackknife coefficient. For the deleted PSU, which is not included in the replicate, the replicate

weights equal zero. The replicate weight for the jth member of the ith PSU can be expressed as follows when the design is not stratified:

$$W_{ij}^{r} = \begin{cases} W_{ij}/\alpha_r & \text{if PSU } i \text{ is included in replicate } r \\ 0 & \text{otherwise} \end{cases}$$

where W_{ij} is the original sampling weight of unit (ij), r is the replicate number, and α_r is the jackknife coefficient.

If your design is stratified, the jackknife method requires at least two PSUs in each stratum. Let stratum $\tilde{h}_r$ be the stratum from which a PSU is deleted to form the rth replicate. Stratum $\tilde{h}_r$ is called the *donor stratum*. The jackknife coefficients are defined as

$$\alpha_r = \frac{n_{\tilde{h}_r} - 1}{n_{\tilde{h}_r}} \quad \text{for } r = 1, 2, \ldots, R$$

where $n_{\tilde{h}_r}$ is the total number of PSUs in the donor stratum for replicate r. For all strata other than the donor stratum, the replicate r weights equal the original sampling weights. For PSUs included from the donor stratum, the replicate weights are computed by dividing the original sampling weights by the jackknife coefficient. For the deleted PSU, which is not included in the replicate, the replicate weights equal zero. The replicate weight for the jth member of the ith PSU in stratum h can be expressed as

$$W_{hij}^{r} = \begin{cases} W_{hij} & \text{if } h \neq \tilde{h}_r \\ W_{hij}/\alpha_r & \text{if } h = \tilde{h}_r \quad \text{and PSU } (hi) \text{ is included in replicate } r \\ 0 & \text{if } h = \tilde{h}_r \quad \text{and PSU } (hi) \text{ is not included in replicate } r \end{cases}$$

You can use the OUTWEIGHTS= method-option to store the replicate weights in a SAS data set. You can also use the OUTJKCOEFS= method-option to store the jackknife coefficients in a SAS data set. See the sections "Jackknife Coefficients Output Data Set" on page 6355 and "Replicate Weights Output Data Set" on page 6355 for details about the contents of these output data sets. You can provide replicate weights and jackknife coefficients to the procedure for subsequent analyses by using a REPWEIGHTS statement. If you provide replicate weights but do not provide jackknife coefficients, PROC SURVEYFREQ uses $\alpha_r = (R-1)/R$ as the jackknife coefficient for all replicates.

Let θ denote the population parameter to be estimated—for example, a proportion, total, odds ratio, or other statistic. Let $\hat{\theta}$ denote the estimate of θ from the full sample, and let $\hat{\theta}_r$ be the estimate from the rth jackknife replicate, which is computed by using the replicate weights. The jackknife variance estimate for $\hat{\theta}$ is computed as

$$\widehat{V}(\hat{\theta}) = \sum_{r=1}^{R} \alpha_r \left(\hat{\theta}_r - \hat{\theta}\right)^2$$

where R is the total number of replicates and α_r is the jackknife coefficient for replicate r.

If a parameter cannot be estimated from some replicate(s), then the variance estimate is computed by using those replicates from which the parameter can be estimated. For example, suppose the

parameter is a column proportion—the proportion of column j for table cell (i, j). If a replicate r contains no observations in column j, then the column j proportion is not estimable from replicate r. In this case, the jackknife variance estimate is computed as

$$\widehat{V}(\hat{\theta}) = \frac{R}{R'} \sum_{r=1}^{R'} \alpha_r \left(\hat{\theta}_r - \hat{\theta}\right)^2$$

where the summation is over the replicates where the parameter θ is estimable, and R' is the number of those replicates.

Confidence Limits

If you specify the CL option in the TABLES statement, PROC SURVEYFREQ computes confidence limits for the proportions in the frequency and crosstabulation tables. The confidence coefficient is determined according to the value of the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits.

For the proportion in table cell (r, c), the confidence limits are computed as

$$\widehat{P}_{rc} \pm \left(t_{df,\alpha/2} \times \text{StdErr}(\widehat{P}_{rc})\right)$$

where $\widehat{P}_{rc}$ is the estimate of the proportion in table cell (r, c), $\text{StdErr}(\widehat{P}_{rc})$ is the standard error of the estimate, and $t_{df,\alpha/2}$ is the $100(1-\alpha/2)$th percentile of the t distribution with df degrees of freedom calculated as described in the section "Degrees of Freedom" on page 6340. The confidence limits for row proportions and column proportions are computed similarly to the confidence limits for table cell proportions.

If you specify the CLWT option in the TABLES statement, PROC SURVEYFREQ computes confidence limits for the weighted frequencies, or totals, in the crosstabulation tables.

For the total in table cell (r, c), the confidence limits are computed as

$$\widehat{N}_{rc} \pm \left(t_{df,\alpha/2} \times \text{StdErr}(\widehat{N}_{rc})\right)$$

where $\widehat{N}_{rc}$ is the estimate of the total frequency in table cell (r, c), $\text{StdErr}(\hat{N}_{rc})$ is the standard error of the estimate, and $t_{df,\alpha/2}$ is the $100(1-\alpha/2)$th percentile of the t distribution with df degrees of freedom calculated as described in the section "Degrees of Freedom" on page 6340. The confidence limits for row totals, column totals, and the overall total are computed similarly to the confidence limits for table cell totals.

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS table, "Table Summary," which contains the number of observations, strata, and clusters that are included in the analysis of the requested table. When you request confidence limits, the "Table Summary" data set also contains the degrees of freedom df and the value of $t_{df,\alpha/2}$ used to compute the confidence limits. See Example 83.3 for more information about this output data set.

Degrees of Freedom

PROC SURVEYFREQ uses the degrees of freedom of the variance estimator to obtain the t-percentile for confidence limits for proportions, totals, and other statistics. The procedure also uses the degrees of freedom in computing the F statistics for the Rao-Scott and Wald chi-square tests.

PROC SURVEYFREQ computes the degrees of freedom based on the variance estimation method and the sample design. Alternatively, you can specify the degrees of freedom in the DF= option in the TABLES statement instead of having the procedure compute it.

For Taylor series variance estimation, PROC SURVEYFREQ calculates the degrees of freedom (df) as the number of clusters minus the number of strata. If there are no clusters, then df equals the number of observations minus the number of strata. If the design is not stratified, then df equals the number of clusters minus one. These numbers are based on the observations included in the analysis of the individual table request. These numbers do not count observations excluded from the table due to missing values. See the section "Missing Values" on page 6323 for details. If you specify the MISSING option, missing values are treated as valid nonmissing levels and are included in computing degrees of freedom. If you specify the NOMCAR option for Taylor series variance estimation, observations with missing values of the TABLES variables are included in computing degrees of freedom.

If you provide replicate weights with a REPWEIGHTS statement, the degrees of freedom equal the number of replicates, which is the number of REPWEIGHTS variables that you provide. Alternatively, you can specify the degrees of freedom in the DF= option in the REPWEIGHTS or TABLES statement.

For BRR variance estimation (when you do not use a REPWEIGHTS statement), PROC SURVEYFREQ calculates the degrees of freedom as the number of strata. PROC SURVEYFREQ bases the number of strata on all valid observations in the data set, unless you specify the DFADJ method-option for VARMETHOD=BRR. When you specify the DFADJ option, the procedure computes the degrees of freedom as the number of nonmissing strata for the individual table request. This excludes any empty strata that occur when observations with missing values of the TABLES variables are removed from the analysis for that table.

For jackknife variance estimation (when you do not use a REPWEIGHTS statement), PROC SURVEYFREQ calculates the degrees of freedom as the number of clusters minus the number of strata. If there are no clusters, then df equals the number of observations minus the number of strata. If the design is not stratified, then df equals the number of clusters minus one. For jackknife variance estimation, PROC SURVEYFREQ bases the number of strata and clusters on all valid observations in the data set, unless you specify the DFADJ method-option for VARMETHOD=JK. When you specify the DFADJ option, the procedure computes the degrees of freedom from the number of nonmissing strata and clusters for the individual table request. This excludes any empty strata or clusters that occur when observations with missing values of the TABLES variables are removed from the analysis for that table.

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS table, "Table Summary," which contains the number of (nonmissing) observations, strata, and clusters that are included in the analysis of the table. If there are missing observations, empty strata, or empty clusters excluded from the analysis, the "Table Summary" data set also contains this information. If you re-

quest confidence limits or chi-square tests, which depend on the degrees of freedom of the variance estimator, the "Table Summary" data set provides the degrees of freedom df. See Example 83.3 for more information about this output data set.

Coefficient of Variation

If you specify the CV option in the TABLES statement, PROC SURVEYFREQ computes the coefficients of variation for the proportion estimates in the frequency and crosstabulation tables. The coefficient of variation is the ratio of the standard error to the estimate.

For the proportion in table cell (r, c), the coefficient of variation is computed as

$$\mathrm{CV}(\widehat{P}_{rc}) = \mathrm{StdErr}(\widehat{P}_{rc}) \;/\; \widehat{P}_{rc}$$

where $\widehat{P}_{rc}$ is the estimate of the proportion in table cell (r, c) and $\mathrm{StdErr}(\widehat{P}_{rc})$ is the standard error of the estimate. The coefficients of variation for row proportions and column proportions are computed similarly.

If you specify the CVWT option in the TABLES statement, PROC SURVEYFREQ computes the coefficients of variation for the weighted frequencies, or estimated totals, in the crosstabulation tables. For the total in table cell (r, c), the coefficient of variation is computed as

$$\mathrm{CV}(\widehat{N}_{rc}) = \mathrm{StdErr}(\widehat{N}_{rc}) \;/\; \widehat{N}_{rc}$$

where $\widehat{N}_{rc}$ is the estimate of the total in table cell (r, c) and $\mathrm{StdErr}(\widehat{N}_{rc})$ is the standard error of the estimate. The coefficients of variation for row totals, column totals, and the overall total are computed similarly.

Design Effect

If you specify the DEFF option in the TABLES statement, PROC SURVEYFREQ computes design effects for the overall proportion estimates in the frequency and crosstabulation tables. The design effect for an estimate is the ratio of the actual variance (estimated based on the sample design) to the variance of a simple random sample with the same number of observations. See Lohr (1999) and Kish (1965) for details.

For Taylor series variance estimation, PROC SURVEYFREQ computes the design effect for the proportion in table cell (r, c) as

$$\begin{aligned}
\mathrm{DEFF}(\widehat{P}_{rc}) &= \widehat{\mathrm{Var}}(\widehat{P}_{rc}) \;/\; \widehat{\mathrm{Var}}_{\mathrm{SRS}}(\widehat{P}_{rc}) \\
&= \widehat{\mathrm{Var}}(\widehat{P}_{rc}) \;/\; \left\{(1-f)\;\widehat{P}_{rc}\;(1-\widehat{P}_{rc})\;/\;(n-1)\right\}
\end{aligned}$$

where $\widehat{P}_{rc}$ is the estimate of the proportion in table cell (r, c), $\widehat{\mathrm{Var}}(\widehat{P}_{rc})$ is the variance of the estimate, f is the overall sampling fraction, and n is the number of observations in the sample.

For Taylor series variance estimation, PROC SURVEYFREQ determines the value of f, the overall sampling fraction, based on the RATE= or TOTAL= option. If you do not specify either of these

options, then PROC SURVEYFREQ assumes the value of f is negligible and does not use a finite population correction in the analysis, as described in the section "Population Totals and Sampling Rates" on page 6322. If you specify RATE=*value*, then PROC SURVEYFREQ uses this value as the overall sampling fraction f. If you specify TOTAL=*value*, then PROC SURVEYFREQ computes f as the ratio of the number of PSUs in the sample to the specified total.

If you specify stratum sampling rates with the RATE=*SAS-data-set* option, then PROC SURVEYFREQ computes stratum totals based on these stratum sampling rates and the number of sample PSUs in each stratum. The procedure sums the stratum totals to form the overall total, and computes f as the ratio of the number of sample PSUs to the overall total. Alternatively, if you specify stratum totals with the TOTAL=*SAS-data-set* option, then PROC SURVEYFREQ sums these totals to compute the overall total. The overall sampling fraction f is then computed as the ratio of the number of sample PSUs to the overall total.

For BRR and jackknife variance estimation, PROC SURVEYFREQ computes the design effect for the proportion in table cell (r, c) as

$$\begin{aligned} \mathrm{DEFF}(\widehat{P}_{rc}) &= \widehat{\mathrm{Var}}(\widehat{P}_{rc}) \,/\, \widehat{\mathrm{Var}}_{\mathrm{SRS}}(\widehat{P}_{rc}) \\ &= \widehat{\mathrm{Var}}(\widehat{P}_{rc}) \,/\, \left\{ \widehat{P}_{rc}\,(1-\widehat{P}_{rc}) \,/\, (n-1) \right\} \end{aligned}$$

where $\widehat{P}_{rc}$ is the estimate of the proportion in table cell (r, c), $\widehat{\mathrm{Var}}(\widehat{P}_{rc})$ is the variance of the estimate, and n is the number of observations in the sample. This computation does not include the overall sampling fraction.

Expected Weighted Frequency

If you specify the EXPECTED option in the TABLES statement, PROC SURVEYFREQ computes expected weighted frequencies for the table cells in two-way tables. The expected weighted frequencies are computed under the null hypothesis that the row and column variables are independent. The expected weighted frequency for table cell (r, c) equals

$$E_{rc} = \widehat{N}_{r\cdot}\, \widehat{N}_{\cdot c} \,/\, \widehat{N}$$

where $\widehat{N}_{r\cdot}$ is the estimated total for row r, $\widehat{N}_{\cdot c}$ is the estimated total for column c, and $\widehat{N}$ is the estimated overall total. Equivalently, the expected weighted frequency can be expressed as

$$E_{rc} = \widehat{P}_{r\cdot}\, \widehat{P}_{\cdot c}\, \widehat{N}$$

These expected values are used in the design-based chi-square tests of independence, as described in the sections "Rao-Scott Chi-Square Test" on page 6346 and "Wald Chi-Square Test" on page 6352.

Risks and Risk Difference

The RISK option provides estimates of risks (or binomial proportions) and risk differences for 2×2 tables, together with their standard errors and confidence limits. Risk statistics include the row 1 risk, row 2 risk, overall risk, and risk difference. If you specify the RISK option, PROC

SURVEYFREQ provides both column 1 and column 2 risks. You can request only column 1 (or only column 2) risks by specifying the RISK1 (or RISK2) option.

The column 1 risk for row 1 is the row 1 proportion for table cell $(1, 1)$. The column 1 risk estimate is computed as the ratio of the estimated total for table cell $(1, 1)$ to the estimated total for row 1,

$$\widehat{P}_{11}^{(1)} = \widehat{N}_{11} \,/\, \widehat{N}_{1\cdot}$$

where the total estimates are computed as described in the section "Totals" on page 6329. The column 1 risk for row 2 is the row 2 proportion for table cell $(2, 1)$, which is estimated as

$$\widehat{P}_{21}^{(2)} = \widehat{N}_{21} \,/\, \widehat{N}_{2\cdot}$$

The overall column 1 risk is the overall proportion in column 1, and its estimate is computed as

$$\widehat{P}_{\cdot 1} = \widehat{N}_{\cdot 1} \,/\, \widehat{N}$$

The column 2 risk estimates are computed similarly.

The row 1 and row 2 risks are the same as the row proportions for a 2×2 table, and their variances are computed as described in the section "Row and Column Proportions" on page 6332. The overall risk is the overall proportion in the column, and its variance computation is described in the section "Proportions" on page 6331. Confidence limits for the column 1 risk for row 1 are computed as

$$\widehat{P}_{11}^{(1)} \pm \left(t_{df,\alpha/2} \times \mathrm{StdErr}(\widehat{P}_{11}^{(1)}) \right)$$

where $\mathrm{StdErr}(\widehat{P}_{11}^{(1)})$ is the standard error of the risk estimate, and $t_{df,\alpha/2}$ is the $100(1-\alpha/2)$th percentile of the t distribution with df degrees of freedom calculated as described in the section "Degrees of Freedom" on page 6340. The value of the confidence coefficient α is determined by the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits. Confidence limits for the other risks are computed similarly.

The risk difference is defined as the row 1 risk minus the row 2 risk. The estimate of the column 1 risk difference $\widehat{RD}_1$ is computed as

$$\begin{aligned} \widehat{RD}_1 &= \widehat{P}_{11}^{(1)} - \widehat{P}_{21}^{(2)} \\ &= \left(\widehat{N}_{11} \,/\, \widehat{N}_{1\cdot} \right) - \left(\widehat{N}_{21} \,/\, \widehat{N}_{2\cdot} \right) \end{aligned}$$

The column 2 risk difference is computed similarly.

PROC SURVEYFREQ estimates the variance of the risk difference by using the variance estimation method that you request. If you request BRR variance estimation (VARMETHOD=BRR), the procedure estimates the variance as described in the section "Balanced Repeated Replication (BRR)" on page 6334. If you request jackknife variance estimation (VARMETHOD=JACKKNIFE), the procedure estimates the variance as described in the section "The Jackknife" on page 6337.

If you do not specify the VARMETHOD= option or a REPWEIGHTS statement, the default variance estimation method is Taylor series (VARMETHOD=TAYLOR). By using Taylor series linearization, the variance estimate for the column 1 risk difference $\widehat{\mathrm{Var}}(\widehat{RD}_1)$ can be expressed as

$$\widehat{\mathrm{Var}}(\widehat{RD}_1) = \widehat{\mathbf{D}}\, \widehat{\mathbf{V}}(\widehat{\mathbf{X}})\, \widehat{\mathbf{D}}'$$

where $\widehat{\mathbf{V}}(\widehat{\mathbf{X}})$ is the covariance matrix of $\widehat{\mathbf{X}}$,

$$\widehat{\mathbf{X}} = (\ \widehat{N}_{11},\ \widehat{N}_{1\cdot},\ \widehat{N}_{21},\ \widehat{N}_{2\cdot}\ )$$

and $\widehat{\mathbf{D}}$ is an array containing the partial derivatives of the risk difference with respect to the elements of $\widehat{\mathbf{X}}$,

$$\widehat{\mathbf{D}} = (\ 1/\widehat{N}_{1\cdot},\ -\widehat{N}_{11}/\widehat{N}_{1\cdot}^{2},\ -1/\widehat{N}_{2\cdot},\ -\widehat{N}_{21}/\widehat{N}_{2\cdot}^{2}\ )$$

See Wolter (1985, pp. 239–242) for details. The variance estimate for the column 2 risk difference is computed similarly.

The standard error of the column 1 risk difference is

$$\text{StdErr}(\widehat{RD}_1) = \sqrt{\widehat{\text{Var}}(\widehat{RD}_1)}$$

Confidence limits for the column 1 risk difference are computed as

$$\widehat{RD}_1 \pm \left(t_{df,\alpha/2} \times \text{StdErr}(\widehat{RD}_1)\right)$$

where $t_{df,\alpha/2}$ is the $100(1-\alpha/2)$th percentile of the t distribution with df degrees of freedom calculated as described in the section "Degrees of Freedom" on page 6340. The value of the confidence coefficient α is determined by the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits. Confidence limits for the column 2 risk difference are computed in the same way.

Odds Ratio and Relative Risks

The OR option provides estimates of the odds ratio, the column 1 relative risk, and the column 2 relative risk for 2×2 tables, together with their confidence limits.

Odds Ratio

For a 2×2 table, the odds of a positive (column 1) response in row 1 is N_{11}/N_{12}. Similarly, the odds of a positive response in row 2 is N_{21}/N_{22}. The odds ratio is formed as the ratio of the row 1 odds to the row 2 odds. The estimate of the odds ratio is computed as

$$\widehat{OR} = \frac{\widehat{N}_{11}\ /\ \widehat{N}_{12}}{\widehat{N}_{21}\ /\ \widehat{N}_{22}} = \frac{\widehat{N}_{11}\ \widehat{N}_{22}}{\widehat{N}_{12}\ \widehat{N}_{21}}$$

The value of the odds ratio can be any nonnegative number. When the row and column variables are independent, the true value of the odds ratio equals 1. An odds ratio greater than 1 indicates that the odds of a positive response are higher in row 1 than in row 2. An odds ratio less than 1 indicates that the odds of positive response are higher in row 2. The strength of association increases with the deviation from 1. See Stokes, Davis, and Koch (2000) and Agresti (2007) for details.

PROC SURVEYFREQ constructs confidence limits for the odds ratio by using the log transform. The $100(1-\alpha)\%$ confidence limits for the odds ratio are computed as

$$\left(\ \widehat{OR} \times \exp(-t_{df,\alpha/2}\ \sqrt{v}),\ \widehat{OR} \times \exp(t_{df,\alpha/2}\ \sqrt{v})\ \right)$$

where

$$v = \widehat{\mathrm{Var}}(\ln \widehat{OR}) = \widehat{\mathrm{Var}}(\widehat{OR}) \;/\; \widehat{OR}^{\,2}$$

is the estimate of the variance of the log odds ratio, and where $t_{df,\alpha/2}$ is the $100(1-\alpha/2)$th percentile of the t distribution with df degrees of freedom. The computation of df is described in the section "Degrees of Freedom" on page 6340. The value of the confidence coefficient α is determined by the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits.

If you request BRR variance estimation (VARMETHOD=BRR), PROC SURVEYFREQ estimates the variance of the odds ratio as described in the section "Balanced Repeated Replication (BRR)" on page 6334. If you request jackknife variance estimation (VARMETHOD=JACKKNIFE), the procedure estimates the variance as described in the section "The Jackknife" on page 6337.

If you do not specify the VARMETHOD= option or a REPWEIGHTS statement, the default variance estimation method is Taylor series (VARMETHOD=TAYLOR). By using Taylor series linearization, the variance estimate for the odds ratio can be expressed as

$$\widehat{\mathrm{Var}}(\widehat{OR}) = \widehat{\mathbf{D}}\,\widehat{\mathbf{V}}(\widehat{\mathbf{N}})\,\widehat{\mathbf{D}}'$$

where $\widehat{\mathbf{V}}(\widehat{\mathbf{N}})$ is the covariance matrix of the estimates of the cell totals $\widehat{\mathbf{N}}$,

$$\widehat{\mathbf{N}} = (\,\widehat{N}_{11},\ \widehat{N}_{12},\ \widehat{N}_{21},\ \widehat{N}_{22}\,)$$

and $\widehat{\mathbf{D}}$ is an array containing the partial derivatives of the odds ratio with respect to the elements of $\widehat{\mathbf{N}}$. The section "Covariance of Totals" on page 6330 describes the computation of $\widehat{\mathbf{V}}(\widehat{\mathbf{N}})$. The array $\widehat{\mathbf{D}}$ is computed as

$$\begin{aligned}\widehat{\mathbf{D}} \;=\; (\;& \widehat{N}_{22}/\widehat{N}_{12}\widehat{N}_{21}, \quad -\widehat{N}_{11}\widehat{N}_{22}/\widehat{N}_{21}\widehat{N}_{12}^{\,2},\\ & -\widehat{N}_{11}\widehat{N}_{22}/\widehat{N}_{12}\widehat{N}_{21}^{\,2}, \quad \widehat{N}_{11}/\widehat{N}_{12}\widehat{N}_{21} \quad)\end{aligned}$$

See Wolter (1985, pp. 239–242) for more information.

Relative Risks

For a 2×2 table, the column 1 relative risk is the ratio of the column 1 risks for row 1 to row 2. As described in the section "Risks and Risk Difference" on page 6342, the column 1 risk for row 1 is the proportion of row 1 observations classified in column 1, and the column 1 risk for row 2 is the proportion of row 2 observations classified in column 1. The estimate of the column 1 relative risk is computed as

$$\widehat{RR}_1 = \frac{\widehat{N}_{11} \;/\; \widehat{N}_{1\cdot}}{\widehat{N}_{21} \;/\; \widehat{N}_{2\cdot}}$$

Similarly, the estimate of the column 2 relative risk is computed as

$$\widehat{RR}_2 = \frac{\widehat{N}_{12} \;/\; \widehat{N}_{1\cdot}}{\widehat{N}_{22} \;/\; \widehat{N}_{2\cdot}}$$

A relative risk greater than 1 indicates that the probability of positive response is greater in row 1 than in row 2. Similarly, a relative risk less than 1 indicates that the probability of positive response

is less in row 1 than in row 2. The strength of association increases with the deviation from 1. See Stokes, Davis, and Koch (2000) and Agresti (2007) for more information.

PROC SURVEYFREQ constructs confidence limits for the relative risk by using the log transform, which is similar to the odds ratio computations described previously. The $100(1-\alpha)\%$ confidence limits for the column 1 relative risk are computed as

$$\left(\widehat{RR}_1 \times \exp(-t_{df,\alpha/2}\sqrt{v}),\ \widehat{RR}_1 \times \exp(t_{df,\alpha/2}\sqrt{v}) \right)$$

where

$$v = \widehat{\mathrm{Var}}(\ln \widehat{RR}_1) = \widehat{\mathrm{Var}}(\widehat{RR}_1) \ / \ \widehat{RR}_1^2$$

is the estimate of the variance of the log column 1 relative risk, and where $t_{df,\alpha/2}$ is the $100(1-\alpha/2)$th percentile of the t distribution with df degrees of freedom. The computation of df is described in the section "Degrees of Freedom" on page 6340. The value of the confidence coefficient α is determined by the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits.

If you request BRR variance estimation (VARMETHOD=BRR), PROC SURVEYFREQ estimates the variance of the column 1 relative risk as described in the section "Balanced Repeated Replication (BRR)" on page 6334. If you request jackknife variance estimation (VARMETHOD=JACKKNIFE), the procedure estimates the variance as described in the section "The Jackknife" on page 6337.

If you do not specify the VARMETHOD= option or a REPWEIGHTS statement, the default variance estimation method is Taylor series (VARMETHOD=TAYLOR). By using Taylor series linearization, the variance estimate for the column 1 relative risk can be expressed as

$$\widehat{\mathrm{Var}}(\widehat{RR}_1) = \widehat{\mathbf{D}}\ \widehat{\mathbf{V}}(\widehat{\mathbf{X}})\ \widehat{\mathbf{D}}'$$

where $\widehat{\mathbf{V}}(\widehat{\mathbf{X}})$ is the covariance matrix of $\widehat{\mathbf{X}}$,

$$\widehat{\mathbf{X}} = (\ \widehat{N}_{11},\ \widehat{N}_{1\cdot},\ \widehat{N}_{21},\ \widehat{N}_{2\cdot}\ )$$

and $\widehat{\mathbf{D}}$ is an array containing the partial derivatives of the column 1 relative risk with respect to the elements of $\widehat{\mathbf{X}}$,

$$\begin{aligned}\widehat{\mathbf{D}} \ = \ (\ & \widehat{N}_{2\cdot}/\widehat{N}_{21}\widehat{N}_{1\cdot}, \quad -\widehat{N}_{11}\widehat{N}_{2\cdot}/\widehat{N}_{21}\widehat{N}_{1\cdot}^2, \\ & -\widehat{N}_{11}\widehat{N}_{2\cdot}/\widehat{N}_{1\cdot}\widehat{N}_{21}^2, \quad \widehat{N}_{11}/\widehat{N}_{21}\widehat{N}_{1\cdot} \quad)\end{aligned}$$

See Wolter (1985, pp. 239–242) for more information.

Confidence limits for the column 2 relative risk are computed similarly.

Rao-Scott Chi-Square Test

The Rao-Scott chi-square test is a design-adjusted version of the Pearson chi-square test, which involves differences between observed and expected frequencies. For two-way tables, the null hypothesis for this test is no association between the row and column variables. For one-way tables,

the null hypothesis is equal proportions for the variable levels. Or you can specify null hypothesis proportions for one-way tables by using the TESTP= option.

Two forms of the design correction are available for the Rao-Scott tests. One form of the design correction uses the proportion estimates, and you request the corresponding Rao-Scott chi-square test with the CHISQ option. The other form of the design correction uses the null hypothesis proportions. You request this test, called the Rao-Scott modified chi-square test, with the CHISQ1 option.

See Lohr (1999), Thomas, Singh, and Roberts (1996), and Rao and Scott (1981, 1984, 1987) for details about design-adjusted chi-square tests.

Two-Way Tables

The Rao-Scott chi-square statistic is computed from the Pearson chi-square statistic and a design correction based on the design effects of the proportions. Under the null hypothesis of no association between the row and column variables, this statistic approximately follows a chi-square distribution with $(R-1)(C-1)$ degrees of freedom. PROC SURVEYFREQ also computes an F statistic that can provide a better approximation.

The Rao-Scott chi-square Q_{RS} is computed as

$$Q_{RS} = Q_P \;/\; D$$

where D is the design correction described in the section "Design Correction for Two-Way Tables" on page 6348, and Q_P is the Pearson chi-square based on the estimated totals. The Pearson chi-square is computed as

$$Q_P = (n/\widehat{N}) \sum_r \sum_c (\widehat{N}_{rc} - E_{rc})^2 \;/\; E_{rc}$$

where n is the sample size, $\widehat{N}$ is the estimated overall total, $\widehat{N}_{rc}$ is the estimated total for table cell (r, c), and E_{rc} is the expected total for table cell (r, c) under the null hypothesis of no association,

$$E_{rc} = \widehat{N}_{r\cdot}\, \widehat{N}_{\cdot c} \;/\; \widehat{N}$$

Under the null hypothesis of no association, the Rao-Scott chi-square Q_{RS} approximately follows a chi-square distribution with $(R-1)(C-1)$ degrees of freedom. A better approximation can be obtained by the F statistic,

$$F = Q_{RS} \;/\; (R-1)(C-1)$$

which has an F distribution with $(R-1)(C-1)$ and $(R-1)(C-1)\kappa$ degrees of freedom under the null hypothesis. The value κ is the degrees of freedom for the variance estimator and depends on the sample design and the variance estimation method. The section "Degrees of Freedom" on page 6340 describes the computation of κ.

Design Correction for Two-Way Tables

If you specify the CHISQ or LRCHISQ option, the design correction D is computed by using the estimated proportions as

$$D = \left\{ \sum_r \sum_c (1 - \widehat{P}_{rc}) \text{ DEFF}(\widehat{P}_{rc}) - \sum_r (1 - \widehat{P}_{r\cdot}) \text{ DEFF}(\widehat{P}_{r\cdot}) \right. \\ \left. - \sum_c (1 - \widehat{P}_{\cdot c}) \text{ DEFF}(\widehat{P}_{\cdot c}) \right\} / (R-1)(C-1)$$

where

$$\begin{aligned} \text{DEFF}(\widehat{P}_{rc}) &= \widehat{\text{Var}}(\widehat{P}_{rc}) / \text{Var}_{\text{SRS}}(\widehat{P}_{rc}) \\ &= \text{Var}(\widehat{P}_{rc}) / \left\{ (1-f)\, \widehat{P}_{rc}\, (1 - \widehat{P}_{rc}) / (n-1) \right\} \end{aligned}$$

as described in the section "Design Effect" on page 6341. $\widehat{P}_{rc}$ is the estimate of the proportion in table cell (r, c), $\widehat{\text{Var}}(\widehat{P}_{rc})$ is the variance of the estimate, f is the overall sampling fraction, and n is the number of observations in the sample. $\text{DEFF}(\widehat{P}_{r\cdot})$, the design effect for the estimate of the proportion in row r, and $\text{DEFF}(\widehat{P}_{\cdot c})$, the design effect for the estimate of the proportion in column c, are computed similarly.

If you specify the CHISQ1 or LRCHISQ1 option for the Rao-Scott modified test, the design correction uses the null hypothesis cell proportions instead of the estimated cell proportions. For two-way tables, the null hypothesis cell proportions are computed as the products of the corresponding row and column proportion estimates. The modified design correction D_0 (based on null hypothesis proportions) is computed as

$$D_0 = \left\{ \sum_r \sum_c (1 - P_{rc}^0) \text{ DEFF}_0(\widehat{P}_{rc}) - \sum_r (1 - \widehat{P}_{r\cdot}) \text{ DEFF}(\widehat{P}_{r\cdot}) \right. \\ \left. - \sum_c (1 - \widehat{P}_{\cdot c}) \text{ DEFF}(\widehat{P}_{\cdot c}) \right\} / (R-1)(C-1)$$

where

$$P_{rc}^0 = \widehat{P}_{r\cdot} \times \widehat{P}_{\cdot c}$$

and

$$\begin{aligned} \text{DEFF}_0(\widehat{P}_{rc}) &= \widehat{\text{Var}}(\widehat{P}_{rc}) / \text{Var}_{\text{SRS}}(P_{rc}^0) \\ &= \widehat{\text{Var}}(\widehat{P}_{rc}) / \left\{ (1-f)\, P_{rc}^0\, (1 - P_{rc}^0) / (n-1) \right\} \end{aligned}$$

One-Way Tables

For one-way tables, the Rao-Scott chi-square statistic provides a design-based goodness-of-fit test for equal proportions. Or if you specify null proportions with the TESTP= option, the Rao-Scott chi-square provides a design-based goodness-of-fit test for the specified proportions. Under the null hypothesis, the Rao-Scott chi-square statistic approximately follows a chi-square distribution with

$(C-1)$ degrees of freedom for a table with C levels. PROC SURVEYFREQ also computes an F statistic that can provide a better approximation.

The Rao-Scott chi-square Q_{RS} is computed as

$$Q_{RS} = Q_P \;/\; D$$

where D is the design correction described in the section "Design Correction for One-Way Tables" on page 6349, and Q_P is the Pearson chi-square based on the estimated totals. The Pearson chi-square is computed as

$$Q_P = (n/\widehat{N}) \sum_c (\widehat{N}_c - E_c)^2 \;/\; E_c$$

where n is the sample size, $\widehat{N}$ is the estimated overall total, $\widehat{N}_c$ is the estimated total for level c, and E_c is the expected total for level c under the null hypothesis. For the null hypothesis of equal proportions, the expected total for level c equals

$$E_c = \widehat{N} \;/\; C$$

For specified null proportions, the expected total for level c equals

$$E_c = \widehat{N} \;\times\; P_c^{\,0}$$

where $P_c^{\,0}$ is the null proportion for level c.

Under the null hypothesis, the Rao-Scott chi-square Q_{RS} approximately follows a chi-square distribution with $(C-1)$ degrees of freedom. A better approximation can be obtained by the F statistic,

$$F = Q_{RS} \;/\; (C-1)$$

which has an F distribution with $(C-1)$ and $(C-1)\kappa$ degrees of freedom under the null hypothesis. The value κ is the degrees of freedom for the variance estimator and depends on the sample design and the variance estimation method. The section "Degrees of Freedom" on page 6340 describes the computation of κ.

Design Correction for One-Way Tables

If you specify the CHISQ or LRCHISQ option, the design correction D is computed by using the estimated proportions as

$$D = \sum_c (1-\widehat{P}_c)\,\mathrm{DEFF}(\widehat{P}_c) \;/\; (C-1)$$

where

$$\begin{aligned}\mathrm{DEFF}(\widehat{P}_c) &= \widehat{\mathrm{Var}}(\widehat{P}_c) \;/\; \mathrm{Var}_{\mathrm{SRS}}(\widehat{P}_c) \\ &= \widehat{\mathrm{Var}}(\widehat{P}_c) \;/\; \left\{(1-f)\;\widehat{P}_c\;(1-\widehat{P}_c) \;/\; (n-1)\right\}\end{aligned}$$

as described in the section "Design Effect" on page 6341. $\widehat{P}_c$ is the proportion estimate for table level c, $\widehat{\mathrm{Var}}(\widehat{P}_c)$ is the variance of the estimate, f is the overall sampling fraction, and n is the number of observations in the sample.

If you specify the CHISQ1 or LRCHISQ1 option for the Rao-Scott modified test, the design correction uses the null hypothesis proportions—either equal proportions for all levels, or the proportions that you specify with the TESTP= option. The modified design correction D_0 is computed as

$$D_0 = \sum_c (1 - {P_c}^0)\ \mathrm{DEFF}_0(\widehat{P}_c)\ /\ (C-1)$$

where

$$\begin{aligned} \mathrm{DEFF}_0(\widehat{P}_c) &= \widehat{\mathrm{Var}}(\widehat{P}_c)\ /\ \mathrm{Var}_{\mathrm{SRS}}({P_c}^0) \\ &= \widehat{\mathrm{Var}}(\widehat{P}_c)\ /\ \left\{(1-f){P_c}^0\ (1-{P_c}^0)\ /\ (n-1)\right\} \end{aligned}$$

and ${P_c}^0 = 1/C$ for equal proportions, or ${P_c}^0$ equals the null proportion for level c if you specify the TESTP= option.

Rao-Scott Likelihood Ratio Chi-Square Test

The Rao-Scott likelihood ratio chi-square test is a design-adjusted version of the likelihood ratio test, which involves ratios between observed and expected frequencies. For two-way tables, the null hypothesis for this test is no association between the row and column variables. For one-way tables, the null hypothesis is equal proportions for the variable levels. Or you can specify null hypothesis proportions for one-way tables by using the TESTP= option.

Two forms of the design correction are available for the Rao-Scott tests. One form of the design correction uses the proportion estimates, and you request the corresponding Rao-Scott likelihood ratio test with the LRCHISQ option. The other form of the design correction uses the null hypothesis proportions. You request this test, called the Rao-Scott modified likelihood ratio test, with the LRCHISQ1 option.

See Lohr (1999), Thomas, Singh, and Roberts (1996), and Rao and Scott (1981, 1984, 1987) for details about design-adjusted chi-square tests.

Two-Way Tables

The Rao-Scott likelihood ratio statistic is computed from the likelihood ratio chi-square statistic and a design correction based on the design effects of the proportions. Under the null hypothesis of no association between the row and column variables, this statistic approximately follows a chi-square distribution with $(R-1)(C-1)$ degrees of freedom. PROC SURVEYFREQ also computes an F statistic that can provide a better approximation.

The Rao-Scott likelihood ratio chi-square G^2_{RS} is computed as

$$G^2_{RS} = G^2\ /\ D$$

where D is the design correction described in the section "Design Correction for Two-Way Tables" on page 6348, and G^2 is the likelihood ratio chi-square based on the estimated totals. The likelihood ratio chi-square is computed as

$$G^2 = 2\ (n/\widehat{N})\ \sum_r \sum_c \widehat{N}_{rc}\ \ln\left(\widehat{N}_{rc}\ /\ E_{rc}\right)$$

where n is the sample size, $\widehat{N}$ is the estimated overall total, $\widehat{N}_{rc}$ is the estimated total for table cell (r, c), and E_{rc} is the expected total for cell (r, c) under the null hypothesis of no association. The expected total for cell (r, c) equals

$$E_{rc} = \widehat{N}_{r\cdot}\ \widehat{N}_{\cdot c}\ /\ \widehat{N}$$

Under the null hypothesis of no association, the Rao-Scott likelihood ratio chi-square G^2_{RS} approximately follows a chi-square distribution with $(R-1)(C-1)$ degrees of freedom. A better approximation can be obtained by the F statistic,

$$F = G^2_{RS}\ /\ (R-1)(C-1)$$

which has an F distribution with $(R-1)(C-1)$ and $(R-1)(C-1)\kappa$ degrees of freedom under the null hypothesis. The value κ is the degrees of freedom for the variance estimator and depends on the sample design and the variance estimation method. The section "Degrees of Freedom" on page 6340 describes the computation of κ.

One-Way Tables

For one-way tables, the Rao-Scott likelihood ratio chi-square statistic provides a design-based goodness-of-fit test for equal proportions. Or if you specify null proportions with the TESTP= option, the Rao-Scott likelihood ratio chi-square provides a design-based goodness-of-fit test for the specified proportions. Under the null hypothesis, the Rao-Scott likelihood ratio statistic approximately follows a chi-square distribution with $(C-1)$ degrees of freedom for a table with C levels. PROC SURVEYFREQ also computes an F statistic that can provide a better approximation.

The Rao-Scott likelihood ratio chi-square G^2_{RS} is computed as

$$G^2_{RS} = G^2\ /\ D$$

where D is the design correction described in the section "Design Correction for One-Way Tables" on page 6349, and G^2 is the likelihood ratio chi-square based on the estimated totals. The likelihood ratio chi-square is computed as

$$G^2 = 2\ \left(\ n\ /\ \widehat{N}\ \right)\ \sum_c \widehat{N}_c\ \ln\left(\widehat{N}_c\ /\ E_c\right)$$

where n is the sample size, $\widehat{N}$ is the estimated overall total, $\widehat{N}_c$ is the estimated total for level c, and E_c is the expected total for level c under the null hypothesis. For the null hypothesis of equal proportions, the expected total for each level equals

$$E_c = \widehat{N}\ /\ C$$

For specified null proportions, the expected total for level c equals

$$E_c = \widehat{N} \times {P_c}^0$$

where ${P_c}^0$ is the null proportion for level c.

Under the null hypothesis of no association, the Rao-Scott likelihood ratio chi-square G^2_{RS} approximately follows a chi-square distribution with $(C-1)$ degrees of freedom. A better approximation can be obtained by the F statistic,

$$F = G^2_{RS} \; / \; (C-1)$$

which has an F distribution with $(C-1)$ and $(C-1)\kappa$ degrees of freedom under the null hypothesis, The value κ is the degrees of freedom for the variance estimator and depends on the sample design and the variance estimation method. The section "Degrees of Freedom" on page 6340 describes the computation of κ.

Wald Chi-Square Test

PROC SURVEYFREQ provides two Wald chi-square tests for independence of the row and column variables in a two-way table: a Wald chi-square test based on the difference between observed and expected weighted cell frequencies, and a Wald log-linear chi-square test based on the log odds ratios. These statistics test for independence of the row and column variables in two-way tables, taking into account the complex survey design. See Bedrick (1983), Koch, Freeman, and Freeman (1975), and Wald (1943) for information about Wald statistics and their applications to categorical data analysis.

For these two tests, PROC SURVEYFREQ computes the generalized Wald chi-square statistic, the corresponding Wald F statistic, and also an adjusted Wald F statistic for tables larger than 2×2. Under the null hypothesis of independence, the Wald chi-square statistic approximately follows a chi-square distribution with $(R-1)(C-1)$ degrees of freedom for large samples. However, it has been shown that this test can perform poorly in terms of actual significance level and power, especially for tables with a large number of cells or for samples with a relatively small number of clusters. See Thomas and Rao (1984 and 1985) and Lohr (1999) for more information. See Felligi (1980) and Hidiroglou, Fuller, and Hickman (1980) for information about the adjusted Wald F statistic. Thomas and Rao (1984) found that the adjusted Wald F statistic provides a more stable test than the chi-square statistic, although its power can be low when the number of sample clusters is not large. See also Korn and Graubard (1990) and Thomas, Singh, and Roberts (1996).

If you specify the WCHISQ option in the TABLES statement, PROC SURVEYFREQ computes a Wald test for independence in the two-way table based on the differences between the observed (weighted) cell frequencies and the expected frequencies.

Under the null hypothesis of independence of the row and column variables, the expected cell frequencies are computed as

$$E_{rc} = \widehat{N}_{r\cdot} \, \widehat{N}_{\cdot c} \; / \; \widehat{N}$$

where $\widehat{N}_{r\cdot}$ is the estimated total for row r, $\widehat{N}_{\cdot c}$ is the estimated total for column c, and $\widehat{N}$ is the estimated overall total, as described in the section "Expected Weighted Frequency" on page 6342. The null hypothesis that the population weighted frequencies equal the expected frequencies can be expressed as

$$H_0 \colon Y_{rc} = N_{rc} \; - \; E_{rc} \; = \; 0$$

for all $r = 1, \ldots (R-1)$ and $c = 1, \ldots (C-1)$. This null hypothesis can be stated equivalently in terms of cell proportions, with the expected cell proportions computed as the products of the marginal row and column proportions.

The generalized Wald chi-square statistic Q_W is computed as

$$Q_W = \widehat{\mathbf{Y}}' \, (\mathbf{H} \, \widehat{\mathbf{V}}(\widehat{\mathbf{N}}) \, \mathbf{H}')^{-1} \, \widehat{\mathbf{Y}}$$

where $\widehat{\mathbf{Y}}$ is the $(R-1)(C-1)$ array of differences between the observed and expected weighted frequencies $(\widehat{N}_{rc} - E_{rc})$, and $(\mathbf{H} \, \widehat{\mathbf{V}}(\widehat{\mathbf{N}}) \, \mathbf{H}')$ estimates the variance of $\widehat{\mathbf{Y}}$.

$\widehat{\mathbf{V}}(\widehat{\mathbf{N}})$ is the covariance matrix of the estimates $\widehat{N}_{rc}$, and its computation is described in the section "Covariance of Totals" on page 6330.

$\mathbf{H}$ is an $(R-1)(C-1)$ by RC matrix containing the partial derivatives of the elements of $\widehat{\mathbf{Y}}$ with respect to the elements of $\widehat{\mathbf{N}}$. The elements of $\mathbf{H}$ are computed as follows, where a denotes a row different from row r, and b denotes a column different from column c:

$$\begin{aligned}
\partial \widehat{Y}_{rc} / \partial \widehat{N}_{rc} &= 1 - \left(\widehat{N}_{r\cdot} + \widehat{N}_{\cdot c} - \widehat{N}_{\cdot c} \, \widehat{N}_{r\cdot} \, / \, \widehat{N} \right) / \, \widehat{N} \\
\partial \widehat{Y}_{rc} / \partial \widehat{N}_{ac} &= - \left(\widehat{N}_{r\cdot} - \widehat{N}_{r\cdot} \, \widehat{N}_{\cdot c} \, / \, \widehat{N} \right) / \, \widehat{N} \\
\partial \widehat{Y}_{rc} / \partial \widehat{N}_{rb} &= - \left(\widehat{N}_{\cdot c} - \widehat{N}_{r\cdot} \, \widehat{N}_{\cdot c} \, / \, \widehat{N} \right) / \, \widehat{N} \\
\partial \widehat{Y}_{rc} / \partial \widehat{Y}_{ab} &= \widehat{N}_{r\cdot} \, \widehat{N}_{\cdot c} \, / \, \widehat{N}^{\,2}
\end{aligned}$$

Under the null hypothesis of independence, the statistic Q_W approximately follows a chi-square distribution with $(R-1)(C-1)$ degrees of freedom for large samples.

PROC SURVEYFREQ computes the Wald F statistic as

$$F_W = Q_W \, / \, (R-1)(C-1)$$

Under the null hypothesis of independence, F_W approximately follows an F distribution with $(R-1)(C-1)$ numerator degrees of freedom. The denominator degrees of freedom are the degrees of freedom for the variance estimator and depend on the sample design and the variance estimation method. The section "Degrees of Freedom" on page 6340 describes the computation of the denominator degrees of freedom. Alternatively, you can specify the denominator degrees of freedom with the DF= option in the TABLES statement.

For tables larger than 2×2, PROC SURVEYFREQ also computes the adjusted Wald F statistic as

$$F_{Adj_W} = \frac{s - k + 1}{k \, s} \, Q_W$$

where $k = (R-1)(C-1)$, and s is the degrees of freedom, which are computed as described in the section "Degrees of Freedom" on page 6340. Alternatively, you can specify the value of s with the DF= option in the TABLES statement. Note that for 2×2 tables, $k = (R-1)(C-1) = 1$, so the adjusted Wald F statistic equals the (unadjusted) Wald F statistic, with the same numerator and denominator degrees of freedom.

Under the null hypothesis, F_{Adj_W} approximately follows an F distribution with k numerator degrees of freedom and $(s - k + 1)$ denominator degrees of freedom.

Wald Log-Linear Chi-Square Test

If you specify the WLLCHISQ option in the TABLES statement, PROC SURVEYFREQ computes a Wald test for independence based on the log odds ratios. See the section "Wald Chi-Square Test" on page 6352 for more information about Wald tests.

For a two-way table of R rows and C columns, the Wald log-linear test is based on the $(R-1)(C-1)$ array of elements $\widehat{Y}_{rc}$,

$$\widehat{Y}_{rc} = log\widehat{N}_{rc} - log\widehat{N}_{rC} - log\widehat{N}_{Rc} + log\widehat{N}_{RC}$$

where $\widehat{N}_{rc}$ is the estimated total for table cell (r, c). The null hypothesis of independence between the row and column variables can be expressed as $H_0: Y_{rc} = 0$ for all $r = 1, \ldots (R-1)$ and $c = 1, \ldots (C-1)$. This null hypothesis can be stated equivalently in terms of cell proportions.

The generalized Wald log-linear chi-square statistic is computed as

$$Q_{WLL} = \widehat{\mathbf{Y}}' \, \widehat{\mathbf{V}}(\widehat{\mathbf{Y}})^{-1} \, \widehat{\mathbf{Y}}$$

where $\widehat{\mathbf{Y}}$ is the $(R-1)(C-1)$ array of the $\widehat{Y}_{rc}$, and $\widehat{\mathbf{V}}(\widehat{\mathbf{Y}})$ estimates the variance of $\widehat{\mathbf{Y}}$,

$$\widehat{\mathbf{V}}(\widehat{\mathbf{Y}}) = \mathbf{A} \, \mathbf{D}^{-1} \, \widehat{V}(\widehat{\mathbf{N}}) \, \mathbf{D}^{-1} \, \mathbf{A}'$$

where $\widehat{\mathbf{V}}(\widehat{\mathbf{N}})$ is the covariance matrix of the estimates $\widehat{N}_{rc}$, which is computed as described in the section "Covariance of Totals" on page 6330. $\mathbf{D}$ is a diagonal matrix with the estimated totals $\widehat{N}_{rc}$ on the diagonal, and $\mathbf{A}$ is the $(R-1)(C-1)$ by $RC \times RC$ linear contrast matrix.

Under the null hypothesis of independence, the statistic Q_{WLL} approximately follows a chi-square distribution with $(R-1)(C-1)$ degrees of freedom for large samples.

PROC SURVEYFREQ computes the Wald log-linear F statistic as

$$F_{WLL} = Q_{WLL} \; / \; (R-1)(C-1)$$

Under the null hypothesis of independence, F_{WLL} approximately follows an F distribution with $(R-1)(C-1)$ numerator degrees of freedom. PROC SURVEYFREQ computes the denominator degrees of freedom as described in the section "Degrees of Freedom" on page 6340. Alternatively, you can specify the denominator degrees of freedom with the DF= option in the TABLES statement.

For tables larger than 2×2, PROC SURVEYFREQ also computes the adjusted Wald log-linear F statistic as

$$F_{Adj_WLL} = \frac{s-k+1}{k \; s} \, Q_{WLL}$$

where $k = (R-1)(C-1)$, and s is the denominator degrees of freedom computed as described in the section "Degrees of Freedom" on page 6340. Alternatively, you can specify the value of s with the DF= option in the TABLES statement. Note that for 2×2 tables, $k = (R-1)(C-1) = 1$, so the adjusted Wald F statistic equals the (unadjusted) Wald F statistic, with the same numerator and denominator degrees of freedom.

Under the null hypothesis, F_{Adj_WLL} approximately follows an F distribution with k numerator degrees of freedom and $(s-k+1)$ denominator degrees of freedom.

Output Data Sets

You can use the Output Delivery System to create a SAS data set from any piece of PROC SURVEYFREQ output. See the section "ODS Table Names" on page 6362 for more information.

PROC SURVEYFREQ also provides an output data set that stores the replicate weights for BRR or jackknife variance estimation and an output data set that stores the jackknife coefficients for jackknife variance estimation.

Replicate Weights Output Data Set

If you specify the OUTWEIGHTS= method-option for VARMETHOD=BRR or JACKKNIFE, PROC SURVEYFREQ stores the replicate weights in an output data set. The OUTWEIGHTS= output data set contains all observations used in the analysis or all valid observations in the DATA= input data set. (A valid observation is an observation that has a positive value of the WEIGHT variable. Valid observations must also have nonmissing values of the STRATA and CLUSTER variables, unless you specify the MISSING option. See the section "Data Summary Table" on page 6356 for details about valid observations.)

The OUTWEIGHTS= data set contains the following variables:

- all variables in the DATA= input data set
- RepWt_1, RepWt_2, . . ., RepWt_n, which are the replicate weight variables

where *n* is the total number of replicates in the analysis. Each replicate weight variable contains the replicate weights for the corresponding replicate. Replicate weights equal zero for those observations not included in the replicate.

After the procedure creates replicate weights for a particular input data set and survey design, you can use the OUTWEIGHTS= method-option to store these replicate weights and then use them again in subsequent analyses, either in PROC SURVEYFREQ or in the other survey procedures. You can use a REPWEIGHTS statement to provide replicate weights for the procedure.

Jackknife Coefficients Output Data Set

If you specify the OUTJKCOEFS= method-option for VARMETHOD=JACKKNIFE, PROC SURVEYFREQ stores the jackknife coefficients in an output data set. The OUTJKCOEFS= output data set contains one observation for each replicate. The OUTJKCOEFS= data set contains the following variables:

- Replicate, which is the replicate number for the jackknife coefficient
- JKCoefficient, which is the jackknife coefficient
- DonorStratum, which is the stratum of the PSU that was deleted to construct the replicate, if you specify a STRATA statement

After the procedure creates jackknife coefficients for a particular input data set and survey design, you can use the OUTJKCOEFS= method-option to store these coefficients and then use them again in subsequent analyses, either in PROC SURVEYFREQ or in the other survey procedures. You can use the JKCOEFS= option in the REPWEIGHTS statement to provide jackknife coefficients for the procedure.

Displayed Output

Data Summary Table

The "Data Summary" table provides information about the input data set and the sample design. PROC SURVEYFREQ displays this table unless you specify the NOSUMMARY option in the PROC SURVEYFREQ statement.

The "Data Summary" table displays the total number of valid observations. To be considered *valid*, an observation must have a nonmissing, positive sampling weight value if you specify a WEIGHT statement. If you do not specify the MISSING option, a valid observation must also have nonmissing values for all STRATA and CLUSTER variables. The number of valid observations can differ from the number of nonmissing observations for an individual table request, which the procedure displays in the frequency or crosstabulation tables. See the section "Missing Values" on page 6323 for more information.

PROC SURVEYFREQ displays the following information in the "Data Summary" table:

- Number of Strata, if you specify a STRATA statement
- Number of Clusters, if you specify a CLUSTER statement
- Number of Observations, which is the total number of valid observations
- Sum of Weights, which is the sum over all valid observations, if you specify a WEIGHT or REPWEIGHTS statement

Stratum Information Table

If you specify the LIST option in the STRATA statement, PROC SURVEYFREQ displays a "Stratum Information" table. This table provides the following information for each stratum:

- Stratum Index, which is a sequential stratum identification number
- STRATA variable(s), which lists the levels of STRATA variables for the stratum
- Number of Observations, which is the number of valid observations in the stratum
- Population Total for the stratum, if you specify the TOTAL= option

- Sampling Rate for the stratum, if you specify the TOTAL= or RATE= option. If you specify the TOTAL= option, the sampling rate is based on the number of valid observations in the stratum.
- Number of Clusters, which is the number of clusters in the stratum, if you specify a CLUSTER statement

Variance Estimation Table

If you specify the VARMETHOD=BRR, VARMETHOD=JACKKNIFE, or NOMCAR option in the PROC SURVEYFREQ statement, the procedure displays a "Variance Estimation" table. If you do not specify any of these options, the procedure creates a "Variance Estimation" table but does not display it. You can store this nondisplayed table in an output data set by using the Output Delivery System (ODS). See the section "ODS Table Names" on page 6362 for more information.

The "Variance Estimation" table provides the following information:

- Method, which is the variance estimation method—Taylor Series, Balanced Repeated Replication, or Jackknife
- Replicate Weights input data set name, if you provide replicate weights with a REPWEIGHTS statement
- Number of Replicates, for VARMETHOD=BRR or VARMETHOD=JACKKNIFE
- Hadamard Data Set name, if you specify the HADAMARD= method-option for VARMETHOD=BRR
- Fay Coefficient, if you specify the FAY method-option for VARMETHOD=BRR
- Missing Levels Included (MISSING), if you specify the MISSING option
- Missing Levels Included (NOMCAR), if you specify the NOMCAR option

Hadamard Matrix

If you specify the PRINTH method-option for VARMETHOD=BRR, PROC SURVEYFREQ displays the Hadamard matrix used to construct replicates for BRR variance estimation. If you provide a Hadamard matrix with the HADAMARD= method-option for VARMETHOD=BRR but the procedure does not use the entire matrix, the procedure displays only the rows and columns that are actually used to construct replicates.

One-Way Frequency Tables

PROC SURVEYFREQ displays one-way frequency tables for all one-way table requests in the TABLES statements, unless you specify the NOPRINT option in the TABLES statement. A one-way table shows the sample frequency distribution of a single variable, and provides estimates for its population distribution in terms of totals and proportions.

If you request a one-way table without specifying options, PROC SURVEYFREQ displays the following information for each level of the variable:

- Frequency count, which is the number of sample observations in the level
- Weighted Frequency, which estimates the population total for the level
- Standard Deviation of Weighted Frequency
- Percent, which estimates the population proportion for the level
- Standard Error of Percent

The one-way table displays weighted frequencies if your analysis includes a WEIGHT or REPWEIGHTS statement, or if you specify the WTFREQ option in the TABLES statement.

The one-way table also displays the Frequency Missing, or the number of observations with missing values.

You can suppress the frequency counts by specifying the NOFREQ option in the TABLES statement. Also, the NOWT option suppresses the weighted frequencies and their standard deviations. The NOPERCENT option suppresses the percentages and their standard errors. The NOSTD option suppresses the standard errors of the percentages and the standard deviations of the weighted frequencies. The NOTOTAL option suppresses the total row of the one-way table.

PROC SURVEYFREQ optionally displays the following information in a one-way table:

- Variance of Weighted Frequency, if you specify the VARWT option
- Confidence Limits for Weighted Frequency, if you specify the CLWT option
- Coefficient of Variation for Weighted Frequency, if you specify the CVWT option
- Test Percent, if you specify the TESTP= option
- Variance of Percent, if you specify the VAR option
- Confidence Limits for Percent, if you specify the CL option
- Coefficient of Variation for Percent, if you specify the CV option
- Design Effect for Percent, if you specify the DEFF option

Crosstabulation Tables

PROC SURVEYFREQ displays all table requests in the TABLES statements, unless you specify the NOPRINT option in the TABLES statement. For two-way to multiway crosstabulation tables, the values of the last variable in the table request form the table columns. The values of the next-to-last variable form the rows. Each level (or combination of levels) of the other variables forms one layer. PROC SURVEYFREQ produces a separate two-way crosstabulation table for each layer of a multiway table.

For each layer, the crosstabulation table displays the row and column variable names and values (or levels). Each two-way table lists levels of the column variable within each level of the row variable.

By default, the procedure displays all levels of the column variable within each level of the row variables, including any column variable levels with zero frequency for that row. For multiway tables, the procedure displays all levels of the row variable for each layer of the table by default, including any row levels with zero frequency for that layer. You can suppress the display of zero frequency levels by specifying the NOSPARSE option.

If you request a crosstabulation table without specifying options, the table displays the following information for each combination of variable levels, or table cell:

- Frequency, which is the number of sample observations in the table cell
- Weighted Frequency, which estimates the population total for the table cell
- Standard Deviation of Weighted Frequency
- Percent, which estimates the population proportion for the table cell
- Standard Error of Percent

The two-way table displays weighted frequencies if your analysis includes a WEIGHT or REPWEIGHTS statement, or if you specify the WTFREQ option in the TABLES statement.

The two-way table also displays the Frequency Missing, or the number of observations with missing values.

You can suppress the frequency counts by specifying the NOFREQ option in the TABLES statement. Also, the NOWT option suppresses the weighted frequencies and their standard deviations. The NOPERCENT option suppresses all percentages and their standard errors. The NOCELLPERCENT option suppresses overall cell percentages and their standard errors, but displays any other percentages (and standard errors) that you request, such as row or column percentages. The NOSTD option suppresses the standard errors of the percentages and the standard deviations of the weighted frequencies. The NOTOTAL option suppresses the row totals and column totals, as well as the overall total.

PROC SURVEYFREQ optionally displays the following information in a two-way table:

- Expected Weighted Frequency, if you specify the EXPECTED option
- Variance of Weighted Frequency, if you specify the VARWT option
- Confidence Limits for Weighted Frequency, if you specify the CLWT option
- Coefficient of Variation for Weighted Frequency, if you specify the CVWT option
- Variance of Percent, if you specify the VAR option
- Confidence Limits for Percent, if you specify the CL option
- Coefficient of Variation for Percent, if you specify the CV option

- Design Effect for Percent, if you specify the DEFF option
- Row Percent, which estimates the population proportion of the row total, if you specify the ROW option
- Standard Error of Row Percent, if you specify the ROW option
- Variance of Row Percent, if you specify the VAR option and the ROW option
- Confidence Limits for Row Percent, if you specify the CL option and the ROW option
- Coefficient of Variation for Row Percent, if you specify the CV option and the ROW option
- Column Percent, which estimates the population proportion of the column total, if you specify the COL option
- Standard Error of Column Percent, if you specify the COL option
- Variance of Column Percent, if you specify the VAR option and the COL option
- Confidence Limits for Column Percent, if you specify the CL option and the COL option
- Coefficient of Variation for Column Percent, if you specify the CV option and the COL option

Statistical Tests

If you specify the CHISQ option for the Rao-Scott chi-square test, the CHISQ1 option for the modified test, the LRCHISQ option for the Rao-Scott likelihood ratio chi-square test, or the LRCHISQ1 option for the modified test, PROC SURVEYFREQ displays the following information:

- Pearson Chi-Square, if you specify the CHISQ or CHISQ1 option
- Likelihood Ratio Chi-Square, if you specify the LRCHISQ or LRCHISQ1 option
- Design Correction
- Rao-Scott Chi-Square, if you specify the CHISQ or CHISQ1 option
- Rao-Scott Likelihood Ratio Chi-Square, if you specify the LRCHISQ or LRCHISQ1 option
- DF, which is the degrees of freedom for the chi-square test
- Pr > ChiSq, which is the *p*-value for the chi-square test
- F Value
- Num DF, which is the numerator degrees of freedom for F
- Den DF, which is the denominator degrees of freedom for F
- Pr > F, which is the *p*-value for the *F* test

If you specify the WCHISQ option for the Wald chi-square test or the WLLCHISQ option for the Wald log-linear chi-square test, PROC SURVEYFREQ displays the following information:

- Wald Chi-Square, if you specify the WCHISQ option
- Wald Log-Linear Chi-Square, if you specify the WLLCHISQ option
- F Value
- Num DF, which is the numerator degrees of freedom for F
- Den DF, which is the denominator degrees of freedom for F
- Pr > F, which is the *p*-value for the *F* test
- Adjusted F Value, for tables larger than 2×2
- Num DF, which is the numerator degrees of freedom for Adjusted F
- Den DF, which is the denominator degrees of freedom for Adjusted F
- Pr > Adj F, which is the *p*-value for the Adjusted *F* test

Risks and Risk Difference

If you specify the RISK option in the TABLES statement for a 2×2 table, PROC SURVEYFREQ displays "Column 1 Risk Estimates" and "Column 2 Risk Estimates" tables. You can display only column 1 or column 2 risks by specifying the RISK1 or RISK2 option, respectively.

The "Risk Estimates" table displays the following information for Row 1, Row 2, Total, and Difference:

- Row, which identifies the risk as Row 1, Row 2, Total, or Difference
- Risk estimate
- Standard Error
- Confidence Limits

In the "Column 1 Risk Estimates" table, the row 1 risk is the column 1 percentage of row 1. The row 2 risk is the column 1 percentage of row 2, and the total risk is the column 1 percentage of the entire table. The risk difference is the row 1 risk minus the row 2 risk. In the "Column 2 Risk Estimates" table, these computations are based on column 2.

Odds Ratio and Relative Risks

If you specify the OR option in the TABLES statement for a 2×2 table, PROC SURVEYFREQ displays the "Odds Ratio" table. This table includes the following information:

- Statistic, which identifies the statistic as the Odds Ratio, the Column 1 Relative Risk, or the Column 2 Relative Risk
- Estimate
- Confidence Limits

ODS Table Names

PROC SURVEYFREQ assigns a name to each table it creates. You can use these names to reference tables when using the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, "Using the Output Delivery System." Table 83.4 lists the table names, along with the corresponding analysis options.

Table 83.4 ODS Tables Produced by PROC SURVEYFREQ

ODS Table Name	Description	Statement	Option
ChiSq	Chi-square test	TABLES	CHISQ
ChiSq1	Modified chi-square test	TABLES	CHISQ1
CrossTabs	Crosstabulation table	TABLES	(n-way table, $n > 1$)
HadamardMatrix	Hadamard matrix	PROC	VARMETHOD=BRR(PRINTH)
LRChiSq	Likelihood ratio test	TABLES	LRCHISQ
LRChiSq1	Modified likelihood ratio test	TABLES	LRCHISQ1
OddsRatio	Odds ratio and relative risks	TABLES	OR (2×2 table)
OneWay	One-way frequency table	PROC	(with no TABLES stmt)
		or TABLES	(one-way table)
Risk1	Column 1 risk estimates	TABLES	RISK or RISK1 (2×2 table)
Risk2	Column 2 risk estimates	TABLES	RISK or RISK2 (2×2 table)
StrataInfo	Stratum information	STRATA	LIST
Summary	Data summary	PROC	default
TableSummary	Table summary (not displayed)	TABLES	default
VarianceEstimation	Variance estimation	PROC	VARMETHOD=JK | BRR
			or NOMCAR
WChiSq	Wald chi-square test	TABLES	WCHISQ (two-way table)
WLLChiSq	Wald log-linear chi-square test	TABLES	WLLCHISQ (two-way table)

Examples: SURVEYFREQ Procedure

Example 83.1: Two-Way Tables

This example uses the SIS_Survey data set from the section "Getting Started: SURVEYFREQ Procedure" on page 6294. The data set contains results from a customer satisfaction survey for a student information system (SIS).

The following PROC SURVEYFREQ statements request a two-way table for Department by Response and customize the crosstabulation table display:

```
proc surveyfreq data=SIS_Survey;
   tables  Department * Response / cv deff nowt nostd nototal;
   strata  State NewUser / list;
   cluster School;
   weight  SamplingWeight;
run;
```

The TABLES statement requests a two-way table of Department by Response. The CV option requests coefficients of variation for the percentage estimates. The DEFF option requests design effects for the percentage estimates. The NOWT option suppresses display of the weighted frequencies, and the NOSTD option suppresses display of standard errors for the estimates. The NOTOTAL option suppresses the row totals, column totals, and overall totals.

The STRATA, CLUSTER, and WEIGHT statements provide sample design information for the procedure, so that the analysis is done according to the sample design used for the survey. The STRATA statement names the variables State and NewUser, which identify the first-stage strata. The LIST option in the STRATA statement requests a "Stratum Information" table. The CLUSTER statement names the variable School, which identifies the clusters or primary sampling units (PSUs). The WEIGHT statement names the sampling weight variable.

Output 83.1.1 displays the "Data Summary" and "Stratum Information" tables produced by PROC SURVEYFREQ. The "Stratum Information" table lists the six strata in the survey and shows the number of observations and the number of clusters, or schools, in each stratum.

Output 83.1.1 Data Summary and Stratum Information

Student Information System Survey

The SURVEYFREQ Procedure

Data Summary

Number of Strata	6
Number of Clusters	370
Number of Observations	1850
Sum of Weights	38899.6482

Stratum Information

Stratum Index	State	NewUser	Number of Obs	Number of Clusters
1	GA	Renewal Customer	315	63
2	GA	New Customer	355	71
3	NC	Renewal Customer	280	56
4	NC	New Customer	420	84
5	SC	Renewal Customer	210	42
6	SC	New Customer	270	54

Output 83.1.2 displays the two-way table of Department by Response. According to the TABLES statement options specified, this two-way table includes coefficients of variation and design effects for the percentage estimates, and it does not show the weighted frequencies or the standard errors of the estimates. It also does not show the row, column, and overall totals.

Output 83.1.2 Two-Way Table of Department by Response

Table of Department by Response

Department	Response	Frequency	Percent	CV for Percent	Design Effect
Faculty	Very Unsatisfied	209	13.4987	0.0865	2.1586
	Unsatisfied	203	13.0710	0.0868	2.0962
	Neutral	346	22.4127	0.0629	2.1157
	Satisfied	254	16.2006	0.0806	2.3232
	Very Satisfied	98	6.2467	0.1362	2.2842
Admin/Guidance	Very Unsatisfied	95	3.6690	0.1277	1.1477
	Unsatisfied	123	4.6854	0.1060	1.0211
	Neutral	235	9.1838	0.0700	0.9166
	Satisfied	201	7.7305	0.0756	0.8848
	Very Satisfied	86	3.3016	0.1252	0.9892

The following PROC SURVEYFREQ statements request a two-way table of Department by Response that includes row percentages, and also a Wald chi-square test of association between the two table variables:

```
proc surveyfreq data=SIS_Survey nosummary;
   tables Department * Response / row nowt wchisq;
   strata State NewUser;
   cluster School;
   weight SamplingWeight;
run;
```

Output 83.1.3 displays the two-way table. The row percentages show the distribution of Response for Department = 'Faculty' and for Department = 'Admin/Guidance'. This is equivalent to a domain or subpopulation analysis of Response, where the domains are Department = 'Faculty' and Department = 'Admin/Guidance'.

Output 83.1.4 displays the Wald chi-square test of association between Department and Response. The Wald chi-square is 11.44, and the corresponding adjusted F value is 2.84 with a p-value of 0.0243. This indicates a significant association between department (faculty or admin/guidance) and satisfaction with the student information system.

Output 83.1.3 Table of Department by Response with Row Percentages

Example 83.2: Multiway Tables (Domain Analysis)

Continuing to use the SIS_Survey data set from the section "Getting Started: SURVEYFREQ Procedure" on page 6294, this example shows how to produce multiway tables. The following PROC SURVEYFREQ statements request a table of Department by SchoolType by Response for the student information system survey:

```
proc surveyfreq data=SIS_Survey;
   tables  Department * SchoolType * Response
           SchoolType * Response;
   strata  State NewUser;
   cluster School;
   weight  SamplingWeight;
run;
```

The TABLES statement requests a multiway table with SchoolType as the row variable, Response as the column variable, and Department as the layer variable. This request produces a separate two-way table of SchoolType by Response for each level of the variable Department. The TABLES statement also requests a two-way table of SchoolType by Response, which totals the multiway table over both levels of Department. As in the previous examples, the STRATA, CLUSTER, and WEIGHT statements provide sample design information, so that the analysis will be done according to the design used for this survey.

Output 83.2.1 displays the multiway table produced by PROC SURVEYFREQ, which includes a table of SchoolType by Response for Department = 'Faculty' and for Department = 'Admin/Guidance'. This is equivalent to a domain or subpopulation analysis of SchoolType by Response, where the domains are Department = 'Faculty' and Department = 'Admin/Guidance'.

Output 83.2.1 Multiway Table of Department by SchoolType by Response

Student Information System Survey

Example 83.3: Output Data Sets

PROC SURVEYFREQ uses the Output Delivery System (ODS) to create output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality. By using ODS, you can create a SAS data set from any piece of PROC SURVEYFREQ output. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

When selecting tables for ODS output data sets, you reference tables by their ODS table names. Each table created by PROC SURVEYFREQ is assigned a name. See the section "ODS Table Names" on page 6362 for a list of the table names provided by PROC SURVEYFREQ.

To save the one-way table of Response from Figure 83.3 in an output data set, use an ODS OUTPUT statement as follows:

```
proc surveyfreq data=SIS_Survey;
   tables  Response / cl nowt;
   ods output OneWay=ResponseTable;
   strata  State NewUser;
   cluster School;
   weight  SamplingWeight;
run;
```

Output 83.3.1 displays the output data set ResponseTable, which contains the one-way table of Response. This data set has six observations, and each of these observations corresponds to a row of the one-way table. The first five observations correspond to the five levels of Response, as they are ordered in the one-way table display, and the last observation corresponds to the overall total, which is the last row of the one-way table. The data set ResponseTable includes a variable corresponding to each column of the one-way table. For example, the variable Percent contains the percentage estimates, and the variables LowerCL and UpperCL contain the lower and upper confidence limits for the percentage estimates.

Output 83.3.1 ResponseTable Output Data Set

Obs	Table	Response	Frequency	Percent	StdErr	LowerCL	UpperCL
1	Table Response	Very Unsatisfied	304	17.1676	1.2872	14.6364	19.6989
2	Table Response	Unsatisfied	326	17.7564	1.2712	15.2566	20.2562
3	Table Response	Neutral	581	31.5965	1.5795	28.4904	34.7026
4	Table Response	Satisfied	455	23.9311	1.4761	21.0285	26.8338
5	Table Response	Very Satisfied	184	9.5483	0.9523	7.6756	11.4210
6	Table Response	.	1850	100.000	_	_	_

PROC SURVEYFREQ also creates a table summary that is not displayed. Some of the information in this table is similar to that contained in the "Data Summary" table, but the table summary describes the data used to analyze the specified table, while the data summary describes the entire input data set. Due to missing values, for example, the number of observations (or strata or clusters) used to analyze a particular table can differ from the number of observations (or strata or clusters) reported for the input data set in the "Data Summary" table. See the section "Missing Values" on page 6323 for more details. If you request confidence limits, the "Table Summary" table also contains the degrees of freedom and the t-value used to compute the confidence limits.

The following statements store the nondisplayed "Table Summary" table in the output data set ResponseSummary:

```
proc surveyfreq data=SIS_Survey;
   tables  Response / cl nowt;
   ods output TableSummary=ResponseSummary;
   strata  State NewUser;
   cluster School;
   weight  SamplingWeight;
run;
```

Output 83.3.2 displays the output data set ResponseSummary.

Output 83.3.2 ResponseSummary Output Data Set

Overview: SURVEYLOGISTIC Procedure

Categorical responses arise extensively in sample survey. Common examples of responses include the following:

- binary: for example, attended graduate school or not
- ordinal: for example, mild, moderate, and severe pain
- nominal: for example, ABC, NBC, CBS, FOX TV network viewed at a certain hour

Logistic regression analysis is often used to investigate the relationship between such discrete responses and a set of explanatory variables. See Binder (1981, 1983); Roberts, Rao, and Kumar (1987); Skinner, Holt, and Smith (1989); Morel (1989); and Lehtonen and Pahkinen (1995) for description of logistic regression for sample survey data.

For binary response models, the response of a sampling unit can take a specified value or not (for example, attended graduate school or not). Suppose $\mathbf{x}$ is a row vector of explanatory variables and π is the response probability to be modeled. The linear logistic model has the form

$$\text{logit}(\pi) \equiv \log\left(\frac{\pi}{1-\pi}\right) = \alpha + \mathbf{x}\boldsymbol{\beta}$$

where α is the intercept parameter and $\boldsymbol{\beta}$ is the vector of slope parameters.

The logistic model shares a common feature with the more general class of generalized linear models—namely, that a function $g = g(\mu)$ of the expected value, μ, of the response variable is assumed to be linearly related to the explanatory variables. Since μ implicitly depends on the stochastic behavior of the response, and since the explanatory variables are assumed to be fixed, the function g provides the link between the random (stochastic) component and the systematic (deterministic) component of the response variable. For this reason, Nelder and Wedderburn (1972) refer to $g(\cdot)$ as a link function. One advantage of the logit function over other link functions is that differences on the logistic scale are interpretable regardless of whether the data are sampled prospectively or retrospectively (McCullagh and Nelder 1989, Chapter 4). Other link functions that are widely

used in practice are the probit function and the complementary log-log function. The SURVEYLOGISTIC procedure enables you to choose one of these link functions, resulting in fitting a broad class of binary response models of the form

$$g(\pi) = \alpha + \mathbf{x}\boldsymbol{\beta}$$

For ordinal response models, the response Y of an individual or an experimental unit might be restricted to one of a usually small number of ordinal values, denoted for convenience by $1, \ldots, D, D+1$ ($D \geq 1$). For example, pain severity can be classified into three response categories as 1=mild, 2=moderate, and 3=severe. The SURVEYLOGISTIC procedure fits a common slopes cumulative model, which is a parallel lines regression model based on the cumulative probabilities of the response categories rather than on their individual probabilities. The cumulative model has the form

$$g(\Pr(Y \leq d \mid \mathbf{x})) = \alpha_d + \mathbf{x}\boldsymbol{\beta}, \quad 1 \leq d \leq D$$

where $\alpha_1, \ldots, \alpha_k$ are k intercept parameters and $\boldsymbol{\beta}$ is the vector of slope parameters. This model has been considered by many researchers. Aitchison and Silvey (1957) and Ashford (1959) employ a probit scale and provide a maximum likelihood analysis; Walker and Duncan (1967) and Cox and Snell (1989) discuss the use of the log-odds scale. For the log-odds scale, the cumulative logit model is often referred to as the *proportional odds* model.

For nominal response logistic models, where the $D+1$ possible responses have no natural ordering, the logit model can also be extended to a *generalized logit* model, which has the form

$$\log\left(\frac{\Pr(Y = i \mid \mathbf{x})}{\Pr(Y = D+1 \mid \mathbf{x})}\right) = \alpha_i + \mathbf{x}\boldsymbol{\beta}_i, \quad i = 1, \ldots, D$$

where the $\alpha_1, \ldots, \alpha_D$ are D intercept parameters and the $\boldsymbol{\beta}_1, \ldots, \boldsymbol{\beta}_D$ are D vectors of parameters. These models were introduced by McFadden (1974) as the *discrete choice* model, and they are also known as *multinomial* models.

The SURVEYLOGISTIC procedure fits linear logistic regression models for discrete response survey data by the method of maximum likelihood. For statistical inferences, PROC SURVEYLOGISTIC incorporates complex survey sample designs, including designs with stratification, clustering, and unequal weighting.

The maximum likelihood estimation is carried out with either the Fisher scoring algorithm or the Newton-Raphson algorithm. You can specify starting values for the parameter estimates. The logit link function in the ordinal logistic regression models can be replaced by the probit function or the complementary log-log function.

Odds ratio estimates are displayed along with parameter estimates. You can also specify the change in the explanatory variables for which odds ratio estimates are desired.

Variances of the regression parameters and odds ratios are computed by using either the Taylor series (linearization) method or replication (resampling) methods to estimate sampling errors of estimators based on complex sample designs (Binder 1983; Särndal, Swensson, and Wretman 1992, Wolter 1985; Rao, Wu, and Yue 1992).

The SURVEYLOGISTIC procedure enables you to specify categorical variables (also known as CLASS variables) as explanatory variables. It also enables you to specify interaction terms in the same way as in the LOGISTIC procedure.

Like many procedures in SAS/STAT software that allow the specification of CLASS variables, the SURVEYLOGISTIC procedure provides a CONTRAST statement for specifying customized hypothesis tests concerning the model parameters. The CONTRAST statement also provides estimation of individual rows of contrasts, which is particularly useful for obtaining odds ratio estimates for various levels of the CLASS variables.

Getting Started: SURVEYLOGISTIC Procedure

The SURVEYLOGISTIC procedure is similar to the LOGISTIC procedure and other regression procedures in the SAS System. See Chapter 51, "The LOGISTIC Procedure," for general information about how to perform logistic regression by using SAS. PROC SURVEYLOGISTIC is designed to handle sample survey data, and thus it incorporates the sample design information into the analysis.

The following example illustrates how to use PROC SURVEYLOGISTIC to perform logistic regression for sample survey data.

In the customer satisfaction survey example in the section "Getting Started: SURVEYSELECT Procedure" on page 6615 of Chapter 87, "The SURVEYSELECT Procedure," an Internet service provider conducts a customer satisfaction survey. The survey population consists of the company's current subscribers from four states: Alabama (AL), Florida (FL), Georgia (GA), and South Carolina (SC). The company plans to select a sample of customers from this population, interview the selected customers and ask their opinions on customer service, and then make inferences about the entire population of subscribers from the sample data. A stratified sample is selected by using the probability proportional to size (PPS) method. The sample design divides the customers into strata depending on their types ('Old' or 'New') and their states (AL, FL, GA, SC). There are eight strata in all. Within each stratum, customers are selected and interviewed by using the PPS with replacement method, where the size variable is Usage. The stratified PPS sample contains 192 customers. The data are stored in the SAS data set SampleStrata. Figure 84.1 displays the first 10 observations of this data set.

Figure 84.1 Stratified PPS Sample (First 10 Observations)

Customer Satisfaction Survey
Stratified PPS Sampling
(First 10 Observations)

Obs	State	Type	Customer ID	Rating	Usage	Sampling Weight
1	AL	New	2178037	Unsatisfied	23.53	14.7473
2	AL	New	75375074	Unsatisfied	99.11	3.5012
3	AL	New	116722913	Satisfied	31.11	11.1546
4	AL	New	133059995	Neutral	52.70	19.7542
5	AL	New	216784622	Satisfied	8.86	39.1613
6	AL	New	225046040	Neutral	8.32	41.6960
7	AL	New	238463776	Satisfied	4.63	74.9483
8	AL	New	255918199	Unsatisfied	10.05	34.5405
9	AL	New	395767821	Extremely Unsatisfied	33.14	10.4719
10	AL	New	409095328	Satisfied	10.67	32.5295

In the SAS data set SampleStrata, the variable CustomerID uniquely identifies each customer. The variable State contains the state of the customer's address. The variable Type equals 'Old' if the customer has subscribed to the service for more than one year; otherwise, the variable Type equals 'New'. The variable Usage contains the customer's average monthly service usage, in hours. The variable Rating contains the customer's responses to the survey. The sample design uses an unequal probability sampling method, with the sampling weights stored in the variable SamplingWeight.

The following SAS statements fit a cumulative logistic model between the satisfaction levels and the Internet usage by using the stratified PPS sample.

```
title 'Customer Satisfaction Survey';
proc surveylogistic data=SampleStrata;
strata state type/list;
model Rating (order=internal) = Usage;
weight SamplingWeight;
run;
```

The PROC SURVEYLOGISTIC statement invokes the SURVEYLOGISTIC procedure. The STRATA statement specifies the stratification variables State and Type that are used in the sample design. The LIST option requests a summary of the stratification. In the MODEL statement, Rating is the response variable and Usage is the explanatory variable. The ORDER=internal is used for the response variable Rating to ask the procedure to order the response levels by using the internal numerical value (1–5) instead of the formatted character value. The WEIGHT statement specifies the variable SamplingWeight that contains the sampling weights.

The results of this analysis are shown in the following figures.

Figure 84.2 Stratified PPS Sample, Model Information

Customer Satisfaction Survey

The SURVEYLOGISTIC Procedure

Model Information

Data Set	WORK.SAMPLESTRATA	
Response Variable	Rating	
Number of Response Levels	5	
Stratum Variables	State	
	Type	
Number of Strata	8	
Weight Variable	SamplingWeight	Sampling Weight
Model	Cumulative Logit	
Optimization Technique	Fisher's Scoring	
Variance Adjustment	Degrees of Freedom (DF)	

PROC SURVEYLOGISTIC first lists the following model fitting information and sample design information in Figure 84.2:

- The link function is the logit of the cumulative of the lower response categories.
- The Fisher scoring optimization technique is used to obtain the maximum likelihood estimates for the regression coefficients.
- The response variable is Rating, which has five response levels.
- The stratification variables are State and Type.
- There are eight strata in the sample.
- The weight variable is SamplingWeight.
- The variance adjustment method used for the regression coefficients is the default degrees of freedom adjustment.

Figure 84.3 lists the number of observations in the data set and the number of observations used in the analysis. Since there is no missing value in this example, observations in the entire data set are used in the analysis. The sums of weights are also reported in this table.

Figure 84.3 Stratified PPS Sample, Number of Observations

Number of Observations Read	192
Number of Observations Used	192
Sum of Weights Read	13262.74
Sum of Weights Used	13262.74

The "Response Profile" table in Figure 84.4 lists the five response levels, their ordered values, and

their total frequencies and total weights for each category. Due to the ORDER=INTERNAL option for the response variable Rating, the category "Extremely Unsatisfied" has the Ordered Value 1, the category "Unsatisfied" has the Ordered Value 2, and so on.

Figure 84.4 Stratified PPS Sample, Response Profile

Response Profile

Ordered Value	Rating	Total Frequency	Total Weight
1	Extremely Unsatisfied	52	2067.1092
2	Unsatisfied	47	2148.7127
3	Neutral	47	3649.4869
4	Satisfied	38	2533.5379
5	Extremely Satisfied	8	2863.8888

Probabilities modeled are cumulated over the lower Ordered Values.

Figure 84.5 displays the output of the stratification summary. There are a total of eight strata, and each stratum is defined by the customer types within each state. The table also shows the number of customers within each stratum.

Figure 84.5 Stratified PPS Sample, Stratification Summary

Stratum Information

Stratum Index	State	Type	N Obs
1	AL	New	22
2		Old	24
3	FL	New	25
4		Old	22
5	GA	New	25
6		Old	25
7	SC	New	24
8		Old	25

Figure 84.6 shows the chi-square test for testing the proportional odds assumption. The test is highly significant, which indicates that the cumulative logit model might not adequately fit the data.

Figure 84.6 Stratified PPS Sample, Testing the Proportional Odds Assumption

Score Test for the Proportional Odds Assumption

Chi-Square	DF	Pr > ChiSq
911.1244	3	<.0001

Figure 84.7 shows the iteration algorithm converged to obtain the MLE for this example. The "Model Fit Statistics" table contains the Akaike information criterion (AIC), the Schwarz criterion (SC), and the negative of twice the log likelihood ($-2 \log L$) for the intercept-only model and the fitted model. AIC and SC can be used to compare different models, and the ones with smaller values are preferred.

Figure 84.7 Stratified PPS Sample, Model Fitting Information

Model Convergence Status

Convergence criterion (GCONV=1E-8) satisfied.

Model Fit Statistics

Criterion	Intercept Only	Intercept and Covariates
AIC	42099.954	41378.851
SC	42112.984	41395.139
-2 Log L	42091.954	41368.851

The table "Testing Global Null Hypothesis: BETA=0" in Figure 84.8 shows the likelihood ratio test, the efficient score test, and the Wald test for testing the significance of the explanatory variable (Usage). All tests are significant.

Figure 84.8 Stratified PPS Sample

Testing Global Null Hypothesis: BETA=0

Test	Chi-Square	DF	Pr > ChiSq
Likelihood Ratio	723.1023	1	<.0001
Score	465.4939	1	<.0001
Wald	4.5212	1	0.0335

Figure 84.9 shows the parameter estimates of the logistic regression and their standard errors.

Figure 84.9 Stratified PPS Sample, Parameter Estimates

Analysis of Maximum Likelihood Estimates

Parameter	DF	Estimate	Standard Error	Wald Chi-Square	Pr > ChiSq
Intercept Extremely Unsatisfied	1	-2.0168	0.3988	25.5769	<.0001
Intercept Unsatisfied	1	-1.0527	0.3543	8.8292	0.0030

Syntax: SURVEYLOGISTIC Procedure

The following statements are available in PROC SURVEYLOGISTIC:

PROC SURVEYLOGISTIC < *options* > ;
BY *variables* ;
CLASS *variable* < *(v-options)* > < *variable* < *(v-options)* > ... > < / *v-options* > ;
CLUSTER *variables* ;
CONTRAST *'label'* *effect values* < *,... effect values* > < / *options* > ;
DOMAIN *variables* < *variable*∗*variable variable*∗*variable*∗*variable ...* > ;
FREQ *variable* ;
MODEL *events/trials* = < *effects* < / *options* > > ;
MODEL *variable* < *(v-options)* > = < *effects* > < / *options* > ;
OUTPUT < **OUT=***SAS-data-set* > < *options* > ;
REPWEIGHTS *variables* < / *options* > ;
STRATA *variables* < / *option* > ;
< *label:* > **TEST** *equation1* < , ... , *equationk* > < / *options* > ;
UNITS *independent1* = *list1* < ... *independentk* = *listk* > < / *options* > ;
WEIGHT *variable* < / *option* > ;

The PROC SURVEYLOGISTIC and MODEL statements are required. The CLASS, CLUSTER, STRATA, and CONTRAST statements can appear multiple times. You should use only one MODEL statement and one WEIGHT statement. The CLASS statement (if used) must precede the MODEL statement, and the CONTRAST statement (if used) must follow the MODEL statement.

The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC SURVEYLOGISTIC statement. The remaining statements are covered in alphabetical order.

PROC SURVEYLOGISTIC Statement

PROC SURVEYLOGISTIC < *options* > **;**

The PROC SURVEYLOGISTIC statement invokes the SURVEYLOGISTIC procedure and optionally identifies input data sets, controls the ordering of the response levels, and specifies the variance estimation method. The PROC SURVEYLOGISTIC statement is required.

ALPHA=*value*

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of α produces $100(1-\alpha)\%$ confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

DATA=*SAS-data-set*

names the SAS data set containing the data to be analyzed. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

INEST=*SAS-data-set*

names the SAS data set that contains initial estimates for all the parameters in the model. BY-group processing is allowed in setting up the INEST= data set. See the section "INEST= Data Set" on page 6421 for more information.

MISSING

treats missing values as a valid (nonmissing) category for all categorical variables, which include CLASS, STRATA, CLUSTER, and DOMAIN variables.

By default, if you do not specify the MISSING option, an observation is excluded from the analysis if it has a missing value. For more information, see the section "Missing Values" on page 6410.

NAMELEN=*n*

specifies the length of effect names in tables and output data sets to be n characters, where n is a value between 20 and 200. The default length is 20 characters.

NOMCAR

requests that the procedure treat missing values in the variance computation as *not missing completely at random* (NOMCAR) for Taylor series variance estimation. When you specify the NOMCAR option, PROC SURVEYLOGISTIC computes variance estimates by analyzing the nonmissing values as a domain or subpopulation, where the entire population includes both nonmissing and missing domains. See the section "Missing Values" on page 6410 for more details.

By default, PROC SURVEYLOGISTIC completely excludes an observation from analysis if that observation has a missing value, unless you specify the MISSING option. Note that the NOMCAR option has no effect on a classification variable when you specify the MISSING option, which treats missing values as a valid nonmissing level.

The NOMCAR option applies only to Taylor series variance estimation. The replication methods, which you request with the VARMETHOD=BRR and VARMETHOD=JACKKNIFE options, do not use the NOMCAR option.

NOSORT

suppresses the internal sorting process to shorten the computation time if the data set is presorted by the STRATA and CLUSTER variables. By default, the procedure sorts the data by the STRATA variables if you use the STRATA statement; then the procedure sorts the data by the CLUSTER variables within strata. If your data are already stored by the order of STRATA and CLUSTER variables, then you can specify this option to omit this sorting process to reduce the usage of computing resources, especially when your data set is very large. However, if you specify this NOSORT option while your data are not presorted by STRATA and CLUSTER variables, then any changes in these variables creates a new stratum or cluster.

RATE=*value* | *SAS-data-set*

R=*value* | *SAS-data-set*

specifies the sampling rate as a nonnegative *value*, or specifies an input data set that contains the stratum sampling rates. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the RATE= option for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option.

If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of PSUs selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative *value* for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section "Specification of Population Totals and Sampling Rates" on page 6422 for more details.

The *value* in the RATE= option or the values of _RATE_ in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYLOGISTIC converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you do not specify the TOTAL= or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= and RATE= options.

TOTAL=*value* | *SAS-data-set*

N=*value* | *SAS-data-set*

specifies the total number of primary sampling units in the study population as a positive *value*, or specifies an input data set that contains the stratum population totals. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the TOTAL= option for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option. If your sample

design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section "Specification of Population Totals and Sampling Rates" on page 6422 for more details.

If you do not specify the TOTAL= or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= and RATE= options.

VARMETHOD=BRR <(*method-options*)>

VARMETHOD=JACKKNIFE | JK <(*method-options*)>

VARMETHOD=TAYLOR

specifies the variance estimation method. VARMETHOD=TAYLOR requests the Taylor series method, which is the default if you do not specify the VARMETHOD= option or the REPWEIGHTS statement. VARMETHOD=BRR requests variance estimation by balanced repeated replication (BRR), and VARMETHOD=JACKKNIFE requests variance estimation by the delete-1 jackknife method.

For VARMETHOD=BRR and VARMETHOD=JACKKNIFE you can specify *method-options* in parentheses. Table 84.1 summarizes the available *method-options*.

Table 84.1 Variance Estimation Method-Options

Keyword	Method	(*Method-Options*)
BRR	Balanced repeated replication	FAY <=*value*> HADAMARD | H=*SAS-data-set* OUTWEIGHTS=*SAS-data-set* PRINTH REPS=*number*
JACKKNIFE | JK	Jackknife	OUTJKCOEFS=*SAS-data-set* OUTWEIGHTS=*SAS-data-set*
TAYLOR	Taylor series	

Method-options must be enclosed in parentheses following the method keyword. For example:

```
varmethod=BRR(reps=60 outweights=myReplicateWeights)
```

The following values are available for the VARMETHOD= option:

BRR <(*method-options*)> requests balanced repeated replication (BRR) variance estimation. The BRR method requires a stratified sample design with two primary sampling units (PSUs) per stratum. See the section "Balanced Repeated Replication (BRR) Method" on page 6429 for more information.

You can specify the following *method-options* in parentheses following VARMETHOD=BRR.

FAY <=*value***>**

requests Fay's method, a modification of the BRR method, for variance estimation. See the section "Fay's BRR Method" on page 6430 for more information.

You can specify the *value* of the Fay coefficient, which is used in converting the original sampling weights to replicate weights. The Fay coefficient must be a nonnegative number less than 1. By default, the value of the Fay coefficient equals 0.5.

HADAMARD=*SAS-data-set*

H=*SAS-data-set*

names a SAS data set that contains the Hadamard matrix for BRR replicate construction. If you do not provide a Hadamard matrix with the HADAMARD= method-option, PROC SURVEYLOGISTIC generates an appropriate Hadamard matrix for replicate construction. See the sections "Balanced Repeated Replication (BRR) Method" on page 6429 and "Hadamard Matrix" on page 6432 for details.

If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the HADAMARD=*SAS-data-set* method-option.

In the HADAMARD= input data set, each variable corresponds to a column of the Hadamard matrix, and each observation corresponds to a row of the matrix. You can use any variable names in the HADAMARD= data set. All values in the data set must equal either 1 or -1. You must ensure that the matrix you provide is indeed a Hadamard matrix—that is, $\mathbf{A}'\mathbf{A} = R\mathbf{I}$, where $\mathbf{A}$ is the Hadamard matrix of dimension R and $\mathbf{I}$ is an identity matrix. PROC SURVEYLOGISTIC does not check the validity of the Hadamard matrix that you provide.

The HADAMARD= input data set must contain at least H variables, where H denotes the number of first-stage strata in your design. If the data set contains more than H variables, the procedure uses only the first H variables. Similarly, the HADAMARD= input data set must contain at least H observations.

If you do not specify the REPS= method-option, then the number of replicates is taken to be the number of observations in the HADAMARD= input data set. If you specify the number of replicates—for example, REPS=*nreps*—then the first *nreps* observations in the HADAMARD= data set are used to construct the replicates.

You can specify the PRINTH option to display the Hadamard matrix that the procedure uses to construct replicates for BRR.

OUTWEIGHTS=*SAS-data-set*

names a SAS data set that contains replicate weights. See the section "Balanced Repeated Replication (BRR) Method" on page 6429 for information about replicate weights. See the section "Replicate Weights Output Data Set" on page 6440 for more details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= method-option is not available when you provide replicate weights with the REPWEIGHTS statement.

PRINTH

displays the Hadamard matrix.

When you provide your own Hadamard matrix with the HADAMARD= method-option, only the rows and columns of the Hadamard matrix that are used by the procedure are displayed. See the sections "Balanced Repeated Replication (BRR) Method" on page 6429 and "Hadamard Matrix" on page 6432 for details.

The PRINTH method-option is not available when you provide replicate weights with the REPWEIGHTS statement because the procedure does not use a Hadamard matrix in this case.

REPS=*number*

specifies the number of replicates for BRR variance estimation. The value of *number* must be an integer greater than 1.

If you do not provide a Hadamard matrix with the HADAMARD= method-option, the number of replicates should be greater than the number of strata and should be a multiple of 4. See the section "Balanced Repeated Replication (BRR) Method" on page 6429 for more information. If a Hadamard matrix cannot be constructed for the REPS= value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the REPS= value that you specify.

If you provide a Hadamard matrix with the HADAMARD= method-option, the value of REPS= must not be less than the number of rows in the Hadamard matrix. If you provide a Hadamard matrix and do not specify the REPS= method-option, the number of replicates equals the number of rows in the Hadamard matrix.

If you do not specify the REPS= or HADAMARD= method-option and do not include a REPWEIGHTS statement, the number of replicates equals the smallest multiple of 4 that is greater than the number of strata.

If you provide replicate weights with the REPWEIGHTS statement, the procedure does not use the REPS= method-option. With a REPWEIGHTS statement, the number of replicates equals the number of REPWEIGHTS variables.

JACKKNIFE | JK <(*method-options*)> requests variance estimation by the delete-1 jackknife method. See the section "Jackknife Method" on page 6431 for details. If you provide replicate weights with a REPWEIGHTS statement, VARMETHOD=JACKKNIFE is the default variance estimation method.

You can specify the following *method-options* in parentheses following VARMETHOD=JACKKNIFE:

OUTWEIGHTS=*SAS-data-set*
names a SAS data set that contains replicate weights. "Jackknife Method" on page 6431 for information about replicate weights. See the section "Replicate Weights Output Data Set" on page 6440 for more details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= method-option is not available when you provide replicate weights with the REPWEIGHTS statement.

OUTJKCOEFS=*SAS-data-set*
names a SAS data set that contains jackknife coefficients. See the section "Jackknife Coefficients Output Data Set" on page 6441 for more details about the contents of the OUTJKCOEFS= data set.

TAYLOR requests Taylor series variance estimation. This is the default method if you do not specify the VARMETHOD= option and if there is no REPWEIGHTS statement. See the section "Taylor Series (Linearization)" on page 6427 for more information.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC SURVEYLOGISTIC to obtain separate analyses on observations in groups defined by the BY variables.

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation (or domain) analysis, where the total number of units in the subpopulation is not known with certainty.

When a BY statement appears, the procedure expects the input data sets to be sorted in the order of the BY variables. The *variables* are one or more variables in the input data set.

If you specify more than one BY statement, the procedure uses only the latest BY statement and ignores any previous ones.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Use the BY statement option NOTSORTED or DESCENDING. The NOTSORTED option does not mean that the data are unsorted, but rather that the data are arranged in groups (ac-

cording to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index of the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variable* < *(v-options)* > < *variable* < *(v-options)* > ... > < / *v-options* > **;**

The CLASS statement names the classification variables to be used in the analysis. The CLASS statement must precede the MODEL statement. You can specify various *v-options* for each variable by enclosing them in parentheses after the variable name. You can also specify global *v-options* for the CLASS statement by placing them after a slash (/). Global *v-options* are applied to all the variables specified in the CLASS statement. However, individual CLASS variable *v-options* override the global *v-options*.

CPREFIX= *n*

specifies that, at most, the first *n* characters of a CLASS variable name be used in creating names for the corresponding dummy variables. The default is $32 - \min(32, \max(2, f))$, where f is the formatted length of the CLASS variable.

DESCENDING

DESC

reverses the sorting order of the classification variable.

LPREFIX= *n*

specifies that, at most, the first *n* characters of a CLASS variable label be used in creating labels for the corresponding dummy variables.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sorting order for the levels of classification variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option might be useful when you use the CONTRAST statement. When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

The following table shows how PROC SURVEYLOGISTIC interprets values of the ORDER= option.

Value of ORDER=	Levels Sorted By
DATA	order of appearance in the input data set
FORMATTED	external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent.

For more information about sorting order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

PARAM=*keyword*

specifies the parameterization method for the classification variable or variables. Design matrix columns are created from CLASS variables according to the following coding schemes; the default is PARAM=EFFECT.

EFFECT specifies effect coding

GLM specifies less-than-full-rank, reference cell coding; this option can be used only as a global option

ORDINAL specifies the cumulative parameterization for an ordinal CLASS variable

POLYNOMIAL | POLY specifies polynomial coding

REFERENCE | REF specifies reference cell coding

ORTHEFFECT orthogonalizes PARAM=EFFECT

ORTHORDINAL | ORTHOTHERM orthogonalizes PARAM=ORDINAL

ORTHPOLY orthogonalizes PARAM=POLYNOMIAL

ORTHREF orthogonalizes PARAM=REFERENCE

If PARAM=ORTHPOLY or PARAM=POLY, and the CLASS levels are numeric, then the ORDER= option in the CLASS statement is ignored, and the internal, unformatted values are used.

EFFECT, POLYNOMIAL, REFERENCE, ORDINAL, and their orthogonal parameterizations are full rank. The REF= option in the CLASS statement determines the reference level for EFFECT, REFERENCE, and their orthogonal parameterizations.

Parameter names for a CLASS predictor variable are constructed by concatenating the CLASS variable name with the CLASS levels. However, for the POLYNOMIAL and orthogonal parameterizations, parameter names are formed by concatenating the CLASS variable name and keywords that reflect the parameterization.

REF=*'level'* | *keyword*

specifies the reference level for PARAM=EFFECT or PARAM=REFERENCE. For an individual (but not a global) variable REF= *option*, you can specify the *level* of the variable to use as the reference level. For a global or individual variable REF= *option*, you can use one of the following *keywords*. The default is REF=LAST.

FIRST	designates the first ordered level as reference.
LAST	designates the last ordered level as reference.

CLUSTER Statement

CLUSTER *variables* **;**

The CLUSTER statement names variables that identify the clusters in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should identify only the first-stage clusters, or primary sampling units (PSUs), in the CLUSTER statement. See the section "Primary Sampling Units (PSUs)" on page 6423 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with the REPWEIGHTS statement, you do not need to specify a CLUSTER statement.

The CLUSTER *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary* for more information.

You can use multiple CLUSTER statements to specify cluster variables. The procedure uses all variables from all CLUSTER statements to create clusters.

CONTRAST Statement

CONTRAST *'label' row-description* < *, ... , row-description* < */ options* > > **;**

where a *row-description* is defined as follows:

effect values < *, . . ., effect values* >

The CONTRAST statement provides a mechanism for obtaining customized hypothesis tests. It is similar to the CONTRAST statement in PROC LOGISTIC and PROC GLM, depending on the coding schemes used with any classification variables involved.

The CONTRAST statement enables you to specify a matrix, $\mathbf{L}$, for testing the hypothesis $\mathbf{L}\boldsymbol{\theta} = 0$, where $\boldsymbol{\theta}$ is the parameter vector. You must be familiar with the details of the model parameteriza-

tion that PROC SURVEYLOGISTIC uses (for more information, see the PARAM= option in the section "CLASS Statement" on page 6389). Optionally, the CONTRAST statement enables you to estimate each row, $\mathbf{l}_i\boldsymbol{\theta}$, of $\mathbf{L}\boldsymbol{\theta}$ and test the hypothesis $\mathbf{l}_i\boldsymbol{\theta} = 0$. Computed statistics are based on the asymptotic chi-square distribution of the Wald statistic.

There is no limit to the number of CONTRAST statements that you can specify, but they must appear after the MODEL statement.

The following parameters are specified in the CONTRAST statement:

label identifies the contrast on the output. A label is required for every contrast specified, and it must be enclosed in quotes.

effect identifies an effect that appears in the MODEL statement. The name INTERCEPT can be used as an effect when one or more intercepts are included in the model. You do not need to include all effects that are included in the MODEL statement.

values are constants that are elements of the **L** matrix associated with the effect. To correctly specify your contrast, it is crucial to know the ordering of parameters within each effect and the variable levels associated with any parameter. The "Class Level Information" table shows the ordering of levels within variables. The E option, described later in this section, enables you to verify the proper correspondence of *values* to parameters.

The rows of **L** are specified in order and are separated by commas. Multiple degree-of-freedom hypotheses can be tested by specifying multiple *row-descriptions*. For any of the full-rank parameterizations, if an effect is not specified in the CONTRAST statement, all of its coefficients in the **L** matrix are set to 0. If too many values are specified for an effect, the extra ones are ignored. If too few values are specified, the remaining ones are set to 0.

When you use effect coding (by default or by specifying PARAM=EFFECT in the CLASS statement), all parameters are directly estimable (involve no other parameters).

For example, suppose an effect that is coded CLASS variable A has four levels. Then there are three parameters $(\alpha_1, \alpha_2, \alpha_3)$ that represent the first three levels, and the fourth parameter is represented by

$$-\alpha_1 - \alpha_2 - \alpha_3$$

To test the first versus the fourth level of A, you would test

$$\alpha_1 = -\alpha_1 - \alpha_2 - \alpha_3$$

or, equivalently,

$$2\alpha_1 + \alpha_2 + \alpha_3 = 0$$

which, in the form $\mathbf{L}\boldsymbol{\theta} = 0$, is

$$\begin{bmatrix} 2 & 1 & 1 \end{bmatrix} \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} = 0$$

Therefore, you would use the following CONTRAST statement:

```
contrast '1 vs. 4' A 2 1 1;
```

To contrast the third level with the average of the first two levels, you would test

$$\frac{\alpha_1 + \alpha_2}{2} = \alpha_3$$

or, equivalently,

$$\alpha_1 + \alpha_2 - 2\alpha_3 = 0$$

Therefore, you would use the following CONTRAST statement:

```
contrast '1&2 vs. 3' A 1 1 -2;
```

Other CONTRAST statements are constructed similarly. For example:

```
contrast '1 vs. 2    '  A  1 -1  0;
contrast '1&2 vs. 4  '  A  3  3  2;
contrast '1&2 vs. 3&4'  A  2  2  0;
contrast 'Main Effect'  A  1  0  0,
                        A  0  1  0,
                        A  0  0  1;
```

When you use the less-than-full-rank parameterization (by specifying PARAM=GLM in the CLASS statement), each row is checked for estimability. If PROC SURVEYLOGISTIC finds a contrast to be nonestimable, it displays missing values in corresponding rows in the results. PROC SURVEYLOGISTIC handles missing level combinations of classification variables in the same manner as PROC LOGISTIC. Parameters corresponding to missing level combinations are not included in the model. This convention can affect the way in which you specify the **L** matrix in your CONTRAST statement. If the elements of **L** are not specified for an effect that contains a specified effect, then the elements of the specified effect are distributed over the levels of the higher-order effect just as the LOGISTIC procedure does for its CONTRAST and ESTIMATE statements. For example, suppose that the model contains effects A and B and their interaction A*B. If you specify a CONTRAST statement involving A alone, the **L** matrix contains nonzero terms for both A and A*B, since A*B contains A.

The degrees of freedom is the number of linearly independent constraints implied by the CONTRAST statement—that is, the rank of **L**.

You can specify the following options after a slash (/).

ALPHA=*value*

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of α produces $100(1-\alpha)\%$ confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

E

requests that the **L** matrix be displayed.

ESTIMATE=*keyword*

requests that each individual contrast (that is, each row, $\mathbf{l}_i\boldsymbol{\beta}$, of $\mathbf{L}\boldsymbol{\beta}$) or exponentiated contrast ($e^{\mathbf{l}_i\boldsymbol{\beta}}$) be estimated and tested. PROC SURVEYLOGISTIC displays the point estimate, its standard error, a Wald confidence interval, and a Wald chi-square test for each contrast. The significance level of the confidence interval is controlled by the ALPHA= option. You can estimate the contrast or the exponentiated contrast ($e^{\mathbf{l}_i\boldsymbol{\beta}}$), or both, by specifying one of the following *keywords*:

PARM	specifies that the contrast itself be estimated
EXP	specifies that the exponentiated contrast be estimated
BOTH	specifies that both the contrast and the exponentiated contrast be estimated

SINGULAR=*value*

tunes the estimability checking. If $\mathbf{v}$ is a vector, define ABS($\mathbf{v}$) to be the largest absolute value of the elements of $\mathbf{v}$. For a row vector $\mathbf{l}$ of the matrix $\mathbf{L}$, define

$$c = \begin{cases} \text{ABS}(\mathbf{l}) & \text{if ABS}(\mathbf{l}) > 0 \\ 1 & \text{otherwise} \end{cases}$$

If ABS($\mathbf{l} - \mathbf{lH}$) is greater than *c*value*, then $\mathbf{l}\boldsymbol{\beta}$ is declared nonestimable. The $\mathbf{H}$ matrix is the Hermite form matrix $\mathbf{I}_0^-\mathbf{I}_0$, where $\mathbf{I}_0^-$ represents a generalized inverse of the information matrix $\mathbf{I}_0$ of the null model. The *value* must be between 0 and 1; the default is 10^{-4}.

DOMAIN Statement

DOMAIN *variables < variable*variable variable*variable*variable ... >* **;**

The DOMAIN statement requests analysis for subpopulations, or domains, in addition to analysis for the entire study population. The DOMAIN statement names the variables that identify domains, which are called domain variables.

It is common practice to compute statistics for domains. The formation of these domains might be unrelated to the sample design. Therefore, the sample sizes for the domains are random variables. In order to incorporate this variability into the variance estimation, you should use a DOMAIN statement.

Note that a DOMAIN statement is different from a BY statement. In a BY statement, you treat the sample sizes as fixed in each subpopulation, and you perform analysis within each BY group independently.

You should use the DOMAIN statement on the entire data set to perform the domain analysis. Creating a new data set from a single domain and analyzing that with PROC SURVEYLOGISTIC yields inappropriate estimates of variance.

A domain variable can be either character or numeric. The procedure treats domain variables as categorical variables. If a variable appears by itself in a DOMAIN statement, each level of this variable determines a domain in the study population. If two or more variables are joined by asterisks (*),

then every possible combination of levels of these variables determines a domain. The procedure performs a descriptive analysis within each domain defined by the domain variables.

The formatted values of the domain variables determine the categorical variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary* for more information.

FREQ Statement

FREQ *variable* **;**

The *variable* in the FREQ statement identifies a variable that contains the frequency of occurrence of each observation. PROC SURVEYLOGISTIC treats each observation as if it appears n times, where n is the value of the FREQ variable for the observation. If it is not an integer, the frequency value is truncated to an integer. If the frequency value is less than 1 or missing, the observation is not used in the model fitting. When the FREQ statement is not specified, each observation is assigned a frequency of 1.

If you use the events/trials syntax in the MODEL statement, the FREQ statement is not allowed because the event and trial variables represent the frequencies in the data set.

MODEL Statement

MODEL *events/trials* = < *effects* < / *options* > > **;**

MODEL *variable* < *(v-options)* > = < *effects* > < / *options* > **;**

The MODEL statement names the response variable and the explanatory effects, including covariates, main effects, interactions, and nested effects; see the section "Specification of Effects" on page 2488 of Chapter 39, "The GLM Procedure," for more information. If you omit the explanatory variables, the procedure fits an intercept-only model. Model options can be specified after a slash (/).

Two forms of the MODEL statement can be specified. The first form, referred to as *single-trial* syntax, is applicable to binary, ordinal, and nominal response data. The second form, referred to as *events/trials* syntax, is restricted to the case of binary response data. The single-trial syntax is used when each observation in the DATA= data set contains information about only a single trial, such as a single subject in an experiment. When each observation contains information about multiple binary-response trials, such as the counts of the number of subjects observed and the number responding, then events/trials syntax can be used.

In the events/trials syntax, you specify two variables that contain count data for a binomial experiment. These two variables are separated by a slash. The value of the first variable, *events*, is the

number of positive responses (or events), and it must be nonnegative. The value of the second variable, *trials*, is the number of trials, and it must not be less than the value of *events*.

In the single-trial syntax, you specify one variable (on the left side of the equal sign) as the response variable. This variable can be character or numeric. Options specific to the response variable can be specified immediately after the response variable with parentheses around them.

For both forms of the MODEL statement, explanatory *effects* follow the equal sign. Variables can be either continuous or classification variables. Classification variables can be character or numeric, and they must be declared in the CLASS statement. When an effect is a classification variable, the procedure enters a set of coded columns into the design matrix instead of directly entering a single column containing the values of the variable.

Response Variable Options

You specify the following options by enclosing them in parentheses after the response variable.

DESCENDING
DESC

reverses the order of response categories. If both the DESCENDING and ORDER= options are specified, PROC SURVEYLOGISTIC orders the response categories according to the ORDER= option and then reverses that order. See the section "Response Level Ordering" on page 6411 for more detail.

EVENT='*category***' | *keyword***

specifies the event category for the binary response model. PROC SURVEYLOGISTIC models the probability of the event category. The EVENT= option has no effect when there are more than two response categories. You can specify the value (formatted if a format is applied) of the event category in quotes or you can specify one of the following keywords. The default is EVENT=FIRST.

FIRST	designates the first ordered category as the event
LAST	designates the last ordered category as the event

One of the most common sets of response levels is {0,1}, with 1 representing the event for which the probability is to be modeled. Consider the example where Y takes the values 1 and 0 for event and nonevent, respectively, and Exposure is the explanatory variable. To specify the value 1 as the event category, use the following MODEL statement:

```
model Y(event='1') = Exposure;
```

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sorting order for the levels of the response variable. By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent.

When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

The following table shows the interpretation of the ORDER= values.

Value of ORDER=	Levels Sorted By
DATA	order of appearance in the input data set
FORMATTED	external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

For more information about sorting order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts* for more information.

REFERENCE='*category*' | *keyword*

REF='*category*' | *keyword*

specifies the reference category for the generalized logit model and the binary response model. For the generalized logit model, each nonreference category is contrasted with the reference category. For the binary response model, specifying one response category as the reference is the same as specifying the other response category as the event category. You can specify the value (formatted if a format is applied) of the reference category in quotes or you can specify one of the following keywords. The default is REF=LAST.

FIRST	designates the first ordered category as the reference
LAST	designates the last ordered category as the reference

Model Options

Model options can be specified after a slash (/). Table 84.2 summarizes the options available in the MODEL statement.

Table 84.2 MODEL Statement Options

Option	Description
Model Specification Options	
LINK=	Specifies link function
NOINT	Suppresses intercept(s)
OFFSET=	Specifies offset variable
Convergence Criterion Options	
ABSFCONV=	Specifies absolute function convergence criterion
FCONV=	Specifies relative function convergence criterion
GCONV=	Specifies relative gradient convergence criterion
XCONV=	Specifies relative parameter convergence criterion
MAXITER=	Specifies maximum number of iterations
NOCHECK	Suppresses checking for infinite parameters

Table 84.2 (continued)

Option	Description
RIDGING=	Specifies technique used to improve the log-likelihood function when its value is worse than that of the previous step
SINGULAR=	Specifies tolerance for testing singularity
TECHNIQUE=	Specifies iterative algorithm for maximization
Options for Adjustment to Variance Estimation	
VADJUST=	Chooses variance estimation adjustment method
Options for Confidence Intervals	
ALPHA=	Specifies α for the $100(1-\alpha)\%$ confidence intervals
CLPARM	Computes confidence intervals for parameters
CLODDS	Computes confidence intervals for odds ratios
Options for Display of Details	
CORRB	Displays correlation matrix
COVB	Displays covariance matrix
EXPB	Displays exponentiated values of estimates
ITPRINT	Displays iteration history
NODUMMYPRINT	Suppresses "Class Level Information" table
PARMLABEL	Displays parameter labels
RSQUARE	Displays generalized R^2
STB	Displays standardized estimates

The following list describes these options.

ABSFCONV=*value*

specifies the absolute function convergence criterion. Convergence requires a small change in the log-likelihood function in subsequent iterations:

$$|l^{(i)} - l^{(i-1)}| < value$$

where $l^{(i)}$ is the value of the log-likelihood function at iteration i. See the section "Convergence Criteria" on page 6418.

ALPHA=*value*

sets the level of significance α for $100(1-\alpha)\%$ confidence intervals for regression parameters or odds ratios. The value α must be between 0 and 1. By default, α is equal to the value of the ALPHA= option in the PROC SURVEYLOGISTIC statement, or $\alpha = 0.05$ if the ALPHA= option is not specified. This option has no effect unless confidence limits for the parameters or odds ratios are requested.

CLODDS

requests confidence intervals for the odds ratios. Computation of these confidence intervals is based on individual Wald tests. The confidence coefficient can be specified with the ALPHA= option.

See the section "Wald Confidence Intervals for Parameters" on page 6434 for more information.

CLPARM

requests confidence intervals for the parameters. Computation of these confidence intervals is based on the individual Wald tests. The confidence coefficient can be specified with the ALPHA= option.

See the section "Wald Confidence Intervals for Parameters" on page 6434 for more information.

CORRB

displays the correlation matrix of the parameter estimates.

COVB

displays the covariance matrix of the parameter estimates.

EXPB

EXPEST

displays the exponentiated values ($e^{\hat{\theta}_i}$) of the parameter estimates $\hat{\theta}_i$ in the "Analysis of Maximum Likelihood Estimates" table for the logit model. These exponentiated values are the estimated odds ratios for the parameters corresponding to the continuous explanatory variables.

FCONV=*value*

specifies the relative function convergence criterion. Convergence requires a small relative change in the log-likelihood function in subsequent iterations:

$$\frac{|l^{(i)} - l^{(i-1)}|}{|l^{(i-1)}| + 1\text{E}{-}6} < value$$

where $l^{(i)}$ is the value of the log likelihood at iteration i. See the section "Convergence Criteria" on page 6418 for details.

GCONV=*value*

specifies the relative gradient convergence criterion. Convergence requires that the normalized prediction function reduction is small:

$$\frac{\mathbf{g}^{(i)\prime}\mathbf{I}^{(i)}\mathbf{g}^{(i)}}{|l^{(i)}| + 1\text{E}{-}6} < value$$

where $l^{(i)}$ is the value of the log-likelihood function, $\mathbf{g}^{(i)}$ is the gradient vector, and $\mathbf{I}^{(i)}$ the (expected) information matrix. All of these functions are evaluated at iteration i. This is the default convergence criterion, and the default value is 1E−8. See the section "Convergence Criteria" on page 6418 for details.

ITPRINT

displays the iteration history of the maximum-likelihood model fitting. The ITPRINT option also displays the last evaluation of the gradient vector and the final change in the $-2\log L$.

LINK=*keyword*

L=*keyword*

specifies the link function that links the response probabilities to the linear predictors. You can specify one of the following keywords. The default is LINK=LOGIT.

CLOGLOG specifies the complementary log-log function. PROC SURVEYLOGISTIC fits the binary complementary log-log model for binary response and fits the cumulative complementary log-log model when there are more than two response categories. Aliases: CCLOGLOG, CCLL, CUMCLOGLOG.

GLOGIT specifies the generalized logit function. PROC SURVEYLOGISTIC fits the generalized logit model where each nonreference category is contrasted with the reference category. You can use the response variable option REF= to specify the reference category.

LOGIT specifies the cumulative logit function. PROC SURVEYLOGISTIC fits the binary logit model when there are two response categories and fits the cumulative logit model when there are more than two response categories. Aliases: CLOGIT, CUMLOGIT.

PROBIT specifies the inverse standard normal distribution function. PROC SURVEYLOGISTIC fits the binary probit model when there are two response categories and fits the cumulative probit model when there are more than two response categories. Aliases: NORMIT, CPROBIT, CUMPROBIT.

See the section "Link Functions and the Corresponding Distributions" on page 6415 for details.

MAXITER=*n*

specifies the maximum number of iterations to perform. By default, MAXITER=25. If convergence is not attained in *n* iterations, the displayed output created by the procedure contains results that are based on the last maximum likelihood iteration.

NOCHECK

disables the checking process to determine whether maximum likelihood estimates of the regression parameters exist. If you are sure that the estimates are finite, this option can reduce the execution time when the estimation takes more than eight iterations. For more information, see the section "Existence of Maximum Likelihood Estimates" on page 6418.

NODUMMYPRINT

suppresses the "Class Level Information" table, which shows how the design matrix columns for the CLASS variables are coded.

NOINT

suppresses the intercept for the binary response model or the first intercept for the ordinal response model.

OFFSET=*name*

names the offset variable. The regression coefficient for this variable is fixed at 1.

PARMLABEL

displays the labels of the parameters in the "Analysis of Maximum Likelihood Estimates" table.

RIDGING=ABSOLUTE | RELATIVE | NONE

specifies the technique used to improve the log-likelihood function when its value in the current iteration is less than that in the previous iteration. If you specify the RIDGING=ABSOLUTE option, the diagonal elements of the negative (expected) Hessian are inflated by adding the ridge value. If you specify the RIDGING=RELATIVE option, the diagonal elements are inflated by a factor of 1 plus the ridge value. If you specify the RIDGING=NONE option, the crude line search method of taking half a step is used instead of ridging. By default, RIDGING=RELATIVE.

RSQUARE

requests a generalized R^2 measure for the fitted model.

For more information, see the section "Generalized Coefficient of Determination" on page 6421.

SINGULAR=*value*

specifies the tolerance for testing the singularity of the Hessian matrix (Newton-Raphson algorithm) or the expected value of the Hessian matrix (Fisher scoring algorithm). The Hessian matrix is the matrix of second partial derivatives of the log likelihood. The test requires that a pivot for sweeping this matrix be at least this *value* times a norm of the matrix. Values of the SINGULAR= option must be numeric. By default, SINGULAR=10^{-12}.

STB

displays the standardized estimates for the parameters for the continuous explanatory variables in the "Analysis of Maximum Likelihood Estimates" table. The standardized estimate of θ_i is given by $\hat{\theta}_i/(s/s_i)$, where s_i is the total sample standard deviation for the ith explanatory variable and

$$s = \begin{cases} \pi/\sqrt{3} & \text{Logistic} \\ 1 & \text{Normal} \\ \pi/\sqrt{6} & \text{Extreme-value} \end{cases}$$

For the intercept parameters and parameters associated with a CLASS variable, the standardized estimates are set to missing.

TECHNIQUE=FISHER | NEWTON

TECH=FISHER | NEWTON

specifies the optimization technique for estimating the regression parameters. NEWTON (or NR) is the Newton-Raphson algorithm and FISHER (or FS) is the Fisher scoring algorithm. Both techniques yield the same estimates, but the estimated covariance matrices are slightly different except for the case where the LOGIT link is specified for binary response data. The default is TECHNIQUE=FISHER. See the section "Iterative Algorithms for Model Fitting" on page 6417 for details.

VADJUST=DF

VADJUST=MOREL <(*Morel-options***)>**

VADJUST=NONE

specifies an adjustment to the variance estimation for the regression coefficients.

By default, PROC SURVEYLOGISTIC uses the degrees of freedom adjustment VADJUST=DF.

If you do not want to use any variance adjustment, you can specify the VADJUST=NONE option. You can specify the VADJUST=MOREL option for the variance adjustment proposed by Morel (1989).

You can specify the following *Morel-options* within parentheses after the VADJUST=MOREL option.

ADJBOUND=ϕ

sets the upper bound coefficient ϕ in the variance adjustment. This upper bound must be positive. By default, the procedure uses $\phi = 0.5$. See the section "Adjustments to the Variance Estimation" on page 6428 for more details on how this upper bound is used in the variance estimation.

DEFFBOUND=δ

sets the lower bound of the estimated design effect in the variance adjustment. This lower bound must be positive. By default, the procedure uses $\delta = 1$. See the section "Adjustments to the Variance Estimation" on page 6428 for more details about how this lower bound is used in the variance estimation.

XCONV=*value*

specifies the relative parameter convergence criterion. Convergence requires a small relative parameter change in subsequent iterations:

$$\max_j |\delta_j^{(i)}| < value$$

where

$$\delta_j^{(i)} = \begin{cases} \theta_j^{(i)} - \theta_j^{(i-1)} & |\theta_j^{(i-1)}| < 0.01 \\ \dfrac{\theta_j^{(i)} - \theta_j^{(i-1)}}{\theta_j^{(i-1)}} & \text{otherwise} \end{cases}$$

and $\theta_j^{(i)}$ is the estimate of the jth parameter at iteration i. See the section "Iterative Algorithms for Model Fitting" on page 6417.

OUTPUT Statement

OUTPUT < **OUT=***SAS-data-set* > < *options* > **;**

The OUTPUT statement creates a new SAS data set that contains all the variables in the input data set and, optionally, the estimated linear predictors and their standard error estimates, the estimates of the cumulative or individual response probabilities, and the confidence limits for the cumulative probabilities. Formulas for the statistics are given in the section "Linear Predictor, Predicted Probability, and Confidence Limits" on page 6438.

If you use the single-trial syntax, the data set also contains a variable named _LEVEL_, which indicates the level of the response that the given row of output is referring to. For example, the value of the cumulative probability variable is the probability that the response variable is as large as the corresponding value of _LEVEL_. For details, see the section "OUT= Data Set in the OUTPUT Statement" on page 6440.

The estimated linear predictor, its standard error estimate, all predicted probabilities, and the confidence limits for the cumulative probabilities are computed for all observations in which the explanatory variables have no missing values, even if the response is missing. By adding observations with missing response values to the input data set, you can compute these statistics for new observations, or for settings of the explanatory variables not present in the data, without affecting the model fit.

OUT=*SAS-data-set*

names the output data set. If you omit the OUT= option, the output data set is created and given a default name by using the DATA*n* convention.

The statistic options in the OUTPUT statement specify the statistics to be included in the output data set and name the new variables that contain the statistics.

LOWER | L=*name*

names the variable that contains the lower confidence limits for π, where π is the probability of the event response if events/trials syntax or the single-trial syntax with binary response is specified; π is cumulative probability (that is, the probability that the response is less than or equal to the value of _LEVEL_) for a cumulative model; and π is the individual probability (that is, the probability that the response category is represented by the value of _LEVEL_) for the generalized logit model. See the ALPHA= option for information about setting the confidence level.

PREDICTED | P=*name*

names the variable that contains the predicted probabilities. For the events/trials syntax or the single-trial syntax with binary response, it is the predicted event probability. For a cumulative model, it is the predicted cumulative probability (that is, the probability that the response variable is less than or equal to the value of _LEVEL_); and for the generalized logit model, it is the predicted individual probability (that is, the probability of the response category represented by the value of _LEVEL_).

PREDPROBS=(*keywords***)**

requests individual, cumulative, or cross validated predicted probabilities. Descriptions of the *keywords* are as follows.

INDIVIDUAL | I requests the predicted probability of each response level. For a response variable Y with three levels, 1, 2, and 3, the individual probabilities are Pr(Y=1), Pr(Y=2), and Pr(Y=3).

CUMULATIVE | C requests the cumulative predicted probability of each response level. For a response variable Y with three levels, 1, 2, and 3, the cumulative probabilities are Pr(Y≤1), Pr(Y≤2), and Pr(Y≤3). The cumulative probability for the last response level always has the constant value of 1. For generalized logit models, the cumulative predicted probabilities are not computed and are set to missing.

CROSSVALIDATE | XVALIDATE | X requests the cross validated individual predicted probability of each response level. These probabilities are derived from the leave-one-out principle; that is, dropping the data of one subject and reestimating the parameter estimates. PROC SURVEYLOGISTIC uses a less expensive one-step approximation to compute the parameter estimates. This option is valid only for binary response models; for nominal and ordinal models, the cross validated probabilities are not computed and are set to missing.

See the section "Details of the PREDPROBS= Option" on page 6404 at the end of this section for further details.

STDXBETA=*name*
names the variable that contains the standard error estimates of XBETA (the definition of which follows).

UPPER | U=*name*
names the variable that contains the upper confidence limits for π, where π is the probability of the event response if events/trials syntax or single-trial syntax with binary response is specified; π is cumulative probability (that is, the probability that the response is less than or equal to the value of _LEVEL_) for a cumulative model; and π is the individual probability (that is, the probability that the response category is represented by the value of _LEVEL_) for the generalized logit model. See the ALPHA= option for information about setting the confidence level.

XBETA=*name*
names the variable that contains the estimates of the linear predictor $\alpha_i + \mathbf{x}\boldsymbol{\beta}$, where i is the corresponding ordered value of _LEVEL_.

You can specify the following option after a slash.

ALPHA=*value*
sets the level of significance α for $100(1-\alpha)\%$ confidence limits for the appropriate response probabilities. The value α must be between 0 and 1. By default, α is equal to the value of the ALPHA= option in the PROC SURVEYLOGISTIC statement, or 0.05 if the ALPHA= option is not specified.

Details of the PREDPROBS= Option

You can request any of the three given types of predicted probabilities. For example, you can request both the individual predicted probabilities and the cross validated probabilities by specifying PREDPROBS=(I X).

When you specify the PREDPROBS= option, two automatic variables _FROM_ and _INTO_ are included for the single-trial syntax and only one variable, _INTO_, is included for the events/trials syntax. The _FROM_ variable contains the formatted value of the observed response. The variable _INTO_ contains the formatted value of the response level with the largest individual predicted probability.

If you specify PREDPROBS=INDIVIDUAL, the OUTPUT data set contains k additional variables representing the individual probabilities, one for each response level, where k is the maximum number of response levels across all BY groups. The names of these variables have the form IP_*xxx*, where *xxx* represents the particular level. The representation depends on the following situations:

- If you specify the events/trials syntax, *xxx* is either Event or Nonevent. Thus, the variable that contains the event probabilities is named IP_Event and the variable containing the nonevent probabilities is named IP_Nonevent.
- If you specify the single-trial syntax with more than one BY group, *xxx* is 1 for the first ordered level of the response, 2 for the second ordered level of the response, and so forth, as given in the "Response Profile" table. The variable that contains the predicted probabilities Pr(Y=1) is named IP_1, where Y is the response variable. Similarly, IP_2 is the name of the variable containing the predicted probabilities Pr(Y=2), and so on.
- If you specify the single-trial syntax with no BY-group processing, *xxx* is the left-justified formatted value of the response level (the value can be truncated so that IP_*xxx* does not exceed 32 characters). For example, if Y is the response variable with response levels 'None,' 'Mild,' and 'Severe,' the variables representing individual probabilities Pr(Y='None'), Pr(Y='Mild'), and Pr(Y='Severe') are named IP_None, IP_Mild, and IP_Severe, respectively.

If you specify PREDPROBS=CUMULATIVE, the OUTPUT data set contains k additional variables that represent the cumulative probabilities, one for each response level, where k is the maximum number of response levels across all BY groups. The names of these variables have the form CP_*xxx*, where *xxx* represents the particular response level. The naming convention is similar to that given by PREDPROBS=INDIVIDUAL. The PREDPROBS=CUMULATIVE values are the same as those output by the PREDICT=keyword, but they are arranged in variables in each output observation rather than in multiple output observations.

If you specify PREDPROBS=CROSSVALIDATE, the OUTPUT data set contains k additional variables representing the cross validated predicted probabilities of the k response levels, where k is the maximum number of response levels across all BY groups. The names of these variables have the form XP_*xxx*, where *xxx* represents the particular level. The representation is the same as that given by PREDPROBS=INDIVIDUAL, except that for the events/trials syntax there are four variables for the cross validated predicted probabilities instead of two:

XP_EVENT_R1E is the cross validated predicted probability of an event when a current event trial is removed.

XP_NONEVENT_R1E is the cross validated predicted probability of a nonevent when a current event trial is removed.

XP_EVENT_R1N is the cross validated predicted probability of an event when a current nonevent trial is removed.

XP_NONEVENT_R1N is the cross validated predicted probability of a nonevent when a current nonevent trial is removed.

REPWEIGHTS Statement

REPWEIGHTS *variables* < / *options* > **;**

The REPWEIGHTS statement names variables that provide replicate weights for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option in the PROC SURVEYLOGISTIC statement. If you do not provide replicate weights for these methods by using a REPWEIGHTS statement, then the procedure constructs replicate weights for the analysis. See the sections "Balanced Repeated Replication (BRR) Method" on page 6429 and "Jackknife Method" on page 6431 for information about replicate weights.

Each REPWEIGHTS variable should contain the weights for a single replicate, and the number of replicates equals the number of REPWEIGHTS variables. The REPWEIGHTS variables must be numeric, and the variable values must be nonnegative numbers.

If you provide replicate weights with a REPWEIGHTS statement, you do not need to specify a CLUSTER or STRATA statement. If you use a REPWEIGHTS statement and do not specify the VARMETHOD= option in the PROC SURVEYLOGISTIC statement, the procedure uses VARMETHOD=JACKKNIFE by default.

If you specify a REPWEIGHTS statement but do not include a WEIGHT statement, the procedure uses the average of each observation's replicate weights as the observation's weight.

You can specify the following options in the REPWEIGHTS statement after a slash (/):

DF=*df*

specifies the degrees of freedom for the analysis. The value of *df* must be a positive number. By default, the degrees of freedom equals the number of REPWEIGHTS variables.

JKCOEFS=*value*

specifies a jackknife coefficient for VARMETHOD=JACKKNIFE. The coefficient *value* must be a nonnegative number less than one. See the section "Jackknife Method" on page 6431 for details about jackknife coefficients.

You can use this option to specify a single value of the jackknife coefficient, which the procedure uses for all replicates. To specify different coefficients for different replicates, use the JKCOEFS=*values* or JKCOEFS=*SAS-data-set* option.

JKCOEFS=*values*

specifies jackknife coefficients for VARMETHOD=JACKKNIFE, where each coefficient corresponds to an individual replicate identified by a REPWEIGHTS variable. You can separate *values* with blanks or commas. The coefficient *values* must be nonnegative numbers less than one. The number of *values* must equal the number of replicate weight variables named in the REPWEIGHTS statement. List these values in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement.

See the section "Jackknife Method" on page 6431 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the JKCOEFS=*SAS-data-set* option. To specify a single jackknife coefficient for all replicates, use the JKCOEFS=*value* option.

JKCOEFS=*SAS-data-set*

names a SAS data set that contains the jackknife coefficients for VARMETHOD=JACKKNIFE. You provide the jackknife coefficients in the JKCOEFS= data set variable JKCoefficient. Each coefficient value must be a nonnegative number less than one. The observations in the JKCOEFS= data set should correspond to the replicates that are identified by the REPWEIGHTS variables. Arrange the coefficients or observations in the JKCOEFS= data set in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement. The number of observations in the JKCOEFS= data set must not be less than the number of REPWEIGHTS variables.

See the section "Jackknife Method" on page 6431 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the JKCOEFS=*values* option. To specify a single jackknife coefficient for all replicates, use the JKCOEFS=*value* option.

STRATA Statement

STRATA | STRATUM *variables* < / *option* > **;**

The STRATA statement names variables that form the strata in a stratified sample design. The combinations of levels of STRATA variables define the strata in the sample.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section "Survey Design Information" on page 6422 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with the REPWEIGHTS statement, you do not need to specify a STRATA statement.

The STRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the STRATA variables determine the levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Language Reference: Concepts* for more information.

You can specify the following option in the STRATA statement after a slash (/):

LIST

displays a "Stratum Information" table, which includes values of the STRATA variables and sampling rates for each stratum. This table also provides the number of observations and number of clusters for each stratum and analysis variable. See the section "Displayed Output" on page 6441 for more details.

TEST Statement

< *label:* > **TEST** *equation1* < , *equation2, . . .* >< / *option* > **;**

The TEST statement tests linear hypotheses about the regression coefficients. The Wald test is used to jointly test the null hypotheses (H_0: $\mathbf{L}\boldsymbol{\theta} = \mathbf{c}$) specified in a single TEST statement. When $\mathbf{c} = \mathbf{0}$ you should specify a CONTRAST statement instead.

Each *equation* specifies a linear hypothesis (a row of the $\mathbf{L}$ matrix and the corresponding element of the $\mathbf{c}$ vector); multiple *equations* are separated by commas. The label, which must be a valid SAS name, is used to identify the resulting output and should always be included. You can submit multiple TEST statements.

The form of an *equation* is as follows:

term < ± *term ...* >< = ± *term* < ± *term ...* >>

where *term* is a parameter of the model, or a constant, or a constant times a parameter. For a binary response model, the intercept parameter is named INTERCEPT; for an ordinal response model, the intercept parameters are named INTERCEPT, INTERCEPT2, INTERCEPT3, and so on. When no equal sign appears, the expression is set to 0. The following illustrates possible uses of the TEST statement:

```
proc surveylogistic;
   model y= a1 a2 a3 a4;
   test1: test intercept + .5 * a2 = 0;
   test2: test intercept + .5 * a2;
   test3: test a1=a2=a3;
   test4: test a1=a2, a2=a3;
run;
```

Note that the first and second TEST statements are equivalent, as are the third and fourth TEST statements.

You can specify the following option in the TEST statement after a slash(/).

PRINT

displays intermediate calculations in the testing of the null hypothesis H_0: $\mathbf{L}\boldsymbol{\theta} = \mathbf{c}$. This includes $\mathbf{L}\widehat{\mathbf{V}}(\hat{\boldsymbol{\theta}})\mathbf{L}'$ bordered by $(\mathbf{L}\hat{\boldsymbol{\theta}} - \mathbf{c})$ and $[\mathbf{L}\widehat{\mathbf{V}}(\hat{\boldsymbol{\theta}})\mathbf{L}']^{-1}$ bordered by $[\mathbf{L}\widehat{\mathbf{V}}(\hat{\boldsymbol{\theta}})\mathbf{L}']^{-1}(\mathbf{L}\hat{\boldsymbol{\theta}} - \mathbf{c})$, where $\hat{\boldsymbol{\theta}}$ is the pseudo-estimator of $\boldsymbol{\theta}$ and $\widehat{\mathbf{V}}(\hat{\boldsymbol{\theta}})$ is the estimated covariance matrix of $\hat{\boldsymbol{\theta}}$.

For more information, see the section "Testing Linear Hypotheses about the Regression Coefficients" on page 6434.

UNITS Statement

UNITS *independent1 = list1 < ... independentk = listk >< / options >* **;**

The UNITS statement enables you to specify units of change for the continuous explanatory variables so that customized odds ratios can be estimated. An estimate of the corresponding odds ratio is produced for each unit of change specified for an explanatory variable. The UNITS statement is ignored for CLASS variables. If the CLODDS option is specified in the MODEL statement, the corresponding confidence limits for the odds ratios are also displayed.

The term *independent* is the name of an explanatory variable, and *list* represents a list of units of change, separated by spaces, that are of interest for that variable. Each unit of change in a list has one of the following forms:

- *number*
- SD or −SD
- *number* * SD

where *number* is any nonzero number and SD is the sample standard deviation of the corresponding independent variable. For example, $X = -2$ requests an odds ratio that represents the change in the odds when the variable X is decreased by two units. $X = 2*\text{SD}$ requests an estimate of the change in the odds when X is increased by two sample standard deviations.

You can specify the following option in the UNITS statement after a slash(/).

DEFAULT=*list*

gives a list of units of change for all explanatory variables that are not specified in the UNITS statement. Each unit of change can be in any of the forms described previously. If the DEFAULT= option is not specified, PROC SURVEYLOGISTIC does not produce customized odds ratio estimates for any explanatory variable that is not listed in the UNITS statement.

For more information, see the section "Odds Ratio Estimation" on page 6434.

WEIGHT Statement

WEIGHT *variable < / option >* **;**

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric, and the sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section "Missing Values" on page 6410 for more information. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

If you do not specify a WEIGHT statement but provide replicate weights with a REPWEIGHTS statement, PROC SURVEYLOGISTIC uses the average of each observation's replicate weights as the observation's weight.

If you do not specify a WEIGHT statement or a REPWEIGHTS statement, PROC SURVEYLOGISTIC assigns all observations a weight of one.

Details: SURVEYLOGISTIC Procedure

Missing Values

If you have missing values in your survey data for any reason, such as nonresponse, this can compromise the quality of your survey results. If the respondents are different from the nonrespondents with regard to a survey effect or outcome, then survey estimates might be biased and cannot accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. After data collection is complete, you can use imputation to replace missing values with acceptable values, and/or you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYLOGISTIC. See Cochran (1977), Kalton and Kaspyzyk (1986), and Brick and Kalton (1996) for more information.

If an observation has a missing value or a nonpositive value for the WEIGHT or FREQ variable, then that observation is excluded from the analysis.

An observation is also excluded if it has a missing value for design variables such as STRATA variables, CLUSTER variables, and DOMAIN variables, unless missing values are regarded as a legitimate categorical level for these variables, as specified by the MISSING option.

By default, if an observation contains missing values for the response, offset, or any explanatory variables used in the independent effects, the observation is excluded from the analysis. This treatment is based on the assumption that the missing values are missing completely at random (MCAR). However, this assumption is not true sometimes. For example, evidence from other surveys might suggest that observations with missing values are systematically different from observations without missing values. If you believe that missing values are not missing completely at random, then you can specify the NOMCAR option to include these observations with missing values in the dependent variable and the independent variables in the variance estimation.

Whether or not the NOMCAR option is used, observations with missing or invalid values for WEIGHT, FREQ, STRATA, CLUSTER, or DOMAIN variables are always excluded, unless the MISSING option is also specified.

When you specify the NOMCAR option, the procedure treats observations with and without missing values for variables in the regression model as two different domains, and it performs a domain analysis in the domain of nonmissing observations.

If you use a REPWEIGHTS statement, all REPWEIGHTS variables must contain nonmissing values.

Model Specification

Response Level Ordering

Response level ordering is important because, by default, PROC SURVEYLOGISTIC models the probabilities of response levels with lower *Ordered Values*. Ordered Values, displayed in the "Response Profile" table, are assigned to response levels in ascending sorted order. That is, the lowest response level is assigned Ordered Value 1, the next lowest is assigned Ordered Value 2, and so on. For example, if your response variable Y takes values in $\{1, \ldots, D+1\}$, then the functions of the response probabilities modeled with the cumulative model are

$$\text{logit}(\Pr(Y \leq i|\mathbf{x})), i = 1, \ldots, D$$

and for the generalized logit model they are

$$\log\left(\frac{\Pr(Y = i|\mathbf{x})}{\Pr(Y = D+1|\mathbf{x})}\right), i = 1, \ldots, D$$

where the highest Ordered Value $Y = D+1$ is the reference level. You can change these default functions by specifying the EVENT=, REF=, DESCENDING, or ORDER= response variable options in the MODEL statement.

For binary response data with event and nonevent categories, the procedure models the function

$$\text{logit}(p) = \log\left(\frac{p}{1-p}\right)$$

where p is the probability of the response level assigned to Ordered Value 1 in the "Response Profiles" table. Since

$$\text{logit}(p) = -\text{logit}(1-p)$$

the effect of reversing the order of the two response levels is to change the signs of α and $\boldsymbol{\beta}$ in the model $\text{logit}(p) = \alpha + \mathbf{x}\boldsymbol{\beta}$.

If your event category has a higher Ordered Value than the nonevent category, the procedure models the nonevent probability. You can use response variable options to model the event probability. For example, suppose the binary response variable Y takes the values 1 and 0 for event and nonevent, respectively, and Exposure is the explanatory variable. By default, the procedure assigns Ordered Value 1 to response level Y=0, and Ordered Value 2 to response level Y=1. Therefore, the procedure models the probability of the nonevent (Ordered Value=1) category. To model the event probability, you can do the following:

- Explicitly state which response level is to be modeled by using the response variable option EVENT= in the MODEL statement:

```
model Y(event='1') = Exposure;
```

- Specify the response variable option DESCENDING in the MODEL statement:

```
model Y(descending)=Exposure;
```

- Specify the response variable option REF= in the MODEL statement as the nonevent category for the response variable. This option is most useful when you are fitting a generalized logit model.

```
model Y(ref='0') = Exposure;
```

- Assign a format to Y such that the first formatted value (when the formatted values are put in sorted order) corresponds to the event. For this example, Y=1 is assigned formatted value 'event' and Y=0 is assigned formatted value 'nonevent.' Since ORDER=FORMATTED by default, Ordered Value 1 is assigned to response level Y=1 so the procedure models the event.

```
proc format;
   value Disease 1='event' 0='nonevent';
run;
proc surveylogistic;
   format Y Disease.;
   model Y=Exposure;
run;
```

CLASS Variable Parameterization

Consider a model with one CLASS variable A with four levels: 1, 2, 5, and 7. Details of the possible choices for the PARAM= option follow.

EFFECT — Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of −1. For instance, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

	Design Matrix		
A	**A1**	**A2**	**A5**
1	1	0	0
2	0	1	0
5	0	0	1
7	−1	−1	−1

For CLASS main effects that use the EFFECT coding scheme, individual parameters correspond to the difference between the effect of each nonreference level and the average over all four levels.

GLM — As in PROC GLM, four columns are created to indicate group membership. The design matrix columns for A are as follows.

	Design Matrix			
A	**A1**	**A2**	**A5**	**A7**
1	1	0	0	0
2	0	1	0	0
5	0	0	1	0
7	0	0	0	1

For CLASS main effects that use the GLM coding scheme, individual parameters correspond to the difference between the effect of each level and the last level.

ORDINAL

Three columns are created to indicate group membership of the higher levels of the effect. For the first level of the effect (which for A is 1), all three dummy variables have a value of 0. The design matrix columns for A are as follows.

	Design Matrix		
A	**A2**	**A5**	**A7**
1	0	0	0
2	1	0	0
5	1	1	0
7	1	1	1

The first level of the effect is a control or baseline level.

For CLASS main effects that use the ORDINAL coding scheme, the first level of the effect is a control or baseline level; individual parameters correspond to the difference between effects of the current level and the preceding level. When the parameters for an ordinal main effect have the same sign, the response effect is monotonic across the levels.

POLYNOMIAL

POLY

Three columns are created. The first represents the linear term (x), the second represents the quadratic term (x^2), and the third represents the cubic term (x^3), where x is the level value. If the CLASS levels are not numeric, they are translated into 1, 2, 3, ... according to their sorting order. The design matrix columns for A are as follows.

	Design Matrix		
A	**APOLY1**	**APOLY2**	**APOLY3**
1	1	1	1
2	2	4	8
5	5	25	125
7	7	49	343

REFERENCE

REF

Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of 0. For instance, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

	Design Matrix		
A	A1	A2	A5
1	1	0	0
2	0	1	0
5	0	0	1
7	0	0	0

For CLASS main effects that use the REFERENCE coding scheme, individual parameters correspond to the difference between the effect of each nonreference level and the reference level.

ORTHEFFECT The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=EFFECT. The design matrix columns for A are as follows.

	Design Matrix		
A	AOEFF1	AOEFF2	AOEFF3
1	1.41421	−0.81650	−0.57735
2	0.00000	1.63299	−0.57735
5	0.00000	0.00000	1.73205
7	−1.41421	−0.81649	−0.57735

ORTHORDINAL

ORTHOTHERM The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=ORDINAL. The design matrix columns for A are as follows.

	Design Matrix		
A	AOORD1	AOORD2	AOORD3
1	−1.73205	0.00000	0.00000
2	0.57735	−1.63299	0.00000
5	0.57735	0.81650	−1.41421
7	0.57735	0.81650	1.41421

ORTHPOLY The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=POLY. The design matrix columns for A are as follows.

	Design Matrix		
A	AOPOLY1	AOPOLY2	AOPOLY5
1	−1.153	0.907	−0.921
2	−0.734	−0.540	1.473
5	0.524	−1.370	−0.921
7	1.363	1.004	0.368

ORTHREF The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=REFERENCE. The design matrix columns for A are as follows.

	Design Matrix		
A	AOREF1	AOREF2	AOREF3
1	1.73205	0.00000	0.00000
2	−0.57735	1.63299	0.00000
5	−0.57735	−0.81650	1.41421
7	−0.57735	−0.81650	−1.41421

Link Functions and the Corresponding Distributions

Four link functions are available in the SURVEYLOGISTIC procedure. The logit function is the default. To specify a different link function, use the LINK= option in the MODEL statement. The link functions and the corresponding distributions are as follows:

- The **logit** function

$$g(p) = \log\left(\frac{p}{1-p}\right)$$

is the inverse of the cumulative logistic distribution function, which is

$$F(x) = \frac{1}{1+e^{-x}}$$

- The **probit** (or normit) function

$$g(p) = \Phi^{-1}(p)$$

is the inverse of the cumulative standard normal distribution function, which is

$$F(x) = \Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-\frac{1}{2}z^2} dz$$

Traditionally, the probit function includes an additive constant 5, but throughout PROC SURVEYLOGISTIC, the terms probit and normit are used interchangeably, previously defined as $g(p)$.

- The **complementary log-log** function

$$g(p) = \log(-\log(1-p))$$

is the inverse of the cumulative extreme-value function (also called the Gompertz distribution), which is

$$F(x) = 1 - e^{-e^x}$$

- The **generalized logit** function extends the binary logit link to a vector of levels $(\pi_1, \ldots, \pi_{k+1})$ by contrasting each level with a fixed level

$$g(\pi_i) = \log\left(\frac{\pi_i}{\pi_{k+1}}\right) \quad i = 1, \ldots, k$$

The variances of the normal, logistic, and extreme-value distributions are not the same. Their respective means and variances are

Distribution	Mean	Variance
Normal	0	1
Logistic	0	$\pi^2/3$
Extreme-value	$-\gamma$	$\pi^2/6$

where γ is the Euler constant. In comparing parameter estimates that use different link functions, you need to take into account the different scalings of the corresponding distributions and, for the complementary log-log function, a possible shift in location. For example, if the fitted probabilities are in the neighborhood of 0.1 to 0.9, then the parameter estimates from using the logit link function should be about $\pi/\sqrt{3} \approx 1.8$ larger than the estimates from the probit link function.

Model Fitting

Determining Observations for Likelihood Contributions

If you use the events/trials syntax, each observation is split into two observations. One has the response value 1 with a frequency equal to the frequency of the original observation (which is 1 if the FREQ statement is not used) times the value of the *events* variable. The other observation has the response value 2 and a frequency equal to the frequency of the original observation times the value of (*trials* − *events*). These two observations have the same explanatory variable values and the same FREQ and WEIGHT values as the original observation.

For either the single-trial or the events/trials syntax, let j index all observations. In other words, for the single-trial syntax, j indexes the actual observations. And, for the events/trials syntax, j indexes the observations after splitting (as described previously). If your data set has 30 observations and you use the single-trial syntax, j has values from 1 to 30; if you use the events/trials syntax, j has values from 1 to 60.

Suppose the response variable in a cumulative response model can take on the ordered values $1, \ldots, k, k+1$, where k is an integer ≥ 1. The likelihood for the jth observation with ordered response value y_j and explanatory variables vector (row vectors) $\mathbf{x}_j$ is given by

$$L_j = \begin{cases} F(\alpha_1 + \mathbf{x}_j\boldsymbol{\beta}) & y_j = 1 \\ F(\alpha_i + \mathbf{x}_j\boldsymbol{\beta}) - F(\alpha_{i-1} + \mathbf{x}_j\boldsymbol{\beta}) & 1 < y_j = i \leq k \\ 1 - F(\alpha_k + \mathbf{x}_j\boldsymbol{\beta}) & y_j = k+1 \end{cases}$$

where $F(.)$ is the logistic, normal, or extreme-value distribution function; $\alpha_1, \ldots, \alpha_k$ are ordered intercept parameters; and $\boldsymbol{\beta}$ is the slope parameter vector.

For the generalized logit model, letting the $k+1$st level be the reference level, the intercepts $\alpha_1, \ldots, \alpha_k$ are unordered and the slope vector $\boldsymbol{\beta}_i$ varies with each logit. The likelihood for the jth observation with ordered response value y_j and explanatory variables vector $\mathbf{x}_j$ (row vectors) is given by

$$
\begin{aligned}
L_j &= \Pr(Y = y_j | \mathbf{x}_j) \\
&= \begin{cases} \dfrac{e^{\alpha_i + \mathbf{x}_j \boldsymbol{\beta}_i}}{1 + \sum_{i=1}^{k} e^{\alpha_i + \mathbf{x}_j \boldsymbol{\beta}_i}} & 1 \le y_j = i \le k \\ \dfrac{1}{1 + \sum_{i=1}^{k} e^{\alpha_i + \mathbf{x}_j \boldsymbol{\beta}_i}} & y_j = k+1 \end{cases}
\end{aligned}
$$

Iterative Algorithms for Model Fitting

Two iterative maximum likelihood algorithms are available in PROC SURVEYLOGISTIC to obtain the pseudo-estimate $\hat{\boldsymbol{\theta}}$ of the model parameter $\boldsymbol{\theta}$. The default is the Fisher scoring method, which is equivalent to fitting by iteratively reweighted least squares. The alternative algorithm is the Newton-Raphson method. Both algorithms give the same parameter estimates; the covariance matrix of $\hat{\boldsymbol{\theta}}$ is estimated in the section "Variance Estimation" on page 6427. For a generalized logit model, only the Newton-Raphson technique is available. You can use the TECHNIQUE= option to select a fitting algorithm.

Iteratively Reweighted Least Squares Algorithm (Fisher Scoring)

Let Y be the response variable that takes values $1, \ldots, k, k+1$ ($k \ge 1$). Let j index all observations and Y_j be the value of response for the jth observation. Consider the multinomial variable $\mathbf{Z}_j = (Z_{1j}, \ldots, Z_{kj})'$ such that

$$
Z_{ij} = \begin{cases} 1 & \text{if } Y_j = i \\ 0 & \text{otherwise} \end{cases}
$$

and $Z_{(k+1)j} = 1 - \sum_{i=1}^{k} Z_{ij}$. With π_{ij} denoting the probability that the jth observation has response value i, the expected value of $\mathbf{Z}_j$ is $\boldsymbol{\pi}_j = (\pi_{1j}, \ldots, \pi_{kj})'$, and $\pi_{(k+1)j} = 1 - \sum_{i=1}^{k} \pi_{ij}$. The covariance matrix of $\mathbf{Z}_j$ is $\mathbf{V}_j$, which is the covariance matrix of a multinomial random variable for one trial with parameter vector $\boldsymbol{\pi}_j$. Let $\boldsymbol{\theta}$ be the vector of regression parameters—for example, $\boldsymbol{\theta} = (\alpha_1, \ldots, \alpha_k, \boldsymbol{\beta}')'$ for cumulative logit model. Let $\mathbf{D}_j$ be the matrix of partial derivatives of $\boldsymbol{\pi}_j$ with respect to $\boldsymbol{\theta}$. The estimating equation for the regression parameters is

$$
\sum_j \mathbf{D}_j' \mathbf{W}_j (\mathbf{Z}_j - \boldsymbol{\pi}_j) = \mathbf{0}
$$

where $\mathbf{W}_j = w_j f_j \mathbf{V}_j^{-1}$, and w_j and f_j are the WEIGHT and FREQ values of the jth observation.

With a starting value of $\boldsymbol{\theta}^{(0)}$, the pseudo-estimate of $\boldsymbol{\theta}$ is obtained iteratively as

$$\boldsymbol{\theta}^{(i+1)} = \boldsymbol{\theta}^{(i)} + (\sum_j \mathbf{D}_j' \mathbf{W}_j \mathbf{D}_j)^{-1} \sum_j \mathbf{D}_j' \mathbf{W}_j (\mathbf{Z}_j - \boldsymbol{\pi}_j)$$

where $\mathbf{D}_j$, $\mathbf{W}_j$, and $\boldsymbol{\pi}_j$ are evaluated at the ith iteration $\boldsymbol{\theta}^{(i)}$. The expression after the plus sign is the step size. If the log likelihood evaluated at $\boldsymbol{\theta}^{(i+1)}$ is less than that evaluated at $\boldsymbol{\theta}^{(i)}$, then $\boldsymbol{\theta}^{(i+1)}$ is recomputed by step-halving or ridging. The iterative scheme continues until convergence is obtained—that is, until $\boldsymbol{\theta}^{(i+1)}$ is sufficiently close to $\boldsymbol{\theta}^{(i)}$. Then the maximum likelihood estimate of $\boldsymbol{\theta}$ is $\hat{\boldsymbol{\theta}} = \boldsymbol{\theta}^{(i+1)}$.

By default, starting values are zero for the slope parameters, and starting values are the observed cumulative logits (that is, logits of the observed cumulative proportions of response) for the intercept parameters. Alternatively, the starting values can be specified with the INEST= option.

Newton-Raphson Algorithm

Let

$$\mathbf{g} = \sum_j w_j f_j \frac{\partial l_j}{\partial \boldsymbol{\theta}}$$

$$\mathbf{H} = \sum_j -w_j f_j \frac{\partial^2 l_j}{\partial \boldsymbol{\theta}^2}$$

be the gradient vector and the Hessian matrix, where $l_j = \log L_j$ is the log likelihood for the jth observation. With a starting value of $\boldsymbol{\theta}^{(0)}$, the pseudo-estimate $\hat{\boldsymbol{\theta}}$ of $\boldsymbol{\theta}$ is obtained iteratively until convergence is obtained:

$$\boldsymbol{\theta}^{(i+1)} = \boldsymbol{\theta}^{(i)} + \mathbf{H}^{-1}\mathbf{g}$$

where $\mathbf{H}$ and $\mathbf{g}$ are evaluated at the ith iteration $\boldsymbol{\theta}^{(i)}$. If the log likelihood evaluated at $\boldsymbol{\theta}^{(i+1)}$ is less than that evaluated at $\boldsymbol{\theta}^{(i)}$, then $\boldsymbol{\theta}^{(i+1)}$ is recomputed by step-halving or ridging. The iterative scheme continues until convergence is obtained—that is, until $\boldsymbol{\theta}^{(i+1)}$ is sufficiently close to $\boldsymbol{\theta}^{(i)}$. Then the maximum likelihood estimate of $\boldsymbol{\theta}$ is $\hat{\boldsymbol{\theta}} = \boldsymbol{\theta}^{(i+1)}$.

Convergence Criteria

Four convergence criteria are allowed: ABSFCONV=, FCONV=, GCONV=, and XCONV=. If you specify more than one convergence criterion, the optimization is terminated as soon as one of the criteria is satisfied. If none of the criteria is specified, the default is GCONV=1E−8.

Existence of Maximum Likelihood Estimates

The likelihood equation for a logistic regression model does not always have a finite solution. Sometimes there is a nonunique maximum on the boundary of the parameter space, at infinity. The ex-

istence, finiteness, and uniqueness of pseudo-estimates for the logistic regression model depend on the patterns of data points in the observation space (Albert and Anderson 1984; Santner and Duffy 1986).

Consider a binary response model. Let Y_j be the response of the ith subject, and let $\mathbf{x}_j$ be the row vector of explanatory variables (including the constant 1 associated with the intercept). There are three mutually exclusive and exhaustive types of data configurations: complete separation, quasi-complete separation, and overlap.

Complete separation

There is a complete separation of data points if there exists a vector $\mathbf{b}$ that correctly allocates all observations to their response groups; that is,

$$\begin{cases} \mathbf{x}_j\mathbf{b} > 0 & Y_j = 1 \\ \mathbf{x}_j\mathbf{b} < 0 & Y_j = 2 \end{cases}$$

This configuration gives nonunique infinite estimates. If the iterative process of maximizing the likelihood function is allowed to continue, the log likelihood diminishes to zero, and the dispersion matrix becomes unbounded.

Quasi-complete separation

The data are not completely separable, but there is a vector $\mathbf{b}$ such that

$$\begin{cases} \mathbf{x}_j\mathbf{b} \geq 0 & Y_j = 1 \\ \mathbf{x}_j\mathbf{b} \leq 0 & Y_j = 2 \end{cases}$$

and equality holds for at least one subject in each response group. This configuration also yields nonunique infinite estimates. If the iterative process of maximizing the likelihood function is allowed to continue, the dispersion matrix becomes unbounded and the log likelihood diminishes to a nonzero constant.

Overlap

If neither complete nor quasi-complete separation exists in the sample points, there is an overlap of sample points. In this configuration, the pseudo-estimates exist and are unique.

Complete separation and quasi-complete separation are problems typically encountered with small data sets. Although complete separation can occur with any type of data, quasi-complete separation is not likely with truly continuous explanatory variables.

The SURVEYLOGISTIC procedure uses a simple empirical approach to recognize the data configurations that lead to infinite parameter estimates. The basis of this approach is that any convergence method of maximizing the log likelihood must yield a solution that gives complete separation, if such a solution exists. In maximizing the log likelihood, there is no checking for complete or quasi-complete separation if convergence is attained in eight or fewer iterations. Subsequent to the eighth iteration, the probability of the observed response is computed for each observation. If the probability of the observed response is one for all observations, there is a complete separation of data points and the iteration process is stopped. If the complete separation of data has not been determined and an observation is identified to have an extremely large probability ($\geq$0.95) of the observed response, there are two possible situations. First, there is overlap in the data set, and the observation is an atypical observation of its own group. The iterative process, if allowed to continue, stops

when a maximum is reached. Second, there is quasi-complete separation in the data set, and the asymptotic dispersion matrix is unbounded. If any of the diagonal elements of the dispersion matrix for the standardized observations vectors (all explanatory variables standardized to zero mean and unit variance) exceeds 5,000, quasi-complete separation is declared and the iterative process is stopped. If either complete separation or quasi-complete separation is detected, a warning message is displayed in the procedure output.

Checking for quasi-complete separation is less foolproof than checking for complete separation. The NOCHECK option in the MODEL statement turns off the process of checking for infinite parameter estimates. In cases of complete or quasi-complete separation, turning off the checking process typically results in the procedure failing to converge.

Model Fitting Statistics

Suppose the model contains s explanatory effects. For the jth observation, let $\hat{\pi}_j$ be the estimated probability of the observed response. The three criteria displayed by the SURVEYLOGISTIC procedure are calculated as follows:

- -2 log likelihood:

$$-2 \text{ Log L} = -2 \sum_j w_j f_j \log(\hat{\pi}_j)$$

  where w_j and f_j are the weight and frequency values, respectively, of the jth observation. For binary response models that use the events/trials syntax, this is equivalent to

$$-2 \text{ Log L} = -2 \sum_j w_j f_j \{r_j \log(\hat{\pi}_j) + (n_j - r_j) \log(1 - \hat{\pi}_j)\}$$

  where r_j is the number of events, n_j is the number of trials, and $\hat{\pi}_j$ is the estimated event probability.

- Akaike information criterion:

$$\text{AIC} = -2 \text{ Log L} + 2p$$

  where p is the number of parameters in the model. For cumulative response models, $p = k + s$, where k is the total number of response levels minus one, and s is the number of explanatory effects. For the generalized logit model, $p = k(s + 1)$.

- Schwarz criterion:

$$\text{SC} = -2 \text{ Log L} + p \log(\sum_j f_j)$$

  where p is the number of parameters in the model. For cumulative response models, $p = k + s$, where k is the total number of response levels minus one, and s is the number of explanatory effects. For the generalized logit model, $p = k(s + 1)$.

The −2 log likelihood statistic has a chi-square distribution under the null hypothesis (that all the explanatory effects in the model are zero), and the procedure produces a p-value for this statistic. The AIC and SC statistics give two different ways of adjusting the −2 log likelihood statistic for the number of terms in the model and the number of observations used.

Generalized Coefficient of Determination

Cox and Snell (1989, pp. 208–209) propose the following generalization of the coefficient of determination to a more general linear model:

$$R^2 = 1 - \left\{ \frac{L(\mathbf{0})}{L(\hat{\boldsymbol{\theta}})} \right\}^{\frac{2}{n}}$$

where $L(\mathbf{0})$ is the likelihood of the intercept-only model, $L(\hat{\boldsymbol{\theta}})$ is the likelihood of the specified model, and n is the sample size. The quantity R^2 achieves a maximum of less than 1 for discrete models, where the maximum is given by

$$R^2_{\max} = 1 - \{L(\mathbf{0})\}^{\frac{2}{n}}$$

Nagelkerke (1991) proposes the following adjusted coefficient, which can achieve a maximum value of 1:

$$\tilde{R}^2 = \frac{R^2}{R^2_{\max}}$$

Properties and interpretation of R^2 and $\tilde{R}^2$ are provided in Nagelkerke (1991). In the "Testing Global Null Hypothesis: BETA=0" table, R^2 is labeled as "RSquare" and $\tilde{R}^2$ is labeled as "Max-rescaled RSquare." Use the RSQUARE option to request R^2 and $\tilde{R}^2$.

INEST= Data Set

You can specify starting values for the iterative algorithm in the INEST= data set.

The INEST= data set contains one observation for each BY group. The INEST= data set must contain the intercept variables (named Intercept for binary response models and Intercept, Intercept2, Intercept3, and so forth, for ordinal response models) and all explanatory variables in the MODEL statement. If BY processing is used, the INEST= data set should also include the BY variables, and there must be one observation for each BY group. If the INEST= data set also contains the _TYPE_ variable, only observations with _TYPE_ value 'PARMS' are used as starting values.

Survey Design Information

Specification of Population Totals and Sampling Rates

To include a finite population correction (*fpc*) in Taylor series variance estimation, you can input either the sampling rate or the population total by using the RATE= or TOTAL= option in the PROC SURVEYLOGISTIC statement. (You cannot specify both of these options in the same PROC SURVEYLOGISTIC statement.) The RATE= and TOTAL= options apply only to Taylor series variance estimation. The procedure does not use a finite population correction for BRR or jackknife variance estimation.

If you do not specify the RATE= or TOTAL= option, the Taylor series variance estimation does not include a finite population correction. For fairly small sampling fractions, it is appropriate to ignore this correction. See Cochran (1977) and Kish (1965) for more information.

If your design has multiple stages of selection and you are specifying the RATE= option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the TOTAL= option for a multistage design, you should input the total number of PSUs in the study population. See the section "Primary Sampling Units (PSUs)" on page 6423 for more details.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you can use the RATE=*value* or TOTAL=*value* option. If your sample design is stratified with different sampling rates or population totals in different strata, use the RATE=*SAS-data-set* or TOTAL=*SAS-data-set* option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the DATA= option.

The secondary data set must contain all the stratification variables listed in the STRATA statement and all the variables in the BY statement. If there are formats associated with the STRATA variables and the BY variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the TOTAL=*SAS-data-set* option, the secondary data set must have a variable named _TOTAL_ that contains the stratum population totals. Or if you specify the RATE=*SAS-data-set* option, the secondary data set must have a variable named _RATE_ that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of _TOTAL_ or _RATE_ for that stratum and ignores the rest.

The *value* in the RATE= option or the values of _RATE_ in the secondary data set must be non-negative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYLOGISTIC converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the TOTAL=*value* option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

Primary Sampling Units (PSUs)

When you have clusters, or primary sampling units (PSUs), in your sample design, the procedure estimates variance from the variation among PSUs when the Taylor series variance method is used. See the section "Taylor Series (Linearization)" on page 6427 for more information.

BRR or jackknife variance estimation methods draw multiple replicates (or subsamples) from the full sample by following a specific resampling scheme. These subsamples are constructed by deleting PSUs from the full sample.

If you use a REPWEIGHTS statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a CLUSTER statement. Otherwise, you should specify a CLUSTER statement whenever your design includes clustering at the first stage of sampling. If you do not specify a CLUSTER statement, then PROC SURVEYLOGISTIC treats each observation as a PSU.

Logistic Regression Models and Parameters

The SURVEYLOGISTIC procedure fits a logistic regression model and estimates the corresponding regression parameters. Each model uses the link function you specified in the LINK= option in the MODEL statement. There are four types of model you can use with the procedure: cumulative logit model, complementary log-log model, probit model, and generalized logit model.

Notation

Let Y be the response variable with categories $1, 2, \ldots, D, D+1$. The p covariates are denoted by a p-dimension row vector $\mathbf{x}$.

For a stratified clustered sample design, each observation is represented by a row vector, $(w_{hij}, \mathbf{y}'_{hij}, y_{hij(D+1)}, \mathbf{x}_{hij})$, where

- $h = 1, 2, \ldots, H$ is the stratum index
- $i = 1, 2, \ldots, n_h$ is the cluster index within stratum h
- $j = 1, 2, \ldots, m_{hi}$ is the unit index within cluster i of stratum h
- w_{hij} denotes the sampling weight
- $\mathbf{y}_{hij}$ is a D-dimensional column vector whose elements are indicator variables for the first D categories for variable Y. If the response of the jth unit of the ith cluster in stratum h falls in category d, the dth element of the vector is one, and the remaining elements of the vector are zero, where $d = 1, 2, \ldots, D$.
- $y_{hij(D+1)}$ is the indicator variable for the $(D+1)$ category of variable Y
- $\mathbf{x}_{hij}$ denotes the k-dimensional row vector of explanatory variables for the jth unit of the ith cluster in stratum h. If there is an intercept, then $x_{hij1} \equiv 1$.

- $\tilde{n} = \sum_{h=1}^{H} n_h$ is the total number of clusters in the sample
- $n = \sum_{h=1}^{H} \sum_{i=1}^{n_h} m_{hi}$ is the total sample size

The following notations are also used:

- f_h denotes the sampling rate for stratum h
- $\boldsymbol{\pi}_{hij}$ is the expected vector of the response variable:

$$\begin{aligned} \boldsymbol{\pi}_{hij} &= E(\mathbf{y}_{hij}|\mathbf{x}_{hij}) \\ &= (\pi_{hij1}, \pi_{hij2}, \ldots, \pi_{hijD})' \\ \pi_{hij(D+1)} &= E(y_{hij(D+1)}|\mathbf{x}_{hij}) \end{aligned}$$

Note that $\pi_{hij(D+1)} = 1 - \mathbf{1}'\boldsymbol{\pi}_{hij}$, where $\mathbf{1}$ is a D-dimensional column vector whose elements are 1.

Logistic Regression Models

If the response categories of the response variable Y can be restricted to a number of ordinal values, you can fit cumulative probabilities of the response categories with a cumulative logit model, a complementary log-log model, or a probit model. Details of cumulative logit models (or proportional odds models) can be found in McCullagh and Nelder (1989). If the response categories of Y are nominal responses without natural ordering, you can fit the response probabilities with a generalized logit model. Formulation of the generalized logit models for nominal response variables can be found in Agresti (1990). For each model, the procedure estimates the model parameter $\boldsymbol{\theta}$ by using a pseudo-log-likelihood function. The procedure obtains the pseudo-maximum likelihood estimator $\hat{\boldsymbol{\theta}}$ by using iterations described in the section "Iterative Algorithms for Model Fitting" on page 6417 and estimates its variance described in the section "Variance Estimation" on page 6427.

Cumulative Logit Model

A cumulative logit model uses the **logit** function

$$g(t) = \log\left(\frac{t}{1-t}\right)$$

as the link function.

Denote the cumulative sum of the expected proportions for the first d categories of variable Y by

$$F_{hijd} = \sum_{r=1}^{d} \pi_{hijr}$$

for $d = 1, 2, \ldots, D$. Then the cumulative logit model can be written as

$$\log\left(\frac{F_{hijd}}{1 - F_{hijd}}\right) = \alpha_d + \mathbf{x}_{hij}\boldsymbol{\beta}$$

with the model parameters

$$\begin{aligned}\boldsymbol{\beta} &= (\beta_1, \beta_2, \ldots, \beta_k)' \\ \boldsymbol{\alpha} &= (\alpha_1, \alpha_2, \ldots, \alpha_D)', \quad \alpha_1 < \alpha_2 < \cdots < \alpha_D \\ \boldsymbol{\theta} &= (\boldsymbol{\alpha}', \boldsymbol{\beta}')'\end{aligned}$$

Complementary Log-Log Model

A complementary log-log model uses the **complementary log-log** function

$$g(t) = \log(-\log(1-t))$$

as the link function. Denote the cumulative sum of the expected proportions for the first d categories of variable Y by

$$F_{hijd} = \sum_{r=1}^{d} \pi_{hijr}$$

for $d = 1, 2, \ldots, D$. Then the complementary log-log model can be written as

$$\log(-\log(1 - F_{hijd})) = \alpha_d + \mathbf{x}_{hij}\boldsymbol{\beta}$$

with the model parameters

$$\begin{aligned}\boldsymbol{\beta} &= (\beta_1, \beta_2, \ldots, \beta_k)' \\ \boldsymbol{\alpha} &= (\alpha_1, \alpha_2, \ldots, \alpha_D)', \quad \alpha_1 < \alpha_2 < \cdots < \alpha_D \\ \boldsymbol{\theta} &= (\boldsymbol{\alpha}', \boldsymbol{\beta}')'\end{aligned}$$

Probit Model

A probit model uses the **probit** (or normit) function, which is the inverse of the cumulative standard normal distribution function,

$$g(t) = \Phi^{-1}(t)$$

as the link function, where

$$\Phi(t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{t} e^{-\frac{1}{2}z^2} dz$$

Denote the cumulative sum of the expected proportions for the first d categories of variable Y by

$$F_{hijd} = \sum_{r=1}^{d} \pi_{hijr}$$

for $d = 1, 2, \ldots, D$. Then the probit model can be written as

$$F_{hijd} = \Phi(\alpha_d + \mathbf{x}_{hij}\boldsymbol{\beta})$$

with the model parameters

$$\begin{aligned}\boldsymbol{\beta} &= (\beta_1, \beta_2, \ldots, \beta_k)' \\ \boldsymbol{\alpha} &= (\alpha_1, \alpha_2, \ldots, \alpha_D)', \quad \alpha_1 < \alpha_2 < \cdots < \alpha_D \\ \boldsymbol{\theta} &= (\boldsymbol{\alpha}', \boldsymbol{\beta}')'\end{aligned}$$

Generalized Logit Model

For nominal response, a generalized logit model is to fit the ratio of the expected proportion for each response category over the expected proportion of a reference category with a logit link function.

Without loss of generality, let category $D+1$ be the reference category for the response variable Y. Denote the expected proportion for the dth category by π_{hijd} as in the section "Notation" on page 6423. Then the generalized logit model can be written as

$$\log\left(\frac{\pi_{hijd}}{\pi_{hij(D+1)}}\right) = \mathbf{x}_{hij}\boldsymbol{\beta}_d$$

for $d = 1, 2, \ldots, D$, with the model parameters

$$\begin{aligned}\boldsymbol{\beta}_d &= (\beta_{d1}, \beta_{d2}, \ldots, \beta_{dk})' \\ \boldsymbol{\theta} &= (\boldsymbol{\beta}_1', \boldsymbol{\beta}_2', \ldots, \boldsymbol{\beta}_D')'\end{aligned}$$

Likelihood Function

Let $\mathbf{g}(\cdot)$ be a link function such that

$$\boldsymbol{\pi} = \mathbf{g}(\mathbf{x}, \boldsymbol{\theta})$$

where $\boldsymbol{\theta}$ is a column vector for regression coefficients. The pseudo-log likelihood is

$$l(\boldsymbol{\theta}) = \sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} w_{hij}\left((\log(\boldsymbol{\pi}_{hij}))'\mathbf{y}_{hij} + \log(\pi_{hij(D+1)})y_{hij(D+1)}\right)$$

Denote the pseudo-estimator as $\hat{\boldsymbol{\theta}}$, which is a solution to the estimating equations:

$$\sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} w_{hij}\mathbf{D}_{hij}\left(\mathrm{diag}(\boldsymbol{\pi}_{hij}) - \boldsymbol{\pi}_{hij}\boldsymbol{\pi}_{hij}'\right)^{-1}(\mathbf{y}_{hij} - \boldsymbol{\pi}_{hij}) = \mathbf{0}$$

where $\mathbf{D}_{hij}$ is the matrix of partial derivatives of the link function $\mathbf{g}$ with respect to $\boldsymbol{\theta}$.

To obtain the pseudo-estimator $\hat{\boldsymbol{\theta}}$, the procedure uses iterations with a starting value $\boldsymbol{\theta}^{(0)}$ for $\boldsymbol{\theta}$. See the section "Iterative Algorithms for Model Fitting" on page 6417 for more details.

Variance Estimation

Due to the variability of characteristics among items in the population, researchers apply scientific sample designs in the sample selection process to reduce the risk of a distorted view of the population, and they make inferences about the population based on the information from the sample survey data. In order to make statistically valid inferences for the population, they must incorporate the sample design in the data analysis.

The SURVEYLOGISTIC procedure fits linear logistic regression models for discrete response survey data by using the maximum likelihood method. In the variance estimation, the procedure uses the Taylor series (linearization) method or replication (resampling) methods to estimate sampling errors of estimators based on complex sample designs, including designs with stratification, clustering, and unequal weighting (Binder (1981, 1983); Roberts, Rao, and Kumar (1987); Skinner, Holt, and Smith (1989); Binder and Roberts (2003); Morel (1989); Lehtonen and Pahkinen (1995); Woodruff (1971); Fuller (1975); Särndal, Swensson, and Wretman (1992); Wolter (1985); Rust (1985); Dippo, Fay, and Morganstein (1984); Rao and Shao (1999); Rao, Wu, and Yue (1992); and Rao and Shao (1996)).

You can use the VARMETHOD= option to specify a variance estimation method to use. By default, the Taylor series method is used. However, replication methods have recently gained popularity for estimating variances in complex survey data analysis. One reason for this popularity is the relative simplicity of replication-based estimates, especially for nonlinear estimators; another is that modern computational capacity has made replication methods feasible for practical survey analysis.

Replication methods draw multiple replicates (also called subsamples) from a full sample according to a specific resampling scheme. The most commonly used resampling schemes are the *balanced repeated replication* (BRR) method and the *jackknife* method. For each replicate, the original weights are modified for the PSUs in the replicates to create replicate weights. The parameters of interest are estimated by using the replicate weights for each replicate. Then the variances of parameters of interest are estimated by the variability among the estimates derived from these replicates. You can use the REPWEIGHTS statement to provide your own replicate weights for variance estimation.

The following sections provide details about how the variance-covariance matrix of the estimated regression coefficients is estimated for each variance estimation method.

Taylor Series (Linearization)

The Taylor series (linearization) method is the most commonly used method to estimate the covariance matrix of the regression coefficients for complex survey data. It is the default variance estimation method used by PROC SURVEYLOGISTIC.

Using the notation described in the section "Notation" on page 6423, the estimated covariance matrix of model parameters $\hat{\boldsymbol{\theta}}$ by the Taylor series method is

$$\widehat{V}(\hat{\boldsymbol{\theta}}) = \widehat{\mathbf{Q}}^{-1}\widehat{\mathbf{G}}\widehat{\mathbf{Q}}^{-1}$$

where

$$
\begin{aligned}
\widehat{\mathbf{Q}} &= \sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} w_{hij}\widehat{\mathbf{D}}_{hij}\left(\mathrm{diag}(\hat{\boldsymbol{\pi}}_{hij}) - \hat{\boldsymbol{\pi}}_{hij}\hat{\boldsymbol{\pi}}'_{hij}\right)^{-1}\widehat{\mathbf{D}}'_{hij} \\
\widehat{\mathbf{G}} &= \frac{n-1}{n-p}\sum_{h=1}^{H}\frac{n_h(1-f_h)}{n_h-1}\sum_{i=1}^{n_h}(\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot})(\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot})' \\
\mathbf{e}_{hi\cdot} &= \sum_{j=1}^{m_{hi}} w_{hij}\widehat{\mathbf{D}}_{hij}\left(\mathrm{diag}(\hat{\boldsymbol{\pi}}_{hij}) - \hat{\boldsymbol{\pi}}_{hij}\hat{\boldsymbol{\pi}}'_{hij}\right)^{-1}(\mathbf{y}_{hij} - \hat{\boldsymbol{\pi}}_{hij}) \\
\bar{\mathbf{e}}_{h\cdot\cdot} &= \frac{1}{n_h}\sum_{i=1}^{n_h}\mathbf{e}_{hi\cdot}
\end{aligned}
$$

and $\mathbf{D}_{hij}$ is the matrix of partial derivatives of the link function $\mathbf{g}$ with respect to $\boldsymbol{\theta}$ and $\widehat{\mathbf{D}}_{hij}$ and the response probabilities $\hat{\boldsymbol{\pi}}_{hij}$ are evaluated at $\hat{\boldsymbol{\theta}}$.

If you specify the TECHNIQUE=NEWTON option in the MODEL statement to request the Newton-Raphson algorithm, the matrix $\widehat{\mathbf{Q}}$ is replaced by the negative (expected) Hessian matrix when the estimated covariance matrix $\widehat{V}(\hat{\boldsymbol{\theta}})$ is computed.

Adjustments to the Variance Estimation

The factor $(n-1)/(n-p)$ in the computation of the matrix $\widehat{\mathbf{G}}$ reduces the small sample bias associated with using the estimated function to calculate deviations (Morel 1989; Hidiroglou, Fuller, and Hickman 1980). For simple random sampling, this factor contributes to the degrees-of-freedom correction applied to the residual mean square for ordinary least squares in which p parameters are estimated. By default, the procedure uses this adjustment in Taylor series variance estimation. It is equivalent to specifying the VADJUST=DF option in the MODEL statement. If you do not want to use this multiplier in the variance estimation, you can specify the VADJUST=NONE option in the MODEL statement to suppress this factor.

In addition, you can specify the VADJUST=MOREL option to request an adjustment to the variance estimator for the model parameters $\hat{\boldsymbol{\theta}}$, introduced by Morel (1989):

$$
\widehat{V}(\hat{\boldsymbol{\theta}}) = \widehat{\mathbf{Q}}^{-1}\widehat{\mathbf{G}}\widehat{\mathbf{Q}}^{-1} + \kappa\lambda\widehat{\mathbf{Q}}^{-1}
$$

where for given nonnegative constants δ and ϕ,

$$
\begin{aligned}
\kappa &= \max\left(\delta,\ p^{-1}\mathrm{tr}\left(\widehat{\mathbf{Q}}^{-1}\widehat{\mathbf{G}}\right)\right) \\
\lambda &= \min\left(\phi, \frac{p}{\tilde{n}-p}\right)
\end{aligned}
$$

The adjustment $\kappa\lambda\widehat{\mathbf{Q}}^{-1}$ does the following:

- reduces the small sample bias reflected in inflated Type I error rates
- guarantees a positive-definite estimated covariance matrix provided that $\widehat{\mathbf{Q}}^{-1}$ exists
- is close to zero when the sample size becomes large

In this adjustment, κ is an estimate of the design effect, which has been bounded below by the positive constant δ. You can use DEFFBOUND=δ in the VADJUST=MOREL option in the MODEL statement to specify this lower bound; by default, the procedure uses $\delta = 1$. The factor λ converges to zero when the sample size becomes large, and λ has an upper bound ϕ. You can use ADJBOUND=ϕ in the VADJUST=MOREL option in the MODEL statement to specify this upper bound; by default, the procedure uses $\phi = 0.5$.

Balanced Repeated Replication (BRR) Method

The balanced repeated replication (BRR) method requires that the full sample be drawn by using a stratified sample design with two primary sampling units (PSUs) per stratum. Let H be the total number of strata. The total number of replicates R is the smallest multiple of 4 that is greater than H. However, if you prefer a larger number of replicates, you can specify the REPS=*number* option. If a $number \times number$ Hadamard matrix cannot be constructed, the number of replicates is increased until a Hadamard matrix becomes available.

Each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix and adjusting the original weights for the remaining PSUs. The new weights are called replicate weights.

Replicates are constructed by using the first H columns of the $R \times R$ Hadamard matrix. The rth ($r = 1, 2, ..., R$) replicate is drawn from the full sample according to the rth row of the Hadamard matrix as follows:

- If the (r, h)th element of the Hadamard matrix is 1, then the first PSU of stratum h is included in the rth replicate and the second PSU of stratum h is excluded.
- If the (r, h)th element of the Hadamard matrix is -1, then the second PSU of stratum h is included in the rth replicate and the first PSU of stratum h is excluded.

The replicate weights of the remaining PSUs in each half sample are then doubled to their original weights. For more detail about the BRR method, see Wolter (1985) and Lohr (1999).

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the VARMETHOD=BRR(PRINTH) method-option. If you provide a Hadamard matrix by specifying the VARMETHOD=BRR(HADAMARD=) method-option, then the replicates are generated according to the provided Hadamard matrix.

Let $\hat{\boldsymbol{\theta}}$ be the estimated regression coefficients from the full sample for $\boldsymbol{\theta}$, and let $\hat{\boldsymbol{\theta}}_r$ be the estimated regression coefficient from the rth replicate by using replicate weights. PROC SURVEYLOGISTIC estimates the covariance matrix of $\hat{\boldsymbol{\theta}}$ by

$$\widehat{\mathbf{V}}(\hat{\boldsymbol{\theta}}) = \frac{1}{R}\sum_{r=1}^{R}\left(\hat{\boldsymbol{\theta}}_r - \hat{\boldsymbol{\theta}}\right)\left(\hat{\boldsymbol{\theta}}_r - \hat{\boldsymbol{\theta}}\right)'$$

with H degrees of freedom, where H is the number of strata.

You can use the VARMETHOD=BRR(OUTWEIGHTS=) method-option to save the replicate weights into a SAS data set.

Fay's BRR Method

Fay's method is a modification of the BRR method, and it requires a stratified sample design with two primary sampling units (PSUs) per stratum. The total number of replicates R is the smallest multiple of 4 that is greater than the total number of strata H. However, if you prefer a larger number of replicates, you can specify the REPS= option.

For each replicate, Fay's method uses a Fay coefficient $0 \leq \epsilon < 1$ to impose a perturbation of the original weights in the full sample that is gentler than using only half samples, as in the traditional BRR method. The Fay coefficient $0 \leq \epsilon < 1$ can be optionally set by the FAY = ϵ method-option. By default, $\epsilon = 0.5$ if only the FAY method-option is used without specifying a value for ϵ (Judkins 1990; Rao and Shao 1999). When $\epsilon = 0$, Fay's method becomes the traditional BRR method. For more details, see Dippo, Fay, and Morganstein (1984), Fay (1984), Fay (1989), and Judkins (1990).

Let H be the number of strata. Replicates are constructed by using the first H columns of the $R \times R$ Hadamard matrix, where R is the number of replicates, $R > H$. The rth ($r = 1, 2, ..., R$) replicate is created from the full sample according to the rth row of the Hadamard matrix as follows:

- If the (r, h)th element of the Hadamard matrix is 1, then the full sample weight of the first PSU in stratum h is multiplied by ϵ and that of the second PSU is multiplied by $2-\epsilon$ to obtain the rth replicate weights.
- If the (r, h)th element of the Hadamard matrix is -1, then the full sample weight of the first PSU in stratum h is multiplied by $2-\epsilon$ and that of the second PSU is multiplied by ϵ to obtain the rth replicate weights.

You can use the VARMETHOD=BRR(OUTWEIGHTS=) method-option to save the replicate weights into a SAS data set.

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the VARMETHOD=BRR(PRINTH) method-option. If you provide a Hadamard matrix by specifying the VARMETHOD=BRR(HADAMARD=) method-option, then the replicates are generated according to the provided Hadamard matrix.

Let $\hat{\boldsymbol{\theta}}$ be the estimated regression coefficients from the full sample for $\boldsymbol{\theta}$. Let $\hat{\boldsymbol{\theta}}_r$ be the estimated regression coefficient obtained from the rth replicate by using replicate weights. PROC SURVEYLOGISTIC estimates the covariance matrix of $\hat{\boldsymbol{\theta}}$ by

$$\widehat{\mathbf{V}}(\hat{\boldsymbol{\theta}}) = \frac{1}{R(1-\epsilon)^2} \sum_{r=1}^{R} \left(\hat{\boldsymbol{\theta}}_r - \hat{\boldsymbol{\theta}}\right)\left(\hat{\boldsymbol{\theta}}_r - \hat{\boldsymbol{\theta}}\right)'$$

with H degrees of freedom, where H is the number of strata.

Jackknife Method

The jackknife method of variance estimation deletes one PSU at a time from the full sample to create replicates. The total number of replicates R is the same as the total number of PSUs. In each replicate, the sample weights of the remaining PSUs are modified by the *jackknife coefficient* α_r. The modified weights are called replicate weights.

The jackknife coefficient and replicate weights are described as follows.

Without Stratification If there is no stratification in the sample design (no STRATA statement), the jackknife coefficients α_r are the same for all replicates:

$$\alpha_r = \frac{R-1}{R} \quad \text{where } r = 1, 2, ..., R$$

Denote the original weight in the full sample for the jth member of the ith PSU as w_{ij}. If the ith PSU is included in the rth replicate ($r = 1, 2, ..., R$), then the corresponding replicate weight for the jth member of the ith PSU is defined as

$$w_{ij}^{(r)} = w_{ij}/\alpha_r$$

With Stratification If the sample design involves stratification, each stratum must have at least two PSUs to use the jackknife method.

Let stratum $\tilde{h}_r$ be the stratum from which a PSU is deleted for the rth replicate. Stratum $\tilde{h}_r$ is called the *donor stratum.* Let $n_{\tilde{h}_r}$ be the total number of PSUs in the donor stratum $\tilde{h}_r$. The jackknife coefficients are defined as

$$\alpha_r = \frac{n_{\tilde{h}_r} - 1}{n_{\tilde{h}_r}}, \quad \text{where } r = 1, 2, ..., R$$

Denote the original weight in the full sample for the jth member of the ith PSU as w_{ij}. If the ith PSU is included in the rth replicate ($r = 1, 2, ..., R$), then the corresponding replicate weight for the jth member of the ith PSU is defined as

$$w_{ij}^{(r)} = \begin{cases} w_{ij} & \text{if } i\text{th PSU is not in the donor stratum } \tilde{h}_r \\ w_{ij}/\alpha_r & \text{if } i\text{th PSU is in the donor stratum } \tilde{h}_r \end{cases}$$

You can use the VARMETHOD=JACKKNIFE(OUTJKCOEFS=) method-option to save the jackknife coefficients into a SAS data set and use the VARMETHOD=JACKKNIFE(OUTWEIGHTS=) method-option to save the replicate weights into a SAS data set.

If you provide your own replicate weights with a REPWEIGHTS statement, then you can also provide corresponding jackknife coefficients with the JKCOEFS= option.

Let $\hat{\boldsymbol{\theta}}$ be the estimated regression coefficients from the full sample for $\boldsymbol{\theta}$. Let $\hat{\boldsymbol{\theta}}_r$ be the estimated regression coefficient obtained from the rth replicate by using replicate weights. PROC SURVEYLOGISTIC estimates the covariance matrix of $\hat{\boldsymbol{\theta}}$ by

$$\widehat{\mathbf{V}}(\hat{\boldsymbol{\theta}}) = \sum_{r=1}^{R} \alpha_r \left(\hat{\boldsymbol{\theta}}_r - \hat{\boldsymbol{\theta}}\right)\left(\hat{\boldsymbol{\theta}}_r - \hat{\boldsymbol{\theta}}\right)'$$

with $R - H$ degrees of freedom, where R is the number of replicates and H is the number of strata, or $R - 1$ when there is no stratification.

Hadamard Matrix

A Hadamard matrix $\mathbf{H}$ is a square matrix whose elements are either 1 or -1 such that

$$\mathbf{H}\mathbf{H}' = k\mathbf{I}$$

where k is the dimension of $\mathbf{H}$ and $\mathbf{I}$ is the identity matrix of order k. The order k is necessarily 1, 2, or a positive integer that is a multiple of 4.

For example, the following matrix is a Hadamard matrix of dimension $k = 8$:

$$\begin{array}{rrrrrrrr}
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\
1 & 1 & -1 & -1 & 1 & 1 & -1 & -1 \\
1 & -1 & -1 & 1 & 1 & -1 & -1 & 1 \\
1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\
1 & -1 & 1 & -1 & -1 & 1 & -1 & 1 \\
1 & 1 & -1 & -1 & -1 & -1 & 1 & 1 \\
1 & -1 & -1 & 1 & -1 & 1 & 1 & -1
\end{array}$$

Domain Analysis

A DOMAIN statement requests the procedure to perform logistic regression analysis for each domain.

For a domain Ω, let I_Ω be the corresponding indicator variable:

$$I_\Omega(h,i,j) = \begin{cases} 1 & \text{if observation } (h,i,j) \text{ belongs to } \Omega \\ 0 & \text{otherwise} \end{cases}$$

Let

$$v_{hij} = w_{hij} I_\Omega(h,i,j) = \begin{cases} w_{hij} & \text{if observation } (h,i,j) \text{ belongs to } \Omega \\ 0 & \text{otherwise} \end{cases}$$

The regression in domain Ω uses v as the weight variable.

Hypothesis Testing and Estimation

Score Statistics and Tests

To understand the general form of the score statistics, let $\mathbf{g}(\boldsymbol{\theta})$ be the vector of first partial derivatives of the log likelihood with respect to the parameter vector $\boldsymbol{\theta}$, and let $\mathbf{H}(\boldsymbol{\theta})$ be the matrix of second partial derivatives of the log likelihood with respect to $\boldsymbol{\theta}$. That is, $\mathbf{g}(\boldsymbol{\theta})$ is the gradient vector, and $\mathbf{H}(\boldsymbol{\theta})$ is the Hessian matrix. Let $\mathbf{I}(\boldsymbol{\theta})$ be either $-\mathbf{H}(\boldsymbol{\theta})$ or the expected value of $-\mathbf{H}(\boldsymbol{\theta})$. Consider a null hypothesis H_0. Let $\hat{\boldsymbol{\theta}}$ be the MLE of $\boldsymbol{\theta}$ under H_0. The chi-square score statistic for testing H_0 is defined by

$$\mathbf{g}'(\hat{\boldsymbol{\theta}})\mathbf{I}^{-1}(\hat{\boldsymbol{\theta}})\mathbf{g}(\hat{\boldsymbol{\theta}})$$

It has an asymptotic χ^2 distribution with r degrees of freedom under H_0, where r is the number of restrictions imposed on $\boldsymbol{\theta}$ by H_0.

Testing the Parallel Lines Assumption

For an ordinal response, PROC SURVEYLOGISTIC performs a test of the parallel lines assumption. In the displayed output, this test is labeled "Score Test for the Equal Slopes Assumption" when the LINK= option is NORMIT or CLOGLOG. When LINK=LOGIT, the test is labeled as "Score Test for the Proportional Odds Assumption" in the output. This section describes the methods used to calculate the test.

For this test, the number of response levels, $D + 1$, is assumed to be strictly greater than 2. Let Y be the response variable taking values $1, \ldots, D, D + 1$. Suppose there are k explanatory variables. Consider the general cumulative model without making the parallel lines assumption:

$$g(\Pr(Y \leq d \mid \mathbf{x})) = (1, \mathbf{x})\boldsymbol{\theta}_d, \quad 1 \leq d \leq D$$

where $g(\cdot)$ is the link function, and $\boldsymbol{\theta}_d = (\alpha_d, \beta_{d1}, \ldots, \beta_{dk})'$ is a vector of unknown parameters consisting of an intercept α_d and k slope parameters $\beta_{k1}, \ldots, \beta_{kd}$. The parameter vector for this general cumulative model is

$$\boldsymbol{\theta} = (\boldsymbol{\theta}_1', \ldots, \boldsymbol{\theta}_D')'$$

Under the null hypothesis of parallelism H_0: $\beta_{1i} = \beta_{2i} = \cdots = \beta_{Di}, 1 \leq i \leq k$, there is a single common slope parameter for each of the s explanatory variables. Let $\beta_1, \ldots, \beta_k$ be the common slope parameters. Let $\hat{\alpha}_1, \ldots, \hat{\alpha}_D$ and $\hat{\beta}_1, \ldots, \hat{\beta}_D$ be the MLEs of the intercept parameters and the common slope parameters. Then, under H_0, the MLE of $\boldsymbol{\theta}$ is

$$\hat{\boldsymbol{\theta}} = (\hat{\boldsymbol{\theta}}_1', \ldots, \hat{\boldsymbol{\theta}}_D')' \quad \text{with} \quad \hat{\boldsymbol{\theta}}_d = (\hat{\alpha}_d, \hat{\beta}_1, \ldots, \hat{\beta}_k)', \quad 1 \le d \le D$$

and the chi-squared score statistic $\mathbf{g}'(\hat{\boldsymbol{\theta}})\mathbf{I}^{-1}(\hat{\boldsymbol{\theta}})\mathbf{g}(\hat{\boldsymbol{\theta}})$ has an asymptotic chi-square distribution with $k(D-1)$ degrees of freedom. This tests the parallel lines assumption by testing the equality of separate slope parameters simultaneously for all explanatory variables.

Wald Confidence Intervals for Parameters

Wald confidence intervals are sometimes called the normal confidence intervals. They are based on the asymptotic normality of the parameter estimators. The $100(1-\alpha)\%$ Wald confidence interval for θ_j is given by

$$\hat{\theta}_j \pm z_{1-\alpha/2}\hat{\sigma}_j$$

where $z_{1-\alpha/2}$ is the $100(1-\alpha/2)$th percentile of the standard normal distribution, $\hat{\theta}_j$ is the pseudo-estimate of θ_j, and $\hat{\sigma}_j$ is the standard error estimate of $\hat{\theta}_j$ in the section "Variance Estimation" on page 6427.

Testing Linear Hypotheses about the Regression Coefficients

Linear hypotheses for $\boldsymbol{\theta}$ are expressed in matrix form as

$$H_0: \mathbf{L}\boldsymbol{\theta} = \mathbf{c}$$

where $\mathbf{L}$ is a matrix of coefficients for the linear hypotheses and $\mathbf{c}$ is a vector of constants. The vector of regression coefficients $\boldsymbol{\theta}$ includes slope parameters as well as intercept parameters. The Wald chi-square statistic for testing H_0 is computed as

$$\chi^2_W = (\mathbf{L}\hat{\boldsymbol{\theta}} - \mathbf{c})'[\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\theta}})\mathbf{L}']^{-1}(\mathbf{L}\hat{\boldsymbol{\theta}} - \mathbf{c})$$

where $\widehat{\mathbf{V}}(\hat{\boldsymbol{\theta}})$ is the estimated covariance matrix in the section "Variance Estimation" on page 6427. Under H_0, χ^2_W has an asymptotic chi-square distribution with r degrees of freedom, where r is the rank of $\mathbf{L}$.

Odds Ratio Estimation

Consider a dichotomous response variable with outcomes *event* and *nonevent*. Let a dichotomous risk factor variable X take the value 1 if the risk factor is present and 0 if the risk factor is absent. According to the logistic model, the log odds function, $g(X)$, is given by

$$g(X) \equiv \log\left(\frac{\Pr(\,event \mid X)}{\Pr(\,nonevent \mid X)}\right) = \beta_0 + \beta_1 X$$

The odds ratio ψ is defined as the ratio of the odds for those with the risk factor ($X = 1$) to the odds for those without the risk factor ($X = 0$). The log of the odds ratio is given by

$$\log(\psi) \equiv \log(\psi(X = 1, X = 0)) = g(X = 1) - g(X = 0) = \beta_1$$

The parameter, β_1, associated with X represents the change in the log odds from $X = 0$ to $X = 1$. So the odds ratio is obtained by simply exponentiating the value of the parameter associated with the risk factor. The odds ratio indicates how the odds of *event* change as you change X from 0 to 1. For instance, $\psi = 2$ means that the odds of an event when $X = 1$ are twice the odds of an event when $X = 0$.

Suppose the values of the dichotomous risk factor are coded as constants a and b instead of 0 and 1. The odds when $X = a$ become $\exp(\beta_0 + a\beta_1)$, and the odds when $X = b$ become $\exp(\beta_0 + b\beta_1)$. The odds ratio corresponding to an increase in X from a to b is

$$\psi = \exp[(b - a)\beta_1] = [\exp(\beta_1)]^{b-a} \equiv [\exp(\beta_1)]^c$$

Note that for any a and b such that $c = b - a = 1, \psi = \exp(\beta_1)$. So the odds ratio can be interpreted as the change in the odds for any increase of one unit in the corresponding risk factor. However, the change in odds for some amount other than one unit is often of greater interest. For example, a change of one pound in body weight might be too small to be considered important, while a change of 10 pounds might be more meaningful. The odds ratio for a change in X from a to b is estimated by raising the odds ratio estimate for a unit change in X to the power of $c = b - a$, as shown previously.

For a polytomous risk factor, the computation of odds ratios depends on how the risk factor is parameterized. For illustration, suppose that Race is a risk factor with four categories: White, Black, Hispanic, and Other.

For the effect parameterization scheme (PARAM=EFFECT) with White as the reference group, the design variables for Race are as follows.

	Design Variables		
Race	X_1	X_2	X_3
Black	1	0	0
Hispanic	0	1	0
Other	0	0	1
White	−1	−1	−1

The log odds for Black is

$$\begin{aligned} g(\text{Black}) &= \beta_0 + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) \\ &= \beta_0 + \beta_1 \end{aligned}$$

The log odds for White is

$$\begin{aligned} g(\text{White}) &= \beta_0 + \beta_1(X_1 = -1) + \beta_2(X_2 = -1) + \beta_3(X_3 = -1)) \\ &= \beta_0 - \beta_1 - \beta_2 - \beta_3 \end{aligned}$$

Therefore, the log odds ratio of Black versus White becomes

$$\begin{aligned}\log(\psi(\text{Black, White})) &= g(\text{Black}) - g(\text{White}) \\ &= 2\beta_1 + \beta_2 + \beta_3\end{aligned}$$

For the reference cell parameterization scheme (PARAM=REF) with White as the reference cell, the design variables for race are as follows.

	Design Variables		
Race	X_1	X_2	X_3
Black	1	0	0
Hispanic	0	1	0
Other	0	0	1
White	0	0	0

The log odds ratio of Black versus White is given by

$$\begin{aligned}\log(\psi(\text{Black, White})) &= g(\text{Black}) - g(\text{White}) \\ &= (\beta_0 + \beta_1(X_1 = 1) + \beta_2(X_2 = 0)) + \beta_3(X_3 = 0)) - \\ &\quad (\beta_0 + \beta_1(X_1 = 0) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0)) \\ &= \beta_1\end{aligned}$$

For the GLM parameterization scheme (PARAM=GLM), the design variables are as follows.

	Design Variables			
Race	X_1	X_2	X_3	X_4
Black	1	0	0	0
Hispanic	0	1	0	0
Other	0	0	1	0
White	0	0	0	1

The log odds ratio of Black versus White is

$$\begin{aligned}\log(\psi(\text{Black, White})) &= g(\text{Black}) - g(\text{White}) \\ &= (\beta_0 + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) + \beta_4(X_4 = 0)) - \\ &\quad (\beta_0 + \beta_1(X_1 = 0) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) + \beta_4(X_4 = 1)) \\ &= \beta_1 - \beta_4\end{aligned}$$

Consider the hypothetical example of heart disease among race in Hosmer and Lemeshow (2000, p. 51). The entries in the following contingency table represent counts.

	Race			
Disease Status	**White**	**Black**	**Hispanic**	**Other**
Present	5	20	15	10
Absent	20	10	10	10

The computation of odds ratio of Black versus White for various parameterization schemes is shown in Table 84.3.

Table 84.3 Odds Ratio of Heart Disease Comparing Black to White

	Parameter Estimates				
PARAM=	$\hat{\beta}_1$	$\hat{\beta}_2$	$\hat{\beta}_3$	$\hat{\beta}_4$	**Odds Ratio Estimates**
EFFECT	0.7651	0.4774	0.0719		$\exp(2 \times 0.7651 + 0.4774 + 0.0719) = 8$
REF	2.0794	1.7917	1.3863		$\exp(2.0794) = 8$
GLM	2.0794	1.7917	1.3863	0.0000	$\exp(2.0794) = 8$

Since the log odds ratio ($\log(\psi)$) is a linear function of the parameters, the Wald confidence interval for $\log(\psi)$ can be derived from the parameter estimates and the estimated covariance matrix. Confidence intervals for the odds ratios are obtained by exponentiating the corresponding confidence intervals for the log odd ratios. In the displayed output of PROC SURVEYLOGISTIC, the "Odds Ratio Estimates" table contains the odds ratio estimates and the corresponding 95% Wald confidence intervals computed by using the covariance matrix in the section "Variance Estimation" on page 6427. For continuous explanatory variables, these odds ratios correspond to a unit increase in the risk factors.

To customize odds ratios for specific units of change for a continuous risk factor, you can use the UNITS statement to specify a list of relevant units for each explanatory variable in the model. Estimates of these customized odds ratios are given in a separate table. Let (L_j, U_j) be a confidence interval for $\log(\psi)$. The corresponding lower and upper confidence limits for the customized odds ratio $\exp(c\beta_j)$ are $\exp(cL_j)$ and $\exp(cU_j)$, respectively, (for $c > 0$); or $\exp(cU_j)$ and $\exp(cL_j)$, respectively, (for $c < 0$). You use the CLODDS= option to request the confidence intervals for the odds ratios.

For a generalized logit model, odds ratios are computed similarly, except D odds ratios are computed for each effect, corresponding to the D logits in the model.

Rank Correlation of Observed Responses and Predicted Probabilities

The predicted mean score of an observation is the sum of the Ordered Values (shown in the "Response Profile" table) minus one, weighted by the corresponding predicted probabilities for that observation; that is, the predicted means score is $\sum_{d=1}^{D+1}(d-1)\hat{\pi}_d$, where $D+1$ is the number of response levels and $\hat{\pi}_d$ is the predicted probability of the dth (ordered) response.

A pair of observations with different observed responses is said to be *concordant* if the observation with the lower ordered response value has a lower predicted mean score than the observation with the higher ordered response value. If the observation with the lower ordered response value has a higher predicted mean score than the observation with the higher ordered response value, then the pair is *discordant*. If the pair is neither concordant nor discordant, it is a *tie*. Enumeration of the total numbers of concordant and discordant pairs is carried out by categorizing the predicted mean score into intervals of length $D/500$ and accumulating the corresponding frequencies of observations.

Let N be the sum of observation frequencies in the data. Suppose there are a total of t pairs with different responses, n_c of them are concordant, n_d of them are discordant, and $t - n_c - n_d$ of them

are tied. PROC SURVEYLOGISTIC computes the following four indices of rank correlation for assessing the predictive ability of a model:

$$
\begin{aligned}
c &= (n_c + 0.5(t - n_c - n_d))/t \\
\text{Somers' } D &= (n_c - n_d)/t \\
\text{Goodman-Kruskal Gamma} &= (n_c - n_d)/(n_c + n_d) \\
\text{Kendall's Tau-}a &= (n_c - n_d)/(0.5N(N-1))
\end{aligned}
$$

Note that c also gives an estimate of the area under the receiver operating characteristic (ROC) curve when the response is binary (Hanley and McNeil 1982).

For binary responses, the predicted mean score is equal to the predicted probability for Ordered Value 2. As such, the preceding definition of concordance is consistent with the definition used in previous releases for the binary response model.

Linear Predictor, Predicted Probability, and Confidence Limits

This section describes how predicted probabilities and confidence limits are calculated by using the pseudo-estimates (MLEs) obtained from PROC SURVEYLOGISTIC. For a specific example, see the section "Getting Started: SURVEYLOGISTIC Procedure" on page 6377. Predicted probabilities and confidence limits can be output to a data set with the OUTPUT statement.

Cumulative Response Models

For a row vector of explanatory variables $\mathbf{x}$, the linear predictor

$$\eta_i = g(\Pr(Y \le i \mid \mathbf{x})) = \alpha_i + \mathbf{x}\boldsymbol{\beta}, \quad 1 \le i \le k$$

is estimated by

$$\hat{\eta}_i = \hat{\alpha}_i + \mathbf{x}\hat{\boldsymbol{\beta}}$$

where $\hat{\alpha}_i$ and $\hat{\boldsymbol{\beta}}$ are the MLEs of α_i and $\boldsymbol{\beta}$. The estimated standard error of η_i is $\hat{\sigma}(\hat{\eta}_i)$, which can be computed as the square root of the quadratic form $(1, \mathbf{x}')\hat{\mathbf{V}}_{\mathbf{b}}(1, \mathbf{x}')'$, where $\hat{\mathbf{V}}_{\mathbf{b}}$ is the estimated covariance matrix of the parameter estimates. The asymptotic $100(1-\alpha)\%$ confidence interval for η_i is given by

$$\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i)$$

where $z_{\alpha/2}$ is the $100(1-\alpha/2)$ percentile point of a standard normal distribution.

The predicted value and the $100(1-\alpha)\%$ confidence limits for $\Pr(Y \le i \mid \mathbf{x})$ are obtained by back-transforming the corresponding measures for the linear predictor.

Link	Predicted Probability	$100(1-\alpha)$ Confidence Limits
LOGIT	$1/(1+e^{-\hat{\eta}_i})$	$1/(1+e^{-\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i)})$
PROBIT	$\Phi(\hat{\eta}_i)$	$\Phi(\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i))$
CLOGLOG	$1-e^{-e^{\hat{\eta}_i}}$	$1-e^{-e^{\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i)}}$

Generalized Logit Model

For a vector of explanatory variables $\boldsymbol{x}$, let π_i denote the probability of obtaining the response value i:

$$\pi_i = \begin{cases} \pi_{k+1} e^{\alpha_i + \mathbf{x}\boldsymbol{\beta}_i} & 1 \le i \le k \\ \dfrac{1}{1+\sum_{j=1}^{k} e^{\alpha_j + \mathbf{x}\boldsymbol{\beta}_j}} & i = k+1 \end{cases}$$

By the *delta method*,

$$\sigma^2(\pi_i) = \left(\frac{\partial \pi_i}{\partial \boldsymbol{\theta}}\right)' \mathbf{V}(\boldsymbol{\theta}) \frac{\partial \pi_i}{\partial \boldsymbol{\theta}}$$

A $100(1-\alpha)\%$ confidence level for π_i is given by

$$\hat{\pi}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\pi}_i)$$

where $\hat{\pi}_i$ is the estimated expected probability of response i and $\hat{\sigma}(\hat{\pi}_i)$ is obtained by evaluating $\sigma(\pi_i)$ at $\boldsymbol{\theta} = \hat{\boldsymbol{\theta}}$.

Output Data Sets

You can use the Output Delivery System (ODS) to create a SAS data set from any piece of PROC SURVEYLOGISTIC output. See the section "ODS Table Names" on page 6447 for more information. For a more detailed description of using ODS, see Chapter 20, "Using the Output Delivery System."

PROC SURVEYLOGISTIC also provides an OUTPUT statement to create a data set that contains estimated linear predictors, the estimates of the cumulative or individual response probabilities, and their confidence limits.

If you use BRR or jackknife variance estimation, PROC SURVEYLOGISTIC provides an output data set that stores the replicate weights and an output data set that stores the jackknife coefficients for jackknife variance estimation.

OUT= Data Set in the OUTPUT Statement

The OUT= data set in the OUTPUT statement contains all the variables in the input data set along with statistics you request by using *keyword=name* options or the PREDPROBS= option in the OUTPUT statement. In addition, if you use the single-trial syntax and you request any of the XBETA=, STDXBETA=, PREDICTED=, LCL=, and UCL= options, the OUT= data set contains the automatic variable _LEVEL_. The value of _LEVEL_ identifies the response category upon which the computed values of XBETA=, STDXBETA=, PREDICTED=, LCL=, and UCL= are based.

When there are more than two response levels, only variables named by the XBETA=, STDXBETA=, PREDICTED=, LOWER=, and UPPER= options and the variables given by PREDPROBS=(INDIVIDUAL CUMULATIVE) have their values computed; the other variables have missing values. If you fit a generalized logit model, the cumulative predicted probabilities are not computed.

When there are only two response categories, each input observation produces one observation in the OUT= data set.

If there are more than two response categories and you specify only the PREDPROBS= option, then each input observation produces one observation in the OUT= data set. However, if you fit an ordinal (cumulative) model and specify options other than the PREDPROBS= options, each input observation generates as many output observations as one fewer than the number of response levels, and the predicted probabilities and their confidence limits correspond to the cumulative predicted probabilities. If you fit a generalized logit model and specify options other than the PREDPROBS= options, each input observation generates as many output observations as the number of response categories; the predicted probabilities and their confidence limits correspond to the probabilities of individual response categories.

For observations in which only the response variable is missing, values of the XBETA=, STDXBETA=, PREDICTED=, UPPER=, LOWER=, and PREDPROBS= options are computed even though these observations do not affect the model fit. This enables, for instance, predicted probabilities to be computed for new observations.

Replicate Weights Output Data Set

If you specify the OUTWEIGHTS= method-option for BRR or jackknife method in the VARMETHOD= option, PROC SURVEYLOGISTIC stores the replicate weights in an output data set. The OUTWEIGHTS= output data set contains all observations used in the analysis or all valid observations in the DATA= input data set. A valid observation is an observation that has a positive value of the WEIGHT variable. Valid observations must also have nonmissing values of the STRATA and CLUSTER variables, unless you specify the MISSING option.

The OUTWEIGHTS= data set contains the following variables:

- all variables in the DATA= input data set
- RepWt_1, RepWt_2, . . ., RepWt_n, which are the replicate weight variables

where n is the total number of replicates in the analysis. Each replicate weight variable contains the replicate weights for the corresponding replicate. Replicate weights equal zero for those observations not included in the replicate.

After the procedure creates replicate weights for a particular input data set and survey design, you can use the OUTWEIGHTS= method-option to store these replicate weights and then use them again in subsequent analyses, either in PROC SURVEYLOGISTIC or in the other survey procedures. You can use the REPWEIGHTS statement to provide replicate weights for the procedure.

Jackknife Coefficients Output Data Set

If you specify the OUTJKCOEFS= method-option for VARMETHOD=JACKKNIFE, PROC SURVEYLOGISTIC stores the jackknife coefficients in an output data set. The OUTJKCOEFS= output data set contains one observation for each replicate. The OUTJKCOEFS= data set contains the following variables:

- Replicate, which is the replicate number for the jackknife coefficient
- JKCoefficient, which is the jackknife coefficient
- DonorStratum, which is the stratum of the PSU that was deleted to construct the replicate, if you specify a STRATA statement

After the procedure creates jackknife coefficients for a particular input data set and survey design, you can use the OUTJKCOEFS= method-option to store these coefficients and then use them again in subsequent analyses, either in PROC SURVEYLOGISTIC or in the other survey procedures. You can use the JKCOEFS= option in the REPWEIGHTS statement to provide jackknife coefficients for the procedure.

Displayed Output

The SURVEYLOGISTIC procedure produces the following output.

Model Information

By default, PROC SURVEYLOGISTIC displays the following information in the "Model Information" table:

- name of the input Data Set
- name and label of the Response Variable if the single-trial syntax is used
- number of Response Levels
- name of the Events Variable if the events/trials syntax is used

- name of the Trials Variable if the events/trials syntax is used
- name of the Offset Variable if the OFFSET= option is specified
- name of the Frequency Variable if the FREQ statement is specified
- name(s) of the Stratum Variable(s) if the STRATA statement is specified
- total Number of Strata if the STRATA statement is specified
- name(s) of the Cluster Variable(s) if the CLUSTER statement is specified
- total Number of Clusters if the CLUSTER statement is specified
- name of the Weight Variable if the WEIGHT statement is specified
- Variance Adjustment method
- Upper Bound ADJBOUND parameter used in the VADJUST=MOREL(ADJBOUND=) option
- Lower Bound DEFFBOUND parameter used in the VADJUST=MOREL(DEFFBOUND=) option
- whether FPC (finite population correction) is used

Variance Estimation

By default, PROC SURVEYLOGISTIC displays the following variance estimation specification in the "Variance Estimation" table:

- variance estimation Method
- Variance Adjustment method
- Upper Bound ADJBOUND parameter used in the VADJUST=MOREL(ADJBOUND=) option
- Lower Bound DEFFBOUND parameter used in the VADJUST=MOREL(DEFFBOUND=) option
- whether FPC (finite population correction) is used
- Number of Replicates if you specify VARMETHOD=BRR or VARMETHOD=JACKKNIFE
- name of the Hadamard Data Set if you specify the VARMETHOD=BRR(HADAMARD=) method-option
- FAY coefficient used if you specify the VARMETHOD=BRR(FAY) method-option
- name of the Replicate Weights Dataset if the REPWEIGHTS statement is used
- whether Missing Levels are created for categorical variables by the MISSING option
- whether observations with Missing Values are included in the analysis due to the NOMCAR option

Data Summary

By default, PROC SURVEYLOGISTIC displays the following information for the entire data set:

- Number of Observations read from the input data set
- Number of Observations used in the analysis

If there is a DOMAIN statement, PROC SURVEYLOGISTIC also displays the following:

- Number of Observations in the current domain
- Number of Observations not in the current domain

If there is a FREQ statement, PROC SURVEYLOGISTIC also displays the following:

- Sum of Frequencies of all the observations read from the input data set
- Sum of Frequencies of all the observations used in the analysis

If there is a WEIGHT statement, PROC SURVEYLOGISTIC also displays the following:

- Sum of Weights of all the observations read from the input data set
- Sum of Weights of all the observations used in the analysis
- Sum of Weights of all the observations in the current domain, if DOMAIN statement is also specified.

Response Profile

By default, PROC SURVEYLOGISTIC displays a “Response Profile” table, which gives, for each response level, the ordered value (an integer between one and the number of response levels, inclusive); the value of the response variable if the single-trial syntax is used or the values “EVENT” and “NO EVENT” if the events/trials syntax is used; the count or frequency; and the sum of weights if the WEIGHT statement is specified.

Class Level Information

If you use a CLASS statement to name classification variables, PROC SURVEYLOGISTIC displays a "Class Level Information" table. This table contains the following information for each classification variable:

- Class, which lists each CLASS variable name

- Value, which lists the values of the classification variable. The values are separated by a white space character; therefore, to avoid confusion, you should not include a white space character within a classification variable value.
- Design Variables, which lists the parameterization used for the classification variables

Stratum Information

When you specify the LIST option in the STRATA statement, PROC SURVEYLOGISTIC displays a "Stratum Information" table, which provides the following information for each stratum:

- Stratum Index, which is a sequential stratum identification number
- STRATA variable(s), which lists the levels of STRATA variables for the stratum
- Population Total, if you specify the TOTAL= option
- Sampling Rate, if you specify the TOTAL= or RATE= option. If you specify the TOTAL= option, the sampling rate is based on the number of nonmissing observations in the stratum.
- N Obs, which is the number of observations
- number of Clusters, if you specify a CLUSTER statement

Maximum Likelihood Iteration History

The "Maximum Likelihood Iterative Phase" table gives the iteration number, the step size (in the scale of 1.0, 0.5, 0.25, and so on) or the ridge value, -2 log likelihood, and parameter estimates for each iteration. Also displayed are the last evaluation of the gradient vector and the last change in the -2 log likelihood. You need to use the ITPRINT option in the MODEL statement to obtain this table.

Score Test

The "Score Test" table displays the score test result for testing the parallel lines assumption, if an ordinal response model is fitted. If LINK=CLOGLOG or LINK=PROBIT, this test is labeled "Score Test for the Parallel Slopes Assumption." The proportion odds assumption is a special case of the parallel lines assumption when LINK=LOGIT. In this case, the test is labeled "Score Test for the Proportional Odds Assumption."

Model Fit Statistics

By default, PROC SURVEYLOGISTIC displays the following information in the "Model Fit Statistics" table:

- "Model Fit Statistics" and "Testing Global Null Hypothesis: BETA=0" tables, which give the various criteria (−2 Log L, AIC, SC) based on the likelihood for fitting a model with intercepts only and for fitting a model with intercepts and explanatory variables. If you specify the NOINT option, these statistics are calculated without considering the intercept parameters. The third column of the table gives the chi-square statistics and p-values for the −2 Log L statistic and for the Score statistic. These test the joint effect of the explanatory variables included in the model. The Score criterion is always missing for the models identified by the first two columns of the table. Note also that the first two rows of the Chi-Square column are always missing, since tests cannot be performed for AIC and SC.
- generalized R^2 measures for the fitted model if you specify the RSQUARE option in the MODEL statement

Type 3 Analysis of Effects

PROC SURVEYLOGISTIC displays the "Type III Analysis of Effects" table if the model contains an effect involving a CLASS variable. This table gives the degrees of freedom, the Wald Chi-square statistic, and the p-value for each effect in the model.

Analysis of Maximum Likelihood Estimates

By default, PROC SURVEYLOGISTIC displays the following information in the "Analysis of Maximum Likelihood Estimates" table:

- the degrees of freedom for Wald chi-square test
- maximum likelihood estimate of the parameter
- estimated standard error of the parameter estimate, computed as the square root of the corresponding diagonal element of the estimated covariance matrix
- Wald chi-square statistic, computed by squaring the ratio of the parameter estimate divided by its standard error estimate
- p-value of the Wald chi-square statistic with respect to a chi-square distribution with one degree of freedom
- standardized estimate for the slope parameter, given by $\hat{\beta}_i / (s/s_i)$, where s_i is the total sample standard deviation for the ith explanatory variable and

$$s = \begin{cases} \pi/\sqrt{3} & \text{logistic} \\ 1 & \text{normal} \\ \pi/\sqrt{6} & \text{extreme-value} \end{cases}$$

You need to specify the STB option in the MODEL statement to obtain these estimates. Standardized estimates of the intercept parameters are set to missing.

- value of ($e^{\hat{\beta}_i}$) for each slope parameter β_i if you specify the EXPB option in the MODEL statement. For continuous variables, this is equivalent to the estimated odds ratio for a one-unit change.
- label of the variable (if space permits) if you specify the PARMLABEL option in the MODEL statement. Due to constraints on the line size, the variable label might be suppressed in order to display the table in one panel. Use the SAS system option LINESIZE= to specify a larger line size to accommodate variable labels. A shorter line size can break the table into two panels, allowing labels to be displayed.

Odds Ratio Estimates

The "Odds Ratio Estimates" table displays the odds ratio estimates and the corresponding 95% Wald confidence intervals. For continuous explanatory variables, these odds ratios correspond to a unit increase in the risk factors.

Association of Predicted Probabilities and Observed Responses

The "Association of Predicted Probabilities and Observed Responses" table displays measures of association between predicted probabilities and observed responses, which include a breakdown of the number of pairs with different responses, and four rank correlation indexes: Somers' *D*, Goodman-Kruskal Gamma, and Kendall's Tau-*a*, and *c*.

Wald Confidence Interval for Parameters

The "Wald Confidence Interval for Parameters" table displays confidence intervals for all the parameters if you use the CLPARM option in the MODEL statement.

Wald Confidence Interval for Odds Ratios

The "Wald Confidence Interval for Odds Ratios" table displays confidence intervals for all the odds ratios if you use the CLODDS option in the MODEL statement.

Estimated Covariance Matrix

PROC SURVEYLOGISTIC displays the following information in the "Estimated Covariance Matrix" table:

- estimated covariance matrix of the parameter estimates if you use the COVB option in the MODEL statement
- estimated correlation matrix of the parameter estimates if you use the CORRB option in the MODEL statement

Linear Hypotheses Testing Results

The "Linear Hypothesis Testing" table gives the result of the Wald test for each TEST statement (if specified).

Hadamard Matrix

If you specify the VARMETHOD=BRR(PRINTH) method-option in the PROC statement, PROC SURVEYLOGISTIC displays the Hadamard matrix.

When you provide a Hadamard matrix with the VARMETHOD=BRR(HADAMARD=) method-option, the procedure displays only used rows and columns of the Hadamard matrix.

ODS Table Names

PROC SURVEYLOGISTIC assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 84.4. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 84.4 ODS Tables Produced by PROC SURVEYLOGISTIC

ODS Table Name	Description	Statement	Option
Association	Association of predicted probabilities and observed responses	MODEL	default
ClassLevelInfo	Class variable levels and design variables	MODEL	default (with CLASS vars)
CLOddsWald	Wald's confidence limits for odds ratios	MODEL	CLODDS
CLparmWald	Wald's confidence limits for parameters	MODEL	CLPARM
ContrastCoeff	L matrix from CONTRAST	CONTRAST	E
ContrastEstimate	Estimates from CONTRAST	CONTRAST	ESTIMATE=
ContrastTest	Wald test for CONTRAST	CONTRAST	default
ConvergenceStatus	Convergence status	MODEL	default
CorrB	Estimated correlation matrix of parameter estimators	MODEL	CORRB
CovB	Estimated covariance matrix of parameter estimators	MODEL	COVB
CumulativeModelTest	Test of the cumulative model assumption	MODEL	(ordinal response)
DomainSummary	Domain summary	DOMAIN	default
FitStatistics	Model fit statistics	MODEL	default

Table 84.4 *continued*

ODS Table Name	Description	Statement	Option
GlobalTests	Test for global null hypothesis	MODEL	default
HadamardMatrix	Hadamard matrix	PROC	PRINTH
IterHistory	Iteration history	MODEL	ITPRINT
LastGradient	Last evaluation of gradient	MODEL	ITPRINT
Linear	Linear combination	PROC	default
LogLikeChange	Final change in the log likelihood	MODEL	ITPRINT
ModelInfo	Model information	PROC	default
NObs	Number of observations	PROC	default
OddsEst	Adjusted odds ratios	UNITS	default
OddsRatios	Odds ratios	MODEL	default
ParameterEstimates	Maximum likelihood estimates of model parameters	MODEL	default
RSquare	R-square	MODEL	RSQUARE
ResponseProfile	Response profile	PROC	default
StrataInfo	Stratum information	STRATA	LIST
TestPrint1	$\mathbf{L}[\mathrm{cov}(\mathbf{b})]\mathbf{L}'$ and $\mathbf{Lb}-\mathbf{c}$	TEST	PRINT
TestPrint2	$\mathrm{Ginv}(\mathbf{L}[\mathrm{cov}(\mathbf{b})]\mathbf{L}')$ and $\mathrm{Ginv}(\mathbf{L}[\mathrm{cov}(\mathbf{b})]\mathbf{L}')(\mathbf{Lb}-\mathbf{c})$	TEST	PRINT
TestStmts	Linear hypotheses testing results	TEST	default
Type3	Type 3 tests of effects	MODEL	default (with CLASS variables)
VarianceEstimation	Variance estimation	PROC	default

By referring to the names of such tables, you can use the ODS OUTPUT statement to place one or more of these tables in output data sets.

Examples: SURVEYLOGISTIC Procedure

Example 84.1: Stratified Cluster Sampling

A market research firm conducts a survey among undergraduate students at a certain university to evaluate three new Web designs for a commercial Web site targeting undergraduate students at the university.

The sample design is a stratified sample where the strata are students' classes. Within each class,

300 students are randomly selected by using simple random sampling without replacement. The total number of students in each class in the fall semester of 2001 is shown in the following table:

Class	Enrollment
1 - Freshman	3,734
2 - Sophomore	3,565
3 - Junior	3,903
4 - Senior	4,196

This total enrollment information is saved in the SAS data set Enrollment by using the following SAS statements:

```
proc format ;
   value Class 1='Freshman' 2='Sophomore'
               3='Junior'   4='Senior';
run;
data Enrollment;
   format Class Class.;
   input Class _TOTAL_;
   datalines;
1 3734
2 3565
3 3903
4 4196
;
```

In the data set Enrollment, the variable _TOTAL_ contains the enrollment figures for all classes. They are also the population size for each stratum in this example.

Each student selected in the sample evaluates one randomly selected Web design by using the following scale:

1	dislike very much
2	dislike
3	neutral
4	like
5	like very much

The survey results are collected and shown in the following table, with the three different Web designs coded as A, B, and C.

Evaluation of New Web Designs						
		Rating Counts				
Strata	Design	1	2	3	4	5
Freshman	A	10	34	35	16	15
	B	5	6	24	30	25
	C	11	14	20	34	21
Sophomore	A	19	12	26	18	25
	B	10	18	32	23	26
	C	15	22	34	9	20
Junior	A	8	21	23	26	22
	B	1	4	15	33	47
	C	16	19	30	23	12
Senior	A	11	14	24	33	18
	B	8	15	25	30	22
	C	2	34	30	18	16

The survey results are stored in a SAS data set WebSurvey by using the following SAS statements:

```
proc format ;
   value Design 1='A' 2='B' 3='C';
   value Rating 1='dislike very much'
                2='dislike'
                3='neutral'
                4='like'
                5='like very much';
run;
data WebSurvey;
   format Class Class. Design Design. Rating Rating. ;
   do Class=1 to 4;
      do Design=1 to 3;
         do Rating=1 to 5;
           input Count @@;
           output;
         end;
      end;
   end;
   datalines;
10 34 35 16 15   8 21 23 26 22   5 10 24 30 21
 1 14 25 23 37  11 14 20 34 21  16 19 30 23 12
19 12 26 18 25  11 14 24 33 18  10 18 32 23 17
 8 15 35 30 12  15 22 34  9 20   2 34 30 18 16
;
data WebSurvey; set WebSurvey;
   if Class=1 then Weight=3734/300;
   if Class=2 then Weight=3565/300;
   if Class=3 then Weight=3903/300;
   if Class=4 then Weight=4196/300;
run;
```

The data set WebSurvey contains the variables Class, Design, Rating, Count, and Weight. The variable class is the stratum variable, with four strata: freshman, sophomore, junior, and senior. The variable Design specifies the three new Web designs: A, B, and C. The variable Rating contains students' evaluations of the new Web designs. The variable counts gives the frequency with which each Web design received each rating within each stratum. The variable weight contains the sampling weights, which are the reciprocals of selection probabilities in this example.

Output 84.1.1 shows the first 20 observations of the data set.

Output 84.1.1 Web Design Survey Sample (First 20 Observations)

Obs	Class	Design	Rating	Count	Weight
1	Freshman	A	dislike very much	10	12.4467
2	Freshman	A	dislike	34	12.4467
3	Freshman	A	neutral	35	12.4467
4	Freshman	A	like	16	12.4467
5	Freshman	A	like very much	15	12.4467
6	Freshman	B	dislike very much	8	12.4467
7	Freshman	B	dislike	21	12.4467
8	Freshman	B	neutral	23	12.4467
9	Freshman	B	like	26	12.4467
10	Freshman	B	like very much	22	12.4467
11	Freshman	C	dislike very much	5	12.4467
12	Freshman	C	dislike	10	12.4467
13	Freshman	C	neutral	24	12.4467
14	Freshman	C	like	30	12.4467
15	Freshman	C	like very much	21	12.4467
16	Sophomore	A	dislike very much	1	11.8833
17	Sophomore	A	dislike	14	11.8833
18	Sophomore	A	neutral	25	11.8833
19	Sophomore	A	like	23	11.8833
20	Sophomore	A	like very much	37	11.8833

The following SAS statements perform the logistic regression:

```
proc surveylogistic data=WebSurvey total=Enrollment;
   stratum Class;
   freq Count;
   class Design;
   model Rating (order=internal) = design ;
   weight Weight;
run;
```

The PROC statement invokes PROC SURVEYLOGISTIC. The TOTAL= option specifies the data set Enrollment, which contains the population totals in the strata. The population totals are used to calculate the finite population correction factor in the variance estimates. The response variable Rating is in the ordinal scale. A cumulative logit model is used to investigate the responses to the Web designs. In the MODEL statement, rating is the response variable, and Design is the effect in the regression model. The ORDER=INTERNAL option is used for the response variable Rating to sort the ordinal response levels of Rating by its internal (numerical) values rather than by the formatted values (for example, 'like very much'). Because the sample design involves stratified

simple random sampling, the STRATA statement is used to specify the stratification variable Class. The WEIGHT statement specifies the variable Weight for sampling weights.

The sample and analysis summary is shown in Output 84.1.2. There are five response levels for the Rating, with 'dislike very much' as the lowest ordered value. The regression model is modeling lower cumulative probabilities by using logit as the link function. Because the TOTAL= option is used, the finite population correction is included in the variance estimation. The sampling weight is also used in the analysis.

Output 84.1.2 Web Design Survey, Model Information

The SURVEYLOGISTIC Procedure

Model Information

Data Set	WORK.WEBSURVEY
Response Variable	Rating
Number of Response Levels	5
Frequency Variable	Count
Stratum Variable	Class
Number of Strata	4
Weight Variable	Weight
Model	Cumulative Logit
Optimization Technique	Fisher's Scoring
Variance Adjustment	Degrees of Freedom (DF)
Finite Population Correction	Used

Response Profile

Ordered Value	Rating	Total Frequency	Total Weight
1	dislike very much	116	1489.0733
2	dislike	227	2933.0433
3	neutral	338	4363.3767
4	like	283	3606.8067
5	like very much	236	3005.7000

Probabilities modeled are cumulated over the lower Ordered Values.

In Output 84.1.3, the score chi-square for testing the proportional odds assumption is 98.1957, which is highly significant. This indicates that the cumulative logit model might not adequately fit the data.

Output 84.1.3 Web Design Survey, Testing the Proportional Odds Assumption

Score Test for the Proportional Odds Assumption

Chi-Square	DF	Pr > ChiSq
98.1957	6	<.0001

An alternative model is to use the generalized logit model with the LINK=GLOGIT option, as shown in the following SAS statements:

```
proc surveylogistic data=WebSurvey total=Enrollment;
   stratum Class;
   freq Count;
   class Design;
   model Rating (ref='neutral') = Design /link=glogit;
   weight Weight;
run;
```

The REF='neutral' option is used for the response variable Rating to indicate that all other response levels are referenced to the level 'neutral.' The option LINK=GLOGIT option requests that the procedure fit a generalized logit model.

The summary of the analysis is shown in Output 84.1.4, which indicates that the generalized logit model is used in the analysis.

Output 84.1.4 Web Design Survey, Model Information

The SURVEYLOGISTIC Procedure

Model Information

Data Set	WORK.WEBSURVEY
Response Variable	Rating
Number of Response Levels	5
Frequency Variable	Count
Stratum Variable	Class
Number of Strata	4
Weight Variable	Weight
Model	Generalized Logit
Optimization Technique	Newton-Raphson
Variance Adjustment	Degrees of Freedom (DF)
Finite Population Correction	Used

Response Profile

Ordered Value	Rating	Total Frequency	Total Weight
1	dislike	227	2933.0433
2	dislike very much	116	1489.0733
3	like	283	3606.8067
4	like very much	236	3005.7000
5	neutral	338	4363.3767

Logits modeled use Rating='neutral' as the reference category.

Output 84.1.5 shows the parameterization for the main effect Design.

Output 84.1.5 Web Design Survey, Class Level Information

Class Level Information

Class	Value	Design Variables	
Design	A	1	0
	B	0	1
	C	−1	−1

The parameter and odds ratio estimates are shown in Output 84.1.6. For each odds ratio estimate, the 95% confidence limits shown in the table contain the value 1.0. Therefore, no conclusion about which Web design is preferred can be made based on this survey.

Output 84.1.6 Web Design Survey, Parameter and Odds Ratio Estimates

Analysis of Maximum Likelihood Estimates

Parameter		Rating	DF	Estimate	Standard Error	Wald Chi-Square	Pr > ChiSq
Intercept		dislike	1	−0.3964	0.0832	22.7100	<.0001

Design B vs C	like very much	1.389	0.925	2.086

Example 84.2: The Medical Expenditure Panel Survey (MEPS)

The U.S. Department of Health and Human Services conducts the Medical Expenditure Panel Survey (MEPS) to produce national and regional estimates of various aspects of health care. The MEPS has a complex sample design that includes both stratification and clustering. The sampling weights are adjusted for nonresponse and raked with respect to population control totals from the Current Population Survey. See the MEPS Survey Background (2006) and Machlin, Yu, and Zodet (2005) for details.

In this example, the 1999 full-year consolidated data file HC-038 (MEPS HC-038, 2002) from the MEPS is used to investigate the relationship between medical insurance coverage and the demographic variables. The data can be downloaded directly from the Agency for Healthcare Research and Quality (AHRQ) Web site at http://www.meps.ahrq.gov/mepsweb/data_stats/download_data_files_detail.jsp?cboPufNumber=HC-038 in either ASCII format or SAS transport format. The Web site includes a detailed description of the data as well as the SAS program used to access and format it.

For this example, the SAS transport format data file for HC-038 is downloaded to 'C:H38.ssp' on a Windows-based PC. The instructions on the Web site lead to the following SAS statements for creating a SAS data set MEPS, which contains only the sample design variables and other variables necessary for this analysis.

```
proc format;
   value racex
      -9 = 'NOT ASCERTAINED'
      -8 = 'DK'
      -7 = 'REFUSED'
      -1 = 'INAPPLICABLE'
      1 = 'AMERICAN INDIAN'
      2 = 'ALEUT, ESKIMO'
      3 = 'ASIAN OR PACIFIC ISLANDER'
      4 = 'BLACK'
      5 = 'WHITE'
      91 = 'OTHER'
      ;
   value sex
      -9 = 'NOT ASCERTAINED'
      -8 = 'DK'
      -7 = 'REFUSED'
      -1 = 'INAPPLICABLE'
      1 = 'MALE'
      2 = 'FEMALE'
      ;
   value povcat9h
      1 = 'NEGATIVE OR POOR'
      2 = 'NEAR POOR'
      3 = 'LOW INCOME'
      4 = 'MIDDLE INCOME'
      5 = 'HIGH INCOME'
      ;
   value inscov9f
```

```
      1 = 'ANY PRIVATE'
      2 = 'PUBLIC ONLY'
      3 = 'UNINSURED'
      ;
   run;
libname mylib '';
filename in1 'H38.SSP';
proc xcopy in=in1 out=mylib import;
run;
data mylib.meps; set mylib.H38;
   label racex= sex= inscov99= povcat99=
      varstr99= varpsu99= perwt99f= totexp99=;
   format racex racex. sex sex.
      povcat99 povcat9h. inscov99 inscov9f.;
   keep inscov99 sex racex povcat99 varstr99
      varpsu99 perwt99f totexp99;
run;
```

There are a total of 24,618 observations in this SAS data set. Each observation corresponds to a person in the survey. The stratification variable is VARSTR99, which identifies the 143 strata in the sample. The variable VARPSU99 identifies the 460 PSUs in the sample. The sampling weights are stored in the variable PERWT99F. The response variable is the health insurance coverage indicator variable, INSCOV99, which has three values:

1	the person had any private insurance coverage any time during 1999
2	the person had only public insurance coverage during 1999
3	the person was uninsured during all of 1999

The demographic variables include gender (SEX), race (RACEX), and family income level as a percent of the poverty line (POVCAT99). The variable RACEX has five categories:

1	American Indian
2	Aleut, Eskimo
3	Asian or Pacific Islander
4	Black
5	White

The variable POVCAT99 is constructed by dividing family income by the applicable poverty line (based on family size and composition), with the resulting percentages grouped into five categories:

1	negative or poor (less than 100%)
2	near poor (100% to less than 125%)
3	low income (125% to less than 200%)
4	middle income (200% to less than 400%)
5	high income (greater than or equal to 400%)

The data set also contains the total health care expenditure in 1999, TOTEXP99, which is used as a covariate in the analysis.

Output 84.2.1 displays the first 30 observations of this data set.

Output 84.2.1 1999 Full-Year MEPS (First 30 Observations)

Obs	SEX	RACE	POVCAT99	INSCOV99	TOTEXP99	PERWT99F	VARSTR99	VARPSU99
1	MALE	WHITE	MIDDLE INCOME	PUBLIC ONLY	2735	14137.86	131	2
2	FEMALE	WHITE	MIDDLE INCOME	ANY PRIVATE	6687	17050.99	131	2
3	MALE	WHITE	MIDDLE INCOME	ANY PRIVATE	60	35737.55	131	2

The following SAS statements fit a generalized logit model for the 1999 full-year consolidated MEPS data:

```
proc surveylogistic data=meps;
   stratum VARSTR99;
   cluster VARPSU99;
   weight PERWT99F;
   class SEX RACEX POVCAT99;
   model INSCOV99 = TOTEXP99 SEX RACEX POVCAT99 / link=glogit;
run;
```

The STRATUM statement specifies the stratification variable VARSTR99. The CLUSTER statement specifies the PSU variable VARPSU99. The WEIGHT statement specifies the sample weight variable PERWT99F. The demographic variables SEX, RACEX, and POVCAT99 are listed in the CLASS statement to indicate that they are categorical independent variables in the MODEL statement. In the MODEL statement, the response variable is INSCOV99, and the independent variables are TOTEXP99 along with the selected demographic variables. The LINK= option requests that the procedure fit the generalized logit model because the response variable INSCOV99 has nominal responses.

The results of this analysis are shown in the following outputs.

PROC SURVEYLOGISTIC lists the model fitting information and sample design information in Output 84.2.2.

Output 84.2.2 MEPS, Model Information

The SURVEYLOGISTIC Procedure

Model Information

Data Set	MYLIB.MEPS
Response Variable	INSCOV99
Number of Response Levels	3
Stratum Variable	VARSTR99
Number of Strata	143
Cluster Variable	VARPSU99
Number of Clusters	460
Weight Variable	PERWT99F
Model	Generalized Logit
Optimization Technique	Newton-Raphson
Variance Adjustment	Degrees of Freedom (DF)

Output 84.2.3 displays the number of observations and the total of sampling weights both in the data set and used in the analysis. Only the observations with positive person-level weight are used in the analysis. Therefore, 1,053 observations with zero person-level weights were deleted.

Output 84.2.3 MEPS, Number of Observations

Number of Observations Read	24618
Number of Observations Used	23565
Sum of Weights Read	2.7641E8
Sum of Weights Used	2.7641E8

Output 84.2.4 lists the three insurance coverage levels for the response variable INSCOV99. The "UNINSURED" category is used as the reference category in the model.

Output 84.2.4 MEPS, Response Profile

Response Profile

Ordered Value	INSCOV99	Total Frequency	Total Weight
1	ANY PRIVATE	16130	204403997
2	PUBLIC ONLY	4241	41809572
3	UNINSURED	3194	30197198

Logits modeled use INSCOV99='UNINSURED' as the reference category.

Output 84.2.5 shows the parameterization in the regression model for each categorical independent variable.

Output 84.2.5 MEPS, Classification Levels

Class Level Information

Class	Value	Design Variables			
SEX	FEMALE	1			
	MALE	-1			
RACEX	ALEUT, ESKIMO	1	0	0	0
	AMERICAN INDIAN	0	1	0	0
	ASIAN OR PACIFIC ISLANDER	0	0	1	0
	BLACK	0	0	0	1
	WHITE	-1	-1	-1	-1
POVCAT99	HIGH INCOME	1	0	0	0
	LOW INCOME	0	1	0	0
	MIDDLE INCOME	0	0	1	0
	NEAR POOR	0	0	0	1
	NEGATIVE OR POOR	-1	-1	-1	-1

Output 84.2.6 displays the parameter estimates and their standard errors.

Output 84.2.6 MEPS, Parameter Estimates

For example, after adjusting for the effects of sex, race, and total health care expenditures, a person with high income is estimated to be 11.595 times more likely than a poor person to choose private health care insurance over no insurance, but only 0.274 times as likely to choose public health insurance over no insurance.

Overview: SURVEYMEANS Procedure

The SURVEYMEANS procedure estimates characteristics of a survey population by using statistics computed from a survey sample. You can estimate statistics such as means, totals, proportions, quantiles, and ratios. PROC SURVEYMEANS also provides domain analysis, which computes estimates for subpopulations or domains. The procedure also estimates variances and confidence limits and performs *t* tests for these statistics. PROC SURVEYMEANS uses either the Taylor series (linearization) method or replication (subsampling) methods to estimate sampling errors of estimators based on complex sample designs. The sample design can be a complex survey sample design with stratification, clustering, and unequal weighting. See Lohr (1999), Särndal, Swensson, and Wretman (1992), and Wolter (1985) for more details.

Getting Started: SURVEYMEANS Procedure

This section demonstrates how you can use the SURVEYMEANS procedure to produce descriptive statistics from sample survey data. For a complete description of PROC SURVEYMEANS, see the section "Syntax: SURVEYMEANS Procedure" on page 6473. The section "Examples: SURVEYMEANS Procedure" on page 6518 provides more complicated examples to illustrate the applications of PROC SURVEYMEANS.

Simple Random Sampling

This example illustrates how you can use PROC SURVEYMEANS to estimate population means and proportions from sample survey data. The study population is a junior high school with a total of 4,000 students in grades 7, 8, and 9. Researchers want to know how much these students spend weekly for ice cream, on average, and what percentage of students spend at least $10 weekly for ice cream.

To answer these questions, 40 students were selected from the entire student population by using simple random sampling (SRS). Selection by simple random sampling means that all students have an equal chance of being selected and no student can be selected more than once. Each student selected for the sample was asked how much he or she spends for ice cream per week, on average. The SAS data set IceCream saves the responses of the 40 students:

```
data IceCream;
   input Grade Spending @@;
   if (Spending < 10) then Group='less';
   else Group='more';
   datalines;
7 7  7  7  8 12  9 10  7  1  7 10  7  3  8 20  8 19  7 2
7 2  9 15  8 16  7  6  7  6  7  6  9 15  8 17  8 14  9 8
9 8  9  7  7  3  7 12  7  4  9 14  8 18  9  9  7  2  7 1
7 4  7 11  9  8  8 10  8 13  7  2  9  6  9 11  7  2  7 9
;
```

The variable Grade contains a student's grade. The variable Spending contains a student's response regarding how much he spends per week for ice cream, in dollars. The variable Group is created to indicate whether a student spends at least $10 weekly for ice cream: Group='more' if a student spends at least $10, or Group='less' if a student spends less than $10.

You can use PROC SURVEYMEANS to produce estimates for the entire student population, based on this random sample of 40 students:

```
title1 'Analysis of Ice Cream Spending';
title2 'Simple Random Sample Design';
proc surveymeans data=IceCream total=4000;
   var Spending Group;
   run;
```

The PROC SURVEYMEANS statement invokes the procedure. The TOTAL=4000 option specifies the total number of students in the study population, or school. The procedure uses this total to adjust variance estimates for the effects of sampling from a finite population. The VAR statement names the variables to analyze, Spending and Group.

Figure 85.1 displays the results from this analysis. There are a total of 40 observations used in the analysis. The "Class Level Information" table lists the two levels of the variable Group. This variable is a character variable, and so PROC SURVEYMEANS provides a categorical analysis for it, estimating the relative frequency or proportion for each level. If you want a categorical analysis for a numeric variable, you can name that variable in the CLASS statement.

Figure 85.1 Analysis of Ice Cream Spending

Analysis of Ice Cream Spending
Simple Random Sample Design

The SURVEYMEANS Procedure

Data Summary

Number of Observations	40

Spending		40	8.750000	0.845139	7.04054539	10.4594546
Group	less	23	0.575000	0.078761	0.41568994	0.7343101
	more	17	0.425000	0.078761	0.26568994	0.5843101

The "Statistics" table displays the estimates for each analysis variable. By default, PROC SURVEYMEANS displays the number of observations, the estimate of the mean, its standard error, and the 95% confidence limits for the mean. You can obtain other statistics by specifying the corresponding *statistic-keywords* in the PROC SURVEYMEANS statement.

The estimate of the average weekly ice cream expense is $8.75 for students at this school. The standard error of this estimate if $0.85, and the 95% confidence interval for weekly ice cream expense is from $7.04 to $10.46. The analysis variable Group is a character variable, and so PROC SURVEYMEANS analyzes it as categorical, estimating the relative frequency or proportion for each level or category. These estimates are displayed in the Mean column of the "Statistics" table. It is estimated that 57.5% of all students spend less than $10 weekly on ice cream, while 42.5% of the students spend at least $10 weekly. The standard error of each estimate is 7.9%.

Stratified Sampling

Suppose that the sample of students described in the previous section was actually selected by using stratified random sampling. In stratified sampling, the study population is divided into nonoverlapping strata, and samples are selected from each stratum independently.

The list of students in this junior high school was stratified by grade, yielding three strata: grades 7, 8, and 9. A simple random sample of students was selected from each grade. Table 85.1 shows the total number of students in each grade.

Table 85.1 Number of Students by Grade

Grade	Number of Students
7	1,824
8	1,025
9	1,151
Total	4,000

To analyze this stratified sample, you need to provide the population totals for each stratum to PROC SURVEYMEANS. The SAS data set StudentTotals contains the information from Table 85.1:

```
data StudentTotals;
   input Grade _total_; datalines;
7 1824
8 1025
9 1151
;
```

The variable Grade is the stratum identification variable, and the variable _TOTAL_ contains the total number of students for each stratum. PROC SURVEYMEANS requires you to use the variable name _TOTAL_ for the stratum population totals.

The procedure uses the stratum population totals to adjust variance estimates for the effects of sampling from a finite population. If you do not provide population totals or sampling rates, then the procedure assumes that the proportion of the population in the sample is very small, and the computation does not involve a finite population correction.

In a stratified sample design, when the sampling rates in the strata are unequal, you need to use sampling weights to reflect this information in order to produce an unbiased mean estimator. In this example, the appropriate sampling weights are reciprocals of the probabilities of selection. You can use the following DATA step to create the sampling weights:

```
data IceCream;
   set IceCream;
   if Grade=7 then Prob=20/1824;
   if Grade=8 then Prob=9/1025;
   if Grade=9 then Prob=11/1151;
   Weight=1/Prob;
```

When you use PROC SURVEYSELECT to select your sample, the procedure creates these sampling weights for you.

The following SAS statements perform the stratified analysis of the survey data:

```
title1 'Analysis of Ice Cream Spending';
title2 'Stratified Simple Random Sample Design';
proc surveymeans data=IceCream total=StudentTotals;
   stratum Grade / list;
   var Spending Group;
   weight Weight;
run;
```

The PROC SURVEYMEANS statement invokes the procedure. The DATA= option names the SAS data set IceCream as the input data set to be analyzed. The TOTAL= option names the data set StudentTotals as the input data set that contains the stratum population totals. Comparing this to the analysis in the section "Simple Random Sampling" on page 6467, notice that the TOTAL=StudentTotals option is used here instead of the TOTAL=4000 option. In this stratified sample design, the population totals are different for different strata, and so you need to provide them to PROC SURVEYMEANS in a SAS data set.

The STRATA statement identifies the stratification variable Grade. The LIST option in the STRATA statement requests that the procedure display stratum information. The WEIGHT statement tells the procedure that the variable Weight contains the sampling weights.

Figure 85.2 displays information about the input data set. There are three strata in the design and 40 observations in the sample. The categorical variable Group has two levels, 'less' and 'more.'

Figure 85.2 Data Summary

```
                    Analysis of Ice Cream Spending

```

Figure 85.3 displays information for each stratum. The table displays a stratum index and the values of the STRATA variable. The stratum index identifies each stratum by a sequentially assigned number. For each stratum, the table gives the population total (total number of students), the sampling rate, and the sample size. The stratum sampling rate is the ratio of the number of students in the

sample to the number of students in the population for that stratum. The table also lists each analysis variable and the number of stratum observations for that variable. For categorical variables, the table lists each level and the number of sample observations in that level.

Figure 85.3 Stratum Information

Stratum Information

Stratum Index	Grade	Population Total	Sampling Rate	N Obs	Variable	Level
1	7	1824	1.10%	20	Spending Group	less

						6
						5

Figure 85.4 shows the following:

- The estimate of average weekly ice cream expense is $9.14 for students in this school, with a standard error of $0.53, and a 95% confidence interval from $8.06 to $10.22.
- An estimate of 54.5% of all students spend less than $10 weekly on ice cream, and 45.5% spend more, with a standard error of 5.8%.

Figure 85.4 Analysis of Ice Cream Spending

Statistics

Variable	Level	N	Mean	Std Error of Mean	95% CL for Mean	
Spending		40	9.141298	0.531799	8.06377052	10.2188254
Group	less	23	0.544555	0.058424	0.42617678	0.6629323
	more	17	0.455445	0.058424	0.33706769	0.5738232

Output Data Sets

PROC SURVEYMEANS uses the Output Delivery System (ODS) to create output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

For example, to save the "Statistics" table shown in Figure 85.4 in the previous section in an output data set, you use the ODS OUTPUT statement as follows:

```
title1 'Analysis of Ice Cream Spending';
title2 'Stratified Simple Random Sample Design';
proc surveymeans data=IceCream total=StudentTotals;
   stratum Grade / list;
   var Spending Group;
   weight Weight;
   ods output Statistics=MyStat;
run;
```

The statement

```
ods output Statistics=MyStat;
```

requests that the "Statistics" table that appears in Figure 85.4 be placed in a SAS data set MyStat.

The PRINT procedure displays observations of the data set MyStat:

```
proc print data=MyStat;
run;
```

Figure 85.5 displays the data set MyStat.

Figure 85.5 The Data Set MyStat

Analysis of Ice Cream Spending
Stratified Simple Random Sample Design

Obs	VarName	Var Level	N	Mean	StdErr	Lower CLMean	Upper CLMean
1	Spending		40	9.141298	0.531799	8.06377052	10.2188254
2	Group	less	23	0.544555	0.058424	0.42617678	0.6629323
3	Group	more	17	0.455445	0.058424	0.33706769	0.5738232

The section "ODS Table Names" on page 6517 gives the complete list of the tables produced by PROC SURVEYMEANS.

Syntax: SURVEYMEANS Procedure

The following statements are available in PROC SURVEYMEANS:

PROC SURVEYMEANS < *options* > < *statistic-keywords* > ;
BY *variables* ;
CLASS *variables* ;
CLUSTER *variables* ;
DOMAIN *variables* < *variable*∗*variable variable*∗*variable*∗*variable ...* > < */ option* > ;
RATIO < *'label'* > *variables / variables* ;
REPWEIGHTS *variables* < */ options* > ;
STRATA *variables* < */ option* > ;
VAR *variables* ;
WEIGHT *variable* ;

The PROC SURVEYMEANS statement invokes the procedure. It optionally names the input data sets, specifies statistics for the procedure to compute, and specifies the variance estimation method. The PROC SURVEYMEANS statement is required.

The VAR statement identifies the variables to be analyzed. The CLASS statement identifies those numeric variables that are to be analyzed as categorical variables. The STRATA statement lists the variables that form the strata in a stratified sample design. The CLUSTER statement specifies cluster identification variables in a clustered sample design. The DOMAIN statement lists the variables that define domains for subpopulation analysis. The RATIO statement requests ratio analysis for means or proportions of analysis variables. The WEIGHT statement names the sampling weight variable. The REPWEIGHTS statement names replicate weight variables for BRR or jackknife variance estimation. You can use a BY statement with PROC SURVEYMEANS to obtain separate analyses for groups defined by the BY variables.

All statements can appear multiple times except the PROC SURVEYMEANS statement and the WEIGHT statement, which can appear only once.

The rest of this section gives detailed syntax information for the BY, CLASS, CLUSTER, DOMAIN, RATIO, REPWEIGHTS, STRATA, VAR, and WEIGHT statements in alphabetical order after the description of the PROC SURVEYMEANS statement.

PROC SURVEYMEANS Statement

PROC SURVEYMEANS < *options* > *statistic-keywords* **;**

The PROC SURVEYMEANS statement invokes the procedure. In this statement, you identify the data set to be analyzed, specify the variance estimation method, and provide sample design information. The DATA= option names the input data set to be analyzed. The VARMETHOD= option specifies the variance estimation method, which is the Taylor series method by default. For Taylor series variance estimation, you can include a finite population correction factor in the analysis by providing either the sampling rate or population total with the RATE= or TOTAL= option. If your design is stratified, with different sampling rates or totals for different strata, then you can input these stratum rates or totals in a SAS data set that contains the stratification variables.

In the PROC SURVEYMEANS statement, you also can use *statistic-keywords* to specify statistics for the procedure to compute. Available statistics include the population mean and population total, together with their variance estimates and confidence limits. You can also request data set summary information and sample design information.

You can specify the following options in the PROC SURVEYMEANS statement.

ALPHA=*α*
sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of α produces $100(1-\alpha)\%$ confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

DATA=*SAS-data-set*
specifies the SAS data set to be analyzed by PROC SURVEYMEANS. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

MISSING
treats missing values as a valid (nonmissing) category for all categorical variables, which include CLASS, STRATA, CLUSTER, and DOMAIN variables.

By default, if you do not specify the MISSING option, an observation is excluded from the analysis if it has a missing value. For more information, see the section "Missing Values" on page 6491.

NOMCAR
requests that the procedure treat missing values in the variance computation as *not missing completely at random* (NOMCAR) for Taylor series variance estimation. When you specify the NOMCAR option, PROC SURVEYMEANS computes variance estimates by analyzing the nonmissing values as a domain or subpopulation, where the entire population includes both nonmissing and missing domains. See the section "Missing Values" on page 6491 for more details.

By default, PROC SURVEYMEANS completely excludes an observation from analysis if that observation has a missing value, unless you specify the MISSING option. Note that the NOMCAR option has no effect on a categorical variable when you specify the MISSING option, which treats missing values as a valid nonmissing level.

The NOMCAR option applies only to Taylor series variance estimation. The replication methods, which you request with the VARMETHOD=BRR and VARMETHOD=JACKKNIFE options, do not use the NOMCAR option.

NONSYMCL

requests nonsymmetric confidence limits for the quantiles when you request quantiles with PERCENTILE= or QUANTILE= option. See the section "Confidence Limits" on page 6505 for more details.

NOSPARSE

suppresses the display of analysis variables with zero frequency in the output. By default, the procedure displays all continuous variable and all levels of categorical variables.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the order in which the values of the categorical variables are to be reported. The following shows how PROC SURVEYMEANS interprets values of the ORDER= option:

DATA	orders values according to their order in the input data set.
FORMATTED	orders values by their formatted values. This order is operating environment dependent. By default, the order is ascending.
FREQ	order values by descending frequency count; the most observed value comes first in the order.
INTERNAL	orders values by their unformatted values, which yields the same order that the SORT procedure does. This order is operating environment dependent.

By default, ORDER=FORMATTED.

The ORDER= option applies to all the categorical variables. When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

PERCENTILE=(*values*)

specifies percentiles you want the procedure to compute. You can separate values with blanks or commas. Each value must be between 0 and 100. You can also use the *statistic-keywords* DECILES, MEDIAN, Q1, Q3, and QUARTILES to request common percentiles.

PROC SURVEYMEANS uses Woodruff method (Dorfman and Valliant 1993; Särndal, Swensson, and Wretman 1992; Francisco and Fuller 1991) to estimate the variances of quantiles. BRR and jackknife variance estimation do not apply to the variance estimation for percentiles. See the section "Quantiles" on page 6504 for more details.

QUANTILE=(*values*)

specifies quantiles you want the procedure to compute. You can separate values with blanks

or commas. Each value must be between 0 and 1. You can also use the *statistic-keywords* DECILES, MEDIAN, Q1, Q3, and QUARTILES to request common quantiles.

PROC SURVEYMEANS uses Woodruff method (Dorfman and Valliant 1993; Särndal, Swensson, and Wretman 1992; Francisco and Fuller 1991) to estimate the variances of quantiles. BRR and jackknife variance estimation do not apply to the variance estimation for quantiles. See the section "Quantiles" on page 6504 for more details.

RATE=*value* | *SAS-data-set*

R=*value* | *SAS-data-set*

specifies the sampling rate as a nonnegative *value*, or specifies an input data set that contains the stratum sampling rates. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the RATE= option for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option.

If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of PSUs selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative *value* for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section "Specification of Population Totals and Sampling Rates" on page 6492 for more details.

The *value* in the RATE= option or the values of _RATE_ in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYMEANS converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you do not specify the TOTAL= or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= and RATE= options.

STACKING

requests that the procedure produce the output data sets by using a stacking table structure, which was the default before SAS 9. The new default is to produce a rectangular table structure in the output data sets.

A rectangular structure creates one observation for each analysis variable in the data set. A stacking structure creates only one observation in the output data set for all analysis variables.

The STACKING option affects the following tables:

- Domain
- Ratio
- Statistics
- StrataInfo

See the section "Rectangular and Stacking Structures in an Output Data Set" on page 6510 for more details.

TOTAL=*value* | *SAS-data-set*
N=*value* | *SAS-data-set*

specifies the total number of primary sampling units in the study population as a positive *value*, or specifies an input data set that contains the stratum population totals. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the TOTAL= option for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section "Specification of Population Totals and Sampling Rates" on page 6492 for more details.

If you do not specify the TOTAL= or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= and RATE= options.

statistic-keywords

specifies the statistics for the procedure to compute. If you do not specify any *statistic-keywords*, PROC SURVEYMEANS computes the NOBS, MEAN, STDERR, and CLM statistics by default.

The statistics produced depend on the type of the analysis variable. If you name a numeric variable in the CLASS statement, then the procedure analyzes that variable as a categorical variable. The procedure always analyzes character variables as categorical. See the section "CLASS Statement" on page 6484 for more information.

PROC SURVEYMEANS computes MIN, MAX, and RANGE for numeric variables but not for categorical variables. For numeric variables, the keyword MEAN produces the mean, but for categorical variables it produces the proportion in each category or level. Also, for categorical variables, the keyword NOBS produces the number of observations for each variable level, and the keyword NMISS produces the number of missing observations for each level. If you request the keyword NCLUSTER for a categorical variable, PROC SURVEYMEANS displays for each level the number of clusters with observations in that level. PROC SURVEYMEANS computes SUMWGT in the same way for both categorical and numeric variables, as the sum of the weights over all nonmissing observations.

PROC SURVEYMEANS performs univariate analysis, analyzing each variable separately. Thus the number of nonmissing and missing observations might not be the same for all analysis variables. See the section "Missing Values" on page 6491 for more information.

When you use a RATIO statement, available statistics computed for a ratio include N, NCLU, SUMWGT, RATIO, STDERR, DF, T, PROBT, and CLM, as shown in the following list. If no statistics are requested, the procedure computes the ratio and its standard error by default for a RATIO statement.

The valid *statistic-keywords* are as follows:

ALL	all statistics listed
CLM	$100(1-\alpha)\%$ two-sided confidence limits for the MEAN, where α is determined by the ALPHA= option; the default is $\alpha = 0.05$
CLSUM	$100(1-\alpha)\%$ two-sided confidence limits for the SUM, where α is determined by the ALPHA= option; the default is $\alpha = 0.05$
CV	coefficient of variation for MEAN
CVSUM	coefficient of variation for SUM
DECILES	the 10th, the 20th, ..., and the 90th percentiles including their standard errors and confidence limits
DF	degrees of freedom for the *t* test
LCLM	$100(1-\alpha)\%$ one-sided lower confidence limit of the MEAN, where α is determined by the ALPHA= option; the default is $\alpha = 0.05$
LCLSUM	$100(1-\alpha)\%$ one-sided lower confidence limit of the SUM, where α is determined by the ALPHA= option; the default is $\alpha = 0.05$
MAX	maximum value
MEAN	mean for a numeric variable, or the proportion in each category for a categorical variable
MEDIAN	median for a numeric variable
MIN	minimum value
NCLUSTER	number of clusters
NMISS	number of missing observations
NOBS	number of nonmissing observations
Q1	lower quartile
Q3	upper quartile
QUARTILES	lower quartile (25%th percentile), median (50%th percentile), and upper quartile (75%th percentile), including their standard errors and confidence limits
RANGE	range, MAX−MIN
STD	standard deviation of the SUM. When you request SUM, the procedure computes STD by default.
STDERR	standard error of the MEAN or RATIO. When you request MEAN or RATIO, the procedure computes STDERR by default.
SUM	weighted sum, $\sum w_i y_i$, or estimated population total when the appropriate sampling weights are used
SUMWGT	sum of the weights, $\sum w_i$

T	t-value and its corresponding p-value with DF degrees of freedom for $H_0 : \theta = 0$ where θ is a requested statistic
UCLM	$100(1-\alpha)\%$ one-sided upper confidence limit of the MEAN, where α is determined by the ALPHA= option; the default is $\alpha = 0.05$
UCLSUM	$100(1-\alpha)\%$ one-sided upper confidence limit of the SUM, where α is determined by the ALPHA= option; the default is $\alpha = 0.05$
VAR	variance of the MEAN or RATIO
VARSUM	variance of the SUM

See the section "Statistical Computations" on page 6493 for details about how PROC SURVEYMEANS computes these statistics.

VARMETHOD=BRR < (*method-options*) >

VARMETHOD=JACKKNIFE | JK < (*method-options*) >

VARMETHOD=TAYLOR

specifies the variance estimation method. VARMETHOD=TAYLOR requests the Taylor series method, which is the default if you do not specify the VARMETHOD= option or the REPWEIGHTS statement. VARMETHOD=BRR requests variance estimation by balanced repeated replication (BRR), and VARMETHOD=JACKKNIFE requests variance estimation by the delete-1 jackknife method.

For VARMETHOD=BRR and VARMETHOD=JACKKNIFE you can specify *method-options* in parentheses. Table 85.2 summarizes the available *method-options*.

Table 85.2 Variance Estimation Method-Options

Keyword	Method	(*Method-Options*)
BRR	Balanced repeated replication	DFADJ FAY <=*value*> HADAMARD | H=*SAS-data-set* OUTWEIGHTS=*SAS-data-set* PRINTH REPS=*number*
JACKKNIFE | JK	Jackknife	DFADJ OUTJKCOEFS=*SAS-data-set* OUTWEIGHTS=*SAS-data-set*
TAYLOR	Taylor series	

Method-options must be enclosed in parentheses following the method keyword. For example:

```
varmethod=BRR(reps=60 outweights=myReplicateWeights)
```

The following values are available for the VARMETHOD= option:

BRR <(*method-options*)> requests balanced repeated replication (BRR) variance estimation. The BRR method requires a stratified sample design with two primary sampling units (PSUs) per stratum. See the section "Balanced Repeated Replication (BRR) Method" on page 6506 for more information.

You can specify the following *method-options* in parentheses following VARMETHOD=BRR.

DFADJ

computes the degrees of freedom as the number of nonmissing strata for an analysis variable. The degrees of freedom for VARMETHOD=BRR equal the number of strata, which by default is based on all valid observations in the data set. But if you specify the DFADJ method-option, PROC SURVEYMEANS does not count any empty strata due to all observations containing missing values for an analysis variable.

See the section "Degrees of Freedom" on page 6498 for more information. See the section "Data and Sample Design Summary" on page 6512 for details about valid observations.

The DFADJ method-option has no effect on categorical variables when you specify the MISSING option, which treats missing values as a valid nonmissing level.

The DFADJ method-option cannot be used when you provide replicate weights with a REPWEIGHTS statement. When you use a REPWEIGHTS statement, the degrees of freedom equal the number of REPWEIGHTS variables (or replicates), unless you specify an alternative value in the DF= option in the REPWEIGHTS statement.

FAY <=*value***>**

requests Fay's method, a modification of the BRR method, for variance estimation. See the section "Fay's BRR Method" on page 6507 for more information.

You can specify the *value* of the Fay coefficient, which is used in converting the original sampling weights to replicate weights. The Fay coefficient must be a nonnegative number less than 1. By default, the value of the Fay coefficient equals 0.5.

HADAMARD=*SAS-data-set*

H=*SAS-data-set*

names a SAS data set that contains the Hadamard matrix for BRR replicate construction. If you do not provide a Hadamard matrix with the HADAMARD= method-option, PROC SURVEYMEANS generates an appropriate Hadamard matrix for replicate construction. See the sections "Balanced Repeated Replication (BRR)

Method" on page 6506 and "Hadamard Matrix" on page 6509 for details.

If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the HADAMARD=*SAS-data-set* method-option.

In the HADAMARD= input data set, each variable corresponds to a column of the Hadamard matrix, and each observation corresponds to a row of the matrix. You can use any variable names in the HADAMARD= data set. All values in the data set must equal either 1 or -1. You must ensure that the matrix you provide is indeed a Hadamard matrix—that is, $\mathbf{A}'\mathbf{A} = R\mathbf{I}$, where $\mathbf{A}$ is the Hadamard matrix of dimension R and $\mathbf{I}$ is an identity matrix. PROC SURVEYMEANS does not check the validity of the Hadamard matrix that you provide.

The HADAMARD= input data set must contain at least H variables, where H denotes the number of first-stage strata in your design. If the data set contains more than H variables, the procedure uses only the first H variables. Similarly, the HADAMARD= input data set must contain at least H observations.

If you do not specify the REPS= method-option, then the number of replicates is taken to be the number of observations in the HADAMARD= input data set. If you specify the number of replicates—for example, REPS=*nreps*—then the first *nreps* observations in the HADAMARD= data set are used to construct the replicates.

You can specify the PRINTH option to display the Hadamard matrix that the procedure uses to construct replicates for BRR.

OUTWEIGHTS=*SAS-data-set*

names a SAS data set that contains replicate weights. See the section "Balanced Repeated Replication (BRR) Method" on page 6506 for information about replicate weights. See the section "Replicate Weights Output Data Set" on page 6509 for more details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= method-option is not available when you provide replicate weights with the REPWEIGHTS statement.

PRINTH

displays the Hadamard matrix.

When you provide your own Hadamard matrix with the HADAMARD= method-option, only the rows and columns of the Hadamard matrix that are used by the procedure are displayed.

See the sections "Balanced Repeated Replication (BRR) Method" on page 6506 and "Hadamard Matrix" on page 6509 for details.

The PRINTH method-option is not available when you provide replicate weights with the REPWEIGHTS statement because the procedure does not use a Hadamard matrix in this case.

REPS=*number*

specifies the number of replicates for BRR variance estimation. The value of *number* must be an integer greater than 1.

If you do not provide a Hadamard matrix with the HADAMARD= method-option, the number of replicates should be greater than the number of strata and should be a multiple of 4. See the section "Balanced Repeated Replication (BRR) Method" on page 6506 for more information. If a Hadamard matrix cannot be constructed for the REPS= value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the REPS= value that you specify.

If you provide a Hadamard matrix with the HADAMARD= method-option, the value of REPS= must not be less than the number of rows in the Hadamard matrix. If you provide a Hadamard matrix and do not specify the REPS= method-option, the number of replicates equals the number of rows in the Hadamard matrix.

If you do not specify the REPS= or HADAMARD= method-option and do not include a REPWEIGHTS statement, the number of replicates equals the smallest multiple of 4 that is greater than the number of strata.

If you provide replicate weights with the REPWEIGHTS statement, the procedure does not use the REPS= method-option. With a REPWEIGHTS statement, the number of replicates equals the number of REPWEIGHTS variables.

JACKKNIFE | JK <(*method-options*)> requests variance estimation by the delete-1 jackknife method. See the section "Jackknife Method" on page 6508 for details. If you provide replicate weights with a REPWEIGHTS statement, VARMETHOD=JACKKNIFE is the default variance estimation method.

You can specify the following *method-options* in parentheses following VARMETHOD=JACKKNIFE:

DFADJ

computes the degrees of freedom as the number of nonmissing strata for an analysis variable. The degrees of freedom for VARMETHOD=BRR equal the number of strata, which by default is based on all valid observations in the data set. But if you specify the DFADJ method-option, PROC SURVEYMEANS does not

count any empty strata due to all observations containing missing values for an analysis variable.

See the section "Degrees of Freedom" on page 6498 for more information. See the section "Data and Sample Design Summary" on page 6512 for details about valid observations.

The DFADJ method-option has no effect on categorical variables when you specify the MISSING option, which treats missing values as a valid nonmissing level.

The DFADJ method-option cannot be used when you provide replicate weights with a REPWEIGHTS statement. When you use a REPWEIGHTS statement, the degrees of freedom equal the number of REPWEIGHTS variables (or replicates), unless you specify an alternative value in the DF= option in the REPWEIGHTS statement.

OUTWEIGHTS=*SAS-data-set*

names a SAS data set that contains replicate weights. See the section "Jackknife Method" on page 6508 for information about replicate weights. See the section "Replicate Weights Output Data Set" on page 6509 for more details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= method-option is not available when you provide replicate weights with the REPWEIGHTS statement.

OUTJKCOEFS=*SAS-data-set*

names a SAS data set that contains jackknife coefficients. See the section "Jackknife Method" on page 6508 for information about jackknife coefficients. See the section "Jackknife Coefficients Output Data Set" on page 6510 for more details about the contents of the OUTJKCOEFS= data set.

TAYLOR

requests Taylor series variance estimation. This is the default method if you do not specify the VARMETHOD= option and if there is no REPWEIGHTS statement. See the section "Statistical Computations" on page 6493 for more information.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC SURVEYMEANS to obtain separate analyses on observations in groups defined by the BY variables.

Note that by using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, where the total number of units

in the subpopulation is not known with certainty. You should use the DOMAIN statement to obtain domain analysis.

When a BY statement appears, the procedure expects the input data sets to be sorted in order of the BY variables. The *variables* are one or more variables in the input data set.

If you specify more than one BY statement, the procedure uses only the latest BY statement and ignores any previous ones.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Use the BY statement option NOTSORTED or DESCENDING. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variables* **;**

The CLASS statement names variables to be analyzed as categorical variables. For categorical variables, PROC SURVEYMEANS estimates the proportion in each category or level, instead of the overall mean. PROC SURVEYMEANS always analyzes character variables as categorical. If you want categorical analysis for a numeric variable, you must include that variable in the CLASS statement.

The CLASS *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLASS variables determine the categorical variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary* for more information.

You can use multiple CLASS statements to specify categorical variables.

When you specify classification variables, you can use the SAS system option SUMSIZE= to limit (or to specify) the amount of memory that is available for data analysis. See the chapter on SAS system options in *SAS Language Reference: Dictionary* for a description of the SUMSIZE= option.

CLUSTER Statement

CLUSTER *variables* **;**

The CLUSTER statement names variables that identify the clusters in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If you provide replicate weights for BRR or jackknife variance estimation with the REPWEIGHTS statement, you do not need to specify a CLUSTER statement.

If your sample design has clustering at multiple stages, you should identify only the first-stage clusters, or primary sampling units (PSUs), in the CLUSTER statement. See the section "Primary Sampling Units (PSUs)" on page 6493 for more information.

The CLUSTER *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary* for more information.

You can use multiple CLUSTER statements to specify cluster variables. The SURVEYMEANS procedure uses variables from all CLUSTER statements to create clusters.

DOMAIN Statement

DOMAIN *variables* < *variable*∗*variable variable*∗*variable*∗*variable ...* > < */ option* > **;**

The DOMAIN statement requests analysis for subpopulations, or domains, in addition to analysis for the entire study population. The DOMAIN statement names the variables that identify domains, which are called domain variables.

It is common practice to compute statistics for domains. The formation of these domains might be unrelated to the sample design. Therefore, the sample sizes for the domains are random variables. In order to incorporate this variability into the variance estimation, you should use a DOMAIN statement.

Note that a DOMAIN statement is different from a BY statement. In a BY statement, you treat the sample sizes as fixed in each subpopulation, and you perform analysis within each BY group independently. See the section "Domain Statistics" on page 6502 for more details.

You should use the DOMAIN statement on the entire data set to perform a domain analysis. Creating a new data set from a single domain and analyzing that with SURVEYMEANS yields inappropriate estimates of variance.

A domain variable can be either character or numeric. The procedure treats domain variables as categorical variables. If a variable appears by itself in a DOMAIN statement, each level of this variable determines a domain in the study population. If two or more variables are joined by asterisks (*),

then every possible combination of levels of these variables determines a domain. The procedure performs a descriptive analysis within each domain defined by the domain variables.

The formatted values of the domain variables determine the categorical variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary* for more information.

You can specify the following option in the DOMAIN statement after a slash (/):

DFADJ

computes the degrees of freedom by using the number of nonempty strata for an analysis variable in a domain.

Given a specific domain, it is possible that there is no sampling unit in the sample falling into a domain for a stratum or there is no valid observations from a stratum in a domain due to missing values. Therefore, a domain might contain empty strata. By default, the procedure counts these empty strata when calculating the degrees of freedom.

However, if you specify the DFADJ option, the procedure makes an adjustment by excluding these empty strata when compute the degrees of freedom. Note that prior to SAS 9.2, the procedure made this adjustment by default.

See the section "Degrees of Freedom" on page 6498 for more information. See the section "Data and Sample Design Summary" on page 6512 for details about valid observations.

The DFADJ option has no effect on categorical variables when you specify the MISSING option, which treats missing values as a valid nonmissing level.

RATIO Statement

RATIO < *'label'* > *variables* / *variables* **;**

The RATIO statement requests ratio analysis for means or proportions of analysis variables. A ratio statement names the variables whose means are used as numerators or denominators in a ratio. Variables appearing before the slash (/), called *numerator variables*, are used as numerators. Variables appearing after the slash (/), called *denominator variables*, are used as denominators. These *variables* can be any number of analysis variables, either continuous or categorical in the input data set, except those named in the BY, CLUSTER, REPWEIGHT, STRATA, and WEIGHT statements.

You can optionally specify a label for each RATIO statement to identify the ratios in the output. Labels must be enclosed in single quotes.

If a RATIO statement does not have any numerator variable or denominator variable specified, the RATIO statement is ignored.

The computation of ratios depends on whether the numerator and denominator variables are continuous or categorical.

For continuous variables, ratios are calculated with the mean of the variables. For example, for continuous variables X, Y, Z, and T, the following RATIO statement requests that the procedure analyze the ratios $\bar{x}/\bar{z}$, $\bar{x}/\bar{t}$, $\bar{y}/\bar{z}$, and $\bar{y}/\bar{t}$:

```
ratio x y / z t;
```

If a continuous variable appears as both a numerator and a denominator variable, the ratio of this variable itself is ignored.

For categorical variables, ratios are calculated with the proportions for the categories of a categorical variable. For example, if the categorical variable Gender has the values 'Male' and 'Female,' with the proportions p_m = Pr(Gender='Male') and p_f = Pr(Gender='Female'), and Y is a continuous variable, then the following RATIO statement requests that the procedure analyze the ratios p_m/p_f, p_f/p_m, $\bar{y}/p_m$, and $\bar{y}/p_f$:

```
ratio Gender y / Gender;
```

If a categorical variable appears as both a numerator and denominator variable, then the ratios of the proportions for all categories are computed, except the ratio of each category with itself.

You can have more than one RATIO statement. Each RATIO statement produces ratios independently by using its own numerator and denominator variables. Each RATIO statement also produces its own ratio analysis table.

Available statistics for a ratio are as follows:

- N, number of observations used to compute the ratio
- NCLU, number of clusters
- SUMWGT, sum of weights
- RATIO, ratio
- STDERR, standard error of ratio
- VAR, variance of ratio
- T, *t*-value of ratio
- PROBT, *p*-value of *t*
- DF, degrees of freedom of *t*
- CLM, two-sided confidence limits of ratio
- UCLM, one-sided upper confidence limit of ratio
- LCLM, one-sided lower confidence limit of ratio

The procedure calculates these statistics based on the *statistic-keywords* that you specified in the PROC SURVEYMEANS statement. If a *statistic-keyword* is not appropriate for a RATIO statement, that *statistic-keyword* is ignored. If no valid statistics are requested for a RATIO statement, the procedure computes the ratio and its standard error by default.

Note that ratios within a domain are currently not available.

When the means or proportions for the numerator and denominator variables in a ratio are calculated, an observation is excluded if it has a missing value in either the continuous numerator variable or the denominator variable. An observation with missing values is also excluded for the categorical numerator or denominator variables, unless the MISSING option is used.

When the denominator for a ratio is zero, then the value of the ratio is displayed as '–Infty', 'Infty', or a missing value, depending on whether the numerator is negative, positive, or zero, respectively; and the corresponding internal value is the special missing value '.M', the special missing value '.I', or the usual missing value, respectively.

REPWEIGHTS Statement

REPWEIGHTS *variables* < / *options* > **;**

The REPWEIGHTS statement names variables that provide replicate weights for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option in the PROC SURVEYMEANS statement. If you do not provide replicate weights for these methods by using a REPWEIGHTS statement, then the procedure constructs replicate weights for the analysis. See the sections "Balanced Repeated Replication (BRR) Method" on page 6506 and "Jackknife Method" on page 6508 for information about replicate weights.

Each REPWEIGHTS variable should contain the weights for a single replicate, and the number of replicates equals the number of REPWEIGHTS variables. The REPWEIGHTS variables must be numeric, and the variable values must be nonnegative numbers.

If you provide replicate weights with a REPWEIGHTS statement, you do not need to specify a CLUSTER or STRATA statement. If you use a REPWEIGHTS statement and do not specify the VARMETHOD= option in the PROC SURVEYMEANS statement, the procedure uses VARMETHOD=JACKKNIFE by default.

If you specify a REPWEIGHTS statement but do not include a WEIGHT statement, the procedure uses the average of each observation's replicate weights as the observation's weight.

You can specify the following options in the REPWEIGHTS statement after a slash (/):

DF=*df*

specifies the degrees of freedom for the analysis. The value of *df* must be a positive number. By default, the degrees of freedom equals the number of REPWEIGHTS variables. See the section "Degrees of Freedom" on page 6498 for details.

PROC SURVEYMEANS uses the DF= value in computing confidence limits for proportions, totals, and other statistics. See the section "Statistical Computations" on page 6493 for details.

JKCOEFS=*value*

specifies a jackknife coefficient for VARMETHOD=JACKKNIFE. The coefficient *value* must

be a nonnegative number less than one. See the section "Jackknife Method" on page 6508 for details about jackknife coefficients.

You can use this option to specify a single value of the jackknife coefficient, which the procedure uses for all replicates. To specify different coefficients for different replicates, use the JKCOEFS=*values* or JKCOEFS=*SAS-data-set* option.

JKCOEFS=*values*
specifies jackknife coefficients for VARMETHOD=JACKKNIFE, where each coefficient corresponds to an individual replicate identified by a REPWEIGHTS variable. You can separate *values* with blanks or commas. The coefficient *values* must be nonnegative numbers less than one. The number of *values* must equal the number of replicate weight variables named in the REPWEIGHTS statement. List these values in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement.

See the section "Jackknife Method" on page 6508 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the JKCOEFS=*SAS-data-set* option. To specify a single jackknife coefficient for all replicates, use the JKCOEFS=*value* option.

JKCOEFS=*SAS-data-set*
names a SAS data set that contains the jackknife coefficients for VARMETHOD=JACKKNIFE. You provide the jackknife coefficients in the JKCOEFS= data set variable JKCoefficient. Each coefficient value must be a nonnegative number less than one. The observations in the JKCOEFS= data set should correspond to the replicates that are identified by the REPWEIGHTS variables. Arrange the coefficients or observations in the JKCOEFS= data set in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement. The number of observations in the JKCOEFS= data set must not be less than the number of REPWEIGHTS variables.

See the section "Jackknife Method" on page 6508 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the JKCOEFS=*values* option. To specify a single jackknife coefficient for all replicates, use the JKCOEFS=*value* option.

STRATA Statement

STRATA *variables* < / *option* > **;**

The STRATA statement names variables that form the strata in a stratified sample design. The combinations of categories of STRATA variables define the strata in the sample.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section "Survey Data Analysis" on page 6492 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with the REPWEIGHTS statement, you do not need to specify a STRATA statement.

The STRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the STRATA variables determine the levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary* for more information.

You can specify the following option in the STRATA statement after a slash (/):

LIST

displays a "Stratum Information" table, which includes values of the STRATA variables and sampling rates for each stratum. This table also provides the number of observations and number of clusters for each stratum and analysis variable. See the section "Displayed Output" on page 6512 for more details.

VAR Statement

VAR *variables* **;**

The VAR statement names the variables to be analyzed.

If you want a categorical analysis for a numeric variable, you must also name that variable in the CLASS statement. For categorical variables, PROC SURVEYMEANS estimates the proportion in each category or level, instead of the overall mean. Character variables are always analyzed as categorical variables. See the section "CLASS Statement" on page 6484 for more information.

When you specify a variable in a RATIO statement, but not in a VAR statement, the procedure includes this variable as an analysis variable.

If you do not specify a VAR statement, then PROC SURVEYMEANS analyzes all variables in the DATA= input data set, except those named in the BY, CLUSTER, REPWEIGHT, STRATA, and WEIGHT statements.

WEIGHT Statement

WEIGHT *variable* **;**

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric, and the sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section "Missing Values" on page 6491 for more information. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

If you do not specify a WEIGHT statement but provide replicate weights with a REPWEIGHTS statement, PROC SURVEYMEANS uses the average of each observation's replicate weights as the observation's weight.

If you do not specify a WEIGHT statement or a REPWEIGHTS statement, PROC SURVEYMEANS assigns all observations a weight of one.

Details: SURVEYMEANS Procedure

Missing Values

If you have missing values in your survey data for any reason, such as nonresponse, this can compromise the quality of your survey results. If the respondents are different from the nonrespondents with regard to a survey effect or outcome, then survey estimates might be biased and cannot accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. After data collection is complete, you can use imputation to replace missing values with acceptable values, and/or you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYMEANS. See Cochran (1977); Kalton and Kaspyzyk (1986); and Brick and Kalton (1996) for more information.

If an observation has a missing value or a nonpositive value for the WEIGHT variable, then that observation is excluded from the analysis.

An observation is also excluded if it has a missing value for design variables such as STRATA variables, CLUSTER variables, and DOMAIN variables, unless missing values are regarded as a legitimate categorical level for these variables, as specified by the MISSING option.

If you specify the MISSING option in the PROC SURVEYMEANS statement, the procedure treats missing values of a categorical variable as a valid category.

By default, when computing statistics for an analysis variable, PROC SURVEYMEANS omits observations with missing values for that variable. The procedure computes statistics for each variable based only on observations that have nonmissing values for that variable. This treatment is based on the assumption that the missing values are missing completely at random (MCAR). However, this assumption is sometimes not true. For example, evidence from other surveys might suggest that observations with missing values are systematically different from observations without missing values. If you believe that missing values are not missing completely at random, then you can specify the NOMCAR option to let variance estimation include these observations with missing values in the analysis variables.

Whether or not the NOMCAR option is used, observations with missing or invalid values for WEIGHT, STRATA, CLUSTER, or DOMAIN variables are always excluded, unless the MISSING option is also specified.

When you specify the NOMCAR option, the procedure treats observations with and without missing values for analysis variables as two different domains, and it performs a domain analysis in the domain of nonmissing observations.

The procedure performs univariate analysis and analyzes each VAR variable separately. Thus, the number of missing observations might be different for different variables. You can specify the keyword NMISS in the PROC SURVEYMEANS statement to display the number of missing values for each analysis variable in the "Statistics" table.

If you use a REPWEIGHTS statement, all REPWEIGHTS variables must contain nonmissing values.

Survey Data Analysis

Specification of Population Totals and Sampling Rates

To include a finite population correction (*fpc*) in Taylor series variance estimation, you can input either the sampling rate or the population total by using the RATE= or TOTAL= option in the PROC SURVEYMEANS statement. (You cannot specify both of these options in the same PROC SURVEYMEANS statement.) The RATE= and TOTAL= options apply only to Taylor series variance estimation. The procedure does not use a finite population correction for BRR or jackknife variance estimation.

If you do not specify the RATE= or TOTAL= option, the Taylor series variance estimation does not include a finite population correction. For fairly small sampling fractions, it is appropriate to ignore this correction. See Cochran (1977) and Kish (1965) for more information.

If your design has multiple stages of selection and you are specifying the RATE= option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the TOTAL= option for a multistage design, you should input the total number of PSUs in the study population. See the section "Primary Sampling Units (PSUs)" on page 6493 for more details.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you can use the RATE=*value* or TOTAL=*value* option. If your sample design is stratified with different sampling rates or population totals in different strata, use the RATE=*SAS-data-set* or TOTAL=*SAS-data-set* option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the DATA= option.

The secondary data set must contain all the stratification variables listed in the STRATA statement and all the variables in the BY statement. If there are formats associated with the STRATA variables and the BY variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the TOTAL=*SAS-data-set* option, the secondary data set must have a variable named _TOTAL_ that contains the stratum population totals. Or if you specify the RATE=*SAS-data-set* option, the secondary data set must have a variable named _RATE_ that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of _TOTAL_ or _RATE_ for that stratum and ignores the rest.

The *value* in the RATE= option or the values of _RATE_ in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value*

in percentage form as a number between 1 and 100, and PROC SURVEYMEANS converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the TOTAL=*value* option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

Primary Sampling Units (PSUs)

When you have clusters, or primary sampling units (PSUs), in your sample design, the procedure estimates variance from the variation among PSUs when the Taylor series variance method is used. See the section "Variance and Standard Error of the Mean" on page 6496 and the section "Variance and Standard Deviation of the Total" on page 6501 for more information.

BRR or jackknife variance estimation methods draw multiple replicates (or subsamples) from the full sample by following a specific resampling scheme. These subsamples are constructed by deleting PSUs from the full sample.

If you use a REPWEIGHTS statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a CLUSTER statement. Otherwise, you should specify a CLUSTER statement whenever your design includes clustering at the first stage of sampling. If you do not specify a CLUSTER statement, then PROC SURVEYMEANS treats each observation as a PSU.

Domain Analysis

It is common practice to compute statistics for subpopulations, or domains, in addition to computing statistics for the entire study population. Analysis for domains that uses the entire sample is called *domain analysis* (subgroup analysis, subpopulation analysis, subdomain analysis). The formation of these subpopulations of interest might be unrelated to the sample design. Therefore, the sample sizes for the subpopulations might actually be random variables.

In order to incorporate this variability into the variance estimation, you should use a DOMAIN statement. Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, where the total number of units in the subpopulation is not known with certainty.

For more detailed information about domain analysis, see Kish (1965).

Statistical Computations

The SURVEYMEANS procedure uses the Taylor series (linearization) method or replication (resampling) methods to estimate sampling errors of estimators based on complex sample designs. For details see Wolter (1985); Lohr (1999); Kalton (1983); Hidiroglou, Fuller, and Hickman (1980); Fuller et al. (1989); Lee, Forthoffer, and Lorimor (1989); Cochran (1977); Kish (1965); Hansen,

Hurwitz, and Madow (1953); Rust (1985); Dippo, Fay, and Morganstein (1984); Rao and Shao (1999); Rao, Wu, and Yue (1992); and Rao and Shao (1996). You can use the VARMETHOD= option to specify a variance estimation method to use. By default, the Taylor series method is used.

The Taylor series method obtains a linear approximation for the estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Woodruff 1971, Fuller 1975). When there are clusters, or PSUs, in the sample design, the procedure estimates variance from the variation among PSUs. When the design is stratified, the procedure pools stratum variance estimates to compute the overall variance estimate. For t tests of the estimates, the degrees of freedom equal the number of clusters minus the number of strata in the sample design.

For a multistage sample design, the Taylor series estimation depends only on the first stage of the sample design. Therefore, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling. This variance estimation method assumes that the first-stage sampling fraction is small, or that the first-stage sample is drawn with replacement, as it often is in practice.

Quite often in complex surveys, respondents have unequal weights, which reflect unequal selection probabilities and adjustments for nonresponse. In such surveys, the appropriate sampling weights must be used to obtain valid estimates for the study population.

However, replication methods have recently gained popularity for estimating variances in complex survey data analysis. One reason for this popularity is the relative simplicity of replication-based estimates, especially for nonlinear estimators; another is that modern computational capacity has made replication methods feasible for practical survey analysis.

Replication methods draw multiple replicates (also called subsamples) from a full sample according to a specific resampling scheme. The most commonly used resampling schemes are the *balanced repeated replication* (BRR) method and the *jackknife* method. For each replicate, the original weights are modified for the PSUs in the replicates to create replicate weights. The population parameters of interest are estimated by using the replicate weights for each replicate. Then the variances of parameters of interest are estimated by the variability among the estimates derived from these replicates. You can use a REPWEIGHTS statement to provide your own replicate weights for variance estimation. For more information about using replication methods to analyze sample survey data, see the section "Replication Methods for Variance Estimation" on page 6506.

Definitions and Notation

For a stratified clustered sample design, together with the sampling weights, the sample can be represented by an $n \times (P + 1)$ matrix

$$\begin{aligned}(\mathbf{w}, \mathbf{Y}) &= \left(w_{hij}, \mathbf{y}_{hij}\right) \\ &= \left(w_{hij}, y_{hij}^{(1)}, y_{hij}^{(2)}, \ldots, y_{hij}^{(P)}\right)\end{aligned}$$

where

- $h = 1, 2, \ldots, H$ is the stratum index

- $i = 1, 2, \ldots, n_h$ is the cluster index within stratum h
- $j = 1, 2, \ldots, m_{hi}$ is the unit index within cluster i of stratum h
- $p = 1, 2, \ldots, P$ is the analysis variable number, with a total of P variables
- $n = \sum_{h=1}^{H} \sum_{i=1}^{n_h} m_{hi}$ is the total number of observations in the sample
- w_{hij} denotes the sampling weight for unit j in cluster i of stratum h
- $\mathbf{y}_{hij} = \left(y_{hij}^{(1)}, y_{hij}^{(2)}, \ldots, y_{hij}^{(P)}\right)$ are the observed values of the analysis variables for unit j in cluster i of stratum h, including both the values of numerical variables and the values of indicator variables for levels of categorical variables.

For a categorical variable C, let l denote the number of levels of C, and denote the level values as $c_1, c_2, \ldots, c_l$. Let $y^{(q)}$ ($q \in \{1, 2, \ldots, P\}$) be an indicator variable for the category $C = c_k$ ($k = 1, 2, \ldots, l$) with the observed value in unit j in cluster i of stratum h:

$$y_{hij}^{(q)} = I_{\{C=c_k\}}(h, i, j) = \begin{cases} 1 & \text{if } C_{hij} = c_k \\ 0 & \text{otherwise} \end{cases}$$

Note that the indicator variable $y_{hij}^{(q)}$ is set to missing when C_{hij} is missing. Therefore, the total number of analysis variables, P, is the total number of numerical variables plus the total number of levels of all categorical variables.

The sampling rate f_h for stratum h, which is used in Taylor series variance estimation, is the fraction of first-stage units (PSUs) selected for the sample. You can use the TOTAL= or RATE= option to input population totals or sampling rates. See the section "Specification of Population Totals and Sampling Rates" on page 6492 for details. If you input stratum totals, PROC SURVEYMEANS computes f_h as the ratio of the stratum sample size to the stratum total. If you input stratum sampling rates, PROC SURVEYMEANS uses these values directly for f_h. If you do not specify the TOTAL= or RATE= option, then the procedure assumes that the stratum sampling rates f_h are negligible, and a finite population correction is not used when computing variances. Replication methods specified by the VARMETHOD=BRR or the VARMETHOD=JACKKNIFE option do not use this finite population correction f_h.

Mean

When you specify the keyword MEAN, the procedure computes the estimate of the mean (mean per element) from the survey data. Also, the procedure computes the mean by default if you do not specify any *statistic-keywords* in the PROC SURVEYMEANS statement.

PROC SURVEYMEANS computes the estimate of the mean as

$$\widehat{\bar{Y}} = \left(\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij}\, y_{hij} \right) / \, w_{...}$$

where

$$w_{...} = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij}$$

is the sum of the weights over all observations in the sample.

Variance and Standard Error of the Mean

When you specify the keyword STDERR, the procedure computes the standard error of the mean. Also, the procedure computes the standard error by default if you specify the keyword MEAN, or if you do not specify any *statistic-keywords* in the PROC SURVEYMEANS statement. The keyword VAR requests the variance of the mean.

Taylor Series Method

When you use VARMETHOD=TAYLOR, or by default if you do not specify the VARMETHOD= option, PROC SURVEYMEANS uses the Taylor series method to estimate the variance of the mean $\widehat{\bar{Y}}$. The procedure computes the estimated variance as

$$\widehat{V}(\widehat{\bar{Y}}) = \sum_{h=1}^{H} \widehat{V_h}(\widehat{\bar{Y}})$$

where if $n_h > 1$,

$$\begin{aligned}
\widehat{V_h}(\widehat{\bar{Y}}) &= \frac{n_h(1-f_h)}{n_h - 1} \sum_{i=1}^{n_h} (e_{hi\cdot} - \bar{e}_{h\cdot\cdot})^2 \\
e_{hi\cdot} &= \left(\sum_{j=1}^{m_{hi}} w_{hij} \, (y_{hij} - \widehat{\bar{Y}}) \right) / \, w_{...} \\
\bar{e}_{h\cdot\cdot} &= \left(\sum_{i=1}^{n_h} e_{hi\cdot} \right) / \, n_h
\end{aligned}$$

and if $n_h = 1$,

$$\widehat{V_h}(\widehat{\bar{Y}}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \le h' \le H \end{cases}$$

Replication Methods

When you specify VARMETHOD=BRR or VARMETHOD=JACKKNIFE, the procedure computes the variance $\widehat{V}(\widehat{\bar{Y}})$ with replication methods by using the variability among replicate estimates to estimate the overall variance. See the section "Replication Methods for Variance Estimation" on page 6506 for more details.

Standard Error

The standard error of the mean is the square root of the estimated variance.

$$\text{StdErr}(\widehat{\bar{Y}}) = \sqrt{\widehat{V}(\widehat{\bar{Y}})}$$

Ratio

When you use a RATIO statement, the procedure produces statistics requested by the *statistic-keywords* in the PROC SURVEYMEANS statement.

Suppose that you want to calculate the ratio of variable Y over variable X. Let x_{hij} be the value of variable X for the jth member in cluster i in the hth stratum.

The ratio of Y over X is

$$\widehat{R} = \frac{\sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} w_{hij}\, y_{hij}}{\sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} w_{hij}\, x_{hij}}$$

PROC SURVEYMEANS uses the Taylor series method to estimate the variance of the ratio $\widehat{R}$ as

$$\widehat{V}(\widehat{R}) = \sum_{h=1}^{H} \widehat{V_h}(\widehat{R})$$

where if $n_h > 1$,

$$\begin{aligned}
\widehat{V_h}(\widehat{R}) &= \frac{n_h(1-f_h)}{n_h - 1} \sum_{i=1}^{n_h} (g_{hi\cdot} - \bar{g}_{h\cdot\cdot})^2 \\
g_{hi\cdot} &= \frac{\sum_{j=1}^{m_{hi}} w_{hij}\,(y_{hij} - x_{hij}\widehat{R})}{\sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} w_{hij}\, x_{hij}} \\
\bar{g}_{h\cdot\cdot} &= \left(\sum_{i=1}^{n_h} g_{hi\cdot}\right) / n_h
\end{aligned}$$

and if $n_h = 1$,

$$\widehat{V_h}(\widehat{R}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \le h' \le H \end{cases}$$

The standard error of the ratio is the square root of the estimated variance:

$$\text{StdErr}(\widehat{R}) = \sqrt{\widehat{V}(\widehat{R})}$$

When the denominator for a ratio is zero, then the value of the ratio is displayed as '–Infty', 'Infty', or a missing value, depending on whether the numerator is negative, positive, or zero, respectively; and the corresponding internal value is the special missing value '.M', the special missing value '.I', or the usual missing value, respectively.

t Test for the Mean

If you specify the keyword T, PROC SURVEYMEANS computes the t-value for testing that the population mean equals zero, $H_0 : \bar{Y} = 0$. The test statistic equals

$$t(\widehat{\bar{Y}}) = \widehat{\bar{Y}} \;/\; \mathrm{StdErr}(\widehat{\bar{Y}})$$

The two-sided p-value for this test is

$$\mathrm{Prob}(\,|T| > |t(\widehat{\bar{Y}})|\,)$$

where T is a random variable with the t distribution with df degrees of freedom.

Degrees of Freedom

PROC SURVEYMEANS computes degrees of freedom df to obtain the $100(1-\alpha)\%$ confidence limits for means, proportions, totals, ratios, and other statistics. The degrees of freedom computation depends on the variance estimation method that you request. Missing values can affect the degrees of freedom computation. See the section "Missing Values" on page 6491 for details.

Taylor Series Variance Estimation

For the Taylor series method, PROC SURVEYMEANS calculates the degrees of freedom for the t test as the number of clusters minus the number of strata. If there are no clusters, then the degrees of freedom equal the number of observations minus the number of strata. If the design is not stratified, then the degrees of freedom equal the number of PSUs minus one.

If in a stratum, all observations are excluded from the analysis due to missing values, then that stratum is called an *empty stratum*. Empty strata are not counted in the total number of strata for the table. Similarly, empty clusters and missing observations are not included in the totals counts of cluster and observations used to compute the degrees of freedom for the analysis.

If you specify the MISSING option, missing values are treated as valid nonmissing levels for a categorical variable and are included in computing degrees of freedom. If you specify the NOMCAR option for Taylor series variance estimation, observations with missing values for an analysis variable are included in computing degrees of freedom.

Replicate-Based Variance Estimation

When there is a REPWEIGHTS statement, the degrees of freedom equal the number of REPWEIGHTS variables, unless you specify an alternative in the DF= option in a REPWEIGHTS statement.

For BRR or jackknife variance estimation without a REPWEIGHT statement, by default PROC SURVEYMEANS computes the degrees of freedom by using all valid observations in the input data set. A valid observation is an observation that has a positive value of the WEIGHT variable and nonmissing values of the STRATA and CLUSTER variables unless you specify the MISSING option. See the section "Data and Sample Design Summary" on page 6512 for details about valid observations.

For BRR variance estimation (including Fay's method) without a REPWEIGHTS statement, PROC SURVEYMEANS calculates the degrees of freedom as the number of strata. PROC SURVEYMEANS bases the number of strata on all valid observations in the data set, unless you specify the DFADJ method-option for VARMETHOD=BRR. When you specify the DFADJ option, the procedure computes the degrees of freedom as the number of nonmissing strata for an analysis variable. This excludes any empty strata that occur when observations with missing values of that analysis variable are removed.

For jackknife variance estimation without a REPWEIGHTS statement, PROC SURVEYMEANS calculates the degrees of freedom as the number of clusters minus the number of strata. If there are no clusters, then df equals the number of observations minus the number of strata. If the design is not stratified, then df equals the number of clusters minus one. For jackknife variance estimation, PROC SURVEYMEANS bases the number of strata and clusters on all valid observations in the data set, unless you specify the DFADJ method-option for VARMETHOD=JK. When you specify the DFADJ option, the procedure computes the degrees of freedom from the number of nonmissing strata and clusters for an analysis variable. This excludes any empty strata or clusters that occur when observations with missing values of an analysis variable are removed.

The procedure displays the degrees of freedom for the t test if you specify the keyword DF in the PROC SURVEYMEANS statement.

Confidence Limits for the Mean

If you specify the keyword CLM, the procedure computes two-sided confidence limits for the mean. Also, the procedure includes the confidence limits by default if you do not specify any *statistic-keywords* in the PROC SURVEYMEANS statement.

The confidence coefficient is determined by the value of the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits. The confidence limits are computed as

$$\hat{\bar{Y}} \pm \mathrm{StdErr}(\hat{\bar{Y}}) \cdot t_{df,\,\alpha/2}$$

where $\hat{\bar{Y}}$ is the estimate of the mean, $\mathrm{StdErr}(\hat{\bar{Y}})$ is the standard error of the mean, and $t_{df,\,\alpha/2}$ is the $100(1-\alpha/2)$th percentile of the t distribution with df calculated as described in the section "*t* Test for the Mean" on page 6498.

If you specify the keyword UCLM, the procedure computes the one-sided upper $100(1-\alpha)\%$ confidence limit for the mean:

$$\hat{\bar{Y}} + \mathrm{StdErr}(\hat{\bar{Y}}) \cdot t_{df,\,\alpha}$$

If you specify the keyword LCLM, the procedure computes the one-sided lower $100(1-\alpha)\%$ confidence limit for the mean:

$$\hat{\bar{Y}} - \text{StdErr}(\hat{\bar{Y}}) \cdot t_{df,\,\alpha}$$

Coefficient of Variation

If you specify the keyword CV, PROC SURVEYMEANS computes the coefficient of variation, which is the ratio of the standard error of the mean to the estimated mean:

$$cv(\bar{Y}) = \text{StdErr}(\hat{\bar{Y}}) \;/\; \hat{\bar{Y}}$$

If you specify the keyword CVSUM, PROC SURVEYMEANS computes the coefficient of variation for the estimated total, which is the ratio of the standard deviation of the sum to the estimated total:

$$cv(Y) = \text{Std}(\hat{Y}) \;/\; \hat{Y}$$

Proportions

If you specify the keyword MEAN for a categorical variable, PROC SURVEYMEANS estimates the proportion, or relative frequency, for each level of the categorical variable. If you do not specify any *statistic-keywords* in the PROC SURVEYMEANS statement, the procedure estimates the proportions for levels of the categorical variables, together with their standard errors and confidence limits.

The procedure estimates the proportion in level c_k for variable C as

$$\hat{p} = \frac{\sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} w_{hij}\; y_{hij}^{(q)}}{\sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} w_{hij}}$$

where $y_{hij}^{(q)}$ is the value of the indicator function for level $C = c_k$, defined in the section "Definitions and Notation" on page 6494, and $y_{hij}^{(q)}$ equals 1 if the observed value of variable C equals c_k, and $y_{hij}^{(q)}$ equals 0 otherwise. Since the proportion estimator is actually an estimator of the mean for an indicator variable, the procedure computes its variance and standard error according to the method outlined in the section "Variance and Standard Error of the Mean" on page 6496. Similarly, the procedure computes confidence limits for proportions as described in the section "Confidence Limits for the Mean" on page 6499.

Total

If you specify the keyword SUM, the procedure computes the estimate of the population total from the survey data. The estimate of the total is the weighted sum over the sample:

$$\hat{Y} = \sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} w_{hij}\; y_{hij}$$

For a categorical variable level, $\hat{Y}$ estimates its total frequency in the population.

Variance and Standard Deviation of the Total

When you specify the keyword STD or the keyword SUM, the procedure estimates the standard deviation of the total. The keyword VARSUM requests the variance of the total.

Taylor Series Method

When you use VARMETHOD=TAYLOR, or by default, PROC SURVEYMEANS uses the Taylor series method to estimate the variance of the total as

$$\widehat{V}(\widehat{Y}) = \sum_{h=1}^{H} \widehat{V_h}(\widehat{Y})$$

where if $n_h > 1$,

$$\begin{aligned}
\widehat{V_h}(\widehat{Y}) &= \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (y_{hi\cdot} - \bar{y}_{h\cdot\cdot})^2 \\
y_{hi\cdot} &= \sum_{j=1}^{m_{hi}} w_{hij}\, y_{hij} \\
\bar{y}_{h\cdot\cdot} &= \left(\sum_{i=1}^{n_h} y_{hi\cdot} \right) / n_h
\end{aligned}$$

and if $n_h = 1$,

$$\widehat{V_h}(\widehat{Y}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \le h' \le H \end{cases}$$

Replication Methods

When you specify VARMETHOD=BRR or VARMETHOD=JACKKNIFE option, the procedure computes the variance $\widehat{V}(\widehat{Y})$ with replication methods by measuring the variability among the estimates derived from these replicates. See the section "Replication Methods for Variance Estimation" on page 6506 for more details.

Standard Deviation

The standard deviation of the total equals

$$\text{Std}(\widehat{Y}) = \sqrt{\widehat{V}(\widehat{Y})}$$

Confidence Limits for the Total

If you specify the keyword CLSUM, the procedure computes confidence limits for the total. The confidence coefficient is determined by the value of the ALPHA= option, which by default equals

0.05 and produces 95% confidence limits. The confidence limits are computed as

$$\widehat{Y} \pm \mathrm{Std}(\widehat{Y}) \cdot t_{df,\,\alpha/2}$$

where $\widehat{Y}$ is the estimate of the total, $\mathrm{Std}(\widehat{Y})$ is the estimated standard deviation, and $t_{df,\,\alpha/2}$ is the $100(1-\alpha/2)$th percentile of the t distribution with df calculated as described in the section "*t* Test for the Mean" on page 6498.

If you specify the keyword UCLSUM, the procedure computes the one-sided upper $100(1-\alpha)\%$ confidence limit for the sum:

$$\widehat{Y} + \mathrm{Std}(\widehat{Y}) \cdot t_{df,\,\alpha}$$

If you specify the keyword LCLSUM, the procedure computes the one-sided lower $100(1-\alpha)\%$ confidence limit for the sum:

$$\widehat{Y} - \mathrm{Std}(\widehat{Y}) \cdot t_{df,\,\alpha}$$

Domain Statistics

When you use a DOMAIN statement to request a domain analysis, the procedure computes the requested statistics for each domain.

For a domain D, let I_D be the corresponding indicator variable:

$$I_D(h,i,j) = \begin{cases} 1 & \text{if observation } (h,i,j) \text{ belongs to } D \\ 0 & \text{otherwise} \end{cases}$$

Let

$$v_{hij} = w_{hij} I_D(h,i,j) = \begin{cases} w_{hij} & \text{if observation } (h,i,j) \text{ belongs to } D \\ 0 & \text{otherwise} \end{cases}$$

The requested statistics for variable y in domain D are computed by using the new weights v.

Domain Mean

The estimated mean of y in the domain D is

$$\widehat{\bar{Y}_D} = \left(\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} v_{hij}\, y_{hij} \right) / \, v_{...}$$

where

$$v_{...} = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} v_{hij}$$

The variance of $\widehat{\bar{Y}_D}$ is estimated by

$$\widehat{V}(\widehat{\bar{Y}_D}) = \sum_{h=1}^{H} \widehat{V_h}(\widehat{\bar{Y}_D})$$

where if $n_h > 1$,

$$\begin{aligned}
\widehat{V_h}(\widehat{\bar{Y}_D}) &= \frac{n_h(1-f_h)}{n_h - 1} \sum_{i=1}^{n_h} (r_{hi\cdot} - \bar{r}_{h\cdot\cdot})^2 \\
r_{hi\cdot} &= \left(\sum_{j=1}^{m_{hi}} v_{hij} \ (y_{hij} - \widehat{\bar{Y}_D}) \right) / \ v_{\cdots} \\
\bar{r}_{h\cdot\cdot} &= \left(\sum_{i=1}^{n_h} r_{hi\cdot} \right) / \ n_h
\end{aligned}$$

and if $n_h = 1$,

$$\widehat{V_h}(\widehat{\bar{Y}_D}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \le h' \le H \end{cases}$$

Domain Total

The estimated total in domain D is

$$\widehat{Y}_D = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} v_{hij} \ y_{hij}$$

and its estimated variance is

$$\widehat{V}(\widehat{Y}_D) = \sum_{h=1}^{H} \widehat{V_h}(\widehat{Y}_D)$$

where if $n_h > 1$,

$$\begin{aligned}
\widehat{V_h}(\widehat{Y}_D) &= \frac{n_h(1-f_h)}{n_h - 1} \sum_{i=1}^{n_h} (z_{hi\cdot} - \bar{z}_{h\cdot\cdot})^2 \\
z_{hi\cdot} &= \sum_{j=1}^{m_{hi}} v_{hij} \ z_{hij} \\
\bar{z}_{h\cdot\cdot} &= \left(\sum_{i=1}^{n_h} z_{hi\cdot} \right) \ / \ n_h
\end{aligned}$$

and if $n_h = 1$,

$$\widehat{V_h}(\widehat{Y}_D) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \le h' \le H \end{cases}$$

Quantiles

Let Y be the variable of interest in a complex survey. Denote $F(t) = Pr(Y \leq t)$ as the cumulative distribution for Y.

For $0 < p < 1$, the pth quantile of the population cumulative distribution function is

$$Y_p = \inf\{y : F(y) \geq p\}$$

Estimate of Quantile

Let $\{y_{hij}, w_{hij}\}$ be the observed values for variable Y associated with sampling weights, where (h, i, j) are the stratum index, cluster index, and member index, respectively, as shown in the section "Definitions and Notation" on page 6494. Let $y_{(1)} < y_{(2)} < \ldots < y_{(d)}$ denote the sample order statistics for variable Y.

An estimate of quantile Y_p is

$$\hat{Y}_p = \begin{cases} y_{(1)} & \text{if } p < \hat{F}(y_{(1)}) \\ y_{(k)} + \dfrac{p - \hat{F}(y_{(k)})}{\hat{F}(y_{(k+1)}) - \hat{F}(y_{(k)})}(y_{(k+1)} - y_{(k)}) & \text{if } \hat{F}(y_{(k)}) \leq p < \hat{F}(y_{(k+1)}) \\ y_{(d)} & \text{if } p = 1 \end{cases}$$

where $\hat{F}(t)$ is the estimated cumulative distribution for Y:

$$\hat{F}(t) = \frac{\sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} w_{hij} I(y_{hij} \leq t)}{\sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} w_{hij}}$$

and $I(\cdot)$ is the indicator function.

Standard Error

PROC SURVEYMEANS uses Woodruff method (Dorfman and Valliant 1993; Särndal, Swensson, and Wretman 1992; Francisco and Fuller 1991) to estimate the variances of quantiles. This method first constructs a confidence interval on a quantile. Then it uses the width of the confidence interval to estimate the standard error of a quantile.

In order to estimate the variance for $\hat{Y}_p$, first the procedure estimates the variance of the estimated distribution function $\hat{F}(\hat{Y}_p)$ by

$$\hat{V}(\hat{F}(\hat{Y}_p)) = \sum_{h=1}^{H} \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (d_{hi\cdot} - \bar{d}_{h\cdot\cdot})^2$$

where

$$d_{hi\cdot} = \left(\sum_{j=1}^{m_{hi}} w_{hij} \left(I(y_{hij} \leq \hat{Y}_p) - \hat{F}(\hat{Y}_p)\right) \right) / w_{\ldots}$$

$$\bar{d}_{h\cdot\cdot} = \left(\sum_{i=1}^{n_h} d_{hi\cdot} \right) / n_h$$

Then $100(1-\alpha)\%$ confidence limits of $\hat{F}(\hat{Y}_p)$ can be constructed by

$$(\hat{p}_L, \quad \hat{p}_U) = \left(\hat{F}(\hat{Y}_p) - t_{df,\,\alpha/2}\sqrt{\hat{V}(\hat{F}(\hat{Y}_p))}, \quad \hat{F}(\hat{Y}_p) + t_{df,\,\alpha/2}\sqrt{\hat{V}(\hat{F}(\hat{Y}_p))}\right)$$

where $t_{df,\,\alpha/2}$ is the $100(1-\alpha/2)$th percentile of the t distribution with df degrees of freedom, described in the section "Degrees of Freedom" on page 6498.

When $(\hat{p}_L, \hat{p}_U)$ is out of the range of [0,1], the procedure does not compute the standard error.

The $\hat{p}_L$th quantile is defined as

$$\hat{Y}_{\hat{p}_L} = \begin{cases} y_{(1)} & \text{if } \hat{p}_L < \hat{F}(y_{(1)}) \\ y_{(k_L)} + \dfrac{\hat{p}_L - \hat{F}(y_{(k_L)})}{\hat{F}(y_{(k_L+1)}) - \hat{F}(y_{(k_L)})}(y_{(k_L+1)} - y_{(k_L)}) & \text{if } \hat{F}(y_{(k_L)}) \le \hat{p}_L < \hat{F}(y_{(k_L+1)}) \\ y_{(d)} & \text{if } \hat{p}_L = 1 \end{cases}$$

and the $\hat{p}_U$th quantile is defined as

$$\hat{Y}_{\hat{p}_U} = \begin{cases} y_{(1)} & \text{if } \hat{p}_U < \hat{F}(y_{(1)}) \\ y_{(k_U)} + \dfrac{\hat{p}_U - \hat{F}(y_{(k_U)})}{\hat{F}(y_{(k_U+1)}) - \hat{F}(y_{(k_U)})}(y_{(k_U+1)} - y_{(k_U)}) & \text{if } \hat{F}(y_{(k_U)}) \le \hat{p}_U < \hat{F}(y_{(k_U+1)}) \\ y_{(d)} & \text{if } \hat{p}_U = 1 \end{cases}$$

The standard error of $\hat{Y}_p$ then is estimated by

$$sd(\hat{Y}_p) = \frac{\hat{Y}_{\hat{p}_U} - \hat{Y}_{\hat{p}_L}}{2t_{df,\,\alpha/2}}$$

where $t_{df,\,\alpha/2}$ is the $100(1-\alpha/2)$th percentile of the t distribution with df degrees of freedom.

Confidence Limits

Symmetric $100(1-\alpha)\%$ confidence limits are computed as

$$\left(\hat{Y}_p - sd(\hat{Y}_p) \cdot t_{df,\,\alpha/2}, \quad \hat{Y}_p + sd(\hat{Y}_p) \cdot t_{df,\,\alpha/2}\right)$$

If you specify the NONSYMCL option in the PROC statement, the procedure computes $100(1-\alpha)\%$ nonsymmetric confidence limits:

$$\left(\hat{Y}_{\hat{p}_L}, \quad \hat{Y}_{\hat{p}_U}\right)$$

Replication Methods for Variance Estimation

Recently replication methods have gained popularity for estimating variances in complex survey data analysis. One reason for this popularity is the relative simplicity of replication-based estimates, especially for nonlinear estimators; another is that modern computational capacity has made replication methods feasible for practical survey analysis. For details see Lohr (1999); Wolter (1985); Rust (1985); Dippo, Fay, and Morganstein (1984); Rao and Shao (1999); Rao, Wu, and Yue (1992); and Rao and Shao (1996).

Replication methods draw multiple replicates (also called subsamples) from a full sample according to a specific resampling scheme. The most commonly used resampling schemes are the *balanced repeated replication* (BRR) method and the *jackknife* method. For each replicate, the original weights are modified for the PSUs in the replicates to create replicate weights. The statistics of interest are estimated by using the replicate weights for each replicate. Then the variances of parameters of interest are estimated by the variability among the estimates derived from these replicates. You can use the REPWEIGHTS statement to provide your own replicate weights for variance estimation.

Balanced Repeated Replication (BRR) Method

The balanced repeated replication (BRR) method requires that the full sample be drawn by using a stratified sample design with two primary sampling units (PSUs) per stratum. Let H be the total number of strata. The total number of replicates R is the smallest multiple of 4 that is greater than H. However, if you prefer a larger number of replicates, you can specify the REPS=*number* option. If a $number \times number$ Hadamard matrix cannot be constructed, the number of replicates is increased until a Hadamard matrix becomes available.

Each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix and adjusting the original weights for the remaining PSUs. The new weights are called replicate weights.

Replicates are constructed by using the first H columns of the $R \times R$ Hadamard matrix. The rth ($r = 1, 2, ..., R$) replicate is drawn from the full sample according to the rth row of the Hadamard matrix as follows:

- If the (r, h)th element of the Hadamard matrix is 1, then the first PSU of stratum h is included in the rth replicate and the second PSU of stratum h is excluded.
- If the (r, h)th element of the Hadamard matrix is -1, then the second PSU of stratum h is included in the rth replicate and the first PSU of stratum h is excluded.

The replicate weights of the remaining PSUs in each half sample are then doubled to their original weights. For more details about the BRR method, see Wolter (1985) and Lohr (1999).

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the VARMETHOD=BRR(PRINTH) method-option. If you provide a Hadamard matrix by specifying the VARMETHOD=BRR(HADAMARD=) method-option, then the replicates are generated according to the provided Hadamard matrix.

Suppose that θ is a population parameter of interest. Let $\hat{\theta}$ be the estimate from the full sample for θ. Let $\hat{\theta}_r$ be the estimate from the rth replicate subsample by using replicate weights. PROC SURVEYMEANS estimates the variance of $\hat{\theta}$ by

$$\widehat{V}(\hat{\theta}) = \frac{1}{R}\sum_{r=1}^{R}\left(\hat{\theta}_r - \hat{\theta}\right)^2$$

with H degrees of freedom, where H is the number of strata.

You can use the VARMETHOD=BRR(OUTWEIGHTS=) method-option to save the replicate weights into a SAS data set.

Fay's BRR Method

Fay's method is a modification of the BRR method, and it requires a stratified sample design with two primary sampling units (PSUs) per stratum. The total number of replicates R is the smallest multiple of 4 that is greater than the total number of strata H. However, if you prefer a larger number of replicates, you can specify the REPS= method-option.

For each replicate, Fay's method uses a Fay coefficient $0 \leq \epsilon < 1$ to impose a perturbation of the original weights in the full sample that is gentler than using only half samples, as in the traditional BRR method. The Fay coefficient $0 \leq \epsilon < 1$ can be optionally set by the FAY = ϵ method-option. By default, $\epsilon = 0.5$ if only the FAY method-option is used without specifying a value for ϵ (Judkins 1990; Rao and Shao 1999). When $\epsilon = 0$, Fay's method becomes the traditional BRR method. For more details, see Dippo, Fay, and Morganstein (1984), Fay (1984), Fay (1989), and Judkins (1990).

Let H be the number of strata. Replicates are constructed by using the first H columns of the $R \times R$ Hadamard matrix, where R is the number of replicates, $R > H$. The rth ($r = 1, 2, ..., R$) replicate is created from the full sample according to the rth row of the Hadamard matrix as follows:

- If the (r, h)th element of the Hadamard matrix is 1, then the full sample weight of the first PSU in stratum h is multiplied by ϵ and that of the second PSU is multiplied by $2-\epsilon$ to obtain the rth replicate weights.
- If the (r, h)th element of the Hadamard matrix is -1, then the full sample weight of the first PSU in stratum h is multiplied by $2-\epsilon$ and that of the second PSU is multiplied by ϵ to obtain the rth replicate weights.

You can use the VARMETHOD=BRR(OUTWEIGHTS=) method-option to save the replicate weights into a SAS data set.

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the VARMETHOD=BRR(PRINTH) method-option. If you provide a Hadamard matrix by specifying the VARMETHOD=BRR(HADAMARD=) method-option, then the replicates are generated according to the provided Hadamard matrix.

Suppose that θ is a population parameter of interest. Let $\hat{\theta}$ be the estimate from the full sample for θ. Let $\hat{\theta}_r$ be the estimate from the rth replicate subsample by using replicate weights. PROC

SURVEYMEANS estimates the variance of $\hat{\theta}$ by

$$\widehat{V}(\hat{\theta}) = \frac{1}{R(1-\epsilon)^2} \sum_{r=1}^{R} \left(\hat{\theta}_r - \hat{\theta}\right)^2$$

with H degrees of freedom, where H is the number of strata.

Jackknife Method

The jackknife method of variance estimation deletes one PSU at a time from the full sample to create replicates. The total number of replicates R is the same as the total number of PSUs. In each replicate, the sample weights of the remaining PSUs are modified by the *jackknife coefficient* α_r. The modified weights are called replicate weights.

The jackknife coefficient and replicate weights are described as follows.

Without Stratification If there is no stratification in the sample design (no STRATA statement), the jackknife coefficients α_r are the same for all replicates:

$$\alpha_r = \frac{R-1}{R} \quad \text{where } r = 1, 2, ..., R$$

Denote the original weight in the full sample for the jth member of the ith PSU as w_{ij}. If the ith PSU is included in the rth replicate ($r = 1, 2, ..., R$), then the corresponding replicate weight for the jth member of the ith PSU is defined as

$$w_{ij}^{(r)} = w_{ij}/\alpha_r$$

With Stratification If the sample design involves stratification, each stratum must have at least two PSUs to use the jackknife method.

Let stratum $\tilde{h}_r$ be the stratum from which a PSU is deleted for the rth replicate. Stratum $\tilde{h}_r$ is called the *donor stratum.* Let $n_{\tilde{h}_r}$ be the total number of PSUs in the donor stratum $\tilde{h}_r$. The jackknife coefficients are defined as

$$\alpha_r = \frac{n_{\tilde{h}_r} - 1}{n_{\tilde{h}_r}} \quad \text{where } r = 1, 2, ..., R$$

Denote the original weight in the full sample for the jth member of the ith PSU as w_{ij}. If the ith PSU is included in the rth replicate ($r = 1, 2, ..., R$), then the corresponding replicate weight for the jth member of the ith PSU is defined as

$$w_{ij}^{(r)} = \begin{cases} w_{ij} & \text{if } i\text{th PSU is not in the donor stratum } \tilde{h}_r \\ w_{ij}/\alpha_r & \text{if } i\text{th PSU is in the donor stratum } \tilde{h}_r \end{cases}$$

You can use the VARMETHOD=JACKKNIFE(OUTJKCOEFS=) method-option to save the jackknife coefficients into a SAS data set and use the VARMETHOD=JACKKNIFE(OUTWEIGHTS=) method-option to save the replicate weights into a SAS data set.

If you provide your own replicate weights with a REPWEIGHTS statement, then you can also provide corresponding jackknife coefficients with the JKCOEFS= option.

Suppose that θ is a population parameter of interest. Let $\hat{\theta}$ be the estimate from the full sample for θ. Let $\hat{\theta}_r$ be the estimate from the rth replicate subsample by using replicate weights. PROC SURVEYMEANS estimates the variance of $\hat{\theta}$ by

$$\widehat{V}(\hat{\theta}) = \sum_{r=1}^{R} \alpha_r \left(\hat{\theta}_r - \hat{\theta}\right)^2$$

with $R - H$ degrees of freedom, where R is the number of replicates and H is the number of strata, or $R - 1$ when there is no stratification.

Hadamard Matrix

A Hadamard matrix $\mathbf{H}$ is a square matrix whose elements are either 1 or -1 such that

$$\mathbf{H}\mathbf{H}' = k\mathbf{I}$$

where k is the dimension of $\mathbf{H}$ and $\mathbf{I}$ is the identity matrix of order k. The order k is necessarily 1, 2, or a positive integer that is a multiple of 4.

For example, the following matrix is a Hadamard matrix of dimension $k = 8$:

$$\begin{array}{rrrrrrrr}
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\
1 & 1 & -1 & -1 & 1 & 1 & -1 & -1 \\
1 & -1 & -1 & 1 & 1 & -1 & -1 & 1 \\
1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\
1 & -1 & 1 & -1 & -1 & 1 & -1 & 1 \\
1 & 1 & -1 & -1 & -1 & -1 & 1 & 1 \\
1 & -1 & -1 & 1 & -1 & 1 & 1 & -1
\end{array}$$

Output Data Sets

You can use the Output Delivery System to create a SAS data set from any piece of PROC SURVEYMEANS output. See the section "ODS Table Names" on page 6517 for more information.

PROC SURVEYMEANS also provides an output data set that stores the replicate weights for BRR or jackknife variance estimation and an output data set that stores the jackknife coefficients for jackknife variance estimation.

Replicate Weights Output Data Set

If you specify the OUTWEIGHTS= method-option for BRR or jackknife method in the VARMETHOD= option, PROC SURVEYMEANS stores the replicate weights in an output data

set. The OUTWEIGHTS= output data set contains all observations used in the analysis or all valid observations in the DATA= input data set. (A valid observation is an observation that has a positive value of the WEIGHT variable. Valid observations must also have nonmissing values of the STRATA and CLUSTER variables, unless you specify the MISSING option. See the section "Data and Sample Design Summary" on page 6512 for details about valid observations.)

The OUTWEIGHTS= data set contains the following variables:

- all variables in the DATA= input data set
- RepWt_1, RepWt_2, . . ., RepWt_n, which are the replicate weight variables

where *n* is the total number of replicates in the analysis. Each replicate weight variable contains the replicate weights for the corresponding replicate. Replicate weights equal zero for those observations not included in the replicate.

After the procedure creates replicate weights for a particular input data set and survey design, you can use the OUTWEIGHTS= method-option to store these replicate weights and then use them again in subsequent analyses, either in PROC SURVEYMEANS or in the other survey procedures. You can use the REPWEIGHTS statement to provide replicate weights for the procedure.

Jackknife Coefficients Output Data Set

If you specify the OUTJKCOEFS= method-option for VARMETHOD=JACKKNIFE, PROC SURVEYMEANS stores the jackknife coefficients in an output data set. The OUTJKCOEFS= output data set contains one observation for each replicate. The OUTJKCOEFS= data set contains the following variables:

- Replicate, which is the replicate number for the jackknife coefficient
- JKCoefficient, which is the jackknife coefficient
- DonorStratum, which is the stratum of the PSU that was deleted to construct the replicate, if you specify a STRATA statement

After the procedure creates jackknife coefficients for a particular input data set and survey design, you can use the OUTJKCOEFS= method-option to store these coefficients and then use them again in subsequent analyses, either in PROC SURVEYMEANS or in the other survey procedures. You can use the JKCOEFS= option in the REPWEIGHTS statement to provide jackknife coefficients for the procedure.

Rectangular and Stacking Structures in an Output Data Set

When you use an ODS output statement to create SAS data sets for certain tables in PROC SURVEYMEANS, there are two types of table structure for a data set: *rectangular* and *stacking*. A rectangular structure creates one observation for each analysis variable in the data set. A stacking structure creates only one observation in the output data set for all analysis variables.

Before SAS 9, the stacking table structure, similar to the table structure in PROC MEANS, was the default in PROC SURVEYMEANS. Since SAS 9, the new default is to produce a rectangular table in the output data sets. You can use the STACKING option to request that the procedure produce the output data sets by using a stacking table structure.

The STACKING option affects the following tables:

- Domain
- Ratio
- Statistics
- StrataInfo

Figure 85.6 and Figure 85.7 shows these two structures for analyzing the following data set:

```
data new;
   input sex$ x;
   datalines;
M 12
F 5
M 13
F 23
F 11
;
```

The following statements request the default rectangular structure of the output data set for the statistics table:

```
proc surveymeans data=new mean;
   ods output statistics=rectangle;
run;
proc print data=rectangle;
run;
```

Figure 85.6 shows the rectangular structure.

Figure 85.6 Rectangular Structure in the Output Data Set

Rectangular Structure in the Output Data Set

Obs	Var Name	Var Level	Mean	StdErr
1	x		12.800000	2.905168
2	sex	F	0.600000	0.244949
3	sex	M	0.400000	0.244949

The following statements specify the STACKING option to request that the output data set have a stacking structure:

```
proc surveymeans data=new mean stacking;
   ods output statistics=stacking;
run;
proc print data=stacking;
run;
```

Figure 85.7 shows the stacking structure of the output data set for the statistics table requested by the STACKING option.

Figure 85.7 Stacking Structure in the Output Data Set Requested by the STACKING option

Stacking Structure in the Output Data Set

Obs	x	x_Mean	x_StdErr	sex_F	sex_F_Mean
1	x	12.800000	2.905168	sex=F	0.600000

Obs	sex_F_StdErr	sex_M	sex_M_Mean	sex_M_StdErr
1	0.244949	sex=M	0.400000	0.244949

Displayed Output

The SURVEYMEANS procedure produces the following output.

Data and Sample Design Summary

The "Data Summary" table provides information about the input data set and the sample design. This table displays the total number of valid observations, where an observation is considered *valid* if it has nonmissing values for all procedure variables other than the analysis variables—that is, for all specified STRATA, CLUSTER, and WEIGHT variables. This number might differ from the number of nonmissing observations for an individual analysis variable, which the procedure displays in the "Statistics" table. See the section "Missing Values" on page 6491 for more information.

PROC SURVEYMEANS displays the following information in the "Data Summary" table:

- Number of Strata, if you specify a STRATA statement
- Number of Clusters, if you specify a CLUSTER statement
- Number of Observations, which is the total number of valid observations
- Sum of Weights, which is the sum over all valid observations, if you specify a WEIGHT statement

Class Level Information

If you use a CLASS statement to name classification variables for categorical analysis, or if you list any character variables in the VAR statement, then PROC SURVEYMEANS displays a "Class Level Information" table. This table contains the following information for each classification variable:

- Class Variable, which lists each CLASS variable name
- Levels, which is the number of values or levels of the classification variable
- Values, which lists the values of the classification variable. The values are separated by a white space character; therefore, to avoid confusion, you should not include a white space character within a classification variable value.

Stratum Information

If you specify the LIST option in the STRATA statement, PROC SURVEYMEANS displays a "Stratum Information" table. This table displays the number of valid observations in each stratum, as well as the number of nonmissing stratum observations for each analysis variable. The "Stratum Information" table provides the following for each stratum:

- Stratum Index, which is a sequential stratum identification number
- STRATA variable(s), which lists the levels of STRATA variables for the stratum
- Population Total, if you specify the TOTAL= option
- Sampling Rate, if you specify the TOTAL= or RATE= option. If you specify the TOTAL= option, the sampling rate is based on the number of valid observations in the stratum.
- N Obs, which is the number of valid observations
- Variable, which lists each analysis variable name
- Levels, which identifies each level for categorical variables
- N, which is the number of nonmissing observations for the analysis variable
- Clusters, which is the number of clusters, if you specify a CLUSTER statement

Variance Estimation

If the variance method is not Taylor series or if the NOMCAR option is used, by default, PROC SURVEYMEANS displays the following variance estimation specifications in the "Variance Estimation" table:

- Method, which is the variance estimation method

- Number of Replicates, which is the number of replicates if you specify the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option
- Hadamard Data Set, which is the name of the SAS data set for the HADAMARD matrix if you specify the VARMETHOD=BRR(HADAMARD=) method-option
- Fay Coefficient, which is the value of the FAY coefficient if you specify the VARMETHOD=BRR(FAY) method-option
- Replicate Weights Data Set, which is the name of the SAS data set that contains the replicate weights
- Missing Levels Included (MISSING), if you specify the MISSING option
- Missing Levels Include (NOMCAR), if you specify the NOMCAR option

Statistics

The "Statistics" table displays all of the statistics that you request with *statistic-keywords* in the PROC SURVEYMEANS statement, except DECILES, MEDIAN, Q1, Q3, and QUARTILES, which are displayed in the "Quantiles" table. If you do not specify any *statistic-keywords*, then by default this table displays the following information for each analysis variable: the sample size, the mean, the standard error of the mean, and the confidence limits for the mean. The "Statistics" table might contain the following information for each analysis variable, depending on which *statistic-keywords* you request:

- Variable name
- Variable Label
- Level, which identifies each level for categorical variables
- N, which is the number of nonmissing observations
- N Miss, which is the number of missing observations
- Minimum
- Maximum
- Range
- Number of Clusters
- Sum of Weights
- DF, which is the degrees of freedom for the t test
- Mean
- Std Error of Mean, which is the standard error of the mean

- Var of Mean, which is the variance of the mean
- t Value, for testing H_0 : population MEAN $= 0$
- Pr $>$ | t |, which is the two-sided p-value for the t test
- $100(1-\alpha)\%$ CL for Mean, which are two-sided confidence limits for the mean
- $100(1-\alpha)\%$ Upper CL for Mean, which is a one-sided upper confidence limit for the mean
- $100(1-\alpha)\%$ Lower CL for Mean, which is a one-sided lower confidence limit for the mean
- Coeff of Variation, which is the coefficients of variation for the mean and the sum
- Sum
- Std Dev, which is the standard deviation of the sum
- Var of Sum, which is the variance of the sum
- $100(1-\alpha)\%$ CL for Sum, which are two-sided confidence limits for the sum
- $100(1-\alpha)\%$ Upper CL for Sum, which is a one-sided upper confidence limit for the sum
- $100(1-\alpha)\%$ Lower CL for Sum, which is a one-sided lower confidence limit for the Sum

Quantiles

The "Quantiles" table displays all the quantiles that you request with either *statistic-keywords* such as DECILES, MEDIAN, Q1, Q3, and QUARTILES, or the PERCENTILE= option, or the QUANTILE= option in the PROC SURVEYMEANS statement.

The "Quantiles" table contains the following information for each quantile:

- Variable name
- Variable Label
- Percentile, which is the requested quantile in the format of %
- Percentile Label, which is the corresponding common name for a percentile if it exists—for example, *Median* for 50th percentile
- Estimate, which is the estimate for a requested quantile with respect to the population distribution
- StdErr, which is the standard error of the quantile
- $100(1-\alpha)\%$ Confidence Limits, which are two-sided confidence limits for the quantile

Domain Analysis

If you use a DOMAIN statement, the procedure displays statistics in each domain in a "Domain Analysis" table. A "Domain Analysis" table contains all the columns in the "Statistics" table, plus columns of domain variable values.

Note that depending on how you define the domains with domain variables, the procedure might produce more than one "Domain Analysis" table. For example, in the DOMAIN statement

```
domain A B*C*D A*C C;
```

you use four definitions to define domains:

- A: all the levels of A
- C: all the levels of C
- A*C: all the interactive levels of A and C
- B*C*D: all the interactive levels of B, C, and D

The procedure displays four "Domain Analysis" tables, one for each domain definition. If you use an ODS OUTPUT statement to create an output data set for domain analysis, the output data set contains a variable Domain whose values are these domain definitions.

Ratio Analysis

The "Ratio Analysis" table displays all of the statistics that you request with *statistic-keywords* in the PROC statement. If you do not specify any *statistic-keywords*, then by default this table displays the ratio and its standard error. The "Ratio Analysis" table might contain the following information for each ratio, depending on which *statistic-keywords* you request:

- Numerator, which identifies the numerator variable of the ratio
- Denominator, which identifies the denominator variable of the ratio
- N, which is the number of observations used in the ratio analysis
- number of Clusters
- Sum of Weights
- DF, which is the degrees of freedom for the t test
- Ratio
- Std Error of Ratio, which is the standard error of the ratio
- Var of Ratio, which is the variance of the ratio

- t Value, for testing H_0 : population RATIO $= 0$
- Pr $> |\ t\ |$, which is the two-sided p-value for the t test
- $100(1-\alpha)\%$ CL for Ratio, which are two-sided confidence limits for the Ratio
- Upper $100(1-\alpha)\%$ CL for Ratio, which are one-sided upper confidence limits for the Ratio
- Lower $100(1-\alpha)\%$ CL for Ratio, which are one-sided lower confidence limits for the Ratio

When you use the ODS OUTPUT statement to create an output data set, if you use labels for your RATIO statement, these labels are saved in the variable Ratio Statement in the output data set.

Hadamard Matrix

If you specify the VARMETHOD=BRR(PRINTH) method-option in the PROC statement, PROC SURVEYMEANS displays the Hadamard matrix.

When you provide a Hadamard matrix with the VARMETHOD=BRR(HADAMARD=) method-option, the procedure displays only used rows and columns of the Hadamard matrix.

ODS Table Names

PROC SURVEYMEANS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 85.3. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 85.3 ODS Tables Produced by PROC SURVEYMEANS

ODS Table Name	Description	Statement	Option
ClassVarInfo	Class level information	CLASS	default
Domain	Statistics in domains	DOMAIN	default
HadamardMatrix	Hadamard matrix	PROC	PRINTH
Ratio	Statistics for ratios	RATIO	default
Quantiles	Quantiles	PROC	default
Statistics	Statistics	PROC	default
StrataInfo	Stratum information	STRATA	LIST
Summary	Data summary	PROC	default
VarianceEstimation	Variance estimation	PROC	default

For example, the following statements create an output data set MyStrata, which contains the

"StrataInfo" table, and an output data set MyStat, which contains the "Statistics" table for the ice cream study discussed in the section "Stratified Sampling" on page 6469:

```
title1 'Analysis of Ice Cream Spending';
title2 'Stratified Simple Random Sample Design';
proc surveymeans data=IceCream total=StudentTotals;
   strata Grade / list;
   var Spending Group;
   weight Weight;
   ods output StrataInfo = MyStrata
              Statistics = MyStat;
run;
```

Examples: SURVEYMEANS Procedure

The section "Getting Started: SURVEYMEANS Procedure" on page 6467 contains examples of analyzing data from simple random sampling and stratified simple random sample designs. This section provides more examples that illustrate how to use PROC SURVEYMEANS.

Example 85.1: Stratified Cluster Sample Design

Consider the example in the section "Stratified Sampling" on page 6469. The study population is a junior high school with a total of 4,000 students in grades 7, 8, and 9. Researchers want to know how much these students spend weekly for ice cream, on the average, and what percentage of students spend at least $10 weekly for ice cream.

The example in the section "Stratified Sampling" on page 6469 assumes that the sample of students was selected using a stratified simple random sample design. This example shows analysis based on a more complex sample design.

Suppose that every student belongs to a study group and that study groups are formed within each grade level. Each study group contains between two and four students. Table 85.4 shows the total number of study groups for each grade.

Table 85.4 Study Groups and Students by Grade

Grade	Number of Study Groups	Number of Students
7	608	1,824
8	252	1,025
9	403	1,151
Total	617	4,000

It is quicker and more convenient to collect data from students in the same study group than to

collect data from students individually. Therefore, this study uses a stratified clustered sample design. The primary sampling units, or clusters, are study groups. The list of all study groups in the school is stratified by grade level. From each grade level, a sample of study groups is randomly selected, and all students in each selected study group are interviewed. The sample consists of eight study groups from the 7th grade, three groups from the 8th grade, and five groups from the 9th grade.

The SAS data set IceCreamStudy saves the responses of the selected students:

```
data IceCreamStudy;
   input Grade StudyGroup Spending @@;
   if (Spending < 10) then Group='less';
      else Group='more';
   datalines;
7  34  7     7  34  7    7 412  4     9  27 14
7  34  2     9 230 15    9  27 15     7 501  2
9 230  8     9 230  7    7 501  3     8  59 20
7 403  4     7 403 11    8  59 13     8  59 17
8 143 12     8 143 16    8  59 18     9 235  9
8 143 10     9 312  8    9 235  6     9 235 11
9 312 10     7 321  6    8 156 19     8 156 14
7 321  3     7 321 12    7 489  2     7 489  9
7  78  1     7  78 10    7 489  2     7 156  1
7  78  6     7 412  6    7 156  2     9 301  8
;
```

In the data set IceCreamStudy, the variable Grade contains a student's grade. The variable StudyGroup identifies a student's study group. It is possible for students from different grades to have the same study group number because study groups are sequentially numbered within each grade. The variable Spending contains a student's response regarding how much he spends per week for ice cream, in dollars. The variable GROUP indicates whether a student spends at least $10 weekly for ice cream. It is not necessary to store the data in order of grade and study group.

The SAS data set StudyGroup is created to provide PROC SURVEYMEANS with the sample design information shown in Table 85.4:

```
data StudyGroups;
   input Grade _total_; datalines;
7 608
8 252
9 403
;
```

The variable Grade identifies the strata, and the variable _TOTAL_ contains the total number of study groups in each stratum. As discussed in the section "Specification of Population Totals and Sampling Rates" on page 6492, the population totals stored in the variable _TOTAL_ should be expressed in terms of the primary sampling units (PSUs), which are study groups in this example. Therefore, the variable _TOTAL_ contains the total number of study groups for each grade, rather than the total number of students.

In order to obtain unbiased estimates, you create sampling weights by using the following SAS statements:

```
data IceCreamStudy;
   set IceCreamStudy;
   if Grade=7 then Prob=8/608;
   if Grade=8 then Prob=3/252;
   if Grade=9 then Prob=5/403;
   Weight=1/Prob;
```

The sampling weights are the reciprocals of the probabilities of selections. The variable Weight contains the sampling weights. Because the sampling design is clustered and all students from each selected cluster are interviewed, the sampling weights equal the inverse of the cluster (or study group) selection probabilities.

The following SAS statements perform the analysis for this sample design:

```
title1 'Analysis of Ice Cream Spending';
title2 'Stratified Clustered Sample Design';
proc surveymeans data=IceCreamStudy total=StudyGroups;
   strata Grade / list;
   cluster StudyGroup;
   var Spending Group;
   weight Weight;
run;
```

Output 85.1.1 provides information about the sample design and the input data set. There are three strata in the sample design, and the sample contains 16 clusters and 40 observations. The variable Group has two levels, 'less' and 'more.'

Output 85.1.1 Data Summary and Class Information

```
                    Analysis of Ice Cream Spending
                  Stratified Clustered Sample Design

                      The SURVEYMEANS Procedure

                             Data Summary

                  Number of Strata                   3
                  Number of Clusters                16
                  Number of Observations            40
                  Sum of Weights                 3162.6

                       Class Level Information

                  Class
                  Variable      Levels    Values

                  Group              2    less more
```

Output 85.1.2 displays information for each stratum. Since the primary sampling units in this design are study groups, the population totals shown in Output 85.1.2 are the total numbers of study groups for each stratum or grade. This differs from Output 85.3, which provides the population totals in

terms of students since students were the primary sampling units for that design. Output 85.1.2 also displays the number of clusters for each stratum and analysis variable.

Output 85.1.2 Stratum Information

Stratum Information

Stratum Index	Grade	Population Total	Sampling Rate	N Obs	Variable	Level
1	7	608	1.32%	20	Spending Group	less more
2	8	252	1.19%	9	Spending Group	less more
3	9	403	1.24%	11	Spending Group	less more

Stratum Information

Stratum Index	Grade	Population Total	Sampling Rate	N Obs	Variable	N
1	7	608	1.32%	20	Spending	20
					Group	17
						3
2	8	252	1.19%	9	Spending	9
					Group	0
						9
3	9	403	1.24%	11	Spending	11
					Group	6
						5

Stratum Information

Stratum Index	Grade	Population Total	Sampling Rate	N Obs	Variable	Clusters
1	7	608	1.32%	20	Spending	8
					Group	8
						3
2	8	252	1.19%	9	Spending	3
					Group	0
						3
3	9	403	1.24%	11	Spending	5
					Group	4
						4

Output 85.1.3 displays the estimates of the average weekly ice cream expenditure and the percentage of students spending at least $10 weekly for ice cream.

Output 85.1.3 Statistics

Statistics						
Variable	Level	N	Mean	Std Error of Mean	95% CL for Mean	
Spending		40	8.923860	0.650859	7.51776370	10.3299565
Group	less	23	0.561437	0.056368	0.43966057	0.6832130
	more	17	0.438563	0.056368	0.31678698	0.5603394

Example 85.2: Domain Analysis

Suppose that you are studying profiles of 800 top-performing companies to provide information about their impact on the economy. You are also interested in the company profiles within each market type. A sample of 66 companies is selected with unequal probability across market types. However, market type is not included in the sample design. Thus, the number of companies within each market type is a random variable in your sample. To obtain statistics within each market type, you should use domain analysis. The data of the 66 companies are saved in the following data set.

```
data Company;
   length Type $14;
   input Type$ Asset Sale Value Profit Employee Weight;
   datalines;
Other            2764.0  1828.0  1850.3   144.0   18.7   9.6

For each company in your sample, the variables are defined as follows:

- Type identifies the type of market for the company.
- Asset contains the company's assets, in millions of dollars.
- Sale contains sales, in millions of dollars.
- Value contains the market value of the company, in millions of dollars.

- Profit contains the profit, in millions of dollars.
- Employee contains the number of employees, in thousands.
- Weight contains the sampling weight.

The following SAS statements use PROC SURVEYMEANS to perform the domain analysis, estimating means, and other statistics for the overall population and also for the subpopulations (or domain) defined by market type. The DOMAIN statement specifies Type as the domain variable:

```
title 'Top Companies Profile Study';
proc surveymeans data=Company total=800 mean sum;
   var Asset Sale Value Profit Employee;
   weight Weight;
   domain Type;
run;
```

Output 85.2.1 shows that there are 66 observations in the sample. The sum of the sampling weights equals 799.8, which is close to the total number of companies in the study population.

Output 85.2.1 Company Profile Study

Top Companies Profile Study

The SURVEYMEANS Procedure

Data Summary

Number of Observations	66
Sum of Weights	799.8

Statistics

Variable	Mean	Std Error of Mean	Sum	Std Dev
Asset	6523.488510	720.557075	5217486	1073829
Sale	4215.995799	839.132506	3371953	847885
Value	2145.935121	342.531720	1716319	359609
Profit	188.788210	25.057876	150993	30144
Employee	36.874869	7.787857	29493	7148.003298

The "Statistics" table in Output 85.2.1 displays the estimates of the mean and total for all analysis variables for the entire set of 800 companies, while Output 85.2.2 shows the mean and total estimates for each company type.

Output 85.2.2 Domain Analysis for Company Profile Study

Example 85.3: Ratio Analysis

Suppose you are interested in the profit per employee and the sale per employee among the 800 top-performing companies in the data in the previous example. The following SAS statements illustrate

how you can use PROC SURVEYMEANS to estimate these ratios:

```
title 'Ratio Analysis in Top Companies Profile Study';
proc surveymeans data=Company total=800 ratio;
   var Profit Sale Employee;
   weight Weight;
   ratio Profit Sale / Employee;
run;
```

The RATIO statement requests the ratio of the profit and the sales to the number of employees.

Output 85.3.1 shows the estimated ratios and their standard errors. Because the profit and the sales figures are in millions of dollars, and the employee numbers are in thousands, the profit per employee is estimated as $5,120 with a standard error of $1,059, and the sales per employee are $114,332 with a standard error of $20,503.

Output 85.3.1 Estimate Ratios

Ratio Analysis in Top Companies Profile Study

The SURVEYMEANS Procedure

Ratio Analysis

Numerator	Denominator	Ratio	Std Err
Sale	Employee	114.332497	20.502742
Profit	Employee	5.119698	1.058939

Example 85.4: Analyzing Survey Data with Missing Values

As described in the section "Missing Values" on page 6491, the SURVEYMEANS procedure excludes an observation from the analysis if it has a missing value for the analysis variable or a nonpositive value for the WEIGHT variable.

However, if there is evidence indicating that the nonrespondents are different from the respondents for your study, you can use the NOMCAR option to compute descriptive statistics among respondents while still counting the number of nonrespondents.

We use the ice cream example in the section "Stratified Sampling" on page 6469 to illustrate how to perform similar analysis when there are missing values.

Suppose that some of the students failed to provide the amounts spent on ice cream, as shown in the following data set, IceCream:

```
data IceCream;
   input Grade Spending @@;
   if Grade=7 then Prob=20/1824;
   if Grade=8 then Prob=9/1025;
   if Grade=9 then Prob=11/1151;
   Weight=1/Prob;
   datalines;
7 7  7  7  8  .  9 10  7  .  7 10  7  3  8 20  8 19  7 2
7 .  9 15  8 16  7  6  7  6  7  6  9 15  8 17  8 14  9 .
9 8  9  7  7  3  7 12  7  4  9 14  8 18  9  9  7  2  7 1
7 4  7 11  9  8  8  .  8 13  7  .  9  .  9 11  7  2  7 9
;
data StudentTotals;
   input Grade _total_; datalines;
7 1824
8 1025
9 1151
;
```

Considering the possibility that those students who did not respond spend differently than those students who did respond, you can use the NOMCAR option to request the analysis to treat the respondents as a domain rather than exclude the nonrespondents.

The following SAS statements produce the desired analysis:

```
title 'Analysis of Ice Cream Spending';
proc surveymeans data=IceCream total=StudentTotals nomcar mean sum;
   strata Grade;
   var Spending;
   weight Weight;
run;
```

Output 85.4.1 summarize the analysis including the variance estimation method.

Output 85.4.1 Analysis of Incomplete Ice Cream Data Excluding Observations with Missing Values

```
                    Analysis of Ice Cream Spending

                      The SURVEYMEANS Procedure

                              Data Summary

                  Number of Strata                   3
                  Number of Observations            40
                  Sum of Weights                  4000

                        Variance Estimation

                  Method                Taylor Series
                  Missing Values    Included (NOMCAR)
```

Output 85.4.2 shows the mean and total estimates when treating respondents as a domain in the student population. Although the point estimates are the same as the analysis without the NOMCAR option, for this particular example, the variance estimations are slightly higher when you assume that the missingness is not completely at random.

Output 85.4.2 Analysis of Incomplete Ice Cream Data Excluding Observations with Missing Values

Statistics

Variable	Mean	Std Error of Mean	Sum	Std Dev
Spending	9.770542	0.652347	32139	3515.126876

Example 85.5: Variance Estimation Using Replication Methods

In order to improve service, the San Francisco Municipal Railway (MUNI) conducts a survey to estimated passenger's average waiting time for MUNI's subway system.

The study uses a stratified cluster sample design. Each MUNI subway line is a stratum. The subway lines included in the study are 'J-Church,' 'K-Ingleside,' 'L-Taraval,' 'M-Ocean View,' 'N-Judah,' and the street car 'F-Market & Wharves.' The MUNI vehicles in service for these lines during a day are primary sampling units. Within each stratum, two vehicles (PSUs) are randomly selected. Then the waiting times of passengers for a selected MUNI vehicle are collected.

Table 85.5 shows the number of passengers that are interviewed in each of the selected MUNI vehicles.

Table 85.5 The Sample of the MUNI Waiting Time Study

MUNI Line	Vehicle	Number of Passengers
F-Market & Wharves	1	65
	2	102
J-Church	1	101
	2	142
K-Ingleside	1	145
	2	180
L-Taraval	1	135
	2	185
M-Ocean View	1	139
	2	203
N-Judah	1	306
	2	234

The collected data are saved in the SAS data set MUNIsurvey. The variable Line indicates which MUNI line a passenger is riding. The variable vehicle identifies the vehicle that a passenger is boarding. The variable Waittime is the time (in minutes) that a passenger waited. The variable weight contains the sampling weights, which are determined by selection probabilities within each stratum.

Output 85.5.1 displays the first 10 observations of the data set MUNIsurvey.

Output 85.5.1 First 10 Observations in the Data Set from the MUNI Subway Survey

MUNI subway passenger waiting time analysis

Obs	line	vehicle	passenger	waittime	weight
1	F-Market & Wharves	1	1	18	59
2	F-Market & Wharves	1	2	0	59
3	F-Market & Wharves	1	3	16	59
4	F-Market & Wharves	1	4	13	59

6	F-Market & Wharves	1	6	13	59
7	F-Market & Wharves	1	7	7	59
8	F-Market & Wharves	1	8	5	59
9	F-Market & Wharves	1	9	16	59
10	F-Market & Wharves	1	10	5	59

Using the VARMETHOD=BRR option, the following SAS statements analyze the MUNI subway survey by using the BRR method to estimate the variance:

```
title 'MUNI passenger waiting time analysis using BRR';
proc surveymeans data=MUNIsurvey mean varmethod=brr mean clm;
   strata line;
   cluster vehicle;
   var waittime;
   weight weight;
run;
```

The STRATUM variable is line, which corresponds to MUNI lines. The two clusters within each stratum are identified by the variable vehicle. The sampling weights are stored in the variable weight. The mean and confident limits of passenger waiting time (in minutes) are requested statistics.

Output 85.5.2 summarizes the data and indicates that the variance estimation method is BRR with 8 replicates.

Output 85.5.2 MUNI Passenger Waiting Time Analysis Using the BRR Method

MUNI passenger waiting time analysis using BRR

The SURVEYMEANS Procedure

Data Summary

Number of Strata	6
Number of Clusters	12
Number of Observations	1937
Sum of Weights	143040

Output 85.5.2 *continued*

```
                    Variance Estimation

                Method                          BRR
                Number of Replicates              8
```

Output 85.5.3 reports that the average passenger waiting time for a MUNI vehicle is 7.33 minutes, with an estimated standard of 0.24 minutes, using the BRR method. The 95% confident limits for the mean are estimated as 6.75 to 7.91 minutes.

Output 85.5.3 MUNI Passenger Waiting Time Analysis Using the BRR Method

```
                              Statistics

                                  Std Error
Variable            Mean          of Mean       95% CL for Mean
-------------------------------------------------------------------
waittime        7.333012         0.237557    6.75172983 7.91429366
-------------------------------------------------------------------
```

Alternatively, the variance can be estimated using the jackknife method if the VARMETHOD=JACKKNIFE option is used. The following SAS statements analyze the MUNI subway survey by using the jackknife method to estimate the variance:

```
title 'MUNI passenger waiting time analysis using jackknife';
proc surveymeans data=MUNIsurvey mean varmethod=jackknife mean clm;
   strata line;
   cluster vehicle;
   var waittime;
   weight weight;
run;
```

Output 85.5.4 summarizes the data and indicates that the variance estimation method is jackknife with 12 replicates.

Output 85.5.4 MUNI Passenger Waiting Time Analysis Using the Jackknife Method

```
          MUNI passenger waiting time analysis using jackknife

                    The SURVEYMEANS Procedure

                          Data Summary

                Number of Strata                  6
                Number of Clusters               12
                Number of Observations         1937

Overview: SURVEYREG Procedure

The SURVEYREG procedure performs regression analysis for sample survey data. This procedure can handle complex survey sample designs, including designs with stratification, clustering, and unequal weighting. The procedure fits linear models for survey data and computes regression coefficients and their variance-covariance matrix. The procedure also provides significance tests for the model effects and for any specified estimable linear functions of the model parameters. Using the regression model, the procedure can compute predicted values for the sample survey data.

PROC SURVEYREG computes the regression coefficient estimators by generalized least squares estimation using elementwise regression. The procedure assumes that the regression coefficients are the same across strata and primary sampling units (PSUs). To estimate the variance-covariance matrix for the regression coefficients, PROC SURVEYREG uses either the Taylor series (linearization) method or replication (resampling) methods to estimate sampling errors of estimators based on complex sample designs. For details see Woodruff (1971); Fuller (1975); Särndal, Swensson, and Wretman (1992); Wolter (1985); Rust (1985); Dippo, Fay, and Morganstein (1984); Rao and Shao (1999); Rao, Wu, and Yue (1992); and Rao and Shao (1996).

Getting Started: SURVEYREG Procedure

This section demonstrates how you can use PROC SURVEYREG to perform a regression analysis for sample survey data. For a complete description of the usage of PROC SURVEYREG, see the section "Syntax: SURVEYREG Procedure" on page 6542. The section "Examples: SURVEYREG Procedure" on page 6582 provides more detailed examples that illustrate the applications of PROC SURVEYREG.

Simple Random Sampling

Suppose that, in a junior high school, there are a total of 4,000 students in grades 7, 8, and 9. You want to know how household income and the number of children in a household affect students' average weekly spending for ice cream.

In order to answer this question, you draw a sample by using simple random sampling from the student population in the junior high school. You randomly select 40 students and ask them their average weekly expenditure for ice cream, their household income, and the number of children in their household. The answers from the 40 students are saved as the SAS data set IceCream:

```
data IceCream;
   input Grade Spending Income Kids @@;
   datalines;
7   7  39  2   7   7  38  1   8  12  47  1
9  10  47  4   7   1  34  4   7  10  43  2
7   3  44  4   8  20  60  3   8  19  57  4
7   2  35  2   7   2  36  1   9  15  51  1
8  16  53  1   7   6  37  4   7   6  41  2
7   6  39  2   9  15  50  4   8  17  57  3
8  14  46  2   9   8  41  2   9   8  41  1
9   7  47  3   7   3  39  3   7  12  50  2
7   4  43  4   9  14  46  3   8  18  58  4
9   9  44  3   7   2  37  1   7   1  37  2
7   4  44  2   7  11  42  2   9   8  41  2
8  10  42  2   8  13  46  1   7   2  40  3
9   6  45  1   9  11  45  4   7   2  36  1
7   9  46  1
;
```

In the data set IceCream, the variable Grade indicates a student's grade. The variable Spending contains the dollar amount of each student's average weekly spending for ice cream. The variable Income specifies the household income, in thousands of dollars. The variable Kids indicates how many children are in a student's family.

The following PROC SURVEYREG statements request a regression analysis:

```
title1 'Ice Cream Spending Analysis';
title2 'Simple Random Sample Design';
proc surveyreg data=IceCream total=4000;
   class Kids;
   model Spending = Income Kids / solution;
run;
```

The PROC SURVEYREG statement invokes the procedure. The TOTAL=4000 option specifies the total in the population from which the sample is drawn. The CLASS statement requests that the procedure use the variable Kids as a classification variable in the analysis. The MODEL statement describes the linear model that you want to fit, with Spending as the dependent variable and Income and Kids as the independent variables. The SOLUTION option in the MODEL statement requests that the procedure output the regression coefficient estimates.

Figure 86.1 displays the summary of the data, the summary of the fit, and the levels of the classification variable Kids. The "Fit Statistics" table displays the denominator degrees of freedom, which are used in F tests and t tests in the regression analysis.

          Parameter      Estimate          Error    t Value    Pr > |t|

          Intercept    -26.084677     2.46720403     -10.57      <.0001
          Income         0.775330     0.04304415      18.01      <.0001
          Kids 1         0.897655     1.12352876       0.80      0.4292
          Kids 2         1.494032     1.24705263       1.20      0.2381
          Kids 3        -0.513181     1.33454891      -0.38      0.7027
          Kids 4         0.000000     0.00000000          .          .

NOTE: The denominator degrees of freedom for the t tests is 39.
      Matrix X'X is singular and a generalized inverse was used to solve the
      normal equations.  Estimates are not unique.
```

Stratified Sampling

Suppose that the previous student sample is actually drawn using a stratified sample design. The strata are grades in the junior high school: 7, 8, and 9. Within strata, simple random samples are selected. Table 86.1 provides the number of students in each grade.

Table 86.1 Students in Grades

Grade	Number of Students
7	1,824
8	1,025
9	1,151
Total	**4,000**

In order to analyze this sample by using PROC SURVEYREG, you need to input the stratification information by creating a SAS data set with the information in Table 86.1. The following SAS statements create such a data set called StudentTotals:

```
data StudentTotals;
   input Grade _TOTAL_;
   datalines;
7 1824
8 1025
9 1151
;
```

The variable Grade is the stratification variable, and the variable _TOTAL_ contains the total numbers of students in each stratum in the survey population. PROC SURVEYREG requires you to use the keyword _TOTAL_ as the name of the variable that contains the population total information.

In a stratified sample design, when the sampling rates in the strata are unequal, you need to use sampling weights to reflect this information. For this example, the appropriate sampling weights are the reciprocals of the probabilities of selection. You can use the following DATA step to create the sampling weights:

```
data IceCream;
   set IceCream;
   if Grade=7 then Prob=20/1824;
   if Grade=8 then Prob=9/1025;
   if Grade=9 then Prob=11/1151;
   Weight=1/Prob;
```

If you use PROC SURVEYSELECT to select your sample, PROC SURVEYSELECT creates these sampling weights for you.

The following statements demonstrate how you can fit a linear model while incorporating the sample design information (stratification):

```
title1 'Ice Cream Spending Analysis';
title2 'Stratified Simple Random Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
   strata Grade /list;
   class Kids;
   model Spending = Income Kids / solution;
   weight Weight;
run;
```

Comparing these statements to those in the section "Simple Random Sampling" on page 6535, you can see how the TOTAL=StudentTotals option replaces the previous TOTAL=4000 option.

The STRATA statement specifies the stratification variable Grade. The LIST option in the STRATA statement requests that the stratification information be included in the output. The WEIGHT statement specifies the weight variable.

Figure 86.4 summarizes the data information, the sample design information, and the fit information. Note that, due to the stratification, the denominator degrees of freedom for F tests and t tests are 37, which is different from the analysis in Figure 86.1.

              Model             4     124.85    <.0001
              Intercept         1     150.95    <.0001
              Income            1     326.89    <.0001
              Kids              3       0.99    0.4081

      NOTE: The denominator degrees of freedom for the F tests is 37.
```

The regression coefficient estimates for the stratified sample, along with their standard errors and associated *t* tests, are displayed in Figure 86.7.

Figure 86.7 Regression Coefficients

Estimated Regression Coefficients

Parameter	Estimate	Standard Error	t Value	Pr > |t|
Intercept	-26.086882	2.44108058	-10.69	<.0001
Income	0.776699	0.04295904	18.08	<.0001
Kids 1	0.888631	1.07000634	0.83	0.4116
Kids 2	1.545726	1.20815863	1.28	0.2087
Kids 3	-0.526817	1.32748011	-0.40	0.6938
Kids 4	0.000000	0.00000000	.	.

NOTE: The denominator degrees of freedom for the t tests is 37.
Matrix X'WX is singular and a generalized inverse was used to solve the normal equations. Estimates are not unique.

You can request other statistics and tests by using PROC SURVEYREG. You can also analyze data from a more complex sample design. The remainder of this chapter provides more detailed information.

Output Data Sets

You can use the OUTPUT statement to create a new SAS data set that contains the estimated linear predictors and their standard error estimates, the residuals from the linear regression, and the confidence limits for the predictors. See the section "OUTPUT Statement" on page 6556 for more details.

You can use the Output Delivery System (ODS) to create SAS data sets that capture the outputs from PROC SURVEYREG. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

For example, to save the "ParameterEstimates" table (Figure 86.7) in the previous section in an output data set, you use the ODS OUTPUT statement as follows:

```
title1 'Ice Cream Spending Analysis';
title2 'Stratified Simple Random Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
   strata Grade /list;
   class Kids;
   model Spending = Income Kids / solution;
   weight Weight;
   ods output ParameterEstimates = MyParmEst;
   run;
```

The statement

```
ods output ParameterEstimates = MyParmEst;
```

requests that the "ParameterEstimates" table that appears in Figure 86.7 be placed into a SAS data set MyParmEst.

The PRINT procedure displays observations of the data set MyParmEst:

```
proc print data=MyParmEst;
run;
```

Figure 86.8 displays the observations in the data set MyParmEst.

Figure 86.8 The Data Set MyParmEst

Ice Cream Spending Analysis
Stratified Simple Random Sample Design

Obs	Parameter	Estimate	StdErr	DenDF	tValue	Probt
1	Intercept	-26.086882	2.44108058	37	-10.69	<.0001
2	Income	0.776699	0.04295904	37	18.08	<.0001
3	Kids 1	0.888631	1.07000634	37	0.83	0.4116
4	Kids 2	1.545726	1.20815863	37	1.28	0.2087
5	Kids 3	-0.526817	1.32748011	37	-0.40	0.6938
6	Kids 4	0.000000	0.00000000	37	.	.

The section "ODS Table Names" on page 6581 gives the complete list of the tables produced by PROC SURVEYREG.

Syntax: SURVEYREG Procedure

The following statements are available in PROC SURVEYREG:

PROC SURVEYREG < *options* > ;
BY *variables* ;
CLASS *variables* ;
CLUSTER *variables* ;
CONTRAST *'label' effect values* < *... effect values* > < / *options* > ;
DOMAIN *variables* < *variable*∗*variable variable*∗*variable*∗*variable ...* > ;
ESTIMATE *'label' effect values* < *... effect values* > < / *options* > ;
MODEL *dependent* = < *effects* > < / *options* > ;
OUTPUT < *keyword* < =*variable-name* > *... keyword* < =*variable-name* > > < / *option* > ;
REPWEIGHTS *variables* < / *options* > ;
STRATA *variables* < / *options* > ;
WEIGHT *variable* ;

The PROC SURVEYREG and MODEL statements are required. If your model contains classification effects, you must list the classification variables in a CLASS statement, and the CLASS

statement must precede the MODEL statement. If you use a CONTRAST statement or an ESTIMATE statement, the MODEL statement must precede the CONTRAST or ESTIMATE statement.

The CLASS, CLUSTER, STRATA, CONTRAST, and ESTIMATE statements can appear multiple times. You should use only one MODEL statement and one WEIGHT statement.

PROC SURVEYREG Statement

PROC SURVEYREG < *options* > **;**

The PROC SURVEYREG statement invokes the procedure. It optionally names the input data sets and specifies the variance estimation method.

You can specify the following options in the PROC SURVEYREG statement.

ALPHA=*α*

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of α produces $100(1-\alpha)\%$ confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

DATA=*SAS-data-set*

specifies the SAS data set to be analyzed by PROC SURVEYREG. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

MISSING

treats missing values as a valid (nonmissing) category for all categorical variables, which include CLASS, STRATA, CLUSTER, and DOMAIN variables.

By default, if you do not specify the MISSING option, an observation is excluded from the analysis if it has a missing value. For more information, see the section "Missing Values" on page 6560.

NOMCAR

requests that the procedure treat missing values in the variance computation as *not missing completely at random* (NOMCAR) for Taylor series variance estimation. When you specify the NOMCAR option, PROC SURVEYREG computes variance estimates by analyzing the nonmissing values as a domain or subpopulation, where the entire population includes both nonmissing and missing domains. See the section "Missing Values" on page 6560 for more details.

By default, PROC SURVEYREG completely excludes an observation from analysis if that observation has a missing value, unless you specify the MISSING option. Note that the NOMCAR option has no effect on a classification variable when you specify the MISSING option, which treats missing values as a valid nonmissing level.

The NOMCAR option applies only to Taylor series variance estimation. The replication methods, which you request with the VARMETHOD=BRR and VARMETHOD=JACKKNIFE options, do not use the NOMCAR option.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sorting order for the levels of classification variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option might be useful when you use the CONTRAST statement. When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

The following table shows how PROC SURVEYREG interprets values of the ORDER= option.

Value of ORDER=	Levels Sorted By
DATA	order of appearance in the input data set
FORMATTED	external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

Note that the specified order also determines the ordering for levels of STRATA and CLUSTER variables.

By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent.

For more information about sorting order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

RATE=*value* | *SAS-data-set*

R=*value* | *SAS-data-set*

specifies the sampling rate as a nonnegative *value*, or specifies an input data set that contains the stratum sampling rates. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the RATE= option for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option.

If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of PSUs selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative *value* for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section "Specification of Population Totals and Sampling Rates" on page 6561 for more details.

The *value* in the RATE= option or the values of _RATE_ in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can

specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYREG converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you do not specify the TOTAL= or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= and RATE= options.

TOTAL=*value* | *SAS-data-set*

N=*value* | *SAS-data-set*

specifies the total number of primary sampling units in the study population as a positive *value*, or specifies an input data set that contains the stratum population totals. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the TOTAL= option for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section "Specification of Population Totals and Sampling Rates" on page 6561 for more details.

If you do not specify the TOTAL= or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= and RATE= options.

TRUNCATE

specifies that class levels should be determined using no more than the first 16 characters of the formatted values of the CLASS, STRATA, and CLUSTER variables. When formatted values are longer than 16 characters, you can use this option in order to revert to the levels as determined in releases before SAS 9.

VARMETHOD=BRR < (*method-options***) >**

VARMETHOD=JACKKNIFE | JK < (*method-options***) >**

VARMETHOD=TAYLOR

specifies the variance estimation method. VARMETHOD=TAYLOR requests the Taylor series method, which is the default if you do not specify the VARMETHOD= option or the REPWEIGHTS statement. VARMETHOD=BRR requests variance estimation by balanced repeated replication (BRR), and VARMETHOD=JACKKNIFE requests variance estimation by the delete-1 jackknife method.

For VARMETHOD=BRR and VARMETHOD=JACKKNIFE you can specify *method-options* in parentheses. Table 86.2 summarizes the available *method-options*.

Table 86.2 Variance Estimation Method-Options

Keyword	Method	(*Method-Options*)
BRR	Balanced repeated replication	FAY <=*value*> HADAMARD | H=*SAS-data-set* OUTWEIGHTS=*SAS-data-set* PRINTH REPS=*number*
JACKKNIFE | JK	Jackknife	OUTJKCOEFS=*SAS-data-set* OUTWEIGHTS=*SAS-data-set*
TAYLOR	Taylor series	

Method-options must be enclosed in parentheses following the method keyword. For example:

```
varmethod=BRR(reps=60 outweights=myReplicateWeights)
```

The following values are available for the VARMETHOD= option:

BRR <(*method-options*)> requests balanced repeated replication (BRR) variance estimation. The BRR method requires a stratified sample design with two primary sampling units (PSUs) per stratum. See the section "Balanced Repeated Replication (BRR) Method" on page 6565 for more information.

You can specify the following *method-options* in parentheses following VARMETHOD=BRR.

FAY <=*value***>**
requests Fay's method, a modification of the BRR method, for variance estimation. See the section "Fay's BRR Method" on page 6566 for more information.

You can specify the *value* of the Fay coefficient, which is used in converting the original sampling weights to replicate weights. The Fay coefficient must be a nonnegative number less than 1. By default, the value of the Fay coefficient equals 0.5.

HADAMARD=*SAS-data-set*

H=*SAS-data-set*
names a SAS data set that contains the Hadamard matrix for BRR replicate construction. If you do not provide a Hadamard matrix with the HADAMARD= method-option, PROC SURVEYREG generates an appropriate Hadamard matrix for replicate construction. See the sections "Balanced Repeated Replication (BRR) Method" on page 6565 and "Hadamard Matrix" on page 6568 for details.

If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard

matrix, you must provide the matrix as a SAS data set in the HADAMARD=*SAS-data-set* method-option.

In the HADAMARD= input data set, each variable corresponds to a column of the Hadamard matrix, and each observation corresponds to a row of the matrix. You can use any variable names in the HADAMARD= data set. All values in the data set must equal either 1 or -1. You must ensure that the matrix you provide is indeed a Hadamard matrix—that is, $\mathbf{A}'\mathbf{A} = R\mathbf{I}$, where $\mathbf{A}$ is the Hadamard matrix of dimension R and $\mathbf{I}$ is an identity matrix. PROC SURVEYREG does not check the validity of the Hadamard matrix that you provide.

The HADAMARD= input data set must contain at least H variables, where H denotes the number of first-stage strata in your design. If the data set contains more than H variables, the procedure uses only the first H variables. Similarly, the HADAMARD= input data set must contain at least H observations.

If you do not specify the REPS= method-option, then the number of replicates is taken to be the number of observations in the HADAMARD= input data set. If you specify the number of replicates—for example, REPS=*nreps*—then the first *nreps* observations in the HADAMARD= data set are used to construct the replicates.

You can specify the PRINTH option to display the Hadamard matrix that the procedure uses to construct replicates for BRR.

OUTWEIGHTS=*SAS-data-set*

names a SAS data set that contains replicate weights. See the section "Balanced Repeated Replication (BRR) Method" on page 6565 for information about replicate weights. See the section "Replicate Weights Output Data Set" on page 6575 for more details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= method-option is not available when you provide replicate weights with the REPWEIGHTS statement.

PRINTH

displays the Hadamard matrix.

When you provide your own Hadamard matrix with the HADAMARD= method-option, only the rows and columns of the Hadamard matrix that are used by the procedure are displayed. See the sections "Balanced Repeated Replication (BRR) Method" on page 6565 and "Hadamard Matrix" on page 6568 for details.

The PRINTH method-option is not available when you provide replicate weights with the REPWEIGHTS statement because the procedure does not use a Hadamard matrix in this case.

REPS=*number*

specifies the number of replicates for BRR variance estimation. The value of *number* must be an integer greater than 1.

If you do not provide a Hadamard matrix with the HADAMARD= method-option, the number of replicates should be greater than the number of strata and should be a multiple of 4. See the section "Balanced Repeated Replication (BRR) Method" on page 6565 for more information. If a Hadamard matrix cannot be constructed for the REPS= value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the REPS= value that you specify.

If you provide a Hadamard matrix with the HADAMARD= method-option, the value of REPS= must not be less than the number of rows in the Hadamard matrix. If you provide a Hadamard matrix and do not specify the REPS= method-option, the number of replicates equals the number of rows in the Hadamard matrix.

If you do not specify the REPS= or HADAMARD= method-option and do not include a REPWEIGHTS statement, the number of replicates equals the smallest multiple of 4 that is greater than the number of strata.

If you provide replicate weights with the REPWEIGHTS statement, the procedure does not use the REPS= method-option. With a REPWEIGHTS statement, the number of replicates equals the number of REPWEIGHTS variables.

JACKKNIFE | JK <(*method-options*)> requests variance estimation by the delete-1 jackknife method. See the section "Jackknife Method" on page 6567 for details. If you provide replicate weights with a REPWEIGHTS statement, VARMETHOD=JACKKNIFE is the default variance estimation method.

You can specify the following *method-options* in parentheses following VARMETHOD=JACKKNIFE:

OUTWEIGHTS=*SAS-data-set*

names a SAS data set that contains replicate weights. See the section "Jackknife Method" on page 6567 for information about replicate weights. See the section "Replicate Weights Output Data Set" on page 6575 for more details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= method-option is not available when you provide replicate weights with the REPWEIGHTS statement.

OUTJKCOEFS=*SAS-data-set*

names a SAS data set that contains jackknife coefficients. See the section "Jackknife Coefficients Output Data Set" on page 6575 for more details about the contents of the OUTJKCOEFS= data set.

TAYLOR requests Taylor series variance estimation. This is the default method if you do not specify the VARMETHOD= option and if there is no REPWEIGHTS statement. See the section "Taylor Series (Linearization)" on page 6564 for more information.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC SURVEYREG to obtain separate analyses on observations in groups defined by the BY variables.

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, where the total number of units in the subpopulation is not known with certainty. For more information about subpopulation analysis for sample survey data, see Cochran (1977).

When a BY statement appears, the procedure expects the input data sets to be sorted in order of the BY variables. If you specify more than one BY statement, the procedure uses only the latest BY statement and ignores any previous ones.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING. The NOTSORTED option does not mean that the data are unsorted, but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variables* **;**

The CLASS statement specifies the classification variables to be used in the model. Typical classification variables are TREATMENT, GENDER, RACE, GROUP, and REPLICATION. If you specify the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. Class levels are determined from the formatted values of the CLASS variables. Thus, you can use formats to group values into levels.

See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary* for more information.

By default, class levels are determined from the entire formatted values of the CLASS variables. Note that this represents a slight change from previous releases in the way in which class levels are determined. Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. If you want to revert to this previous behavior, you can use the TRUNCATE option in the PROC SURVEYREG statement.

You can use multiple CLASS statements to specify classification variables.

CLUSTER Statement

CLUSTER *variables* **;**

The CLUSTER statement specifies variables that identify clusters in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should identify only the first-stage clusters, or primary sampling units (PSUs), in the CLUSTER statement.

If you provide replicate weights for BRR or jackknife variance estimation with the REPWEIGHTS statement, you do not need to specify a CLUSTER statement.

The CLUSTER *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary* for more information.

By default, clusters are determined from the entire formatted values of the CLUSTER variables. Note that this represents a slight change from previous releases in the way in which clusters are determined. Prior to SAS 9, clusters were determined by using no more than the first 16 characters of the formatted values. If you want to revert to this previous behavior, you can use the TRUNCATE option in the PROC SURVEYREG statement.

You can use multiple CLUSTER statements to specify cluster variables. The procedure uses variables from all CLUSTER statements to create clusters.

CONTRAST Statement

CONTRAST *'label' effect values* < */ options* > **;**

CONTRAST *'label' effect values* < *. . . effect values* > < */ options* > **;**

The CONTRAST statement provides custom hypothesis tests for linear combinations of the regression parameters $H_0: \mathbf{L}\boldsymbol{\beta} = \mathbf{0}$, where $\mathbf{L}$ is the vector or matrix you specify and $\boldsymbol{\beta}$ is the vector of regression parameters. Thus, to use this feature, you must be familiar with the details of the model parameterization used by PROC SURVEYREG. For information about the parameterization, see the section "GLM Parameterization of Classification Variables and Effects" on page 369 in Chapter 18, "Shared Concepts and Topics."

Each term in the MODEL statement, called an *effect*, is a variable or a combination of variables. You can specify an effect with a variable name or a special notation by using variable names and operators. For more details about how to specify an effect, see the section "Specification of Effects" on page 2488 in Chapter 39, "The GLM Procedure."

For each CONTRAST statement, PROC SURVEYREG computes Wald's F test. The procedure displays this value with the degrees of freedom, and identifies it with the contrast label. The numerator degrees of freedom for Wald's F test equal rank($\mathbf{L}$). The denominator degrees of freedom equal the number of clusters (or the number of observations if there is no CLUSTER statement) minus the number of strata. Alternatively, you can use the DF= option in the MODEL statement to specify the denominator degrees of freedom.

You can specify any number of CONTRAST statements, but they must appear after the MODEL statement.

In the CONTRAST statement,

label	identifies the contrast in the output. A label is required for every contrast specified. Labels must be enclosed in single quotes.
effect	identifies an effect that appears in the MODEL statement. You can use the INTERCEPT keyword as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the MODEL statement.
values	are constants that are elements of $\mathbf{L}$ associated with the effect.

You can specify the following options in the CONTRAST statement after a slash (/):

E

displays the entire coefficient $\mathbf{L}$ vector or matrix.

NOFILL

requests no filling in higher-order effects. When you specify only certain portions of $\mathbf{L}$, by default PROC SURVEYREG constructs the remaining elements from the context. (For more information, see the section "Specification of ESTIMATE Expressions" on page 2509 in Chapter 39, "The GLM Procedure.")

When you specify the NOFILL option, PROC SURVEYREG does not construct the remaining portions and treats the vector or matrix **L** as it is defined in the CONTRAST statement.

SINGULAR=*value*

tunes the estimability checking. If **v** is a vector, define ABS(**v**) to be the largest absolute value of the elements of **v**. For a row vector **l** of the matrix **L** , define

$$c = \begin{cases} \text{ABS}(\mathbf{l}) & \text{if ABS}(\mathbf{l}) > 0 \\ 1 & \text{otherwise} \end{cases}$$

If ABS(**l**−**lH**) is greater than *c*value*, then $\mathbf{l}\boldsymbol{\beta}$ is declared nonestimable. Here, **H** is the matrix $(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{X}$. The *value* must be between 0 and 1; the default is 10^{-4}.

As stated previously, the CONTRAST statement enables you to perform hypothesis tests $H_0: \mathbf{L}\boldsymbol{\beta} = 0$.

If the **L** matrix contains more than one contrast, then you can separate the rows of the **L** matrix with commas.

For example, for the model

```
proc surveyreg;
   class A B;
   model Y=A B;
run;
```

with A at 5 levels and B at 2 levels, the parameter vector is

$$(\mu \;\; \alpha_1 \;\; \alpha_2 \;\; \alpha_3 \;\; \alpha_4 \;\; \alpha_5 \;\; \beta_1 \;\; \beta_2)$$

To test the hypothesis that the pooled A linear and A quadratic effect is zero, you can use the following **L** matrix:

$$\mathbf{L} = \begin{bmatrix} 0 & -2 & -1 & 0 & 1 & 2 & 0 & 0 \\ 0 & 2 & -1 & -2 & -1 & 2 & 0 & 0 \end{bmatrix}$$

The corresponding CONTRAST statement is

```
contrast 'A Linear & Quadratic'
         a -2 -1  0  1  2,
         a  2 -1 -2 -1  2;
```

DOMAIN Statement

DOMAIN *variables* < *variable** *variable variable** *variable** *variable ...* > **;**

The DOMAIN statement requests analysis for subpopulations, or domains, in addition to analysis for the entire study population. The DOMAIN statement names the variables that identify domains, which are called domain variables.

It is common practice to compute statistics for domains. The formation of these domains might be unrelated to the sample design. Therefore, the sample sizes for the domains are random variables. In order to incorporate this variability into the variance estimation, you should use a DOMAIN statement.

Note that a DOMAIN statement is different from a BY statement. In a BY statement, you treat the sample sizes as fixed in each subpopulation, and you perform analysis within each BY group independently.

You should use the DOMAIN statement on the entire data set to perform the domain analysis. Creating a new data set from a single domain and analyzing that with SURVEYREG yields inappropriate estimates of variance.

A domain variable can be either character or numeric. The procedure treats domain variables as categorical variables. If a variable appears by itself in a DOMAIN statement, each level of this variable determines a domain in the study population. If two or more variables are joined by asterisks (*), then every possible combination of levels of these variables determines a domain. The procedure performs a descriptive analysis within each domain defined by the domain variables.

The formatted values of the domain variables determine the categorical variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary* for more information.

ESTIMATE Statement

ESTIMATE *'label' effect values < / options >* **;**

ESTIMATE *'label' effect values < ... effect values > < / options >* **;**

You can use an ESTIMATE statement to estimate a linear function of the regression parameters by multiplying a row vector $\mathbf{l}$ by the parameter estimate vector $\hat{\boldsymbol{\beta}}$.

Each term in the MODEL statement, called an *effect*, is a variable or a combination of variables. You can specify an effect with a variable name or with a special notation by using variable names and operators.

For more details about how to specify an effect, see the section "Specification of Effects" on page 2488 in Chapter 39, "The GLM Procedure."

PROC SURVEYREG checks the linear function for estimability. (See the SINGULAR= option).

The procedure displays the estimate $\mathbf{l}\hat{\boldsymbol{\beta}}$ along with its standard error and t test. If you specify the CLPARM option in the MODEL statement, PROC SURVEYREG also displays confidence limits for the linear function. By default, the degrees of freedom for the t test equal the number of clusters (or the number of observations if there is no CLUSTER statement) minus the number of strata. Alternatively, you can specify the degrees of freedom with the DF= option in the MODEL statement.

You can specify any number of ESTIMATE statements, but they must appear after the MODEL statement.

In the ESTIMATE statement,

label identifies the linear function **l** in the output. A label is required for every function specified. Labels must be enclosed in single quotes.

effect identifies an effect that appears in the MODEL statement. You can use the INTERCEPT keyword as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the MODEL statement.

values are constants that are elements of the vector **l** associated with the effect. For example, the following statement forms an estimate that is the difference between the parameters estimated for the first and second levels of the CLASS variable A:

```
estimate 'A1 vs A2' A  1 -1;
```

You can specify the following options in the ESTIMATE statement after a slash (/):

DIVISOR=*value*

specifies a value by which to divide all coefficients so that fractional coefficients can be entered as integers.

For example, you can use

```
estimate '1/3(A1+A2) - 2/3A3' a 1 1 -2 / divisor=3;
```

instead of

```
estimate '1/3(A1+A2) - 2/3A3' a 0.33333 0.33333 -0.66667;
```

E

displays the entire coefficient vector **l**.

NOFILL

requests no filling in higher-order effects. When you specify only certain portions of the vector **l**, by default PROC SURVEYREG constructs the remaining elements from the context. (See the section "Specification of ESTIMATE Expressions" on page 2509 in Chapter 39, "The GLM Procedure.") When you specify the NOFILL option, PROC SURVEYREG does not construct the remaining portions and treats the vector **l** as it is defined in the ESTIMATE statement.

SINGULAR=*value*

tunes the estimability checking. If **v** is a vector, define ABS(**v**) to be the largest absolute value of the elements of **v**. For a row vector **l**, define

$$c = \begin{cases} \text{ABS}(\mathbf{l}) & \text{if ABS}(\mathbf{l}) > 0 \\ 1 & \text{otherwise} \end{cases}$$

If ABS($\mathbf{l}-\mathbf{lH}$) is greater than c*$value$, then $\mathbf{l}\boldsymbol{\beta}$ is declared nonestimable. Here, $\mathbf{H}$ is the matrix $(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{X}$. The *value* must be between 0 and 1; the default is 10^{-4}.

MODEL Statement

MODEL *dependent* = < *effects* > < / *options* > **;**

The MODEL statement specifies the dependent (response) variable and the independent (regressor) variables or effects. The dependent variable must be numeric. Each term in a MODEL statement, called an *effect*, is a variable or a combination of variables. You can specify an effect with a variable name or with special notation by using variable names and operators. For more information about how to specify an effect, see the section "Specification of Effects" on page 2488 in Chapter 39, "The GLM Procedure."

Only one MODEL statement is allowed for each PROC SURVEYREG statement. If you specify more than one MODEL statement, the procedure uses the first model and ignores the rest.

You can specify the following options in the MODEL statement after a slash (/).

ADJRSQ
requests the procedure compute the adjusted multiple R-square.

ANOVA
requests the ANOVA table be produced in the output. By default, the ANOVA table is not printed in the output.

CLPARM
requests confidence limits for the parameter estimates. The SURVEYREG procedure determines the confidence coefficient by using the ALPHA= option, which by default equals 0.05 and produces 95% confidence bounds. The CLPARM option also requests confidence limits for all the estimable linear functions of regression parameters in the ESTIMATE statements.

Note that when there is a CLASS statement, you need to use the SOLUTION option with the CLPARM option to obtain the parameter estimates and their confidence limits.

COVB
displays the estimated covariance matrix of the estimated regression estimates.

DEFF
displays design effects for the regression coefficient estimates.

DF=*value*
specifies the denominator degrees of freedom for the F tests and the degrees of freedom for the t tests. The default is the number of clusters (or the number of observations if there is no CLUSTER statement) minus the number of actual strata. The number of actual strata equals the number of strata in the data before collapsing minus the number of strata collapsed plus 1. See the section "Stratum Collapse" on page 6572 for details about "collapsing of strata."

I | INVERSE
displays the inverse or the generalized inverse of the $\mathbf{X}'\mathbf{X}$ matrix. When there is a WEIGHT variable, the procedure displays the inverse or the generalized inverse of the $\mathbf{X}'\mathbf{W}\mathbf{X}$ matrix, where $\mathbf{W}$ is the diagonal matrix constructed from WEIGHT variable values.

NOINT
omits the intercept from the model.

PARMLABEL
displays the labels of the parameters in the "Estimated Regression Coefficients" table.

SINGULAR=*value*
tunes the estimability checking. If $\mathbf{v}$ is a vector, define ABS($\mathbf{v}$) to be the largest absolute value of the elements of $\mathbf{v}$. For a row vector $\mathbf{l}$ of the matrix $\mathbf{L}$, define

$$c = \begin{cases} \text{ABS}(\mathbf{l}) & \text{if ABS}(\mathbf{l}) > 0 \\ 1 & \text{otherwise} \end{cases}$$

If ABS($\mathbf{l}-\mathbf{lH}$) is greater than c*$value$, then $\mathbf{l}\boldsymbol{\beta}$ is declared nonestimable. Here, $\mathbf{H}$ is the matrix $(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{X}$. The *value* must be between 0 and 1; the default is 10^{-4}.

SOLUTION
displays a solution to the normal equations, which are the parameter estimates. The SOLUTION option is useful only when you use a CLASS statement. If you do not specify a CLASS statement, PROC SURVEYREG displays parameter estimates by default. But if you specify a CLASS statement, PROC SURVEYREG does not display parameter estimates unless you also specify the SOLUTION option.

VADJUST=DF | NONE
specifies whether to use degrees of freedom adjustment $(n-1)/(n-p)$ in the computation of the matrix $\mathbf{G}$ for the variance estimation. If you do not specify the VADJUST= option, by default, PROC SURVEYREG uses the degrees-of-freedom adjustment that is equivalent to the VARADJ=DF option. If you do not want to use this variance adjustment, you can specify the VADJUST=NONE option.

X | XPX
displays the $\mathbf{X}'\mathbf{X}$ matrix, or the $\mathbf{X}'\mathbf{W}\mathbf{X}$ matrix when there is a WEIGHT variable, where $\mathbf{W}$ is the diagonal matrix constructed from WEIGHT variable values. The X option also displays the crossproducts vector $\mathbf{X}'\mathbf{y}$ or $\mathbf{X}'\mathbf{W}\mathbf{y}$.

OUTPUT Statement

OUTPUT < **OUT=***SAS-data-set* > < *keyword* < =*variable-name* > ... *keyword* < =*variable-name* > > < / *option* > ;

The OUTPUT statement creates a new SAS data set that contains all the variables in the input data set and, optionally, the estimated linear predictors and their standard error estimates, the residuals from the linear regression, and the confidence limits for the predictors.

You can specify the following options in the OUTPUT statement.

OUT=*SAS-data-set*
gives the name of the new output data set. By default, the procedure uses the DATA*n* convention to name the new data set.

keyword < =variable-name >

specifies the statistics to include in the output data set and names the new variables that contain the statistics. You can specify a keyword for each desired statistic (see the following list of keywords). Optionally, you can name a statistic by providing a variable name followed an equal sign to contain the statistic. For example,

```
output out=myOutDataSet p=myPredictor;
```

creates a SAS data set myOutDataSet that contains the predicted values in the variable myPredictor.

The keywords allowed and the statistics they represent are as follows:

LCLM | L — lower bound of a $100(1-\alpha)\%$ confidence interval for the expected value (mean) of the predicted value. The α level is equal to the value of the ALPHA= option in the OUTPUT statement or, if this option is not specified, to the ALPHA= option in the PROC SURVEYREG statement. If neither of these options is set, then $\alpha = 0.05$ by default, resulting in the lower bound for a 95% confidence interval. If no variable name is given for this keyword, the default variable name is _LCLM_.

PREDICTED | PRED | P — predicted values. If no variable name is given for this keyword, the default variable name is _PREDICTED_.

RESIDUAL | R — residuals, calculated as ACTUAL − PREDICTED. If no variable name is given for this keyword, the default variable name is _RESIDUAL_.

STDP | STD — standard error of the mean predicted value. If no variable name is given for this keyword, the default variable name is _STD_.

UCLM | U — upper bound of a $100(1-\alpha)\%$ confidence interval for the expected value (mean) of the predicted value. The α level is equal to the value of the ALPHA= option in the OUTPUT statement or, if this option is not specified, to the ALPHA= option in the PROC SURVEYREG statement. If neither of these options is set, then $\alpha = 0.05$ by default, resulting in the upper bound for a 95% confidence interval. If no variable name is given for this keyword, the default variable name is _UCLM_.

The following option is available in the OUTPUT statement and is specified after a slash(/):

ALPHA=α

specifies the level of significance α for $100(1-\alpha)\%$ confidence intervals. By default, α is equal to the value of the ALPHA= option in the PROC SURVEYREG statement or 0.05 if that option is not specified. You can use values between 0 and 1.

REPWEIGHTS Statement

REPWEIGHTS *variables* < / *options* > **;**

The REPWEIGHTS statement names variables that provide replicate weights for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option in the PROC SURVEYREG statement. If you do not provide replicate weights for these methods by using a REPWEIGHTS statement, then the procedure constructs replicate weights for the analysis. See the sections "Balanced Repeated Replication (BRR) Method" on page 6565 and "Jackknife Method" on page 6567 for information about replicate weights.

Each REPWEIGHTS variable should contain the weights for a single replicate, and the number of replicates equals the number of REPWEIGHTS variables. The REPWEIGHTS variables must be numeric, and the variable values must be nonnegative numbers.

If you provide replicate weights with a REPWEIGHTS statement, you do not need to specify a CLUSTER or STRATA statement. If you use a REPWEIGHTS statement and do not specify the VARMETHOD= option in the PROC SURVEYREG statement, the procedure uses VARMETHOD=JACKKNIFE by default.

If you specify a REPWEIGHTS statement but do not include a WEIGHT statement, the procedure uses the average of each observation's replicate weights as the observation's weight.

You can specify the following options in the REPWEIGHTS statement after a slash (/):

DF=*df*

specifies the denominator degrees of freedom for various tests in the regression analysis. The value of *df* must be a positive number. See the section "Degrees of Freedom" on page 6568 for details. By default, the denominator degrees of freedom equals the number of REPWEIGHTS variables.

JKCOEFS=*value*

specifies a jackknife coefficient for VARMETHOD=JACKKNIFE. The coefficient *value* must be a nonnegative number less than one. See the section "Jackknife Method" on page 6567 for details about jackknife coefficients.

You can use this option to specify a single value of the jackknife coefficient, which the procedure uses for all replicates. To specify different coefficients for different replicates, use the JKCOEFS=*values* or JKCOEFS=*SAS-data-set* option.

JKCOEFS=*values*

specifies jackknife coefficients for VARMETHOD=JACKKNIFE, where each coefficient corresponds to an individual replicate identified by a REPWEIGHTS variable. You can separate *values* with blanks or commas. The coefficient *values* must be nonnegative numbers less than one. The number of *values* must equal the number of replicate weight variables named in the REPWEIGHTS statement. List these values in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement.

See the section "Jackknife Method" on page 6567 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the JKCOEFS=*SAS-data-set* option. To specify a single jackknife coefficient for all replicates, use the JKCOEFS=*value* option.

JKCOEFS=*SAS-data-set*

names a SAS data set that contains the jackknife coefficients for VARMETHOD=JACKKNIFE. You provide the jackknife coefficients in the JKCOEFS= data set variable JKCoefficient. Each coefficient value must be a nonnegative number less than one. The observations in the JKCOEFS= data set should correspond to the replicates that are identified by the REPWEIGHTS variables. Arrange the coefficients or observations in the JKCOEFS= data set in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement. The number of observations in the JKCOEFS= data set must not be less than the number of REPWEIGHTS variables.

See the section "Jackknife Method" on page 6567 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the JKCOEFS=*values* option. To specify a single jackknife coefficient for all replicates, use the JKCOEFS=*value* option.

STRATA Statement

STRATA *variables* < */options* > **;**

The STRATA statement specifies variables that form the strata in a stratified sample design. The combinations of categories of STRATA variables define the strata in the sample.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section "Specification of Population Totals and Sampling Rates" on page 6561 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with the REPWEIGHTS statement, you do not need to specify a STRATA statement.

The STRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. By default, strata are determined from the entire formatted values of the STRATA variables. Note that this represents a slight change from previous releases in the way in which strata are determined. Prior to SAS 9, strata were determined by using no more than the first 16 characters of the formatted values. If you want to revert to this previous behavior, you can use the TRUNCATE option in the PROC SURVEYREG statement.

Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary* for more information.

You can use multiple STRATA statements to specify stratum variables.

You can specify the following options in the STRATA statement after a slash (/):

LIST

displays a "Stratum Information" table, which includes values of the STRATA variables, and the number of observations, number of clusters, population total, and sampling rate for each stratum. This table also displays stratum collapse information.

NOCOLLAPSE

prevents the procedure from collapsing, or combining, strata that have only one sampling unit for the Taylor series variance estimation. By default, the procedure collapses strata that contain only one sampling unit for the Taylor series method. See the section "Stratum Collapse" on page 6572 for details.

WEIGHT Statement

WEIGHT | WGT *variable* **;**

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric, and the sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section "Missing Values" on page 6560 for more information. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

If you do not specify a WEIGHT statement but provide replicate weights with a REPWEIGHTS statement, PROC SURVEYREG uses the average of each observation's replicate weights as the observation's weight.

If you do not specify a WEIGHT statement or a REPWEIGHTS statement, PROC SURVEYREG assigns all observations a weight of one.

Details: SURVEYREG Procedure

Missing Values

If you have missing values in your survey data for any reason, such as nonresponse, this can compromise the quality of your survey results. If the respondents are different from the nonrespondents with regard to a survey effect or outcome, then survey estimates might be biased and cannot accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. After data collection is complete, you can use imputation to replace missing values with acceptable values, and/or you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYREG. See Cochran (1977), Kalton and Kaspyzyk (1986), and Brick and Kalton (1996) for more information.

If an observation has a missing value or a nonpositive value for the WEIGHT variable, then that observation is excluded from the analysis.

An observation is also excluded if it has a missing value for design variables such as STRATA variables, CLUSTER variables, and DOMAIN variables, unless missing values are regarded as a legitimate categorical level for these variables, as specified by the MISSING option.

By default, if an observation contains missing values for the dependent variable or for any variable used in the independent effects, the observation is excluded from the analysis. This treatment is based on the assumption that the missing values are missing completely at random (MCAR). However, this assumption sometimes is not true. For example, evidence from other surveys might suggest that observations with missing values are systematically different from observations without missing values. If you believe that missing values are not missing completely at random, then you can specify the NOMCAR option to include these observations with missing values in the dependent variable and the independent variables in the variance estimation.

Whether or not the NOMCAR option is used, observations with missing or invalid values for WEIGHT, STRATA, CLUSTER, or DOMAIN variables are always excluded, unless the MISSING option is also specified.

When you specify the NOMCAR option, the procedure treats observations with and without missing values for variables in the regression model as two different domains, and it performs a domain analysis in the domain of nonmissing observations.

If you use a REPWEIGHTS statement, all REPWEIGHTS variables must contain nonmissing values.

Survey Design Information

Specification of Population Totals and Sampling Rates

To include a finite population correction (*fpc*) in Taylor series variance estimation, you can input either the sampling rate or the population total by using the RATE= or TOTAL= option in the PROC SURVEYREG statement. (You cannot specify both of these options in the same PROC SURVEYREG statement.) The RATE= and TOTAL= options apply only to Taylor series variance estimation. The procedure does not use a finite population correction for BRR or jackknife variance estimation.

If you do not specify the RATE= or TOTAL= option, the Taylor series variance estimation does not include a finite population correction. For fairly small sampling fractions, it is appropriate to ignore this correction. See Cochran (1977) and Kish (1965) for more information.

If your design has multiple stages of selection and you are specifying the RATE= option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the TOTAL= option for a multistage design, you should input the total number of PSUs in the study population. See the section "Primary Sampling Units (PSUs)" on page 6562 for more details.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you can use the RATE=*value* or TOTAL=*value* option. If your sample design is stratified with different sampling rates or population totals in different strata, use the RATE=*SAS-data-set* or TOTAL=*SAS-data-set* option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the DATA= option.

The secondary data set must contain all the stratification variables listed in the STRATA statement and all the variables in the BY statement. If there are formats associated with the STRATA variables and the BY variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the TOTAL=*SAS-data-set* option, the secondary data set must have a variable named _TOTAL_ that contains the stratum population totals. Or if you specify the RATE=*SAS-data-set* option, the secondary data set must have a variable named _RATE_ that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of _TOTAL_ or _RATE_ for that stratum and ignores the rest.

The *value* in the RATE= option or the values of _RATE_ in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYREG converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the TOTAL=*value* option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

Primary Sampling Units (PSUs)

When you have clusters, or primary sampling units (PSUs), in your sample design, the procedure estimates variance from the variation among PSUs when the Taylor series variance method is used. See the section "Variance Estimation" on page 6564 for more information.

BRR or jackknife variance estimation methods draw multiple replicates (or subsamples) from the full sample by following a specific resampling scheme. These subsamples are constructed by deleting PSUs from the full sample.

If you use a REPWEIGHTS statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a CLUSTER statement. Otherwise, you should specify a CLUSTER statement whenever your design includes clustering at the first stage of sampling. If you do not specify a CLUSTER statement, then PROC SURVEYREG treats each observation as a PSU.

Computational Details

Notation

For a stratified clustered sample design, observations are represented by an $n \times (p+2)$ matrix

$$(\mathbf{w}, \mathbf{y}, \mathbf{X}) = (w_{hij}, y_{hij}, \mathbf{x}_{hij})$$

where

- $\mathbf{w}$ denotes the sampling weight vector
- $\mathbf{y}$ denotes the dependent variable
- $\mathbf{X}$ denotes the $n \times p$ design matrix. (When an effect contains only classification variables, the columns of $\mathbf{X}$ that correspond this effect contain only 0s and 1s; no reparameterization is made.)
- $h = 1, 2, \ldots, H$ is the stratum index
- $i = 1, 2, \ldots, n_h$ is the cluster index within stratum h
- $j = 1, 2, \ldots, m_{hi}$ is the unit index within cluster i of stratum h
- p is the total number of parameters (including an intercept if the INTERCEPT effect is included in the MODEL statement)
- $n = \sum_{h=1}^{H} \sum_{i=1}^{n_h} m_{hi}$ is the total number of observations in the sample

Also, f_h denotes the sampling rate for stratum h. You can use the TOTAL= or RATE= option to input population totals or sampling rates. See the section "Specification of Population Totals and Sampling Rates" on page 6561 for details. If you input stratum totals, PROC SURVEYREG computes f_h as the ratio of the stratum sample size to the stratum total. If you input stratum sampling rates, PROC SURVEYREG uses these values directly for f_h. If you do not specify the TOTAL= or RATE= option, then the procedure assumes that the stratum sampling rates f_h are negligible, and a finite population correction is not used when computing variances.

Regression Coefficients

PROC SURVEYREG solves the normal equations $\mathbf{X}'\mathbf{W}\mathbf{X}\boldsymbol{\beta} = \mathbf{X}'\mathbf{W}\mathbf{y}$ by using a modified sweep routine that produces a generalized (g2) inverse $(\mathbf{X}'\mathbf{W}\mathbf{X})^{-}$ and a solution (Pringle and Rayner 1971)

$$\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-}\mathbf{X}'\mathbf{W}\mathbf{y}$$

where $\mathbf{W}$ is the diagonal matrix constructed from WEIGHT variable values.

For models with class variables, there are more design matrix columns than there are degrees of freedom (df) for the effect. Thus, there are linear dependencies among the columns. In this case, the parameters are not estimable; there is an infinite number of least squares solutions. PROC

SURVEYREG uses a generalized (g2) inverse to obtain values for the estimates. The solution values are not displayed unless you specify the SOLUTION option in the MODEL statement. The solution has the characteristic that estimates are zero whenever the design column for that parameter is a linear combination of previous columns. (In strict terms, the solution values should not be called estimates.) With this full parameterization, hypothesis tests are constructed to test linear functions of the parameters that are estimable.

Variance Estimation

PROC SURVEYREG uses the Taylor series method or replication (resampling) methods to estimate sampling errors of estimators based on complex sample designs (Woodruff (1971); Fuller (1975); Fuller, Kennedy, Schnell, Sullivan, and Park (1989); Särndal, Swensson, and Wretman (1992); Wolter (1985); Rust (1985); Dippo, Fay, and Morganstein (1984); Rao and Shao (1999); Rao, Wu, and Yue (1992); and Rao and Shao (1996)). You can use the VARMETHOD= option to specify a variance estimation method to use. By default, the Taylor series method is used. However, replication methods have recently gained popularity for estimating variances in complex survey data analysis. One reason for this popularity is the relative simplicity of replication-based estimates, especially for nonlinear estimators; another is that modern computational capacity has made replication methods feasible for practical survey analysis.

Replication methods draw multiple replicates (also called subsamples) from a full sample according to a specific resampling scheme. The most commonly used resampling schemes are the *balanced repeated replication* (BRR) method and the *jackknife* method. For each replicate, the original weights are modified for the PSUs in the replicates to create replicate weights. The parameters of interest are estimated by using the replicate weights for each replicate. Then the variances of parameters of interest are estimated by the variability among the estimates derived from these replicates. You can use the REPWEIGHTS statement to provide your own replicate weights for variance estimation.

The following sections provide details about how the variance-covariance matrix of the estimated regression coefficients is estimated for each variance estimation method.

Taylor Series (Linearization)

The Taylor series (linearization) method is the most commonly used method to estimate the covariance matrix of the regression coefficients for complex survey data. It is the default variance estimation method used by PROC SURVEYREG.

Use the notation described in the section "Notation" on page 6563 to denote the residuals from the linear regression as

$$\mathbf{r} = \mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}$$

with r_{hij} as its elements. Let the $p \times p$ matrix $\mathbf{G}$ be defined as

$$\mathbf{G} = \frac{n-1}{n-p} \sum_{h=1}^{H} \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot})'(\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot})$$

where

$$\begin{aligned}
\mathbf{e}_{hij} &= w_{hij} r_{hij} \mathbf{x}_{hij} \\
\mathbf{e}_{hi\cdot} &= \sum_{j=1}^{m_{hi}} \mathbf{e}_{hij} \\
\bar{\mathbf{e}}_{h\cdot\cdot} &= \frac{1}{n_h} \sum_{i=1}^{n_h} \mathbf{e}_{hi\cdot}
\end{aligned}$$

The Taylor series estimate of the covariance matrix of $\hat{\boldsymbol{\beta}}$ is

$$\widehat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-}\mathbf{G}(\mathbf{X}'\mathbf{W}\mathbf{X})^{-}$$

The factor $(n-1)/(n-p)$ in the computation of the matrix $\mathbf{G}$ reduces the small sample bias associated with using the estimated function to calculate deviations (Hidiroglou, Fuller, and Hickman 1980). For simple random sampling, this factor contributes to the degrees of freedom correction applied to the residual mean square for ordinary least squares in which p parameters are estimated. By default, the procedure use this adjustment in the variance estimation. If you do not want to use this multiplier in variance estimation, you can specify the VADJUST=NONE option in the MODEL statement to suppress this factor.

Balanced Repeated Replication (BRR) Method

The balanced repeated replication (BRR) method requires that the full sample be drawn by using a stratified sample design with two primary sampling units (PSUs) per stratum. Let H be the total number of strata. The total number of replicates R is the smallest multiple of 4 that is greater than H. However, if you prefer a larger number of replicates, you can specify the REPS=*number* option. If a $number \times number$ Hadamard matrix cannot be constructed, the number of replicates is increased until a Hadamard matrix becomes available.

Each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix and adjusting the original weights for the remaining PSUs. The new weights are called replicate weights.

Replicates are constructed by using the first H columns of the $R \times R$ Hadamard matrix. The rth ($r = 1, 2, ..., R$) replicate is drawn from the full sample according to the rth row of the Hadamard matrix as follows:

- If the (r, h)th element of the Hadamard matrix is 1, then the first PSU of stratum h is included in the rth replicate and the second PSU of stratum h is excluded.
- If the (r, h)th element of the Hadamard matrix is -1, then the second PSU of stratum h is included in the rth replicate and the first PSU of stratum h is excluded.

The replicate weights of the remaining PSUs in each half sample are then doubled to their original weights. For more detail about the BRR method, see Wolter (1985) and Lohr (1999).

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the VARMETHOD=BRR(PRINTH) method-option. If you provide a Hadamard matrix by specifying the VARMETHOD=BRR(HADAMARD=) method-option, then the replicates are generated according to the provided Hadamard matrix.

Let $\hat{\boldsymbol{\beta}}$ be the estimated regression coefficients from the full sample for $\boldsymbol{\beta}$, and let $\hat{\boldsymbol{\beta}}_r$ be the estimated regression coefficient from the rth replicate by using replicate weights. PROC SURVEYREG estimates the covariance matrix of $\hat{\boldsymbol{\beta}}$ by

$$\widehat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) = \frac{1}{R}\sum_{r=1}^{R}\left(\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}}\right)\left(\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}}\right)'$$

with H degrees of freedom, where H is the number of strata.

You can use the VARMETHOD=BRR(OUTWEIGHTS=) method-option to save the replicate weights into a SAS data set.

Fay's BRR Method

Fay's method is a modification of the BRR method, and it requires a stratified sample design with two primary sampling units (PSUs) per stratum. The total number of replicates R is the smallest multiple of 4 that is greater than the total number of strata H. However, if you prefer a larger number of replicates, you can specify the REPS= option.

For each replicate, Fay's method uses a Fay coefficient $0 \leq \epsilon < 1$ to impose a perturbation of the original weights in the full sample that is gentler than using only half samples, as in the traditional BRR method. The Fay coefficient $0 \leq \epsilon < 1$ can be optionally set by the FAY = ϵ method-option. By default, $\epsilon = 0.5$ if only the FAY method-option is used without specifying a value for ϵ (Judkins 1990; Rao and Shao 1999). When $\epsilon = 0$, Fay's method becomes the traditional BRR method. For more details, see Dippo, Fay, and Morganstein (1984), Fay (1984), Fay (1989), and Judkins (1990).

Let H be the number of strata. Replicates are constructed by using the first H columns of the $R \times R$ Hadamard matrix, where R is the number of replicates, $R > H$. The rth ($r = 1, 2, ..., R$) replicate is created from the full sample according to the rth row of the Hadamard matrix as follows:

- If the (r, h)th element of the Hadamard matrix is 1, then the full sample weight of the first PSU in stratum h is multiplied by ϵ and that of the second PSU is multiplied by $2-\epsilon$ to obtain the rth replicate weights.
- If the (r, h)th element of the Hadamard matrix is -1, then the full sample weight of the first PSU in stratum h is multiplied by $2-\epsilon$ and that of the second PSU is multiplied by ϵ to obtain the rth replicate weights.

You can use the VARMETHOD=BRR(OUTWEIGHTS=) method-option to save the replicate weights into a SAS data set.

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the VARMETHOD=BRR(PRINTH) method-option. If you provide a Hadamard matrix by specifying the VARMETHOD=BRR(HADAMARD=) method-option, then the replicates are generated according to the provided Hadamard matrix.

Let $\hat{\boldsymbol{\beta}}$ be the estimated regression coefficients from the full sample for $\boldsymbol{\beta}$. Let $\hat{\boldsymbol{\beta}}_r$ be the estimated regression coefficient obtained from the rth replicate by using replicate weights. PROC SURVEYREG estimates the covariance matrix of $\hat{\boldsymbol{\beta}}$ by

$$\widehat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) = \frac{1}{R(1-\epsilon)^2} \sum_{r=1}^{R} \left(\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}}\right)\left(\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}}\right)'$$

with H degrees of freedom, where H is the number of strata.

Jackknife Method

The jackknife method of variance estimation deletes one PSU at a time from the full sample to create replicates. The total number of replicates R is the same as the total number of PSUs. In each replicate, the sample weights of the remaining PSUs are modified by the *jackknife coefficient* α_r. The modified weights are called replicate weights.

The jackknife coefficient and replicate weights are described as follows.

Without Stratification If there is no stratification in the sample design (no STRATA statement), the jackknife coefficients α_r are the same for all replicates:

$$\alpha_r = \frac{R-1}{R} \quad \text{where } r = 1, 2, ..., R$$

Denote the original weight in the full sample for the jth member of the ith PSU as w_{ij}. If the ith PSU is included in the rth replicate ($r = 1, 2, ..., R$), then the corresponding replicate weight for the jth member of the ith PSU is defined as

$$w_{ij}^{(r)} = w_{ij}/\alpha_r$$

With Stratification If the sample design involves stratification, each stratum must have at least two PSUs to use the jackknife method.

Let stratum $\tilde{h}_r$ be the stratum from which a PSU is deleted for the rth replicate. Stratum $\tilde{h}_r$ is called the *donor stratum.* Let $n_{\tilde{h}_r}$ be the total number of PSUs in the donor stratum $\tilde{h}_r$. The jackknife coefficients are defined as

$$\alpha_r = \frac{n_{\tilde{h}_r} - 1}{n_{\tilde{h}_r}} \quad \text{where } r = 1, 2, ..., R$$

Denote the original weight in the full sample for the jth member of the ith PSU as w_{ij}. If the ith PSU is included in the rth replicate ($r = 1, 2, ..., R$), then the corresponding replicate weight for the jth member of the ith PSU is defined as

$$w_{ij}^{(r)} = \begin{cases} w_{ij} & \text{if } i\text{th PSU is not in the donor stratum } \tilde{h}_r \\ w_{ij}/\alpha_r & \text{if } i\text{th PSU is in the donor stratum } \tilde{h}_r \end{cases}$$

You can use the VARMETHOD=JACKKNIFE(OUTJKCOEFS=) method-option to save the jackknife coefficients into a SAS data set and use the VARMETHOD=JACKKNIFE(OUTWEIGHTS=) method-option to save the replicate weights into a SAS data set.

If you provide your own replicate weights with a REPWEIGHTS statement, then you can also provide corresponding jackknife coefficients with the JKCOEFS= option.

Let $\hat{\boldsymbol{\beta}}$ be the estimated regression coefficients from the full sample for $\boldsymbol{\beta}$. Let $\hat{\boldsymbol{\beta}}_r$ be the estimated regression coefficient obtained from the rth replicate by using replicate weights. PROC SURVEYREG estimates the covariance matrix of $\hat{\boldsymbol{\beta}}$ by

$$\widehat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) = \sum_{r=1}^{R} \alpha_r \left(\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}}\right)\left(\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}}\right)'$$

with $R - H$ degrees of freedom, where R is the number of replicates and H is the number of strata, or $R - 1$ when there is no stratification.

Hadamard Matrix

A Hadamard matrix $\mathbf{H}$ is a square matrix whose elements are either 1 or -1 such that

$$\mathbf{H}\mathbf{H}' = k\mathbf{I}$$

where k is the dimension of $\mathbf{H}$ and $\mathbf{I}$ is the identity matrix of order k. The order k is necessarily 1, 2, or a positive integer that is a multiple of 4.

For example, the following matrix is a Hadamard matrix of dimension $k = 8$:

$$\begin{array}{rrrrrrrr} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 & 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 & 1 & -1 & -1 & 1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & -1 & 1 & -1 & -1 & 1 & -1 & 1 \\ 1 & 1 & -1 & -1 & -1 & -1 & 1 & 1 \\ 1 & -1 & -1 & 1 & -1 & 1 & 1 & -1 \end{array}$$

Degrees of Freedom

PROC SURVEYREG produces tests for the significance of model effects, regression parameters, estimable functions specified in the ESTIMATE statement, and contrasts specified in the CONTRAST

statement. It computes all these tests taking into account the sample design. The degrees of freedom for these tests differ from the degrees of freedom for the ANOVA table, which does not consider the sample design.

Denominator Degrees of Freedom

The denominator *df* refers to the denominator degrees of freedom for *F* tests and to the degrees of freedom for *t* tests in the analysis.

For the Taylor series method, the denominator *df* equals the number of clusters minus the actual number of strata. If there are no clusters, the denominator *df* equals the number of observations minus the actual number of strata. The *actual number of strata* equals the following:

- one, if there is no STRATA statement
- the number of strata in the sample, if there is a STRATA statement but the procedure does not collapse any strata
- the number of strata in the sample after collapsing, if there is a STRATA statement and the procedure collapses strata that have only one sampling unit

Alternatively, you can specify your own denominator *df* by using the DF= option in the MODEL statement.

For the BRR method (including Fay's method) without a REPWEIGHTS statement, the denominator *df* equals the number of strata.

For the jackknife method without a REPWEIGHTS statement, the denominator *df* is equal to the number of replicates minus the *actual number of strata*.

When there is a REPWEIGHTS statement, the denominator *df* equals the number of REPWEIGHTS variables, unless you specify an alternative in the DF= option in a REPWEIGHTS statement.

Numerator Degrees of Freedom

The numerator *df* refers to the numerator degrees of freedom for the Wald *F* statistic associated with an effect or with a contrast. The procedure computes the Wald *F* statistic for an effect as a Type III test; that is, the test has the following properties:

- The hypothesis for an effect does not involve parameters of other effects except for containing effects (which it must involve to be estimable).
- The hypotheses to be tested are invariant to the ordering of effects in the model.

See the section "Testing Effects" on page 6570 for more information. The numerator *df* for the Wald *F* statistic for a contrast is the rank of the **L** matrix that defines the contrast.

Testing Effects

For each effect in the model, PROC SURVEYREG computes an $\mathbf{L}$ matrix such that every element of $\mathbf{L}\boldsymbol{\beta}$ is estimable; the $\mathbf{L}$ matrix has the maximum possible rank associated with the effect. To test the effect, the procedure uses the Wald F statistic for the hypothesis H_0: $\mathbf{L}\boldsymbol{\beta} = 0$. The Wald F statistic equals

$$F_{\text{Wald}} = \frac{(\mathbf{L}\hat{\boldsymbol{\beta}})'(\mathbf{L}'\widehat{\mathbf{V}}\mathbf{L})^{-1}(\mathbf{L}\hat{\boldsymbol{\beta}})}{\text{rank}(\mathbf{L})}$$

with numerator degrees of freedom equal to rank($\mathbf{L}$) and denominator degrees of freedom equal to the number of clusters minus the number of strata (unless you have specified the denominator degrees of freedom with the DF= option in the MODEL statement; see the section "Denominator Degrees of Freedom" on page 6569). It is possible that the $\mathbf{L}$ matrix cannot be constructed for an effect, in which case that effect is not testable. For more information about how the matrix $\mathbf{L}$ is constructed, see the discussion in Chapter 15, "The Four Types of Estimable Functions."

Analysis of Variance (ANOVA)

PROC SURVEYREG produces an analysis of variance table for the model specified in the MODEL statement. This table is identical to the one produced by the GLM procedure for the model. PROC SURVEYREG computes ANOVA table entries by using the sampling weights, but not the sample design information about stratification and clustering.

The degrees of freedom (*df*) displayed in the ANOVA table are the same as those in the ANOVA table produced by PROC GLM. The Total DF is the total degrees of freedom used to obtain the regression coefficient estimates. The Total DF equals the total number of observations minus 1 if the model includes an intercept. If the model does not include an intercept, the Total DF equals the total number of observations. The Model DF equals the degrees of freedom for the effects in the MODEL statement, not including the intercept. The Error DF equals the Total DF minus the Model DF.

Multiple R-Square

PROC SURVEYREG computes a multiple R-square for the weighted regression as

$$R^2 = 1 - \frac{\text{SS}_{error}}{\text{SS}_{total}}$$

where SS_{error} is the error sum of squares in the ANOVA table

$$\text{SS}_{error} = \mathbf{r}'\mathbf{W}\mathbf{r}$$

and SS_{total} is the total sum of squares

$$\text{SS}_{total} = \begin{cases} \mathbf{y}'\mathbf{W}\mathbf{y} & \text{if no intercept} \\ \mathbf{y}'\mathbf{W}\mathbf{y} - \left(\sum_{h=1}^{H}\sum_{i=1}^{n_h}\sum_{j=1}^{m_{hi}} w_{hij}y_{hij}\right)^2 / w_{\cdots} & \text{otherwise} \end{cases}$$

where $w_{\cdots}$ is the sum of the sampling weights over all observations.

Adjusted R-Square

If you specify the option ADJRSQ in the MODEL statement, PROC SURVEYREG computes an multiple R-square adjusted as the weighted regression as

$$\text{ADJRSQ} = \begin{cases} 1 - \dfrac{n(1-R^2)}{n-p} & \text{if no intercept} \\ 1 - \dfrac{(n-1)(1-R^2)}{n-p} & \text{otherwise} \end{cases}$$

where R^2 is the multiple R-square.

Root Mean Square Errors

PROC SURVEYREG computes the square root of mean square errors as

$$\sqrt{\text{MSE}} = \sqrt{n \ \text{SS}_{error} \ / \ (n-p) \ w_{..}}$$

where $w_{..}$ is the sum of the sampling weights over all observations.

Design Effect

If you specify the DEFF option in the MODEL statement, PROC SURVEYREG calculates the design effects for the regression coefficients. The design effect of an estimate is the ratio of the actual variance to the variance computed under the assumption of simple random sampling:

$$\text{DEFF} = \frac{\text{variance under the sample design}}{\text{variance under simple random sampling}}$$

See Kish (1965, p. 258) for more details. PROC SURVEYREG computes the numerator as described in the section "Variance Estimation" on page 6564. And the denominator is computed under the assumption that the sample design is simple random sampling, with no stratification and no clustering.

To compute the variance under the assumption of simple random sampling, PROC SURVEYREG calculates the sampling rate as follows. If you specify both sampling weights and sampling rates (or population totals) for the analysis, then the sampling rate under simple random sampling is calculated as

$$f_{\text{SRS}} = n \ / \ w_{..}$$

where n is the sample size and $w_{..}$ (the sum of the weights over all observations) estimates the population size. If the sum of the weights is less than the sample size, f_{SRS} is set to zero. If you specify sampling rates for the analysis but not sampling weights, then PROC SURVEYREG computes the sampling rate under simple random sampling as the average of the stratum sampling rates:

$$f_{\text{SRS}} = \frac{1}{H} \sum_{h=1}^{H} f_h$$

If you do not specify sampling rates (or population totals) for the analysis, then the sampling rate under simple random sampling is assumed to be zero:

$$f_{\text{SRS}} = 0$$

Stratum Collapse

If there is only one sampling unit in a stratum, then PROC SURVEYREG cannot estimate the variance for this stratum for the Taylor series method. To estimate stratum variances, by default the procedure collapses, or combines, those strata that contain only one sampling unit. If you specify the NOCOLLAPSE option in the STRATA statement, PROC SURVEYREG does not collapse strata and uses a variance estimate of zero for any stratum that contains only one sampling unit.

Note that stratum collapse only applies to Taylor series variance estimation (the default method, also specified by VARMETHOD=TAYLOR). The procedure does not collapse strata for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option.

If you do not specify the NOCOLLAPSE option for the Taylor series method, PROC SURVEYREG collapses strata according to the following rules. If there are multiple strata that contain only one sampling unit each, then the procedure collapses, or combines, all these strata into a new pooled stratum. If there is only one stratum with a single sampling unit, then PROC SURVEYREG collapses that stratum with the preceding stratum, where strata are ordered by the STRATA variable values. If the stratum with one sampling unit is the first stratum, then the procedure combines it with the following stratum.

If you specify stratum sampling rates by using the RATE=*SAS-data-set* option, PROC SURVEYREG computes the sampling rate for the new pooled stratum as the weighted average of the sampling rates for the collapsed strata. See the section "Computational Details" on page 6563 for details. If the specified sampling rate equals 0 for any of the collapsed strata, then the pooled stratum is assigned a sampling rate of 0. If you specify stratum totals by using the TOTAL=*SAS-data-set* option, PROC SURVEYREG combines the totals for the collapsed strata to compute the sampling rate for the new pooled stratum.

Sampling Rate of the Pooled Stratum from Collapse

Assuming that PROC SURVEYREG collapses single-unit strata $h_1, h_2, \ldots, h_c$ into the pooled stratum, the procedure calculates the sampling rate for the pooled stratum as

$$f_{\text{Pooled Stratum}} = \begin{cases} 0 & \text{if any of } f_{h_l} = 0 \text{ where } l = 1, 2, \ldots, c \\ \left(\sum_{l=1}^{c} n_{h_l} f_{h_l}^{-1} \right)^{-1} \sum_{l=1}^{c} n_{h_l} & \text{otherwise} \end{cases}$$

Contrasts

You can use the CONTRAST statement to perform custom hypothesis tests. If the hypothesis is testable in the univariate case, the Wald F statistic for $H_0 : \mathbf{L}\boldsymbol{\beta} = 0$ is computed as

$$F_{\text{Wald}} = \frac{(\mathbf{L}_{\text{Full}}\hat{\boldsymbol{\beta}})'(\mathbf{L}'_{\text{Full}}\widehat{\mathbf{V}}\mathbf{L}_{\text{Full}})^{-1}(\mathbf{L}_{\text{Full}}\hat{\boldsymbol{\beta}})}{\text{rank}(\mathbf{L})}$$

where $\mathbf{L}$ is the contrast vector or matrix you specify, $\boldsymbol{\beta}$ is the vector of regression parameters, $\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-}\mathbf{X}'\mathbf{W}\mathbf{Y}$, $\widehat{\mathbf{V}}$ is the estimated covariance matrix of $\hat{\boldsymbol{\beta}}$, rank($\mathbf{L}$) is the rank of $\mathbf{L}$, and $\mathbf{L}_{\text{Full}}$ is a matrix such that

- $\mathbf{L}_{\text{Full}}$ has the same number of columns as $\mathbf{L}$
- $\mathbf{L}_{\text{Full}}$ has full row rank
- the rank of $\mathbf{L}_{\text{Full}}$ equals the rank of the $\mathbf{L}$ matrix
- all rows of $\mathbf{L}_{\text{Full}}$ are estimable functions
- the Wald F statistic computed using the $\mathbf{L}_{\text{Full}}$ matrix is equivalent to the Wald F statistic computed by using the $\mathbf{L}$ matrix with any row deleted that is a linear combination of previous rows

If $\mathbf{L}$ is a full-rank matrix and all rows of $\mathbf{L}$ are estimable functions, then $\mathbf{L}_{\text{Full}}$ is the same as $\mathbf{L}$. It is possible that $\mathbf{L}_{\text{Full}}$ matrix cannot be constructed for contrasts in a CONTRAST statement, in which case the contrasts are not testable.

Domain Analysis

A DOMAIN statement requests that the procedure perform regression analysis for each domain.

For a domain D, let I_D be the corresponding indicator variable:

$$I_D(h,i,j) = \begin{cases} 1 & \text{if observation } (h,i,j) \text{ belongs to domain } D \\ 0 & \text{otherwise} \end{cases}$$

Let

$$v_{hij} = w_{hij} I_D(h,i,j) = \begin{cases} w_{hij} & \text{if observation } (h,i,j) \text{ belongs to domain } D \\ 0 & \text{otherwise} \end{cases}$$

The regression in domain D uses v as the weight variable.

Computational Resources

Due to the nature of survey data analysis, the SURVEYREG procedure requires more memory compared to analysis that uses the same regression model in the GLM procedure. For details about

the amount of memory related to the modeling, see the section "Computational Resources" on page 2544 in Chapter 39, "The GLM Procedure."

The memory needed in the SURVEYREG procedure to handle the survey design is described as follows.

Let

- H be the total number of strata
- n_c be the total clusters in your sample across all H strata if it is a cluster sampling
- p be the total number of parameters in the model

The memory needed (in bytes) is

$$48H + 8pH + 4p(p+1)H$$

For a cluster sampling, the additional memory needed (in bytes) is

$$48H + 8pH + 4p(p+1)H + 4p(p+1)n_c + 16n_c$$

Other small amounts of additional memory are also used by the SURVEYREG procedure. However, when you have large number of clusters or strata, or large number of parameters in your model, the memory described previously dominates the total memory usage in the procedure.

Output Data Sets

You can use the Output Delivery System (ODS) to create a SAS data set from any piece of PROC SURVEYREG output. See the section "ODS Table Names" on page 6581 for more information. For a more detailed description of using ODS, see Chapter 20, "Using the Output Delivery System."

PROC SURVEYREG also provides an OUTPUT statement to create a data set that contains estimated linear predictors and their standard error estimates, the residuals from the linear regression, and the confidence limits for the predictors.

If you use BRR or jackknife variance estimation, PROC SURVEYREG provides an output data set that stores the replicate weights and an output data set that stores the jackknife coefficients for jackknife variance estimation.

OUT= Data Set Created by the OUTPUT Statement

The OUTPUT statement produces an output data set that contains the following:

- all original data from the SAS data set input to PROC SURVEYREG
- the new variables corresponding to the diagnostic measures specified with statistics keywords in the OUTPUT statement (PREDICTED=, RESIDUAL=, and so on)

When any independent variable in the analysis (including all classification variables) is missing for an observation, then all new variables that correspond to diagnostic measures are missing for the observation in the output data set.

When a dependent variable in the analysis is missing for an observation, then the residual variable that corresponds to R is also missing in the output data set. However, the variables corresponding to LCLM, P, STDP, and UCLM are not missing.

Replicate Weights Output Data Set

If you specify the OUTWEIGHTS= method-option for BRR or jackknife method in the VARMETHOD= option, PROC SURVEYREG stores the replicate weights in an output data set. The OUTWEIGHTS= output data set contains all observations used in the analysis or all valid observations in the DATA= input data set. A valid observation is an observation that has a positive value of the WEIGHT variable. Valid observations must also have nonmissing values of the STRATA and CLUSTER variables, unless you specify the MISSING option.

The OUTWEIGHTS= data set contains the following variables:

- all variables in the DATA= input data set
- RepWt_1, RepWt_2, . . ., RepWt_n, which are the replicate weight variables

where n is the total number of replicates in the analysis. Each replicate weight variable contains the replicate weights for the corresponding replicate. Replicate weights equal zero for those observations not included in the replicate.

After the procedure creates replicate weights for a particular input data set and survey design, you can use the OUTWEIGHTS= method-option to store these replicate weights and then use them again in subsequent analyses, either in PROC SURVEYREG or in the other survey procedures. You can use the REPWEIGHTS statement to provide replicate weights for the procedure.

Jackknife Coefficients Output Data Set

If you specify the OUTJKCOEFS= method-option for VARMETHOD=JACKKNIFE, PROC SURVEYREG stores the jackknife coefficients in an output data set. The OUTJKCOEFS= output data set contains one observation for each replicate. The OUTJKCOEFS= data set contains the following variables:

- Replicate, which is the replicate number for the jackknife coefficient
- JKCoefficient, which is the jackknife coefficient

- DonorStratum, which is the stratum of the PSU that was deleted to construct the replicate, if you specify a STRATA statement

After the procedure creates jackknife coefficients for a particular input data set and survey design, you can use the OUTJKCOEFS= method-option to store these coefficients and then use them again in subsequent analyses, either in PROC SURVEYREG or in the other survey procedures. You can use the JKCOEFS= option in the REPWEIGHTS statement to provide jackknife coefficients for the procedure.

Displayed Output

The SURVEYREG procedure produces the following output.

Data Summary

By default, PROC SURVEYREG displays the following information in the "Data Summary" table:

- Number of Observations, which is the total number of observations used in the analysis, excluding observations with missing values
- Sum of Weights, if you specify a WEIGHT statement
- Mean of the dependent variable in the MODEL statement, or Weighted Mean if you specify a WEIGHT statement
- Sum of the dependent variable in the MODEL statement, or Weighted Sum if you specify a WEIGHT statement

Design Summary

When you specify a CLUSTER statement or a STRATA statement, the procedure displays a "Design Summary" table, which provides the following sample design information:

- Number of Strata, if you specify a STRATA statement
- Number of Strata Collapsed, if the procedure collapses strata
- Number of Clusters, if you specify a CLUSTER statement
- Overall Sampling Rate used to calculate the design effect, if you specify the DEFF option in the MODEL statement

Domain Summary

By default, PROC SURVEYREG displays the following information in the "Domain Summary" table:

- Number of Observations, which is the total number of observations used in the analysis
- total number of observations in the current domain
- total number of observations not in the current domain
- Sum of Weights for the observations in the current domain, if you specify a WEIGHT statement

Fit Statistics

By default, PROC SURVEYREG displays the following regression statistics in the "Fit Statistics" table:

- R-square for the regression
- Root MSE, which is the square root of the mean square error
- Denominator DF, which is the denominator degrees of freedom for the F tests and also the degrees of freedom for the t tests produced by the procedure

Variance Estimation

If the variance method is not Taylor series (see the section "Variance Estimation" on page 6564) or if the NOMCAR option is used, by default, PROC SURVEYREG displays the following variance estimation specifications the "Variance Estimation" table:

- Method, which is the variance estimation method
- Number of Replicates, which is the number of replicates if you specify the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option
- Hadamard Data Set, which is the name of the SAS data set for the HADAMARD matrix if you specify the VARMETHOD=BRR(HADAMARD=) method-option in the VARMETHOD=BRR option
- Fay Coefficient, which is the value of the FAY coefficient if you specify the VARMETHOD=BRR(FAY) method-option
- Replicate Weights Dataset, which is the name of the SAS data set that contains the replicate weights
- Missing Levels, which indicates whether a missing category for categorical variables is created depending on whether you specify the MISSING option

- Missing Values, which indicates whether observations with missing values are included in the analysis, depending on whether you specify the NOMCAR option

Stratum Information

When you specify the LIST option in the STRATA statement, PROC SURVEYREG displays a "Stratum Information" table, which provides the following information for each stratum:

- Stratum Index, which is a sequential stratum identification number
- STRATA variable(s), which lists the levels of STRATA variables for the stratum
- Population Total, if you specify the TOTAL= option
- Sampling Rate, if you specify the TOTAL= option or the RATE= option. If you specify the TOTAL= option, the sampling rate is based on the number of nonmissing observations in the stratum.
- N Obs, which is the number of observations
- number of Clusters, if you specify a CLUSTER statement
- Collapsed, which has the value 'Yes' if the stratum is collapsed with another stratum before analysis

If PROC SURVEYREG collapses strata, the "Stratum Information" table also displays stratum information for the new, collapsed stratum. The new stratum has a Stratum Index of 0 and is labeled 'Pooled.'

Class Level Information

If you use a CLASS statement to name classification variables, PROC SURVEYREG displays a "Class Level Information" table. This table contains the following information for each classification variable:

- Class Variable, which lists each CLASS variable name
- Levels, which is the number of values or levels of the classification variable
- Values, which lists the values of the classification variable. The values are separated by a white space character; therefore, to avoid confusion, you should not include a white space character within a classification variable value.

X'X Matrix

If you specify the XPX option in the MODEL statement, PROC SURVEYREG displays the $\mathbf{X}'\mathbf{X}$ matrix. When there is a WEIGHT variable, the procedure displays the $\mathbf{X}'\mathbf{W}\mathbf{X}$ matrix. This option also displays the crossproducts vector $\mathbf{X}'\mathbf{y}$ or $\mathbf{X}'\mathbf{W}\mathbf{y}$, where $\mathbf{y}$ is the response vector (dependent variable).

Inverse Matrix of X'X

If you specify the INV option in the MODEL statement, PROC SURVEYREG displays the inverse or the generalized inverse of the $\mathbf{X}'\mathbf{X}$ matrix. When there is a WEIGHT variable, the procedure displays the inverse or the generalized inverse of the $\mathbf{X}'\mathbf{W}\mathbf{X}$ matrix.

ANOVA for Dependent Variable

If you specify the ANOVA option in the model statement, PROC SURVEYREG displays an analysis of variance table for the dependent variable. This table is identical to the ANOVA table displayed by the GLM procedure.

Tests of Model Effects

By default, PROC SURVEYREG displays a "Tests of Model Effects" table, which provides Wald's F test for each effect in the model. The table contains the following information for each effect:

- Effect, which is the effect name
- Num DF, which is the numerator degrees of freedom for Wald's F test
- F Value, which is Wald's F statistic
- Pr > F, which is the significance probability corresponding to the F Value

A footnote displays the denominator degrees of freedom, which is the same for all effects.

Estimated Regression Coefficients

PROC SURVEYREG displays the "Estimated Regression Coefficients" table by default when there is no CLASS statement. Also, the procedure displays this table when you specify a CLASS statement and also specify the SOLUTIONS option in the MODEL statement. This table contains the following information for each regression parameter:

- Parameter, which identifies the effect or regressor variable
- Estimate, which is the estimate of the regression coefficient
- Standard Error, which is the standard error of the estimate
- t Value, which is the t statistic for testing H_0: Parameter $= 0$
- Pr > | t |, which is the two-sided significance probability corresponding to the t Value

Covariance of Estimated Regression Coefficients

When you specify the COVB option in the MODEL statement, PROC SURVEYREG displays the "Covariance of Estimated Regression Coefficients" matrix.

Coefficients of Contrast

When you specify the E option in a CONTRAST statement, PROC SURVEYREG displays a "Coefficients of Contrast" table for the contrast. You can use this table to check the coefficients you specified in the CONTRAST statement. Also, this table gives a note for a nonestimable contrast.

Analysis of Contrasts

If you specify a CONTRAST statement, PROC SURVEYREG produces an "Analysis of Contrasts" table, which displays Wald's F test for the contrast. If you use more than one CONTRAST statement, the procedure displays all results in the same table. The "Analysis of Contrasts" table contains the following information for each contrast:

- Contrast, which is the label of the contrast
- Num DF, which is the numerator degrees of freedom for Wald's F test
- F Value, which is Wald's F statistic for testing H_0: Contrast $= 0$
- Pr > F, which is the significance probability corresponding to the F Value

Coefficients of Estimate

When you specify the E option in an ESTIMATE statement, PROC SURVEYREG displays a "Coefficients of Estimate" table for the linear function of the regression parameters in the ESTIMATE statement. You can use this table to check the coefficients you specified in the ESTIMATE statement. Also, this table gives a note for a nonestimable function.

Analysis of Estimable Functions

If you specify an ESTIMATE statement, PROC SURVEYREG checks the function for estimability. If the function is estimable, PROC SURVEYREG produces an "Analysis of Estimable Functions" table, which displays the estimate and the corresponding t test. If you use more than one ESTIMATE statement, the procedure displays all results in the same table. The table contains the following information for each estimable function:

- Parameter, which is the label of the function
- Estimate, which is the estimate of the estimable linear function

- Standard Error, which is the standard error of the estimate
- t Value, which is the t statistic for testing H_0: Estimable Function $= 0$
- Pr > | t |, which is the two-sided significance probability corresponding to the t Value

Hadamard Matrix

If you specify the VARMETHOD=BRR(PRINTH) method-option in the PROC statement, PROC SURVEYREG displays the Hadamard matrix.

When you provide a Hadamard matrix with the VARMETHOD=BRR(HADAMARD=) method-option, the procedure displays only used rows and columns of the Hadamard matrix.

ODS Table Names

PROC SURVEYREG assigns a name to each table it creates. You can use these names to reference the table when by using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 86.3. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 86.3 ODS Tables Produced by PROC SURVEYREG

ODS Table Name	Description	Statement	Option
ANOVA	ANOVA for dependent variable	MODEL	ANOVA
ClassVarInfo	Class level information	CLASS	default
ContrastCoef	Coefficients of contrast	CONTRAST	E
Contrasts	Analysis of contrasts	CONTRAST	default
CovB	Covariance of estimated regression coefficients	MODEL	COVB
DataSummary	Data summary	PROC	default
DesignSummary	Design summary	STRATA | CLUSTER	default
DomainSummary	Domain summary	DOMAIN	default
Effects	Tests of model effects	MODEL	defect
EstimateCoef	Coefficients of estimate	ESTIMATE	E
Estimates	Analysis of estimable functions	ESTIMATE	default
FitStatistics	Fit statistics	MODEL	default
HadamardMatrix	Hadamard matrix	PROC	PRINTH
InvXPX	Inverse matrix of $\mathbf{X}'\mathbf{X}$	MODEL	INV
ParameterEstimates	Estimated regression coefficients	MODEL	SOLUTION
StrataInfo	Stratum information	STRATA	LIST

Table 86.3 (continued)

ODS Table Name	Description	Statement	Option
VarianceEstimation	Variance estimation	PROC	default
XPX	$\mathbf{X}'\mathbf{X}$ matrix	MODEL	XPX

By referring to the names of such tables, you can use the ODS OUTPUT statement to place one or more of these tables in output data sets.

For example, the following statements create an output data set MyStrata, which contains the "StrataInfo" table, an output data set MyParmEst, which contains the "ParameterEstimates" table, and an output data set Cov, which contains the "CovB" table for the ice cream study discussed in the section "Stratified Sampling" on page 6538:

```
title1 'Ice Cream Spending Analysis';
title2 'Stratified Simple Random Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
   strata Grade /list;
   class Kids;
   model Spending = Income Kids / solution covb;
   weight Weight;
   ods output StrataInfo = MyStrata
              ParameterEstimates = MyParmEst
              CovB = Cov;
run;
```

Note that the option CovB is specified in the MODEL statement in order to produce the covariance matrix table.

Examples: SURVEYREG Procedure

Example 86.1: Simple Random Sampling

This example investigates the relationship between the labor force participation rate (LFPR) of women in 1968 and 1972 in large cities in the United States. A simple random sample of 19 cities is drawn from a total of 200 cities. For each selected city, the LFPRs are recorded and saved in a SAS data set Labor. In the following DATA step, LFPR in 1972 is contained in the variable LFPR1972, and the LFPR in 1968 is identified by the variable LFPR1968:

```
data Labor;
   input City $ 1-16 LFPR1972 LFPR1968;
   datalines;
New York         .45     .42
Los Angeles      .50     .50
Chicago          .52     .52
Philadelphia     .45     .45
Detroit          .46     .43
San Francisco    .55     .55
Boston           .60     .45
Pittsburgh       .49     .34
St. Louis        .35     .45
Connecticut      .55     .54
Washington D.C.  .52     .42
Cincinnati       .53     .51
Baltimore        .57     .49
Newark           .53     .54
Minn/St. Paul    .59     .50
Buffalo          .64     .58
Houston          .50     .49
Patterson        .57     .56
Dallas           .64     .63
;
```

Assume that the LFPRs in 1968 and 1972 have a linear relationship, as shown in the following model:

$$\text{LFPR1972} = \beta_0 + \beta_1 * \text{LFPR1968} + \text{error}$$

You can use PROC SURVEYREG to obtain the estimated regression coefficients and estimated standard errors of the regression coefficients. The following statements perform the regression analysis:

```
title 'Study of Labor Force Participation Rates of Women';
proc surveyreg data=Labor total=200;
   model LFPR1972 = LFPR1968;
run;
```

Here, the TOTAL=200 option specifies the finite population total from which the simple random sample of 19 cities is drawn. You can specify the same information by using the sampling rate option RATE=0.095 (19/200=.095).

Output 86.1.1 summarizes the data information and the fit information.

Output 86.1.1 Summary of Regression Using Simple Random Sampling

Study of Labor Force Participation Rates of Women

The SURVEYREG Procedure

Regression Analysis for Dependent Variable LFPR1972

Data Summary

Number of Observations	19
Mean of LFPR1972	0.52684
Sum of LFPR1972	10.01000

Fit Statistics

R-square	0.3970
Root MSE	0.05657
Denominator DF	18

Output 86.1.2 presents the significance tests for the model effects and estimated regression coefficients. The F tests and t tests for the effects in the model are also presented in these tables.

Output 86.1.2 Regression Coefficient Estimates

Tests of Model Effects

Effect	Num DF	F Value	Pr > F
Model	1	13.84	0.0016
Intercept	1	4.63	0.0452
LFPR1968	1	13.84	0.0016

NOTE: The denominator degrees of freedom for the F tests is 18.

Estimated Regression Coefficients

Parameter	Estimate	Standard Error	t Value	Pr > |t|
Intercept	0.20331056	0.09444296	2.15	0.0452
LFPR1968	0.65604048	0.17635810	3.72	0.0016

NOTE: The denominator degrees of freedom for the t tests is 18.

From the regression performed by PROC SURVEYREG, you obtain a positive estimated slope for the linear relationship between the LFPR in 1968 and the LFPR in 1972. The regression coefficients are all significant at the 5% level. The effects Intercept and LFPR1968 are significant in the model at the 5% level. In this example, the F test for the overall model without intercept is the same as the effect LFPR1968.

Example 86.2: Simple Random Cluster Sampling

This example illustrates the use of regression analysis in a simple random cluster sample design. The data are from Särndal, Swensson, and Wretman (1992, p. 652).

A total of 284 Swedish municipalities are grouped into 50 clusters of neighboring municipalities. Five clusters with a total of 32 municipalities are randomly selected. The results from the regression analysis in which clusters are used in the sample design are compared to the results of a regression analysis that ignores the clusters. The linear relationship between the population in 1975 and in 1985 is investigated.

The 32 selected municipalities in the sample are saved in the data set Municipalities:

```
data Municipalities;
   input Municipality Cluster Population85 Population75;
   datalines;
205   37    5    5
206   37   11   11
207   37   13   13

 10    2   60   50
 94   17    7    7
 95   17   16   16
 96   17   13   11
 97   17   12   11
 98   17   70   67
 99   17   20   20
100   17   31   28
101   17   49   48
276   50    6    7
277   50    9   10
278   50   24   26
279   50   10    9
280   50   67   64
281   50   39   35
282   50   29   27
283   50   10    9
284   50   27   31
 52   10    7    6
 53   10    9    8
 54   10   28   27
 55   10   12   11
 56   10  107  108
;
```

The variable Municipality identifies the municipalities in the sample; the variable Cluster indicates the

cluster to which a municipality belongs; and the variables Population85 and Population75 contain the municipality populations in 1985 and in 1975 (in thousands), respectively. A regression analysis is performed by PROC SURVEYREG with a CLUSTER statement:

```
title1 'Regression Analysis for Swedish Municipalities';
title2 'Cluster Simple Random Sampling';
proc surveyreg data=Municipalities total=50;
   cluster Cluster;
   model Population85=Population75;
run;
```

The TOTAL=50 option specifies the total number of clusters in the sampling frame.

Output 86.2.1 displays the data and design summary. Since the sample design includes clusters, the procedure displays the total number of clusters in the sample in the "Design Summary" table.

Output 86.2.1 Regression Analysis for Simple Random Cluster Sampling

```
Regression Analysis for Swedish Municipalities
        Cluster Simple Random Sampling

          The SURVEYREG Procedure

Regression Analysis for Dependent Variable Population85

                Data Summary

Number of Observations            32
Mean of Population85           27.50000
Sum of Population85           880.00000

              Design Summary

Number of Clusters                5
```

Output 86.2.2 displays the fit statistics and regression coefficient estimates. In the "Estimated Regression Coefficients" table, the estimated slope for the linear relationship is 1.05, which is significant at the 5% level; but the intercept is not significant. This suggests that a regression line crossing the original can be established between populations in 1975 and in 1985.

Output 86.2.2 Regression Analysis for Simple Random Cluster Sampling

```
                Fit Statistics

R-square                0.9860
Root MSE                3.0488
Denominator DF               4
```

Output 86.2.2 *continued*

Estimated Regression Coefficients

Parameter	Estimate	Standard Error	t Value	Pr > |t|
Intercept	-0.0191292	0.89204053	-0.02	0.9839
Population75	1.0546253	0.05167565	20.41	<.0001

NOTE: The denominator degrees of freedom for the t tests is 4.

The CLUSTER statement is necessary in PROC SURVEYREG in order to incorporate the sample design. If you do not specify a CLUSTER statement in the regression analysis, as in the following statements, the standard deviation of the regression coefficients are incorrectly estimated.

```
title1 'Regression Analysis for Swedish Municipalities';
title2 'Simple Random Sampling';
proc surveyreg data=Municipalities total=284;
   model Population85=Population75;
run;
```

The analysis ignores the clusters in the sample, assuming that the sample design is a simple random sampling. Therefore, the TOTAL= option specifies the total number of municipalities, which is 284.

Output 86.2.3 displays the regression results ignoring the clusters. Compared to the results in Output 86.2.1, the regression coefficient estimates are the same. However, without using clusters, the regression coefficients have a smaller variance estimate, as in Output 86.2.3. By using clusters in the analysis, the estimated regression coefficient for effect Population75 is 1.05, with the estimated standard error 0.05, as displayed in Output 86.2.1; without using the clusters, the estimate is 1.05, but with the estimated standard error 0.04, as displayed in Output 86.2.3. To estimated the variance of the regression coefficients correctly, you should include the clustering information in the regression analysis.

Output 86.2.3 Regression Analysis for Simple Random Sampling

Regression Analysis for Swedish Municipalities

NOTE: The denominator degrees of freedom for the t tests is 31.
```

Example 86.3: Regression Estimator for Simple Random Sample

Using auxiliary information, you can construct the regression estimators to provide more accurate estimates of the population characteristics that are of interest. With ESTIMATE statements in PROC SURVEYREG, you can specify a regression estimator as a linear function of the regression parameters to estimate the population total. This example illustrates this application, by using the data in the previous example.

In this sample, a linear model between the Swedish populations in 1975 and in 1985 is established:

$$\text{Population85} = \alpha + \beta * \text{Population75} + \text{error}$$

Assuming that the total population in 1975 is known to be 8200 (in thousands), you can use the ESTIMATE statement to predict the 1985 total population by using the following statements:

```
title1 'Regression Analysis for Swedish Municipalities';
title2 'Estimate Total Population';
proc surveyreg data=Municipalities total=50;
   cluster Cluster;
   model Population85=Population75;
   estimate '1985 population' Intercept 284 Population75 8200;
run;
```

Since each observation in the sample is a municipality and there is a total of 284 municipalities in Sweden, the coefficient for Intercept (α) in the ESTIMATE statement is 284 and the coefficient for Population75 (β) is the total population in 1975 (8.2 million).

Output 86.3.1 displays the regression results and the estimation of the total population. By using the linear model, you can predict the total population in 1985 to be 8.64 million, with a standard error of 0.26 million.

Output 86.3.1 Use the Regression Estimator to Estimate the Population Total

```
Regression Analysis for Swedish Municipalities
Estimate Total Population

The SURVEYREG Procedure

1985 population    8642.49485    258.558613      33.43      <.0001

NOTE: The denominator degrees of freedom for the t tests is 4.
```

Example 86.4: Stratified Sampling

This example illustrates the use of the SURVEYREG procedure to perform a regression in a stratified sample design. Consider a population of 235 farms producing corn in Nebraska and Iowa. You are interested in the relationship between corn yield (CornYield) and total farm size (FarmArea).

Each state is divided into several regions, and each region is used as a stratum. Within each stratum, a simple random sample with replacement is drawn. A total of 19 farms is selected by using a stratified simple random sample. The sample size and population size within each stratum are displayed in Table 86.4.

Table 86.4 Number of Farms in Each Stratum

			Number of Farms	
Stratum	**State**	**Region**	**Population**	**Sample**
1	Iowa	1	100	3
2		2	50	5
3		3	15	3
4	Nebraska	1	30	6
5		2	40	2
Total			**235**	**19**

Three models for the data are considered:

- Model I — Common intercept and slope:

$$\text{Corn Yield} = \alpha + \beta * \text{Farm Area}$$

- Model II — Common intercept, different slope:

$$\text{Corn Yield} = \begin{cases} \alpha + \beta_{\text{Iowa}} * \text{Farm Area} & \text{if the farm is in Iowa} \\ \alpha + \beta_{\text{Nebraska}} * \text{Farm Area} & \text{if the farm is in Nebraska} \end{cases}$$

- Model III — Different intercept and different slope:

$$\text{Corn Yield} = \begin{cases} \alpha_{\text{Iowa}} + \beta_{\text{Iowa}} * \text{Farm Area} & \text{if the farm is in Iowa} \\ \alpha_{\text{Nebraska}} + \beta_{\text{Nebraska}} * \text{Farm Area} & \text{if the farm is in Nebraska} \end{cases}$$

Data from the stratified sample are saved in the SAS data set Farms. In the data set Farms, the variable Weight represents the sampling weight. In the following DATA step, the sampling weights are the reciprocals of selection probabilities:

```
data Farms;
   input State $ Region FarmArea CornYield Weight;
   datalines;
Iowa     1 100  54 33.333
Iowa     1  83  25 33.333
Iowa     1  25  10 33.333
Iowa     2 120  83 10.000
Iowa     2  50  35 10.000
Iowa     2 110  65 10.000
Iowa     2  60  35 10.000
Iowa     2  45  20 10.000
Iowa     3  23   5  5.000
Iowa     3  10   8  5.000
Iowa     3 350 125  5.000
Nebraska 1 130  20  5.000
Nebraska 1 245  25  5.000
Nebraska 1 150  33  5.000
Nebraska 1 263  50  5.000
Nebraska 1 320  47  5.000
Nebraska 1 204  25  5.000
Nebraska 2  80  11 20.000
Nebraska 2  48   8 20.000
;
```

The information about population size in each stratum is saved in the SAS data set StratumTotals:

```
data StratumTotals;
   input State $ Region _TOTAL_;
   datalines;
Iowa     1 100
Iowa     2  50
Iowa     3  15
Nebraska 1  30
Nebraska 2  40
;
```

Using the sample data from the data set Farms and the control information data from the data set StratumTotals, you can fit Model I by using PROC SURVEYREG with the following statements:

```
title1 'Analysis of Farm Area and Corn Yield';
title2 'Model I: Same Intercept and Slope';
proc surveyreg data=Farms total=StratumTotals;
   strata State Region / list;
   model CornYield = FarmArea / covB;
   weight Weight;
run;
```

Output 86.4.1 displays the data summary and stratification information fitting Model I. The sampling rates are automatically computed by the procedure based on the sample sizes and the population totals in strata.

Output 86.4.1 Data Summary and Stratum Information Fitting Model I

Intercept	11.8162978	5.31981027	2.22	0.0433
FarmArea	0.2126576	0.04560949	4.66	0.0004

NOTE: The denominator degrees of freedom for the t tests is 14.

Covariance of Estimated Regression Coefficients

	Intercept	FarmArea
Intercept	28.300381277	-0.146471538
FarmArea	-0.146471538	0.0020802259

Alternatively, you can assume that the linear relationship between corn yield (CornYield) and farm area (FarmArea) is different among the states (Model II). In order to analyze the data by using this model, you create auxiliary variables FarmAreaNE and FarmAreaIA to represent farm area in different states:

$$\text{FarmAreaNE} = \begin{cases} 0 & \text{if the farm is in Iowa} \\ \text{FarmArea} & \text{if the farm is in Nebraska} \end{cases}$$

$$\text{FarmAreaIA} = \begin{cases} \text{FarmArea} & \text{if the farm is in Iowa} \\ 0 & \text{if the farm is in Nebraska} \end{cases}$$

The following statements create these variables in a new data set called FarmsByState and use PROC SURVEYREG to fit Model II:

```
data FarmsByState; set Farms;
   if State='Iowa' then do;
      FarmAreaIA=FarmArea ; FarmAreaNE=0; end;
   else do;
      FarmAreaIA=0 ; FarmAreaNE=FarmArea; end;
run;
```

The following statements perform the regression by using the new data set FarmsByState. The analysis uses the auxiliary variables FarmAreaIA and FarmAreaNE as the regressors:

```
title1 'Analysis of Farm Area and Corn Yield';
title2 'Model II: Same Intercept, Different Slopes';
proc SURVEYREG data=FarmsByState total=StratumTotals;
   strata State Region;
   model CornYield = FarmAreaIA FarmAreaNE / covB;
   weight Weight;
run;
```

Output 86.4.3 displays the fit statistics and parameter estimates. The estimated slope parameters for each state are quite different from the estimated slope in Model I. The results from the regression show that Model II fits these data better than Model I.

Output 86.4.3 Regression Results from Fitting Model II

```
                Analysis of Farm Area and Corn Yield
              Model II: Same Intercept, Different Slopes

                        The SURVEYREG Procedure

          Regression Analysis for Dependent Variable CornYield

                             Fit Statistics

                        Root MSE           11.6759
                        Denominator DF          14

                     Estimated Regression Coefficients

                                    Standard
 Parameter       Estimate            Error    t Value    Pr > |t|

 Intercept     4.04234816     3.80934848       1.06      0.3066
 FarmAreaIA    0.41696069     0.05971129       6.98      <.0001
 FarmAreaNE    0.12851012     0.02495495       5.15      0.0001

NOTE: The denominator degrees of freedom for the t tests is 14.

          Covariance of Estimated Regression Coefficients

                        Intercept        FarmAreaIA        FarmAreaNE

Intercept         14.511135861      -0.118001232      -0.079908772
FarmAreaIA        -0.118001232       0.0035654381      0.0006501109
FarmAreaNE        -0.079908772       0.0006501109      0.0006227496
```

For Model III, different intercepts are used for the linear relationship in two states. The following statements illustrate the use of the NOINT option in the MODEL statement associated with the CLASS statement to fit Model III:

```
title2 'Model III: Different Intercepts and Slopes';
proc SURVEYREG data=FarmsByState total=StratumTotals;
   strata State Region;
   class State;
   model CornYield = State FarmAreaIA FarmAreaNE / noint covB solution;
   weight Weight;
run;
```

The model statement includes the classification effect State as a regressor. Therefore, the parameter estimates for effect State present the intercepts in two states.

Output 86.4.4 displays the regression results for fitting Model III, including parameter estimates, and covariance matrix of the regression coefficients. The estimated covariance matrix shows a lack of correlation between the regression coefficients from different states. This suggests that Model III might be the best choice for building a model for farm area and corn yield in these two states.

However, some statistics remain the same under different regression models—for example, Weighted Mean of CornYield. These estimators do not rely on the particular model you use.

Output 86.4.4 Regression Results for Fitting Model III

Analysis of Farm Area and Corn Yield
Model III: Different Intercepts and Slopes

Example 86.5: Regression Estimator for Stratified Sample

This example uses the corn yield data from the previous example to illustrate how to construct a regression estimator for a stratified sample design.

As in Example 86.3, by incorporating auxiliary information into a regression estimator, the procedure can produce more accurate estimates of the population characteristics that are of interest. In this example, the sample design is a stratified sample design. The auxiliary information is the total farm areas in regions of each state, as displayed in Table 86.5. You want to estimate the total corn yield by using this information under the three linear models given in Example 86.4.

Table 86.5 Information for Each Stratum

			Number of Farms		
Stratum	**State**	**Region**	**Population**	**Sample**	**Total Farm Area**
1	Iowa	1	100	3	
2		2	50	5	13,200
3		3	15	3	
4	Nebraska	1	30	6	8,750
5		2	40	2	
Total			**235**	**19**	**21,950**

The regression estimator to estimate the total corn yield under Model I can be obtained by using PROC SURVEYREG with an ESTIMATE statement:

```
title1 'Estimate Corn Yield from Farm Size';
title2 'Model I: Same Intercept and Slope';
proc surveyreg data=Farms total=StratumTotals;
   strata State Region / list;
   class  State Region;
   model  CornYield = FarmArea State*Region /solution;
   weight Weight;
   estimate 'Estimate of CornYield under Model I'
            INTERCEPT 235 FarmArea 21950
            State*Region 100 50 15 30 40 /e;
run;
```

To apply the constraint in each stratum that the weighted total number of farms equals to the total number of farms in the stratum, you can include the strata as an effect in the MODEL statement, effect State*Region. Thus, the CLASS statement must list the STRATA variables, State and Region, as classification variables. The following ESTIMATE statement specifies the regression estimator, which is a linear function of the regression parameters:

```
estimate 'Estimate of CornYield under Model I'
         INTERCEPT 235 FarmArea 21950
         State*Region 100 50 15 30 40 /e;
```

This linear function contains the total for each explanatory variable in the model. Because the sampling units are farms in this example, the coefficient for Intercept in the ESTIMATE statement is

the total number of farms (235); the coefficient for FarmArea is the total farm area listed in Table 86.5 (21950); and the coefficients for effect State*Region are the total number of farms in each strata (as displayed in Table 86.5).

Output 86.5.1 displays the results of the ESTIMATE statement. The regression estimator for the total of CornYield in Iowa and Nebraska is 7464 under Model I, with a standard error of 927.

Output 86.5.1 Regression Estimator for the Total of CornYield under Model I

```
                    Estimate Corn Yield from Farm Size
                    Model I: Same Intercept and Slope

                        The SURVEYREG Procedure

            Regression Analysis for Dependent Variable CornYield

                     Analysis of Estimable Functions

                                                  Standard
 Parameter                              Estimate       Error  t Value  Pr > |t|

 Estimate of CornYield under Model I  7463.52329  926.841541     8.05    <.0001

       NOTE: The denominator degrees of freedom for the t tests is 14.
```

Under Model II, a regression estimator for totals can be obtained by using the following statements:

```
title1 'Estimate Corn Yield from Farm Size';
title2 'Model II: Same Intercept, Different Slopes';
proc surveyreg data=FarmsByState total=StratumTotals;
   strata State Region;
   class  State Region;
   model  CornYield = FarmAreaIA FarmAreaNE
                      state*region /solution;
   weight Weight;
   estimate 'Total of CornYield under Model II'
            INTERCEPT 235 FarmAreaIA 13200 FarmAreaNE 8750
            State*Region 100 50 15 30 40 /e;
run;
```

In this model, you also need to include strata as a fixed effect in the MODEL statement. Other regressors are the auxiliary variables FarmAreaIA and FarmAreaNE (defined in Example 86.4). In the following ESTIMATE statement, the coefficient for Intercept is still the total number of farms; and the coefficients for FarmAreaIA and FarmAreaNE are the total farm area in Iowa and Nebraska, respectively, as displayed in Table 86.5. The total number of farms in each strata are the coefficients for the strata effect:

```
   estimate 'Total of CornYield under Model II'
            INTERCEPT 235 FarmAreaIA 13200 FarmAreaNE 8750
            State*Region 100 50 15 30 40 /e;
```

Output 86.5.2 displays that the results of the regression estimator for the total of corn yield in two states under Model II is 7580 with a standard error of 859. The regression estimator under Model II has a slightly smaller standard error than under Model I.

Output 86.5.2 Regression Estimator for the Total of CornYield under Model II

```
                    Estimate Corn Yield from Farm Size
                  Model II: Same Intercept, Different Slopes

                          The SURVEYREG Procedure

             Regression Analysis for Dependent Variable CornYield

                      Analysis of Estimable Functions

                                                  Standard
Parameter                              Estimate        Error   t Value   Pr > |t|

Total of CornYield under Model II   7580.48657   859.180439      8.82     <.0001

        NOTE: The denominator degrees of freedom for the t tests is 14.
```

Finally, you can apply Model III to the data and estimate the total corn yield. Under Model III, you can also obtain the regression estimators for the total corn yield for each state. Three ESTIMATE statements are used in the following statements to create the three regression estimators:

```
title1 'Estimate Corn Yield from Farm Size';
title2 'Model III: Different Intercepts and Slopes';
proc SURVEYREG data=FarmsByState total=StratumTotals;
   strata State Region;
   class  State Region;
   model  CornYield = state FarmAreaIA FarmAreaNE
      State*Region /noint solution;
   weight Weight;
   estimate 'Total CornYield in Iowa under Model III'
             State 165 0 FarmAreaIA 13200 FarmAreaNE  0
             State*region 100 50 15  0  0 /e;
   estimate 'Total CornYield in Nebraska under Model III'
             State 0 70 FarmAreaIA 0 FarmAreaNE 8750
             State*Region 0 0 0 30 40 /e;
   estimate 'Total CornYield in both states under Model III'
             State 165 70 FarmAreaIA 13200 FarmAreaNE 8750
             State*Region 100 50 15 30 40 /e;
run;
```

The fixed effect State is added to the MODEL statement to obtain different intercepts in different states, by using the NOINT option. Among the ESTIMATE statements, the coefficients for explanatory variables are different depending on which regression estimator is estimated. For example, in the ESTIMATE statement

```
   estimate 'Total CornYield in Iowa under Model III'
             State 165 0 FarmAreaIA 13200 FarmAreaNE  0
             State*region 100 50 15  0  0 /e;
```

the coefficients for the effect State are 165 and 0, respectively. This indicates that the total number of farms in Iowa is 165 and the total number of farms in Nebraska is 0, because the estimation is the total corn yield in Iowa only. Similarly, the total numbers of farms in three regions in Iowa are

used for the coefficients of the strata effect State*Region, as displayed in Table 86.5.

Output 86.5.3 displays the results from the three regression estimators by using Model III. Since the estimations are independent in each state, the total corn yield from both states is equal to the sum of the estimated total of corn yield in Iowa and Nebraska, $6246 + 1334 = 7580$. This regression estimator is the same as the one under Model II. The variance of regression estimator of the total corn yield in both states is the sum of variances of regression estimators for total corn yield in each state. Therefore, it is not necessary to use Model III to obtain the regression estimator for the total corn yield unless you need to estimate the total corn yield for each individual state.

Output 86.5.3 Regression Estimator for the Total of CornYield under Model III

```
                    Estimate Corn Yield from Farm Size
                 Model III: Different Intercepts and Slopes

                          The SURVEYREG Procedure

             Regression Analysis for Dependent Variable CornYield

                      Analysis of Estimable Functions

                                                          Standard
Parameter                                      Estimate       Error  t Value

Total CornYield in Iowa under Model III      6246.10697  851.272372     7.34
Total CornYield in Nebraska under Model III  1334.37961  116.302948    11.47
Total CornYield in both states under Model III 7580.48657 859.180439     8.82

                      Analysis of Estimable Functions

          Parameter                                    Pr > |t|

          Total CornYield in Iowa under Model III        <.0001
          Total CornYield in Nebraska under Model III    <.0001
          Total CornYield in both states under Model III <.0001

       NOTE: The denominator degrees of freedom for the t tests is 14.
```

Example 86.6: Stratum Collapse

In a stratified sample, it is possible that some strata might have only one sampling unit. When this happens, PROC SURVEYREG collapses the strata that contain a single sampling unit into a pooled stratum. For more detailed information about stratum collapse, see the section "Stratum Collapse" on page 6572.

Suppose that you have the following data:

```
data Sample;
   input Stratum X Y W;
   datalines;
10 0 0 5
10 1 1 5
11 1 1 10
11 1 2 10
12 3 3 16
33 4 4 45
14 6 7 50
12 3 4 16
;
```

The variable Stratum is again the stratification variable, the variable X is the independent variable, and the variable Y is the dependent variable. You want to regress Y on X. In the data set Sample, both Stratum=33 and Stratum=14 contain one observation. By default, PROC SURVEYREG collapses these strata into one pooled stratum in the regression analysis.

To input the finite population correction information, you create the SAS data set StratumTotals:

```
data StratumTotals;
   input Stratum _TOTAL_;
   datalines;
10 10
11 20
12 32
33 40
33 45
14 50
15  .
66 70
;
```

The variable Stratum is the stratification variable, and the variable _TOTAL_ contains the stratum totals. The data set StratumTotals contains more strata than the data set Sample. Also in the data set StratumTotals, more than one observation contains the stratum totals for Stratum=33:

```
33 40
33 45
```

PROC SURVEYREG allows this type of input. The procedure simply ignores strata that are not present in the data set Sample; for the multiple entries of a stratum, the procedure uses the first observation. In this example, Stratum=33 has the stratum total _TOTAL_=40.

The following SAS statements perform the regression analysis:

```
title1 'Stratified Sample with Single Sampling Unit in Strata';
title2 'With Stratum Collapse';
proc SURVEYREG data=Sample total=StratumTotals;
   strata Stratum/list;
   model Y=X;
   weight W;
run;
```

Output 86.6.1 shows that there are a total of five strata in the input data set and two strata are collapsed into a pooled stratum. The denominator degrees of freedom is 4, due to the collapse (see the section "Denominator Degrees of Freedom" on page 6569).

Output 86.6.1 Summary of Data and Regression

```
        Stratified Sample with Single Sampling Unit in Strata
                      With Stratum Collapse

                    The SURVEYREG Procedure

          Regression Analysis for Dependent Variable Y

                        Data Summary

          Number of Observations              8
          Sum of Weights                157.00000
          Weighted Mean of Y              4.31210
          Weighted Sum of Y             677.00000

                        Design Summary

        Number of Strata                      5
        Number of Strata Collapsed            2

                        Fit Statistics

              R-square            0.9564
              Root MSE            0.5111
              Denominator DF           4
```

Output 86.6.2 displays the stratification information, including stratum collapse. Under the column Collapsed, the fourth stratum (Stratum=14) and the fifth (Stratum=33) are marked as 'Yes,' which indicates that these two strata are collapsed into the pooled stratum (Stratum Index=0). The sampling rate for the pooled stratum is 2% (see the section "Sampling Rate of the Pooled Stratum from Collapse" on page 6572).

Output 86.6.2 Stratification Information

```
                          Stratum Information

    Stratum                                              Population    Sampling
     Index      Collapsed      Stratum        N Obs          Total        Rate

       2                          11             2             20      10.0%
       3                          12             2             32      6.25%
       4         Yes              14             1             50      2.00%
       5         Yes              33             1             40      2.50%

       0         Pooled                          2             90      2.22%

NOTE: Strata with only one observation are collapsed into the stratum with
      Stratum Index "0".
```

Output 86.6.3 displays the parameter estimates and the tests of the significance of the model effects.

Output 86.6.3 Parameter Estimates and Effect Tests

```
                        Tests of Model Effects

                Effect        Num DF    F Value    Pr > F

                Model              1     173.01    0.0002
                Intercept          1       0.00    0.9961
                X                  1     173.01    0.0002

        NOTE: The denominator degrees of freedom for the F tests is 4.

                    Estimated Regression Coefficients

                                        Standard
         Parameter      Estimate          Error    t Value    Pr > |t|

         Intercept    0.00179469    0.34306373       0.01      0.9961
         X            1.12598708    0.08560466      13.15      0.0002

        NOTE: The denominator degrees of freedom for the t tests is 4.
```

Alternatively, if you prefer not to collapse strata with a single sampling unit, you can specify the NOCOLLAPSE option in the STRATA statement:

```
title1 'Stratified Sample with Single Sampling Unit in Strata';
title2 'Without Stratum Collapse';
proc SURVEYREG data=Sample total=StratumTotals;
   strata Stratum/list nocollapse;
model Y = X;
weight W;
run;
```

Output 86.6.4 does not contain the stratum collapse information displayed in Output 86.6.1, and the denominator degrees of freedom are 3 instead of 4.

Output 86.6.4 Summary of Data and Regression

```
            Stratified Sample with Single Sampling Unit in Strata
                          Without Stratum Collapse

                          The SURVEYREG Procedure

                Regression Analysis for Dependent Variable Y

                              Data Summary

                    Number of Observations             8
                    Sum of Weights             157.00000
                    Weighted Mean of Y           4.31210
                    Weighted Sum of Y          677.00000
```

Output 86.6.4 *continued*

Design Summary	
Number of Strata	5
Fit Statistics	
R-square	0.9564
Root MSE	0.5111
Denominator DF	3

In Output 86.6.5, although the fourth stratum and the fifth stratum contain only one observation, no stratum collapse occurs.

Output 86.6.5 Stratification Information

Stratum Information

Stratum Index	Stratum	N Obs	Population Total	Sampling Rate
1	10	2	10	20.0%
2	11	2	20	10.0%
3	12	2	32	6.25%
4	14	1	50	2.00%
5	33	1	40	2.50%

As a result of not collapsing strata, the standard error estimates of the parameters, shown in Output 86.6.6, are different from those in Output 86.6.3, as are the tests of the significance of model effects.

Output 86.6.6 Parameter Estimates and Effect Tests

NOTE: The denominator degrees of freedom for the t tests is 3.

Example 86.7: Domain Analysis

Recall that in the section "Getting Started: SURVEYREG Procedure" on page 6535, you collected a stratified simple random sample from a junior high school to examine how household income and the number of children in a household affect students' average weekly spending for ice cream. You can also use the same sample to estimate the average weekly spending among male and female students, respectively. This is often called domain analysis (subgroup analysis). You can use PROC SURVEYREG to perform domain analysis as in this example. The data set follows:

```
data IceCreamDataDomain;
   input Grade Spending Income Gender$ @@;
   datalines;
7   7  39  M   7   7  38  F   8  12  47  F
9  10  47  M   7   1  34  M   7  10  43  M
7   3  44  M   8  20  60  F   8  19  57  M
7   2  35  M   7   2  36  F   9  15  51  F
8  16  53  F   7   6  37  F   7   6  41  M
7   6  39  M   9  15  50  M   8  17  57  F
8  14  46  M   9   8  41  M   9   8  41  F
9   7  47  F   7   3  39  F   7  12  50  M
7   4  43  M   9  14  46  F   8  18  58  M
9   9  44  F   7   2  37  F   7   1  37  M
7   4  44  M   7  11  42  M   9   8  41  M
8  10  42  M   8  13  46  F   7   2  40  F
9   6  45  F   9  11  45  M   7   2  36  F
7   9  46  F
;
data IceCreamDataDomain;
   set IceCreamDataDomain;
   if Grade=7 then Prob=20/1824;
   if Grade=8 then Prob=9/1025;
   if Grade=9 then Prob=11/1151;
   Weight=1/Prob;
```

In the data set IceCreamDataDomain, the variable Grade indicates a student's grade, which is the stratification variable. The variable Spending contains the dollar amount of each student's average weekly spending for ice cream. The variable Income specifies the household income, in thousands

of dollars. The variable Gender indicates a student's gender. The sampling weights are created by using the reciprocals of the probabilities of selection, as follows:

```
data StudentTotals;
   input Grade _TOTAL_;
   datalines;
7 1824
8 1025
9 1151
;
```

In the data set StudentTotals, the variable Grade is the stratification variable, and the variable _TOTAL_ contains the total numbers of students in the strata in the survey population.

The following statements demonstrate how you can estimate the average spending in the subgroup of male students:

```
title1 'Ice Cream Spending Analysis';
title2 'Domain Analysis by Gender';
proc surveyreg data=IceCreamDataDomain total=StudentTotals;
   strata Grade;
   model Spending = Income;
   domain Gender;
run;
```

Output 86.7.1 gives a summary of the domains.

Output 86.7.1 Domain Analysis Summary

Example 86.8: Variance Estimate Using the Jackknife Method

This example uses the stratified sample in the section "Stratified Sampling" on page 6538 to illustrate how to estimate the variances with replication methods.

As shown in the section "Stratified Sampling," the selected sample is saved in the SAS data set IceCream. The variable Grade that indicates a student's grade is the stratification variable. The variable Spending contains the dollar amount of each student's average weekly spending for ice cream. The variable Income specifies the household income, in thousands of dollars. The variable Kids indicates how many children are in a student's family. The variable Weight contains sampling weights.

In this example, we use the jackknife method to estimate the variance, saving the replicate weights generated by the procedure into a SAS data set:

```
title1 'Ice Cream Spending Analysis';
title2 'Use the jackknife method to estimate the variance';
proc surveyreg data=IceCream
   varmethod=JACKKNIFE(outweights=JKWeights);
   strata Grade;
   class Kids;
   model Spending = Income Kids / solution;
   weight Weight;
run;
```

The option VARMETHOD=JACKKNIFE requests the procedure to estimate the variance by using the jackknife method. The option OUTWEIGHTS=*JKWeights* provides a SAS data set named JKWeights that contains the replicate weights used in the computation.

Output 86.8.1 shows the summary of the data and the variance estimation method. There are a total of 40 replicates generated by the procedure.

Output 86.8.1 Variance Estimation Using the Jackknife Method

```
                    Ice Cream Spending Analysis
              Use the jackknife method to estimate the variance

                      The SURVEYREG Procedure

             Regression Analysis for Dependent Variable Spending

                           Data Summary

                Number of Observations               40
                Sum of Weights                   4000.0
                Weighted Mean of Spending       9.14130
                Weighted Sum of Spending        36565.2

                           Design Summary

                     Number of Strata             3

                        Variance Estimation

                   Method                    Jackknife
                   Number of Replicates             40
```

Output 86.8.2 displays the parameter estimates and their standard errors, as well as the tests of model effects that use the jackknife method.

Output 86.8.2 Variance Estimation Using the Jackknife Method

```
                          Tests of Model Effects

                Effect       Num DF    F Value    Pr > F

                Model             4     110.48    <.0001
                Intercept         1     133.30    <.0001
                Income            1     289.16    <.0001
                Kids              3       0.90    0.4525

        NOTE: The denominator degrees of freedom for the F tests is 37.
```

Output 86.8.2 *continued*

Estimated Regression Coefficients

Parameter	Estimate	Standard Error	t Value	Pr > |t|
Intercept	-26.086882	2.58771182	-10.08	<.0001
Income	0.776699	0.04567521	17.00	<.0001
Kids 1	0.888631	1.12799263	0.79	0.4358
Kids 2	1.545726	1.25598146	1.23	0.2262
Kids 3	-0.526817	1.42555453	-0.37	0.7138
Kids 4	0.000000	0.00000000	.	.

NOTE: The denominator degrees of freedom for the t tests is 37.
Matrix X'WX is singular and a generalized inverse was used to solve the normal equations. Estimates are not unique.

Output 86.8.3 prints the first 6 observation in the output data set JKWeights, which contains the replicate weights.

The data set JKWeights contains all the variable in the data set IceCream, in addition to the replicate weights variables named RepWt_1, RepWt_2, ..., RepWt_40.

For example, the first observation (student) from stratum Grade=7 is deleted to create the first replicate. Therefore, stratum Grade=7 is the donor stratum for the first replicate, and the corresponding replicate weights are saved in the variable RepWt_1.

Because the first observation is deleted in the first replicate, RepWt_1=0 for the first observation. For observations from strata other than the donor stratum Grade=7, their replicate weights remain the same as in the variable Weight, while the rest of the observations in stratum Grade=7 are multiplied by the reciprocal of the corresponding jackknife coefficient, 0.95 for the first replicate.

Output 86.8.3 The Jackknife Replicate Weights for the First 6 Observations

The Jackknife Weights for the First 6 Obs

Overview: SURVEYSELECT Procedure

The SURVEYSELECT procedure provides a variety of methods for selecting probability-based random samples. The procedure can select a simple random sample or can sample according to a complex multistage sample design that includes stratification, clustering, and unequal probabilities of selection. With probability sampling, each unit in the survey population has a known, positive probability of selection. This property of probability sampling avoids selection bias and enables you to use statistical theory to make valid inferences from the sample to the survey population.

To select a sample with PROC SURVEYSELECT, you input a SAS data set that contains the sampling frame or list of units from which the sample is to be selected. You also specify the selection method, the desired sample size or sampling rate, and other selection parameters. PROC SURVEYSELECT selects the sample and produces an output data set that contains the selected units, their selection probabilities, and their sampling weights. When you select a sample in multiple stages, you invoke the procedure separately for each stage of selection, inputting the frame and selection parameters for each current stage.

PROC SURVEYSELECT provides methods for both equal probability sampling and probability proportional to size (PPS) sampling. In equal probability sampling, each unit in the sampling frame, or in a stratum, has the same probability of being selected for the sample. In PPS sampling, a unit's selection probability is proportional to its size measure. For details about probability sampling methods, see Lohr (1999), Kish (1965, 1987), Kalton (1983), and Cochran (1977).

PROC SURVEYSELECT provides the following equal probability sampling methods:

- simple random sampling
- unrestricted random sampling (with replacement)
- systematic random sampling
- sequential random sampling

This procedure also provides the following probability proportional to size (PPS) methods:

- PPS sampling without replacement
- PPS sampling with replacement
- PPS systematic sampling
- PPS algorithms for selecting two units per stratum
- sequential PPS sampling with minimum replacement

The procedure uses fast, efficient algorithms for these sample selection methods. Thus, it performs well even for large input data sets or sampling frames, which might occur in practice for large-scale sample surveys.

PROC SURVEYSELECT can perform stratified sampling by selecting samples independently within the specified strata, or nonoverlapping subgroups of the survey population. Stratification controls the distribution of the sample size in the strata. It is widely used in practice toward meeting a variety of survey objectives. For example, with stratification you can ensure adequate sample sizes for subgroups of interest, including small subgroups, or you can use stratification toward improving the precision of the overall estimates. When you use a systematic or sequential selection method, PROC SURVEYSELECT can also sort by control variables within strata for the additional control of implicit stratification.

For stratified sampling, PROC SURVEYSELECT provides survey design methods to allocate the total sample size among the strata. Available allocation methods include proportional, Neyman, and optimal allocation. Optimal allocation maximizes the estimation precision within the available resources, taking into account stratum sizes, costs, and variances.

PROC SURVEYSELECT provides replicated sampling, where the total sample is composed of a set of replicates, and each replicate is selected in the same way. You can use replicated sampling to study variable nonsampling errors, such as variability in the results obtained by different interviewers. You can also use replication to compute standard errors for the combined sample estimates.

Getting Started: SURVEYSELECT Procedure

In this example, an Internet service provider conducts a customer satisfaction survey. The survey population consists of the company's current subscribers. The company plans to select a sample of customers from this population, interview the selected customers, and then make inferences about the entire survey population from the sample data.

The SAS data set Customers contains the sampling frame, which is the list of units in the survey population. The sample of customers will be selected from this sampling frame. The data set Customers is constructed from the company's customer database. It contains one observation for each customer, with a total of 13,471 observations.

The following PROC PRINT statements display the first 10 observations of the data set Customers and produce Figure 87.1:

```
title1 'Customer Satisfaction Survey';
title2 'First 10 Observations';
proc print data=Customers(obs=10);
run;
```

8	832-90-2397	AL	Old	1563
9	586-45-0178	GA	New	615
10	801-24-5317	SC	New	728

In the SAS data set Customers, the variable CustomerID uniquely identifies each customer. The variable State contains the state of the customer's address. The company has customers in four states: Georgia (GA), Alabama (AL), Florida (FL), and South Carolina (SC). The variable Type equals 'Old' if the customer has subscribed to the service for more than one year; otherwise, the variable Type equals 'New'. The variable Usage contains the customer's average monthly service usage, in minutes.

The following sections illustrate the use of PROC SURVEYSELECT for probability sampling with three different designs for the customer satisfaction survey. All three designs are one-stage, with customers as the sampling units. The first design is simple random sampling without stratification. In the second design, customers are stratified by state and type, and the sample is selected by simple random sampling within strata. In the third design, customers are sorted within strata by usage, and the sample is selected by systematic random sampling within strata.

Simple Random Sampling

The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set by using simple random sampling:

```
title1 'Customer Satisfaction Survey';
title2 'Simple Random Sampling';
proc surveyselect data=Customers
   method=srs n=100 out=SampleSRS;
run;
```

The PROC SURVEYSELECT statement invokes the procedure. The DATA= option names the SAS data set Customers as the input data set from which to select the sample. The METHOD=SRS option specifies simple random sampling as the sample selection method. In simple random sampling, each unit has an equal probability of selection, and sampling is without replacement. Without-replacement sampling means that a unit cannot be selected more than once. The N=100 option specifies a sample size of 100 customers. The OUT= option stores the sample in the SAS data set named SampleSRS.

Figure 87.2 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A sample of 100 customers is selected from the data set Customers by simple random sampling. With simple random sampling and no stratification in the sample design, the selection probability is the same for all units in the sample. In this sample, the selection probability for each customer equals 0.007423, which is the sample size (100) divided by the population size (13,471). The sampling weight equals 134.71 for each customer in the sample, where the weight is the inverse of the selection probability. If you specify the STATS option, PROC SURVEYSELECT includes the selection probabilities and sampling weights in the output data set. (This information is always included in the output data set for more complex designs.)

The random number seed is 39647. PROC SURVEYSELECT uses this number as the initial seed for random number generation. Because the SEED= option is not specified in the PROC SURVEYSELECT statement, the seed value is obtained by using the time of day from the computer's clock. You can specify SEED=39647 to reproduce this sample.

Figure 87.2 Sample Selection Summary

                Selection Method    Simple Random Sampling

                   Input Data Set            CUSTOMERS
                   Random Number Seed            39647
                   Sample Size                     100
                   Selection Probability      0.007423
                   Sampling Weight              134.71
                   Output Data Set           SAMPLESRS
```

The sample of 100 customers is stored in the SAS data set SampleSRS. PROC SURVEYSELECT does not display this output data set. The following PROC PRINT statements display the first 20 observations of SampleSRS:

```
title1 'Customer Satisfaction Survey';
title2 'Sample of 100 Customers, Selected by SRS';
title3 '(First 20 Observations)';
proc print data=SampleSRS(obs=20);
run;
```

Figure 87.3 displays the first 20 observations of the output data set SampleSRS, which contains the sample of customers. This data set includes all the variables from the DATA= input data set Customers. If you do not want to include all variables, you can use the ID statement to specify which variables to copy from the input data set to the output (sample) data set.

Stratified Sampling

In this section, stratification is added to the sample design for the customer satisfaction survey. The sampling frame, or list of all customers, is stratified by State and Type. This divides the sampling frame into nonoverlapping subgroups formed from the values of the State and Type variables. Samples are then selected independently within the strata.

PROC SURVEYSELECT requires that the input data set be sorted by the STRATA variables. The following PROC SORT statements sort the Customers data set by the stratification variables State and Type:

```
proc sort data=Customers;
   by State Type;
run;
```

The following PROC FREQ statements display the crosstabulation of the Customers data set by State and Type:

```
title1 'Customer Satisfaction Survey';
title2 'Strata of Customers';
proc freq data=Customers;
   tables State*Type;
run;
```

Figure 87.4 presents the table of State by Type for the 13,471 customers. There are four states and two levels of Type, forming a total of eight strata.

Figure 87.4 Stratification of Customers by State and Type

```
                    Customer Satisfaction Survey
                        Strata of Customers

         |  25.89 |  14.40 |  40.29
         |  64.26 |  35.74 |
         |  40.65 |  39.66 |
---------+--------+--------+
SC       |   1684 |    875 |   2559
         |  12.50 |   6.50 |  19.00
         |  65.81 |  34.19 |
         |  19.63 |  17.89 |
---------+--------+--------+
Total        8580     4891    13471
            63.69    36.31   100.00
```

The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set according to the stratified sample design:

```
title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling';
proc surveyselect data=Customers
      method=srs n=15
      seed=1953 out=SampleStrata;
   strata State Type;
run;
```

The STRATA statement names the stratification variables State and Type. In the PROC SURVEYSELECT statement, the METHOD=SRS option specifies simple random sampling. The N=15 option specifies a sample size of 15 customers for each stratum. If you want to specify different sample sizes for different strata, you can use the N=*SAS-data-set* option to name a secondary data set that contains the stratum sample sizes. The SEED=1953 option specifies '1953' as the initial seed for random number generation.

Figure 87.5 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A total of 120 customers are selected.

Figure 87.5 Sample Selection Summary

```

                                    Type

                   Input Data Set            CUSTOMERS
                   Random Number Seed             1953
                   Stratum Sample Size              15
                   Number of Strata                  8
                   Total Sample Size               120
                   Output Data Set         SAMPLESTRATA
```

The following PROC PRINT statements display the first 30 observations of the output data set SampleStrata:

```
title1 'Customer Satisfaction Survey';
title2 'Sample Selected by Stratified Design';
title3 '(First 30 Observations)';
proc print data=SampleStrata(obs=30);
run;
```

Figure 87.6 displays the first 30 observations of the output data set SampleStrata, which contains the sample of 120 customers, 15 customers from each of the eight strata. The variable SelectionProb contains the selection probability for each customer in the sample. Because customers are selected with equal probability within strata in this design, the selection probability equals the stratum sample size (15) divided by the stratum population size. The selection probabilities differ from stratum to stratum because the stratum population sizes differ. The selection probability for each customer in the first stratum (State='AL' and Type='New') is 0.012116, and the selection probability for customers in the second stratum is 0.021246. The variable SamplingWeight contains the sampling weights, which are computed as inverse selection probabilities.

Stratified Sampling with Control Sorting

The next sample design for the customer satisfaction survey uses stratification by State, as well as control sorting by Type and Usage within State. After stratification and control sorting, customers are selected by systematic random sampling within strata. Selection by systematic sampling, together with control sorting before selection, spreads the sample uniformly over the range of type and usage values within each stratum or state. The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set according to this design:

```
title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling with Control Sorting';
proc surveyselect data=Customers
      method=sys rate=.02
      seed=1234 out=SampleControl;
   strata State;
   control Type Usage;
run;
```

The STRATA statement names the stratification variable State. The CONTROL statement names the control variables Type and Usage. In the PROC SURVEYSELECT statement, the METHOD=SYS option requests systematic random sampling. The RATE=.02 option specifies a sampling rate of 2% for each stratum. The SEED=1234 option specifies the initial seed for random number generation.

Figure 87.7 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A sample of 271 customers is selected by using systematic random sampling within strata determined by State. The sampling frame Customers is sorted by control variables Type and Usage within strata. The type of sorting is serpentine, which is the default when SORT=NEST is not specified. See the section "Sorting by CONTROL Variables" on page 6644 for a description of serpentine sorting. The sorted data set replaces the input data set. (To leave the input data set unsorted and store the sorted input data in another data set, use the OUTSORT= option.) The output data set SampleControl contains the sample of customers.

Figure 87.7 Sample Selection Summary

```

```

Syntax: SURVEYSELECT Procedure

The following statements are available in PROC SURVEYSELECT:

PROC SURVEYSELECT *options* ;
  STRATA *variables* < / *options* > ;
  CONTROL *variables* ;
  SIZE *variable* ;
  ID *variables* ;

The PROC SURVEYSELECT statement invokes the procedure and optionally identifies input and output data sets. It also specifies the selection method, the sample size, and other sample design parameters. The SURVEYSELECT statement is required.

The SIZE statement identifies the variable that contains the size measures of the sampling units. It is required for any selection method that is probability proportional to size (PPS).

The remaining statements are optional. The STRATA statement identifies a variable or set of variables that stratify the input data set. When you specify a STRATA statement, PROC SURVEYSELECT selects samples independently from the strata formed by the STRATA variables. The STRATA statement also provides options to allocate the total sample size among the strata.

The CONTROL statement identifies variables for ordering units within strata. It can be used for systematic and sequential sampling methods. The ID statement identifies variables to copy from the input data set to the output data set of selected units.

The rest of this section gives detailed syntax information about the CONTROL, ID, SIZE, and STRATA statements in alphabetical order after the description of the PROC SURVEYSELECT statement.

PROC SURVEYSELECT Statement

PROC SURVEYSELECT *options* ;

The PROC SURVEYSELECT statement invokes the procedure and optionally identifies input and output data sets. If you do not name a DATA= input data set, the procedure selects the sample from the most recently created SAS data set. If you do not name an OUT= output data set to contain the sample of selected units, the procedure still creates an output data set and names it according to the DATA*n* convention.

The PROC SURVEYSELECT statement also specifies the sample selection method, the sample size, and other sample design parameters. If you do not specify a selection method, PROC SURVEYSELECT uses simple random sampling (METHOD=SRS) if there is no SIZE statement. If you do specify a SIZE statement and do not specify a selection method, PROC SURVEYSELECT uses probability proportional to size selection without replacement (METHOD=PPS). You must specify the sample size or sampling rate unless you request a method that selects two units from each stratum (METHOD=PPS_BREWER or METHOD=PPS_MURTHY).

You can use the SAMPSIZE=*n* option to specify the sample size, or you can use the SAMPSIZE=*SAS-data-set* option to name a secondary input data set that contains stratum sample sizes. You can also specify stratum sampling rates, minimum size measures, maximum size measures, and certainty size measures in the secondary input data set. See the descriptions of the SAMPSIZE=, SAMPRATE=, MINSIZE=, MAXSIZE=, CERTSIZE=, and CERTSIZE=P= options for more information. You can name only one secondary input data set in each invocation of the procedure. See the section "Secondary Input Data Set" on page 6656 for details.

Table 87.1 lists the options available with the PROC SURVEYSELECT statement. Descriptions follow in alphabetical order.

Table 87.1 PROC SURVEYSELECT Statement Options

Task	Options
Specify the input data set	DATA=
Specify output data sets	OUT= OUTSORT=
Suppress displayed output	NOPRINT
Specify selection method	METHOD=
Specify sample size	SAMPSIZE= SELECTALL
Specify sampling rate	SAMPRATE= NMIN= NMAX=
Specify number of replicates	REPS=
Adjust size measures	MINSIZE= MAXSIZE=
Specify certainty size measures	CERTSIZE= CERTSIZE=P=
Specify sorting type	SORT=
Specify random number seed	SEED=
Control OUT= contents	JTPROBS OUTALL OUTHITS OUTSEED OUTSIZE STATS

You can specify the following options in the PROC SURVEYSELECT statement.

CERTSIZE

requests certainty selection, where the certainty size values are provided in the secondary input data set. Use the CERTSIZE option when you have already named the secondary data set in another option, such as the SAMPSIZE=*SAS-data-set* option. See the section "Secondary Input Data Set" on page 6656 for details.

In certainty selection, PROC SURVEYSELECT automatically selects all sampling units with size measures greater than or equal to the stratum certainty size values. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method specified in the METHOD= option. The CERTSIZE option is available for METHOD=PPS and METHOD=PPS_SAMPFORD.

You provide the stratum certainty size values in the secondary input data set variable _CERTSIZE_. Each certainty size value must be a positive number. The variable Certain in the OUT= data set identifies the certainty selections, which have selection probabilities equal to 1.

If you want to specify a single certainty size value for all strata, you can use the CERTSIZE=*certain* option.

CERTSIZE=*certain*

specifies the certainty size value. PROC SURVEYSELECT automatically selects all sampling units with size measures greater than or equal to the value *certain*. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method specified in the METHOD= option. The CERTSIZE= option is available for METHOD=PPS and METHOD=PPS_SAMPFORD.

The value of *certain* must be a positive number. The variable Certain in the OUT= data set identifies the certainty selections, which have selection probabilities equal to 1.

If you request a stratified sample design with the STRATA statement and specify the CERTSIZE=*certain* option, PROC SURVEYSELECT uses the value *certain* for all strata. If you do not want to use the same certainty size for all strata, use the CERTSIZE=*SAS-data-set* option to specify a certainty size value for each stratum.

CERTSIZE=*SAS-data-set*

names a SAS data set that contains certainty size values for the strata. PROC SURVEYSELECT automatically selects all sampling units with size measures greater than or equal to the stratum certainty size values. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method specified in the METHOD= option. The CERTSIZE= option is available for METHOD=PPS and METHOD=PPS_SAMPFORD.

You provide the stratum certainty size values in the CERTSIZE= data set variable _CERTSIZE_. Each certainty size value must be a positive number. The variable Certain in the OUT= data set identifies the certainty selections, which have selection probabilities equal to 1.

The CERTSIZE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the CERTSIZE= data set as in the DATA= data set. The CERTSIZE= data set must include a variable named _CERTSIZE_ that contains the certainty size value for each stratum. The CERTSIZE= data set is a secondary input data set. See the section "Secondary Input Data Set" on page 6656 for details. You can name only one secondary input data set in each invocation of the procedure.

If you want to specify a single certainty size value for all strata, you can use the CERTSIZE=*certain* option.

CERTSIZE=P

requests certainty proportion selection, where the stratum certainty proportions are provided in the secondary input data set. Use the CERTSIZE=P option when you have already named the secondary data set in another option, such as the SAMPSIZE=*SAS-data-set* option. See the section "Secondary Input Data Set" on page 6656 for details.

In certainty proportion selection, PROC SURVEYSELECT automatically selects all sampling units with size measures greater than or equal to the stratum certainty proportion of the total stratum size. The procedure repeats this process with the remaining units until no more certainty units are selected. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method specified in the METHOD= option. The CERTSIZE=P option is available for METHOD=PPS and METHOD=PPS_SAMPFORD.

You provide the stratum certainty proportions in the secondary input data set variable _CERTP_. Each certainty proportion must be a positive number. You can specify a proportion value as a number between 0 and 1. Or you can specify a proportion value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

The variable Certain in the OUT= data set identifies the certainty selections, which have selection probabilities equal to 1.

If you want to specify a single certainty proportion for all strata, you can use the CERTSIZE=P=*p* option.

CERTSIZE=P=*p*

specifies the certainty proportion. PROC SURVEYSELECT automatically selects all sampling units with size measures greater than or equal to the proportion p of the total stratum size. The procedure repeats this process with the remaining units until no more certainty units are selected. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method specified in the METHOD= option. The CERTSIZE=P= option is available for METHOD=PPS and METHOD=PPS_SAMPFORD.

The value of p must be a positive number. You can specify p as a number between 0 and 1. Or you can specify p in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

The variable Certain in the OUT= data set identifies the certainty selections, which have selection probabilities equal to 1.

If you request a stratified sample design with the STRATA statement and specify the CERTSIZE=P=p option, PROC SURVEYSELECT uses the certainty proportion p for all strata. If you do not want to use the same certainty proportion for all strata, use the CERTSIZE=P=*SAS-data-set* option to specify a certainty proportion for each stratum.

CERTSIZE=P=*SAS-data-set*

names a SAS data set that contains the certainty proportions for the strata. PROC SURVEYSELECT automatically selects all sampling units with size measures greater than

or equal to the certainty proportion of the total stratum size. The procedure repeats this process with the remaining units until no more certainty units are selected. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method specified in the METHOD= option. The CERTSIZE=P= option is available for METHOD=PPS and METHOD=PPS_SAMPFORD.

You provide the stratum certainty proportions in the CERTSIZE=P= data set variable _CERTP_. Each certainty proportion must be a positive number. You can specify a proportion value as a number between 0 and 1. Or you can specify a proportion value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

The variable Certain in the OUT= data set identifies the certainty selections, which have selection probabilities equal to 1.

The CERTSIZE=P= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the CERTSIZE=P= data set as in the DATA= data set. The CERTSIZE=P= data set must include a variable named _CERTP_ that contains the certainty proportion for each stratum. The CERTSIZE=P= data set is a secondary input data set. See the section "Secondary Input Data Set" on page 6656 for details. You can name only one secondary input data set in each invocation of the procedure.

If you want to specify a single certainty proportion for all strata, you can use the CERTSIZE=P=*p* option.

DATA=*SAS-data-set*

names the SAS data set from which PROC SURVEYSELECT selects the sample. If you omit the DATA= option, the procedure uses the most recently created SAS data set. In sampling terminology, the input data set is the *sampling frame*, or list of units from which the sample is selected.

JTPROBS

includes joint probabilities of selection in the OUT= output data set. This option is available for the following probability proportional to size selection methods: METHOD=PPS, METHOD=PPS_SAMPFORD, and METHOD=PPS_WR. By default, PROC SURVEYSELECT outputs joint selection probabilities for METHOD=PPS_BREWER and METHOD=PPS_MURTHY, which select two units per stratum.

For details about computation of joint selection probabilities for a particular sampling method, see the method description in the section "Sample Selection Methods" on page 6645. For more information about the contents of the output data set, see the section "Sample Output Data Set" on page 6657.

MAXSIZE

requests adjustment of size measures according to the stratum maximum size values provided in the secondary input data set. Use the MAXSIZE option when you have already named the secondary input data set in another option, such as the SAMPSIZE=*SAS-data-set* option. See the section "Secondary Input Data Set" on page 6656 for details.

You provide the stratum maximum size values in the secondary input data set variable _MAXSIZE_. Each maximum size value must be a positive number.

When a size measure exceeds the specified maximum value for its stratum, PROC SURVEYSELECT adjusts the size measure downward to equal the maximum size value. The variable AdjustedSize in the OUT= data set contains the adjusted size measures.

The MAXSIZE option is available when you use a SIZE statement for probability proportional to size selection and a STRATA statement.

If you want to specify a single maximum size value for all strata, you can use the MAXSIZE=*max* option.

MAXSIZE=*max*

specifies the maximum size value. The value of *max* must be a positive number.

When any size measure exceeds the value *max*, PROC SURVEYSELECT adjusts the size measure downward to equal *max*. The variable AdjustedSize in the OUT= data set contains the adjusted size measures.

The MAXSIZE=*max* option is available when you use a SIZE statement for selection with probability proportional to size.

If you request a stratified sample design with the STRATA statement and specify the MAXSIZE=*max* option, PROC SURVEYSELECT uses the maximum size *max* for all strata. If you do not want to use the same maximum size for all strata, use the MAXSIZE=*SAS-data-set* option to specify a maximum size value for each stratum.

MAXSIZE=*SAS-data-set*

names a SAS data set that contains the maximum size values for the strata. You provide the stratum maximum size values in the MAXSIZE= data set variable _MAXSIZE_. Each maximum size value must be a positive number.

When any size measure exceeds the maximum size value for its stratum, PROC SURVEYSELECT adjusts the size measure downward to equal the maximum size value. The variable AdjustedSize in the OUT= data set contains the adjusted size measures.

The MAXSIZE=*SAS-data-set* option is available when you use a SIZE statement for probability proportional to size selection and a STRATA statement for stratified selection.

The MAXSIZE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the MAXSIZE= data set as in the DATA= data set. The MAXSIZE= data set must include a variable named _MAXSIZE_ that contains the maximum size value for each stratum. The MAXSIZE= data set is a secondary input data set. See the section "Secondary Input Data Set" on page 6656 for details. You can name only one secondary input data set in each invocation of the procedure.

If you want to specify a single maximum size value for all strata, you can use the MAXSIZE=*max* option.

METHOD=*name*

M=*name*

specifies the method for sample selection. If you do not specify the METHOD= option, by default, PROC SURVEYSELECT uses simple random sampling (METHOD=SRS) if there is no SIZE statement. If you specify a SIZE statement, the default selection method is probability proportional to size without replacement (METHOD=PPS).

Valid values for *name* are as follows:

PPS

requests selection with probability proportional to size and without replacement. See the section "PPS Sampling without Replacement" on page 6648 for details. If you specify METHOD=PPS, you must name the size measure variable in the SIZE statement.

PPS_BREWER

BREWER

requests selection according to Brewer's method. Brewer's method selects two units from each stratum with probability proportional to size and without replacement. See the section "Brewer's PPS Method" on page 6652 for details. If you specify METHOD=PPS_BREWER, you must name the size measure variable in the SIZE statement. You do not need to specify the sample size with the SAMPSIZE= option, because Brewer's method selects two units from each stratum.

PPS_MURTHY

MURTHY

requests selection according to Murthy's method. Murthy's method selects two units from each stratum with probability proportional to size and without replacement. See the section "Murthy's PPS Method" on page 6653 for details. If you specify METHOD=PPS_MURTHY, you must name the size measure variable in the SIZE statement. You do not need to specify the sample size with the SAMPSIZE= option, because Murthy's method selects two units from each stratum.

PPS_SAMPFORD

SAMPFORD

requests selection according to Sampford's method. Sampford's method selects units with probability proportional to size and without replacement. See the section "Sampford's PPS Method" on page 6653 for details. If you specify METHOD=PPS_SAMPFORD, you must name the size measure variable in the SIZE statement.

PPS_SEQ

CHROMY

requests sequential selection with probability proportional to size and with minimum replacement. This method is also known as Chromy's method. See the section "PPS Sequential Sampling" on page 6651 for details. If you specify METHOD=PPS_SEQ, you must name the size measure variable in the SIZE statement.

PPS_SYS

requests systematic selection with probability proportional to size. See the section "PPS Systematic Sampling" on page 6650 for details. If you specify METHOD=PPS_SYS, you must name the size measure variable in the SIZE statement.

PPS_WR

requests selection with probability proportional to size and with replacement. See the section "PPS Sampling with Replacement" on page 6650 for details. If you specify METHOD=PPS_WR, you must name the size measure variable in the SIZE statement.

SEQ

requests sequential selection according to Chromy's method. If you specify METHOD=SEQ and do not specify a size measure variable with the SIZE statement, PROC SURVEYSELECT uses sequential zoned selection with equal probability and without replacement. See the section "Sequential Random Sampling" on page 6647 for details. If you specify METHOD=SEQ and also name a size measure variable in the SIZE statement, PROC SURVEYSELECT uses METHOD=PPS_SEQ, which is sequential selection with probability proportional to size and with minimum replacement. See the section "PPS Sequential Sampling" on page 6651 for more information.

SRS

requests simple random sampling, which is selection with equal probability and without replacement. See the section "Simple Random Sampling" on page 6646 for details. METHOD=SRS is the default if you do not specify the METHOD= option and also do not specify a SIZE statement.

SYS

requests systematic random sampling. If you specify METHOD=SYS and do not specify a size measure variable with the SIZE statement, PROC SURVEYSELECT uses systematic selection with equal probability. See the section "Systematic Random Sampling" on page 6647 for more information. If you specify METHOD=SYS and also name a size measure variable in the SIZE statement, PROC SURVEYSELECT uses METHOD=PPS_SYS, which is systematic selection with probability proportional to size. See the section "PPS Systematic Sampling" on page 6650 for details.

URS

requests unrestricted random sampling, which is selection with equal probability and with replacement. See the section "Unrestricted Random Sampling" on page 6646 for details.

MINSIZE

requests adjustment of size measures according to the stratum minimum size values provided in the secondary input data set. Use the MINSIZE option when you have already named the secondary input data set in another option, such as the SAMPSIZE=*SAS-data-set* option. See the section "Secondary Input Data Set" on page 6656 for details.

You provide the stratum minimum size values in the secondary input data set variable _MINSIZE_. Each minimum size value must be a positive number.

When a size measure is less than the specified minimum value for its stratum, PROC SURVEYSELECT adjusts the size measure upward to equal the minimum size value. The variable AdjustedSize in the OUT= data set contains the adjusted size measures.

The MINSIZE option is available when you specify a SIZE statement for probability proportional to size selection and a STRATA statement.

If you want to specify a single minimum size value for all strata, you can use the MINSIZE=*min* option.

MINSIZE=*min*

specifies the minimum size value. The value of *min* must be a positive number.

When any size measure is less than the value *min*, PROC SURVEYSELECT adjusts the size measure upward to equal *min*. The variable AdjustedSize in the OUT= data set contains the adjusted size measures.

The MINSIZE=*min* option is available when you specify a SIZE statement for selection with probability proportional to size.

If you request a stratified sample design with the STRATA statement and specify the MINSIZE=*min* option, PROC SURVEYSELECT uses the minimum size *min* for all strata. If you do not want to use the same minimum size for all strata, use the MINSIZE=*SAS-data-set* option to specify a minimum size value for each stratum.

MINSIZE=*SAS-data-set*

names a SAS data set that contains the minimum size values for the strata. You provide the stratum minimum size values in the MINSIZE= data set variable _MINSIZE_. Each minimum size value must be a positive number.

When any size measure is less than the minimum size value for its stratum, PROC SURVEYSELECT adjusts the size measure upward to equal the minimum size measure. The variable AdjustedSize in the OUT= data set contains the adjusted size measures.

The MINSIZE=*SAS-data-set* option is available when you specify a SIZE statement for probability proportional to size selection and a STRATA statement.

The MINSIZE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the MINSIZE= data set as in the DATA= data set. The MINSIZE= data set must include a variable named _MINSIZE_ that contains the minimum size measure for each stratum. The MINSIZE= data set is a secondary input data set. See the section "Secondary Input Data Set" on page 6656 for details. You can name only one secondary input data set in each invocation of the procedure.

If you want to specify a single minimum size measure for all strata, you can use the MINSIZE=*min* option.

NMAX=*n*

specifies the maximum stratum sample size *n* for the SAMPRATE= option. When you specify the SAMPRATE= option, PROC SURVEYSELECT calculates the stratum sample size by multiplying the total number of units in the stratum by the specified sampling rate. If this sample size is greater than the value NMAX=*n*, then PROC SURVEYSELECT selects only *n* units.

The maximum sample size *n* must be a positive integer. The NMAX= option is available only with the SAMPRATE= option, which can be used with equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ).

NMIN=*n*

specifies the minimum stratum sample size *n* for the SAMPRATE= option. When you specify the SAMPRATE= option, PROC SURVEYSELECT calculates the stratum sample size by multiplying the total number of units in the stratum by the specified sampling rate. If this sample size is less than the value NMIN=*n*, then PROC SURVEYSELECT selects *n* units.

The minimum sample size *n* must be a positive integer. The NMIN= option is available only with the SAMPRATE= option, which can be used with equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ).

NOPRINT

suppresses the display of all output. You can use the NOPRINT option when you want only to create an output data set. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, "Using the Output Delivery System."

OUT=*SAS-data-set*

names the output data set that contains the sample. If you omit the OUT= option, the data set is named DATA*n*, where *n* is the smallest integer that makes the name unique.

The output data set contains the units selected for the sample, as well as design information and selection statistics, depending on the selection method and output options you specify. See descriptions of the options JTPROBS, OUTHITS, OUTSEED, OUTSIZE, and STATS, which specify information to include in the output data set. See the section "Sample Output Data Set" on page 6657 for details about the contents of the output data set.

By default, the output data set contains only those units selected for the sample. To include all observations from the input data set in the output data set, use the OUTALL option.

By default, the output data set includes one observation for each unit selected. When the unit is selected multiple times, which can occur when you use with-replacement or with-minimum-replacement selection methods, the OUT= data set variable NumberHits contains the number of hits or selections for each unit. To produce a separate observation for each hit or selection, specify the OUTHITS option.

If you specify the NOSAMPLE option in the STRATA statement, PROC SURVEYFREQ allocates the total sample size among the strata but does not select the sample. In this case, the OUT= data set contains the allocated sample sizes. See the section "Allocation Output Data Set" on page 6660 for details.

OUTALL

includes all observations from the input data set in the output data set. By default, the output data set includes only those observations selected for the sample. When you specify the OUTALL option, the output data set includes all observations from DATA= and also contains a variable to indicate each observation's selection status. The variable Selected equals 1 for an observation selected for the sample, and equals 0 for an observation not selected. For information about the contents of the output data set, see the section "Sample Output Data Set" on page 6657.

The OUTALL option is available only for equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ).

OUTHITS

includes a separate observation in the output data set for each selection when the same unit is selected more than once. A unit can be selected more than once only by methods that select with replacement or with minimum replacement, which include METHOD=URS, METHOD=PPS_WR, METHOD=PPS_SYS, and METHOD=PPS_SEQ.

By default, the output data set contains one observation for each selected unit, even if it is selected more than once, and the variable NumberHits contains the number of hits or selections for that unit. See the section "Sample Output Data Set" on page 6657 for details about the contents of the output data set.

The OUTHITS option is available for selection methods that select with replacement or with minimum replacement (METHOD=URS, METHOD=PPS_WR, METHOD=PPS_SYS, and METHOD=PPS_SEQ).

OUTSEED

includes the initial seed for each stratum in the output data set. The variable InitialSeed contains the stratum initial seeds. See the section "Sample Output Data Set" on page 6657 for details about the contents of the output data set.

To reproduce the same sample for any stratum in a subsequent execution of PROC SURVEYSELECT, you can specify the same stratum initial seed with the SEED=*SAS-data-set* option, along with the same sample selection parameters. See the section "Sample Selection Methods" on page 6645 for information about initial seeds and random number generation in PROC SURVEYSELECT.

The "Sample Selection Summary" table displays the initial random number seed for the entire sample selection, which is the same as the initial seed for the first stratum when the design is stratified. To reproduce the entire sample, you can specify this same seed value in the SEED= option, along with the same sample selection parameters.

OUTSIZE

includes additional design and sampling frame parameters in the output data set. If you specify the OUTSIZE option, PROC SURVEYSELECT includes the sample size or sampling rate in the output data set. When you specify the OUTSIZE option and also specify the SIZE statement, the procedure outputs the size measure total for the sampling frame. If you do not specify the SIZE statement, the procedure outputs the total number of sampling units in the frame. Also, PROC SURVEYSELECT includes the minimum size measure if you specify

the MINSIZE= option, the maximum size measure if you specify the MAXSIZE= option, and the certainty size measure if you specify the CERTSIZE= option.

If you have a stratified design, the output data set includes the stratum-level values of these parameters. Otherwise, the output data set includes the overall population-level values.

For information about the contents of the output data set, see the section "Sample Output Data Set" on page 6657.

OUTSORT=*SAS-data-set*

names an output data set that contains the sorted input data set. This option is available when you specify a CONTROL statement for systematic or sequential selection methods (METHOD=SYS, METHOD=PPS_SYS, METHOD=SEQ, and METHOD=PPS_SEQ). PROC SURVEYSELECT sorts the input data set by the CONTROL variables within strata before selecting the sample.

If you specify CONTROL variables but do not name an output data set with the OUTSORT= option, then the sorted data set replaces the input data set.

REPS=*nreps*

specifies the number of sample replicates. The value of *nreps* must be a positive integer.

When you specify the REPS= option, PROC SURVEYSELECT selects *nreps* independent samples, each with the same specified sample size or sampling rate and the same sample design. The variable Replicate in the OUT= data set contains the sample replicate number.

You can use replicated sampling to provide a simple method of variance estimation for any form of statistic, as well as to evaluate variable nonsampling errors such as interviewer differences. See Lohr (1999), Wolter (1985), Kish (1965, 1987), and Kalton (1983) for information about replicated sampling.

SAMPRATE=*r*

RATE=*r*

specifies the sampling rate, which is the proportion of units to select for the sample. The sampling rate *r* must be a positive number. You can specify *r* as a number between 0 and 1. Or you can specify *r* in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

The SAMPRATE= option is available only for equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ). For systematic random sampling (METHOD=SYS), PROC SURVEYSELECT uses the inverse of the sampling rate *r* as the interval. See the section "Systematic Random Sampling" on page 6647 for details. For other selection methods, PROC SURVEYSELECT converts the sampling rate *r* to the sample size before selection by multiplying the total number of units in the stratum or frame by the sampling rate and rounding up to the nearest integer.

If you request a stratified sample design with the STRATA statement and specify the SAMPRATE=*r* option, PROC SURVEYSELECT uses the sampling rate *r* for each stratum. If you do not want to use the same sampling rate for each stratum, use the SAMPRATE=(*values*) option or the SAMPRATE=*SAS-data-set* option to specify a sampling rate for each stratum.

SAMPRATE=(*values*)

RATE=(*values*)

specifies stratum sampling rates. You can separate *values* with blanks or commas. The number of SAMPRATE= values must equal the number of strata in the input data set.

List the stratum sampling rate values in the order in which the strata appear in the input data set. When you use the SAMPRATE=(*values*) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

Each stratum sampling rate value must be a positive number. You can specify a rate value as a number between 0 and 1. Or you can specify a rate value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

The SAMPRATE= option is available only for equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ). For systematic random sampling (METHOD=SYS), PROC SURVEYSELECT uses the inverse of the stratum sampling rate as the interval for the stratum. See the section "Systematic Random Sampling" on page 6647 for details about systematic sampling. For other selection methods, PROC SURVEYSELECT converts the stratum sampling rate to a stratum sample size before selection by multiplying the total number of units in the stratum by the sampling rate and rounding up to the nearest integer.

SAMPRATE=*SAS-data-set*

RATE=*SAS-data-set*

names a SAS data set that contains stratum sampling rates. The SAMPRATE= data set should have a variable _RATE_ that contains the sampling rate for each stratum.

Each sampling rate value must be a positive number. You can specify each value as a number between 0 and 1. Or you can specify a value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

The SAMPRATE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the SAMPRATE= data set as in the DATA= data set.

The SAMPRATE= option is available only for equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ). For systematic random sampling (METHOD=SYS), PROC SURVEYSELECT uses the inverse of the stratum sampling rate as the interval for the stratum. See the section "Systematic Random Sampling" on page 6647 for details. For other selection methods, PROC SURVEYSELECT converts the stratum sampling rate to the stratum sample size before selection by multiplying the total number of units in the stratum by the sampling rate and rounding up to the nearest integer.

SAMPSIZE=*n*

N=*n*

specifies the sample size, which is the number of units to select for the sample. The sample size *n* must be a positive integer. For selection methods that select without replacement, the sample size *n* must not exceed the number of units in the input data set.

If you specify the ALLOC= option in the STRATA statement, PROC SURVEYSELECT allocates the total sample size among the strata according to the allocation method you request in the ALLOC= option. In this case, SAMPSIZE=*n* specifies the total sample size to be allocated among the strata.

Otherwise, if you specify the SAMPSIZE=*n* option and request a stratified sample design with the STRATA statement, PROC SURVEYSELECT selects *n* units from each stratum. For methods that select without replacement, the sample size *n* must not exceed the number of units in any stratum. If you do not want to select the same number of units from each stratum, use the SAMPSIZE=(*values*) option or the SAMPSIZE=*SAS-data-set* option to specify a sample size for each stratum.

For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units available in the stratum. If you specify the SELECTALL option, PROC SURVEYSELECT selects all stratum units when the stratum sample size exceeds the number of units in the stratum.

SAMPSIZE=(*values***)**

N=(*values***)**

specifies sample sizes for the strata. You can separate *values* with blanks or commas. The number of SAMPSIZE= values must equal the number of strata in the input data set.

List the stratum sample size values in the order in which the strata appear in the input data set. When you use the SAMPSIZE=(*values*) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

Each stratum sample size value must be a positive integer. For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units available in the stratum. If you specify the SELECTALL option, PROC SURVEYSELECT selects all stratum units when the stratum sample size exceeds the number of units in the stratum.

SAMPSIZE=*SAS-data-set*

N=*SAS-data-set*

names a SAS data set that contains the sample sizes for the strata.

You provide the stratum sample sizes in the SAMPSIZE= input data set variable named _NSIZE_ or SampleSize. Each stratum sample size value must be a positive integer.

The SAMPSIZE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the SAMPSIZE= data set as in the DATA= data set. The SAMPSIZE= data set is a secondary

input data set. See the section "Secondary Input Data Set" on page 6656 for details. You can name only one secondary input data set in each invocation of the procedure.

For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units available in the stratum. If you specify the SELECTALL option, PROC SURVEYSELECT selects all stratum units when the stratum sample size exceeds the number of units in the stratum.

SEED=*number*

specifies the initial seed for random number generation. The SEED= value must be a positive integer. If you do not specify the SEED= option, or if the SEED= value is negative or zero, PROC SURVEYSELECT uses the time of day from the computer's clock to obtain the initial seed. See the section "Sample Selection Methods" on page 6645 for more information.

Whether or not you specify the SEED= option, PROC SURVEYSELECT displays the value of the initial seed in the "Sample Selection Summary" table. If you need to reproduce the same sample in a subsequent execution of PROC SURVEYSELECT, you can specify this same seed value in the SEED= option, along with the same sample selection parameters, and PROC SURVEYSELECT will reproduce the sample.

If you request a stratified sample design with the STRATA statement, you can use the SEED=*SAS-data-set* option to specify an initial seed for each stratum. Otherwise, PROC SURVEYSELECT generates random numbers continuously across strata from the random number stream initialized by the SEED= value, as described in the section "Sample Selection Methods" on page 6645.

You can use the OUTSEED option to include the stratum initial seeds in the output data set.

SEED=*SAS-data-set*

names a SAS data set that contains initial seeds for the strata. You provide the stratum seeds in the SEED= input data set variable _SEED_ or InitialSeed.

The initial seed values must be positive integers. If the initial seed value for the first stratum is not a positive integer, PROC SURVEYSELECT uses the time of day from the computer's clock to obtain the initial seed. If the initial seed value for a subsequent stratum is not a positive integer, PROC SURVEYSELECT continues to use the random number stream already initialized by the seed for the previous stratum. See the section "Sample Selection Methods" on page 6645 for more information.

The SEED= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the SEED= data set as in the DATA= data set. The SEED= data set is a secondary input data set. See the section "Secondary Input Data Set" on page 6656 for details. You can name only one secondary input data set in each invocation of the procedure.

You can use the OUTSEED option to include the stratum initial seeds in the output data set.

Whether or not you specify the SEED= option, PROC SURVEYSELECT displays the value of the initial seed in the "Sample Selection Summary" table. If you need to reproduce the same sample in a subsequent execution of PROC SURVEYSELECT, you can specify this

same seed value in the SEED= option, along with the same sample selection parameters, and PROC SURVEYSELECT will reproduce the sample.

If you specify initial seeds by strata with the SEED=*SAS-data-set* option, you can reproduce the same sample in a subsequent execution of PROC SURVEYSELECT by specifying these same stratum initial seeds, along with the same sample selection parameters. If you need to reproduce the same sample for only a subset of the strata, you can use the same initial seeds for those strata in the subset.

SELECTALL

requests that PROC SURVEYSELECT select all stratum units when the stratum sample size exceeds the total number of units in the stratum. By default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units in the stratum, unless you are using a with-replacement selection method.

The SELECTALL option is available for the following without-replacement selection methods: METHOD=SRS, METHOD=SYS, METHOD=SEQ, METHOD=PPS, and METHOD=PPS_SAMPFORD.

The SELECTALL option is not available for with-replacement selection methods, with-minimum-replacement methods, or those PPS methods that select two units per stratum.

SORT=NEST | SERP

specifies the type of sorting by CONTROL variables. The option SORT=NEST requests nested sorting, and SORT=SERP requests hierarchic serpentine sorting. The default is SORT=SERP. See the section "Sorting by CONTROL Variables" on page 6644 for descriptions of serpentine and nested sorting. Where there is only one CONTROL variable, the two types of sorting are equivalent.

This option is available when you specify a CONTROL statement for systematic or sequential selection methods (METHOD=SYS, METHOD=PPS_SYS, METHOD=SEQ, and METHOD=PPS_SEQ). When you specify a CONTROL statement, PROC SURVEYSELECT sorts the input data set by the CONTROL variables within strata before selecting the sample.

When you specify a CONTROL statement, you can also use the OUTSORT= option to name an output data set that contains the sorted input data set. Otherwise, if you do not specify the OUTSORT= option, then the sorted data set replaces the input data set.

STATS

includes selection probabilities and sampling weights in the OUT= output data set for equal probability selection methods when you do not specify a STRATA statement. This option is available for the following equal probability selection methods: METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ. For PPS selection methods and stratified designs, the output data set contains selection probabilities and sampling weights by default. For more information about the contents of the output data set, see the section "Sample Output Data Set" on page 6657.

CONTROL Statement

CONTROL *variables* **;**

The CONTROL statement names variables for sorting the input data set. The CONTROL variables can be character or numeric.

PROC SURVEYSELECT sorts the input data set by the CONTROL variables before selecting the sample. If you also specify a STRATA statement, PROC SURVEYSELECT sorts by CONTROL variables within strata. Control sorting is available for systematic and sequential selection methods (METHOD=SYS, METHOD=PPS_SYS, METHOD=SEQ, and METHOD=PPS_SEQ).

By default (or if you specify the SORT=SERP option), PROC SURVEYSELECT uses hierarchic serpentine sorting by the CONTROL variables. If you specify the SORT=NEST option, the procedure uses nested sorting. For more information about serpentine and nested sorting, see the section "Sorting by CONTROL Variables" on page 6644.

You can use the OUTSORT= option to name an output data set that contains the sorted input data set. If you do not specify the OUTSORT= option when you use the CONTROL statement, then the sorted data set replaces the input data set.

ID Statement

ID *variables* **;**

The ID statement names variables from the DATA= input data set to be included in the OUT= data set of selected units. If there is no ID statement, PROC SURVEYSELECT includes all variables from the DATA= data set in the OUT= data set. The ID variables can be character or numeric.

SIZE Statement

SIZE *variable* **;**

The SIZE statement names one and only one size measure variable, which contains the sampling unit size measures that are used for selection with probability proportional to size. The SIZE variable must be numeric. When the value of an observation's SIZE variable is missing or nonpositive, that observation is excluded from the sample selection.

The SIZE statement is required for all PPS selection methods, which include METHOD=PPS, METHOD=PPS_BREWER, METHOD=PPS_MURTHY, METHOD=PPS_SAMPFORD, METHOD=PPS_SEQ, METHOD=PPS_SYS, and METHOD=PPS_WR. For details about how size measures are used, see the descriptions of PPS methods in the section "Sample Selection Methods" on page 6645.

Note that an observation's size measure, specified in the SIZE statement and used for PPS selection, is not the same as the sample size. The sample size is the number of units to select for the sample, and you can specify the sample size with the SAMPSIZE= option.

STRATA Statement

STRATA *variables* < / *options* > **;**

You can specify a STRATA statement to partition the input data set into nonoverlapping groups defined by the STRATA variables. PROC SURVEYSELECT then selects independent samples from these strata, according to the selection method and design parameters specified in the PROC SURVEYSELECT statement. For information about the use of stratification in sample design, see Lohr (1999), Kalton (1983), Kish (1965, 1987), and Cochran (1977).

The *variables* are one or more variables in the input data set. The STRATA variables function much like BY variables, and PROC SURVEYSELECT expects the input data set to be sorted in order of the STRATA variables.

If you specify a CONTROL statement, or if you specify METHOD=PPS, the input data set must be sorted in ascending order of the STRATA variables. This means you cannot use the STRATA option NOTSORTED or DESCENDING when you specify a CONTROL statement or METHOD=PPS.

If your input data set is not sorted by the STRATA variables in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with the STRATA variables in a BY statement.
- Specify the option NOTSORTED or DESCENDING in the STRATA statement for the SURVEYSELECT procedure (when you do not specify a CONTROL statement or METHOD=PPS). The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the STRATA variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the STRATA variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the *Base SAS Procedures Guide*.

Allocation Options

The STRATA options request allocation of the total sample size among the strata. You can specify the total sample size in the SAMPSIZE= option in the PROC SURVEYSELECT statement. When you request allocation with the ALLOC= option in the STRATA statement, PROC SURVEYSELECT allocates the total sample size among the strata according to the allocation method you name. You can request proportional allocation (ALLOC=PROP), optimal allocation

(ALLOC=OPTIMAL), or Neyman allocation (ALLOC=NEYMAN). See the section "Sample Size Allocation" on page 6654 for details about these methods.

Instead of requesting that PROC SURVEYSELECT compute the sample allocation, you can directly specify the allocation proportions by using the ALLOC=(*values*) option or the ALLOC=*SAS-data-set* option. Then PROC SURVEYSELECT allocates the total sample size among the strata according to the proportions you specify.

By default, PROC SURVEYSELECT computes the allocation of the total sample size among the strata and then selects the sample by using the allocated sample sizes. If you specify the NOSAMPLE option, PROC SURVEYSELECT computes the allocation but does not select the sample. In this case the OUT= output data set contains the stratum sample sizes computed according to the specified allocation method. See the section "Allocation Output Data Set" on page 6660 for details.

You can specify the following options in the STRATA statement.

ALLOC=*name*

specifies the method for allocating the total sample size among the strata. The following values for *name* are available:

PROPORTIONAL

PROP

requests proportional allocation, which allocates the total sample size in proportion to the stratum sizes, where the stratum size is the number of sampling units in the stratum. See the section "Sample Size Allocation" on page 6654 for details.

OPTIMAL

OPT

requests optimal allocation, which allocates the total sample size among the strata in proportion to stratum sizes, stratum variances, and stratum costs. See the section "Sample Size Allocation" on page 6654 for more information. If you specify ALLOC=OPTIMAL, you must provide the stratum variances with the VAR, VAR=(*values*), or VAR=*SAS-data-set* option. You must provide the stratum costs with the COST, COST=(*values*), or COST=*SAS-data-set* option.

NEYMAN

requests Neyman allocation, which allocates the total sample size among the strata in proportion to the stratum sizes and variances. See the section "Sample Size Allocation" on page 6654 for more information. If you specify ALLOC=NEYMAN, you must provide the stratum variances with the VAR, VAR=(*values*), or VAR=*SAS-data-set* option.

ALLOC=(*values***)**

lists stratum allocation proportions. You can separate *values* with blanks or commas.

Each allocation proportion specifies the percent of the total sample size to allocate to the corresponding stratum. The number of ALLOC= values must equal the number of strata in the input data set. The sum of the allocation proportions must equal 1.

Each allocation proportion must be a positive number. You can specify each value as a number between 0 and 1. Or you can specify a value in percentage form as a number between 1 and

100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

List the allocation proportions in the order in which the strata appear in the input data set. If you use the ALLOC=(*values*) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

ALLOC=*SAS-data-set*

names a SAS data set that contains stratum allocation proportions. You provide the stratum allocation proportions in the ALLOC= data set variable _ALLOC_.

Each allocation proportion specifies the percent of the total sample size to allocate to the corresponding stratum. The sum of the allocation proportions must equal 1.

Each allocation proportion must be a positive number. You can specify the value as a number between 0 and 1. Or you can specify the value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

The ALLOC= data set should contain all the STRATA variables, with the same type and length as in the DATA= input data set. The STRATA groups should appear in the same order in the ALLOC= data set as in the DATA= data set. The ALLOC= data set is a secondary input data set. See the section "Secondary Input Data Set" on page 6656 for details. You can name only one secondary data set in each invocation of the procedure.

COST

indicates that stratum costs are included in the secondary input data set. Use the COST option when you have already named the secondary input data set in another option, such as the VAR=*SAS-data-set* option. You provide the stratum costs in the secondary input data set variable _COST_.

A stratum cost represents the per-unit cost, or the survey cost of a single unit in the stratum. Each stratum cost must be a positive number. Cost values are required if you specify the ALLOC=OPTIMAL option.

COST=(*values***)**

specifies stratum costs, which are required if you specify the ALLOC=OPTIMAL option. You can separate *values* with blanks or commas.

A stratum cost represents the per-unit cost, or the survey cost of a single unit in the stratum. Each stratum cost must be a positive number.

The number of COST= values must equal the number of strata in the input data set. List the stratum costs in the order in which the strata appear in the input data set. If you use the COST=*values* option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

COST=*SAS-data-set*

names a SAS data set that contains the stratum costs. You provide the stratum costs in the COST= data set variable _COST_.

A stratum cost represents the per-unit cost, or the survey cost of a single unit in the stratum. Each stratum cost must be a positive number. Stratum costs are required if you specify the ALLOC=OPTIMAL option.

The COST= data set should contain all the STRATA variables, with the same type and length as in the DATA= input data set. The STRATA groups should appear in the same order in the COST= data set as in the DATA= data set. The COST= data set is a secondary input data set. See the section "Secondary Input Data Set" on page 6656 for details. You can name only one secondary input data set in each invocation of the procedure.

NOSAMPLE

requests that SURVEYSELECT allocate the total sample size among the strata but not select the sample. When you specify the NOSAMPLE option, the OUT= output data set contains the stratum sample sizes that PROC SURVEYSELECT computes. See the section "Allocation Output Data Set" on page 6660 for details.

VAR

indicates that stratum variances are included in the secondary input data set. Use the VAR option when you have already named the secondary input data set in another option, such as the COST=*SAS-data-set* option. You provide the stratum variances in the secondary input data set variable _VAR_.

Each stratum variance must be a positive number. Stratum variances are required if you specify ALLOC=OPTIMAL or ALLOC=NEYMAN.

VAR=(*values*)

lists stratum variances, which are required if you specify ALLOC=OPTIMAL or ALLOC=NEYMAN. You can separate *values* with blanks or commas.

Each stratum variance must be a positive number. The number of VAR= values must equal the number of strata in the input data set. List the stratum variances in the order in which the strata appear in the input data set. If you use the VAR=(*values*) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

VAR=*SAS-data-set*

names a SAS data set that contains the stratum variances. You provide the stratum variances in the VAR= data set variable _VAR_.

Each stratum variance must be a positive number. Stratum variances are required if you specify ALLOC=OPTIMAL or ALLOC=NEYMAN.

The VAR= data set should contain all the STRATA variables, with the same type and length as in the DATA= input data set. The STRATA groups should appear in the same order in the VAR= data set as in the DATA= data set. The VAR= data set is a secondary input data set. See the section "Secondary Input Data Set" on page 6656 for details. You can name only one secondary input data set in each invocation of the procedure.

Details: SURVEYSELECT Procedure

Missing Values

If an observation has a missing or nonpositive value for the SIZE variable, PROC SURVEYSELECT excludes that observation from the sample selection. The procedure provides a log note that gives the number of observations omitted due to missing or nonpositive size measures.

PROC SURVEYSELECT treats missing STRATA variable values like any other STRATA variable value. The missing values form a separate stratum.

If a value of _NSIZE_ (or SampleSize) is missing in the SAMPSIZE= secondary input data set, then PROC SURVEYSELECT cannot select a sample from that stratum. Similarly, if other secondary data set variables have missing values for a stratum, a sample cannot be selected from that stratum. These variables include _NRATE_, _MINSIZE_, _MAXSIZE_, _CERTSIZE_, and _CERTP_. See the section "Secondary Input Data Set" on page 6656 for details.

If a value of _ALLOC_, _VAR_, or _COST_ is missing in the secondary input data set, PROC SURVEYSELECT cannot compute the sample allocation.

Sorting by CONTROL Variables

If you specify a CONTROL statement, PROC SURVEYSELECT sorts the input data set by the CONTROL variables before selecting the sample. If you also specify a STRATA statement, the procedure sorts by CONTROL variables within strata. Sorting by CONTROL variables is available for systematic and sequential selection methods, which include METHOD=SYS, METHOD=PPS_SYS, METHOD=SEQ, and METHOD=PPS_SEQ. Sorting provides additional control over the distribution of the sample, giving some benefits of proportionate stratification.

By default, the sorted data set replaces the input data set. Or you can use the OUTSORT= option to name an output data set that contains the sorted input data set.

PROC SURVEYSELECT provides two types of sorting: hierarchic serpentine sorting and nested sorting. By default (or if you specify the SORT=SERP option), the procedure uses serpentine sorting. If you specify the SORT=NEST option, then the procedure sorts by the CONTROL variables according to nested sorting. These two types of sorting are equivalent when there is only one CONTROL variable.

If you request nested sorting, PROC SURVEYSELECT sorts observations in the same order as PROC SORT does for an ascending sort by the CONTROL variables. See the chapter "The SORT Procedure" in the *Base SAS Procedures Guide* for more information. PROC SURVEYSELECT sorts within strata if you also specify a STRATA statement. The procedure first arranges the input observations in ascending order of the first CONTROL variable. Then within each level of the

first control variable, the procedure arranges the observations in ascending order of the second CONTROL variable. This continues for all CONTROL variables specified.

In hierarchic serpentine sorting, PROC SURVEYSELECT sorts by the first CONTROL variable in ascending order. Then within the first level of the first CONTROL variable, the procedure sorts by the second CONTROL variable in ascending order. Within the second level of the first CONTROL variable, the procedure sorts by the second CONTROL variable in descending order. Sorting by the second CONTROL variable continues to alternate between ascending and descending sorting throughout all levels of the first CONTROL variable. If there is a third CONTROL variable, the procedure sorts by that variable within levels formed from the first two CONTROL variables, again alternating between ascending and descending sorting. This continues for all CONTROL variables specified. This sorting algorithm minimizes the change from one observation to the next with respect to the CONTROL variable values, thus making nearby observations more similar. For more information about serpentine sorting, see Chromy (1979) and Williams and Chromy (1980).

Sample Selection Methods

PROC SURVEYSELECT provides a variety of methods for selecting probability-based random samples. With probability sampling, each unit in the survey population has a known, positive probability of selection. This property of probability sampling avoids selection bias and enables you to use statistical theory to make valid inferences from the sample to the survey population. See Lohr (1999), Kish (1965, 1987), Kalton (1983), and Cochran (1977) for more information about probability sampling.

In equal probability sampling, each unit in the sampling frame, or in a stratum, has the same probability of being selected for the sample. PROC SURVEYSELECT provides the following methods that select units with equal probability: simple random sampling, unrestricted random sampling, systematic random sampling, and sequential random sampling. In simple random sampling, units are selected *without replacement*, which means that a unit cannot be selected more than once. Both systematic and sequential equal probability sampling are also without replacement. In unrestricted random sampling, units are selected *with replacement*, which means that a unit can be selected more than once. In with-replacement sampling, the *number of hits* refers to the number of times a unit is selected.

In probability proportional to size (PPS) sampling, a unit's selection probability is proportional to its size measure. PROC SURVEYSELECT provides the following methods that select units with probability proportional to size (PPS): PPS sampling without replacement, PPS sampling with replacement, PPS systematic sampling, PPS sequential sampling, Brewer's method, Murthy's method, and Sampford's method. PPS sampling is often used in cluster sampling, where you select clusters (or groups of sampling units) of varying size in the first stage of selection. For example, clusters might be schools, hospitals, or geographical areas, and the final sampling units might be students, patients, or citizens. Cluster sampling can provide efficiencies in frame construction and other survey operations. See Lohr (1999), Kalton (1983), Kish (1965), and the other references cited in the following sections for more information.

All the probability sampling methods provided by PROC SURVEYSELECT use random numbers in their selection algorithms, as described in the following sections and in the references cited. PROC

SURVEYSELECT uses a uniform random number function to generate streams of pseudo-random numbers from an initial starting point, or *seed*. You can use the SEED= option to specify the initial seed. If you do not specify the SEED= option, PROC SURVEYSELECT uses the time of day from the computer's clock to obtain the initial seed. PROC SURVEYSELECT generates uniform random numbers according to the method of Fishman and Moore (1982), which uses a prime modulus multiplicative generator with modulus 2^{31} and multiplier 397204094. PROC SURVEYSELECT uses the same uniform random number generator as the RANUNI function. For more information about the RANUNI function, see *SAS Language Reference: Dictionary*.

The following sections give detailed descriptions of the sample selection methods available in PROC SURVEYSELECT. In these sections, n_h denotes the sample size (the number of units in the sample) for stratum h, and N_h denotes the population size (number of units in the population) for stratum h, for $h = 1, 2, \ldots, H$. When the sample design is not stratified, n denotes the sample size, and N denotes the population size. For PPS sampling, M_{hi} represents the size measure for unit i in stratum h, $M_{h\cdot}$ is the total of all size measures for the population of stratum h, and $Z_{hi} = M_{hi}/M_{h\cdot}$ is the relative size of unit i in stratum h.

Simple Random Sampling

The method of simple random sampling (METHOD=SRS) selects units with equal probability and without replacement. Each possible sample of n different units out of N has the same probability of being selected. The selection probability for each individual unit equals n/N. When you request stratified sampling with a STRATA statement, PROC SURVEYSELECT selects samples independently within strata. The selection probability for a unit in stratum h equals n_h/N_h for stratified simple random sampling.

By default, PROC SURVEYSELECT uses Floyd's ordered hash table algorithm for simple random sampling. This algorithm is fast, efficient, and appropriate for large data sets. See Bentley and Floyd (1987) and Bentley and Knuth (1986) for details.

If there is not enough memory available for Floyd's algorithm, PROC SURVEYSELECT switches to the sequential algorithm of Fan, Muller, and Rezucha (1962), which requires less memory but might require more time to select the sample. When PROC SURVEYSELECT uses the alternative sequential algorithm, it writes a note to the log. To request the sequential algorithm, even if enough memory is available for Floyd's algorithm, you can specify METHOD=SRS2 in the PROC SURVEYSELECT statement.

Unrestricted Random Sampling

The method of unrestricted random sampling (METHOD=URS) selects units with equal probability and with replacement. Because units are selected with replacement, a unit can be selected for the sample more than once. The expected number of selections or hits for each unit equals n/N when sampling without stratification. For stratified sampling, the expected number of hits for a unit in stratum h equals n_h/N_h. Note that the expected number of hits exceeds one when the sample size n is greater than the population size N.

For unrestricted random sampling, by default, the output data set contains one observation for each distinct unit selected for the sample, together with a variable NumberHits that gives the number of times the observation was selected. But if you specify the OUTHITS option, then the output data set contains a separate observation for each selection, so that a unit selected three times, for example, is represented by three observations in the output data set. For information about the contents of the output data set, see the section "Sample Output Data Set" on page 6657.

Systematic Random Sampling

The method of systematic random sampling (METHOD=SYS) selects units at a fixed interval throughout the sampling frame or stratum after a random start. If you specify the sample size (or the stratum sample sizes) with the SAMPSIZE= option, PROC SURVEYSELECT uses a fractional interval to provide exactly the specified sample size. The interval equals N/n, or N_h/n_h for stratified sampling. The selection probability for each unit equals n/N, or n_h/N_h for stratified sampling. If you specify the sampling rate (or the stratum sampling rates) with the SAMPRATE= option, PROC SURVEYSELECT uses the inverse of the rate as the interval for systematic selection. The selection probability for each unit equals the specified rate.

Systematic random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum at equal intervals, thus providing implicit stratification. You can use the CONTROL statement to order the input data set by the CONTROL variables before sample selection. If you also use a STRATA statement, PROC SURVEYSELECT sorts by the CONTROL variables within strata. If you do not specify a CONTROL statement, PROC SURVEYSELECT applies systematic selection to the observations in the order in which they appear in the input data set.

Sequential Random Sampling

If you specify the option METHOD=SEQ and do not include a SIZE statement, PROC SURVEYSELECT uses the equal probability version of Chromy's method for sequential random sampling. This method selects units sequentially with equal probability and without replacement. See Chromy (1979) and Williams and Chromy (1980) for details. See the section "PPS Sequential Sampling" on page 6651 for a description of Chromy's PPS selection method.

Sequential random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum, thus providing implicit stratification according to the order of units in the frame or stratum. You can use the CONTROL statement to sort the input data set by the CONTROL variables before sample selection. If you also use a STRATA statement, PROC SURVEYSELECT sorts by the CONTROL variables within strata. By default (or if you specify the SORT=SERP option), the procedure uses hierarchic serpentine ordering for sorting. If you specify the SORT=NEST option, the procedure uses nested sorting. See the section "Sorting by CONTROL Variables" on page 6644 for descriptions of serpentine and nested sorting. If you do not specify a CONTROL statement, PROC SURVEYSELECT applies sequential selection to the observations in the order in which they appear in the input data set.

Following Chromy's method of sequential selection, PROC SURVEYSELECT randomly chooses a starting unit from the entire stratum (or frame, if the design is not stratified). With this unit as the

first one, the procedure treats the stratum units as a closed loop. This is done so that all pairwise (joint) selection probabilities are positive and an unbiased variance estimator can be obtained. The procedure numbers units sequentially from the random start to the end of the stratum and then continues from the beginning of the stratum until all units are numbered.

Beginning with the randomly chosen starting unit, PROC SURVEYSELECT accumulates the expected number of selections or hits, where the expected number of selections $\mathrm{E}[S_{hi}]$ equals n_h/N_h for all units i in stratum h. The procedure computes

$$I_{hi} = \mathrm{Int}\Big(\sum_{j=1}^{i} \mathrm{E}[S_{hj}]\Big) = \mathrm{Int}(i\, n_h/N_h)$$

$$F_{hi} = \mathrm{Frac}\Big(\sum_{j=1}^{i} \mathrm{E}[S_{hj}]\Big) = \mathrm{Frac}(i\, n_h/N_h)$$

where Int denotes the integer part of the number, and Frac denotes the fractional part.

Considering each unit sequentially, Chromy's method determines whether unit i is selected by comparing the total number of selections for the first $i-1$ units,

$$T_{h(i-1)} = \sum_{j=1}^{i-1} S_{hj}$$

with the value of $I_{h(i-1)}$.

If $T_{h(i-1)} = I_{h(i-1)}$, Chromy's method determines whether or not unit i is selected as follows. If $F_{hi} = 0$ or $F_{h(i-1)} > F_{hi}$, then unit i is selected with certainty. Otherwise, unit i is selected with probability

$$(F_{hi} - F_{h(i-1)})/(1 - F_{h(i-1)})$$

If $T_{h(i-1)} = I_{h(i-1)} + 1$, Chromy's method determines whether or not unit i is selected as follows. If $F_{hi} = 0$ or $F_{hi} > F_{h(i-1)}$, then the unit is not selected. Otherwise, unit i is selected with probability

$$F_{hi}/F_{h(i-1)}$$

PPS Sampling without Replacement

If you specify the option METHOD=PPS, PROC SURVEYSELECT selects units with probability proportional to size and without replacement. The selection probability for unit i in stratum h equals $n_h Z_{hi}$, where n_h is the sample size for stratum h, and Z_{hi} is the relative size of unit i in stratum h. The relative size equals $M_{hi}/M_{h.}$, which is the ratio of the size measure for unit i in stratum h (M_{hi}) to the total of all size measures for stratum h ($M_{h.}$).

Because selection probabilities cannot exceed 1, the relative size for each unit must not exceed $1/n_h$ for METHOD=PPS. This requirement can be expressed as $Z_{hi} <= 1/n_h$, or equivalently, $M_{hi} <= M_{h.}/n_h$. If your size measures do not meet this requirement, you can adjust the size

measures by using the MAXSIZE= or MINSIZE= option. Or you can request certainty selection for the larger units by using the CERTSIZE= or CERTSIZE=P= option. Alternatively, you can use a selection method that does not have this relative size restriction, such as PPS with minimum replacement (METHOD=PPS_SEQ).

PROC SURVEYSELECT uses the Hanurav-Vijayan algorithm for PPS selection without replacement. Hanurav (1967) introduced this algorithm for the selection of two units per stratum, and Vijayan (1968) generalized it for the selection of more than two units. The algorithm enables computation of joint selection probabilities and provides joint selection probability values that usually ensure nonnegativity and stability of the Sen-Yates-Grundy variance estimator. See Fox (1989), Golmant (1990), and Watts (1991) for details.

Notation in the remainder of this section drops the stratum subscript h for simplicity, but selection is still done independently within strata if you specify a stratified design. For a stratified design, n now denotes the sample size for the current stratum, N denotes the stratum population size, and M_i denotes the size measure for unit i in the stratum. If the design is not stratified, this notation applies to the entire sampling frame.

According to the Hanurav-Vijayan algorithm, PROC SURVEYSELECT first orders units within the stratum in ascending order by size measure, so that $M_1 \leq M_2 \leq \ldots \leq M_N$. Then the procedure selects the PPS sample of n observations as follows:

1. The procedure randomly chooses one of the integers $1, 2, \ldots, n$ with probability $\theta_1, \theta_2, \ldots, \theta_n$, where

   $$\theta_i = n(Z_{N-n+i+1} - Z_{N-n+i})(T + iZ_{N-n+1})/T$$

   where $Z_j = M_j/M$ and

   $$T = \sum_{j=1}^{N-n} Z_j$$

   By definition, $Z_{N+1} = 1/n$ to ensure that $\sum_{i=1}^{n} \theta_i = 1$.

2. If i is the integer selected in step 1, the procedure includes the last $(n-i)$ units of the stratum in the sample, where the units are ordered by size measure as described previously. The procedure then selects the remaining i units according to steps 3 through 6.

3. The procedure defines new normed size measures for the remaining $(N-n+i)$ stratum units that were not selected in steps 1 and 2:

   $$Z_j^* = \begin{cases} Z_j/(T + iZ_{N-n+1}) & \text{for } j = 1, \ldots, N-n+1 \\ Z_{N-n+1}/(T + iZ_{N-n+1}) & \text{for } j = N-n+2, \ldots, N-n+i \end{cases}$$

4. The procedure selects the next unit from the first $(N-n+1)$ stratum units with probability proportional to $a_j(1)$, where

   $$\begin{aligned} a_1(1) &= iZ_1^* \\ a_j(1) &= iZ_j^* \textstyle\prod_{k=1}^{j-1}\big(1-(i-1)\,P_k\big) \quad \text{for } j = 2, \ldots, N-n+1 \end{aligned}$$

   and

   $$P_k = M_k/(M_{k+1} + M_{k+2} + \cdots + M_{N-n+i})$$

5. If stratum unit j_1 is the unit selected in step 4, then the procedure selects the next unit from units $(j_1 + 1)$ through $(N - n + 2)$ with probability proportional to $a_j(2, j_1)$, where

$$a_{j_1+1}(2, j_1) = (i-1)Z^*_{j_1+1}$$

$$a_j(2, j_1) = (i-1)Z^*_j \prod_{k=j_1+1}^{j-1} \left(1 - (i-2)P_k\right) \quad \text{for} \quad j = j_1 + 2, \ldots, N - n + 2$$

6. The procedure repeats step 5 until all n sample units are selected.

If you specify the JTPROBS option, PROC SURVEYSELECT computes the joint selection probabilities for all pairs of selected units in each stratum. The joint selection probability for units i and j in the stratum equals

$$P_{(ij)} = \sum_{r=1}^{n} \theta_r K_{ij}^{(r)}$$

where

$$K_{ij} = \begin{cases} 1 & N - n + r < i \le N - 1 \\ rZ_{N-n+1}/(T + rZ_{N-n+1}) & N - n < i \le N - n + r, \quad j > N - n + r \\ rZ_i/(T + rZ_{N-n+1}) & 1 \le i \le N - n, \quad j > N - n + r \\ \pi_{ij}^{(r)} & j \le N - n + r \end{cases}$$

$$\pi_{ij}^{(r)} = \frac{r(r-1)}{2} P_i Z_j \prod_{k=1}^{i-1} (1 - P_k)$$

$$P_k = M_k/(M_{k+1} + M_{k+2} + \cdots + M_{N-n+r})$$

PPS Sampling with Replacement

If you specify the option METHOD=PPS_WR, PROC SURVEYSELECT selects units with probability proportional to size and with replacement. The procedure makes n_h independent random selections from the stratum of N_h units, selecting with probability $Z_{hi} = M_{hi}/M_{h.}$. Because units are selected with replacement, a unit can be selected for the sample more than once. The expected number of selections or hits for unit i in stratum h equals $n_h Z_{hi}$. If you specify the JTPROBS option, PROC SURVEYSELECT computes the joint expected number of hits for all pairs of selected units in each stratum. The joint expected number of hits for units i and j in stratum h equals

$$P_{h(ij)} = \begin{cases} n_h(n_h - 1)Z_{hi}Z_{hj} & \text{for} \quad j \ne i \\ n_h(n_h - 1)Z_{hi}Z_{hi}/2 & \text{for} \quad j = i \end{cases}$$

PPS Systematic Sampling

If you specify the option METHOD=PPS_SYS, PROC SURVEYSELECT selects units by systematic random sampling with probability proportional to size. Systematic sampling selects

units at a fixed interval throughout the stratum or sampling frame after a random start. PROC SURVEYSELECT uses a fractional interval to provide exactly the specified sample size. The interval equals $M_{h\cdot}/n_h$ for stratified sampling and M/n for sampling without stratification. Depending on the sample size and the values of the size measures, it might be possible for a unit to be selected more than once. The expected number of selections or hits for unit i in stratum h equals $n_h M_{hi}/M_{h\cdot} = n_h Z_{hi}$. See Cochran (1977, pp. 265–266) and Madow (1949) for details.

Systematic random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum at equal intervals, thus providing implicit stratification. You can use the CONTROL statement to order the input data set by the CONTROL variables before sample selection. If you also use a STRATA statement, PROC SURVEYSELECT sorts by the CONTROL variables within strata. If you do not specify a CONTROL statement, PROC SURVEYSELECT applies systematic selection to the observations in the order in which they appear in the input data set.

PPS Sequential Sampling

If you specify the option METHOD=PPS_SEQ, PROC SURVEYSELECT uses Chromy's method of sequential random sampling. See Chromy (1979) and Williams and Chromy (1980) for details. Chromy's method selects units sequentially with probability proportional to size and with minimum replacement. Selection *with minimum replacement* means that the actual number of hits for a unit can equal the integer part of the expected number of hits for that unit, or the next largest integer. This can be compared to selection *without replacement*, where each unit can be selected only once, so the number of hits can equal 0 or 1. The other alternative is selection *with replacement*, where there is no restriction on the number of hits for each unit, so the number of hits can equal $0, 1, \cdots, n_h$, where n_h is the stratum sample size.

Sequential random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum, thus providing implicit stratification according to the order of units in the frame or stratum. You can use the CONTROL statement to sort the input data set by the CONTROL variables before sample selection. If you also use a STRATA statement, PROC SURVEYSELECT sorts by the CONTROL variables within strata. By default (or if you specify the SORT=SERP option), the procedure uses hierarchic serpentine ordering to sort the sampling frame by the CONTROL variables within strata. If you specify the SORT=NEST option, the procedure uses nested sorting. See the section "Sorting by CONTROL Variables" on page 6644 for descriptions of serpentine and nested sorting. If you do not specify a CONTROL statement, PROC SURVEYSELECT applies sequential selection to the observations in the order in which they appear in the input data set.

According to Chromy's method of sequential selection, PROC SURVEYSELECT first chooses a starting unit randomly from the entire stratum, with probability proportional to size. The procedure uses this unit as the first one and treats the stratum observations as a closed loop. This is done so that all pairwise (joint) expected number of hits are positive and an unbiased variance estimator can be obtained. The procedure numbers observations sequentially from the random start to the end of the stratum and then continues from the beginning of the stratum until all units are numbered.

Beginning with the randomly chosen starting unit, Chromy's method partitions the ordered stratum sampling frame into n_h zones of equal size. There is one selection from each zone and a total of

n_h selections or hits, although fewer than n_h distinct units might be selected. Beginning with the random start, the procedure accumulates the expected number of hits and computes

$$\mathrm{E}[S_{hi}] = n_h Z_{hi}$$

$$I_{hi} = \mathrm{Int}\Big(\sum_{j=1}^{i} \mathrm{E}[S_{hj}]\Big)$$

$$F_{hi} = \mathrm{Frac}\Big(\sum_{j=1}^{i} \mathrm{E}[S_{hj}]\Big)$$

where $\mathrm{E}[S_{hi}]$ represents the expected number of hits for unit i in stratum h, Int denotes the integer part of the number, and Frac denotes the fractional part.

Considering each unit sequentially, Chromy's method determines the actual number of hits for unit i by comparing the total number of hits for the first $i-1$ units,

$$T_{h(i-1)} = \sum_{j=1}^{i-1} S_{hj}$$

with the value of $I_{h(i-1)}$.

If $T_{h(i-1)} = I_{h(i-1)}$, Chromy's method determines the total number of hits for the first i units as follows. If $F_{hi} = 0$ or $F_{h(i-1)} > F_{hi}$, then $T_{hi} = I_{hi}$. Otherwise, $T_{hi} = I_{hi} + 1$ with probability

$$(F_{hi} - F_{h(i-1)})/(1 - F_{h(i-1)})$$

And the number of hits for unit i equals $T_{hi} - T_{h(i-1)}$.

If $T_{h(i-1)} = I_{h(i-1)} + 1$, Chromy's method determines the total number of hits for the first i units as follows. If $F_{hi} = 0$, then $T_{hi} = I_{hi}$. If $F_{hi} > F_{h(i-1)}$, then $T_{hi} = I_{hi} + 1$. Otherwise, $T_{hi} = I_{hi} + 1$ with probability

$$F_{hi}/F_{h(i-1)}$$

Brewer's PPS Method

Brewer's method (METHOD=PPS_BREWER) selects two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit i in stratum h equals $2M_{hi}/M_{h.} = 2Z_{hi}$.

Brewer's algorithm first selects a unit with probability

$$\frac{Z_{hi}(1 - Z_{hi})}{D_h(1 - 2Z_{hi})}$$

where

$$D_h = \sum_{i=1}^{N_h} \frac{Z_{hi}(1 - Z_{hi})}{1 - 2Z_{hi}}$$

Then a second unit is selected from the remaining units with probability

$$\frac{Z_{hj}}{1 - Z_{hi}}$$

where unit i is the first unit selected. The joint selection probability for units i and j in stratum h equals

$$P_{h(ij)} = \frac{2Z_{hi}Z_{hj}}{D_h}\left(\frac{1 - Z_{hi} - Z_{hj}}{(1 - 2Z_{hi})(1 - 2Z_{hj})}\right)$$

Brewer's method requires that the relative size Z_{hi} be less than 0.5 for all units. See Cochran (1977, pp. 261–263) and Brewer (1963) for details. Brewer's method yields the same selection probabilities and joint selection probabilities as Durbin's method. See Cochran (1977) and Durbin (1967) for details.

Murthy's PPS Method

Murthy's method (METHOD=PPS_MURTHY) selects two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit i in stratum h equals

$$P_{hi} = Z_{hi}\big(1 + K - (Z_{hi}/(1 - Z_{hi}))\big)$$

where $Z_{hi} = M_{hi}/M_{h\cdot}$ and

$$K = \sum_{j=1}^{N}\big(Z_{hj}/(1 - Z_{hj})\big)$$

Murthy's algorithm first selects a unit with probability Z_{hi}. Then a second unit is selected from the remaining units with probability $Z_{hj}/(1 - Z_{hi})$, where unit i is the first unit selected. The joint selection probability for units i and j in stratum h equals

$$P_{h(ij)} = Z_{hi}Z_{hj}\left(\frac{2 - Z_{hi} - Z_{hj}}{(1 - Z_{hi})(1 - Z_{hj})}\right)$$

See Cochran (1977, pp. 263–265) and Murthy (1957) for details.

Sampford's PPS Method

Sampford's method (METHOD=PPS_SAMPFORD) is an extension of Brewer's method that selects more than two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit i in stratum h equals $n_h M_{hi}/M_{h\cdot} = n_h Z_{hi}$.

Sampford's method first selects a unit from stratum h with probability Z_{hi}. Then subsequent units are selected with probability proportional to

$$\lambda_i = \frac{Z_{hi}}{1 - n_h\, Z_{hi}}$$

and with replacement. If the same unit appears more than once in the sample of size n_h, then Sampford's algorithm rejects that sample and selects a new sample. The sample is accepted if it contains n_h distinct units.

If you specify the JTPROBS option, PROC SURVEYSELECT computes the joint selection probabilities for all pairs of selected units in each stratum. The joint selection probability for units i and j in stratum h equals

$$P_{h(ij)} = K_h \lambda_i \lambda_j \sum_{t=2}^{n_h} \Big(t - n_h \left(P_{hi} + P_{hj}\right) L_{n_h - t}(ij) \Big) / n_h^{t-2}$$

where

$$L_m = \sum_{S(m)} \lambda_{i_1} \lambda_{i_2} \cdots \lambda_{i_m}$$

and $S(m)$ denotes all possible samples of size m, for $m = 1, 2, \ldots, N_h$. The sum $L_m(ij)$ is defined similarly to L_m but sums over all possible samples of size m that do not include units i and j, and

$$K_h = \left(\sum_{t=1}^{n_h} t \; L_{n_h - t} / n_h^t \right)^{-1}$$

Sampford's method requires that the relative size Z_{hi} be less than $1/n_h$ for all units. See Cochran (1977, pp. 262–263) and Sampford (1967) for details.

Sample Size Allocation

If you specify the ALLOC= option in the STRATA statement, PROC SURVEYSELECT allocates the total sample size among the strata according to the method you request. You specify the total sample size in the SAMPSIZE=*n* option in the PROC SURVEYSELECT statement.

PROC SURVEYSELECT provides proportional allocation (ALLOC=PROP), optimal allocation (ALLOC=OPTIMAL), and Neyman allocation (ALLOC=NEYMAN). See Lohr (1999), Kish (1965), and Cochran (1977) for more information about these allocation methods. Alternatively, you can directly specify the allocation proportions by using the ALLOC=(*values*) option or the ALLOC=*SAS-data-set* option. Then PROC SURVEYSELECT allocates the total sample size among the strata according to the proportions that you specify.

Proportional Allocation

When you specify the ALLOC=PROP option, PROC SURVEYSELECT allocates the total sample size among the strata in proportion to the stratum sizes, where the stratum size is the number of sampling units in the stratum. The allocation proportion of the total sample size for stratum h equals

$$f_h^* = N_h / N$$

where N_h is the number of sampling units in stratum h and N is the total number of sampling units for all strata. Based on this allocation proportion, the target sample size for stratum h is

$$n_h^* = f_h^* \times n$$

where n is the total sample size that you specify in the SAMPSIZE= option.

The target sample size values, n_h^*, might not be integers, but the stratum sample sizes must be integers. PROC SURVEYSELECT uses a rounding algorithm to convert the n_h^* to integer values n_h and maintain the requested total sample size n. The rounding algorithm includes the restriction that all values of n_h must be at least 1, so that at least one unit will be selected from each stratum. For without-replacement selection methods, PROC SURVEYSELECT also requires that each stratum sample size must not exceed the total number of sampling units in the stratum, $n_h <= N_h$. If a target stratum sample size exceeds the number of units in the stratum, PROC SURVEYSELECT allocates the maximum number of units, N_h, to the stratum, and then allocates the remaining total sample size proportionally among the remaining strata.

PROC SURVEYSELECT provides the target allocation proportions f_h^* in the output data set variable AllocProportion. The variable ActualProportion contains the actual proportions for the allocated sample sizes n_h. For stratum h, the actual proportion is computed as

$$f_h = n_h/n$$

where n_h is the allocated sample size for stratum h, and n is the total sample size. The actual proportions f_h can differ from the target allocation proportions f_h^* due to rounding and the restrictions that $n_h >= 1$ and $n_h <= N_h$.

Optimal Allocation

When you specify the ALLOC=OPTIMAL option, PROC SURVEYSELECT allocates the total sample size among the strata in proportion to stratum sizes, stratum costs, and stratum variances. Optimal allocation minimizes the overall variance for a specified cost, or equivalently minimizes the overall cost for a specified variance. See Lohr (1999), Cochran (1977) and Kish (1965) for details. For optimal allocation, the proportion of the total sample size for stratum h is computed as

$$f_h^* = \frac{N_h S_h}{\sqrt{C_h}} \Big/ \sum_{i=1}^{H} \frac{N_i S_i}{\sqrt{C_i}}$$

where N_h is the number of sampling units in stratum h, S_h is the standard deviation within stratum h, C_h is the unit cost within stratum h, and H is the total number of strata. The target sample size for stratum h is $n_h^* = f_h^* \times n$, where n is the total sample size. As for proportional allocation, the values of n_h^* are converted to integer sample sizes n_h by using a rounding algorithm that requires the sum of the stratum sample sizes to equal n. The final sample sizes n_h are also required to be at least 1, and the final sample sizes must not exceed the stratum sizes for without-replacement selection methods.

Neyman Allocation

When you specify the ALLOC=NEYMAN option, PROC SURVEYSELECT allocates the total sample size among the strata in proportion to stratum sizes and stratum variances. Neyman allocation is a special case of optimal allocation, where the costs per unit are the same for all strata. For Neyman allocation, the proportion of the total sample size for stratum h is computed as

$$f_h^* = N_h S_h / \sum_{i=1}^{H} N_i S_i$$

The target sample size for stratum h is $n_h^* = f_h^* \times n$. The n_h^* are converted to integer sample sizes n_h by using a rounding algorithm that requires the sum of the stratum sizes to equal n. The final sample sizes n_h are required to be at least 1, and the final sample sizes must not exceed the stratum sizes for without-replacement selection methods.

Secondary Input Data Set

The primary input data set for PROC SURVEYSELECT is the DATA= data set, which contains the list of units from which the sample is selected. You can use a secondary input data set to provide stratum-level design and selection information, such as sample sizes or rates, certainty size values, or stratum costs. This secondary input data set is sometimes called the SAMPSIZE= input data set. You can provide stratum sample sizes in the _NSIZE_ (or SampleSize) variable in the SAMPSIZE= data set.

The secondary input data set must contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the secondary data set as in the DATA= data set. You can name only one secondary data set in each invocation of the procedure.

You must name the secondary input data set in the appropriate PROC SURVEYSELECT or STRATA option, and use the designated variable name to provide the stratum-level values. For example, if you want to provide stratum-level costs for sample allocation, you name the secondary data set in the COST=*SAS-data-set* option in the STRATA statment. The data set must include the stratum costs in a variable named _COST_. You can use the secondary input data set for more than one option if it is appropriate for your design. For example, the secondary data set can include both stratum costs and stratum variances, which are required for optimal allocation (ALLOC=OPTIMAL).

Instead of using a separate secondary input data set, you can include secondary information in the DATA= data set along with the sampling frame. When you include secondary information in the DATA= data set, name the DATA= data set in the appropriate options, and include the required variables in the DATA= data set.

Table 87.2 lists the available secondary data set variables, together with their descriptions and the corresponding options.

Table 87.2 PROC SURVEYSELECT Secondary Data Set Variables

Variable	Description	Statement	Option
ALLOC	Allocation proportion	STRATA	ALLOC=
CERTP	Certainty proportion	PROC	CERTSIZE=P=
CERTSIZE	Certainty size	PROC	CERTSIZE=
COST	Cost	STRATA	COST=
MAXSIZE	Maximum size	PROC	MAXSIZE=
MINSIZE	Minimum size	PROC	MINSIZE=
NSIZE	Sample size	PROC	SAMPSIZE=
RATE	Sampling rate	PROC	SAMPRATE=
SEED	Random number seed	PROC	SEED=
VAR	Variance	STRATA	VAR=

Sample Output Data Set

Unless you specify the NOSAMPLE option in the STRATA statement, PROC SURVEYSELECT selects a sample and creates a SAS data set that contains the sample of selected units. If you specify the NOSAMPLE option, PROC SURVEYSELECT allocates the total sample size among the strata but does not select the sample. When you specify the NOSAMPLE option, the output data set contains the allocated sample sizes. See the section "Allocation Output Data Set" on page 6660 for details.

You can specify the name of the sample output data set in the OUT= option in the PROC SURVEYSELECT statement. If you omit the OUT= option, the data set is named DATA*n*, where *n* is the smallest integer that makes the name unique.

By default, the output data set contains one observation for each unit selected for the sample. But if you specify the OUTALL option, the output data set includes all observations from the input data set. With OUTALL, the output data set also contains a variable to indicate each observation's selection status. The variable Selected equals 1 for an observation selected for the sample, and equals 0 for an observation not selected. The OUTALL option is available only for equal probability selection methods.

By default, the output data set contains one observation for each selected unit, even if the unit is selected more than once, and the variable NumberHits contains the number of hits or selections for that unit. A unit might be selected more than once if you use a with-replacement or with-minimum-replacement selection method (METHOD=URS, METHOD=PPS_WR, METHOD=PPS_SYS, or METHOD=PPS_SEQ). If you specify the OUTHITS option, the output data set contains a separate observation for each hit or selection.

The output data set contains design information and selection statistics, depending on the selection method and output options you specify. The output data set can include the following variables:

- Selected, which indicates whether or not the observation is selected for the sample. This variable is included if you specify the OUTALL option. Selected equals 1 for an observation selected for the sample or 0 for an observation not selected.

- STRATA variables, which you specify in the STRATA statement
- Replicate, which is the sample replicate number. This variable is included when you request replicated sampling with the REPS= option.
- ID variables, which you name in the ID statement
- CONTROL variables, which you specify in the CONTROL statement
- Zone, which is the selection zone. This variable is included for METHOD=PPS_SEQ.
- SIZE variable, which you specify in the SIZE statement
- AdjustedSize, which is the adjusted size measure. This variable is included if you request adjusted sizes with the MINSIZE= or MAXSIZE= option.
- Certain, which indicates certainty selection. This variable is included if you specify the CERTSIZE= or CERTSIZE=P= option. Certain equals 1 for units included with certainty because their size measures exceed the certainty size value or the certainty proportion; otherwise, Certain equals 0.
- NumberHits, which is the number of hits or selections. This variable is included for selection methods that are with replacement or with minimum replacement (METHOD=URS, METHOD=PPS_WR, METHOD=PPS_SYS, and METHOD=PPS_SEQ).

The output data set includes the following variables if you request a PPS selection method or if you specify the STATS option for other methods:

- ExpectedHits, which is the expected number of hits or selections. This variable is included for selection methods that are with replacement or with minimum replacement, and so might select the same unit more than once (METHOD=URS, METHOD=PPS_WR, METHOD=PPS_SYS, and METHOD=PPS_SEQ).
- SelectionProb, which is the probability of selection. This variable is included for selection methods that are without replacement.
- SamplingWeight, which is the sampling weight. This variable equals the inverse of ExpectedHits or SelectionProb.

For METHOD=PPS_BREWER and METHOD=PPS_MURTHY, which select two units from each stratum with probability proportional to size, the output data set contains the following variable:

- JtSelectionProb, which is the joint probability of selection for the two units selected from the stratum

If you specify the JTPROBS option to compute joint probabilities of selection for METHOD=PPS or METHOD=PPS_SAMPFORD, then the output data set contains the following variables:

- Unit, which is an identification variable that numbers the selected units sequentially within each stratum

- JtProb_1, JtProb_2, JtProb_3, . . . , where the variable JtProb_1 contains the joint probability of selection for the current unit and unit 1. Similarly, JtProb_2 contains the joint probability of selection for the current unit and unit 2, and so on.

If you specify the JTPROBS option for METHOD=PPS_WR, then the output data set contains the following variables:

- Unit, which is an identification variable that numbers the selected units sequentially within each stratum
- JtHits_1, JtHits_2, JtHits_3, . . . , where the variable JtHits_1 contains the joint expected number of hits for the current unit and unit 1. Similarly, JtHits_2 contains the joint expected number of hits for the current unit and unit 2, and so on.

If you specify the OUTSIZE option, the output data set contains the following variables. If you specify a STRATA statement, the output data set includes stratum-level values of these variables. Otherwise, the output data set contains population-level values of these variables.

- MinimumSize, which is the minimum size measure specified with the MINSIZE= option. This variable is included if you specify the MINSIZE= option.
- MaximumSize, which is the maximum size measure specified with the MAXSIZE= option. This variable is included if you specify the MAXSIZE= option.
- CertaintySize, which is the certainty size measure specified with the CERTSIZE= option. This variable is included if you specify the CERTSIZE= option.
- CertaintyProp, which is the certainty proportion specified with the CERTSIZE=P= option. This variable is included if you specify the CERTSIZE=P= option.
- Total, which is the total number of sampling units in the stratum. This variable is included if there is no SIZE statement.
- TotalSize, which is the total of size measures in the stratum. This variable is included if there is a SIZE statement.
- TotalAdjSize, which is the total of adjusted size measures in the stratum. This variable is included if you specify a SIZE statement and if you request adjusted sizes with the MAXSIZE= or MINSIZE= option.
- SamplingRate, which is the sampling rate. This variable is included if you specify the SAMPRATE= option.
- SampleSize, which is the sample size. This variable is included if you specify the SAMPSIZE= option, or if you specify METHOD=PPS_BREWER or METHOD=PPS_MURTHY, which selects two units from each stratum.

If you specify the OUTSEED option, the output data set contains the following variable:

- InitialSeed, which is the initial seed for the stratum.

If you specify the ALLOC= option in the STRATA statement, the output data set contains the following variables:

- Total, which is the total number of sampling units in the stratum
- Variance, which is the stratum variance. This variable is included if you specify the VAR, VAR=(*values*), or VAR=*SAS-data-set* option for ALLOC=OPTIMAL or ALLOC=NEYMAN.
- Cost, which is the stratum cost. This variable is included if you specify the COST, COST=(*values*), or COST=*SAS-data-set* option for ALLOC=OPTIMAL.
- AllocProportion, which is the target allocation proportion, or the proportion of the total sample size to allocate to the stratum. PROC SURVEYSELECT computes this proportion by using the specified allocation method.
- SampleSize, which is the sample size allocated to the stratum
- ActualProportion, which is the actual proportion allocated to the stratum. The value of ActualProportion equals the allocated stratum sample size divided by the total sample size. This value can differ from the target AllocProportion due to rounding and other restrictions. See the section "Sample Size Allocation" on page 6654 for details.

Allocation Output Data Set

When you specify the NOSAMPLE option in the STRATA statement, PROC SURVEYSELECT allocates the total sample size among the strata but does not select the sample. In this case, the OUT= data set contains the allocated sample sizes.

You can specify the name of the allocation output data set with the OUT= option in the PROC SURVEYSELECT statement. If you omit the OUT= option, the data set is named DATA*n*, where *n* is the smallest integer that makes the name unique.

The allocation output data set can include the following variables:

- STRATA variables, which you specify in the STRATA statement
- Total, which is the total number of sampling units in the stratum
- Variance, which is the stratum variance. This variable is included if you specify the VAR, VAR=(*values*), or VAR=*SAS-data-set* option for ALLOC=OPTIMAL or ALLOC=NEYMAN.

- Cost, which is the stratum cost. This variable is included if you specify the COST, COST=(*values*), or COST=*SAS-data-set* option for ALLOC=OPTIMAL.
- AllocProportion, which is the target allocation proportion, or the proportion of the total sample size to allocate to the stratum. PROC SURVEYSELECT computes this proportion by using the specified allocation method.
- SampleSize, which is the sample size allocated to the stratum
- ActualProportion, which is the actual proportion allocated to the stratum. The value of ActualProportion equals the allocated stratum sample size divided by the total sample size. This value can differ from the target AllocProportion due to rounding and other restrictions. See the section "Sample Size Allocation" on page 6654 for details.

Displayed Output

By default, PROC SURVEYSELECT displays two tables that summarize the sample selection, the "Sample Selection Method" table and the "Sample Selection Summary" table.

If you request sample allocation but no sample selection, PROC SURVEYSELECT displays two tables that summarize the allocation, the "Sample Allocation Method" table and the "Sample Allocation Summary" table.

You can suppress display of these tables by specifying the NOPRINT option.

PROC SURVEYSELECT creates an output data set that contains the units selected for the sample. Or if you request sample allocation but no sample selection, PROC SURVEYSELECT creates an output data set that contains the sample size allocation results. (See the sections "Sample Output Data Set" on page 6657 and "Allocation Output Data Set" on page 6660 for information about these output data sets.) The procedure does not display the output data set that it creates. Use PROC PRINT, PROC REPORT, or any other SAS reporting tool to display the output data set.

PROC SURVEYSELECT displays the following information in the "Sample Selection Method" table:

- Selection Method
- Size Measure variable, if you specify a SIZE statement
- Minimum Size Measure, if you specify the MINSIZE= option
- Maximum Size Measure, if you specify the MAXSIZE= option
- Certainty Size Measure, if you specify the CERTSIZE= option
- Certainty Proportion, if you specify the CERTSIZE=P= option
- Strata Variables, if you specify a STRATA statement
- Control Variables, if you specify a CONTROL statement

- type of Control Sorting, Serpentine or Nested, if you specify a CONTROL statement
- type of Allocation, if you specify the ALLOC= option in the STRATA statement

PROC SURVEYSELECT displays the following information in the "Sample Selection Summary" table:

- Input Data Set name
- Sorted Data Set name, if you specify the OUTSORT= option
- Random Number Seed
- Sample Size or Stratum Sample Size, if you specify the SAMPSIZE=*n* option
- Sample Size Data Set, if you specify the SAMPSIZE=*SAS-data-set* option
- Sampling Rate or Stratum Sampling Rate, if you specify the SAMPRATE=*r* option
- Sampling Rate Data Set, if you specify the SAMPRATE=*SAS-data-set* option
- Minimum Sample Size or Stratum Minimum Sample Size, if you specify the NMIN= option with the SAMPRATE= option
- Maximum Sample Size or Stratum Maximum Sample Size, if you specify the NMAX= option with the SAMPRATE= option
- Allocation Input Data Set name, if you specify the ALLOC=*SAS-data-set* option in the STRATA statement
- Variance Input Data Set name, if you specify the VAR=*SAS-data-set* option in the STRATA statement.
- Cost Input Data Set name, if you specify the COST=*SAS-data-set* option in the STRATA statement.
- Selection Probability, if you specify METHOD=SRS, METHOD=SYS, or METHOD=SEQ and do not specify a STRATA statement
- Expected Number of Hits, if you specify METHOD=URS and do not specify a STRATA statement
- Sampling Weight for equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, METHOD=SEQ) if you do not specify a STRATA statement
- Number of Strata, if you specify a STRATA statement
- Number of Replicates, if you specify the REPS= option
- Total Sample Size, if you specify a STRATA statement or the REPS= option
- Output Data Set name

If you specify the NOSAMPLE option in the STRATA statement, PROC SURVEYSELECT allocates the total sample among the strata but does not select the sample. When you specify the NOSAMPLE option, PROC SURVEYSELECT displays the "Sample Allocation Method" table, which includes the following information:

- Allocation method
- Strata Variables

When you specify the NOSAMPLE option in the STRATA statement, PROC SURVEYSELECT also displays the "Sample Allocation Summary" table, which includes the following information:

- Input Data Set name
- Allocation Input Data Set name, if you specify the ALLOC=*SAS-data-set* option in the STRATA statement
- Variance Input Data Set name, if you specify the VAR=*SAS-data-set* option in the STRATA statement
- Cost Input Data Set name, if you specify the COST=*SAS-data-set* option in the STRATA statement
- Number of Strata
- Total Sample Size
- Allocation Output Data Set name

ODS Table Names

PROC SURVEYSELECT assigns a name to each table it creates. You can use these names to reference tables when using the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, "Using the Output Delivery System." Table 87.3 lists the table names.

Table 87.3 ODS Tables Produced by PROC SURVEYSELECT

ODS Table Name	Description	Statement	Option
Method	Sample selection method	PROC	default
Summary	Sample selection summary	PROC	default

Examples: SURVEYSELECT Procedure

Example 87.1: Replicated Sampling

This example uses the Customers data set from the section "Getting Started: SURVEYSELECT Procedure" on page 6615. The data set Customers contains an Internet service provider's current subscribers, and the service provider wants to select a sample from this population for a customer satisfaction survey.

This example illustrates replicated sampling, which selects multiple samples from the survey population according to the same design. You can use replicated sampling to provide a simple method of variance estimation, or to evaluate variable nonsampling errors such as interviewer differences. See Lohr (1999), Wolter (1985), Kish (1965, 1987), and Kalton (1983) for information about replicated sampling.

This design includes four replicates, each with a sample size of 50 customers. The sampling frame is stratified by State and sorted by Type and Usage within strata. Customers are selected by sequential random sampling with equal probability within strata. The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set by using this design:

```
title1 'Customer Satisfaction Survey';
title2 'Replicated Sampling';
proc surveyselect data=Customers
      method=seq n=(8 12 20 10)
      reps=4
      seed=40070 out=SampleRep;
   strata State;
   control Type Usage;
run;
```

The STRATA statement names the stratification variable State. The CONTROL statement names the control variables Type and Usage. In the PROC SURVEYSELECT statement, the METHOD=SEQ option requests sequential random sampling. The REPS=4 option specifies four replicates of this sample. The N=(8 12 20 10) option lists the stratum sample sizes for each replicate. The N= option lists the stratum sample sizes in the same order as the strata appear in the Customers data set, which has been sorted by State. The sample size of eight customers corresponds to the first stratum, State = 'AL'. The sample size 12 corresponds to the next stratum, State = 'FL', and so on. The SEED=40070 option specifies '40070' as the initial seed for random number generation.

Output 87.1.1 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A total of 200 customers is selected in four replicates. PROC SURVEYSELECT selects each replicate by using sequential random sampling within strata determined by State. The sampling frame Customers is sorted by the control variables Type and Usage within strata, according to hierarchic serpentine sorting. The output data set SampleRep contains the sample.

Output 87.1.1 Sample Selection Summary

```
                    Customer Satisfaction Survey
                        Replicated Sampling

                     The SURVEYSELECT Procedure

Selection Method      Sequential Random Sampling
                      With Equal Probability

          Output Data Set           SAMPLEREP
```

The following PROC PRINT statements display the selected customers for the first stratum, State = 'AL', from the output data set SampleRep:

```
title1 'Customer Satisfaction Survey';
title2 'Sample Selected by Replicated Design';
title3 '(First Stratum)';
proc print data=SampleRep;
   where State = 'AL';
run;
```

Output 87.1.2 displays the 32 sample customers of the first stratum (State = 'AL') from the output data set SampleRep, which includes the entire sample of 200 customers. The variable SelectionProb contains the selection probability, and SamplingWeight contains the sampling weight. Because customers are selected with equal probability within strata in this design, all customers in the same stratum have the same selection probability. These selection probabilities and sampling weights apply to a single replicate, and the variable Replicate contains the sample replicate number.

Output 87.1.2 Customer Sample (First Stratum)

Customer Satisfaction Survey
Sample Selected by Replicated Design
(First Stratum)

Obs	State	Replicate	CustomerID	Type	Usage	Selection Prob	Sampling Weight

Example 87.2: PPS Selection of Two Units per Stratum

This example describes hospital selection for a survey by using PROC SURVEYSELECT. A state health agency plans to conduct a statewide survey of a variety of different hospital services. The agency plans to select a probability sample of individual discharge records within hospitals by using a two-stage sample design. First-stage units are hospitals, and second-stage units are patient discharges during the study period. Hospitals are stratified first according to geographic region and then by rural/urban type and size of hospital. Two hospitals are selected from each stratum with probability proportional to size.

The data set HospitalFrame contains all hospitals in the first geographical region of the state:

```
data HospitalFrame;
   input Hospital$ Type$ SizeMeasure @@;
   if (SizeMeasure < 20) then Size='Small ';
      else if (SizeMeasure < 50) then Size='Medium';
      else Size='Large ';
   datalines;
034 Rural  0.870   107 Rural  1.316
079 Rural  2.127   223 Rural  3.960
236 Rural  5.279   165 Rural  5.893
086 Rural  0.501   141 Rural 11.528
042 Urban  3.104   124 Urban  4.033
006 Urban  4.249   261 Urban  4.376
195 Urban  5.024   190 Urban 10.373
038 Urban 17.125   083 Urban 40.382
259 Urban 44.942   129 Urban 46.702
133 Urban 46.992   218 Urban 48.231
026 Urban 61.460   058 Urban 65.931
119 Urban 66.352
;
```

In the SAS data set HospitalFrame, the variable Hospital identifies the hospital. The variable Type equals 'Urban' if the hospital is located in an urban area, and 'Rural' otherwise. The variable SizeMeasure contains the hospital's size measure, which is constructed from past data on service utilization for the hospital together with the desired sampling rates for each service. This size measure reflects the amount of relevant survey information expected from the hospital. See Drummond et al. (1982) for details about this type of size measure. The variable Size equals 'Small', 'Medium', or 'Large', depending on the value of the hospital's size measure.

The following PROC PRINT statements display the data set Hospital Frame and produce Output 87.2.1:

```
title1 'Hospital Utilization Survey';
title2 'Sampling Frame, Region 1';
proc print data=HospitalFrame;
run;
```

Output 87.2.1 Sampling Frame

Hospital Utilization Survey
Sampling Frame, Region 1

Obs	Hospital	Type	Size Measure	Size
1	034	Rural	0.870	Small
2	107	Rural	1.316	Small
3	079	Rural	2.127	Small
4	223	Rural	3.960	Small
5	236	Rural	5.279	Small
6	165	Rural	5.893	Small
7	086	Rural	0.501	Small
8	141	Rural	11.528	Small
9	042	Urban	3.104	Small
10	124	Urban	4.033	Small
11	006	Urban	4.249	Small
12	261	Urban	4.376	Small
13	195	Urban	5.024	Small
14	190	Urban	10.373	Small
15	038	Urban	17.125	Small
16	083	Urban	40.382	Medium
17	259	Urban	44.942	Medium
18	129	Urban	46.702	Medium
19	133	Urban	46.992	Medium
20	218	Urban	48.231	Medium
21	026	Urban	61.460	Large
22	058	Urban	65.931	Large
23	119	Urban	66.352	Large

The following PROC SURVEYSELECT statements select a probability sample of hospitals from the HospitalFrame data set by using a stratified design with PPS selection of two units from each stratum:

```
title1 'Hospital Utilization Survey';
title2 'Stratified PPS Sampling';
proc surveyselect data=HospitalFrame
      method=pps_brewer
      seed=48702 out=SampleHospitals;
   size SizeMeasure;
   strata Type Size notsorted;
run;
```

The STRATA statement names the stratification variables Type and Size. The NOTSORTED option specifies that observations with the same STRATA variable values are grouped together but are not necessarily sorted in alphabetical or increasing numerical order. In the HospitalFrame data set, Size = 'Small' precedes Size = 'Medium'.

In the PROC SURVEYSELECT statement, the METHOD=PPS_BREWER option requests sample selection by Brewer's method, which selects two units per stratum with probability proportional to size. The SEED=48702 option specifies '48702' as the initial seed for random number generation.

The SIZE statement names SizeMeasure as the size measure variable. It is not necessary to specify the sample size with the N= option, because Brewer's method always selects two units from each stratum.

Output 87.2.2 displays the output from PROC SURVEYSELECT. A total of eight hospitals were selected from the four strata. The data set SampleHospitals contains the selected hospitals.

Output 87.2.2 Sample Selection Summary

Hospital Utilization Survey
Stratified PPS Sampling

The SURVEYSELECT Procedure

Selection Method	Brewer's PPS Method
Size Measure	SizeMeasure
Strata Variables	Type
	Size

Input Data Set	HOSPITALFRAME
Random Number Seed	48702
Stratum Sample Size	2
Number of Strata	4
Total Sample Size	8
Output Data Set	SAMPLEHOSPITALS

The following PROC PRINT statements display the sample hospitals and produce Output 87.2.3:

```
title1 'Hospital Utilization Survey';
title2 'Sample Selected by Stratified PPS Design';
proc print data=SampleHospitals;
run;
```

Output 87.2.3 Sample Hospitals

Hospital Utilization Survey
Sample Selected by Stratified PPS Design

Obs	Type	Size	Hospital	Size Measure	Selection Prob	Sampling Weight	Jt Selection Prob
1	Rural	Small	079	2.127	0.13516	7.39868	0.01851
2	Rural	Small	236	5.279	0.33545	2.98106	0.01851
3	Urban	Small	006	4.249	0.17600	5.68181	0.01454
4	Urban	Small	195	5.024	0.20810	4.80533	0.01454
5	Urban	Medium	133	46.992	0.41357	2.41795	0.11305
6	Urban	Medium	218	48.231	0.42448	2.35584	0.11305
7	Urban	Large	026	61.460	0.63445	1.57617	0.31505
8	Urban	Large	058	65.931	0.68060	1.46929	0.31505

The variable SelectionProb contains the selection probability for each hospital in the sample. The variable JtSelectionProb contains the joint probability of selection for the two sample hospitals in the same stratum. The variable SamplingWeight contains the sampling weight component for this first stage of the design. The final-stage weight components, which correspond to patient record selection within hospitals, can be multiplied by the hospital weight components to obtain the overall sampling weights.

Example 87.3: PPS (Dollar-Unit) Sampling

A small company wants to audit employee travel expenses in an effort to improve the expense reporting procedure and possibly reduce expenses. The company does not have resources to examine all expense reports and wants to use statistical sampling to objectively select expense reports for audit.

The data set TravelExpense contains the dollar amount of all employee travel expense transactions during the past month:

```
data TravelExpense;
   input ID$ Amount @@;
   if (Amount < 500) then Level='1_Low ';
      else if (Amount > 1500) then Level='3_High';
      else Level='2_Avg ';
   datalines;
110  237.18   002  567.89   234  118.50
743   74.38   411 1287.23   782  258.10
216  325.36   174  218.38   568 1670.80
302  134.71   285 2020.70   314   47.80
139 1183.45   775  330.54   425  780.10
506  895.80   239  620.10   011  420.18
672  979.66   142  810.25   738  670.85
192  314.58   243   87.50   263 1893.40
496  753.30   332  540.65   486 2580.35
614  230.56   654  185.60   308  688.43
784  505.14   017  205.48   162  650.42
289 1348.34   691   30.50   545 2214.80
517  940.35   382  217.85   024  142.90
478  806.90   107  560.72
;
```

In the SAS data set TravelExpense, the variable ID identifies the travel expense report. The variable Amount contains the dollar amount of the reported expense. The variable Level equals '1_Low', '2_Avg', or '3_High', depending on the value of Amount.

In the sample design for this audit, expense reports are stratified by Level. This ensures that each of these expense levels is included in the sample and also permits a disproportionate allocation of the sample, selecting proportionately more of the expense reports from the higher levels. Within strata, the sample of expense reports is selected with probability proportional to the amount of the expense, thus giving a greater chance of selection to larger expenses. In auditing terms, this is known as monetary-unit sampling. See Wilburn (1984) for details.

PROC SURVEYSELECT requires that the input data set be sorted by the STRATA variables. The following PROC SORT statements sort the TravelExpense data set by the stratification variable Level.

```
proc sort data=TravelExpense;
   by Level;
run;
```

Output 87.3.1 displays the sampling frame data set TravelExpense, which contains 41 observations.

Output 87.3.1 Sampling Frame

Travel Expense Audit

41	545	2214.80	3_High

The following PROC SURVEYSELECT statements select a probability sample of expense reports from the TravelExpense data set by using the stratified design with PPS selection within strata:

```
title1 'Travel Expense Audit';
title2 'Stratified PPS (Dollar-Unit) Sampling';
proc surveyselect data=TravelExpense
      method=pps n=(6 10 4)
      seed=47279 out=AuditSample;
   size Amount;
   strata Level;
run;
```

The STRATA statement names the stratification variable Level. The SIZE statement specifies the size measure variable Amount. In the PROC SURVEYSELECT statement, the METHOD=PPS option requests sample selection with probability proportional to size and without replacement. The N=(6 10 4) option specifies the stratum sample sizes, listing the sample sizes in the same order as the strata appear in the TravelExpense data set. The sample size of 6 corresponds to the first stratum, Level = '1_Low'; the sample size of 10 corresponds to the second stratum, Level = '2_Avg'; and 4 corresponds to the last stratum, Level = '3_High'. The SEED=47279 option specifies '47279' as the initial seed for random number generation.

Output 87.3.2 displays the output from PROC SURVEYSELECT. A total of 20 expense reports are selected for audit. The data set AuditSample contains the sample of travel expense reports.

Output 87.3.2 Sample Selection Summary

```
                    Travel Expense Audit
                Stratified PPS (Dollar-Unit) Sampling

                     The SURVEYSELECT Procedure

Example 87.4: Proportional Allocation

This example uses the Customers data set from the section "Getting Started: SURVEYSELECT Procedure" on page 6615. The data set Customers contains an Internet service provider's current subscribers, and the service provider wants to select a sample from this population for a customer satisfaction survey. This example illustrates proportional allocation, which allocates the total sample size among the strata in proportion to the strata sizes.

The section "Getting Started: SURVEYSELECT Procedure" on page 6615 gives an example of stratified sampling, where the list of customers is stratified by State and Type. Figure 87.4 displays the strata in a table of State by Type for the 13,471 customers. There are four states and two levels of Type, forming a total of eight strata. A sample of 15 customers was selected from each stratum by using the following PROC SURVEYSELECT statements:

```
title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling';
proc surveyselect data=Customers
      method=srs n=15
      seed=1953 out=SampleStrata;
   strata State Type;
run;
```

The STRATA statement names the stratification variables State and Type. In the PROC SURVEYSELECT statement, the N=15 option specifies a sample size of 15 customers for each stratum.

Instead of specifying the number of customers to select from each stratum, you can specify the total sample size and request allocation of the total sample size among the strata. The following PROC SURVEYSELECT statements request proportional allocation, which allocates the total sample size in proportion to the stratum sizes:

```
title1 'Customer Satisfaction Survey';
title2 'Proportional Allocation';
proc surveyselect data=Customers
      n=1000 out=SampleSizes;
   strata State Type / alloc=prop nosample;
run;
```

The STRATA statement names the stratification variables State and Type. In the STRATA statement, the ALLOC=PROP option requests proportional allocation. The NOSAMPLE option requests that no sample be selected after the procedure computes the sample size allocation. In the PROC SURVEYSELECT statement, the N=1000 option specifies a total sample size of 1000 customers to be allocated among the strata.

Output 87.4.1 displays the output from PROC SURVEYSELECT, which summarizes the sample allocation. The total sample size of 1000 is allocated among the eight strata by using proportional allocation. The allocated sample sizes are stored in the SAS data set SampleSizes.

Output 87.4.1 Proportional Allocation Summary

```
                    Customer Satisfaction Survey
                      Proportional Allocation

                     The SURVEYSELECT Procedure

                  Allocation          Proportional
                  Strata Variables    State
                                      Type

              Input Data Set                   CUSTOMERS
              Number of Strata                         8
              Total Sample Size                     1000
              Allocation Output Data Set     SAMPLESIZES
```

The following PROC PRINT statements display the allocation output data set SampleSizes, which is shown in Output 87.4.2:

```
title1 'Customer Satisfaction Survey';
title2 'Proportional Allocation';
proc print data=SampleSizes;
run;
```

Output 87.4.2 Stratum Sample Sizes

Customer Satisfaction Survey
Proportional Allocation

Obs	State	Type	Total	Alloc Proportion	Sample Size	Actual Proportion
1	AL	New	1238	0.09190	92	0.092
2	AL	Old	706	0.05241	52	0.052
3	FL	New	2170	0.16109	161	0.161
4	FL	Old	1370	0.10170	102	0.102
5	GA	New	3488	0.25893	259	0.259
6	GA	Old	1940	0.14401	144	0.144
7	SC	New	1684	0.12501	125	0.125
8	SC	Old	875	0.06495	65	0.065

The output data set SampleSizes includes one observation for each of the eight strata, which are identified by the stratification variables State and Type. The variable Total contains the number of sampling units in the stratum, and the variable AllocProportion contains the proportion of the total sample size to allocate to the stratum. The variable SampleSize contains the allocated stratum sample size. For the first stratum (State='AL' and Type='New'), the total number of sampling units is 1238 customers, the allocation proportion is 0.09190, and the allocated sample size is 92 customers. The sum of the allocated sample sizes equals the requested total sample size of 1000 customers.

The output data set also includes the variable ActualProportion, which contains actual stratum proportions of the total sample size. The actual proportion for a stratum equals the stratum sample size divided by the total sample size. For the first stratum (State='AL' and Type='New'), the actual proportion is 0.092, while the allocation proportion is 0.09190. The target sample sizes computed from the allocation proportions are often not integers, and PROC SURVEYSELECT uses a rounding algorithm to obtain integer sample sizes and maintain the requested total sample size. Due to rounding and other restrictions, the actual proportions can differ from the target allocation proportions. See the section "Sample Size Allocation" on page 6654 for details.

If you want to use the allocated sample sizes in a later invocation of PROC SURVEYSELECT, you can name the allocation data set in the N=*SAS-data-set* option, as shown in the following PROC SURVEYSELECT statements:

```
title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling';
proc surveyselect data=Customers
      method=srs n=SampleSizes
      seed=1953 out=SampleStrata;
   strata State Type;
run;
```

Overview: TCALIS Procedure

Structural equation modeling is an important statistical tool in social and behavioral sciences. Structural equations express relationships among a system of variables that can be either observed variables (manifest variables) or unobserved hypothetical variables (latent variables). For an introduction to latent variable models, see Loehlin (2004), Bollen (1989b), Everitt (1984), or Long (1983); and for manifest variables with measurement errors, see Fuller (1987).

In structural models, as opposed to functional models, all variables are taken to be random rather than having fixed levels. For maximum likelihood (default) and generalized least squares estimation in PROC TCALIS, the random variables are assumed to have an approximately multivariate normal distribution. Nonnormality, especially high kurtosis, can produce poor estimates and grossly incorrect standard errors and hypothesis tests, even in large samples. Consequently, the assumption of normality is much more important than in models with nonstochastic exogenous variables. You should remove outliers and consider transformations of nonnormal variables before using PROC TCALIS with maximum likelihood (default) or generalized least squares estimation. If the number of observations is sufficiently large, Browne's asymptotically distribution-free (ADF) estimation method can be used.

You can use the TCALIS procedure to estimate parameters and test hypotheses for constrained and unconstrained problems in various situations, including but not limited to the following:

- exploratory and confirmatory factor analysis of any order
- linear measurement-error models or regression with errors in variables
- multiple and multivariate linear regression
- multiple-group structural equation modeling with mean and covariance structures
- path analysis and causal modeling
- simultaneous equation models with reciprocal causation
- structured covariance and mean matrices

To specify models in PROC TCALIS, you can use a variety of modeling languages:

- FACTOR—supports the input of factor-variable relations
- LINEQS—like the EQS program (Bentler 1995), uses equations to describe variable relationships
- LISMOD—utilizes LISREL (Jöreskog and Sörbom 1985) model matrices for defining models
- MSTRUCT—supports direct parameterization in the mean and covariance matrices
- PATH—provides an intuitive causal path specification interface
- RAM—utilizes the formulation of the reticular action model (McArdle and McDonald 1984)
- REFMODEL—provides a quick way for model referencing and respecification

Various modeling languages are provided to suit a wide range of researchers' background and modeling philosophy. However, statistical situations might arise when one modeling language is more convenient than the others. This will be discussed in the section "Which Modeling Language?" on page 6714.

In addition to basic model specification, you can set various parameter constraints in PROC TCALIS. Equality constraints on parameters can be achieved by simply giving the same parameter names in different parts of the model. Boundary, linear, and nonlinear constraints are supported as well. If parameters in the model are dependent on additional parameters, you can define the dependence by using the PARAMETERS and the SAS programming statements.

Before the data are analyzed, researchers might be interested in studying some statistical properties of the data. PROC TCALIS can provide the following statistical summary of the data:

- covariance and mean matrices and their properties
- descriptive statistics like means, standard deviations, univariate skewness, and kurtosis measures
- multivariate measures of kurtosis
- weight matrix and its descriptive properties

After a model is fitted and accepted by the researcher, PROC TCALIS can provide the following supplementary statistical analysis:

- computing squared multiple correlations and determination coefficients
- direct and indirect effects partitioning with standard error estimates
- model modification tests such as Lagrange multiplier and Wald tests
- computing fit summary indices
- computing predicted moments of the model
- residual analysis
- factor rotations
- standardized solutions with standard errors
- testing parametric functions, individually or simultaneously

When fitting a model, you need to choose an estimation method. The following estimation methods are supported in the TCALIS procedure:

- diagonally weighted least squares (DWLS, with optional weight matrix input)
- generalized least squares (GLS, with optional weight matrix input)
- maximum likelihood (ML, for multivariate normal data); this is the default method
- unweighted least squares (ULS)
- weighted least squares or asymptotically distribution-free method (WLS or ADF, with optional weight matrix input)

Estimation methods implemented in PROC TCALIS do not exhaust all alternatives in the field. For example, partial least squares (PLS) is not implemented. See the section "Estimation Criteria" on page 6888 for details about estimation criteria used in PROC TCALIS. Note that there is a SAS/STAT procedure called PROC PLS, which employs the partial least squares technique but for a different class of models than those of PROC TCALIS. For general path analysis with latent variables, consider using PROC TCALIS.

All estimation methods need some starting values for the parameter estimates. You can provide starting values for any parameters. If there is any estimate without a starting value provided, PROC TCALIS determines the starting value by using one or any combination of the following methods:

- approximate factor analysis
- default initial values
- instrumental variable method
- matching observed moments of exogenous variables
- McDonald's (McDonald and Hartmann 1992) method
- ordinary least squares estimation
- random number generation, if a seed is provided
- two-stage least squares estimation

Although no methods for initial estimates are completely foolproof, the initial estimation methods provided by PROC TCALIS behave reasonably well in most common applications.

With initial estimates, PROC TCALIS will iterate the solutions so as to achieve the optimum solution as defined by the estimation criterion. This is a process known as optimization. Because numerical problems can occur in any optimization process, the TCALIS procedure offers several optimization algorithms so that you can choose alternative algorithms when the one being used fails. The following optimization algorithms are supported in PROC TCALIS:

- Levenberg-Marquardt algorithm (Moré, 1978)
- trust-region algorithm (Gay 1983)
- Newton-Raphson algorithm with line search
- ridge-stabilized Newton-Raphson algorithm
- various quasi-Newton and dual quasi-Newton algorithms: Broyden-Fletcher-Goldfarb-Shanno and Davidon-Fletcher-Powell, including a sequential quadratic programming algorithm for processing nonlinear equality and inequality constraints
- various conjugate gradient algorithms: automatic restart algorithm of Powell (1977), Fletcher-Reeves, Polak-Ribiere, and conjugate descent algorithm of Fletcher (1980)

In addition to the ability to save output tables as data sets by using the ODS OUTPUT statement, PROC TCALIS supports the following types of output data sets so that you can save your analysis results for later use:

- OUTEST= data sets for storing parameter estimates and their covariance estimates
- OUTFIT= data sets for storing fit indices and some pertinent modeling information
- OUTMODEL= data sets for storing model specifications and final estimates
- OUTSTAT= data sets for storing descriptive statistics, residuals, predicted moments, and latent variable scores regression coefficients
- OUTWGT= data sets for storing the weight matrices used in the modeling

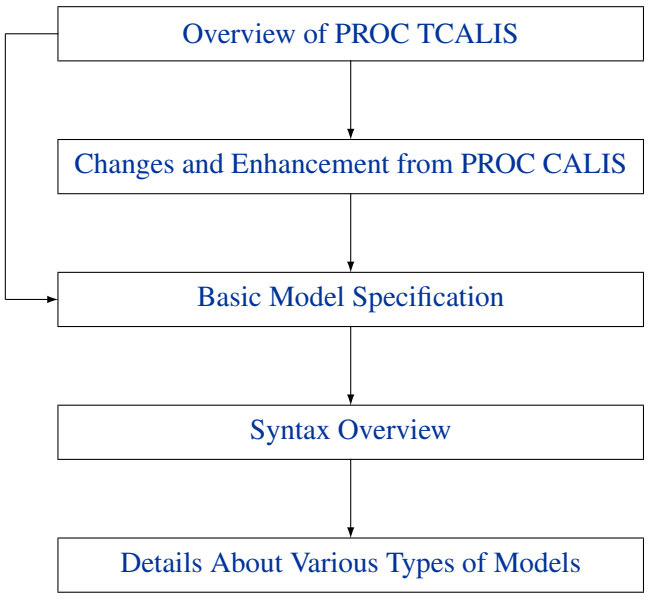
The OUTEST=, OUTMODEL=, and OUTWGT= data sets can be used as input data sets for subsequent analyses. That is, in addition to the input data provided by the DATA= option, PROC TCALIS supports the following input data sets for various purposes in the analysis:

- INEST= data sets for providing initial parameter estimates. An INEST= data set could be an OUTEST= data set created from a previous analysis.
- INMODEL= data sets for providing model specifications and initial estimates. An INMODEL= data set could be an OUTMODEL= data set created from a previous analysis.
- INWGT= data sets for providing the weight matrices. An INWGT= data set could be an OUTWGT= data set created from a previous analysis.

The TCALIS procedure uses ODS Graphics to create graphs as part of its output. High-quality residual histograms are available in PROC TCALIS. See Chapter 21, "Statistical Graphics Using ODS," for general information about ODS Graphics. See the section "ODS Graphics" on page 6952 and the PLOTS= option on page 6741 for specific information about the statistical graphics available with the TCALIS procedure.

A Guide to the PROC TCALIS Documentation

The TCALIS procedure fits structural equation models using a variety of modeling languages. This chapter provides documentation for all of them. Additionally, some sections provide introductions to the model specification, the theory behind the software, and other technical details. While some introductory material and examples are provided, this chapter is not a textbook for structural equation modeling and related topics. For didactic treatment of structural equation models with latent variables, see the books by Bollen (1989b) and Loehlin (2004). Therefore, reading this chapter sequentially is not a good strategy for learning about PROC TCALIS. This section provides a guide or "road map" to the rest of the PROC TCALIS chapter starting with the basics and continuing



through more advanced topics. Many sections assume that you already have a basic understanding of structural equation modeling.

The following table shows three different skills levels of using the TCALIS procedure (basic, intermediate, and advanced) and their milestones:

Level	Milestone
Basic	You are able to specify simple models, but might make mistakes
Intermediate	You are able to specify more sophisticated models with few syntactic and semantic mistakes
Advanced	You are able to use the advanced options provided by PROC TCALIS

In the next three sections, each skills level is discussed, followed by an introductory section of the reference topics that are not covered in any of the skills levels.

Guide to the Basic Skills Level

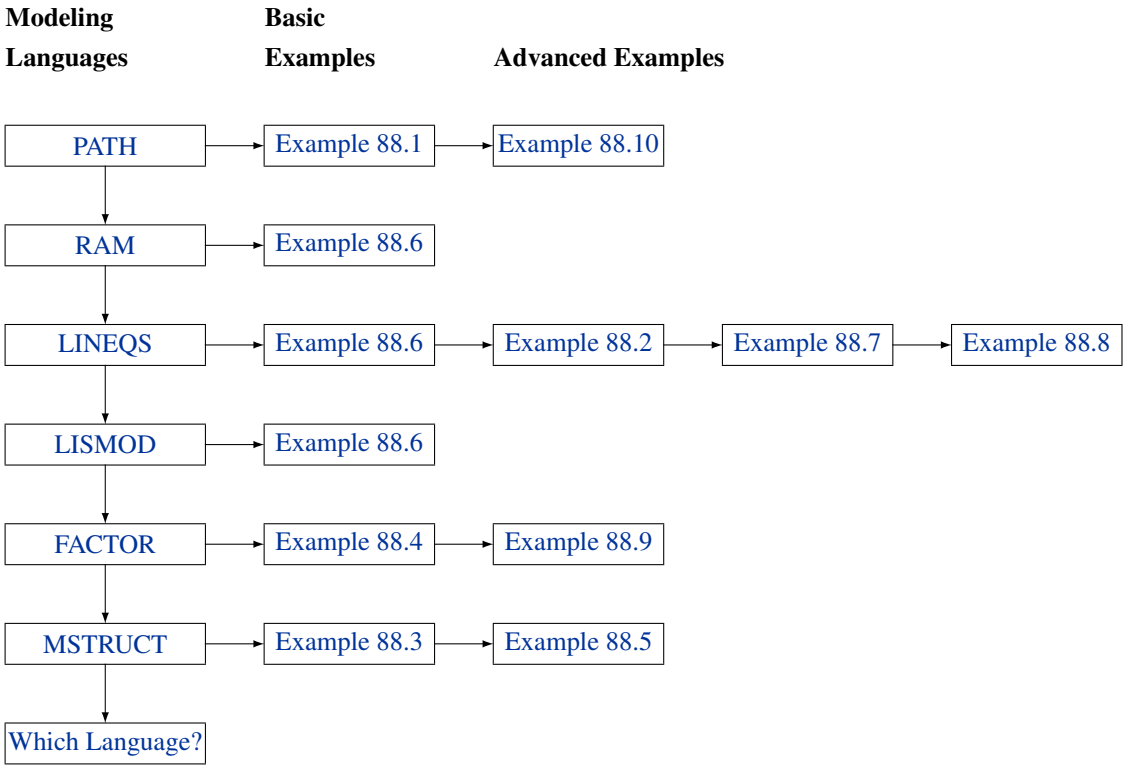
Overview of PROC TCALIS

The section "Overview: TCALIS Procedure" on page 6681 gives you an overview of the PROC TCALIS procedure and an overall picture of the TCALIS procedure but without the details.

Changes and Enhancement from PROC CALIS

Read the section "Changes and Enhancement from PROC CALIS" on page 6695 if you have previous experience with PROC CALIS, the predecessor of PROC TCALIS. If you have not used PROC CALIS previously, you may skip this section.

Basic Model Specification



The structural equation example in the section "Getting Started: TCALIS Procedure" on page 6704 provides the best starting point for learning the basic model specification. You learn how to represent your theory by using a path diagram and then translate the diagram into the PATH model for PROC TCALIS to analyze. Because the PATH modeling language is new, this example is useful whether or not you have previous experience with PROC CALIS. The PATH model is specified in the section "PATH Model" on page 6706. The corresponding results are shown and discussed in Example 88.1.

After you learn about the PATH modeling language and an example of its application, you can either continue to learn more modeling languages or skip to the syntax overview. However, you do not need to learn all of the modeling languages in PROC TCALIS. Any one of the modeling languages (LINEQS, LISMOD, PATH, or RAM) is sufficient for specifying a very wide class of structural equation models. PROC TCALIS provides different kinds of modeling languages because different researchers might have previously learned different modeling languages or approaches.

You can go to the next step for an overview of the PROC TCALIS syntax and learn other modeling languages at a later time. See "Getting Started: TCALIS Procedure" on page 6704 for a brief overview of the various modeling languages. In these examples, model specifications are shown and explained, but no analysis results are discussed. Each subsection discusses the same model but uses a different modeling language. In the subsections "LISMOD Model" on page 6709, "LINEQS Model" on page 6708, and "RAM Model" on page 6707, you learn how to specify a structural equation model equivalently by using the LINEQS, LISMOD, and RAM modeling languages, respectively. In the subsection "A Factor Model Example" on page 6710, you learn how to specify a confirmatory factor model by using the FACTOR modeling language. In the subsection "Direct Covariance Structures Analysis" on page 6712, you learn how to specify the covariance structures directly on the covariance matrix by using the MSTRUCT modeling language.

After studying the examples in the "Getting Started: TCALIS Procedure" section, you can strengthen your understanding of the various modeling languages by studying more examples such as those in section "Examples: TCALIS Procedure" on page 6953. Unlike the examples in the "Getting Started: TCALIS Procedure" section, examples in the "Examples: TCALIS Procedure" section include the analysis results, in addition to the explanations of the model specifications. The following figure provides a guide to studying the examples in the "Examples: TCALIS Procedure" section.

Figure 88.1 A Guide for Studying the Examples

In this guide, the various modeling languages are listed in sequence. However, only the PATH modeling language is a prerequisite of other modeling languages. You are not required to learn the languages in the order presented in this guide. For example, you can skip the RAM modeling language and learn the LINEQS model specification after you finish the PATH model language. Similarly, you can learn the LISMOD language without going through the RAM or LINEQS modeling languages if you are familiar with the traditional Keesling-Wiley-Jöreskog measurement and structural models (Keesling 1972; Wiley 1973; Jöreskog 1973).

You can learn each modeling language by studying the examples in the "Getting Started: TCALIS Procedure" sections and in the "Examples: TCALIS Procedure" sections. Examples are listed for each modeling language with the basic examples listed before the more advanced examples. The basic examples are required, and the more advanced examples can be skimmed in the first reading. You might need to revisit the more advanced examples as your understanding grows. A summary of the examples is presented next.

Example 88.1. Path Analysis: Stability of Alienation

In this example, you learn how to specify a simple PATH model and interpret the basic estimation results. The results are shown in considerable detail. The output and analyses include: a model summary, initial model specification, initial estimation method, optimization history and results, residual analyses, residual graphics, estimation results, squared multiple correlations, and standardized results.

Example 88.2. Simultaneous Equations with Mean Structures and Reciprocal Paths

In this econometric example, you learn how to specify models using the LINEQS modeling language. This example also illustrates the specification of reciprocal effects, the simultaneous analysis of the mean and covariance structures, the setting of bounds for parameters, and the definitions of meta-parameters by using the PARAMETERS and SAS programming statements. You also learn how to shorten your output results by using some global display options such as the PSHORT and NOSTAND options in the PROC TCALIS statement.

Example 88.3. A Direct Covariance Structures Model

In this example, you fit your covariance structures directly on the covariance matrix by using the MSTRUCT modeling language. You also learn how to use the FITINDEX statement to create a customized model fit summary and how to save the fit summary statistics into an external file.

Example 88.4. Confirmatory Factor Analysis: Cognitive Abilities

Confirmatory factor analysis is illustrated in this example by using the FACTOR modeling language. In addition, you use the MODIFICATION option in the PROC TCALIS statement to compute LM test indices for model modifications.

Example 88.5. Testing Equality of Two Covariance Matrices Using A Multiple-Group Analysis

In this example, a simple multiple-group analysis is illustrated by the MSTRUCT modeling language. You also learn how to use the **ods select** statement to customize your printed output.

Example 88.6. Illustrating Various General Modeling Languages

This example extends Example 88.1, which uses the PATH modeling language, and shows how to use the other general modeling languages: RAM, LINEQS, and LISMOD. These modeling languages enable you to specify the same path model as in Example 88.1 and get equivalent results. This example shows the connections between the general modeling languages supported in PROC TCALIS. A good understanding of Example 88.1 is a prerequisite for this example.

Example 88.7. Fitting a Latent Growth Curve Model

This is an advanced example that illustrates the use of structural equation modeling techniques for fitting latent growth curve models. In this example, you learn how to specify random intercepts and random slopes by using the LINEQS modeling language. In addition to the modeling of the covariance structures, you also learn how to specify the mean structure parameters.

Example 88.8. Higher-Order and Hierarchical Factor Models

This is an advanced example for confirmatory factor analysis. It involves the specifications of higher-order and hierarchical factor models. Because higher-order factor models cannot be specified by the FACTOR modeling language, you need to use the LINEQS model specification instead.

A second-order factor model and a bifactor model are fit. Linear constraints on parameters are illustrated by using the PARAMETERS and the SAS programming statements. Relationships between the second-order factor model and the bifactor model are numerically illustrated.

Example 88.9. Linear Relations Among Factor Loadings

This is an advanced example of a first-order confirmatory factor analysis by using the FACTOR modeling language. In this example, you learn how to use the PARAMETERS and the SAS programming statements to set up dependent parameters in your model. You also learn how to specify the correlation structures for a specific confirmatory factor model.

Example 88.10. A Multiple-group Model for Purchasing Behavior

This is a sophisticated example of analyzing a path model. The PATH modeling language is used. In this example, a two-group analysis of mean and covariance structures is conducted. You learn how to use a SAS macro to organize your model specification, the REFMODEL statement to reference properly defined models, and the SIMTEST statement to test a priori simultaneous hypotheses.

Once you are familiar with various modeling languages, you might wonder which modeling language should be used in a given situation. The section "Which Modeling Language?" on page 6714 provides some guidelines and suggestions.

Syntax Overview

Now that you have some basic understanding of the modeling languages of PROC TCALIS, you can look at the global structure of PROC TCALIS specifications. The section "Syntax: TCALIS Procedure" on page 6715 shows the syntactic structure of PROC TCALIS. However, reading the "Syntax: TCALIS Procedure" section sequentially might not be a good strategy. The statements used in PROC TCALIS are classified in the section "Classes of Statements" on page 6716. Understanding this section is a prerequisite for understanding single-group and multiple-group analyses in PROC TCALIS. Syntax for single-group analyses is described in the section "Single-Group Analysis Syntax" on page 6719, and syntax for multiple-group analyses is described in the section "Multiple-Group Multiple-Model Analysis Syntax" on page 6720.

You might also want to get an overview of the options on the PROC TCALIS statement in the section "PROC TCALIS Statement" on page 6721. However, you can skip the detailed listing of the available options on the PROC TCALIS statement. Most of these details serve as references, so they are consulted only when needed. You can just read the summary tables for the available options on the PROC TCALIS statement in the following subsections:

- "Data Set Options" on page 6721
- "Model and Estimation Options" on page 6722
- "Options for Fit Statistics" on page 6722
- "Options for Statistical Analysis" on page 6723

- "Global Display Options" on page 6724
- "Optimization Options" on page 6725

Details About Various Types of Models

Several subsections in the section "Details: TCALIS Procedure" on page 6819 will help you gain a deeper understanding of the various types of modeling languages:

Language	Section
FACTOR:	"The FACTOR Model" on page 6863
LINEQS:	"The LINEQS Model" on page 6839
LISMOD:	"The LISMOD Model and Submodels" on page 6847
MSTRUCT:	"The MSTRUCT Model" on page 6877
PATH:	"The PATH Model" on page 6870
RAM:	"The RAM Model" on page 6855

The specification techniques you learn from the examples cover only parts of the modeling language. A more complete treatment of the modeling languages is covered in these subsections. In addition, you can also learn the mathematical models, model restrictions, and default parameterization of all supported modeling languages in these subsections.

Guide to the Intermediate Skills Level

At the intermediate level, you learn to minimize your mistakes in model specification and to establish more sophisticated modeling techniques. The following topics in the "Details: TCALIS Procedure" section or elsewhere can help:

- "Naming Variables and Parameters" on page 6880

  This section summarizes the naming rules and conventions for variable and parameter names in specifying models.

- "Setting Constraints on Parameters" on page 6882

  This section covers various techniques of constraining parameters in model specifications.

- "Automatic Variable Selection" on page 6887

  This section discusses how PROC TCALIS treats variables in the models and variables in the data sets. It also discusses situations where the specification of the VAR statement specification is deemed necessary.

- "Computational Problems" on page 6932

  This section discusses computational problems that occur quite commonly in structural equation modeling. It also discusses some possible remedies of the computational problem.

- "Missing Values" on page 6919

  This small section describes the default treatment of missing values.

- REFMODEL statement on page 6811 and RENAMEPARM statement on page 6812

  These statements are useful when you need to make references to well-defined models when specifying a "new" model. See Example 88.10 for an application.

Revisit topics and examples covered at the basic level, as needed, to help you better understand the topics at the intermediate level.

Guide to the Advanced Skills Level

At the advanced level, you learn to use the advanced data analysis and output control tools supported by PROC TCALIS.

Advanced Data Analysis Tools

The following advanced data analysis topics are discussed:

- Assessment of fit

  The section "Assessment of Fit" on page 6900 presents the fit indices used in PROC TCALIS. However, the more important topics covered in this section are about how model fit indices are organized and used, how residuals can be used to gauge the fitting of individual parts of the model, and how the coefficients of determination are defined for equations.

  To customize your fit summary table, you can use the options on the FITINDEX statement.

- Effect partitioning

  The section "Total, Direct, and Indirect Effects" on page 6913 discusses the total, direct, and indirect effects and their computations. The stability coefficient of reciprocal causation is also defined.

  To customize the effect analysis, you can use the EFFPART statement.

- Counting and adjusting degrees of freedom

  The section "Counting the Degrees of Freedom" on page 6897 describes how PROC TCALIS computes model fit degrees of freedom and how you can use some options on the PROC TCALIS statement to make degrees-of-freedom adjustments.

  To adjust the model fit degrees of freedom, you can use the DFREDUCE= and NOADJDF options in the PROC TCALIS statement.

- Standardized solutions

  Standardization schemes used in PROC TCALIS are described and discussed in the section "Standardized Solutions" on page 6915.

Standardized solutions are displayed by default. You can turn them off by using the NOSTAND option of the PROC TCALIS statement.

- Model modifications

  In the section "Modification Indices" on page 6917, modification indices such as Lagrange multiplier test indices and Wald statistics are defined and discussed. These indices can be used either to enhance your model fit or to make your model more precise.

  To limit the modification process only to those parameters of interest, you can use the LMTESTS statement to customize the sets of LM tests conducted on potential parameters.

- A Priori Parametric Function Testing

  You can use the TESTFUNC statement to test a priori hypotheses individually. You can use the SIMTEST statement to test a priori hypotheses simultaneously.

Advanced Output Control Tools

To be more effective in presenting your analysis results, you need to be more sophisticated in controlling your output. Some customization tools have been discussed in the previous section "Advanced Data Analysis Tools" on page 6692 and might have been mentioned in the examples included in the basic and the intermediate levels. In the following topics, these output control tools are presented in a more organized way so that you can have a systematic study scheme of these tools.

- Global output control tools in PROC TCALIS

  You can control output displays in PROC TCALIS either by the global display options or by the individual output printing options. Each global display option typically controls more than one output display, while each individual output display controls only one output display. The global display options can both enable and suppress output displays, and they can also alter the format of the output.

  See the ALL, PRINT, PSHORT, PSUMMARY, and NOPRINT options for ways to control the appearances of the output. See the section "Global Display Options" on page 6724 for details about the global display options and their relationships with the individual output display options. Also see the ORDERALL, ORDERGROUPS, ORDERMODELS, ORDERSPEC, PARMNAME, PRIMAT, NOORDERSPEC, NOPARMNAME, NOSTAND, and NOSE options which control the output formats.

- Customized analysis tools in PROC TCALIS

  Many individual output displays in PROC TCALIS can be customized via specific options or statements. If you do not use these customization tools, the default output will usually contain a large number of displays or displays with very large dimensions. These customized analysis tools are as follows:

  – The ON=, OFF=, ON(ONLY)= options in the FITINDEX statement enable you to select individual or groups of model fit indices or modeling information to display. You can still save the information of *all* fit indices in an external file by using the OUTFIT= option.

  - The EFFPART statement enables you to customize the effect analysis. You display only those effects of substantive interest.
  - The LMTESTS statement enables you to customize the sets of LM tests of interest. You test only those potential parameters that are theoretically and substantively possible.

- Output selection and destinations by the ODS system

  This kind of output control is used not only for PROC TCALIS, but is used for all procedures that support the ODS system. The most common uses include output selection and output destinations assignment. You use the ODS SELECT statement together with the ODS table names or graph names to select particular output displays. See the section "ODS Table Names" on page 6939 for these names in PROC TCALIS.

  The default output destination of PROC TCALIS is the listing destination. You can add or change the destinations by using statements such as **`ods html`** (for html output), **`ods rtf`** (for rich text output), and so on. For details, see Chapter 20, "Using the Output Delivery System."

Reference Topics

Some topics in the "Details: TCALIS Procedure" section are intended primarily for references—you consult them only when you encounter specific problems in the PROC TCALIS modeling or when you need to know the very fine technical details in certain special situations. Many of these reference topics in the "Details: TCALIS Procedure" section are not required for practical applications of structural equation modeling. The following technical topics are discussed:

- Measures of multivariate kurtosis and skewness

  This is covered in the section "Measures of Multivariate Kurtosis" on page 6919.

- Estimation criteria and the mathematical functions for estimation

  The section "Estimation Criteria" on page 6888 presents formulas for various estimation criteria. The relationships among these criteria are shown in the section "Relationships among Estimation Criteria" on page 6893. To optimize an estimation criterion, you usually need its gradient and Hessian functions. These functions are detailed in the section "Gradient, Hessian, Information Matrix, and Approximate Standard Errors" on page 6894, where you can also find information about the computation of the standard error estimates in PROC TCALIS.

- Initial estimation

  Initial estimates are necessary for all kinds of iterative optimization techniques. They are described in section "Initial Estimates" on page 6922.

- Use of optimization techniques

  Optimization techniques are covered in section "Use of Optimization Techniques" on page 6923. See this section if you need to fine-tune the optimization.

- Output displays and control

  The output displays in PROC TCALIS are listed in the section "Displayed Output" on page 6935. General requirements for the displays are also shown.

  With the ODS system, each table and graph has a name, which can be used on the ODS OUTPUT or ODS SELECT statement. See the section "ODS Table Names" on page 6939 for the ODS table and graph names.

- Input and output files

  PROC TCALIS supports several input and output data files for data, model information, weight matrices, estimates, fit indices, and estimation and descriptive statistics. The uses and the structures of these input and output data files are described in the sections "Input Data Sets" on page 6819 and "Output Data Sets" on page 6823.

Changes and Enhancement from PROC CALIS

PROC TCALIS was modified from PROC CALIS. PROC TCALIS is not a simple functional enhancement of PROC CALIS. The basic computational architecture of PROC TCALIS is quite different from that of PROC CALIS. Hence, some discrepancies between the two procedures are less apparent. There are also some temporary discrepancies due to issues that are still being resolved.

In this section, new functionalities in PROC TCALIS are described, followed by some lists for comparing the options and statements available in PROC CALIS and PROC TCALIS. Finally, ODS table names in PROC CALIS are listed with their corresponding new names in PROC TCALIS.

New Features

There are several notably new features in PROC TCALIS:

- new modeling languages
- multiple-group analysis
- improved mean structures analysis
- general parametric functions testing
- customizable fit summary table
- improved standardized results
- improved effects analysis
- customizable Lagrange multiplier tests

- more rotation options in exploratory factor analysis
- input order respecting
- improved OUTRAM= data set format

These new functionalities are outlined in the following sections.

New Modeling Languages in PROC TCALIS

To accommodate various modeling backgrounds and philosophies of researchers, more modeling languages are supported in PROC TCALIS. Three new modeling languages are provided: LISMOD, MSTRUCT, and PATH.

The LISMOD modeling language is a matrix-based parameter specification method modified from the LISREL model developed by Jöreskog and Sörbom. You can specify parameters as matrix entries by using the LISMOD language. For details, see the LISMOD statement on page 6772.

The MSTRUCT modeling language is also a matrix-based parameter specification method. You can specify parameters directly in the structured mean and covariance matrices in this language. For details, see the MSTRUCT statement on page 6792.

The PATH modeling language provides a tool to specify causal relations among variables by using paths (represented by arrows). It is especially suitable for path analysis, although it can also be applied to general structural models. For details, see the PATH statement on page 6799.

Although the FACTOR and RAM modeling languages are not new, their syntax has been changed for easier specifications. The FACTOR and RAM modeling languages are both matrix-based specification methods in PROC CALIS. When you specify parameters in your model, you must use row and column numbers of the model matrices to refer to the variables involved. However, in PROC TCALIS these matrix-based languages are replaced by the more intuitive approach. For confirmatory factor analysis in PROC TCALIS, you can specify the factors to variables paths (or loadings) by using the factor and variable names directly in the FACTOR statement. For the RAM specification in PROC TCALIS, you no longer need to implicitly assume a certain order for the variables and factors in matrices, as you do in PROC CALIS. Also, you no longer need to use the matrix numbers to refer to the types of parameter specifications. In each parameter specification of the RAM statement in PROC TCALIS, the variables and the parameter type involved are specified directly by using the variable names or meaningful keywords for parameter types.

To provide a quick and easy way to specify similar models, the REFMODEL statement is provided in PROC TCALIS. Using this statement, you can specify a new model by referring to another well-defined model. Supporting options PARM_PREFIX= and PARM_SUFFIX= and the RENAMEPARM statement enable you to change parameter names efficiently.

Multiple-Group Analysis

You can do multiple-group analysis in PROC TCALIS. Groups can also be fitted by multiple models simultaneously. You can use multiple GROUP statements to define independent groups of data.

Within the scope of each GROUP statement, you can set group-specific attributes and options for the associated group. See the GROUP statement on page 6764 for details.

You can use multiple MODEL statements to define models and the groups they fit. Within the scope of each MODEL statement, you specify your model by using one of the modeling languages provided by PROC TCALIS. You can use different modeling languages for different models. You can also set model-specific analysis and options for the model within the scope of a MODEL statement. See the MODEL statement on page 6789 for details.

Improved Mean Structures Analysis

In PROC CALIS, the mean structures are analyzed by means of augmented uncorrected moment matrices. This approach is an viable option only for maximum likelihood estimation. Often, this approach creates some interpretation problems in standardized results, R-square calculations, and so on. It is also difficult to set the mean parameters by using this approach.

In PROC TCALIS, the mean structures are analyzed directly as a term in the objective function being optimized. This method is applicable to all estimation methods and yields more interpretable results. You can use the MEANSTR option in the PROC TCALIS or MODEL statements to specify the analysis of mean structures explicitly. Alternatively, when you specify Intercept terms in LINEQS models, parameters in the MEAN statements, or parameters in the intercept or mean vector in the MATRIX statements, the mean structures of the model will be analyzed automatically.

As a result of the improved mean structures analysis, AUG, NOINT, UCOV, and UCORR options are obsolete in PROC TCALIS.

General Parametric Function Testing

You can test any differentiable parametric functions separately or simultaneously by using the TESTFUNC and the SIMTEST statements. A parametric function can be either a parameter in the model or a computed function defined by the SAS Programming statements. PROC TCALIS will analytically generate the necessary partial derivatives for computing the test statistics.

Customizable Fit Summary Table

In PROC TCALIS, you can customize the display of the fit summary table by selecting a subset of the fit indices to display. See the FITINDEX statement on page 6760 for details. You can also choose a particular type of chi-square correction for model fit chi-square statistics. A new OUTFIT= option enables you to store the fit indices in an external data set.

Improved Standardized Results

Standardized parameter estimates with standard errors are provided by default in PROC TCALIS. You can turn off the printing of standard error estimates by the NOSE option. To suppress the printing of the entire standardized results, you can use the NOSTAND option.

The standardized results in PROC TCALIS are somewhat different from that of PROC CALIS. In particular, in PROC TCALIS path coefficients attached to error terms will remain equal to 1 after standardization. The error variances are rescaled appropriately so as to maintain mathematical consistency. In contrast, after standardization PROC CALIS will make all error variances equal to 1 and the path coefficients attached to error terms will not be 1 in general. For interpretation, this is not desirable because error terms, by nature, should be a non-deterministic term added without modification (that is, multiplied by a path coefficient) to the deterministic terms in an equation. In this sense, the standardized method in PROC TCALIS is more interpretable.

Improved Effect Analysis

There are several improvements regarding the effects partitioning in PROC TCALIS. First, standardized effects are displayed in addition to unstandardized effects. Second, standard error estimates are provided for the standardized and unstandardized effects. Third, you can customize the effects analysis by using the EFFPART statement. This will enable you to display only those effects of interest. See the EFFPART statement on page 6751 statement for details.

Customizable Lagrange Multiplier Tests

In PROC TCALIS, you can set your own regions of the parameter space for the Lagrange multiplier (LM) tests. In the LMTESTS statement, you define sets of parameter regions. In each set, you include the regions of interest. In the output, LM statistics ranked within sets are displayed. The parameter that improves the model fit the most appears first. You can also set other display options in the LMTESTS statement.

More Rotation Options in Exploratory Factor Analysis

PROC TCALIS provides more orthogonal and oblique rotation options for exploratory factor analytic solutions. See the ROTATE= option in the FACTOR statement on page 6752 for details.

Input Order Respecting

When you use the LINEQS statement, PROC TCALIS will display equations in the order you specify in the input. The terms within each equation are also ordered the same way you specify them. Unfortunately, PROC CALIS does not have these properties. PROC CALIS might display equations and terms in a certain order that is not consistent with the input.

PROC TCALIS also respects the order of parameter specification in the following statements:

- COV
- MEAN
- PATH

- PCOV
- PVAR
- RAM
- STD

If you want to order the specification by parameter types, you can use the ORDERSPEC option.

PROC TCALIS also respects order when displaying model and group results. By default, the output results for models or groups follow the order of your input. By using the ORDERMODELS and ORDERGROUPS options, the output results for models or groups are ordered by the model or group numbers provided in the specification. The ORDERALL option combines all these ordering options.

Improved OUTRAM= Data Set Format

The OUTRAM= data sets in PROC CALIS stores the model specifications in terms of the RAM model matrix entries, even if the original model is specified by the LINEQS or FACTOR modeling language. The problem is that the modeler who did not write the original code in the RAM modeling language might not understand the contents of the OUTRAM= data set. This inconsistency is eliminated in PROC TCALIS by means of the new OUTMODEL= option (although you can still use the OUTRAM= option for the same purpose). In the OUTMODEL= data sets, different types of models would have different types of observations. The types of observations resemble closely the original modeling language used. See the OUTMODEL= option and the section "OUTMODEL= SAS-data-set" on page 6827 for more details.

Inactive Statements and Options

Inactive statements and options are those available in PROC CALIS, but not available in PROC TCALIS.

The COSAN statement is currently inactive in PROC TCALIS. COSAN model specification might be available in future releases of PROC TCALIS.

The following options are currently inactive in PROC TCALIS, but might be added back in future releases:

Option	Description	TCALIS Treatment
FDCODE	uses the finite difference method for partial derivatives	uses analytic differentiations by default
HESSALG	specifies the algorithm for computing the Hessian	
NODIAG	suppresses the fitting of the diagonal elements in the covariance or correlation matrices	
OUTJAC	outputs the Jacobian pattern in an external file	
PJACPAT	prints the Jacobian pattern	

The following options are inactive in PROC TCALIS, and there is no plan to put these options back:

Option	Description	TCALIS Treatment
AUGMENT	uses the augmented moment matrices with mean structure analysis	specifies the mean structures in models directly
NOINT	uses the uncorrected covariance or correlation matrices for analyses	eliminates this option
PREDET	displays the predetermined elements in moment matrices	eliminates this display
PVEC	displays the final estimates, std errors, t-values, and gradients in separate vector forms	uses the PRINT or PALL option to display these results in a single table
UCORR	analyzes the uncorrected correlation matrix	eliminates this option
UCOV	analyzes the uncorrected covariance matrix	eliminates this option

Note that even though the UCORR and UCOV options are not supported in PROC TCALIS, you can still provide SAS data sets with TYPE=UCORR or TYPE=UCOV in the DATA= option. PROC TCALIS will utilize the information provided in the data set to compute the corrected covariance or correlation matrix for analysis.

New Statements and Options

The following are new statements in the TCALIS procedure:

Statement	Description
DETERM on page 6750	sets groups of variables for computing the determination coefficients
EFFPART on page 6729	displays and partitions the effects in the model
FITINDEX on page 6760	controls the fit summary output
GROUP on page 6764	defines groups and controls the corresponding data processing
LISMOD on page 6772	specifies a LISREL model
LMTESTS on page 6776	defines the Lagrange multiplier test regions
MEAN on page 6788	specifies the mean parameters
MODEL on page 6789	defines models and controls the corresponding modeling and analysis options
MSTRUCT on page 6792	specifies the direct covariance and mean model
OUTFILES on page 6796	controls multiple output data sets
PATH on page 6799	specifies the PATH model
PCOV on page 6802	specifies the covariance and partial covariance parameters
PVAR on page 6803	specifies the variance and partial variance parameters
REFMODEL on page 6811	specifies the base model for references
RENAMEPARM on page 6812	renames parameters
SIMTEST on page 6814	defines simultaneous parametric function tests
TESTFUNC on page 6817	tests individual parametric functions

The following are new options available in the PROC TCALIS statement:

Option	Description
CHICORRECT= on page 6727	specifies the chi-square correction factor
INMODEL= on page 6730	specifies the data set that contains the input model information
INWGTINV on page 6731	specifies that the INWGT= data set contains the inverse of the weight matrix
MEANSTR on page 6733	analyzes the mean structures
NOORDERSPEC on page 6735	displays the parameter specifications and results according to the input order
NOPARMNAME on page 6735	suppresses the display of parameter names
NOSTAND on page 6735	suppresses the display of standardized results
ORDERALL on page 6738	displays the specifications and results by the group numbers, model numbers, and parameter types
ORDERGROUPS on page 6738	displays the specifications and results for groups by the group numbers
ORDERMODELS on page 6738	displays the specifications and results for models by the model numbers
ORDERSPEC on page 6738	displays the specifications and results for parameters by the parameter types
OUTFIT= on page 6739	specifies the output data set for storing the fit statistics
OUTMODEL= on page 6739	specifies the output data set for storing the model specification and results
PARMNAME on page 6740	displays the parameter names in output

Changes in ODS Table Names

PROC CALIS assigns an ODS table name to each output it creates. Not all of these ODS table names are preserved in PROC TCALIS. In the following table, ODS table names for the CALIS procedure are listed together with the corresponding new ODS table name(s) in PROC TCALIS. Some of these ODS table names have been changed in PROC TCALIS, while others are unchanged or deleted.

CALIS ODS Table Name	TCALIS Table Name(s)
AddParms	(unchanged)
AsymStdRes	(unchanged)
AveAsymStdRes	(unchanged)
AveNormRes	(unchanged)
AveRawRes	(unchanged)

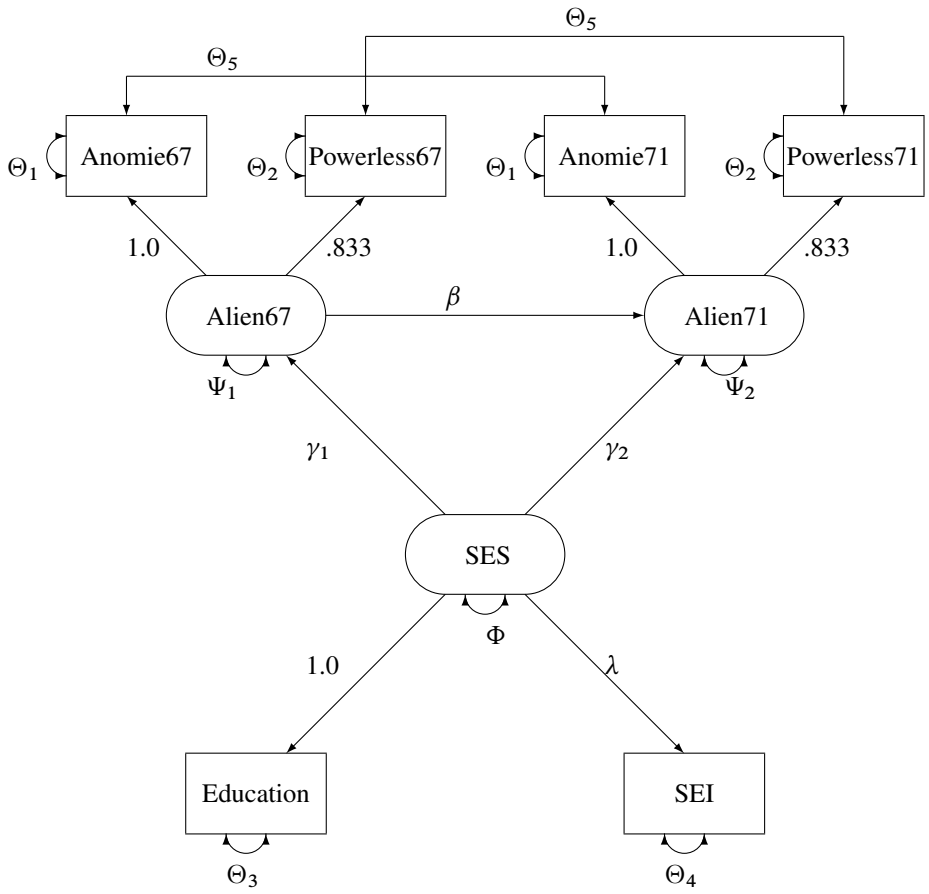
Getting Started: TCALIS Procedure

A Structural Equation Example

This example from Wheaton et al. (1977) illustrates the basic uses of the TCALIS procedure and the relationships among the LINEQS, LISMOD, PATH, and RAM modeling languages. Different structural models for these data are analyzed in Jöreskog and Sörbom (1985) and in Bentler (1985, p. 28). The data contain the following six (manifest) variables collected from 932 people in rural regions of Illinois:

Anomie67:	Anomie 1967
Powerless67:	Powerlessness 1967
Anomie71:	Anomie 1971
Powerless71:	Powerlessness 1971
Education:	Education level (years of schooling)
SEI:	Duncan's socioeconomic index (SEI)



The covariance matrix of the these six variables is stored in the data set named Wheaton.

It is assumed that anomie and powerlessness are indicators of an alienation factor and that education and SEI are indicators for a socioeconomic status (SES) factor. Hence, the analysis contains three latent variables (factors):

Alien67:	Alienation 1967
Alien71:	Alienation 1971
SES:	Socioeconomic status (SES)

The following path diagram shows the structural model used in Bentler (1985, p. 29) and slightly modified in Jöreskog and Sörbom (1985, p. 56):

Figure 88.2 Path Diagram of Stability and Alienation Example

In the path diagram shown in Figure 88.2, regressions of variables are represented by one-headed arrows. Regression coefficients are indicated along these one-headed arrows. Variances and covariances among the variables are represented by two-headed arrows. Error variances and covariances are also represented by two-headed arrows. This scheme of representing paths, variances and covariances, and error variances and covariances (McArdle 1988; McDonald 1985) is helpful in translating the path diagram to the PATH or RAM model input in the TCALIS procedure.

PATH Model

Specification by using the PATH modeling language is direct and intuitive in PROC TCALIS once a path diagram is drawn. The following statements specify the path diagram almost intuitively:

```
proc tcalis nobs=932 data=Wheaton;
   path
      Anomie67     <-  Alien67   1.0,
      Powerless67  <-  Alien67   0.833,
      Anomie71     <-  Alien71   1.0,
      Powerless71  <-  Alien71   0.833,
      Education    <-  SES       1.0,
      SEI          <-  SES       lambda,
      Alien67      <-  SES       gamma1,
      Alien71      <-  SES       gamma2,
      Alien71      <-  Alien67   beta;
   pvar
      Anomie67     = theta1,
      Powerless67  = theta2,
      Anomie71     = theta1,
      Powerless71  = theta2,
      Education    = theta3,
      SEI          = theta4,
      Alien67      = psi1,
      Alien71      = psi2,
      SES          = phi;
   pcov
      Anomie67    Anomie71    = theta5,
      Powerless67 Powerless71 = theta5;
run;
```

In the PROC TCALIS statement, you specify Wheaton as the input data set, which contains the covariance matrix of the variables.

In the PATH model specification, all the one-headed arrows in the path diagram are represented as path entries in the PATH statement, with entries separated by commas. In each path entry, you specify a pair of variables and the direction of the path (either <– or –>), followed by a path coefficient, which is either a fixed constant or a parameter with a name in the specification.

All the two-headed arrows each with the same source and destination are represented as entries in the PVAR statement, with entries separated by commas. In the PVAR statement, you specify the variance or error (or partial) variance parameters. In each entry, you specify a variable and then a parameter name or a fixed parameter value. If the variable involved is exogenous in the model (serves only as a predictor; never being pointed at by one-headed arrows), you are specifying a variance parameter for an exogenous variable in the PVAR statement. Otherwise, you are specifying an error variance (or a partial variance) parameter for an endogenous variable.

All other two-headed arrows are represented as entries in the PCOV statement, with entries separated by commas. In the PCOV statement, you specify the covariance or error (or partial) covariance parameters. In each entry, you specify a pair of variables and then a parameter name or a fixed parameter value. If both variables involved in an entry are exogenous, you are specifying a covariance parameter. If both variables involved in an entry are endogenous, you are specifying an error (or partial) covariance parameter. When one variable is exogenous and the other is endogenous in an

entry, you are specifying a partial covariance parameter that can be interpreted as the covariance between the exogenous variable and the error of the endogenous variable.

See Example 88.1 for the results of the current PATH model analysis. For more information about the PATH modeling language, see the section "The PATH Model" on page 6870 and the PATH statement on page 6799.

RAM Model

The PATH modeling language is not the only specification method that you can use to represent the path diagram. You can also use the RAM, LINEQS or LISMOD modeling language to represent the diagram equivalently.

The RAM model specification in PROC TCALIS resembles that of the PATH model, as shown in the following statements:

```
proc tcalis nobs=932 data=Wheaton;
   ram
      path  Anomie67     <-  Alien67   1.0,
      path  Powerless67  <-  Alien67   0.833,
      path  Anomie71     <-  Alien71   1.0,
      path  Powerless71  <-  Alien71   0.833,
      path  Education    <-  SES       1.0,
      path  SEI          <-  SES       lambda,
      path  Alien67      <-  SES       gamma1,
      path  Alien71      <-  SES       gamma2,
      path  Alien71      <-  Alien67   beta,
      pvar  Anomie67                   theta1,
      pvar  Powerless67                theta2,
      pvar  Anomie71                   theta1,
      pvar  Powerless71                theta2,
      pvar  Education                  theta3,
      pvar  SEI                        theta4,
      pvar  Alien67                    psi1,
      pvar  Alien71                    psi2,
      pvar  SES                        phi,
      pcov  Anomie67    Anomie71       theta5,
      pcov  Powerless67 Powerless71    theta5;
run;
```

In the RAM statement, you specify a list of entries for parameters, with entries separated by commas. In each entry, you specify the type of parameter (PATH, PVAR, or PCOV in the code), the associated variable or pair of variables and the path direction if applicable, and then a parameter name or a fixed parameter value. The types of parameters you specify in this RAM model are for path coefficients, variances or partial variances, and covariances or partial covariances. They bear the same meanings as those in the PATH model specified previously. The RAM model specification is therefore quite similar to the PATH model specification—except that in the RAM model you put all parameter specification in the same list under the RAM statement, whereas you specify different types of parameters separately under different statements in the PATH model.

See Example 88.6 for partial results of the current RAM model analysis. For more information about the RAM modeling language, see the section "The RAM Model" on page 6855 and the RAM statement on page 6805.

LINEQS Model

The LINEQS modeling language uses equations to specify functional relationships among variables, as shown in the following statements:

```
proc tcalis nobs=932 data=Wheaton;
   lineqs
      Anomie67     = 1.0    f_Alien67 + E1,
      Powerless67  = 0.833  f_Alien67 + E2,
      Anomie71     = 1.0    f_Alien71 + E3,
      Powerless71  = 0.833  f_Alien71 + E4,
      Education    = 1.0    f_SES     + E5,
      SEI          = lambda f_SES     + E6,
      f_Alien67    = gamma1 f_SES     + D1,
      f_Alien71    = gamma2 f_SES     + beta f_Alien67 + D2;
   std
      E1           = theta1,
      E2           = theta2,
      E3           = theta1,
      E4           = theta2,
      E5           = theta3,
      E6           = theta4,
      D1           = psi1,
      D2           = psi2,
      f_SES        = phi;
   cov
      E1  E3       = theta5,
      E2  E4       = theta5;
run;
```

In the LINEQS statement, equations are separated by commas. In each equation, you specify an endogenous variable on the left-hand side, and then predictors and path coefficients on the right-hand side of the equal side. The set of equations specified in this LINEQS model is equivalent to the system of paths specified in the preceding PATH (or RAM) model. However, there are some notable differences between the LINEQS and the PATH specifications.

First, in the LINEQS modeling language you must specify the error terms explicitly as exogenous variables. For example, E1, E2, and D1 are error terms in the specification. In the PATH (or RAM) modeling language, you do not need to specify error terms explicitly.

Second, equations specified in the LINEQS modeling language are oriented by the endogenous variables. Each endogenous variable can appear on the left-hand side of an equation only **once** in the LINEQS statement. All the corresponding predictor variables must then be specified on the right-hand side of the equation. For example, f_Alien71 is predicted from f_Alien67 and f_SES in the last equation of the LINEQS statement. In the PATH or RAM modeling language, however, you would specify the same functional relationships in two separate paths.

Third, you must follow some naming conventions for latent variables when using the LINEQS modeling language. The names of latent variables that are not errors or disturbances must start with an ‘f’ or ‘F’. Also, the names of the error variables must start with ‘e’ or ‘E’ and the names of the disturbance variables must start with ‘d’ or ‘D’. For example, variables Alien67, Alien71, and SES serve as latent factors in the previous PATH or RAM model specification. To comply

with the naming conventions, these variables are named with an extra prefix 'f_' in the LINEQS model specification—that is, f_Alien67, f_Alien71, and f_SES, respectively. In addition, because of the naming conventions of the LINEQS modeling language, E1–E6 serve as error terms and D1–D1 serve as disturbances in the specification.

A consequence of explicit specification of error terms in the LINEQS statement is that the partial variance and partial covariance concepts used in the PATH and RAM modeling languages are no longer needed. They are replaced by the variances or covariances of the error terms or disturbances. Errors and disturbances are exogenous variables by nature. Hence, in terms of variance and covariance specification, they are treated exactly the same way as other non-error exogenous variables in the LINEQS modeling language. That is, variance parameters for all exogenous variables, including errors and disturbances, are specified in the STD statement, and covariance parameters among exogenous variables, including errors and disturbances, are specified in COV statement.

See Example 88.6 for partial results of the current LINEQS model analysis. For more information about the LINEQS modeling language, see the section "The LINEQS Model" on page 6839 and the LINEQS statement on page 6766.

LISMOD Model

The LISMOD language is quite different from the LINEQS, PATH, and RAM modeling languages. In the LISMOD specification, you define parameters as entries in model matrices, as shown in the following statements:

```
proc tcalis nobs=932 data=Wheaton;
   lismod
      yvar = Anomie67 Powerless67 Anomie71 Powerless71,
      xvar = Education SEI,
      etav = Alien67 Alien71,
      xiv  = SES;
   matrix _LAMBDAY_ [1,1] = 1.0,
                    [2,1] = 0.833,
                    [3,2] = 1.0,
                    [4,2] = 0.833;
   matrix _LAMBDAX_ [1,1] = 1.0,
                    [2,1] = lambda;
   matrix _GAMMA_   [1,1] = gamma1,
                    [2,1] = gamma2;
   matrix _BETA_    [2,1] = beta;
   matrix _THETAY_  [1,1] = theta1,
                    [2,2] = theta2,
                    [3,3] = theta1,
                    [4,4] = theta2,
                    [3,1] = theta5,
                    [4,2] = theta5;
   matrix _THETAX_  [1,1] = theta3,
                    [2,2] = theta4;
   matrix _PSI_     [1,1] = psi1,
                    [2,2] = psi2;
   matrix _PHI_     [1,1] = phi;
run;
```

In the LISMOD statement, you specify the lists of variables in the model. In the MATRIX statements, you specify the parameters in the LISMOD model matrices. Each MATRIX statement contains the matrix name of interest and then locations of the parameters, followed by the parameter names or fixed parameter values. It would be difficult to explain the LISMOD specification here without better knowledge about the formulation of the mathematical model. For this purpose, see the section "The LISMOD Model and Submodels" on page 6847 and the LISMOD statement on page 6772. See also Example 88.6 for partial results of the current LISMOD model analysis.

A Factor Model Example

In addition to the general modeling languages such as PATH, RAM, LINEQS, and LISMOD, the TCALIS procedure provides a specialized language for factor analysis. In the FACTOR modeling language, you can specify either exploratory or confirmatory factor models. For exploratory factor models, you can specify the number of factors, factor extraction method, and rotation algorithm, among many other options. For confirmatory factor models, you can specify the variable-factor relationships, factor variances and covariances, and the error variances.

For example, the following is an exploratory factor model fitted to the Wheaton et al. (1977) data by using PROC TCALIS:

```
proc tcalis nobs=932 data=Wheaton;
   factor n=2 rotate=varimax;
run;
```

In this model, you want to get the varimax-rotated solution with two factors. By default, the factor extraction method is maximum likelihood (METHOD=ML). Maximum likelihood exploratory factor analysis by PROC TCALIS can also be done equivalently by the FACTOR procedure, as shown in the following statements for the Wheaton et al. (1977) data:

```
proc factor nobs=932 data=Wheaton n=2 rotate=varimax method=ml;
run;
```

Note that METHOD=ML is necessary because maximum likelihood is not the default method in PROC FACTOR.

Whereas you can use either the TCALIS or FACTOR procedure to fit certain exploratory factor models, you can only use the TCALIS procedure to fit confirmatory factor models. In a confirmatory factor model, you are assumed to have some prior knowledge about the variable-factor relations. For example, in your substantive theory, some observed variables are not related to certain factors in the model. The following statements illustrate the specification of a confirmatory factor model for Wheaton et al. (1977) data:

```
proc tcalis nobs=932 data=Wheaton;
   factor
      Alien67 -> Anomie67 Powerless67    = 1.0 load1,
      Alien71 -> Anomie71 Powerless71    = 1.0 load2,
      SES     -> Education SEI           = 1.0 load3;
   pvar
      Alien67      = phi11,
      Alien71      = phi22,
      SES          = phi33,
      Anomie67     = theta1,
      Powerless67  = theta2,
      Anomie71     = theta3,
      Powerless71  = theta4,
      Education    = theta5,
      SEI          = theta6;
   cov
      Alien71 Alien67 = phi21,
      SES     Alien67 = phi31,
      SES     Alien71 = phi32;
run;
```

Unlike the model fitted by the PATH, RAM, LINEQS, or LISMOD modeling language in previous sections, the confirmatory factor model considered here is purely a measurement model—that is, there are no functional relationships among factors in the model (beyond the covariances among factors) and hence it is a different model. In the FACTOR statement, you specify factors on the left-hand side of the entries, followed by arrows and the manifest variables that are related to the factors. On the right-hand side of the entries, you specify either parameter names or fixed parameter values for the corresponding factor loadings. In this example, there are three factors with three loadings to estimate. In the PVAR statement, you specify the parameters for factor variances and error variances of manifest variables. In the COV statement, you specify the factor covariances. As compared with the PATH, RAM, LINEQS, or LISMOD, the factor modeling language has more restrictions on parameters. These restrictions are listed as follows:

- factor-factor paths and variable-to-factor paths are not allowed
- error covariances and factor-error covariances are not allowed

For more information about exploratory and confirmatory factor models and the FACTOR modeling language, see the section "The FACTOR Model" on page 6863 or the FACTOR statement on page 6752.

Direct Covariance Structures Analysis

Previous examples are concerned with the implied covariance structures from the functional relationships among manifest and latent variables. In some cases, direct modeling of the covariance structures is not only possible, but indeed more convenient. The MSTRUCT modeling language in PROC TCALIS is designed for this purpose. Consider the following four variables from the Wheaton et al. (1977) data set:

Anomie67:	Anomie 1967
Powerless67:	Powerlessness 1967
Anomie71:	Anomie 1971
Powerless71:	Powerlessness 1971

The covariance structures are hypothesized as follows:

$$\Sigma = \begin{pmatrix} \phi_1 & \theta_1 & \theta_2 & \theta_1 \\ \theta_1 & \phi_2 & \theta_1 & \theta_3 \\ \theta_2 & \theta_1 & \phi_1 & \theta_1 \\ \theta_1 & \theta_3 & \theta_1 & \phi_2 \end{pmatrix}$$

where:

ϕ_1:	Variance of Anomie
ϕ_2:	Variance of Powerlessness
θ_1:	Covariance between Anomie and Powerlessness
θ_2:	Covariance between Anomie measures
θ_3:	Covariance between Powerlessness measures

In the hypothesized covariance structures, the variances of Anomie and Powerlessness measures are assumed to stay constant over the two time points. Their covariances are also independent of the time of measurements. To test the tenability of this covariance structure model, you can use the following statements of the MSTRUCT modeling language:

```
proc tcalis nobs=932 data=Wheaton;
   mstruct
      var = Anomie67 Powerless67 Anomie71 Powerless71;
   matrix _COV_ [1,1] = phi1,
                [2,2] = phi2,
                [3,3] = phi1,
                [4,4] = phi2,
                [2,1] = theta1,
                [3,1] = theta2,
                [3,2] = theta1,
                [4,1] = theta1,
                [4,2] = theta3,
                [4,3] = theta1;
run;
```

In the MSTRUCT statement, you specify the list of variables of interest with the VAR= option. The order of the variables in the list will be the order in the hypothesized covariance matrix. Next, you use the MATRIX _COV_ statement to specify the parameters in the covariance matrix. The specification is a direct translation from the hypothesized covariance matrix. For example, the [1,1] element of the covariance matrix is fitted by the free parameter phi1. Depending on the hypothesized model, you can also specify fixed constants for the elements in the covariance matrix. If an element in the covariance matrix is not specified by either a parameter name or a constant, it is assumed to be a fixed zero.

The analysis of this model is carried out in Example 88.3.

The MSTRUCT modeling language appears to be more restrictive than any of the other modeling languages discussed, in regard to the following limitations:

- It does not explicitly support latent variables in modeling.
- It does not explicitly support modeling of linear functional relations among variables (for example, paths).

However, these limitations are more apparent than real. In PROC TCALIS, the parameters defined in models can be dependent. These dependent parameters can be defined further as functions of other parameters in the PARAMETERS and the SAS programming statements. With these capabilities, it is possible to fit structural models with latent variables and with linear functional relations by using the MSTRUCT modeling language. However, this requires a certain level of sophistication in statistical knowledge and in programming. Therefore, it is recommended that the MSTRUCT modeling language be used only when the covariance and mean structures are modeled directly.

For more information about the MSTRUCT modeling language, see the section "The MSTRUCT Model" on page 6877 and the MSTRUCT statement on page 6792.

Which Modeling Language?

Various modeling languages are supported in PROC TCALIS because researchers are trained in or adhere to different schools of modeling. Different modeling languages reflect different modeling terminology and philosophies. The statistical and mathematical consequences by using these various modeling languages, however, might indeed be the same. In other words, you can use more than one modeling languages for certain types of models without affecting the statistical analysis. Given the choices, which modeling language is preferred? There are two guidelines for this:

- Use the modeling language that you are most familiar with.
- Use the most specialized modeling language whenever it is possible.

The first guideline calls for researchers' knowledge about a particular modeling language. Use the language you know the best. For example, some researchers might find equation input language like LINEQS the most suitable, while others might feel more comfortable using matrix input language like LISMOD.

The second guideline depends on the nature of the model at hand. For example, to specify a factor-analysis model in the TCALIS procedure, the specialized FACTOR language, instead of the LISMOD language, is recommended. Using a more specialized the modeling language is less error-prone. In addition, using a specialized language like FACTOR in this case amounts to giving the TCALIS procedure additional information about the specific mathematical properties of the model. This additional information is used to enhance computational efficiency and to provide more specialized results. Another example is fitting an equi-covariance model. You can simply use the MSTRUCT model specification, in which you specify the same parameter for all off-diagonal elements of the covariance elements. This is direct and intuitive. Alternatively, you could tweak a LINEQS model that would predict the same covariance for all variables. However, this is indirect and error-prone, especially for novice modelers.

In PROC TCALIS, the FACTOR and MSTRUCT modeling languages are considered more specialized, while other languages are more general in applications. Whenever possible, you should use the more specialized languages.

Syntax: TCALIS Procedure

PROC TCALIS < *options* > ;
- **BASEMODEL** *model number* < / *options* > ;

Classes of Statements

To better understand the syntax of PROC TCALIS, it is useful to classify the statements into classes. These classes of statements are described in the following sections.

PROC TCALIS Statement

is the main statement that invokes the TCALIS procedure. You can specify options for input and output data sets, printing, statistical analysis, and computations in this statement. The options specified in the PROC TCALIS statement will propagate to all groups and models, but are superseded by the options specified in the individual GROUP or MODEL statements.

GROUP Statement

signifies the beginning of a group specification. A group in the TCALIS procedure is an independent sample of observations. You can specify options for input and output data sets, printing, and statistical computations in this statement. Some of these group options in the GROUP statement can also be specified in the MODEL or PROC TCALIS statement, but the options specified in the GROUP statement supersede those specified in the MODEL or PROC TCALIS statement for the group designated in the GROUP statement. For group options that are available in both of the GROUP and PROC TCALIS statements, see the section "Options Available in the GROUP and PROC TCALIS Statements" on page 6765. For group options that are available in the GROUP, MODEL, and PROC TCALIS statements, see the section "Options Available in GROUP, MODEL, and PROC TCALIS Statements" on page 6765. If no GROUP statement is used, a single-group analysis is assumed. The group options for a single-group analysis are specified in the PROC TCALIS statement.

The GROUP statement can be followed by subsidiary group specification statements, which specify further data processing procedures for the group designated in the GROUP statement.

Subsidiary Group Specification Statements

are for specifying additional data processing attributes for the input data. These statements are summarized in the following table:

Statement	Description
FREQ on page 6763	specifies the frequency variable for the input observations
PARTIAL on page 6798	specifies the partial variables
VAR on page 6818	specifies the set of variables in analysis
WEIGHT on page 6818	specifies the weight variable for the input observations

These statements can be used after the PROC TCALIS statement or each GROUP statement. Again, the specifications within the scope of the GROUP statement supersede those specified after the PROC TCALIS statement for the group designated in the GROUP statement.

MODEL Statement

signifies the beginning of a model specification. In the MODEL statement, you can specify the fitted groups, input and output data sets for model specification or estimates, printing options, statistical analysis, and computational options. Some of the options in the MODEL statement can also be specified in the PROC TCALIS statement. These options are called model options. Model options specified in the MODEL statement supersede those specified in the PROC TCALIS statement. For model options that are available in both of the MODEL and PROC TCALIS statements, see the section "Options Available in the MODEL and PROC TCALIS Statements" on page 6791. If no MODEL statement is used, a single model is assumed and the model options are specified in the PROC TCALIS statement.

Some of the options in the MODEL statement can also be specified in the GROUP statement. These options are called group options. The group options in the MODEL statement are transferred to the groups being fitted, but they are superseded by the group options specified in the associated GROUP statement. For group options that are available in the GROUP and the MODEL statements, see the section "Options Available in GROUP, MODEL, and PROC TCALIS Statements" on page 6765.

The MODEL statement itself does not define the model being fitted to the data; the main and subsidiary model specification statements that follow immediately after the MODEL statement do. These statements are described in the next two sections.

Main Model Specification Statements

are for specifying the type of the modeling language and the main features of the model. These statements are summarized in the following table:

Statement	Description
FACTOR on page 6752	specifies confirmatory or exploratory factor models
LINEQS on page 6766	specifies models by using linear equations
LISMOD on page 6772	specifies models in terms of LISREL-like model matrices
MSTRUCT on page 6792	specifies parameters directly in the mean and covariance matrices
PATH on page 6799	specifies models by using the causal paths of variables
RAM on page 6805	specifies models by using RAM-like lists of parameters
REFMODEL on page 6811	specifies a base model from which the target model is modified

You can use one of these statements for specifying one model. Each statement in the list represents a particular type of modeling language. After the main model specification statement, you might need to add subsidiary model specification statements, as described in the following section, to complete the model specification.

Subsidiary Model Specification Statements

are used to supplement the model specification. They are specific to the types of the modeling languages invoked by the main model specification statements, as shown in the following table:

Statement	Specification	Modeling Languages
COV on page 6747	covariance parameters	FACTOR, LINEQS
MATRIX on page 6784	parameters in matrices	LISMOD, MSTRUCT
MEAN on page 6788	mean or intercept parameters	FACTOR, LINEQS, PATH
PCOV on page 6802	(partial) covariance parameters	PATH
PVAR on page 6803	(partial) variance parameters	FACTOR, PATH
RENAMEPARM on page 6812	new parameters by renaming	REFMODEL
STD on page 6815	variance parameters	LINEQS

Notice that the RAM modeling language does not have any subsidiary model specification statements, because all model specification can be done in the RAM statement.

Model Analysis Statements

are used to request specific statistical analysis, as shown in the following table:

Statement	Analysis
DETERM on page 6750	sets variable groups for computing the determination coefficients; same as the STRUCTEQ statement
EFFPART on page 6729	displays and partitions the effects in the model
FITINDEX on page 6760	controls the fit summary output
LMTESTS on page 6776	defines the Lagrange multiplier test regions
SIMTEST on page 6814	defines simultaneous parametric function tests
STRUCTEQ on page 6750	sets variable groups for computing the determination coefficients; same as the DETERM statement
TESTFUNC on page 6817	tests individual parametric functions

Notice that the DETERM and the STRUCTEQ statements function exactly the same way.

Optimization Statements

are used to define additional parameters and parameter constraints, to fine-tune the optimization techniques, or to set the printing options in optimization, as shown in the following table:

Statement	Description
BOUNDS on page 6746	defines the bounds of parameters
LINCON on page 6766	defines the linear constraints of parameters
NLINCON on page 6794	defines the nonlinear constraints of parameters
NLOPTIONS on page 6795	sets the optimization techniques and printing options

Other Statements

that are not listed in preceding sections are summarized in the following table:

Statement	Description
BY on page 6746	fits a model to different groups separately
OUTFILES on page 6796	controls multiple output data sets
PARAMETERS on page 6798	defines additional parameters or superparameters
SAS programming statements on page 6814	define parameters or functions

Note that SAS programming statements include the ARRAY statement and the mathematical statements for defining parameter interdependence.

Single-Group Analysis Syntax

PROC TCALIS < *options* > ;
subsidiary group specification statements ;
main model specification statement ;
subsidiary model specification statements ;
model analysis statements ;
optimization statements ;
other statements ;

In a single-group analysis, there is only one group and one model. Because all model or group specifications are unambiguous, the MODEL and GROUP statements are not necessary. The order of the statements is not important for parsing purposes, although you might still like to order them in a particular way to aid understanding. Notice that the OUTFILES statement is not necessary in single-group analyses, as it is designed for multiple-group situations. Output file options in a single-group analysis can be specified in the PROC TCALIS statement.

Multiple-Group Multiple-Model Analysis Syntax

PROC TCALIS < *options* > ;
  subsidiary group specification statements ;
  model analysis statements ;
  GROUP *1* < / *group options* > ;
    subsidiary group specification statements ;
  GROUP *2* < / *group options* > ;
    subsidiary group specification statements ;
  MODEL *1* < / *model options* > ;
    main model specification statement ;
    subsidiary model specification statements ;
    model analysis statements ;
  MODEL *2* < / *model options* > ;
    main model specification statement ;
    subsidiary model specification statements ;
    model analysis statements ;
  optimization statements ;
  other statements ;

The multiple uses of the GROUP and the MODEL statements characterize the multiple-group multiple-model analysis. Unlike the single-group analysis, the order of some statements in a multiple-group multiple-model syntax is important for parsing purposes.

A GROUP statement signifies the beginning of a group specification block and designates a group number for the group. The scope of a GROUP statement extends to the subsequent subsidiary group specification statements until another MODEL or GROUP statement is encountered. In the preceding syntax, GROUP 1 and GROUP 2 have separate blocks of subsidiary group specification statements. By using additional GROUP statements, you can add as many groups as your situation calls for. Subsidiary group specification statements declared before the first GROUP statement are in the scope of the PROC TCALIS statement. This means that these subsidiary group specification statements are applied globally to all groups unless they are respecified locally within the scopes of individual GROUP statements.

A MODEL statement signifies the beginning of a model specification block and designates a model number for the model. The scope of a MODEL statement extends to the subsequent main and subsidiary model specification statements until another MODEL or GROUP statement is encountered. In the preceding syntax, MODEL 1 and MODEL 2 have separate blocks of main and subsidiary model specification statements. By using additional MODEL statements, you can add as many models as your situation calls for. If you use at least one MODEL statement, any main and subsidiary model specification statements declared before the first MODEL statement are ignored.

Some model analysis statements are also bounded by the scope of the MODEL statements. These statements are: DETERM, EFFPART, LMTESTS, and STRUCTEQ. These statements are applied only locally to the model in which they belong. To apply these statements globally to all models, put these statements before the first MODEL statement.

Other model analysis statements are not bounded by the scope of the MODEL statements. These statements are: FITINDEX, SIMTEST, and TESTFUNC. Because these statements are not model-specific, you can put these statements anywhere in a PROC TCALIS run.

Optimization and other statements are not bounded by the scope of either the GROUP or MODEL statements. You can specify them anywhere between the PROC TCALIS and the run statements without affecting the parsing of the models and the groups. For clarity of presentation, they are shown as last statement block in the syntax. Notice that the BY statement is not supported in a multiple-group setting.

PROC TCALIS Statement

PROC TCALIS < *options* > **;**

This statement invokes the procedure. There are many options in the PROC TCALIS statement. These options, together with brief descriptions, are classified into different categories in the next few sections. An alphabetical listing of these options with more details then follows.

Data Set Options

You can use the following options to specify input and output data sets:

Option	Description
DATA=	inputs the data
INEST=	inputs the initial values and constraints
INMODEL=	inputs the model specifications
INWGT=	inputs the weight matrix
OUTEST=	outputs the estimates and their covariance matrix
OUTFIT=	outputs the fit indices
OUTMODEL=	outputs the model specifications
OUTSTAT=	outputs the statistical results
OUTWGT=	outputs the weight matrix

Model and Estimation Options

You can use these options to specify details about estimation, models, and computations:

Option	Description
CORRELATION	analyzes correlation matrix
COVARIANCE	analyzes covariance matrix
DEMPHAS=	emphasizes the diagonal entries
EDF=	defines number of observations by the number of error degrees of freedom
INWGTINV	specifies that the INWGT= data set contains the inverse of the weight matrix
MEANSTR	analyzes the mean structures
METHOD=	specifies the estimation method
NOBS=	defines the number of observations
RANDOM=	specifies the seed for randomly generated initial values
RDF=	defines nobs by the number of regression df
RIDGE=	specifies the ridge factor for the covariance matrix
START=	specifies a constant for initial values
VARDEF=	specifies the variance divisor
WPENALTY=	specifies the penalty weight to fit correlations
WRIDGE=	specifies the ridge factor for the weight matrix

Options for Fit Statistics

You can use these options to modify the default behavior of fit index computations and display and to specify output file for fit indices:

Option	Description
ALPHAECV=	specifies the α level for computing the confidence interval of ECV (Browne and Cudeck 1993)
ALPHARMS=	specifies the α level for computing the confidence interval of RMSEA (Steiger and Lind 1980)
CHICORRECT=	specifies the chi-square correction factor
CLOSEFIT=	defines the close fit value
DFREDUCE=	reduces the degrees of freedom for model fit chi-square test
NOADJDF	requests no degrees-of-freedom adjustment be made for active constraints
NOINDEXTYPE	suppresses the printing of fit index types
OUTFIT=	specifies the output data set for storing fit indices

These options can also be specified in the FITINDEX statement. However, to control the display of individual fit indices, you must use the ON= and OFF= options of the FITINDEX statement.

Options for Statistical Analysis

You can use these options to request specific statistical analysis and display and to set the parameters for statistical analysis:

Option	Description
ASYCOV=	specifies the formula for computing asymptotic covariances
BIASKUR	computes the skewness and kurtosis without bias corrections
EFFPART | TOTEFF	displays total, direct, and indirect effects
G4=	specifies the algorithm for computing standard errors
KURTOSIS	computes and displays kurtosis
MODIFICATION	computes modification indices
NOMOD	suppresses modification indices
NOSTAND	suppresses the standardized output
NOSTDERR	suppresses standard error computations
PCORR	displays analyzed and estimated moment matrix
PCOVES	displays the covariance matrix of estimates
PDETERM	computes the determination coefficients
PESTIM	prints parameter estimates
PINITIAL	prints initial pattern and values
PLATCOV	computes the latent variable covariances and score coefficients
PLOTS=	specifies ODS Graphics selection
PWEIGHT	displays the weight matrix
RESIDUAL=	specifies the type of residuals being computed
SIMPLE	prints univariate statistics
SLMW=	specifies the probability limit for Wald tests
STDERR	computes the standard errors

Global Display Options

There are two different kinds of global display options: one is for selecting output; the other is for controlling the format or order of output.

You can use the following options to select printed output:

Option	Description
NOPRINT	suppresses the displayed output
PALL	displays all displayed output (ALL)
PRINT	adds default displayed output
PSHORT	reduces default output (SHORT)
PSUMMARY	displays fit summary only (SUMMARY)

In contrast to individual output printing options described in the section "Options for Statistical Analysis" on page 6723, the global display options typically control more than one output or analysis. The relations between these two types of options are summarized in the following table:

Options	PALL	PRINT	default	PSHORT	PSUMMARY
fit indices	*	*	*	*	*
linear dependencies	*	*	*	*	*
PESTIM	*	*	*	*	
iteration history	*	*	*	*	
PINITIAL	*	*	*		
SIMPLE	*	*	*		
STDERR	*	*	*		
RESIDUAL	*	*			
KURTOSIS	*	*			
PLATCOV	*	*			
TOTEFF	*	*			
PCORR	*				
MODIFICATION	*				
PWEIGHT	*				
PCOVES					
PDETERM					
PRIMAT					

Each column in the table represents a global display option. An "*" in the column means that the individual output or analysis option listed in the corresponding row turns on when the global display option in the corresponding column is specified.

Note that the column labeled with "default" is for default printing. If the NOPRINT option is not specified, a default set of output is displayed. The PRINT and PALL options add to the default output, while the PSHORT and PSUMMARY options reduce from the default output.

Note also that the PCOVES, PDETERM, and PRIMAT options cannot be turned on by any global display options. They must be specified individually.

The following global display options are for controlling formats and order of the output:

Option	Description
NOORDERSPEC	displays model specifications and results according to the input order
NOPARMNAME	suppresses the printing of parameter names in results
ORDERALL	orders all output displays according to the model numbers, group numbers, and parameter types
ORDERGROUPS	orders the group output displays according to the group numbers
ORDERMODELS	orders the model output displays according to the model numbers
ORDERSPEC	orders the model output displays according to the parameter types within each model
PARMNAME	displays parameter names in model specifications and results
PRIMAT	displays estimation results in matrix form

Optimization Options

You can use the following options to control the behavior of the optimization. Most of these options are also available in the NLOPTIONS statement.

Option	Description
ASINGULAR=	specifies the absolute singularity criterion for inverting the information matrix
COVSING=	specifies the singularity tolerance of the information matrix
FCONV=	specifies the relative function convergence criterion
GCONV=	specifies the gradient convergence criterion
INSTEP=	specifies the initial step length (RADIUS=, SALPHA=)
LINESEARCH=	specifies the line-search method
LSPRECISION=	specifies the line-search precision (SPRECISION=)
MAXFUNC=	specifies the maximum number of function calls
MAXITER=	specifies the maximum number of iterations
MSINGULAR=	specifies the relative M singularity of the information matrix
OMETHOD | TECHNIQUE=	specifies the minimization method
SINGULAR=	specifies the singularity criterion for matrix inversion
UPDATE=	specifies the update method for some optimization techniques
VSINGULAR=	specifies the relative V singularity of information matrix

Listing of PROC TCALIS Statement Options

ALPHAECV=α

specifies a $(1-\alpha)100\%$ confidence interval ($0 \leq \alpha \leq 1$) for the Browne and Cudeck (1993) expected cross-validation index (ECVI). The default value is $\alpha = 0.1$, which corresponds to a 90% confidence interval for the ECVI.

ALPHARMS=α

specifies a $(1-\alpha)100\%$ confidence interval ($0 \leq \alpha \leq 1$) for the Steiger and Lind (1980) root mean square error of approximation (RMSEA) coefficient (see Browne and Du Toit 1992). The default value is $\alpha = 0.1$, which corresponds to a 90% confidence interval for the RMSEA.

ASINGULAR | ASING=*r*

specifies an absolute singularity criterion r ($r > 0$), for the inversion of the information matrix, which is needed to compute the covariance matrix. The default value for r or *ASING* is the square root of the smallest positive double precision value.

When inverting the information matrix, the following singularity criterion is used for the diagonal pivot $d_{j,j}$ of the matrix:

$$|d_{j,j}| \leq \max(ASING, VSING * |H_{j,j}|, MSING * \max(|H_{1,1}|, \ldots, |H_{n,n}|))$$

where *VSING* and *MSING* are the specified values in the VSINGULAR= and MSINGULAR= options, respectively, and $H_{j,j}$ is the j-th diagonal element of the information matrix. Note that in many cases a normalized matrix $\mathbf{D}^{-1}\mathbf{H}\mathbf{D}^{-1}$ is decomposed (where $D^2 = diag(H)$), and the singularity criteria are modified correspondingly.

ASYCOV | ASC=*name*

specifies the formula for asymptotic covariances used in the weight matrix $\mathbf{W}$ for WLS and DWLS estimation. The ASYCOV option is effective only if METHOD= WLS or METHOD=DWLS and no INWGT= input data set is specified. The following formulas are implemented:

BIASED: Browne's (1984) formula (3.4)
biased asymptotic covariance estimates; the resulting weight matrix is at least positive semidefinite. This is the default for analyzing a covariance matrix.

UNBIASED: Browne's (1984) formula (3.8)
asymptotic covariance estimates corrected for bias; the resulting weight matrix can be indefinite (that is, can have negative eigenvalues), especially for small N.

CORR: Browne and Shapiro's (1986) formula (3.2)
(identical to DeLeeuw's (1983) formulas (2,3,4)) the asymptotic variances of the diagonal elements are set to the reciprocal of the value r specified by the WPENALTY= option (default: $r = 100$). This formula is the default for analyzing a correlation matrix.

CAUTION: Using the WLS and DWLS methods with the ASYCOV=CORR option assumes that you are fitting a correlation (rather than a covariance) structure. Because the fixed diagonal of a correlation matrix for some models does not contribute to the model's degrees of freedom, you can specify the DFREDUCE=*i* option to reduce the degrees of freedom by the number of manifest variables used in the model.

See the section "Counting the Degrees of Freedom" on page 6897 for more information.

BIASKUR
computes univariate skewness and kurtosis by formulas uncorrected for bias.

See the section "Measures of Multivariate Kurtosis" on page 6919 for more information.

CHICORRECT | CHICORR= *name* | *c*
specifies a correction factor c for the chi-square statistics for model fit. You can specify a *name* for a built-in correction factor or a value between 0 and 1 as the CHICORRECT= value. The model fit chi-square statistic is computed as:

$$\chi^2 = (1 - c)(N - k)F$$

where N is the total number of observations, k is the number of independent groups, and F is the optimized function value.

Valid *names* for the CHICORRECT= value are as follows:

EQVARCOV | COMPSYM specifies the correction factor due to Box (1949) for testing equal variances and equal covariances in a covariance matrix. The correction factor is:

$$c = \frac{p(p+1)^2(2p-3)}{6n(p-1)(p^2+p-4)}$$

where p represents the number of variables and $n = (N - 1)$, with N denoting the number of observations in a single group analysis.

CIRCULARITY | CIRCULAR | TYPEH | SPHERICITY specifies the correction factor due to Mauchly (1940) for testing circularity or Huynh and Feldt Type H matrix. The correction factor is:

$$c = \frac{2p^2 - 3p + 3}{6n(p-1)}$$

where p represents the number of variables and $n = (N - 1)$, with N denoting the number of observations in a single group analysis.

EQCOVMAT specifies the correction factor due to Box (1949) for testing equality of covariance matrices. The correction factor is:

$$c = \frac{2p^2 + 3p - 1}{6(p+1)(k-1)}\left(\sum_{i=1}^{k}\frac{1}{n_i} - \frac{1}{\sum_{i=1}^{k} n_i}\right)$$

where p represents the number of variables, k represents the number of groups, and $n_i = (N_i - 1)$, with N_i denoting the number of observations in the i-th group.

CLOSEFIT=*p*

defines the criterion value p for indicating a close fit. The smaller the better fit. The default value for close fit is .05.

CORRELATION | CORR

analyzes the correlation matrix, instead of the default covariance matrix. See the COVARIANCE option for more details.

COVARIANCE | COV

analyzes the covariance matrix. Because this is also the default analysis in PROC TCALIS, you can simply omit this option when you analyze covariance rather than correlation matrices. If the DATA= input data set is a TYPE=CORR data set (containing a correlation matrix and standard deviations), the default COV option means that the covariance matrix is computed and analyzed.

Unlike many other SAS/STAT procedures (for example, the FACTOR procedure) that analyze correlation matrices by default, PROC TCALIS uses a different default because statistical theories of structural equation modeling or covariance structure analysis are mostly developed for covariance matrices. You must use the CORR option if correlation matrices are analyzed.

COVSING=*r*

specifies a nonnegative threshold r, which determines whether the eigenvalues of the information matrix are considered to be zero. If the inverse of the information matrix is found to be singular (depending on the VSINGULAR=, MSINGULAR=, ASINGULAR=, or SINGULAR= option), a generalized inverse is computed using the eigenvalue decomposition of the singular matrix. Those eigenvalues smaller than r are considered to be zero. If a generalized inverse is computed and you do not specify the NOPRINT option, the distribution of eigenvalues is displayed.

DATA=*SAS-data-set*

specifies an input data set that can be an ordinary SAS data set or a specially structured TYPE=CORR, TYPE=COV, TYPE=UCORR, TYPE=UCOV, TYPE=SSCP, or TYPE=FACTOR SAS data set, as described in the section "Input Data Sets" on page 6819. If the DATA= option is omitted, the most recently created SAS data set is used.

DEMPHAS | DE=*r*

changes the initial values of all variance parameters by the relationship:

$$s_{new} = r(|s_{old}| + 1)$$

where s_{new} is the new initial value and s_{old} is the original initial value. The initial values of all variance parameters should always be nonnegative to generate positive definite predicted model matrices in the first iteration. By using values of $r > 1$, for example, $r = 2$, $r = 10$, and so on, you can increase these initial values to produce predicted model matrices with high positive eigenvalues in the first iteration. The DEMPHAS= option is effective independent of the way the initial values are set; that is, it changes the initial values set in the model specification as well as those set by an INMODEL= data set and those automatically generated for the FACTOR, LINEQS, LISMOD, PATH, or RAM models. It also affects the initial values set by the START= option, which uses, by default, DEMPHAS=100 if a covariance matrix is analyzed and DEMPHAS=10 for a correlation matrix.

DFREDUCE | DFRED=*i*

reduces the degrees of freedom of the model fit χ^2 test by i. In general, the number of degrees of freedom is the total number of nonredundant elements in all moment matrices minus the number of parameters, t. Because negative values of i are allowed, you can also increase the number of degrees of freedom by using this option. If the DFREDUCE= option is used in a correlation structure analysis, PROC TCALIS does not additionally reduce the degrees of freedom by the number of constant elements in the diagonal of the predicted model matrix, which is otherwise done automatically. See the section "Counting the Degrees of Freedom" on page 6897 for more information.

EDF | DFE=*n*

makes the effective number of observations $n + 1$. You can also use the NOBS= option to specify the number of observations.

EFFPART | PARTEFF | TOTEFF | TE

computes and displays total, direct, and indirect effects for the unstandardized and standardized estimation results. Standard errors for the effects are also computed. Note that this displayed output is not automatically included in the output generated by the PALL option.

Note also that in some situations computations of total effects and their partitioning are not appropriate. While total and indirect effects must converge in recursive models (models with no cyclic paths among variables), they do not always converge in nonrecursive models. When total or indirect effects do not converge, it is not appropriate to partition the effects. Therefore, before partitioning the total effects, the convergence criterion must be met. To check the convergence of the effects, PROC TCALIS computes and displays the "stability coefficient of reciprocal causation"— that is, the largest modulus of the eigenvalues of the $\boldsymbol{\beta}$ matrix, which is the square matrix that contains the path coefficients of all endogenous variables in the model. Stability coefficients less than one provide a necessary and sufficient condition for the convergence of the total and the indirect effects. Otherwise, PROC TCALIS does not show results for total effects and their partitioning. See the section "Stability Coefficient of Reciprocal Causation" on page 6915 for more information about the computation of the stability coefficient.

FCONV | FTOL=*r*

specifies the relative function convergence criterion. The optimization process is terminated when the relative difference of the function values of two consecutive iterations is smaller than the specified value of r; that is,

$$\frac{|f(x^{(k)}) - f(x^{(k-1)})|}{\max(|f(x^{(k-1)})|, FSIZE)} \leq r$$

where *FSIZE* can be defined by the FSIZE= option in the NLOPTIONS statement. The default value is $r = 10^{-FDIGITS}$, where *FDIGITS* either can be specified in the NLOPTIONS statement or is set by default to $-\log_{10}(\epsilon)$, where ϵ is the machine precision.

G4=*i*

instructs that the algorithm to compute the approximate covariance matrix of parameter estimates used for computing the approximate standard errors and modification indices when the information matrix is singular. If the number of parameters t used in the model you analyze

is smaller than the value of i, the time-expensive Moore-Penrose (G4) inverse of the singular information matrix is computed by eigenvalue decomposition. Otherwise, an inexpensive pseudo (G1) inverse is computed by sweeping. By default, $i = 60$.

See the section "Estimation Criteria" on page 6888 for more details.

GCONV | GTOL=*r*

specifies the relative gradient convergence criterion.

Termination of all techniques (except the CONGRA technique) requires the following normalized predicted function reduction to be smaller than r. That is,

$$\frac{[g(x^{(k)})]'[\mathbf{G}^{(k)}]^{-1}g(x^{(k)})}{\max(|f(x^{(k)})|, FSIZE)} \leq r$$

where *FSIZE* can be defined by the FSIZE= option in the NLOPTIONS statement. For the CONGRA technique (where a reliable Hessian estimate $\mathbf{G}$ is not available),

$$\frac{\| g(x^{(k)}) \|_2^2 \quad \| s(x^{(k)}) \|_2}{\| g(x^{(k)}) - g(x^{(k-1)}) \|_2 \max(|f(x^{(k)})|, FSIZE)} \leq r$$

is used. The default value is $r = 10^{-8}$.

INEST | INVAR | ESTDATA=*SAS-data-set*

specifies an input data set that contains initial estimates for the parameters used in the optimization process and can also contain boundary and general linear constraints on the parameters. Typical applications of this option are to specify an OUTEST= data set from a previous PROC TCALIS analysis. The initial estimates are taken from the values of the PARMS observation in the INEST= data set.

INMODEL | INRAM=*SAS-data-set*

specifies an input data set that contains in RAM list form all information needed to specify an analysis model. The INMODEL= data set is described in the section "Input Data Sets" on page 6819. Typically, this input data set is an OUTMODEL= data set (possibly modified) from a previous PROC TCALIS analysis. If you use an INMODEL= data set to specify the analysis model, you should not use any of the main or subsidiary model specification statements, but you can use the BOUNDS and PARAMETERS statements and program statements. If the INMODEL= option is omitted, you should define the analysis model with one of the main model specification statements.

INSTEP=*r*

For highly nonlinear objective functions, such as the EXP function, the default initial radius of the trust-region algorithms (TRUREG, DBLDOG, and LEVMAR) or the default step length of the line-search algorithms can produce arithmetic overflows. If an arithmetic overflow occurs, specify decreasing values of $0 < r < 1$ such as INSTEP=1E−1, INSTEP=1E−2, INSTEP=1E−4, and so on, until the iteration starts successfully.

- For trust-region algorithms (TRUREG, DBLDOG, and LEVMAR), the INSTEP option specifies a positive factor for the initial radius of the trust region. The default initial trust-region radius is the length of the scaled gradient, and it corresponds to the default radius factor of $r = 1$.

- For line-search algorithms (NEWRAP, CONGRA, and QUANEW), INSTEP specifies an upper bound for the initial step length for the line search during the first five iterations. The default initial step length is $r = 1$.

For more details, see the section "Computational Problems" on page 6932.

INWGT< (INV) >=*SAS-data-set*

specifies an input data set that contains the weight matrix **W** used in generalized least squares (GLS), weighted least squares (WLS, ADF), or diagonally weighted least squares (DWLS) estimation, if you do not specify the INV option at the same time. The weight matrix must be positive definite because its inverse must be defined in the computation of the objective function. If the weight matrix **W** defined by an INWGT= data set is not positive definite, it can be ridged using the WRIDGE= option. See the section "Estimation Criteria" on page 6888 for more information. If you specify the INWGT(INV)= option, the INWGT= data set contains the inverse of the weight matrix, rather than the weight matrix itself. Specifying the INWGT(INV)= option is equivalent to specifying the INWGT= and INWGTINV options simultaneously. With the INWGT(INV)= specification, the input matrix is not required to be positive definite. See the INWGTINV option for more details. If no INWGT= data set is specified, default settings for the weight matrices are used in the estimation process. The INWGT= data set is described in the section "Input Data Sets" on page 6819. Typically, this input data set is an OUTWGT= data set from a previous PROC TCALIS analysis.

INWGTINV

specifies that the INWGT= data set contains the inverse of the weight matrix, rather than the weight matrix itself. This option is effective only with an input weight matrix specified in the INWGT= data set and with the generalized least squares (GLS), weighted least squares (WLS or ADF), or diagonally weighted least squares (DWLS) estimation. With this option, the input matrix provided in the INWGT= data set is not required to be positive definite. Also, the ridging requested by the WRIDGE= option is ignored when you specify the INWGTINV option.

KURTOSIS | KU

computes and displays univariate kurtosis and skewness, various coefficients of multivariate kurtosis, and the numbers of observations that contribute most to the normalized multivariate kurtosis. See the section "Measures of Multivariate Kurtosis" on page 6919 for more information. Using the KURTOSIS option implies the SIMPLE display option. This information is computed only if the DATA= data set is a raw data set, and it is displayed by default if the PRINT option is specified. The multivariate least squares kappa and the multivariate mean kappa are displayed only if you specify METHOD=WLS and the weight matrix is computed from an input raw data set. All measures of skewness and kurtosis are corrected for the mean. Using the BIASKUR option displays the biased values of univariate skewness and kurtosis.

LINESEARCH | LIS | SMETHOD | SM=*i*

specifies the line-search method for the CONGRA, QUANEW, and NEWRAP optimization techniques. Refer to Fletcher (1980) for an introduction to line-search techniques. The value of i can be any integer between 1 and 8, inclusively; the default is $i = 2$.

LIS=1 specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is similar to one used by the Harwell subroutine library.

LIS=2 specifies a line-search method that needs more function calls than gradient calls for quadratic and cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option.

LIS=3 specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option.

LIS=4 specifies a line-search method that needs the same number of function and gradient calls for stepwise extrapolation and cubic interpolation.

LIS=5 specifies a line-search method that is a modified version of LIS=4.

LIS=6 specifies golden-section line search (Polak 1971), which uses only function values for linear approximation.

LIS=7 specifies bisection line search (Polak 1971), which uses only function values for linear approximation.

LIS=8 specifies the Armijo line-search technique (Polak 1971), which uses only function values for linear approximation.

LSPRECISION | LSP=*r*

SPRECISION | SP=*r*

specifies the degree of accuracy that should be obtained by the line-search algorithms LIS=2 and LIS=3. Usually an imprecise line search is inexpensive and successful. For more difficult optimization problems, a more precise and more expensive line search might be necessary (Fletcher 1980, p.22). The second (default for NEWRAP, QUANEW, and CONGRA) and third line-search methods approach exact line search for small LSPRECISION= values. If you have numerical problems, you should decrease the LSPRECISION= value to obtain a more precise line search. The default LSPRECISION= values are displayed in the following table.

OMETHOD=	UPDATE=	LSP default
QUANEW	DBFGS, BFGS	$r = 0.4$
QUANEW	DDFP, DFP	$r = 0.06$
CONGRA	all	$r = 0.1$
NEWRAP	no update	$r = 0.9$

For more details, refer to Fletcher (1980, pp. 25–29).

MAXFUNC | MAXFU=*i*

specifies the maximum number i of function calls in the optimization process. The default values are displayed in the following table.

OMETHOD=	MAXFUNC default
LEVMAR, NEWRAP, NRRIDG, TRUREG	$i = 125$
DBLDOG, QUANEW	$i = 500$
CONGRA	$i = 1000$

The default is used if you specify MAXFUNC=0. The optimization can be terminated only after completing a full iteration. Therefore, the number of function calls that is actually performed can exceed the number that is specified by the MAXFUNC= option.

MAXITER | MAXIT=*i* < *n* >

specifies the maximum number i of iterations in the optimization process. The default values are displayed in the following table.

OMETHOD=	MAXITER default
LEVMAR, NEWRAP, NRRIDG, TRUREG	$i = 50$
DBLDOG, QUANEW	$i = 200$
CONGRA	$i = 400$

The default is used if you specify MAXITER=0 or if you omit the MAXITER option.

The optional second value n is valid only for OMETHOD=QUANEW with nonlinear constraints. It specifies an upper bound n for the number of iterations of an algorithm and reduces the violation of nonlinear constraints at a starting point. The default is n=20. For example, specifying

```
maxiter= . 0
```

means that you do not want to exceed the default number of iterations during the main optimization process and that you want to suppress the feasible point algorithm for nonlinear constraints.

MEANSTR

invokes the analysis of mean structures. By default, no mean structures are analyzed. You can also analyze the mean structures by specifying any mean or intercept parameters in your model without using the MEANSTR option.

METHOD | MET | M=*name*

specifies the method of parameter estimation. The default is METHOD=ML. Valid values for *name* are as follows:

ML | M | MAX
: performs normal-theory maximum-likelihood parameter estimation. The ML method requires a nonsingular covariance or correlation matrix.

GLS | G
: performs generalized least squares parameter estimation. If no INWGT= data set is specified, the GLS method uses the inverse sample covariance or correlation matrix as the weight matrix **W**. Therefore, METHOD=GLS requires a nonsingular covariance or correlation matrix.

WLS | W | ADF	performs weighted least squares parameter estimation. If no INWGT= data set is specified, the WLS method uses the inverse matrix of estimated asymptotic covariances of the sample covariance or correlation matrix as the weight matrix **W**. In this case, the WLS estimation method is equivalent to Browne's asymptotically distribution-free estimation (Browne 1982, 1984). The WLS method requires a nonsingular weight matrix.
DWLS | D	performs diagonally weighted least squares parameter estimation. If no INWGT= data set is specified, the DWLS method uses the inverse diagonal matrix of asymptotic variances of the input sample covariance or correlation matrix as the weight matrix **W**. The DWLS method requires a nonsingular diagonal weight matrix.
ULS | LS | U	performs unweighted least squares parameter estimation.
LSML | LSM | LSMAX	performs unweighted least squares followed by normal-theory maximum-likelihood parameter estimation.
LSGLS | LSG	performs unweighted least squares followed by generalized least squares parameter estimation.
LSWLS | LSW | LSADF	performs unweighted least squares followed by weighted least squares parameter estimation.
LSDWLS | LSD	performs unweighted least squares followed by diagonally weighted least squares parameter estimation.
NONE | NO	uses no estimation method. This option is suitable for checking the validity of the input information and for displaying the model matrices and initial values.

MODIFICATION | MOD

computes and displays Lagrange multiplier (LM) test indices for constant parameter constraints, equality parameter constraints, and active boundary constraints, as well as univariate and multivariate Wald test indices. The modification indices are not computed in the case of unweighted or diagonally weighted least squares estimation.

The Lagrange multiplier test (Bentler 1986; Lee 1985; Buse 1982) provides an estimate of the χ^2 reduction that results from dropping the constraint. For constant parameter constraints and active boundary constraints, the approximate change of the parameter value is displayed also. You can use this value to obtain an initial value if the parameter is allowed to vary in a modified model. See the section "Modification Indices" on page 6917 for more information.

Relying solely on the LM tests to modify your model can lead to unreliable models that capitalize purely on sampling errors. See MacCallum, Roznowski, and Necowitz (1992) for the use of LM tests.

MSINGULAR | MSING=*r*

specifies a relative singularity criterion r ($r > 0$) for the inversion of the information matrix, which is needed to compute the covariance matrix. If you do not specify the SINGULAR= option, the default value for r or *MSING* is 1E−12; otherwise, the default value is 1E−4 × *SING*, where *SING* is the specified SINGULAR= value.

When inverting the information matrix, the following singularity criterion is used for the diagonal pivot $d_{j,j}$ of the matrix:

$$|d_{j,j}| \leq \max(ASING, VSING * |H_{j,j}|, MSING * \max(|H_{1,1}|, \ldots, |H_{n,n}|))$$

where *ASING* and *VSING* are the specified values of the ASINGULAR= and VSINGULAR= options, respectively, and $H_{j,j}$ is the j-th diagonal element of the information matrix. Note that in many cases a normalized matrix $\mathbf{D}^{-1}\mathbf{H}\mathbf{D}^{-1}$ is decomposed (where $D^2 = diag(H)$), and the singularity criteria are modified correspondingly.

NOADJDF
turns off the automatic adjustment of degrees of freedom when there are active constraints in the analysis. When the adjustment is in effect, most fit statistics and the associated probability levels will be affected. This option should be used when you believe that the active constraints observed in the current sample will have little chance to occur in repeated sampling. See the section "Adjustment of Degrees of Freedom" on page 6899 for more discussion on the issue.

NOBS= *nobs*
specifies the number of observations. If the DATA= input data set is a raw data set, *nobs* is defined by default to be the number of observations in the raw data set. The NOBS= and EDF= options override this default definition. You can use the RDF= option to modify the *nobs* specification. If the DATA= input data set contains a covariance, correlation, or scalar product matrix, you can specify the number of observations either by using the NOBS=, EDF=, and RDF= options in the PROC TCALIS statement or by including a _TYPE_='N' observation in the DATA= input data set.

NOINDEXTYPE
disables the display of index types in the fit summary table.

NOMOD
suppresses the computation of modification indices. The NOMOD option is useful in connection with the PALL option because it saves computing time.

NOORDERSPEC
prints the model results in the order they appear in the input specifcations. This is the default printing behavior. You can use this option to reset the default at a local model when the ORDERSPEC option might have been set in a statement at a more global level.

NOPARMNAME
suppresses the printing of parameter names in the model results. The default is to print the parameter names.

NOPRINT | NOP
suppresses the displayed output. Note that this option temporarily disables the Output Delivery System (ODS). See Chapter 20, "Using the Output Delivery System," for more information.

NOSTAND
suppresses the printing of standardized results. The default is to print the standardized results.

NOSTDERR | NOSE

specifies that standard errors should not be computed. Standard errors are not computed for unweighted least squares (ULS) or diagonally weighted least squares (DWLS) estimation. In general, standard errors are computed even if the STDERR display option is not used (for file output).

OMETHOD | OM=*name*

TECHNIQUE | TECH=*name*

specifies the optimization method or technique. Because there is no single nonlinear optimization algorithm available that is clearly superior (in terms of stability, speed, and memory) for all applications, different types of optimization methods or techniques are provided in the TCALIS procedure. The optimization method or technique is specified by using one of the following *names* in the OMETHOD= option:

CONGRA | CG chooses one of four different conjugate-gradient optimization algorithms, which can be more precisely defined with the UPDATE= option and modified with the LINESEARCH= option. The conjugate-gradient techniques need only $O(t)$ memory compared to the $O(t^2)$ memory for the other three techniques, where t is the number of parameters. On the other hand, the conjugate-gradient techniques are significantly slower than other optimization techniques and should be used only when memory is insufficient for more efficient techniques. When you choose this option, UPDATE=PB by default. This is the default optimization technique if there are more than 400 parameters to estimate.

DBLDOG | DD performs a version of double dogleg optimization, which uses the gradient to update an approximation of the Cholesky factor of the Hessian. This technique is, in many aspects, very similar to the dual quasi-Newton method, but it does not use line search. The implementation is based on Dennis and Mei (1979) and Gay (1983).

LEVMAR | LM | MARQUARDT performs a highly stable (but for large problems, memory- and time-consuming) Levenberg-Marquardt optimization technique, a slightly improved variant of the Moré (1978) implementation. This is the default optimization technique if there are fewer than 40 parameters to estimate.

NEWRAP | NRA performs a usually stable (but for large problems, memory- and time-consuming) Newton-Raphson optimization technique. The algorithm combines a line-search algorithm with ridging, and it can be modified with the LINESEARCH= option. In releases prior to Release 6.11, this option invokes the NRRIDG option.

NRRIDG | NRR | NR | NEWTON performs a usually stable (but for large problems, memory- and time-consuming) Newton-Raphson optimization technique. This algorithm does not perform a line search. Since OMETHOD=NRRIDG uses an orthogonal decomposition of the approximate Hessian, each iteration of OMETHOD=NRRIDG can be slower than that of OMETHOD=NEWRAP, which works with

Cholesky decomposition. However, usually OMETHOD=NRRIDG needs fewer iterations than OMETHOD=NEWRAP.

QUANEW | QN
: chooses one of four different quasi-Newton optimization algorithms that can be more precisely defined with the UPDATE= option and modified with the LINESEARCH= option. If boundary constraints are used, these techniques sometimes converge slowly. When you choose this option, UPDATE=DBFGS by default. If nonlinear constraints are specified in the NLINCON statement, a modification of Powell's (1982a, 1982b) VMCWD algorithm is used, which is a sequential quadratic programming (SQP) method. This algorithm can be modified by specifying VERSION=1, which replaces the update of the Lagrange multiplier estimate vector μ to the original update of Powell (1978a, 1978b) that is used in the VF02AD algorithm. This can be helpful for applications with linearly dependent active constraints. The QUANEW technique is the default optimization technique if there are nonlinear constraints specified or if there are more than 40 and fewer than 400 parameters to estimate. The QUANEW algorithm uses only first-order derivatives of the objective function and, if available, of the nonlinear constraint functions.

TRUREG | TR
: performs a usually very stable (but for large problems, memory- and time-consuming) trust-region optimization technique. The algorithm is implemented similar to Gay (1983) and Moré and Sorensen (1983).

NONE | NO
: does not perform any optimization. This option is similar to METHOD=NONE, but OMETHOD=NONE also computes and displays residuals and goodness-of-fit statistics. If you specify METHOD=ML, METHOD=LSML, METHOD=GLS, METHOD=LSGLS, METHOD=WLS, or METHOD=LSWLS, this option enables computing and displaying (if the display options are specified) of the standard error estimates and modification indices corresponding to the input parameter estimates.

For fewer than 40 parameters ($t < 40$), OMETHOD=LEVMAR (Levenberg-Marquardt) is the default optimization technique. For $40 \leq t < 400$, OMETHOD=QUANEW (quasi-Newton) is the default method, and for $t \geq 400$, OMETHOD=CONGRA (conjugate gradient) is the default method. Each optimization method or technique can be modified in various ways. See the section "Use of Optimization Techniques" on page 6923 for more details.

UPDATE | UPD=*name*

specifies the update method for the quasi-Newton or conjugate-gradient optimization technique.

For OMETHOD=CONGRA, the following updates can be used:

PB
: performs the automatic restart update method of Powell (1977) and Beale (1972). This is the default.

FR
: performs the Fletcher-Reeves update (Fletcher 1980, p. 63).

PR
: performs the Polak-Ribiere update (Fletcher 1980, p. 66).

CD performs a conjugate-descent update of Fletcher (1987).

For OMETHOD=DBLDOG, the following updates (Fletcher 1987) can be used:

DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the Cholesky factor of the Hessian matrix. This is the default.

DDFP performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.

For OMETHOD=QUANEW, the following updates (Fletcher 1987) can be used:

BFGS performs original BFGS update of the inverse Hessian matrix. This is the default for earlier releases.

DFP performs the original DFP update of the inverse Hessian matrix.

DBFGS performs the dual BFGS update of the Cholesky factor of the Hessian matrix. This is the default.

DDFP performs the dual DFP update of the Cholesky factor of the Hessian matrix.

ORDERALL
prints the model and group results in the order of the model or group numbers, starting from the smallest number. It also arrange some model results by the parameter types. In effect, this option turns on the ORDERGROUPS, ORDERMODELS, and ORDERSPEC options. The ORDERALL is not a default option. By default, the printing of the results follow the order of the input specifications.

ORDERGROUPS | ORDERG
prints the group results in the order of the group numbers, starting from the smallest number. The default behavior, however, is to print the group results in the order they appear in the input specifications.

ORDERMODELS | ORDERMO
prints the model results in the order of the model numbers, starting from the smallest number. The default behavior, however, is to print the model results in the order they appear in the input specifications.

ORDERSPEC
arranges some model results by the types of parameters. The default behavior, however, is to print the results in the order they appear in the input specifications.

OUTEST=*SAS-data-set*
creates an output data set that contains the parameter estimates, their gradient, Hessian matrix, and boundary and linear constraints. For METHOD=ML, METHOD=GLS, and METHOD=WLS, the OUTEST= data set also contains the information matrix, the approximate covariance matrix of the parameter estimates ((generalized) inverse of information matrix), and approximate standard errors. If linear or nonlinear equality or active inequality constraints are present, the Lagrange multiplier estimates of the active constraints, the projected Hessian, and the Hessian of the Lagrange function are written to the data set.

See the section "OUTEST= SAS-data-set" on page 6823 for a description of the OUTEST= data set. If you want to create a permanent SAS data set, you must specify a two-level name. Refer to the chapter titled "SAS Data Files" in *SAS Language Reference: Concepts* for more information about permanent data sets.

OUTFIT=*SAS-data-set*
creates an output data set that contains the values of the fit indices. See the section "OUTFIT= SAS-data-set" on page 6837 for details.

OUTMODEL | OUTRAM=*SAS-data-set*
creates an output data set that contains the model information for the analysis, the parameter estimates, and their standard errors. An OUTMODEL= data set can be used as an input INMODEL= data set in a subsequent analysis by PROC TCALIS. The OUTMODEL= data set also contains a set of fit indices; the section "OUTMODEL= SAS-data-set" on page 6827 provides more details. If you want to create a permanent SAS data set, you must specify a two-level name.

Refer to the chapter titled "SAS Data Files" in *SAS Language Reference: Concepts* for more information about permanent data sets.

OUTSTAT=*SAS-data-set*
creates an output data set that contains the BY group variables, the analyzed covariance or correlation matrices, and the predicted and residual covariance or correlation matrices of the analysis. You can specify the correlation or covariance matrix in an OUTSTAT= data set as an input DATA= data set in a subsequent analysis by PROC TCALIS. See the section "OUTSTAT= SAS-data-set" on page 6832 for a description of the OUTSTAT= data set. If the model contains latent variables, this data set also contains the predicted covariances between latent and manifest variables and the latent variable score regression coefficients (see the PLATCOV option on page 6741). If the FACTOR statement is used, the OUTSTAT= data set also contains the rotated and unrotated factor loadings, the unique variances, the matrix of factor correlations, the transformation matrix of the rotation, and the matrix of standardized factor loadings.

You can use the latent variable score regression coefficients with PROC SCORE to compute factor scores.

If you want to create a permanent SAS data set, you must specify a two-level name.

Refer to the chapter titled "SAS Data Files" in *SAS Language Reference: Concepts* for more information about permanent data sets.

OUTWGT=*SAS-data-set*
creates an output data set that contains the elements of the weight matrix $\mathbf{W}$ or the its inverse $\mathbf{W}^{-1}$ used in the estimation process. The inverse of the weight matrix is output only when you specify an INWGT= data set with the INWGT= and INWGTINV options (or the INWGT(INV)= option alone) in the same analysis. As a result, the entries in the INWGT= and OUTWGT= data sets are consistent. In other situations where the weight matrix is computed by the procedure or obtained from the OUTWGT= data set without the INWGTINV option, the weight matrix is output in the OUTWGT= data set. Furthermore, if the weight matrix is computed by the procedure, the OUTWGT= data set contains the elements of the weight matrix on which the WRIDGE= and the WPENALTY= options are applied.

You cannot create an OUTWGT= data set with an unweighted least squares or maximum likelihood estimation. The weight matrix is defined only in the GLS, WLS (ADF), or DWLS fit function. An OUTWGT= data set can be used as an input INWGT= data set in a subsequent analysis by PROC TCALIS. See the section "OUTWGT= SAS-data-set" on page 6836 for the description of the OUTWGT= data set. If you want to create a permanent SAS data set, you must specify a two-level name.

Refer to the chapter titled "SAS Data Files" in *SAS Language Reference: Concepts* for more information about permanent data sets.

PALL | ALL

displays all optional output except the output generated by the PCOVES and PDETERM options.

CAUTION: The PALL option includes the very expensive computation of the modification indices. If you do not really need modification indices, you can save computing time by specifying the NOMOD option in addition to the PALL option.

PARMNAME

prints the parameter names in the model results. This is the default behavior. You can use this option to reset the default at a local MODEL statement when the NOPARMNAME option might have been set in a statement at a more global level.

PCORR | CORR

displays the covariance or correlation matrix that is analyzed and the predicted model covariance or correlation matrix.

PCOVES | PCE

displays the following:

- the information matrix
- the approximate covariance matrix of the parameter estimates (generalized inverse of the information matrix)
- the approximate correlation matrix of the parameter estimates

The covariance matrix of the parameter estimates is not computed for estimation methods ULS and DWLS. This displayed output is not included in the output generated by the PALL option.

PDETERM | PDE

displays three coefficients of determination: the determination of all equations (DETAE), the determination of the structural equations (DETSE), and the determination of the manifest variable equations (DETMV). These determination coefficients are intended to be global means of the squared multiple correlations for different subsets of model equations and variables. The coefficients are displayed only when you specify a FACTOR, LINEQS, LISMOD, PATH, or RAM model, but they are displayed for all five estimation methods: ULS, GLS, ML, WLS, and DWLS.

You can use the STRUCTEQ statement to define which equations are structural equations. If you do not use the STRUCTEQ statement, PROC TCALIS uses its own default definition to identify structural equations.

The term "structural equation" is not defined in a unique way. The LISREL program defines the structural equations by the user-defined BETA matrix. In PROC TCALIS, the default definition of a structural equation is an equation that has a dependent left-side variable that appears at least once on the right side of another equation, or an equation that has at least one right-side variable that appears at the left side of another equation. Therefore, PROC TCALIS sometimes identifies more equations as structural equations than the LISREL program does.

PESTIM | PES
displays the parameter estimates. In some cases, this includes displaying the standard errors and t values.

PINITIAL | PIN
displays the model specification with initial estimates and the vector of initial values.

PLATCOV | PLC
displays the following:

- the estimates of the covariances among the latent variables
- the estimates of the covariances between latent and manifest variables
- the latent variable score regression coefficients

The estimated covariances between latent and manifest variables and the latent variable score regression coefficients are written to the OUTSTAT= data set. You can use the score coefficients with PROC SCORE to compute factor scores.

PLOTS | PLOT < = *plot-request* >
PLOTS | PLOT < = (*plot-request* < ... *plot-request* >) >
specifies the ODS graphical plots. Currently, the only available ODS graphical plots in PROC TCALIS are for residual histograms. Also, when the residual histograms are requested, the bar charts of residual tallies are suppressed. To display these bar charts with the residual histograms, you must use the RESIDUAL(TALLY) option.

When you specify only one *plot-request*, you can omit the parentheses around the *plot-request*. For example:

PLOTS=ALL
PLOTS=RESIDUALS

The following table shows the available *plot-requests*:

Plot-request	Plot Description
ALL	all available plots
NONE	no ODS graphical plots
RESIDUALS	distribution of residuals

To request the ODS graphical plots, you must also specify the `ods graphics on` statement. For more information about the ODS GRAPHICS statement, see Chapter 21, "Statistical Graphics Using ODS."

PRIMAT | PMAT
displays parameter estimates, approximate standard errors, and *t* values in matrix form if you specify the analysis model using the RAM or LINEQS statement.

PRINT | PRI
adds the options KURTOSIS, RESIDUAL, PLATCOV, and TOTEFF to the default output.

PSHORT | SHORT | PSH
excludes the output produced by the PINITIAL, SIMPLE, and STDERR options from the default output.

PSUMMARY | SUMMARY | PSUM
displays the fit assessment table only.

PWEIGHT | PW
displays the weight matrix **W** used in the estimation. The weight matrix is displayed after the WRIDGE= and the WPENALTY= options are applied to it. However, if you specify an INWGT= data set by the INWGT= and INWGTINV options (or the INWGT(INV)= option alone) in the same analysis, this option displays the elements of the inverse of the weight matrix.

RADIUS=*r*
is an alias for the INSTEP= option for Levenberg-Marquardt minimization.

RANDOM =*i*
specifies a positive integer as a seed value for the pseudo-random number generator to generate initial values for the parameter estimates for which no other initial value assignments in the model definitions are made. Except for the parameters in the diagonal locations of the central matrices in the model, the initial values are set to random numbers in the range $0 \leq r \leq 1$. The values for parameters in the diagonals of the central matrices are random numbers multiplied by 10 or 100. See the section "Initial Estimates" on page 6922 for more information.

RDF | DFR=*n*
makes the effective number of observations the actual number of observations minus the RDF= value. The degree of freedom for the intercept should not be included in the RDF= option. If you use PROC TCALIS to compute a regression model, you can specify RDF= *number-of-regressor-variables* to get approximate standard errors equal to those computed by PROC REG.

RESIDUAL | RES <(TALLY | TALLIES)> <= NORM | VARSTAND | ASYSTAND>
displays the raw and normalized residual covariance matrix, the rank order of the largest residuals, and a bar chart of the residual tallies. This information is displayed by default when you specify the PRINT option.

Three types of normalized or standardized residual matrices can be chosen with the RESIDUAL= specification.

RESIDUAL= NORM	normalized residuals
RESIDUAL= VARSTAND	variance standardized residuals

RESIDUAL= ASYSTAND	asymptotically standardized residuals

When ODS graphical plots of residuals are also requested, the bar charts of residual tallies are suppressed. They are replaced with high quality graphical histograms showing residual distributions. If you still want to display the bar charts in this situation, use the RESIDUAL(TALLY) or RESIDUAL(TALLY)= option.

See the section "Assessment of Fit" on page 6900 for more details.

RIDGE< =*r* >
defines a ridge factor r for the diagonal of the covariance or correlation matrix $\mathbf{S}$ that is analyzed. The matrix $\mathbf{S}$ is transformed to:

$$\mathbf{S} \longrightarrow \tilde{\mathbf{S}} = \mathbf{S} + r(\mathrm{diag}(\mathbf{S}))$$

If you do not specify r in the RIDGE option, PROC TCALIS tries to ridge the covariance or correlation matrix $\mathbf{S}$ so that the smallest eigenvalue is about 10^{-3}. Because the weight matrix in the GLS method is the same as the observed covariance or correlation matrix, the RIDGE= option also applies to the weight matrix for the GLS estimation, unless you input the weight matrix by the INWGT= option.

CAUTION: The covariance or correlation matrix in the OUTSTAT= output data set does not contain the ridged diagonal.

SALPHA=*r*
is an alias for the INSTEP= option for line-search algorithms.

SIMPLE | S
displays means, standard deviations, skewness, and univariate kurtosis if available. This information is displayed when you specify the PRINT option. If the KURTOSIS option is specified, the SIMPLE option is set by default.

SINGULAR | SING =*r*
specifies the singularity criterion r $(0 < r < 1)$ used, for example, for matrix inversion. The default value is the square root of the relative machine precision or, equivalently, the square root of the largest double precision value that, when added to 1, results in 1.

SLMW=*r*
specifies the probability limit used for computing the stepwise multivariate Wald test. The process stops when the univariate probability is smaller than r. The default value is $r = 0.05$.

SPRECISION | SP=*r*
is an alias for the LSPRECISION= option.

START =*r*
specifies initial estimates for parameters as multiples of the r value. In all TCALIS models, you can supply initial estimates individually as parenthesized values after each parameter name. Unspecified initial estimates are usually computed by various reasonable initial estimation methods in PROC TCALIS. If none of the initialization methods is able to compute all the unspecified initial estimates, then the remaining unspecified initial estimates are set to

r, $10|r|$, or $100|r|$. For variance parameters, $100|r|$ is used for covariance structure analyses and $10|r|$ is used for correlation structure analyses. For other types of parameters, r is used. The default value is $r = 0.5$. If the DEMPHAS= option is used, the initial values of the variance parameters are multiplied by the value specified in the DEMPHAS= option. See the section "Initial Estimates" on page 6922 for more information.

STDERR | SE

displays approximate standard errors if estimation methods other than unweighted least squares (ULS) or diagonally weighted least squares (DWLS) are used (and the NOSTDERR option is not specified). If you specify neither the STDERR nor the NOSTDERR option, the standard errors are computed for the OUTMODEL= data set. This information is displayed by default when you specify the PRINT option.

VARDEF= DF | N | WDF | WEIGHT | WGT

specifies the divisor used in the calculation of covariances and standard deviations. The default value is VARDEF=DF. The values and associated divisors are displayed in the following table, where k is the number of partial variables specified in the PARTIAL statement. When a WEIGHT statement is used, w_j is the value of the WEIGHT variable in the jth observation, and the summation is performed only over observations with positive weight.

Value	Description	Divisor
DF	degrees of freedom	$N - k - 1$
N	number of observations	N
WDF	sum of weights DF	$\sum_j^N w_j - k - 1$
WEIGHT | WGT	sum of weights	$\sum_j^N w_j$

VSINGULAR | VSING=*r*

specifies a relative singularity criterion r ($r > 0$) for the inversion of the information matrix, which is needed to compute the covariance matrix. If you do not specify the SINGULAR= option, the default value for r or *VSING* is 1E−8; otherwise, the default value is *SING*, which is the specified SINGULAR= value.

When inverting the information matrix, the following singularity criterion is used for the diagonal pivot $d_{j,j}$ of the matrix:

$$|d_{j,j}| \leq \max(ASING, VSING * |H_{j,j}|, MSING * \max(|H_{1,1}|, \ldots, |H_{n,n}|))$$

where *ASING* and *MSING* are the specified values of the ASINGULAR= and MSINGULAR= options, respectively, and $H_{j,j}$ is the j-th diagonal element of the information matrix. Note that in many cases a normalized matrix $\mathbf{D}^{-1}\mathbf{H}\mathbf{D}^{-1}$ is decomposed (where $D^2 = diag(H)$), and the singularity criteria are modified correspondingly.

WPENALTY | WPEN=*r*

specifies the penalty weight $r \geq 0$ for the WLS and DWLS fit of the diagonal elements of a correlation matrix (constant 1s). The criterion for weighted least squares estimation of a correlation structure is

$$\mathbf{F}_{WLS} = \sum_{i=2}^{n}\sum_{j=1}^{i-1}\sum_{k=2}^{n}\sum_{l=1}^{k-1} w^{ij,kl}(s_{ij} - c_{ij})(s_{kl} - c_{kl}) + r\sum_{i}^{n}(s_{ii} - c_{ii})^2$$

where r is the penalty weight specified by the WPENALTY=r option and the $w^{ij,kl}$ are the elements of the inverse of the reduced $(n(n-1)/2) \times (n(n-1)/2)$ weight matrix that contains only the nonzero rows and columns of the full weight matrix $\mathbf{W}$. The second term is a penalty term to fit the diagonal elements of the correlation matrix. The default value is 100. The reciprocal of this value replaces the asymptotic variance corresponding to the diagonal elements of a correlation matrix in the weight matrix $\mathbf{W}$, and it is effective only with the ASYCOV=CORR option. The often used value $r = 1$ seems to be too small in many cases to fit the diagonal elements of a correlation matrix properly. The default WPENALTY= value emphasizes the importance of the fit of the diagonal elements in the correlation matrix. You can decrease or increase the value of r if you want to decrease or increase the importance of the diagonal elements fit. This option is effective only with the WLS or DWLS estimation method and the analysis of a correlation matrix.

See the section "Estimation Criteria" on page 6888 for more details.

CAUTION: If you input the weight matrix by the INWGT= option, the WPENALTY= option is ignored.

WRIDGE=*r*

defines a ridge factor r for the diagonal of the weight matrix $\mathbf{W}$ used in GLS, WLS, or DWLS estimation. The weight matrix $\mathbf{W}$ is transformed to

$$\mathbf{W} \longrightarrow \tilde{\mathbf{W}} = \mathbf{W} + r(\text{diag}(\mathbf{W}))$$

The WRIDGE= option is applied on the weight matrix before the following actions occur:

- the WPENALTY= option is applied on it
- the weight matrix is written to the OUTWGT= data set
- the weight matrix is displayed

CAUTION: If you input the weight matrix by the INWGT= option, the OUTWGT= data set will contain the same weight matrix without the ridging requested by the WRIDGE= option. This ensures that the entries in the INWGT= and OUTWGT= data sets are consistent. The WRIDGE= option is ignored if you input the inverse of the weight matrix by the INWGT= and INWGTINV options (or the INWGT(INV)= option alone).

BASEMODEL Statement

REFMODEL | BASEMODEL *model_number* < / *options* > **;**

where *model_number* represents a model number between 1 and 9999.

See the REFMODEL statement on page 6811 for details.

BOUNDS Statement

BOUNDS *constraint* < , *constraint* . . . > **;**

where *constraint* represents
< *number operator* > *parameter-list* < *operator number* >

You can use the BOUNDS statement to define boundary constraints for any independent parameter that has its name specified in the main or subsidiary model specification statements, the PARAMETERS statement, or the INMODEL= data set. You cannot define boundary constraints for dependent parameters created in SAS programming statements or elsewhere.

Valid operators are <=, <, >=, >, and = (or, equivalently, LE, LT, GE, GT, and EQ). The following is an example of the BOUNDS statement:

```
bounds         0.   <= a1-a9 x    <= 1. ,
              -1.   <= c2-c5             ,
                       b1-b10 y   >= 0. ;
```

You must separate boundary constraints with a comma, and you can specify more than one BOUNDS statement. The feasible region for a parameter is the intersection of all boundary constraints specified for that parameter; if a parameter has a maximum lower boundary constraint larger than its minimum upper bound, the parameter is set equal to the minimum of the upper bounds.

The active set strategies made available in PROC TCALIS treat strict inequality constraints < or > as if they were just inequality constriants <= or >=. For example, if you require x be strictly bigger than zero so as to prevent an undefined value for $y = log(x)$, specifying the following statement is insufficient:

```
BOUNDS x > 0;
```

Specify the following statement instead:

```
BOUNDS x > 1E-8;
```

If the TCALIS procedure encounters negative variance estimates during the minimization process, serious convergence problems can occur. You can use the BOUNDS statement to constrain these parameters to nonnegative values. Although allowing negative values for variances might lead to a better model fit with smaller χ^2 value, it adds difficulties in interpretation.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC TCALIS to obtain separate analyses on observations in groups defined by the BY variables in the input data set. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the TCALIS procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

The BY statement is not supported if you define more than one group by using the GROUP statements.

For more information about the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide.*

COV Statement

COV *assignment* < , *assignment* . . . > **;**

where *assignment* represents
variables < ∗ *variables2* > = *parameter-spec*

The COV statement is a subsidiary model specification statement for the FACTOR and LINEQS models. In the LINEQS model, the COV statement defines the covariances among the exogenous variables, including errors and disturbances. In the FACTOR model, the COV statement defines the factor covariances. In each *assignment* of the COV statement, you specify variables in the *variables* and the *variables2* lists, followed by the covariance parameter specification in the *parameter-spec* list. Covariances with only values given are fixed constants. Covariances with names given are free parameters to estimate. You can also specify initial values for these free parameters by putting the parenthesized initial values after the parameter names. The *assignment*s in the COV statement must be separated by commas. You can use only one COV statement in each model specification.

Consider a LINEQS model with exogenous variables V1, V2, V3, and V4. The following is a COV statement specification of the LINEQS model:

```
cov V2 V1 = 0.3,
    V3 V1 = phi1 (0.4),
    V3 V2 = phi2,
    V4 V3 = phi2;
```

In this statement, you specify **cov(V2,V1)** as a fixed constant at 0.3, **cov(V3,V1)** as parameter phi1 with an initial value at 0.4, **cov(V3,V2)** and **cov(V4,V3)** as a free parameter phi2 without an initial value.

Note that the *variables* and *variables2* lists on the left-hand side of the equal sign of the COV statement should contain only names of exogenous variables. In LINEQS models, exogenous variables

can be either observed or latent (including errors and disturbances). However, in the FACTOR models, only covariances among latent factors can be specified.

If the right-hand-side parameter list is longer than the left-hand-side variable list, the right-hand-side list is shortened to the length of the variable list. If the right-hand-side list is shorter than the variable list, the right-hand-side list is filled with repetitions of the last item in the list.

You can use one of two alternatives to specify covariance parameters. The first alternative uses only one variable list and refers to all distinct pairs of variables within the list. The second alternative uses two variable lists separated by an asterisk and refers to all pairs of variables among the two lists.

Within-List Covariances

Using k variable names in the *variables* list on the left-hand side of an equal sign in a COV statement means that the parameter list (*parameter-spec*) on the right-hand side refers to all $k(k-1)/2$ distinct variable pairs. Order is very important. The order relation between the left-hand-side variable pairs and the right-hand-side parameter list is illustrated by the following within-list covariances specification in the COV statement:

```
cov E1-E4 = PHI1-PHI6 ;
```

This specification is equivalent to the following specification:

```
cov E2 E1 = phi1,
    E3 E1 = phi2, E3 E2 = phi3,
    E4 E1 = phi4, E4 E2 = phi5, E4 E3 = phi6;
```

Because **cov(a,b)** is the same as **cov(b,a)**, you need to specify only one of them for a covariance parameter of any two variables.

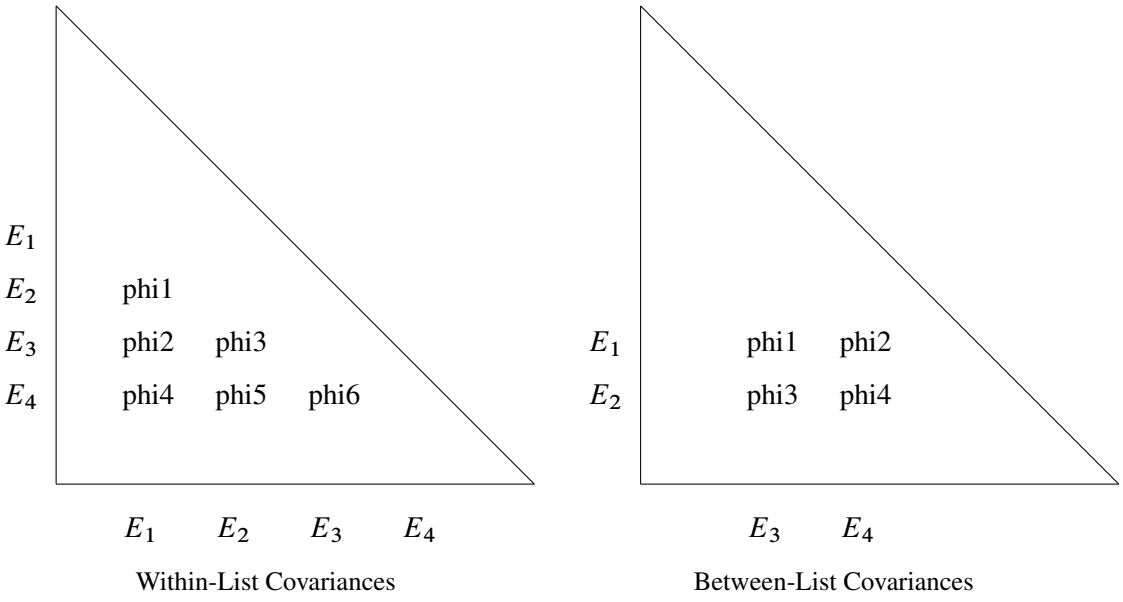
When you use prefix names on the right-hand sides, you do not have to count the exact number of parameters. For example, the following statement generates distinct parameter names by appending distinct numbers to the prefix phi:

```
cov E1-E4 = phi__ ;
```

Between-List Covariances

Using k_1 and k_2 variable names in the two lists (separated by an asterisk) on the left-hand side of an equal sign in a COV statement means that the covariance parameter list on the right-hand side refers to all $k_1 \times k_2$ distinct variable pairs. Again, order is very important. The order relation between the left-hand-side variable pairs and the right-hand-side parameter list is illustrated by the following between-list covariances specification:

```
cov E1 E2 * E3 E4 = phi1-phi4;
```



This is equivalent to the following specification:

```
cov  E1 E3 = phi1, E1 E4 = phi2,
     E2 E3 = phi3, E2 E4 = phi4;
```

Using prefix names on the right-hand sides lets you achieve the same purpose without counting the number of parameters. That is, you can specify the between-list covariances equivalently by the following statement:

```
cov  E1 E2 * E3 E4 = phi__ ;
```

Figure 88.3 Within-List and Between-List Covariances

Automatic Covariance Parameters among Exogenous Manifest Variables

In LINEQS models, all covariances among exogenous manifest variables are free parameters to estimate unless you specify otherwise in the COV statement. The parameter names for these covariances are generated by PROC TCALIS with the prefix _Add and appended with integer suffixes. If you want any of these covariances be fixed values, you must specify them explicitly in the COV statement.

Emphasis must be put on the **manifest variables** for automatic covariance parameters generation. Covariaces among exogenous latent variables by default are fixed zeros unless they are specified otherwise in the COV statement. The same applies to any covariance between an exogenous latent variable and an exogenous manifest variable. Only among the set of exogenous mainfest variables are the covariance parameters automatically generated if they are not specified explicitly in the COV statement. This is different than the case of variance parameters. Variances of **all** exogenous variables are automatically generated if they are not explicitly specified in the STD statement.

Modifying a Parameter Specification from a Reference Model

If you define a new LINEQS model by using a reference (or base) model in the REFMODEL statement, in some situations you might want to modify some parameter specifications from the COV statement of the reference model before transferring the specifications to the new model. If you want to change a particular COV parameter specification from the reference model, you can simply put the corresponding parameter location with a new parameter specification in the new model. If you want to delete a particular parameter location from the reference model, you can put that parameter location with a missing parameter value in the new model. For example, if the covariance between variables V1 and V2 are defined in the reference model and you do not want this parameter location in your new model, you can use the following statement to delete the parameter location in the new model:

```
cov  V1 V2 = .;
```

Note that the missing value syntax is valid only when you use with the REFMODEL statement. See the section "Modifying a LINEQS Model from a Reference Model" on page 6769 for a more detailed example of LINEQS model respecification.

In LINEQS models, all covariances among exogenous manifest variables are free parameters to estimate unless you specify otherwise in the COV statement. This is also true for LINEQS models specified under the REFMODEL statement. In the reference model, covariance parameters generated by PROC TCALIS are named with the _Add prefix and appended with integer suffixes. These parameter specifications in the reference model do **not** transfer to the new model. Only after the new model is resolved from the reference model, the REFMODEL statement options, the RENAMEPARM statement, and model respecifications do the remaining unspecified covariances among exogenous manifest variables generate additional covariance parameters with the _Add prefix and integer suffixes. In this way, the covariance parameters in the new model are not constrained to be the same as the corresponding parameters in the reference model. If you want any of these covariance parameters to be constrained across the models, you must specify them explicitly in the COV statement of the reference model so that the covariance specification is transferred to the new model.

DETERM Statement

DETERM | STRUCTEQ *variables* < / *option* > **;**

where *option* represents:
LABEL | NAME = *name*

The DETERM statement is used to compute the determination coefficient of the listed dependent *variables* in the model. The precursor of the DETERM statement is the STRUCTEQ statement, which enables you to define the list of the dependent variables of the structural equations. Because the term *structural equation* is not defined in a unique way, a more generic concept of determination coefficients is revealed by the DETERM statement.

You can specify the DETERM statement as many times as you want for computing determination

coefficients for the sets of dependent *variables* of interest. You can label each set of dependent variables by using the LABEL= option. Note that you cannot use the DETERM statement in an MSTRUCT model because there are no dependent variables in this type of model.

EFFPART Statement

EFFPART *effect* < , *effect*> **;**

where *effect* represents:
variables < *direction variables2* >
and *direction* is the direction of the effect, as indicated by one of the following: –>, >, <–, or <.

In the EFFPART statement, you select those effects you want to analyze by partitioning the total effects into direct and indirect effects, with estimated standard errors. The EFFPART or TOTEFF option of the PROC TCALIS statement also enables you to analyze effects. The difference is that the EFFPART or TOTEFF option displays effects on *all* endogenous variables, while the EFFPART statement shows only the effects of interest. In addition, the EFFPART statement enables you to arrange the effects in any way you like. Hence, the EFFPART statement offers a more precise and organized way to present various results of effects.

The EFFPART statement supports the following three types of effect specifications:

- > or –> direction
  Example:

  ```
  effpart X1 X3-X5 -> Y1 Y2;
  ```

  This will display *four* separate tables, respectively for the effects of X1, X3, X4, and X5 on Y1 and Y2. Each table contains the total, direct, and indirect effects of an X-variable on the two Y-variables.

- < or <– direction
  Example:

  ```
  effpart Y1 Y2 <- X1 X3-X5;
  ```

  This will display *two* separate tables, respectively for the effects on Y1 and Y2, by X1, X3, X4, and X5. Each table contains the total, direct, and indirect effects of the four X-variables on a Y-variable. Certainly, the results produced from this statement are essentially the same as the previous statement. The difference is about the organization of the effects in the tables.

- no direction
  Example:

  ```
  effpart Y1 Y2 X1-X3;
  ```

  In this case, variables on the list are analyzed one by one to determine the nature of the effects. If a variable has nonzero effects on any other variables in the model, a table of the total, direct, and indirect effects of the variable on those variables is displayed. If a variable is

endongenous, a table of total, direct, and indirect effects of those variables that have nonzero effects on the variable is displayed. Note that an endogenous variable in a model might also have effects on other endogenous variables. Therefore, the two cases mentioned are not mutually exclusive—a variable listed in the EFFPART statement might yield two tables for effect analysis.

FACTOR Statement

FACTOR < *EFA_options* | *CFA_spec* > **;**

where *EFA_options* are exploratory factor analysis options, *CFA_spec* is confirmatory factor analysis specification defined as:

factor-variables-relation < , *factor-variables-relation* > ...

and each *factor-variables-relation* is defined as:

factor –> *variables* = *parameter-spec*

In the FACTOR statement, you can specify either *EFA_options*, *CFA_spec*, or neither of these. However, you cannot specify both *EFA_options* and *CFA_spec* at the same time.

If an *EFA_option* (exploratory factor analysis option) is specified immediately after the FACTOR statement, or neither *EFA_options* nor *factor-variable-relations* are specified in the FACTOR statement, an exploratory factor model is analyzed. Otherwise, specifying an *CFA_spec* (confirmatory factor analysis specification) invokes a confirmatory factor model. These two types of models are discussed in the next two sections.

Exploratory Factor Analysis

For the exploratory factor model with orthogonal factors, PROC TCALIS assumes the following model structures for the population covariance or correlation matrix $\mathbf{C}$:

$$\mathbf{C} = \mathbf{F}\mathbf{F}' + \mathbf{U}$$

where $\mathbf{F}$ is the factor loading matrix and $\mathbf{U}$ is a diagonal matrix of error variances. In this section, p denotes the number of manifest variables corresponding to the rows and columns of matrix $\mathbf{C}$, and n denotes the number of factors (or components, if the COMPONENT option is specified in the FACTOR statement) corresponding to the columns of the factor loading matrix $\mathbf{F}$. While the number of manifest variables is set automatically by the number of variables in the VAR statement or in the input data set, the number of factors can be set by the N= option in the FACTOR statement.

The unrestricted exploratory factor model is not identified because any orthogonal rotated factor loading matrix $\tilde{\mathbf{F}} = \mathbf{F}\boldsymbol{\Theta}$ satisfies the same model structures as $\mathbf{F}$ does, where $\boldsymbol{\Theta}$ is any orthogonal matrix so that $\boldsymbol{\Theta}'\boldsymbol{\Theta} = \boldsymbol{\Theta}\boldsymbol{\Theta}' = \mathbf{I}$. Mathematically, the covariance or correlation structures can be expressed as:

$$\mathbf{C} = \tilde{\mathbf{F}}\tilde{\mathbf{F}}' + \mathbf{U} = \mathbf{F}\boldsymbol{\Theta}\,\boldsymbol{\Theta}'\mathbf{F}' + \mathbf{U} = \mathbf{F}\mathbf{F}' + \mathbf{U}$$

To obtain an identified orthogonal factor solution as a starting point, the $n(n-1)/2$ elements in the upper triangle of $\mathbf{F}$ are constrained to zeros in PROC TCALIS. Initial estimates for factor loadings and unique variances are computed by an algebraic method of approximate factor analysis. Given the initial estimates, final estimates are obtained through the iterative optimization of an objective function, which depends on the estimation method specified in the METHOD= option (default with ML—maximum likelihood) of the PROC TCALIS statement.

To make the factor solution more interpretable, you can use the ROTATE= option in the FACTOR statement to obtain a rotated factor loading matrix with a "simple" pattern. Rotation can be orthogonal or oblique. The rotated factors remain uncorrelated after an orthogonal rotation but would be correlated after an oblique rotation. The model structures of an oblique solution are expressed in the following equation:

$$\mathbf{C} = \tilde{\mathbf{F}}\mathbf{P}\tilde{\mathbf{F}}' + \mathbf{U}$$

where $\tilde{\mathbf{F}}$ is the rotated factor loading matrix and $\mathbf{P}$ is a symmetric matrix for factor correlations. See the sections "The FACTOR Model" on page 6863 and "Exploratory Factor Analysis Models" on page 6865 for more details about exploratory factor models.

You can also do exploratory factor analysis by the more dedicated FACTOR procedure. Even though extensive comparisons of the factor analysis capabilities between the FACTOR and TCALIS procedures are not attempted here, some general points can be made here. In general, the FACTOR procedure provides more factor analysis options than the TCALIS procedure does, although both procedures have some unique factor analysis features that are not shared by the other. PROC TCALIS requires more computing time and memory than PROC FACTOR because it is designed for more general structural estimation problems and is not able to exploit all the special properties of the unconstrained factor analysis model. For maximum likelihood analysis, you can use either PROC FACTOR (with METHOD=ML, which is not the default method in PROC FACTOR) or PROC TCALIS. Because the initial unrotated factor solution obtained by PROC FACTOR uses a different set of identification constraints than that of PROC TCALIS, you would observe different initial ML factor solutions for the procedures. Nonetheless, the initial solutions by both procedures are statistically equivalent.

The following exploratory factor analysis options are available in the FACTOR statement.

COMPONENT | COMP

computes a component analysis instead of a factor analysis (the diagonal matrix $\mathbf{U}$ in the model is set to 0). Note that the rank of $\mathbf{FF}'$ is equal to the number n of components in $\mathbf{F}$. If n is smaller than the number of variables in the moment matrix $\mathbf{C}$, the matrix of predicted model values is singular and maximum likelihood estimates for $\mathbf{F}$ cannot be computed. You should compute ULS estimates in this case.

HEYWOOD | HEY

constrains the diagonal elements of $\mathbf{U}$ to be nonnegative. Equivalently, you can constrain these elements to positive values by the BOUNDS statement.

GAMMA=*p*

specifies the orthomax weight used with the option ROTATE=ORTHOMAX. Alternatively, you can use ROTATE=ORTHOMAX(*p*) with *p* representing the orthomax weight. There is no restriction on valid values for the orthomax weight, although the most common values are

between 0 and the number of variables. The default GAMMA= value is one, resulting in the varimax rotation.

N=*n*

specifies the number of first-order factors or components. The number of factors (n) should not exceed the number of manifest variables (p) in the analysis. For the saturated model with $n = p$, the COMP option should generally be specified for $\mathbf{U} = 0$; otherwise, $df < 0$. For $n = 0$ no factor loadings are estimated, and the model is $\mathbf{C} = \mathbf{U}$, with $\mathbf{U} = diag$. By default, $n = 1$.

NORM< = KAISER | NONE >

Kaiser-normalizes the rows of the factor pattern for rotation. NORM=KAISER, which is the default, has exactly the same effect as NORM. You can turn off the normalization by NORM=NONE.

RCONVERGE=*p*

RCONV=*p*

specifies the convergence criterion for rotation cycles. Rotation stops when the scaled change of the simplicity function value is less than the RCONVERGE= value. The default convergence criterion is:

$$|f_{new} - f_{old}|/K < \epsilon$$

where f_{new} and f_{old} are simplicity function values of the current cycle and the previous cycle, respectively, $K = max(1, |f_{old}|)$ is a scaling factor, and ϵ is 1E–9 by default and is modified by the RCONVERGE= value.

RITER=*i*

specifies the maximum number of cycles i for factor rotation. The default i is the greater of 10 times the number of variables and 100.

ROTATE | R=*name*

specifies an orthogonal or oblique rotation of the initial factor solution. Although ROTATE=PRINCIPAL is actually not a rotation method, it is put here for convenience. By default, ROTATE=NONE.

Valid *names* for orthogonal rotations are as follows:

BIQUARTIMAX | BIQMAX specifies orthogonal biquartimax rotation. This corresponds to the specification ROTATE=ORTHOMAX(0.5).

EQUAMAX | E specifies orthogonal equamax rotation. This corresponds to the specification ROTATE=ORTHOMAX with GAMMA=*n*/2.

FACTORPARSIMAX | FPA specifies orthogonal factor parsimax rotation. This corresponds to the specification ROTATE=ORTHOMAX with GAMMA=*n*.

NONE | N specifies that no rotation be performed, leaving the original orthogonal solution.

ORTHCF(*p1*,*p2*) | ORCF(*p1*,*p2*) specifies the orthogonal Crawford-Ferguson rotation (Crawford and Ferguson 1970) with the weights *p1* and *p2* for variable parsimony and factor parsimony, respectively. See the definitions of weights in Chapter 33, "The FACTOR Procedure."

ORTHGENCF(*p1*,*p2*,*p3*,*p4*) | ORGENCF(*p1*,*p2*,*p3*,*p4*) specifies the orthogonal generalized Crawford-Ferguson rotation (Jennrich 1973), with the four weights *p1*, *p2*, *p3*, and *p4*. For the definitions of these weights, see the section "Simplicity Functions for Rotations" on page 1572 in Chapter 33, "The FACTOR Procedure."

ORTHOMAX<(*p1*)> | ORMAX<(*p1*)> specifies the orthomax rotation (see Harman 1976) with orthomax weight *p1*. If ROTATE=ORTHOMAX is used, the default *p1* value is 1 unless specified otherwise in the GAMMA= option. Alternatively, ROTATE=ORTHOMAX(*p1*) specifies *p1* as the orthomax weight or the GAMMA= value. For the definitions of the orthomax weight, see the section "Simplicity Functions for Rotations" on page 1572 in Chapter 33, "The FACTOR Procedure."

PARSIMAX | PA specifies orthogonal parsimax rotation. This corresponds to the specification ROTATE=ORTHOMAX with

$$\text{GAMMA} = \frac{p \times (n-1)}{p+n-2}$$

PRINCIPAL | PC specifies a principal axis rotation. If ROTATE=PRINCIPAL is used with a factor rather than a component model, the following rotation is performed:

$$\mathbf{F}_{new} = \mathbf{F}_{old}\mathbf{T}, \quad \text{with} \quad \mathbf{F}'_{old}\mathbf{F}_{old} = \mathbf{T}\mathbf{\Lambda}\mathbf{T}'$$

where the columns of matrix $\mathbf{T}$ contain the eigenvectors of $\mathbf{F}'_{old}\mathbf{F}_{old}$.

QUARTIMAX | QMAX | Q specifies orthogonal quartimax rotation. This corresponds to the specification ROTATE=ORTHOMAX(0).

VARIMAX | V specifies orthogonal varimax rotation. This corresponds to the specification ROTATE=ORTHOMAX with GAMMA=1.

Valid *name*s for oblique rotations are as follows:

BIQUARTIMIN | BIQMIN specifies biquartimin rotation. It corresponds to the specification ROTATE=OBLIMIN(.5) or ROTATE=OBLIMIN with TAU=.5.

COVARIMIN | CVMIN specifies covarimin rotation. It corresponds to the specification ROTATE=OBLIMIN(1) or ROTATE=OBLIMIN with TAU=1.

OBBIQUARTIMAX | OBIQMAX specifies oblique biquartimax rotation.

OBEQUAMAX | OE specifies oblique equamax rotation.

OBFACTORPARSIMAX | OFPA specifies oblique factor parsimax rotation.

OBLICF(*p1*,*p2*) | OBCF(*p1*,*p2*) specifies the oblique Crawford-Ferguson rotation (Crawford and Ferguson 1970) with the weights *p1* and *p2* for variable parsimony and factor parsimony, respectively. For the definitions of these weights, see the section "Simplicity Functions for Rotations" on page 1572 in Chapter 33, "The FACTOR Procedure."

OBLIGENCF(*p1*,*p2*,*p3*,*p4*) | OBGENCF(*p1*,*p2*,*p3*,*p4*) specifies the oblique generalized Crawford-Ferguson rotation (Jennrich 1973) with the four weights *p1*, *p2*, *p3*, and *p4*. For the definitions of these weights, see the section "Simplicity Functions for Rotations" on page 1572 in Chapter 33, "The FACTOR Procedure."

OBLIMIN<(*p1*)> | OBMIN<(*p1*)> specifies the oblimin rotation with oblimin weight *p1*. If ROTATE=OBLIMIN is used, the default *p1* value is zero unless specified otherwise in the TAU= option. Alternatively, ROTATE=OBLIMIN(*p1*) specifies *p1* as the oblimin weight or the TAU= value. For the definitions of the oblimin weight, see the section "Simplicity Functions for Rotations" on page 1572 in Chapter 33, "The FACTOR Procedure."

OBPARSIMAX | OPA specifies oblique parsimax rotation.

OBQUARTIMAX | OQMAX specifies oblique quartimax rotation. This is the same as the QUARTIMIN method.

OBVARIMAX | OV specifies oblique varimax rotation.

QUARTIMIN | QMIN specifies quartimin rotation. It is the same as the oblique quartimax method. It also corresponds to the specification ROTATE=OBLIMIN(0) or ROTATE=OBLIMIN with TAU=0.

TAU=*p*

specifies the oblimin weight used with the option ROTATE=OBLIMIN. Alternatively, you can use ROTATE=OBLIMIN(*p*) with *p* representing the oblimin weight. There is no restriction on valid values for the oblimin weight, although for practical purposes a negative or zero value is recommended. The default TAU= value is 0, resulting in the quartimin rotation.

Confirmatory Factor Analysis

FACTOR *factor-variable-relations* **;**
PVAR *partial variance parameters* **;**
COV *covariance parameters* **;**
MEAN *mean parameters* **;**

If you specify at least one *factor-variable-relation*, a confirmatory factor analysis is assumed. Whenever applicable, you can use the PVAR, COV, and MEAN statements to specify the variance, partial variance, covariance, and mean parameters. The model structures for the covariance matrix **C** of the confirmatory factor model are described in the following equation:

$$\mathbf{C} = \mathbf{FPF}' + \mathbf{U}$$

where **F** is the factor loading matrix, **P** is a symmetric matrix for factor correlations, and **U** is a diagonal matrix of error variances.

If the mean structures are also analyzed, the model structures for the mean vector $\boldsymbol{\mu}$ of the confirmatory factor model are described in the following equation:

$$\boldsymbol{\mu} = \boldsymbol{\alpha} + \mathbf{F}\boldsymbol{\nu}$$

where $\boldsymbol{\alpha}$ is the intercept vector for the observed variables and $\boldsymbol{\nu}$ is the vector for factor means. See the sections "The FACTOR Model" on page 6863 and "Confirmatory Factor-Analysis Models" on page 6866 for more details about confirmatory factor models.

You can use the PVAR statement to specify factor variance parameters in the diagonal of matrix **P**, or the error variances in the diagonal of matrix **U**. These variances, by default, are automatically added as free parameters in the factor model even if you do not specify them. However, if you want to set constraints on these parameters, it is useful to define them explicitly by using the PVAR statement. For example, you might like to set some variances to fixed constants, or you might want to set equality constraints by using the same parameter name at different parameter locations in your model.

You can use the COV statement to specify factor covariance parameters. These factor covariances are the off-diagonal elements of matrix **P**. Unlike the factor variances, factor covariances are assumed to be fixed zeros by default. Note that you cannot use the COV statement to specify the error covariances—they are always fixed zeros in the confirmatory factor-analysis model.

You can use the MEAN statement to specify the means of the factors in vector $\boldsymbol{\nu}$ and the intercepts of the manifest variables in vector $\boldsymbol{\alpha}$. All the factor means and intercepts are fixed zeros if you do not specify them explicitly.

Suppose that you want to fit a factor model with nine manifest variables V1-V9. In this factor model, you assume a general factor and three group-factors, with three variables defining each group-factor. The following FACTOR statement shows the specification of such a model:

```
factor
   g_factor -> V1-V9 (9 * g_load__),
   factor_a -> V1-V3 (3 * load_a__),
   factor_b -> V4-V6 (3 * load_b__),
   factor_c -> V7-V9 (3 * load_c__);
```

In this example, you are fitting a factor matrix of the following form:

	g_factor	factor_a	factor_b	factor_c
V1	g_load1	load_a1		
V2	g_load2	load_a2		
V3	g_load3	load_a3		
V4	g_load4		load_b1	
V5	g_load5		load_b2	
V6	g_load6		load_b3	
V7	g_load7			load_c1
V8	g_load8			load_c2
V9	g_load9			load_c3

The blanks in the factor matrix denotes fixed zeros. Because you do not specify the covariances by using the COV statement, g_factor, factor_a, factor_b, and factor_c are all uncorrelated in the model.

Modifying a FACTOR Model from a Reference Model

In this section, it is assumed that you use a REFMODEL statement within the scope of a MODEL statement and the reference model (or base model) is a factor model, either exploratory or confirmatory. The reference model is referred to as the old model, while the model makes reference to this old model is referred to as the new model. If the new model is not intended to be an exact copy of the old FACTOR model, you can use the following extended FACTOR modeling language to make modifications from the old model before transferring the specifications to the new model.

Before discussing the syntax for modifying factor models, there are two cases where using the REFMODEL statement for defining new factor models are not recommended. First, if your old model is an exploratory factor-analysis model, then specification by using the FACTOR modeling language in the new model will replace the old model completely. In this case, the use of the REFMODEL statement is superfluous and should be avoided. Second, if your old model is a confirmatory factor-analysis model, then specification of an exploratory factor model by using the FACTOR statement in the new model will also replace the old model completely. Again, in this case the use of the REFMODEL statement is superfluous and should be avoided.

The nontrivial case where you might find the REFMODEL statement useful is when you modify an old confirmatory factor model to form a new confirmatory factor model. This nontrivial case is the focus of discussion in the remaining of the section.

The extended FACTOR modeling language for modifying model specification bears the same syntax as that of the ordinary FACTOR modeling language (see the section "Confirmatory Factor Analysis" on page 6756). The syntax is:

FACTOR *factor-variable-relation* **;**
PVAR *partial variance parameters* **;**
COV *covariance parameters* **;**
MEAN *mean parameters* **;**

The new model is formed by integrating with the old model in the following ways:

Duplication: If you do not specify in the new model a parameter location that exists in the old model, the old parameter specification is duplicated in the new model.

Addition: If you specify in the new model a parameter location that does not exist in the old model, the new parameter specification is added in the new model.

Deletion: If you specify in the new model a parameter location that also exists in the old model and the new parameter is denoted by the missing value '.', the old parameter specification is not copied into the new model.

Replacement: If you specify in the new model a parameter location that also exists in the old model and the new parameter is not denoted by the missing value '.', the new parameter specification replaces the old one in the new model.

For example, consider the following two-group analysis:

```
proc tcalis;
   group 1 / data=d1;
   group 2 / data=d2;
   model 1 / group=1;
      factor
         F1 -> V1-V3 = 1. load1 load2,
         F2 -> V4-V6 = 1. load3 load4,
         F3 -> V7-V9 = 1. load5 load6;
      cov
         F1 F2 = c12,
         F2 F3 = c23;
      pvar
         F1-F3 = c1-c3,
         V1-V9 = ev1-ev9;
   model 2 / group=2;
      refmodel 1;
      factor
         F1 -> V1 = loada,
         F2 -> V4 = loadb,
         F3 -> V7 = loadc;
      cov
         F1 F2 = .,
         F1 F3 = c13;
   run;
```

In this specification, you specify model 2 by referring to model 1 in the REFMODEL statement; model 2 is the new model which refers to the old model, model 1. Because the PVAR statement is not used in new model, all variance and partial variance parameter specifications in the PVAR statement of the old model are duplicated in the new model. The covariance parameter c23 for covariance between F2 and F3 in the COV statement of the old model is also duplicated in the new model. Similarly, loading parameters load1–load6 for some specific factor matrix locations are duplicated from the old model to the new model.

In the new model, there is an additional parameter specification that does not exist in the old model. In the COV statement of the new model, covariance parameter c13 for the covariance between F1 and F3 is added.

In the same statement, the covariance between F1 and F2 is denoted by the missing value '.'. This means that this parameter location in the old model should not be included in the new model. The consequence of this deletion from the old model is that the covariance between F1 and F2 is a fixed zero in the new model.

Finally, the three new loading specifications in the FACTOR statement of the new model replaces the fixed ones in the old model. They are now free parameters loada, loadb, and loadc in the new model.

FITINDEX Statement

FITINDEX *option* < *option* . . . > **;**

You can use the FITINDEX statement to set the options for computing and displaying the fit indices, or to output the fit indices. All but the OFF= and ON= options of the FITINDEX statement are also available in the PROC TCALIS statement. The options set in the FITINDEX statement will overwrite those set in the PROC TCALIS statement.

For the listing of fit indices and their definitions, see the section "Overall Model Fit Indices" on page 6903. Note that not all fit indices are available with all estimation methods, which is specified by the METHOD= option of the PROC TCALIS statement. See the section "Fit Indices and Estimation Methods" on page 6910 for more details.

The options of the FITINDEX statement are as follows:

ALPHAECV=α

specifies a $(1-\alpha)100\%$ confidence interval ($0 \leq \alpha \leq 1$) for the Browne and Cudeck (1993) expected cross validation index (ECVI). See the ALPHAECV= option of the PROC TCALIS statement on page 6726.

ALPHARMS=α

specifies a $(1-\alpha)100\%$ confidence interval ($0 \leq \alpha \leq 1$) for the Steiger and Lind (1980) root mean square error of approximation (RMSEA) coefficient. See the ALPHARMS= option of the PROC TCALIS statement on page 6726.

CHICORRECT | CHICORR = *name* **|** *c*

specifies a correction factor c for the chi-square statistics for model fit. See the CHICORRECT= option of the PROC TCALIS statement on page 6727.

CLOSEFIT=*p*

defines the criterion value p for indicating a close fit. See the CLOSEFIT= option of the PROC TCALIS statement on page 6728.

DFREDUCE=*i*

reduces the degrees of freedom of the χ^2 test by i. See the DFREDUCE= option of the PROC TCALIS statement on page 6728.

NOADJDF

turns off the automatic adjustment of degrees of freedom when there are active constraints in the analysis. See the NOADJDF option of the PROC TCALIS statement on page 6735.

NOINDEXTYPE

disables the display of index types in the fit summary table. See the NOINDEXTYPE option of the PROC TCALIS statement on page 6735.

OFF | OFFLIST= [*names***] | {***names***}**

turns off the printing of one or more fit indices or modeling information as indicated by *names*, where a *name* represents a fit index, a group of fit indices, or modeling information.

Names must be specified inside a pair of parentheses and separated by spaces. By default, all fit indices are printed. See the ON= option for the value of *names*.

ON | ONLIST < (ONLY) > = [*names***] | {***names***}**

turns on the printing of one or more fit indices or modeling information as indicated by *names*, where a *name* represents a fit index, a group of fit indices, or modeling information. *Names* must be specified inside a pair of parentheses and separated by spaces. Because all fit indices and modeling information are printed by default, using an ON= list alone is redundant. When both ON= and OFF= lists are specified, the ON= list will override the OFF= list for those fit indices or modeling information that appear on both lists. If an ON(ONLY)= list is used, only those fit indices or modeling information specified in the list will be printed. Effectively, an ON(ONLY)= list is the same as the specification with an ON= list with the same selections and an OFF=ALL list in the FITINDEX statement.

Output Control of Fit Index Groups and Modeling Information Group

You can use the following *names* to refer to the groups of fit indices or modeling information available in PROC TCALIS:

ABSOLUTE	Absolute or stand-alone fit indices that measures the model fit without using a baseline model.
ALL	All fit indices available in PROC TCALIS.
INCREMENTAL	Incremental fit indices that measure model fit by comparing with a baseline model.
MODELINFO	General modeling information including sample size, number of variables, number of variables, and so on.
PARSIMONY	Fit indices that take model parsimony into account.

Output Control of Modeling Information

You can use the following *names* to refer to the individual modeling information available in PROC TCALIS:

INDCHI	Chi-square statistic for the independence model.
INDCHIDF	Degrees of freedom of the chi-square statistic for the independence model.
NACTCON	Number of active constraints.
NMOMENTS	Number of elements in the moment matrices being modeled.
NOBS	Number of observations assumed in the analysis.
NPARMS	Number of independent parameters.
NVAR	Number of variables.

Output Control of Absolute Fit Indices
You can use the following *names* to refer to the individual absolute fit indices available in PROC TCALIS:

CHISQ	Chi-square statistic for model fit.
CN	Hoelter's critical N.
CONTRIBUTION	Percentage contribution to the chi-square value for multiple-group analyses.
DF	Degrees of freedom for the chi-square test for model fit.
ELLIPTIC	Elliptical chi-square statistic for ML and GLS methods in single-group analyses without mean structures.
FUNCVAL	Optimized function value.
GFI	Goodness-of-fit index by Jöreskog and Sörbom.
PROBCHI	P-value of the chi-square statistic for model fit.
PROBELLIPTIC	P-value of the elliptical chi-square statistic.
RMSR	Root mean square residual.
SRMSR	Standardized root mean square residual.
ZTEST	Z-test of Wilson and Hilferty.

Output Control of Parsimonious Fit Indices
You can use the following *names* to refer to the individual parsimonious fit indices available in PROC TCALIS:

AGFI	Adjusted GFI.
AIC	Akaike information criterion.
CAIC	Bozdogan corrected AIC.
CENTRALITY	McDonald centrality measure.
ECVI	Expected cross-validation index.
LL_ECVI	Lower confidence limit for ECVI.
LL_RMSEA	Lower confidence limit for RMSEA.
PGFI	Parsimonious GFI.
PROBCLFIT	Probability of close fit.
RMSEA	Root mean squares of error approximation.
SBC	Schwarz Bayesian criterion.
UL_ECVI	Upper confidence limit for ECVI .
UL_RMSEA	Upper confidence limit for RMSEA.

Output Control of Incremental Fit Indices
You can use the following *names* to refer to the individual incremental fit indices available in PROC TCALIS:

BENTLERCFI	Bentler comparative fit index.
BENTLERNFI	Bentler-Bonett normed fit index.
BENTLERNNFI	Bentler-Bonett non-normed fit index.
BOLLENNFI	Bollen normed fit index (Rho1).
BOLLENNNFI	Bollen non-normed fit index (Delta2).
PNFI	James et al. parsimonious normed fit index.

OUTFIT=*SAS-data-set*
creates an output data set containing the values of the fit indices. This is the same as the OUTFIT= option of the PROC TCALIS statement on page 6739. See the section "OUTFIT= SAS-data-set" on page 6837 for details.

FREQ Statement

FREQ *variable* **;**

If one variable in your data set represents the frequency of occurrence for the other values in the observation, specify the variable's name in a FREQ statement. PROC TCALIS then treats the data set as if each observation appears n_i times, where n_i is the value of the FREQ variable for observation i. Only the integer portion of the value is used. If the value of the FREQ variable is less than 1 or is missing, that observation is not included in the analysis. The total number of observations is considered to be the sum of the FREQ values. You can use only one FREQ statement within the scope of each GROUP or the PROC TCALIS statement.

GROUP Statement

GROUP *i* < / *options* > **;**

where *i* is an assigned group number between 1 and 9999, inclusively.

The GROUP statement signifies the beginning of a group specification block and designates a group number for the group. All subsidiary group specification statements after a GROUP statement belong in that group until another MODEL or GROUP statement is used. The subsidiary group specification statements refer to one of the following four statements:

- FREQ statement on page 6763
- PARTIAL statement on page 6798
- VAR statement on page 6818
- WEIGHT statement on page 6818

For example, consider the following statements:

```
proc tcalis;
   var X1-X4;
   group 1 / label='Women' data=women_data;
      freq  Z;
   group 2 / label='Men' data=men_data;
      partial P;
   model 1 / group = 1-2;
      factor N=1; /* One factor exploratory factor analysis */
   run;
```

In the GROUP statements, two groups are defined. Group 1, labeled as 'Women', refers to the data set women_data. Group 2, labeled as 'Men', refers to the data set men_data. Both groups are fitted by an exploratory factor model defined in model 1, as indicated in the GROUP= option of the MODEL statement. While the frequency variable Z defined in the FREQ statement is applicable only to group 1, the partial variable P defined in the PARTIAL statement is applicable only to group 2. However, the VAR statement, which appears before the definitions of both groups, applies globally to both group 1 and group 2. Therefore, variables X1–X4 are the analysis variables in the two groups.

You can set group-specific *options* in each GROUP statement. All but one (that is, the LABEL= option) of these *options* are also available in the MODEL and PROC TCALIS statements. If you set these group-specific *options* in the PROC TCALIS statement, they will apply to all groups unless you respecify them in the GROUP statement. If you set these group-specific *options* in the MODEL statement, they will apply to all groups that are fitted by the associated model. In general, the group-specific options are transfered from the PROC TCALIS statement to the MODEL statements (if present) and then to the fitted groups. In the transferring process, options are overwritten by the newer ones. If you want to apply some group-specific options to a particular group only, you should set those options in the GROUP statement corresponding to that group.

Option Available in the GROUP Statement Only

LABEL | NAME=*name*

specifies a label for the current group. You can use any valid SAS names up to 256 characters for labels. You can also use quote strings for the labels. This option can be specified only in the GROUP statement, not the PROC TCALIS statement.

Options Available in the GROUP and PROC TCALIS Statements

These options are available in the GROUP and PROC TCALIS statements:

Option	Description
DATA= on page 6728	specifies the input data set
INWGT= on page 6731	specifies the data set that contains the weight matrix
OUTSTAT= on page 6739	specifies the data set for storing the statistical results
OUTWGT= on page 6739	specifies the data set for storing the weight matrix

See the section "Listing of PROC TCALIS Statement Options" on page 6726 for more details about these options. If you specify these options in the PROC TCALIS statement, they are transferred to *all* GROUP statements. They might be overwritten by the respecifications in the individual GROUP statements.

Options Available in GROUP, MODEL, and PROC TCALIS Statements

These options are available in the GROUP, MODEL and PROC TCALIS statements:

Option	Description
BIASKUR on page 6727	computes the skewness and kurtosis without bias corrections
EDF= on page 6729	defines nobs by the number of error df
KURTOSIS on page 6731	computes and displays kurtosis
NOBS= on page 6735	defines the number of observations (nobs)
PCORR on page 6740	displays analyzed and estimated moment matrix
PLOTS= on page 6741	specifies ODS Graphics selection
PWEIGHT on page 6818	displays the weight matrix
RDF | DFR= on page 6742	defines nobs by the number of regression df
RESIDUAL | RES on page 6742	computes the default residuals
RESIDUAL | RES= on page 6742	specifies the type of residuals
RIDGE on page 6743	specifies the ridge factor for covariance matrix
SIMPLE on page 6743	prints univariate statistics
VARDEF= on page 6744	specifies variance divisor
WPENALTY= on page 6744	specifies the penalty weight to fit correlations
WRIDGE= on page 6745	specifies the ridge factor for the weight matrix

If you specify these options in the PROC TCALIS statement, they are transferred to all MODEL statements. These options are overwritten by the respecifications in the individual MODEL statements. After these options are resolved in a given MODEL statement, they are transferred further to the GROUP statements of which the associated groups are fitted by the model. Again, these options might be overwritten by the respecifications in the individual GROUP statements.

LINCON Statement

LINCON *constraint* < , *constraint* . . . > **;**

where *constraint* represents one of the following:

- *number operator linear-term*
- *linear-term operator number*

and *linear-term* is

< + | − >< *coefficient* ∗ > *parameter* << + | − >< *coefficient* ∗ > *parameter* . . . >

The LINCON statement specifies a set of linear equality or inequality constraints of the following form:

$$\sum_{j=1}^{n} a_{ij} x_j \leq b_i, \quad i = 1, \ldots, m$$

The constraints must be separated by commas. Each linear constraint i in the statement consists of a linear combination $\sum_j a_{ij} x_j$ of a subset of the n parameters x_j, $j = 1, \ldots, n$, and a constant value b_i separated by a comparison operator. Valid operators are <=, <, >=, >, and = or, equivalently, LE, LT, GE, GT, and EQ. PROC TCALIS cannot enforce the strict inequalities < or >. Note that the coefficients a_{ij} in the linear combination must be constant numbers and must be followed by an asterisk and the name of a parameter (that is, listed in the PARMS, main, or subsidiary model specification statements). The following is an example of the LINCON statement that sets a linear constraint on parameters x1 and x2:

```
lincon       x1 + 3 * x2 <= 1;
```

Although you can easily express boundary constraints in LINCON statements, for many applications it is much more convenient to specify both the BOUNDS and the LINCON statements in the same PROC TCALIS call.

LINEQS Statement

LINEQS *equation* < , *equation* . . . > **;**

where *equation* represents:

dependent = *term* < + *term* . . . >

and each *term* represents one of the following:

- *coefficient-name* < *(number)* > *variable-name*
- *prefix-name* < *(number)* > *variable-name*
- < *number* > *variable-name*

The LINEQS statement is a main model specification statement that invokes the LINEQS modeling language. You can specify at most one LINEQS statement in a model, within the scope of either the PROC TCALIS statement or a MODEL statement. To completely specify a LINEQS model, you

might need to add some subsidiary model specification statements. The following is the syntax for the LINEQS modeling language:

LINEQS *model equations* **;**
STD *partial variance parameters* **;**
COV *covariance parameters* **;**
MEAN *mean parameters* **;**

In the LINEQS statement, you use equations to specify the linear functional relations among manifest or latent variables. Equations in the LINEQS statement are separated by commas.

In the STD statement, you specify the variance parameters. In the COV statement, you specify the covariance parameters. In the MEAN statement, you specify the mean parameters. For details of these subsidiary model specification statements, see the syntax of these statements.

In the LINEQS statement, in addition to the functional relations among variables, you specify the coefficient parameters of interest in the equations. There are four types of parameters you can specify in equations, as shown in the following example:

```
lineqs
   V1 = 1.       F1 + E1,
   V2 = b2       F1 + E2,
   V3 = b2       F1 + E3,
   V4 = b4 (.4) F1 + E4;
```

In this example, you have manifest variables V1–V4, which are related to a latent factor, denoted by F1, as specified in the equations. In each equation, you have one outcome variable (V-variable), one predictor variable (F1), and one error variable (E-variable). The following four types of parameters have been specified:

- free or constrained parameters with starting values

  The coefficient parameter b4 in the fourth equation is a free parameter to estimate. A starting value for a parameter can be specified inside parentheses following the parameter name. In this case, the starting value for b4 is 0.4. As shown in the equations, it is not constrained with any other coefficient parameters because b4 is specified at only one location.

- free or constrained parameters without starting values

  The coefficient parameter b2 in the second and the third equations is a parameter to estimate. No starting value is given for the parameter. With the same parameter name b2, the path coefficients with predictor variable F1 in the second and the third equation are thus implicitly constrained to be equal.

- explicitly fixed parameter values

  Any fixed constant preceding a predictor variable is a fixed parameter (for example, the constant coefficient 1 for F1 in the first equation).

- implicitly fixed parameter values

  If there is neither a parameter nor a constant preceding a predictor variable in an equation, the coefficient associated with that predictor variable is assumed to be a fixed parameter at one.

For example, the coefficients preceding all error variables (E-variables) are fixed at 1. Any coefficients associated with unspecified predictor variables in equations are fixed zeros.

Parameters with no starting values will be initialized by various heuristic and effective methods in PROC TCALIS. See the section "Initial Estimates" on page 6922 for details.

If your model contains many unconstrained parameters and it is too cumbersome to find different parameter names, you can specify all those parameters by the same prefix name. A prefix name is a short name called "root" followed by double underscores '__'. Whenever a prefix name is encountered, the TCALIS procedure generates a parameter name by appending a unique integer to the root. Hence, the prefix name should have few characters so that the generated parameter name is not longer than thirty-two characters. To avoid unintentional equality constraints, the prefix names should not coincide with explicitly defined parameter names.

Certainly, coefficient parameters are only a subset of parameters of a model. Other parameters like variance, covariance and mean parameters should be specified in the subsidiary model statements for the LINEQS modeling language—that is, the COV, MEAN, and STD statements.

Representing Latent Variables in the LINEQS Model

Because latent variables are widely used in structural equation modeling, PROC TCALIS needs a way to identify different types of latent variables specified in the LINEQS model. This is accomplished by following some naming conventions for the latent variables. See the section "Naming Variables in the LINEQS Model" on page 6840 for details about these naming rules. Essentially, latent factors (systematic sources) must start with letter 'F' or 'f'. Error terms must start with letter 'E', 'e', 'D', or 'd'. Prefix 'E' or 'e' represents the error term of an endogenous manifest variable. Prefix 'D' or 'd' represent represents disturbance (or error) term of an endogenous latent variable. Although 'D' and 'E' variables are conceptually different, for modeling purposes 'D' and 'E' prefixes are not distinguished in PROC TCALIS. Essentially, only the distinction between latent factors (systematic sources) and errors or disturbances (unsystematic sources) is critical in specifying a proper model analyzed by PROC TCALIS. Manifest variables in PROC TCALIS do not need to follow additional naming rules beyond those required by the general SAS system—they only need to have references in the input data set.

Types of Variables and Semantic Rules of Equations

Depending on their roles in the system of equations, variables in a LINEQS model can be classified into endogenous or exogenous. An endogenous variable is a variable that serves as an outcome variable (left-hand side of an equation) in one of the equations. All other variables are exogenous variables, including those manifest variables that never appear in any places of any equation but are specified in the VAR statement.

The syntactic rules for equations are far from sufficient to define the system of equations that the LINEQS model would accept. You must also observe the following semantic rules:

- Only manifest or latent variables can be endogenous. This means that you cannot specify any

error or disturbances variables on the left-hand side of equations. This also means that error and disturbance variables are always exogenous in the LINEQS model.

- An endogenous variable appearing on the left-hand side of an equation cannot appear on the left-hand side of another equation. In other words, you have to specify all the predictors for an endogenous variable in a single equation.
- An endogenous variable appearing on the left-hand side of an equation cannot appear on the right-hand side of the same equation.
- Each equation must contain one and only one **unique** error term, be it an E-variable for manifest outcome variable or a D-variable for latent outcome variable. If, indeed, you want to specify an equation without an error term, you might equivalently set the variance of the error term to a fixed zero in the STD statement.

Mean Structures in Equations

To fit a LINEQS model with mean structures, you can specify the MEANSTR option in the PROC TCALIS or the associated MODEL statement. Alternatively, you can use the Intercept variable in equations for including intercept terms or the MEAN statement to specify the mean parameters. Conceptually, the Intercept variable is a special "variable" containing the value one for each observation. You do not need to have this variable in your input data set, nor do you need to generate it in the DATA step. It serves as a notational convenience in the LINEQS modeling language. The actual intercept parameter is expressed as a coefficient parameter with the intercept variable. For example, consider the following LINEQS model specification.

```
lineqs
   V1 = a1 (10) Intercept +          F1 + E1,
   V2 =                    + b2      F1 + E2,
   V3 = a2      Intercept + b2       F1 + E3,
   V4 = a2      Intercept + b4 (.4)  F1 + E4;
```

In the first equation, a1, with a starting value at 10, is the intercept parameter for V1. The intercept parameters for V3 and V4 are constrained to be the same. They are named a2 in the equations. Even though there is no Intercept variable specified in the equation for endogenous variable V2, its intercept parameter is assumed to be a fixed zero. This is because once you use at least one Intercept variable in an equation or you specify at least one mean parameter in the MEAN statement, mean structure analysis is activated and all mean and intercept parameters have default values at zero, unless you specify parameter names or other fixed values explicitly in the equations or in the MEAN statement.

Modifying a LINEQS Model from a Reference Model

In this section, it is assumed that you use a REFMODEL statement within the scope of a MODEL statement and the reference model (or base model) is a LINEQS model. The reference model will be referred to as the old model, while the model being defined is referred to as the new model. If the new model is not intended to be an exact copy of the old model, you can use the following extended

LINEQS modeling language to make modifications within the scope of the MODEL statement for the new model.

The syntax of the extended LINEQS modeling language is the same as that of the ordinary LINEQS modeling language (see the section "LINEQS Statement" on page 6766):

LINEQS *model equations* **;**
STD *partial variance parameters* **;**
COV *covariance parameters* **;**
MEAN *mean parameters* **;**

The new model is formed by integrating with the old model in the following ways:

Duplication: If you do not specify in the new model an equation with an outcome variable (that is, a variable on the left of the equal sign) that exists in the old model, the equation with that outcome variable in the old model is duplicated in the new model. For specifications other than the LINEQS statement, if you do not specify in the new model a parameter location that exists in the old model, the old parameter specification is duplicated in the new model.

Addition: If you specify in the new model an equation with an outcome variable that does not exist as an outcome variable in the equations of the old model, the equation is added in the new model. For specifications other than the LINEQS statement, if you specify in the new model a parameter location that does not exist in the old model, the new parameter specification is added in the new model.

Deletion: If you specify in the new model an equation with an outcome variable that also exists as an outcome variable in an equation of the old model and you specify the missing value '.' as the only term on the right-hand side of the equation in the new model, the equation with the same outcome variable in the old model is not copied into the new model. For specifications other than the LINEQS statement, if you specify in the new model a parameter location that also exists in the old model and the new parameter is denoted by the missing value '.', the old parameter specification is not copied into the new model.

Replacement: If you specify in the new model an equation with an outcome variable that also exists as an outcome variable in an equation of the model and the right-hand side of the equation in the new model is not denoted by the missing value '.', the new equation replaces the old equation with the same outcome variable in the new model. For specifications other than the LINEQS statement, if you specify in the new model a parameter location that also exists in the old model and the new parameter is not denoted by the missing value '.', the new parameter specification replaces the old one in the new model.

For example, in the following two-group analysis you specify model 2 by referring to model 1 in the REFMODEL statement.

```
proc tcalis;
   group 1 / data=d1;
   group 2 / data=d2;
   model 1 / group=1;
      lineqs
         V1   =      1 F1   + E1,
         V2   =  load1 F1   + E2,
         V3   =  load2 F1   + E3,
         F1   =     b1 V4   + b2 V5 + b3 V6 + D1;
      std
         E1-E3  = ve1-ve3,
         D1     = vd1,
         V4-V6  = phi4-phi6;
      cov
         E1 E2 = cve12;
   model 2 / group=2;
      refmodel 1;
      lineqs
         V3   = load1 F1 + E3;
      cov
         E1 E2 = .,
         E2 E3 = cve23;
   run;
```

Model 2 is the new model which refers to the old model, model 1. This example illustrates the four types of model integration:

- Duplication: All equations, except the one with outcome variable V3, in the old model are duplicated in the new model. All specifications in the STD and COV statements, except the covariance between E1 and E2, in the old model are also duplicated in the new model.
- Addition: The parameter cve23 for the covariance between E2 and E3 is added in the new model.
- Deletion: The specification of covariance between E1 and E2 in the old model is not copied into the new model, as indicated by the missing value '.' specified in the new model.
- Replacement: The equation with V3 as the outcome variable in the old model is replaced with a new equation in the model. The new equation uses parameter load1 so that it is now constrained to be the same as the regression coefficient in the equation with V2 as the outcome variable.

LISMOD Statement

LISMOD < *var_lists* > **;**

where *var_lists* represent one or more of the following:

- YVAR | YV | Y = *variables*
- XVAR | XV | X = *variables*
- ETAVAR | ETAV | ETA = *variables*
- XIVAR | XIV | XI | KSIVAR | KSIV | KSI = *variables*

LISMOD stands for LISrel MODeling, where LISREL is the program developed by Jöreskog and Sörbom (1988). Like the original implementation of LISREL, LISMOD uses a matrix specification interface. To complete the LISMOD specification, you might need to add as many MATRIX statements as needed, as shown in the following statement structure for the LISMOD model:

LISMOD *variable lists* **;**
MATRIX *matrix-name parameters-in-matrix* **;**
Repeat the MATRIX statement as needed **;**

The matrix-name in the MATRIX statement should be one of the twelve model matrices in LISMOD, as listed in the following:

- Matrices in structural model: _ALPHA_, _KAPPA_, _BETA_, _GAMMA_, _PHI_, _PSI_
- Matrices in measurement model for y-variables: _NUY_, _LAMBDAY_, _THETAY_
- Matrices in measurement model for x-variables: _NUX_, _LAMBDAX_, _THETAX_

See the section "Model Matrices in the LISMOD Model" on page 6849 for definitions of these matrices and their roles in the LISMOD modeling language. See the MATRIX statement on page 6784 for the details of parameter specification.

In the LISMOD statement, you can set the following four lists of variables:

- YVAR= list is for manifest variables y that are directly related to the endogenous latent eta-variables. Variables in the list are called y-variables.
- XVAR= list is for manifest variables x that are directly related to the exogenous latent ksi-variables. Variables in the list are called x-variables.
- ETAVAR= list is for endogenous latent variables η. Variables in the list are called eta-variables.
- XIVAR= list is for exogenous latent variables ξ. Variables in the list are called xi- or ksi-variables.

The order of variables in the lists of the LISMOD statement is important. The order is used to define the variable order in rows and columns of the LISMOD model matrices.

Depending on the model of interest, you might not need to set all the lists of variables. When some variable lists are not specified, the full model reduces to specialized submodels. However, to be a proper submodel in the LISMOD modeling language, it is necessary (but not sufficient) that at least one of the yvar= or xvar= lists is defined. See the section "LISMOD Submodels" on page 6851 for the details about LISMOD submodels that PROC TCALIS can handle.

An example of a LISMOD model specification is shown as follows:

```
proc tcalis;
   lismod xvar=x1-x3 yvar=y1-y6 xivar=xi etavar=eta1-eta2;
   matrix _LAMBDAY_   [,1]  = 1. load3 load4,
                      [,2]  = 0. 0. 0. 1. load5 load6;
   matrix _THETAY_    [1,1] = ey1-ey3,
                      [2,1] = cey;
   matrix _LAMBDAX_   [,]   = 1. load1 load2;
   matrix _THETAX_    [1,1] = 3*ex;
   matrix _GAMMA_     [,1]  = beta1 beta2;
   matrix _PHI_       [1,1] = phi;
   matrix _PSI_       [1,1] = psi1-psi2;
run;
```

In this example, you have three x-variables x1–x3, six y-variables y1–y6, one ξ-variable xi, and two η-variables eta1–eta2. The numbers of variables in these lists define the dimensions of the LISMOD model matrices. For example, matrix _LAMBDAY_ is 6×2, with y1–y6 as the row variables and eta1–eta2 as the column variables. Matrix _THETAX_ is 3×3, with x1–x3 as the row and column variables. In the MATRIX statements, you specify parameters in the elements of the matrices. After the matrix name, you specify in the parentheses '[' and ']' the starting row and column numbers of the first element to be parameterized. After the equal sign, you specify fixed or free parameters for the matrix elements.

Depending on how you specify the starting row and column numbers, the parameter specification might proceed differently. See the MATRIX statement on page 6784 for a detailed description. In this example, the first specification of the parameters in the _LAMBDAY_ matrix starts from [,1]—meaning that it starts from the first column and will proceed downwards. As a result, the [1,1] element is a fixed constant 1.0, the [2,1] element is a free parameter called load3, and the [3,1] element is a free parameter called load4. Similarly, in the second specification in the _LAMBDAY_ matrix, the [1,2], [2,2], [3,2], and [4,2] elements take constant values 0, 0, 0, and 1, respectively, and the [5,2] and [6,2] elements are free parameters load5 and load6, respectively.

You can also specify the parameters of a row using similar notation. For example, with the notation [2,] for the starting row and column numbers, specification proceeds to the left with the same second row in the matrix.

If you have both starting row and column numbers specified, such as that in the first specification in matrix _THETAY_, the parameter specification starts from [1,1] and proceeds to the next row and column numbers—that is [2,2], [3,3], and so on. This results in specifying the diagonal elements of matrix _THETAY_ as free parameters ey1, ey2, and ey3.

With the notation [,], there are no starting row and column numbers specified. Specification will start from the first valid element in the matrix and proceeds row-wise for all valid elements in the matrix. For example, in the matrix _LAMBDAX_ statement, the [1,1] element of matrix _LAMBDAX_ is a fixed constant 1, and the [1,2] and [1,3] elements are free parameters load1 and load2, respectively.

Modifying a LISMOD Model from a Reference Model

In this section, it is assumed that you use a REFMODEL statement within the scope of a MODEL statement and the reference model (or base model) is also a LISMOD model. The reference model is referred to as the old model, while the model that makes reference to this old model is referred to as the new model. If the new model is not intended to be an exact copy of the old model, you can use the following extended LISMOD modeling language to make modifications within the scope of the MODEL statement for the new model. The syntax is similar to, but not exactly the same as, the ordinary LISMOD modeling language (see the section "LISMOD Statement" on page 6772). The respecification syntax for a LISMOD model is shown as follows:

LISMOD ;
  MATRIX *matrix-name parameters-in-matrix* ;
  Repeat the MATRIX statement as needed ;

First, in the respecification you should not put any variable lists in the LISMOD statement. The reason is that the parameter respecifications in the new model make reference to the variable lists of the old model. Therefore, the variable lists in the new model are implicitly assumed to be exactly the same as those in the old model. Because of this, the LISMOD statement is entirely optional for the respecification in the new model.

Second, you can use MATRIX *matrix-name* statements to modify the old model by using the same syntax as in the LISMOD modeling language. The *matrix-name* can be one of the twelve possible LISMOD matrices. In addition, in the respecification syntax you can use the missing value '.' to drop a parameter specification from the old model.

The new model is formed by integrating with the old model in the following ways:

Duplication: If you do not specify in the new model a parameter location that exists in the old model, the old parameter specification is duplicated in the new model.

Addition: If you specify in the new model a parameter location that does not exist in the old model, the new parameter specification is used in the new model.

Deletion: If you specify in the new model a parameter location that also exists in the old model and the new parameter is denoted by the missing value '.', the old parameter specification is not copied into the new model.

Replacement: If you specify in the new model a parameter location that also exists in the old model and the new parameter is not denoted by the missing value '.', the new parameter specification replaces the old one in the new model.

For example, in the following two-group analysis you specify model 2 by referring to model 1 in the REFMODEL statement.

```
proc tcalis;
   group 1 / data=d1;
   group 2 / data=d2;
   model 1 / group=1;
      lismod xvar=X1-X3 yvar=Y1-Y6 xivar=xi etavar=eta1-eta2;
      matrix _LAMBDAY_   [,1]  = 1. load3 load4,
                         [,2]  = 0. 0. 0. 1. load5 load6;
      matrix _THETAY_    [1,1] = ey1-ey3,
                         [2,1] = cey;
      matrix _LAMBDAX_   [,]   = 1. load1 load2;
      matrix _THETAX_    [1,1] = 3*ex;
      matrix _GAMMA_     [,1]  = beta1 beta2;
      matrix _PHI_       [1,1] = phi;
      matrix _PSI_       [1,1] = psi1-psi2;
   model 2 / group=2;
      refmodel 1;
      matrix _THETAY_    [2,1] = .;
      matrix _THETAX_    [1,1] = ex1-ex3;
      matrix _BETA_      [2,1] = beta;
   run;
```

In this example, model 2 is the new model which refers to the old model, model 1. It illustrates the four types of model integration:

- Duplication: All parameter locations and specifications in the old model are duplicated in the new model, except the [2,1] element in matrix _THETAY_ and the diagonal of matrix _THETAX_, which are being modified in the new model.
- Addition: The _BETA_[2,1] parameter location is added with a new parameter beta in the new model. This indicates that *eta1* is a predictor variable of *eta2* in the new model, but not in the old model.
- Deletion: Because the missing value '.' is used for the parameter value, the _THETAY_[2,1] parameter location is no longer defined as a free parameter in the new model. In the old model, the same location is defined by the free parameter cey.
- Replacement: The diagonal elements of the _THETAX_ matrix in the new model are now defined by three distinct parameters ex1–ex3. This replaces the old specification where a single constrained parameter ex is applied to all the diagonal elements in the _THETAX_ matrix.

LMTESTS Statement

LMTESTS *option* < *option . . .* > **;**

where *option* represents one of the following:

- *display-option*
- *test-set*

and *test-set* represents one of the following:

- *set-name* = [*regions*]
- *set-name* = { *regions* }

where *set-name* is the name of the set of Lagrange multiplier (LM) tests defined by the *regions* that follow after the equal sign and *regions* are keywords denoting specific sets of parameters in the model.

You can use the LMTESTS statement to set *display-options* or to customize the *test-sets* for the LM tests. The LMTESTS statement is one of the model analysis statements. It can be used within the scope of the TCALIS statement so that the options will apply to all models. It can also be used within the scope of each MODEL statement so that the options will apply only locally. Therefore, different models within a TCALIS run can have very different LMTESTS *options*.

The LM Tests Display Options

The following are the *display-options* for the LM tests:

DEFAULT
conducts the default sets of LM tests for freeing fixed parameters in the model. This option is used when you need to reset the default sets of LM tests in the local model. For example, you might have turned off the default LM tests by using the NODEFAULT option in the LMTESTS statement within the scope of PROC TCALIS statement. However, for the model under the scope of a particular MODEL statement, you can use this DEFAULT option in the local LMTESTS statement to turn on the default LM tests again.

MAXRANK
sets the maximum number of rankings within a set of LM tests. The actual number of test rankings might be smaller because the number of possible LM tests within a set might be smaller than the maximum number requested.

NODEFAULT
turns off the default sets of LM tests for freeing fixed parameters in the model. As a result, only the customized LM tests defined in the *test-sets* of the LMTESTS statement are conducted and displayed. Note that the LM tests for equality and active boundary constraints are not turned off by this option. If you specify this option in the LMTESTS statement within the scope of the PROC TCALIS statement, it will propagate to all models.

NORANK
turns off the ranking of the LM tests. Ranking of the LM tests is done automatically when

the model modification indices are requested. The NORANK option is ignored if you also set the MAXRANK option.

LMMAT
prints the sets of LM tests in matrix form, in addition to the normal LM test results.

The Customized Sets of LM Tests: Syntax of the Test-sets

In addition to the *display-options*, you can define customized sets of LM tests as *test-sets* in the LMTESTS statement. You can define as many *test-sets* as you like. Ranking of the LM tests will be done individually for each *test-set*. For example, the following LMTESTS statement requests that the default sets of LM tests not be conducted by the NODEFAULT option. Instead, two customized *test-sets* are defined.

```
lmtests nodefault MyFirstSet=[ALL] MySecondSet=[COVEXOG COVERR];
```

The first customized set MyFirstSet pulls all possible parameter locations together for the LM test ranking (ALL keyword). The second customized set MySecondSet pulls only the covariances among exogenous variables (COVEXOG keyword) and among errors (COVERR keyword) together for the LM test ranking.

Two different kinds of *regions* for LM tests are supported in PROC TCALIS: matrix-based or non-matrix-based.

The matrix-based *regions* can be used if you are familiar with the matrix representations of various types of models. Note that defining *test-sets* by using matrix-based *regions* does not mean that LM tests are printed in matrix format. It means only that the parameter locations within the specified matrices are included into the specific *test-sets* for LM test ranking. For matrix output of LM tests, use the LMMAT option in the LMTESTS statement.

Non-matrix-based *regions* do not assume the knowledge of the model matrices. They are easier to use in most situations. In addition, non-matrix-based *regions* can cover special subsets of parameter locations that cannot be defined by model matrices and submatrices. For example, because of the compartmentalization according to independent and dependent variables in the LINEQS model matrices, the sets of LM tests defined by the LINEQS matrix-based *regions* are limited. For example, you cannot use any matrix-based *regions* to request LM tests for new paths to existing independent variables in the LINEQS model. Such a matrix does not exist in the original specification. However, you can use the non-matrix based *region* NEWENDO to refer to these new paths.

The *regions* for parameter locations are specified by keywords in the LMTESTS statement. Because the *regions* are specific to the types of models, they are described separately for each model type in the following.

The LM Test Regions for FACTOR Models

Keywords for Matrix-Based Regions

FACTERRV | FACTERRV
specifies the error variances.

FACTFCOR | FACTFCOR
specifies the covariances among factors.

FACTINTE | FACTINTE
specifies the intercepts.

FACTLOAD | FACTLOAD
specifies the factor loadings.

FACTMEAN | FACTMEAN
specifies the factor means.

See the section "Model Matrices in the FACTOR Model" on page 6864 for definitions of these FACTOR model matrices.

Keywords for Non-Matrix-Based Regions

ALL
specifies all parameter locations.

COV
specifies the covariances among factors.

COVERR
specifies the covariances among errors.

COVFACT | COVLV
specifies the covariances among factors.

FIRSTMOMENTS
specifies the means of factors and the intercepts.

INTERCEPTS
specifies the intercepts.

LOADINGS
specifies the factor loadings.

MEANS | MEAN
specifies the means of factors.

The LM Test Regions for LINEQS Models

Keywords for Matrix-Based Regions

EQSALPHA | EQSALPHA
specifies the intercepts of dependent variables.

EQSBETA | EQSBETA
specifies effects of dependent variables on dependent variables.

EQSGAMMA | _EQSGAMMA_SUB_ | EQSGAMMA | EQSGAMMASUB
specifies the effects of independent variables (excluding errors) on dependent variables. Because effects of errors on dependent variables are restricted to ones in the LINEQS model, LM tests on _EQSGAMMA_ and _EQSGAMMA_SUB_ (submatrix of _EQSGAMMA_) are the same.

EQSNU | _EQSNU_SUB_ | EQSNU | EQSNUSUB
specifies the means of independent variables (excluding errors). Because means of errors are restricted to zero in the LINEQS model, LM tests on _EQSNU_ and _EQSNU_SUB_ (submatrix of _EQSNU_) are the same.

EQSPHI | EQSPHI
specifies variances and covariances among all independent variables, including errors.

EQSPHI11 | EQSPHI11
specifies variances and covariances among independent variables, excluding errors.

EQSPHI21 | EQSPHI21
specifies covariances between errors and disturbances with other independent variables.

EQSPHI22 | EQSPHI22
specifies variances and covariances among errors and disturbances.

See the section "Matrix Representation of the LINEQS Model" on page 6841 for definitions of these model matrices and submatrices.

Keywords for Non-Matrix-Based Regions

ALL
specifies all possible parameter locations.

COV
specifies all covariances among independent variables, including errors and disturbances.

COVERR
specifies covariances among errors or disturbances.

COVEXOG
specifies covariances among independent variables, excluding errors and disturbances.

COVEXOGERR
specifies covariances of errors and disturbances with other independent variables.

COVLV | COVFACT
specifies covariances among latent variables (excluding errors and disturbances).

COVMV | COVOV
specifies covariance among independent manifest variables.

EQUATION | EQUATIONS
specifies all possible linear relationships among variables.

FIRSTMOMENTS
specifies means and intercepts.

INTERCEPTS | INTERCEPT
specifies intercepts of dependent variables.

LV–>LV
specifies all possible effects of latent factors on latent factors.

LV–>MV | MV<–LV
specifies all possible effects of latent factors on manifest variables.

LV<–MV | MV–>LV
specifies all possible effects of manifest variables on latent factors.

MEANS | MEAN
specifies the means of independent factors.

MV–>MV
specifies all possible effects of manifest variables on manifest variables.

NEWDEP | NEWENDO
specifies effects of other variables on the independent variables in the original model.

PATHS | PATH
specifies all possible linear relationships among variables.

The LM Test Regions for LISMOD Models

Keywords for Matrix-Based Regions

ALPHA | ALPHA
specifies the _ALPHA_ matrix.

BETA | BETA
specifies the _BETA_ matrix.

GAMMA | GAMMA
specifies the _GAMMA_ matrix.

KAPPA | KAPPA
specifies the _KAPPA_ matrix.

LAMBDA | LAMBDA
specifies the _LAMBDAX_ and _LAMBDAY_ matrices.

LAMBDAX | LAMBDAX
specifies the _LAMBDAX_ matrix.

LAMBDAY | LAMBDAY
specifies the _LAMBDAY_ matrix.

_NU_ | NU
specifies the _NUX_ and _NUY_ matrices.

NUX | NUX
specifies the _NUX_ matrix.

NUY | NUY
specifies the _NUY_ matrix.

PHI | PHI
specifies the _PHI_ matrix.

PSI | PSI
specifies the _PSI_ matrix.

THETA | THETA
specifies the _THETAX_ and _THETAY_ matrices.

THETAX | THETAX
specifies the _THETAX_ matrix.

THETAY | THETAY
specifies the _THETAY_ matrix.

Keywords for Non-Matrix-Based Regions

ALL
specifies all model matrices.

COV
specifies all covariance parameters in _THETAY_, _THETAX_, _PHI_, and _PSI_.

COVERR
specifies all covariances for errors or disturbances in _THETAY_, _THETAX_, and _PSI_.

COVFACT | COVLV
specifies all covariances among latent factors in _PHI_ when the ξ-variables exist, and in _PSI_ when the η-variables exist without the presence of the ξ-variables.

FIRSTMOMENTS
specifies all intercepts and means in _NUY_, _NUX_, _ALPHA_, and _KAPPA_.

INTERCEPTS | INTERCEPT
specifies all intercepts in _NUY_, _NUX_, and _ALPHA_.

LOADING | LOADINGS
specifies the coefficients in _LAMBDAY_ and _LAMBDAX_.

LV–>LV
specifies the effects of latent variables on latent variables. Depending on the type of LISMOD model, the _BETA_ and _GAMMA_ might be involved.

LV–>MV | MV<–LV
specifies the effects of latent variables on manifest variables. Depending on the type of LISMOD model, the _LAMBDAY_, _LAMBDAX_, and _GAMMA_ matrices might be involved.

MEANS | MEAN
specifies the mean parameters. Depending on the type of LISMOD model, the _ALPHA_ and _KAPPA_ matrices might be involved.

MV–>MV
specifies effects of manifest variables on manifest variables. Depending on the type of LISMOD model, the _BETA_ and _GAMMA_ matrices might be involved.

PATHS | PATH
specifies all path coefficients. Depending on the type of LISMOD model, the _LAMBDAY_, _LAMBDAX_, _BETA_, and _GAMMA_ matrices might be involved.

The LM Test Regions for MSTRUCT Models

Keywords for Matrix-Based Regions

MSTRUCTCOV | _COV_ | MSTRUCTCOV
specifies the _MSTRUCTCOV_ or _COV_ matrix.

MSTRUCTMEAN | _MEAN_ | MSTRUCTMEAN
specifies the _MSTRUCTMEAN_ or _MEAN_vector.

Keywords for Non-Matrix-Based Regions

ALL
specifies the _MSTRUCTCOV_ (or _COV_) and _MSTRUCTMEAN_ (or _MEAN_) matrices.

COV
specifies the _MSTRUCTCOV_ or _COV_ matrix.

MEANS | MEAN
specifies the _MSTRUCTMEAN_ or _MEAN_ matrix.

The LM Test Regions for PATH and RAM Models

Keywords for Matrix-Based Regions

RAMA | _A_ | RAMA
specifies the _RAMA_ matrix.

RAMALPHA | RAMALPHA
specifies the _RAMALPHA_ matrix.

RAMBETA | RAMBETA
specifies the _RAMBETA_ matrix.

RAMGAMMA | RAMGAMMA
specifies the _RAMGAMMA_ matrix.

RAMNU | RAMNU
specifies the _RAMNU_ matrix.

RAMP | _P_ | RAMP
specifies the _RAMP_ matrix.

RAMP11 | RAMP11
specifies the _RAMP11_ matrix.

RAMP21 | RAMP21
specifies the _RAMP21_ matrix.

RAMP22 | RAMP22
specifies the _RAMP22_ matrix.

RAMW | _W_ | RAMW
specifies the _RAMW_ vector.

Keywords for Non-Matrix-Based Regions

ALL
specifies all possible parameter locations.

ARROWS | ARROW
specifies all possible paths (that is, the entries in the _RAMA_ matrix).

COV
specifies all covariances and partial covariances (that is, the entries in the _RAMP_ matrix).

COVERR
specifies partial covariances among endogenous variables (that is, the entries in the _RAMP11_ matrix).

COVEXOG
specifies covariances among exogenous variables (that is, the entries in the _RAMP22_ matrix).

COVEXOGERR
specifies partial covariances of endogenous variables with exogenous variables (that is, the entries in the _RAM21_ matrix).

COVLV | COVFACT
specifies covariance among latent factors (that is, entries in _RAMP11_ pertaining to latent variables).

COVMV | COVOV
specifies covariance among manifest variables (that is, entries in _RAMP11_ pertaining to manifest variables).

FIRSTMOMENTS
specifies means or intercepts (that is, entries in _RAMW_ vector).

INTERCEPTS | INTERCEPT
specifies intercepts for endogenous variables (that is, entries in _RAMALPHA_ vector).

LV–>LV
specifies effects of latent variables on latent variables.

LV–>MV | MV<–LV
specifies effects of latent variables on manifest variables.

LV<–MV | MV–>LV
specifies effects of manifest variables on latent variables.

MEANS | MEAN
specifies the means of exogenous variables (that is, entries in the _RAMNU_ vector).

MV–>MV
specifies effects of manifest variables on manifest variables.

NEWENDO
specifies new paths to the exogenous variables in the original model.

PATHS | PATH
specifies all possible paths (that is, the entries in the _RAMA_ matrix).

MATRIX Statement

MATRIX *matrix-name* < *location* > = *parameter-spec* < , *location* = *parameter-spec* . . . > **;**

In MATRIX statements, you specify fixed constants or free parameters for the elements of the model matrix referred by the *matrix-name*. The *location* indicates the starting row and column numbers of the matrix being specified and the *parameter-spec* is a list of free or fixed parameters for the elements in the matrix. You can also assign initial values for the free parameters in the *parameter-spec* list.

The MATRIX statement is a subsidiary model specification statement of the LISMOD and MSTRUCT modeling languages. You might need to use the MATRIX statements as many times as needed for specifying your model. However, you can use the MATRIX statement at most once for each distinct model matrix.

Valid Matrix Names for the LISMOD modeling language

There are 12 model matrices in the LISMOD model and they correspond to the following *matrix-names* for the LISMOD modeling language:

- matrices in the measurement model for the y-variables

  LAMBDAY the matrix of regression coefficients of the y-variables on the eta-variables

  NUY the vector of intercept terms of the y-variables

  THETAY the error covariance matrix for the y-variables

- matrices in the measurement model for the x-variables

  LAMBDAX the matrix of regression coefficients of the x-variables on the ksi-variables

  NUX the vector of intercept terms of the x-variables

  THETAX the error covariance matrix for the x-variables

- matrices in the structural model

  ALPHA the vector of intercept terms of the eta-variables

  BETA the matrix of regression coefficients of the eta-variables on the eta-variables

  GAMMA the matrix of regression coefficients of the eta-variables on the ksi-variables

  KAPPA the mean vector for the ksi-variables

  PHI the covariance matrix for the ksi-variables

  PSI the error covariance matrix for the eta-variables

Valid Matrix Names for the MSTRUCT Modeling Language

the following *matrix-names* are valid for the MSTRUCT modeling language:

COV the covariance matrix

MEAN the mean vector

Specifying Locations in Model Matrices

There are four different ways to specify the starting *location* of the parameter matrix in question. Each way of specification leads to different continuation direction for assigning the parameters specified in the *parameter-spec* list. Assuming that there are n ($n \geq 1$) parameters specified in the *parameter-spec* list, the four different parameter assignment schemes due to different ways of starting *location* specification are described as follows:

[*i* , *j*] The elements in the *parameter-spec* list correspond to the diagonally continued matrix elements [*i,j*], [*i*+1,*j*+1], ..., [*i*+*n*-1,*j*+*n*-1]. The number of elements is defined by the length of the *parameter-spec* and is eventually terminated by the matrix boundaries. If the *parameter-spec* list contains just one element (constant or variable), then it is assigned to the matrix element [*i,j*].

[*i* ,] In this type of row-wise specification, the elements in the *parameter-spec* list correspond to the horizontally continued matrix elements [*i,1*], [*i,2*], ..., [*i,n*]. For a rectangular or non-symmetric square matrix with *k* columns, the number of elements in *parameter-spec* should not exceed *k*. For a symmetric matrix, because you need to specify lower triangle elements only (upper triangular elements are duplicated from the lower triangle elements automatically), the number of elements in *parameter-spec* list for this type of row-wise specification should not exceed *i*.

[, *j*] In this type of column-wise specification, the elements in the *parameter-spec* list correspond to the vertically continued matrix elements [*i,j*], [*i*+1,*j*], ..., [*i*+*n*-1,*j*]. For a rectangular or nonsymmetric square matrix, the value of *i* is 1. For a symmetric matrix, because you need to specify the lower triangular elements only (upper triangular elements are duplicated from the lower triangle elements automatically), the value of *i* in this type of column-wise specification is *j*.

[,] Unspecified location: The elements of the *parameter-spec* list are assigned to all valid matrix positions starting at the element [1,1] and continuing row-wise, until reaching the last element of the *parameter-spec* list or the last valid matrix position. For a symmetric matrix, the valid positions are the elements in the lower triangle since the other triangle receives the symmetric allocation automatically.

When there is no starting *location* specified, it is equivalent to using [,] for an *unspecified location*.

Specifying Parameters in Model Matrices

The *parameter-spec* list contains numeric values or parameter names, or both, that are assigned to the matrix elements starting at a specified position and proceeding in a specified direction, which are determined by the way of the starting *location* specification.

The syntax for the *parameter-spec* list is the same as the *parameter-spec* list for the STD statement. There are three types of specification in the *parameter-spec* list, as described in the following.

- Parameter names alone represent parameters in the model without starting values.
- Parameter names followed by numbers inside a pair of parentheses represent parameters in the model with starting values provided in the parentheses.
- Numbers alone represent fixed constant values for the corresponding matrix elements.

For example, consider the following *parameter-spec* list.

```
0. 1. A2-A5 (1.4 1.9 2.5) 5.
```

The first two matrix elements are assigned with fixed values 0 and 1, respectively. The next element is a parameter named A2 with no initial value provided. The next three matrix elements are assigned with parameters A3, A4, and A5 with initial values 1.4, 1.9, and 2.5, respectively. The next matrix element is assigned with a constant 5. At first glance, the initial values in the parentheses are seemingly assigned to A2, A3, and A4, respectively. However, because A2–A5 is a shorthand of four consecutive parameters, the preceding *parameter-spec* list is equivalent to:

```
0. 1. A2 A3 A4 A5 (1.4 1.9 2.5) 5.
```

With this explicit specification, it is clearer to see that the initial values in the parentheses are assigned to parameters A3–A5, respectively.

If your model contains many unconstrained parameters and it is too cumbersome to find different parameter names, you can specify all those parameters by the same prefix name. A prefix name is a short name called "root" followed by double underscores '__'. Whenever a prefix name is encountered, the TCALIS procedure generates a parameter name by appending a unique integer to the root. Hence, the prefix name should have few characters so that the generated parameter name is not longer than thirty-two characters. For example, consider the following *parameter-spec* list.

```
0. 1. 4 * A__ (1.4 1.9 2.5) 5.
```

If the prefix name A__ has not been specified previously, then A1, A2, A3, and A4 are generated by the **4 * A__** syntax. However, if the prefix name A__ has been specified, say, twice, previously, then A3, A4, A5, and A6 are generated by the same **4 * A__** syntax.

To avoid unintentional equality constraints, the prefix names should not coincide with explicitly defined parameter names. For example, consider the following specification.

```
matrix _mean_ = B1 B2 2 * B__;
```

If the prefix name B__ has not been specified previously, then B1 and B2 are generated for the third and the fourth elements, respectively, of the mean vector. However, these two parameter names are the same as those assigned explicitly to the first and the second elements of the mean vectors, resulting to two equality constraints that might not have been intended.

Modifying a Parameter Specification from a Reference Model

If you define a new LISMOD or MSTRUCT model by using a reference (or base) model in the REFMODEL statement, in some situations you might want to modify some parameter specifications from the MATRIX statement of the reference model before transferring the specifications to the new model. If you want to change a particular MATRIX parameter specification from the reference model, you can simply put the corresponding parameter location with a new parameter specification in the new model. If you want to delete a particular parameter location from the reference model, you can put that parameter location with the missing value '.' in the new model. For example, suppose you are defining a new LISMOD model by using the REFMODEL statement and the covariance between variables F1 and F2 is defined as a fixed or free parameter in the reference model. If you do not want this parameter specification to be copied into your new model, you can use the following specification in the new model:

```
matrix _PHI_  F1 F2 = .;
```

Notice that the missing value syntax is valid only when you use the REFMODEL statement. See the section "Modifying a LISMOD Model from a Reference Model" on page 6774 for a more detailed example of LISMOD model respecification. See the section "Modifying an MSTRUCT Model from a Reference Model" on page 6793 for a more detailed example of MSTRUCT model respecification.

MEAN Statement

MEAN *assignment* < , *assignment* . . . > **;**

where *assignment* represents:
variables = *parameter-spec*

The MEAN statement invokes the fitting of the mean structures of the model. The MEAN statement is one of the subsidiary model specification statements for supplementing modeling specification. You can use the MEAN statements to specify mean parameters in the FACTOR, LINEQS, and PATH modeling languages. You can also use the MEAN statement to specify the intercept parameters in the FACTOR or PATH modeling languages. The syntax of the MEAN statement is essentially the same as that of the STD or PVAR statement.

In each *assignment* of the MEAN statement, you put the *variables* on the left-hand side of the equal sign and specify the parameters on the right-hand side *parameter-spec*. Like elsewhere in the PROC TCALIS syntax, in *parameter-spec* you can put numbers for fixed values or parameter names for free or constrained parameters. Parameter names are optionally followed by numbers in parentheses for starting values. See the STD statement on page 6815 for examples.

In the FACTOR or PATH model, the variables in each *assignment* can be exogenous or endogenous. If a variable in the *variables* list is exogenous, the corresponding parameter is the mean parameter for the variable. Otherwise, the corresponding parameter is the intercept parameter for the variable. In the LINEQS model, however, only non-error type exogenous variables (that is, not E- or D- variables) can be used in the MEAN statement. The parameters are for the means of the exogenous variables. You cannot specify the intercept parameters in the MEAN statement of the LINEQS modeling language. Instead, you should specify intercepts in the equations of the LINEQS statement.

Automatic Mean Parameters among Exogenous Variables

If the names of any exogenous manifest variables in the LINEQS model are not included in the MEAN statement, the means of those exogenous manifest variables are assumed to be parameters to estimate. These parameters will be named automatically with the prefix _Add and appended with integer suffixes. However, all other mean parameters other than those for exogenous manifest variables are fixed zeros by default unless they are specified otherwise in the MEAN statement. In addition, all intercept parameters are assumed to be fixed zeros, unless they are specified otherwise in the LINEQS statement.

Modifying a Parameter Specification from a Reference Model

If you define a new FACTOR, LINEQS, or PATH model by using a reference (or base) model in the REFMODEL statement, in some situations you might want to modify some parameter specifications from the MEAN statement of the reference model before transferring the specifications to the new model. If you want to change a particular MEAN parameter specification from the reference model, you can simply put the corresponding parameter location with a new parameter specification in the new model. If you want to delete a particular parameter location from the reference model, you can put that parameter location with the missing value '.' in the new model. For example, suppose you are defining a new LINEQS model by using the REFMODEL statement and the mean of variable F1 is defined as a fixed or free parameter in the reference model. If you do not want this parameter specification to be copied into your new model, you can use the following specification in the new model:

```
mean F1 = .;
```

Notice that the missing value syntax is valid only when you use with the REFMODEL statement. See the section "Modifying a FACTOR Model from a Reference Model" on page 6758 for a more detailed example of FACTOR model respecification. See the section "Modifying a LINEQS Model from a Reference Model" on page 6769 for a more detailed example of LINEQS model respecification. See the section "Modifying a PATH Model from a Reference Model" on page 6800 for a more detailed example of PATH model respecification.

In LINEQS models, all means of exogenous manifest variables are free parameters to estimate unless you specify otherwise in the MEAN statement (see the section "Automatic Mean Parameters among Exogenous Variables" on page 6788). This is also true for LINEQS models specified under the REFMODEL statement. In the reference model, mean parameters generated by PROC TCALIS are named with the _Add prefix and appended with integer suffixes. These parameter specifications in the reference model do **not** transfer to the new model. Only after the new model is resolved from the reference model, the REFMODEL statement options, the RENAMEPARM statement options, and model respecifications are the additional mean parameters with the _Add prefix generated for the remaining unspecified means of exogenous manifest variables. In this way, the generated mean parameters for the exogenous mainfest variables in the new model are not constrained to be the same as the corresponding means in the reference model. If you want any of these mean parameters to be constrained across the models, you must specify them explicitly in the MEAN statement of the reference model so that the constrained mean specifications are transferred to the new model.

MODEL Statement

MODEL *i* < / *options* > **;**

where *i* is an assigned model number between 1 and 9999, inclusively.

A MODEL statement signifies the beginning of a model specification block and designates a model number for the model. All main and subsidiary model specification statements after a MODEL statement belong in that model until another MODEL or GROUP statement is encountered.

The MODEL statement itself does not serve the purpose of model specification, which is actually done by the main and subsidiary model specification statements that follow it. The MODEL statement serves as a "place-holder" of specification of a single model. It also makes the reference to a model easier with an assigned model number. For example, consider the following statements:

```
proc tcalis;
   group 1 / data=women_data;
   group 2 / data=men_data;
   model 1 / group=1 label='Women Model';
      {model 1 specification here}
   model 2 / group=2 label='Men Model';
      {model 2 specification here}
   run;
```

This example illustrates a two-group analysis with two models. One is model 1 labeled as 'Women Model' in a MODEL statement. Another is model 2 labeled as 'Men Model' in another MODEL statement. The two groups, group 1 and group 2, as defined in two separate GROUP statements, are fitted by model 1 and model 2, respectively, as indicated by the GROUP= option of the MODEL statements. Within the scope of model 1, you provide model specification statements by using the main and subsidiary model specification statements. Usually, one of the following main model specification statements is used: FACTOR, LINEQS, LISMOD, MSTRUCT, PATH, RAM, or REFMODEL. Similarly, you provide another set of model specification statements within the scope of model 2.

Hence, for an analysis with a single group, the use of the MODEL statement is not necessary because the model that fits the group is unambiguous.

You can set model-specific *options* in each MODEL statement. All but two of these *options* are also available in the PROC TCALIS statement. If you set these *options* in the PROC TCALIS statement, they will apply to all models, unless you respecify them in the local MODEL statements. If you want to apply some *options* only to a particular model, set these *options* in the MODEL statement corresponding to that model.

You can also set group-specific *options* in the MODEL statement. These group *options* will apply to the groups that are specified in GROUP= option of the MODEL statement. See the section "Options Available in the GROUP and PROC TCALIS Statements" on page 6765 for a detailed descriptions of these group *options*.

Option Available in MODEL Statement Only

LABEL | NAME=*name*
specifies a label for the model. You can use any valid SAS names up to 256 characters for labels. You can also use quote strings for labels.

GROUP | GROUPS=*int-list*
specifies a list of integers *int-list* of group numbers representing the groups to be fitted by the model.

Options Available in the MODEL and PROC TCALIS Statements

These options are available in the MODEL and PROC TCALIS statements. If you specify these options in the PROC TCALIS statement, they are transferred to all MODEL statements. These options might be overwritten by the respecifications in the local MODEL statements.

Option	Description
CORRELATION on page 6728	analyzes correlation matrix
COVARIANCE on page 6728	analyzes covariance matrix
DEMPHAS= on page 6728	emphasizes the diagonal entries
EFFPART | TOTEFF on page 6729	displays total, direct, and indirect effects
INEST= on page 6730	specifies the data set that contains the initial values and constraints
INMODEL | INRAM= on page 6730	specifies the data set that contains the model specifications
MEANSTR on page 6733	analyzes the mean structures
MODIFICATION on page 6734	computes modification indices
NOMOD on page 6735	suppresses modification indices
NOORDERSPEC on page 6735	displays model specifications and results according to the input order
NOPARMNAME on page 6735	suppresses the printing of parameter names in results
NOSTAND on page 6735	suppresses the standardized output
NOSTDERR on page 6735	suppresses standard error computations
ORDERSPEC on page 6738	orders the model output displays according to the parameter types within each model
OUTEST= on page 6738	specifies the data set that outputs the estimates and their covariance matrix
OUTMODEL | OUTRAM= on page 6739	specifies the output data set for storing the model specification and results
PARMNAME on page 6740	displays parameter names in model specifications and results
PDETERM on page 6740	computes the determination coefficients
PESTIM on page 6741	prints parameter estimates
PINITIAL on page 6741	prints initial pattern and values
PLATCOV on page 6741	computes the latent variable covariances and scoring coefficients
PRIMAT on page 6741	displays results in matrix forms
STDERR on page 6744	computes the standard errors

Options Available in MODEL, GROUP, and PROC TCALIS Statements

Some options in the GROUP statement can also be specified in the MODEL statements. Group options that are specified the MODEL statements are transferred to the GROUP statements that define the groups fitted by the associated models in the MODEL statements. This is a little bit more convenient than setting the common group options individually in the GROUP statements for all fitted groups by a model. See the section "Options Available in GROUP, MODEL, and PROC TCALIS Statements" on page 6765 for a reference of these options.

MSTRUCT Statement

MSTRUCT *VAR* = variables **;**

MSTRUCT stands for matrix structures. As opposed to other modeling languages, in which the mean and covariance structures are implied from paths, equations, or complicated model matrix computations, the MSTRUCT language is for direct structured mean and covariance models.

In the MSTRUCT statement, you define the list of variables. To complete the specification, you must use additional MATRIX statements to specify the parameters:

MSTRUCT *variables* **;**
  MATRIX _COV_ *parameters-in-matrix* **;**
  MATRIX _MEAN_ *parameters-in-matrix* **;**

You use the MATRIX _COV_ statement to specify the covariance and variance parameters in the structured covariance matrix. When applicable, you use the MATRIX _MEAN_ statement to specify the parameters in the structured mean vector. Each of these matrices can be specified no more than once within a model. See the MATRIX statement on page 6784 for details.

The order of variables in the *var_list* of the MSTRUCT statement is important. It is used to refer to the row and column variables of the _COV_ and the _MEAN_ matrices. The variables specified in the list should be present in the input data set intended for the MSTRUCT model. With direct mean and covariance structures on the observed variables, no latent variables are explicitly involved in the MSTRUCT modeling language. However, this does not mean that the MSTRUCT modeling language cannot handle latent variable models. With additional specifications in the PARAMETERS and the SAS programming statements, it is possible to fit certain latent variable models by using the MSTRUCT modeling language. Despite this, the code might get too complicated and error-prone. Hence, using the MSTRUCT modeling language for latent variable modeling is not recommended to novice users. The LINEQS, LISMOD, PATH, or RAM modeling language should be considered first for latent variable modeling.

Modifying an MSTRUCT Model from a Reference Model

In this section, it is assumed that you use a REFMODEL statement within the scope of a MODEL statement and the reference model (or base model) is also an MSTRUCT model. The reference model will be referred to as the old model, while the model that makes reference to the old model is referred to as the new model. If the new model is not intended to be an exact copy of the old model, you can use the following extended MSTRUCT modeling language to make modifications within the scope of the MODEL statement for the new model. The syntax is similar to, but not exactly the same as, the ordinary MSTRUCT modeling language, as in the section "MSTRUCT Statement" on page 6792. The syntax for respecifying or modifying an MSTRUCT model takes the following form:

MSTRUCT ;
  MATRIX _COV_ *parameters-in-matrix* ;
  MATRIX _MEAN_ *parameters-in-matrix* ;

First, in the respecification, you should not put any VAR= list in the MSTRUCT statement, as you would do for specifying the original base model. The reason is that parameter respecifications in the new model make reference to the variables in the VAR= list of the old model. Therefore, the VAR= list in the new model is implicitly assumed to be exactly the same as that in the old model. This renders the specification of a VAR= list of the MSTRUCT statement of the new model unnecessary. Because the VAR= option is the only possible option in the MSTRUCT statement, it also implies that the entire MSTRUCT statement is only optional for the new model.

Second, you can use the MATRIX _COV_ and MATRIX _MEAN_ statements to modify from the old model by using the same syntax as in ordinary MSTRUCT modeling language. In addition, in the respecification syntax, you can use the missing value '.' to drop a parameter location from the old model.

The new model is formed by integrating with the old model in the following ways:

Duplication: If you do not specify in the new model a parameter location that exists in the old model, the old parameter specification is duplicated in the new model.

Addition: If you specify in the new model a parameter location that does not exist in the old model, the new parameter specification is used in the new model.

Deletion: If you specify in the new model a parameter location that also exists in the old model and the new parameter is denoted by the missing value '.', the old parameter specification is not copied into the new model.

Replacement: If you specify in the new model a parameter location that also exists in the old model and the new parameter is not denoted by the missing value '.', the new parameter specification replaces the old one in the new model.

For example, consider the following statements for a two-group analysis:

```
proc tcalis;
   group 1 / data=d1;
   group 2 / data=d2;
   model 1 / group=1;
      mstruct var=V1-V6;
      matrix _COV_ [1,1] = 6*vparm (8.),
                   [2,]  = cv21,
                   [3,]  = cv31,
                   [4,]  = cv41 cv42 cv43,
                   [5,]  = cv51 cv52 cv53 cv54,
                   [6,]  = cv61 cv62 cv63 cv64 cv65;
   model 2 / group=2;
      refmodel 1;
      matrix _COV_ [2,]  = 3.,
                   [3,2] = cv32,
                   [4,]  = . . . ,
                   [5,]  = . . . ,
                   [6,]  = . . . ;
   run;
```

In these statements, you specify model 2 by referring to model 1 in the REFMODEL statement. Hence, model 2 is called the new model that refers to the old model, model 1. Because they are not respecified in the new model, all parameters on the diagonal of the covariance matrix are duplicated from the old model for the new model. Similarly, parameter locations associated with the cv54, cv64, and cv65 parameters are also duplicated in the new model.

An added parameter in the new model is cv32 for the covariance between V3 and V2. This parameter location is not specified in the old model.

In the new model, parameters for the covariances between the variable sets {V1 V2 V3} and {V4 V5 V6} are all deleted from the old model. The corresponding parameter locations for these covariances are given missing values '.' in the new model, indicating that they are no longer free parameters as in the old model. Deleting these parameters amounts to setting the corresponding covariances to fixed zeros in the new model.

Finally, covariance between V2 and V1 is changed from a free parameter cv21 in the old model to a fixed constant 3 in the new model. This illustrates the replacement rule of the respecification syntax.

NLINCON Statement

NLINCON | **NLC** *constraint* < , *constraint* . . . > **;**

where *constraint* represents one of the following:

- *number operator variable-list number operator*
- *variable-list operator number*
- *number operator variable-list*

You can specify nonlinear equality and inequality constraints with the NLINCON or NLC statement. The QUANEW optimization subroutine is used when you specify nonlinear constraints by using the NLINCON statement.

The syntax of the NLINCON statement is similar to that of the BOUNDS statement, except that the NLINCON statement must contain the names of variables that are defined in the program statements and are defined as continuous functions of parameters in the model. They must not be confused with the variables in the data set.

As with the BOUNDS statement, one- or two-sided constraints are allowed in the NLINCON statement; equality constraints must be one sided. Valid operators are <=, <, >=, >, and = (or, equivalently, LE, LT, GE, GT, and EQ).

PROC TCALIS cannot enforce the strict inequalities < or > but instead treats them as <= and >=, respectively. The listed nonlinear constraints must be separated by commas. The following is an example of the NLINCON statement that constrains the nonlinear parametric function $x_1 * x_1 + u_1$ to a fixed value of 1:

```
nlincon    xx = 1;
xx = x1 * x1 + u1;
```

Note that x1 and u1 are parameters defined in the model. The following three NLINCON statements, which require xx1, xx2, and xx3 to be between zero and ten, are equivalent:

```
nlincon  0. <= xx1-xx3,
               xx1-xx3 <= 10;
nlincon 0. <= xx1-xx3 <= 10.;
nlincon 10. >= xx1-xx3 >= 0.;
```

NLOPTIONS Statement

NLOPTIONS *options* **;**

Many options that are available in SAS/OR PROC NLP can be specified for the optimization subroutines in PROC TCALIS by using the NLOPTIONS statement. The NLOPTIONS statement provides more displayed and file output control on the results of the optimization process, and it permits the same set of termination criteria as in PROC NLP. These are more technical options that you might not need to specify in most cases.

Several statistical procedures support the use of NLOPTIONS statement. The syntax of NLOPTIONS statement is common to all these procedures and can be found in the section "Nonlinear Optimization: The NLOPTIONS Statement" on page 391 in Chapter 18, "Shared Concepts and Topics."

See the section "Use of Optimization Techniques" on page 6923 for more information about the use of optimization techniques in PROC TCALIS.

OUTFILES Statement

OUTFILES | **OUTFILE** *file_option* < *file_option . . .* > **;**

where *file_option* represents one of the following:

- OUTMODEL | OUTRAM= *file_name* [MODEL= *int_list* < , *int_list* >]
- OUTSTAT= *file_name* [GROUP= *int_list* < , *int_list* >]
- OUTWGT= *file_name* [GROUP= *int_list* < , *int_list* >]

with *file_name* representing an output file name and *int_list* representing list of model or group numbers

Use the OUTFILES statement when you need to output multiple-group or multiple-model information to output files in a complex way. In each OUTFILES statement, each possible *file_option* should appear no more than once. However, as needed, you can use the OUTFILES statement more than once. For example, suppose you want to create two OUTWGT= files for different sets of groups. You can specify the OUTFILES statement twice, as shown in the following specification:

```
outfiles outwgt=file1 [group=1,2];
outfiles outwgt=file2 [group=3,4];
```

In the first OUTFILES statement, the weights for groups 1 and 2 are output to the file file1. In the second OUTFILES statement, the weights for groups 3 and 4 are output to the file file2.

When the OUTMODEL=, OUTSTAT=, or OUTWGT= option is intended for **all** groups or models, you can simply specify the option in the PROC TCALIS statement. Only when you need to output the group (model) information from **more than one** group (model), **but not all** groups (models), to a single output file does the use the OUTFILES statement become necessary. For example, consider the following specification:

```
proc tcalis method=gls;
   outfiles outmodel=outmodel [model=1,3]
            outwgt=outwgt [group=1,2]
            outstat=outstat [group=2,3];
   group 1 / data=g1;
   group 2 / data=g2;
   group 3 / data=g3 outwgt=outwgt3;
   model 1 / group=1;
      factor N=3;
   model 2 / group=2;
      factor N=2;
   model 3 / group=3;
      factor N=3;
   run;
```

You fit three different factor models to three groups: model 1 for group 1, model 2 for group 2, and model 3 for group 3. In the OUTFILES statement, you output model information from models 1 and 3 to an output file named outmodel, weight matrices from groups 1 and 2 to outwgt, and statistics from groups 2 and 3 to outstat. In each of these output files, you have information from more than one (but not all) groups or models. In the GROUP statement for group 3, you have another OUTWGT= file named outwgt3 for group 3 alone.

Note that you cannot specify the preceding output file organization by using the following statements:

```
proc tcalis method=gls;
   group 1 / data=g1 outwgt=outwgt;
   group 2 / data=g2 outwgt=outwgt outstat=outstat;
   group 3 / data=g3 outwgt=outwgt3 outstat=outstat;
   model 1 / group=1 outmodel=outmodel;
      factor N=3;
   model 2 / group=2;
      factor N=2;
   model 3 / group=3 outmodel=outmodel;
      factor N=3;
   run;
```

This specification will not work because SAS forbids the repeated specification of the same output file in the same PROC TCALIS run. That is, you cannot specify OUTWGT=outwgt, OUTSTAT=outstat, or OUTMODEL=outmodel more than once in the PROC TCALIS run without causing file invocation problems (however, multiple specification of the same input file is not a problem).

The OUTFILES statement is intended for arranging output files in a complex way. The use of the OUTFILES statement is unnecessary in the following situations:

- If you have a single-sample analysis, you do not need to use the GROUP statement. As a result, you can simply use the OUTSTAT= or OUTWGT= options in the PROC TCALIS statement for specifying the output destinations. Therefore, the OUTFILES statement is not needed.
- If you have a single model in your analysis, you do not need to use the MODEL statement. As a result, you can simply use the OUTMODEL= options in the PROC TCALIS statement for specifying the output destination. Therefore, the OUTFILES statement is not needed.
- If you have multiple groups or multiple models in your analysis and information for all groups or models is output to the same file, you do not need to use the OUTFILES statement. You can simply use the OUTSTAT=, OUTWGT=, or OUTMODEL= options in the PROC TCALIS statement because the output file information is automatically propagated from the PROC TCALIS statement to the groups or models.
- If you have multiple groups or multiple models in your analysis and each group or model has a unique output data file destination (including cases where some groups or models might not have any output files), you do not need to use the OUTFILES statement. You can simply specify the OUTSTAT=, OUTWGT=, or OUTMODEL= options in the GROUP or MODEL statements.

PARAMETERS Statement

PARAMETERS | PARMS *parameter(s)* << = > *number(s)* >
<< , > *parameter(s)* << = > *number(s)* > . . . > ;

The PARAMETERS statement defines additional parameters that are not specified in your models. You can specify more than one PARAMETERS statement. The *parameters* can be followed by an equal sign and a number list. The values of the *numbers* list are assigned as initial values to the preceding parameters in the *parameters* list. For example, each of the following statements assigns the initial values ALPHA=.5 and BETA=-.5 for the parameters used in SAS programming statements:

```
parameters alfa beta=.5 -.5;
parameters alfa beta (.5 -.5);
parameters alfa beta .5 -.5;
parameters alfa=.5 beta (-.5);
```

The number of parameters and the number of values do not have to match. When there are fewer values than parameter names, either the RANDOM= or START= option is used. When there are more values than parameter names, the extra values are dropped. Parameters listed in the PARAMETERS statement can be assigned initial values by program statements or by the START= or RANDOM= option in the PROC TCALIS statement.

Do not confuse the PARAMETERS statement with the VAR statement. While you specify the parameters of the model in the PARAMETERS statement, you specify analysis variables in the VAR statement. See the VAR statement on page 6818 for more details.

CAUTION: The OUTMODEL= or OUTMODEL= data sets do not contain any information about the PARAMETERS statement or the SAS programming statements.

PARTIAL Statement

PARTIAL *variables* ;

If you want the analysis to be based on a partial correlation or covariance matrix, use the PARTIAL statement to list the variables used to partial out the variables in the analysis. You can specify only one PARTIAL statement within the scope of each GROUP or PROC TCALIS statement.

PATH Statement

PATH *path* < , *path* . . . > **;**

where *path* represents:
variable direction variable parameter-spec
and *direction* represents one of the following: –>, >, <–, <

In the PATH statement, you specify the paths in your model. You can specify at most one PATH statement in a model, within the scope of either the PROC TCALIS statement or a MODEL statement. To complete the PATH model specifications, you might need to add some subsidiary model specification statements. The following is the syntax for the PATH modeling language:

PATH *path lists* **;**
PVAR *partial variance parameters* **;**
PCOV *partial covariance parameters* **;**
MEAN *mean parameters* **;**

In the PATH statement, you specify paths of variables in your model, excluding paths from the errors or disturbances. Paths in the PATH statement are separated by commas. In the PVAR statement, you specify parameters for either variances or partial variances. In the PCOV statement, you specify parameters for either covariances or partial covariances. In the MEAN statement, you specify parameters for either means or intercepts. For details about these subsidiary model specification statements, refer to the syntax of the individual statements.

In each path, you have one outcome variable and one predictor variable. The variables in a path can be manifest or latent. The specified direction determines the predictor and outcome variables. The *variable* being aimed at is the outcome variable and the other *variable* is the predictor variable. The path coefficient parameter is specified after each path in *parameter-spec*. For example, in the following statement you specify a model with four paths, each with predictor variable F1 and one outcome manifest variable.

```
PATH
   V1  <-  F1    1,
   V2  <-  F1    b2,
   V3  <-  F1    b2,
   V4  <-  F1    b4 (.4);
```

As shown in the example, the *parameter-spec* is one of the following three types:

- fixed path coefficients

  The *parameter-spec* for the first path to V1 is a fixed path coefficient at 1.

- free or constrained parameters without starting values

  The *parameter-specs* for the second and third paths to V2 and V3, respectively, are the same path coefficient parameter b2 with no starting value given. Because the same parameter name is used for the two path coefficients, the coefficients are constrained in the model.

- free or constrained parameters with starting values

  The *parameter-spec* for the last path to V4 is a free parameter named b4 with a starting value at 0.4.

If an outcome variable has more than one predictor variable, you have more than one path specification for the outcome variable. The following PATH statement shows an extension of the previous specification.

```
PATH
   V1  <-  F1    1,
   V3  ->  V1    b1 (.2),
   V2  <-  F1    b2,
   V3  <-  F1    b2,
   V4  <-  F1    b4 (.4);
```

As compared with the previous example, an additional path is specified in second path specification of the current PATH statement. In the specification `V3` is a predictor of `V1`, in addition to the predictor `F1` in the first path specification. The additional path `V3 –> V1` has a path coefficient parameter named `b1`, with a starting value at 0.2.

Note that because the display of path results follows the way you specify the paths, you should arrange the order of the input paths in the most desirable way.

Modifying a PATH Model from a Reference Model

In this section, it is assumed that you use a REFMODEL statement within the scope of a MODEL statement and the reference model (or base model) is also a PATH model. The reference model is referred to as the old model, while the model that makes reference to this old model is referred to as the new model. If the new model is not intended to be an exact copy of the old model, you can use the following extended PATH modeling language to make modifications within the scope of the MODEL statement for the new model. The syntax is the same as the ordinary PATH modeling language, as in the section "PATH Statement" on page 6799. The respecification syntax for a PATH model is as follows:

PATH *path lists* **;**
  PVAR *partial variance parameters* **;**
  PCOV *partial covariance parameters* **;**
  MEAN *mean parameters* **;**

The new model is formed by integrating with the old model in the following ways:

Duplication: If you do not specify in the new model a parameter location that exists in the old model, the old parameter specification is duplicated in the new model.

Addition: If you specify in the new model a parameter location that does not exist in the old model, the new parameter specification is used in the new model.

Deletion: If you specify in the new model a parameter location that also exists in the old model and the new parameter is denoted by the missing value '.', the old parameter specification is not copied into the new model.

Replacement: If you specify in the new model a parameter location that also exists in the old model and the new parameter is not denoted by the missing value '.', the new parameter specification replaces the old one in the new model.

For example, consider the following specification of a two-group analysis:

```
proc tcalis;
   group 1 / data=d1;
   group 2 / data=d2;
   model 1 / group=1;
      path
         V1 <- F1   1.,
         V2 <- F1   load1,
         V3 <- F1   load2,
         F1 <- V4   b1,
         F1 <- V5   b2,
         F1 <- V6   b3;
      pvar
         E1-E3    = ve1-ve3,
         F1       = vd1,
         V5-V6    = phi4-phi6;
      pcov
         V1 V2    = cve12;
   model 2 / group=2;
      refmodel 1;
      path
         V3 <- F1   load1,
      pcov
         V1 V2    =  .,
         V2 V3    = cve23;
   run;
```

You specify model 2 by referring to model 1 in the REFMODEL statement. Model 2 is the new model that refers to the old model, model 1. This example illustrates the four types of model integration rules for the new model:

- Duplication: All parameter specifications, except for the partial covariance between V1 and V2 and the V3 <– F1 path in the old model, are duplicated in the new model.
- Addition: The parameter cve23 for the partial covariance between V2 and V3 is added in the new model because there is no corresponding specification in the old model.
- Deletion: The specification of partial covariance between V1 and V2 in the old model is not copied into the new model, as indicated by the missing value '.' specified in the new model.
- Replacement: The new path V3 <– F1 replaces the same path in the old model with parameter load1 for the path coefficient. Thus, in the new model paths V3 <– F1 and v2 <– F1 are now constrained to have the same path coefficient parameter load1.

PCOV Statement

PCOV *assignment* < , *assignment* . . . > **;**

where *assignment* represents:

variables < ∗ *variables2* > = *parameter-spec*

The PCOV statement defines the covariance or partial covariance parameters in the PATH model. You can use the PCOV statement with the PATH modeling language only. On the left-hand side of each assignment, variables involved are listed in the variables and variables2 lists. In the parameter-spec list, covariance or partial covariance parameters are specified. Names in the parameter-spec represent covariance or partial covariance parameters to estimate. Numbers enclosed in parentheses in the parameter-spec list are initial values for the parameters. Numbers not enclosed in parentheses in the parameter-spec list are fixed values for covariances or partial covariances. The *assignment*s in the PCOV statement must be separated by commas. You can specify only one PCOV statement in each model specification.

The syntax of the PCOV statement is the same as the COV statement. Refer to the COV statement on page 6747 for details about specifying within- and between- list (partial) covariances.

The concept behind the PCOV statement, however, is broader than that of the COV statement. The PCOV statement supports the partial covariance parameter specification in addition to the covariance parameter specification. The COV statement supports only the latter type of parameters. This discrepancy is also reflected from the sets of *variables* and *variables2* you can use in the PCOV statement. In the COV statement, variables on the left-hand side of an *assignment* must be exogenous. However, in the PCOV statement, both exogenous and endogenous variables can be specified. If both variables are exogenous in a specification of the PCOV statement, you are defining a covariance parameter between the variables. If both variables are endogenous, you are defining a partial covariance parameter between of the variables. This partial covariance is usually interpreted as error covariance between the two endogenous variables. If one variable is exogenous while the other is endogenous, you are defining a covariance parameter between the exogenous variable and the error term for the endogenous variable.

Automatic Covariance Parameters among Exogenous Manifest Variables

In the PATH model, all covariances among exogenous manifest variables are automatically free parameters to estimate unless you specify otherwise in the PCOV statement. The parameter names for these covariances will be generated by PROC TCALIS with the prefix _Add, appended with unique integer for each occurrence. If you want any of these covariances to be fixed values, you must specify them explicitly in the PCOV statement.

By default covariances among exogenous latent variables are fixed zeros unless they are specified otherwise in the PCOV statement. The same applies to any partial covariance among endogenous variables and to any partial covariance between an exogenous latent variable and an exogenous manifest variable.

This is different from the case of partial variance parameters specified in the PVAR statement. Variances of **all** exogenous variables and partial variances of **all** endogenous variables are automatically free parameters if they are not specified otherwise in the PVAR statement.

Modifying a Parameter Specification from a Reference Model

If you define a new PATH model by using a reference (or base) model in the REFMODEL statement, in some situations you might want to modify some parameter specifications from the PCOV statement of the reference model before transferring the specifications to the new model. If you want to change a particular PCOV parameter specification from the reference model, you can simply put the corresponding parameter location with a new parameter specification in the new model. If you want to delete a particular parameter location from the reference model, you can put that parameter location with the missing value '.' in the new model. For example, suppose you are defining a new PATH model by using the REFMODEL statement and the covariance between variables F1 and V2 is defined as a fixed or free parameter in the reference model. If you do not want this parameter specification to be copied into your new model, you can use the following specification in the new model:

```
PCOV F1 V2 = .;
```

Note that the missing value syntax is valid only when used with the REFMODEL statement. See the section "Modifying a PATH Model from a Reference Model" on page 6800 for a more detailed example of PATH model respecification.

In the PATH model, all covariances among exogenous manifest variables are free parameters to estimate unless you specify otherwise in the PCOV statement (see the section "Automatic Covariance Parameters among Exogenous Manifest Variables" on page 6802). This is also true for PATH models specified under the REFMODEL statement. In the reference model, covariance parameters generated by PROC TCALIS are named with the _Add prefix and appended with integer suffixes. These parameter specifications in the reference model do **not** transfer to the new model. Only after the new model is resolved from the reference model, the REFMODEL statement options, the RENAMEPARM statement, and the model respecifications are the additional covariance parameters with the _Add prefix generated for the unspecified covariances among exogenous manifest variables. In this way, the covariance parameters in the new model are not constrained to be the same as the corresponding parameters in the reference model. If you want any of these covariance parameters constrained across the models, you must specify them explicitly in the PCOV statement of the reference model so that the covariance specifications are transferred to the new model.

PVAR Statement

PVAR *assignment* < , *assignment . . .* > **;**

where *assignment* represents:
variables = *parameter-spec*

The PVAR statement defines the variance or partial variance parameters in FACTOR and PATH models. In each *assignment* in the PVAR statement, you specify *variables* on the left-hand side and the *parameter-spec* on the right-hand side of an equal sign. The *assignments* in the PVAR statement must be separated by commas. The *variables* listed on the left-hand side of the equal sign are any variables defined in the model. If a variable in the list is an exogenous variable, then the correspond-

ing parameter in the *parameter-spec* list is a variance parameter of the variable. If a variable in the list is an endogenous variable, then the corresponding parameter in the *parameter-spec* is a partial variance parameter of the variable. In most cases, the partial variance of an endogenous variable can be interpreted as the error variance for the variable.

The syntax of the PVAR statement is exactly the same as that of the STD statement. As in the STD statement, in the PVAR statement you can specify free or constrained parameters with or without starting or fixed values. You can also use prefixes to generate parameter names. Refer to the STD statement on page 6815 for details and examples.

The difference between the PVAR and the STD statements is conceptual in nature. In the STD statement, you can specify only variance parameters for exogenous variables. However, in the PVAR statement, both exogenous and endogenous variables can be put on the *variables* list. This treatment is needed in the FACTOR and PATH modeling languages because error variables in these models are not explicitly named.

Automatic Variance and Partial Variance Parameters among Variables

If the name of a variable (manifest or latent) in the FACTOR or PATH model does not appear in the PVAR statement, the variance or partial variance of the variable is assumed to be a parameter to estimate. These parameters will be named automatically with the prefix _Add and appended with integer suffixes. Therefore, the entire PVAR statement is optional in the sense that all variance and partial variance parameters will be generated automatically for the FACTOR or PATH model in PROC TCALIS. However, if you need to constrain these parameters, or assign fixed values, the PVAR statement specification must be used.

Modifying a Parameter Specification from a Reference Model

If you define a new FACTOR or PATH model by using a reference (or base) model in the REFMODEL statement, in some situations you might want to modify some parameter specifications from the PVAR statement of the reference model before transferring the specifications to the new model. If you want to change a particular PVAR parameter specification from the reference model, you can simply put the corresponding parameter location with a new parameter specification in the new model. If you want to delete a particular parameter location from the reference model, you can put that parameter location with the missing value '.' in the new model. For example, suppose you are defining a new PATH model by using the REFMODEL statement and the partial variance of variable `V2` is defined as a fixed or free parameter in the reference model. If you do not want this parameter specification to be copied into your new model, you can use the following specification in the new model:

```
pvar V2 = .;
```

Note that the missing value syntax is valid only when you use the REFMODEL statement. See the section "Modifying a FACTOR Model from a Reference Model" on page 6758 for a more detailed example of FACTOR model respecification. See the section "Modifying a PATH Model from a Reference Model" on page 6800 for a more detailed example of PATH model respecification.

In confirmatory factor or PATH models, all variances or partial variances among variables are free parameters to estimate unless you specify otherwise in the PVAR statement (see the section "Automatic Variance and Partial Variance Parameters among Variables" on page 6804). This is also true for confirmatory factor and LINEQS models specified under the REFMODEL statement. In the reference model, (partial) variance parameters generated by PROC TCALIS are named with the _Add prefix and appended with integer suffixes. These parameter specifications in the reference model do **not** transfer to the new model. Only after the new model is resolved from the reference model, the REFMODEL statement options, the RENAMEPARM statement options, and model re-specifications do the remaining unspecified (partial) variances of variables generate additional (partial) variance parameters with the _Add prefix and integer suffixes. In this way, the (partial) variance parameters in the new model are not constrained to be the same as the corresponding parameters in the reference model. If you want any of these (partial) variance parameters to be constrained across the models, you must specify them explicitly in the PVAR statement of the reference model so that the (partial) variance specification is transferred to the new model.

RAM Statement

RAM *list-entry* < , *list-entry* . . . > **;**

where *list-entry* represents:
parameter-type variable1 < *direction* > < *variable2* > *parameter-spec*
and *direction* can be one of the following: –>, >, <–, <

RAM stands for the reticular action model, developed by McArdle(1980). In the RAM statement, you specify various kinds of parameters in the model. In each *list-entry*, you specify the type of parameter in *parameter-type*, variables involved in *variable1* and, if applicable, in *variable2*, path direction in *direction*, parameter name and value in *parameter-spec*. *List-entries* must be separated by commas.

Types of RAM Parameters

The first keyword in each RAM *list-entry* is the parameter type, represented as *parameter-type* in the syntax. You can use one of the following keywords (not case-sensitive) for *parameter-type*:

_A_ or _RAMA_	a parameter in the A matrix of the RAM model (see the PATH keyword)
_P_ or _RAMP_	a parameter in the P matrix of the RAM model (see the PCOV and PVAR keywords)
_W_ or _RAMW_	a parameter in the vector for means and intercepts (see the MEAN and INTERCEPT keywords)
INTERCEPT	the intercept of an endogenous variable, manifest or latent
MEAN	the mean of an exogenous variable, manifest of latent
PATH	the path coefficient for a pair of outcome and predictor variables
PCOV	the partial covariance or covariance between a pair of variables
PVAR	the partial variance or variance of a variable

Keywords _A_, _P_, and _W_ refer to the matrix elements of the RAM model matrices _A_, _P_, and _W_, respectively. See the section "Model Matrices in the RAM Model" on page 6856 for detailed descriptions of these matrices. Elements in matrix _A_ are path coefficients; therefore the _A_ keyword is the same as the PATH keyword for specifying these matrix elements. Elements in matrix _P_ are either (partial) variances or (partial) covariances; therefore the _P_ keyword is the same as the PVAR or PCOV keyword for specifying these matrix elements. Elements in matrix _W_ are either means or intercepts; therefore the _W_ keyword is the same as the MEAN or INTERCEPT keyword for specifying these matrix elements.

Path Coefficients Parameters with Keyword _A_ or PATH

To specify the paths and the associated coefficients, you can use either the _A_ or PATH keyword for *parameter-type*. A pair of variables must be specified in *variable1* and *variable2*. The *direction* must also be inserted between the pair of variables with the PATH keyword. The following is an example of the list-entries for path coefficients:

```
path    a -> b    x1,
path    c <- b    x2,
```

The first path is from variable a to variable b with a path coefficient parameter named x1. The second path is from variable b to variable c with a path coefficient parameter named x2. However, if you use the _A_ keyword, you must not specify the *direction*, as it is implicitly assumed to be an arrow pointing to left, <–. For example, the following specification using the _A_ keyword is equivalent to the previous specification.

```
_A_    b   a     x1,
_A_    c   b     x2,
```

Partial Variance and Variance Parameters with Keyword _P_ or PVAR

To specify the variance or partial variance parameters, you can use the _P_ or PVAR keyword for *parameter-type*. If you use _P_, *variable1* and *variable2* must be the same variable name. If you use PVAR, only *variable1* needs to be specified. Specification for *direction* should be omitted. If the variable is exogenous, you are defining a variance parameter. Otherwise, you are defining a partial variance parameter. Partial variance in the RAM model can be interpreted as the error variance for an endogenous variable.

For example, assume that b is an exogenous variable in your model. In the following specification, you define the variance of b as a parameter named v1, with an initial estimate of 1.0:

```
PVAR    b     v1 (1.0),
```

This specification is equivalent to the following specification by using the _P_ keyword for *parameter-type*:

```
_P_   b  b    v1 (1.0),
```

Partial Covariance and Covariance Parameters with Keyword _P_ or PCOV

To specify the covariance or partial covariance parameters, you can use the _P_ or PCOV keyword for *parameter-type*. You must specify both *variable1* and *variable2*, where *variable1* and *variable2* are different variable names. Specification for *direction* should be omitted. Whereas it is a semantic error if *variable1* and *variable2* are the same name with the PCOV keyword, it is permissible to do so with the _P_ keyword. However, for the latter you are supposed to define a parameter location for the variance or partial variance of a variable, instead of the covariance or partial covariance parameter that is considered in this section.

The following shows a specification of a covariance parameter:

```
PCOV   a  b    v12 (0.5),
```

If both a and b are exogenous variables in your model, the preceding code specifies the covariance between a and b as a free parameter named v12, with a starting value at 0.5. Equivalently, you can use the _P_ keyword, as shown in the following specification:

```
_P_   a  b    v12 (0.5),
```

Note that if both a and b are both endogenous variables in your model, you can still use the preceding specification. But the interpretation is different. For endogenous a and b, v12 is treated as a partial covariance parameter. In almost all situations, this partial covariance is interpreted as the error covariance for variables a and b. Or, the model assumes correlated errors associated with variables a and b.

In fact, you can also specify the partial covariance between an exogenous variable and an endogenous variable. Suppose that a is exogenous and b is endogenous in your model. The preceding specifications are for specifying the covariance parameter between a and the error term for b. This is certainly a cumbersome interpretation. Fortunately, covariances between exogenous variables and error variables are considered inelegant in most statistical models. This kind of specification should be rare in practice.

Means and Intercepts with Keyword _W_, INTERCEPT, or MEAN

To specify the mean or intercept parameters, you can use the _W_, INTERCEPT, or MEAN keyword for *parameter-type*. You must specify *variable1* in the *list-entry*. Specifications for *variable2* and *direction* are not applicable and should be omitted. With the MEAN keyword, *variable1* is supposed to be an exogenous variable. With the INTERCEPT keyword, *variable1* is supposed to be an endogenous variable. With the _W_ keyword, however, *variable1* can be either exogenous or endogenous. In this case, whether a mean or an intercept parameter is being specified is determined by the TCALIS procedure.

For example, in the following specification the mean of f1 is a free parameter named mean1 while the intercept for a is a constant value 2.0:

```
mean        f1    mean1,
intercept    a    2.0,
```

Equivalently, you can specify using the _W_ keyword, as shown in the following:

```
_W_          f1    mean1,
_W_           a    2.0,
```

Variable Names for *variable1* and *variable2*

In each *list-entry*, you have to specify a variable name for *variable1* and possibly a variable name for *variable2* also. PROC TCALIS needs to distinguish names for observed and latent variables in your model. Variable names that are referenced in the input data set are for observed variables; otherwise, they are for latent variables. Therefore, you can make up any latent variable names in the RAM model specification, as long as these names follow the general SAS naming conventions and do not match any of the names in the input data set. Notice that in the RAM model specification, all latent variable names are for the latent factors, and names for error or disturbance terms are never needed. Error variances and covariances can be specified using the corresponding endogenous variables names as references in the *list-entries* with the PCOV or PVAR keyword for parameter-type. Hence, creating names for error or disturbance terms is not necessary in the RAM model specification.

Parameter Names and Initial Values

After you specify the type of parameter in *parameter-type*, the associated variables in *variable1* and *variable2* (when applicable), and the *direction* for paths (if applicable), the last piece information of *list-entry* is *parameter-spec*, which can be one of the following three types:

- fixed constants

  For example, in the following specification the intercept of variable a is fixed at 2.0.

  ```
  intercept    a    2.0,
  ```

- free or constrained parameter names without starting values

  For example, in the following specification the mean of variable f1 is a parameter named mean1.

  ```
  mean         f1    mean1,
  ```

  The starting value of mean1 is generated by PROC TCALIS.

- free or constrained parameter names with starting values

  For example, in the following specification the variance (if b is exogenous in the model) or error variance (if b is endogenous in the model) of variable b is a parameter named v1, with a starting value 1.0.

  ```
  PVAR         b     v1 (1.0),
  ```

Automatic Variance and Partial Variance Parameters

If the partial variance or variance parameter for any variable (manifest or latent) in the RAM model is not explicitly specified in the RAM *list-entries*, it will be added automatically as a free parameter. Each parameter is named with the prefix _Add and appended with a unique integer. Therefore, PVAR *parameter-type* entries for variables are optional when they are free and unconstrained parameters. However, if you need to set constraints on these parameters or to assign fixed parameter values, PVAR *list-entries* for the corresponding variables are necessary.

Automatic Covariance Parameters

All covariances among exogenous *manifest* variables in the RAM model are free parameters automatically unless specified otherwise in the *list-entries* with the PCOV keyword for *parameter-type*. Each automatic covariance parameter is named by PROC TCALIS with the _Add prefix and appended with an unique integer. If you want any of these covariances to be fixed values or constrained via name references, you must specify them explicitly in the PCOV *list-entries*.

Covariances among exogenous *latent* variables by default are fixed zeros unless specified otherwise in the PCOV *list-entries*. The same applies to any partial covariance among endogenous variables and to any partial covariance between an exogenous latent variable and an exogenous manifest variable.

Automatic Mean Parameters

All means of exogenous manifest variables in the RAM model are free parameters automatically unless specified otherwise in the MEAN *list-entries*. Each automatic mean parameter is named by PROC TCALIS with the _Add prefix and appended with an unique integer. If you want any of these means be fixed values or constrained via name references, you must specify them explicitly in the MEAN *list-entries*.

Modifying a RAM Model from a Reference Model

In this section, it is assumed that you use a REFMODEL statement within the scope of a MODEL statement and that the reference model (or base model) is also a RAM model. The reference model will be referred to as the old model, while the model that makes reference to this old model is referred to as the new model. If the new model is not intended to be an exact copy of the old model, you can use the following extended RAM modeling language to make modifications on the model specification. The syntax for modifications is the same as the ordinary RAM modeling language (see the section "RAM Statement" on page 6805). The syntax for respecifying/modifying the RAM model is as follows.

RAM *list-entry* < *, list-entry . . .* > **;**

where *list-entry* represents:

parameter-type variable1 < *direction* > < *variable2* > *parameter-spec*

and *direction* represents one of the following: –>, >, <–, <

The new model is formed by integrating with the old model in the following ways:

Duplication: If you do not specify in the new model a parameter location that exists in the old model, the old parameter specification is duplicated in the new model.

Addition: If you specify in the new model a parameter location that does not exist in the old model, the new parameter specification is added to the new model.

Deletion: If you specify in the new model a parameter location that also exists in the old model and the new parameter is denoted by the missing value '.', the old parameter specification is not copied into the new model.

Replacement: If you specify in the new model a parameter location that also exists in the old model and the new parameter is not denoted by the missing value '.', the new parameter specification replaces the old one in the new model.

For example, consider the following two-group analysis:

```
proc tcalis;
   group 1 / data=d1;
   group 2 / data=d2;
   model 1 / group=1;
      ram
         path V1 <- F1   1.,
         path V2 <- F1   load1,
         path V3 <- F1   load2,
         path F1 <- V4   b1,
         path F1 <- V5   b2
         path F1 <- V6   b3
         pvar E1         ve1,
         pvar E2         ve2,
         pvar E3         ve3,
         pvar F1         vd1,
         pvar V4         phi4,
         pvar V5         phi5,
         pvar V6         phi6,
         pcov V1 V2      cve12;
   model 2 / group=2;
      refmodel 1;
      ram
         path V3 <- F1   load1,
         pcov V1 V2      .    ,
         pcov V2 V3      cve23;
   run;
```

In this example, you specify model 2 by referring to model 1 in the REFMODEL statement. Model 2 is the new model which refers to the old model, model 1. This example illustrates the four types of model integration process by PROC TCALIS:

- Duplication: All parameter specifications, except for the partial covariance between V1 and V2, and the V3 <– F1 path in the old model are duplicated in the new model.
- Addition: The parameter cve23 for the partial covariance between V2 and V3 is added in the new model.
- Deletion: The specification of partial covariance between V1 and V2 in the old model is not copied into the new model, as indicated by the missing value '.' in the specification.
- Replacement: The new path V3 <– F1 replaces the same path in the old model with another parameter for the path coefficient. Thus, in the new model paths V3 <– F1 and V2 <– F1 are constrained to have the same path coefficient parameter load1.

In the RAM model, partial variances or variances of all variables, means of exogenous mainfest variables, and the covariances among exogenous mainfest variables are automatically free parameters unless you specify otherwise in the *list-entries* of the RAM statement. See the sections "Automatic Variance and Partial Variance Parameters" on page 6809, "Automatic Covariance Parameters" on page 6809, and "Automatic Mean Parameters" on page 6809 for more details. This is also true for RAM models specified under the REFMODEL statement. In the reference model, parameters generated by PROC TCALIS are named with the _Add prefix and appended with integer suffixes. These automatically generated parameters in the reference model do **not** transfer to the new model. Only after the new model is resolved from the reference model, the REFMODEL statement options, the RENAMEPARM statement, and the model respecification are the automatic parameters of the new RAM model generated. In this way, the generated parameters in the new model are not constrained to be the same as the corresponding parameters in the reference model. If you want any of these parameters be constrained across the models, you must specify them explicitly in the *list-entries* of the RAM statement of the reference model so that these specifications are transferred to the new model via the REFMODEL statement.

REFMODEL Statement

REFMODEL | **BASEMODEL** *model_number* < / *options* > **;**

where *model_number* represents a model number between 1 and 9999, inclusively, and *options* are for renaming parameters.

The REFMODEL statement is not a modeling language itself. It is a tool for referencing and modifying models. It is classified into one of the modeling languages because its role is similar to other modeling languages.

REFMODEL *model_number* < / *options* > **;**
  RENAMEPARM *parameter renaming* **;**
  main model specification statement **;**
  subsidiary model specification statements **;**

In the REFMODEL statement, you put the *model_number* of the model you are making reference to. The reference model must be well-defined in the same PROC TCALIS run. In the *options*, you

can rename all the parameters in the reference model by adding prefix or suffix so that the current model has a new set of parameters.

The following options are available in the REFMODEL statement:

ALLNEWPARMS
appends to the parameter names in the reference model with _mdl and then an integer suffix denoting the model number of the current model. For example, if qq is a parameter in the reference model for a current model with model number 3, then this option creates qq_mdl3 as a new parameter name.

PARM_PREFIX=*prefix*
inserts to all parameter names in the reference model with the *prefix* provided. For example, if qq is a parameter in the reference model for a current model, then **PARM_PREFIX=pre_** creates pre_qq as a new parameter name.

PARM_SUFFIX=*suffix*
appends to all parameter names in the reference model with the *suffix* provided. For example, if qq is a parameter in the reference model for a current model, then **PARM_SUFFIX=_suf** creates qq_suf as a new parameter name.

Instead of renaming all parameters, you can also rename parameters individually by using the RENAMEPARM statement within the scope of the REFMODEL statement.

You can also add the main and subsidiary model specification statements to modify a particular part from the reference model. For example, you might like to add or delete some equations or paths, or to change a fixed parameter to a free parameter or vice versa in the new model. All can be done in the respecification in the main and subsidiary model specification statements within the scope of the MODEL statement to which the REFMODEL statement belongs. Naturally, the modeling language used in respecification must be the same as that of the reference model. See the individual statements for modeling languages for the syntax of respecification. Note that when you respecify models by using the main and subsidiary model specification statements together with the RENAMEPARM statement or the REFMODEL options for changing parameter names, the parameter name changes occur after respecifications.

RENAMEPARM Statement

RENAMEPARM *assignment* < , *assignment . . .* > **;**

where *assignment* represents:
old_parameters = *parameter-spec*

You can use the RENAMEPARM statement to rename parameters or to change the types of parameters of a reference model so that new parameters are transferred to the new model in question. The RENAMEPARM statement is a subsidiary model specification statement that should be used together with the REFMODEL statement. The syntax of the RENAMEPARM statement is similar to that of the STD statement—except that in the RENAMEPARM statement, you put parameter names on the left-hand side of equal signs, whereas you put variable names on the left-hand side in

the STD statement. You can use no more than one RENAMEPARM statement within the scope of each REFMODEL statement.

In the REFMODEL statement, you transfer all the model specification information from a base model to the new model being specified. The RENAMEPARM statement enables you to modify the parameter names or types in the base model before transferring them to the new model. For example, in the following example, you define model 2, which is a new model, by referring it to model 1, the base model, in the REFMODEL statement.

```
model 1;
   lineqs
      V1 =    F1 + E1,
      V2 = b2 F1 + E2,
      V3 = b3 F1 + E3,
      V4 = b4 F1 + E4;
   std F1 = vF1,
      E1-E4 = ve1-ve4;
model 2;
   refmodel 1;
   renameparm ve1-ve4=new1-new4, b2=newb2(.2), b4=.3;
```

Basically, the LINEQS model specification in model 1 is transferred to model 2. In addition, you redefine some parameters in the base model by using the RENAMEPARM statement. This example illustrates two kinds of modifications that the RENAMEPARM statement can do:

- creating new parameters in the new model

  The error variances for E1–E4 in model 2 are different from those defined in model 1 because new parameters new1–new4 are now used. Parameter b2 is renamed as newb2 with a starting value at 0.2 in model 2. So the two models have distinct path coefficients for the F1-to-V2 path.

- changing free parameters into fixed constants

  By using the specification b4=.3 in the RENAMEPARM statement, b4 is no longer a free parameter in model 2. The path coefficient for the F1-to-V4 path in model 2 is now fixed at 0.3.

The RENAMEPARM statement is handy when you have just few parameters to change in the reference model defined by the REFMODEL statement. However, when there are a lot of parameters to modify, the RENAMEPARM statement might not be very efficient. For example, to make all parameters unique to the current model, you might consider using the ALLNEWPARMS, PARM_PREFIX, or PARM_SUFFIX option in the REFMODEL statement.

SAS Programming Statements

You can use SAS programming statements to define dependent parameters, parametric functions, and equality constraints among parameters.

Several statistical procedures support the use of SAS programming statements. The syntax of SAS programming statements are common to all these procedures and can be found in the section "Programming Statements" on page 410 in Chapter 18, "Shared Concepts and Topics."

SIMTEST Statement

SIMTEST *sim_test* < *sim_test . . .* > **;**

where *sim_test* represents one of the following:

- *test_name* = [*functions*]
- *test_name* = { *functions* }

and *functions* are either parameters in the model or parametric functions computed in the SAS programming statements.

When the estimates in a model are asymptotically multivariate-normal, continuous and differentiable functions of the estimates are also multivariate-normally distributed. In the SIMTEST statement, you can test these parametric functions simultaneously. The null hypothesis for the simultaneous tests is assumed to have the following form:

$$H_0 : h_1(\theta) = 0, h_2(\theta) = 0, \ldots$$

where θ is the set of model parameters (independent or dependent) in the analysis and each $h_i()$ is a continuous and differentiable function of the model parameters.

To test parametric functions simultaneously in the SIMTEST statement, you first assign a name for the simultaneously test in *test_name*. Then you put the parametric functions for the simultaneous test inside a pair of parentheses: either the '{' and '}' pair, or the '[' and ']' pair. For example, if θ_1, θ_2, θ_3, and θ_4 are parameters in the model and you want to test the equality of θ_1 and θ_2 and the equality of θ_3 and θ_4 simultaneously, you can use the following statements:

```
simtest
   Equality_test = [t1_t2_diff t3_t4_diff];
t1_t2_diff   = theta1 - theta2;
t3_t4_diff   = theta3 - theta4;
```

In the SIMTEST statement, you test two functions t1_t2_diff and t3_t4_diff simultaneously in the test named Equality_test. The two parametric functions t1_t2_diff and t3_t4_diff are computed in the SAS programming statements as differences of some parameters in the model.

See also the TESTFUNC statement on page 6817 for testing parametric functions individually.

STD Statement

STD *assignment* < , *assignment* . . . > **;**

where *assignment* represents:

variables = *parameter-spec*

The STD statement defines the variance parameters in the LINEQS models. STD, instead of VAR, is used as the statement name for defining variance parameters because it avoids conflicts with the VAR statement for specifying variables for analysis. You can specify no more than one STD statement with each LINEQS statement.

In each *assignment* of the STD statement, you specify the variance parameters of the *variables*. The *variables* are specified on the left-hand side of the equal sign of each *assignment*, while the parameter in the *parameter-spec* list on the right-hand side of the equal sign might be one of the following types:

- free or constrained parameters without starting values

  Names in the *parameter-spec* list denote parameters to estimate. They might be free or constrained parameters.

- free or constrained parameters with starting values

  Names followed by numbers inside a pair of parentheses in the *parameter-spec* list denote free or constrained parameters with starting values given by the parenthesized numbers.

- fixed parameter values

  Fixed constants not inside a pair of parentheses in the *parameter-spec* list denote fixed parameter values.

The *assignments* in the STD statement must be separated by commas. The *variables* listed on the left-hand side of the equal sign should contain only names of exogenous variables—that is, variance parameters in the LINEQS model are defined only for exogenous mainfest or latent variables, errors, and disturbances.

If the *parameter-spec* list is longer than the *variables* list, the *parameter-spec* list is shortened to the length of the *variables* list. If the *parameter-spec* is shorter than the *variables* list, the *parameter-spec* list is filled with repetitions of the last item in the list.

The *parameter-spec* list can contain prefix names. A prefix name is a short name called "root" followed by two underscores, '__'. A prefix name without a root (that is, as in '__') has its root replaced with parm. Whenever a prefix name is encountered, the TCALIS procedure generates a parameter name by appending a unique integer to the root of the prefix name. The root of the prefix name should have few characters so that the generated parameter name is not longer than 32 characters. To avoid unintentional equality constraints, the prefix names should not coincide with explicitly defined parameter names.

To illustrate various specification in the STD statement, consider the following statement:

```
std E1-E6 = vp1 GEN__ (1. 2.) GEN__ 4. vp5 ;
```

You specify the variance of E1 as a free parameter vp1 with a starting value at 1. The variance of E2 is a parameter named GEN1, with a starting value at 2. The variance of E3 is a parameter named GEN2, without a starting value provided. The variance of E4 is fixed at 4. The variance of E5 is parameter vp5, without a starting value given. Finally, the variance of E6 is denoted also by parameter vp5 because the *parameter-spec* list is shorter than the *variables* list so that the last member in the *parameter-spec* list is repeated.

Automatic Variance Parameters among Exogenous Variables

If the names of any exogenous variables (manifest, latent, or errors) in the LINEQS model are not included in the STD statement, the variances of those exogenous variables are assumed to be parameters to estimate. These parameters will be named automatically with the prefix _Add and appended with a unique integer in each name generation.

Modifying a Parameter Specification from a Reference Model

If you define a new LINEQS model by using a reference (or base) model in the REFMODEL statement, in some situations you might want to modify some parameter specifications from the STD statement of the reference model before transferring the specifications to the new model. If you want to change a particular STD parameter specification from the reference model, you can simply put the corresponding parameter location with a new parameter specification in the new model. If you want to delete a particular parameter location from the reference model, you can put that parameter location with the missing value '.' in the new model. For example, suppose you are defining a new LINEQS model by using the REFMODEL statement and the variance of variable V1 is defined as a fixed or free parameter in the reference model. If you do not want this parameter specification to be copied into your new model, you can use the following specification in the new model:

```
std V1 = .;
```

Notice that the missing value syntax is valid only when you use the REFMODEL statement. For a more detailed example of the LINEQS model respecification (see the section "Modifying a LINEQS Model from a Reference Model" on page 6769).

In the LINEQS model, all variances among exogenous variables are free parameters to estimate unless you specify otherwise in the STD statement (see the section "Automatic Variance Parameters among Exogenous Variables" on page 6816). This is also true for LINEQS models specified under the REFMODEL statement. In the reference model, variance parameters generated by PROC TCALIS are named with the _Add prefix and appended with integer suffixes. These parameter specifications in the reference model do **not** transfer to the new model. Only after the new model is resolved from the reference model, the REFMODEL statement options, the RENAMEPARM statement options, and the model respecifications are the unspecified variances of exogenous variables generated as free parameters named with the _Add prefix and integer suffixes. In this way, the variance parameters in the new model are not constrained to be the same as the corresponding parameters in the reference model. If you want any of these variance parameters constrained across the models, you must specify them explicitly in the STD statement of the reference model so that the variance specification is transferred to the new model.

STRUCTEQ Statement

STRUCTEQ *variables* < / *label* > **;**

where *label* represents:
LABEL | NAME = *name*

The STRUCTEQ statement functions exactly the same as the DETERM statement.

TESTFUNC Statement

TESTFUNC *functions* **;**

where *functions* are either parameters in the model or parametric functions computed in the SAS programming statements.

When the estimates in a model are asymptotically multivariate-normal, any continuous and differentiable function of the estimates is also normally distributed. In the TESTFUNC statement, you can test these parametric functions using z-tests. The form of the null hypothesis is as follows:

$H_0 : h(\theta) = 0$

where θ is the set of model parameters (independent or dependent) in the analysis and $h()$ is a continuous and differentiable function of the model parameters.

For example, if θ_1, θ_2, and θ_3 are parameters in the model, and you want to test whether θ_1 and θ_2 are the same and whether θ_3 is the same as the average of θ_1 and θ_2, you can use the following statements:

```
testfunc   t1_t2_diff t3_t1t2_diff;
t1_t2_diff   = theta1 - theta2;
t3_t1t2_diff = theta3 - (theta1 + theta2)/2;
```

In the TESTFUNC statement, you test two functions: t1_t2_diff and t3_t1t2_diff. These two functions are defined in the SAS programming statements that follow after the TESTFUNC statement. Thus, t1_t2_diff represents the difference between θ_1 and θ_2, and t3_t1t2_diff represents the difference between θ_3 and the average of θ_1 and θ_2.

See the SIMTEST statement if you want to test several null hypotheses simultaneously.

VAR Statement

VAR *variables* **;**

The VAR statement lists the numeric variables to be analyzed. It is one of the subsidiary group specification statements. You can use the VAR statement no more than once within the scope of each GROUP or the PROC TCALIS statement.

Variables in the VAR statement of the associated group are included in the corresponding model if the model is one of the following types: LINEQS, PATH, or RAM. Any VAR variables that are not mentioned in the model specification by using the main and subsidiary model specification statements are treated as exogenous variables in the model. This also means that for these models the use of the VAR statement in the associated groups is not necessary when all observed variables intended for analysis are already mentioned in the main and subsidiary model specification statements. Given the model specification, PROC TCALIS finds the set of observed variables for analysis automatically. You need the VAR statement only when you want to force the inclusion of those observed variables not mentioned in the model specification.

For the FACTOR model, the VAR variables of the associated groups are included in the model only for an exploratory factor analysis. The VAR statement is ignored for a confirmatory factor analysis, in which the observed variables can be defined only through the *factor-variable-relations* in the FACTOR statement.

The VAR statement of the associated group is ignored when the corresponding model is of either the LISMOD or MSTRUCT type. The observed variables for these two types of models must be defined in the variable lists of the LISMOD or MSTRUCT statement. For the LISMOD model, each observed variable for analysis is defined in either the YVAR= or XVAR= option of the LISMOD statement. For the MSTRUCT model, all observed variables for analysis are defined in the VAR= option of the MSTRUCT statement.

The VAR statement should not be confused with the PARAMETERS statement. In the PARAMETERS statement, you specify additional *parameters* in the model. Parameters are population quantities that characterize the functional relationships, variations, or covariation among variables. Unfortunately, parameters are sometimes referred to as *variables* in the optimization context. You have to make sure that all variables specified in the VAR statement correspond to the variables in the input data set, while the parameters specified in the PARAMETERS statement are population quantities that characterize distributions of the variables and their relationships.

WEIGHT Statement

WEIGHT *variable* **;**

The WEIGHT statement specifies the weight variable for the observations. It is one of the subsidiary group specification statements. You can use the WEIGHT statement no more than once within the scope of each GROUP statement or the PROC TCALIS statement.

Weighting is often done when the error variance associated with each observation is different and the values of the weight variable are proportional to the reciprocals of the variances. The WEIGHT and FREQ statements have a similar effect, except the WEIGHT statement does not alter the number of observations unless VARDEF=WGT or VARDEF=WDF. An observation is used in the analysis only if the WEIGHT variable is greater than 0 and is not missing.

Details: TCALIS Procedure

Input Data Sets

You can use four different kinds of input data sets in the TCALIS procedure, and you can use them simultaneously. The DATA= data set contains the data to be analyzed, and it can be an ordinary SAS data set containing raw data or a special TYPE=COV, TYPE=UCOV, TYPE=CORR, TYPE=UCORR, TYPE=SSCP, or TYPE=FACTOR data set containing previously computed statistics. The INEST= data set specifies an input data set that contains initial estimates for the parameters used in the optimization process, and it can also contain boundary and general linear constraints on the parameters. If the model does not change too much, you can use an OUTEST= data set from a previous PROC TCALIS analysis; the initial estimates are taken from the values of the _TYPE_=PARMS observation. The INMODEL= or INRAM= data set contains information of the analysis models (except for user-written programming statements). Often the INMODEL= data set is created as the OUTMODEL= data set from a previous PROC TCALIS analysis. See the section "OUTMODEL= SAS-data-set" on page 6827 for the structure of both OUTMODEL= and INMODEL= data sets. Using the INWGT= data set enables you to read in the weight matrix $\mathbf{W}$ that can be used in generalized least squares, weighted least squares, or diagonally weighted least squares estimation.

DATA= SAS-data-set

A TYPE=COV, TYPE=UCOV, TYPE=CORR, or TYPE=UCORR data set can be created by the CORR procedure or various other procedures. It contains means, standard deviations, the sample size, the covariance or correlation matrix, and possibly other statistics depending on which procedure is used.

If your data set has many observations and you plan to run PROC TCALIS several times, you can save computer time by first creating a TYPE=COV, TYPE=UCOV, TYPE=CORR, or TYPE=UCORR data set and using it as input to PROC TCALIS.

For example, assuming that PROC TCALIS is first run with an OUTMODEL=MODEL option, you can run the following statements in subsequent analyses with the same model in the first run:

```
* create TYPE=COV data set;
proc corr cov nocorr data=raw outp=cov(type=cov);
run;
* analysis using correlations;
proc tcalis corr data=cov inmodel=model;
run;
* analysis using covariances;
proc tcalis data=cov inmodel=model;
run;
```

Most procedures automatically set the TYPE= option of an output data set appropriately. However, the CORR procedure sets TYPE=CORR unless an explicit TYPE= option is used. Thus, (TYPE=COV) is needed in the preceding PROC CORR request, since the output data set is a covariance matrix. If you use a DATA step with a SET statement to modify this data set, you must declare the TYPE=COV, TYPE=UCOV, TYPE=CORR, or TYPE=UCORR attribute in the new data set.

You can use a VAR statement with PROC TCALIS when reading a TYPE=COV, TYPE=UCOV, TYPE=CORR, TYPE=UCORR, or TYPE=SSCP data set to select a subset of the variables or change the order of the variables.

CAUTION: Problems can arise from using the CORR procedure when there are missing data. By default, PROC CORR computes each covariance or correlation from all observations that have values present for the pair of variables involved ("pairwise deletion"). The resulting covariance or correlation matrix can have negative eigenvalues. A correlation or covariance matrix with negative eigenvalues is recognized as a singular matrix in PROC TCALIS, and you cannot compute (default) generalized least squares or maximum likelihood estimates. You can specify the RIDGE option to ridge the diagonal of such a matrix to obtain a positive definite data matrix. If the NOMISS option is used with the CORR procedure, observations with any missing values are completely omitted from the calculations ("listwise deletion"), and there is no possibility of negative eigenvalues (but there is still a chance for a singular matrix).

PROC TCALIS can also create a TYPE=COV, TYPE=UCOV, TYPE=CORR, or TYPE=UCORR data set that includes all the information needed for repeated analyses.

If the data set DATA=RAW does not contain missing values, the following statements should give the same PROC TCALIS results as the previous example:

```
* using correlations;
proc tcalis corr data=raw outstat=cov inmodel=model;
run;
* using covariances;
proc tcalis data=cov inmodel=model;
run;
```

You can create a TYPE=COV, TYPE=UCOV, TYPE=CORR, TYPE=UCORR, or TYPE=SSCP data set in a DATA step. Be sure to specify the TYPE= option in parentheses after the data set name in the DATA statement and include the _TYPE_ and _NAME_ variables. If you want to analyze the

covariance matrix but your DATA= data set is a TYPE=CORR or TYPE=UCORR data set, you should include an observation with _TYPE_=STD giving the standard deviation of each variable. By default, PROC TCALIS analyzes the recomputed covariance matrix even when a TYPE=CORR data set is provided, as shown in the following statements:

```
data correl(type=corr);
   input _type_ $ _name_ $ X1-X3;
   datalines;
std    .    4.   2.   8.
corr   X1   1.0   .    .
corr   X2    .7 1.0   .
corr   X3    .5   .4 1.0
;
proc tcalis inmodel=model;
run;
```

INEST= SAS-data-set

You can use the INEST= (or INVAR=) input data set to specify the initial values of the parameters used in the optimization and to specify boundary constraints and the more general linear constraints that can be imposed on these parameters.

The variables of the INEST= data set must correspond to the following:

- a character variable _TYPE_ that indicates the type of the observation
- *n* numeric variables with the parameter names used in the specified PROC TCALIS model
- the BY variables that are used in a DATA= input data set
- a numeric variable _RHS_ (right-hand side); needed only if linear constraints are used
- additional variables with names corresponding to constants used in the programming statements

The content of the _TYPE_ variable defines the meaning of the observation of the INEST= data set. PROC TCALIS recognizes observations with the following _TYPE_ specifications.

PARMS — specifies initial values for parameters that are defined in the model statements of PROC TCALIS. The _RHS_ variable is not used. Additional variables can contain the values of constants that are referred to in programming statements. At the beginning of each run of PROC TCALIS, the values of the constants are read from the PARMS observation for initializing the constants in the SAS programming statements.

UPPERBD | UB — specifies upper bounds with nonmissing values. The use of a missing value indicates that no upper bound is specified for the parameter. The _RHS_ variable is not used.

LOWERBD | LB — specifies lower bounds with nonmissing values. The use of a missing value indicates that no lower bound is specified for the parameter. The _RHS_ variable is not used.

LE | <= | < — specifies the linear constraint $\sum_j a_{ij}x_j \leq b_i$. The n parameter values contain the coefficients a_{ij}, and the _RHS_ variable contains the right-hand-side b_i. The use of a missing value indicates a zero coefficient a_{ij}.

GE | >= | > — specifies the linear constraint $\sum_j a_{ij}x_j \geq b_i$. The n parameter values contain the coefficients a_{ij}, and the _RHS_ variable contains the right-hand-side b_i. The use of a missing value indicates a zero coefficient a_{ij}.

EQ | = — specifies the linear constraint $\sum_j a_{ij}x_j = b_i$. The n parameter values contain the coefficients a_{ij}, and the _RHS_ variable contains the right-hand-side b_i. The use of a missing value indicates a zero coefficient a_{ij}.

The constraints specified in the INEST=, INVAR=, or ESTDATA= data set are added to the constraints specified in BOUNDS and LINCON statements.

You can use an OUTEST= data set from a PROC TCALIS run as an INEST= data set in a new run. However, be aware that the OUTEST= data set also contains the boundary and general linear constraints specified in the previous run of PROC TCALIS. When you are using this OUTEST= data set without changes as an INEST= data set, PROC TCALIS adds the constraints from the data set to the constraints specified by a BOUNDS and LINCON statement. Although PROC TCALIS automatically eliminates multiple identical constraints, you should avoid specifying the same constraint a second time.

INMODEL= SAS-data-set

This data set is usually created in a previous run of PROC TCALIS. It is useful if you want to reanalyze a problem in a different way such as using a different estimation method. You can alter an existing OUTMODEL= data set in the DATA step to create the INMODEL= data set that describes a modified model. See the section "OUTMODEL= SAS-data-set" on page 6827 for more details about the INMODEL= data set.

INWGT= SAS-data-set

This data set enables you to specify a weight matrix other than the default matrix for the generalized, weighted, and diagonally weighted least squares estimation methods. If you also specify the INWGTINV option (or use the INWGT(INV)= option), the INWGT= data set is assumed to contain the inverse of the weight matrix, rather than the weight matrix itself. The specification of any INWGT= data set for unweighted least squares or maximum likelihood estimation is ignored. For generalized and diagonally weighted least squares estimation, the INWGT= data set must contain a _TYPE_ and a _NAME_ variable as well as the manifest variables used in the analysis. The value of the _NAME_ variable indicates the row index i of the weight w_{ij}. For weighted least squares, the INWGT= data set must contain _TYPE_, _NAME_, _NAM2_, and _NAM3_ variables as well as the manifest variables used in the analysis. The values of the _NAME_, _NAM2_, and _NAM3_ variables indicate the three indices i, j, k of the weight $w_{ij,kl}$. You can store information other than the

weight matrix in the INWGT= data set, but only observations with _TYPE_=WEIGHT are used to specify the weight matrix **W**. This property enables you to store more than one weight matrix in the INWGT= data set. You can then run PROC TCALIS with each of the weight matrices by changing only the _TYPE_ observation in the INWGT= data set with an intermediate DATA step.

See the section "OUTWGT= SAS-data-set" on page 6836 for more details about the INWGT= data set.

Output Data Sets

OUTEST= SAS-data-set

The OUTEST= (or OUTVAR=) data set is of TYPE=EST and contains the final parameter estimates, the gradient, the Hessian, and boundary and linear constraints. For METHOD=ML, METHOD=GLS, and METHOD=WLS, the OUTEST= data set also contains the approximate standard errors, the information matrix (crossproduct Jacobian), and the approximate covariance matrix of the parameter estimates ((generalized) inverse of the information matrix). If there are linear or nonlinear equality or active inequality constraints at the solution, the OUTEST= data set also contains Lagrange multipliers, the projected Hessian matrix, and the Hessian matrix of the Lagrange function.

The OUTEST= data set can be used to save the results of an optimization by PROC TCALIS for another analysis with either PROC TCALIS or another SAS procedure. Saving results to an OUTEST= data set is advised for expensive applications that cannot be repeated without considerable effort.

The OUTEST= data set contains the BY variables, two character variables _TYPE_ and _NAME_, t numeric variables corresponding to the parameters used in the model, a numeric variable _RHS_ (right-hand side) that is used for the right-hand-side value b_i of a linear constraint or for the value $f = f(x)$ of the objective function at the final point x^* of the parameter space, and a numeric variable _ITER_ that is set to zero for initial values, set to the iteration number for the OUTITER output, and set to missing for the result output.

The _TYPE_ observations in Table 88.2 are available in the OUTEST= data set, depending on the request.

Table 88.2 _TYPE_ Observations in the OUTEST= Data Set

TYPE	Description
ACTBC	if there are active boundary constraints at the solution x^*, three observations indicate which of the parameters are actively constrained, as follows:

NAME	Description
GE	indicates the active lower bounds
LE	indicates the active upper bounds
EQ	indicates the active masks

COV	contains the approximate covariance matrix of the parameter estimates; used in computing the approximate standard errors.
COVRANK	contains the rank of the covariance matrix of the parameter estimates.
CRPJ_LF	contains the Hessian matrix of the Lagrange function (based on CRPJAC).
CRPJAC	contains the approximate Hessian matrix used in the optimization process. This is the inverse of the information matrix.
EQ	if linear constraints are used, this observation contains the ith linear constraint $\sum_j a_{ij}x_j = b_i$. The parameter variables contain the coefficients a_{ij}, $j = 1, \ldots, n$, the _RHS_ variable contains b_i, and _NAME_=ACTLC or _NAME_=LDACTLC.
GE	if linear constraints are used, this observation contains the ith linear constraint $\sum_j a_{ij}x_j \geq b_i$. The parameter variables contain the coefficients a_{ij}, $j = 1, \ldots, n$, and the _RHS_ variable contains b_i. If the constraint i is active at the solution x^*, then _NAME_=ACTLC or _NAME_=LDACTLC.
GRAD	contains the gradient of the estimates.
GRAD_LF	contains the gradient of the Lagrange function. The _RHS_ variable contains the value of the Lagrange function.
HESSIAN	contains the Hessian matrix.
HESS_LF	contains the Hessian matrix of the Lagrange function (based on HESSIAN).
INFORMAT	contains the information matrix of the parameter estimates (only for METHOD=ML, METHOD=GLS, or METHOD=WLS).
INITGRAD	contains the gradient of the starting estimates.
INITIAL	contains the starting values of the parameter estimates.

Table 88.2 *continued*

TYPE	Description
JACNLC	contains the Jacobian of the nonlinear constraints evaluated at the final estimates.
LAGM BC	contains Lagrange multipliers for masks and active boundary constraints.

NAME	Description
GE	indicates the active lower bounds
LE	indicates the active upper bounds
EQ	indicates the active masks

LAGM LC	contains Lagrange multipliers for linear equality and active inequality constraints in pairs of observations containing the constraint number and the value of the Lagrange multiplier.

NAME	Description
LEC_NUM	number of the linear equality constraint
LEC_VAL	corresponding Lagrange multiplier value
LIC_NUM	number of the linear inequality constraint
LIC_VAL	corresponding Lagrange multiplier value

LAGM NLC	contains Lagrange multipliers for nonlinear equality and active inequality constraints in pairs of observations that contain the constraint number and the value of the Lagrange multiplier.

NAME	Description
NLEC_NUM	number of the nonlinear equality constraint
NLEC_VAL	corresponding Lagrange multiplier value
NLIC_NUM	number of the linear inequality constraint
NLIC_VAL	corresponding Lagrange multiplier value

LE	if linear constraints are used, this observation contains the ith linear constraint $\sum_j a_{ij} x_j \leq b_i$. The parameter variables contain the coefficients a_{ij}, $j = 1, \ldots, n$, and the _RHS_ variable contains b_i. If the constraint i is active at the solution x^*, then _NAME_=ACTLC or _NAME_=LDACTLC.
LOWERBD | LB	if boundary constraints are used, this observation contains the lower bounds. Those parameters not subjected to lower bounds contain missing values. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.

Table 88.2 *continued*

TYPE	Description
NACTBC	all parameter variables contain the number n_{abc} of active boundary constraints at the solution x^*. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.
NACTLC	all parameter variables contain the number n_{alc} of active linear constraints at the solution x^* that are recognized as linearly independent. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.
NLC_EQ NLC_GE NLC_LE	contains values and residuals of nonlinear constraints. The _NAME_ variable is described as follows:

NAME	Description
NLC	inactive nonlinear constraint
NLCACT	linear independent active nonlinear constraint
NLCACTLD	linear dependent active nonlinear constraint

NLDACTBC	contains the number of active boundary constraints at the solution x^* that are recognized as linearly dependent. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.
NLDACTLC	contains the number of active linear constraints at the solution x^* that are recognized as linearly dependent. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.
NOBS	contains the number of observations.
PARMS	contains the final parameter estimates. The _RHS_ variable contains the value of the objective function.
PCRPJ_LF	contains the projected Hessian matrix of the Lagrange function (based on CRPJAC).
PHESS_LF	contains the projected Hessian matrix of the Lagrange function (based on HESSIAN).
PROJCRPJ	contains the projected Hessian matrix (based on CRPJAC).
PROJGRAD	if linear constraints are used in the estimation, this observation contains the $n - n_{act}$ values of the projected gradient $g_Z = Z'g$ in the variables corresponding to the first $n - n_{act}$ parameters. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.
PROJHESS	contains the projected Hessian matrix (based on HESSIAN).
STDERR	contains approximate standard errors (only for METHOD=ML, METHOD=GLS, or METHOD=WLS).

Table 88.2 *continued*

TYPE	Description
TERMINAT	the _NAME_ variable contains the name of the termination criterion.
UPPERBD | UB	if boundary constraints are used, this observation contains the upper bounds. Those parameters not subjected to upper bounds contain missing values. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.

If the technique specified by the OMETHOD= option cannot be performed (for example, no feasible initial values can be computed or the function value or derivatives cannot be evaluated at the starting point), the OUTEST= data set can contain only some of the observations (usually only the PARMS and GRAD observations).

OUTMODEL= SAS-data-set

The OUTMODEL= (or OUTRAM=) data set is of TYPE=CALISMDL and contains the model specification and the computed parameter estimates and standard error estimates. This data set is intended to be reused as an INMODEL= data set to specify good initial values in a subsequent analysis by PROC TCALIS.

The OUTMODEL= data set contains the following variables:

- the BY variables, if any
- an _MDLNUM_ variable for model numbers, if used
- a character variable _TYPE_, which takes various values indicating the type of model specification
- a character variable _NAME_, which indicates the model type, parameter name, or variable name
- a character variable _VAR1_, which is the name or number of the first variable in the specification
- a character variable _VAR2_, which is the name or number of the second variable in the specification
- a numerical variable _ESTIM_ for the final estimate of the parameter location
- a numerical variable _STDERR_ for the standard error estimate of the parameter location

Each observation (record) of the OUTMODEL= data set contains a piece of information regarding the model specification. Depending on the type of the specification indicated by the value of the _TYPE_ variable, the meanings of _NAME_, _VAR1_, and _VAR2_ differ. The following tables summarize the meanings of the _NAME_, _VAR1_, and _VAR2_ variables for each value of the _TYPE_ variable, given the type of the model.

FACTOR Models

Value of _TYPE_	Specification Type	_NAME_	_VAR1_	_VAR2_
MDLTYPE	model type	model type		
ADDPVAR	added (partial) variance	parameter	variable	
COV	covariance	parameter	first variable	second variable
LOADING	factor loading	parameter	manifest variable	factor variable
MEAN	mean or intercept	parameter	variable	
PVAR	(partial) variance	parameter	variable	

For factor models, the value of the _NAME_ variable is either EFACTOR (exploratory factor model) or CFACTOR (confirmatory factor model) for the _TYPE_=MDLTYPE observation. Other observations specify the parameters in the model. The _NAME_ values for these observations are the parameter names. Any observation with a _TYPE_ value of COV or LOADING is for specifying a parameter associated with two variables. The _VAR1_ and _VAR2_ values of such an observation indicate the variables involved. Any observation with a _TYPE_ value of ADDPVAR, MEAN, or PVAR is for specifying a parameter associated with a single variable. The _VAR1_ value of such an observation indicates the variable involved, while the _VAR2_ value is not used.

LINEQS Models

Value of _TYPE_	Specification Type	_NAME_	_VAR1_	_VAR2_
MDLTYPE	model type	model type		
ADDCOV	added covariance	parameter	first variable	second variable
ADDMEAN	added mean	parameter	variable	
ADDSTD	added variance	parameter	variable	
COV	covariance	parameter	first variable	second variable
EQUATION	path coefficient	parameter	outcome variable	predictor variable
MEAN	mean	parameter	variable	
STD	variance	parameter	variable	

The value of the _NAME_ variable is LINEQS for the _TYPE_=MDLTYPE observation. Other observations specify the parameters in the model. The _NAME_ values for these observations are the parameter names. Any observation with a _TYPE_ value of ADDCOV, COV, or EQUATION is for specifying a parameter associated with two variables. The _VAR1_ and _VAR2_ values of such an observation indicate the variables involved. Any observation with a _TYPE_ value of ADDMEAN, ADDSTD, MEAN, or STD is for specifying a parameter associated with a single variable. The _VAR1_ value of such an observation indicates the variables involved, while the _VAR2_ value is not used.

LISMOD Models

Value of _TYPE_	Specification Type	_NAME_	_VAR1_	_VAR2_
MDLTYPE	model type	model type		
XVAR	x-variable	variable	variable number	
YVAR	y-variable	variable	variable number	
ETAVAR	eta-variable	variable	variable number	
XIVAR	xi-variable	variable	variable number	
ADDKAPPA	added _KAPPA_ entry	parameter	row number	
ADDPHI	added _PHI_ entry	parameter	row number	column number
ADDPSI	added _PSI_ entry	parameter	row number	column number
ADDTHETAX	added _THETAX_ entry	parameter	row number	column number
ADDTHETAY	added _THETAY_ entry	parameter	row number	column number
ALPHA	_ALPHA_ entry	parameter	row number	
BETA	_BETA_ entry	parameter	row number	column number
GAMMA	_BETA_ entry	parameter	row number	column number
KAPPA	_KAPPA_ entry	parameter	row number	
LAMBDAX	_LAMBDAX_ entry	parameter	row number	column number
LAMBDAY	_LAMBDAY_ entry	parameter	row number	column number
NUX	_NUX_ entry	parameter	row number	
NUY	_NUY_ entry	parameter	row number	
PHI	_PHI_ entry	parameter	row number	column number
PSI	_PSI_ entry	parameter	row number	column number
THETAX	_THETAX_ entry	parameter	row number	column number
THETAY	_THETAY_ entry	parameter	row number	column number

The value of the _NAME_ variable is LISMOD for the _TYPE_=MDLTYPE observation. Other observations specify either the variables or the parameters in the model.

Observations with _TYPE_ values equal to XVAR, YVAR, ETAVAR, and XIVAR indicate the variables on the respective lists in the model. The _NAME_ variable of these observations stores the names of the variables, while the _VAR1_ variable stores the variable numbers on the respective list. The variable numbers in this data set are not arbitrary—that is, they define the variable orders in the rows and columns of the LISMOD model matrices. The _VAR2_ variable of these observations is not used.

All other observations in this data set specify the parameters in the model. The _NAME_ values of these observations are the parameter names. The corresponding _VAR1_ and _VAR2_ values of these observations indicate the row and column locations of the parameters in the LISMOD model matrices specified in the _TYPE_ variable. For example, when the value of _TYPE_ is ADDPHI or PHI, the parameter specified is located in the _PHI_ matrix, with its row and column numbers indicated by the _VAR1_ and _VAR2_ values, respectively. Some observations for specifying parameters do not have values in the _VAR2_ variable. This means that the associated LISMOD matrices are vectors so that the column numbers are always 1 for these observations.

MSTRUCT Models

Value of _TYPE_	Specification Type	_NAME_	_VAR1_	_VAR2_
MDLTYPE	model type	model type		
VAR	variable	variable	variable number	
COVMAT	covariance	parameter	row number	column number
MEANVEC	mean	parameter	row number	

The value of the _NAME_ variable is MSTRUCT for the _TYPE_=MDLTYPE observation. Other observations specify either the variables or the parameters in the model. Observations with _TYPE_ values equal to VAR indicate the variables in the model. The _NAME_ variable of these observations stores the names of the variables, while the _VAR1_ variable stores the variable numbers on the variable list. The variable numbers in this data set are not arbitrary—that is, they define the variable orders in the rows and columns of the mean and covariance matrices. The _VAR2_ variable of these observations is not used.

All other observations in this data set specify the parameters in the model. The _NAME_ values of these observations are the parameter names. The corresponding _VAR1_ and _VAR2_ values of these observations indicate the row and column locations of the parameters in the mean or covariance matrix, as specified in the _TYPE_ model. For example, when the value of _TYPE_ is COVMAT, the parameter specified is located in the covariance matrix, with its row and column numbers indicated by the _VAR1_ and _VAR2_ values, respectively. For observations with _TYPE_=MEANVEC, the _VAR2_ variable is not used because the column numbers are always 1 for parameters in the mean vector.

PATH Models

Value of _TYPE_	Specification Type	_NAME_	_VAR1_	_VAR2_
MDLTYPE	model type	model type		
ADDPCOV	added (partial) covariance	parameter	first variable	second variable
ADDMEAN	added mean	parameter	variable	
ADDPVAR	added (partial) variance	parameter	variable	
LEFT	path coefficient	parameter	outcome variable	predictor variable
MEAN	mean	parameter	variable	
PCOV	(partial) covariance	parameter	first variable	second variable
PVAR	(partial) variance	parameter	variable	
RIGHT	path coefficient	parameter	predictor variable	outcome variable

The value of the _NAME_ variable is PATH for the _TYPE_=MDLTYPE observation. Other observations specify the parameters in the model. The _NAME_ values for these observations are the parameter names. Any observation with a _TYPE_ value of ADDPCOV, LEFT, PCOV, or RIGHT is for specifying a parameter associated with two variables. The _VAR1_ and _VAR2_ values of such an observation indicate the variables involved. Any observation with a _TYPE_ value of ADDMEAN, ADDPVAR, ADDSTD, MEAN, or PVAR is for specifying a parameter associated with a single variable. The _VAR1_ value of such an observation indicates the variable involved, while the _VAR2_ value is not used.

RAM Models

Value of _TYPE_	Specification Type	_NAME_	_VAR1_	_VAR2_
MDLTYPE	model type	model type		
_A_	matrix _A_ entry	parameter	first variable	second variable
_P_	matrix _P_ entry	parameter	first variable	second variable
_W_	vector _W_ entry	parameter	variable	
ADDMEAN	added mean	parameter	variable	
ADDPCOV	added (partial) covariance	parameter	first variable	second variable
ADDPVAR	added (partial) variance	parameter	variable	
INTERCEP	intercept	parameter	variable	
LEFT	path coefficient	parameter	outcome variable	predictor variable
MEAN	mean	parameter	variable	
PCOV	(partial) covariance	parameter	first variable	second variable
PVAR	(partial) variance	parameter	variable	
RIGHT	path coefficient	parameter	predictor variable	outcome variable

The value of the _NAME_ variable is RAM for the _TYPE_=MDLTYPE observation. Other observations specify the parameters in the model. The _NAME_ values for these observations are for the parameter names. Any observation with a _TYPE_ value of _A_, _P_, ADDPCOV, LEFT, PCOV, or RIGHT is for specifying a parameter associated with two variables. The _VAR1_ and _VAR2_ values of such an observation indicate the variables involved. Any observation with a _TYPE_ value of _W_, ADDMEAN, ADDPVAR, INTERCEP, MEAN, or PVAR is for specifying a parameter associated with a single variable. The _VAR1_ value of such an observation indicates the variable involved, while the _VAR2_ value is not used.

Reading an OUTMODEL= Data Set As an INMODEL= Data Set in Subsequent Analyses

When the OUTMODEL= data set is treated as an INMODEL= data set in subsequent analyses, you need to pay attention to those observations with _TYPE_ values prefixed by "ADD" (for example, ADDCOV, ADDMEAN, or ADDSTD). These observations represent parameter locations added automatically by PROC TCALIS in a previous run. Because the context of the new analyses might be different, these observations for added parameter locations might not be suitable in the new runs any more. Hence, these observations are *not* read as input model information. Fortunately, after reading the INMODEL= specification in the new analyses, TCALIS analyzes the new model specification again. It then adds an appropriate set of parameters in the new context when necessary.

OUTSTAT= SAS-data-set

The OUTSTAT= data set is similar to the TYPE=COV, TYPE=UCOV, TYPE=CORR, or TYPE=UCORR data set produced by the CORR procedure. The OUTSTAT= data set contains the following variables:

- the BY variables, if any
- the _GPNUM_ variable for groups numbers, if used in the analysis
- two character variables, _TYPE_ and _NAME_
- the manifest and the latent variables analyzed

The OUTSTAT= data set contains the following information (when available) in the observations:

- the mean and standard deviation
- the skewness and kurtosis (if the DATA= data set is a raw data set and the KURTOSIS option is specified)
- the number of observations
- if the WEIGHT statement is used, sum of the weights
- the correlation or covariance matrix to be analyzed
- the predicted correlation or covariance matrix
- the standardized or normalized residual correlation or covariance matrix
- if the model contains latent variables, the predicted covariances between latent and manifest variables and the latent variable (or factor) score regression coefficients (see the PLATCOV option on page 6741)

In addition, for FACTOR models the OUTSTAT= data set contains:

- the unrotated factor loadings, the error variances, and the matrix of factor correlations
- the standardized factor loadings and factor correlations
- the rotation matrix, rotated factor loadings, and factor correlations
- standardized rotated factor loadings and factor correlations

If effects are analyzed, the OUTSTAT= data set also contains:

- direct, indirect, and total effects and their standard error estimates
- standardized direct, indirect, and total effects and their standard error estimates

Each observation in the OUTSTAT= data set contains some type of statistic as indicated by the _TYPE_ variable. The values of the _TYPE_ variable are shown in the following tables:

Basic Descriptive Statistics

Value of _TYPE_	Contents
CORR	correlations analyzed
COV	covariances analyzed
KURTOSIS	univariate kurtosis
MEAN	means
N	sample size
SKEWNESS	univariate skewness
STD	standard deviations
SUMWGT	sum of weights (if the WEIGHT statement is used)

For the _TYPE_=CORR or COV observations, the _NAME_ variable contains the name of the manifest variable that corresponds to each row for the covariance or correlation. For other observations, _NAME_ is blank.

Predicted Moments and Residuals

value of _TYPE_	Contents
METHOD=NONE	
ASRES	asymptotically standardized residuals
NRES	normalized residuals
PRED	predicted moments
RES	raw residuals
SRES	variance standardized residuals
METHOD=DWLS	
DWLSASRS	DWLS asymptotically standardized residuals
DWLSNRES	DWLS normalized residuals
DWLSPRED	DWLS predicted moments
DWLSRES	DWLS raw residuals
DWLSSRES	DWLS variance standardized residuals
METHOD=GLS	
GLSASRES	GLS asymptotically standardized residuals
GLSNRES	GLS normalized residuals
GLSPRED	GLS predicted moments
GLSRES	GLS raw residuals
GLSSRES	GLS variance standardized residuals
METHOD=ML	
MAXASRES	ML asymptotically standardized residuals
MAXNRES	ML normalized residuals
MAXPRED	ML predicted moments
MAXRES	ML raw residuals
MAXSRES	ML variance standardized residuals
METHOD=ULS	
ULSASRES	ULS asymptotically standardized residuals
ULSNRES	ULS normalized residuals
ULSPRED	ULS predicted moments
ULSRES	ULS raw residuals
ULSSRES	ULS variance standardized residuals
METHOD=WLS	
WLSASRES	WLS asymptotically standardized residuals
WLSNRES	WLS normalized residuals
WLSPRED	WLS predicted moments
WLSRES	WLS raw residuals
WLSSRES	WLS variance standardized residuals

For residuals or predicted moments of means, the _NAME_ variable is a fixed value denoted by _Mean_. For residuals or predicted moments for covariances or correlations, the _NAME_ variable is used for names of variables.

Effects and Latent Variable Scores Regression Coefficients

Value of _TYPE_	Contents
Unstandardized Effects	
DEFFECT	direct effects
DEFF_SE	standard error estimates for direct effects
IEFFECT	indirect effects
IEFF_SE	standard error estimates for indirect effects
TEFFECT	total effects
TEFF_SE	standard error estimates for total effects
Standardized Effects	
SDEFF	standardized direct effects
SDEFF_SE	standard error estimates for standardized direct effects
SIEFF	standardized indirect effects
SIEFF_SE	standard error estimates for standardized indirect effects
STEFF	standardized total effects
STEFF_SE	standard error estimates for standardized total effects
Latent Variable Scores Coefficients	
LSSCORE	latent variable (or factor) scores regression coefficients for ULS method
SCORE	latent variable (or factor) scores regression coefficients other than ULS method

For latent variable or factor scores coefficients, the _NAME_ variable contains factor or latent variables in the observations. For other observations, the _NAME_ variable contains manifest or latent variable names.

You can use the latent variable score regression coefficients with PROC SCORE to compute factor scores. If the analyzed matrix is a covariance rather than a correlation matrix, the _TYPE_=STD observation is not included in the OUTSTAT= data set. In this case, the standard deviations can be obtained from the diagonal elements of the covariance matrix. Dropping the _TYPE_=STD observation prevents PROC SCORE from standardizing the observations before computing the factor scores.

Factor Analysis Results

Value of _TYPE_	Contents
ERRVAR	error variances
FCORR	factor correlations or covariances
LOADINGS	unrotated factor loadings
RFCORR	rotated factor correlations or covariances
RLOADING	rotated factor loadings
ROTMAT	rotation matrix
STDFCORR	standardized factor correlations
STDLOAD	standardized factor loadings
STDRFCOR	standardized rotated factor correlations or covariances
STDRLOAD	standardized rotated factor loadings

For the _TYPE_=ERRVAR observation, the _NAME_ variable is blank. For all other observations, the _NAME_ variable contains factor names.

OUTWGT= SAS-data-set

You can create an OUTWGT= data set that is of TYPE=WEIGHT and contains the weight matrix used in generalized, weighted, or diagonally weighted least squares estimation. The OUTWGT= data set contains the weight matrix on which the WRIDGE= and the WPENALTY= options are applied. However, if you input the inverse of the weight matrix with the INWGT= and INWGTINV options (or the INWGT(INV)= option alone) in the same analysis, the OUTWGT= data set contains the same elements of the inverse of the weight matrix. For unweighted least squares or maximum likelihood estimation, no OUTWGT= data set can be written. The weight matrix used in maximum likelihood estimation is dynamically updated during optimization. When the ML solution converges, the final weight matrix is the same as the predicted covariance or correlation matrix, which is included in the OUTSTAT= data set (observations with _TYPE_ =MAXPRED).

For generalized and diagonally weighted least squares estimation, the weight matrices $\mathbf{W}$ of the OUTWGT= data set contain all elements w_{ij}, where the indices i and j correspond to all manifest variables used in the analysis. Let $varnam_i$ be the name of the ith variable in the analysis. In this case, the OUTWGT= data set contains n observations with the variables shown in the following table:

Variable	Contents
TYPE	WEIGHT (character)
NAME	name of variable $varnam_i$ (character)
$varnam_1$	weight w_{i1} for variable $varnam_1$ (numeric)
$\vdots$	$\vdots$
$varnam_n$	weight w_{in} for variable $varnam_n$ (numeric)

For weighted least squares estimation, the weight matrix $\mathbf{W}$ of the OUTWGT= data set contains only the nonredundant elements $w_{ij,kl}$. In this case, the OUTWGT= data set contains $n(n+1)(2n+1)/6$ observations with the variables shown in the following table:

Variable	Contents
TYPE	WEIGHT (character)
NAME	name of variable $varnam_i$ (character)
NAM2	name of variable $varnam_j$ (character)
NAM3	name of variable $varnam_k$ (character)
$varnam_1$	weight $w_{ij,k1}$ for variable $varnam_1$ (numeric)
$\vdots$	$\vdots$
$varnam_n$	weight $w_{ij,kn}$ for variable $varnam_n$ (numeric)

Symmetric redundant elements are set to missing values.

OUTFIT= SAS-data-set

You can create an OUTFIT= data set that is of TYPE=CALISFIT and contains the values of the fit indices of your analysis. If you use two estimation methods such as LSML or LSWLS, the fit indices are for the second analysis. An OUTFIT=data set contains the following variables:

- a character variable _TYPE_ for the types of fit indices
- a character variable _INDEX_ for the names of the fit indices
- a numerical variable _VALUE_ for the numerical values of the fit indices
- a character variable _PRINT_ for the character-formatted fit index values.

The possible values of _TYPE_ are:

ModelInfo:	basic modeling statistics and information
Absolute:	standalone fit indices
Parsimony:	fit indices that take model parsimony into account
Incremental:	fit indices that are based on comparison with a baseline model

Possible Values of _INDEX_ When _TYPE_=ModelInfo

Value of _INDEX_	Description
N Observations	number of observations use in the analysis
N Variables	number of variables
N Moments	number of mean or covariance elements
N Parameters	number of parameters
N Active Constraints	number of active constraints in the solution
Independence Model Chi-Square	chi-square value for the independence model
Independence Model Chi-Square DF	the degrees of freedom for the independence model chi-square

Possible Values of _INDEX_ When _TYPE_=Absolute

Value of _INDEX_	Description
Fit Function	fit function value
Percent Contribution to Chi-Square	percentage contribution to the chi-square value
Chi-Square	model chi-square value
Chi-Square DF	the degrees of freedom for model chi-square test
Pr > Chi-Square	the probability of obtaining a larger chi-square than the observed value
Elliptic Corrected Chi-Square	the elliptic-corrected chi-square value
Pr > Elliptic Corr. Chi-Square	the probability of obtaining a larger elliptic-corrected chi-square value
Z-test of Wilson and Hilferty	Z-test of Wilson and Hilferty
Hoelter Critical N	the N value that will make a significant chi-square when multiplied to the fit function value
Root Mean Square Residual (RMSR)	root mean square residual
Standardized RMSR (SRMSR)	standardized root mean square residual
Goodness of Fit Index (GFI)	Jöreskog and Sörbom goodness-of-fit index

Possible Values of _INDEX_ When _TYPE_=Parsimony

Value of _INDEX_	Description
Adjusted GFI (AGFI)	goodness-of-fit index adjusted for the degrees of freedom of the model
Parsimonious GFI	Mulaik et al. modification of the GFI
RMSEA Estimate	Steiger and Lind (1980) root mean square error approximation
RMSEA Lower **r**% Confidence Limit	the lower **r**%[1] confidence limit for RMSEA
RMSEA Upper **r**% Confidence Limit	the upper **r**%[1] confidence limit for RMSEA
Probability of Close Fit	Browne and Cudeck (1993) test of close fit
ECVI Estimate	expected cross-validation index
ECVI Lower **r**% Confidence Limit	the lower **r**%[2] confidence limit for ECVI
ECVI Upper **r**% Confidence Limit	the upper **r**%[2] confidence limit for ECVI
Akaike Information Criterion	Akaike information criterion
Bozdogan CAIC	Bozdogan (1987) consistent AIC
Schwarz Bayesian Criterion	Schwarz (1978) Bayesian criterion
McDonald Centrality	McDonald and Hartmann (1992) measure of centrality

1. The value of **r** is one minus the ALPHARMS= value. By default, **r**=90.
2. The value of **r** is one minus the ALPHAECV= value. By default, **r**=90.

Possible Values of _INDEX_ When _TYPE_=Incremental

Value of _INDEX_	Description
Bentler Comparative Fit Index	Bentler (1995) comparative fit index
Bentler-Bonett NFI	Bentler and Bonett (1980) normed fit index
Bentler-Bonett Non-normed Index	Bentler and Bonett (1980) non-normed fit index
Bollen Normed Index Rho1	Bollen normed ρ_1
Bollen Non-normed Index Delta2	Bollen non-normed δ_2
James et al. Parsimonious NFI	James, Mulaik, and Brett (1982) parsimonious normed fit index

The LINEQS Model

The LINEQS modeling language is adapted from the EQS program by Bentler (1995). The statistical models that LINEQS or EQS analyzes are essentially the same as other general modeling languages such as LISMOD, RAM, and PATH in PROC TCALIS. However, the terminology and approach of the LINEQS or EQS modeling language are different from other languages. They are based on the theoretical model developed by Bentler and Weeks (1980). For convenience, models analyzed using the LINEQS modeling language will be called LINEQS models. It is noted that these so-called LINEQS models can also be analyzed by other general modeling languages in PROC TCALIS.

In the LINEQS (or the original EQS) model, relationships among variables are represented by a system of equations. For example:

$$Y_1 = a_0 + a_1 X_1 + a_2 X_2 + E_1$$

$$Y_2 = b_0 + b_1 X_1 + b_2 Y_1 + E_2$$

On the left-hand side of each equation, an outcome variable is hypothesized to be a linear function of one or more predictor variables and an error, which are all specified on the right-hand side of the equation. The parameters specified in an equation are the effects (or regression coefficients) of the predictor variables. For example, in the preceding equations, Y_1 and Y_2 are outcome variables; E_1 and E_2 are error variables; a_1, a_2, b_1, and b_2 are effect parameters (or regression coefficients); and a_0 and b_0 are intercept parameters. Variables X_1 and X_2 serve as predictors in the first equation, while variables X_1 and Y_1 serve as predictors in the second equation.

This is almost the same representation as in multiple regression models. However, the LINEQS model entails more. It supports a system of equations that can also include latent variables, measurement errors, and correlated errors.

Types of Variables in the LINEQS Model

The distinction between dependent and independent variables is important in the LINEQS model.

A variable is dependent if it appears on the left-hand side of an equation in the model. A dependent variable might be observed (manifest) or latent. It might or might not appear on the right-hand

side of other equations, but it cannot appear on the left-hand sides of two or more equations. Error variables cannot be dependent in the LINEQS model.

A variable in the LINEQS model is independent if it is not dependent. Independent variables can be observed (manifest) or latent. All error variables must be independent in the LINEQS model.

Dependent variables are also referred to as endogenous variables. These names are interchangeable. Similarly, independent variables are interchangeable with exogenous variables.

Whereas an outcome variable in any equation must be a dependent variable, a predictor variable in an equation is not necessarily an independent variable in the entire LINEQS model. For example, Y_1 is a predictor variable in the second equation of the preceding example, but it is a dependent variable in the LINEQS model. In sum, the predictor-outcome nature of a variable is determined within a single equation, while the exogenous-endogenous (independent-dependent) nature of variable is determined within the entire system of equations.

In addition to the dependent-independent variable distinction, variables in the LINEQS model are distinguished according to whether they are observed in the data. Variables that are observed in research are called observed or manifest variables. Hypothetical variables that are not observed in the LINEQS model are latent variables.

Two types of latent variables should be distinguished: one is error variables; the other is non-error variables. An error variable is unique to an equation. It serves as the unsystematic source of effect for the outcome variable in an equation. If the outcome variable in the equation is latent, the corresponding error variable is also called disturbance. In contrast, non-error or systematic latent variables are called factors. Factors are unmeasured hypothetical constructs in your model. They are systematic sources that explain or describe functional relationships in your model.

Both manifest variables and latent factors can be dependent or independent. However, error or disturbance terms must be independent (or exogenous) variables in your model.

Naming Variables in the LINEQS Model

Whether a variable in each equation is an outcome or a predictor variable is prescribed by the modeler. Whether a variable is independent or dependent can be determined by analyzing the entire system of equations in the model. Whether a variable is observed or latent can be determined if it is referenced in your data set. However, whether a latent variable serves as a factor or an error can be determined only if you provide the specific information.

To distinguish latent factors from errors and both from manifest variables, the following rules for naming variables in the LINEQS model are followed:

- Manifest variables are referenced in the input data set. You use their names in the LINEQS model specification directly. There is no additional naming rule for the manifest variables in the LINEQS model beyond those required by the SAS system.
- Latent factor variables must start with letter F or f (for factor).
- Error variables must start with letter E or e (for error), or D or d (for disturbance). Although you might enforce the use of D- (or d-) variables for disturbances, it is not required. For flexibility, disturbance variables can also start with letter E or e in the LINEQS model.

- The names of latent variables, errors, and disturbances (F-, E-, and D- variables) should not coincide with the names of manifest variables.
- You should not use Intercept as a name for any variable. This name is reserved for intercept specification in LINEQS model equations.

Matrix Representation of the LINEQS Model

As a programming language, the LINEQS model uses equations to describes relationships among variables. But as a mathematical model, the LINEQS model is more conveniently described by matrix terms. In this section, the LINEQS matrix model is described.

Suppose in a LINEQS model that there are n_i independent variables and n_d dependent variables. The vector of the independent variables is denoted by ξ, in the order of manifest variables, latent factors, and error variables. The vector of dependent variables is denoted by η, in the order of manifest variables and latent factors. The LINEQS model matrices are defined as follows:

α $(n_d \times 1)$:	intercepts of dependent variables
β $(n_d \times n_d)$:	effects of dependent variables (in columns) on dependent variables (in rows)
γ $(n_d \times n_i)$:	effects of independent variables (in columns) on dependent variables (in rows)
Φ $(n_i \times n_i)$:	covariance matrix of independent variables
ν $(n_i \times 1)$:	means of independent variables

The model equation of the LINEQS model is:

$$\eta = \alpha + \beta\eta + \gamma\xi$$

Assuming that $(I - \beta)$ is invertible, under the model the covariance matrix of all variables $(\eta', \xi')'$ is structured as:

$$\Sigma_a = \begin{pmatrix} (I-\beta)^{-1}\gamma\Phi\gamma'(I-\beta)^{-1\prime} & (I-\beta)^{-1}\gamma\Phi \\ \Phi\gamma'(I-\beta)^{-1\prime} & \Phi \end{pmatrix}$$

The mean vector of all variables $(\eta', \xi')'$ is structured as:

$$\mu_a = \begin{pmatrix} (I-\beta)^{-1}(\alpha + \gamma\nu) \\ \nu \end{pmatrix}$$

As is shown in the structured covariance and mean matrices, the means and covariances of independent variables are direct model parameters in ν and Φ; whereas the means and covariances of dependent variables are functions of various model matrices and hence functions of model parameters.

The covariance and mean structures of all observed variables are obtained by selecting the elements in Σ_a and μ_a. Mathematically, define a selection matrix G of dimensions $n \times (n_d + n_i)$, where n is the number of observed variables in the model. The selection matrix G contains zeros and ones as its elements. Each row of G has exactly one nonzero element at the position that corresponds to the

location of an observed row variable in Σ_a or μ_a. With each row of G selecting a distinct observed variable, the structured covariance matrix of all observed variables is represented by the following:

$$\Sigma = G\Sigma_a G'$$

The structured mean vector of all observed variables is represented by:

$$\mu = G\mu_a$$

Partitions of Some LINEQS Model Matrices and Their Restrictions

There are some restrictions in some of the LINEQS model matrices. Although these restrictions do not affect the derivation of the covariance and mean structures, they are enforced in the LINEQS model specification.

Model Restrictions on the β Matrix

The diagonal of the β matrix must be zeros. This prevents the direct regression of dependent variables on themselves. Hence, in the LINEQS statement you cannot specify the same variable on both the left-hand and the right-hand sides of the same equation.

Partitions of the γ Matrix and the Associated Model Restrictions

The columns of the γ matrix refer to the variables in ξ, in the order of mainfest variables, latent factors, and error variables. In the LINEQS model, the following partition of the γ matrix is assumed:

$$\gamma = \begin{pmatrix} \gamma_0 & E \end{pmatrix}$$

where γ_0 is an $n_d \times (n_i - n_d)$ matrix for the effects of independent manifest variables and latent factors on the dependent variables and E is an $n_d \times n_d$ permutation matrix for the effects of errors on the dependent variables.

The dimension of submatrix E is $n_d \times n_d$ because in the LINEQS model each dependent variable signifies an equation with an error term. In addition, because E is a permutation matrix (which is formed by exchanging rows of an identity matrix of the same order), the partition of the γ matrix ensures that each dependent variable is associated with a **unique** error term and that the effect of each error term on its associated dependent variable is 1.

As a result of the error term restriction, in the LINEQS statement you must specify a unique error term in each equation. The coefficient associated with the error term can only be a fixed value at one, either explicitly (with 1.0 inserted immediately before the error term) or implicitly (with no coefficient specified).

Partitions of the ν Vector and the Associated Model Restrictions

The ν vector contains the means of independent variables, in the order of the manifest, latent factor, and error variables. In the LINEQS model, the following partition of the ν vector is assumed:

$$\nu = \begin{pmatrix} \nu_0 \\ 0 \end{pmatrix}$$

where ν_0 is an $(n_i - n_d) \times 1$ vector for the means of independent manifest variables and latent factors and 0 is a null vector of dimension n_d for the means of errors or disturbances. Again, the dimension of the null vector is n_d because each dependent variable is associated uniquely with an error term. This partition restricts the means of errors or disturbances to zeros.

Hence, when specifying a LINEQS model, you cannot specify the means of errors (or disturbances) as free parameter or fixed values other than zero in the MEAN statement.

Partitions of the Φ matrix

The Φ matrix is for the covariances of the independent variables, in the order of the manifest, latent factor, and error variables. The following partition of the Φ matrix is assumed:

$$\Phi = \begin{pmatrix} \Phi_{11} & \Phi_{21}' \\ \Phi_{21} & \Phi_{22} \end{pmatrix}$$

where Φ_{11} is an $(n_i - n_d) \times (n_i - n_d)$ covariance matrix for the independent manifest variables and latent factors, Φ_{22} is an $n_d \times n_d$ covariance matrix for the errors, and Φ_{21} is an $n_d \times (n_i - n_d)$ covariance matrix for the errors with other independent variables in the LINEQS model. Because Φ is symmetric, Φ_{11} and Φ_{22} are also symmetric.

There are actually no model restrictions placed on the submatrices of the partition. However, in most statistical applications, errors represent unsystematic sources of effects and therefore they are not to be correlated with other systematic sources. This implies that submatrix Φ_{21} is a null matrix. However, Φ_{21} being null is not enforced in the LINEQS model specification. If you ever specify a covariance between an error variable and a non-error independent variable in the COV statement, as a workaround trick or otherwise, you should provide your own theoretical justifications.

Summary of Matrices and Submatrices in the LINEQS Model

Let n_d be the number of dependent variables and n_i be the number of independent variables. The names, roles, and dimensions of the LINEQS model matrices and submatrices are summarized in the following table:

Matrix	Name	Description	Dimensions
Model Matrices			
α	_EQSALPHA_	intercepts of dependent variables	$n_d \times 1$
β	_EQSBETA_	effects of dependent (column) variables on dependent (row) variables	$n_d \times n_d$
γ	_EQSGAMMA_	effects of independent (column) variables on dependent (row) variables	$n_d \times n_i$
ν	_EQSNU_	means of independent variables	$n_i \times 1$
Φ	_EQSPHI_	covariance matrix of independent variables	$n_i \times n_i$
Submatrices			
γ_0	_EQSGAMMA_SUB_	effects of independent variables, excluding errors, on dependent variables	$n_d \times (n_i - n_d)$
ν_0	_EQSNU_SUB_	means of independent variables, excluding errors	$(n_i - n_d) \times 1$
Φ_{11}	_EQSPHI11_	covariance matrix of independent variables, excluding errors	$(n_i - n_d) \times (n_i - n_d)$
Φ_{21}	_EQSPHI21_	covariances of errors with other independent variables	$n_d \times (n_i - n_d)$
Φ_{22}	_EQSPHI22_	covariance matrix of errors	$n_d \times n_d$

Specification of the LINEQS Model

Specification in Equations

In the LINEQS statement, you specify intercepts and effect parameters (or regression coefficients) along with the variable relationships in equations. In terms of model matrices, you specify the α vector and the β and γ matrices in the LINEQS statement without using any matrix language.

For example:

$$Y = b_0 + b_1 X_1 + b_2 F_2 + E_1$$

In this equation, you specify Y as an outcome variable, X_1 and F_2 as predictor variables, and E_1 as an error variable. The parameters in the equation are the intercept b_0 and the path coefficients (or effects) b_1 and b_2.

This kind of model equation is specified in the LINEQS statement. For example, the previous equation translates into the following LINEQS statement specification:

```
lineqs Y = b0 Intercept + b1 X1 + b2 F2 + E1;
```

If the mean structures of the model are not of interest, the intercept term can be omitted. The specification becomes:

```
lineqs Y =  b1 X1 + b2 F2 + E1;
```

See the LINEQS statement on page 6766 for the details in syntax.

Because of the LINEQS model restrictions (see the section "Partitions of Some LINEQS Model Matrices and Their Restrictions" on page 6842), you must also follow these rules when specifying LINEQS model equations:

- A dependent variable can appear only on the left-hand side of an equation once. In other words, you must put all predictor variables for a dependent variable in one equation. This is different from some econometric models where a dependent variable can appear on the left-hand sides of two equations to represent an equilibrium point. This limitation, however, can be resolved by reparameterization in some cases. See Example 88.2.
- A dependent variable that appears on the left-hand side of an equation cannot appear on the right-hand side of the same equation. If you measure the same characteristic at different time points and the previous measurement serves as a predictor of the next measurement, you should use different variable names for the measurements so as to comply with this rule.
- An error term must be specified in each equation and must be unique. The same error name cannot appear in two or more equations. When an equation is truly intended to have no error term, it should be represented equivalently in the LINEQS equation by introducing an error term with zero variance (specified in the STD statement).
- The regression coefficient or effect associated with an error term must be fixed at one (1.0). This is done automatically by omitting any fixed constants or parameters associated with the error terms. Inserting a parameter or a fixed value other than one immediately before an error term is not allowed.

Mean, Variance, and Covariance Parameter Specification

In addition to the intercept and effect parameters specified in equations, the means, variances, and covariances among all independent variables are parameters in the LINEQS model. An exception is that the means of all error variables are restricted to fixed zeros in the LINEQS model. To specify the mean, variance, and covariance parameters, you use the MEAN, STD, and the COV statements, respectively.

The means, variances, and covariances among dependent variables are not parameters themselves in the model. Rather, they are complex functions of the model parameters. See the section "Matrix Representation of the LINEQS Model" on page 6841 for mathematical details.

Default Parameters in the LINEQS Model

Model-restricted values in the LINEQS model include the zero direct effects of any variables on themselves (that is, the diagonal of β matrix contains zeros only), the predetermined effects of error variables (that is, each element of the E submatrix in γ is always either one or zero) and the predetermined means of error variables (that is, ν elements pertaining to error means are always zero). These fixed values are always enforced and cannot be specified differently. All other elements or locations in the LINEQS model matrices can be specified as parameters (free, constrained, or fixed) in the LINEQS and the subsidiary model specification statements, as described in the previous section.

If a location (or an element) in a LINEQS model matrix is not model-restricted and you do not specify a parameter for it, a default parameter will be assumed for this location. There are two types of default parameters. One is automatic free parameters and the other is fixed zeros.

Automatic Free Parameters

In the LINEQS model, automatic free parameters are generated for the variances of all independent variables (manifest variables, latent factors, and latent errors), the covariances among all manifest independent variables (but not latent factors nor errors), and the means of all manifest independent variables if the mean structures are modeled. The name of each automatic free parameter is generated with the _Add prefix and appended with a unique integer.

In terms of LINEQS model matrices, automatic parameters are applied to all diagonal elements of the Φ_{11} submatrix, to all off-diagonal elements of the Φ_{11} submatrix pertaining to the manifest independent variable in rows and in columns, to the diagonal elements of the Φ_{22} submatrix, and to the elements in the ν_0 subvector pertaining to the manifest independent variables in rows.

Default Fixed Zeros

Unspecified locations (elements) of LINEQS model matrices that are neither model-restricted nor automatic free parameters will be fixed at zeros by default.

Rationale of the Default Parameters in the LINEQS Model

To explain the automatic free parameters in the LINEQS model, note that manifest independent variables are explanatory variables in your model. Their means, variances, and covariances are not functions of other parameters in the model. Rather, together with other parameters, they explain the means, variances, and covariances of the dependent variables. Therefore, means, variances, and covariances of manifest independent variables should be saturated as free parameters unless you are also testing a theoretical pattern of these parameters. Otherwise, failing to do this might add unnecessary constraints to your model.

The same argument applies to the latent independent variables. However, because latent variable means, variances, and covariances are not observed, the treatment is different. Only the variances of latent independent variables (factors or errors) are automatic free parameters. The means and covariances among latent independent variables are fixed zeros by default.

You can override the default parameters by manual specification in the STD, COV, and MEAN statements. Manual specification of these parameters becomes necessary when you are testing theoretical covariance or mean patterns or when these parameters are constrained with other parameters in your model. For example, when you test a fixed covariance matrix pattern, you have to manually specify the fixed values for the variances of, and covariances among, exogenous manifest variables in the STD and COV statements.

The LISMOD Model and Submodels

As a statistical model, the LISMOD modeling language is derived from the LISREL model proposed by Jöreskog and others (see Keesling 1972; Wiley 1973; Jöreskog 1973). But as a computer language, the LISMOD modeling language is quite different from the LISREL program. To maintain the consistence of specification syntax within the TCALIS procedure, the LISMOD modeling language departs from the original LISREL programming language. In addition, to make the programming a little easier, some terminological changes from LISREL are made in LISMOD.

For brevity, models specified by the LISMOD modeling language are called LISMOD models, although it is noted that you can also specify these so-called LISMOD models by other general modeling languages supported in PROC TCALIS.

The following descriptions of LISMOD models are basically the same as that of the original LISREL models. The main modifications are the names for the model matrices.

The LISMOD model is described by three component models. The first one is the structural equation model that describes the relationships among latent constructs or factors. The other two are measurement models that relate latent factors to manifest variables.

Structural Equation Model

The structural equation model for latent factors is:

$$\eta = \alpha + \beta\eta + \Gamma\xi + \zeta$$

where:
η is a random vector of n_η endogenous latent factors
ξ is a random vector of n_ξ exogenous latent factors
ζ is a random vector of errors
α is a vector of intercepts
β is a matrix of regression coefficients of η variables on other η variables
Γ is a matrix of regression coefficients of η on ξ

There are some assumptions in the structural equation model. To prevent a random variable in η from regressing directly on itself, the diagonal elements of β are assumed to be zeros. Also, $(I - \beta)^{-1}$ is assumed to be nonsingular, and ζ is uncorrelated with ξ.

The covariance matrix of ζ is denoted by Ψ and its expected value is a null vector. The covariance matrix of ξ is denoted by Φ and its expected value is denoted by κ.

Because variables in the structural equation model are not observed, to analyze the model these latent variables must somehow relate to the manifest variables. The measurement models, which will be discussed in the subsequent sections, provide such relations.

Measurement Model for y

$$y = \nu_y + \Lambda_y \eta + \epsilon$$

where:
y is a random vector of n_y manifest variables
ϵ is a random vector of errors for y
ν_y is a vector of intercepts for y
Λ_y is a matrix of regression coefficients of y on η

It is assumed that ϵ is uncorrelated with either η or ζ. The covariance matrix of ϵ is denoted by Θ_y and its expected value is the null vector.

Measurement Model for x

$$x = \nu_x + \Lambda_x \xi + \delta$$

where:
x is a random vector of n_x manifest variables
δ is a random vector of errors for x
ν_x is a vector of intercepts for x
Λ_x is a matrix of regression coefficients of x on ξ

It is assumed that δ is uncorrelated with ξ, ϵ, or ζ. The covariance matrix of δ is denoted by Θ_x and its expected value is a null vector.

Covariance and Mean Structures

Under the structural and measurement equations and the model assumptions, the covariance structures of the manifest variables $(y', x')'$ are expressed as:

$$\Sigma = \begin{pmatrix} \Lambda_y (I-\beta)^{-1}(\Gamma\Phi\Gamma' + \Psi)(I-\beta')^{-1}\Lambda_y' + \Theta_y & \Lambda_y (I-\beta)^{-1}\Gamma\Phi\Lambda_x' \\ \Lambda_x \Phi\Gamma'(I-\beta')^{-1}\Lambda_y' & \Lambda_x \Phi\Lambda_x' + \Theta_x \end{pmatrix}$$

The mean structures of the manifest variables $(y', x')'$ are expressed as:

$$\mu = \begin{pmatrix} \nu_y + \Lambda_y (I-\beta)^{-1}(\alpha + \Gamma\kappa) \\ \nu_x + \Lambda_x \kappa \end{pmatrix}$$

Model Matrices in the LISMOD Model

The parameters of the LISMOD model are elements in the model matrices, which are summarized as follows:

Matrix	Name	Description	Dimensions	Row Variables	Column Variables
α	_ALPHA_	intercepts for η	$n_\eta \times 1$	η (ETAVAR=)	N/A
β	_BETA_	effects of η on η	$n_\eta \times n_\eta$	η (ETAVAR=)	η (ETAVAR=)
Γ	_GAMMA_	effects of ξ on η	$n_\eta \times n_\xi$	η (ETAVAR=)	ξ (XIVAR=)
Ψ	_PSI_	error covariance matrix for η	$n_\eta \times n_\eta$	η (ETAVAR=)	η (ETAVAR=)
Φ	_PHI_	covariance matrix for ξ	$n_\xi \times n_\xi$	ξ (XIVAR=)	ξ (XIVAR=)
κ	_KAPPA_	mean vector for ξ	$n_\xi \times 1$	ξ (XIVAR=)	N/A
ν_y	_NUY_	intercepts for y	$n_y \times 1$	y (YVAR=)	N/A
Λ_y	_LAMBDAY_	effects of η on y	$n_y \times n_\eta$	y (YVAR=)	η (ETAVAR=)
Θ_y	_THETAY_	error covariance matrix for y	$n_y \times n_y$	y (YVAR=)	y (YVAR=)
ν_x	_NUX_	intercepts for x	$n_x \times 1$	x (XVAR=)	N/A
Λ_x	_LAMBDAX_	effects of ξ on x	$n_x \times n_\xi$	x (XVAR=)	ξ (XIVAR=)
Θ_x	_THETAX_	error covariance matrix for x	$n_x \times n_x$	x (XVAR=)	x (XVAR=)

There are twelve model matrices in the LISMOD model. Not all of them are used in all situations. See the section "LISMOD Submodels" on page 6851 for details. In the table, each model matrix is given a name in the column Name, followed by a brief description of the parameters in the matrix, the dimensions, and the row and column variables being referred to. In the second column of the table, the LISMOD matrix names are used in the MATRIX statements when specifying the LISMOD model. In the last two columns of the table, following the row or column variables are the variable list (for example, ETAVAR=, YVAR=, and so on) in parentheses. These lists are used in the LISMOD statement for defining variables.

Specification of the LISMOD Model

The LISMOD specification is characterized by two tasks. The first task is to define the variables in the model. The second task is to specify the parameters in the LISMOD model matrices.

Specifying Variables

The first task is accomplished in the LISMOD statement. In the LISMOD statement, you define the lists of variables of interest: YVAR=, XVAR=, ETAVAR=, and XIVAR= lists, respectively for the y-variables, x-variables, η-variables, and the ξ-variables. While you provide the names of variables in these lists, you also define implicitly the numbers of four types of variables: n_y, n_x, n_η, and n_ξ. The variables on the YVAR= and XVAR= lists are manifest variables and therefore must be present in the analyzed data set. The variables on the ETAVAR= and XIVAR= lists are latent factors, the names of which are assigned by the researcher to represent their roles in the substantive theory. Once these lists are defined, the dimensions of the model matrices are also defined by the number of variables on various lists. In addition, the variable orders on the lists are referred to by the row and column variables of the model matrices.

Specifying Parameters in Model Matrices

The second task is accomplished by the MATRIX statements. In each MATRIX statement, you specify the model matrix by using the matrix names described in the previous table. Then you specify the parameters (free or fixed) in the locations of the model matrix. You can use as many MATRIX statements as needed for defining your model. But each model matrix can only be specified in one MATRIX statement and each MATRIX statement is used for specifying one model matrix.

An Example

In the section "LISMOD Model" on page 6709, the LISMOD modeling language is used to specify the model described in the section "A Structural Equation Example" on page 6704. In the LISMOD statement, you define four lists of variables, as shown in the following statement:

```
lismod
   yvar  = Anomie67 Powerless67 Anomie71 Powerless71,
   xvar  = Education SEI,
   etav  = Alien67 Alien71,
   xivar = SES;
```

Endogenous latent factors are specified in the ETAVAR= list. Exogenous latent factors are specified in the XIVAR= list. In this case, Alien67 and Alien71 are the η-variables, and SES is the only ξ-variable in the model. Manifest variables that are indicators of endogenous latent factors in η are specified in the YVAR= list. In this case, they are the Anomie and Powerless variables, measured in two different time points. Manifest variables that are indicators of exogenous latent factors in ξ are specified in the XVAR= list. In this case, they are the Education and the SEI variables. Implicitly, the dimensions of the model matrices are defined by these lists already; that is, $n_y = 4$, $n_x = 2$, $n_\eta = 2$, and $n_\xi = 1$.

The MATRIX statements are used to specify parameters in the model matrices. For example, in the following statement you define the _LAMBDAX_ (Λ_x) matrix with two nonzero entries:

```
matrix _LAMBDAX_ [1,1] = 1.0,
                 [2,1] = lambda;
```

The first parameter location is for [1,1], which is the effect of SES (the first variable in the XIVAR= list) on Education (the first element in the XVAR= list). A fixed value of 1.0 is specified there. The second parameter location is for [2,1], which is the effect of SES (the first variable in the XIVAR= list) on SEI (the second variable in the XVAR= list). A parameter named lambda without initial value is specified there.

Another example is shown as follows:

```
matrix _THETAY_  [1,1] = theta1,
                 [2,2] = theta2,
                 [3,3] = theta1,
                 [4,4] = theta2,
                 [3,1] = theta5,
                 [4,2] = theta5;
```

In this MATRIX statement, the error variances and covariances (that is, the Θ_y matrix) for the y-variables are specified. The diagonal elements of the _THETAY_ matrix are specified by parameters theta1, theta2, theta1, and theta2, respectively, for the four y-variables Anomie67, Powerless67, Anomie71, and Powerless71. By using the same parameter name theta1, the error variances for Anomie67 and Anomie71 are implicitly constrained. Similarly, the error variances for Powerless67 and Powerless71 are also implicitly constrained. Two more parameter locations are specified. The error covariance between Anomie67 and Anomie71 and the error covariance between Powerless67 and Powerless71 are both represented by the parameter theta5. Again, this is an implicit constraint on the covariances. All other unspecified elements in the _THETAY_ matrix are treated as fixed zeros.

In this example, no parameters are specified for matrices _ALPHA_, _KAPPA_, _NUY_, or _NUX_. Therefore, mean structures are not modeled.

LISMOD Submodels

It is not necessary to specify all four lists of variables in the LISMOD statement. When some lists are unspecified in the LISMOD statement, PROC TCALIS will analyze submodels derived logically from the specified lists of variables. For example, if only y- and x- variable lists are specified, the submodel being analyzed would be a multivariate regression model with manifest variables only. Not all combinations of lists will lead to meaningful submodels, however. To determine whether and how a submodel (which is formed by a certain combination of variable lists) can be analyzed, the following three principles in the LISMOD modeling language are applied:

- Submodels with at least one of the YVAR= and XVAR= lists are required.
- Submodels that have an ETAVAR= list but no YVAR= list cannot be analyzed.
- When a submodel has a YVAR= (an XVAR=) list but without an ETAVAR= (a XIVAR=) list, it is assumed that the set of y-variables (x-variables) is equivalent to the η-variables (ξ-variables). Hereafter, this principle is referred to as an equivalence interpretation.

Apparently, the third principle is the same as the situation where the latent factors η (or ξ) are perfectly measured by the manifest variables y (or x). That is, in such a perfect measurement model,

Λ_y (Λ_x) is an identity matrix and Θ_y (Θ_x) and ν_y (ν_x) are both null. This can be referred to as a perfect measurement interpretation. However, the equivalence interpretation stated in the last principle presumes that there are actually no measurement equations at all. This is important because under the equivalence interpretation, matrices Λ_y (Λ_x), Θ_y (Θ_x) and ν_y (ν_x) are non-existent rather than fixed quantities, which is assumed under the perfect measurement interpretation. Hence, the x-variables are treated as *exogenous* variables with the equivalence interpretation, but they are still treated as *endogenous* with the perfect measurement interpretation. Ultimately, whether x-variables are treated as exogenous or endogenous will affect the default or automatic parameterization. See the section "Default Parameters in the LISMOD Model" on page 6854 for more details.

By using these three principles, the models and submodels that PROC TCALIS analyzes are summarized in the following table, followed by detailed descriptions of these models and submodels.

	Presence of Lists	Description	Model Equations	Non-fixed Model Matrices
Presence of Both x and y Variables				
1	YVAR=, ETAVAR=, XVAR=, XIVAR=	full model	$y = \nu_y + \Lambda_y\eta + \epsilon$ $x = \nu_x + \Lambda_x\xi + \delta$ $\eta = \alpha + \beta\eta + \Gamma\xi + \zeta$	ν_y,Λ_y,Θ_y ν_x,Λ_x,Θ_x,κ,Φ α ,β,Γ,Ψ
2	YVAR=, XVAR=, XIVAR=	full model with $y \equiv \eta$	$x = \nu_x + \Lambda_x\xi + \delta$ $y = \alpha + \beta y + \Gamma\xi + \zeta$	ν_x,Λ_x,Θ_x,κ,Φ α,β,Γ,Ψ
3	YVAR=, ETAVAR=, XVAR=	full model with $x \equiv \xi$	$y = \nu_y + \Lambda_y\eta + \epsilon$ $\eta = \alpha + \beta\eta + \Gamma x + \zeta$	ν_y,Λ_y,Θ_y α ,β,Γ,Ψ,κ,Φ
4	YVAR=, XVAR=	regression $(y \equiv \eta)$ $(x \equiv \xi)$	$y = \alpha + \beta y + \Gamma x + \zeta$, or $(I - \beta)^{-1} y = \alpha + \Gamma x + \zeta$	α,β,Γ,Ψ,κ,Φ
Presence of x Variables and Absence of y Variables				
5	XVAR=, XIVAR=	factor model for x	$x = \nu_x + \Lambda_x\xi + \delta$	ν_x,Λ_x,Θ_x,κ,Φ
6	XVAR=	x-structures $(x \equiv \xi)$		κ,Φ
Presence of y Variables and Absence of x Variables				
7	YVAR=, ETAVAR=	factor model for y	$y = \nu_y + \Lambda_y\eta + \epsilon$ $\eta = \alpha + \beta\eta + \zeta$	ν_y,Λ_y,Θ_y α,β,Ψ
8	YVAR=	y-structures $(y \equiv \eta)$	$y = \alpha + \beta y + \zeta$, or $(I - \beta)^{-1} y = \alpha + \zeta$	α,β,Ψ
9	YVAR=, ETAVAR=, XIVAR=	second-order factor model	$y = \nu_y + \Lambda_y\eta + \epsilon$ $\eta = \alpha + \beta\eta + \Gamma\xi + \zeta$	ν_y,Λ_y,Θ_y α,β,Γ,Ψ,κ,Φ
10	YVAR=, XIVAR=	factor model $(y \equiv \eta)$	$y = \alpha + \beta y + \Gamma\xi + \zeta$, or $(I - \beta)^{-1} y = \alpha + \Gamma\xi + \zeta$	α,β,Γ,Ψ,κ,Φ

Models 1, 2, 3, and 4 — Presence of Both x and y Variables

Submodels 1, 2, 3, and 4 are characterized by the presence of both x- and y- variables in the model. Model 1 is in fact the full model with the presence of all four types of variables. All twelve model matrices are parameter matrices in this model.

Depending on the absence of the latent factor lists, manifest variables can replace the role of the latent factors in models 2–4. For example, the absence of the ETAVAR= list in model 2 means y is equivalent to η ($y \equiv \eta$). Consequently, you cannot, nor do you need to, use the MATRIX statement to specify parameters in the _LAMBDAY_, _THETAY_, or _NUY_ matrices under this model. Similarly, because x is equivalent to ξ ($x \equiv \xi$) in model 3, you cannot, nor do you need to, use the MATRIX statement to specify the parameters in the _LAMBDAX_, _THETAX_, or _NUX_ matrices. In model 4, y is equivalent to η ($y \equiv \eta$) and x is equivalent to ξ ($x \equiv \xi$). None of the six model matrices in the measurement equations are defined in the model. Matrices in which you can specify parameters by using the MATRIX statement are listed in the last column of the table.

Describing model 4 as a regression model is a simplification. Because y can regress on itself in the model equation, the regression description is not totally accurate for model 4. Nonetheless, if β is a null matrix, the equation describes a multivariate regression model with outcome variables y and predictor variables x. This model is the TYPE 2A model in LISREL VI (Jöreskog and Sörbom, 1985).

You should also be aware of the changes in meaning of the model matrices when there is an equivalence between latent factors and manifest variables. For example, in model 4 the Φ and κ are now the covariance matrix and mean vector, respectively, of manifest variables x, while in model 1 (the complete model) these matrices are of the latent factors ξ.

Models 5 and 6 — Presence of x Variables and Absence of y Variables

Models 5 and 6 are characterized by the presence of the x-variables and the absence of y-variables.

Model 5 is simply a factor model for measured variables x, with Λ_x representing the factor loading matrix, Θ_x the error covariance matrix, and Φ the factor covariance matrix. If mean structures are modeled, κ represents the factor means and ν_x is the intercept vector. This is the TYPE 1 submodel in LISREL VI (Jöreskog and Sörbom, 1985).

Model 6 is a special case where there is no model equation. You specify the mean and covariance structures (in κ and Φ, respectively) for the manifest variables x directly. The x-variables are treated as exogenous variables in this case. Because this submodel uses direct mean and covariance structures for measured variables, it can also be handled more easily by the MSTRUCT modeling language. See the MSTRUCT statement and the section "The MSTRUCT Model" on page 6877 for more details.

Note that because η-variables cannot exist in the absence of y-variables (see one of the three aforementioned principles in deriving submodels), adding the ETAVAR= list alone to these two submodels does not generate new submodels that can be analyzed by PROC TCALIS.

Models 7, 8 ,9 and 10—Presence of y Variables and Absence of x Variables

Models 7–10 are characterized by the presence of the y-variables and the absence of x-variables.

Model 7 is a factor model for y-variables (TYPE 3B submodel in LISREL VI). It is similar to model 5, but with regressions among latent factors allowed. When β is null, model 7 functions the same as model 5. It becomes a factor model for y-variables, with Λ_y representing the factor loading matrix, Θ_y the error covariance matrix, Ψ the factor covariance matrix, α the factor means, and ν_y the intercept vector.

Model 8 (TYPE 2B submodel in LISREL VI) is a model for studying the mean and covariance structures of y-variables, with regression among y-variables allowed. When β is null, the mean structures of y are specified in α and the covariance structures are specified in Ψ. This is similar to model 6. However, there is an important distinction. In model 6, the x variables are treated as exogenous (no model equation at all). But the y-variables are treated as endogenous in model 8 (with or without $\beta = 0$). Consequently, the default parameterization would be different for these two submodels. See the section "Default Parameters in the LISMOD Model" on page 6854 for details about the default parameterization.

Model 9 represents a modified version of second-order factor model for y. It would be a standard second-order factor model when β is null. This is the TYPE 3A submodel in LISREL VI. With β being null, η represents the first-order factors and ξ represents the second-order factors. The first- and second- order factor loading matrices are Λ_y and Γ, respectively.

Model 10 is another form of factor model when β is null, with factors represented by ξ and manifest variables represented by y. However, if β is indeed a null matrix in applications, you might want to use model 5, in which the factor model specification is more direct and intuitive.

Default Parameters in the LISMOD Model

When a model matrix is defined in a LISMOD model (or submodel), you can specify fixed values or parameters for the elements in the matrix. See the MATRIX statement on page 6784 for the syntax of specification. All other unspecified elements in the model matrices will be set by default. There are two types of default parameters: one is automatic free parameters; the other is fixed zeros.

Automatic Free Parameters

Automatic additions of free parameters are done to ensure the model is properly parameterized. Each automatic parameters is prefixed with _Add and appended with an unique integer. The following rules are used to add parameters in the LISMOD model matrices:

- _THETAX_, _THETAY_, _PSI_, and _PHI_ matrices: If a matrix in this group is defined in a LISMOD submodel or full model, its diagonal elements are automatically represented by free parameters unless they are specified explicitly in the MATRIXstatements. This ensures that these covariance matrices will have nonzero variances.
- _PHI_ matrix: For LISMOD submodels with XVAR= list specified but XIVAR= unspecified, all the off-diagonal elements of the _PHI_ are automatic free parameters. In this case, because ξ and x are equivalent, its covariance matrix Φ is the covariance matrix of **exogenous**

manifest variables. Because exogenous covariances among manifest variables are not predicted as functions of any other parameters in the LISMOD model, they should be saturated by free parameters in the model unless there are theoretical reasons not to do so (for example, when you are testing a fixed pattern of these covariances). Failure to treat covariances among mainfest variables as free parameters is equivalent to fixing these values to constants, which leads to an overly restrictive model.

- _KAPPA_ matrix: For LISMOD submodels with XVAR= list specified but XIVAR= unspecified, all the elements of the _KAPPA_ vector are automatic free parameters if the mean structures are fitted. The reason for this is the same as the previous rule for adding covariance parameters among exogenous manifest variables. Exogenous manifest variables serve as explanatory variables in your model, and their means are not predicted by relationships with other variables. Unless you are also testing hypothesized mean values for the exogenous manifest variables, in general you should allow these means to be free parameters in the LISMOD model.

These three rules for automatic free parameters are in line with the treatments in the LINEQS, RAM, and PATH models. See, for example, the section "Default Parameters in the LINEQS Model" on page 6846 and the section "Rationale of the Default Parameters in the LINEQS Model" on page 6846 for details about the treatments of automatic free parameters.

Default Fixed Zeros

Matrix elements that are unspecified and are not automatic free parameters will be fixed at zeros by default.

The RAM Model

The RAM modeling language is adapted from the basic RAM model developed by McArdle (1980). For brevity, models specified by the RAM modeling language are called RAM models, although it is noted that you can also specify these so-called RAM models by other general modeling languages supported in PROC TCALIS.

Types of Variables in the RAM Model

A variable in the RAM model is manifest if it is observed and is defined in the input data set. A variable in the RAM model is latent if it is not manifest. Because error variables are not explicitly named in the RAM model, all latent variables in the RAM model are considered as factors (non-error-type latent variables).

A variable in the RAM model is endogenous if it ever serves as an outcome variable in the RAM model. That is, an endogenous variable has at least one path (or an effect) from another variable in the model. A variable is exogenous if it is not endogenous. Endogenous variables are also referred to as dependent variables, while exogenous variables are also referred to as independent variables.

In the RAM model, exogenous/endogenous and latent/manifest distinctions for variables are not essential to the definitions of model matrices, although they are useful for conceptual understanding when the model matrices are partitioned.

Naming Variables in the RAM Model

Manifest variables in the RAM model are referenced in the input data set. Their names must not be longer than 32 characters. There is no further restrictions beyond those required by the SAS system.

Latent variables in the RAM model are those not being referenced in the input data set. Their names must not be longer than 32 characters. Unlike the LINEQS model, you do not need to use any specific prefix (for example, 'F' or 'f') for the latent factor names. The reason is that error or disturbance variables in the RAM model are not named explicitly in the RAM model. Thus, any variable names that are not referenced in the input data set are for latent factors.

As a general naming convention, you should not use Intercept as either a manifest or latent variable name.

Model Matrices in the RAM Model

In terms of the number of model matrices involved, the RAM model is the simplest among all the general structural equations models supported by PROC TCALIS. Essentially, there are only three model matrices in the RAM model: one for the interrelationships among variables, one for the variances and covariances, and one for the means and intercepts. These matrices are discussed in the following.

Matrix A $(n_a \times n_a)$: Effects of Column Variables on Row Variables

The row and column variables of matrix A are the set of manifest and latent variables in the RAM model. Unlike the LINEQS model, the set of latent variables in the RAM model matrix does not include the error or disturbance variables. Each entry or element in the A matrix represents an effect of the associated column variable on the associated row variable or a path coefficient from the associated column variable to the associated row variable. A zero entry means an absence of a path or an effect.

The pattern of matrix A determines whether a variable is endogenous or exogenous. A variable in the RAM model is endogenous if its associated row in the A matrix has at least one nonzero entry. Any other variable in the RAM model is exogenous.

Mathematically, you do not need to arrange the set of variables for matrix A in a particular order, as long as the order of variables is the same for the rows and the columns. However, arranging the variables according to whether they are endogenous or exogenous is useful to show the partitions of the model matrices and certain mathematical properties. See the section "Partitions of the RAM Model Matrices and Some Restrictions" on page 6858 for details.

Matrix P ($n_a \times n_a$): Variances, Covariances, Partial Variances, and Partial Covariances

The row and column variables of matrix P refer to the same set of manifest and latent variables defined in the RAM model matrix A. The diagonal entries of P contain variances or partial variances of variables. If a variable is exogenous, then the corresponding diagonal element in the P matrix represents its variance. Otherwise, the corresponding diagonal element in the P matrix represents its partial variance. This partial variance is an unsystematic source of variance not explained by the interrelationships of variables in the model. In most cases, you can interpret a partial variance as the error variance for an endogenous variable.

The off-diagonal elements of P contain covariances or partial covariances among variables. An off-diagonal element in P associated with exogenous row and column variables represents covariance between the two exogenous variables. An off-diagonal element in P associated with endogenous row and column variables represents **partial** covariance between the two variables. This partial covariance is unsystematic, in the sense that it is not explained by the interrelationships of variables in the model. In most cases, you can interpret a partial covariance as the error covariance between the two endogenous variables involved. An off-diagonal element in P associated with one exogenous variable and one endogenous variable in the row and column represents the covariance between the exogenous variable and the error of the endogenous variable. While this interpretation sounds a little awkward and inelegant, this kind of covariance, fortunately, is rare in most applications.

Vector W ($n_a \times 1$): Intercepts and Means

The row variables of vector W refer to the same set of manifest and latent variables defined in the RAM model matrix A. Elements in W represent either intercepts or means. An element in W associated with an exogenous row variable represents the mean of the variable. An element in W associated with an endogenous row variable represents the intercept term for the variable.

Covariance and Mean Structures

Assuming that $(I - A)$ is invertible, where I is the identity matrix of the same dimension as A, the structured covariance matrix of all variables (including latent variables) in the RAM model is shown as follows:

$$\Sigma_a = (I - A)^{-1} P (I - A)^{-1\prime}$$

The structured mean vector of all variables is shown as follows:

$$\mu_a = (I - A)^{-1} W$$

The covariance and mean structures of all manifest variables are obtained by selecting the elements in Σ_a and μ_a. This can be achieved by defining a selection matrix G of dimensions $n \times n_a$, where n is the number of manifest variables in the model. The selection matrix G contains zeros and ones as its elements. Each row of G has exactly one nonzero element at the position that corresponds to the location of a manifest row variable in Σ_a or μ_a. With each row of G selecting a distinct manifest variable, the structured covariance matrix of all manifest variables is expressed as the following:

$$\Sigma = G \Sigma_a G'$$

The structured mean vector of all observed variables is expressed as the following:

$$\mu = G \mu_a$$

Partitions of the RAM Model Matrices and Some Restrictions

There are some model restrictions in the RAM model matrices. Although these restrictions do not affect the derivation of the covariance and mean structures, they are enforced in the RAM model specification.

For convenience, it is useful to assume that n_a variables are arranged in the order of n_d endogenous (or dependent) variables and the n_i exogenous (independent) variables in the rows and columns of the model matrices.

Model Restrictions on the A Matrix

The A matrix is partitioned as:

$$A = \begin{pmatrix} \beta & \gamma \\ 0 & 0 \end{pmatrix}$$

where β is an $n_d \times n_d$ matrix for paths or effects from (column) endogenous variables to (row) endogenous variables and γ is an $n_d \times n_i$ matrix for paths or effects from (column) exogenous variables to (row) endogenous variables.

As shown in the matrix partitions, there are four submatrices. The two at the lower parts are seemingly structured to zeros. However, this should not be interpreted as restrictions imposed by the model. The zero submatrices are artifacts created by the exogenous-endogenous arrangement of the row and column variables. The only restriction on the A matrix is that the diagonal elements must all be zeros. This implies that the diagonal elements of the submatrix β are also zeros. This restriction prevents a direct path from any endogenous variable to itself. There are no restrictions on the pattern of γ.

Partition of the P Matrix

The P matrix is partitioned as:

$$P = \begin{pmatrix} P_{11} & P_{21}' \\ P_{21} & P_{22} \end{pmatrix}$$

where P_{11} is an $n_d \times n_d$ partial covariance matrix for the endogenous variables, P_{22} is an $n_i \times n_i$ covariance matrix for the exogenous variables, and P_{21} is an $n_i \times n_d$ covariance matrix between the exogenous variables and the error terms for the endogenous variables. Because P is symmetric, P_{11} and P_{22} are also symmetric.

There are virtually no model restrictions placed on these submatrices. However, in most statistical application, errors for endogenous variables represent unsystematic sources of effects and therefore they are not to be correlated with other systematic sources such as the exogenous variables in the RAM model. This means that in most practical applications P_{21} would be a null matrix, although this is not enforced in PROC TCALIS.

Partition of the W Vector

The W vector is partitioned as:

$$W = \begin{pmatrix} \alpha \\ \nu \end{pmatrix}$$

where α is an $n_d \times 1$ vector for intercepts of the endogenous variables and ν is an $n_i \times 1$ vector for the means of the exogenous variables. There is no model restriction on these subvectors.

Summary of Matrices and Submatrices in the RAM Model

Let n_a be the total number of manifest and latent variables in the RAM model. Of these n_a variables, n_d are endogenous and n_i are exogenous. Suppose that the rows and columns of the RAM model matrices A and P and the rows of W are arranged in the order of n_d endogenous variables and then n_i exogenous variables. The names, roles, and dimensions of the RAM model matrices and submatrices are summarized in the following table:

Matrix	Name	Description	Dimensions
Model Matrices			
A	_A_ or _RAMA_	effects of column variables on row variables, or paths from the column variables to the row variables	$n_a \times n_a$
P	_P_ or _RAMP_	(partial) variances and covariances	$n_a \times n_a$
W	_W_ or _RAMW_	intercepts and means	$n_a \times 1$
Submatrices			
β	_RAMBETA_	effects of endogenous variables on endogenous variables	$n_d \times n_d$
γ	_RAMGAMMA_	effects of exogenous variables on endogenous variables	$n_d \times n_i$
P_{11}	_RAMP11_	error variances and covariances for endogenous variables	$n_d \times n_d$
P_{21}	_RAMP21_	covariances between exogenous variables and error terms for endogenous variables	$n_d \times n_i$
P_{22}	_RAMP22_	variances and covariances for exogenous variables	$n_i \times n_i$
α	_RAMALPHA_	intercepts for endogenous variables	$n_d \times 1$
ν	_RAMNU_	means for exogenous variables	$n_i \times 1$

Specification of the RAM Model

In PROC CALIS, the RAM model specification is a matrix-oriented modeling language. That is, you have to define the row and column variables for the model matrices and specify the parameters in terms of matrix entries. This is not the case in PROC TCALIS. You no longer need to specify the RAM model parameters as matrix entries. Instead, you specify the model by using the variable names directly. Representing the RAM model matrices is done internally by PROC TCALIS.

To specify the RAM model parameters, you use the RAM statement to list each parameter location. There are three types of parameter listings, which correspond to the elements in the three model matrices. The three types of parameter listings are described in the following.

(1) Specification of Effects or Paths in Model Matrix A

If in your model there is a path from V2 to V1 and the associated effect parameter is named parm1 with 0.5 as the starting value, you can use one of the following list-entries of the RAM statement to specify this parameter location:

```
_A_      V1     V2   parm1  (0.5),
path     V1 <-  V2   parm1  (0.5),
path     V2 ->  V1   parm1  (0.5),
```

(2) Specification of (Partial) Variances and (Partial) Covariances in Model Matrix P

If V2 is an exogenous variable in the RAM model and you want to specify its variance as a parameter named parm2 with 10 as the starting value, you can use one of the following list-entries of the RAM statement:

```
_P_      V2     V2   parm2  (10.),
pvar     V2          parm2  (10.),
```

If V1 is an endogenous variable in the RAM model and you want to specify its partial variance or error variance as a parameter named parm3 with 5 as the starting value, you can use one of the following list-entries of the RAM statement:

```
_P_      V1     V1   parm3  (5.),
pvar     V1          parm3  (5.),
```

Notice that this partial variance specification has the same format as that for the variance parameter of an exogenous variable.

If you want to specify (partial) covariance between two variables V3 and V4 as a parameter named parm4 with 5 as the starting value, you can use one of the following list-entries of the RAM statement:

```
_P_      V3     V4   parm4  (5.),
pcov     V3     V4   parm4  (5.),
```

(3) Specification of Means and Intercepts in Model Matrix _W_

Means and intercepts are specified when the mean structures of the model are of interest. If V5 is an exogenous variable and you want to specify its mean as a parameter named parm5 with 11 as the starting value, you can use one of the following list-entries of the RAM statement:

```
_W_      V5    parm5  (11.),
mean     V5    parm5  (11.),
```

If V6 is an endogenous variable and you want to specify its intercept as a parameter named parm6 with 7 as the starting value, you can use one of the following list-entries of the RAM statement:

```
_W_          V6    parm6  (7.),
intercept    V6    parm6  (7.),
```

Note that this specification bears the same format as that for the mean parameter of an exogenous variable.

Specifying Parameters without Initial Values

If you do not have any knowledge about the initial value for a parameter, you can omit the initial value specification and let PROC TCALIS to compute it. For example, you can just provide the parameter locations and parameter names as shown in the following specifications:

```
_A_          V1     V2   parm1,
intercept    V6          parm6,
```

Specifying Fixed Parameter Values

If you want to specify a fixed parameter value, you do not need to provide the parameter name. Instead, you just provide the fixed value without parentheses at the end of the list-entry. The following shows examples for specifying fixed parameters:

```
_PCOV_       V3   V4     5.,
mean         V5          11.,
```

A Complete RAM Model Specification Example

Essentially, you can specify all parameters and their locations of the RAM model in the RAM statement. No subsidiary model specification statements are needed in the RAM model—that is, all information regarding the model is specified in the RAM statement. Each parameter location specification is a list-entry in the RAM statement, and these list-entries are separated by commas. For example,

```
ram
   path     V1 <-  V2   parm1  (.5),
   path     V1 <-  V3   parm2      ,
   pvar     V1          errv   (1.),
   pvar     V2          parm3  (10.),
   pvar     V3          parm4  (10.),
   pcov     V3     V2   parm5  (5.);
```

Notice that although the order of the list-entries is not critical to the model specification, it is the same order that is used in output displays. See the RAM statement on page 6805 for more details about the syntax.

Default Parameters in the RAM Model

The effect of any variable on itself is restricted to zero in the RAM model. In other words, it is invalid to specify:

```
ram
   path     V1  <-  V1  parm;
```

In matrix terms, you cannot have any nonzero diagonal element in the β submatrix. All other elements in the RAM model matrices can be specified as free or fixed parameters.

If an element in a model matrix is not subject to model restrictions and is not specified explicitly, a default parameter will be applied to the location. There are two types of default parameters: one is automatic free parameter; and the other is fixed zero.

Automatic Free Parameters

The set of automatic parameters in the RAM model is essentially derived in the same way as those in the LINEQS model. That is, in the LINEQS model the set of automatic parameters includes the variances of and covariances among manifest exogenous variables, the means of manifest exogenous variables when the mean structures are modeled, and the variances of all exogenous latent variables (factors and errors). All these automatic free parameters are applied similarly to the RAM model.

The only difficulty about this generalization is the definition of error variances in the RAM model. Unlike the LINEQS model, error terms in the RAM model are not named explicitly. The question is what the error variances in the LINEQS model correspond to in the RAM model. As described previously, error variances in the RAM model are recast as the partial variances of the corresponding endogenous variables. As a result, the set of automatic parameters in the RAM model includes the variances or partial variances of all variables—that is, variances when the variables are exogenous, partial variances when the variables are endogenous.

As in the LINEQS model, the reason for automatic parameter generation is to safeguard a proper RAM model specification. See the section "Rationale of the Default Parameters in the LINEQS Model" on page 6846 for a more detailed discussion.

In terms of the RAM model matrices, the set of automatic parameters in the RAM model includes:

- all P matrix diagonal elements, which are either variances of exogenous variables (manifest or latent) or partial variances of endogenous variables (manifest or latent)
- those P matrix off-diagonal elements with their rows and columns corresponding to manifest exogenous variables
- those W matrix elements with their rows corresponding to manifest exogenous variables, provided that the mean structures are modeled

Each of these automatic mean, intercept, variance, partial variance, covariance, and partial covariance parameters is named with the prefix _Add, and appended with an unique integer.

Default Fixed Zeros

All unspecified parameter locations that are neither model-restricted nor automatic free parameters in the RAM model matrices are fixed zeros by default.

Relating the RAM Model to the PATH Model

The mathematical model for the RAM and the PATH modeling languages is the same. As a result, the two modeling languages are also quite similar in their syntax. See the section "Relating the PATH Model to the RAM Model" on page 6876 for details.

The FACTOR Model

The FACTOR modeling language is used for specifying exploratory and confirmatory factor-analysis models. You can use other general modeling languages such as LINEQS, LISMOD, PATH, and RAM to specify a factor model. But the FACTOR modeling language is more convenient for specifying factor models and is more specialized in outputting factor-analytic results. For convenience, models specified by the FACTOR modeling language are called FACTOR models.

Types of Variables in the FACTOR Model

Each variable in the FACTOR model is either manifest or latent. Manifest variables are those variables that are measured in the research. They must be present in the input data set. Latent variables are not measured. Each latent variable in the FACTOR model can either be a factor or an error term.

Factors are unmeasured hypothetical constructs for explaining the covariances among manifest variables, while errors are the unique parts of the manifest variables that are not explained by the (common) factors.

In the FACTOR model, all manifest variables are endogenous, which means that they are predicted from the latent variables. In contrast, all latent variables in the FACTOR model are exogenous, which means that they serve as predictors only.

Naming Variables in the FACTOR Model

Manifest variables in the FACTOR model are referenced in the input data set. In the FACTOR model specification, you use their names as they appear in the input data set. Manifest variable names must not be longer than 32 characters. There are no further restrictions on these names beyond those required by the SAS system.

Error variables in the FACTOR model are not named explicitly, although they are assumed in the model. You can name latent factors only in confirmatory FACTOR models. Factor names must not be longer than 32 characters and must be distinguishable from the manifest variable names in the

same analysis. You do not need to name factors in exploratory FACTOR models, however. Latent factors named Factor1, Factor2, and so on are generated automatically in exploratory FACTOR models.

Model Matrices in the FACTOR Model

Suppose in the FACTOR model that there are p manifest variables and n factors. The FACTOR model matrices are summarized as follows:

Matrix F $(p \times n)$: Factor Loading Matrix

The rows of F represent the p manifest variables, while the columns represent the n factors. Each row of F contains the factor loadings of a variable on all factors in the model.

Matrix P $(n \times n)$: Factor Covariance Matrix

The P matrix is a symmetric matrix for the variances of and covariances among the n factors.

Matrix U $(p \times p)$: Error Covariance Matrix

The U matrix represents an $p \times p$ diagonal matrix for the error variances for the manifest variables. Elements in this matrix are the parts of variances of the manifest variables that are not explained by the common factors. Note that all off-diagonal elements of U are fixed zeros in the FACTOR model.

Vector a $(p \times 1)$: Intercepts

If the mean structures are analyzed, vector a represents the intercepts of the manifest variables.

Vector v $(n \times 1)$: Factor Means

If the mean structures are analyzed, vector v represents the means of the factors.

Matrix Representation of the FACTOR Model

Let y be a $p \times 1$ vector of manifest variables, ξ be an $n \times 1$ vector of latent factors, and e be a $p \times 1$ vector of errors. The factor model is written as:

$$y = a + F\xi + e$$

With the model matrix definitions in the previous section, the covariance matrix Σ $(p \times p)$ of manifest variables is structured as:

$$\Sigma = FPF' + U$$

The mean vector μ $(p \times p)$ of manifest variables is structured as:

$$\mu = a + Fv$$

Exploratory Factor Analysis Models

So far confirmatory and exploratory models are not distinguished in deriving the covariance and mean structures. These two types of models are now distinguished in terms of the required structures or restrictions in model matrices.

Traditionally, exploratory factor analysis is applied when the relationships of manifest variables with factors have not been well-established in research. All manifest variables are allowed to have nonzero loadings on the factors in the model. First, factors are extracted and an initial solution is obtained. Then, for ease of interpretation a final factor solution is usually derived by rotating the factor space. Factor-variable relationships are determined by interpreting the final factor solution. This is different from the confirmatory factor analysis in which the factor-variable relationships are prescribed and to be confirmed.

Nonetheless, in terms of initial model fitting, exploratory factor analysis is not different from confirmatory factor analysis. In PROC TCALIS, the initial exploratory factor solution is obtained from a specific confirmatory factor model with restricted model matrices, which are described as follows:

- The factor loading matrix F has $p \times (n-1)/2$ fixed zeros at the upper triangle portion of the matrix.
- The factor covariance matrix P is an identity matrix, which means that factors are not correlated.
- The error covariance matrix U is a diagonal matrix.
- The mean structures are not modeled. That is, no specification in a or v vector is allowed.

For example, for an analysis with nine variables and three factors, the relevant model matrices of an exploratory FACTOR model have the following patterns:

$$F = \begin{pmatrix} * & 0 & 0 \\ * & * & 0 \\ * & * & * \\ * & * & * \\ * & * & * \\ * & * & * \\ * & * & * \\ * & * & * \\ * & * & * \end{pmatrix}$$

$$P = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

and

$$U = \begin{pmatrix} * & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & * & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & * & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & * & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & * & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & * & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & * & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * \end{pmatrix}$$

where * denotes free parameters in the model matrices.

It is emphasized that most of these patterns are put on the initial factor solutions only. If an initial factor solution is rotated afterward, only the pattern of the error covariance matrix U remains unchanged. That is, it is still a diagonal matrix after rotation. In general, rotating a factor solution will eliminate the fixed zero pattern in the upper triangle of the factor loading matrix F. If you apply an orthogonal rotation, the factor covariance matrix P will not change. It is an identity matrix before and after rotation. However, if you apply an oblique rotation, in general the rotated factor covariance matrix P will not be an identity matrix and the off-diagonal elements will not be zeros.

Confirmatory Factor-Analysis Models

In confirmatory FACTOR models, there are no imposed patterns on the F, P, a, and v model matrices. All elements in these model matrices can be specified. However, for model identification, you might need to specify some factor loadings or factor variances as constants.

The only model restriction in confirmatory FACTOR models is placed on U, which must be a diagonal matrix, as in exploratory FACTOR models too.

For example, for a confirmatory factor analysis with nine variables and three factors, you might specify the following patterns for the model matrices:

$$F = \begin{pmatrix} 1 & 0 & 0 \\ * & 0 & 0 \\ * & 0 & 0 \\ 0 & 1 & 0 \\ 0 & * & 0 \\ 0 & * & 0 \\ 0 & 0 & 1 \\ 0 & 0 & * \\ 0 & 0 & * \end{pmatrix}$$

$$P = \begin{pmatrix} * & * & * \\ * & * & * \\ * & * & * \end{pmatrix}$$

and

$$U = \begin{pmatrix} * & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & * & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & * & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & * & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & * & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & * & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & * & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * \end{pmatrix}$$

where * denotes free parameters in the model matrices.

In this confirmatory factor model, mean structures are not modeled. In addition, there are some distinctive features that underscore the differences between confirmatory and exploratory models:

- Factor loading matrix F contains mostly zero elements and few nonzero free parameters, a pattern which is seen in most confirmatory factor models. In contrast, in exploratory factor models most elements in the F matrix are nonzero parameters.
- Factor loading matrix F contains fixed values of ones. These fixed values are used for model identification purposes (that is, identifying the scales of the latent variables). In general, you always have to make sure that your confirmatory factor models are identified by putting fixed values in appropriate parameter locations in the model matrices. However, this is not a concern in exploratory FACTOR models because identification has been ensured by imposing certain patterns on the model matrices.
- The nonzero off-diagonal parameters in the factor covariance matrix P indicate that correlated factors are hypothesized in the confirmatory factor model. This cannot be the case with the initial model of exploratory FACTOR models, where the P matrix must be an identity matrix before rotation.

Summary of Matrices in the FACTOR Model

Let p be the number of manifest variables and n be the number of factors in the FACTOR model. The names, roles, and dimensions of the FACTOR model matrices are shown in the following table:

Matrix	Name	Description	Dimensions
F	_FACTLOAD_	factor loading matrix	$p \times n$
P	_FACTFCOR_	factor covariance matrix	$n \times n$
U	_FACTERRV_	error covariance matrix	$p \times p$
a	_FACTINTE_	intercepts	$p \times 1$
v	_FACTMEAN_	factor means	$n \times 1$

Specification of the Exploratory Factor Model

Because all initial model matrices of exploratory FACTOR models are predefined in PROC TCALIS, you do not need to specify any other parameters in the model matrices. To obtain desired factor solutions, you can use various options for exploratory factor analysis in the FACTOR statement. These options are the *EFA_options* in the FACTOR statement. Two main types of *EFA_options* are shown as follows:

- options for factor extraction: COMPONENT, HEYWOOD, N=.
- options for factor rotation: GAMMA=, NORM=, RCONVERGE=, RITER=, ROTATE=, TAU=.

For example, the following statement requests that three factors are extracted, followed by a varimax rotation of the initial factor solution:

```
factor n=3 rotate=varimax;
```

See the FACTOR statement on page 6752 for details about the *EFA_options*.

Specification of the Confirmatory Factor Model

To specify a confirmatory FACTOR model, you specify the factor-variable relationships in the FACTOR statement, the factor variances and error variances in the PVAR statement, the factor covariances in the COV statement, and the means and intercepts in the MEAN statement.

Specification of Factor-Variable Relationships

The *CFA_spec* in the FACTOR statement is for specifying the factor-variables relationships. For example, in the following statement you specify three factors F1, F2, and F3 that are related to different clusters of observed variables V1–V9:

```
factor
   F1  -> V1-V3  = 1. parm1 (.4) parm2 (.4),
   F2  -> V4-V6  = 1. parm3 parm4,
   F3  -> V7-V9  = 1. parm5 parm6 (.3);
```

In the specification, variable V1 has a fixed loading of 1.0 on F1. Variables V2 and V3 have loadings on F1 also. These two loadings are free parameters named parm1 and parm2, respectively. Initial estimates can be set in parentheses after the free parameters. For example, both parm1 and parm2 have initial values at 0.4. Similarly, relationships of factor F2 with V4–V6, and of factor F3 with V7–V9 are defined in the same FACTOR statement. Providing initial estimates for parameters is optional. In this example, parm3, parm4, and parm5 are all free parameters without initial values provided. PROC TCALIS can determine appropriate initial estimates for these parameters. See the descriptions about *CFA_spec* in the FACTOR statement on page 6752 for more details about the syntax.

Specification of Factor Variances and Error Variances

You can specify the factor variances and error variances in the PVAR statement. For example, consider the following statement:

```
pvar F1–F3  = fvar1–fvar3,
     V1–V9  = evar1–evar9 (9*10.);
```

In the PVAR statement, you specify the variances of factors F1, F2, and F3 as free parameters fvar1, fvar2, and fvar3, respectively; and the error variances for manifest variables V1–V9 as free parameters evar1–evar9, respectively. Each of the error variance parameters is given a starting value at 10. See the PVAR statement on page 6803 for more details about the syntax.

Specification of Factor Covariances

You can specify the factor covariances in the COV statement. For example, you specify the covariances among factors F1, F2, and F3 in the following statement:

```
cov F1 F2  = cov12,
    F1 F3  = cov13,
    F2 F3  = cov23;
```

The covariance parameters are named cov12, cov13, and cov23, respectively. They represent the lower triangular elements of the factor covariance matrix P. See the COV statement on page 6802 for more details about the syntax.

Specification of Means and Intercepts

If mean structures are of interest, you can also specify the factor means and the intercepts for the manifest variables in the MEAN statement. For example, consider the following statement:

```
mean F1–F3 = fmean1–fmean3,
     V1–V9 = 9*12.;
```

In this statement, you specify the factor means of F1, F2, and F3 as free parameters fmean1, fmean2, and fmean3, respectively; and the intercepts for variables V1–V9 as fixed parameters at 12. See the MEAN statement on page 6788 for more details about the syntax.

Default Parameters in the FACTOR Model

In the initial exploratory FACTOR model, all fixed and free parameters of the model are prescribed or set by default. These prescribed or default parameters include a fixed pattern for the factor loading matrix F, a diagonal pattern for the error variance matrix U, and an identity matrix for factor covariance matrix P. See the section "Exploratory Factor Analysis Models" on page 6865 for more details about the patterns of the exploratory FACTOR model.

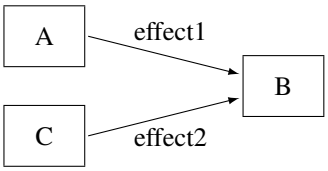
In the confirmatory FACTOR model, the error covariance matrix U is restricted to be a diagonal matrix. In other words, covariances of errors are restricted to zeros. Other than that, you can specify any other parameter locations in the all model matrices. These includes all the parameter locations

in the factor loading matrix F, the factor covariance matrix P, the diagonal of the error covariance matrix U, the factor mean vector v, and the intercept vector a. If any of these parameter locations are not specified, default parameters are applied. There are two types of default parameters: one is automatic free parameter, and the other is fixed zero.

Automatic Free Parameters

The set of automatic free parameters in the confirmatory FACTOR model are:

- the variances of factors; that is, the diagonal elements of the factor covariance matrix P
- the error variances for the manifest variables; that is, the diagonal elements of the error covariance matrix U



Each automatic free parameter is named with prefix _Add and appended with a unique integer. The reason for automatic parameter generation is to safeguard a proper FACTOR model specification. See the section "Rationale of the Default Parameters in the LINEQS Model" on page 6846 for a more detailed explanation.

Default Fixed Zeros

All unspecified parameter locations that are neither model-imposed specifications nor automatic free parameters in the confirmatory FACTOR model matrices are fixed zeros by default.

The PATH Model

The PATH modeling language is supported in PROC TCALIS as a more intuitive modeling tool. It is designed so that specification by using the PATH modeling language translates effortlessly from the path diagram. For example, given the following simple path diagram:

you can use the PATH statement to specify the paths easily:

```
path    A -> B   effect1,
        C -> B   effect2;
```

In the first entry of the PATH statement, the path A –> B is specified. The associated path coefficient or effect is named effect1. Similarly, in the second entry, the C –> B path is specified with effect2 as the associated effect parameter. In addition to the path coefficients or effects in the path diagram,

you can also specify other types of parameters by using the PVAR and PCOV statements. See the section "A Structural Equation Example" on page 6704 for a more detailed example of the PATH model specification.

Despite its simple representation of the path diagram, the PATH modeling language is general enough to handle a wide class of structural models that can also be handled by other general modeling languages such as LINEQS, LISMOD, or RAM. For brevity, models specified by the PATH modeling language are called PATH models.

Types of Variables in the PATH Model

When you specify the paths in the PATH model, you typically use arrows (such as <– or –>) to denote "causal" paths. For example, in the preceding path diagram or the PATH statement, you specify that B is an outcome variable with predictors A and C, respectively in two paths. An outcome variable is the variable being pointed to in a path specification, while the predictor variable is the one where the arrow starts from.

Whereas the outcome–predictor relationship describes the roles of variables in each single path, the endogenous–exogenous relationship describes the roles of variables in the entire system of paths. In a system of path specification, a variable is endogenous if it is pointed to by at least one arrow or it serves as an outcome variable in a path at least once. Otherwise, it is exogenous. In the preceding path diagram, for example, variable B is endogenous and both variables A and C are exogenous. Note that although any variable that serves as an outcome variable at least in one path must be endogenous, it does not mean that all endogenous variables must serve only as outcome variables in all paths. An endogenous variable in a model might also serve as a predictor variable in a path. For example, variable B in the following PATH statement is an endogenous variable, and it serves as an outcome variable the first path but as a predictor variable in the second path.

```
path    A -> B   effect1,
        B -> C   effect2;
```

A variable is a manifest or observed variable in the PATH model if it is measured and exists in the input data set. Otherwise, it is a latent variable. Because error variables are not explicitly defined in the PATH modeling language, all latent variables that are named in the PATH model are *factors*, which are considered to be the systematic source of effects in the model. Any manifest variable in the PATH model can be endogenous or exogenous. This same is true for any latent factor in the PATH model.

Because you do not name error variables in the PATH model, you do not need to specify paths from errors to any endogenous variables. Error terms are implicitly assumed for all endogenous variables in the PATH model. If error variables are not named, how can one specify the error variance parameters? In the PATH model, error variances are expressed equivalently as partial variances for the associated endogenous variables. These partial variances are set by default in the PATH modeling language. Therefore, you do not need to specify error variance parameters explicitly unless constraints on these parameters are required in the model. You can use the PVAR statement to specify the error variance or partial variance parameters explicitly.

Naming Variables in the PATH Model

Manifest variables in the PATH model are referenced in the input data set. Their names must not be longer than 32 characters. There is no further restrictions beyond those required by the SAS system. You use the names of manifest variables directly in the PATH model specification.

Because you do not name error variables in the PATH model, all latent variables named in the PATH model specification are factors (non-errors). Factor names in the PATH model must not be longer than 32 characters, and they should be different from the manifest variables. Unlike the LINEQS model, you do not need to use any specific prefix for the latent factor names in the PATH model.

As a general naming convention, you should not use Intercept as either a manifest or latent variable name.

Specification of the PATH Model

(1) Specification of Effects or Paths

You specify the "causal" paths or linear functional relationships among variables in the PATH statement. For example, in your model there is a path from v2 to v1 and the effect parameter is named parm1 with a starting value at 0.5, you can use either of these specifications:

```
path     v1 <-  v2   parm1  (0.5);
path     v2 ->  v1   parm1  (0.5);
```

If you have more than one path in your model, path specifications should be separated by commas, as shown in the following PATH statement:

```
path
   v1 <-  v2   parm1  (0.5),
   v2 <-  v3   parm2  (0.3);
```

Because the PATH statement can be used only once in each model specification, all paths in the model must be specified together in a single PATH statement. See the PATH statement on page 6799 for more details about the syntax.

(2) Specification of Variances and Partial (Error) Variances

If v2 is an exogenous variable in the PATH model and you want to specify its variance as a parameter named parm2 with a starting value at 10, you can use the following PVAR statement specification:

```
pvar     v2  = parm2 (10.);
```

If v1 is an endogenous variable in the PATH model and you want to specify its partial variance or error variance as a parameter named parm3 with a starting value at 5.0, you can also use the following PVAR statement specification:

```
pvar     v1 = parm3 (5.0);
```

Therefore, the PVAR statement can be used for both exogenous and endogenous variables. When a variable in the statement is exogenous (which can be automatically determined by PROC TCALIS), you are specifying the variance parameter of the variable. Otherwise, you are specifying the partial or error variance for an endogenous variable.

If you have more than one variance or partial variance parameters to specify in your model, you can put a variable list on the left-hand side of the equal sign, and a parameter list on the right-hand side, as shown in the following PVAR statement specification:

```
pvar
   v1 v2 v3 = parm1 (0.5) parm2 parm3;
```

In the specification, variance or partial variance parameters for variables v1–v3 are parm1, parm2, and parm3, respectively. Only parm1 is given an initial value at 0.5. The initial values for other parameters are generated by PROC TCALIS.

You can also separate the specifications into several entries in the PVAR statement. Entries should be separated by commas. For example, the preceding specification is equivalent to the following specification:

```
pvar
   v1 = parm1 (0.5),
   v2 = parm2,
   v3 = parm3;
```

Because the PVAR statement can be used only once in each model specification, all variance and partial variance parameters in the model must be specified together in a single PVAR statement. See the PVAR statement on page 6803 for more details about the syntax.

(3) Specification of Covariances and Partial Covariances

If you want to specify (partial) covariance between two variables v3 and v4 as a parameter named parm4 with a starting value at 3, you can use the following PCOV statement specification:

```
pcov  v3  v4 = parm4 (5.);
```

Whether parm4 is a covariance or partial covariance parameter depends on the variables types of v3 and v4. If both v3 and v4 are exogenous variables (manifest or latent), parm4 is a covariance parameter between v3 and v4. If both v3 and v4 are endogenous variables (manifest or latent), parm4 is a parameter for the covariance between the errors for v3 and v4. In other words, it is a partial covariance or error covariance parameter for v3 and v4.

A less common case is when one of the variables is exogenous and the other is endogenous. In this case, parm4 is a parameter for the partial covariance between the endogenous variable and the exogenous variable, or the covariance between the error for the endogenous variable and the exogenous variable. Fortunately, such covariances are relatively uncommon in statistical modeling. Their uses confuse the roles of systematic and unsystematic sources in the model and lead to difficulties in interpretations. Therefore, you should almost always avoid this kind of partial covariances.

Like the syntax of the PVAR statement, you can specify a list of (partial) covariance parameters in the PCOV statement. For example, consider the following statement:

```
pcov
   v1 v2 = parm4,
   v1 v3 = parm5,
   v2 v3 = parm6;
```

In the specification, three (partial) covariance parameters parm4, parm5, and parm6 are specified, respectively, for the variable pairs (v1,v2), (v1,v3), and (v2,v3). Entries for (partial) covariance specification are separated by commas.

Because the PCOV statement can only be used once in each model specification, all covariance and partial covariance parameters in the model must be specified together in a single PCOV statement. See the PCOV statement on page 6802 for more details about the syntax.

(4) Specification of Means and Intercepts

Means and intercepts are specified when the mean structures of the model are of interest. You can specify mean and intercept parameters in the MEAN statement. For example, consider the following statement:

```
mean     V5 = parm5   (11.);
```

If V5 is an exogenous variable (which is determined by PROC TCALIS automatically), you are specifying parm5 as the mean parameter of V5. If V5 is an endogenous variable, you are specifying parm5 as the intercept parameter for V5.

Because each named variable in the PATH model is either exogenous or endogenous (exclusively), each variable in the PATH model would have either a mean or an intercept parameter (but not both) to specify in the MEAN statement. Like the syntax of the PVAR statement, you can specify a list of mean or intercept parameters in the MEAN statement. For example, in the following statement you specify a list of mean or intercept parameters for variables v1-v4:

```
mean
   v1-v4 = parm6-parm9;
```

This specification is equivalent to the following specification with four entries of parameter specifications:

```
mean
   v1 = parm6,
   v2 = parm7,
   v3 = parm8,
   v4 = parm9;
```

Again, entries in the MEAN statement must be separated by commas, as shown in the preceding statement.

Because the MEAN statement can only be used once in each model specification, all mean and intercept parameters in the model must be specified together in a single MEAN statement. See the MEAN statement on page 6788 for more details about the syntax.

Specifying Parameters without Initial Values

If you do not have any knowledge about the initial value for a parameter, you can omit the initial value specification and let PROC TCALIS compute it. For example, you can just provide the parameter locations and parameter names as in the following specification:

```
path    v1 <- v2   parm1;
   pvar v2 = parm2,
        v1 = parm3;
```

Specifying Fixed Parameter Values

If you want to specify a fixed parameter value, you do not need to provide a parameter name. Instead, you provide the fixed value (without parentheses) in the specification.

For example, the path coefficient for the path is fixed at 1.0 and the (partial) variance of F1 is also fixed at 1.0.

```
path    v1 <- F1  1.;
   pvar
        F1 = 1.;
```

A Complete PATH Model Specification Example

To show a more complete PATH model specification, the RAM model example in the section "A Complete RAM Model Specification Example" on page 6861 is translated into the PATH model specification in the following statements:

```
path     v1 <-  v2   parm1  (.5),
         v1 <-  v3   parm2      ;
   pvar  v1 = errv   (1.),
         v2 = parm3  (10.),
         v3 = parm4  (10.);
   pcov  v3 v2 =  parm5  (5.);
```

The PATH model specification is very much the same as the RAM model specification. All paths specified in the RAM model are translated into specification in the PATH statement. All other specification are translated into the PVAR, PCOV, and MEAN statements.

Default Parameters in the PATH Model

The treatment of restricted and default parameters in the PATH model is essentially the same as that of the RAM model (see the section "Default Parameters in the RAM Model" on page 6862).

The PATH model does not allow the specification of the effect of any variable on itself. In other words, it is invalid to specify the following:

```
path     v1  <-  v1  parm;
```

The coefficient for such a path is always zero, meaning that the path should not exist in any PATH model. Other than this restriction, any other parameters supported by the PATH model can be specified in the PATH, PVAR, PCOV, and the MEAN statements. If a parameter location in the PATH model is not specified, a default parameter will be applied to that location. There are two types of default parameters: one is automatic free parameters, and the other is fixed zeros.

Automatic Free Parameters

The set of automatic free parameters in the PATH model is derived essentially in the same way as in the RAM or LINEQS model. That is, automatic free parameters of the PATH model include:

- the variances or partial (or error) variances of all variables, manifest or latent. Consequently, all possible variance or partial variance parameters that can be specified in the PVAR statement are automatic free parameters unless explicitly specified otherwise.
- the means of exogenous manifest variables when the mean structures are modeled. That is, all mean parameters pertaining to exogenous manifest variables that can be specified in the MEAN statement are automatic free parameters unless explicitly specified otherwise.
- the covariances among all exogenous manifest latent variables. That is, all covariance parameters pertaining to all possible pairs of exogenous manifest variables that can be specified in the PCOV statement are automatic free parameters unless explicitly specified otherwise.

The reason for automatic parameter generation is to safeguard a proper PATH model specification. See the section "Rationale of the Default Parameters in the LINEQS Model" on page 6846 for a more detailed explanation.

An automatic parameter name is generated by PROC TCALIS for each of these automatic mean, intercept, variance, partial variance, covariance, and partial covariance parameters. Each automatic parameter name is prefixed with _Add and appended with a unique integer.

Default Fixed Zeros

All unspecified parameter locations that are neither set by model-restricted values nor generated with automatic free parameters in the PATH model are fixed zeros by default.

Relating the PATH Model to the RAM Model

Mathematically, the PATH model is essentially the RAM model. You can consider the PATH model to share exactly the same set of model matrices as in the RAM model. See the section "Model Matrices in the RAM Model" on page 6856 and the section "Summary of Matrices and Submatrices in the RAM Model" on page 6859 for details about the RAM model matrices. In the RAM model, the A matrix contains effects or path coefficients for describing relationships among variables. In the PATH model, you specify these effect or coefficient parameters in the PATH statement. The P matrix in the RAM model contains (partial) variance and (partial) covariance parameters. In the PATH model, you use the PVAR and PCOV statements to specify these parameters. The W vector

in the RAM model contains the mean and intercept parameters, while in the PATH model you use the MEAN statement to specify these parameters. By using these model matrices in the PATH model, the covariance and mean structures are derived in the same way as that of the RAM model. See the section "The RAM Model" on page 6855 for derivations of the model structures.

Because the mathematical model behind the PATH and the RAM modeling languages are essentially the same, it is no wonder that the PATH and the RAM syntax for model specification resemble to each other. That is, all path specifications in the PATH statement translate into the PATH *list-entries* of the RAM statement. All PVAR, PCOV, and MEAN specifications of the PATH model translate into the PVAR, PCOV, and MEAN (or INTERCEPT) *list-entries*, respectively, in the RAM statement.

The MSTRUCT Model

In contrast to other modeling languages where the mean and covariance structures are implied from the specification of equations, paths, variable-factor relations, mean parameters, variance parameters, or covariance parameters, the MSTRUCT modeling language is supported in PROC TCALIS for modeling mean and covariance structures directly.

A simple example for using the MSTRUCT modeling language is the testing of a covariance model with equal variances and covariances. Suppose that a variable was measured five times in an experiment. The covariance matrix of these five measurements is hypothesized to have the following structure:

$$\Sigma = \Sigma(\theta)$$

where

$$\theta = (\phi, \tau)$$

and

$$\Sigma(\theta) = \begin{pmatrix} \phi & \tau & \tau & \tau & \tau \\ \tau & \phi & \tau & \tau & \tau \\ \tau & \tau & \phi & \tau & \tau \\ \tau & \tau & \tau & \phi & \tau \\ \tau & \tau & \tau & \tau & \phi \end{pmatrix}$$

For model structures that are hypothesized directly on the covariance matrix, the MSTRUCT modeling language is the most convenient to use. You can also use other general modeling languages such as LINEQS, PATH, or RAM to fit the same model structures, but the specification is less straightforward and more error-prone. For convenience, models specified using the MSTRUCT modeling language are called MSTRUCT models.

Model Matrices in the MSTRUCT Model

Suppose that there are p observed variables. The two model matrices, their names, their roles, and their dimensions are summarized in the following table:

Matrix	Name	Description	Dimensions
Σ	_COV_ or _MSTRUCTCOV_	structured covariance matrix	$p \times p$
μ	_MEAN_ or _MSTRUCTMEAN_	structured mean vector	$p \times 1$

Specification of the MSTRUCT Model

Specifying Variables

In the MSTRUCT statement, you specify the list of p manifest variables of interest in the VAR= list. For example, you specify v1–v5 as the variables analyzed in your MSTRUCT model by this statement:

```
mstruct VAR= v1 v2 v3 v4 v5;
```

See the MSTRUCT statement on page 6792 for details about the syntax.

The manifest variables in the VAR= list must be referenced in the input set. The number of variables in the VAR= list determines the dimensions of the _COV_ and the _MEAN_ matrices in the model. In addition, the order of variables determines the order of row and column variables in the model matrices.

Specifying Parameters in Model Matrices

Denote the parameter vector in the MSTRUCT model as θ. The dimension of θ depends on your hypothesized model. In the preceding example, θ contains two parameters in ϕ and τ. You can use the MATRIX statement to specify these parameters in the _COV_ matrix:

```
matrix _COV_ [1,1] = 5*phi,  /* phi for all diagonal elements */
             [2, ] = tau,    /* tau for all off-diagonal elements */
             [3, ] = 2*tau,
             [4, ] = 3*tau,
             [5, ] = 4*tau;
```

In this MATRIX statement, the five diagonal elements, starting from the [1,1] element of the covariance matrix, are fitted by the phi parameter. The specification 5*phi is a short-hand for specifying phi five times, respectively for each of the five diagonal elements in the covariance matrix. All other lower triangular elements are fitted by the tau parameter, as shown in the MATRIX statement. For example, with [3,] the elements starting from the first element of the third row of the _COV_ matrix are parameterized by the tau parameter. The specification 2*tau repeats the specification two times, meaning that the [3,1] and [3,2] elements are both fitted by the same parameter tau. Similarly, all lower triangular elements (not including the diagonal elements) of the _COV_ matrix are fitted by the tau parameter. The specification of the upper triangular elements (diagonal excluded) of the _COV_ matrix is not needed because the _COV_ matrix is symmetric. The specification in

the lower triangular elements is transferred automatically to the upper triangular elements. See the MATRIX statement on page 6784 for details about the syntax.

Default Parameters in the MSTRUCT Model

You can specify either fixed values or parameters (with or without initial values) for the elements in the _COV_ and _MEAN_ model matrices. If some elements are not specified, default parameters are applied. There are two types of default parameters: one is automatic free parameters, and the other is fixed zeros. They are applied in different situations.

Automatic Free Parameters

If no MATRIX statements are used to specify parameters in your model matrices, automatic free parameters are generated for all elements in the _COV_ matrix. For example, if you do not use the MATRIX statement to specify any element in the _COV_ matrix, free parameters are generated for all variances and covariances in the _COV_ matrix in the model. Similarly, free parameters are generated for the _MEAN_ vector when the mean structures are invoked by the MEANSTR option in the PROC TCALIS or MODEL statement. Each automatic free parameter is named with a prefix _Add and appended with a unique integer.

Default Fixed Zeros

If you specify **at least one** parameter (fixed or free) for an element in a model matrix using the MATRIX statement, no automatic free parameters will be generated for that matrix. All unspecified locations in the _COV_ and _MEAN_ model matrices are fixed zeros by default.

How and Why the Default Parameters Are Treated Differently in the MSTRUCT Model

Notice that the default parameter treatment in the MSTRUCT model is different from other types of models. For example, in the LINEQS model variances of and covariances among exogenous manifest variables are all automatic free parameters. These automatic free parameters are generated by PROC TCALIS. In the MSTRUCT model, however, automatic free parameters are either generated for all elements in a model matrix (when nothing is specified for the matrix or when the MATRIX statement is not used for the MSTRUCT model) or not generated at all (when at least one element in the _COV_ matrix is specified).

The reason is that there is no distinction between exogenous (independent) and endogenous (dependent) variables in the MSTRUCT model. Automatic free parameters for variances of, and covariances among, exogenous manifest variables are thus irrelevant.

Because of the particular default parameter treatment, when fitting an MSTRUCT model you must make sure that each diagonal element in your _COV_ matrix is set as a free, constrained, or fixed parameter, in accordance with your theoretical model. If you specify some elements in the model matrix but omit the specification of some diagonal elements, the default zero variances would lead to a nonpositive definite _COV_ model matrix, making the model fitting problematic.

Naming Variables and Parameters

Follow these rules when you name your variables:

- The usual naming conventions of the SAS system.
- Variable names are not more than 32 characters.
- When you create latent variable names, make sure that they are not used in the input data set that is being analyzed.
- For the LINEQS model, error or disturbance variables must start with 'E', 'e', 'D', or 'd.'
- For the LINEQS model, non-error-type latent variables (that is, factors) must start with 'F' or 'f.'
- For modeling languages other than LINEQS, names for errors or disturbances are not needed. As a result, you do not need to distinguish latent factors from errors or disturbances by using particular prefixes. Variable names that are not referenced in the analyzed data set are supposed to be latent factors.
- You should not use Intercept (case-insensitive) as a variable name in your data set or as a latent variable name in your model.

Follow these rules when you name your parameters:

- The usual naming conventions of the SAS system.
- Parameter names are not more than 32 characters.
- Use a prefix-name when you want to generate new parameter names automatically. A prefix-name contains a short string of characters called "root," followed by double underscores '__'. Each occurrence of such a prefix-name generates a new parameter name by replacing the two trailing underscores with a unique integer. For example, occurrences of Gen__ generate Gen1, Gen2, . . . etc.
- A special prefix-name is the one without a root—that is, it contains only double underscores '__'. Occurrences of '__' generate _Parm1, _Parm2, and so on.
- Automatic parameter names are generated by PROC TCALIS for automatic free parameters in the model. The purpose of adding these parameters is to safeguard ill-defined models. Automatic parameter names start with the prefix _Add and appended with unique integers. For example, _Add1, _Add2, and so on.
- Avoid using parameter names that start with either _, _Add, or _Parm. These names might get confused with the generated names by PROC TCALIS. The confusions might lead to unintended constraints to your model if the parameter names you use match those generated by PROC TCALIS exactly.

- Avoid using parameter names that are roots of prefix-names. For example, you should not use Gen as a parameter name if Gen__ is also used in the same model specification. Although violation of this rule might not distort the model specification, it might cause ambiguities and confusion.

Finally, in PROC TCALIS parameter names and variable names are not distinguished by explicit declarations. That is, a valid SAS name can be used as a parameter name or a variable name in any model supported by PROC TCALIS. Whether a name in a model specification is for a parameter or a variable is determined by the syntactic structure. For example, consider the following path specification:

```
proc tcalis;
   path
      a -> b  c;
   run;
```

PROC TCALIS parses the path specification according to the syntactic structure of the PATH statement and determines that a and b are variable names and c is a parameter name. Consider another specification as follows:

```
proc tcalis;
   path
      a -> b  b;
   run;
```

This is a syntactically correct specification. Variables a and b are defined in a path relationship with a path coefficient parameter also named b. While such a name conflict between parameter and variable names would not confuse PROC TCALIS in terms of model specification and fitting, it would create unnecessary confusions in programming and result interpretations. Hence, using parameter names that match variable names exactly is a bad practice and should be avoided.

Setting Constraints on Parameters

The TCALIS procedure offers a very flexible way to constrain parameters. There are two main methods for specifying constraints. One is explicit specification by using specially designed statements for constraints. The other is implicit specification by using the SAS programming statements.

Explicit Specification of Constraints

Explicit constraints can be set in the following ways:

- specifying boundary constraints on independent parameters in the BOUNDS statement
- specifying general linear equality and inequality constraints on independent parameters in the LINCON statement
- specifying general nonlinear equality and inequality constraints on parametric functions in the NLINCON statement

BOUNDS Statement

You can specify one-sided or two-sided boundaries on independent parameters in the BOUNDS statement. For example, in the following statement you constrain parameter var1 to be nonnegative and parameter effect to be between 0 and 5.

```
bounds   var1 >= 0,
         0. <= effect <= 5.;
```

Note that if your upper and lower bounds are the same for a parameter, it effectively sets a fixed value for that parameter. As a result, PROC TCALIS will reduce the number of independent parameters by one automatically. Note also that only independent parameters are allowed to be bounded in the BOUNDS statement.

LINCON Statement

You can specify equality or inequality linear constraints on independent parameters in the LINCON statement. For example, in the following statement you specify a linear inequality constraint on parameters beta1, beta2, and beta3 and an equality constraint on parameters gamma1 and gamma2.

```
lincon   beta1 - .5 * beta2 - .5 * beta3  >= 0.,
         gamma1 - gamma2 = 0.;
```

In the inequality constraint, beta1 is set to be at least as large as the average of beta2 and beta3. In the equality constraint, gamma1 and gamma2 are set to be equal. Note that in PROC TCALIS a nonredundant linear equality constraint on independent parameters effectively reduces the number of parameters by one.

NLINCON Statement

You can specify equality or inequality nonlinear constraints for parameters in the NLINCON statement. While you can only constrain the independent parameters in the BOUNDS and the LINCON statements, you can constrain any of the following in the NLINCON statement:

- independent parameters
- dependent parameters
- parametric functions computed by the SAS programming statements

For example, consider the following statements:

```
nlincon
    IndParm >= 0,           /* constraint 1 */
    0 <= DepParm <= 10,     /* constraint 2 */
    ParmFunc1 >= 3,         /* constraint 3 */
    0 <=  ParmFunc2 <= 8;   /* constraint 4 */

/* SAS Programming statements in the following */
DepParm   = Indparm1 + IndParm5;
ParmFunc1 = IndParm1 - .5 * IndParm2 - .5 * IndParm3;
ParmFunc2 = (IndParm1 - 7.)**2 + SQRT(DepParm * IndParm4) * ParmFunc1;
```

You specify four nonlinear constraints by using the NLINCON statement. Labeled in a comment as "constraint 1" is a one-sided boundary constraint for independent parameter IndParm. Labeled in a comment as "constraint 2" is a two-sided boundary constraint for dependent parameter DepParm. Labeled in a comment as "constraint 3" is a one-sided inequality constraint on parametric function named ParmFunc1. Finally, labeled in a comment as "constraint 4" is a two-sided inequality constraint on parametric function named ParmFunc2. Parametric functions ParmFunc1 and ParmFunc2 are defined and computed in the SAS programming statements after the NLINCON statement specification.

Constraint 1 could have been set in the BOUNDS statement because it is just a simple boundary constraint on an independent parameter. Constraint 3 could have been set in the LINCON statement because the definition of ParmFunc1 in a SAS programming statement shows that it is a linear function of independent parameters. The purpose of including these special cases of "nonlinear constraints" in this example is to show the flexibility of the NLINCON statement. However, whenever possible, the BOUNDS or the LINCON statement specification should be considered first because computationally they are more efficient than the equivalent specification in the NLINCON statement.

Specification in the NLINCON statement becomes necessary when you want to constrain dependent parameters or nonlinear parametric functions. For example, constraint 2 is a two-sided boundary constraint on the dependent parameter DepParm, which is defined as a linear function of independent parameters in a SAS programming statement. Constraints on dependent parameters are not allowed in the BOUNDS statement. Constraint 4 is a two-sided inequality constraint on the nonlinear parametric function ParmFunc2, which is defined as a nonlinear function of other parametric functions and parameters in the SAS programming statements. Again, you cannot use the LINCON statement to specify nonlinear constraints.

Implicit Constraint Specification

An implicit way to specify constraints is to use your own SAS programming statements together with the PARAMETERS statement to express special properties of the parameter estimates. This kind of reparameterization tool is also present in McDonald's COSAN implementation (McDonald 1978) but is considerably easier to use in the TCALIS procedure. PROC TCALIS is able to compute analytic first- and second-order derivatives that you would have to specify using the COSAN program.

Some traditional ways to enforce parameter constraints by using reparameterization or parameter transformation (McDonald 1980) are considered in the following:

- **one-sided boundary constraints of the form:**

  $$q \geq a \qquad \text{or} \qquad q \leq b$$

  where the parameter of interest is q, which should be at least as large as (or at most as small as) a given constant value a (or b). This inequality constraint can be expressed as an equality constraint:

  $$q = a + x^2 \qquad \text{or} \qquad q = b - x^2$$

  in which the new parameter x is unconstrained.

  For example, inequality constraint $q \geq 7$ can be accomplished by the following statements:

  ```
  parameters  x (0.);
  q = 7 + x * x;
  ```

  In this specification, you essentially redefine q as a parametric function of x, which is not constrained and has a starting value at 0.

- **two-sided boundary constraints of the form:**

  $$a \leq q \leq b$$

  where the parameter of interest is q, which should be located between two given constant values a and b, with $a < b$. This inequality constraint can be expressed as the following equality constraint:

  $$q = a + (b - a)\frac{\exp(x)}{1 + \exp(x)}$$

  where the new parameter x is unconstrained.

  For example, to implement $1 \leq q \leq 5$ in PROC TCALIS, you can use the following statements:

  ```
  parameters x (0.);
  u = exp(x);
  q = 1 + 4 * u / (1 + u);
  ```

In this specification, q becomes a dependent parameter which is nonlinearly related to independent parameter x, which is an independent parameter defined in the PARAMETERS statement with a starting value of 0.

- **one-sided order constraints of the form:**

$$q_1 \leq q_2, \quad q_1 \leq q_3, \quad \ldots, \quad q_1 \leq q_k$$

where $q_1, \ldots, q_k$ are the parameters of interest. These inequality constraints can be expressed as the following set of equality constraints:

$$q_1 = x_1, \quad q_2 = x_1 + x_2^2, \quad \ldots, \quad q_k = x_1 + x_k^2$$

where the new parameters $x_1, \ldots, x_k$ are unconstrained.

For example, to implement $q_1 \leq q_2$, $q_1 \leq q_3$, and $q_1 \leq q_4$ simultaneously, you can use the following statements:

```
parameters x1-x4 (4*0.);
q1 = x1;
q2 = x1 + x2 * x2;
q3 = x1 + x3 * x3;
q4 = x1 + x4 * x4;
```

In this specification, you essentially redefine q_1–q_4 as dependent parameters that are functions of x_1–x_4, which are defined as independent parameters in the PARAMETERS statement with starting values of zeros. No constraints on x_i's are needed. The way that q_i's are computed in the SAS programming statements guarantees the required order constraints on q_i's are satisfied.

- **two-sided order constraints of the form:**

$$q_1 \leq q_2 \leq q_3 \leq \ldots \leq q_k$$

These inequality constraints can be expressed as the following set of equality constraints:

$$q_1 = x_1, \quad q_2 = q_1 + x_2^2, \quad \ldots \quad q_k = q_{k-1} + x_k^2$$

where the new parameters $x_1, \ldots, x_k$ are unconstrained.

For example, to implement $q_1 \leq q_2 \leq q_3 \leq q_4$ simultaneously, you can use the following statements:

```
parameters x1-x4 (4*0.);
q1 = x1;
q2 = q1 + x2 * x2;
q3 = q2 + x3 * x3;
q4 = q3 + x4 * x4;
```

In this specification, you redefine q_1–q_4 as dependent parameters that are functions of x_1–x_4, which are defined as independent parameters in the PARAMETERS statement. Each x_i has a starting value of zero without being constrained in estimation. The order relation of q_i's are satisfied by the way they are computed in the SAS programming statements.

- **linear equation constraints of the form:**

$$\sum_{i}^{k} b_i q_i = a$$

where q_i's are the parameters of interest, b_i's are constant coefficients, a is a constant, and k is an integer greater than one. This linear equation can be expressed as the following system of equations with unconstrained new parameters $x_1, x_2, \ldots, x_k$:

$$\begin{aligned} q_i &= x_i / b_i \qquad (i < k) \\ q_k &= (a - \sum_{j}^{k-1} x_j)/b_k \end{aligned}$$

For example, consider the following linear constraint on independent parameters q_1–q_3:

$$3q_1 + 2q_2 - 5q_3 = 8$$

You can use the following statements to implement the linear constraint:

```
parameters x1-x2 (2*0.);
q1 = x1 / 3;
q2 = x2 / 2;
q3 = -(8 - x1 - x2) / 5;
```

In this specification, q_1–q_3 become dependent parameters that are functions of $x1$ and $x2$. The linear constraint on q_1 and q_3 are satisfied by the way they are computed. In addition, after reparameterization the number of independent parameters drops to two.

Refer to McDonald (1980) and Browne (1982) for further notes on reparameterization techniques.

Explicit or Implicit Specification of Constraints?

Explicit and implicit constraint techniques differ in their specifications and lead to different computational steps in optimizing a solution. The explicit constraint specification that uses the supported statements incurs additional computational routines within the optimization steps. In contrast, the implicit reparameterization method does not incur additional routines for evaluating constraints during the optimization. Rather, it changes the constrained problem to a non-constrained one. This costs more in computing function derivatives and in storing parameters.

If the optimization problem is small enough to apply the Levenberg-Marquardt or Newton-Raphson algorithm, use the BOUNDS and the LINCON statements to set explicit boundary and linear constraints. If the problem is so large that you must use a quasi-Newton or conjugate gradient algorithm, reparameterization techniques might be more efficient than the BOUNDS and LINCON statements.

Automatic Variable Selection

When you specify your model, you use the main and subsidiary model statements to define variable relationships and parameters. PROC TCALIS checks the variables mentioned in these statements against the variable list of the input data set. If a variable in your model is also found in your data set, PROC TCALIS knows that it is a manifest variable. Otherwise, it is either a latent variable or an invalid variable.

To save computational resources, only manifest variables defined in your model are automatically selected for analysis. For example, even if you have 100 variables in your input data set, only a covariance matrix of 10 manifest variables is computed for the analysis of the model if only 10 variables are selected for analysis.

In some special circumstances, the automatic variable selection performed for the analysis might be a drawback. For example, if you are interested in modification indices connected to some of the variables that are not used in the model, automatic variable selection in the specification stage will exclude those variables from consideration in computing modification indices. Fortunately, a little trick can be done. You can use the VAR statement to include as many exogenous manifest variables as needed. Any variables in the VAR statement that are defined in the input data set but are not used in the main and subsidiary model specification statements are included in the model as exogenous manifest variables.

For example, the first three steps in a stepwise regression analysis of the Werner Blood Chemistry data (Jöreskog and Sörbom 1988, p. 111) can be performed as follows:

```
proc tcalis data=dixon method=gls nobs=180 print mod;
   var    x1-x7;
   lineqs y = e;
   std    e = var;
run;
proc tcalis data=dixon method=gls nobs=180 print mod;
   var    x1-x7;
   lineqs y = g1 x1 + e;
   std    e = var;
run;
proc tcalis data=dixon method=gls nobs=180 print mod;
   var    x1-x7;
   lineqs y = g1 x1 + g6 x6 + e;
   std    e = var;
run;
```

In the first analysis, no independent manifest variables are included in the regression equation for dependent variable y. However, x1–x7 are specified in the VAR statement so that in computing the Lagrange multiplier tests these variables would be treated as potential predictors in the regression equation for dependent variable y. Similarly, in the next analysis, x1 is already a predictor in the regression equation, while x2–x7 are treated as potential predictors in the LM tests. In the last analysis, x1 and x6 are predictors in the regression equation, while other x-variables are treated as potential predictors in the LM tests.

Estimation Criteria

The following five estimation methods are available in PROC TCALIS:

- unweighted least squares (ULS)
- generalized least squares (GLS)
- normal-theory maximum likelihood (ML)
- weighted least squares (WLS, ADF)
- diagonally weighted least squares (DWLS)

Default weight matrices $\mathbf{W}$ are computed for GLS, WLS, and DWLS estimation. You can also provide your own weight matrices by using an INWGT= data set.

PROC TCALIS does not implement all estimation methods in the field. As mentioned in the section "Overview: TCALIS Procedure" on page 6681, partial least squares (PLS) is not implemented. The PLS method is developed under less restrictive statistical assumptions. It circumvents some computational and theoretical problems encountered by the existing estimation methods in PROC TCALIS; however, PLS estimates are less efficient in general. When the statistical assumptions of PROC TCALIS are tenable (for example, large sample size, correct distributional assumptions, and so on), ML, GLS, or WLS methods yield better estimates than the PLS method. Note that there is a SAS/STAT procedure called PROC PLS that employs the partial least squares technique, but for a different class of models than those of PROC TCALIS. For example, in a PROC TCALIS model each latent variable is typically associated with only a subset of manifest variables (predictor or outcome variables). However, in PROC PLS latent variables are not prescribed with subsets of manifest variables. Rather, they are extracted from linear combinations of all manifest predictor variables. Therefore, for general path analysis with latent variables you should use PROC TCALIS.

ULS, GLS, and ML Discrepancy functions

In each estimation method, the parameter vector is estimated iteratively by a nonlinear optimization algorithm that minimizes a discrepancy function F, which is also known as the fit function in the literature. With p denoting the number of manifest variables, $\mathbf{S}$ the sample $p \times p$ covariance matrix for a sample with size N, $\bar{\boldsymbol{x}}$ the $p \times 1$ vector of sample means, $\boldsymbol{\Sigma}$ the fitted covariance matrix, and $\boldsymbol{\mu}$ the vector of fitted means, the discrepancy function for unweighted least squares (ULS) estimation is:

$$F_{ULS} = 0.5Tr[(\mathbf{S} - \boldsymbol{\Sigma})^2] + (\bar{\boldsymbol{x}} - \boldsymbol{\mu})'(\bar{\boldsymbol{x}} - \boldsymbol{\mu})$$

The discrepancy function for generalized least squares estimation (GLS) is:

$$F_{GLS} = 0.5Tr[(\mathbf{W}^{-1}(\mathbf{S} - \boldsymbol{\Sigma}))^2] + (\bar{\boldsymbol{x}} - \boldsymbol{\mu})'\mathbf{W}^{-1}(\bar{\boldsymbol{x}} - \boldsymbol{\mu})$$

By default, $\mathbf{W} = \mathbf{S}$ is assumed so that F_{GLS} is the normal theory generalized least squares discrepancy function.

The discrepancy function for normal-theory maximum likelihood estimation (ML) is:

$$F_{ML} = Tr(\mathbf{S}\mathbf{\Sigma}^{-1}) - p + ln(|\mathbf{\Sigma}|) - ln(|\mathbf{S}|) + (\bar{\boldsymbol{x}} - \boldsymbol{\mu})'\mathbf{\Sigma}^{-1}(\bar{\boldsymbol{x}} - \boldsymbol{\mu})$$

In each of the discrepancy functions, $\mathbf{S}$ and $\bar{\boldsymbol{x}}$ are considered to be given and $\mathbf{\Sigma}$ and $\boldsymbol{\mu}$ are functions of model parameter vector $\mathbf{\Theta}$. That is:

$$F = F(\mathbf{\Sigma}(\mathbf{\Theta}), \boldsymbol{\mu}(\mathbf{\Theta}); \mathbf{S}, \bar{\boldsymbol{x}})$$

Estimating $\mathbf{\Theta}$ by using a particular estimation method amounts to choosing a vector $\boldsymbol{\theta}$ that minimizes the corresponding discrepancy function F.

When the mean structures are not modeled or when the mean model is saturated by parameters, the last term of each fit function vanishes. That is, they become:

$$F_{ULS} = 0.5Tr[(\mathbf{S} - \mathbf{\Sigma})^2]$$

$$F_{GLS} = 0.5Tr[(\mathbf{W}^{-1}(\mathbf{S} - \mathbf{\Sigma}))^2]$$

$$F_{ML} = Tr(\mathbf{S}\mathbf{\Sigma}^{-1}) - p + ln(|\mathbf{\Sigma}|) - ln(|\mathbf{S}|)$$

If, instead of being a covariance matrix, $\mathbf{S}$ is a correlation matrix in the discrepancy functions, $\mathbf{\Sigma}$ would naturally be interpreted as the fitted correlation matrix. Although whether $\mathbf{S}$ is a covariance or correlation matrix makes no difference in minimizing the discrepancy functions, correlational analyses that use these functions are problematic because of the following issues:

- The diagonal of the fitted correlation matrix $\mathbf{\Sigma}$ might contain values other than ones, which violates the requirement of being a correlation matrix.
- Whenever available, standard errors computed for correlation analysis in PROC TCALIS are straightforward generalizations of those of covariance analysis. In very limited cases these standard errors are good approximations. However, in general they are not even asymptotically correct.
- The model fit chi-square statistic for correlation analysis might not follow the theoretical distribution, thus making model fit testing difficult.

Despite these issues in correlation analysis, if your primary interest is to obtain the estimates in the correlation models, you might still find PROC TCALIS results for correlation analysis useful.

PROC TCALIS is primarily developed for the analysis of covariance structures, and hence COVARIANCE is the default option in the procedure. Depending on the nature of research, you can add the mean structures in the analysis. However, for the analysis of correlation structures, you can not add the mean structures for modeling in PROC TCALIS.

WLS and ADF Discrepancy Functions

Another important discrepancy function to consider is the weighted least squares (WLS) function. Let $u = (s, \bar{\boldsymbol{x}})$ be a $p(p+3)/2$ vector containing all nonredundant elements in the sample covariance matrix $\mathbf{S}$ and sample mean vector $\bar{\boldsymbol{x}}$, with $s = vecs(\mathbf{S})$ representing the vector of the

$p(p+1)/2$ lower triangle elements of the symmetric matrix $\mathbf{S}$, stacking row by row. Similarly, let $\eta = (\sigma, \mu)$ be a $p(p+3)/2$ vector containing all nonredundant elements in the fitted covariance matrix $\mathbf{\Sigma}$ and the fitted mean vector $\boldsymbol{\mu}$, with $\sigma = vecs(\mathbf{\Sigma})$ representing the vector of the $p(p+1)/2$ lower triangle elements of the symmetric matrix $\mathbf{\Sigma}$.

The WLS discrepancy function is:

$$F_{WLS} = (u-\eta)'\mathbf{W}^{-1}(u-\eta)$$

where $\mathbf{W}$ is a positive definite symmetric weight matrix with $(p(p+3)/2)$ rows and columns. Because η is a function of model parameter vector $\mathbf{\Theta}$ under the structural model, you can write the WLS function as:

$$F_{WLS} = (u-\eta(\mathbf{\Theta}))'\mathbf{W}^{-1}(u-\eta(\mathbf{\Theta}))$$

Suppose that u converges to $\eta_o = (\sigma_o, \mu_o)$ with increasing sample size, where σ_o and μ_o denote the population covariance matrix and mean vector, respectively. By default, the WLS weight matrix $\mathbf{W}$ in PROC TCALIS is computed from the raw data as a consistent estimate of the asymptotic covariance matrix $\mathbf{\Gamma}$ of $\sqrt{N}(u-\eta_o)$, with $\mathbf{\Gamma}$ partitioned as

$$\Gamma = \begin{pmatrix} \mathbf{\Gamma}_{ss} & \mathbf{\Gamma}'_{\bar{x}s} \\ \mathbf{\Gamma}_{\bar{x}s} & \mathbf{\Gamma}_{\bar{x}\bar{x}} \end{pmatrix}$$

where $\mathbf{\Gamma}_{ss}$ denotes the $(p(p+1)/2) \times (p(p+1)/2)$ asymptotic covariance matrix for $\sqrt{N}(s-\sigma_o)$, $\mathbf{\Gamma}_{\bar{x}\bar{x}}$ denotes the $p \times p$ asymptotic covariance matrix for $\sqrt{N}(\bar{x}-\mu_o)$, and $\mathbf{\Gamma}_{\bar{x}s}$ denotes the $p \times (p(p+1)/2)$ asymptotic covariance matrix between $\sqrt{N}(\bar{x}-\mu_o)$ and $\sqrt{N}(s-\sigma_o)$.

To compute the default weight matrix $\mathbf{W}$ as a consistent estimate of $\mathbf{\Gamma}$, define a similar partition of the weight matrix $\mathbf{W}$ as:

$$\mathbf{W} = \begin{pmatrix} \mathbf{W}_{ss} & \mathbf{W}'_{\bar{x}s} \\ \mathbf{W}_{\bar{x}s} & \mathbf{W}_{\bar{x}\bar{x}} \end{pmatrix}$$

Each of the submatrices in the partition can now be computed from the raw data. First, define the biased sample covariance for variables i and j as:

$$\mathbf{t}_{ij} = \frac{1}{N}\sum_{r=1}^{N}(x_{ri}-\bar{x}_i)(x_{rj}-\bar{x}_j)$$

and the sample fourth-order central moment for variables i, j, k, and l as:

$$\mathbf{t}_{ij,kl} = \frac{1}{N}\sum_{r=1}^{N}(x_{ri}-\bar{x}_i)(x_{rj}-\bar{x}_j)(x_{rk}-\bar{x}_k)(x_{rl}-\bar{x}_l)$$

The submatrices in $\mathbf{W}$ are computed by:

$$[\mathbf{W}_{ss}]_{ij,kl} = \mathbf{t}_{ij,kl} - \mathbf{t}_{ij}\mathbf{t}_{kl}$$

$$[\mathbf{W}_{\bar{x}s}]_{i,kl} = \frac{1}{N}\sum_{r=1}^{N}(x_{ri}-\bar{x}_i)(x_{rk}-\bar{x}_k)(x_{rl}-\bar{x}_l)$$

$$[\mathbf{W}_{\bar{x}\bar{x}}]_{ij} = \mathbf{t}_{ij}$$

Assuming the existence of finite eighth-order moments, this default weight matrix $\mathbf{W}$ is a consistent but biased estimator of the asymptotic covariance matrix $\mathbf{\Gamma}$.

By using the ASYCOV option, you can use Browne's (1984, formula (3.8)) unbiased estimator of $\mathbf{\Gamma}_{ss}$ as:

$$\begin{aligned}[\mathbf{W}_{ss}]_{ij,kl} &= \frac{N(N-1)}{(N-2)(N-3)}(\mathbf{t}_{ij,kl} - \mathbf{t}_{ij}\mathbf{t}_{kl}) \\ &\quad -\frac{N}{(N-2)(N-3)}(\mathbf{t}_{ik}\mathbf{t}_{jl} + \mathbf{t}_{il}\mathbf{t}_{jk} - \frac{2}{N-1}\mathbf{t}_{ij}\mathbf{t}_{kl})\end{aligned}$$

There is no guarantee that $\mathbf{W}_{ss}$ computed this way is positive semidefinite. However, the second part is of order $O(N^{-1})$ and does not destroy the positive semidefinite first part for sufficiently large N. For a large number of independent observations, default settings of the weight matrix $\mathbf{W}$ result in asymptotically distribution-free parameter estimates with unbiased standard errors and a correct χ^2 test statistic (Browne 1982, 1984).

With the default weight matrix $\mathbf{W}$ computed by PROC TCALIS, the WLS estimation is also called as the asymptotically distribution-free (ADF) method. In fact, as options in PROC TCALIS, METHOD=WLS and METHOD=ADF are totally equivalent, even though WLS in general might include cases with special weight matrices other than the default weight matrix.

When the mean structures are not modeled, the WLS discrepancy function is still the same quadratic form statistic. However, with only the elements in covariance matrix being modeled, the dimensions of u and η are both reduced to $p(p+1)/2 \times 1$, and the dimension of the weight matrix is now $(p(p+1)/2) \times (p(p+1)/2)$. That is, the WLS discrepancy function for covariance structure models is:

$$F_{WLS} = (s-\sigma)'\mathbf{W}_{ss}^{-1}(s-\sigma)$$

If $\mathbf{S}$ is a correlation rather than a covariance matrix, the default setting of the $\mathbf{W}_{ss}$ is a consistent estimator of the asymptotic covariance matrix $\mathbf{\Gamma}_{ss}$ of $\sqrt{N}(s-\sigma_o)$ (Browne and Shapiro 1986; DeLeeuw 1983), with s and σ_o representing vectors of sample and population correlations, respectively. Elementwise, $\mathbf{W}_{ss}$ is expressed as:

$$\begin{aligned}[\mathbf{W}_{ss}]_{ij,kl} &= r_{ij,kl} - \frac{1}{2}r_{ij}(r_{ii,kl} + r_{jj,kl}) - \frac{1}{2}r_{kl}(r_{kk,ij} + r_{ll,ij}) \\ &\quad +\frac{1}{4}r_{ij}r_{kl}(r_{ii,kk} + r_{ii,ll} + r_{jj,kk} + r_{jj,ll})\end{aligned}$$

where

$$r_{ij} = \frac{\mathbf{t}_{ij}}{\sqrt{\mathbf{t}_{ii}\mathbf{t}_{jj}}}$$

and

$$r_{ij,kl} = \frac{\mathbf{t}_{ij,kl}}{\sqrt{\mathbf{t}_{ii}\mathbf{t}_{jj}\mathbf{t}_{kk}\mathbf{t}_{ll}}}$$

The asymptotic variances of the diagonal elements of a correlation matrix are 0. That is,

$$[\mathbf{W}_{ss}]_{ii,ii} = 0$$

for all i. Therefore, the weight matrix computed this way is always singular. In this case, the discrepancy function for weighted least squares estimation is modified to:

$$\begin{aligned} F_{WLS} &= \sum_{i=2}^{n}\sum_{j=1}^{i-1}\sum_{k=2}^{n}\sum_{l=1}^{k-1}[\mathbf{W}_{ss}]^{ij,kl}([\mathbf{S}]_{ij}-[\mathbf{\Sigma}]_{ij})([\mathbf{S}]_{kl}-[\mathbf{\Sigma}]_{kl}) \\ &\quad +r\sum_{i}^{n}([\mathbf{S}]_{ii}-[\mathbf{\Sigma}]_{ii})^2 \end{aligned}$$

where r is the penalty weight specified by the WPENALTY=r option and the $[\mathbf{W}_{ss}]^{ij,kl}$ are the elements of the inverse of the reduced $(n(n-1)/2)\times(n(n-1)/2)$ weight matrix that contains only the nonzero rows and columns of the full weight matrix $\mathbf{W}_{ss}$.

The second term is a penalty term to fit the diagonal elements of the correlation matrix $\mathbf{S}$. The default value of $r = 100$ can be decreased or increased by the WPENALTY= option. The often used value of $r = 1$ seems to be too small in many cases to fit the diagonal elements of a correlation matrix properly.

Note that when you model correlation structures, no mean structures can be modeled simultaneously in the same model.

DWLS Discrepancy Functions

Storing and inverting the huge weight matrix $\mathbf{W}$ in WLS estimation requires considerable computer resources. A compromise is found by implementing the diagonally weighted least squares (DWLS) method that uses only the diagonal of the weight matrix $\mathbf{W}$ from the WLS estimation in the following discrepancy function:

$$\begin{aligned} F_{DWLS} &= (u-\eta)'[\mathrm{diag}(\mathbf{W})]^{-1}(u-\eta) \\ &= \sum_{i=1}^{n}\sum_{j=1}^{i}[\mathbf{W}_{ss}]^{-1}_{ij,ij}([\mathbf{S}]_{ij}-[\mathbf{\Sigma}]_{ij})^2+\sum_{i=1}^{n}[\mathbf{W}_{\bar{x}\bar{x}}]^{-1}_{ii}(\bar{x}_i-\boldsymbol{\mu}_i)^2 \end{aligned}$$

When only the covariance structures are modeled, the discrepancy function becomes:

$$F_{DWLS} = \sum_{i=1}^{n}\sum_{j=1}^{i}[\mathbf{W}_{ss}]^{-1}_{ij,ij}([\mathbf{S}]_{ij}-[\mathbf{\Sigma}]_{ij})^2$$

For correlation models, the discrepancy function is:

$$F_{DWLS} = \sum_{i=2}^{n}\sum_{j=1}^{i-1}[\mathbf{W}_{ss}]^{-1}_{ij,ij}([\mathbf{S}]_{ij}-[\mathbf{\Sigma}]_{ij})^2+r\sum_{i=1}^{n}([\mathbf{S}]_{ii}-[\mathbf{\Sigma}]_{ii})^2$$

where r is the penalty weight specified by the WPENALTY=r option. Note that no mean structures can be modeled simultaneously with correlation structures when using the DWLS method.

As the statistical properties of DWLS estimates are still not known, standard errors for estimates are not computed for the DWLS method.

Input Weight Matrices

In GLS, WLS, or DWLS estimation you can change from the default settings of weight matrices $\mathbf{W}$ by using an INWGT= data set. The TCALIS procedure requires a positive definite weight matrix that has positive diagonal elements.

Multiple-Group Discrepancy Function

Suppose that there are k independent groups in the analysis and N_1, N_2, ..., N_k are the sample sizes for the groups. The overall discrepancy function $F(\mathbf{\Theta})$ is expressed as a weighted sum of individual discrepancy functions F_i's for the groups:

$$F(\mathbf{\Theta}) = \sum_{i=1}^{k} t_i F_i(\mathbf{\Theta})$$

where

$$t_i = \frac{N_i - 1}{N - k}$$

is the weight of the discrepancy function for group i, and

$$N = \sum_{i=1}^{k} N_i$$

is the total number of observations in all groups. In PROC TCALIS, all discrepancy function F_i's in the overall discrepancy function must belong to the same estimation method. You cannot specify different estimation methods for the groups in a multiple-group analysis. However, you can fit covariance and mean structures to a group but fit covariance structures only to another group.

Relationships among Estimation Criteria

If only the covariance or correlation structures are considered, the five estimation functions, F_{ULS}, F_{GLS}, F_{ML}, F_{WLS}, and F_{DWLS}, belong to the following two groups:

- The functions F_{ULS}, F_{GLS}, and F_{ML} take into account all n^2 elements of the symmetric residual matrix $\mathbf{S} - \mathbf{\Sigma}$. This means that the off-diagonal residuals contribute twice to the discrepancy function F, as lower and as upper triangle elements.

- The functions F_{WLS} and F_{DWLS} take into account only the $n(n+1)/2$ lower triangular elements of the symmetric residual matrix $\mathbf{S}-\mathbf{\Sigma}$. This means that the off-diagonal residuals contribute to the discrepancy function F only once.

The F_{DWLS} function used in PROC TCALIS differs from that used by the LISREL 7 program. Formula (1.25) of the LISREL 7 manual (Jöreskog and Sörbom 1988, p. 23) shows that LISREL groups the F_{DWLS} function in the first group by taking into account all n^2 elements of the symmetric residual matrix $\mathbf{S}-\mathbf{\Sigma}$.

- Relationship between DWLS and WLS:
  PROC TCALIS: The F_{DWLS} and F_{WLS} discrepancy functions deliver the same results for the special case that the weight matrix $\mathbf{W} = \mathbf{W}_{ss}$ used by WLS estimation is a diagonal matrix.
  LISREL 7: This is not the case.

- Relationship between DWLS and ULS:
  LISREL 7: The F_{DWLS} and F_{ULS} estimation functions deliver the same results for the special case that the diagonal weight matrix $\mathbf{W} = \mathbf{W}_{ss}$ used by DWLS estimation is an identity matrix.
  PROC TCALIS: To obtain the same results with F_{DWLS} and F_{ULS} estimation, set the diagonal weight matrix $\mathbf{W} = \mathbf{W}_{ss}$ used in DWLS estimation to:

$$[\mathbf{W}_{ss}]_{ik,ik} = \begin{cases} 1. & \text{if } i = k \\ 0.5 & \text{otherwise} \end{cases} \qquad (k \le i)$$

  Because the reciprocal elements of the weight matrix are used in the discrepancy function, the off-diagonal residuals are weighted by a factor of 2.

Gradient, Hessian, Information Matrix, and Approximate Standard Errors

For a single-sample setting with a discrepancy function $F = F(\mathbf{\Sigma}(\mathbf{\Theta}), \boldsymbol{\mu}(\mathbf{\Theta}); \mathbf{S}, \bar{\boldsymbol{x}})$, the gradient is defined as the first partial derivatives of the discrepancy function with respect to the model parameters $\mathbf{\Theta}$:

$$g(\mathbf{\Theta}) = \frac{\partial}{\partial \mathbf{\Theta}} F(\mathbf{\Theta})$$

The Hessian is defined as the second partial derivatives of the discrepancy function with respect to the model parameters $\mathbf{\Theta}$:

$$H(\mathbf{\Theta}) = \frac{\partial^2}{\partial \mathbf{\Theta} \partial \mathbf{\Theta}'} F(\mathbf{\Theta})$$

Suppose that the mean and covariance structures fit perfectly with $\mathbf{\Theta} = \mathbf{\Theta}_o$ in the population. The information matrix is defined as:

$$I(\mathbf{\Theta}_o) = \frac{1}{2}\mathcal{E}(H(\mathbf{\Theta}_o))$$

where the expectation $\mathcal{E}(\cdot)$ is taken over the sampling space of $\mathbf{S}, \bar{\boldsymbol{x}}$.

The information matrix plays a significant role in statistical theory. Under certain regularity conditions, the inverse of the information matrix $I^{-1}(\mathbf{\Theta}_o)$ is the asymptotic covariance matrix for $\sqrt{N}(\hat{\mathbf{\Theta}} - \mathbf{\Theta}_o)$, where N denotes the sample size and $\hat{\mathbf{\Theta}}$ is an estimator.

In practice, $\mathbf{\Theta}_o$ is never known and can only be estimated. The information matrix is therefore estimated by the so-called empirical information matrix:

$$I(\hat{\mathbf{\Theta}}) = \frac{1}{2}H(\hat{\mathbf{\Theta}})$$

which is evaluated at the values of the sample estimates $\hat{\mathbf{\Theta}}$. Notice that this empirical information matrix, rather than the unknown $I(\mathbf{\Theta}_o)$, is the "information matrix" displayed in PROC TCALIS output.

Taking the inverse of the empirical information matrix with sample size adjustment, PROC TCALIS approximates the estimated covariance matrix of $\hat{\mathbf{\Theta}}$ by:

$$((N-1)I(\hat{\mathbf{\Theta}}))^{-1} = ((N-1)\frac{1}{2}H(\hat{\mathbf{\Theta}}))^{-1} = \frac{2}{N-1}H^{-1}(\hat{\mathbf{\Theta}})$$

Approximate standard errors for $\hat{\mathbf{\Theta}}$ can then be computed as the square roots of the diagonal elements of the estimated covariance matrix. The theory about the empirical information matrix, the approximate covariance matrix of the parameter estimates, and the approximate standard errors applies to all but the ULS and DWLS estimation methods. Standard errors are therefore not computed with the ULS and DWLS estimation methods.

If a given Hessian or information matrix is singular, PROC TCALIS offers two ways to compute a generalized inverse of the matrix and, therefore, two ways to compute approximate standard errors of implicitly constrained parameter estimates, t values, and modification indices. Depending on the G4= specification, either a Moore-Penrose inverse or a G2 inverse is computed. The expensive Moore-Penrose inverse computes an estimate of the null space by using an eigenvalue decomposition. The cheaper G2 inverse is produced by sweeping the linearly independent rows and columns and zeroing out the dependent ones.

Multiple-Group Extensions

In the section "Multiple-Group Discrepancy Function" on page 6893, the overall discrepancy function for multiple-group analysis is defined. The same notation is applied here. To begin with, the overall discrepancy function $F(\mathbf{\Theta})$ is expressed as a weighted sum of individual discrepancy functions F_i's for the groups as follows:

$$F(\mathbf{\Theta}) = \sum_{i=1}^{k} t_i F_i(\mathbf{\Theta})$$

where

$$t_i = \frac{N_i - 1}{N - k}$$

is the weight for group i,

$$N = \sum_{i=1}^{k} N_i$$

is the total sample size, and N_i is the sample size for group i.

The gradient $g(\boldsymbol{\Theta})$ and the Hessian $H(\boldsymbol{\Theta})$ are now defined as weighted sum of individual functions. That is,

$$g(\boldsymbol{\Theta}) = \sum_{i=1}^{k} t_i g_i(\boldsymbol{\Theta}) = \sum_{i=1}^{k} t_i \frac{\partial}{\partial \boldsymbol{\Theta}} F_i(\boldsymbol{\Theta})$$

and

$$H(\boldsymbol{\Theta}) = \sum_{i=1}^{k} t_i H_i(\boldsymbol{\Theta}) = \sum_{i=1}^{k} t_i \frac{\partial^2}{\partial \boldsymbol{\Theta} \partial \boldsymbol{\Theta}'} F_i(\boldsymbol{\Theta})$$

Suppose that the mean and covariance structures fit perfectly with $\boldsymbol{\Theta} = \boldsymbol{\Theta}_o$ in the population. If each t_i converges to a fixed constant τ_i ($\tau_i > 0$) with increasing total sample size, the information matrix can be written as:

$$I(\boldsymbol{\Theta}_o) = \frac{1}{2} \sum_{i=1}^{k} \tau_i \mathcal{E}(H_i(\boldsymbol{\Theta}_o))$$

To approximate this information matrix, an empirical counterpart is used:

$$I(\hat{\boldsymbol{\Theta}}) = \frac{1}{2} \sum_{i=1}^{k} t_i H_i(\hat{\boldsymbol{\Theta}})$$

which is evaluated at the values of the sample estimates $\hat{\boldsymbol{\Theta}}$. Again, this empirical information matrix, rather than the unknown $I(\boldsymbol{\Theta}_o)$, is the "information matrix" output in PROC TCALIS results.

Taking the inverse of the empirical information matrix with sample size adjustment, PROC TCALIS approximates the estimated covariance matrix of $\hat{\boldsymbol{\Theta}}$ in multiple-group analysis by:

$$((N-k) I(\hat{\boldsymbol{\Theta}}))^{-1} = ((N-k) \frac{1}{2} H(\hat{\boldsymbol{\Theta}}))^{-1} = \frac{2}{N-k} \sum_{i=1}^{k} t_i H_i^{-1}(\hat{\boldsymbol{\Theta}})$$

Approximate standard errors for $\hat{\boldsymbol{\Theta}}$ can then be computed as the square roots of the diagonal elements of the estimated covariance matrix. Again, for ULS and DWLS estimation, the theory does not apply and so there are no standard errors computed in these cases.

Testing Rank Deficiency in the Approximate Covariance Matrix for Parameter Estimates

When computing the approximate covariance matrix and hence the standard errors for the parameter estimates, inversion of the scaled information matrix or Hessian matrix is involved. The numerical condition of the information matrix can be very poor in many practical applications, especially for the analysis of unscaled covariance data. The following four-step strategy is used for the inversion of the information matrix.

1. The inversion (usually of a normalized matrix $\mathbf{D}^{-1}\mathbf{H}\mathbf{D}^{-1}$) is tried using a modified form of the Bunch and Kaufman (1977) algorithm, which allows the specification of a different singularity criterion for each pivot. The following three criteria for the detection of rank loss in the information matrix are used to specify thresholds:

   - *ASING* specifies absolute singularity.
   - *MSING* specifies relative singularity depending on the whole matrix norm.
   - *VSING* specifies relative singularity depending on the column matrix norm.

   If no rank loss is detected, the inverse of the information matrix is used for the covariance matrix of parameter estimates, and the next two steps are skipped.

2. The linear dependencies among the parameter subsets are displayed based on the singularity criteria.

3. If the number of parameters t is smaller than the value specified by the G4= option (the default value is 60), the Moore-Penrose inverse is computed based on the eigenvalue decomposition of the information matrix. If you do not specify the NOPRINT option, the distribution of eigenvalues is displayed, and those eigenvalues that are set to zero in the Moore-Penrose inverse are indicated. You should inspect this eigenvalue distribution carefully.

4. If PROC TCALIS did not set the right subset of eigenvalues to zero, you can specify the COVSING= option to set a larger or smaller subset of eigenvalues to zero in a further run of PROC TCALIS.

Counting the Degrees of Freedom

When fitting covariance and mean structure models, the population moments are hypothesized to be functions of model parameters $\boldsymbol{\Theta}$. The population moments refer to the first-order moments (means) and the second-order central moments (variances of and covariances among the variables). Usually, the number of nonredundant population moments is larger than the number of model parameters for a structural model. The difference between the two is the degrees of freedom (df) of your model.

Formally, define a multiple-group situation where you have k independent groups in your model. The set of variables in each group might be different so that you have $p_1, p_2, \ldots, p_k$ mainfest or observed variables for the k groups. It is assumed that the primary interest is to study the covariance structures. The inclusion of mean structures is optional for each of these groups. Define

$\delta_1, \delta_2, \cdots, \delta_k$ as zero-one indicators of the mean structures for the groups. If δ_i takes the value of one, it means that the mean structures of group i is modeled. The total number of nonredundant elements in the moment matrices is thus computed by:

$$q = \sum_{i=1}^{k} (p_i(p_i + 1)/2 + \delta_i p_i)$$

The first term in the summation represents the number of lower triangular elements in the covariance or correlation matrix, while the second term represents the number of elements in the mean matrix. Let t be the total number of independent parameters **in the model**. The degrees of freedom is:

$$df = q - (t - c)$$

where c represents the number of linear equality constraints imposed on the independent parameters in the model. In effect, the $(t-c)$ expression means that each nonredundant linear equality constraint reduces one independent parameter.

Counting the Number of Independent Parameters

To count the number of independent parameters in the model, first you have to distinguish them from the dependent parameters. Dependent parameters are expressed as functions of other parameters in the SAS programming statements. That is, a parameter is dependent if it appears at the left-hand side of the equal sign in a SAS programming statement.

A parameter is independent if it is not dependent. An independent parameter can be specified in the main or subsidiary model specification statements or the PARMS statement, or it is generated automatically by PROC TCALIS as additional parameters. Quite intuitively, all independent parameter specified in the main or subsidiary model specification statements are independent parameters **in the model**. All automatic parameters added by PROC TCALIS are also independent parameters **in the model**.

Intentionally or not, some independent parameters specified in the PARMS statement might not be counted as independent parameters in the model. Independent parameters in the PARMS statement belong in the model only when they are used to define at least one dependent parameter specified in the main or subsidiary model specification statements. This restriction eliminates the counting of superfluous independent parameters which have no bearing of model specification.

Note that when counting the number of independent parameters, you are counting the number of distinct independent parameter names but not the number of distinct parameter locations for independent parameters. For example, consider the following statement for defining the error variances in a LINEQS model:

```
std    E1-E3 = vare1 vare2 vare3;
```

You define three variance parameter locations with three independent parameters vare1, vare2, and vare3. However, in the following specification:

```
std    E1-E3 = vare vare vare;
```

you still have three variance parameter locations to define, but the number of independent parameter is only one, which is the parameter named vare.

Counting the Number of Linear Equality Constraints

The linear equality constraints refer to those specified in the BOUNDS or LINCON statement. For example, consider the following specification:

```
bounds  3 <= parm01 <= 3;
lincon  3 * parm02 + 2 * parm03 = 12;
```

In the BOUNDS statement, parm01 is constrained to a fixed number 3, and in the LINCON statement, parm02 and parm03 are constrained linearly. In effect, these two statements reduce two independent parameters from the model. In the degrees of freedom formula, the value of c is 2 for this example.

Adjustment of Degrees of Freedom

In some cases, computing degrees of freedom for model fit is not so straightforward. Two important cases are considered in the following.

The first case is when you set linear inequality or boundary constraints in your model, and these inequality or boundary constraints become "active" in your final solution. For example, you might have set inequality boundary and linear constraints as:

```
bounds  0 <= var01;
lincon  3 * beta1 + 2 * beta2 >= 7;
```

The optimal solution occurs at the boundary point so that you observe in the final solution the following two equalities:

```
var01 = 0,
3 * beta1 + 2 * beta2 = 7
```

These two active constraints reduce the number of independent parameters of your original model. As a result, PROC TCALIS will automatically increase the degrees of freedom by the number of active linear constraints. Adjusting degrees of freedom not only affects the significance of the model fit chi-square statistic, but it also affects the computation of many fit statistics and indices. Refer to Dijkstra (1992) for a discussion of the validity of statistical inferences with active boundary constraints.

Automatically adjusting df in such a situation might not be totally justified in all cases. Statistical estimation is subject to sampling fluctuation. Active constraints might not occur when fitting the same model in new samples. If the researcher believes that those linear inequality and boundary constraints have a small chance of becoming active in repeated sampling, it might be more suitable to turn off the automatic adjustment by using the NOADJDF option in the PROC TCALIS statement.

Another case where you need to pay attention to the computation of degrees of freedom is when you fit correlation models. The degrees-of-freedom calculation in PROC TCALIS applies mainly to models with covariance structures with or without mean structures. When you model correlation structures, the degrees of freedom calculation in PROC TCALIS is a straightforward generalization

of the covariance structures. It does not take the fixed ones at the diagonal elements of the sample correlation matrix into account. Some might argue that with correlation structures, the degrees of freedom should be reduced by the total number of diagonal elements in the correlation matrices in the model. While PROC TCALIS does not do this automatically, you can use the DFREDUCE=*i* option to specify the adjustment, where i can be any positive or negative integer. The df value is reduced by the DFREDUCE= value.

A Different Type of Degrees of Freedom

The degrees of freedom for model fitting has to be distinguished from another type of degrees of freedom. In a regression problem, the number of degrees of freedom for the error variance estimate is the number of observations in the data set minus the number of parameters. The NOBS=, DFR= (RDF=), and DFE= (EDF=) options refer to degrees of freedom in this sense. However, these values are not related to the degrees of freedom for the model fit statistic. The NOBS=, DFR=, and DFE= options should be used in PROC TCALIS to specify the effective number of observations in the input data set only.

Assessment of Fit

In PROC TCALIS, there are three main tools for assessing model fit:

- residuals for the fitted means or covariances
- overall model fit indices
- squared multiple correlations and determination coefficients

This section contains a collection of formulas for these assessment tools. The following notation is used:

- N for the total sample size
- k for the total number of independent groups in analysis
- p for the number of manifest variables
- t for the number of parameters to estimate
- $\boldsymbol{\Theta}$ for the t-vector of parameters, $\hat{\boldsymbol{\Theta}}$ for the estimated parameters
- $\mathbf{S} = (s_{ij})$ for the $p \times p$ input covariance or correlation matrix
- $\bar{\boldsymbol{x}} = (\bar{x}_i)$ for the p-vector of sample means
- $\hat{\boldsymbol{\Sigma}} = \boldsymbol{\Sigma}(\hat{\boldsymbol{\Theta}}) = (\hat{\sigma}_{ij})$ for the predicted covariance or correlation matrix
- $\hat{\boldsymbol{\mu}} = (\hat{\mu}_i)$ for the predicted mean vector

- δ for indicating the modeling of the mean structures
- $\mathbf{W}$ for the weight matrix
- f_{min} for the minimized function value of the fitted model
- d_{min} for the degrees of freedom of the fitted model

In multiple-group analyses, subscripts are used to distinguish independent groups or samples. For example, $N_1, N_2, \ldots, N_r, \ldots, N_k$ denote the sample sizes for k groups. Similarly, notation such as p_r, $\mathbf{S}_r$, $\bar{\boldsymbol{x}}_r$, $\hat{\boldsymbol{\Sigma}}_r$, $\hat{\boldsymbol{\mu}}_r$, δ_r, and $\mathbf{W}_r$ is used for multiple-group situations.

Residuals

Residuals indicate how well each entry or element in the mean or covariance matrix is fitted. Large residuals indicate bad fit.

PROC TCALIS computes four types of residuals and writes them to the OUTSTAT= data set when requested.

- **raw residuals**

  $$s_{ij} - \hat{\sigma}_{ij}, \quad \bar{x}_i - \hat{\mu}_i$$

  for the covariance and mean residuals, respectively. The raw residuals are displayed whenever the PALL, PRINT, or RESIDUAL option is specified.

- **variance standardized residuals**

  $$\frac{s_{ij} - \hat{\sigma}_{ij}}{\sqrt{s_{ii}s_{jj}}}, \quad \frac{\bar{x}_i - \hat{\mu}_i}{\sqrt{s_{ii}}}$$

  for the covariance and mean residuals, respectively. The variance standardized residuals are displayed when you specify one of the following:

  - the PALL, PRINT, or RESIDUAL option and METHOD=NONE, METHOD=ULS, or METHOD=DWLS
  - RESIDUAL=VARSTAND

  The variance standardized residuals are equal to those computed by the EQS 3 program (Bentler 1995).

- **asymptotically standardized residuals**

  $$\frac{s_{ij} - \hat{\sigma}_{ij}}{\sqrt{v_{ij,ij}}}, \quad \frac{\bar{x}_i - \hat{\mu}_i}{\sqrt{u_{ii}}}$$

  for the covariance and mean residuals, respectively; with

  $$v_{ij,ij} = (\hat{\boldsymbol{\Gamma}}_1 - \mathbf{J}_1 \hat{\mathrm{Cov}}(\hat{\boldsymbol{\Theta}})\mathbf{J}_1')_{ij,ij}$$

$$u_{ii} = (\hat{\mathbf{\Gamma}}_2 - \mathbf{J}_2 \hat{\mathrm{Cov}}(\hat{\mathbf{\Theta}})\mathbf{J}_2')_{ii}$$

where $\hat{\mathbf{\Gamma}}_1$ is the $p^2 \times p^2$ estimated asymptotic covariance matrix of sample covariances, $\hat{\mathbf{\Gamma}}_2$ is the $p \times p$ estimated asymptotic covariance matrix of sample means, $\mathbf{J}_1$ is the $p^2 \times t$ Jacobian matrix $d\,\mathbf{\Sigma}/d\,\mathbf{\Theta}$, $\mathbf{J}_2$ is the $p \times t$ Jacobian matrix $d\,\boldsymbol{\mu}/d\,\mathbf{\Theta}$, and $\hat{Cov}(\hat{\mathbf{\Theta}})$ is the $t \times t$ estimated covariance matrix of parameter estimates, all evaluated at the sample moments and estimated parameter values. See the next section for the definitions of $\hat{\mathbf{\Gamma}}_1$ and $\hat{\mathbf{\Gamma}}_2$. Asymptotically standardized residuals are displayed when one of the following conditions is met:

- The PALL, the PRINT, or the RESIDUAL option is specified, and METHOD=ML, METHOD=GLS, or METHOD=WLS, and the expensive information and Jacobian matrices are computed for some other reason.
- RESIDUAL= ASYSTAND is specified.

The asymptotically standardized residuals are equal to those computed by the LISREL 7 program (Jöreskog and Sörbom 1988) except for the denominator in the definition of matrix $\hat{\mathbf{\Gamma}}_1$.

- **normalized residuals**

$$\frac{s_{ij} - \hat{\sigma}_{ij}}{\sqrt{(\hat{\mathbf{\Gamma}}_1)_{ij,ij}}}, \quad \frac{\bar{x}_i - \hat{\mu}_i}{\sqrt{(\hat{\mathbf{\Gamma}}_2)_{ii}}}$$

for the covariance and mean residuals, respectively; with $\hat{\mathbf{\Gamma}}_1$ as the $p^2 \times p^2$ estimated asymptotic covariance matrix of sample covariances; and $\hat{\mathbf{\Gamma}}_2$ as the $p \times p$ estimated asymptotic covariance matrix of sample means.

Diagonal elements of $\hat{\mathbf{\Gamma}}_1$ and $\hat{\mathbf{\Gamma}}_2$ are defined for the following methods:

- **GLS**: $(\hat{\mathbf{\Gamma}}_1)_{ij,ij} = \frac{1}{(N-1)}(s_{ii}s_{jj} + s_{ij}^2)$ and $(\hat{\mathbf{\Gamma}}_2)_{ii} = \frac{1}{(N-1)}s_{ii}$
- **ML**: $(\hat{\mathbf{\Gamma}}_1)_{ij,ij} = \frac{1}{(N-1)}(\hat{\sigma}_{ii}\hat{\sigma}_{jj} + \hat{\sigma}_{ij}^2)$ and $(\hat{\mathbf{\Gamma}}_2)_{ii} = \frac{1}{(N-1)}\hat{\sigma}_{ii}$
- **WLS**: $(\hat{\mathbf{\Gamma}}_1)_{ij,ij} = \frac{1}{(N-1)}W_{ij,ij}$ and $(\hat{\mathbf{\Gamma}}_2)_{ii} = \frac{1}{(N-1)}s_{ii}$

where $\mathbf{W}$ in the **WLS** method is the weight matrix for the second-order moments.

Normalized residuals are displayed when one of the following conditions is met:

- The PALL, PRINT, or RESIDUAL option is specified, and METHOD=ML, METHOD=GLS, or METHOD=WLS, and the expensive information and Jacobian matrices are **not** computed for some other reasons.
- RESIDUAL=NORM is specified.

The normalized residuals are equal to those computed by the LISREL VI program (Jöreskog and Sörbom 1985) except for the definition of the denominator in computing matrix $\hat{\mathbf{\Gamma}}_1$.

For estimation methods that are not "best" generalized least squares estimators (Browne 1982, 1984), such as METHOD=NONE, METHOD=ULS, or METHOD=DWLS, the assumption of an asymptotic covariance matrix $\mathbf{\Gamma}_1$ of sample covariances does not seem to be appropriate. In this

case, the normalized residuals should be replaced by the more relaxed variance standardized residuals. Computation of asymptotically standardized residuals requires computing the Jacobian and information matrices. This is computationally very expensive and is done only if the Jacobian matrix has to be computed for some other reasons—that is, if at least one of the following items is true:

- The default, PRINT, or PALL displayed output is requested, and neither the NOMOD nor NOSTDERR option is specified.
- Either the MODIFICATION (included in PALL), PCOVES, or STDERR (included in default, PRINT, and PALL output) option is requested or RESIDUAL=ASYSTAND is specified.
- The LEVMAR or NEWRAP optimization technique is used.
- An OUTMODEL= data set is specified without using the NOSTDERR option.
- An OUTEST= data set is specified without using the NOSTDERR option.

Since normalized residuals use an overestimate of the asymptotic covariance matrix of residuals (the diagonals of $\mathbf{\Gamma}_1$ and $\mathbf{\Gamma}_2$), the normalized residuals cannot be larger than the asymptotically standardized residuals (which use the diagonal of the form $\mathbf{\Gamma} - \mathbf{J}\hat{\mathrm{C}}\mathrm{ov}(\hat{\mathbf{\Theta}})\mathbf{J}'$).

Together with the residual matrices, the values of the average residual, the average off-diagonal residual, and the rank order of the largest values are displayed. The distributions of the normalized and standardized residuals are displayed also.

Overall Model Fit Indices

Instead of assessing the model fit by looking at a number of residuals of the fitted moments, an overall model fit index measures model fit by a single number. Although an overall model fit index is precise and easy to use, there are indeed many choices of overall fit indices. Unfortunately, researchers do not always have a consensus on the best set of indices to use in all occasions.

PROC TCALIS produces a large number of overall model fit indices in the fit summary table. If you prefer to display only a subset of these fit indices, you can use the ONLIST(ONLY)= option of the FITINDEX statement to customize the fit summary table.

Fit indices are classified into three classes in the fit summary table of PROC TCALIS:

- absolute or standalone Indices
- parsimony indices
- incremental indices

Absolute or Standalone Indices

These indices are constructed so that they measure model fit without comparing with a baseline model and without taking the model complexity into account. They measure the absolute fit of the model.

- **fit function or discrepancy function**
  The fit function or discrepancy function F is minimized during the optimization. See the section "Estimation Criteria" on page 6888 for definitions of various discrepancy functions available in PROC TCALIS. For a multiple-group analysis, the fit function can be written as a weighted average of discrepancy functions for k independent groups as:

  $$F = \sum_{r=1}^{k} a_r F_r$$

  where $a_r = \frac{(N_j - 1)}{(N-k)}$ and F_r are the group weight and the discrepancy function for the r-th group, respectively. Notice that although the groups are assumed to be independent in the model, in general F_r's are not independent when F is being minimized. The reason is that F_r's might have shared parameters in $\mathbf{\Theta}$ during estimation.

  The minimized function value of F will be denoted as f_{min}, which is always positive, with small values indicating good fit.

- **χ^2 test statistic**
  For the ML, GLS, and the WLS estimation, the overall χ^2 measure for testing model fit is:

  $$\chi^2 = (N - k) * f_{min}$$

  where f_{min} is the function value at the minimum, N is the total sample size, and k is the number of independent groups. The associated degrees of freedom is denoted by d_{min}.

  For the ML estimation, this gives the likelihood ratio test statistic of the specified structural model in the null hypothesis against an unconstrained saturated model in the alternative hypothesis. The χ^2 test is valid only if the observations are independent and identically distributed, the analysis is based on the nonstandardized sample covariance matrix $\mathbf{S}$, and the sample size N is sufficiently large (Browne 1982; Bollen 1989b; Jöreskog and Sörbom 1985). For ML and GLS estimates, the variables must also have an approximately multivariate normal distribution.

  In the output fit summary table of PROC TCALIS, the notation "Prob > Chi-Square" means "the probability of obtaining a greater χ^2 value than the observed value under the null hypothesis." This probability is also known as the p-value of the chi-square test statistic.

- **adjusted χ^2 value (Browne 1982)**
  If the variables are p-variate elliptic rather than normal and have significant amounts of multivariate kurtosis (leptokurtic or platykurtic), the χ^2 value can be adjusted to:

  $$\chi^2_{ell} = \frac{\chi^2}{\eta_2}$$

  where η_2 is the multivariate relative kurtosis coefficient.

- **Z-test (Wilson and Hilferty 1931)**
  The Z-test of Wilson and Hilferty assumes a p-variate normal distribution:

  $$Z = \frac{\sqrt[3]{\frac{\chi^2}{d}} - (1 - \frac{2}{9d})}{\sqrt{\frac{2}{9d}}}$$

  where d is the degrees of freedom of the model. Refer to McArdle (1988) and Bishop, Fienberg, and Holland (1977, p. 527) for an application of the Z-test.

- **critical N index (Hoelter 1983)**

$$\text{CN} = \frac{\chi^2_{crit}}{f_{min}} + 1$$

where χ^2_{crit} is the critical chi-square value for the given d degrees of freedom and probability $\alpha = 0.05$. Refer to Bollen (1989b, p. 277). Hoelter (1983) suggests that CN should be at least 200; however, Bollen (1989b) notes that the CN value might lead to an overly pessimistic assessment of fit for small samples.

- **root mean square residual (RMR)**
For a single-group analysis, the RMR is the root of the mean of the squared residuals:

$$\text{RMR} = \sqrt{\frac{2}{p(p+1+2\delta)}[\sum_{i}^{p}\sum_{j}^{i}(s_{ij}-\hat{\sigma}_{ij})^2 + \delta\sum_{i}^{p}(\bar{x}_i-\hat{\mu}_i)^2]}$$

For multiple-group analysis, PROC TCALIS computes the root mean square residual RMR_r for each group first. To obtain an overall RMR measure for the analysis, individual RMR_r's are weighted by the group weights $a_r = \frac{N_r-1}{N-k}$. That is,

$$\text{overall RMR} = \sqrt{\sum_{r=1}^{k} a_r \text{RMR}_r^2}$$

- **standardized root mean square residual (SRMR)**
For a single-group analysis, the SRMR is the root of the mean of the squared standardized residuals:

$$\text{SRMR} = \sqrt{\frac{2}{p(p+1+2\delta)}[\sum_{i}^{p}\sum_{j}^{i}\frac{(s_{ij}-\hat{\sigma}_{ij})^2}{s_{ii}s_{jj}} + \delta\sum_{i}^{p}\frac{(\bar{x}_i-\hat{\mu}_i)^2}{s_{ii}}]}$$

Similar to the calculation of the overall RMR, an overall measure of SRMR in a multiple-group analysis is a weighted average of the individual SRMR's. That is, with $a_r = \frac{N_r-1}{N-k}$

$$\text{overall SRMR} = \sqrt{\sum_{r=1}^{k} a_r \text{SRMR}_r^2}$$

- **goodness-of-fit index (GFI)**
For a single-group analysis, the goodness-of-fit index for the ULS, GLS, and ML estimation methods is:

$$GFI = 1 - \frac{Tr((\mathbf{W}^{-1}(\mathbf{S}-\hat{\boldsymbol{\Sigma}}))^2) + \delta(\bar{\boldsymbol{x}}-\hat{\boldsymbol{\mu}})'\mathbf{W}^{-1}(\bar{\boldsymbol{x}}-\hat{\boldsymbol{\mu}})}{Tr((\mathbf{W}^{-1}\mathbf{S})^2) + \delta\bar{\boldsymbol{x}}'\mathbf{W}^{-1}\bar{\boldsymbol{x}}}$$

with $\mathbf{W} = I$ for ULS, $\mathbf{W} = \mathbf{S}$ for GLS, and $\mathbf{W} = \hat{\boldsymbol{\Sigma}}$. For WLS and DWLS estimation,

$$GFI = 1 - \frac{(u-\hat{\eta})'\mathbf{W}^{-1}(u-\hat{\eta})}{u'\mathbf{W}^{-1}u}$$

where u is the vector of observed moments and $\hat{\eta}$ is the vector of fitted moments. When the mean structures are modeled, vectors u and $\hat{\eta}$ contains all the nonredundant elements vecs(**S**) in the covariance matrix and all the means. That is,

$$u = (\text{vecs}'(\mathbf{S}), \bar{\boldsymbol{x}}')', \quad \hat{\eta} = (\text{vecs}'(\hat{\boldsymbol{\Sigma}}), \hat{\boldsymbol{\mu}}')'$$

and the symmetric weight matrix **W** is of dimension $p \times (p+3)/2$. When the mean structures are not modeled, vectors u and $\hat{\eta}$ contains all the nonredundant elements vecs(**S**) in the covariance matrix only. That is,

$$u = \text{vecs}(\mathbf{S}), \quad \hat{\eta} = \text{vecs}(\hat{\boldsymbol{\Sigma}})$$

and the symmetric weight matrix **W** is of dimension $p \times (p+1)/2$. In addition, for the DWLS estimation, **W** is a diagonal matrix.

For a constant weight matrix **W**, the goodness-of-fit index is 1 minus the ratio of the minimum function value and the function value before any model has been fitted. The GFI should be between 0 and 1. The data probably do not fit the model if the GFI is negative or much larger than 1.

For a multiple-group analysis, individual GFI_r's are computed for groups. The overall measure is a weighted average of individual GFI_r's, using weight $a_r = \frac{N_r - 1}{N - k}$. That is,

$$\text{overall GFI} = \sum_{r=1}^{k} a_r \text{GFI}_r$$

Parsimony Indices

These indices are constructed so that the model complexity is taken into account when assessing model fit. In general, models with more parameters (fewer degrees of freedom) are penalized.

- **adjusted goodness-of-fit index (AGFI)**
  The AGFI is the GFI adjusted for the degrees of freedom d of the model,

  $$\text{AGFI} = 1 - \frac{c}{d}(1 - \text{GFI})$$

  where

  $$c = \sum_{r=1}^{k} \frac{p_k(p_k + 1 + 2\delta_k)}{2}$$

  computes the total number of elements in the covariance matrices and mean vectors for modeling. For single-group analyses, the AGFI corresponds to the GFI in replacing the total sum of squares by the mean sum of squares.

  CAUTION:

  - Large p and small d can result in a negative AGFI. For example, GFI= 0.90, p= 19, and d= 2 result in an AGFI of −8.5.

- AGFI is not defined for a saturated model, due to division by $d = 0$.
- AGFI is not sensitive to losses in d.

The AGFI should be between 0 and 1. The data probably do not fit the model if the AGFI is negative or much larger than 1. For more information, refer to Mulaik et al. (1989).

- **parsimonious goodness-of-fit index (PGFI)**
The PGFI (Mulaik et al. 1989) is a modification of the GFI that takes the parsimony of the model into account:

$$\text{PGFI} = \frac{d_{min}}{d_0}\text{GFI}$$

where d_{min} is the model degrees of freedom and d_0 is the degrees of freedom for the independence model. See the section "Incremental Indices" on page 6909 for the definition of independence model. The PGFI uses the same parsimonious factor as the parsimonious normed Bentler-Bonett index (James, Mulaik, and Brett 1982).

- **RMSEA index (Steiger and Lind 1980; Steiger 1998)**
The Steiger and Lind (1980) (see also Steiger 1998) root mean square error approximation (RMSEA) coefficient is:

$$\epsilon = \sqrt{k}\sqrt{\max(\frac{f_{min}}{d_{min}} - \frac{1}{(N-k)}, 0)}$$

The lower and upper limits of the $(1-\alpha)$%-confidence interval are computed using the cumulative distribution function of the noncentral chi-squared distribution $\Phi(x|\lambda, d)$. With $x = (N-k)\,f_{min}$, λ_L satisfying $\Phi(x|\lambda_L, d_{min}) = 1-\frac{\alpha}{2}$, and λ_U satisfying $\Phi(x|\lambda_U, d_{min}) = \frac{\alpha}{2}$:

$$(\epsilon_{\alpha_L}; \epsilon_{\alpha_U}) = (\sqrt{k}\sqrt{\frac{\lambda_L}{(N-k)d_{min}}}; \sqrt{k}\sqrt{\frac{\lambda_U}{(N-k)d_{min}}})$$

Refer to Browne and Du Toit (1992) for more details. The size of the confidence interval can be set by the option ALPHARMS=α, $0 \le \alpha \le 1$. The default is $\alpha = 0.1$, which corresponds to the 90% confidence interval for the RMSEA.

- **probability for test of close fit (Browne and Cudeck 1993)**
The traditional exact χ^2 test hypothesis $H_0{:}\,\epsilon = 0$ is replaced by the null hypothesis of close fit $H_0{:}\,\epsilon \le 0.05$ and the exceedance probability P is computed as:

$$P = 1 - \Phi(x|\lambda^*, d_{min})$$

where $x = (N-k)\,f_{min}$ and $\lambda^* = 0.05^2(N-k)d_{min}/k$. The null hypothesis of close fit is rejected if P is smaller than a pre-specified level (for example, $P < 0.05$).

- **ECVI: expected cross validation index (Browne and Cudeck 1993)**
The following formulas for ECVI are limited to the case of single-sample analysis without mean structures. For other cases, ECVI is not defined in PROC TCALIS. For GLS and WLS, the estimator c of the ECVI is linearly related to AIC, Akaike's Information Criterion (Akaike 1974; 1987):

$$c = f_{min} + \frac{2t}{N-1}$$

For ML estimation, c_{ML} is used:

$$c_{ML} = f_{min} + \frac{2t}{N-p-2}$$

For GLS and WLS, the confidence interval $(c_L; c_U)$ for ECVI is computed using the cumulative distribution function $\Phi(x|\lambda, d_{min})$ of the noncentral chi-squared distribution,

$$(c_L; c_U) = (\frac{\lambda_L + p(p+1)/2 + t}{(N-1)}; \frac{\lambda_U + p(p+1)/2 + t}{(N-1)})$$

with $x = (N-1)\,f_{min}$, $\Phi(x|\lambda_U, d_{min}) = \frac{\alpha}{2}$, and $\Phi(x|\lambda_L, d_{min}) = 1 - \frac{\alpha}{2}$.
For ML, the confidence interval $(c_L^*; c_U^*)$ for ECVI is:

$$(c_L^*; c_U^*) = (\frac{\lambda_L^* + p(p+1)/2 + t}{N-p-2}; \frac{\lambda_U^* + p(p+1)/2 + t}{N-p-2})$$

where $x = (N-p-2)\,f_{min}$, $\Phi(x|\lambda_U^*, d_{min}) = \frac{\alpha}{2}$ and $\Phi(x|\lambda_L^*, d_{min}) = 1 - \frac{\alpha}{2}$. Refer to Browne and Cudeck (1993). The size of the confidence interval can be set by the option ALPHAECV=α, $0 \leq \alpha \leq 1$. The default is $\alpha = 0.1$, which corresponds to the 90% confidence interval for the ECVI.

- **Akaike's information criterion (AIC) (Akaike 1974; 1987)**
  This is a criterion for selecting the best model among a number of candidate models. The model that yields the smallest value of AIC is considered the best.

  $$\text{AIC} = \chi^2 - 2d_{min}$$

- **consistent Akaike's information criterion (CAIC) (Bozdogan 1987)**
  This is another criterion, similar to AIC, for selecting the best model among alternatives. The model that yields the smallest value of CAIC is considered the best. CAIC is preferred by some people to AIC or the χ^2 test.

  $$\text{CAIC} = \chi^2 - (ln(N) + 1)d_{min}$$

- **Schwarz's Bayesian criterion (SBC) (Schwarz 1978; Sclove 1987)**
  This is another criterion, similar to AIC, for selecting the best model. The model that yields the smallest value of SBC is considered the best. SBC is preferred by some people to AIC or the χ^2 test.

  $$\text{SBC} = \chi^2 - ln(N)d_{min}$$

- **McDonald's measure of centrality (McDonald and Hartmann 1992)**

  $$\text{CENT} = \exp(-\frac{(\chi^2 - d_{min})}{2N})$$

Incremental Indices

These indices are constructed so that the model fit is assessed through the comparison with a baseline model. The baseline model is usually the independence model where all covariances among manifest variables are assumed to be zeros. The only parameters in the independence model are the diagonals of covariance matrix. If modeled, the mean structures are saturated in the independence model. For multiple-group analysis, the overall independence model consists of component independence models for each group.

In the following, let f_0 and d_0 denote the minimized discrepancy function value and the associated degrees of freedom, respectively, for the independence model; and f_{min} and d_{min} denote the minimized discrepancy function value and the associated degrees of freedom, respectively, for the model being fitted in the null hypothesis.

- **Bentler comparative fit index (Bentler 1995)**

$$\text{CFI} = 1 - \frac{\max((N-k)f_{min} - d_{min}, 0)}{\max((N-k)f_0 - d_0, 0)}$$

- **Bentler-Bonett normed fit index (NFI) (Bentler and Bonett 1980)**

$$\Delta = \frac{f_0 - f_{min}}{f_0}$$

  Mulaik et al. (1989) recommend the parsimonious weighted form called parsimonious normed fit index (PNFI) (James, Mulaik, and Brett 1982).

- **Bentler-Bonett nonnormed coefficient (Bentler and Bonett 1980)**

$$\rho = \frac{f_0/d_0 - f_{min}/d_{min}}{f_0/d_0 - 1/(N-k)}$$

  Refer to Tucker and Lewis (1973).

- **normed index ρ_1 (Bollen 1986)**

$$\rho_1 = \frac{f_0/d_0 - f_{min}/d_{min}}{f_0/d_0}$$

  ρ_1 is always less than or equal to 1; $\rho_1 < 0$ is unlikely in practice. Refer to the discussion in Bollen (1989a).

- **nonnormed index Δ_2 (Bollen 1989a)**

$$\Delta_2 = \frac{f_0 - f_{min}}{f_0 - \frac{d_{min}}{(N-k)}}$$

  is a modification of Bentler and Bonett's Δ that uses d and "lessens the dependence" on N. Refer to the discussion in Bollen (1989b). Δ_2 is identical to Mulaik et al.'s (1989) IFI2 index.

- **parsimonious normed fit index (James, Mulaik, and Brett 1982)**
  The PNFI is a modification of Bentler-Bonett's normed fit index that takes parsimony of the model into account,

  $$\text{PNFI} = \frac{d_{min}}{d_0}\frac{(f_0 - f_{min})}{f_0}$$

  The PNFI uses the same parsimonious factor as the parsimonious GFI of Mulaik et al. (1989).

Fit Indices and Estimation Methods

Note that not all fit indices are reasonable or appropriate for all estimation methods set by the METHOD= option of the PROC TCALIS statement. The availability of fit indices is summarized as follows:

- Adjusted (elliptic) chi-square and its probability are available only for METHOD=ML or GLS and with the presence of raw data input.
- For METHOD=ULS or DWLS, probability of the chi-square value, RMSEA and its confidence intervals, probability of close fit, ECVI and its confidence intervals, critical N index, Z-test, AIC, CAIC, SBC, and measure of centrality are not appropriate and therefore not displayed.

Individual Fit Indices for Multiple Groups

When you compare the fits of individual groups in a multiple-group analysis, you can examine the residuals of the groups to gauge which group is fitted better than the others. While examining residuals is good for knowing specific locations with inadequate fit, summary measures like fit indices for individual groups would be more convenient for overall comparisons among groups.

Although the overall fit function is a weighted sum of individual fit functions for groups, these individual functions are not statistically independent. Therefore, in general you cannot partition the degrees of freedom or χ^2 value according to the groups. This eliminates the possibility of breaking down those fit indices that are functions of degrees of freedom or χ^2 for group comparison purposes. Bearing this fact in mind, PROC TCALIS computes only a limited number of descriptive fit indices for individual groups.

- **fit function**
  The overall fit function is:

  $$F = \sum_{r=1}^{k} a_r F_r$$

  where $a_r = \frac{(N_j - 1)}{(N - k)}$ and F_r are the group weight and the discrepancy function for group r, respectively. The value of unweighted fit function F_r for the r-th group is denoted by:

  $$f_r$$

  This f_r value provides a measure of fit in the r-th group without taking the sample size into account. The large the f_r, the worse the fit for the group.

- **percentage contribution to the chi-square**
  The percentage contribution of group r to the chi-square is:

  $$\text{percentage contribution} = a_r f_r / f_{min} \times 100\%$$

  where f_r is the value of F_r with F minimized at the value f_{min}. This percentage value provides a descriptive measure of fit of the moments in group r, weighted by its sample size. The group with the largest percentage contribution accounts for the most lack of fit in the overall model.

- **root mean square residual (RMR)**
  For the r-th group, the total number of moments being modeled is:

  $$g = \frac{p_r(p_r + 1 + 2\delta_r)}{2}$$

  where p_r is the number of variables and δ_r is the indicator variable of the mean structures in the r-th group. The root mean square residual for the r-th group is:

  $$\text{RMR}_r = \sqrt{\frac{1}{g}[\sum_i^{p_r}\sum_j^{i}([\mathbf{S}_r]_{ij} - [\hat{\boldsymbol{\Sigma}}_r]_{ij})^2 + \delta_r \sum_i^{p_r}([\bar{\boldsymbol{x}}_r]_i - [\hat{\boldsymbol{\mu}}_r]_i)^2]}$$

- **standardized root mean square residual (SRMR)**
  For the r-th group, the standardized root mean square residual is:

  $$\text{SRMR} = \sqrt{\frac{1}{g}[\sum_i^{p_r}\sum_j^{i}\frac{([\mathbf{S}_r]_{ij} - [\hat{\boldsymbol{\Sigma}}_r]_{ij})^2}{[\mathbf{S}_r]_{ii}[\mathbf{S}_r]_{jj}} + \delta_r \sum_i^{p_r}\frac{([\bar{\boldsymbol{x}}_r]_i - [\hat{\boldsymbol{\mu}}_r]_i)^2}{[\mathbf{S}_r]_{ii}}]}$$

- **goodness-of-fit index (GFI)**
  For the ULS, GLS, and ML estimation, the goodness-of-fit index (GFI) for the r-th group is:

  $$GFI = 1 - \frac{Tr((\mathbf{W}_r^{-1}(\mathbf{S}_r - \hat{\boldsymbol{\Sigma}}_r))^2) + \delta_r(\bar{\boldsymbol{x}}_r - \hat{\boldsymbol{\mu}}_r)'\mathbf{W}_r^{-1}(\bar{\boldsymbol{x}}_r - \hat{\boldsymbol{\mu}}_r)}{Tr((\mathbf{W}_r^{-1}\mathbf{S}_r)^2) + \delta_r \bar{\boldsymbol{x}}_r'\mathbf{W}_r^{-1}\bar{\boldsymbol{x}}_r}$$

  with $\mathbf{W}_r = I$ for ULS, $\mathbf{W}_r = \mathbf{S}_r$ for GLS, and $\mathbf{W}_r = \hat{\boldsymbol{\Sigma}}_r$. For the WLS and DWLS estimation,

  $$GFI = 1 - \frac{(u_r - \hat{\eta}_r)'\mathbf{W}_r^{-1}(u_r - \hat{\eta}_r)}{u_r'\mathbf{W}_r^{-1}u_r}$$

  where u_r is the vector of observed moments and $\hat{\eta}_r$ is the vector of fitted moments for the r-th group ($r = 1, \ldots, k$).

  When the mean structures are modeled, vectors u_r and $\hat{\eta}_r$ contain all the nonredundant elements $\text{vecs}(\mathbf{S}_r)$ in the covariance matrix and all the means, and $\mathbf{W}_r$ is the weight matrix for covariances and means. When the mean structures are not modeled, u_r, $\hat{\eta}_r$, and $\mathbf{W}_r$ contain elements pertaining to the covariance elements only. Basically, formulas presented here are the same as the case for a single-group GFI. The only thing added here is the subscript r to denote individual group measures.

- **Bentler-Bonnett normed fit index (NFI)**
  For the r-th group, the Bentler-Bonnett NFI is:

$$\Delta_r = \frac{f_{0r} - f_r}{f_{0r}}$$

  where f_{0r} is the function value for fitting the independence model to the r-th group. The larger the value of Δ_r, the better is the fit for the group. Basically, the formula here is the same as the overall Bentler-Bonnet NFI. The only difference is that the subscript r is added to denote individual group measures.

Squared Multiple Correlations and Determination Coefficients

In the section, squared multiple correlations for endogenous variables are defined. Squared multiple correlation is computed for all of these five estimation methods: ULS, GLS, ML, WLS, and DWLS. These coefficients are also computed as in the LISREL VI program of Jöreskog and Sörbom (1985). The DETAE, DETSE, and DETMV determination coefficients are intended to be multivariate generalizations of the squared multiple correlations for different subsets of variables. These coefficients are displayed only when you specify the PDETERM option.

- **R^2 values corresponding to endogenous variables**

$$R^2 = 1 - \frac{\widehat{\mathrm{Evar}}(y)}{\widehat{\mathrm{Var}}(y)}$$

  where y denotes an endogenous variable, $\widehat{\mathrm{Var}}(y)$ denotes its variance, and $\widehat{\mathrm{Evar}}(y)$ denotes its error (or unsystematic) variance. The variance and error variance are estimated under the model.

- **total determination of all equations**

$$\mathrm{DETAE} = 1 - \frac{|\widehat{\mathrm{Ecov}}(\mathbf{y}, \boldsymbol{\eta})|}{|\widehat{\mathrm{Cov}}(\mathbf{y}, \boldsymbol{\eta})|}$$

  where the $\mathbf{y}$ vector denotes all manifest dependent variables, the $\boldsymbol{\eta}$ vector denotes all latent dependent variables, $\widehat{\mathrm{Cov}}(\mathbf{y}, \boldsymbol{\eta})$ denotes the covariance matrix of $\mathbf{y}$ and $\boldsymbol{\eta}$, and $\widehat{\mathrm{Ecov}}(\mathbf{y}, \boldsymbol{\eta})$ denotes the error covariance matrix of $\mathbf{y}$ and $\boldsymbol{\eta}$. The covariance matrices are estimated under the model.

- **total determination of latent equations**

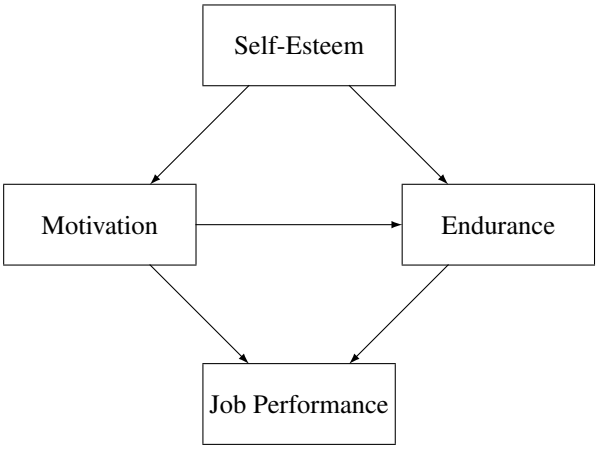
$$\mathrm{DETSE} = 1 - \frac{|\widehat{\mathrm{Ecov}}(\boldsymbol{\eta})|}{|\widehat{\mathrm{Cov}}(\boldsymbol{\eta})|}$$

  where the $\boldsymbol{\eta}$ vector denotes all latent dependent variables, $\widehat{\mathrm{Cov}}(\boldsymbol{\eta})$ denotes the covariance matrix of $\boldsymbol{\eta}$, and $\widehat{\mathrm{Ecov}}(\boldsymbol{\eta})$ denotes the error covariance matrix of $\boldsymbol{\eta}$. The covariance matrices are estimated under the model.

- **total determination of the manifest equations**

$$\text{DETMV} = 1 - \frac{|\widehat{\text{Ecov}}(\mathbf{y})|}{|\widehat{\text{Cov}}(\mathbf{y})|}$$

where the $\mathbf{y}$ vector denotes all manifest dependent variables, $\widehat{\text{Cov}}(\mathbf{y})$ denotes the covariance matrix of $\mathbf{y}$, $\widehat{\text{Ecov}}(\mathbf{y})$ denotes the error covariance matrix of $\mathbf{y}$, and $|A|$ denotes the determinant of matrix A. All the covariance matrices in the formula are estimated under the model.



You can also use the DETERM statement to request the computations of determination coefficients for any subsets of dependent variables.

Total, Direct, and Indirect Effects

Most structural equation models involve the specification of the effects of variables on each other. Whenever you specify equations in the LINEQS model, paths in the PATH model, path coefficient parameters in the RAM model, variable-factor relations in the FACTOR model, or regression coefficients in model matrices of the LISMOD model, you are specifying direct effects of predictor variables on outcome variables. All direct effects are represented by the associated regression coefficients, either fixed or free, in the specifications. You can examine the direct effect estimates easily in the output for model estimation.

However, direct effects are not the only effects that are important. In some cases, the indirect effects or total effects are of interest too. For example, suppose Self-Esteem is an important factor of Job Performance in your theory. Although it does not have a direct effect on Job Performance, it affects Job Performance through its influences on Motivation and Endurance. Also, Motivation has a direct effect on Endurance in your theory. The following path diagram summarizes such a theory:

Figure 88.4 Direct and Indirect Effects of Self-Esteem on Job Performance

Clearly, each path in the diagram represents a direct effect of a predictor variable on an outcome variable. Less apparent are the total and indirect effects implied by the same path diagram. Despite

this, interesting theoretical questions regarding the total and indirect effects can be raised in such a model. For example, even though there is no direct effect of Self-Esteem on Job Performance, what is its indirect effect on Job Performance? In addition to its direct effect on Job Performance, Motivation also has an indirect effect on Job Performance via its effect on Endurance. So, what is the total effect of Motivation on Job Performance and what portion of this total effect is indirect? The TOTEFF option of the TCALIS statement and the EFFPART statement are designed to address these questions. By using the TOTEFF option or the EFFPART statement, PROC TCALIS can compute the total, direct, and indirect effects of any sets of predictor variables on any sets of outcome variables. In this section, formulas for computing these effects are presented.

Formulas for Computing Total, Direct and Indirect Effects

No matter which modeling language is used, variables in a model can be classified into three groups. The first group is the so-called dependent variables, which serve as outcome variables at least once in the model. The other two groups consist of the remaining independent variables, which never serve as outcome variables in the model. The second group consists of independent variables that are unsystematic sources such as error and disturbance variables. The third group consists of independent variables that are systematic sources only.

Any variable, no matter which group it falls into, can have effects on the first group of variables. By definition, however, effects of variables in the first group on the other two groups do not exist. Because the effects of unsystematic sources in the second group are treated as residual effects on the first group of dependent variables, these effects are trivial in the sense that they always serve as direct effects only. That is, the effects from the second group of unsystematic sources partition trivially—total effects are always the same as the direct effects for this group. Therefore, for the purpose of effect analysis or partitioning, only the first group (dependent variables) and the third group (systematic independent variables) are considered.

Define u to be the set of n_u dependent variables in the first group and w to be the set of n_w systematic independent variables in the third group. Variables in both groups can be manifest or latent. All variables in the effect analysis is thus represented by the vector $(u', w')'$.

The $(n_u + n_w) \times (n_u + n_w)$ matrix $\mathbf{D}$ of **direct** effects refers to the path coefficients from all column variables to the row variables. This matrix is represented by:

$$\mathbf{D} = \begin{pmatrix} \beta & \gamma \\ 0 & 0 \end{pmatrix}$$

where β is an $(n_u \times n_u)$ matrix for direct effects of dependent variables on dependent variables and γ is an $(n_u \times n_w)$ matrix for direct effects of systematic independent variables on dependent variables. By definition, there should not be any direct effects on independent variables, and therefore the lower submatrices of $\mathbf{D}$ are null. In addition, by model restrictions the diagonal elements of matrix β must be zeros.

Correspondingly, the $(n_u + n_w) \times (n_u + n_w)$ matrix $\mathbf{T}$ of **total** effects of column variables on the row variables is computed by:

$$\mathbf{T} = \begin{pmatrix} (I - \beta)^{-1} - I & (I - \beta)^{-1}\gamma \\ 0 & 0 \end{pmatrix}$$

Finally, the $(n_u + n_w) \times (n_u + n_w)$ matrix **M** of **indirect** effects of column variables on the row variables is computed by the difference between **T** and **D** as:

$$\mathbf{M} = \begin{pmatrix} (I-\beta)^{-1} - I - \beta & (I-\beta)^{-1}\gamma - \gamma \\ 0 & 0 \end{pmatrix}$$

In PROC TCALIS, any subsets of **D**, **T**, and **M** can be requested via the specification in the EFFPART statement. All you need to do is to specify the sets of column variables (variables that have effects on others) and row variables (variables that receive the effects, direct or indirect). Specifications of the column and row variables are done conveniently by specifying variable names—no matrix terminology is needed. This feature is very handy if you have some focused subsets of effects that you want to analyze a priori. See the EFFPART statement on page 6751 for details about specifications.

Stability Coefficient of Reciprocal Causation

For recursive models (that is, models without cyclical paths of effects), using the preceding formulas for computing the total effect and the indirect effect is appropriate without further restrictions. However, for non-recursive models (that is, models with reciprocal effects or cyclical effects) the appropriateness of the preceding formulas for effect computations is restricted to situations with the convergence of the total effects.

A necessary and sufficient condition for the convergence of total effects (with or without cyclical paths) is when all eigenvalues, complex or real, of the $\boldsymbol{\beta}$ matrix fall into a unit circle (see Bentler and Freeman 1983). Equivalently, define the stability coefficient of reciprocal causation as the largest length (modulus) of the eigenvalues of the $\boldsymbol{\beta}$ matrix. A stability coefficient less than one would ensure that all eigenvalues, complex or real, of the $\boldsymbol{\beta}$ matrix fall into a unit circle. Hence, stability coefficient that is less than one is a necessary and sufficient condition for the convergence of the total effects, which in turn substantiates the appropriateness of total and indirect effect computations. Whenever effect analysis or partitioning is requested, PROC TCALIS will check the appropriateness of effect computations by evaluating the stability coefficient of reciprocal causation. If the stability coefficient is greater than one, computations of the total and indirect effects will not be done.

Standardized Solutions

Standardized solutions are useful when you want to compare parameter values that are measured on quite different scales. PROC TCALIS provides standardized solutions routinely. In standardizing a solution, parameters are classified into five groups:

- **path coefficients, regression coefficients, or direct effects**
  With each parameter α in this group, there is an associated outcome variable and a predictor variable. Denote the predicted variance of the outcome variable by σ_o^2 and the variance of the predictor variable by σ_p^2, the standardized parameter α^* is:

  $$\alpha^* = \alpha \frac{\sigma_p}{\sigma_o}$$

- **fixed ones for the path coefficients attached to error or disturbance terms**
  These fixed values are unchanged in standardization.

- **variances and covariances among exogenous variables, excluding errors and disturbances**
  Let σ_{ij} be the covariance between variables i and j. In this notation, σ_{ii} is the variance of variable i. The standardized covariance σ^*_{ij} is:

  $$\sigma^*_{ij} = \frac{\sigma_{ij}}{\sqrt{\sigma_{ii}\sigma_{jj}}}$$

  When $i = j$, σ^*_{ii} takes the value of 1 for all i. Also, σ^*_{ij} is the correlation between the i-th and j-th variables.

- **variances and covariances among errors or disturbances**
  Denote the error covariance parameter as θ_{ij} so that θ_{ii} represents the variance parameter of error variable i. Associated with each error or disturbance variable i is a unique outcome variable. Let the variance of such an outcome variable be σ_{ii}. In the standardized solution, the error covariance θ_{ij} is rescaled as:

  $$\theta^*_{ij} = \frac{\theta_{ij}}{\sqrt{\sigma_{ii}\sigma_{jj}}}$$

  Notice that when $i = j$, θ^*_{ii} is not standardized to 1 in general. In fact, the error (disturbance) variance is simply rescaled by the reciprocal of the variance of the associated dependent variable. As a result, the rescaled error (disturbance) variance represents the proportion of variation of the dependent variable due to the unsystematic source. By the same token, θ^*_{ij} does not represent the correlation between errors i and j. It is a rescaled covariance of the errors involved.

- **intercepts and means of variables**
  These parameters are fixed zeros in the standardized solution.

While formulas for the standardized solution are useful in computing the parameter values in the standardized solution, it is conceptually more useful to explain how variables are being transformed in the standardization process. The following provides a summary of the transformation process:

- Observed and latent variables, excluding errors or disturbances, are centered and then divided by their corresponding standard deviations. Therefore, in the standardized solution, all these variables will have variance equal to 1. In other words, these variables are truly standardized.

- Errors or disturbances are divided by the standard deviations of the corresponding outcome variables. In the standardized solution, these variables will not have variance equal to 1 in general. However, the rescaled error variances represent the proportion of unexplained or unsystematic variance of the corresponding outcome variables. Therefore, errors or disturbances in the standardized solution are simply rescaled but not standardized.

Standardized total, direct, and indirect effects are computed using formulas presented in the section "Total, Direct, and Indirect Effects" on page 6913, but with the standardized parameter values substituted into the formulas.

Although parameter values associated with different scales are made more comparable in the standardized solution, a precaution should be mentioned. In the standardized solution, the original constraints on parameters in the unstandardized solution are usually lost. These constraints, however, might underscore some important theoretical position that needs to be maintained in the model. Destroying these constraints in the standardized solution means that interpretations or comparisons of parameter values in the standardized solution are made without maintaining the original theoretical position. You must judge whether such a departure from the original constraints poses conceptual difficulties for interpreting the standardized solution.

Modification Indices

While fitting structural equation models is mostly a confirmatory analytic procedure, it does not prevent you from exploring what might have been a better model given the data. After fitting your theoretical structural equation model, you might want to modify the original model in order to do one of the following:

- add free parameters to improve the model fit significantly
- reduce the number of parameters without affecting the model fit too much

The first kind of model modification can be achieved by using the Lagrange multiplier (LM) test indices. Parameters that have the largest LM indices would increase the model fit the most. In general, adding more parameters to your model improves the overall model fit, as measured by those absolute or standalone fit indices (see the section "Overall Model Fit Indices" on page 6903 for more details). However, adding parameters liberally makes your model more prone to sampling errors. It also makes your model more complex and less interpretable in most cases. A disciplined use of LM test indices is highly recommended. In addition to the model fit improvement indicated by the LM test indices, you should also consider the theoretical significance when adding particular parameters. See Example 88.10 for an illustration of the use of LM test indices for improving model fit.

The second kind of model modification can be achieved by using the Wald statistics. Parameters that are not significant in your model may be removed from the model without affecting the model fit too much. In general, removing parameters from your model decreases the model fit, as measured by those absolute or standalone fit indices (see the section "Overall Model Fit Indices" on page 6903 for more details). However, for just a little sacrifice in model fit, removing non-significant parameters increases the simplicity and precision of your model, which is the virtue that any modeler should look for.

Whether adding parameters by using the LM test indices or removing unnecessary parameters by the Wald statistics, you should not treat your modified model as if it were your original hypothesized model. That is, you should not publish your modified model as if it were hypothesized a priori. It is perfectly fine to use modification indices to gain additional insights for future research. But if you want to publish your modified model together with your original model, you should report the modification process that leads to your modified model. Theoretical justifications of the modified model should be supplemented if you want to make strong statements to support your modified

model. Whenever possible, the best practice is to show reasonable model fit of the modified model with new data.

To modify your model either by LM test indices or Wald statistics, you can use the MODIFICATION or MOD option in the PROC TCALIS statement. To customize the LM tests by setting specific regions of parameters, you can use the LMTESTS statements. PROC TCALIS computes and displays the following default set of modification indices:

- **univariate Lagrange multiplier (LM) test indices for parameters in the model**
  These are second-order approximations of the decrease in the χ^2 value that would result from allowing the *fixed parameter values* in the model to be freed to estimate. LM test indices are ranked within their own parameter regions in the model. The ones that suggest biggest model improvements (that is, largest χ^2 drop) are ranked first. Depending on the type of your model, the set of possible parameter regions varies. For example, in a RAM model, modification indices are ranked in three different parameter regions for the covariance structures: path coefficients, variances of and covariances among exogenous variables, and the error variances and covariances. In addition to the value of the Lagrange multiplier, the corresponding p-value ($df = 1$) and the approximate change of the parameter value are displayed.

  If you use the LMMAT option in the LMTESTS statement, LM test indices are shown as elements in model matrices. Not all elements in a particular model matrix will have LM test indices. Elements that are already free parameters in the model do not have LM test indices. Instead, the parameter names are shown. Elements that are model restricted values (for example, direct path from a variable to itself must be zero) are labeled Excluded in the matrix output. When you customize your own regions of LM tests, some elements might also be excluded from a custom set of LM tests. These elements are also labeled as Excluded in the matrix output. If an LM test for freeing a parameter would result in a singular information matrix, the corresponding element in the matrix is labeled as Singular.

- **univariate Lagrange multiplier test indices for releasing equality constraints**
  These are second-order approximations of the decrease in the χ^2 value that would result from the release of *equality constraints*. Multiple equality constraints containing $n > 2$ parameters are tested successively in n steps, each assuming the release of one of the equality-constrained parameters. The expected change of the parameter values of the separated parameter and the remaining parameter cluster are displayed, too.

- **univariate Lagrange multiplier test indices for releasing active boundary constraints**
  These are second-order approximations of the decrease in the χ^2 value that would result from the release of the *active boundary constraints* specified in the BOUNDS statement.

- **stepwise multivariate Wald statistics for constraining free parameters to 0**
  These are second-order approximations of the increases in χ^2 value that would result from constraining free parameters to zero in a stepwise fashion. In each step, the parameter that would lead to the smallest increase in the multivariate χ^2 value is set to 0. Besides the multivariate χ^2 value and its p-value, the univariate increments are also displayed. The process stops when the univariate p-value is smaller than the specified value in the SLMW= option, of which the default value is 0.05.

All of the preceding tests are approximations. You can often obtain more accurate tests by actually fitting different models and computing likelihood ratio tests. For more details about the Wald and the Lagrange multiplier test, refer to MacCallum (1986), Buse (1982), Bentler (1986), or Lee (1985). Note that relying solely on the LM tests to modify your model can lead to unreliable models that capitalize purely on sampling errors. See MacCallum, Roznowski, and Necowitz (1992) for the use of LM tests.

For large model matrices, the computation time for the default modification indices can considerably exceed the time needed for the minimization process.

The modification indices are not computed for unweighted least squares or diagonally weighted least squares estimation.

Missing Values

If the DATA= data set contains raw data (rather than a covariance or correlation matrix), observations with missing values for any variables in the analysis are omitted from the computations. If a covariance or correlation matrix is read, missing values are allowed as long as every pair of variables has at least one nonmissing value.

Measures of Multivariate Kurtosis

In many applications, the manifest variables are not even approximately multivariate normal. If this happens to be the case with your data set, the default generalized least squares and maximum likelihood estimation methods are not appropriate, and you should compute the parameter estimates and their standard errors by an asymptotically distribution-free method, such as the WLS estimation method. If your manifest variables are multivariate normal, then they have a zero relative multivariate kurtosis, and all marginal distributions have zero kurtosis (Browne 1982). If your DATA= data set contains raw data, PROC TCALIS computes univariate skewness and kurtosis and a set of multivariate kurtosis values. By default, the values of univariate skewness and kurtosis are corrected for bias (as in PROC UNIVARIATE), but using the BIASKUR option enables you to compute the uncorrected values also. The values are displayed when you specify the PROC TCALIS statement option KURTOSIS.

In the following formulas, N denotes the sample size and p denotes the number of variables.

- **corrected variance for variable** z_j

$$\sigma_j^2 = \frac{1}{N-1}\sum_{i}^{N}(z_{ij} - \bar{z}_j)^2$$

- **uncorrected univariate skewness for variable** z_j

$$\gamma_{1(j)} = \frac{N \sum_i^N (z_{ij} - \bar{z}_j)^3}{\sqrt{N[\sum_i^N (z_{ij} - \bar{z}_j)^2]^3}}$$

- **corrected univariate skewness for variable** z_j

$$\gamma_{1(j)} = \frac{N}{(N-1)(N-2)} \frac{\sum_i^N (z_{ij} - \bar{z}_j)^3}{\sigma_j^3}$$

- **uncorrected univariate kurtosis for variable** z_j

$$\gamma_{2(j)} = \frac{N \sum_i^N (z_{ij} - \bar{z}_j)^4}{[\sum_i^N (z_{ij} - \bar{z}_j)^2]^2} - 3$$

- **corrected univariate kurtosis for variable** z_j

$$\gamma_{2(j)} = \frac{N(N+1)}{(N-1)(N-2)(N-3)} \frac{\sum_i^N (z_{ij} - \bar{z}_j)^4}{\sigma_j^4} - \frac{3(N-1)^2}{(N-2)(N-3)}$$

- **Mardia's multivariate kurtosis**

$$\gamma_2 = \frac{1}{N} \sum_i^N [(z_i - \bar{z})' S^{-1} (z_i - \bar{z})]^2 - p(p+2)$$

- **relative multivariate kurtosis**

$$\eta_2 = \frac{\gamma_2 + p(p+2)}{p(p+2)}$$

- **normalized multivariate kurtosis**

$$\kappa_0 = \frac{\gamma_2}{\sqrt{8p(p+2)/N}}$$

- **Mardia based kappa**

$$\kappa_1 = \frac{\gamma_2}{p(p+2)}$$

- **mean scaled univariate kurtosis**

$$\kappa_2 = \frac{1}{3p} \sum_j^p \gamma_{2(j)}$$

- **adjusted mean scaled univariate kurtosis**

$$\kappa_3 = \frac{1}{3p}\sum_{j}^{p}\gamma^*_{2(j)}$$

with

$$\gamma^*_{2(j)} = \begin{cases} \gamma_{2(j)} & , \quad \text{if} \quad \gamma_{2(j)} > \frac{-6}{p+2} \\ \frac{-6}{p+2} & , \quad \text{otherwise} \end{cases}$$

If variable Z_j is normally distributed, the uncorrected univariate kurtosis $\gamma_{2(j)}$ is equal to 0. If Z has an p-variate normal distribution, Mardia's multivariate kurtosis γ_2 is equal to 0. A variable Z_j is called *leptokurtic* if it has a positive value of $\gamma_{2(j)}$ and is called *platykurtic* if it has a negative value of $\gamma_{2(j)}$. The values of κ_1, κ_2, and κ_3 should not be smaller than the following lower bound (Bentler 1985):

$$\hat{\kappa} \geq \frac{-2}{p+2}$$

PROC TCALIS displays a message if κ_1, κ_2, or κ_3 falls below the lower bound.

If weighted least squares estimates (METHOD=WLS or METHOD=ADF) are specified and the weight matrix is computed from an input raw data set, the TCALIS procedure computes two more measures of multivariate kurtosis.

- **multivariate mean kappa**

$$\kappa_4 = \frac{1}{m}\sum_{i}^{p}\sum_{j}^{i}\sum_{k}^{j}\sum_{l}^{k}\hat{\kappa}_{ij,kl} - 1$$

where

$$\hat{\kappa}_{ij,kl} = \frac{s_{ij,kl}}{s_{ij}s_{kl} + s_{ik}s_{jl} + s_{il}s_{jk}}$$

and $m = p(p+1)(p+2)(p+3)/24$ is the number of elements in the vector $s_{ij,kl}$ (Bentler 1985).

- **multivariate least squares kappa**

$$\kappa_5 = \frac{s_4' s_2}{s_2' s_2} - 1$$

where s_2 is the vector of the elements in the denominator of $\hat{\kappa}$ (Bentler 1985) and s_4 is the vector of the $s_{ij,kl}$, which is defined as:

$$s_{ij,kl} = \frac{1}{N}\sum_{r=1}^{N}(z_{ri} - \bar{z}_i)(z_{rj} - \bar{z}_j)(z_{rk} - \bar{z}_k)(z_{rl} - \bar{z}_l)$$

The occurrence of significant nonzero values of Mardia's multivariate kurtosis γ_2 and significant amounts of some of the univariate kurtosis values $\gamma_{2(j)}$ indicate that your variables are not multivariate normal distributed. Violating the multivariate normality assumption in (default) generalized least squares and maximum likelihood estimation usually leads to the wrong approximate standard errors and incorrect fit statistics based on the χ^2 value. In general, the parameter estimates are more stable against violation of the normal distribution assumption. For more details, refer to Browne (1974, 1982, 1984).

Initial Estimates

Each optimization technique requires a set of initial values for the parameters. To avoid local optima, the initial values should be as close as possible to the globally optimal solution. You can check for local optima by running the analysis with several different sets of initial values; the RANDOM= option in the PROC TCALIS statement is useful in this regard.

Except for the case of exploratory FACTOR model, you can specify initial estimates manually for all different types of models. If you do not specify some of the initial estimates and the RANDOM= option is not used, PROC TCALIS will use a combination of good strategic methods to compute initial estimates for your model.

These initial estimation methods are used in PROC TCALIS:

- two-stage least squares estimation
- instrumental variable method (Hägglund 1982; Jennrich 1987)
- approximate factor analysis method
- ordinary least squares estimation
- estimation method of McDonald (McDonald and Hartmann 1992)
- observed moments of manifest exogenous variables

The choice of initial estimation methods is dependent on the data and on the model. In general, it is difficult to tell in advance which initial estimation methods will be used for a given analysis. However, PROC TCALIS displays the methods used to obtain initial estimates in the output.

Poor initial values can cause convergence problems, especially with maximum likelihood estimation. Sufficiently large positive initial values for variance estimates (as compared with the covariance estimates) might help prevent a nonnegative definite initial predicted covariance model matrix from happening. If maximum likelihood estimation fails to converge, it might help to use METHOD=LSML, which uses the final estimates from an unweighted least squares analysis as initial estimates for maximum likelihood. Or you can fit a slightly different but better-behaved model and produce an OUTMODEL= data set, which can then be modified in accordance with the original model and used as an INMODEL= data set to provide initial values for another analysis.

If you are analyzing a covariance or scalar product matrix, be sure to take into account the scales of the variables. The default initial values might be inappropriate when some variables have extremely large or small variances.

Use of Optimization Techniques

No algorithm for optimizing general nonlinear functions exists that can always find the global optimum for a general nonlinear minimization problem in a reasonable amount of time. Since no single optimization technique is invariably superior to others, PROC TCALIS provides a variety of optimization techniques that work well in various circumstances. However, you can devise problems for which none of the techniques in PROC TCALIS can find the correct solution. All optimization techniques in PROC TCALIS use $O(n^2)$ memory except the conjugate gradient methods, which use only $O(n)$ of memory and are designed to optimize problems with many parameters.

The PROC TCALIS statement NLOPTIONS can be especially helpful for tuning applications with nonlinear equality and inequality constraints on the parameter estimates. Some of the options available in NLOPTIONS can also be invoked as PROC TCALIS options. The NLOPTIONS statement can specify almost the same options as the SAS/OR NLP procedure.

Nonlinear optimization requires the repeated computation of the following:

- the function value (optimization criterion)
- the gradient vector (first-order partial derivatives)
- for some techniques, the (approximate) Hessian matrix (second-order partial derivatives)
- values of linear and nonlinear constraints
- the first-order partial derivatives (Jacobian) of nonlinear constraints

For the criteria used by PROC TCALIS, computing the gradient takes more computer time than computing the function value, and computing the Hessian takes *much* more computer time and memory than computing the gradient, especially when there are many parameters to estimate. Unfortunately, optimization techniques that do not use the Hessian usually require many more iterations than techniques that do use the (approximate) Hessian, and so they are often slower. Techniques that do not use the Hessian also tend to be less reliable (for example, they might terminate at local rather than global optima).

The available optimization techniques are displayed in the following table and can be chosen by the OMETHOD=$name$ option.

OMETHOD=	Optimization Technique
LEVMAR	Levenberg-Marquardt method
TRUREG	trust-region method
NEWRAP	Newton-Raphson method with line search
NRRIDG	Newton-Raphson method with ridging
QUANEW	quasi-Newton methods (DBFGS, DDFP, BFGS, DFP)
DBLDOG	double-dogleg method (DBFGS, DDFP)
CONGRA	conjugate gradient methods (PB, FR, PR, CD)

The following table shows, for each optimization technique, which derivatives are needed (first-order or second-order) and what kind of constraints (boundary, linear, or nonlinear) can be imposed on the parameters.

	Derivatives		Constraints		
OMETHOD=	First Order	Second Order	Boundary	Linear	Nonlinear
LEVMAR	x	x	x	x	-
TRUREG	x	x	x	x	-
NEWRAP	x	x	x	x	-
NRRIDG	x	x	x	x	-
QUANEW	x	-	x	x	x
DBLDOG	x	-	x	x	-
CONGRA	x	-	x	x	-

The Levenberg-Marquardt, trust-region, and Newton-Raphson techniques are usually the most reliable, work well with boundary and general linear constraints, and generally converge after a few iterations to a precise solution. However, these techniques need to compute a Hessian matrix in each iteration. Computing the approximate Hessian in each iteration can be very time- and memory-consuming, especially for large problems (more than 60 or 100 parameters, depending on the computer used). For large problems, a quasi-Newton technique, especially with the BFGS update, can be far more efficient.

For a poor choice of initial values, the Levenberg-Marquardt method seems to be more reliable.

If memory problems occur, you can use one of the conjugate gradient techniques, but they are generally slower and less reliable than the methods that use second-order information.

There are several options to control the optimization process. You can specify various termination criteria. You can specify the GCONV= option to specify a relative gradient termination criterion. If there are active boundary constraints, only those gradient components that correspond to inactive constraints contribute to the criterion. When you want very precise parameter estimates, the GCONV= option is useful. Other criteria that use relative changes in function values or parameter estimates in consecutive iterations can lead to early termination when active constraints cause small steps to occur. The small default value for the FCONV= option helps prevent early termination. Using the MAXITER= and MAXFUNC= options enables you to specify the maximum number of iterations and function calls in the optimization process. These limits are especially useful in combination with the INMODEL= and OUTMODEL= options; you can run a few iterations at a time, inspect the results, and decide whether to continue iterating.

Nonlinearly Constrained QN Optimization

The algorithm used for nonlinearly constrained quasi-Newton optimization is an efficient modification of Powell's (1978a, 1978b, 1982a, 1982b) Variable Metric Constrained WatchDog (VMCWD) algorithm. A similar but older algorithm (VF02AD) is part of the Harwell library. Both VMCWD and VF02AD use Fletcher's VE02AD algorithm (also part of the Harwell library) for positive definite quadratic programming. The PROC TCALIS QUANEW implementation uses a quadratic programming subroutine that updates and downdates the approximation of the Cholesky factor when the active set changes. The nonlinear QUANEW algorithm is not a feasible point algorithm, and the value of the objective function might not necessarily decrease (minimization) or increase (maximization) monotonically. Instead, the algorithm tries to reduce a linear combination of the objective function and constraint violations, called the *merit function*.

The following are similarities and differences between this algorithm and VMCWD:

- A modification of this algorithm can be performed by specifying VERSION=1, which replaces the update of the Lagrange vector μ with the original update of Powell (1978a, 1978b), which is used in VF02AD. This can be helpful for some applications with linearly dependent active constraints.
- If the VERSION= option is not specified or VERSION=2 is specified, the evaluation of the Lagrange vector μ is performed in the same way as Powell (1982a, 1982b) describes.
- Instead of updating an approximate Hessian matrix, this algorithm uses the dual BFGS (or DFP) update that updates the Cholesky factor of an approximate Hessian. If the condition of the updated matrix gets too bad, a restart is done with a positive diagonal matrix. At the end of the first iteration after each restart, the Cholesky factor is scaled.
- The Cholesky factor is loaded into the quadratic programming subroutine, automatically ensuring positive definiteness of the problem. During the quadratic programming step, the Cholesky factor of the projected Hessian matrix $\mathbf{Z}_k'\mathbf{G}\mathbf{Z}_k$ and the QT decomposition are updated simultaneously when the active set changes. Refer to Gill et al. (1984) for more information.
- The line-search strategy is very similar to that of Powell (1982a, 1982b). However, this algorithm does not call for derivatives during the line search; hence, it generally needs fewer derivative calls than function calls. The VMCWD algorithm always requires the same number of derivative and function calls. It was also found in several applications of VMCWD that Powell's line-search method sometimes uses steps that are too long during the first iterations. In those cases, you can use the INSTEP= option specification to restrict the step length α of the first iterations.
- The watchdog strategy is similar to that of Powell (1982a, 1982b). However, this algorithm does not return automatically after a fixed number of iterations to a former better point. A return here is further delayed if the observed function reduction is close to the expected function reduction of the quadratic model.
- Although Powell's termination criterion still is used (as FCONV2), the QUANEW implementation uses two additional termination criteria (GCONV and ABSGCONV).

This algorithm is automatically invoked when you specify the NLINCON statement. The nonlinear QUANEW algorithm needs the Jacobian matrix of the first-order derivatives (constraints normals) of the constraints:

$$(\nabla c_i) = (\frac{\partial c_i}{\partial x_j}), \quad i = 1, \ldots, nc, j = 1, \ldots, n$$

where nc is the number of nonlinear constraints for a given point x.

You can specify two update formulas with the UPDATE= option:

- UPDATE=DBFGS performs the dual BFGS update of the Cholesky factor of the Hessian matrix. This is the default.
- UPDATE=DDFP performs the dual DFP update of the Cholesky factor of the Hessian matrix.

This algorithm uses its own line-search technique. All options and parameters (except the INSTEP= option) controlling the line search in the other algorithms do not apply here. In several applications, large steps in the first iterations are troublesome. You can specify the INSTEP= option to impose an upper bound for the step size α during the first five iterations. The values of the LCSINGULAR=, LCEPSILON=, and LCDEACT= options (which control the processing of linear and boundary constraints) are valid only for the quadratic programming subroutine used in each iteration of the nonlinear constraints QUANEW algorithm.

Optimization and Iteration History

The optimization and iteration histories are displayed by default because it is important to check for possible convergence problems. The optimization history includes the following summary of information about the initial state of the optimization:

- the number of constraints that are active at the starting point, or more precisely, the number of constraints that are currently members of the working set. If this number is followed by a plus sign, there are more active constraints, of which at least one is temporarily released from the working set due to negative Lagrange multipliers.
- the value of the objective function at the starting point
- if the (projected) gradient is available, the value of the largest absolute (projected) gradient element
- for the TRUREG and LEVMAR subroutines, the initial radius of the trust region around the starting point

The optimization history ends with some information concerning the optimization result:

- the number of constraints that are active at the final point, or more precisely, the number of constraints that are currently members of the working set. If this number is followed by a plus sign, there are more active constraints, of which at least one is temporarily released from the working set due to negative Lagrange multipliers.
- the value of the objective function at the final point
- if the (projected) gradient is available, the value of the largest absolute (projected) gradient element
- other information specific to the optimization technique

The iteration history generally consists of one line of displayed output containing the most important information for each iteration.

The iteration history always includes the following:

- the iteration number
- the number of iteration restarts
- the number of function calls
- the number of active constraints
- the value of the optimization criterion
- the difference between adjacent function values
- the maximum of the absolute gradient components that correspond to inactive boundary constraints

An apostrophe trailing the number of active constraints indicates that at least one of the active constraints is released from the active set due to a significant Lagrange multiplier.

For the Levenberg-Marquardt technique (LEVMAR), the iteration history also includes the following information:

- an asterisk trailing the iteration number when the computed Hessian approximation is singular and consequently ridged with a positive lambda value. If all or the last several iterations show a singular Hessian approximation, the problem is not sufficiently identified. Thus, there are other locally optimal solutions that lead to the same optimum function value for different parameter values. This implies that standard errors for the parameter estimates are not computable without the addition of further constraints.
- the value of the Lagrange multiplier (lambda). This value is 0 when the optimum of the quadratic function approximation is inside the trust region (a trust-region-scaled Newton step

can be performed) and is greater than 0 when the optimum of the quadratic function approximation is located at the boundary of the trust region (the scaled Newton step is too long to fit in the trust region and a quadratic constraint optimization is performed). Large values indicate optimization difficulties. For a nonsingular Hessian matrix, the value of lambda should go to 0 during the last iterations, indicating that the objective function can be well approximated by a quadratic function in a small neighborhood of the optimum point. An increasing lambda value often indicates problems in the optimization process.

- the value of the ratio ρ (rho) between the actually achieved difference in function values and the predicted difference in the function values on the basis of the quadratic function approximation. Values much less than 1 indicate optimization difficulties. The value of the ratio ρ indicates the goodness of the quadratic function approximation. In other words, $\rho << 1$ means that the radius of the trust region has to be reduced; a fairly large value of ρ means that the radius of the trust region does not need to be changed. And a value close to or larger than 1 means that the radius can be increased, indicating a good quadratic function approximation.

For the Newton-Raphson technique (NRRIDG), the iteration history also includes the following information:

- the value of the ridge parameter. This value is 0 when a Newton step can be performed, and it is greater than 0 when either the Hessian approximation is singular or a Newton step fails to reduce the optimization criterion. Large values indicate optimization difficulties.
- the value of the ratio ρ (rho) between the actually achieved difference in function values and the predicted difference in the function values on the basis of the quadratic function approximation. Values much less than 1.0 indicate optimization difficulties.

For the Newton-Raphson with line-search technique (NEWRAP), the iteration history also includes the following information:

- the step size α (alpha) computed with one of the line-search algorithms
- the slope of the search direction at the current parameter iterate. For minimization, this value should be significantly negative. Otherwise, the line-search algorithm has difficulty reducing the function value sufficiently.

For the trust-region technique (TRUREG), the iteration history also includes the following information:

- an asterisk after the iteration number when the computed Hessian approximation is singular and consequently ridged with a positive lambda value.
- the value of the Lagrange multiplier (lambda). This value is zero when the optimum of the quadratic function approximation is inside the trust region (a trust-region-scaled Newton step can be performed) and is greater than zero when the optimum of the quadratic function approximation is located at the boundary of the trust region (the scaled Newton step is too

long to fit in the trust region and a quadratically constrained optimization is performed). Large values indicate optimization difficulties. As in Gay (1983), a negative lambda value indicates the special case of an indefinite Hessian matrix (the smallest eigenvalue is negative in minimization).

- the value of the radius Δ of the trust region. Small trust-region radius values combined with large lambda values in subsequent iterations indicate optimization problems.

For the quasi-Newton (QUANEW) and conjugate gradient (CONGRA) techniques, the iteration history also includes the following information:

- the step size (alpha) computed with one of the line-search algorithms
- the descent of the search direction at the current parameter iterate. This value should be significantly smaller than 0. Otherwise, the line-search algorithm has difficulty reducing the function value sufficiently.

Frequent update restarts (rest) of a quasi-Newton algorithm often indicate numerical problems related to required properties of the approximate Hessian update, and they decrease the speed of convergence. This can happen particularly if the ABSGCONV= termination criterion is too small—that is, when the requested precision cannot be obtained by quasi-Newton optimization. Generally, the number of automatic restarts used by conjugate gradient methods are much higher.

For the nonlinearly constrained quasi-Newton technique, the iteration history also includes the following information:

- the maximum value of all constraint violations,

$$\text{conmax} = \max(|c_i(x)| : c_i(x) < 0)$$

- the value of the predicted function reduction used with the GCONV and FCONV2 termination criteria,

$$\text{pred} = |g(x^{(k)})s(x^{(k)})| + \sum_{i=1}^{m} |\lambda_i c_i(x^{(k)})|$$

- the step size α of the quasi-Newton step. Note that this algorithm works with a special line-search algorithm.
- the maximum element of the gradient of the Lagrange function,

$$\begin{aligned} \text{lfgmax} &= \nabla_x L(x^{(k)}, \lambda^{(k)}) \\ &= \nabla_x f(x^{(k)}) - \sum_{i=1}^{m} \lambda_i^{(k)} \nabla_x c_i(x^{(k)}) \end{aligned}$$

For the double dogleg technique, the iteration history also includes the following information:

- the parameter λ of the double-dogleg step. A value $\lambda = 0$ corresponds to the full (quasi) Newton step.
- the slope of the search direction at the current parameter iterate. For minimization, this value should be significantly negative.

Line-Search Methods

In each iteration k, the (dual) quasi-Newton, hybrid quasi-Newton, conjugate gradient, and Newton-Raphson minimization techniques use iterative line-search algorithms that try to optimize a linear, quadratic, or cubic approximation of the nonlinear objective function f of n parameters x along a feasible descent search direction $s^{(k)}$ as follows:

$$f(x^{(k+1)}) = f(x^{(k)} + \alpha^{(k)} s^{(k)})$$

by computing an approximately optimal scalar $\alpha^{(k)} > 0$. Since the outside iteration process is based only on the approximation of the objective function, the inside iteration of the line-search algorithm does not have to be perfect. Usually, it is satisfactory that the choice of α significantly reduces (in a minimization) the objective function. Criteria often used for termination of line-search algorithms are the Goldstein conditions (Fletcher 1987).

Various line-search algorithms can be selected by using the LIS= option on page 6731. The line-search methods LIS=1, LIS=2, and LIS=3 satisfy the left-hand-side and right-hand-side Goldstein conditions (Fletcher 1987). When derivatives are available, the line-search methods LIS=6, LIS=7, and LIS=8 try to satisfy the right-hand-side Goldstein condition; if derivatives are not available, these line-search algorithms use only function calls.

The line-search method LIS=2 seems to be superior when function evaluation consumes significantly less computation time than gradient evaluation. Therefore, LIS=2 is the default value for Newton-Raphson, (dual) quasi-Newton, and conjugate gradient optimizations.

Restricting the Step Length

Almost all line-search algorithms use iterative extrapolation techniques that can easily lead to feasible points where the objective function f is no longer defined (resulting in indefinite matrices for ML estimation) or is difficult to compute (resulting in floating point overflows). Therefore, PROC TCALIS provides options that restrict the step length or trust region radius, especially during the first main iterations.

The inner product $g's$ of the gradient g and the search direction s is the slope of $f(\alpha) = f(x + \alpha s)$ along the search direction s with step length α. The default starting value $\alpha^{(0)} = \alpha^{(k,0)}$ in each line-search algorithm ($\min_{\alpha>0} f(x + \alpha s)$) during the main iteration k is computed in three steps:

1. Use either the difference $df = |f^{(k)} - f^{(k-1)}|$ of the function values during the last two consecutive iterations or the final stepsize value α^- of the previous iteration $k-1$ to compute a first value $\alpha_1^{(0)}$.

- Using the DAMPSTEP<r> option:

$$\alpha_1^{(0)} = \min(1, r\alpha^-)$$

The initial value for the new step length can be no larger than r times the final step length α^- of the previous iteration. The default is $r = 2$.

- Not using the DAMPSTEP option:

$$\alpha_1^{(0)} = \begin{cases} step & \text{if } 0.1 \leq step \leq 10 \\ 10 & \text{if } step > 10 \\ 0.1 & \text{if } step < 0.1 \end{cases}$$

with

$$step = \begin{cases} df/|g's| & \text{if } |g's| \geq \epsilon \max(100df, 1) \\ 1 & \text{otherwise} \end{cases}$$

This value of $\alpha_1^{(0)}$ can be too large and can lead to a difficult or impossible function evaluation, especially for highly nonlinear functions such as the EXP function.

2. During the first five iterations, the second step enables you to reduce $\alpha_1^{(0)}$ to a smaller starting value $\alpha_2^{(0)}$ using the INSTEP=r option:

$$\alpha_2^{(0)} = \min(\alpha_1^{(0)}, r)$$

After more than five iterations, $\alpha_2^{(0)}$ is set to $\alpha_1^{(0)}$.

3. The third step can further reduce the step length by

$$\alpha_3^{(0)} = \min(\alpha_2^{(0)}, \min(10, u))$$

where u is the maximum length of a step inside the feasible region.

The INSTEP=r option lets you specify a smaller or larger radius of the trust region used in the first iteration by the trust-region, double-dogleg, and Levenberg-Marquardt algorithms. The default initial trust region radius is the length of the scaled gradient (Moré 1978). This default length for the initial trust region radius corresponds to the default radius factor of $r = 1$. This choice is successful in most practical applications of the TRUREG, DBLDOG, and LEVMAR algorithms. However, for bad initial values used in the analysis of a covariance matrix with high variances or for highly nonlinear constraints (such as using the EXP function) in your SAS programming statements, the default start radius can result in arithmetic overflows. If this happens, you can try decreasing values of INSTEP=r ($0 < r < 1$), until the iteration starts successfully. A small factor r also affects the trust region radius of the next steps because the radius is changed in each iteration by a factor $0 < c \leq 4$ depending on the ρ ratio. Reducing the radius corresponds to increasing the ridge parameter λ that produces smaller steps directed closer toward the gradient direction.

Computational Problems

First Iteration Overflows

Analyzing a covariance matrix that includes high variances in the diagonal and using bad initial estimates for the parameters can easily lead to arithmetic overflows in the first iterations of the minimization algorithm. The line-search algorithms that work with cubic extrapolation are especially sensitive to arithmetic overflows. If this occurs with quasi-Newton or conjugate gradient minimization, you can specify the INSTEP= option to reduce the length of the first step. If an arithmetic overflow occurs in the first iteration of the Levenberg-Marquardt algorithm, you can specify the INSTEP= option to reduce the trust region radius of the first iteration. You also can change the minimization technique or the line-search method. If none of these help, you can consider doing the following:

- scaling the covariance matrix
- providing better initial values
- changing the model

No Convergence of Minimization Process

If convergence does not occur during the minimization process, perform the following tasks:

- If there are *negative variance estimates*, you can do either of the following:
  - Specify the BOUNDS statement to obtain nonnegative variance estimates.
  - Specify the HEYWOOD option, if the FACTOR statement is specified.
- Change the estimation method to obtain a better set of initial estimates. For example, if you use METHOD=ML, you can do either of the following:
  - Change to METHOD=LSML.
  - Run some iterations with METHOD=DWLS or METHOD=GLS, write the results in an OUTMODEL= data set, and use the results as initial values specified by an INMODEL= data set in a second run with METHOD=ML.
- Change the optimization technique. For example, if you use the default OMETHOD=LEVMAR, you can do either of the following:
  - Change to OMETHOD=QUANEW or to OMETHOD=NEWRAP.
  - Run some iterations with OMETHOD=CONGRA, write the results in an OUTMODEL= data set, and use the results as initial values specified by an INMODEL= data set in a second run with a different OMETHOD= technique.

- Change or modify the update technique or the line-search algorithm or both when using OMETHOD=QUANEW or OMETHOD=CONGRA. For example, if you use the default update formula and the default line-search algorithm, you can do any or all of the following:
  - Change the update formula with the UPDATE= option.
  - Change the line-search algorithm with the LIS= option.
  - Specify a more precise line search with the LSPRECISION= option, if you use LIS=2 or LIS=3.
- Add more iterations and function calls by using the MAXIT= and MAXFU= options.
- Change the initial values. For many categories of model specifications, PROC TCALIS computes an appropriate set of initial values automatically. However, for some of the model specifications (for example, structural equations with latent variables on the left-hand side and manifest variables on the right-hand side), PROC TCALIS might generate very obscure initial values. In these cases, you have to set the initial values yourself.
  - Increase the initial values of the variance parameters by one of the following ways:
    - Set the variance parameter values in the model specification manually.
    - Use the DEMPHAS= option to increase all initial variance parameter values.
  - Use a slightly different, but more stable, model to obtain preliminary estimates.
  - Use additional information to specify initial values, for example, by using other SAS software like the FACTOR, REG, SYSLIN, and MODEL (SYSNLIN) procedures for the modified, unrestricted model case.

Unidentified Model

The parameter vector $\boldsymbol{\Theta}$ in the structural model

$$\boldsymbol{\Sigma} = \boldsymbol{\Sigma}(\boldsymbol{\Theta})$$

is said to be identified in a parameter space G, if

$$\boldsymbol{\Sigma}(\boldsymbol{\Theta}) = \boldsymbol{\Sigma}(\tilde{\boldsymbol{\Theta}}), \quad \tilde{\boldsymbol{\Theta}} \in G$$

implies $\boldsymbol{\Theta} = \tilde{\boldsymbol{\Theta}}$. The parameter estimates that result from an unidentified model can be very far from the parameter estimates of a very similar but identified model. They are usually machine dependent. Do not use parameter estimates of an unidentified model as initial values for another run of PROC TCALIS.

Singular Predicted Covariance Model Matrix

Sometimes you might inadvertently specify models with singular predicted covariance model matrices (for example, by fixing diagonal elements to zero). In such cases, you cannot compute maximum likelihood estimates (the ML function value F is not defined). Since singular predicted covariance model matrices can also occur temporarily in the minimization process, PROC TCALIS tries in such

cases to change the parameter estimates so that the predicted covariance model matrix becomes positive definite. This process does not always work well, especially if there are fixed instead of free diagonal elements in the predicted covariance model matrices. A famous example where you cannot compute ML estimates is a component analysis with fewer components than given manifest variables. See the section "FACTOR Statement" on page 6752 for more details. If you continue to obtain a singular predicted covariance model matrix after changing initial values and optimization techniques, then your model might be specified so that ML estimates cannot be computed.

Saving Computing Time

For large models, the most computing time is needed to compute the modification indices. If you do not really need the Lagrange multipliers or multiple Wald test indices (the univariate Wald test indices are the same as the t values), using the NOMOD option can save a considerable amount of computing time.

Predicted Covariance Matrices with Negative Eigenvalues

A covariance matrix cannot have negative eigenvalues, since a negative eigenvalue means that some linear combination of the variables has negative variance. PROC TCALIS displays a warning if the predicted covariance matrix has negative eigenvalues but does not actually compute the eigenvalues. Sometimes this warning can be triggered by 0 or very small positive eigenvalues that appear negative because of numerical error. If you want to be sure that the predicted covariance matrix you are fitting can be considered to be a variance-covariance matrix, you can use the SAS/IML command *VAL=EIGVAL(U)* to compute the vector *VAL* of eigenvalues of matrix **U**.

Negative R^2 Values

The estimated squared multiple correlations R^2 of the endogenous variables are computed using the estimated error variances:

$$R_i^2 = 1 - \frac{\widehat{var(\zeta_i)}}{\widehat{var(\eta_i)}}$$

When $\widehat{var(\zeta_i)} > \widehat{var(\eta_i)}$, R_i^2 is negative. This might indicate poor model fit or R^2 is an inappropriate measure for the model. For the latter case, for example, negative R^2 might be due to cyclical (nonrecursive) paths in the model so that the R^2 interpretation is not appropriate.

Displayed Output

The output of PROC TCALIS includes the following:

- a list of basic modeling information such as: the data set, the number of records read and used in the raw data set, the number of observations assumed by the statistical analysis, and the model type. When a multiple-group analysis is specified, the groups and their corresponding models are listed. This output assumes at least the PSHORT option.
- a list of all variables in the models. This output is displayed by default or by the PINITIAL option. It will not be displayed when you use the PSHORT or the PSUMMARY option.

  Depending on the modeling language, the variable lists vary, as shown in the following:

  – FACTOR: a list of the variables and the factors
  – LINEQS, PATH, and RAM: a list of the endogenous and exogenous variables specified in the model
  – LISMOD: a list of x-, y-, ξ-, and η- variables specified in the model
  – MSTRUCT: a list of the manifest variables specified in the model
- initial model specification. This output is displayed by default or by the PINITIAL option. It will not be displayed when you use the PSHORT or the PSUMMARY option.

  Depending on the modeling language, the sets of output vary, as shown in the following:

  – FACTOR: factor loading matrix, factor covariance matrix, intercepts, factor means, and error variances as specified initially in the model. The initial values for free parameters, the fixed values, and the parameter names are also displayed.
  – LINEQS: linear equations, variance and covariance parameters, and mean parameters as specified initially in the model. The initial values for free parameters, the fixed values, and the parameter names are also displayed.
  – LISMOD: all model matrices as specified initially in the model. The initial values for free parameters, the fixed values, and the parameter names are also displayed.
  – MSTRUCT: initial covariance matrix and mean vectors, with parameter names and initial values displayed.
  – PATH: the path list, variance and covariance parameters, intercept and mean parameters as specified initially in the model. The initial values for free parameters, the fixed values, and the parameter names are also displayed.
  – RAM: a list of parameters, their types, names, and initial values.
- mean and standard deviation of each manifest variable if you specify the SIMPLE option, as well as skewness and kurtosis if the DATA= data set is a raw data set and you specify the KURTOSIS option.

- various coefficients of multivariate kurtosis and the numbers of observations that contribute most to the normalized multivariate kurtosis if the DATA= data set is a raw data set and the KURTOSIS option is used or you specify at least the PRINT option. See the section "Measures of Multivariate Kurtosis" on page 6919 for more information.

- covariance or correlation matrix to be analyzed and the value of its determinant if you specify the output option PCORR or PALL. A zero determinant indicates a singular data matrix. In this case, the generalized least squares estimates with default weight matrix **S** and maximum likelihood estimates cannot be computed.

- the weight matrix **W** or its inverse is displayed if GLS, WLS, or DWLS estimation is used and you specify the PWEIGHT or PALL option.

- initial estimation methods for generating initial estimates. This output is displayed by default. It will not be displayed when you use the PSHORT or the PSUMMARY option.

- vector of parameter names and initial values and gradients. This output is displayed by default, unless you specify the PSUMMARY or NOPRINT option.

- special features of the optimization technique chosen if you specify at least the PSHORT option.

- optimization history if at least the PSHORT option is specified. For more details, see the section "Use of Optimization Techniques" on page 6923.

- specific output requested by options in the NLOPTIONS statement; for example, parameter estimates, gradient, constraints, projected gradient, Hessian, projected Hessian, Jacobian of nonlinear constraints, estimated covariance matrix of parameter estimates, and information matrix. Note that the estimated covariance of parameter estimates and the information matrix are not printed for the ULS and DWLS estimation methods.

- fit summary table with various model fit test statistics or fit indices, and some basic modeling information. For the listing of fit indices and their definitions, see the section "Overall Model Fit Indices" on page 6903. Note that for ULS and DWLS estimation methods, many of those fit indices that are based on model fit χ^2 are not displayed. See the section "Overall Model Fit Indices" on page 6903 for details. This output can be suppressed by the NOPRINT option.

- fit comparison for multiple-group analysis. See the section "Individual Fit Indices for Multiple Groups" on page 6910 for the fit indices for group comparison. This output can be suppressed by the NOPRINT option.

- the predicted covariance matrix and its determinant and mean vector, if you specify the output option PCORR or PALL.

- residual and normalized residual matrix if you specify the RESIDUAL option or at least the PRINT option. The variance standardized or asymptotically standardized residual matrix can be displayed also. The average residual and the average off-diagonal residual are also displayed. Note that normalized or asymptotically standardized residuals are not applicable for the ULS and DWLS estimation methods.

  See the section "Residuals" on page 6901 for more details.

- rank order of the largest normalized residuals if you specify the RESIDUAL option or at least the PRINT option.
- bar chart of the normalized residuals if you specify the RESIDUAL option or at least the PRINT option.
- plotting of smoothed density functions of residuals if you request the ODS Graphics by the PLOTS= option.
- equations of linear dependencies among the parameters used in the model specification if the information matrix is recognized as singular at the final solution.
- the estimation results and the standardized results. Except for ULS or DWLS estimates, the approximate standard errors and t values are also displayed. This output is displayed by default or if you specify the PESTIM option or at least the PSHORT option.

  Depending on the modeling language, the sets of output vary, as shown in the following:

  - FACTOR: factor loading matrix, rotation matrix, rotated factor loading matrix (if rotation requested), factor covariance matrix, intercepts, factor means, and error variances in the model. Factor rotation matrix is printed for the unstandardized solution.
  - LINEQS: linear equations, variance and covariance parameters, and mean parameters in the model.
  - LISMOD: all model matrices in the model.
  - MSTRUCT: covariance matrix and mean vectors.
  - PATH: the path list, variance and covariance parameters, intercept and mean parameters.
  - RAM: a list of parameters, their types, names, and initial values.
- squared multiple correlations table which displays the error variance, total variance, and the squared multiple correlation of each endogenous variable in the model. The total variances are the diagonal elements of the predicted covariance matrix. This output is displayed if you specify the PESTIM option or at least the PSHORT option.
- the total determination of all equations, the total determination of the latent equations, and the total determination of the manifest equations if you specify the PDETERM or the PALL option. See the section "Assessment of Fit" on page 6900 for more details. If you specify subsets of variables in the DETERM statements, the corresponding determination coefficients will also be shown. If one of the determinants in the formula for computing the determination coefficient is zero, the corresponding coefficient is displayed as the missing value '.'.
- the matrix of estimated covariances among the latent variables in the model if you specify the PLATCOV option or at least the PRINT option.
- the matrix of estimated covariances between latent and manifest variables in the model if you specify the PLATCOV option or at least the PRINT option.
- the vector of estimated means for the latent and manifest variables in the model if you specify the PLATCOV option or at least the PRINT option.

- the matrix **FSR** of latent variable scores regression coefficients if you specify the PLATCOV option or at least the PRINT option. The **FSR** matrix is a generalization of Lawley and Maxwell's (1971, p.109) factor scores regression matrix,

  $$\mathbf{FSR} = \hat{\mathbf{\Sigma}}_{yx}\hat{\mathbf{\Sigma}}_{xx}^{-1}$$

  where $\hat{\mathbf{\Sigma}}_{xx}$ is the $p \times p$ predicted covariance matrix among manifest variables and $\hat{\mathbf{\Sigma}}_{yx}$ is the $m \times p$ matrix of the predicted covariances between latent and manifest variables, with p being the number of manifest variables, and m being the number of latent variables. You can multiply the observed values by this matrix to estimate the scores of the latent variables used in your model.

- stability coefficient of reciprocal causation if you request the effect analysis by using the EFFPART or TOTEFF option, and you must not use the NOPRINT option.

- the matrices for the total, direct, and indirect effects if you specify the EFFPART or TOTEFF option or at least the PRINT option, and you must not use the NOPRINT option. Unstandardized and standardized effects are printed in separate tables. Standard errors for the all estimated effects are also included in the output. Additional tables for effects are available if you request specialized effect analysis in the EFFPART statements.

- the matrix of rotated factor loadings and the orthogonal transformation matrix if you specify the ROTATE= and PESTIM options or at least the PSHORT options. This output is available for the FACTOR models.

- factor scores regression matrix, if you specify the PESTIM option or at least the PSHORT option. The determination of manifest variables is displayed only if you specify the PDETERM option.

- univariate Lagrange multiplier indices if you specify the MODIFICATION (or MOD) or the PALL option. The value of a Lagrange multiplier (LM) index indicates the approximate drop in χ^2 when the corresponding fixed parameter in the original model is freely estimated. The corresponding probability (with $df = 1$) and the estimated change of the parameter value are printed. Ranking of the LM indices is automatically done for prescribed parameter subsets of the original model. The LM indices with greatest improvement of χ^2 model fit appear in the beginning of the ranking list. Note that LM indices are not applicable to the ULS and the DWLS estimation methods. See the section "Modification Indices" on page 6917 for more detail.

- matrices of univariate Lagrange multiplier (LM) indices if you specify the MODIFICATION (or MOD) or the PALL option, and the LMMAT option in the LMTESTS statement. These matrices are predefined in PROC TCALIS, or you can specify them in the LMTESTS statements. If releasing a fixed parameter in the matrix would result in a singular information matrix, the string 'Singular' is displayed instead of the Lagrange multiplier index. If a fixed entry in the matrix is restricted by the model (for example, fixed ones for coefficients associated with error terms) or being excluded in the specified subsets in the LMTESTS statement, the string 'Excluded' is displayed. Note that matrices for LM indices are not printed for the ULS and the DWLS estimation methods. See the section "Modification Indices" on page 6917 for more detail.

- univariate Lagrange multiplier test indices for releasing equality constraints if you specify the MODIFICATION (or MOD) or the PALL option. Note that this output is not applicable to the ULS and the DWLS estimation methods. See the section "Modification Indices" on page 6917 for more detail.
- univariate Lagrange multiplier test indices for releasing active boundary constraints specified by the BOUNDS statement if you specify the MODIFICATION (or MOD) or the PALL option. Note that this output is not applicable to the ULS and the DWLS estimation methods. See the section "Modification Indices" on page 6917 for more detail.
- the stepwise multivariate Wald test for constraining estimated parameters to zero constants if the MODIFICATION (or MOD) or the PALL option is specified and the univariate probability is larger than the value specified in the PMW= option (default PMW=0.05). Note that this output is not applicable to the ULS and the DWLS estimation methods. See the section "Modification Indices" on page 6917 for more details.

ODS Table Names

PROC TCALIS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

There are numerous ODS tables in the TCALIS procedure. The conditions for these ODS tables to display vary a lot. For convenience in presentation, the ODS tables for the PROC TCALIS procedure are organized in the following categories:

- ODS tables for descriptive statistics and residual analysis
- ODS tables for model specification and results
- ODS tables for supplementary model analysis
- ODS tables for modification indices
- ODS tables for optimization control and results

Many ODS tables are displayed when you set either a specialized option in a certain statement or a global display option in the PROC TCALIS statement. Rather than requesting displays by setting specialized options separately, you can request a group of displays by using a global display option.

There are five global display levels, represented by five options: PALL (highest), PRINT, *default*, PSHORT, and PSUMMARY. The higher the level, the more output requested. The *default* printing level is in effect when you do not specify any other global printing options in the PROC TCALIS statement. See the section "Global Display Options" on page 6724 for details.

In the following description of ODS tables whenever applicable, the lowest level of global printing options for an ODS table to print is listed. It is understood that global printing options at higher levels can also be used. For example, if PSHORT is the global display option to print an ODS table, you can also use PALL, PRINT, or *default*.

ODS Tables for Descriptive Statistics and Residual Analysis

These ODS tables are group-oriented, meaning that each group has its own set of tables in the output. To display these tables in your output, you can set a specialized option in either the PROC TCALIS or GROUP statement. If the specialized option is set in the PROC TCALIS statement, it will apply to all groups. If the option is set in the GROUP statement, it will apply to the associated group only. Alternatively, you can set a global printing option in the PROC TCALIS statement to print these tables. Either a specialized or a global printing option is sufficient to print the tables.

Table Names for Descriptive Statistics

ODS Table Name	Description	Specialized Option	Global Display Option
ContKurtosis	Contributions to kurtosis from observations	KURTOSIS	PRINT
InCorr	Input correlation matrix	PCORR	PALL
InCorrDet	Determinant of the input correlation matrix	PCORR	PALL
InCov	Input covariance matrix	PCORR	PALL
InCovDet	Determinant of the input covariance matrix	PCORR	PALL
InMean	Input mean vector	PCORR	PALL
Kurtosis	Kurtosis, with raw data input	KURTOSIS	PRINT
PredCorr	Predicted correlation matrix	PCORR	PALL
PredCorrDet	Determinant of the predicted correlation matrix	PCORR	PALL
PredCov	Predicted covariance matrix	PCORR	PALL
PredCovDet	Determinant of the predicted covariance matrix	PCORR	PALL
PredMean	Predicted mean vector	PCORR	PALL
SimpleStatistics	Simple statistics, with raw data input	SIMPLE	default
Weights	Weight matrix	PWEIGHT	PALL
WeightsDet	Determinant of the weight matrix	PWEIGHT	PALL

Table Names for Residual Displays

ODS Table Name	Description	Specialized Option	Global Display Option
AsymStdRes	Asymptotically standardized residual matrix	RESIDUAL=ASYSTAND[1]	PALL
AveAsymStdRes	Average of absolute asymptotically standardized residual values	RESIDUAL=ASYSTAND[1]	PALL
AveNormRes	Average of absolute normalized residual values	RESIDUAL=NORM[1]	PALL
AveRawRes	Average of absolute raw residual values	RESIDUAL	PALL
AveVarStdRes	Average of absolute variance standardized residual values	RESIDUAL=VARSTAND[1]	PALL
DistAsymStdRes	Distribution of asymptotically standardized residuals	RESIDUAL=ASYSTAND[1]	PALL
DistNormRes	Distribution of normalized residuals	RESIDUAL=NORM[1]	PALL
DistRawRes	Distribution of raw residuals	RESIDUAL	PALL
DistVarStdRes	Distribution of variance standardized residuals	RESIDUAL=VARSTAND[1]	PALL
NormRes	Normalized residual matrix	RESIDUAL=NORM[1]	PALL
RawRes	Raw residual matrix	RESIDUAL[2]	PALL
RankAsymStdRes	Rank order of asymptotically standardized residuals	RESIDUAL=ASYSTAND[1]	PALL
RankNormRes	Rank order of normalized residuals	RESIDUAL=NORM[1]	PALL
RankRawRes	Rank order of raw residuals	RESIDUAL	PALL
RankVarStdRes	Rank order of variance standardized residuals	RESIDUAL=VARSTAND[1]	PALL
VarStdRes	Variance standardized residual matrix	RESIDUAL=VARSTAND[1]	PALL

1. In effect, the RESIDUAL= option specifies the RESIDUAL option and the type of residuals requested after the equal sign. For example, if you set RESIDUAL=ASYSTAND, asymptotically standardized residuals are requested, in addition to the printing of the tables enabled by the RESIDUAL option. In some cases, the RESIDUAL= option cannot be honored due to the specific estimation method or data type used. When this occurs, PROC TCALIS will determine the appropriate sets of normalized or standardized residuals to display. A warning message with an explanation will be printed.
2. Raw residuals are also printed for correlation analysis even if RESIDUAL or PALL is not specified.

ODS Tables for Model Specification and Results

Some ODS tables of this group are model-oriented. Others are not. Model-oriented ODS tables are printed for each model, while others are printed no more than once no matter how many models you have.

Non-Model-Oriented ODS Tables

The ODS tables that are not model-oriented are listed in the following table:

ODS Table Name	Description	Global Display Option	Additional Specification Required
AddParms	Estimates for additional parameters	PSHORT	PARAMETERS statement
AddParmsInit	Initial values for additional parameters	PSHORT	PARAMETERS statement
Fit	Fit summary	PSUMMARY	
GroupFit	Fit comparison among groups	PSUMMARY	Multiple groups
ModelingInfo	General modeling information	PSHORT	
ModelSummary	Summary of models and their labels and types	PSHORT	Multiple models[1]
ParmFunc	Parametric function testing	PSHORT	TESTFUNC statement
SimTest	Simultaneous tests of parametric functions	PSHORT	SIMTEST statement

1. This table is displayed when you have multiple models that have labels specified by the LABEL= option, or when you define a model with more than a single level of reference by using the REFMODEL option. Otherwise, the ModelingInfo table contains all pertinent information regarding the models in the analysis.

Model-Oriented ODS Tables

These ODS tables are model-oriented, meaning that each model has its own set of ODS tables in the output. There are three types of model specification and results printing in PROC TCALIS: initial specification, (unstandardized) estimated model results, and standardized model results. To distinguish these three types of ODS tables, different suffixes for the ODS table names are used. An "Init" suffix indicates initial specification, while a "Std" suffix indicates standardized solutions. All other tables are for unstandardized solutions.

These ODS tables require some specialized options to print. If you set the specialized option in the PROC TCALIS statement, it applies to all models. If you set the specialized option in the MODEL statement, it applies to the associated model only. Alternatively, to print **all** these ODS tables, you can use the PSHORT or any higher level global printing option in the PROC TCALIS statement. Either a specialized or a global printing option is sufficient to print these ODS tables. The following is a summary of the specialized and global printing options for these three types of ODS tables:

Type of ODS Tables	Table Name Suffix	Specialized Option	Global Display Option
Initial specification	Init	PINITIAL	PSHORT
Unstandardized solutions	(none)	PESTIM	PSHORT
Standardized solutions	Std	PESTIM, and NOSTAND not used	PSHORT

In the following list of ODS tables, the prefixes of the ODS table names indicate the modeling language required for the ODS tables to print. The last column of the list indicates whether the PRIMAT option is needed to print the corresponding ODS tables in matrix formats. You can use the PRIMAT option either in the PROC TCALIS or MODEL statement. If you want matrix output for all models, set this option in the PROC TCALIS statement. If you want matrix output for a specific model, set this option in the associated MODEL statement only.

ODS Table Name	Description	Additional Option
FACTORCov	Estimated factor covariances	
FACTORCovInit	Initial factor covariances	
FACTORCovStd	Factor correlations	
FACTORErrVar	Estimated error variances	
FACTORErrVarInit	Initial error variances	
FACTORErrVarStd	Standardized results for error variances	
FACTORIntercepts	Estimated intercepts	
FACTORInterceptsInit	Initial intercepts	
FACTORLoadings	Estimated factor loadings	
FACTORLoadingsInit	Initial factor loadings	
FACTORLoadingsStd	Standardized factor loadings	
FACTORMeans	Estimated factor means	
FACTORMeansInit	Initial factor means	
FACTORRotCov	Estimated rotated factor covariances	
FACTORRotCovStd	Rotated factor correlations	
FACTORRotErrVar	Error variances in rotated solution	
FACTORRotErrVarStd	Standardized results for error variances in rotated solution	
FACTORRotLoadings	Rotated factor loadings	
FACTORRotLoadingsStd	Standardized rotated factor loadings	
FACTORRotMat	Rotation matrix	
FACTORScoresRegCoef	Factor scores regression coefficients	
FACTORVariables	Variables in the analysis	
LINEQSAlpha	Estimated intercept vector	PRIMAT
LINEQSAlphaInit	Initial intercept vector	PRIMAT
LINEQSBeta	Estimated _EQSBETA_ matrix	PRIMAT
LINEQSBetaInit	Initial _EQSBETA_ matrix	PRIMAT
LINEQSBetaStd	Standardized results for _EQSBETA_ matrix	PRIMAT
LINEQSCovExog	Estimated covariances among exogenous variables	
LINEQSCovExogInit	Initial covariances among exogenous variables	
LINEQSCovExogStd	Standardized results for covariances among exogenous variables	
LINEQSEq	Estimated equations	
LINEQSEqInit	Initial equations	
LINEQSEqStd	Standardized equations	
LINEQSGamma	Estimated _EQSGAMMA_ matrix	PRIMAT
LINEQSGammaInit	Initial _EQSGAMMA_ matrix	PRIMAT

ODS Table Name	Description	Additional Option
LINEQSGammaStd	Standardized results for _EQSGAMMA_ matrix	PRIMAT
LINEQSMeans	Estimated means for exogenous variables	
LINEQSMeansInit	Initial means for exogenous variables	
LINEQSNu	Estimated mean vector	PRIMAT
LINEQSNuInit	Initial mean vector	PRIMAT
LINEQSPhi	Estimated _EQSPHI_ matrix	PRIMAT
LINEQSPhiInit	Initial _EQSPHI_ matrix	PRIMAT
LINEQSPhiStd	Standardized results for _EQSPHI_ matrix	PRIMAT
LINEQSVarExog	Estimated variances of exogenous variables	
LINEQSVarExogInit	Initial variances of exogenous variables	
LINEQSVarExogStd	Standardized results for variances of exogenous variables	
LINEQSVariables	Exogenous and endogenous variables	
LISMODAlpha	Estimated _ALPHA_ vector	
LISMODAlphaInit	Initial _ALPHA_ vector	
LISMODBeta	Estimated _BETA_ matrix	
LISMODBetaInit	Initial _BETA_ matrix	
LISMODBetaStd	Standardized _BETA_ matrix	
LISMODGamma	Estimated _GAMMA_ matrix	
LISMODGammaInit	Initial _GAMMA_ matrix	
LISMODGammaStd	Standardized _GAMMA_ matrix	
LISMODKappa	Estimated _KAPPA_ vector	
LISMODKappaInit	Initial _KAPPA_ vector	
LISMODLambdaX	Estimated _LAMBDAX_ matrix	
LISMODLambdaXInit	Initial _LAMBDAX_ matrix	
LISMODLambdaXStd	Standardized _LAMBDAX_ matrix	
LISMODLambdaY	Estimated _LAMBDAY_ matrix	
LISMODLambdaYInit	Initial _LAMBDAY_ matrix	
LISMODLambdaYStd	Standardized _LAMBDAY_ matrix	
LISMODNuX	Estimated _NUX_ vector	
LISMODNuXInit	Initial _NUX_ vector	
LISMODNuY	Estimated _NUY_ vector	
LISMODNuYInit	Initial _NUY_ vector	
LISMODPhi	Estimated _PHI_ matrix	
LISMODPhiInit	Initial _PHI_ matrix	
LISMODPhiStd	Standardized _PHI_ matrix	
LISMODPsi	Estimated _PSI_ matrix	
LISMODPsiInit	Initial _PSI_ matrix	
LISMODPsiStd	Standardized _PSI_ matrix	
LISMODThetaX	Estimated _THETAX_ matrix	
LISMODThetaXInit	Initial _THETAX_ matrix	
LISMODThetaXStd	Standardized _THETAX_ matrix	
LISMODThetaY	Estimated _THETAY_ matrix	
LISMODThetaYInit	Initial _THETAY_ matrix	
LISMODThetaYStd	Standardized _THETAY_ matrix	

ODS Table Name	Description	Additional Option
LISMODVariables	Variables in the model	
MSTRUCTCov	Estimated _COV_ matrix	
MSTRUCTCovInit	Initial _COV_ matrix	
MSTRUCTCovStd	Standardized _COV_ matrix	
MSTRUCTMean	Estimated _MEAN_ vector	
MSTRUCTMeanInit	Initial _MEAN_ vector	
MSTRUCTVariables	Variables in the model	
PATHCovErrors	Estimated error covariances	
PATHCovErrorsInit	Initial error covariances	
PATHCovErrorsStd	Standardized error covariances	
PATHCovVarErr	Estimated covariances bewteen exogenous variables and errors	
PATHCovVarErrInit	Initial covariances bewteen exogenous variables and errors	
PATHCovVarErrStd	Standardized results for covariances bewteen exogenous variables and errors	
PATHCovVars	Estimated covariances among exogenous variables	
PATHCovVarsInit	Initial covariances among exogenous variables	
PATHCovVarsStd	Standardized results for covariances among exogenous variables	
PATHList	Estimated path list	
PATHListInit	Initial path list	
PATHListStd	Standardized path list	
PATHMeansIntercepts	Estimated intercepts	
PATHMeansInterceptsInit	Initial intercepts	
PATHVariables	Exogenous and endogenous variables	
PATHVarParms	Estimated variances or error variances	
PATHVarParmsInit	Initial variances or error variances	
PATHVarParmsStd	Standardized results for variances or error variances	
RAMAMat	Estimated _A_ matrix	PRIMAT
RAMAMatInit	Initial _A_ matrix	PRIMAT
RAMAMatStd	Standardized results of _A_ matrix	PRIMAT
RAMList	List of RAM estimates	
RAMListInit	List of initial RAM estimates	
RAMListStd	Standardized results for RAM estimates	
RAMPMat	Estimated _P_ matrix	PRIMAT
RAMPMatInit	Initial _P_ matrix	PRIMAT
RAMPMatStd	Standardized results of _P_ matrix	PRIMAT
RAMVariables	Exogenous and endogenous variables	
RAMWVec	Estimated mean and intercept vector	PRIMAT
RAMWVecInit	Initial mean and intercept vector	PRIMAT

ODS Tables for Supplementary Model Analysis

These ODS tables are model-oriented. They are printed for each model in your analysis. To display these ODS tables, you can set some specialized **options** in either the PROC TCALIS or MODEL statement. If the specialized options are used in the PROC TCALIS statement, they apply to all models. If the specialized options are used in the MODEL statement, they apply to the associated model only. For some of these ODS tables, certain specialized **statements** for the model might also enable the printing. Alternatively, you can use the global printing options in the PROC TCALIS statement to print these ODS tables. Either a specialized option (or statement) or a global printing option is sufficient to print a particular ODS table.

ODS Table Name	Description	Specialized Option or Statement	Global Display Option
Determination	Coefficients of determination	PDETERM DETERM[4]	default
DirectEffects	Direct effects	TOTEFF[1]	PRINT
DirectEffectsStd	Standardized direct effects	TOTEFF[1,3]	PRINT
EffectsOf	Effects of the listed variables	EFFPART[2]	PRINT
EffectsOn	Effects on the listed variables	EFFPART[2]	PRINT
IndirectEffects	Indirect effects	TOTEFF[1]	PRINT
IndirectEffectsStd	Standardized indirect effects	TOTEFF[1,3]	PRINT
LatentScoresRegCoef	Latent variable scores regression coefficients	PLATCOV	PRINT
PredCovLatent	Predicted covariances among latent variables	PLATCOV	PRINT
PredCovLatMan	Predicted covariances between latent and manifest variables	PLATCOV	PRINT
PredMeanLatent	Predicted means of latent variables	PLATCOV	PRINT
SqMultCorr	Squared multiple correlations	PESTIM	PSHORT
Stability	Stability coefficient of reciprocal causation	PDETERM, DETERM[4]	default
StdEffectsOf	Standardized effects of the listed variables	EFFPART[2,3]	PSHORT
StdEffectsOn	Standardized effects on the listed variables	EFFPART[2,3]	PSHORT
TotalEffects	Total effects	TOTEFF[1]	PRINT
TotalEffectsStd	Standardized total effects	TOTEFF[1,3]	PRINT

1. This refers to the TOTEFF or EFFPART option in the PROC TCALIS or MODEL statement.
2. This refers to the EFFPART statement specifications.
3. NOSTAND option must not be specified in the MODEL or PROC TCALIS statement.
4. PDETERM is an option specified in the PROC TCALIS or MODEL statement, while DETERM is a statement name.

ODS Tables for Model Modification Indices

To print the ODS tables for model modification indices, you can use the MODIFICATION option in either the PROC TCALIS or MODEL statement. When this option is set in the PROC TCALIS statement, it applies to all models. When this option is set in the MODEL statement, it applies to the associated model only. Alternatively, you can also use the PALL option in the PROC TCALIS statement to print these ODS tables.

If the NOMOD option is set in the PROC TCALIS statement, these ODS tables are not printed for all models, unless the MODIFICATION is respecified in the individual MODEL statements. If the NOMOD option is set in the MODEL statement, then the ODS tables for modification do not print for the associated model.

For convenience in presentation, three different classes of ODS tables for model modifications are described in the following. First, ODS tables for ranking of LM indices are the default printing when the MODIFICATION option is specified. Second, ODS tables for LM indices in matrix forms require an additional option to print. Last, ODS tables for other modification indices, including the Wald test indices, require specific data-analytic conditions to print. While the first two classes of ODS tables are model-oriented (that is, each model has its own sets of output), the third one is not.

ODS Table Names for Ranking of LM indices

Rankings of LM indices in separate regions of parameter space are the default printing format. You can turn off this default printing by the NODEFAULT option in the LMTESTS statement for models. If you want to print matrices of LM test indices rather than the rankings of LM test indices, you can use the NORANK or MAXRANK=0 option in the LMTESTS statement.

These ODS tables are specific to the types of modeling languages used. This is noted in the last column of the following table.

ODS Table Name	Description	Model
LMRankCov	Covariances among variables	MSTRUCT
LMRankCovErr	Covariances among errors	LINEQS
LMRankCovErrofVar	Covariances among errors of variables	RAM or PATH
LMRankCovExog	Covariances among existing exogenous variables	LINEQS, PATH, or RAM
LMRankCovFactors	Covariance among factors	FACTOR
LMRankErrorVar	Error variances	FACTOR
LMRankFactMeans	Factor means	FACTOR
LMRankIntercepts	Intercepts	FACTOR, LINEQS, PATH, or RAM
LMRankLoadings	Factor loadings	FACTOR
LMRankMeans	Means of existing variables	LINEQS, MSTRUCT, PATH, or RAM
LMRankPaths	All possible paths in the model	PATH or RAM

ODS Table Name	Description	Model
LMRankPathsFromEndo	Paths from existing endogenous variables	LINEQS
LMRankPathsFromExog	Paths from existing exogenous variables	LINEQS
LMRankPathsNewEndo	Paths to existing exogenous variables	LINEQS
LMRankLisAlpha	LISMOD _ALPHA_	LISMOD
LMRankLisBeta	LISMOD _BETA_	LISMOD
LMRankLisGamma	LISMOD _GAMMA_	LISMOD
LMRankLisKappa	LISMOD _KAPPA_	LISMOD
LMRankLisLambdaX	LISMOD _LAMBDAX_	LISMOD
LMRankLisLambdaY	LISMOD _LAMBDAY_	LISMOD
LMRankLisNuX	LISMOD _NUX_	LISMOD
LMRankLisNuY	LISMOD _NUY_	LISMOD
LMRankLisPhi	LISMOD _PHI_	LISMOD
LMRankLisPsi	LISMOD _PSI_	LISMOD
LMRankLisThetaX	LISMOD _THETAX_	LISMOD
LMRankLisThetaY	LISMOD _THETAY_	LISMOD
LMRankMySet	Customized sets of new parameters defined in LMTESTS statements	any model

ODS Table Names for Lagrange Multiplier Tests in Matrix Form

To print matrices of LM test indices for a model, you must also use the LMMAT option in the LMTESTS statement for the model. This option itself is not sufficient for **all** the matrices of LM tests to print. Only those matrices associated with the LM test indices that are selected (by default or by customized sets) in the LMTESTS statement will be printed.

These ODS tables are specific to the types of modeling languages used in the model. This is noted in the last column of the following table.

ODS Table Name	Description	Model
LMEqsAlpha	_EQSALPHA_ vector	LINEQS
LMEqsBeta	_EQSBETA_ matrix	LINEQS
LMEqsGammaSub	_EQSGAMMA_ matrix, excluding entries with error variables in columns	LINEQS
LMEqsNewDep	New rows for expanding _EQSBETA_ and _EQSGAMMA_ matrices	LINEQS
LMEqsNuSub	_EQSNU_ vector, excluding fixed zero means for error variables	LINEQS
LMEqsPhi	_EQSPHI_ matrix	LINEQS
LMEqsPhi11	Upper left partition (exogenous variances and covariances) of the _EQSPHI_ matrix	LINEQS
LMEqsPhi21	Lower left partition (error variances and covariances) of the _EQSPHI_ matrix	LINEQS
LMEqsPhi22	Lower right partition (error variances and covariances) of the _EQSPHI_ matrix	LINEQS

ODS Table Name	Description	Model
LMFactErrv	Vector of error variances	FACTOR
LMFactFcov	Factor covariance matrix	FACTOR
LMFactInte	Intercept vector	FACTOR
LMFactLoad	Factor loading matrix	FACTOR
LMFactMean	Factor mean vector	FACTOR
LMLisAlpha	LISMOD _ALPHA_ vector	LISMOD
LMLisBeta	LISMOD _BETA_ matrix	LISMOD
LMLisGamma	LISMOD _GAMMA_ matrix	LISMOD
LMLisKappa	LISMOD _KAPPA_ vector	LISMOD
LMLisLambdaX	LISMOD _LAMBDAX_ matrix	LISMOD
LMLisLambdaY	LISMOD _LAMBDAY_ matrix	LISMOD
LMLisNuX	LISMOD _NUX_ vector	LISMOD
LMLisNuY	LISMOD _NUY_ vector	LISMOD
LMLisPhi	LISMOD _PHI_ matrix	LISMOD
LMLisPsi	LISMOD _PSI_ matrix	LISMOD
LMLisThetaX	LISMOD _THETAX_ matrix	LISMOD
LMLisThetaY	LISMOD _THETAY_ matrix	LISMOD
LMMstructCov	Covariance matrix	MSTRUCT
LMMstructMean	Mean vector	MSTRUCT
LMRamA	_RAMA_ matrix	RAM
LMRamALower	Lower partitions of the _RAMA_ matrix	RAM
LMRamAUpper	Upper partitions of the _RAMA_ matrix	RAM
LMRamAlpha	_RAMALPHA_ matrix	RAM
LMRamBeta	Upper left partition of the _RAMA_ matrix	RAM
LMRamGamma	Upper right partition of the _RAMA_ matrix	RAM
LMRamNu	_RAMNU_ matrix	RAM
LMRamP	_RAMP_ matrix	RAM
LMRamP11	Upper left partition of the _RAMP_ matrix	RAM
LMRamP21	Lower left partition of the _RAMP_ matrix	RAM
LMRamP22	Lower right partition of the _RAMP_ matrix	RAM
LMRamW	_RAMW_ matrix	RAM

ODS Table Names for Other Modification Indices

The following table shows the ODS tables for the remaining modification indices.

ODS Table Name	Description	Additional Requirement
LagrangeBoundary	LM tests for active boundary constraints	Presence of active boundary constraints
LagrangeDepParmEquality	LM tests for equality constraints in dependent parameters	Presence of equality constraints in dependent parameters
LagrangeEquality	LM tests for equality constraints	Presence of equality constraints in independent parameters
WaldTest	Wald tests for testing existing parameters equaling zeros	At least one insignificant parameter value

ODS Table for Optimization Control and Results

To display the ODS tables for optimization control and results, you must specify any of the following global display options in the PROC TCALIS statement: PSHORT, PRINT, PALL, or default (that is, NOPRINT is not specified). Also, you must not use the NOPRINT option in the NLOPTIONS statement. For some of these tables, you must also specify additional options, either in the PROC TCALIS or the NLOPTIONS statement. Some restrictions might apply. Additional options and restrictions are noted in the last column.

ODS Table Name	Description	Additional Option Required or Restriction
CovParm	Covariances of parameters	PCOVES[1] or PALL[2], restriction[3]
ConvergenceStatus	Convergence status	
DependParmsResults	Final dependent parameter estimates	Restriction[4]
DependParmsStart	Initial dependent parameter estimates	Restriction[4]
Information	Information matrix	PCOVES[1] or PALL[2], restriction[3]
InitEstMethod	Initial estimation methods	
InputOptions	Optimization options	PALL[2]
IterHist	Iteration history	
IterStart	Iteration start	
IterStop	Iteration stop	
Lagrange	First and second order Lagrange multipliers	PALL[2]
LinCon	Linear constraints	PALL[2], restriction[5]
LinConDel	Deleted constraints	PALL[2], restriction[5]
LinConSol	Linear constraints evaluated at solution	PALL[2], restriction[5]
LinDep	Linear dependencies of parameter estimates	Restriction[6]
ParameterEstimatesResults	Final estimates	
ParameterEstimatesStart	Initial estimates	
ProblemDescription	Problem description	
ProjGrad	Projected gradient	PALL[2]

1. PCOVES option is specified in the PROC TCALIS statement.
2. PALL option is specified in the NLOPTIONS statement.
3. Estimation method must not be ULS or DWLS.
4. Existence of dependent parameters.
5. Linear equality or boundary constraints are imposed.
6. Existence of parameter dependencies during optimization, but not due to model specification.

ODS Graphics

To request graphics with PROC TCALIS, you must first enable ODS Graphics by specifying the **ods graphics on** statement. See Chapter 21, "Statistical Graphics Using ODS," for more information. In the following table, ODS graph names and the options to display the graphs are listed.

ODS Graph Name	Plot Description	PLOTS= Option
AsymStdResidualHistogram	Asymptotically standardized residuals	PLOTS=RESIDUALS and RESIDUAL=ASYMSTD, METHOD= is not ULS or DWLS
NormResidualHistogram	Normalized residuals	PLOTS=RESIDUALS and RESIDUAL=NORM
RawResidualHistogram	Raw residuals	PLOTS=RESIDUALS
VarStdResidualHistogram	Variance standardized residuals	PLOTS=RESIDUALS and RESIDUAL=VARSTD

Examples: TCALIS Procedure

Example 88.1: Path Analysis: Stability of Alienation

The following covariance matrix from Wheaton et al. (1977) has served to illustrate the performance of several implementations for the analysis of structural equation models. Two different models have been analyzed by an early implementation of LISREL and are mentioned in Jöreskog (1978). You can also find a more detailed discussion of these models in the LISREL VI manual (Jöreskog and Sörbom 1985). A slightly modified model for this covariance matrix is included in the EQS 2.0 manual (Bentler 1985, p. 28). The path diagram of this model is displayed in Figure 88.2. The same model is reanalyzed here by PROC TCALIS. However, for the analysis with the EQS implementation, the SEI variable is rescaled by a factor of 0.1 to make the matrix less ill-conditioned. Since the Levenberg-Marquardt or Newton-Raphson optimization techniques are used with PROC CALIS, rescaling the data matrix is not necessary and, therefore, is not done here. The results reported here reflect the estimates based on the original covariance matrix.

run;

ods graphics off;
```

Since no METHOD= option has been used, maximum likelihood estimates are computed by default. In this example, no global display options are specified. This means that PROC TCALIS prints the default set of results.

PROC TCALIS can produce a high-quality residual histogram that is useful for showing the distribution of residuals. To request the residual histogram, you must first enable ODS Graphics by specifying the **ods graphics on** statement, as shown in the preceding statements before the PROC TCALIS statement. Then, the residual histogram is requested by the **plots=residuals** option in the PROC TCALIS statement.

Output 88.1.1 displays the modeling information and variables in the analysis.

Output 88.1.1 Model Specification and Variables

```
                        Stability of Alienation
                        PATH Model Specification

                          Variables in the Model

Endogenous     Manifest    Anomie67  Anomie71  Education  Powerless67
                           Powerless71  SEI
               Latent      Alien67  Alien71
Exogenous      Manifest
               Latent      SES

                  Number of Endogenous Variables = 8
                  Number of Exogenous Variables  = 1
```

Output 88.1.1 shows that the data set Wheaton was used with 932 observations. The model is specified with the PATH modeling language. Variables in the model are classified into different categories according to their roles. All manifest variables are endogenous in the model. Also, three latent variables are hypothesized in the model: Alien67, Alien71, and SES. While Alien67 and Alien71 are endogenous, SES is exogenous in the model.

Output 88.1.2 echoes the initial specification of the PATH model.

Output 88.1.2 Initial Estimates

Initial Estimates for PATH List

Path			Parameter	Estimate
Anomie67	<-	Alien67		1.00000
Powerless67	<-	Alien67		0.83300
Anomie71	<-	Alien71		1.00000
Powerless71	<-	Alien71		0.83300
Education	<-	SES		1.00000
SEI	<-	SES	lambda	.
Alien67	<-	SES	gamma1	.
Alien71	<-	SES	gamma2	.
Alien71	<-	Alien67	beta	.

Initial Estimates for Variance Parameters

Variance Type	Variable	Parameter	Estimate
Error	Anomie67	theta1	.
	Powerless67	theta2	.
	Anomie71	theta1	.
	Powerless71	theta2	.
	Education	theta3	.
	SEI	theta4	.
	Alien67	psi1	.
	Alien71	psi2	.
Exogenous	SES	phi	.

Initial Estimates for Covariances Among Errors

Error of	Error of	Parameter	Estimate
Anomie67	Anomie71	theta5	.
Powerless67	Powerless71	theta5	.

In Output 88.1.2, numerical values for estimates are the initial values you input in the model specification. If the associated parameter name for a numerical estimate is blank, it means that the estimate is a fixed value, which would not be changed in the estimation. For example, the first five paths have fixed path coefficients with the fixed values given. For numerical estimates with parameter names given, the numerical values serve as initial values, which would be changed during the estimation. In Output 88.1.2, you actually do not have this kind of specification. All free parameters specified in the model are with missing initial values, denoted by '.'. For example, lambda, gamma1, theta1, and psi1, among others, are free parameters without initial values given. The initial values of these parameters will be generated by PROC TCALIS automatically.

You can examine this output to ensure that the desired model is being analyzed. PROC TCALIS outputs the initial specifications or the estimation results in the order you specify in the model, unless you use reordering options such as ORDERSPEC and ORDERALL. Therefore, the input order of specifications is important—it determines how your output would look.

Simple descriptive statistics are displayed in Output 88.1.3.

Output 88.1.3 Descriptive Statistics

Simple Statistics

	Variable	Mean	Std Dev
Anomie67	Anomie (1967)	0	3.44006
Powerless67	Powerlessness (1967)	0	3.06007
Anomie71	Anomie (1971)	0	3.54006
Powerless71	Powerlessness (1971)	0	3.16006
Education	Education	0	3.10000
SEI	Occupational Status Index	0	21.21999

Because the input data set contains only the covariance matrix, the means of the manifest variables are assumed to be zero. Note that this has no impact on the estimation, unless a mean structure model is being analyzed.

Initial estimates are necessary in all kinds of optimization problems. They could be provided by users or automatically generated by PROC TCALIS. As shown in Output 88.1.2, you did not provide any initial estimates for all free parameters. PROC TCALIS uses a combination of well-behaved mathematical methods to complete the initial estimation. The initial estimation methods for the current analysis are shown in Output 88.1.4.

Output 88.1.4 Optimization Starting Point

Initial Estimation Methods

1 Instrumental Variables Method
2 McDonald Method
3 Two-Stage Least Squares

Optimization Start
Parameter Estimates

N	Parameter	Estimate	Gradient
1	lambda	4.99508	-0.00206
2	gamma1	-0.62322	-0.04069
3	gamma2	-0.20437	-0.03816
4	beta	0.66589	0.03789
5	theta1	3.51433	-0.00409
6	theta2	3.65991	0.01182

Convergence criterion (ABSGCONV=0.00001) satisfied.
```

The convergence status is important for the validity of your solution. In most cases, you should interpret your results only when the solution is converged. In this example, you obtain a converged solution, as shown in the message at the bottom of the table. The final objective function value is 0.01448, which is the minimized function value during the optimization. If problematic solutions such as nonconvergence are encountered, PROC TCALIS issues an error message.

The fit summary statistics are displayed in Output 88.1.6. By default, PROC TCALIS displays all available fit indices and modeling information.

Output 88.1.6 Fit Summary

Fit Summary		
Modeling Info	N Observations	932

	Schwarz Bayesian Criterion	-48.0509
	McDonald Centrality	0.9976
Incremental Index	Bentler Comparative Fit Index	0.9979
	Bentler-Bonett NFI	0.9937
	Bentler-Bonett Non-normed Index	0.9965
	Bollen Normed Index Rho1	0.9895
	Bollen Non-normed Index Delta2	0.9979
	James et al. Parsimonious NFI	0.5962

First, the fit summary table starts with some basic modeling information, as shown in Output 88.1.6. You can check the number of observations, number of variables, number of moments being fitted, number of parameters, number of active constraints in the solution, and the independent model chi-square and its degrees of freedom in this modeling information category. Next, three types of fit indices are shown: absolute, parsimony, and incremental.

The absolute indices are fit measures that are interpreted without referring to any baseline model and without adjusting model parsimony. The chi-square test statistic is the best-known absolute index in this category. In this example, the p-value of the chi-square is 0.1419, which is larger than the conventional 0.05 value. From a statistical hypothesis testing point of view, this model cannot be rejected. The Z-test of Wilson and Hilferty is also insignificant at $\alpha = .05$, which echoes the result of the chi-square test. Other absolute indices can also be consulted. Although it seems that there are no clear conventional levels for these indices to indicate an acceptable model fit, you can always use these indices to compare the relative fit between different models.

Next, the parsimony fit indices take the model parsimony into account. These indices adjust the model fit by the degrees of freedom (or the number of the parameters) of the model in certain ways. The advantage of these indices is that merely increasing the number of parameters in the model might not necessarily improve the model fit indicated by these indices. Models with large numbers of parameters are penalized. There is no uniform way to interpret all these indices. However, for the relatively well-known RMSEA estimate, by convention values under 0.05 indicate good fit. The RMSEA value for this example is 0.0231, and so this is a very good fit. For interpretations of other parsimony indices, you can consult the original articles for these indices.

Last, the incremental fit indices are computed based on comparison with a baseline model, usually the independence model where all mainfest variables are assumed to be uncorrelated. The independence model fit statistic is shown under the Modeling Info category of the same fit summary table. In this example, the model fit chi-square of the independence model is 2131.43, with 15 degrees of freedom. The incremental indices show how well the hypothesized model improves over the independence model for the data. Various incremental fit indices have been proposed. In the fit summary table, there are six of such fit indices. Large values for these indices are desired. It has been suggested that values larger than .9 for these indices indicate acceptable model fit. In this example, all incremental indices but James et al. parsimonious NFI show that the hypothesized model fits well.

There is no consensus as to which fit index is the best to judge model fit. Probably, with artificial data and model, all fit indices can be shown defective in some aspects of measuring model fit. Conventional wisdom is to look at all fit indices and determine whether the majority of them are close to the desirable ranges of values. In this example, almost all fit indices are good, and so it is safe to conclude that the model fits well.

Nowadays, most researchers do pay less attention to the model fit chi-square statistic because it tends to reject all meaningful models with minimum departures from the truth. Although the model fit chi-square test statistic is an impeccable statistical inference tool when the underlying statistical assumptions are satisfied, for practical purposes it is just too powerful to accept any useful and reasonable models with only tiny imperfections. Some fit indices are more popular than others. Standardized RMSR, RMSEA estimate, adjusted AGFI, and Bentler's comparative fit index are frequently reported in empirical research for judging model fit. In this example, all these measures show good model fit of the hypothesized model. While there are certainly legitimate reasons why these fit indices are more popular than others, they are out of the current scope of discussion.

PROC TCALIS can perform a detailed residual analysis. Large residuals might indicate misspecification of the model. In Output 88.1.7, raw residuals are reported and ranked.

Output 88.1.7 Raw Residuals and Ranking

SEI	Anomie67	0.46484

The model performs the poorest concerning the covariances of Education with all measures of Powerless and Anomie. This might suggest a misspecification of the functional relationships of Education with other variables in the model. However, because the model fit is quite good, such a possible misspecification should not be a serious concern in the analysis.

The histogram of the asymptotically standardized residuals is displayed in Output 88.1.9, which also shows the normal and kernel approximations.

Output 88.1.9 Distribution of Asymptotically Standardized Residuals

The residual distribution looks quite symmetrical. It shows a small to medium departure from the normal distribution, as evidenced by the discrepancies between the kernel and the normal distribution curves.

Estimation results are shown in Output 88.1.10.

Output 88.1.10 Estimation Results

Covariances Among Errors

Error of	Error of	Parameter	Estimate	Standard Error	t Value
Anomie67	Anomie71	theta5	0.90580	0.12167	7.44472
Powerless67	Powerless71	theta5	0.90580	0.12167	7.44472

The paths, variances and partial (or error) variances, and covariances and partial covariances are shown. When you have fixed parameters such as the first five path coefficients in the output, the standard errors and t values are all blanks. For free or constrained estimates, standard errors and t values are computed. Researchers in structural equation modeling usually use the value 2 as an approximate critical value for the observed t values. The reason is that the estimates are asymptotically normal, and so the two-sided critical point with $\alpha = 0.05$ is 1.96, which is close to 2. Using this criterion, all estimates shown in Output 88.1.10 are significantly different from zero, supporting the presence of these parameters in the model.

Squared multiple correlations are shown in Output 88.1.11.

Output 88.1.11 Squared Multiple Correlations

Squared Multiple Correlations

SEI	259.57639	450.28798	0.4235
Alien67	5.67046	8.29601	0.3165
Alien71	4.51479	9.00786	0.4988

For each endogenous variable in the model, the corresponding squared multiple correlation is computed by:

$$1 - \frac{\text{error variance}}{\text{total variance}}$$

In regression analysis, this is the percentage of explained variance of the endogenous variable by the predictors. However, this interpretation is complicated or even uninterpretable when your structural equation model has correlated errors or reciprocal casual relations. In these situations, it is not uncommon to see negative R-squares. Negative R-squares do not necessarily mean that your model is wrong or the model prediction is weak. Rather, the R-square interpretation is questionable in these situations.

When your variables are measured on different scales, comparison of path coefficients cannot be made directly. For example, in Output 88.1.10, the path coefficient for path Education <– SES is fixed at one, while the path coefficient for path SEI <– SES is 5.369. It would be very simple-minded to conclude that the effect of SES on SEI is larger than that SES on Education. Because SEI and Education are measured on different scales, direct comparison of the corresponding path coefficients is simply inappropriate.

In alleviating this problem, some might resort to the standardized solution for a better comparison. In a standardized solution, because the variances of manifest variables and systematic predictors are all standardized to ones, you hope the path coefficients are more comparable. In this example, PROC TCALIS standardizes your results in Output 88.1.12.

Standardized Results for Covariances Among Errors

Error of	Error of	Parameter	Estimate	Standard Error	t Value
Anomie67	Anomie71	theta5	0.07391	0.01013	7.29574
Powerless67	Powerless71	theta5	0.09440	0.01274	7.40922

Now, the standardized path coefficient for path Education <– SES is 0.830, while the standardized path coefficient for path SEI <– SES is 0.651. So the standardized effect of SES on SEI is actually smaller than that of SES on Education.

Furthermore, in PROC TCALIS the standardized estimates are computed with standard error estimates and t values so that you can make statistical inferences on the standardized estimates as well.

PROC TCALIS might differ from other software in its standardization scheme. Unlike other software that might standardize the path coefficients that attach to the error terms (unsystematic sources), PROC TCALIS keeps these path coefficients at ones (not shown in the output). Unlike other software that might also standardize the corresponding error variances to ones, the error variances in the standardized solution of PROC TCALIS are rescaled so as to keep the mathematical consistency of the model.

Essentially, in PROC TCALIS only variances of mainfest and non-error-type latent variables are standardized to ones. The error variances are rescaled, but not standardized. For example, in the standardized solution shown in Output 88.1.12, the error variances for all endogenous variables are not ones (see the middle portion of the output). Only the variance for the latent variable SES is standardized to one. See the section "Standardized Solutions" on page 6915 for the logic of the standardization scheme adopted by PROC TCALIS.

In appearance, the standardized solution is like a correlational analysis on the standardized manifest variables with standardized exogenous latent factors. Unfortunately, this statement is oversimplified, if not totally inappropriate. In standardizing a solution, the implicit equality constraints are likely destroyed. In this example, the unstandardized error variances for Anomie67 and Anomie71 are both 3.608, represented by a common parameter theta1. However, after standardization, these

error variances have different values at 0.303 and 0.286, respectively. In addition, fixed parameter values are no longer fixed in a standardized solution (for example, the first five paths in the current example). The issue of standardization is common to all other SEM software and beyond the current discussion. PROC TCALIS provides the standardized solution so that users can interpret the standardized estimates whenever they find them appropriate.

Example 88.2: Simultaneous Equations with Mean Structures and Reciprocal Paths

The supply-and-demand food example of Kmenta (1971, pp. 565, 582) is used to illustrate PROC TCALIS for the estimation of intercepts and coefficients of simultaneous equations in econometrics. The model is specified by two simultaneous equations containing two endogenous variables Q and P, and three exogenous variables D, F, and Y:

$$Q_t(demand) = \alpha_1 + \beta_1 P_t + \gamma_1 D_t$$

$$Q_t(supply) = \alpha_2 + \beta_2 P_t + \gamma_2 F_t + \gamma_3 Y_t$$

for $t = 1, \ldots, 20$.

To analyze this model in PROC TCALIS, the second equation needs to be written in another form. For instance, in the LINEQS model each endogenous variable must appear on the left-hand side of exactly one equation. To satisfy this requirement, you can rewrite the second equation as an equation for P_t as:

$$P_t = -\frac{\alpha_2}{\beta_2} + \frac{1}{\beta_2} Q_t - \frac{\gamma_2}{\beta_2} F_t - \frac{\gamma_3}{\beta_2} Y_t$$

or, equivalently reparameterized as:

$$P_t = \theta_1 + \theta_2 Q_t + \theta_3 F_t + \theta_4 Y_t$$

where

$$\theta_1 = -\frac{\alpha_2}{\beta_2}, \quad \theta_2 = \frac{1}{\beta_2}, \quad \theta_3 = -\frac{\gamma_2}{\beta_2}, \quad \theta_4 = -\frac{\gamma_3}{\beta_2}$$

This new equation for P_t together with the first equation for Q_t suggest the following LINEQS model specification in PROC TCALIS:

```

```

The LINEQS modeling language is used in this example because its specification is similar to the original equations. In the LINEQS statement, you essentially input the two model equations for Q and P. Parameters for intercepts and regression coefficients are also specified in the equations. Note that Intercept in the two equations is treated as a special variable that contains ones for all observations. Intercept is not a variable in the data set, nor do you need to create such a variable in your data set. Hence, the variable Intercept does not represent the intercept parameter itself. Instead, the intercept parameters for the two equations are the coefficients attached to Intercept. In this example, the intercept parameters are alpha1 and theta1, respectively, in the two equations. As required, error terms E1 and E2 are added to complete the equation specification.

In the STD statement, you specify eps1 and eps2, respectively, for the variance parameters of the error terms. In the COV, you specify eps3 for the covariance parameter between the error terms. In the BOUNDS statement, you set lower bounds for the error variances so that estimates of eps1 and eps2 would be nonnegative.

In this example, the PSHORT and the NOSTAND options are used in the PROC TCALIS statement. The PSHORT option suppresses a large amount of the output. For example, initial estimates are not printed and simple descriptive statistics and standard errors are not computed. The NOSTAND option suppresses the printing of the standardized results. Because the default printing in PROC TCALIS might produce a large amount of output, using these printing options make your output more concise and readable. Whenever appropriate, it is recommended that you consider using these printing options.

The estimated equations are shown in Output 88.2.1.

Output 88.2.1 Linear Equations

```
                          Linear Equations

                  0.6650 theta4
                 -2.3429
```

The estimates of intercepts and regression coefficients are shown directly in the equations. Any number in an equation followed by an asterisk is an estimate. For the estimates in equations, the parameter names are shown underneath the associated variables. Any number in an equation not followed by an asterisk is a fixed value. For example, the value 1.0000 attached to the error term in each of the output equation is fixed. Also, for fixed coefficients there are no parameter names underneath the associated variables.

All but the intercept estimates in the equation for predicting P are statistically significant at $\alpha = 0.05$ (when using an approximate critical value of 2). The t ratio for theta1 is -1.590, which implies that this intercept might have been zero in the population. However, because you have reparameterized the original model to use the LINEQS model specification, transformed parameters like theta1 in this model might not be of primary interest. Therefore, you might not need to pay any attention to the significance of the theta1 estimate. There is a way to use the original econometric parameters to specify the LINEQS model. It is discussed in the later part of this example.

Estimates for variance, covariance, and mean parameters are shown in Output 88.2.2.

Output 88.2.2 Variance, Covariance, and Mean Parameters

Estimates for Variances of Exogenous Variables

Covariances Among Exogenous Variables

Var1	Var2	Parameter	Estimate	Standard Error	t Value
E1	E2	eps3	-18.87270	8.77951	-2.14963
F	D	_Add4	74.02539	38.44699	1.92539
Y	D	_Add5	22.99211	16.90102	1.36040
Y	F	_Add6	-21.58158	17.94544	-1.20262

Mean Parameters

Variable Type	Variable	Parameter	Estimate	Standard Error	t Value
Observed	D	_Add7	97.53500	2.71410	35.93643
	F	_Add8	96.62500	2.91560	33.14071
	Y	_Add9	10.50000	1.35724	7.73628

Parameters with a name prefix _Add are added automatically by PROC TCALIS. These parameters are added as free parameters to complete the model specification. In PROC TCALIS, variances and covariances among the set of exogenous manifest variables must be parameters. You either specify them explicitly or let the TCALIS procedure to add them. If you need to constrain or to fix these parameters, then you must specify them explicitly. When your model also fits the mean structures, the same principle applies to the means of the exogenous manifest variables. In this example, because variables D, F, and Y are all exogenous manifest variables, their associated means, variances and covariances must be parameters in the model.

The squared multiple correlations for the equations are shown in Output 88.2.3.

Output 88.2.3 Squared Multiple Correlations

Squared Multiple Correlations

Variable	Error Variance	Total Variance	R-Square
Q	3.51274	14.11128	0.7511
P	105.06749	35.11850	-1.9918

For endogenous variable P, the R-square is -1.9918, which is obviously an invalid value. In fact, because there are correlated errors (between E1 and E2) and reciprocal paths (paths to and from Q and P), the model departs from the regular assumptions of multiple regression analysis. As a result, you should not interpret the R-squares for this example.

If you are interested in estimating the parameters in the original econometric model (that is, α_2, β_2, γ_2, and γ_3), the previous reparameterized LINEQS model does not serve your purpose well enough. However, using the relations between these original parameters with the θ parameters in the reparameterized LINEQS model, you can set up some "super-parameters" in the LINEQS model as follows:

```
proc tcalis data=Food pshort nostand;
   lineqs
      Q = alpha1 Intercept + beta1  P  + gamma1 D + E1,
      P = theta1 Intercept + theta2 Q  + theta3 F + theta4 Y + E2;
   std
      E1-E2 = eps1-eps2;
   cov
      E1-E2 = eps3;
   bounds
      eps1-eps2 >= 0. ;
   parameters alpha2 (50.) beta2 gamma2 gamma3 (3*.25);
      theta1  = -alpha2 / beta2;
      theta2  = 1 / beta2;
      theta3  = -gamma2 / beta2;
      theta4  = -gamma3 / beta2;
run;
```

In this new specification, only the PARAMETERS statement and the SAS programming statements following it are new. In the PARAMETERS statement, you define super-parameters alpha2, beta2, gamma2, and gamma3, and put initial values for them in parentheses. These parameters are the original econometric parameters of interest. The SAS programming statements that follow the PARAMETERS statement are used to define the functional relationships of the super-parameters with the parameters in the LINEQS model. Consequently, in this new specification, theta1, theta2, theta3, and theta4 are no longer independent parameters in the model, as they are in the previous reparameterized model. Instead, alpha2, beta2, gamma2, and gamma3 are independent parameters in this new specification. By fitting this new model, you get the same set of estimates as those in the previous LINEQS model. In addition, you get estimates of the super-parameters, as shown in Output 88.2.4.

Output 88.2.4 Additional Parameters

Additional Parameters

Type	Parameter	Estimate	Standard Error	t Value
Independent	alpha2	51.94452	11.70002	4.43969
	beta2	0.23731	0.09877	2.40262
	gamma2	0.22082	0.04161	5.30695
	gamma3	0.36971	0.07060	5.23649

You can now interpret the results in terms of the original econometric parameterization. As shown in Output 88.2.4, all these estimates are significant, despite the fact that one of the transformed parameter estimates in the linear equations of the LINEQS model is not. You can obtain almost equivalent results by applying the SAS/ETS procedure SYSLIN on this problem.

Example 88.3: A Direct Covariance Structures Model

In the section "Direct Covariance Structures Analysis" on page 6712, the MSTRUCT modeling language is used to specify a model with direct covariance structures. In the model, four variables from the data set of Wheaton et al. (1977) are used. The analysis is carried out in this example to investigate the tenability of the hypothesized covariance structures.

The four variables used are: Anomie67, Powerless67, Anomie71, and Powerless71. The hypothesized covariance matrix is structured as:

$$\Sigma = \begin{pmatrix} \phi_1 & \theta_1 & \theta_2 & \theta_1 \\ \theta_1 & \phi_2 & \theta_l & \theta_3 \\ \theta_2 & \theta_1 & \phi_1 & \theta_1 \\ \theta_1 & \theta_3 & \theta_1 & \phi_2 \end{pmatrix}$$

where:

ϕ_1: variance of anomie

ϕ_2: variance of powerlessness

θ_1: covariance between anomie and powerlessness

θ_2: covariance between anomie measures

θ_3: covariance between powerlessness measures

In this example, you hypothesize the covariance structures directly, as opposed to those models with implied covariance structures from path models (see Example 88.1), structural equations (see Example 88.2), or other types of models. The basic assumption of the direct covariance structures in this example is that Anomie and Powerless were invariant over the measurement periods employed. This implies that the time of measurement did not change the variances and covariances of the

measures. Therefore, both Anomie67 and Anomie71 have the same variance parameter ϕ_1, and both Powerless67 and Powerless71 have the same variance parameter ϕ_2. These two parameters, ϕ_1 and ϕ_2, are hypothesized on the diagonal of the covariance matrix Σ. In the same structured covariance matrix, θ_1 represents the covariance between Anomie and Powerless, without regard to the time of measurement. The θ_2 parameter represents the covariance between the Anomie measures, or the reliability of the Anomie measure. Similarly, the θ_2 parameter represents the covariance between the Powerless measures, or the reliability of the Anomie measure.

As explained in the section "Direct Covariance Structures Analysis" on page 6712, you can use the MSTRUCT modeling language to specify the hypothesized covariance structures directly, as shown in the following statements:

```
proc tcalis nobs=932 data=Wheaton psummary;
   fitindex on(only)=[chisq df probchi] outfit=savefit;
   mstruct
      var = Anomie67 Powerless67 Anomie71 Powerless71;
   matrix _COV_ [1,1] = phi1,
                [2,2] = phi2,
                [3,3] = phi1,
                [4,4] = phi2,
                [2,1] = theta1,
                [3,1] = theta2,
                [3,2] = theta1,
                [4,1] = theta1,
                [4,2] = theta3,
                [4,3] = theta1;
run;
```

In the MSTRUCT statement you specify the variables in the VAR= list. The order of variables in this VAR= list is assumed to be the same as that in the row and column of the hypothesized covariance matrix. Next, in the MATRIX statement you specify parameters as entries in the hypothesized covariance matrix _COV_. Only the lower diagonal elements need to be specified because covariance matrices, by nature, are symmetric. Redundant specification of the upper triangular elements are unnecessary as PROC TCALIS has the information accounted for. You can also set initial estimates by putting parenthesized numbers after the parameter names. But in this example you let PROC TCALIS determine all the initial estimates.

In the PROC TCALIS statement, the PSUMMARY option is used. As a global display option, this option suppresses a lot of displayed output and requests only the fit summary table be printed. This way you can eliminate quite a lot of displayed output that is not of your primary interest. In this example, the specification of the covariance structures is straightforward, and you do not need any output regarding the initial estimation or standardized solution. Suppose that you are not even concerned with the estimates of the parameters because you are not yet sure if this model is good enough for the data. All you want to know at this stage is whether the hypothesized covariance structures fit the data well. Therefore, the PSUMMARY option would serve your purpose well in this example.

In fact, even the fit summary table can be trimmed down quite a bit if you only want to look at certain specific fit indices. In the FITINDEX statement of this example, the ON(ONLY)= option turns on the printing of the model fit chi-square, its df, and p-value only. This does not mean that you must lose the information of all other fit indices. In addition to the printed output, you can save

all fit indices in an output data set. To this end, you can use the OUTFIT= option in the FITINDEX statement. In this example, you save the results of all fit indices in a SAS data set called savefit.

The entire printed output is shown in Output 88.3.1.

Output 88.3.1 Testing Direct Covariance Structures

Fit Summary

Chi-Square	221.5798
Chi-Square DF	5
Pr > Chi-Square	0.0000

As you can see, the displayed output is very precise. It contains only a fit summary table with three statistics. The p-value for the mode fit chi-square test indicates that the hypothesized structures should be rejected at $\alpha = 0.05$. Therefore, this rather restrictive direct covariance structure model does not fit the data well. A less restrictive covariance structure model with more parameters is needed to better account for the variances and covariances of the variables.

All fit indices are saved in the savefit data set. To view it, you can use the following statement:

```
proc print data=savefit;
run;
```

All indices, their types and values are shown in Output 88.3.2.

Output 88.3.2 Saved Fit Indices

The results of various fit indices from this output data set confirm that the hypothesized model does not fit the data well.

As an aside, it is noted with some shorthand notation, the specification of the MSTRUCT model parameters that use the MATRIX statements can be made a little more precise for the current example. This is shown as follows:

```
proc tcalis nobs=932 data=Wheaton psummary;
   fitindex on(only)=[chisq df probchi] outfit=savefit;
   mstruct
      var = Anomie67 Powerless67 Anomie71 Powerless71;
   matrix _COV_ [1,1] = phi1 phi2 phi1 phi2;
                [2, ] = theta1,
                [3, ] = theta2 theta1,
                [4, ] = theta1 theta3 theta1;
run;
```

In the first entry of the MATRIX statement, the notation [1,1] represents that the parameter list specified after the equal sign starts with the [1,1] element of the _COV_ matrix and proceeds down the diagonal. In the next three entries, the notations [2,], [3,], and [4,] represent that parameter lists start with the first elements of the second, third, and fourth rows, respectively, and proceed to the next (right) elements on the same rows. See the syntax of the MATRIX statement on page 6784 for more details about this kind of shorthand notation.

Example 88.4: Confirmatory Factor Analysis: Cognitive Abilities

In this example, cognitive abilities of 64 students from a middle school were measured. The fictitious data contain nine cognitive test scores. Three of the scores were for reading skills, three others were for math skills, and the remaining three were for writing skills. The covariance matrix for the nine variables was obtained. A confirmatory factor analysis with three factors was conducted. The following is the input data set and the PROC TCALIS specification for the analysis:

```
title "Confirmatory Factor Analysis Using the FACTOR Modeling Language";
title2 "Cognitive Data";
data cognitive1(type=cov);
   _type_='cov';
   input _name_ $ reading1 reading2 reading3 math1 math2 math3
         writing1 writing2 writing3;
   datalines;
reading1 83.024    .      .      .      .      .      .      .      .
reading2 50.924 108.243   .      .      .      .      .      .      .
reading3 62.205  72.050 99.341   .      .      .      .      .      .
math1    22.522  22.474 25.731 82.214   .      .      .      .      .
math2    14.157  22.487 18.334 64.423 96.125   .      .      .      .
math3    22.252  20.645 23.214 49.287 58.177 88.625   .      .      .

;
```

```
proc tcalis data=cognitive1 nobs=64 modification;
   factor
      Read_Factor   -> reading1-reading3  = load1-load3,
      Math_Factor   -> math1-math3        = load4-load6,
      Write_Factor  -> writing1-writing3  = load7-load9;
   pvar
      Read_Factor Math_Factor Write_Factor = 3 * 1.,
      reading1-reading3 math1-math3 writing1-writing3 = errvar1-errvar9;
run;
```

In the PROC TCALIS statement, the number of observations is specified with the NOBS= option. The MODIFICATION option in the same statement requests model modification indices be computed.

The FACTOR modeling language is the most handy tool for specifying confirmatory factor models. The FACTOR statement is used to invoke this modeling language. Entries in the FACTOR statement are for specifying factor-variables relationships and are separated by commas. In each entry, you first specify a latent factor, followed by the right arrow sign –>. Then you specify the observed variables that have nonzero loadings on the factor. Next, an equal sign is used to signify the specification of the loading parameters that follow. The loading parameters can be names (parameters without initial estimates), numbers (fixed values), or names followed by parenthesized numbers (parameter with initial values). In this example, there are three factors: Read_Factor, Math_Factor, and Write_Factor. These factors have simple cluster structures with the nine observed variables. Each observed variable has only one loading on exactly one factor, yielding a total of nine loading parameters named load1–load9. No initial estimates are specified for them. They are computed by PROC TCALIS.

In the PVAR statement, you specify the variances of the factors and the error variances for the observed variables. The factor variances in this model are fixed at ones for identification purposes. The error variances for the observed variables are free parameters without initial estimates, named errvar1–errvar9, respectively.

The covariances of the factors are not specified in the model, meaning that the factors are uncorrelated by default. Certainly, this might not be reasonable. But for illustration purposes, this uncorrelated factor model is fitted. With the MODIFICATION option in the PROC TCALIS statement, LM (Lagrange Multiplier) tests are conducted. The results of LM tests can suggest the inclusion of additional parameters for a better model fit. If the uncorrelated factor model is indeed unreasonable, it is shown in the results of the LM tests.

In Output 88.4.1, the initial model specification is echoed in matrix form. The observed variables and factors are also displayed.

In the table for initial factor loading matrix, the nine loading parameters are shown to have simple cluster relations with the factors. In the table for initial factor covariance matrix, the diagonal matrix shows that the factors are not correlated. The diagonal elements are fixed at ones so that this matrix is also a correlation matrix for the factors. In the table for initial error variances, the nine variance parameters are shown. No initial estimates were specified, as indicated by the missing values '.'.

In Output 88.4.2, initial estimates are generated by the instrumental variable method and the McDonald method.

Output 88.4.2 Optimization of the Uncorrelated Factor Model: Initial Estimates

Incremental Index	Bentler Comparative Fit Index	0.9052
	Bentler-Bonett NFI	0.8185
	Bentler-Bonett Non-normed Index	0.8736
	Bollen Normed Index Rho1	0.7580
	Bollen Non-normed Index Delta2	0.9087
	James et al. Parsimonious NFI	0.6139

Using the chi-square model test criterion, the uncorrelated factor model should be rejected at $\alpha = 0.05$. The RMSEA estimate is 0.1147, which is not indicative of a good fit according to Browne and Cudeck (1993). Other indices might suggest only a marginal good fit. For example, Bentler's comparative fit index and Bollen non-normed index delta2 are both above 0.90. However, many other do not attain this 0.90 level. For example, adjusted GFI is only 0.759. It is thus safe to conclude that there could be some improvements on the model fit.

The MODIFICATION option in the PROC TCALIS statement has been used to request for computing the LM test indices for model modifications. The results are shown in Output 88.4.5.

Output 88.4.5 Lagrange Multiplier Tests

Three different tables for ranking the LM test results are shown. In the first table, the new loading parameters that would improve the model fit the most are shown first. For example, in the first row a new factor loading of writing1 on the Read_Factor is suggested to improve the model fit the most. The LM Stat value is 9.77. This is an approximation of the chi-square drop if this parameter was included in the model. The Pr > ChiSq value of 0.0018 indicates a significant improvement of model fit at $\alpha = 0.05$. Nine more new loading parameters are suggested in the table, with less and less statistical significance in the change of model fit chi-square. Note that these approximate chi-squares are one-at-a-time chi-square changes. That means that the overall chi-square drop is not a simple sum of individual chi-square changes when you include two or more new parameters in the modified model.

The other two tables in Output 88.4.5 shows the new parameters in factor covariances, error variances, or error covariances that would result in a better model fit. The table for the new parameters of the factor covariance matrix indicates that adding each of the covariances among factors might lead to a statistically significant improvement in model fit. This confirms with the initial argument that uncorrelated factors might not reasonable in this case—it fails to explain the covariances among observed variables through the correlations among latent factors. The largest LM Stat value in this table is 8.95, which is smaller than that of the largest LM Stat for the factor loading parameters. Despite this, it is more reasonable to add the covariance parameters among factors first to determine whether that improves the model fit. To do this, you need to add the COV statement for specifying the covariances among factors to the original code. The following statements are used to specify the modified factor model with covariances among factors:

```
proc tcalis data=cognitive1 nobs=64;
   factor
      Read_Factor   -> reading1-reading3  = load1-load3,
      Math_Factor   -> math1-math3        = load4-load6,
      Write_Factor  -> writing1-writing3  = load7-load9;
   pvar
      Read_Factor Math_Factor Write_Factor = 3 * 1.,
      reading1-reading3 math1-math3 writing1-writing3 = errvar1-errvar9;
   cov Read_Factor Math_Factor Write_Factor = fcov1-fcov3;
run;
```

The fit summary is shown in Output 88.4.6.

Output 88.4.6 Fit of the Correlated Factor Model

Fit Summary

Modeling Info	N Observations	64
	N Variables	9
	N Moments	45
	N Parameters	21
	N Active Constraints	0
	Independence Model Chi-Square	272.0467
	Independence Model Chi-Square DF	36
Absolute Index	Fit Function	0.4677
	Chi-Square	29.4667
	Chi-Square DF	24
	Pr > Chi-Square	0.2031
	Z-Test of Wilson & Hilferty	0.8320
	Hoelter Critical N	79
	Root Mean Square Residual (RMSR)	5.7038
	Standardized RMSR (SRMSR)	0.0607
	Goodness of Fit Index (GFI)	0.9109
Parsimony Index	Adjusted GFI (AGFI)	0.8330
	Parsimonious GFI	0.6073
	RMSEA Estimate	0.0601
	RMSEA Lower 90% Confidence Limit	.
	RMSEA Upper 90% Confidence Limit	0.1244
	Probability of Close Fit	0.3814
	ECVI Estimate	1.2602
	ECVI Lower 90% Confidence Limit	.
	ECVI Upper 90% Confidence Limit	1.5637
	Akaike Information Criterion	-18.5333
	Bozdogan CAIC	-94.3465
	Schwarz Bayesian Criterion	-70.3465
	McDonald Centrality	0.9582
Incremental Index	Bentler Comparative Fit Index	0.9768
	Bentler-Bonett NFI	0.8917
	Bentler-Bonett Non-normed Index	0.9653
	Bollen Normed Index Rho1	0.8375
	Bollen Non-normed Index Delta2	0.9780
	James et al. Parsimonious NFI	0.5945

The model fit chi-square value is 29.27, which is about 20 less than the model with uncorrelated factors. The p-value is 0.20, indicating a fairly satisfactory model fit. The RMSEA value is 0.06, which is close to 0.05, a value recommended as an indication of good model fit by Browne and Cudeck (1993). More fit indices that do not attain the 0.9 level with the uncorrelated factor model now have values close to or above 0.9. These include the goodness-of-fit index (GFI), McDonald centrality, Bentler-Bonnet NFI, and Bentler-Bonnet non-normed index. By all counts, the correlated factor model is a much better fit than the uncorrelated factor model.

In Output 88.4.7, the estimation results for factor loadings are shown. All these loadings are statistically significant, indicating non-chance relationships with the factors.

Output 88.4.7 Estimation of the Factor Loading Matrix

Factor Loading Matrix: Estimate/StdErr/t-value

	Read_Factor	Math_Factor	Write_Factor
reading1	6.7657 1.0459 6.4689 [load1]	0	0
reading2	7.8579 1.1890 6.6090 [load2]	0	0

math2	errvar5	24.89032	8.98327	2.77074
math3	errvar6	42.12110	9.20362	4.57658
writing1	errvar7	27.24965	10.36489	2.62903
writing2	errvar8	49.28881	11.39812	4.32429
writing3	errvar9	48.10684	11.48868	4.18733

All t values except the one for reading3 are bigger than 2, a value close to a critical t-value at $\alpha = 0.05$. This means that the error variance for reading3 could have been zero in the population, or it could have been nonzero but the current sample just has this nonsignificant value by chance (that is, a Type 2 error). Further research is needed to confirm either way.

In addition to the parameter estimation results, PROC TCALIS also outputs supplementary results that could be useful for interpretations. In Output 88.4.10, the squared multiple correlations and the factor scores regression coefficients are shown.

Output 88.4.10 Supplementary Estimation Results

writing2	0.00152	0.00131	0.02446
writing3	0.00161	0.00138	0.02587

The percentages of variance for the observed variables that can be explained by the factors are shown in the R-Square column of the table for squared multiple correlations (R-squares). These R-squares can be interpreted meaningfully because there is no reciprocal relationships among variables or correlated errors in the model. All estimates of R-squares are bounded between 0 and 1.

In the table for factor scores regression coefficients, entries are coefficients for the variables you can use to create the factor scores. The larger the coefficient, the more influence of the corresponding variable for creating the factor scores. It makes intuitive sense to see the cluster pattern of these coefficients—the reading measures are more important to create the latent variable scores of Read_Factor and so on.

Example 88.5: Testing Equality of Two Covariance Matrices Using a Multiple-Group Analysis

You can use PROC TCALIS to do multiple-group or multiple-sample analysis. The groups in the analysis must be independent. In this example, a relatively simple multiple-group analysis is carried out. The covariance matrices of two independent groups are tested for equality. Hence, individual

covariance matrices are actually not structured. Rather, they are constrained to be the same under the null hypothesis. See Example 88.10 for a more sophisticated example of multiple-group analysis.

In this example, a reaction time experiment was conducted on two groups of individuals. One group ($N = 20$) was considered to be an expert group with prior training related to the tasks of the experiment. Another group ($N = 18$) was a control group without prior training. Three tasks of dexterity were administered to all individuals. These tasks differed by their required complexity levels of body skills. They were labeled as high, medium, and low complexities.

Apparently, the differential performance of the two groups under different task complexities was the primary research objective. In this example, however, you are interested in testing whether the groups have the same covariance matrix for the tasks. Equality of covariance matrices might be an essential assumption in some statistical tests for comparing group means. In this example, you will use PROC TCALIS to see the tenability of such an assumption. The covariance matrices for the two groups are stored in the data sets Expert and Novice, as shown in the following:

```
data expert(type=cov);
   input _type_ $ _name_ $ high medium low;
   datalines;
COV   high    5.88     .       .
COV   medium  2.88    7.16     .
COV   low     3.12    4.44    8.14
;

data novice(type=cov);
   input _type_ $ _name_ $ high medium low;
   datalines;
COV   high    6.42     .       .
COV   medium  1.24    8.25     .
COV   low     4.26    2.75    7.99
;
```

These data sets are read into the analysis through the GROUP statements in the following PROC TCALIS specification:

```
proc tcalis;
   group 1 / data=expert nobs=20 label="Expert";
   group 2 / data=novice nobs=18 label="Novice";
   model 1 / groups=1,2;
      mstruct
         var=high medium low;
         matrix _COV_ [1,1] = v_high v_medium v_low,
                      [2,]  = cov21,
                      [3,]  = cov31 cov32;
   fitindex NoIndexType On(only)=[chisq df probchi]
            chicorrect=eqcovmat;
   ods select ModelingInfo MSTRUCTVariables MSTRUCTCovInit Fit;
run;
```

The first GROUP statement defines group 1 for the expert group. The second GROUP statement defines group 2 for the novice group. The NOBS= option is used in both statements to provide the number of observations of these groups. The LABEL= option is used in these statements to provide meaningful group labels.

The MODEL statement defines MODEL 1. In the analysis, this model fits both groups 1 and 2, as indicated by the GROUPS= option of the statement. An MSTRUCT model for MODEL 1 is defined immediately afterward. Three variables, high, medium, and low, are specified in the VAR= option of the MSTRUCT statement. These three variables are also the row and column variables in the _COV_ matrix defined in the MATRIX statement.

In the first entry of the MATRIX statement, the diagonal elements of the _COV_ matrix are specified. Starting with the element [1,1] (and implicitly followed by [2,2] and [3,3]), variances for the three variables are parameters named v_high, v_medium, and v_low, respectively. In the second entry of the MATRIX statement, parameter specification starts with (and also ends with) the first element of the second row (that is, [2,1]) of the _COV_ matrix. The covariance between the variables high and medium is specified as cov21. In the last entry of the MATRIX statement, parameter specification starts with the first element of the third row (that is, [3,1] and then [3,2]) of the _COV_ matrix. The covariance between the variables high and low is specified as cov31 and the covariance between the variables medium and low is specified as cov32. No initial values are provided in this example. PROC TCALIS generates initial values by some reasonable methods.

There are six parameters in the covariance matrix _COV_, which also has six nonredundant elements in its general form as a symmetric matrix. Hence, model 1 is saturated. If this model were to fit a single group, it would have indicated a perfect model fit with zero chi-square value. Such a model is quite trivial and not of interest. But with two independent groups being fitted by this single model, it becomes a nontrivial model in which you test the equality of the two covariance matrices. Having this main purpose in mind, you use options in the FITINDEX statement to extract the relevant results that could answer your question. First, you use the NOINDEXTYPE option to suppress the printing of the index types in the fit summary table. Then, you use the ON(ONLY)= option to specify the fit indices printed in the fit summary table. In this example, only the model fit chi-square statistic, degrees of freedom, and the probability value of the test are requested. Finally, you use the CHICORRECT=EQCOVMAT option to request a chi-square correction for the test of equality of covariance matrices. This correction is due to Box (1949) and is implemented in PROC TCALIS as a built-in chi-square correction option.

In addition, because you are not interested in all displayed output, you use the ODS SELECT statement to display only those output (or ODS tables) of interest. In this example, only the modeling information, the variables involved, the initial covariance matrix specification, and the fit summary table are printed. All output in PROC TCALIS are named as an ODS table. To locate a particular output in PROC TCALIS, you must know the corresponding ODS table names. See the section "ODS Table Names" on page 6939 for a listing of ODS table names used by PROC TCALIS.

Output 88.5.1 displays some information regarding the basic model setup.

Output 88.5.1 Modeling Information and Initial Specification

Modeling Information

Group	Label	Data Set	N Obs	Model	Type
1	Expert	WORK.EXPERT	20	Model 1	MSTRUCT
2	Novice	WORK.NOVICE	18	Model 1	MSTRUCT

Output 88.5.1 *continued*

Model 1. Variables in the Model

high medium low

Number of Variables = 3

Model 1. Initial MSTRUCT _COV_ Matrix

	high	medium	low
high	. [v_high]	. [cov21]	. [cov31]
medium	. [cov21]	. [v_medium]	. [cov32]
low	. [cov31]	. [cov32]	. [v_low]

The modeling information table summarizes some basic information about the two groups. Both of them are fitted by model 1. The next table shows the variables involved: high, medium, and low. The order of variables in this table is the same as that of the row and column variables of the covariance model matrix, which is shown next. The parameters for the entries in the covariance matrix are shown. The names of parameters are displayed in parentheses. No initial estimates are given as input, as indicated by the missing value '.'.

The fit summary table is shown in Output 88.5.2, which has been much simplified for the current example due to the uses of some options in the FITINDEX statement.

Output 88.5.2 Model Fit

Fit Summary

Chi-Square	2.4924
Chi-Square DF	6
Pr > Chi-Square	0.8693

As shown in Table 88.5.2, the chi-square test statistic is 2.4924. With six degrees of freedom, the test statistic is not significant at $\alpha = 0.01$. Therefore, the fitted model is supported, which means that the equality of the covariance matrices of the groups is tenable.

Example 88.6: Illustrating Various General Modeling Languages

In PROC TCALIS, you can use many different modeling languages to specify the same model. The choice of modeling language depends on personal preferences and the purposes of the analysis. See the section "Which Modeling Language?" on page 6714 for guidance. In this example, the data and the model in Example 88.1 are used to illustrate how a particular model can be specified by various general modeling languages.

RAM Model Specification

In Example 88.1, the PATH modeling language was used. The PATH modeling language is closely related to the RAM modeling language. The following RAM model specification shows similar syntax to that of the PATH model specification.

```
proc tcalis nobs=932 data=Wheaton;
   ram
      path Anomie67     <-  Alien67   1.0,
      path Powerless67  <-  Alien67   0.833,
      path Anomie71     <-  Alien71   1.0,
      path Powerless71  <-  Alien71   0.833,
      path Education    <-  SES       1.0,
      path SEI          <-  SES       lambda,
      path Alien67      <-  SES       gamma1,
      path Alien71      <-  SES       gamma2,
      path Alien71      <-  Alien67   beta,
      pvar Anomie67                   theta1,
      pvar Powerless67                theta2,
      pvar Anomie71                   theta1,
      pvar Powerless71                theta2,
      pvar Education                  theta3,
      pvar SEI                        theta4,
      pvar Alien67                    psi1,
      pvar Alien71                    psi2,
      pvar SES                        phi,
      pcov Anomie67       Anomie71    theta5,
      pcov Powerless67    Powerless71 theta5;
run;
```

In the RAM model, a list of parameter locations are specified in the RAM statement. In each entry of the list, the parameter type, the variables involved, and the parameter are specified in order. These entries are separated by commas.

The parameter type is listed first in each list entry. In this example, three parameter types are specified: PATH, PVAR, and PCOV. These types correspond to the PATH, PVAR, and PCOV statements in the PATH model specification. There are other parameter types you can use for the RAM model specification, but they are not shown in this example. See the RAM statement on page 6805 for more details.

The variables involved are specified after the parameter type in each list entry. Depending on the parameter type, the number of variables required is either one or two. For entries with the PATH

parameter type, two variables must be specified—one for the outcome and one for the predictor. In this example, the two variables involved in the PATH entries are separated by arrows "<–" that indicate the prediction directions. When the arrows are not specified, the first variable is assumed to be the outcome variable, and the second one is the predictor variable. For the PVAR entries, which stand for partial variance, only one variable is required after the parameter type specification. For the PCOV entries, which stand for partial covariance, two variables are required. The order of these two variables in the PCOV entries is not important, however.

The last specification in each list entry is the parameter. The parameter can either be a fixed value (a numerical value alone), a free parameter without an initial value (a name alone), or a free parameter with an initial value (a name followed by a parenthesized numerical value). In this example, you specify five fixed values for the path coefficients (or effects) in the first five entries. In the next four paths and all other PVAR and PCOV entries, you specify free parameters without initial values.

When comparing with the PATH model specification, the RAM specification is quite similar. Certainly, the model fit would be the same because both specifications are mathematically equivalent. Unlike the PATH model that uses different tables for displaying different types of estimates, all estimates of the RAM model are displayed in a single table as shown in Output 88.6.1.

Output 88.6.1 RAM Model Estimates

	Alien67			psi1	5.67046	0.42301	13.40500
	Alien71			psi2	4.51479	0.33532	13.46394
	SES			phi	6.61634	0.63914	10.35190
Partial Cov	Anomie67		Anomie71	theta5	0.90580	0.12167	7.44472
	Powerless67		Powerless71	theta5	0.90580	0.12167	7.44472

These RAM model estimates match the set of estimates using the PATH model specification.

LINEQS Model Specification

Another way to specify the model in Example 88.1 is to use the LINEQS modeling language, which is shown in the following:

```
proc tcalis nobs=932 data=Wheaton;
   lineqs
      Anomie67     = 1.0    f_Alien67 + E1,
      Powerless67  = 0.833  f_Alien67 + E2,
      Anomie71     = 1.0    f_Alien71 + E3,
      Powerless71  = 0.833  f_Alien71 + E4,
      Education    = 1.0    f_SES     + E5,
      SEI          = lambda f_SES     + E6,
      f_Alien67    = gamma1 f_SES     + D1,
      f_Alien71    = gamma2 f_SES     + beta f_Alien67 + D2;
   std
      E1           = theta1,
      E2           = theta2,
      E3           = theta1,
      E4           = theta2,
      E5           = theta3,
      E6           = theta4,
      D1           = psi1,
      D2           = psi2,
      f_SES        = phi;
   cov
      E1  E3       = theta5,
      E2  E4       = theta5;
run;
```

In the LINEQS model, all paths in the PATH model are now specified in equations. In each equation, you list an outcome variable on the left-hand-side of the equation and all its predictors (including the error or disturbance variable) on the right-hand-side of the equation. Because each outcome variable can only be specified in exactly one equation, the number of equations in the LINEQS model and the number of paths in the corresponding PATH model do not match necessarily. In this example, there are eight equations in the LINEQS statement, but there would be nine paths specified in the corresponding PATH model.

In addition, in the LINEQS model, you need to follow a convention of naming latent variables. Names for latent variables that are neither errors nor disturbances must start with either 'F' or 'f.' Names for errors must start with either 'E' or 'e,' while names for disturbances must start with either 'D' or 'd.' Recall that in the PATH model specification, no such convention is imposed. For example, f_Alien67, f_Alien71, and f_SES are latent factors in the LINEQS model. They are not error terms, and so they must start with the 'f' prefix. However, this prefix is not needed in the PATH model. Furthermore, there are no explicit error terms that need to be specified in the PATH model, let alone specific prefixes for the error terms.

The PVAR statement in the PATH model is now replaced with the STD statement in the LINEQS model, and the PCOV statement with the COV statement. Recall that the PVAR and PCOV statements in the PATH model are for the partial variance and partial covariance specifications. The partial variance or covariance concepts are used in the PATH or RAM model specification because error terms are not named explicitly. But for the LINEQS model, errors or disturbances are

named explicitly as **exogenous** variables so that the partial variance or covariance concepts are no longer necessary. In this example, the variances of the errors ("E"-variables) and disturbances ("D"-variables) specified in the STD statement of the LINEQS model correspond to the partial variances of the endogenous variables specified in the PVAR statement of the PATH model. Similarly, covariances of errors specified in the COV statement of the LINEQS model correspond to the partial covariances of endogenous variables specified in the PCOV statement of the PATH model. The estimation results of the LINEQS model are shown in Output 88.6.2. Again, they are essentially the same estimates obtained from the PATH model specified in Example 88.1.

Output 88.6.2 LINEQS Model Estimates

Linear Equations

```
Anomie67     =    1.0000 f_Alien67 +  1.0000 E1
Powerless67  =    0.8330 f_Alien67 +  1.0000 E2
Anomie71     =    1.0000 f_Alien71 +  1.0000 E3
Powerless71  =    0.8330 f_Alien71 +  1.0000 E4
Education    =    1.0000 f_SES     +  1.0000 E5
SEI          =    5.3688*f_SES     +  1.0000 E6
Std Err           0.4337 lambda
t Value          12.3788
f_Alien67    =   -0.6299*f_SES     +  1.0000 D1

Covariances Among Exogenous Variables

Var1	Var2	Parameter	Estimate	Standard Error	t Value
E1	E3	theta5	0.90580	0.12167	7.44472
E2	E4	theta5	0.90580	0.12167	7.44472

LISMOD Specification

You can also specify general structural models by using the LISMOD modeling language. See the section "The LISMOD Model and Submodels" on page 6847 for details.

Four types of variables must be recognized before you can specify a LISMOD model. The η-variables (eta-variables) are latent factors that are endogenous, or predicted by other latent factors. The ξ-variables (xi-variables) are exogenous latent variables that are not predicted by any other variables. The y-variables are manifest variables that are indicators of the η-variables, and the x-variables are manifest variables that are indicators of the ξ-variables. In this example, Alien67 and Alien71 are the η-variables, and SES is the ξ-variable in the model. Manifest indicators for Alien67 and Alien71 include Anomie67, Powerless67, Anomie71, and Powerless71, which are the y-variables. Manifest indicators for SES include Education and SEI, which are the x-variables.

After defining these four types of variables, the parameters of the model are defined as entries in the model matrices. The _LAMBDAY_, _LAMBDAX_, _GAMMA_, and _BETA_ are matrices for the path coefficients or effects. The _THETAY, _THETAX_, _PSI_, and _PHI_ are matrices for the variances and covariances.

The following is the LISMOD specification for the model in Example 88.1:

```
proc tcalis nobs=932 data=Wheaton;
   lismod
      yvar   = Anomie67 Powerless67 Anomie71 Powerless71,
      xvar   = Education SEI,
      etavar = Alien67  Alien71,
      xivar  = SES;
   matrix _LAMBDAY_
      [1,1]  = 1,
      [2,1]  = 0.833,
      [3,2]  = 1,
      [4,2]  = 0.833;
   matrix _LAMBDAX_
      [1,1]  = 1,
      [2,1]  = lambda;
   matrix _GAMMA_
      [1,1]  = gamma1,
      [2,1]  = gamma2;
   matrix _BETA_
      [2,1]  = beta;
   matrix _THETAY_
      [1,1]  = theta1-theta2 theta1-theta2,
      [3,1]  = theta5,
      [4,2]  = theta5;
   matrix _THETAX_
      [1,1]  = theta3-theta4;
   matrix _PSI_
      [1,1]  = psi1-psi2;
   matrix _PHI_
      [1,1]  = phi;
run;
```

In the LISMOD statement, you specify the four lists of variables in the model. The orders of the variables in these lists are not arbitrary. They are the orders applied to the row and column variables in the model matrices, of which the parameter locations are specified.

The estimated model is divided into three conceptual parts. The first part is the measurement model that relates the η-variables with the y-variables, as shown in Output 88.6.3:

Output 88.6.3 LISMOD Model Measurement Model for the Eta-Variables

LAMBDAY Matrix: Estimate/StdErr/t-value

	Alien67	Alien71
Anomie67	1.0000	0
Powerless67	0.8330	0
Anomie71	0	1.0000
Powerless71	0	0.8330

THETAY Matrix: Estimate/StdErr/t-value

	Anomie67	Powerless67	Anomie71	Powerless71
Anomie67	3.6080 0.2009 17.9572 [theta1]	0	0.9058 0.1217 7.4447 [theta5]	0
Powerless67	0	3.5949 0.1645 21.8556 [theta2]	0	0.9058 0.1217 7.4447 [theta5]
Anomie71	0.9058 0.1217 7.4447 [theta5]	0	3.6080 0.2009 17.9572 [theta1]	0
Powerless71	0	0.9058 0.1217 7.4447 [theta5]	0	3.5949 0.1645 21.8556 [theta2]

The _LAMBDAY_ matrix contains the coefficients or effects of the η-variables on the y-variables. All these estimates are fixed constants as specified. The _THETAY_ matrix contains the error

variances and covariances for the y-variables. Three free parameters are located in this matrix: theta1, theta2, and theta5.

The second part of the estimated model is the measurement model that relates the ξ-variable with the x-variables, as shown in Output 88.6.4:

Output 88.6.4 LISMOD Model Measurement Model for the Xi-Variables

```
_LAMBDAX_ Matrix: Estimate/StdErr/t-value

                              SES

        Education          1.0000

        SEI                5.3688
                           0.4337
                          12.3788
                         [lambda]

_THETAX_ Matrix: Estimate/StdErr/t-value

                 Education             SEI

Education          2.9937               0
                   0.4986
                   6.0040
                  [theta3]

SEI                      0        259.5764
                                   18.3115
                                   14.1756
                                  [theta4]
```

The _LAMBDAX_ matrix contains the coefficients or effects of the ξ-variable SES on the x-variables. The effect of SES on Education is fixed at one. The effect of SES on SEI is represented by the free parameter lambda, which is estimated at 5.3688. The _THETAX_ matrix contains the error variances and covariances for the x-variables. Two free parameters are located in this matrix: theta3 and theta4.

The last part of the estimated model is the structural model that relates the latent variables η and ξ, as shown in Output 88.6.5:

Output 88.6.5 LISMOD Structural Model for the Latent Variables

```
                    _BETA_ Matrix: Estimate/StdErr/t-value

                                  Alien67        Alien71

                    Alien67             0              0

                    Alien71        0.5931              0
                                   0.0468
                                  12.6788
                                   [beta]

                    _GAMMA_ Matrix: Estimate/StdErr/t-value

                                                    SES

                           Alien67                -0.6299
                                                   0.0563
                                                 -11.1809
                                                 [gamma1]

                           Alien71                -0.2409
                                                   0.0549
                                                  -4.3884
                                                 [gamma2]

                    _PSI_ Matrix: Estimate/StdErr/t-value

                                  Alien67        Alien71

                    Alien67        5.6705              0
                                   0.4230
                                  13.4050
                                   [psi1]

                    Alien71             0         4.5148
                                                  0.3353
                                                 13.4639
                                                  [psi2]

                     _PHI_ Matrix: Estimate/StdErr/t-value

                                                  SES

                              SES                6.6163
                                                 0.6391
                                                10.3519
                                                  [phi]
```

The _BETA_ matrix contains effects of η-variables on themselves. In our example, there is only one such effect. The effect of Alien67 on Alien71 is represented by the free parameter beta. The

GAMMA matrix contains effects of the ξ-variable, which is SES in this example, on the η-variables Alien67 on Alien71. These effects are represented by free parameters gamma1 and gamma2. The _PSI_ matrix contains the error variances and covariances in the structural model. In this example, psi1 and psi2 are two free parameters for the error variances. Finally, the _PHI_ matrix is the covariance matrix for the ξ-variables. In this example, there is only one ξ-variable so that this matrix contains only the estimated variance of SES. This variance is represented by the parameter phi.

The estimates obtained from fitting the LISMOD model are the same as those from fitting the equivalent PATH, RAM, or LINEQS model. To some researchers the LISMOD modeling language might be more familiar, while for others modeling languages such as PATH, RAM, or LINEQS are more convenient to use.

Example 88.7: Fitting a Latent Growth Curve Model

Latent factors in structural equation modeling are constructed to represent important unobserved hypothetical constructs. However, with some manipulations latent factors can also represent random effects in models. In this example, a simple latent growth curve model is considered. You use latent factors to represent the random intercepts and slopes in the latent growth curve model.

Sixteen individuals were invited to a training program that was designed to boost self-confidence. During the training, the individuals' confidence levels were measured at five time points: initially and four more times separated by equal intervals. The data are stored in the following SAS data set:

```
data growth;
   input y1 y2 y3 y4 y5;
   datalines;
17.6  21.4  25.6  32.1  37.7
13.2  14.3  18.9  20.3  25.4
11.6  13.5  17.4  22.1  39.6
10.7  11.1  13.2  18.2  21.4
18.7  23.7  28.6  31.5  34.0
18.3  19.2  20.5  23.2  25.9
 9.2  13.5  17.8  19.2  21.1
18.3  23.5  27.9  30.2  34.6
11.2  15.6  20.8  22.7  30.4
17.0  22.9  26.9  31.9  35.6
10.4  13.6  18.0  25.6  29.3
17.7  19.0  22.5  28.5  30.7
14.5  19.4  21.1  28.8  31.5
20.0  21.4  28.9  30.2  35.6
14.6  19.3  21.7  28.5  32.0
11.7  15.2  19.1  23.7  28.7
;
```

First, consider a simple linear regression model for the confidence levels at time t due to training. That is,

$$y_t = \alpha + \beta T_t + e_t$$

where y_t represents the confidence level at time t ($t = 1, 2, \ldots, 5$), α represents the intercept, β represents the slope or the effect of training, T_t represents the fixed time point at t ($T_1 = 0$ and $T_i = T_{i-1} + 1$), and e_t is the error term at time t.

This simple linear regression assumes that the effect of training (slope) and the intercept are constants for the individuals. However, individual differences are rules rather than exceptions. It is thus more reasonable to argue that an index i for individuals should be added to the intercept and slope in the model. As a result, the following individualized regression model is derived:

$$y_{it} = \alpha_i + \beta_i T_t + e_t$$

where $i = 1, 2, \ldots, 16$. In this model, individuals are assumed to have different intercepts and slopes (regression coefficients). Note that theoretically e_t could also be "individualized" as e_{ti} in the model. But this is not done because such a model would be unnecessarily complicated without gaining additional insights in return.

Unfortunately, this individualized model with individual intercepts and slopes cannot be estimated directly. If you treat each α_i and β_i as fixed parameters, you are going to have too many parameters for the model to be identified or estimable. A workable solution is to treat α and β in the original linear regression model as random variables instead. That is, the latent growth curve model of interest is as follows:

$$y_t = \alpha + \beta T_t + e_t$$

where (α, β) is bivariate normal with unknown means, variances, and covariance. Therefore, instead of having 16 intercepts and 16 slopes to estimate in the individualized regression model, the final latent growth curve model has to estimate only two means, two variances and one covariance in the bivariate distribution of (α, β).

To use PROC TCALIS to fit this latent growth curve model, the random intercept and effect are treated as if they were covarying latent factors. To make them stand out more as latent variables, the random intercept and slope are renamed as f_α and f_β in the following structural equation:

$$y_t = f_\alpha + T_t f_\beta + e_t$$

where f_α and f_β are bivariate-normal latent variables. This model assumes that the error distribution is time dependent (with the index t). A simpler version is to make this error term invariant over time, which is then represented by the following model with constrained error variances:

$$y_t = f_\alpha + T_t f_\beta + e$$

This constrained model is considered first. The LINEQS modeling language is used to specify this constrained model, as shown in the following statements.

```
proc tcalis method=ml data=growth nostand noparmname;
   lineqs
      y1 = f_alpha               + e1,
      y2 = f_alpha  +  1 f_beta + e2,
      y3 = f_alpha  +  2 f_beta + e3,
      y4 = f_alpha  +  3 f_beta + e4,
      y5 = f_alpha  +  4 f_beta + e5;
   std
      f_alpha   = parm__,
      f_beta    = parm__,
      e1-e5     = 5 * evar;
   cov
      f_alpha f_beta = parm__;
   mean
      f_alpha   = parm__,
      f_beta    = parm__;
   fitindex on(only)=[chisq df probchi];
run;
```

In the LINEQS model specification, f_alpha and f_beta are treated as latent factors representing the random intercept and random slope, respectively. The f_ prefix for latent factors is not arbitrary but is required as a convention in the LINEQS modeling language. See the sections "Naming Variables in the LINEQS Model" on page 6840 and "Naming Variables and Parameters" on page 6880 for details.

At $T_1 = 0$, y_1 represents the initial confidence measurement so that it is not subject to the random effect f_beta. The next four measurements y_2, y_3, y_4, and y_5 are measured at time points T_2, T_3, T_4, and T_5, respectively. These are fixed time points with constant values 1, 2, 3, and 4, respectively, in the equations of the LINEQS statement.

The means, variances and covariances of f_alpha and f_beta are parameters in the model. The variances of these two latent variables are specified in the STD statement, while their covariance is specified in the COV statement. The means of f_alpha and f_beta are specified in the MEAN statement. Notice that the parameter name parm__ is used for all these parameters. Parameter names ending with two underscores ('__') are used as generic names for generating new parameter names. Each time such a generic name is parsed, PROC TCALIS replaces the underscores with an unique integer. Therefore, in the various locations of parm__ in the LINEQS model, the actual parameter names registered with PROC TCALIS are parm1, parm2, ..., parm5. For example, the variance parameters of f_alpha and f_beta are named parm1 and parm2, respectively, and the mean parameter of f_beta is named parm5.

The error variances for e1–e5 are also specified in the STD statement. Using the shorthand notation 5 *, the parameter name evar is repeated five times for the five error variances. This implicitly constrains the error variances for e1–e5 to be equal.

Special printing options are used in this example. In the PROC TCALIS statement, the NOSTAND option is specified because standardized solution is not of interest. The reason is that $y1$-$y5$ were already measured on comparable scales, making standardization unnecessary for interpretations. Another printing option specified is the NOPARMNAME option in the PROC TCALIS statement.

This option suppresses the printing of parameter names in the output for estimation. This makes the output look more precise when you do not need direct references to the parameter names. Still another printing option used is the ON(ONLY)= option of the FITINDEX statement. This option trims down the display of fit indices to include only those listed in the option. See the FITINDEX statement on page 6760 for details.

The fit summary table is shown in Output 88.7.1.

Output 88.7.1 Random Intercepts and Effects with Constrained Error Variances: Model Fit

Fit Summary

Chi-Square	31.4310
Chi-Square DF	14
Pr > Chi-Square	0.0048

In Output 88.7.1, the chi-square value in the fit summary table is 31.431 ($df = 14$, $p < 0.01$), which is a statistically significant result that might indicate a poor model fit. Despite that, it is illustrative to continue to look at the main estimation results, which are shown in the following table.

Output 88.7.2 Estimation of Random Intercepts and Effects with Constrained Error Variances

Estimates for Variances of Exogenous Variables

Variable Type	Variable	Estimate	Standard Error	t Value
Latent	f_alpha	13.89140	5.81540	2.38873
	f_beta	0.80742	0.42198	1.91342
Error	e1	3.32185	0.70031	4.74342
	e2	3.32185	0.70031	4.74342
	e3	3.32185	0.70031	4.74342
	e4	3.32185	0.70031	4.74342
	e5	3.32185	0.70031	4.74342

Covariances Among Exogenous Variables

Var1	Var2	Estimate	Standard Error	t Value
f_alpha	f_beta	-0.35281	1.13815	-0.30998

Mean Parameters

Variable Type	Variable	Estimate	Standard Error	t Value
Latent	f_alpha	14.15875	1.02906	13.75890
	f_beta	4.04813	0.27563	14.68665

In Output 88.7.2, the estimated variance of the random intercept α, which is represented by the variance estimate of the latent factor f_alpha, is 13.891 ($t = 2.389$). In the next row of the same table, the variance estimate of the random effect β, which is represented by the variance estimate of the latent factor f_beta, is 0.807 ($t = 1.913$).

The covariance of the random intercept and the random effect is shown in the next table for "Covariances Among Exogenous Variables." A negative estimate of -0.353 is shown. This means that the initial self-confidence level and the boosting effect of training are negatively correlated. The higher the initial self-confidence level, the smaller the training effect.

In the last table for the "Mean Parameters," the estimated mean of the random intercept is 14.159, which is an estimate of the averaged initial self-confidence level. The estimated mean of random effect is 4.048, which is an estimate of the averaged training effect.

Given that the model does not fit that well, perhaps you should not take the interpretations of these estimates so seriously. Knowing that the distribution of the errors might have been time-dependent, you now try to improve the fit of the model by relaxing the constraint about common error variances. This can be done by using the following specification:

```
proc tcalis method=ml data=growth nostand noparmname;
   lineqs
      y1 = f_alpha              + e1,
      y2 = f_alpha  +  1 f_beta + e2,
      y3 = f_alpha  +  2 f_beta + e3,
      y4 = f_alpha  +  3 f_beta + e4,
      y5 = f_alpha  +  4 f_beta + e5;
   std
      f_alpha   = parm__,
      f_beta    = parm__,
      e1-e5     = 5 * parm__;
   cov
      f_alpha f_beta = parm__;
   mean
      f_alpha   = parm__,
      f_beta    = parm__;
   fitindex on(only)=[chisq df probchi];
run;
```

In this new specification, there is only one change in the STD statement from the previous specification. That is, you now use five different parameters for the five error variances, as highlighted in the following:

```
   e1-e5   = 5 * parm__;
```

This specification is equivalent to putting parm__ five times for the five error variance parameters, which is shown as follows:

```
   e1-e5   = parm__ parm__ parm__ parm__ parm__;
```

The model fit summary is shown in Output 88.7.3.

Output 88.7.3 Random Intercepts and Effects with Unconstrained Error Variances: Model Fit

Fit Summary

Chi-Square	11.6250
Chi-Square DF	10
Pr > Chi-Square	0.3109

As you can see from the fit summary table, the chi-square for the unconstrained model is 11.625 ($df = 10$, $p > .10$). This indicates an acceptable model fit. The chi-square difference test can also be conducted for testing the previous constrained model against this new model. The chi-square difference is $19.81 = 31.431 - 11.625$. With df=4, this chi-square difference value is statistically significant at α=0.01, indicating a significant improvement of model fit by using the unconstrained model.

Estimation results are shown in Output 88.7.4.

Output 88.7.4 Estimation of Random Intercepts and Effects with Unconstrained Error Variances

Estimates for Variances of Exogenous Variables

Variable Type	Variable	Estimate	Standard Error	t Value
Latent	f_alpha	14.70071	5.66943	2.59298
	f_beta	0.45059	0.29867	1.50867
Error	e1	2.81712	1.35332	2.08164
	e2	0.32213	0.46118	0.69848
	e3	1.94429	0.86824	2.23935
	e4	1.88569	1.21306	1.55448
	e5	14.65193	5.99354	2.44462

Covariances Among Exogenous Variables

Var1	Var2	Estimate	Standard Error	t Value
f_alpha	f_beta	0.35291	0.90366	0.39054

Mean Parameters

Variable Type	Variable	Estimate	Standard Error	t Value
Latent	f_alpha	14.03046	1.01534	13.81851
	f_beta	3.96793	0.22612	17.54781

The estimation results for the unconstrained model present a slightly different picture than the constrained model. While the estimates for the means and variances of the random intercept and the random training effect look similar in both models, estimates of the covariance between the random intercept and the random training effect are quite different in the two models. The covariance esti-

mate is negative (−0.353) in the constrained model, but it is positive (0.353) in the unconstrained model. However, because the covariance estimates are not statistically significant in both models ($t = -0.310$ and 0.391, respectively), you wonder whether the current data are showing strong evidence that supports one way or another. To get a clearer picture, perhaps more data should be collected and the model should be fit again to check for the significance of the covariance between the random intercept and slope. If the covariance estimate is still not significant, future models might have this covariance fixed at 0 in analysis.

Example 88.8: Higher-Order and Hierarchical Factor Models

In this example, confirmatory higher-order and hierarchical factor models are fitted by PROC TCALIS.

In higher-order factor models, factors are at different levels. The higher-order factors explain the relationships among factors at the next lower level, in the same way that the first-order factors explain the relationships among manifest variables. For example, in a two-level higher factor model you have nine manifest variables V1–V9 with three first-order factors F1–F3. The first-order factor pattern of the model might appear like the following:

	F1	F2	F3
V1	x		
V2	x		
V3	x		
V4		x	
V5		x	
V6		x	
V7			x
V8			x
V9			x

where each "x" marks a nonzero factor loading and all other unmarked entries are fixed zeros in the model. To explain the correlations among the first-order factors, a second-order factor F4 is hypothesized with the following second-order factor pattern:

	F4
F1	x
F2	x
F3	x

If substantiated by your theory, you might have higher-order factor models with more than two levels.

In hierarchical factor models, all factors are at the same (first-order) level but are different in their clusters of manifest variables related. Using the terminology of Yung, Thissen, and McLeod (1999), factors in hierarchical factor models are classified into "layers." The factors in the first layer partition the manifest variables into clusters so that each factor has a distinct cluster of related manifest

variables. This part of the factor pattern of the hierarchical factor model is similar to that of the first-order factor model for manifest variables. The next layer of factors in the hierarchical factor model again partitions the manifest variables into clusters. However, this time each cluster contains at least two clusters of manifest variables that are formed in the previous layer. For example, the following is a factor pattern of a confirmatory hierarchical factor model with two layers:

	First Layer			Second Layer
	F1	F2	F3	F4
V1	x			x
V2	x			x
V3	x			x
V4		x		x
V5		x		x
V6		x		x
V7			x	x
V8			x	x
V9			x	x

F1–F3 are first-layer factors and F4 is the only second-layer factor. This special kind of two-layer hierarchical pattern is also known as a bifactor solution. In a bifactor solution, there are two classes of factors—group factors and a general factor. For example, in the preceding hierarchical factor pattern F1–F3 are group factors for different abilities and F4 is a general factor such as "intelligence" (see, for example, Holzinger and Swineford 1937). See Mulaik and Quartetti (1997) for more examples and distinctions among various types of hierarchical factor models. Certainly, if substantiated by your theory, hierarchical factor models with more than two layers are possible.

In this example, you use PROC TCALIS to fit these two types of confirmatory factor models. First, you fit a second-order factor model to a real data set. Then you fit a bifactor model to the same data set. In the final section of this example, an informal account of the relationship between the higher-order and hierarchical factor models is attempted. Techniques for constraining parameters using PROC TCALIS are also shown. This final section might be too technical in the first reading. Interested readers are referred to articles by Mulaik and Quartetti (1997), Schmid and Leiman (1957), and Yung, Thissen, and McLeod (1999), for more details.

A Second-Order Factor Analysis Model

In this section, a second-order confirmatory factor analysis model is applied to a correlation matrix of Thurstone reported by McDonald (1985). The correlation matrix is read into a SAS data set in the following statements:

```
data Thurst(type=corr);
title "Example of THURSTONE resp. McDONALD (1985, p.57, p.105)";
   _type_ = 'corr'; input _name_ $ V1-V9;
   label V1='Sentences' V2='Vocabulary' V3='Sentence Completion'
         V4='First Letters' V5='Four-letter Words' V6='Suffices'
         V7='Letter series' V8='Pedigrees' V9='Letter Grouping';
   datalines;
V1  1.       .      .      .      .      .      .      .      .
V2   .828   1.      .      .      .      .      .      .      .
V3   .776   .779   1.      .      .      .      .      .      .
V4   .439   .493    .460  1.      .      .      .      .      .
V5   .432   .464    .425   .674  1.      .      .      .      .
V6   .447   .489    .443   .590   .541  1.      .      .      .
V7   .447   .432    .401   .381   .402   .288  1.      .      .
V8   .541   .537    .534   .350   .367   .320   .555  1.      .
V9   .380   .358    .359   .424   .446   .325   .598   .452  1.
;
```

Variables in this data set are measures of cognitive abilities. Three factors are assumed for these nine variable V1–V9. These three factors are the first-order factors in the analysis. A second-order factor is also assumed to explain the correlations among the three first-order factors.

The following statements define a second-order factor model by using the LINEQS modeling language.

```
proc tcalis corr data=Thurst method=max nobs=213 nose nostand;
   lineqs
      V1      = X11 Factor1                                  + E1,
      V2      = X21 Factor1                                  + E2,
      V3      = X31 Factor1                                  + E3,
      V4      =             X42 Factor2                      + E4,
      V5      =             X52 Factor2                      + E5,
      V6      =             X62 Factor2                      + E6,
      V7      =                         X73 Factor3          + E7,
      V8      =                         X83 Factor3          + E8,
      V9      =                         X93 Factor3          + E9,
      Factor1 =                                   L1g FactorG + E10,
      Factor2 =                                   L2g FactorG + E11,
      Factor3 =                                   L3g FactorG + E12;
   std
      FactorG   = 1. ,
      E1-E12    = U1-U9 W1-W3;
   bounds
      0. <= U1-U9;
   fitindex ON(ONLY)=[chisq df probchi];
   /* SAS Programming Statements: Dependent parameter definitions */
      W1  = 1. - L1g * L1g;
      W2  = 1. - L2g * L2g;
      W3  = 1. - L3g * L3g;
run;
```

In the first nine equations of the LINEQS statement, variables V1–V3 are manifest indicators of latent factor Factor1, variables V4–V6 are manifest indicators of latent factor Factor2, and variables

V7–V9 are manifest indicators of latent factor Factor3. In the last three equations of the LINEQS statement, the three first-order factors Factor1–Factor3 are predicted by a common source: FactorG. Hence, Factor1–Factor3 are correlated due to the common source FactorG in the model.

An error term is added to each equation in the LINEQS statement. These error terms E1–E12 are needed because the factors are not assumed to be perfect predictors of the corresponding outcome variables.

In the STD statement, you specify variance parameters for all independent or exogenous variables in the model: FactorG, and E1–E12. The variance of FactorG is fixed at one for identification. Variances for E1–E9 are given parameter names U1–U9, respectively. Variances for E10–E12 are given parameter names W1–W3, respectively. Note that for model identification purposes, W1–W3 are defined as dependent parameters in the SAS programming statements. That is,

$$W_i = 1. - L_{ig}^2 \quad (i = 1, 2, 3)$$

These dependent parameter definitions ensure that the variances for Factor1–Factor3 are fixed at ones for identification.

In the BOUNDS statement, you specify that variance parameters U1–U9 must be positive in the solution.

In addition to the statements for model specification, options are used to control the output. In the PROC TCALIS statement, the NOSE and NOSTAND options suppress the display of standard errors and standardized results. In the FITINDEX statement, the ON(ONLY)= option requests only the model fit chi-square and its associated degrees of freedom and p-value be shown in the fit summary table. Using options in PROC TCALIS to reduce the amount the of printout is a good practice. It makes your output more focused, as you output only what you need in a particular situation.

In Output 88.8.1, parameters and their initial values, gradients, and bounds are shown.

Convergence criterion (GCONV=1E-8) satisfied.

First, there are 21 independent parameters in the optimization by using 45 "Functions (Observations)." The so-called functions refer to the moments in the model that are structured with parameters. Nine lower bounds, which are specified for the error variance parameters, are specified in the optimization. The next table for iteration history shows that the optimization stops in 11 iterations. The notes at the bottom of table show that the solution converges without problems.

In the fit summary table shown in Output 88.8.3, the chi-square model fit value is 38.196, with df=24, and p=0.033. This indicates a satisfactory model fit.

Output 88.8.3 Fit Summary

Fit Summary

Chi-Square	38.1963
Chi-Square DF	24
Pr > Chi-Square	0.0331

The fitted equations with final estimates are shown in Output 88.8.4. Interpretations of these loadings are not done here. The last table in this output shows various variance estimates. These estimates are classified by whether they are for the latent variables, error variables, or disturbance variables.

                    L2g
Factor3 =    0.8150*FactorG +  1.0000 E12
                    L3g
```

Estimates for Variances of Exogenous Variables

Variable Type	Variable	Parameter	Estimate
Latent	FactorG		1.00000
Error	E1	U1	0.18150
	E2	U2	0.16493
	E3	U3	0.26713
	E4	U4	0.30150
	E5	U5	0.36450
	E6	U6	0.50642
	E7	U7	0.39033
	E8	U8	0.48137
	E9	U9	0.50510
Disturbance	E10	W1	0.32420
	E11	W2	0.38879
	E12	W3	0.33576

For illustration purposes, you might check whether the model constraints put on the variances of Factor1–Factor3 are honored (although this should have been taken care of in the optimization). For example, the variance of Factor1 should be:

$$1 = (\text{Loading on FactorG})^2 + \text{Variance of E10}$$

Extracting the estimates from the output, you have:

$$(0.8221)^2 + 0.32420 = 1.0000$$

So, this model constraint is verified.

A Bifactor Model

A bifactor model (or a hierarchical factor model with two layers) for the same data set is now considered. In this model, the same set of factors as in the preceding higher-order factor model are used. The most notable difference is that the second-order factor FactorG in the higher-order factor model is no longer a factor of the first-order factors Factor1–Factor3. Instead, FactorG, like Factor1–Factor3, now also serves as a factor of the observed variable V1–V9. Unlike Factor1–Factor3, FactorG is considered to be a *general* factor in the sense that *all* observed variables have direct functional relationships with it. In contrast, Factor1–Factor3 are *group* factors in the sense that each of them has a direct functional relationship with only one group of *observed* variables. Because of the coexistence of a general factor and group factors at the same factor level, such a hierarchical model is also called a bifactor model.

The bifactor model is specified in the following statements:

```
proc tcalis corr data=Thurst method=max nobs=213 nose nostand;
   lineqs
      V1 = X11 Factor1                        + X1g FactorG + E1,
      V2 = X21 Factor1                        + X2g FactorG + E2,
      V3 = X31 Factor1                        + X3g FactorG + E3,
      V4 =            X42 Factor2             + X4g FactorG + E4,
      V5 =            X52 Factor2             + X5g FactorG + E5,
      V6 =            X62 Factor2             + X6g FactorG + E6,
      V7 =                       X73 Factor3  + X7g FactorG + E7,
      V8 =                       X83 Factor3  + X8g FactorG + E8,
      V9 =                       X93 Factor3  + X9g FactorG + E9;
   std
      Factor1-Factor3 = 3 * 1.,
      FactorG         = 1. ,
      E1-E9           = U1-U9;
   bounds
      0. <= U1-U9;
   fitindex ON(ONLY)=[chisq df probchi];
run;
```

In the LINEQS statement, there are only nine equations for the manifest variables in the model. Unlike the second-order factor model fitted previously, Factor1–Factor3 are no longer functionally related to FactorG and therefore there are no equations with Factor1–Factor3 as outcome variables.

All factors in the bifactor model are uncorrelated. The factor variances are all fixed at 1 in the STD statement. The variance parameters for E1–E9 are named U1–U9, respectively. The BOUNDS statement, again, is specified so that only positive estimates are accepted for error variance estimates. Like the previous PROC TCALIS run, options are specified in the PROC TCALIS and the FITINDEX statements to reduce the amount of default output.

There are more parameters in this model than in the preceding higher-order factor model, as shown in Output 88.8.5, which shows the optimization information.

Convergence criterion (GCONV=1E-8) satisfied.

There are 27 parameters in the bifactor model: nine for the loadings on the group factors Factor1–Factor3, nine for the loadings on the general factor FactorG, and nine for the variances of errors E1–E9. The optimization converges in 14 iterations without problems.

A fit summary table is shown in Output 88.8.6

Output 88.8.6 Fit Summary

```
                          Fit Summary

                Chi-Square            24.2163
                Chi-Square DF              18
                Pr > Chi-Square        0.1481
```

The fit of this model is quite good. The chi-square value is 24.216, with df=18 and p=0.148. This is expected because the bifactor model has more parameters than the second-order factor model, which already has a good fit with fewer parameters.

Estimation results are shown in Output 88.8.7. Estimates are left uninterpreted because they are not the main interest of this example.

One might ask whether this bifactor (hierarchical) model provides a significantly better fit than the previous second-order model. Can one use a chi-square difference test for nested models to answer this question? The answer is yes.

Although it is not obvious that the previous second-order factor model is nested within the current bifactor model, a general nested relationship between the higher-order factor and the hierarchical factor model is formally proved by Yung, Thissen, and McLeod (1999). Therefore, a chi-square difference test can be conducted using the following DATA step:

```
data _null_;
   df0 = 24; chi0 = 38.1963;
   df1 = 18; chi1 = 24.2163;
   diff = chi0-chi1;
   p = 1.-probchi(chi0-chi1,df0-df1);
   put 'Chi-square difference = ' diff;
   put 'p-value = ' p;
run;
```

The results are shown in the following:

Output 88.8.8 Chi-square Difference Test

```
Chi-square difference = 13.98
p-value = 0.0298603746
```

The chi-square difference is 13.98, with df=6 and p=0.02986. If α-level is set at 0.05, the bifactor model indicates a significantly better fit. But if α-level is set at 0.01, statistically the two models fit equally well to the data.

In the next section, it is demonstrated that the second-order factor model is indeed nested within the bifactor model, and hence the chi-square test conducted in the previous section is justified. In

addition, through the demonstration of the nested relationship between the two classes of models, you can see how some parameter constraints in structural equation model can be set up in PROC TCALIS.

For some practical researchers, the technical details involved in the next section might not be of interest and therefore could be skipped.

A Constrained Bifactor Model and Its Equivalence to the Second-Order Factor Model

To demonstrate that the second-order factor model is indeed nested within the bifactor model, a constrained bifactor model is fitted in this section. This constrained bifactor model is essentially the same as the preceding bifactor model, but with additional constraints on the factor loadings. Hence, the constrained bifactor model is nested within the unconstrained bifactor model.

Furthermore, if it can be shown that the constrained bifactor model is equivalent to the previous second-order factor, then the second-order factor model must also be nested within the unconstrained bifactor model. As a result, it justifies the chi-square difference test conducted in the previous section.

The construction of such a constrained bifactor model is based on Yung, Thissen, and McLeod (1999). In the following statements, a constrained bifactor model is specified.

```
proc tcalis corr data=Thurst method=max nobs=213 nose nostand;
   lineqs
      V1 = X11 Factor1                          + X1g FactorG + E1,
      V2 = X21 Factor1                          + X2g FactorG + E2,
      V3 = X31 Factor1                          + X3g FactorG + E3,
      V4 =              X42 Factor2             + X4g FactorG + E4,
      V5 =              X52 Factor2             + X5g FactorG + E5,
      V6 =              X62 Factor2             + X6g FactorG + E6,
      V7 =                          X73 Factor3 + X7g FactorG + E7,
      V8 =                          X83 Factor3 + X8g FactorG + E8,
      V9 =                          X93 Factor3 + X9g FactorG + E9;
   std
      Factor1-Factor3 = 3 * 1.,
      FactorG         = 1. ,
      E1-E9           = U1-U9;
   bounds
      0. <= U1-U9;
   fitindex ON(ONLY)=[chisq df probchi];
   parameters p1 (.5) p2 (.5) p3 (.5);
   /* Proportionality constraints */
   X1g = p1 * X11;
   X2g = p1 * X21;
   X3g = p1 * X31;
   X4g = p2 * X42;
   X5g = p2 * X52;
   X6g = p2 * X62;
   X7g = p3 * X73;
   X8g = p3 * X83;
   X9g = p3 * X93;
run;
```

In this constrained model, a PARAMETERS statement and nine SAS programming statements are added to the previous bifactor model. In the PARAMETERS statement, three new independent parameters are added: p1, p2, and p3. These parameters represent the proportions that constrain the factor loadings of the observed variables on the group factors Factor1–Factor3 and the general factor FactorG. They are all free parameters and have initial values at 0.5. The next nine SAS programming statements represent the proportionality constraints imposed. For example, X1g–X3g are now dependent parameters expressed as functions of p1, X11, X21, and X31. Adding three new parameters (in the PARAMETERS statement) and redefining nine original parameters as dependent (in the SAS programming statements) is equivalent to adding six ($= 9 - 3$) constraints to the original bifactor model. Mathematically, the additional statements in specifying the constrained bifactor model realizes the following six constraints:

$$\frac{\text{X1g}}{\text{X11}} = \frac{\text{X2g}}{\text{X21}} = \frac{\text{X3g}}{\text{X31}}$$

$$\frac{\text{X4g}}{\text{X42}} = \frac{\text{X5g}}{\text{X52}} = \frac{\text{X6g}}{\text{X62}}$$

$$\frac{\text{X7g}}{\text{X73}} = \frac{\text{X8g}}{\text{X83}} = \frac{\text{X9g}}{\text{X93}}$$

Obviously, with these six constraints the current constrained bifactor model is nested within the unconstrained version. What remains to be shown is that this constrained bifactor model is indeed equivalent to the previous second-order factor model. If so, the second-order factor model is also nested within the unconstrained bifactor model. One evidence for the equivalence of the current constrained bifactor model and the second-order factor model is from the fit summary table shown in Output 88.8.10. But first, it is also useful to consider the optimization information of the constrained bifactor model, which is shown in Output 88.8.9.

Convergence criterion (GCONV=1E-8) satisfied.

As shown Output 88.8.9, there are 21 independent parameters in the constrained bifactor model for the 45 "Functions (Observations)." These numbers match those of the second-order factor model exactly. The optimization shows some problems in initial iterations. The iteration numbers with asterisks indicate that the Hessian matrix is not positive definite in those iterations. But as long as the final converged iteration is not marked with this asterisk, the problems exhibited in early iterations do not raise any concern, as in the current case. Next, the fit summary is shown in Output 88.8.10.

Output 88.8.10 Model Fit

Fit Summary

Chi-Square	38.1963
Chi-Square DF	24
Pr > Chi-Square	0.0331

In Output 88.8.10, the chi-square value in the fit summary table is 38.196, with df=24, and p=0.033. Again, these numbers match those of the second-order factor model exactly. These matches (same model fit with the same number of parameters) are necessary (but not sufficient) to show that the constrained bifactor model is equivalent to the second-order model. Stronger evidence is now presented.

In Output 88.8.11, estimation results of the constrained bifactor model are shown.

Output 88.8.11 Estimation Results

	E7	U7	0.39033
	E8	U8	0.48138
	E9	U9	0.50510

According to Yung, Thissen, and McLeod (1999), two models are equivalent if there is a one-to-one correspondence of the parameters in the models. This fact is illustrated for the constrained bifactor model and the second-order factor model.

First, the error variances for E1–E9 in the second-order factor model are transformed directly (using an identity map) to that of the bifactor models. The nine error variances in Output 88.8.4 for the second-order factor model match those of the constrained bifactor model exactly in Output 88.8.11. In addition, the variances of factors are fixed at one in both models.

The error variances and the factor loadings at both factor levels in Output 88.8.4 for the second-order factor model are now transformed to yield the loading estimates in the constrained bifactor model. Denote P_1 as the first-order factor loading matrix, P_2 as the second-order factor loading matrix, and U_1^2 be the matrix of variances for disturbances. That is, for the second-order factor model,

$$P_1 = \begin{pmatrix} 0.9047 & 0 & 0 \\ 0.9138 & 0 & 0 \\ 0.8561 & 0 & 0 \\ 0 & 0.8358 & 0 \\ 0 & 0.7972 & 0 \\ 0 & 0.7026 & 0 \\ 0 & 0 & 0.7808 \\ 0 & 0 & 0.7202 \\ 0 & 0 & 0.7035 \end{pmatrix}$$

$$P_2 = \begin{pmatrix} 0.8221 \\ 0.7818 \\ 0.8150 \end{pmatrix}$$

$$U_1^2 = \begin{pmatrix} 0.3242 & 0 & 0 \\ 0 & 0.3888 & 0 \\ 0 & 0 & 0.3358 \end{pmatrix}$$

According to Yung, Thissen, and McLeod (1999), the transformation to obtain the estimates in the equivalent constrained bifactor model is:

$$\begin{aligned} L_1 &= P_1 U_1 \\ L_2 &= P_1 P_2 \end{aligned}$$

where L_1 is the matrix of the first-layer factor loadings (that is, loadings on group factors Factor1–Factor3), and L_2 is the matrix of the second-layer factor loadings (that is, loadings on FactorG) in the constrained bifactor model. Carrying out the matrix calculations for L_1 and L_2 shows that:

$$L_1 = \begin{pmatrix} 0.5151 & 0 & 0 \\ 0.5203 & 0 & 0 \\ 0.4875 & 0 & 0 \\ 0 & 0.5212 & 0 \\ 0 & 0.4971 & 0 \\ 0 & 0.4381 & 0 \\ 0 & 0 & 0.4525 \\ 0 & 0 & 0.4173 \\ 0 & 0 & 0.4077 \end{pmatrix}$$

$$L_2 = \begin{pmatrix} 0.7438 \\ 0.7512 \\ 0.7038 \\ 0.6534 \\ 0.6232 \\ 0.5493 \\ 0.6364 \\ 0.5870 \\ 0.5734 \end{pmatrix}$$

With very minor numerical differences and ignorable sign changes, these transformation results match the estimated loadings observed in Output 88.8.11 for the constrained bifactor model. Therefore, the second-order factor model is shown to be equivalent to the constrained bifactor model, and hence is nested within the unconstrained bifactor model.

Example 88.9: Linear Relations among Factor Loadings

In this example, a confirmatory factor-analysis model with linear constraints on loadings is specified by the FACTOR modeling language of PROC TCALIS. SAS programming statements are used to set the constraints. In the context of the current example, the differences between fitting covariance structures and correlation structures will also be discussed.

The correlation matrix of six variables from Kinzer and Kinzer (N=326) is used by Guttman (1957) as an example that yields an approximate simplex. McDonald (1980) uses this data set as an example of factor analysis where he assumes that the loadings on the second factor are linear functions of the loadings on the first factor. Let **B** be the factor loading matrix containing the two factors and six variables so that:

$$\mathbf{B} = \begin{pmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \\ b_{31} & b_{32} \\ b_{41} & b_{42} \\ b_{51} & b_{52} \\ b_{61} & b_{62} \end{pmatrix}$$

and

$$b_{j2} = \alpha + \beta b_{j1}, \quad j = 1, \ldots, 6$$

The correlation structures are represented by:

$$\mathbf{P} = \mathbf{B}\mathbf{B}' + \Psi$$

where $\Psi = \text{diag}(\psi_{11}, \psi_{22}, \psi_{33}, \psi_{44}, \psi_{55}, \psi_{66})$ represents the diagonal matrix of unique variances for the variables.

With parameters α and β being unconstrained, McDonald (1980) has fitted an underidentified model with seven degrees of freedom. Browne (1982) imposes the following identification condition:

$$\beta = -1$$

In this example, Browne's identification condition is imposed. The following is the specification of the confirmatory factor model using the FACTOR modeling language.

```
data kinzer(type=corr);

   b52 = alpha - b51;
   b62 = alpha - b61;
   fitindex on(only)=[chisq df probchi];
run;
```

In the FACTOR statement, you specify two factors, named factor1 and factor2, for the variables. In this model, all manifest variables have nonzero loadings on the two factors. These loading parameters are specified after the equal signs and are named with the prefix 'b.' Initial estimates are given in the parentheses. For example, in the first entry of factor-variable relations, you specify loadings of var1–var6 on factor1. All these loadings are free parameters and are given the same initial value 6. Loadings of var1–var6 on factor2 are also defined as parameters in the same statement. However, they are dependent parameters because they are functionally dependent on other independent parameters, as shown in the SAS programming statements afterwards. Initial values for these dependent parameters are thus unnecessary.

In the PVAR statement, the factor variances are fixed at ones, while the error variances for the variables are free parameters named psi1–psi6. Again, initial estimates are provided in the parentheses that follow after the parameter names.

An additional parameter alpha is specified in the PARAMETERS statement with an initial value of 1. Then, six SAS programming statements are used to define the loadings on the second factor as functions of the loadings on the first factor. Lastly, the FITINDEX statement is used to trim the results in the fit summary table.

In the specification, there are twelve loadings in the FACTOR statement and six unique variances in the PVAR statement. Adding the parameter alpha in the list, there are 19 parameters in total. However, the loading parameters are not all independent of each other. As defined in the SAS programming statements, six loadings are dependent. This reduces the number of free parameters to 13. Hence the degrees of freedom for the model is $8 = 21 - 13$. Notice that the factor variances are fixed at 1 and covariances among factors are fixed zeros by default.

In Output 88.9.1, a concise fit summary table is shown. The chi-square test statistic of model fit is 10.337 with df=8 (p=0.242). This indicates a good model fit.

Output 88.9.1 Fit of the Correlation Structures

Fit Summary

Chi-Square	10.3374
Chi-Square DF	8
Pr > Chi-Square	0.2421

The estimated factor loading matrix is presented in Output 88.9.2, and the estimated error variances and the estimate for alpha are presented in Output 88.9.3.

Output 88.9.2 Loading Estimates

Factor Loading Matrix

	factor1	factor2
var1	0.3609	0.6174
	[b11]	[b12]
var2	0.3212	0.6571
	[b21]	[b22]
var3	0.4859	0.4923
	[b31]	[b32]
var4	0.5745	0.4038
	[b41]	[b42]
var5	0.7985	0.1797
	[b51]	[b52]
var6	0.6736	0.3046
	[b61]	[b62]

Output 88.9.3 Unique Variances and the Additional Parameter

Error Variances

Variable	Parameter	Estimate
var1	psi1	0.53036
var2	psi2	0.44986
var3	psi3	0.48756
var4	psi4	0.47278
var5	psi5	0.31125
var6	psi6	0.53815

Additional Parameters

Type	Parameter	Estimate
Independent	alpha	0.97825

All these estimates are essentially the same as reported in Browne (1982). Notice that there are no standard error estimates in the output, as requested by the NOSE option in the PROC TCALIS statement. Standard error estimates are not of interest in this example.

In fitting the preceding factor model, wrong covariance structures rather than the intended correlation structures have been specified. As pointed out by Browne (1982), fitting such covariance structures directly is not entirely appropriate for analyzing correlations. For example, when fitting the correlation structures, the diagonal elements of $\mathbf{P}$ must always be fixed ones. This fact has never been enforced in the preceding specification. A simple check of the estimates will illustrate the problem. In Output 88.9.2, the loading estimates of VAR1 on the two factors are 0.3609 and 0.6174, respectively. In Output 88.9.3, the error variance estimate for VAR1 is 0.53036. The fitted variance of VAR1 can therefore be computed by the following equation:

$$\text{fitted variance} = 0.3609^2 + 0.6174^2 + 0.53036 = 1.0418$$

This fitted value is quite a bit off from 1.00, as required for the standardized variance of VAR1.

Fortunately, even though the wrong covariance structure model has been analyzed, the preceding analysis is not completely useless. For the current confirmatory factor model, according to Browne (1982) the estimates obtained from fitting the wrong covariance structure model are still consistent (as if they were estimating the population parameters in the correlation structures). However, the chi-square test statistic as reported previously is not correct.

Note that using the CORR option in the PROC TCALIS statement will not solve the problem. By specifying the CORR option you merely request PROC TCALIS to use the correlation matrix directly as a covariance matrix in the objective function for model fitting. It still would not constrain the fitting of the diagonal elements to 1 during estimation.

In the next section, a solution to the stated problem is suggested. It is not claimed that this is the only solution or the best solution. Alternative treatments of the problem are possible.

Fitting the Correct Correlation Structures

This main idea of this solution is to embed the intended correlation structures (with correct constraints on the diagonal elements of the correlation matrix) into a covariance structure model so that the estimation methods of PROC TCALIS can be applied legitimately to the specially constructed covariance structures.

First, the issue of the fixed ones on the diagonal of the correlation structure model is addressed. That is, the diagonal elements of the correlation structures represented by $(\mathbf{BB}' + \Psi)$ must be fitted by ones. This can be accomplished by constraining the error variances as dependent parameters of the loadings, as shown in the following:

$$\Psi_{jj} = 1. - b_{j1}^2 - b_{j2}^2, \quad j = 1, \ldots, 6$$

Other constraints might also serve the purpose, but the ones just presented are the most convenient and intuitive.

Now, due to the fact that discrepancy functions used in PROC TCALIS are derived for covariance matrices rather than correlation matrices, PROC TCALIS is essentially set up for analyzing covariance structures (with or without mean structures), but not correlation structures. Hence, the statistical theory behind PROC TCALIS applies to covariance structure analysis, but it might not generalize to correlation structure analysis in all situations. Despite that, with some manipulations PROC TCALIS can fit the correct correlation structures to the current data without compromising the statistical theory. These manipulations are now discussed. Recall that the correlation structures are represented by:

$$\mathbf{P} = \mathbf{BB}' + \Psi$$

As before, in the $\mathbf{B}$ matrix, there are six linear constraints on the factor loadings. In addition, the diagonal elements of $(\mathbf{BB}' + \Psi)$ are constrained to ones, as done by defining the error variances as dependent parameters of the loadings in the preceding equation. To analyze the correlation structures by using PROC TCALIS, a covariance structure model with such correlation structures embedded is now specified. That is, the covariance structure to be fitted by PROC TCALIS is as follows:

$$\mathbf{\Sigma} = \mathbf{DPD}' = \mathbf{D}(\mathbf{BB}' + \Psi)\mathbf{D}'$$

where $\mathbf{D}$ is a 6 x 6 diagonal matrix containing the population standard deviations for the manifest variables. Theoretically, it is legitimate that you analyze this covariance structure model for studying the embedded correlation structures. In addition, it does not matter whether your input matrix is a correlation or covariance matrix, or any rescaled covariance matrix (by multiplying any variables by any positive constants). You would get correct results if you could somehow specify these covariance structures correctly in PROC TCALIS. However, there seems to be nowhere in PROC TCALIS that you can specify the diagonal matrix $\mathbf{D}$ for the population standard deviations. So what can one do with this formulation? The answer is to rewrite the covariance structure model in a form similar to the usual confirmatory factor model, as presented in the following.

Let $\mathbf{T} = \mathbf{DB}$ and $\mathbf{K} = \mathbf{D}\Psi\mathbf{D}'$. The covariance structure model of interest can now be rewritten as:

$$\mathbf{\Sigma} = \mathbf{TT}' + \mathbf{K}$$

This form of covariance structures implies a confirmatory factor model with factor loading matrix $\mathbf{T}$ and error covariance matrix $\mathbf{K}$. This confirmatory factor model can certainly be specified using

the FACTOR modeling language, in much the same way you specify a confirmatory factor model in the preceding section. However, because you are actually more interested in estimating the basic set of parameters in matrices **B** and Ψ of the embedded correlation structures, you would define the model parameters as functions of this basic set of parameters of interest. This can be accomplished by using the PARAMETERS and the SAS programming statements.

All in all, you can use the following statements to set up such a confirmatory factor model with the desired correlation structures embedded.

```
proc tcalis data=Kinzer nobs=326 nose;
   factor
      factor1 -> var1-var6 = t11 t21 t31 t41 t51 t61,
      factor2 -> var1-var6 = t12 t22 t32 t42 t52 t62;
   pvar
      factor1-factor2 = 2 * 1.,
      var1-var6       = k1-k6;
   parameters alpha (1.) d1-d6 (6 * 1.)
              b11 b21 b31 b41 b51 b61 (6 *.6),
              b12 b22 b32 b42 b52 b62
              psi1-psi6;
   /* SAS Programming Statements */
   /* 12 Constraints on Correlation structures */
   b12  = alpha - b11;
   b22  = alpha - b21;
   b32  = alpha - b31;
   b42  = alpha - b41;
   b52  = alpha - b51;
   b62  = alpha - b61;
   psi1 = 1. - b11 * b11 - b12 * b12;
   psi2 = 1. - b21 * b21 - b22 * b22;
   psi3 = 1. - b31 * b31 - b32 * b32;
   psi4 = 1. - b41 * b41 - b42 * b42;
   psi5 = 1. - b51 * b51 - b52 * b52;
   psi6 = 1. - b61 * b61 - b62 * b62;
   /* Defining Covariance Structure Parameters */
   t11  = d1 * b11;
   t21  = d2 * b21;
   t31  = d3 * b31;
   t41  = d4 * b41;
   t51  = d5 * b51;
   t61  = d6 * b61;
   t12  = d1 * b12;
   t22  = d2 * b22;
   t32  = d3 * b32;
   t42  = d4 * b42;
   t52  = d5 * b52;
   t62  = d6 * b62;
   k1   = d1 * d1 * psi1;
   k2   = d2 * d2 * psi2;
   k3   = d3 * d3 * psi3;
   k4   = d4 * d4 * psi4;
   k5   = d5 * d5 * psi5;
   k6   = d6 * d6 * psi6;
   fitindex on(only)=[chisq df probchi];
run;
```

First, you notice that specifications in the FACTOR and the PVAR statements are essentially unchanged from the previous specification, except that the parameters are named differently here to reflect different model matrices. In the current specification, the factor loading parameters in matrix **T** are named with prefix 't,' and the error variance parameters in matrix **K** are named with prefix 'k.' Specification of these parameters reflects the covariance structures. As you see in the last block of the SAS programming statements statements, all these parameters are functions of the correlation structure parameters in **B**, Ψ, and **D**.

Next, in the PARAMETERS statement, all correlation structure parameters are defined with initial values provided. These are the parameters of interest: alpha is used to define dependencies among loadings, d's are the population standard deviations, b's are the loading parameters, and psi's are the error variance parameters. There are 25 parameters specified in this statement, but not all of them are free or independent.

In the first block of SAS programming statements, parameter dependencies or constraints on the correlation structures are specified. The first six statements realize the required linear relations among the factor loadings:

$$b_{j2} = \alpha - b_{j1}, \quad j = 1, \ldots, 6$$

The next six statements constrain the error variances so as to ensure that an embedded correlation structure model is being fitted. That is, each error variance is dependent on the corresponding loadings, as prescribed by the following equation:

$$\Psi_{jj} = 1. - b_{j1}^2 - b_{j2}^2, \quad j = 1, \ldots, 6$$

These twelve constraints reduce the number of independent parameters to 13, as expected.

The next block of SAS programming statements are essentially for relating the correlation structure parameters to the covariance structures that are specified in the FACTOR and the PVAR statements. These SAS programming statements realize the required relations: $\mathbf{T} = \mathbf{DB}$ and $\mathbf{K} = \mathbf{D}\Psi\mathbf{D}'$, but in non-matrix forms:

$$t_{ji} = d_j b_{ji} \quad (j = 1, \ldots, 6; \quad i = 1, 2)$$

$$k_{jj} = d_j d_j \Psi_{jj} \quad (j = 1, \ldots, 6)$$

where d_j denotes the j-th diagonal element of **D**.

The fit summary is presented in Output 88.9.4. The chi-square test statistic is 14.63 with df=8 (p=0.067). This shows that the previous chi-square test based on fitting a wrong covariance structure model is indeed questionable.

Output 88.9.4 Model Fit of the Correlation Structures

Fit Summary

Chi-Square	14.6269
Chi-Square DF	8
Pr > Chi-Square	0.0668

Estimates of the loadings and error variances are presented in Output 88.9.5. These estimates are for the covariance structure model with loading matrix **T** and error covariance matrix **K**. They are rescaled versions of the correlation structure parameters and are not of primary interest themselves.

Except for the population standard deviation parameter d's, all other parameters estimated in the current model can be compared with those from the previous fitting of an incorrect covariance structure model. Although estimates in the current model do not differ very much from those in the previous specification, it is at least reassuring that they are obtained from fitting a correctly specified covariance structure model with the intended correlation structures embedded.

Example 88.10: A Multiple-Group Model for Purchasing Behavior

In this example, data were collected from customers who made purchases from a retail company during years 2002 and 2003. A two-group structural equation model is fitted to the data.

The variables are:

Spend02:	total purchase amount in 2002
Spend03:	total purchase amount in 2003
Courtesy:	rating of the courtesy of the customer service
Responsive:	rating of the responsiveness of the customer service
Helpful:	rating of the helpfulness of the customer service
Delivery:	rating of the timeliness of the delivery
Pricing:	rating of the product pricing
Availability:	rating of the product availability
Quality:	rating of the product quality

For the ratings scales, nine-point scales were used. Customers could respond 1 to 9 on these scales, with 1 representing "extremely unsatisfied" and 9 representing "extremely satisfied." Data were collected from two different regions, which will be labeled as Region 1 ($N = 378$) and Region 2 ($N = 423$), respectively. The ratings were collected at the end of year 2002 so that they represent customers' purchasing experience in year 2002.

The central questions of the study are:

- How does the overall customer service affect the current purchases and predict future purchases?
- How does the overall product quality affect the current purchases and predict future purchases?
- Do current purchases predict future purchases?
- Do the two regions have different structural models for predicting the purchases?

In stating these research questions, you use several constructs that might or might not correspond to objective measurements. Current and future purchases are certainly measurable directly by the spending of the customers. That is, because customer service and product satisfaction/qualities were surveyed between 2002 and 2003, Spend02 would represent current purchases and Spend03 would represent future purchases in the study. Both variables Spend02 and Spend03 are objective measurements without measurement errors. All you need to do is to extract the information from the transaction records. But how about hypothetical constructs like customer service quality and product quality? How would you measure them in the model?

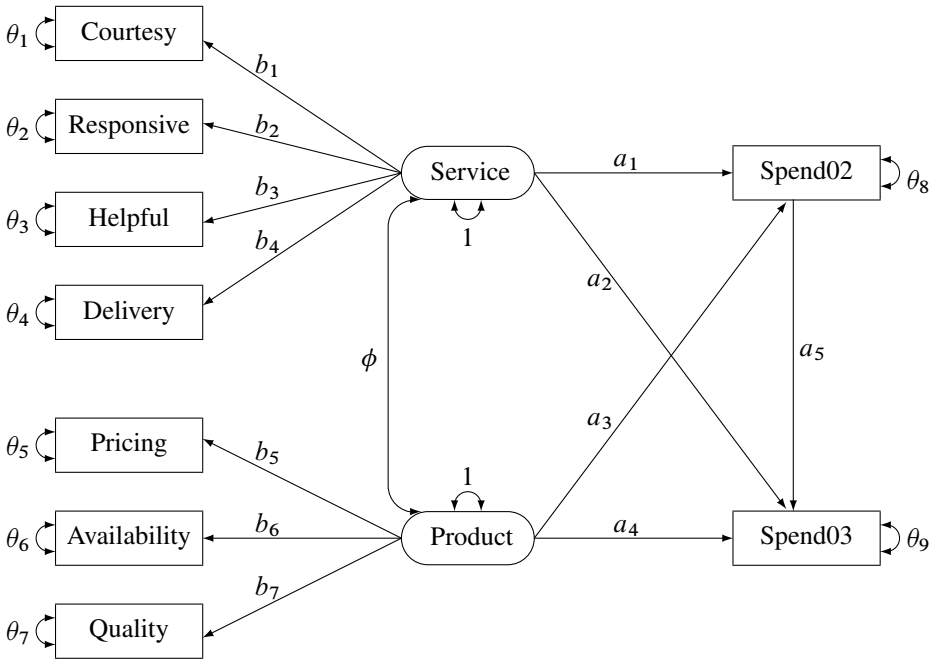
In measuring these hypothetical constructs, one might ask customers' perception about the service or product quality directly in a single question. A simple survey with two questions about the customer service and product qualities could then be what you need. These questions are called indicators (or indicator variables) of the underlying constructs. However, using just one indicator (question) for each of these hypothetical constructs would be quite unreliable—that is, measurement errors might dominate in the data collection process. Therefore, multiple indicators are usually recommended for measuring such hypothetical constructs.

There are two main advantages of using multiple indicators for hypothetical constructs. The first one is conceptual and the other is statistical/mathematical.

First, hypothetical constructs might conceptually be multifaceted themselves. Measuring a hypothetical construct by a single indicator does not capture the full meaning of the construct. For example, the product quality might refer to the durability of the product, the outlook of the product, the pricing of the product, and the availability of product, among others. The customer service quality might refer to the politeness of the customer service, the timeliness of the delivery, and the responsiveness of customer services, among others. Therefore, multiple indicators for a single hypothetical construct might be necessary if you want to cover the multifaceted aspects of a given hypothetical construct.

Second, from a statistical point of view, the reliability would be higher if you combine correlated indicators for a construct than if you use a single indicator only. Therefore, combining correlated indicators would lead to more accurate and reliable results.

One way to combine correlated indicators is to use a simple sum of them to represent the underlying hypothetical construct. However, a better way is to use the structural equation modeling technique that represents each indicator (variable) as a function of the underlying hypothetical construct plus an error term. In structural equation modeling, hypothetical constructs are constructed as latent factors, which are unobserved systematic (that is, non-error) variables. Theoretically, latent factors are free from measurement errors, and so the estimation through the structural equation modeling technique is more accurate than if you just use simple sums of indicators to represent hypothetical constructs. Therefore, structural equation modeling approach is the method of the choice in the current analysis.



In practice, you must also make sure that there are enough indicators for the identification of the underlying latent factor, and hence the identification of the entire model. Necessary and sufficient rules for identification are very complicated to describe and are out of the scope of the current discussion (however, see Bollen 1989b for discussions of identification rules for various classes of structural equation models). Some simple rules of thumb may be useful as a guidance. For example, for unconstrained situations, you should at least have three indicators (variables) measured for a latent factor. Unfortunately, these rules of thumb do not guarantee identification in every case.

In this example, Service and Product are latent factors in the structural equation model that represents service and product qualities, respectively. In the model, these two latent factors are reflected by the ratings of the customers. Ratings on the Courtesy, Responsive, Helpful, and Delivery scales are indicators of Service. Ratings on the Pricing, Availability, and Quality scales are indicators of Product (that is, product quality).

A Path Diagram

A path diagram is used to represent the structural equation model for the purchase behavior. In Figure 88.5, observed or manifest variables are represented by rectangles, and latent variables are represented by ovals. As mentioned, two latent variables or factors, Service and Product are created as overall measures of customer service and product qualities, respectively.

Figure 88.5 Path Diagram of Purchasing Behavior

The left part of the diagram represents the measurement model of the latent variables. The Service factor has four indicators: Courtesy, Responsive, Helpful, and Delivery. The path coefficients to these observed variables from the Service factor are b_1, b_2, b_3, and b_4, respectively. Similarly, the Product variable has three indicators: Pricing, Availability, and Quality, with path coefficients b_5, b_6, and b_7, respectively.

The two latent factors are predictors of the purchase amounts Spend02 and Spend03. In addition, Spend02 also serves as a predictor of Spend03. Path coefficients or effects for this part of functional relationships are represented by a1–a5 in the diagram.

Each variable in the path diagram has a variance parameter. For endogenous or dependent variables, which serve as outcome variables in the model, the variance parameters are the error variances that are not accounted for by the predictors. For example, in the current model all observed variables are endogenous variables. The double-headed arrows tagged on these variables represent error variances. In the diagram, θ_1 to θ_9 are the names of these error variance parameters. For exogenous or independent variables, which never serve as outcome variables in the model, the variance parameters are the (total) variances of these variables. For example, in the diagram the double-headed arrows tagged on Service and Product represent the variances of these two latent variables. In the current model, both of these variances are fixed at one.

When the double-headed arrows are pointing to two variables, they represent covariances in the path diagram. For example, in Figure 88.5 the covariance between Service and Product is represented by the parameter ϕ.

A Macro for the Basic Path Model

For the moment, it is hypothesized that both Region 1 and Region 2 data are fitted by the same model as shown in Figure 88.5. Once the path diagram is drawn, it is readily translated into the PATH modeling language. See the PATH statement on page 6799 for details about how to use the PATH modeling language to specify structural equation models. A macro for the path model in Figure 88.5 using the PATH modeling language is shown in the following:

```
%macro BasepathModel;
path
   Service -> Spend02          a1,
   Service -> Spend03          a2,
   Product -> Spend02          a3,
   Product -> Spend03          a4,
   Spend02 -> Spend03          a5,
   Service -> Courtesy         b1,

```

The name of this macro is BasePathModel. Defining a model by a SAS macro is not essential to run PROC TCALIS. You could have inserted the PATH model code directly into a PROC TCALIS run. The reason for using a macro here is to facilitate the presentation of the subsequent code so that the coding structure is made clearer. In the BasePathModel macro, the PATH statement captures all the path coefficient specification as well as the direction of the paths in the model. The first five paths are for defining how Spend02 and Spend03 are predicted from the latent variables Service, Product, and Spend02. The next seven paths are for defining the measurement model.

The PVAR statement captures the specification of the error variances and the variances of exogenous variables. The PCOV statement captures the specification of covariance between the two latent variables in the model.

The MEAN statement captures the specification of means and intercepts. Unlike some other representation schemes proposed by various researchers in the field, the mean parameters are not depicted in Figure 88.5. The reason is that representing the mean and intercept parameters in the path diagram would usually obscure the "causal" paths, which are of primary interest. In addition, it is a simple matter to specify the mean and intercept parameters in the MEAN statement without the help of a path diagram when you follow these principles:

- Each variable in the path diagram has a mean parameter that can be specified in the MEAN statement.
- For exogenous variables, the specifications in the MEAN statement are for the means of these variables.
- For endogenous variables, the specifications in the MEAN statement are for the intercepts of these variables.
- For variables that are not specified in the MEAN statement, their means or intercepts are fixed zeros by default.
- The total number of mean parameters should not exceed the number of observed variables.

Because all nine observed variables are endogenous in the model, their specification in the MEAN statement are for nine intercepts: intercept01–intercept07, InterSpend02, and InterSpend03. The means of the latent variables Service and Product are also specified in the MEAN statement as fixed zeros.

A Restrictive Model with Invariant Mean and Covariance Structures

The following shows the SAS data set being analyzed and the PROC TCALIS specification of a restrictive mean and covariance structure model:

   group 2 / data=region2 label="Region 2" nobs=423;
   model 1 / group=1,2;
      %BasepathModel
   run;
```

In the PROC TCALIS specification, you use the GROUP statements to specify the data for the two regions. Using the DATA= options in the GROUP statements, you assign the Region 1 data to group 1 and the Region 2 data to group 2. You label the two groups by the LABEL= options. Because the number of observations are not defined in the data sets, you use the NOBS= options in the GROUP statements to provide this information.

In the MODEL statement, you specify in the GROUP= option that both Groups 1 and 2 are fitted by the same model—model 1. Next, the BasePathModel macro is included for defining the model

for the two groups. Equivalently, you can use two MODEL statements to define two models for the two groups. This way you must also constrain each parameter in the two models. But using a single MODEL statement for the two groups is a short cut for defining such a restrictive model with total parameter invariance among groups.

The OMETHOD=NRR (Newton-Raphson ridge optimization) is used because the default Levenberg-Marquardt optimization did not converge in 1000 iterations.

In Output 88.10.1, a summary of modeling information is presented. Each group is listed with its associated data set, number of observations, and its corresponding model and the model type. In the current analysis, the same model is fitted to both groups. Next, a table for the types of variables is presented. As intended, all nine observed (manifest) variables are endogenous and all latent variables are exogenous in the model.

Output 88.10.1 Modeling Information and Variables

	Bollen Normed Index Rho1	-5.5994
	Bollen Non-normed Index Delta2	-7.5029
	James et al. Parsimonious NFI	-6.4783

The model chi-square statistic is 2818.732. With df=77 and $p < .0001$, the null hypothesis for the mean and covariance structures is rejected. All incremental fit indices are negative. These negative indices indicate a bad model fit, as compared with the independence model. The same fact can be deduced by comparing the chi-square values of the independence model and the structural model defined. The independence model has five degrees of freedom less (five parameters more) than the structural model but the chi-square value is only 399.747, much less than the model fit chi-square value of 2818.132. Because variables in social and behavioral sciences are almost always expected to correlate with each other, a structural model that explains relationships even worse than the independence model is deemed inappropriate for the data. The RMSEA for the structural model is .2985, which also indicates a bad model fit. However, GFI, AGFI, and Parsimonious GFI indicate good model fit, which is a little surprising given the fact that all other indices indicate the opposite and the overall model is pretty restrictive in the first place.

There is a warning in the output:

```
WARNING: Model 1. Although all predicted variances for the
         latent variables are positive, the corresponding
         predicted covariance matrix is not positive definite.
         It has one negative eigenvalue.
```

PROC TCALIS routinely checks the properties of the predicted covariance matrix. It will issue warnings when there are problems. In this case, the predicted covariance matrix for the latent variables is not positive definite and has one negative eigenvalue. The same fact can also be deduced from the output:

Output 88.10.3 Covariance of Latent Variables

Model 1. Covariances Among Exogenous Variables

Var1	Var2	Parameter	Estimate	Standard Error	t Value
Service	Product	phi	-0.78911	0.05542	-14.23750

In Output 88.10.3, the covariance between Service and Product is estimated at -1.115. Recall that the variances of these two variables are fixed at ones. Therefore, the predicted covariance matrix for the latent variables is:

$$\begin{pmatrix} 1.000 & -1.115 \\ -1.115 & 1.000 \end{pmatrix}$$

This matrix is certainly not a proper covariance matrix, as the covariance is larger in magnitude than the variances. The eigenvalues for this matrix are 2.115 and $-.115$, indicating a negative definite covariance matrix for the latent variables.

A Model with Unconstrained Parameters for the Two Regions

With all the bad model fit indications and the problematic predicted covariance matrix for the latent variables, you might conclude that an overly restricted model has been fit. Region 1 and Region 2 might not share exactly the same set of parameters. How about fitting a model at the other extreme with all parameters unconstrained for the two groups (regions)? Such a model can be easily specified, as shown in the following statements.

```
proc tcalis omethod=nrr;
   group 1 / data=region1 label="Region 1" nobs=378;
   group 2 / data=region2 label="Region 2" nobs=423;
   model 1 / groups=1;
      %BasepathModel
   model 2 / groups=2;
      refmodel 1/ AllNewParms;
   run;
```

Unlike the previous specification, in the current specification group 2 is now fitted by a new model labeled as model 2. This model is based on model 1, as specified in REFMODEL statement. The ALLNEWPARMS option in the REFMODEL statement request that all parameters specified in model 1 be renamed so that they become new parameters. As a result, this specification gives different sets of estimates for model 1 and model 2, although both models have the same path structures and a comparable set of parameters.

The optimization converges in 10 iterations without problems. The fit summary table is displayed in Output 88.10.4. The chi-square statistic is 29.613 (df= 46, $p = .97$). The theoretical model is not rejected. Many other measures of fit also indicate very good model fit. For example, GFI, AGFI, Bentler CFI, Bentler-Bonett NFI, Bollen non-normed index delta2 are all close to one, and RMSEA is close to zero.

Output 88.10.4 Fit Summary

	Bollen Non-normed Index Delta2	1.0463
	James et al. Parsimonious NFI	0.5916

Notice that because there are no constraints between the two models for the groups, you might have fit the two sets of data by the respective models separately and gotten exactly the same results as in the current analysis. For example, you get two model fit chi-square values from separate analyses. Adding up these two chi-squares will give you the same overall chi-square as in Output 88.10.4.

PROC TCALIS also provides a table for comparing relative model fit of the groups. In Output 88.10.5, basic modeling information and some measures of fit for the two groups are shown along with the corresponding overall measures.

Output 88.10.5 Fit Comparison among Groups

Fit Comparison Among Groups

	Bentler-Bonett NFI	0.9259	0.9950	0.8730

When you examine the results of this table, the first thing you have to realize is that in general the group statistics are not independent. For example, although the overall chi-square statistic can be written as the weighted sum of fit functions of the groups, in general it does not imply that the individual terms are statistically independent. In the current two-group analysis, the overall chi-square is written as:

$$T = (N_1 - 1) f_1 + (N_2 - 1) f_2$$

where N_1 and N_2 are sample sizes for the groups, f_1 and f_2 are the discrepancy functions for the groups. Even though T is chi-square distributed under the null hypothesis, in general the individual terms $(N_1 - 1) f_1$ and $(N_2 - 1) f_2$ are not chi-square distributed under the same null hypothesis. So when you compare the group fits by using the statistics in Output 88.10.5, you should treat those as descriptive measures only.

The current model is a special case where f_1 and f_2 are actually independent of each other. The reason is that there are no constrained parameters for the models fitted to the two groups. This would imply that the individual terms $(N_1 - 1) f_1$ and $(N_2 - 1) f_2$ are chi-squared distributed under the null hypothesis. Nonetheless, this fact is not important to our group comparison by using the descriptive statistics in Output 88.10.5. The values of f_1 and f_2 are shown in the row labeled "Fit Function." Group 1 (Region 1) is fitted better by its model ($f_1 = .0023$) than is group 2 (Region 2) by its model ($f_2 = .0681$). Next, the percentage contributions to the overall chi-square statistic for the two groups are shown. Group 1 contributes only 3% ($= (N_1 - 1) f_1 / T \times 100\%$) while Group 2 contributes 97%. Other measures like RMSR, SRMSR, and Bentler-Bonett NFI show that group 1 data are fitted better. The GFI's show equal fits for the two groups, however.

Despite a very good fit, the current model is not intended to be the final model. It was fitted mainly for illustration purposes. For multiple-group analysis, cross-group constraints are of primary

interest and should be explored whenever appropriate. The first fitting with all model parameters constrained for the groups has been shown to be too restrictive, while the current model with no cross-group constraints fits very well–so well that it might have overfit unnecessarily. A multiple-group model between these extremes is now explored. The following specification is for such an intermediate model with cross-group constraints.

```
proc tcalis omethod=nrr modification;
   group 1 / data=region1 label="Region 1" nobs=378;
   group 2 / data=region2 label="Region 2" nobs=423;
   model 1 / groups=1;
      %BasepathModel
   model 2 / groups=2;
      refmodel 1;
      mean
         Spend02 Spend03 = G2_InterSpend02 G2_InterSpend03,
         Courtesy Responsive Helpful
         Delivery Pricing Availability
         Quality = G2_intercept01-G2_intercept07;
   simtest
      SpendDiff       = (Spend02Diff Spend03Diff)
      MeasurementDiff = (CourtesyDiff ResponsiveDiff
                         HelpfulDiff DeliveryDiff
                         PricingDiff AvailabilityDiff
                         QualityDiff);
   Spend02Diff      = G2_InterSpend02 - InterSpend02;
   Spend03Diff      = G2_InterSpend03 - InterSpend03;
   CourtesyDiff     = G2_intercept01  - intercept01;
   ResponsiveDiff   = G2_intercept02  - intercept02;
   HelpfulDiff      = G2_intercept03  - intercept03;
   DeliveryDiff     = G2_intercept04  - intercept04;
   PricingDiff      = G2_intercept05  - intercept05;
   AvailabilityDiff = G2_intercept06  - intercept06;
   QualityDiff      = G2_intercept07  - intercept07;
   run;
```

In this specification, Region 1 is fitted by model 1, which is essentially unchanged from the previous analyses. Region 2 is fitted by model 2, which, again, is modified from model 1, as specified in the REFMODEL statement. The modification being made is the addition of unique mean parameters. In the MEAN statement, nine new parameters are specified. All these parameters are prefixed with G2_ to be distinguished from the parameters in model 1. Parameters G2_InterSpend02 and G2_InterSpend03 are intercepts for variables Spend02 and Spend03, respectively. Parameters G2_intercept01–G2_intercept07 are intercepts for the indicator measures of the latent variables. Because the latent variables in the model have means at fixed zeros, the intercept parameters G2_intercept01–G2_intercept07 and G2_InterSpend02 are also the means for the corresponding variables. To summarize, in this multiple-group model the covariance structures for the two regions are constrained to be the same, while the means structures are allowed to be unconstrained.

Additional statistics or tests are requested in the current PROC TCALIS run. The MODIFICATION option in the PROC TCALIS statement requests the Lagrange Multiplier tests and Wald tests be conducted. The Lagrange Multiplier tests provide information about which constrained or fixed parameters could be freed or added so as to improve the overall model fit. The Wald tests provide

information about which existing parameters could be fixed at zeros (or eliminated) without significantly affecting the overall model fit. These tests will be discussed with more details when the results are presented.

In the SIMTEST statement, two simultaneous tests are requested. The first simultaneous test is named SpendDiff, which includes two parametric functions Spend02Diff and Spend03Diff. The second simultaneous test is named MeasurementDiff, which includes seven parametric functions: CourtesyDiff, ResponsiveDiff, HelpfulDiff, DeliveryDiff, PricingDiff, AvailabilityDiff, and QualityDiff. The null hypothesis of these simultaneous tests is of the form:

$$H_0 : t_i = 0 \quad (i = 1 \ldots k)$$

where k is the number of parametric functions within the simultaneous test. In the current analysis, the component parametric functions are defined in the SAS programming statements, which are shown in the last block of the specification. Essentially, all these parametric functions represent the differences of the mean or intercept parameters between the two models for groups. The first simultaneous test is intended to test whether the mean or intercept parameters in the structural models are the same, while the second simultaneous test is intended to test whether the mean parameters in the measurement models are the same.

The fit summary table is shown in Output 88.10.6.

	Bollen Non-normed Index Delta2	0.8808
	James et al. Parsimonious NFI	0.6904

The chi-square value is 107.55 (df=68, p=0.0016), which is statistically significant. The null hypothesis of the mean and covariance structures is rejected if α-level at 0.01 or larger is chosen. However, in practical structural equation modeling, the chi-square test is not the only criterion, or even an important criterion, for evaluating model fit. The RMSEA estimate for the current model is .0382, which indicates a good fit. The probability level of close fit is .9969, indicating that a good population fit (RMSEA $<$ 0.05) hypothesis cannot be rejected. GFI, AGFI, and parsimonious GFI all indicate good fit. However, the incremental indices show only respectable model fit.

Comparison of the model fit to the groups is shown in Output 88.10.7.

Output 88.10.7 Fit Comparison among Groups

Fit Comparison Among Groups

		Overall	Region 1	Region 2

	Percent Contribution to Chi-Square	100	44	56
	Root Mean Square Residual (RMSR)	0.1577	0.1552	0.1599
	Standardized RMSR (SRMSR)	0.0678	0.0792	0.0557
	Goodness of Fit Index (GFI)	1.0000	1.0000	1.0000
	Bentler-Bonett NFI	0.7310	0.7260	0.7348

Looking at the percentage contribution to the chi-square, the Region 2 fitting shows a worse fit. However, this might be due to the larger sample size in Region 2. When comparing the fit of the two regions by using RMSR, which does not take the sample size into account, the fitting of two groups are about the same. The standardized RMSR even shows that Region 2 is fitted better. So, it seems to be safe to conclude that the models fit almost equally well (or badly) for the two regions.

Constrained parameter estimates for the two regions are shown in Output 88.10.8.

Output 88.10.8 Estimates of Path Coefficients and Other Covariance Parameters

Model 1. Covariances Among Exogenous Variables

Var1	Var2	Parameter	Estimate	Standard Error	t Value
Service	Product	phi	0.33725	0.07061	4.77599

All parameter estimates but one are statistically significant at $\alpha = 0.05$. The parameter a1, which represents the path coefficient from Service to Spend02, has a t-value of 1.76. This is only marginally significant. Although all these results bear the title of model 1, these estimates are the same for model 2, of which the corresponding results are not shown here.

The mean and intercept parameters for the two models (regions) are shown in Output 88.10.9.

Output 88.10.9 Estimates of Means and Intercepts

	Quality	G2_intercept07	5.11900	0.08034	63.71500

All the mean and intercept estimates are statistically significant at $\alpha = 0.01$. Except for the fixed zero means for Service and Product, a quick glimpse of these mean and intercepts estimates shows a quite different pattern for the two models. Do these estimates truly differ beyond chance? The simultaneous tests of these parameter estimates shown in Output 88.10.10 can confirm this.

In Output 88.10.10, there are two simultaneous tests, as requested in the original statements.

Output 88.10.10 Simultaneous Tests

Simultaneous Tests

Simultaneous Test	Parametric Function	Function Value	DF	Chi-Square	p Value
SpendDiff			2	10458	<.0001
	Spend02Diff	-27.25000	1	10225	<.0001
	Spend03Diff	14.18831	1	185.86725	<.0001
MeasurementDiff			7	1610	<.0001
	CourtesyDiff	-1.90000	1	286.58605	<.0001
	ResponsiveDiff	-1.99700	1	279.63659	<.0001
	HelpfulDiff	1.30300	1	141.59942	<.0001
	DeliveryDiff	2.01900	1	239.35318	<.0001
	PricingDiff	1.00300	1	85.52567	<.0001
	AvailabilityDiff	-1.76100	1	278.09360	<.0001
	QualityDiff	-0.85200	1	53.06240	<.0001

The first one is SpendDiff, which tests simultaneously the hypotheses that:

$$H_0 : \text{G2_InterSpend02 - InterSpend02} = 0$$
$$H_0 : \text{G2_InterSpend03 - InterSpend03} = 0$$

The exceedingly large chi-square value 10548 suggests the composite null hypothesis is false. Individual tests for these hypotheses suggest each of these hypotheses should be rejected. The chi-square values for individual tests are 10225 and 185.97, respectively.

Similarly, the simultaneous and individual tests of the intercepts in the measurement model suggest that the two models (groups) differ significantly in the means of the measured variables. Region 2 has significantly higher means in variables Helpful, Delivery, and Pricing, but significantly lower means in variables Courtesy, Responsive, Availability, and Quality.

Now you are ready to answer the main research questions asked. The overall customer service (Service) does affect the future purchase (Spend03), but not the current purchase (Spend02), as the path coefficient a1 is only marginally significant. This perhaps is an artifact because the rating was done after the purchases in 2002. That is, purchases in 2002 had been done before the impression about customer service was fully formed. However, this argument cannot explain why overall customer service (Service) also shows a strong and significant relationship with purchases in 2002 (Spend02). Nonetheless, customer service and product quality do affect the future purchases (Spend03) in an expected way, even after partialling out the effect of the previous purchase amount (Spend02). Apart from the mean differences of the variables, the common measurement and prediction (or structural) models fit the two regions very well.

Because the current model fits well and most parts of fitting meet your expectations, you might accept this model without looking for further improvement. Nonetheless, for illustration purposes, it would be useful to consider the LM test results. In Output 88.10.11, ranked LM statistics for the path coefficients in model 1 and model 2 are shown.

Path coefficients that lead to better improvement (larger chi-square drop) are shown first in the tables. For example, the first path coefficient suggested to be freed in model 1 is the Service <– Courtesy path. The associated p-value is 0.0008 and the estimated change of parameter value is −0.171. The second path coefficient is for the Service <– Helpful path, but it is not significant at the 0.05 level. So, is it good to add the Service <– Courtesy path to model 1, based on the LM test results? The answer is that it depends on your applications and the theoretical and practical implications. For instance, the Service –> Courtesy path, which is a part of the measurement model, is already specified in model 1. Even though the LM test statistic shows a significant drop of model fit chi-square, adding the Service <– Courtesy path might destroy the measurement model and lead to problematic interpretations. In this case, it is wise not to add the Service <– Courtesy path, which is suggested by the LM test results.

LM tests for the path coefficients in model 2 are shown in the bottom of Output 88.10.11. Quite a few of these tests suggest significant improvements in model fit. Again, you are cautioned against adding these paths blindly.

LM tests for the error variances and covariances are shown in Output 88.10.12.

Using $\alpha = 0.05$, you might consider adding two pairs of correlated errors in model 2. The first pair is for Delivery and Courtesy, which has a p-value less than 0.0001. The second pair is Pricing and Responsive, which has a p-value of 0.027. Again, adding correlated errors (in the PCOV statement) should not be a pure statistical consideration. You should also consider theoretical and practical implications.

LM tests for other subsets of parameters are also conducted. Some subsets do not have parameters that can be freed and so they are not shown here. Other subsets are simply not shown here for conserving space.

PROC TCALIS ranks and outputs the LM test results for some default subsets of parameters. You have seen the subsets for path coefficients and correlated errors in the two previous outputs. Some other LM test results are not shown. With this kind of default LM output, there could be a huge amount of modification indices to look at. Fortunately, you can limit the LM test results to any subsets of potential parameters that you might be interested in. With your substantive knowledge, you can define such meaningful subsets of potential parameters by using the LMTESTS statement. The LM test indices and rankings will then be done for each predefined subset of potential parameters.

With these customized LM results, you can limit your attention to consider only those meaningful parameters to be added. See the LMTESTS statement on page 6776 for details.

The next group of LM tests is for releasing implicit equality constraints in your model, as shown in Output 88.10.13.

Output 88.10.13 LM Tests for Equality Constraints

Recall that the measurement and the prediction models for the two regions are constrained to be the same by model referencing (that is, the REFMODEL statement). Output 88.10.13 shows you which parameter can be unconstrained so that your overall model fit might improve. For example, if you unconstrain the first parameter a1 for the two models, the expected chi-square drop (LM Stat) is about 0.0155, which is not significant ($p = .9008$). The associated parameter changes are small too. However, if you consider unconstraining parameter b1, the expected drop of chi-square is 19.17 ($p < 0.0001$). There are two rows for this parameter. Each row represents a parameter location to be released from the equality constraint. Consider the first row first. If you rename the coefficient for the Courtesy <– Service path in model 1 to a new parameter, say "new" (while keeping b1 as the parameter for the Courtesy <– Service path in model 2), and fit the model again, the new estimate of b1 will be 0.2851 larger than the previous b1 estimate. The estimate of "new" would be 0.3191 less than the previous b1 estimate. The second row for the b1 parameter shows similar but reflected results. It is for renaming the parameter location in model 2. For this example each equality constraint has exactly two locations, one for model 1 and one for model 2. That is the reason why you always observe reflected results for freeing the locations successively. Reflected results are not the case if you have equality constraints with more than two parameter locations.

Another example of big expected improvement of model fit is by freeing the constrained variances of Courtesy among the two models. The corresponding row to look at is the row with parameter theta01, where the parameter type is labeled "COVERR" and the values for the Var1 and Var2 are both "Courtesy." The LM statistic is 45.247, which is a significant chi-square drop if you free either parameter locations. If you choose to rename the error variance for Courtesy in model 1, the new theta01 estimate will be 0.8064 smaller than the original theta01 estimate. The new estimate of the error variance for Courtesy in model 2 will be 0.7204 larger than the previous theta01 estimate. Finally, the constrained parameter theta03, which is the error variance parameter for Helpful in both models, is also a potential constraint that can be released with a significant model fit improvement.

In addition to the LM statistics for suggesting ways to improve model fit, PROC TCALIS also computes the Wald tests to show which parameters can be constrained to zero without jeopardizing the model fit significantly. The Wald test results are shown in Output 88.10.14.

Output 88.10.14 Wald Tests

Stepwise Multivariate Wald Test

	------Cumulative Statistics-----			--Univariate Increment--	
Parm	Chi-Square	DF	Pr > ChiSq	Chi-Square	Pr > ChiSq
a1	3.09039	1	0.0788	3.09039	0.0788

In Output 88.10.14, you see that a1 is suggested to be a fixed zero parameter (or eliminated from the model) by the Wald test. Fixing this parameter to zero (or dropping the Spend02 <– Service path from the model) is expected to increase the model fit chi-square by 3.090 (p=.079), which is only marginally significant at $\alpha = .05$.

As is the case for the LM test statistics, you should not automatically adhere to the suggestions by the Wald statistics. Substantive and theoretical considerations should always be considered when determining whether a parameter should be added or dropped.

Overview: TPSPLINE Procedure

The TPSPLINE procedure uses the penalized least squares method to fit a nonparametric regression model. It computes thin-plate smoothing splines to approximate smooth multivariate functions observed with noise. The TPSPLINE procedure allows great flexibility in the possible form of the regression surface. In particular, PROC TPSPLINE makes no assumptions of a parametric form for the model. The generalized cross validation (GCV) function can be used to select the amount of smoothing.

The TPSPLINE procedure complements the methods provided by the standard SAS regression procedures such as the GLM, REG, and NLIN procedures. These procedures can handle most situations in which you specify the regression model and the model is known up to a fixed number of parameters. However, when you have no prior knowledge about the model, or when you know that the data cannot be represented by a model with a fixed number of parameters, you can use the TPSPLINE procedure to model the data.

The TPSPLINE procedure uses the penalized least squares method to fit the data with a flexible model in which the number of effective parameters can be as large as the number of unique design points. Hence, as the sample size increases, the model space increases as well, enabling the thin-plate smoothing spline to fit more complicated situations.

The main features of the TPSPLINE procedure are as follows:

- provides penalized least squares estimates
- supports the use of multidimensional data
- supports multiple SCORE statements
- fits both semiparametric models and nonparametric models
- provides options for handling large data sets
- supports multiple dependent variables
- enables you to choose a particular model by specifying the model degrees of freedom or smoothing parameter

Penalized Least Squares Estimation

Penalized least squares estimation provide a way to balance fitting the data closely and avoiding excessive roughness or rapid variation. A penalized least squares estimate is a surface that minimizes the penalized least squares over the class of all surfaces satisfying sufficient regularity conditions.

Define $\mathbf{x}_i$ as a d-dimensional covariate vector from an $n \times d$ matrix $\mathbf{X}$, $\mathbf{z}_i$ as a p-dimensional covariate vector, and y_i as the observation associated with $(\mathbf{x}_i, \mathbf{z}_i)$. Assuming that the relation between $\mathbf{z}_i$ and y_i is linear but the relation between $\mathbf{x}_i$ and y_i is unknown, you can fit the data by using a semiparametric model as follows:

$$y_i = f(\mathbf{x}_i) + \mathbf{z}_i \boldsymbol{\beta} + \epsilon_i$$

where f is an unknown function that is assumed to be reasonably smooth, $\epsilon_i, i = 1, \cdots, n$, are independent, zero-mean random errors, and $\boldsymbol{\beta}$ is a p-dimensional unknown parametric vector.

This model consists of two parts. The $\mathbf{z}_i \boldsymbol{\beta}$ is the parametric part of the model, and the $\mathbf{z}_i$ are the regression variables. The $f(\mathbf{x}_i)$ is the nonparametric part of the model, and the $\mathbf{x}_i$ are the smoothing variables.

The ordinary least squares method estimates $f(\mathbf{x}_i)$ and $\boldsymbol{\beta}$ by minimizing the quantity:

$$\frac{1}{n}\sum_{i=1}^{n}(y_i - f(\mathbf{x}_i) - \mathbf{z}_i\boldsymbol{\beta})^2$$

However, the functional space of $f(\mathbf{x})$ is so large that you can always find a function f that interpolates the data points. In order to obtain an estimate that fits the data well and has some degree of smoothness, you can use the penalized least squares method.

The penalized least squares function is defined as

$$S_\lambda(f) = \frac{1}{n}\sum_{i=1}^{n}(y_i - f(\mathbf{x}_i) - \mathbf{z}_i\boldsymbol{\beta})^2 + \lambda J_2(f)$$

where $J_2(f)$ is the penalty on the roughness of f and is defined, in most cases, as the integral of the square of the second derivative of f.

The first term measures the goodness of fit and the second term measures the smoothness associated with f. The λ term is the smoothing parameter, which governs the trade-off between smoothness and goodness of fit. When λ is large, it more heavily penalizes rougher fits. Conversely, a small value of λ puts more emphasis on the goodness of fit.

The estimate f_λ is selected from a reproducing kernel Hilbert space, and it can be represented as a linear combination of a sequence of basis functions. Hence, the final estimates of f can be written as

$$\hat{f}_\lambda(\mathbf{x}_i) = \theta_0 + \sum_{j=1}^{d}\theta_j\mathbf{x}_{ij} + \sum_{j=1}^{p}\delta_j B_j(\mathbf{x}_j)$$

where B_j is the basis function, which depends on where the data $\mathbf{x}_i$ are located, and $\boldsymbol{\theta} = \{\theta_0, \ldots, \theta_d\}$ and $\boldsymbol{\delta} = \{\delta_1, \ldots, \delta_p\}$ are the coefficients that need to be estimated.

For a fixed λ, the coefficients $(\boldsymbol{\theta}, \boldsymbol{\delta}, \boldsymbol{\beta})$ can be estimated by solving an $n \times n$ system.

The smoothing parameter can be chosen by minimizing the generalized cross validation (GCV) function.

If you write

$$\hat{\mathbf{y}} = \mathbf{A}(\lambda)\mathbf{y}$$

then $\mathbf{A}(\lambda)$ is referred to as the *hat* or *smoothing* matrix, and the GCV function $GCV(\lambda)$ is defined as

$$GCV(\lambda) = \frac{(1/n)\|(\mathbf{I} - \mathbf{A}(\lambda))\mathbf{y}\|^2}{[(1/n)\mathrm{tr}(\mathbf{I} - \mathbf{A}(\lambda))]^2}$$

PROC TPSPLINE with Large Data Sets

The calculation of the penalized least squares estimate is computationally intensive. The amount of memory and CPU time needed for the analysis depends on the number of unique design points, which corresponds to the number of unknown parameters to be estimated.

You can specify the D= option in the MODEL statement to reduce the number of unknown parameters. The option groups design points by the specified range (see the D= option on page 7070).

PROC TPSPLINE selects one design point from the group and treats all observations in the group as replicates of that design point. Calculation of the thin-plate smoothing spline estimates is based on the reprocessed data. The way to choose the design point from a group depends on the order of the data. Hence, different orders of input data might result in different estimates.

This option, by combining several design points into one, reduces the number of unique design points, thereby approximating the original data. The value you specify for the D= option determines the width of the range used to group the data.

Getting Started: TPSPLINE Procedure

The following example demonstrates how you can use the TPSPLINE procedure to fit a semiparametric model.

Suppose that y is a continuous variable and x1 and x2 are two explanatory variables of interest. To fit a bivariate thin-plate spline model, you can use a MODEL statement similar to that used in many regression procedures in the SAS System:

```
proc tpspline;
    model y = (x1 x2);
run;
```

The TPSPLINE procedure can fit semiparametric models; the parentheses in the preceding MODEL statement separate the smoothing variables from the regression variables. The following statements illustrate this syntax:

```
proc tpspline;
    model y = z1 (x1 x2);
run;
```

This model assumes a linear relation with z1 and an unknown functional relation with x1 and x2.

If you want to fit several responses by using the same explanatory variables, you can save computation time by using the multiple responses feature in the MODEL statement. For example, if y1 and y2 are two response variables, the following MODEL statement can be used to fit two models. Separate analyses are then performed for each response variable.

```
proc tpspline;
    model y1 y2 = (x1 x2);
run;
```

The following example illustrates the use of PROC TPSPLINE. The data are from Bates et al. (1987).

```

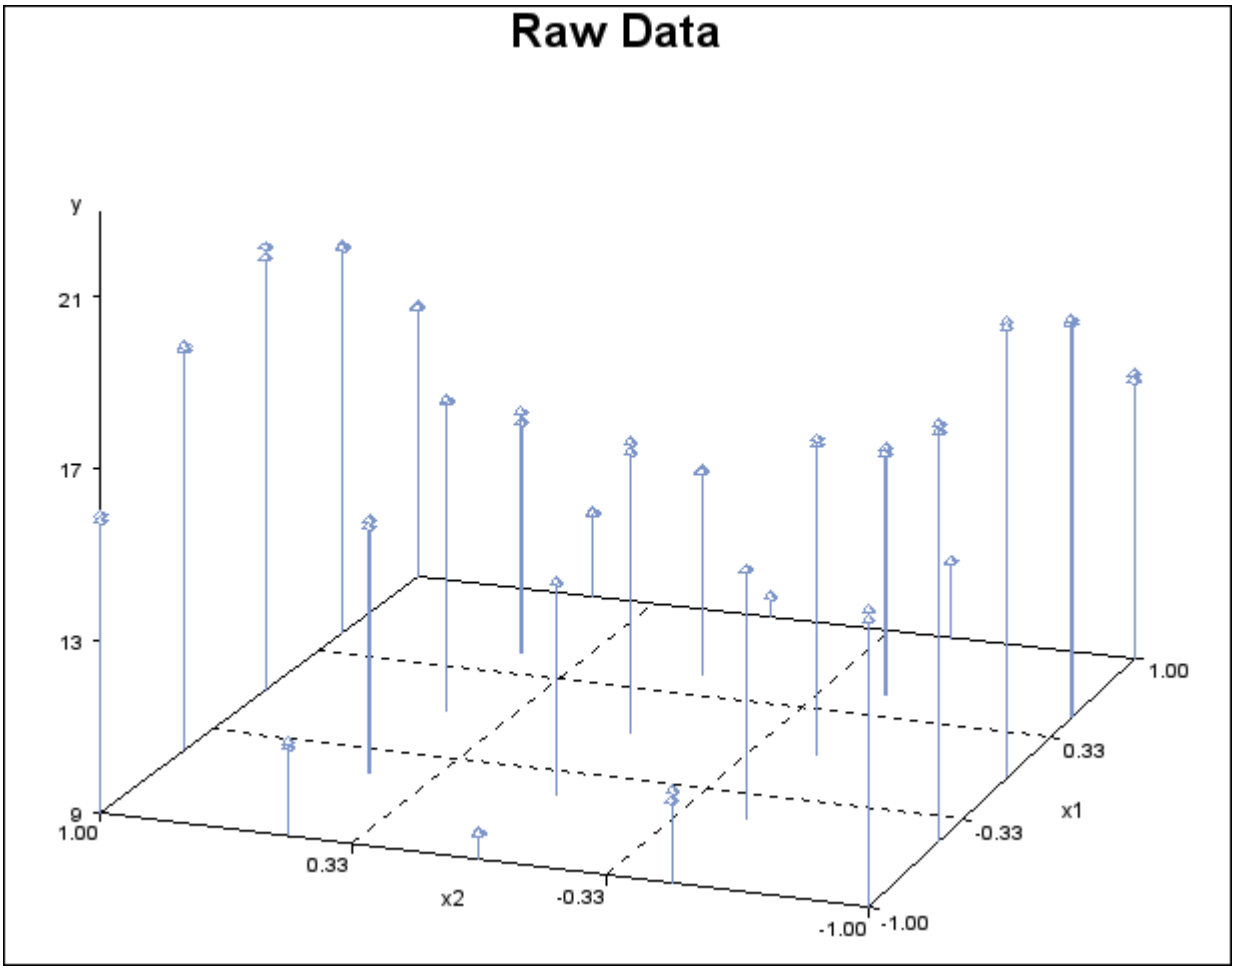
The data set Measure contains three variables x1, x2, and y. Suppose that you want to fit a surface by using the variables x1 and x2 to model the response y. The variables x1 and x2 are spaced evenly on a $[-1 \times 1] \times [-1 \times 1]$ square, and the response y is generated by adding a random error to a function $f(x_1, x_2)$. The raw data are plotted by using the G3D procedure. In order to visualize those replicates, half of the data are shifted a little bit by adding a small value (0.001) to x1 values, as in the following statements:

```
data Measure1;
   set Measure;
run;



proc sort data=Measure1;
   by x2 x1;
run;

data Measure1;
   set Measure1;
   if mod(_N_, 2) = 0 then x1=x1+0.001;
run;

proc g3d data=Measure1;
   scatter x2*x1=y /size=.5
                    zmin=9 zmax=21
                    zticknum=4;
   title "Raw Data";
run;
```

Figure 89.1 displays the raw data.

Figure 89.1 Plot of Data Set MEASURE

The following statements invoke the TPSPLINE procedure, by using the Measure data set as input. In the MODEL statement, the x1 and x2 variables are listed as smoothing variables. The LOGNLAMBDA= option returns a list of GCV values with $\log_{10}(n\lambda)$ ranging from -4 to -2. The OUTPUT statement creates the data set estimate to contain the predicted values and the 95% upper and lower confidence limits.

```
proc tpspline data=Measure;
   model y=(x1 x2) /lognlambda=(-4 to -2 by 0.1);
   output out=estimate pred uclm lclm;
run;

proc print data=estimate;
run;
```

The results of this analysis are displayed in the following figures. Figure 89.2 shows that the data set Measure contains 50 observations with 25 unique design points. The final model contains no parametric regression terms and 2 smoothing variables. The order derivative in the penalty is 2 by default, and the dimension of polynomial space is 3. See the section "Computational Formulas" on page 7073 for definitions.

The GCV values are listed along with the $\log_{10}$ of $n\lambda$. The value of $\log_{10}(n\lambda)$ that minimizes the GCV function is around -3.5. The final thin-plate smoothing spline estimate is based on LOGNLAMBDA = -3.4762. The residual sum of squares is 0.246110, and the degrees of freedom are 24.593203. The standard deviation, defined as $RSS/(\text{tr}(\mathbf{I}-\mathbf{A}))$, is 0.098421. The predictions and 95% confidence limits are displayed in Figure 89.3.

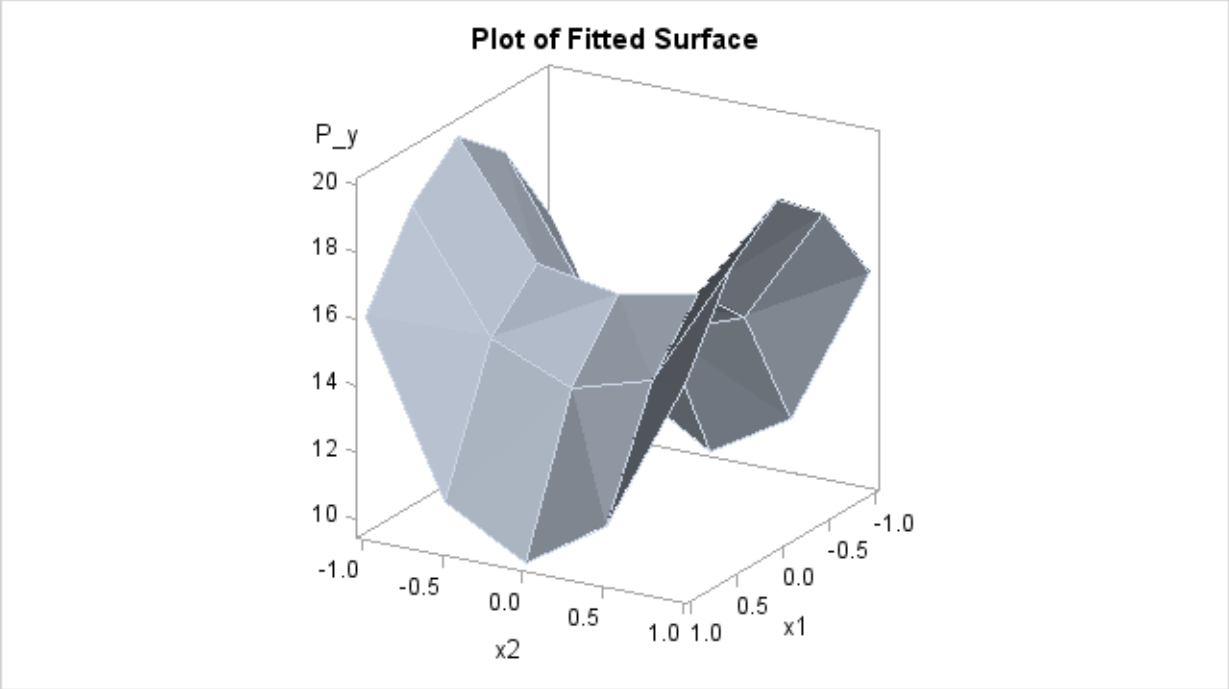
The fitted surface is plotted with PROC TEMPLATE and PROC SGRENDER as follows:

```
data pred_half;
   set estimate;
      if mod(_N_,2)=0 then output;
run;



proc template;
    define statgraph surface;
    dynamic _X _Y _Z _T;
    begingraph /designheight=360;
        entrytitle _T;
        layout overlay3d/rotate=120 cube=false
                         xaxisopts=(label="x1")
                         yaxisopts=(label="x2")
                         zaxisopts=(label="P_y");
                         surfaceplotparm x=_X y=_Y z=_Z;
        endlayout;
    endgraph;
    end;
run;

ods graphics on;

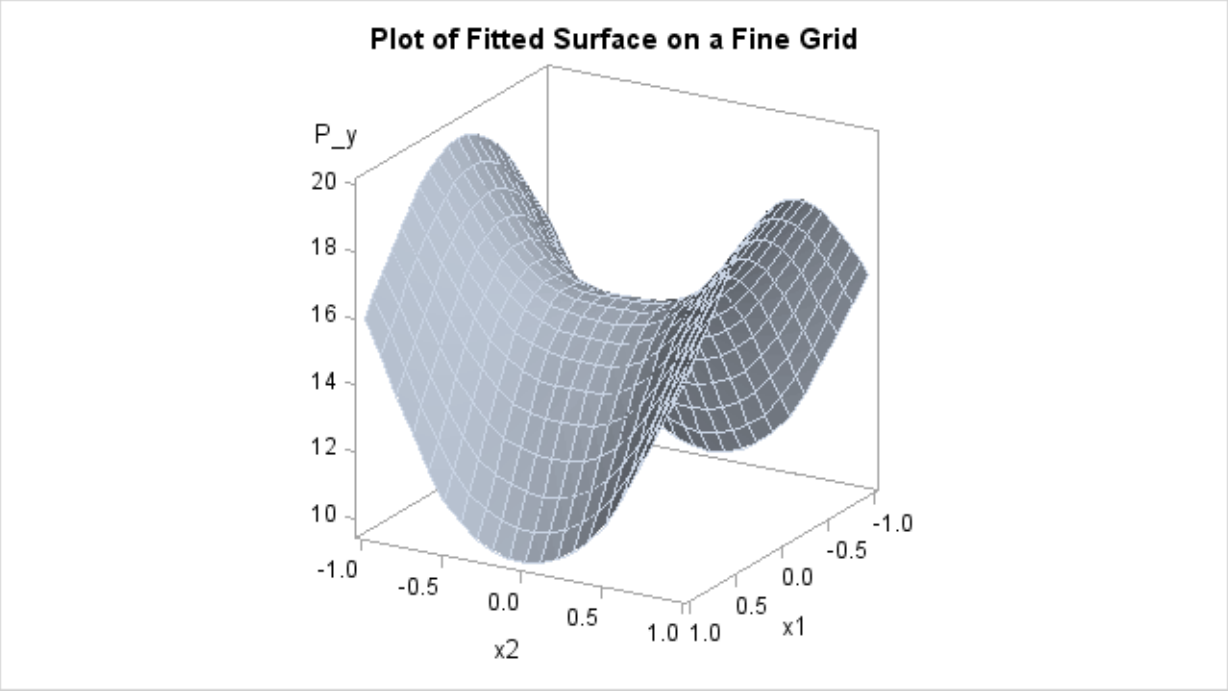
proc sgrender data=pred_half template=surface;
    dynamic _X='x1' _Y='x2' _Z='y' _T='Plot of Fitted Surface';
run;
```

The resulting plot is displayed in Figure 89.4.

Figure 89.4 Plot of PROC TPSPLINE Fit of Data Set MEASURE

Because the data in the data set Measure are very sparse, the fitted surface is not smooth. To produce a smoother surface, the following statements generate the data set pred in order to obtain a finer grid. The SCORE statement evaluates the fitted surface at those new design points.

```
data pred;
   do x1=-1 to 1 by 0.1;
      do x2=-1 to 1 by 0.1;
         output;
      end;
   end;
run;



proc tpspline data=measure;
   model y=(x1 x2)/lognlambda=(-4 to -2 by 0.1);
   score data=pred out=predy;
run;

proc sgrender data=predy template=surface;
    dynamic _X='x1' _Y='x2' _Z='P_y' _T='Plot of Fitted Surface on a Fine Grid';
run;

ods graphics off;
```

The surface plot based on the finer grid is displayed in Figure 89.5. The plot shows that a parametric model with quadratic terms of x1 and x2 provides a reasonable fit to the data.

Figure 89.5 Plot of TPSPLINE Fit

Syntax: TPSPLINE Procedure

The following statements are available in PROC TPSPLINE:

PROC TPSPLINE < *option* > **;**
MODEL *dependents* = < *variables* > *(variables)* < */options* > **;**
SCORE *data=SAS-data-set out=SAS-data-set* **;**
OUTPUT < *out=SAS-data-set* > *keyword* ··· *keyword* **;**
BY *variables* **;**
FREQ *variable* **;**
ID *variables* **;**

The syntax in PROC TPSPLINE is similar to that of other regression procedures in the SAS System. The PROC TPSPLINE and MODEL statements are required. The SCORE statement can appear multiple times; all other statements appear only once.

The statements available for PROC TPSPLINE are described in alphabetical order after the description of the PROC TPSPLINE statement.

PROC TPSPLINE Statement

PROC TPSPLINE < *option* > **;**

The PROC TPSPLINE statement invokes the procedure. You can specify the following option.

DATA=*SAS-data-set*
specifies the SAS data set to be read by PROC TPSPLINE. The default value is the most recently created data set.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC TPSPLINE to obtain separate analysis on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the TPSPLINE procedure. The NOTSORTED option does not mean that the data are unsorted

but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FREQ Statement

FREQ *variable* **;**

If one variable in your input data set represents the frequency of occurrence for other values in the observation, specify the variable's name in a FREQ statement. PROC TPSPLINE treats the data as if each observation appears n times, where n is the value of the FREQ variable for the observation. If the value of the FREQ variable is less than one, the observation is not used in the analysis. Only the integer portion of the value is used.

ID Statement

ID *variables* **;**

The variables in the ID statement are copied from the input data set to the OUT= data set. If you omit the ID statement, only the variables used in the MODEL statement and requested statistics are included in the output data set.

MODEL Statement

MODEL *dependents = < regression variables > (smoothing variables) < /options >* **;**

The MODEL statement specifies the dependent variables, the independent regression variables, which are listed with no parentheses, and the independent smoothing variables, which are listed inside parentheses.

The regression variables are optional. At least one smoothing variable is required, and it must be listed after the regression variables. No variables can be listed in both the regression variable list and the smoothing variable list.

If you specify more than one dependent variable, PROC TPSPLINE calculates a thin-plate smoothing spline estimate for each dependent variable, by using the regression variables and smoothing variables specified on the right side.

If you specify regression variables, PROC TPSPLINE fits a semiparametric model by using the regression variables as the linear part of the model.

You can specify the following options in the MODEL statement.

ALPHA=*number*

specifies the significance level α of the confidence limits on the final thin-plate smoothing spline estimate when you request confidence limits to be included in the output data set. Specify *number* as a value between 0 and 1. The default value is 0.05. See the section "OUTPUT Statement" on page 7072 for more information about the OUTPUT statement.

DF=*number*

specifies the degrees of freedom of the thin-plate smoothing spline estimate, defined as

$$\mathrm{df} = \mathrm{tr}(\mathbf{A}(\lambda))$$

where $\mathbf{A}(\lambda)$ is the *hat* matrix. Specify *number* as a value between zero and the number of unique design points n_q. Smaller df values cause more penalty on the roughness and thus smoother fits.

DISTANCE=*number*

D=*number*

defines a range such that if the L_∞ distance between two data points $(\mathbf{x}_i, \mathbf{z}_i)$ and $(\mathbf{x}_j, \mathbf{z}_j)$ satisfies

$$\|\mathbf{x}_i - \mathbf{x}_j\|_\infty \leq D/2$$

then these data points are treated as replicates, where $\mathbf{x}_i$ are the smoothing variables and $\mathbf{z}_i$ are the regression variables.

You can use the DISTANCE= option to reduce the number of unique design points by treating nearby data as replicates. This can be useful when you have a large data set. Larger DISTANCE= option values cause fewer n_q points. The default value is 0.

PROC TPSPLINE uses the DISTANCE= value to group points as follows: The data are first sorted by the smoothing variables in the order in which they appear in the MODEL statement. The first point in the sorted data becomes the first unique point. Subsequent points have their x-values set equal to that point until the first point where the maximum distance in one dimension is larger than $D/2$. This point becomes the next unique point, and so on. Because of this sequential processing, the set of unique points differs depending on the order of the smoothing variables in the MODEL statement.

For example, with a model that has two smoothing variables (x1,x2), the data are first sorted by x1 and x2 (in that order), and then uniqueness is assessed sequentially. The first point in the sorted data $\mathbf{x}_1 = (\mathsf{x1}_1, \mathsf{x2}_1)$ becomes the first unique point, $\mathbf{u}_1 = (\mathsf{u1}_1, \mathsf{u2}_1)$. Subsequent points $\mathbf{x}_i = (\mathsf{x1}_i, \mathsf{x2}_i)$ are set equal to $\mathbf{u}_1$ until the algorithm comes to a point with $\max(|\mathsf{x1}_i - \mathsf{u1}_1|, |\mathsf{x2}_i - \mathsf{u2}_1|) > D/2$. This point becomes the second unique point $\mathbf{u}_2$, and we proceed from there.

LAMBDA0=*number*

specifies the smoothing parameter, λ_0, to be used in the thin-plate smoothing spline estimate. By default, PROC TPSPLINE uses the λ parameter that minimizes the GCV function for the final fit. The LAMBDA0= value must be positive. Larger λ_0 values cause smoother fits.

LAMBDA=*list-of-values*

specifies a set of values for the λ parameter. PROC TPSPLINE returns a GCV value for each λ point that you specify. You can use the LAMBDA= option to study the GCV function curve for a set of values for λ. All values listed in the LAMBDA= option must be positive.

LOGNLAMBDA0=*number*

LOGNL0=*number*

specifies the smoothing parameter λ_0 on the $\log_{10}(n\lambda)$ scale. If you specify both the LOGNL0= and LAMBDA0= options, only the value provided by the LOGNL0= option is used. Larger $\log_{10}(n\lambda_0)$ values cause smoother fits. By default, PROC TPSPLINE uses the λ parameter that minimizes the GCV function for the estimate.

LOGNLAMBDA=*list-of-values*

LOGNL=*list-of-values*

specifies a set of values for the λ parameter on the $\log_{10}(n\lambda)$ scale. PROC TPSPLINE returns a GCV value for each λ point that you specify. You can use the LOGNLAMBDA= option to study the GCV function curve for a set of λ values. If you specify both the LOGNL= and LAMBDA= options, only the list of values provided by the LOGNL= option is used.

In some cases, the LOGNL= option might be preferred over the LAMBDA= option. Because the LAMBDA= value must be positive, a small change in that value can result in a major change in the GCV value. If you instead specify λ on the $\log_{10}(n\lambda)$ scale, the allowable range is enlarged to include negative values. Thus, the GCV function is less sensitive to changes in LOGNLAMBDA.

The DF= option, LAMBDA0= option, and LOGNLAMBDA0= option all specify exact smoothness of a nonparametric fit. If you want to fit a model with specified smoothness, the DF= option is preferable to the other two options because $(0, n_q)$, the range of df, is much smaller in length than $(0, \infty)$ of λ and $(-\infty, \infty)$ of $\log_{10}(n\lambda)$.

M=*number*

specifies the order of the derivative in the penalty term. The M= value must be a positive integer. The default value is $\max(2, \text{int}(d/2) + 1)$, where d is the number of smoothing variables.

SCORE Statement

SCORE *DATA=SAS-data-set* *OUT=SAS-data-set* **;**

The SCORE statement calculates predicted values for a new data set. If you have multiple data sets to predict, you can specify multiple SCORE statements. You must use a SCORE statement for each data set.

The following keywords must be specified in the SCORE statement.

DATA=*SAS-data-set*
specifies the input SAS data set containing the smoothing variables **x** and regression variables **z**. The predicted response ($\hat{y}$) value is computed for each (**x**, **z**) pair. The data set must include all independent variables specified in the MODEL statement.

OUT=*SAS-data-set*
specifies the name of the SAS data set to contain the predictions.

OUTPUT Statement

OUTPUT *OUT=SAS-data-set <keyword ··· keyword >* **;**

The OUTPUT statement creates a new SAS data set containing diagnostic measures calculated after fitting the model.

You can request a variety of diagnostic measures that are calculated for each observation in the data set. The new data set contains the variables specified in the MODEL statement in addition to the requested variables. If no *keyword* is present, the data set contains only the predicted values.

Details on the specifications in the OUTPUT statement are as follows.

OUT=*SAS-data-set*
specifies the name of the new data set to contain the diagnostic measures. This specification is required.

keyword
specifies the statistics to include in the output data set. The names of the new variables that contain the statistics are formed by using a prefix of one or more characters to identify the statistic, followed by an underscore (_), followed by the dependent variable name.

For example, suppose that you have two dependent variables—say, y1 and y2—and you specify the keywords PRED, ADIAG, and UCLM. The output SAS data set will contain the following variables:

- P_y1 and P_y2
- ADIAG_y1 and ADIAG_y2
- UCLM_y1 and UCLM_y2

The keywords and the statistics they represent are as follows:

RESID | R	residual values, calculated as ACTUAL − PREDICTED
PRED	predicted values
STD	standard error of the mean predicted value

UCLM	upper limit of the confidence interval for the expected value of the dependent variables. By default, PROC TPSPLINE computes 95% confidence limits.
LCLM	lower limit of the confidence interval for the expected value of the dependent variables. By default, PROC TPSPLINE computes 95% confidence limits.
ADIAG	diagonal element of the hat matrix associated with the observation
COEF	coefficients arranged in the order of $(\theta_0, \theta_1, \cdots, \theta_d, \delta_1, \cdots \delta_{n_q})$, where n_q is the number of unique data points. This option can be used only when there is only one dependent variable in the model.

Details: TPSPLINE Procedure

Computational Formulas

The theoretical foundations for the thin-plate smoothing spline are described in Duchon (1976, 1977) and Meinguet (1979). Further results and applications are given in Wahba and Wendelberger (1980), Hutchinson and Bischof (1983), and Seaman and Hutchinson (1985).

Suppose that $\mathcal{H}_m$ is a space of functions whose partial derivatives of total order m are in $L_2(E^d)$, where E^d is the domain of $\mathbf{x}$.

Now, consider the data model

$$y_i = f(\mathbf{x}_i) + \epsilon_i, i = 1, \ldots, n$$

where $f \in \mathcal{H}_m$.

Using the notation from the section "Penalized Least Squares Estimation" on page 7058, for a fixed λ, estimate f by minimizing the penalized least squares function

$$\frac{1}{n}\sum_{i=1}^{n}(y_i - f(\mathbf{x}_i) - \mathbf{z}_i\boldsymbol{\beta})^2 + \lambda J_m(f)$$

$\lambda J_m(f)$ is the penalty term to enforce smoothness on f. There are several ways to define $J_m(f)$. For the thin-plate smoothing spline, with $\mathbf{X}$ of dimension d, define $J_m(f)$ as

$$J_m(f) = \int_{-\infty}^{\infty}\cdots\int_{-\infty}^{\infty}\sum\frac{m!}{\alpha_1!\cdots\alpha_d!}\left(\frac{\partial^m f}{\partial x_1{}^{\alpha_1}\cdots\partial x_d{}^{\alpha_d}}\right)^2 \mathrm{d}x_1\cdots\mathrm{d}x_d$$

where $\sum_i \alpha_i = m$. Under this definition, $J_m(f)$ will give zero penalty to some functions. The space that is spanned by the set of polynomials contributing zero penalty is called the polynomial space. The dimension of the polynomial space M is a function of dimension d and order m of the smoothing penalty.

When $d = 2$ and $m = 2$, $J_m(f)$ is as follows:

$$J_2(f) = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\left(\left(\frac{\partial^2 f}{\partial {x_1}^2}\right)^2 + 2\left(\frac{\partial^2 f}{\partial x_1 \partial x_2}\right)^2 + \left(\frac{\partial^2 f}{\partial {x_2}^2}\right)^2\right) \mathrm{d}x_1 \mathrm{d}x_2$$

and $M = \text{sizeof}(\{1, x_1, x_2\}) = 3$.

In general, m and d must satisfy the condition that $2m - d > 0$. For the sake of simplicity, the formulas and equations that follow assume $m = 2$. See Wahba (1990) and Bates et al. (1987) for more details.

Duchon (1976) showed that f_λ can be represented as

$$f_\lambda(\mathbf{x}_i) = \theta_0 + \sum_{j=1}^{d} \theta_j \mathbf{x}_{i\,j} + \sum_{j=1}^{n} \delta_j E_2(\mathbf{x}_i - \mathbf{x}_j)$$

where $E_2(\mathbf{s}) = \frac{1}{2^3\pi}\|\mathbf{s}\|^2 \log(\|\mathbf{s}\|)$ for $d = 2$. For derivations of $E_2(\mathbf{s})$ for other values of d, see Villalobos and Wahba (1987).

If you define $\mathbf{K}$ with elements $\mathbf{K}_{ij} = E_2(\mathbf{x}_i - \mathbf{x}_j)$ and $\mathbf{T}$ with elements $\mathbf{T}_{ij} = (\mathbf{X}_{ij})$, the goal is to find coefficients β, θ, and δ that minimize

$$S_\lambda(\beta, \theta, \delta) = \frac{1}{n}\|\mathbf{y} - \mathbf{T}\theta - \mathbf{K}\delta - \mathbf{Z}\beta\|^2 + \lambda \delta^T \mathbf{K} \delta$$

A unique solution is guaranteed if the matrix $\mathbf{T}$ is of full rank and $\delta^T \mathbf{K} \delta \geq 0$.

If $\alpha = \begin{pmatrix} \theta \\ \beta \end{pmatrix}$ and $\mathbf{X} = (\mathbf{T}\ \mathbf{Z})$, the expression for S_λ becomes

$$\frac{1}{n}\|\mathbf{y} - \mathbf{X}\alpha - \mathbf{K}\delta\|^2 + \lambda \delta^T \mathbf{K} \delta$$

The coefficients α and δ can be obtained by solving

$$\begin{aligned} (\mathbf{K} + n\lambda \mathbf{I}_n)\delta + \mathbf{X}\alpha &= \mathbf{y} \\ \mathbf{X}^T \delta &= \mathbf{0} \end{aligned}$$

To compute α and δ, let the QR decomposition of $\mathbf{X}$ be

$$\mathbf{X} = (\mathbf{Q}_1\ \mathbf{Q}_2)\begin{pmatrix} \mathbf{R} \\ \mathbf{0} \end{pmatrix}$$

where $(\mathbf{Q}_1\ \mathbf{Q}_2)$ is an orthogonal matrix and $\mathbf{R}$ is an upper triangular, with $\mathbf{X}^T\mathbf{Q}_2 = 0$ (Dongarra et al. 1979).

Since $\mathbf{X}^T\delta = 0$, δ must be in the column space of $\mathbf{Q}_2$. Therefore, δ can be expressed as $\delta = \mathbf{Q}_2\gamma$ for a vector γ. Substituting $\delta = \mathbf{Q}_2\gamma$ into the preceding equation and multiplying through by $\mathbf{Q}_2^T$ gives

$$\mathbf{Q}_2^T(\mathbf{K} + n\lambda\mathbf{I})\mathbf{Q}_2\gamma = \mathbf{Q}_2^T\mathbf{y}$$

or

$$\delta = \mathbf{Q}_2\gamma = \mathbf{Q}_2[\mathbf{Q}_2^T(\mathbf{K} + n\lambda\mathbf{I})\mathbf{Q}_2]^{-1}\mathbf{Q}_2^T\mathbf{y}$$

The coefficient α can be obtained by solving

$$\mathbf{R}\alpha = \mathbf{Q}_1^T[\mathbf{y} - (\mathbf{K} + n\lambda\mathbf{I})\delta]$$

The influence matrix $\mathbf{A}(\lambda)$ is defined as

$$\hat{\mathbf{y}} = \mathbf{A}(\lambda)\mathbf{y}$$

and has the form

$$\mathbf{A}(\lambda) = \mathbf{I} - n\lambda\mathbf{Q}_2[\mathbf{Q}_2^T(K + n\lambda\mathbf{I})\mathbf{Q}_2]^{-1}\mathbf{Q}_2^T$$

Similar to the regression case, and if you consider the trace of $\mathbf{A}(\lambda)$ as the degrees of freedom for the model and the trace of $(\mathbf{I} - \mathbf{A}(\lambda))$ as the degrees of freedom for the error, the estimate σ^2 can be represented as

$$\hat{\sigma}^2 = \frac{RSS(\lambda)}{\text{tr}(\mathbf{I} - \mathbf{A}(\lambda))}$$

where $RSS(\lambda)$ is the residual sum of squares. Theoretical properties of these estimates have not yet been published. However, good numerical results in simulation studies have been described by several authors. For more information, see O'Sullivan and Wong (1987), Nychka (1986a, 1986b, 1988), and Hall and Titterington (1987).

Confidence Intervals

Viewing the spline model as a Bayesian model, Wahba (1983) proposed Bayesian confidence intervals for smoothing spline estimates as follows:

$$\hat{f}_\lambda(\mathbf{x}_i) \pm z_{\alpha/2}\sqrt{\hat{\sigma}^2 a_{ii}(\lambda)}$$

where $a_{ii}(\lambda)$ is the ith diagonal element of the $\mathbf{A}(\lambda)$ matrix and $z_{\alpha/2}$ is the $1 - \alpha/2$ quantile of the standard normal distribution. The confidence intervals are interpreted as intervals "across the function" as opposed to pointwise intervals.

Suppose that you fit a spline estimate that consists of a true function f and a random error term, ϵ_i, to experimental data. In repeated experiments, it is likely that about $100(1-\alpha)\%$ of the confidence intervals cover the corresponding true values, although some values are covered every time and other values are not covered by the confidence intervals most of the time. This effect is more pronounced when the true surface or surface has small regions of particularly rapid change.

Smoothing Parameter

The quantity λ is called the smoothing parameter, which controls the balance between the goodness of fit and the smoothness of the final estimate.

A large λ heavily penalizes the mth derivative of the function, thus forcing $f^{(m)}$ close to 0. A small λ places less of a penalty on rapid change in $f^{(m)}(\mathbf{x})$, resulting in an estimate that tends to interpolate the data points.

The smoothing parameter greatly affects the analysis, and it should be selected with care. One method is to perform several analyses with different values for λ and compare the resulting final estimates.

A more objective way to select the smoothing parameter λ is to use the "leave-out-one" cross validation function, which is an approximation of the predicted mean squares error. A generalized version of the leave-out-one cross validation function is proposed by Wahba (1990) and is easy to calculate. This generalized cross validation (GCV) function is defined as

$$GCV(\lambda) = \frac{(1/n)\|(\mathbf{I} - \mathbf{A}(\lambda))\mathbf{y}\|^2}{[(1/n)\mathrm{tr}(\mathbf{I} - \mathbf{A}(\lambda))]^2}$$

The justification for using the GCV function to select λ relies on asymptotic theory. Thus, you cannot expect good results for very small sample sizes or when there is not enough information in the data to separate the model from the error component. Simulation studies suggest that for independent and identically distributed Gaussian noise, you can obtain reliable estimates of λ for n greater than 25 or 30. Note that, even for large values of n (say, $n \geq 50$), in extreme Monte Carlo simulations there might be a small percentage of unwarranted extreme estimates in which $\hat{\lambda} = 0$ or $\hat{\lambda} = \infty$ (Wahba 1983). Generally, if σ^2 is known to within an order of magnitude, the occasional extreme case can be readily identified. As n gets larger, the effect becomes weaker.

The GCV function is fairly robust against nonhomogeneity of variances and non-Gaussian errors (Villalobos and Wahba 1987). Andrews (1988) has provided favorable theoretical results when variances are unequal. However, this selection method is likely to give unsatisfactory results when the errors are highly correlated.

The GCV value might be suspect when λ is extremely small because computed values might become indistinguishable from zero. In practice, calculations with $\lambda = 0$ or λ near 0 can cause numerical instabilities resulting in an unsatisfactory solution. Simulation studies have shown that a λ with $\log_{10}(n\lambda) > -8$ is small enough that the final estimate based on this λ almost interpolates the data points. A GCV value based on a $\lambda \leq 10^{-8}$ might not be accurate.

ODS Table Names

PROC TPSPLINE assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets.

These names are listed in the following table. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 89.1 ODS Tables Produced by PROC TPSPLINE

ODS Table Name	Description	Statement	Option
DataSummary	Data summary	PROC	default
FitSummary	Fit parameters and fit summary	PROC	default
FitStatistics	Model fit statistics	PROC	default
GCVFunction	GCV table	MODEL	LOGNLAMBDA, LAMBDA

By referring to the names of such tables, you can use the ODS OUTPUT statement to place one or more of these tables in output data sets.

For example, the following statements create an output data set named FitStats containing the FitStatistics table, an output data set named DataInfo containing the DataSummary table, an output data set named ModelInfo containing the FitSummary table, and an output data set named GCVFunc containing the GCVFunction table.

```
proc tpspline data=Melanoma;
   model Incidences=Year /LOGNLAMBDA=(-4 to 0 by 0.2);
   ods output FitStatistics = FitStats
              DataSummary   = DataInfo
              FitSummary    = ModelInfo
              GCVFunction   = GCVFunc;
run;
```

Examples: TPSPLINE Procedure

Example 89.1: Partial Spline Model Fit

This example analyzes the data set Measure that was introduced in the section "Getting Started: TPSPLINE Procedure" on page 7060. That analysis determined that the final estimated surface can be represented by a quadratic function for one or both of the independent variables. This example illustrates how you can use PROC TPSPLINE to fit a partial spline model. The data set Measure is fit by using the following model:

$$y = \beta_0 + \beta_1 x_1 + \beta x_1^2 + f(x_2)$$

The model has a parametric component (associated with the x_1 variable) and a nonparametric component (associated with the x_2 variable). The following statements fit a partial spline model:

```
data Measure;
   set Measure;
   x1sq = x1*x1;
run;

data pred;
   do x1=-1 to 1 by 0.1;
      do x2=-1 to 1 by 0.1;
         x1sq = x1*x1;
         output;
      end;
   end;
run;

proc tpspline data= measure;
   model y = x1 x1sq (x2);
   score data = pred
         out  = predy;
run;
```

Output 89.1.1 displays the results from these statements.

Output 89.1.1 Output from PROC TPSPLINE

```

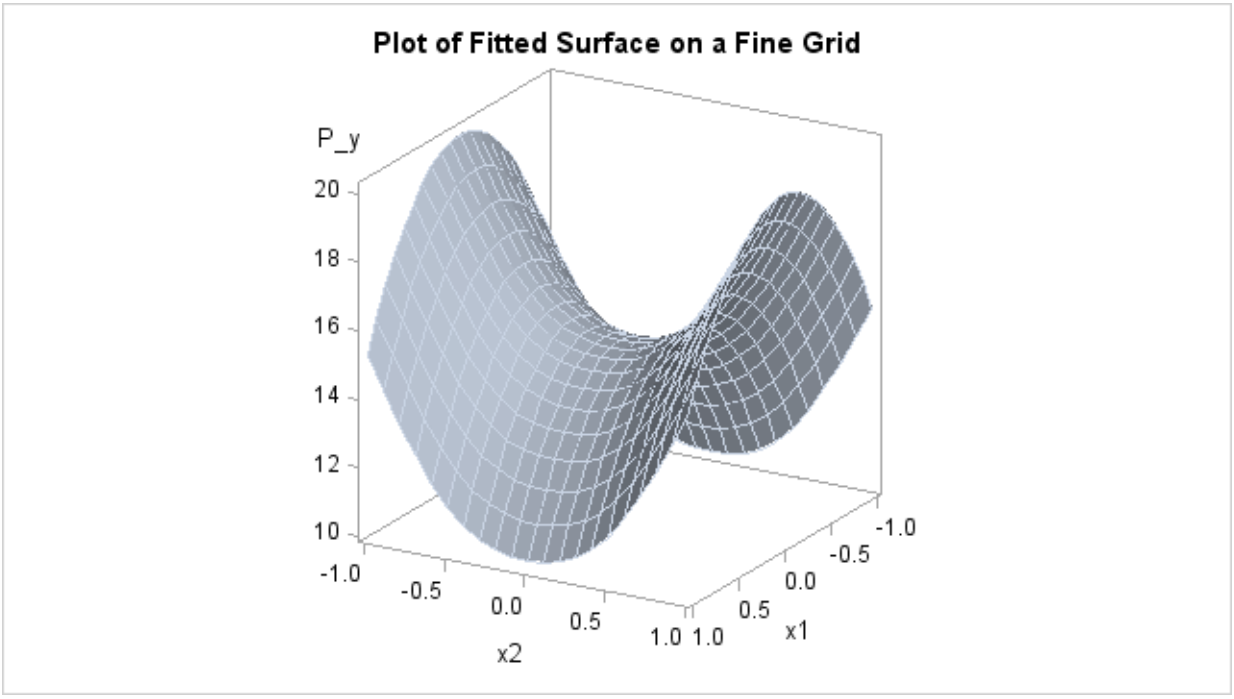
                Number of Smoothing Variables          1
                Order of Derivative in the Penalty     2
                Dimension of Polynomial Space          4

                         Summary Statistics
                        of Final Estimation

                   log10(n*Lambda)            -2.2374
                   Smoothing Penalty         205.3461
                   Residual SS                 8.5821
                   Tr(I-A)                    43.1534
                   Model DF                    6.8466
                   Standard Deviation          0.4460
```

As displayed in Output 89.1.1, there are five unique design points for the smoothing variable x_2 and two regression variables in the model (x_1, x_1^2). The dimension of the polynomial space is sizeof$(\{1, x_1, x_1^2, x_2\}) = 4$. The standard deviation of the estimate is much larger than the one based on the model with both x_1 and x_2 as smoothing variables (0.445954 compared to 0.098421). One of the many possible explanations might be that the number of unique design points of the smoothing variable is too small to warrant an accurate estimate for $f(x_2)$.

The following statements produce a surface plot for the partial spline model by using the surface template defined in page 7066:



```
ods graphics on;

proc sgrender data=predy template=surface;
    dynamic _X='x1' _Y='x2' _Z='P_y' _T='Plot of Fitted Surface on a Fine Grid';
run;

ods graphics off;
```

The surface displayed in Output 89.1.2 is similar to the one estimated by using the full nonparametric model (displayed in Output 89.5).

Output 89.1.2 Plot of PROC TPSPLINE Fit from the Partial Spline Model

Example 89.2: Spline Model with Higher-Order Penalty

This example continues the analysis of the data set Measure to illustrate how you can use PROC TPSPLINE to fit a spline model with a higher-order penalty term. Spline models with high-order penalty terms move low-order polynomial terms into the polynomial space. Hence, there is no penalty for these terms, and they can vary without constraint.

As shown in the previous analyses, the final model for the data set Measure must include quadratic terms for both x_1 and x_2. This example fits the following model:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_1^2 + \beta_3 x_2 + \beta_4 x_2^2 + \beta_5 x_1 x_2 + f(x_1, x_2)$$

The model includes quadratic terms for both variables, although it differs from the usual linear model. The nonparametric term $f(x_1, x_2)$ explains the variation of the data unaccounted for by a simple quadratic surface.

To modify the order of the derivative in the penalty term, specify the M= option. The following statements specify the option M=3 in order to include the quadratic terms in the polynomial space:

```
data Measure;
   set Measure;
   x1sq = x1*x1;
   x2sq = x2*x2;
   x1x2 = x1*x2;
;

proc tpspline data= Measure;
   model y = (x1 x2) / m=3;
   score data = pred
         out = predy;
run;
```

Output 89.2.1 displays the results from these statements.

Output 89.2.1 Output from PROC TPSPLINE with M=3

```

Summary Statistics of Final Estimation	
log10(n*Lambda)	-3.7831
Smoothing Penalty	2092.4495
Residual SS	0.2731
Tr(I-A)	29.1716
Model DF	20.8284
Standard Deviation	0.0968

The model contains six terms in the polynomial space (sizeof($\{1, x_1, x_1^2, x_1x_2, x_2, x_2^2\}$) = 6). Compare Output 89.2.1 with Output 89.1.1: the LOGNLAMBDA value and the smoothing penalty differ significantly. Note that, in general, these terms are not directly comparable for different models. The final estimate based on this model is close to the estimate based on the model by using the default, M=2.

In the following statements, the REG procedure fits a quadratic surface model to the data set Measure:

```
proc reg data= Measure;
   model y = x1 x1sq x2 x2sq x1x2;
run;
```

The results are displayed in Output 89.2.2.

Output 89.2.2 Quadratic Surface Model: The REG Procedure

Raw Data

The REG Procedure

Output 89.2.2 *continued*

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	14.90834	0.12519	119.09	<.0001
x1	1	0.01292	0.09015	0.14	0.8867
x1sq	1	-4.85194	0.15237	-31.84	<.0001
x2	1	0.02618	0.09015	0.29	0.7729
x2sq	1	5.20624	0.15237	34.17	<.0001
x1x2	1	-0.04814	0.12748	-0.38	0.7076

The REG procedure produces slightly different results. To fit a similar model with PROC TPSPLINE, you can use a MODEL statement specifying the degrees of freedom with the DF= option. You can also use a large value for the LOGNLAMBDA0= option to force a parametric model fit.

Because there is one degree of freedom for each of the terms intercept, x1, x2, x1sq, x2sq, and x1x2, the DF=6 option is used as follows:

```
proc tpspline data=measure;
   model  y=(x1 x2) /m=3 df=6 lognlambda=(-4 to 1 by 0.2);
   score data = pred
         out = predy;
run;
```

The results are displayed in Output 89.2.3. PROC TPSPLINE displays the list of GCV values for comparison.

Summary Statistics of Final Estimation

log10(n*Lambda)	2.3830
Smoothing Penalty	0.0000
Residual SS	8.9384
Tr(I−A)	43.9997
Model DF	6.0003
Standard Deviation	0.4507

The final estimate is based on 6.000330 degrees of freedom because there are already 6 degrees of freedom in the polynomial space and the search range for λ is not large enough (in this case, setting DF=6 is equivalent to setting $\lambda = \infty$).

The standard deviation and RSS (Output 89.2.3) are close to the sum of squares for the error term and the root MSE from the linear regression model (Output 89.2.2), respectively.

For this model, the optimal LOGNLAMBDA is around -3.8, which produces a standard deviation estimate of 0.096765 (see Output 89.2.1) and a GCV value of 0.016051, while the model specifying DF=6 results in a LOGNLAMBDA larger than 1 and a GCV value larger than 0.23074. The nonparametric model, based on the GCV, should provide better prediction, but the linear regression model can be more easily interpreted.

Example 89.3: Multiple Minima of the GCV Function

The data in this example represent the deposition of sulfate (SO_4) at 179 sites in the 48 contiguous states of the United States in 1990. Each observation records the latitude and longitude of the site as well as the SO_4 deposition at the site measured in grams per square meter (g/m^2).

You can use PROC TPSPLINE to fit a surface that reflects the general trend and that reveals underlying features of the data, which are shown in the following DATA step:

```
data so4;
input latitude longitude so4 @@;
datalines;
32.45833  87.24222 1.403 34.28778  85.96889 2.103
33.07139 109.86472 0.299 36.07167 112.15500 0.304
31.95056 112.80000 0.263 33.60500  92.09722 1.950

... more lines ...

43.87333 104.19222 0.306 44.91722 110.42028 0.210
45.07611  72.67556 2.646
;
data pred;
   do latitude = 25 to 47 by 1;
      do longitude = 68 to 124 by 1;
         output;
      end;
   end;
run;
```

The preceding statements create the SAS data set so4 and the data set pred in order to make predictions on a regular grid. The following statements fit a surface for SO_4 deposition. The ODS OUTPUT statement creates a data set called GCV to contain the GCV values for LOGNLAMBDA in the range from -6 to 1.

```
proc tpspline data=so4;
   ods output GCVFunction=gcv;
   model so4 = (latitude longitude) /lognlambda=(-6 to 1 by 0.1);
   score data=pred out=prediction1;
run;
```

Partial output from these statements is displayed in Output 89.3.1 and Output 89.3.2.

Output 89.3.1 Partial Output from PROC TPSPLINE for Data Set SO_4

Raw Data

The TPSPLINE Procedure
Dependent Variable: so4

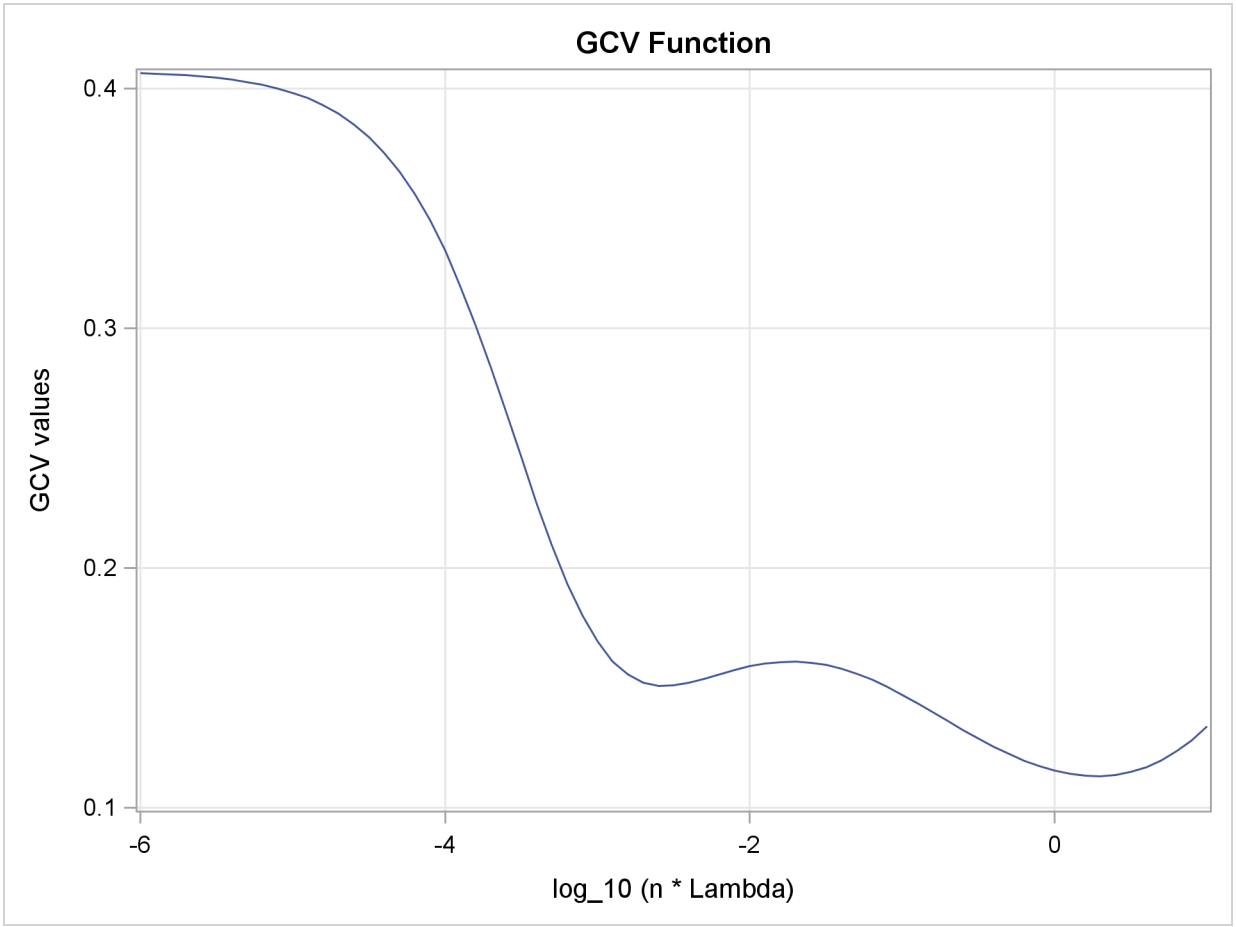
Dimension of Polynomial Space	3

Output 89.3.2 Partial Output from PROC TPSPLINE for Data Set SO_4

Summary Statistics
of Final Estimation

log10(n*Lambda)	0.2770
Smoothing Penalty	2.4588
Residual SS	12.4450
Tr(I-A)	140.2750
Model DF	38.7250
Standard Deviation	0.2979

The following statements use PROC TEMPLATE to produce Output 89.3.3:



```
proc template;
define statgraph plotgcv;
begingraph;
   entrytitle "GCV Function";
   layout overlay/xaxisopts=(griddisplay=on label="log_10 (n * Lambda)")
                  yaxisopts=(griddisplay=on label="GCV values");
                  seriesplot x=lognlambda y=gcv;
   endlayout;
endgraph;
end;
run;

ods graphics on;

proc sgrender data=gcv template=plotgcv;run;
```

Output 89.3.3 displays the plot of the GCV function versus NLAMBDA in $\log_{10}$ scale. The GCV function has two minima. PROC TPSPLINE locates the global minimum at 0.277005. The plot also displays a local minimum located around -2.56. Note that the TPSPLINE procedure might not always find the global minimum, although it did in this case.

Output 89.3.3 GCV Function of SO_4 Data Set

The following analysis specifies the option LOGNLAMBDA0=-2.56. The output is displayed in Output 89.3.4.

```
proc tpspline data=so4;
   model so4 = (latitude longitude) /lognlambda0=-2.56;
   score data=pred out=prediction2;
run;
```

Summary Statistics of Final Estimation

log10(n*Lambda)	-2.5600
Smoothing Penalty	177.2144
Residual SS	0.0438
Tr(I-A)	7.2086
Model DF	171.7914
Standard Deviation	0.0779

The smoothing penalty in Output 89.3.4 is much larger than that displayed in Output 89.3.1. The estimate in Output 89.3.1 uses a large λ value and, therefore, the surface is smoother than the estimate by using LOGNLAMBDA=−2.56 (Output 89.3.4).

The estimate based on LOGNLAMBDA=−2.56 has a larger value for the degrees of freedom, and it has a much smaller standard deviation.

However, a smaller standard deviation in nonparametric regression does not necessarily mean that the estimate is good: a small λ value always produces an estimate closer to the data and, therefore, a smaller standard deviation.

The following statements use PROC TEMPLATE to define a template to produce two contour plots of the estimates by the two minima. A graph of two contour plots is then rendered by the SGRENDER procedure.

```
proc template;
define statgraph two_contour;
begingraph /designheight=360;
   entrytitle "TPSPLINE Fits";
   layout lattice / columns=2 rows=1
                    columndatarange=unionall
                    rowdatarange=unionall
                    columngutter=10;
      rowaxes;
         rowaxis / offsetmin=0 offsetmax=0 display=all
                   linearopts=(thresholdmin=0 thresholdmax=0);
      endrowaxes;

      layout overlay/
         xaxisopts=(offsetmin=0 offsetmax=0
                    linearopts=(thresholdmin=0 thresholdmax=0))
         yaxisopts=(display=none);
         entry "lognlambda = 0.277"/location=outside valign=top
               textattrs=graphlabeltext;
         scatterplot x=longitude y=latitude /primary=true markerattrs=(size=0);
         contourplotparm x=longitude y=latitude z=P_so4/
                         name="cont1" nlevels=5
                         contourtype=gradient;
         contourplotparm x=longitude y=latitude z=P_so4/
                         contourtype=labeledline nlevels=5;
      endlayout;

      layout overlay/
         xaxisopts=(offsetmin=0 offsetmax=0
                    linearopts=(thresholdmin=0 thresholdmax=0))
         yaxisopts=(display=none);
         entry "loglambda = -2.56"/location=outside valign=top
               textattrs=graphlabeltext;
         scatterplot x=longitude y=latitude /primary=true markerattrs=(size=0);
         contourplotparm x=longitude y=latitude z=P_so4_b/
                         name="cont2" nlevels=5
                         contourtype=gradient;
         contourplotparm x=longitude y=latitude z=P_so4_b/
                         contourtype=labeledline nlevels=5;
      endlayout;

      row2headers;
         continuouslegend "cont1" / title="Predicted SO4" pad=(left=10);
      endrow2headers;

   endlayout;
endgraph;
end;
run;
```

Compare the two estimates by examining the contour plots of both estimates (Output 89.3.5).

Output 89.3.5 Contour Plot of TPSPLINE Estimates with Different Lambdas

As the contour plots show, the estimate with LOGNLAMBDA=0.277 might represent the underlying trend, while the estimate with the LOGNLAMBDA=–2.56 is very rough and might be modeling the noise component.

Example 89.4: Large Data Set Application

This example illustrates how you can use the D= option to decrease the computation time needed by the TPSPLINE procedure. Note that, while the D= option can be helpful in decreasing computation time for large data sets, it might produce unexpected results when used with small data sets.

The following statements generate the data set large:

```
data large;
   do x=-5 to 5 by 0.02;
      y=5*sin(3*x)+1*rannor(57391);
      output;
   end;
run;
```

The data set large contains 501 observations with one independent variable x and one dependent variable y. The following statements invoke PROC TPSPLINE to produce a thin-plate smoothing spline estimate and the associated 99% confidence interval. The output statistics are saved in the data set fit1.

```
proc tpspline data=large;
   model y  =(x) /lognlambda=(-5 to -1 by 0.2) alpha=0.01;
   output out=fit1 pred lclm uclm;
run;
```

The results from this MODEL statement are displayed in Output 89.4.1.

Output 89.4.1 Output from PROC TPSPLINE without the D= Option

The difference between the two estimates is minimal. However, the CPU time for the second MODEL statement is only about $1/7$ of the CPU time used in the first model fit.

The following statements produce a plot for comparison of the two estimates:

```
data fit2;
   set fit2;
   P1_y     = P_y;
   LCLM1_y  = LCLM_y;
   UCLM1_y  = UCLM_y;
   drop P_y LCLM_y UCLM_y;

proc sort data=fit1;
   by x y;
proc sort data=fit2;
   by x y;

data comp;
   merge fit1 fit2;
      by x y;
   label p1_y   ="Yhat1" p_y="Yhat0"
         lclm_y ="Lower CL"
         uclm_y ="Upper CL";

ods graphics on;

proc sgplot data=comp;
   title "Comparison of Two Estimates";
   title2 "with and without the D= Option";

   yaxis label="Predicted y Values";
   xaxis label="x";

   band x=x lower=lclm_y upper=uclm_y /name="range"
                     legendlabel="99% CI of Predicted y without D=";
   series x=x y=P_y/ name="P_y" legendlabel="Predicted y without D="
                     lineattrs=graphfit(thickness=1px pattern=shortdash);
   series x=x y=P1_y/ name="P1_y" legendlabel="Predicted y with D="
                     lineattrs=graphfit(thickness=1px color=red);
   discretelegend "range" "P_y" "P1_y";
run;

ods graphics off;
```

The estimates from fit1 and fit2 are displayed in Output 89.4.3 with the 99% confidence interval from the fit1 output data set.

Output 89.4.3 Comparison of Two PROC TPSPLINE Fits with and without the D= Option

Example 89.5: Computing a Bootstrap Confidence Interval

This example illustrates how you can construct a bootstrap confidence interval by using the multiple responses feature in PROC TPSPLINE.

Numerous epidemiological observations have indicated that exposure to solar radiation is an important factor in the etiology of melanoma. The following data present age-adjusted melanoma incidences for 37 years from the Connecticut Tumor Registry (Houghton, Flannery, and Viola 1980). The data are analyzed by Ramsay and Silverman (1997).

```
data melanoma;
   input  year incidences @@;
datalines;
1936    0.9   1937   0.8  1938   0.8  1939   1.3
1940    1.4   1941   1.2  1942   1.7  1943   1.8
1944    1.6   1945   1.5  1946   1.5  1947   2.0
1948    2.5   1949   2.7  1950   2.9  1951   2.5
1952    3.1   1953   2.4  1954   2.2  1955   2.9
1956    2.5   1957   2.6  1958   3.2  1959   3.8
1960    4.2   1961   3.9  1962   3.7  1963   3.3
1964    3.7   1965   3.9  1966   4.1  1967   3.8
1968    4.7   1969   4.4  1970   4.8  1971   4.8
1972    4.8
;
```

The variable incidences records the number of melanoma cases per 100,000 people for the years 1936 to 1972. The following model fits the data and requests a 90% Bayesian confidence interval along with the estimate:

```
proc tpspline data=melanoma;
   model incidences = (year) /alpha = 0.1;
   output out = result pred uclm lclm;
run;
```

The output is displayed in Output 89.5.1

Output 89.5.1 Output from PROC TPSPLINE for the MELANOMA Data

```
                    Comparison of Two Estimates
                  with and without the D= Option

                       The TPSPLINE Procedure
                 Dependent Variable:  incidences

                      Summary of Input Data Set

              Number of Non-Missing Observations    37
              Number of Missing Observations         0
              Unique Smoothing Design Points        37

                      Summary of Final Model

              Number of Regression Variables        0
              Number of Smoothing Variables         1

              Dimension of Polynomial Space         2
```

Output 89.5.1 *continued*

Summary Statistics of Final Estimation	
log10(n*Lambda)	-0.0607
Smoothing Penalty	0.5171
Residual SS	1.2243
Tr(I-A)	22.5852
Model DF	14.4148
Standard Deviation	0.2328

The following statements produce a plot of the estimated curve:

```
ods graphics on;

proc sgplot data=result;
   title "Age-adjusted Melanoma Incidence for 37 Years";

   xaxis label="year";
   yaxis label="Incidences";

   band x=year lower=lclm_incidences upper=uclm_incidences/name="range"
               legendlabel="90% CI of Predicted incidences";
   scatter x=year y=incidences/name="obs" legendlabel="incidences";
   series x=year y=p_incidences/name="pred"
               legendlabel="predicted values of incidences"
               lineattrs=graphfit(thickness=1px);

   discretelegend "range" "obs" "pred";
run;
```

The estimated curve is displayed with 90% confidence interval bands in Output 89.5.2. The number of melanoma incidences exhibits a periodic pattern and increases over the years. The periodic pattern is related to sunspot activity and the accompanying fluctuations in solar radiation.

Output 89.5.2 PROC TPSPLINE Estimate and 90% Confidence Interval of Data Set MELANOMA

Wang and Wahba (1995) compare several bootstrap confidence intervals to Bayesian confidence intervals for smoothing splines. Both bootstrap and Bayesian confidence intervals are across-the-curve intervals, not pointwise intervals. They concluded that bootstrap confidence intervals work as well as Bayesian intervals concerning average coverage probability. Additionally, bootstrap confidence intervals appear to be better for small sample sizes. Based on their simulation, the "percentile-t interval" bootstrap interval performs better than the other types of bootstrap intervals.

Suppose that $\hat{f}_{\hat{\lambda}}$ and $\hat{\sigma}$ are the estimates of f and σ from the data. Assume that $\hat{f}_{\hat{\lambda}}$ is the "true" f, and generate the bootstrap sample as follows:

$$y_i^* = \hat{f}_{\hat{\lambda}}(\mathbf{x}_i) + \epsilon_i^*, \quad i = 1, \cdots, n$$

where $\boldsymbol{\epsilon}^* = (\epsilon_1^*, \cdots, \epsilon_n^*)^T \sim N(0, \hat{\sigma}\mathbf{I})$. Denote $f_{\hat{\lambda}}^*(\mathbf{x}_i)$ as the random variable of the bootstrap estimate at $\mathbf{x}_i$. Repeat this process K times, so that at each point $\mathbf{x}_i$, you have K bootstrap estimates $\hat{f}_{\hat{\lambda}}(\mathbf{x}_i)$ or K realizations of $f_{\hat{\lambda}}^*(\mathbf{x}_i)$. For each fixed $\mathbf{x}_i$, consider the following statistic D_i^*, which is similar to the Student's t statistic:

$$D_i^* = \left(f_{\hat{\lambda}}^*(\mathbf{x}_i) - \hat{f}_{\hat{\lambda}}(\mathbf{x}_i)\right) / \hat{\sigma}_i{}^*$$

where $\hat{\sigma}_i{}^*$ is the estimate of $\hat{\sigma}$ based on the ith bootstrap sample.

Suppose $\chi_{\alpha/2}$ and $\chi_{1-\alpha/2}$ are the lower and upper $\alpha/2$ points, respectively, of the empirical distribution of D_i^*. The $(1-\alpha)100\%$ bootstrap confidence interval is defined as

$$\left(\hat{f}_{\hat{\lambda}}(\mathbf{x}_i) - \chi_{1-\alpha/2}\hat{\sigma},\ \ \hat{f}_{\hat{\lambda}}(\mathbf{x}_i) - \chi_{\alpha/2}\hat{\sigma}\right)$$

Bootstrap confidence intervals are easy to interpret and can be used with any distribution. However, because they require K model fits, their construction is computationally intensive.

The multiple dependent variables feature in PROC TPSPLINE enables you to fit multiple models with the same independent variables. The procedure calculates the matrix decomposition part of the calculations only once, regardless of the number of dependent variables in the model. These calculations are responsible for most of the computing time used by the TPSPLINE procedure. This feature is particularly useful when you need to generate a bootstrap confidence interval.

To construct a bootstrap confidence interval, perform the following tasks:

- Fit the data by using PROC TPSPLINE and obtain estimates $\hat{f}_{\hat{\lambda}}(\mathbf{x}_i)$ and $\hat{\sigma}$.
- Generate K bootstrap samples based on $\hat{f}_{\hat{\lambda}}(\mathbf{x}_i)$ and $\hat{\sigma}$.
- Fit the K bootstrap samples with the TPSPLINE procedure to obtain estimates of $\hat{f}^*_{\hat{\lambda}}(\mathbf{x}_i)$ and $\hat{\sigma}_i^*$.
- Compute D_i^* and the values $\chi_{\alpha/2}$ and $\chi_{1-\alpha/2}$.

The following statements illustrate this process:

```
proc tpspline data=melanoma;
   model incidences = (year) /alpha = 0.05;
   output out = result pred uclm lclm;
run;
```

The output from the initial PROC TPSPLINE analysis is displayed in Output 89.5.3. The data set result contains the predicted values and confidence limits from the analysis.

Output 89.5.3 Output from PROC TPSPLINE for the MELANOMA Data

```

Output 89.5.3 *continued*

Summary of Final Model

Number of Regression Variables	0
Number of Smoothing Variables	1
Order of Derivative in the Penalty	2
Dimension of Polynomial Space	2

Summary Statistics of Final Estimation

log10(n*Lambda)	-0.0607
Smoothing Penalty	0.5171
Residual SS	1.2243
Tr(I-A)	22.5852
Model DF	14.4148
Standard Deviation	0.2328

The following statements illustrate how you can obtain a bootstrap confidence interval for the Melanoma data set. The following statements create the data set bootstrap. The observations are created with information from the preceding PROC TPSPLINE execution; as displayed in Output 89.5.3, $\hat{\sigma} = 0.232823$. The values of $\hat{f}_{\hat{\lambda}}(\mathbf{x}_i)$ are stored in the data set result in the variable P_incidence.

```
data bootstrap;
   set result;
   array y{1070} y1-y1070;
   do i=1 to 1070;
      y{i} = p_incidences + 0.232823*rannor(123456789);
   end;
   keep y1-y1070 p_incidences year;
run;

proc tpspline data=bootstrap;
   ods output FitStatistics=FitResult;
   id p_incidences;
   model y1-y1070 = (year);
   output out=result2;
run;
```

The DATA step generates 1,070 bootstrap samples based on the previous estimate from PROC TPSPLINE. For this data set, some of the bootstrap samples result in λs (selected by the GCV function) that cause problematic behavior. Thus, an additional 70 bootstrap samples are generated.

The ODS listing destination is closed before PROC TPSPLINE is invoked. The model fits all the y1...y1070 variables as dependent variables, and the models are fit for all bootstrap samples simultaneously. The output data set result2 contains the variables year, y1...y1070, p_y1...p_y1070, and p_incidences.

The ODS OUTPUT statement writes the FitStatistics table to the data set FitResult. The data set FitResult contains the two variables Parameter and Value. The FitResult data set is used in subsequent calculations for D_i^*.

In the data set FitResult, there are 63 estimates with a standard deviation of zero, suggesting that the estimates provide perfect fits of the data and are caused by $\hat{\lambda}$s that are approximately equal to zero. For small sample sizes, there is a positive probability that the λ chosen by the GCV function will be zero (Wang and Wahba 1995).

In the following steps, these cases are removed from the bootstrap samples as "bad" samples: they represent failure of the GCV function.

The following SAS statements manipulate the data set FitResult, retaining the standard deviations for all bootstrap samples and merging FitResult with the data set result2, which contains the estimates for bootstrap samples. In the final data set boot, the D_i^* statistics are calculated.

```
data FitResult;
   set FitResult;
   if Parameter="Standard Deviation";
   keep Value;
run;

proc transpose data=FitResult out=sd prefix=sd;

data result2;
   if _N_ = 1 then set sd;
   set result2;

data boot;
   set result2;
   array y{1070}  p_y1-p_y1070;
   array sd{1070} sd1-sd1070;
   do i=1 to 1070;
      if sd{i} > 0 then do;
         d = (y{i} - P_incidences)/sd{i};
         obs = _N_;
         output;
      end;
   end;
   keep d obs P_incidences year;
run;
```

The following SAS statements retain the first 1,000 bootstrap samples and calculate the values $\chi_{\alpha/2}$ and $\chi_{1-\alpha/2}$ with $\alpha = 0.1$.

```
proc sort data=boot;
   by obs;
run;

data boot;
   set boot;
      by obs;
   retain n;

   if first.obs then n=1;
      else n=n+1;
   if n > 1000 then delete;
run;

proc sort data=boot;
   by obs d;
run;

data chi1 chi2 ;
   set boot;
   if (_N_ = (obs-1)*1000+50)  then output chi1;
   if (_N_ = (obs-1)*1000+950) then output chi2;
run;

proc sort data=result;
   by year;
run;

proc sort data=chi1;
   by year;
run;

proc sort data=chi2;
   by year;
run;

data result;
   merge result
      chi1(rename=(d=chi05))
      chi2(rename=(d=chi95));
   keep year incidences P_incidences lower upper
        LCLM_incidences UCLM_incidences;

   lower = -chi95*0.232823 + P_incidences;
   upper = -chi05*0.232823 + P_incidences;

   label  lower="Lower 90% CL (Bootstrap)"
          upper="Upper 90% CL (Bootstrap)"
          lclm_incidences="Lower 90% CL (Bayesian)"
          uclm_incidences="Upper 90% CL (Bayesian)";
run;
```

The data set result contains the variables year and incidences, the PROC TPSPLINE estimate P_incidences, and the 90% Bayesian and 90% bootstrap confidence intervals.

The following statements produce Output 89.5.4:

```
proc sgplot data=result;
   title "Age-adjusted Melanoma Incidence for 37 Years";

   xaxis label="year";
   yaxis label="Incidences";

   band x=year lower=lclm_incidences upper=uclm_incidences/name="bayesian"
               legendlabel="90% Bayesian CI of Predicted incidences"
               fillattrs=(color=red);
   band x=year lower=lower upper=upper/name="bootstrap"
               legendlabel="90% Bootstrap CI of Predicted incidences"
               transparency=0.05;
   scatter x=year y=incidences/name="obs" legendlabel="incidences";
   series x=year y=p_incidences/name="pred"
               legendlabel="predicted values of incidences"
               lineattrs=graphfit(thickness=1px);

   discretelegend "bayesian" "bootstrap" "obs" "pred";
run;

ods graphics off;
```

Output 89.5.4 displays the plot of the variable incidences, the predicted values, and the Bayesian and bootstrap confidence intervals.

The plot shows that the bootstrap confidence interval is similar to the Bayesian confidence interval. However, the Bayesian confidence interval is symmetric around the estimates, while the bootstrap confidence interval is not.

Output 89.5.4 Comparison of Bayesian and Bootstrap Confidence Interval for Data Set MELANOMA

Overview: TRANSREG Procedure

The TRANSREG (transformation regression) procedure fits linear models, optionally with smooth, spline, Box-Cox, and other nonlinear transformations of the variables. You can use PROC TRANSREG to fit a curve through a scatter plot or fit multiple curves, one for each level of a classification variable. You can also constrain the functions to be parallel or monotone or have the same intercept. PROC TRANSREG can be used to code experimental designs and classification variables prior to their use in other analyses.

The TRANSREG procedure fits many types of linear models, including the following:

- ordinary regression and ANOVA
- metric and nonmetric conjoint analysis (Green and Wind 1975; de Leeuw, Young, and Takane 1976)
- linear models with Box-Cox (1964) transformations of the dependent variables
- regression with a smooth (Reinsch 1967), spline (de Boor 1978; van Rijckevorsel 1982), monotone spline (Winsberg and Ramsay 1980), or penalized B-spline (Eilers and Marx 1996) fit function
- metric and nonmetric vector and ideal point preference mapping (Carroll 1972)
- simple, multiple, and multivariate regression with variable transformations (Young, de Leeuw, and Takane 1976; Winsberg and Ramsay 1980; Breiman and Friedman 1985)
- redundancy analysis (Stewart and Love 1968) with variable transformations (Israels 1984)
- canonical correlation analysis with variable transformations (van der Burg and de Leeuw 1983)
- response surface regression (Meyers 1976; Khuri and Cornell 1987) with variable transformations

The data set can contain variables measured on nominal, ordinal, interval, and ratio scales (Siegel 1956). You can specify any mix of these variable types for the dependent and independent variables. PROC TRANSREG can do the following:

- transform nominal variables by scoring the categories to minimize squared error (Fisher 1938), or treat nominal variables as classification variables
- transform ordinal variables by monotonically scoring the ordered categories so that order is weakly preserved (adjacent categories can be merged) and squared error is minimized. Ties can be optimally untied or left tied (Kruskal 1964). Ordinal variables can also be transformed to ranks.
- transform interval and ratio scale of measurement variables linearly or nonlinearly with spline (de Boor 1978; van Rijckevorsel 1982), monotone spline (Winsberg and Ramsay 1980), penalized B-spline (Eilers and Marx 1996), smooth (Reinsch 1967), or Box-Cox (Box and Cox 1964) transformations. In addition, logarithmic, exponential, power, logit, and inverse trigonometric sine transformations are available.

Transformations produced by the PROC TRANSREG multiple regression algorithm, requesting spline transformations, are often similar to transformations produced by the ACE smooth regression method of Breiman and Friedman (1985). However, ACE does not explicitly optimize a loss function (de Leeuw 1986), while PROC TRANSREG explicitly minimizes a squared-error criterion.

PROC TRANSREG extends the ordinary general linear model by providing optimal variable transformations that are iteratively derived. PROC TRANSREG iterates until convergence, alternating two major steps: finding least-squares estimates of the model parameters given the current scoring of the data, and finding least-squares estimates of the scoring parameters given the current set of model parameters. This is called the method of alternating least squares (Young 1981).

For more background on alternating least-squares optimal scaling methods and transformation regression methods, see Young, de Leeuw, and Takane (1976), Winsberg and Ramsay (1980), Young (1981), Gifi (1990), Schiffman, Reynolds, and Young (1981), van der Burg and de Leeuw (1983), Israels (1984), Breiman and Friedman (1985), and Hastie and Tibshirani (1986). (These are just a few of the many relevant sources.)

There have been a number of enhancements to PROC TRANSREG with this release, and a few changes. The most notable enhancement is the addition of graphical displays produced through ODS Graphics. Now, fit, transformation, residual, and other plots are created when you enable ODS Graphics. See the sections "Fitting a Curve through a Scatter Plot" on page 7109, "Box-Cox Transformations" on page 7181, "Using Splines and Knots" on page 7192, "Linear and Nonlinear Regression Functions" on page 7209, "Simultaneously Fitting Two Regression Functions" on page 7213, "Smoothing Splines" on page 7222, and "ODS Graphics" on page 7301 for more information. See Example 90.1, Example 90.2, Example 90.3, and Example 90.6 for examples. The PBSPLINE transformation (penalized B-spline) is new with this release. It can be used to fit curves through a scatter plot with an automatic selection of the smoothing parameter. See the sections "Fitting a Curve through a Scatter Plot" on page 7109 and "Penalized B-Splines" on page 7219, and see Example 90.3 for an example. How the results of the SMOOTH transformation are used in PROC TRANSREG has changed with this release. In particular, some aspects of the syntax along with the coefficients, degrees of freedom, and predicted values have changed. See the section "Smoothing Splines Changes and Enhancements" on page 7227 for more information about the changes, and see the NSR algorithm option for a way to restore the old functionality. Also, the iteration history table is not printed in certain models, such as those with smoothing splines and penalized B-splines, where it is known that no iterations are necessary. See the section "Iteration History Changes and Enhancements" on page 7230 for more information.

New options include the following:
ORTHOGONAL *t-option* – requests an orthogonal-contrast coding
STANDORTH *t-option* – requests a standardized-orthogonal coding
PLOTS= PROC statement option – ODS Graphics selection
NSR *a-option* – no smoothing spline model restrictions
TSUFFIX= *a-option* – shortens transformed variable labels
PBSPLINE *transform* – penalized B-splines

New options for penalized B-splines include the following:
AIC *t-option* – Akaike's information criterion
AICC *t-option* – corrected AIC
CV *t-option* – cross validation criterion
GCV *t-option* – generalized cross validation criterion
RANGE *t-option* – LAMBDA= specifies a range, not a list
SBC *t-option* – Schwarz's Bayesian criterion

Changed options include the following:
LAMBDA= *t-option* – smoothing parameter list or range, now used with PBSPLINE
EVENLY= *t-option* – evenly spaced interior knots, now creates evenly spaced exterior knots as well
SMOOTH *transform* – new *df* calculations, printed output
SSPLINE *transform* – new *df* calculations, just like SMOOTH

Getting Started: TRANSREG Procedure

This section provides several examples that illustrate a few of the more basic features of PROC TRANSREG.

Fitting a Curve through a Scatter Plot

PROC TRANSREG can fit curves through data and detect nonlinear relationships among variables. This example uses a subset of the data from an experiment in which nitrogen oxide emissions from a single cylinder engine are measured for various combinations of fuel and equivalence ratio (Brinkman 1981). The following statements create the SAS data set:

```
title 'Gasoline and Emissions Data';

data Gas;
   input Fuel :$8. EqRatio NOx @@;
   label EqRatio = 'Equivalence Ratio'
         NOx     = 'Nitrogen Oxide Emissions';
   datalines;
Ethanol  0.907 3.741 Ethanol  0.761 2.295 Ethanol  1.108 1.498
Ethanol  1.016 2.881 Ethanol  1.189 0.760 Ethanol  1.001 3.120
Ethanol  1.231 0.638 Ethanol  1.123 1.170 Ethanol  1.042 2.358

... more lines ...

Ethanol  0.655 1.900
;
```

The next step fits a spline or curve through the data and displays the regression results. For information about splines and knots, see the sections "Smoothing Splines" on page 7222, "Linear and Nonlinear Regression Functions" on page 7209, "Simultaneously Fitting Two Regression Functions" on page 7213, and "Using Splines and Knots" on page 7192, as well as Example 90.1. The following statements produce Figure 90.1:

```
ods graphics on;

* Request a Spline Transformation of Equivalence Ratio;
proc transreg data=Gas solve ss2 plots=(transformation obp residuals);
   model identity(nox) = spline(EqRatio / nknots=4);
run;
```

The SOLVE algorithm option, or *a-option*, requests a direct solution for both the transformation and the parameter estimates. For many models, PROC TRANSREG with the SOLVE *a-option* can produce exact results without iteration. The SS2 (Type II sums of squares) *a-option* requests regression and ANOVA results. The PLOTS= option requests plots of the variable transformations, a plot of the observed values by the predicted values, and a plot of the residuals. The dependent variable NOx was specified with an IDENTITY transformation, which means that it will not be transformed, just as in ordinary regression. The independent variable EqRatio, in contrast, is transformed by using a cubic spline with four knots. The NKNOTS= option is known as a transformation option, or *t-option*. Graphical results are enabled with the two ODS statements that precede the PROC TRANSREG step, and the results are terminated with the final two ODS statements. The results are shown in Figure 90.1 through Figure 90.5.

Figure 90.1 Iteration, ANOVA, and Regression Results

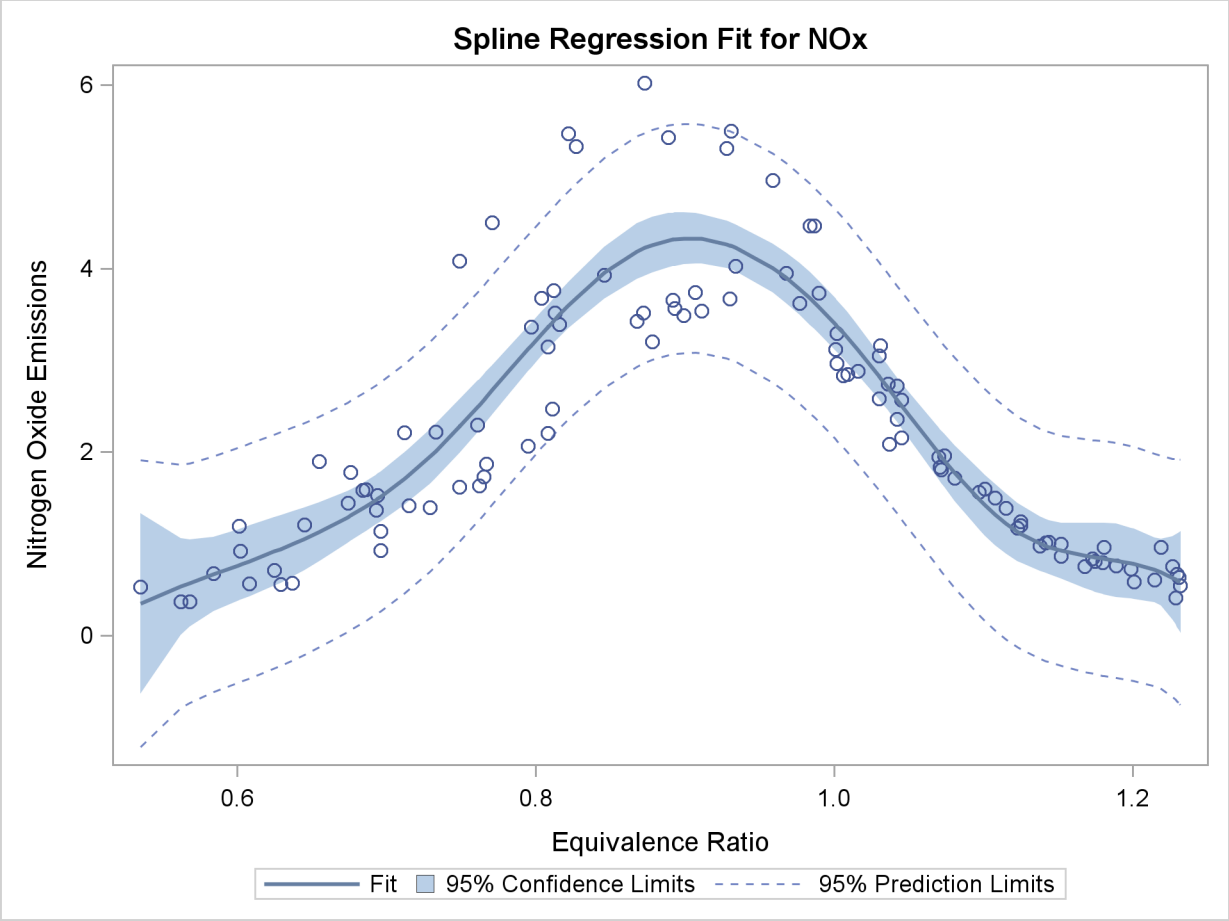
Dependent Mean	2.25022	Adj R-Sq	0.8122
Coeff Var	27.26334		

Univariate Regression Table Based on the Usual Degrees of Freedom

Variable	DF	Coefficient	Type II Sum of Squares	Mean Square	F Value	Pr > F	Label
Intercept	1	8.3165407	324.065	324.065	861.04	<.0001	Intercept
Spline(EqRatio)	7	-6.5740158	180.095	25.728	68.36	<.0001	Equivalence Ratio

PROC TRANSREG increases the squared multiple correlation from the original value of 0.00917 to 0.82429. Iteration 0 shows the fit before the data are transformed, and iteration 1 shows the fit after the transformation, which was directly solved for in the initial iteration. The change values for iteration 0 show the change from the original EqRatio variable to the transformed EqRatio variable. For this model, no improvement on the initial solution is possible, so in iteration 1, all change values are zero. The ANOVA and regression results show that you are fitting a model with 7 model parameters, 4 knots plus a degree 3 or cubic spline. The overall model fit is identical to the test for the spline transformation, since there is only one term in the model besides the intercept, and the results are significant at the 0.0001 level. The transformations are shown next in Figure 90.2.

Figure 90.2 Transformations



The transformation plots show the identity transformation of NOx and the nonlinear spline transformation of EqRatio. These plots are requested with the PLOTS=TRANSFORMATION option. The plot on the left shows that NOx is unchanged, which is always the case with the IDENTITY transformation. In contrast, the spline transformation of EqRatio is nonlinear. It is this nonlinear transformation of EqRatio that accounts for the increase in fit that is shown in the iteration history table.

Figure 90.3 Residuals

The residuals plot in Figure 90.3 shows the residuals as a function of the transformed independent variable.

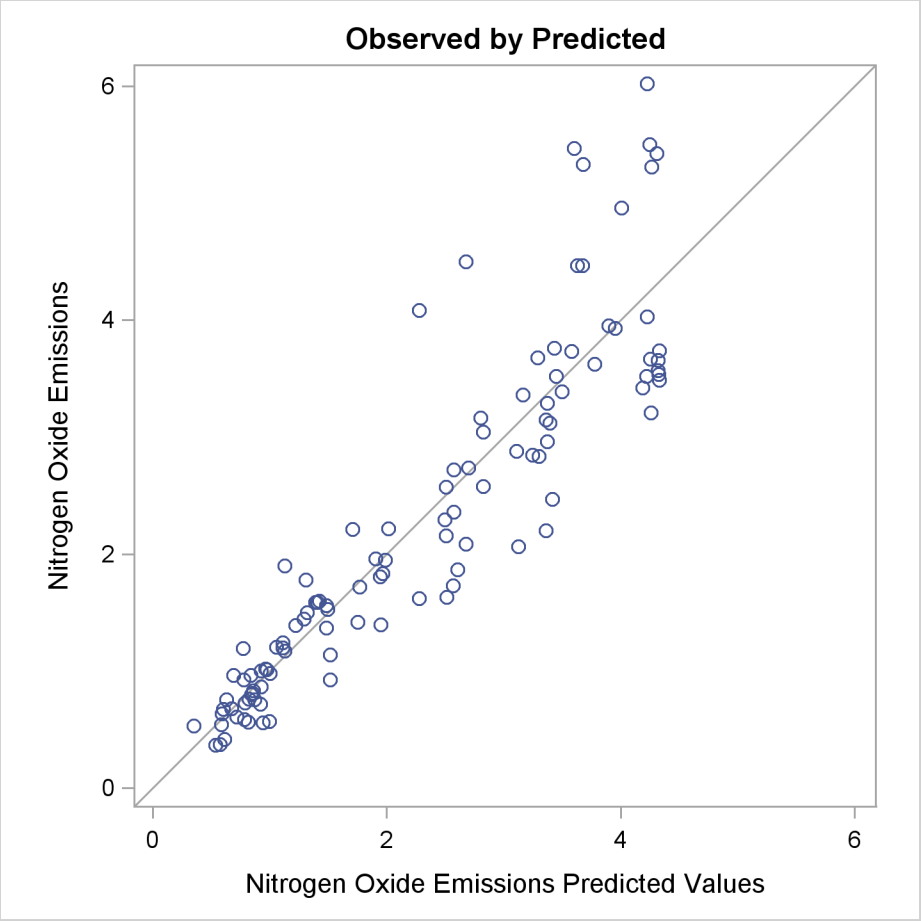


Figure 90.4 Fitting a Curve through a Scatter Plot

The "Spline Regression Fit" plot in Figure 90.4 displays the nonlinear regression function plotted through the original data, along with 95% confidence and prediction limits. This plot clearly shows that nitrous oxide emissions are largest in the middle range of equivalence ratio, 0.08 to 1.0, and are much lower for the extreme values of equivalence ratio, such as around 0.6 and 1.2.

This plot is produced by default when ODS Graphics is enabled and when there is an IDENTITY dependent variable and one non-CLASS independent variable. The plot consists of an ordinary scatter plot of NOx plotted as a function of EqRatio. It also contains the predicted values of NOx, which are a function of the spline transformation of EqRatio (or TEqRatio shown previously), and are plotted as a function of EqRatio. Similarly, it contains confidence limits based on NOx and TEqRatio.

Figure 90.5 Observed by Predicted

The "Observed by Predicted" values plot in Figure 90.5 displays the dependent variable plotted as a function of the regression predicted values along with a linear regression line, which for this plot always has a slope of 1. This plot was requested with the OBP or OBSERVEDBYPREDICTED suboption in the PLOTS= option. The residual differences between the transformed data and the regression line show how well the nonlinearly transformed data fit a linear-regression model. The residuals look mostly random; however, they are larger for larger values of NOx, suggesting that maybe this is not the optimal model. You can also see this by examining the fit of the function through the original scatter plot in Figure 90.4. Near the middle of the function, the residuals are much larger. You can refit the model, this time requesting separate functions for each type of fuel. You can request the original scatter plot, without any regression information and before the variables are transformed, by specifying the SCATTER suboption in the PLOTS= option.

These next statements fit an additive model with separate functions for each of the different fuels. The statements produce Figure 90.6 through Figure 90.9.

```
* Separate Curves and Intercepts;
proc transreg data=Gas solve ss2 additive plots=(transformation obp);
   model identity(nox) = class(Fuel / zero=none) |
                         spline(EqRatio / nknots=4 after);
run;
```

The ADDITIVE *a-option* requests an additive model, where the regression coefficients are absorbed into the transformations, and so the final regression coefficients are all one. The specification CLASS(Fuel / ZERO=NONE) recodes fuel into a set of three binary variables, one for each of the three fuels in this data set. The vertical bar between the CLASS and SPLINE specifications request both main effects and interactions. For this model, it requests both a separate intercept and a separate spline function for each fuel. The original two variables, Fuel and EqRatio, are replaced by six variables—three binary intercept terms and three spline variables. The three spline variables are zero when their corresponding intercept binary variable is zero, and nonzero otherwise. The nonzero parts are optimally transformed by the analysis. The AFTER *t-option* specified with the SPLINE transformation specifies that the four knots should be selected independently for each of the three spline transformations, *after* EqRatio is crossed with the CLASS variable. Alternatively, and by default, the knots are chosen by examining EqRatio before it is crossed with the CLASS variable, and the same knots are used for all three transformations. The results are shown in Figure 90.6.

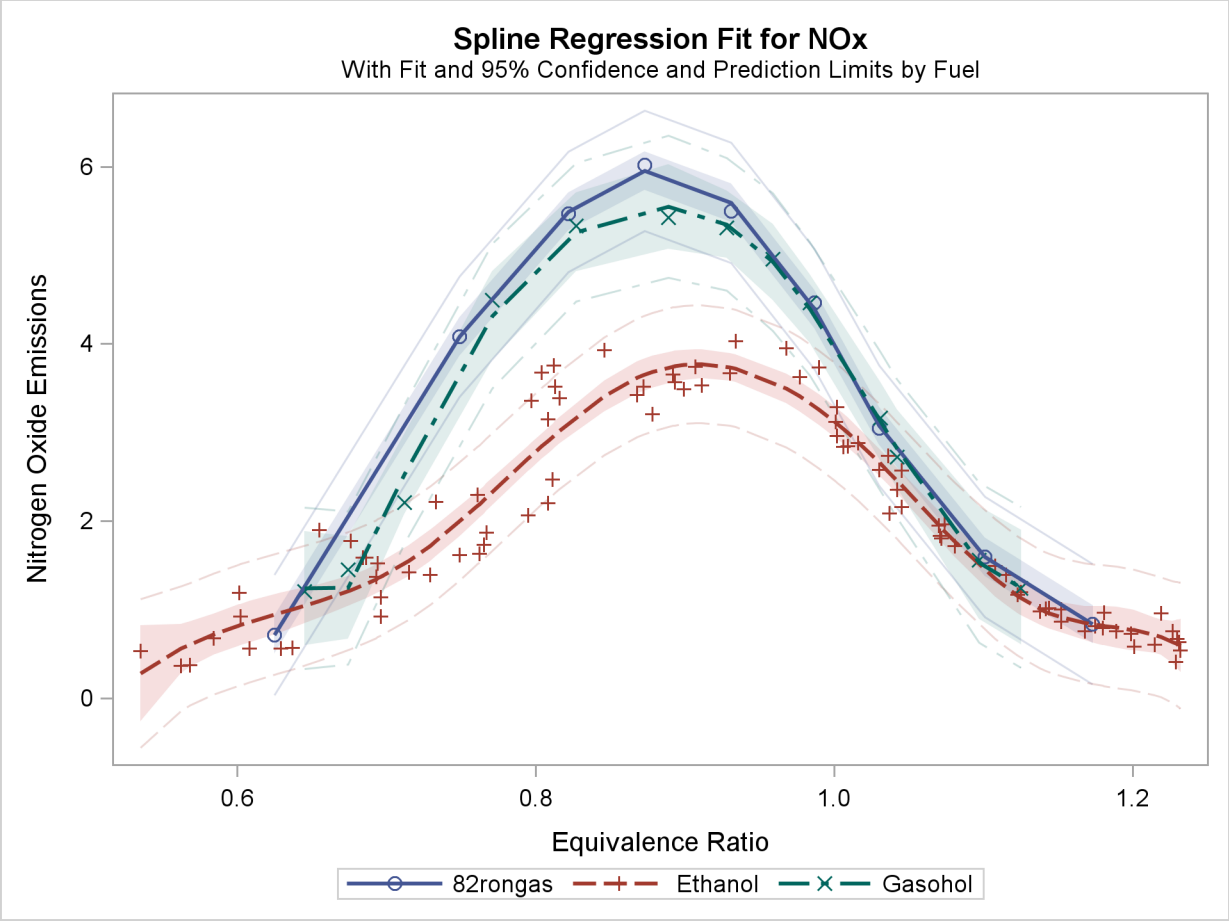
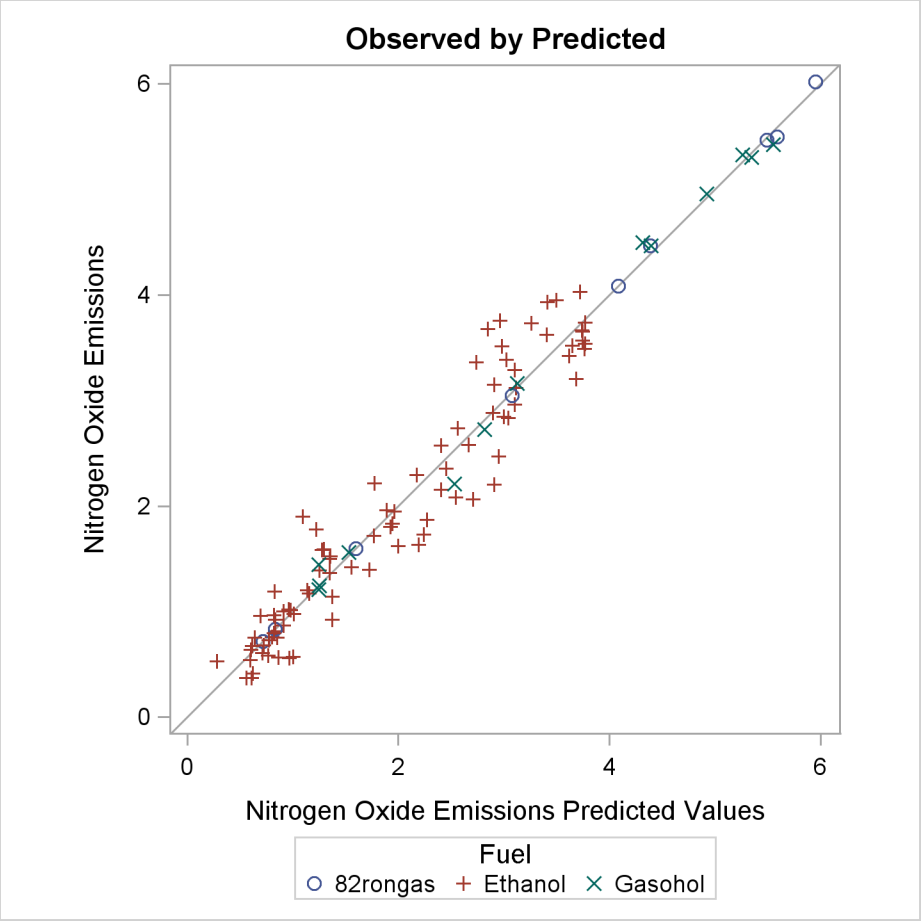
ZERO=SUM and ZERO=NONE coefficient tests are not exact when there are iterative transformations. Those tests are performed holding all transformations fixed, and so are generally liberal.



The first iteration history table in Figure 90.6 hows that PROC TRANSREG increases the squared multiple correlation from the original value of 0.18543 to 0.95870. The remaining iteration histories pertain to PROC TRANSREG's process of comparing models to test hypotheses. The important thing to look for is convergence in all of the tables.

Figure 90.7 Transformations



The transformations, shown in Figure 90.7, show that for all three groups, the transformation of EqRatio is approximately quadratic.

Figure 90.8 Fitting Curves through a Scatter Plot

The fit plot, shown in Figure 90.8, shows that there are in fact three distinct functions in the data. The increase in fit over the previous model comes from individually fitting each group instead of providing an aggregate fit.

Figure 90.9 Observed by Predicted

The residuals in the observed by predicted plot displayed in Figure 90.9 are much better for this analysis.

You could fit a model that is "in between" the two models shown previously. This next model provides for separate intercepts for each group, but calls for a common function. There are still three functions, one per group, but their shapes are the same, and they are equidistant or parallel. This model is requested by omitting the vertical bar so that separate intercepts are requested, but not separate curves within each group. The following statements fit the separate intercepts model and create Figure 90.10:

```
* Separate Intercepts;
proc transreg data=Gas solve ss2 additive;
   model identity(nox) = class(Fuel / zero=none)
                         spline(EqRatio / nknots=4);
run;
```

The ANOVA table and fit plot are shown in Figure 90.10.

Gasoline and Emissions Data

The TRANSREG Procedure

Univariate ANOVA Table Based on the Usual Degrees of Freedom

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	9	196.7548	21.86165	100.61	<.0001
Error	100	21.7294	0.21729		
Corrected Total	109	218.4842			

Figure 90.10 *continued*

Now, squared multiple correlation is 0.9005, which is smaller than the model with the unconstrained separate curves, but larger than the model with only one curve. Because of the restrictions on the shapes, these curves do not track the data as well as the previous model. However, this model is more parsimonious with many fewer parameters.

There are other ways to fit curves through scatter plots in PROC TRANSREG. For example, you could use smoothing splines or penalized B-splines, as is illustrated next. The following statements fit separate curves through each group by using penalized B-splines and produce Figure 90.11:

```
* Separate Curves and Intercepts with Penalized B-Splines;
proc transreg data=Gas ss2 plots=transformation lprefix=0;
   model identity(nox) = class(Fuel / zero=none) * pbspline(EqRatio);
run;

ods graphics off;
```

This example asks for a separate penalized B-spline transformation, PBSPLINE, of equivalence ratio for each type of fuel. The LPREFIX=0 *a-option* is specified in the PROC statement so that zero characters of the CLASS variable name (Fuel) are used in constructing the labels for the coded variables. The result is label components like "Ethanol" instead of the more redundant "Fuel Ethanol". The results of this analysis are shown in Figure 90.11.

```

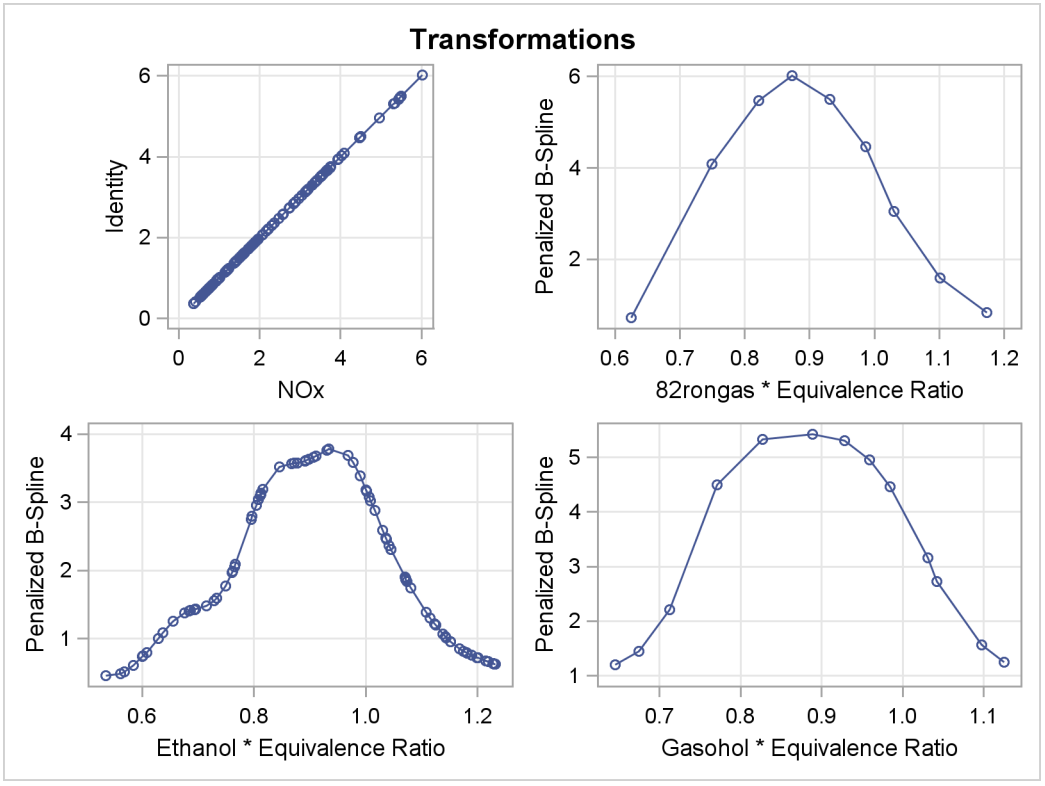
Figure 90.11 *continued*



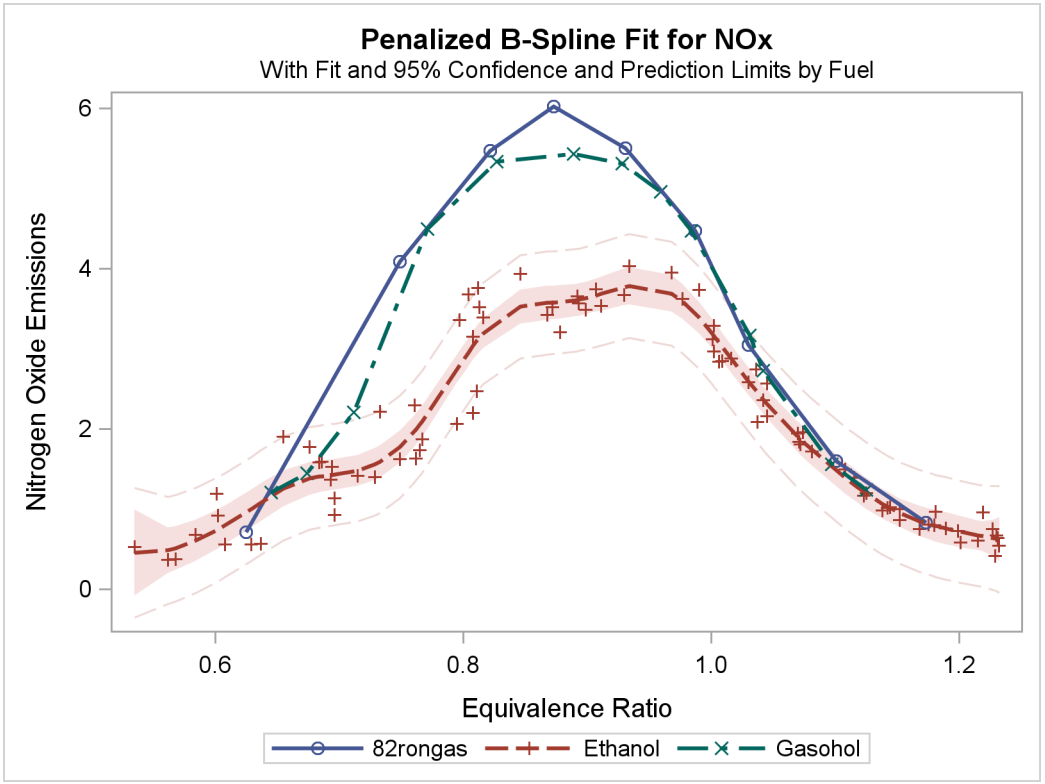


Figure 90.11 *continued*

With penalized B-splines, the degrees of freedom are based on the trace of the transformation hat matrix and are typically not integers. The first panel of plots shows AICC as a function of lambda, the smoothing parameter. The smoothing parameter is automatically chosen, and since the smoothing parameters range from essentially 0 to almost 800, it is clear that some functions are smoother than others. The plots of the criterion (AICC in this example) as a function of lambda use a linear scale for the horizontal axis when the range of lambdas is small, as in the first and third plot, and a log scale when the range is large, as in the second plot. The transformation for equivalence ratio for Ethanol required more smoothing than for the other two fuels. All three have an overall quadratic shape, but for Ethanol, the function more closely follows the smaller variations in the data. You could get similar results with SPLINE by using more knots.

For other examples of curve fitting by using PROC TRANSREG, see the sections "Smoothing Splines" on page 7222, "Linear and Nonlinear Regression Functions" on page 7209, "Simultaneously Fitting Two Regression Functions" on page 7213, and "Using Splines and Knots" on page 7192, as well as Example 90.3. These examples include cases where multiple curves are fit through scatter plots with multiple groups. Special cases include linear models with separate slopes and separate intercepts. Many constraints on the slopes, curves, and intercepts are possible.

Main-Effects ANOVA

This example shows how to use PROC TRANSREG to code and fit a main-effects ANOVA model. PROC TRANSREG has very extensive and versatile options for coding or creating so-called dummy variables. PROC TRANSREG is commonly used to code classification variables before they are used for analysis in other procedures. See the sections "Using the DESIGN Output Option" on page 7293 and "Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO" on page 7297. In this example, the input data set contains the dependent variables `y`, factors `x1` and `x2`, and 12 observations. PROC TRANSREG can be useful for coding even before running procedures with a CLASS statement because of its detailed options that enable you to control how the coded variable names and labels are constructed. The following statements perform a main-effects ANOVA and display the results in Figure 90.12 and Figure 90.13:

```
title 'Introductory Main-Effects ANOVA Example';

data a;
   input y x1 $ x2 $;
   datalines;
8 a a
7 a a
4 a b
3 a b
5 b a
4 b a
2 b b
1 b b
8 c a
7 c a
5 c b
2 c b
;
```

```
* Fit a main-effects ANOVA model with 1, 0, -1 coding;
proc transreg ss2;
   model identity(y) = class(x1 x2 / effects);
   output coefficients replace;
run;

* Display TRANSREG output data set;
proc print label;
   format intercept -- x2a 5.2;
run;
```

The SS2 *a-option* requests results based on Type II sums of squares. The simple ANOVA model is fit by designating y as an IDENTITY variable, which specifies no transformation. The independent variables are specified with a CLASS expansion, which replaces them with coded variables. There are $(3-1)+(2-1)=3$ coded variables created by the CLASS specification, since the two CLASS variables have 3 and 2 different values or levels. In this case, the EFFECTS *t-option* is specified. This option requests an *effects coding* (displayed in Figure 90.13), which is also called a deviations from means or 0, 1, –1 coding. The OUTPUT statement requests an output data set with the data and coded variables. The COEFFICIENTS output option, or *o-option*, adds the parameter estimates and marginal means to the data set. The REPLACE *o-option* specifies that the transformed variables should replace the original variables in the output data set. The output data set variable names are the same as the original variable name. In an example like this, there are no nonlinear transformations; the transformed variables are the same as the original variables. The REPLACE *o-option* is used to eliminate unnecessary and redundant transformed variables from the output data set. The results of the PROC TRANSREG step are shown in Figure 90.12.

Class.x2a	1	1.8333333	40.333	40.333	42.09	0.0002	x2 a

Figure 90.12 shows the ANOVA results, fit statistics, and regression tables. The output data set, with the coded design, parameter estimates and means, is shown in Figure 90.13. For more information about PROC TRANSREG for ANOVA and other codings, see the section "ANOVA Codings" on page 7230.

Figure 90.13 Output Data Set from PROC TRANSREG

Introductory Main-Effects ANOVA Example

Obs	_TYPE_	_NAME_	y	Intercept	x1 a	x1 b	x2 a	x1	x2
1	SCORE	ROW1	8	1.00	1.00	0.00	1.00	a	a
2	SCORE	ROW2	7	1.00	1.00	0.00	1.00	a	a
3	SCORE	ROW3	4	1.00	1.00	0.00	-1.00	a	b
4	SCORE	ROW4	3	1.00	1.00	0.00	-1.00	a	b
5	SCORE	ROW5	5	1.00	0.00	1.00	1.00	b	a
6	SCORE	ROW6	4	1.00	0.00	1.00	1.00	b	a
7	SCORE	ROW7	2	1.00	0.00	1.00	-1.00	b	b
8	SCORE	ROW8	1	1.00	0.00	1.00	-1.00	b	b
9	SCORE	ROW9	8	1.00	-1.00	-1.00	1.00	c	a
10	SCORE	ROW10	7	1.00	-1.00	-1.00	1.00	c	a
11	SCORE	ROW11	5	1.00	-1.00	-1.00	-1.00	c	b
12	SCORE	ROW12	2	1.00	-1.00	-1.00	-1.00	c	b
13	M COEFFI	y	.	4.67	0.83	-1.67	1.83		
14	MEAN	y	.	.	5.50	3.00	6.50		

The output data set has three kinds of observations, identified by values of _TYPE_ as follows:

- When _TYPE_='SCORE', the observation contains the following information about the dependent and independent variables:
  - y is the original dependent variable.
  - x1 and x2 are the independent classification variables, and the Intercept through x2 a columns contain the main-effects design matrix that PROC TRANSREG creates. The variable names are Intercept, x1a, x1b, and x2a. Their labels are shown in the listing.
- When _TYPE_='M COEFFI', the observation contains coefficients of the final linear model (parameter estimates).
- When _TYPE_='MEAN', the observation contains the marginal means.

The observations with _TYPE_='SCORE' form the score or data partition of the output data set, and the observations with _TYPE_='M COEFFI' and _TYPE_='MEAN' form the output statistics partition of the output data set.

Syntax: TRANSREG Procedure

The following statements are available in PROC TRANSREG:

```
PROC TRANSREG <DATA=SAS-data-set>
                <PLOTS=(plot-requests)>
                <OUTTEST=SAS-data-set> <a-options> <o-options> ;
  MODEL  <transform(dependents   </ t-options>)>
         <transform(dependents   </ t-options>) . . . =>
           transform(independents </ t-options>)
         <transform(independents </ t-options>) . . . > </ a-options> ;
  OUTPUT <OUT=SAS-data-set> <o-options> ;
  ID variables ;
  FREQ variable ;
  WEIGHT variable ;
  BY variables ;
```

To use PROC TRANSREG, you need both the PROC TRANSREG and MODEL statements. To produce an OUT= output data set, the OUTPUT statement is required. PROC TRANSREG enables you to specify the same options in more than one statement. All of the MODEL statement *a-options* (algorithm options) and all of the OUTPUT statement *o-options* (output options) can also be specified in the PROC TRANSREG statement. You can abbreviate all *a-options*, *o-options*, and *t-options* (transformation options) to their first three letters. This is a special feature of PROC TRANSREG and is not generally true of other SAS/STAT procedures. See Table 90.1 for a list of options available in the PROC TRANSREG statement.

The PROC TRANSREG statement starts the TRANSREG procedure. Optionally, this statement identifies an input and an OUTTEST= data set, specifies the algorithm and other computational details, requests displayed output, and controls the contents of the OUT= data set (which is created with the OUTPUT statement). The DATA= and OUTTEST= options can appear only in the PROC TRANSREG statement. All *a-options* and *o-options* are described in the sections on either the MODEL or OUTPUT statement, in which these options can also be specified.

The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC TRANSREG statement. The remaining statements are described in alphabetical order.

PROC TRANSREG Statement

PROC TRANSREG < **DATA=***SAS-data-set* >
< **PLOTS=***(plot-requests)* >
< **OUTTEST=***SAS-data-set* > < *a-options* > < *o-options* > **;**

The PROC TRANSREG statement invokes the TRANSREG procedure. Optionally, this statement identifies an input and an OUTTEST= data set, specifies the algorithm and other computational details, requests displayed output, and controls the contents of the OUT= data set (which is created with the OUTPUT statement). The DATA=, OUTTEST=, and PLOTS= options can appear only in the PROC TRANSREG statement. The options listed in Table 90.1 are available in the PROC TRANSREG statement. The *a-options* are also available in the MODEL statement, and the *o-options* are also available in the OUTPUT statement.

Table 90.1 Options Available in the PROC TRANSREG Statement

Option	Description
Data Set Options (PROC Statement)	
DATA=	specifies input SAS data set
OUTTEST=	specifies output test statistics data set
ODS Graphics (PROC Statement)	
PLOTS=	specifies ODS Graphics selection
Input Control (PROC or MODEL)	
REITERATE	restarts the iterations
TYPE=	specifies input observation type
Method and Iterations (PROC or MODEL)	
CCONVERGE=	specifies minimum criterion change
CONVERGE=	specifies minimum data change
MAXITER=	specifies maximum number of iterations
METHOD=	specifies iterative algorithm
NCAN=	specifies number of canonical variables
NSR	specifies no restrictions on smoothing models
SINGULAR=	specifies singularity criterion
SOLVE	attempts direct solution instead of iteration

Table 90.1 *continued*

Option	Description
Missing Data Handling (PROC or MODEL)	
INDIVIDUAL	fits each model individually (METHOD=MORALS)
MONOTONE=	includes monotone special missing values
NOMISS	excludes observations with missing values
UNTIE=	unties special missing values
Intercept and CLASS Variables (PROC or MODEL)	
CPREFIX=	specifies CLASS coded variable name prefix
LPREFIX=	specifies CLASS coded variable label prefix
NOINT	specifies no intercept or centering
ORDER=	specifies order of CLASS variable levels
REFERENCE=	controls output of reference levels
SEPARATORS=	controls CLASS coded variable label separators
Control Displayed Output (PROC or MODEL)	
ALPHA=	specifies confidence limits alpha
CL	displays parameter estimate confidence limits
DETAIL	displays model specification details
HISTORY	displays iteration histories
NOPRINT	suppresses displayed output
PBOXCOXTABLE	prints the Box-Cox log likelihood table
RSQUARE	displays the R square
SHORT	suppresses the iteration histories
SS2	displays regression results
TEST	displays ANOVA table
TSUFFIX=	shortens transformed variable labels
UTILITIES	displays conjoint part-worth utilities
Standardization (PROC or MODEL)	
ADDITIVE	fits additive model
NOZEROCONSTANT	does not zero constant variables
TSTANDARD=	specifies transformation standardization
Predicted Values, Residuals, Scores (PROC or OUTPUT)	
CANONICAL	outputs canonical scores
CLI	outputs individual confidence limits
CLM	outputs mean confidence limits
DESIGN=	specifies design matrix coding
DREPLACE	replaces dependent variables
IREPLACE	replaces independent variables
LEVERAGE	outputs leverage
NORESTOREMISSING	does not restore missing values
NOSCORES	suppresses output of scores
PREDICTED	outputs predicted values
REDUNDANCY=	outputs redundancy variables
REPLACE	replaces all variables

Table 90.1 *continued*

Option	Description
RESIDUALS	outputs residuals
Output Data Set Coefficients (PROC or OUTPUT)	
COEFFICIENTS	outputs coefficients
COORDINATES=	outputs ideal point coordinates
MEANS	outputs marginal means
MREDUNDANCY	outputs redundancy analysis coefficients
Output Data Set Variable Name Prefixes (PROC or OUTPUT)	
ADPREFIX=	specifies dependent variable approximations
AIPREFIX=	specifies independent variable approximations
CDPREFIX=	specifies canonical dependent variables
CILPREFIX=	specifies conservative individual lower CL
CIPREFIX=	specifies canonical independent variables
CIUPREFIX=	specifies conservative-individual-upper CL
CMLPREFIX=	specifies conservative-mean-lower CL
CMUPREFIX=	specifies conservative-mean-upper CL
DEPENDENT=	specifies METHOD=MORALS untransformed dependent
LILPREFIX=	specifies liberal-individual-lower CL
LIUPREFIX=	specifies liberal-individual-upper CL
LMLPREFIX=	specifies liberal-mean-lower CL
LMUPREFIX=	specifies liberal-mean-upper CL
PPREFIX=	specifies predicted values
RDPREFIX=	specifies residuals
RPREFIX=	specifies redundancy variables
TDPREFIX=	specifies transformed dependents
TIPREFIX=	specifies transformed independents
Macros Variables (PROC or OUTPUT)	
MACRO	creates macro variables
Other Options (PROC or OUTPUT)	
APPROXIMATIONS	outputs dependent and independent approximations
CCC	outputs canonical correlation coefficients
CEC	outputs canonical elliptical point coordinates
CPC	outputs canonical point coordinates
CQC	outputs canonical quadratic point coordinates
DAPPROXIMATIONS	outputs approximations to transformed dependents
IAPPROXIMATIONS	outputs approximations to transformed independents
MEC	outputs elliptical point coordinates
MPC	outputs point coordinates
MQC	outputs quadratic point coordinates
MRC	outputs multiple regression coefficients

DATA=*SAS-data-set*

specifies the SAS data set to be analyzed. If you do not specify the DATA= option, PROC TRANSREG uses the most recently created SAS data set. The data set must be an ordinary SAS data set; it cannot be a special TYPE= data set.

OUTTEST=*SAS-data-set*

specifies an output data set to contain hypothesis tests results. When you specify the OUTTEST= option, the data set contains ANOVA results. When you specify the SS2 *a-option*, regression tables are also output. When you specify the UTILITIES *o-option*, conjoint analysis part-worth utilities are also output. For more information about the OUTTEST= data set, see the section "OUTTEST= Output Data Set" on page 7275.

PLOTS <(*global-plot-options***)> <= *plot-request* <(options)>>**

PLOTS <(*global-plot-options***)> <= (***plot-request* <(options)> **<... *plot-request* <(options)>>)>**

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=none
plots=(residuals transformation)
plots(unpack)=boxcox
plots(unpack)=(transformation boxcox(p=0))
plots=(residuals(unpack) transformation(dep unp) boxcox(t rmse))
```

You must enable ODS Graphics before requesting plots, for example, like this:

```
ods graphics on;

proc transreg plots=all;
   model identity(y) = pbspline(x);
run;

ods graphics off;
```

For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." If you have enabled ODS Graphics but do not specify the PLOTS= option, then PROC TRANSREG produces a default set of plots. The fit, scatter, residual, and observed-by-predicted plots are available with METHOD=MORALS and also with METHOD=UNIVARIATE when there is only one dependent variable. When no method is specified and there is more than one dependent variable, and when regression plots are requested, the default method is set to METHOD=MORALS. When there is more than one dependent variable, when METHOD= is not specified, or when METHOD=MORALS is specified and PLOTS=ALL is specified, the plots that are produced might be different from those you would see with METHOD=UNIVARIATE and PLOTS=ALL. Certain plots appear by default when ODS Graphics is enabled and certain combinations of options are specified. The Box-Cox $F = t^2$ and log-likelihood plots appear when a BOXCOX dependent variable transformation is specified. The regression fit plot appears for models with a single dependent variable that is not transformed (for example, IDENTITY(y)), a single quantitative independent variable that might or might not be transformed, and at most one CLASS independent variable. Preference mapping plots appear when the COORDINATES *o-option* is used.

The global plot options include the following:

INTERPOLATE

INT

uses observations that are excluded from the analysis for interpolation in the fit and transformation plots. By default, observations with zero weight are excluded from all plots. These include observations with a zero, negative, or missing weight or frequency and observations excluded due to missing and invalid values. You can specify PLOTS(INTERPOLATE)=(*plot-requests*) to include some of these observations in the plots. You might want to use this option, for example, with sparse data sets to show smoother functions over the range of the data (see the section "The PLOTS(INTERPOLATE) Option" on page 7302). Observations with missing values in CLASS variables are excluded from the plots even when PLOTS(INTERPOLATE) is specified.

ONLY

ONL

suppresses the default plots. Only plots specifically requested are displayed.

UNPACKPANEL

UNPACK

UNP

suppresses paneling. By default, multiple plots can appear in some output panels. Specify UNPACKPANEL to get each plot in a separate panel. You can specify PLOTS(UNPACKPANEL) to unpack the default plots. You can also specify UNPACKPANEL as a suboption with TRANSFORMATION, RESIDUALS, PBSPLINE, and BOXCOX.

The plot requests include the following:

ALL

produces all appropriate plots. You can specify other options with ALL; for example, to request all plots and unpack only the residuals, specify PLOTS=(ALL RES(UNP)).

BOXCOX < (options) >

BOX < (options) >

requests a display of the results of the Box-Cox transformation. These results are displayed by default when there is a Box-Cox transformation. The BOXCOX plot request has the following options:

P=*n*

adds t or $F = t^2$ curves to the legend for the functions where $p(t) < n$, where t is the t statistic corresponding to the optimal lambda. You can specify P=0 to suppress the legend and P=1 to see all curves in the legend. The default value comes from the BOXCOX(variable / ALPHA=p) specification, which by default is 0.05.

RMSE

RMS

plots the root mean square error as a function of lambda.

T

plots t statistics rather than $F = t^2$ statistics.

UNPACKPANEL

UNPACK

UNP

plots the t or $F = t^2$ and log-likelihood plots in separate panels.

FIT < (options) >

requests a regression fit plot. This plot is produced by default whenever it is appropriate. It is produced when the dependent variable is specified with the IDENTITY *transform*, and when there is one quantitative independent variable (for example, IDENTITY for linear fit or SPLINE or one of the other transformations for a nonlinear fit) and at most one CLASS variable. When there is a CLASS variable, separate fits are produced within levels based on your model. You would specify the FIT plot request only to specify a FIT option or with the ONLY global plot option. The FIT plot request has the following options:

NOCLM

suppresses the confidence limits in regression fit plots.

NOCLI

suppresses the individual prediction limits in regression fit plots.

NOOBS

suppresses the observations showing only the fit function and optionally the confidence and prediction limits.

NONE

suppresses all plots.

OBSERVEDBYPREDICTED

OBP

OBS

plots the transformed dependent variable as a function of the regression predicted values.

PBSPLINE < (UNPACKPANEL) >

PBS < (UNPACK) >

requests the penalized B-spline criterion plots. You would specify the PBSPLINE plot request only to specify a PBSPLINE option or with the ONLY global plot option. The PBSPLINE plot request has the following option:

UNPACKPANEL

UNPACK

UNP

plots each criterion plot in a separate panel.

PREFMAP

PRE

plots ideal point or vector preference mapping results when either two IDENTITY or two POINT independent variables are specified along with the COORDINATES option.

RESIDUALS < (options) >

RES < (options) >

plots the residuals as a function of each of the transformed independent variables, except coded CLASS variables. The RESIDUALS plot request has the following options:

CLASS

CLA

plots the residuals as a function of each of the transformed independent variables, including coded CLASS variables. Note that the ALL plot request, which you use to request all plots, specifies the RESIDUALS plot request without the CLASS option.

UNPACKPANEL

UNPACK

UNP

plots the residuals in separate plots, not several per panel.

SMOOTH

SMO

adds a LOESS smooth function to the residuals plots.

SCATTER

SCA

plots the scatter plot of observed data, before the transformations, for models with a single quantitative dependent variable, a single quantitative independent variable, and at most one CLASS independent variable.

TRANSFORMATION < (options) >

TRA < (options) >

plots the variable transformations. The TRANSFORMATION plot request has the following options:

DEPENDENTS

DEP

plots only the dependent variable transformations.

INDEPENDENTS

IND

plots only the independent variable transformations.

UNPACKPANEL

UNPACK

UNP

plots the transformations in separate plots, not several per panel.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC TRANSREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for PROC TRANSREG. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the *Base SAS Procedures Guide*.

FREQ Statement

FREQ *variable* **;**

If one variable in the input data set represents the frequency of occurrence for other values in the observation, specify the variable's name in a FREQ statement. PROC TRANSREG then treats the data set as if each observation appeared *n* times, where *n* is the value of the FREQ variable for the observation. Noninteger values of the FREQ variable are truncated to the largest integer less than the FREQ value. The observation is used in the analysis only if the value of the FREQ statement variable is greater than or equal to 1.

ID Statement

ID *variables* **;**

The ID statement includes additional character or numeric variables in the OUT= data set. The variables must be contained in the input data set. The first variable is used to label points in PREFMAP plots. These variables are also used in some plots as tip variables.

MODEL Statement

MODEL < *transform*(*dependents* < / *t-options* >) >
< *transform*(*dependents* < / *t-options* >) . . . =>
transform(*independents* < / *t-options* >)
< *transform*(*independents* < / *t-options* >) . . . > < / *a-options* > **;**

The MODEL statement specifies the dependent and independent variables (*dependents* and *independents*, respectively) and specifies the transformation (*transform*) to apply to each variable. Only one MODEL statement can appear in PROC TRANSREG. The *t-options* are transformation options, and the *a-options* are algorithm options. The *t-options* provide details for the transformation; these depend on the *transform* chosen. The *t-options* are listed after a slash in the parentheses that enclose the variable list (either *dependents* or *independents*). The *a-options* control the algorithm used, details of iteration, details of how the intercept and coded variables are generated, and displayed output details. The *a-options* are listed after the entire model specification (the *dependents*, *independents*, transformations, and *t-options*) and after a slash. You can also specify the algorithm options in the PROC TRANSREG statement. When you specify the DESIGN *o-option*, *dependents* and an equal sign are not required. The operators *, |, and @ from the GLM procedure are available for interactions with the CLASS expansion and the IDENTITY transformation. They are used as follows:

```
   Class(a * b ...
         c | d ...
         e | f ... @ n)
Identity(a * b ...
         c | d ...
         e | f ... @ n)
```

In addition, transformations and spline expansions can be crossed with classification variables as follows:

transform`(var) * class(group)`
transform`(var) | class(group)`

See the section "Types of Effects" on page 2488 in Chapter 39, "The GLM Procedure," for a description of the @, *, and | operators and see the section "Model Statement Usage" on page 7179 for information about how to use these operators in PROC TRANSREG. Note that nesting is not implemented in PROC TRANSREG.

The next three sections discuss the transformations available (*transforms*) (see the section "Families of Transformations" on page 7140), the transformation options (*t-options*) (see the section "Transformation Options (t-options)" on page 7147), and the algorithm options (*a-options*) (see the section "Algorithm Options (a-options)" on page 7158).

Families of Transformations

In the MODEL statement, *transform* specifies a transformation in one of the following five families:

Variable expansions	preprocess the specified variables, replacing them with more variables.
Nonoptimal transformations	preprocess the specified variables, replacing each one with a single new nonoptimal, nonlinear transformation.
Nonlinear fit transformations	preprocess the specified variable, replacing it with a smooth transformation, fitting one or more nonlinear functions through a scatter plot.
Optimal transformations	replace the specified variables with new, iteratively derived optimal transformation variables that fit the specified model better than the original variable (except for contrived cases where the transformation fits the model exactly as well as the original variable).
Other transformations	are the IDENTITY and SSPLINE transformations. These do not fit into the preceding categories.

The transformations and expansions listed in Table 90.2 are available in the MODEL statement.

Table 90.2 Transformation Families

Transformation	Description
Variable Expansions	
BSPLINE	B-spline basis
CLASS	set of coded variables
EPOINT	elliptical response surface
POINT	circular response surface & PREFMAP
PSPLINE	piecewise polynomial basis
QPOINT	quadratic response surface
Nonoptimal Transformations	
ARSIN	inverse trigonometric sine
EXP	exponential
LOG	logarithm
LOGIT	logit
POWER	raises variables to specified power
RANK	transforms to ranks
Nonlinear Fit Transformations	
BOXCOX	Box-Cox
PBSPLINE	penalized B-splines
SMOOTH	noniterative smoothing spline
Optimal Transformations	
LINEAR	linear
MONOTONE	monotonic, ties preserved
MSPLINE	monotonic B-spline

Table 90.2 *continued*

Transformation	Description
OPSCORE	optimal scoring
SPLINE	B-spline
UNTIE	monotonic, ties not preserved
Other Transformations	
IDENTITY	identity, no transformation
SSPLINE	iterative smoothing spline

You can use any transformation with either dependent or independent variables (except the SMOOTH and PBSPLINE transformations, which can be used only with independent variables, and BOXCOX, which can be used only with dependent variables). However, the variable expansions are usually more appropriate for independent variables.

The *transform* is followed by a variable (or list of variables) enclosed in parentheses. Here is an example:

```
model log(y) = class(x);
```

This example finds a LOG transformation of y and performs a CLASS expansion of x. Optionally, depending on the *transform*, the parentheses can also contain *t-options*, which follow the variables and a slash. Here is an example:

```
model identity(y) = spline(x1 x2 / nknots=3);
```

The preceding statement finds SPLINE transformations of x1 and x2. The NKNOTS= *t-option* used with the SPLINE transformation specifies three knots. The `identity(y)` transformation specifies that y is not to be transformed.

The rest of this section provides syntax details for members of the five families of transformations listed at the beginning of this section. The *t-options* are discussed in the section "Transformation Options (t-options)" on page 7147.

Variable Expansions

PROC TRANSREG performs variable expansions before iteration begins. Variable expansions expand the original variables into a typically larger set of new variables. The original variables are those that are listed in parentheses after *transform*, and they are sometimes referred to by the name of the *transform*. For example, in CLASS(x1 x2), x1 and x2 are sometimes referred to as CLASS expansion variables or simply CLASS variables, and the expanded variables are referred to as coded or sometimes "dummy" variables. Similarly, in POINT(Dim1 Dim2), Dim1 and Dim2 are sometimes referred to as POINT variables.

The resulting variables are not transformed by the iterative algorithms after the initial preprocessing. Observations with missing values for these types of variables are excluded from the analysis.

The POINT, EPOINT, and QPOINT variable expansions are used in preference mapping analyses (also called PREFMAP, external unfolding, ideal point regression) (Carroll 1972) and for response

surface regressions. These three expansions create circular, elliptical, and quadratic response or preference surfaces (see the section "Point Models" on page 7255 and Example 90.6). The CLASS variable expansion is used for main-effects ANOVA.

The following list provides syntax and details for the variable expansion *transforms*.

BSPLINE

BSP

expands each variable to a B-spline basis. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY= *t-options* with the BSPLINE expansion. When DEGREE=n (3 by default) with k knots (0 by default), $n + k + 1$ variables are created. In addition, the original variable appears in the OUT= data set before the ID variables. For example, **`bspline(x)`** expands x into x_0 x_1 x_2 x_3 and outputs x as well. The x_: variables contain the B-spline basis vectors (which are the same basis vectors that the SPLINE and MSPLINE transformations use internally). The columns of the BSPLINE expansion sum to a column of ones, so an implicit intercept model is fit when the BSPLINE expansion is specified. If you specify the BSPLINE expansion for more than one variable, the model is less than full rank. Variables specified in a BSPLINE expansion must be numeric, and they are typically continuous. See the sections "SPLINE and MSPLINE Transformations" on page 7261 and "SPLINE, BSPLINE, and PSPLINE Comparisons" on page 7264 for more information about B-splines.

CLASS

CLA

expands the variables to a set of coded or "dummy" variables. PROC TRANSREG uses the values of the formatted variables to determine class membership. The specification **`class(x1 x2)`** fits a simple main-effects model, **`class(x1 | x2)`** fits a main-effects and interactions model, and **`class(x1|x2|x3|x4@2 x1*x2*x3)`** fits a model with all main effects, all two-way interactions, and one three-way interaction. Variables specified with the CLASS expansion can be either character or numeric; numeric variables should be discrete. See the section "ANOVA Codings" on page 7230 for more information about CLASS variables. See the section "Model Statement Usage" on page 7179 for information about how to use the operators @, *, and | in PROC TRANSREG.

EPOINT

EPO

expands the variables for an elliptical response surface regression or for an elliptical ideal point regression. Specify the COORDINATES *o-option* to output PREFMAP ideal elliptical point model coordinates to the OUT= data set. Each axis of the ellipse (or ellipsoid) is oriented in the same direction as one of the variables. The EPOINT expansion creates a new variable for each original variable. The value of each new variable is the square of each observed value for the corresponding original variable. The regression analysis then uses both sets of variables (original and squared). Variables specified with the EPOINT expansion must be numeric, and they are typically continuous. See the section "Point Models" on page 7255 and Example 90.6 for more information about point models.

POINT

POI

expands the variables for a circular response surface regression or for a circular ideal point regression. Specify the COORDINATES *o-option* to output PREFMAP ideal point model coordinates to the OUT= data set. The POINT expansion creates a new variable having a value for each observation that is the sum of squares of all the POINT variables. This new variable is added to the set of variables and is used in the regression analysis. For more information about ideal point regression, see Carroll (1972). Variables specified with the POINT expansion must be numeric, and they are typically continuous. See the section "Point Models" on page 7255 and Example 90.6 for more information about point models.

PSPLINE

PSP

expands each variable to a piecewise polynomial basis. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY *t-options* with PSPLINE. When DEGREE=n (3 by default) with k knots (0 by default), $n + k$ variables are created. In addition, the original variable appears in the OUT= data set before the ID variables. For example, **`pspline(x / nknots=1)`** expands x into x_1 x_2 x_3 x_4 and outputs x as well. Unlike BSPLINE, an intercept is not implicit in the columns of PSPLINE. Variables specified with the PSPLINE expansion must be numeric, and they are typically continuous. See the sections "SPLINE, BSPLINE, and PSPLINE Comparisons" on page 7264 and "Using Splines and Knots" on page 7192 for more information about splines. Also see Smith (1979) for a good introduction to piecewise polynomial splines.

QPOINT

QPO

expands the variables for a quadratic response surface regression or for a quadratic ideal point regression. Specify the COORDINATES *o-option* to output PREFMAP quadratic ideal point model coordinates to the OUT= data set. For m QPOINT variables, $m(m+1)/2$ new variables are created containing the squares and crossproducts of the original variables. The regression analysis uses both sets (original and crossed). Variables specified with the QPOINT expansion must be numeric, and they are typically continuous. See the section "Point Models" on page 7255 and Example 90.6 for more information about point models.

Nonoptimal Transformations

The nonoptimal transformations, like the variable expansions, are computed before the iterative algorithm begins. Nonoptimal transformations create a single new transformed variable that replaces the original variable. The new variable is not transformed by the subsequent iterative algorithms (except for a possible linear transformation with missing value estimation). The following list provides syntax and details for nonoptimal variable transformations.

ARSIN

ARS

finds an inverse trigonometric sine transformation. Variables specified in the ARSIN *transform* must be numeric and in the interval ($-1.0 \leq x \leq 1.0$), and they are typically continuous.

EXP

exponentiates variables (x is transformed to a^x). To specify the value of a, use the PARAMETER= *t-option*. By default, a is the mathematical constant $e = 2.718\ldots$. Variables specified with the EXP *transform* must be numeric, and they are typically continuous.

LOG

transforms variables to logarithms (x is transformed to $\log_a(x)$). To specify the base of the logarithm, use the PARAMETER= *t-option*. The default is a natural logarithm with base $e = 2.718\ldots$. Variables specified with the LOG *transform* must be numeric and positive, and they are typically continuous.

LOGIT

finds a logit transformation on the variables. The logit of x is $\log(x/(1-x))$. Unlike other transformations, LOGIT does not have a three-letter abbreviation. Variables specified with the LOGIT *transform* must be numeric and in the interval $(0.0 < x < 1.0)$, and they are typically continuous.

POWER
POW

raises variables to a specified power (x is transformed to x^a). You must specify the power parameter a by specifying the PARAMETER= *t-option* following the variables. Here is an example:

```
power(variable / parameter=number)
```

You can use POWER for squaring variables (PARAMETER=2), reciprocal transformations (PARAMETER=–1), square roots (PARAMETER=0.5), and so on. Variables specified with the POWER *transform* must be numeric, and they are typically continuous.

RANK
RAN

transforms variables to ranks. Ranks are averaged within ties. The smallest input value is assigned the smallest rank. Variables specified in the RANK *transform* must be numeric.

Nonlinear Fit Transformations

Nonlinear fit transformations, like nonoptimal transformations, are computed before the iterative algorithm begins. Nonlinear fit transformations create a single new transformed variable that replaces the original variable and provides one or more smooth functions through a scatter plot. The new variable is not transformed by the subsequent iterative algorithms. The nonlinear fit transformations, unlike the nonoptimal transformations, use information in the other variables in the model to find the transformations. The nonlinear fit transformations, unlike the optimal transformations, do not minimize a squared-error criterion. The following list provides syntax and details for nonoptimal variable transformations.

BOXCOX
BOX

finds a Box-Cox (1964) transformation of the specified variables. The BOXCOX transformation can be used only with dependent variables. The ALPHA=, CLL=, CONVENIENT,

GEOMETRICMEAN, LAMBDA=, and PARAMETER= *t-options* can be used with the BOXCOX transformation. Variables specified in the BOXCOX *transform* must be numeric, and they are typically continuous. See the section "Box-Cox Transformations" on page 7181 and Example 90.2 for more information about Box-Cox transformations.

PBSPLINE

PBS

is a noniterative penalized B-spline transformation (Eilers and Marx 1996). The PBSPLINE transformation can be used only with independent variables. By default with PBSPLINE, a cubic spline is fit with 100 evenly spaced knots, three evenly spaced exterior knots, and a difference matrix of order three (DEGREE=3 NKNOTS=100 EVENLY=3 PARAMETER=3). Variables specified in the PBSPLINE *transform* must be numeric, and they are typically continuous. See the section "Penalized B-Splines" on page 7219 and Example 90.3 for more information about penalized B-splines.

SMOOTH

SMO

is a noniterative smoothing spline transformation (Reinsch 1967). You can specify the smoothing parameter with either the SM= or the PARAMETER= *t-option*. The default smoothing parameter is SM=0. The SMOOTH transformation can be used only with independent variables. Variables specified with the SMOOTH *transform* must be numeric, and they are typically continuous. How the results of the SMOOTH transformation are used in PROC TRANSREG has changed with this release. In particular, some aspects of the syntax along the coefficients and predicted values have changed. See the NSR *a-option* for a way to restore the old functionality. See the sections "Smoothing Splines" on page 7222 and "Smoothing Splines Changes and Enhancements" on page 7227 for more information about smoothing splines.

Optimal Transformations

Optimal transformations are iteratively derived. Missing values for these types of variables can be optimally estimated (see the section "Missing Values" on page 7249). The following list provides syntax and details for optimal transformations.

LINEAR

LIN

finds an optimal linear transformation of each variable. For variables with no missing values, the transformed variable is the same as the original variable. For variables with missing values, the transformed nonmissing values have a different scale and origin than the original values. Variables specified in the LINEAR *transform* must be numeric. See the section "OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations" on page 7260 for more information about optimal scaling.

MONOTONE

MON

finds a monotonic transformation of each variable, with the restriction that ties are preserved. The Kruskal (1964) secondary least-squares monotonic transformation is used. This transformation weakly preserves order and category membership (ties). Variables specified with the MONOTONE *transform* must be numeric, and they are typically discrete. See the section "OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations" on page 7260 for more information about optimal scaling.

MSPLINE

MSP

finds a monotonically increasing B-spline transformation with monotonic coefficients (de Boor 1978; de Leeuw 1986) of each variable. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY= *t-options* with MSPLINE. By default, PROC TRANSREG fits a quadratic spline with no knots. Variables specified with the MSPLINE *transform* must be numeric, and they are typically continuous. See the section "SPLINE and MSPLINE Transformations" on page 7261 for more information about monotone splines.

OPSCORE

OPS

finds an optimal scoring of each variable. The OPSCORE transformation assigns scores to each class (level) of the variable. The Fisher (1938) optimal scoring method is used. Variables specified with the OPSCORE *transform* can be either character or numeric; numeric variables should be discrete. See the sections "Character OPSCORE Variables" on page 7253 and "OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations" on page 7260 for more information about optimal scaling.

SPLINE

SPL

finds a B-spline transformation (de Boor 1978) of each variable. By default, PROC TRANSREG fits a cubic spline with no knots. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY= *t-options* with SPLINE. Variables specified with the SPLINE *transform* must be numeric, and they are typically continuous. See the sections "SPLINE and MSPLINE Transformations" on page 7261, "Specifying the Number of Knots" on page 7262, and "SPLINE, BSPLINE, and PSPLINE Comparisons" on page 7264, and "Using Splines and Knots" on page 7192 for more information about splines.

UNTIE

UNT

finds a monotonic transformation of each variable without the restriction that ties are preserved. PROC TRANSREG uses the Kruskal (1964) primary least-squares monotonic transformation method. This transformation weakly preserves order but not category membership (it might untie some previously tied values). Variables specified with the UNTIE *transform* must be numeric, and they are typically discrete. See the section "OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations" on page 7260 for more information about optimal scaling.

Other Transformations

IDENTITY
IDE

specifies variables that are not changed by the iterations. Typically, the IDENTITY transformation is used with a simple variable list, such as **identity(x1-x5)**. However, you can also specify interaction terms. For example, **identity(x1 | x2)** creates x1, x2, and the product x1*x2; and **identity(x1 | x2 | x3)** creates x1, x2, x1*x2, x3, x1*x3, x2*x3, and x1*x2*x3. See the section "Model Statement Usage" on page 7179 for information about how to use the operators @, *, and | in PROC TRANSREG. Variables specified in the IDENTITY *transform* must be numeric.

The IDENTITY transformation is used for variables when no transformation and no missing data estimation are desired. However, the REFLECT *t-option*, the ADDITIVE *a-option*, and the TSTANDARD=Z, and TSTANDARD=CENTER options can linearly transform all variables, including IDENTITY variables, after the iterations. Observations with missing values in IDENTITY variables are excluded from the analysis, and no optimal scores are computed for missing values in IDENTITY variables.

SSPLINE
SSP

finds an iterative smoothing spline transformation of each variable. The SSPLINE transformation does not generally minimize squared error. You can specify the smoothing parameter with either the SM= *t-option* or the PARAMETER= *t-option*. The default smoothing parameter is SM=0. Variables specified with the SSPLINE *transform* must be numeric, and they are typically continuous. How the results of the SSPLINE transformation are used in PROC TRANSREG has changed with this release to be consistent with the changes to SMOOTH. In particular, some aspects of the syntax along the coefficients and predicted values have changed. See the section "Smoothing Splines Changes and Enhancements" on page 7227 for more information about the changes, and see the NSR *a-option* for a way to restore the old functionality.

Transformation Options (t-options)

If you use a nonoptimal, nonlinear fit, optimal, or other transformation, you can use *t-options*, which specify additional details of the transformation. The *t-options* are specified within the parentheses that enclose variables and are listed after a slash. You can use *t-options* with both the dependent and the independent variables. Here is an example of using just one *t-option*:

```
proc transreg;
   model identity(y)=spline(x / nknots=3);
   output;
run;
```

The preceding statements find an optimal variable transformation (SPLINE) of the independent variable, and they use a *t-option* to specify the number of knots (NKNOTS=). The following is a more complex example:

```
proc transreg;
   model mspline(y / nknots=3)=class(x1 x2 / effects);
   output;
run;
```

These statements find a monotone spline transformation (MSPLINE with three knots) of the dependent variable and perform a CLASS expansion with effects coding of the independents.

The *t-options* listed in Table 90.3 are available in the MODEL statement.

Table 90.3 Transformation Options

Option	Description
Nonoptimal Transformation	
ORIGINAL	uses original mean and variance
Parameter Specification	
PARAMETER=	specifies miscellaneous parameters
SM=	specifies smoothing parameter
Penalized B-Spline	
AIC	uses Akaike's information criterion
AICC	uses corrected AIC
CV	uses cross validation criterion
GCV	uses generalized cross validation criterion
LAMBDA=	specifies smoothing parameter list or range
RANGE	specifies a LAMBDA= range, not a list
SBC	uses Schwarz's Bayesian criterion
Spline	
DEGREE=	specifies the degree of the spline
EVENLY=	spaces the knots evenly
EXKNOTS=	specifies exterior knots
KNOTS=	specifies the interior knots or break points
NKNOTS=	creates *n* knots
CLASS Variable	
CPREFIX=	specifies CLASS coded variable name prefix
DEVIATIONS	specifies a deviations-from-means coding
EFFECTS	specifies a deviations-from-means coding
LPREFIX=	specifies CLASS coded variable label prefix
ORDER=	specifies order of CLASS variable levels
ORTHOGONAL	specifies an orthogonal-contrast coding
SEPARATORS=	specifies CLASS coded variable label separators
STANDORTH	specifies a standardized-orthogonal coding
ZERO=	controls reference levels
Box-Cox	
ALPHA=	specifies confidence interval alpha
CLL=	specifies convenient lambda list
CONVENIENT	uses a convenient lambda

Table 90.3 *continued*

Option	Description
GEOMETRICMEAN	scales transformation using geometric mean
LAMBDA=	specifies power parameter list
Other t-options	
AFTER	specifies operations occur after the expansion
CENTER	specifies center before the analysis begins
NAME=	renames variables
REFLECT	reflects the variable around the mean
TSTANDARD=	specifies transformation standardization
Z	standardizes before the analysis begins

The following sections discuss the *t-options* available for nonoptimal, nonlinear fit, optimal, and other transformations.

Nonoptimal Transformation t-options

ORIGINAL

ORI

matches the variable's final mean and variance to the mean and variance of the original variable. By default, the mean and variance are based on the transformed values. The ORIGINAL *t-option* is available for all of the nonoptimal transformations.

Parameter t-options

PARAMETER=*number*

PAR=*number*

specifies the transformation parameter. The PARAMETER= *t-option* is available for the BOXCOX, EXP, LOG, POWER, SMOOTH, SSPLINE, and PBSPLINE transformations. For BOXCOX, the parameter is the value to add to each value of the variable before a Box-Cox transformation. For EXP, the parameter is the value to be exponentiated; for LOG, the parameter is the base value; and for POWER, the parameter is the power. For SMOOTH and SSPLINE, the parameter is the raw smoothing parameter. (See the SM= option for an alternative way to specify the smoothing parameter.) The default for the PARAMETER= *t-option* for the BOXCOX transformation is 0 and for the LOG and EXP transformations is $e = 2.718\ldots$. The default parameter for SMOOTH and SSPLINE is computed from SM=0. For the POWER transformation, you must specify the PARAMETER= *t-option*; there is no default. For PBSPLINE, the parameter is the order of the difference matrix, which provides some control over the smoothness of the transformation. The default order parameter with PBSPLINE is the maximum of the DEGREE= *t-option*, and 1. With PBSPLINE, the default is DEGREE=3 and PARAMETER=3, which works well for most problems.

SM=*n*

specifies a smoothing parameter in the range 0 to 100, just like PROC GPLOT uses. For example, SM=50 in PROC TRANSREG is equivalent to I=SM50 in the SYMBOL statement with PROC GPLOT. You can specify the SM= *t-option* only with the SMOOTH and SSPLINE transformations. The smoothness of the function increases as the value of the smoothing parameter increases. By default, SM=0.

Spline t-options

The following *t-options* are available with the SPLINE, MSPLINE and PBSPLINE transformations and with the PSPLINE and BSPLINE expansions.

DEGREE=*n*

DEG=*n*

specifies the degree of the spline transformation. The degree must be a nonnegative integer. The defaults are DEGREE=3 for SPLINE, PSPLINE, and BSPLINE variables and DEGREE=2 for MSPLINE variables.

The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

EVENLY<=*n***>**

EVE<=*n***>**

is used with the NKNOTS= *t-option* to space the knots evenly. The differences between adjacent knots are constant.

If you specify NKNOTS=k and EVENLY, k knots are created at

$$\text{minimum} + i((\text{maximum} - \text{minimum})/(k+1))$$

for $i = 1, \ldots, k$. Here is an example:

```
spline(x / nknots=2 evenly)
```

When the variable x has a minimum of 4 and a maximum of 10, then the two interior knots are 6 and 8. Without the EVENLY *t-option*, the NKNOTS= *t-option* places knots at percentiles, so the knots are not evenly spaced. By default for the BSPLINE expansion and the SPLINE and MSPLINE transformations, the smaller exterior knots are all the same and all just a little smaller than the minimum. Similarly, by default, the larger exterior knots are all the same and all just a little larger than the maximum. However, if you specify EVENLY=*n*, then the n exterior knots are evenly spaced as well. The number of exterior knots must be greater than or equal to the degree. You can specify values larger than the degree when you want to interpolate slightly beyond the range or your data. The exterior knots must be less than the minimum or greater than the maximum; hence the knots across all sets are not precisely equally spaced. For example, with data ranging from 0 to 10, and with EVENLY=3 and NKNOTS=4, the first exterior knots are –4.000000000001, –2.000000000001, and –0.000000000001, the interior knots are 2, 4, 6, and 8, and the second exterior knots are 10.000000000001, 12.000000000001, and 14.000000000001.

With the BSPLINE and PSPLINE expansions and the SPLINE and MSPLINE transformations, evenly spaced knots are not the default. With the PBSPLINE transformation, evenly spaced interior and exterior knots are the default. If you want unevenly spaced knots with PBSPLINE, you must use the KNOTS= *t-option*.

EXKNOTS=*number-list*

EXK=*number-list*

specifies exterior knots for SPLINE and MSPLINE transformations and BSPLINE expansions. Usually, this *t-option* is not needed; PROC TRANSREG automatically picks suitable exterior knots. The only time you need to use this option is when you want to ensure that the exact same basis is used for different splines, such as when you apply coefficients from one spline transformation to a variable in a different data set (see the section "Scoring Spline Variables" on page 7204).

Specify one or two values. If the minimum EXKNOTS= value is less than the minimum data value, it is used as the exterior knot. If the maximum EXKNOTS= value is greater than the maximum data value, it is used as the exterior knot. Otherwise these values are ignored. When EXKNOTS= is specified with the CENTER or Z *t-options*, the knots apply to the original variable, not to the centered or standardized variable.

The B-spline transformations and expansions use a knot list consisting of exterior knots (values just smaller than the minimum), the specified (interior) knots, and exterior knots (values just larger than the minimum). You can use the DETAIL *a-option* to see all of these knots. If you use different exterior knots, you get different but equivalent B-spline bases. You can specify exterior knots in either the KNOTS= or EXKNOTS= *t-options*; however, for the BSPLINE expansion, the KNOTS= *t-option* creates extra all-zero basis columns, whereas the EXKNOTS= *t-option* gives you the correct basis. See the EVENLY= *t-option* for an alternative way to specify exterior knots.

KNOTS=*number-list* | *n* **TO** *m* **BY** *p*

KNO=*number-list* | *n* **TO** *m* **BY** *p*

specifies the interior knots or break points. By default, there are no knots. The first time you specify a value in the knot list, it indicates a discontinuity in the nth (from DEGREE=n) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the $(n-1)$th derivative of the transformation function at the value of the knot. Knots can be repeated any number of times for decreasing smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the KNOTS= *t-option* with the NKNOTS= *t-option*. You should keep the number of knots small (see the section "Specifying the Number of Knots" on page 7262).

NKNOTS=*n*

NKN=*n*

creates n knots, the first at the $100/(n+1)$ percentile, the second at the $200/(n+1)$ percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if NKNOTS=3, knots are placed at the 25th percentile, the median, and the 75th percentile. You can use the EVENLY= *t-option* along with NKNOTS= to get evenly spaced knots. By default, with the BSPLINE and PSPLINE expansions and the SPLINE and MSPLINE transformations, NKNOTS=0. By default, with the PBSPLINE transformation, NKNOTS=100.

The value specified for the NKNOTS= *t-option* must be ≥ 0.

You cannot use the NKNOTS= *t-option* with the KNOTS= *t-option*.

You should keep the number of knots small (see the section "Specifying the Number of Knots" on page 7262).

Penalized B-Spline t-options

The following *t-options* are available with the PBSPLINE transformation.

AIC

specifies that the procedure should select the smoothing parameter, λ, that minimizes the (Akaike 1973) information criterion (AIC). By default, the (AICC) criterion is minimized.

AICC

specifies that the procedure should select the smoothing parameter, λ, that minimizes the corrected Akaike information criterion (Hurvich, Simonoff, and Tsai 1998). This is the default criterion unless the AIC, CV, GCV, or SBC *t-option* is specified.

CV

specifies that the procedure should select the smoothing parameter, λ, that minimizes the cross validation criterion (CV). By default, the (AICC) criterion is minimized.

GCV

specifies that the procedure should select the smoothing parameter, λ, that minimizes the generalized cross validation criterion (Craven and Wahba 1979). By default, the (AICC) criterion is minimized.

LAMBDA=*number-list*

LAM=*number-list*

specifies a list of penalized B-spline smoothing parameters. By default, PROC TRANSREG considers lambdas in the range 0 to 1E6. Alternatively, you can specify the RANGE *t-option* with LAMBDA=, such as LAMBDA=1E3 1E5 RANGE, to only consider lambdas in a narrower range. Note that the algorithm might not actually evaluate the criterion at the minimum and maximum if it does not have to. In particular, it avoids evaluating the criterion at LAMBDA=0 (no smoothing) unless it is the only LAMBDA= value specified. You can also specify a list of lambdas, such as LAMBDA=1 TO 10, and the procedure selects the best lambda from the list. In all cases, the lambda that minimizes the specified criterion (or AICC by default) is chosen.

RANGE

RAN

specifies that the LAMBDA= *t-option* specifies two lambdas that define a range of values, from which an optimal lambda is selected. By default, PROC TRANSREG considers lambdas in the range 0 to 1E6.

SBC

specifies that the procedure should select the smoothing parameter, λ, that minimizes Schwarz's Bayesian criterion (Schwarz 1978; Judge et al. 1980). By default, the (AICC) criterion is minimized.

Class Variable t-options

CPREFIX=*n* | *number-list*

CPR=*n* | *number-list*

specifies the number of first characters of a CLASS expansion variable's name to use in constructing names for coded variables. When you specify CPREFIX= as an *a-option* or an *o-option*, it specifies the default for all CLASS variables. When you specify CPREFIX= as a *t-option*, it overrides the default only for selected variables. A different CPREFIX= value can be specified for each CLASS variable by specifying the CPREFIX=number-list *t-option*, like the ZERO=*formatted-value t-option*.

DEVIATIONS

DEV

requests a deviations-from-means coding of CLASS variables. The coded design matrix has values of 0, 1, and –1 for reference levels. This coding is referred to as "deviations-from-means," "effects," "center-point," or "full-rank" coding. For example, here is the coding for two-, three-, four-, and five-level factors:

	Number of Levels									
	Two	Three		Four			Five			
a	1	1	0	1	0	0	1	0	0	0
b	-1	0	1	0	1	0	0	1	0	0
c		-1	-1	0	0	1	0	0	1	0
d				-1	-1	-1	0	0	0	1
e							-1	-1	-1	-1

EFFECTS

EFF

See the DEVIATIONS *t-option*.

LPREFIX=*n* | *number-list*

LPR=*n* | *number-list*

specifies the number of first characters of a CLASS expansion variable's label (or name if no label is specified) to use in constructing labels for the coded variables. When you specify LPREFIX= as an *a-option* or an *o-option*, it specifies the default for all CLASS variables. When you specify LPREFIX= as a *t-option*, it overrides the default only for selected variables. A different LPREFIX= value can be specified for each CLASS variable by specifying the LPREFIX=number-list *t-option*, like the ZERO=*formatted-value t-option*.

ORDER=DATA | FREQ | FORMATTED | INTERNAL

ORD=DAT | FRE | FOR | INT

specifies the order in which the CLASS variable levels are to be reported. The default is ORDER=INTERNAL. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine dependent. When you specify ORDER= as an *a-option* or an *o-option*, it specifies the default ordering for all CLASS variables. When you specify ORDER= as a *t-option*, it overrides the default ordering only for selected variables. You can specify a different ORDER= value for each CLASS specification.

ORTHOGONAL

ORT

requests an orthogonal-contrast coding of CLASS variables. For example, here is the orthogonal-contrast coding for two-, three-, four-, and five-level factors:

	Number of Levels									
	Two	Three		Four			Five			
a	1	1	-1	1	-1	-1	1	-1	-1	-1
b	-1	0	2	0	2	-1	0	2	-1	-1
c		-1	-1	0	0	3	0	0	3	-1
d				-1	-1	-1	0	0	0	4
e							-1	-1	-1	-1

The sum of the coded values within each column is zero, all columns within a factor are orthogonal, and the ith column represents a contrast between the ith level and the combination of all preceding levels and the last level. The $\mathbf{X}$ matrix is orthogonal and $\mathbf{X}'\mathbf{X}$ is diagonal with this coding only if the experimental design is orthogonal.

SEPARATORS='*string-1***' <'***string-2***'>**

SEP='*string-1***' <'***string-2***'>**

specifies separators for creating CLASS expansion variable labels. By default, SEPARATORS=' ' * ' ("blank" and "blank asterisk blank"). When you specify SEPARATORS= as an *a-option* or an *o-option*, it specifies the default separators for all CLASS variables. When you specify SEPARATORS= as a *t-option*, it overrides the default only for selected variables. You can specify a different SEPARATORS= value for each CLASS specification.

STANDORTH

STA

ORTHEFFECT

requests a standardized-orthogonal coding of CLASS variables. For example, here is the standardized-orthogonal coding for two-, three-, four-, and five-level factors:

	Number of Levels									
	Two	Three		Four			Five			
a	1	1.22	-0.71	1.41	-0.82	-0.58	1.58	-0.91	-0.65	-0.50
b	-1	0.00	1.41	0.00	1.63	-0.58	0.00	1.83	-0.65	-0.50
c		-1.22	-0.71	0.00	0.00	1.73	0.00	0.00	1.94	-0.50
d				-1.41	-0.82	-0.58	0.00	0.00	0.00	2.00
e							-1.58	-0.91	-0.65	-0.50

The sum of the coded values within each column is zero, the sum of squares of the coded values within each column is equal to the number of levels, all columns within a factor are orthogonal, and the *i*th column represents a contrast between the *i*th level and the combination of all preceding levels and the last level. The $\mathbf{X}$ matrix is orthogonal and $\mathbf{X}'\mathbf{X}$ is diagonal ($\mathbf{X}'\mathbf{X} = n\mathbf{I}$, the number of observations times an identity matrix) with this coding only if the experimental design is orthogonal.

ZERO=FIRST | LAST | NONE | SUM

ZER=FIR | LAS | NON | SUM

ZERO='*formatted-value***' <'***formatted-value***' ... >**

is used with CLASS variables. The default is ZERO=LAST.

The specification CLASS(variable / ZERO=FIRST) sets to missing the coded variable for the first of the sorted categories, implying a zero coefficient for that category.

The specification CLASS(variable / ZERO=LAST) sets to missing the coded variable for the last of the sorted categories, implying a zero coefficient for that category.

The specification CLASS(variable / ZERO='*formatted-value*') sets to missing the coded variable for the category with a formatted value that matches '*formatted-value*', implying a zero coefficient for that category. With ZERO=*formatted-value*, the first formatted value applies to the first variable in the specification, the second formatted value applies to the next variable that was not previously mentioned, and so on. For example, `class(a a*b b b*c c / zero='x' 'y' 'z')` specifies that the reference level for a is 'x', for b is 'y', and for c is 'z'. With ZERO='*formatted-value*', the procedure first looks for exact matches between the formatted values and the specified value. If none are found, leading blanks are stripped from both and the values are compared again. If zero or two or more matches are found, warnings are issued.

The specifications ZERO=FIRST, ZERO=LAST, and ZERO='*formatted-value*' are used for reference cell models. The Intercept parameter estimate is the marginal mean for the reference cell, and the other marginal means are obtained by adding the intercept to the coded variable coefficients.

The specification CLASS(variable / ZERO=NONE) sets to missing none of the coded variables. The columns of the expansion sum to a column of ones, so an implicit intercept model is fit. If you specify ZERO=NONE for more than one variable, the model is less than full rank. In the model `model identity(y) = class(x / zero=none)`, the coefficients are cell means.

The specification CLASS(variable / ZERO=SUM) sets to missing none of the coded variables, and the coefficients for the coded variables created from the variable sum to 0. This creates a less-than-full-rank model, but the coefficients are uniquely determined due to the sum-to-zero constraint.

In the presence of iterative transformations, hypothesis tests for ZERO=NONE and ZERO=SUM levels are not exact; they are liberal because a model with an explicit intercept is fit inside the iterations. There is no provision for adjusting the transformations while setting to 0 a parameter that is redundant given the explicit intercept and the other parameters.

Box-Cox t-options

The following *t-options* are available only with the BOXCOX transformation of the dependent variable (see the section "Box-Cox Transformations" on page 7181 and Example 90.2).

ALPHA=*p*

ALP=*p*

specifies the Box-Cox alpha for the confidence interval for the power parameter. By default, ALPHA=0.05.

CLL=*number-list*

specifies the Box-Cox convenient lambda list. When the confidence interval for the power parameter includes one of the values in this list, PROC TRANSREG reports it and can optionally use the convenient power parameter instead of the more optimal power parameter. The default is CLL=1.0 0.0 0.5 –1.0 –0.5 2.0 –2.0 3.0 –3.0. By default, a linear transformation is preferred over log, square root, inverse, inverse square root, quadratic, inverse quadratic, cubic, and inverse cubic. If you specify the CONVENIENT *t-option*, then PROC TRANSREG uses the first convenient power parameter in the list that is in the confidence interval. For example, if the optimal power parameter is 0.25 and 0.0 is in the confidence interval but not 1.0, then the convenient power parameter is 0.0.

CONVENIENT

CON

specifies that a power parameter from the CLL= *t-option* list is to be used for the final transformation instead of the LAMBDA= *t-option* value if a CLL= value is in the confidence interval. See the CLL= *t-option* for more information about its usage.

GEOMETRICMEAN

GEO

divides the Box-Cox transformation by $\dot{y}^{\lambda-1}$, where $\dot{y}$ is the geometric mean of the variable to be transformed. This form of the Box-Cox transformation essentially converts the transformation back to original units, and hence it permits direct comparison of the residual sums of squares for models with different power parameters.

LAMBDA=*number-list*

LAM=*number-list*

specifies a list of Box-Cox power parameters. The default is LAMBDA=–3 TO 3 BY 0.25. PROC TRANSREG tries each power parameter in the list and picks the best one. However, when the CONVENIENT *t-option* is specified, PROC TRANSREG chooses a convenient value from the confidence interval instead of the optimal value. For example, if the optimal power parameter is 0.25 and 0.0 is in the confidence interval but not 1.0, then the convenient power parameter 0.0 (log transformation) is chosen instead of the more optimal parameter 0.25. See the CLL= *t-option* for more information about its usage.

Other t-options

AFTER
AFT

requests that certain operations occur after the expansion. This *t-option* affects the NKNOTS= *t-option* when the SPLINE or MSPLINE transformation is crossed with a CLASS specification. For example, if the original spline variable (1 2 3 4 5 6 7 8 9) is expanded into the three variables (1 2 3 0 0 0 0 0 0), (0 0 0 4 5 6 0 0 0), and (0 0 0 0 0 0 7 8 9), then, by default, NKNOTS=1 would use the overall median of 5 as the knot for all three variables. When you specify the AFTER *t-option*, the knots for the three variables are 2, 5, and 8. Note that the structural zeros are ignored when the internal knot list is created, but they are not ignored for the exterior knots.

You can also specify the AFTER *t-option* with the RANK, SMOOTH, and PBSPLINE transformations. The following specifications compute ranks and smooth transformations within groups, after crossing, ignoring the structural zeros:

```
class(x / zero=none) | rank(z / after)
class(x / zero=none) | smooth(z / after)
```

CENTER
CEN

centers the variables before the analysis begins (in contrast to the TSTANDARD=CENTER option, which centers after the analysis ends). The CENTER *t-option* can be used instead of running PROC STANDARD before PROC TRANSREG (see the section "Centering" on page 7298). When the KNOTS= *t-option* is specified with CENTER, the knots apply to the original variable, not to the centered variable. PROC TRANSREG centers the knots.

NAME=(*variable-list*)
NAM=(*variable-list*)

renames variables as they are used in the MODEL statement. This *t-option* lets you use a variable more than once.

For example, if x is a character variable, then the following step stores both the original character variable x and a numeric variable xc that contains category numbers in the OUT= data set:

```
proc transreg data=a;
   model identity(y) = opscore(x / name=(xc));
   output;
   id x;
run;
```

With the CLASS and IDENTITY transformations, which can contain interaction effects, the first name applies to the first variable in the specification, the second name applies to the next variable that was not previously mentioned, and so on. For example, **identity(a a * b b b * c c / name=(g h i))** specifies that the new name for a is g, for b is h, and for c is i. The same assignment is used for the (not useful) specification **identity(a a b b c c / name=(g h i))**. For all *transforms* other than CLASS and IDENTITY (all those in which interactions are not supported), repeated variables are not handled specially. For example,

spline(a a b b c c / name=(a g b h c i)) creates six variables: a copy of a named a, another copy of a named g, a copy of b named b, another copy of b named h, a copy of c named c, and another copy of c named i.

REFLECT

REF

reflects the transformation

$$y = -(y - \bar{y}) + \bar{y}$$

after the iterations are completed and before the final standardization and results calculations. This *t-option* is particularly useful with the dependent variable in a conjoint analysis. When the dependent variable consists of ranks with the most preferred combination assigned 1.0, the REFLECT *t-option* reflects the transformation so that positive utilities mean high preference. (See Example 90.4.)

TSTANDARD=CENTER | NOMISS | ORIGINAL | Z

TST=CEN | NOM | ORI | Z

specifies the standardization of the transformed variables for the hypothesis tests and in the OUT= data set (see the section "Centering" on page 7298). By default, TSTANDARD=ORIGINAL. When you specify TSTANDARD= as an *a-option* or an *o-option*, it determines the default standardization for all variables. When you specify TSTANDARD= as a *t-option*, it overrides the default standardization only for selected variables. You can specify a different TSTANDARD= value for each transformation. For example, to perform a redundancy analysis with standardized dependent variables, specify the following:

```
model identity(y1-y4 / tstandard=z) = identity(x1-x10);
```

Z

centers and standardizes the variables to variance one before the analysis begins (in contrast to the TSTANDARD=Z option, which standardizes after the analysis ends). The Z *t-option* can be used instead of running PROC STANDARD before PROC TRANSREG (see the section "Centering" on page 7298). When the KNOTS= *t-option* is specified with Z, the knots apply to the original variable, not to the standardized variable. PROC TRANSREG standardizes the knots.

Algorithm Options (a-options)

This section discusses the options that can appear in the PROC TRANSREG or MODEL statement as *a-options*. They are listed after the entire model specification and after a slash. Here is an example:

```
proc transreg;
   model spline(y / nknots=3)=log(x1 x2 / parameter=2)
         / nomiss maxiter=50;
   output;
run;
```

In the preceding statements, NOMISS and MAXITER= are *a-options*. (SPLINE and LOG are *transforms*, and NKNOTS= and PARAMETER= are *t-options*.) The statements find a spline transformation with 3 knots on y and a base 2 logarithmic transformation on x1 and x2. The NOMISS *a-option* excludes all observations with missing values, and the MAXITER= *a-option* specifies the maximum number of iterations.

The *a-options* listed in Table 90.4 are available in the PROC TRANSREG or MODEL statement.

Table 90.4 Options Available in the PROC TRANSREG or MODEL Statement

Option	Description
Input Control	
REITERATE	restarts iterations
TYPE=	specifies input observation type
Method and Iterations	
CCONVERGE=	specifies minimum criterion change
CONVERGE=	specifies minimum data change
MAXITER=	specifies maximum number of iterations
METHOD=	specifies iterative algorithm
NCAN=	specifies number of canonical variables
NSR	specifies no restrictions on smoothing models
SINGULAR=	specifies singularity criterion
SOLVE	attempts direct solution instead of iteration
Missing Data Handling	
INDIVIDUAL	fits each model individually (METHOD=MORALS)
MONOTONE=	includes monotone special missing values
NOMISS	excludes observations with missing values
UNTIE=	unties special missing values
Intercept and CLASS Variables	
CPREFIX=	specifies CLASS coded variable name prefix
LPREFIX=	specifies CLASS coded variable label prefix
NOINT	specifies no intercept or centering
ORDER=	specifies order of CLASS variable levels
REFERENCE=	controls output of reference levels
SEPARATORS=	specifies CLASS coded variable label separators
Control Displayed Output	
ALPHA=	specifies confidence limits alpha
CL	displays parameter estimate confidence limits
DETAIL	displays model specification details
HISTORY	displays iteration histories
NOPRINT	suppresses displayed output
PBOXCOXTABLE	prints the Box-Cox log likelihood table
RSQUARE	displays the R square
SHORT	suppresses the iteration histories
SS2	displays regression results
TEST	displays ANOVA table

Table 90.4 *continued*

Option	Description
TSUFFIX=	shortens transformed variable labels
UTILITIES	displays conjoint part-worth utilities
Standardization	
ADDITIVE	fits additive model
NOZEROCONSTANT	does not zero constant variables
TSTANDARD=	specifies transformation standardization

The following list provides details about these *a-options*. The *a-options* are available in the PROC TRANSREG or MODEL statement.

ADDITIVE

ADD

creates an additive model by multiplying the values of each independent variable (after the TSTANDARD= standardization) by that variable's corresponding multiple regression coefficient. This process scales the independent variables so that the predicted-values variable for the final dependent variable is simply the sum of the final independent variables. An additive model is a univariate multiple regression model. As a result, the ADDITIVE *a-option* is not valid if METHOD=CANALS, or if METHOD=REDUNDANCY or METHOD=UNIVARIATE with more than one dependent variable.

ALPHA=*number*

ALP=*number*

specifies the level of significance for all of the confidence limits. By default, ALPHA=0.05.

CCONVERGE=*n*

CCO=*n*

specifies the minimum change in the criterion being optimized (squared multiple correlation for METHOD=MORALS and METHOD=UNIVARIATE, average squared multiple correlation for METHOD=REDUNDANCY, average squared canonical correlation for METHOD=CANALS) that is required to continue iterating. By default, CCONVERGE=0.0.

CL

requests confidence limits on the parameter estimates in the displayed output.

CONVERGE=*n*

CON=*n*

specifies the minimum average absolute change in standardized variable scores that is required to continue iterating. By default, CONVERGE=0.00001. Average change is computed over only those variables that can be transformed by the iterations; that is, all LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, and SSPLINE variables and nonoptimal transformation variables with missing values.

CPREFIX=*n*

CPR=*n*

specifies the number of first characters of a CLASS expansion variable's name to use in constructing names for coded variables. Coded variable names are constructed from the first n characters of the CLASS expansion variable's name and the first $32 - n$ characters of the formatted CLASS expansion variable's value. For example, if the variable ClassVariable has values 1, 2, and 3, then, by default, the coded variables are named ClassVariable1, ClassVariable2, and ClassVariable3. However, with CPREFIX=5, the coded variables are named Class1, Class2, and Class3. When CPREFIX=0, coded variable names are created entirely from the CLASS expansion variable's formatted values. Valid values range from –1 to 31, where –1 indicates the default calculation and 0 to 31 are the number of prefix characters to use. The default, –1, sets n to 32 – min(32, max(2, *fl*)), where *fl* is the format length. When you specify CPREFIX= as an *a-option* or an *o-option*, it specifies the default for all CLASS variables. When you specify CPREFIX= as a *t-option*, it overrides the default only for selected variables.

DETAIL

DET

reports on details of the model specification. For example, it reports the knots and coefficients for splines, reference levels for CLASS variables, Box-Cox results, the smoothing parameter, and so on. The DETAIL option can take two optional suboptions, NOCOEFFICIENTS and NOKNOTS (or NOC and NOK). To suppress knots from the details listing, specify DETAIL(NOKNOTS). To suppress coefficients from the details listing, specify DETAIL(NOCOEFFICIENTS). To suppress both knots and coefficients from the details listing, specify DETAIL(NOKNOTS NOCOEFFICIENTS).

SOLVE

SOL

DUMMY

DUM

provides a canonical initialization. When there are no monotonicity constraints, when there is at most one canonical variable in each set, and when there is enough available memory, PROC TRANSREG (with the SOLVE *a-option*) can usually directly solve for the optimal solution in only one iteration. The initialization iteration is number 0, which is slower and uses more memory than other iterations. However, for some models, specifying the SOLVE *a-option* can greatly decrease the amount of time required to find the optimal transformations. During iteration 0, each variable is replaced by an expanded variable and the model is fit to the larger, expanded set of variables. For example, an OPSCORE variable is expanded into coded (or "dummy") variables, as if CLASS were specified, and a SPLINE variable is expanded into a B-spline basis, as if BSPLINE were specified. Then for each expanded variable, the results of iteration zero are constructed by multiplying the expanded basis times the $\boldsymbol{\beta}$ subvector to get the optimal transformation. This *a-option* can be useful even in models where a direct solution is not possible, because it provides good initial transformations of all the variables.

HISTORY

HIS

displays the iteration histories even when the NOPRINT *a-option* is specified.

INDIVIDUAL

IND

fits each model for each dependent variable individually. This means, for example, that when INDIVIDUAL is specified, missing values in one dependent variable will not cause that observation to be deleted for the other models with the other dependent variables. In contrast, by default, missing values in any variable in any model can cause the observation to be deleted for all models. The INDIVIDUAL *a-option* can be specified only with METHOD=MORALS.

This *a-option* also affects the order of the output. By default, the number of observations table is printed once at the beginning of the output. With INDIVIDUAL, a number of observations table appears for each model.

LPREFIX=*n*

LPR=*n*

specifies the number of first characters of a CLASS expansion variable's label (or name if no label is specified) to use in constructing labels for coded variables. Coded variable labels are constructed from the first n characters of the CLASS expansion variable's name and the first $127 - n$ characters of the formatted CLASS expansion variable's value. Valid values range from –1 to 127. Values of 0 to 127 specify the number of name or label characters to use. The default is –1, which specifies that PROC TRANSREG should pick a value depending on the length of the prefix and the formatted class value. When you specify LPREFIX= as an *a-option* or an *o-option*, it determines the default for all CLASS variables. When you specify LPREFIX= as a *t-option*, it overrides the default only for selected variables.

MAXITER=*n*

MAX=*n*

specifies the maximum number of iterations (see the section "Controlling the Number of Iterations" on page 7251). By default, MAXITER=30. You can specify MAXITER=0 to save time when no transformations are requested.

METHOD=CANALS | MORALS | REDUNDANCY | UNIVARIATE

MET=CAN | MOR | RED | UNI

specifies the iterative algorithm. By default, METHOD=UNIVARIATE, unless you specify options that cannot be handled by the UNIVARIATE algorithm. Specifically, the default is METHOD=MORALS for the following situations:

- if you specify LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, or SSPLINE transformations for the independent variables
- if you specify the ADDITIVE *a-option* with more than one dependent variable
- if you specify the IAPPROXIMATIONS *o-option*
- if you specify the INDIVIDUAL *a-option*
- if ODS Graphics is enabled, regression plots are produced, and there is more than one dependent variable

CANALS specifies canonical correlation with alternating least squares. This jointly transforms all dependent and independent variables to maximize the average of the first *n* squared canonical correlations, where *n* is the value of the NCAN= *a-option*.

MORALS specifies multiple optimal regression with alternating least squares. This transforms each dependent variable, along with the set of independent variables, to maximize the squared multiple correlation.

REDUNDANCY jointly transforms all dependent and independent variables to maximize the average of the squared multiple correlations (see the section "Redundancy Analysis" on page 7256).

UNIVARIATE transforms each dependent variable to maximize the squared multiple correlation, while the independent variables are not transformed.

MONOTONE=*two-letters*

MON=*two-letters*

specifies the first and last special missing value in the list of those special missing values to be estimated with within-variable order and category constraints. By default, there are no order constraints on missing value estimates. The *two-letters* value must consist of two letters in alphabetical order. For example, MONOTONE=DF means that the estimate of .D must be less than or equal to the estimate of .E, which must be less than or equal to the estimate of .F; no order constraints are placed on estimates of ._, .A through .C, and .G through .Z. For details, see the section "Missing Values" on page 7249.

NCAN=*n*

NCA=*n*

specifies the number of canonical variables to use in the METHOD=CANALS algorithm. By default, NCAN=1. The value of the NCAN= *a-option* must be ≥ 1.

When canonical coefficients and coordinates are included in the OUT= data set, the NCAN= *a-option* also controls the number of rows of the canonical coefficient matrices in the data set. If you specify an NCAN= value larger than the minimum of the number of dependent variables and the number of independent variables, PROC TRANSREG displays a warning and sets the NCAN= *a-option* to the maximum value.

NOINT

NOI

omits the intercept from the OUT= data set and suppresses centering of data. You cannot specify the NOINT *a-option* with iterative transformations since there is no provision for optimal scaling without an intercept. The NOINT *a-option* can be specified only when there is no implicit intercept and when all of the data in a BY group absolutely will not change during the iterations.

NOMISS

NOM

excludes all observations with missing values from the analysis, but does not exclude them from the OUT= data set. If you omit the NOMISS *a-option*, PROC TRANSREG simultaneously computes the optimal transformations of the nonmissing values and estimates the missing values that minimize squared error. For details, see the section "Missing Values" on page 7249.

Casewise deletion of observations with missing values occurs when the NOMISS *a-option* is specified, when there are missing values in expansions, when there are missing values in METHOD=UNIVARIATE independent variables, when there are weights less than or equal to 0, or when there are frequencies less than 1. Excluded observations are output with a blank value for the _TYPE_ variable, and they have a weight of 0. They do not contribute to the analysis but are scored and transformed as *supplementary* or passive observations.

See the section "Passive Observations" on page 7255 for more information about excluded observations.

NOPRINT

NOP

suppresses the display of all output unless you specify the HISTORY *a-option*. The NOPRINT *a-option* without the HISTORY *a-option* disables the Output Delivery System (ODS), including ODS Graphics, for the duration of the procedure run. The NOPRINT *a-option* with the HISTORY *a-option* disables all output except the iteration history, again including ODS Graphics, for the duration of the procedure run. For more information, see Chapter 20, "Using the Output Delivery System."

NOZEROCONSTANT

NOZERO

NOZ

specifies that constant variables are expected and should not be zeroed. By default, constant variables are zeroed. This option is useful when PROC TRANSREG is used to code experimental designs for discrete choice models (see the section "Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO" on page 7297). When these designs are very large, it might be more efficient to use the DESIGN=*n* *a-option*. It might be that attributes are constant within a block of *n* observations, so you need to specify the NOZEROCONSTANT *a-option* to get the correct results. You can specify this option in the PROC TRANSREG, MODEL, and OUTPUT statements.

NSR

specifies that no restrictions are placed on the use of SMOOTH and SSPLINE and the ordinary least squares is used to find the coefficients and predicted values. By default, only certain types of models can be specified with SMOOTH and ordinary least squares is not used to find the coefficients and predicted values. See the section "Smoothing Splines Changes and Enhancements" on page 7227 for more information about the NSR option and smooth transformations.

ORDER=DATA | FREQ | FORMATTED | INTERNAL

ORD=DAT | FRE | FOR | INT

specifies the order in which the CLASS variable levels are to be reported. The default is ORDER=INTERNAL. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine dependent. When you specify ORDER= as an *a-option* or an *o-option*, it determines the default ordering for all CLASS variables. When you specify ORDER= as a *t-option*, it overrides the default ordering only for selected variables.

DATA	sorts by order of appearance in the input data set.
FORMATTED	sorts by formatted value.
FREQ	sorts by descending frequency count; levels with the most observations appear first.
INTERNAL	sorts by unformatted value.

PBOXCOXTABLE

PBO

prints the Box-Cox table with the log likelihood displayed as a function of lambda. The important information in this table is displayed in the Box-Cox plot, so when ODS Graphics is in effect and the plot is produced, the table is not produced by default. When ODS Graphics is not in effect or when the plot is not produced, the table is produced by default. Specify the PBOXCOXTABLE option if you want to see the table in addition to the plot.

REFERENCE=NONE | MISSING | ZERO

REF=NON | MIS | ZER

specifies how reference levels of CLASS variables are to be treated. The options are REFERENCE=NONE, the default, in which reference levels are suppressed; REFERENCE=MISSING, in which reference levels are displayed and output with missing values; and REFERENCE=ZERO, in which reference levels are displayed and output with zeros. You can specify the REFERENCE= option in the PROC TRANSREG, MODEL, or OUTPUT statement, and you can specify it independently for the OUT= data set and the displayed output. When you specify it in only one statement, it sets the option for both the displayed output and the OUT= data set.

REITERATE

REI

enables PROC TRANSREG to use previous transformations as starting points. The REITERATE *a-option* affects only variables that are iteratively transformed (specified as LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, and SSPLINE). For iterative transformations, the REITERATE *a-option* requests a search in the input data set for a variable that consists of the value of the TDPREFIX= or TIPREFIX= *o-option* followed by the original variable name. If such a variable is found, it is used to provide the initial values for the first iteration. The final transformation is a member of the transformation family defined by the original variable, not the transformation family defined by the initialization variable. See the section "Using the REITERATE Algorithm Option" on page 7252 for more information about the REITERATE option.

RSQUARE

RSQ

prints a table with only the model R square.

SEPARATORS='*string-1***' <'***string-2***'>**

SEP='*string-1***' <'***string-2***'>**

specifies separators for creating CLASS expansion variable labels. By default, SEPARATORS=' ' * ' ("blank" and "blank asterisk blank"). The first value is used to separate variable names and values in interactions. The second value is used to separate interaction components. For example, the label for the coded variable for the A=1 and B=2 cell is, by default, 'A 1 * B 2'. If SEPARATORS='=' 'x' is specified, then the label is 'A=1xB=2'. When you specify SEPARATORS= as an *a-option* or an *o-option*, it determines the default separators for all CLASS variables. When you specify SEPARATORS= as a *t-option*, it overrides the default only for selected variables.

SHORT

SHO

suppresses the iteration histories.

SINGULAR=*n*

SIN=*n*

specifies the largest value within rounding error of zero. By default, SINGULAR=1E–12. PROC TRANSREG uses the value of the SINGULAR= *a-option* for checking $1 - R^2$ when constructing full-rank matrices of predictor variables, checking denominators before dividing, and so on. PROC TRANSREG computes the regression coefficients by sweeping with rational pivoting.

SS2

produces a regression table based on Type II sums of squares. Tests of the contribution of each transformation to the overall model are displayed and output to the OUTTEST= data set when you specify the OUTTEST= option. When you specify the SS2 *a-option*, the TEST *a-option* is automatically specified for you. See the section "Hypothesis Tests" on page 7264 for more information about the TEST and SS2 options. You can suppress the variable labels in the regression tables by specifying the NOLABEL option in the OPTIONS statement.

TEST

TES

generates an ANOVA table. PROC TRANSREG tests the null hypothesis that the vector of scoring coefficients for all of the transformations is zero. See the section "Hypothesis Tests" on page 7264 for more information about the TEST option.

TSUFFIX=*n*

TSU=*n*

specifies the number of characters in "Transformation" to append to variable labels for transformed variables. By default, all characters are used.

TSTANDARD=CENTER | NOMISS | ORIGINAL | Z
TST=CEN | NOM | ORI | Z

specifies the standardization of the transformed variables for the hypothesis tests and in the OUT= data set. By default, TSTANDARD=ORIGINAL. When you specify TSTANDARD= as an *a-option* or an *o-option*, it determines the default standardization for all variables. When you specify TSTANDARD= as a *t-option*, it overrides the default standardization only for selected variables.

CENTER centers the output variables to mean zero, but the variances are the same as the variances of the input variables.

NOMISS sets the means and variances of the transformed variables in the OUT= data set, computed over all output values that correspond to nonmissing values in the input data set, to the means and variances computed from the nonmissing observations of the original variables. The TSTANDARD=NOMISS specification is useful with missing data. When a variable is linearly transformed, the final variable contains the original nonmissing values and the missing value estimates. In other words, the nonmissing values are unchanged. If your data have no missing values, TSTANDARD=NOMISS and TSTANDARD=ORIGINAL produce the same results.

ORIGINAL sets the means and variances of the transformed variables to the means and variances of the original variables. This is the default.

Z standardizes the variables to mean zero, variance one.

The final standardization is affected by other options. If you also specify the ADDITIVE *a-option*, the TSTANDARD= option specifies an intermediate step in computing the final means and variances. The final independent variables, along with their means and standard deviations, are scaled by the regression coefficients, creating an additive model with all coefficients equal to one.

For nonoptimal variable transformations, the means and variances of the original variables are actually the means and variances of the nonlinearly transformed variables, unless you specify the ORIGINAL nonoptimal *t-option* in the MODEL statement. For example, if a variable x with no missing values is specified as LOG, then, by default, the final transformation of x is simply the log of x, not the log of x standardized to the mean of x and variance of x.

TYPE='*text***'|***name***
TYP='***text***'|***name***

specifies the valid value for the _TYPE_ variable in the input data set. If PROC TRANSREG finds an input _TYPE_ variable, it uses only observations with a _TYPE_ value that matches the TYPE= value. This enables a PROC TRANSREG OUT= data set containing coefficients to be used as input to PROC TRANSREG without requiring a WHERE statement to exclude the coefficients. If a _TYPE_ variable is not in the data set, all observations are used. The default is TYPE='SCORE', so if you do not specify the TYPE= *a-option*, only observations with _TYPE_='SCORE' are used. Do not confuse this *a-option* with the data set TYPE= option. The DATA= data set must be an ordinary SAS data set.

PROC TRANSREG displays a note when it reads observations with blank values of _TYPE_, but it does not automatically exclude those observations. Data sets created by the

TRANSREG and PRINQUAL procedures have blank _TYPE_ values for those observations that were excluded from the analysis due to nonpositive weights, nonpositive frequencies, or missing data. When these observations are read again, they are excluded for the same reason that they were excluded from their original analysis, not because their _TYPE_ value is blank.

UNTIE=*two-letters*

UNT=*two-letters*

specifies the first and last special missing values in the list of those special missing values that are to be estimated with within-variable order constraints but no category constraints. The *two-letters* value must consist of two letters in alphabetical order. By default, there are category constraints but no order constraints on special missing value estimates. For details, see the sections "Missing Values" on page 7249 and "Optimal Scaling" on page 7259.

UTILITIES

UTI

produces a table of the part-worth utilities from a conjoint analysis. Utilities, their standard errors, and the relative importance of each factor are displayed and output to the OUTTEST= data set when you specify the OUTTEST= option. When you specify the UTILITIES *a-option*, the TEST *a-option* is automatically specified for you. See Example 90.4 and Example 90.5 for more information about conjoint analysis.

OUTPUT Statement

OUTPUT *OUT=SAS-data-set* < *o-options* > **;**

The OUTPUT statement creates a new SAS data set that contains coefficients, marginal means, and information about the original and transformed variables. The information about original and transformed variables composes the score partition of the data set; observations have _TYPE_='SCORE'. The coefficients and marginal means compose the coefficient partition of the data set; observations have _TYPE_='M COEFFI' or _TYPE_='MEAN'. Other values of _TYPE_ are possible; for details, see "_TYPE_ and _NAME_ Variables" later in this chapter. For details about data set structure, see the section "Output Data Set" on page 7267. To specify the name of the output data set, use the OUT= option.

OUT=*SAS-data-set*

specifies the output data set for the data, transformed data, predicted values, residuals, scores, coefficients, and so on. When you use an OUTPUT statement but do not use the OUT= specification, PROC TRANSREG creates a data set and uses the DATA*n* convention. If you want to create a permanent SAS data set, you must specify a two-level name (see "SAS Files" in *SAS Language Reference: Concepts* and "Introduction to DATA Step Processing" in the *Base SAS Procedures Guide* for details).

To control the contents of the data set and variable names, use one or more of the *o-options*. You can also specify these options in the PROC TRANSREG statement.

Output Options (o-options)

The options listed in Table 90.5 are available in the OUTPUT statement. These options include the OUT= option and all of the *o-options*. Many of the statistics created in the OUTPUT statement are exactly the same as statistics created by PROC REG. More details are given in the sections "Predicted and Residual Values" on page 5531, "Model Fit and Diagnostic Statistics" on page 5557 in Chapter 73, "The REG Procedure," and Chapter 4, "Introduction to Regression Procedures."

Table 90.5 Options Available in the OUTPUT Statement

Option	Description
Identify output data set	
OUT=	outputs data set
Predicted Values, Residuals, Scores	
CANONICAL	outputs canonical scores
CLI	outputs individual confidence limits
CLM	outputs mean confidence limits
DESIGN=	specifies design matrix coding
DREPLACE	replaces dependent variables
IREPLACE	replaces independent variables
LEVERAGE	outputs leverage
NORESTOREMISSING	does not restore missing values
NOSCORES	suppresses output of scores
PREDICTED	outputs predicted values
REDUNDANCY=	outputs redundancy variables
REPLACE	replaces all variables
RESIDUALS	outputs residuals
Output Data Set Coefficients	
COEFFICIENTS	outputs coefficients
COORDINATES=	outputs ideal point coordinates
MEANS	outputs marginal means
MREDUNDANCY	outputs redundancy analysis coefficients
Output Data Set Variable Name Prefixes	
ADPREFIX=	specifies dependent variable approximations
AIPREFIX=	specifies independent variable approximations
CDPREFIX=	specifies canonical dependent variables
CILPREFIX=	specifies conservative individual lower CL
CIPREFIX=	specifies canonical independent variables
CIUPREFIX=	specifies conservative-individual-upper CL
CMLPREFIX=	specifies conservative-mean-lower CL
CMUPREFIX=	specifies conservative-mean-upper CL
DEPENDENT=	specifies METHOD=MORALS untransformed dependent
LILPREFIX=	specifies liberal-individual-lower CL
LIUPREFIX=	specifies liberal-individual-upper CL
LMLPREFIX=	specifies liberal-mean-lower CL
LMUPREFIX=	specifies liberal-mean-upper CL

Table 90.5 *continued*

Option	Description
RDPREFIX=	specifies residuals
PPREFIX=	specifies predicted values
RPREFIX=	specifies redundancy variables
TDPREFIX=	specifies transformed dependents
TIPREFIX=	specifies transformed independents
Macros Variables	
MACRO	creates macro variables
Other Options	
APPROXIMATIONS	outputs dependent and independent approximations
CCC	outputs canonical correlation coefficients
CEC	outputs canonical elliptical point coordinates
CPC	outputs canonical point coordinates
CQC	outputs canonical quadratic point coordinates
DAPPROXIMATIONS	outputs approximations to transformed dependents
IAPPROXIMATIONS	outputs approximations to transformed independents
MEC	outputs elliptical point coordinates
MPC	outputs point coordinates
MQC	outputs quadratic point coordinates
MRC	outputs multiple regression coefficients

For the coefficients partition, the COEFFICIENTS, COORDINATES, and MEANS *o-options* provide the coefficients that are appropriate for your model. For more explicit control of the coefficient partition, use the options that control details and prefixes. The following list provides details about these options.

ADPREFIX=*name*

ADP=*name*

specifies a prefix for naming the dependent variable predicted values. The default is ADPREFIX=P when you specify the PREDICTED *o-option*; otherwise, it is ADPREFIX=A. When you specify the ADPREFIX= *o-option*, the PREDICTED *o-option* is automatically specified for you. The ADPREFIX= *o-option* is the same as the PPREFIX= *o-option*.

AIPREFIX=*name*

AIP=*name*

specifies a prefix for naming the independent variable approximations. The default is AIPREFIX=A. When you specify the AIPREFIX= *o-option*, the IAPPROXIMATIONS *o-option* is automatically specified for you.

APPROXIMATIONS

APPROX

APP

is equivalent to specifying both the DAPPROXIMATIONS and the IAPPROXIMATIONS *o-options*. If you specify METHOD=UNIVARIATE, then the APPROXIMATIONS *o-option* specifies only the DAPPROXIMATIONS *o-option*.

CANONICAL

CAN

outputs canonical variables to the OUT= data set. When you specify METHOD=CANALS, the CANONICAL *o-option* is automatically specified for you. The CDPREFIX= *o-option* specifies a prefix for naming the dependent canonical variables (default Cand), and the CIPREFIX= *o-option* specifies a prefix for naming the independent canonical variables (default Cani).

CCC

outputs canonical correlation coefficients to the OUT= data set.

CDPREFIX=*name*

CDP=*name*

provides a prefix for naming the canonical dependent variables. The default is CDPREFIX=Cand. When you specify the CDPREFIX= *o-option*, the CANONICAL *o-option* is automatically specified for you.

CEC

outputs canonical elliptical point model coordinates to the OUT= data set.

CILPREFIX=*name*

CIL=*name*

specifies a prefix for naming the conservative-individual-lower confidence limits. The default prefix is CIL. When you specify the CILPREFIX= *o-option*, the CLI *o-option* is automatically specified for you.

CIPREFIX=*name*

CIP=*name*

provides a prefix for naming the canonical independent variables. The default is CIPREFIX=Cani. When you specify the CIPREFIX= *o-option*, the CANONICAL *o-option* is automatically specified for you.

CIUPREFIX=*name*

CIU=*name*

specifies a prefix for naming the conservative-individual-upper confidence limits. The default prefix is CIU. When you specify the CIUPREFIX= *o-option*, the CLI *o-option* is automatically specified for you.

CLI

outputs individual confidence limits to the OUT= data set. The names of the confidence limits variables are constructed from the original dependent variable names and the prefixes specified in the following *o-options*: LILPREFIX= (default LIL for liberal individual lower), CILPREFIX= (default CIL for conservative individual lower), LIUPREFIX= (default LIU for liberal individual upper), and CIUPREFIX= (default CIU for conservative individual upper). When there are no monotonicity constraints, the liberal and conservative limits are the same.

CLM

outputs mean confidence limits to the OUT= data set. The names of the confidence limits variables are constructed from the original dependent variable names and the prefixes specified in

the following *o-options*: LMLPREFIX= (default LML for liberal mean lower), CMLPREFIX= (default CML for conservative mean lower), LMUPREFIX= (default LMU for liberal mean upper), and CMUPREFIX= (default CMU for conservative mean upper). When there are no monotonicity constraints, the liberal and conservative limits are the same.

CMLPREFIX=*name*

CML=*name*

specifies a prefix for naming the conservative-mean-lower confidence limits. The default prefix is CML. When you specify the CMLPREFIX= *o-option*, the CLM *o-option* is automatically specified for you.

CMUPREFIX=*name*

CMU=*name*

specifies a prefix for naming the conservative-mean-upper confidence limits. The default prefix is CMU. When you specify the CMUPREFIX= *o-option*, the CLM *o-option* is automatically specified for you.

COEFFICIENTS

COE

outputs either multiple regression coefficients or raw canonical coefficients to the OUT= data set. If you specify METHOD=CANALS (in the MODEL or PROC TRANSREG statement), then the COEFFICIENTS *o-option* outputs the first *n* canonical variables, where *n* is the value of the NCAN= *a-option* (specified in the MODEL or PROC TRANSREG statement). Otherwise, the COEFFICIENTS *o-option* includes multiple regression coefficients in the OUT= data set. In addition, when you specify the CLASS expansion for any independent variable, the COEFFICIENTS *o-option* also outputs marginal means.

COORDINATES<=*n*>

COO<=*n*>

outputs either ideal point or vector model coordinates for preference mapping to the OUT= data set. When METHOD=CANALS, these coordinates are computed from canonical coefficients; otherwise, the coordinates are computed from multiple regression coefficients. For details, see the section "Point Models" on page 7255.

When ODS Graphics is enabled and vector model coordinates are requested, a plot is produced with points for each row and vectors for each column. If the vectors are plotted based on the actual computed coordinates, then often the vectors are short. A better graphical display is produced when the vectors are stretched. The absolute lengths of each vector can optionally be changed by specifying COORDINATES=*n*. Then the vector coordinates are all multiplied by *n*. Usually, *n* is a value such as 2, 2.5, or 3. The default is 2.5. Specify COORDINATES=1 if you want to see the vectors without any stretching. The relative lengths of the different vectors are important and interpretable, and these are preserved by the stretching.

CPC

outputs canonical point model coordinates to the OUT= data set.

CQC

outputs canonical quadratic point model coordinates to the OUT= data set.

DAPPROXIMATIONS

DAP

outputs the approximations of the transformed dependent variables to the OUT= data set. These are the target values for the optimal transformations. With METHOD=UNIVARIATE and METHOD=MORALS, the dependent variable approximations are the ordinary predicted values from the linear model. The names of the approximation variables are constructed from the ADPREFIX= *o-option* (default A) and the original dependent variable names. For ordinary predicted values, use the PREDICTED *o-option* instead of the DAPPROXIMATIONS *o-option*, since the PREDICTED *o-option* uses a more relevant prefix ("P" instead of "A") and a more relevant variable label suffix ("Predicted Values" instead of "Approximations").

DESIGN<=*n*>

DES<=*n*>

specifies that your primary goal is design matrix coding, not analysis. Specifying the DESIGN *o-option* makes the procedure run faster. The DESIGN *o-option* sets the default method to UNIVARIATE and the default MAXITER= value to zero. It suppresses computing the regression coefficients, unless they are needed for some other option. Furthermore, when the DESIGN *o-option* is specified, the MODEL statement is not required to have an equal sign. When no MODEL statement equal sign is specified, all variables are considered independent variables, all options that require dependent variables are ignored, and the IREPLACE *o-option* is automatically specified for you.

You can use DESIGN=*n* for coding very large data sets, where *n* is the number of observations to code at one time. For example, to code a data set with a large number of observations, you can specify DESIGN=100 or DESIGN=1000 to process the data set in blocks of 100 or 1000 observations. If you specify the DESIGN *o-option* rather than DESIGN=*n*, PROC TRANSREG tries to process all observations at once, which might not work with very large data sets. Specify the NOZEROCONSTANT *a-option* with DESIGN=*n* to ensure that constant variables within blocks are not zeroed. See the sections "Using the DESIGN Output Option" on page 7293 and "Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO" on page 7297 for more information about the DESIGN option.

DEPENDENT=*name*

DEP=*name*

specifies the untransformed dependent variable for OUT= data sets with METHOD=MORALS when there is more than one dependent variable. The default is DEPENDENT=_DEPEND_.

DREPLACE

DRE

replaces the original dependent variables with the transformed dependent variables in the OUT= data set. The names of the transformed variables in the OUT= data set correspond to the names of the original dependent variables in the input data set. By default, both the original dependent variables and the transformed dependent variables (with names constructed from the TDPREFIX= (default T) *o-option* and the original dependent variable names) are included in the OUT= data set.

IAPPROXIMATIONS

IAP

outputs the approximations of the transformed independent variables to the OUT= data set.

These are the target values for the optimal transformations. The names of the approximation variables are constructed from the AIPREFIX= *o-option* (default A) and the original independent variable names. When you specify the AIPREFIX= *o-option*, the IAPPROXIMATIONS *o-option* is automatically specified for you. The IAPPROXIMATIONS *o-option* is not valid when METHOD=UNIVARIATE.

IREPLACE

IRE

replaces the original independent variables with the transformed independent variables in the OUT= data set. The names of the transformed variables in the OUT= data set correspond to the names of the original independent variables in the input data set. By default, both the original independent variables and the transformed independent variables (with names constructed from the TIPREFIX= *o-option* (default T) and the original independent variable names) are included in the OUT= data set.

LEVERAGE<=*name***>**

LEV<=*name***>**

creates a variable with the specified name in the OUT= data set that contains leverages. Specifying the LEVERAGE *o-option* is equivalent to specifying LEVERAGE=Leverage.

LILPREFIX=*name*

LIL=*name*

specifies a prefix for naming the liberal-individual-lower confidence limits. The default prefix is LIL. When you specify the LILPREFIX= *o-option*, the CLI *o-option* is automatically specified for you.

LIUPREFIX=*name*

LIU=*name*

specifies a prefix for naming the liberal-individual-upper confidence limits. The default prefix is LIU. When you specify the LIUPREFIX= *o-option*, the CLI *o-option* is automatically specified for you.

LMLPREFIX=*name*

LML=*name*

specifies a prefix for naming the liberal-mean-lower confidence limits. The default prefix is LML. When you specify the LMLPREFIX= *o-option*, the CLM *o-option* is automatically specified for you.

LMUPREFIX=*name*

LMU=*name*

specifies a prefix for naming the liberal-mean-upper confidence limits. The default prefix is LMU. When you specify the LMUPREFIX= *o-option*, the CLM *o-option* is automatically specified for you.

MACRO(*keyword=name...***)**

MAC(*keyword=name...***)**

creates macro variables. Most of the options available within the MACRO *o-option* are rarely

needed. By default, PROC TRANSREG creates a macro variable named _TrgInd with a complete list of independent variables created by the procedure. When PROC TRANSREG is being used for design matrix creation prior to running a procedure without a CLASS statement, this macro provides a convenient way to use the results from PROC TRANSREG. For example, a PROC LOGISTIC step that uses a design matrix coded by PROC TRANSREG can use the following MODEL statement:

```
model y=&_trgind;
```

PROC TRANSREG, also by default, creates a macro variable named _TrgIndN, which contains the number of variables in the _TrgInd list. These macro variables can be used in an ARRAY statement as follows:

```
array indvars[&_trgindn] &_trgind;
```

See the sections "Using the DESIGN Output Option" on page 7293 and "Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO" on page 7297 for examples of using the default macro variables.

The available *keywords* are as follows.

DN=*name* specifies the name of a macro variable that contains the number of dependent variables. By default, a macro variable named _TrgDepN is created. This is the number of variables in the DL= list and the number of macro variables created by the DV= and DE= specifications.

IN=*name* specifies the name of a macro variable that contains the number of independent variables. By default, a macro variable named _TrgIndN is created. This is the number of variables in the IL= list and the number of macro variables created by the IV= and IE= specifications.

DL=*name* specifies the name of a macro variable that contains the list of the dependent variables. By default, a macro variable named _TrgDep is created. These are the variable names of the final transformed variables in the OUT= data set. For example, if there are three dependent variables, y1–y3, then _TrgDep contains, by default, Ty1 Ty2 Ty3 (or y1 y2 y3 if you specify the REPLACE *o-option*).

IL=*name* specifies the name of a macro variable that contains the list of the independent variables. By default, a macro variable named _TrgInd is created. These are the variable names of the final transformed variables in the OUT= data set. For example, if there are three independent variables, x1–x3, then _TrgInd contains, by default, Tx1 Tx2 Tx3 (or x1 x2 x3 if you specify the REPLACE *o-option*).

DV=*prefix* specifies a prefix for creating a list of macro variables, each of which contains one dependent variable name. For example, if there are three dependent variables, y1–y3, and you specify **macro(dv=Dep)**, then three macro variables, Dep1, Dep2, and Dep3, are created, containing Ty1, Ty2, and Ty3, respectively (or y1, y2, and y3 if you specify the REPLACE *o-option*). By default, no list is created.

IV=*prefix* specifies a prefix for creating a list of macro variables, each of which contains one independent variable name. For example, if there are three independent variables, x1–x3, and you specify **macro(iv=Ind)**, then three macro variables, Ind1, Ind2, and Ind3, are created, containing Tx1, Tx2, and TX3, respectively (or x1, x2, and x3 if you specify the REPLACE *o-option*). By default, no list is created.

DE=*prefix* specifies a prefix for creating a list of macro variables, each of which contains one dependent variable effect. This list shows the origin of each model term. Each effect consists of two or more parts, and each part consists of a value in 32 columns followed by a blank. For example, if you specify **macro(de=d)**, then a macro variable d1 is created for **identity(y)**. The d1 macro variable is shown next, wrapped onto two lines:

```
4                                TY
IDENTITY                         Y
```

The first part is the number of parts (4), the second part is the transformed variable name, the third part is the transformation, and the last part is the input variable name. By default, no list is created.

IE=*prefix* specifies a prefix for creating a list of macro variables, each of which contains one independent variable effect. This list shows the origin of each model term. Each effect consists of two or more parts, and each part consists of a value in 32 columns followed by a blank. For example, if you specify **macro(ie=I)**, then three macro variables, I1, I2, and I3, are created for **class(x1 | x2)** when both x1 and x2 have values of 1 and 2. These macro variables are shown next, with extra white space removed:

```
5     Tx11     CLASS    x1   1
5     Tx21     CLASS    x2   1
8     Tx11x21  CLASS    x1   1      CLASS    x2   1
```

For CLASS variables, the formatted level appears after the variable name. The first two effects are the main effects, and the last is the interaction term. By default, no list is created.

MEANS

MEA

outputs marginal means for CLASS variable expansions to the OUT= data set.

MEC

outputs multiple regression elliptical point model coordinates to the OUT= data set.

MPC

outputs multiple regression point model coordinates to the OUT= data set.

MQC

outputs multiple regression quadratic point model coordinates to the OUT= data set.

MRC

outputs multiple regression coefficients to the OUT= data set.

MREDUNDANCY

MRE

outputs multiple redundancy analysis coefficients to the OUT= data set.

NORESTOREMISSING

NORESTORE

NOR

specifies that missing values should not be restored when the OUT= data set is created. By default, the coded CLASS variable contains a row of missing values for observations in which the CLASS variable is missing. When you specify the NORESTOREMISSING *o-option*, these observations contain a row of zeros instead. This is useful when PROC TRANSREG is used to code experimental designs for discrete choice models and there is a constant alternative indicated by a missing value.

NOSCORES

NOS

excludes original variables, transformed variables, predicted values, residuals, and scores from the OUT= data set. You can use the NOSCORES *o-option* with various other options to create an OUT= data set that contains only a coefficient partition (for example, a data set consisting entirely of coefficients and coordinates).

PREDICTED

PRE

P

outputs predicted values, which for METHOD=UNIVARIATE and METHOD=MORALS are the ordinary predicted values from the linear model, to the OUT= data set. The names of the predicted values' variables are constructed from the PPREFIX= *o-option* (default P) and the original dependent variable names. When you specify the PPREFIX= *o-option*, the PREDICTED *o-option* is automatically specified for you.

PPREFIX=*name*

PDPREFIX=*name*

PDP=*name*

specifies a prefix for naming the dependent variable predicted values. The default is PPREFIX=P when you specify the PREDICTED *o-option*; otherwise, it is PPREFIX=A. When you specify the PPREFIX= *o-option*, the PREDICTED *o-option* is automatically specified for you. The PPREFIX= *o-option* is the same as the ADPREFIX= *o-option*.

RDPREFIX=*name*

RDP=*name*

specifies a prefix for naming the residual (dependent) variables to the OUT= data set. The default is RDPREFIX=R. When you specify the RDPREFIX= *o-option*, the RESIDUALS *o-option* is automatically specified for you.

REDUNDANCY< =STANDARDIZE | UNSTANDARDIZE >
RED< =STA | UNS >

outputs redundancy variables to the OUT= data set, either standardized or unstandardized. Specifying the REDUNDANCY *o-option* is the same as specifying REDUNDANCY=STANDARDIZE. The results of the REDUNDANCY *o-option* depends on the TSTANDARD= option. You must specify TSTANDARD=Z to get results based on standardized data. The TSTANDARD= option controls how the data that go into the redundancy analysis are scaled, and REDUNDANCY=STANDARDIZE|UNSTANDARDIZE controls how the redundancy variables are scaled. The REDUNDANCY *o-option* is automatically specified for you when you specify the METHOD=REDUNDANCY *a-option*. The RPREFIX= *o-option* specifies a prefix (default Red) for naming the redundancy variables.

REFERENCE=NONE | MISSING | ZERO
REF=NON | MIS | ZER

specifies how reference levels of CLASS variables are to be treated. The options are REFERENCE=NONE, the default, in which reference levels are suppressed; REFERENCE=MISSING, in which reference levels are displayed and output with missing values; and REFERENCE=ZERO, in which reference levels are displayed and output with zeros. You can specify the REFERENCE= option in the PROC TRANSREG, MODEL, or OUTPUT statement, and you can specify it independently for the OUT= data set and the displayed output. When you specify it in only one statement, it sets the option for both the displayed output and the OUT= data set.

REPLACE
REP

is equivalent to specifying both the DREPLACE and the IREPLACE *o-options*.

RESIDUALS
RES
R

outputs the differences between the transformed dependent variables and their predicted values. The names of the residual variables are constructed from the RDPREFIX= *o-option* (default R) and the original dependent variable names.

RPREFIX=*name*
RPR=*name*

provides a prefix for naming the redundancy variables. The default is RPREFIX=Red. When you specify the RPREFIX= *o-option*, the REDUNDANCY *o-option* is automatically specified for you.

TDPREFIX=*name*
TDP=*name*

specifies a prefix for naming the transformed dependent variables. By default, TDPREFIX=T. The TDPREFIX= *o-option* is ignored when you specify the DREPLACE *o-option*.

TIPREFIX=*name*
TIP=*name*

specifies a prefix for naming the transformed independent variables. By default, TIPREFIX=T. The TIPREFIX= *o-option* is ignored when you specify the IREPLACE *o-option*.

WEIGHT Statement

WEIGHT *variable* **;**

When you use a WEIGHT statement, a weighted residual sum of squares is minimized. The WEIGHT statement has no effect on degrees of freedom or number of observations, but the weights affect most other calculations. The observation is used in the analysis only if the value of the WEIGHT statement variable is greater than 0.

Details: TRANSREG Procedure

Model Statement Usage

MODEL < *transform(dependents* < / *t-options* >)>
< *transform(dependents* < / *t-options* >) . . . =>
transform(independents < / *t-options* >)
< *transform(independents* < / *t-options* >) . . . > < / *a-options* > **;**

Here are some examples of model statements:

- linear regression

```
model identity(y) = identity(x);
```

- a linear model with a nonlinear regression function

```
model identity(y) = spline(x / nknots=5);
```

- multiple regression

```
model identity(y) = identity(x1-x5);
```

- multiple regression with nonlinear transformations

```
model spline(y / nknots=3) = spline(x1-x5 / nknots=3);
```

- multiple regression with nonlinear but monotone transformations

```
model mspline(y / nknots=3) = mspline(x1-x5 / nknots=3);
```

- multivariate multiple regression

```
model identity(y1-y4) = identity(x1-x5);
```

- canonical correlation

```
model identity(y1-y4) = identity(x1-x5) / method=canals;
```

- redundancy analysis

```
model identity(y1-y4) = identity(x1-x5) / method=redundancy;
```

- preference mapping, vector model (Carroll 1972)

```
model identity(Attrib1-Attrib3) = identity(Dim1-Dim2);
```

- preference mapping, ideal point model (Carroll 1972)

```
model identity(Attrib1-Attrib3) = point(Dim1-Dim2);
```

- preference mapping, ideal point model, elliptical (Carroll 1972)

```
model identity(Attrib1-Attrib3) = epoint(Dim1-Dim2);
```

- preference mapping, ideal point model, quadratic (Carroll 1972)

```
model identity(Attrib1-Attrib3) = qpoint(Dim1-Dim2);
```

- metric conjoint analysis

```
model identity(Subj1-Subj50) = class(a b c d e f / zero=sum);
```

- nonmetric conjoint analysis

```
model monotone(Subj1-Subj50) = class(a b c d e f / zero=sum);
```

- main effects, two-way interaction

```
model identity(y) = class(a|b);
```

- less-than-full-rank model—main effects and two-way interaction are constrained to sum to zero

```
model identity(y) = class(a|b / zero=sum);
```

- main effects and all two-way interactions

```
model identity(y) = class(a|b|c@2);
```

- main effects and all two- and three-way interactions

```
model identity(y) = class(a|b|c);
```

- main effects and only the b*c two-way interaction

```
model identity(y) = class(a b c b*c);
```

- seven main effects, three two-way interactions

```
model identity(y) = class(a b c d e f g a*b a*c a*d);
```

- deviations-from-means (effects or $(1, 0, -1)$) coding, with an a reference level of '1' and a b reference level of '2'

```
model identity(y) = class(a|b / deviations zero='1' '2');
```

- cell-means coding (implicit intercept)

```
model identity(y) = class(a*b / zero=none);
```

- reference cell model

```
model identity(y) = class(a|b / zero='1' '1');
```

- reference line with change in line parameters

```
model identity(y) = class(a) | identity(x);
```

- reference curve with change in curve parameters

```
model identity(y) = class(a) | spline(x);
```

- separate curves and intercepts

```
model identity(y) = class(a / zero=none) | spline(x);
```

- quantitative effects with interaction

```
model identity(y) = identity(x1 | x2);
```

- separate quantitative effects with interaction within each cell

```
model identity(y) = class(a * b / zero=none) | identity(x1 | x2);
```

Box-Cox Transformations

Box-Cox (1964) transformations are used to find potentially nonlinear transformations of a dependent variable. The Box-Cox transformation has the form

$$\begin{array}{ll} (y^{\lambda} - 1)/\lambda & \lambda \neq 0 \\ \log(y) & \lambda = 0 \end{array}$$

This family of transformations of the positive dependent variable y is controlled by the parameter λ. Transformations linearly related to square root, inverse, quadratic, cubic, and so on are all

special cases. The limit as λ approaches 0 is the log transformation. More generally, Box-Cox transformations of the following form can be fit:

$$\begin{array}{ll} ((y+c)^{\lambda}-1)/(\lambda g) & \lambda \neq 0 \\ \log(y+c)/g & \lambda = 0 \end{array}$$

By default, $c = 0$. The parameter c can be used to rescale y so that it is strictly positive. By default, $g = 1$. Alternatively, g can be $\dot{y}^{\lambda-1}$, where $\dot{y}$ is the geometric mean of y.

The BOXCOX transformation in PROC TRANSREG can be used to perform a Box-Cox transformation of the dependent variable. You can specify a list of power parameters by using the LAMBDA= *t-option*. By default, LAMBDA=–3 TO 3 BY 0.25. The procedure chooses the optimal power parameter by using a maximum likelihood criterion (Draper and Smith 1981, pp. 225–226). You can specify the PARAMETER=*c* transformation option when you want to shift the values of y, usually to avoid negatives. To divide by $\dot{y}^{\lambda-1}$, specify the GEOMETRICMEAN *t-option*.

Here are three examples of using the LAMBDA= *t-option*:

```
model BoxCox(y / lambda=0) = identity(x1-x5);
model BoxCox(y / lambda=-2 to 2 by 0.1) = identity(x1-x5);
model BoxCox(y) = identity(x1-x5);
```

Here is the first example:

```
model BoxCox(y / lambda=0) = identity(x1-x5);
```

LAMBDA=0 specifies a Box-Cox transformation with a power parameter of 0. Since a single value of 0 was specified for LAMBDA=, there is no difference between the following models:

```
model BoxCox(y / lambda=0) = identity(x1-x5);
model log(y) = identity(x1-x5);
```

Here is the second example:

```
model BoxCox(y / lambda=-2 to 2 by 0.1) = identity(x1-x5);
```

LAMBDA= specifies a list of power parameters. PROC TRANSREG tries each power parameter in the list and picks the best transformation. A maximum likelihood approach (Draper and Smith 1981, pp. 225–226) is used. With Box-Cox transformations, PROC TRANSREG finds the transformation before the usual iterations begin. Note that this is quite different from PROC TRANSREG's usual approach of iteratively finding optimal transformations with ordinary and alternating least squares. It is analogous to SMOOTH and PBSPLINE, which also find transformations before the iterations begin based on a criterion other than least squares.

Here is the third example:

```
model BoxCox(y) = identity(x1-x5);
```

The default LAMBDA= list of –3 TO 3 BY 0.25 is used.

The procedure prints the optimal power parameter, a confidence interval on the power parameter (based on the ALPHA= *t-option*), a "convenient" power parameter (selected from the CLL= *t-option* list), and the log likelihood for each power parameter tried (see Example 90.2).

To illustrate how Box-Cox transformations work, data were generated from the model

$$y = e^{x+\epsilon}$$

where $\epsilon \sim \mathrm{N}(0, 1)$. The transformed data can be fit with a linear model

$$\log(y) = x + \epsilon$$

The following statements produce Figure 90.14 through Figure 90.15:

```
title 'Basic Box-Cox Example';

data x;
   do x = 1 to 8 by 0.025;
      y = exp(x + normal(7));
      output;
   end;
run;

ods graphics on;

title2 'Default Options';

proc transreg data=x test;
   model BoxCox(y) = identity(x);
run;
```

Figure 90.14 Basic Box-Cox Example, Default Output

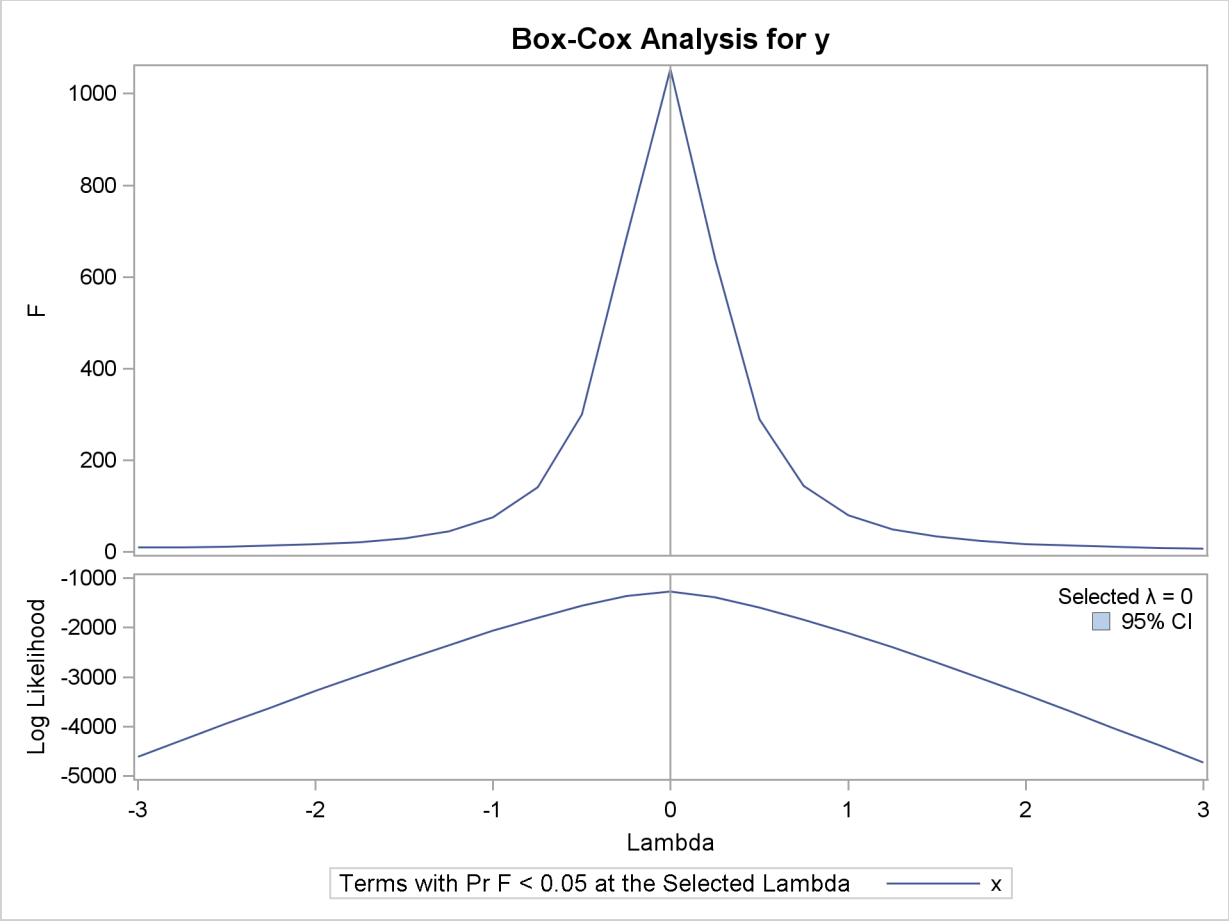

Figure 90.14 shows that PROC TRANSREG correctly selects the log transformation $\lambda = 0$, with a narrow confidence interval. The $F = t^2$ plot shows that F is at its largest in the vicinity of the optimal Box-Cox transformation.

The rest of the output, which contains the ANOVA results, is shown in Figure 90.15.

Figure 90.15 Basic Box-Cox Example, Default Output

```
                    Dependent Variable BoxCox(y)

                Number of Observations Read           281
                Number of Observations Used           281
```

Figure 90.15 *continued*

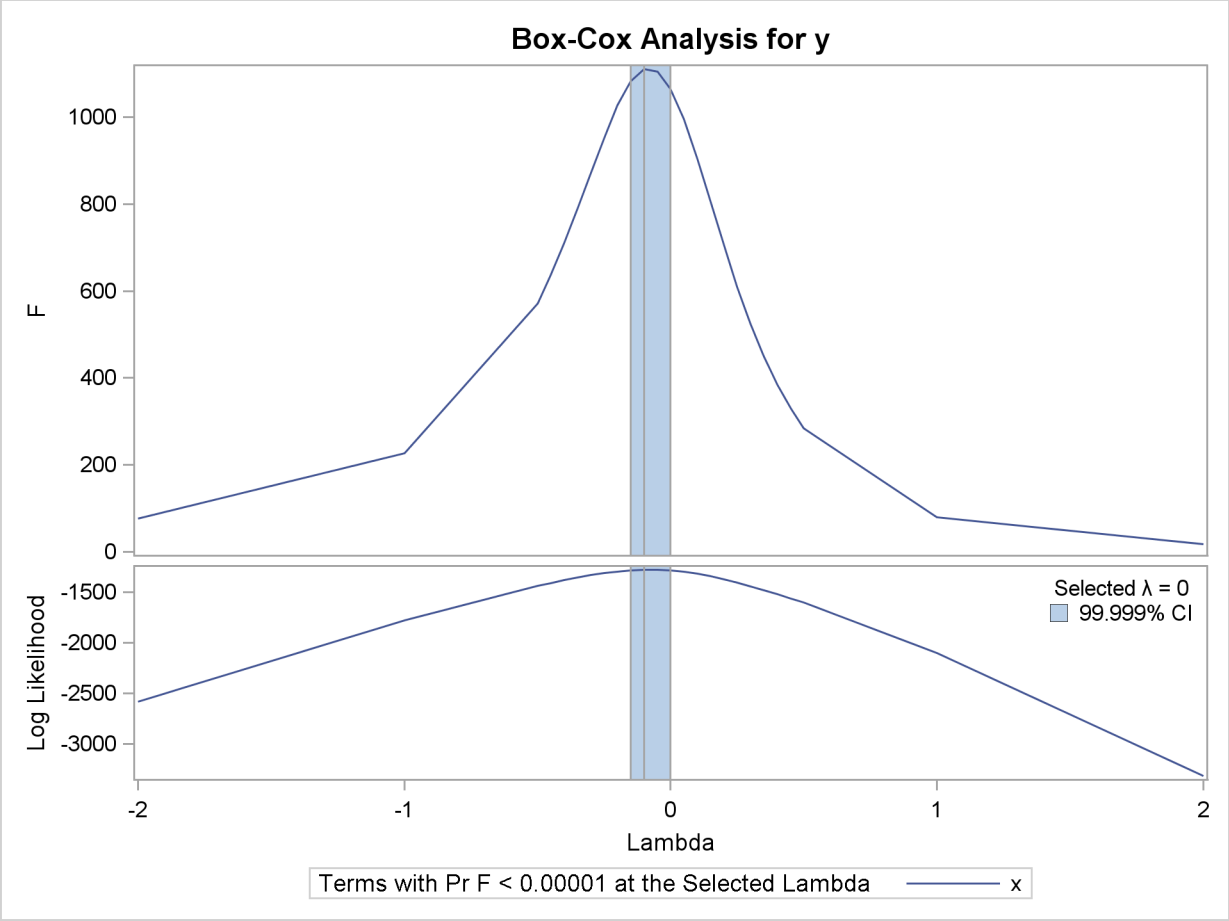
The TRANSREG Procedure Hypothesis Tests for BoxCox(y)

Univariate ANOVA Table Based on the Usual Degrees of Freedom

Source	DF	Sum of Squares	Mean Square	F Value	Liberal p
Model	1	1145.884	1145.884	1053.66	>= <.0001
Error	279	303.421	1.088		
Corrected Total	280	1449.305			

The above statistics are not adjusted for the fact that the dependent variable was transformed and so are generally liberal.

Root MSE	1.04285	R-Square	0.7906
Dependent Mean	4.49653	Adj R-Sq	0.7899
Coeff Var	23.19225	Lambda	0.0000



This next example uses several options. The LAMBDA= *t-option* specifies power parameters sparsely from –2 to –0.5 and 0.5 to 2 just to get the general shape of the log-likelihood function in that region. Between –0.5 and 0.5, more power parameters are tried. The CONVENIENT *t-option* is specified so that if a power parameter like $\lambda = 1$ or $\lambda = 0$ is found in the confidence interval, it is used instead of the optimal power parameter. PARAMETER=2 is specified to add 2 to each y before performing the transformations. ALPHA=0.00001 specifies a wide confidence interval.

These next statements perform the Box-Cox analysis and produce Figure 90.16 and Figure 90.17:

```
title2 'Several Options Demonstrated';

proc transreg data=x ss2 details
              plots=(transformation(dependent) scatter
                     observedbypredicted);
   model BoxCox(y / lambda=-2 -1 -0.5 to 0.5 by 0.05 1 2
                    convenient parameter=2 alpha=0.00001) =
         identity(x);
run;
```

Figure 90.16 Basic Box-Cox Example, Several Options Demonstrated

The results in Figure 90.16 and Figure 90.17 show that the optimal power parameter is –0.1, but 0 is in the confidence interval, and hence a log transformation is chosen. The actual Box-Cox transformation, the original scatter plot, and observed by predicted values plot are shown in Figure 90.17.

Figure 90.17 *continued*

Figure 90.17 *continued*

The next example shows how to find a Box-Cox transformation without an independent variable. This seeks to normalize the univariate histogram. This example generates 500 random observations from a lognormal distribution. In addition, a constant variable z is created that is all zero. This is because PROC TRANSREG requires some independent variable to be specified, even if it is constant. Two options are specified in the PROC TRANSREG statement. MAXITER=0 is specified because the Box-Cox transformation is performed before any iterations are begun. No iterations are needed since no other work is required. The NOZEROCONSTANT *a-option* (which can be abbreviated NOZ) is specified so that PROC TRANSREG does not print any warnings when it encounters the constant independent variable. The MODEL statement asks for a Box-Cox transformation of y and an IDENTITY transformation (which does nothing) of the constant variable z. Finally, PROC UNIVARIATE is run to show a histogram of the original variable y, and the Box-Cox transformation, Ty. The following statements fit the univariate Box-Cox model and produce Figure 90.18:

```
title 'Univariate Box-Cox';

data x;
   call streaminit(17);
   z = 0;
   do i = 1 to 500;
      y = rand('lognormal');
      output;
   end;
run;

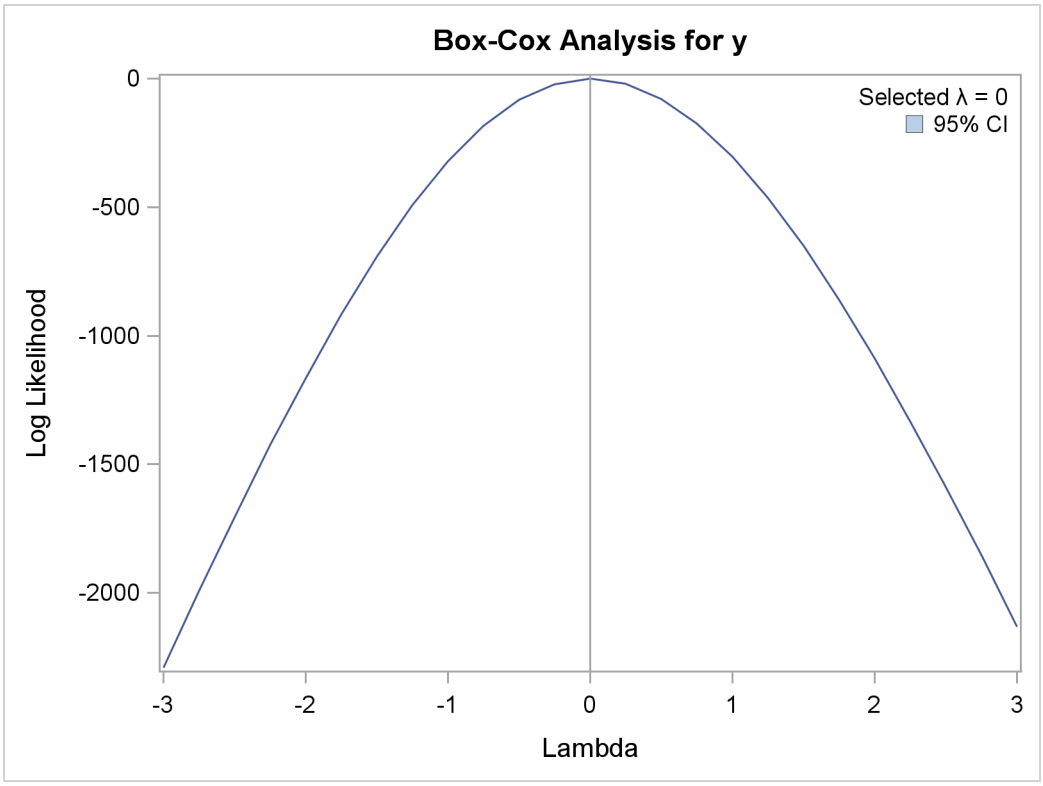
proc transreg maxiter=0 nozeroconstant;
   model BoxCox(y) = identity(z);
   output;
run;

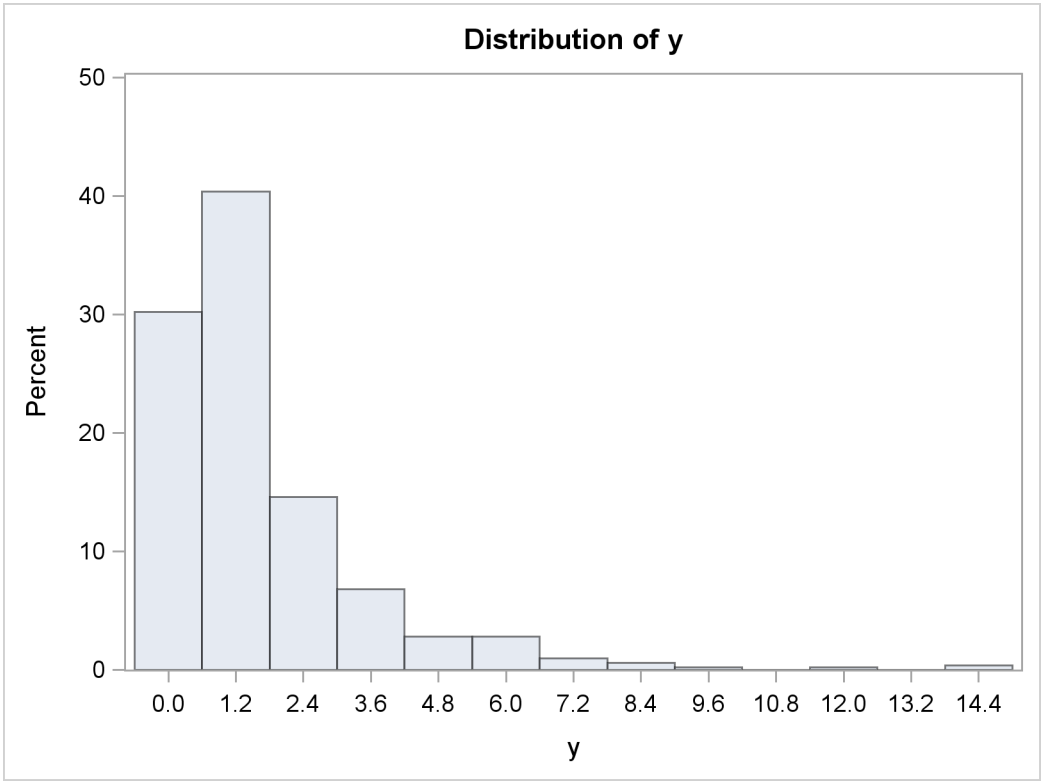
proc univariate noprint;
   histogram y ty;
run;

ods graphics off;
```

The PROC TRANSREG results in Figure 90.18 show that zero is chosen for lambda, so a log transformation is chosen. The first histogram shows that the original data are skewed, but a log transformation makes the data appear much more nearly normal.

Figure 90.18 Box-Cox with No Independent Variable





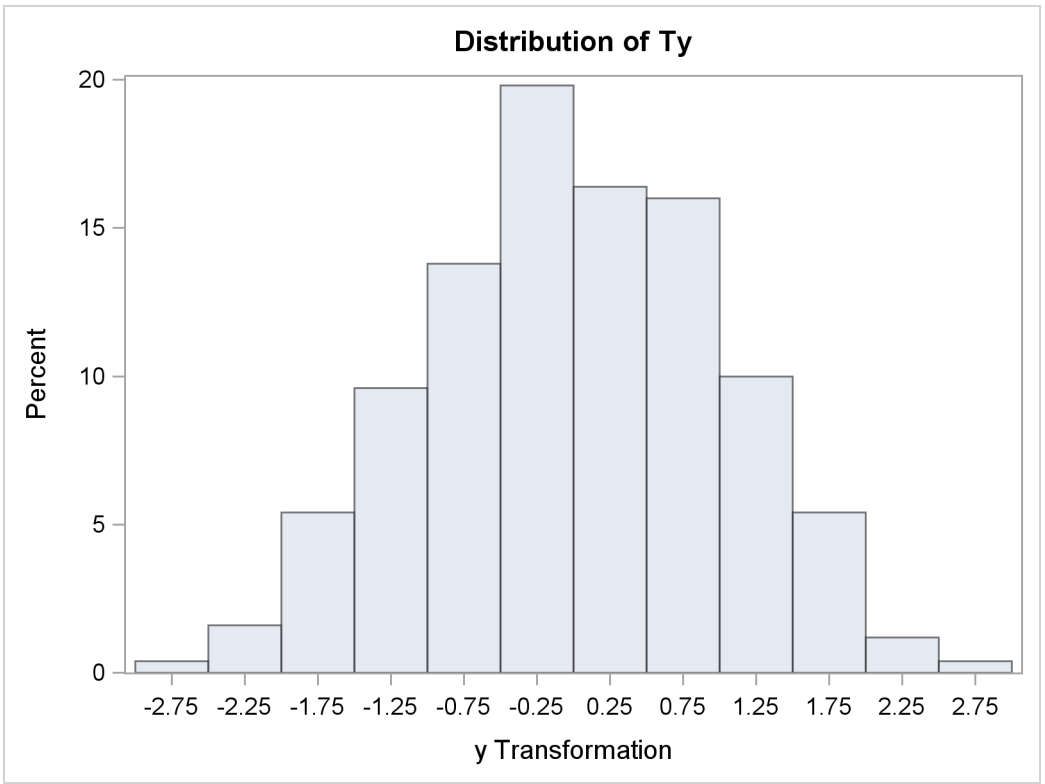


Figure 90.18 *continued*

Using Splines and Knots

This section illustrates some properties of splines. *Splines* are curves, and they are usually required to be continuous and smooth. Splines are usually defined as piecewise polynomials of degree n with function values and first $n-1$ derivatives that agree at the points where they join. The abscissa or X-axis values of the join points are called *knots*. The term "spline" is also used for polynomials (splines with no knots) and piecewise polynomials with more than one discontinuous derivative. Splines with no knots are generally smoother than splines with knots, which are generally smoother than splines with multiple discontinuous derivatives. Splines with few knots are generally smoother than splines with many knots; however, increasing the number of knots usually increases the fit of the spline function to the data. Knots give the curve freedom to bend to more closely follow the data. See Smith (1979) for an excellent introduction to splines.

In this section, an artificial data set is created with a variable y that is a discontinuous function of x. (See Figure 90.20.) Notice that the function has four unconnected parts, each of which is a curve. Notice too that there is an overall quadratic trend—that is, ignoring the shapes of the individual curves, at first the y values tend to decrease as x increases, then y values tend to increase. While these artificial data are clearly not realistic, their distinct pattern helps illustrate how splines work. The following statements create the data set, fit a simple linear regression model, and produce Figure 90.19 through Figure 90.20:

```
title 'An Illustration of Splines and Knots';

* Create in y a discontinuous function of x.;

data a;
   x = -0.000001;
   do i = 0 to 199;
      if mod(i, 50) = 0 then do;
         c = ((x / 2) - 5)**2;
         if i = 150 then c = c + 5;
         y = c;
      end;
      x = x + 0.1;
      y = y - sin(x - c);
      output;
   end;
run;

ods graphics on;

title2 'A Linear Regression Fit';
proc transreg data=a plots=scatter rsquare;
   model identity(y) = identity(x);
run;
```

The R square for the linear regression is 0.1006. The linear fit results in Figure 90.19 show the predicted values of y given x. It can clearly be seen in Figure 90.19 that the linear regression model is not appropriate for these data.

Figure 90.19 A Linear Regression Fit

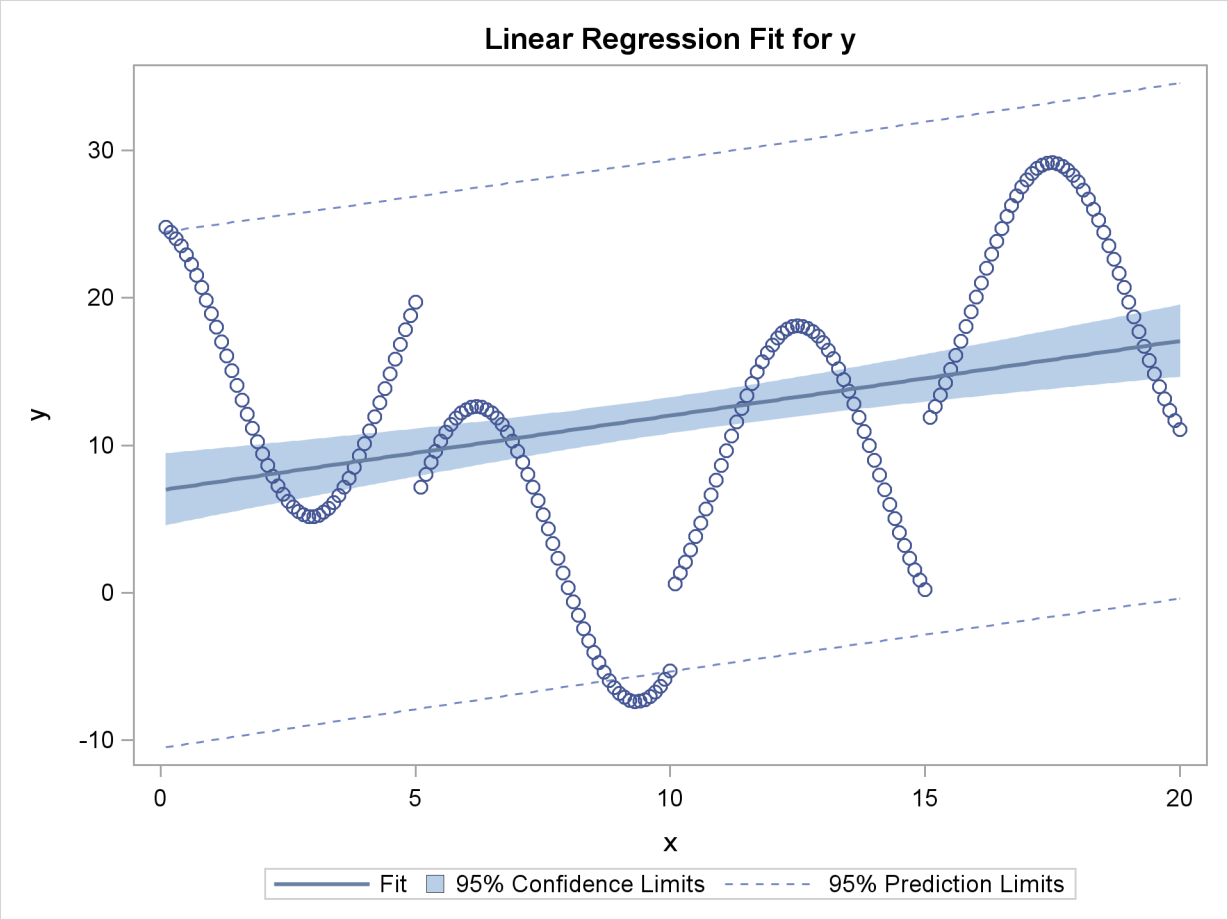
```
An Illustration of Splines and Knots
A Linear Regression Fit

The TRANSREG Procedure

The TRANSREG Procedure Hypothesis Tests for Identity(y)

R-Square      0.1006
```

Figure 90.19 *continued*



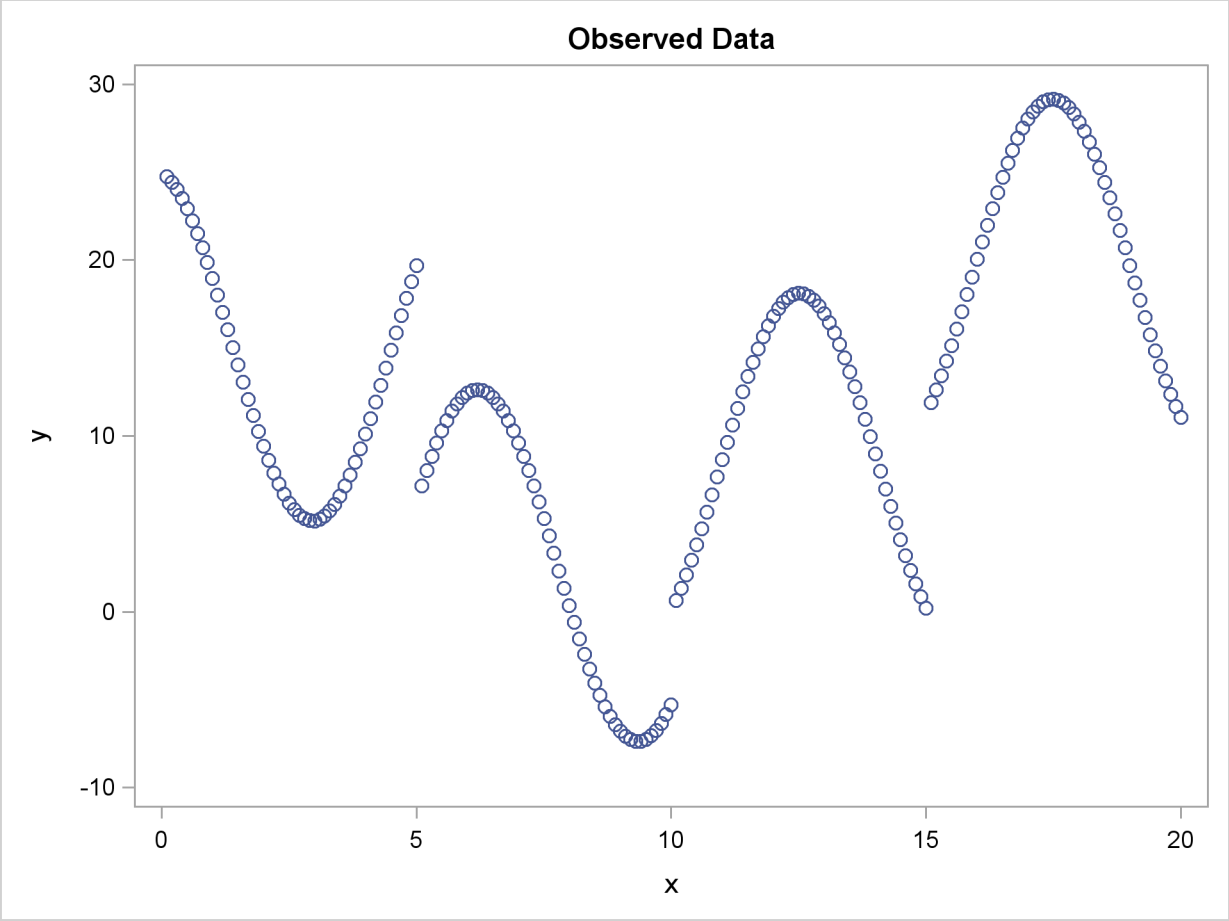


Figure 90.20 The Original Scatter Plot

The next PROC TRANSREG step finds a degree-two spline transformation with no knots, which is a quadratic polynomial. The spline is a weighted sum of a single constant, a single straight line, and a single quadratic curve. The following statements perform the quadratic analysis and produce Figure 90.21:

```
title2 'A Quadratic Polynomial Fit';

proc transreg data=A;
   model identity(y)=spline(x / degree=2);
run;
```

The R square in Figure 90.21 increases from 0.10061, which is the linear fit value from before, to 0.40720. The plot shows that the quadratic regression function does not fit any of the individual curves well, but it does follow the overall trend in the data. Since the overall trend is quadratic, if you were to fit a degree-three spline with no knots (not shown) would increase R square by only a small amount.

Algorithm converged.

Figure 90.21 *continued*

The next step uses the default degree of three, for a piecewise cubic polynomial, and requests knots at the known break points, x=5, 10, and 15. This requests a spline that is continuous, has continuous first and second derivatives, and has a third derivative that is discontinuous at 5, 10, and 15. The spline is a weighted sum of a single constant, a single straight line, a single quadratic curve, a cubic curve for the portion of x less than 5, a different cubic curve for the portion of x between 5 and 10, a different cubic curve for the portion of x between 10 and 15, and another cubic curve for the portion of x greater than 15. The following statements fit the spline model and produce Figure 90.22:

```
title2 'A Cubic Spline Fit with Knots at X=5, 10, 15';

proc transreg data=a;
   model identity(y) = spline(x / knots=5 10 15);
run;
```

The new R square in Figure 90.22 is 0.61730. The plot shows that the spline is less smooth than the quadratic polynomial and follows the data more closely than the quadratic polynomial.

Figure 90.22 A Cubic Spline Fit

The TRANSREG Procedure

TRANSREG MORALS Algorithm Iteration History for Identity(y)

Iteration Number	Average Change	Maximum Change	R-Square	Criterion Change	Note
1	0.85367	3.88449	0.10061		
2	0.00000	0.00000	0.61730	0.51670	Converged

Algorithm converged.

Figure 90.22 *continued*

The same model could be fit with a DATA step and PROC REG, as follows:

```
data b;              /* A is the data set used by transreg */
   set a(keep=x y);
   x1=x;                        /* x                        */
   x2=x**2;                     /* x squared                */
   x3=x**3;                     /* x cubed                  */
   x4=(x> 5)*((x-5)**3);        /* change in x**3 after  5 */
   x5=(x>10)*((x-10)**3);       /* change in x**3 after 10 */
   x6=(x>15)*((x-15)**3);       /* change in x**3 after 15 */
run;

proc reg;
   model y=x1-x6;
run; quit;
```

The output from these previous statements is not displayed. The assignment statements and comments show how you can construct terms that can be used to fit the same model.

In the next step, each knot is repeated three times, so the first, second, and third derivatives are discontinuous at x=5, 10, and 15, but the spline is continuous at the knots. The spline is a weighted sum of the following:

- a single constant
- a line for the portion of x less than 5
- a quadratic curve for the portion of x less than 5
- a cubic curve for the portion of x less than 5
- a different line for the portion of x between 5 and 10
- a different quadratic curve for the portion of x between 5 and 10
- a different cubic curve for the portion of x between 5 and 10
- a different line for the portion of x between 10 and 15
- a different quadratic curve for the portion of x between 10 and 15
- a different cubic curve for the portion of x between 10 and 15
- another line for the portion of x greater than 15
- another quadratic curve for the portion of x greater than 15
- another cubic curve for the portion of x greater than 15

The spline is continuous since there is not a separate constant or separate intercept in the formula for the spline for each knot. The following statements perform this analysis and produce Figure 90.23:

```
title3 'First - Third Derivatives Discontinuous at X=5, 10, 15';

proc transreg data=a;
   model identity(y) = spline(x / knots=5 5 5 10 10 10 15 15 15);
run;
```

Now the R square in Figure 90.23 is 0.95542, and the spline closely follows the data, except at the knots.

Figure 90.23 Spline with Discontinuous Derivatives

```

Figure 90.23 *continued*

The same model could be fit with a DATA step and PROC REG, as follows:

```
data b;
   set a(keep=x y);
   x1=x;                          /* x                          */
   x2=x**2;                       /* x squared                  */
   x3=x**3;                       /* x cubed                    */
   x4=(x>5)   * (x- 5);           /* change in x    after  5 */
   x5=(x>10)  * (x-10);           /* change in x    after 10 */
   x6=(x>15)  * (x-15);           /* change in x    after 15 */
   x7=(x>5)   * ((x-5)**2);       /* change in x**2 after  5 */
   x8=(x>10)  * ((x-10)**2);      /* change in x**2 after 10 */
   x9=(x>15)  * ((x-15)**2);      /* change in x**2 after 15 */
   x10=(x>5)  * ((x-5)**3);       /* change in x**3 after  5 */
   x11=(x>10) * ((x-10)**3);      /* change in x**3 after 10 */
   x12=(x>15) * ((x-15)**3);      /* change in x**3 after 15 */
run;

proc reg;
   model y=x1-x12;
run; quit;
```

The output from these previous statements is not displayed. The assignment statements and comments show how you can construct terms that can be used to fit the same model.

Each knot is repeated four times in the next step. Now the spline function is discontinuous at the knots, and it can follow the data more closely. The following statements perform this analysis and produce Figure 90.24:

```
title3 'Discontinuous Function and Derivatives';

proc transreg data=a;
   model identity(y) = spline(x / knots=5 5 5 5 10 10 10 10
                                     15 15 15 15);
run;
```

Now the R square in Figure 90.24 is 0.99254. In this step, each separate curve is approximated by a cubic polynomial (with no knots within the separate polynomials). (Note, however, that the separate functions are connected in the plot, because PROC TRANSREG cannot currently produce separate functions for a model like this. Usually, you would use a CLASS variable to get separate functions.)

Figure 90.24 Discontinuous Spline Fit

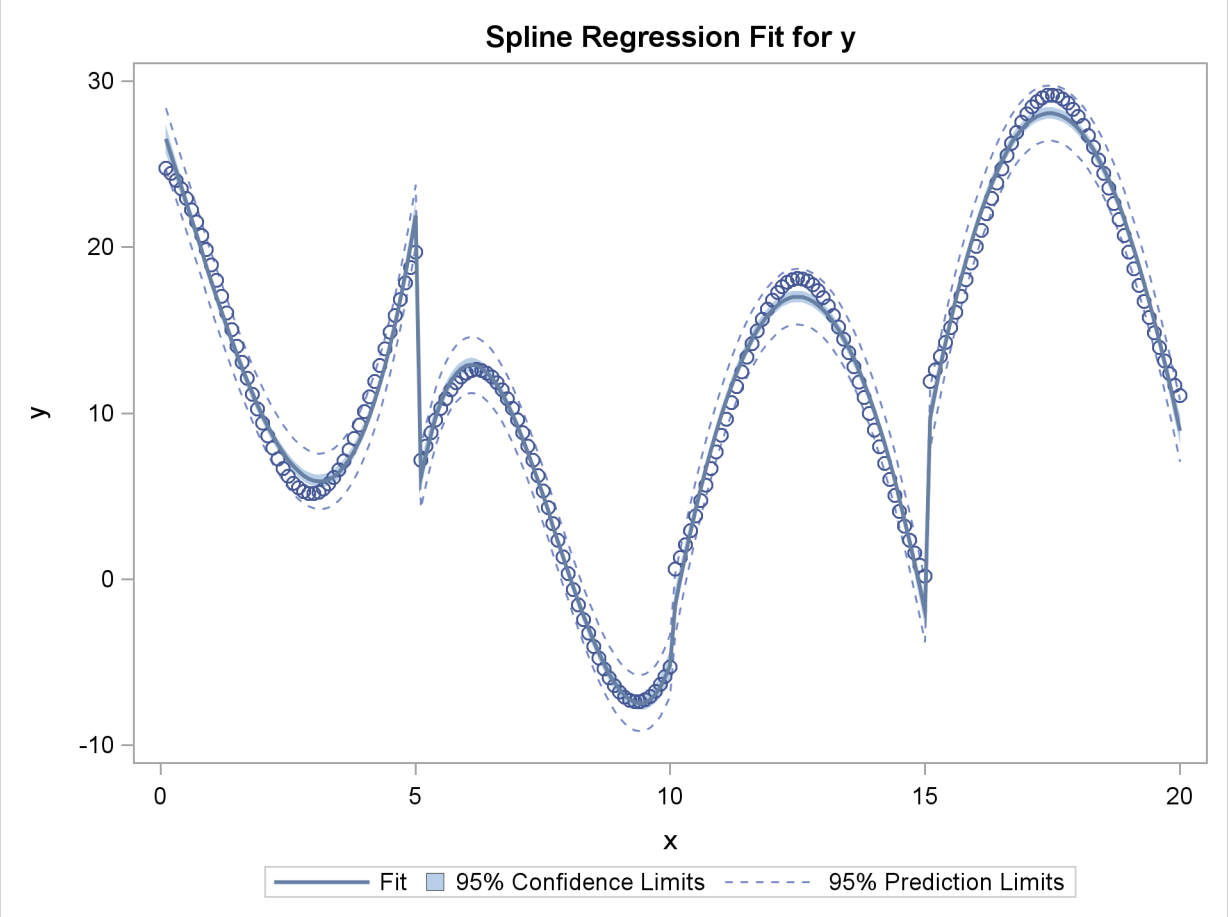
Discontinuous Function and Derivatives



The TRANSREG Procedure

TRANSREG MORALS Algorithm Iteration History for Identity(y)

Iteration Number	Average Change	Maximum Change	R-Square	Criterion Change	Note
1	0.90271	3.29184	0.10061		
2	0.00000	0.00000	0.99254	0.89193	Converged

Algorithm converged.

Figure 90.24 *continued*

To solve this problem with a DATA step and PROC REG, you would need to create all of the variables in the preceding DATA step (the B data set for the piecewise polynomial with discontinuous third derivatives), plus the following three variables:

```
x13=(x >  5);   /* intercept change after  5 */
x14=(x > 10);   /* intercept change after 10 */
x15=(x > 15);   /* intercept change after 15 */
```

The next two examples use the NKNOTS= *t-option* to specify the number of knots but not their location. NKNOTS=4 places knots at the quintiles, whereas NKNOTS=9 places knots at the deciles. The spline and its first two derivatives are continuous. The following statements produce Figure 90.25 and Figure 90.26:

```
title3 'Four Knots';

proc transreg data=a;
   model identity(y) = spline(x / nknots=4);
run;

title3 'Nine Knots';

proc transreg data=a;
   model identity(y) = spline(x / nknots=9);
run;

ods graphics off;
```

The R-square values displayed in Figure 90.25 and Figure 90.26 are 0.74450 and 0.95256, respectively. Even though the knots are not optimally placed, the spline can closely follow the data with NKNOTS=9.

Figure 90.26 *continued*

Scoring Spline Variables

This section shows you how to find spline transformations of variables in one data set and apply the same transformations to variables in another data set. This is illustrated with artificial data. In these data sets, the variable y is approximately a linear function of nonlinear transformations of the variables x, w, and z. The model is fit using data set X, and those results are used to score data set Z. The following statements create the two data sets:

```
title 'An Illustration of Splines and Knots';
title2 'Scoring Spline Variables';

data x;
   do i = 1 to 5000;
      w = normal(7);
      x = normal(7);
      z = normal(7);
      y = w * w + log(5 + x) + sin(z) + normal(7);
      output;
   end;
run;
```

```
data z;
   do i = 1 to 5000;
      w = normal(1);
      x = normal(1);
      z = normal(1);
      y = w * w + log(5 + x) + sin(z) + normal(1);
      output;
   end;
run;
```

First, you run PROC TRANSREG to fit the transformation regression model asking for spline transformations of the three independent variables. You must use the EXKNOTS= *t-option*, because you need to use the same knots, both interior and exterior, with both data sets. By default, the exterior knots will be different if the minima and maxima are different in the two data sets, so you get the wrong results if you do not specify the EXKNOTS= *t-option* with values less than the minima and greater than the maxima of the six x, y, and w variables. If the ranges in all three pairs were different, you would need separate spline transformation for each variable with different knot and exterior knot specifications. The following statements fit the spline model:

```
proc transreg data=x solve details ss2;
   ods output splinecoef=c;
   model identity(y) = spline(w x z / knots=-1.5 to 1.5 by 0.5
                                      exknots=-5 5);
   output out=d;
run;
```

The results of this step are not displayed. The nonprinting "SplineCoef" table is output to a SAS data set. This data set contains the coefficients that were used to get the spline transformations and can be used to transform variables in other data sets. These coefficients are also in the details table. However, in the "SplineCoef" table, they are in a form directly suitable for use with PROC SCORE.

The next step reads the second input data set, Z, and generates an output data set with the B-spline basis for each of the variables:

```
proc transreg data=z design;
   model bspl(w x z / knots=-1.5 to 1.5 by 0.5 exknots=-5 5);
   output out=b;
run;
```

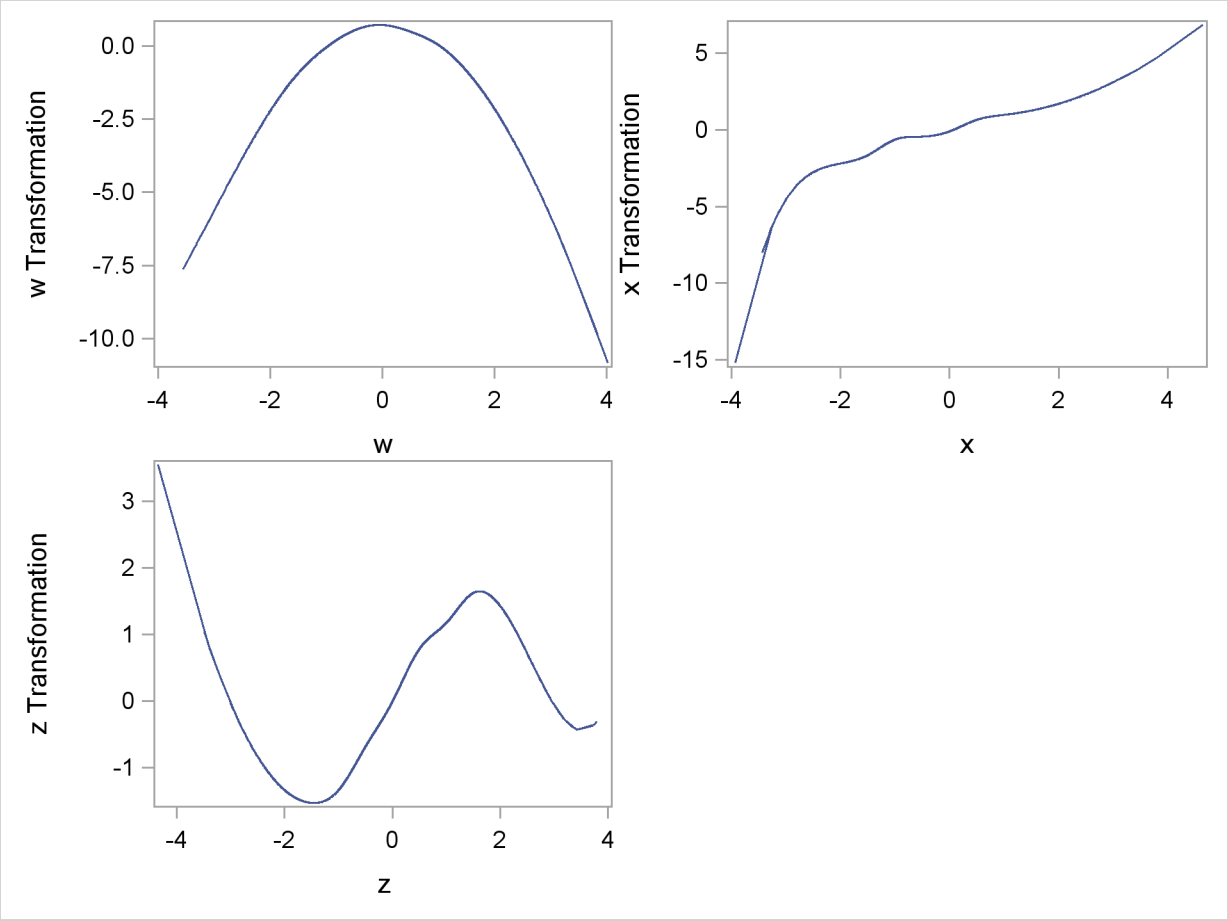
Note that the same interior and exterior knots are used in both of the previous steps. The next three steps score the B-spline bases created in the previous step by using the coefficients generated in the first PROC TRANSREG step. PROC SCORE is run once for each SPLINE variable in the statements that follow:

```
proc score data=b score=c out=o1(rename=(spline=bw w=nw));
   var w:;
run;

proc score data=b score=c out=o2(rename=(spline=bx x=nx));
   var x:;
run;

proc score data=b score=c out=o3(rename=(spline=bz z=nz));
   var z:;
run;
```

The following steps merge the three transformations with the original data and plot the results:



```
data all;
   merge d(keep=w x z tw tx tz) o1(keep=nw bw)
         o2(keep=nx bx) o3(keep=nz bz);
run;

proc template;
   define statgraph twobytwo;
   begingraph;
      layout lattice / rows=2 columns=2;
            layout overlay;
               seriesplot y=tw x=w  / connectorder=xaxis;
               seriesplot y=bw x=nw / connectorder=xaxis;
            endlayout;
            layout overlay;
               seriesplot y=tx x=x  / connectorder=xaxis;
               seriesplot y=bx x=nx / connectorder=xaxis;
            endlayout;
            layout overlay;
               seriesplot y=tz x=z  / connectorder=xaxis;
               seriesplot y=bz x=nz / connectorder=xaxis;
            endlayout;
         endlayout;
      endgraph;
   end;
run;

proc sgrender data=all template=twobytwo;
run;
```

The plots in Figure 90.27 show that the two transformations for each variable, original and scored, are the same function. The two functions in each plot are on top of each other and are indistinguishable. Furthermore, PROC TRANSREG found the functional forms that were used to generate the data: quadratic for w, log for x, and sine for z.

Figure 90.27 Scoring Spline Variables Example

The next statements show how to run PROC TRANSREG, output the interior and exterior knots to an output data set with ODS, extract the knots, and use them in a DATA step to re-create the B-spline basis that PROC TRANSREG makes. In practice, you would never need to use a DATA step to make the B-spline basis since PROC TRANSREG does it automatically. The following statements show how you could do it yourself:

```
data x;
   input x @@;
   datalines;
1 2 3 4 5 6 7 8 9 10
;
ods output details=d;
proc transreg details design;
   model bspline(x / nkn=3);
   output out=y;
run;
```

```
%let k = 0;
data d;
   set d;
   length d $ 20;
   retain d ' ';
   if description ne ' ' then d = description;
   if d = 'Degree' then call symput('d', compress(formattedvalue));
   if d = 'Number of Knots'
      then call symput('k', compress(formattedvalue));
   if index(d, 'Knots') and not index(d, 'Number');
   keep d numericvalue;
run;

%let nkn = %eval(&d * 2 + &k); /* total number of knots   */
%let nb  = %eval(&d + 1 + &k); /* number of cols in basis */

proc transpose data=d out=k(drop=_name_) prefix=Knot; run;

proc print; format k: 20.16; run;

data b(keep=x:);
   if _n_ = 1 then set k; /* read knots from transreg */
   array k[&nkn] knot1-knot&nkn;        /* knots      */
   array b[&nb] x_0 - x_%eval(&nb - 1); /* basis      */
   array w[%eval(2 * &d)];              /* work       */
   set x;
   do i = 1 to &nb; b[i] = 0; end;

   * find the index of first knot greater than current data value;
   do ki = 1 to &nkn while(k[ki] le x); end;
   kki = ki - &d - 1;

   * make the basis;
   b[1 + kki] = 1;
   do j = 1 to &d;
      w[&d + j] = k[ki + j - 1] - x;
      w[j] = x - k[ki - j];
      s = 0;
      do i = 1 to j;
         t = w[&d + i] + w[j + 1 - i];
         if t ne 0.0 then t = b[i + kki] / t;
         b[i + kki] = s + w[&d + i] * t;
         s = w[j + 1 - i] * t;
      end;
      b[j + 1 + kki] = s;
   end;
run;

proc compare data=y(keep=x:) compare=b
   criterion=1e-12 note nosummary;
   title3 "should be no differences";
run;
```

The output from these steps is not shown. There are several things to note about the DATA step. It produces the same basis as PROC TRANSREG only because it uses exactly the same interior and exterior knots. The exterior knots (0.999999999999 and 10.000000000001) are just slightly smaller than 1 (the minimum in x) and just slightly greater than 10 (the maximum in x). Both exterior knots appear in the list three times, because a cubic (degree 3) polynomial was requested. The complete knot list is: 0.999999999999 0.999999999999 0.999999999999 3 6 8 10.000000000001 10.000000000001 10.000000000001. The exterior knots do not have any particular interpretation, but they are needed by the algorithm to construct the proper basis. The construction method computes differences between each value and the nearby knots. The algorithm that makes the B-spline basis is not very obvious, particularly compared to the polynomial spline basis. However, the B-spline basis is much better behaved numerically than a polynomial-spline basis, so that is why it is used.

Linear and Nonlinear Regression Functions

This section shows how to use PROC TRANSREG in simple regression (one dependent variable and one independent variable) to find the optimal regression line, a nonlinear but monotone regression function, and a nonlinear and nonmonotone regression function. To find a linear regression function, specify the IDENTITY transformation of the independent variable. For a monotone curve, specify the MSPLINE transformation of the independent variable. To relax the monotonicity constraint, specify the SPLINE transformation. You can get more flexibility in spline functions by specifying knots. The more knots you specify, the more freedom the function has to follow minor variations in the data. This example uses artificial data. While these artificial data are clearly not realistic, their distinct pattern helps illustrate how splines work. The following statements generate the data and produce Figure 90.28 through Figure 90.31:

```
title 'Linear and Nonlinear Regression Functions';

* Generate an Artificial Nonlinear Scatter Plot;
data a;
   do i = 1 to 500;
      x = i / 2.5;
      y = -((x/50)-1.5)**2 + sin(x/8) + sqrt(x)/5 + 2*log(x) + cos(x);
      x = x / 21;
      if y > 2 then output;
   end;
run;

ods graphics on;
ods select fitplot(persist);

title2 'Linear Regression';

proc transreg data=a;
   model identity(y)=identity(x);
run;
```

```

proc transreg data=a;
   model identity(y)=mspline(x / nknots=9);
run;

title2 'A Nonlinear Regression Function';

proc transreg data=a;
   model identity(y)=spline(x / nknots=9);
run;

title2 'A Nonlinear Regression Function, 100 Knots';

proc transreg data=a;
   model identity(y)=spline(x / nknots=100);
run;

ods graphics off;
ods select all;
```

Figure 90.28 Linear Regression

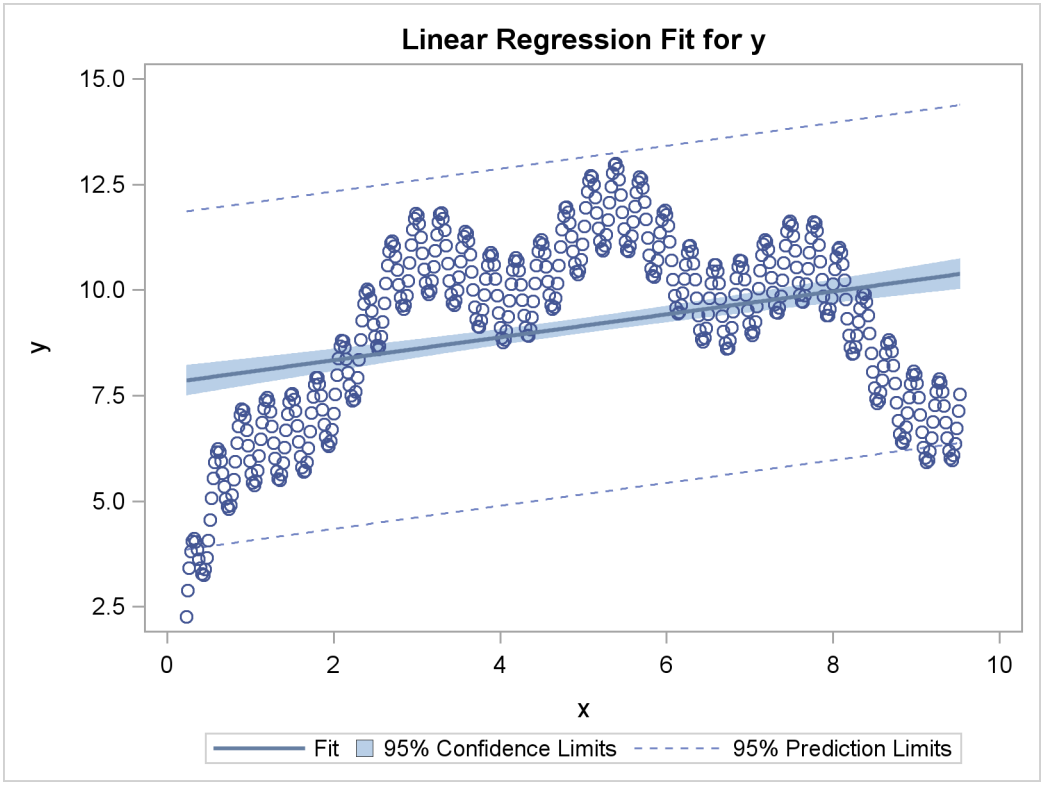

Figure 90.29 A Monotone Regression Function

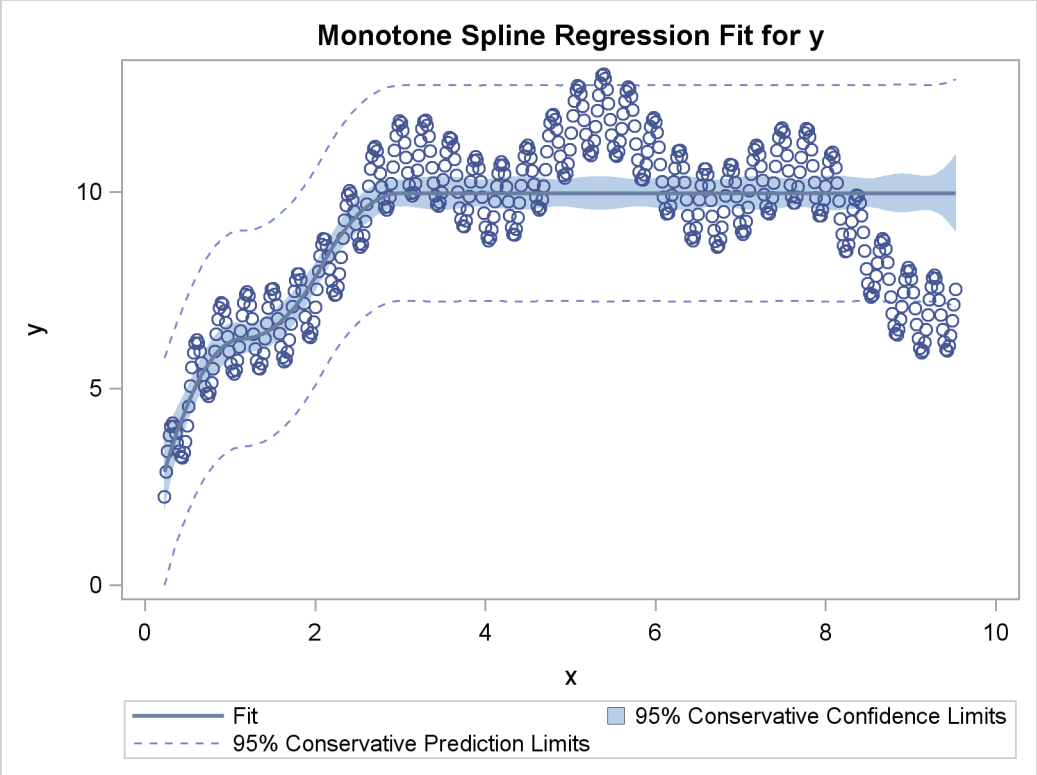

Figure 90.30 A Nonlinear Regression Function

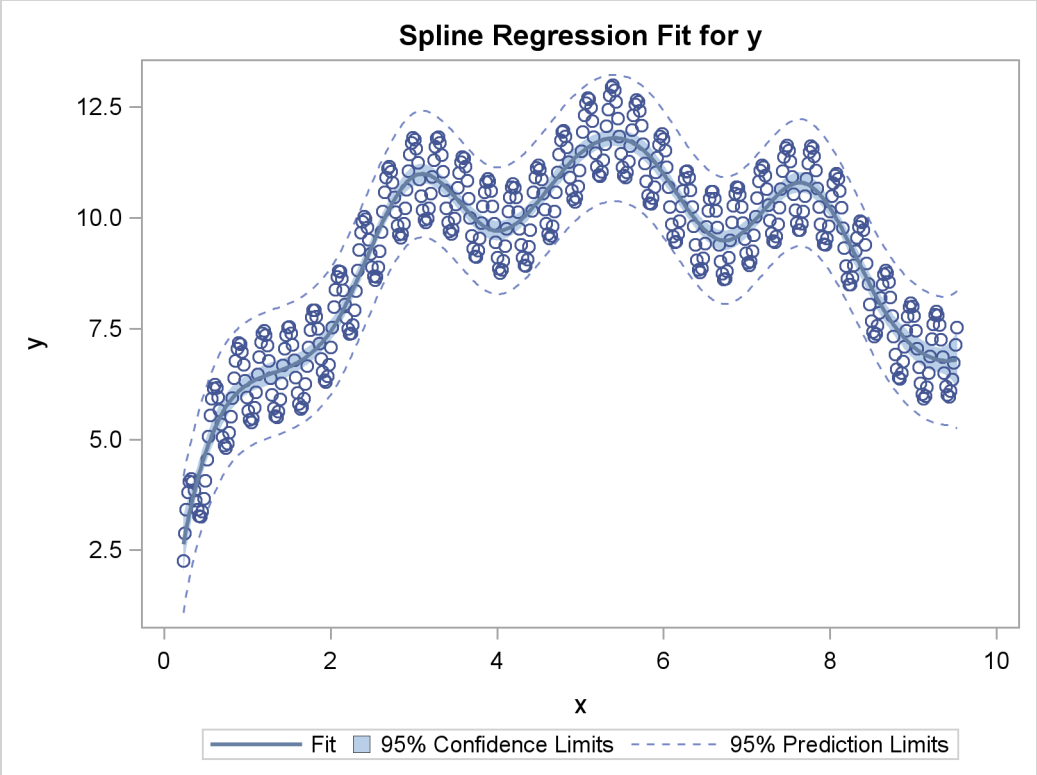

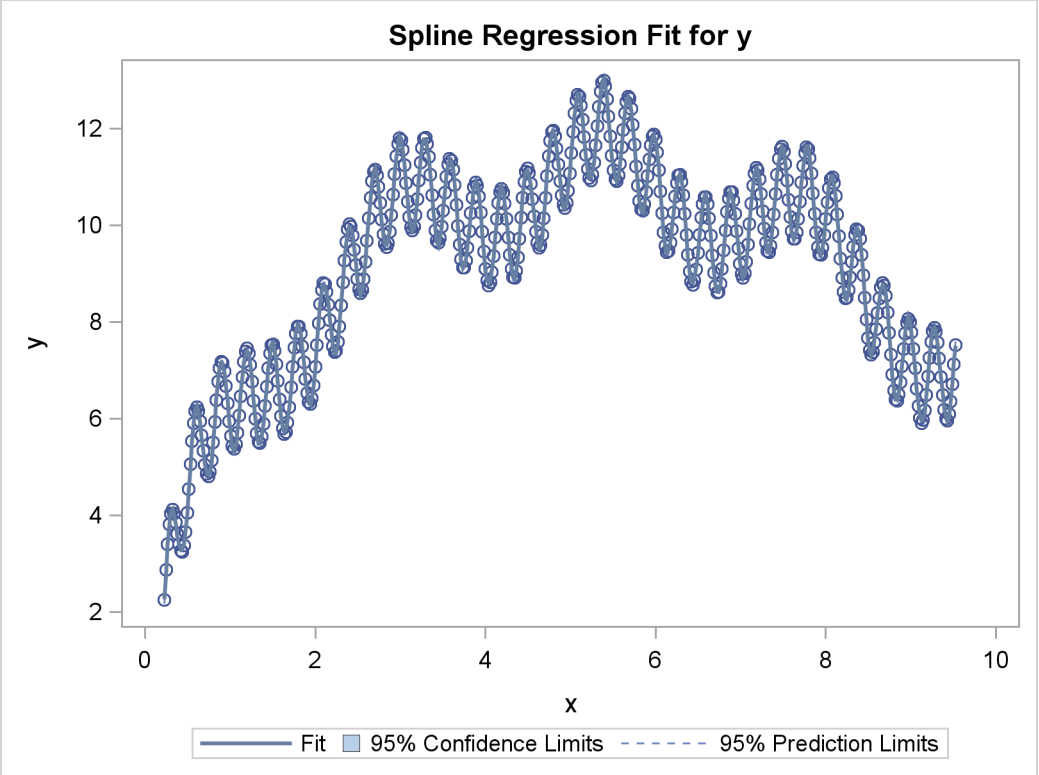

Figure 90.31 A Less-Smooth Nonlinear Regression Function

The squared correlation is only 0.15 for the linear regression in Figure 90.28. Clearly, a simple linear regression model is not appropriate for these data. By relaxing the constraints placed on the regression line, the proportion of variance accounted for increases from 0.15 (linear) to 0.61 (monotone in Figure 90.29) to 0.90 (nonlinear but smooth in Figure 90.30) to almost 1.0 with 100 knots (nonlinear and not very smooth in Figure 90.28). Relaxing the linearity constraint permits the regression function to bend and more closely follow the right portion of the scatter plot. Relaxing the monotonicity constraint permits the regression function to follow the periodic portion of the left side of the plot more closely. The nonlinear MSPLINE transformation is a quadratic spline with knots at the deciles. The first nonlinear nonmonotonic SPLINE transformation is a cubic spline with knots at the deciles.

Different knots and different degrees would produce slightly different results. The two nonlinear regression functions could be closely approximated by simpler piecewise linear regression functions. The monotone function could be approximated by a two-piece line with a single knot at the elbow. The first nonmonotone function could be approximated by a six-piece function with knots at the five elbows.

With this type of problem (one dependent variable with no missing values that is not transformed and one independent variable that is nonlinearly transformed), PROC TRANSREG always iterates exactly twice (although only one iteration is necessary). The first iteration reports the R square for the linear regression line and finds the optimal transformation of x. Since the data change in the first iteration, a second iteration is performed, which reports the R square for the final nonlinear regression function, and zero data change. The predicted values, which are a linear function of the optimal transformation of x, contain the Y coordinates for the nonlinear regression function.

The variance of the predicted values divided by the variance of y is the R square for the fit of the nonlinear regression function. When x is monotonically transformed, the transformation of x is always monotonically increasing, but the predicted values increase if the correlation is positive and decrease for negative correlations.

Simultaneously Fitting Two Regression Functions

One application of ordinary multiple regression is fitting two or more regression lines through a single scatter plot. With PROC TRANSREG, this application can easily be generalized to fit separate or parallel curves. To illustrate, consider a data set with two groups and a group membership variable g that has the value 1 for one group and 2 for the other group. The data set also has a continuous independent variable x and a continuous dependent variable y. When g is crossed with x, the variables g1x and g2x both have a large partition of zeros. For this reason, the KNOTS= *t-option* is specified instead of the NKNOTS= *t-option*. (The latter would put a number of knots in the partition of zeros.) The following example generates an artificial data set with two curves. While these artificial data are clearly not realistic, their distinct pattern helps illustrate how fitting simultaneous regression functions works. The following statements generate data and show how PROC TRANSREG fits lines, curves, and monotone curves through a scatter plot:

```
title 'Separate Curves, Separate Intercepts';

data a;
   do x = -2 to 3 by 0.025;
      g = 1;
      y = 8*(x*x + 2*cos(x*6)) + 15*normal(7654321);
      output;
      g = 2;
      y = 4*(-x*x + 4*sin(x*4)) - 40 + 15*normal(7654321);
      output;
   end;
run;

ods graphics on;
ods select fitplot(persist);

title 'Parallel Lines, Separate Intercepts';

proc transreg data=a solve;
   model identity(y)=class(g) identity(x);
run;

title 'Parallel Monotone Curves, Separate Intercepts';

proc transreg data=a;
   model identity(y)=class(g) mspline(x / knots=-1.5 to 2.5 by 0.5);
run;
```

```
title 'Parallel Curves, Separate Intercepts';

proc transreg data=a solve;
   model identity(y)=class(g) spline(x / knots=-1.5 to 2.5 by 0.5);
run;

title 'Separate Slopes, Same Intercept';

proc transreg data=a;
   model identity(y)=class(g / zero=none) * identity(x);
run;

title 'Separate Monotone Curves, Same Intercept';

proc transreg data=a;
   model identity(y) = class(g / zero=none) *
                       mspline(x / knots=-1.5 to 2.5 by 0.5);
run;

title 'Separate Curves, Same Intercept';

proc transreg data=a solve;
   model identity(y) = class(g / zero=none) *

Penalized B-Splines

You can use penalized B-splines (Eilers and Marx 1996) to fit a smooth curve through a scatter plot with an automatic selection of the smoothing parameter. See Example 90.3 for an example. With penalized B-splines, you can find a transformation that minimizes any of the following criteria: CV, GCV, AIC, AICC, or SBC. These criteria are all functions of λ. For many problems, all of these criteria produce nearly identical results. However, for some problems, the choice of criterion can have a large effect. When the default results are not satisfactory, try the other criteria. Information criteria such as AIC and AICC are defined in different ways in the statistical literature, and these differences can be seen in different SAS procedures. Typically, the definitions differ only by a positive (additive or multiplicative) constant, so they are equivalent, and each of the definitions of the same criterion produces the same selection of λ. The definitions that PROC TRANSREG uses match the definitions that PROC REG uses. The penalized B-spline matrices, statistics, and criteria are defined as follows:

n	number of observations
$\mathbf{y}$	dependent variable
$\mathbf{W}$	diagonal matrix of observation weights
w_i	weight for the ith observation
$\mathbf{B}$	B-spline basis for the independent variable
λ	nonnegative smoothing parameter
$\mathbf{D}$	difference matrix, penalizes lack of smoothness

$\mathbf{H} = \mathbf{B}(\mathbf{B}'\mathbf{W}\mathbf{B} + \lambda\mathbf{D}'\mathbf{D})^{-1}\mathbf{B}'$	hat matrix
h_{ii}	ith diagonal element of $\mathbf{H}$
$\hat{\mathbf{y}} = \mathbf{H}\mathbf{y}$	penalized B-spline transformation of $\mathbf{y}$
$\text{SSE} = \sum_{i=1}^{n} w_i(y_i - \hat{y}_i)^2$	error sum of squares
$t = \sum_{i=1}^{n} w_i h_{ii}$	weighted trace of $\mathbf{H}$
$\sum_{i=1}^{n} w_i \left(\frac{y_i - \hat{y}_i}{1 - h_{ii}}\right)^2$	CV - cross validation criterion
$\sum_{i=1}^{n} w_i \left(\frac{y_i - \hat{y}_i}{n - t}\right)^2$	GCV - generalized cross validation criterion
$n \log(\text{SSE}/n) + 2t$	AIC - Akaike's information criterion
$1 + \log(\text{SSE}/n) + \frac{2(t+1)}{n-t-2}$	AICC - corrected AIC (default)
$n \log(\text{SSE}/n) + t \log(n)$	SBC - Schwarz's Bayesian criterion

For more information about constructing the B-spline basis, see Example 90.65 and the section "Using Splines and Knots" on page 7192. The nonzero elements of **D**, order 1 are (1 –1), order 2 are (1 –2 1), order 3 (the default) are (1 –3 3 –1), order 4 are (1 –4 6 –4 1), and so on. The nonzero elements for each order are made from the nonzero elements from the preceding order by subtraction: $\mathbf{d}'_{i+1} = (\mathbf{d}'_i \quad 0) - (0 \quad \mathbf{d}'_i)$. Within an order, the first nonzero element of row i is in column i—that is, each row of **D** is made from the preceding row by shifting the nonzero elements to the right one position. For example, with $k = 4$ knots, order $o = 3$, and degree $d = 3$, **D** is the $((d + 1 + k - o) \times (d + 1 + k))$ matrix:

$$\begin{bmatrix} 1 & -3 & 3 & -1 & 0 & 0 & 0 & 0 \\ 0 & 1 & -3 & 3 & -1 & 0 & 0 & 0 \\ 0 & 0 & 1 & -3 & 3 & -1 & 0 & 0 \\ 0 & 0 & 0 & 1 & -3 & 3 & -1 & 0 \\ 0 & 0 & 0 & 0 & 1 & -3 & 3 & -1 \end{bmatrix} \quad \text{where} \quad \begin{array}{rcccc} & 1 & -1 & 0 & \\ - & 0 & 1 & -1 & \\ \hline & 1 & -2 & 1 & 0 \\ - & 0 & 1 & -2 & 1 \\ \hline & 1 & -3 & 3 & -1 \end{array}$$

The weighted trace of the hat matrix, $t = \sum_{i=1}^{n} w_i h_{ii}$, provides an estimate of the number of parameters needed to find the transformation and is used in *df* calculations. Note, however, that in some cases, particularly with error-free or nearly error-free data, this value can be *much* larger than you might expect. You might be able to directly create a function by using SPLINE or BSPLINE with many fewer parameters that fits essentially just as well as the penalized B-spline function.

By default with PBSPLINE, a cubic spline is fit with 100 evenly spaced knots, three evenly spaced exterior knots, and a difference matrix of order three. Options are specified as follows:

PBSPLINE(x / DEGREE=3 NKNOTS=100 EVENLY=3 PARAMETER=3). By default, PROC TRANSREG searches for an optimal lambda in the range 0 to 1E6 by using parabolic interpolation and Brent's (Brent 1973; Press et al. 1989) method. Alternatively, you can specify a lambda range or a list of lambdas by using the LAMBDA= option. Be aware, however, LAMBDA=0 and values near zero might cause numerical problems including floating point errors. Also be aware that larger lambdas might cause numerical problems—for example, the error sum of squares for the model, $\Sigma(y - \hat{y})^2$, might be greater than the total sum of squares, $\Sigma(y - \bar{y})^2$—implying that the model with the transformation fits less well than simply predicting by using the mean. When this happens, you will see this message: ERROR: Degenerate transformation with PBSPLINE.

You can fit a single curve through a scatter plot (y × x) as follows:

```
model identity(y) = pbspline(x);
```

Alternatively, you can fit multiple curves through a scatter plot, one for each level of Group, as follows:

```
model identity(y) = class(group / zero=none) * pbspline(x);
```

There are several options for how the smoothing parameter, λ, is chosen. Usually, you do not specify the smoothing parameter, λ, and you let PROC TRANSREG choose λ for you by minimizing one of the information or cross validation criteria. By default, PROC TRANSREG first considers ranges defined by $\lambda = 0$ and $\lambda = 1, 10, 100, 1000, 10,000, 100,000, 1,000,000$. If it finds a range that includes the minimum, it stops and does not consider larger λ values. Then it performs further searches in that range. For example, if the initial evaluations at $\lambda = 1$ and $\lambda = 10$ show that there is at least a local minimum in the range 0 to 10, then larger values are not considered. Note that the zero smoothing case, $\lambda = 0$, provides a boundary on the range even though the criterion is not evaluated at $\lambda = 0$. The criterion is not evaluated at $\lambda = 0$ unless LAMBDA=0 is the only value specified. Also note that the default approach is not the same as specifying the options LAMBDA=0 1E6 RANGE. When a range of values is specified, along with the RANGE *t-option*, PROC TRANSREG does not try to find smaller ranges based on powers of 10.

PROC TRANSREG avoids evaluating the criterion for LAMBDA= values at or near zero unless you force it to consider them. This is because zero smoothing is rarely interesting and the results are numerically unstable. Values of λ at or near zero often result in predicted values that are far outside the range of the data, particularly with interpolation and x values that do not appear in the data set. Also, zero smoothing is prone to numerical problems including floating point errors. This is particularly true when there is a small number of observations, a large number of knots, a high degree, or a perfect or near perfect fit. If you force PROC TRANSREG to evaluate the criterion at or near $\lambda = 0$, you can easily get bad results.

Note that when some observations appear more than once, such as when you have the kind of data where you can use a FREQ statement, then you should consider directly specifying lambda based on a preliminary analysis, ignoring the frequencies. Alternatively, specify a range of λ values, such as LAMBDA=0.1 1E6 RANGE, that steers λ away from values near zero. With the default lambda list, a cross validation criterion does not perform well in choosing a smoothing parameter with replicated data. Leaving one observation out of the computations changes the frequency for that observation from one positive integer to the next smaller positive integer, so in some sense, the point corresponding to that observation is never really left out of any computations. The resulting fit will be undersmoothed unless you specify a larger λ.

Smoothing Splines

You can use PROC TRANSREG to plot and output to a SAS data set the same smoothing spline function that the GPLOT procedure creates. You request a smoothing spline transformation by specifying SMOOTH in the MODEL statement. The smoothing parameter can be specified with either the SM= or the PARAMETER= *o-option*. The results are saved in the independent variable transformation (for example, Tx, when the independent variable is x) and the predicted values variable (for example, Py, when the dependent variable is y). The smooth regression function is displayed through PROC TRANSREG and ODS Graphics in Figure 90.41.

While you would normally display the results by using only PROC TRANSREG and ODS Graphics, you can also use PROC GPLOT to verify that the two procedures produce the same results. PROC GPLOT produces Figure 90.42. The PROC GPLOT plot request **y * x = 1** displays the data as stars. The specification **y * x = 2** with I=SM50 requests the smooth curve through the scatter plot. It is overlaid with **Py * x = 3**, which displays with large dots the smooth function created by PROC TRANSREG. The following statements produce Figure 90.41 and Figure 90.42:

```
title h=1.5 'Smoothing Splines';

ods graphics on;

data x;
   do x = 1 to 100 by 2;
      do rep = 1 to 3;
         y = log(x) + sin(x / 10) + normal(7);
         output;
      end;
   end;
run;

proc transreg;
   model identity(y) = smooth(x / sm=50);
   output p;
run;

proc gplot;
   axis1 minor=none label=(angle=90 rotate=0);
   axis2 minor=none;
   symbol1 color=blue v=circle i=none;  /* data              */
   symbol2 color=blue v=none   i=sm50;  /* gplot's smooth    */
   symbol3 color=red  v=dot    i=none;  /* transreg's smooth */
   plot y*x=1 y*x=2 py*x=3 / overlay haxis=axis2 vaxis=axis1 frame;
run; quit;
```

Note in Figure 90.42 that the smoothed values from PROC TRANSREG, shown by the large dots, exactly fall on the curve produced by PROC GPLOT.
