Software

The procedures and applications in SAS/STAT software were implemented by the following members of the development staff. Program development includes design, programming, debugging, support, and documentation. In the following list, the names of the developers who currently provide primary support are listed first; other developers and previous developers are also listed.

ACECLUS	Ann Kuo, Warren S. Sarle, Donna Lucas Watts
ANOVA	Randall D. Tobias, Yang C. Yuan
BOXPLOT	Bucky Ransdell, Robert N. Rodriguez
CALIS	Yiu-Fai Yung
CANCORR	Ann Kuo, Warren S. Sarle, Donna Lucas Watts
CANDISC	Warren F. Kuhfeld, Warren S. Sarle, Yang C. Yuan
CATMOD	Robert E. Derr, John P. Sall, Donna Lucas Watts
CLUSTER	Bart Killam, Warren S. Sarle
CORRESP	Warren F. Kuhfeld
DISCRIM	Warren F. Kuhfeld, Warren S. Sarle, Yang C. Yuan
DISTANCE	Ann Kuo
FACTOR	Yiu-Fai Yung, John P. Sall, Warren S. Sarle
FASTCLUS	Bart Killam, Warren S. Sarle, Donna Lucas Watts
FREQ	Donna Lucas Watts, John P. Sall
GAM	Weijie Cai, Randall D. Tobias, Robert Cohen

GENMOD	Gordon Johnston
GLIMMIX	Oliver Schabenberger
GLM	Randall D. Tobias, James H. Goodnight, John P. Sall, Warren S. Sarle, Yang C. Yuan
GLMMOD	Randall D. Tobias
GLMSELECT	Robert Cohen
HPMIXED	Tianlin Wang
INBREED	Wendy Czika, Anthony Baiching An
KDE	Bucky Ransdell, Russell D. Wolfinger
KRIGE2D	Alexander Kolovos, Bart Killam
LATTICE	Oliver Schabenberger, Russell D. Wolfinger
LIFEREG	Colin Chen, Gordon Johnston
LIFETEST	Ying So
LOESS	Robert Cohen
LOGISTIC	Robert E. Derr, Ying So
MCMC	Fang Chen
MDS	Warren S. Sarle, Warren F. Kuhfeld
MI	Yang C. Yuan
MIANALYZE	Yang C. Yuan
MIXED	Oliver Schabenberger, Russell D. Wolfinger
MODECLUS	Ann Kuo, Warren S. Sarle
MULTTEST	Robert E. Derr, Russell D. Wolfinger
NESTED	Randall D. Tobias, Leigh A. Ihnen
NLIN	Oliver Schabenberger, Don Erdman, James H. Goodnight, Leigh A. Ihnen
NLMIXED	Oliver Schabenberger, Russell D. Wolfinger
NPAR1WAY	Donna Lucas Watts, Jane Evans, John P. Sall
ORTHOREG	Randall D. Tobias, John P. Sall
PHREG	Ying So
PLAN	Pushpal K Mukhopadhyay, Randall D. Tobias, Leigh A. Ihnen
PLS	Randall D. Tobias
POWER	John Castelloe
PRINCOMP	Ann Kuo, Warren S. Sarle
PRINQUAL	Warren F. Kuhfeld
PROBIT	Colin Chen, Gordon Johnston
PSS	Wayne Watson
QUANTREG	Colin Chen
REG	Robert Cohen, Leigh A. Ihnen, John P. Sall
ROBUSTREG	Colin Chen
RSREG	Robert E. Derr, Randall D. Tobias, John P. Sall
SCORE	Ann Kuo, Donna Lucas Watts
SEQDESIGN	Yang C. Yuan
SEQTEST	Yang C. Yuan
SIM2D	Alexander Kolovos, Bart Killam
SIMNORMAL	Bart Killam
STDIZE	Ann Kuo
STEPDISC	Warren F. Kuhfeld, Warren S. Sarle, Yang C. Yuan
SURVEYFREQ	Donna Lucas Watts

SURVEYLOGISTIC	Anthony Baiching An, Pushpal K Mukhopadhyay
SURVEYMEANS	Anthony Baiching An
SURVEYREG	Anthony Baiching An, Pushpal K Mukhopadhyay
SURVEYSELECT	Donna Lucas Watts
TCALIS	Yiu-Fai Yung
TPSPLINE	Weijie Cai, Randall D. Tobias
TRANSREG	Warren F. Kuhfeld
TREE	Bucky Ransdell, Warren S. Sarle
TTEST	John Castelloe, James H. Goodnight, Padraic Neville, Warren S. Sarle,
VARCLUS	Warren S. Sarle
VARCOMP	Tianlin Wang, Oliver Schabenberger, James H. Goodnight, Randall D. Tobias, Russell D. Wolfinger
VARIOGRAM	Alexander Kolovos, Bart Killam
Probability Routines	Georges Guirguis
Numerical and Graphical Routines	Anthony Baiching An, Fang Chen, Robert Cohen, Mike Cybrynski, Robert E. Derr, Jane Evans, Georges Guirguis, Warren F. Kuhfeld, Warren S. Sarle, Oliver Schabenberger, Randall D. Tobias, Donna Lucas Watts, Yang C. Yuan, Leigh A. Ihnen, Richard D. Langston, Katherine Ng, John P. Sall, Tianlin Wang

The following people contribute to SAS/STAT software with their leadership and support: Robert Cohen, Warren F. Kuhfeld, Robert N. Rodriguez, Oliver Schabenberger, Maura E. Stokes, and Randall D. Tobias.

Testing

Shu An, Jack J. Berry, Ming-Chun Chang, Jared L. Dean, Bruce Elsheimer, Kelly M. Graham, Gregory D. Goodwin, Gerardo I. Hurtado, Cheryl LeSaint, Ming Liao, Yu Liang, Mark Traccarella, Greg Weier, Li Yang, Fouad G. Younan

Technical Support

Rob Agnelli, Craig DeVault, Phil Gibbs, Duane Hayes, Elizabeth S. Edwards, Kathleen Kiernan, Eddie Routten, Annette Sanders, Paul T. Savarese, David Schlotzhauer, Mike Stockstill

Acknowledgments

Many people make significant and continuing contributions to the development of SAS software products. The following are some of the people who have contributed significant amounts of their time to help us make improvements to SAS/STAT software. This includes research and consulting, testing, and reviewing documentation. We are grateful for the involvement of these members of the statistical community and the many others who are not mentioned here for their feedback, suggestions, and consulting.

Overview

SAS 9.2 brings many new procedures and new enhancements to existing procedures to SAS/STAT software.

ODS Statistical Graphics

Prior to SAS 9.1, creating graphics with statistical procedures generally required additional programming. SAS 9.1 introduced an experimental extension to the Output Delivery System (ODS), which was used by over two dozen SAS/STAT and SAS/ETS procedures to create statistical graphics as automatically as they create tables. This new functionality, referred to as ODS Statistical Graphics (or ODS Graphics for short), requires minimal additional syntax, and it provides displays commonly needed for data analysis and statistical modeling, including scatter plots, histograms, and box-and-whisker plots.

In SAS 9.2, ODS Graphics is production, and over 50 procedures in SAS/STAT, SAS/ETS, SAS/QC, and Base SAS have been modified to use it. Many new plots are now produced by these procedures, either by default or with the specification of procedure options.

The functionality of ODS Graphics has been extended with the addition of new graph types, ODS styles designed for statistical work, and a point-and-click editor for enhancing titles, labels, and other graph features. You can also modify graphs by changing their underlying templates, which are supplied by SAS and are written in the Graph Template Language (GTL). The LISTING destination is now supported by ODS Graphics. A new family of SAS/GRAPH procedures uses ODS Graphics to create standalone plots, such as scatterplots overlaid with smoothers, which are particularly useful for exploratory data analysis. The new SGRENDER procedure provides a way to create customized displays by writing your own templates with the GTL.

See Chapter 21, "Statistical Graphics Using ODS," for an introduction to ODS Graphics and general information about ODS Graphics. The syntax for requesting plots with statistical procedures is described in the procedure chapters.

Note that a SAS/GRAPH license is now required to use ODS Graphics.

New Related Software

SAS/STAT users will be interested in SAS/IML® Studio, formerly known as SAS® Stat Studio, which is new software for data exploration and analysis. SAS/IML Studio provides a highly flexible programming environment in which you can run SAS/STAT or SAS/IML® analyses and display the results with dynamically linked graphics and data tables. SAS/IML Studio is intended for data analysts who write SAS programs to solve statistical problems but need more versatility for data exploration and model building. The programming language in SAS/IML Studio, which is called IMLPlus, is an enhanced version of the SAS/IML programming language. IMLPlus extends SAS/IML to provide new language features, including the ability to create and manipulate statistical graphics, call SAS procedures as functions, and call computational programs written in C, C++, Java, and Fortran. SAS/IML Studio runs on a PC in the Microsoft Windows operating environment.

SAS/IML Studio also includes an experimental interface to the R language. The IMLPlus language includes functions that transfer data between SAS data sets and R data frames, and between SAS/IML matrices and R matrices.

SAS/IML Studio is also the successor to the SAS/INSIGHT® product and provides the same interactive functionality. It is distributed with the SAS/IML product. For more information about SAS/IML Studio, see the *SAS/IML Studio User's Guide* and *SAS/IML Studio for SAS/STAT Users*.

New Procedures

SAS 9.2 brings a number of new procedures to SAS/STAT software. Several of these procedures have been previously available as Web downloads for SAS 9.1.3: GLIMMIX, GLMSELECT, and QUANTREG. The GLMSELECT procedure performs effect selection in the framework of general linear models. The QUANTREG procedure performs quantile regression. The GLIMMIX procedure analyzes generalized linear mixed models. All of these procedures are production with SAS 9.2 and are available on all platforms.

In addition, Bayesian capabilities were introduced to three procedures via Web downloads for SAS 9.1.3. The BGENMOD, BLIFEREG, and BPHREG procedures were experimental versions of the GENMOD, LIFEREG, and PHREG procedures that used the Gibbs sampler to produce posterior distributions while also providing trace plots and convergence diagnostics. These capabilities have been rolled into the GENMOD, LIFEREG, and PHREG procedures for SAS 9.2 and are now production software.

The MCMC, SEQDESIGN, and SEQTEST procedures were introduced as experimental procedures in SAS 9.2, and they became production in SAS 9.2M2.

The MCMC procedure is a general purpose Markov chain Monte Carlo (MCMC) simulation procedure that is designed to fit a variety of Bayesian models. You specify a likelihood function for the data and a prior distribution for the parameters. PROC MCMC obtains samples from the corresponding posterior distributions, produces summary and diagnostic statistics, and saves the posterior samples in an output data set.

The SEQDESIGN and SEQTEST procedures are tools for group sequential analysis. The SEQDESIGN procedure designs interim analyses for clinical trials, and the SEQTEST procedure performs interim analyses.

The experimental HPMIXED procedure uses a number of specialized high-performance techniques to fit linear mixed models with variance component structure. The HPMIXED procedure is specifically designed to cope with estimation problems that involve a large number of fixed effects, a large number of random effects, or a large number of observations. The models supported by the HPMIXED procedure are a subset of the models that you can fit with the MIXED procedure, and PROC HPMIXED can provide substantial performance improvements in terms of memory requirements and computational speed.

The experimental TCALIS procedure updates the CALIS procedure for structural equation modeling. It will become the CALIS procedure in the next release of SAS/STAT software.

Highlights of Enhancements

The Power and Sample Size application (PSS), previously available as a Web application, has been rewritten as a Java client. Its documentation is now included here; see Chapter 68, "The Power and Sample Size Application."

In addition, over two hundred enhancements have been added to existing procedure in SAS/STAT. For example,

- The TTEST procedure provides simple crossover analysis as well as equivalence tests.
- Jackknife and BRR variance estimation and domain analysis are now provided by all of the survey data analysis procedures.
- The POWER procedure now provides power for a number of additional analyses.

- The GENMOD procedure fits zero-inflated Poisson regression models. PROC GENMOD also provides deletion and diagnostics statistics for its GEE models and provides graphics for these statistics.
- The PHREG procedure adds a HAZARDRATIO statement for computing hazard ratios, including hazard ratios in the presence of interactions.
- The GLIMMIX procedure introduces the COVTEST statement for inference about covariance parameters. In addition, PROC GLIMMIX provides new estimation methods: Laplace and adaptive quadrature.
- An experimental EFFECT statement can be found in the GLIMMIX, GLMSELECT, and QUANTREG procedures. It enables you to construct special collections of columns for design matrices (for example, splines and multimember effects).

Finally, note that this documentation contains several new introductory chapters. See Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," Chapter 6, "Introduction to Mixed Modeling Procedures," Chapter 19, "Introduction to Power and Sample Size Analysis," and Chapter 18, "Shared Concepts and Topics."

More information about the changes and enhancements follow. The details can be found in the documentation for the individual procedures.

CALIS Procedure

Standardized root mean square residuals (SRMSR) are now listed in the fit summary table, and PROC CALIS now offers residual plots. See below for more information on the TCALIS procedure.

CLUSTER Procedure

The PLOTS option in the PROC CLUSTER statement produces plots of the cubic clustering criterion (CCC), the pseudo F (PSF) statistic, and the pseudo t^2 (PST2) statistic, all plotted against the number of clusters.

CORRESP Procedure

The correspondence analysis plot is produced by default when ODS Graphics is enabled.

FACTOR Procedure

You can produce a number of graphs with the PLOTS= option in the PROC FACTOR statement. These include various factor pattern plots, reference structures, and scree and variance explained plots. You can now use the OUT= option in conjunction with a PARTIAL statement. The PARPREFIX= option in the PROC statement specifies the prefix for the residual variables in the output data sets.

FREQ Procedure

The FREQ procedure can now produce frequency plots, cumulative frequency plots, deviation plots, odds ratio plots, and kappa plots. You can now request equivalence and noninferiority tests for the binomial proportion and proportion difference. New confidence limits for the binomial proportion (such as Agresti-Coull, Jeffreys, and Wilson) are now available, as well as unconditional exact confidence limits for the proportion difference. You can request Zelen's exact test for equal odds ratios by specifying the EQOR option in the EXACT statement.

GAM Procedure

The GAM procedure is production with SAS 9.2. PROC GAM now produces graphs, including smoothing component plots and additive component plots. The target for an additive logistic model no longer has to be numeric; PROC GAM offers the same types of options for response and classification variables that are available in procedures such as PROC LOGISTIC and PROC GENMOD. The ANODEV=NOREFIT option in the MODEL statement enables a fast approximation analysis of deviance.

GENMOD Procedure

The BAYES statement produces Bayesian analysis via Gibbs sampling for most of the statistical analyses provided by the GENMOD procedure. This release also includes deletion diagnostics and plots for GLMs and GEEs, zero-inflated Poisson regression models, and AIC and QIC model fit statistics. Martingale residuals are now production. The LSMEANS statement now produces inverse link estimates.

GLIMMIX Procedure

The GLIMMIX procedure fits statistical models to data with correlations or nonconstant variability and where the response is not necessarily normally distributed. These generalized linear mixed models (GLMM), like linear mixed models, assume normal (Gaussian) random effects. Conditional on these random effects, data can have any distribution in the exponential family. The binary, binomial, Poisson, and negative binomial distributions, for example, are discrete members of this family. The normal, beta, gamma, and chi-square distributions are representatives of the continuous distributions in this family. The GLIMMIX procedure was first made available for SAS 9.1.3 as a Web download.

In SAS 9.2, the GLIMMIX procedure provides Laplace and adaptive quadrature estimation methods, and, with them, a likelihood-based empirical estimator. In addition, a new bias-corrected estimator is available. The experimental EFFECT statement provides for the creation of splines as well as other special effects. The COVTEST statement enables likelihood-based inference about the covariance parameters. A number of additional covariance structures have been added, including heterogeneous AR(1), heterogeneous compound symmetry, linear structures, heterogeneous Toeplitz, penalized B-spline, spatial anisotropic, and the Matérn covariance structure. Step-down multiplicity adjustments are now supported for all ADJUST= methods in the LSMEANS, ESTIMATE, and LSMESTIMATE statements, except for ADJUST=NELSON in the LSMEANS statement.

The DDFM=KR(FIRSTRORDER) option drops the second-derivative term in the KR calculations. The OUTDESIGN= option in the PROC GLIMMIX statement enables you to write the **X** and **Z** matrix to an output data set. New graphics include boxplots of data and/or residuals with respect to classification effects as well as plots of odds ratios and their confidence limits. The diffogram, meanplot, anomplot, and controlplot have been enhanced.

GLM Procedure

New graphics are now produced for means and for LS-means comparisons. The experimental EFFECTSIZE option in the MODEL statement adds measures of effect size to many analysis of variance tables. The PLOTS=DIAGNOSTICS and the PLOTS=RESIDUAL options in the PROC GLM statement produce summary diagnostics and residual plots, respectively.

GLMPOWER Procedure

The new ORDER= option in the PROC GLMPOWER statement specifies the sorting order for the levels of all of the classification variables specified in the CLASS statement. Continuous variables are now supported, and the noncentrality parameter is computed.

GLMSELECT Procedure

The GLMSELECT procedure performs effect selection in the framework of general linear models. A variety of model selection methods are available, including the LASSO method of Tibshirani (1996) and the related LAR method of Efron et al. (2004). The procedure offers extensive capabilities for customizing the selection with a wide variety of selection and stopping criteria, from traditional and computationally efficient significance-level-based criteria to more computationally intensive validation-based criteria. The procedure also provides graphical summaries of the selection search.

Enhancements in SAS 9.2 include an OUTDESIGN= option to obtain the design matrix, a PARMLABELSTYLE= option to control the style of the parameter labels, and an experimental EFFECT statement that you can use to create splines, polynomials, multimember, and collection effects.

HPMIXED Procedure (Experimental)

The experimental HPMIXED procedure uses a number of specialized high-performance techniques to fit linear mixed models with variance component structure. The HPMIXED procedure is specifically designed to cope with estimation problems that involve a large number of fixed effects, a large number of random effects, or a large number of observations. While the HPMIXED procedure fits only a subset of the models fit by the MIXED procedure and it does not provide the breadth of confirmatory inference that is available with the MIXED procedure, it can have considerably better performance in terms of memory requirements and computational speed.

KRIGE2D Procedure

ODS Graphics has been added to the KRIGE2D procedure, which now can produce scatter plots and prediction plots.

LIFEREG Procedure

The BAYES statement provides Bayesian analysis via Gibbs sampling.

LIFETEST Procedure

The LIFETEST procedure now produces the Nelson-Aalen estimates of the cumulative hazard function. The number of subjects at risk can be displayed for the Kaplan-Meier survival curves. Comparison methods are available for the k-sample test, and you can now specify a smoother hazard function using the kernel method.

LOGISTIC Procedure

The LOGISTIC procedure performs Firth's penalized maximum likelihood. The MULTIPASS option forces the procedure to reread the input data set as needed rather than requiring its storage in memory or in a temporary file on disk. Estimated culmulative probabilities have been added to the SCORE statement output. The CONTRAST statement now includes the inverse link. The ROC-CONTRAST statement compares different ROC models. Odds ratios in the presence of interactions are now computed, and odds ratio plots are provided. Note that the GRAPHICS statement has been replaced with the PLOTS= option in the PROC statement. The EFFECT plot can now handle multiple CLASS and continuous variables. Standard errors are now produced for the exact parameter estimates.

LOESS Procedure

The LOESS procedure includes a PRESEARCH option that uses a preliminary grid search to improve the chance of finding a global optimum of the selection criterion when a golden section search is used.

Macros

The %POWTABLE macro renders the output of the POWER and GLMPOWER procedures in rectangular form, and it optionally produces simplified results by using weighted means across chosen variables. The %ModStyle macro modifies the colors, line styles, and marker symbols displayed in ODS Graphics plots.

MCMC Procedure

The MCMC procedure is a flexible simulation-based procedure that is suitable for fitting a wide range of Bayesian models. To use the procedure, you need to specify a likelihood function for the data and a prior distribution for the parameters. You might also need to specify hyperprior distributions if you are fitting hierarchical models. PROC MCMC then obtains samples from the corresponding posterior distributions, produces summary and diagnostic statistics, and saves the posterior samples in an output data set that can be used for further analysis. You can analyze data that have any likelihood, prior, or hyperprior with PROC MCMC, as long as these functions are programmable using the SAS DATA step functions. The parameters can enter the model linearly or in any nonlinear functional form. The default algorithm that PROC MCMC uses is an adaptive blocked random-walk Metropolis algorithm that uses a normal proposal distribution.

MDS Procedure

ODS Graphics has been added to the MDS procedure, which now can produce fit plots, coefficient plots, and configuration plots.

MIXED Procedure

The RESIDUAL and INFLUENCE options in the MODEL statement are now production. The PLOTS= option in the PROC MIXED statement is now available to specify graphics.

MULTTEST Procedure

The MULTTEST procedure now provides the adaptive Holm, adaptive Hochberg, adaptive FDR, bootstrap FDR, pFDR, and permutation FDR p-value adjustments. ODS Graphics has been added to PROC MULTTEST, and plots of adjusted p-value plots, raw p-values by rank and histogram, and p-values by test are now available. Satterthwaite degrees of freedom are now provided for the t test. The EPSILON= option in the PROC MULTTEST statement specifies the comparison value.

NLIN Procedure

The ALPHA= option has been added to the PROC NLIN and OUTPUT statements. The PDATA= option in the PARAMETERS statement enables you to assign starting values for parameters through a SAS data set. The DER option in the OUTPUT statement saves the first derivatives of the model with respect to the parameters to the OUTPUT data set.

NLMIXED Procedure

The EMPIRICAL option in the PROC NLMIXED statement requests that the covariance matrix of the parameter estimates be computed as a likelihood-based empirical ("sandwich") estimator (White 1982). Subject-specific gradients can be added to a SAS data set with the SUBGRADIENT option in the PROC NLMIXED statement.

NPAR1WAY Procedure

ODS Graphics has been added to the NPAR1WAY procedure, and you can request boxplots, a median plot, and an empirical distribution plot with the PLOTS= option in the PROC NPAR1WAY statement. PROC NPAR1WAY now computes the Hodges-Lehmann estimate of location shift for two-sample data with the HL option. Confidence limits are provided, and you can request exact confidence limits by specifying the HL option in the EXACT statement. Tests based on Conover scores are now available, including exact tests.

PHREG Procedure

The CLASS statement, previously available only in the TPHREG procedure, is now included with the PHREG procedure. The BAYES statement provides Bayesian analysis via Gibbs sampling. PROC PHREG now fits the piecewise exponential model, which is specified in the BAYES statement. Bayesian baseline survival prediction becomes available with SAS 9.2 as well. The HAZARDRATIO statement provides a new facility for computing hazard ratios, including hazard ratios in the presence of interactions. The PLOTS option in the PROC PHREG statement produces baseline survival function plots. Profile-likelihood confidence limits are now available for hazard ratios produced in classical analyses. Firth's penalized likelihood method is provided as well.

PLS Procedure

The PLS procedure now produces more graphics, including a correlation loadings plot. The MISSING option for handling missing values with imputation is now production.

POWER Procedure

The new LOGISTIC statement performs power and sample size analyses for the likelihood ratio chi-square test of a single predictor in binary logistic regression, possibly in the presence of one or more covariates (where all predictors are independent of each other). The new TWOSAMPLEWILCOXON statement performs power and sample size analyses for the Wilcoxon-Mann-Whitney test for two independent groups. The ONESAMPLEFREQ statement now covers equivalence, noninferiority, and confidence interval precision for a proportion. The PAIREDFREQ statement offers new input parameterizations, including raw proportions and correlation.

PRINCOMP Procedure

The PRINCOMP procedure now produces more graphics, including an ellipse plot. It includes an ID statement and incorporates ID variables as tips in its scatter plots. The PARPREFIX= option in the PROC PRINCOMP statement specifies a prefix for naming the residual variables in the OUT= data set and the OUTSTAT= data set.

PRINQUAL Procedure

The PRINQUAL procedure now produces graphs. These include a multidimensional preference analysis plot and a variable transformation plot.

PROBIT Procedure

The PROBIT procedure now offers a predicted probability plot.

PSS Application

The PSS application has been converted to a Java client application and no longer requires a Web server. It now offers a relative risk parameterization for the two proportions analysis. New analyses covered include equivalence and noninferiority for proportions, confidence interval for one proportion, Wilcoxon-Mann-Whitney for two distributions, logistic regression, and GLM contrasts for interactions.

QUANTREG Procedure

Quantile regression extends the regression model to conditional quantiles of the response variable, such as the 90th percentile. Quantile regression is particularly useful when the rate of change in the conditional quantile, expressed by the regression coefficients, depends on the quantile. The main advantage of quantile regression over least squares regression is its flexibility for modeling data with heterogeneous conditional distributions. The QUANTREG procedure was first made available as a Web download for SAS 9.1.3.

With SAS 9.2, the QUANTREG procedure becomes production. In addition, it now includes the experimental EFFECT statement for generating splines and the ability to output results for multiple quantiles in the OUTPUT statement.

REG Procedure

The REG procedure now includes a lack-of-fit test. The PARTIAL option in the MODEL statement requests partial regression plots for each regressor; the PARTIALDATA option displays partial regression data. Heteroscedasticity-consistent (White) standard errors are now available, and you can obtain a heteroscedasticity-consistent covariance matrix for use with the ACOV, HCC, or WHITE option in the MODEL statement and for heteroscedasticity-consistent tests with the TEST statement.

RSREG Procedure

ODS Graphics has been added to the RSREG procedure. New graphs include diagnostic plots, ridge plots, and surface plots.

SEQDESIGN Procedure

The SEQDESIGN procedure designs interim analyses for clinical trials. PROC SEQDESIGN computes the boundary values and required sample sizes for the trial. The boundary values are derived in such a way that the overall Type I and Type II error probability levels are maintained at the levels specified in the design. Available methods include fixed boundary shape methods (which include unified family methods such as the O'Brien-Fleming method), Whitehead methods, and error spending methods. In addition to the boundary values, the SEQDESIGN procedure computes a variety of quantities such as average sample sizes and stopping probabilities.

SEQTEST Procedure

The SEQTEST procedure is used in conjunction with the SEQDESIGN procedure to carry out interim analyses for clinical trials. At each stage, you analyze all the data available at that point with a statistical procedure and compute a test statistic and its information level. You then use the SEQTEST procedure to compare the test statistic with the boundary values for that stage. If the information levels of the data do not match the levels specified in the design, the SEQTEST procedure modifies the boundary levels appropriately. In addition, the SEQTEST procedure computes quantities such as average sample sizes, stopping probabilities, and conditional power. At the conclusion of the trial, the SEQTEST procedure computes parameter estimates, *p*-values, and confidence limits.

SIM2D Procedure

ODS Graphics has been added to the SIM2D procedure. Means plots and scatter plots of the observed data are now available.

SIMNORMAL Procedure

The SIMNORMAL procedure becomes production with this release.

STDIZE Procedure

The NOTRUNCATE option in the FREQ statement specifies that frequency values are not truncated to integers. Quantile methods now accept noninteger frequencies and handle weights. In order to improve numerical precision, PROC STDIZE now creates double-precision values for output variables instead of inheriting the length of the variables in the analysis.

SURVEYFREQ Procedure

The SURVEYFREQ procedure now provides variance estimation by balanced repeated replication (BRR) and the jackknife methods, in addition to the Taylor series method. You can provide replicate weights for the new replication methods with a REPWEIGHTS statement, or the procedure can construct the replicate weights. PROC SURVEYFREQ now computes odds ratio and relative risk estimates. The new NOMCAR option in the PROC SURVEYFREQ statement requests a subpopulation analysis of the set of respondents for Taylor series variance estimation.

SURVEYLOGISTIC Procedure

The SURVEYLOGISTIC procedure now provides variance estimation by balanced repeated replication (BRR) and the jackknife methods, in addition to the Taylor series method. You can provide replicate weights for the new replication methods with a REPWEIGHTS statement, or the procedure can construct the replicate weights. The OUTPUT and DOMAIN statements are now available. The new NOMCAR option in the PROC SURVEYLOGISTIC statement requests a subpopulation analysis of the set of respondents for Taylor series variance estimation.

SURVEYMEANS Procedure

The SURVEYMEANS procedure now provides variance estimation by balanced repeated replication (BRR) and the jackknife methods, in addition to the Taylor series method. You can provide replicate weights for the new replication methods with a REPWEIGHTS statement, or the procedure can construct the replicate weights. The new NOMCAR option in the PROC SURVEYMEANS statement requests a subpopulation analysis of the set of respondents for Taylor series variance estimation. PROC SURVEYMEANS now computes percentiles (Woodruff variance estimation only).

SURVEYREG Procedure

The SURVEYREG procedure now provides variance estimation by balanced repeated replication (BRR) and the jackknife methods, in addition to the Taylor series method. You can provide replicate weights for the new replication methods with a REPWEIGHTS statement, or the procedure can construct the replicate weights. In addition, PROC SURVEYREG also includes a DOMAIN statement, for domain analysis. The OUTPUT statement enables you to produce predicted values and residuals and put them into a SAS data set. The ORDER= option has been added to the PROC SURVEYREG statement. The new NOMCAR option in the PROC SURVEYREG statement requests a subpopulation analysis of the set of respondents for Taylor series variance estimation.

SURVEYSELECT Procedure

The SURVEYSELECT procedure now provides methods to allocate the total sample size among the strata. Allocation methods include proportional, Neyman, and optimal allocation.

TCALIS Procedure (Experimental)

The TCALIS procedure is experimental in SAS 9.2. It enables you to perform the same kind of statistical analyses that you can do with PROC CALIS. In addition, PROC TCALIS provides functionality such as multiple-group analysis, enhanced mean structure analysis, path-like model specification, support of LISREL-type models, customizable effect analysis, general parametric function testing, customizable Lagrange multiplier tests, and so on. Currently, you can specify COSAN models only in PROC CALIS, but not in PROC TCALIS.

TRANSREG Procedure

The TRANSREG procedure include new options for existing splines to make exterior knot specification easier and more flexible. PROC TRANSREG now includes the penalized B-spline. A number of plots are now produced, including Box-Cox plots, preference mapping, regression residuals, and scatter plots.

TTEST Procedure

The TTEST procedure now performs TOST equivalence analyses, analyses of treatment and period in AB/BA crossover designs, weighted Satterthwaite tests and confidence intervals, analyses of ratios, and one-sided analyses. It supports both normal and lognormal data. Sasabuchi tests and Fieller confidence intervals are computed for normal ratios. PROC TTEST now provides graphs, including histograms, densities, box plots, profiles, agreement plots, Q-Q plots, and interval plots. The new ORDER= option in the PROC TTEST statement specifies the sorting order for the levels of classification variables (specified in the CLASS statement) and crossover treatment variables (specified in the CROSSOVER option in the VAR statement).

VARCOMP Procedure

The METHOD=GRR option has been added to provide gauge repeatability and reproducibility analysis. The CL option has been added to the MODEL statement to compute confidence limits for all of the parameters of interest. This applies to the balanced one-way or two-way designs for METHOD=TYPE1 or GRR. Autocorrelation statistics and tests are now available.

VARIOGRAM Procedure

Autocorrelation statistics are now available. In addition, PROC VARIOGRAM produces graphics, including a scatter plot of the observed data, histogram of the pairwise distance distribution, plots of the empirical classical and robust semivariograms, and panels of the empirical classical and robust semivariogram plots.

Overview of SAS/STAT Software

SAS/STAT software provides comprehensive statistical tools for a wide range of statistical analyses, including analysis of variance, categorical data analysis, cluster analysis, multiple imputation, multivariate analysis, nonparametric analysis, power and sample size computations, psychometric analysis, regression, survey data analysis, and survival analysis. A few examples include nonlinear mixed models, generalized linear models, correspondence analysis, and robust regression. The software is constantly being updated to reflect new methodology.

In addition to over sixty procedures for statistical analysis, SAS/STAT software also includes the Market Research Application (MRA), a point-and-click interface to commonly used techniques in

market research. The Analyst Application provides convenient access to some of the more commonly used statistical analyses in SAS/STAT software including analysis of variance, regression, logistic regression, mixed models, survival analysis, and some multivariate techniques. Also, the Power and Sample Size Application (PSS) is an interface to power and sample size computations. The Analyst Application and MRA are documented separately.

Experimental Software

Experimental software is sometimes included as part of a production-release product. It is provided to (sometimes targeted) customers in order to obtain feedback. All experimental uses are marked Experimental in this document. Whenever an experimental procedure, statement, or option is used, a message is printed to the SAS log to indicate that it is experimental.

The design and syntax of experimental software might change before any production release. Experimental software has been tested prior to release, but it has not necessarily been tested to production-quality standards, and so should be used with care.

About This Book

Since SAS/STAT software is a part of the SAS System, this book assumes that you are familiar with Base SAS software and with the books *SAS Language Reference: Dictionary*, *SAS Language Reference: Concepts* and the *Base SAS Procedures Guide*. It also assumes that you are familiar with basic SAS System concepts such as creating SAS data sets with the DATA step and manipulating SAS data sets with the procedures in Base SAS software (for example, the PRINT and SORT procedures).

Chapter Organization

This book is organized as follows.

Chapter 1, "What's New in SAS/STAT," provides information about the changes and enhancements to SAS/STAT software in SAS 9.2. It describes several new procedures as well as numerous new features.

Chapter 2, this chapter, provides an overview of SAS/STAT software and summarizes related information, products, and services. The remaining introductory chapters provide some introduction to the broad areas covered by SAS/STAT software.

Chapter 18, "Shared Concepts and Topics," provides information on topics that are common to multiple procedures such as parameterization of model effects, the EFFECT statement, and the

NLOPTIONS statement. Chapter 19, "Introduction to Power and Sample Size Analysis," provides documentation for the Power and Sample Size Application (PSS).

Chapter 20, "Using the Output Delivery System," explains the fundamentals of using the Output Delivery System (ODS) to manage your SAS output. Chapter 21, "Statistical Graphics Using ODS," describes the extension to ODS that enables many statistical procedures to create statistical graphics as easily as tables.

Subsequent chapters describe the SAS procedures that make up SAS/STAT software. These chapters appear in alphabetical order by procedure name and are organized as follows:

- The "Overview" section provides a brief description of the analysis provided by the procedure.
- The "Getting Started" section provides a quick introduction to the procedure through a simple example.
- The "Syntax" section describes the SAS statements and options that control the procedure.
- The "Details" section discusses methodology and miscellaneous details, such as ODS tables and ODS graphics.
- The "Examples" section contains examples using the procedure.
- The "References" section contains references for the methodology and for examples of the procedure.

Following the chapters on the SAS/STAT procedures, Chapter A, "Special SAS Data Sets," documents the special SAS data sets associated with SAS/STAT procedures.

Typographical Conventions

This book uses several type styles for presenting information. The following list explains the meaning of the typographical conventions used in this book:

roman	is the standard type style used for most text.
UPPERCASE ROMAN	is used for SAS statements, options, and other SAS language elements when they appear in the text. However, you can enter these elements in your own SAS programs in lowercase, uppercase, or a mixture of the two.
UPPERCASE BOLD	is used in the "Syntax" sections' initial lists of SAS statements and options.
oblique	is used for user-supplied values for options in the syntax definitions. In the text, these values are written in *italic*.
helvetica	is used for the names of variables and data sets when they appear in the text.

bold	is used to refer to matrices and vectors.
italic	is used for terms that are defined in the text, for emphasis, and for references to publications.
`monospace`	is used for example code. In most cases, this book uses lowercase type for SAS code.

Options Used in Examples

Output of Examples

Most of the output shown in this book is produced with the following SAS System options:

```
options linesize=80 pagesize=500 nonumber nodate;
```

The STATISTICAL style is used to create the HTML output and graphs that appears in the online documentation. A style template controls stylistic elements such as colors, fonts, and presentation attributes. The style template is specified in the ODS HTML statement as follows:

```
ods html style=statistical;
```

See Chapter 21, "Statistical Graphics Using ODS," for more information about styles.

If you run the examples, you may get slightly different output. This is a function of the SAS System options used and the precision used by your computer for floating-point calculations.

Where to Turn for More Information

This section describes other sources of information about SAS/STAT software.

Accessing the SAS/STAT Sample Library

The SAS/STAT sample library includes many examples that illustrate the use of SAS/STAT software, including the examples used in this documentation. To access these sample programs, select the **Help** pull-down menu and then select **Getting Started with SAS Software**. From the **Contents** list, choose **Learning to Use SAS** and then **Sample SAS Programs**. Select the **SAS/STAT** product.

Online Documentation

This documentation is available online with the SAS System. If you are using the SAS windowing environment with pull-down menus, you can select **SAS Help and Documentation** from the **Help** menu. Under the **Contents** tab select **SAS/STAT** and then select *SAS/STAT User's Guide* from the list of available topics.

Alternatively, you can type **help STAT** in the command line. Note that you can use the online facility to search the documentation. You can also access the documentation from the SAS Web site. Go to **support.sas.com** and select **Documentation** for more detail.

SAS Institute Technical Support Services

As with all SAS Institute products, the SAS Institute Technical Support staff is available to respond to problems and answer technical questions regarding the use of SAS/STAT software.

Related SAS Software

Many features not found in SAS/STAT software are available in other parts of the SAS System. If you don't find something you need in SAS/STAT software, try looking for the feature in the following SAS software products.

Base SAS Software

The features provided by SAS/STAT software are in addition to the features provided by Base SAS software. Many data management and reporting capabilities you will need are part of Base SAS software. Refer to *SAS Language Reference: Concepts*, *SAS Language Reference: Dictionary*, and the *Base SAS Procedures Guide* for documentation of Base SAS software.

SAS DATA Step

The DATA step is your primary tool for reading and processing data in the SAS System. The DATA step provides a powerful general purpose programming language that enables you to perform all kinds of data processing tasks. The DATA step is documented in *SAS Language Reference: Concepts*.

Base SAS Procedures

Base SAS software includes many useful SAS procedures. Base SAS procedures are documented in the *Base SAS Procedures Guide*. The following is a list of Base SAS procedures you may find useful:

CORR	compute correlations
RANK	compute rankings or order statistics
STANDARD	standardize variables to a fixed mean and variance
MEANS	compute descriptive statistics and summarizing or collapsing data over cross sections
TABULATE	print descriptive statistics in tabular format
UNIVARIATE	compute descriptive statistics

SAS/ETS Software

SAS/ETS software provides SAS procedures for econometrics and time series analysis. It includes capabilities for forecasting, systems modeling and simulation, seasonal adjustment, and financial analysis and reporting. In addition, SAS/ETS software includes an interactive time series forecasting system.

SAS/GRAPH Software

SAS/GRAPH software includes procedures that create two- and three-dimensional high-resolution color graphics plots and charts. You can generate output that graphs the relationship of data values to one another, enhance existing graphs, or simply create graphics output that is not tied to data.

SAS/IML Software

SAS/IML software gives you access to a powerful and flexible programming language (Interactive Matrix Language) in a dynamic, interactive environment. The fundamental object of the language is a data matrix. You can use SAS/IML software interactively (at the statement level) to see results immediately, or you can store statements in a module and execute them later. The programming is dynamic because necessary activities such as memory allocation and dimensioning of matrices are done automatically. SAS/IML software is of interest to users of SAS/STAT software because it enables you to program your methods in the SAS System.

SAS/INSIGHT Software

SAS/INSIGHT software is a highly interactive tool for data analysis. You can explore data through a variety of interactive graphs including bar charts, scatter plots, box plots, and three-dimensional rotating plots. You can examine distributions and perform parametric and nonparametric regression, analyze general linear models and generalized linear models, examine correlation matrixes, and perform principal component analyses. Any changes you make to your data show immediately in all graphs and analyses. You can also configure SAS/INSIGHT software to produce graphs and analyses tailored to the way you work.

SAS/INSIGHT software may be of interest to users of SAS/STAT software for interactive graphical viewing of data, editing data, exploratory data analysis, and checking distributional assumptions.

SAS/OR Software

SAS/OR software provides SAS procedures for operations research and project planning and includes a point-and-click interface to project management. Its capabilities include the following:

- solving transportation problems
- linear, integer, and mixed-integer programming
- nonlinear programming
- scheduling projects
- plotting Gantt charts
- drawing network diagrams
- solving optimal assignment problems
- network flow programming

SAS/OR software may be of interest to users of SAS/STAT software for its mathematical programming features. In particular, the NLP procedure in SAS/OR software solves nonlinear programming problems, and it can be used for constrained and unconstrained maximization of user-defined likelihood functions.

SAS/QC Software

SAS/QC software provides a variety of procedures for statistical quality control and quality improvement. SAS/QC software includes procedures for

- Shewhart control charts
- cumulative sum control charts
- moving average control charts
- process capability analysis
- Ishikawa diagrams
- Pareto charts
- experimental design

SAS/QC software also includes the ADX interface for experimental design.

SAS/IML Studio

SAS/STAT users may be interested in the new SAS/IML Studio (formerly known as SAS Stat Studio). SAS/IML Studio is a tool for data exploration and analysis; it provides a highly flexible programming environment in which you can run SAS/STAT or SAS/IML analyses and display the results with dynamically linked graphics and data tables. You can also call SAS procedures from a SAS/IML program. SAS/IML Studio is intended for data analysts who write SAS programs to solve statistical problems but need more versatility for data exploration and model building.

The programming language in SAS/IML Studio, which is called *IMLPlus*, is an enhanced version of the SAS/IML programming language. IMLPlus extends SAS/IML to provide new language features such as the ability to create and manipulate statistical graphics and to call SAS procedures. SAS/IML Studio runs on a PC in the Microsoft Windows operating environment.

SAS/IML Studio also includes an experimental interface to the R language. The IMLPlus language includes functions that transfer data between SAS data sets and R data frames, and between SAS/IML matrices and R matrices.

SAS/IML Studio is distributed with the SAS/IML product and is also intended to be the successor to the SAS/INSIGHT product. For more information about SAS/IML Studio, see the *SAS/IML Studio User's Guide* and *SAS/IML Studio for SAS/STAT Users*.

Overview: Statistical Modeling

There are more than 70 procedures in SAS/STAT software, and the majority of them are dedicated to solving problems in statistical modeling. The goal of this chapter is to provide a roadmap to statistical models and to modeling tasks, enabling you to make informed choices about the appropriate modeling context and tool. This chapter also introduces important terminology, notation, and concepts used throughout this documentation. Subsequent introductory chapters discuss model families and related procedures.

It is difficult to capture the complexity of statistical models in a simple scheme, so the classification used here is necessarily incomplete. It is most practical to classify models in terms of simple criteria, such as the presence of random effects, the presence of nonlinearity, characteristics of the data, and so on. That is the approach used here. After a brief introduction to statistical modeling in general terms, the chapter describes a number of model classifications and relates them to modeling tools in SAS/STAT software.

Statistical Models

Deterministic and Stochastic Models

Purely mathematical models, in which the relationships between inputs and outputs are captured entirely in deterministic fashion, can be important theoretical tools but are impractical for describing observational, experimental, or survey data. For such phenomena, researchers usually allow the model to draw on stochastic as well as deterministic elements. When the uncertainty of realizations leads to the inclusion of random components, the resulting models are called *stochastic* models. A *statistical* model, finally, is a stochastic model that contains *parameters*, which are unknown constants that need to be estimated based on assumptions about the model and the observed data.

There are many reasons why statistical models are preferred over deterministic models. For example:

- Randomness is often introduced into a system in order to achieve a certain balance or representativeness. For example, random assignment of treatments to experimental units allows unbiased inferences about treatment effects. As another example, selecting individuals for a survey sample by random mechanisms ensures a representative sample.
- Even if a deterministic model can be formulated for the phenomenon under study, a stochastic model can provide a more parsimonious and more easily comprehended description. For example, it is possible in principle to capture the result of a coin toss with a deterministic model, taking into account the properties of the coin, the method of tossing, conditions of the medium through which the coin travels and of the surface on which it lands, and so on. A very complex model is required to describe the simple outcome—heads or tails. Alternatively, you can describe the outcome quite simply as the result of a stochastic process, a Bernoulli variable that results in heads with a certain probability.

- It is often sufficient to describe the average behavior of a process, rather than each particular realization. For example, a regression model might be developed to relate plant growth to nutrient availability. The explicit aim of the model might be to describe how the average growth changes with nutrient availability, not to predict the growth of an individual plant. The support for the notion of averaging in a model lies in the nature of expected values, describing typical behavior in the presence of randomness. This, in turn, requires that the model contain stochastic components.

The defining characteristic of statistical models is their dependence on parameters and the incorporation of stochastic terms. The properties of the model and the properties of quantities derived from it must be studied in a long-run, average sense through expectations, variances, and covariances. The fact that the parameters of the model must be estimated from the data introduces a stochastic element in applying a statistical model: because the model is not deterministic but includes randomness, parameters and related quantities derived from the model are likewise random. The properties of parameter estimators can often be described only in an asymptotic sense, imagining that some aspect of the data increases without bound (for example, the number of observations or the number of groups).

The process of estimating the parameters in a statistical model based on your data is called *fitting* the model. For many classes of statistical models there are a number of procedures in SAS/STAT software that can perform the fitting. In many cases, different procedures solve identical estimation problems—that is, their parameter estimates are identical. In some cases, the same model parameters are estimated by different statistical principles, such as least squares versus maximum likelihood estimation. Parameter estimates obtained by different methods typically have different statistical properties—distribution, variance, bias, and so on. The choice between competing estimation principles is often made on the basis of properties of the estimators. Distinguishing properties might include (but are not necessarily limited to) computational ease, interprative ease, bias, variance, mean squared error, and consistency.

Model-Based and Design-Based Randomness

A statistical model is a description of the data-generating mechanism, not a description of the specific data to which it is applied. The aim of a model is to capture those aspects of a phenomenon that are relevant to inquiry and to explain how the data could have come about as a realization of a random experiment. These relevant aspects might include the genesis of the randomness and the stochastic effects in the phenomenon under study. Different schools of thought can lead to different model formulations, different analytic strategies, and different results. Coarsely, you can distinguish between a viewpoint of *innate* randomness and one of *induced* randomness. This distinction leads to model-based and design-based inference approaches.

In a design-based inference framework, the random variation in the observed data is induced by random *selection* or random *assignment*. Consider the case of a survey sample from a finite population of size N; suppose that $\mathcal{F}_N = \{y_i : i \in U_N\}$ denotes the finite set of possible values and U_N is the index set $U_N = \{1, 2, \ldots, N\}$. Then a sample S, a subset of U_N, is selected by probability rules. The realization of the random experiment is the selection of a particular set S; the associated values selected from $\mathcal{F}_N$ are considered fixed. If properties of a design-based sampling estimator

are evaluated, such as bias, variance, and mean squared error, they are evaluated with respect to the distribution induced by the sampling mechanism.

Design-based approaches also play an important role in the analysis of data from controlled experiments by randomization tests. Suppose that k treatments are to be assigned to kr homogeneous experimental units. If you form k sets of r units with equal probability, and you assign the jth treatment to the tth set, a completely randomized experimental design (CRD) results. A design-based view treats the potential response of a particular treatment for a particular experimental unit as a constant. The stochastic nature of the error-control design is induced by randomly selecting one of the potential responses.

Statistical models are often used in the design-based framework. In a survey sample the model is used to motivate the choice of the finite population parameters and their sample-based estimators. In an experimental design, an assumption of additivity of the contributions from treatments, experimental units, observational errors, and experimental errors leads to a linear statistical model. The approach to statistical inference where statistical models are used to construct estimators and their properties are evaluated with respect to the distribution induced by the sample selection mechanism is known as *model-assisted inference* (Särndal, Swensson, and Wretman 1992).

In a purely model-based framework, the only source of random variation for inference comes from the unknown variation in the responses. Finite population values are thought of as a realization of a superpopulation model that describes random variables $Y_1, Y_2, \cdots$. The observed values $y_1, y_2, \cdots$ are realizations of these random variables. A model-based framework does not imply that there is only one source of random variation in the data. For example, mixed models might contain random terms that represent selection of effects from hierarchical (super-) populations at different granularity. The analysis takes into account the hierarchical structure of the random variation, but it continues to be model based.

A design-based approach is implicit in SAS/STAT procedures whose name commences with SURVEY, such as the SURVEYFREQ, SURVEYMEANS, SURVEYREG, and SURVEYLOGISTIC procedures. Inferential approaches are model based in other SAS/STAT procedures. For more information about analyzing survey data with SAS/STAT software, see Chapter 14, "Introduction to Survey Procedures."

Model Specification

If the model is accepted as a description of the data-generating mechanism, then its parameters are estimated using the data at hand. Once the parameter estimates are available, you can apply the model to answer questions of interest about the study population. In other words, the model becomes the lens through which you view the problem itself, in order to ask and answer questions of interest. For example, you might use the estimated model to derive new predictions or forecasts, to test hypotheses, to derive confidence intervals, and so on.

Obviously, the model must be "correct" to the extent that it sufficiently describes the data-generating mechanism. Model selection, diagnosis, and discrimination are important steps in the model-building process. This is typically an iterative process, starting with an initial model and refining it. The first important step is thus to formulate your knowledge about the data-generating process and to express the real observed phenomenon in terms of a statistical model. A statistical model describes the distributional properties of one or more variables, the *response* variables. The extent of

the required distributional specification depends on the model, estimation technique, and inferential goals. This description often takes the simple form of a model with additive error structure:

$$\text{response} = \text{mean} + \text{error}$$

In mathematical notation this simple model equation becomes

$$Y = f(x_1, \cdots, x_k; \beta_1, \cdots, \beta_p) + \epsilon$$

In this equation Y is the *response* variable, often also called the *dependent* variable or the *outcome* variable. The terms $x_1, \cdots, x_k$ denote the values of k regressor variables, often termed the *covariates* or the "independent" variables. The terms $\beta_1, \cdots, \beta_p$ denote parameters of the model, unknown constants that are to be estimated. The term ϵ denotes the random disturbance of the model; it is also called the residual term or the error term of the model.

In this simple model formulation, stochastic properties are usually associated only with the ϵ term. The covariates $x_1, \cdots, x_k$ are usually known values, not subject to random variation. Even if the covariates are measured with error, so that their values are in principle random, they are considered fixed in most models fit by SAS/STAT software. In other words, stochastic properties under the model are derived conditional on the xs. If ϵ is the only stochastic term in the model, and if the errors have a mean of zero, then the function $f(\cdot)$ is the *mean function* of the statistical model. More formally,

$$\mathrm{E}[Y] = f(x_1, \cdots, x_k; \beta_1, \cdots, \beta_p)$$

where $\mathrm{E}[\cdot]$ denotes the expectation operator.

In many applications, a simple model formulation is inadequate. It might be necessary to specify not only the stochastic properties of a single error term, but also how model errors associated with different observations relate to each other. A simple additive error model is typically inappropriate to describe the data-generating mechanism if the errors do not have zero mean or if the variance of observations depends on their means. For example, if Y is a Bernoulli random variable that takes on the values 0 and 1 only, a regression model with additive error is not meaningful. Models for such data require more elaborate formulations involving probability distributions.

Classes of Statistical Models

Linear and Nonlinear Models

A statistical estimation problem is nonlinear if the estimating equations—the equations whose solution yields the parameter estimates—depend on the parameters in a nonlinear fashion. Such estimation problems typically have no closed-form solution and must be solved by iterative, numerical techniques.

Nonlinearity in the mean function is often used to distinguish between linear and nonlinear models. A model has a nonlinear mean function if the derivative of the mean function with respect to the

parameters depends on at least one other parameter. Consider, for example, the following models that relate a response variable Y to a single regressor variable x:

$$\mathrm{E}[Y|x] = \beta_0 + \beta_1 x$$
$$\mathrm{E}[Y|x] = \beta_0 + \beta_1 x + \beta_2 x^2$$
$$\mathrm{E}[Y|x] = \beta + x/\alpha$$

In these expressions, $\mathrm{E}[Y|x]$ denotes the expected value of the response variable Y at the fixed value of x. (The conditioning on x simply indicates that the predictor variables are assumed to be non-random. Conditioning is often omitted for brevity in this and subsequent chapters.)

The first model in the previous list is a simple linear regression (SLR) model. It is linear in the parameters β_0 and β_1 since the model derivatives do not depend on unknowns:

$$\frac{\partial}{\beta_0}(\beta_0 + \beta_1 x) = 1$$
$$\frac{\partial}{\beta_1}(\beta_0 + \beta_1 x) = x$$

The model is also linear in its relationship with x (a straight line). The second model is also linear in the parameters, since

$$\frac{\partial}{\beta_0}\left(\beta_0 + \beta_1 x + \beta_2 x^2\right) = 1$$
$$\frac{\partial}{\beta_1}\left(\beta_0 + \beta_1 x + \beta_2 x^2\right) = x$$
$$\frac{\partial}{\beta_2}\left(\beta_0 + \beta_1 x + \beta_2 x^2\right) = x^2$$

However, this second model is *curvilinear*, since it exhibits a curved relationship when plotted against x. The third model, finally, is a nonlinear model since

$$\frac{\partial}{\beta}(\beta + x/\alpha) = 1$$
$$\frac{\partial}{\alpha}(\beta + x/\alpha) = -\frac{x}{\alpha^2}$$

The second of these derivatives depends on a parameter α. A model is nonlinear if it is not linear in at least one parameter. Only the third model is a nonlinear model. A graph of $\mathrm{E}[Y]$ versus the regressor variable thus does not indicate whether a model is nonlinear. A curvilinear relationship in this graph can be achieved by a model that is linear in the parameters.

Nonlinear mean functions lead to nonlinear estimation. It is important to note, however, that nonlinear estimation arises also because of the estimation principle or because the model structure contains nonlinearity in other parts, such as the covariance structure. For example, fitting a simple linear regression model by minimizing the sum of the absolute residuals leads to a nonlinear estimation problem despite the fact that the mean function is linear.

Regression Models and Models with Classification Effects

A linear regression model in the broad sense has the form

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where $\mathbf{Y}$ is the vector of response values, $\mathbf{X}$ is the matrix of regressor effects, $\boldsymbol{\beta}$ is the vector of regression parameters, and $\boldsymbol{\epsilon}$ is the vector of errors or residuals. A regression model in the narrow sense—as compared to a classification model—is a linear model in which all regressor effects are continuous variables. In other words, each effect in the model contributes a single column to the $\mathbf{X}$ matrix and a single parameter to the overall model. For example, a regression of subjects' weight (Y) on the regressors age (x_1) and body mass index (bmi, x_2) is a regression model in this narrow sense. In symbolic notation you can write this regression model as

$$\text{weight} = \text{age} + \text{bmi} + \text{error}$$

This symbolic notation expands into the statistical model

$$Y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \epsilon_i$$

Single parameters are used to model the effects of age (β_1) and bmi (β_2), respectively.

A classification effect, on the other hand, is associated with possibly more than one column of the $\mathbf{X}$ matrix. Classification with respect to a variable is the process by which each observation is associated with one of k levels; the process of determining these k levels is referred to as *levelization* of the variable. Classification variables are used in models to identify experimental conditions, group membership, treatments, and so on. The actual values of the classification variable are not important, and the variable can be a numeric or a character variable. What is important is the association of discrete values or levels of the classification variable with groups of observations. For example, in the previous illustration, if the regression also takes into account the subjects' gender, this can be incorporated in the model with a two-level classification variable. Suppose that the values of the gender variable are coded as "F" and "M," respectively. In symbolic notation the model

$$\text{weight} = \text{age} + \text{bmi} + \text{gender} + \text{error}$$

expands into the statistical model

$$Y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \tau_1 I(\text{gender} = \text{"F"}) + \tau_2 I(\text{gender} = \text{"M"}) + \epsilon_i$$

where $I(\text{gender} = \text{"F"})$ is the indicator function that returns 1 if the value of the gender variable is "F" and 0 otherwise. Parameters τ_1 and τ_2 are associated with the gender classification effect. This form of parameterizing the gender effect in the model is only one of several different methods of incorporating the levels of a classification variable in the model. This form, the so-called singular parameterization, is the most general approach, and it is used in the GLM, MIXED, and GLIMMIX procedures. Alternatively, classification effects with various forms of nonsingular parameterizations are available in such procedures as GENMOD and LOGISTIC. See the documentation for the individual SAS/STAT procedures on their respective facilities for parameterizing classification

variables and the section "Parameterization of Model Effects" on page 368 in Chapter 18, "Shared Concepts and Topics," for general details.

Models that contain only classification effects are often identified with *analysis of variance* (ANOVA) models, because ANOVA methods are frequently used in their analysis. This is particularly true for experimental data where the model effects comprise effects of the treatment and error-control design. However, classification effects appear more widely than in models to which analysis of variance methods are applied. For example, many mixed models, where parameters are estimated by restricted maximum likelihood, consist entirely of classification effects but do not permit the sum of squares decomposition typical for ANOVA techniques.

Many models contain both continuous and classification effects. For example, a continuous-by-class effect consists of at least one continuous variable and at least one classification variable. Such effects are convenient, for example, to vary slopes in a regression model by the levels of a classification variable. Also, recent enhancements to linear modeling syntax in some SAS/STAT procedures (including GLIMMIX and GLMSELECT) enable you to construct sets of columns in $\mathbf{X}$ matrices from a single continuous variable. An example is modeling with splines where the values of a continuous variable x are expanded into a spline basis that occupies multiple columns in the $\mathbf{X}$ matrix. For purposes of the analysis you can treat these columns as a single unit or as individual, unrelated columns. For more details, see the section "Constructed Effects and the EFFECT Statement (Experimental)" on page 377 in Chapter 18, "Shared Concepts and Topics."

Univariate and Multivariate Models

A multivariate statistical model is a model in which multiple response variables are modeled jointly. Suppose, for example, that your data consist of heights (h_i) and weights (w_i) of children, collected over several years (t_i). The following separate regressions represent two univariate models:

$$w_i = \beta_{w0} + \beta_{w1} t_i + \epsilon_{wi}$$
$$h_i = \beta_{h0} + \beta_{h1} t_i + \epsilon_{hi}$$

In the univariate setting, no information about the children's heights "flows" to the model about their weights and vice versa. In a multivariate setting, the heights and weights would be modeled jointly. For example:

$$\begin{aligned} \mathbf{Y}_i = \begin{bmatrix} w_i \\ h_i \end{bmatrix} &= \mathbf{X}\boldsymbol{\beta} + \begin{bmatrix} \epsilon_{wi} \\ \epsilon_{hi} \end{bmatrix} \\ &= \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}_i \\ \boldsymbol{\epsilon}_i &\sim \left(\mathbf{0}, \begin{bmatrix} \sigma_1^2 & \sigma_{12} \\ \sigma_{12} & \sigma_2^2 \end{bmatrix} \right) \end{aligned}$$

The vectors $\mathbf{Y}_i$ and $\boldsymbol{\epsilon}_i$ collect the responses and errors for the two observation that belong to the same subject. The errors from the same child now have the correlation

$$\text{Corr}[\epsilon_{wi}, \epsilon_{hi}] = \frac{\sigma_{12}}{\sqrt{\sigma_1^2 \sigma_2^2}}$$

and it is through this correlation that information about heights "flows" to the weights and vice versa. This simple example shows only one approach to modeling multivariate data, through the

use of covariance structures. Other techniques involve seemingly unrelated regressions, systems of linear equations, and so on.

Multivariate data can be coarsely classified into three types. The response vectors of *homogeneous multivariate data* consist of observations of the same attribute. Such data are common in repeated measures experiments and longitudinal studies, where the same attribute is measured repeatedly over time. Homogeneous multivariate data also arise in spatial statistics where a set of geostatistical data is the incomplete observation of a single realization of a random experiment that generates a two-dimensional surface. One hundred measurements of soil electrical conductivity collected in a forest stand compose a single observation of a 100-dimensional homogeneous multivariate vector. *Heterogeneous multivariate* observations arise when the responses that are modeled jointly refer to different attributes, such as in the previous example of children's weights and heights. There are two important subtypes of heterogeneous multivariate data. In *homocatanomic multivariate data* the observations come from the same distributional family. For example, the weights and heights might both be assumed to be normally distributed. With *heterocatanomic multivariate data* the observations can come from different distributional families. The following are examples of heterocatanomic multivariate data:

- For each patient you observe blood pressure (a continuous outcome), the number of prior episodes of an illness (a count variable), and whether the patient has a history of diabetes in the family (a binary outcome). A multivariate model that models the three attributes jointly might assume a lognormal distribution for the blood pressure measurements, a Poisson distribution for the count variable and a Bernoulli distribution for the family history.
- In a study of HIV/AIDS survival, you model jointly a patients CD4 cell count over time—itself a homogeneous multivariate outcome—and the survival of the patient (event-time data).

Fixed, Random, and Mixed Models

Each term in a statistical model represents either a *fixed effect* or a *random effect*. Models in which all effects are fixed are called fixed-effects models. Similarly, models in which all effects are random—apart from possibly an overall intercept term—are called random-effects models. Mixed models, then, are those models that have fixed-effects and random-effects terms. In matrix notation, the linear fixed, linear random, and linear mixed model are represented by the following model equations, respectively:

$$\begin{aligned}\mathbf{Y} &= \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon} \\ \mathbf{Y} &= \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon} \\ \mathbf{Y} &= \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}\end{aligned}$$

In these expressions, $\mathbf{X}$ and $\mathbf{Z}$ are design or regressor matrices associated with the fixed and random effects, respectively. The vector $\boldsymbol{\beta}$ is a vector of fixed-effects parameters, and the vector $\boldsymbol{\gamma}$ represents the random effects. The mixed modeling procedures in SAS/STAT software assume that the random effects $\boldsymbol{\gamma}$ follow a normal distribution with variance-covariance matrix $\mathbf{G}$ and, in most cases, that the random effects have mean zero.

Random effects are often associated with classification effects, but this is not necessary. As an example of random regression effects, you might want to model the slopes in a growth model

as consisting of two components: an overall (fixed-effects) slope that represents the slope of the average individual, and individual-specific random deviations from the overall slope. The $\mathbf{X}$ and $\mathbf{Z}$ matrix would then have column entries for the regressor variable associated with the slope. You are modeling fixed and randomly varying regression coefficients.

Having random effects in your model has a number of important consequences:

- Some observations are no longer uncorrelated but instead have a covariance that depends on the variance of the random effects.
- You can and should distinguish between the inference spaces; inferences can be drawn in a broad, intermediate, and narrow inference space. In the narrow inference space, conclusions are drawn about the particular values of the random effects selected in the study. The broad inference space applies if inferences are drawn with respect to all possible levels of the random effects. The intermediate inference space can be applied for effects consisting of more than one random term, when inferences are broad with respect to some factors and narrow with respect to others. In fixed-effects models, there is no corresponding concept to the broad and intermediate inference spaces.
- Depending on the structure of $\mathbf{G}$ and $\text{Var}[\boldsymbol{\epsilon}]$ and also subject to the balance in your data, there might be no closed-form solution for the parameter estimates. Although the model is linear in $\boldsymbol{\beta}$, iterative estimation methods might be required to estimate all parameters of the model.
- Certain concepts, such as least squares means and Type III estimable functions, are meaningful only for fixed effects.
- By using random effects, you are modeling variation through variance. Variation in data simply implies that things are not equal. Variance, on the other hand, describes a feature of a random variable. Random effects in your model are random variables: they model variation through variance.

It is important to properly determine the nature of the model effects as fixed or random. An effect is either fixed or random by its very nature; it is improper to consider it fixed in one analysis and random in another depending on what type of results you want to produce. If, for example, a treatment effect is random and you are interested in comparing treatment means, and only the levels selected in the study are of interest, then it is not appropriate to model the treatment effect as fixed so that you can draw on least squares mean analysis. The appropriate strategy is to model the treatment effect as random and to compare the solutions for the treatment effects in the narrow inference space.

In determining whether an effect is fixed or random, it is helpful to inquire about the *genesis* of the effect. If the levels of an effect are randomly sampled, then the effect is a random effect. The following are examples:

- In a large clinical trial, drugs A, B, and C are applied to patients in various clinical centers. If the clinical centers are selected at random from a population of possible clinics, their effect on the response is modeled with a random effect.
- In repeated measures experiments with people or animals as subjects, subjects are declared to be random because they are selected from the larger population to which you want to generalize.

- Fertilizers could be applied at a number of levels. Three levels are randomly selected for an experiment to represent the population of possible levels. The fertilizer effects are random effects.

Quite often it is not possible to select effects at random, or it is not known how the values in the data became part of the study. For example, suppose you are presented with a data set consisting of student scores in three school districts, with four to ten schools in each district and two to three classrooms in each school. How do you decide which effects are fixed and which are random? As another example, in an agricultural experiment conducted in successive years at two locations, how do you decide whether location and year effects are fixed or random? In these situations, the fixed or random nature of the effect might be debatable, bearing out the adage that "one modeler's fixed effect is another modeler's random effect." However, this fact does not constitute license to treat as random those effects that are clearly fixed, or vice versa.

When an effect cannot be randomized or it is not known whether its levels have been randomly selected, it can be a random effect if its impact on the outcome variable is of a stochastic nature—that is, if it is the realization of a random process. Again, this line of thinking relates to the genesis of the effect. A random year, location, or school district effect is a placeholder for different environments that cannot be selected at random but whose effects are the cumulative result of many individual random processes. Note that this argument does not imply that effects are random because the experimenter does not know much about them. The key notion is that effects represent something, whether or not that something is known to the modeler. Broadening the inference space beyond the observed levels is thus possible, although you might not be able to articulate what the realizations of the random effects represent.

A consequence of having random effects in your model is that some observations are no longer uncorrelated but instead have a covariance that depends on the variance of the random effect. In fact, in some modeling applications random effects might be used not only to model heterogeneity in the parameters of a model, but also to induce correlations among observations. The typical assumption about random effects in SAS/STAT software is that the effects are normally distributed.

For more information about mixed modeling tools in SAS/STAT software, see Chapter 6, "Introduction to Mixed Modeling Procedures."

Generalized Linear Models

A class of models that has gained increasing importance in the past several decades is the class of generalized linear models. The theory of generalized linear models originated with Nelder and Wedderburn (1972) and Wedderburn (1974), and was subsequently made popular in the monograph by McCullagh and Nelder (1989). This class of models extends the theory and methods of linear models to data with nonnormal responses. Before this theory was developed, modeling of nonnormal data typically relied on transformations of the data, and the transformations were chosen to improve symmetry, homogeneity of variance, or normality. Such transformations have to be performed with care because they also have implications for the error structure of the model, Also, back-transforming estimates or predicted values can introduce bias.

Generalized linear models also apply a transformation, known as the *link function*, but it is applied to a deterministic component, the mean of the data. Furthermore, generalized linear model take the

distribution of the data into account, rather than assuming that a transformation of the data leads to normally distributed data to which standard linear modeling techniques can be applied.

To put this generalization in place requires a slightly more sophisticated model setup than that required for linear models for normal data:

- The *systematic* component is a linear predictor similar to that in linear models, $\eta = \mathbf{x}'\boldsymbol{\beta}$. The linear predictor is a linear function in the parameters. In contrast to the linear model, η does not represent the mean function of the data.
- The *link function* $g(\cdot)$ relates the linear predictor to the mean, $g(\mu) = \eta$. The link function is a monotonic, invertible function. The mean can thus be expressed as the inversely linked linear predictor, $\mu = g^{-1}(\eta)$. For example, a common link function for binary and binomial data is the logit link, $g(t) = \log\{t/(1-t)\}$. The mean function of a generalized linear model with logit link and a single regressor can thus be written as

$$\log\left\{\frac{\mu}{1-\mu}\right\} = \beta_0 + \beta_1 x$$

$$\mu = \frac{1}{1+\exp\{-\beta_0 - \beta_1 x\}}$$

  This is known as a logistic regression model.
- The *random component* of a generalized linear model is the distribution of the data, assumed to be a member of the exponential family of distributions. Discrete members of this family include the Bernoulli (binary), binomial, Poisson, geometric, and negative binomial (for a given value of the scale parameter) distribution. Continuous members include the normal (Gaussian), beta, gamma, inverse gaussian, and exponential distribution.

The standard linear model with normally distributed error is a special case of a generalized linear model; the link function is the identity function and the distribution is normal.

Latent Variable Models

Latent variable modeling involves variables that are not observed directly in your research. It has a relatively long history, dating back from the measure of general intelligence by common factor analysis (Spearman 1904) to the emergence of modern-day structural equation modeling (Jöreskog 1973; Keesling, 1972; Wiley, 1973).

Latent variables are involved in almost all kinds of regression models. In a broad sense, all additive error terms in regression models are latent variables simply because they are not measured in research. Hereafter, however, a narrower sense of latent variables is used when referring to latent variable models. Latent variables are *systematic* unmeasured variables that are also referred to as *factors*. For example, in the following diagram a simple relation between Emotional Intelligence and Career Achievement is shown:

In the diagram, both Emotional Intelligence and Career Achievement are treated as latent factors. They are hypothetical constructs in your model. You hypothesize that Emotional Intelligence is a "causal factor" or predictor of Career Achievement. The symbol β represents the regression coefficient or the effect of Emotional Intelligence on Career Achievement. However, the "causal relationship" or prediction is not perfect. There is an error term δ, which accounts for the unsystematic part of the prediction. You can represent the preceding diagram by using the following linear equation:

$$\mathrm{CA} = \beta \mathrm{EI} + \delta$$

where CA represents Career Achievement and EI represents Emotional Intelligence. The means of the latent factors in the linear model are arbitrary, and so they are assumed to be zero. The error variable δ also has a zero mean with an unknown variance. This equation represents the so-called "structural model," where the "true" relationships among latent factors are theorized.

In order to model this theoretical model with latent factors, some observed variables must somehow relate to these factors. This calls for the measurement models for latent factors. For example, Emotional Intelligence could be measured by some established tests. In these tests, individuals are asked to respond to certain special situations that involve stressful decision making, personal confrontations, and so on. Their responses to these situations are then rated by experts or a standardized scoring system. Suppose there are three such tests and the test scores are labeled as X1, X2 and X3, respectively. The measurement model for the latent factor Emotional Intelligence is specified as follows:

$$\begin{aligned} \mathrm{X1} &= a_1 \mathrm{EI} + e_1 \\ \mathrm{X2} &= a_2 \mathrm{EI} + e_2 \\ \mathrm{X3} &= a_3 \mathrm{EI} + e_3 \end{aligned}$$

where a_1, a_2, and a_3 are regression coefficients and e_1, e_2, and e_3 are measurement errors. Measurement errors are assumed to be independent of the latent factors EI and CA. In the measurement model, X1, X2, and X3 are called the indicators of the latent variable EI. These observed variables are assumed to be centered in the model, and therefore no intercept terms are needed. Each of the indicators is a scaled measurement of the latent factor EI plus a unique error term.

Similarly, you need to have a measurement model for the latent factor CA. Suppose that there are four observed indicators Y1, Y2, Y3, and Y4 (for example, Job Status) for this latent factor. The measurement model for CA is specified as follows:

$$\begin{aligned} \mathrm{Y1} &= a_4 \mathrm{CA} + e_4 \\ \mathrm{Y2} &= a_5 \mathrm{CA} + e_5 \\ \mathrm{Y3} &= a_6 \mathrm{CA} + e_6 \\ \mathrm{Y4} &= a_7 \mathrm{CA} + e_7 \end{aligned}$$

where a_4, a_5, a_6, and a_7 are regression coefficients and e_4, e_5, e_6, and e_7 are error terms. Again, the error terms are assumed to be independent of the latent variables EI and CA, and Y1, Y2, Y3, and Y4 are centered in the equations.

Given the data for the measured variables, you analyze the structural and measurement models simultaneously by the structural equation modeling techniques. In other words, estimation of β, a_1–a_7, and other parameters in the model are carried out simultaneously in the modeling.

Modeling involving the use of latent factors is quite common in social and behavioral sciences, personality assessment, and marketing research. Hypothetical constructs, although not observable, are very important in building theories in these areas.

Another use of latent factors in modeling is to "purify" the predictors in regression analysis. A common assumption in linear regression models is that predictors are measured without errors. That is, in the following linear equation x is assumed to have been measured without errors:

$$y = \alpha + \beta x + \epsilon$$

However, if x has been contaminated with measurement errors that cannot be ignored, the estimate of β might be biased severely so that the true relationship between x and y would be masked.

A measurement model for x provides a solution to such a problem. Let F_x be a "purified" version of x. That is, F_x is the "true" measure of x without measurement errors, as described in the following equation:

$$x = F_x + \delta$$

where δ represents a random measurement error term. Now, the linear relationship of interest is specified in the following new linear regression equation:

$$y = \alpha + \beta F_x + \epsilon$$

In this equation, F_x, which is now free from measurement errors, replaces x in the original equation. With measurement errors taken into account in the simultaneous fitting of the measurement and the new regression equations, estimation of β is unbiased; hence it reflects the true relationship much better.

Certainly, introducing latent factors in models is not a "free lunch." You must pay attention to the identification issues induced by the latent variable methodology. That is, in order to estimate the parameters in structural equation models with latent variables, you must set some identification constraints in these models. There are some established rules or conventions that would lead to proper model identification and estimation. See Chapter 17, "Introduction to Structural Equation Modeling with Latent Variables," for examples and general details.

In addition, because of the nature of latent variables, estimation in structural equation modeling with latent variables does not follow the same form as that of linear regression analysis. Instead of defining the estimators in terms of the data matrices, most estimation methods in structural equation modeling use the fitting of the first- and second- order moments. Hence, estimation principles described in the section "Classical Estimation Principles" on page 42 do not apply to structural equation modeling. However, you can see the section "Estimation Criteria" on page 6888 in Chapter 88, "The TCALIS Procedure (Experimental)," for details about estimation in structural equation modeling with latent variables.

Bayesian Models

Statistical models based on the classical (or *frequentist*) paradigm treat the parameters of the model as fixed, unknown constants. They are not random variables, and the notion of probability is derived in an objective sense as a limiting relative frequency. The Bayesian paradigm takes a different

approach. Model parameters are random variables, and the probability of an event is defined in a subjective sense as the degree to which you believe that the event is true. This fundamental difference in philosophy leads to profound differences in the statistical content of estimation and inference. In the frequentist framework, you use the data to best estimate the unknown value of a parameter; you are trying to pinpoint a value in the parameter space as well as possible. In the Bayesian framework, you use the data to update your beliefs about the *behavior* of the parameter to assess its distributional properties as well as possible.

Suppose you are interested in estimating θ from data $\mathbf{Y} = [Y_1, \cdots, Y_n]$ by using a statistical model described by a density $p(\mathbf{y}|\theta)$. Bayesian philosophy states that θ cannot be determined exactly, and uncertainty about the parameter is expressed through probability statements and distributions. You can say, for example, that θ follows a normal distribution with mean 0 and variance 1, if you believe that this distribution best describes the uncertainty associated with the parameter.

The following steps describe the essential elements of Bayesian inference:

1. A probability distribution for θ is formulated as $\pi(\theta)$, which is known as the *prior* distribution, or just the prior. The prior distribution expresses your beliefs, for example, on the mean, the spread, the skewness, and so forth, about the parameter prior to examining the data.
2. Given the observed data $\mathbf{Y}$, you choose a statistical model $p(\mathbf{y}|\theta)$ to describe the distribution of $\mathbf{Y}$ given θ.
3. You update your beliefs about θ by combining information from the prior distribution and the data through the calculation of the *posterior* distribution, $p(\theta|\mathbf{y})$.

The third step is carried out by using Bayes' theorem, from which this branch of statistical philosophy derives its name. The theorem enables you to combine the prior distribution and the model in the following way:

$$p(\theta|\mathbf{y}) = \frac{p(\theta, \mathbf{y})}{p(\mathbf{y})} = \frac{p(\mathbf{y}|\theta)\pi(\theta)}{p(\mathbf{y})} = \frac{p(\mathbf{y}|\theta)\pi(\theta)}{\int p(\mathbf{y}|\theta)\pi(\theta)d\theta}$$

The quantity $p(\mathbf{y}) = \int p(\mathbf{y}|\theta)\pi(\theta)\, d\theta$ is the normalizing constant of the posterior distribution. It is also the marginal distribution of $\mathbf{Y}$, and it is sometimes called the marginal distribution of the data.

The likelihood function of θ is any function proportional to $p(\mathbf{y}|\theta)$—that is, $L(\theta) \propto p(\mathbf{y}|\theta)$. Another way of writing Bayes' theorem is

$$p(\theta|\mathbf{y}) = \frac{L(\theta)\pi(\theta)}{\int L(\theta)\pi(\theta)\, d\theta}$$

The marginal distribution $p(\mathbf{y})$ is an integral; therefore, provided that it is finite, the particular value of the integral does not yield any additional information about the posterior distribution. Hence, $p(\theta|\mathbf{y})$ can be written up to an arbitrary constant, presented here in proportional form, as

$$p(\theta|\mathbf{y}) \propto L(\theta)\pi(\theta)$$

Bayes' theorem instructs you how to update existing knowledge with new information. You start from a prior belief $\pi(\theta)$, and, after learning information from data $\mathbf{y}$, you change or update the

belief on θ and obtain $p(\theta|\mathbf{y})$. These are the essential elements of the Bayesian approach to data analysis.

In theory, Bayesian methods offer a very simple alternative to statistical inference—all inferences follow from the posterior distribution $p(\theta|\mathbf{y})$. However, in practice, only the most elementary problems enable you to obtain the posterior distribution analytically. Most Bayesian analyses require sophisticated computations, including the use of simulation methods. You generate samples from the posterior distribution and use these samples to estimate the quantities of interest.

Both Bayesian and classical analysis methods have their advantages and disadvantages. Your choice of method might depend on the goals of your data analysis. If prior information is available, such as in the form of expert opinion or historical knowledge, and you want to incorporate this information into the analysis, then you might consider Bayesian methods. In addition, if you want to communicate your findings in terms of probability notions that can be more easily understood by nonstatisticians, Bayesian methods might be appropriate. The Bayesian paradigm can provide a framework for answering specific scientific questions that a single point estimate cannot sufficiently address. On the other hand, if you are interested in estimating parameters and in formulating inferences based on the properties of the parameter estimators, then there is no need to use Bayesian analysis. When the sample size is large, Bayesian inference often provides results for parametric models that are very similar to the results produced by classical, frequentist methods.

For more information, see Chapter 7, "Introduction to Bayesian Analysis Procedures."

Classical Estimation Principles

An estimation principle captures the set of rules and procedures by which parameter estimates are derived. When an estimation principle "meets" a statistical model, the result is an *estimation problem*, the solution of which are the parameter estimates. For example, if you apply the estimation principle of least squares to the SLR model $Y_i = \beta_0 + \beta_1 x_i + \epsilon_i$, the estimation problem is to find those values $\widehat{\beta}_0$ and $\widehat{\beta}_1$ that minimize

$$\sum_{i=1}^{n} (y_i - \beta_0 - \beta_1 x_i)^2$$

The solutions are the least squares estimators.

The two most important classes of estimation principles in statistical modeling are the least squares principle and the likelihood principle. All principles have in common that they provide a metric by which you measure the distance between the data and the model. They differ in the nature of the metric; least squares relies on a geometric measure of distance, while likelihood inference is based on a distance that measures plausability.

Least Squares

The idea of the ordinary least squares (OLS) principle is to choose parameter estimates that minimize the squared distance between the data and the model. In terms of the general, additive model,

$$Y_i = f(x_{i1}, \cdots, x_{ik}; \beta_1, \cdots, \beta_p) + \epsilon_i$$

the OLS principle minimizes

$$\text{SSE} = \sum_{i=1}^{n} \left(y_i - f(x_{i1}, \cdots, x_{ik}; \beta_1, \cdots, \beta_p)\right)^2$$

The least squares principle is sometimes called "nonparametric" in the sense that it does not require the distributional specification of the response or the error term, but it might be better termed "distributionally agnostic." In an additive-error model it is only required that the model errors have zero mean. For example, the specification

$$\begin{aligned} Y_i &= \beta_0 + \beta_1 x_i + \epsilon_i \\ \text{E}[\epsilon_i] &= 0 \end{aligned}$$

is sufficient to derive ordinary least squares (OLS) estimators for β_0 and β_1 and to study a number of their properties. It is easy to show that the OLS estimators in this SLR model are

$$\begin{aligned} \widehat{\beta}_1 &= \left(\sum_{i=1}^{n} (Y_i - \overline{Y}) \sum_{i=1}^{n} (x_i - \overline{x})\right) \Big/ \sum_{i=1}^{n} (x_i - \overline{x})^2 \\ \widehat{\beta}_0 &= \overline{Y} - \widehat{\beta}_1 \overline{x} \end{aligned}$$

Based on the assumption of a zero mean of the model errors, you can show that these estimators are unbiased, $\text{E}[\widehat{\beta}_1] = \beta_1$, $\text{E}[\widehat{\beta}_0] = \beta_0$. However, without further assumptions about the distribution of the ϵ_i, you cannot derive the variability of the least squares estimators or perform statistical inferences such as hypothesis tests or confidence intervals. In addition, depending on the distribution of the ϵ_i, other forms of least squares estimation can be more efficient than OLS estimation.

The conditions for which ordinary least squares estimation is efficient are zero mean, homoscedastic, uncorrelated model errors. Mathematically,

$$\begin{aligned} \text{E}[\epsilon_i] &= 0 \\ \text{Var}[\epsilon_i] &= \sigma^2 \\ \text{Cov}[\epsilon_i, \epsilon_j] &= 0 \text{ if } i \neq j \end{aligned}$$

The second and third assumption are met if the errors have an *iid* distribution—that is, if they are independent and identically distributed. Note, however, that the notion of stochastic independence is stronger than that of absence of correlation. Only if the data are normally distributed does the latter implies the former.

The various other forms of the least squares principle are motivated by different extensions of these assumptions in order to find more efficient estimators.

Weighted Least Squares

The objective function in weighted least squares (WLS) estimation is

$$\text{SSE}_w = \sum_{i=1}^{n} w_i \left(Y_i - f(x_{i1}, \cdots, x_{ik}; \beta_1, \cdots, \beta_p)\right)^2$$

where w_i is a weight associated with the ith observation. A situation where WLS estimation is appropriate is when the errors are uncorrelated but not homoscedastic. If the weights for the observations are proportional to the reciprocals of the error variances, $\text{Var}[\epsilon_i] = \sigma^2/w_i$, then the weighted least squares estimates are best linear unbiased estimators (BLUE). Suppose that the weights w_i are collected in the diagonal matrix $\mathbf{W}$ and that the mean function has the form of a linear model. The weighted sum of squares criterion then can be written as

$$\text{SSE}_w = (\mathbf{Y} - \mathbf{X}\boldsymbol{\beta})' \mathbf{W} (\mathbf{Y} - \mathbf{X}\boldsymbol{\beta})$$

which gives rise to the weighted normal equations

$$(\mathbf{X}'\mathbf{W}\mathbf{X})\boldsymbol{\beta} = \mathbf{X}'\mathbf{W}\mathbf{Y}$$

The resulting WLS estimator of $\boldsymbol{\beta}$ is

$$\widehat{\boldsymbol{\beta}}_w = \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-} \mathbf{X}'\mathbf{W}\mathbf{Y}$$

Iteratively Reweighted Least Squares

If the weights in a least squares problem depend on the parameters, then a change in the parameters also changes the weight structure of the model. Iteratively reweighted least squares (IRLS) estimation is an iterative technique that solves a series of weighted least squares problems, where the weights are recomputed between iterations. IRLS estimation can be used, for example, to derive maximum likelihood estimates in generalized linear models.

Generalized Least Squares

The previously discussed least squares methods have in common that the observations are assumed to be uncorrelated—that is, $\text{Cov}[\epsilon_i, \epsilon_j] = 0$, whenever $i \neq j$. The weighted least squares estimation problem is a special case of a more general least squares problem, where the model errors have a general convariance matrix, $\text{Var}[\boldsymbol{\epsilon}] = \boldsymbol{\Sigma}$. Suppose again that the mean function is linear, so that the model becomes

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon} \qquad \boldsymbol{\epsilon} \sim (\mathbf{0}, \boldsymbol{\Sigma})$$

The generalized least squares (GLS) principle is to minimize the generalized error sum of squares

$$\text{SSE}_g = (\mathbf{Y} - \mathbf{X}\boldsymbol{\beta})' \boldsymbol{\Sigma}^{-1} (\mathbf{Y} - \mathbf{X}\boldsymbol{\beta})$$

This leads to the generalized normal equations

$$(\mathbf{X}'\boldsymbol{\Sigma}^{-1}\mathbf{X})\boldsymbol{\beta} = \mathbf{X}'\boldsymbol{\Sigma}^{-1}\mathbf{Y}$$

and the GLS estimator

$$\widehat{\boldsymbol{\beta}}_g = \left(\mathbf{X}'\boldsymbol{\Sigma}^{-1}\mathbf{X}\right)^{-}\mathbf{X}'\boldsymbol{\Sigma}^{-1}\mathbf{Y}$$

Obviously, WLS estimation is a special case of GLS estimation, where $\boldsymbol{\Sigma} = \sigma^2\mathbf{W}^{-1}$—that is, the model is

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon} \qquad \boldsymbol{\epsilon} \sim \left(\mathbf{0}, \sigma^2\mathbf{W}^{-1}\right)$$

Likelihood

There are several forms of likelihood estimation and a large number of offshoot principles derived from it, such as pseudo-likelihood, quasi-likelihood, composite likelihood, etc. The basic likelihood principle is *maximum likelihood*, which asks to estimate the model parameters by those quantities that maximize the likelihood function of the data. The likelihood function is the joint distribution of the data, but in contrast to a probability mass or density function, it is thought of as a function of the parameters, given the data. The heuristic appeal of the maximum likelihood estimates (MLE) is that these are the values that make the observed data "most likely." Especially for discrete response data, the value of the likelihood function is the ordinate of a probability mass function, even if the likelihood is not a probability function. Since a statistical model is thought of as a representation of the data-generating mechanism, what could be more preferable as parameter estimates than those values that make it most likely that the data at hand will be observed?

Maximum likelihood estimates, if they exist, have appealing statistical properties. Under fairly mild conditions, they are best-asymptotic-normal (BAN) estimates—that is, their asymptotic distribution is normal, and no other estimator has a smaller asymptotic variance. However, their statistical behavior in finite samples is often difficult to establish, and you have to appeal to the asymptotic results that hold as the sample size tends to infinity. For example, maximum likelihood estimates are often biased estimates and the bias disappears as the sample size grows. A famous example is random sampling from a normal distribution. The corresponding statistical model is

$$\begin{aligned} Y_i &= \mu + \epsilon_i \\ \epsilon_i &\sim \textit{iid}\ N(0, \sigma^2) \end{aligned}$$

where the symbol $\sim$ is read as "is distributed as" and *iid* is read as "independent and identically distributed." Under the normality assumption, the density function of y_i is

$$f(y_i; \mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left\{-\frac{1}{2}\left(\frac{y_i - \mu}{\sigma}\right)^2\right\}$$

and the likelihood for a random sample of size n is

$$L(\mu, \sigma^2; \mathbf{y}) = \prod_{i=1}^{n} \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left\{-\frac{1}{2}\left(\frac{y_i - \mu}{\sigma}\right)^2\right\}$$

Maximizing the likelihood function $L(\mu, \sigma^2; \mathbf{y})$ is equivalent to maximizing the log-likelihood function $\log L = l(\mu, \sigma^2; \mathbf{y})$,

$$\begin{aligned} l(\mu, \sigma^2; \mathbf{y}) &= \sum_{i=1}^{n} -\frac{1}{2}\left(\log\{2\pi\} + \frac{(y_i - \mu)^2}{\sigma^2} + \log\{\sigma^2\}\right) \\ &= -\frac{1}{2}\left(n\log\{2\pi\} + n\log\{\sigma^2\} + \sum_{i=1}^{n}(y_i - \mu)^2/\sigma^2\right) \end{aligned}$$

The maximum likelihood estimators of μ and σ^2 are thus

$$\widehat{\mu} = \frac{1}{n}\sum_{i=1}^{n} Y_i = \overline{Y} \qquad \widehat{\sigma}^2 = \frac{1}{n}\sum_{i=1}^{n} (Y_i - \widehat{\mu})^2$$

The MLE of the mean μ is the sample mean, and it is an unbiased estimator of μ. However, the MLE of the variance σ^2 is not an unbiased estimator. It has bias

$$\mathrm{E}\left[\widehat{\sigma}^2 - \sigma^2\right] = -\frac{1}{n}\sigma^2$$

As the sample size n increases, the bias vanishes.

For certain classes of models, special forms of likelihood estimation have been developed to maintain the appeal of likelihood-based statistical inference and to address specific properties that are believed to be shortcomings:

- The bias in maximum likelihood parameter estimators of variances and covariances has led to the development of restricted (or residual) maximum likelihood (REML) estimators that play an important role in mixed models.
- Quasi-likelihood methods do not require that the joint distribution of the data be specified. These methods derive estimators based on only the first two moments (mean and variance) of the joint distributions and play an important role in the analysis of correlated data.
- The idea of composite likelihood is applied in situations where the likelihood of the vector of responses is intractable but the likelihood of components or functions of the full-data likelihood are tractable. For example, instead of the likelihood of $\mathbf{Y}$, you might consider the likelihood of pairwise differences $Y_i - Y_j$.
- The pseudo-likelihood concept is also applied when the likelihood function is intractable, but the likelihood of a related, simpler model is available. An important difference between quasi-likelihood and pseudo-likelihood techniques is that the latter make distributional assumptions to obtain a likelihood function in the pseudo-model. Quasi-likelihood methods do not specify the distributional family.
- The penalized likelihood principle is applied when additional constraints and conditions need to be imposed on the parameter estimates or the resulting model fit. For example, you might augment the likelihood with conditions that govern the smoothness of the predictions or that prevent overfitting of the model.

Least Squares or Likelihood

For many statistical modeling problems, you have a choice between a least squares principle and the maximum likelihood principle. Table 3.1 compares these two basic principles.

Table 3.1 Least Squares and Maximum Likelihood

Criterion	Least Squares	Maximum Likelihood
Requires specification of joint distribution of data	No, but in order to perform confirmatory inference (tests, confidence intervals), a distributional assumption is needed, or an appeal to asymptotics.	Yes, no progress can be made with the genuine likelihood principle without knowing the distribution of the data.
All parameters of the model are estimated	No. In the additive-error type models, least squares provides estimates of only the parameters in the mean function. The residual variance, for example, must be estimated by some other method—typically by using the mean squared error of the model.	Yes
Estimates always exist	Yes, but they might not be unique, such as when the $\mathbf{X}$ matrix is singular.	No, maximum likelihood estimates do not exist for all estimation problems.
Estimators are biased	Unbiased, provided that the model is correct—that is, the errors have zero mean.	Often biased, but asymptotically unbiased
Estimators are consistent	Not necessarily, but often true. Sometimes estimators are consistent even in a misspecified model, such as when misspecification is in the covariance structure.	Almost always
Estimators are best linear unbiased estimates (BLUE)	Typically, if the least squares assumptions are met.	Not necessarily: estimators are often nonlinear in the data and are often biased.
Asymptotically most efficient	Not necessarily	Typically
Easy to compute	Yes	No

Inference Principles for Survey Data

Design-based and model-assisted statistial inference for survey data requires that the randomness due to the selection mechanism be taken into account. This can require special estimation principles and techniques.

The SURVEYMEANS, SURVEYFREQ, SURVEYREG, and SURVEYLOGISTIC procedures support design-based and/or model-assisted inference for sample surveys. Suppose π_i is the selection probability for unit i in sample S. The inverse of the inclusion probability is known as sampling weight and is denoted by w_i. Briefly, the idea is to apply a relationship that exists in the population to the sample and to take into account the sampling weights. For example, to estimate the finite population total $T_N = \sum_{i \in U_N} y_i$ based on the sample S, you can accumulate the sampled values while properly weighting: $\widehat{T}_\pi = \sum_{i \in S} w_i y_i$. It is easy to verify that $\widehat{T}_\pi$ is design-unbiased in the sense that $\mathrm{E}[\widehat{T}_\pi | \mathcal{F}_N] = T_N$ (see Cochran 1997).

When a statistical model is present, similar ideas apply. For example, if β_{N0} and β_{N1} are finite population quantities for a simple linear regression working model that minimize the sum of squares

$$\sum_{i \in U_N} (y_i - \beta_{0N} - \beta_{1N} x_i)^2$$

in the population, then the sample-based estimators $\widehat{\beta}_{0S}$ and $\widehat{\beta}_{1S}$ are obtained by minimizing the weighted sum of squares

$$\sum_{i \in S} w_i (y_i - \hat{\beta}_{0S} - \hat{\beta}_{1S} x_i)^2$$

in the sample, taking into account the inclusion probabilities.

In model-assisted inference, weighted least squares or pseudo-maximum likelihood estimators are commonly used to solve such estimation problems. Maximum pseudo-likelihood or weighted maximum likelihood estimators for survey data maximize a sample-based estimator of the population likelihood. Assume a working model with uncorrelated responses such that the finite population log-likelihood is

$$\sum_{i \in U_N} l(\theta_{1N}, \ldots, \theta_{pN}; y_i),$$

where $\theta_{1N}, \ldots, \theta_{pN}$ are finite population quantities. For independent sampling, one possible sample-based estimator of the population log likelihood is

$$\sum_{i \in S} w_i l(\theta_{1N}, \ldots, \theta_{pN}; y_i)$$

Sample-based estimators $\widehat{\theta}_{1S}, \ldots, \widehat{\theta}_{pS}$ are obtained by maximizing this expression.

Design-based and model-based statistical analysis might employ the same statistical model (for example, a linear regression) and the same estimation principle (for example, weighted least squares), and arrive at the same estimates. The design-based estimation of the precision of the estimators differs from the model-based estimation, however. For complex surveys, design-based variance estimates are in general different from their model-based counterpart. The SAS/STAT procedures for survey data (SURVEYMEANS, SURVEYFREQ, SURVEYREG, and SURVEYLOGISTIC procedures) compute design-based variance estimates for complex survey data. See the section "Variance Estimation" on page 267, in Chapter 14, "Introduction to Survey Procedures," for details about design-based variance estimation.

Statistical Background

Hypothesis Testing and Power

In statistical hypothesis testing, you typically express the belief that some effect exists in a population by specifying an alternative hypothesis H_1. You state a null hypothesis H_0 as the assertion that the effect does *not* exist and attempt to gather evidence to reject H_0 in favor of H_1. Evidence is gathered in the form of sample data, and a statistical test is used to assess H_0. If H_0 is rejected but there really is *no* effect, this is called a *Type I error*. The probability of a Type I error is usually designated "alpha" or α, and statistical tests are designed to ensure that α is suitably small (for example, less than 0.05).

If there is an effect in the population but H_0 is *not* rejected in the statistical test, then a *Type II error* has been committed. The probability of a Type II error is usually designated "beta" or β. The probability $1-\beta$ of avoiding a Type II error—that is, correctly rejecting H_0 and achieving statistical significance, is called the *power* of the test.

An important goal in study planning is to ensure an acceptably high level of power. Sample size plays a prominent role in power computations because the focus is often on determining a sufficient sample size to achieve a certain power, or assessing the power for a range of different sample sizes.

There are several tools available in SAS/STAT software for power and sample size analysis. PROC POWER covers a variety of analyses such as t tests, equivalence tests, confidence intervals, binomial proportions, multiple regression, one-way ANOVA, survival analysis, logistic regression, and the Wilcoxon rank-sum test. PROC GLMPOWER supports more complex linear models. The Power and Sample Size application provides a user interface and implements many of the analyses supported in the procedures.

Important Linear Algebra Concepts

A *matrix* $\mathbf{A}$ is a rectangular array of numbers. The *order* of a matrix with n rows and k columns is $(n \times k)$. The element in row i, column j of $\mathbf{A}$ is denoted as a_{ij}, and the notation $\left[a_{ij}\right]$ is sometimes used to refer to the two-dimensional row-column array

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1k} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2k} \\ a_{31} & a_{32} & a_{33} & \cdots & a_{3k} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & a_{n3} & \cdots & a_{nk} \end{bmatrix} = \left[a_{ij}\right]$$

A *vector* is a one-dimensional array of numbers. A *column vector* has a single column ($k = 1$). A *row vector* has a single row ($n = 1$). A *scalar* is a matrix of order (1×1)—that is, a single number.

A *square* matrix has the same row and column order, $n = k$. A *diagonal* matrix is a square matrix where all off-diagonal elements are zero, $a_{ij} = 0$ if $i \neq j$. The *identity* matrix $\mathbf{I}$ is a diagonal matrix with $a_{ii} = 1$ for all i. The *unit vector* $\mathbf{1}$ is a vector where all elements are 1. The *unit matrix* $\mathbf{J}$ is a matrix of all 1s. Similarly, the elements of the null vector and the null matrix are all 0.

Basic matrix operations are as follows:

Addition — If $\mathbf{A}$ and $\mathbf{B}$ are of the same order, then $\mathbf{A} + \mathbf{B}$ is the matrix of elementwise sums,

$$\mathbf{A} + \mathbf{B} = \left[a_{ij} + b_{ij}\right]$$

Subtraction — If $\mathbf{A}$ and $\mathbf{B}$ are of the same order, then $\mathbf{A} - \mathbf{B}$ is the matrix of elementwise differences,

$$\mathbf{A} - \mathbf{B} = \left[a_{ij} - b_{ij}\right]$$

Dot product — The dot product of two n-vectors $\mathbf{a}$ and $\mathbf{b}$ is the sum of their elementwise products,

$$\mathbf{a} \cdot \mathbf{b} = \sum_{i=1}^{n} a_i b_i$$

The dot product is also known as the *inner product* of $\mathbf{a}$ and $\mathbf{b}$. Two vectors are said to be *orthogonal* if their dot product is zero.

Multiplication — Matrices $\mathbf{A}$ and $\mathbf{B}$ are said to be conformable for $\mathbf{AB}$ multiplication if the number of columns in $\mathbf{A}$ equals the number of rows in $\mathbf{B}$. Suppose that $\mathbf{A}$ is of order $(n \times k)$ and that $\mathbf{B}$ is of order $(k \times p)$. The product $\mathbf{AB}$ is then defined as the $(n \times p)$ matrix of the dot products of the ith row of $\mathbf{A}$ and the jth column of $\mathbf{B}$,

$$\mathbf{AB} = \left[\mathbf{a_i} \cdot \mathbf{b_j}\right]_{n \times p}$$

Transposition — The transpose of the $(n \times k)$ matrix $\mathbf{A}$ is denoted as $\mathbf{A}'$ or $\mathbf{A}^T$ or $\mathbf{A}^{\mathrm{T}}$ and is obtained by interchanging the rows and columns,

$$\mathbf{A}' = \begin{bmatrix} a_{11} & a_{21} & a_{31} & \cdots & a_{n1} \\ a_{12} & a_{22} & a_{23} & \cdots & a_{n2} \\ a_{13} & a_{23} & a_{33} & \cdots & a_{n3} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{1k} & a_{2k} & a_{3k} & \cdots & a_{nk} \end{bmatrix} = \left[a_{ji}\right]$$

A *symmetric* matrix is equal to its transpose, $\mathbf{A} = \mathbf{A}'$. The inner product of two $(n \times 1)$ column vectors $\mathbf{a}$ and $\mathbf{b}$ is $\mathbf{a} \cdot \mathbf{b} = \mathbf{a}'\mathbf{b}$.

Matrix Inversion

Regular Inverses

The right inverse of a matrix $\mathbf{A}$ is the matrix that yields the identity when $\mathbf{A}$ is postmultiplied by it. Similarly, the left inverse of $\mathbf{A}$ yields the identity if $\mathbf{A}$ is premultiplied by it. $\mathbf{A}$ is said to be

invertible and $\mathbf{B}$ is said to be the inverse of $\mathbf{A}$, if $\mathbf{B}$ is its right and left inverse, $\mathbf{BA} = \mathbf{AB} = \mathbf{I}$. This requires $\mathbf{A}$ to be square and nonsingular. The inverse of a matrix $\mathbf{A}$ is commonly denoted as $\mathbf{A}^{-1}$. The following results are useful in manipulating inverse matrices (assuming both $\mathbf{A}$ and $\mathbf{C}$ are invertible):

$$\begin{aligned}
\mathbf{A}\mathbf{A}^{-1} &= \mathbf{A}^{-1}\mathbf{A} = \mathbf{I} \\
\left(\mathbf{A}'\right)^{-1} &= \left(\mathbf{A}^{-1}\right)' \\
\left(\mathbf{A}^{-1}\right)^{-1} &= \mathbf{A} \\
(\mathbf{AC})^{-1} &= \mathbf{C}^{-1}\mathbf{A}^{-1} \\
\text{rank}(\mathbf{A}) &= \text{rank}\left(\mathbf{A}^{-1}\right)
\end{aligned}$$

If $\mathbf{D}$ is a diagonal matrix with nonzero entries on the diagonal—that is, $\mathbf{D} = \text{diag}\,(d_1, \cdots, d_n)$—then $\mathbf{D}^{-1} = \text{diag}\,(1/d_1, \cdots, 1/d_n)$. If $\mathbf{D}$ is a block-diagonal matrix whose blocks are invertible, then

$$\mathbf{D} = \begin{bmatrix} \mathbf{D}_1 & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{D}_2 & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{D}_3 & \cdots & \mathbf{0} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{D}_n \end{bmatrix} \qquad \mathbf{D}^{-1} = \begin{bmatrix} \mathbf{D}_1^{-1} & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{D}_2^{-1} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{D}_3^{-1} & \cdots & \mathbf{0} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{D}_n^{-1} \end{bmatrix}$$

In statistical applications the following two results are particularly important, because they can significantly reduce the computational burden in working with inverse matrices.

Partitioned Matrix Suppose $\mathbf{A}$ is a nonsingular matrix that is partitioned as

$$\mathbf{A} = \begin{bmatrix} \mathbf{A}_{11} & \mathbf{A}_{12} \\ \mathbf{A}_{21} & \mathbf{A}_{22} \end{bmatrix}$$

Then, provided that all the inverses exist, the inverse of $\mathbf{A}$ is given by

$$\mathbf{A}^{-1} = \begin{bmatrix} \mathbf{B}_{11} & \mathbf{B}_{12} \\ \mathbf{B}_{21} & \mathbf{B}_{22} \end{bmatrix}$$

where $\mathbf{B}_{11} = \left(\mathbf{A}_{11} - \mathbf{A}_{12}\mathbf{A}_{22}^{-1}\mathbf{A}_{21}\right)^{-1}$, $\mathbf{B}_{12} = -\mathbf{B}_{11}\mathbf{A}_{12}\mathbf{A}_{22}^{-1}$, $\mathbf{B}_{21} = -\mathbf{A}_{22}^{-1}\mathbf{A}_{21}\mathbf{B}_{11}$, and $\mathbf{B}_{22} = \left(\mathbf{A}_{22} - \mathbf{A}_{21}\mathbf{A}_{11}^{-1}\mathbf{A}_{12}\right)^{-1}$.

Patterned Sum Suppose $\mathbf{R}$ is $(n \times n)$ nonsingular, $\mathbf{G}$ is $(k \times k)$ nonsingular, and $\mathbf{B}$ and $\mathbf{C}$ are $(n \times k)$ and $(k \times n)$ matrices, respectively. Then the inverse of $\mathbf{R} + \mathbf{BGC}$ is given by

$$(\mathbf{R} + \mathbf{BGC})^{-1} = \mathbf{R}^{-1} - \mathbf{R}^{-1}\mathbf{B}\left(\mathbf{G}^{-1} + \mathbf{C}\mathbf{R}^{-1}\mathbf{B}\right)^{-1}\mathbf{C}\mathbf{R}^{-1}$$

This formula is particularly useful if $k << n$ and $\mathbf{R}$ has a simple form that is easy to invert. This case arises, for example, in mixed models where $\mathbf{R}$ might be a diagonal or block-diagonal matrix, and $\mathbf{B} = \mathbf{C}'$.

Another situation where this formula plays a critical role is in the computation of regression diagnostics, such as in determining the effect of removing an observation from the analysis. Suppose that $\mathbf{A} = \mathbf{X}'\mathbf{X}$ represents the crossproduct

matrix in the linear model $\mathrm{E}[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$. If $\mathbf{x}_i'$ is the ith row of the $\mathbf{X}$ matrix, then $(\mathbf{X}'\mathbf{X} - \mathbf{x}_i\mathbf{x}_i')$ is the crossproduct matrix in the same model with the ith observation removed. Identifying $\mathbf{B} = -\mathbf{x}_i$, $\mathbf{C} = \mathbf{x}_i'$, and $\mathbf{G} = \mathbf{I}$ in the preceding inversion formula, you can obtain the expression for the inverse of the crossproduct matrix:

$$\left(\mathbf{X}'\mathbf{X} - \mathbf{x}_i\mathbf{x}_i'\right)^{-1} = \mathbf{X}'\mathbf{X} + \frac{\left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{x}_i\mathbf{x}_i'\left(\mathbf{X}'\mathbf{X}\right)^{-1}}{1 - \mathbf{x}_i'\left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{x}_i}$$

This expression for the inverse of the reduced data crossproduct matrix enables you to compute "leave-one-out" deletion diagnostics in linear models without refitting the model.

Generalized Inverse Matrices

If $\mathbf{A}$ is rectangular (not square) or singular, then it is not invertible and the matrix $\mathbf{A}^{-1}$ does not exist. Suppose you want to find a solution to simultaneous linear equations of the form

$$\mathbf{A}\mathbf{b} = \mathbf{c}$$

If $\mathbf{A}$ is square and nonsingular, then the unique solution is $\mathbf{b} = \mathbf{A}^{-1}\mathbf{c}$. In statistical applications, the case where $\mathbf{A}$ is $(n \times k)$ rectangular is less important than the case where $\mathbf{A}$ is a $(k \times k)$ square matrix of rank less than k. For example, the normal equations in ordinary least squares (OLS) estimation in the model $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$ are

$$\left(\mathbf{X}'\mathbf{X}\right)\boldsymbol{\beta} = \mathbf{X}'\mathbf{Y}$$

A *generalized inverse* matrix is a matrix $\mathbf{A}^-$ such that $\mathbf{A}^-\mathbf{c}$ is a solution to the linear system. In the OLS example, a solution can be found as $\left(\mathbf{X}'\mathbf{X}\right)^-\mathbf{X}'\mathbf{Y}$, where $\left(\mathbf{X}'\mathbf{X}\right)^-$ is a generalized inverse of $\mathbf{X}'\mathbf{X}$.

The following four conditions are often associated with generalized inverses. For the square or rectangular matrix $\mathbf{A}$ there exist matrices $\mathbf{G}$ that satisfy

$$\begin{array}{lrcl} \text{(i)} & \mathbf{AGA} & = & \mathbf{A} \\ \text{(ii)} & \mathbf{GAG} & = & \mathbf{G} \\ \text{(iii)} & (\mathbf{AG})' & = & \mathbf{AG} \\ \text{(iv)} & (\mathbf{GA})' & = & \mathbf{GA} \end{array}$$

The matrix $\mathbf{G}$ that satisfies all four conditions is unique and is called the Moore-Penrose inverse, after the first published work on generalized inverses by Moore (1920) and the subsequent definition by Penrose (1955). Only the first condition is required, however, to provide a solution to the linear system above.

Pringle and Rayner (1971) introduced a numbering system to distinguish between different types of generalized inverses. A matrix that satisfies only condition (i) is a g_1-inverse. The g_2-inverse satistifes conditions (i) and (ii). It is also called a *reflexive* generalized inverse. Matrices satisfying conditions (i)–(iii) or conditions (i), (ii), and (iv) are g_3-inverses. Note that a matrix that satisfies the first three conditions is a right generalized inverse, and a matrix that satisfies conditions (i), (ii), and (iv) is a left generalized inverse. For example, if $\mathbf{B}$ is $(n \times k)$ of rank k, then $\left(\mathbf{B}'\mathbf{B}\right)^{-1}\mathbf{B}'$ is

a left generalized inverse of **B**. The notation g_4-inverse for the Moore-Penrose inverse, satisfying conditions (i)–(iv), is often used by extension, but note that Pringle and Rayner (1971) do not use it; rather, they call such a matrix "the" generalized inverse.

If the $(n \times k)$ matrix **X** is rank-deficient—that is, $\text{rank}(\mathbf{X}) < \min\{n, k\}$—then the system of equations

$$\left(\mathbf{X}'\mathbf{X}\right)\boldsymbol{\beta} = \mathbf{X}'\mathbf{Y}$$

does not have a unique solution. A particular solution depends on the choice of the generalized inverse. However, some aspects of the statistical inference are invariant to the choice of the generalized inverse. If **G** is a generalized inverse of $\mathbf{X}'\mathbf{X}$, then $\mathbf{X}\mathbf{G}\mathbf{X}'$ is invariant to the choice of **G**. This result comes into play, for example, when you are computing predictions in an OLS model with a rank-deficient **X** matrix, since it implies that the predicted values

$$\mathbf{X}\widehat{\boldsymbol{\beta}} = \mathbf{X}\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{y}$$

are invariant to the choice of $\left(\mathbf{X}'\mathbf{X}\right)^{-}$.

Matrix Differentiation

Taking the derivative of expressions involving matrices is a frequent task in statistical estimation. Objective functions that are to be minimized or maximized are usually written in terms of model matrices and/or vectors whose elements depend on the unknowns of the estimation problem. Suppose that **A** and **B** are real matrices whose elements depend on the scalar quantities β and θ—that is, $\mathbf{A} = \left[a_{ij}(\beta, \theta)\right]$, and similarly for **B**.

The following are useful results in finding the derivative of elements of a matrix and of functions involving a matrix. For more in-depth discussion of matrix differentiation and matrix calculus, see, for example, Magnus and Neudecker (1999) and Harville (1997).

The derivative of **A** with respect to β is denoted $\dot{\mathbf{A}}_{\beta}$ and is the matrix of the first derivatives of the elements of **A**:

$$\dot{\mathbf{A}}_{\beta} = \frac{\partial}{\partial\beta}\mathbf{A} = \left[\frac{\partial a_{ij}(\beta, \theta)}{\partial\beta}\right]$$

Similarly, the second derivative of **A** with respect to β and θ is the matrix of the second derivatives

$$\ddot{\mathbf{A}}_{\beta\theta} = \frac{\partial^2}{\partial\beta\partial\theta}\mathbf{A} = \left[\frac{\partial^2 a_{ij}(\beta, \theta)}{\partial\beta\partial\theta}\right]$$

The following are some basic results involving sums, products, and traces of matrices:

$$\begin{aligned}
\frac{\partial}{\partial\beta}c_1\mathbf{A} &= c_1\dot{\mathbf{A}}_\beta \\
\frac{\partial}{\partial\beta}(\mathbf{A}+\mathbf{B}) &= \dot{\mathbf{A}}_\beta + \dot{\mathbf{B}}_\beta \\
\frac{\partial}{\partial\beta}(c_1\mathbf{A}+c_2\mathbf{B}) &= c_1\dot{\mathbf{A}}_\beta + c_2\dot{\mathbf{B}}_\beta \\
\frac{\partial}{\partial\beta}\mathbf{AB} &= \mathbf{A}\dot{\mathbf{B}}_\beta + \dot{\mathbf{A}}_\beta\mathbf{B} \\
\frac{\partial}{\partial\beta}\text{trace}(\mathbf{A}) &= \text{trace}\left(\dot{\mathbf{A}}_\beta\right) \\
\frac{\partial}{\partial\beta}\text{trace}(\mathbf{AB}) &= \text{trace}\left(\mathbf{A}\dot{\mathbf{B}}_\beta\right) + \text{trace}\left(\dot{\mathbf{A}}_\beta\mathbf{B}\right)
\end{aligned}$$

The next set of results is useful in finding the derivative of elements of $\mathbf{A}$ and of functions of $\mathbf{A}$, if $\mathbf{A}$ is a nonsingular matrix:

$$\begin{aligned}
\frac{\partial}{\partial\beta}\mathbf{x}'\mathbf{A}^{-1}\mathbf{x} &= -\mathbf{x}'\mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\mathbf{A}^{-1}\mathbf{x} \\
\frac{\partial}{\partial\beta}\mathbf{A}^{-1} &= -\mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\mathbf{A}^{-1} \\
\frac{\partial}{\partial\beta}|\mathbf{A}| &= |\mathbf{A}|\,\text{trace}\left(\mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\right) \\
\frac{\partial}{\partial\beta}\log\{|\mathbf{A}|\} &= \frac{1}{|\mathbf{A}|}\frac{\partial}{\partial\beta}\mathbf{A} = \text{trace}\left(\mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\right) \\
\frac{\partial^2}{\partial\beta\,\partial\theta}\mathbf{A}^{-1} &= -\mathbf{A}^{-1}\ddot{\mathbf{A}}_{\beta\theta}\mathbf{A}^{-1} + \mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\mathbf{A}^{-1}\dot{\mathbf{A}}_\theta\mathbf{A}^{-1} + \mathbf{A}^{-1}\dot{\mathbf{A}}_\theta\mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\mathbf{A}^{-1} \\
\frac{\partial^2}{\partial\beta\,\partial\theta}\log\{|\mathbf{A}|\} &= \text{trace}\left(\mathbf{A}^{-1}\ddot{\mathbf{A}}_{\beta\theta}\right) - \text{trace}\left(\mathbf{A}^{-1}\dot{\mathbf{A}}_\beta\mathbf{A}^{-1}\dot{\mathbf{A}}_\theta\right)
\end{aligned}$$

Now suppose that $\mathbf{a}$ and $\mathbf{b}$ are column vectors that depend on β and/or θ and that $\mathbf{x}$ is a vector of constants. The following results are useful for manipulating derivatives of linear and quadratic forms:

$$\begin{aligned}
\frac{\partial}{\partial\mathbf{x}}\mathbf{a}'\mathbf{x} &= \mathbf{a} \\
\frac{\partial}{\partial\mathbf{x}'}\mathbf{B}\mathbf{x} &= \mathbf{B} \\
\frac{\partial}{\partial\mathbf{x}}\mathbf{x}'\mathbf{B}\mathbf{x} &= \left(\mathbf{B}+\mathbf{B}'\right)\mathbf{x} \\
\frac{\partial^2}{\partial\mathbf{x}\partial\mathbf{x}'}\mathbf{x}'\mathbf{B}\mathbf{x} &= \mathbf{B}+\mathbf{B}'
\end{aligned}$$

Matrix Decompositions

To decompose a matrix is to express it as a function—typically a product—of other matrices that have particular properties such as orthogonality, diagonality, triangularity. For example, the Cholesky decomposition of a symmetric positive definite matrix $\mathbf{A}$ is $\mathbf{CC}' = \mathbf{A}$, where $\mathbf{C}$ is a lower-triangular matrix. The spectral decomposition of a symmetric matrix is $\mathbf{A} = \mathbf{PDP}'$, where $\mathbf{D}$ is a diagonal matrix and $\mathbf{P}$ is an orthogonal matrix.

Matrix decomposition play an important role in statistical theory as well as in statistical computations. Calculations in terms of decompositions can have greater numerical stability. Decompositions are often necessary to extract information about matrices, such as matrix rank, eigenvalues, or eigenvectors. Decompositions are also used to form special transformations of matrices, such as to form a "square-root" matrix. This section briefly mentions several decompositions that are particularly prevalent and important.

LDU, LU, and Cholesky Decomposition

Every square matrix $\mathbf{A}$, whether it is positive definite or not, can be expressed in the form $\mathbf{A} = \mathbf{LDU}$, where $\mathbf{L}$ is a unit lower-triangular matrix, $\mathbf{D}$ is a diagonal matrix, and $\mathbf{U}$ is a unit upper-triangular matrix. (The diagonal elements of a unit triangular matrix are 1.) Because of the arrangement of the matrices, the decomposition is called the LDU decomposition. Since you can absorb the diagonal matrix into the triangular matrices, the decomposition

$$\mathbf{A} = \mathbf{LD}^{1/2}\mathbf{D}^{1/2}\mathbf{U} = \mathbf{L}^*\mathbf{U}^*$$

is also referred to as the LU decomposition of $\mathbf{A}$.

If the matrix $\mathbf{A}$ is positive definite, then the diagonal elements of $\mathbf{D}$ are positive and the LDU decomposition is unique. Furthermore, we can add more specificity to this result in that for a symmetric, positive definite matrix, there is a unique decomposition $\mathbf{A} = \mathbf{U}'\mathbf{DU}$, where $\mathbf{U}$ is unit upper-triangular and $\mathbf{D}$ is diagonal with positive elements. Absorbing the square root of $\mathbf{D}$ into $\mathbf{U}$, $\mathbf{C} = \mathbf{D}^{1/2}\mathbf{U}$, the decomposition is known as the *Cholesky* decomposition of a positive-definite matrix:

$$\mathbf{B} = \mathbf{U}'\mathbf{D}^{1/2}\,\mathbf{D}^{1/2}\mathbf{U} = \mathbf{C}'\mathbf{C}$$

where $\mathbf{C}$ is upper triangular.

If $\mathbf{B}$ is $(n \times n)$ symmetric nonnegative definite of rank k, then we can extend the Cholesky decomposition as follows. Let $\mathbf{C}^*$ denote the lower-triangular matrix such that

$$\mathbf{C}^* = \begin{bmatrix} \mathbf{C}_{k\times k} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}$$

Then $\mathbf{B} = \mathbf{CC}'$.

Spectral Decomposition

Suppose that $\mathbf{A}$ is an $(n \times n)$ symmetric matrix. Then there exists an orthogonal matrix $\mathbf{Q}$ and a diagonal matrix $\mathbf{D}$ such that $\mathbf{A} = \mathbf{QDQ}'$. Of particular importance is the case where the orthogonal

matrix is also orthonormal—that is, its column vectors have unit norm. Denote this orthonormal matrix as $\mathbf{P}$. Then the corresponding diagonal matrix—$\mathbf{\Lambda} = \text{diag}(\lambda_i, \cdots, \lambda_n)$, say—contains the eigenvalues of $\mathbf{A}$. The spectral decomposition of $\mathbf{A}$ can be written as

$$\mathbf{A} = \mathbf{P}\mathbf{\Lambda}\mathbf{P}' = \sum_{i=1}^{n} \lambda_i \mathbf{p}_i \mathbf{p}_i'$$

where $\mathbf{p}_i$ denotes the ith column vector of $\mathbf{P}$. The right-side expression decomposes $\mathbf{A}$ into a sum of rank-1 matrices, and the weight of each contribution is equal to the eigenvalue associated with the ith eigenvector. The sum furthermore emphasizes that the rank of $\mathbf{A}$ is equal to the number of nonzero eigenvalues.

Harville (1997, p. 538) refers to the spectral decomposition of $\mathbf{A}$ as the decomposition that takes the previous sum one step further and accumulates contributions associated with the distinct eigenvalues. If $\lambda_i^*, \cdots, \lambda_k^*$ are the distinct eigenvalues and $\mathbf{E}_j = \sum \mathbf{p}_i \mathbf{p}_i'$, where the sum is taken over the set of columns for which $\lambda_i = \lambda_j^*$, then

$$\mathbf{A} = \sum_{i=1}^{k} \lambda_j^* \mathbf{E}_j$$

You can employ the spectral decomposition of a nonnegative definite symmetric matrix to form a "square-root" matrix of $\mathbf{A}$. Suppose that $\mathbf{\Lambda}^{1/2}$ is the diagonal matrix containing the square roots of the λ_i. Then $\mathbf{B} = \mathbf{P}\mathbf{\Lambda}^{1/2}\mathbf{P}'$ is a square-root matrix of $\mathbf{A}$ in the sense that $\mathbf{BB} = \mathbf{A}$, because

$$\mathbf{BB} = \mathbf{P}\mathbf{\Lambda}^{1/2}\mathbf{P}'\mathbf{P}\mathbf{\Lambda}^{1/2}\mathbf{P}' = \mathbf{P}\mathbf{\Lambda}^{1/2}\mathbf{\Lambda}^{1/2}\mathbf{P}' = \mathbf{P}\mathbf{\Lambda}\mathbf{P}'$$

Generating the Moore-Penrose inverse of a matrix based on the spectral decomposition is also simple. Denote as $\mathbf{\Delta}$ the diagonal matrix with typical element

$$\delta_i = \begin{cases} 1/\lambda_i & \lambda_i \neq 0 \\ 0 & \lambda_i = 0 \end{cases}$$

Then the matrix $\mathbf{P}\mathbf{\Delta}\mathbf{P}' = \sum \delta_i \mathbf{p}_i \mathbf{p}_i'$ is the Moore-Penrose (g_4-generalized) inverse of $\mathbf{A}$.

Singular-Value Decomposition

The singular-value decomposition is related to the spectral decomposition of a matrix, but it is more general. The singular-value decomposition can be applied to any matrix. Let $\mathbf{B}$ be an $(n \times p)$ matrix of rank k. Then there exist orthogonal matrices P and Q of order $(n \times n)$ and $(p \times p)$, respectively, and a diagonal matrix $\mathbf{D}$ such that

$$\mathbf{P}'\mathbf{B}\mathbf{Q} = \mathbf{D} = \begin{bmatrix} \mathbf{D}_1 & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}$$

where $\mathbf{D}_1$ is a diagonal matrix of order k. The diagonal elements of $\mathbf{D}_1$ are strictly positive. As with the spectral decomposition, this result can be written as a decomposition of $\mathbf{B}$ into a weighted sum of rank-1 matrices

$$\mathbf{B} = -\mathbf{P}\mathbf{D}\mathbf{Q}' = \sum_{i=1}^{n} d_i \mathbf{p}_i \mathbf{q}_i'$$

The scalars $d_1, \cdots, d_k$ are called the *singular values* of the matrix $\mathbf{B}$. They are the positive square roots of the nonzero eigenvalues of the matrix $\mathbf{B}'\mathbf{B}$. If the singular-value decomposition is applied to a symmetric, nonnegative definite matrix $\mathbf{A}$, then the singular values $d_1, \cdots, d_n$ are the nonzero eigenvalues of $\mathbf{A}$ and the singular-value decomposition is the same as the spectral decomposition.

As with the spectral decomposition, you can use the results of the singular-value decomposition to generate the Moore-Penrose inverse of a matrix. If $\mathbf{B}$ is $(n \times p)$ with singular-value decomposition $\mathbf{PDQ}'$, and if $\mathbf{\Delta}$ is a diagonal matrix with typical element

$$\delta_i = \begin{cases} 1/d_i & |d_i| \neq 0 \\ 0 & d_i = 0 \end{cases}$$

then $\mathbf{Q\Delta P}'$ is the g_4-generalized inverse of $\mathbf{B}$.

Expectations of Random Variables and Vectors

If Y is a discrete random variable with mass function $p(y)$ and support (possible values) $y_1, y_2, \cdots$, then the expectation (expected value) of Y is defined as

$$\mathrm{E}[Y] = \sum_{j=1}^{\infty} y_j \; p(y_j)$$

provided that $\sum |y_j| p(y_j) < \infty$, otherwise the sum in the definition is not well-defined. The expected value of a function $h(y)$ is similarly defined: provided that $\sum |h(y_j)| p(y_j) < \infty$,

$$\mathrm{E}[h(Y)] = \sum_{j=1}^{\infty} h(y_j) \; p(y_j)$$

For continuous random variables, similar definitions apply, but summation is replaced by integration over the support of the random variable. If X is a continuous random variable with density function $f(x)$, and $\int |x| f(x) dx < \infty$, then the expectation of X is defined as

$$\mathrm{E}[X] = \int_{-\infty}^{\infty} x f(x) \, dx$$

The expected value of a random variable is also called its *mean* or its first moment. A particularly important function of a random variable is $h(Y) = (Y - \mathrm{E}[Y])^2$. The expectation of $h(Y)$ is called the *variance* of Y or the second central moment of Y. When you study the properties of multiple random variables, then you might be interested in aspects of their joint distribution. The covariance between random variables Y and X is defined as the expected value of the function $(Y - \mathrm{E}[Y])(X - \mathrm{E}[X])$, where the expectation is taken under the bivariate joint distribution of Y and X:

$$\mathrm{Cov}[Y, X] = \mathrm{E}[(Y - \mathrm{E}[Y])(X - \mathrm{E}[X])] = \mathrm{E}[YX] - \mathrm{E}[Y]\mathrm{E}[X] = \int \int x \, y f(x, y) \; dxdy - \mathrm{E}[Y]\mathrm{E}[X]$$

The *covariance* between a random variable and itself is the variance, $\mathrm{Cov}[Y, Y] = \mathrm{Var}[Y]$.

In statistical applications and formulas, random variables are often collected into vectors. For example, a random sample of size n from the distribution of Y generates a random vector of order $(n \times 1)$,

$$\mathbf{Y} = \begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_n \end{bmatrix}$$

The expected value of the $(n \times 1)$ random vector $\mathbf{Y}$ is the vector of the means of the elements of $\mathbf{Y}$:

$$\mathbf{E}[\mathbf{Y}] = [\mathrm{E}[Y_i]] = \begin{bmatrix} \mathrm{E}[Y_1] \\ \mathrm{E}[Y_2] \\ \vdots \\ \mathrm{E}[Y_n] \end{bmatrix}$$

It is often useful to directly apply rules about working with means, variances, and covariances of random vectors. To develop these rules, suppose that $\mathbf{Y}$ and $\mathbf{U}$ denote two random vectors with typical elements $Y_1, \cdots, Y_n$ and $U_1, \cdots, U_k$. Further suppose that $\mathbf{A}$ and $\mathbf{B}$ are constant (nonstochastic) matrices, that $\mathbf{a}$ is a constant vector, and that the c_i are scalar constants.

The following rules enable you to derive the mean of a linear function of a random vector:

$$\begin{aligned} \mathrm{E}[\mathbf{A}] &= \mathbf{A} \\ \mathrm{E}[\mathbf{Y} + \mathbf{a}] &= \mathrm{E}[\mathbf{Y}] \\ \mathrm{E}[\mathbf{AY} + \mathbf{a}] &= \mathbf{A}\mathrm{E}[\mathbf{Y}] + \mathbf{a} \\ \mathrm{E}[\mathbf{Y} + \mathbf{U}] &= \mathrm{E}[\mathbf{Y}] + \mathrm{E}[\mathbf{U}] \end{aligned}$$

The *covariance matrix* of $\mathbf{Y}$ and $\mathbf{U}$ is the $(n \times k)$ matrix whose typical element in row i, column j is the covariance between Y_i and U_j. The covariance matrix between two random vectors is frequently denoted with the Cov "operator."

$$\begin{aligned} \mathrm{Cov}[\mathbf{Y}, \mathbf{U}] &= \left[\mathrm{Cov}[Y_i, U_j]\right] \\ &= \mathrm{E}\left[(\mathbf{Y} - \mathrm{E}[\mathbf{Y}])\,(\mathbf{U} - \mathrm{E}[\mathbf{U}])'\right] = \mathrm{E}\left[\mathbf{YU}'\right] - \mathrm{E}[\mathbf{Y}]\mathrm{E}[\mathbf{U}]' \\ &= \begin{bmatrix} \mathrm{Cov}[Y_1, U_1] & \mathrm{Cov}[Y_1, U_2] & \mathrm{Cov}[Y_1, U_3] & \cdots & \mathrm{Cov}[Y_1, U_k] \\ \mathrm{Cov}[Y_2, U_1] & \mathrm{Cov}[Y_2, U_2] & \mathrm{Cov}[Y_2, U_3] & \cdots & \mathrm{Cov}[Y_2, U_k] \\ \mathrm{Cov}[Y_3, U_1] & \mathrm{Cov}[Y_3, U_2] & \mathrm{Cov}[Y_3, U_3] & \cdots & \mathrm{Cov}[Y_3, U_k] \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathrm{Cov}[Y_n, U_1] & \mathrm{Cov}[Y_n, U_2] & \mathrm{Cov}[Y_n, U_3] & \cdots & \mathrm{Cov}[Y_n, U_k] \end{bmatrix} \end{aligned}$$

The *variance matrix* of a random vector $\mathbf{Y}$ is the covariance matrix between $\mathbf{Y}$ and itself. The variance matrix is frequently denoted with the Var "operator."

$$\begin{aligned}\mathrm{Var}[\mathbf{Y}] &= \mathrm{Cov}[\mathbf{Y},\mathbf{Y}] = \left[\mathrm{Cov}[Y_i, Y_j]\right] \\ &= \mathrm{E}\left[(\mathbf{Y}-\mathrm{E}[\mathbf{Y}])\,(\mathbf{Y}-\mathrm{E}[\mathbf{Y}])'\right] = \mathrm{E}\left[\mathbf{Y}\mathbf{Y}'\right] - \mathrm{E}[\mathbf{Y}]\mathrm{E}[\mathbf{Y}]'\end{aligned}$$

$$= \begin{bmatrix} \mathrm{Cov}[Y_1,Y_1] & \mathrm{Cov}[Y_1,Y_2] & \mathrm{Cov}[Y_1,Y_3] & \cdots & \mathrm{Cov}[Y_1,Y_n] \\ \mathrm{Cov}[Y_2,Y_1] & \mathrm{Cov}[Y_2,Y_2] & \mathrm{Cov}[Y_2,Y_3] & \cdots & \mathrm{Cov}[Y_2,Y_n] \\ \mathrm{Cov}[Y_3,Y_1] & \mathrm{Cov}[Y_3,Y_2] & \mathrm{Cov}[Y_3,Y_3] & \cdots & \mathrm{Cov}[Y_3,Y_n] \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathrm{Cov}[Y_n,Y_1] & \mathrm{Cov}[Y_n,Y_2] & \mathrm{Cov}[Y_n,Y_3] & \cdots & \mathrm{Cov}[Y_n,Y_n] \end{bmatrix}$$

$$= \begin{bmatrix} \mathrm{Var}[Y_1] & \mathrm{Cov}[Y_1,Y_2] & \mathrm{Cov}[Y_1,Y_3] & \cdots & \mathrm{Cov}[Y_1,Y_n] \\ \mathrm{Cov}[Y_2,Y_1] & \mathrm{Var}[Y_2] & \mathrm{Cov}[Y_2,Y_3] & \cdots & \mathrm{Cov}[Y_2,Y_n] \\ \mathrm{Cov}[Y_3,Y_1] & \mathrm{Cov}[Y_3,Y_2] & \mathrm{Var}[Y_3] & \cdots & \mathrm{Cov}[Y_3,Y_n] \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathrm{Cov}[Y_n,Y_1] & \mathrm{Cov}[Y_n,Y_2] & \mathrm{Cov}[Y_n,Y_3] & \cdots & \mathrm{Var}[Y_n] \end{bmatrix}$$

Because the variance matrix contains variances on the diagonal and covariances in the off-diagonal positions, it is also referred to as the *variance-covariance matrix* of the random vector $\mathbf{Y}$.

If the elements of the covariance matrix $\mathrm{Cov}[\mathbf{Y},\mathbf{U}]$ are zero, the random vectors are uncorrelated. If $\mathbf{Y}$ and $\mathbf{U}$ are normally distributed, then a zero covariance matrix implies that the vectors are stochastically independent. If the off-diagonal elements of the variance matrix $\mathrm{Var}[\mathbf{Y}]$ are zero, the elements of the random vector $\mathbf{Y}$ are uncorrelated. If $\mathbf{Y}$ is normally distributed, then a diagonal variance matrix implies that its elements are stochastically independent.

Suppose that $\mathbf{A}$ and $\mathbf{B}$ are constant (nonstochastic) matrices and that c_i denotes a scalar constant. The following results are useful in manipulating covariance matrices:

$$\begin{aligned}\mathrm{Cov}[\mathbf{A}\mathbf{Y},\mathbf{U}] &= \mathbf{A}\mathrm{Cov}[\mathbf{Y},\mathbf{U}] \\ \mathrm{Cov}[\mathbf{Y},\mathbf{B}\mathbf{U}] &= \mathrm{Cov}[\mathbf{Y},\mathbf{U}]\mathbf{B}' \\ \mathrm{Cov}[\mathbf{A}\mathbf{Y},\mathbf{B}\mathbf{U}] &= \mathbf{A}\mathrm{Cov}[\mathbf{Y},\mathbf{U}]\mathbf{B}' \\ \mathrm{Cov}[c_1\mathbf{Y}_1 + c_2\mathbf{U}_1, c_3\mathbf{Y}_2 + c_4\mathbf{U}_2] &= c_1c_3\mathrm{Cov}[\mathbf{Y}_1,\mathbf{Y}_2] + c_1c_4\mathrm{Cov}[\mathbf{Y}_1,\mathbf{U}_2] \\ &\quad + c_2c_3\mathrm{Cov}[\mathbf{U}_1,\mathbf{Y}_2] + c_2c_4\mathrm{Cov}[\mathbf{U}_1,\mathbf{U}_2]\end{aligned}$$

Since $\mathrm{Cov}[\mathbf{Y},\mathbf{Y}] = \mathrm{Var}[\mathbf{Y}]$, these results can be applied to produce the following results, useful in manipulating variances of random vectors:

$$\begin{aligned}\mathrm{Var}[\mathbf{A}] &= \mathbf{0} \\ \mathrm{Var}[\mathbf{A}\mathbf{Y}] &= \mathbf{A}\mathrm{Var}[\mathbf{Y}]\mathbf{A}' \\ \mathrm{Var}[\mathbf{Y}+\mathbf{x}] &= \mathrm{Var}[\mathbf{Y}] \\ \mathrm{Var}[\mathbf{x}'\mathbf{Y}] &= \mathbf{x}'\mathrm{Var}[\mathbf{Y}]\mathbf{x} \\ \mathrm{Var}[c_1\mathbf{Y}] &= c_1^2\mathrm{Var}[\mathbf{Y}] \\ \mathrm{Var}[c_1\mathbf{Y} + c_2\mathbf{U}] &= c_1^2\mathrm{Var}[\mathbf{Y}] + c_2^2\mathrm{Var}[\mathbf{U}] + 2c_1c_2\mathrm{Cov}[\mathbf{Y},\mathbf{U}]\end{aligned}$$

Another area where expectation rules are helpful is quadratic forms in random variables. These forms arise particularly in the study of linear statistical models and in linear statistical inference. Linear inference is statistical inference about linear function of random variables, even if those random variables are defined through nonlinear models. For example, the parameter estimator $\widehat{\boldsymbol{\theta}}$ might be derived in a nonlinear model, but this does not prevent statistical questions from being raised that can be expressed through linear functions of $\boldsymbol{\theta}$; for example,

$$H_0: \begin{cases} \theta_1 - 2\theta_2 = 0 \\ \theta_2 - \theta_3 = 0 \end{cases}$$

if $\mathbf{A}$ is a matrix of constants and $\mathbf{Y}$ is a random vector, then

$$\mathrm{E}[\mathbf{Y}'\mathbf{A}\mathbf{Y}] = \mathrm{trace}(\mathbf{A}\mathrm{Var}[\mathbf{Y}]) + \mathrm{E}[\mathbf{Y}]'\mathbf{A}\mathrm{E}[\mathbf{Y}]$$

Mean Squared Error

The mean squared error is arguably the most important criterion used to evaluate the performance of a predictor or an estimator. (The subtle distinction between predictors and estimators is that random variables are predicted and constants are estimated.) The mean squared error is also useful to relay the concepts of bias, precision, and accuracy in statistical estimation. In order to examine a mean squared error, you need a target of estimation or prediction, and a predictor or estimator that is a function of the data. Suppose that the target, whether a constant or a random variable, is denoted as U. The mean squared error of the estimator or predictor $T(\mathbf{Y})$ for U is

$$\mathrm{MSE}\left[T(\mathbf{Y}); U\right] = \mathrm{E}\left[(T(\mathbf{Y}) - U)^2\right]$$

The reason for using a squared difference to measure the "loss" between $T(\mathbf{Y})$ and U is mostly convenience; properties of squared differences involving random variables are more easily examined than, say, absolute differences. The reason for taking an expectation is to remove the randomness of the squared difference by averaging over the distribution of the data.

Consider first the case where the target U is a constant—say, the parameter β—and denote the mean of the estimator $T(\mathbf{Y})$ as μ_T. The mean squared error can then be decomposed as

$$\begin{aligned} \mathrm{MSE}[T(\mathbf{Y}; \beta] &= \mathrm{E}\left[(T(\mathbf{Y}) - \beta)^2\right] \\ &= \mathrm{E}\left[(T(\mathbf{Y}) - \mu_T)^2\right] - \mathrm{E}\left[(\beta - \mu_T)^2\right] \\ &= \mathrm{Var}[T(\mathbf{Y})] + (\beta - \mu_T)^2 \end{aligned}$$

The mean squared error thus comprises the variance of the estimator and the squared bias. The two components can be associated with an estimator's precision (small variance) and its accuracy (small bias).

If $T(\mathbf{Y})$ is an unbiased estimator of β—that is, if $\mathrm{E}[T(\mathbf{Y})] = \beta$—then the mean squared error is simply the variance of the estimator. By choosing an estimator that has minimum variance, you also choose an estimator that has minimum mean squared error among all unbiased estimators. However, as you can see from the previous expression, bias is also an "average" property; it is defined as an

expectation. It is quite possible to find estimators in some statistical modeling problems that have smaller mean squared error than a minimum variance unbiased estimator; these are estimators that permit a certain amount of bias but improve on the variance. For example, in models where regressors are highly collinear, the ordinary least squares estimator continues to be unbiased. However, the presence of collinearity can induce poor precision and lead to an erratic estimator. Ridge regression stabilizes the regression estimates in this situation, and the coefficient estimates are somewhat biased, but the bias is more than offset by the gains in precision.

When the target U is a random variable, you need to carefully define what an unbiased prediction means. If the statistic and the target have the same expectation, $\mathrm{E}[U] = \mathrm{E}[T(\mathbf{Y})]$, then

$$\mathrm{MSE}\left[T(\mathbf{Y}); U\right] = \mathrm{Var}[T(\mathbf{Y})] + \mathrm{Var}[U] - 2\mathrm{Cov}[T(\mathbf{Y}), U]$$

In many instances the target U is a new observation that was not part of the analysis. If the data are uncorrelated, then it is reasonable to assume in that instance that the new observation is also not correlated with the data. The mean squared error then reduces to the sum of the two variances. For example, in a linear regression model where U is a new observation Y_0 and $T(\mathbf{Y})$ is the regression estimator

$$\widehat{Y}_0 = \mathbf{x}_0' \left(\mathbf{X}'\mathbf{X}\right)^{-1} \mathbf{X}'\mathbf{Y}$$

with variance $\mathrm{Var}[Y_0] = \sigma^2 \mathbf{x}_0' \left(\mathbf{X}'\mathbf{X}\right)^{-1} \mathbf{x}_0$, the mean squared prediction error for Y_0 is

$$\mathrm{MSE}\left[\widehat{Y}; Y_0\right] = \sigma^2 \left(\mathbf{x}_0' \left(\mathbf{X}'\mathbf{X}\right)^{-1} \mathbf{x}_0 + 1\right)$$

and the mean squared prediction error for predicting the mean $\mathrm{E}[Y_0]$ is

$$\mathrm{MSE}\left[\widehat{Y}; \mathrm{E}[Y_0]\right] = \sigma^2 \mathbf{x}_0' \left(\mathbf{X}'\mathbf{X}\right)^{-1} \mathbf{x}_0$$

Linear Model Theory

This section presents some basic statistical concepts and results for the linear model with homoscedastic, uncorrelated errors in which the parameters are estimated by ordinary least squares. The model can be written as

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon} \qquad \boldsymbol{\epsilon} \sim (0, \sigma^2 \mathbf{I})$$

where $\mathbf{Y}$ is an $(n \times 1)$ vector and $\mathbf{X}$ is an $(n \times k)$ matrix of known constants. The model equation implies the following expected values:

$$\mathrm{E}[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$$

$$\mathrm{Var}[\mathbf{Y}] = \sigma^2 \mathbf{I} \Leftrightarrow \mathrm{Cov}[Y_i, Y_j] = \begin{cases} \sigma^2 & i = j \\ 0 & \text{otherwise} \end{cases}$$

Finding the Least Squares Estimators

Finding the least squares estimator of $\boldsymbol{\beta}$ can be motivated as a calculus problem or by considering the geometry of least squares. The former approach simply states that the OLS estimator is the vector $\widehat{\boldsymbol{\beta}}$ that minimizes the objective function

$$\text{SSE} = (\mathbf{Y} - \mathbf{X}\boldsymbol{\beta})' (\mathbf{Y} - \mathbf{X}\boldsymbol{\beta})$$

Applying the differentiation rules from the section "Matrix Differentiation" on page 53 leads to

$$\begin{aligned}\frac{\partial}{\partial \boldsymbol{\beta}}\text{SSE} &= \frac{\partial}{\partial \boldsymbol{\beta}}(\mathbf{Y}'\mathbf{Y} - 2\mathbf{Y}'\mathbf{X}\boldsymbol{\beta} + \boldsymbol{\beta}'\mathbf{X}'\mathbf{X}\boldsymbol{\beta}) \\ &= \mathbf{0} - 2\mathbf{X}'\mathbf{Y} + 2\mathbf{X}'\mathbf{X}\boldsymbol{\beta} \\ \frac{\partial^2}{\partial \boldsymbol{\beta}\partial \boldsymbol{\beta}}\text{SSE} &= \mathbf{X}'\mathbf{X}\end{aligned}$$

Consequently, the solution to the *normal equations*, $\mathbf{X}'\mathbf{X}\boldsymbol{\beta} = \mathbf{X}'\mathbf{Y}$, solves $\frac{\partial}{\partial \boldsymbol{\beta}}\text{SSE} = 0$, and the fact that the second derivative is nonnegative definite guarantees that this solution minimizes SSE. The geometric argument to motivate ordinary least squares estimation is as follows. Assume that $\mathbf{X}$ is of rank k. For any value of $\boldsymbol{\beta}$, such as $\tilde{\boldsymbol{\beta}}$, the following identity holds:

$$\mathbf{Y} = \mathbf{X}\tilde{\boldsymbol{\beta}} + \left(\mathbf{Y} - \mathbf{X}\tilde{\boldsymbol{\beta}}\right)$$

The vector $\mathbf{X}\tilde{\boldsymbol{\beta}}$ is a point in a k-dimensional subspace of R^n, and the residual $(\mathbf{Y} - \mathbf{X}\tilde{\boldsymbol{\beta}})$ is a point in an $(n-k)$-dimensional subspace. The OLS estimator is the value $\widehat{\boldsymbol{\beta}}$ that minimizes the distance of $\mathbf{X}\tilde{\boldsymbol{\beta}}$ from $\mathbf{Y}$, implying that $\mathbf{X}\widehat{\boldsymbol{\beta}}$ and $(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}})$ are orthogonal to each other; that is,

$(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}})'\mathbf{X}\widehat{\boldsymbol{\beta}} = \mathbf{0}$. This in turn implies that $\widehat{\boldsymbol{\beta}}$ satisfies the normal equations, since

$$\widehat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y} = \widehat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{X}\widehat{\boldsymbol{\beta}} \Leftrightarrow \mathbf{X}'\mathbf{X}\widehat{\boldsymbol{\beta}} = \mathbf{X}'\mathbf{Y}$$

Full-Rank Case

If $\mathbf{X}$ is of full column rank, the OLS estimator is unique and given by

$$\widehat{\boldsymbol{\beta}} = \left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{Y}$$

The OLS estimator is an unbiased estimator of $\boldsymbol{\beta}$—that is,

$$\begin{aligned}\text{E}[\widehat{\boldsymbol{\beta}}] &= \text{E}\left[\left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{Y}\right] \\ &= \left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{X}'\text{E}[\mathbf{Y}] = \left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{X}\boldsymbol{\beta} = \boldsymbol{\beta}\end{aligned}$$

Note that this result holds if $\text{E}[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$; in other words, the condition that the model errors have mean zero is sufficient for the OLS estimator to be unbiased. If the errors are homoscedastic and uncorrelated, the OLS estimator is indeed the *best* linear unbiased estimator (BLUE) of $\boldsymbol{\beta}$—that is, no other estimator that is a linear function of $\mathbf{Y}$ has a smaller mean squared error. The fact that the estimator is unbiased implies that no other linear estimator has a smaller variance. If, furthermore, the model errors are normally distributed, then the OLS estimator has minimum variance among all unbiased estimators of $\boldsymbol{\beta}$, whether they are linear or not. Such an estimator is called a *uniformly minimum variance unbiased estimator*, or UMVUE.

Rank-Deficient Case

In the case of a rank-deficient $\mathbf{X}$ matrix, a generalized inverse is used to solve the normal equations:

$$\widehat{\boldsymbol{\beta}} = \left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{Y}$$

Although a g_1-inverse is sufficient to solve a linear system, computational expedience and interpretation of the results often dictate the use of a generalized inverse with reflexive properties (that is, a g_2-inverse; see the section "Generalized Inverse Matrices" on page 52 for details). Suppose, for example, that the $\mathbf{X}$ matrix is partitioned as $\mathbf{X} = [\mathbf{X}_1 \ \mathbf{X}_2]$, where $\mathbf{X}_1$ is of full column rank and each column in $\mathbf{X}_2$ is a linear combination of the columns of $\mathbf{X}_1$. The matrix

$$\mathbf{G}_1 = \begin{bmatrix} \left(\mathbf{X}_1'\mathbf{X}_1\right)^{-1} & \left(\mathbf{X}_1'\mathbf{X}_1\right)^{-1}\mathbf{X}_1'\mathbf{X}_2 \\ -\mathbf{X}_2'\mathbf{X}_1\left(\mathbf{X}_1'\mathbf{X}_1\right)^{-1} & \mathbf{0} \end{bmatrix}$$

is a g_1-inverse of $\mathbf{X}'\mathbf{X}$ and

$$\mathbf{G}_2 = \begin{bmatrix} \left(\mathbf{X}_1'\mathbf{X}_1\right)^{-1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}$$

is a g_2-inverse. If the least squares solution is computed with the g_1-inverse, then computing the variance of the estimator requires additional matrix operations and storage. On the other hand, the variance of the solution that uses a g_2-inverse is proportional to G_2.

$$\begin{aligned} \text{Var}\left[\mathbf{G}_1\mathbf{X}'\mathbf{Y}\right] &= \sigma^2\mathbf{G}_1\mathbf{X}'\mathbf{X}\mathbf{G}_1 \\ \text{Var}\left[\mathbf{G}_2\mathbf{X}'\mathbf{Y}\right] &= \sigma^2\mathbf{G}_2\mathbf{X}'\mathbf{X}\mathbf{G}_2 = \sigma^2\mathbf{G}_2 \end{aligned}$$

If a generalized inverse $\mathbf{G}$ of $\mathbf{X}'\mathbf{X}$ is used to solve the normal equations, then the resulting solution is a biased estimator of $\boldsymbol{\beta}$ (unless $\mathbf{X}'\mathbf{X}$ is of full rank, in which case the generalized inverse is "the" inverse), since $\text{E}\left[\widehat{\boldsymbol{\beta}}\right] = \mathbf{G}\mathbf{X}'\mathbf{X}\boldsymbol{\beta}$, which is not in general equal to $\boldsymbol{\beta}$.

If you think of estimation as "estimation without bias," then $\widehat{\boldsymbol{\beta}}$ is the estimator of something, namely $\mathbf{G}\mathbf{X}\boldsymbol{\beta}$. Since this is not a quantity of interest and since it is not unique—it depends on your choice of $\mathbf{G}$—Searle (1971, p. 169) cautions that in the less-than-full-rank case, $\widehat{\boldsymbol{\beta}}$ is a solution to the normal equations and "nothing more."

Analysis of Variance

The identity

$$\mathbf{Y} = \mathbf{X}\tilde{\boldsymbol{\beta}} + \left(\mathbf{Y} - \mathbf{X}\tilde{\boldsymbol{\beta}}\right)$$

holds for all vectors $\tilde{\boldsymbol{\beta}}$, but only for the least squares solution is the residual $(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}})$ orthogonal to the predicted value $\mathbf{X}\widehat{\boldsymbol{\beta}}$. Because of this orthogonality, the additive identity holds not only for the vectors themselves, but also for their lengths (Pythagorean theorem):

$$||\mathbf{Y}||^2 = ||\mathbf{X}\widehat{\boldsymbol{\beta}}||^2 + ||(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}})||^2$$

Note that $\mathbf{X}\widehat{\boldsymbol{\beta}} = \mathbf{X}\left(\mathbf{X}'\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{Y} = \mathbf{H}\mathbf{Y}$ and note that $\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}} = (\mathbf{I} - \mathbf{H})\mathbf{Y} = \mathbf{M}\mathbf{Y}$. The matrices $\mathbf{H}$ and $\mathbf{M} = \mathbf{I} - \mathbf{H}$ play an important role in the theory of linear models and in statistical computations. Both are *projection* matrices—that is, they are symmetric and idempotent. (An idempotent matrix $\mathbf{A}$ is a square matrix that satisfies $\mathbf{A}\mathbf{A} = \mathbf{A}$. The eigenvalues of an idempotent matrix take on the values 1 and 0 only.) The matrix $\mathbf{H}$ projects onto the subspace of R^n that is spanned by the columns of $\mathbf{X}$. The matrix $\mathbf{M}$ projects onto the orthogonal complement of that space. Because of these properties you have $\mathbf{H}' = \mathbf{H}$, $\mathbf{H}\mathbf{H} = \mathbf{H}$, $\mathbf{M}' = \mathbf{M}$, $\mathbf{M}\mathbf{M} = \mathbf{M}$, $\mathbf{H}\mathbf{M} = \mathbf{0}$.

The Pythagorean relationship now can be written in terms of $\mathbf{H}$ and $\mathbf{M}$ as follows:

$$||\mathbf{Y}||^2 = \mathbf{Y}'\mathbf{Y} = ||\mathbf{H}\mathbf{Y}||^2 + ||\mathbf{M}\mathbf{Y}||^2 = \mathbf{Y}'\mathbf{H}'\mathbf{H}\mathbf{Y} + \mathbf{Y}'\mathbf{M}'\mathbf{M}\mathbf{Y} = \mathbf{Y}'\mathbf{H}\mathbf{Y} + \mathbf{Y}'\mathbf{M}\mathbf{Y}$$

If $\mathbf{X}'\mathbf{X}$ is deficient in rank and a generalized inverse is used to solve the normal equations, then you work instead with the projection matrices $\mathbf{H} = \mathbf{X}\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'$. Note that if $\mathbf{G}$ is a generalized inverse of $\mathbf{X}'\mathbf{X}$, then $\mathbf{X}\mathbf{G}\mathbf{X}'$, and hence also $\mathbf{H}$ and $\mathbf{M}$, are invariant to the choice of $\mathbf{G}$.

The matrix $\mathbf{H}$ is sometimes referred to as the "hat" matrix because when you premultiply the vector of observations with $\mathbf{H}$, you produce the fitted values, which are commonly denoted by placing a "hat" over the $\mathbf{Y}$ vector, $\widehat{\mathbf{Y}} = \mathbf{H}\mathbf{Y}$.

The term $\mathbf{Y}'\mathbf{Y}$ is the uncorrected total sum of squares (SST) of the linear model, $\mathbf{Y}'\mathbf{M}\mathbf{Y}$ is the error (residual) sum of squares (SSR), and $\mathbf{Y}'\mathbf{H}\mathbf{Y}$ is the uncorrected model sum of squares. This leads to the analysis of variance table shown in Table 3.2.

Table 3.2 Analysis of Variance with Uncorrected Sums of Squares

Source	df	Sum of Squares
Model	rank($\mathbf{X}$)	$\text{SSM} = \mathbf{Y}'\mathbf{H}\mathbf{Y} = \widehat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y}$
Residual	$n - \text{rank}(\mathbf{X})$	$\text{SSR} = \mathbf{Y}'\mathbf{M}\mathbf{Y} = \mathbf{Y}'\mathbf{Y} - \widehat{\boldsymbol{\beta}}\mathbf{X}'\mathbf{Y} = \sum_{i=1}^{n}\left(Y_i - \widehat{Y}_i\right)^2$
Uncorr. Total	n	$\text{SST} = \mathbf{Y}'\mathbf{Y} = \sum_{i=1}^{n} Y_i^2$

When the model contains an intercept term, then the analysis of variance is usually corrected for the mean, as shown in Table 3.3.

Table 3.3 Analysis of Variance with Corrected Sums of Squares

Source	df	Sum of Squares
Model	rank($\mathbf{X}$) $- 1$	$\text{SSM}_c = \widehat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y} - n\overline{Y}^2 = \sum_{i=1}^{n}\left(\widehat{Y}_i - \overline{Y}_i\right)^2$
Residual	$n - \text{rank}(\mathbf{X})$	$\text{SSR} = \mathbf{Y}'\mathbf{M}\mathbf{Y} = \mathbf{Y}'\mathbf{Y} - \widehat{\boldsymbol{\beta}}\mathbf{X}'\mathbf{Y} = \sum_{i=1}^{n}\left(Y_i - \widehat{Y}_i\right)^2$
Corrected Total	$n - 1$	$\text{SST}_c = \mathbf{Y}'\mathbf{Y} - n\overline{Y}^2 = \sum_{i=1}^{n}\left(Y_i - \overline{Y}\right)^2$

The *coefficient of determination*, also called the R-square statistic, measures the proportion of the total variation explained by the linear model. In models with intercept, it is defined as the ratio

$$R^2 = 1 - \frac{\text{SSR}}{\text{SST}_c} = 1 - \frac{\sum_{i=1}^{n}\left(Y_i - \widehat{Y}_i\right)^2}{\sum_{i=1}^{n}\left(Y_i - \overline{Y}\right)^2}$$

In models without intercept, the R-square statistic is a ratio of the uncorrected sums of squares

$$R^2 = 1 - \frac{\text{SSR}}{\text{SST}} = 1 - \frac{\sum_{i=1}^{n}\left(Y_i - \widehat{Y}_i\right)^2}{\sum_{i=1}^{n} Y_i^2}$$

Estimating the Error Variance

The least squares principle does not provide for a parameter estimator for σ^2. The usual approach is to use a method-of-moments estimator that is based on the sum of squared residuals. If the model is correct, then the mean square for error, defined to be SSR divided by its degrees of freedom,

$$\begin{aligned}\widehat{\sigma}^2 &= \frac{1}{n - \text{rank}(\mathbf{X})}\left(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}}\right)'\left(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}}\right)\\ &= \text{SSR}/(n - \text{rank}(\mathbf{X}))\end{aligned}$$

is an unbiased estimator of σ^2.

Maximum Likelihood Estimation

To estimate the parameters in a linear model with mean function $\text{E}[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$ by maximum likelihood, you need to specify the distribution of the response vector $\mathbf{Y}$. In the linear model with a continuous response variable, it is commonly assumed that the response is normally distributed. In that case, the estimation problem is completely defined by specifying the mean and variance of $\mathbf{Y}$ in addition to the normality assumption. The model can be written as $\mathbf{Y} \sim N(\mathbf{X}\boldsymbol{\beta}, \sigma^2\mathbf{I})$, where the notation $N(\mathbf{a}, \mathbf{V})$ indicates a multivariate normal distribution with mean vector $\mathbf{a}$ and variance matrix $\mathbf{V}$. The log likelihood for $\mathbf{Y}$ then can be written as

$$l(\boldsymbol{\beta}, \sigma^2; \mathbf{y}) = -\frac{n}{2}\log\{2\pi\} - \frac{n}{2}\log\{\sigma^2\} - \frac{1}{2\sigma^2}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})'(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})$$

This function is maximized in $\boldsymbol{\beta}$ when the sum of squares $(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})'(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})$ is minimized. The maximum likelihood estimator of $\boldsymbol{\beta}$ is thus identical to the ordinary least squares estimator. To maximize $l(\boldsymbol{\beta}, \sigma^2; \mathbf{y})$ with respect to σ^2, note that

$$\frac{\partial l(\boldsymbol{\beta}, \sigma^2; \mathbf{y})}{\partial \sigma^2} = -\frac{n}{2\sigma^2} + \frac{1}{2\sigma^4}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})'(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})$$

Hence the MLE of σ^2 is the estimator

$$\begin{aligned}\widehat{\sigma}^2_M &= \frac{1}{n}\left(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}}\right)'\left(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}}\right)\\ &= \text{SSR}/n\end{aligned}$$

This is a biased estimator of σ^2, with a bias that decreases with n.

Estimable Functions

A function $\mathbf{L}\boldsymbol{\beta}$ is said to be estimable if there exists a linear combination of the expected value of $\mathbf{Y}$, such as $\mathbf{K}\mathrm{E}[\mathbf{Y}]$, that equals $\mathbf{L}\boldsymbol{\beta}$. Since $\mathrm{E}[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$, the definition of estimability implies that $\mathbf{L}\boldsymbol{\beta}$ is estimable if there is a matrix $\mathbf{K}$ such that $\mathbf{L} = \mathbf{K}\mathbf{X}$. Another way of looking at this result is that the rows of $\mathbf{X}$ form a generating set from which all estimable functions can be constructed.

The concept of estimability of functions is important in the theory and application of linear models because hypotheses of interest are often expressed as linear combinations of the parameter estimates (for example, hypotheses of equality between parameters, $\beta_1 = \beta_2 \Leftrightarrow \beta_1 - \beta_2 = 0$). Since estimability is not related to the particular value of the parameter estimate, but to the row space of $\mathbf{X}$, you can test only hypotheses that consist of estimable functions. Further, because estimability is not related to the value of $\boldsymbol{\beta}$ (Searle 1971, p. 181), the choice of the generalized inverse in a situation with rank-deficient $\mathbf{X}'\mathbf{X}$ matrix is immaterial, since

$$\mathbf{L}\widehat{\boldsymbol{\beta}} = \mathbf{K}\mathbf{X}\widehat{\boldsymbol{\beta}} = \mathbf{K}\mathbf{X}\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{Y}$$

where $\mathbf{X}\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}$ is invariant to the choice of generalized inverse.

$\mathbf{L}\boldsymbol{\beta}$ is estimable if and only if $\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}(\mathbf{X}'\mathbf{X}) = \mathbf{L}$ (see, for example, Searle 1971, p. 185). If $\mathbf{X}$ is of full rank, then the *Hermite* matrix $(\mathbf{X}'\mathbf{X})^{-}(\mathbf{X}'\mathbf{X})$ is the identity, which implies that all linear functions are estimable in the full-rank case.

See Chapter 15, "The Four Types of Estimable Functions," for many details about the various forms of estimable functions in SAS/STAT.

Test of Hypotheses

Consider a general linear hypothesis of the form $H\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{d}$, where $\mathbf{L}$ is a $(k \times p)$ matrix. It is assumed that $\mathbf{d}$ is such that this hypothesis is linearly consistent—that is, that there exists *some* $\boldsymbol{\beta}$ for which $\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$. This is always the case if $\mathbf{d}$ is in the column space of $\mathbf{L}$, if $\mathbf{L}$ has full row rank, or if $\mathbf{d} = \mathbf{0}$; the latter is the most common case. Since many linear models have a rank-deficient $\mathbf{X}$ matrix, the question arises whether the hypothesis is testable. The idea of testability of a hypothesis is—not surprisingly—connected to the concept of estimability as introduced previously. The hypothesis $H\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ is testable if it consists of estimable functions.

There are two important approaches to testing hypotheses in statistical applications—the reduction principle and the linear inference approach. The reduction principle states that the validity of the hypothesis can be inferred by comparing a suitably chosen summary statistic between the model at hand and a reduced model in which the constraint $\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ is imposed. The linear inference approach relies on the fact that $\widehat{\boldsymbol{\beta}}$ is an estimator of $\boldsymbol{\beta}$ and its stochastic properties are known, at least approximately. A test statistic can then be formed using $\widehat{\boldsymbol{\beta}}$, and its behavior under the restriction $\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ can be ascertained.

The two principles lead to identical results in certain—for example, least squares estimation in the classical linear model. In more complex situations the two approaches lead to similar but not identical results. This is the case, for example, when weights or unequal variances are involved, or when $\widehat{\boldsymbol{\beta}}$ is a nonlinear estimator.

Reduction Tests

The two main reduction principles are the sum of squares reduction test and the likelihood ratio test. The test statistic in the former is proportional to the difference of the residual sum of squares between the reduced model and the full model. The test statistic in the likelihood ratio test is proportional to the difference of the log likelihoods between the full and reduced models. To fix these ideas, suppose that you are fitting the model $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$, where $\boldsymbol{\epsilon} \sim N(\mathbf{0}, \sigma^2\mathbf{I})$. Suppose that SSR denotes the residual sum of squares in this model and that SSR_H is the residual sum of squares in the model for which $\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ holds. Then under the hypothesis the ratio

$$(\text{SSR}_H - \text{SSR})/\sigma^2$$

follows a chi-square distribution with degrees of freedom equal to the rank of $\mathbf{L}$. Maybe surprisingly, the residual sum of squares in the full model is distributed independently of this quantity, so that under the hypothesis,

$$F = \frac{(\text{SSR}_H - \text{SSR})/\text{rank}(\mathbf{L})}{\text{SSR}/(n - \text{rank}(\mathbf{X}))}$$

follows an F distribution with $\text{rank}(\mathbf{L})$ numerator and $n - \text{rank}(\mathbf{X})$ denominator degrees of freedom. Note that the quantity in the denominator of the F statistic is a particular estimator of σ^2—namely, the unbiased moment-based estimator that is customarily associated with least squares estimation. It is also the restricted maximum likelihood estimator of σ^2 if $\mathbf{Y}$ is normally distributed.

In the case of the likelihood ratio test, suppose that $l(\widehat{\boldsymbol{\beta}}, \widehat{\sigma}^2; \mathbf{y})$ denotes the log likelihood evaluated at the ML estimators. Also suppose that $l(\widehat{\boldsymbol{\beta}}_H, \widehat{\sigma}^2_H; \mathbf{y})$ denotes the log likelihood in the model for which $\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ holds. Then under the hypothesis the statistic

$$\lambda = 2\left(l(\widehat{\boldsymbol{\beta}}, \widehat{\sigma}^2; \mathbf{y}) - l(\widehat{\boldsymbol{\beta}}_H, \widehat{\sigma}^2_H; \mathbf{y})\right)$$

follows approximately a chi-square distribution with degrees of freedom equal to the rank of $\mathbf{L}$. In the case of a normally distributed response, the log-likelihood function can be profiled with respect to $\boldsymbol{\beta}$. The resulting profile log likelihood is

$$l(\widehat{\sigma}^2; \mathbf{y}) = -\frac{n}{2}\log\{2\pi\} - \frac{n}{2}\left(\log\{\widehat{\sigma}^2\}\right)$$

and the likelihood ratio test statistic becomes

$$\lambda = n\left(\log\left\{\widehat{\sigma}^2_H\right\} - \log\left\{\widehat{\sigma}^2\right\}\right) = n\left(\log\{\text{SSR}_H\} - \log\{\text{SSR}\}\right) = n\left(\log\{\text{SSR}_H/\text{SSR}\}\right)$$

The preceding expressions show that, in the case of normally distributed data, both reduction principles lead to simple functions of the residual sums of squares in two models. As Pawitan (2001, p. 151) puts it, there is, however, an important difference not in the computations but in the statistical content. The least squares principle, where sum of squares reduction tests are widely used, does not require a distributional specification. Assumptions about the distribution of the data are added to provide a framework for confirmatory inferences, such as the testing of hypotheses. This framework stems directly from the assumption about the data's distribution, or from the sampling distribution of the least squares estimators. The likelihood principle, on the other hand, requires a distributional specification at the outset. Inference about the parameters is implicit in the model; it is the result of further *computations* following the estimation of the parameters. In the least squares framework, inference about the parameters is the result of further *assumptions*.

Linear Inference

The principle of linear inference is to formulate a test statistic for $H\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ that builds on the linearity of the hypothesis about $\boldsymbol{\beta}$. For many models that have linear components, the estimator $\mathbf{L}\widehat{\boldsymbol{\beta}}$ is also linear in $\mathbf{Y}$. It is then simple to establish the distributional properties of $\mathbf{L}\widehat{\boldsymbol{\beta}}$ based on the distributional assumptions about $\mathbf{Y}$ or based on large-sample arguments. For example, $\widehat{\boldsymbol{\beta}}$ might be a nonlinear estimator, but it is known to asymptotically follow a normal distribution; this is the case in many nonlinear and generalized linear models.

If the sampling distribution or the asymptotic distribution of $\widehat{\boldsymbol{\beta}}$ is normal, then one can easily derive quadratic forms with known distributional properties. For example, if the random vector $\mathbf{U}$ is distributed as $N(\boldsymbol{\mu}, \boldsymbol{\Sigma})$, then $\mathbf{U}'\mathbf{A}\mathbf{U}$ follows a chi-square distribution with rank($\mathbf{A}$) degrees of freedom and noncentrality parameter $1/2\boldsymbol{\mu}'\mathbf{A}\boldsymbol{\mu}$, provided that $\mathbf{A}\boldsymbol{\Sigma}\mathbf{A}\boldsymbol{\Sigma} = \mathbf{A}\boldsymbol{\Sigma}$.

In the classical linear model, suppose that $\mathbf{X}$ is deficient in rank and that $\widehat{\boldsymbol{\beta}} = \left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{Y}$ is a solution to the normal equations. Then, if the errors are normally distributed,

$$\widehat{\boldsymbol{\beta}} \sim N\left(\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{X}\boldsymbol{\beta}, \sigma^2\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{X}\left(\mathbf{X}'\mathbf{X}\right)^{-}\right)$$

Because $H\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ is testable, $\mathbf{L}\boldsymbol{\beta}$ is estimable, and thus $\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{X} = \mathbf{L}$, as established in the previous section. Hence,

$$\mathbf{L}\widehat{\boldsymbol{\beta}} \sim N\left(\mathbf{L}\boldsymbol{\beta}, \sigma^2\mathbf{L}\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{L}'\right)$$

The conditions for a chi-square distribution of the quadratic form

$$(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d})'\left(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'\right)^{-}(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d})$$

are thus met, provided that

$$(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-}\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-}\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}' = (\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-}\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'$$

This condition is obviously met if $\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'$ is of full rank. The condition is also met if $\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'^{-}$ is a reflexive inverse (a g_2-inverse) of $\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}$.

The test statistic to test the linear hypothesis $H\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{d}$ is thus

$$F = \frac{(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d})'\left(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'\right)^{-}(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d})/\text{rank}(\mathbf{L})}{SSR/(n - \text{rank}(\mathbf{X}))}$$

and it follows an F distribution with rank($\mathbf{L}$) numerator and $n - \text{rank}(\mathbf{X})$ denominator degrees of freedom under the hypothesis.

This test statistic looks very similar to the F statistic for the sum of squares reduction test. This is no accident. If the model is linear and parameters are estimated by ordinary least squares, then you can show that the quadratic form $(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d})'\left(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'\right)^{-}(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d})$ equals the differences in the residual sum of squares, $\text{SSR}_H - \text{SSR}$, where SSR_H is obtained as the residual sum of squares from OLS estimation in a model that satisfies $\mathbf{L}\boldsymbol{\beta} = \mathbf{d}$. However, this correspondence between the two test formulations does not apply when a different estimation principle is used. For example, assume that $\boldsymbol{\epsilon} \sim N(\mathbf{0}, \mathbf{V})$ and that $\boldsymbol{\beta}$ is estimated by generalized least squares:

$$\widehat{\boldsymbol{\beta}}_g = \left(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{V}^{-1}\mathbf{Y}$$

The construction of $\mathbf{L}$ matrices associated with hypotheses in SAS/STAT software is frequently based on the properties of the $\mathbf{X}$ matrix, not of $\mathbf{X}'\mathbf{V}^{-}\mathbf{X}$. In other words, the construction of the $\mathbf{L}$ matrix is governed only by the design. A sum of squares reduction test for $H: \mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ that uses the generalized residual sum of squares $(\mathbf{Y} - \widehat{\boldsymbol{\beta}}_g)'\mathbf{V}^{-1}(\mathbf{Y} - \widehat{\boldsymbol{\beta}}_g)$ is not identical to a linear hypothesis test with the statistic

$$F^* = \frac{\widehat{\boldsymbol{\beta}}_g'\mathbf{L}'\left(\mathbf{L}\left(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}\right)^{-}\mathbf{L}'\right)^{-}\mathbf{L}\widehat{\boldsymbol{\beta}}_g}{\text{rank}(\mathbf{L})}$$

Furthermore, $\mathbf{V}$ is usually unknown and must be estimated as well. The estimate for $\mathbf{V}$ depends on the model, and imposing a constraint on the model would change the estimate. The asymptotic distribution of the statistic F^* is a chi-square distribution. However, in practical applications the F distribution with rank($\mathbf{L}$) numerator and ν denominator degrees of freedom is often used because it provides a better approximation to the sampling distribution of F^* in finite samples. The computation of the denominator degrees of freedom ν, however, is a matter of considerable discussion. A number of methods have been proposed and are implemented in various forms in SAS/STAT (see, for example, the degrees-of-freedom methods in the MIXED and GLIMMIX procedures).

Residual Analysis

The model errors $\boldsymbol{\epsilon} = \mathbf{Y} - \mathbf{X}\boldsymbol{\beta}$ are unobservable. Yet important features of the statistical model are connected to them, such as the distribution of the data, the correlation among observations, and the constancy of variance. It is customary to diagnose and investigate features of the model errors through the fitted residuals $\widehat{\boldsymbol{\epsilon}} = \mathbf{Y} - \widehat{\mathbf{Y}} = \mathbf{Y} - \mathbf{H}\mathbf{Y} = \mathbf{M}\mathbf{Y}$. These residuals are projections of the data onto the null space of $\mathbf{X}$ and are also referred to as the "raw" residuals to contrast them with other forms of residuals that are transformations of $\widehat{\boldsymbol{\epsilon}}$. For the classical linear model, the statistical properties of $\widehat{\boldsymbol{\epsilon}}$ are affected by the features of that projection and can be summarized as follows:

$$\begin{aligned} \text{E}[\widehat{\boldsymbol{\epsilon}}] &= \mathbf{0} \\ \text{Var}[\widehat{\boldsymbol{\epsilon}}] &= \sigma^2\mathbf{M} \\ \text{rank}(\mathbf{M}) &= n - \text{rank}(\mathbf{X}) \end{aligned}$$

Furthermore, if $\boldsymbol{\epsilon} \sim N(\mathbf{0}, \sigma^2\mathbf{I})$, then $\widehat{\boldsymbol{\epsilon}} \sim N(\mathbf{0}, \sigma^2\mathbf{M})$.

Because $\mathbf{M} = \mathbf{I} - \mathbf{H}$, and the "hat" matrix $\mathbf{H}$ satisfies $\partial\widehat{\mathbf{Y}}/\partial\mathbf{Y}$, the hat matrix is also the leverage matrix of the model. If h_{ii} denotes the ith diagonal element of $\mathbf{H}$ (the leverage of observation i), then the leverages are bounded in a model with intercept, $1/n \leq h_{ii} \leq 1$. Consequently, the variance of a raw residual is less than that of an observation: $\text{Var}[\widehat{\epsilon}_i] = \sigma^2(1 - h_{ii}) < \sigma^2$. In applications where the variability of the data is estimated from fitted residuals, the estimate is invariably biased low. An example is the computation of an empirical semivariogram based on fitted (detrended) residuals.

More important, the diagonal entries of $\mathbf{H}$ are not necessarily identical; the residuals are heteroscedastic. The "hat" matrix is also not a diagonal matrix; the residuals are correlated. In summary, the only property that the fitted residuals $\widehat{\boldsymbol{\epsilon}}$ share with the model errors is a zero mean. It is thus commonplace to use transformations of the fitted residuals for diagnostic purposes.

Raw and Studentized Residuals

A *standardized* residual is a raw residual that is divided by its standard deviation:

$$\widehat{\epsilon}_i^* = \frac{Y_i - \widehat{Y}_i}{\sqrt{\mathrm{Var}[Y_i - \widehat{Y}_i]}} = \frac{\widehat{\epsilon}_i}{\sqrt{\sigma^2(1-h_{ii})}}$$

Because σ^2 is unknown, residual standardization is usually not practical. A *studentized* residual is a raw residual that is divided by its estimated standard deviation. If the estimate of the standard deviation is based on the same data that were used in fitting the model, the residual is also called an *internally studentized* residual:

$$\widehat{\epsilon}_{is} = \frac{Y_i - \widehat{Y}_i}{\sqrt{\widehat{\mathrm{Var}}[Y_i - \widehat{Y}_i]}} = \frac{\widehat{\epsilon}_i}{\sqrt{\widehat{\sigma}^2(1-h_{ii})}}$$

If the estimate of the residual's variance does not involve the ith observation, it is called an *externally studentized* residual. Suppose that $\widehat{\sigma}^2_{-i}$ denotes the estimate of the residual variance obtained without the ith observation; then the externally studentized residual is

$$\widehat{\epsilon}_{ir} = \frac{\widehat{\epsilon}_i}{\sqrt{\widehat{\sigma}^2_{-i}(1-h_{ii})}}$$

Scaled Residuals

A scaled residual is simply a raw residual divided by a scalar quantity that is not an estimate of the variance of the residual. For example, residuals divided by the standard deviation of the response variable are scaled and referred to as Pearson or Pearson-type residuals:

$$\widehat{\epsilon}_{ic} = \frac{Y_i - \widehat{Y}_i}{\sqrt{\widehat{\mathrm{Var}}[Y_i]}}$$

In generalized linear models, where the variance of an observation is a function of the mean μ and possibly of an extra scale parameter, $\mathrm{Var}[Y] = a(\mu)\phi$, the Pearson residual is

$$\widehat{\epsilon}_{iP} = \frac{Y_i - \widehat{\mu}_i}{\sqrt{a(\widehat{\mu})}}$$

because the sum of the squared Pearson residuals equals the Pearson X^2 statistic:

$$X^2 = \sum_{i=1}^{n} \widehat{\epsilon}_{iP}^2$$

When the scale parameter ϕ participates in the scaling, the residual is also referred to as a Pearson-type residual:

$$\widehat{\epsilon}_{iP} = \frac{Y_i - \widehat{\mu}_i}{\sqrt{a(\widehat{\mu})\phi}}$$

Other Residuals

You might encounter other residuals in SAS/STAT software. A "leave-one-out" residual is the difference between the observed value and the residual obtained from fitting a model in which the observation in question did not participate. If $\widehat{Y}_i$ is the predicted value of the ith observation and $\widehat{Y}_{i,-i}$ is the predicted value if Y_i is removed from the analysis, then the "leave-one-out" residual is

$$\widehat{\epsilon}_{i,-i} = Y_i - \widehat{Y}_{i,-i}$$

Since the sum of the squared "leave-one-out" residuals is the PRESS statistic (prediction sum of squares; Allen 1974), $\widehat{\epsilon}_{i,-i}$ is also called the PRESS residual. The concept of the PRESS residual can be generalized if the deletion residual can be based on the removal of sets of observations. In the classical linear model, the PRESS residual for case deletion has a particularly simple form:

$$\widehat{\epsilon}_{i,-i} = Y_i - \widehat{Y}_{i,-i} = \frac{\widehat{\epsilon}_i}{1 - h_{ii}}$$

That is, the PRESS residual is simply a scaled form of the raw residual, where the scaling factor is a function of the leverage of the observation.

When data are correlated, $\mathrm{Var}[\mathbf{Y}] = \mathbf{V}$, you can scale the vector of residuals rather than scale each residual separately. This takes the covariances among the observations into account. This form of scaling is accomplished by forming the Cholesky root $\mathbf{C}'\mathbf{C} = \mathbf{V}$, where $\mathbf{C}'$ is a lower-triangular matrix. Then $\mathbf{C}'^{-1}\mathbf{Y}$ is a vector of uncorrelated variables with unit variance. The Cholesky residuals in the model $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$ are

$$\widehat{\boldsymbol{\epsilon}}_C = \mathbf{C}'^{-1}\left(\mathbf{Y} - \mathbf{X}\widehat{\boldsymbol{\beta}}\right)$$

In generalized linear models, the fit of a model can be measured by the scaled deviance statistic D^*. It measures the difference between the log likelihood under the model and the maximum log likelihood that is achievable. In models with a scale parameter ϕ, the deviance is $D = \phi \times D^* = \sum_{i=1}^{n} d_i$. The deviance residuals are the signed square roots of the contributions to the deviance statistic:

$$\widehat{\epsilon}_{id} = \mathrm{sign}\{y_i - \widehat{\mu}_i\}\sqrt{d_i}$$

Sweep Operator

The sweep operator (Goodnight 1979) is closely related to Gauss-Jordan elimination and the Forward Doolittle procedure. The fact that a sweep operation can produce a generalized inverse by in-place mapping with minimal storage and that its application invariably leads to some form of matrix inversion is important, but this observation does not do justice to the pervasive relevance of sweeping to statistical computing. In this section the sweep operator is discussed as a conceptual tool for further insight into linear model operations. Consider the nonnegative definite, symmetric, partitioned matrix

$$\mathbf{A} = \begin{bmatrix} \mathbf{A}_{11} & \mathbf{A}_{12} \\ \mathbf{A}'_{12} & \mathbf{A}_{22} \end{bmatrix}$$

Sweeping a matrix consists of performing a series of row operations akin to Gauss-Jordan elimination. Basic row operations are the multiplication of a row by a constant and the addition of a

multiple of one row to another. The sweep operator restricts row operations to pivots on the diagonal elements of a matrix; further details about the elementary operations can be found in Goodnight (1979). The process of sweeping the matrix $\mathbf{A}$ on its leading partition is denoted as Sweep$(\mathbf{A}, \mathbf{A}_{11})$ and leads to

$$\text{Sweep}(\mathbf{A}, \mathbf{A}_{11}) = \begin{bmatrix} \mathbf{A}_{11}^{-} & \mathbf{A}_{11}^{-}\mathbf{A}_{12} \\ -\mathbf{A}_{12}'\mathbf{A}_{11}^{-} & \mathbf{A}_{22} - \mathbf{A}_{12}'\mathbf{A}_{11}^{-}\mathbf{A}_{12} \end{bmatrix}$$

If the kth row and column are set to zero when the pivot is zero (or in practice, less than some singularity tolerance), the generalized inverse in the leading position of the swept matrix is a reflexive, g_2-inverse. Suppose that the crossproduct matrix of the linear model is augmented with a "Y-border" as follows:

$$\mathbf{C} = \begin{bmatrix} \mathbf{X}'\mathbf{X} & \mathbf{X}'\mathbf{Y} \\ \mathbf{Y}'\mathbf{X} & \mathbf{Y}'\mathbf{Y} \end{bmatrix}$$

Then the result of sweeping on the rows of $\mathbf{X}$ is

$$\begin{aligned} \text{Sweep}(\mathbf{C}, \mathbf{X}) &= \begin{bmatrix} (\mathbf{X}'\mathbf{X})^{-} & (\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{Y} \\ -\mathbf{Y}'\mathbf{X}(\mathbf{X}'\mathbf{X})^{-} & \mathbf{Y}'\mathbf{Y} - \mathbf{Y}'\mathbf{X}(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{Y} \end{bmatrix} \\ &= \begin{bmatrix} (\mathbf{X}'\mathbf{X})^{-} & \widehat{\boldsymbol{\beta}} \\ -\widehat{\boldsymbol{\beta}} & \mathbf{Y}'\mathbf{M}\mathbf{Y} \end{bmatrix} = \begin{bmatrix} (\mathbf{X}'\mathbf{X})^{-} & \widehat{\boldsymbol{\beta}} \\ -\widehat{\boldsymbol{\beta}} & \text{SSR} \end{bmatrix} \end{aligned}$$

The "Y-border" has been transformed into the least squares solution and the residual sum of squares.

Partial sweeps are common in model selection. Suppose that the $\mathbf{X}$ matrix is partitioned as $[\mathbf{X}_1 \ \mathbf{X}_2]$, and consider the augmented crossproduct matrix

$$\mathbf{C} = \begin{bmatrix} \mathbf{X}_1'\mathbf{X}_1 & \mathbf{X}_1'\mathbf{X}_2 & \mathbf{X}_1'\mathbf{Y} \\ \mathbf{X}_2'\mathbf{X}_1 & \mathbf{X}_2'\mathbf{X}_2 & \mathbf{X}_2'\mathbf{Y} \\ \mathbf{Y}'\mathbf{X}_1 & \mathbf{Y}'\mathbf{X}_2 & \mathbf{Y}'\mathbf{Y} \end{bmatrix}$$

Sweeping on the $\mathbf{X}_1$ partition yields

$$\text{Sweep}(\mathbf{C}, \mathbf{X}_1) = \begin{bmatrix} (\mathbf{X}_1'\mathbf{X}_1)^{-} & (\mathbf{X}_1'\mathbf{X}_1)^{-}\mathbf{X}_1'\mathbf{X}_2 & (\mathbf{X}_1'\mathbf{X}_1)^{-}\mathbf{X}_1'\mathbf{Y} \\ -\mathbf{X}_2'\mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^{-} & \mathbf{X}_2'\mathbf{M}_1\mathbf{X}_2 & \mathbf{X}_2'\mathbf{M}_1\mathbf{Y} \\ \mathbf{Y}'\mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^{-} & \mathbf{Y}'\mathbf{M}_1\mathbf{X}_2 & \mathbf{Y}'\mathbf{M}_1\mathbf{Y} \end{bmatrix}$$

where $\mathbf{M}_1 = \mathbf{I} - \mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^{-}\mathbf{X}_1'$. The entries in the first row of this partition are the generalized inverse of $\mathbf{X}'\mathbf{X}$, the coefficients for regressing $\mathbf{X}_2$ on $\mathbf{X}_1$, and the coefficients for regressing $\mathbf{Y}$ on $\mathbf{X}_1$. The diagonal entries $\mathbf{X}_2'\mathbf{M}_1\mathbf{X}_2$ and $\mathbf{Y}'\mathbf{M}_1\mathbf{Y}$ are the sum of squares and crossproduct matrices for regressing $\mathbf{X}_2$ on $\mathbf{X}_1$ and for regressing $\mathbf{Y}$ on $\mathbf{X}_1$, respectively. As you continue to sweep the matrix, the last cell in the partition contains the residual sum of square of a model in which $\mathbf{Y}$ is regressed on all columns swept up to that point.

The sweep operator is not only useful to conceptualize the computation of least squares solutions, Type I and Type II sums of squares, and generalized inverses. It can also be used to obtain other statistical information. For example, adding the logarithms of the pivots of the rows that are swept yields the log determinant of the matrix.

Overview: Regression Procedures

This chapter provides an overview of procedures in SAS/STAT software that perform regression analysis. The REG procedure provides the most general analysis capabilities for the linear regression model. But many other procedures can fit linear regression models, and many procedures are specifically designed for more general regression problems, such as robust regression, generalized linear regression, nonlinear regression, nonparametric regression, regression modeling of survey data, regression modeling of survival data, and regression modeling of transformed variables. The aim of this chapter is to provide a brief road map and delineation of the various SAS/STAT procedures that can fit regression models.

A sampling of the procedures that fall into this category are the CATMOD, GAM, GENMOD, GLIMMIX, GLM, LIFEREG, LOESS, LOGISTIC, MIXED, NLIN, NLMIXED, ORTHOREG, PHREG, PLS, PROBIT, REG, ROBUSTREG, RSREG, SURVEYLOGISTIC, SURVEYREG, and TRANSREG procedures.

This chapter also briefly mentions several procedures in SAS/ETS software.

Introduction

Recall from Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," that the general regression problem is to model the mean of a random vector $\mathbf{Y}$ as a function of a parameters and covariates in a statistical model. The many forms of regression models have their origin in the characteristics of the response variable (discrete or continuous, normal or nonnormal distributed), assumptions about the form of the model (linear, nonlinear, or generalized linear), assumptions about the data generating mechanism (survey, observational, or experimental data), and estimation principles. The following procedures, listed in alphabetical order, perform at least one type of regression analysis.

CATMOD analyzes data that can be represented by a contingency table. PROC CATMOD fits linear models to functions of response frequencies, and it can be used for linear and logistic regression. See Chapter 8, "Introduction to Categorical Data Analysis Procedures," and Chapter 28, "The CATMOD Procedure," for more information.

GAM fits generalized additive models. The models fitted with the GAM procedure are nonparameteric in that the usual assumption of a linear predictor is relaxed. The name stems from the fact that the models consist of additive, smooth functions in the regression variables. The GAM procedure can fit additive models to nonnormal data. See Chapter 36, "The GAM Procedure," for more information.

GENMOD fits generalized linear models. PROC GENMOD is especially suited for responses with discrete outcomes, and it performs logistic regression and Poisson regression as well as fitting generalized estimating equations for repeated measures data. Bayesian analysis capabilities for generalized linear models are also

available with the GENMOD procedure. See Chapter 8, "Introduction to Categorical Data Analysis Procedures," and Chapter 37, "The GENMOD Procedure," for more information.

GLIMMIX — fits generalized linear mixed models by likelihood-based methods. In addition to many other analyses, PROC GLIMMIX can perform simple, multiple, polynomial, and weighted regression. The GLIMMIX procedure can also fit linear mixed models and models without random effects. See Chapter 38, "The GLIMMIX Procedure," for more information.

GLM — uses the method of least squares to fit general linear models. In addition to many other analyses, PROC GLM can perform simple, multiple, polynomial, and weighted regression. PROC GLM has many of the same input/output capabilities as PROC REG, but it does not provide as many diagnostic tools or allow interactive changes in the model or data. See Chapter 5, "Introduction to Analysis of Variance Procedures," and Chapter 39, "The GLM Procedure," for more information.

LIFEREG — fits parametric models to failure-time data that might be right censored. These types of models are commonly used in survival analysis. See Chapter 14, "Introduction to Survey Procedures," and Chapter 48, "The LIFEREG Procedure," for more information.

LOESS — fits nonparametric models using a local regression method. PROC LOESS is suitable for modeling regression surfaces where the underlying parametric form is unknown and where robustness in the presence of outliers is required. See Chapter 50, "The LOESS Procedure," for more information.

LOGISTIC — fits logistic models for binomial and ordinal outcomes. PROC LOGISTIC provides a wide variety of model-building methods and computes numerous regression diagnostics. See Chapter 8, "Introduction to Categorical Data Analysis Procedures," and Chapter 51, "The LOGISTIC Procedure," for more information.

MIXED — fits linear mixed models by likelihood-based techniques. In addition to many other analyses, PROC MIXED can fit models without random effects; hence, the procedure can perform simple, multiple, polynomial, and weighted regression. See Chapter 56, "The MIXED Procedure," for more information.

NLIN — fits general nonlinear regression models by the method of nonlinear least squares. Several different iterative methods are available. See Chapter 60, "The NLIN Procedure," for more information.

NLMIXED — fits general nonlinear mixed regression models by the method of maximum likelihood. With the NLMIXED procedure you can specify a custom objective function for parameter estimation and fit models with or without random effects. See Chapter 61, "The NLMIXED Procedure," for more information.

ORTHOREG — performs regression by using the Gentleman-Givens computational method. For ill-conditioned data, PROC ORTHOREG can produce more accurate parameter estimates than other procedures such as PROC GLM and PROC REG. See Chapter 63, "The ORTHOREG Procedure," for more information.

PHREG — fits Cox proportional hazards regression models to survival data. See Chapter 64, "The PHREG Procedure," for more information.

PLS performs partial least squares regression, principal components regression, and reduced rank regression, with cross validation for the number of components. See Chapter 66, "The PLS Procedure," for more information.

PROBIT performs probit regression as well as logistic regression and ordinal logistic regression. The PROBIT procedure is useful when the dependent variable is either dichotomous or polychotomous and the independent variables are continuous. See Chapter 71, "The PROBIT Procedure," for more information.

QUANTREG models the effects of covariates on the conditional quantiles of a response variable by means of quantile regression. See Chapter 72, "The QUANTREG Procedure," for more information.

REG performs linear regression with many diagnostic capabilities, selects models by using one of nine methods, produces scatter plots of raw data and statistics, highlights scatter plots to identify particular observations, and allows interactive changes in both the regression model and the data used to fit the model. See Chapter 73, "The REG Procedure," for more information.

ROBUSTREG performs robust regression by using Huber M estimation and high breakdown value estimation. PROC ROBUSTREG is suitable for detecting outliers and providing resistant (stable) results in the presence of outliers. See Chapter 74, "The ROBUSTREG Procedure," for more information.

RSREG builds quadratic response-surface regression models. PROC RSREG analyzes the fitted response surface to determine the factor levels of optimum response and performs a ridge analysis to search for the region of optimum response. See Chapter 75, "The RSREG Procedure," for more information.

SURVEYLOGISTIC fits logistic models for binary and ordinal outcomes to survey data by maximum likelihood. See Chapter 84, "The SURVEYLOGISTIC Procedure," for more information.

SURVEYREG fits linear regression models to survey data by generalized least squares by using elementwise regresssion. See Chapter 86, "The SURVEYREG Procedure," for more information.

TRANSREG fits univariate and multivariate linear models, optionally with spline and other nonlinear transformations. Models include ordinary regression and ANOVA, multiple and multivariate regression, metric and nonmetric conjoint analysis, metric and nonmetric vector and ideal point preference mapping, redundancy analysis, canonical correlation, and response surface regression. See Chapter 90, "The TRANSREG Procedure," for more information.

Several SAS/ETS procedures also perform regression. The following procedures are documented in the *SAS/ETS User's Guide*.

AUTOREG implements regression models that use time-series data where the errors are autocorrelated. See Chapter 8, "The AUTOREG Procedure" (*SAS/ETS User's Guide*), for more details.

COUNTREG analyzes regression models in which the dependent variable takes nonnegative integer or count values. See Chapter 10, "The COUNTREG Procedure" (*SAS/ETS User's Guide*), for more details.

MODEL	handles nonlinear simultaneous systems of equations, such as econometric models. See Chapter 18, "The MODEL Procedure" (*SAS/ETS User's Guide*), for more details.
PANEL	analyzes a class of linear econometric models that commonly arise when time series and cross-sectional data are combined. See Chapter 19, "The PANEL Procedure" (*SAS/ETS User's Guide*), for more details.
PDLREG	performs regression analysis with polynomial distributed lags. See Chapter 20, "The PDLREG Procedure" (*SAS/ETS User's Guide*), for more details.
SYSLIN	handles linear simultaneous systems of equations, such as econometric models. See Chapter 26, "The SYSLIN Procedure" (*SAS/ETS User's Guide*), for more details.

Introductory Example: Linear Regression

Regression analysis is the analysis of the relationship between a response or outcome variable and another set of variables. The relationship is expressed through a statistical model equation that predicts a *response variable* (also called a *dependent variable* or *criterion*) from a function of *regressor variables* (also called *independent variables, predictors, explanatory variables, factors,* or *carriers*) and *parameters*. In a linear regression model the predictor function is linear in the parameters (but not necessarily linear in the regressor variables). The parameters are estimated so that a measure of fit is optimized. For example, the equation for the ith observation might be

$$Y_i = \beta_0 + \beta_1 x_i + \epsilon_i$$

where Y_i is the response variable, x_i is a regressor variable, β_0 and β_1 are unknown parameters to be estimated, and ϵ_i is an error term. This model is termed the simple linear regression (SLR) model, because it is linear in β_0 and β_1 and contains only a single regressor variable.

Suppose you are using regression analysis to relate a child's weight to a child's height. One application of a regression model with the response variable Weight is to predict a child's weight for a known height. Suppose you collect data by measuring heights and weights of 19 randomly selected schoolchildren. A simple linear regression model with the response variable weight and the regressor variable height can be written as the following equation:

$$\text{Wght}_i = \beta_0 + \beta_1 \text{Height}_i + \epsilon_i$$

where

Wght_i	is the response variable for the ith child.
Height_i	is the regressor variable for the ith child.
β_0, β_1	are the unknown regression parameters.
ϵ_i	is the unobservable random error associated with the ith observation.

The following DATA step creates a SAS data set identifying the children and their observed heights (variable Height) and weights (variable Wght).

Figure 4.1 displays the default tabular output of the REG procedure for this model. Nineteen observations are read from the data set and all observations are used in the analysis. The estimates of the two regression parameters are $\widehat{\beta}_0 = -143.02692$ and $\widehat{\beta}_1 = 3.89903$. These estimates are obtained by the least squares principle. See the sections "Classical Estimation Principles" and "Linear Model Theory" in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," for details about the principle of least squares estimation and its role in linear model analysis. For a general discussion of the theory of least squares estimation of linear models and its application to regression and analysis of variance, refer to one of the applied regression texts, including Draper and Smith (1981), Daniel and Wood (1980), Johnston (1972), and Weisberg (1985).

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	7193.24912	7193.24912	57.08	<.0001
Error	17	2142.48772	126.02869		
Corrected Total	18	9335.73684			

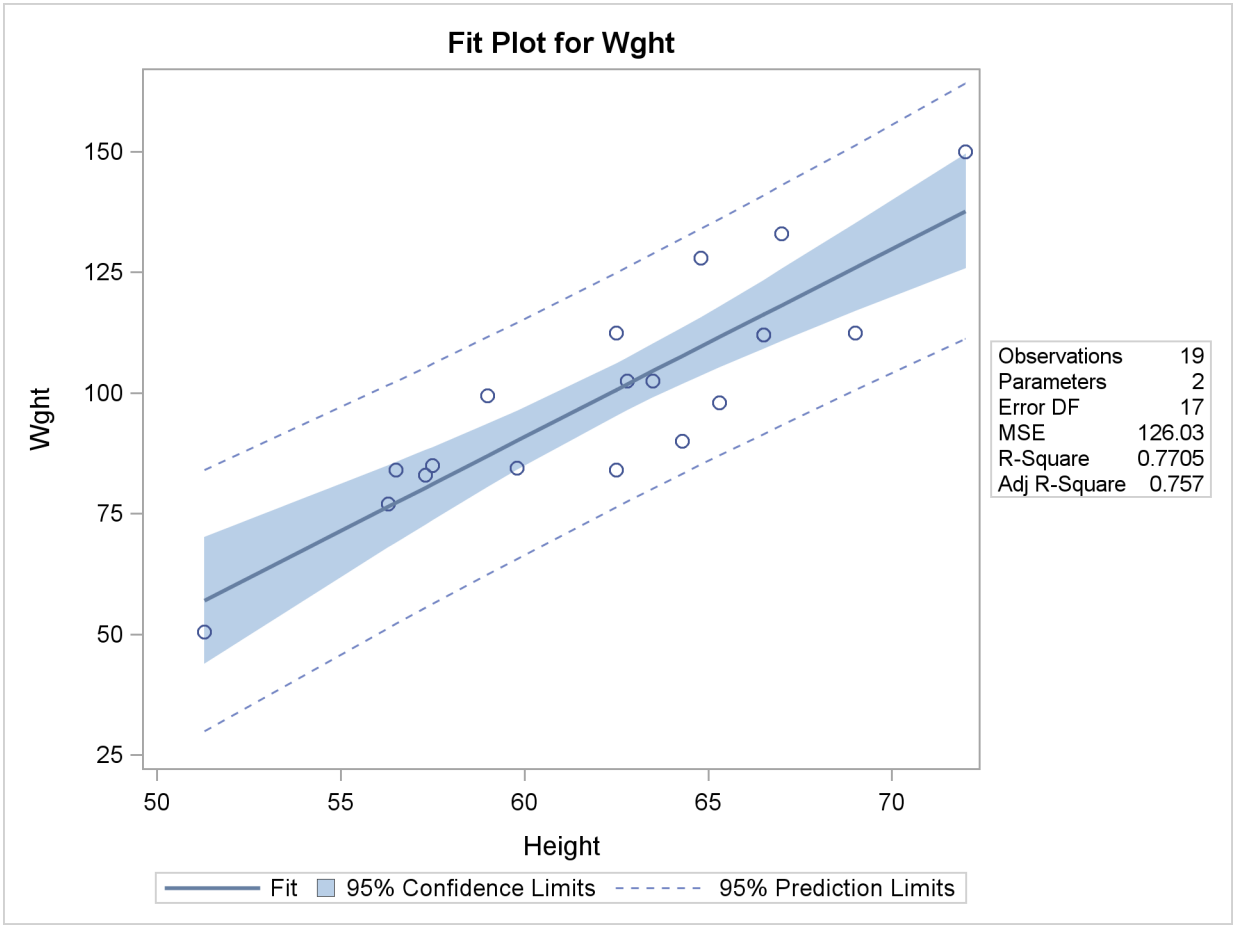
Root MSE	11.22625	R-Square	0.7705
Dependent Mean	100.02632	Adj R-Sq	0.7570
Coeff Var	11.22330		

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	-143.02692	32.27459	-4.43	0.0004
Height	1	3.89903	0.51609	7.55	<.0001

Based on the least squares estimates shown in Figure 4.1, the fitted regression line relating height to weight is described by the equation

$$\widehat{\text{Wght}} = -143.02692 + 3.89903 \times \text{Height}$$



The "hat" notation is used to denote the predicted variable on the left side of the prediction equation to emphasize that $\widehat{\text{Wght}}$ is not one of the original observations but a value predicted under the regression model that has been fit to the data. At the least squares solution the residual sum of squares

$$\text{SSE} = \sum_{i=1}^{19} (\text{Wght}_i - \beta_0 - \beta_1 \text{Height}_i)^2$$

is minimized and the achieved criterion value is displayed in the analysis of variance table as the error sum of squares (2142.48772).

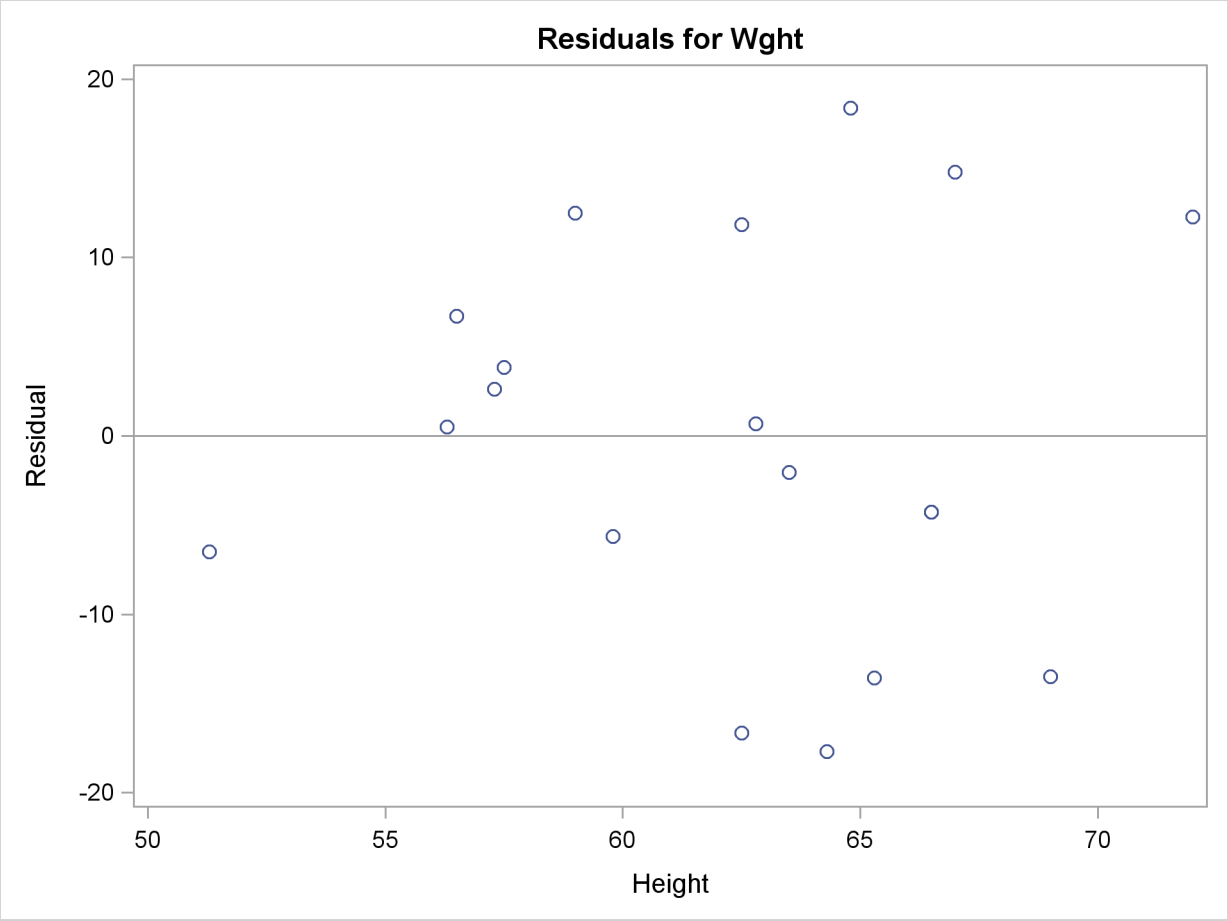


Figure 4.2 displays the fit plot induced by the `ODS GRAPHICS ON;` statement. The fit plot shows the positive slope of the fitted line. The average weight of a child changes by $\widehat{\beta}_1 = 3.89903$ units for each unit change in height. The 95% confidence limits in the fit plot are pointwise limits that cover the mean weight for a particular height with probability 0.95. The prediction limits, which are wider than the confidence limits, show the pointwise limits that cover a new observation for a given height with probability 0.95.

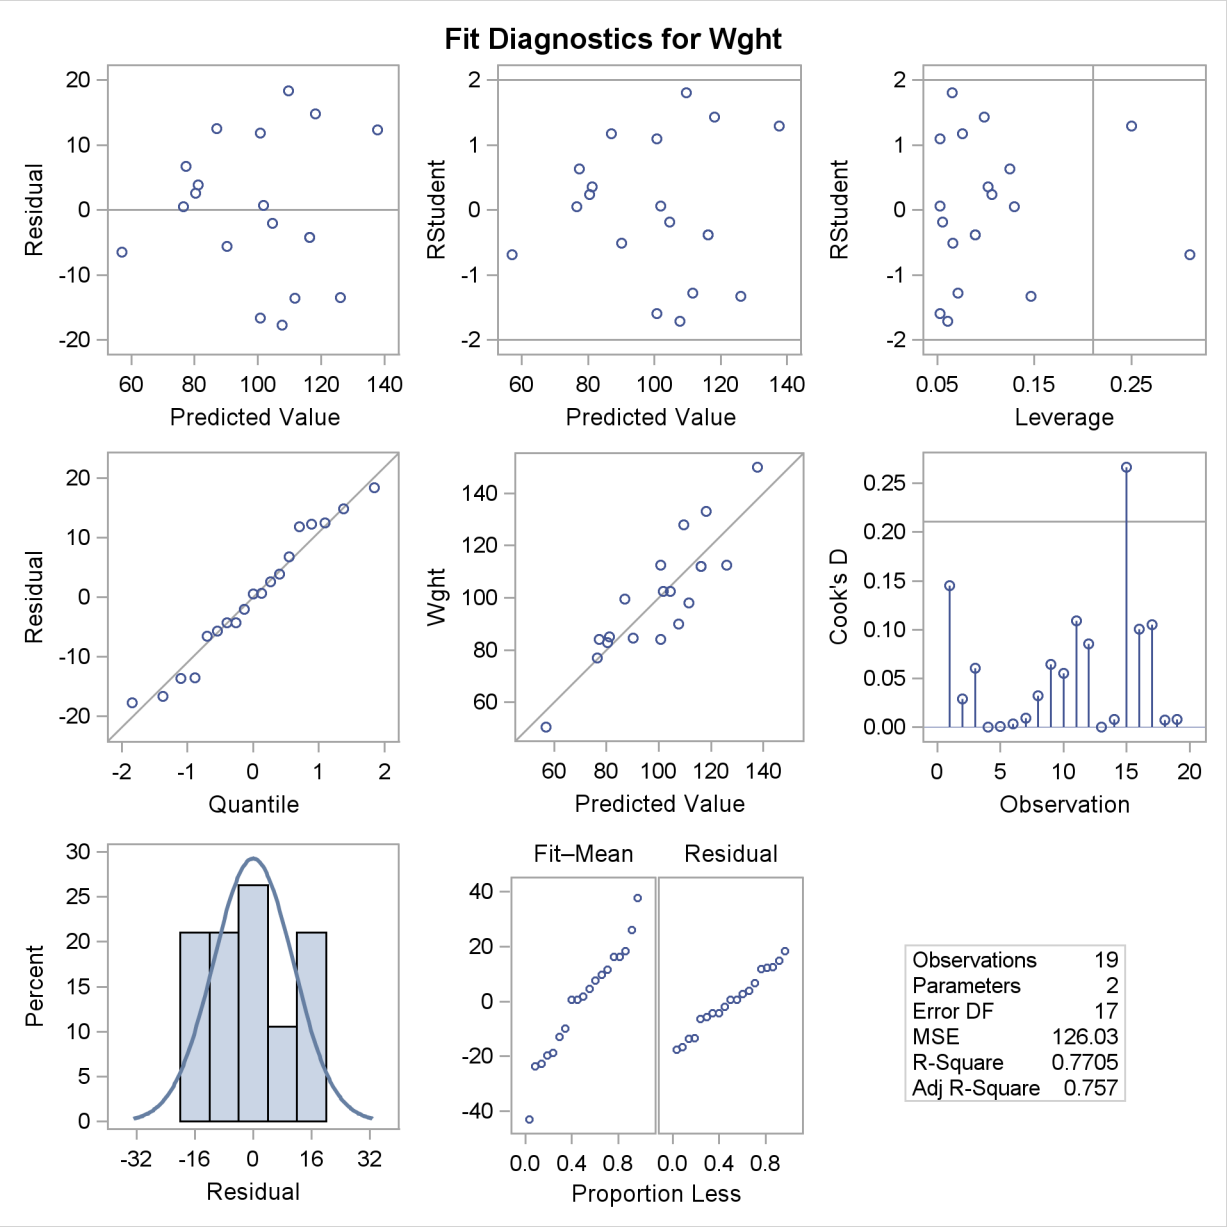
Figure 4.2 Fit Plot for Regression of Weight on Height



Regression is often used in an exploratory fashion to look for empirical relationships, such as the relationship between Height and Wght. In this example, Height is not the cause of Wght. You would need a controlled experiment to confirm the relationship scientifically. See the section "Comments on Interpreting Regression Statistics" on page 107 for more information. A separate question from a possible cause-and-effect relationship between the two variables involved in this regression is whether the simple linear regression model adequately describes the relationship in these data. If the usual assumptions about the model errors ϵ_i are met in the SLR model, then the errors should have zero mean and equal variance and be uncorrelated. Because the children were randomly selected, the observations from different children are not correlated. If the mean function of the model is correctly specified, the fitted residuals $\text{Wght}_i - \widehat{\text{Wght}}_i$ should scatter about the zero reference line without discernible structure. The residual plot in Figure 4.3 confirms this behavior.

Figure 4.3 Residual Plot for Regression of Weight on Height

An even more detailed look at the model-data agreement is gained with the panel of regression diagnostics in Figure 4.4. The graph in the upper-left panel repeats the raw residual plot in Figure 4.3. The plot of the RSTUDENT residuals shows externally studentized residuals that take into account heterogeneity in the variability of the residuals. RSTUDENT residuals that exceed the threshold values of ± 2 often indicate outlying observations. The residual-by-leverage plot shows that two observations have high leverage—that is, they are unusual in their height values relative to the other children. The normal-probability Q-Q plot in the second row of the panel shows that the normality assumption for the residuals is reasonable. The plot of the Cook's D statistic shows that observation 15 exceeds the threshold value; this indicates that the observation for this child is influential on the regression parameter estimates.

Figure 4.4 Panel of Regression Diagnostics

For detailed information about the interpretation of regression diagnostics and about ODS statistical graphics with the REG procedure, see Chapter 73, "The REG Procedure."

SAS/STAT regression procedures produce the following information for a typical regression analysis:

- parameter estimates derived by using the least squares criterion
- estimates of the variance of the error term
- estimates of the variance or standard deviation of the sampling distribution of the parameter estimates
- tests of hypotheses about the parameters

SAS/STAT regression procedures can produce many other specialized diagnostic statistics, including the following:

- collinearity diagnostics to measure how strongly regressors are related to other regressors and how this affects the stability and variance of the estimates (REG)
- influence diagnostics to measure how each individual observation contributes to determining the parameter estimates, the SSE, and the fitted values (LOGISTIC, MIXED, REG, RSREG)
- lack-of-fit diagnostics that measure the lack of fit of the regression model by comparing the error variance estimate to another pure error variance that is not dependent on the form of the model (CATMOD, PROBIT, RSREG)
- diagnostic scatter plots that check the fit of the model and highlighted scatter plots that identify particular observations or groups of observations (REG)
- predicted and residual values, and confidence intervals for the mean and for an individual value (GLM, LOGISTIC, REG)
- time-series diagnostics for equally spaced time-series data that measure how much errors might be related across neighboring observations. These diagnostics can also measure functional goodness of fit for data sorted by regressor or response variables (REG, SAS/ETS procedures).

Many SAS/STAT procedures produce general and specialized statistical graphics through ODS Graphics to diagnose the fit of the model and the model-data agreement, and to highlight observations that are influential on the analysis. Figure 4.2 and Figure 4.3, for example, are two of the ODS statistical graphs produced by the REG procedure by default for the simple linear regression model. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." For specific information about the ODS statistical graphs available with a SAS/STAT procedure, see the PLOTS option in the "Syntax" section for the PROC statement and the "ODS Table Names" section in the "Details" section of the individual procedure documentation.

Linear Regression: The REG Procedure

The REG procedure is a general-purpose procedure for linear regression that does the following:

- handles multiple regression models
- provides nine model-selection methods
- allows interactive changes both in the model and in the data used to fit the model
- allows linear equality restrictions on parameters
- tests linear hypotheses and multivariate hypotheses
- produces collinearity diagnostics, influence diagnostics, and partial regression leverage plots

- saves estimates, predicted values, residuals, confidence limits, and other diagnostic statistics in output SAS data sets
- generates plots of data and of various statistics
- "paints" or highlights scatter plots to identify particular observations or groups of observations
- uses, optionally, correlations or crossproducts for input

Model-Selection Methods in Linear Regression Models

An important step in building statistical models is to determine which effects and variables affect the response variable and to form a model that fits the data well without incurring the negative effects of overfitting the model. Models that are overfit—that is, contain too many regressor variables and unimportant regressor variables—have a tendency to be too closely molded to a a particular set of data, have unstable regression coefficients, and possibly have poor predictive precision. In situations where many potential regressor variables are available for inclusion in a regression model, guided, numerical variable-selection methods offer one approach to model building.

The model-selection techniques for linear regression models implemented in the REG procedure are as follows:

NONE — specifies that no selection be made. This method is the default and uses the full model given in the MODEL statement to fit the linear regression.

FORWARD — specifies that variables be selected based on a forward-selection algorithm. This method starts with no variables in the model and adds variables one by one to the model. At each step, the variable added is the one that most improves the fit of the model. You can also specify groups of variables to treat as a unit during the selection process. An option enables you to specify the criterion for inclusion.

BACKWARD — specifies that variables be selected based on a backward-elimination algorithm. This method starts with a full model and eliminates variables one by one from the model. At each step, the variable with the smallest contribution to the model is deleted. You can also specify groups of variables to treat as a unit during the selection process. An option enables you to specify the criterion for exclusion.

STEPWISE — specifies that variables be selected for the model based on a stepwise-regression algorithm, which combines forward-selection and backward-elimination steps. This method is a modification of the forward-selection method in that variables already in the model do not necessarily stay there. You can also specify groups of variables to treat as a unit during the selection process. Again, options enable you to specify criteria for entry into the model and for remaining in the model.

MAXR — specifies that model formation be based on the maximum R^2 improvement. This method tries to find the best one-variable model, the best two-variable model, and so on. The MAXR method differs from the STEPWISE method in that many more models are evaluated. The MAXR method considers all possible variable exchanges before making any exchange. The STEPWISE method might

remove the "worst" variable without considering what the "best" remaining variable might accomplish, whereas MAXR would consider what the "best" remaining variable might accomplish. Consequently, model building based on the maximum R^2 improvement typically takes much longer to run than stepwise model building.

MINR — specifies that model formation be based on the minimum R^2 improvement. This method closely resembles MAXR, but the switch chosen is the one that produces the smallest increase in R^2.

RSQUARE — finds a specified number of models having the highest R^2 in each of a range of model sizes.

CP — finds a specified number of models with the lowest C_p within a range of model sizes.

ADJRSQ — finds a specified number of models having the highest adjusted R^2 within a range of model sizes.

The GLMSELECT procedure has been specifically designed for the purpose of model building in linear models. In addition to having a wider array of selection methods and criteria compared to the REG procedure, the GLMSELECT procedure also supports classification variables. See Chapter 42, "The GLMSELECT Procedure," for more information.

Regression with the REG and GLM Procedures

In terms of the assumptions about the basic model and the estimation principles, the REG and GLM procedures are very closely related. Both procedures estimate parameters by ordinary or weighted least squares and assume homoscedastic, uncorrelated model errors with zero mean. An assumption of normality of the model errors is not necessary for parameter estimation, but it is implied in confirmatory inference based on the parameter estimates—that is, the computation of tests, p-values, and confidence and prediction intervals.

The GLM procedure supports a CLASS statement for the levelization of classification variables; see the section "Parameterization of Model Effects" on page 368 in Chapter 18, "Shared Concepts and Topics," on the parameterization of classification variables in statistical models. Classification variables are accommodated in the REG procedure by the inclusion of the necessary dummy regressor variables.

Most of the statistics based on predicted and residual values that are available in PROC REG are also available in PROC GLM. However, PROC GLM does not produce collinearity diagnostics, influence diagnostics, or scatter plots. In addition, PROC GLM allows only one model and fits the full model.

Both procedures are interactive, in that they do not stop after processing a RUN statement. The procedures accept statements until a QUIT statement is submitted.

Response Surface Regression: The RSREG Procedure

The RSREG procedure fits a quadratic response-surface model, which is useful in searching for factor values that optimize a response. The following features in PROC RSREG make it preferable to other regression procedures for analyzing response surfaces:

- automatic generation of quadratic effects
- a lack-of-fit test
- solutions for critical values of the surface
- eigenvalues of the associated quadratic form
- a ridge analysis to search for the direction of optimum response

Partial Least Squares Regression: The PLS Procedure

The PLS procedure fits models by using any of a number of linear predictive methods, including *partial least squares* (PLS). Ordinary least squares regression, as implemented in the GLM or REG procedure, has the single goal of minimizing sample response prediction error by seeking linear functions of the predictors that explain as much variation in each response as possible. The techniques implemented in the PLS procedure have the additional goal of accounting for variation in the predictors under the assumption that directions in the predictor space that are well sampled should provide better prediction for *new* observations when the predictors are highly correlated. All of the techniques implemented in the PLS procedure work by extracting successive linear combinations of the predictors, called *factors* (also called *components* or *latent vectors*), which optimally address one or both of these two goals—explaining response variation and explaining predictor variation. In particular, the method of partial least squares balances the two objectives, seeking factors that explain both response and predictor variation.

Generalized Linear Regression

As outlined in the section "Generalized Linear Models" on page 37 of Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," the class of generalized linear model generalizes the linear regression model in two ways:

- by allowing the data to come from a distribution that is a member of the exponential family of distributions
- by introducing a link function $g(\cdot)$ that provides a mapping between the linear predictor $\eta = \mathbf{x}'\boldsymbol{\beta}$ and the mean of the data, $g(\mathrm{E}[Y]) = \eta$. The link function is monotonic, so that $\mathrm{E}[Y] = g^{-1}(\eta)$ and $g^{-1}(\cdot)$ is called the inverse link function.

One of the most commonly used generalized linear regression models is the logistic model for binary or binomial data. Suppose that Y denotes a binary outcome variable that takes on the values 1 and 0 with probabilities π and $1 - \pi$, respectively. The probability π is also referred to as the "success probability," supposing that the coding $Y = 1$ corresponds to a success in a Bernoulli experiment. The success probability is also the mean of Y, and one of the aims of logistic regression analysis is to study how regressor variables affect the outcome probabilities or functions thereof, such as odds ratios.

The logistic regression model for π is defined by a linear predictor $\eta = \mathbf{x}'\boldsymbol{\beta}$ and the logit link function:

$$\text{logit}\{\Pr(Y = 0)\} = \log\left\{\frac{\pi}{1-\pi}\right\} = \mathbf{x}'\boldsymbol{\beta}$$

The inversely linked linear predictor function in this model is

$$\Pr(Y = 0) = \frac{1}{1 + \exp\{-\eta\}}$$

An extension of the dichotomous logistic regression model is models for multinomial (polychotomous) data. Two classes of models for multinomial data can be fit with procedures in SAS/STAT software: models for ordinal data that rely on cumulative link functions and models for nominal (unordered) outcomes that rely on generalized logits. The next section briefly discusses SAS/STAT procedures for logistic regression. See Chapter 8, "Introduction to Categorical Data Analysis Procedures," for more information about the comparison of the procedures mentioned there with respect to analysis of categorical responses.

Logistic Regression

The SAS/STAT procedures CATMOD, GENMOD, GLIMMIX, LOGISTIC, and PROBIT can fit generalized linear models for binary, binomial, and multinomial outcomes.

CATMOD provides maximum likelihood estimation for logistic regression, including the analysis of logits for dichotomous outcomes and the analysis of generalized logits for polychotomous outcomes. The CATMOD procedure can analyze data represented by a contingency table.

GENMOD is a general modeling procedure for generalized linear models. It estimates parameters by maximum likelihood. Like the LOGISTIC procedure, it uses CLASS and MODEL statements in SAS/STAT procedures to form the statistical model and can fit models to binary and ordinal outcomes. The GENMOD procedure does not fit generalized logit models for nominal outcomes. However, the procedure also provides the capability of solving generalized estimating equations (GEE) to model correlated data and can perform a Bayesian analysis.

GLIMMIX is a general modeling procedure for generalized linear mixed models. If the model does not contain random effects, the GLIMMIX procedure fits generalized linear models by the method of maximum likelihood. In the class of logistic regression models, the procedure can fit models to binary, binomial, ordinal, and nominal outcomes.

LOGISTIC is specifically designed for logistic regression and estimates parameters by maximum likelihood. The procedure fits the usual logistic regression model for binary data as well as models with cumulative link function for ordinal data (such as the proportional odds model) and the generalized logit model for nominal data. The LOGISTIC procedure offers a number of variable selection methods and can perform conditional and exact conditional logistic regression analysis.

PROBIT calculates maximum likelihood estimates of regression parameters and the natural (or threshold) response rate for quantal response data from biological assays or other discrete event data. This includes probit, logit, ordinal logistic, and extreme value (or gompit) regression models.

SURVEYLOGISTIC is designed for logistic regression and estimates parameters by maximum likelihood. The procedure incorporates complex survey sample designs, including designs with stratification, clustering, and unequal weighting.

Other Generalized Linear Models

When a generalized linear model is formed with distributions other than the binary, binomial, or multinomial, you can use the GENMOD and GLIMMIX procedures for parameter estimation and inference.

Both procedures can accommodate correlated observations, but they use different techniques to accomplish this goal. The GENMOD procedure can fit correlated data models via generalized estimating equations that rely on a first- and second-moment specification for the response data and a working correlation assumption. With the GLIMMIX procedure, you can model correlations between the observations by (1) specifying random effects in the conditional distribution that induce a marginal correlation structure or (2) direct modeling of the marginal dependence. The GLIMMIX procedure employs likelihood-based techniques in parameter estimation.

The GENMOD procedure supports a Bayesian analysis through its BAYES statement.

With the GLIMMIX procedure you can vary the distribution or link function on an observation-by-observation basis.

To fit a generalized linear model with a distribution that is not available in the GENMOD or GLIMMIX procedure, you can use the NLMIXED procedure and code the log-likelihood function of an observation with SAS programming statements.

Regression for Ill-Conditioned Data: The ORTHOREG Procedure

The ORTHOREG procedure performs linear least squares regression by using the Gentleman-Givens computational method, and it can produce more accurate parameter estimates for ill-conditioned data. PROC GLM and PROC REG produce very accurate estimates for most problems. However, if you have very ill-conditioned data, consider using the ORTHOREG procedure. The collinearity diagnostics in PROC REG can help you to determine whether PROC ORTHOREG would be useful.

Quantile Regression: The QUANTREG Procedure

The QUANTREG procedure models the effects of covariates on the conditional quantiles of a response variable by means of quantile regression.

Ordinary least squares regression models the relationship between one or more covariates X and the conditional mean of the response variable $\mathrm{E}[Y|X = x]$. Quantile regression extends the regression model to conditional quantiles of the response variable, such as the 90th percentile. Quantile regression is particularly useful when the rate of change in the conditional quantile, expressed by the regression coefficients, depends on the quantile. An advantage of quantile regression over least squares regression is its flexibility for modeling data with heterogeneous conditional distributions. Data of this type occur in many fields, including biomedicine, econometrics, and ecology.

Features that you will find in the QUANTREG procedure include the following:

- simplex, interior point, and smoothing algorithms for estimation
- sparsity, rank, and resampling methods for confidence intervals
- asymptotic and bootstrap methods to estimate covariance and correlation matrices of the parameter estimates
- Wald and likelihood ratio tests for the regression parameter estimates
- regression quantile spline fits

Nonlinear Regression

Recall from Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," that a nonlinear regression model is a statistical model in which the mean function depends on the model parameters in a nonlinear function. The SAS/STAT procedures that can fit general, nonlinear models are the NLIN and NLMIXED procedures. The procedures have the following in common:

- Nonlinear models are fit by iterative methods.
- You must provide an expression for the model through programming statements.
- Analytic derivatives of the objective function with respect to the parameters are calculated automatically.
- A grid search is available to select the best starting values for the parameters from a set of starting points that you provide.

The following items reflect some important differences between the NLIN and NLMIXED procedures:

- Parameters are estimated by nonlinear least squares with the NLIN procedure and by maximum likelihood with the NLMIXED procedure.
- The NLMIXED procedure enables you to construct nonlinear models that contain normally distributed random effects.
- The NLIN procedure requires that you declare all model parameters in the PARAMETERS statement and assign starting values. The NLMIXED procedure determines the parameters in your model based on the PARAMETER statement and the other modeling statements. It is not necessary to supply starting values for all parameters in the NLMIXED procedure, but it is highly recommended.
- The residual variance is not a parameter in models fit with the NLIN procedure, but it is in models fit with the NLMIXED procedure.
- The default iterative optimization method in the NLIN procedure is the Gauss-Newton method; the default method in the NLMIXED procedure is the quasi-Newton method. Other optimization techniques are available in both procedures.

Nonlinear models are fit with iterative techniques that begin from starting values and attempt to iteratively improve on the estimates by updating the estimates. There is no guarantee that the solution achieved when the iterative algorithm converges will correspond to a global optimum.

Nonparametric Regression

Regression models that suppose a parametric form express the mean of an observation as a function of regressor variables $x_1, \cdots, x_k$ and parameters $\beta_1, \cdots, \beta_p$:

$$\mathrm{E}[Y] = f(x_1, \cdots, x_k; \beta_1, \cdots, \beta_p)$$

Nonparametric regression techniques not only relax the assumption of linearity in the regression parameters, but they also do not require that you specify a precise functional form for the relationship between response and regressor variables. Consider a regression problem where the relationship between response Y and regressor X is to be modeled. It is assumed that $\mathrm{E}[Y_i] = g(x_i) + \epsilon_i$, where $g(\cdot)$ is an unspecified regression function. Two primary approaches in nonparametric regression modeling are as follows:

- approximate $g(x_i)$ locally by a parametric function constructed from information in a local neighborhood of x_i
- approximate the unknown function $g(x_i)$ by a smooth, flexible function and determine the necessary smoothness and continuity properties from the data

The SAS/STAT procedures LOESS, GAM, and TPSPLINE fit nonparametric regression models by one of these methods.

Local Regression: The LOESS Procedure

The LOESS procedure implements a local regression approach for estimating regression surfaces pioneered by Cleveland, Devlin, and Grosse (1988). No assumptions about the parametric form of the entire regression surface are made with the LOESS procedure. Only a parametric form of the local approximation is specified by the user. Furthermore, the LOESS procedure is suitable when there are outliers in the data and a robust fitting method is necessary.

Smooth Function Approximation: The TPSPLINE Procedure

The TPSPLINE procedure decomposes the regressor contributions to the mean function into parametric components and into smooth functional components. Suppose that the regressor variables are collected into the vector $\mathbf{x}$ and that this vector is partitioned as $\mathbf{x} = [\mathbf{x}_1' \ \mathbf{x}_2']'$. The relationship between Y and $\mathbf{x}_2$ is linear (parametric) and the relationship between Y and $\mathbf{x}_1$ is nonparametric. The TPSPLINE procedure fits models of the form

$$\mathrm{E}[Y] = g(\mathbf{x}_1) + \mathbf{x}_2'\boldsymbol{\beta}$$

The function $g(\cdot)$ can be represented as a sequence of spline basis functions.

The parameters are estimated by a penalized least squares method. The penalty is applied to the usual least squares criterion to obtain a regression estimate that fits the data well and to prevent the fit from attempting to interpolate the data (fit the data too closely).

Generalized Additive Models: The GAM Procedure

Generalized additive models are nonparametric models in which one or more regressor variables are present and can make different smooth contributions to the mean function. For example, if $\mathbf{x}_i = [x_{i1}, x_{i2}, \cdots, x_{ik}]$ is a vector of k regressor for the ith observation, then an additive model represents the mean function as

$$\mathrm{E}[Y] = f_0 + f_1(x_{i1}) + f_2(x_{i2}) + \cdots + f_3(x_{i3})$$

The individual functions f_j can have a parametric or nonparametric form. If all f_j are parametric, the GAM procedure fits a fully parametric model. If some f_j are nonparametric, the GAM procedure fits a semiparametric model. Otherwise, the models are fully nonparametric.

The generalization of additive models is akin to the generalization for linear models: nonnormal data are accommodated by explicitly modeling the distribution of the data as a member of the exponential family and by applying a monotonic link function that provides a mapping between the predictor and the mean of the data.

Robust Regression: The ROBUSTREG Procedure

The ROBUSTREG procedure implements algorithms to detect outliers and provide resistant (stable) results in the presence of outliers. The ROBUSTREG procedure provides four such methods: M estimation, LTS estimation, S estimation, and MM estimation.

- M estimation was introduced by Huber (1973), and it is the simplest approach both computationally and theoretically. Although it is not robust with respect to leverage points, it is still used extensively in analyzing data for which it can be assumed that the contamination is mainly in the response direction.
- Least trimmed squares (LTS) estimation is a high breakdown value method introduced by Rousseeuw (1984). The breakdown value is a measure of the proportion of contamination that an estimation method can withstand and still maintain its robustness.
- S estimation is a high breakdown value method introduced by Rousseeuw and Yohai (1984). With the same breakdown value, it has a higher statistical efficiency than LTS estimation.
- MM estimation, introduced by Yohai (1987), combines high breakdown value estimation and M estimation. It has both the high breakdown property and a higher statistical efficiency than S estimation.

Regression with Transformations: The TRANSREG Procedure

The TRANSREG procedure can fit many standard linear models. In addition, PROC TRANSREG can find nonlinear transformations of the data and fit a linear model to the transformed variables. This is in contrast to PROC REG and PROC GLM, which fit linear models to data, or PROC NLIN, which fits nonlinear models to data. The TRANSREG procedure fits many types of linear models, including the following:

- ordinary regression and ANOVA
- metric and nonmetric conjoint analysis
- metric and nonmetric vector and ideal point preference mapping
- simple, multiple, and multivariate regression with variable transformations
- redundancy analysis with variable transformations
- canonical correlation analysis with variable transformations
- response surface regression with variable transformations

Interactive Features in the CATMOD, GLM, and REG Procedures

The CATMOD, GLM, and REG procedures do not stop after processing a RUN statement. More statements can be submitted as a continuation of the previous statements. Many new features in these procedures are useful to request after you have reviewed the results from previous statements. The procedures stop if a DATA step or another procedure is requested or if a QUIT statement is submitted.

Statistical Background in Linear Regression

The remainder of this chapter outlines the way in which many SAS/STAT regression procedures calculate various regression quantities. The discussion focuses on the linear regression models. General statistical background about linear statistical models can be found in the section "Linear Model Theory" of Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software."

Exceptions and further details are documented with individual procedures.

Linear Regression Models

In matrix notation, a linear model is written as

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where $\mathbf{X}$ is the $(n \times k)$ design matrix (rows are observations and columns are the regressors), $\boldsymbol{\beta}$ is the $(k \times 1)$ vector of unknown parameters, and $\boldsymbol{\epsilon}$ is the $(n \times 1)$ vector of unobservable model errors. The first column of $\mathbf{X}$ is usually a vector of 1s and is used to estimate the intercept term.

The statistical theory of linear models is based on strict classical assumptions. Ideally, the response is measured with all the factors controlled in an experimentally determined environment. If you cannot control the factors experimentally, some tests must be interpreted as being conditional on the observed values of the regressors.

Other assumptions are as follows:

- The form of the model is correct (all important explanatory variables have been included). This assumption is reflected mathematically in the assumption of a zero mean of the model errors, $\mathrm{E}[\boldsymbol{\epsilon}] = \mathbf{0}$.
- Regressor variables are measured without error.
- The expected value of the errors is zero.
- The variance of the error (and thus the dependent variable) for the ith observation is σ^2/w_i, where w_i is a known weight factor. Usually, $w_i = 1$ for all i and thus σ^2 is the common, constant variance.
- The errors are uncorrelated across observations.

When hypotheses are tested, or when confidence and prediction intervals are computed, an additional assumption is made that the errors are normally distributed.

Parameter Estimates and Associated Statistics

The Least Squares Estimators

Least squares estimators of the regression parameters are found by solving the normal equations

$$\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)\boldsymbol{\beta} = \mathbf{X}'\mathbf{W}\mathbf{Y}$$

for the vector $\boldsymbol{\beta}$, where $\mathbf{W}$ is a diagonal matrix with the observed weights on the diagonal. The resulting estimator of the parameter vector is

$$\widehat{\boldsymbol{\beta}} = \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{W}\mathbf{Y}$$

This is an unbiased estimator, since

$$\begin{aligned}\mathrm{E}\left[\widehat{\boldsymbol{\beta}}\right] &= \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{W}\mathrm{E}[\mathbf{Y}] \\ &= \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{W}\mathbf{X}\boldsymbol{\beta} = \boldsymbol{\beta}\end{aligned}$$

Notice that the only assumption necessary in order for the least squares estimators to be unbiased is that of a zero mean of the model errors. If the estimator is evaluated at the observed data, it is referred to Subidxleast squaresestimate (Introduction to Regression)as the least squares estimate,

$$\widehat{\boldsymbol{\beta}} = \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}\mathbf{X}'\mathbf{W}\mathbf{y}$$

If the standard classical assumptions are met, the least squares estimators of the regression parameters are the best linear unbiased estimators (BLUE). In other words, the estimators have minimum variance in the class of estimators that are unbiased and that are linear functions of the responses. If the additional assumption of normally distributed errors is satisfied, then the following are true:

- The statistics that are computed have the proper sampling distributions for hypothesis testing.
- Parameter estimators are normally distributed.
- Various sums of squares are distributed proportional to chi-square, at least under proper hypotheses.
- Ratios of estimators to standard errors follow the Student's t distribution under certain hypotheses.
- Appropriate ratios of sums of squares follow an F distribution for certain hypotheses.

When regression analysis is used to model data that do not meet the assumptions, the results should be interpreted in a cautious, exploratory fashion. The significance probabilities under these circumstances are unreliable.

Box (1966) and Mosteller and Tukey (1977, Chapters 12 and 13) discuss the problems that are encountered with regression data, especially when the data are not under experimental control.

Estimating the Precision

Assume for the present that $\mathbf{X}'\mathbf{W}\mathbf{X}$ has full column rank k (this assumption is relaxed later). The variance of the error terms, $\mathrm{Var}[\epsilon_i] = \sigma^2$, is then estimated by the mean square error

$$s^2 = \mathrm{MSE} = \frac{\mathrm{SSE}}{n-k} = \frac{1}{n-k}\sum_{i=1}^{n} w_i \left(y_i - \mathbf{x}_i'\boldsymbol{\beta}\right)^2$$

where $\mathbf{x}_i'$ is the ith row of the design matrix $\mathbf{X}$. The residual variance estimate is also unbiased: $\mathrm{E}[s^2] = \sigma^2$.

The covariance matrix of the least squares estimators is

$$\mathrm{Var}\left[\widehat{\boldsymbol{\beta}}\right] = \sigma^2 \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}$$

An estimate of the covariance matrix is obtained by replacing σ^2 with its estimate, s^2 in the preceding formula. This estimate is often referred to as COVB in SAS/STAT modeling procedures:

$$\mathrm{COVB} = \widehat{\mathrm{Var}}\left[\widehat{\boldsymbol{\beta}}\right] = s^2 \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}$$

The correlation matrix of the estimates, often referred to as CORRB, is derived by scaling the covariance matrix: Let $\mathbf{S} = \mathrm{diag}\left(\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}\right)^{-\frac{1}{2}}$. Then the correlation matrix of the estimates is

$$\mathrm{CORRB} = \mathbf{S}\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1}\mathbf{S}$$

The estimated standard error of the ith parameter estimator is obtained as the square root of the ith diagonal element of the COVB matrix. Formally,

$$\mathrm{STDERR}\left(\widehat{\boldsymbol{\beta}}_i\right) = \sqrt{\left[s^2(\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}\right]_{ii}}$$

The ratio

$$t = \frac{\widehat{\boldsymbol{\beta}}_i}{\mathrm{STDERR}\left(\widehat{\boldsymbol{\beta}}_i\right)}$$

follows a Student's t distribution with $(n-k)$ degrees of freedom under the hypothesis that β_i is zero and provided that the model errors are normally distributed.

Regression procedures display the t ratio and the significance probability, which is the probability under the hypothesis $H\colon \beta_i = 0$ of a larger absolute t value than was actually obtained. When the probability is less than some small level, the event is considered so unlikely that the hypothesis is rejected.

Type I SS and Type II SS measure the contribution of a variable to the reduction in SSE. Type I SS measure the reduction in SSE as that variable is entered into the model in sequence. Type II SS are the increment in SSE that results from removing the variable from the full model. Type II SS are equivalent to the Type III and Type IV SS reported in the GLM procedure. If Type II SS are used in the numerator of an F test, the test is equivalent to the t test for the hypothesis that the parameter is zero. In polynomial models, Type I SS measure the contribution of each polynomial term after it is orthogonalized to the previous terms in the model. The four types of SS are described in Chapter 15, "The Four Types of Estimable Functions."

Coefficient of Determination

The coefficient of determination in a regression model, also known as the R-square statistic (R^2), measures the proportion of variability in the response that is explained by the regressor variables. In a linear regression model with intercept, R^2 is defined as

$$R^2 = 1 - \frac{\text{SSE}}{\text{SST}}$$

where SSE is the residual (error) sum of squares and SST is the total sum of squares corrected for the mean. The adjusted R^2 statistic is an alternative to R^2 that takes into account the number of parameters in the model. This statistic is calculated as

$$\text{ADJRSQ} = 1 - \frac{n-i}{n-p}\left(1 - R^2\right)$$

where n is the number of observations used to fit the model, p is the number of parameters in the model (including the intercept), and i is 1 if the model includes an intercept term, and 0 otherwise.

R^2 statistics also play an important indirect role in regression calculations. For example, the proportion of variability explained by regressing all other variables in a model on a particular regressor can provide insights into the interrelationship among the regressors.

Tolerances and variance inflation factors measure the strength of interrelationships among the regressor variables in the model. If all variables are orthogonal to each other, both tolerance and variance inflation are 1. If a variable is very closely related to other variables, the tolerance approaches 0 and the variance inflation gets very large. Tolerance (TOL) is 1 minus the R^2 that results from the regression of the other variables in the model on that regressor. Variance inflation (VIF) is the diagonal of $(\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}$, if $(\mathbf{X}'\mathbf{W}\mathbf{X})$ is scaled to correlation form. The statistics are related as

$$\text{VIF} = \frac{1}{\text{TOL}}$$

Explicit and Implicit Intercepts

A linear model contains an *explicit* intercept if the $\mathbf{X}$ matrix contains a column whose nonzero values do not vary, typically a column of ones. Many SAS/STAT procedures automatically add this column of ones as the first column in the $\mathbf{X}$ matrix. Procedures that support a NOINT option in the MODEL statement provide the capability to suppress the automatic addition of the intercept column.

In general, models without intercept should be the exception, especially if your model does not contain classification variables. An overall intercept is provided in many models to adjust for the grand total or overall mean in your data. A simple linear regression without intercept, such as

$$\text{E}[Y_i] = \beta_1 x_i + \epsilon_i$$

assumes that Y has mean zero if X takes on the value zero. This might not be a reasonable assumption.

If you explicitly suppress the intercept in a statistical model, the calculation and interpretation of your results can change. For example, the exclusion of the intercept in the following PROC REG

statements leads to a different calculation of the R-square statistic. It also affects the calculation of the sum of squares in the analysis of variance for the model. For example, the model and error sum of squares add up to the uncorrected total sum of squares in the absence of an intercept.

```
proc reg;
   model y = x / noint;
quit;
```

Many statistical models contain an *implicit* intercept. This occurs when a linear function of one or more columns in the $\mathbf{X}$ matrix produces a column of constant, nonzero values. For example, the presence of a CLASS variable in the GLM parameterization always implies an intercept in the model. If a model contains an implicit intercept, adding an intercept to the model does not alter the quality of the model fit, but it changes the interpretation (and number) of the parameter estimates.

The way in which the implicit intercept is detected and accounted for in the analysis depends on the procedure. For example, the following statements in the GLM procedure lead to an implied intercept:

```
proc glm;
   class a;
   model y = a / solution noint;
run;
```

Whereas the analysis of variance table uses the uncorrected total sum of squares (due to the NOINT option), the implied intercept does not lead to a redefinition or recalculation of the R-square statistic (compared to the model without the NOINT option). Also, because the intercept is implied by the presence of the CLASS variable a in the model, the same error sum of squares results whether the NOINT option is specified or not.

A different approach is taken, for example, by the TRANSREG procedure. The ZERO=NONE option in the CLASS parameterization of the following statements leads to an implicit intercept model:

```
proc transreg;
   model ide(y) = class(a / zero=none) / ss2;
run;
```

The analysis of variance table or the regression fit statistics are not affected in the TRANSREG procedure. Only the interpretation of the parameter estimates changes because of the way in which the intercept is accounted for in the model.

Implied intercepts not only occur when classification effects are present in the model. They also occur with B-splines and other sets of constructed columns.

Models Not of Full Rank

If the $\mathbf{X}$ matrix is not of full rank, then a generalized inverse can be used to solve the normal equations to minimize the SSE:

$$\widehat{\boldsymbol{\beta}} = \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-}\mathbf{X}'\mathbf{W}\mathbf{y}$$

However, these estimates are not unique since there are an infinite number of solutions corresponding to different generalized inverses. PROC REG and other regression procedures choose a nonzero solution for all variables that are linearly independent of previous variables and a zero solution for other variables. This corresponds to using a generalized inverse in the normal equations, and the expected values of the estimates are the Hermite normal form of $\mathbf{X}'\mathbf{W}\mathbf{X}$ multiplied by the true parameters:

$$\mathrm{E}\left[\widehat{\boldsymbol{\beta}}\right] = \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-}\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)\boldsymbol{\beta}$$

Degrees of freedom for the estimates that correspond to singularities are not counted (reported as zero). The hypotheses that are not testable have t tests displayed as missing. The message that the model is not of full rank includes a display of the relations that exist in the matrix.

See the sections "Generalized Inverse Matrices" and "Linear Model Theory" in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," on the nature and construction of generalized inverses and their importance for statistical inference in linear models.

Predicted and Residual Values

After the model has been fit, predicted and residual values are usually calculated, graphed, and output. The predicted values are calculated from the estimated regression equation; the raw residuals are calculated as the observed minus the predicted value. Often other forms of residuals are used for model diagnostics, such as studentized or cumulative residuals. Some procedures can calculate standard errors of residuals, predicted mean values, and individual predicted values.

Consider the ith observation where $\mathbf{x}_i'$ is the row of regressors, $\widehat{\boldsymbol{\beta}}$ is the vector of parameter estimates, and s^2 is the estimate of the residual variance (the mean squared error). The *leverage* value of the ith observation is defined as

$$h_i = w_i \mathbf{x}_i' \left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-1} \mathbf{x}_i$$

where $\mathbf{X}$ is the design matrix for the observed data, $\mathbf{x}_i'$ is an arbitrary regressor vector (possibly but not necessarily a row of $\mathbf{X}$), $\mathbf{W}$ is a diagonal matrix with the observed weights on the diagonal, and w_i is the weight corresponding to $\mathbf{x}_i'$.

Then the predicted mean and the standard error of the predicted mean are

$$\begin{aligned} \widehat{y}_i &= \mathbf{x}_i'\widehat{\boldsymbol{\beta}} \\ \mathrm{STDERR}(\widehat{y}_i) &= \sqrt{s^2 h_i / w_i} \end{aligned}$$

The standard error of the individual (future) predicted value y_i is

$$\mathrm{STDERR}(y_i) = \sqrt{s^2(1 + h_i)/w_i}$$

If the predictor vector $\mathbf{x}_i$ corresponds to an observation in the analysis data, then the raw residual for that observation and the standard error of the raw residual are defined as

$$\begin{aligned} \mathrm{RESID}_i &= y_i - \mathbf{x}_i'\widehat{\boldsymbol{\beta}} \\ \mathrm{STDERR}(\mathrm{RESID}_i) &= \sqrt{s^2(1 - h_i)/w_i} \end{aligned}$$

The *studentized residual* is the ratio of the raw residual and its estimated standard error. Symbolically,

$$\text{STUDENT}_i = \frac{\text{RESID}_i}{\text{STDERR}(\text{RESID}_i)}$$

There are two kinds of intervals involving predicted values that are associated with a measure of confidence: the *confidence* interval for the mean value of the response and the *prediction* (or *forecasting*) interval for an individual observation. As discussed in the section "Mean Squared Error" in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," both intervals are based on the mean squared error of predicting a target based on the result of the model fit. The difference in the expressions for the confidence interval and the prediction interval comes about because the target of estimation is a constant in the case of the confidence interval (the mean of an observation) and the target is a random variable in the case of the prediction interval (a new observation).

For example, you can construct a confidence interval for the ith observation that contains the true mean value of the response with probability $1-\alpha$. The upper and lower limits of the confidence interval for the mean value are

$$\begin{aligned}\text{LowerM} &= \mathbf{x}_i'\widehat{\boldsymbol{\beta}} - t_{\alpha/2,\nu}\sqrt{s^2 h_i / w_i} \\ \text{UpperM} &= \mathbf{x}_i'\widehat{\boldsymbol{\beta}} + t_{\alpha/2,\nu}\sqrt{s^2 h_i / w_i}\end{aligned}$$

where $t_{\alpha/2,\nu}$ is the tabulated t quantile with degrees of freedom equal to the degrees of freedom for the mean squared error, $\nu = n - \text{rank}(\mathbf{X})$.

The limits for the prediction interval for an individual response are

$$\begin{aligned}\text{LowerI} &= \mathbf{x}_i'\widehat{\boldsymbol{\beta}} - t_{\alpha/2,\nu}\sqrt{s^2(1+h_i) / w_i} \\ \text{UpperI} &= \mathbf{x}_i'\widehat{\boldsymbol{\beta}} + t_{\alpha/2,\nu}\sqrt{s^2(1+h_i) / w_i}\end{aligned}$$

Influential observations are those that, according to various criteria, appear to have a large influence on the analysis. One measure of influence, Cook's D, measures the change to the estimates that results from deleting an observation:

$$\text{COOKD}_i = \frac{1}{k}\text{STUDENT}_i^2\left(\frac{\text{STDERR}(\widehat{y}_i)}{\text{STDERR}(\text{RESID}_i)}\right)^2$$

where k is the number of parameters in the model (including the intercept). For more information, see Cook (1977, 1979).

The *predicted residual* for observation i is defined as the residual for the ith observation that results from dropping the ith observation from the parameter estimates. The sum of squares of predicted residual errors is called the *PRESS statistic*:

$$\begin{aligned}\text{PRESID}_i &= \frac{\text{RESID}_i}{1-h_i} \\ \text{PRESS} &= \sum_{i=1}^{n} w_i \text{PRESID}_i^2\end{aligned}$$

Testing Linear Hypotheses

Testing of linear hypothesis based on estimable functions is discussed in the section "Test of Hypotheses" on page 66 in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," and the construction of special sets of estimable functions corresponding to Type I–Type IV hypotheses is discussed in Chapter 15, "The Four Types of Estimable Functions." In linear regression models, testing of general linear hypotheses follows along the same lines. Test statistics are usually formed based on sums of squares associated with the hypothesis in question. Furthermore, when $\mathbf{X}$ is of full rank—as is the case in many regression models—the consistency of the linear hypothesis is guaranteed.

Recall from Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," that the general form of a linear hypothesis for the parameters is $H\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{d}$, where $\mathbf{L}$ is $(q \times k)$, $\boldsymbol{\beta}$ is $(k \times 1)$, and $\mathbf{d}$ is $(q \times 1)$. To test this hypothesis, the linear function is taken with respect to the parameter estimates: $\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d}$. This linear function in $\widehat{\boldsymbol{\beta}}$ has variance

$$\mathrm{Var}\left[\mathbf{L}\widehat{\boldsymbol{\beta}}\right] = \mathbf{L}\mathrm{Var}[\widehat{\boldsymbol{\beta}}]\mathbf{L}' = \sigma^2\mathbf{L}\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-}\mathbf{L}'$$

The *sum of squares due to the hypothesis* is a simple quadratic form:

$$\mathrm{SS}(H) = \mathrm{SS}(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d}) = \left(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d}\right)'\left(\mathbf{L}\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-}\mathbf{L}'\right)^{-1}\left(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{d}\right)$$

If this hypothesis is testable, then $\mathrm{SS}(H)$ can be used in the numerator of an F statistic:

$$F = \frac{\mathrm{SS}(H)/q}{s^2} = \frac{\mathrm{SS}(\mathbf{L}\mathbf{b} - \mathbf{d})/q}{s^2}$$

If $\widehat{\boldsymbol{\beta}}$ is normally distributed, which follows as a consequence of normally distributed model errors, then this statistic follows an F distribution with q numerator degrees of freedom and $n - \mathrm{rank}(\mathbf{X})$ denominator degrees of freedom. Note that it was assumed in this derivation that $\mathbf{L}$ is of full row rank q.

Multivariate Tests

Multivariate hypotheses involve several dependent variables in the form

$$H\colon \mathbf{L}\boldsymbol{\beta}\mathbf{M} = \mathbf{d}$$

where $\mathbf{L}$ is a linear function on the regressor side, $\boldsymbol{\beta}$ is a matrix of parameters, $\mathbf{M}$ is a linear function on the dependent side, and $\mathbf{d}$ is a matrix of constants. The special case (handled by PROC REG) in which the constants are the same for each dependent variable is expressed as

$$(\mathbf{L}\boldsymbol{\beta} - \mathbf{c}\mathbf{j})\mathbf{M} = \mathbf{0}$$

where $\mathbf{c}$ is a column vector of constants and $\mathbf{j}$ is a row vector of 1s. The special case in which the constants are 0 is then

$$\mathbf{L}\boldsymbol{\beta}\mathbf{M} = \mathbf{0}$$

These multivariate tests are covered in detail in Morrison (1976), Timm (1975), Mardia, Kent, and Bibby (1979), Bock (1975), and other works cited in Chapter 9, "Introduction to Multivariate Procedures."

Notice that in contrast to the tests discussed in the preceding section, $\boldsymbol{\beta}$ here is a matrix of parameter estimates. Suppose that the matrix of estimates is denoted as $\mathbf{B}$. To test the multivariate hypothesis, construct two matrices, $\mathbf{H}$ and $\mathbf{E}$, that correspond to the numerator and denominator of a univariate F test:

$$\begin{aligned}\mathbf{H} &= \mathbf{M}'(\mathbf{LB}-\mathbf{cj})'(\mathbf{L}(\mathbf{X}'\mathbf{WX})^{-}\mathbf{L}')^{-1}(\mathbf{LB}-\mathbf{cj})\mathbf{M} \\ \mathbf{E} &= \mathbf{M}'\left(\mathbf{Y}'\mathbf{WY}-\mathbf{B}'(\mathbf{X}'\mathbf{WX})\mathbf{B}\right)\mathbf{M}\end{aligned}$$

Four test statistics, based on the eigenvalues of $\mathbf{E}^{-1}\mathbf{H}$ or $(\mathbf{E}+\mathbf{H})^{-1}\mathbf{H}$, are formed. Let λ_i be the ordered eigenvalues of $\mathbf{E}^{-1}\mathbf{H}$ (if the inverse exists), and let ξ_i be the ordered eigenvalues of $(\mathbf{E}+\mathbf{H})^{-1}\mathbf{H}$. It happens that $\xi_i = \lambda_i/(1+\lambda_i)$ and $\lambda_i = \xi_i/(1-\xi_i)$, and it turns out that $\rho_i = \sqrt{\xi_i}$ is the ith canonical correlation.

Let p be the rank of $(\mathbf{H}+\mathbf{E})$, which is less than or equal to the number of columns of $\mathbf{M}$. Let q be the rank of $\mathbf{L}(\mathbf{X}'\mathbf{WX})^{-}\mathbf{L}'$. Let v be the error degrees of freedom and $s = \min(p,q)$. Let $m = (|p-q|-1)/2$, and let $n = (v-p-1)/2$. Then the following statistics test the multivariate hypothesis in various ways, and their p-values can be approximated by F distributions. Note that in the special case that the rank of $\mathbf{H}$ is 1, all of these F statistics will be the same and the corresponding p-values will in fact be exact, since in this case the hypothesis is really univariate.

Wilks' Lambda

If

$$\Lambda = \frac{\det(\mathbf{E})}{\det(\mathbf{H}+\mathbf{E})} = \prod_{i=1}^{n}\frac{1}{1+\lambda_i} = \prod_{i=1}^{n}(1-\xi_i)$$

then

$$F = \frac{1-\Lambda^{1/t}}{\Lambda^{1/t}}\cdot\frac{rt-2u}{pq}$$

is approximately F distributed, where

$$\begin{aligned} r &= v - \frac{p-q+1}{2} \\ u &= \frac{pq-2}{4} \\ t &= \begin{cases} \sqrt{\frac{p^2q^2-4}{p^2+q^2-5}} & \text{if } p^2+q^2-5>0 \\ 1 & \text{otherwise} \end{cases}\end{aligned}$$

The degrees of freedom are pq and $rt-2u$. The distribution is exact if $\min(p,q)\le 2$. (See Rao 1973, p. 556.)

Pillai's Trace

If

$$\mathbf{V} = \text{trace}\left(\mathbf{H}(\mathbf{H}+\mathbf{E})^{-1}\right) = \sum_{i=1}^{n} \frac{\lambda_i}{1+\lambda_i} = \sum_{i=1}^{n} \xi_i$$

then

$$F = \frac{2n+s+1}{2m+s+1} \cdot \frac{\mathbf{V}}{s-\mathbf{V}}$$

is approximately F distributed with $s(2m+s+1)$ and $s(2n+s+1)$ degrees of freedom.

Hotelling-Lawley Trace

If

$$U = \text{trace}\left(\mathbf{E}^{-1}\mathbf{H}\right) = \sum_{i=1}^{n} \lambda_i = \sum_{i=1}^{n} \frac{\xi_i}{1-\xi_i}$$

then for $n > 0$

$$F = (U/c)((4+(pq+2)/(b-1))/(pq))$$

is approximately F distributed with pq and $4+(pq+2)/(b-1)$ degrees of freedom, where $b = (p+2n)(q+2n)/(2(2n+1)(n-1))$ and $c = (2+(pq+2)/(b-1))/(2n)$; while for $n \leq 0$

$$F = \frac{2(sn+1)\mathbf{U}}{s^2(2m+s+1)}$$

is approximately F with $s(2m+s+1)$ and $2(sn+1)$ degrees of freedom.

Roy's Maximum Root

If $\Theta = \lambda_1$, then

$$F = \Theta\frac{v-r+q}{r}$$

where $r = \max(p,q)$ is an upper bound on F that yields a lower bound on the significance level. Degrees of freedom are r for the numerator and $v-r+q$ for the denominator.

Tables of critical values for these statistics are found in Pillai (1960).

Exact Multivariate Tests

Beginning with SAS 9, if you specify the MSTAT=EXACT option in the appropriate statement, p-values for three of the four tests are computed exactly (Wilks' lambda, the Hotelling-Lawley

trace, and Roy's greatest root), and the p-values for the fourth (Pillai's trace) are based on an F approximation that is more accurate (but occasionally slightly more liberal) than the default. The exact p-values for Roy's greatest root benefit the most, since in this case the F approximation provides only a lower bound for the p-value. If you use the F-based p-value for this test in the usual way, declaring a test significant if $p < 0.05$, then your decisions might be very liberal. For example, instead of the nominal 5% Type I error rate, such a procedure can easily have an actual Type I error rate in excess of 30%. By contrast, basing such a procedure on the exact p-values will result in the appropriate 5% Type I error rate, under the usual regression assumptions.

The MSTAT=EXACT option is supported in the ANOVA, CANCORR, CANDISC, GLM, and REG procedures.

The exact p-values are based on the following sources:

- **Wilks' lambda:** Lee (1972), Davis (1979)
- **Pillai's trace:** Muller (1998)
- **Hotelling-Lawley trace:** Davis (1970), Davis (1980)
- **Roy's greatest root:** Davis (1972), Pillai and Flury (1984)

Note that, although the MSTAT=EXACT p-value for Pillai's trace is still approximate, it has "substantially greater accuracy" than the default approximation (Muller 1998).

Since most of the MSTAT=EXACT p-values are not based on the F distribution, the columns in the multivariate tests table corresponding to this approximation—in particular, the F value and the numerator and denominator degrees of freedom—are no longer displayed, and the column containing the p-values is labeled "P Value" instead of "Pr > F." Suppose, for example, you use the following PROC ANOVA statements to perform a multivariate analysis of an archaeological data set:

```
data Skulls;
   input Loc $20. Basal Occ Max;
   datalines;
Minas Graes, Brazil  2.068 2.070 1.580

                NOTE: F Statistic for Wilks' Lambda is exact.
```

If you specify MSTAT=EXACT in the MANOVA statement, as in the following statements, then the displayed output is the much simpler table shown in Figure 4.6.

```
proc anova data=Skulls;
   class Loc;
   model Basal Occ Max = Loc / nouni;
   manova h=Loc / mstat=exact;
   ods select MultStat;
run;
```

Figure 4.6 Multivariate Tests with MSTAT=EXACT

The ANOVA Procedure
Multivariate Analysis of Variance

MANOVA Tests for the Hypothesis of No Overall Loc Effect
H = Anova SSCP Matrix for Loc
E = Error SSCP Matrix

S=2 M=0 N=3

Statistic	Value	P-Value
Wilks' Lambda	0.60143661	0.6032
Pillai's Trace	0.44702843	0.5521
Hotelling-Lawley Trace	0.58210348	0.6337
Roy's Greatest Root	0.35530890	0.7641

Notice that the p-value for Roy's greatest root is substantially larger in the new table, and correspondingly more in line with the p-values for the other tests.

If you reference the underlying ODS output object for the table of multivariate statistics, it is important to note that its structure does not depend on the value of the MSTAT= specification. In particular, it always contains columns corresponding to both the default MSTAT=FAPPROX and the MSTAT=EXACT tests. Moreover, since the MSTAT=FAPPROX tests are relatively cheap to compute, the columns corresponding to them are always filled in, even though they are not displayed when you specify MSTAT=EXACT. On the other hand, for MSTAT=FAPPROX (which is the default), the column of exact p-values contains missing values, and is not displayed.

Comments on Interpreting Regression Statistics

In most applications, regression models are merely useful approximations. Reality is often so complicated that you cannot know what the true model is. You might have to choose a model more on the basis of what variables can be measured and what kinds of models can be estimated than on a rigorous theory that explains how the universe really works. However, even in cases where theory is lacking, a regression model can be an excellent predictor of the response if the model is carefully formulated from a large sample. The interpretation of statistics such as parameter estimates might nevertheless be highly problematic.

Statisticians usually use the word "prediction" in a technical sense. *Prediction* in this sense does not refer to "predicting the future" (statisticians call that *forecasting*) but rather to guessing the response from the values of the regressors in an observation taken under the same circumstances as the sample from which the regression equation was estimated. If you developed a regression model for predicting consumer preferences in 1977, it might not give very good predictions in 2007 no matter how well it did in 1977. If it is the future you want to predict, your model must include whatever relevant factors might change over time. If the process you are studying does in fact change over time, you must take observations at several, perhaps many, different times. Analysis of such data is the province of SAS/STAT procedures such as MIXED and GLIMMIX and SAS/ETS

procedures such as AUTOREG and STATESPACE. See Chapter 38, "The GLIMMIX Procedure," and Chapter 56, "The MIXED Procedure," for more information about modeling serial correlation in longitudinal, repeated measures, or time series data with SAS/STAT mixed modeling procedures. See the *SAS/ETS User's Guide* for more information about the AUTOREG and STATESPACE procedures.

The comments in the rest of this section are directed toward linear least squares regression. For more detailed discussions of the interpretation of regression statistics, see Darlington (1968), Mosteller and Tukey (1977), Weisberg (1985), and Younger (1979).

Interpreting Parameter Estimates from a Controlled Experiment

Parameter estimates are easiest to interpret in a controlled experiment in which the regressors are manipulated independently of each other. In a well-designed experiment, such as a randomized factorial design with replications in each cell, you can use lack-of-fit tests and estimates of the standard error of prediction to determine whether the model describes the experimental process with adequate precision. If so, a regression coefficient estimates the amount by which the mean response changes when the regressor is changed by one unit while all the other regressors are unchanged. However, if the model involves interactions or polynomial terms, it might not be possible to interpret individual regression coefficients. For example, if the equation includes both linear and quadratic terms for a given variable, you cannot physically change the value of the linear term without also changing the value of the quadratic term. Sometimes it might be possible to recode the regressors, such as by using orthogonal polynomials, to simplify the interpretation.

If the nonstatistical aspects of the experiment are also treated with sufficient care (such as the use of placebos and double blinds), then you can state conclusions in causal terms; that is, this change in a regressor causes that change in the response. Causality can never be inferred from statistical results alone or from an observational study.

If the model you fit is not the true model, then the parameter estimates can depend strongly on the particular values of the regressors used in the experiment. For example, if the response is actually a quadratic function of a regressor but you fit a linear function, the estimated slope can be a large negative value if you use only small values of the regressor, a large positive value if you use only large values of the regressor, or near zero if you use both large and small regressor values. When you report the results of an experiment, it is important to include the values of the regressors. It is also important to avoid extrapolating the regression equation outside the range of regressors in the sample.

Interpreting Parameter Estimates from an Observational Study

In an observational study, parameter estimates can be interpreted as the expected difference in response of two observations that differ by one unit on the regressor in question and that have the same values for all other regressors. You cannot make inferences about "changes" in an observational study since you have not actually changed anything. It might not be possible even in principle to change one regressor independently of all the others. Neither can you draw conclusions about causality without experimental manipulation.

If you conduct an observational study and you do not know the true form of the model, interpretation of parameter estimates becomes even more convoluted. A coefficient must then be interpreted as an average over the sampled population of expected differences in response of observations that differ by one unit on only one regressor. The considerations that are discussed under controlled experiments for which the true model is not known also apply.

Comparing Parameter Estimates

Two coefficients in the same model can be directly compared only if the regressors are measured in the same units. You can make any coefficient large or small just by changing the units. If you convert a regressor from feet to miles, the parameter estimate is multiplied by 5280.

Sometimes standardized regression coefficients are used to compare the effects of regressors measured in different units. Standardized estimates are defined as the estimates that result when all variables are standardized to a mean of 0 and a variance of 1. Standardized estimates are computed by multiplying the original estimates by the sample standard deviation of the regressor variable and dividing by the sample standard deviation of the dependent variable.

Standardizing the variables effectively makes the standard deviation the unit of measurement. This makes sense only if the standard deviation is a meaningful quantity, which usually is the case only if the observations are sampled from a well-defined population. In a controlled experiment, the standard deviation of a regressor depends on the values of the regressor selected by the experimenter. Thus, you can make a standardized regression coefficient large by using a large range of values for the regressor.

In some applications you might be able to compare regression coefficients in terms of the practical range of variation of a regressor. Suppose that each independent variable in an industrial process can be set to values only within a certain range. You can rescale the variables so that the smallest possible value is zero and the largest possible value is one. Then the unit of measurement for each regressor is the maximum possible range of the regressor, and the parameter estimates are comparable in that sense. Another possibility is to scale the regressors in terms of the cost of setting a regressor to a particular value, so comparisons can be made in monetary terms.

Correlated Regressors

In an experiment, you can often select values for the regressors such that the regressors are orthogonal (not correlated with each other). Orthogonal designs have enormous advantages in interpretation. With orthogonal regressors, the parameter estimate for a given regressor does not depend on which other regressors are included in the model, although other statistics such as standard errors and p-values might change.

If the regressors are correlated, it becomes difficult to disentangle the effects of one regressor from another, and the parameter estimates can be highly dependent on which regressors are used in the model. Two correlated regressors might be nonsignificant when tested separately but highly significant when considered together. If two regressors have a correlation of 1.0, it is impossible to separate their effects.

It might be possible to recode correlated regressors to make interpretation easier. For example, if X and Y are highly correlated, they could be replaced in a linear regression by $X + Y$ and $X - Y$ without changing the fit of the model or statistics for other regressors.

Errors in the Regressors

If there is error in the measurements of the regressors, the parameter estimates must be interpreted with respect to the measured values of the regressors, not the true values. A regressor might be statistically nonsignificant when measured with error even though it would have been highly significant if measured accurately.

Probability Values (*p*-Values)

Probability values (p-values) do not necessarily measure the importance of a regressor. An important regressor can have a large (nonsignificant) p-value if the sample is small, if the regressor is measured over a narrow range, if there are large measurement errors, or if another closely related regressor is included in the equation. An unimportant regressor can have a very small p-value in a large sample. Computing a confidence interval for a parameter estimate gives you more useful information than just looking at the p-value, but confidence intervals do not solve problems of measurement errors in the regressors or highly correlated regressors.

Interpreting R^2

R^2 is usually defined as the proportion of variance of the response that is predictable from (can be explained by) the regressor variables. It might be easier to interpret $\sqrt{1 - R^2}$, which is approximately the factor by which the standard error of prediction is reduced by the introduction of the regressor variables.

R^2 is easiest to interpret when the observations, including the values of both the regressors and response, are randomly sampled from a well-defined population. Nonrandom sampling can greatly distort R^2. For example, excessively large values of R^2 can be obtained by omitting from the sample observations with regressor values near the mean.

In a controlled experiment, R^2 depends on the values chosen for the regressors. A wide range of regressor values generally yields a larger R^2 than a narrow range. In comparing the results of two experiments on the same variables but with different ranges for the regressors, you should look at the standard error of prediction (root mean square error) rather than R^2.

Whether a given R^2 value is considered to be large or small depends on the context of the particular study. A social scientist might consider an R^2 of 0.30 to be large, while a physicist might consider 0.98 to be small.

You can always get an R^2 arbitrarily close to 1.0 by including a large number of completely unrelated regressors in the equation. If the number of regressors is close to the sample size, R^2 is very biased. In such cases, the adjusted R^2 and related statistics discussed by Darlington (1968) are less misleading.

If you fit many different models and choose the model with the largest R^2, all the statistics are biased and the p-values for the parameter estimates are not valid. Caution must be taken with the interpretation of R^2 for models with no intercept term. As a general rule, no-intercept models should be fit only when theoretical justification exists and the data appear to fit a no-intercept framework. The R^2 in those cases is measuring something different (see Kvalseth 1985).

Incorrect Data Values

All regression statistics can be seriously distorted by a single incorrect data value. A decimal point in the wrong place can completely change the parameter estimates, R^2, and other statistics. It is important to check your data for outliers and influential observations. Residual and influence diagnostics are particularly useful in this regard.

When a data point is declared as influential or as outlying as measured by a particular model diagnostic, this does not imply that the case should be excluded from the analysis. The label "outlier" does not have a negative connotation. It means that a data point is unusual with respect to the model at hand. If your data follow a strong curved trend and you fit a linear regression, then many data points might be labeled as outliers not because they are "bad" or incorrect data values, but because your model is not appropriate.

Overview: Analysis of Variance Procedures

The statistical term "analyis of variance" is used in a variety of circumstances in statistical theory and applications. In the *narrowest* sense, and the original sense of the phrase, it signifies a decomposition of a variance into contributing components. This was the sense used by R. A. Fisher when he defined the term to mean the expression of genetic variance as a sum of variance components due to environment, heredity, and so forth:

$$\sigma^2 = \sigma_1^2 + \sigma_2^2 + \cdots + \sigma_p^2$$

In this sense of the term, the SAS/STAT procedures that fit variance component models, such as the GLIMMIX, HPMIXED, MIXED, NESTED, and VARCOMP procedures, are "true" analysis of variance procedures.

Analysis of variance methodology in a slightly broader sense—and the sense most frequently understood today—applies the idea of an additive decomposition of variance to an additive decomposition of *sums of squares*, whose expected values are functionally related to components of variation. A collection of sums of squares that measure and can be used for inference about meaningful features of a model is called a *sum of squares analysis of variance*, whether or not such a collection is an additive decomposition. In a linear model, the decomposition of sums of squares can be expressed in terms of projections onto orthogonal subspaces spanned by the columns of the design matrix $\mathbf{X}$. This is the general approach followed in the section "Analysis of Variance" on page 63 in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software." Depending on the statistical question at hand, the projections can be formulated based on estimable functions, with different types of estimable functions giving rise to different types of sums of squares. Note that not all sum of squares analyses necessarily correspond to additive decompositions. For example, the Type III sums of squares often test hypotheses about the model that are more meaningful than those corresponding to the Type I sums of squares. But while the Type I sums of squares additively decompose the sum of squares due to all model contributions, the Type III sums of squares do not necessarily add up to any useful quantity. The four types of estimable functions in SAS/STAT software, their interpretation, and their construction are discussed in Chapter 15, "The Four Types of Estimable Functions." The application of sum of squares analyses is not necessarily limited to models with classification effects (factors). The methodology also applies to linear regression models that contain only continuous regressor variables.

An even broader sense of the term "analysis of variance" pertains to statistical models that contain classification effects (factors), and in particular, to models that contain *only* classification effects. Any statistical approach that measures features of such a model and can be used for inference is called a *general analysis of variance*. Thus the procedures for general analysis of variance in SAS/STAT are considered to be those that can fit statistical models containing factors, whether the data are experimental or observational. Some procedures for general analysis of variance have a statistical estimation principle that gives rise to a sum of squares analysis as discussed previously; others express a factor's contribution to the model fit in some other form. Note that this view of analysis of variance includes, for example, maximum likelihood estimation in generalized linear models with the GENMOD procedure, restricted maximum likelihood estimation in linear mixed models with the MIXED procedure, the estimation of variance components with the VARCOMP procedure, the comparison of means of groups with the TTEST procedure, and the nonparametric analysis of rank scores with the NPAR1WAY procedure, and so on.

In summary, analysis of variance in the contemporary sense of statistical modeling and analysis is more aptly described as *analysis of variation*, the study of the influences on the variation of a phenomenon. This can take, for example, the following forms:

- an analysis of variance table based on sums of squares followed by more specific inquiries into the relationship among factors and their levels
- a deviance decomposition in a generalized linear model
- a series of Type III tests followed by comparisons of least squares means in a mixed model

Procedures That Perform Sum of Squares Analysis of Variance

The flagship procedure in SAS/STAT software for linear modeling with sum of squares analysis techniques is the GLM procedure. It handles most standard analysis of variance problems. The following list provides descriptions of PROC GLM and other procedures that are used for more specialized situations:

ANOVA — performs analysis of variance, multivariate analysis of variance, and repeated measures analysis of variance for *balanced* designs. PROC ANOVA also performs multiple comparison tests on arithmetic means.

GLM — performs analysis of variance, regression, analysis of covariance, repeated measures analysis, and multivariate analysis of variance. PROC GLM produces several diagnostic measures, performs tests for random effects, provides contrasts and estimates for customized hypothesis tests, provides tests for means adjusted for covariates, and performs multiple-comparison tests on both arithmetic and adjusted means.

LATTICE — computes the analysis of variance and analysis of simple covariance for data from an experiment with a lattice design. PROC LATTICE analyzes balanced square lattices, partially balanced square lattices, and some rectangular lattices.

MIXED — performs mixed model analysis of variance and repeated measures analysis of variance via covariance structure modeling. When you choose one of the method-of-moment estimation techniques, the MIXED procedure produces an analysis of variance table with sums of squares, mean squares, and expected mean squares. PROC MIXED constructs statistical tests and intervals, allows customized contrasts and estimates, and computes empirical Bayes predictions.

NESTED — performs analysis of variance and analysis of covariance for purely nested random models.

ORTHOREG — performs regression by using the Gentleman-Givens computational method. For ill-conditioned data, PROC ORTHOREG can produce more accurate parameter estimates than other procedures, such as PROC GLM. See Chapter 63, "The ORTHOREG Procedure," for more information.

VARCOMP — estimates variance components for random or mixed models. If you choose the METHOD=TYPE1 or METHOD=GRR option, the VARCOMP procedure produces an analysis of variance table with sums of squares that correspond to the random effects in your models.

TRANSREG — fits univariate and multivariate linear models, optionally with spline and other nonlinear transformations. Models include ordinary regression and ANOVA, multiple and multivariate regression, metric and nonmetric conjoint analysis, metric and nonmetric vector and ideal point preference mapping, redundancy analysis, canonical correlation, and response surface regression. See Chapter 90, "The TRANSREG Procedure," for more information.

Procedures That Perform General Analysis of Variance

Many procedures in SAS/STAT enable you to incorporate classification effects into your model and to perform statistical inferences for experimental factors and their interactions. These procedures do not necessarily rely on sums of squares decompositions to perform these inferences.

CATMOD	fits linear models and performs analysis of variance and repeated measures analysis of variance for categorical responses. See Chapter 8, "Introduction to Categorical Data Analysis Procedures," and Chapter 28, "The CATMOD Procedure," for more information.
GENMOD	fits generalized linear models. PROC GENMOD is especially suited for responses with discrete outcomes, and it performs logistic regression and Poisson regression as well as fitting generalized estimating equations for repeated measures data. Bayesian analysis capabilities for generalized linear models are also available with the GENMOD procedure. See Chapter 8, "Introduction to Categorical Data Analysis Procedures," and Chapter 37, "The GENMOD Procedure," for more information.
GLIMMIX	fits generalized linear mixed models by likelihood-based methods. PROC GLIMMIX offers many facilities for analyzing and comparing classification effects and their levels, including multiplicity-adjusted linear estimates. See Chapter 38, "The GLIMMIX Procedure," for more information.
LOGISTIC	fits logistic models for binomial and ordinal outcomes. PROC LOGISTIC provides a wide variety of model-building methods and computes numerous regression diagnostics. See Chapter 8, "Introduction to Categorical Data Analysis Procedures," and Chapter 51, "The LOGISTIC Procedure," for more information.
NPAR1WAY	performs nonparametric one-way analysis of rank scores.
TTEST	compares the means of two groups of observations.

The following section discusses procedures in SAS/STAT that compute analysis of variance in models with classification factors in the narrow sense—that is, they produce analysis of variance tables and form F tests based on sums of squares, mean squares, and expected mean squares.

The subsequent sections discuss procedures that perform statistical inference in models with classification effects in the broader sense.

The following section also presents an overview of some of the fundamental features of analysis of variance. Subsequent sections describe how this analysis is performed with procedures in SAS/STAT software. For more detail, see the chapters for the individual procedures. Additional sources are described in the section "References" on page 125.

Statistical Details for Analysis of Variance

From Sums of Squares to Linear Hypotheses

Analysis of variance (ANOVA) is a technique for analyzing data in which one or more *response* (or *dependent* or simply Y) variables are measured under various conditions identified by one or more classification variables. The combinations of levels for the classification variables form the cells of the design for the data. This design can be the result of a controlled experiment or the result of an observational study in which you observe factors and factor level combinations in an uncontrolled environment. For example, an experiment might measure weight change (the dependent variable) for men and women who participated in three different weight-loss programs. The six cells of the design are formed by the six combinations of gender (men, women) and program (A, B, C).

In an analysis of variance, the variation in the response is separated into variation attributable to differences between the classification variables and variation attributable to random error. An analysis of variance constructs tests to determine the significance of the classification effects. A typical goal in such an analysis is to compare means of the response variable for various combinations of the classification variables.

The least squares principle is central to computing sums of squares in analysis of variance models. Suppose that you are fitting the linear model $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$ and that the error terms satisfy the usual assumptions (uncorrelated, zero mean, homogeneous variance). Further, suppose that $\mathbf{X}$ is partitioned according to several model effects, $\mathbf{X} = [\mathbf{X}_1\ \mathbf{X}_2 \cdots \mathbf{X}_k]$. If $\widehat{\boldsymbol{\beta}}$ denotes the ordinary least squares solution for this model, then the sum of squares attributable to the overall model can be written as

$$\text{SSM} = \widehat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y} = \mathbf{Y}'\mathbf{H}\mathbf{Y}$$

where $\mathbf{H}$ is the "hat" matrix $\mathbf{H} = \mathbf{X}(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'$. (This model sum of squares is not yet corrected for the presence of an explicit or implied intercept. This adjustment would consist of subtracting $n\overline{Y}^2$ from SSM.) Because of the properties of the hat matrix $\mathbf{H}$, you can write $\mathbf{X}' = \mathbf{X}'\mathbf{H}$ and $\mathbf{H}\mathbf{X} = \mathbf{X}$. The (uncorrected) model sum of squares thus can also be written as

$$\text{SSM} = \widehat{\boldsymbol{\beta}}'(\mathbf{X}'\mathbf{X})\widehat{\boldsymbol{\beta}}$$

This step is significant, because it demonstrates that sums of squares can be identified with quadratic functions in the least squares coefficients. The generalization of this idea is to do the following:

- consider hypotheses of interest in an analysis of variance model
- express the hypotheses in terms of linear estimable functions of the parameters
- compute the sums of squares associated with the estimable function
- construct statistical tests based on the sums of squares

Decomposing a model sum of squares into sequential, additive components, testing the significance of experimental factors, comparing factor levels, and performing other statistical inferences fall within this generalization. Suppose that $\mathbf{L}\boldsymbol{\beta}$ is an estimable function (see the section "Estimable Functions" on page 66 in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," and Chapter 15, "The Four Types of Estimable Functions," for details). The sum of squares associated with the hypothesis $H\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ is

$$\mathrm{SS}(H) = \mathrm{SS}(\mathbf{L}\boldsymbol{\beta} = \mathbf{0}) = \widehat{\boldsymbol{\beta}}'\mathbf{L}'\left(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}'\right)^{-1}\mathbf{L}\widehat{\boldsymbol{\beta}}$$

One application would be to form sums of squares associated with the different components of $\mathbf{X}$. For example, you can form a matrix $\mathbf{L}_2$ matrix such that $\mathbf{L}_2\boldsymbol{\beta} = \mathbf{0}$ tests the effect of adding the columns for $\mathbf{X}_2$ to an empty model or to test the effect of adding $\mathbf{X}_2$ to a model that already contains $\mathbf{X}_1$.

These sums of squares can also be expressed as the difference between two residual sums of squares, since $\mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ can be thought of as a (linear) restriction on the parameter estimates in the model:

$$\mathrm{SS}(H) = \mathrm{SSR}(\text{constrained model}) - \mathrm{SSR}(\text{full model})$$

If, in addition to the usual assumptions mentioned previously, the model errors are assumed to be normally distributed, then $\mathrm{SS}(H)$ follows a distribution that is proportional to a chi-square distribution. This fact, and the independence of $\mathrm{SS}(H)$ from the residual sum of squares, enables you to construct F tests based on sums of squares in least squares models.

The extension of sum of squares analysis of variance to general analysis of variance for classification effects depends on the fact that the distributional properties of quadratic forms in normal random variables are well understood. It is not necessary to first formulate a sum of squares to arrive at an exact or even approximate F test. The generalization of the expression for $\mathrm{SS}(H)$ is to form test statistics based on quadratic forms

$$\widehat{\boldsymbol{\beta}}'\mathbf{L}'\,\mathrm{Var}\left[\mathbf{L}\widehat{\boldsymbol{\beta}}\right]^{-1}\mathbf{L}\widehat{\boldsymbol{\beta}}$$

that follow a chi-square distribution if $\widehat{\boldsymbol{\beta}}$ is normally distributed.

Tests of Effects Based on Expected Mean Squares

Statistical tests in analysis of variance models can be constructed by comparing independent mean squares. To test a particular null hypothesis, you compute the ratio of two mean squares that have the same expected value under that hypothesis; if the ratio is much larger than 1, then that constitutes significant evidence against the null. In particular, in an analysis of variance model with fixed effects only, the expected value of each mean square has two components: quadratic functions of fixed parameters and random variation. For example, for a fixed effect called A, the expected value of its mean square is

$$\mathrm{E}[\mathrm{MS(A)}] = \mathrm{Q}(\boldsymbol{\beta}) + \sigma^2$$

where σ^2 is the common variance of the ϵ_i.

Under the null hypothesis of no A effect, the fixed portion Q($\boldsymbol{\beta}$) of the expected mean square is zero. This mean square is then compared to another mean square—say, MS(E)—that is independent of the first and has the expected value σ^2. The ratio of the two mean squares

$$F = \frac{\text{MS(A)}}{\text{MS(E)}}$$

has an F distribution under the null hypothesis.

When the null hypothesis is false, the numerator term has a larger expected value, but the expected value of the denominator remains the same. Thus, large F values lead to rejection of the null hypothesis. The probability of getting an F value at least as large as the one observed given that the null hypothesis is true is called the *significance probability value* (or the p-value). A p-value of less than 0.05, for example, indicates that data with *no* A effect will yield F values as large as the one observed less than 5% of the time. This is usually considered moderate evidence that there *is* a real A effect. Smaller p-values constitute even stronger evidence. Larger p-values indicate that the effect of interest is less than random noise. In this case, you can conclude either that there is no effect at all or that you do not have enough data to detect the differences being tested.

The actual pattern in expected mean squares of terms related to fixed quantities (Q($\boldsymbol{\beta}$)) and functions of variance components depends on which terms in your model are fixed effects and which terms are random effects. This has bearing on how F statistics can be constructed. In some instances, exact tests are not available, such as when a linear combination of expected mean squares is necessary to form a proper denominator for an F test and a Satterthwaite approximation is used to determine the degrees of freedom of the approximation. The GLM and MIXED procedures can generate tables of expected mean squares and compute degrees of freedom by Satterthwaite's method. The MIXED and GLIMMIX procedures can apply Satterthwaite approximations and other degrees-of-freedom computations more widely than in analysis of variance models. See the section "Fixed, Random, and Mixed Models" on page 35 in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," for a discussion of fixed versus random effects in statistical models.

Analysis of Variance for Fixed-Effect Models

PROC GLM for General Linear Models

The GLM procedure is the flagship tool for classical analysis of variance in SAS/STAT software. It performs analysis of variance by using least squares regression to fit general linear models. Among the statistical methods available in PROC GLM are regression, analysis of variance, analysis of covariance, multivariate analysis of variance, repeated measures analysis, and partial correlation analysis.

While PROC GLM can handle most common analysis of variance problems, other procedures are more efficient or have more features than PROC GLM for certain specialized analyses, or they can handle specialized models that PROC GLM cannot. Much of the rest of this chapter is concerned with comparing PROC GLM to other procedures.

PROC ANOVA for Balanced Designs

When you design an experiment, you choose how many experimental units to assign to each combination of levels (or cells) in the classification. In order to achieve good statistical properties and simplify the computations, you typically attempt to assign the same number of units to every cell in the design. Such designs are called *balanced designs*.

In SAS/STAT software, you can use the ANOVA procedure to perform analysis of variance for balanced data. The ANOVA procedure performs computations for analysis of variance that assume the balanced nature of the data. These computations are simpler and more efficient than the corresponding general computations performed by PROC GLM. Note that PROC ANOVA can be applied to certain designs that are not balanced in the strict sense of equal numbers of observations for all cells. These additional designs include all one-way models, regardless of how unbalanced the cell counts are, as well as Latin squares, which do not have data in all cells. In general, however, the ANOVA procedure is recommended only for balanced data. **If you use ANOVA to analyze a design that is not balanced, you must assume responsibility for the validity of the output.** You are responsible for recognizing incorrect results, which might include negative values reported for the sums of squares. If you are not certain that your data fit into a balanced design, then you probably need the framework of general linear models in the GLM procedure.

Comparing Group Means

The *F* test for a classification factor that has more than two levels tells you whether the level effects are significantly different from each other, but it does not tell you which levels differ from which other levels.

If the level comparisons are expressed through differences of the arithmetic cell means, you can use the MEANS statement in the GLM and ANOVA procedure for comparison. If arithmetic means are not appropriate for comparison, for example, because your data are unbalanced or means need to be adjusted for other model effects, then you can use the LSMEANS statement in the GLIMMIX, GLM, and MIXED procedures for level comparisons.

If you have specific comparisons in mind, you can use the CONTRAST statement in these procedures to make these comparisons. However, if you make many comparisons that use some given significance level (0.05, for example), you are more likely to make a type 1 error (incorrectly rejecting a hypothesis that the means are equal) simply because you have more chances to make the error.

Multiple-comparison methods give you more detailed information about the differences among the means and enable you to control error rates for a multitude of comparisons. A variety of multiple-comparison methods are available with the MEANS statement in both the ANOVA and GLM procedures, as well as the LSMEANS statement in the GLIMMIX, GLM, and MIXED procedures. These are described in detail in the section "Multiple Comparisons" on page 2514 in Chapter 39, "The GLM Procedure," and in Chapter 38, "The GLIMMIX Procedure," and Chapter 56, "The MIXED Procedure."

PROC TTEST for Comparing Two Groups

If you want to perform an analysis of variance and have only one classification variable with two levels, you can use PROC TTEST. In this special case, the results generated by PROC TTEST are equivalent to the results generated by PROC ANOVA or PROC GLM.

You can use PROC TTEST with balanced or unbalanced groups. In addition to the test assuming equal variances, PROC TTEST also performs a Satterthwaite test assuming unequal variances.

The TTEST procedure also performs equivalence tests, computes confidence limits, and supports both normal and lognormal data. If you have an AB/BA crossover design with no carryover effects, then you can use the TTEST procedure to analyze the treatment and period effects.

The PROC NPAR1WAY procedure performs nonparametric analogues to t tests. See Chapter 16, "Introduction to Nonparametric Analysis," for an overview and Chapter 62, "The NPAR1WAY Procedure," for details on PROC NPAR1WAY.

Analysis of Variance for Categorical Data and Generalized Linear Models

A *categorical variable* is defined as one that can assume only a limited number of values. For example, a person's gender is a categorical variable that can assume one of two values. Variables with levels that simply name a group are said to be measured on a *nominal scale*. Categorical variables can also be measured using an *ordinal scale*, which means that the levels of the variable are ordered in some way. For example, responses to an opinion poll are usually measured on an ordinal scale, with levels ranging from "strongly disagree" to "no opinion" to "strongly agree."

For two categorical variables, one measured on an ordinal scale and one measured on a nominal scale, you can assign scores to the levels of the ordinal variable and test whether the mean scores for the different levels of the nominal variable are significantly different. This process is analogous to performing an analysis of variance on continuous data, which can be performed by PROC CATMOD. If there are n nominal variables, rather than 1, then PROC CATMOD can perform an n-way analysis of variance of the mean scores.

For two categorical variables measured on a nominal scale, you can test whether the distribution of the first variable is significantly different for the levels of the second variable. This process is an analysis of variance of proportions, rather than means, and can be performed by PROC CATMOD. The corresponding n-way analysis of variance can also be performed by PROC CATMOD.

See Chapter 8, "Introduction to Categorical Data Analysis Procedures," and Chapter 28, "The CATMOD Procedure," for more information.

The GENMOD procedure uses maximum likelihood estimation to fit generalized linear models. This family includes models for categorical data such as logistic, probit, and complementary log-log regression for binomial data and Poisson regression for count data, as well as continuous models

such as ordinary linear regression, gamma, and inverse gaussian regression models. PROC GENMOD performs analysis of variance through likelihood ratio and Wald tests of fixed effects in generalized linear models, and provides contrasts and estimates for customized hypothesis tests. It performs analysis of repeated measures data with generalized estimating equation (GEE) methods.

See Chapter 8, "Introduction to Categorical Data Analysis Procedures," and Chapter 37, "The GENMOD Procedure," for more information.

Nonparametric Analysis of Variance

Analysis of variance is sensitive to the distribution of the error term. If the error term is not normally distributed, the statistics based on normality can be misleading. The traditional test statistics are called *parametric tests* because they depend on the specification of a certain probability distribution except for a set of free parameters. Parametric tests are said to depend on distributional assumptions. Nonparametric methods perform the tests without making any strict distributional assumptions. Even if the data are distributed normally, nonparametric methods are often almost as powerful as parametric methods.

Most nonparametric methods are based on taking the ranks of a variable and analyzing these ranks (or transformations of them) instead of the original values. The NPAR1WAY procedure performs a nonparametric one-way analysis of variance. Other nonparametric tests can be performed by taking ranks of the data (using the RANK procedure) and using a regular parametric procedure (such as GLM or ANOVA) to perform the analysis. Some of these techniques are outlined in the description of PROC RANK in *SAS Language Reference: Concepts* and in Conover and Iman (1981).

Constructing Analysis of Variance Designs

Analysis of variance is most often used for data from designed experiments. You can use the PLAN procedure to construct designs for many experiments. For example, PROC PLAN constructs designs for completely randomized experiments, randomized blocks, Latin squares, factorial experiments, certain balanced incomplete block designs, and balanced crossover designs.

Randomization, or randomly assigning experimental units to cells in a design and to treatments within a cell, is another important aspect of experimental design. For either a new or an existing design, you can use PROC PLAN to randomize the experimental plan.

Additional features for design of experiments are available in SAS/QC software. The FACTEX and OPTEX procedures can construct a wide variety of designs, including factorials, fractional factorials, and D-optimal or A-optimal designs. These procedures, as well as the ADX Interface, provide features for randomizing and replicating designs; saving the design in an output data set; and interactively changing the design by changing its size, use of blocking, or the search strategies used. For more information, see the *SAS/QC User's Guide*.

References

Analysis of variance was pioneered by R. A. Fisher (1925). For a general introduction to analysis of variance, see an intermediate statistical methods textbook such as Steel and Torrie (1980), Snedecor and Cochran (1980), Milliken and Johnson (1984), Mendenhall (1968), John (1971), Ott (1977), or Kirk (1968). A classic source is Scheffé (1959). Freund, Littell, and Spector (1991) bring together a treatment of these statistical methods and SAS/STAT software procedures. Schlotzhauer and Littell (1997) cover how to perform *t* tests and one-way analysis of variance with SAS/STAT procedures. Texts on linear models include Searle (1971), Graybill (1976), and Hocking (1984). Kennedy and Gentle (1980) survey the computing aspects. Other references include the following:

Overview: Mixed Modeling Procedures

A mixed model is a model that contains fixed and random effects. Since all statistical models contain some stochastic component and many models contain a residual error term, the preceding sentence deserves some clarification. The classical linear model $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$ contains the parameters $\boldsymbol{\beta}$ and the random vector $\boldsymbol{\epsilon}$. The vector $\boldsymbol{\beta}$ is a vector of fixed-effects parameters; its elements are unknown constants to be estimated from the data. A mixed model in the narrow sense also contains random effects, which are unobservable random variables. If the vector of random effects is denoted by $\boldsymbol{\gamma}$, then a linear mixed model can be written as

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$$

In a broader sense, mixed modeling and mixed model software is applied to special cases and generalizations of this model. For example, a purely random effects model, $\mathbf{Y} = \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$, or a correlated-error model, $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$, is subsumed by mixed modeling methodology.

Over the last few decades virtually every form of classical statistical model has been enhanced to accommodate random effecs. The linear model has been extended to the linear mixed model, generalized linear models have been extended to generalized linear mixed models, and so on. In parallel with this trend, SAS/STAT software offers a number of classical and contemporary mixed modeling tools. The aim of this chapter is to provide a brief introduction and comparison of the procedures for mixed model analysis (in the broad sense) in SAS/STAT software. The theory and application of mixed models are discussed at length in many monographs, including Milliken and Johnson (1992), Diggle, Liang, and Zeger (1994), Davidian and Giltinan (1995), Verbeke and Molenberghs (1997, 2000), Vonesh and Chinchilli (1997), Demidenko (2004), Molenberghs and Verbeke (2005), and Littell et al. (2006).

The following procedures in SAS/STAT software can perform mixed and random effects analysis to various degrees:

GLM — is primarily a tool for fitting linear models by least squares. The GLM procedure has some capabilities for including random effects in a statistical model and for performing statistical tests in mixed models. Repeated measures analysis is also possible with the GLM procedure, assuming unstructured covariance modeling. Estimation methods for covariance parameters in PROC GLM are based on the method of moments, and a portion of its output applies only to the fixed-effects model.

GLIMMIX — fits generalized linear mixed models by likelihood-based techniques. As in the MIXED procedure, covariance structures are modeled parametrically. The GLIMMIX procedure also has built-in capabilities for mixed model smoothing and joint modeling of heterocatanomic multivariate data.

HPMIXED — fits linear mixed models with simple covariance structures by sparse-matrix techniques. The experimental HPMIXED procedure is designed to handle large mixed model problems, such as the solution of mixed model equations with thousands of fixed-effects parameters and random-effects solutions.

LATTICE — computes the analysis of variance and analysis of simple covariance for data from an experiment with a lattice design. PROC LATTICE analyzes balanced square lattices, partially balanced square lattices, and some rectangular lattices. Analyses performed with the LATTICE procedure can also be performed as mixed models for complete or incomplete block designs with the MIXED procedure.

MIXED — performs mixed model analysis and repeated measures analysis by way of structured covariance models. The MIXED procedure estimates parameters by likelihood or moment-based techniques. You can compute mixed model diagnostics and influence analysis for observations and groups of observations. The default fitting method maximizes the restricted likelihood of the data under the assumption that the data are normally distributed and any missing data are missing at random. This general framework accommodates many common correlated-data methods, including variance component models and repeated measures analyses.

NESTED — performs analysis of variance and analysis of covariance for purely nested random-effects models. Because of its customized algorithms, PROC NESTED can be useful for large data sets with nested random effects.

NLMIXED fits mixed models in which the fixed or random effects enter nonlinearly. The NLMIXED procedure requires that you specify components of your mixed model via programming statements. Some built-in distributions enable you to easily specify the conditional distribution of the data, given the random effects.

VARCOMP estimates variance components for random or mixed models.

The focus in the remainder of this chapter is on procedures designed for random effects and mixed model analysis: the GLIMMIX, HPMIXED, MIXED, NESTED, NLMIXED, and VARCOMP procedures. The important distinction between fixed and random effects in statistical models is addressed in the section "Fixed, Random, and Mixed Models" on page 35, in Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software."

Types of Mixed Models

Linear, Generalized Linear, and Nonlinear Mixed Models

The linear model shown at the beginning of this chapter was incomplete because the distributional properties of the random variables and their relationship were not specified. In this section the specification of the models is completed and the three model classes, linear mixed models (LMM), generalized linear mixed models (GLMM), and nonlinear mixed models (NLMM), are delineated.

Linear Mixed Model

It is a defining characteristic of the class of linear mixed models (LMM), the class of generalized linear mixed models (GLMM), and the class of nonlinear mixed models (NLMM) that the random effects are normally distributed. In the linear mixed model, this also applies to the error term; furthermore, the errors and random effects are uncorrelated. The standard linear mixed model (LMM) is thus represented by the following assumptions:

$$\begin{aligned} \mathbf{Y} &= \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon} \\ \boldsymbol{\gamma} &\sim N(\mathbf{0}, \mathbf{G}) \\ \boldsymbol{\epsilon} &\sim N(\mathbf{0}, \mathbf{R}) \\ \mathrm{Cov}[\boldsymbol{\gamma}, \boldsymbol{\epsilon}] &= \mathbf{0} \end{aligned}$$

The matrices $\mathbf{G}$ and $\mathbf{R}$ are covariance matrices for the random effects and the random errors, respectively. A *G-side* random effect in a mixed model is an element of $\boldsymbol{\gamma}$, and its variance is expressed through an element in $\mathbf{G}$. An *R-side* random variable is an element of $\boldsymbol{\epsilon}$, and its variance is an element of $\mathbf{R}$. The GLIMMIX, HPMIXED, and MIXED procedures express the $\mathbf{G}$ and $\mathbf{R}$ matrix in parametric form—that is, you structure the covariance matrix, and its elements are expressed as functions of some parameters, known as the *covariance parameters* of the mixed models. The

NLMIXED procedure also parameterizes the covariance structure, but you accomplish this with programming statements rather than with predefined syntax.

Since the right side of the model equation contains multiple random variables, the stochastic properties of $\mathbf{Y}$ can be examined by conditioning on the random effects, or through the marginal distribution. Because of the linearity of the G-side random effects and the normality of the random variables, the conditional and the marginal distribution of the data are also normal with the following mean and variance matrices:

$$\begin{aligned}\mathbf{Y}|\boldsymbol{\gamma} &\sim N(\mathbf{X}\boldsymbol{\beta}+\mathbf{Z}\boldsymbol{\gamma},\mathbf{R})\\ \mathbf{Y} &\sim N(\mathbf{X}\boldsymbol{\beta},\mathbf{V})\\ \mathbf{V} &= \mathbf{Z}\mathbf{G}\mathbf{Z}'+\mathbf{R}\end{aligned}$$

Parameter estimation in linear mixed models is based on likelihood or method-of-moment techniques. The default estimation procedure in the MIXED procedure is restricted (residual) maximum likelihood, a form of likelihood estimation that accounts for the parameters in the fixed-effects structure of the model to reduce the bias in the covariance parameter estimates. Moment-based estimation of the covariance parameters is available in the MIXED procedure through the METHOD= option in the PROC MIXED statement. The moment-based estimators are associated with sums of squares, expected mean squares (EMS), and the solution of EMS equations.

Parameter estimation by likelihood-based techniques in linear mixed models maximizes the marginal (restricted) log likelihood of the data—that is, the log likelihood is formed from $\mathbf{Y} \sim N(\mathbf{X}\boldsymbol{\beta},\mathbf{V})$. This is a model for $\mathbf{Y}$ with mean $\mathbf{X}\boldsymbol{\beta}$ and covariance matrix $\mathbf{V}$, a correlated-error model. Such *marginal models* arise, for example, in the analysis of time series data, repeated measures, or spatial data, and are naturally subsumed into the linear mixed model family. Furthermore, some mixed models have an equivalent formulation as a correlated-error model, when both give rise to the same marginal mean and covariance matrix. For example, a mixed model with a single variance component is identical to a correlated-error model with compound-symmetric covariance structure, provided that the common correlation is positive.

Generalized Linear Mixed Model

In a generalized linear mixed model (GLMM) the G-side random effects are part of the linear predictor, $\boldsymbol{\eta} = \mathbf{X}\boldsymbol{\beta}+\mathbf{Z}\boldsymbol{\gamma}$, and the predictor is related nonlinearly to the conditional mean of the data

$$\mathrm{E}[\mathbf{Y}|\boldsymbol{\gamma}] = g^{-1}(\boldsymbol{\eta}) = g^{-1}(\mathbf{X}\boldsymbol{\beta}+\mathbf{Z}\boldsymbol{\gamma})$$

where $g^{-1}(\cdot)$ is the inverse link funtion. The conditional distribution of the data, given the random effects, is a member of the exponential family of distributions, such as the binary, binomial, Poisson, gamma, beta, or chi-square distribution. Because the normal distribution is also a member of the exponential family, the class of the linear mixed models is a subset of the generalized linear mixed models. In order to completely specify a GLMM, you need to do the following:

1. Formulate the linear predictor, including fixed and random effects.
2. Choose a link function.

3. Choose the distribution of the response, conditional on the random effects, from the exponential family.

As an example, suppose that s pairs of twins are randomly selected in a matched-pair design. One of the twins in each pair receives a treatment and the outcome variable is some binary measure. This is a study with s clusters (subjects) and each cluster is of size 2. If Y_{ij} denotes the binary response of twin $j = 1, 2$ in cluster i, then a linear predictor for this experiment could be

$$\eta_{ij} = \beta_0 + \tau x_{ij} + \gamma_i$$

where x_{ij} denotes a regressor variable that takes on the value 1 for the treated observation in each pair, and 0 otherwise. The γ_i are pair-specific random effects that model heterogeneity across sets of twins and that induce a correlation between the members of each pair. By virtue of random sampling the sets of twins, it is reasonable to assume that the γ_i are independent and have equal variance. This leads to a diagonal $\mathbf{G}$ matrix,

$$\text{Var}[\boldsymbol{\gamma}] = \text{Var}\begin{bmatrix} \gamma_1 \\ \gamma_2 \\ \gamma_3 \\ \vdots \\ \gamma_s \end{bmatrix} = \begin{bmatrix} \sigma^2_\gamma & 0 & 0 & \cdots & 0 \\ 0 & \sigma^2_\gamma & 0 & \cdots & 0 \\ 0 & 0 & \sigma^2_\gamma & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & \sigma^2_\gamma \end{bmatrix}$$

A common link function for binary data is the logit link, which leads in the second step of model formulation to

$$\begin{aligned} \text{E}\left[Y_{ij}|\gamma_i\right] = \mu_{ij}|\gamma_i &= \frac{1}{1+\exp\{-\eta_{ij}\}} \\ \text{logit}\left\{\frac{\mu_{ij}|\gamma_i}{1-\mu_{ij}|\gamma_i}\right\} &= \eta_{ij} \end{aligned}$$

The final step, choosing a distribution from the exponential family, is automatic in this example; only the binary distribution comes into play to model the distribution of $Y_{ij}|\gamma_i$.

As for the linear mixed model, there is a marginal model in the case of a generalized linear mixed model that results from integrating the joint distribution over the random effects. This marginal distribution is elusive for many GLMMs, and parameter estimation proceeds by either approximating the model or by approximating the marginal integral. Details of these approaches are described in the section "Generalized Linear Mixed Models Theory" on page 2218, in Chapter 38, "The GLIMMIX Procedure."

A marginal model, one that models correlation through the $\mathbf{R}$ matrix and does not involve G-side random effects, can also be formulated in the GLMM family; such models are the extension of the correlated-error models in the linear mixed model family. Because nonnormal distributions in the exponential family exhibit a functional mean-variance relationship, fully parametric estimation is not possible in such models. Instead, estimating equations are formed based on first-moment (mean) and second-moment (covariance) assumptions for the marginal data. The approaches for modeling correlated nonnormal data via generalized estimating equations (GEE) fall into this category (see, for example, Liang and Zeger 1986; Zeger and Liang 1986).

Nonlinear Mixed Model

In a nonlinear mixed model (NLMM), the fixed and/or random effects enter the conditional mean function nonlinearly. If the mean function is a general, nonlinear function, then it is customary to assume that the conditional distribution is normal, such as in modeling growth curves or pharmacokinetic response. This is not a requirement, however.

An example of a nonlinear mixed model is the following logistic growth curve model for the jth observation of the ith subject (cluster):

$$
\begin{aligned}
f(\boldsymbol{\beta}, \boldsymbol{\gamma}_i, x_{ij}) &= \frac{\beta_1 + \gamma_{i1}}{1 + \exp[-(x_{ij} - \beta_2)/(\beta_3 + \gamma_{i2})]} \\
Y_{ij} &= f(\boldsymbol{\beta}, \boldsymbol{\gamma}_i, x_{ij}) + \epsilon_{ij} \\
\begin{bmatrix} \gamma_{i1} \\ \gamma_{i2} \end{bmatrix} &\sim N\left(\begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} \sigma_1^2 & \sigma_{12} \\ \sigma_{21} & \sigma_2^2 \end{bmatrix} \right) \\
Y_{ij} | \gamma_{i1}, \gamma_{i2} &\sim N(0, \sigma_\epsilon^2)
\end{aligned}
$$

The inclusion of R-side covariance structures in GLMM and NLMM models is not as straightforward as in linear mixed models for the following reasons:

- The normality of the conditional distribution in the LMM enables straightforward modeling of the covariance structure because the mean structure and covariance structure are not functionally related.
- The linearity of the random effects in the LMM leads to a marginal distribution that incorporates the **R** matrix in a natural and meaningful way.

To incorporate R-side covariance structures when random effects enter nonlinearly or when the data are not normally distributed requires estimation approaches that rely on linearizations of the mixed model. Among such estimation methods are the pseudo-likelihood methods that are available with the GLIMMIX procedure. Generalized estimating equations also solve this marginal estimation problem for nonnormal data; these are available with the GENMOD procedure.

Models for Clustered and Hierarchical Data

Mixed models are often applied in situations where data are clustered, grouped, or otherwise hierarchically organized. For example, observations might be collected by randomly selecting schools in a school district, then randomly selecting classrooms within schools, followed by selecting students within the classroom. A longitudinal study might randomly select individuals and take repeatedly measurements on them. In the first example, a school is a cluster of observations, which consists of smaller clusters (classrooms) and so on. In the longitudinal example the observations for a particular individual form a cluster. Mixed models are popular analysis tools for hierarchically organized data for the following reasons:

- The selection of groups is often performed randomly, so that the associated effects are random effects.
- The data from different clusters are independent by virtue of the random selection or by assumption.
- The observations from the same cluster are often correlated, such as the repeated observations in a repeated measures or longitudinal study.
- It is often believed that there is heterogeneity in model parameters across subjects; for example, slopes and intercepts might differ across individuals in a longitudinal growth study. This heterogeneity, if due to stochastic sources, can be modeled with random effects.

A linear mixed models with clustered, hierarchical structure can be written as a special case of the general linear mixed model by introducing appropriate subscripts. For example, a mixed model with one type of clustering and s clusters can be written as

$$\mathbf{Y}_i = \mathbf{X}_i\boldsymbol{\beta} + \mathbf{Z}_i\boldsymbol{\gamma}_i + \boldsymbol{\epsilon}_i \quad i = 1, \cdots, s$$

In SAS/STAT software, the clusters are referred to as *subjects*, and the effects that define clusters in your data can be specified with the SUBJECT= option in the GLIMMIX, HPMIXED, MIXED, and NLMIXED procedures. The vector $\mathbf{Y}_i$ collects the n_i observations for the ith subject. In certain disciplines, the organization of a hierarchical model is viewed in a *bottom-up* form, where the measured observations represent the first level, these are collected into units at the second level, and so forth. In the school data example, the bottom-up approach considers a student's score as the level-1 observation, the classroom as the level-2 unit, and the school district as the level-3 unit (if these were also selected from a population of districts).

The following points are noteworthy about mixed models with SUBJECT= specification:

- A SUBJECT= option is available in the RANDOM statements of the GLIMMIX, HPMIXED, MIXED, and NLMIXED procedures and in the REPEATED statement of the MIXED procedure.
- A SUBJECT= specification is required with the NLMIXED procedure. It is not required with any other mixed modeling procedure in SAS/STAT software.
- Specifying models with subjects is usually more computationally efficient in the MIXED and GLIMMIX procedures, especially if the SUBJECT= effects are identical or contained within each other. The computational efficiency of the HPMIXED procedure is not dependent on SUBJECT= effects in the manner in which the MIXED and GLIMMIX procedures are affected.
- There is no limit to the number of SUBJECT= effects with the MIXED, HPMIXED, and GLIMMIX procedures—that is, you can achieve an arbitrary depth of the nesting.

Models with Subjects and Groups

The concept of a subject as a unit of clustering observations in a mixed model has been described in the preceding section. This concept is important for mixed modeling with the GLIMMIX, HPMIXED, MIXED, and NLMIXED procedures. Observations from two subjects are considered uncorrelated in the analysis. Observations from the same subject are potentially correlated, depending on your specification of the covariance structure. Random effects at the subject level always lead to correlation in the marginal distribution of the observations that belong to the subject.

The GLIMMIX, HPMIXED, and MIXED procedures also support the notion of a GROUP= effect in the specification of the covariance structure. Like a subject effect, a G-side group effect identifies independent random effects. In addition to a subject effect, the group effect assumes that the realizations of the random effects correspond to draws from different distributions; in other words, each level of the group effect is associated with a different set of covariance parameters. For example, the following statements in any of these procedures fit a random coefficient model with fixed intercept and slope and subject-specific random intercept and slope:

```
class id;
model y = x;
random intercept x / subject=id;
```

The interpretation of the RANDOM statement is that for each ID an independent draw is made from a bivariate normal distribution with zero mean and a diagonal covariance matrix. In the following statements (in any of these procedures) these independent draws come from different bivariate normal distributions depending on the value of the grp variable.

```
class id grp;
model y = x;
random intercept x / subject=id group=grp;
```

Adding GROUP= effects in your model increases the flexibility to model heterogeneity in the covariance parameters, but it can add numerical complexity to the estimation process.

Linear Mixed Models

You can fit linear mixed models in SAS/STAT software with the GLM, GLIMMIX, HPMIXED, LATTICE, MIXED, NESTED, and VARCOMP procedures.

The procedure specifically designed for statistical estimation in linear mixed models is the MIXED procedure. To fit the linear mixed model

$$\begin{aligned} \mathbf{Y} &= \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon} \\ \boldsymbol{\gamma} &\sim N(\mathbf{0}, \mathbf{G}) \\ \boldsymbol{\epsilon} &\sim N(\mathbf{0}, \mathbf{R}) \\ \mathrm{Cov}[\boldsymbol{\gamma}, \boldsymbol{\epsilon}] &= \mathbf{0} \end{aligned}$$

with the MIXED procedure, you specify the fixed-effects design matrix $\mathbf{X}$ in the MODEL statement, the random-effects design matrix $\mathbf{Z}$ in the RANDOM statement, the covariance matrix of the random effects $\mathbf{G}$ with options (SUBJECT=, GROUP=, TYPE=) in the RANDOM statement, and the $\mathbf{R}$ matrix in the REPEATED statement.

By default, covariance parameters are estimated by restricted (residual) maximum likelihood. In supported models, the METHOD=TYPE1, METHOD=TYPE2, and METHOD=TYPE3 options lead to method-of-moment-based estimators and analysis of variance. The MIXED procedure provides an extensive list of diagnostics for mixed models, from various residual graphics to observationwise and groupwise influence diagnostics.

The NESTED procdedure performs an analysis of variance in nested random effects models. The VARCOMP procedure can be used to estimate variance components associated with random effects in random and mixed models. The LATTICE procedure computes analysis of variance for balanced and partially balanced square lattices. You can fit the random and mixed models supported by these procedures with the MIXED procedure as well. Some specific analyses, such as the analysis of Gauge R & R studies in the VARCOMP procedure (Burdick, Borror, and Montgomery 2005), are unique to the specialized procedures.

The GLIMMIX procedure can fit most of the models that you can fit with the MIXED procedure, but it does not offer method-of-moment-based estimation and analysis of variance in the narrow sense. Also, PROC GLIMMIX does not support the same array of covariance structures as the MIXED procedure and does not support a sampling-based Bayesian analysis. An in-depth comparison of the GLIMMIX and MIXED procedures can be found in the section "Comparing the GLIMMIX and MIXED Procedures" on page 2268, in Chapter 38, "The GLIMMIX Procedure."

Comparing the MIXED and GLM Procedures

Random- and mixed-effects models can also be fit with the GLM procedure, but the *philosophy* of the two procedures is different. The following lists important differences between the GLM and MIXED procedures in fitting random and mixed models:

- The default estimation method for covariance parameters in the MIXED procedure is restricted maximum likelihood. Covariance parameters are estimated by the method of moments by solving expressions for expected mean squares.
- In the GLM procedure, fixed and random effects are listed in the MODEL statement. Only fixed effects are listed in the MODEL statement of the MIXED procedure. In the GLM procedure, random effects must be repeated in the RANDOM statement.
- You can request tests for model effects by adding the TEST option in the RANDOM statement of the GLM procedure. PROC GLM then constructs exact tests for random effects if possible and constructs approximate tests if exact tests are not possible. For details on how the GLM procedure constructs tests for random effects, see the section "Computation of Expected Mean Squares for Random Effects" on page 2540, in Chapter 39, "The GLM Procedure." Tests for fixed effects are constructed by the MIXED procedure as Wald-type *F* tests, and the degrees of freedom for these tests can be determined by a variety of methods.
- Some of the output of the GLM procedure applies only to the fixed effects part of the model, whether a RANDOM statement is specified or not.
- Variance components are independent in the GLM procedure and covariance matrices are generally unstructured. The default covariance structure for variance components in the MIXED procedure is also a variance component structure, but the procedure offers a large number of parametric structures to model covariation among random effects and observations.

Comparing the MIXED and HPMIXED Procedures

The experimental HPMIXED procedure is designed to solve large mixed model problems by using sparse matrix techniques. The largeness of a mixed model can take many forms: a large number of observations, large number of columns in the $\mathbf{X}$ matrix, a large number of random effects, or a large number of covariance parameters. The province of the HPMIXED procedure is parameter estimation, inference, and prediction in mixed models with large $\mathbf{X}$ and/or $\mathbf{Z}$ matrices, many observations, but relatively few covariance parameters.

The models that you can fit with the HPMIXED procedure and its postprocessing analyses are a subset of the models and analyses available with the MIXED procedure. With the experimental HPMIXED procedure in SAS 9.2, you can model only G-side random effects with variance component structure or an unstructured covariance matrix in a Cholesky parameterization. R-side random effects and direct modeling of their covariance structures are not supported. A high-performance computing tool has to make concessions with respect to the supported analyses to balance performance and generality.

To some extent, the generality of the MIXED procedure precludes it from serving as a high-performance computing tool for all the model-data scenarios that the procedure can potentially estimate parameters for. For example, although efficient sparse algorithms are available to estimate variance components in large mixed models, the computational configuration changes profoundly when, for example, standard error adjustments and degrees of freedom by the Kenward-Roger method are requested.

Generalized Linear Mixed Models

Generalized linear mixed models can be fit with the GLIMMIX and NLMIXED procedures in SAS/STAT software. The GLIMMIX procedure is specifically designed to fit this class of models and offers syntax very similar to the syntax of other linear modeling procedures, such as the MIXED procedure. Consider a generalized linear model with linear predictor and link function

$$\mathrm{E}[\mathbf{Y}|\boldsymbol{\gamma}] = g^{-1}(\boldsymbol{\eta}) = g^{-1}(\mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma})$$

and distribution in the exponential family. The fixed-effects design matrix $\mathbf{X}$ is specified in the MODEL statement of the GLIMMIX procedure, and the random-effects design matrix $\mathbf{Z}$ is specified in the RANDOM statement, along with the covariance matrix of the random effects and the covariance matrix of R-side random variables. The link function and (conditional) distribution are determined by defaults or through options in the MODEL statement.

The GLIMMIX procedure can fit heterocatanomic multivariate data—that is, data that stem from different distributions. For example, one measurement taken on a patient might be a continuous, normally distributed outcome, whereas another measurement might be a binary indicator of medical history. The GLIMMIX procedure also provides capabilities for mixed model smoothing and mixed model splines.

The GLIMMIX procedure offers an extensive array of postprocessing features to produce output statistics and to perform linear inference. The ESTIMATE and LSMESTIMATE statements support multiplicity-adjusted p-values for the protection of the familywise Type-I error rate. The LSMEANS statement supports the slicing of interactions, simple effect differences, and ODS statistical graphs for group comparisons.

The default estimation technique in the GLIMMIX procedure depends on the class of models fit. For linear mixed models, the default technique is restricted maximum likelihood, as in the MIXED procedure. For generalized linear mixed models, the estimation is based on linearization methods (pseudo-likelihood) or on integral approximation by adaptive quadrature or Laplace methods.

The NLMIXED procedure facilitates the fitting of generalized linear mixed models through several built-in distributions from the exponential family (binary, binomial, gamma, negative binomial, Poisson). You have to code the linear predictor and link function with SAS programming statements and assign starting values to all parameters, including the covariance parameters. Although it is not required to specify starting values with the NLMIXED procedure, because the procedure assigns a default value of 1.0 to every parameter not explictly given a starting value, it is highly recommended that you specify good starting values. The default estimation technique of the NLMIXED procedure, an adaptive Gauss-Hermite quadrature, is also available in the GLIMMIX procedure through the METHOD=QUAD option in the PROC GLIMMIX statement. The Laplace approximation that is available in the NLMIXED procedure by setting QPOINTS=1 is available in the GLIMMIX procedure through the METHOD=LAPLACE option.

Comparing the GENMOD and GLIMMIX Procedures

The GENMOD and GLIMMIX procedures can fit generalized linear models and estimate the parameters by maximum likelihood. For multinomial data, the GENMOD procedure fits cumulative link models for ordinal data. The GLIMMIX procedure fits these models and generalized logit models for nominal data.

When data are correlated, you can use the REPEATED statement in the GENMOD procedure to fit marginal models via generalized estimating equations. A working covariance structure is assumed and the standard errors of the parameter estimates are computed according to an empirical ("sandwich") estimator that is robust to the misspecification of the covariance structure. Marginal generalized linear models for correlated data can also be fit with the GLIMMIX procedure by specifying the random effects as R-side effects. The empirical covariance estimators are available through the EMPIRICAL= option in the PROC GLIMMIX statement. The essential difference between the estimation approach taken by the GLIMMIX procedure, and generalized estimating equations, is that the latter estimate the covariance parameters by the method of moments, whereas the GLIMMIX procedure uses likelihood-based techniques.

The GENMOD procedure supports nonsingular parameterizations of classification variables through its CLASS statement. The GLIMMIX procedure supports only the standard, GLM-type singular parameterization of CLASS variables. For the differences between these parameterizations, see the section "Parameterization of Model Effects" on page 368, in Chapter 18, "Shared Concepts and Topics."

Nonlinear Mixed Models: The NLMIXED Procedure

PROC NLMIXED handles models in which the fixed or random effects enter nonlinearly. It requires that you specify a conditional distribution of the data given the random effects, with available distributions including the normal, binomial, and Poisson. You can alternatively code your own distribution with SAS programming statements. Under a normality assumption for the random effects, PROC NLMIXED performs maximum likelihood estimation via adaptive Gaussian quadrature and a dual quasi-Newton optimization algorithm. Besides standard maximum likelihood results, you can obtain empirical Bayes predictions of the random effects and estimates of arbitrary functions of the parameters with delta-method standard errors. PROC NLMIXED has a wide variety of applications, two of the most common being nonlinear growth curves and overdispersed binomial data.

Overview

SAS/STAT software provides Bayesian capabilities in four procedures: GENMOD, LIFEREG, MCMC, and PHREG. The GENMOD, LIFEREG, and PHREG procedures provide Bayesian analysis in addition to the standard frequentist analyses they have always performed. Thus, these procedures provide convenient access to Bayesian modeling and inference for generalized linear models, accelerated life failure models, Cox regression models, and piecewise constant baseline hazard models (also known as piecewise exponential models). The MCMC procedure is a general procedure that fits Bayesian models with arbitrary priors and likelihood functions.

This chapter provides an overview of Bayesian statistics; describes specific sampling algorithms used in these four procedures; and discusses posterior inference and convergence diagnostics computations. Sources that provide in-depth treatment of Bayesian statistics can be found at the end of this chapter, in the section "A Bayesian Reading List" on page 173. Additional chapters contain syntax, details, and examples for the individual procedures GENMOD (see Chapter 37, "The GENMOD Procedure"), LIFEREG (see Chapter 48, "The LIFEREG Procedure"), MCMC (see Chapter 52, "The MCMC Procedure"), and PHREG (see Chapter 64, "The PHREG Procedure").

Introduction

The most frequently used statistical methods are known as *frequentist* (or *classical*) methods. These methods assume that unknown parameters are fixed constants, and they define probability by using limiting relative frequencies. It follows from these assumptions that probabilities are objective and that you cannot make probabilistic statements about parameters because they are fixed. Bayesian methods offer an alternative approach; they treat parameters as random variables and define probability as "degrees of belief" (that is, the probability of an event is the degree to which you believe the event is true). It follows from these postulates that probabilities are subjective and that you can make probability statements about parameters. The term "Bayesian" comes from the prevalent usage of Bayes' theorem, which was named after the Reverend Thomas Bayes, an eighteenth century Presbyterian minister. Bayes was interested in solving the question of inverse probability: after observing a collection of events, what is the probability of one event?

Suppose you are interested in estimating θ from data $\mathbf{y} = \{y_1, \ldots, y_n\}$ by using a statistical model described by a density $p(\mathbf{y}|\theta)$. Bayesian philosophy states that θ cannot be determined exactly, and uncertainty about the parameter is expressed through probability statements and distributions. You can say that θ follows a normal distribution with mean 0 and variance 1, if it is believed that this distribution best describes the uncertainty associated with the parameter. The following steps describe the essential elements of Bayesian inference:

1. A probability distribution for θ is formulated as $\pi(\theta)$, which is known as the *prior* distribution, or just the prior. The prior distribution expresses your beliefs (for example, on the mean, the spread, the skewness, and so forth) about the parameter before you examine the data.
2. Given the observed data $\mathbf{y}$, you choose a statistical model $p(\mathbf{y}|\theta)$ to describe the distribution of $\mathbf{y}$ given θ.
3. You update your beliefs about θ by combining information from the prior distribution and the data through the calculation of the *posterior* distribution, $p(\theta|\mathbf{y})$.

The third step is carried out by using Bayes' theorem, which enables you to combine the prior distribution and the model in the following way:

$$p(\theta|\mathbf{y}) = \frac{p(\theta, \mathbf{y})}{p(\mathbf{y})} = \frac{p(\mathbf{y}|\theta)\pi(\theta)}{p(\mathbf{y})} = \frac{p(\mathbf{y}|\theta)\pi(\theta)}{\int p(\mathbf{y}|\theta)\pi(\theta)d\theta}$$

The quantity

$$p(\mathbf{y}) = \int p(\mathbf{y}|\theta)\pi(\theta)d\theta$$

is the normalizing constant of the posterior distribution. This quantity $p(\mathbf{y})$ is also the marginal distribution of $\mathbf{y}$, and it is sometimes called the marginal distribution of the data. The likelihood function of θ is any function proportional to $p(\mathbf{y}|\theta)$; that is, $L(\theta) \propto p(\mathbf{y}|\theta)$. Another way of writing Bayes' theorem is as follows:

$$p(\theta|\mathbf{y}) = \frac{L(\theta)\pi(\theta)}{\int L(\theta)\pi(\theta)d\theta}$$

The marginal distribution $p(\mathbf{y})$ is an integral. As long as the integral is finite, the particular value of the integral does not provide any additional information about the posterior distribution. Hence, $p(\theta|\mathbf{y})$ can be written up to an arbitrary constant, presented here in proportional form as:

$$p(\theta|\mathbf{y}) \propto L(\theta)\pi(\theta)$$

Simply put, Bayes' theorem tells you how to update existing knowledge with new information. You begin with a prior belief $\pi(\theta)$, and after learning information from data $\mathbf{y}$, you change or update your belief about θ and obtain $p(\theta|\mathbf{y})$. These are the essential elements of the Bayesian approach to data analysis.

In theory, Bayesian methods offer simple alternatives to statistical inference—all inferences follow from the posterior distribution $p(\theta|\mathbf{y})$. In practice, however, you can obtain the posterior distribution with straightforward analytical solutions only in the most rudimentary problems. Most Bayesian analyses require sophisticated computations, including the use of simulation methods. You generate samples from the posterior distribution and use these samples to estimate the quantities of interest. PROC MCMC uses a self-tuning Metropolis algorithm (see the section "Metropolis and Metropolis-Hastings Algorithms" on page 152). The GENMOD, LIFEREG, and PHREG procedures use the Gibbs sampler (see the section "Gibbs Sampler" on page 154). An important aspect of any analysis is assessing the convergence of the Markov chains. Inferences based on nonconverged Markov chains can be both inaccurate and misleading.

Both Bayesian and classical methods have their advantages and disadvantages. From a practical point of view, your choice of method depends on what you want to accomplish with your data analysis. If you have prior information (either expert opinion or historical knowledge) that you want to incorporate into the analysis, then you should consider Bayesian methods. In addition, if you want to communicate your findings in terms of probability notions that can be more easily understood by nonstatisticians, Bayesian methods might be appropriate. The Bayesian paradigm can often provide a framework for answering specific scientific questions that a single point estimate cannot sufficiently address. Alternatively, if you are interested only in estimating parameters based on the likelihood, then numerical optimization methods, such as the Newton-Raphson method, can

give you very precise estimates and there is no need to use a Bayesian analysis. For further discussions of the relative advantages and disadvantages of Bayesian analysis, see the section "Bayesian Analysis: Advantages and Disadvantages" on page 149.

Background in Bayesian Statistics

Prior Distributions

A prior distribution of a parameter is the probability distribution that represents your uncertainty about the parameter before the current data are examined. Multiplying the prior distribution and the likelihood function together leads to the posterior distribution of the parameter. You use the posterior distribution to carry out all inferences. You cannot carry out any Bayesian inference or perform any modeling without using a prior distribution.

Objective Priors versus Subjective Priors

Bayesian probability measures the degree of belief that you have in a random event. By this definition, probability is highly subjective. It follows that all priors are *subjective priors*. Not everyone agrees with this notion of subjectivity when it comes to specifying prior distributions. There has long been a desire to obtain results that are objectively valid. Within the Bayesian paradigm, this can be somewhat achieved by using prior distributions that are "objective" (that is, that have a minimal impact on the posterior distribution). Such distributions are called *objective* or *noninformative* priors (see the next section). However, while noninformative priors are very popular in some applications, they are not always easy to construct. See DeGroot and Schervish (2002, Section 1.2) and Press (2003, Section 2.2) for more information about interpretations of probability. See Berger (2006) and Goldstein (2006) for discussions about objective Bayesian versus subjective Bayesian analysis.

Noninformative Priors

Roughly speaking, a prior distribution is noninformative if the prior is "flat" relative to the likelihood function. Thus, a prior $\pi(\theta)$ is noninformative if it has minimal impact on the posterior distribution of θ. Other names for the noninformative prior are *vague*, *diffuse*, and *flat* prior. Many statisticians favor noninformative priors because they appear to be more objective. However, it is unrealistic to expect that noninformative priors represent total ignorance about the parameter of interest. In some cases, noninformative priors can lead to *improper posteriors* (nonintegrable posterior density). You cannot make inferences with improper posterior distributions. In addition, noninformative priors are often not invariant under transformation; that is, a prior might be noninformative in one parameterization but not necessarily noninformative if a transformation is applied. A common choice for a noninformative prior is the flat prior, which is a prior distribution that assigns equal likelihood on all possible values of the parameter. Intuitively this makes sense, and in some cases,

such as linear regression, flat priors on the regression parameter are noninformative. However, this is not necessarily true in all cases. For example, suppose there is a binomial experiment with n Bernoulli trials where y 1s are observed. You want to make inferences about the unknown success probability p. A uniform prior on p,

$$\pi(p) \propto 1$$

might appear to be noninformative. However, using the uniform prior is actually equivalent to adding two observations to the data, one 1 and one 0. With small n and y, the added observations can be very influential to the parameter estimate of p.

To see this, note that the likelihood is this:

$$p^y(1-p)^{n-y}$$

The maximum likelihood estimator (MLE) of p is y/n. The uniform prior can be written as a beta distribution with both the shape (α) and scale (β) parameters being 1:

$$\pi(p) \propto p^{\alpha-1}(1-p)^{\beta-1}$$

The posterior distribution of p is proportional to the following:

$$p^{\alpha+y-1}(1-p)^{\beta+n-y-1}$$

which is beta($\alpha + y, \beta + n - y$). Therefore, the posterior mean is this:

$$\frac{\alpha + y}{\alpha + \beta + n} = \frac{1 + y}{2 + n}$$

and it can be quite different from the MLE if both n and y are small. See Box and Tiao (1973) for a more formal development of noninformative priors. See Kass and Wasserman (1996) for techniques for deriving noninformative priors.

Improper Priors

A prior $\pi(\theta)$ is said to be improper if

$$\int \pi(\theta) d\theta = \infty$$

For example, a uniform prior distribution on the real line, $\pi(\theta) \propto 1$, for $-\infty < \theta < \infty$, is an improper prior. Improper priors are often used in Bayesian inference since they usually yield noninformative priors and proper posterior distributions. Improper prior distributions can lead to posterior impropriety (improper posterior distribution). To determine whether a posterior distribution is proper, you need to make sure that the normalizing constant $\int p(\mathbf{y}|\theta)p(\theta)d\theta$ is finite for all $\mathbf{y}$. If an improper prior distribution leads to an improper posterior distribution, inference based on the improper posterior distribution is invalid.

The GENMOD, LIFEREG, and PHREG procedures allow the use of improper priors—that is, the flat prior on the real line—for regression coefficients. These improper priors do not lead to any improper posterior distributions in the models that these procedures fit. PROC MCMC allows the use of any prior, as long as the distribution is programmable using DATA step functions. However, the procedure does not verify whether the posterior distribution is integrable. You must ensure this yourself.

Informative Priors

An informative prior is a prior that is not dominated by the likelihood and that has an impact on the posterior distribution. If a prior distribution dominates the likelihood, it is clearly an informative prior. These types of distributions must be specified with care in actual practice. On the other hand, the proper use of prior distributions illustrates the power of the Bayesian method: information gathered from the previous study, past experience, or expert opinion can be combined with current information in a natural way. See the "Examples" sections of the GENMOD and PHREG procedure chapters for instructions about constructing informative prior distributions.

Conjugate Priors

A prior is said to be a conjugate prior for a family of distributions if the prior and posterior distributions are from the same family, which means that the form of the posterior has the same distributional form as the prior distribution. For example, if the likelihood is binomial, $y \sim \text{Bin}(n, \theta)$, a conjugate prior on θ is the beta distribution; it follows that the posterior distribution of θ is also a beta distribution. Other commonly used conjugate prior/likelihood combinations include the normal/normal, gamma/Poisson, gamma/gamma, and gamma/beta cases. The development of conjugate priors was partially driven by a desire for computational convenience—conjugacy provides a practical way to obtain the posterior distributions. The Bayesian procedures do not use conjugacy in posterior sampling.

Jeffreys' Prior

A very useful prior is Jeffreys' prior (Jeffreys 1961). It satisfies the local uniformity property: a prior that does not change much over the region in which the likelihood is significant and does not assume large values outside that range. It is based on the Fisher information matrix. Jeffreys' prior is defined as

$$\pi(\theta) \propto |I(\theta)|^{1/2}$$

where $|\ |$ denotes the determinant and $I(\theta)$ is the Fisher information matrix based on the likelihood function $p(\mathbf{y}|\theta)$:

$$I(\theta) = -E\left[\frac{\partial^2 \log p(\mathbf{y}|\theta)}{\partial \theta^2}\right]$$

Jeffreys' prior is locally uniform and hence noninformative. It provides an automated scheme for finding a noninformative prior for any parametric model $p(\mathbf{y}|\theta)$. Another appealing property of Jeffreys' prior is that it is invariant with respect to one-to-one transformations. The invariance property means that if you have a locally uniform prior on θ and $\phi(\theta)$ is a one-to-one function of θ, then $p(\phi(\theta)) = \pi(\theta) \cdot |\phi'(\theta)|^{-1}$ is a locally uniform prior for $\phi(\theta)$. This invariance principle carries through to multidimensional parameters as well. While Jeffreys' prior provides a general recipe for obtaining noninformative priors, it has some shortcomings: the prior is improper for many models, and it can lead to improper posterior in some cases; and the prior can be cumbersome to use in high dimensions. PROC GENMOD calculates Jeffreys' prior automatically for any generalized linear model. You can set it as your prior density for the coefficient parameters, and it does not lead to improper posteriors. You can construct Jeffreys' prior for a variety of statistical models in PROC MCMC. See the section "Logistic Regression Model with Jeffreys' Prior" on page 3598 for an example. PROC MCMC does not guarantee that the corresponding posterior distribution is proper, and you need to exercise extra caution in this case.

Bayesian Inference

Bayesian inference about θ is primarily based on the posterior distribution of θ. There are various ways in which you can summarize this distribution. For example, you can report your findings through point estimates. You can also use the posterior distribution to construct hypothesis tests or probability statements.

Point Estimation and Estimation Error

Classical methods often report the maximum likelihood estimator (MLE) or the method of moments estimator (MOME) of a parameter. In contrast, Bayesian approaches often use the posterior mean. The definition of the posterior mean is given by

$$E(\theta|\mathbf{y}) = \int \theta\ p(\theta|\mathbf{y})\ d\theta$$

Other commonly used posterior estimators include the posterior median, defined as

$$\theta\colon P(\theta \geq \text{median}|\mathbf{y}) = P(\text{median} \leq \theta|\mathbf{y}) = \frac{1}{2}$$

and the posterior mode, defined as the value of θ that maximizes $p(\theta|\mathbf{y})$.

The variance of the posterior density (simply referred to as the *posterior variance*) describes the uncertainty in the parameter, which is a random variable in the Bayesian paradigm. A Bayesian analysis typically uses the posterior variance, or the posterior standard deviation, to characterize the dispersion of the parameter. In multidimensional models, covariance or correlation matrices are used.

If you know the distributional form of the posterior density of interest, you can report the exact posterior point estimates. When models become too difficult to analyze analytically, you have to use simulation algorithms, such as the Markov chain Monte Carlo (MCMC) method to obtain posterior estimates (see the section "Markov Chain Monte Carlo Method" on page 151). All of the Bayesian procedures rely on MCMC to obtain all posterior estimates. Using only a finite number of samples, simulations introduce an additional level of uncertainty to the accuracy of the estimates. *Monte Carlo standard error (MCSE)*, which is the standard error of the posterior mean estimate, measures the simulation accuracy. See the section "Standard Error of the Mean Estimate" on page 170 for more information.

The posterior standard deviation and the MCSE are two completely different concepts: the posterior standard deviation describes the uncertainty in the parameter, while the MCSE describes only the uncertainty in the parameter estimate as a result of MCMC simulation. The posterior standard deviation is a function of the sample size in the data set, and the MCSE is a function of the number of iterations in the simulation.

Hypothesis Testing

Suppose you have the following null and alternative hypotheses: H_0 is $\theta \in \Theta_0$ and H_1 is $\theta \in \Theta_0^c$, where Θ_0 is a subset of the parameter space and Θ_0^c is its complement. Using the posterior distribution $\pi(\theta|\mathbf{y})$, you can compute the posterior probabilities $P(\theta \in \Theta_0|\mathbf{y})$ and $P(\theta \in \Theta_0^c|\mathbf{y})$, or the probabilities that H_0 and H_1 are true, respectively. One way to perform a Bayesian hypothesis test is to accept the null hypothesis if $P(\theta \in \Theta_0|\mathbf{y}) \geq P(\theta \in \Theta_0^c|\mathbf{y})$ and vice versa, or to accept the null hypothesis if $P(\theta \in \Theta_0|\mathbf{y})$ is greater than a predefined threshold, such as 0.75, to guard against falsely accepted null distribution.

It is more difficult to carry out a point null hypothesis test in a Bayesian analysis. A point null hypothesis is a test of $H_0\colon \theta = \theta_0$ versus $H_1\colon \theta \neq \theta_0$. If the prior distribution $\pi(\theta)$ is a continuous density, then the posterior probability of the null hypothesis being true is 0, and there is no point in carrying out the test. One alternative is to restate the null to be a small interval hypothesis: $\theta \in \Theta_0 = (\theta_0 - a, \theta_0 + a)$, where a is a very small constant. The Bayesian paradigm can deal with an interval hypothesis more easily. Another approach is to give a mixture prior distribution to θ with a positive probability of p_0 on θ_0 and the density $(1 - p_0)\pi(\theta)$ on $\theta \neq \theta_0$. This prior ensures a nonzero posterior probability on θ_0, and you can then make realistic probabilistic comparisons. For more detailed treatment of Bayesian hypothesis testing, see Berger (1985).

Interval Estimation

The Bayesian set estimates are called *credible sets*, which is also known as *credible intervals*. This is analogous to the concept of confidence intervals used in classical statistics. Given a posterior distribution $p(\theta|\mathbf{y})$, A is a credible set for θ if

$$P(\theta \in A|\mathbf{y}) = \int_A p(\theta|\mathbf{y})d\theta$$

For example, you can construct a 95% credible set for θ by finding an interval, A, over which $\int_A p(\theta|\mathbf{y}) = 0.95$.

You can construct credible sets that have equal tails. A $100(1-\alpha)\%$ equal-tail interval corresponds to the $100(\alpha/2)$th and $100(1-\alpha/2)$th percentiles of the posterior distribution. Some statisticians prefer this interval because it is invariant under transformations. Another frequently used Bayesian credible set is called the *highest posterior density* (HPD) interval.

A $100(1-\alpha)\%$ HPD interval is a region that satisfies the following two conditions:

1. The posterior probability of that region is $100(1-\alpha)\%$.
2. The minimum density of any point within that region is equal to or larger than the density of any point outside that region.

The HPD is an interval in which most of the distribution lies. Some statisticians prefer this interval because it is the smallest interval.

One major distinction between Bayesian and classical sets is their interpretation. The Bayesian probability reflects a person's subjective beliefs. Following this approach, a statistician can make the claim that θ is inside a credible interval with measurable probability. This property is appealing because it enables you to make a direct probability statement about parameters. Many people find this concept to be a more natural way of understanding a probability interval, which is also easier to explain to nonstatisticians. A confidence interval, on the other hand, enables you to make a claim that the interval covers the true parameter. The interpretation reflects the uncertainty in the sampling procedure; a confidence interval of $100(1-\alpha)\%$ asserts that, in the long run, $100(1-\alpha)\%$ of the realized confidence intervals cover the true parameter.

Bayesian Analysis: Advantages and Disadvantages

Bayesian methods and classical methods both have advantages and disadvantages, and there are some similarities. When the sample size is large, Bayesian inference often provides results for parametric models that are very similar to the results produced by frequentist methods. Some advantages to using Bayesian analysis include the following:

- It provides a natural and principled way of combining prior information with data, within a solid decision theoretical framework. You can incorporate past information about a parameter and form a prior distribution for future analysis. When new observations become available, the previous posterior distribution can be used as a prior. All inferences logically follow from Bayes' theorem.
- It provides inferences that are conditional on the data and are exact, without reliance on asymptotic approximation. Small sample inference proceeds in the same manner as if one had a large sample. Bayesian analysis also can estimate any functions of parameters directly, without using the "plug-in" method (a way to estimate functionals by plugging the estimated parameters in the functionals).
- It obeys the likelihood principle. If two distinct sampling designs yield proportional likelihood functions for θ, then all inferences about θ should be identical from these two designs. Classical inference does not in general obey the likelihood principle.
- It provides interpretable answers, such as "the true parameter θ has a probability of 0.95 of falling in a 95% credible interval."
- It provides a convenient setting for a wide range of models, such as hierarchical models and missing data problems. MCMC, along with other numerical methods, makes computations tractable for virtually all parametric models.

There are also disadvantages to using Bayesian analysis:

- It does not tell you how to select a prior. There is no correct way to choose a prior. Bayesian inferences require skills to translate subjective prior beliefs into a mathematically formulated prior. If you do not proceed with caution, you can generate misleading results.
- It can produce posterior distributions that are heavily influenced by the priors. From a practical point of view, it might sometimes be difficult to convince subject matter experts who do not agree with the validity of the chosen prior.
- It often comes with a high computational cost, especially in models with a large number of parameters. In addition, simulations provide slightly different answers unless the same random seed is used. Note that slight variations in simulation results do not contradict the early claim that Bayesian inferences are exact. The posterior distribution of a parameter is exact, given the likelihood function and the priors, while simulation-based estimates of posterior quantities can vary due to the random number generator used in the procedures.

For more in-depth treatments of the pros and cons of Bayesian analysis, see Berger (1985, Sections 4.1 and 4.12), Berger and Wolpert (1988), Bernardo and Smith (1994, with a new edition coming out), Carlin and Louis (2000, Section 1.4), Robert (2001, Chapter 11), and Wasserman (2004, Section 11.9).

The following sections provide detailed information about the Bayesian methods provided in SAS.

Markov Chain Monte Carlo Method

The Markov chain Monte Carlo (MCMC) method is a general simulation method for sampling from posterior distributions and computing posterior quantities of interest. MCMC methods sample successively from a target distribution. Each sample depends on the previous one, hence the notion of the Markov chain. A Markov chain is a sequence of random variables, $\theta^1, \theta^2, \cdots$, for which the random variable θ^t depends on all previous θs only through its immediate predecessor θ^{t-1}. You can think of a Markov chain applied to sampling as a mechanism that traverses randomly through a target distribution without having any memory of where it has been. Where it moves next is entirely dependent on where it is now.

Monte Carlo, as in Monte Carlo integration, is mainly used to approximate an expectation by using the Markov chain samples. In the simplest version

$$\int_S g(\theta)p(\theta)d\theta \cong \frac{1}{n}\sum_{t=1}^{n} g(\theta^t)$$

where $g(\cdot)$ is a function of interest and θ^t are samples from $p(\theta)$ on its support S. This approximates the expected value of $g(\theta)$. The earliest reference to MCMC simulation occurs in the physics literature. Metropolis and Ulam (1949) and Metropolis et al. (1953) describe what is known as the Metropolis algorithm (see the section "Metropolis and Metropolis-Hastings Algorithms" on page 152). The algorithm can be used to generate sequences of samples from the joint distribution of multiple variables, and it is the foundation of MCMC. Hastings (1970) generalized their work, resulting in the Metropolis-Hastings algorithm. Geman and Geman (1984) analyzed image data by using what is now called Gibbs sampling (see the section "Gibbs Sampler" on page 154). These MCMC methods first appeared in the mainstream statistical literature in Tanner and Wong (1987).

The Markov chain method has been quite successful in modern Bayesian computing. Only in the simplest Bayesian models can you recognize the analytical forms of the posterior distributions and summarize inferences directly. In moderately complex models, posterior densities are too difficult to work with directly. With the MCMC method, it is possible to generate samples from an arbitrary posterior density $p(\theta|\mathbf{y})$ and to use these samples to approximate expectations of quantities of interest. Several other aspects of the Markov chain method also contributed to its success. Most importantly, if the simulation algorithm is implemented correctly, the Markov chain is guaranteed to converge to the target distribution $p(\theta|\mathbf{y})$ under rather broad conditions, regardless of where the chain was initialized. In other words, a Markov chain is able to improve its approximation to the true distribution at each step in the simulation. Furthermore, if the chain is run for a very long time (often required), you can recover $p(\theta|\mathbf{y})$ to any precision. Also, the simulation algorithm is easily extensible to models with a large number of parameters or high complexity, although the "curse of dimensionality" often causes problems in practice.

Properties of Markov chains are discussed in Feller (1968), Breiman (1968), and Meyn and Tweedie (1993). Ross (1997) and Karlin and Taylor (1975) give a non-measure-theoretic treatment of stochastic processes, including Markov chains. For conditions that govern Markov chain convergence and rates of convergence, see Amit (1991), Applegate, Kannan, and Polson (1990), Chan (1993), Geman and Geman (1984), Liu, Wong, and Kong (1991a, b), Rosenthal (1991a, b), Tierney

(1994), and Schervish and Carlin (1992). Besag (1974) describes conditions under which a set of conditional distributions gives a unique joint distribution. Tanner (1993), Gilks, Richardson, and Spiegelhalter (1996), Chen, Shao, and Ibrahim (2000), Liu (2001), Gelman et al. (2004), Robert and Casella (2004), and Congdon (2001, 2003, 2005) provide both theoretical and applied treatments of MCMC methods. You can also see the section "A Bayesian Reading List" on page 173 for a list of books with varying levels of difficulty of treatment of the subject and its application to Bayesian statistics.

Metropolis and Metropolis-Hastings Algorithms

The Metropolis algorithm is named after its inventor, the American physicist and computer scientist Nicholas C. Metropolis. The algorithm is simple but practical, and it can be used to obtain random samples from any arbitrarily complicated target distribution of any dimension that is known up to a normalizing constant. The Bayesian procedures use a special case of the Metropolis algorithm called the Gibbs sampler to obtain posterior samplers.

Suppose you want to obtain T samples from a univariate distribution with probability density function $f(\theta|\mathbf{y})$. Suppose θ^t is the tth sample from f. To use the Metropolis algorithm, you need to have an initial value θ^0 and a symmetric *proposal* density $q(\theta^{t+1}|\theta^t)$. For the $(t+1)$th iteration, the algorithm generates a sample from $q(\cdot|\cdot)$ based on the current sample θ^t, and it makes a decision to either accept or reject the new sample. If the new sample is accepted, the algorithm repeats itself by starting at the new sample. If the new sample is rejected, the algorithm starts at the current point and repeats. The algorithm is self-repeating, so it can be carried out as long as required. In practice, you have to decide the total number of samples needed in advance and stop the sampler after that many iterations have been completed.

Suppose $q(\theta_{\text{new}}|\theta^t)$ is a symmetric distribution. The proposal distribution should be an easy distribution from which to sample, and it must be such that $q(\theta_{\text{new}}|\theta^t) = q(\theta^t|\theta_{\text{new}})$, meaning that the likelihood of jumping to θ_{new} from θ^t is the same as the likelihood of jumping back to θ^t from θ_{new}. The most common choice of the proposal distribution is the normal distribution $N(\theta^t, \sigma)$ with a fixed σ. The Metropolis algorithm can be summarized as follows:

1. Set $t = 0$. Choose a starting point θ^0. This can be an arbitrary point as long as $f(\theta^0|\mathbf{y}) > 0$.
2. Generate a new sample, θ_{new}, by using the proposal distribution $q(\cdot|\theta^t)$.
3. Calculate the following quantity:

$$r = \min\left\{\frac{f(\theta_{\text{new}}|\mathbf{y})}{f(\theta^t|\mathbf{y})}, 1\right\}$$

4. Sample u from the uniform distribution $U(0,1)$.
5. Set $\theta^{t+1} = \theta_{\text{new}}$ if $u < r$; otherwise set $\theta^{t+1} = \theta^t$.
6. Set $t = t + 1$. If $t < T$, the number of desired samples, return to step 2. Otherwise, stop.

Note that the number of iteration keeps increasing regardless of whether a proposed sample is accepted.

This algorithm defines a chain of random variates whose distribution will converge to the desired distribution $f(\theta|\mathbf{y})$, and so from some point forward, the chain of samples is a sample from the distribution of interest. In Markov chain terminology, this distribution is called the *stationary distribution* of the chain, and in Bayesian statistics, it is the posterior distribution of the model parameters. The reason that the Metropolis algorithm works is beyond the scope of this documentation, but you can find more detailed descriptions and proofs in many standard textbooks, including Roberts (1996) and Liu (2001). The random-walk Metropolis algorithm is used in PROC MCMC.

You are not limited to a symmetric random-walk proposal distribution in establishing a valid sampling algorithm. A more general form, the Metropolis-Hastings (MH) algorithm, was proposed by Hastings (1970). The MH algorithm uses an asymmetric proposal distribution: $q(\theta_{\text{new}}|\theta^t) \neq q(\theta^t|\theta_{\text{new}})$. The difference in its implementation comes in calculating the ratio of densities:

$$r = \min\left\{\frac{f(\theta_{\text{new}}|\mathbf{y})q(\theta^t|\theta_{\text{new}})}{f(\theta^t|\mathbf{y})q(\theta_{\text{new}}|\theta^t)}, 1\right\}$$

Other steps remain the same.

The extension of the Metropolis algorithm to a higher-dimensional $\boldsymbol{\theta}$ is straightforward. Suppose $\boldsymbol{\theta} = (\theta_1, \theta_2, \cdots, \theta_k)'$ is the parameter vector. To start the Metropolis algorithm, select an initial value for each θ_k and use a multivariate version of proposal distribution $q(\cdot|\cdot)$, such as a multivariate normal distribution, to select a k-dimensional new parameter. Other steps remain the same as those previously described, and this Markov chain eventually converges to the target distribution of $f(\boldsymbol{\theta}|\mathbf{y})$. Chib and Greenberg (1995) provide a useful tutorial on the algorithm.

Independence Sampler

Another type of Metropolis algorithm is the "independence" sampler. It is called the independence sampler because the proposal distribution in the algorithm does not depend on the current point as it does with the random-walk Metropolis algorithm. For this sampler to work well, you want to have a proposal distribution that mimics the target distribution and have the acceptance rate be as high as possible.

1. Set $t = 0$. Choose a starting point θ^0. This can be an arbitrary point as long as $f(\theta^0|\mathbf{y}) > 0$.
2. Generate a new sample, θ_{new}, by using the proposal distribution $q(\cdot)$. The proposal distribution does not depend on the current value of θ^t.
3. Calculate the following quantity:

$$r = \min\left\{\frac{f(\theta_{\text{new}}|\mathbf{y})/q(\theta_{\text{new}})}{f(\theta^t|\mathbf{y})/q(\theta^t)}, 1\right\}$$

4. Sample u from the uniform distribution $U(0, 1)$.

5. Set $\theta^{t+1} = \theta_{\text{new}}$ if $u < r$; otherwise set $\theta^{t+1} = \theta^t$.
6. Set $t = t + 1$. If $t < T$, the number of desired samples, return to step 2. Otherwise, stop.

A good proposal density should have thicker tails than those of the target distribution. This requirement sometimes can be difficult to satisfy especially in cases where you do not know what the target posterior distributions are like. In addition, this sampler does not produce independent samples as the name seems to imply, and sample chains from independence samplers can get stuck in the tails of the posterior distribution if the proposal distribution is not chosen carefully. The independence sampler is used in PROC MCMC.

Gibbs Sampler

The Gibbs sampler, named by Geman and Geman (1984) after the American physicist Josiah W. Gibbs, is a special case of the Metropolis sampler in which the proposal distributions exactly match the posterior conditional distributions and proposals are accepted 100% of the time. Gibbs sampling requires you to decompose the joint posterior distribution into full conditional distributions for each parameter in the model and then sample from them. The sampler can be efficient when the parameters are not highly dependent on each other and the full conditional distributions are easy to sample from. Some researchers favor this algorithm because it does not require an instrumental proposal distribution as Metropolis methods do. However, while deriving the conditional distributions can be relatively easy, it is not always possible to find an efficient way to sample from these conditional distributions.

Suppose $\boldsymbol{\theta} = (\theta_1, \ldots, \theta_k)'$ is the parameter vector, $p(\mathbf{y}|\boldsymbol{\theta})$ is the likelihood, and $\pi(\boldsymbol{\theta})$ is the prior distribution. The full posterior conditional distribution of $\pi(\theta_i|\theta_j, i \neq j, \mathbf{y})$ is proportional to the joint posterior density; that is,

$$\pi(\theta_i|\theta_j, i \neq j, \mathbf{y}) \propto p(\mathbf{y}|\boldsymbol{\theta})\pi(\boldsymbol{\theta})$$

For instance, the one-dimensional conditional distribution of θ_1 given $\theta_j = \theta_j^*, 2 \leq j \leq k$, is computed as the following:

$$\pi(\theta_1|\theta_j = \theta_j^*, 2 \leq j \leq k, \mathbf{y}) = p(\mathbf{y}|(\boldsymbol{\theta} = (\theta_1, \theta_2^*, \ldots, \theta_k^*)')\pi(\boldsymbol{\theta} = (\theta_1, \theta_2^*, \ldots, \theta_k^*)')$$

The Gibbs sampler works as follows:

1. Set $t = 0$, and choose an arbitrary initial value of $\boldsymbol{\theta}^{(0)} = \{\theta_1^{(0)}, \ldots, \theta_k^{(0)}\}$.
2. Generate each component of $\boldsymbol{\theta}$ as follows:
   - draw $\theta_1^{(t+1)}$ from $\pi(\theta_1|\theta_2^{(t)}, \ldots, \theta_k^{(t)}, \mathbf{y})$
   - draw $\theta_2^{(t+1)}$ from $\pi(\theta_2|\theta_1^{(t+1)}, \theta_3^{(t)}, \ldots, \theta_k^{(t)}, \mathbf{y})$

- ...
- draw $\theta_k^{(t+1)}$ from $\pi(\theta_k|\theta_1^{(t+1)}, \ldots, \theta_{k-1}^{(t+1)}, \mathbf{y})$

3. Set $t = t + 1$. If $t < T$, the number of desired samples, return to step 2. Otherwise, stop.

The name "Gibbs" was introduced by Geman and Geman (1984). Gelfand et al. (1990) first used Gibbs sampling to solve problems in Bayesian inference. See Casella and George (1992) for a tutorial on the sampler. The GENMOD, LIFEREG, and PHREG procedures update parameters using the Gibbs sampler.

Adaptive Rejection Sampling Algorithm

The GENMOD, LIFEREG, and PHREG procedures use the adaptive rejection sampling (ARS) algorithm to sample parameters sequentially from their univariate full conditional distributions. The ARS algorithm is a rejection algorithm that was originally proposed by Gilks and Wild (1992). Given a log-concave density (the log of the density is concave), you can construct an envelope to the density by using linear segments. You then use the linear segment envelope as a proposal density (it becomes a piecewise exponential density on the original scale and is easy to generate samplers from) in the rejection sampling. The log-concavity condition is met in some of the models fit by the procedures. For example, the posterior densities for the regression parameters in the generalized linear models are log-concave under flat priors. When this condition fails, the ARS algorithm calls for an additional Metropolis-Hasting step (Gilks, Best, and Tan 1995), and the modified algorithm becomes the adaptive rejection metropolis sampling (ARMS) algorithm. The GENMOD, LIFEREG, and PHREG procedures can recognize whether a model is log-concave and select the appropriate sampler for the problem at hand.

The GENMOD, LIFEREG, and PHREG procedures implement the ARMS algorithm based on code kindly provided by Walter R. Gilks, University of Leeds (Gilks 2003), to obtain posterior samples. For a detailed description and explanation of the algorithm, see Gilks and Wild (1992) and Gilks, Best, and Tan (1995).

Burn-in, Thinning, and Markov Chain Samples

Burn-in refers to the practice of discarding an initial portion of a Markov chain sample so that the effect of initial values on the posterior inference is minimized. For example, suppose the target distribution is $N(0, 1)$ and the Markov chain was started at the value 10^6. The chain might quickly travel to regions around 0 in a few iterations. However, including samples around the value 10^6 in the posterior mean calculation can produce substantial bias in the mean estimate. In theory, if the Markov chain is run for an infinite amount of time, the effect of the initial values decreases to zero. In practice, you do not have the luxury of infinite samples. In practice, you assume that after t iterations, the chain has reached its target distribution and you can throw away the early portion and use the good samples for posterior inference. The value of t is the burn-in number.

With some models you might experience poor mixing (or slow convergence) of the Markov chain. This can happen, for example, when parameters are highly correlated with each other. Poor mixing means that the Markov chain slowly traverses the parameter space (see the section "Visual Analysis

via Trace Plots" on page 156 for examples of poorly mixed chains) and the chain has high dependence. High sample autocorrelation can result in biased Monte Carlo standard errors. A common strategy is to *thin* the Markov chain in order to reduce sample autocorrelations. You thin a chain by keeping every kth simulated draw from each sequence. You can safely use a thinned Markov chain for posterior inference as long as the chain converges. It is important to note that thinning a Markov chain can be wasteful because you are throwing away a $\frac{k-1}{k}$ fraction of all the posterior samples generated. MacEachern and Berliner (1994) show that you always get more precise posterior estimates if the entire Markov chain is used. However, other factors, such as computer storage or plotting time, might prevent you from keeping all samples.

To use the GENMOD, LIFEREG, MCMC, and PHREG procedures, you need to determine the total number of samples to keep ahead of time. This number is not obvious and often depends on the type of inference you want to make. Mean estimates do not require nearly as many samples as small-tail percentile estimates. In most applications, you might find that keeping a few thousand iterations is sufficient for reasonably accurate posterior inference. In all four procedures, the relationship between the number of iterations requested, the number of iterations kept, and the amount of thinning is as follows:

$$\text{kept} = \left[\frac{\text{requested}}{\text{thinning}} \right]$$

where [ ] is the rounding operator.

Assessing Markov Chain Convergence

Simulation-based Bayesian inference requires using simulated draws to summarize the posterior distribution or calculate any relevant quantities of interest. You need to treat the simulation draws with care. There are usually two issues. First, you have to decide whether the Markov chain has reached its stationary, or the desired posterior, distribution. Second, you have to determine the number of iterations to keep after the Markov chain has reached stationarity. Convergence diagnostics help to resolve these issues. Note that many diagnostic tools are designed to verify a necessary but not sufficient condition for convergence. There are no conclusive tests that can tell you when the Markov chain has converged to its stationary distribution. You should proceed with caution. Also, note that you should check the convergence of *all* parameters, and not just those of interest, before proceeding to make any inference. With some models, certain parameters can appear to have very good convergence behavior, but that could be misleading due to the slow convergence of other parameters. If some of the parameters have bad mixing, you cannot get accurate posterior inference for parameters that appear to have good mixing. See Cowles and Carlin (1996) and Brooks and Roberts (1998) for discussions about convergence diagnostics.

Visual Analysis via Trace Plots

Trace plots of samples versus the simulation index can be very useful in assessing convergence. The trace tells you if the chain has not yet converged to its stationary distribution—that is, if it needs a

longer burn-in period. A trace can also tell you whether the chain is mixing well. A chain might have reached stationarity if the distribution of points is not changing as the chain progresses. The aspects of stationarity that are most recognizable from a trace plot are a relatively constant mean and variance. A chain that mixes well traverses its posterior space rapidly, and it can jump from one remote region of the posterior to another in relatively few steps. Figure 7.1 through Figure 7.4 display some typical features that you might see in trace plots. The traces are for a parameter called γ.

Figure 7.1 Essentially Perfect Trace for γ

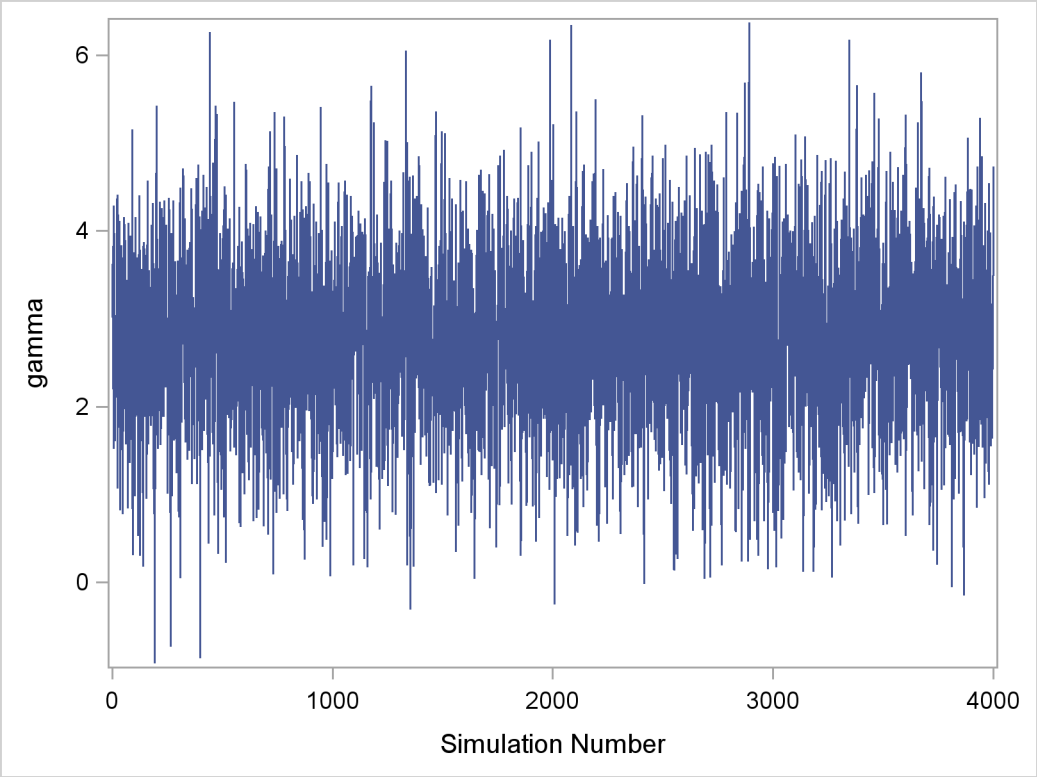

Figure 7.1 displays a "perfect" trace plot. Note that the center of the chain appears to be around the value 3, with very small fluctuations. This indicates that the chain could have reached the right distribution. The chain is mixing well; it is exploring the distribution by traversing to areas where its density is very low. You can conclude that the mixing is quite good here.

Figure 7.2 Nonconvergence of γ

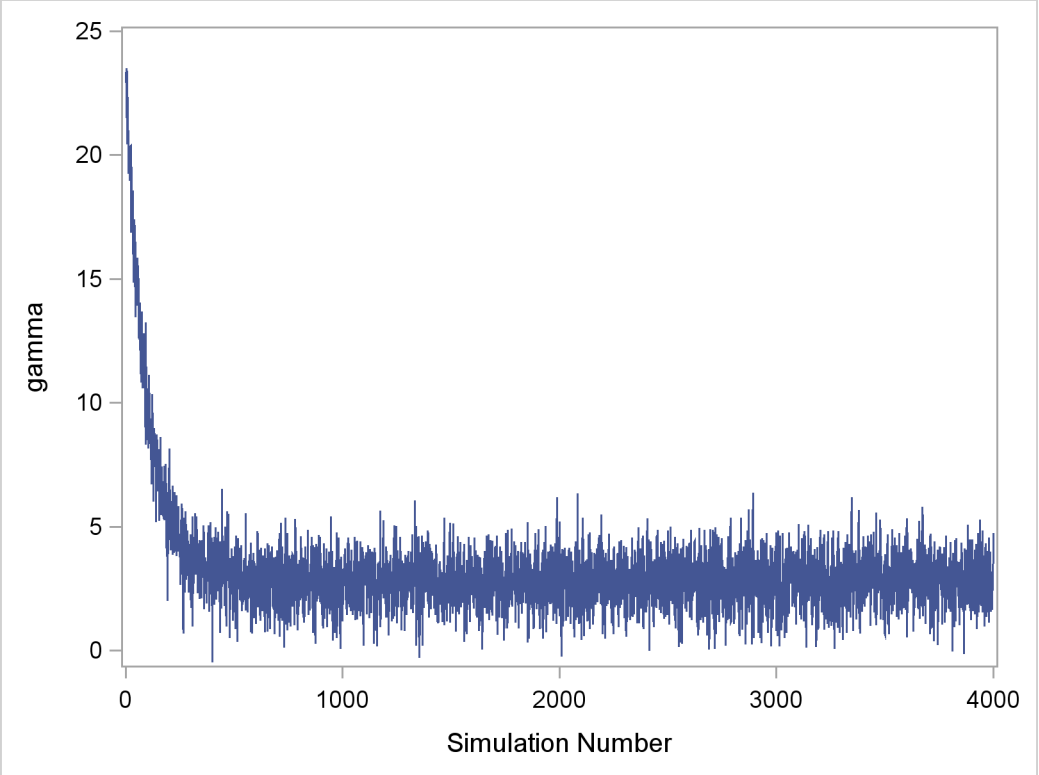

Figure 7.2 displays a trace plot for a chain that starts at a very remote initial value and makes its way to the targeting distribution. The first few hundred observations should be discarded. This chain appears to be mixing very well locally. It travels relatively quickly to the target distribution, reaching it in a few hundred iterations. If you have a chain that looks like this, you would want to increase the burn-in sample size. If you need to use this sample to make inferences, you would want to use only the samples toward the end of the chain.

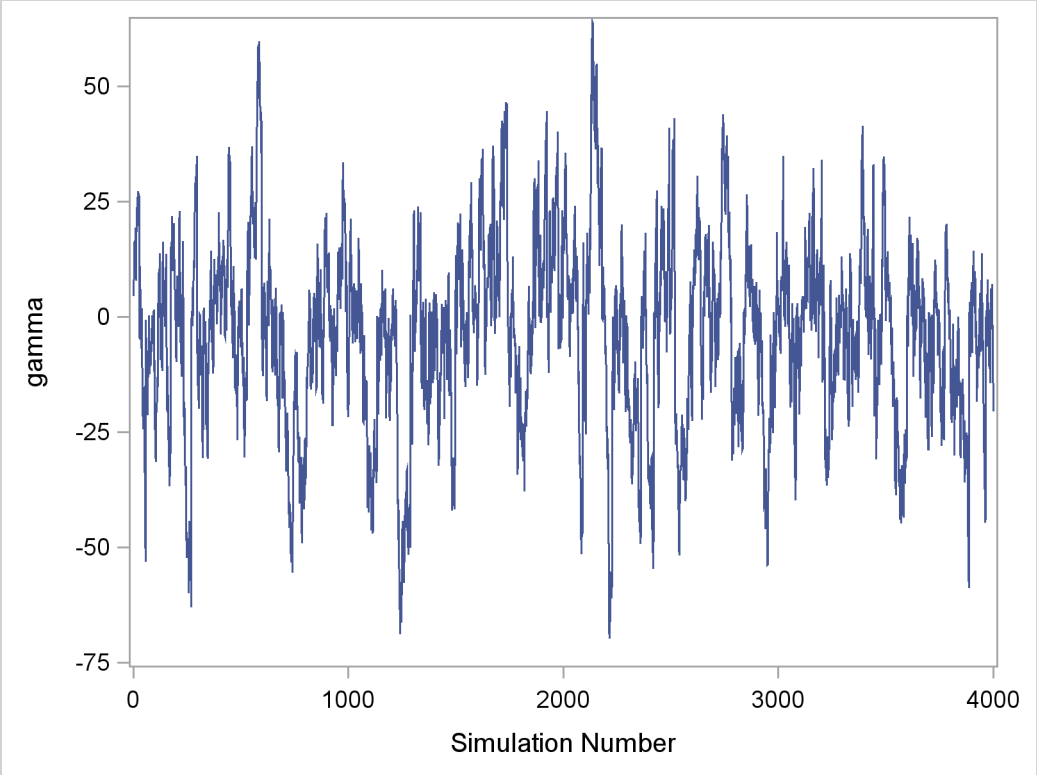
Figure 7.3 Marginal Mixing for γ



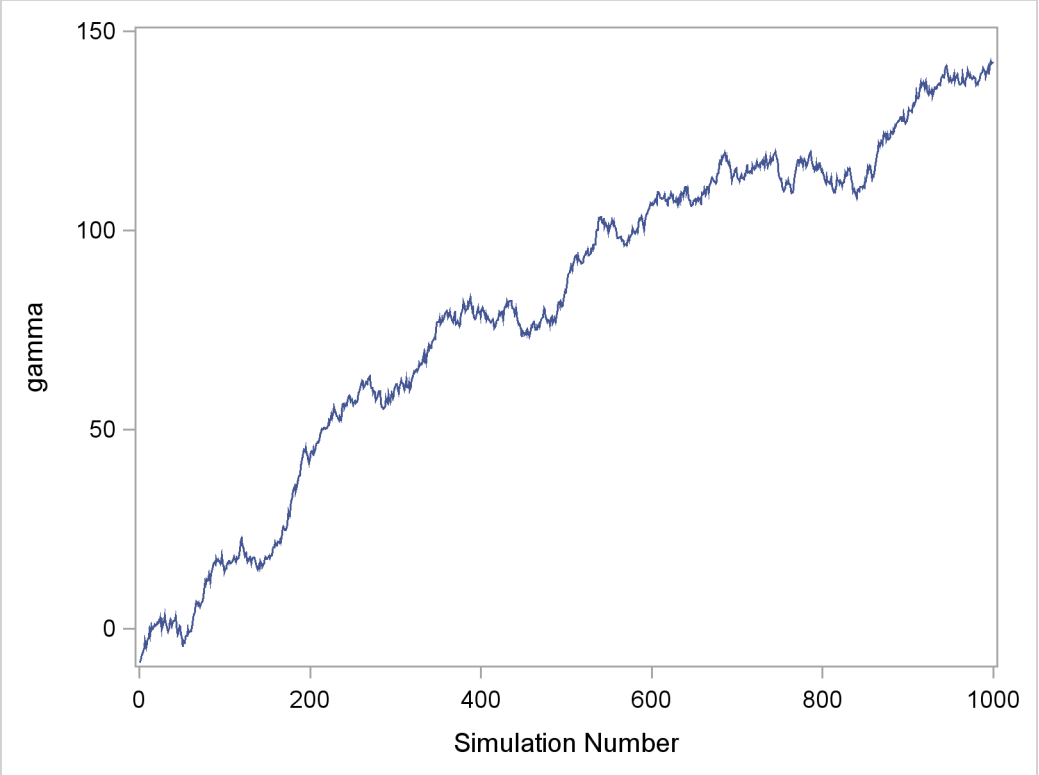


Figure 7.3 demonstrates marginal mixing. The chain is taking only small steps and does not traverse its distribution quickly. This type of trace plot is typically associated with high autocorrelation among the samples. To obtain a few thousand independent samples, you need to run the chain for much longer.

Figure 7.4 Bad Mixing, Nonconvergence of γ

The trace plot shown in Figure 7.4 depicts a chain with serious problems. It is mixing very slowly, and it offers no evidence of convergence. You would want to try to improve the mixing of this chain. For example, you might consider reparameterizing your model on the log scale. Run the Markov chain for a long time to see where it goes. This type of chain is entirely unsuitable for making parameter inferences.

Statistical Diagnostic Tests

The Bayesian procedures include several statistical diagnostic tests that can help you assess Markov chain convergence. For a detailed description of each of the diagnostic tests, see the following subsections. Table 7.1 provides a summary of the diagnostic tests and their interpretations.

Table 7.1 Convergence Diagnostic Tests Available in the Bayesian Procedures

Name	Description	Interpretation of the Test
Gelman-Rubin	Uses parallel chains with dispersed initial values to test whether they all converge to the same target distribution. Failure could indicate the presence of a multi-mode posterior distribution (different chains converge to different local modes) or the need to run a longer chain (burn-in is yet to be completed).	One-sided test based on a variance ratio test statistic. Large $\widehat{R}_c$ values indicate rejection.

Table 7.1 (continued)

Name	Description	Interpretation of the test
Geweke	Tests whether the mean estimates have converged by comparing means from the early and latter part of the Markov chain.	Two-sided test based on a z-score statistic. Large absolute z values indicate rejection.
Heidelberger-Welch (stationarity test)	Tests whether the Markov chain is a covariance (or weakly) stationary process. Failure could indicate that a longer Markov chain is needed.	One-sided test based on a Cramer–von Mises statistic. Small p-values indicate rejection.
Heidelberger-Welch (half-width test)	Reports whether the sample size is adequate to meet the required accuracy for the mean estimate. Failure could indicate that a longer Markov chain is needed.	If a relative half-width statistic is greater than a predetermined accuracy measure, this indicates rejection.
Raftery-Lewis	Evaluates the accuracy of the estimated (desired) percentiles by reporting the number of samples needed to reach the desired accuracy of the percentiles. Failure could indicate that a longer Markov chain is needed.	If the total samples needed are fewer than the Markov chain sample, this indicates rejection.
autocorrelation	Measures dependency among Markov chain samples.	High correlations between long lags indicate poor mixing.
effective sample size	Relates to autocorrelation; measures mixing of the Markov chain.	Large discrepancy between the effective sample size and the simulation sample size indicates poor mixing.

Gelman and Rubin Diagnostics

Gelman and Rubin diagnostics (Gelman and Rubin 1992; Brooks and Gelman 1997) are based on analyzing multiple simulated MCMC chains by comparing the variances within each chain and the variance between chains. Large deviation between these two variances indicates nonconvergence.

Define $\{\theta^t\}$, where $t = 1, \ldots, n$, to be the collection of a single Markov chain output. The parameter θ^t is the tth sample of the Markov chain. For notational simplicity, θ is assumed to be single dimensional in this section.

Suppose you have M parallel MCMC chains that were initialized from various parts of the target distribution. Each chain is of length n (after discarding the burn-in). For each θ^t, the simulations are labeled as θ_m^t, where $t = 1, \ldots, n$ and $m = 1, \ldots, M$. The between-chain variance B and the within-chain variance W are calculated as

$$
\begin{aligned}
B &= \frac{n}{M-1}\sum_{m=1}^{M}(\bar{\theta}_m^{\cdot}-\bar{\theta}_{\cdot}^{\cdot})^2, \quad \text{where } \bar{\theta}_m^{\cdot}=\frac{1}{n}\sum_{t=1}^{n}\theta_m^t, \quad \bar{\theta}_{\cdot}^{\cdot}=\frac{1}{M}\sum_{m=1}^{M}\bar{\theta}_m^{\cdot} \\
W &= \frac{1}{M}\sum_{m=1}^{M}s_m^2, \quad \text{where } s_m^2=\frac{1}{n-1}\sum_{t=1}^{n}(\theta_m^t-\bar{\theta}_m^{\cdot})^2
\end{aligned}
$$

The posterior marginal variance, $\text{var}(\theta|\mathbf{y})$, is a weighted average of W and B. The estimate of the variance is

$$
\widehat{V}=\frac{n-1}{n}W+\frac{M+1}{nM}B
$$

If all M chains have reached the target distribution, this posterior variance estimate should be very close to the within-chain variance W. Therefore, you would expect to see the ratio $\widehat{V}/W$ be close to 1. The square root of this ratio is referred to as the *potential scale reduction factor* (PSRF). A large PSRF indicates that the between-chain variance is substantially greater than the within-chain variance, so that longer simulation is needed. If the PSRF is close to 1, you can conclude that each of the M chains has stabilized, and they are likely to have reached the target distribution.

A refined version of PSRF is calculated, as suggested by Brooks and Gelman (1997), as

$$
\widehat{\mathrm{R}}_c=\sqrt{\frac{\hat{d}+3}{\hat{d}+1}\cdot\frac{\widehat{V}}{W}}=\sqrt{\frac{\hat{d}+3}{\hat{d}+1}\left(\frac{n-1}{n}+\frac{M+1}{nM}\frac{B}{W}\right)}
$$

where

$$
\hat{d}=\frac{2\widehat{V}^2}{\widehat{\text{Var}}(\widehat{V})}
$$

and

$$
\begin{aligned}
\widehat{\text{Var}}(\widehat{V}) &= \left(\frac{n-1}{n}\right)^2\frac{1}{M}\widehat{\text{Var}}(s_m^2)+\left(\frac{M+1}{nM}\right)^2\frac{2}{M-1}B^2 \\
&\quad +2\frac{(M+1)(n-1)}{n^2M}\frac{n}{M}\left(\widehat{\text{cov}}(s_m^2,(\bar{\theta}_m^{\cdot})^2)-2\bar{\theta}_{\cdot}^{\cdot}\widehat{\text{cov}}(s_m^2,\bar{\theta}_m^{\cdot})\right)
\end{aligned}
$$

All the Bayesian procedures also produce an upper $100(1-\alpha/2)\%$ confidence limit of $\widehat{\mathrm{R}}_c$. Gelman and Rubin (1992) showed that the ratio B/W in $\widehat{\mathrm{R}}_c$ has an F distribution with degrees of freedom

$M-1$ and $2W^2M/\widehat{\text{Var}}(s_m^2)$. Because you are concerned only if the scale is large, not small, only the upper $100(1-\alpha/2)\%$ confidence limit is reported. This is written as

$$\sqrt{\left(\frac{n-1}{n}+\frac{M+1}{nM}\cdot F_{1-\alpha/2}\left(M-1,\frac{2W^2}{\widehat{\text{Var}}(s_m^2)/M}\right)\right)\cdot\frac{\hat{d}+3}{\hat{d}+1}}$$

In the Bayesian procedures, you can specify the number of chains that you want to run. Typically three chains are sufficient. The first chain is used for posterior inference, such as mean and standard deviation; the other $M-1$ chains are used for computing the diagnostics and are discarded afterward. This test can be computationally costly, because it prolongs the simulation M-fold.

It is best to choose different initial values for all M chains. The initial values should be as dispersed from each other as possible so that the Markov chains can fully explore different parts of the distribution before they converge to the target. Similar initial values can be risky because all of the chains can get stuck in a local maximum; that is something this convergence test cannot detect. If you do not supply initial values for all the different chains, the procedures generate them for you.

Geweke Diagnostics

The Geweke test (Geweke 1992) compares values in the early part of the Markov chain to those in the latter part of the chain in order to detect failure of convergence. The statistic is constructed as follows. Two subsequences of the Markov chain $\{\theta^t\}$ are taken out, with $\{\theta_1^t : t=1,\ldots,n_1\}$ and $\{\theta_2^t : t=n_a,\ldots,n\}$, where $1<n_1<n_a<n$. Let $n_2=n-n_a+1$, and define

$$\bar{\theta}_1=\frac{1}{n_1}\sum_{t=1}^{n_1}\theta^t \quad\text{and}\quad \bar{\theta}_2=\frac{1}{n_2}\sum_{t=n_a}^{n}\theta^t$$

Let $\hat{s}_1(0)$ and $\hat{s}_2(0)$ denote consistent spectral density estimates at zero frequency (see the subsection "Spectral Density Estimate at Zero Frequency" on page 164 for estimation details) for the two MCMC chains, respectively. If the ratios n_1/n and n_2/n are fixed, $(n_1+n_2)/n<1$, and the chain is stationary, then the following statistic converges to a standard normal distribution as $n\to\infty$:

$$Z_n=\frac{\bar{\theta}_1-\bar{\theta}_2}{\sqrt{\frac{\hat{s}_1(0)}{n_1}+\frac{\hat{s}_2(0)}{n_2}}}$$

This is a two-sided test, and large absolute z-scores indicate rejection.

Spectral Density Estimate at Zero Frequency

For one sequence of the Markov chain $\{\theta_t\}$, the relationship between the h-lag covariance sequence of a time series and the spectral density, f, is

$$s_h = \frac{1}{2\pi}\int_{-\pi}^{\pi} \exp(\mathrm{i}\omega h) f(\omega) d\omega$$

where i indicates that ωh is the complex argument. Inverting this Fourier integral,

$$f(\omega) = \sum_{h=-\infty}^{\infty} s_h \exp(-\mathrm{i}\omega h) = s_0 \left(1 + 2\sum_{h=1}^{\infty} \rho_h \cos(\omega h)\right)$$

It follows that

$$f(0) = \sigma^2 \left(1 + 2\sum_{h=1}^{\infty} \rho_h\right)$$

which gives an autocorrelation adjusted estimate of the variance. In this equation, σ^2 is the naive variance estimate of the sequence $\{\theta_t\}$ and ρ_h is the lag h autocorrelation. Due to obvious computational difficulties, such as calculation of autocorrelation at infinity, you cannot effectively estimate $f(0)$ by using the preceding formula. The usual route is to first obtain the *periodogram* $p(\omega)$ of the sequence, and then estimate $f(0)$ by smoothing the estimated periodogram. The periodogram is defined to be

$$p(\omega) = \frac{1}{n}\left[\left(\sum_{t=1}^{n} \theta_t \sin(\omega t)\right)^2 + \left(\sum_{t=1}^{n} \theta_t \cos(\omega t)\right)^2\right]$$

The procedures use the following way to estimate $\hat{f}(0)$ from p (Heidelberger and Welch 1981). In $p(\omega)$, let $\omega = \omega_k = 2\pi k/n$ and $k = 1, \ldots, [\frac{n}{2}]$.[1] A smooth spectral density in the domain of $(0, \pi]$ is obtained by fitting a gamma model with the log link function, using $p(\omega_k)$ as response and $x_1(\omega_k) = \sqrt{3}(4\omega_k/(2\pi) - 1)$ as the only regressor. The predicted value $\hat{f}(0)$ is given by

$$\hat{f}(0) = \exp(\hat{\beta}_0 - \sqrt{3}\hat{\beta}_1)$$

where $\hat{\beta}_0$ and $\hat{\beta}_1$ are the estimates of the intercept and slope parameters, respectively.

[1] This is equivalent to the fast Fourier transformation of the original time series θ_t.

Heidelberger and Welch Diagnostics

The Heidelberger and Welch test (Heidelberger and Welch 1981, 1983) consists of two parts: a stationary portion test and a half-width test. The stationarity test assesses the stationarity of a Markov chain by testing the hypothesis that the chain comes from a covariance stationary process. The half-width test checks whether the Markov chain sample size is adequate to estimate the mean values accurately.

Given $\{\theta^t\}$, set $S_0 = 0$, $S_n = \sum_{t=1}^{n} \theta^t$, and $\bar{\theta} = (1/n)\sum_{t=1}^{n} \theta^t$. You can construct the following sequence with s coordinates on values from $\frac{1}{n}, \frac{2}{n}, \cdots, 1$:

$$B_n(s) = (S_{[ns]} - [ns]\bar{\theta})/(n\,\hat{p}(0))^{1/2}$$

where [ ] is the rounding operator, and $\hat{p}(0)$ is an estimate of the spectral density at zero frequency that uses the second half of the sequence (see the section "Spectral Density Estimate at Zero Frequency" on page 164 for estimation details). For large n, B_n converges in distribution to a Brownian bridge (Billingsley 1986). So you can construct a test statistic by using B_n. The statistic used in these procedures is the Cramer–von Mises statistic[2]; that is $\int_0^1 B_n(s)^2 ds = CVM(B_n)$. As $n \to \infty$, the statistic converges in distribution to a standard Cramer–von Mises distribution. The integral $\int_0^1 B_n(s)^2 ds$ is numerically approximated using Simpson's rule.

Let $y_i = B_n(s)^2$, where $s = 0, \frac{1}{n}, \cdots, \frac{n-1}{n}, 1$, and $i = ns = 0, 1, \cdots, n$. If n is even, let $m = n/2$; otherwise, let $m = (n-1)/2$. The Simpson's approximation to the integral is

$$\int_0^1 B_n(s)^2 ds \approx \frac{1}{3n}\left[y_0 + 4(y_1 + \cdots + y_{2m-1}) + 2(y_2 + \cdots + y_{2m-2}) + y_{2m}\right]$$

Note that Simpson's rule requires an even number of intervals. When n is odd, y_n is set to be 0 and the value does not contribute to the approximation.

This test can be performed repeatedly on the same chain, and it helps you identify a time t when the chain has reached stationarity. The whole chain, $\{\theta^t\}$, is first used to construct the Cramer–von Mises statistic. If it passes the test, you can conclude that the entire chain is stationary. If it fails the test, you drop the initial 10% of the chain and redo the test by using the remaining 90%. This process is repeated until either a time t is selected or it reaches a point where there are not enough data remaining to construct a confidence interval (the cutoff proportion is set to be 50%).

The part of the chain that is deemed stationary is put through a half-width test, which reports whether the sample size is adequate to meet certain accuracy requirements for the mean estimates. Running the simulation less than this length of time would not meet the requirement, while running it longer would not provide any additional information that is needed. The statistic calculated here is the *relative half-width* (RHW) of the confidence interval. The RHW for a confidence interval of level $1-\alpha$ is

[2] The von Mises distribution was first introduced by von Mises (1918). The density function is $p(\theta|\mu\kappa) \sim M(\mu,\kappa) = [2\pi I_0(\kappa)]^{-1}\exp(\kappa\cos(\theta-\mu))$ $(0 \le \theta \le 2\pi)$, where the function $I_0(\kappa)$ is the modified Bessel function of the first kind and order zero, defined by $I_0(\kappa) = (2\pi)^{-1}\int_0^{2\pi}\exp(\kappa\cos(\theta-\mu))d\theta$.

$$\text{RHW} = \frac{z_{(1-\alpha/2)} \cdot (\hat{s}_n/n)^{1/2}}{\hat{\theta}}$$

where $z_{(1-\alpha/2)}$ is the z-score of the $100(1-\alpha/2)$th percentile (for example, $z_{(1-\alpha/2)} = 1.96$ if $\alpha = 0.05$), $\hat{s}_n$ is the variance of the chain estimated using the spectral density method (see explanation in the section "Spectral Density Estimate at Zero Frequency" on page 164), n is the length, and $\hat{\theta}$ is the estimated mean. The RHW quantifies accuracy of the $1-\alpha$ level confidence interval of the mean estimate by measuring the ratio between the sample standard error of the mean and the mean itself. In other words, you can stop the Markov chain if the variability of the mean stabilizes with respect to the mean. An implicit assumption is that large means are often accompanied by large variances. If this assumption is not met, then this test can produce false rejections (such as a small mean around 0 and large standard deviation) or false acceptance (such as a very large mean with relative small variance). As with any other convergence diagnostics, you might want to exercise caution in interpreting the results.

The stationarity test is one-sided; rejection occurs when the p-value is greater than $1-\alpha$. To perform the half-width test, you need to select an α level (the default of which is 0.05) and a predetermined tolerance value ϵ (the default of which is 0.1). If the calculated RHW is greater than ϵ, you conclude that there are not enough data to accurately estimate the mean with $1-\alpha$ confidence under tolerance of ϵ.

Raftery and Lewis Diagnostics

If your interest lies in posterior percentiles, you want a diagnostic test that evaluates the accuracy of the estimated percentiles. The Raftery-Lewis test (Raftery and Lewis 1992, 1996) is designed for this purpose. Notation and deductions here closely resemble those in Raftery and Lewis (1996).

Suppose you are interested in a quantity θ_q such that $P(\theta \leq \theta_q|\mathbf{y}) = q$, where q can be an arbitrary cumulative probability, such as 0.025. This θ_q can be empirically estimated by finding the $[n \cdot 100 \cdot q]$th number of the sorted $\{\theta^t\}$. Let $\hat{\theta}_q$ denote the estimand, which corresponds to an estimated probability $P(\theta \leq \hat{\theta}_q) = \hat{P}_q$. Because the simulated posterior distribution converges to the true distribution as the simulation sample size grows, $\hat{\theta}_q$ can achieve any degree of accuracy if the simulator is run for a very long time. However, running too long a simulation can be wasteful. Alternatively, you can use coverage probability to measure accuracy and stop the chain when a certain accuracy is reached.

A stopping criterion is reached when the estimated probability is within $\pm r$ of the true cumulative probability q, with probability s, such as $P(\hat{P}_q \in (q-r, q+r)) = s$. For example, suppose you want the coverage probability s to be 0.95 and the amount of tolerance r to be 0.005. This corresponds to requiring that the estimate of the cumulative distribution function of the 2.5th percentile be estimated to within ± 0.5 percentage points with probability 0.95.

The Raftery-Lewis diagnostics test finds the number of iterations, M, that need to be discarded (burn-ins) and the number of iterations needed, N, to achieve a desired precision. Given a predefined cumulative probability q, these procedures first find $\hat{\theta}_q$, and then they construct a binary $0-1$ process $\{Z_t\}$ by setting $Z_t = 1$ if $\theta^t \leq \hat{\theta}_q$ and 0 otherwise for all t. The sequence $\{Z_t\}$ is itself not a Markov chain, but you can construct a subsequence of $\{Z_t\}$ that is approximately Markovian if it

is sufficiently k-thinned. When k becomes reasonably large, $\{Z_t^{(k)}\}$ starts to behave like a Markov chain.

Next, the procedures find this thinning parameter k. The number k is estimated by comparing the Bayesian information criterion (BIC) between two Markov models: a first-order and a second-order Markov model. A jth-order Markov model is one in which the current value of $\{Z_t^{(k)}\}$ depends on the previous j values. For example, in a second-order Markov model,

$$\begin{aligned} & p\left(Z_t^{(k)} = z_t | Z_{t-1}^{(k)} = z_{t-1}, Z_{t-2}^{(k)} = z_{t-2}, \cdots, Z_0^{(k)} = z_0\right) \\ = \quad & p\left(Z_t^{(k)} = z_t | Z_{t-1}^{(k)} = z_{t-1}, Z_{t-2}^{(k)} = z_{t-2}\right) \end{aligned}$$

where $z_i = \{0, 1\}, i = 0, \cdots, t$. Given $\{Z_t^{(k)}\}$, you can construct two transition count matrices for a second-order Markov model:

	$z_t = 0$		$z_t = 1$	
	$z_{t-1} = 0$	$z_{t-1} = 1$	$z_{t-1} = 0$	$z_{t-1} = 1$
$z_{t-2} = 0$	w_{000}	w_{010}	w_{001}	w_{011}
$z_{t-2} = 1$	w_{100}	w_{110}	w_{101}	w_{111}

For each k, the procedures calculate the BIC that compares the two Markov models. The BIC is based on a likelihood ratio test statistic that is defined as

$$G_k^2 = 2 \sum_{i=0}^{1} \sum_{j=0}^{1} \sum_{l=0}^{1} w_{ijl} \log \frac{w_{ijl}}{\hat{w}_{ijl}}$$

where $\hat{w}_{ijl}$ is the expected cell count of w_{ijl} under the null model, the first-order Markov model, where the assumption $(Z_t^{(k)} \perp Z_{t-2}^{(k)}) | Z_{t-1}^{(k)}$ holds. The formula for the expected cell count is

$$\hat{w}_{ijl} = \frac{\sum_i w_{ijl} \cdot \sum_l w_{ijl}}{\sum_i \sum_l w_{ijl}}$$

The BIC is $G_k^2 - 2\log(n_k - 2)$, where n_k is the k-thinned sample size (every kth sample starting with the first), with the last two data points discarded due to the construction of the second-order Markov model. The thinning parameter k is the smallest k for which the BIC is negative. When k is found, you can estimate a transition probability matrix between state 0 and state 1 for $\{Z_t^{(k)}\}$:

$$Q = \begin{pmatrix} 1-\alpha & \alpha \\ \beta & 1-\beta \end{pmatrix}$$

Because $\{Z_t^{(k)}\}$ is a Markov chain, its equilibrium distribution exists and is estimated by

$$\pi = (\pi_0, \pi_1) = \frac{(\beta, \alpha)}{\alpha + \beta}$$

where $\pi_0 = P(\theta \leq \theta_q | \mathbf{y})$ and $\pi_1 = 1 - \pi_0$. The goal is to find an iteration number m such that after m steps, the estimated transition probability $P(Z_m^{(k)} = i | Z_0^{(k)} = j)$ is within ϵ of equilibrium π_i for $i, j = 0, 1$. Let $e_0 = (1, 0)$ and $e_1 = 1 - e_0$. The estimated transition probability after step m is

$$P(Z_m^{(k)} = i | Z_0^{(k)} = j) = e_j \left[\begin{pmatrix} \pi_0 & \pi_1 \\ \pi_0 & \pi_1 \end{pmatrix} + \frac{(1-\alpha-\beta)^m}{\alpha+\beta} \begin{pmatrix} \alpha & -\alpha \\ -\beta & \beta \end{pmatrix} \right] e_j^\top$$

which holds when

$$m = \frac{\log\left(\frac{(\alpha+\beta)\epsilon}{\max(\alpha,\beta)}\right)}{\log(1-\alpha-\beta)}$$

assuming $1 - \alpha - \beta > 0$.

Therefore, by time m, $\{Z_t^{(k)}\}$ is sufficiently close to its equilibrium distribution, and you know that a total size of $M = mk$ should be discarded as the burn-in.

Next, the procedures estimate N, the number of simulations needed to achieve desired accuracy on percentile estimation. The estimate of $P(\theta \leq \theta_q | \mathbf{y})$ is $\bar{Z}_n^{(k)} = \frac{1}{n} \sum_{t=1}^{n} Z_t^{(k)}$. For large n, $\bar{Z}_n^{(k)}$ is normally distributed with mean q, the true cumulative probability, and variance

$$\frac{1}{n} \frac{(2-\alpha-\beta)\alpha\beta}{(\alpha+\beta)^3}$$

$P(q - r \leq \bar{Z}_n^{(k)} \leq q + r) = s$ is satisfied if

$$n = \frac{(2-\alpha-\beta)\alpha\beta}{(\alpha+\beta)^3} \left\{ \frac{\Phi^{-1}\left(\frac{s+1}{2}\right)}{r} \right\}^2$$

Therefore, $N = nk$.

By using similar reasoning, the procedures first calculate the minimal number of iterations needed to achieve the desired accuracy, assuming the samples are independent:

$$N_{min} = \left\{ \Phi^{-1} \left(\frac{s+1}{2} \right) \right\}^2 \frac{q(1-q)}{r^2}$$

If $\{\theta^t\}$ does not have that required sample size, the Raftery-Lewis test is not carried out. If you still want to carry out the test, increase the number of Markov chain iterations.

The ratio N/N_{min} is sometimes referred to as the *dependence factor*. It measures deviation from posterior sample independence: the closer it is to 1, the less correlated are the samples. There are a few things to keep in mind when you use this test. This diagnostic tool is specifically designed for the percentile of interest and does not provide information about convergence of the chain as a whole (Brooks and Roberts 1999). In addition, the test can be very sensitive to small changes. Both N and N_{min} are inversely proportional to r^2, so you can expect to see large variations in these numbers with small changes to input variables, such as the desired coverage probability or the cumulative probability of interest. Last, the time until convergence for a parameter can differ substantially for different cumulative probabilities.

Autocorrelations

The sample autocorrelation of lag h is defined in terms of the sample autocovariance function:

$$\hat{\rho}(h) = \frac{\hat{\gamma}(h)}{\hat{\gamma}(0)}, \quad |h| < n$$

The sample autocovariance function of lag h (of $\left\{\theta_i^t\right\}$) is defined by

$$\hat{\gamma}(h) = \frac{1}{n-h} \sum_{t=1}^{n-h} \left(\theta_i^{t+h} - \bar{\theta}_i \right) \left(\theta_i^t - \bar{\theta}_i \right), \quad 0 \le h < n$$

Effective Sample Size

You can use autocorrelation and trace plots to examine the mixing of a Markov chain. A closely related measure of mixing is the effective sample size (ESS) (Kass et al. 1998).

ESS is defined as follows:

$$\text{ESS} = \frac{n}{\tau} = \frac{n}{1 + 2\sum_{k=1}^{\infty} \rho_k(\theta)}$$

where n is the total sample size and $\rho_k(\theta)$ is the autocorrelation of lag k for θ. The quantity τ is referred to as the autocorrelation time. To estimate τ, the Bayesian procedures first find a cutoff point k after which the autocorrelations are very close to zero, and then sum all the ρ_k up to that point. The cutoff point k is such that $\rho_k < 0.01$ or $\rho_k < 2s_k$, where s_k is the estimated standard deviation:

$$s_k = 2\sqrt{\left(\frac{1}{n}\left(1 + 2\sum_{j=1}^{k-1}\rho_k^2(\theta)\right)\right)}$$

ESS and τ are inversely proportional to each other, and low ESS or high τ indicates bad mixing of the Markov chain.

Summary Statistics

Let $\boldsymbol{\theta}$ be a p-dimensional parameter vector of interest: $\boldsymbol{\theta} = \{\theta_1, \ldots, \theta_p\}$. For each $i \in \{1, \ldots, p\}$, there are n observations: $\theta_i = \{\theta_i^t,\ t = 1, \ldots, n\}$.

Mean

The posterior mean is calculated by using the following formula:

$$E(\theta_i|\mathbf{y}) \approx \bar{\theta}_i = \frac{1}{n}\sum_{t=1}^{n}\theta_i^t, \text{ for } i = 1, \ldots, n$$

Standard Deviation

Sample standard deviation (expressed in variance term) is calculated by using the following formula:

$$\mathrm{Var}(\theta_i|\mathbf{y}) \approx s_i^2 = \frac{1}{n-1}\sum_{t=1}^{n}\left(\theta_i^t - \bar{\theta}_i\right)^2$$

Standard Error of the Mean Estimate

Suppose you have n iid samples, the mean estimate is $\bar{\theta}_i$, and the sample standard deviation is s_i. The standard error of the estimate is $\hat{\sigma}_i/\sqrt{n}$. However, positive autocorrelation (see the section "Autocorrelations" on page 169 for a definition) in the MCMC samples makes this an underestimate. To take account of the autocorrelation, the Bayesian procedures correct the standard error by using effective sample size (see the section "Effective Sample Size" on page 169).

Given an effective sample size of m, the standard error for $\bar{\theta}_i$ is $\hat{\sigma}_i/\sqrt{m}$. The procedures use the following formula (expressed in variance term):

$$\widehat{\mathrm{Var}}(\bar{\theta}_i) = \frac{1 + 2\sum_{k=1}^{\infty}\rho_k(\theta_i)}{n} \cdot \frac{\sum_{t=1}^{n}\left(\theta_i^t - \bar{\theta}_i\right)^2}{(n-1)}$$

The standard error of the mean is also known as the Monte Carlo standard error (MCSE). The MCSE provides a measurement of the accuracy of the posterior estimates, and small values do not necessarily indicate that you have recovered the true posterior mean.

Percentiles

Sample percentiles are calculated using Definition 5 (see Chapter 4, "The UNIVARIATE Procedure" (*Base SAS Procedures Guide: Statistical Procedures*),).

Correlation

Correlation between θ_i and θ_j is calculated as

$$r_{ij} = \frac{\sum_{t=1}^{n} \left(\theta_i^t - \bar{\theta}_i\right)\left(\theta_j^t - \bar{\theta}_j\right)}{\sqrt{\sum_t \left(\theta_i^t - \bar{\theta}_i\right)^2 \sum_t \left(\theta_j^t - \bar{\theta}_j\right)^2}}$$

Covariance

Covariance θ_i and θ_j is calculated as

$$s_{ij} = \sum_{t=1}^{n} \left(\theta_i^t - \bar{\theta}_i\right)\left(\theta_j^t - \bar{\theta}_j\right)/(n-1)$$

Equal-Tail Credible Interval

Let $\pi\left(\theta_i|\mathbf{y}\right)$ denote the marginal posterior cumulative distribution function of θ_i. A $100\,(1-\alpha)\,\%$ Bayesian equal-tail credible interval for θ_i is $\left(\theta_i^{\alpha/2}, \theta_i^{1-\alpha/2}\right)$, where $\pi\left(\theta_i^{\alpha/2}|\mathbf{y}\right) = \frac{\alpha}{2}$, and $\pi\left(\theta_i^{1-\alpha/2}|\mathbf{y}\right) = 1 - \frac{\alpha}{2}$. The interval is obtained using the empirical $\frac{\alpha}{2}$th and $(1-\frac{\alpha}{2})$th percentiles of $\left\{\theta_i^t\right\}$.

Highest Posterior Density (HPD) Interval

For a definition of an HPD interval, see the section "Interval Estimation" on page 149. The procedures use the Chen-Shao algorithm (Chen and Shao 1999; Chen, Shao, and Ibrahim 2000) to estimate an empirical HPD interval of θ_i:

1. Sort $\left\{\theta_i^t\right\}$ to obtain the ordered values:

$$\theta_{i(1)} \leq \theta_{i(2)} \leq \cdots \leq \theta_{i(n)}$$

2. Compute the $100\,(1-\alpha)\,\%$ credible intervals:

$$R_j\,(n) = \left(\theta_{i(j)}, \theta_{i(j+[(1-\alpha)n])}\right)$$

for $j = 1, 2, \ldots, n - [(1-\alpha)\,n]$.

3. The $100\,(1-\alpha)\,\%$ HPD interval, denoted by $R_{j*}\,(n)$, is the one with the smallest interval width among all credible intervals.

Deviance Information Criterion (DIC)

The deviance information criterion (DIC) (Spiegelhalter et al. 2002) is a model assessment tool, and it is a Bayesian alternative to Akaike's information criterion (AIC) and the Bayesian information criterion (BIC, also known as the Schwarz criterion). The DIC uses the posterior densities, which means that it takes the prior information into account. The criterion can be applied to nonnested models and models that have non-iid data. Calculation of the DIC in MCMC is trivial—it does not require maximization over the parameter space, like the AIC and BIC. A smaller DIC indicates a better fit to the data set.

Letting $\boldsymbol{\theta}$ be the parameters of the model, the deviance information formula is

$$\text{DIC} = \overline{D(\boldsymbol{\theta})} + p_D = D(\bar{\boldsymbol{\theta}}) + 2p_D$$

where

$D(\boldsymbol{\theta}) = 2\,(\log(f(\mathbf{y})) - \log(p(\mathbf{y}|\boldsymbol{\theta})))$: deviance

where

$p(\mathbf{y}|\boldsymbol{\theta})$: likelihood function with the normalizing constants.

$f(\mathbf{y})$: a standardizing term that is a function of the data alone. This term is constant with respect to the parameter and is irrelevant when you compare different models that have the same likelihood function. Since the term cancels out in DIC comparisons, its calculation is often omitted.

NOTE: You can think of the deviance as the difference in twice the log likelihood between the saturated, $f(\mathbf{y})$, and fitted, $p(\mathbf{y}|\boldsymbol{\theta})$, models.

$\bar{\boldsymbol{\theta}}$: posterior mean, approximated by $\frac{1}{n}\sum_{t=1}^{n}\boldsymbol{\theta}^t$

$\overline{D(\boldsymbol{\theta})}$: posterior mean of the deviance, approximated by $\frac{1}{n}\sum_{t=1}^{n} D(\boldsymbol{\theta}^t)$. The expected deviation measures how well the model fits the data.

$D(\bar{\boldsymbol{\theta}})$: deviance evaluated at $\bar{\boldsymbol{\theta}}$, equal to $-2\log(p(\mathbf{y}|\bar{\boldsymbol{\theta}}))$. It is the deviance evaluated at your "best" posterior estimate.

p_D: effective number of parameters. It is the difference between the measure of fit and the deviance at the estimates: $\overline{D(\boldsymbol{\theta})} - D(\bar{\boldsymbol{\theta}})$. This term describes the complexity of the model, and it serves as a penalization term that corrects deviance's propensity toward models with more parameters.

A Bayesian Reading List

This section lists a number of Bayesian textbooks of varying difficulty degrees and a few tutorial/review papers.

Textbooks

Introductory Books

Berry, D. A. (1996), *Statistics: A Bayesian Perspective*, London: Duxbury Press.

Overview: Categorical Data Analysis Procedures

There are two approaches to performing categorical data analyses. The first computes statistics based on tables defined by *categorical variables* (variables that assume only a limited number of discrete values), performs hypothesis tests about the association between these variables, and requires the assumption of a randomized process; following Stokes, Davis, and Koch (2000), call these methods *randomization procedures*. The other approach investigates the association by modeling a categorical response variable, regardless of whether the explanatory variables are continuous or categorical; call these methods *modeling procedures*. Several procedures in SAS/STAT software can be used for the analysis of categorical data.

The randomization procedures are:

FREQ builds frequency tables or contingency tables and can produce numerous statistics. For one-way frequency tables, it can perform tests for equal proportions, specified proportions, or the binomial proportion. For contingency tables, it can compute various tests and measures of association and agreement including chi-square statistics, odds ratios, correlation statistics, Fisher's exact test for any size

two-way table, kappa, and trend tests. In addition, it performs stratified analysis, computing Cochran-Mantel-Haenszel statistics and estimates of the common relative risk. Exact p-values and confidence intervals are available for various test statistics and measures. See Chapter 35, "The FREQ Procedure," for more information.

SURVEYFREQ incorporates complex sample designs to analyze one-way, two-way, and multiway crosstabulation tables. Estimates population totals and proportions and performs tests of goodness-of-fit and independence. See Chapter 14, "Introduction to Survey Procedures," and Chapter 83, "The SURVEYFREQ Procedure," for more information.

The modeling procedures, which require a categorical response variable, are:

CATMOD fits linear models to functions of categorical data, facilitating such analyses as regression, analysis of variance, linear modeling, log-linear modeling, logistic regression, and repeated measures analysis. Maximum likelihood estimation is used for the analysis of logits and generalized logits, and weighted least squares analysis is used for fitting models to other response functions. Iterative proportional fitting (IPF), which avoids the need for parameter estimation, is available for fitting hierarchical log-linear models when there is a single population. See Chapter 28, "The CATMOD Procedure," for more information.

GENMOD fits generalized linear models with maximum-likelihood methods. This family includes logistic, probit, and complementary log-log regression models for binomial data, Poisson and negative binomial regression models for count data, and multinomial models for ordinal response data. It performs likelihood ratio and Wald tests for Type I, Type III, and user-defined contrasts. It analyzes repeated measures data with generalized estimating equation (GEE) methods. Bayesian analysis capabilities for generalized linear models are also available. See Chapter 37, "The GENMOD Procedure," for more information.

GLIMMIX fits generalized linear mixed models with maximum-likelihood methods. If the model does not contain random effects, the GLIMMIX procedure fits generalized linear models by the method of maximum likelihood. This family includes logistic, probit, and complementary log-log regression models for binomial data, Poisson and negative binomial regression models for count data, and multinomial models for ordinal response data. See Chapter 38, "The GLIMMIX Procedure," for more information.

LOGISTIC fits linear logistic regression models for discrete response data with maximum-likelihood methods. It provides four variable selection methods, computes regression diagnostics, and compares and outputs receiver operating characteristic curves. It can also perform stratified conditional logistic regression analysis for binary response data and exact conditional regression analysis for binary and nominal response data. The logit link function in the logistic regression models can be replaced by the probit function or the complementary log-log function. See Chapter 51, "The LOGISTIC Procedure," for more information.

PROBIT fits models with probit, logit, or complementary log-log links for quantal assay or other discrete event data. It is mainly designed for dose-response analysis

with a natural response rate. It computes the fiducial limits for the dose variable and provides various graphical displays for the analysis. See Chapter 71, "The PROBIT Procedure," for more information.

SURVEYLOGISTIC fits logistic models for binary and ordinal outcomes to survey data by maximum likelihood, incorporating complex survey sample designs. See Chapter 84, "The SURVEYLOGISTIC Procedure," for more information.

Also see Chapter 3, "Introduction to Statistical Modeling with SAS/STAT Software," and Chapter 4, "Introduction to Regression Procedures," for more information about all the modeling and regression procedures.

Other procedures that can be used for categorical data analysis and modeling are:

CORRESP performs simple and multiple correspondence analyses, using a contingency table, Burt table, binary table, or raw categorical data as input. See Chapter 9, "Introduction to Multivariate Procedures," and Chapter 30, "The CORRESP Procedure," for more information.

PRINQUAL performs a principal component analysis of qualitative and/or quantitative data, and multidimensional preference analysis. See Chapter 9, "Introduction to Multivariate Procedures," and Chapter 70, "The PRINQUAL Procedure," for more information.

TRANSREG fits univariate and multivariate linear models, optionally with spline and other nonlinear transformations. Models include ordinary regression and ANOVA, multiple and multivariate regression, metric and nonmetric conjoint analysis, metric and nonmetric vector and ideal point preference mapping, redundancy analysis, canonical correlation, and response surface regression. See Chapter 4, "Introduction to Regression Procedures," and Chapter 90, "The TRANSREG Procedure," for more information.

Introduction

A *categorical variable* is a variable that assumes only a limited number of discrete values. The measurement scale for a categorical variable is unrestricted. It can be *nominal*, which means that the observed levels are not ordered. It can be *ordinal*, which means that the observed levels are ordered in some way. Or it can be *interval*, which means that the observed levels are ordered and numeric and that any interval of one unit on the scale of measurement represents the same amount, regardless of its location on the scale. One example of a categorical variable is litter size; another is the number of times a subject has been married. A variable that lies on a nominal scale is sometimes called a *qualitative* or *classification variable*.

Categorical data result from observations on multiple subjects where one or more categorical variables are observed for each subject. If there is only one categorical variable, then the data are generally represented by a *frequency table*, which lists each observed value of the variable and its frequency of occurrence.

If there are two or more categorical variables, then a subject's *profile* is defined as the subject's observed values for each of the variables. Such categorical data can be represented by a frequency table that lists each observed profile and its frequency of occurrence.

If there are exactly two categorical variables, then the data are often represented by a two-dimensional *contingency table*, which has one row for each level of variable 1 and one column for each level of variable 2. The intersections of rows and columns, called *cells*, correspond to variable profiles, and each cell contains the frequency of occurrence of the corresponding profile.

If there are more than two categorical variables, then the data can be represented by a *multidimensional contingency table*. There are two commonly used methods for displaying such tables, and both require that the variables be divided into two sets.

- In the first method, one set contains a row variable and a column variable for a two-dimensional contingency table, and the second set contains all of the other variables. The variables in the second set are used to form a set of profiles. Thus, the data are represented as a series of two-dimensional contingency tables, one for each profile. This is the data representation used by PROC FREQ. For example, if you request tables for RACE*SEX*AGE*INCOME, the FREQ procedure represents the data as a series of contingency tables: the row variable is AGE, the column variable is INCOME, and the combinations of levels of RACE and SEX form a set of profiles.
- In the second method, one set contains the independent variables, and the other set contains the dependent variables. Profiles based on the independent variables are called *population profiles*, whereas those based on the dependent variables are called *response profiles*. A two-dimensional contingency table is then formed, with one row for each population profile and one column for each response profile. Since any subject can have only one population profile and one response profile, the contingency table is uniquely defined. This is the data representation used by the modeling procedures.

NOTE: Modeling procedures for categorical data analysis only require that the response variable be categorical—the explanatory variables are allowed to be continuous or categorical. However, note that PROC CATMOD was designed to handle contingency table data, and it does not efficiently handle continuous covariates.

Sampling Frameworks and Distribution Assumptions

This section discusses the sampling frameworks and distribution assumptions for the modeling and randomization procedures.

Simple Random Sampling: One Population

Suppose you take a simple random sample of 100 people and ask each person the following question, "Of the three colors red, blue, and green, which is your favorite?" You then tabulate the results in a frequency table as shown in Table 8.1.

Table 8.1 One-Way Frequency Table

	Favorite Color			
	Red	**Blue**	**Green**	**Total**
Frequency	52	31	17	100
Proportion	0.52	0.31	0.17	1.00

In the population you are sampling, you assume there is an unknown probability that a population member, selected at random, would choose any given color. In order to estimate that probability, you use the sample proportion

$$p_j = \frac{n_j}{n}$$

where n_j is the frequency of the jth response and n is the total frequency.

Because of the random variation inherent in any random sample, the frequencies have a probability distribution representing their relative frequency of occurrence in a hypothetical series of samples. For a simple random sample, the distribution of frequencies for a frequency table with three levels is as follows. The probability that the first frequency is n_1, the second frequency is n_2, and the third is $n_3 = n - n_1 - n_2$, is given by

$$\Pr(n_1, n_2, n_3) = \frac{n!}{n_1! n_2! n_3!} \pi_1^{n_1} \pi_2^{n_2} \pi_3^{n_3}$$

where π_j is the true probability of observing the jth response level in the population.

This distribution, called the *multinomial distribution*, can be generalized to any number of response levels. The special case of two response levels is called the *binomial distribution*.

Simple random sampling is the type of sampling required by the (non-survey) modeling procedures when there is one population. The modeling procedures use the multinomial distribution to estimate a probability vector and its covariance matrix. If the sample size is sufficiently large, then the probability vector is approximately normally distributed as a result of central limit theory. This result is used to compute appropriate test statistics for the specified statistical model.

Stratified Simple Random Sampling: Multiple Populations

Suppose you take two simple random samples, 50 men and 50 women, and ask the same question as before. You are now sampling two different populations that may have different response probabilities. The data can be tabulated as shown in Table 8.2.

Table 8.2 Two-Way Contingency Table: Sex by Color

	Favorite Color			
Sex	**Red**	**Blue**	**Green**	**Total**
Male	30	10	10	50
Female	20	10	20	50
Total	50	20	30	100

Note that the row marginal totals (50, 50) of the contingency table are fixed by the sampling design, but the column marginal totals (50, 20, 30) are random. There are six probabilities of interest for this table, and they are estimated by the sample proportions

$$p_{ij} = \frac{n_{ij}}{n_i}$$

where n_{ij} denotes the frequency for the ith population and the jth response and n_i is the total frequency for the ith population. For this contingency table, the sample proportions are shown in Table 8.3.

Table 8.3 Table of Sample Proportions by Sex

	Favorite Color			
Sex	**Red**	**Blue**	**Green**	**Total**
Male	0.60	0.20	0.20	1.00
Female	0.40	0.20	0.40	1.00

The probability distribution of the six frequencies is the *product multinomial distribution*

$$\Pr(n_{11}, n_{12}, n_{13}, n_{21}, n_{22}, n_{23}) = \frac{n_1! n_2! \pi_{11}^{n_{11}} \pi_{12}^{n_{12}} \pi_{13}^{n_{13}} \pi_{21}^{n_{21}} \pi_{22}^{n_{22}} \pi_{23}^{n_{23}}}{n_{11}! n_{12}! n_{13}! n_{21}! n_{22}! n_{23}!}$$

where π_{ij} is the true probability of observing the jth response level in the ith population. The product multinomial distribution is simply the product of two or more individual multinomial distributions since the populations are independent. This distribution can be generalized to any number of populations and response levels.

Stratified simple random sampling is the type of sampling required by the modeling procedures when there is more than one population. The product multinomial distribution is used to estimate a probability vector and its covariance matrix. If the sample sizes are sufficiently large, then the probability vector is approximately normally distributed as a result of central limit theory, and this result is used to compute appropriate test statistics for the specified statistical model. The statistics

are known as Wald statistics, and they are approximately distributed as chi-square when the null hypothesis is true.

Observational Data: Analyzing the Entire Population

Sometimes the observed data do not come from a random sample but instead represent a complete set of observations on some population. For example, suppose a class of 100 students is classified according to sex and favorite color. The results are shown in Table 8.4.

In this case, you could argue that all of the frequencies are fixed since the entire population is observed; therefore, there is no sampling error. On the other hand, you could hypothesize that the observed table has only fixed marginals and that the cell frequencies represent one realization of a conceptual process of assigning color preferences to individuals. The assignment process is open to hypothesis, which means that you can hypothesize restrictions on the joint probabilities.

Table 8.4 Two-Way Contingency Table: Sex by Color

	Favorite Color			
Sex	**Red**	**Blue**	**Green**	**Total**
Male	16	21	20	57
Female	12	20	11	43
Total	28	41	31	100

The usual hypothesis (sometimes called *randomness*) is that the distribution of the column variable (Favorite Color) does not depend on the row variable (Sex). This implies that, for each row of the table, the assignment process corresponds to a simple random sample (without replacement) from the finite population represented by the column marginal totals (or by the column marginal subtotals that remain after sampling other rows). The hypothesis of randomness implies that the probability distribution on the frequencies in the table is the *hypergeometric distribution*.

If the same row and column variables are observed for each of several populations, then the probability distribution of all the frequencies can be called the *multiple hypergeometric distribution.* Each population is called a *stratum*, and an analysis that draws information from each stratum and then summarizes across them is called a *stratified analysis* (or a *blocked analysis* or a *matched analysis*). PROC FREQ does such a stratified analysis, computing test statistics and measures of association.

In general, the populations are formed on the basis of cross-classifications of independent variables. Stratified analysis is a method of adjusting for the effect of these variables without being forced to estimate parameters for them. Note that PROC LOGISTIC can perform analyses on stratified tables as well, using the usual modeling procedure assumptions, by using conditional or exact conditional logistic regression.

The multiple hypergeometric distribution is the one used by PROC FREQ for the computation of Cochran-Mantel-Haenszel statistics. These statistics are in the class of *randomization model test statistics*, which require minimal assumptions for their validity. PROC FREQ uses the multiple hypergeometric distribution to compute the mean and the covariance matrix of a function vector

in order to measure the deviation between the observed and expected frequencies with respect to a particular type of alternative hypothesis. If the cell frequencies are sufficiently large, then the function vector is approximately normally distributed as a result of central limit theory, and PROC FREQ uses this result to compute a quadratic form that has a chi-square distribution when the null hypothesis is true.

Randomized Experiments

Consider a *randomized experiment* in which patients are assigned to one of two treatment groups according to a randomization process that allocates 50 patients to each group. After a specified period of time, each patient's status (cured or uncured) is recorded. Suppose the data shown in Table 8.5 give the results of the experiment. The null hypothesis is that the two treatments are equally effective. Under this hypothesis, treatment is a randomly assigned label that has no effect on the cure rate of the patients. But this implies that each row of the table represents a simple random sample from the finite population whose cure rate is described by the column marginal totals. Therefore, the column marginals (58, 42) are fixed under the hypothesis. Since the row marginals (50, 50) are fixed by the allocation process, the hypergeometric distribution is induced on the cell frequencies. Randomized experiments can also be specified in a stratified framework, and Cochran-Mantel-Haenszel statistics can be computed relative to the corresponding multiple hypergeometric distribution.

Table 8.5 Two-Way Contingency Table: Treatment by Status

	Status		
Treatment	**Cured**	**Uncured**	**Total**
1	36	14	50
2	22	28	50
Total	58	42	100

Relaxation of Sampling Assumptions

As indicated previously, the modeling procedures assume that the data are from a stratified simple random sample, so they use the product multinomial distribution. If the data are not from such a sample, then in many cases it is still possible to use a modeling procedure by arguing that each row of the contingency table *does* represent a simple random sample from some hypothetical population. The extent to which the inferences are generalizable depends on the extent to which the hypothetical population is perceived to resemble the target population.

Similarly, the Cochran-Mantel-Haenszel statistics use the multiple hypergeometric distribution, which requires fixed row and column marginal totals in each contingency table. If the sampling process does not yield a table with fixed margins, then it is usually possible to fix the margins through conditioning arguments similar to the ones used by Fisher when he developed the Exact

Test for 2×2 tables. In other words, if you want fixed marginal totals, you can generally make your analysis conditional on those observed totals.

For more information on sampling models for categorical data, see Bishop, Fienberg, and Holland (1975, Chapter 13) and Agresti (2002, Chapter 1.2).

Comparison of PROC FREQ and the Modeling Procedures

PROC FREQ is used primarily to investigate the relationship between two variables; any confounding variables are taken into account by stratification rather than by parameter estimation. Modeling procedures are used to investigate the relationship among many variables, all of which are integrated into a parametric model.

When a modeling procedure estimates the covariance matrix of the frequencies, it assumes that the frequencies were obtained by a stratified simple random-sampling procedure. However, some modeling procedures can handle different sampling methods. PROC CATMOD can analyze input data that consists of a function vector and a covariance matrix, so you can estimate the covariance matrix of the frequencies in the appropriate manner before modeling the data. PROC SURVEYLOGISTIC can analyze data from a completely different, but known, sampling scheme.

For the FREQ procedure, Fisher's Exact Test and Cochran-Mantel-Haenszel (CMH) statistics are based on the hypergeometric distribution, which corresponds to fixed marginal totals. However, by conditioning arguments, these tests are generally applicable to a wide range of sampling procedures. Similarly, the Pearson and likelihood-ratio chi-square statistics can be derived under a variety of sampling situations.

PROC FREQ can do some traditional nonparametric analysis (such as the Kruskal-Wallis test and Spearman's correlation) since it can generate rank scores internally. Fisher's Exact Test and the CMH statistics are also inherently nonparametric. However, the main vehicle for nonparametric analyses in the SAS System is the NPAR1WAY procedure.

A large sample size is required for the validity of the chi-square distributions, the standard errors, and the covariance matrices for PROC FREQ and the modeling procedures. If sample size is a problem, then PROC FREQ has the advantage with its CMH statistics because it does not use any degrees of freedom to estimate parameters for confounding variables. In addition, PROC FREQ can compute exact p-values for any two-way table, provided that the sample size is sufficiently small in relation to the size of the table. It can also produce exact p-values for many tests, including the test of binomial proportions, the Cochran-Armitage test for trend, and the Jonckheere-Terpstra test for ordered differences among classes. PROC LOGISTIC can perform exact conditional logistic regression and Firth's penalized-likelihood regression to compensate for small sample sizes.

See the procedure chapters for more information. In addition, some well-known texts that deal with analyzing categorical data are listed in the "References" section of this chapter.

Comparison of Modeling Procedures

The CATMOD, GENMOD, GLIMMIX, LOGISTIC, PROBIT, and SURVEYLOGISTIC procedures can all be used for statistical modeling of categorical data.

The CATMOD procedure treats all explanatory (independent) variables as classification variables by default, and you specify continuous covariates in the DIRECT statement. The other procedures treat covariates as continuous by default, and you specify the classification variables in the CLASS statement.

The CATMOD procedure provides weighted least squares estimation of many response functions, such as means, cumulative logits, and proportions, and you can also compute and analyze other response functions that can be formed from the proportions corresponding to the rows of a contingency table. In addition, a user can input and analyze a set of response functions and user-supplied covariance matrix with weighted least squares. PROC CATMOD also provides maximum likelihood estimation for binary and polytomous logistic regression.

The GENMOD procedure is also a general statistical modeling tool which fits generalized linear models to data; it fits several useful models to categorical data including logistic regression, the proportional odds model, and Poisson and negative binomial regression for count data. The GENMOD procedure also provides a facility for fitting generalized estimating equations to correlated response data that are categorical, such as repeated dichotomous outcomes. The GENMOD procedure fits models using maximum likelihood estimation. PROC GENMOD can perform Type I and Type III tests, and it provides predicted values and residuals. Bayesian analysis capabilities for generalized linear models are also available.

The GLIMMIX procedure fits many of the same models as the GENMOD procedure but also allows the inclusion of random effects. The GLIMMIX procedure fits models using maximum likelihood estimation.

The LOGISTIC procedure is specifically designed for logistic regression. It performs the usual logistic regression analysis for dichotomous outcomes and it fits the proportional odds model and the generalized logit model for ordinal and nominal outcomes, respectively, by the method of maximum likelihood. This procedure has capabilities for a variety of model-building techniques, including stepwise, forward, and backward selection. It computes predicted values, the receiver operating characteristics (ROC) curve and the area beneath the curve, and a number of regression diagnostics. It can create output data sets containing these values and other statistics. PROC LOGISTIC can perform a conditional logistic regression analysis (matched-set and case-controlled) for binary response data. For small data sets, PROC LOGISTIC can perform exact conditional logistic regression. Firth's bias-reducing penalized-likelihood method can also be used in place of conditional and exact conditional logistic regression.

The PROBIT procedure is designed for quantal assay or other discrete event data. In additional to performing the logistic regression analysis, it can estimate the threshold response rate. PROC PROBIT can also estimate the values of independent variables that yield a desired response.

The SURVEYLOGISTIC procedure performs logistic regression for binary, ordinal, and nominal responses under a specified complex sampling scheme, instead of the usual stratified simple random sampling.

Stokes, Davis, and Koch (2000) provide substantial discussion of these procedures, particularly the use of the FREQ, LOGISTIC, GENMOD, and CATMOD procedures for statistical modeling.

Logistic Regression

Dichotomous Response

You have many choices of performing logistic regression in the SAS System. The CATMOD, GENMOD, GLIMMIX, LOGISTIC, PROBIT, and SURVEYLOGISTIC procedures fit the usual logistic regression model.

PROC CATMOD might not be efficient when there are continuous independent variables with large numbers of different values. For a continuous variable with a very limited number of values, PROC CATMOD might still be useful.

PROC GLIMMIX enables you to specify random effects in the models; in particular, you can fit a random-intercept logistic regression model.

PROC LOGISTIC provides the capability of model-building and performs conditional and exact conditional logistic regression. It can also use Firth's bias-reducing penalized likelihood method.

PROC PROBIT enables you to estimate the natural response rate and compute fiducial limits for the dose variable.

The LOGISTIC, GENMOD, GLIMMIX, PROBIT, and SURVEYLOGISTIC procedures can analyze summarized data by enabling you to input the numbers of events and trials; the ratio of events to trials must be between 0 and 1.

Ordinal Response

PROC LOGISTIC fits the proportional odds model to the ordinal response data by default, PROC PROBIT fits this model if you specify the logistic distribution, and PROC GENMOD and PROC GLIMMIX fit this model if you specify the CLOGIT link and the multinomial distribution. PROC CATMOD fits the cumulative logit or adjacent-category logit response functions.

Nominal Response

When the response variable is nominal, there is no concept of ordering of the response values. Response functions called *generalized logits* can be fit by the CATMOD, GLIMMIX, and LOGISTIC procedures. PROC CATMOD fits this model by default; PROC GLIMMIX and PROC LOGISTIC require you to specify the GLOGIT link.

Numerical Differences

Differences in the way the models are parameterized and fit might result in different parameter estimates if you perform logistic regression in each of these procedures.

- Parameter estimates from the procedures can differ in sign depending on the ordering of response levels, which you can change if you want.
- The parameter estimates associated with a categorical independent variable might differ among the procedures, since the estimates depend on the coding of the indicator variables in the design matrix. By default, the design matrix column produced by PROC CATMOD and PROC LOGISTIC for a binary independent variable is coded using the values 1 and −1 (deviation from the mean coding, which is a full-rank parameterization). The same column produced by the CLASS statement of PROC GENMOD, PROC GLIMMIX, and PROC PROBIT is coded using 1 and 0 (GLM coding, which is less-than-full-rank parameterization). As a result, the parameter estimate printed by PROC LOGISTIC is one-half of the estimate produced by PROC GENMOD. Both PROC GENMOD and PROC LOGISTIC allow you to select either a full-rank parameterization or the less-than-full-rank parameterization. The GLIMMIX and PROBIT procedures allow only the less-than-full-rank parameterization for the CLASS variables. The CATMOD procedure allows only full-rank parameterizations. See the "Details" sections in the chapters on the CATMOD, GENMOD, GLIMMIX, LOGISTIC, and PROBIT procedures for more information on the generation of the design matrices used by these procedures. See Chapter 18, "Shared Concepts and Topics," for a general discussion of the various parameterizations.
- The maximum-likelihood algorithm used differs among the procedures. PROC LOGISTIC uses the Fisher's scoring method by default, while PROC PROBIT, PROC GENMOD, PROC GLIMMIX, and PROC CATMOD use the Newton-Raphson method. The parameter estimates should be the same for all three procedures, and the standard errors should be the same for the logistic model. For the normal and extreme-value (Gompertz) distributions in PROC PROBIT, which correspond to the probit and cloglog links, respectively, in PROC GENMOD and PROC LOGISTIC, the standard errors might differ. In general, tests computed using the standard errors from the Newton-Raphson method are more conservative.
- The LOGISTIC, GENMOD, GLIMMIX, and PROBIT procedures can fit a cumulative regression model for ordinal response data by using maximum-likelihood estimation. PROC LOGISTIC and PROC GENMOD use a different parameterization from that of PROC PROBIT, which results in different intercept parameters. Estimates of the slope parameters, however, should be the same for both procedures. The estimated standard errors of the slope estimates are slightly different between the procedures because of the different computational algorithms used as default.

Overview: Multivariate Procedures

The procedures discussed in this chapter investigate relationships among variables without designating some as independent and others as dependent. Principal component analysis and common factor analysis examine relationships within a single set of variables, whereas canonical correlation looks at the relationship between two sets of variables. The following is a brief description of SAS/STAT multivariate procedures:

CORRESP performs simple and multiple correspondence analyses, with a contingency table, Burt table, binary table, or raw categorical data as input. Correspondence analysis is a weighted form of principal component analysis that is appropriate for frequency data. The results are displayed in plots and tables and are also available in output data sets.

PRINCOMP performs a principal component analysis and outputs standardized or unstandardized principal component scores. The results are displayed in plots and tables and are also available in output data sets.

PRINQUAL performs a principal component analysis of qualitative data and multidimensional preference analysis. The results are displayed in plots and are also available in output data sets.

FACTOR performs principal component and common factor analyses with rotations and outputs component scores or estimates of common factor scores. The results are displayed in plots and tables and are also available in output data sets.

CANCORR performs a canonical correlation analysis and outputs canonical variable scores. The results are displayed in tables and are also available in output data sets for plotting.

Many other SAS/STAT procedures can also analyze multivariate data—for example, the CATMOD, GLM, REG, CALIS, and TRANSREG procedures as well as the procedures for clustering and discriminant analysis.

The purpose of *principal component analysis* (Rao 1964) is to derive a small number of linear combinations (principal components) of a set of variables that retain as much of the information in the original variables as possible. Often a small number of principal components can be used in place of the original variables for plotting, regression, clustering, and so on. Principal component analysis can also be viewed as an attempt to uncover approximate linear dependencies among variables.

The purpose of *common factor analysis* (Mulaik 1972) is to explain the correlations or covariances among a set of variables in terms of a limited number of unobservable, latent variables. The latent variables are not generally computable as linear combinations of the original variables. In common factor analysis, it is assumed that the variables are linearly related if not for uncorrelated random error or *unique variation* in each variable; both the linear relations and the amount of unique variation can be estimated.

Principal component and common factor analysis are often followed by rotation of the components or factors. *Rotation* is the application of a nonsingular linear transformation to components or common factors to aid interpretation.

The purpose of *canonical correlation analysis* (Mardia, Kent, and Bibby 1979) is to explain or summarize the relationship between two sets of variables by finding a small number of linear combinations from each set of variables that have the highest possible between-set correlations. Plots of the canonical variables can be useful in examining multivariate dependencies. If one of the two sets of variables consists of dummy variables generated from a classification variable, the canonical correlation is equivalent to canonical discriminant analysis (see Chapter 27, "The CANDISC Procedure"). If both sets of variables are dummy variables, canonical correlation is equivalent to simple correspondence analysis.

The purpose of *correspondence analysis* (Lebart, Morineau, and Warwick 1984; Greenacre 1984; Nishisato 1980) is to summarize the associations between a set of categorical variables in a small number of dimensions. Correspondence analysis computes scores on each dimension for each row and column category in a contingency table. Plots of these scores show the relationships among the categories.

The PRINQUAL procedure obtains linear and nonlinear transformations of variables by using the method of alternating least squares (Young 1981) to optimize properties of the transformed variables' covariance or correlation matrix. PROC PRINQUAL nonlinearly transforms variables, improving their fit to a principal component model. The name, PRINQUAL, for principal components of qualitative data, comes from the special case analysis of fitting a principal component model to nominal and ordinal scale of measurement variables (Young, Takane, and de Leeuw 1978). However, PROC PRINQUAL also has facilities for smoothly transforming continuous variables. All of PROC PRINQUAL's transformations are also available in the TRANSREG procedure, which fits regression models with nonlinear transformations. PROC PRINQUAL can also perform metric and nonmetric multidimensional preference (MDPREF) analyses (Carroll 1972) and produce plots of the results.

Comparison of the PRINCOMP and FACTOR Procedures

Although PROC FACTOR can be used for common factor analysis, the default method is principal components. PROC FACTOR produces the same results as PROC PRINCOMP except that scoring coefficients from PROC FACTOR are normalized to give principal component scores with unit variance, whereas PROC PRINCOMP by default produces principal component scores with variance equal to the corresponding eigenvalue. PROC PRINCOMP can also compute scores standardized to unit variance. Both procedures produce graphical results through ODS Graphics.

PROC PRINCOMP has the following advantages over PROC FACTOR:

- PROC PRINCOMP is slightly faster if a small number of components is requested.
- PROC PRINCOMP can analyze somewhat larger problems in a fixed amount of memory.
- PROC PRINCOMP can output scores from an analysis of a partial correlation or covariance matrix.
- PROC PRINCOMP is simpler to use.

PROC FACTOR has the following advantages over PROC PRINCOMP for principal component analysis:

- PROC FACTOR produces more output.
- PROC FACTOR does rotations.

If you want to perform a common factor analysis, you must use PROC FACTOR instead of PROC PRINCOMP. Principal component analysis should never be used if a common factor solution is desired (Dziuban and Harris 1973; Lee and Comrey 1979).

Comparison of the PRINCOMP and PRINQUAL Procedures

The PRINCOMP procedure performs principal component analysis. The PRINQUAL procedure finds linear and nonlinear transformations of variables to optimize properties of the transformed variables' covariance or correlation matrix. One property is the sum of the first n eigenvalues, which is a measure of the fit of a principal component model with n components. Use PROC PRINQUAL to find nonlinear transformations of your variables or to perform a multidimensional preference analysis. Use PROC PRINCOMP to fit a principal component model to your data or to PROC PRINQUAL's output data set. PROC PRINCOMP produces a report of the principal component analysis, a number of graphical displays, and output data sets. PROC PRINQUAL produces only a few graphs and an output data set.

Comparison of the PRINCOMP and CORRESP Procedures

As summarized previously, PROC PRINCOMP performs a principal component analysis of interval-scaled data. PROC CORRESP performs correspondence analysis, which is a weighted form of principal component analysis that is appropriate for frequency data. If your data are categorical, use PROC CORRESP instead of PROC PRINCOMP. Both procedures produce graphical displays of the results with ODS Graphics. The plots produced by PROC CORRESP graphically show relationships among the categories of the categorical variables.

Comparison of the PRINQUAL and CORRESP Procedures

Both PROC PRINQUAL and PROC CORRESP can be used to summarize associations among variables measured on a nominal scale. PROC PRINQUAL searches for a single nonlinear transformation of the original scoring of each nominal variable that optimizes some aspect of the covariance matrix of the transformed variables. For example, PROC PRINQUAL could be used to find scorings that maximize the fit of a principal component model with one component. PROC CORRESP uses the crosstabulations of nominal variables, not covariances, and produces multiple scores for each category of each nominal variable. The main conceptual difference between PROC PRINQUAL and PROC CORRESP is that PROC PRINQUAL assumes that the categories of a nominal variable correspond to values of a single underlying interval variable, whereas PROC CORRESP assumes that there are multiple underlying interval variables and therefore uses different category scores for each dimension of the correspondence analysis. Scores from PROC CORRESP on the first dimension match the single set of PROC PRINQUAL scores (with appropriate standardizations for both analyses).

Comparison of the TRANSREG and PRINQUAL Procedures

Both the TRANSREG and PRINQUAL procedures are data transformation procedures that have many of the same transformations. These procedures can either directly perform the specified transformation (such as taking the logarithm of the variable) or search for an optimal transformation (such as a spline with a specified number of knots). Both procedures can use an iterative, alternating least squares analysis. Both procedures create an output data set that can be used as input to other procedures. PROC PRINQUAL displays relatively little output, whereas PROC TRANSREG displays many results. PROC TRANSREG has two sets of variables, usually dependent and independent, and it fits linear models such as ordinary regression and ANOVA, multiple and multivariate regression, metric and nonmetric conjoint analysis, metric and nonmetric vector and ideal point preference mapping, redundancy analysis, canonical correlation, and response surface regression. In contrast, PROC PRINQUAL has one set of variables, fits a principal component model or multidimensional preference analysis, and can also optimize other properties of a correlation or

covariance matrix. PROC TRANSREG performs hypothesis testing and can be used to code experimental designs prior to their use in other analyses. PROC TRANSREG can also perform Box-Cox transformations and fit models with smoothing spline and penalized B-spline transformations.

See Chapter 4, "Introduction to Regression Procedures," for comparisons of the TRANSREG and REG procedures.

Example: Contrasting Univariate and Multivariate Analyses 203
References 208

Overview: Discriminant Procedures

The SAS procedures for discriminant analysis fit data with one classification variable and several quantitative variables. The purpose of discriminant analysis can be to find one or more of the following:

- a mathematical rule, or *discriminant function*, for guessing to which class an observation belongs, based on knowledge of the quantitative variables only
- a set of linear combinations of the quantitative variables that best reveals the differences among the classes
- a subset of the quantitative variables that best reveals the differences among the classes

The SAS discriminant procedures are as follows:

DISCRIM	computes various discriminant functions for classifying observations. Linear or quadratic discriminant functions can be used for data with approximately multivariate normal within-class distributions. Nonparametric methods can be used without making any assumptions about these distributions.
CANDISC	performs a canonical analysis to find linear combinations of the quantitative variables that best summarize the differences among the classes.
STEPDISC	uses forward selection, backward elimination, or stepwise selection to try to find a subset of quantitative variables that best reveals differences among the classes.

Background: Discriminant Procedures

The term *discriminant analysis* (Fisher 1936; Cooley and Lohnes 1971; Tatsuoka 1971; Kshirsagar 1972; Lachenbruch 1975, 1979; Gnanadesikan 1977; Klecka 1980; Hand 1981, 1982; Silverman 1986) refers to several different types of analyses. Classificatory discriminant analysis is used to classify observations into two or more known groups on the basis of one or more quantitative variables. Classification can be done by either a parametric method or a nonparametric method in the DISCRIM procedure. A parametric method is appropriate only for approximately normal within-class distributions. The method generates either a linear discriminant function (the within-class covariance matrices are assumed to be equal) or a quadratic discriminant function (the within-class covariance matrices are assumed to be unequal).

When the distribution within each group is not assumed to have any specific distribution or is assumed to have a distribution different from the multivariate normal distribution, nonparametric methods can be used to derive classification criteria. These methods include the kernel method and nearest-neighbor methods. The kernel method uses uniform, normal, Epanechnikov, biweight, or triweight kernels in estimating the group-specific density at each observation. The within-group covariance matrices or the pooled covariance matrix can be used to scale the data.

The performance of a discriminant function can be evaluated by estimating error rates (probabilities of misclassification). Error count estimates and posterior probability error rate estimates can be evaluated with PROC DISCRIM. When the input data set is an ordinary SAS data set, the error rates can also be estimated by cross validation.

In multivariate statistical applications, the data collected are largely from distributions different from the normal distribution. Various forms of nonnormality can arise, such as qualitative variables or variables with underlying continuous but nonnormal distributions. If the multivariate normality assumption is violated, the use of parametric discriminant analysis might not be appropriate. When a parametric classification criterion (linear or quadratic discriminant function) is derived from a nonnormal population, the resulting error rate estimates might be biased.

If your quantitative variables are not normally distributed, or if you want to classify observations on the basis of categorical variables, you should consider using the CATMOD or LOGISTIC procedure to fit a categorical linear model with the classification variable as the dependent variable. Press and Wilson (1978) compare logistic regression and parametric discriminant analysis and conclude that logistic regression is preferable to parametric discriminant analysis in cases for which the variables do not have multivariate normal distributions within classes. However, if you do have normal within-class distributions, logistic regression is less efficient than parametric discriminant analysis. Efron (1975) shows that with two normal populations having a common covariance matrix, logistic regression is between one-half and two-thirds as effective as the linear discriminant function in achieving asymptotically the same error rate.

Do not confuse discriminant analysis with cluster analysis. All varieties of discriminant analysis require prior knowledge of the classes, usually in the form of a sample from each class. In cluster analysis, the data do not include information about class membership; the purpose is to construct a classification. See Chapter 11, "Introduction to Clustering Procedures."

Canonical discriminant analysis is a dimension-reduction technique related to principal components and canonical correlation, and it can be performed by both the CANDISC and DISCRIM procedures. A discriminant criterion is always derived in PROC DISCRIM. If you want canonical discriminant analysis without the use of a discriminant criterion, you should use PROC CANDISC. Stepwise discriminant analysis is a variable-selection technique implemented by the STEPDISC procedure. After selecting a subset of variables with PROC STEPDISC, use any of the other discriminant procedures to obtain more detailed analyses. PROC CANDISC and PROC STEPDISC perform hypothesis tests that require the within-class distributions to be approximately normal, but these procedures can be used descriptively with nonnormal data.

Another alternative to discriminant analysis is to perform a series of univariate one-way ANOVAs. All three discriminant procedures provide summaries of the univariate ANOVAs. The advantage of the multivariate approach is that two or more classes that overlap considerably when each variable is viewed separately might be more distinct when examined from a multivariate point of view.

Example: Contrasting Univariate and Multivariate Analyses

Consider an artificial data set with two classes of observations indicated by 'H' and 'O'. The following statements generate and plot the data:

```
data random;
   drop n;

   Group = 'H';
   do n = 1 to 20;
      x = 4.5 + 2 * normal(57391);
      y = x + .5 + normal(57391);
      output;
   end;

   Group = 'O';
   do n = 1 to 20;
      x = 6.25 + 2 * normal(57391);
      y = x - 1 + normal(57391);
      output;
   end;

run;

proc sgplot noautolegend;
   scatter y=y x=x / markerchar=group group=group;
run;
```

The plot is shown in Figure 10.1.

Figure 10.1 Groups for Contrasting Univariate and Multivariate Analyses

The following statements perform a canonical discriminant analysis and display the results in Figure 10.2:

```
proc candisc anova;
   class Group;
   var x y;
run;
```

```

The univariate R squares are very small, 0.0503 for x and 0.0037 for y, and neither variable shows a significant difference between the classes at the 0.10 level.

The multivariate test for differences between the classes is significant at the 0.0003 level. Thus, the multivariate analysis has found a highly significant difference, whereas the univariate analyses failed to achieve even the 0.10 level. The raw canonical coefficients for the first canonical variable, Can1, show that the classes differ most widely on the linear combination -1.205756217 x + 1.010412967 y or approximately y - 1.2 x. The R square between Can1 and the class variable is 0.357963 as given by the squared canonical correlation, which is much higher than either univariate R square.

In this example, the variables are highly correlated within classes. If the within-class correlation were smaller, there would be greater agreement between the univariate and multivariate analyses.

Overview: Clustering Procedures

You can use SAS clustering procedures to cluster the observations or the variables in a SAS data set. Both hierarchical and disjoint clusters can be obtained. Only numeric variables can be analyzed directly by the procedures, although the DISTANCE procedure can compute a distance matrix that uses character or numeric variables.

The purpose of cluster analysis is to place objects into groups, or clusters, suggested by the data, not defined a priori, such that objects in a given cluster tend to be similar to each other in some sense, and objects in different clusters tend to be dissimilar. You can also use cluster analysis to summarize data rather than to find "natural" or "real" clusters; this use of clustering is sometimes called *dissection* (Everitt 1980).

Any generalization about cluster analysis must be vague because a vast number of clustering methods have been developed in several different fields, with different definitions of clusters and similarity among objects. The variety of clustering techniques is reflected by the variety of terms used for cluster analysis: botryology, classification, clumping, competitive learning, morphometrics, nosography, nosology, numerical taxonomy, partitioning, Q-analysis, systematics, taximetrics, taxonorics, typology, unsupervised pattern recognition, vector quantization, and winner-take-all learning. Good (1977) has also suggested aciniformics and agminatics.

Several types of clusters are possible:

- Disjoint clusters place each object in one and only one cluster.
- Hierarchical clusters are organized so that one cluster can be entirely contained within another cluster, but no other kind of overlap between clusters is allowed.
- Overlapping clusters can be constrained to limit the number of objects that belong simultaneously to two clusters, or they can be unconstrained, allowing any degree of overlap in cluster membership.
- Fuzzy clusters are defined by a probability or grade of membership of each object in each cluster. Fuzzy clusters can be disjoint, hierarchical, or overlapping.

The data representations of objects to be clustered also take many forms. The most common are as follows:

- a square distance or similarity matrix, in which both rows and columns correspond to the objects to be clustered. A correlation matrix is an example of a similarity matrix.
- a coordinate matrix, in which the rows are observations and the columns are variables, as in the usual SAS multivariate data set. The observations, the variables, or both can be clustered.

The SAS procedures for clustering are oriented toward disjoint or hierarchical clusters from coordinate data, distance data, or a correlation or covariance matrix. The following procedures are used for clustering:

CLUSTER	performs hierarchical clustering of observations by using eleven agglomerative methods applied to coordinate data or distance data.
FASTCLUS	finds disjoint clusters of observations by using a k-means method applied to coordinate data. PROC FASTCLUS is especially suitable for large data sets.
MODECLUS	finds disjoint clusters of observations with coordinate or distance data by using nonparametric density estimation. It can also perform approximate nonparametric significance tests for the number of clusters.
VARCLUS	performs both hierarchical and disjoint clustering of variables by using oblique multiple-group component analysis.
TREE	draws tree diagrams, also called *dendrograms* or *phenograms*, by using output from the CLUSTER or VARCLUS procedure. PROC TREE can also create a data set indicating cluster membership at any specified level of the cluster tree.

The following procedures are useful for processing data prior to the actual cluster analysis:

ACECLUS	attempts to estimate the pooled within-cluster covariance matrix from coordinate data without knowledge of the number or the membership of the clusters (Art, Gnanadesikan, and Kettenring 1982). PROC ACECLUS outputs a data set containing canonical variable scores to be used in the cluster analysis proper.

DISTANCE computes various measures of distance, dissimilarity, or similarity between the observations (rows) of a SAS data set. PROC DISTANCE also provides various nonparametric and parametric methods for standardizing variables. Different variables can be standardized with different methods.

PRINCOMP performs a principal component analysis and outputs principal component scores.

STDIZE standardizes variables by using any of a variety of location and scale measures, including mean and standard deviation, minimum and range, median and absolute deviation from the median, various M-estimators and A-estimators, and some scale estimators designed specifically for cluster analysis.

Massart and Kaufman (1983) is the best elementary introduction to cluster analysis. Other important texts are Anderberg (1973), Sneath and Sokal (1973), Duran and Odell (1974), Hartigan (1975), Titterington, Smith, and Makov (1985), McLachlan and Basford (1988), and Kaufmann and Rousseeuw (1990). Hartigan (1975) and Spath (1980) give numerous FORTRAN programs for clustering. Any prospective user of cluster analysis should study the Monte Carlo results of Milligan (1980), Milligan and Cooper (1985), and Cooper and Milligan (1988). Important references on the statistical aspects of clustering include MacQueen (1967), Wolfe (1970), Scott and Symons (1971), Hartigan (1977, 1978, 1981, 1985), Symons (1981), Everitt (1981), Sarle (1983), Bock (1985), and Thode, Mendell, and Finch (1988). Bayesian methods have important advantages over maximum likelihood; see Binder (1978, 1981), Banfield and Raftery (1993), and Bensmail et al. (1997). For fuzzy clustering, see Bezdek (1981) and Bezdek and Pal (1992). The signal-processing perspective is provided by Gersho and Gray (1992). See Blashfield and Aldenderfer (1978) for a discussion of the fragmented state of the literature on cluster analysis.

Clustering Variables

Factor rotation is often used to cluster variables, but the resulting clusters are fuzzy. It is preferable to use PROC VARCLUS if you want hard (nonfuzzy), disjoint clusters. Factor rotation is better if you want to be able to find overlapping clusters. It is often a good idea to try both PROC VARCLUS and PROC FACTOR with an oblique rotation, compare the amount of variance explained by each, and see how fuzzy the factor loadings are and whether there seem to be overlapping clusters.

You can use PROC VARCLUS to harden a fuzzy factor rotation; use PROC FACTOR to create an output data set containing scoring coefficients and initialize PROC VARCLUS with this data set as follows:

```
proc factor rotate=promax score outstat=fact;
run;

proc varclus initial=input proportion=0;
run;
```

You can use any rotation method instead of the PROMAX method. The SCORE and OUTSTAT= options are necessary in the PROC FACTOR statement. PROC VARCLUS reads the correlation

matrix from the data set created by PROC FACTOR. The INITIAL=INPUT option tells PROC VARCLUS to read initial scoring coefficients from the data set. The option PROPORTION=0 keeps PROC VARCLUS from splitting any of the clusters.

Clustering Observations

PROC CLUSTER is easier to use than PROC FASTCLUS because one run produces results from one cluster up to as many as you like. You must run PROC FASTCLUS once for each number of clusters.

The time required by PROC FASTCLUS is roughly proportional to the number of observations, whereas the time required by PROC CLUSTER with most methods varies with the square or cube of the number of observations. Therefore, you can use PROC FASTCLUS with much larger data sets than PROC CLUSTER.

If you want to hierarchically cluster a data set that is too large to use with PROC CLUSTER directly, you can have PROC FASTCLUS produce, for example, 50 clusters, and let PROC CLUSTER analyze these 50 clusters instead of the entire data set. The MEAN= data set produced by PROC FASTCLUS contains two special variables:

- The variable _FREQ_ gives the number of observations in the cluster.
- The variable _RMSSTD_ gives the root mean square across variables of the cluster standard deviations.

These variables are automatically used by PROC CLUSTER to give the correct results when clustering clusters. For example, you could specify Ward's minimum variance method (Ward 1963):

```
proc fastclus maxclusters=50 mean=temp;
   var x y z;
run;

proc cluster method=ward outtree=tree;
   var x y z;
run;
```

Or you could specify Wong's hybrid method (Wong 1982):

```
proc fastclus maxclusters=50 mean=temp;
   var x y z;
run;

proc cluster method=density hybrid outtree=tree;
   var x y z;
run;
```

More detailed examples are given in Chapter 29, "The CLUSTER Procedure."

Characteristics of Methods for Clustering Observations

Many simulation studies comparing various methods of cluster analysis have been performed. In these studies, artificial data sets containing known clusters are produced using pseudo-random-number generators. The data sets are analyzed by a variety of clustering methods, and the degree to which each clustering method recovers the known cluster structure is evaluated. See Milligan (1981) for a review of such studies. In most of these studies, the clustering method with the best overall performance has been either average linkage or Ward's minimum variance method. The method with the poorest overall performance has almost invariably been single linkage. However, in many respects, the results of simulation studies are inconsistent and confusing.

When you attempt to evaluate clustering methods, it is essential to realize that most methods are biased toward finding clusters possessing certain characteristics related to size (number of members), shape, or dispersion. Methods based on the least squares criterion (Sarle 1982), such as k-means and Ward's minimum variance method, tend to find clusters with roughly the same number of observations in each cluster. Average linkage is somewhat biased toward finding clusters of equal variance. Many clustering methods tend to produce compact, roughly hyperspherical clusters and are incapable of detecting clusters with highly elongated or irregular shapes. The methods with the least bias are those based on nonparametric density estimation such as single linkage and density linkage.

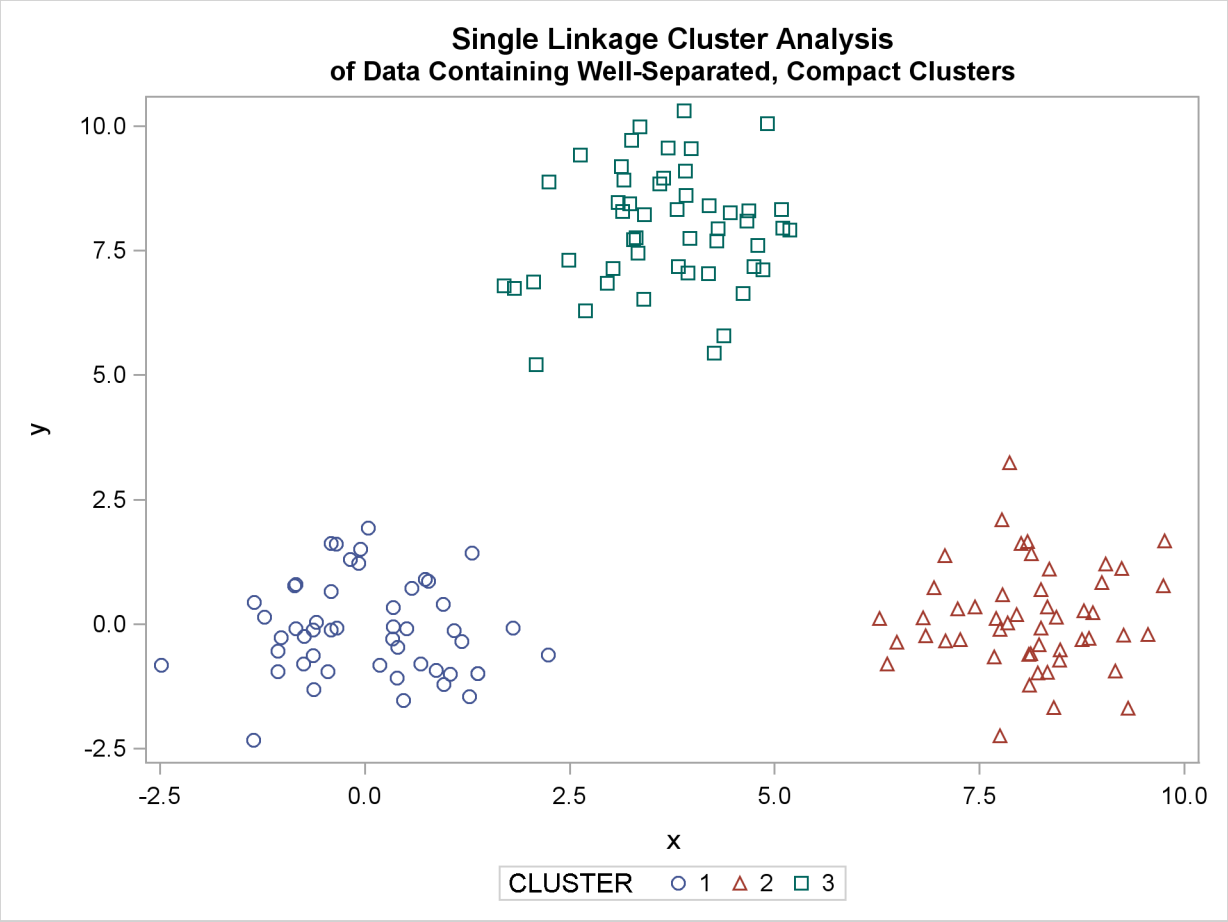
Most simulation studies have generated compact (often multivariate normal) clusters of roughly equal size or dispersion. Such studies naturally favor average linkage and Ward's method over most other hierarchical methods, especially single linkage. It would be easy, however, to design a study that uses elongated or irregular clusters in which single linkage would perform much better than average linkage or Ward's method (see some of the following examples). Even studies that compare clustering methods that use "realistic" data might unfairly favor particular methods. For example, in all the data sets used by Mezzich and Solomon (1980), the clusters established by field experts are of equal size. When interpreting simulation or other comparative studies, you must, therefore, decide whether the artificially generated clusters in the study resemble the clusters you suspect might exist in your data in terms of size, shape, and dispersion. If, like many people doing exploratory cluster analysis, you have no idea what kinds of clusters to expect, you should include at least one of the relatively unbiased methods, such as density linkage, in your analysis.

The rest of this section consists of a series of examples that illustrate the performance of various clustering methods under various conditions. The first, and simplest, example shows a case of well-separated clusters. The other examples show cases of poorly separated clusters, clusters of unequal size, parallel elongated clusters, and nonconvex clusters.

Well-Separated Clusters

If the population clusters are sufficiently well separated, almost any clustering method performs well, as demonstrated in the following example, which uses single linkage. In this and subsequent examples, the output from the clustering procedures is not shown, but cluster membership is dis-

played in scatter plots. The SAS autocall macro MODSTYLE is specified to change the default marker symbols for the plot. For more information about autocall libraries, see *SAS Macro Language: Reference*. The following SAS statements produce Figure 11.1:



```
data compact;
   keep x y;

run;
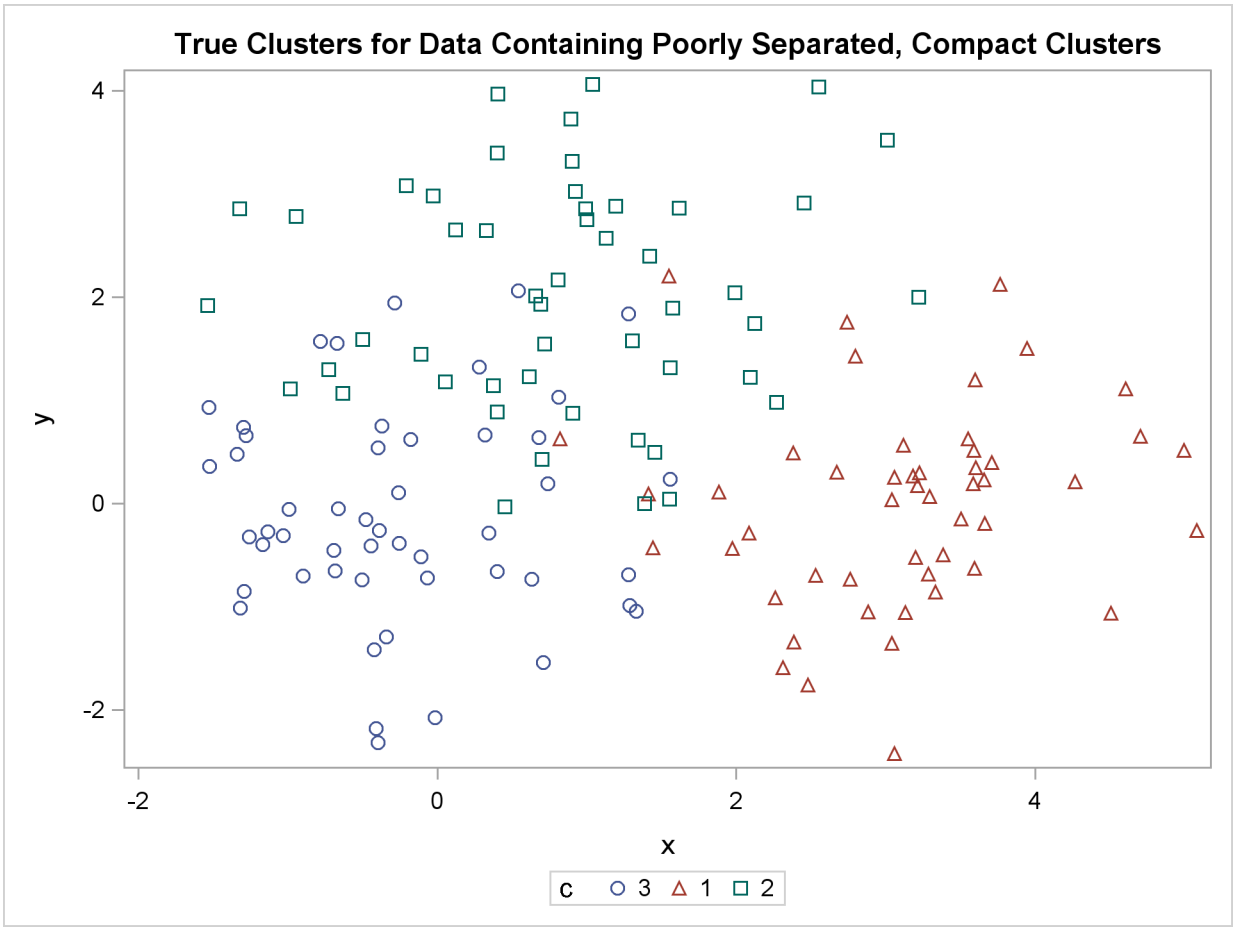
```

Figure 11.1 Data Containing Well-Separated, Compact Clusters: PROC CLUSTER with METHOD=SINGLE and PROC SGPLOT



Poorly Separated Clusters

To see how various clustering methods differ, you must examine a more difficult problem than that of the previous example.

The following data set is similar to the first except that the three clusters are much closer together. This example demonstrates the use of PROC FASTCLUS and five hierarchical methods available in PROC CLUSTER. To help you compare methods, this example plots true, generated clusters. Also included is a bubble plot of the density estimates obtained in conjunction with two-stage density linkage in PROC CLUSTER. The following SAS statements produce Figure 11.2:

```
data closer;
   keep x y c;
   n=50; scale=1;

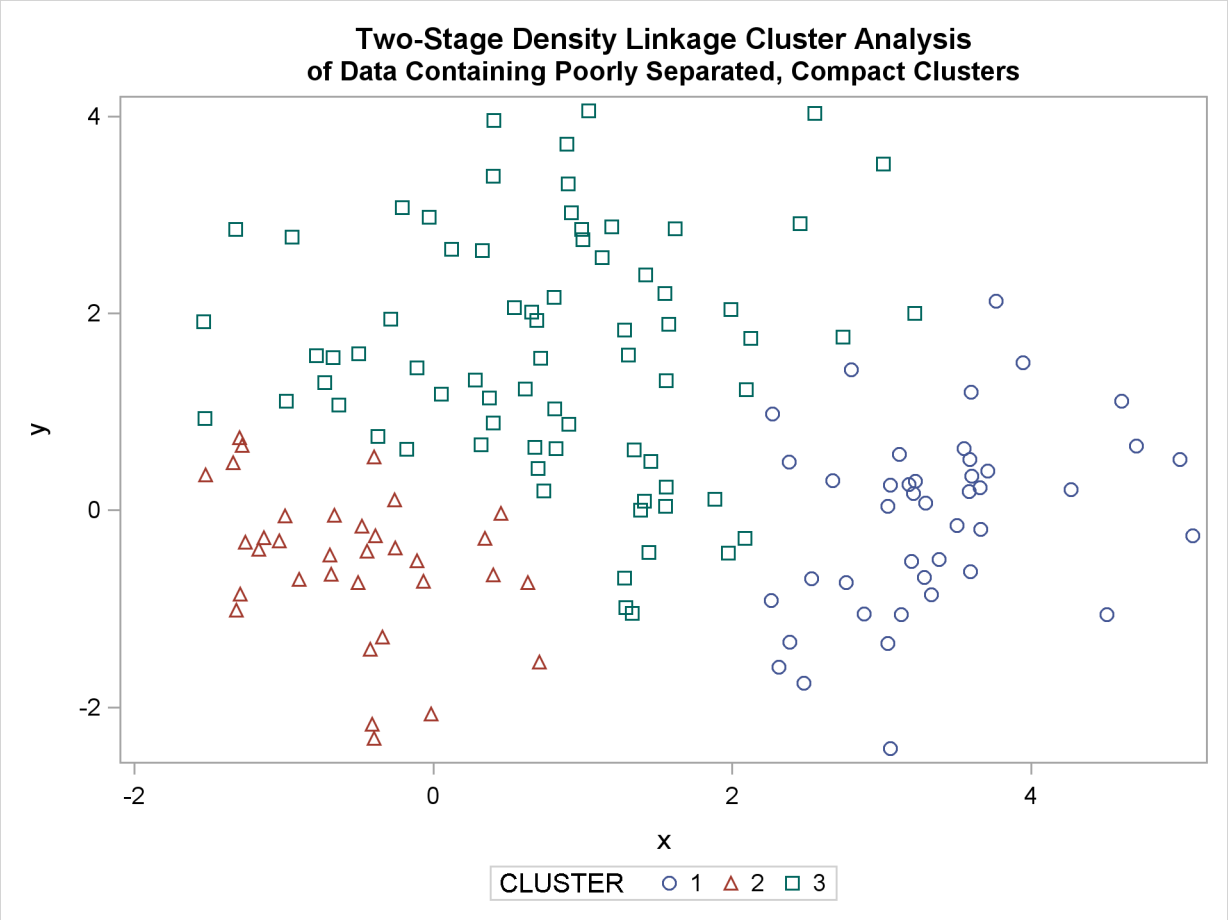
axis2 minor=none;

proc gplot;
   bubble y*x=_dens_/frame vaxis=axis1 haxis=axis2 bsize=10;
   title h=1.2 'Estimated Densities';
   title2 h=1 'for Data Containing Poorly Separated, Compact Clusters';
run;
```

Figure 11.7 Data Containing Poorly Separated, Compact Clusters: PROC CLUSTER with METHOD=TWOSTAGE



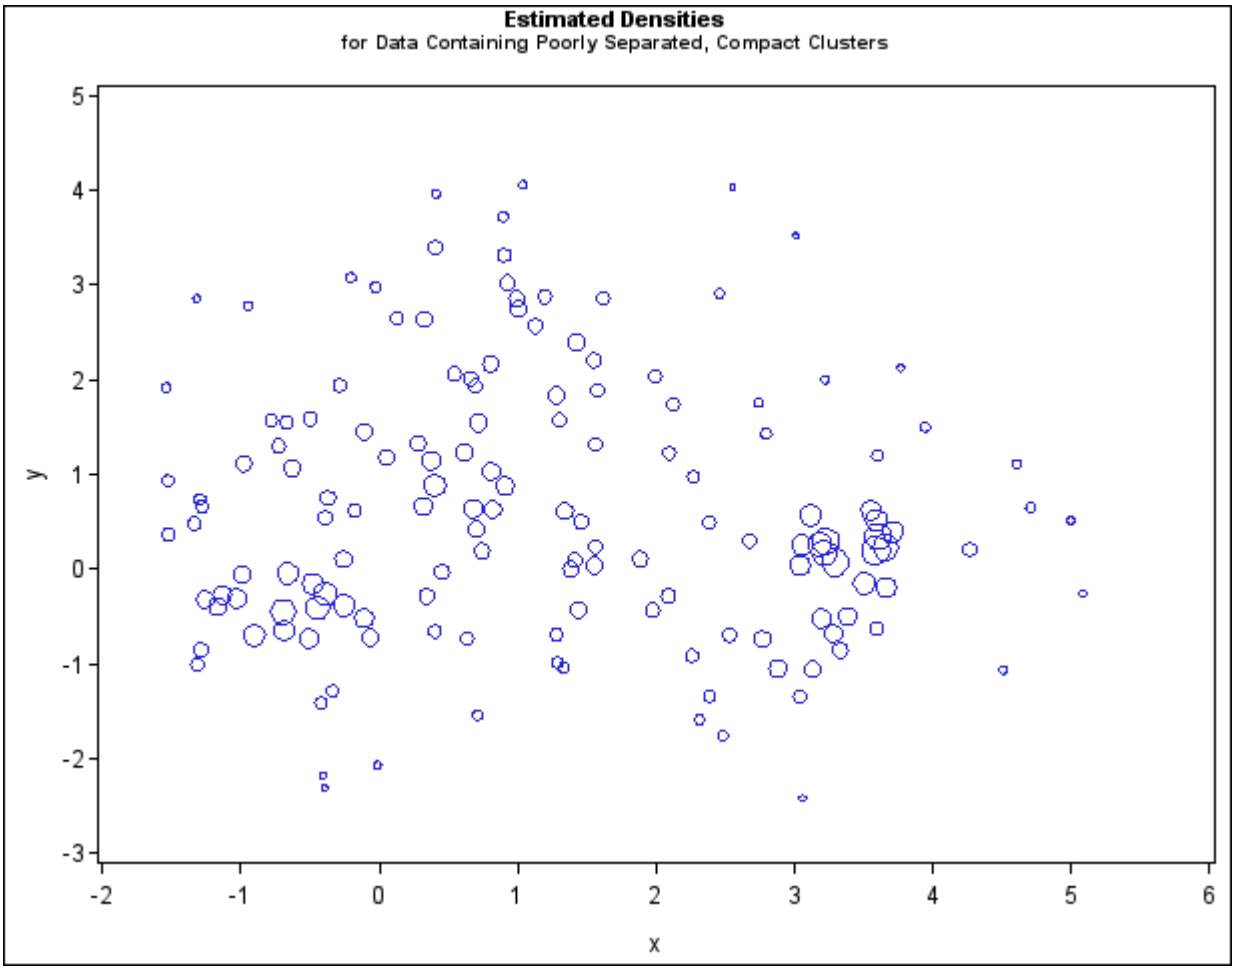


Figure 11.8 Data Containing Poorly Separated, Compact Clusters: PROC CLUSTER with METHOD=TWOSTAGE

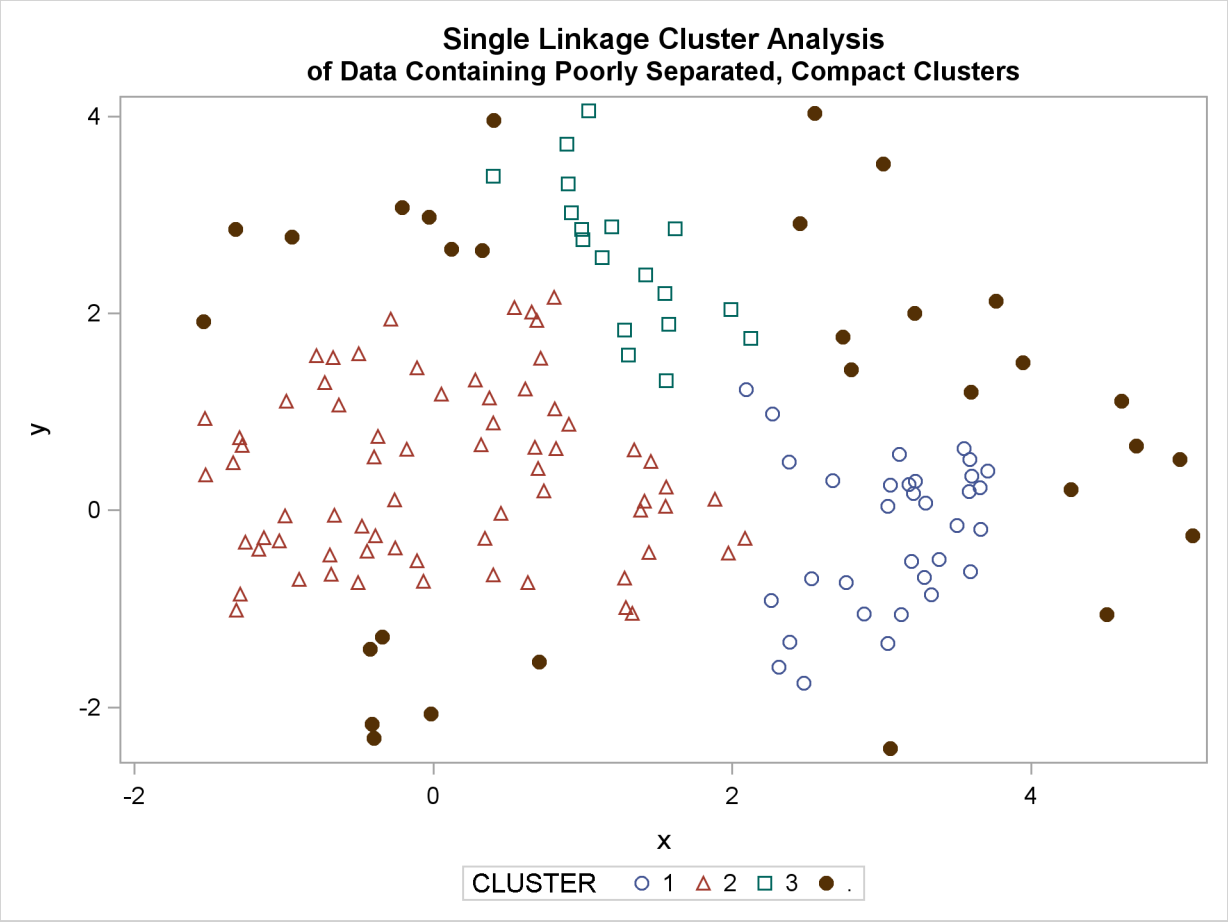
In two-stage density linkage, each cluster is a region surrounding a local maximum of the estimated probability density function. If you think of the estimated density function as a landscape with mountains and valleys, each mountain is a cluster, and the boundaries between clusters are placed near the bottoms of the valleys.



The following SAS statements produce Figure 11.9:

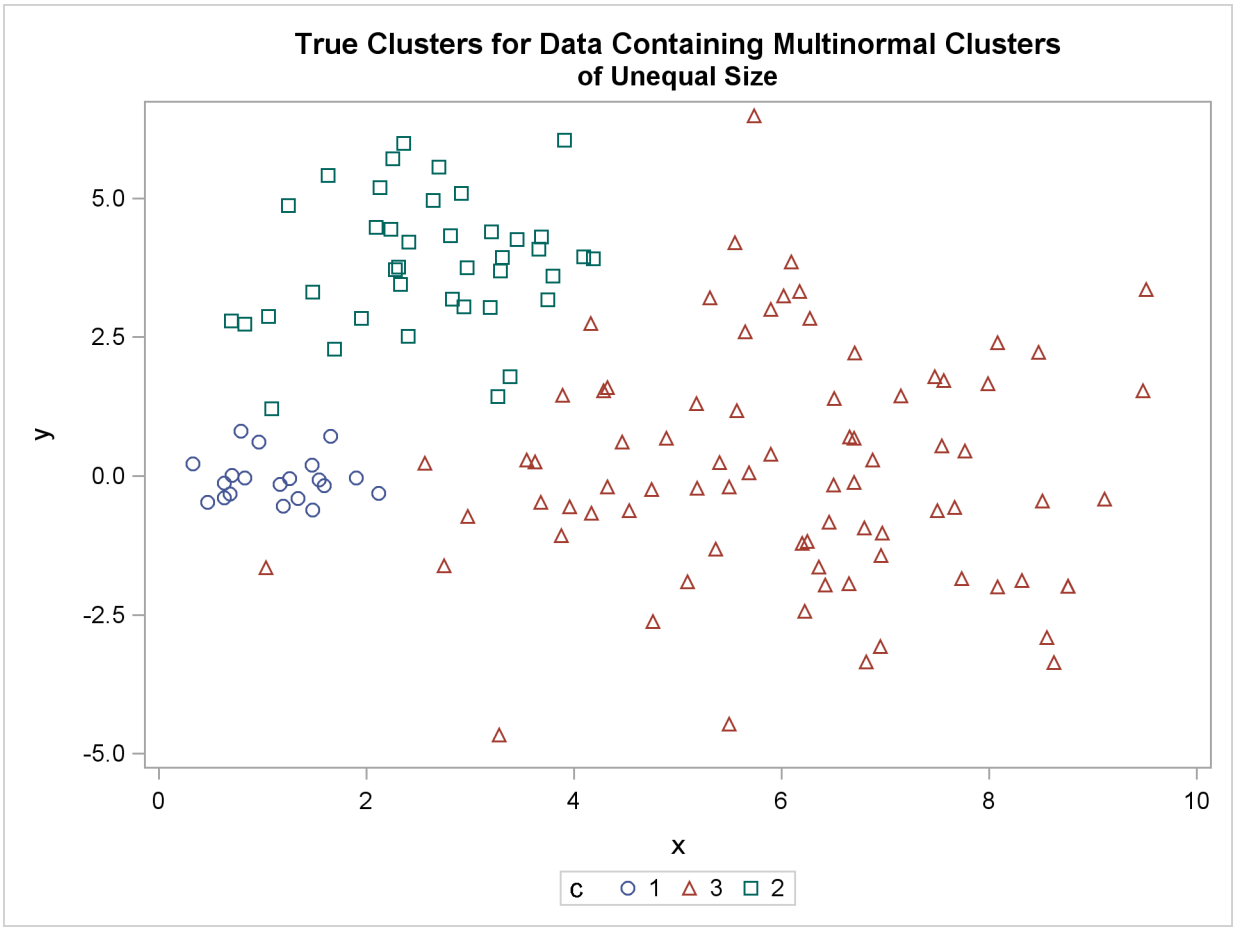
```
proc cluster data=closer outtree=tree
             method=single noprint;
   var x y;
run;

proc tree data=tree noprint out=out n=3 dock=5;
   copy x y;
   title 'Single Linkage Cluster Analysis';
   title2 'of Data Containing Poorly Separated, Compact Clusters';
run;

proc sgplot;
   scatter y=y x=x / group=cluster;
run;
```

Figure 11.9 Data Containing Poorly Separated, Compact Clusters: PROC CLUSTER with METHOD=SINGLE

The two least squares methods, PROC FASTCLUS and Ward's, yield the most uniform cluster sizes and the best recovery of the true clusters. This result is expected since these two methods are biased toward recovering compact clusters of equal size. With average linkage, the lower-left cluster is too large; with the centroid method, the lower-right cluster is too large; and with two-stage density linkage, the top cluster is too large. The single linkage analysis resembles average linkage except for the large number of outliers resulting from the DOCK= option in the PROC TREE statement; the outliers are plotted as filled circles (missing values).



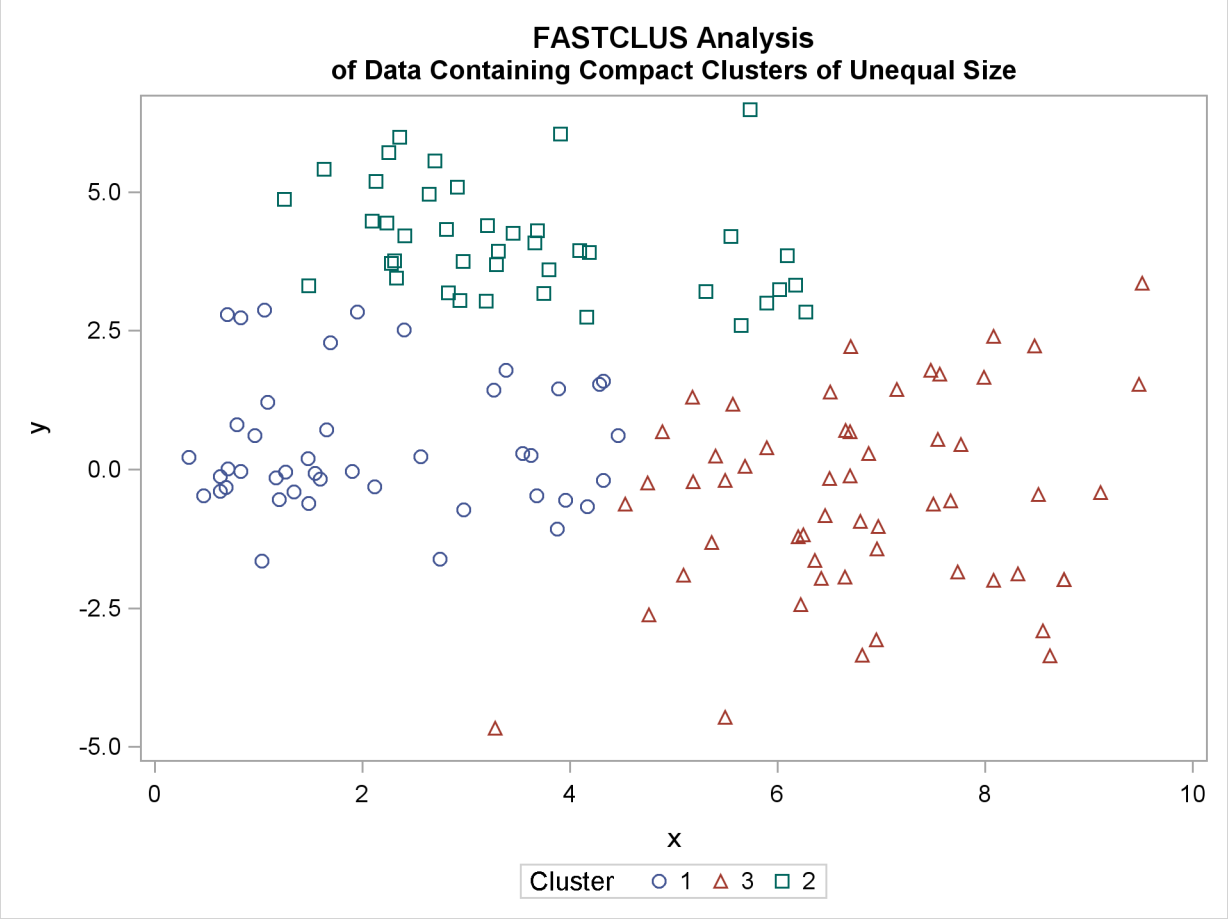
Multinormal Clusters of Unequal Size and Dispersion

In this example, there are three multinormal clusters that differ in size and dispersion. PROC FASTCLUS and five of the hierarchical methods available in PROC CLUSTER are used. To help you compare methods, the true, generated clusters are plotted.

The following SAS statements produce Figure 11.10:

```
data unequal;
   keep x y c;
   mx=1; my=0; n=20; scale=.5; c=1; link generate;
   mx=6; my=0; n=80; scale=2.; c=3; link generate;
   mx=3; my=4; n=40; scale=1.; c=2; link generate;
   stop;
generate:
   do i=1 to n;
      x=rannor(1)*scale+mx;
      y=rannor(1)*scale+my;
      output;
   end;
   return;
title 'True Clusters for Data Containing Multinormal Clusters';
title2 'of Unequal Size';
proc sgplot;
   scatter y=y x=x / group=c;
run;
```

Figure 11.10 Data Containing Generated Clusters of Unequal Size



The following statements use the FASTCLUS procedure to find three clusters and then use the SGPLOT procedure to plot the clusters. The following statements produce Figure 11.11:

```
proc fastclus data=unequal out=out maxc=3 noprint;
   var x y;
   title 'FASTCLUS Analysis';
   title2 'of Data Containing Compact Clusters of Unequal Size';
run;

proc sgplot;
   scatter y=y x=x / group=cluster;
run;
```

             method=single noprint;
   var x y;
run;

proc tree data=tree noprint out=out n=3 dock=5;
   copy x y;
   title 'Single Linkage Cluster Analysis';
   title2 'of Data Containing Compact Clusters of Unequal Size';
run;

proc sgplot;
   scatter y=y x=x / group=cluster;
run;
```

Figure 11.17 Data Containing Compact Clusters of Unequal Size: PROC CLUSTER with METHOD=SINGLE

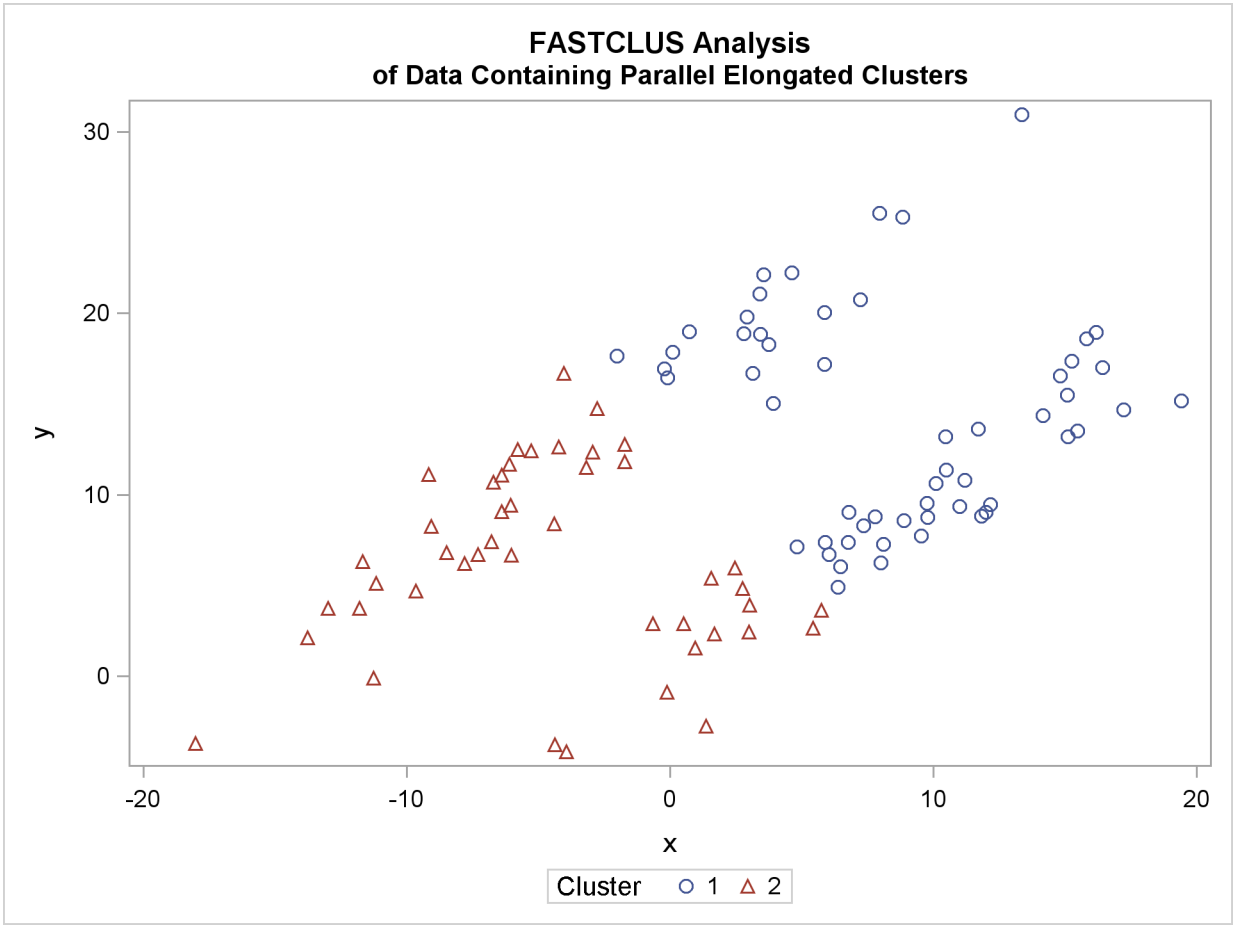
In the PROC FASTCLUS analysis, the smallest cluster, in the bottom-left portion of the plot, has stolen members from the other two clusters, and the upper-left cluster has also acquired some observations that rightfully belong to the larger, lower-right cluster. With Ward's method, the upper-left

cluster is separated correctly, but the lower-left cluster has taken a large bite out of the lower-right cluster. For both of these methods, the clustering errors are in accord with the biases of the methods to produce clusters of equal size. In the average linkage analysis, both the upper-left and lower-left clusters have encroached on the lower-right cluster, thereby making the variances more nearly equal than in the true clusters. The centroid method, which lacks the size and dispersion biases of the previous methods, obtains an essentially correct partition.

Two-stage density linkage does almost as well, even though the compact shapes of these clusters favor the traditional methods. Single linkage also produces excellent results.

Elongated Multinormal Clusters

In this example, the data are sampled from two highly elongated multinormal distributions with equal covariance matrices. The following SAS statements produce Figure 11.18:



```
data elongate;
   keep x y;
   ma=8; mb=0; link generate;
   ma=6; mb=8; link generate;
   stop;
generate:
   do i=1 to 50;
      a=rannor(7)*6+ma;
      b=rannor(7)+mb;
      x=a-b;
      y=a+b;
      output;
   end;
   return;
proc fastclus data=elongate out=out maxc=2 noprint;
run;

%modstyle(name=ClusterStyle2,parent=Statistical,type=CLM,
markers=Circle Triangle circlefilled);
ods listing style=ClusterStyle;

proc sgplot;
   scatter y=y x=x / group=cluster;
   title 'FASTCLUS Analysis';
   title2 'of Data Containing Parallel Elongated Clusters';
run;
```

Notice that PROC FASTCLUS found two clusters, as requested by the MAXC= option. However, it attempted to form spherical clusters, which are obviously inappropriate for these data.

run;

proc sgplot;
   scatter y=y x=x / group=cluster;
   title 'Two-Stage Density Linkage Cluster Analysis';
   title2 'of Data Containing Parallel Elongated Clusters';
run;
```

Figure 11.20 Data Containing Parallel Elongated Clusters: PROC CLUSTER with METHOD=TWOSTAGE

PROC FASTCLUS and average linkage fail miserably. Ward's method and the centroid method (not shown) produce almost the same results. Two-stage density linkage, however, recovers the correct clusters. Single linkage (not shown) finds the same clusters as two-stage density linkage except for some outliers.

In this example, the population clusters have equal covariance matrices. If the within-cluster covariances are known, the data can be transformed to make the clusters spherical so that any of the clustering methods can find the correct clusters. But when you are doing a cluster analysis, you do not know what the true clusters are, so you cannot calculate the within-cluster covariance matrix. Nevertheless, it is sometimes possible to estimate the within-cluster covariance matrix without knowing the cluster membership or even the number of clusters, using an approach invented by Art, Gnanadesikan, and Kettenring (1982). A method for obtaining such an estimate is available in the ACECLUS procedure.

In the following analysis, PROC ACECLUS transforms the variables X and Y into the canonical variables CAN1 and CAN2. The latter are plotted and then used in a cluster analysis by Ward's method. The clusters are then plotted with the original variables X and Y.

The following SAS statements produce Figure 11.21 and Figure 11.22:

```
proc aceclus data=elongate out=ace p=.1;
   var x y;

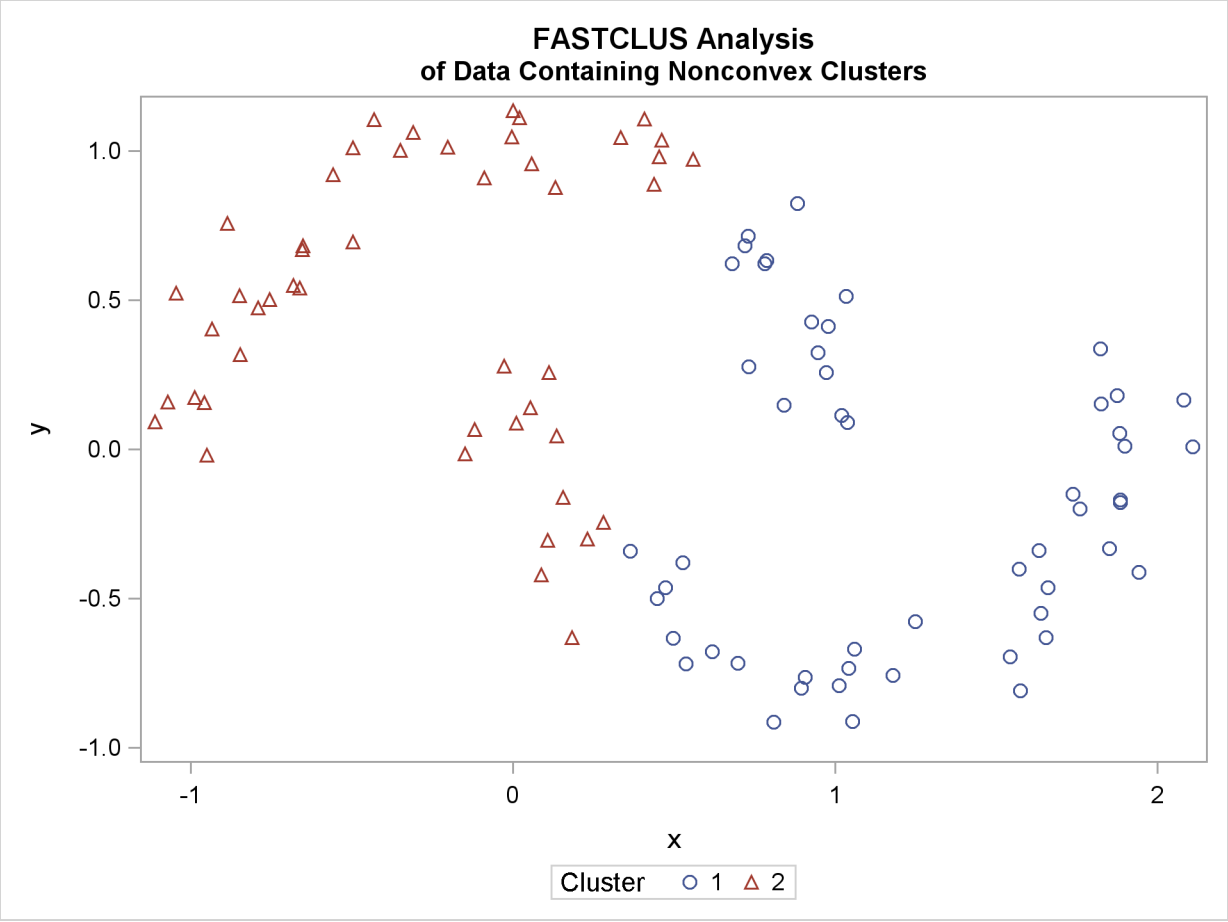
Figure 11.23 Transformed Data Containing Parallel Elongated Clusters: PROC CLUSTER with METHOD=WARD

Nonconvex Clusters



If the population clusters have very different covariance matrices, using PROC ACECLUS is of no avail. Although methods exist for estimating multinormal clusters with unequal covariance matrices (Wolfe 1970; Symons 1981; Everitt and Hand 1981; Titterington, Smith, and Makov 1985; McLachlan and Basford 1988), these methods tend to have serious problems with initialization and might converge to degenerate solutions. For unequal covariance matrices or radically nonnormal distributions, the best approach to cluster analysis is through nonparametric density estimation, as in density linkage. The next example illustrates population clusters with nonconvex density contours. The following SAS statements produce Figure 11.24:

```
data noncon;
   keep x y;
   do i=1 to 100;
      a=i*.0628319;
      x=cos(a)+(i>50)+rannor(7)*.1;
      y=sin(a)+(i>50)*.3+rannor(7)*.1;
      output;
   end;
```

```
proc fastclus data=noncon out=out maxc=2 noprint;

run;
```

Figure 11.26 Data Containing Nonconvex Clusters: PROC CLUSTER with METHOD=TWOSTAGE

Ward's method and average linkage (not shown) do better than PROC FASTCLUS but not as well as the centroid method. Two-stage density linkage recovers the correct clusters, as does single linkage (not shown).

The preceding examples are intended merely to illustrate some of the properties of clustering methods in common use. If you intend to perform a cluster analysis, you should consult more systematic and rigorous studies of the properties of clustering methods, such as Milligan (1980).

The Number of Clusters

There are no completely satisfactory methods that can be used for determining the number of population clusters for any type of cluster analysis (Everitt 1979; Hartigan, J. A. 1985; Bock 1985).

If your purpose in clustering is dissection—that is, to summarize the data without trying to uncover real clusters—it might suffice to look at R square for each variable and pooled over all variables. Plots of R square against the number of clusters are useful.

It is always a good idea to look at your data graphically. If you have only two or three variables, use PROC SGPLOT to make scatter plots identifying the clusters. With more variables, use PROC CANDISC to compute canonical variables for plotting.

Ordinary significance tests, such as analysis of variance F tests, are not valid for testing differences between clusters. Since clustering methods attempt to maximize the separation between clusters, the assumptions of the usual significance tests, parametric or nonparametric, are drastically violated. For example, if you take a sample of 100 observations from a single univariate normal distribution, have PROC FASTCLUS divide it into two clusters, and run a t test between the clusters, you usually obtain a p-value of less than 0.0001. For the same reason, methods that purport to test for clusters against the null hypothesis that objects are assigned randomly to clusters (such as McClain and Rao 1975; Klastorin 1983) are useless.

Most valid tests for clusters either have intractable sampling distributions or involve null hypotheses for which rejection is uninformative. For clustering methods based on distance matrices, a popular null hypothesis is that all permutations of the values in the distance matrix are equally likely (Ling 1973; Hubert 1974). Using this null hypothesis, you can do a permutation test or a rank test. The trouble with the permutation hypothesis is that, with any real data, the null hypothesis is implausible even if the data do not contain clusters. Rejecting the null hypothesis does not provide any useful information (Hubert and Baker 1977).

Another common null hypothesis is that the data are a random sample from a multivariate normal distribution (Wolfe 1970, 1978; Duda and Hart 1973; Lee 1979). The multivariate normal null hypothesis arises naturally in normal mixture models (Titterington, Smith, and Makov 1985; McLachlan and Basford 1988). Unfortunately, the likelihood ratio test statistic does not have the usual asymptotic χ^2 distribution because the regularity conditions do not hold. Approximations to the asymptotic distribution of the likelihood ratio have been suggested (Wolfe 1978), but the adequacy of these approximations is debatable (Everitt 1981; Thode, Mendell, and Finch 1988). For small samples, bootstrapping seems preferable (McLachlan and Basford 1988). Bayesian inference provides a promising alternative to likelihood ratio tests for the number of mixture components for both normal mixtures and other types of distributions (Binder 1978, 1981; Banfield and Raftery 1993; Bensmail et al. 1997).

The multivariate normal null hypothesis is better than the permutation null hypothesis, but it is not satisfactory because there is typically a high probability of rejection if the data are sampled from a distribution with lower kurtosis than a normal distribution, such as a uniform distribution. The tables in Englemann and Hartigan (1969), for example, generally lead to rejection of the null hypothesis when the data are sampled from a uniform distribution. Hawkins, Muller, and ten Krooden (1982, pp. 337–340) discuss a highly conservative Bonferroni method for the use of hypothesis testing. The conservativeness of this approach might compensate to some extent for the liberalness exhibited by tests based on normal distributions when the population is uniform.

Perhaps a better null hypothesis is that the data are sampled from a uniform distribution (Hartigan 1978; Arnold 1979; Sarle 1983). The uniform null hypothesis leads to conservative error rates when the data are sampled from a strongly unimodal distribution such as the normal. However, in two or more dimensions and depending on the test statistic, the results can be very sensitive to the shape of the region of support of the uniform distribution. Sarle (1983) suggests using a hyperbox with sides proportional in length to the singular values of the centered coordinate matrix.

Given that the uniform distribution provides an appropriate null hypothesis, there are still serious difficulties in obtaining sampling distributions. Some asymptotic results are available (Hartigan 1978, 1985; Pollard 1981; Bock 1985) for the within-cluster sum of squares, the criterion that PROC FASTCLUS and Ward's minimum variance method attempt to optimize. No distributional theory for finite sample sizes has yet appeared. Currently, the only practical way to obtain sampling distributions for realistic sample sizes is by computer simulation.

Arnold (1979) used simulation to derive tables of the distribution of a criterion based on the determinant of the within-cluster sum of squares matrix $|\mathbf{W}|$. Both normal and uniform null distributions were used. Having obtained clusters with either PROC FASTCLUS or PROC CLUSTER, you can compute Arnold's criterion with the ANOVA or CANDISC procedure. Arnold's tables provide a conservative test because PROC FASTCLUS and PROC CLUSTER attempt to minimize the trace of $\mathbf{W}$ rather than the determinant. Marriott (1971, 1975) also provides useful information about $|\mathbf{W}|$ as a criterion for the number of clusters.

Sarle (1983) used extensive simulations to develop the cubic clustering criterion (CCC), which can be used for crude hypothesis testing and estimating the number of population clusters. The CCC is based on the assumption that a uniform distribution on a hyperrectangle will be divided into clusters shaped roughly like hypercubes. In large samples that can be divided into the appropriate number of hypercubes, this assumption gives very accurate results. In other cases the approximation is generally conservative. For details about the interpretation of the CCC, consult Sarle (1983).

Milligan and Cooper (1985) and Cooper and Milligan (1988) compared 30 methods of estimating the number of population clusters by using four hierarchical clustering methods. The three criteria that performed best in these simulation studies with a high degree of error in the data were a pseudo F statistic developed by Calinski and Harabasz (1974), a statistic referred to as $J_e(2)/J_e(1)$ by Duda and Hart (1973) that can be transformed into a pseudo t^2 statistic, and the cubic clustering criterion. The pseudo F statistic and the CCC are displayed by PROC FASTCLUS; these two statistics and the pseudo t^2 statistic, which can be applied only to hierarchical methods, are displayed by PROC CLUSTER. It might be advisable to look for consensus among the three statistics—that is, local peaks of the CCC and pseudo F statistic combined with a small value of the pseudo t^2 statistic and a larger pseudo t^2 for the next cluster fusion. It must be emphasized that these criteria are appropriate only for compact or slightly elongated clusters, preferably clusters that are roughly multivariate normal.

Recent research has tended to deemphasize mixture models in favor of nonparametric models in which clusters correspond to modes in the probability density function. Hartigan and Hartigan (1985) and P. M. Hartigan (1985) developed a test of unimodality versus bimodality in the univariate case.

Nonparametric tests for the number of clusters can also be based on nonparametric density estimates. This approach requires much weaker assumptions than mixture models, namely, that the observations are sampled independently and that the distribution can be estimated nonparametrically. Silverman (1986) describes a bootstrap test for the number of modes using a Gaussian kernel density estimate, but problems have been reported with this method under the uniform null distribution. Further developments in nonparametric methods are given by Mueller and Sawitzki (1991), Minnotte (1992), and Polonik (1993). All of these methods suffer from heavy computational requirements.

One useful descriptive approach to the number-of-clusters problem is provided by Wong and Schaack (1982), based on a kth-nearest-neighbor density estimate. The kth-nearest-neighbor clustering method developed by Wong and Lane (1983) is applied with varying values of k. Each value of k yields an estimate of the number of modal clusters. If the estimated number of modal clusters is constant for a wide range of k values, there is strong evidence of at least that many modes in the population. A plot of the estimated number of modes against k can be highly informative. Attempts to derive a formal hypothesis test from this diagnostic plot have met with difficulties, but a simulation approach similar to Silverman's (1986) does seem to work (Girman 1994). The simulation, of course, requires considerable computer time.

Sarle and Kuo (1993) document a less expensive approximate nonparametric test for the number of clusters that has been implemented in the MODECLUS procedure. This test sacrifices statistical efficiency for computational efficiency. The method for conducting significance tests is described in the chapter on the MODECLUS procedure. This method has the following useful features:

- No distributional assumptions are required.
- The choice of smoothing parameter is not critical since you can try any number of different values.
- The data can be coordinates or distances.
- Time and space requirements for the significance tests are no worse than those for obtaining the clusters.
- The power is high enough to be useful for practical purposes.

The method for computing the p-values is based on a series of plausible approximations. There are as yet no rigorous proofs that the method is infallible. Neither are there any asymptotic results. However, simulations for sample sizes ranging from 20 to 2000 indicate that the p-values are almost always conservative. The only case discovered so far in which the p-values are liberal is a uniform distribution in one dimension for which the simulated error rates exceed the nominal significance level only slightly for a limited range of sample sizes.

Overview: Scoring, Standardization, and Ranking Procedures

Several SAS/STAT procedures are utilities that produce an output data set with new variables that are transformations of data in the input data set. SAS/STAT software includes four of these procedures. The RANK procedure produces rank scores across observations, the SCORE procedure constructs functions across the variables, and the STANDARD and STDIZE procedures transform each variable individually.

RANK	ranks the observations of each numeric variable and outputs ranks or rank scores. For a complete discussion of the RANK procedure, see the *Base SAS Procedures Guide: Statistical Procedures*.
SCORE	constructs new variables that are linear combinations of old variables according to a scoring data set. This procedure is used with the FACTOR procedure and other procedures that output scoring coefficients.
STANDARD	standardizes variables to a given mean and standard deviation. For a complete discussion of PROC STANDARD, see the *Base SAS Procedures Guide: Statistical Procedures*.
STDIZE	standardizes variables by subtracting a location measure and dividing by a scale measure. A variety of location and scale measures are provided. Such measures include the mean, median, Huber's estimate, Tukey's biweight estimate, and Andrew's wave estimate.

Overview

Data that measure lifetime or the length of time until the occurrence of an event are called *lifetime, failure time,* or *survival* data. For example, variables of interest might be the lifetime of diesel engines, the length of time a person stayed on a job, or the survival time for heart transplant patients. Such data have special considerations that must be incorporated into any analysis.

Survival data consist of a response (event time, failure time, or survival time) variable that measures the duration of time until a specified event occurs and possibly a set of independent variables thought to be associated with the failure time variable. These independent variables (concomitant variables, covariates, or prognostic factors) can be either discrete, such as sex or race, or continuous, such as age or temperature. The system that gives rise to the event of interest can be biological (as for most medical data) or physical (as for engineering data). The purpose of survival analysis is to model the underlying distribution of the failure time variable and to assess the dependence of the failure time variable on the independent variables.

An intrinsic characteristic of survival data is the possibility for censoring of observations (that is, the actual time until the event is not observed). Such censoring can arise from withdrawal from the experiment or termination of the experiment. Because the response is usually a duration, some of the possible events may not yet have occurred when the period for data collection has terminated. For example, clinical trials are conducted over a finite period of time with staggered entry of patients. That is, patients enter a clinical trial over time, and thus the length of follow-up varies by individuals; consequently, the time to the event may not be ascertained on all patients in the study. Additionally, some of the responses may be lost to follow-up (for example, a participant may move or refuse to

continue to participate) before termination of data collection. In either case, only a lower bound on the failure time of the censored observations is known. These observations are said to be *right censored*. Thus, an additional variable is incorporated into the analysis to indicate which failure times are observed event times and which are censored times. More generally, the failure time might only be known to be smaller than a given value (*left censored*) or known to be within a given interval (*interval censored*). There are numerous possible censoring schemes that arise in survival analysis. The monograph by Maddala (1983) discusses several related types of censoring situations, and the text by Kalbfleisch and Prentice (1980) also discusses several censoring schemes. Data with censored observations cannot be analyzed by ignoring the censored observations because, among other considerations, the longer-lived individuals are generally more likely to be right censored. The method of analysis must take the censoring into account and correctly use the censored observations as well as the uncensored observations.

Another characteristic of survival data is that the response cannot be negative. This suggests that a transformation of the survival time such as a log transformation might be necessary or that specialized methods might be more appropriate than those that assume a normal distribution for the error term. It is especially important to check any underlying assumptions as a part of the analysis because some of the models used are very sensitive to these assumptions.

Survival Analysis Procedures

There are three SAS procedures for analyzing survival data: LIFEREG, LIFETEST, and PHREG. PROC LIFEREG is a parametric regression procedure for modeling the distribution of survival time with a set of concomitant variables. PROC LIFETEST is a nonparametric procedure for estimating the survivor function, comparing the underlying survival curves of two or more samples, and testing the association of survival time with other variables. PROC PHREG is a semiparametric procedure that fits the Cox proportional hazards model and its extensions.

The LIFEREG Procedure

The LIFEREG procedure fits parametric accelerated failure time models to survival data that may be left, right, or interval censored. The parametric model is of the form

$$y = \mathbf{x}'\boldsymbol{\beta} + \sigma\epsilon$$

where y is usually the log of the failure time variable, $\mathbf{x}$ is a vector of covariate values, $\boldsymbol{\beta}$ is a vector of unknown regression parameters, σ is an unknown scale parameter, and ϵ is an error term. The baseline distribution of the error term can be specified as one of several possible distributions including (but not limited to) the log normal, log logistic, and Weibull distributions. Several texts that discuss these parametric models are Kalbfleisch and Prentice (1980), Lawless (1982), Nelson (1990), and Meeker and Escobar (1998). For more information about PROC LIFEREG, see Chapter 48, "The LIFEREG Procedure."

The LIFETEST Procedure

The LIFETEST procedure computes nonparametric estimates of the survival distribution function. You can request either the product-limit (Kaplan and Meier 1958) or the life-table (actuarial) estimate of the distribution. The texts by Cox and Oakes (1984) and Kalbfleisch and Prentice (1980) provide good discussions of the product-limit estimator, and the texts by Lee (1992) and Elandt-Johnson and Johnson (1980) include detailed discussions of the life-table estimator. PROC LIFETEST computes nonparametric tests to compare the survival curves of two or more groups. The procedure also computes rank tests of association of the survival time variable with other concomitant variables as given in Kalbfleisch and Prentice (1980, Chapter 6). For more information about PROC LIFETEST, see Chapter 49, "The LIFETEST Procedure."

The PHREG Procedure

The PHREG procedure fits the proportional hazards model of Cox (1972, 1975) to survival data that might be right censored. The Cox model is a semiparametric model in which the hazard function of the survival time is given by

$$\lambda(t;\mathbf{x}) = \lambda_0(t)e^{\boldsymbol{\beta}'\mathbf{x}(t)}$$

where $\lambda_0(t)$ is an unspecified baseline hazard function, $\mathbf{x}(t)$ is a vector of covariate values (possibly time-dependent), and $\boldsymbol{\beta}$ is a vector of unknown regression parameters. The model is referred to as a semiparametric model because part of the model involves the unspecified baseline function over time (which has an infinite dimension) and the other part involves a finite number of regression parameters. Several texts that discuss the Cox regression models are Collett (1994), Cox and Oakes (1984), Kalbfleisch and Prentice (1980), and Lawless (1982). Extensions of the Cox model are discussed in Therneau and Grambsch (2000), Andersen et al. (1992), and Fleming and Harrington (1991). For more information about PROC PHREG, see Chapter 64, "The PHREG Procedure."

Survival Analysis with SAS/STAT Procedures

The typical goal in survival analysis is to characterize the distribution of the survival time for a given population, to compare the survival distributions among different groups, or to study the relationship between the survival time and some concomitant variables.

A first step in the analysis of a set of survival data is to use PROC LIFETEST to compute and plot the estimate of the distribution of the survival time. In many applications, there are often several survival curves to compare. For example, you want to compare the survival experiences of patients who receive different treatments for their disease. The association between covariates and the survival time variable can be investigated by computing estimates of the survival distribution function within strata defined by the covariates. In particular, if the proportional hazards model is

appropriate, the estimates of the log(-log(SURVIVAL)) plotted against the log(TIME) variable should give approximately parallel lines, where SURVIVAL is the survival distribution estimate and TIME is the failure time variable. Additionally, these lines should be approximately straight if the Weibull model is appropriate.

Statistics that test for association between failure time and covariates can be used to select covariates for further investigation. The LIFETEST procedure computes linear rank statistics using either Wilcoxon or log-rank scores. These statistics and their estimated covariance matrix can be used with the REG procedure with the option METHOD=RSQUARE to find the subset of variables that produce the largest joint test statistic for association. An illustration of this methodology is given in Example 49.1 of Chapter 49, "The LIFETEST Procedure."

Another approach to examining the relationship between the concomitant variables and survival time is through a regression model in which the survival time has a distribution that depends on the concomitant variables. The regression coefficients can be interpreted as describing the direction and strength of the relationship of each explanatory variable on the effect of the survival time.

In many biological systems, the Cox model might be a reasonable description of the relationship between the distribution of the survival time and the prognostic factors. You use PROC PHREG to fit the Cox regression model. The regression coefficient is interpreted as the increase of the log-hazard ratio resulting in the increase of one unit in the covariate. However, the underlying hazard function is left unspecified and, as in any other model, the results can be misleading if the proportional hazards assumptions do not hold.

Accelerated failure time models are popular for survival data of physical systems. In many cases, the underlying survival distribution is known empirically. You use PROC LIFEREG to fit these parametric models. Also, PROC LIFEREG can accommodate data with left-censored or interval-censored observations, which are not allowed in PROC PHREG.

A common technique for checking the validity of a regression model is to embed it in a larger model and use the likelihood ratio test to check whether the reduction to the actual model is valid. Other techniques include examining the residuals. Both PROC LIFEREG and PROC PHREG produce predicted values, residuals, and other computed values that can be used to assess the model adequacy.

Bayesian Survival Analysis with SAS/STAT Procedures

Bayesian analysis of survival models can be requested in the LIFEREG and PHREG procedures. In addition to the Cox model, PROC PHREG also allow you to fit a piecewise exponential model. In Bayesian analysis, the model parameters are treated as random variables, and inference about parameters is based on the posterior distribution of the parameters. A posterior distribution is a weighted likelihood function of the data with a prior distribution of the parameters using the Bayes theorem. The prior distribution enables you to incorporate into the analysis knowledge or experience of the likely range of values of the parameters of interest. You can specify normal or uniform prior distributions for the model regression coefficients in both LIFEREG and PHREG procedures. In addition, you can specify a gamma or improper prior distribution for the scale or variance parameter

in PROC LIFEREG. For the piecewise exponential model in PROC PHREG, you can specify normal or uniform prior distributions for the log-hazard parameters; alternatively, you can specify gamma or improper prior distributions for the hazards parameters. If you have no prior knowledge of the parameter values, you can use a noninformative prior distribution, and the results of a Bayesian analysis will be very similar to a classical analysis based on maximum likelihood.

A closed form of the posterior distribution is often not feasible, and a Markov chain Monte Carlo method by Gibbs sampling is used to simulate samples from the posterior distribution. You can perform inference by using the simulated samples, for example, to estimate the probability that a function of the parameters of interest lies within a specified range of values.

See Chapter 7, "Introduction to Bayesian Analysis Procedures," for an introduction to the basic concepts of Bayesian statistics. Also see "Bayesian Analysis: Advantages and Disadvantages" on page 149 for a discussion of the advantages and disadvantages of Bayesian analysis. See Ibrahim, Chen, and Sinha (2001), Gelman et al. (2004), and Gilks, Richardson, and Spiegelhalter (1996) for more information about Bayesian analysis, including guidance about choosing prior distributions.

Overview: Survey Sampling and Analysis Procedures

This chapter introduces the SAS/STAT procedures for survey sampling and describes how you can use these procedures to analyze survey data.

Researchers often use sample survey methodology to obtain information about a large population by selecting and measuring a sample from that population. Due to variability among items, researchers apply scientific probability-based designs to select the sample. This reduces the risk of a distorted view of the population and enables statistically valid inferences to be made from the sample. See Lohr (1999), Kalton (1983), Cochran (1977), and Kish (1965) for more information about statistical sampling and analysis of complex survey data. To select probability-based random samples from a study population, you can use the SURVEYSELECT procedure, which provides a variety of methods for probability sampling. To analyze sample survey data, you can use the SURVEYMEANS, SURVEYFREQ, SURVEYREG, and SURVEYLOGISTIC procedures, which incorporate the sample design into the analyses.

Many SAS/STAT procedures, such as the MEANS, FREQ, GLM and LOGISTIC procedures, can compute sample means, produce crosstabulation tables, and estimate regression relationships. However, in most of these procedures, statistical inference is based on the assumption that the sample is

drawn from an infinite population by simple random sampling. If the sample is in fact selected from a finite population by using a complex survey design, these procedures generally do not calculate the estimates and their variances according to the design actually used. Using analyses that are not appropriate for your sample design can lead to incorrect statistical inferences.

The SURVEYMEANS, SURVEYFREQ, SURVEYREG, and SURVEYLOGISTIC procedures properly analyze complex survey data by taking into account the sample design. These procedures can be used for multistage or single-stage designs, with or without stratification, and with or without unequal weighting. The survey analysis procedures provide a choice of variance estimation methods, which include Taylor series linearization, balanced repeated replication (BRR), and the jackknife.

Table 14.1 briefly describes the sampling and analysis procedures in SAS/STAT software.

Table 14.1 Sampling and Analysis Procedures in SAS/STAT Software

PROC SURVEYSELECT

The Survey Procedures

The SURVEYSELECT procedure provides methods for probability sample selection. The SURVEYMEANS, SURVEYFREQ, SURVEYREG, and SURVEYLOGISTIC procedures provide statistical analyses for sample survey data. The following sections contain brief descriptions of these procedures. See the chapters on these procedures for more detailed information.

PROC SURVEYSELECT

The SURVEYSELECT procedure provides a variety of methods for selecting probability-based random samples. The procedure can select a simple random sample or can sample according to a complex multistage sample design that includes stratification, clustering, and unequal probabilities of selection. With probability sampling, each unit in the survey population has a known, positive probability of selection. This property of probability sampling avoids selection bias and enables you to use statistical theory to make valid inferences from the sample to the survey population.

PROC SURVEYSELECT provides methods for both equal probability sampling and probability proportional to size (PPS) sampling. In PPS sampling, a unit's selection probability is proportional to its size measure. PPS sampling is often used in cluster sampling, where you select clusters (groups of sampling units) of varying size in the first stage of selection. Available PPS methods include without replacement, with replacement, systematic, and sequential with minimum replacement. The procedure can apply these methods for stratified and replicated sample designs.

For stratified sampling, PROC SURVEYSELECT provides survey design methods to allocate the total sample size among the strata. Available allocation methods include proportional, Neyman, and optimal allocation. Optimal allocation maximizes the estimation precision within the available resources, taking into account stratum sizes, costs, and variances.

See Chapter 87, "The SURVEYSELECT Procedure," for more information.

PROC SURVEYMEANS

The SURVEYMEANS procedure produces estimates of population means and totals from sample survey data. The procedure also computes estimates of proportions for categorical variables, estimates of quantiles for continuous variables, and ratio estimates of means and proportions. For all of these statistics, PROC SURVEYMEANS provides standard errors, confidence limits, and *t* tests.

PROC SURVEYMEANS provides domain analysis, which computes estimates for subpopulations or domains, in addition to analysis for the entire study population. Formation of subpopulations can be unrelated to the sample design, and so the domain sample sizes can actually be random variables.

Domain analysis takes this variability into account by using the entire sample in estimating the variance of domain estimates. Domain analysis is also known as subgroup analysis, subpopulation analysis, or subdomain analysis.

See Chapter 85, "The SURVEYMEANS Procedure," for more information.

PROC SURVEYFREQ

The SURVEYFREQ procedure produces one-way to *n*-way frequency and crosstabulation tables from sample survey data. These tables include estimates of population totals, population proportions (overall proportions, and also row and column proportions), and corresponding standard errors. Confidence limits, coefficients of variation, and design effects are also available. The procedure provides a variety of options to customize the table display.

For one-way frequency tables, PROC SURVEYFREQ provides Rao-Scott chi-square goodness-of-fit tests, which are adjusted for the sample design. You can test a null hypothesis of equal proportions for a one-way frequency table, or you can input custom null hypothesis proportions for the test. For two-way frequency tables, PROC SURVEYFREQ provides design-adjusted tests of independence, or no association, between the row and column variables. These tests include the Rao-Scott chi-square test, the Rao-Scott likelihood ratio test, the Wald chi-square test, and the Wald log-linear chi-square test.

For 2×2 tables, PROC SURVEYFREQ computes estimates and confidence limits for risks (or row proportions), the risk difference, the odds ratio, and relative risks.

See Chapter 83, "The SURVEYFREQ Procedure," for more information.

PROC SURVEYREG

The SURVEYREG procedure performs regression analysis for sample survey data. The procedure fits linear models and computes regression coefficients and their variance-covariance matrix. The procedure enables you to specify classification effects by using the same syntax as in the GLM procedure.

PROC SURVEYREG provides hypothesis tests for the model effects. The procedure also provides custom hypothesis tests for linear combinations of the regression parameters. The procedure computes confidence limits for the parameter estimates, as well as for any specified linear functions of the regression parameters. The procedure can produce an output data set that contains the predicted values from the linear regression, their standard errors and confidence limits, and the residuals.

PROC SURVEYREG also performs regression analysis for domains or population subgroups.

See Chapter 86, "The SURVEYREG Procedure," for more information.

PROC SURVEYLOGISTIC

The SURVEYLOGISTIC procedure provides logistic regression analysis for sample survey data. Logistic regression analysis investigates the relationship between discrete responses and a set of explanatory variables. PROC SURVEYLOGISTIC fits linear logistic regression models for discrete response survey data by the method of maximum likelihood and incorporates the sample design into the analysis. The SURVEYLOGISTIC procedure enables you to specify categorical classification variables (also known as CLASS variables) as explanatory variables in the model by using the same syntax for main effects and interactions as in the GLM and LOGISTIC procedures.

The following link functions are available for regression in PROC SURVEYLOGISTIC: the cumulative logit function (CLOGIT), the generalized logit function (GLOGIT), the probit function (PROBIT), and the complementary log-log function (CLOGLOG). The procedure performs maximum likelihood estimation of the regression coefficients with either the Fisher scoring algorithm or the Newton-Raphson algorithm.

PROC SURVEYLOGISTIC also performs logistic regression analysis for domains or subgroups.

See Chapter 84, "The SURVEYLOGISTIC Procedure," for more information.

Survey Design Specification

Survey sampling is the process of selecting a probability-based sample from a finite population according to a sample design. You then collect data from these selected units and use them to estimate characteristics of the entire population.

A *sample design* encompasses the rules and operations by which you select sampling units from the population and the computation of sample statistics, which are estimates of the population values of interest. The objective of your survey often determines appropriate sample designs and valid data collection methodology. A complex sample design can include stratification, clustering, multiple stages of selection, and unequal weighting. The survey procedures can be used for single-stage designs or for multistage designs, with or without stratification, and with or without unequal weighting.

To analyze your survey data with the SURVEYMEANS, SURVEYFREQ, SURVEYREG, and SURVEYLOGISTIC procedures, you need to specify sample design information for the procedures. This information can include design strata, clusters, and sampling weights. All the survey analysis procedures use the same syntax for specifying sample design information. You provide sample design information with the STRATA, CLUSTER, and WEIGHT statements, and with the RATE= or TOTAL= option in the PROC statement.

If you provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a STRATA or CLUSTER statement. Otherwise, you should specify STRATA and CLUSTER statements whenever your design includes stratification and clustering.

When there are clusters, or PSUs, in the sample design, the procedures estimate variance by using the PSUs, as described in the section "Variance Estimation" on page 267. For a multistage sample design, the variance estimation depends only on the first stage of the sample design. So the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling.

The following sections provide brief descriptions of basic sample design concepts and terminology used in the survey procedures. See Lohr (1999), Kalton (1983), Cochran (1977), and Kish (1965) for more detailed information.

Population

Population refers to the target population or group of individuals of interest for study. Often, the primary objective is to estimate certain characteristics of this population, called *population values*. A *sampling unit* is an element or an individual in the target population. A *sample* is a subset of the population that is selected for the study.

Before you use the survey procedures, you should have a well-defined target population, sampling units, and an appropriate sample design.

In order to select a sample according to your sample design, you need to have a list of sampling units in the population. This is called a *sampling frame*. PROC SURVEYSELECT selects a sample by using this sampling frame.

Stratification

Stratified sampling involves selecting samples independently within strata, which are nonoverlapping subgroups of the survey population. Stratification controls the distribution of the sample size in the strata. It is widely used to meet a variety of survey objectives. For example, with stratification you can ensure adequate sample sizes for subgroups of interest, including small subgroups, or you can use stratification to improve the precision of overall estimates. To improve precision, units within strata should be as homogeneous as possible for the characteristics of interest.

Clustering

Cluster sampling involves selecting clusters, which are groups of sampling units. For example, clusters might be schools, hospitals, or geographical areas, and sampling units might be students, patients, or citizens. Cluster sampling can provide efficiency in frame construction and other survey operations. However, it can also result in a loss in precision of your estimates, compared to a nonclustered sample of the same size. To minimize this effect, units within clusters should be as heterogeneous as possible for the characteristics of interest.

Multistage Sampling

In *multistage sampling*, you select an initial or first-stage sample based on groups of elements in the population, called *primary sampling units* or *PSUs*.

Then you create a second-stage sample by drawing a subsample from each selected PSU in the first-stage sample. By repeating this operation, you can select a higher-stage sample. If you include all the elements from the selected primary sampling units, then the two-stage sample is a cluster sample.

Sampling Weights

Sampling weights, or *survey weights*, are positive values associated with the units in your sample. Ideally, the weight of a sampling unit should be the "frequency" that the sampling unit represents in the target population.

Often, sampling weights are the reciprocals of the selection probabilities for the sampling units. When you use PROC SURVEYSELECT, the procedure generates the sampling weight component for each stage of the design, and you can multiply these sampling weight components to obtain the final sampling weights. Sometimes, sampling weights also include nonresponse adjustments, postsampling stratification, or regression adjustments by using supplemental information.

When the sampling units have unequal weights, you must provide the weights to the survey analysis procedures. If you do not specify sampling weights, the procedures use equal weights in the analyses.

Population Totals and Sampling Rates

If you use Taylor series variance estimation, the survey procedures include a finite population correction factor in the analysis if you input either the sampling rate or the population total.

The sampling rate is the ratio of the sample size (the number of sampling units in the sample) n to the population size (the total number of sampling units in the target population) N, $f = n/N$. This ratio is also called the *sampling fraction*. If you select a sample without replacement, the extra efficiency compared to selecting a sample with replacement can be measured by the *finite population correction* (*fpc*) factor, $(1 - f)$.

If your analysis includes a finite population correction factor, you can input either the sampling rate or the population total. Otherwise, the procedures do not use the *fpc* in computing variance estimates. For fairly small sampling fractions, it is appropriate to ignore this correction. See Cochran (1977) and Kish (1965) for details.

As discussed in the section "Variance Estimation" on page 267, for a multistage sample design, the variance estimation depends only on the first stage of the sample design. Therefore, if you are specifying the sampling rate, you should input the *first-stage sampling rate*, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the target population.

If you use BRR or jackknife variance estimate, the procedures do not include a finite population correction in the analysis, and so you do not need to input the sampling rate or the population total.

Variance Estimation

The survey analysis procedures provide a choice of variance estimation methods for complex survey designs. In addition to the Taylor series linearization method, the procedures offer two replication-based or resampling methods—balanced repeated replication (BRR) and the delete-1 jackknife. These variance estimation methods usually give similar, satisfactory results (Lohr 1999; Särndal, Swensson, and Wretman 1992; Wolter 1985). The choice of a variance estimation method can depend on the sample design used, the sample design information available, the parameters to be estimated, and computational issues. See Lohr (1999) for more details.

The Taylor series linearization method is appropriate for all designs where the first-stage sample is selected with replacement, or where the first-stage sampling fraction is small, as it often is in practice. The Taylor series method obtains a linear approximation for the estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Fuller 1975; Woodruff 1971). When there are clusters, or primary sampling units (PSUs), in the sample design, the procedures estimate the variance from the variation among the PSUs. When the design is stratified, the procedures pool stratum variance estimates to compute the overall variance estimate.

For a multistage sample design, the Taylor series variance method depends only on the first stage of the sample design. So the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling.

Replication methods for variance estimation draw multiple replicates (or subsamples) from the full sample by following a specific resampling scheme. Commonly used resampling schemes include *balanced repeated replication* (BRR) and the *jackknife*. The parameter of interest is estimated from each replicate, and the variability among the replicate estimates is used to estimate the overall variance of the parameter estimate.

The BRR variance estimation method requires a stratified sample design with two PSUs in each stratum. Each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix and adjusting the original weights for the remaining PSUs. The adjusted weights are called *replicate weights*. The survey procedures also provide Fay's method, which is a modification of the BRR method.

The jackknife method deletes one PSU at a time from the full sample to create replicates, and modifies the original weights to obtain replicate weights. The total number of replicates equals the number of PSUs. If the sample design is stratified, each stratum must contain at least two PSUs, and the jackknife is applied separately within each stratum.

Instead of having the survey procedures generate replicate weights for the analysis, you can directly input your own replicate weights. This can be useful if you need to do multiple analyses with the same set of replicate weights, or if you have access to replicate weights without complete design information.

See the chapters on the survey procedures for complete details. For more information about variance estimation for sample survey data, see Lohr (1999); Wolter (1985); Särndal, Swensson, and Wretman (1992); Lee, Forthoffer, and Lorimor (1989); Cochran (1977); Kish (1965); and Hansen, Hurwitz, and Madow (1953).

Example: Survey Sampling and Analysis Procedures

This section demonstrates how you can use the survey procedures to select a probability-based sample and then analyze the survey data to make inferences about the population. The analyses include descriptive statistics and regression analysis. This example is a survey of income and expenditures for a group of households in North Carolina and South Carolina. The goals of the survey are as follows:

- to estimate total income and total living expenses
- to estimate the median income and the median living expenses
- to investigate the linear relationship between income and living expenses

Sample Selection

To select a sample with PROC SURVEYSELECT, you input a SAS data set that contains the sampling frame or list of units from which the sample is to be selected. You also specify the selection method, the desired sample size or sampling rate, and other selection parameters. PROC SURVEYSELECT selects the sample and produces an output data set that contains the selected units, their selection probabilities, and their sampling weights. See Chapter 87, "The SURVEYSELECT Procedure," for more details about PROC SURVEYSELECT.

In this example, the sample design is a stratified sample design, with households as the sampling units and selection by simple random sampling. The SAS data set HHFrame contains the sampling frame, which is the list of households in the survey population. The sampling frame is stratified by the variables State and Region. Within strata, households are selected by simple random sampling. The following PROC SURVEYSELECT statements select a probability sample of households according to this sample design:

```
proc surveyselect data=HHFrame out=HHSample
                  method=srs n=(3, 5, 3, 6, 2);
   strata State Region;
run;
```

The STRATA statement names the stratification variables State and Region. In the PROC SURVEYSELECT statement, the DATA= option names the SAS data set HHFrame as the input data set (or sampling frame) from which to select the sample. The OUT= option stores the sample in the SAS data set named HHSample. The METHOD=SRS option specifies simple random sampling as the sample selection method. The N= option specifies the stratum sample sizes.

The SURVEYSELECT procedure then selects a stratified random sample of households and produces the output data set HHSample, which contains the selected households together with their selection probabilities and sampling weights. The data set HHSample also contains the sampling unit identification variable Id and the stratification variables State and Region from the input data set HHFrame.

Survey Data Analysis

You can use the SURVEYMEANS and SURVEYREG procedures to estimate population values and perform regression analyses for survey data. The following example briefly shows the capabilities of these procedures. See Chapter 85, "The SURVEYMEANS Procedure," and Chapter 86, "The SURVEYREG Procedure," for more information.

The following PROC SURVEYMEANS statements estimate the total income and living expenses for the survey population based on the data from the stratified sample design:

```
proc surveymeans data=HHSample sum median;
   var Income Expense;
   strata State Region;
   weight Weight;
run;
```

The PROC SURVEYMEANS statement invokes the procedure, and the DATA= option names the SAS data set HHSample as the input data set to be analyzed. The keywords SUM and MEDIAN request estimates of population totals and medians.

The VAR statement specifies the two analysis variables Income and Expense. The STRATA statement names the stratification variables State and Region. The WEIGHT statement specifies the sampling weight variable Weight.

You can use PROC SURVEYREG to perform regression analysis for survey data. Suppose that, in order to explore the relationship between household income and living expenses in the survey population, you choose the following linear model:

$$\text{Expense} = \alpha + \beta * \text{Income} + \text{error}$$

The following PROC SURVEYREG statements fit this linear model for the survey population based on the data from the stratified sample design:

```
proc surveyreg data=HHSample;
   strata State Region ;
   model  Expense = Income;
   weight Weight;
run;
```

The STRATA statement names the stratification variables State and Region. The MODEL statement specifies the model, with Expense as the dependent variable and Income as the independent variable. The WEIGHT statement specifies the sampling weight variable Weight.

Overview

Many regression and analysis of variance procedures in SAS/STAT label tests for various effects in the model as Type I, Type II, Type III, or Type IV. These four types of hypotheses might not always be sufficient for a statistician to perform all desired inferences, but they should suffice for the vast majority of analyses. This chapter explains the hypotheses involved in each of the four test types. For additional discussion, see Freund, Littell, and Spector (1991) or Milliken and Johnson (1984).

The primary context of the discussion is testing linear hypotheses in least squares regression and analysis of variance, such as with PROC GLM. In this context, tests correspond to hypotheses about linear functions of the true parameters and are evaluated using sums of squares of the estimated parameters. Thus, there will be frequent references to Type I, II, III, and IV (estimable) functions and corresponding Type I, II, III, and IV sums of squares, or simply SS.

Estimability

Given a response or dependent variable $\mathbf{Y}$, predictors or independent variables $\mathbf{X}$, and a linear expectation model $\mathrm{E}[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$ relating the two, a primary analytical goal is to estimate or test for

the significance of certain linear combinations of the elements of $\boldsymbol{\beta}$. For least squares regression and analysis of variance, this is accomplished by computing linear combinations of the observed $\mathbf{Y}$s. An unbiased linear estimate of a specific linear function of the individual βs, say $\mathbf{L}\boldsymbol{\beta}$, is a linear combination of the $\mathbf{Y}$s that has an expected value of $\mathbf{L}\boldsymbol{\beta}$. Hence, the following definition:

> A linear combination of the parameters $\mathbf{L}\boldsymbol{\beta}$ is estimable if and only if a linear combination of the $\mathbf{Y}$s exists that has expected value $\mathbf{L}\boldsymbol{\beta}$.

Any linear combination of the $\mathbf{Y}$s, for instance $\mathbf{KY}$, will have expectation $\mathrm{E}[KY] = \mathbf{KX}\boldsymbol{\beta}$. Thus, the expected value of any linear combination of the $\mathbf{Y}$s is equal to that same linear combination of the rows of $\mathbf{X}$ multiplied by $\boldsymbol{\beta}$. Therefore,

> $\mathbf{L}\boldsymbol{\beta}$ is estimable if and only if there is a linear combination of the rows of $\mathbf{X}$ that is equal to $\mathbf{L}$—that is, if and only if there is a $\mathbf{K}$ such that $\mathbf{L} = \mathbf{KX}$.

Thus, the rows of $\mathbf{X}$ form a generating set from which any estimable $\mathbf{L}$ can be constructed. Since the row space of $\mathbf{X}$ is the same as the row space of $\mathbf{X}'\mathbf{X}$, the rows of $\mathbf{X}'\mathbf{X}$ also form a generating set from which all estimable $\mathbf{L}$s can be constructed. Similarly, the rows of $(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{X}$ also form a generating set for $\mathbf{L}$.

Therefore, if $\mathbf{L}$ can be written as a linear combination of the rows of $\mathbf{X}$, $\mathbf{X}'\mathbf{X}$, or $(\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{X}$, then $\mathbf{L}\boldsymbol{\beta}$ is estimable.

In the context of least squares regression and analysis of variance, an estimable linear function $\mathbf{L}\boldsymbol{\beta}$ can be estimated by $\mathbf{L}\widehat{\boldsymbol{\beta}}$, where $\widehat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{Y}$. From the general theory of linear models, the unbiased estimator $\mathbf{L}\widehat{\boldsymbol{\beta}}$ is, in fact, the *best* linear unbiased estimator of $\mathbf{L}\boldsymbol{\beta}$, in the sense of having minimum variance as well as maximum likelihood when the residuals are normal. To test the hypothesis that $\mathbf{L}\boldsymbol{\beta} = \mathbf{0}$, compute the sum of squares

$$\mathrm{SS}(H_0\colon\ \mathbf{L}\boldsymbol{\beta} = \mathbf{0}) = (\mathbf{L}\widehat{\boldsymbol{\beta}})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-1}\mathbf{L}\widehat{\boldsymbol{\beta}}$$

and form an F test with the appropriate error term. Note that in contexts more general than least squares regression (for example, generalized and/or mixed linear models), linear hypotheses are often tested by analogous sums of squares of the estimated linear parameters $(\mathbf{L}\widehat{\boldsymbol{\beta}})'(\mathrm{Var}[\mathbf{L}\widehat{\boldsymbol{\beta}}])^{-1}\mathbf{L}\widehat{\boldsymbol{\beta}}$.

General Form of an Estimable Function

This section demonstrates a shorthand technique for displaying the generating set for any estimable $\mathbf{L}$. Suppose

$$\mathbf{X} = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 1 \end{bmatrix} \quad \text{and} \quad \boldsymbol{\beta} = \begin{bmatrix} \mu \\ A_1 \\ A_2 \\ A_3 \end{bmatrix}$$

$\mathbf{X}$ is a generating set for $\mathbf{L}$, but so is the smaller set

$$\mathbf{X}^* = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{bmatrix}$$

$\mathbf{X}^*$ is formed from $\mathbf{X}$ by deleting duplicate rows.

Since all estimable $\mathbf{L}$s must be linear functions of the rows of $\mathbf{X}^*$ for $\mathbf{L}\boldsymbol{\beta}$ to be estimable, an $\mathbf{L}$ for a single-degree-of-freedom estimate can be represented symbolically as

$$L1 \times (1\ 1\ 0\ 0) + L2 \times (1\ 0\ 1\ 0) + L3 \times (1\ 0\ 0\ 1)$$

or

$$\mathbf{L} = (L1 + L2 + L3,\ L1,\ L2,\ L3)$$

For this example, $\mathbf{L}\boldsymbol{\beta}$ is estimable if and only if the first element of $\mathbf{L}$ is equal to the sum of the other elements of $\mathbf{L}$ or if

$$\mathbf{L}\boldsymbol{\beta} = (L1 + L2 + L3) \times \mu + L1 \times A_1 + L2 \times A_2 + L3 \times A_3$$

is estimable for any values of $L1$, $L2$, and $L3$.

If other generating sets for $\mathbf{L}$ are represented symbolically, the symbolic notation looks different. However, the inherent nature of the rules is the same. For example, if row operations are performed on $\mathbf{X}^*$ to produce an identity matrix in the first 3×3 submatrix of the resulting matrix

$$\mathbf{X}^{**} = \begin{bmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & -1 \\ 0 & 0 & 1 & -1 \end{bmatrix}$$

then $\mathbf{X}^{**}$ is also a generating set for $\mathbf{L}$. An estimable $\mathbf{L}$ generated from $\mathbf{X}^{**}$ can be represented symbolically as

$$\mathbf{L} = (L1,\ L2,\ L3,\ L1 - L2 - L3)$$

Note that, again, the first element of $\mathbf{L}$ is equal to the sum of the other elements.

With multiple generating sets available, the question arises as to which one is the best to represent $\mathbf{L}$ symbolically. Clearly, a generating set containing a minimum of rows (of full row rank) and a maximum of zero elements is desirable.

The generalized g_2-inverse $(\mathbf{X}'\mathbf{X})^-$ of $\mathbf{X}'\mathbf{X}$ computed by the modified sweep operation (Goodnight 1979) has the property that $(\mathbf{X}'\mathbf{X})^-\mathbf{X}'\mathbf{X}$ usually contains numerous zeros. For this reason, in PROC GLM the nonzero rows of $(\mathbf{X}'\mathbf{X})^-\mathbf{X}'\mathbf{X}$ are used to represent $\mathbf{L}$ symbolically.

If the generating set represented symbolically is of full row rank, the number of symbols $(L1, L2, \ldots)$ represents the maximum rank of any testable hypothesis (in other words, the maximum number of linearly independent rows for any $\mathbf{L}$ matrix that can be constructed). By letting each symbol in turn take on the value of 1 while the others are set to 0, the original generating set can be reconstructed.

Introduction to Reduction Notation

Reduction notation can be used to represent differences in sums of squares (SS) for two models. The notation $R(\mu, A, B, C)$ denotes the complete main-effects model for effects A, B, and C. The notation

$$R(A \mid \mu, B, C)$$

denotes the difference between the model SS for the complete main-effects model containing A, B, and C and the model SS for the reduced model containing only B and C.

In other words, this notation represents the differences in model SS produced by

```
proc glm;
   class a b c;
   model y = a b c;
run;
```

and

```
proc glm;
   class b c;
   model y = b c;
run;
```

As another example, consider a regression equation with four independent variables. The notation $R(\beta_3, \beta_4 \mid \beta_1, \beta_2)$ denotes the differences in model SS between

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_4 x_4 + \epsilon$$

and

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \epsilon$$

This is the difference in the model SS for the models produced, respectively, by

```
model y = x1 x2 x3 x4;
```

and

```
model y = x1 x2;
```

The following examples demonstrate the ability to manipulate the symbolic representation of a generating set. Note that any operations performed on the symbolic notation have corresponding row operations that are performed on the generating set itself.

Examples

A One-Way Classification Model

For the model

$$Y = \mu + A_i + \epsilon \qquad i = 1, 2, 3$$

the general form of estimable functions $\mathbf{L}\boldsymbol{\beta}$ is (from the previous example)

$$\mathbf{L}\boldsymbol{\beta} = L1 \times \mu + L2 \times A_1 + L3 \times A_2 + (L1 - L2 - L3) \times A_3$$

Thus,

$$\mathbf{L} = (L1, L2, L3, L1 - L2 - L3)$$

Tests involving only the parameters A_1, A_2, and A_3 must have an $\mathbf{L}$ of the form

$$\mathbf{L} = (0, L2, L3, -L2 - L3)$$

Since this $\mathbf{L}$ for the A parameters involves only two symbols, hypotheses with at most two degrees of freedom can be constructed. For example, letting $(L2, L3)$ be $(1, 0)$ and $(0, 1)$, respectively, yields

$$\mathbf{L} = \begin{bmatrix} 0 & 1 & 0 & -1 \\ 0 & 0 & 1 & -1 \end{bmatrix}$$

The preceding $\mathbf{L}$ can be used to test the hypothesis that $A_1 = A_2 = A_3$. For this example, any $\mathbf{L}$ with two linearly independent rows with column 1 equal to zero produces the same sum of squares. For example, a joint test for linear and quadratic effects of A

$$\mathbf{L} = \begin{bmatrix} 0 & 1 & 0 & -1 \\ 0 & 1 & -2 & 1 \end{bmatrix}$$

gives the same SS. In fact, for any $\mathbf{L}$ of full row rank and any nonsingular matrix $\mathbf{K}$ of conformable dimensions,

$$\text{SS}(H_0\colon\ \mathbf{L}\boldsymbol{\beta} = 0) = \text{SS}(H_0\colon\ \mathbf{KL}\boldsymbol{\beta} = 0)$$

A Three-Factor Main-Effects Model

Consider a three-factor main-effects model involving the CLASS variables A, B, and C, as shown in Table 15.1.

Table 15.1 Three-Factor Main-Effects Model

Obs	A	B	C
1	1	2	1
2	1	1	2
3	2	1	3
4	2	2	2
5	2	2	2

The general form of an estimable function is shown in Table 15.2.

Table 15.2 General Form of an Estimable Function for Three-Factor Main-Effects Model

Parameter	Coefficient
μ (Intercept)	$L1$
$A1$	$L2$
$A2$	$L1 - L2$
$B1$	$L4$
$B2$	$L1 - L4$
$C1$	$L6$
$C2$	$L1 + L2 - L4 - 2 \times L6$
$C3$	$-L2 + L4 + L6$

Since only four symbols ($L1$, $L2$, $L4$, and $L6$) are involved, any testable hypothesis will have at most four degrees of freedom. If you form an $\mathbf{L}$ matrix with four linearly independent rows according to the preceding rules, then testing $\mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ is equivalent to testing that E[$\mathbf{Y}$] is uniformly 0. Symbolically,

$$\text{SS}(H_0\text{: } \mathbf{L}\boldsymbol{\beta} = 0) = R(\mu, A, B, C)$$

In a main-effects model, the usual hypothesis of interest for a main effect is the equality of all the parameters. In this example, it is not possible to unambiguously test such a hypothesis because of confounding: any test for the equality of the parameters for any one of A, B, or C will necessarily involve the parameters for the other two effects. One way to proceed is to construct a maximum rank hypothesis (MRH) involving only the parameters of the main effect in question. This can be done using the general form of estimable functions. Note the following:

- To get an MRH involving only the parameters of A, the coefficients of $\mathbf{L}$ associated with μ, $B1$, $B2$, $C1$, $C2$, and $C3$ must be equated to zero. Starting at the top of the general form, let $L1 = 0$, then $L4 = 0$, then $L6 = 0$. If $C2$ and $C3$ are not to be involved, then $L2$ must also be zero. Thus, $A1 - A2$ is not estimable; that is, the MRH involving only the A parameters has zero rank and $R(A \mid \mu, B, C) = 0$.
- To obtain the MRH involving only the B parameters, let $L1 = L2 = L6 = 0$. But then to remove $C2$ and $C3$ from the comparison, $L4$ must also be set to 0. Thus, $B1 - B2$ is not estimable and $R(B \mid \mu, A, C) = 0$.
- To obtain the MRH involving only the C parameters, let $L1 = L2 = L4 = 0$. Thus, the MRH involving only C parameters is

  $$C1 - 2 \times C2 + C3 = K \qquad \text{(for any } K\text{)}$$

  or any multiple of the left-hand side equal to K. Furthermore,

  $$\text{SS}(H_0\text{: } C1 - 2 \times C2 + C3 = 0) = R(C \mid \mu, A, B)$$

A Multiple Regression Model

Suppose

$$\mathrm{E}[Y] = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3$$

where the $\mathbf{X}'\mathbf{X}$ matrix has full rank. The general form of estimable functions is as shown in Table 15.3.

Table 15.3 General Form of Estimable Functions for a Multiple Regression Model When $\mathbf{X}'\mathbf{X}$ Matrix Is of Full Rank

Parameter	Coefficient
β_0	$L1$
β_1	$L2$
β_2	$L3$
β_3	$L4$

For example, to test the hypothesis that $\beta_2 = 0$, let $L1 = L2 = L4 = 0$ and let $L3 = 1$. Then $\mathrm{SS}(\mathbf{L}\boldsymbol{\beta} = \mathbf{0}) = R(\beta_2 \mid \beta_0, \beta_1, \beta_3)$. In this full-rank case, all parameters, as well as any linear combination of parameters, are estimable.

Suppose, however, that $X3 = 2x_1 + 3x_2$. The general form of estimable functions is shown in Table 15.4.

Table 15.4 General Form of Estimable Functions for a Multiple Regression Model When $\mathbf{X}'\mathbf{X}$ Matrix Is Not of Full Rank

Parameter	Coefficient
β_0	$L1$
β_1	$L2$
β_2	$L3$
β_3	$2 \times L2 + 3 \times L3$

For this example, it is possible to test $H_0: \beta_0 = 0$. However, β_1, β_2, and β_3 are not jointly estimable; that is,

$$\begin{aligned} R(\beta_1 \mid \beta_0, \beta_2, \beta_3) &= 0 \\ R(\beta_2 \mid \beta_0, \beta_1, \beta_3) &= 0 \\ R(\beta_3 \mid \beta_0, \beta_1, \beta_2) &= 0 \end{aligned}$$

Estimable Functions

Type I SS and Estimable Functions

In PROC GLM, the Type I SS and the associated hypotheses they test are byproducts of the modified sweep operator used to compute a generalized g_2-inverse of $\mathbf{X}'\mathbf{X}$ and a solution to the normal equations. For the model $\mathrm{E}[Y] = x_1\beta_1 + x_2\beta_2 + x_3\beta_3$, the Type I SS for each effect are as follows:

Effect	Type I SS
x_1	$R(\beta_1)$
x_2	$R(\beta_2 \mid \beta_1)$
x_3	$R(\beta_3 \mid \beta_1, \beta_2)$

Note that some other SAS/STAT procedures compute Type I hypotheses by sweeping $\mathbf{X}'\mathbf{X}$ (for example, PROC MIXED and PROC GLIMMIX), but their test statistics are not necessarily equivalent to the results of using those procedures to fit models that contain successively more effects.

The Type I SS are model-order dependent; each effect is adjusted only for the preceding effects in the model.

There are numerous ways to obtain a Type I hypothesis matrix $\mathbf{L}$ for each effect. One way is to form the $\mathbf{X}'\mathbf{X}$ matrix and then reduce $\mathbf{X}'\mathbf{X}$ to an upper triangular matrix by row operations, skipping over any rows with a zero diagonal. The nonzero rows of the resulting matrix associated with x_1 provide an $\mathbf{L}$ such that

$$\mathrm{SS}(H_0\colon\ \mathbf{L}\boldsymbol{\beta} = \mathbf{0}) = R(\beta_1)$$

The nonzero rows of the resulting matrix associated with x_2 provide an $\mathbf{L}$ such that

$$\mathrm{SS}(H_0\colon\ \mathbf{L}\boldsymbol{\beta} = \mathbf{0}) = R(\beta_2 \mid \beta_1)$$

The last set of nonzero rows (associated with x_3) provide an $\mathbf{L}$ such that

$$\mathrm{SS}(H_0\colon\ \mathbf{L}\boldsymbol{\beta} = \mathbf{0}) = R(\beta_3 \mid \beta_1, \beta_2)$$

Another more formalized representation of Type I generating sets for x_1, x_2, and x_3, respectively, is

$$\begin{aligned}
\mathbf{G}_1 &= (\ \mathbf{X}_1'\mathbf{X}_1 \ \mid \ \mathbf{X}_1'\mathbf{X}_2 \ \mid \ \mathbf{X}_1'\mathbf{X}_3 \ ) \\
\mathbf{G}_2 &= (\ 0 \ \mid \ \mathbf{X}_2'\mathbf{M}_1\mathbf{X}_2 \ \mid \ \mathbf{X}_2'\mathbf{M}_1\mathbf{X}_3 \ ) \\
\mathbf{G}_3 &= (\ 0 \ \mid \ 0 \ \mid \ \mathbf{X}_3'\mathbf{M}_2\mathbf{X}_3 \ )
\end{aligned}$$

where

$$\mathbf{M}_1 = \mathbf{I} - \mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^{-}\mathbf{X}_1'$$

and

$$\mathbf{M}_2 = \mathbf{M}_1 - \mathbf{M}_1\mathbf{X}_2(\mathbf{X}_2'\mathbf{M}_1\mathbf{X}_2)^-\mathbf{X}_2'\mathbf{M}_1$$

Using the Type I generating set $\mathbf{G}_2$ (for example), if an $\mathbf{L}$ is formed from linear combinations of the rows of $\mathbf{G}_2$ such that $\mathbf{L}$ is of full row rank and of the same row rank as $\mathbf{G}_2$, then SS(H_0: $\mathbf{L}\boldsymbol{\beta} = \mathbf{0}$) = $R(\beta_2 \mid \beta_1)$.

In the GLM procedure, the Type I estimable functions displayed symbolically when the E1 option is requested are

$$\begin{aligned}
\mathbf{G}_1^* &= (\mathbf{X}_1'\mathbf{X}_1)^-\mathbf{G}_1 \\
\mathbf{G}_2^* &= (\mathbf{X}_2'\mathbf{M}_1\mathbf{X}_2)^-\mathbf{G}_2 \\
\mathbf{G}_3^* &= (\mathbf{X}_3'\mathbf{M}_2\mathbf{X}_3)^-\mathbf{G}_3
\end{aligned}$$

As can be seen from the nature of the generating sets $\mathbf{G}_1$, $\mathbf{G}_2$, and $\mathbf{G}_3$, only the Type I estimable functions for β_3 are guaranteed not to involve the β_1 and β_2 parameters. The Type I hypothesis for β_2 can (and often does) involve β_3 parameters, and likewise the Type I hypothesis for β_1 often involves β_2 and β_3 parameters.

There are, however, a number of models for which the Type I hypotheses are considered appropriate. These are as follows:

- balanced ANOVA models specified in proper sequence (that is, interactions do not precede main effects in the MODEL statement and so forth)
- purely nested models (specified in the proper sequence)
- polynomial regression models (in the proper sequence)

Type II SS and Estimable Functions

For main-effects models and regression models, the general form of estimable functions can be manipulated to provide tests of hypotheses involving only the parameters of the effect in question. The same result can also be obtained by entering each effect in turn as the last effect in the model and obtaining the Type I SS for that effect. These are the *Type II SS*. Using a modified reversible sweep operator, it is possible to obtain the Type II SS without actually refitting the model.

Thus, the **Type II SS correspond to the R notation in which each effect is adjusted for all other appropriate effects**. For a regression model such as

$$\mathrm{E}[Y] = x_1\beta_1 + x_2\beta_2 + x_3\beta_3$$

the Type II SS correspond to

Effect	Type II SS
x_1	$R(\beta_1 \mid \beta_2, \beta_3)$
x_2	$R(\beta_2 \mid \beta_1, \beta_3)$
x_3	$R(\beta_3 \mid \beta_1, \beta_2)$

For a main-effects model (A, B, and C as classification variables), the Type II SS correspond to

Effect	Type II SS
A	$R(A \mid B, C)$
B	$R(B \mid A, C)$
C	$R(C \mid A, B)$

As the discussion in the section "A Three-Factor Main-Effects Model" on page 275 indicates, for regression and main-effects models the Type II SS provide an MRH for each effect that does not involve the parameters of the other effects.

In order to see what effects are appropriate to adjust for in computing Type II estimable functions, note that for models involving interactions and nested effects, in the absence of a priori parametric restrictions, it is not possible to obtain a test of a hypothesis for a main effect free of parameters of higher-level interactions effects with which the main effect is involved. It is reasonable to assume, then, that any test of a hypothesis concerning an effect should involve the parameters of that effect and only those other parameters with which that effect is involved. The concept of effect containment helps to define this involvement.

Contained Effect

Given two effects $F1$ and $F2$, $F1$ is said to be *contained in* $F2$ provided that the following two conditions are met:

- Both effects involve the same continuous variables (if any).
- $F2$ has more CLASS variables than $F1$ does, and if $F1$ has CLASS variables, they all appear in $F2$.

Note that the intercept effect μ is contained in all pure CLASS effects, but it is not contained in any effect involving a continuous variable. No effect is contained by μ.

Type II, Type III, and Type IV estimable functions rely on this definition, and they all have one thing in common: the estimable functions involving an effect $F1$ also involve the parameters of all effects that contain $F1$, and they do not involve the parameters of effects that do not contain $F1$ (other than $F1$).

Hypothesis Matrix for Type II Estimable Functions

The Type II estimable functions for an effect $F1$ have an $\mathbf{L}$ (before reduction to full row rank) of the following form:

- All columns of $\mathbf{L}$ associated with effects not containing $F1$ (except $F1$) are zero.
- The submatrix of $\mathbf{L}$ associated with effect $F1$ is $(\mathbf{X}_1'\mathbf{M}\mathbf{X}_1)^-(\mathbf{X}_1'\mathbf{M}\mathbf{X}_1)$.
- Each of the remaining submatrices of $\mathbf{L}$ associated with an effect $F2$ that contains $F1$ is $(\mathbf{X}_1'\mathbf{M}\mathbf{X}_1)^-(\mathbf{X}_1'\mathbf{M}\mathbf{X}_2)$.

In these submatrices,

$$\begin{aligned}
\mathbf{X}_0 &= \text{the columns of } \mathbf{X} \text{ whose associated effects do not contain } F1 \\
\mathbf{X}_1 &= \text{the columns of } \mathbf{X} \text{ associated with } F1 \\
\mathbf{X}_2 &= \text{the columns of } \mathbf{X} \text{ associated with an } F2 \text{ effect that contains } F1 \\
\mathbf{M} &= \mathbf{I} - \mathbf{X}_0(\mathbf{X}_0'\mathbf{X}_0)^-\mathbf{X}_0'
\end{aligned}$$

For the model

```
class A B;
model Y = A B A*B;
```

the Type II SS correspond to

$$R(A \mid \mu, B), \quad R(B \mid \mu, A), \quad R(A * B \mid \mu, A, B)$$

for effects A, B, and $A * B$, respectively. For the model

```
class A B C;
model Y =  A B(A) C(A B);
```

the Type II SS correspond to

$$R(A \mid \mu), \quad R(B(A) \mid \mu, A), \quad R(C(AB) \mid \mu, A, B(A))$$

for effects A, $B(A)$ and $C(A\,B)$, respectively. For the model

```
model Y = x x*x;
```

the Type II SS correspond to

$$R(X \mid \mu, X * X) \text{ and } R(X * X \mid \mu, X)$$

for x and $x * x$, respectively.

Note that, as in the situation for Type I tests, PROC MIXED and PROC GLIMMIX compute Type I hypotheses by sweeping $\mathbf{X}'\mathbf{X}$, but their test statistics are not necessarily equivalent to the results of sequentially fitting with those procedures models that contain successively more effects; while PROC TRANSREG computes tests labeled as being Type II by leaving out each effect in turn, but the specific linear hypotheses associated with these tests might not be precisely the same as the ones derived from successively sweeping $\mathbf{X}'\mathbf{X}$.

Example of Type II Estimable Functions

For a 2×2 factorial with w observations per cell, the general form of estimable functions is shown in Table 15.5. Any nonzero values for $L2$, $L4$, and $L6$ can be used to construct $\mathbf{L}$ vectors for computing the Type II SS for A, B, and $A * B$, respectively.

Table 15.5 General Form of Estimable Functions for 2×2 Factorial

Effect	Coefficient
μ	$L1$
$A1$	$L2$
$A2$	$L1 - L2$
$B1$	$L4$
$B2$	$L1 - L4$
$AB11$	$L6$
$AB12$	$L2 - L6$
$AB21$	$L4 - L6$
$AB22$	$L1 - L2 - L4 + L6$

For a balanced 2×2 factorial with the same number of observations in every cell, the Type II estimable functions are shown in Table 15.6.

Table 15.6 Type II Estimable Functions for Balanced 2×2 Factorial

	Coefficients for Effect		
Effect	A	B	$A * B$
μ	0	0	0
$A1$	$L2$	0	0
$A2$	$-L2$	0	0
$B1$	0	$L4$	0
$B2$	0	$-L4$	0
$AB11$	$0.5 * L2$	$0.5 * L4$	$L6$
$AB12$	$0.5 * L2$	$-0.5 * L4$	$-L6$
$AB21$	$-0.5 * L2$	$0.5 * L4$	$-L6$
$AB22$	$-0.5 * L2$	$-0.5 * L4$	$L6$

Now consider an unbalanced 2×2 factorial with two observations in every cell except the $AB22$ cell, which contains only one observation. The general form of estimable functions is the same as if it were balanced, since the same effects are still estimable. However, the Type II estimable functions for A and B are not the same as they were for the balanced design. The Type II estimable functions for this unbalanced 2×2 factorial are shown in Table 15.7.

Table 15.7 Type II Estimable Functions for Unbalanced 2×2 Factorial

	Coefficients for Effect		
Effect	A	B	$A * B$
μ	0	0	0
$A1$	$L2$	0	0
$A2$	$-L2$	0	0
$B1$	0	$L4$	0
$B2$	0	$-L4$	0
$AB11$	$0.6 * L2$	$0.6 * L4$	$L6$
$AB12$	$0.4 * L2$	$-0.6 * L4$	$-L6$
$AB21$	$-0.6 * L2$	$0.4 * L4$	$-L6$
$AB22$	$-0.4 * L2$	$-0.4 * L4$	$L6$

By comparing the hypothesis being tested in the balanced case to the hypothesis being tested in the unbalanced case for effects A and B, you can note that the Type II hypotheses for A and B are dependent on the cell frequencies in the design. For unbalanced designs in which the cell frequencies are not proportional to the background population, the Type II hypotheses for effects that are contained in other effects are of questionable value.

However, if an effect is not contained in any other effect, the Type II hypothesis for that effect is an MRH that does not involve any parameters except those associated with the effect in question.

Thus, Type II SS are appropriate for the following models:

- any balanced model
- any main-effects model
- any pure regression model
- an effect not contained in any other effect (regardless of the model)

In addition to the preceding models, Type II SS are generally accepted by most statisticians for purely nested models.

Type III and IV SS and Estimable Functions

When an effect is contained in another effect, the Type II hypotheses for that effect are dependent on the cell frequencies. The philosophy behind both the Type III and Type IV hypotheses is that the hypotheses tested for any given effect should be the same for all designs with the same general form of estimable functions.

To demonstrate this concept, recall the hypotheses being tested by the Type II SS in the balanced 2×2 factorial shown in Table 15.6. Those hypotheses are precisely the ones that the Type III

and Type IV hypotheses employ for all 2×2 factorials that have at least one observation per cell. The Type III and Type IV hypotheses for a design without missing cells usually differ from the hypothesis employed for the same design with missing cells since the general form of estimable functions usually differs.

Many SAS/STAT procedures can perform tests of Type III hypotheses, but only PROC GLM offers Type IV tests as well.

Type III Estimable Functions

Type III hypotheses are constructed by working directly with the general form of estimable functions. The following steps are used to construct a hypothesis for an effect $F1$:

1. For every effect in the model except $F1$ and those effects that contain $F1$, equate the coefficients in the general form of estimable functions to zero.

   If $F1$ is not contained in any other effect, this step defines the Type III hypothesis (as well as the Type II and Type IV hypotheses). If $F1$ is contained in other effects, go on to step 2. (See the section "Type II SS and Estimable Functions" on page 279 for a definition of when effect $F1$ is contained in another effect.)

2. If necessary, equate new symbols to compound expressions in the $F1$ block in order to obtain the simplest form for the $F1$ coefficients.

3. Equate all symbolic coefficients outside the $F1$ block to a linear function of the symbols in the $F1$ block in order to make the $F1$ hypothesis orthogonal to hypotheses associated with effects that contain $F1$.

By once again observing the Type II hypotheses being tested in the balanced 2×2 factorial, it is possible to verify that the A and $A * B$ hypotheses are orthogonal and also that the B and $A * B$ hypotheses are orthogonal. This principle of orthogonality between an effect and any effect that contains it holds for all balanced designs. Thus, construction of Type III hypotheses for any design is a logical extension of a process that is used for balanced designs.

The Type III hypotheses are precisely the hypotheses being tested by programs that reparameterize using the usual assumptions (for example, constraining all parameters for an effect to sum to zero). When no missing cells exist in a factorial model, Type III SS coincide with Yates' weighted squares-of-means technique. When cells are missing in factorial models, the Type III SS coincide with those discussed in Harvey (1960) and Henderson (1953).

The following discussion illustrates the construction of Type III estimable functions for a 2×2 factorial with no missing cells.

To obtain the $A * B$ interaction hypothesis, start with the general form and equate the coefficients for effects μ, A, and B to zero, as shown in Table 15.8.

Table 15.8 Type III Hypothesis for $A * B$ Interaction

Effect	**General Form**	$L1 = L2 = L4 = 0$
μ	$L1$	0
$A1$	$L2$	0
$A2$	$L1 - L2$	0
$B1$	$L4$	0
$B2$	$L1 - L4$	0
$AB11$	$L6$	$L6$
$AB12$	$L2 - L6$	$-L6$
$AB21$	$L4 - L6$	$-L6$
$AB22$	$L1 - L2 - L4 + L6$	$L6$

The last column in Table 15.8 represents the form of the MRH for $A * B$.

To obtain the Type III hypothesis for A, first start with the general form and equate the coefficients for effects μ and B to zero (let $L1 = L4 = 0$). Next let $L6 = K \times L2$, and find the value of K that makes the A hypothesis orthogonal to the A*B hypothesis. In this case, $K = 0.5$. Each of these steps is shown in Table 15.9.

In Table 15.9, the fourth column (under $L6 = K \times L2$) represents the form of all estimable functions not involving μ, $B1$, or $B2$. The prime difference between the Type II and Type III hypotheses for A is the way K is determined. Type II chooses K as a function of the cell frequencies, whereas Type III chooses K such that the estimable functions for A are orthogonal to the estimable functions for $A * B$.

Table 15.9 Type III Hypothesis for A

Effect	**General Form**	$L1 = L4 = 0$	$L6 = K \times L2$	$K = 0.5$
μ	$L1$	0	0	0
$A1$	$L2$	$L2$	$L2$	$L2$
$A2$	$L1 - L2$	$-L2$	$-L2$	$-L2$
$B1$	$L4$	0	0	0
$B2$	$L1 - L4$	0	0	0
$AB11$	$L6$	$L6$	$K * L2$	$0.5 * L2$
$AB12$	$L2 - L6$	$L2 - L6$	$(1 - K) * L2$	$0.5 * L2$
$AB21$	$L4 - L6$	$-L6$	$-K * L2$	$-0.5 * L2$
$AB22$	$L1 - L2 - L4 + L6$	$-L2 + L6$	$-(1 - K) * L2$	$-0.5 * L2$

An example of Type III estimable functions in a 3×3 factorial with unequal cell frequencies and missing diagonals is given in Table 15.10 (N_1 through N_6 represent the nonzero cell frequencies).

Table 15.10 3×3 Factorial Design with Unequal Cell Frequencies and Missing Diagonals

		B		
		1	2	3
A	1		N_1	N_2
	2	N_3		N_4
	3	N_5	N_6	

For any nonzero values of N_1 through N_6, the Type III estimable functions for each effect are shown in Table 15.11.

Table 15.11 Type III Estimable Functions for 3×3 Factorial Design with Unequal Cell Frequencies and Missing Diagonals

Effect	A	B	$A * B$
μ	0	0	0
$A1$	$L2$	0	0
$A2$	$L3$	0	0
$A3$	$-L2 - L3$	0	0
$B1$	0	$L5$	0
$B2$	0	$L6$	0
$B3$	0	$-L5 - L6$	0
$AB12$	$0.667 * L2 + 0.333 * L3$	$0.333 * L5 + 0.667 * L6$	$L8$
$AB13$	$0.333 * L2 - 0.333 * L3$	$-0.333 * L5 - 0.667 * L6$	$-L8$
$AB21$	$0.333 * L2 + 0.667 * L3$	$0.667 * L5 + 0.333 * L6$	$-L8$
$AB23$	$-0.333 * L2 + 0.333 * L3$	$-0.667 * L5 - 0.333 * L6$	$L8$
$AB31$	$-0.333 * L2 - 0.667 * L3$	$0.333 * L5 - 0.333 * L6$	$L8$
$AB32$	$-0.667 * L2 - 0.333 * L3$	$-0.333 * L5 + 0.333 * L6$	$-L8$

Type IV Estimable Functions

By once again looking at the Type II hypotheses being tested in the balanced 2×2 factorial (see Table 15.6), you can see another characteristic of the hypotheses employed for balanced designs: the coefficients of lower-order effects are averaged across each higher-level effect involving the same subscripts. For example, in the A hypothesis, the coefficients of $AB11$ and $AB12$ are equal to one-half the coefficient of $A1$, and the coefficients of $AB21$ and $AB22$ are equal to one-half the coefficient of $A2$. With this in mind, the basic concept used to construct Type IV hypotheses is that the coefficients of any effect, say $F1$, are distributed equitably across higher-level effects that contain $F1$. When missing cells occur, this same general philosophy is adhered to, but care must be taken in the way the distributive concept is applied.

Construction of Type IV hypotheses begins as does the construction of the Type III hypotheses. That is, for an effect $F1$, equate to zero all coefficients in the general form that do not belong to $F1$ or to any other effect containing $F1$. If $F1$ is not contained in any other effect, then the Type IV hypothesis (and Type II and III) has been found. If $F1$ is contained in other effects, then simplify,

if necessary, the coefficients associated with $F1$ so that they are all free coefficients or functions of other free coefficients in the $F1$ block.

To illustrate the method of resolving the free coefficients outside the $F1$ block, suppose that you are interested in the estimable functions for an effect A and that A is contained in AB, AC, and ABC. (In other words, the main effects in the model are A, B, and C.)

With missing cells, the coefficients of intermediate effects (here they are AB and AC) do not always have an equal distribution of the lower-order coefficients, so the coefficients of the highest-order effects are determined first (here it is ABC). Once the highest-order coefficients are determined, the coefficients of intermediate effects are automatically determined.

The following process is performed for each free coefficient of A in turn. The resulting symbolic vectors are then added together to give the Type IV estimable functions for A.

1. Select a free coefficient of A, and set all other free coefficients of A to zero.
2. If any of the levels of A have zero as a coefficient, equate all of the coefficients of higher-level effects involving that level of A to zero. This step alone usually resolves most of the free coefficients remaining.
3. Check to see if any higher-level coefficients are now zero when the coefficient of the associated level of A is not zero. If this situation occurs, the Type IV estimable functions for A are not unique.
4. For each level of A in turn, if the A coefficient for that level is nonzero, count the number of times that level occurs in the higher-level effect. Then equate each of the higher-level coefficients to the coefficient of that level of A divided by the count.

An example of a 3×3 factorial with four missing cells (N_1 through N_5 represent positive cell frequencies) is shown in Table 15.12.

Table 15.12 3×3 Factorial Design with Four Missing Cells

		B		
		1	2	3
A	1	N_1	N_2	
	2	N_3	N_4	
	3			N_5

The Type IV estimable functions are shown in Table 15.13.

Table 15.13 Type IV Estimable Functions for 3×3 Factorial Design with Four Missing Cells

Effect	A	B	$A*B$
μ	0	0	0
$A1$	$-L3$	0	0
$A2$	$L3$	0	0
$A3$	0	0	0
$B1$	0	$L5$	0
$B2$	0	$-L5$	0
$B3$	0	0	0
$AB11$	$-0.5*L3$	$0.5*L5$	$L8$
$AB12$	$-0.5*L3$	$-0.5*L5$	$-L8$
$AB21$	$0.5*L3$	$0.5*L5$	$-L8$
$AB22$	$0.5*L3$	$-0.5*L5$	$L8$
$AB33$	0	0	0

A Comparison of Type III and Type IV Hypotheses

For the vast majority of designs, Type III and Type IV hypotheses for a given effect are the same. Specifically, they are the same for any effect $F1$ that is not contained in other effects for any design (with or without missing cells). For factorial designs with no missing cells, the Type III and Type IV hypotheses coincide for all effects. When there are missing cells, the hypotheses can differ. By using the GLM procedure, you can study the differences in the hypotheses and then decide on the appropriateness of the hypotheses for a particular model.

The Type III hypotheses for three-factor and higher completely nested designs with unequal Ns in the lowest level differ from the Type II hypotheses; however, the Type IV hypotheses do correspond to the Type II hypotheses in this case.

When missing cells occur in a design, the Type IV hypotheses might not be unique. If this occurs in PROC GLM, you are notified, and you might need to consider defining your own specific comparisons.

Overview: Nonparametric Analysis

In statistical inference, or hypothesis testing, the traditional tests are called *parametric tests* because they depend on the specification of a probability distribution (such as the normal) except for a set of free parameters. Parametric tests are said to depend on distributional assumptions. *Nonparametric tests*, on the other hand, do not require any strict distributional assumptions. Even if the data are distributed normally, nonparametric methods are often almost as powerful as parametric methods.

Many nonparametric methods analyze the ranks of a variable rather than the original values. Procedures such as PROC NPAR1WAY calculate the ranks for you and then perform appropriate nonparametric tests. However, there are some situations in which you use a procedure such as PROC RANK to calculate ranks and then use another procedure to perform the appropriate test. See the section "Obtaining Ranks" on page 297 for details.

Although the NPAR1WAY procedure is specifically targeted for nonparametric analysis, many other procedures also perform nonparametric analyses. Some general references on nonparametrics include Hollander and Wolfe (1999), Conover (1999), Gibbons and Chakraborti (1992), Hettmansperger (1984), Randles and Wolfe (1979), and Lehmann (1975).

Testing for Normality

Many parametric tests assume an underlying normal distribution for the population. If your data do not meet this assumption, you might prefer to use a nonparametric analysis.

Base SAS software provides several tests for normality in the UNIVARIATE procedure. Depending on your sample size, PROC UNIVARIATE performs the Kolmogorov-Smirnov, Shapiro-Wilk, Anderson-Darling, and Cramér-von Mises tests. For more information, see the chapter "The UNIVARIATE Procedure" in the *Base SAS Procedures Guide*.

Comparing Distributions

To test the hypothesis that two or more groups of observations have identical distributions, use the NPAR1WAY procedure, which provides empirical distribution function (EDF) statistics. The procedure calculates the Kolmogorov-Smirnov test, the Cramér-von Mises test, and, when the data are classified into only two samples, the Kuiper test. Exact *p*-values are available for the two-sample Kolmogorov-Smirnov test. To obtain these tests, use the EDF option in the PROC NPAR1WAY statement. See Chapter 62, "The NPAR1WAY Procedure," for details.

One-Sample Tests

Base SAS software provides two one-sample tests in the UNIVARIATE procedure: a sign test and the Wilcoxon signed rank test. Both tests are designed for situations where you want to make an inference about the location (median) of a population. For example, suppose you want to test whether the median resting pulse rate of marathon runners differs from a specified value.

By default, both of these tests examine the hypothesis that the median of the population from which the sample is drawn is equal to a specified value, which is zero by default. The Wilcoxon signed rank test requires that the distribution be symmetric; the sign test does not require this assumption. These tests can also be used for the case of two related samples; see the section "Comparing Two Independent Samples" on page 293 for more information.

These two tests are automatically provided by the UNIVARIATE procedure. For details, formulas, and examples, see the chapter "The UNIVARIATE Procedure" in the *Base SAS Procedures Guide*.

Two-Sample Tests

This section describes tests appropriate for two independent samples (for example, two groups of subjects given different treatments) and for two related samples (for example, before-and-after measurements on a single group of subjects). Related samples are also referred to as paired samples or matched pairs.

Comparing Two Independent Samples

SAS/STAT software provides several nonparametric tests for location and scale differences for two independent samples.

When you perform these tests, your data should consist of a random sample of observations from two different populations. Your goal is to compare either the location parameters (medians) or the scale parameters of the two populations. For example, suppose your data consist of the number of days in the hospital for two groups of patients: those who received a standard surgical procedure and those who received a new, experimental surgical procedure. These patients are a random sample from the population of patients who have received the two types of surgery. Your goal is to decide whether the median hospital stays differ for the two populations.

Tests in the NPAR1WAY Procedure

The NPAR1WAY procedure provides the following location tests: Wilcoxon rank sum test (Mann-Whitney U test), median test, Savage test, and Van der Waerden (normal scores) test. Note that the Wilcoxon rank sum test can also be obtained from the FREQ procedure. PROC NPAR1WAY provides Hodges-Lehmann estimation of the location shift between two samples, including asymptotic (Moses) and exact confidence limits.

In addition, PROC NPAR1WAY produces the following tests for scale differences: Siegel-Tukey test, Ansari-Bradley test, Klotz test, and Mood test. PROC NPAR1WAY also provides the Conover test, which can be used to test for differences in both location and scale.

Additionally, PROC NPAR1WAY provides tests that use the input data observations as scores, enabling you to produce a wide variety of tests. You can construct any scores for your data with the DATA step, and then PROC NPAR1WAY computes the corresponding linear rank test. You can directly analyze the raw data this way, producing the permutation test known as Pitman's test.

When data are sparse, skewed, or heavily tied, the usual asymptotic tests might not be appropriate. In these situations, exact tests might be suitable for analyzing your data. The NPAR1WAY procedure can produce exact *p*-values for all of the two-sample tests for location and scale differences.

See Chapter 62, "The NPAR1WAY Procedure," for details, formulas, and examples of these tests.

Tests in the FREQ Procedure

The FREQ procedure provides nonparametric tests that compare the location of two groups and that test for independence between two variables.

The situation in which you want to compare the location of two groups of observations corresponds to a table with two rows. In this case, the asymptotic Wilcoxon rank sum test can be obtained by using SCORES=RANK in the TABLES statement and by looking at either of the following:

- the Mantel-Haenszel statistic in the list of tests for no association. This is labeled as "Mantel Haenszel Chi-Square," and PROC FREQ displays the statistic, the degrees of freedom, and the p-value. To obtain this statistic, specify the CHISQ option in the TABLES statement.
- the CMH statistic 2 in the section on Cochran-Mantel-Haenszel statistics. PROC FREQ displays the statistic, the degrees of freedom, and the p-value. To obtain this statistic, specify the CMH2 option in the TABLES statement.

When you test for independence, the question being answered is whether the two variables of interest are related in some way. For example, you might want to know if student scores on a standard test are related to whether students attended a public or private school. One way to think of this situation is to consider the data as a two-way table; the hypothesis of interest is whether the rows and columns are independent. In the preceding example, the groups of students would form the two rows, and the scores would form the columns. The special case of a two-category response (Pass/Fail) leads to a 2×2 table; the case of more than two categories for the response (A/B/C/D/F) leads to a $2 \times c$ table, where c is the number of response categories.

For testing whether two variables are independent, PROC FREQ provides Fisher's exact test. For a 2×2 table, PROC FREQ automatically provides Fisher's exact test when you specify the CHISQ option in the TABLES statement. For a $2 \times c$ table, use the FISHER option in the EXACT statement to obtain the test.

See Chapter 35, "The FREQ Procedure," for details, formulas, and examples of these tests.

Comparing Two Related Samples

SAS/STAT software provides the following nonparametric tests for comparing the locations of two related samples:

- Wilcoxon signed rank test
- sign test
- McNemar's test

The first two tests are available in the UNIVARIATE procedure, and the last test is available in the FREQ procedure. When you perform these tests, your data should consist of pairs of measurements for a random sample from a single population. For example, suppose your data consist of SAT

scores for students before and after attending a course on how to prepare for the SAT. The pairs of measurements are the scores before and after the course, and the students should be a random sample of students who attended the course. Your goal in analysis is to decide whether the median change in scores is significantly different from zero.

Tests in the UNIVARIATE Procedure

By default, PROC UNIVARIATE performs a Wilcoxon signed rank test and a sign test. To use these tests on two related samples, perform the following steps:

1. In the DATA step, create a new variable that contains the differences between the two related variables.
2. Run PROC UNIVARIATE, using the new variable in the VAR statement.

See the chapter "The UNIVARIATE Procedure" in the *Base SAS Procedures Guide* for details and examples of these tests.

Tests in the FREQ Procedure

The FREQ procedure can be used to obtain McNemar's test, which is simply another special case of a Cochran-Mantel-Haenszel statistic (and also of the sign test). The AGREE option in the TABLES statement produces this test for 2×2 tables, and exact p-values are also available for this test. See Chapter 35, "The FREQ Procedure," for more information.

Tests for *k* Samples

Comparing *k* Independent Samples

One goal in comparing k independent samples is to determine whether the location parameters (medians) of the populations are different. Another goal is to determine whether the scale parameters for the populations are different. For example, suppose new employees are randomly assigned to one of three training programs. At the end of the program, the employees are given a standard test that provides a rating score of their job ability. The goal of analysis is to compare the median scores for the three groups and decide whether the differences are real or due to chance alone.

To compare k independent samples, either the NPAR1WAY or the FREQ procedure provides a Kruskal-Wallis test. PROC NPAR1WAY also provides the Savage, median, and Van der Waerden (normal scores) tests. In addition, PROC NPAR1WAY produces the following tests for scale differences: Siegel-Tukey test, Ansari-Bradley test, Klotz test, and Mood test. PROC NPAR1WAY also

provides the Conover test, which can be used to test for differences in both location and scale. Note that you can obtain exact *p*-values for all of these tests.

Additionally, you can specify the SCORES=DATA option to use the input data observations as scores. This enables you to produce a very wide variety of tests. You can construct any scores for your data with the DATA step, and then PROC NPAR1WAY computes the corresponding linear rank and one-way ANOVA tests. You can also analyze the raw data with the SCORES=DATA option; for two-sample data, this permutation test is known as Pitman's test.

See Chapter 62, "The NPAR1WAY Procedure," for details, formulas, and examples.

To produce a Kruskal-Wallis test in the FREQ procedure, use SCORES=RANK and the CMH2 option in the TABLES statement. Then, look at the second Cochran-Mantel-Haenszel statistic (labeled "Row Mean Scores Differ") to obtain the Kruskal-Wallis test. The FREQ procedure also provides the Jonckheere-Terpstra test, which is more powerful than the Kruskal-Wallis test for comparing k samples against ordered alternatives. The exact test is also available. In addition, you can obtain a ridit analysis, developed by Bross (1958), by specifying SCORES=RIDIT or SCORES=MODRIDIT in the TABLES statement in the FREQ procedure. See Chapter 35, "The FREQ Procedure," for more information.

Comparing *k* Dependent Samples

Friedman's test enables you to compare the locations of three or more dependent samples. You can obtain Friedman's chi-square with the FREQ procedure by using the CMH2 option and SCORES=RANK and by looking at the second CMH statistic in the output. For an example, see Chapter 35, "The FREQ Procedure." This chapter also contains formulas and other details about the CMH statistics. For a discussion of how to use the RANK and GLM procedures to obtain Friedman's test, see Ipe (1987).

Measures of Correlation and Associated Tests

The CORR procedure in Base SAS software provides several nonparametric measures of association and associated tests. It computes Spearman's rank-order correlation, Kendall's tau-*b*, and Hoeffding's measure of dependence, and it provides tests for each of these statistics. PROC CORR also computes Spearman's partial rank-order correlation and Kendall's partial tau-*b*. Finally, PROC CORR computes Cronbach's coefficient alpha for raw and standardized variables. This statistic can be used to estimate the reliability coefficient. For a general discussion of correlations, formulas, interpretation, and examples, see the chapter "The CORR Procedure" in the *Base SAS Procedures Guide*.

The FREQ procedure also provides some nonparametric measures of association: gamma, Kendall's tau-b, Stuart's tau-c, Somer's D, and the Spearman rank correlation. The output includes the measure, the asymptotic standard error, confidence limits, and the asymptotic test that the measure equals zero. For the Spearman rank correlation, you can optionally request an exact p-value for the test that the correlation equals zero. For more information, see Chapter 35, "The FREQ Procedure."

Obtaining Ranks

The primary procedure for obtaining ranks is the RANK procedure in Base SAS software. Note that the PRINQUAL and TRANSREG procedures also provide rank transformations. With all three of these procedures, you can create an output data set and use it as input to another SAS/STAT procedure or to the IML procedure. For more information, see the chapter "The RANK Procedure" in the *Base SAS Procedures Guide*. Also see Chapter 70, "The PRINQUAL Procedure," and Chapter 90, "The TRANSREG Procedure."

In addition, you can specify SCORES=RANK in the TABLES statement in the FREQ procedure. PROC FREQ then uses ranks to perform the analyses requested and generates nonparametric analyses.

For more discussion of the rank transform, see Iman and Conover (1979); Conover and Iman (1981); Hora and Conover (1984); Iman, Hora, and Conover (1984); Hora and Iman (1988); and Iman (1988).

Kernel Density Estimation

The KDE procedure performs either univariate or bivariate kernel density estimation. Statistical *density estimation* involves approximating a hypothesized probability density function from observed data. *Kernel density estimation* is a nonparametric technique for density estimation in which a known density function (the kernel) is averaged across the observed data points to create a smooth approximation.

PROC KDE uses a Gaussian density as the kernel, and its assumed variance determines the smoothness of the resulting estimate. PROC KDE outputs the kernel density estimate to a SAS data set, which you can then use with other procedures for plotting or analysis. PROC KDE also computes a variety of common statistics, including estimates of the percentiles of the hypothesized probability density function.

For more information, see Chapter 45, "The KDE Procedure."

Overview: Structural Equation Modeling with Latent Variables

You can use the CALIS or TCALIS procedure for analysis of covariance structures, fitting systems of linear structural equations, and path analysis. These terms are more or less interchangeable, but they emphasize different aspects of the analysis. The analysis of covariance structures refers to the formulation of a model for the variances and covariances among a set of variables and the fitting of the model to an observed covariance matrix. In linear structural equations, the model is formulated as a system of equations relating several random variables with assumptions about the variances and covariances of the random variables. In path analysis, the model is formulated as a path diagram, in which arrows connecting variables represent variances, covariances, and regression (or path) coefficients. Path models and linear structural equation models can be converted to models of the covariance matrix and can, therefore, be fitted by the methods of covariance structure analysis. All

of these methods support the use of hypothetical latent variables and measurement errors in the models.

Loehlin (1987) provides an excellent introduction to latent variable models by using path diagrams and structural equations. A more advanced treatment of structural equation models with latent variables is given by Bollen (1989). Fuller (1987) provides a highly technical statistical treatment of measurement-error models.

TCALIS and CALIS Procedures

In SAS 9.2, the newly developed TCALIS procedure serves as an enhanced version of the older CALIS procedure. The TCALIS procedure has most of the capabilities of the CALIS procedure. In addition, it has some new capabilities that are not available in PROC CALIS. These new capabilities include multiple-group analysis, mean structures analysis, and a whole spectrum of modeling languages, among others. See Chapter 88, "The TCALIS Procedure (Experimental)," for more details about the new features available in PROC TCALIS. In this chapter, statistical analyses in the examples are done using PROC TCALIS.

Comparison of the TCALIS and SYSLIN Procedures

The SYSLIN procedure in SAS/ETS software can also fit certain kinds of path models and linear structural equation models. PROC TCALIS differs from PROC SYSLIN in that PROC TCALIS is more general in the use of latent variables in the models. Latent variables are unobserved, hypothetical variables, as distinct from manifest variables, which are the observed data. PROC SYSLIN allows at most one latent variable, the error term, in each equation. PROC TCALIS allows several latent variables to appear in an equation—in fact, all the variables in an equation can be latent as long as there are other equations that relate the latent variables to manifest variables.

Both the TCALIS and SYSLIN procedures enable you to specify a model as a system of linear equations. When there are several equations, a given variable might be a dependent variable in one equation and an independent variable in other equations. Therefore, additional terminology is needed to describe unambiguously the roles of variables in the system. Variables with values that are determined jointly and simultaneously by the system of equations are called *endogenous variables*. Variables with values that are determined outside the system—that is, in a manner separate from the process described by the system of equations—are called exogenous variables. The purpose of the system of equations is to explain the variation of each endogenous variable in terms of exogenous variables or other endogenous variables or both. Refer to Loehlin (1987, p. 4) for further discussion of endogenous and exogenous variables. In the econometric literature, error and disturbance terms are usually distinguished from exogenous variables, but in systems with more than one latent variable in an equation, the distinction is not always clear.

In PROC SYSLIN, endogenous variables are identified by the ENDOGENOUS statement. In PROC TCALIS, endogenous variables are identified by the procedure automatically after you specify the model. With different modeling languages, the identification of endogenous variables by PROC TCALIS is done by different sets of rules. For example, when you specify structural equations by using the LINEQS modeling language in PROC TCALIS, endogenous variables are assumed to be those that appear on the left-hand sides of the equations; a given variable can appear on the left-hand side of at most one equation. When you specify your model by using the PATH modeling language in PROC TCALIS, endogenous variables are those variables pointed to by arrows at least once in the path specifications.

PROC SYSLIN provides many methods of estimation, some of which are applicable only in special cases. For example, ordinary least squares estimates are suitable in certain kinds of systems but might be statistically biased and inconsistent in other kinds. PROC TCALIS provides three major methods of estimation that can be used with most models. Both the TCALIS and SYSLIN procedures can do maximum likelihood estimation, which PROC TCALIS calls ML and PROC SYSLIN calls FIML. PROC SYSLIN can be much faster than PROC TCALIS in those special cases for which it provides computationally efficient estimation methods. However, PROC TCALIS has a variety of sophisticated algorithms for maximum likelihood estimation that might be much faster than FIML in PROC SYSLIN.

PROC TCALIS can impose a wider variety of constraints on the parameters, including nonlinear constraints, than can PROC SYSLIN. For example, PROC TCALIS can constrain error variances or covariances to equal specified constants, or it can constrain two error variances to have a specified ratio.

Model Specification

PROC TCALIS provides several modeling languages to specify a model. Different modeling languages in PROC TCALIS are signified by the main model specification statement used. In the TCALIS procedure, FACTOR, LINEQS, LISMOD, MSTRUCT, PATH, and RAM are the main modeling specification statements. Each of these statements invokes a specific modeling language. Depending on your modeling philosophy and the type of the model, you can choose a modeling language that is most suitable for your application. Models specified using structural equations can be transcribed directly into the LINEQS statement. Models that are hypothesized using path diagrams can be described easily in the PATH or RAM statement. First-order confirmatory or exploratory factor models are most conveniently specified using the FACTOR and MATRIX statements. Traditional LISREL models are supported through the LISMOD and MATRIX statements. Finally, patterned covariance and mean models can be specified directly by the MSTRUCT and MATRIX statements.

For most applications, the PATH and LINEQS statements are the easiest to use. In other cases, the FACTOR, LISMOD, MSTRUCT, or RAM statement might be more suitable. See the section "Which Modeling Language?" on page 6714 in Chapter 88, "The TCALIS Procedure (Experimental)," for a more detailed discussion.

You can save a model specification in an OUTMODEL= data set, which can then be used with the INMODEL= option to specify the model in a subsequent analysis.

Estimation Methods

The TCALIS procedure provides five methods of estimation specified by the METHOD= option:

DWLS	diagonally weighted least squares
ULS	unweighted least squares
GLS	normal theory generalized least squares
ML	maximum likelihood for multivariate normal distributions
WLS	weighted least squares for arbitrary distributions

Each estimation method is based on finding parameter estimates that minimize a badness-of-fit or discrepancy function, which measures the difference between the observed sample covariance matrix and the fitted (or predicted) covariance matrix, given the model and the parameter estimates. See the section "Estimation Criteria" on page 6888 in Chapter 88, "The TCALIS Procedure (Experimental)," for formulas, or refer to Loehlin (1987, pp. 54–62) and Bollen (1989, pp. 104–123) for further discussion.

The default is METHOD=ML, which is the most popular method for applications. The option METHOD=GLS usually produces very similar results to those produced by METHOD=ML. Asymptotically, ML and GLS are the same. Both methods assume a multivariate normal distribution in the population. The WLS method with default weight matrix, which is equivalent to the asymptotically distribution free (ADF) method, yields asymptotically normal estimates regardless of the distribution in the population. When the multivariate normal assumption is in doubt, especially if the variables have high kurtosis, you should seriously consider the WLS method. When a correlation matrix is analyzed, only the WLS can produce correct standard error estimates. However, in order to use the WLS method with the expected statistical properties, sample size must be large. Several thousands might be a minimum requirement.

The ULS and DWLS methods yield reasonable estimates under less restrictive assumptions. You can apply these methods to normal or nonnormal situations, or to covariance or correlation matrices. The drawback is that the statistical qualities of the estimates seem to be unknown. For this reason, PROC TCALIS does not provide standard errors or test statistics with these two methods.

You cannot use METHOD=ML or METHOD=GLS if the observed covariance matrix is singular. You could either remove variables involved in the linear dependencies or use less restrictive estimation methods like ULS. Specifying METHOD=ML assumes that the predicted covariance matrix is nonsingular. If ML fails because of a singular predicted covariance matrix, you need to examine whether the model specification leads to the singularity. If so, modify the model specification to eliminate the problem. If not, you probably need to use other estimation methods.

You should remove outliers and try to transform variables that are skewed or heavy-tailed. This applies to all estimation methods, since all the estimation methods depend on the sample covariance matrix, and the sample covariance matrix is a poor estimator for distributions with high kurtosis (Bollen 1989, pp. 415–418; Huber 1981; Hampel et al. 1986). PROC TCALIS displays estimates of univariate and multivariate kurtosis (Bollen 1989, pp. 418–425) if you specify the KURTOSIS option in the PROC TCALIS statement.

Statistical Inference

When you specify the ML, GLS, or WLS estimation with appropriate models, PROC TCALIS can compute the following:

- a chi-square goodness-of-fit test of the specified model versus the alternative that the data are from a population with unconstrained covariance matrix (Loehlin 1987, pp. 62–64; Bollen 1989, pp. 110, 115, 263–269)
- approximate standard errors of the parameter estimates (Bollen 1989, pp. 109, 114, 286), displayed with the STDERR option
- various modification indices, requested via the MODIFICATION or MOD option, that give the approximate change in the chi-square statistic that would result from removing constraints on the parameters or constraining additional parameters to zero (Bollen 1989, pp. 293–303)

If you have two models such that one model results from imposing constraints on the parameters of the other, you can test the constrained model against the more general model by fitting both models with PROC TCALIS. If the constrained model is correct, the difference between the chi-square goodness of fit statistics for the two models has an approximate chi-square distribution with degrees of freedom equal to the difference between the degrees of freedom for the two models (Loehlin 1987, pp. 62–67; Bollen 1989, pp. 291–292).

All of the test statistics and standard errors computed under ML and GLS depend on the assumption of multivariate normality. Normality is a much more important requirement for data with random independent variables than it is for fixed independent variables. If the independent variables are random, distributions with high kurtosis tend to give liberal tests and excessively small standard errors, while low kurtosis tends to produce the opposite effects (Bollen 1989, pp. 266–267, 415–432).

All test statistics and standard errors computed by PROC TCALIS are based on asymptotic theory and should not be trusted in small samples. There are no firm guidelines on how large a sample must be for the asymptotic theory to apply with reasonable accuracy. Some simulation studies have indicated that problems are likely to occur with sample sizes less than 100 (Loehlin 1987, pp. 60–61; Bollen 1989, pp. 267–268). Extrapolating from experience with multiple regression would suggest that the sample size should be at least 5 to 20 times the number of parameters to be estimated in order to get reliable and interpretable results. The WLS method might even require that the sample size be over several thousand.

The asymptotic theory requires that the parameter estimates be in the interior of the parameter space. If you do an analysis with inequality constraints and one or more constraints are active at the solution (for example, if you constrain a variance to be nonnegative and the estimate turns out to be zero), the chi-square test and standard errors might not provide good approximations to the actual sampling distributions.

For modeling correlation structures, the only theoretically correct method is the WLS method with the default ASYCOV=CORR option. For other methods, standard error estimates for modeling correlation structures might be inaccurate even for sample sizes as large as 400. The chi-square statistic

is generally the same regardless of which matrix is analyzed, provided that the model involves no scale-dependent constraints. However, if the purpose is to obtain reasonable parameter estimates for the correlation structures only, then you might find other estimation methods useful as well.

If you fit a model to a correlation matrix and the model constrains one or more elements of the predicted matrix to equal 1.0, the degrees of freedom of the chi-square statistic must be reduced by the number of such constraints. PROC TCALIS attempts to determine which diagonal elements of the predicted correlation matrix are constrained to a constant, but it might fail to detect such constraints in complicated models, particularly when programming statements are used. If this happens, you should add parameters to the model to release the constraints on the diagonal elements.

Goodness-of-Fit Statistics

In addition to the chi-square test, there are many other statistics for assessing the goodness of fit of the predicted correlation or covariance matrix to the observed matrix.

Akaike's (1987) information criterion (AIC) and Schwarz's (1978) Bayesian criterion (SBC) are useful for comparing models with different numbers of parameters—the model with the smallest value of AIC or SBC is considered best. Based on both theoretical considerations and various simulation studies, SBC seems to work better, since AIC tends to select models with too many parameters when the sample size is large.

There are many descriptive measures of goodness of fit that are scaled to range approximately from zero to one: the goodness-of-fit index (GFI) and GFI adjusted for degrees of freedom (AGFI) (Jöreskog and Sörbom 1988), centrality (McDonald 1989), and the parsimonious fit index (James, Mulaik, and Brett 1982). Bentler and Bonett (1980) and Bollen (1986) have proposed measures for comparing the goodness of fit of one model with another in a descriptive rather than inferential sense.

The root mean squared error approximation (RMSEA) proposed by Steiger and Lind (1980) does not assume a true model being fitted to the data. It measures the discrepancy between the fitted model and the covariance matrix in the population. For samples, RMSEA and confidence intervals can be estimated. Statistical tests for determining whether the population RMSEA's fall below certain specified values are available (Browne and Cudeck 1993). In the same vein, Browne and Cudeck (1993) propose the expected cross validation index (ECVI) that measures how good a model is for predicting future sample covariances. Point estimate and confidence intervals for ECVI are also developed.

None of these measures of goodness of fit are related to the goodness of prediction of the structural equations. Goodness of fit is assessed by comparing the observed correlation or covariance matrix with the matrix computed from the model and parameter estimates. Goodness of prediction is assessed by comparing the actual values of the endogenous variables with their predicted values, usually in terms of root mean squared error or proportion of variance accounted for (R^2). For latent endogenous variables, root mean squared error and R^2 can be estimated from the fitted model.

Optimization Methods

PROC TCALIS uses a variety of nonlinear optimization algorithms for computing parameter estimates. These algorithms are very complicated and do not always work. PROC TCALIS will generally inform you when the computations fail, usually by displaying an error message about the iteration limit being exceeded. When this happens, you might be able to correct the problem simply by increasing the iteration limit (MAXITER= and MAXFUNC=). However, it is often more effective to change the optimization method (OMETHOD=) or initial values. For more details, see the section "Use of Optimization Techniques" on page 6923 in Chapter 88, "The TCALIS Procedure (Experimental)," and refer to Bollen (1989, pp. 254–256).

PROC TCALIS might sometimes converge to a local optimum rather than the global optimum. To gain some protection against local optima, you can run the analysis several times with different initial estimates. The RANDOM= option in the PROC TCALIS statement is useful for generating a variety of initial estimates.

Structural Equation Models and the LINEQS Modeling Language

Consider fitting a linear equation to two observed variables, Y and X. Simple linear regression uses the model of a particular form, labeled for purposes of discussion, as model form A.

Model Form A

$$Y = \alpha + \beta X + E_Y$$

with the following assumption:

$$\mathrm{Cov}(X, E_Y) = 0$$

where α and β are coefficients to be estimated and E_Y is an error term. If the values of X are fixed, the values of E_Y are assumed to be independent and identically distributed realizations of a normally distributed random variable with mean zero and variance $\mathrm{Var}(E_Y)$. If X is a random variable, X and E_Y are assumed to have a bivariate normal distribution with zero correlation and variances $\mathrm{Var}(X)$ and $\mathrm{Var}(E_Y)$, respectively. Under either set of assumptions, the usual formulas hold for the estimates of the coefficients and their standard errors (see Chapter 4, "Introduction to Regression Procedures").

In the REG or SYSLIN procedure, you would fit a simple linear regression model with a MODEL statement listing only the names of the manifest variables, as shown in the following statements:

```
proc reg;
   model y = x;
run;
```

You can also fit this model with PROC TCALIS, but you must explicitly specify the error terms and the parameter name for the regression coefficient (except for the intercept, which is assumed to be present in each equation). The following specification in PROC TCALIS is equivalent to the preceding regression model:

```
proc tcalis;
   lineqs
      y = beta x + ey;
run;
```

where beta is the parameter name for the regression coefficient and ey is the error term of the equation. You do not need to type an "*" between beta and x to indicate the multiplication of the variable by the coefficient.

You might use other names for the parameters and the error terms, but there are rules to follow in the LINEQS model specification. The LINEQS statement uses the convention that the names of error terms begin with the letter E or e, disturbances (errors terms for latent variables) in equations begin with D or d, and other latent variables begin with F or f for "factor." Names of variables in the input SAS data set can, of course, begin with any letter.

Optionally, you can specify the variance parameters of exogenous variables explicitly by using the STD statement as follows:

```
proc tcalis;
   lineqs
      y  = beta x + ey;
   std
      x  = vx,
      ey = vey;
run;
```

where vx and vey represent the variance of x and ey, respectively. Explicitly giving these variance parameters names would be useful when you need to set constraints on these parameters by referring to their names. In this simple case without constraints, however, naming these variance parameters is not necessary.

Although naming variance parameters for exogenous variables is optional, naming the regression coefficients when they should be free parameters is not. Consider the following statements:

```
proc tcalis;
   lineqs
      y = x + ey;
run;
```

In this specification, you leave out the regression coefficient beta from the preceding LINEQS model. Instead of being a parameter to estimate, the regression coefficient in this specification is a fixed constant 1.

In certain special situations where you need to specify a regression equation without an error term, you can explicitly set the variance of the error term to zero. For example, the following statements, in effect, will fit an equation without an error term:

```
proc tcalis;
   lineqs
      y = beta x + ey;
   std
      ey = 0;
run;
```

In this specification, the mean of the error term ey is presumably zero, as all error terms in the PROC TCALIS are set to have fixed zero means. Together with the zero variance specification for ey in the STD statement, ey is essentially a zero constant in the equation.

By default, PROC TCALIS analyzes the covariance matrix. This is exactly the opposite of PROC CALIS or PROC FACTOR, which analyzes the correlation matrix by default. Most applications that use PROC TCALIS should employ the default covariance structure analysis.

Since the analysis of covariance structures is based on modeling the covariance matrix and the covariance matrix contains no information about means, PROC TCALIS neglects the intercept parameter by default. To estimate the intercept, you can add the intercept term explicitly into the LINEQS statement. For example, the following statements fit a regression model with the estimation of the intercept alpha:

```
proc tcalis;
   lineqs
      y = alpha intercept + beta x + ey;
run;
```

In the LINEQS statement, intercept represents a "variable" with a constant value of 1; hence, the coefficient alpha is the intercept parameter. Notice that with the simultaneous analysis of mean and covariance structures, you have to provide either the raw data or the means and covariances in your input data set.

Other commonly used options in the PROC TCALIS statement include the following:

- MODIFICATION to display model modification indices
- NOBS to specify the number of observations
- NOSE to suppress the display of approximate standard errors
- RESIDUAL to display residual correlations or covariances
- TOTEFF to display total and indirect effects

For ordinary unconstrained regression models, there is no reason to use PROC TCALIS instead of PROC REG. But suppose that the observed variables Y and X are contaminated by errors (especially measurement errors), and you want to estimate the linear relationship between their true, error-free scores. The model can be written in several forms. A model of form B is as follows.

Model Form B

$$\begin{aligned} Y &= \alpha + \beta F_X + E_Y \\ X &= F_X + E_X \end{aligned}$$

with the following assumption:

$$\mathrm{Cov}(F_X, E_X) = \mathrm{Cov}(F_X, E_Y) = \mathrm{Cov}(E_X, E_Y) = 0$$

This model has two error terms, E_Y and E_X, as well as another latent variable F_X representing the true value corresponding to the manifest variable X. The true value corresponding to Y does not appear explicitly in this form of the model.

The assumption in model form B that the error terms and the latent variable F_X are jointly uncorrelated is of critical importance. This assumption must be justified on substantive grounds such as the physical properties of the measurement process. If this assumption is violated, the estimators might be severely biased and inconsistent.

You can express model form B in the LINEQS statement as follows:

```
proc tcalis;
   lineqs
      y = beta fx + ey,
      x = fx + ex;
   std
      fx = vfx,
      ey = vey,
      ex = vex;
run;
```

In this specification, you specify a variance for each of the latent variables in this model by using the STD statement. You can specify either a name, in which case the variance is considered a parameter to be estimated, or a number, in which case the variance is constrained to equal that numeric value. In this model, vfx, vey, and vex are variance parameters to estimate.

The variances of endogenous variables are predicted from the model and hence are not parameters. Covariances involving latent exogenous variables are assumed to be zero by default.

Fuller (1987, pp. 18–19) analyzes a data set from Voss (1969) involving corn yields (Y) and available soil nitrogen (X) for which there is a prior estimate of the measurement error for soil nitrogen $\mathrm{Var}(E_X)$ of 57. You can fit model form B with this constraint to the data by using the following statements:

```
data corn(type=cov);
   input _type_ $ _name_ $ y x;
   datalines;
n    . 11       11
mean . 97.4545  70.6364
cov  y 87.6727  .
cov  x 104.8818 304.8545
;
```

```
proc tcalis data=corn;
   lineqs y = beta fx + ey,
          x = fx + ex;
   std ex = 57,
       fx = vfx,
       ey = vey;
run;
```

In the STD statement, the variance of ex is given as the constant value 57. PROC TCALIS produces the estimates shown in Figure 17.1.

Figure 17.1 Measurement Error Model for Corn Data

```
                          Linear Equations

                y       =    0.4232*fx   +  1.0000 ey
                Std Err      0.1658 beta
                t Value      2.5520
                x       =    1.0000 fx   +  1.0000 ex

             Estimates for Variances of Exogenous Variables

Variable                                                  Standard
Type          Variable    Parameter      Estimate          Error       t Value

Error         ex                          57.00000
Latent        fx          vfx           247.85450      136.33508       1.81798
Error         ey          vey            43.29105       23.92488       1.80946
```

PROC TCALIS also displays information about the initial estimates that can be useful if there are optimization problems. If there are no optimization problems, the initial estimates are usually not of interest; they are not reproduced in the examples in this chapter.

You can write an equivalent model (labeled here as model form C) by using a latent variable F_Y to represent the true value corresponding to Y.

Model Form C

$$\begin{aligned} Y &= F_Y + E_Y \\ X &= F_X + E_X \\ F_Y &= \alpha + \beta F_X \end{aligned}$$

with the following assumption:

$$\mathrm{Cov}(F_X, E_X) = \mathrm{Cov}(F_X, E_X) = \mathrm{Cov}(E_X, E_Y) = 0$$

The first two equations express the observed variables in terms of a true score plus error; these two equations are called the measurement model. The third equation, expressing the relationship

between the latent true-score variables, is called the structural or causal model. The decomposition of a model into a measurement model and a structural model (Keesling 1972; Wiley 1973; Jöreskog 1973) has been popularized by the program LISREL (Jöreskog and Sörbom 1988). The statements for fitting this model are shown in the following:

```
proc tcalis;
   lineqs
      y   = fy + ey,
      x   = fx + ex,
      fy  = beta fx + dfy;
   std
      fx  = vfx,
      ey  = vey,
      ex  = vex,
      dfy = 0;
run;
```

As a syntactic requirement, each equation in the LINEQS statement should have an error term. As discussed before, because dfy has a fixed variance 0 in the STD statement, in effect, there is no error term in the structural equation with the outcome variable fy.

You do not need to include the variance of F_Y in the STD statement because the variance of F_Y is determined by the structural model in terms of the variance of F_X—that is, $\mathrm{Var}(F_Y)=\beta^2\ \mathrm{Var}(F_X)$.

Correlations or covariances involving endogenous variables are derived from the model. For example, the structural equation in model form C implies that F_Y and F_X are correlated unless β is zero. In all of the models discussed so far, the latent exogenous variables are assumed to be jointly uncorrelated. For example, in model form C, E_Y, E_X, and F_X are assumed to be uncorrelated. If you want to specify a model in which E_Y and E_X, say, are correlated, you can use the COV statement to specify the numeric value of the covariance $\mathrm{Cov}(E_Y, E_X)$ between E_Y and E_X, or you can specify a name to make the covariance a parameter to be estimated. For example:

```
proc tcalis;
   lineqs
      y   = fy + ey,
      x   = fx + ex,
      fy  = beta fx + dfy;
   std
      fx  = vfx,
      ey  = vey,
      ex  = vex,
      dfy = 0;
   cov
      ey ex = ceyex;
run;
```

This COV statement specifies that the covariance between ey and ex is a parameter named ceyex. All covariances that are not listed in the COV statement and that are not determined by the model are assumed to be zero. If the model contained two or more manifest exogenous variables, their covariances would be set as free parameters by default.

Identification of Models

Unfortunately, if you try to fit models of form B or form C without additional constraints, you cannot obtain unique estimates of the parameters. These models have four parameters (one coefficient and three variances). The covariance matrix of the observed variables Y and X has only three elements that are free to vary, since Cov(Y,X)=Cov(X,Y). The covariance structure can, therefore, be expressed as three equations in four unknown parameters. Since there are fewer equations than unknowns, there are many different sets of values for the parameters that provide a solution for the equations. Such a model is said to be underidentified.

If the number of parameters equals the number of free elements in the covariance matrix, then there might exist a unique set of parameter estimates that exactly reproduce the observed covariance matrix. In this case, the model is said to be just identified or saturated.

If the number of parameters is less than the number of free elements in the covariance matrix, there might exist no set of parameter estimates that reproduces the observed covariance matrix. In this case, the model is said to be overidentified. Various statistical criteria, such as maximum likelihood, can be used to choose parameter estimates that approximately reproduce the observed covariance matrix. If you use ML, GLS, or WLS estimation, PROC TCALIS can perform a statistical test of the goodness of fit of the model under the certain statistical assumptions.

If the model is just identified or overidentified, it is said to be identified. If you use ML, GLS, or WLS estimation for an identified model, PROC TCALIS can compute approximate standard errors for the parameter estimates. For underidentified models, PROC TCALIS obtains approximate standard errors by imposing additional constraints resulting from the use of a generalized inverse of the Hessian matrix.

You cannot guarantee that a model is identified simply by counting the parameters. For example, for any latent variable, you must specify a numeric value for the variance, or for some covariance involving the variable, or for a coefficient of the variable in at least one equation. Otherwise, the scale of the latent variable is indeterminate, and the model will be underidentified regardless of the number of parameters and the size of the covariance matrix. As another example, an exploratory factor analysis with two or more common factors is always underidentified because you can rotate the common factors without affecting the fit of the model.

PROC TCALIS can usually detect an underidentified model by computing the approximate covariance matrix of the parameter estimates and checking whether any estimate is linearly related to other estimates (Bollen 1989, pp. 248–250), in which case PROC TCALIS displays equations showing the linear relationships among the estimates. Another way to obtain empirical evidence regarding the identification of a model is to run the analysis several times with different initial estimates to see if the same final estimates are obtained.

Bollen (1989) provides detailed discussions of conditions for identification in a variety of models.

The following example is inspired by Fuller (1987, pp. 40–41). The hypothetical data are counts of two types of cells, cells forming rosettes and nucleated cells, in spleen samples. It is reasonable to assume that counts have a Poisson distribution; hence, the square roots of the counts should have a constant error variance of 0.25.

You can use PROC TCALIS to fit a model of form C to the square roots of the counts without constraints on the parameters, as displayed in the following statements:

```
data spleen;
   input rosette nucleate;
   sqrtrose=sqrt(rosette);
   sqrtnucl=sqrt(nucleate);
   datalines;
4 62
5 87
5 117
6 142
8 212
9 120
12 254
13 179
15 125
19 182
28 301
51 357
;
proc tcalis data=spleen;
   lineqs sqrtrose = factrose + err_rose,
          sqrtnucl = factnucl + err_nucl,
          factrose = beta factnucl + disturb;
   std err_rose = v_rose,
       err_nucl = v_nucl,
       factnucl = v_factnu,
       disturb  = 0;
run;
```

This model is underidentified. PROC TCALIS displays the following warning:

```
WARNING: Estimation problem not identified: More parameters to
         estimate ( 4 ) than the total number of mean and
         covariance elements ( 3 ).
```

Then it diagnoses the indeterminacy as follows:

```
NOTE: Covariance matrix for the estimates is not full rank.
NOTE: The variance of some parameter estimates is zero or
      some parameter estimates are linearly related to other
      parameter estimates as shown in the following equations:

v_rose     =       0.207718   +       0.108978   *   beta
                              +       0.916873   *   v_nucl
                              -       0.916873   *   v_factnu
```

The constraint that the error variances equal 0.25 can be imposed by modifying the STD statement:

```
proc tcalis data=spleen;
   lineqs sqrtrose = factrose + err_rose,
          sqrtnucl = factnucl + err_nucl,
          factrose = beta factnucl + disturb;
   std err_rose = .25,
       err_nucl = .25,
       factnucl = v_factnu,
       disturb  = 0;
run;
```

This model is overidentified and the chi-square goodness-of-fit test yields a p-value of 0.0219, as displayed in Figure 17.2.

Figure 17.2 Spleen Data: Fit Statistics for Overidentified Model

	James et al. Parsimonious NFI	0.6043

PROC TCALIS arranges the fit statistics according to their types: absolute, parsimony, and incremental. After displaying some important modeling information in the fit summary table, the absolute fit indices are printed. Absolute indices are those model fit statistics that assess the model fit without comparing to a "null" model. The most typical fit index of the this type is the chi-square fit statistic. Nonsignificance of the chi-square indicates good model fit. Other popular absolute fit indices include the root mean square residual (RMSR), the standardized RMSR (SRMSR), and the goodness-of-fit index (GFI). By convention, a good model should have an SRMSR smaller than 0.05 and a GFI larger than 0.90.

Parsimony indices are those fit indices that assess the model fit without comparing with a null model, but with the number of parameters in the model taking into account. These fit indices favor precise models. If two models have the same chi-square value for the same data set but have different number of parameters in the models, the model with fewer parameters will have a better parsimony fit statistic. The most popular parsimony index displayed in the table is perhaps the root mean squared error of approximation, or RMSEA (Steiger and Lind 1980). An RMSEA below 0.05 is recommended for a good model fit (Browne and Cudeck 1993). Another popular index in this category is the adjusted GFI (AGFI). By convention, an AGFI above 0.90 is required for a good model fit.

Finally, the incremental fit indices are those indices that measure model fit by comparing with a null model. A null model is usually the independence model that assumes the measured variables are all uncorrelated. The most popular incremental index is Bentler's CFI. By convention, a CFI above 0.90 is required for a good model fit.

After the model fit summary, the parameter estimates are displayed in Figure 17.3.

Figure 17.3 Spleen Data: Parameter Estimates for Overidentified Model

Linear Equations

```
sqrtrose =    1.0000 factrose +  1.0000 err_rose
sqrtnucl =    1.0000 factnucl +  1.0000 err_nucl
factrose =    0.4034*factnucl +  1.0000 disturb
Std Err       0.0508 beta
t Value       7.9439
```

Estimates for Variances of Exogenous Variables

Variable Type	Variable	Parameter	Estimate	Standard Error	t Value
Error	err_rose		0.25000		
	err_nucl		0.25000		
Latent	factnucl	v_factnu	10.45846	4.56608	2.29047
Disturbance	disturb		0		

Overall, the model does not provide a good fit. The sample size is so small that the p-value of the chi-square test should not be taken to be accurate, but to get a small p-value with such a small sample indicates it is possible that the model is seriously deficient. The deficiency could be due to any of the following:

- The error variances are not both equal to 0.25.
- The error terms are correlated with each other or with the true scores.
- The observations are not independent.
- There is a nonzero disturbance in the linear relation between factrose and factnucl.
- The relation between factrose and factnucl is not linear.
- The actual distributions are not adequately approximated by the multivariate normal distribution.

A simple and plausible modification to the model is to make the "disturbance term" disturb a real random variable with nonzero variance in the structural model. This can be done by giving the variance of disturb a parameter name in the STD statement, as shown in the following statements:

```
proc tcalis data=spleen;
   lineqs sqrtrose = factrose + err_rose,
          sqrtnucl = factnucl + err_nucl,
          factrose = beta factnucl + disturb;
   std err_rose = .25,
       err_nucl = .25,
       factnucl = v_factnu,
       disturb  = v_dist;
run;
```

In the STD statement, v_dist is now specified as a free variance parameter to be estimated. The parameter estimates are produced in Figure 17.4.

Figure 17.4 Spleen Data: Parameter Estimated for Just Identified Model

```
                          Linear Equations

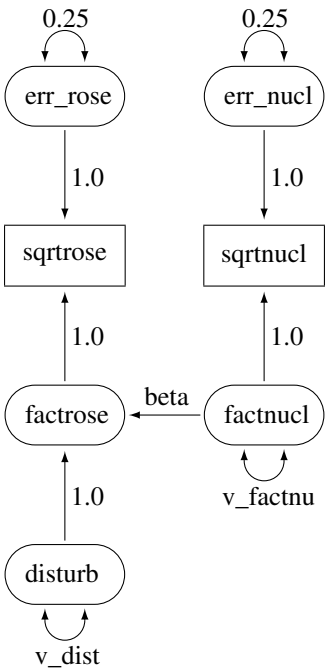
              sqrtrose =    1.0000 factrose +  1.0000 err_rose
              sqrtnucl =    1.0000 factnucl +  1.0000 err_nucl
              factrose =    0.3907*factnucl +  1.0000 disturb
              Std Err       0.0771 beta
              t Value       5.0692

               Estimates for Variances of Exogenous Variables

Variable                                                  Standard
Type          Variable    Parameter      Estimate          Error       t Value

Error         err_rose                    0.25000
              err_nucl                    0.25000
Latent        factnucl    v_factnu       10.50458        4.58577       2.29069
Disturbance   disturb     v_dist          0.38153        0.28556       1.33607
```

As shown in Figure 17.4, the variance of disturb is estimated at 0.382. Due to the inclusion of this new parameter, estimates for beta and v_factnu also shift a little bit from the previous analysis.



Because this model is just identified or saturated, there are no degrees of freedom for the chi-square goodness-of-fit test.

Path Diagrams and the PATH Modeling Language

Complicated models are often easier to understand when they are expressed as path diagrams. One advantage of path diagrams over equations is that variances and covariances can be shown directly in the path diagram. Loehlin (1987) provides a detailed discussion of path diagrams. Another advantage is that the path diagram can be translated easily into the PATH modeling language supported by PROC TCALIS.

It is customary to write the names of manifest variables in rectangles and the names of latent variables in ovals. The coefficients in each equation are indicated by drawing arrows from the independent variables to the dependent variable. Covariances between exogenous variables are drawn as two-headed arrows. The variance of an exogenous variable can be displayed as a two-headed arrow with both heads pointing to the exogenous variable, since the variance of a variable is the covariance of the variable with itself. Figure 17.5 displays a path diagram for the spleen data, explicitly showing all latent variables (including error terms) and variances of exogenous variables.

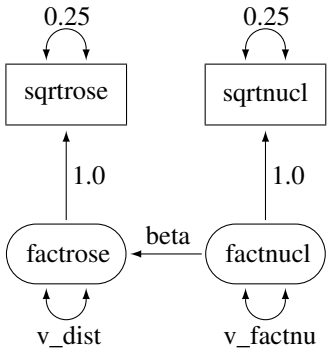


Figure 17.5 Path Diagram: Spleen

There is an easier way to draw the path diagram based on McArdle's reticular action model (RAM) (McArdle and McDonald 1984). McArdle uses the convention that a two-headed arrow that points to an endogenous variable actually refers to the error or disturbance term associated with that variable. A two-headed arrow with both heads pointing to the same endogenous variable represents the

error or disturbance variance for the equation that determines the endogenous variable; there is no need to draw a separate oval for the error or disturbance term. Similarly, a two-headed arrow connecting two endogenous variables represents the covariance between the error of disturbance terms associated with the endogenous variables. The RAM conventions enable the previous path diagram to be simplified, as shown in Figure 17.6.

Figure 17.6 Simplified Path Diagram: Spleen

The PATH modeling language in PROC TCALIS provides a simple way to transcribe a path diagram based on the reticular action model. In the PATH modeling languages, there are three statements to capture the specifications in path diagrams:

- The PATH statement enables you to specify each of the one-headed arrows (paths). The parameters specified in the PATH statement are the path (regression) coefficients.
- The PVAR statement enables you to specify each of the double-headed arrows with both heads pointing to the ***same*** variable. In general, you specify *partial* (or total) variance parameters in the PVAR statement. If the variable being pointed at is *exogenous*, a (total) variance parameter is specified. If the variable being pointed at is *endogenous*, a partial or an error variance parameter is specified.
- The PCOV statement enables you to specify each of the double-headed arrows with its heads pointing to ***different*** variables. In general, you specify (*partial*) covariance parameters in the PCOV statement. The two most common cases are as follows: (1) If the heads of a double-headed arrow are connecting two *exogenous* variables, a covariance parameter between the two variables is specified; and (2) If the heads of a double-headed arrow are connecting two *endogenous* variables, an error covariance parameter for the two variables is specified. This error covariance is also a partial covariance between the endogenous variables.

For example, the path diagram for the spleen data in Figure 17.6 can be specified with the PATH modeling language as follows:

```
proc tcalis data=spleen outmodel=splmod1;
   path
      sqrtrose <- factrose   1.0,
      sqrtnucl <- factnucl   1.0,
      factrose <- factnucl   beta;
   pvar
      sqrtrose = 0.25,      /* error variance for sqrtrose */
      sqrtnucl = 0.25,      /* error variance for sqrtnucl */
      factrose = v_dist,    /* disturbance variance for factrose */
      factnucl = v_factnu;  /* variance of factnucl */
run;
```

One notable item in the specification is that each of the single-headed or double-headed arrows in the path diagram is transcribed into an entry in either the PATH or PVAR statement:

- **PATH** statement:
  The paths "sqrtrose <– factrose" and "sqrtnucl <– factnucl" in the PATH statement are followed by the constant 1, indicating fixed path coefficients. The path "factrose <– factnucl" is followed by a parameter named beta, indicating a free path coefficient to estimate in the model.

- **PVAR** statement:
  A fixed value 0.25 is specified after the equal signs of sqrtrose and sqrtnucl in the PVAR statement. Because sqrtrose and sqrtnucl are endogenous in the model, you are fixing the error variances of sqrtrose and sqrtnucl to 0.25 in the specification.
  In the last two entries of the PVAR statement, you are putting parameter names after the equal signs. Because factrose and factnucl are exogenous in the model, v_dist and v_factnu are variance parameters of factrose and factnucl, respectively.

Because there are no double-headed arrows each pointing to different variables in the path diagram, the PCOV statement is not needed in the model specification. The resulting output of the PATH model is displayed in Figure 17.7.

Figure 17.7 Spleen Data: RAM Model

PATH List

Path			Parameter	Estimate	Standard Error	t Value
sqrtrose	<-	factrose		1.00000		
sqrtnucl	<-	factnucl		1.00000		
factrose	<-	factnucl	beta	0.39074	0.07708	5.06920

Variance Parameters

Variance Type	Variable	Parameter	Estimate	Standard Error	t Value
Error	sqrtrose		0.25000		
	sqrtnucl		0.25000		
	factrose	v_dist	0.38153	0.28556	1.33607
Exogenous	factnucl	v_factnu	10.50458	4.58577	2.29069

In the PROC TCALIS statement, the OUTMODEL=SPLMOD1 option is used. This will save the model specification, together with final estimates in a SAS data set called SPLMOD1. This special type of SAS data set is called "CALISMDL." The following statements are used to display the contents of this OUTMODEL= data set:

```
proc print data=splmod1;
run;
```

As displayed in Figure 17.8, the first record saves the model type, which is the PATH model specification in this case. The next seven records save the information about the PATH model: 3 paths and 4 partial variances specifications.

Figure 17.8 Spleen Data: OUTMODEL= Data Set with Final Parameter Estimates

3	LEFT		sqrtnucl	factnucl	1.0000	.
4	LEFT	beta	factrose	factnucl	0.3907	0.07708
5	PVAR		sqrtrose		0.2500	.
6	PVAR		sqrtnucl		0.2500	.
7	PVAR	v_dist	factrose		0.3815	0.28556
8	PVAR	v_factnu	factnucl		10.5046	4.58577

In each record, the variables involved, the parameter name, the final estimate, and the standard error estimate are stored. For records with fixed parameters, the parameter names entries are blanks and the standard error estimates are indicated by missing values. This data set can be used as input to another run of the TCALIS procedure with the INMODEL= option in the PROC TCALIS statement. For example, if the iteration limit is exceeded, you can use the CALISMODEL data set to start a new run that begins with the final estimates from the last run. Or you can change the data set to add or remove constraints or modify the model in various other ways. The easiest way to change a CALISMDL data set is to use the FSEDIT procedure, but you can also use a DATA step. For example, you could set the variance of the disturbance term to zero, effectively removing the disturbance from the equation, by removing the parameter name v_dist in the _NAME_ variable and setting the value of the estimate to zero in the _ESTIM_ variable:

```
data splmod2(type=calismdl);
   set splmod1;
   if _name_='v_dist' then
      do;
         _name_=' ';
         _estim_=0;
      end;
run;
```

Hence, due to the fixed zero error variance for factrose, a model with perfect prediction of factrose from factnucl is specified in the new CALISMDL data set SPLMOD2. This data set serves as the INMODEL= data set in the following statements for another PROC TCALIS run:

```
proc tcalis data=spleen inmodel=splmod2;
run;
```

The main estimation results are displayed in Figure 17.9.

Figure 17.9 Spleen Data: PATH Model Estimates with INMODEL= Data Set

PATH List

Path			Parameter	Estimate	Standard Error	t Value
sqrtrose	<-	factrose		1.00000		
sqrtnucl	<-	factnucl		1.00000		
factrose	<-	factnucl	beta	0.40340	0.05078	7.94391

Variance Parameters

Variance Type	Variable	Parameter	Estimate	Standard Error	t Value
Error	sqrtrose		0.25000		
	sqrtnucl		0.25000		
	factrose		0		
Exogenous	factnucl	v_factnu	10.45846	4.56608	2.29047

As can be seen in Figure 17.9, error variance for factrose is a fixed zero in the final results. Because of this modification in the current model specified in the SPLMOD2 data set, the estimates of beta and v_factnu are different from those of the previous model results, which are stored in the SPLMOD1 data set.

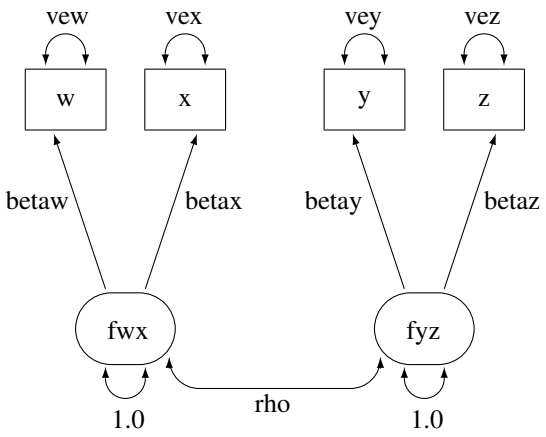
Some Measurement Models

Psychometric test theory involves many kinds of models relating scores on psychological and educational tests to latent variables representing intelligence or various underlying abilities. The following example uses data on four vocabulary tests from Lord (1957). Tests W and X have 15 items each and are administered with very liberal time limits. Tests Y and Z have 75 items and are administered under time pressure. The covariance matrix is read by the following DATA step:

```
data lord(type=cov);
   input _type_ $ _name_ $ w x y z;
   datalines;
n    . 649       .       .       .
cov w 86.3979    .       .       .
cov x 57.7751 86.2632    .       .
cov y 56.8651 59.3177 97.2850    .
cov z 58.8986 59.6683 73.8201 97.8192
;
```

The psychometric model of interest states that W and X are determined by a single common factor F_{WX}, and Y and Z are determined by a single common factor F_{YZ}. The two common factors are expected to have a positive correlation, and it is desired to estimate this correlation. It is convenient to assume that the common factors have unit variance, so their correlation will be equal to their covariance. The error terms for all the manifest variables are assumed to be uncorrelated with each other and with the common factors. The model (labeled here as model form D) is as follows.

Model Form D



$$
\begin{aligned}
W &= \beta_W F_{WX} + E_W \\
X &= \beta_X F_{WX} + E_X \\
Y &= \beta_Y F_{YZ} + E_Y \\
Z &= \beta_Z F_{YZ} + E_Z
\end{aligned}
$$

with the following assumptions:

$$
\begin{aligned}
\text{Var}(F_{WX}) &= \text{Var}(F_{YZ}) = 1 \\
\text{Cov}(F_{WX}, F_{YZ}) &= \rho \\
\text{Cov}(E_W, E_X) &= \text{Cov}(E_W, E_Y) = \text{Cov}(E_W, E_Z) = \text{Cov}(E_X, E_Y) \\
&= \text{Cov}(E_X, E_Z) = \text{Cov}(E_Y, E_Z) = \text{Cov}(E_W, F_{WX}) \\
&= \text{Cov}(E_W, F_{YZ}) = \text{Cov}(E_X, F_{WX}) = \text{Cov}(E_X, F_{YZ}) \\
&= \text{Cov}(E_Y, F_{WX}) = \text{Cov}(E_Y, F_{YZ}) = \text{Cov}(E_Z, F_{WX}) \\
&= \text{Cov}(E_Z, F_{YZ}) = 0
\end{aligned}
$$

The corresponding path diagram is shown in Figure 17.10.

Figure 17.10 Path Diagram: Lord

With the following rules, the conversion from the path diagram to the PATH model specification is very straightforward:

- Each single-headed arrow in the path diagram is specified in the PATH statement.
- Each double-headed arrow that points to a single variable is specified in the PVAR statement.
- Each double-headed arrow that points to two distinct variables is specified in the PCOV statement.

Hence, this path diagram can be converted easily to a PATH model as follows:

```
title 'H4: Unconstrained';
proc tcalis data=lord outmodel=model4;
   path
      w <- fwx    betaw,
      x <- fwx    betax,
      y <- fyz    betay,
      z <- fyz    betaz;
   pvar
      fwx fyz = 2 * 1.0,
      w x y z = vew vex vey vez;
   pcov
      fwx fyz = rho;
run;
```

The major results are displayed in Figure 17.11 and Figure 17.12.

Exogenous	fwx		1.00000		
	fyz		1.00000		
Error	w	vew	30.13796	2.47037	12.19979
	x	vex	26.93217	2.43065	11.08021
	y	vey	24.87396	2.35986	10.54044
	z	vez	22.56264	2.35028	9.60000

Covariances Among Exogenous Variables

Var1	Var2	Parameter	Estimate	Standard Error	t Value
fwx	fyz	rho	0.89855	0.01865	48.17998

It is convenient to create the OUTMODEL= data set called model4 for use in fitting other models with additional constraints. The same analysis can be performed with the LINEQS statement, as specified in the following:

```
title 'H4: Unconstrained; LINEQS Specification';
proc tcalis data=lord;
   lineqs w = betaw fwx + ew,
          x = betax fwx + ex,
          y = betay fyz + ey,
          z = betaz fyz + ez;
   std fwx fyz = 2 * 1.,
       ew ex ey ez = vew vex vey vez;
   cov fwx fyz = rho;
run;
```

Unlike the PATH model specification, in the LINEQS specification you need to specify the error terms explicitly in the LINEQS statement. In the STD statement, you would need to specify the variance parameters for the exogenous variables, including both of the factors and the error terms. However, using the PATH model specification, no explicit names for error or disturbance terms are needed. As a result, the exogenous variance and error variance parameters are both specified in the PVAR statement. This treatment generalizes to the following useful rule about the PATH model specification:

- Each variable in the PATH model specification or path diagram should have a variance or partial variance parameter specified in the PVAR statement—as either an exogenous variance or a partial variance due to error.

The main results from the LINEQS model specification are displayed in Figure 17.13.

Figure 17.13 Lord Data: Using LINEQS Statement for RAM Model, Hypothesis H4

	ex	vex	26.93217	2.43065	11.08021
	ey	vey	24.87396	2.35986	10.54044
	ez	vez	22.56264	2.35028	9.60000

Covariances Among Exogenous Variables

Var1	Var2	Parameter	Estimate	Standard Error	t Value
fwx	fyz	rho	0.89855	0.01865	48.17998

Aside from the output format, all estimates in the LINEQS model results in Figure 17.13 match those of the PATH model results in Figure 17.12. In some situations, the PATH and LINEQS statements might yield slightly different results due to the inexactness of the numerical optimization; the discrepancies can be reduced by specifying a more stringent convergence criterion such as GCONV=1E–4 or GCONV=1E–6.

Subsequent analyses are illustrated with the PATH statement rather than the LINEQS statement because it is easier to translate the path diagram to the PATH model specification.

In an analysis of these data by Jöreskog and Sörbom (1979, pp. 54–56; Loehlin 1987, pp. 84–87), four hypotheses are considered:

H_1: $\rho = 1$,
$\beta_W = \beta_X$, $\mathrm{Var}(E_W) = \mathrm{Var}(E_X) (or \mathrm{vew} = \mathrm{vex})$,
$\beta_Y = \beta_Z$, $\mathrm{Var}(E_Y) = \mathrm{Var}(E_Z) (or \mathrm{vey} = \mathrm{vez})$

H_2: same as H_1: except ρ is unconstrained

H_3: $\rho = 1$

H_4: model form D without any additional constraints

The hypothesis H_3 says that there is really just one common factor instead of two; in the terminology of test theory, W, X, Y, and Z are said to be congeneric. The hypothesis H_2 says that W and X have the same true scores and have equal error variance; such tests are said to be parallel. The hypothesis H_2 also requires Y and Z to be parallel. The hypothesis H_1 says that W and X are parallel tests, Y and Z are parallel tests, and all four tests are congeneric.

It is most convenient to fit the models in the opposite order from that in which they are numbered. The previous analysis fit the model for H_4 and created an OUTMODEL= data set called model4. The hypothesis H_3 can be fitted directly or by modifying the model4 data set. Since H_3 differs from H_4 only in that ρ is constrained to equal 1, the model4 data set can be modified by finding the observation for which _NAME_='rho' and changing the variable _NAME_ to a blank value (meaning that the observation represents a constant rather than a parameter to be fitted) and by setting the variable _ESTIM_ to the value 1. The following statements create a new model stored in the model3 data set that is modified from the model4 data set:

```
data model3(type=calismdl);
   set model4;
   if _name_='rho' then
      do;
         _name_=' ';
         _estim_=1;
      end;
run;
```

In other words, the model information stored in data set model3 is specified exactly as hypothesis H_3 requires. This data set is then read as an INMODEL= data set for the following PROC TCALIS run:

```
title 'H3: W, X, Y, and Z are congeneric';
proc tcalis data=lord inmodel=model3;
run;
```

Another way to specify the model under hypothesis H_3 is to specify the entire PATH model anew, such as in the following statements:

```
title 'H3: W, X, Y, and Z are congeneric';
proc tcalis data=lord;
   path  w <- f  betaw,
         x <- f  betax,
         y <- f  betay,
         z <- f  betaz;
   pvar
      f = 1,
      w x y z = vew vex vey vez;
run;
```

This would produce essentially the same results as those of the analysis based on the model stored in the data set model3. The main results from the analysis with the INMODEL=MODEL3 data set are displayed in Figure 17.14.

Figure 17.14 Lord Data: Major Results for Hypothesis H3

Covariances Among Exogenous Variables

Var1	Var2	Estimate	Standard Error	t Value
fwx	fyz	1.00000		

The hypothesis H_2 requires that several pairs of parameters be constrained to have equal estimates. With PROC TCALIS, you can impose this constraint by giving the same name to parameters that are constrained to be equal. This can be done directly in the PATH and PVAR statements or by using the DATA step to change the values in the model4 data set.

First, you can specify the model directly under the hypothesis H_2; the following PATH model is specified:

```
title 'H2: W and X parallel, Y and Z parallel';
proc tcalis data=lord;
   path
      w <- fwx   betawx,
      x <- fwx   betawx,
      y <- fyz   betayz,
      z <- fyz   betayz;
   pvar
      fwx fyz = 2 * 1.0,
      w x y z = vewx vewx veyz veyz;
   pcov
      fwx fyz = rho;
run;
```

Alternatively, if you use the DATA step to modify from the model4 data set, you would specify a new data set called model2 for storing the model information under the hypothesis H_2, as shown in the following statements:

```
data model2(type=calismdl);
   set model4;
   if _name_='betaw' then _name_='betawx';
   if _name_='betax' then _name_='betawx';
   if _name_='betay' then _name_='betayz';
   if _name_='betaz' then _name_='betayz';
   if _name_='vew' then _name_='vewx';
   if _name_='vex' then _name_='vewx';
   if _name_='vey' then _name_='veyz';
   if _name_='vez' then _name_='veyz';
run;
```

Then you would use model2 as the INMODEL= data set in the following PROC TCALIS run:

```
title 'H2: W and X parallel, Y and Z parallel';
proc tcalis data=lord inmodel=model2;
run;
```

The main results from either of these analyses are displayed in Figure 17.15.

Var1	Var2	Parameter	Estimate	Standard Error	t Value
fwx	fyz	rho	0.89864	0.01865	48.18011

The hypothesis H_1 requires one more constraint in addition to those in H_2. Again, there are two ways to do this. First, a direct model specification is shown in the following statements:

```
title 'H1: W and X parallel, Y and Z parallel, all congeneric';
proc tcalis data=lord;
   path
      w <- f   betawx,
      x <- f   betawx,
      y <- f   betayz,
      z <- f   betayz;
   pvar
      f       = 1.0,
      w x y z = vewx vewx veyz veyz;
run;
```

Alternatively, you can modify the model2 data set to create a new data set model2 that stores the model information required by the hypothesis H_1, as shown in the following statements:

```
data model1(type=calismdl);
   set model2;
   if _name_='rho' then
      do;
         _name_=' ';
         _estim_=1;
      end;
run;
```

You can then pass the model information stored in model1 as an INMODEL= data set in the following PROC TCALIS run:

```
title 'H1: W and X parallel, Y and Z parallel, all congeneric';
proc tcalis data=lord inmodel=model1;
run;
```

The main results from either of these analyses are displayed in Figure 17.16.

	z	veyz	26.28501	1.39954	18.78118

Covariances Among Exogenous Variables

Var1	Var2	Estimate	Standard Error	t Value
fwx	fyz	1.00000		

The goodness-of-fit tests for the four hypotheses are summarized in the following table.

Hypothesis	Number of Parameters	χ^2	Degrees of Freedom	*p*-value	$\hat{\rho}$
H_1	4	37.33	6	0.0000	1.0
H_2	5	1.93	5	0.8583	0.8986
H_3	8	36.21	2	0.0000	1.0
H_4	9	0.70	1	0.4018	0.8986

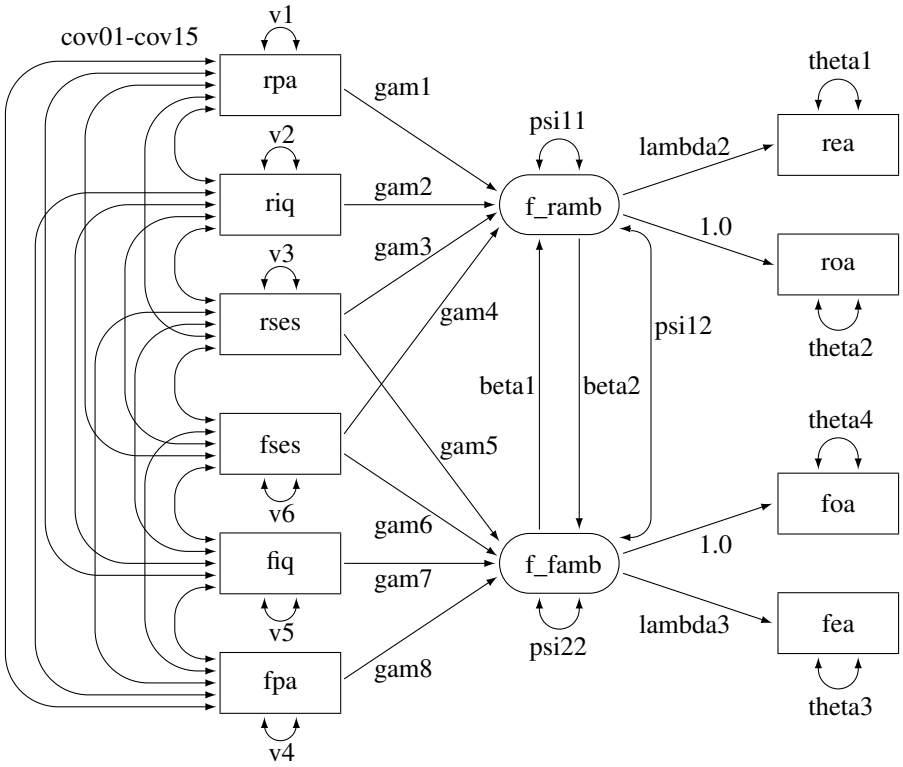
The hypotheses H_1 and H_3, which posit $\rho = 1$, can be rejected. Hypotheses H_2 and H_4 seem to be consistent with the available data. Since H_2 is obtained by adding four constraints to H_4, you can test H_2 versus H_4 by computing the differences of the chi-square statistics and their degrees of freedom, yielding a chi-square of 1.23 with 4 degrees of freedom, which is obviously not significant. So hypothesis H_2 is consistent with the available data.

The estimates of ρ for H_2 and H_4 are almost identical, about 0.90, indicating that the speeded and unspeeded tests are measuring almost the same latent variable, even though the hypotheses that stated they measured exactly the same latent variable are rejected.

A Combined Measurement-Structural Model with Reciprocal Influence and Correlated Residuals

To illustrate a more complex model, this example uses some well-known data from Haller and Butterworth (1960). Various models and analyses of these data are given by Duncan, Haller, and Portes (1968), Jöreskog and Sörbom (1988), and Loehlin (1987).

The study is concerned with the career aspirations of high school students and how these aspirations are affected by close friends. The data are collected from 442 seventeen-year-old boys in Michigan. There are 329 boys in the sample who named another boy in the sample as a best friend. The observations to be analyzed consist of the data from these 329 boys paired with the data from their best friends.



The method of data collection introduces two statistical problems. First, restricting the analysis to boys whose best friends are in the original sample causes the reduced sample to be biased. Second, since the data from a given boy might appear in two or more observations, the observations are not independent. Therefore, any statistical conclusions should be considered tentative. It is difficult to accurately assess the effects of the dependence of the observations on the analysis, but it could be argued on intuitive grounds that since each observation has data from two boys and since it seems likely that many of the boys will appear in the data set at least twice, the effective sample size might be as small as half of the reported 329 observations.

The correlation matrix, taken from Jöreskog and Sörbom (1988), is shown in the following DATA step:

```
title 'Peer Influences on Aspiration: Haller & Butterworth (1960)';
data aspire(type=corr);
   _type_='corr';

;
```

The model analyzed by Jöreskog and Sörbom (1988) is displayed in the path diagram in Figure 17.17.

Figure 17.17 Path Diagram: Career Aspiration – Jöreskog and Sörbom (1988)

Two latent variables, f_ramb and f_famb, represent the respondent's level of ambition and his best friend's level of ambition, respectively. The model states that the respondent's ambition is determined by his intelligence (riq) and socioeconomic status (rses), his perception of his parents' aspiration for him (rpa), and his friend's socioeconomic status (fses) and ambition (f_famb). It is assumed that his friend's intelligence (fiq) and parental aspiration (fpa) affect the respondent's ambition only indirectly through the friend's ambition (f_famb). Ambition is indexed by the manifest variables of occupational (roa) and educational aspiration (rea), which are assumed to have uncorrelated residuals. The path coefficient from ambition to occupational aspiration is set to 1.0 to determine the scale of the ambition latent variable.

This model can be analyzed with PROC TCALIS by using the PATH modeling language, as shown in the following statements:

```
proc tcalis corr data=aspire nobs=329;
   path
      /* measurement model for aspiration */
      rea <-  f_ramb    lambda2,
      roa <-  f_ramb    1.,
      foa <-  f_famb    1.,
      fea <-  f_famb    lambda3,
      /* structural model of influences */
      f_ramb <- rpa     gam1,
      f_ramb <- riq     gam2,
      f_ramb <- rses    gam3,
      f_ramb <- fses    gam4,
      f_famb <- rses    gam5,
      f_famb <- fses    gam6,
      f_famb <- fiq     gam7,
      f_famb <- fpa     gam8,
      f_ramb <- f_famb  beta1,
      f_famb <- f_ramb  beta2;
   pvar
      f_ramb = psi11,
      f_famb = psi22,
      rpa riq rses fpa fiq fses = v1-v6,
      rea roa fea foa = theta1-theta4;
   pcov
      f_ramb f_famb = psi12,
      rpa riq rses fpa fiq fses = 15 * cov__;
run;
```

In this specification, the names of the parameters correspond to those used by Jöreskog and Sörbom (1988). Since this TYPE=CORR data set does not contain an observation with _TYPE_='N' giving the sample size, it is necessary to specify the NOBS= option in the PROC TCALIS statement.

Specifying a name followed by double underscores is a quick way to generate unique parameter names. The double underscores are replaced with a unique number each time a new parameter name is generated. For example, in the COV statement, the specification

```
rpa riq rses fpa fiq fses = 15 * cov__;
```

is equivalent to

```
rpa riq rses fpa fiq fses = cov01-cov15;
```

In the PROC TCALIS statement, the CORR option is used to indicate that the correlation matrix is fitted by the model. Fitting correlation matrices by covariance structure modeling method is plagued with some statistical issues. For example, the chi-square statistic might not follow the theoretical distribution well, and the estimates of standard errors might not be accurate. Nonetheless, the correlation matrix is fitted here for illustration and comparison purposes.

The results from this analysis are displayed in Figure 17.18.

Jöreskog and Sörbom (1988) present more detailed results from a second analysis in which two constraints are imposed:

- The coefficients connecting the latent ambition variables are equal (that is, beta1 = beta2).
- The covariance of the disturbances of the ambition variables is zero (that is, psi12 = 0).

This analysis can be performed by changing the names beta1 and beta2 to beta and omitting the line from the COV statement for psi12, as shown in the following statements:

```
proc tcalis corr data=aspire nobs=329;
   path
      /* measurement model for aspiration */
      rea <-  f_ramb    lambda2,
      roa <-  f_ramb    1.,
      foa <-  f_famb    1.,
      fea <-  f_famb    lambda3,
      /* structural model of influences */
      f_ramb <- rpa     gam1,
      f_ramb <- riq     gam2,
      f_ramb <- rses    gam3,
      f_ramb <- fses    gam4,
      f_famb <- rses    gam5,
      f_famb <- fses    gam6,
      f_famb <- fiq     gam7,
      f_famb <- fpa     gam8,
      f_ramb <- f_famb  beta,
      f_famb <- f_ramb  beta;
   pvar
      f_ramb = psi11,
      f_famb = psi22,
      rpa riq rses fpa fiq fses = v1-v6,
      rea roa fea foa = theta1-theta4;
   pcov
      rpa riq rses fpa fiq fses = 15 * cov__;
 run;
```

The fit summary is displayed in Figure 17.19, and the estimation results are displayed in Figure 17.20.

The difference between the chi-square values for the two preceding models is $26.8987 - 26.6972 = 0.2015$ with 2 degrees of freedom, which is far from significant. This indicates that the restricted model (analysis 2) fits as well as the unrestricted model (analysis 1). However, the chi-square test of the restricted model against the alternative of a completely unrestricted covariance matrix yields a p-value of 0.0596, which indicates that the model might not be entirely satisfactory (p-values from these data are probably too small because of the dependence of the observations).

Loehlin (1987) points out that the models considered are unrealistic in at least two respects. First, the variables of parental aspiration, intelligence, and socioeconomic status are assumed to be measured without error. Loehlin adds uncorrelated measurement errors to the model and assumes, for illustrative purposes, that the reliabilities of these variables are known to be 0.7, 0.8, and 0.9, respectively. In practice, these reliabilities would need to be obtained from a separate study of the same or a very similar population. If these constraints are omitted, the model is not identified. However, constraining parameters to a constant in an analysis of a correlation matrix might make the chi-square goodness-of-fit test inaccurate, so there is more reason to be skeptical of the p-values. Second, the error terms for the respondent's aspiration are assumed to be uncorrelated with the corresponding terms for his friend. Loehlin introduces a correlation between the two educational aspiration error terms and between the two occupational aspiration error terms. These additions produce the path diagram for Loehlin's model 1 shown in Figure 17.21.

Figure 17.21 Path Diagram: Career Aspiration – Loehlin (1987)

In Figure 17.21, the observed variables rpa, riq, rses, fses, fiq, and fpa are all treated as measurements with errors. Their purified counterparts f_rpa, f_riq, f_rses, f_fses, f_fiq, and f_fpa are latent variables created in the model to represent measurements without errors. Path coefficients from these latent variables to the observed variables are fixed coefficients, indicating the square roots of the theoretical reliabilities in the model. These latent variables, rather than the observed counterparts, serve as predictors of the ambition variables f_ramb and f_famb. Correlated errors for the occupational aspiration variables and the educational aspiration variables are also shown in Figure 17.21. The error covariance for the educational aspiration variables rea and fea is indicated by the parameter covea, and the error covariance for the occupational aspiration variables roa and foa is indicated by the parameter covoa.

The statements for fitting this model by using the PATH modeling language are as follows:

```
proc tcalis corr data=aspire nobs=329;
   path
      /* measurement model for aspiration */
      rea  <-  f_ramb    lambda2,
      roa  <-  f_ramb    1.,
      foa  <-  f_famb    1.,
      fea  <-  f_famb    lambda3,

      /* measurement model for intelligence and environment */
      rpa  <-  f_rpa     0.837,
      riq  <-  f_riq     0.894,
      rses <-  f_rses    0.949,
      fses <-  f_fses    0.949,
      fiq  <-  f_fiq     0.894,
      fpa  <-  f_fpa     0.837,

      /* structural model of influences */
      f_ramb <- f_rpa     gam1,
      f_ramb <- f_riq     gam2,
      f_ramb <- f_rses    gam3,
      f_ramb <- f_fses    gam4,
      f_famb <- f_rses    gam5,
      f_famb <- f_fses    gam6,
      f_famb <- f_fiq     gam7,
      f_famb <- f_fpa     gam8,
      f_ramb <- f_famb    beta1,
      f_famb <- f_ramb    beta2;
   pvar
      f_ramb = psi11,
      f_famb = psi22,
      f_rpa f_riq f_rses f_fses f_fiq f_fpa = 6 * 1.0,
      rea roa fea foa                       = theta1-theta4,
      rpa riq rses fpa fiq fses             = err1-err6;
   pcov
      f_ramb f_famb   = psi12,

Since the p-value for the chi-square test is 0.5266, this model clearly cannot be rejected. However, Schwarz's Bayesian criterion for this model (SBC $= -63.3356$) is somewhat larger than for Jöreskog and Sörbom's (1988) analysis 2 (SBC $= -71.6343$), suggesting that a more parsimonious model would be desirable.

Since it is assumed that the same model applies to all the boys in the sample, the path diagram should be symmetric with respect to the respondent and his friend. In particular, the corresponding coefficients should be equal. By imposing equality constraints on the 15 pairs of corresponding coefficients, this example obtains Loehlin's (1987) model 2. The PATH model is as follows, where an OUTMODEL= data set is created to facilitate subsequent hypothesis tests:

```
proc tcalis corr data=aspire nobs=329 outmodel=model2;
   path
      /* measurement model for aspiration */

Covariances Among Errors

Error of	Error of	Parameter	Estimate	Standard Error	t Value
f_ramb	f_famb	psi12	-0.00344	0.04931	-0.06981
rea	fea	covea	0.02160	0.03144	0.68686
roa	foa	covoa	0.11208	0.03257	3.44076

The test of Loehlin's (1987) model 2 against model 1 yields a chi-square of $19.0697 - 12.0132 = 7.0565$ with 15 degrees of freedom, which is clearly not significant. This indicates the restricted model 2 fits at least as well as model 1. Schwarz's Bayesian criterion (SBC) is also much lower for model 2 (-143.2200) than for model 1 (-63.3356). Hence, model 2 seems preferable on both substantive and statistical grounds.

A question of substantive interest is whether the friend's socioeconomic status (SES) has a significant direct influence on a boy's ambition. This can be addressed by omitting the paths from f_fses to f_ramb and from f_rses to f_famb designated by the parameter name gam4, yielding Loehlin's (1987) model 3:

```
title2 'Loehlin (1987) analysis: Model 3';
data model3(type=calismdl);
   set model2;
   if _name_='gam4' then
      do;
         _name_=' ';
         _estim_=0;
      end;
run;
proc tcalis corr data=aspire nobs=329 inmodel=model3;
run;
```

The fit summary is displayed in Figure 17.26.

	Bollen Normed Index Rho1	0.9590
	Bollen Non-normed Index Delta2	1.0071
	James et al. Parsimonious NFI	0.6274

The chi-square value for testing model 3 versus model 2 is $23.0365 - 19.0697 = 3.9668$ with 1 degree of freedom and a p-value of 0.0464. Although the parameter is of marginal significance, the estimate in model 2 (0.0756) is small compared to the other coefficients, and SBC indicates that model 3 is preferable to model 2.

Another important question is whether the reciprocal influences between the respondent's and friend's ambitions are needed in the model. To test whether these paths are zero, set the parameter beta for the paths linking f_ramb and f_famb to zero to obtain Loehlin's (1987) model 4:

```
title2 'Loehlin (1987) analysis: Model 4';
data model4(type=calismdl);
   set model2;
   if _name_='beta' then
      do;
         _name_=' ';
         _estim_=0;
      end;
run;

proc tcalis corr data=aspire nobs=329 inmodel=model4;
run;
```

The fit summary is displayed in Figure 17.27, and the estimation results are displayed in Figure 17.28.

Covariances Among Errors

Error of	Error of	Parameter	Estimate	Standard Error	t Value
f_ramb	f_famb	psi12	0.05479	0.02699	2.03009
rea	fea	covea	0.02127	0.03150	0.67534
roa	foa	covoa	0.11245	0.03258	3.45136

The chi-square value for testing model 4 versus model 2 is $20.9981 - 19.0697 = 1.9284$ with 1 degree of freedom and a p-value of 0.1649. Hence, there is little evidence of reciprocal influence.

Loehlin's (1987) model 2 has not only the direct paths connecting the latent ambition variables f_ramb and f_famb but also a covariance between the disturbance terms d_ramb and d_famb to allow for other variables omitted from the model that might jointly influence the respondent and his friend. To test the hypothesis that this covariance is zero, set the parameter psi12 to zero, yielding Loehlin's (1987) model 5:

```
title2 'Loehlin (1987) analysis: Model 5';
data model5(type=calismdl);
   set model2;
   if _name_='psi12' then
      do;
         _name_=' ';
         _estim_=0;
      end;
run;

proc tcalis corr data=aspire nobs=329 inmodel=model5;
run;
```

The fit summary is displayed in Figure 17.29, and the estimation results are displayed in Figure 17.30.

Covariances Among Errors

Error of	Error of	Parameter	Estimate	Standard Error	t Value
f_ramb	f_famb		0		
rea	fea	covea	0.02120	0.03094	0.68516
roa	foa	covoa	0.11197	0.03254	3.44068

The chi-square value for testing model 5 versus model 2 is $19.0745 - 19.0697 = 0.0048$ with 1 degree of freedom. This test statistic is insignificant. Omitting the covariance between the disturbance terms, therefore, causes hardly any deterioration in the fit of the model.

These data fail to provide evidence of direct reciprocal influence between the respondent's and friend's ambitions or of a covariance between the disturbance terms when these hypotheses are considered separately. Notice, however, that the covariance psi12 between the disturbance terms increases from -0.003344 for model 2 to 0.05479 for model 4. Before you conclude that all of these paths can be omitted from the model, it is important to test both hypotheses together by setting both beta and psi12 to zero as in Loehlin's (1987) model 7:

```
title2 'Loehlin (1987) analysis: Model 7';
data model7(type=calismdl);
   set model2;
   if _name_='psi12'|_name_='beta' then
      do;
         _name_=' ';
         _estim_=0;
      end;
run;

proc tcalis corr data=aspire nobs=329 inmodel=model7;
run;
```

The fit summary is displayed in Figure 17.31, and the estimation results are displayed in Figure 17.32.

Covariances Among Errors

Error of	Error of	Parameter	Estimate	Standard Error	t Value
f_ramb	f_famb		0		
rea	fea	covea	0.04535	0.02918	1.55444
roa	foa	covoa	0.12085	0.03214	3.75976

When model 7 is tested against models 2, 4, and 5, the *p*-values are respectively 0.0433, 0.0370, and 0.0123, indicating that the combined effect of the reciprocal influence and the covariance of the disturbance terms is statistically significant. Thus, the hypothesis tests indicate that it is acceptable to omit either the reciprocal influences or the covariance of the disturbances, but not both.

It is also of interest to test the covariances between the error terms for educational (covea) and occupational aspiration (covoa), since these terms are omitted from Jöreskog and Sörbom's (1988) models. Constraining covea and covoa to zero produces Loehlin's (1987) model 6:

```
title2 'Loehlin (1987) analysis: Model 6';
data model6(type=calismdl);
   set model2;
   if _name_='covea'|_name_='covoa' then
      do;
         _name_=' ';
         _estim_=0;
      end;

Fit Summary

Modeling Info	N Observations	329
	N Variables	10
	N Moments	55
	N Parameters	25
	N Active Constraints	0
	Independence Model Chi-Square	872.0008
	Independence Model Chi-Square DF	45
Absolute Index	Fit Function	0.1020
	Chi-Square	33.4475
	Chi-Square DF	30
	Pr > Chi-Square	0.3035
	Z-Test of Wilson & Hilferty	0.5151
	Hoelter Critical N	431
	Root Mean Square Residual (RMSR)	0.0306
	Standardized RMSR (SRMSR)	0.0306
	Goodness of Fit Index (GFI)	0.9802
Parsimony Index	Adjusted GFI (AGFI)	0.9638
	Parsimonious GFI	0.6535
	RMSEA Estimate	0.0187
	RMSEA Lower 90% Confidence Limit	.
	RMSEA Upper 90% Confidence Limit	0.0471
	Probability of Close Fit	0.9686
	ECVI Estimate	0.2597
	ECVI Lower 90% Confidence Limit	.
	ECVI Upper 90% Confidence Limit	0.3164
	Akaike Information Criterion	-26.5525
	Bozdogan CAIC	-170.4342
	Schwarz Bayesian Criterion	-140.4342
	McDonald Centrality	0.9948
Incremental Index	Bentler Comparative Fit Index	0.9958
	Bentler-Bonett NFI	0.9616
	Bentler-Bonett Non-normed Index	0.9937
	Bollen Normed Index Rho1	0.9425
	Bollen Non-normed Index Delta2	0.9959
	James et al. Parsimonious NFI	0.6411

The chi-square value for testing model 6 versus model 2 is $33.4476 - 19.0697 = 14.3779$ with 2 degrees of freedom and a p-value of 0.0008, indicating that there is considerable evidence of correlation between the error terms.

The following table summarizes the results from Loehlin's (1987) seven models.

Model	χ^2	df	*p*-value	SBC
1. Full model	12.0132	13	0.5266	−63.3356
2. Equality constraints	19.0697	28	0.8960	−143.2200
3. No SES path	23.0365	29	0.7749	−145.0492
4. No reciprocal influence	20.9981	29	0.8592	−147.0876
5. No disturbance correlation	19.0745	29	0.9194	−149.0111
6. No error correlation	33.4475	30	0.3035	−140.4342
7. Constraints from both 4 and 5	25.3466	30	0.7080	−148.5351

For comparing models, you can use a DATA step to compute the differences of the chi-square statistics and *p*-values:

```
data _null_;
   array achisq[7] _temporary_
      (12.0132 19.0697 23.0365 20.9981 19.0745 33.4475 25.3466);
   array adf[7] _temporary_
      (13 28 29 29 29 30 30);
   retain indent 16;
   file print;
   input ho ha @@;
   chisq = achisq[ho] - achisq[ha];
   df = adf[ho] - adf[ha];
   p = 1 - probchi( chisq, df);
   if _n_ = 1 then put
      / +indent 'model comparison   chi**2   df  p-value'
      / +indent '-------------------------------------';
   put +indent +3 ho ' versus ' ha @18 +indent chisq 8.4 df 5. p 9.4;
datalines;
2 1    3 2    4 2    5 2    7 2    7 4    7 5    6 2
;
```

The DATA step displays the table in Figure 17.34.

Figure 17.34 Career Aspiration Data: Model Comparisons

```
          Peer Influences on Aspiration: Haller & Butterworth (1960)
                       Loehlin (1987) analysis: Model 6

               model comparison   chi**2   df  p-value
               -------------------------------------
                  2  versus 1     7.0565   15   0.9561
                  3  versus 2     3.9668    1   0.0464
                  4  versus 2     1.9284    1   0.1649
                  5  versus 2     0.0048    1   0.9448
                  7  versus 2     6.2769    2   0.0433
                  7  versus 4     4.3485    1   0.0370
                  7  versus 5     6.2721    1   0.0123
                  6  versus 2    14.3778    2   0.0008
```

Although none of the seven models can be rejected when tested against the alternative of an unrestricted covariance matrix, the model comparisons make it clear that there are important differences

among the models. Schwarz's Bayesian criterion indicates model 5 as the model of choice. The constraints added to model 5 in model 7 can be rejected (p=0.0123), while model 5 cannot be rejected when tested against the less constrained model 2 (p=0.9448). Hence, among the small number of models considered, model 5 has strong statistical support. However, as Loehlin (1987, p. 106) points out, many other models for these data could be constructed. Further analysis should consider, in addition to simple modifications of the models, the possibility that more than one friend could influence a boy's aspirations, and that a boy's ambition might have some effect on his choice of friends. Pursuing such theories would be statistically challenging.

This chapter introduces a number of concepts that are common to one or more procedures in SAS/STAT, such as the parameterization of effects, the use of the experimental EFFECT statement, and so on. The beginning of each major section displays a listing of the procedures for which the shared topic is relevant.

Levelization of Classification Variables

A classification variable is a variable that enters the statistical analysis or model not through its values, but through its levels. The process of associating values of a variable with levels is termed *levelization*.

A sufficient, but not necessary, condition for a procedure to perform levelization of classification variables is the presence of a CLASS statement. Hence, this section applies to all SAS/STAT procedures that support a CLASS statement. Some procedures use different syntax elements to request levelization of variables (for example, the TRANSREG procedure).

During the process of levelization, observations that share the same value are assigned to the same level. The manner in which values are grouped can be affected by the inclusion of formats. The sort order of the levels can be determined with the ORDER= option in the procedure statement. With the GENMOD, GLMSELECT, and LOGISTIC procedures, you can also control the sorting order separately for each variable in the CLASS statement.

Consider the data on nine observations in Table 18.1. The variable A is integer valued, and variable X is a continuous variable with a missing value for the fourth observations. The fourth and fifth columns of Table 18.1 apply two different formats to the variable X.

Table 18.1 Example Data for Levelization

Obs	A	x	format x 3.0	format x 3.1
1	1	1.09	1	1.1
2	1	1.13	1	1.1
3	1	1.27	1	1.3
4	2	.	.	.
5	2	2.26	2	2.3
6	2	2.48	2	2.5
7	3	3.34	3	3.3
8	3	3.34	3	3.3
9	3	3.14	3	3.1

By default, levelization of the variables groups observations by the formatted value of the variable, except for numerical variables where no explicit format is provided. These are sorted by their internal value. The levelization of the four columns in table Table 18.1 leads to the level assignment in Table 18.2.

Table 18.2 Values and Levels

	A		X		format x 3.0		format x 3.1	
Obs	**Value**	**Level**	**Value**	**Level**	**Value**	**Level**	**Value**	**Level**
1	2	1	1.09	1	1	1	1.1	1
2	2	1	1.13	2	1	1	1.1	1
3	2	1	1.27	3	1	1	1.3	2
4	3	2	.	.	.	.	.	.
5	3	2	2.26	4	2	2	2.3	3
6	3	2	2.48	5	2	2	2.5	4
7	4	3	3.34	7	3	3	3.3	6
8	4	3	3.34	7	3	3	3.3	6
9	4	3	3.14	6	3	3	3.1	5

The ORDER= option in the PROC statement specifies the sorting order for the levels of CLASS variables. When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values. To order numeric class levels with no explicit format by their BEST12. formatted values, you can specify this format explicitly for the CLASS variables.

The following table shows how values of the ORDER= option are interpreted.

Value of ORDER=	**Levels Sorted By**
DATA	order of appearance in the input data set
FORMATTED	external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

For FORMATTED and INTERNAL values, the sort order is machine dependent. For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

The GLMSELECT, LOGISTIC, and GENMOD procedures support a MISSING option in the CLASS statement. When this option is in effect, missing values ('.' for a numeric variable and blanks for a character variable) are included in the levelization and are assigned a level. Table 18.3 displays the results of levelizing the values in Table 18.1 when the MISSING option is in effect.

Table 18.3 Values and Levels with MISSING Option

	A		X		format x 3.0		format x 3.1	
Obs	Value	Level	Value	Level	Value	Level	Value	Level
1	2	1	1.09	2	1	2	1.1	2
2	2	1	1.13	3	1	2	1.1	2
3	2	1	1.27	4	1	2	1.3	3
4	3	2	.	1	.	1	.	1
5	3	2	2.26	5	2	3	2.3	4
6	3	2	2.48	6	2	3	2.5	5
7	4	3	3.34	8	3	4	3.3	7
8	4	3	3.34	8	3	4	3.3	7
9	4	3	3.14	7	3	4	3.1	6

When the MISSING option is not specified, or for procedures whose CLASS statement does not support this option, it is important to understand the implications of missing values for your statistical analysis. When a SAS/STAT procedure levelizes the CLASS variables, an observation for which a CLASS variable has a missing value is excluded from the analysis. This is true regardless of whether the variable is used to form the statistical model. Consider, for example, the case where some observations contain missing values for variable A but the records for these observations are otherwise complete with respect to all other variables in the statistical models. The analysis results from the following statements do not include any observations for which variable A contains missing values, even though A is not specified in the MODEL statement:

```
class A B;
model y = B x B*x;
```

Many statistical procedures print a "Number of Observations" table that shows the number of observations read from the data set and the number of observations used in the analysis. You should pay careful attention to this table—especially when your data set contains missing values—to ensure that no observations are unintentionally excluded from the analysis.

Parameterization of Model Effects

Recall the general form of a linear regression model defined in Chapter 3, "Regression Models and Models with Classification Effects":

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

This section describes how matrices of regressor effects such as $\mathbf{X}$ are constructed in SAS/STAT. These constructions, or *parameterization* rules, apply to regression models, models with classification effects, generalized linear models, and mixed models. The simplest and most general parameterization rules are the ones used in the GLM procedure, and they are discussed first. Several procedures also support alternate parameterizations of classification variables, including the GENMOD,

GLMSELECT, LOGISTIC, SURVEYLOGISTIC, and PHREG procedures. These are discussed after the GLM parameterization of classification variables and model effects.

All modeling procedures that support classification variables and effects have a CLASS statement. Procedures that additionally support the supplemental parameterizations have a PARAM= option in the CLASS statement.

GLM Parameterization of Classification Variables and Effects

This section applies to the following procedures:
GAM, GENMOD, GLIMMIX, GLM, GLMPOWER, GLMSELECT, LIFEREG, LOGISTIC, MI, MIXED, MULLTEST, ORTHOREG, PHREG, PLS, QUANTREG, ROBUSTREG, and SURVEYLOGISTIC.

Intercept

By default, linear models in SAS/STAT automatically include a column of 1s in $\mathbf{X}$ corresponding to an intercept parameter. In many procedures you can use the NOINT option in the MODEL statement to suppress this intercept. The NOINT option is useful, for example, when the MODEL statement contains a classification effect and you want the parameter estimates to be in terms of the mean response for each level of that effect.

Regression Effects

Numeric variables, or polynomial terms involving them, can be included in the model as regression effects (covariates). The actual values of such terms are included as columns of the relevant model matrices. You can use the bar operator with a regression effect to generate polynomial effects. For instance, X|X|X expands to X X*X X*X*X, a cubic model.

Main Effects

If a classification variable has m levels, the GLM parameterization generates m columns for its main effect in the model matrix. Each column is an indicator variable for a given level. The order of the columns is the sort order of the values of their levels and frequently can be controlled with the ORDER= option in the procedure or CLASS statement.

Table 18.4 is an example where β_0 denotes the intercept and A and B are classification variables with two and three levels, respectively.

Table 18.4 Example of Main Effects

Data		I	A		B		
A	B	β_0	A1	A2	B1	B2	B3
1	1	1	1	0	1	0	0
1	2	1	1	0	0	1	0
1	3	1	1	0	0	0	1
2	1	1	0	1	1	0	0
2	2	1	0	1	0	1	0
2	3	1	0	1	0	0	1

Typically, there are more columns for these effects than there are degrees of freedom to estimate them. In other words, the GLM parameterization of main effects is *singular*.

Interaction Effects

Often a model includes interaction (crossed) effects to account for how the effect of a variable changes with the values of other variables. With an interaction, the terms are first reordered to correspond to the order of the variables in the CLASS statement. Thus, B*A becomes A*B if A precedes B in the CLASS statement. Then, the GLM parameterization generates columns for all combinations of levels that occur in the data. The order of the columns is such that the rightmost variables in the interaction change faster than the leftmost variables (Table 18.5). Note that in the MIXED and GLIMMIX procedures, which support both fixed- and random-effects models, empty columns (that is, columns that would contain all 0s) are not generated for fixed effects, but they are generated for random effects.

Table 18.5 Example of Interaction Effects

Data		I	A		B			A*B					
A	B	β_0	A1	A2	B1	B2	B3	A1B1	A1B2	A1B3	A2B1	A2B2	A2B3
1	1	1	1	0	1	0	0	1	0	0	0	0	0
1	2	1	1	0	0	1	0	0	1	0	0	0	0
1	3	1	1	0	0	0	1	0	0	1	0	0	0
2	1	1	0	1	1	0	0	0	0	0	1	0	0
2	2	1	0	1	0	1	0	0	0	0	0	1	0
2	3	1	0	1	0	0	1	0	0	0	0	0	1

In the preceding matrix, main-effects columns are not linearly independent of crossed-effects columns; in fact, the column space for the crossed effects contains the space of the main effect.

When your model contains many interaction effects, you might be able to code them more parsimoniously by using the bar operator (|). The bar operator generates all possible interaction effects. For example, A|B|C expands to A B A*B C A*C B*C A*B*C. To eliminate higher-order interaction effects, use the at sign (@) in conjunction with the bar operator. For instance, A|B|C|D@2 expands to A B A*B C A*C B*C D A*D B*D C*D.

Nested Effects

Nested effects are generated in the same manner as crossed effects. Hence, the design columns generated by the following two statements are the same (but the ordering of the columns is different):

```
model Y=A B(A);

model Y=A A*B;
```

The nesting operator in SAS/STAT software is more of a notational convenience than an operation distinct from crossing. Nested effects are typically characterized by the property that the nested variables never appear as main effects. The order of the variables within nesting parentheses is made to correspond to the order of these variables in the CLASS statement. The order of the columns is such that variables outside the parentheses index faster than those inside the parentheses, and the rightmost nested variables index faster than the leftmost variables (Table 18.6).

Table 18.6 Example of Nested Effects

Data		I	A		B(A)					
A	B	β_0	A1	A2	B1A1	B2A1	B3A1	B1A2	B2A2	B3A2
1	1	1	1	0	1	0	0	0	0	0
1	2	1	1	0	0	1	0	0	0	0
1	3	1	1	0	0	0	1	0	0	0
2	1	1	0	1	0	0	0	1	0	0
2	2	1	0	1	0	0	0	0	1	0
2	3	1	0	1	0	0	0	0	0	1

Continuous-Nesting-Class Effects

When a continuous variable nests or crosses with a classification variable, the design columns are constructed by multiplying the continuous values into the design columns for the classification effect (Table 18.7).

Table 18.7 Example of Continuous-Nesting-Class Effects

Data		I	A		X(A)	
X	A	β_0	A1	A2	X(A1)	X(A2)
21	1	1	1	0	21	0
24	1	1	1	0	24	0
22	1	1	1	0	22	0
28	2	1	0	1	0	28
19	2	1	0	1	0	19
23	2	1	0	1	0	23

This model estimates a separate intercept and a separate slope for X within each level of A.

Continuous-by-Class Effects

Continuous-by-class effects generate the same design columns as continuous-nesting-class effects. Table 18.8 shows the construction of the X*A effect. The two columns for this effect are the same as the columns for the X(A) effect in Table 18.7.

Table 18.8 Example of Continuous-by-Class Effects

Data		**I**	**X**	A		X*A	
X	A	β_0	X	A1	A2	X*A1	X*A2
21	1	1	21	1	0	21	0
24	1	1	24	1	0	24	0
22	1	1	22	1	0	22	0
28	2	1	28	0	1	0	28
19	2	1	19	0	1	0	19
23	2	1	23	0	1	0	23

You can use continuous-by-class effects together with pure continuous effects to test for homogeneity of slopes.

General Effects

An example that combines all the effects is X1*X2*A*B*C(D E). The continuous list comes first, followed by the crossed list, followed by the nested list in parentheses. You should be aware of the sequencing of parameters when you use statements that depend on the ordering of parameters, such as the CONTRAST or ESTIMATE statements in a number of procedures, used to estimate and test functions of the parameter.

Effects might be renamed by the procedure to correspond to ordering rules. For example, B*A(E D) might be renamed A*B(D E) to satisfy the following:

- Classification variables that occur outside parentheses (crossed effects) are sorted in the order in which they appear in the CLASS statement.
- Variables within parentheses (nested effects) are sorted in the order in which they appear in the CLASS statement.

The sequencing of the parameters generated by an effect can be described by which variables have their levels indexed faster:

- Variables in the crossed list index faster than variables in the nested list.
- Within a crossed or nested list, variables to the right index faster than variables to the left.

For example, suppose a model includes four effects—A, B, C, and D—each having two levels, 1 and 2. If the CLASS statement is

```
class A B C D;
```

then the order of the parameters for the effect B*A(C D), which is renamed A*B(C D), is

$$\begin{array}{llll} A_1B_1C_1D_1 \rightarrow & A_1B_2C_1D_1 \rightarrow & A_2B_1C_1D_1 \rightarrow & A_2B_2C_1D_1 \rightarrow \\ A_1B_1C_1D_2 \rightarrow & A_1B_2C_1D_2 \rightarrow & A_2B_1C_1D_2 \rightarrow & A_2B_2C_1D_2 \rightarrow \\ A_1B_1C_2D_1 \rightarrow & A_1B_2C_2D_1 \rightarrow & A_2B_1C_2D_1 \rightarrow & A_2B_2C_2D_1 \rightarrow \\ A_1B_1C_2D_2 \rightarrow & A_1B_2C_2D_2 \rightarrow & A_2B_1C_2D_2 \rightarrow & A_2B_2C_2D_2 \end{array}$$

Note that first the crossed effects B and A are sorted in the order in which they appear in the CLASS statement so that A precedes B in the parameter list. Then, for each combination of the nested effects in turn, combinations of A and B appear. The B effect changes fastest because it is rightmost in the cross list. Then A changes next fastest, and D changes next fastest. The C effect changes slowest because it is leftmost in the nested list.

Other Parameterizations

This section applies to the following procedures:
GENMOD, GLMSELECT, LOGISTIC, and PHREG.

Some SAS/STAT procedures, including GENMOD, GLMSELECT, and LOGISTIC, support nonsingular parameterizations for classification effects. A variety of these nonsingular parameterizations are available. In these procedures you use the PARAM= option in the CLASS statement to specify the parameterization.

Consider a model with one CLASS variable A that has four levels, 1, 2, 5, and 7. Details of the possible choices for the PARAM= option follow.

EFFECT

Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of −1. For instance, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

Effect Coding

	Design Matrix		
A	**A1**	**A2**	**A5**
1	1	0	0
2	0	1	0
5	0	0	1
7	−1	−1	−1

Parameter estimates of CLASS main effects that use the effect coding scheme estimate the difference in the effect of each nonreference level compared to the average effect over all four levels.

Note that the EFFECT parameterization is the default parameterization in the CATMOD procedure. See the section "Generation of the Design Matrix" on page 1153, in Chapter 28, "The CATMOD Procedure," for further details about parameterization of model effects with the CATMOD procedure.

GLM

As in the GLM procedure, four columns are created to indicate group membership. The design matrix columns for A are as follows.

GLM Coding				
	Design Matrix			
A	**A1**	**A2**	**A5**	**A7**
1	1	0	0	0
2	0	1	0	0
5	0	0	1	0
7	0	0	0	1

Parameter estimates of CLASS main effects that use the GLM coding scheme estimate the difference in the effects of each level compared to the last level. See the previous section for details about the GLM parameterization of model effects.

ORDINAL

THERMOMETER

Three columns are created to indicate group membership of the higher levels of the effect. For the first level of the effect (which for A is 1), all three dummy variables have a value of 0. The design matrix columns for A are as follows.

Ordinal Coding			
	Design Matrix		
A	**A2**	**A5**	**A7**
1	0	0	0
2	1	0	0
5	1	1	0
7	1	1	1

The first level of the effect is a control or baseline level. Parameter estimates of CLASS main effects, using the ORDINAL coding scheme, estimate the differences between effects of successive levels. When the parameters have the same sign, the effect is monotonic across the levels.

POLYNOMIAL

POLY

Three columns are created. The first represents the linear term (x), the second represents the quadratic term $\left(x^2\right)$, and the third represents the cubic term $\left(x^3\right)$, where x is the level value. If the CLASS levels are not numeric, they are translated into 1, 2, 3, ... according to their sorting order. The design matrix columns for A are as follows.

Polynomial Coding			
	Design Matrix		
A	**APOLY1**	**APOLY2**	**APOLY3**
1	1	1	1
2	2	4	8
5	5	25	125
7	7	49	343

REFERENCE

REF

Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of 0. For instance, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

Reference Coding			
	Design Matrix		
A	**A1**	**A2**	**A5**
1	1	0	0
2	0	1	0
5	0	0	1
7	0	0	0

Parameter estimates of CLASS main effects that use the reference coding scheme estimate the difference in the effect of each nonreference level compared to the effect of the reference level.

The REFERENCE parameterization is also available through the MODEL statement in the CATMOD procedure. See the section "Generation of the Design Matrix" on page 1153, in Chapter 28, "The CATMOD Procedure," for further details about parameterization of model effects with the CATMOD procedure.

ORTHEFFECT

The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=EFFECT. The design matrix columns for A are as follows.

Orthogonal Effect Coding			
	Design Matrix		
A	**AOEFF1**	**AOEFF2**	**AOEFF3**
1	1.41421	−0.81650	−0.57735
2	0	1.63299	−0.57735
5	0	0	1.73205
7	−1.41421	−0.81649	−0.57735

ORTHORDINAL

ORTHOTHERM The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=ORDINAL. The design matrix columns for A are as follows.

Orthogonal Ordinal Coding			
	Design Matrix		
A	**AOORD1**	**AOORD2**	**AOORD3**
1	−1.73205	0	0
2	0.57735	−1.63299	0
5	0.57735	0.81650	−1.41421
7	0.57735	0.81650	1.41421

ORTHPOLY The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=POLY. The design matrix columns for A are as follows.

Orthogonal Polynomial Coding			
	Design Matrix		
A	**AOPOLY1**	**AOPOLY2**	**AOPOLY5**
1	−1.153	0.907	−0.921
2	−0.734	−0.540	1.473
5	0.524	−1.370	−0.921
7	1.363	1.004	0.368

ORTHREF The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=REFERENCE. The design matrix columns for A are as follows.

Orthogonal Reference Coding			
	Design Matrix		
A	**AOREF1**	**AOREF2**	**AOREF3**
1	1.73205	0	0
2	−0.57735	1.63299	0
5	−0.57735	−0.81650	1.41421
7	−0.57735	−0.81650	−1.41421

Constructed Effects and the EFFECT Statement (Experimental)

This section applies to the following procedures:
GLIMMIX, GLMSELECT, and QUANTREG.

The experimental EFFECT statement in SAS 9.2 is supported by the GLIMMIX, GLMSELECT, and QUANTREG procedures. The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects formed from continuous or classification variables, as discussed in the section "GLM Parameterization of Classification Variables and Effects" on page 369. For example, the terms A, B, x, A*x, A*B, and sub in the following statements define fixed, random, and subject effects of the usual type in a mixed model, respectively:

```
proc glimmix;
   class A B sub;
   model y = A B x A*x;
   random A*B / subject=sub;
run;
```

A constructed effect, on the other hand, is assigned through the EFFECT statement. For example, in the following program, the EFFECT statement defines a constructed effect named spl:

```
proc glimmix;
   class A B SUB;
   effect spl = spline(x);
   model y = A B A*spl;
   random A*B / subject=sub;
run;
```

The columns of spl are formed from the data set variable x as a cubic B-spline basis with three equally spaced interior knots.

Each constructed effect corresponds to a collection of columns that are referred to by using the name you supply. You can specify multiple EFFECT statements, and all EFFECT statements must precede the MODEL statement.

The general syntax for the EFFECT statement with *effect-specification* is

EFFECT *effect-name* = **effect-type** (*var-list* < / *effect-options* >) **;**

The name of the effect is specified after the EFFECT keyword. This name can appear in only one EFFECT statement and cannot be the name of a variable in the input data set. The effect type is specified after an equal sign, followed by a list of variables used in constructing the effect within parentheses. Effect-type specific options can be specified after a slash (/) following the variable list.

The following *effect-types* are available and subsequently discussed.

COLLECTION	is a collection effect defining one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.
MULTIMEMBER | MM	is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.
POLYNOMIAL | POLY	is a multivariate polynomial effect in the specified numeric variables.
SPLINE	is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Collection Effects

EFFECT *name*=**COLLECTION(***var-list* <**/ DETAILS**>**) ;**

You use a collection effect to define a set of variables that are treated as a single effect with multiple degrees of freedom. The variables in *var-list* can be continuous or classification variables. The columns in the design matrix contributed by a collection effect are the design columns of its constituent variables in the order in which they appear in the definition of the collection effect. If you specify the DETAILS option, then a table showing the constituents of the collection effect is displayed.

Multimember Effects

EFFECT *name*=**MULTIMEMBER(***var-list* <**/** *mm-options*>**) ;**

EFFECT *name*=**MM(***var-list* <**/** *mm-options*>**) ;**

A multimember effect is formed from one or more classification variables in such a way that each observation can be associated with one or more levels of the union of the levels of the classification variables. In other words, a multimember effect is a classification-type effect with possibly more than one nonzero column entry for each observation. Multimember effects are useful, for example, in modeling the following:

- nurses' effects on patient recovery in hospitals
- teachers' effects on student scores
- lineage effects in genetic studies (see Example 38.16 in Chapter 38, "The GLIMMIX Procedure," for an application with random multimember effects in a genetic diallel experiment)

The levels of a multimember effect consist of the union of formatted values of the variables defining this effect. Each such level contributes one column to the design matrix. For each observation, the

value corresponding to each level of the multimember effect in the design matrix is the number of times that this level occurs for the observation.

For example, the following data provide teacher information and end-of-year test scores for students after two semesters:

Student	Score	Teacher1	Teacher2
Mary	87	Tobias	Cohen
Tom	89	Rodriguez	Tobias
Fred	82	Cohen	Cohen
Jane	88	Tobias	.
Jack	99	.	.

For example, Mary had different teachers in the two semesters, Fred had the same teacher in both semesters, and Jane received instruction only in the first semester.

You can model the effect of the teachers on student performance by using a multimember effect specified as follows:

```
CLASS teacher1 teacher2;
EFFECT teacher = MM(teacher1 teacher2);
```

The levels of the teacher effect are {“Cohen”, “Rodriguez”, “Tobias”} and the associated design matrix columns are as follows:

Student	Cohen	Rodriguez	Tobias
Mary	1	0	1
Tom	0	1	1
Fred	2	0	0
Jane	0	0	1
Jack	.	.	.

You can specify the following *mm-options* after a slash (*/*):

DETAILS
requests a table showing the levels of the multimember effect.

NOEFFECT
specifies that, for observations with all missing levels of the multimember variables, the values in the corresponding design matrix columns are set to zero. If, in the preceding example, the teacher effect is defined by

```
EFFECT teacher = MM(teacher1 teacher2 / noeffect);
```

then the associated design matrix columns values for Jack are all zero. This enables you to include Jack in the analysis even though there is no effect of teachers on his performance.

A situation where it is important to designate observations as having no effect due to a classification variable is the analysis of crossover designs, where lagged treatment levels are used to

model the carryover effects of treatments between periods. Since there is no carryover effect for the first period, the treatment lag effect in a crossover design can be modeled with a multimember effect that consists of a single classification variable and the NOEFFECT option, as in the following statements:

```
CLASS Treatment lagTreatment;
EFFECT Carryover = MM(lagTreatment / noeffect);
```

The lagTreatment variable contains a missing value for the first period. Otherwise, it contains the value of the treatment variable for the preceding period.

STDIZE
specifies that for each observation, the entries in the design matrix corresponding to the multimember effect are scaled to have a sum of one.

WEIGHT=(*wght-list***)**
specifies numeric variables used to weigh the contributions of each of the classification effects that define the constructed multimember effect. The number of variables in the WEIGHT= list must match the number of classification variables defining the effect.

Polynomial Effects

This section discusses the construction of multivariate polynomial effects through the experimental EFFECT statement in the GLIMMIX and GLMSELECT procedures. You request a polynomial effect with the syntax

EFFECT *name*=**POLYNOMIAL(***var-list* < / *polynomial-options* >**) ;**

EFFECT *name*=**POLY(***var-list* < / *polynomial-options* >**) ;**

The variables in *var-list* must be numeric. A design matrix column is generated for each term of the specified polynomial. By default, each of these terms is treated as a separate effect for the purpose of model building. For example, the statements

```
proc glmselect;
   effect MyPoly = polynomial(x1-x3/degree=2);
   model y = MyPoly;
run;
```

yield the identical analysis to the statements

```
proc glmselect;
   model y = x1 x2 x3 x1*x1 x1*x2 x1*x3 x2*x2 x2*x3 x3*x3;
run;
```

You can specify the following *polynomial-options* after a slash (/):

DEGREE=*n*
specifies the degree of the polynomial. The degree must be a positive integer. The degree is typically a small integer, such as 1, 2, or 3. The default is DEGREE=1.

DETAILS

requests a table showing the details of the specified polynomial, including the number of terms generated. If you specify the STANDARDIZE option, then a table showing the standardization details is also produced.

LABELSTYLE=(*style-opts***)**

LABELSTYLE=*style-opt*

specifies how the terms in the polynomial are labeled. By default, powers are shown with ^ as the exponentiation operator and ∗ as the multiplication operator. For example, a polynomial term such as $x_1^3 x_2 x_3^2$ is labeled x1^3*x2*x3^2. You can change the style of the label by using the following *style-opts* within parentheses. If you specify a single *style-opt*, then you can omit the enclosing parentheses.

EXPAND

specifies that each variable with an exponent greater than one is written as products of that variable. For example, the term $x_1^3 x_2 x_3^2$ receives the label x1*x1*x1*x2*x3*x3.

EXPONENT < =*quoted string* **>**

specifies that each variable with an exponent greater than one is written using exponential notation. By default, the symbol ^ is used as the exponentiation operator. If you supply the optional quoted string after an equal sign, then that string is used as the exponentiation operator. For example, if you specify

```
LABELSTYLE=(EXPONENT="**")
```

then the term $x_1^3 x_2 x_3^2$ receives the label x1**3*x2*x3**2.

INCLUDENAME

specifies that the name of the effect followed by an underscore is used as a prefix for term labels. For example, the statement

```
EFFECT MyPoly=POLYNOMIAL(x1/degree=2 labelstyle=INCLUDENAME)
```

generates terms with labels MyPoly_x1 and MyPoly_x1^2. The INCLUDENAME option is ignored if you specify the NOSEPARATE option in the EFFECT=POLYNOMIAL statement.

PRODUCTSYMBOL =NONE | *quoted string*

specifies that the supplied string be used as the product symbol. For example, the statement

```
EFFECT MyPoly=POLYNOMIAL(x1 x2 / degree=2 mdegree=1
                                 labelstyle=(PRODUCTSYMBOL=" "))
```

generates terms with labels x1, x2, and x1 x2.

If you specify PRODUCTSYMBOL=NONE, then the labels are formed by juxtaposing the constituent variable names.

MDEGREE=*n*

specifies the maximum degree of any variable in a term of the polynomial. This degree must

be a positive integer. The default is the degree of the specified polynomial. For example, the statement

```
EFFECT MyPoly=POLYNOMIAL(x1 x2/degree=4 MDEGREE=2);
```

generates the terms x_1, x_2, x_1^2, x_1x_2, x_2^2,$x_1^2x_2$, and $x_1x_2^2$.

NOSEPARATE

specifies that the polynomial is treated as a single effect with multiple degrees of freedom. The effect name that you specify is used as the constructed effect name and the labels of the terms are used as labels of the corresponding parameters.

STANDARDIZE < (*centerscale-opts*) > < = *standardize-opt* >

specifies that the variables defining the polynomial are standardized. By default, the standardized variables receive prefix "s_" in the variable names.

You can use the following *centerscale-opts* to specify how the center and scale are estimated:

METHOD=MOMENTS

specifies that the center is estimated by the variable mean and the scale is estimated by the standard deviation. Note that if a weight variable is specified using a WEIGHT statement, the observations with invalid weights are ignored when forming the mean and standard deviation, but the weights are otherwise not used. Note that only observations that are used in performing the analysis are used for the standardization.

METHOD=RANGE

specifies that the center is estimated by the midpoint of the variable range and the scale is estimated as half the variable range. Any observation that has a missing value for any regressor used in the model is ignored when computing the range of variables in a polynomial effect. Observations with valid regressor values but missing or invalid values of frequency variables, weight variables, or dependent variables are used in computing variable ranges. The default (if you do not specify the METHOD= suboption) is METHOD=RANGE.

METHOD=WMOMENTS

is the same as METHOD=MOMENTS except that weighted means and weighted standard deviations are used.

Let

$$
\begin{aligned}
n &= \text{number of observations used in the analysis} \\
w &= \text{weight variable} \\
f &= \text{frequency variable} \\
x &= \text{variable to be standardized} \\
x_{(n)} &= \text{Max}_{i=1}^{n}(x_i) \\
x_{(1)} &= \text{Min}_{i=1}^{n}(x_i) \\
F &= \text{sum of frequencies} \\
&= \Sigma_{i=1}^{n} f_i \\
WF &= \text{sum of weighted frequencies} \\
&= \Sigma_{i=1}^{n} w_i f_i
\end{aligned}
$$

Table 18.9 shows how the center and scale are computed for each of the supported methods:

Table 18.9 Center and Scale Estimates by Method

Method	Center	Scale
Range	$(x_{(n)} - x_{(1)})/2$	$(x_{(n)} + x_{(1)})/2$
Moments	$\bar{x} = \Sigma_{i=1}^{n} f_i x_i / F$	$\sqrt{\Sigma_{i=1}^{n} f_i (x_i - \bar{x})^2/(F-1)}$
WMoments	$\bar{x}_w = \Sigma_{i=1}^{n} w_i f_i x_i / WF$	$\sqrt{\Sigma_{i=1}^{n} w_i f_i (x_i - \bar{x}_w)^2/(F-1)}$

PREFIX=NONE | *quoted string*

specifies the prefix that is appended to standardized variables when forming the term labels. If you omit this option, the default prefix is "s_". If you specify PREFIX=NONE, then standardized variables are not prefixed.

You can control whether the standardization is to center, scale, or both center and scale by specifying a *standardize-opt*:

CENTER

specifies that variables are centered but not scaled. For a variable x,

$$\text{s_x} = x - \text{center}$$

CENTERSCALE

specifies that variables are centered and scaled. This is the default if you do not specify a *standardization-opt*. For a variable x,

$$\text{s_x} = \frac{x - \text{center}}{\text{scale}}$$

NONE

specifies that no standardization is performed.

SCALE

specifies that variables are scaled but not centered. For a variable x,

$$\text{s_x} = \frac{x}{\text{scale}}$$

Spline Effects

This section discusses the construction of spline effects through the experimental EFFECT statement in the GLIMMIX, GLMSELECT, and QUANTREG procedures. You can also include spline effects in statistical models by other means. The TRANSREG procedure has dedicated facilities for including regression splines in your model and controlling the construction of the splines. For example, you can use the TRANSREG procedure to fit a spline function but restrict the function to be always increasing or decreasing (monotone). See the section "Using Splines and Knots" on page 7192 in Chapter 90, "The TRANSREG Procedure," for more information about using splines with the TRANSREG procedure. The GAM and TPSPLINE procedures also can model the effects of regressor variables in terms of smooth functions that are generated from spline bases. For more information see Chapter 36, "The GAM Procedure," and Chapter 89, "The TPSPLINE Procedure."

A spline effect expands variables into spline bases whose form depends on the options that you specify. You can find details about regression splines and spline bases in the section "Splines and Spline Bases" on page 387. You request a spline effect with the syntax

EFFECT *name*=**SPLINE(***var-list* < / *spline-options* >**) ;**

The variables in *var-list* must be numeric. Design matrix columns are generated separately for each of these variables and the set of columns is collectively referred to with the specified name. By default, the spline basis generated for each variable is a cubic B-spline basis with three equally spaced knots positioned between the minimum and maximum values of that variable. This yields by default seven design matrix columns for each of the variables in the SPLINE effect.

You can specify the following *spline-options* after a slash (/):

BASIS=BSPLINE

specifies a B-spline basis for the spline expansion. For splines of degree d defined with n knots, this basis consists of $n + d + 1$ columns. In order to completely specify the B-spline basis, d left-side boundary knots and $\max\{d, 1\}$ right-side boundary knots are also required. See the suboptions KNOTMETHOD=, DATABOUNDARY=, KNOTMIN=, and KNOTMAX= for details about how to specify the positions of both the internal and boundary knots. This is the default if you do not specify the BASIS= suboption.

BASIS=TPF(*options***)**

specifies a truncated power function basis for the spline expansion. For splines of degree d defined with n knots for a variable x, this basis consists of an intercept, polynomials x, $x^2,\ldots,x^d$ and one truncated power function for each of the n knots. Note that unlike the B-spline basis no boundary knots are required. See the suboption KNOTMETHOD= for details about how you can specify the position of the internal knots.

You can modify the number of columns when you request BASIS=TPF with the following suboptions:

NOINT
excludes the intercept column.

NOPOWERS
excludes the intercept and polynomial columns.

DATABOUNDARY
specifies that the extremes of the data be used as boundary knots when building a B-spline basis.

DEGREE=*n*
specifies the degree of the spline transformation. The degree must be a nonnegative integer. The degree is typically a small integer, such as 0, 1, 2, or 3. The default is DEGREE=3.

DETAILS
requests tables showing the knot locations and the knots associated with each spline basis function.

KNOTMAX=*value*
specifies that, for each variable in the EFFECT statement, the right-side boundary knots be equally spaced starting at the maximum of the variable and ending at the specified value. This option is ignored for variables whose maximum value is greater than the specified value or if the DATABOUNDARY option is also specified.

KNOTMETHOD=*knot-method***<(***knot-options***)>**
specifies how the knots for spline effects are constructed. You can choose from the following *knot-methods* and affect the knot construction further with the type-specific *knot-options*:

EQUAL<(*n***)>**
specifies that n equally spaced knots be positioned between the extremes of the data. The default is $n = 3$. For a B-spline basis, any needed boundary knots continue to be equally spaced unless the DATABOUNDARY option has also been specified. KNOTMETHOD=EQUAL is the default if no *knot-method* is specified.

LIST(*number-list***)**
specifies the list of internal knots to be used in forming the spline basis columns. For a B-spline basis, the data extremes are used as boundary knots.

LISTWITHBOUNDARY(*number-list***)**
specifies the list of all knots in forming the spline basis columns. When you use a truncated power function basis, this list is interpreted as the list of internal knots. When you use a B-spline basis of degree d, then the first d entries are used as left-side boundary knots and the last MAX(d, 1) entries in the list are used as right-side boundary knots.

MULTISCALE<(*multiscale-options***)>**
specifies that multiple B-spline bases be generated, corresponding to sets with an increasing number of internal knots. As you increase the number of internal knots, the spline basis you generate is able to approximate features of the data at finer scales. So, by generating bases at multiple scales, you facilitate the modeling of both coarse- and fine-grained features of the data. For scale i, the spline basis corresponds to 2^i equally

spaced internal knots. By default, the bases for scales 0–7 are generated. For each scale, a separate spline effect is generated. The name of the constructed spline effect at scale *i* is formed by appending _S*i* to the effect name you specify in the EFFECT statement. If you specify multiple variables in the EFFECT statement, then spline bases are generated separately for each variable at each scale and the name of the corresponding effect is obtained by appending the variable name followed by _S*i* to the name in the EFFECT statement. For example, the following statement generates effects named spl_x1_S0, spl_x1_S1, spl_x1_S2, . . ., spl_x1_S7 and spl_x2_S1, spl_x2_S2, . . ., spl_x2_S7:

```
EFFECT spl = spline(x1 x2 / knotmethod=multiscale);
```

This option is ignored if you specify the BASIS=TPF suboption. It is not available for spline effects specified in the RANDOM statement of the GLIMMIX procedure.

You can control which scales are included with the following *multiscale-options*:

STARTSCALE=*n*
where *n* is a positive integer. The default is STARTSCALE=0.

ENDSCALE=*n*
where *n* is a positive integer. The default is ENDSCALE=7.

PERCENTILES(*n***)**
requests that internal knots be placed at *n* equally spaced percentiles of the variable or variables named in the EFFECT statement. For example, the following statement positions internal knots at the deciles of the variable x. For a B-spline basis, the extremes of the data are used as boundary knots:

```
EFFECT spl = spline(x / knotmethod=percentiles(9));
```

RANGEFRACTIONS(*fraction-list***)**
requests that internal knots be placed at each fraction of the ranges of the variables in the EFFECT statement. For example, if variable x1 ranges between 1 and 3, and variable x2 ranges between 0 and 20, then the following EFFECT statement uses internal knots 1.2, 2, and 2.5 for variable x1 and internal knots 2, 10, and 15 for variable x2:

```
EFFECT spl = spline(x1 x2 / knotmethod=rangefractions(.1 .5 .75));
```

For a B-spline basis, the data extremes are used as boundary knots.

KNOTMIN=*value*
specifies that for each variable in the EFFECT statement, the left-side boundary knots be equally spaced starting at the specified value and ending at the minimum of the variable. This option is ignored for variables whose minimum value is less than the specified value or if the DATABOUNDARY option is also specified.

SEPARATE
specifies that when multiple variables are specified in the EFFECT statement, the spline basis for each variable is treated as a separate effect. The names of these separated effects are formed by appending an underscore followed by the name of the variable to the name that you specify in the EFFECT statement. For example, the effect names generated with the following statement are spl_x1 and spl_x2:

```
EFFECT spl = spline(x1 x2 / separate);
```

In procedures that support variable selection, such as the GLMSELECT procedure, these two effects can enter or leave the model independently during the selection process. Separated effects are not supported in the RANDOM statement of the GLIMMIX procedure

SPLIT

specifies that each individual column in the design matrix corresponding to the spline effect is treated as a separate effect that can enter or leave the model independently. Names for these split effects are generated by appending the variable name and an index for each column to the name that you specify in the EFFECT statement. For example, the effects generated for the spline effect in the following statement are spl_x1:1, spl_x1:2, ...,spl_x1:7, spl_x2:1, spl_x2:2, ...,spl_x2:7:

```
EFFECT spl = spline(x1 x2 / split);
```

The SPLIT option is not supported in the GLIMMIX procedure.

Splines and Spline Bases

This section provides details about the construction of spline bases with the experimental EFFECT statement. A spline function is a piecewise polynomial function where the individual polynomials have the same degree and connect smoothly at join points whose abscissa values, referred to as knots, are prespecified. You can use spline functions to fit curves to a wide variety of data.

A spline of degree 0 is a step function with steps located at the knots. A spline of degree 1 is a piecewise linear function where the lines connect at the knots. A spline of degree 2 is a piecewise quadratic curve whose values and slopes coincide at the knots. A spline of degree 3 is a piecewise cubic curve whose values, slopes, and curvature coincide at the knots. Visually, a cubic spline is a smooth curve, and it is the most commonly used spline when a smooth fit is desired. Note that when no knots are used, splines of degree d are simply polynomials of degree d.

More formally, suppose you specify knots $k_1 < k_2 < k_3 < \cdots < k_n$. Then a spline of degree $d \geq 0$ is a function $S(x)$ with $d-1$ continuous derivatives such that

$$S(x) = \begin{cases} P_0(x) & x < k_1 \\ P_i(x) & k_i \leq x < k_{i+1};\ i = 1, 2, \ldots, n-1 \\ P_n(x) & x \geq k_n \end{cases}$$

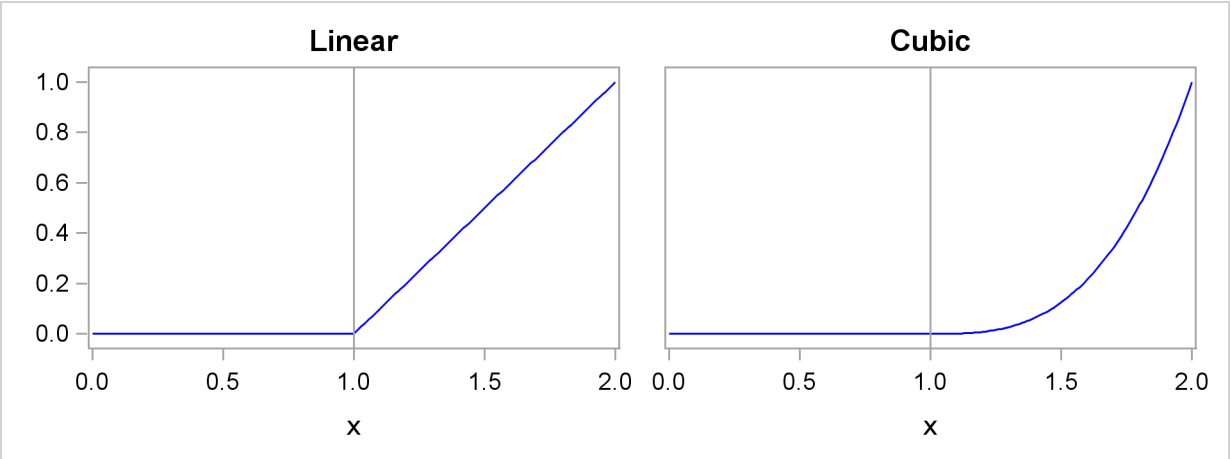
where each $P_i(x)$ is a polynomial of degree d. The requirement that $S(x)$ has $d-1$ continuous derivatives is satisfied by requiring that the function values and all derivatives up to order $d-1$ of the adjacent polynomials at each knot match.

A counting argument yields the number of parameters that define a spline with n knots. There are $n+1$ polynomials of degree d, giving $(n+1)(d+1)$ coefficients. However, there are d restrictions at each of the n knots, so the number of free parameters is $(n+1)(d+1) - nd = n + d + 1$. In mathematical terminology this says that the dimension of the vector space of splines of degree d on n distinct knots is $n + d + 1$. If you have $n + d + 1$ basis vectors, then you can fit a curve to your

data by regressing your dependent variable by using this basis for the corresponding design matrix columns. In this context, such a spline is known as a regression spline. The EFFECT statement provides a simple mechanism for obtaining such a basis.

If you remove the restriction that the knots of a spline must be distinct and allow repeated knots, then you can obtain functions with less smoothness and even discontinuities at the repeated knot location. For a spline of degree d and a repeated knot with multiplicity $m \leq d$, the piecewise polynomials that join such a knot are required to have only $d - m$ matching derivatives. Note that this increases the number of free parameters by $m - 1$ but also decreases the number of distinct knots by $m - 1$. Hence the dimension of the vector space of splines of degree d with n knots is still $n + d + 1$, provided that any repeated knot has a multiplicity less than or equal to d.

The EFFECT statement provides support for the commonly used *truncated power function* basis and *B-spline* basis. With exact arithmetic and by using the complete basis, you will obtain the same fit with either of these bases. The following sections provide details about constructing spline bases for the space of splines of degree d with n knots satisfying $k_1 \leq k_2 \leq k_3 < \cdots \leq k_n$.



Truncated Power Function Basis

A truncated power function for a knot k_i is a function defined by

$$t_i(x) = \begin{cases} 0 & x < k_i \\ (x - k_i)^d & x \geq k_i \end{cases}$$

Figure 18.1 shows such functions for $d = 1$ and $d = 3$ with a knot at $x = 1$.

Figure 18.1 Truncated Power Functions with Knot at $x = 1$

The name is derived from the fact that these functions are shifted power functions that get truncated to zero to the left of the knot. These functions are piecewise polynomial functions with two pieces whose function values and derivatives of all orders up to $d - 1$ are zero at the defining knot. Hence these functions are splines of degree d. It is easy to see that these n functions are linearly independent. However, they do not form a basis, because such a basis requires $n + d + 1$ functions. The usual way to add $d + 1$ additional basis functions is to use the polynomials $1, x, x^2, \ldots, x^d$.

These $d + 1$ functions together with the n truncated power functions $t_i(x), i = 1, 2, \ldots, n$ form the truncated power basis.

Note that each time a knot is repeated, the associated exponent used in the corresponding basis function is reduced by 1. For example, for splines of degree d with 3 repeated knots $k_i = k_{i+1} = k_{i+2}$ the corresponding basis functions are $t_i(x) = ((x - k_i)_+^d$, $t_{i+1}(x) = ((x - k_i)_+^{d-1}$, and $t_{i+2}(x) = ((x - k_i)_+^{d-2}$. Provided that the multiplicity of each repeated knot is less than or equal to the degree, this construction continues to yield a basis for the associated space of splines.

The main advantage of the truncated power function basis is the simplicity of its construction and the ease of interpreting the parameters in a model corresponding to these basis functions. However, there are two weaknesses when you use this basis for regression. These functions grow rapidly without bound as x increases, resulting in numerical precision problems when the x data span a wide range. Furthermore, many or even all of these basis functions can be nonzero when evaluated at some x value, resulting in a design matrix with few zeros that precludes the use of sparse matrix technology to speed up computation. This weakness can be addressed by using a B-spline basis.

B-Spline Basis

A B-spline basis can be built by starting with a set of Haar basis functions, which are functions that are 1 between adjacent knots and zero elsewhere, and then applying a simple linear recursion relationship d times, yielding the $n + d + 1$ needed basis functions. For the purpose of building the B-spline basis, the n prespecified knots are referred to as internal knots. This construction requires d additional knots, known as boundary knots, to be positioned to the left of the internal knots, and MAX$(d, 1)$ boundary knots to be positioned to the right of the internal knots. The actual values of these boundary knots can be arbitrary. The EFFECT statement provides several methods for placing the needed boundary knots, including the common method of using repeated values of the data extremes as the boundary knots. The boundary knot placement affects the precise form of the basis functions generated but not the following two desirable properties:

1. The B-spline basis functions are nonzero over an interval spanning at most $d + 2$ knots. This yields design matrix columns each of whose rows contain at most $d + 2$ adjacent nonzero entries.

2. The computation of the basis functions at any x value is numerically stable and does not require evaluating powers of this value.

The following figures show the B-spline bases defined on [0, 1] with 4 equally spaced internal knots at 0.2, 0.4, 0.6, and 0.8.

Figure 18.2 shows a linear B-spline basis. Note that this basis consists of 6 functions each of which is nonzero over an interval spanning at most 3 knots.

Figure 18.2 Linear B-Spline Basis with Four Equally Spaced Interior Knots

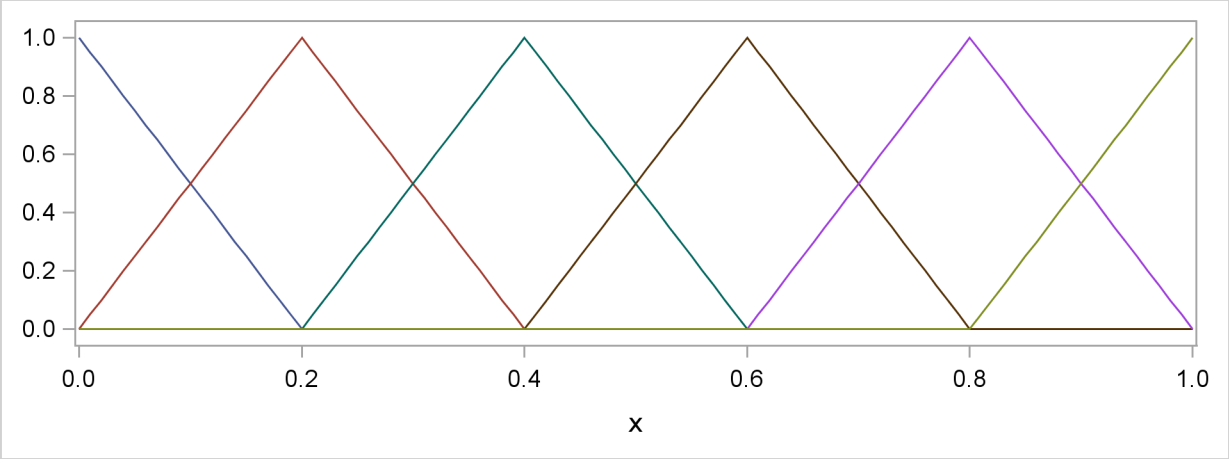


Figure 18.3 shows a cubic B-spline basis where the needed boundary knots are positioned at $x = 0$ and $x = 1$. Note that this basis consists of 8 functions, each of which is nonzero over an interval spanning at most 5 knots.

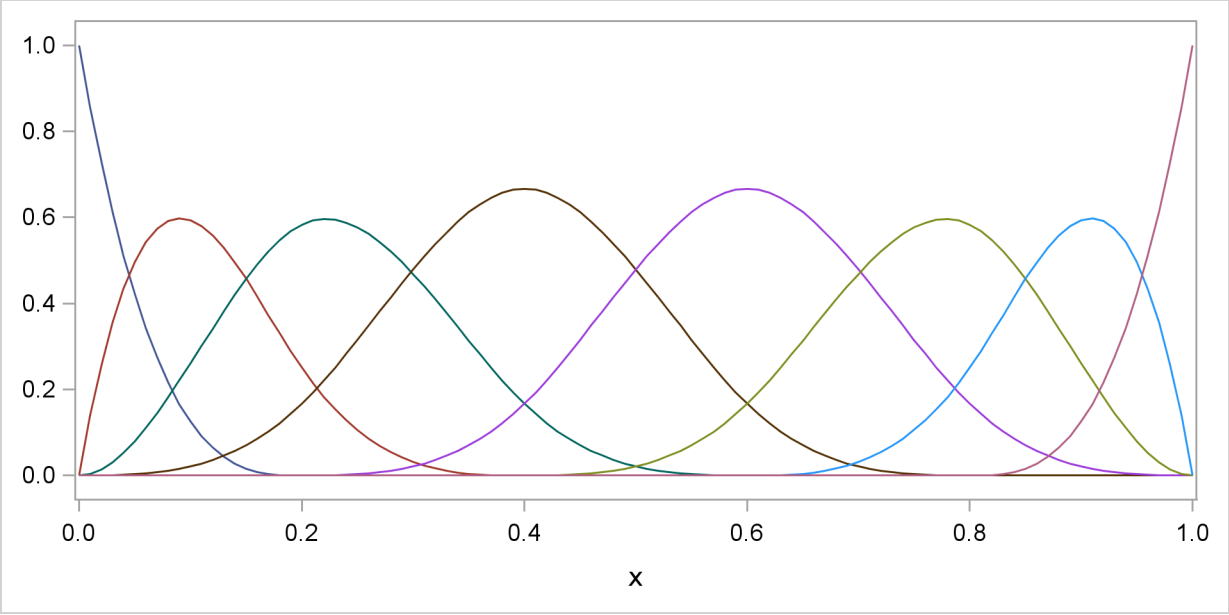
Figure 18.3 Cubic B-Spline Basis with Four Equally Spaced Interior Knots



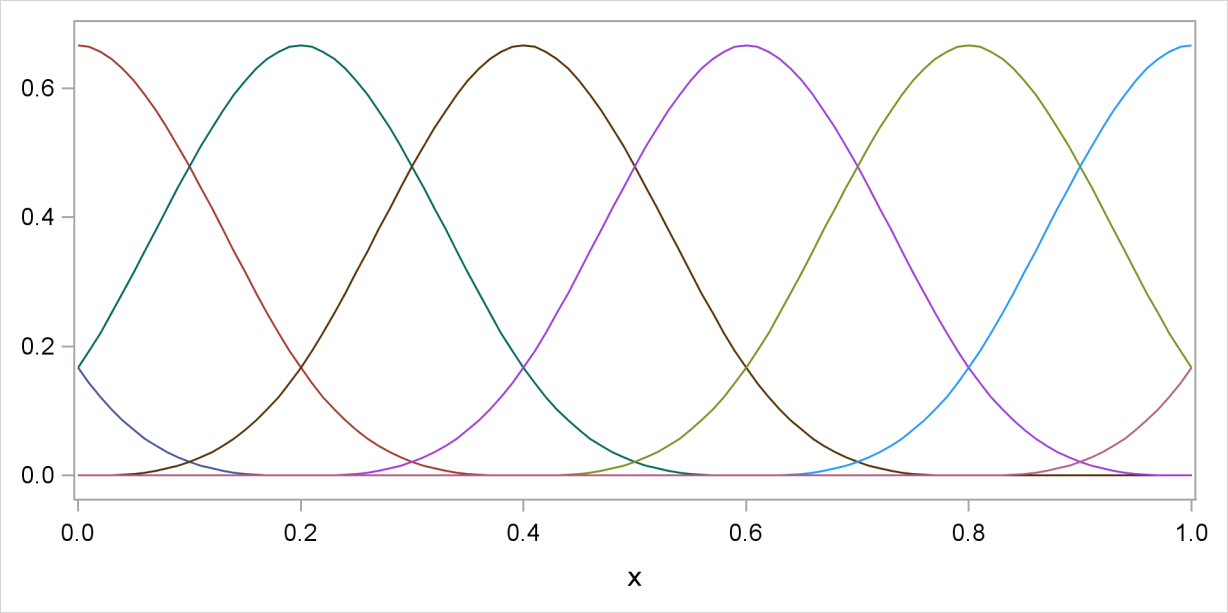


Figure 18.4 shows a different cubic B-spline basis where the needed left-side boundary knots are positioned at −0.6, −0.4, −0.2, and 0. The right-side boundary knots are positioned at 1, 1.2, 1.4, and 1.6. Note that, as in the basis shown in Figure 18.3, this basis consists of 8 functions, each of which is nonzero over an interval spanning at most 5 knots. The different positioning of the boundary knots has merely changed the shape of the individual basis functions.

Figure 18.4 Cubic B-Spline Basis with Equally Spaced Boundary and Interior Knots

You can find details about this construction in Hastie, Tibshirani, and Friedman (2001).

Nonlinear Optimization: The NLOPTIONS Statement

This section applies to the following procedures:
GLIMMIX, HPMIXED, and TCALIS. See the individual procedure chapters on deviations from the common syntax and defaults shown here.

Syntax

The NLOPTIONS statement provides you with syntax to control aspects of the nonlinear optimizations in the GLIMMIX, HPMIXED, and TCALIS procedures.

NLOPTIONS < *options* > **;**

The nonlinear optimization options are described in alphabetical order after Table 18.10, which summarizes the options by category. The notation used in describing the options is generic in the sense that $\boldsymbol{\psi}$ denotes the $p \times 1$ vector of parameters for the optimization and ψ_i is its ith element. The objective function being minimized, its $p \times 1$ gradient vector, and its $p \times p$ Hessian matrix are denoted as $f(\boldsymbol{\psi})$, $\mathbf{g}(\boldsymbol{\psi})$, and $\mathbf{H}(\boldsymbol{\psi})$, respectively. The gradient with respect to the ith parameter is denoted as $g_i(\boldsymbol{\psi})$. Superscripts in parentheses denote the iteration count; for example, $f(\boldsymbol{\psi})^{(k)}$ is the value of the objective function at iteration k. In the mixed model procedures, the

parameter vector ψ might consist of fixed effects only, covariance parameters only, or fixed effects and covariance parameters. In the TCALIS procedure, ψ consists of all independent parameters defined in the models and in the PARAMETERS statement.

Table 18.10 Options to Control Aspects of the Optimization

Option	Description
Optimization	
HESCAL=	determines the type of Hessian scaling
INHESSIAN=	specifies the start for approximated Hessian
LINESEARCH=	specifies the line-search method
LSPRECISION=	specifies the line-search precision
RESTART=	specifies the iteration number for update restart
TECHNIQUE=	determines the minimization technique
UPDATE=	determines the update technique
Termination Criteria	
ABSCONV=	tunes an absolute function convergence criterion
ABSFCONV=	tunes an absolute function convergence criterion
ABSGCONV=	tunes the absolute gradient convergence criterion
ABSXCONV=	tunes the absolute parameter convergence criterion
FCONV=	tunes the relative function convergence criterion
FCONV2=	tunes another relative function convergence criterion
FSIZE=	specifies the value used in FCONV, GCONV criterion
GCONV=	tunes the relative gradient convergence criterion
GCONV2=	tunes another relative gradient convergence criterion
MAXFUNC=	specifies the maximum number of function calls
MAXITER=	specifies the maximum number of iterations
MAXTIME=	specifies the upper limit seconds of CPU time
MINITER=	specifies the minimum number of iterations
XCONV=	specifies the relative parameter convergence criterion
XSIZE=	specifies the value used in XCONV criterion
Step Length	
DAMPSTEP=	dampens steps in line search
INSTEP=	specifies the initial trust region radius
MAXSTEP=	specifies the maximum trust region radius
Printed Output	
PALL	displays (almost) all printed output
PHISTORY	displays optimization history
NOPRINT	suppresses all printed output
Covariance Matrix Tolerances	
ASINGULAR=	absolute singularity for inertia
MSINGULAR=	relative M singularity for inertia
VSINGULAR=	relative V singularity for inertia

Table 18.10 *continued*

Option	Description
Constraint Specifications	
LCEPSILON=	range for active constraints
LCDEACT=	LM tolerance for deactivating
LCSINGULAR=	tolerance for dependent constraints
Remote Monitoring	
SOCKET=	specifies the fileref for remote monitoring

ABSCONV=*r*

ABSTOL=*r*

specifies an absolute function convergence criterion. For minimization, termination requires $f(\boldsymbol{\psi}^{(k)}) \leq r$. The default value of r is the negative square root of the largest double-precision value, which serves only as a protection against overflows.

ABSFCONV=*r* **<** *n* **>**

ABSFTOL=*r* **<** *n* **>**

specifies an absolute function convergence criterion. For all techniques except NMSIMP, termination requires a small change of the function value in successive iterations:

$$|f(\boldsymbol{\psi}^{(k-1)}) - f(\boldsymbol{\psi}^{(k)})| \leq r$$

The same formula is used for the NMSIMP technique, but $\boldsymbol{\psi}(k)$ is defined as the vertex with the lowest function value, and $\boldsymbol{\psi}^{(k-1)}$ is defined as the vertex with the highest function value in the simplex. The default value is $r = 0$. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

ABSGCONV=*r* **<** *n* **>**

ABSGTOL=*r* **<** *n* **>**

specifies an absolute gradient convergence criterion. Termination requires the maximum absolute gradient element to be small:

$$\max_j |g_j(\boldsymbol{\psi}^{(k)})| \leq r$$

This criterion is not used by the NMSIMP technique. The default value is r =1E−5. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

ABSXCONV=*r* **<** *n* **>**

ABSXTOL=*r* **<** *n* **>**

specifies an absolute parameter convergence criterion. For all techniques except NMSIMP, termination requires a small Euclidean distance between successive parameter vectors,

$$\| \boldsymbol{\psi}^{(k)} - \boldsymbol{\psi}^{(k-1)} \|_2 \leq r$$

For the NMSIMP technique, termination requires either a small length $\alpha^{(k)}$ of the vertices of a restart simplex,

$$\alpha^{(k)} \leq r$$

or a small simplex size,

$$\delta^{(k)} \leq r$$

where the simplex size $\delta^{(k)}$ is defined as the L1 distance from the simplex vertex $\boldsymbol{\xi}^{(k)}$ with the smallest function value to the other p simplex points $\boldsymbol{\psi}_l^{(k)} \neq \boldsymbol{\xi}^{(k)}$:

$$\delta^{(k)} = \sum_{\boldsymbol{\psi}_l \neq y} \| \boldsymbol{\psi}_l^{(k)} - \boldsymbol{\xi}^{(k)} \|_1$$

The default is r =1E−8 for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

ASINGULAR=*r*

ASING=*r*

specifies an absolute singularity criterion for the computation of the inertia (number of positive, negative, and zero eigenvalues) of the Hessian and its projected forms. The default value is the square root of the smallest positive double-precision value.

DAMPSTEP<=*r***>**

specifies that the initial step length value $\alpha^{(0)}$ for each line search (used by the QUANEW, CONGRA, or NEWRAP technique) cannot be larger than r times the step length value used in the former iteration. If the DAMPSTEP option is specified but r is not specified, the default is $r = 2$. The DAMPSTEP=*r* option can prevent the line-search algorithm from repeatedly stepping into regions where some objective functions are difficult to compute or where they could lead to floating-point overflows during the computation of objective functions and their derivatives. The DAMPSTEP=*r* option can save time-consuming function calls during the line searches of objective functions that result in very small steps.

FCONV=*r***<** *n***>**

FTOL=*r***<** *n***>**

specifies a relative function convergence criterion. For all techniques except NMSIMP, termination requires a small relative change of the function value in successive iterations,

$$\frac{|f(\boldsymbol{\psi}^{(k)}) - f(\boldsymbol{\psi}^{(k-1)})|}{\max(|f(\boldsymbol{\psi}^{(k-1)})|, \text{FSIZE})} \leq r$$

where FSIZE is defined by the FSIZE= option. The same formula is used for the NMSIMP technique, but $\boldsymbol{\psi}^{(k)}$ is defined as the vertex with the lowest function value, and $\boldsymbol{\psi}^{(k-1)}$ is defined as the vertex with the highest function value in the simplex.

The default is $r = 10^{-\text{FDIGITS}}$, where FDIGITS is by default $-\log_{10}\{\epsilon\}$ and ϵ is the machine precision. Some procedures, such as the GLIMMIX procedure, enable you to change the value with the FDIGITS= option in the PROC statement. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

FCONV2=*r*< *n* >

FTOL2=*r*< *n* >

specifies a second function convergence criterion. For all techniques except NMSIMP, termination requires a small predicted reduction,

$$df^{(k)} \approx f(\boldsymbol{\psi}^{(k)}) - f(\boldsymbol{\psi}^{(k)} + \mathbf{s}^{(k)})$$

of the objective function. The predicted reduction

$$\begin{aligned} df^{(k)} &= -\mathbf{g}^{(k)'}\mathbf{s}^{(k)} - \frac{1}{2}\mathbf{s}^{(k)'}\mathbf{H}^{(k)}\mathbf{s}^{(k)} \\ &= -\frac{1}{2}\mathbf{s}^{(k)'}\mathbf{g}^{(k)} \leq r \end{aligned}$$

is computed by approximating the objective function f by the first two terms of the Taylor series and substituting the Newton step,

$$\mathbf{s}^{(k)} = -[\mathbf{H}^{(k)}]^{-1}\mathbf{g}^{(k)}$$

For the NMSIMP technique, termination requires a small standard deviation of the function values of the $p+1$ simplex vertices $\boldsymbol{\psi}_l^{(k)}$, $l = 0, \ldots, p$,

$$\sqrt{\frac{1}{n+1}\sum_l \left[f(\boldsymbol{\psi}_l^{(k)}) - \overline{f}(\boldsymbol{\psi}^{(k)})\right]^2} \leq r$$

where $\overline{f}(\boldsymbol{\psi}^{(k)}) = \frac{1}{p+1}\sum_l f(\boldsymbol{\psi}_l^{(k)})$. If there are p_{act} boundary constraints active at $\boldsymbol{\psi}^{(k)}$, the mean and standard deviation are computed only for the $n+1-p_{act}$ unconstrained vertices. The default value is $r =$1E−6 for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

FSIZE=*r*

specifies the FSIZE parameter of the relative function and relative gradient termination criteria. The default value is $r = 0$. For more details, see the FCONV= and GCONV= options.

GCONV=*r*< *n* >

GTOL=*r*< *n* >

specifies a relative gradient convergence criterion. For all techniques except CONGRA and NMSIMP, termination requires that the normalized predicted function reduction be small,

$$\frac{\mathbf{g}(\boldsymbol{\psi}^{(k)})'[\mathbf{H}^{(k)}]^{-1}\mathbf{g}(\boldsymbol{\psi}^{(k)})}{\max(|f(\boldsymbol{\psi}^{(k)})|, \mathrm{FSIZE})} \leq r$$

where FSIZE is defined by the FSIZE= option. For the CONGRA technique (where a reliable Hessian estimate $\mathbf{H}$ is not available), the following criterion is used:

$$\frac{\| \mathbf{g}(\boldsymbol{\psi}^{(k)}) \|_2^2 \quad \| \mathbf{s}(\boldsymbol{\psi}^{(k)}) \|_2}{\| \mathbf{g}(\boldsymbol{\psi}^{(k)}) - \mathbf{g}(\boldsymbol{\psi}^{(k-1)}) \|_2 \max(|f(\boldsymbol{\psi}^{(k)})|, \mathrm{FSIZE})} \leq r$$

This criterion is not used by the NMSIMP technique. The default value is $r =$1E−8. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

GCONV2=*r*< *n* >

GTOL2=*r*< *n* >

specifies another relative gradient convergence criterion. For least-squares problems and the TRUREG, LEVMAR, NRRIDG, and NEWRAP techniques, the following criterion of Browne (1982) is used:

$$\max_j \frac{|\mathbf{g}_j(\boldsymbol{\psi}^{(k)})|}{\sqrt{f(\boldsymbol{\psi}^{(k)})\mathbf{H}^{(k)}_{j,j}}} \leq r$$

This criterion is not used by the other techniques. The default value is $r = 0$. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

HESCAL=0 | 1 | 2 | 3

HS=0 | 1 | 2 | 3

specifies the scaling version of the Hessian (or crossproduct Jacobian) matrix used in NRRIDG, TRUREG, LEVMAR, NEWRAP, or DBLDOG optimization.

If HS is not equal to 0, the first iteration and each restart iteration set the diagonal scaling matrix $D^{(0)} = \text{diag}(d_i^{(0)})$:

$$d_i^{(0)} = \sqrt{\max(|H_{i,i}^{(0)}|, \epsilon)}$$

where $H_{i,i}^{(0)}$ are the diagonal elements of the Hessian (or crossproduct Jacobian). In every other iteration, the diagonal scaling matrix $D^{(0)} = \text{diag}(d_i^{(0)})$ is updated depending on the HS option:

HS=0 specifies that no scaling be done.

HS=1 specifies the Moré (1978) scaling update:

$$d_i^{(k+1)} = \max\left[d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}\right]$$

HS=2 specifies the Dennis, Gay, and Welsch (1981) scaling update:

$$d_i^{(k+1)} = \max\left[0.6 * d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}\right]$$

HS=3 specifies that d_i be reset in each iteration:

$$d_i^{(k+1)} = \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}$$

In each scaling update, ϵ is the relative machine precision. The default value is HS=0. Scaling of the Hessian can be time-consuming in the case where general linear constraints are active.

INHESSIAN< =*r* >

INHESS< =*r* >

specifies how the initial estimate of the approximate Hessian is defined for the quasi-Newton techniques QUANEW and DBLDOG. There are two alternatives:

- If you do not use the r specification, the initial estimate of the approximate Hessian is set to the Hessian at $\psi^{(0)}$.
- If you do use the r specification, the initial estimate of the approximate Hessian is set to the multiple of the identity matrix $r\mathbf{I}$.

By default, if you do not specify the option INHESSIAN=r, the initial estimate of the approximate Hessian is set to the multiple of the identity matrix $r\mathbf{I}$, where the scalar r is computed from the magnitude of the initial gradient.

INSTEP=*r*

SALPHA=*r*

RADIUS=*r*

reduces the length of the first trial step during the line search of the first iterations. For highly nonlinear objective functions, such as the EXP function, the default initial radius of the trust-region algorithm TRUREG or DBLDOG or the default step length of the line-search algorithms can result in arithmetic overflows. If this occurs, you should specify decreasing values of $0 < r < 1$ such as INSTEP=1E−1, INSTEP=1E−2, INSTEP=1E−4, and so on, until the iteration starts successfully.

- For trust-region algorithms (TRUREG, DBLDOG), the INSTEP= option specifies a factor $r > 0$ for the initial radius $\Delta^{(0)}$ of the trust region. The default initial trust-region radius is the length of the scaled gradient. This step corresponds to the default radius factor of $r = 1$.
- For line-search algorithms (NEWRAP, CONGRA, QUANEW), the INSTEP= option specifies an upper bound for the initial step length for the line search during the first five iterations. The default initial step length is $r = 1$.
- For the Nelder-Mead simplex algorithm, by using TECH=NMSIMP, the INSTEP=r option defines the size of the start simplex.

LCDEACT=*r*

LCD=*r*

specifies a threshold r for the Lagrange multiplier that determines whether an active inequality constraint remains active or can be deactivated. For maximization, r must be greater than zero; for minimization, r must be smaller than zero. An active inequality constraint can be deactivated only if its Lagrange multiplier is less than the threshold value. The default value is

$$r = \pm \min(0.01, \max(0.1 \times \text{ABSGCONV}, 0.001 \times \text{gmax}^{(k)}))$$

where "+" stands for maximization, "-" stands for minimization, ABSGCONV is the value of the absolute gradient criterion, and $\text{gmax}^{(k)}$ is the maximum absolute element of the gradient or the projected gradient.

LCEPSILON=*r* ≥ 0

LCEPS=*r* ≥ 0

LCE=*r* ≥ 0

specifies the range for active and violated boundary constraints. If the point $\boldsymbol{\psi}^{(k)}$ satisfies the condition

$$|\sum_{j=1}^{k} a_{ij}\psi_j^{(k)} - b_i| \leq r \times (|b_i| + 1)$$

the constraint i is recognized as an active constraint. Otherwise, the constraint i is either an inactive inequality or a violated inequality or equality constraint. The default value is r =1E−8. During the optimization process, the introduction of rounding errors can force the optimization to increase the value of r by a factor of $10, 100, \ldots$. If this happens, it is indicated by a message displayed in the log.

LCSINGULAR=*r* ≥ 0

LCSING=*r* ≥ 0

LCS=*r* $\geq$

specifies a criterion r, used in the update of the QR decomposition, that determines whether an active constraint is linearly dependent on a set of other active constraints. The default value is r =1E−8. The larger r becomes, the more the active constraints are recognized as being linearly dependent. If the value of r is larger than 0.1, it is reset to 0.1.

LINESEARCH=*i*

LIS=*i*

specifies the line-search method for the CONGRA, QUANEW, and NEWRAP optimization techniques. See Fletcher (1987) for an introduction to line-search techniques. The value of i can be $1, \ldots, 8$. For CONGRA, QUANEW, and NEWRAP, the default value is $i = 2$.

LIS=1 specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is similar to one used by the Harwell subroutine library.

LIS=2 specifies a line-search method that needs more function than gradient calls for quadratic and cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option.

LIS=3 specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option.

LIS=4 specifies a line-search method that needs the same number of function and gradient calls for stepwise extrapolation and cubic interpolation.

LIS=5 specifies a line-search method that is a modified version of LIS=4.

LIS=6 specifies golden section line search (Polak 1971), which uses only function values for linear approximation.

LIS=7 specifies bisection line search (Polak 1971), which uses only function values for linear approximation.

LIS=8 specifies the Armijo line-search technique (Polak 1971), which uses only function values for linear approximation.

LSPRECISION=*r*

LSP=*r*

specifies the degree of accuracy that should be obtained by the line-search algorithms LIS=2 and LIS=3. Usually an imprecise line search is inexpensive and successful. For more difficult optimization problems, a more precise and expensive line search might be necessary (Fletcher 1987). The second line-search method (which is the default for the NEWRAP, QUANEW, and CONGRA techniques) and the third line-search method approach exact line search for small LSPRECISION= values. If you have numerical problems, you should try to decrease the LSPRECISION= value to obtain a more precise line search. The default values are shown in Table 18.11.

Table 18.11 Default Values for Line-Search Precision

TECH=	UPDATE=	LSP Default
QUANEW	DBFGS, BFGS	$r = 0.4$
QUANEW	DDFP, DFP	$r = 0.06$
CONGRA	all	$r = 0.1$
NEWRAP	no update	$r = 0.9$

For more details, see Fletcher (1987).

MAXFUNC=*i*

MAXFU=*i*

specifies the maximum number i of function calls in the optimization process. The default values are as follows:

- TRUREG, NRRIDG, NEWRAP, LEVMAR: 125
- QUANEW, DBLDOG: 500
- CONGRA: 1000
- NMSIMP: 3000

Note that the optimization can terminate only after completing a full iteration. Therefore, the number of function calls that are actually performed can exceed the number that is specified by the MAXFUNC= option.

MAXITER=*i*

MAXIT=*i*

specifies the maximum number i of iterations in the optimization process. The default values are as follows:

- TRUREG, NRRIDG, NEWRAP, LEVMAR: 50

- QUANEW, DBLDOG: 200
- CONGRA: 400
- NMSIMP: 1000

These default values are also valid when *i* is specified as a missing value.

MAXSTEP=*r*<*n*>
specifies an upper bound for the step length of the line-search algorithms during the first *n* iterations. By default, *r* is the largest double-precision value and *n* is the largest integer available. Setting this option can improve the speed of convergence for the CONGRA, QUANEW, and NEWRAP techniques.

MAXTIME=*r*
specifies an upper limit of *r* seconds of CPU time for the optimization process. The default value is the largest floating-point double representation of your computer. Note that the time specified by the MAXTIME= option is checked only once at the end of each iteration. Therefore, the actual running time can be much longer than that specified by the MAXTIME= option. The actual running time includes the rest of the time needed to finish the iteration and the time needed to generate the output of the results.

MINITER=*i*
MINIT=*i*
specifies the minimum number of iterations. The default value is 0. If you request more iterations than are actually needed for convergence to a stationary point, the optimization algorithms can behave strangely. For example, the effect of rounding errors can prevent the algorithm from continuing for the required number of iterations.

MSINGULAR=*r* > 0
MSING=*r* > 0
specifies a relative singularity criterion for the computation of the inertia (number of positive, negative, and zero eigenvalues) of the Hessian and its projected forms. The default value is 1E−12.

NOPRINT
suppresses output related to optimization such as the iteration history. The GLIMMIX and HPMIXED procedures do not support printing options in the NLOPTIONS statement.

PALL
displays all optional output for optimization. This option is supported only by the TCALIS procedure.

PHISTORY
PHIST
displays the optimization history. The PHISTORY option is implied if the PALL option is specified. The PHISTORY option is supported only by the TCALIS procedure.

RESTART=*i > 0*

REST=*i > 0*

specifies that the QUANEW or CONGRA algorithm is restarted with a steepest descent/ascent search direction after, at most, i iterations. Default values are as follows:

- CONGRA: UPDATE=PB: restart is performed automatically, i is not used.
- CONGRA: UPDATE≠PB: $i = \min(10p, 80)$, where p is the number of parameters.
- QUANEW: i is the largest integer available.

SINGULAR=*r*

SING=*r*

specifies the singularity criterion r, $r0 \leq r \leq 1$, that is used for the inversion of the Hessian matrix. The default value is 1E−8.

SOCKET=*fileref*

specifies the fileref that contains the information needed for remote monitoring. See the section "Remote Monitoring" on page 403 for more details.

TECHNIQUE=*value*

TECH=*value*

OMETHOD=*value*

OM=*value*

specifies the optimization technique. You can find additional information about choosing an optimization technique in the section "Choosing an Optimization Algorithm" on page 405. Valid values for the TECHNIQUE= option are as follows:

- CONGRA
  performs a conjugate-gradient optimization, which can be more precisely specified with the UPDATE= option and modified with the LINESEARCH= option. When you specify this option, UPDATE=PB by default.
- DBLDOG
  performs a version of double-dogleg optimization, which can be more precisely specified with the UPDATE= option. When you specify this option, UPDATE=DBFGS by default.
- LEVMAR
  performs a highly stable but, for large problems, memory- and time-consuming Levenberg-Marquardt optimization technique, a slightly improved variant of the Moré (1978) implementation. You can also specify this technique with the alias LM or MARQUARDT. In the TCALIS procedure, this is the default optimization technique if there are fewer than 40 parameters to estimate. The GLIMMIX and HPMIXED procedures do not support this optimization technique.
- NMSIMP
  performs a Nelder-Mead simplex optimization. The TCALIS procedure does not support this optimization technique.
- NONE
  does not perform any optimization. This option can be used for the following:

  - to perform a grid search without optimization
  - to compute estimates and predictions that cannot be obtained efficiently with any of the optimization techniques
  - to obtain inferences for known values of the covariance parameters
- NEWRAP
  performs a Newton-Raphson optimization combining a line-search algorithm with ridging. The line-search algorithm LIS=2 is the default method.
- NRRIDG
  performs a Newton-Raphson optimization with ridging.
- QUANEW
  performs a quasi-Newton optimization, which can be defined more precisely with the UPDATE= option and modified with the LINESEARCH= option.
- TRUREG
  performs a trust-region optimization.

UPDATE=*method*
UPD=*method*

specifies the update method for the quasi-Newton, double-dogleg, or conjugate-gradient optimization technique. Not every update method can be used with each optimizer.

The following are the valid methods for the UPDATE= option:

- BFGS
  performs the original Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the inverse Hessian matrix.
- DBFGS
  performs the dual BFGS update of the Cholesky factor of the Hessian matrix. This is the default update method.
- DDFP
  performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
- DFP
  performs the original DFP update of the inverse Hessian matrix.
- PB
  performs the automatic restart update method of Powell (1977) and Beale (1972).
- FR
  performs the Fletcher-Reeves update (Fletcher 1987).
- PR
  performs the Polak-Ribiere update (Fletcher 1987).
- CD
  performs a conjugate-descent update of Fletcher (1987).

VERSION=1 | 2
VS=1 | 2

specifies the version of the quasi-Newton optimization technique with nonlinear constraints.

VS=1 specifies the update of the μ vector as in Powell (1978a, 1978b) (update like VF02AD).

VS=2 specifies the update of the μ vector as in Powell (1982a, 1982b) (update like VMCWD).

The default is VERSION=2.

VSINGULAR=*r* > 0

VSING=*r* > 0

specifies a relative singularity criterion for the computation of the inertia (number of positive, negative, and zero eigenvalues) of the Hessian and its projected forms. The default value is $r = 1\text{E}{-8}$.

XCONV=*r***<** *n***>**

XTOL=*r***<** *n***>**

specifies the relative parameter convergence criterion. For all techniques except NMSIMP, termination requires a small relative parameter change in subsequent iterations:

$$\frac{\max_j |\psi_j^{(k)} - \psi_j^{(k-1)}|}{\max(|\psi_j^{(k)}|, |\psi_j^{(k-1)}|, \text{XSIZE})} \leq r$$

For the NMSIMP technique, the same formula is used, but $\psi_j^{(k)}$ is defined as the vertex with the lowest function value and $\psi_j^{(k-1)}$ is defined as the vertex with the highest function value in the simplex.

The default value is $r = 1\text{E}{-8}$ for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

XSIZE=*r*

specifies the XSIZE parameter of the relative parameter termination criterion, $r \geq 0$. The default value is $r = 0$. For more details, see the XCONV= option.

Remote Monitoring

SAS/EmMonitor is an application for Windows that enables you to monitor a CPU-intensive application running on a remote server. Remote monitoring is support through the NLOPTIONS statement.

On the server side, a FILENAME statement assigns a fileref to a SOCKET-type device that defines the IP address of the client and the port number for listening. The fileref is then specified in the SOCKET= option in the NLOPTIONS statement to control the SAS/EmMonitor application. The following statements show an example of server-side code:

```
filename sock socket 'your.pc.address.com:6943';

proc glimmix data=bigdataset;
   class year;
   model y1 = x1 x2 x3 / dist=gamma link=log;
   random x1 x3 / type=rsmooth knotmethod=kdtree(bucket=8)
                  subject=year;
   nloptions tech=nrridg gconv=2.e-5 socket=sock;
run;
```

On the client side, the SAS/EmMonitor application is started with the following syntax:

EmMonitor *options*

The options are as follows:

-p port_number	defines the port number.
-t title	defines the title of the SAS/EmMonitor window.
-k	keeps the monitor alive when the iteration is completed.

The default port number is 6943.

By default, the PC client displays on its **Graph** tab the objective function of the optimization process as the first Plot Group. The largest absolute gradient can be monitored as the next Plot Group. You can intervene in the optimization process through the **Stop Current** and **Stop All** buttons. Signaling the server by clicking these buttons effectively terminates the optimization. In a singly iterative optimization, clicking either of the two buttons halts the optimization process when the signal is received on the server side. The current parameter estimates are accepted, and postoptimization processing is based on these values. Note that this is different from a condition where the usual termination criterion is not met, such as when the maximum number of iterations is exceeded. If an optimization does not meet the termination criterion, no postprocessing occurs.

In doubly iterative processes, the **Stop All** button terminates the overall optimization process and accepts the current estimates. The **Stop Current** button stops the current optimization and uses the current parameter estimates to start the next optimization.

The server does not need to be running when you start the SAS/EmMonitor application, and you can start or stop it at any time during the iteration process. You need to remember only the port number.

If you do not start the PC client, or if you close it prematurely, it will have no effect on the server side. In other words, the iteration process will continue until one of the criteria for termination is met.

Choosing an Optimization Algorithm

First- or Second-Order Algorithms

The factors that go into choosing a particular optimization technique for a particular problem are complex. Trial and error can be involved.

For many optimization problems, computing the gradient takes more computer time than computing the function value. Computing the Hessian sometimes takes *much* more computer time and memory than computing the gradient, especially when there are many decision variables. Unfortunately, optimization techniques that do not use some kind of Hessian approximation usually require many more iterations than techniques that do use a Hessian matrix, and, as a result, the total run time of these techniques is often longer. Techniques that do not use the Hessian also tend to be less reliable. For example, they can terminate more easily at stationary points than at global optima.

Table 18.12 shows which derivatives are required for each optimization technique (FOD: first-order derivatives (=gradient evaluation); SOD: second-order derivatives (=Hessian evaluation)).

Table 18.12 First-Order and Second-Order Derivatives

Algorithm	FOD	SOD
LEVMAR	x	x
TRUREG	x	x
NEWRAP	x	x
NRRIDG	x	x
QUANEW	x	-
DBLDOG	x	-
CONGRA	x	-
NMSIMP	-	-

The second-derivative methods TRUREG, NEWRAP, and NRRIDG are best for small problems where the Hessian matrix is not expensive to compute. Sometimes the NRRIDG algorithm can be faster than the TRUREG algorithm, but TRUREG can be more stable. The NRRIDG algorithm requires only one matrix with $p(p+1)/2$ double words; TRUREG and NEWRAP require two such matrices. Here, p denotes the number of parameters in the optimization.

The first-derivative methods QUANEW and DBLDOG are best for medium-sized problems where the objective function and the gradient are much faster to evaluate than the Hessian. The QUANEW and DBLDOG algorithms, in general, require more iterations than TRUREG, NRRIDG, and NEWRAP, but each iteration can be much faster. The QUANEW and DBLDOG algorithms require only the gradient to update an approximate Hessian, and they require slightly less memory than TRUREG or NEWRAP (essentially one matrix with $p(p+1)/2$ double words).

The first-derivative method CONGRA is best for large problems where the objective function and the gradient can be computed much faster than the Hessian and where too much memory is required to store the (approximate) Hessian. The CONGRA algorithm, in general, requires more iterations than QUANEW or DBLDOG, but each iteration can be much faster. Because CONGRA requires

only a factor of p double-word memory, many large applications can be solved only by CONGRA.

The no-derivative method NMSIMP is best for small problems where derivatives are not continuous or are very difficult to compute.

Each optimization method employs one or more convergence criteria that determine when it has converged. An algorithm is considered to have converged when any one of the convergence criteria is satisfied. For example, under the default settings, the QUANEW algorithm will converge if ABSGCONV <1E−5, FCONV $< 10^{-FDIGITS}$, or GCONV <1E−8.

Algorithm Descriptions

Trust Region Optimization (TRUREG)

The trust region method uses the gradient $\mathbf{g}(\boldsymbol{\psi}^{(k)})$ and the Hessian matrix $\mathbf{H}(\boldsymbol{\psi}^{(k)})$; thus, it requires that the objective function $f(\boldsymbol{\psi})$ have continuous first- and second-order derivatives inside the feasible region.

The trust region method iteratively optimizes a quadratic approximation to the nonlinear objective function within a hyperelliptic trust region with radius Δ that constrains the step size corresponding to the quality of the quadratic approximation. The trust region method is implemented based on Dennis, Gay, and Welsch (1981), Gay (1983), and Moré and Sorensen (1983).

The trust region method performs well for small to medium-sized problems, and it does not need many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms might be more efficient.

Newton-Raphson Optimization with Line Search (NEWRAP)

The NEWRAP technique uses the gradient $\mathbf{g}(\boldsymbol{\psi}^{(k)})$ and the Hessian matrix $\mathbf{H}(\boldsymbol{\psi}^{(k)})$; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region. If second-order derivatives are computed efficiently and precisely, the NEWRAP method can perform well for medium-sized to large problems, and it does not need many function, gradient, and Hessian calls.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. Otherwise, a combination of ridging and line search is performed to compute successful steps. If the Hessian is not positive definite, a multiple of the identity matrix is added to the Hessian matrix to make it positive definite (Eskow and Schnabel 1991).

In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic interpolation and cubic extrapolation (LIS=2).

Newton-Raphson Ridge Optimization (NRRIDG)

The NRRIDG technique uses the gradient $\mathbf{g}(\boldsymbol{\psi}^{(k)})$ and the Hessian matrix $\mathbf{H}(\boldsymbol{\psi}^{(k)})$; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. If at least one of these two conditions is not satisfied, a multiple of the identity matrix is added to the Hessian matrix.

The NRRIDG method performs well for small to medium-sized problems, and it does not require many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms might be more efficient.

Because the NRRIDG technique uses an orthogonal decomposition of the approximate Hessian, each iteration of NRRIDG can be slower than that of the NEWRAP technique, which works with a Cholesky decomposition. Usually, however, NRRIDG requires fewer iterations than NEWRAP.

Quasi-Newton Optimization (QUANEW)

The (dual) quasi-Newton method uses the gradient $\mathbf{g}(\boldsymbol{\psi}^{(k)})$, and it does not need to compute second-order derivatives because they are approximated. It works well for medium-sized to moderately large optimization problems, where the objective function and the gradient are much faster to compute than the Hessian. However, in general, it requires more iterations than the TRUREG, NEWRAP, and NRRIDG techniques, which compute second-order derivatives. QUANEW is the default optimization algorithm because it provides an appropriate balance between the speed and stability required for most nonlinear mixed model applications.

The QUANEW technique is one of the following, depending upon the value of the UPDATE= option:

- the original quasi-Newton algorithm, which updates an approximation of the inverse Hessian
- the dual quasi-Newton algorithm, which updates the Cholesky factor of an approximate Hessian (default)

You can specify four update formulas with the UPDATE= option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the Cholesky factor of the Hessian matrix. This is the default.
- DDFP performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
- BFGS performs the original BFGS update of the inverse Hessian matrix.
- DFP performs the original DFP update of the inverse Hessian matrix.

In each iteration, a line search is performed along the search direction to find an approximate optimum. The default line-search method uses quadratic interpolation and cubic extrapolation to obtain a step size α satisfying the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit of the step size. Violating the left-side Goldstein condition can affect the positive definiteness of the quasi-Newton update. In that case, either the update is skipped or the iterations are restarted with an identity matrix, resulting in the steepest descent or ascent search direction. You can specify line-search algorithms other than the default with the LIS= option.

The QUANEW algorithm uses its own line-search technique. Not all options and parameters (except the INSTEP= option) controlling the line search in the other algorithms apply here. In several applications, large steps in the first iterations are troublesome. You can use the INSTEP= option to impose an upper bound for the step size α during the first five iterations. You can also use the INHESSIAN[=r] option to specify a different starting approximation for the Hessian. If you specify only the INHESSIAN option, the Cholesky factor of a (possibly ridged) finite-difference approximation of the Hessian is used to initialize the quasi-Newton update process.

Double-Dogleg Optimization (DBLDOG)

The double-dogleg optimization method combines the ideas of the quasi-Newton and trust region methods. In each iteration, the double-dogleg algorithm computes the step $\mathbf{s}^{(k)}$ as the linear combination of the steepest descent or ascent search direction $\mathbf{s}_1^{(k)}$ and a quasi-Newton search direction $\mathbf{s}_2^{(k)}$,

$$\mathbf{s}^{(k)} = \alpha_1 \mathbf{s}_1^{(k)} + \alpha_2 \mathbf{s}_2^{(k)}$$

The step is requested to remain within a prespecified trust region radius; see Fletcher (1987, p. 107). Thus, the DBLDOG subroutine uses the dual quasi-Newton update but does not perform a line search. You can specify two update formulas with the UPDATE= option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno update of the Cholesky factor of the Hessian matrix. This is the default.
- DDFP performs the dual Davidon, Fletcher, and Powell update of the Cholesky factor of the Hessian matrix.

The double-dogleg optimization technique works well for medium-sized to moderately large optimization problems, where the objective function and the gradient are much faster to compute than the Hessian. The implementation is based on Dennis and Mei (1979) and Gay (1983), but it is extended for dealing with boundary and linear constraints. The DBLDOG technique generally requires more iterations than the TRUREG, NEWRAP, or NRRIDG technique, which requires second-order derivatives; however, each of the DBLDOG iterations is computationally cheap. Furthermore, the DBLDOG technique requires only gradient calls for the update of the Cholesky factor of an approximate Hessian.

Conjugate Gradient Optimization (CONGRA)

Second-order derivatives are not required by the CONGRA algorithm and are not even approximated. The CONGRA algorithm can be expensive in function and gradient calls, but it requires only

$O(p)$ memory for unconstrained optimization. In general, many iterations are required to obtain a precise solution, but each of the CONGRA iterations is computationally cheap. You can specify four different update formulas for generating the conjugate directions by using the UPDATE= option:

- PB performs the automatic restart update method of Powell (1977) and Beale (1972). This is the default.
- FR performs the Fletcher-Reeves update (Fletcher 1987).
- PR performs the Polak-Ribiere update (Fletcher 1987).
- CD performs a conjugate-descent update of Fletcher (1987).

The default often behaves best for typical examples, whereas UPDATE=CD can perform poorly.

The CONGRA subroutine should be used for optimization problems with large p. For the unconstrained or boundary-constrained case, CONGRA requires only $O(p)$ bytes of working memory, whereas all other optimization methods require order $O(p^2)$ bytes of working memory. During p successive iterations, uninterrupted by restarts or changes in the working set, the conjugate gradient algorithm computes a cycle of p conjugate search directions. In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic interpolation and cubic extrapolation to obtain a step size α satisfying the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit for the step size. Other line-search algorithms can be specified with the LIS= option.

Nelder-Mead Simplex Optimization (NMSIMP)

The Nelder-Mead simplex method does not use any derivatives and does not assume that the objective function has continuous derivatives. The objective function itself needs to be continuous. This technique is quite expensive in the number of function calls, and it might be unable to generate precise results for $p \gg 40$.

The original Nelder-Mead simplex algorithm is implemented and extended to boundary constraints. This algorithm does not compute the objective for infeasible points, but it changes the shape of the simplex adapting to the nonlinearities of the objective function, which contributes to an increased speed of convergence. It uses a special termination criterion.

Programming Statements

This section applies to the following procedures:
CALIS, GLIMMIX, MCMC, NLIN, NLMIXED, and TCALIS.

The majority of the modeling procedures in SAS/STAT can take advantage of the fact that the statistical model can easily be translated into programming syntax (statements and options). Several procedures, however, require additional flexibility in specifying models—for example, when the model contains general nonlinear functions, when it is necessary to specify complicated restrictions, or when user-supplied expressions need to be evaluated. These procedures, listed at the beginning of the section, support—in addition to the usual procedure statements and options—programming statements that can be used in the SAS DATA step.

The following are valid statements:

ABORT;
CALL *name* < **(** *expression* < **,** *expression . . .* > **)** >**;**
DELETE;
DO < *variable* **=** *expression*
< **TO** *expression*> < **BY** *expression*>
< **,** *expression* < **TO** *expression*> < **BY** *expression* > . . . >
>
< **WHILE** *expression* > < **UNTIL** *expression* >**;**
END;
GOTO *statement-label*;
IF *expression*;
IF *expression* **THEN** *program-statement*;
ELSE *program-statement*;
variable **=** *expression*;
variable **+** *expression*;
LINK *statement-label*;
PUT < *variable*> < **=** > < *...* >**;**
RETURN;
SELECT < **(** *expression* **)** >**;**
STOP;
SUBSTR(*variable, index, length* **) =** *expression*;
WHEN (*expression*) *program-statement*;
OTHERWISE *program-statement*;

For the most part, these programming statements work the same as they do in the SAS DATA step, as documented in *SAS Language Reference: Concepts*. However, there are several differences:

- The ABORT statement does not allow any arguments.
- The DO statement does not allow a character index variable. Thus

```
do i = 1,2,3;
```

is supported, whereas the following statement is not supported:

```
do i = 'A','B','C';
```

- Not all procedures support LAG functionality. For example, the GLIMMIX procedure does not support lags.
- The PUT statement, used mostly for program debugging, supports only some of the features of the DATA step PUT statement, and it has some features not available with the DATA step PUT statement:
  - The PUT statement does not support line pointers, factored lists, iteration factors, overprinting, _INFILE_, the colon (:) format modifier, or "$".
  - The PUT statement does support expressions, but the expression must be enclosed in parentheses. For example, the following statement displays the square root of x:

    ```
    put (sqrt(x));
    ```

  - The PUT statement supports the item _PDV_ to display a formatted listing of all variables in the program. For example:

    ```
    put _pdv_;
    ```

- The WHEN and OTHERWISE statements enable you to specify more than one target statement. That is, DO/END groups are not necessary for multiple-statement WHENs. For example, the following syntax is valid:

```
select;
   when (exp1) stmt1;
               stmt2;
   when (exp2) stmt3;
               stmt4;
end;
```

Please consult the individual chapters for other, procedure-specific differences between programming statements and the SAS DATA step and for procedure-specific details, limitations, and rules.

The LINK statement is used in a program to jump immediately to the label *statement_label* and to continue program execution at that point. It is not used to specify a link function in a generalized linear model.

When coding your programming statements, you should avoid defining variables that begin with an underscore (_), because they might conflict with internal variables created by procedures that support programming statements.

Overview

Power and sample size analysis optimizes the resource usage and design of a study, improving chances of conclusive results with maximum efficiency. The standard statistical testing paradigm implicitly assumes that Type I errors (mistakenly concluding significance when there is no true effect) are more costly than Type II errors (missing a truly significant result). This may be appropriate for your situation, or the relative costs of the two types of error may be reversed. For example, in screening experiments for drug development, it is often less damaging to carry a few false positives

forward for follow-up testing than to miss potential leads. Power and sample size analysis can help you achieve your desired balance between Type I and Type II errors. With optimal designs and sample sizes, you can improve your chances of detecting effects that might otherwise have been ignored, save money and time, and perhaps minimize risks to subjects.

Relevant tools in SAS/STAT software for power and sample size analysis include the following:

- the GLMPOWER procedure
- the POWER procedure
- the Power and Sample Size application
- the %POWTABLE macro
- various procedures, statements, and functions in Base SAS and SAS/STAT for developing customized formulas and simulations

These tools, discussed in detail in the section "SAS/STAT Tools for Power and Sample Size Analysis" on page 419, deal exclusively with *prospective* analysis—that is, planning for a future study. This is in contrast to *retrospective* analysis for a past study, which is not supported by the main tools. Although retrospective analysis is more convenient to perform, it is often uninformative or misleading, especially when power is computed directly based on observed data.

The goals of prospective power and sample size analysis include the following:

- determining the sample size required to get a significant result with adequate probability (power)
- characterizing the power of a study to detect a meaningful effect
- computing the probability of achieving the desired precision of a confidence interval, or the sample size required to ensure this probability
- conducting what-if analyses to assess how sensitive the power or required sample size is to other factors

The phrase *power analysis* is used for the remainder of this document as a shorthand to represent any or all of these goals. For more information about the GLMPOWER procedure, see Chapter 41, "The GLMPOWER Procedure." For more information about the POWER procedure, see Chapter 67, "The POWER Procedure." For more information about the Power and Sample Size application, see Chapter 68, "The Power and Sample Size Application."

Coverage of Statistical Analyses

The GLMPOWER procedure covers power analysis for Type III tests and contrasts of fixed effects in univariate linear models, optionally with covariates. The covariates can be continuous or categorical. Tests and contrasts involving random effects are not supported.

The POWER procedure covers power analysis for the following:

- t tests, equivalence tests, and confidence intervals for means
- tests, equivalence tests, and confidence intervals for binomial proportions
- multiple regression
- tests of correlation and partial correlation
- one-way analysis of variance
- rank tests for comparing two survival curves
- logistic regression with binary response
- Wilcoxon Mann-Whitney rank-sum test

The Power and Sample Size application covers a large subset of the analyses in the GLMPOWER and POWER procedures.

Statistical Background

Hypothesis Testing, Power, and Confidence Interval Precision

Standard Hypothesis Tests

In statistical hypothesis testing, you typically express the belief that some effect exists in a population by specifying an alternative hypothesis H_1. You state a null hypothesis H_0 as the assertion that the effect does *not* exist and attempt to gather evidence to reject H_0 in favor of H_1. Evidence is gathered in the form of sample data, and a statistical test is used to assess H_0. If H_0 is rejected but there really is *no* effect, this is called a *Type I error*. The probability of a Type I error is usually designated "alpha" or α, and statistical tests are designed to ensure that α is suitably small (for example, less than 0.05).

If there is an effect in the population but H_0 is *not* rejected in the statistical test, then a *Type II error* has been committed. The probability of a Type II error is usually designated "beta" or β. The probability $1-\beta$ of avoiding a Type II error (that is, correctly rejecting H_0 and achieving statistical significance) is called the *power* of the test.

Most, but not all, of the power analyses in the GLMPOWER and POWER procedures are based on such standard hypothesis tests.

Equivalence and Noninferiority

Whereas the standard two-sided hypothesis test for a parameter μ (such as a mean difference) aims to demonstrate that it is significantly different than a null value μ_0:

$$H_0{:}\mu = \mu_0$$
$$H_1{:}\mu \neq \mu_0$$

an equivalence test instead aims to demonstrate that it is *significantly similar* to some value, expressed in terms of a range θ_L, θ_U around that value:

$$H_0{:}\mu < \theta_L \quad \text{or} \quad \mu > \theta_U$$
$$H_1{:}\theta_L \leq \mu \leq \theta_U$$

Whereas the standard one-sided hypothesis test for μ (say, the upper one-sided test) aims to demonstrate that it is significantly greater than μ_0:

$$H_0{:}\mu \leq \mu_0$$
$$H_1{:}\mu > \mu_0$$

a corresponding noninferiority test aims to demonstrate that it is *not significantly less* than μ_0, expressed in terms of a margin $\delta > 0$:

$$H_0{:}\mu \leq \mu_0 - \delta$$
$$H_1{:}\mu > \mu_0 - \delta$$

Corresponding forms of these hypotheses with the inequalities reversed apply to lower one-sided noninferiority tests (sometimes called *nonsuperiority* tests).

The POWER procedure performs power analyses for equivalence tests for one-sample, paired, and two-sample tests of normal and lognormal mean differences and ratios. It also supports noninferiority tests for a variety of analyses of means, proportions, and correlation, both directly (with a MARGIN= option representing δ) and indirectly (with an option for a custom null value representing the sum or difference of μ_0 and δ).

Confidence Interval Precision

An analysis of confidence interval precision is analogous to a traditional power analysis, with *CI Half-Width* taking the place of effect size and *Prob(Width)* taking the place of power. The *CI Half-Width* is the margin of error associated with the confidence interval, the distance between the point estimate and an endpoint. The *Prob(Width)* is the probability of obtaining a confidence interval with *at most* a target half-width.

The POWER procedure performs confidence interval precision analyses for *t*-based confidence intervals for one-sample, paired, and two-sample designs, and for several varieties of confidence intervals for a binomial proportion.

Computing Power and Sample Size

For some statistical models and tests, power analysis calculations are exact—that is, they are based on a mathematically accurate formula that expresses power in terms of the other components. Such formulas typically involve either enumeration or noncentral versions of the distribution of the test statistic.

When a power computation is based on a noncentral t, F, or chi-square distribution, the noncentrality parameter generally has the same form as the test statistic, with the conjectured population parameters in place of their corresponding estimators.

For example, the test statistic for a two-sample t test is computed as follows:

$$t = N^{\frac{1}{2}}(w_1 w_2)^{\frac{1}{2}}\left(\frac{\bar{x}_2 - \bar{x}_1 - \mu_0}{s_p}\right)$$

where N is the total sample size, w_1 and w_2 are the group allocation weights, $\bar{x}_1$ and $\bar{x}_2$ are the sample means, μ_0 is the null mean difference, and s_p is the pooled standard deviation. Under the null hypothesis, the statistic $F = t^2$ is distributed as $F(1, N-2)$. In general, F has a noncentral F distribution $F(1, N-2, \delta^2)$ where

$$\delta = N^{\frac{1}{2}}(w_1 w_2)^{\frac{1}{2}}\left(\frac{\mu_{\text{diff}} - \mu_0}{\sigma}\right)$$

and μ_{diff} and σ are the (unknown) true mean difference and common group standard deviation, respectively. Note that the square-root noncentrality δ is exactly the same as the t statistic except that the estimators of mean difference and standard deviation are replaced by their correponding true population values.

The power for the two-sided two-sample t test with significance level α is computed as

$$P\left(F \geq F_{1-\alpha}(1, N-2)\right)$$

where F is distributed as $F(1, N-2, \delta^2)$ and $F_{1-\alpha}(1, N-2)$ is the $100(1-\alpha)\%$ quantile of the central F distribution with 1 and $N-2$ degrees of freedom. See the section "Customized Power Formulas (DATA Step)" on page 428 for an example of the implementation of this formula in the DATA step.

In the absence of exact mathematical results, approximate formulas can sometimes be used. When neither exact power computations nor reasonable approximations are possible, simulation provides an increasingly viable alternative. You specify values for model parameters and use them to randomly generate a large number of hypothetical data sets. Applying the statistical test to each data set, you estimate power with the percentage of times the null hypothesis is rejected. While the simulation approach is computationally intensive, faster computing makes this less of an issue. A simulation-based power analysis is always a valid option, and, with a large number of data set replications, it can often be more accurate than approximations. See the section "Empirical Power Simulation (DATA Step, SAS/STAT Software)" on page 429 for an example of an empirical power simulation.

Sample size is usually computed by iterative numerical methods because it often cannot be expressed in closed form as a function of the other parameters. Sample size tends to appear in both a noncentrality parameter and a degrees of freedom term for the critical value.

Power and Study Planning

Power analysis is most effective when performed at the study planning stage, and as such it encourages early collaboration between researcher and statistician. It also focuses attention on effect sizes and variability in the underlying scientific process, concepts that both researcher and statistician should consider carefully at this stage.

There are many factors involved in a power analysis, such as the research objective, design, data analysis method, power, sample size, Type I error, variability, and effect size. By performing a power analysis, you can learn about the relationships between these factors, optimizing those that are under your control and exploring the implications of those that are fixed or unknown.

Components of Study Planning

Even when the research questions and study design seem straightforward, the ensuing power analysis can seem technically daunting. It is often helpful to break the process down into five components:

- **Study Design**: What is the structure of the planned design? This must be clearly and completely specified. What groups and treatments ("cells" and "factors" of the design) are going to be assessed, and what will be the relative sizes of those cells? How is each case going to be studied—that is, what is the primary outcome measure ("dependent variable")? Will covariates be measured and included in the statistical model?
- **Scenario Model**: What are your beliefs about patterns in the data? Imagine that you had unlimited time and resources to execute the study design, so that you could gather an "infinite data set." Characterize that infinite data set as best you can using a mathematical model, realizing that it will be a simplification of reality. Alternatively, as is common with complex linear models, you may decide to construct an "exemplary" data set that mimics the infinite data set. However you do this, your scenario model should capture the key features of the study design and the main relationships among the primary outcome variables and study factors.
- **Effects and Variability**: What exactly are the "signals and noises" in the patterns you suspect? Set specific values for the parameters of your scenario model, keeping at most one unspecified. It is often enlightening to consider a variety of realistic possibilities for the key values by performing a sensitivity analysis, to explore the consequences of competing views on what the infinite data set might look like.
- **Statistical Method**: How will you cast your model in statistical terms and conduct the eventual data analysis? Define the statistical models and procedures that will be used to embody the study design and estimate and/or test the effects central to the research question. What significance levels will be used? Will one- or two-sided tests be used?
- **Aim of Assessment**: Finally, what needs to be determined in the power analysis? Most often you want to examine the statistical powers obtained across the various scenarios for

the effects, variability, alternative varieties of the statistical procedures to be used, and the feasible total sample sizes. Sometimes the goal is to find sample size values that provide given levels of power, say 85%, 90%, or 95%.

Effect Size

There is some confusion in practice about how to postulate the effect size. One alternative is to specify the effect size that represents minimal clinical significance; then the result of the power analysis reveals the chances of detecting a minimally meaningful effect size. Often this minimal effect size is so small that it requires excessive resources to detect. Another alternative is to make an educated guess of the true underlying effect size. Then the power analysis determines the chance of detecting the effect size that is believed to be true. The choice is ultimately determined by the research goals. Finally, you can specify a collection of possible values, perhaps spanning the range between minimally meaningful effects and larger surmised effects.

You can arrive at values for required quantities in a power analysis, such as effect sizes and measures of variability, in many different ways. For example, you can use pilot data, results of previous studies reported in literature, educated guesses derived from theory, or educated guesses derived from partial data (a small sample or even just quantiles).

Uncertainty and Sensitivity Analysis

Uncertainty is a fact of life in any power analysis, because at least some of the numbers used are best guesses of unknown values. The result of a power calculation, whether it be achieved power or required sample size or something else, serves only as a point estimate, conditional on the conjectured values of the other components. It is not feasible in general to quantify the variability involved in using educated guesses or undocumented results to specify these components. If observed data are used, relevant adjustments for variability in the data tend to be problematic in the sense of producing confidence intervals for power that are too wide for practical use. But there is a useful way for you to characterize the uncertainty in your power analysis, and also discover the extent to which statistical power is affected by each component. You can posit a reasonable range for each input component, vary each one within its range, and observe the variety of results in the form of tables or graphs.

SAS/STAT Tools for Power and Sample Size Analysis

This section demonstrates how you can use the different SAS power analysis tools mentioned in the section “Overview” on page 413 to generate graphs, tables, and narratives; implement your own power formulas; and simulate empirical power.

Suppose you want to compute the power of a two-sample *t* test. You conjecture that the mean difference is between 5 and 6 and that the common group standard deviation is between 12 and 18. You plan to use a significance level between 0.05 and 0.1 and a sample size between 100 and 200. The following SAS statements use the POWER procedure to compute the power for these scenarios:

```
proc power;
   twosamplemeans test=diff
      meandiff = 5 6
      stddev = 12 18
      alpha = 0.05 0.1
      ntotal = 100 200
      power = .;
run;
```

Figure 19.1 shows the results. Depending on the plausibility of the various combinations of input parameter values, the power ranges between 0.379 and 0.970.

Figure 19.1 PROC POWER Tabular Output

The POWER Procedure
Two-sample t Test for Mean Difference

Computed Power

Index	Alpha	Mean Diff	Std Dev	N Total	Power
1	0.05	5	12	100	0.541
2	0.05	5	12	200	0.834
3	0.05	5	18	100	0.280
4	0.05	5	18	200	0.498
5	0.05	6	12	100	0.697
6	0.05	6	12	200	0.940
7	0.05	6	18	100	0.379
8	0.05	6	18	200	0.650
9	0.10	5	12	100	0.664
10	0.10	5	12	200	0.902
11	0.10	5	18	100	0.397
12	0.10	5	18	200	0.623
13	0.10	6	12	100	0.799
14	0.10	6	12	200	0.970
15	0.10	6	18	100	0.505
16	0.10	6	18	200	0.759

The following seven sections illustrate additional ways of displaying these results using the different SAS tools.

Basic Graphs (POWER, GLMPOWER, Power and Sample Size Application)

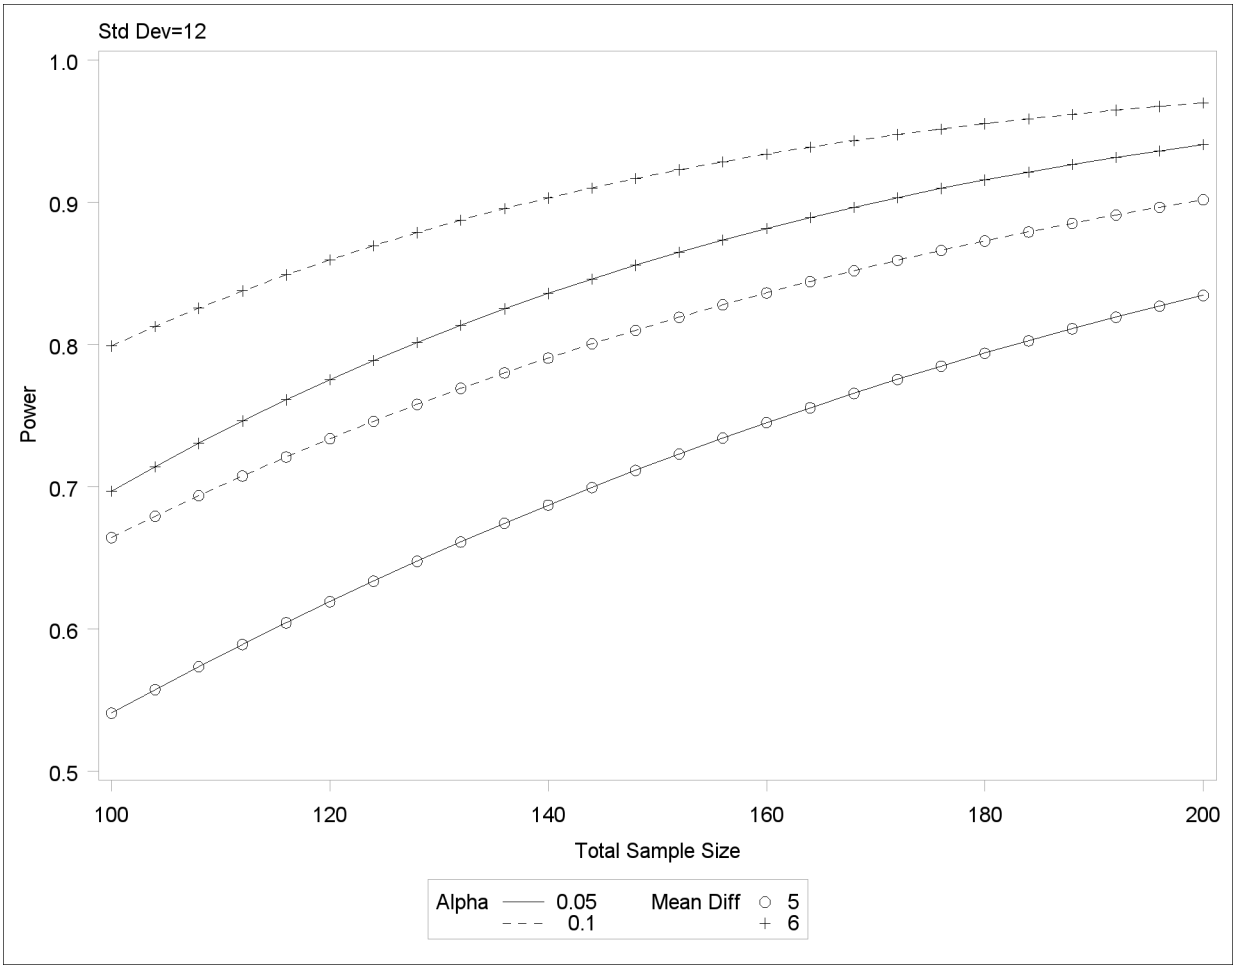
If you include a PLOT statement, the GLMPOWER and POWER procedures produce standard power curves, representing any multi-valued input parameters with varying line styles, symbols, colors, and/or panels. The Power and Sample Size application also has an option to produce power curves.

To display default power curves for the preceding PROC POWER call, simply add the PLOT statement with no arguments as follows:

```
proc power plotonly;
   twosamplemeans test=diff
      meandiff = 5 6
      stddev = 12 18
      alpha = 0.05 0.1
      ntotal = 100 200
      power = .;
   plot;
run;
```

Figure 19.2 shows the results. Note that the line style varies by the significance level α, the symbol varies by the mean difference, and the panel varies by standard deviation.

Figure 19.2 PROC POWER Default Graphical Output



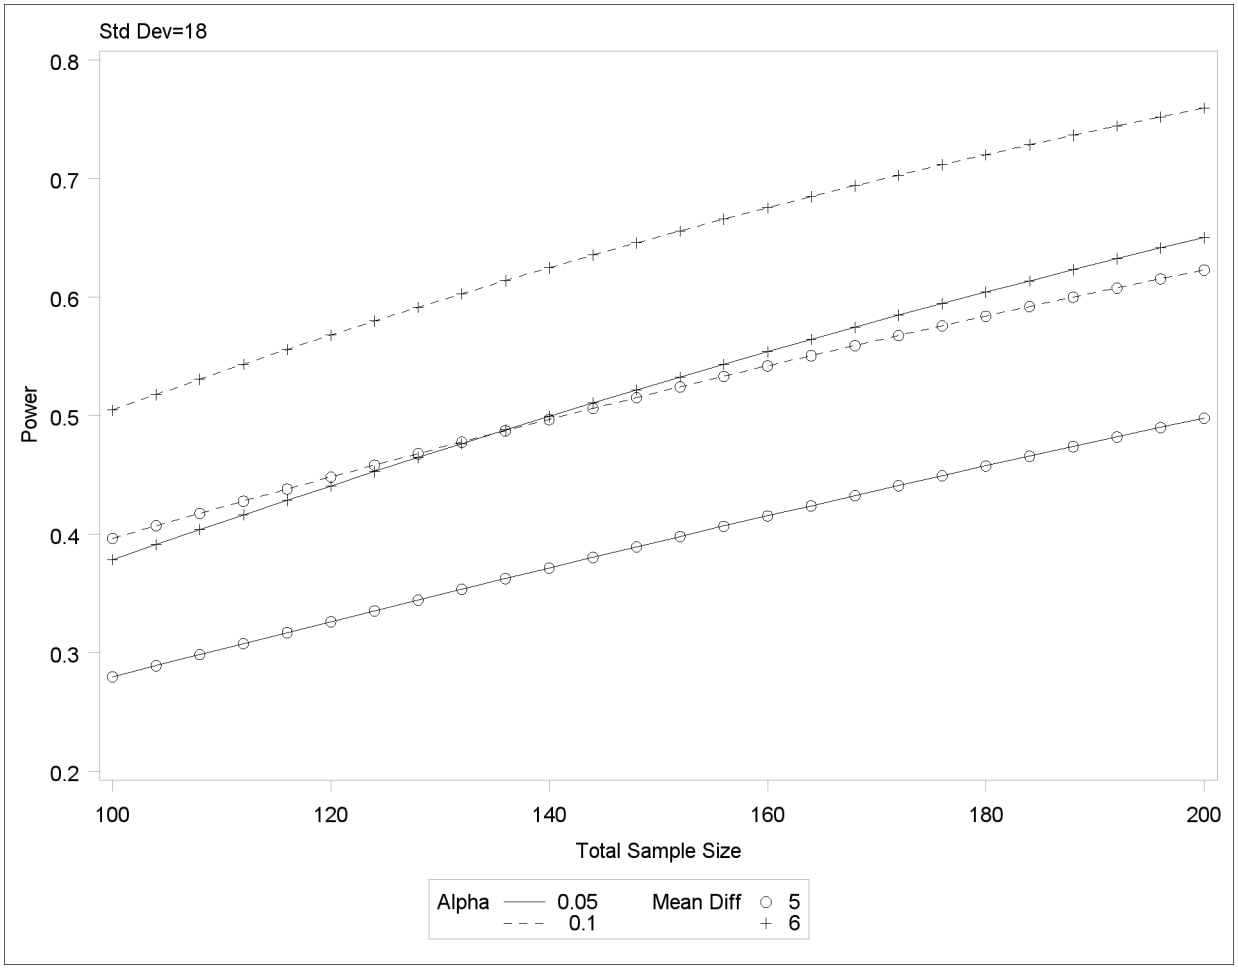


Figure 19.2 *continued*

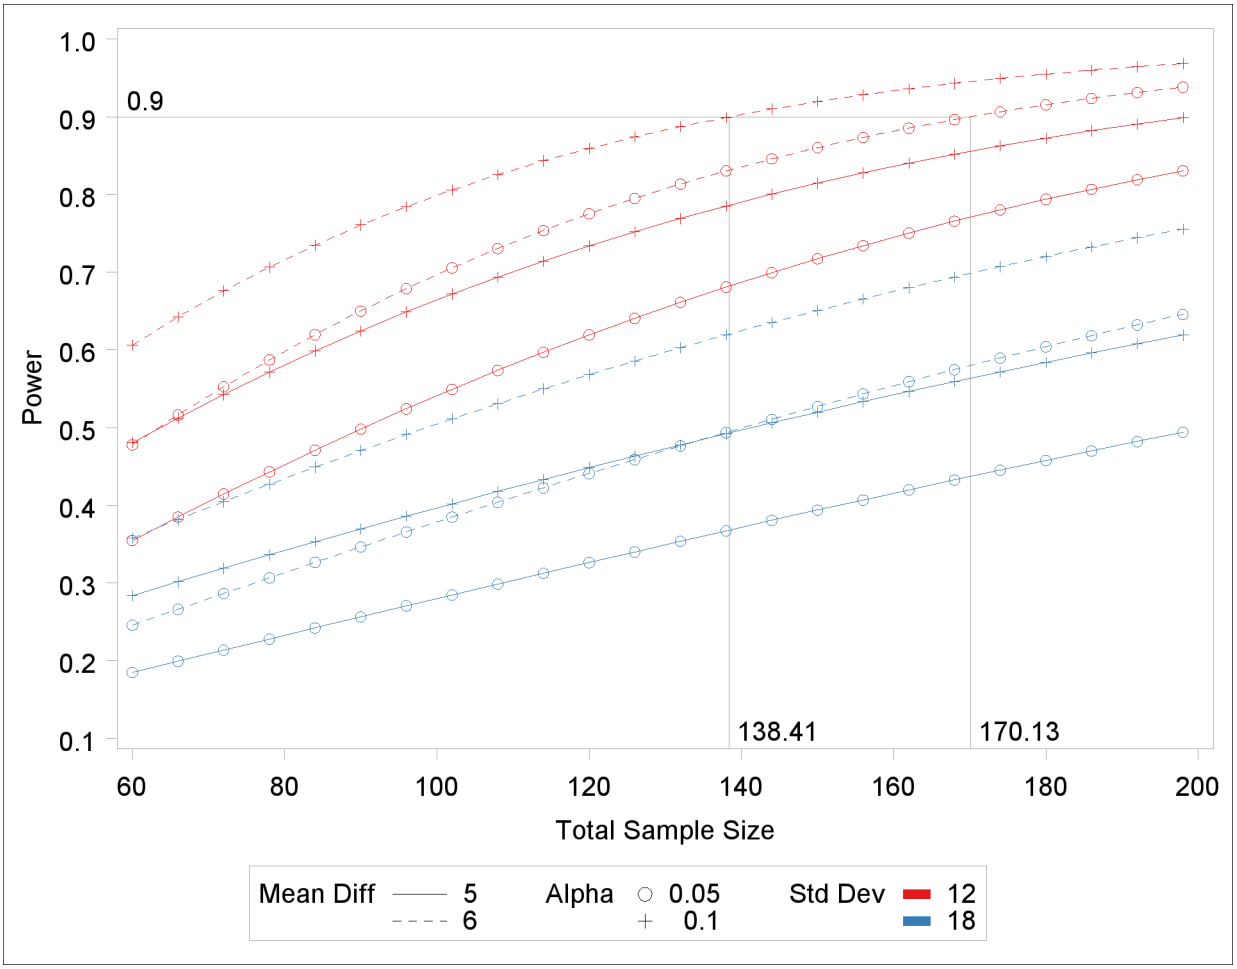
Highly Customized Graphs (POWER, GLMPOWER)

Example 67.8 of Chapter 67, "The POWER Procedure," demonstrates various ways you can modify and enhance plots created in the GLMPOWER or POWER procedures:

- assigning analysis parameters to axes
- fine-tuning a sample size axis
- adding reference lines
- linking plot features to analysis parameters
- choosing key (legend) styles
- modifying symbol locations



For example, replace the default PLOT statement with the following statement to modify the graphical results in Figure 19.2 to lower the minimum sample size to 60, show a reference line at

power=0.9 with corresponding sample size values, distinguish standard deviation by color instead of panel, and swap the roles of α and mean difference:

```
plot
   min=60
   yopts=(ref=0.9 crossref=yes)
   vary(color by stddev, linestyle by meandiff, symbol by alpha);
```

Figure 19.3 shows the results. The plot reveals that only the scenarios with the largest mean difference and smallest standard deviation achieve a power of at least 0.9 for this sample size range.

Figure 19.3 PROC POWER Customized Graphical Output

Formatted Tables (%POWTABLE Macro)

The %POWTABLE macro renders the output of the POWER and GLMPOWER procedures in rectangular form, and it optionally produces simplified results using weighted means across chosen variables. PROC REPORT and the Output Delivery System (ODS) are used to generate the tables. Base SAS and SAS/STAT 9.1 or higher versions are required.

You can run the %POWTABLE macro for the output in Figure 19.1 to display the results in a form more suitable for quickly discerning relationships among parameters. First use the ODS OUTPUT statement to assign the "Output" table produced by the POWER procedure to a data set as follows:

```
ods output output=powdata;
```

Next, specify the same PROC POWER statements that generate Figure 19.1. Finally, use the %POWTABLE macro to assign analysis parameters to table dimensions. To create a table of computed power values with mean difference assigned to rows, sample size and α assigned to columns, and standard deviation assigned to "panels" (rendered by default as rows separated by blank lines), specify the following statements:

```
%powtable ( Data = powdata,
            Entries = power,
            Rows = meandiff,
            Cols = ntotal alpha,
            Panels = stddev )
```

Figure 19.4 shows the results.

Figure 19.4 %POWTABLE Macro Output

The POWTABLE Macro

Entries are Power

		N Total			
		100		200	
Std Dev	Mean Diff	Alpha 0.05	Alpha 0.10	Alpha 0.05	Alpha 0.10
12	5	0.541	0.664	0.834	0.902
	6	0.697	0.799	0.940	0.970
18	5	0.280	0.397	0.498	0.623
	6	0.379	0.505	0.650	0.759

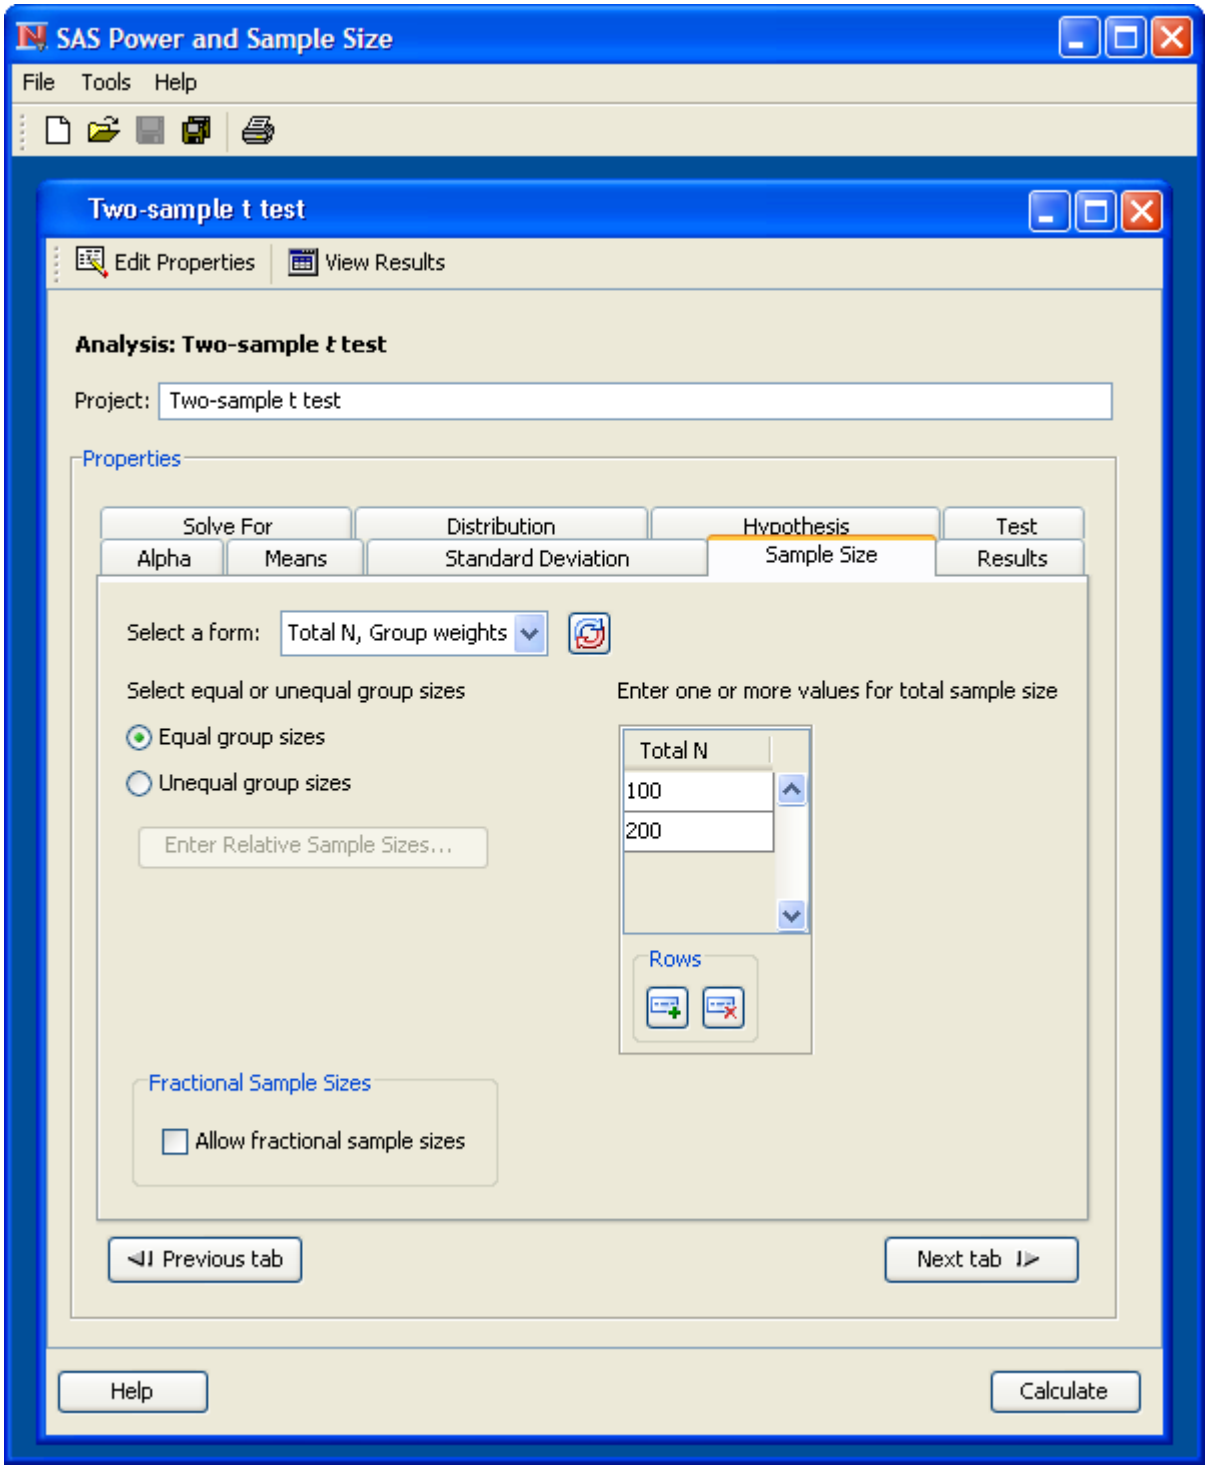
Narratives and Graphical User Interface (Power and Sample Size Application)

The Power and Sample Size application produces narratives for the results. Narratives are descriptions of the input parameters and a statement about the computed power or sample size.

For example, the Power and Sample Size application creates the following narrative for the scenario corresponding to the first row in Figure 19.1:

"For a two-sample pooled t test of a normal mean difference with a two-sided significance level of 0.05, assuming a common standard deviation of 12, a total sample size of 100 assuming a balanced

design has a power of 0.541 to detect a mean difference of 5."



The Power and Sample Size application also provides multiple input parameter options, stores the results in a project format, displays power curves, and shows the SAS log and SAS code. You can access each project to review the results or to edit your input parameters and produce another analysis.

Where appropriate, several alternate ways of entering values for certain parameters are offered. For example, in the two-sample *t* test analysis, sample sizes can be entered in any of several parameterizations:

- total sample size in a balanced design
- sample size per group in a balanced design
- total sample size and group allocation weights
- groupwise sample sizes

See Figure 19.5 for an illustration of the application, showing the sample size input page for a two-sample *t* test.

Figure 19.5 Power and Sample Size Application

Customized Power Formulas (DATA Step)

If you want to perform a power compuation for an analysis that is not currently supported directly in SAS/STAT tools, and you have a power formula, then you can program the formula in the DATA step.

For purposes of illustration, here is the power formula in the section "Computing Power and Sample Size" on page 417 implemented in the DATA step to compute power for the *t* test example:

```
data tpow;
   do meandiff = 5, 6;
      do stddev = 12, 18;
         do alpha = 0.05, 0.1;
            do ntotal = 100, 200;
               ncp = ntotal * 0.5 * 0.5 * meandiff**2 / stddev**2;
               critval = finv(1-alpha, 1, ntotal-2, 0);
               power = sdf('f', critval, 1, ntotal-2, ncp);
               output;
            end;
         end;
      end;
   end;
run;

proc print data=tpow;
run;
```

The output is shown in Figure 19.6.

Figure 19.6 Customized Power Formula (DATA Step)

Obs	meandiff	stddev	alpha	ntotal	ncp	critval	power
1	5	12	0.05	100	4.3403	3.93811	0.54102

3	5	12	0.10	100	4.3403	2.75743	0.66434
4	5	12	0.10	200	8.6806	2.73104	0.90171
5	5	18	0.05	100	1.9290	3.93811	0.27981
6	5	18	0.05	200	3.8580	3.88885	0.49793
7	5	18	0.10	100	1.9290	2.75743	0.39654
8	5	18	0.10	200	3.8580	2.73104	0.62287
9	6	12	0.05	100	6.2500	3.93811	0.69689
10	6	12	0.05	200	12.5000	3.88885	0.94043
11	6	12	0.10	100	6.2500	2.75743	0.79895
12	6	12	0.10	200	12.5000	2.73104	0.96985
13	6	18	0.05	100	2.7778	3.93811	0.37857
14	6	18	0.05	200	5.5556	3.88885	0.65012
15	6	18	0.10	100	2.7778	2.75743	0.50459
16	6	18	0.10	200	5.5556	2.73104	0.75935

Empirical Power Simulation (DATA Step, SAS/STAT Software)

You can obtain a highly accurate power estimate by simulating the power empirically. You need to use this approach for analyses that are not supported directly in SAS/STAT tools and for which you lack a power formula. But the simulation approach is also a viable alternative to existing power approximations. A high number of simulations will yield a more accurate estimate than a non-exact power approximation.

Although exact power computations for the two-sample t test are supported in several of the SAS/STAT tools, suppose for purposes of illustration that you want to simulate power for the continuing t test example. This section describes how you can use the DATA step and SAS/STAT software to do this.

The simulation involves generating a large number of data sets according to the distributions defined by the power analysis input parameters, computing the relevant p-value for each data set, and then estimating the power as the proportion of times that the p-value is significant.

The following statements compute a power estimate along with a 95% confidence interval for power for the first scenario in the two-sample t test example, with 10,000 simulations:

```
%let meandiff =     5;
%let stddev   =    12;
%let alpha    =  0.05;
%let ntotal   =   100;
%let nsim     = 10000;

data simdata;
   call streaminit(123);
   do isim = 1 to &nsim;
      do i = 1 to floor(&ntotal/2);
         group = 1;
         y = rand('normal', 0        , &stddev);
         output;
         group = 2;
         y = rand('normal', &meandiff, &stddev);
         output;
      end;
   end;
run;

ods listing close;
proc ttest data=simdata;
   ods output ttests=tests;
   by isim;
   class group;
   var y;
run;
ods listing;
```

```
data tests;
   set tests;
   where method="Pooled";
   issig = probt < &alpha;
run;

proc freq data=tests;
   ods select binomialprop;
   tables issig / binomial(level='1');
run;
```

First the DATA step is used to randomly generate *nsim*=10,000 data sets based on the *meandiff*, *stddev*, and *ntotal* parameters and the normal distribution, consistent with the assumptions underlying the two-sample *t* test. These data sets are contained in a large SAS data set called simdata indexed by the variable isim.

The CALL STREAMINIT(123) statement initializes the random number generator with a specific sequence and ensures repeatable results for purposes of this example. (**NOTE:** Skip this step when you are performing actual power simulations.)

The TTEST procedure is run using isim as a BY variable, with the ODS LISTING CLOSE statement to suppress output. The ODS OUTPUT statement saves the "TTests" table to a data set called tests. The *p*-values are contained in a column called probt.

The subsequent DATA step defines a variable called issig to flag the significant *p*-values.

Finally, the FREQ procedure computes the empirical power estimate as the estimate of $P(\text{issig} = 1)$ and provides approximate and exact confidence intervals for this estimate.

Figure 19.7 shows the results. The estimated power is 0.5388 with 95% confidence interval (0.5290, 0.5486). Note that the exact power of 0.541 shown in the first row in Figure 19.1 is contained within this tight confidence interval.

Figure 19.7 Simulated Power (DATA Step, SAS/STAT Software)

The FREQ Procedure

Binomial Proportion for issig = 1

Proportion	0.5388
ASE	0.0050
95% Lower Conf Limit	0.5290
95% Upper Conf Limit	0.5486
Exact Conf Limits	
95% Lower Conf Limit	0.5290
95% Upper Conf Limit	0.5486

Overview: Using the Output Delivery System

Most SAS procedures use the Output Delivery System (ODS) to manage their output. ODS enables you to do the following:

- display your output in hypertext markup language (HTML), Rich Text Format (RTF), PDF, PostScript, SAS listing (the default), or other formats
- create SAS data sets directly from tables or plots
- select or exclude individual pieces of output

- customize the layout, format, headers, and style of your output
- produce graphs with ODS Graphics in many procedures (see Chapter 21, "Statistical Graphics Using ODS")

This chapter discusses some typical applications of ODS with SAS software. For complete documentation on the Output Delivery System, see the *SAS Output Delivery System: User's Guide*.

Output Objects and ODS Destinations

All SAS procedures produce *output objects* that ODS delivers to various *ODS destinations*, according to the default specifications for the procedure or according to your own specifications. Typically, you see the output objects displayed as tables, data sets, or graphs. Underlying all output (for example, a table of parameter estimates) are two component parts:

- the data component, which consists of the results computed by a SAS procedure
- the template, which contains the instructions for formatting and displaying the results

You define the form that the output should take when you specify an ODS destination. Some supported destinations are as follows:

- LISTING destination (the standard SAS listing), which is open by default
- HTML destination, for viewing in a browser
- RTF, for inclusion in Microsoft Word
- PDF, PostScript, and PCL, for high-fidelity printers
- OUTPUT destination, for saving results to SAS data sets
- DOCUMENT destination, for saving, modifying and replaying your output

You can open multiple ODS destinations at the same time so that a single procedure step can produce output for multiple destinations. If you do not supply any ODS statements, ODS delivers all output to the LISTING destination. You can specify an output style for each ODS destination. The style controls the foreground, background, colors, lines, fonts, and so on.

Each output object has an associated template, provided by SAS, that defines its presentation format. You can use the TEMPLATE procedure to view or alter these templates or to create new templates, changing the headers, formats, column order, and so on. For more information, see the chapter titled "The Template Procedure" in the *SAS Output Delivery System: User's Guide*.

The following statements provide an example of temporarily closing the LISTING destination and making an output data set, Parm, from the parameter estimates table from PROC REG. Closing the

LISTING destination is not required, but it is done frequently in the examples in this chapter for efficiency. Closing the LISTING suppresses the generation of output that is not needed or used. This is particularly beneficial with graphics. This example uses the SASHELP.Class data set, one of the sample data sets in the SASHELP library that are automatically available for your use. The following statements produce Figure 20.1:

```
title 'Getting Started with ODS';

ods listing close;

proc reg data=sashelp.class;
   model height=weight;
   ods output ParameterEstimates=parms;
run;

ods listing;

proc print noobs data=parms;
run;
```

Getting Started with ODS

Model	Dependent	Variable	DF	Estimate	StdErr	tValue	Probt
MODEL1	Height	Intercept	1	42.57014	2.67989	15.89	<.0001
MODEL1	Height	Weight	1	0.19761	0.02616	7.55	<.0001

The ODS OUTPUT statement contains a table name, an equal sign, and the name of the output SAS data set to create. The table names can be found using the ODS TRACE statement, which is described in the next section. Also see Example 20.4 for more information.

Paths and Selection

You use the ODS statement to provide instructions to ODS. You can use ODS statements to specify options for different destinations, specify the output style, and select and exclude output. Here are some examples:

```
/* open the HTML destination with the statistical style */
ods html style=Statistical;

/* select only the parameter estimates table */
ods select ParameterEstimates;

/* output the parameter estimates table to a SAS data set*/
ods output ParameterEstimates=Parms;
```

```
/* exclude the number of observations, ANOVA, and fit statistics tables */
ods exclude NObs ANOVA FitStatistics;
```

In order to select, exclude, or modify a table, you must first know its name. You can obtain the table names in several ways:

- You can obtain table names from the individual procedure chapter or from the individual procedure section of the SAS online Help system. See the "ODS Table Names" section within the "Details" section of the procedure documentation chapter.
- You can use the SAS Results window to view the names of the tables created in your SAS session (see the section "ODS and the SAS Results Window" on page 440 for more information).
- You can use the ODS TRACE statement to find the names of tables created in your SAS session. The ODS TRACE statement writes identifying information to the SAS log or listing for each generated output table.

If you are working interactively with reasonably small data sets, then the ODS TRACE statement is usually the most convenient way to find the names. Specify the ODS TRACE ON statement prior to the procedure statements that create the output for which you want information. For example, the following statements write the trace record for the specific tables created in the REG procedure step:

```
ods trace on;
proc reg;
   model y=x;
   model z=x;
run;
ods trace off;
```

By default, the trace record is written to the SAS log. The output from this step is as follows:

```
Output Added:
-------------
Name:        NObs
Label:       Number of Observations
Template:    Stat.Reg.NObs
Path:        Reg.MODEL1.Fit.y.NObs
-------------

Output Added:
-------------
Name:        ANOVA
Label:       Analysis of Variance
Template:    Stat.REG.ANOVA
Path:        Reg.MODEL1.Fit.y.ANOVA
-------------
```

```
Output Added:
-------------
Name:       FitStatistics
Label:      Fit Statistics
Template:   Stat.REG.FitStatistics
Path:       Reg.MODEL1.Fit.y.FitStatistics
-------------

Output Added:
-------------
Name:       ParameterEstimates
Label:      Parameter Estimates
Template:   Stat.REG.ParameterEstimates
Path:       Reg.MODEL1.Fit.y.ParameterEstimates
-------------

Output Added:
-------------
Name:       NObs
Label:      Number of Observations
Template:   Stat.Reg.NObs
Path:       Reg.MODEL2.Fit.z.NObs
-------------

Output Added:
-------------
Name:       ANOVA
Label:      Analysis of Variance
Template:   Stat.REG.ANOVA
Path:       Reg.MODEL2.Fit.z.ANOVA
-------------

Output Added:
-------------
Name:       FitStatistics
Label:      Fit Statistics
Template:   Stat.REG.FitStatistics
Path:       Reg.MODEL2.Fit.z.FitStatistics
-------------

Output Added:
-------------
Name:       ParameterEstimates
Label:      Parameter Estimates
Template:   Stat.REG.ParameterEstimates
Path:       Reg.MODEL2.Fit.z.ParameterEstimates
-------------
```

Alternatively, you can specify the LISTING option (**`ods trace on / listing;`**), which writes the trace record, interleaved with the procedure output, to the LISTING destination.

The trace record contains the name of each created table and its associated label, template, and path. The label provides a description of the table. The path shows the output hierarchy for the table (see,

for example, Figure 20.2). In this example, the hierarchy has a level for the REG procedure, a level for the model (MODEL1 or MODEL2), a level for the fit results, a level for the dependent variable (y or z), and a level for the table name (**NObs**, **ANOVA**, **FitStatistics**, **ParameterEstimates**, **NObs**, **ANOVA**, **FitStatistics**, **ParameterEstimates**). The path shown in the trace record is fully qualified. Often, you can omit levels and instead use a partially qualified path. A partially qualified path consists of any part of the full path that begins immediately after a period and continues to the end of the full path. For example, the full path for the parameter estimates for the first model in the preceding regression analysis is **Reg.Model1.Fit.y.ParameterEstimates**. This table can be referenced in any of the following ways:

ParameterEstimates	name
y.ParameterEstimates	partially qualified path
fit.y.ParameterEstimates	partially qualified path
Model1.fit.y.ParameterEstimates	partially qualified path
Reg.Model1.fit.y.ParameterEstimates	fully qualified path

When a procedure creates multiple tables that have the same name, as in the preceding example, you have several selection options. You can specify the name, a full path, or a partially qualified path when you refer to a table (for example, when you select it or exclude it from display). You can also specify a WHERE clause. For example, you can specify any of the following statements to display both tables of parameter estimates:

```
ods select ParameterEstimates;

ods select y.ParameterEstimates z.ParameterEstimates;

ods select Reg.Model1.Fit.y.ParameterEstimates
           Reg.Model2.Fit.z.ParameterEstimates;

ods select where = (_path_ ? 'Parameter');
```

There are other possibilities as well. The first ODS SELECT statement specifies the single name, which is shared by both tables. The second statement specifies a partially qualified path for both tables. The third statement specifies the full path for both tables. The fourth statement selects every object (table or graph) that contains the string **Parameter** anywhere in its path. Note that in the first three statements, selection is case insensitive. Any combination of uppercase and lowercase letters will work. This is not true in the fourth statement, which uses an ordinary SAS comparison of character strings. The following WHERE clause selection is case insensitive:

```
ods select where = (lowcase(_path_) ? 'parameter');
```

You can also select objects based on a WHERE clause and the label path. The following statements turn on the trace record, display a label path in addition to the name path, and select all tables that have the string 'var' in the label:

```
ods trace on / label;
ods select where = (lowcase(_label_) ? 'var');
```

A subset of the trace record for PROC REG with this select list, showing just the name and label paths, is as follows:

```
Path:       Reg.MODEL1.Fit.y.ANOVA
Label Path: 'The Reg Procedure'.'MODEL1'.'Fit'.y.'Analysis of Variance'
Path:       Reg.MODEL2.Fit.z.ANOVA
Label Path: 'The Reg Procedure'.'MODEL2'.'Fit'.z.'Analysis of Variance'
```

The ODS SELECT statement selects the ANOVA tables, because they have the string 'Analysis of Variance' (which when lowercased contains 'var') in their labels. WHERE clause selection is also useful for selecting all of the objects within a group or level of the path hierarchy (the group 'MODEL2' or 'Fit'). You can specify any part of the path or label path—for example, '.z.', the variable z ignoring any 'z' that might be in the middle of a word; '2.F', model 2 fit tables and any other table that has the string '2.F' in its path; and so on.

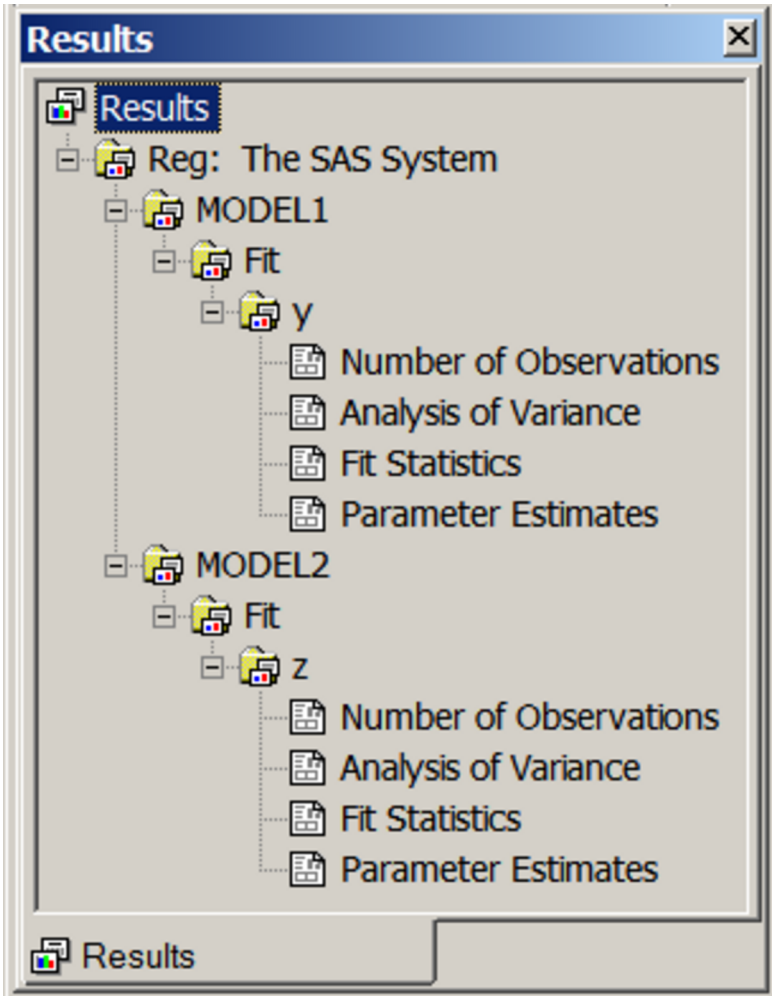
ODS records the specified table names in its internal selection or exclusion list, and then it processes the output it receives. Note that ODS maintains an overall selection or exclusion list that pertains to all ODS destinations, and it maintains a separate selection or exclusion list for each ODS destination. The list for a specific destination provides the primary filtering step. The restrictions that you specify in the overall list are added to the destination-specific lists.

Suppose, for example, that your LISTING exclusion list (that is, the list of tables you want to exclude from the LISTING destination) contains the **FitStatistics** table, which you specify with the following statement:

```
ods listing exclude FitStatistics;
```

Suppose also that your overall selection list (that is, the list of tables you want to select for all destinations) contains the tables **ParameterEstimates** and **FitStatistics**, which you specify with the following statement:

```
ods select ParameterEstimates FitStatistics;
```



ODS then sends only the **ParameterEstimates** and **FitStatistics** tables to all open destinations except the LISTING destination. It sends only the **ParameterEstimates** table to the LISTING destination because the table **FitStatistics** is excluded from that destination.

Some SAS procedures, such as PROC REG and PROC GLM, support RUN-group processing, which means that a RUN statement does not end the procedure. A QUIT statement explicitly ends such procedures. If you omit the QUIT statement, a PROC or a DATA statement implicitly ends such procedures. When you use ODS with procedures that support RUN-group processing, it is good programming practice to specify a QUIT statement at the end of the procedure. This causes ODS to clear the selection or exclusion list, and you are less likely to encounter unexpected results.

ODS and the SAS Results Window

The SAS Results window contains a running record of the output from your SAS session. In the display manager, select **View ► Results** to open the Results window. Figure 20.2 displays the Results window from the PROC REG step shown previously.

Figure 20.2 The Results Window from the SAS Explorer

When you click on the output table names in the Results window, you link directly to the output in the output window (or HTML browser if you specify the HTML destination). The Results window contains a row for each level of the path and for each table. You can also use the Results window to determine the names of the templates associated with each output table. Right-click on the table name and then select **Properties.** You can see all of the templates from the Results window by selecting **View ► Templates ► Sashelp.Tmplmst**. Then click on a product such as **`Stat`**, a procedure such as **`REG`**, and a template such as **`ParameterEstimates`**.

Controlling Output Appearance with Templates

A template is a description of how output should appear when it is formatted. Templates describe several characteristics of the output, including headers, column ordering, style information, justification, and formats. Each table in the output has a template, and all SAS templates are stored in the SASHELP library. You can find the template associated with a particular output table or column by using the ODS TRACE statement or the SAS Results window. You can create or modify a template with the TEMPLATE procedure. For example, you can specify different column headings or different orders of columns in a table.

There are a number of different types of templates including column and table templates, graphical templates, and style templates. A column or table template applies to the specific columns or tables that reference the template. Graphical templates are discussed in more detail in Chapter 21, "Statistical Graphics Using ODS." A style template applies to an entire SAS job, including all tables and graphs, and can be specified with the STYLE= option in a valid ODS destination, such as HTML, RTF, or PDF. You can specify a style as follows:

```
ods html style=Statistical;
```

A style template controls stylistic elements such as colors, fonts, and presentation attributes. You can change the style to give your output different looks and color schemes. You can also reference style information in table templates for individual headers and data cells. You can modify all types of templates with PROC TEMPLATE. For information about creating your own styles, see the *SAS Output Delivery System: User's Guide*.

You can display the contents of a template by running PROC TEMPLATE with a SOURCE statement and a template name, as in the following example:

```
proc template;
   source Stat.REG.ANOVA;
   source Stat.GLM.OverallANOVA;
run;
```

Note that in many cases, a template definition is at least in part based on another template. When you see the PARENT=*template* option in a template definition, you need to look at the specified template to see more about the rest of the template definition. To illustrate, consider the following PROC GLM step:

```
proc glm data=x;
   model y = x;
run; quit;
```

The ANOVA table from this step is displayed in Figure 20.3.

Figure 20.3 PROC GLM ANOVA Table with the Default Template

Getting Started with ODS

The GLM Procedure

Dependent Variable: y

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	77.05005975	77.05005975	190.53	<.0001
Error	8	3.23526554	0.40440819		
Corrected Total	9	80.28532529			

The sums of squares and mean squares are presented with eight decimal places. You can change the templates to change the formats of those columns to use fewer decimal places. First, you can use the ODS TRACE statement when you run PROC GLM to determine the name of the template:

```
ods trace output;
proc glm data=x;
   model y = x;
   run; quit;
ods trace off;
```

The trace output results include the following:

```
Output Added:
-------------
Name:        OverallANOVA
Label:       Overall ANOVA
Template:    stat.GLM.OverallANOVA
Path:        GLM.ANOVA.y.OverallANOVA
-------------
```

From this, you can see that the template for the overall ANOVA table is **stat.GLM.OverallANOVA**. You can submit the following statements to see the overall ANOVA table template:

```
proc template;
   source stat.glm.overallanova;
run;
```

Here are the results:

```
define table Stat.GLM.Overallanova;
   notes "Over-all ANOVA";
   top_space = 1;
   parent = Stat.GLM.ANOVA;
   double_space;
end;
```

The results show that this template inherits its definition from a parent template named **Stat.GLM.ANOVA**. Submit the following statements to see the parent template:

```
proc template;
   source stat.glm.anova;
run;
```

Some of the results are as follows:

```
.
.
.

define SS;
   parent = Stat.GLM.SS;
end;

define MS;
   parent = Stat.GLM.MS;
end;

.
.
.
```

These columns inherit there definitions from the parent columns named **Stat.GLM.SS** and **Stat.GLM.MS**. This is all of the information that you need to redefine these columns, but you can run PROC TEMPLATE again as follows to see more information about how these templates are defined:

```
proc template;
   source Stat.GLM.SS;
   source Stat.GLM.MS;
run;
```

The results are as follows:

```
define column Stat.GLM.Ss;
   notes "Parent for GLM ANOVA Sums of Squares columns";
   parent = Common.ANOVA.SS;
end;
define column Stat.GLM.Ms;
   notes "Parent for GLM ANOVA Mean Squares columns";
   parent = Common.ANOVA.MS;
end;
```

These columns inherit there definitions from the columns named **Common.ANOVA.SS** and **Common.ANOVA.MS**. You can run PROC TEMPLATE as follows to see their definitions:

```
proc template;
   source Common.ANOVA.SS;
   source Common.ANOVA.MS;
run;
```

The results are as follows:

```
define column Common.ANOVA.Ss;
   notes "Default ANOVA Sum of squares column";
   header = "Sum of Squares";
   translate _val_=._ into "";
end;
define column Common.ANOVA.Ms;
   notes "Default ANOVA Mean square column";
   header = "Mean Square";
   translate _val_=._ into "";
end;
```

You can redefine **Common.ANOVA.SS** and **Common.ANOVA.MS** to change all **SS** and **MS** columns in ANOVA tables. This would be the most general redefinition. More specifically, you can redefine **Stat.GLM.SS** and **Stat.GLM.MS** to change **SS** and **MS** columns in ANOVA tables produced by PROC GLM. Finally, and most specifically, you can change the **SS** and **MS** columns in just the overall ANOVA table template. In this example, the **Stat.GLM.SS** and **Stat.GLM.MS** columns are redefined as follows, so that results are displayed with fewer decimal places:

```
proc template;
   edit Stat.GLM.SS;
      choose_format=max format_width=8;
   end;
   edit Stat.GLM.MS;
      choose_format=max format_width=8;
   end;
run;
```

The CHOOSE_FORMAT=MAX option along with FORMAT_WIDTH=8 chooses the format for each column based on the maximum value in that column and an overall width of 8. Note that you are editing and not replacing the definition, so column header and other information in the definition is not lost. The following step uses the new templates:

```
proc glm data=x;
   model y = x;
run; quit;
```

The new ANOVA results, using the edited templates, are shown in Figure 20.4. You can see that the original results in Figure 20.3 have eight decimal places, whereas the new results in Figure 20.4 have only five decimal places and an overall format width of eight.

Figure 20.4 PROC GLM ANOVA Table after Template Customization

Getting Started with ODS

The GLM Procedure

Dependent Variable: y

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	77.05006	77.05006	190.53	<.0001
Error	8	3.23527	0.40441		
Corrected Total	9	80.28533			

The preceding PROC TEMPLATE step produces the following notes:

```
NOTE: Overwriting existing template/link: Stat.GLM.Ss
NOTE: COLUMN 'Stat.GLM.Ss' has been saved to: SASUSER.TEMPLAT
NOTE: Overwriting existing template/link: Stat.GLM.Ms
NOTE: COLUMN 'Stat.GLM.Ms' has been saved to: SASUSER.TEMPLAT
```

When you run PROC TEMPLATE to modify or edit a template, the template is by default stored in your SASUSER library. You can then modify the path that ODS uses to look up templates with the ODS PATH statement—for example, to access these new templates in a later SAS session. This enables you to create a new default set of templates to modify the display format for all of your SAS output. You can specify the SHOW option in the ODS PATH statement to determine the current path. The following statements illustrate the ODS path:

```
ods path show;
libname mytpls '.';
ods path (prepend) mytpls.template(update);
ods path show;

proc template;
   edit Stat.GLM.SS;
      choose_format=max format_width=8;
   end;
   edit Stat.GLM.MS;
      choose_format=max format_width=8;
   end;
run;
```

The results of the first statement are as follows:

```
Current ODS PATH list is:

1. SASUSER.TEMPLAT(UPDATE)
2. SASHELP.TMPLMST(READ)
```

This shows that the SASUSER.TEMPLAT file is open for storing new templates and retrieving templates for use. After that, the SASHELP.TMPLMST file is used, but it is open only for Read access. You cannot modify templates in SASHELP. The second and third statements add a template library to the front of this list in the current directory. The fourth statement shows the new path list, which is as follows:

```
Current ODS PATH list is:

1. MYTPLS.TEMPLATE(UPDATE)
2. SASUSER.TEMPLAT(UPDATE)
3. SASHELP.TMPLMST(READ)
```

The PROC TEMPLATE step produces the following notes showing that the templates are now stored in MYTPLS.TEMPLATE:

```
NOTE: Overwriting existing template/link: Stat.GLM.Ss
NOTE: COLUMN 'Stat.GLM.Ss' has been saved to: MYTPLS.TEMPLATE
NOTE: Overwriting existing template/link: Stat.GLM.Ms
NOTE: COLUMN 'Stat.GLM.Ms' has been saved to: MYTPLS.TEMPLATE
```

In all cases, the original template definitions in SASHELP.TMPLMST are not changed. You can delete your custom template and restore the default template as follows:

```
proc template;
   delete Stat.GLM.SS;
   delete Stat.GLM.MS;
run;
```

It is good practice to delete any template redefinitions that you do not want to be permanent, because otherwise they will persist beyond the duration of your SAS session.

ODS and the NOPRINT Option

Many SAS procedures support a NOPRINT option that you can use when you want to create an output data set but without displaying any output. You use an option (such as OUTEST= or an OUTPUT statement with an OUT= option) in addition to the procedure's NOPRINT option to create a data set and suppress displayed output.

You can also use ODS to create output data sets by using the ODS OUTPUT statement. However, if you specify the NOPRINT option, the procedure might not send any output to ODS. In most procedures that support a NOPRINT option, NOPRINT means no ODS. (However, there are a few procedures that for historical reasons still might produce some output even when NOPRINT is specified.) When you want to create output data sets through the ODS OUTPUT statement, and you want to suppress the display of all output, specify the following statement instead of using the NOPRINT option:

```
ods select none;
```

Alternatively, you can close the active ODS destinations, for example, like this:

```
ods html close;
ods listing close;
```

Note that ODS statements do not instruct a procedure to generate output. Instead, they specify how ODS should manage output once it is created. You must ensure that the proper procedure options are in effect, or the output will not be generated. For example, the following statements do not create the requested data set Parms:

```
proc glm;
   ods output ParameterEstimates=Parms;
   class x;
   model y=x;
run; quit;
```

This is because the SOLUTION option was not specified in the MODEL statement. Since PROC GLM did not create the table, ODS cannot make the output data set. When you execute these statements, the following message is displayed in the log:

```
WARNING: Output 'ParameterEstimates' was not created.
```

The following step creates the output data set:

```
proc glm;
   ods output ParameterEstimates=Parms;
   class x;
   model y=x / solution;
run; quit;
```

Examples: Using the Output Delivery System

This section provides examples of making HTML output, selecting and excluding output, tracing ODS output, using the Results window, creating ODS output data sets, modifying templates, creating hyperlinks, and using ODS Graphics.

Example 20.1: Creating HTML Output with ODS

This example demonstrates how you can use the ODS HTML statement to display your output in HTML. The following statements create the data set Scores, which contains the golf scores of boys and girls in a physical education class:

```
title 'Comparing Group Means';

data Scores;
   input Gender $ Score @@;
   datalines;
f 75  f 76  f 80  f 77  f 80  f 77  f 73
m 82  m 80  m 85  m 85  m 78  m 87  m 82
;
```

The TTEST procedure is used to compare the scores. The ODS HTML statement specifies the name of the file to contain the HTML output. The following statements create the HTML file *ttest.htm*:

```
ods html body='ttest.htm' style=statistical;

proc ttest;
   class Gender;
   var Score;
run;

ods html close;
```

By default, the LISTING destination receives all output generated during your SAS session. In this example, the ODS HTML statement opens the HTML destination as well, and both destinations receive the generated output. Note that you must specify the following statement before you can view your output in a browser:

```
ods html close;
```

If you do not close the HTML destination, your HTML file might contain no output or incomplete output, or you might experience other unexpected results.

The following statements use ODS to display the output in HTML with a table of contents by using the STATISTICAL style of output, but this time closing the LISTING destination:

```
ods listing close;
ods html body='ttest.htm' contents='ttestc.htm' frame='ttestf.htm'
         style=statistical;

proc ttest;
   class Gender;
   var Score;
run;

ods html close;
ods listing;
```

The ODS HTML statement specifies three files. The BODY= option specifies the file that contains the SAS output. The CONTENTS= option specifies the file that contains the table of contents. The FRAME= option specifies the file that displays both the table of contents and the output. You can open the FRAME= file (*ttestf.htm*) in your browser to view the table of contents together with the generated output (see Output 20.1.1). By default, the HTML files are generated in your current working directory. You can instead specify paths, such as `frame='html/ttestf.htm'`, to put a file in a subdirectory.

Note that if you specify the ODS HTML statement with only the BODY= argument, no table of contents is created. The table of contents contains the descriptive label for each output table produced in the PROC TTEST step. You can select any label in the table of contents and the corresponding output will be displayed on the right side of the browser window.

Output 20.1.1 HTML Output with a Table of Contents, the FRAME='ttestf.htm' File

Table of Contents

1. Ttest
   - Score
     - Statistics
     - Confidence Limits
     - T-Tests
     - Equality of Variances

Comparing Group Means

The TTEST Procedure

Variable: Score

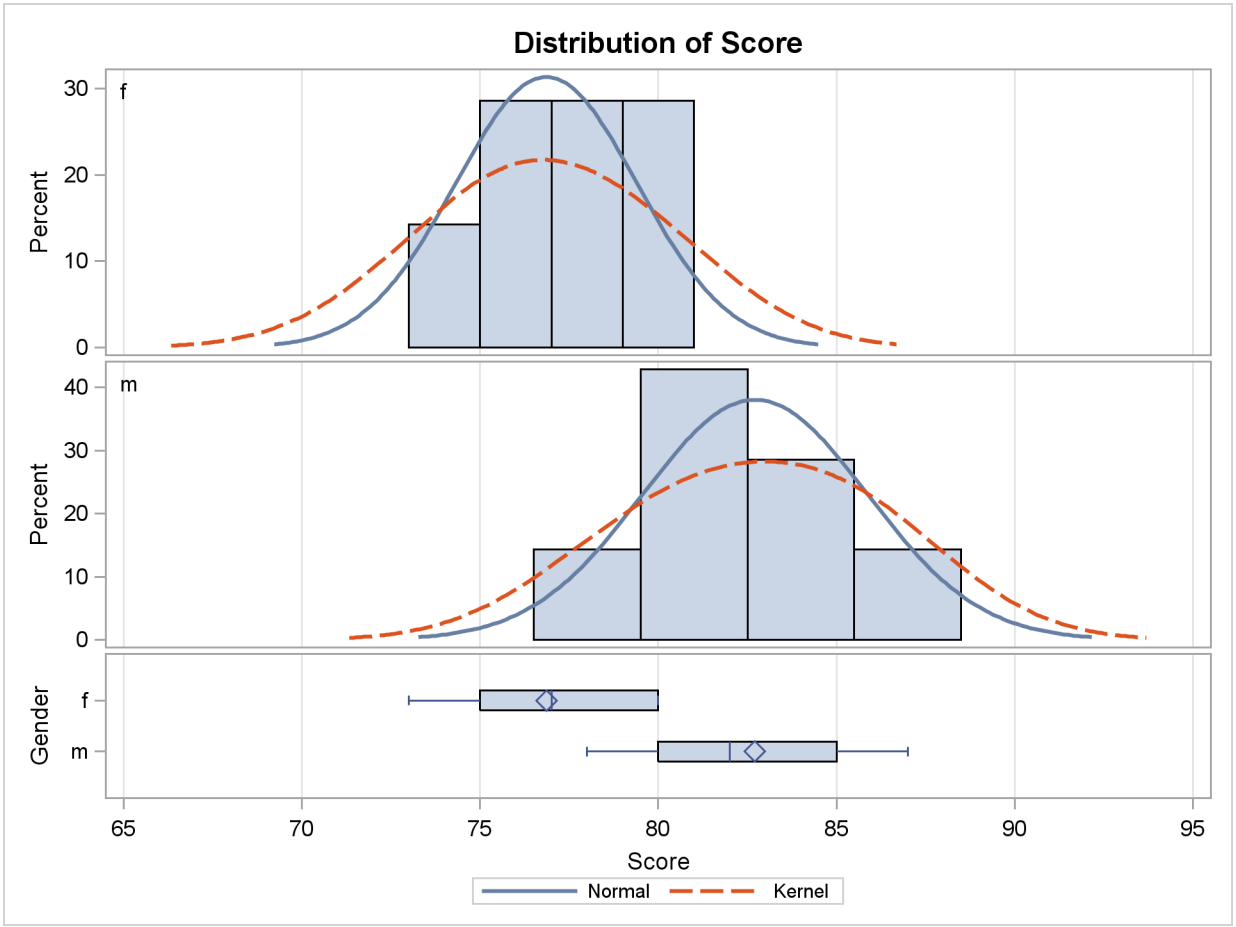
Gender	N	Mean	Std Dev	Std Err	Minimum	Maximum
f	7	76.8571	2.5448	0.9619	73.0000	80.0000
m	7	82.7143	3.1472	1.1895	78.0000	87.0000
Diff (1-2)		-5.8571	2.8619	1.5298		

Gender	Method	Mean	95% CL Mean		Std Dev	95% CL Std Dev	
f		76.8571	74.5036	79.2107	2.5448	1.6399	5.6039
m		82.7143	79.8036	85.6249	3.1472	2.0280	6.9303
Diff (1-2)	Pooled	-5.8571	-9.1902	-2.5241	2.8619	2.0522	4.7242
Diff (1-2)	Satterthwaite	-5.8571	-9.2064	-2.5078			

Method	Variances	DF	t Value	Pr > |t|
Pooled	Equal	12	-3.83	0.0024
Satterthwaite	Unequal	11.496	-3.83	0.0026

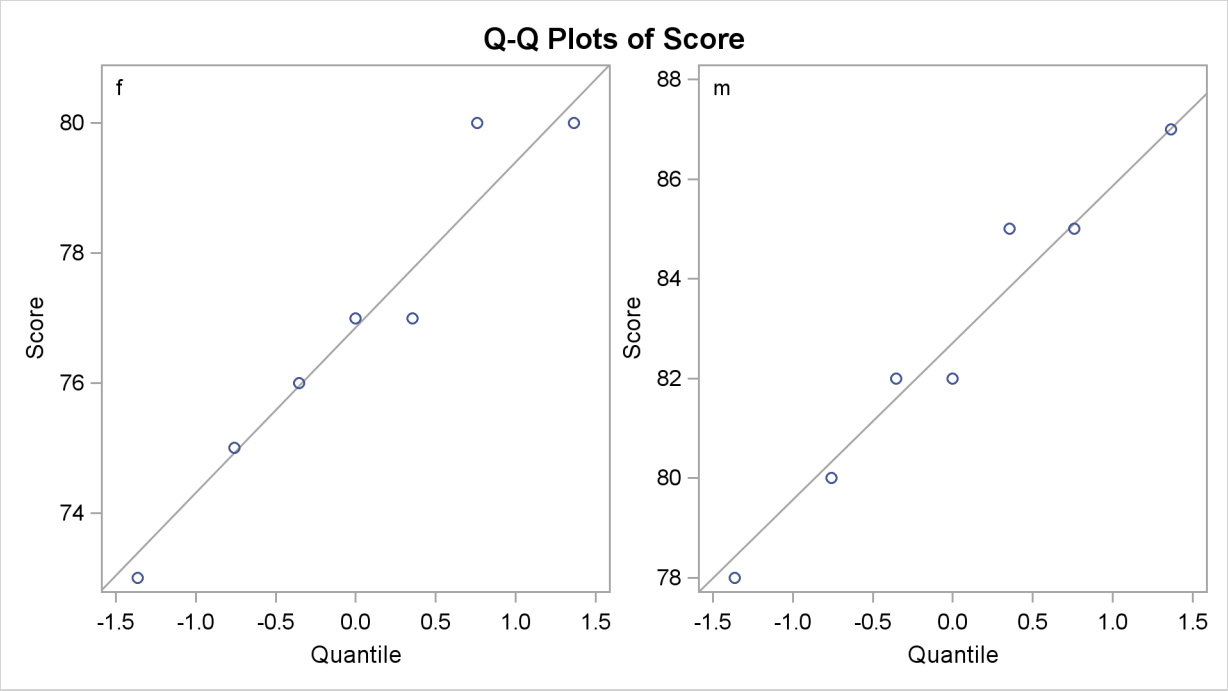
Equality of Variances				
Method	Num DF	Den DF	F Value	Pr > F
Folded F	6	6	1.53	0.6189

You could enable ODS Graphics by adding an ODS GRAPHICS ON statement as follows:



```
ods graphics on;
ods listing close;
ods html body='ttest.htm' contents='ttestc.htm' frame='ttestf.htm'
         style=statistical;

proc ttest;
   class Gender;
   var Score;
run;



ods html close;
ods listing;
ods graphics off;
```

Then in addition to the tables, you would also get the graphs shown in Figure 20.1.2. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS."

Output 20.1.2 PROC TTEST Graphs

Output 20.1.2 *continued*

Example 20.2: Selecting ODS Tables for Display

You can use the ODS SELECT statement to deliver only a subset of the tables or graphs to ODS destinations. The following statements create an input SAS data set and use PROC GLM to perform an analysis of an unbalanced two-way experimental design:

```
title 'Unbalanced Two-way Design';

data twoway;
   input Treatment Block y @@;
   datalines;
1 1 17   1 1 28   1 1 19   1 1 21   1 1 19
1 2 43   1 2 30   1 2 39   1 2 44   1 2 44
1 3 16
2 1 21   2 1 21   2 1 24   2 1 25
2 2 39   2 2 45   2 2 42   2 2 47
2 3 19   2 3 22   2 3 16
3 1 22   3 1 30   3 1 33   3 1 31
3 2 46
3 3 26   3 3 31   3 3 26   3 3 33   3 3 29   3 3 25
;
```

```
proc glm data=twoway;
   class Treatment Block;
   model y = Treatment | Block;
   means Treatment;
   lsmeans Treatment;

   ods select ModelANOVA Means;
   ods trace on;
   ods show;
run;
```

The ODS SELECT statement specifies that only the two tables **ModelANOVA** and **Means** are to be delivered to the ODS destinations. In this example, no ODS destinations are explicitly opened. Therefore, only the default LISTING destination receives the procedure output. The ODS SHOW statement displays the current overall selection list in the SAS log. The ODS SHOW statement is not required; it is used here simply to show the effects of the ODS SELECT statement. The results of the ODS SHOW statement are as follows:

```
Current OVERALL select list is:
1. ModelANOVA
2. Means
```

The ODS TRACE statement writes the trace record of the ODS output objects to the SAS log. The trace record is as follows:

```
Output Added:
-------------
Name:        ModelANOVA
Label:       Type I Model ANOVA
Template:    stat.GLM.Tests
Path:        GLM.ANOVA.y.ModelANOVA
-------------

Output Added:
-------------
Name:        ModelANOVA
Label:       Type III Model ANOVA
Template:    stat.GLM.Tests
Path:        GLM.ANOVA.y.ModelANOVA
-------------

Output Added:
-------------
Name:        Means
Label:       Means
Template:    stat.GLM.Means
Path:        GLM.Means.Treatment.Means
-------------
```

Note that there are two tables with the name **ModelANOVA**. One contains the "Type I Model ANOVA" table, and the other contains the "Type III Model ANOVA" table. If you wanted to select only one of them, you could specify either of the labels in the ODS SELECT statement instead of the name. You would specify one of the following:

```
ods select 'Type I Model ANOVA' Means;
ods select 'Type III Model ANOVA' Means;
```

In the following statements, the ODS SHOW statement writes the current overall selection list to the SAS log, the QUIT statement ends the PROC GLM step, and the second ODS SHOW statement writes the selection list to the log after PROC GLM terminates:

```
ods show;
quit;
ods show;
```

The results of these statements are as follows:

```
ods show;

Current OVERALL select list is:
1. ModelANOVA
2. Means

quit;
ods show;

Current OVERALL select list is: ALL
```

PROC GLM supports interactive RUN-group processing. Before the QUIT statement is executed, PROC GLM is active and the ODS selection list remains at its previous setting. The list includes only the two tables, **ModelANOVA** and **Means**. After the QUIT statement, when PROC GLM is no longer active, the selection list is reset to ALL. The displayed output, shown in Output 20.2.1, consists of the three selected tables (two **ModelANOVA** tables and the **Means** table). Note that the LS-means results are not displayed even though an LSMEANS statement was specified. This is because the LS-means table, named **LSMeans**, is not specified in the ODS SELECT statement. Other tables are suppressed as well.

Output 20.2.1 The Selected Tables from PROC GLM

3	11	30.1818182	6.3058414

For more information about ODS exclusion and selection lists, see the section "Paths and Selection" on page 435.

Example 20.3: Excluding ODS Tables from Display

The following example demonstrates how you can use the ODS EXCLUDE statement to exclude particular tables from ODS destinations. This example also creates a SAS data set from the excluded table and uses it to create a specialized plot.

The data are from Hemmerle and Hartley (1973). The response variable consists of measurements from an oven experiment, and the model contains a fixed effect a and random effects b and a*b. The following statements create the input SAS data set:

```
title 'Oven Measurements';

data hh;
   input a b y @@;
   datalines;
1 1 237   1 1 254    1 1 246
1 2 178   1 2 179
2 1 208   2 1 178    2 1 187
2 2 146   2 2 145    2 2 141
3 1 186   3 1 183
3 2 142   3 2 125    3 2 136
;
```

The following ODS statements are submitted before the analysis, which will be done with the MIXED procedure:

```
ods listing close;
ods html body='mixed.htm' contents='mixedc.htm' frame='mixedf.htm'
         style=statistical;

ods exclude ParmSearch(persist);
ods show;
```

The ODS HTML statement specifies the filenames to contain the output generated from the statements that follow. The ODS EXCLUDE statement excludes the table **ParmSearch** from display. Although the table is excluded from the displayed output, the information contained in the **ParmSearch** table is graphically summarized in a later step.

The PERSIST option in the ODS EXCLUDE statement excludes the table for the entire SAS session or until you execute an ODS SELECT statement or an ODS EXCLUDE NONE statement. If you omit the PERSIST option, the exclusion list is cleared when the procedure terminates. The resulting exclusion list is displayed next:

```
Current OVERALL exclude list is:
1. ParmSearch(PERSIST)
```

The MIXED procedure is run to fit the model:

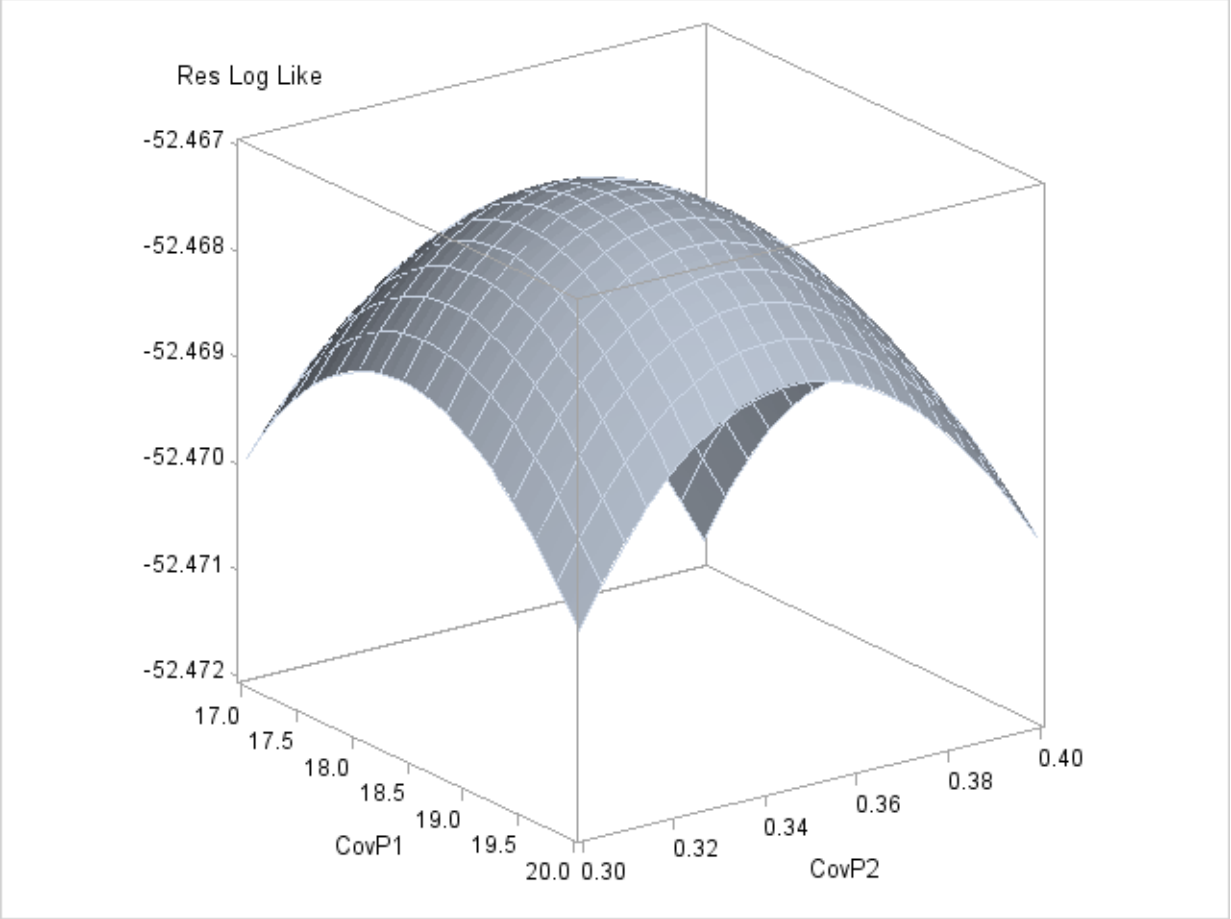
```
proc mixed data=hh;
   class a b;
   model y = a;
   random b a*b;
   parms (17 to 20 by 0.1) (.3 to .4 by .005) (1.0);
   ods output ParmSearch=parms;
run;

ods show;
```

All output from PROC MIXED, except the **ParmSearch** table, is delivered to the HTML and LISTING destinations. The ODS OUTPUT statement outputs the table **ParmSearch** to a SAS data set called Parms.

The ODS SHOW statement again displays the overall current exclusion list after PROC MIXED has terminated. The results of the ODS SHOW statement are displayed next:

```
Current OVERALL exclude list is:
1. ParmSearch(PERSIST)
```



The **ParmSearch** table is saved in the Parms data set (as specified in the ODS OUTPUT statement). The following steps plot the surface of the residual log likelihood as a function of the covariance parameters and produce Output 20.3.1:

```
proc template;
   define statgraph surface;
      begingraph;
         layout overlay3d;
            surfaceplotparm x=CovP1 y=CovP2 z=ResLogLike;
         endlayout;
      endgraph;
   end;
run;

proc sgrender data=parms template=surface;
run;
ods html close;
```

PROC TEMPLATE is used to create a template for displaying the data as a three-dimensional surface plot. The plot is displayed with the ODS Graphics procedure SGRENDER. For more information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS."

Output 20.3.1 HTML Output from PROC MIXED

Example 20.4: Creating an Output Data Set from an ODS Table

In this example, the GENMOD procedure is used to perform Poisson regression, and part of the resulting procedure output is written to a SAS data set with the ODS OUTPUT statement. Insurance claims data are classified by two factors: age group (with two levels) and car type (with three levels). The following statements create the data set Insure:

```
title 'Insurance Claims';

data Insure;
   input n c Car $ Age;
   ln = log(n);
   datalines;
 500   42  Small  1
1200   37  Medium 1
 100    1  Large  1
 400  101  Small  2
 500   73  Medium 2
 300   14  Large  2
;
```

The variable n represents the number of insurance policyholders, and the variable c represents the number of insurance claims. The variable Car represents the type of car involved (classified into three groups), and the variable Age is the age of a policyholder (classified into two groups).

You can use PROC GENMOD to perform a Poisson regression analysis of these data with a log link function. Assume that the number of claims variable c has a Poisson probability distribution and the log of its mean, μ_i, is related to the factors Car and Age.

The following statements obtain the names of the tables produced by this PROC GENMOD run. The ODS TRACE statement lists the trace record. If you already know the names, such as by looking them up in the procedure documentation, you do not have to run this step. The following step displays the trace information:

```
ods trace on;

proc genmod data=insure;
   class car age;
   model c = car age / dist   = poisson
                       link   = log
                       offset = ln
                       obstats;
run;
ods trace off;
```

The trace record from the SAS log is displayed next:

```
Output Added:
-------------
Name:        ModelInfo
Label:       Model Information
Template:    Stat.Genmod.ModelInfo
```

```
Path:       Genmod.ModelInfo
-------------

Output Added:
-------------
Name:       NObs
Label:      Number of observations summary
Template:   Stat.Genmod.NObs
Path:       Genmod.NObs
-------------

Output Added:
-------------
Name:       ClassLevels
Label:      Class Level Information
Template:   Stat.Genmod.Classlevels
Path:       Genmod.ClassLevels
-------------

Output Added:
-------------
Name:       ParmInfo
Label:      Parameter Information
Template:   Stat.Genmod.Parminfo
Path:       Genmod.ParmInfo
-------------

Output Added:
-------------
Name:       ModelFit
Label:      Criteria For Assessing Goodness Of Fit
Template:   stat.genmod.ModelFit
Path:       Genmod.ModelFit
-------------

Output Added:
-------------
Name:       ConvergenceStatus
Label:      Convergence Status
Template:   Stat.Genmod.ConvergenceStatus
Path:       Genmod.ConvergenceStatus
-------------

Output Added:
-------------
Name:       ParameterEstimates
Label:      Analysis Of Parameter Estimates
Template:   stat.genmod.parameterestimates
Path:       Genmod.ParameterEstimates
-------------

Output Added:
-------------
Name:       ObStats
```

```
Label:       Observation Statistics
Template:    Stat.Genmod.Obstats
Path:        Genmod.ObStats
-------------
```

In the following step, the ODS OUTPUT statement writes the ODS table **ObStats** to a SAS data set named myObStats. The LISTING destination is closed so that no output is displayed. All of the usual data set options, such as the KEEP= or RENAME= option, can be used in the ODS OUTPUT statement. Thus, to create the myObStats data set so that it contains only certain columns from the **ObStats** table, you can use the data set options as follows:

```
ods listing close;
proc genmod data=insure;
   class car age;
   model c = car age / dist=poisson link=log offset=ln obstats;
   ods output ObStats=myObStats(keep=car age pred
                                rename=(pred=PredictedValue));
run;
```

The KEEP= option in the ODS OUTPUT statement specifies that only the variables Car, Age, and Pred are written to the data set, and the Pred variable is renamed PredictedValue. The following statements sort the output data set myObStats, reopen the LISTING destination for output, and produce Output 20.4.1:

```
proc sort data=myObStats;
   by descending PredictedValue;
run;

ods listing;
proc print data=myObStats noobs;
   title2 'Values of Car, Age, and the Predicted Values';
run;
```

When a destination is closed, it remains closed until it is explicitly reopened.

Output 20.4.1 The ObStats Table Created as a SAS Data Set

Insurance Claims
Values of Car, Age, and the Predicted Values

Car	Age	Predicted Value
Small	2	107.2011
Medium	2	67.025444
Medium	1	42.974556
Small	1	35.798902
Large	2	13.773459
Large	1	1.2265414

Example 20.5: Creating an Output Data Set: Subsetting the Data

This example demonstrates how you can create an output data set with the ODS OUTPUT statement and also use data set selection keywords to limit the output that ODS writes to a SAS data set. The data set, called Color, contains the eye color and hair color of children from two different regions of Europe. The data are recorded as cell counts, where the variable Count contains the number of children exhibiting each of the 15 combinations of eye and hair color. The following statements create the SAS data set:

```
title 'Hair Color of European Children';

data Color;
   input Region Eyes $ Hair $ Count @@;
   label Eyes  ='Eye Color'
         Hair  ='Hair Color'
         Region='Geographic Region';
   datalines;
1 blue  fair   23  1 blue  red     7  1 blue  medium 24
1 blue  dark   11  1 green fair   19  1 green red     7
1 green medium 18  1 green dark   14  1 brown fair   34
1 brown red     5  1 brown medium 41  1 brown dark   40
1 brown black   3  2 blue  fair   46  2 blue  red    21
2 blue  medium 44  2 blue  dark   40  2 blue  black   6
2 green fair   50  2 green red    31  2 green medium 37
2 green dark   23  2 brown fair   56  2 brown red    42
2 brown medium 53  2 brown dark   54  2 brown black  13
;
```

The following statements close the LISTING destination and sort the observations in the Color data set by the Region variable:

```
ods listing close;

proc sort data=Color;
   by Region;
run;
```

The following ODS OUTPUT statement creates the **ChiSq** table as a SAS data set named myStats:

```
ods output ChiSq=myStats
           (drop=Table
            where=(Statistic =: 'Chi' or
                   Statistic =: 'Like'));
```

Note that you can obtain the names of the tables created by any procedure in the individual procedure chapter or from the individual procedure section of the SAS online Help system. (See the "ODS Table Names" section in the "Details" section of the documentation.) You can also determine the names of tables with the ODS TRACE statement (see Example 20.4 and Example 20.2). The DROP= data set option excludes variables from the new data set. The WHERE= data set option se-

lects observations for output to the new data set myStats—specifically, those that begin with 'Chi' or 'Like'.

The following statements create Output 20.5.1:

```
proc freq data=Color order=data;
   weight Count;
   tables Eyes*Hair / testp=(30 12 30 25 3);
   by Region;
run;

ods listing;
proc print data=myStats noobs;
run;
```

The FREQ procedure is used to create and analyze a crosstabulation table from the two categorical variables Eyes and Hair, for each value of the variable Region. No ODS destinations are open until the ODS LISTING statement is encountered just prior to running the PRINT procedure.

Output 20.5.1 Output Data Set from PROC FREQ and ODS

Hair Color of European Children

Region	Statistic	DF	Value	Prob
1	Chi-Square	8	12.6331	0.1251
1	Likelihood Ratio Chi-Square	8	14.1503	0.0779
2	Chi-Square	8	18.2839	0.0192
2	Likelihood Ratio Chi-Square	8	23.3021	0.0030

Example 20.6: RUN-Group Processing

Some SAS procedures, such as PROC REG and PROC GLM, permit you to submit statements, followed by a RUN statement, followed by more statements and more RUN statements. Each group of statements, followed by a RUN statement, is called a RUN group. These procedures can produce several blocks of output for each of several RUN groups. The procedure stays active until a QUIT statement, a DATA statement, another PROC statement, or the end of the SAS session is encountered. However, ODS settings are by default cleared at RUN-group boundaries. In the following analysis, PROC REG is used to compute the covariance matrix of the estimates for two different models, and the covariance matrices are saved in a single SAS data set. The PERSIST= option in the ODS OUTPUT statement is required to make this happen. The PERSIST= option maintains ODS settings across RUN statements for procedures that support RUN-group processing.

Consider the following population growth trends. The population of the United States from 1790 to 1970 is fit to linear and quadratic functions of time. Note that the quadratic term, YearSq, is created in the DATA step; this is necessary since polynomial effects such as Year*Year cannot be specified in the MODEL statement in PROC REG. The data are as follows:

```
title1 'US Population Study';
title2 'Concatenating Two Tables into One Data Set';

data USPopulation;
   input Population @@;
   retain Year 1780;
   Year=Year+10;
   YearSq=Year*Year;
   Population=Population/1000;
   datalines;
3929 5308 7239 9638 12866 17069 23191 31443 39818 50155
62947 75994 91972 105710 122775 131669 151325 179323 203211
;
```

In the following statements, PROC REG is used, and the ODS OUTPUT statement with the PERSIST= option creates a data set with the **CovB** table (the covariance matrix of the estimates):

```
proc reg data=USPopulation;
   ods output covb(persist=run)=Bmatrix;
   var YearSq;
   model Population = Year / covb;
run;
```

The MODEL statement defines the regression model, and the COVB matrix is requested. The RUN statement executes PROC REG and the model is fit, producing a covariance matrix of the estimates with two rows and two columns. The results are displayed in Output 20.6.1 and Output 20.6.2.

Output 20.6.1 Regression Results for the Model Population

```
                          US Population Study
                  Concatenating Two Tables into One Data Set

                              The REG Procedure
                                Model: MODEL1
                          Dependent Variable: Population

                   Number of Observations Read          19
                   Number of Observations Used          19

                Coeff Var             25.98271
```

Output 20.6.1 *continued*

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	-1958.36630	142.80455	-13.71	<.0001
Year	1	1.07879	0.07593	14.21	<.0001

Output 20.6.2 CovB Matrix for the Model Population

Covariance of Estimates

Variable	Intercept	Year
Intercept	20393.138485	-10.83821461
Year	-10.83821461	0.0057650078

In the next step, the YearSq variable is added to the model and the model is again fit, producing a covariance matrix of the estimates with three rows and three columns:

```
add YearSq;
print;
run; quit;
```

The new COVB matrix is displayed in Output 20.6.3.

Output 20.6.3 CovB Matrix for the Model Population

US Population Study
Concatenating Two Tables into One Data Set

The REG Procedure
Model: MODEL1.1
Dependent Variable: Population

Covariance of Estimates

Variable	Intercept	Year	YearSq
Intercept	711450.62602	-757.2493826	0.2013282694
Year	-757.2493826	0.8061328943	-0.000214361
YearSq	0.2013282694	-0.000214361	5.7010894E-8

The PERSIST=RUN option maintains the ODS selection list across RUN statements for procedures that support RUN-group processing. If the PERSIST=RUN option is omitted, the selection list is cleared when the RUN statement is encountered and only the first COVB matrix is selected. Because the PERSIST=RUN option is specified, the selection list remains in effect throughout the PROC REG step. This ensures that each of the COVB matrices is selected and output. The following

statements display the ODS OUTPUT SAS data set and create Output 20.6.4:

```
proc print;
run;
```

Output 20.6.4 Results of the ODS OUTPUT Statement: Specifying the PERSIST Option

US Population Study
Concatenating Two Tables into One Data Set

Obs	_Run_	Model	Dependent	Variable	Intercept	Year	YearSq
1	1	MODEL1	Population	Intercept	20393.138485	-10.83821461	.
2	1	MODEL1	Population	Year	-10.83821461	0.0057650078	.
3	2	MODEL1.1	Population	Intercept	711450.62602	-757.2493826	0.2013282694

5	2	MODEL1.1	Population	YearSq	0.2013282694	-0.000214361	5.7010894E-8

Note that even though the two COVB matrices do not have the same rows or columns, ODS automatically combines the two tables into one data set.

Example 20.7: ODS Output Data Sets and Using PROC TEMPLATE to Customize Output

You can use ODS statements, the DATA step, and PROC TEMPLATE to modify the appearance of your displayed tables or to display results in forms not directly produced by any procedure. The following example, similar to that given in Olinger and Tobias (1998), runs an analysis with PROC GLM. This example has several parts. It creates output data sets with the ODS OUTPUT statement, combines and manipulates those data sets, displays the results by using a standard SAS template, modifies a template by using PROC TEMPLATE, and displays the output data sets by using the modified template. Each step works toward the final goal of taking multiple tables and creating a custom display of those tables in a way that cannot be directly done by PROC GLM.

The following statements create a SAS data set named Histamine that contains the experimental data:

```
title1 'Histamine Study';

data Histamine;
   input Drug $12. Depleted $ hist0 hist1 hist3 hist5;
   logHist0 = log(hist0); logHist1 = log(Hist1);
   logHist3 = log(hist3); logHist5 = log(Hist5);
   datalines;
Morphine      N  .04  .20  .10  .08
Morphine      N  .02  .06  .02  .02
Morphine      N  .07 1.40  .48  .24
Morphine      N  .17  .57  .35  .24
```

```
Morphine      Y  .10  .09  .13  .14
Morphine      Y  .07  .07  .06  .07
Morphine      Y  .05  .07  .06  .07
Trimethaphan  N  .03  .62  .31  .22
Trimethaphan  N  .03 1.05  .73  .60
Trimethaphan  N  .07  .83 1.07  .80
Trimethaphan  N  .09 3.13 2.06 1.23
Trimethaphan  Y  .10  .09  .09  .08
Trimethaphan  Y  .08  .09  .09  .10
Trimethaphan  Y  .13  .10  .12  .12
Trimethaphan  Y  .06  .05  .05  .05
;
```

The data set comes from a preclinical drug experiment (Cole and Grizzle 1966). In order to study the effect of two different drugs on histamine levels in the blood, researchers administer the drugs to 13 animals, and the levels of histamine in the animals' blood is measured after 0, 1, 3, and 5 minutes. The response variable is the logarithm of the histamine level.

In the analysis that follows, PROC GLM is used to perform a repeated measures analysis, naming the drug and depletion status as between-subject factors in the MODEL statement and naming post-administration measurement time as the within-subject factor. For more information about this study and its analysis, see Example 39.7 in Chapter 39, "The GLM Procedure." Here are the PROC GLM statements that you would run to perform the analysis:

```
ods trace output;

proc glm data=Histamine;
   class Drug Depleted;
   model LogHist0--LogHist5 = Drug Depleted Drug*Depleted / nouni;
   repeated Time 4 (0 1 3 5) polynomial / summary printe;
run; quit;
```

The portion of the trace output containing the fully qualified paths is shown next:

```
Path:       GLM.Data.ClassLevels
Path:       GLM.Data.NObs

```

The goal here is to output the within-subjects multivariate statistics and the between-subjects ANOVA table to SAS data sets for use in subsequent steps. The following statements run the analysis and save the desired results to output data sets:

```
ods listing close;

proc glm data=Histamine;
   class Drug Depleted;
   model LogHist0--LogHist5 = Drug Depleted Drug*Depleted / nouni;
   repeated Time 4 (0 1 3 5) polynomial / summary printe;
   ods output MultStat                    = HistWithin
              BetweenSubjects.ModelANOVA = HistBetween;
run; quit;

ods listing;
```

The LISTING destination is closed so that no output is displayed. The ODS OUTPUT statement creates two SAS data sets, named HistWithin and HistBetween, from the two ODS tables. This analysis creates the following tables:

```
Path:       GLM.Repeated.MANOVA.Model.Time.MultStat
Path:       GLM.Repeated.MANOVA.Model.Time_Drug.MultStat
Path:       GLM.Repeated.MANOVA.Model.Time_Depleted.MultStat
Path:       GLM.Repeated.MANOVA.Model.Time_Drug_Depleted.MultStat
Path:       GLM.Repeated.BetweenSubjects.ModelANOVA
```

Here is the full trace output for the model ANOVA table:

```
Output Added:
-------------
Name:       ModelANOVA
Label:      Type III Model ANOVA
Template:   stat.GLM.Tests
Path:       GLM.Repeated.BetweenSubjects.ModelANOVA
-------------
```

All of the multivariate test results are routed to the HistWithin data set. This is because all multivariate test tables are named **MultStat**, even though they occur in different directories in the output directory hierarchy. Only the between-subject ANOVA table appears in the HistBetween data set, even though there are also other tables named **ModelANOVA**. ODS selects just the one specific table for the HistBetween data set because of the partial path (**BetweenSubjects.ModelANOVA**) in the second specification. For more information about names and qualified path names, see the discussion in the section "Paths and Selection" on page 435.

The following statements show the names and the variable labels for the two data sets and produce Output 20.7.1:

```
proc contents data=HistBetween p;
   ods select position;
run;
```

```
proc contents data=HistWithin p;
   ods select position;
run;
```

Output 20.7.1 The Variable Names and Labels for the Two Data Sets

The next steps are designed to produce a more parsimonious display of the most important information in Output 20.7.2. The next step creates a data set named HistTests. Only the observations from the input data sets that are needed for interpretation are included. The variable Hypothesis in the HistWithin data set is renamed Source, and the NumDF variable is renamed DF. The renamed variables correspond to the variable names found in the HistBetween data set. These names are chosen since the template for the **ModelANOVA** table will be used in subsequent steps. An explicit length for the new variable Source is provided since the input variables, Hypothesis and Source, have different lengths. The following statements produce Output 20.7.3:

```
data HistTests;
   length Source $ 20;
   set HistBetween(where =(Source    ^= 'Error'))
       HistWithin (rename=(Hypothesis =  Source NumDF=DF)
                   where =(Statistic  = 'Hotelling-Lawley Trace'));
run;

proc print label;
   title2 'Listing of the Combined Data Set';
run;
```

Output 20.7.3 Listing of the HistTests Data Set: Histamine Study

Histamine Study

The amount of information contained in the HistTests data set is appropriate for interpreting the analysis; however, there is still extra information, and the information of interest is not being displayed in a compact or useful form. This data set consists of multiple tables, an ANOVA table with between-subjects information, and multivariate statistics tables with the variables renamed to match the names in the ANOVA table. This form was chosen so that the data set could be displayed using PROC GLM's ANOVA template. A template specifies how the data set should be displayed and which columns should be displayed. The output from the ODS TRACE statements shows that the template associated with PROC GLM's ANOVA table is named **`Stat.GLM.Tests`**. You can use the **`Stat.GLM.Tests`** template to display the SAS data set HistTests, as follows:

```
title2 'Listing of the Selections, Using a Standard Template';
proc sgrender data=histtests template=Stat.GLM.Tests;
run;
```

The SGRENDER procedure displays the DATA= data set with the specified TEMPLATE= template. (Note that you can use PROC SGRENDER to display both graphs and tables.) The results are displayed in Output 20.7.4.

Output 20.7.4 Listing of the Data Set Using a Standard PROC GLM ANOVA Template

Histamine Study
Listing of the Selections, Using a Standard Template

Source	DF	SS	Mean Square	F Value	Pr > F
Drug	1	5.99336243	5.99336243	2.71	0.1281
Depleted	1	15.44840703	15.44840703	6.98	0.0229
Drug*Depleted	1	4.69087508	4.69087508	2.12	0.1734
Time	3	.	.	24.03	0.0001
Time_Drug	3	.	.	5.78	0.0175
Time_Depleted	3	.	.	21.31	0.0002
Time_Drug_Depleted	3	.	.	12.48	0.0015

Alternatively and equivalently, you could display the results by using a DATA step as follows:

```
title2 'Listing of the Selections, Using a Standard Template';

data _null_;
   set histtests;
   file print ods=(template='Stat.GLM.Tests');
   put _ods_;
run;
```

The next steps will create a final display of these results, this time by using a custom template. This example shows you how to use PROC TEMPLATE to do the following:

- redefine the format for the SS and Mean Square columns
- include the table title and footnote in the body of the table
- translate the missing values for SS and Mean Square in the rows corresponding to multivariate tests to asterisks (to see the footnote)
- add a column depicting the level of significance of each effect

The following statements create a custom template:

```
proc template;
   define table CombinedTests;
      parent=Stat.GLM.Tests;

      header '#Histamine Study##';
      footer '#* - Test computed using Hotelling-Lawley trace';

      column Source DF SS MS FValue ProbF Star;

      define Source; width=20; end;
      define DF; format=bestd3.; end;
      define SS;
         parent=Stat.GLM.SS
         choose_format=max format_width=7;
         translate _val_ = . into '  *';
      end;
      define MS;
         parent=Stat.GLM.MS
         choose_format=max format_width=7;
         translate _val_ = . into '  *';
      end;
      define Star;
         compute as ProbF;
         translate _val_ <= 0.001 into 'xxx',
                   _val_ <= 0.01  into 'xx',
                   _val_ <= 0.05  into 'x',
                   _val_ >  0.05  into '';
         pre_space=1 width=3 just=l;
      end;
   end;
run;
```

The CHOOSE_FORMAT=MAX option along with FORMAT_WIDTH=7 chooses the format for each column based on the maximum value and an overall width of 7. Alternatively, you could have specified a format directly by specifying, for example, FORMAT=7.2 or FORMAT=D8.3. The TRANSLATE statements provide values to display in place of the original values. The first two TRANSLATE statements display missing values as an asterisk with leading blanks added to ensure alignment with the decimal place. The third TRANSLATE statement displays *p*-values greater than 0.05 as a blank, values greater than 0.01 but less than or equal to 0.05 as a single 'x', and so on. Note that the ProbF column is printed twice—once in the usual way as a numeric column with a PVALUE format and once with a column of blanks or x's. For detailed information about PROC TEMPLATE, see "The Template Procedure" in the *SAS Output Delivery System: User's Guide*. The following statements display the HistTests data set by using the customized template:

```
title2 'Listing of the Selections, Using a Customized Template';

proc sgrender data=HistTests template=CombinedTests;
run;
```

The results are displayed in Output 20.7.5.

Output 20.7.5 Display of the Data Sets Using a Customized Template: Histamine Study

Histamine Study
Listing of the Selections, Using a Customized Template

Histamine Study

	Num DF	Sum of Squares	Mean Square	F Value	Pr > F

Time_Drug_Depleted	3	*	*	12.48	0.0015	xx

* - Test computed using Hotelling-Lawley trace

These next steps display the same table, but this time changing the background color for the entire row to highlight effects with p-values < 0.001 and also those with p-values < 0.01. The table is displayed three times. Output 20.7.6 displays the results by using bold green and yellow backgrounds and a bold font. Output 20.7.7 displays the results by using much subtler cyan and yellow backgrounds and a bold font. Output 20.7.8 displays the results by using very subtle cyan and gray backgrounds and a normal font. This control is provided by the CELLSTYLE statement in PROC TEMPLATE. There are many things you can do with the CELLSTYLE statement to enhance your output. Several more will be shown in other examples in this chapter. These next steps create the custom template with varying colors and fonts, and display the results by using PROC SGRENDER:

```
%macro hilight(c1,c2);
   proc template;
        define table CombinedTests;
           parent=Stat.GLM.Tests;

           header '#Histamine Study##';
           footer '#* - Test computed using Hotelling-Lawley trace';

           column Source DF SS MS FValue ProbF;

           cellstyle probf <= 0.001 as {background=&c1},
                     probf <= 0.01  as {background=&c2};

           define DF; format=bestd3.; end;
           define SS;
              parent=Stat.GLM.SS
              choose_format=max format_width=7;
              translate _val_ = . into '  *';
           end;
           define MS;
              parent=Stat.GLM.MS
              choose_format=max format_width=7;
```

```
            translate _val_ = . into '   *';
         end;
      end;
   run;

   proc sgrender data=HistTests template=CombinedTests;
   run;
%mend;

ods html style=statistical;

%hilight(CX22FF22 fontweight=bold, CXFFFF22 fontweight=bold)
%hilight(CXAAFFFF fontweight=bold, CXFFFFDD fontweight=bold)
%hilight(CXEEFAFA, CXEEEEEE)

ods html close;
```

SAS color values can be expressed as RGB (red, green, blue) values of the form CXRRGGBB. RR, GG, and BB are all integers in the range 0 to 255 but expressed in a HEX2. format (00 to FF) that specify the red, green, and blue values, respectively. You can run the following steps to see the correspondence between the integer and HEX formatting of values in the range 0 to 255:

```
data _null_;
   do color = 0 to 255;
      put color 3. +1 color hex2.;
      end;
   run;
```

The results of this step are not shown. Hexadecimal values 0 through F represent the numbers 0 to 15. A hex value xy can be converted to an integer as follows: $16x + y$. For example, BC is $16 \times 11 + 12 = 188$. Common colors are CXFF0000 (red), CX00FF00 (green), CX0000FF (blue), CXFFFF00 (yellow, a mix of red and green), CXFF00FF (magenta, a mix of red and blue), CX00FFFF (cyan, a mix of green and blue), CXFFFFFF (white, a mix of red, green, and blue), CX000000 (black, no color), CXDDDDDD (very light gray), CX222222 (very dark gray), and so on. Colors become lighter as the RGB values increase and darker as they decrease. For example, cyan (CX00FFFF) can be lightened by increasing the red component from 00 to FF until eventually it becomes indistinguishable from white. It can be darkened by jointly decreasing the green and blue values until it becomes indistinguishable from black.

The three CELLSTYLE statements that set the colors after the macro variables are substituted are as follows:

```
cellstyle probf <= 0.001 as {background=CX22FF22 fontweight=bold},
          probf <= 0.01  as {background=CXFFFF22 fontweight=bold};
cellstyle probf <= 0.001 as {background=CXAAFFFF fontweight=bold},
          probf <= 0.01  as {background=CXFFFFDD fontweight=bold};
cellstyle probf <= 0.001 as {background=CXEEFAFA},
          probf <= 0.01  as {background=CXEEEEEE};
```

The first color, CX22FF22, for the smallest p-values in the first table is a bold green color. The first table uses almost pure green and pure yellow, but a little red and blue are added to slightly lighten the colors. The second table uses a cyan and yellow that are very light due to the addition of AA

(170) red and DD (221) blue, respectively. The third table uses a cyan that is not much different from light gray, and a light gray that is not much different from white.

Example 20.8: HTML Output with Hyperlinks between Tables

This example demonstrates how you can use ODS to provide links between different parts of your HTML procedure output. In this example, a table is created where each row contains a link to another table with more information about that row.

Suppose that you are analyzing a 4×4 factorial experiment for an industrial process, testing for differences in the number of defective products manufactured by different machines, using different sources of raw material. The data set Experiment is created as follows:

```
title 'Product Defects Experiment';

data Experiment;
   do Supplier = 'A', 'B', 'C', 'D';
      do Machine = 1 to 4;
         do rep = 1 to 5;
            input Defects @@;

;
```

Suppose that you are interested in fitting a model to determine the effect that the supplier of raw material and machine type have on the number of defects in the products. If the F test for a factor is significant, you might like to follow up with a multiple-comparison test for the levels of that factor. The tables of interest are the model ANOVA and the multiple-comparison output. Since this is a balanced experiment, the ANOVA procedure computes the appropriate analysis. The following statements produce these tables and Figure 20.8.1:

```
ods listing close;
ods html body='anovab.htm' style=statistical anchor='anova1';
ods trace output;

proc anova data=Experiment;
   ods select ModelANOVA MCLines;
   class Supplier Machine;
   model Defects = Supplier Machine;
   means Supplier Machine / tukey;
run; quit;
```

```
ods html close;
ods listing;
```

The LISTING destination is closed to avoid generating the output twice. ODS writes the HTML output to the file *anovab.htm*. The ANCHOR= option specifies *anova1* as the root name for the HTML anchor tags. This means that within the HTML document, the URL for the first table will be *anova1*, the URL for the second table will be *anova2*, and so on.

Output 20.8.1 ANOVA and Multiple-Comparison Results: Histamine Study

Product Defects Experiment

The ANOVA Procedure

Tukey's Studentized Range (HSD) Test for Defects

Means with the same letter are not significantly different.

Tukey Grouping	Mean	N	Machine
A	11.7500	20	2
A			
A	11.5000	20	4
B	10.1500	20	1
C	8.1500	20	3

The ODS trace output (not shown) shows that PROC ANOVA uses the **Stat.GLM.Tests** template to format the ANOVA table. The following statements demonstrate how you can link a row of the ANOVA table to the corresponding multiple-comparison table by modifying the table template, using the original values and the URLs for the second and third tables (*anova2* and *anova3*):

```
proc template;
   edit Stat.GLM.Tests;
      edit Source;
         cellstyle _val_ = 'Supplier' as {url="#ANOVA2"},
                   _val_ = 'Machine'  as {url="#ANOVA3"};
      end;
   end;
run;
```

This template alters the values in the **Source** column ('Supplier' and 'Machine') of the ANOVA tests table by using the CELLSTYLE statement. The values of 'Supplier' and 'Machine' are displayed as hyperlinks in the HTML, and clicking them takes you to the links *anova2* and *anova3*, which are the multiple-comparison tables.

You can see the value to use in the URL by viewing the HTML source file, *anovab.htm*. You can either open the HTML file in a text editor or view it in a browser window and select **View ► Source**. Search for '<a name=' to find the URL names. The first table is *anova1*, the second is *anova2*, the third is *anova3*, and so on. If the ANCHOR= option had not been used in the ODS HTML statement, the names would have been *IDX*, *IDX1*, *IDX2*, and so on. Note that if you do not use the ODS SELECT statement, or if you do anything to change the tables that come out, the names will be different. The statements create the *Supplier* label as a link that enables you to open the table of means from the "Tukey's Studentized Range Test for Defects" associated with the Supplier variable. Similarly, *Machine* provides a link to the table of means from the "Tukey's Studentized Range Test for Defects" associated with the Machine variable.

Next, the analysis is run again, this time by using the modified template. The following statements produce the results:

```
ods listing close;
ods html body='anovab.htm' style=statistical anchor='anova1';

proc anova data=Experiment;
   ods select ModelANOVA MCLines;
   class Supplier Machine;
   model Defects = Supplier Machine;
   means Supplier Machine / tukey;
run; quit;

ods html close;
ods listing;
```

The ANOVA table is displayed in Output 20.8.2.

Output 20.8.2 HTML Output from PROC ANOVA: Linked Output

The ANOVA Procedure

Dependent Variable: Defects

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	6	3604.775000	600.795833	304.12	<.0001
Error	73	144.212500	1.975514		
Corrected Total	79	3748.987500			

R-Square	Coeff Var	Root MSE	Defects Mean
0.961533	13.53097	1.405530	10.38750

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Supplier	3	3441.637500	1147.212500	580.72	<.0001
Machine	3	163.137500	54.379167	27.53	<.0001

The underlined text displayed in Output 20.8.2 shows the links, *Supplier* and *Machine*, that you created with the modified template. When you click a link, the appropriate multiple-comparison table opens in your browser. Output 20.8.3 shows the table from the *Supplier* link.

Output 20.8.3 Linked Output: Multiple-Comparison Table from PROC ANOVA

Means with the same letter are not significantly different.

B	12.7000	20	B
C	4.6000	20	A
C			
C	4.1500	20	C

When you run the PROC TEMPLATE step shown previously, the following note is printed in the SAS log:

```
NOTE: TABLE 'Stat.GLM.Tests' has been saved to: SASUSER.TEMPLAT
```

You can see that there are now two versions of the template by running the following statements:

```
proc template;
   list Stat.GLM.Tests;
run;
```

These statements produce Output 20.8.4.

Output 20.8.4 The Templates

```
                    Product Defects Experiment

                Listing of: SASUSER.TEMPLAT
                Path Filter is: Stat.GLM.Tests
                Sort by: PATH/ASCENDING

                Obs    Path                Type
                -------------------------------
                 1     Stat.GLM.Tests      Table

                Listing of: SASHELP.TMPLMST
                Path Filter is: Stat.GLM.Tests
                Sort by: PATH/ASCENDING

                Obs    Path                Type
                -------------------------------
                 1     Stat.GLM.Tests      Table
```

You can delete your custom template and restore the default template as follows:

```
proc template;
   delete Stat.GLM.Tests;
run;
```

The following note is printed in the SAS log:

```
NOTE: 'Stat.GLM.Tests' has been deleted from: SASUSER.TEMPLAT
```

Example 20.9: HTML Output with Graphics and Hyperlinks

This example demonstrates how you can use ODS to create links between each bar in a bar chart (Output 20.9.1) and other parts of the analysis (Output 20.9.2). The data in this example are selected from a larger experiment on the use of drugs in the treatment of leprosy (Snedecor and Cochran 1967, p. 422). Variables in the study are as follows:

Drug	two antibiotics ('a' and 'd') and a control ('f')
PreTreatment	a pretreatment score of leprosy bacilli
PostTreatment	a posttreatment score of leprosy bacilli

The data set is created as follows:

```
title 'Treatment of Leprosy';

data drugtest;
   input Drug $ PreTreatment PostTreatment @@;
   datalines;
a 11  6  a  8  0  a  5  2  a 14  8  a 19 11
a  6  4  a 10 13  a  6  1  a 11  8  a  3  0
d  6  0  d  6  2  d  7  3  d  8  1  d 18 18
d  8  4  d 19 14  d  8  9  d  5  1  d 15  9
f 16 13  f 13 10  f 11 18  f  9  5  f 21 23
f 16 12  f 12  5  f 12 16  f  7  1  f 12 20
;
```

The following statement opens the HTML destination:

```
ods html body='glmb.htm' contents='glmc.htm' frame='glmf.htm'
         style=statistical;
```

The ODS HTML statement specifies the body filename, generates a table of contents for the output, and generates a frame to contain the body and table of contents. The following statements perform the analysis:

```
proc glm data=drugtest;
   class drug;
   model PostTreatment = drug | PreTreatment / solution;
   lsmeans drug / stderr pdiff;
   ods output LSMeans=lsmeans;
run; quit;
```

The ODS OUTPUT statement writes the table of LS-means to the data set named lsmeans. PROC GLM performs an analysis of covariance and computes LS-means for the variable Drug.

The following steps demonstrate how you can create links to connect the results of different analyses. In this example, the table of LS-means is graphically summarized in a horizontal bar chart. Each bar is linked to a plot that displays the relationship between the PostTreatment response variable and the PreTreatment variable for the drug corresponding to the bar. Note that PROC GLM can use ODS Graphics to create LS-means graphs that are different from the one constructed here. You do not have to run the following steps to get PROC GLM's standard LS-means plots. The following DATA step creates a new variable named DrugClick that matches each drug value with an HTML file:

```
data lsmeans;
   set lsmeans;
   if drug='a' then DrugClick='drug1.htm';
   if drug='d' then DrugClick='drug2.htm';
   if drug='f' then DrugClick='drug3.htm';
run;
```

The variable DrugClick is used in the chart. The variable provides the connection information for linking the two parts of the analysis together. The files referred to in these statements are created in a later step. The following statements create the chart:

```
ods graphics / imagemap=yes height=2in width=6.4in;

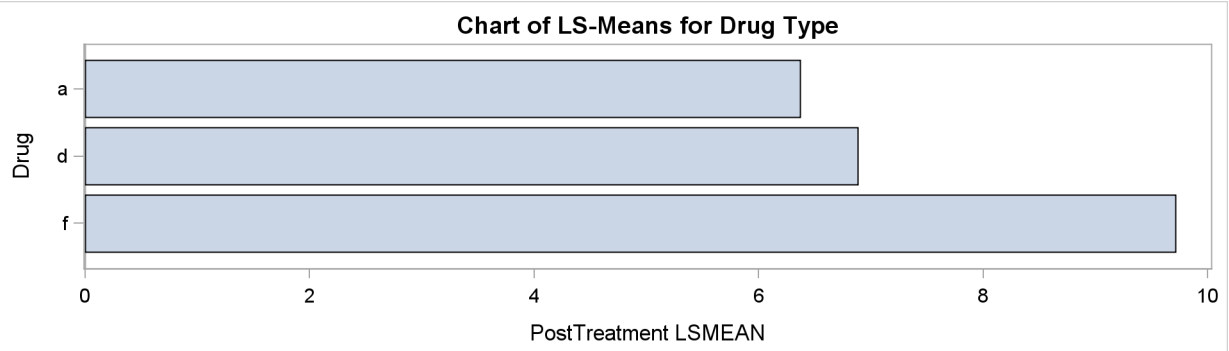
proc sgplot data=lsmeans;
   title 'Chart of LS-Means for Drug Type';
   hbar drug / response=lsmean stat=mean
               url=drugclick;
   footnote j=l 'Click on the bar to see a plot of PostTreatment '
                'versus PreTreatment for the corresponding drug.';
   format lsmean 6.3;
run;

ods graphics off;
footnote;
ods html close;
```

The chart is created with the ODS Graphics procedure SGPLOT. For more information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." The ODS GRAPHICS statement is not required before you run SG procedures. However, in this case, it is necessary to specify IMAGEMAP=YES so that the URL= option will work properly. The size of the graph is also specified with the HEIGHT= and WIDTH= options. PROC SGPLOT is used, and the HBAR statement requests a horizontal bar chart for the variable Drug. The lengths of the bars represent the values of the

LSMean variable. The URL= option specifies the variable DrugClick as the HTML linking variable. The FOOTNOTE statement provides text that indicates how to use the links in the graph.

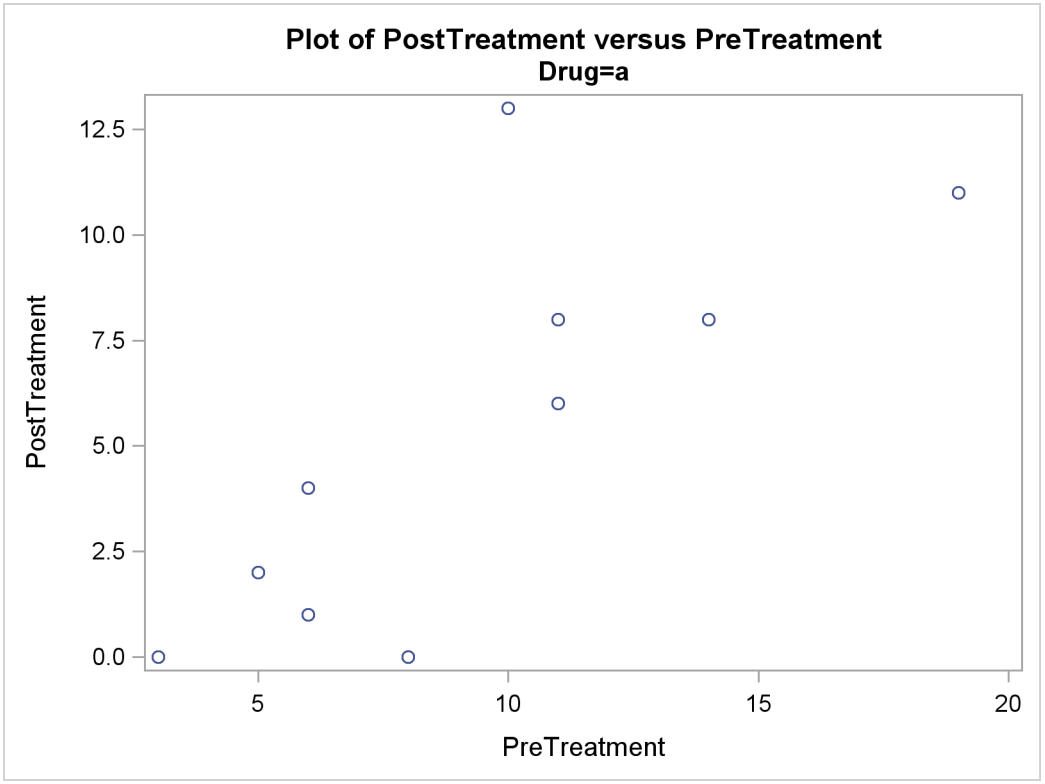
The following statements provide that second analysis. The three files referred to by the DrugClick variable are created as follows:



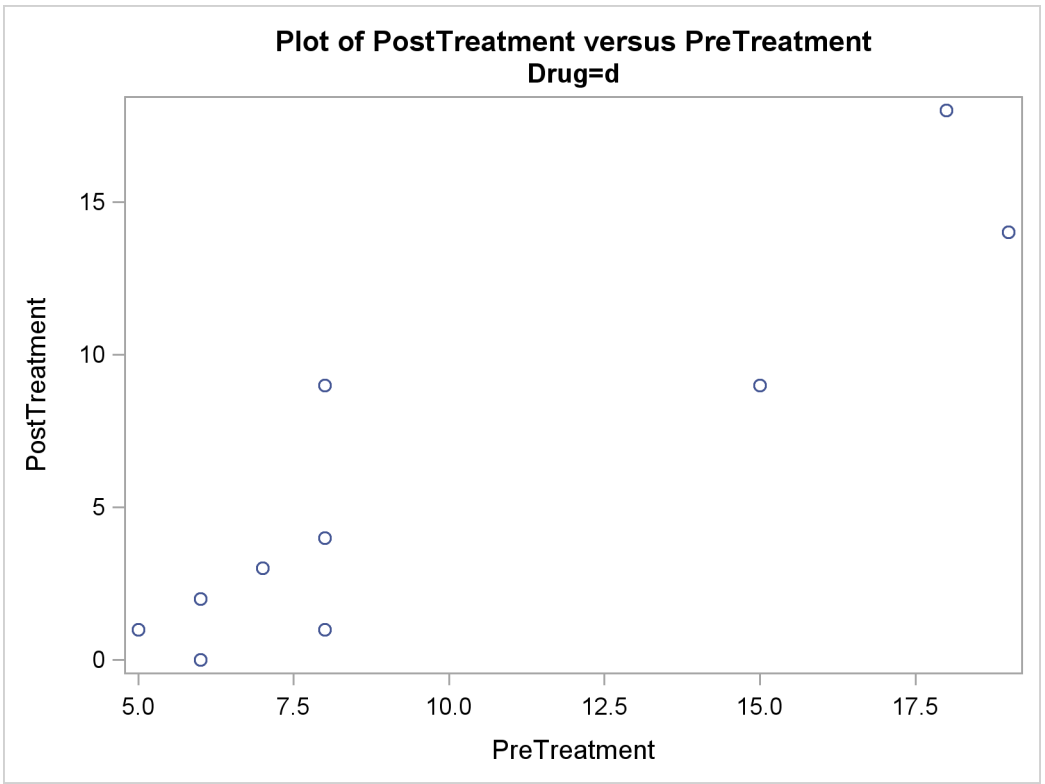
```
ods html body='drug1.htm' newfile=page style=statistical;

proc sgplot data=drugtest;
   title 'Plot of PostTreatment versus PreTreatment';
   scatter y=PostTreatment x=PreTreatment;
   by drug notsorted;
run;
ods html close;
```

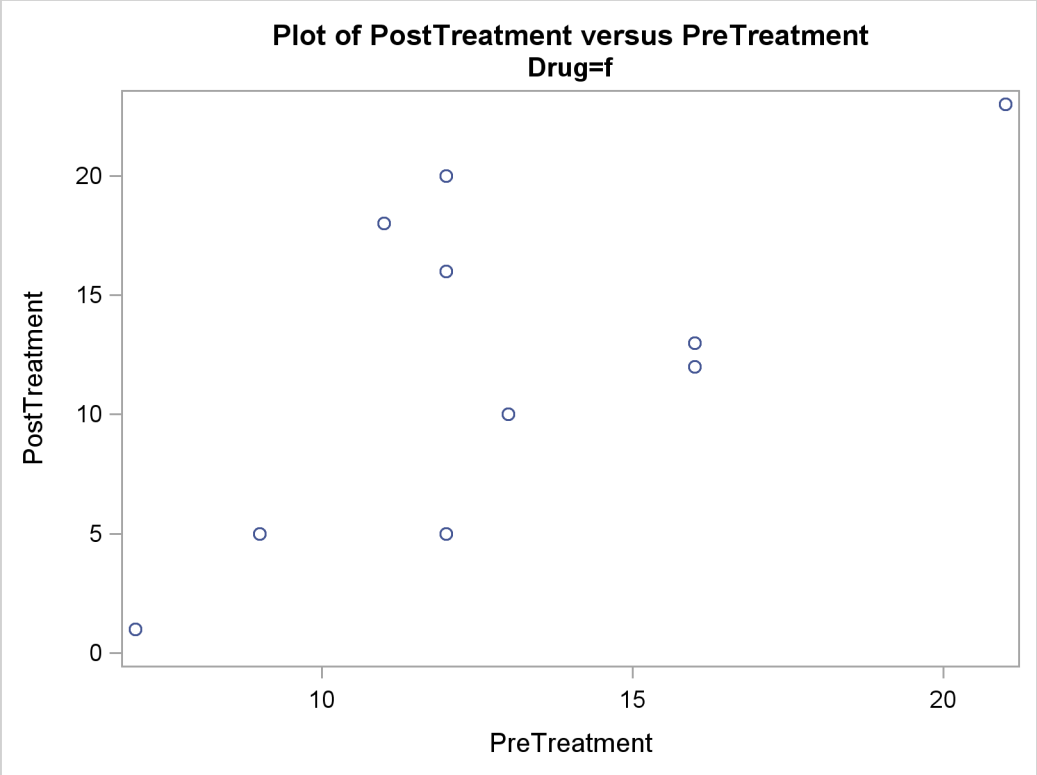
The NEWFILE= option in the ODS HTML statement creates a new HTML file for each page of output. Note that page breaks occur only when a procedure explicitly starts a new page. The NEWFILE= option also increments the filename numeric suffix for each new HTML file created, with the first filename corresponding to that given in the BODY= option, *drug1.htm*.



PROC SGPLOT is used, producing a plot of the variable PostTreatment versus the variable PreTreatment for each value of the Drug variable. Three plots are created, and each plot is contained in a separate HTML file. The files are named *drug1.htm*, *drug2.htm*, and *drug3.htm*. The filenames match those filenames specified as values of the DrugClick variable. By default, the HTML files are generated in your current working directory. You can instead specify a path, such as `frame='html/drug2.htm'`, to put a file in a subdirectory. The chart in Output 20.9.1 displays the difference in LS-means for each drug type. When you click on a bar that represents a value of the variable Drug, the browser opens the plot of PostTreatment versus PostTreatment variables that corresponds to that value of the variable Drug. Output 20.9.2 displays the plots for each drug type.



Output 20.9.1 Bar Chart of LS-Means by Drug Type with Links to Plots



Click on the bar to see a plot of PostTreatment versus PreTreatment for the corresponding drug.

Output 20.9.2 Plots by Drug Type

Output 20.9.2 *continued*

Example 20.10: Correlation and Covariance Matrices

This example demonstrates how you can use ODS to set the background color of individual cells in a table. The color is set to reflect the magnitude of the value in the cell. You can use color to call attention to larger values and to see the pattern in the data in a way that is hard to visualize just by looking at the numbers. This is illustrated with correlation and covariance matrices. The data for this first part of this example are ratings of automobiles. The following statements create the data set:

```
title 'Rating of Automobiles';

data cars;
   input Origin $ 1-8 Make $ 10-19 Model $ 21-36
         (MPG Reliability Acceleration Braking Handling Ride
          Visibility Comfort Quiet Cargo) (1.);
   datalines;
GMC       Buick      Century          3334444544
GMC       Buick      Electra          2434453555

... more lines ...

GMC       Pontiac    Sunbird          3134533234
;
```

The following steps edit the template that PROC CORR uses to display the correlation matrix. The CELLSTYLE statement sets the background color to light gray for correlations equal to 1 or –1. Values less than –0.75 or greater than 0.75 are set to red. Values less than –0.50 or greater than 0.50 are set to blue. Values less than –0.25 or greater than 0.25 are set to cyan. Values in the range –0.25 to 0.25 are set to white. PROC CORR is then run using the custom template. Finally, the default template is restored. The following statements produce Output 20.10.1:

```
proc template;
   edit Base.Corr.StackedMatrix;
      column (RowName RowLabel) (Matrix) * (Matrix2);
      edit matrix;
         cellstyle _val_  = -1.00 as {backgroundcolor=CXEEEEEE},
                   _val_ <= -0.75 as {backgroundcolor=red},
                   _val_ <= -0.50 as {backgroundcolor=blue},
                   _val_ <= -0.25 as {backgroundcolor=cyan},
                   _val_ <=  0.25 as {backgroundcolor=white},
                   _val_ <=  0.50 as {backgroundcolor=cyan},
                   _val_ <=  0.75 as {backgroundcolor=blue},
                   _val_ <   1.00 as {backgroundcolor=red},
                   _val_  =  1.00 as {backgroundcolor=CXEEEEEE};
         end;
      end;
   run;

ods html body='corr.html' style=statistical;
ods listing close;
proc corr data=cars noprob;
   ods select PearsonCorr;
run;
ods listing;
ods html close;

proc template;
   delete Base.Corr.StackedMatrix;
run;
```

Output 20.10.1 Correlation Matrix from PROC CORR

Rating of Automobiles

Cargo	-0.03075	0.35261	-0.12112	0.20880	-0.14274	0.39108	0.35585	0.53836	0.33846	1.00000

The preceding statements used a small number of discrete colors to show the range of values. In contrast, the following statements use a color gradient. The SAS autocall macro **Paint** is available for generating the CELLSTYLE colors list with a list of interpolated colors. If your site has installed the autocall libraries supplied by SAS and uses the standard configuration of software supplied by SAS, you need to ensure that the SAS system option MAUTOSOURCE is in effect to begin using autocall macros. The macros do not have to be included (for example, with a %INCLUDE statement). They can be called directly once they are properly installed. For more information about autocall libraries, see *SAS Macro Language: Reference*.

Usually, you can use the **Paint** macro by specifying a list of values and a list of colors. Here is an example for values ranging from 0 to 10:

```
%paint(values=0 to 10 by 0.5,
       colors=white cyan blue magenta red)

proc print data=colors;
run;
```

The **Paint** macro prints the following information to the SAS log:

```
Legend:
         0 = White
       2.5 = Cyan
         5 = Blue
       7.5 = Magenta
        10 = Red
```

A value of 0 maps to white, a value of 2.5 maps to cyan, values in the range 0 to 2.5 map to colors in the range from white to cyan, and so on. The **Paint** macro for this step creates an output data set, Colors, which is shown in Output 20.10.2.

Output 20.10.2 Color Interpolation

Rating of Automobiles

Obs	Start	_RGB_
1	0.0	CXFFFFFF
2	0.5	CXCBFFFF
3	1.0	CX97FFFF
4	1.5	CX63FFFF
5	2.0	CX2FFFFF
6	2.5	CX05FFFF
7	3.0	CX00D1FF
8	3.5	CX009CFF
9	4.0	CX0068FF
10	4.5	CX0034FF
11	5.0	CX0000FF
12	5.5	CX3400FF
13	6.0	CX6800FF
14	6.5	CX9C00FF
15	7.0	CXD100FF
16	7.5	CXFA00FF
17	8.0	CXFF00D1
18	8.5	CXFF009C
19	9.0	CXFF0068
20	9.5	CXFF0034
21	10.0	CXFF0000

This shows the color interpolation for a series of points. You could use a smaller BY value in the **Paint** macro to get more points along the color gradient. Note, however, that a few dozen colors are usually sufficient for most purposes.

The following steps use the **Paint** macro to create a color gradient for a correlation matrix, edit the template, display the results, and restore the default template:

```
%paint(values=-1 to 1 by 0.05, macro=setstyle,
       colors=CXEEEEEE red magenta blue cyan white
              cyan blue magenta red CXEEEEEE
              -1 -0.99 -0.75 -0.5 -0.25 0 0.25 0.5 0.75 0.99 1)

proc template;
   edit Base.Corr.StackedMatrix;
      column (RowName RowLabel) (Matrix) * (Matrix2);
      edit matrix;
         %setstyle(backgroundcolor)
         end;
      end;
   run;

ods html body='corr.html' style=statistical;
ods listing close;
proc corr data=cars noprob;
   ods select PearsonCorr;
run;
```

```
ods listing;
ods html close;

proc template;
   delete Base.Corr.StackedMatrix;
run;
```

The VALUES= option creates a range of values from –1 to 1 with an increment of 0.05. The **Paint** macro generates a CELLSTYLE **_val_ <=** *value* **as {backgroundcolor=** *color***},** line for each value in the list. Specifically, it generates a macro named SETSTYLE, from the MACRO= option, that contains the entire CELLSTYLE statement for use in PROC TEMPLATE. The argument to the macro is the option that you want to set. In this case, it is the background color. You could specify **foreground** instead to set the color of the numbers themselves. The first part of the generated statement is as follows:

```
cellstyle _val_<=-1 as {backgroundcolor=CXEFEEEE},
          _val_<=-0.95 as {backgroundcolor=CXFF0020},
          _val_<=-0.9 as {backgroundcolor=CXFF0062},
          _val_<=-0.85 as {backgroundcolor=CXFF008D},
          _val_<=-0.8 as {backgroundcolor=CXFF00CF},
```

The color mapping for a correlation matrix can be a bit more involved than it is for most tables. This is because you might want the maximum correlations, 1 and –1, to be displayed using colors outside the gradient used for other values. Usually, you specify the color list, and the **Paint** macro maps the first color to the minimum value, the last color to the maximum value, and colors in between using equal increments and values based on the minimum and maximum. Alternatively, you can provide these values, and that is what is done in this example. The legend, displayed in the SAS log, is as follows for the **Paint** macro step:

```
Legend:
      -1 = CXEEEEEE
   -0.99 = Red
   -0.75 = Magenta
    -0.5 = Blue
   -0.25 = Cyan
       0 = White
    0.25 = Cyan
     0.5 = Blue
    0.75 = Magenta
    0.99 = Red
       1 = CXEEEEEE
```

Values in the range –0.99 to 0.99 follow the interpolation red to magenta to blue to cyan to white to cyan to blue to magenta to red. Of course the actual correlations for these data do not span this entire range, so a pure red background will not appear in the matrix. Correlations of 1 and –1 are displayed as light gray. The resulting correlation matrix is displayed in Output 20.10.3. Notice that there are now a number of shades of colors, particularly shades of blues, not just a few discrete colors. The largest values are displayed in shades of purple and magenta.

Output 20.10.3 Correlation Matrix from PROC CORR with a Color Gradient

Rating of Automobiles

The CORR Procedure

Next, the same technique is used to display the covariance and correlation matrices of a heteroscedastic autoregressive model. The data are based on the famous growth measurement data of Pothoff and Roy (1964), but are modified here to illustrate the technique of painting the entries of a matrix. The original data are used, for example, in the second example of the PROC MIXED documentation. The data consist of four repeated growth measurements of 11 girls and 16 boys. The measurements from two adjacent children in the original data were combined and rearranged here to emulate a repeated measures sequence with 8 observations. The following statements create the data set:

```
title 'Analysis of Repeated Growth Measures';

data pr;
   input Person Gender $ y1 y2 y3 y4 y5 y6 y7 y8;
   array y{8};
   do time=5,7,8,4,3,2,1;
      Response = y{time};
      Age      = time+7;
      output;
   end;
   datalines;
 1   F   21.0  20.0  21.5  23.0  21.0  21.5  24.0  25.5
 2   F   20.5  24.0  24.5  26.0  23.5  24.5  25.0  26.5
 3   F   21.5  23.0  22.5  23.5  20.0  21.0  21.0  22.5
 4   F   21.5  22.5  23.0  25.0  23.0  23.0  23.5  24.0
 5   F   20.0  21.0  22.0  21.5  16.5  19.0  19.0  19.5
 6   F   24.5  25.0  28.0  28.0  26.0  25.0  29.0  31.0
 7   M   21.5  22.5  23.0  26.5  23.0  22.5  24.0  27.5
 8   M   25.5  27.5  26.5  27.0  20.0  23.5  22.5  26.0
 9   M   24.5  25.5  27.0  28.5  22.0  22.0  24.5  26.5
10   M   24.0  21.5  24.5  25.5  23.0  20.5  31.0  26.0
11   M   27.5  28.0  31.0  31.5  23.0  23.0  23.5  25.0
```

```
12   M   21.5  23.5  24.0  28.0  17.0  24.5  26.0  29.5
13   M   22.5  25.5  25.5  26.0  23.0  24.5  26.0  30.0
;
```

The following statements create a macro that sets colors for the covariance matrix, SETSTYLE1, create a macro that sets colors for the correlation matrix, SETSTYLE2, edit the templates, run the analysis with PROC GLIMMIX, and restore the default templates:

```
* You need to run the analysis once to know that 20 is a good maximum;
%paint(values=0 to 20 by 0.25,
       colors=cyan blue magenta red, macro=setstyle1)

%paint(values=0 to 1 by 0.05,
       colors=cyan blue magenta red, macro=setstyle2)

proc template;
   edit Stat.Glimmix.V;
      column Subject Index Row Col;
      edit Col;
         %setstyle1(backgroundcolor)
      end;
   end;
   edit Stat.Glimmix.VCorr;
      column Subject Index Row Col;
      edit Col;
         %setstyle2(backgroundcolor)
      end;
   end;
run;

ods html body='ar1.html' style=statistical;
ods listing close;
proc glimmix data=pr;
   class person gender time;
   model response = gender age gender*age;
   random _residual_ / sub=person type=arh(1) v residual vcorr;
   ods select v vcorr;
run;
ods listing;
ods html close;

proc template;
   delete Stat.Glimmix.V;
   delete Stat.Glimmix.VCorr;
run;
```

The results are displayed in Output 20.10.4 and Output 20.10.5. Both the covariance and correlation matrices have a structure that is more obvious when colors are added to the display. In particular, the colors clearly show the banded structure of the correlation matrix.

Output 20.10.4 Heteroscedastic AR(1) Covariance Matrix

Analysis of Repeated Growth Measures

The GLIMMIX Procedure

5	2.4983	2.7966	3.9795	5.0318	5.5959	3.3181	2.1720
6	1.4814	1.6582	2.3596	2.9836	3.3181	4.0075	2.6232
7	0.9697	1.0855	1.5446	1.9530	2.1720	2.6232	3.4976

Output 20.10.5 Heteroscedastic AR(1) Correlation Matrix

Estimated V Correlation Matrix for Person 1

Row	Col1	Col2	Col3	Col4	Col5	Col6	Col7
1	1.0000	0.7007	0.4910	0.3440	0.2410	0.1689	0.1183
2	0.7007	1.0000	0.7007	0.4910	0.3440	0.2410	0.1689
3	0.4910	0.7007	1.0000	0.7007	0.4910	0.3440	0.2410
4	0.3440	0.4910	0.7007	1.0000	0.7007	0.4910	0.3440
5	0.2410	0.3440	0.4910	0.7007	1.0000	0.7007	0.4910
6	0.1689	0.2410	0.3440	0.4910	0.7007	1.0000	0.7007
7	0.1183	0.1689	0.2410	0.3440	0.4910	0.7007	1.0000

Alternatively, you could just use the `Paint` macro to do the color interpolation, and use its output data set to create other types of style effects. The following statements show one way to set the font to bold and set the foreground color based on the values of the covariances:

```
%let inc = 0.25;

%paint(values=0 to 20 by &inc, colors=blue magenta red)

data cntlin;
   set colors;
   fmtname = 'paintfmt';
   label = _rgb_;
   end = start + &inc;
   keep start end label fmtname;
   run;

proc format cntlin=cntlin;
   run;
```

```
proc template;
   edit Stat.Glimmix.V;
      column Subject Index Row Col;
      edit Col;
         style = {foreground=paintfmt8. font_weight=bold};
      end;
   end;
run;

ods html body='ar1.html' style=statistical;
ods listing close;
proc glimmix data=pr;
   class person gender time;
   model response = gender age gender*age;
   random _residual_ / sub=person type=arh(1) v residual;
   ods select v;
run;
ods listing;
ods html close;

proc template;
   delete Stat.Glimmix.V;
run;
```

The **Paint** macro creates the SAS data set Colors with the result of the interpolation. This data set can be processed to create a format. The DATA step creates a range of values from Start to End and assigns a color to Label based on the color computed by the **Paint** macro. This data set is input to PROC FORMAT to create the format PAINTFMT. PROC TEMPLATE uses this format to set the color of the values in the table. The cell value is evaluated using the specified FOREGROUND= format for every cell in the table, and the appropriate color is assigned. PROC GLIMMIX does the analysis, and the results are displayed in Output 20.10.6.

Output 20.10.6 Heteroscedastic AR(1) Covariance Matrix

Analysis of Repeated Growth Measures

The GLIMMIX Procedure

Estimated V Matrix for Person 1

Row	Col1	Col2	Col3	Col4	Col5	Col6	Col7
1	19.1973	10.5505	7.3707	4.5756	2.4983	1.4814	0.9697
2	10.5505	11.8104	8.2508	5.1220	2.7966	1.6582	1.0855
3	7.3707	8.2508	11.7407	7.2885	3.9795	2.3596	1.5446
4	4.5756	5.1220	7.2885	9.2159	5.0318	2.9836	1.9530
5	2.4983	2.7966	3.9795	5.0318	5.5959	3.3181	2.1720
6	1.4814	1.6582	2.3596	2.9836	3.3181	4.0075	2.6232
7	0.9697	1.0855	1.5446	1.9530	2.1720	2.6232	3.4976

Many other effects could be achieved by using this approach and different options in the STYLE= specification.

Introduction

Effective graphics are indispensable for modern statistical analysis. They reveal patterns, differences, and uncertainty that are not readily apparent in tabular output. Graphics provoke questions that stimulate deeper investigation, and they add visual clarity and rich content to reports and presentations.

In earlier SAS releases, creating graphs with statistical procedures typically required additional programming steps such as creating output data sets with the values to plot, modifying these data sets with a DATA step program, and using traditional SAS/GRAPH procedures to produce the plots.

SAS 9.2 eliminates the need for additional programming by providing new functionality, referred to as ODS Statistical Graphics (or ODS Graphics for short). ODS Graphics is an extension of ODS (the Output Delivery System). ODS manages procedure output and lets you display it in a variety of destinations, such as HTML and RTF. With ODS Graphics, statistical procedures now produce graphs as automatically as they produce tables, and graphs are now integrated with tables in the ODS output. ODS Graphics is available in procedures in SAS/STAT, Base SAS, SAS/ETS, SAS/QC, SAS/GRAPH, and other products (see the section "Procedures That Support ODS Graphics" on page 528). Note that SAS/GRAPH software is required for ODS Graphics functionality.

ODS Graphics is enabled when you specify the following statement:

```
ods graphics on;
```

When ODS Graphics is enabled, procedures that support ODS Graphics create appropriate graphs, either by default or when you specify procedure options for requesting specific graphs. These options are documented in the "Syntax" section of each procedure chapter, and the "Details" section of each chapter provides an "ODS Graphics" subsection that lists the graphs that are available. Once ODS Graphics is enabled, it stays enabled for the duration of your SAS session. Alternatively, you can turn it off as follows:

```
ods graphics off;
```

For example, you might consider disabling ODS Graphics if your goal is solely to produce computational results. Often though, you can specify ODS GRAPHICS ON and then leave it on. Throughout this chapter, ODS Graphics is enabled only once per section.

This chapter provides a basic introduction to ODS Graphics along with more detailed information. The following list provides a guide to reading this chapter:

- If you want to see a few of the many graphs that are produced by statistical procedures by using ODS Graphics, see the section "Getting Started with ODS Statistical Graphics" on page 501.
- If you are using ODS Graphics for the first time, read the section "A Primer on ODS Statistical Graphics" on page 519, which provides the minimum information that you need to get started.
- If you need to create plots of raw data or your own customized plots of statistical results, see the section "Statistical Graphics Procedures" on page 589, which describes new SAS/GRAPH procedures that use ODS Graphics.
- If you need information about specialized topics such as accessing your graphs, making changes to your graphs, and working with ODS styles, see the detailed discussions starting with the section "Syntax" on page 529 and including the section "Examples of ODS Statistical Graphics" on page 601.

If you are unfamiliar with ODS, see Chapter 20, "Using the Output Delivery System." For complete documentation about the Output Delivery System, see the *SAS Output Delivery System: User's Guide*. For complete documentation about ODS graph templates, see the *SAS/GRAPH: Graph Template Language User's Guide* and the *SAS/GRAPH: Graph Template Language Reference*. For complete documentation about the Graphics Editor, see the *Getting Started with the SAS/GRAPH Statistical Graphics Editor*. Also see the *SAS/GRAPH: Statistical Graphics Procedures Guide* for information about the statistical graphics procedures.

Getting Started with ODS Statistical Graphics

This section provides examples that illustrate the most basic uses of ODS Graphics with a few of the many plots that are produced by statistical procedures. These examples also illustrate several ODS styles that are useful for statistical analysis.

Default Plots for Simple Linear Regression with PROC REG

This example is taken from the section "Getting Started: REG Procedure" on page 5436 of Chapter 73, "The REG Procedure." It uses the following data from a study of 19 children:

```
data Class;
   input Name $ Height Weight Age @@;
   datalines;
Alfred  69.0 112.5 14  Alice  56.5  84.0 13  Barbara 65.3  98.0 13

... more lines ...

;
```

A larger version of this data set is available in the SASHELP library, and later examples use this data set by specifying **data=sashelp.class**.

The following statements use PROC REG to fit a simple linear regression model in which Weight is the response variable and Height is the independent variable:

```
ods graphics on;

proc reg data=Class;
   model Weight = Height;
run; quit;
```

The ODS GRAPHICS ON statement is specified to request ODS Graphics in addition to the usual tabular output. The statement ODS GRAPHICS OFF is not used here, but it can be specified to disable ODS Graphics.

The graphical output consists of a fit diagnostics panel, a residual plot, and a fit plot. These plots are integrated with the tabular output and are shown in Figure 21.1, Figure 21.2, and Figure 21.3, respectively. The results are displayed in the STATISTICAL style.

Figure 21.1 Fit Diagnostics Panel

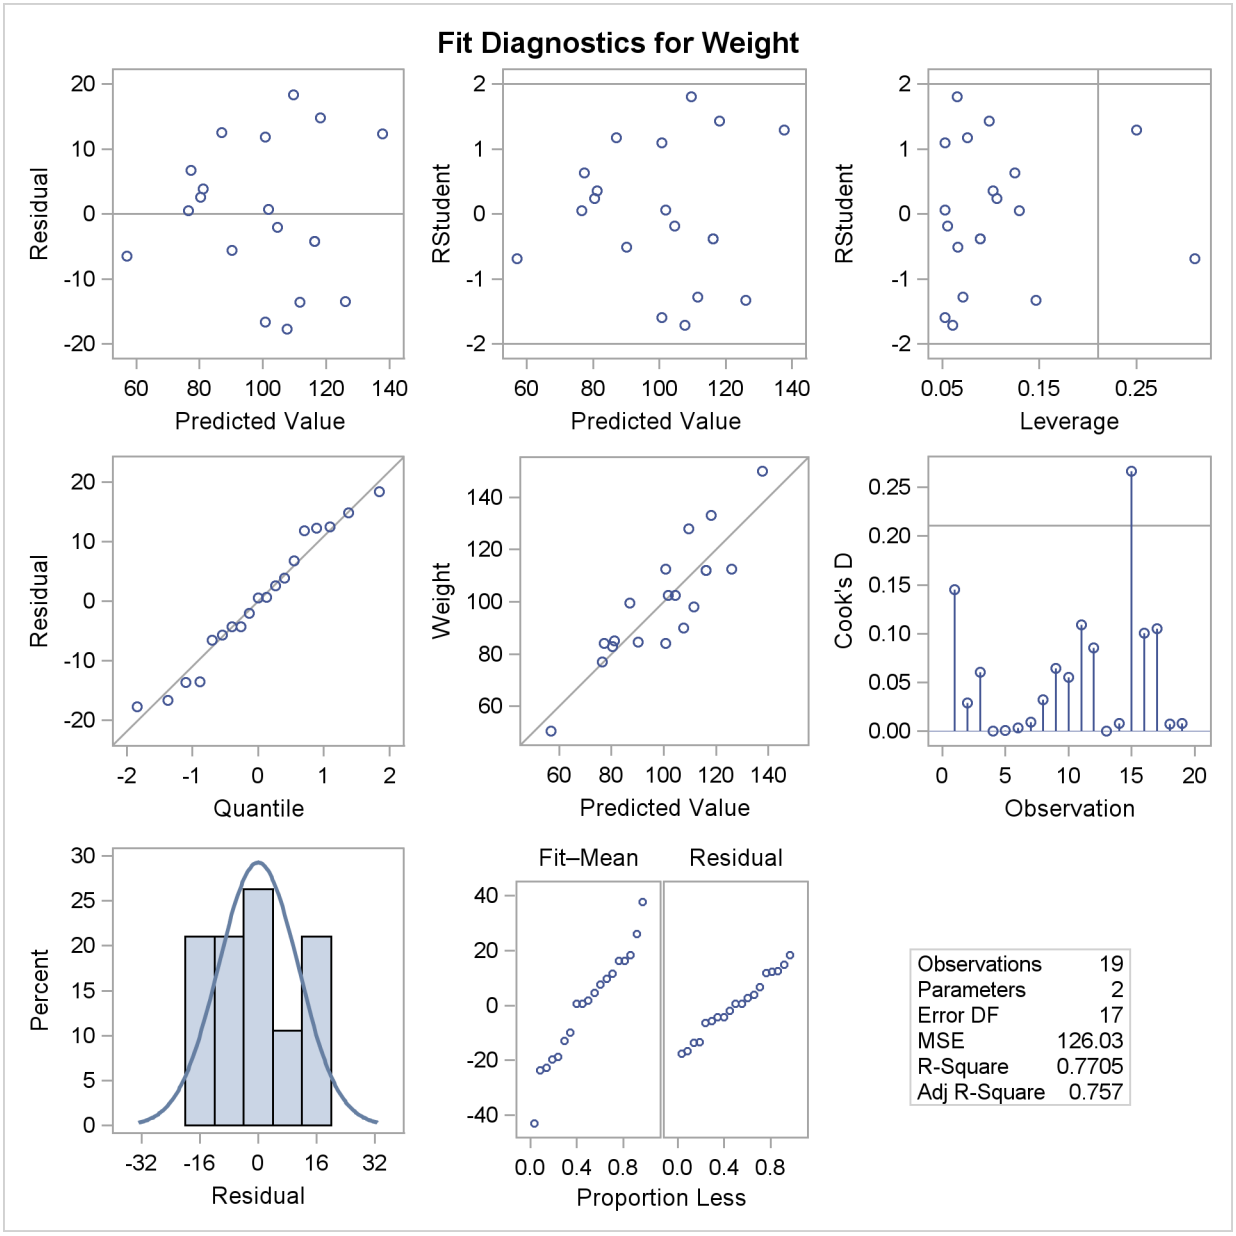

Figure 21.2 Residual Plot

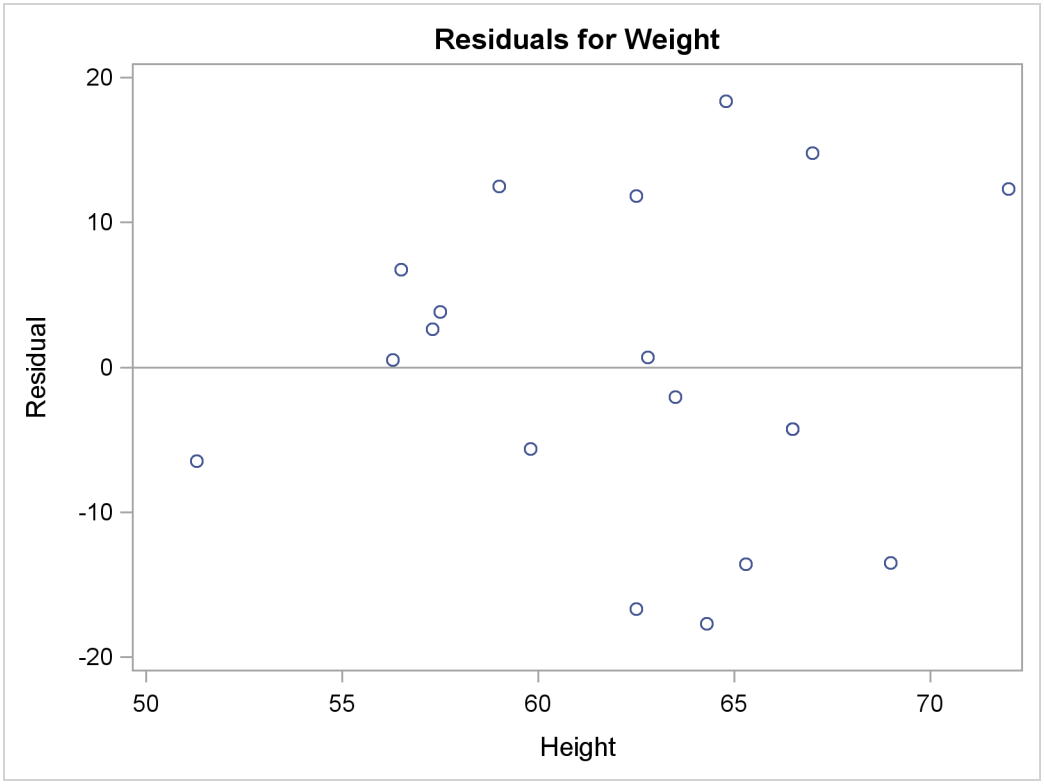

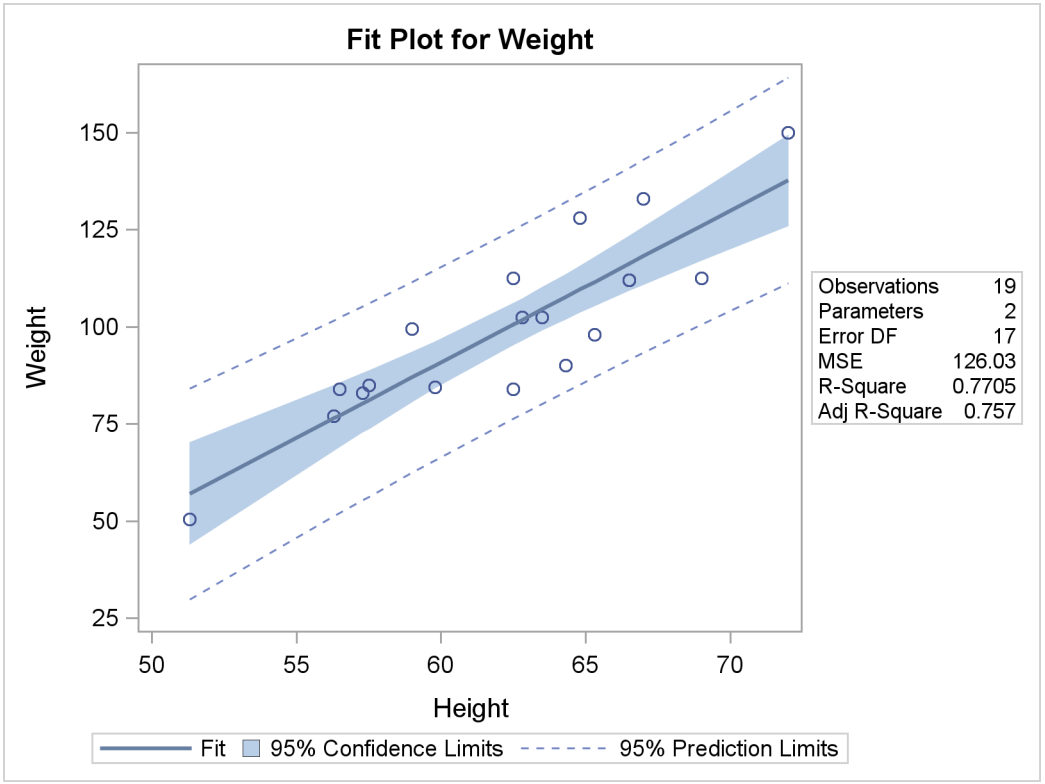

Figure 21.3 Fit Plot

ODS styles control the colors and general appearance of all graphs and tables, and SAS provides several styles that are recommended for use with statistical graphics. The STATISTICAL style is the default style in SAS/STAT documentation and is used unless another style is explicitly specified. The default style that you see when you run SAS depends on the ODS destination. Specifically, the default style for the LISTING destination is LISTING, the default style for the HTML destination is DEFAULT, and the default style for the RTF destination is RTF. These and other styles are shown in this chapter. For more information about styles, see the section "Graph Styles" on page 520 and the section "Styles" on page 554.

Survival Estimate Plot with PROC LIFETEST

This example is taken from Example 49.2 of Chapter 49, "The LIFETEST Procedure." It shows how to construct a product-limit survival estimate plot. Both the ODS GRAPHICS statement and procedure options are used to request the plot.

The following statements create a SAS data set with disease-free times for three risk categories:

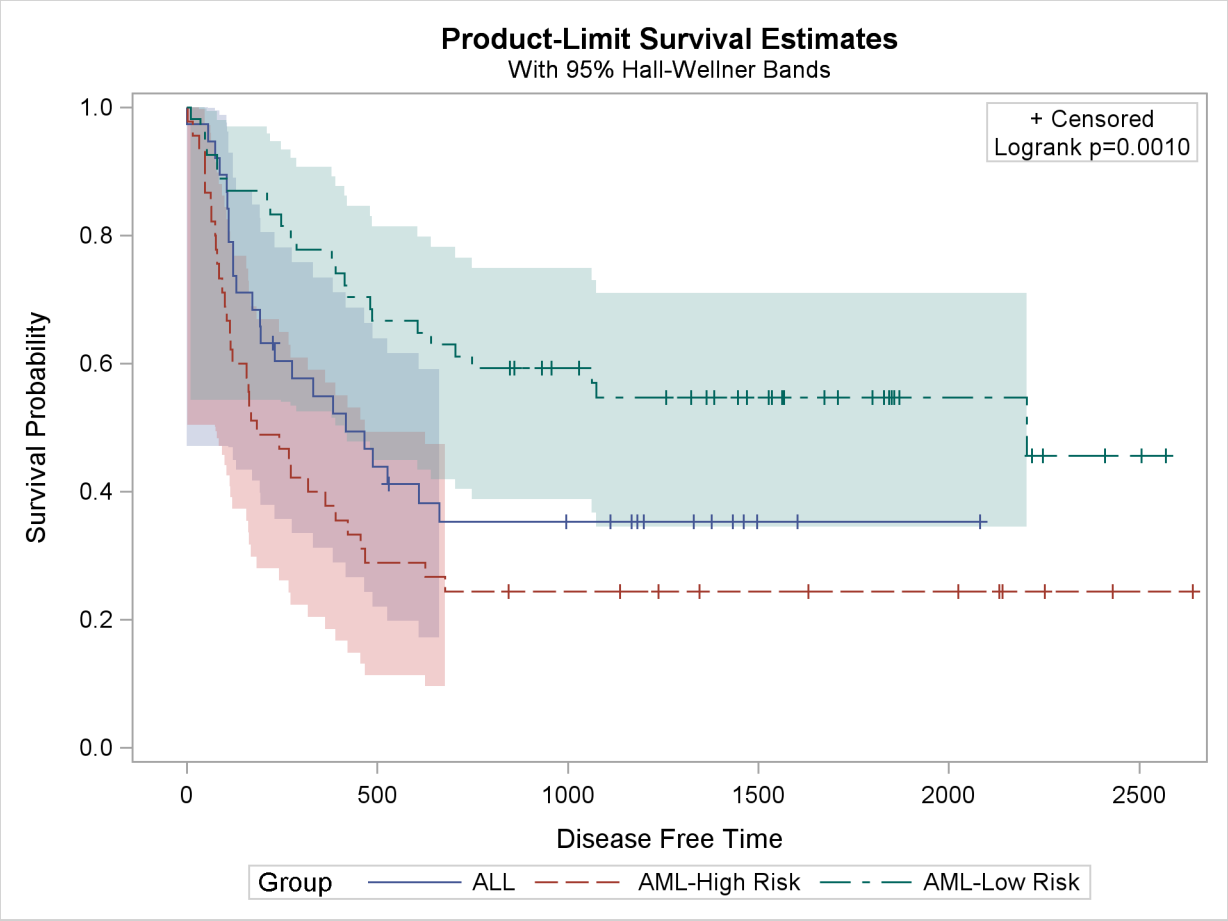
```
proc format;
   value risk 1='ALL' 2='AML-Low Risk' 3='AML-High Risk';
run;

data BMT;
   input Group T Status @@;
   format Group risk.;
   label T='Disease Free Time';
   datalines;
1 2081 0 1 1602 0 1 1496 0 1 1462 0 1 1433 0

... more lines ...

;
```

The following statements use PROC LIFETEST to compute the product-limit estimate of the survivor function for each risk category:



```
ods graphics on;

proc lifetest data=BMT plots=survival(cb=hw test);
   time T * Status(0);
   strata Group / test=logrank;
run;
```

The ODS GRAPHICS ON statement requests ODS Graphics functionality, and the PLOTS=SURVIVAL option requests a plot of the estimated survival curves. The CB=HW suboption requests Hall-Wellner confidence bands, and the TEST suboption displays the *p*-value for the log-rank test in a plot inset.

Figure 21.4 displays the plot; note that tabular output is not shown. The results are displayed in the STATISTICAL style. Patients in the AML-Low Risk group are disease-free longer than those in the ALL group, who in turn fare better than those in the AML-High Risk group.

Figure 21.4 Survival Plot

Contour and Surface Plots with PROC KDE

This example is taken from the section "Getting Started: KDE Procedure" on page 2886 in Chapter 45, "The KDE Procedure." Here, in addition to the ODS GRAPHICS statement, procedure options are used to request plots. The following statements simulate 1,000 observations from a bivariate normal density with means (0,0), variances (10,10), and covariance 9:

```
data bivnormal;
   do i = 1 to 1000;
      z1 = rannor(104);
      z2 = rannor(104);
      z3 = rannor(104);
      x  = 3*z1+z2;
      y  = 3*z1+z3;
      output;
   end;
run;
```

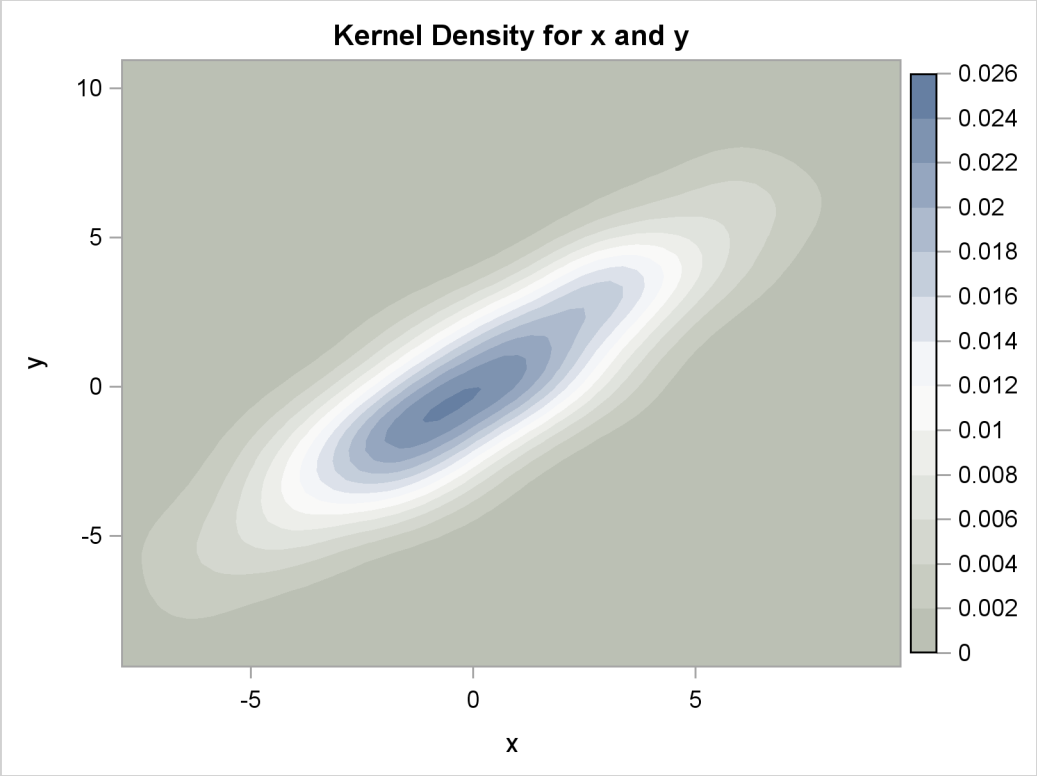
The following statements request a bivariate kernel density estimate for the variables x and y:

```
ods graphics on;

proc kde data=bivnormal;
   bivar x y / plots=contour surface;
run;
```

The PLOTS= option requests a contour plot and a surface plot of the estimate (displayed in Figure 21.5 and Figure 21.6, respectively). The results are displayed in the STATISTICAL style. For more information about the graphics available in PROC KDE, see the section "ODS Graphics" on page 2904 of Chapter 45, "The KDE Procedure."

Figure 21.5 Contour Plot of Estimated Density



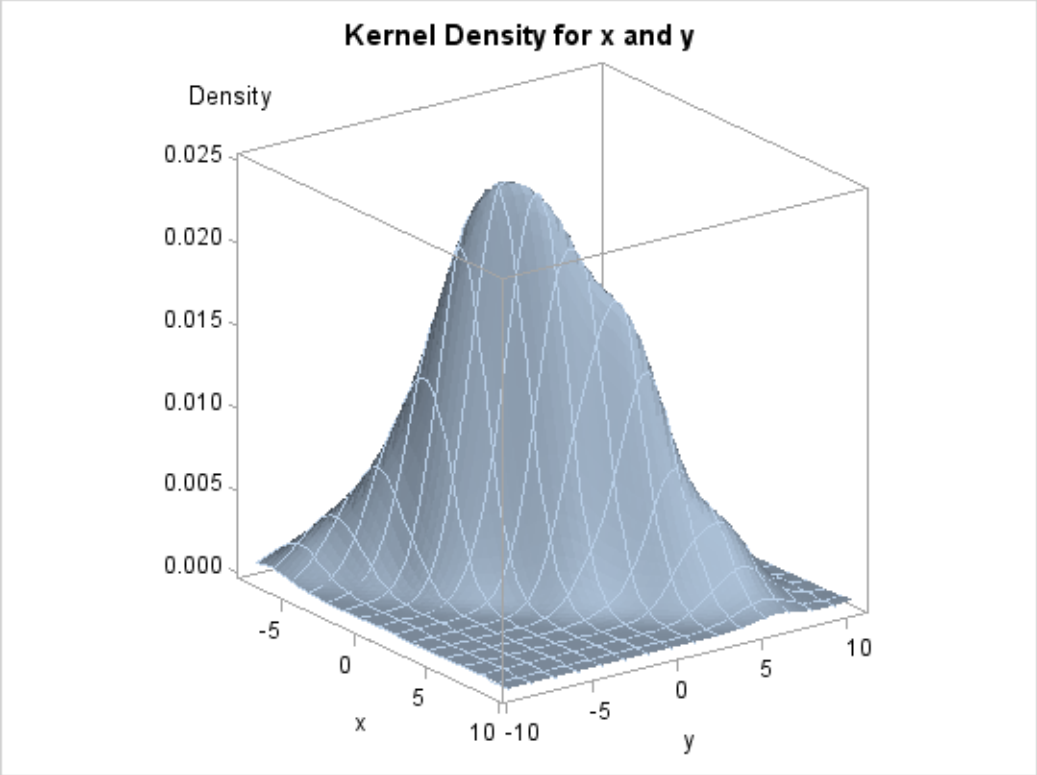


Figure 21.6 Surface Plot of Estimated Density

Contour Plots with PROC KRIGE2D

This example is taken from Example 46.2 of Chapter 46, "The KRIGE2D Procedure." The following statements create a SAS data set that contains measurements of coal seam thickness:

```
data thick;
   input East North Thick @@;
   label Thick='Coal Seam Thickness';
   datalines;
 0.7  59.6  34.1   2.1  82.7  42.2   4.7  75.1  39.5

... more lines ...

;
```

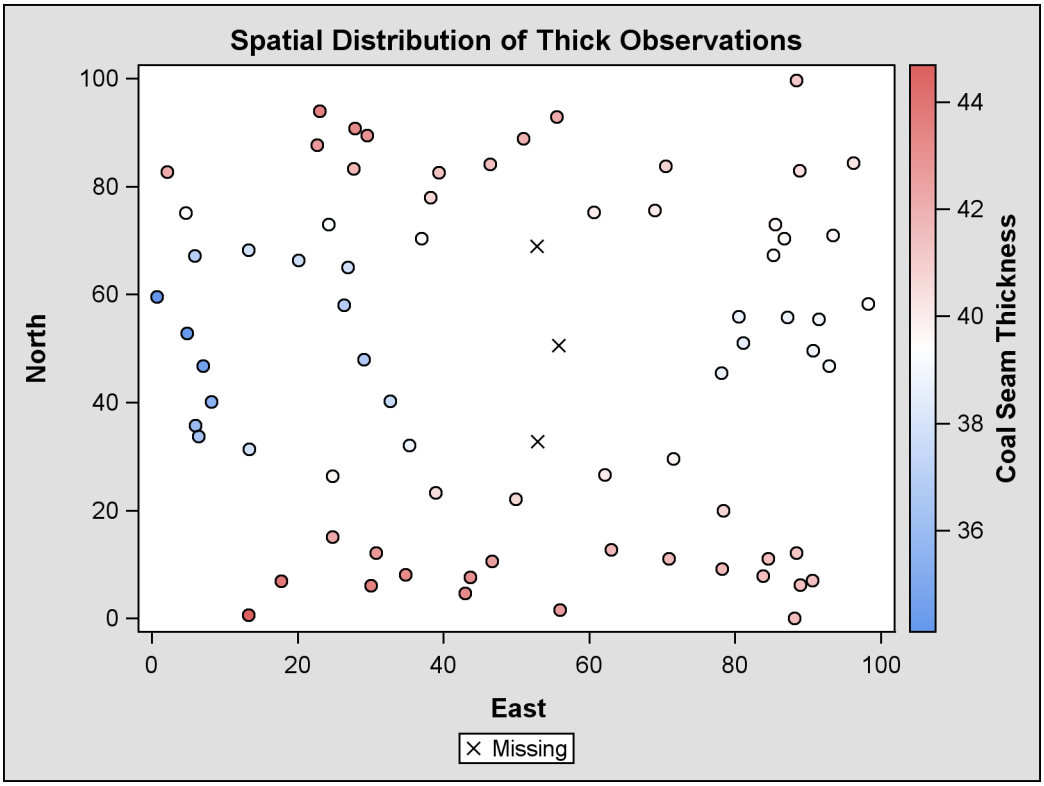
The following statements set the output style to DEFAULT and run PROC KRIGE2D:

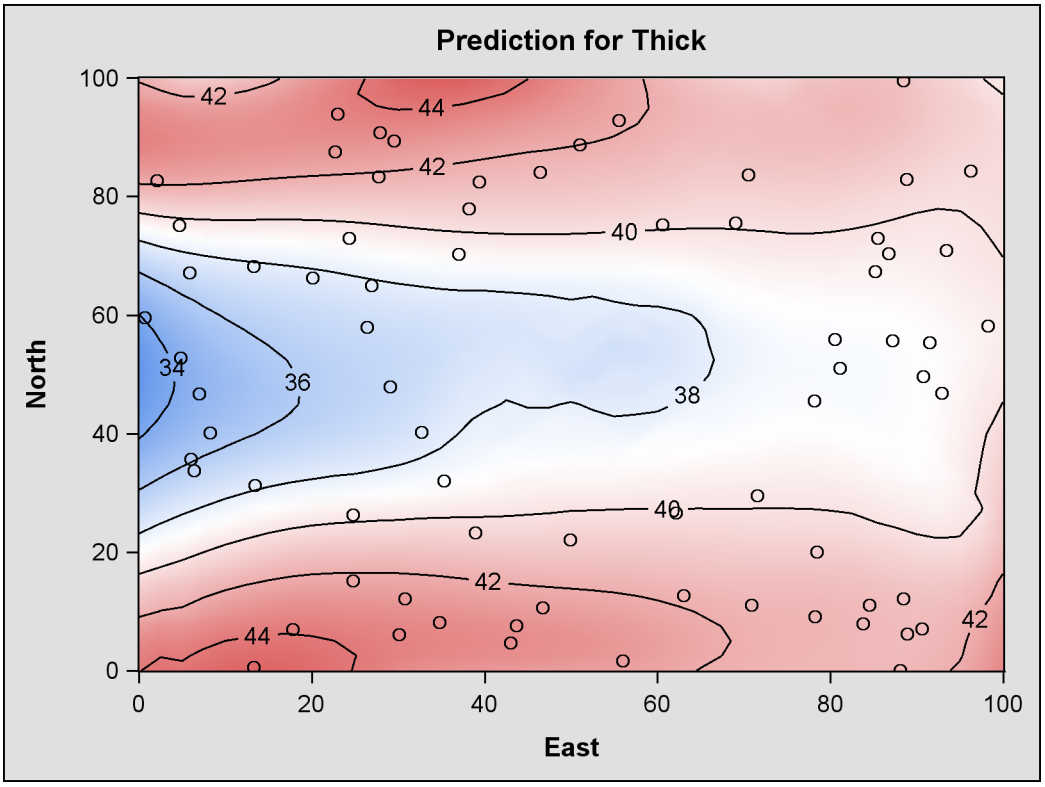
```
ods listing style=default;
ods graphics on;

proc krige2d data=thick outest=predictions
             plots=(observ(showmissing)
                    pred(fill=pred line=pred obs=linegrad)
                    pred(fill=se line=se obs=linegrad));
   coordinates xc=East yc=North;
   predict var=Thick r=60;
   model scale=7.2881 range=30.6239 form=gauss;
   grid x=0 to 100 by 2.5 y=0 to 100 by 2.5;
run;
```

The PLOTS=OBSERV(SHOWMISSING) option produces a scatter plot of the data along with the locations of any missing data. The PLOTS=PRED option produces maps of the kriging predictions and standard errors. Two instances of the PLOTS=PRED option are specified with suboptions that customize the plots. The results are shown in Figure 21.7.

Figure 21.7 PROC KRIGE2D Results Using the DEFAULT Style





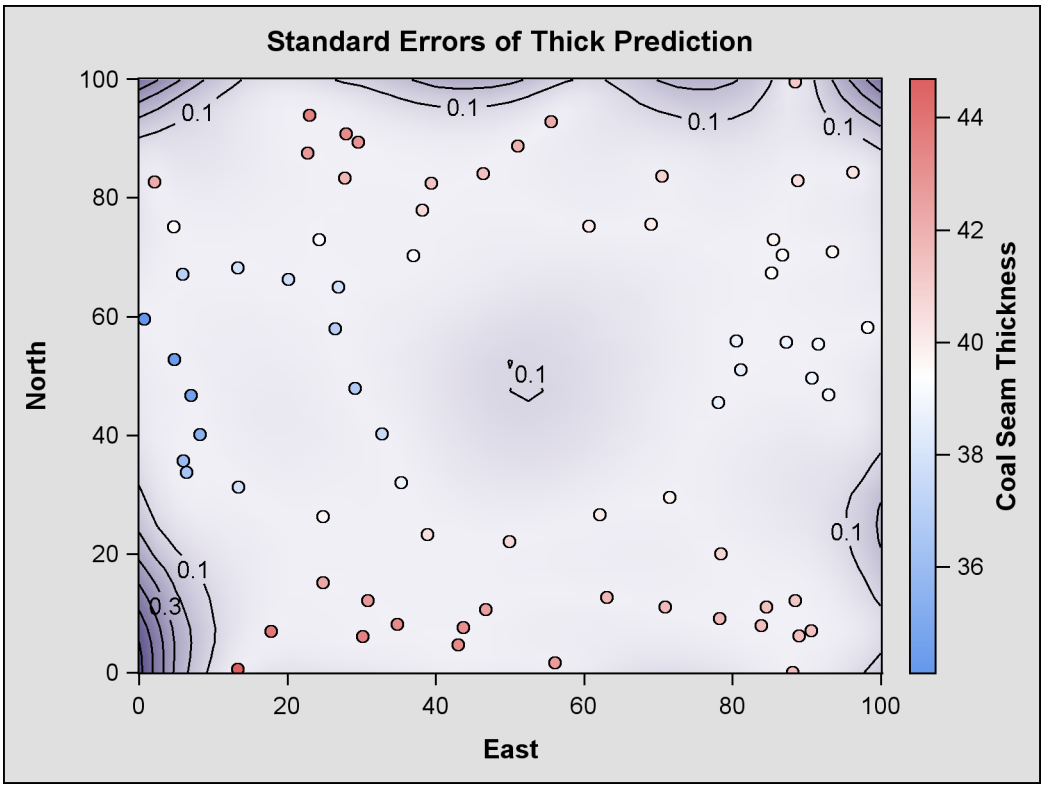


Figure 21.7 *continued*

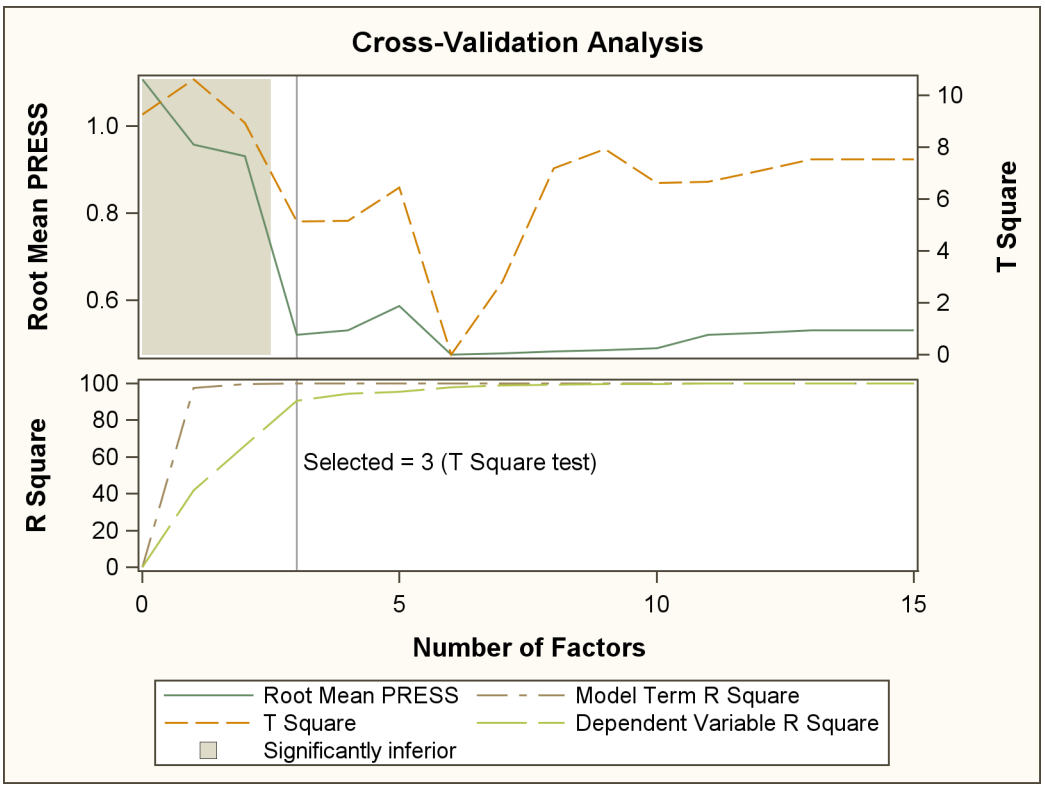
Partial Least Squares Plots with PROC PLS

This example is taken from the section "Getting Started: PLS Procedure" on page 4767 of Chapter 66, "The PLS Procedure." The following statements create a SAS data set that contains measurements of biological activity in the Baltic Sea:

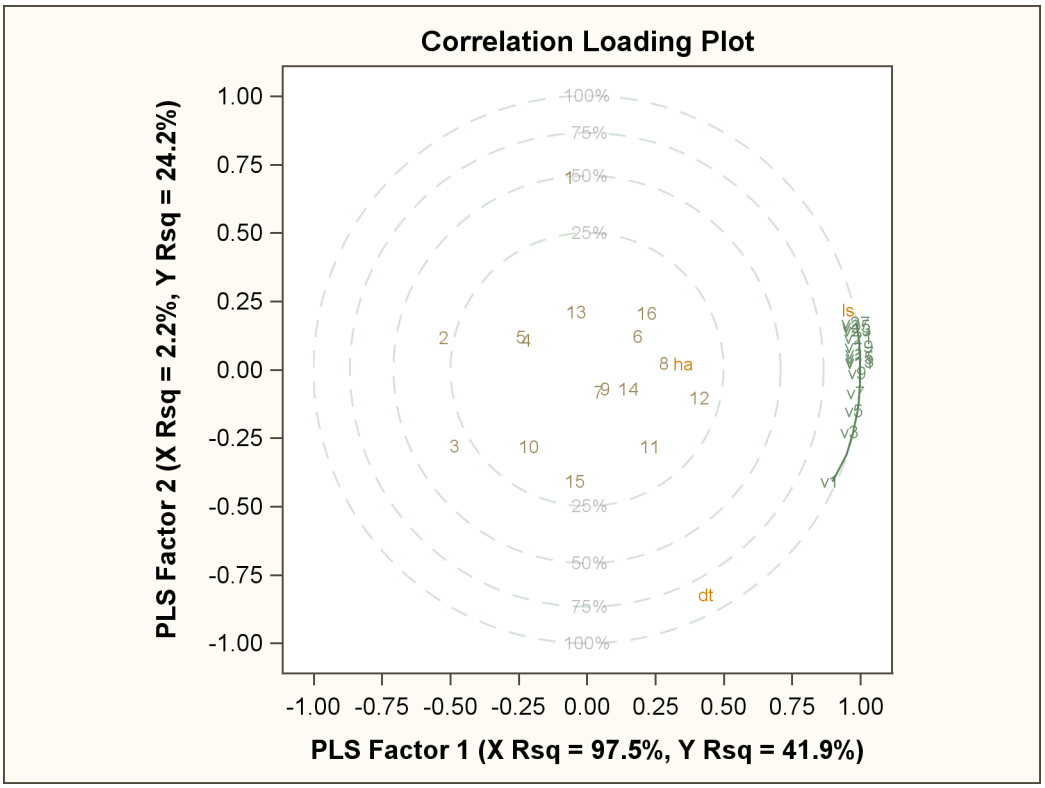
```
data Sample;
   input obsnam $ v1-v27 ls ha dt @@;
   datalines;
EM1   2766 2610 3306 3630 3600 3438 3213 3051 2907 2844 2796
      2787 2760 2754 2670 2520 2310 2100 1917 1755 1602 1467
      1353 1260 1167 1101 1017         3.0110  0.0000   0.00

... more lines ...

;
```



The following statements set the output style to ANALYSIS and run PROC PLS:



```
ods listing style=analysis;
ods graphics on;

proc pls data=sample cv=split cvtest(seed=104);
   model ls ha dt = v1-v27;
run;
```

By default, the procedure produces a plot for the cross validation analysis and a correlation loading plot (see Figure 21.8).

Figure 21.8 Partial Least Squares Results Using the ANALYSIS Style

Box-Cox Transformation Plot with PROC TRANSREG

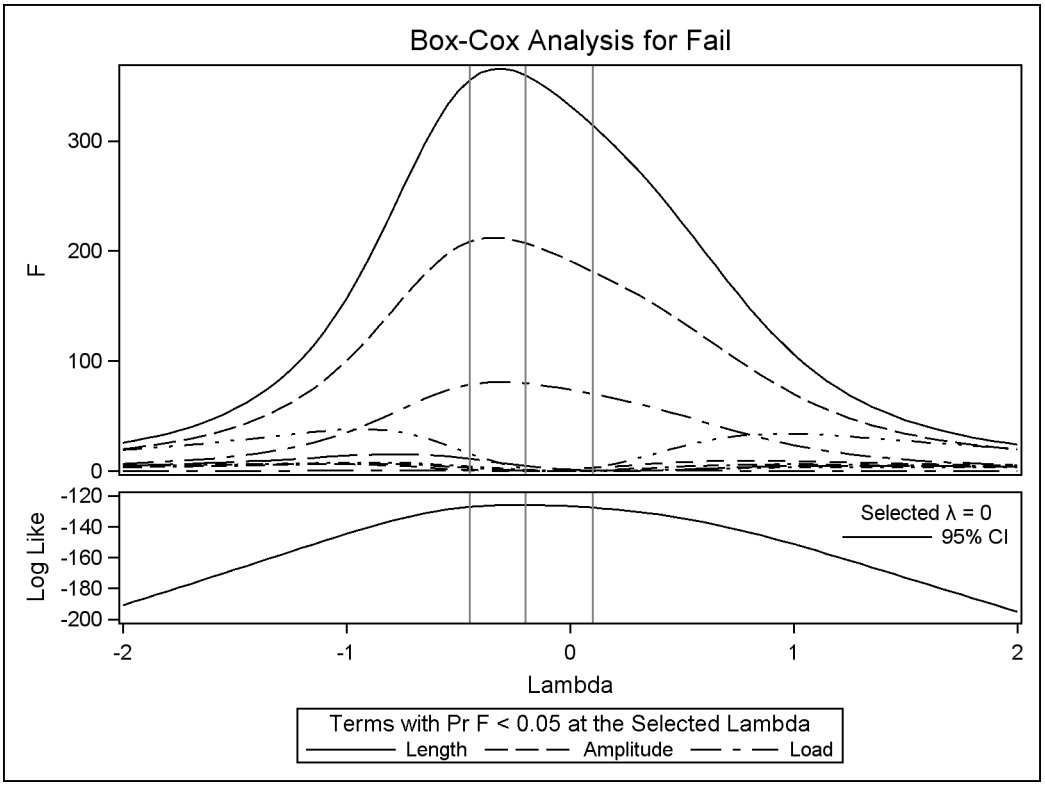
This example is taken from Example 90.2 of Chapter 90, "The TRANSREG Procedure." The following statements create a SAS data set that contains failure times for yarn:

```
proc format;
   value a -1 =   8 0 =   9 1 =  10;
   value l -1 = 250 0 = 300 1 = 350;
   value o -1 =  40 0 =  45 1 =  50;
run;

data yarn;
   input Fail Amplitude Length Load @@;
   format amplitude a. length l. load o.;
   label fail = 'Time in Cycles until Failure';
   datalines;
 674 -1 -1 -1    370 -1 -1  0    292 -1 -1  1    338  0 -1 -1

... more lines ...

;
```



The following statements set the output style to JOURNAL2 and run PROC TRANSREG:

```
ods listing style=journal2;
ods graphics on;

proc transreg data=yarn;
   model BoxCox(fail / convenient lambda=-2 to 2 by 0.05) =
         qpoint(length amplitude load);
run;
```

The log-likelihood plot in Figure 21.9 suggests a Box-Cox transformation with $\lambda = 0$.

Figure 21.9 Box-Cox "Significant Effects" Using the JOURNAL2 Style

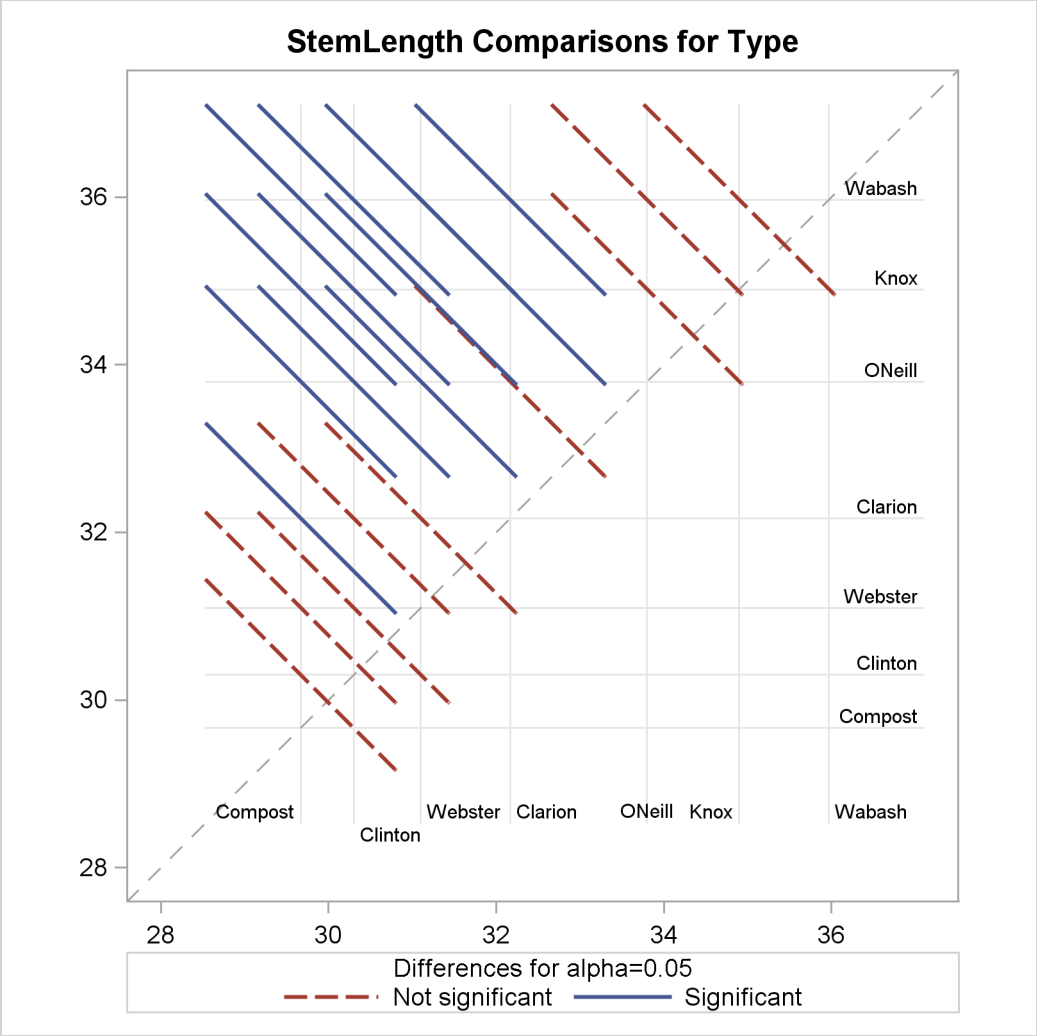
LS-Means Diffogram with PROC GLIMMIX

This example is taken from the section "Graphics for LS-Mean Comparisons" on page 2288 of Chapter 38, "The GLIMMIX Procedure." The following statements create a SAS data set that contains measurements from an experiment that investigates how snapdragons grow in various soils:

```
data plants;
   input Type $ @;
   do Block = 1 to 3;
      input StemLength @;
      output;
   end;
   datalines;
Clarion   32.7 32.3 31.5

... more lines ...

;
```



The following statements set the output style to STATISTICAL and run PROC GLIMMIX:

```
ods listing style=statistical;
ods graphics on;

proc glimmix data=plants order=data plots=diffogram;
   class Block Type;
   model StemLength = Block Type;
   lsmeans Type;
run;
```

The PLOTS=DIFFOGRAM option produces a diffogram, shown in Figure 21.10, that displays all of the pairwise least squares mean differences and indicates which are significant.

Figure 21.10 LS-Means Diffogram Using the STATISTICAL Style

Principal Component Analysis Plots with PROC PRINCOMP

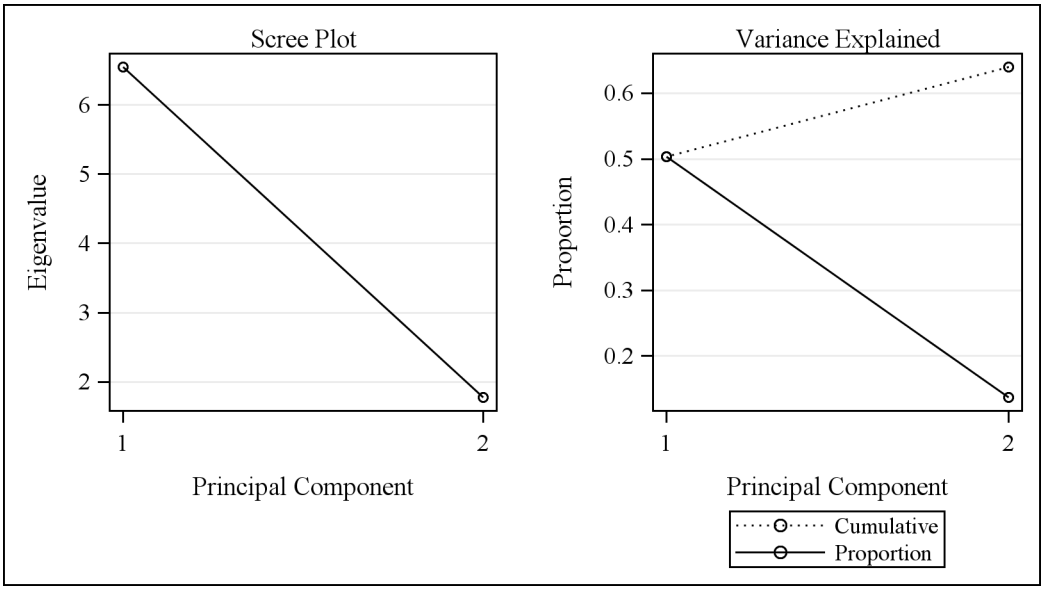
This example is taken from Example 69.3 of Chapter 69, "The PRINCOMP Procedure." The following statements create a SAS data set that contains ratings of job performance of police officers:

```
options validvarname=any;

data Jobratings;
   input ('Communication Skills'n
          'Problem Solving'n
          'Learning Ability'n
          'Judgment Under Pressure'n
          'Observational Skills'n
          'Willingness to Confront Problems'n
          'Interest in People'n
          'Interpersonal Sensitivity'n
          'Desire for Self-Improvement'n
          'Appearance'n
          'Dependability'n
          'Physical Ability'n
          'Integrity'n
          'Overall Rating'n) (1.);
   datalines;
26838853879867

... more lines ...

;
```



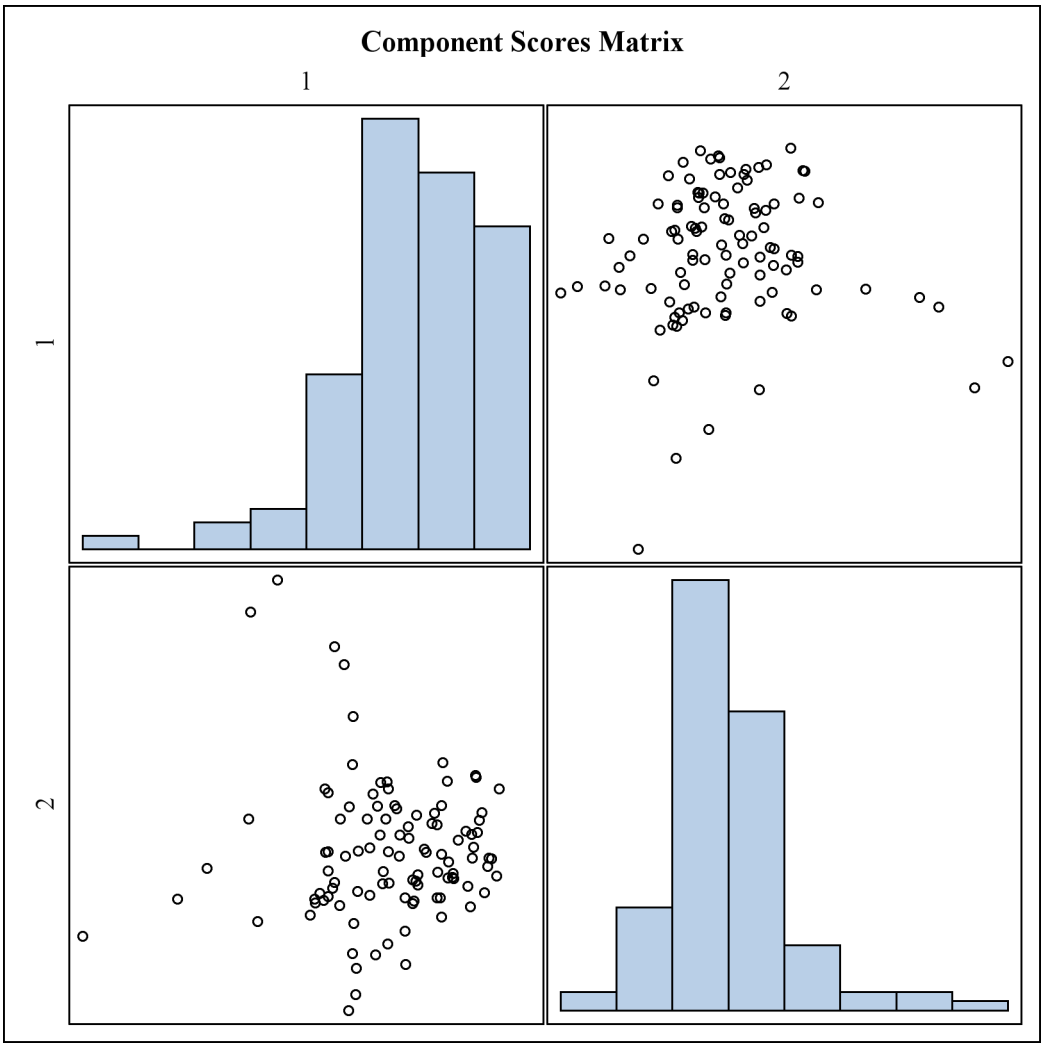
The following statements set the output style to RTF and run PROC PRINCOMP:

```
ods listing style=rtf;
ods graphics on;

proc princomp data=Jobratings(drop='Overall Rating'n) n=2
              plots=(Matrix PatternProfile);
run;
```

The plots are requested by the PLOTS=(MATRIX PATTERNPROFILE) option. The results, shown in Figure 21.11, contain the default scree and variance-explained plots, along with a scatter plot matrix of component scores and a pattern profile plot.

Figure 21.11 Principal Components Using the RTF Style



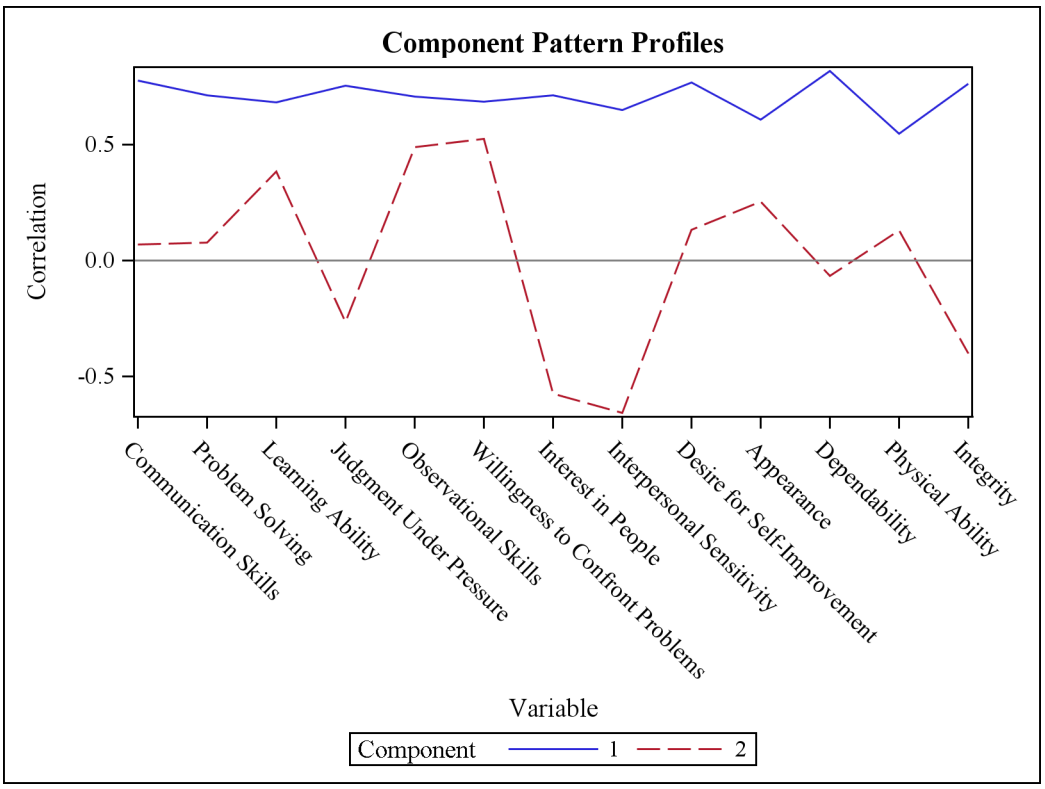


Figure 21.11 *continued*

Grouped Scatter Plot with PROC SGPLOT

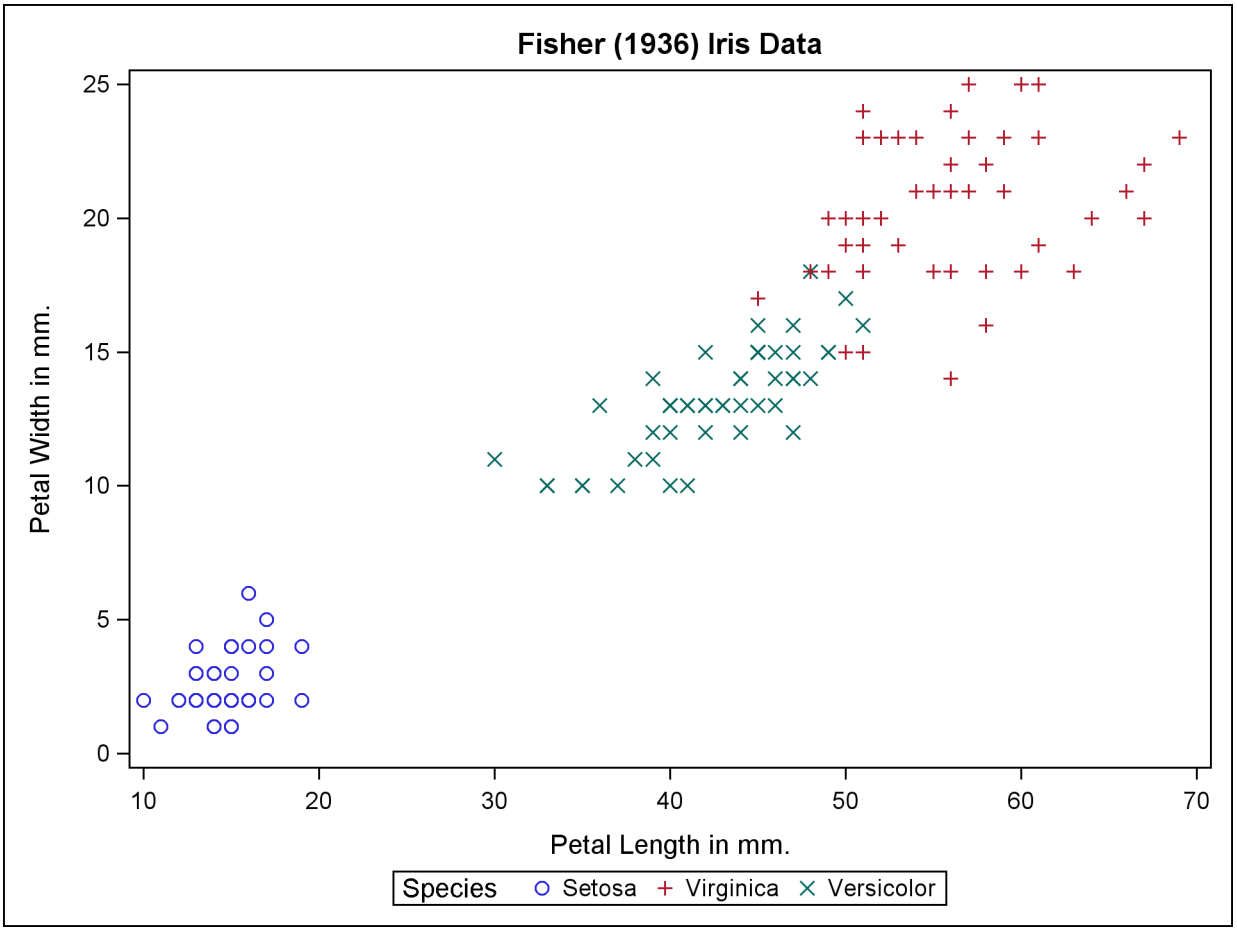
This example is taken from Example 31.1 of Chapter 31, "The DISCRIM Procedure." The following statements create a SAS data set from the iris data:

```
proc format;
   value specname
      1='Setosa    '
      2='Versicolor'
      3='Virginica ';
run;

data iris;
   input SepalLength SepalWidth PetalLength PetalWidth
         Species @@;
   format Species specname.;
   label SepalLength='Sepal Length in mm.'
         SepalWidth ='Sepal Width in mm.'
         PetalLength='Petal Length in mm.'
         PetalWidth ='Petal Width in mm.';
   datalines;
50 33 14 02 1 64 28 56 22 3 65 28 46 15 2 67 31 56 24 3

... more lines ...

;
```



The following statements set the output style to LISTING and run PROC SGPLOT to make a scatter plot, grouped by iris species:

```
ods listing style=listing;

proc sgplot data=iris;
   title 'Fisher (1936) Iris Data';
   scatter x=petallength y=petalwidth / group=species;
run;
```

The results are shown in Figure 21.12.

Figure 21.12 Scatter Plot That Uses the LISTING Style

See the section "Statistical Graphics Procedures" on page 589 and the *SAS/GRAPH: Statistical Graphics Procedures Guide* for more information about PROC SGPLOT (statistical graphics plot) and other SG procedures. You do not need to enable ODS Graphics in order to use SG procedures (because making plots with ODS Graphics is their sole function).

A Primer on ODS Statistical Graphics

You invoke ODS Graphics by specifying the following statement:

```
ods graphics on;
```

ODS Graphics remains in effect for all procedure steps until you turn it off with the following statement:

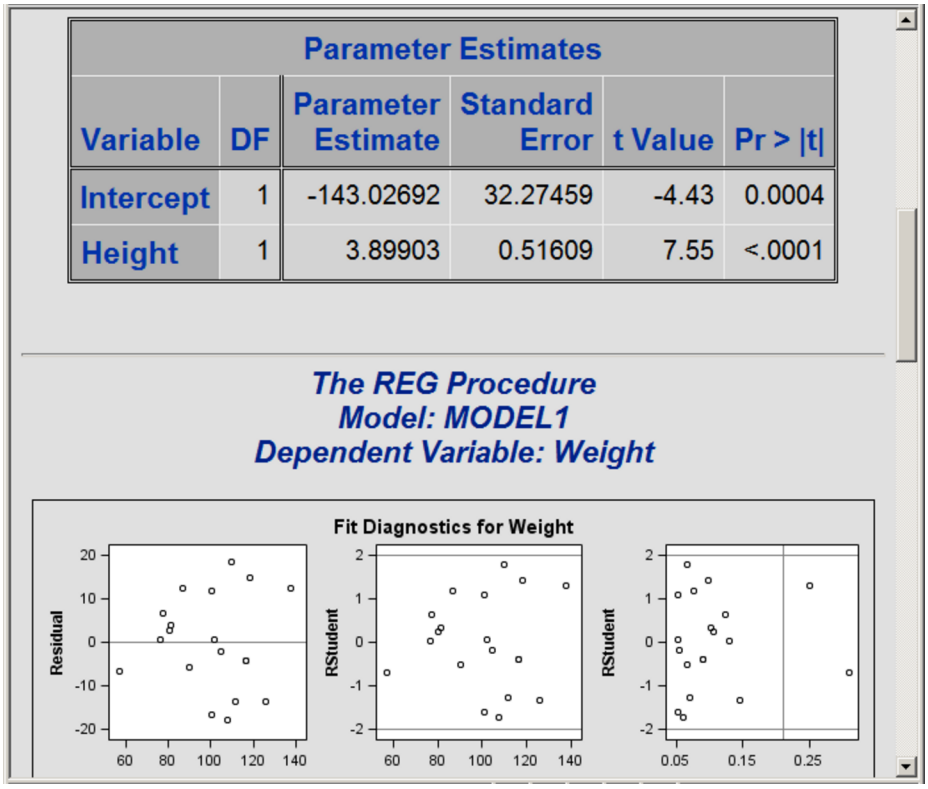
```
ods graphics off;
```

See the section "Syntax" on page 529 for details about the more commonly used ODS GRAPHICS statement options. Once you have invoked ODS Graphics, creating graphical output with procedures is as simple as creating tabular output. You can use control your output in the following ways:

- ODS destination statements (such as ODS HTML or ODS RTF) specify where you want your graphs displayed. See Figure 21.13 for an example of HTML output. See the section "ODS Destination Statements" on page 532 for a list of the supported destinations. See the section "Syntax" on page 529 for details about the more commonly used ODS destination statement options.
- ODS SELECT and ODS EXCLUDE statements select and exclude graphs from your output. See the section "Selecting and Excluding Graphs" on page 540 for an example of how to select graphs.
- ODS OUTPUT statements create SAS data sets from the data object used to make the plot. See the section "Specifying an ODS Destination for Graphics" on page 535 for an example.
- Procedure options specify which graphs to create. For each procedure, these options are described in the "Syntax" section of the procedure chapter. Typically, you use the PLOTS= option to control all graphs. The available graphs are listed in the "ODS Graphics" section, which is found in the "Details" section of each procedure chapter. Many graphs are produced by default.
- ODS styles control the general appearance and consistency of all graphs and tables. See the sections "Graph Styles" on page 520 and "Styles" on page 554 for more information about styles.
- ODS templates modify the layout and details of each graph. See the section "Graph Templates" on page 577 for more information about templates.

  NOTE: A default template is provided by SAS for each graph, so you do not need to know anything about templates to create statistical graphics.

You can also access individual graphs, control the resolution and size of graphs, and modify your graphs (as explained in the sections beginning with "Selecting and Viewing Graphs" on page 535). Alternatively, you can use special statistical graphics procedures to create custom graphs directly (see the section "Statistical Graphics Procedures" on page 589).



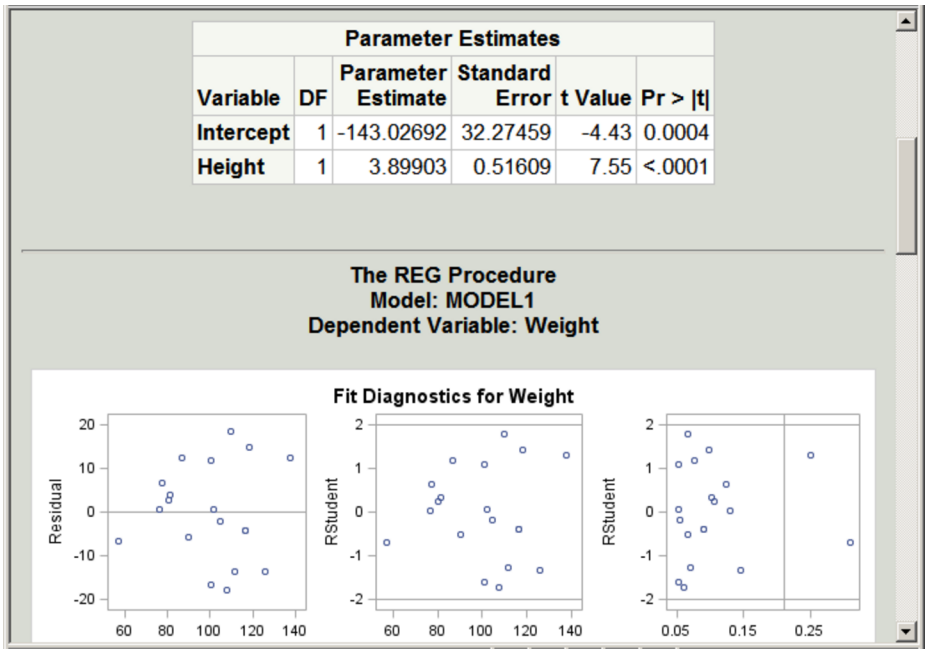
Graph Styles

ODS styles control the overall appearance of graphs and tables. They specify colors, fonts, line styles, and other attributes of graph elements. The following styles are recommended for statistical work:

- The DEFAULT style is a color style intended for general-purpose work. See Figure 21.13 for an example of the DEFAULT style, which is the default style for the HTML destination. Most other styles inherit some of their elements from this style.
- The STATISTICAL style is a color style recommended for output in Web pages or color print media. The STATISTICAL style might not necessarily print well on black-and-white devices. See Figure 21.14 for an example. This is the default style for SAS/STAT documentation.
- The ANALYSIS style is a color style with a somewhat different appearance from the STATISTICAL style. See Figure 21.8 for an example.
- The JOURNAL family of styles (JOURNAL and JOURNAL2) consists of black-and-white or gray-scale styles that are recommended for graphs that appear in journals and in other black-and-white publications. See Figure 21.15 for an example of the JOURNAL style, see Figure 21.9 for an example of the JOURNAL2 style, and see Example 21.3 for a comparison of the two styles.
- The RTF style is used to produce graphs to insert into a Microsoft Word document or a Microsoft PowerPoint slide. See Figure 21.11 for an example of the RTF style, which is the default style for the RTF destination.

There are many other styles including the LISTING style, which is the default style for the LISTING destination.

Figure 21.13 HTML Output from PROC REG with DEFAULT Style



Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	-143.02692	32.27459	-4.43	0.0004
Height	1	3.89903	0.51609	7.55	<.0001

The REG Procedure
Model: MODEL1
Dependent Variable: Weight

Figure 21.15 HTML Output from PROC REG with the Journal Style

You specify a style with the STYLE= option in the ODS destination statement. For example, the following statement requests HTML output produced with the JOURNAL style:

```
ods html style=Journal;
```

Similarly, the following statement sets the style for the LISTING destination:

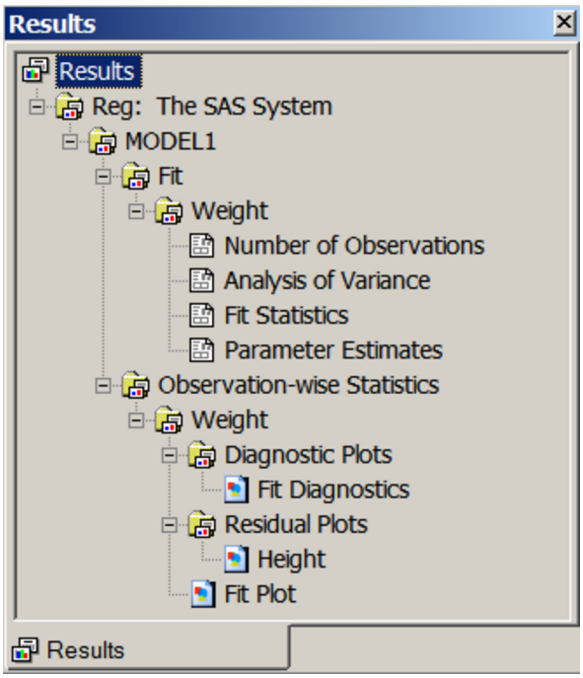
```
ods listing style=Statistical;
```

The style specified with the STYLE= option in the ODS LISTING statement applies only to graphs. The legacy SAS monospace format is used for tables.

The color styles are a compromise in the sense that some graph elements are intentionally over-distinguished to facilitate black-and-white printing. For example, fit lines that correspond to different classification levels are distinguished by both colors and line patterns. You can use the **`ModStyle`** SAS autocall macro (see the section "Creating an All-Color Style by Using the ModStyle Macro" on page 564) to modify a style so that it relies only on color for distinguishability. More generally, you can modify the colors, fonts, and other attributes of graph elements in a style by editing the style definition file. More information is provided in the section "Styles" on page 554, and detailed information is in the *SAS Output Delivery System: User's Guide*.

ODS Destinations

ODS can send your graphs and tables to a number of different destinations including RTF (rich text format), HTML (hypertext markup language), LISTING (the SAS LISTING destination), DOCUMENT (the ODS document), and PDF (portable document format). You use an ODS statement to open a destination, as in the following examples:



```
ods html body='b.htm';
ods rtf;
ods listing;
ods document name=MyDoc(write);
ods pdf file="contour.pdf";
```

You can close destinations individually or all at once, as in the following examples:

```
ods html close;
ods rtf close;
ods listing close;
ods document close;
ods pdf close;
ods _all_ close;
```

For most ODS destinations (for example, HTML, RTF, and PDF), graphs and tables are integrated in the output, and you view your output with an appropriate viewer, such as a web browser for HTML. However, the default LISTING destination is different. If you are using the LISTING destination in the SAS windowing environment, you view your graphs individually by clicking the graph icons in the Results window, as illustrated in Figure 21.16. This action invokes a host-dependent graph viewer (for example, Microsoft Photo Editor on Windows). The graphs produced with ODS Graphics are *not* displayed with traditional graphs in the Graph window.

Figure 21.16 SAS Results Window

If you are using the SAS windowing environment and you prefer to view integrated output, you should specify a destination such as HTML or RTF. At the same time, you can prevent the Output window from appearing by closing the LISTING destination, as in the following statements:

```
ods listing close;
ods html;
```

A graph is created for every open destination. When you open a new destination, you should close all destinations that you do not need. Closing destinations makes your jobs run faster and with fewer resources, because fewer graphs are produced.

Accessing Individual Graphs

If you are writing a paper or creating a presentation, you need to access your graphs individually. There are various ways to do this, depending on the ODS destination. Three particularly useful methods are as follows:

- If you are viewing RTF output, you can simply copy and paste your graphs from the viewer into a Microsoft Word document or a Microsoft PowerPoint slide.
- If you are viewing HTML output, you can copy and paste your graphs from the viewer, or you can right-click the graph and save it to a file. Copying and pasting from RTF is preferable because the default resolution is higher than with HTML. See the section "Specifying the Size and Resolution of Graphs" on page 525 for details.
- You can save your graphs in image files and then include them into a paper or presentation. For example, you can save your graphs as PNG files and include them into a paper that you are writing with LaTeX or into an HTML document.

You can specify the graphics image format and the file name in the ODS GRAPHICS statement. For example, the following statements, when submitted before a procedure step that produces multiple graphs, save the graphs in PostScript files named *myname.ps*, *myname1.ps*, and so on:

```
ods listing close;
ods latex;
ods graphics on / imagefmt=ps imagename='myname';
```

See the section "Image File Types" on page 541 for details about the file types available with various destinations, how they are named, and how they are saved.

If you are using the LISTING destination and the SAS windowing environment, you can also copy from the default viewer into a Microsoft Word document or a Microsoft PowerPoint slide.

Specifying the Size and Resolution of Graphs

Two factors to consider when you are creating graphs for a paper or presentation are the size of the graph and its resolution. You can specify the size of a graph in the ODS GRAPHICS statement. The following examples show typical ways to change the size of your graphs:

```
ods graphics on / width=6in;
ods graphics on / height=4in;
ods graphics on / width=4.5in height=3.5in;
```

You can change the resolution with the IMAGE_DPI= option in any ODS destination statement, as in the following example:

```
ods html image_dpi=300;
```

The default resolution of graphs created with the HTML and LISTING destinations is 100 DPI (dots per inch), whereas the default with the RTF destination is 200 DPI. An increase in resolution often improves the quality of the graphs, but it also increases the size of the image file. See the section "Graph Size and Resolution" on page 547 for more information about graph size and resolution.

Modifying Your Graphs

Although ODS Graphics is designed to automate the creation of high-quality statistical graphics, on occasion you might need to modify your graphs. There are two ways you can make modifications, depending on whether the changes you want to make are data-dependent and immediate (for a specific graph you are preparing for a paper or presentation), or whether they are persistent (applied to a graph each time you run the procedure). You can make immediate, ad hoc changes by using the ODS Graphics Editor, which provides a point-and-click interface. You can make persistent changes by modifying the ODS graph template for a particular plot. A graph template is a program, written in the Graph Template Language (GTL), that specifies the layout and details of a graph.

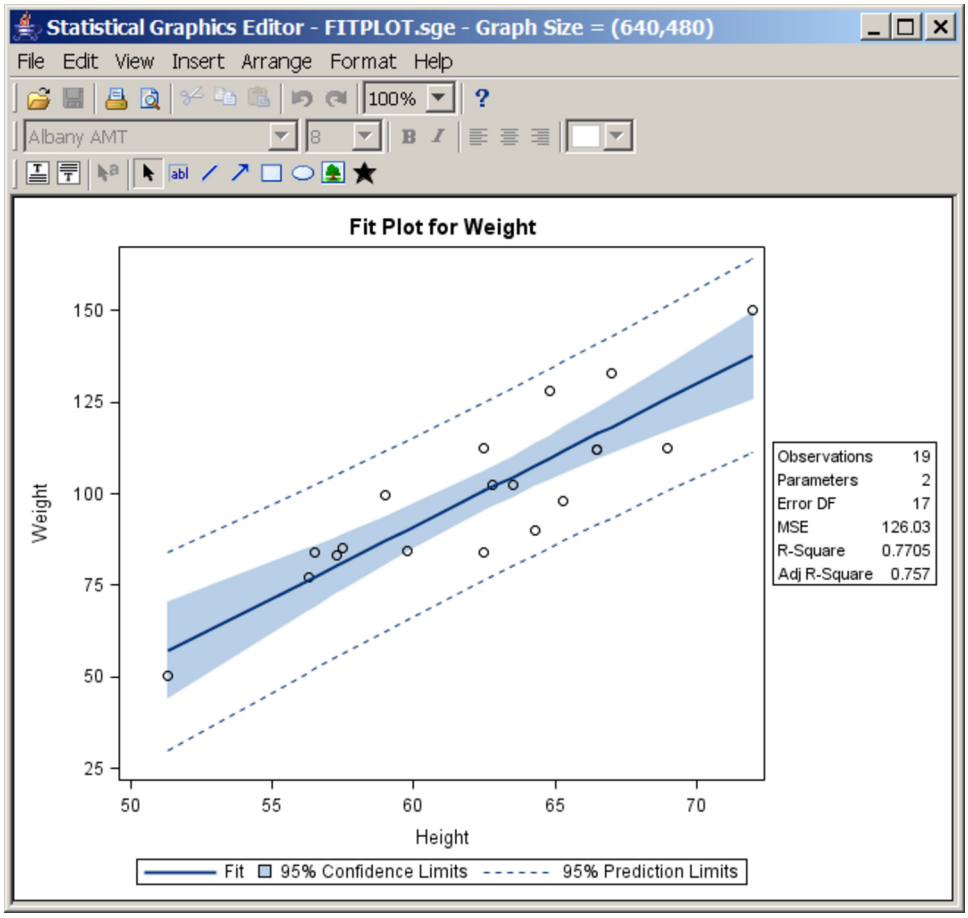
NOTE: SAS provides a template for each graph it creates, so you do not need to know anything about templates to create statistical graphics.

You can use the ODS Graphics Editor to customize titles and labels, annotate data points, add text, and change the properties of graph elements. After you have modified your graph, you can save it as a PNG image file or as an SGE file, which preserves the editing context. You can open SGE files with the ODS Graphics Editor and resume editing.

You can invoke the ODS Graphics Editor in the SAS windowing environment, provided that the LISTING destination is open and that you have enabled ODS Graphics to create editable graphs. The steps for doing this are described in the section "ODS Graphics Editor" on page 548. Also see *Getting Started with the SAS/GRAPH Statistical Graphics Editor*.

Figure 21.17 shows the ODS Graphics Editor window for a fit plot created by PROC REG. Figure 21.18 shows modifications made with tools in the ODS Graphics Editor. The title has been changed, and the legend has been repositioned.

Figure 21.17 ODS Graphics Editor Invoked with a Fit Plot



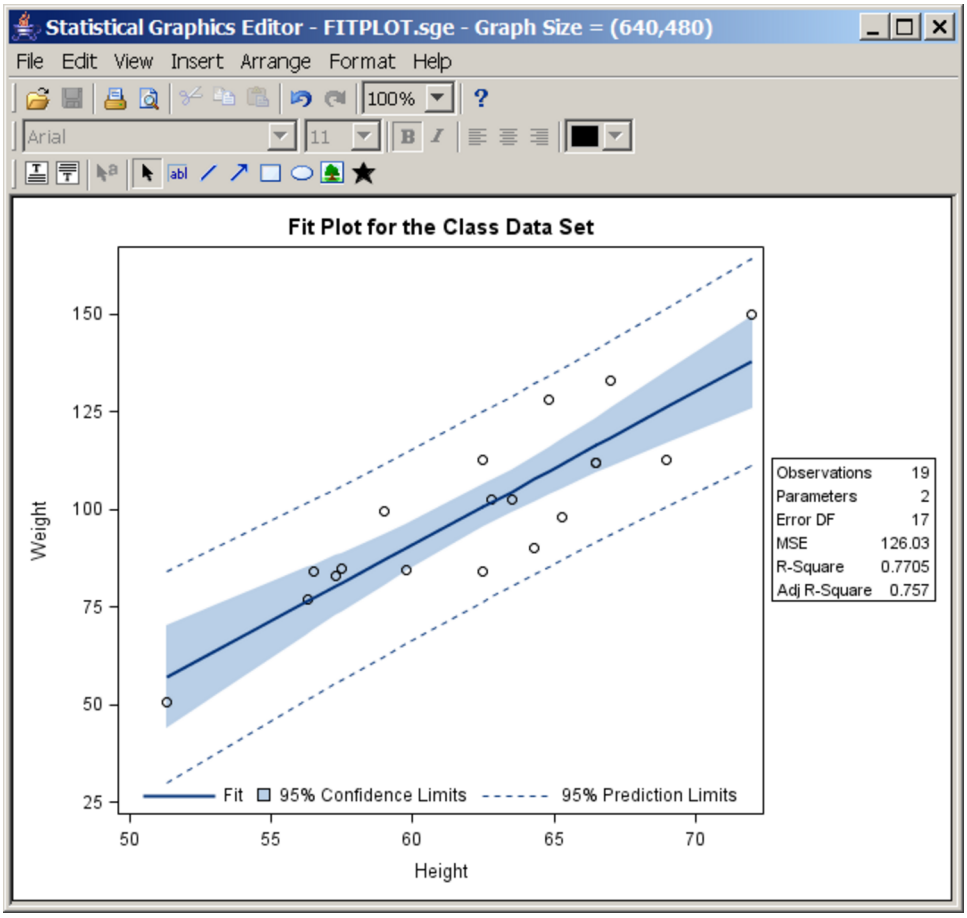


Figure 21.18 Point-and-Click Modifications Made with the ODS Graphics Editor

Procedures That Support ODS Graphics

SAS procedures that support ODS Graphics include the following:

SAS/STAT		**SAS/QC**	**SAS/ETS**
ANOVA	MI	ANOM	ARIMA
BOXPLOT	MIXED	CAPABILITY	AUTOREG
CALIS	MULTTEST	CUSUM	ENTROPY
CLUSTER	NPAR1WAY	MACONTROL	ESM
CORRESP	PHREG	PARETO	EXPAND
FACTOR	PLS	RELIABILITY	MODEL
FREQ	PRINCOMP	SHEWHART	PANEL
GAM	PRINQUAL		SIMILARITY
GENMOD	PROBIT	**Base**	SYSLIN
GLIMMIX	QUANTREG	CORR	TIMESERIES
GLM	REG	FREQ	UCM
GLMSELECT	ROBUSTREG	UNIVARIATE	VARMAX
KDE	RSREG		X12
KRIGE2D	SEQDESIGN		
LIFEREG	SEQTEST		**SAS/HPF**
LIFETEST	SIM2D		HPF
LOESS	TCALIS		HPFENGINE
LOGISTIC	TRANSREG		
MCMC	TTEST		**Risk Dimensions**
MDS	VARIOGRAM		RISK

For details about the specific graphs available with a particular procedure, see the PLOTS= option syntax and the "ODS Graphics" section in the corresponding procedure chapter. The procedure names in the preceding table are links to the "ODS Graphics" section for the SAS/STAT procedures.

Procedures That Support ODS Graphics and Traditional Graphics

A number of procedures that support ODS Graphics produced traditional graphics in previous releases of SAS. These include the UNIVARIATE procedure in Base SAS; the LIFEREG, LIFETEST, and REG procedures in SAS/STAT; and the ANOM, CAPABILITY, CUSUM, MACONTROL, PARETO, RELIABILITY, and SHEWHART procedures in SAS/QC. All of these procedures continue to produce traditional graphics, but in some cases, they do so only when ODS Graphics is not enabled. For more information about the interaction between traditional graphics and ODS graphics in other procedures, see the documentation for that procedure.

Traditional graphs are saved in SAS graphics catalogs and are controlled by the GOPTIONS statement. In contrast, ODS Graphics produces graphs in standard image file formats (not graphics catalogs), and their appearance and layout are controlled by ODS styles and templates.

Syntax

The following sections document some of the most commonly used options in the ODS GRAPHICS statement (section "ODS GRAPHICS Statement" on page 529) and other statements used with ODS Graphics (section "ODS Destination Statements" on page 532). You can find the complete syntax in the *SAS Output Delivery System: User's Guide*. In addition, information about the PLOTS= option is provided in the section "PLOTS= Option" on page 533. Statistical procedures that produce ODS Graphics all have a PLOTS= option that is used to select graphs and control some aspects of the graphs.

ODS GRAPHICS Statement

ODS GRAPHICS < **OFF** | **ON** > < / *options* > **;**

The ODS GRAPHICS statement enables ODS to create graphics. By default, ODS Graphics is not enabled. You can enable ODS Graphics by using either of the following equivalent statements:

```
ods graphics on;
ods graphics;
```

You specify one of these statements prior to your procedure invocation, as illustrated in the examples beginning with "Default Plots for Simple Linear Regression with PROC REG" on page 501. Any procedure that supports ODS Graphics then produces graphics, either by default or when you specify procedure options for requesting particular graphs.

To disable ODS Graphics, specify the following statement:

```
ods graphics off;
```

The following is a subset of the options, syntax, and capabilities available in the ODS GRAPHICS statement. See the *SAS Output Delivery System: User's Guide* for more information.

ANTIALIAS=ON | OFF

controls the use of antialiasing to smooth the components of a graph. Without antialiasing, pixels are simply set or not set. With antialiasing, pixels at the edge of a line or other object are set to an intermediate color, which makes smoother and more professional looking graphics. Text displayed in a graph is always antialiased. Antialiasing is very time consuming for larger graphical displays, and its benefits decrease as the number of points increases, so it is turned off by default for plots with many points. If the number of observations in the ODS output object exceeds the ANTIALIASMAX= threshold (10,000 by default), then antialiasing is not used, even if you specify the option ANTIALIAS=ON. The default is ANTIALIAS=ON.

ANTIALIASMAX=*n*

specifies the maximum number of markers or lines to be antialiased before antialiasing is

disabled. For example, if there are more than 10,000 point markers and ANTIALIASMAX=10,000 (the default), then no markers are antialiased.

BORDER=ON | OFF
specifies whether to draw the graph with a border. BORDER=ON is the default.

HEIGHT=*dimension*
specifies the height of the graph. The default is HEIGHT=480PX (480 pixels). You can also specify height in inches (for example, HEIGHT=5IN) or centimeters (for example, HEIGHT=12CM).

IMAGEFMT=< *image-file-type* **| STATIC >**
specifies the image format for graphs. By default, IMAGEFMT=STATIC and ODS dynamically uses the best quality static image format for the active output destination. The available image formats include: BMP (Microsoft Windows device independent bitmap), DIB (Microsoft Windows device independent bitmap), EMF (Microsoft NT enhanced metafile), EPSI (Adobe encapsulated PostScript interchange), GIF (graphics interchange format), JFIF (JPEG file interchange format), JPEG (Joint Photographic Experts Group), PBM (portable bitmap), PCD (Photo CD), PDF (Portable Document Format), PICT (the QuickDraw Picture Format), PNG (Portable Network Graphic), PS (PostScript image file format), TIFF (tagged image file format), WMF (Microsoft Windows Metafile Format), XBM (X11 Bitmap graphics), and XPM (X11 Pixel Map graphics). If the specified image format is not valid for the active output destination, the device is automatically remapped to the default image format.

IMAGEMAP=ON | OFF
controls tooltip generation in the HTML destination. The default is IMAGEMAP=OFF, which means that no tooltips are generated. Tooltips are text boxes that appear in HTML output when you hover over a part of the plot with your mouse pointer (see Example 21.1).

IMAGENAME=< *base-file-name* **>**
specifies the base image file name. The default is the name of the output object. You can determine the name of the output object by using the ODS TRACE statement (see the section "Determining Graph Names and Labels" on page 538). The base image name should not include an extension. ODS automatically adds the increment value and the appropriate extension (which is specific to the output destination). See the section "Specifying Base File Names" on page 543 for an example.

LABELMAX=*n*
specifies the maximum number of labeled areas before labeling is disabled. For example, if LABELMAX=50, and there are more than 50 points with labels, then no points are labeled. The default is LABELMAX=200.

MAXLEGENDAREA=*n*
specifies the maximum percentage of the overall graph area that a legend can occupy. The default is MAXLEGENDAREA=20. Larger legends are dropped from the display.

RESET< *=option* **>**
resets one or more ODS GRAPHICS options to their default settings. The RESET and RESET=ALL options are equivalent. If you want to reset more than one option, but not all of the

options, then you must specify RESET= separately for each option you reset (for example, `ods graphics on / reset=antialias reset=index;`). The RESET= options include the following:

ALL
resets all of the resettable options to their defaults.

ANTIALIAS
resets the ANTIALIAS= option to its default.

ANTIALIASMAX
resets the ANTIALIASMAX= option to its default.

BORDER
resets the BORDER= option to its default.

INDEX
resets the index counter that is appended to static image files.

HEIGHT
resets the HEIGHT= option to its default.

IMAGEMAP
resets the IMAGEMAP= option to its default.

LABELMAX
resets the LABELMAX= option to its default.

SCALE
resets the SCALE= option to its default.

TIPMAX
resets the TIPMAX= option to its default.

WIDTH
resets the WIDTH= option to its default.

SCALE=ON | OFF
specifies whether the fonts and symbol markers are scaled proportionally with the size of the graph. The default is SCALE=ON. For examples, see Figure 21.29 and Figure 21.30.

TIPMAX=*n*
specifies the maximum number of distinct tooltips permitted before tooltips are disabled. Tooltips are text boxes that appear when you hover over a part of the plot with your mouse pointer. For example, if TIPMAX=400, and there are more than 400 points in a scatter plot, then no tooltips appear. The default is TIPMAX=500.

WIDTH=*dimension*
specifies the width of the graph. The default is WIDTH=640PX (640 pixels). You can also specify widths in inches (for example, WIDTH=5in) or centimeters (for example, WIDTH=12cm).

ODS Destination Statements

ODS has a number of statements that control the destination of ODS output. The ODS destination statements that are most commonly used with ODS Graphics are: ODS DOCUMENT, ODS HTML, ODS LATEX, ODS LISTING, ODS PCL, ODS PDF, ODS PS, and ODS RTF. Specifying a statement opens a destination, unless the CLOSE option is specified. Each of the following statements opens an ODS destination:

```
ods html;
ods rtf;
ods html image_dpi=300;
ods listing style=Statistical;
```

Each of the following statements closes an ODS destination:

```
ods html close;
ods rtf close;
ods listing close;
```

There are two options that are commonly used in ODS destination statements to control aspects of ODS Graphics:

IMAGE_DPI=*dpi*
: specifies the dots per inch (DPI), which is the image resolution for graphical output. The default varies depending on the destination. For example, the default is 100 for HTML and 200 for RTF.

STYLE=*style-name*
: specifies the style definition. Commonly used styles include DEFAULT, LISTING, STATISTICAL, JOURNAL, JOURNAL2, RTF, and ANALYSIS.

Other options provide you with ways to control the files that are created. For example, the following statement opens the HTML destination:

```
ods html body='b.html' contents='c.html' frame='a.html';
```

This statement also writes the body of the output to the file *b.html*, the table of contents to the file *c.html*, and an overall frame containing both the contents and the output to the file *a.html*. Alternatively, you can specify FILE= instead of BODY=.

If you are using a destination for which individual graphs are created (for example, LISTING or HTML), you can use the GPATH= option to specify the directory where your graphics files are saved, as in the following example:

```
ods html gpath="C:\figures";
```

See the sections "Image File Types" on page 541, "Saving Graphics Image Files" on page 544, "LISTING Destination" on page 545, "HTML Destination" on page 545, and "LATEX Destination" on page 546 for more information about individual image files and options specified in the ODS

Destination statements. For complete details about the ODS destination statements, see the *SAS Output Delivery System: User's Guide*.

PLOTS= Option

Each statistical procedure that produces ODS Graphics has a PLOTS= option that is used to select graphs and specify some options. The syntax of the PLOTS= option is as follows:

PLOTS <(*global-plot-options*)> <= *plot-request* <*(options)*>>
PLOTS <(*global-plot-options*)> <= (*plot-request* <*(options)*> <... *plot-request* <*(options)*>>)>

The PLOTS= option has a common overall syntax for all statistical procedures, but the specific global plot options, plot requests, and plot options vary across procedures. This section discusses only a few of the options available in the PLOTS= option. For more information about the PLOTS= option, see the "Syntax" section for each procedure that produces ODS Graphics. There are only a limited number of things that you can control with the PLOTS= option. Most graphical details are controlled either by graph templates (see the section "Graph Templates" on page 577) or by styles (see the section "Styles" on page 554).

The PLOTS= option usually appears in the PROC statement. However, for some procedures, certain analyses and hence certain plots can appear only if an additional statement is specified. These procedures often have a PLOTS= option in that other statement. For example, the PHREG procedure has a PLOTS= option in the BAYES statement, which is used to perform a Bayesian analysis. See the "Syntax" section of each procedure chapter for more information. The following examples illustrate the syntax of the PLOTS= option:

```
plots=all
plots=none
plots=residuals
plots=residuals(smooth)
plots=(trace autocorr)
plots(unpack)
plots(unpack)=diagnostics
plots=diagnostics(unpack)
plots(only)=freqplot
plots=(scree(unpack) loadings(plotref) preloadings(flip))
plots(unpack maxparmlabel=0 stepaxis=number)=coefficients
plots(sigonly)=(rawprob adjusted(unpack))
```

Also see the "Getting Started" sections "Survival Estimate Plot with PROC LIFETEST" on page 504, "Contour and Surface Plots with PROC KDE" on page 505, "Contour Plots with PROC KRIGE2D" on page 507, "LS-Means Diffogram with PROC GLIMMIX" on page 513, and "Principal Component Analysis Plots with PROC PRINCOMP" on page 515 for examples of the PLOTS= option.

The simplest PLOTS= specifications are of the form PLOTS=*plot-request* or PLOTS=(*plot-requests*). When there is more than one plot request, the plot-request list must appear in parentheses. Each plot request either requests a plot (for example, RESIDUALS) or provides you with a

place to specify plot-specific options (for example, DIAGNOSTICS(UNPACK)). Some simple and typical plot requests are explained next:

- PLOTS=ALL requests all plots that are relevant to the analysis. This does not mean that all plots that the procedure can produce are produced. Plots that are produced for one set of options might not appear with PLOTS=ALL and a different set of options. In some cases, certain plots are not produced unless certain options or statements outside the PLOTS= option are specified.
- PLOTS=NONE disables ODS Graphics for just that step. You can use this option instead of specifying ODS GRAPHICS OFF before a procedure step and ODS GRAPHICS ON after the step when you want to suppress graphics for only that step.
- PLOTS=RESIDUALS requests a plot of residuals in a modeling procedure such as PROC REG.
- PLOTS=RESIDUALS(SMOOTH) requests the residuals plot along with a smooth fit function.
- PLOTS=(TRACE AUTOCORR) requests trace and autocorrelation plots in procedures with Bayesian analysis options.

Global plot options appear in parentheses after the option name and before the equal sign. These options affect many or all of the plots. The UNPACK option is a commonly used global plot option. It specifies that plots that are normally produced with multiple plots per panel (or "packed") should be unpacked and appear in multiple panels with one plot in each panel. The specification PLOTS(UNPACK)=(*plot-requests*) unpacks all paneled plots. The UNPACK option is also used as an option in a plot request when you only want to unpack certain panels. For example, the option PLOTS=(DIAGNOSTICS(UNPACK) PARTIAL PREDICTIONS) unpacks just the diagnostics panel. In some cases, unpacked plots contain additional information that is not found in the smaller packed versions. The UNPACK option is not available for all plot requests; it is just available with plots that have multiple panels by default.

Another commonly used global plot option is the ONLY option. Many procedures produce default plots, and additional plots can be requested in the PLOTS= option. Specifying PLOTS=(*plot-requests*) while omitting the default plots does not prevent the default plots from being produced. The ONLY option is used when you only want to see the plots specifically listed in the plot-request list. Procedures that produce no default plots typically do not provide an ONLY option. You can use ODS SELECT and ODS EXCLUDE (see the section "Selecting and Excluding Graphs" on page 540) to select and exclude graphs, but in some situations the ONLY option is more convenient. It is typically more efficient to select plots by using the PLOTS(ONLY)= option, because the procedure does not do extra work to generate a plot that is excluded by the PLOTS(ONLY)= option. In contrast, ODS SELECT and ODS EXCLUDE have their effect after the procedure has done the work to generate the plot.

Selecting and Viewing Graphs

This section describes techniques for selecting and viewing your graphs. Topics include:

- specifying an ODS destination for graphics
- viewing your graphs in the SAS windowing environment
- referring to graphs by name when using ODS
- selecting and excluding graphs from your output

Specifying an ODS Destination for Graphics

If you do not specify an ODS destination, then the LISTING destination is used by default. Here is an example of how you can specify the HTML destination:

```
ods graphics on;
ods html;

proc reg data=sashelp.class;
   model Weight = Height;
run; quit;

ods html close;
```

This ODS HTML statement creates an HTML file with a default name. See the section "Specifying a File for ODS Output" on page 536 to see how to specify a file name. Other destinations are specified in a similar way. For example, you can specify an RTF destination with the following statements:

```
ods graphics on;
ods rtf;

. . .

ods rtf close;
```

The destinations that ODS supports for graphics are as follows:

Destination	Destination Family
DOCUMENT	
HTML	MARKUP
LATEX	MARKUP
LISTING	
PCL	PRINTER
PDF	PRINTER
PS	PRINTER
RTF	

You can close the LISTING destination if you are only interested in displaying your output in a different destination. For example, if you want to see your output only in the RTF destination, you can specify the following statements:

```
ods graphics on;
ods listing close;
ods rtf;

. . .

ods rtf close;
ods listing;
```

Closing unneeded destinations makes your jobs run faster and creates fewer files. More generally, it makes your jobs consume fewer resources, because a graph is otherwise created for every open destination. The last statement opens the LISTING destination after you are finished using the RTF destination.

You can also use the ODS OUTPUT destination to create an output data set from the data object used to make a plot. Here is an example:

```
ods graphics on;

proc reg data=sashelp.class;
   ods output fitplot=myfitplot;
   model Weight = Height;
run; quit;
```

Specifying a File for ODS Output

You can specify a file name for your output with the FILE= option in the ODS destination statement, as in the following example:

```
ods html file="test.htm";
```

The output is written to the file *test.htm*, which is saved in the SAS current folder. At startup, the SAS current folder is the same directory in which you started your SAS session. If you are using the SAS windowing environment, then the current folder is displayed in the status line at the bottom of the main SAS window. If you do not specify a file name for your output, then SAS provides

a default file name, which depends on the ODS destination. This file is saved in the SAS current folder. You can always check the SAS log to verify the name of the file in which your output is saved. For example, suppose you specify the following statement:

```
ods html;
```

Then the following message is displayed in the SAS log:

```
NOTE: Writing HTML Body file: sashtml.htm
```

The default file names for each destination are specified in the SAS Registry. For example, Figure 21.31 shows that the default file name in the SAS Registry for the RTF destination is *sasrtf.rtf*. For more information, see the SAS Companion for your operating system.

Viewing Your Graphs in the SAS Windowing Environment

The mechanism for viewing graphics created with ODS can vary depending on your operating system, which viewers are installed on your computer, and the ODS destination you have selected. If you do not specify an ODS destination, then the LISTING destination is used by default. If you are using the SAS windowing environment, go to the Results window and find the icon for the corresponding graph. You can double-click the graph icon to display the graph in the default viewer that is configured on your computer for the corresponding image file type (see Figure 21.16).

If you are using the SAS windowing environment and you specify an HTML destination, then the results are displayed by default in the SAS Results window as they are being generated. Depending on your configuration, this can also apply to the PDF and RTF destinations. If you are using the LATEX or the PS destinations, you must use a PostScript viewer, such as GSview. For information about the windowing environment in a different operating system, see the SAS Companion for that operating system.

If you do not want to view the results as they are being generated, then select **Tools ► Options ► Preference** from the menu at the top of the main SAS window. Then in the **Results** tab, clear **View results as they are generated** checkbox.

You can change the default to use an external viewer instead of the Results window. Select **Tools ► Options ► Preferences** from the menu at the top of the main SAS window. Then in the **Results** tab select **Preferred web browser**. Your results are displayed in the default viewer that is configured on your computer for the corresponding destination.

You can also choose your browser for HTML output. Select **Tools ► Options ► Preferences** from the menu at the top of the main SAS window. Then in the **Web** tab, select **Other browser**, and type (or browse) the path of your preferred browser.

Determining Graph Names and Labels

Procedures assign a name to each graph they create with ODS Graphics. This enables you to refer to ODS graphs in the same way that you refer to ODS tables (see the section "Paths and Selection" on page 435 in Chapter 20, "Using the Output Delivery System"). You can determine the names of graphs in several ways:

- You can look up graph names in the "ODS Graphics" section of chapters for procedures that use ODS Graphics. For example, see the section "ODS Graphics" on page 5589 in Chapter 73, "The REG Procedure."
- You can use the Results window to view the names of ODS graphs created in your SAS session. See the section "ODS and the SAS Results Window" on page 440 in Chapter 20, "Using the Output Delivery System," for more information.
- You can use the ODS TRACE ON statement to list the names of graphs created by your SAS session. This statement adds identifying information in the SAS log (or optionally in the SAS LISTING) for each graph that is produced. See the section "Paths and Selection" on page 435 in Chapter 20, "Using the Output Delivery System," for more information.

The graph name is not the same as the name of the image file that contains the graph (see the section "Naming Graphics Image Files" on page 542).

This example revisits the analysis described in the section "Contour and Surface Plots with PROC KDE" on page 505. To determine which output objects are created by ODS, you specify the ODS TRACE ON statement prior to the procedure statements as follows:

```
ods graphics on;
ods trace on;

proc kde data=bivnormal;
   bivar x y / plots=contour surface;
run;

ods trace off;
```

The trace record from the SAS log is as follows:

```
Output Added:
-------------
Name:        Inputs
Template:    Stat.KDE.Inputs
Path:        KDE.Bivar1.x_y.Inputs
-------------

Output Added:
-------------
Name:        Controls
Template:    Stat.KDE.Controls
```

```
Path:       KDE.Bivar1.x_y.Controls
-------------

Output Added:
-------------
Name:       ContourPlot
Label:      Contour Plot
Template:   Stat.KDE.Graphics.Contour
Path:       KDE.Bivar1.x_y.ContourPlot
-------------

Output Added:
-------------
Name:       SurfacePlot
Label:      Density Surface
Template:   Stat.KDE.Graphics.Surface
Path:       KDE.Bivar1.x_y.SurfacePlot
-------------
```

By default, PROC KDE creates table objects named **Inputs** and **Controls**, and it creates graph objects named **ContourPlot** and **SurfacePlot**. In addition to the name, the trace record provides the label, template, and path for each output object. Graph templates are distinguished from table templates by a naming convention that uses the procedure name in the second level and **Graphics** in the third level. For example, the fully qualified template name for the surface plot created by PROC KDE is **Stat.KDE.Graphics.SurfacePlot**.

You can specify the LISTING option in the ODS TRACE ON statement to write the trace record to the LISTING destination as follows:

```
ods trace on / listing;
```

Each table and graph has a path, which was previously shown in the trace output. The path consists of the plot name preceded by the names of one or more output groups. Each table and graph also has a label path, which can be seen by adding the LABEL option to the ODS TRACE ON statement, after a slash, as follows:

```
ods trace on / label;

proc kde data=bivnormal;
   bivar x y / plots=contour surface;
run;

ods trace off;
```

A portion of the trace output is shown next:

```
Path:       KDE.Bivar1.x_y.Inputs
Label Path: 'The KDE Procedure'.'Bivariate Analysis'.'x and y'.'KDE.Bivar1.x_y'

Path:       KDE.Bivar1.x_y.Controls
Label Path: 'The KDE Procedure'.'Bivariate Analysis'.'x and y'.'KDE.Bivar1.x_y'

Path:       KDE.Bivar1.x_y.ContourPlot
```

```
Label Path: 'The KDE Procedure'.'Bivariate Analysis'.'x and y'.'Contour Plot'

Path:       KDE.Bivar1.x_y.SurfacePlot
Label Path: 'The KDE Procedure'.'Bivariate Analysis'.'x and y'.'Density Surface'
```

The label path contains the information that you see in the HTML table of contents. Names are fixed, they do not vary, and they are not data- or context-dependent. In contrast, labels often reflect data- or context-dependent information.

Selecting and Excluding Graphs

You can use the ODS SELECT and ODS EXCLUDE statements along with graph and table names to specify which ODS outputs are displayed. See the section "Paths and Selection" on page 435 in Chapter 20, "Using the Output Delivery System," for more information about how to use these statements.

This section shows several examples of selecting and excluding graphs by using the data set and trace output created in the section "Determining Graph Names and Labels" on page 538. The following statements use the ODS SELECT statement to select only two graphs, **ContourPlot** and **SurfacePlot**, for display in the output:

```
proc kde data=bivnormal;
   ods select ContourPlot SurfacePlot;
   bivar x y / plots=contour surface;
run;
```

Equivalently, the following statements use the ODS EXCLUDE statement to exclude the two tables:

```
proc kde data=bivnormal;
   ods exclude Inputs Controls;
   bivar x y / plots=contour surface;
run;
```

You can select or exclude graphs by using either the name or the label. Labels must be specified in quotes. In the context of this example, the following two statements are equivalent:

```
ods select contourplot;
ods select 'Contour Plot';
```

You can also specify multiple levels of the path, as in the following example:

```
ods select x_y.contourplot;
ods select 'x and y'.'Contour Plot';
ods select 'x and y'.contourplot;
ods select x_y.'Contour Plot';
```

Paths and label paths can be mixed, as in the last two statements. All four of the preceding statements select the same plot. Furthermore, selection based directly on the names and labels is case insensitive. The following all select the same plot:

```
ods select x_y.contourplot;
ods select 'x and y'.'Contour Plot';
```

```
ods select X_Y.CONTOURPLOT;
ods select 'X AND Y'.'CONTOUR PLOT';
```

It is sometimes useful to specify a WHERE clause in an ODS SELECT or ODS EXCLUDE statement. This enables you to specify expressions based on either the path or the label path. You can base your selection on two automatic variables _path_ and _label_. The following two statements select every object whose path contains the string 'plot' and every object whose label path contains the string 'plot', respectively, ignoring the case in the name and label:

```
ods select where = (lowcase(_path_)  ? 'plot');
ods select where = (lowcase(_label_) ? 'plot');
```

The question mark operator means that the second expression (the string 'plot') is contained in the first expression (the lowercase version of the name or label). For example, all of the following names match 'plot' in the WHERE clause: plot, SurfacePlot, SURFACEPLOT, FitPlot, pLoTtInG, Splotch, and so on. Since WHERE clause selection is based on SAS string comparisons, selection is case sensitive. The LOWCASE function is used to ensure a match even when the specified string does not match the case of the actual name or label.

WHERE clauses are particularly useful when you want to select all of the objects in a group. A group is a level of the path or label path hierarchy before the last level. In the following step, all of the objects whose name path contains 'DiagnosticPlots' are selected:

```
proc reg data=sashelp.class plots(unpack);
   ods select where = (_path_ ? 'DiagnosticPlots');
   model Weight = Height;
run; quit;
```

These are the plots that come from unpacking the PROC REG diagnostics panel of plots. All are in a group named 'DiagnosticPlots'.

Graphics Image Files

Accessing your graphs as individual image files is useful when you want to include them in various types of documents. The default image file type depends on the ODS destination, but there are other supported image file types that you can specify. You can also specify the names for your graphics image files and the directory in which you want to save them. This section describes the image file types supported by ODS Graphics, and it explains how to name and save graphics image files.

Image File Types

If you are using the LISTING, HTML or LATEX destinations, your graphs are individually produced in a specific image file type, such as PNG (Portable Network Graphics). If you are using a destination in the PRINTER family or the RTF destination, the graphs are contained in the ODS output file and cannot be accessed as individual image files. However, you can open an RTF out-

put file in Microsoft Word and then copy and paste the graphs into another document, such as a Microsoft PowerPoint presentation. This is illustrated in Example 21.2.

Table 21.1 shows the various ODS destinations supported by ODS Graphics, the viewer that is appropriate for displaying graphs in each destination, and the image file types supported for each destination.

Table 21.1 Destinations and Image File Types Supported by ODS Graphics

Destination	Destination Family	Recommended Viewer	Image File Types
DOCUMENT		Not applicable	Not applicable
HTML	MARKUP	Web browser	PNG (default), GIF, JPEG,
LATEX	MARKUP	PostScript or PDF viewer after compiling the LaTeX file	PostScript (default), EPSI, GIF, JPEG, PDF, PNG
LISTING		Default viewer in your system for the specified file type	PNG (default), GIF, BMP, DIB, EMF, EPSI, GIF, JFIF, JPEG, PBM, PS, TIFF, WMF
PCL	PRINTER	not applicable	Contained in PRN file
PDF	PRINTER	PDF viewer, such as Adobe Reader	Contained in PDF file
PS	PRINTER	PostScript viewer, such as GSview	Contained in PostScript file
RTF		Word processor, such as Microsoft Word	Contained in RTF file

For destinations such as PDF and RTF, you can control the types of the images that are contained in the file even though individual files are not made for each image. The default image file type is PNG, and other image types are available. See the *SAS Output Delivery System: User's Guide* for more information.

Naming Graphics Image Files

The following discussion applies to the destinations where ODS graphs are created as individual image files (for example, HTML, LISTING, and LATEX). The names of graphics image files are determined by a base file name, an index counter, and an extension. By default, the base file name is the ODS graph name (see the section "Determining Graph Names and Labels" on page 538). There is an index counter for each base file name. The extension indicates the image file type. The first time a graph object with a given base file name is created, the file name consists only of the base file name and the extension. If a graph with the same base file name is created multiple times, then an index counter is appended to the base file name to avoid overwriting previously created images.

To illustrate, consider the following statements:

```
proc kde data=bivnormal;
   ods select ContourPlot SurfacePlot;
   bivar x y / plots=contour surface;
run;
```

If you run this step at the beginning of a SAS session, the two graphics image files created are *ContourPlot.png* and *SurfacePlot.png*. If you immediately rerun these statements, then ODS creates the same graphs in different image files named *ContourPlot1.png* and *SurfacePlot1.png*. The next time, the image files are named *ContourPlot2.png* and *SurfacePlot2.png*. The index starts at zero, and one is added each time the same name is used. Note, however, that when the index is at zero, it is not added to the file name.

Resetting the Index Counter

You can specify the RESET=INDEX option in the ODS GRAPHICS statement to reset the index counter. This is useful when you need to have predictable names. It is particularly useful when you are running a SAS program multiple times in the same session. The following statement resets the index:

```
ods graphics on / reset=index;
```

The index counter is reinitialized at the beginning of your SAS session or if you specify the RESET=INDEX option in the ODS GRAPHICS statement. Graphics image files with the same name are overwritten.

Specifying Base File Names

You can specify a base file name for all your graphics image files with the IMAGENAME= option in the ODS GRAPHICS statement as follows:

```
ods graphics on / imagename="MyName";
```

You can also specify the RESET=INDEX option as follow:

```
ods graphics on / reset=index imagename="MyName";
```

The IMAGENAME= option overrides the default base file name. With the preceding statement, the graphics image files are named *MyName*, *MyName1*, *MyName2*, and so on.

Specifying Image File Types

You can specify the image file type for the LISTING, HTML, or LATEX destinations with the IMAGEFMT= option in the ODS GRAPHICS statement as follows:

```
ods graphics on / imagefmt=gif;
```

For more information, see the section "ODS GRAPHICS Statement" on page 529.

Naming Graphics Image Files with Multiple Destinations

Since the index counter depends only on the base file name, if you specify multiple ODS destinations for your output, then the index counter is increased independently of the destination. For example, the following statements create image files named *ContourPlot.png* and *SurfacePlot.png* that correspond to the LISTING destination; and *ContourPlot1.png* and *SurfacePlot1.png* that correspond to the HTML destination:

```
ods listing;
ods html;
ods graphics on / reset;

proc kde data=bivnormal;
   ods select ContourPlot SurfacePlot;
   bivar x y / plots=contour surface;
run;

ods _all_ close;
ods listing;
```

When you specify one of the destinations in the PRINTER family or the RTF destination, your ODS graphs are embedded in the document, so the index counter is not affected. For example, the following statements create image files *ContourPlot.png* and *SurfacePlot.png* for the LISTING destinations, but no image files for the RTF destination:

```
ods listing;
ods rtf;
ods graphics on / reset;

proc kde data=bivnormal;
   ods select ContourPlot SurfacePlot;
   bivar x y / plots=contour surface;
run;

ods _all_ close;
```

Saving Graphics Image Files

Knowing where your graphics image files are saved and how they are named is particularly important if you are running in batch mode, if you have disabled the SAS Results window (see the section "Viewing Your Graphs in the SAS Windowing Environment" on page 537), or if you plan to access the files for inclusion in a paper or presentation. The following discussion assumes you are running SAS under the Windows operating system. If you are running on a different operating system, see the SAS Companion for your operating system.

Your graphics image files are saved by default in the SAS current folder. If you are using the SAS windowing environment, the current folder is displayed in the status line at the bottom of the main SAS window. If you are running your SAS programs in batch mode, the graphs are saved by default

in the same directory where you started your SAS session. For example, suppose the SAS current folder is *C:\myfiles*. If you specify the ODS GRAPHICS statement, then your graphics image files are saved in the directory *C:\myfiles*. Unlike traditional graphics, ODS Graphics are not saved in a catalog in your WORK directory.

With the LISTING, HTML, and LATEX destinations, you can specify a directory for saving your graphics image files. With a destination in the PRINTER family and with the RTF destination, you can specify a directory only for your output file. The remainder of this discussion provides details for each destination type.

LISTING Destination

If you are using the LISTING destination, the individual graphs are created as PNG files by default. You can use the GPATH= option in the ODS LISTING statement to specify the directory where your graphics files are saved. For example, if you want to save your graphics image files in *C:\figures*, then you can specify the following:

```
ods listing gpath="C:\figures";
```

It is important to note that the GPATH= option applies only to ODS Graphics. It does not affect the behavior of graphics created with traditional SAS/GRAPH procedures.

HTML Destination

If you are using the HTML destination, the individual graphs are created as PNG files by default. You can use the PATH= and GPATH= options in the ODS HTML statement to specify the directory where your HTML and graphics files are saved, respectively. This also gives you more control over your graphs. For example, if you want to save your HTML file named *test.htm* in the *C:\myfiles* directory, but you want to save your graphics image files in *C:\myfiles\png*, then you can specify the following:

```
ods html path  ="C:\myfiles"
         gpath = "C:\myfiles\png"
         file  = "test.htm";
```

When you specify the URL= suboption with the GPATH= option, SAS creates relative paths for the links and references to the graphics image files in the HTML file. This is useful for building output files that are easily moved from one location to another. For example, the following statements create a relative path to the *png* directory in all the links and references contained in *test.htm*:

```
ods html path  = "C:\myfiles"
         gpath = "C:\myfiles\png" (url="png/")
         file  = "test.htm";
```

If you do not specify the URL= suboption, SAS creates absolute paths that are hard-coded in the HTML file. These can cause broken links if you move the files. For more information, see the ODS HTML statement in the *SAS Output Delivery System: User's Guide*.

LATEX Destination

LaTeX is a document preparation system for high-quality typesetting. The ODS LATEX statement produces output in the form of a LaTeX source file that is ready to compile in LaTeX. When you request ODS Graphics for a LATEX destination, ODS creates the requested graphs as PostScript files by default, and the LaTeX source file includes references to these image graphics files. You can compile the LaTeX file, or you can ignore this file and simply access the individual PostScript files to include your graphs in a different LaTeX document, such as a paper that you are writing. You can specify the PATH= and GPATH= options in the ODS LATEX statement, as explained previously for the ODS HTML statement. See Example 21.3 for an illustration. The ODS LATEX statement is an alias for the ODS MARKUP statement with the TAGSET=LATEX option. For more information, see the *SAS Output Delivery System: User's Guide*.

The default image file type for the LATEX destination is PostScript. When you use LaTeX to compile your document, the graphics format for included images is Postscript. However, if you prefer to use pdfLaTeX, you can specify a different format such as JPEG, PDF, or PNG, any of which can be directly included into your pdfLaTeXdocument. To specify one of these formats, you use the IMAGEFMT= option in the ODS GRAPHICS statement. For more information, see the LaTeX documentation for the `graphicx` package.

Creating Graphs in Multiple Destinations

This section illustrates how to send your output to more than one destination with a single execution of your SAS statements. For example, to create the default LISTING output and also both HTML and RTF output, you can specify the ODS HTML and the ODS RTF statements before your procedure statements.

```
ods html;
ods rtf;

. . .

ods _all_ close;
```

The ODS _ALL_ CLOSE statement closes all open destinations.

You can also specify multiple instances of the same destination. For example, using the data in the section "Contour and Surface Plots with PROC KDE" on page 505, the following statements save the contour plot to the file *contour.pdf* and the surface plot to the file *surface.pdf*:

```
ods pdf file="contour.pdf";
ods pdf select ContourPlot;
ods pdf(id=srf) file="surface.pdf";
ods pdf(id=srf) select SurfacePlot;
ods graphics on;

proc kde data=bivnormal;
   ods select ContourPlot SurfacePlot;
```

```
   bivar x y / plots=contour surface;
run;

ods _all_ close;
```

The ID= option assigns the name **srf** to the second instance of the PDF destination. Without the ID= option, the second ODS PDF statement closes the destination that was opened by the previous ODS PDF statement, and it opens a new instance of the PDF destination. In that case, the file *contour.pdf* is not created. For more information, see the ODS PDF statement in the *SAS Output Delivery System: User's Guide*.

Graph Size and Resolution

ODS provides options for specifying the size and resolution of graphs. You can specify the size of a graph in the ODS GRAPHICS statement and the resolution in an ODS destination statement. There are two other ways to change the size of a graph, but they are rarely needed. The three methods are as follows:

- Usually, you specify WIDTH=, HEIGHT=, or both in the ODS GRAPHICS statement to change the size of a graph.
- To modify the size of a particular graph, specify the dimensions with the DESIGNHEIGHT= and DESIGNWIDTH= options in the BEGINGRAPH statement in the template definition. Some templates contain the specification DESIGNWIDTH=DEFAULTDESIGNHEIGHT, which sets the width of the graph to the default height, or DESIGNHEIGHT=DEFAULTDESIGNWIDTH, which sets the height of the graph to the default width.
- To modify the size of all of your ODS graphs, specify the dimensions with the OUTPUTHEIGHT= and OUTPUTWIDTH= options in the style definition.

The following examples show typical ways to change the size of your graphs:

```
ods graphics on / width=6in;
ods graphics on / height=4in;
ods graphics on / width=4.5in height=3.5in;
```

The dimensions of the graph can be specified in pixels (for example, 200PX), inches (for example, 3IN), or centimeters (for example, 8CM). The default dimensions of ODS Graphics are 640 pixels wide and 480 pixels high, and these values determine the default aspect ratio. The actual size of the graph in inches depends on your printer or display device. For example, if the resolution of your printer is 100 dots per inch, and you want a graph that is 4 inches wide, you should set the width to 400 pixels.

If you specify only one dimension, the other is determined by the default aspect ratio—that is, height=0.75 × width. For best results, you should create your graphs by using the exact size that is

used to display the graphs in your paper or presentation. In other words, avoid generating them at one size and then expanding or shrinking them for inclusion into the your document.

By default, fonts and symbol markers are automatically scaled with the size of the graph. You can suppress this scaling with the SCALE= option, as in the following example:

```
ods graphics on / scale=off;
```

The default resolution of graphs created with HTML and LISTING is 100 DPI (dots per inch), whereas the default with RTF is 200 DPI. The 200 DPI value is recommended if you are copying and pasting graphs into a Microsoft PowerPoint presentation or a Microsoft Word document. Graphs shown in SAS/STAT documentation are typically generated at 300 DPI for display in PDF and 100 DPI for display in HTML.

You can change the resolution with the IMAGE_DPI= option in any ODS destination statement, as in the following example:

```
ods html image_dpi=300;
```

An increase in resolution often improves the quality of the graphs, but it also greatly increases the size of the image file. Going from 100 DPI to 300 DPI increases the size of the image file by roughly a factor of $(300/100)^2 = 9$. Even when you are using a higher DPI for most of your graphs, you should consider using a lower DPI for some, such as contour plots, that create large files even at a lower DPI.

If you increase the resolution, you might need to compensate by reducing the size of the graph, as in the following example:

```
ods graphics on / width=4.5in  height=3.5in;
```

Increasing DPI also increases the amount of memory needed for your program to complete. You can increase the amount of memory available to ODS Graphics with an option when you invoke SAS, as in the following example:

```
-jreoptions '(-Xmx256m)'
```

You can modify the default amount of memory available to ODS Graphics by changing JREOPTIONS in your SAS configuration file to the settings –Xmx*nnn*m –Xms*nnn*m, where *nnn* is the amount of memory in megabytes. An example is –Xmx256m –Xms256m. In either case, the exact syntax varies depending on your operating system, and the amount of memory that you can allocate varies from system to system. For more information, see the SAS Companion for your operating system.

ODS Graphics Editor

The ODS Graphics Editor is a point-and-click interface that you can use to modify a specific graph created by ODS Graphics. For example, if you need to enhance a graph for a paper or presentation, you can use the ODS Graphics Editor to customize the title, modify the axis labels, annotate particular data points, and change graph element properties such as fonts, colors, and line styles.

This section explains how to enable ODS Graphics to create editable graphs and how to invoke the ODS Graphics Editor. You can use the ODS Graphics Editor in the SAS windowing environment, provided that the LISTING destination is open and that you have first enabled ODS Graphics to create editable graphs. **NOTE:** The LISTING destination is typically open by default. There are three steps you must take to edit a graph:

1 You must first enable the creation of editable graphs in one of three ways:
- use an ODS statement to temporarily enable this feature
- use a SAS command to temporarily enable this feature
- use the SAS Registry Editor to permanently enable this feature

Creating editable graphs takes additional resources, so you might not want to permanently enable this feature.

2 You submit your SAS code and create editable graphs.

3 You invoke the ODS Graphics Editor and edit the plot.

Step 2 involves submitting SAS code in the usual way, and no special instructions are needed for creating graphs that can be edited. Steps 1 and 3 are explained in more detail in the following sections.

Enabling the Creation of Editable Graphs

Temporarily Enable Creation of Editable Graphs by Using an ODS Statement

You can enable the creation of editable graphs within a SAS session by submitting the following statement:

```
ods listing sge=on;
```

You can disable the creation of editable graphs by submitting the following statement:

```
ods listing sge=off;
```

Temporarily Enable Creation of Editable Graphs by Using a SAS Command

Alternatively, you can enable the creation of editable graphs for the duration of your SAS session by first selecting the Results window and then entering **`sgedit on`** in the command line. SAS confirms that the creation of editable graphs is enabled by displaying a message in the bottom left corner of the SAS window. The command must be entered from the Results window. If you enter it from any other window, it is ignored.

Permanently Enable Creation of Editable Graphs across SAS Sessions

You can create a default setting that enables or disables the creation of editable graphs across SAS sessions via the 'ODS Graphics Editor' setting in the SAS Registry. You can change this setting in the SAS windowing environment as follows:

1. Open the Registry Editor by entering **regedit** in the command line.
2. Select **SAS_REGISTRY ► ODS ► GUI ► RESULTS**.
3. In the **Value Data** field, click **ODS Graphics Editor** to open the Edit String Value window, and type **On** to enable the creation of editable graphs or type **Off** to disable it.
4. Click **OK**.

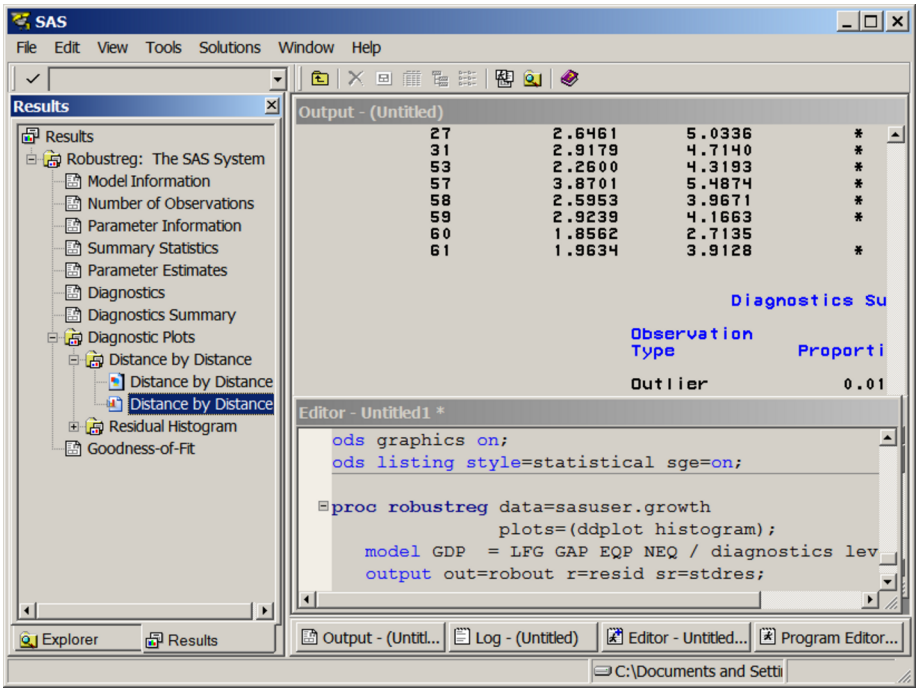
Editing a Graph with the ODS Graphics Editor

The ODS Graphics Editor is illustrated using the following example:

```
data sasuser.growth;
   input country $ GDP LFG EQP NEQ GAP @@;
   datalines;
Argentin  0.0089 0.0118 0.0214 0.2286 0.6079
Austria   0.0332 0.0014 0.0991 0.1349 0.5809

... more lines ...

Zambia   -0.0110 0.0275 0.0702 0.2012 0.8695
Zimbabwe  0.0110 0.0309 0.0843 0.1257 0.8875
;



ods graphics on;
ods listing style=statistical sge=on;

proc robustreg data=sasuser.growth
               plots=(ddplot histogram);
   model GDP  = LFG GAP EQP NEQ / diagnostics leverage;
   output out=robout r=resid sr=stdres;
run;

ods listing sge=off;
```

The DATA and the PROC ROBUSTREG steps are submitted to SAS, in this case from the SAS windowing environment, as shown in Figure 21.19. Two versions of the graph are created: one in an uneditable PNG file (for example, *DDPlot.png*) and one in an editable SGE file (for example, *DDPlot.sge*). Both are saved in the SAS current folder. You can edit the graph in one of three ways:

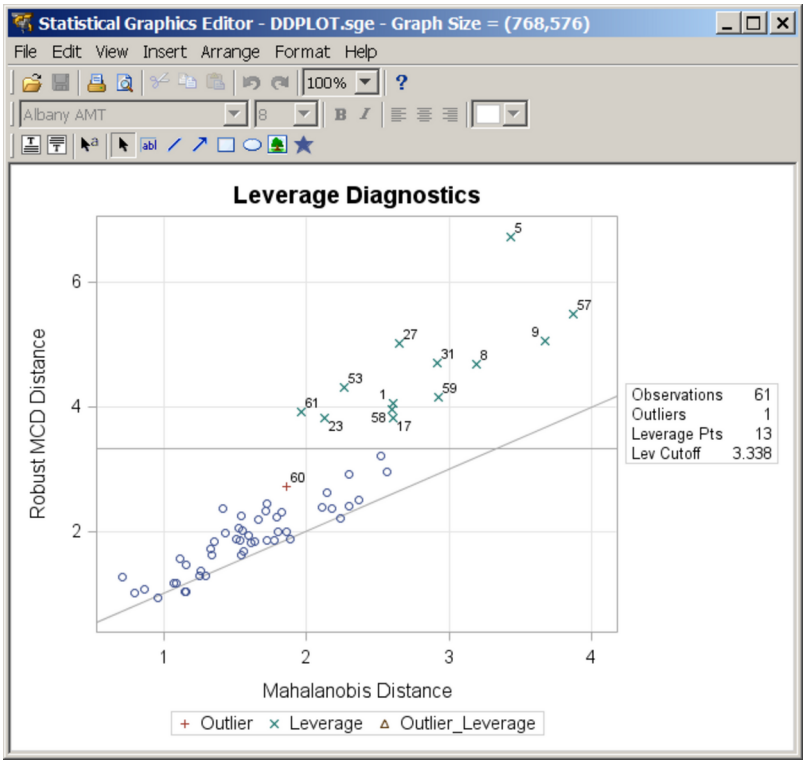
Figure 21.19 Results Window with Icons for Editable Plots

- In the Results window, double-click the second graph icon for the graph you want to edit (see Figure 21.19). The second icon corresponds to the SGE file, and the first icon corresponds to the PNG file. Clicking the first graph icon invokes a host-dependent graph viewer (for example, Microsoft Photo Editor on Windows), not the ODS Graphics Editor. **NOTE:** The Editor window might be hidden behind other windows in the SAS windowing environment.
- You can edit the graph by selecting it in the SAS Explorer window. You must first navigate to the SAS current folder and to the SGE files.
- You can open the graph from outside of SAS. For example, if you are running SAS under the Windows operating system, you can click on the graph's SGE file to open it with the ODS Graphics Editor.

Figure 21.20 shows the ODS Graphics Editor window for the editable diagnostic plot created by PROC ROBUSTREG. In Figure 21.21, various tools in the ODS Graphics Editor are used to modify the title and annotate a particular point. The edited plot can be saved as a PNG file or as an SGE file by selecting **File ► Save As**. After saving the plot, you can edit it again through the SAS Explorer window or by selecting **File ► Open** from the ODS Graphics Editor window. Alternatively, you can reopen the saved plot for editing without first invoking SAS. For example, if you are running SAS under the Windows operating system, you can click on the plot to open it with the ODS Graphics Editor.

The ODS Graphics Editor does not permit you to make structural changes to a graph (such as moving the positions of data points). The ODS Graphics Editor provides you with a point-and-click way to make one-time changes to a specific graph, whereas the template language (see the section "Graph Templates" on page 577) provides you with a programmatic way to make template changes that persist every time you run the procedure. For complete details about the tools available in the ODS Graphics Editor, see *Getting Started with the SAS/GRAPH Statistical Graphics Editor*.

Figure 21.20 Diagnostic Plot before Editing



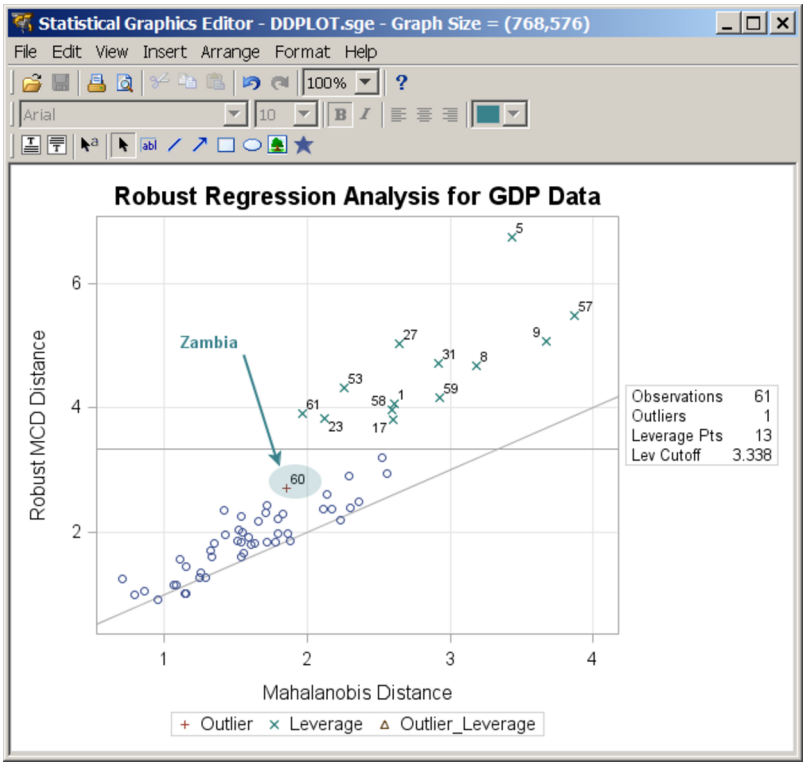


Figure 21.21 Diagnostic Plot after Editing

The Default Template Libraries and the ODS PATH

The default table, graph, and style templates that SAS provides are stored in the library SASHELP.Tmplmst. By default, if you modify a template, it is stored in the library SASUSER.Templat. By default, ODS searches SASUSER.Templat for templates, and then it searches SASHELP.Tmplmst if it does not find the requested template in SASUSER.Templat. You can see the list of template libraries by submitting the following statement:

```
ods path show;
```

Here are the results:

```
Current ODS PATH list is:

1. SASUSER.TEMPLAT(UPDATE)
2. SASHELP.TMPLMST(READ)
```

You can change the ODS PATH to add template libraries that you create or change the order that the libraries are searched. This is discussed in detail in the sections "Saving Customized Templates" on page 587, "Using Customized Templates" on page 587, and "Reverting to the Default Templates" on page 588. However, this section discusses the default template libraries that you use when you have not modified the ODS path. SAS always finds the templates it provides in SASHELP.Tmplmst if you did not store a modified template in SASUSER.Templat. Otherwise, it finds and uses your modified template in SASUSER.Templat. You can see a list of all of the templates that you have modified as follows:

```
proc template;
   list / store=sasuser.templat;
run;
```

You can delete any template that you modified (so that ODS finds the default template that SAS supplied) by specifying it on a DELETE statement, as in the following example:

```
proc template;
   delete Stat.REG.Graphics.ResidualPlot;
run;
```

ODS never deletes the template in SASHELP.Tmplmst, so you can safely run the preceding step, even if the template you specify does not exist in SASUSER.Templat. You can run the following step to delete the entire SASUSER.Templat library of customized templates so that ODS uses only the SAS supplied templates:

```
ods path sashelp.tmplmst(read);
proc datasets library=sasuser;
   delete templat(memtype=itemstor);
run;
ods path sasuser.templat(update) sashelp.tmplmst(read);
```

It is good practice to delete templates that you have customized when you are done with them, so that they are not unexpectedly used later. See the section "Reverting to the Default Templates" on page 588 for more information.

Styles

ODS styles control the overall appearance of your output. Usually, the only thing you need to do with styles is specify them in an ODS destination statement, as in the following example:

```
ods html body='b.html' style=Statistical;
```

However, you can also modify existing styles and even write your own styles. You can also specify style elements in custom templates that you write, or you can modify which style elements are used in templates supplied by SAS. This section provides an overview of styles and style elements, which are the components of a style. It also describes how to customize a style definition and how to specify a default style for your output. Only the most commonly used styles, style elements, and style changes are discussed here. For complete details about styles, see the *SAS Output Delivery System: User's Guide*.

An Overview of Styles

An ODS style definition provides formatting information for specific visual aspects of your SAS output (see the section "Style Elements and Attributes" on page 555). The appearance of tables and graphs is coordinated within a particular style. For tables, this information typically includes a list of font definitions and a list of colors. Each font definition specifies a family, size, weight, and style. Colors are associated with common areas of output, including titles, footnotes, BY groups, table headers, and table cells. For graphs, styles also control the appearance of graph elements including lines, markers, fonts and colors. ODS styles also include elements specific to statistical graphics, such as the style of fitted lines, confidence bands, and prediction limits. For more information about styles, see the *SAS Output Delivery System: User's Guide*.

You can specify a style by using the STYLE= option in an ODS destination statement such as HTML, PDF, RTF, or PRINTER. You can also specify a style in the LISTING destination; however, it affects graphs but not tables. Each style produces output with the same content, but with a different visual appearance. For example, the following statement requests output produced with the JOURNAL style:

```
ods html style=Journal;
```

You can use any SAS style or any style that you define yourself. The following statements list the names of all of the styles and then display four of them:

```
proc template;
   list styles;
   source Styles.Default;
   source Styles.Statistical;
   source Styles.Journal;
   source Styles.RTF;
run;
```

The results of this step (not shown) are a list of over fifty styles in the SAS listing and four style definitions in the SAS log. The style definitions are often hundreds of lines long. See the section "Style Definitions and Colors" on page 557 for more information about style definitions. While you can use any style, only seven styles are typically used with ODS Graphics. They are described in Table 21.2.

Table 21.2 Styles

Style	Default in	Description
DEFAULT	HTML	A color style whose dominant colors are blue, gray, and white, with bold sans-serif fonts. See Figure 21.13.
STATISTICAL	SAS/STAT documentation	A color style whose dominant colors are blue, creamy gray, and white, with sans-serif fonts. See Figure 21.14.
LISTING	LISTING	A color style, similar to DEFAULT, but with a white background. See Figure 21.12.
JOURNAL		A black-and-white style with filled areas, and with sans-serif fonts. See Output 21.3.1.
JOURNAL2		A black-and-white style, similar to JOURNAL, but with empty areas. See Output 21.3.2.
RTF	RTF	A color style whose dominant colors are blue, white, and black, with Times Roman fonts. See Figure 21.11.
ANALYSIS		A color style, similar to STATISTICAL, whose dominant color is tan. See Figure 21.8.

Each ODS destination has its own default style, as shown in Table 21.2. Most output in SAS/STAT documentation uses the STATISTICAL style. However, throughout this chapter, you can see examples of other styles. For more information about styles, see the *SAS Output Delivery System: User's Guide*.

Style Elements and Attributes

An ODS style definition is composed of a set of *style elements*. A style element is a collection of *style attributes* that applies to a particular feature or aspect of the output. A value is specified for each attribute in a style definition. For example, **`GraphFit`** is the style element used for fit lines, and its attributes include: **`LineThickness`**, **`LineStyle`**, **`MarkerSize`**, **`MarkerSymbol`**, **`ContrastColor`**, and **`Color`**.

In general, style definitions control the overall appearance of ODS tables and graphs. For tables, style definitions specify features such as background color, table borders, and color scheme; and they specify the fonts, sizes, and color for the text and values in a table and its headers. For graphs, style definitions specify the following features:

- background color
- graph dimensions (height and width)
- borders
- line styles for axes and grid lines
- fonts, sizes, and colors for titles, footnotes, axis labels, axis values, and data labels. See the section "Modifying Graph Fonts in Styles" on page 570 for an illustration.
- marker symbols, colors, and sizes for data points and outliers
- line styles for needles
- line and curve styles for fitted models and predicted values. See "Modifying Other Graph Elements in Styles" on page 573 for an illustration.
- line and curve styles for confidence and prediction limits
- fill colors for histogram bars, confidence bands, and confidence ellipses
- colors for box plot features
- colors for surfaces
- color ramps for contour plots

SAS supplies a template for each plot that is created by statistical procedures. A graph template is a program that specifies the layout and details of a graph. See the section "Graph Templates" on page 577 for more information about templates. Some template options are specified with a style reference of the form **`style-element`**, or occasionally **`style-element:attribute`**. For example, the symbol, color, and size of markers for basic scatter plots are specified in a template SCATTERPLOT statement as follows:

```
scatterplot x=x y=y / markerattrs=GraphDataDefault;
```

The preceding statement specifies that the appearance for markers is controlled by the **`GraphDataDefault`** element. Consistent use of this element guarantees a common appearance of markers across all scatter plots, based on the style definition that you are using.

In general, ODS Graphics features are determined by style element attributes unless they are overridden by a statement or option in the graph template. For example, suppose that a classification variable is specified with the GROUP= option in a SCATTERPLOT template statement as follows:

```
scatterplot x=X y=Y / group=GroupVar;
```

Then the colors for markers that correspond to the classification levels are assigned by using the style element attributes **`GraphData1:ContrastColor`** through **`GraphData12:ContrastColor`**.

Style definitions are created and modified with PROC TEMPLATE. For more information, see the *SAS Output Delivery System: User's Guide*. You need to understand the relationships between style elements and graph features if you want to create your own style definition or modify a style definition. This is explained in the following sections.

Style Definitions and Colors

The default style definitions that SAS provides are stored in the *Styles* directory of SASHELP.Tmplmst. You can display, edit, and save style definitions by using the same methods available for modifying template definitions, as explained in the section "The Default Template Libraries and the ODS PATH" on page 553 and the series of sections beginning with "Displaying Templates" on page 583. In particular, you can display a style definition by using one of these methods:

- From the Templates window in the SAS windowing environment, expand the SASHELP.Tmplmst node under **Templates**, and then select **Styles** to display the contents of this folder. To open the Templates window, type **odst** in the command line.
- Use the SOURCE statement in PROC TEMPLATE.

For example, the following statements display the DEFAULT style definition in the SAS log:

```
proc template;
   source Styles.Default;
run;
```

The following are some of the results:

```
define style Styles.Default;
   . . .
   class GraphColors
      "Abstract colors used in graph styles" /
      . . .
      'gconramp3cend' = cxFF0000
      'gconramp3cneutral' = cxFF00FF
      'gconramp3cstart' = cx0000FF
      . . .
      'gdata12' = cxDDD17E
      'gdata11' = cxB7AEF1
      'gdata10' = cx87C873
      'gdata9' = cxCF974B
      'gdata8' = cxCD7BA1
      'gdata6' = cxBABC5C
      'gdata7' = cx94BDE1
      'gdata4' = cxA9865B
      'gdata5' = cxB689CD
      'gdata3' = cx66A5A0
      'gdata2' = cxDE7E6F
      'gdata1' = cx7C95CA;
   . . .
```

The first part of this list shows that the shading for certain filled plots, such as some contour plots goes, from blue (`'gconramp3cstart' = cx0000FF`) to magenta (`'gconramp3cneutral' = cxFF00FF`) to red (`'gconramp3cend' = cxFF0000`). All colors are specified in values of the form CX*rrggbb*, where the last six characters specify RGB (red, green, blue) values on the hexadecimal scale of 00 to FF (or 0 to 255 base 10). The second part of the list (`'gdata1' = cx7C95CA`)

shows that the dominant component of the **GraphData1** color is blue because the blue component of the color (CA, which corresponds to 202 base 10) is greater than both the green component (95, which corresponds to 149 base 10) and the red component (7C, which corresponds to 124 base 10).

You can change any part of the style and then submit the style back into SAS, after first submitting a PROC TEMPLATE statement. See the sections "Saving Customized Templates" on page 587, "Using Customized Templates" on page 587, and "Reverting to the Default Templates" on page 588 for more information about modifying, using, and restoring templates. The principles discussed in those sections apply to all templates—table, style, and graph.

Some Common Style Elements

The DEFAULT style is the parent for the styles used for statistical graphics work. You can see all of the elements of the DEFAULT style by running the following step:

```
proc template;
   source styles.default;
run;
```

The source listing of the definition of the DEFAULT style is hundreds of lines long. If you run PROC TEMPLATE with the SOURCE statement for most other styles, you see **parent = styles.default**, and you do not see all of the elements in the style unless you also run the preceding step.

Only a few of the style elements are referenced in the templates that SAS provides for statistical procedures. The most commonly used style elements, along with the defaults for the noncolor attributes of the DEFAULT style, are shown next (**Color** applies to filled areas, and **ContrastColor** applies to markers and lines):

Graph	graph size, outer border appearance, and background color **Padding = 0** **BackgroundColor**
GraphConfidence	graph size, outer border appearance, and background color **LineThickness = 1px** **LineStyle = 1** **MarkerSize = 7px** **MarkerSymbol = "triangle"** **ContrastColor** **Color**
GraphData1	attributes related to first grouped data items **MarkerSymbol = "circle"** **LineStyle = 1** **ContrastColor** **Color**

GraphData2	attributes related to second grouped data items
	MarkerSymbol = "plus"
	LineStyle = 4
	ContrastColor
	Color
GraphData3	attributes related to third grouped data items
	MarkerSymbol = "X"
	LineStyle = 8
	ContrastColor
	Color
GraphData4	attributes related to fourth grouped data items
	MarkerSymbol = "triangle"
	LineStyle = 5
	ContrastColor
	Color
GraphData*n*	attributes related to *n*th grouped data items
	MarkerSymbol
	LineStyle
	ContrastColor
	Color
GraphDataDefault	attributes related to non-grouped data items
	EndColor
	NeutralColor
	StartColor
	MarkerSize = 7px
	MarkerSymbol = "circle"
	LineThickness = 1px
	LineStyle = 1
	ContrastColor
	Color
GraphFit	primary fit line, such as a normal density curve
	LineThickness = 2px
	LineStyle = 1
	MarkerSize = 7px
	MarkerSymbol = "circle"
	ContrastColor
	Color
GraphFit2	secondary fit line, such as a kernel density curve
	LineThickness = 2px
	LineStyle = 4
	MarkerSize = 7px
	MarkerSymbol = "X"
	ContrastColor
	Color

GraphGridLines	horizontal and vertical grid lines drawn at major tick marks **Displayopts = "auto"** **LineThickness = 1px** **LineStyle = 1** **ContrastColor** **Color**
GraphOutlier	outlier data for the graph **LineThickness = 2px** **LineStyle = 42** **MarkerSize = 7px** **MarkerSymbol = "circle"** **ContrastColor** **Color**
GraphPredictionLimits	fills for prediction limits **LineThickness = 1px** **LineStyle = 2** **MarkerSize = 7px** **MarkerSymbol = "chain"** **ContrastColor** **Color**
GraphReference	horizontal and vertical reference lines and drop lines **LineThickness = 1px** **LineStyle = 1** **ContrastColor** **Color**
GraphDataText	text font and color for point and line labels **Font = GraphFonts('GraphDataFont')** (where **'GraphDataFont' = ("<sans-serif>, <MTsans-serif>",7pt))** **Color**
GraphValueText	text font and color for axis tick values and legend values **Font = GraphFonts('GraphValueFont')** (where **'GraphValueFont' = ("<sans-serif>, <MTsans-serif>",9pt)**) **Color**
GraphLabelText	text font and color for axis labels and legend title **Font = GraphFonts('GraphLabelFont')** (where **'GraphLabelFont' = ("<sans-serif>, <MTsans-serif>",10pt,bold)**) **Color**
GraphFootnoteText	text font and color for footnote(s) **Font = GraphFonts('GraphFootnoteFont')** (where **'GraphFootnoteFont' = ("<sans-serif>, <MTsans-serif>",10pt)**) **Color**

GraphTitleText	text font and color for title(s) **Font = GraphFonts('GraphTitleFont')** (where **'GraphTitleFont' = ("<sans-serif>, <MTsans-serif>",11pt,bold)**) **Color**
GraphWalls	vertical wall(s) bounded by axes **LineThickness = 1px** **LineStyle = 1** **FrameBorder = on** **ContrastColor** **BackgroundColor** **Color**

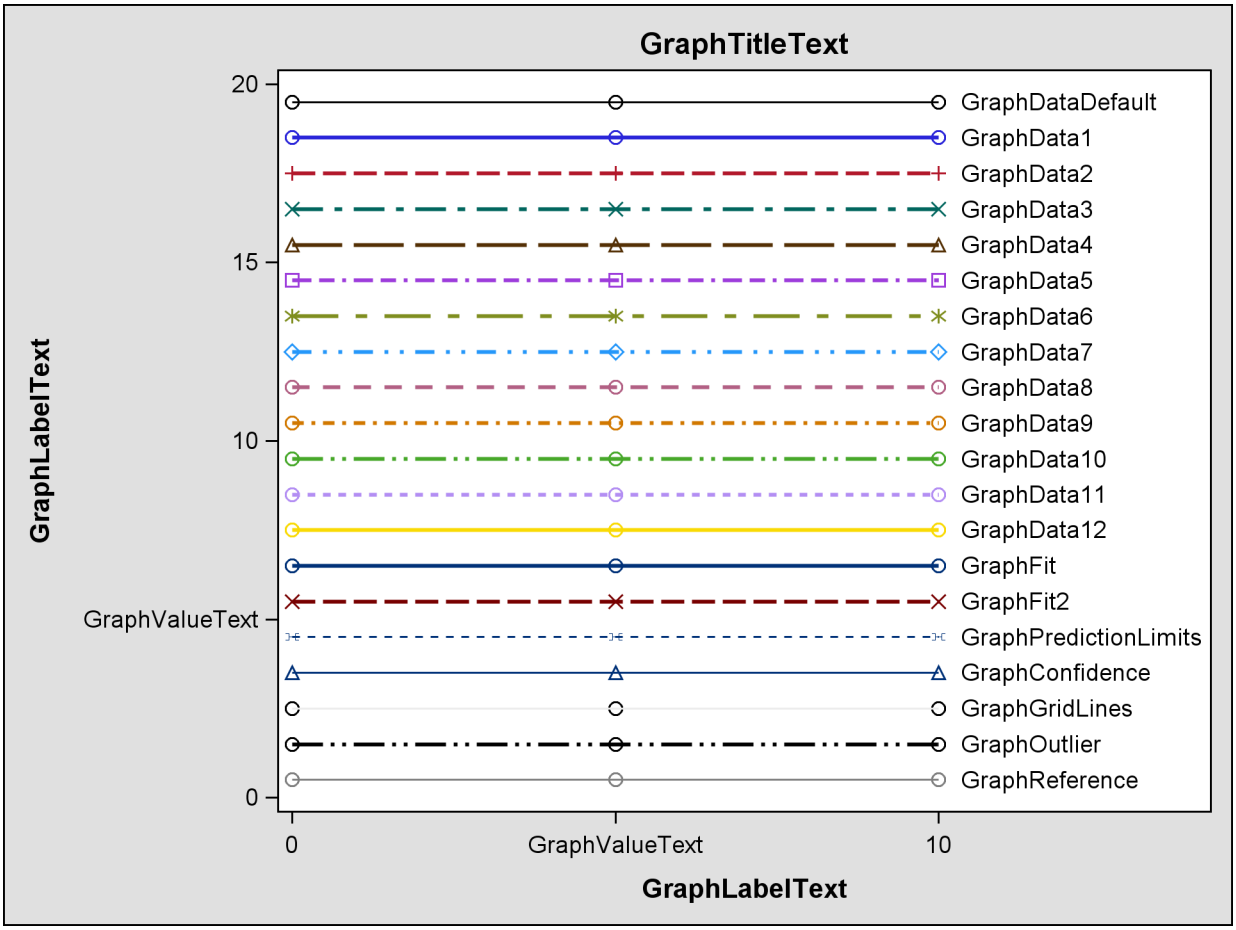
You refer to these elements in graph templates as **style-element** or as **style-element:attribute** (for example **GraphDataDefault:ContrastColor**). The default values are not shown for the color attributes since they are typically defined indirectly. For example, **Graph:BackgroundColor** (the color that fills the box outside the graph) is defined elsewhere in the style as **colors('docbg')**. The style also defines: **'docbg' = color_list('bgA')** and **'bgA' = cxE0E0E0**. This shows that the background is a shade of gray that is much closer to white (CXFFFFFF) than to black (CX000000). You can see the background color in Figure 21.22. This shade of gray might seem darker (closer to CX000000) than you might expect based on just the RGB values. Your perception of a color change is not a linear function of the change in RGB values.

You can use the following program to see the color and other attributes for a number of style elements:

```
proc format; value vf 5 = 'GraphValueText'; run;

data x;
   array y[20] y0 - y19;
   do x = 1 to 20; y[x] = x - 0.5; end;
   do x = 0 to 10 by 5; output; end;
   label y0 = 'GraphLabelText' x = 'GraphLabelText';
   format x y0 vf.;
run;

%macro d;
   %do i = 1 %to 12;
      reg y=y%eval(19-&i) x=x / lineattrs=GraphData&i markerattrs=GraphData&i
                                curvelabel="  GraphData&i" curvelabelpos=max;
   %end;
%mend;



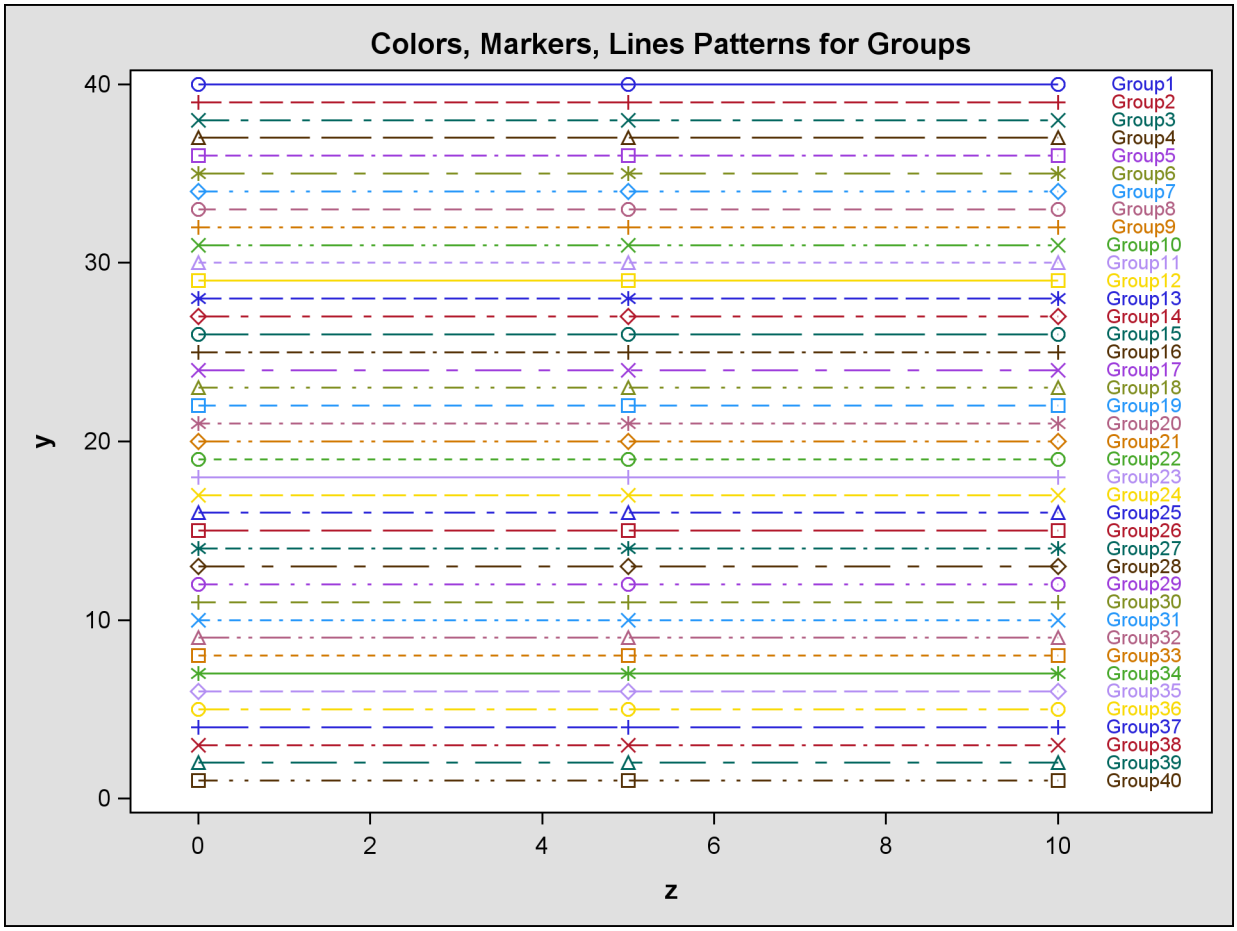
%macro l(i, l);
   reg y=y&i x=x / lineattrs=&l markerattrs=&l curvelabel="  &l"
                   curvelabelpos=max;
%mend;

ods listing style=default;
```

```
proc sgplot noautolegend;
   title 'GraphTitleText';
   %d
   %l(19, GraphDataDefault)
   %l( 6, GraphFit)
   %l( 5, GraphFit2)
   %l( 4, GraphPredictionLimits)
   %l( 3, GraphConfidence)
   %l( 2, GraphGridLines)
   %l( 1, GraphOutlier)
   %l( 0, GraphReference)
   xaxis values=(0 5 10);
run;
```

The results in Figure 21.22 display the attributes for a number of the elements of the DEFAULT style.

Figure 21.22 Attributes of Style Elements in the DEFAULT Style



When there is a group or classification variable, the colors, markers, and lines that distinguish the groups are derived from the **GraphData***n* elements that are defined with the style. In the DEFAULT style, these are elements **GraphData1** through **GraphData12**. There can be any number of groups even though only 12 **GraphData***n* style elements are defined in the DEFAULT style. The following

steps create a data set with 40 groups, display one line per group, and produce Figure 21.23:

```
data x;
   do y = 40 to 1 by -1;
      group = 'Group' || put(41 - y, 2. -L);
      do x = 0 to 10 by 5;
         if x = 10 then do; z = 11; l = group; end;
         else           do; z = .;  l = ' ';   end;
         output;
      end;
   end;
run;

proc sgplot data=x;
   title 'Colors, Markers, Lines Patterns for Groups';
   series  y=y x=x / group=group markers;
   scatter y=y x=z / group=group markerchar=l;
run;
```

Figure 21.23 Markers and Lines Cycle with Different Periods in Groups

The colors, markers, and line patterns in Figure 21.23 repeat in cycles. The **GraphData1** – **GraphData8** lines in Figure 21.22 exactly match the **Group1** – **Group8** lines in Figure 21.23. After that, there are differences due to the cyclic construction of the grouped style definition. This is explained next.

The DEFAULT style defines a marker symbol only in **GraphData1** through **GraphData7**. The seven markers are: circle, plus, X, triangle, square, asterisk, and diamond. With the explicit style reference in Figure 21.22, the actual symbol, when no symbol is specified, is the circle. This is what you see for **GraphData8** through **GraphData12**. With the group variable in Figure 21.23, the symbols repeat in cycles. Hence, **Group1**, **Group8**, **Group15**, and so on, are all circles. Similarly, **Group2**, **Group9**, **Group16**, and so on, are all pluses. The DEFAULT style defines 11 different line styles for **GraphData1** through **GraphData11**: 1, 4, 8, 5, 14, 26, 15, 20, 41, 42, and 2. Hence, **Group1**, **Group12**, **Group23**, and so on, all have the same line style, which is a solid line. Similarly, **Group2**, **Group13**, **Group24**, and so on, all have line style 4. There are twelve different colors, so **Group1**, **Group13**, **Group25**, and so on, all have the same colors. Overall, there are $12 \times 11 \times 7 = 924$ color/line/marker combinations that appear before any combination repeats. You can use the **ModStyle** SAS autocall macro (see the section "Creating an All-Color Style by Using the ModStyle Macro" on page 564) to conveniently change these style attributes.

Creating an All-Color Style by Using the ModStyle Macro

Many styles are designed to make color plots where lines, functions, and groups of observations can be distinguished even when the plot is sent to a black-and-white printer. Hence, lines differ not only in color but also in pattern. Similarly, markers differ in color and symbol.

You can change that behavior with the **ModStyle** autocall macro. It creates a new style by modifying a parent style and reordering the colors, line patterns, and marker symbols in the **GraphData***n* style elements (see section "Some Common Style Elements" on page 558). By default, the macro creates a new style that distinguishes lines and groups only by color. The macro is documented in its header.

The following example illustrates the default use of the macro and is taken from the section "Fitting a Curve through a Scatter Plot" on page 7109 of Chapter 90, "The TRANSREG Procedure." The data come from an experiment in which nitrogen oxide emissions from a single cylinder engine are measured for various combinations of fuel and equivalence ratio. The following statements create the SAS data set:

```
data Gas;
   input Fuel :$8. EqRatio NOx @@;
   label EqRatio = 'Equivalence Ratio'
         NOx     = 'Nitrogen Oxide Emissions';
   datalines;
Ethanol  0.907 3.741 Ethanol  0.761 2.295 Ethanol  1.108 1.498

... more lines ...

;
```

The following statements fit separate curves for each group and produce Figure 21.24 and Figure 21.25:

```
ods listing style=statistical;
ods graphics on;

proc transreg data=Gas ss2 plots=transformation lprefix=0;
   model identity(nox) = class(Fuel / zero=none) * pbspline(EqRatio);
run;

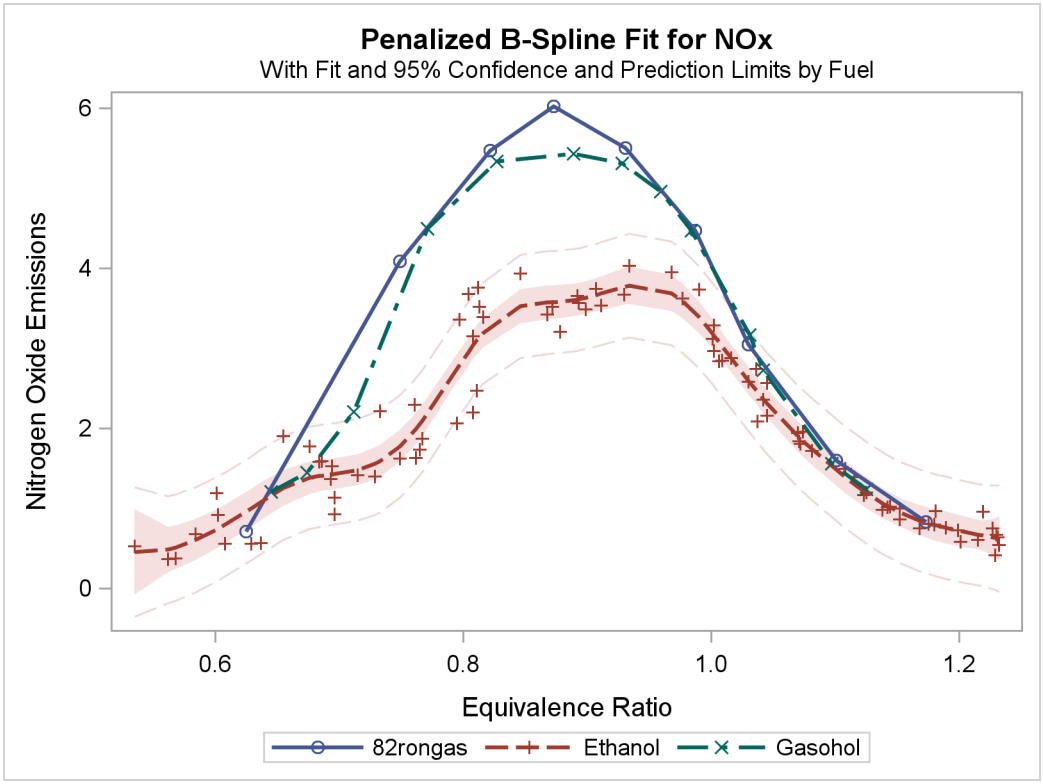
%modstyle(parent=statistical, name=StatColor)
ods listing style=StatColor;

proc transreg data=Gas ss2 plots=transformation lprefix=0;
   model identity(nox) = class(Fuel / zero=none) * pbspline(EqRatio);
run;
```

The first PROC TRANSREG step uses the STATISTICAL style to create the fit plot in Figure 21.24, which uses different colors, line patterns, and markers for each group. Then the macro creates a new style, called STATCOLOR, that inherits its characteristics from the STATISTICAL style. Only the attributes of the lines and markers are changed. In Figure 21.25, which is created with the modified style, the groups are differentiated only by color. This is the easiest and most common way for you to use this macro. However, you can use it to perform other style modifications as illustrated in the section "Changing the Default Markers and Lines" on page 567. See the macro header for more information.

You do not have to include autocall macros (for example, with a **%include** statement). You can call them directly once they are properly installed. If your site has installed the autocall libraries supplied by SAS and uses the standard configuration of SAS supplied software, you need to ensure that the SAS system option MAUTOSOURCE is in effect to begin using the autocall macros. For more information about autocall libraries, see the *SAS Macro Language: Reference*. For details about installing autocall macros, consult your host documentation.

Figure 21.24 Fit Plot with the STATISTICAL Style



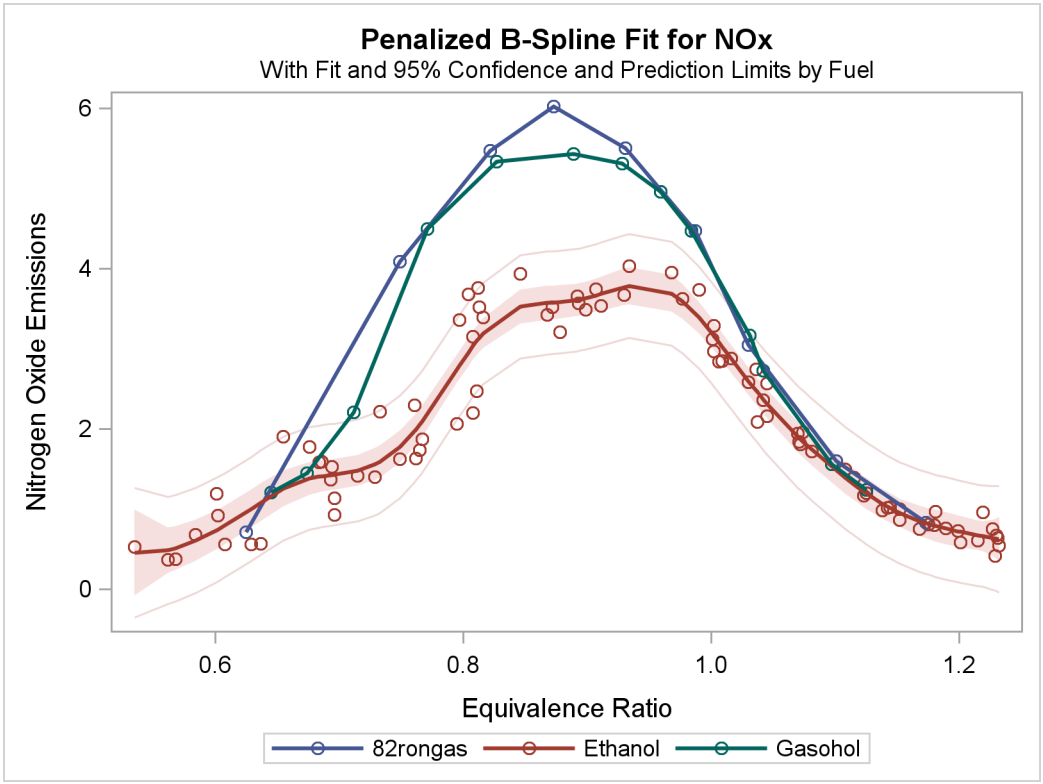


Figure 21.25 Fit Plot with the Modified Style

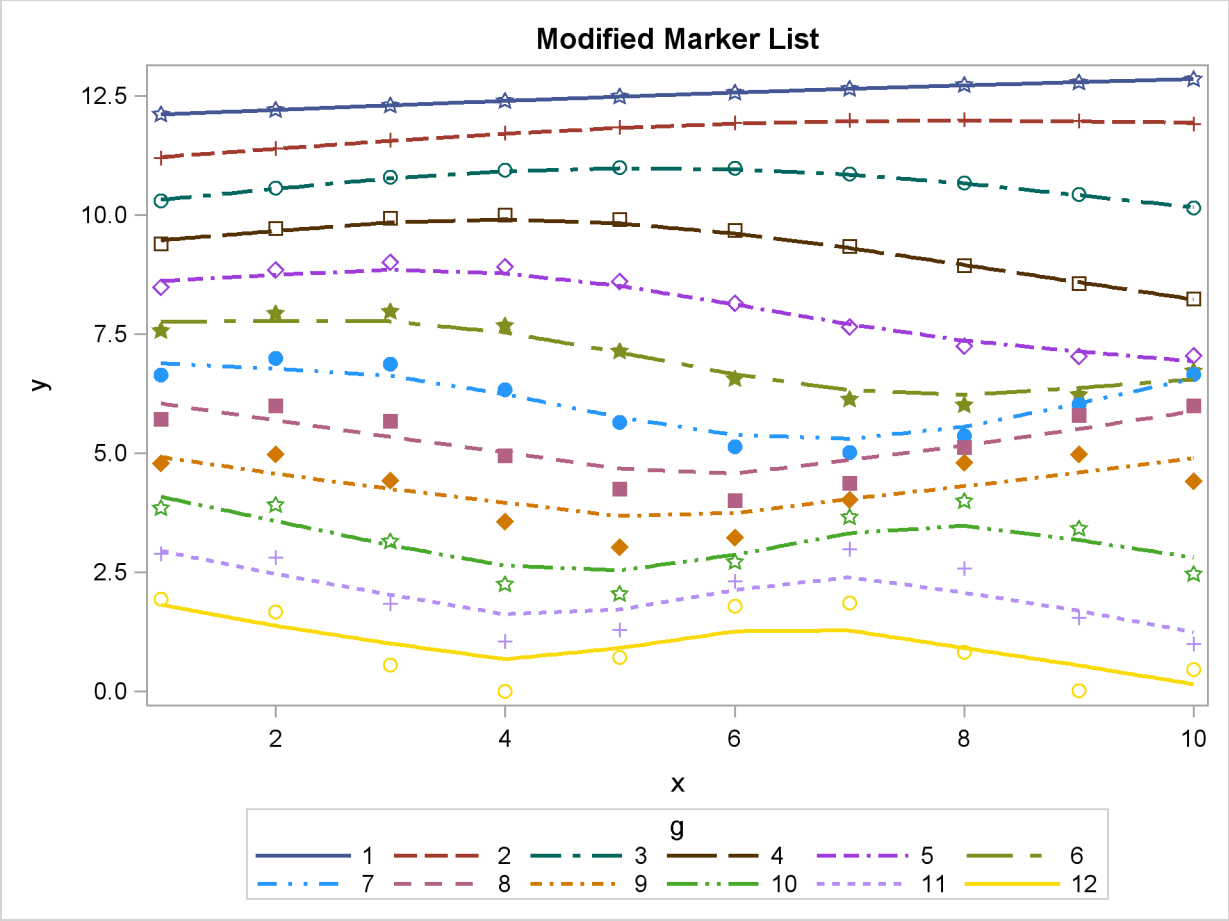
Changing the Default Markers and Lines

The preceding section shows how to use the **ModStyle** autocall macro to create an all-color style. You can also use the **ModStyle** macro to change markers and line styles. This example creates a new style called MARKSTYLE that inherits from the STATISTICAL style but uses a different set of markers. The following statements create artificial data, change the marker list, and display the results:

```
data x;
   do g = 1 to 12;
      do x = 1 to 10;
         y = 13 - g + sin(x * 0.1 * g);
         output;
      end;
   end;
run;



%modstyle(name=markstyle, parent=statistical, type=CLM,
          markers=star plus circle square diamond starfilled
                  circlefilled squarefilled diamondfilled)

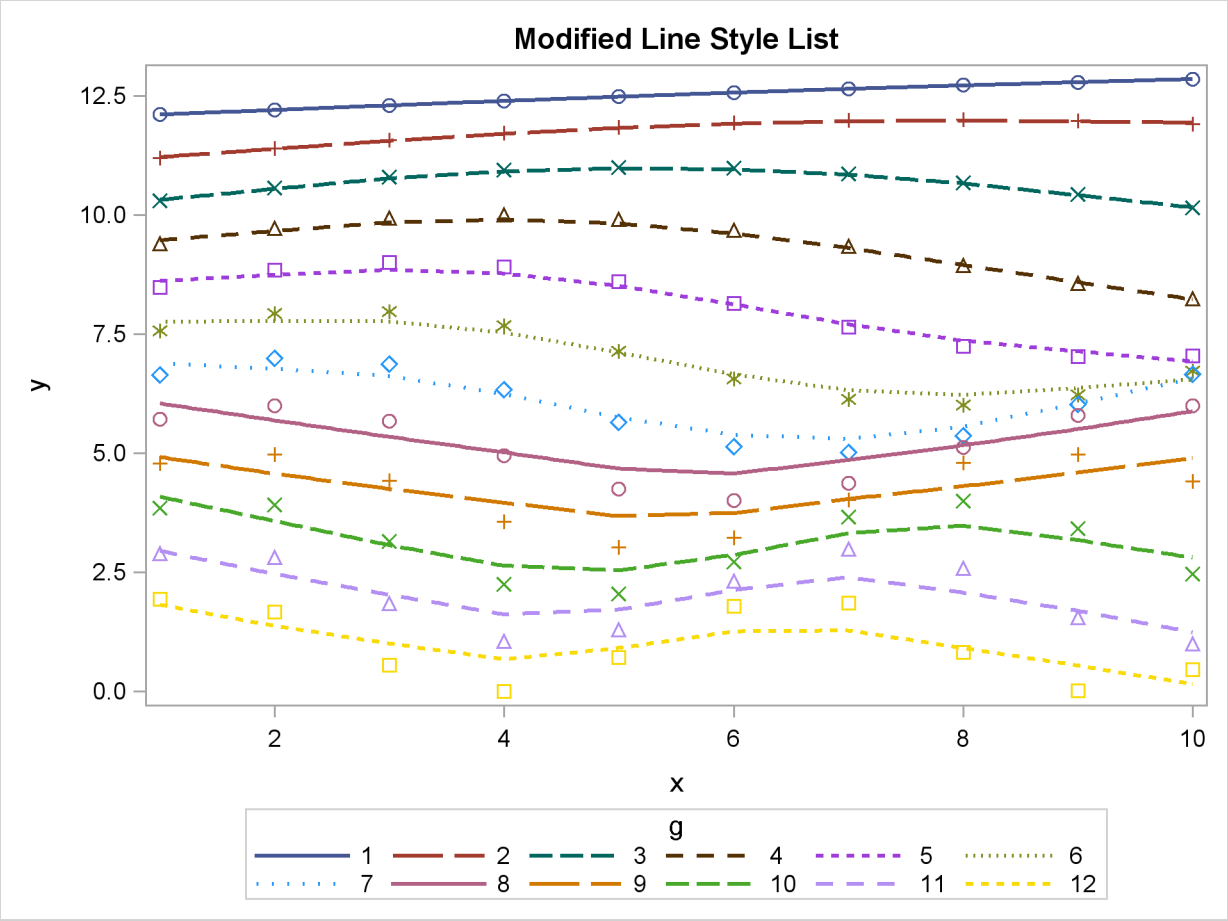
ods listing style=markstyle;

proc sgplot;
   title 'Modified Marker List';
   loess y=y x=x / group=g;
run;
```

The NAME= option specifies the new style name, and the PARENT= option specifies the parent style. The TYPE= option controls the method of cycling through colors, lines, and markers. The default, TYPE=LMbyC, fixes (holds constant) the line styles and markers, while cycling through the color list. This is illustrated in the section "Creating an All-Color Style by Using the ModStyle Macro" on page 564. This example uses TYPE=CLM to cycle through colors, line styles, and markers (holding none of them fixed). Other TYPE= values are described in the macro header. The values specified with the TYPE= option are case sensitive ('by' is lower case and the 'L', 'C', and 'M' are upper case). The new marker list is specified with the MARKERS= option. The results are displayed in Figure 21.26. The marker list is reused in the tenth and subsequent groups since only nine markers are defined.

Figure 21.26 A Modified Style with a New List of Markers

The following statements create a new style called LINESTYLE that inherits from the STATISTICAL style and changes the line list:



```
%modstyle(name=linestyle, parent=statistical, type=CLM,
          linestyles=Solid LongDash MediumDash Dash ShortDash Dot ThinDot)

ods listing style=linestyle;

proc sgplot;
   title 'Modified Line Style List';
   loess y=y x=x / group=g;
run;
```

The new line list is specified with the LINESTYLES= option. The results are displayed in Figure 21.27. In this example, each of the first seven groups uses a dash pattern that is shorter than the previous group. The line list is reused in the eighth and subsequent groups since only seven line patterns are defined.

Figure 21.27 Modified Style with a New List of Line Styles

You can learn more about style modification by examining the new styles, as in the following example:

```
proc template;
   source styles.markstyle;
   source styles.linestyle;
run;
```

The results show the definitions of **GraphData1** through **GraphData32** that the macro created. An abridged listing of the results follows:

```
define style Styles.Markstyle;
   parent = Styles.statistical;
   . . .
   style GraphData1 /
      markersymbol = "star"
      linestyle = 1
      contrastcolor = ColorStyles('c1')
      color = FillStyles('f1');
```

```
   . . .
   style GraphData32 /
      markersymbol = "diamond"
      linestyle = 42
      contrastcolor = ColorStyles('c8')
      color = FillStyles('f8');
end;

define style Styles.Linestyle;
   parent = Styles.statistical;
   . . .
   style GraphData1 /
      markersymbol = "circle"
      linestyle = 1
      contrastcolor = ColorStyles('c1')
      color = FillStyles('f1');
   . . .
   style GraphData32 /
      markersymbol = "triangle"
      linestyle = 20
      contrastcolor = ColorStyles('c8')
      color = FillStyles('f8');
end;
```

You can use the NUMBEROFGROUPS= option in the **ModStyle** macro to control the number of **GraphData***n* style elements created in the new style.

Modifying Graph Fonts in Styles

You can modify an ODS style to customize the general appearance of plots produced with ODS Graphics, just as you can modify a style to customize the general appearance of ODS tables. This section shows you how to customize fonts used in graphs. The following statements show the STATISTICAL style:

```
proc template;
   source Styles.Statistical;
run;
```

The portion of the style that controls fonts is shown next:

```
style GraphFonts /
   'GraphDataFont' = ("<sans-serif>, <MTsans-serif>",7pt)
   'GraphUnicodeFont' = ("<MTsans-serif-unicode>",9pt)
   'GraphValueFont' = ("<sans-serif>, <MTsans-serif>",9pt)
   'GraphLabelFont' = ("<sans-serif>, <MTsans-serif>",10pt)
   'GraphFootnoteFont' = ("<sans-serif>, <MTsans-serif>",10pt,italic)
   'GraphTitleFont' = ("<sans-serif>, <MTsans-serif>",11pt,bold)
   'GraphAnnoFont' = ("<sans-serif>, <MTsans-serif>",10pt);
```

The following fonts are the ones typically used for the text in most graphs:

- **GraphDataFont** is the smallest font. It is used for text that needs to be small (labels for points in scatter plots, labels for contours, and so on)
- **GraphValueFont** is the next largest font. It is used for axis value (tick marks) labels and legend entry labels.
- **GraphLabelFont** is the next largest font. It is used for axis labels and legend titles.
- **GraphFootnoteFont** is the next largest font. It is used for all footnotes.
- **GraphTitleFont** is the largest font. It is used for all titles.

The following statements define a style named NEWSTYLE that replaces the graph fonts in the DEFAULT style with italic Times New Roman fonts, which are available with the Windows operating system:

```
proc template;
   define style Styles.NewStyle;
      parent=Styles.Statistical;
      replace GraphFonts  /
         'GraphDataFont'     = ("<MTserif>, Times New Roman",7pt)
         'GraphUnicodeFont'  = ("<MTserif>, Times New Roman",9pt)
         'GraphValueFont'    = ("<MTserif>, Times New Roman",9pt)
         'GraphLabelFont'    = ("<MTserif>, Times New Roman",10pt)
         'GraphFootnoteFont' = ("<MTserif>, Times New Roman",10pt)
         'GraphTitleFont'    = ("<MTserif>, Times New Roman",11pt)
         'GraphAnnoFont'     = ("<MTserif>, Times New Roman",10pt);
   end;
run;
```

For more information about the DEFINE, PARENT, and REPLACE statements, see the *SAS/GRAPH: Graph Template Language Reference*.

The "Getting Started" section of Chapter 74, "The ROBUSTREG Procedure," creates the following data set to illustrate the use of the PROC ROBUSTREG for robust regression:

```
data stack;
   input  x1 x2 x3 y @@;
   datalines;
80  27  89  42    80  27  88  37    75  25  90  37

... more lines ...

;
```

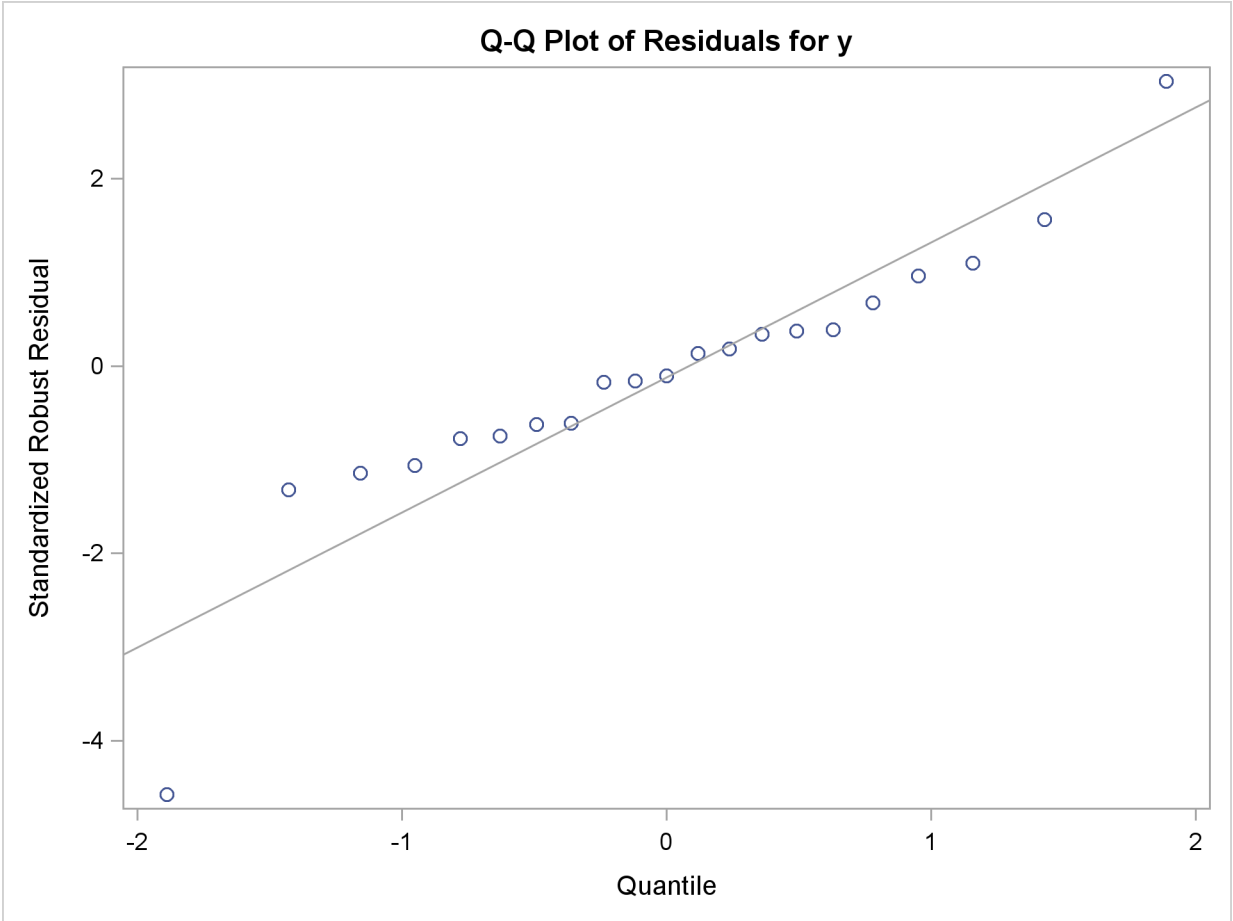
The following statements create a Q-Q plot that uses the STATISTICAL style (see Figure 21.28) and the NEWSTYLE style (see Figure 21.29):

```
ods listing style=Statistical;
ods graphics on;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;
ods listing close;
ods listing style=NewStyle;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;
```

Figure 21.28 Q-Q Plot That Uses the STATISTICAL Style



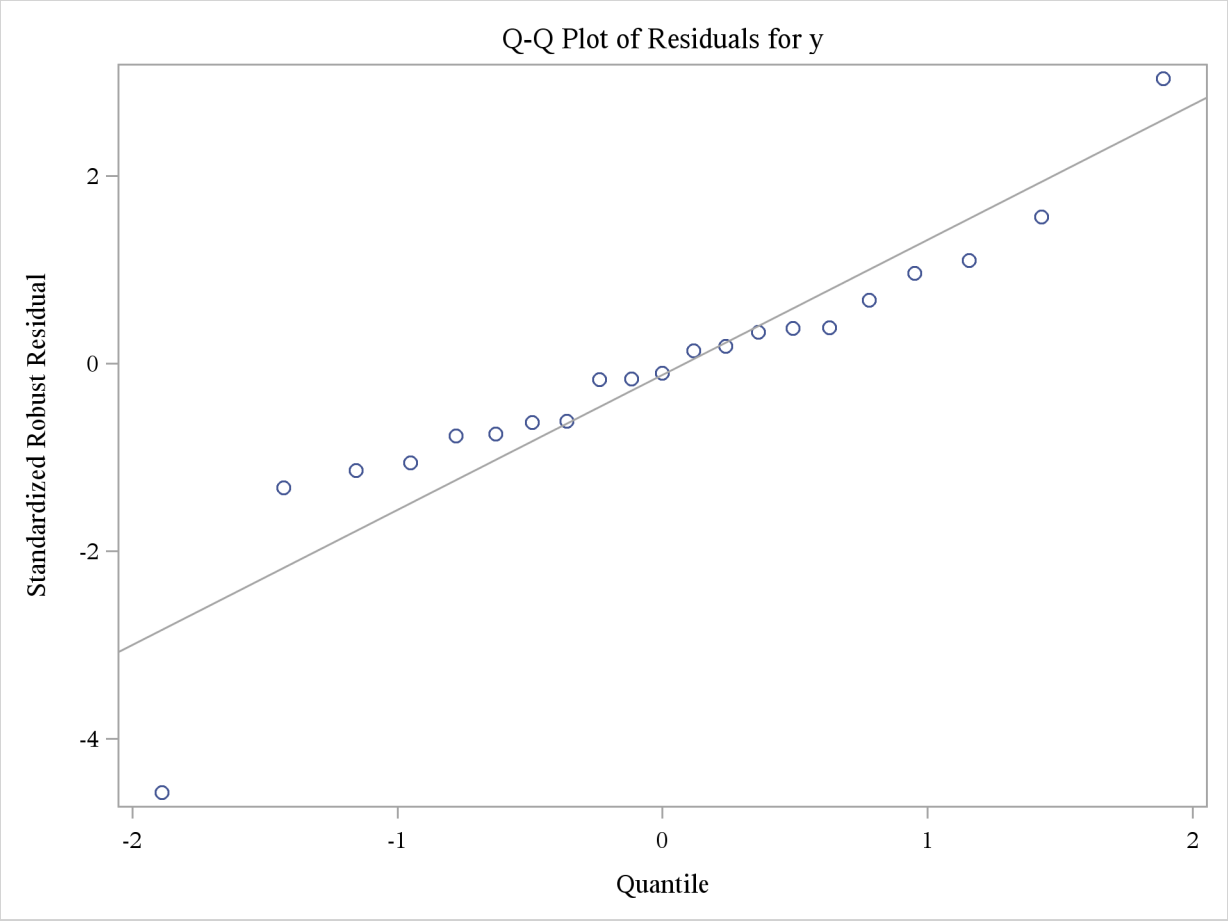


Figure 21.29 Q-Q Plot That Uses the NEWSTYLE Style

Although this example illustrates the use of a style with graphical output from a particular procedure, a style is applied to *all* of your output (graphs and tables) in the destination for which you specify the style. See the section "Changing the Default Style" on page 575 for information about specifying a default style for all your output.

Modifying Other Graph Elements in Styles

This section illustrates how to modify other style elements for graphics, specifically the style element **`GraphReference`**, which controls the attributes of reference lines. You can run the following statements to learn more about the **`GraphReference`** style element:

```
proc template;
   source styles.statistical;
run;
```

The following are the first two lines of the source listing:

```
define style Styles.Statistical;
   parent = styles.default;
```

There is no mention of **GraphReference** in the complete listing of the source because **GraphReference** is inherited from the parent style. Most styles inherit many of their attributes from other styles. To find out more, you must list the parent style, as in the following example:

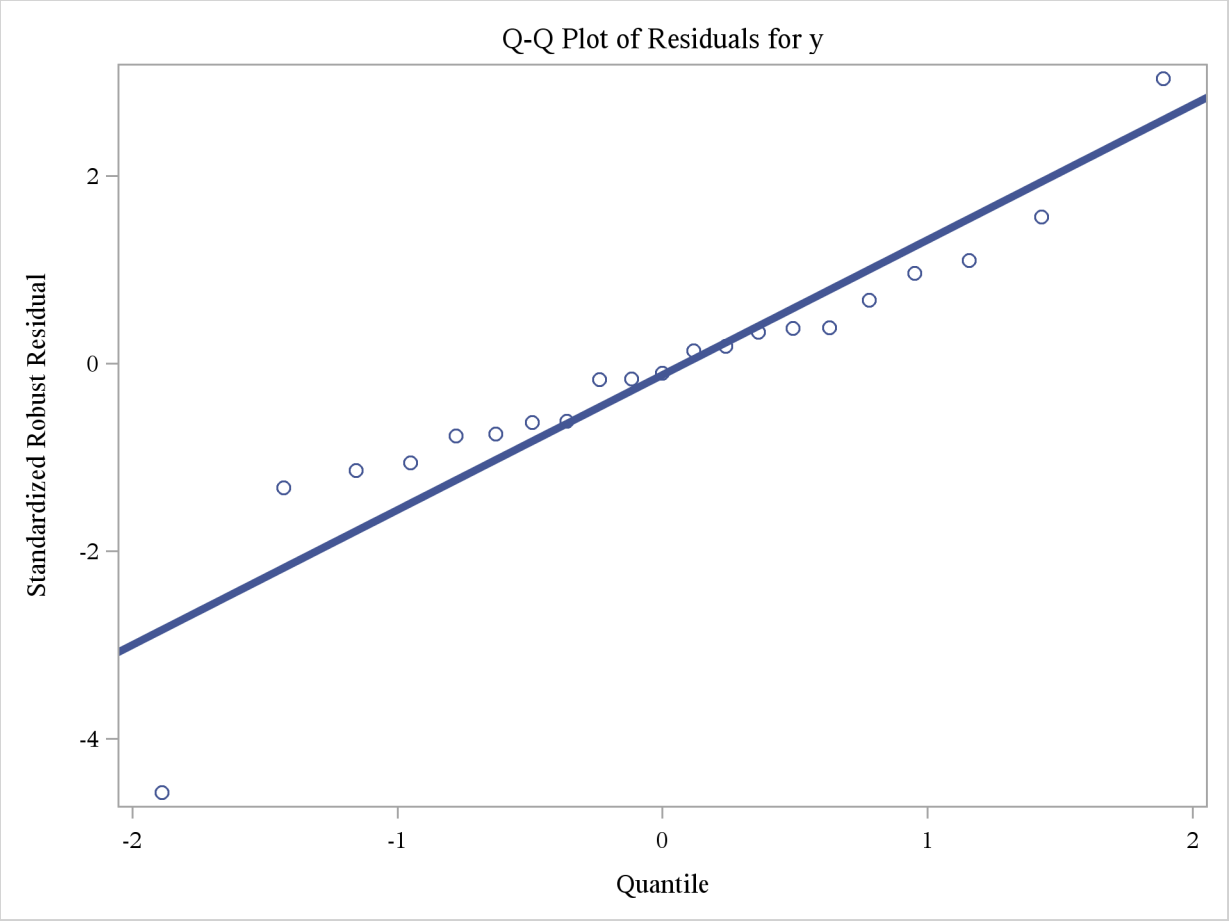
```
proc template;
   source styles.default;
run;
```

Styles that you typically use with ODS Graphics inherit most of their attributes from only one style, the DEFAULT style. A few of the other styles inherit from several parents. You might have to repeat this process multiple times to find the first parent. However, with the STATISTICAL style, you only need to run this one extra step, and the results contain the following:

```
class GraphReference /
   linethickness = 1px
   linestyle = 1
   contrastcolor = GraphColors('greferencelines');
```

To specify a line thickness of 4 pixels for all reference lines, add the following statement to the definition of the NEWSTYLE style in the section "Modifying Graph Fonts in Styles" on page 570:

```
replace GraphReference / linethickness=4px;
```



The following statements modify the style and produce the Q-Q plot shown in Figure 21.30:

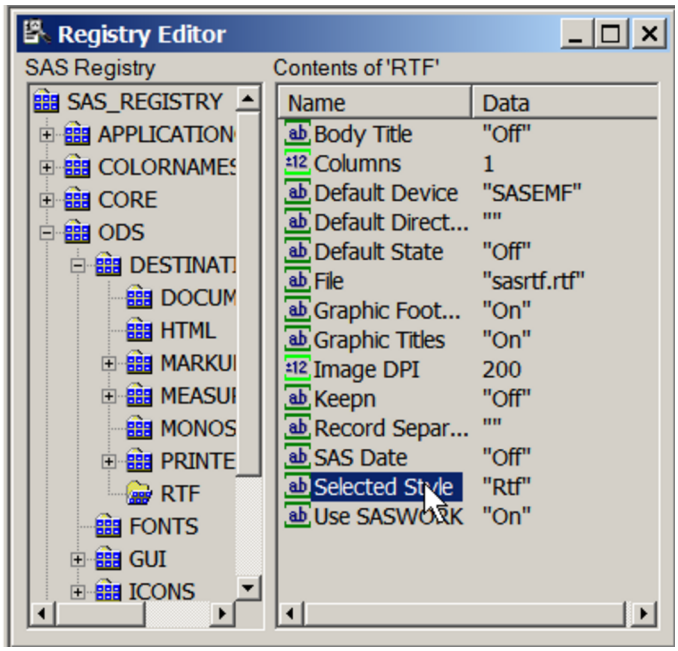
```
proc template;
   define style Styles.NewStyle;
      parent=Styles.Statistical;
      replace GraphFonts  /
         'GraphDataFont'     = ("<MTserif>, Times New Roman",7pt)
         'GraphUnicodeFont'  = ("<MTserif>, Times New Roman",9pt)
         'GraphValueFont'    = ("<MTserif>, Times New Roman",9pt)
         'GraphLabelFont'    = ("<MTserif>, Times New Roman",10pt)
         'GraphFootnoteFont' = ("<MTserif>, Times New Roman",10pt)
         'GraphTitleFont'    = ("<MTserif>, Times New Roman",11pt)
         'GraphAnnoFont'     = ("<MTserif>, Times New Roman",10pt);
      replace GraphReference / linethickness=4px;
   end;
run;

ods listing style=NewStyle;
ods graphics on;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;
```

Figure 21.30 Q-Q Plot That Uses the NEWSTYLE Style with a Thicker Line

You can use this approach to modify other attributes of the line, such as **`LineStyle`** and **`ContrastColor`**. These style modifications apply to all graphs that display reference lines, and not just to Q-Q plots produced by PROC ROBUSTREG. You can control the attributes of specific graphs by modifying the graph template, as discussed in the section "Graph Templates" on page 577. Values specified directly in a graph template override style attributes.



When you are done with the NEWSTYLE style, you do not need to restore the STATISTICAL style template since you did not modify it. Rather, you inherited from the STATISTICAL style.

Changing the Default Style

The default style for each ODS destination is specified in the SAS Registry. For example, the default style for the HTML destination is DEFAULT and the default style for the RTF destination is RTF. You can specify a default style for all of your output in a particular ODS destination. This is useful if you want to use a different SAS style, if you have modified one of the styles supplied by SAS (see the section "Style Definitions and Colors" on page 557), or if you have defined your own style. For example, you can specify the JOURNAL style as the default style for RTF output.

The recommended approach for specifying a default style is as follows. Open the SAS Registry Editor by typing **regedit** in the command line. Expand the node **ODS ► DESTINATIONS** and select a destination (for example, select **RTF**). Double-click the **Selected Style** item, shown in Figure 21.31, and specify a style. This can be any style supplied by SAS or a user-defined style, as long as it can be found with the current ODS path (for example, specify **Journal**). You can specify a default style for the other destinations in a similar way.

Figure 21.31 SAS Registry Editor

ODS searches sequentially through each element of the ODS PATH list for the first style definition that matches the name of the style specified in the SAS Registry. The first style definition found is used. (See the sections "Saving Customized Templates" on page 587, "Using Customized Templates" on page 587, and "Reverting to the Default Templates" on page 588 for more information about the ODS PATH.) If you are specifying a customized style as your default style, the following are useful suggestions:

- If you save your style in SASUSER.Templat, verify that the name of your default style matches the name of the style specified in the SAS Registry. For example suppose the RTF style is specified for the RTF destination in the SAS Registry. You can name your style RTF and save it in SASUSER.Templat. This blocks the RTF style in SASHELP.Tmplmst (provided that you did not alter the default sequence in the ODS PATH).
- If you save your style in a user-defined template library, verify that this template library is the first in the current ODS PATH list. Include the ODS PATH statement in your SAS autoexec file so that it is executed at startup.

For the HTML destination, an alternative approach for specifying a default style is as follows. From the menu at the top of the main SAS window, select **Tools ► Options ► Preferences**. In the **Results** tab, check the **Create HTML** box and select a style from the pull-down menu.

Graph Templates

Graph templates control the layout and details of graphs produced with ODS Graphics. SAS provides a template for every graph produced by statistical procedures. Graph template definitions are written in the Graph Template Language (GTL). This powerful language includes statements for specifying plot layouts (such as lattices or overlays), plot types (such as scatter plots and histograms), and text elements (such as titles, footnotes, and insets). It also provides support for built-in computations (such as histogram binning) and the evaluation of expressions. Options are available for specifying colors, marker symbols, and other attributes of plot features.

Graphs, like all SAS output, are constructed from two underlying components, a data component (or data object) and a template. Procedures supply a table of data values and statistical results to plot. Together, the data object and the template form an output object that ODS displays in one or more output destinations. You can control this display in two ways. You can use the ODS Graphics Editor (discussed in the section "ODS Graphics Editor" on page 548) to modify the output object (but not the underlying data object or template), and you can use the GTL to modify the template. With just a little knowledge of the GTL, you can modify or edit templates, even when you do not understand most of the syntax used in the template definition. See examples starting with Example 21.5.

NOTE: You do not need to know anything about the GTL to create statistical graphics.

This section provides an overview of the Graph Template Language. It also describes how to locate, display, edit, and save templates. A *template definition* is a set of SAS statements that is used together with PROC TEMPLATE to create a compiled template. In addition to graph templates, two other common types of templates are table templates and style templates. A table template describes how to display the output for an output object that is rendered as a table. A style template provides formatting information for visual aspects of your SAS output, including both tables and graphs. In most applications, you do not have to modify the templates that are supplied by SAS. However, when customization is necessary, you can modify the default template with the template language and PROC TEMPLATE.

Compiled templates are saved in a *template library* (also called a *template store*), which is a member of a SAS data library. The default templates supplied by SAS are stored in the SASHELP.Tmplmst template library. If you are using the SAS windowing environment, an easy way to display, edit, and save your templates is by using the Templates window. For detailed information about managing templates, see the *SAS Output Delivery System: User's Guide* and the *SAS/GRAPH: Graph Template Language User's Guide*. For details about the syntax of the graph template language, see the *SAS/GRAPH: Graph Template Language Reference*.

The Graph Template Language

Graph template definitions begin with a DEFINE STATGRAPH statement in PROC TEMPLATE, and they end with an END statement. Embedded in every graph template is a BEGINGRAPH/ENDGRAPH block, and embedded in that block are one or more LAYOUT blocks. You can specify the DYNAMIC statement to define dynamic variables (which the procedure uses to pass

values to the template definition), the MVAR and NMVAR statements to define macro variables (which you can use to pass values to the template definition), and the NOTES statement to provide descriptive information about the graph. The default templates supplied by SAS for statistical procedures are often lengthy and complex, because they provide ODS Graphics with comprehensive and detailed information about graph construction. Here is one of the simpler graph templates for a statistical procedure:

```
define statgraph Stat.MDS.Graphics.Fit;
   notes "MDS Fit Plot";
   dynamic head;
   begingraph / designwidth=defaultdesignheight;
      entrytitle HEAD;
      layout overlayequated / equatetype=square;
         scatterplot y=FITDATA x=FITDIST / markerattrs=(size=5px);
         lineparm slope=1 x=0 y=0 / extend=true lineattrs=GRAPHREFERENCE;
      endlayout;
   endgraph;
end;
```

This template, supplied for the MDS procedure, creates a scatter plot of two variables, FitData and FitDist, along with a diagonal reference line that passes through the origin. The plot is square and the axes are equated so that a centimeter on one axis represents the same data range as a centimeter on the other axis. The plot title is provided by the evaluation of the dynamic variable Head, which is set by the procedure. It is not unusual for this plot to contain hundreds or even thousands of points, so a five-pixel marker is specified, which is smaller than the seven-pixel marker used by default in most styles.

The statements available in the graph template language can be classified as follows:

- Control statements specify the conditional or iterative flow of control. By default, flow of control is sequential. In other words, each statement is used in the order in which it appears.
- Layout statements specify the arrangement of the components of the graph. Layout statements are arranged in blocks that begin with a LAYOUT statement and end with an ENDLAYOUT statement. The blocks can be nested. Within a layout block, there can be plot, text, and other statements that define one or more graph components. Options provide control for attributes of layouts and components.
- Plot statements specify a number of commonly used displays, including scatter plots, histograms, contour plots, surface plots, and box plots. Plot statements are always provided within a layout block. The plot statements include options to specify the data columns from the source objects that are used in the graph. For example, in the SCATTERPLOT statement, there are mandatory X= and Y= arguments that specify which data columns are used for the X (horizontal) and Y (vertical) axes in the plot. (In the preceding example, FitData and FitDist are the names of columns int the data object that PROC MDS creates for this graph.) There is also a GROUP= option that specifies a data column as an optional classification variable.
- Text statements specify the descriptions that accompany graphs. An entry is any textual description, including titles, footnotes, and legends; it can include symbols to identify graph elements.

The following statements display another of the simpler template definitions—the definition of the scatter plot available in PROC KDE (see Figure 45.6.1 in Chapter 45, "The KDE Procedure"):

```
proc template;
   define statgraph Stat.KDE.Graphics.ScatterPlot;
      dynamic _TITLE _DEPLABEL _DEPLABEL2;
      BeginGraph;
         EntryTitle _TITLE;
         layout Overlay;
            scatterplot x=X y=Y / markerattrs=GRAPHDATADEFAULT;
         EndLayout;
      EndGraph;
   end;
run;
```

Here, the PROC TEMPLATE and RUN statements have been added to show how you would compile the template if you wanted to modify it. The DEFINE STATGRAPH statement in PROC TEMPLATE begins the graph template definition, and the END statement ends the definition. The DYNAMIC statement defines three dynamic variables that PROC KDE sets at run time. The variable _Title provides the title of the graph. The variables _DepLabel and _DepLabel2 contain the names of the X- and Y-variables, respectively. If you were to modify this template, you could use these dynamic text variables in any text element of the graph definition.

The overall display is specified with the LAYOUT OVERLAY statement inside the BEGINGRAPH/ENDGRAPH block. The title of the graph is specified with the ENTRYTITLE statement. The main plot is a scatter plot specified with the SCATTERPLOT statement. The options in the SCATTERPLOT statement are given after the slash and specify display options such as marker attributes (symbol, color, and size). These attributes can be specified directly, as in the PROC MDS template, or more typically by using indirect references to style attributes, as in the PROC KDE template. The values of these attributes are specified in the definition of the style you are using and are automatically set to different values if you specify a different style. For more information about style references, see the section "Styles" on page 554. The ENDLAYOUT statement ends the main layout block. For details about the syntax of the graph template language, see the *SAS/GRAPH: Graph Template Language Reference*.

You can write your own templates and use them to display raw data or output from procedures. For example, consider the iris data from Example 31.1 of Chapter 31, "The DISCRIM Procedure." The following statements create the SAS data set:

```
proc format;
   value specname
      1='Setosa    '
      2='Versicolor'
      3='Virginica ';
run;

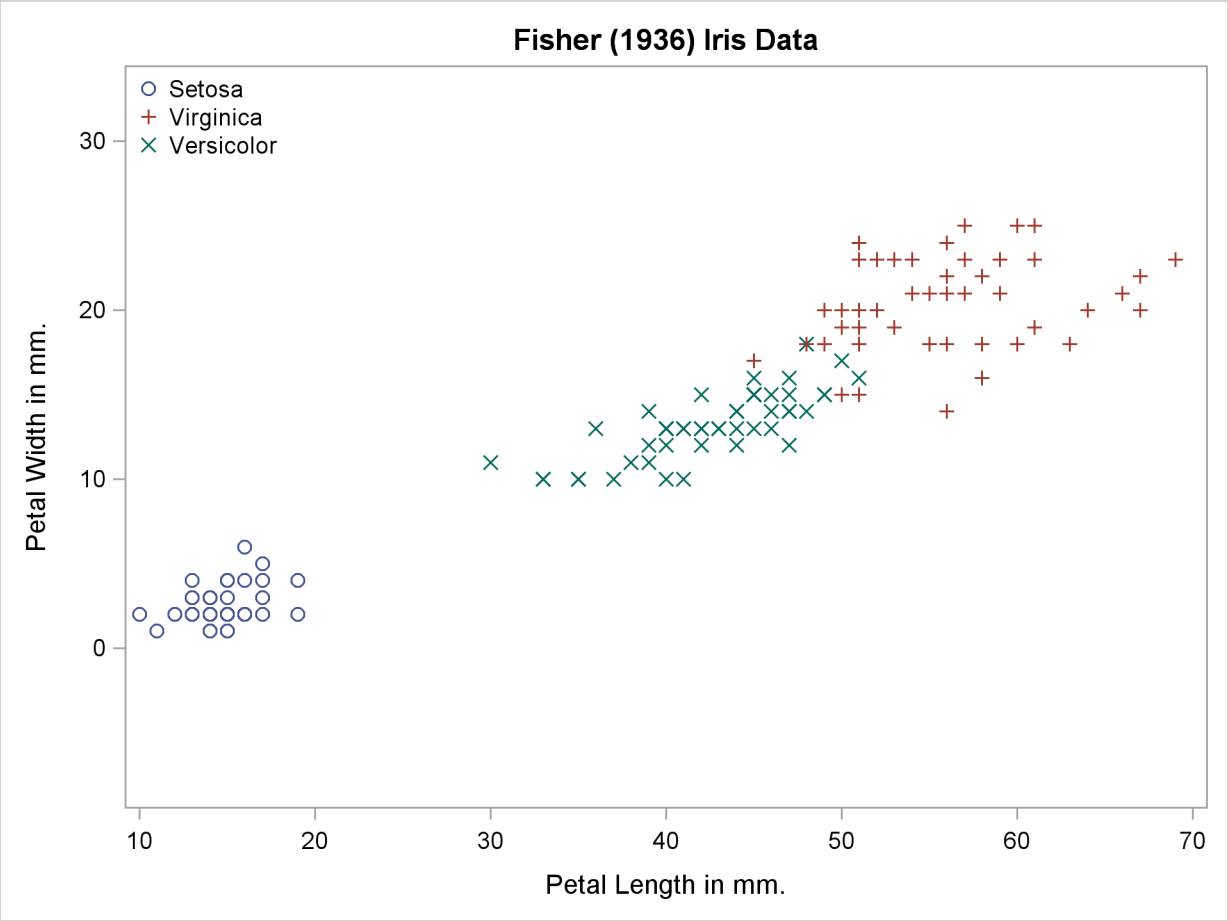
data iris;
   input SepalLength SepalWidth PetalLength PetalWidth
         Species @@;
   format Species specname.;
   label SepalLength='Sepal Length in mm.'
         SepalWidth ='Sepal Width in mm.'
         PetalLength='Petal Length in mm.'
         PetalWidth ='Petal Width in mm.';
   datalines;
50 33 14 02 1 64 28 56 22 3 65 28 46 15 2 67 31 56 24 3

... more lines ...

;
```

The following statements create a template for a scatter plot of the variables PetalLength and PetalWidth with a legend:

```
proc template;
   define statgraph scatter;
      begingraph;
         entrytitle 'Fisher (1936) Iris Data';
         layout overlayequated / equatetype=fit;
            scatterplot x=petallength y=petalwidth /
                        group=species name='iris';
            layout gridded / autoalign=(topleft);
               discretelegend 'iris' / border=false opaque=false;
            endlayout;
         endlayout;
      endgraph;
   end;
run;
```



The layout is OVERLAYEQUATED, which equates the plot. However, unlike the PROC MDS template, which used EQUATETYPE=SQUARE to make a square plot, the EQUATETYPE=FIT option specifies that the lengths of the axes in this plot should fill the entire plotting area. A legend is placed internally in the top-left portion of the plot. There are three groups of observations, indicated by the three species, and each group is plotted with a separate color and symbol that depends on the ODS style. The legend identifies each group. The NAME= option provides the link between the SCATTERPLOT statement and the DISCRETELEGEND statement. An explicit link is needed since some graphical displays are based on multiple SCATTERPLOT statements or other plotting statements.

The following step creates the plot by using the SGRENDER procedure, the Iris data set, and the custom template **scatter**:

```
proc sgrender data=iris template=scatter;
run;
```

The syntax of PROC SGRENDER is very simple, because all of the graphical options appear in the template. The scatter plot in Figure 21.32 shows the results.

Figure 21.32 Petal Width and Petal Length in Three Iris Species

The intent of this example is to illustrate how you can write a template to create a scatterplot. PROC TEMPLATE and PROC SGRENDER provide you with the power to create highly customized displays. However, usually you can use the SGPLOT, SGSCATTER or SGPANEL procedures instead, which are much simpler to use. These procedures are discussed in section "Statistical Graphics Procedures" on page 589. See the section "Grouped Scatter Plot with PROC SGPLOT" on page 517 and Figure 21.12 for an example that plots these data with PROC SGPLOT.

Locating Templates

Before you can customize a graph, you must determine which template is used to create the original graph. You can do this by submitting the ODS TRACE ON statement before the procedure statements that create the graph. The fully qualified template name is displayed in the SAS log. Here is an example:

```
ods trace on;
ods graphics on;

proc reg data=sashelp.class;
   model Weight = Height;
run; quit;
```

The preceding statements create the following trace output, which provides information about both the graphs and tables produced by PROC REG:

```
Output Added:
-------------
Name:        NObs
Label:       Number of Observations
Template:    Stat.Reg.NObs
Path:        Reg.MODEL1.Fit.Weight.NObs
-------------

Output Added:
-------------
Name:        ANOVA
Label:       Analysis of Variance
Template:    Stat.REG.ANOVA
Path:        Reg.MODEL1.Fit.Weight.ANOVA
-------------

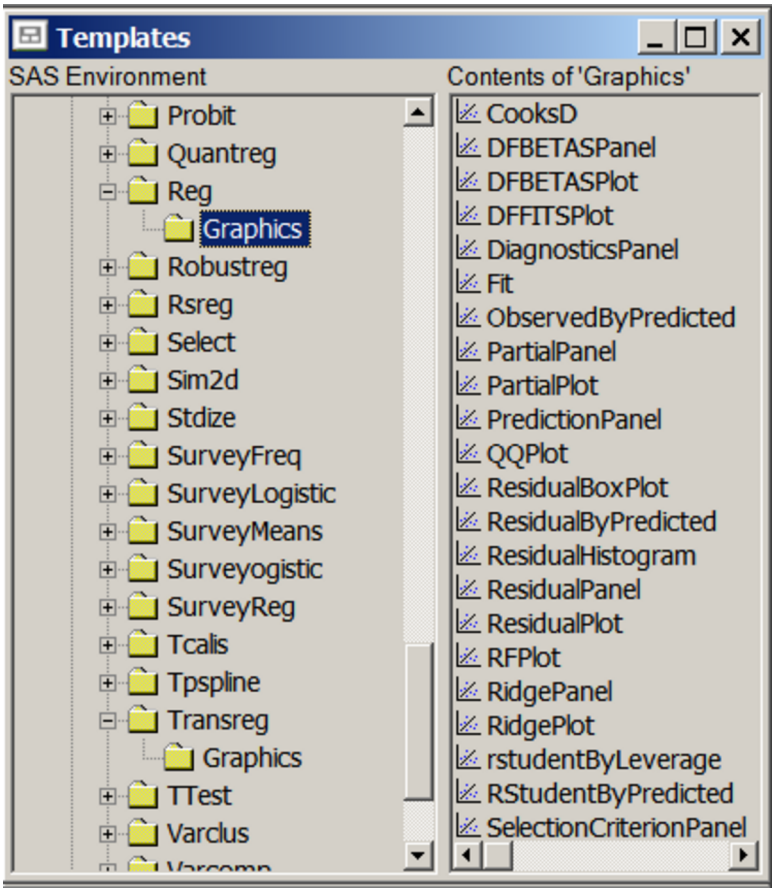
Output Added:
-------------
Name:        FitStatistics
Label:       Fit Statistics
Template:    Stat.REG.FitStatistics
Path:        Reg.MODEL1.Fit.Weight.FitStatistics
-------------

Output Added:
-------------
Name:        ParameterEstimates
Label:       Parameter Estimates
Template:    Stat.REG.ParameterEstimates
Path:        Reg.MODEL1.Fit.Weight.ParameterEstimates
-------------
```

```
Output Added:
-------------
Name:        DiagnosticsPanel
Label:       Fit Diagnostics
Template:    Stat.REG.Graphics.DiagnosticsPanel
Path:        Reg.MODEL1.ObswiseStats.Weight.DiagnosticPlots.DiagnosticsPanel
-------------

Output Added:
-------------
Name:        ResidualPlot
Label:       Height
Template:    Stat.REG.Graphics.ResidualPlot
Path:        Reg.MODEL1.ObswiseStats.Weight.ResidualPlots.ResidualPlot
-------------

Output Added:
-------------
Name:        FitPlot
Label:       Fit Plot
Template:    Stat.REG.Graphics.Fit
Path:        Reg.MODEL1.ObswiseStats.Weight.FitPlot
-------------
```



This is also illustrated in Example 21.5 and the section "Paths and Selection" on page 435 in Chapter 20, "Using the Output Delivery System."

Displaying Templates

Once you have found the fully qualified name of a template, you can display its definition (source program) by using one of these methods:

- Open the Templates window by issuing the command **odstemplates** (**odst** for short) in the command line of the SAS windowing environment. The template window is shown in Figure 21.33. If you expand the SASHELP.Tmplmst node, you can view all the available templates and double-click any template icon to display its definition. This is illustrated in Example 21.5.
- Use the SOURCE statement in PROC TEMPLATE to display a template definition in the SAS log or write the definition to a file.

Figure 21.33 Requesting the Templates Window in the Command Line

For example, the following statements display the template for the PROC REG residual plot:

```
proc template;
   source Stat.REG.Graphics.ResidualPlot;
run;
```

The template is displayed as follows:

```
define statgraph Stat.Reg.Graphics.ResidualPlot;
   notes "Residual Plot";
   dynamic _XVAR _SHORTXLABEL _TITLE _LOESSLABEL _DEPNAME
           _MODELLABEL _SMOOTH;
   BeginGraph;
      entrytitle halign=left textattrs=GRAPHVALUETEXT
         _MODELLABEL halign=center
         textattrs=GRAPHTITLETEXT _TITLE " for " _DEPNAME;
      entrytitle textattrs=GRAPHVALUETEXT _LOESSLABEL;
      layout overlay / xaxisopts=(shortlabel=_SHORTXLABEL);
         referenceline y=0;
         scatterplot y=RESIDUAL x=_XVAR / primary=true
            rolename=(_tip1=OBSERVATION _id1=ID1 _id2=ID2
            _id3=ID3 _id4=ID4 _id5=ID5) tip=(y x
```

```
            _tip1 _id1 _id2 _id3 _id4 _id5);
         if (EXISTS(_SMOOTH))
            loessplot y=_SMOOTH x=_XVAR /
               tiplabel=(y="Smoothed Residual");
         endif;
      endlayout;
   EndGraph;
end;
```

PROC TEMPLATE also tells you where the template is located. In this case, it prints the following note:

```
NOTE: Path 'Stat.Reg.Graphics.ResidualPlot' is in: SASHELP.TMPLMST.
```

The word "Path" in ODS refers to any name or label hierarchy. In the note, the levels of the template name form a path. In the trace output, the levels of the plot name form a different path.

Editing Templates

You can modify the format and appearance of a particular graph by doing the following:

- Modify its template definition (source program).
- Submit the revised template to create a new compiled template.
- Ensure that the ODS search path finds and uses your new template.

Template libraries are designated read-only (such as SASHELP.Tmplmst) or updatable (such as SASUSER.Templat).

If you view the templates in an updatable template library from the Templates window, you can select **Open** or **Edit** from the pop-up menu. Either the Template Browser or Template Editor window opens. In the Template Editor window, you can make changes and submit the code directly. For read-only templates or when you select **Open**, the Template Browser window opens and you must copy the definition to an editor window to make changes. Since templates supplied by SAS are in the read-only SASHELP library, an easy way to obtain an editable program file is to use the SOURCE statement with the FILE= option in PROC TEMPLATE to write the template definition to a file as follows:

```
proc template;
   source Stat.REG.Graphics.ResidualPlot / file="residtpl.sas";
run;
```

By default, the file is saved in the SAS current folder. Alternatively, you can omit the slash and the FILE= option and copy and paste the source from the SAS log into an editor. Either way, you must add a PROC TEMPLATE statement before the generated source statements and a RUN statement after the END statement before you submit your modified definition.

Graph definitions are self-contained and do not support inheritance or "parenting" as do table definitions. Consequently, the EDIT statement in PROC TEMPLATE is not supported for graph definitions.

Here are some important points about what you can and cannot change in a template supplied by SAS while preserving its overall functionality:

- Do not change the template name. A statistical procedure can access only a predefined list of templates. If you change the name, the procedure cannot find your template. You must keep the original name and make sure that it is in a template library that is read before SASHELP.Tmplmst. You control this with the ODS PATH statement (see the section "The Default Template Libraries and the ODS PATH" on page 553, the section "Saving Customized Templates" on page 587, and subsequent sections for more information about the ODS PATH).
- Do not change the names of columns. The underlying data object contains predefined column names that you must use. Be very careful if you change how a column is used in a template. Usually, columns are not interchangeable.
- Do not change the names of DYNAMIC variables. Procedures set values only for a predefined list of dynamic variables. Changing dynamic variable names can lead to runtime errors. Do not add dynamic variables, because the procedure cannot set their values. A few procedures document additional dynamic variables that can be defined in the template if you want to add more information to the output, such additional statistics in an inset table. See the section "Modifying the Layout and Adding a New Inset Table" on page 627 for an example.
- Do not change the names of statements (for example, from a SCATTERPLOT to a NEEDLEPLOT or other type of plot).

You can change any of the following:

- You can add macro variables that behave like dynamic variables. They are resolved at the time that the statistical procedure is run, and not at the time that the template is compiled. They are defined with an MVAR or NMVAR statement at the beginning the template. You can set the value of each macro variable with a %LET statement before the statistical procedure is run. See Example 21.10. You can also move a variable from a DYNAMIC statement to an MVAR or NMVAR statement if you want to set it yourself rather than letting the procedure set it.
- You can change the graph size.
- You can change graph titles, footnotes, axis labels, and any other text that appears in the graph.
- You can change which plot features are displayed.
- You can change axis features, such as grid lines, offsets, view ports, tick value formatting, and so on.
- You can change the content and arrangement of insets (small tables of statistics embedded in some graphs).

- You can change the legend location, contents, border, background, title, and so on.

See the *SAS/GRAPH: Graph Template Language Reference* for information about the syntax of the statements in the Graph Template Language.

Saving Customized Templates

After you edit the template definition, you can submit your PROC TEMPLATE statements as you would any other SAS program. If you are using the Template Editor window, select **Submit** from the **Run** menu. See Example 21.5. Alternatively, submit your PROC TEMPLATE statements from the Program Editor. ODS automatically saves the compiled template in the first template library that it can update, according to the currently defined ODS path. If you have not changed the ODS path, then the modified template is saved in the SASUSER.Templat template library. You can display the current ODS path with the following statement:

```
ods path show;
```

Here are the log messages for the default path:

```
Current ODS PATH list is:

1. SASUSER.TEMPLAT(UPDATE)
2. SASHELP.TMPLMST(READ)
```

If you want to store modified templates in another template library, you can use the ODS PATH statement to add that template library to the front of the list. To use these templates, you must make sure the ODS path is set correctly before you attempt to access them in the other SAS sessions. See the section "Using Customized Templates" on page 587.

Using Customized Templates

When you create ODS output (either graphs or tables), ODS searches sequentially through each library in the ODS PATH list for a template that matches the one requested. If you have not changed the default ODS path, then ODS searches the SASUSER.Templat library first, then SASHELP.Tmplmst. ODS uses the first template that it finds with the requested name. **NOTE:** Templates with the same name can exist in more than one template library.

The ODS PATH statement specifies the libraries to search, as well as the order in which to search them. You can change the default path by using the ODS PATH statement. For example, the following statement sets the ODS path so that the template library WORK.Mystore is searched first, followed by SASHELP.Tmplmst:

```
ods path work.mystore(update) sashelp.tmplmst(read);
```

The UPDATE option provides update access as well as read access to WORK.Mystore. The READ option provides read-only access to SASHELP.Tmplmst. With this path, the template library SASUSER.Templat is no longer searched. You can verify this with the following statement:

```
ods path show;
```

Here are the log messages generated by the preceding statement:

```
Current ODS PATH list is:

1. WORK.MYSTORE(UPDATE)
2. SASHELP.TMPLMST(READ)
```

For more information, see the *SAS Output Delivery System: User's Guide* and the *SAS/GRAPH: Graph Template Language User's Guide*. Example 21.5 illustrates all the steps of displaying, editing, saving, and using customized templates.

Reverting to the Default Templates

Customized templates are stored in SASUSER.Templat or in some other template library that you create. The templates supplied by SAS are in the read-only template library SASHELP.Tmplmst. If you have modified any of the supplied templates and you want to use the original default templates, you can change your ODS path as follows:

```
ods path sashelp.tmplmst(read) sasuser.templat(update);
```

This way the default templates are found first. Alternatively, you can save all of your customized templates in a user-defined template library (for example WORK.Mystore). To access these templates, you submit the following statement before running your analysis:

```
ods path mylib.mystore(update) sashelp.tmplmst(read);
```

When you are done, you can reset the default ODS path as follows:

```
ods path reset;
```

This restores the ODS path to its original state (`sasuser.templat(update) sashelp.tmplmst(read)`). You can also save your customized template as part of your SAS program. You can delete it from the SASUSER.Templat template library when you are done, as in the following statements:

```
proc template;
   delete Stat.REG.Graphics.ResidualPlot;
run;
```

The following note is printed in the SAS log:

```
NOTE: 'Stat.REG.Graphics.ResidualPlot' has been deleted from: SASUSER.TEMPLAT
```

You can run the following step to delete the entire SASUSER.Templat library of customized templates:

```
ods path sashelp.tmplmst(read);
proc datasets library=sasuser;
   delete templat(memtype=itemstor);
run;
ods path sasuser.templat(update) sashelp.tmplmst(read);
```

Statistical Graphics Procedures

There are three statistical graphics procedures in SAS/GRAPH that use ODS Graphics and provide convenient syntax for creating a variety of plots from raw data or from procedure output.

SGSCATTER	creates single-cell and multi-cell scatter plots and scatter plot matrices with optional fits and ellipses.
SGPLOT	creates single-cell plots with a variety of plot and chart types.
SGPANEL	creates single-page or multi-page panels of plots and charts conditional on classification variables.

In addition, the SGRENDER procedure in SAS/GRAPH provides a way to create plots from graph templates that you have modified or written yourself.

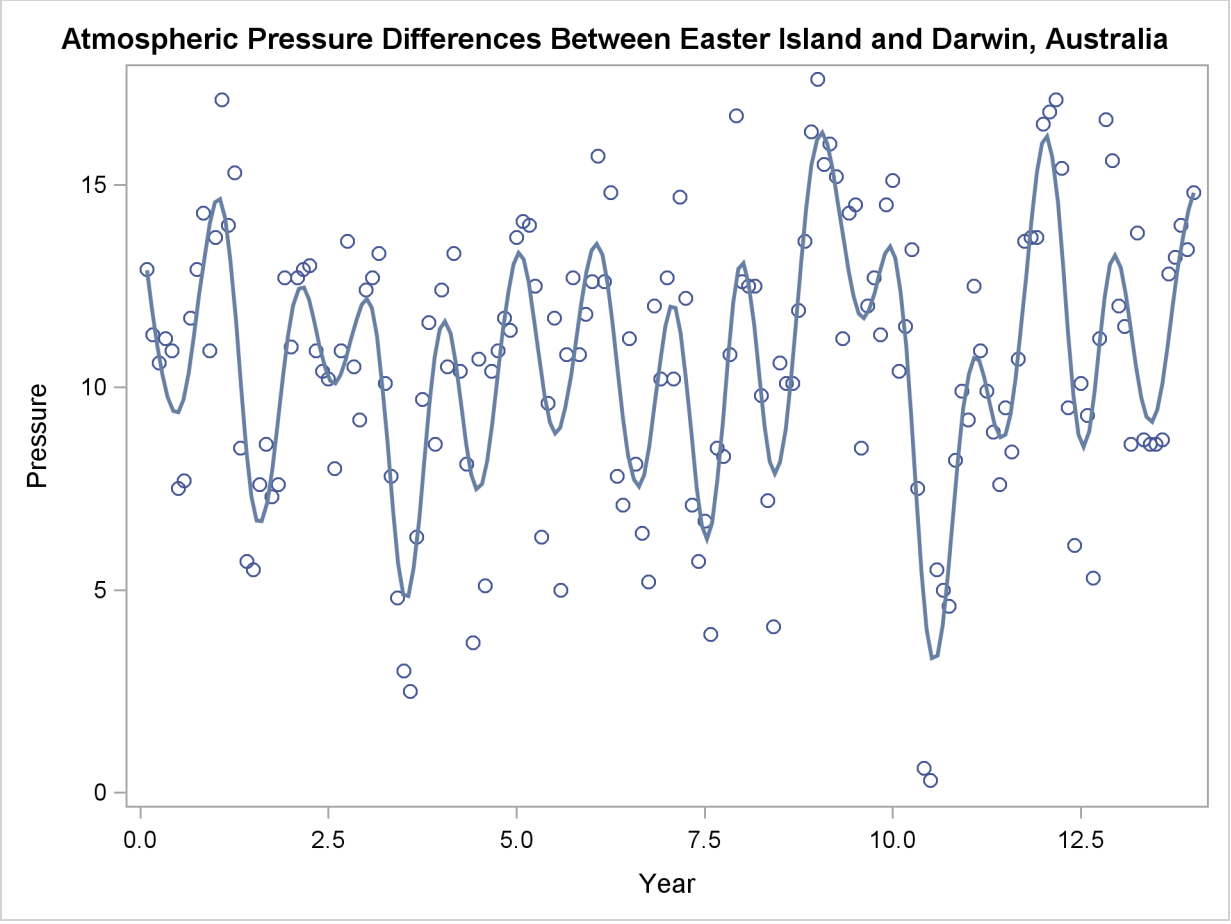
See the *SAS/GRAPH: Statistical Graphics Procedures Guide* for more information. You do not need to enable ODS Graphics in order to use the SG procedures.

These procedures do much more than make scatter plots. They can produce density plots, dot plots, needle plots, series plots, horizontal and vertical bar charts, histograms, and box plots. They can also compute and display loess fits, polynomial fits, penalized B-spline fits, reference lines, bands, and ellipses. PROC SGRENDER is the most flexible because it uses the Graph Template Language. The syntax for the other SG procedures is much simpler than that of the GTL, and so these procedures are recommended for creating most plots commonly required in statistical work.

The SGPLOT Procedure

PROC SGPLOT provides a simple way to make a variety of scatter plots. This example is taken from Example 50.4 of Chapter 50, "The LOESS Procedure." The following statements create a SAS data set that contains information about differences in ocean pressure over time:

```
data ENSO;
   input Pressure @@;
   Year = _n_ / 12;
   datalines;
12.9  11.3  10.6  11.2  10.9   7.5   7.7  11.7



... more lines ...
```

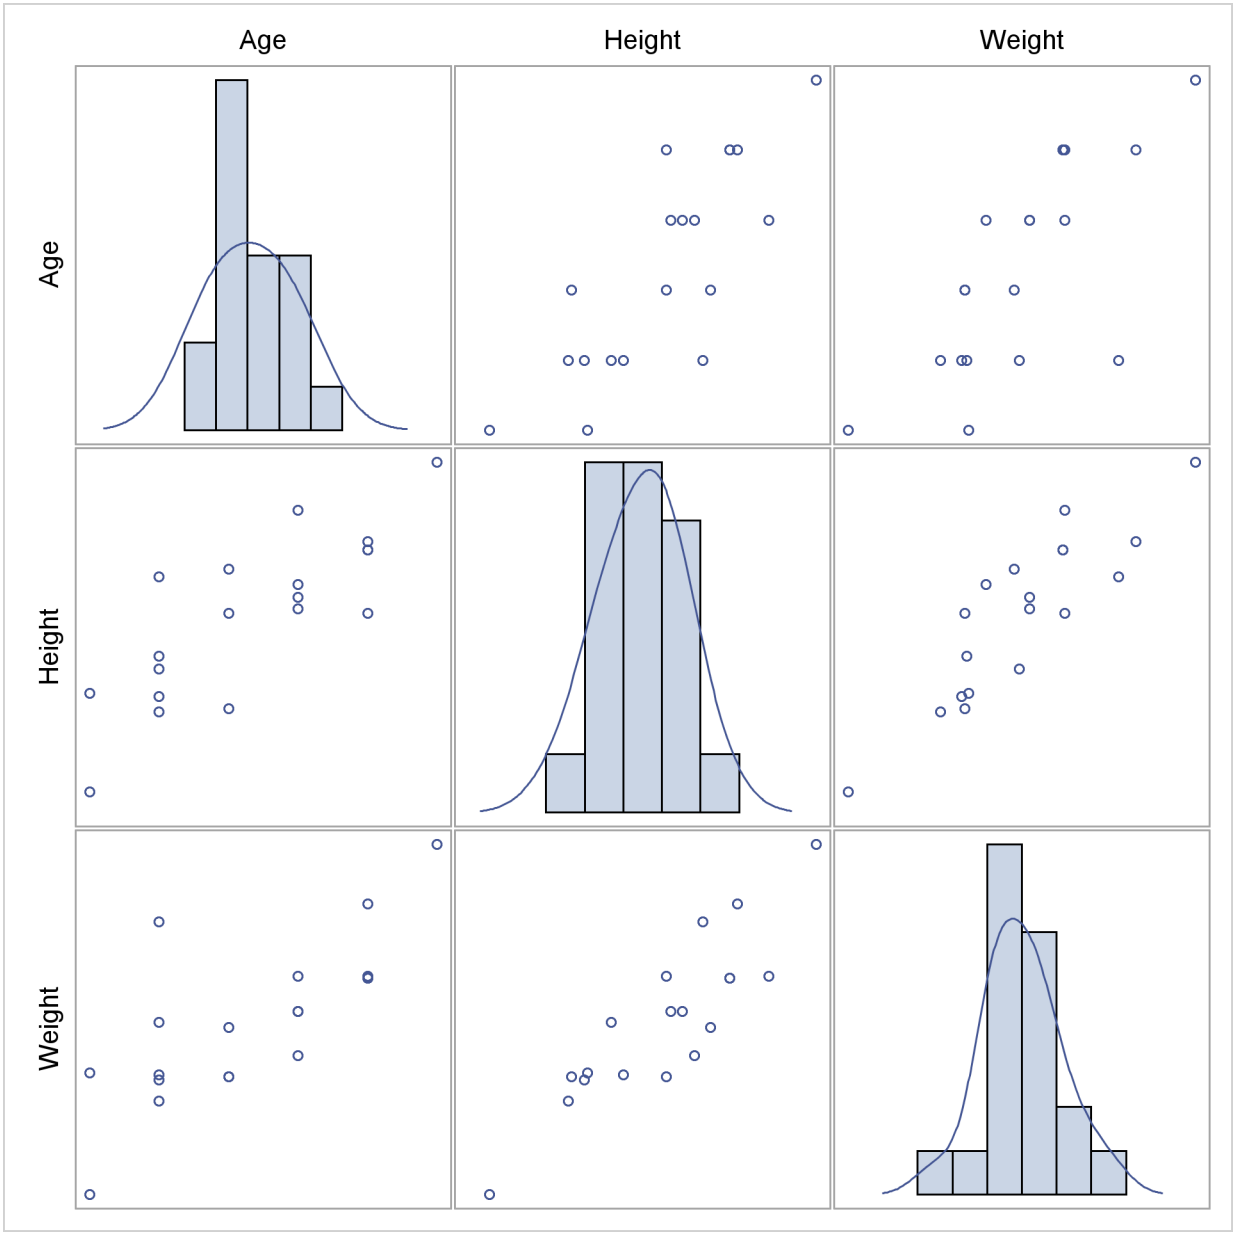
```
;
```

The following statements create a scatter plot of points along with a penalized B-spline fit to the data and produce Figure 21.34:

```
proc sgplot data=enso noautolegend;
   title 'Atmospheric Pressure Differences Between '
         'Easter Island and Darwin, Australia';
   pbspline y=pressure x=year;
run;
```

Figure 21.34 Penalized B-Spline Fit with PROC SGPLOT

See Chapter 90, "The TRANSREG Procedure," for more information about penalized B-splines. Also see the section "Grouped Scatter Plot with PROC SGPLOT" on page 517 and Figure 21.12 for an example of a scatter plot with groups of observations.



The SGSCATTER Procedure

You can use the SGSCATTER procedure to produce scatter plot matrices. The following step creates a scatter plot matrix from all of the numeric variables in the Class data set available in the SASHELP library and produces Figure 21.35:

```
proc sgscatter data=sashelp.class;
   matrix _numeric_ / diagonal=(kernel histogram);
run;
```

The diagonal cells of Figure 21.35 contain a histogram and a kernel density fit. The off-diagonal cells contain all pairs of scatter plots.

Figure 21.35 Scatter Plot Matrix with PROC SGSCATTER

The MATRIX statement creates a symmetric $n \times n$ scatter plot matrix. Other statements are available as well. The PLOT statement creates a panel containing one or more individual scatter plots. The COMPARE statement creates a rectangular $m \times n$ scatter plot matrix. Linear and nonlinear fits can be added, and many graphical features can be requested with options.

The SGPANEL Procedure

The SGPANEL procedure creates paneled plots and charts with one or more classification variables. Classification variables can be designated as row or column variables, or there can be multiple classifications. Graphs are drawn for each combination of the levels of classification variables, showing a subset of the data in each cell.

This example is taken from Example 38.6 of Chapter 38, "The GLIMMIX Procedure." The following statements create the input SAS data sets:

```
data times;
   input time1-time23;
   datalines;
122  150  166  179  219  247  276  296  324  354  380  445
478  508  536  569  599  627  655  668  723  751  781
;

data cows;
   if _n_ = 1 then merge times;
   array t{23} time1 - time23;
   array w{23} weight1 - weight23;
   input cow iron infection weight1-weight23 @@;
   do i=1 to 23;
      weight = w{i};
      tpoint = (t{i}-t{1})/10;
      output;
   end;
   keep cow iron infection tpoint weight;
   datalines;
 1 0 0  4.7    4.905  5.011  5.075  5.136  5.165  5.298  5.323
        5.416  5.438  5.541  5.652  5.687  5.737  5.814  5.799
        5.784  5.844  5.886  5.914  5.979  5.927  5.94

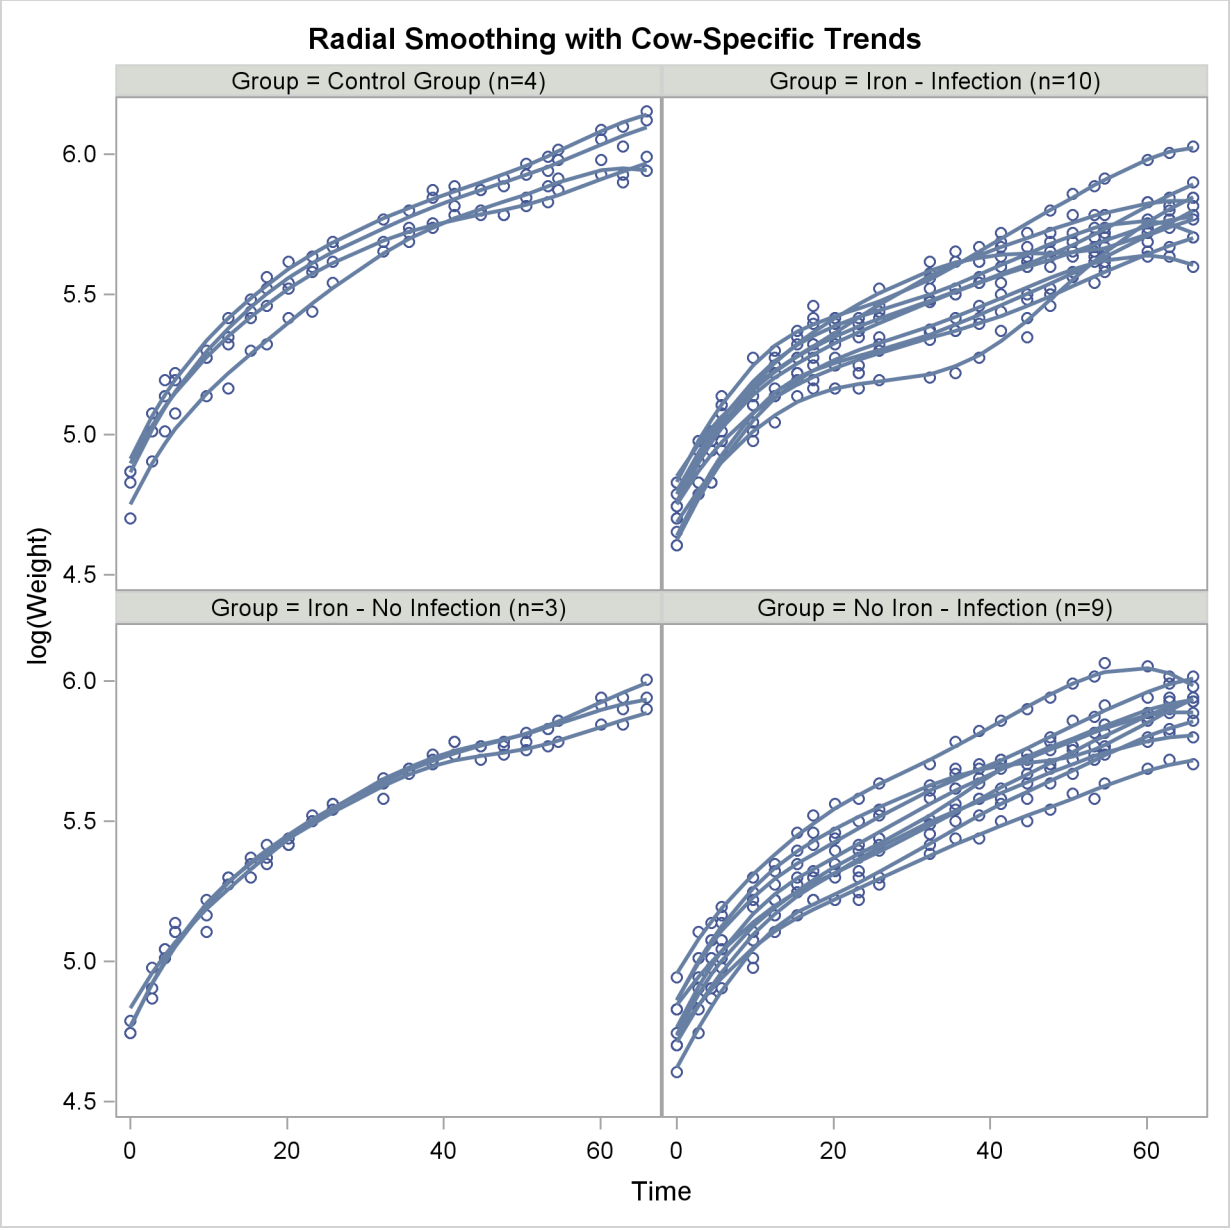
... more lines ...

;
```

First, PROC GLIMMIX is run to fit the model, and then the results are prepared for plotting:

```
proc glimmix data=cows;
  t2 = tpoint / 100;
  class cow iron infection;
  model weight = iron infection iron*infection tpoint;
  random t2 / type=rsmooth subject=cow
                  knotmethod=kdtree(bucket=100 knotinfo);
  output out=gmxout pred(blup)=pred;
  nloptions tech=newrap;
run;

data plot;
  set gmxout;
  length Group $ 26;
       if (iron=0) and (infection=0) then group='Control Group (n=4)';
  else if (iron=1) and (infection=0) then group='Iron - No Infection (n=3)';
  else if (iron=0) and (infection=1) then group='No Iron - Infection (n=9)';
  else group = 'Iron - Infection (n=10)';
run;



proc sort data=plot; by group cow;
run;
```

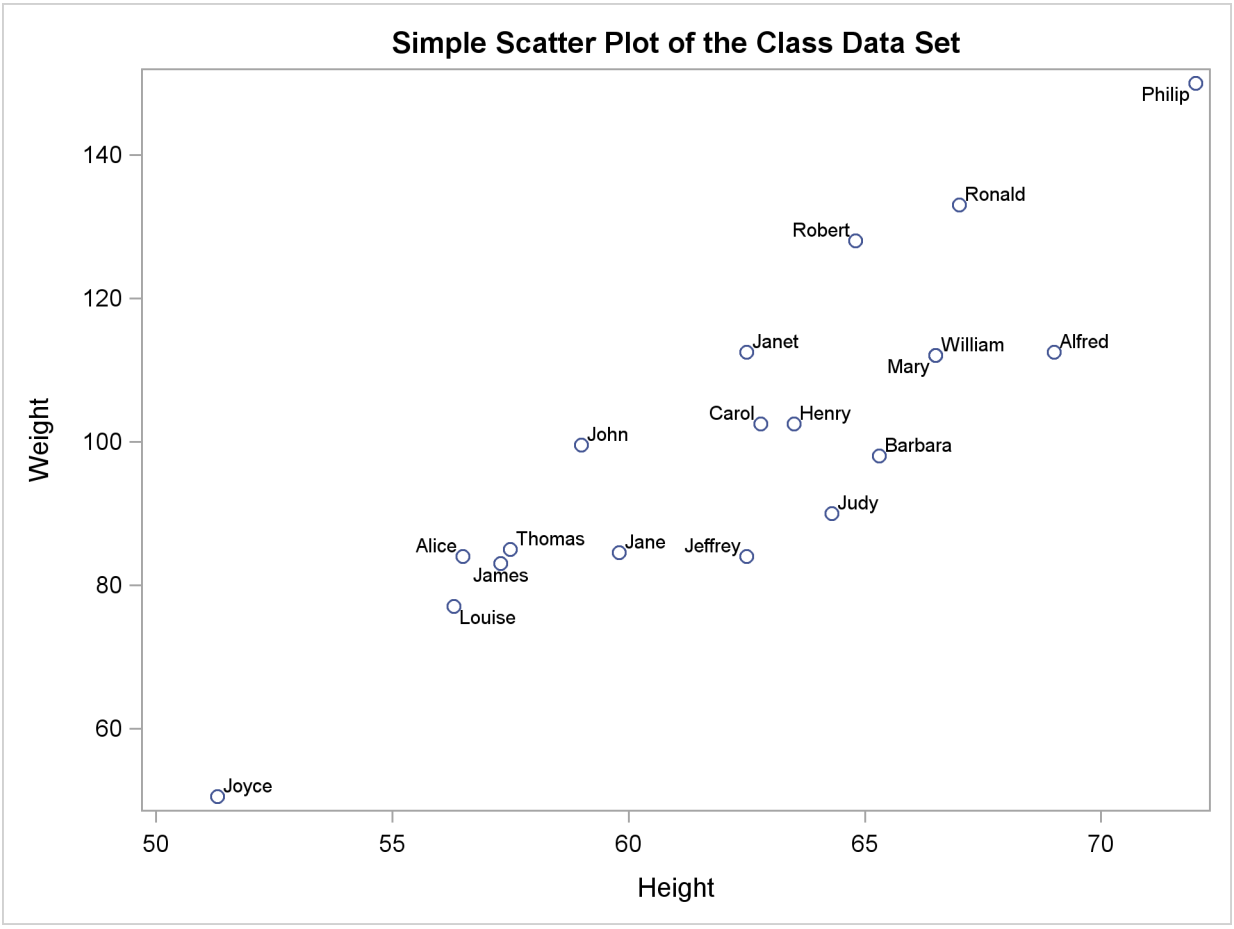
The following statements produce graphs of the observed data and fitted profiles in the four groups:

```
proc sgpanel data=plot noautolegend;
  title 'Radial Smoothing with Cow-Specific Trends';
  label tpoint='Time' weight='log(Weight)';
  panelby group / columns=2 rows=2;
  scatter x=tpoint y=weight;
  series  x=tpoint y=pred / group=cow lineattrs=GraphFit;
run;
```

The results are shown in Figure 21.36.

Figure 21.36 Fit Using PROC SGPANEL

The SGRENDER Procedure



The SGRENDER procedure produces a graph from an input SAS data set and an ODS graph template. With PROC SGRENDER and the Graph Template Language (GTL), you can create highly customized graphs. The following steps create a simple scatter plot of the Class data set available in the SASHELP library and produce Figure 21.37:

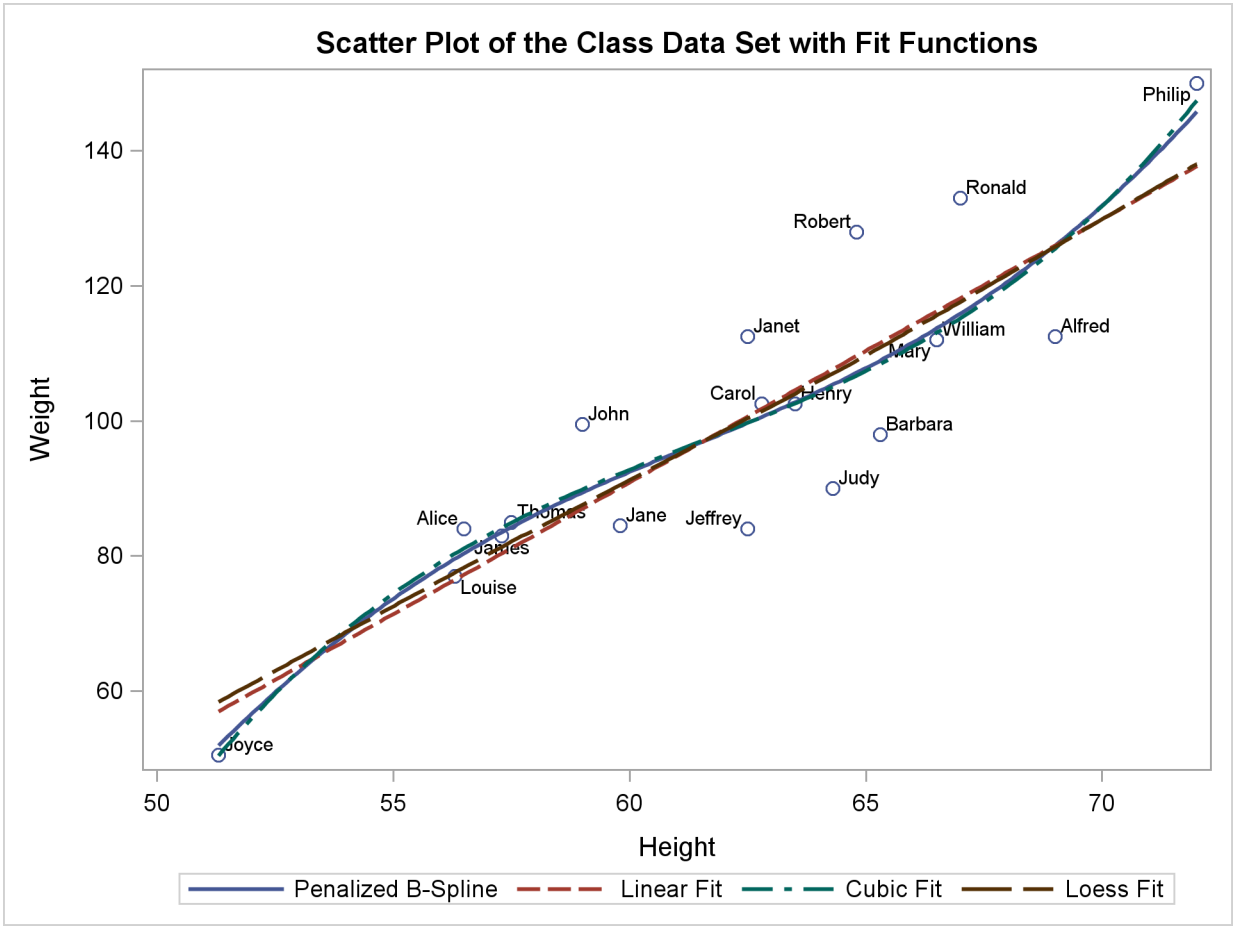
```
proc template;
   define statgraph Scatter;
      begingraph;
         entrytitle "Simple Scatter Plot of the Class Data Set";
         layout overlay;
            scatterplot y=weight x=height / datalabel=name;
         endlayout;
      endgraph;
   end;
run;

proc sgrender data=sashelp.class template=scatter;
run;
```

The template definition consists of an outer block that begins with a DEFINE statement and ends with an END statement. Inside of that is a BEGINGRAPH/ENDGRAPH block. Inside that block, the ENTRYTITLE statement provides the plot title, and the LAYOUT OVERLAY block contains the statement or statements that define the graph. In this case, there is just a single SCATTERPLOT statement that names the Y-axis (vertical) variable, the X-axis (horizontal) variable, and an optional variable that contains labels for the points. The PROC SGRENDER statement simply specifies the input data set and the template. The real work in using PROC SGRENDER is writing the template.

Figure 21.37 Scatter Plot of Labeled Points with PROC SGRENDER

The following steps add a series of fit functions to the scatter plot and create a legend by adding statements to the **Scatter** template:



```
proc template;
   define statgraph Scatter;
      begingraph;
         entrytitle "Scatter Plot of the Class Data Set with Fit Functions";
         layout overlay;
            scatterplot y=weight x=height / datalabel=name;
            pbsplineplot y=weight x=height / name='pbs'
                         legendlabel='Penalized B-Spline'
                         lineattrs=GraphData1;
            regressionplot y=weight x=height / degree=1 name='line'
                         legendlabel='Linear Fit'
                         lineattrs=GraphData2;
            regressionplot y=weight x=height / degree=3 name='cubic'
                         legendlabel='Cubic Fit'
                         lineattrs=GraphData3;
            loessplot y=weight x=height / name='loess'
                         legendlabel='Loess Fit'
                         lineattrs=GraphData4;
```

```
            discretelegend 'pbs' 'line' 'cubic' 'loess';
         endlayout;
      endgraph;
   end;
run;

proc sgrender data=sashelp.class template=scatter;
run;
```

The line attributes for each function are specified with different style elements, **GraphData1** through **GraphData4**, so that the functions are adequately identified in the legend. The preceding statements create Figure 21.38.

Figure 21.38 Scatter Plot and Fit Functions with PROC SGRENDER

The following statements create a four-panel display of the Class data set and produce Figure 21.39:

```
proc template;
   define statgraph Panel;
      begingraph;
         entrytitle "Paneled Display of the Class Data Set";

         layout lattice / rows=2 columns=2 rowgutter=10 columngutter=10;

            layout overlay;
               scatterplot y=weight x=height;
               pbsplineplot y=weight x=height;
            endlayout;

            layout overlay / xaxisopts=(label='Weight');
               histogram weight;
            endlayout;

            layout overlay / yaxisopts=(label='Height');
               boxplot y=height;
            endlayout;

            layout overlay / xaxisopts=(offsetmin=0.1 offsetmax=0.1)
                             yaxisopts=(offsetmin=0.1 offsetmax=0.1);
               scatterplot  y=weight x=height / markercharacter=sex
                  name='color' markercolorgradient=age;
               continuouslegend 'color'/ title='Age';
            endlayout;

         endlayout;
      endgraph;
   end;
run;

proc sgrender data=sashelp.class template=panel;
run;
```

In this template, the outermost layout is a LAYOUT LATTICE. It creates a 2×2 panel of plots with a ten-pixel separation (or gutter) between each plot. Inside the lattice are four LAYOUT OVERLAY blocks—each defining one of the graphs. The first is a simple scatter plot with a nonlinear penalized B-spline fit. The second is a histogram of the dependent variable Weight. The third is a box plot of the independent variable Height. The fourth simultaneously shows height, weight, age, and sex for the students in the class. Each axis has an offset added at both the maximum and minimum. This provides padding between the axes and the data.

Figure 21.39 Multiple Panels Using PROC SGRENDER

Many other types of graphs are available with the SG procedures. However, even the few examples provided here show the power and flexibility available for making professional-quality statistical graphics. See the *SAS/GRAPH: Graph Template Language User's Guide* and the *SAS/GRAPH: Statistical Graphics Procedures Guide* for more information.

Examples of ODS Statistical Graphics

Example 21.1: Creating Graphs with Tool Tips in HTML

This example demonstrates how to request graphics in HTML that are enhanced with tooltip displays, which appear when you move a mouse over certain features of the graph. When you specify the HTML destination and the IMAGEMAP=ON option in the ODS GRAPHICS statement, an image map of coordinates for tooltips is generated along with the HTML output file. Individual graphs are saved as PNG files.

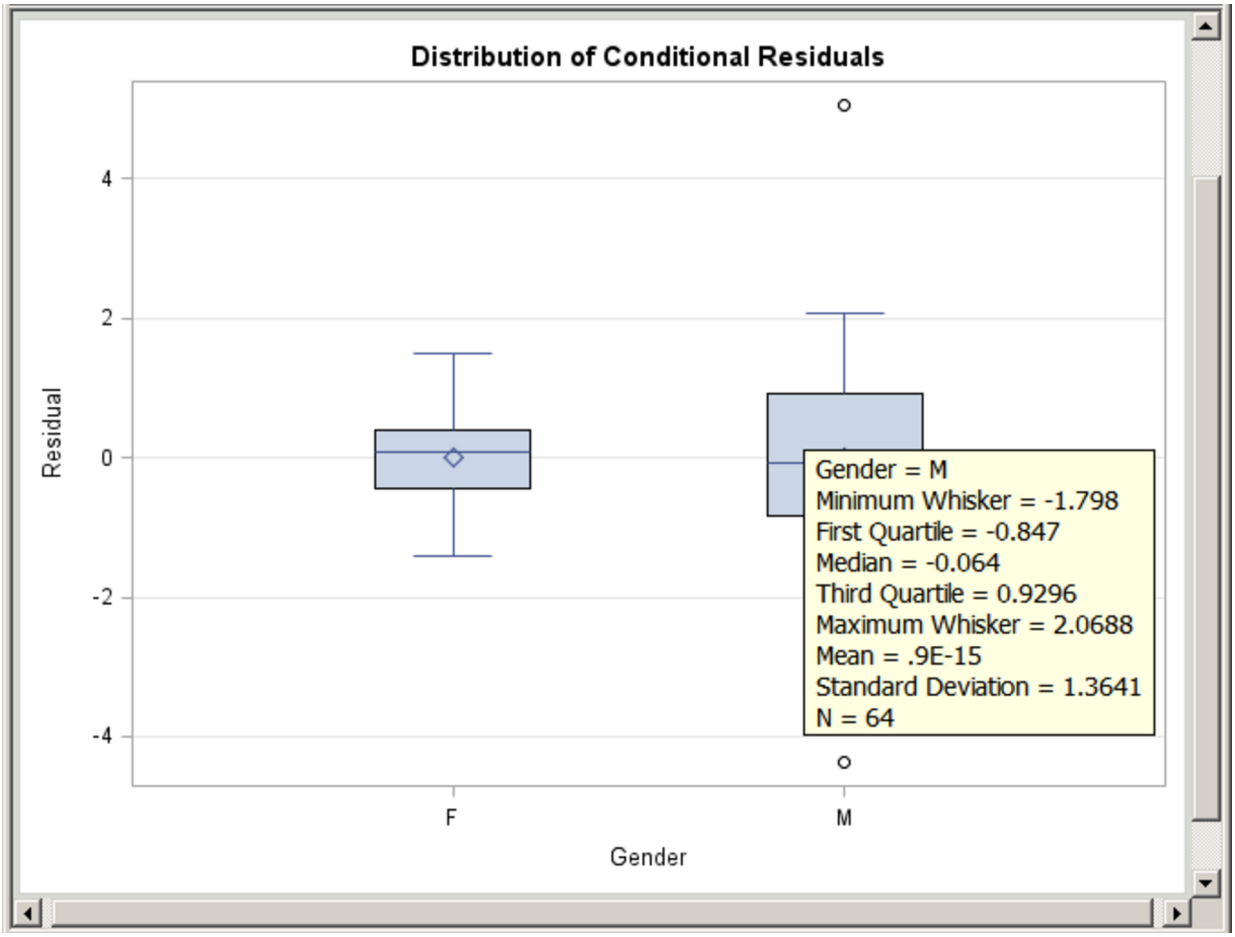
Example 56.2 and Example 56.8 of Chapter 56, "The MIXED Procedure," analyze a data set with repeated growth measurements for 27 children. The following step creates the data set:

```
data pr;
   input Person Gender $ y1 y2 y3 y4 @@;
   y=y1; Age=8;  output;
   y=y2; Age=10; output;
   y=y3; Age=12; output;
   y=y4; Age=14; output;
   drop y1-y4;
   datalines;
 1  F  21.0  20.0  21.5  23.0      2  F  21.0  21.5  24.0  25.5

... more lines ...

;
```

The following statements fit a mixed model with random intercepts and slopes for each child:



```
ods graphics on / imagemap=on;
ods html body='b.html' style=statistical;

proc mixed data=pr method=ml plots=boxplot;
   ods select 'Conditional Residuals by Gender';
   class Person Gender;
   model y = Gender Age Gender*Age;
   random intercept Age / type=un subject=Person;
run;

ods html close;
```

The PLOTS=BOXPLOT option in the PROC MIXED statement requests box plots of observed values and residuals for each classification main effect in the model (Gender and Person). Only the by-gender box plots are actually created due to the ODS SELECT statement, which uses the plot label to select the plot. Output 21.1.1 displays the results. Moving the mouse over a box plot displays a tooltip with summary statistics for the class level. Graphics with tooltips are supported for only the HTML destination.

Output 21.1.1 Box Plot with Tool Tips

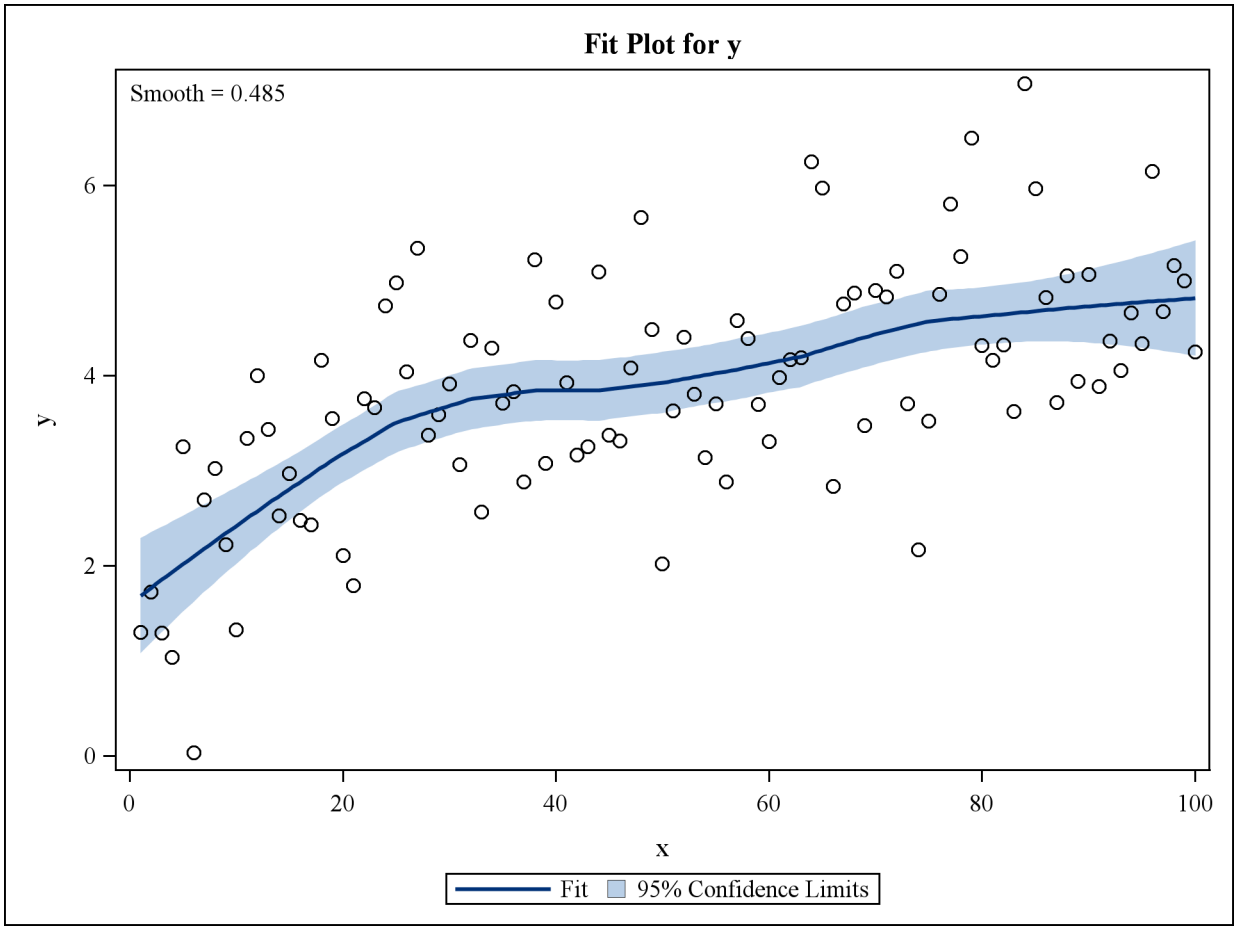
Example 21.2: Creating Graphs for a Presentation

The RTF destination provides the easiest way to create ODS graphs for inclusion into a paper or presentation. You can specify the ODS RTF statement to create a file that is easily imported into a document (such as Microsoft Word or WordPerfect) or a presentation (such as Microsoft PowerPoint).

The following statements simulate 100 observations from the model $y = \log(x) + e$, where $x = 1, \ldots, 100$ and e has a normal distribution with mean 0 and variance 1:

```
data one;
   do x = 1 to 100;
      y = log(x) + normal(104);
      output;
   end;
run;
```

The following statements request a loess fit and save the output in the file *loess.rtf*:



```
ods listing close;
ods rtf file="loess.rtf";
ods graphics on;

proc loess data=one;
   model y = x / clm residual;
run;

ods rtf close;
ods listing;
```

The output file includes various tables and the following plots: a plot of the selection criterion versus smoothing parameter, a fit plot with 95% confidence bands, a plot of residual by regressors, and a diagnostics panel. The fit plot is produced with the RTF style and is shown in Output 21.2.1.

Output 21.2.1 Loess Fit Plot with the RTF Style

If you are running SAS in the Windows operating system, you can open the RTF file in Microsoft Word and simply copy and paste the graphs into Microsoft PowerPoint. In general, RTF output is convenient for exchange of graphical results between Windows applications through the clipboard.

Alternatively, if you request ODS Graphics with the LISTING or HTML destinations, then your individual graphs are created as PNG files by default. You can insert these files into a Microsoft PowerPoint presentation. See the sections "Naming Graphics Image Files" on page 542 and "Saving Graphics Image Files" on page 544 for information about how the image files are named and saved.

Example 21.3: Creating Graphs in PostScript Files

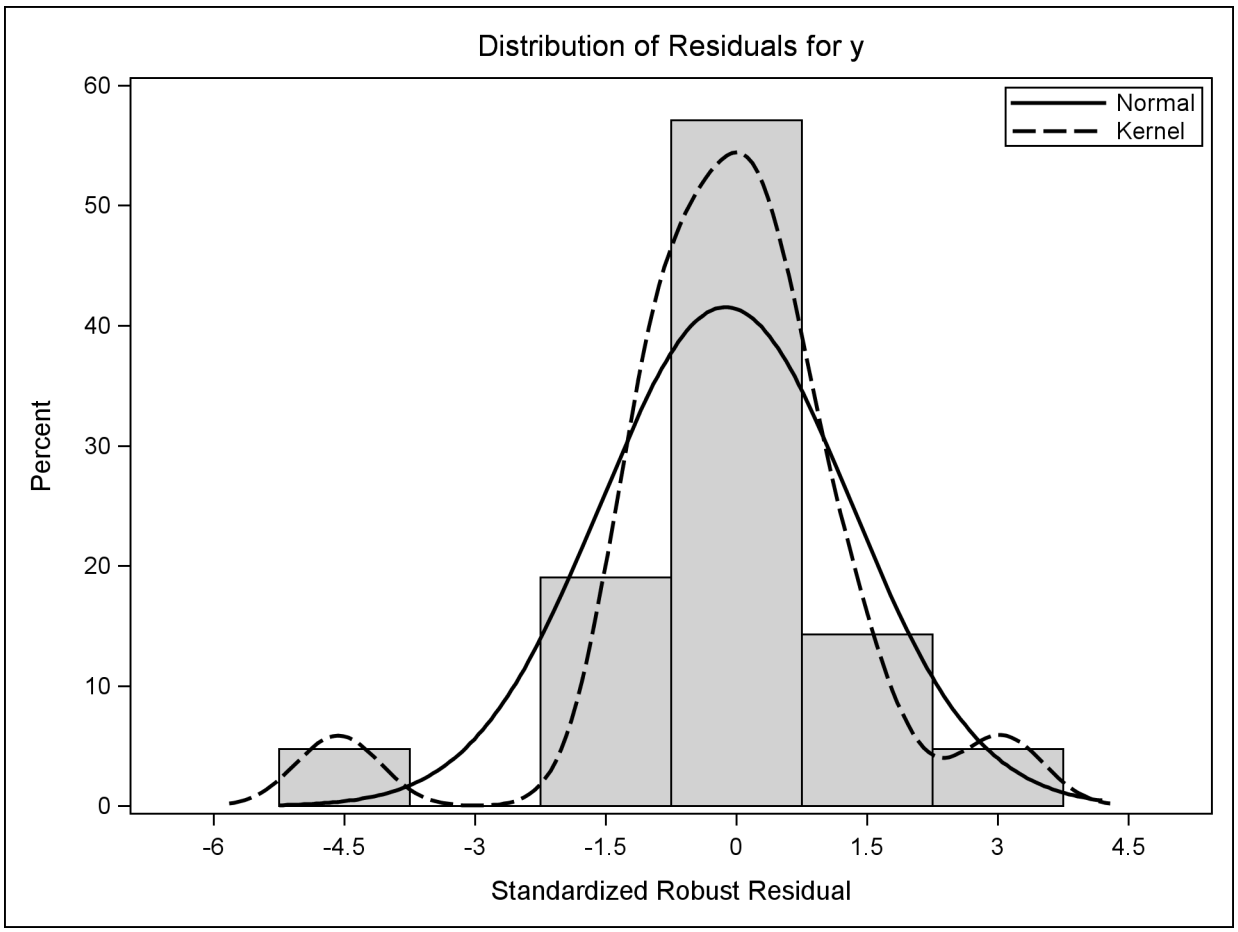
This example illustrates how to create individual graphs in PostScript files. This is particularly useful when you want to include them in a LaTeX document. Consider again the data set Stack created by the following statements:

```
data stack;
   input  x1 x2 x3 y @@;
   datalines;
80  27  89  42    80  27  88  37    75  25  90  37

... more lines ...

;
```

The following statements close the LISTING destination, open the LATEX destination with the JOURNAL style, and request a histogram of standardized robust residuals computed with PROC ROBUSTREG:



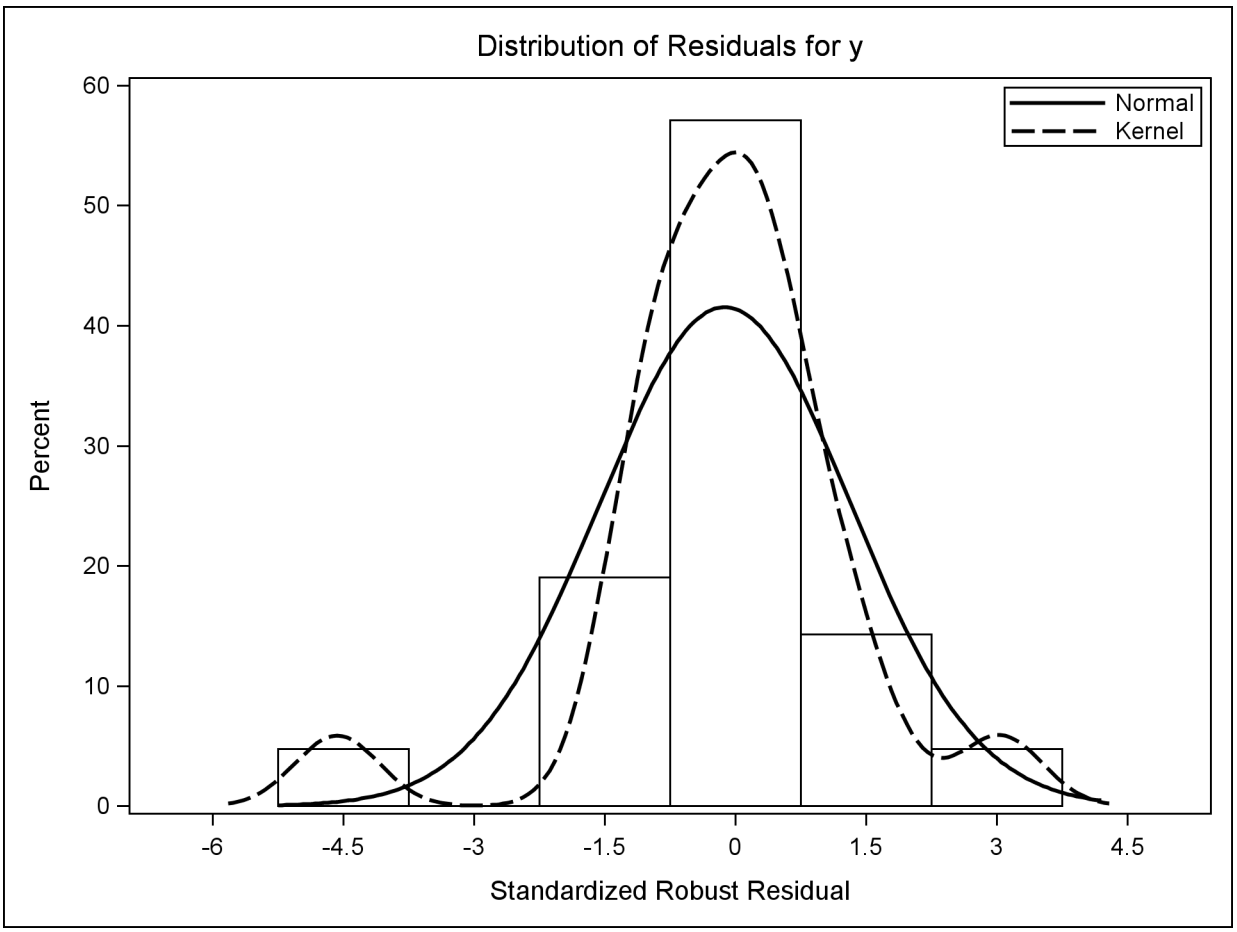
```
ods graphics on / reset=index;
ods listing close;
ods latex style=Journal;

proc robustreg data=stack plots=histogram;
   model y = x1 x2 x3;
run;

ods latex close;
ods listing;
```

The JOURNAL style displays gray-scale graphs that are suitable for a journal. When you specify the ODS LATEX destination, ODS creates a PostScript file for each individual graph in addition to a LaTeX source file that includes the tabular output and references to the PostScript files. By default, these files are saved in the SAS current folder. The histogram shown in Output 21.3.1 is saved by default in a file named *Histogram.ps*. See the section "Naming Graphics Image Files" on page 542 for details about how graphics image files are named. If both the LISTING destination (which is open unless you explicitly close it) and the LATEX destination are open, then two files are created: *Histogram.ps* and *Histogram1.ps*. If the RESET=INDEX option is not specified in the ODS GRAPHICS statement, and if you run the step more than once, the final name is based on an incremented index.

Output 21.3.1 Histogram Using the JOURNAL Style



You can use the JOURNAL2 style for a different appearance—the bars are not filled. The following step produces Output 21.3.2:

```
ods graphics on / reset=index;
ods listing close;
ods latex style=Journal2;

proc robustreg data=stack plots=histogram;
   model y = x1 x2 x3;
run;

ods latex close;
ods listing;
```

Output 21.3.2 Histogram Using the JOURNAL2 Style

If you are writing a paper, you can include the graphs in your own LaTeX source file by referencing the names of the individual PostScript graphics files. In this situation, you might not find it necessary to use the LaTeX source file created by SAS. Alternatively, you can include PNG files into a LaTeX document, after using some other ODS destination (such as HTML) to create the PNG files.

Example 21.4: Displaying Graphs Using the DOCUMENT Procedure

This example illustrates the use of the ODS DOCUMENT destination and the DOCUMENT procedure to display your ODS graphs. You can use this approach whenever you want to generate and save your output (both tables and graphs) and then display or replay it later, potentially in subsets or more than once. This approach is particularly useful when you want to display your output in multiple ODS destinations, or when you want to use different styles without rerunning your SAS program. This approach is also useful when you want to break your output into separate parts for inclusion into different parts of a document such as a LaTeX file.

Consider again the data set Stack created by the following statements:

```
data stack;
   input  x1 x2 x3 y @@;
   datalines;
80  27  89  42    80  27  88  37    75  25  90  37

... more lines ...

;
```

The following statements request a Q-Q plot from PROC ROBUSTREG with the Stack data:

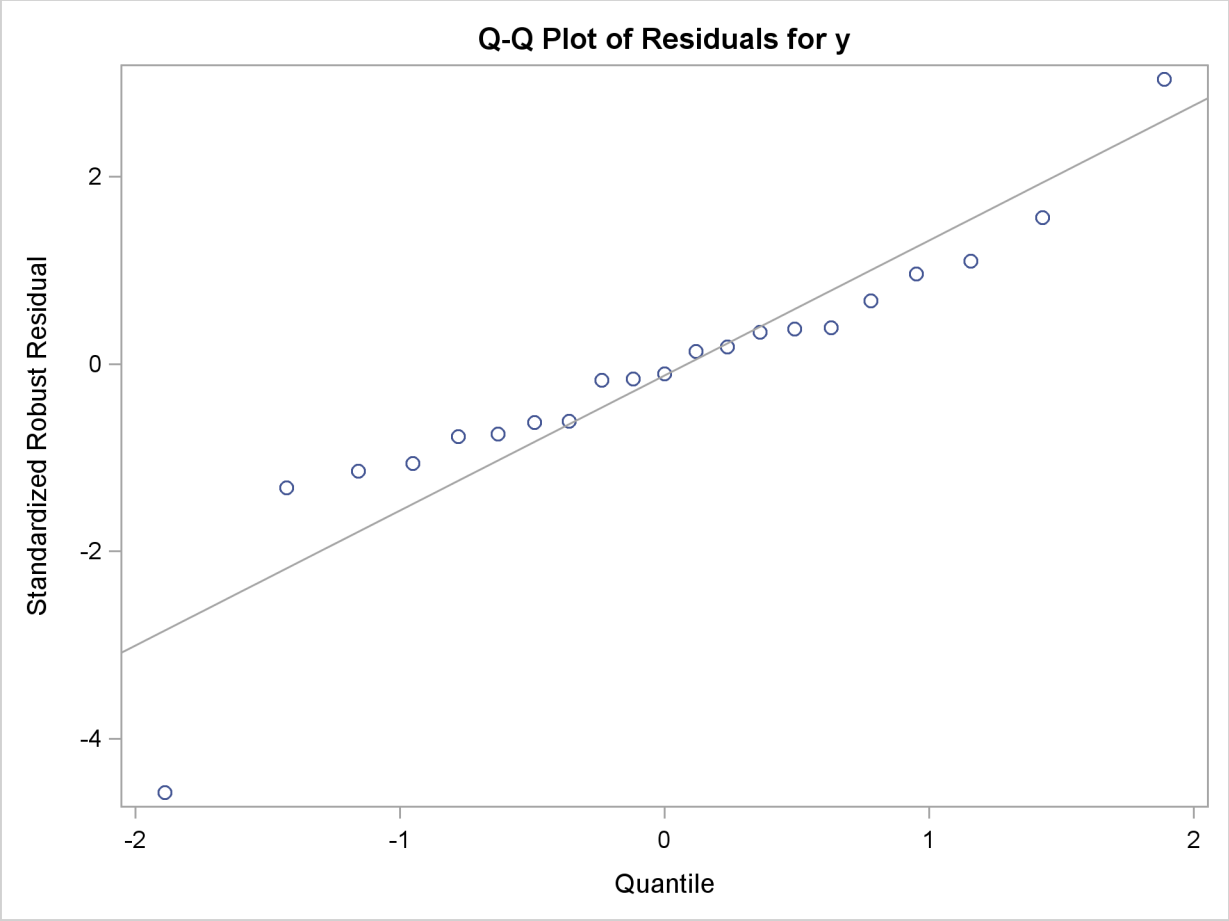
```
ods listing close;
ods document name=QQDoc(write);

proc robustreg data=stack plots=qqplot;
   model y = x1 x2 x3;
run; quit;

ods document close;
ods listing;
```

The ODS DOCUMENT statement opens an ODS document named **QQDoc**. All of the results—tables, graphs, titles, notes, footnotes, headers—are stored in the ODS document. None of them are displayed since no other destination is open. In order to display the Q-Q plot with PROC DOCUMENT, you first need to determine its name. You can do this by specifying the ODS TRACE ON statement prior to the procedure statements (see the section "Determining Graph Names and Labels" on page 538 for more information). Alternatively, you can type **odsdocuments** (or **odsd** for short) in the command line to open the Documents window, which you can then use to manage your ODS documents.

The following statements specify an HTML destination and display the residual Q-Q plot by using the REPLAY statement in PROC DOCUMENT:



```
ods html body='b.htm';

proc document name=QQDoc;
   ods select QQPlot;
   replay;
run; quit;

ods html close;
```

Subsequent steps can replay one or more objects from the same ODS document. By default, the REPLAY statement attempts to display every output object stored in the ODS document, but here only the Q-Q plot is displayed because it is specified by the ODS SELECT statement. The plot is displayed in Output 21.4.1.

Output 21.4.1 Q-Q Plot Displayed by PROC DOCUMENT

As an alternative to running PROC DOCUMENT with an ODS SELECT statement, you can run PROC DOCUMENT with a *document path* for the Q-Q plot in the REPLAY statement. This approach is preferable when the ODS document contains a large volume of output, so that PROC DOCUMENT does not attempt to process every piece of output stored in the ODS document.

You can determine the ODS document path for the Q-Q plot by specifying the LIST statement with the LEVELS=ALL option in PROC DOCUMENT as follows:

```
proc document name=QQDoc;
   list / levels=all;
run; quit;
```

The contents of the ODS document **QQDoc** are shown in Output 21.4.2.

Output 21.4.2 Contents of the ODS Document `QQDoc`

```
Listing of: \Work.Qqdoc\
Order by: Insertion
Number of levels: All

  Obs    Path                                                                  Type
-------------------------------------------------------------------------------------
       1 \Robustreg#1                                                          Dir
       2 \Robustreg#1\ModelInfo#1                                              Table
       3 \Robustreg#1\NObs#1                                                   Table
       4 \Robustreg#1\ParmInfo#1                                               Table
       5 \Robustreg#1\SummaryStatistics#1                                      Table
       6 \Robustreg#1\ParameterEstimates#1                                     Table
       7 \Robustreg#1\DiagSummary#1                                            Table
       8 \Robustreg#1\DiagnosticPlots#1                                        Dir
       9 \Robustreg#1\DiagnosticPlots#1\QQPlot#1                               Graph
      10 \Robustreg#1\GoodFit#1                                                Table
```

The ODS document path of the `QQPlot` entry in the `QQDoc` ODS document, as shown in Output 21.4.2, is `\Robustreg#1\DiagnosticPlots#1\QQPlot#1`.

You can use this path to display the residual Q-Q plot with PROC DOCUMENT as follows:

```
proc document name=QQDoc;
   replay \Robustreg#1\DiagnosticPlots#1\QQPlot#1;
run; quit;
```

You can also determine the ODS document path from the Results window or the Documents window. Right-click the object icon and select **Properties**.

The SAS/STAT documentation process uses the ODS document. SAS output is saved into an ODS document that is then replayed into sections of the documentation, which is prepared using LaTeX. In general, when you send your output to the DOCUMENT destination, you can use PROC DOCUMENT to rearrange, duplicate, or remove output from the results of a procedure or a database query. For more information, see the ODS DOCUMENT statement in the section "Dictionary of ODS Language Statements" and the chapter "The DOCUMENT Procedure" in the *SAS Output Delivery System: User's Guide*.

Example 21.5: Customizing Graphs Through Template Changes

This example shows how to use PROC TEMPLATE to customize the appearance and content of an ODS graph. It is divided into several parts; each part illustrates a different aspect of the template that you can easily change. You are never required to change a template, but you can if you want to change aspects of the plot.

Modifying Graph Titles and Axis Labels

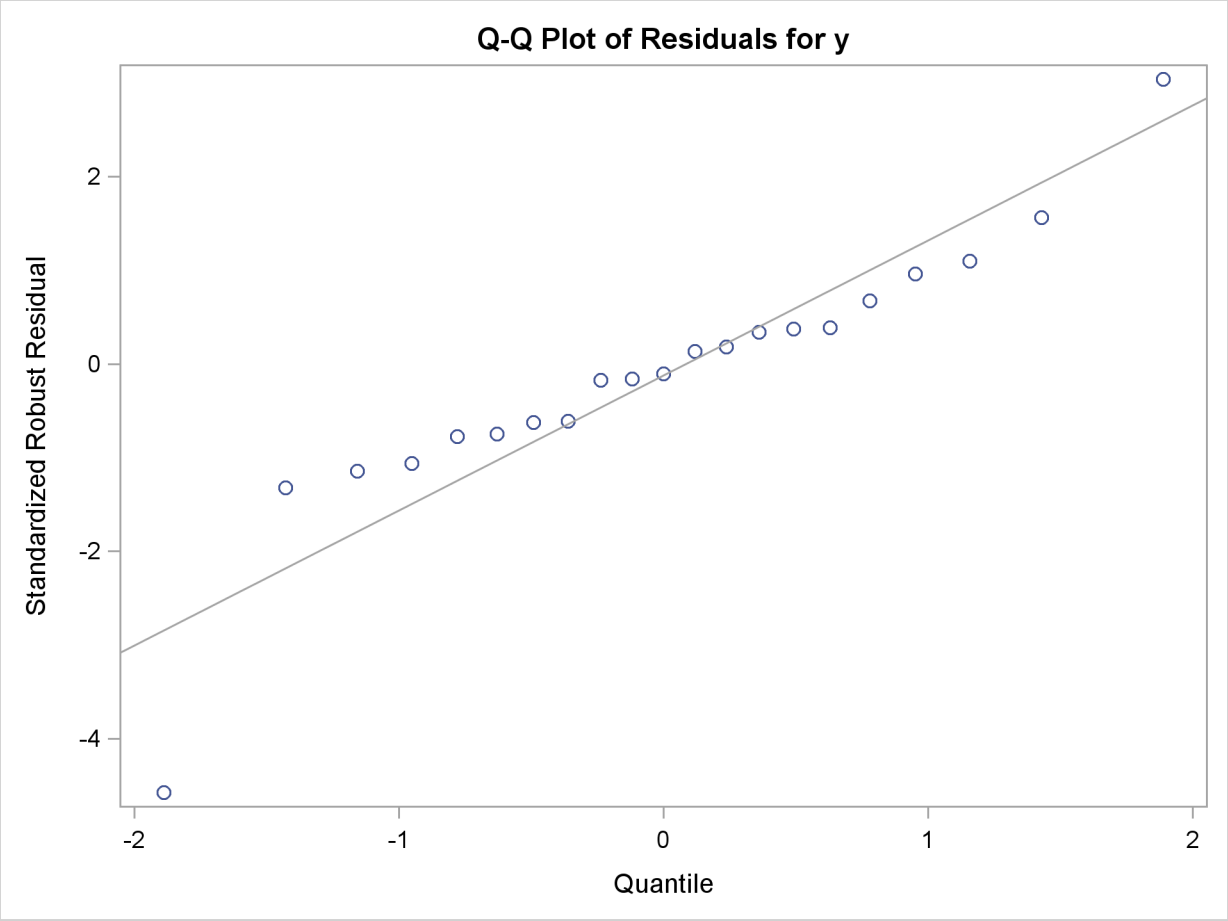
This section illustrates the discussion in the section "Graph Templates" on page 577 in the context of changing the default title and Y-axis label for a Q-Q plot created with PROC ROBUSTREG. Consider again the data set Stack created by the following statements:

```
data stack;
   input  x1 x2 x3 y @@;
   datalines;
80  27  89  42    80  27  88  37    75  25  90  37

... more lines ...

;
```

The following statements request a Q-Q plot for robust residuals created by PROC ROBUSTREG:



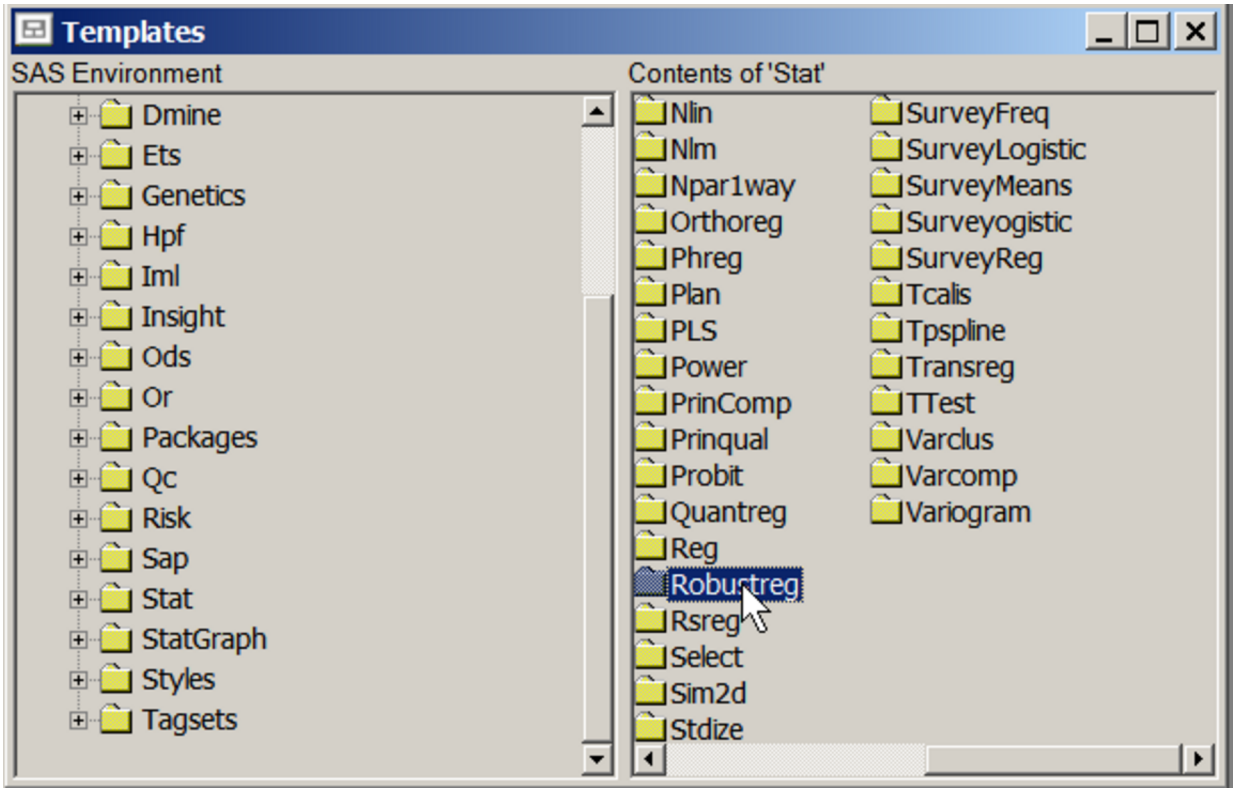
```
ods trace on;
ods graphics on;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;

ods trace off;
```

The Q-Q plot is shown in Output 21.5.1.

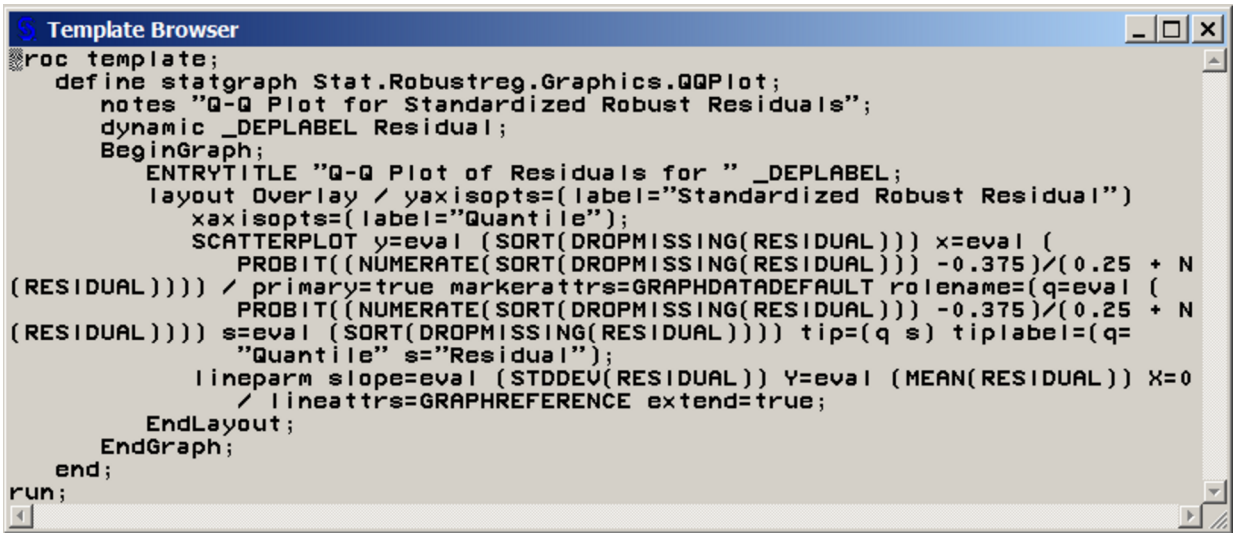
Output 21.5.1 Default Q-Q Plot from PROC ROBUSTREG



The ODS TRACE ON statement requests a record of all the ODS output objects created by PROC ROBUSTREG. The trace output is as follows:

```
Output Added:
-------------
Name:        QQPlot
Label:       Residual Q-Q Plot
Template:    Stat.Robustreg.Graphics.QQPlot
Path:        Robustreg.DiagnosticPlots.QQPlot
-------------
```

ODS Graphics creates the Q-Q plot from an ODS data object named **QQPlot** and a graph template named **Stat.Robustreg.Graphics.QQPlot**, which is the default template provided by SAS. Default templates supplied by SAS are saved in the SASHELP.Tmplmst template library (see the section "Graph Templates" on page 577).



To display the default template definition, open the Templates window by typing **odstemplates** (or **odst** for short) in the command line. Expand SASHELP.Tmplmst and click the **Stat** folder. Output 21.5.2 shows the contents of the **Stat** folder.

Output 21.5.2 The Template Window

Next, open the **Robustreg** folder and then open the **Graphics** folder. Then right-click the `QQPlot` template icon and select **Open**. This opens the Template Browser window shown in Output 21.5.3. You can copy this template to an editor to edit it.

Output 21.5.3 Default Template Definition for Q-Q Plot

Alternatively, you can submit the following statements to display the **QQPlot** template definition in the SAS log:

```
proc template;
   source Stat.Robustreg.Graphics.QQPlot;
run;
```

The SOURCE statement specifies the fully qualified template name. You can copy and paste the template source into the Program Editor and modify it. The template, with a PROC TEMPLATE and RUN statement added, is shown next:

```
proc template;
   define statgraph Stat.Robustreg.Graphics.QQPlot;
      notes "Q-Q Plot for Standardized Robust Residuals";
      dynamic _DEPLABEL Residual;
      BeginGraph;
         ENTRYTITLE "Q-Q Plot of Residuals for " _DEPLABEL;
         layout Overlay / yaxisopts=(label="Standardized Robust Residual")
            xaxisopts=(label="Quantile");
            SCATTERPLOT y=eval (SORT(DROPMISSING(RESIDUAL))) x=eval (
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) / primary=true markerattrs=GRAPHDATADEFAULT
               rolename=(q=eval (
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) s=eval (SORT(DROPMISSING(RESIDUAL))))
               tip=(q s) tiplabel=(q="Quantile" s="Residual");
            lineparm slope=eval (STDDEV(RESIDUAL)) Y=eval (MEAN(RESIDUAL))
               X=0 / lineattrs=GRAPHREFERENCE extend=true;
         EndLayout;
      EndGraph;
   end;
run;
```

In the template, the default title of the Q-Q plot is specified by the ENTRYTITLE statement. The variable _DepLabel is a dynamic variable that provides the name of the dependent variable in the regression analysis. In this case, the name is y. In this template, the label for the axes are specified by the LABEL= suboption of the YAXISOPTS= option for the LAYOUT OVERLAY statement. In other templates, the axis labels come from the column labels of the X-axis and Y-axis columns of the data object. You can see these labels by specifying ODS OUTPUT with the plot data object and running PROC CONTENTS with the resulting SAS data set.

Suppose you want to change the default title to "Analysis of Residuals", and you want the Y-axis label to display the name of the dependent variable. First, replace the ENTRYTITLE statement with the following statement:

```
entrytitle "Analysis of Residuals";
```

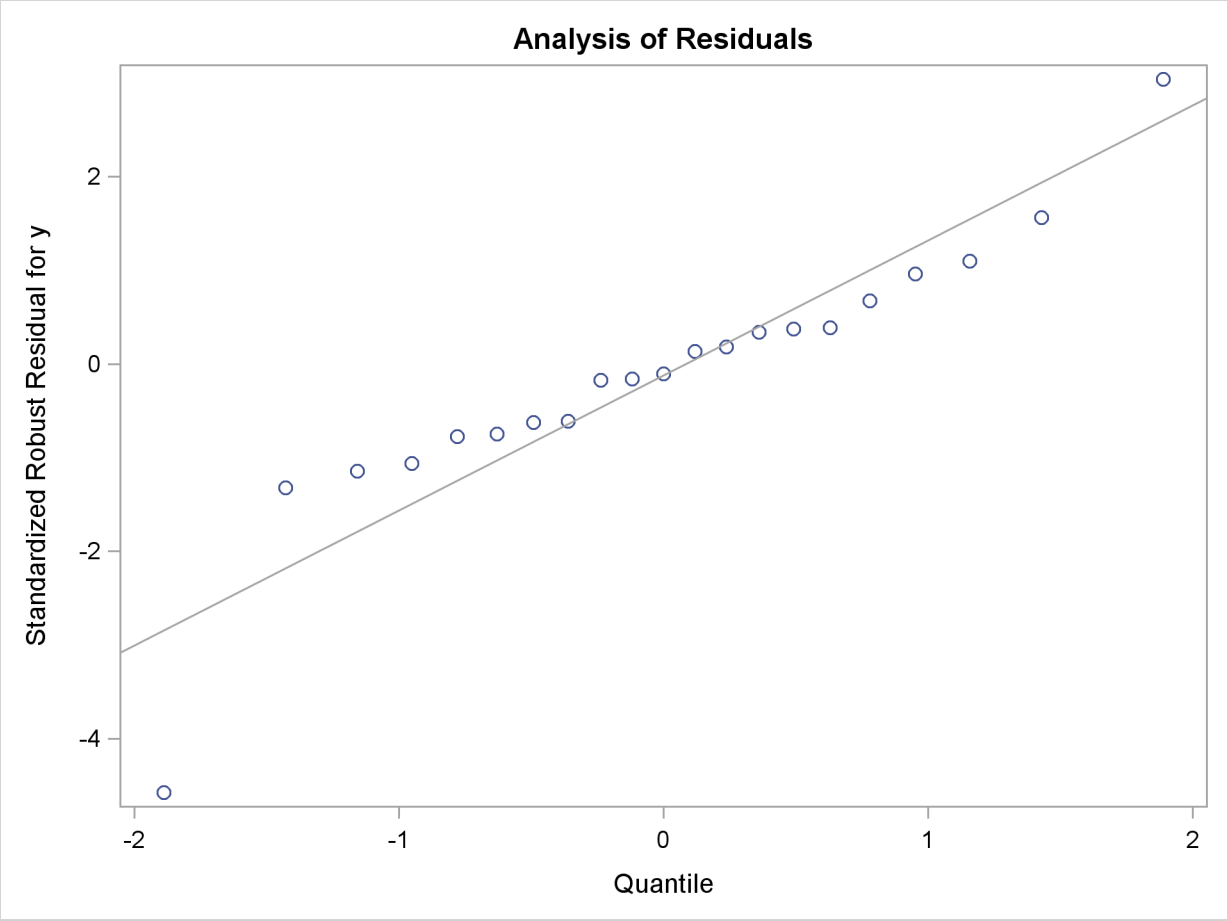
Next, replace the LABEL= suboption with the following:

```
label=("Standardized Robust Residual for " _DEPLABEL)
```

You can use dynamic text variables such as _DepLabel in any text element.

You can then submit the modified template definition as you would any SAS program, for example, by selecting **Submit** from the **Run** menu. After submitting the PROC TEMPLATE statements, you should see the following message in the SAS log:

```
NOTE: STATGRAPH 'Stat.Robustreg.Graphics.QQPlot' has been
  saved to: SASUSER.TEMPLAT
```



For more information about graph definitions and the graph template language, see the section "Graph Templates" on page 577.

Finally, resubmit the PROC ROBUSTREG statements to display the Q-Q plot created with your modified template. The following statements create Output 21.5.4:

```
proc template;
   define statgraph Stat.Robustreg.Graphics.QQPlot;
      notes "Q-Q Plot for Standardized Robust Residuals";
      dynamic _DEPLABEL Residual;
      BeginGraph;
         entrytitle "Analysis of Residuals";
         layout Overlay /
            yaxisopts=(label=("Standardized Robust Residual for " _DEPLABEL))
            xaxisopts=(label="Quantile");
            SCATTERPLOT y=eval (SORT(DROPMISSING(RESIDUAL))) x=eval (
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) / primary=true markerattrs=GRAPHDATADEFAULT
               rolename=(q=eval (
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) s=eval (SORT(DROPMISSING(RESIDUAL))))
               tip=(q s) tiplabel=(q="Quantile" s="Residual");
            lineparm slope=eval (STDDEV(RESIDUAL)) Y=eval (MEAN(RESIDUAL))
               X=0 / lineattrs=GRAPHREFERENCE extend=true;
         EndLayout;
      EndGraph;
   end;
run;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;
```

Output 21.5.4 Q-Q Plot with Modified Title and Y-Axis Label

If you have not changed the default ODS path, the modified template **QQPlot** is used automatically because SASUSER.Templat occurs before SASHELP.Tmplmst in the ODS search path. See the sections "Saving Customized Templates" on page 587, "Using Customized Templates" on page 587, and "Reverting to the Default Templates" on page 588 for more information about the ODS PATH.

You do not need to rerun the PROC ROBUSTREG analysis after you modify a graph template if you have stored the plot in an ODS document. After you modify your template, you can submit the PROC DOCUMENT statements in Example 21.4 to replay the Q-Q plot with the modified template. You can run the following statements to revert to the default template:

```
proc template;
   delete Stat.Robustreg.Graphics.QQPlot;
run;
```

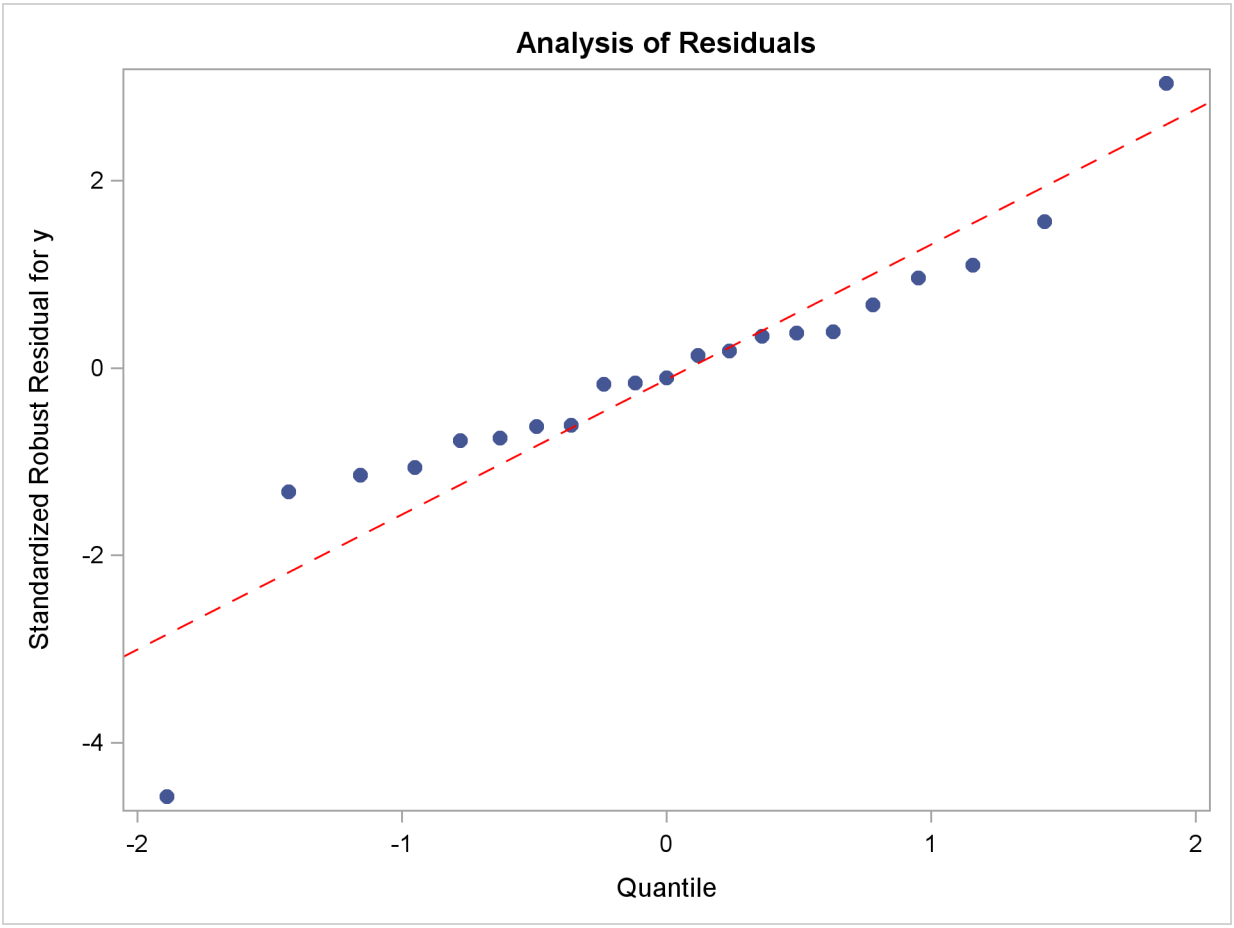
Modifying Colors, Line Styles, and Markers

This section shows you how to customize colors, line attributes, and marker symbol attributes by modifying a graph template. In the **QQPlot** template definition shown in Output 21.5.3, the SCATTERPLOT statement specifies a scatter plot of normal quantiles versus ordered stan-

dardized residuals. The attributes of the marker symbol in the scatter plot are specified by: **MarkerAttrs=GraphDataDefault**. This is a reference to the style element **GraphDataDefault**. See the section "Style Elements and Attributes" on page 555 for more information.

The actual value of the marker symbol depends on the style that you are using. In this case, since the STATISTICAL style is used, the marker symbol is a circle. You can specify a filled circle as the marker symbol by overriding the symbol portion of the style specification as follows: **MarkerAttrs=GraphDataDefault(symbol=CircleFilled)**.

The value of the SYMBOL= option can be any valid marker symbol or a reference to a style attribute of the form **style-element:attribute**. It is recommended that you use style attributes because they are chosen to provide consistency and appropriate emphasis based on display principles for statistical graphics. If you specify values directly in a template, you are overriding the style and you run the risk of creating a graph that is inconsistent with the style definition. For more information about the syntax of the Graph Template Language and style elements for graphics, see the *SAS/GRAPH: Graph Template Language Reference* and the *SAS Output Delivery System: User's Guide*.



Similarly, you can change the line color and pattern with the LINEATTRS= option in the LINEPARM statement. The LINEPARM statement displays a straight line specified by slope and intercept parameters. The following option changes the color of the line to red and the line pattern to dashed, by overriding those aspects of the style specification: **LineAttrs=GraphReference(color=red pattern=dash)**. To see the results, submit the modified template definition and the PROC ROBUSTREG statements as follows to create Output 21.5.5:

```
proc template;
   define statgraph Stat.Robustreg.Graphics.QQPlot;
      notes "Q-Q Plot for Standardized Robust Residuals";
      dynamic _DEPLABEL Residual;
      BeginGraph;
         entrytitle "Analysis of Residuals";
         layout Overlay /
            yaxisopts=(label=("Standardized Robust Residual for " _DEPLABEL))
            xaxisopts=(label="Quantile");
            SCATTERPLOT y=eval (SORT(DROPMISSING(RESIDUAL))) x=eval(
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) / primary=true
               markerattrs=GraphDataDefault(symbol=CircleFilled)
               rolename=(q=eval (
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) s=eval (SORT(DROPMISSING(RESIDUAL))))
               tip=(q s) tiplabel=(q="Quantile" s="Residual");
            lineparm slope=eval (STDDEV(RESIDUAL)) Y=eval (MEAN(RESIDUAL))
               X=0 / lineattrs=GraphReference(color=red pattern=dash)
                     extend=true;
         EndLayout;
      EndGraph;
   end;
run;
```

```
ods graphics on;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;
```

Output 21.5.5 Q-Q Plot with Modified Marker Symbols and Line

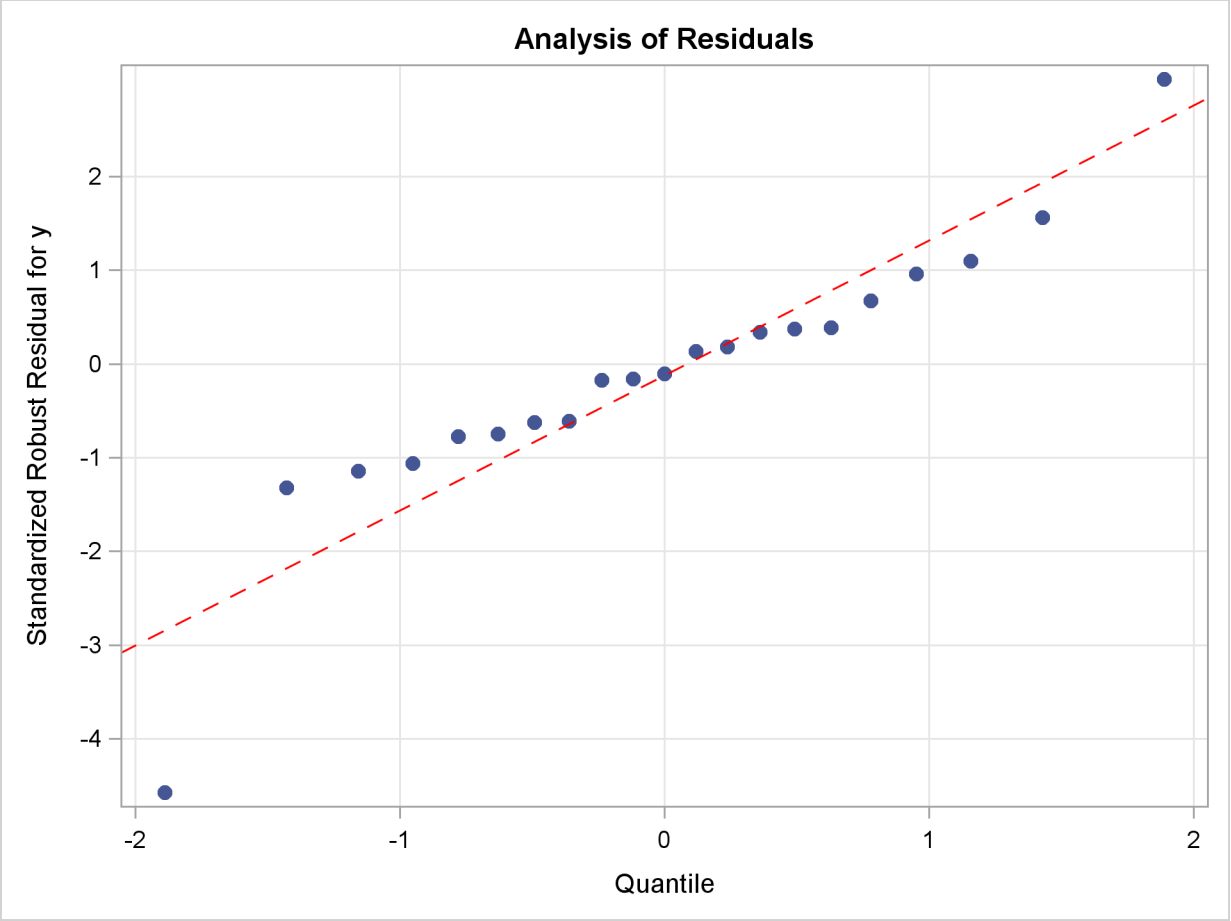
Alternatively, you can replay the plot with PROC DOCUMENT, as in Example 21.4.

Modifying Tick Marks and Grid Lines

This section illustrates how to modify axis tick marks and control grid lines. For example, you can specify the following statement to request tick marks ranging from –4 to 2 in the Y-axis:

```
layout Overlay / yaxisopts=(linearopts=(tickvaluelist=(-4 -3 -2 -1 0 1 2)));
```

The LINEAROPTS= option is used for standard linearly scaled axes (as opposed to log-scaled axes). You use the TICKVALUELIST= to specify the tick marks.



You can control the grid lines by using the GRIDDISPLAY= suboption in the YAXISOPTS= option. Typically, you specify either GRIDDISPLAY=AUTO_OFF (grid lines are not displayed unless the **GraphGridLines** element in the current style contains **DisplayOpts="ON"**) or GRIDDISPLAY=AUTO_ON (grid lines are displayed unless the **GraphGridLines** element in the current style contains **DisplayOpts="OFF"**). Here, the template is modified by specifying GRIDDISPLAY=AUTO_ON for both axes. The following statements produce Output 21.5.6:

```
proc template;
   define statgraph Stat.Robustreg.Graphics.QQPlot;
      notes "Q-Q Plot for Standardized Robust Residuals";
      dynamic _DEPLABEL Residual;
      BeginGraph;
         entrytitle "Analysis of Residuals";
         layout Overlay / yaxisopts=(gridDisplay=Auto_On
            linearopts=(tickvaluelist=(-4 -3 -2 -1 0 1 2))
            label=("Standardized Robust Residual for " _DEPLABEL))
            xaxisopts=(gridDisplay=Auto_On label="Quantile");
            SCATTERPLOT y=eval (SORT(DROPMISSING(RESIDUAL))) x=eval(
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) / primary=true
               markerattrs=GraphDataDefault(symbol=CircleFilled)
               rolename=(q=eval (
               PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/(0.25
               + N(RESIDUAL)))) s=eval (SORT(DROPMISSING(RESIDUAL))))
               tip=(q s) tiplabel=(q="Quantile" s="Residual");
            lineparm slope=eval (STDDEV(RESIDUAL)) Y=eval (MEAN(RESIDUAL))
               X=0 / lineattrs=GraphReference(color=red pattern=dash)
                     extend=true;
         EndLayout;
      EndGraph;
   end;
run;

ods graphics on;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;
```

Output 21.5.6 Q-Q Plot with Modified Y-Axis Tick Marks and Grids

You can restore the default template by running the following step:

```
proc template;
   delete Stat.Robustreg.Graphics.QQPlot;
run;
```

See the section "Modifying the Style to Show Grid Lines" on page 619 for more information about grid lines.

Modifying the Style to Show Grid Lines

The section "Modifying Tick Marks and Grid Lines" on page 618 explains that grid lines in graphs are controlled both by template options and by the style. Some graphs never display grid lines because they would interfere with the display. Some graphs always display grid lines because they are a critical part of the display. In both cases, grid control is so important that the template writer is not willing to give control to the style. If you want to change the grid display setting for these graphs, you must edit their templates. Most templates, however, let the style control the grid lines. They either do not display grid lines unless the style forces them on, or they display grid lines unless the style forces them off. The STATISTICAL, DEFAULT, and most other styles use

the setting **DisplayOpts = "Auto"**. Then templates that specify GRIDDISPLAY=AUTO_OFF (the default) do not display grid lines, and templates that specify GRIDDISPLAY=AUTO_ON do display grid lines. You can easily make a new style with **DisplayOpts = "On"** or **DisplayOpts = "Off"** if you would prefer to see grid lines more or less often. This example shows how to set **DisplayOpts = "On"**.

First, you need to find the style source for setting grid lines. The following step displays the STATISTICAL and DEFAULT styles:

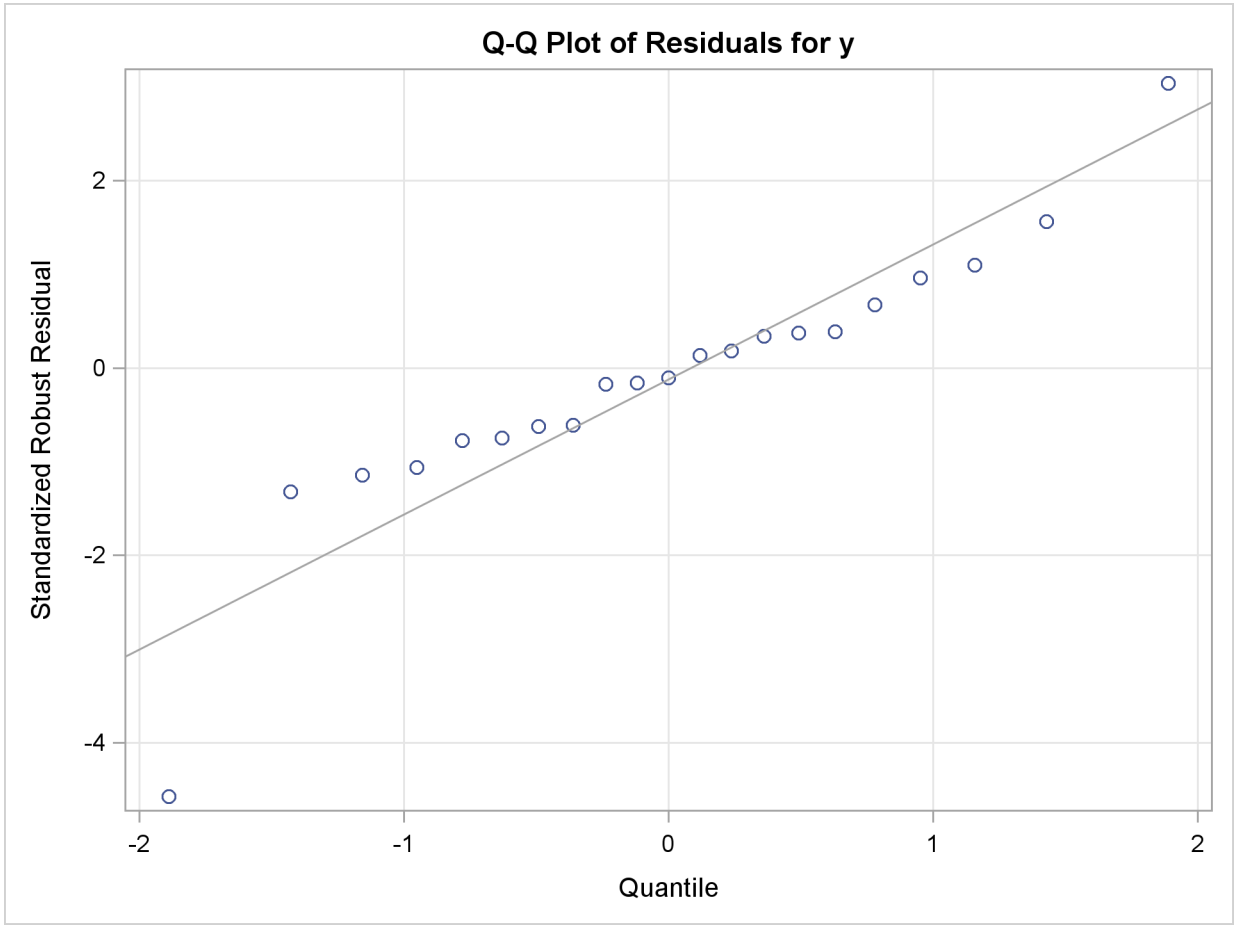
```
proc template;
   source Styles.Statistical;
   source Styles.Default;
run;
```

The advantage of displaying both styles together is you can do one search of the results. If grids are defined in the STATISTICAL style, you will find that first. Otherwise, you will first find the definition in the DEFAULT style. An abridged version of the results follows:

```
. . .
class GraphGridLines /
   displayopts = "auto"
   linethickness = 1px
   linestyle = 1
   contrastcolor = GraphColors('ggrid')
   color = GraphColors('ggrid');
. . .
```

You can use this to create a new style that inherits from the STATISTICAL style, but sets the display options for grids to ON, as in the following example:

```
proc template;
   define style Styles.MyGrids;
      parent=styles.statistical;
      class GraphGridLines /
         displayopts = "on"
         linethickness = 1px
         linestyle = 1
         contrastcolor = GraphColors('ggrid')
         color = GraphColors('ggrid');
   end;
run;
```



You can use this new style as in the following example:

```
ods graphics on;
ods listing style=mygrids;

proc robustreg data=stack plots=qqplot;
   ods select QQPlot;
   model y = x1 x2 x3;
run;
```

The preceding statements produce Output 21.5.7, which shows the Q-Q plot with grid lines displayed. The default graph template, supplied by SAS, is used because the custom template created in the section "Modifying Tick Marks and Grid Lines" on page 618 is deleted at the end of that section.

Output 21.5.7 A Style that Makes Grid Lines the Typical Default

Example 21.6: Customizing Survival Plots

PROC LIFETEST, like other statistical procedures, provides a PLOTS= option and other options for modifying its output without requiring template changes. See Chapter 49, "The LIFETEST Procedure," for more information. Those options are sufficient for most purposes. This example shows ways that you can change the template when those options are not sufficient.

This example changes the default title of the survival plot in PROC LIFETEST from "Product-Limit Survival Estimate" to "Kaplan-Meier Plot" through a template change. Subsequent parts of this example change other aspects of the plot including the legend, inset table, ticks, and the overall layout—all through template changes.

This example uses the BMT data set from the section "Survival Estimate Plot with PROC LIFETEST" on page 504. The following steps create the SAS data set:

```
proc format;
   value risk 1='ALL' 2='AML-Low Risk' 3='AML-High Risk';
run;

data BMT;
   input Group T Status @@;
   format Group risk.;
   label T='Disease Free Time';
   datalines;
1 2081 0 1 1602 0 1 1496 0 1 1462 0 1 1433 0

... more lines ...

;
```

The following statements run PROC LIFETEST to determine the template name:

```
ods graphics on;
ods trace output;

proc lifetest data=BMT plots=survival(cb=hw test);
   time T * Status(0);
   strata Group / test=logrank;
run;

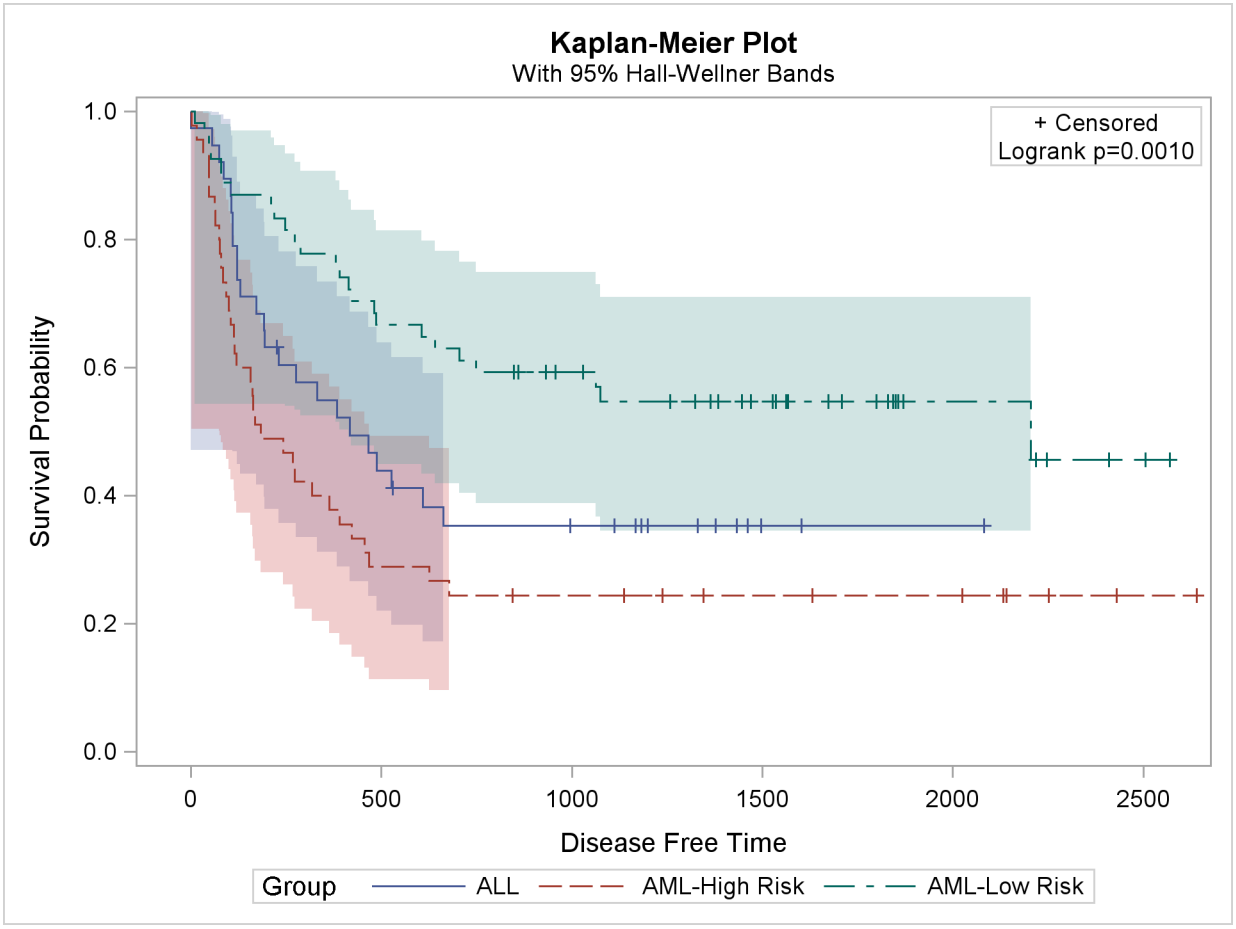
ods trace off;
```

The trace output results (not shown) show that the template name for the survival plot is `Stat.Lifetest.Graphics.ProductLimitSurvival`. The following statements display the template:

```
proc template;
   source Stat.Lifetest.Graphics.ProductLimitSurvival;
run;
```

Modifying the Plot Title

The template source listing is lengthy, but to change the title, you only need to find and modify the ENTRYTITLE statements. Many templates have conditional logic (IF statements, for example) and multiple overlays, so it is important that you find all of the relevant ENTRYTITLE statements.



The following abridged version of the statements show how you redefine the template:

```
proc template;
   define statgraph Stat.Lifetest.Graphics.ProductLimitSurvival;
      dynamic . . .;
      BeginGraph;
         if (NSTRATA=1)
            if (EXISTS(STRATUMID))
            entrytitle "Kaplan-Meier Plot for " STRATUMID;
         else
            entrytitle "Kaplan-Meier Plot";
         endif;
         if (PLOTATRISK)
            entrytitle "with Number of Subjects at Risk" / textattrs=
            GRAPHVALUETEXT;
         endif;
         layout overlay / xaxisopts=(shortlabel=XNAME offsetmin=.05
            linearopts=(viewmax=MAXTIME)) yaxisopts=(label=
            "Survival Probability" shortlabel="Survival" linearopts=(
            viewmin=0 viewmax=1 tickvaluelist=(0 .2 .4 .6 .8 1.0)));
            . . .
         endlayout;
         else
            entrytitle "Kaplan-Meier Plot";
         if (EXISTS(SECONDTITLE))
            entrytitle SECONDTITLE / textattrs=GRAPHVALUETEXT;
         endif;
         layout overlay / xaxisopts=(shortlabel=XNAME offsetmin=.05
            linearopts=(viewmax=MAXTIME)) yaxisopts=(label=
            "Survival Probability" shortlabel="Survival" linearopts=(
            viewmin=0 viewmax=1 tickvaluelist=(0 .2 .4 .6 .8 1.0)));
            . . .
         endlayout;
         endif;
      EndGraph;
   end;
run;

proc lifetest data=BMT plots=survival(cb=hw test);
   time T * Status(0);
   strata Group / test=logrank;
run;
```

The preceding steps create Output 21.6.1.

Output 21.6.1 Kaplan-Meier Plot

You can restore the default template by running the following step:

```
proc template;
   delete Stat.Lifetest.Graphics.ProductLimitSurvival;
run;
```

Modifying the Axes, Legend, and Inset Table

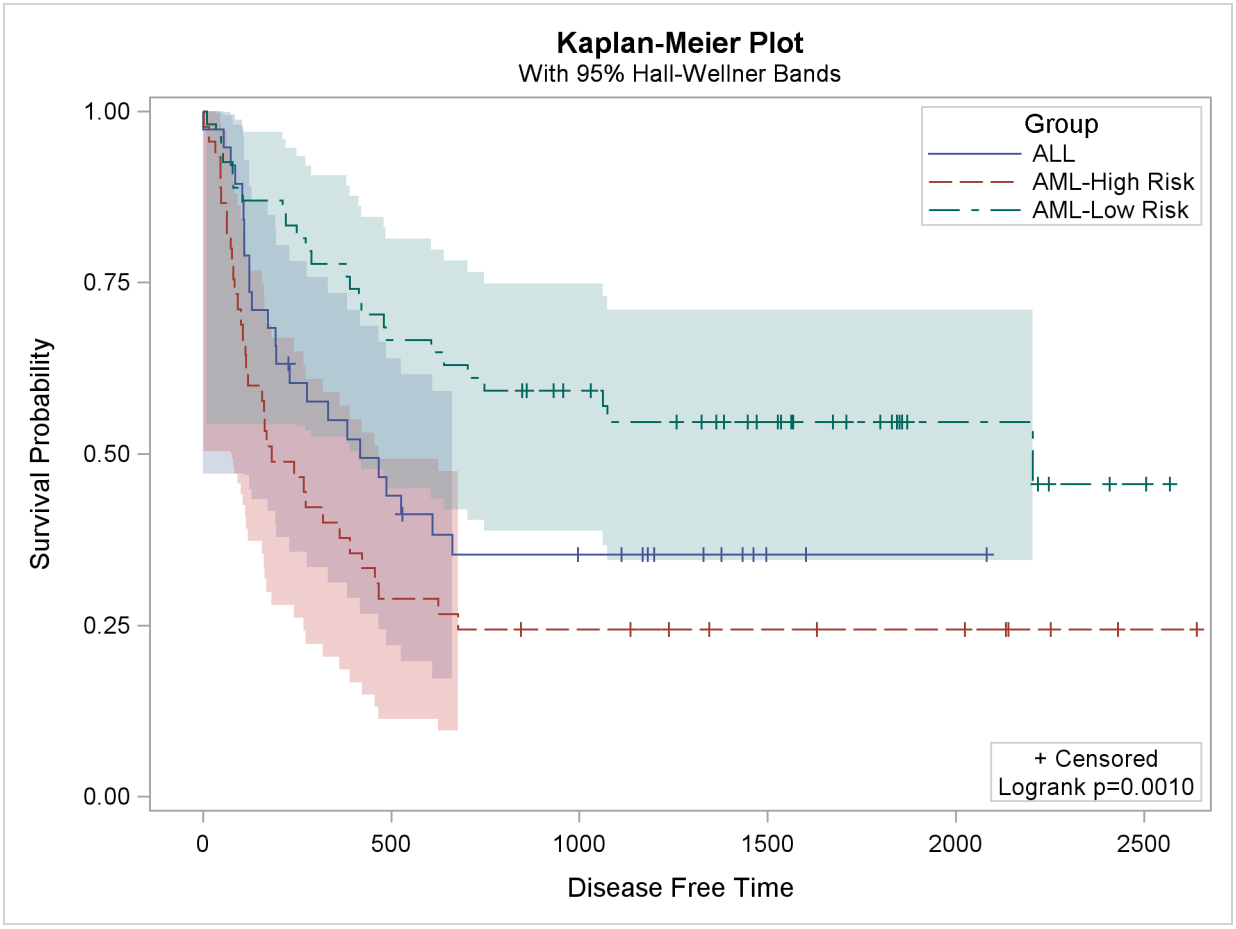
You can also change other aspects of this plot. The template options **linearopts=(viewmin=0 viewmax=1 tickvaluelist=(0 .2 .4 .6 .8 1.0))** control the minimum value displayed, the maximum value displayed, and the ticks. You can change the range of the vertical axis or the ticks by changing this option everywhere that it occurs. The following specification changes the ticks but not the range of values: **linearopts=(viewmin=0 viewmax=1 tickvaluelist=(0 .25 .5 .75 1.0))**.

There are many other features of this template that you can easily modify. For example, you can change the locations of the inset table and the legend, which are controlled by the following two statements, respectively:

```
layout gridded / rows=2 autoalign=(TOPRIGHT BOTTOMLEFT TOP BOTTOM)
                 border=true BackgroundColor=GraphWalls:Color Opaque=true;

DiscreteLegend "Survival" / title=GROUPNAME location=outside;
```

The LAYOUT GRIDDED statement produces the two-row inset table displayed in the top right corner. The AUTOALIGN= option provides the preferred locations inside the plot for this table, ordered from most preferred to least preferred. You can add new locations or rearrange the existing locations. The DISCRETELEGEND statement places the legend outside of the plot. You can move it inside and print only one legend entry across each row instead of three. This has the effect of changing the orientation of the legend from a row to a column. The modified statements are as follows:



```
layout gridded / rows=2
   autoalign=(BottomRight TOPRIGHT BOTTOMLEFT TOP BOTTOM)
    border=true BackgroundColor=GraphWalls:Color Opaque=true;

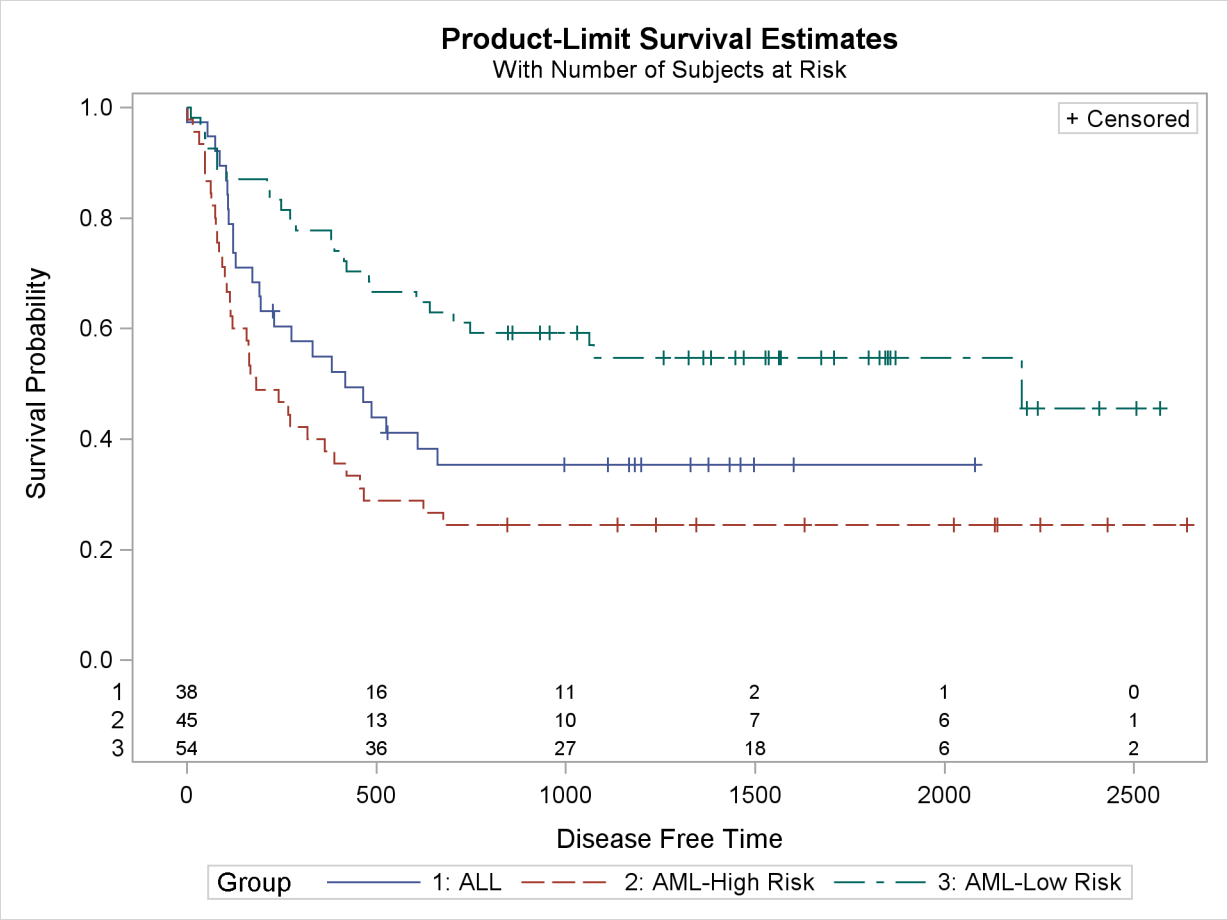
DiscreteLegend "Survival" / title=GROUPNAME across=1 location=inside
    autoalign=(TopRight BottomLeft Top Bottom);
```

The full template with these modifications is not shown here, but the new template along with the following statements produce Output 21.6.2:

```
proc lifetest data=BMT plots=survival(cb=hw test);
   time T * Status(0);
   strata Group / test=logrank;
run;
```

Output 21.6.2 Kaplan-Meier Plot with Legend Modifications

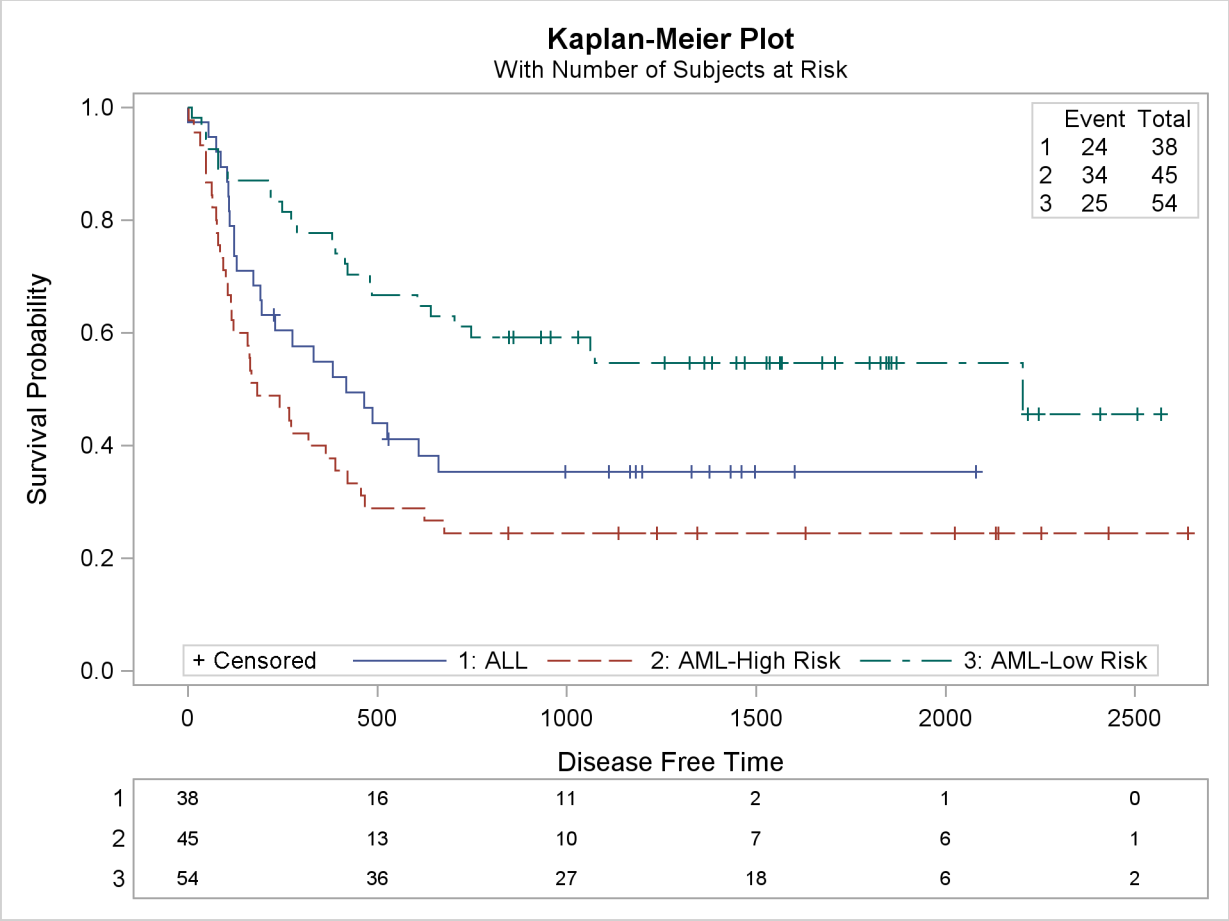
You can restore the default template by running the following step:



```
proc template;
   delete Stat.Lifetest.Graphics.ProductLimitSurvival;
run;
```

Modifying the Layout and Adding a New Inset Table

Example 49.2 of Chapter 49, "The LIFETEST Procedure," uses the following statements to make the plot shown in Output 21.6.3:



```
proc lifetest data=BMT plots=survival(atrisk=0 to 2500 by 500);
   ods select SurvivalPlot;
   time T * Status(0);
   strata Group / test=logrank adjust=sidak;
   run;
```

Output 21.6.3 Default Survival Plot with Number of Subjects At Risk

Output 21.6.3 displays the estimated disease-free survival functions for the three leukemia groups with the number of subjects at risk at 0, 500, 1000, 1500, 2000, and 2500 days. The rest of this example shows you how to modify the template to produce the plot displayed in Output 21.6.4. This new plot differs from the old plot in several ways. It has a new inset table in the top right corner with the number of observations and the number of events in the each stratum. The legend has been moved inside the plot and combined with the old inset table that showed the marker for censored observations. The information about the subjects at risk has been moved into a table below the plot. Also, the title change from the first part of the example has been retained.

Output 21.6.4 Kaplan-Meier Plot with a Different Layout

These changes are easy, if they are broken down and performed one step at a time. You can use the template with the new title from the beginning of this example as a starting point for these modifications. Before proceeding, you should notice the outermost layouts of this template, which are shown next:

```
proc template;
   define statgraph Stat.Lifetest.Graphics.ProductLimitSurvival;
      . . .
      BeginGraph;
         if (NSTRATA=1)
            . . .
         layout overlay / . . .;
            . . .
         endlayout;
         else
            . . .
         layout overlay / . . .;
            . . .
         endlayout;
         endif;
      EndGraph;
   end;
run;
```

This template consists of two major parts: a layout that is used when there is only one stratum and a layout that is used with more than one stratum. Every section of this example has more than one stratum, so it is the changes to the second layout (or more precisely the ELSE portion of the template) that are affecting the results.

PROC LIFETEST makes available a series of dynamic variables that it does not display by default. See the section "Additional Dynamic Variables for Survival Plots Using ODS Graphics" on page 3157 in Chapter 49, "The LIFETEST Procedure," for information about these dynamic variables. You can use these dynamic variables to add the new inset table to the plot. The following step creates the table in a gridded layout that is added to the second layout:

```
proc template;
   define statgraph Stat.Lifetest.Graphics.ProductLimitSurvival;
      . . .
      BeginGraph;
         if (NSTRATA=1)
            . . .
         layout overlay / . . .;
            . . .
         endlayout;
         else
            . . .
         layout overlay / . . .;
            . . .
            dynamic NObs1 NObs2 NObs3 NEvent1 NEvent2 NEvent3;
            layout gridded / columns=3 border=TRUE autoalign=(TopRight);
               entry "";      entry "Event";   entry "Total";
               entry "1";     entry NEvent1;   entry NObs1;
               entry "2";     entry NEvent2;   entry NObs2;
               entry "3";     entry NEvent3;   entry Nobs3;
            endlayout;
         endlayout;
         endif;
      EndGraph;
   end;
run;
```

The at-risk information in Output 21.6.3 is produced by a BLOCKPLOT statement in the second layout. The modified template, with the first layout removed (since it is not needed in this example) and the BLOCKPLOT statement displayed is as follows:

```
proc template;
   define statgraph Stat.Lifetest.Graphics.ProductLimitSurvival;
      . . .
      BeginGraph;
         layout overlay / . . .;
            . . .
            if (PLOTATRISK)
               innermargin / align=bottom;
               blockplot x=TATRISK block=ATRISK / class=CLASSATRISK
                  repeatedvalues=true display=(label values)
                  valuehalign=start valuefitpolicy=truncate
                  labelposition=left labelattrs=GRAPHVALUETEXT
                  valueattrs=GRAPHDATATEXT(size=7pt)
```

```
                  includemissingclass=false;
               endinnermargin;
               endif;
               . . .
               dynamic NObs1 NObs2 NObs3 NEvent1 NEvent2 NEvent3;
               layout gridded / columns=3 border=TRUE autoalign=(TopRight);
                  entry "";      entry "Event";   entry "Total";
                  entry "1";     entry NEvent1;   entry NObs1;
                  entry "2";     entry NEvent2;   entry NObs2;
                  entry "3";     entry NEvent3;   entry Nobs3;
               endlayout;
            endlayout;
         EndGraph;
      end;
   run;
```

In the next step, the at-risk information is moved out of the plot and into a table below the plot. The template is given a new overall layout—a LAYOUT LATTICE that has two panels stacked vertically, one for the plot and one for the at-risk information. Using ROWWEIGHTS=(.85 .15), the plot on top occupies 85% of the display and the at-risk information in the second panel occupies 15%. The option COLUMNDATARANGE=UNIONALL is used to create a common axis across the two panels. In these next steps, you also move the legend inside (similar to the previous part of this example) and rearrange the three inset boxes. The new template structure is as follows:

```
proc template;
   define statgraph Stat.Lifetest.Graphics.ProductLimitSurvival;
      . . .
      BeginGraph;
         . . .
         layout lattice /  rows=2 columns=1 columndatarange=unionall
                           rowweights=(.85 .15);

            layout overlay / . . .;
               . . .
               DiscreteLegend "Survival" / location=inside
                              autoalign=(BottomRight);
               . . .
               layout gridded / rows=1 autoalign=(BottomLeft)
                     border=true BackgroundColor=GraphWalls:Color
                     Opaque =true;
                  entry "+ Censored";
               endlayout;
               . . .
               dynamic NObs1 NObs2 NObs3 NEvent1 NEvent2 NEvent3;
               layout gridded / columns=3 border=TRUE autoalign=(TopRight);
                  entry "";      entry "Event";   entry "Total";
                  entry "1";     entry NEvent1;   entry NObs1;
                  entry "2";     entry NEvent2;   entry NObs2;
                  entry "3";     entry NEvent3;   entry Nobs3;
               endlayout;
            endlayout;

            layout overlay / xaxisopts=(display=none);
               blockplot x=TATRISK block=ATRISK / class=CLASSATRISK
```

```
                    repeatedvalues=true display=(label values)
                    valuehalign=start valuefitpolicy=truncate
                    labelposition=left labelattrs=GRAPHVALUETEXT
                    valueattrs=GRAPHDATATEXT(size=7pt)
                    includemissingclass=false;
            endlayout;
         endlayout;
      EndGraph;
   end;
run;
```

You can further simplify the plot by removing the title from the legend (which is currently the variable name Group) and instead adding "+ Censored" (the contents of the inset table) to the legend in place of the title, as in the following statement:

```
DiscreteLegend "Survival" / title="+ Censored"
   titleattrs=GraphValueText location=inside autoalign=(Bottom);
```

The option TITLEATTRS=GRAPHVALUETEXT is specified so that the "+ Censored" appears in the same font as the other entries in the legend and appears to be just another part of the legend. All of the statements for making the old inset table can now be removed from the template. The full template also plots bands, which are not used in this example, so they can be removed as well. The resulting template is as follows:

```
proc template;
   define statgraph Stat.Lifetest.Graphics.ProductLimitSurvival;

      dynamic NStrata xName plotAtRisk plotCensored plotCL plotHW plotEP
         labelCL labelHW labelEP maxTime StratumID classAtRisk plotBand
         plotTest GroupName yMin Transparency SecondTitle TestName pValue;

      BeginGraph;

         entrytitle "Kaplan-Meier Plot";
         if (EXISTS(SECONDTITLE))
            entrytitle SECONDTITLE / textattrs=GRAPHVALUETEXT;
         endif;

         layout lattice / rows=2 columns=1 columndatarange=unionall
                          rowweights=(.85 .15);

            layout overlay / xaxisopts=(shortlabel=XNAME offsetmin=.05
               linearopts=(viewmax=MAXTIME)) yaxisopts=(label=
               "Survival Probability" shortlabel="Survival" linearopts=(
               viewmin=0 viewmax=1 tickvaluelist=(0 .2 .4 .6 .8 1.0)));

               stepplot y=SURVIVAL x=TIME / group=STRATUM index=STRATUMNUM
                  name="Survival" rolename=(_tip1=ATRISK _tip2=EVENT) tip=(y
                  x Time _tip1 _tip2);

               if (PLOTCENSORED)
                  scatterplot y=CENSORED x=TIME / group=STRATUM index=
```

```
                  STRATUMNUM markerattrs=(symbol=plus);
               endif;

               DiscreteLegend "Survival" / title="+ Censored"
                  titleattrs=GraphValueText location=inside
                  autoalign=(BOTTOM);

               dynamic NObs1 NObs2 NObs3 NEvent1 NEvent2 NEvent3;
               layout gridded / columns=3 border=TRUE autoalign=(TopRight);
                  entry "";      entry "Event";   entry "Total";
                  entry "1";     entry NEvent1;   entry NObs1;
                  entry "2";     entry NEvent2;   entry NObs2;
                  entry "3";     entry NEvent3;   entry Nobs3;
               endlayout;
            endlayout;

            layout overlay / xaxisopts=(display=none);
               blockplot x=TATRISK block=ATRISK / class=CLASSATRISK
                     repeatedvalues=true display=(label values)
                     valuehalign=start valuefitpolicy=truncate
                     labelposition=left labelattrs=GRAPHVALUETEXT
                     valueattrs=GRAPHDATATEXT(size=7pt)
                     includemissingclass=false;
            endlayout;
         endlayout;
      EndGraph;
   end;
run;
```

The following step uses the new template to create the desired plot:

```
proc lifetest data=BMT plots=survival(atrisk=0 to 2500 by 500);
   ods select SurvivalPlot;
   time T * Status(0);
   strata Group / test=logrank adjust=sidak;
   run;
```

The plot is displayed in Output 21.6.4 at the beginning of this section.

This example removed a great deal of functionality from the default template, so that the final, modified template would be relatively simple and understandable. This is not necessary. The template could have been modified without deleting the first LAYOUT OVERLAY and other statements. The strategy for template modification illustrated in this example can be applied to any complicated template: identify the overall structure, isolate the relevant pieces, and then make changes in stages. Since the modified template will no longer work for all analyses, it is important that you delete it when you are done, as in the following example:

```
proc template;
   delete Stat.Lifetest.Graphics.ProductLimitSurvival;
run;
```

Example 21.7: Customizing Panels

This example illustrates how to modify the regression fit diagnostics panel shown in Figure 21.1 so that it displays a subset of the component plots. The original panel consists of eight plots and a summary statistics box. The ODS trace output from PROC REG shown previously shows that the template for the diagnostics panel is **Stat.REG.Graphics.DiagnosticsPanel**. The following statements display the template:

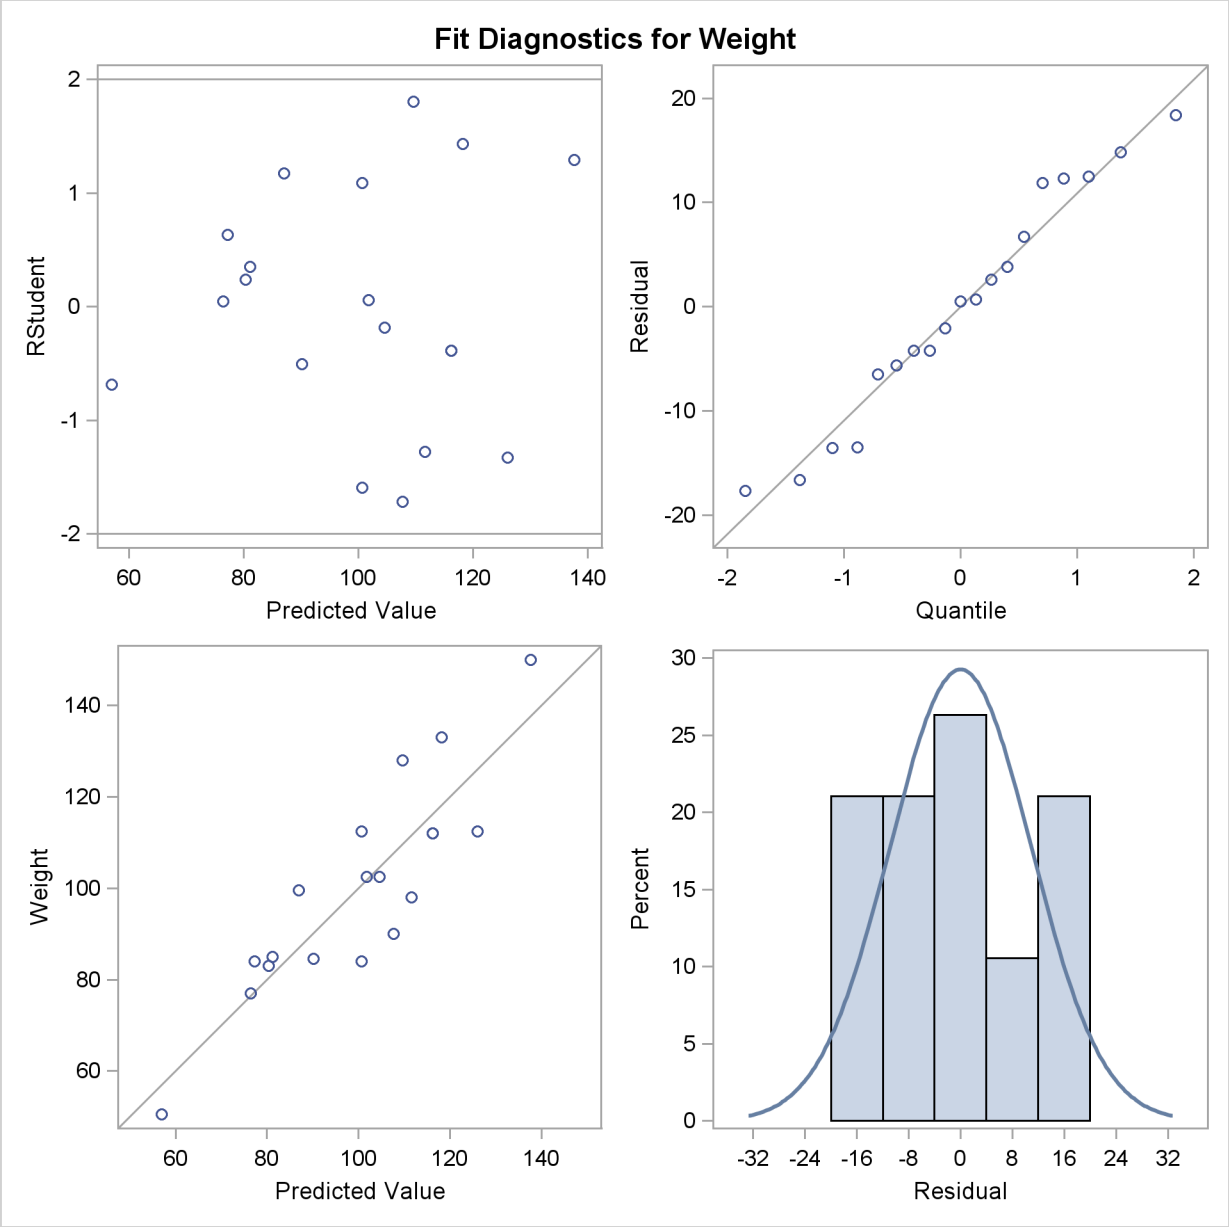
```
proc template;
   source Stat.REG.Graphics.DiagnosticsPanel;
run;
```

An abridged version of the results is shown next:

```
define statgraph Stat.Reg.Graphics.DiagnosticsPanel;
   notes "Diagnostics Panel";
   dynamic . . .;
   BeginGraph / designheight=defaultDesignWidth;
      entrytitle halign=left textattrs=GRAPHVALUETEXT _MODELLABEL
         halign=center textattrs=GRAPHTITLETEXT "Fit Diagnostics"
         " for " _DEPNAME;
      layout lattice / columns=3 rowgutter=10 columngutter=10
         shrinkfonts=true rows=3;
         layout overlay / xaxisopts=(shortlabel='Predicted');
            . . .
         endlayout;
         layout overlay / xaxisopts=(shortlabel='Predicted');
            . . .
         endlayout;
         layout overlay / xaxisopts=(label='Leverage' offsetmax=0.05)
            . . .
         endlayout;
         layout overlay / yaxisopts=(label="Residual" shortlabel=
            "Resid") xaxisopts=(label="Quantile");
            . . .
         endlayout;
         layout overlayequated / xaxisopts=(shortlabel='Predicted')
            . . .
         endlayout;
         layout overlay / xaxisopts=(linearopts=(integer=true) label=
            "Observation" shortlabel="Obs" offsetmax=0.05) yaxisopts=(
            offsetmin=0.05 offsetmax=0.05);
            . . .
         endlayout;
         layout overlay / xaxisopts=(label="Residual") yaxisopts=(label
            ="Percent");
            . . .
         endlayout;
         layout lattice / columns=2 rows=1 rowdatarange=unionall
            columngutter=0;
            . . .
         endlayout;
         if (_SHOWSTATS =1)
```

```
            layout overlay;
            . . .
         endLayout;
         endif;
         if (_SHOWSTATS = 2)
            layout overlay / yaxisopts=(gridDisplay=auto_off label=
            "Residual");
            . . .
         endlayout;
         endif;
      endlayout;
   EndGraph;
end;
```

The outermost components of the template are a BEGINGRAPH/ENDGRAPH block with a lattice layout with ROWS=3 and COLUMNS=3 that defines the 3×3 panel of plots. Inside that are nine layouts, one for each cell, the last of which is conditionally defined. The LAYOUT statements define the components of the panel from left to right and top to bottom. You can eliminate some of the panels and produce a 2×2 panel as follows:



```
proc template;
   define statgraph Stat.Reg.Graphics.DiagnosticsPanel;
      notes "Diagnostics Panel";
      dynamic _DEPLABEL _DEPNAME _MODELLABEL _OUTLEVLABEL _TOTFREQ _NPARM
         _NOBS _OUTCOOKSDLABEL _SHOWSTATS _NSTATSCOLS _DATALABEL _SHOWNObs
         _SHOWTOTFREQ _SHOWNParm _SHOWEDF _SHOWMSE _SHOWRSquare
         _SHOWAdjRSq _SHOWSSE _SHOWDepMean _SHOWCV _SHOWAIC _SHOWBIC
         _SHOWCP _SHOWGMSEP _SHOWJP _SHOWPC _SHOWSBC _SHOWSP _EDF _MSE
         _RSquare _AdjRSq _SSE _DepMean _CV _AIC _BIC _CP _GMSEP _JP _PC
         _SBC _SP;
      BeginGraph / designheight=defaultDesignWidth;
         entrytitle halign=left textattrs=GRAPHVALUETEXT _MODELLABEL
            halign=center textattrs=GRAPHTITLETEXT "Fit Diagnostics"
            " for " _DEPNAME;
         layout lattice / columns=2 rowgutter=10 columngutter=10
            shrinkfonts=true rows=2;
            layout overlay / xaxisopts=(shortlabel='Predicted');
               referenceline y=-2;
               referenceline y=2;
               scatterplot y=RSTUDENT x=PREDICTEDVALUE / primary=true
                  datalabel=_OUTLEVLABEL rolename=(_tip1=OBSERVATION _id1=
                  ID1 _id2=ID2 _id3=ID3 _id4=ID4 _id5=ID5) tip=(y x _tip1
                  _id1 _id2 _id3 _id4 _id5);
            endlayout;
            layout overlay / yaxisopts=(label="Residual" shortlabel=
               "Resid") xaxisopts=(label="Quantile");
               lineparm slope=eval (STDDEV(RESIDUAL)) y=eval (
                  MEAN(RESIDUAL)) x=0 / extend=true lineattrs=
                  GRAPHREFERENCE;
               scatterplot y=eval (SORT(DROPMISSING(RESIDUAL))) x=eval (
                  PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)/
                  (0.25 + N(RESIDUAL)))) / markerattrs=GRAPHDATADEFAULT
                  primary=true
                  rolename=(s=eval (SORT(DROPMISSING(RESIDUAL))) nq=eval (
```

```
                PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL))) -0.375)
                /(0.25 + N(RESIDUAL)))))) tiplabel=(nq="Quantile"
                s="Residual")
                tip=(nq s);
            endlayout;
            layout overlayequated / xaxisopts=(shortlabel='Predicted')
               yaxisopts=(label=_DEPLABEL shortlabel="Observed")
               equatetype=square;
               lineparm slope=1 x=0 y=0 / extend=true lineattrs=
                  GRAPHREFERENCE;
               scatterplot y=DEPVAR x=PREDICTEDVALUE / primary=true
                  datalabel=_OUTLEVLABEL rolename=(_tip1=OBSERVATION _id1=
                  ID1 _id2=ID2 _id3=ID3 _id4=ID4 _id5=ID5) tip=(y x _tip1
                  _id1 _id2 _id3 _id4 _id5);
            endlayout;
            layout overlay / xaxisopts=(label="Residual") yaxisopts=(label
               ="Percent");
               histogram RESIDUAL / primary=true;
               densityplot RESIDUAL / name="Normal" legendlabel="Normal"
                  lineattrs=GRAPHFIT;
            endlayout;
         endlayout;
      EndGraph;
   end;
run;

proc reg data=sashelp.class;
   model Weight = Height;
run; quit;
```

This template plots the residuals by predicted values, the Q-Q plot, the actual by predicted plot, and the residual histogram. The results are shown in Output 21.7.1.

Output 21.7.1 Diagnostics Panel with Four Plots

This new template is a straightforward modification of the original template. The COLUMNS=2 and ROWS=2 options in the LAYOUT LATTICE statement request a 2×2 lattice. The LAYOUT statement blocks for components 1, 3, 6, 8, and 9 are deleted. **NOTE:** You do not need to understand every aspect of a template to modify it if you can recognize the overall structure and a few key options.

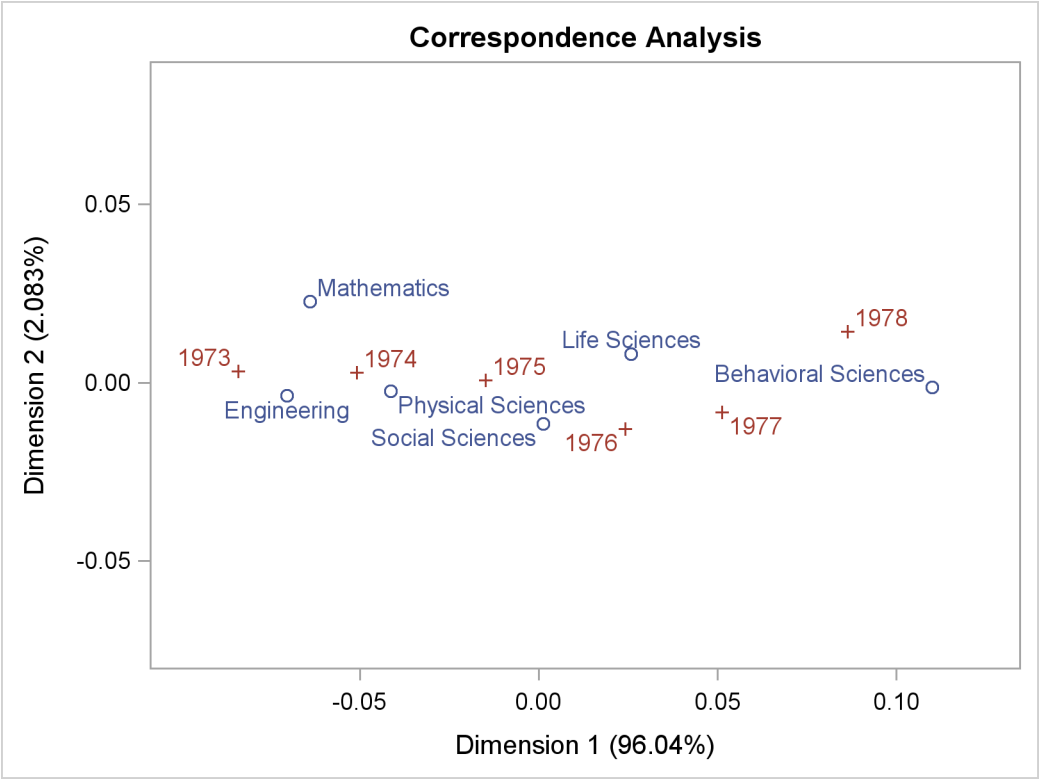
You can restore the original template as follows:

```
proc template;
   delete Stat.REG.Graphics.DiagnosticsPanel;
run;
```

Example 21.8: Customizing Axes and Reference Lines

This example illustrates several ways that you can change the plot axes in a scatter plot. The example uses PROC CORRESP to perform a correspondence analysis. It is taken from the section "Getting Started: CORRESP Procedure" on page 1320 of Chapter 30, "The CORRESP Procedure." It uses the following data:

```
title "Number of Ph.D.'s Awarded from 1973 to 1978";



data PhD;
   input Science $ 1-19 y1973-y1978;
   label y1973 = '1973'
         y1974 = '1974'
         y1975 = '1975'
         y1976 = '1976'
         y1977 = '1977'
         y1978 = '1978';
   datalines;
Life Sciences       4489 4303 4402 4350 4266 4361
Physical Sciences   4101 3800 3749 3572 3410 3234
Social Sciences     3354 3286 3344 3278 3137 3008
Behavioral Sciences 2444 2587 2749 2878 2960 3049
Engineering         3338 3144 2959 2791 2641 2432
Mathematics         1222 1196 1149 1003  959  959
;
```

The following steps perform the correspondence analysis and create Output 21.8.1:

```
ods graphics on;
ods trace on;

proc corresp data=PhD short;
   ods select configplot;
   var y1973-y1978;
   id Science;
run;
```

Output 21.8.1 Default Scatter Plot

The trace output for this step (not shown) shows that the template for this plot is **Stat.Corresp.Graphics.Configuration**. The following step displays this template:

```
proc template;
   source Stat.Corresp.Graphics.Configuration;
run;
```

The results are as follows:

```
define statgraph Stat.Corresp.Graphics.Configuration;
   dynamic xVar yVar head legend;
   begingraph;
      entrytitle HEAD;
      layout overlayequated / equatetype=fit xaxisopts=(offsetmin=0.1
         offsetmax=0.1) yaxisopts=(offsetmin=0.1 offsetmax=0.1);
         scatterplot y=YVAR x=XVAR / group=GROUP index=INDEX
            datalabel=LABEL datalabelattrs=GRAPHVALUETEXT
            name="Type" tip=(y x datalabel group)
            tiplabel=(group="Point");
         if (LEGEND)
            discretelegend "Type";
         endif;
      endlayout;
   endgraph;
end;
```

You can add reference lines to the scatter plot at specified X and Y values by using the REFERENCELINE statement, as in the following example:

```
proc template;
   define statgraph Stat.Corresp.Graphics.Configuration;
      dynamic xVar yVar head legend;
      begingraph;
         entrytitle HEAD;
         layout overlayequated / equatetype=fit xaxisopts=(offsetmin=0.1
            offsetmax=0.1) yaxisopts=(offsetmin=0.1 offsetmax=0.1);

            referenceline x=0;
            referenceline y=0;

            scatterplot y=YVAR x=XVAR / group=GROUP index=INDEX
               datalabel=LABEL datalabelattrs=GRAPHVALUETEXT
               name="Type" tip=(y x datalabel group)
               tiplabel=(group="Point");
            if (LEGEND)
               discretelegend "Type";
            endif;
         endlayout;
      endgraph;
   end;
run;

proc corresp data=PhD short;
   ods select configplot;
   var y1973-y1978;
   id Science;
run;
```

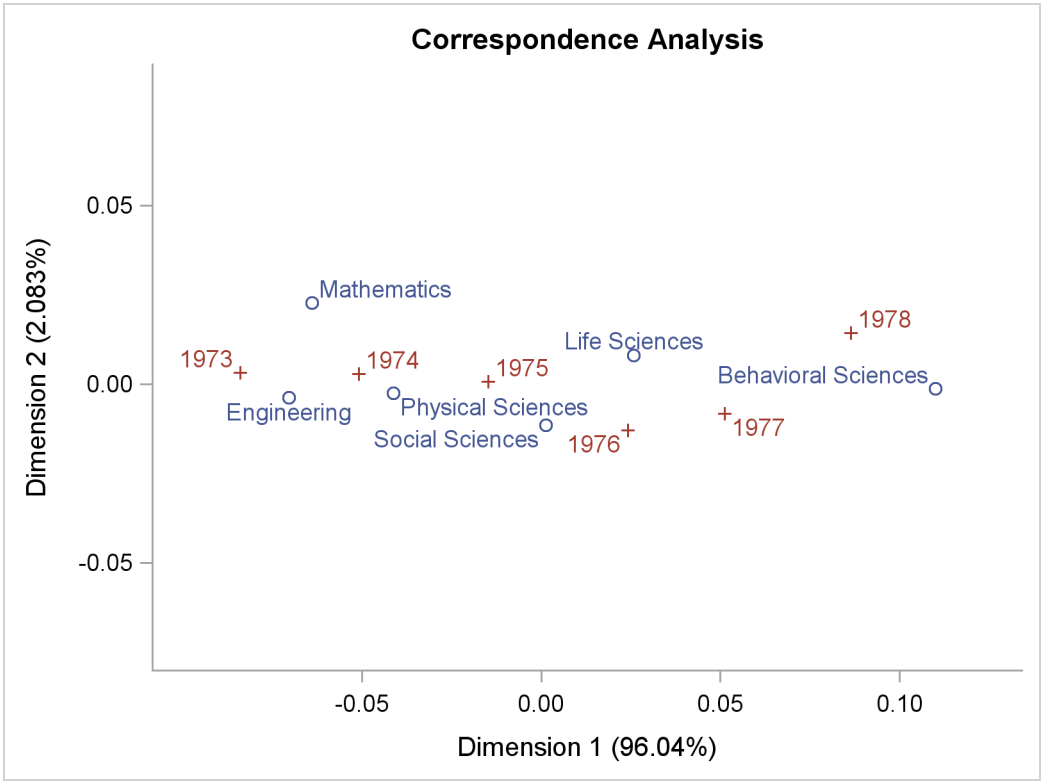
When you modify templates, it is important to note that the order of the statements within the LAYOUT OVERLAYEQUATED (or more typically, the LAYOUT OVERLAY) is significant. Here, the reference lines are added before the scatter plot so that the reference lines are drawn before the scatter plot. Consequently, labels and markers that coincide with the reference lines are drawn over the reference lines. The results, with reference lines, are displayed in Output 21.8.2.

Output 21.8.2 Scatter Plot with Reference Lines Added

You can restore the default graph template as follows:

```
proc template;
   delete Stat.Corresp.Graphics.Configuration;
run;
```

The next steps show how you can change the style so that a frame is not shown:



```
proc template;
   define style noframe;
      parent=styles.statistical;
      style graphwalls from graphwalls / frameborder=off;
   end;
run;

ods listing style=noframe;

proc corresp data=PhD short;
   ods select configplot;
   var y1973-y1978;
   id Science;
run;
```

The results, shown in Output 21.8.3, display an X-axis and a Y-axis without a frame. Unlike the previous change, which affects only the **ConfigPlot** display, this change affects all plots created with the NOFRAME style.

Output 21.8.3 Scatter Plot with No Axis Frame

Alternatively, you can also add reference lines and delete the entire axis frame using the WALLDISPLAY=NONE and the DISPLAY= option in the graph template, as in the following example:

```
proc template;
   define statgraph Stat.Corresp.Graphics.Configuration;
      dynamic xVar yVar head legend;
      begingraph;
         entrytitle HEAD;

         layout overlayequated / equatetype=fit walldisplay=none
            xaxisopts=(display=(tickvalues) offsetmin=0.1 offsetmax=0.1)
            yaxisopts=(display=(tickvalues) offsetmin=0.1 offsetmax=0.1);

            referenceline x=0;
            referenceline y=0;

            scatterplot y=YVAR x=XVAR / group=GROUP index=INDEX
               datalabel=LABEL datalabelattrs=GRAPHVALUETEXT
               name="Type" tip=(y x datalabel group)
               tiplabel=(group="Point");
            if (LEGEND)
               discretelegend "Type";
            endif;
         endlayout;
      endgraph;
   end;
run;
```

```
ods listing style=statistical;

proc corresp data=PhD short;
   ods select configplot;
   var y1973-y1978;
   id Science;
run;
```

The results are shown in Output 21.8.4.

Output 21.8.4 Scatter Plot with Internal Axes

Instead of DISPLAY=(TICKVALUES), you can use DISPLAY=NONE (not shown) to remove the tick values from the display as well. You can change the tick values, as in the following example:

```
proc template;
   define statgraph Stat.Corresp.Graphics.Configuration;
      dynamic xVar yVar head legend;
      begingraph;
         entrytitle HEAD;

         layout overlayequated / equatetype=fit
            commonaxisopts=(tickvaluelist=(0))
            xaxisopts=(offsetmin=0.1 offsetmax=0.1)
            yaxisopts=(offsetmin=0.1 offsetmax=0.1);

            referenceline x=0;
            referenceline y=0;
```

```
            scatterplot y=YVAR x=XVAR / group=GROUP index=INDEX
               datalabel=LABEL datalabelattrs=GRAPHVALUETEXT
               name="Type" tip=(y x datalabel group)
               tiplabel=(group="Point");
            if (LEGEND)
               discretelegend "Type";
            endif;
         endlayout;
      endgraph;
   end;
run;

proc corresp data=PhD short;
   ods select configplot;
   var y1973-y1978;
   id Science;
run;
```

Since the axes in this plot are equated, the ticks are specified using the option **commonaxisopts=(tickvaluelist=(*tick-value-list*))**. This example only shows ticks at zero, but you can specify lists of values instead. The results are shown in Output 21.8.5.

Output 21.8.5 Scatter Plot with Tick Marks Specified

If the axes are not equated, then the tick value list is specified with the LINEAROPTS= option, as in the following statement:

```
layout overlay / xaxisopts=(linearopts=(viewmin=-0.1 viewmax=0.1
                                        tickvaluelist=(-0.1 0 0.1))
                            offsetmin=0.1 offsetmax=0.1)
                 yaxisopts=(linearopts=(viewmin=-0.1 viewmax=0.1
                                        tickvaluelist=(-0.1 0 0.1))
                            offsetmin=0.1 offsetmax=0.1);
```

The preceding statement uses the VIEWMIN= and VIEWMAX= options to specify the beginning and end of the data range that is shown. Specifying a tick value list does not extend or restrict the range of data shown in the plot. When axes share common options, it might be more convenient to use a macro to specify the options. The following two statements are equivalent to the preceding statement:

```
%let opts = linearopts=(viewmin=-0.1 viewmax=0.1
            tickvaluelist=(-0.1 0 0.1)) offsetmin=0.1 offsetmax=0.1;
layout overlay / xaxisopts=(&opts) yaxisopts=(&opts);
```

You can restore the default graph template as follows:

```
proc template;
   delete Stat.Corresp.Graphics.Configuration;
run;
```

Example 21.9: Customizing the Style for Box Plots

This example demonstrates how to modify the style for box plots. This example is taken from Example 21.1. The following step creates the data set:

```
data pr;
   input Person Gender $ y1 y2 y3 y4 @@;
   y=y1; Age=8;  output;
   y=y2; Age=10; output;
   y=y3; Age=12; output;
   y=y4; Age=14; output;
   drop y1-y4;
   datalines;
 1  F  21.0  20.0  21.5  23.0      2  F  21.0  21.5  24.0  25.5

... more lines ...

;
```

The next step displays the STATISTICAL and DEFAULT styles:

```
proc template;
   source Styles.Statistical;
   source Styles.Default;
run;
```

If you search for 'box', you will find the style element that controls some aspects of the box plot:

```
class GraphBox /
   capstyle = "serif"
   connect = "mean"
   displayopts = "fill caps median mean outliers";
```

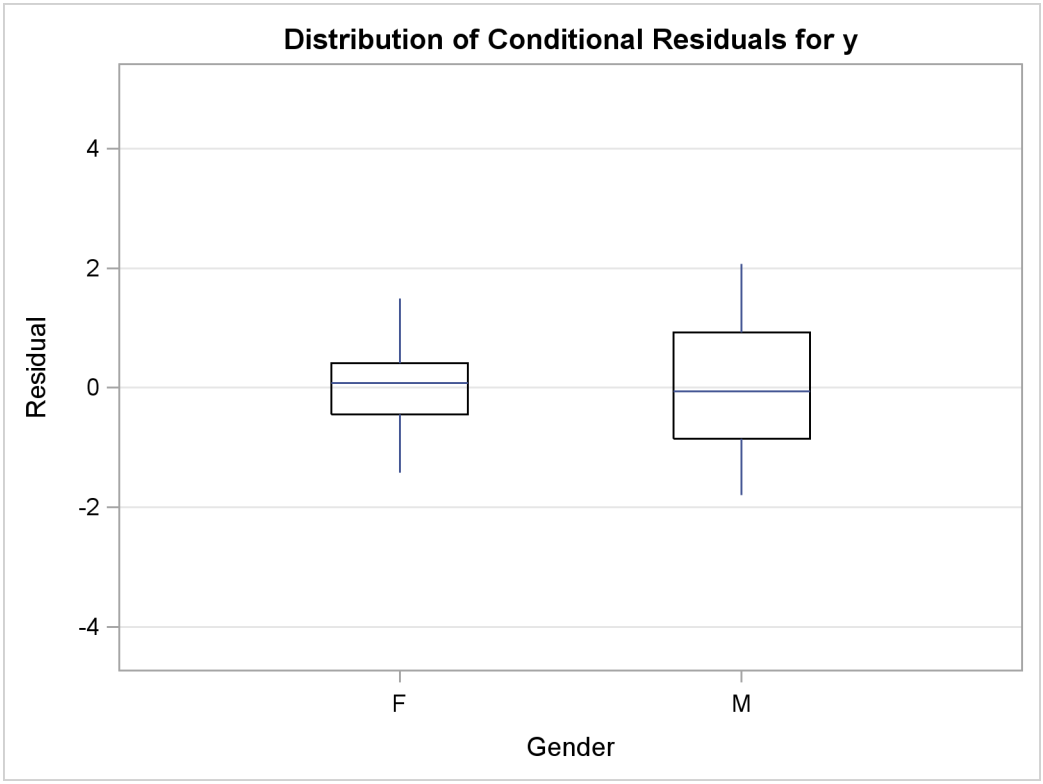
You can learn more about the **GraphBox** style element and its attributes in the section on the BOXPLOT statement in the *SAS/GRAPH: Graph Template Language Reference* and in the section on "ODS Style Elements" in the *SAS Output Delivery System: User's Guide*.

The following statements create two new styles by modifying attributes of the **GraphBox** style element. The first style is a sparse style; the box is outlined (not filled) and the median is shown but not the mean. In contrast, the second style produces a filled box, with caps on the whiskers that shows the mean, median, and outliers. In addition, the box is notched. The following statements create the two styles:

```
proc template;
   define style boxstylesparse;
      parent=styles.statistical;
      style GraphBox / capstyle = "line" displayopts = "median";
   end;
   define style boxstylerich;
      parent=styles.statistical;
      style GraphBox / capstyle = "bracket"
            displayopts = "fill caps median mean outliers notches";
   end;
run;
```

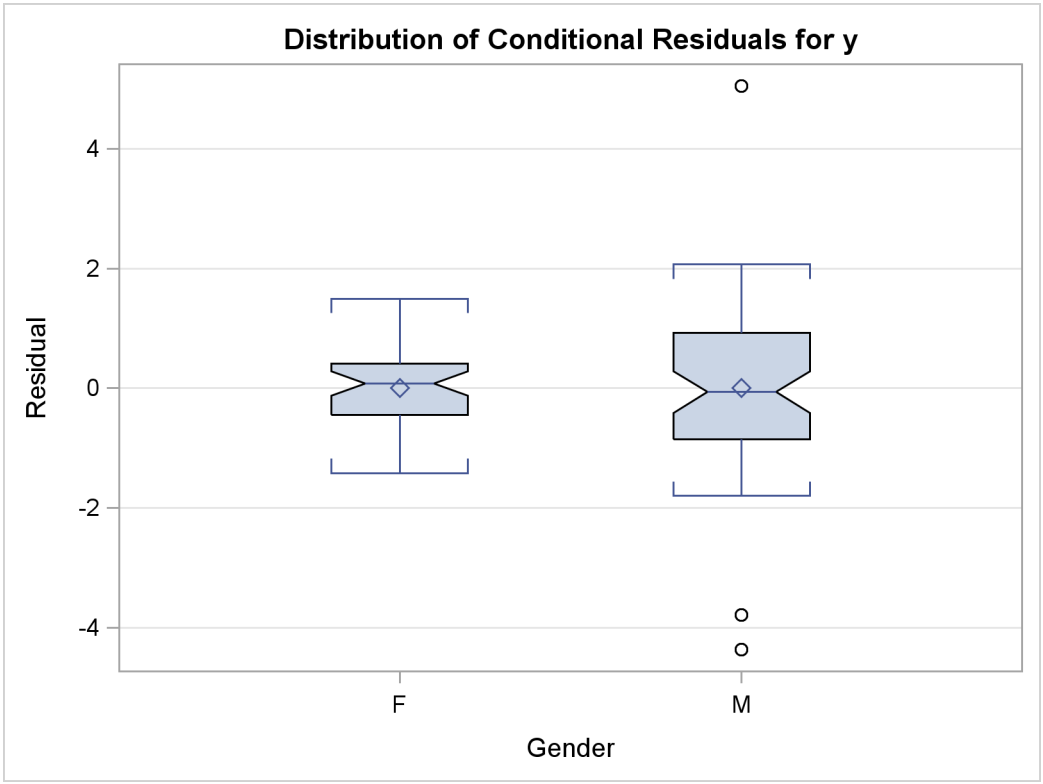
The following steps run PROC MIXED and create box plots that use the two styles:

```
ods graphics on;
ods listing style=boxstylesparse;



proc mixed data=pr method=ml plots=boxplot;
   ods select 'Conditional Residuals by Gender';
   class Person Gender;
   model y = Gender Age Gender*Age;
   random intercept Age / type=un subject=Person;
run;

ods listing style=boxstylerich;



proc mixed data=pr method=ml plots=boxplot;
   ods select 'Conditional Residuals by Gender';
   class Person Gender;
   model y = Gender Age Gender*Age;
   random intercept Age / type=un subject=Person;
run;
```

The results with the sparse style are displayed in Output 21.9.1, and the results with the richer style are displayed in Output 21.9.2. See Output 21.1.1 in Example 21.1 to see the results using the STATISTICAL style.

Output 21.9.1 Box Plot with the Sparse Style

Output 21.9.2 Box Plot with the Richer Style

Example 21.10: Adding Text to Every Graph

This example shows how to add text to one or more graphs. For example, you can create a macro variable, with project and date information, as follows:

```
%let date = Project 17.104, &sysdate;
```

In order to add this information to a set of graphs, you need to first know the names of their templates. You can list the names of every graph template for SAS/STAT procedures or for a particular procedure as follows:

```
proc template;
   list stat     / where=(type='Statgraph');
   list stat.reg / where=(type='Statgraph');
run;
```

The results for PROC REG are shown in Output 21.10.1.

Output 21.10.1 PROC REG Templates

```

11     Stat.Reg.Graphics.QQPlot                                Statgraph
12     Stat.Reg.Graphics.RFPlot                                Statgraph
13     Stat.Reg.Graphics.RStudentByPredicted                   Statgraph
14     Stat.Reg.Graphics.ResidualBoxPlot                       Statgraph
15     Stat.Reg.Graphics.ResidualByPredicted                   Statgraph
16     Stat.Reg.Graphics.ResidualHistogram                     Statgraph
17     Stat.Reg.Graphics.ResidualPanel                         Statgraph
18     Stat.Reg.Graphics.ResidualPlot                          Statgraph
19     Stat.Reg.Graphics.RidgePanel                            Statgraph
20     Stat.Reg.Graphics.RidgePlot                             Statgraph
21     Stat.Reg.Graphics.SelectionCriterionPanel               Statgraph
22     Stat.Reg.Graphics.SelectionCriterionPlot                Statgraph
23     Stat.Reg.Graphics.StepSelectionCriterionPanel           Statgraph
24     Stat.Reg.Graphics.StepSelectionCriterionPlot            Statgraph
25     Stat.Reg.Graphics.VIFPlot                               Statgraph
26     Stat.Reg.Graphics.rstudentByLeverage                    Statgraph
```

You can show the source for the graph templates for SAS/STAT procedures or for a particular procedure as follows:

```
options ls=96;
proc template;
   source stat     / where=(type='Statgraph');
   source stat.reg / where=(type='Statgraph');
options ls=80;
```

The results of this step are not shown. However, Example 21.7 shows a portion of the template for the PROC REG diagnostics panel. Here, the OPTIONS statement is used to set a line size of 96, which sometimes works better than the smaller default line sizes when showing the source for large and complicated templates.

An abridged version of the first few lines of the diagnostics panel template is displayed next:

```
define statgraph Stat.Reg.Graphics.DiagnosticsPanel;
   notes "Diagnostics Panel";
   dynamic . . .;
   BeginGraph / designheight=defaultDesignWidth;
      entrytitle halign=left textattrs=GRAPHVALUETEXT _MODELLABEL
         halign=center textattrs=GRAPHTITLETEXT "Fit Diagnostics"
         " for " _DEPNAME;
      . . .
```

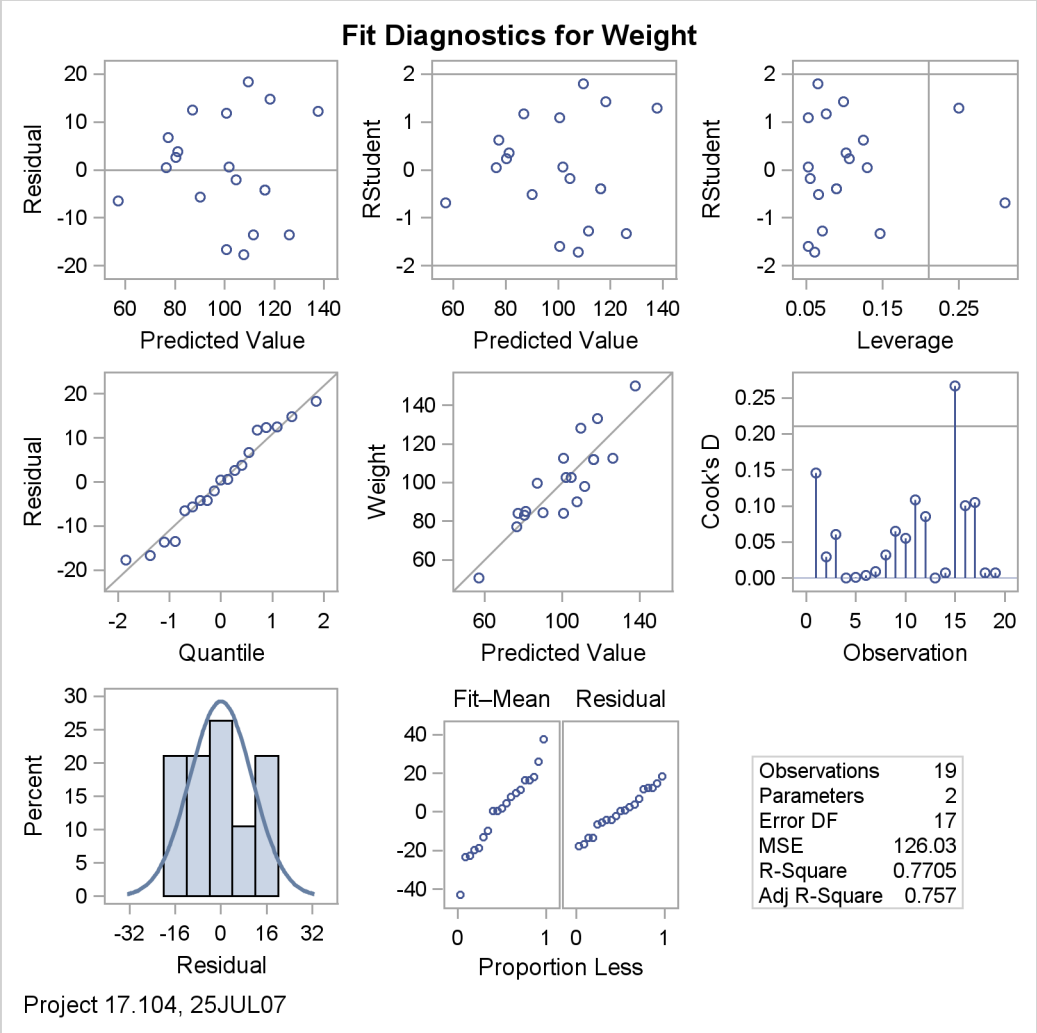
Adding a Date and Project Stamp to a Few Graphs

You can add the project and date to the bottom of all graphs produced with PROC REG by putting a PROC TEMPLATE statement in front of the template source code, and adding an MVAR and ENTRYFOOTNOTE statement after every BEGINGRAPH statement, as in the following example:

```
proc template;
   define statgraph Stat.Reg.Graphics.DiagnosticsPanel;
      notes "Diagnostics Panel";
      dynamic . . .;
      BeginGraph / designheight=defaultDesignWidth;

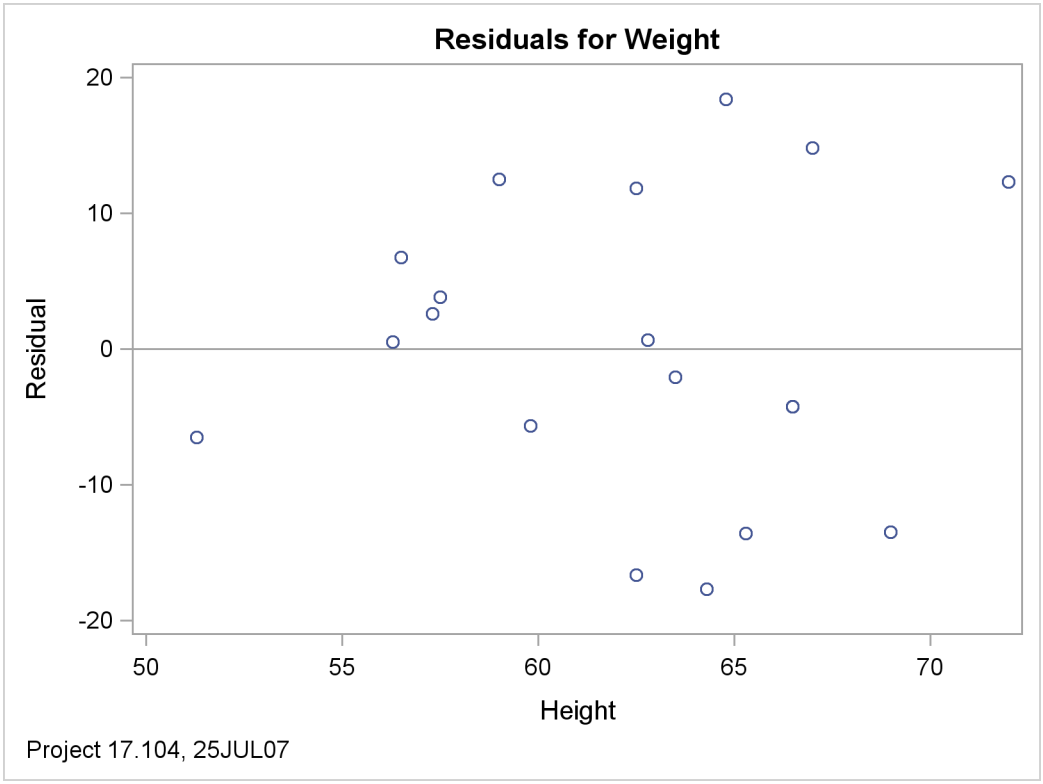
         mvar date;
         entryfootnote halign=left textattrs=GraphValueText date;

         entrytitle halign=left textattrs=GRAPHVALUETEXT _MODELLABEL
            halign=center textattrs=GRAPHTITLETEXT "Fit Diagnostics"
            " for " _DEPNAME;
         . . .
```

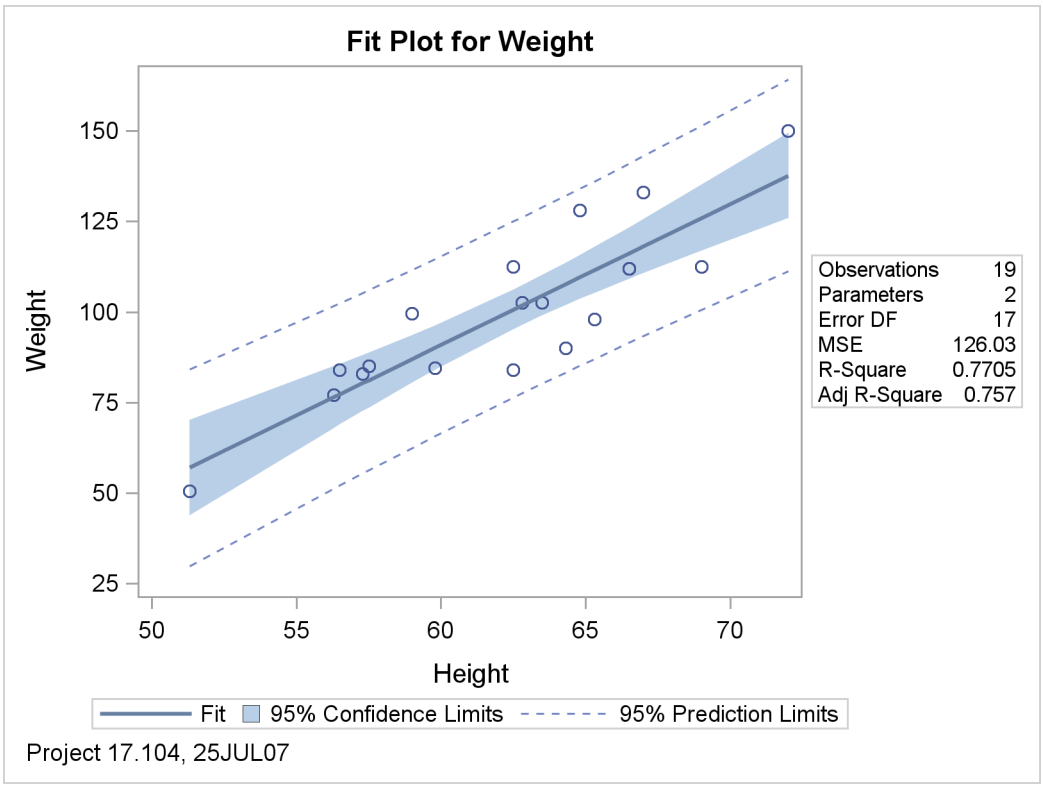


The MVAR statement enables you to dynamically customize the template and graph at procedure run time, just as the DYNAMIC statement enables the procedure to dynamically customize the template and graph. With the MVAR statement, you can modify the template once and reuse that modification as the macro changes over time: Alternatively, you can modify the templates as follows:

```
entryfootnote halign=left textattrs=GRAPHVALUETEXT "&date";
```



However, you would then have to resubmit your templates every time the macro variable changed. The substitution for the macro variable date occurs at different times in the two preceding cases. In the former case, ODS looks for the value of the macro variable date at the time the template is used, and then the current date variable is used to set the text in the ENTRYFOOTNOTE statement, every time the template is used. In the latter case, SAS substitutes the value of the macro variable once, at the time that the PROC TEMPLATE step is executed.



The following steps use the Class data set and produce Output 21.10.2:

Output 21.10.2 PROC REG Plots with Project and Date Stamp

Output 21.10.2 *continued*

You can restore all of the default templates for PROC REG by running the following step:

```
proc template;
   delete stat.reg;
run;
```

Alternatively, you can specify **delete stat** to restore all SAS/STAT templates to their default definitions.

You can add text to the top or the bottom of a graph by using the ENTRYTITLE or the ENTRYFOOTNOTE statement, respectively. With both statements, you can put the text in the HALIGN=RIGHT, HALIGN=LEFT, or HALIGN=CENTER positions. You can add text to titles even if they already have a centered title. For example, the ENTRYTITLE statement in the diagnostic panel has text on the left (which is conditionally displayed) and a centered title:

```
entrytitle halign=left textattrs=GraphValueText _MODELLABEL
   halign=center textattrs=GraphTitleText "Fit Diagnostics"
   " for " _DEPNAME;
```

The current title can be followed by HALIGN=RIGHT and more text.

Adding Data Set Information to a Graph

You might, for example, want to add text to a set of graphs that indicates the most recently created data set. The following example shows you how you can do this with the syslast macro variable:

```
%let data = &syslast;

. . .

mvar data;
entrytitle halign=left textattrs=GraphValueText "Data: " data
   halign=center textattrs=GraphTitleText "Fit Diagnostics"
   " for " _DEPNAME;

. . .
```

Of course, this only makes sense when you are analyzing the last data set created. Alternatively, you can incorporate the name of the data set in the title, as in the following example:

```
%let data = &syslast;

. . .

mvar data;
entrytitle halign=center textattrs=GraphTitleText
           "Fit Diagnostics for Data Set " data;

. . .
```

Adding a Date and Project Stamp to All Graphs

Sometimes, you can automate the process of template modification. For example, you can automatically add an MVAR and ENTRYFOOTNOTE statement to every graph template, as in the following example:

```
options ls=256;

proc template;
   source / where=(type='Statgraph') file="tpls.sas";
run;

options ls=80;

data _null_;
   infile 'tpls.sas' lrecl=256 pad;
   input line $ 1-256;
   file 'newtpls.sas';
   put line;
   line = left(lowcase(line));
   if line =: 'begingraph' then
      put 'mvar __date;' /
          'entryfootnote halign=left textattrs=GraphValueText __date;';

   file log;
   if index(line, '__date') then
      put 'ERROR: Name __date already used.' / line;
   if index(line, 'entryfootnote') then put line;
run;

proc template;
   %include 'newtpls.sas' / nosource;
run;
```

These statements write all ODS graph templates to a file, read that file, and write out a new file with an MVAR and ENTRYFOOTNOTE statement added after every BEGINGRAPH statement. Then these new templates are compiled with PROC TEMPLATE. These steps assume that no BEGINGRAPH statement is longer than 256 characters. Most graphs do not have footnotes. Those that do will now have multiple footnotes. You might want to manually combine them or write a more complicated program to handle them. These steps also assume that the name __date is not used anywhere. However, the program does check this and also lists all ENTRYFOOTNOTE statements. Be careful to check the SAS log to ensure that all templates compile without error. Also, before using templates that are automatically modified, make sure your modifications are reasonable.

You can delete SASUSER.Templat and hence all modified templates (assuming the default ODS PATH) as follows:

```
ods path sashelp.tmplmst(read);
proc datasets library=sasuser;
   delete templat(memtype=itemstor);
run;
ods path sasuser.templat(update) sashelp.tmplmst(read);
```

Example 21.11: PROC TEMPLATE Statement Order and Primary Plots

This example uses artificial data to illustrate two basic principles of template writing: that statement order matters and that one of the plotting statements is the primary statement. The data are a sample from a bivariate normal distribution. A custom graph template and PROC SGRENDER are used to plot the data along with vectors and ellipses. The plot consists of four components: a scatterplot of the data; vectors whose end points come from other variables in the data set; ellipses whose parameters are specified in the template; and reference lines whose locations are specified in the template. Initially, thick lines are used to show what happens at the places where the lines and points intersect.

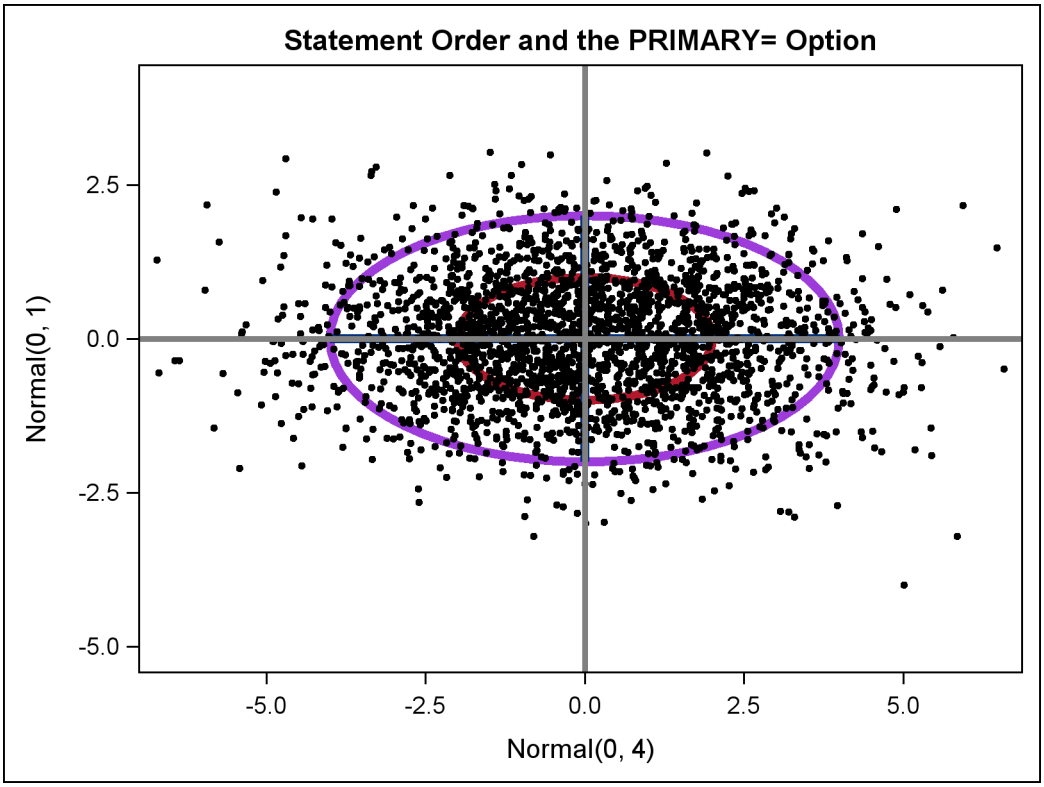
The following steps create the input SAS data set:

```
data x;
   input x y;
   label x = 'Normal(0, 4)' y = 'Normal(0, 1)';
   datalines;
-4  0
 4  0
 0 -2
 0  2
;

data y(drop=i);
   do i = 1 to 2500;
      r1 = normal( 104 );
      r2 = normal( 104 ) * 2;
      output;
   end;
run;

data all;
   merge x y;
run;
```

The data set All contains four variables. The variables r1 and r2 contain the random data. These variables contain 2500 nonmissing observations. The data set also contains the variables x and y, which contain the end points for the vectors. These variables contain four nonmissing observations and 2496 observations that are all missing. A data set like this is not unusual when creating overlaid plots. Different overlays often require input data with very different sizes.



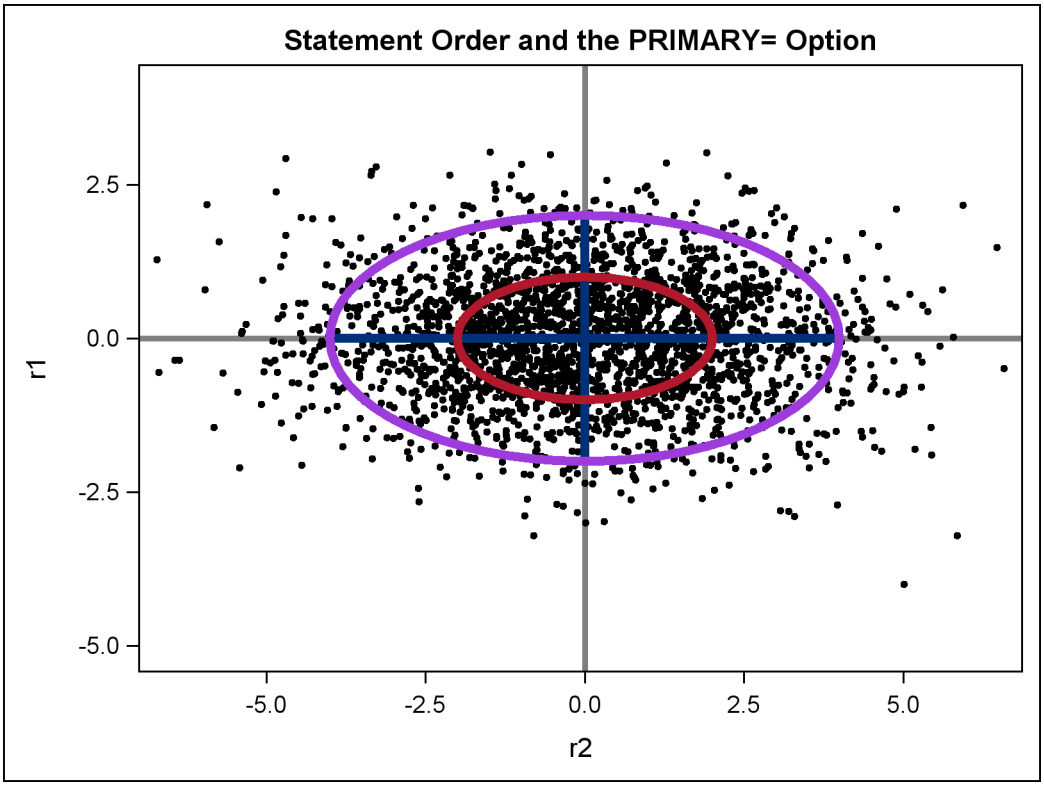
First, the data are plotted by using a template that is deliberately constructed to demonstrate a number of problems that can occur with statement order. The following steps create Output 21.11.1:

```
proc template;
   define statgraph Plot;
      begingraph;
         entrytitle 'Statement Order and the PRIMARY= Option';
         layout overlayequated / equatetype=fit;
            ellipseparm semimajor=eval(sqrt(4)) semiminor=1
                        slope=0 xorigin=0 yorigin=0 /
                        outlineattrs=GraphData2(pattern=solid thickness=5);
            ellipseparm semimajor=eval(2 * sqrt(4)) semiminor=2
                        slope=0 xorigin=0 yorigin=0 /
                        outlineattrs=GraphData5(pattern=solid thickness=5);
            vectorplot  y=y x=x xorigin=0 yorigin=0 /
                        arrowheads=false lineattrs=GraphFit(thickness=5);
            scatterplot y=r1 x=r2 /
                        markerattrs=(symbol=circlefilled size=3);
            referenceline x=0 / lineattrs=(thickness=3);
            referenceline y=0 / lineattrs=(thickness=3);
         endlayout;
      endgraph;
   end;
run;

ods listing style=listing;

proc sgrender data=all template=plot;
run;
```

Output 21.11.1 Statements Specified in a Nonoptimal Order



There are a number of problems with the plot in Output 21.11.1. The reference lines obliterate the vectors, and the data are on top of everything but the reference lines. It might be more reasonable to plot the reference lines first, the data next, the vectors next, and the ellipses last. The following steps do this and produce Output 21.11.2:

```
proc template;
   define statgraph Plot;
      begingraph;
         entrytitle 'Statement Order and the PRIMARY= Option';
         layout overlayequated / equatetype=fit;
            referenceline x=0 / lineattrs=(thickness=3);
            referenceline y=0 / lineattrs=(thickness=3);
            scatterplot y=r1 x=r2 /
                        markerattrs=(symbol=circlefilled size=3);
            vectorplot  y=y x=x xorigin=0 yorigin=0 /
                        arrowheads=false lineattrs=GraphFit(thickness=5);
            ellipseparm semimajor=eval(sqrt(4)) semiminor=1
                        slope=0 xorigin=0 yorigin=0 /
                        outlineattrs=GraphData2(pattern=solid thickness=5);
            ellipseparm semimajor=eval(2 * sqrt(4)) semiminor=2
                        slope=0 xorigin=0 yorigin=0 /
                        outlineattrs=GraphData5(pattern=solid thickness=5);
         endlayout;
      endgraph;
   end;
run;

ods listing style=listing;

proc sgrender data=all template=plot;
run;
```

Output 21.11.2 Statement Order Fixed

Output 21.11.2 looks better than Output 21.11.1, but the labels for the axes have changed. Output 21.11.1 has the labels of the variables x and y as axis labels, whereas Output 21.11.2 uses the names of the variables r1 and r2. This is because in the Output 21.11.1, the first plot is the vector plot of x and y (which have labels), and in Output 21.11.2, the first plot is the scatter plot of r1 and r2 (which do not have labels). By default, the first plot is the *primary plot*, and the primary plot is used to determine the axis type and labels. You can designate the vector plot as the primary plot with the PRIMARY=TRUE option. The following statements make the final plot, this time with default line thicknesses, and produce Output 21.11.3:

```
proc template;
   define statgraph Plot;
      begingraph;
         entrytitle 'Statement Order and the PRIMARY= Option';
         layout overlayequated / equatetype=fit;
            referenceline x=0;
            referenceline y=0;
            scatterplot y=r1 x=r2 / markerattrs=(symbol=circlefilled size=3);

            vectorplot  y=y x=x xorigin=0 yorigin=0 / primary=true
                        arrowheads=false lineattrs=GraphFit;

            ellipseparm semimajor=eval(sqrt(4)) semiminor=1
                        slope=0 xorigin=0 yorigin=0 /
                        outlineattrs=GraphData2(pattern=solid);
            ellipseparm semimajor=eval(2 * sqrt(4)) semiminor=2
                        slope=0 xorigin=0 yorigin=0 /
                        outlineattrs=GraphData5(pattern=solid);
         endlayout;
      endgraph;
   end;
run;

ods listing style=listing;

proc sgrender data=all template=plot;
run;
```

Output 21.11.3 Statement Order Fixed and Primary Plot Specified

The axis labels in Output 21.11.3 and the overprinting of plot elements look better than in the previous plots. You can further adjust the line thicknesses if you want to emphasize or deemphasize components of this plot. The following list discusses the syntax of the GTL statements used in this example.

- The template has an ENTRYTITLE statement that specifies the title.
- The template has an equated overlay. This means that a centimeter on one axis represents the same data range as a centimeter on the other axis. This is done instead of the more common LAYOUT OVERLAY since with these data, the shape and geometry of the data have meaning even though the ranges of the two axis variables are different. The option EQUATETYPE=SQUARE is used to make a square plot, but since the X-axis variable has a larger range than the Y-axis variable, and since the default plot size is wider than high, EQUATETYPE=FIT is specified. The axes are equated but use the available space.
- A vertical reference line is drawn at X=0, and a horizontal reference line is drawn at Y=0.
- The scatter plot is based on the Y-axis variable `r2` and the X-axis variable `r1`. The markers are filled circles with a size of three pixels. This is smaller than the default size and works well with a plot that displays many points.
- The vector plot is based on the Y-axis variable `y` and the X-axis variable `x`. The vectors are solid lines with no heads emanating from the origin (X=0 and Y=0). The color and other line attributes such as thickness come from the attributes of the **`GraphFit`** style element. This is the primary plot, so the default axis labels are the variable labels for the X= and Y= variables if they exist or the variable names if the variables do not have labels.
- The plot also displays two ellipses with X=0 and Y=0 at their center. Their widths are expressions, and their heights are constant. The expressions are not needed in this example; they are used to illustrate the syntax. The SEMIMAJOR= option specifies half the length of the major axis for the ellipse, and the SEMIMINOR= option specifies half the length of the minor axis for the ellipse. The SLOPE= option specifies the slope of the major axis for the ellipse. The colors of the ellipses and other line properties are based on the **`GraphData2`** and **`GraphData5`** style elements, but the line pattern attribute from the style is overridden.

Overview: ACECLUS Procedure

The ACECLUS (approximate covariance estimation for clustering) procedure obtains approximate estimates of the pooled within-cluster covariance matrix when the clusters are assumed to be multivariate normal with equal covariance matrices. Neither cluster membership nor the number of clusters needs to be known. PROC ACECLUS is useful for preprocessing data to be subsequently clustered by the CLUSTER or FASTCLUS procedure.

Many clustering methods perform well with spherical clusters but poorly with elongated elliptical clusters (Everitt 1980, 77–97). If the elliptical clusters have roughly the same orientation and eccentricity, you can apply a linear transformation to the data to yield a spherical within-cluster covariance matrix—that is, a covariance matrix proportional to the identity. Equivalently, the distance between observations can be measured in the metric of the inverse of the pooled within-cluster

covariance matrix. The remedy is difficult to apply, however, because you need to know what the clusters are in order to compute the sample within-cluster covariance matrix. One approach is to estimate iteratively both cluster membership and within-cluster covariance (Wolfe 1970; Hartigan 1975). Another approach is provided by Art, Gnanadesikan, and Kettenring (1982). They have devised an ingenious method for estimating the within-cluster covariance matrix without knowledge of the clusters. The method can be applied before any of the usual clustering techniques, including hierarchical clustering methods.

First, Art, Gnanadesikan, and Kettenring (1982) obtain a decomposition of the total-sample sum-of-squares-and-crossproducts (SSCP) matrix into within-cluster and between-cluster SSCP matrices computed from pairwise differences between observations, rather than differences between observations and means. Then, they show how the within-cluster SSCP matrix based on pairwise differences can be approximated without knowing the number or the membership of the clusters. The approximate within-cluster SSCP matrix can be used to compute distances for cluster analysis, or it can be used in a canonical analysis similar to canonical discriminant analysis. For more information, see Chapter 27, "The CANDISC Procedure."

Art, Gnanadesikan, and Kettenring demonstrate by Monte Carlo calculations that their method can produce better clusters than the Euclidean metric even when the approximation to the within-cluster SSCP matrix is poor or the within-cluster covariances are moderately heterogeneous. The algorithm used by the ACECLUS procedure differs slightly from the algorithm used by Art, Gnanadesikan, and Kettenring. In the following sections, the PROC ACECLUS algorithm is described first; then, differences between PROC ACECLUS and the method used by Art, Gnanadesikan, and Kettenring are summarized.

Background

It is well known from the literature on nonparametric statistics that variances and, hence, covariances can be computed from pairwise differences instead of deviations from means. (For example, Puri and Sen (1971, pp. 51–52) show that the variance is a U statistic of degree 2.) Let $\mathbf{X} = (x_{ij})$ be the data matrix with n observations (rows) and v variables (columns), and let $\bar{x}_j$ be the mean of the jth variable. The sample covariance matrix $\mathbf{S} = (s_{jk})$ is usually defined as

$$s_{jk} = \frac{1}{n-1} \sum_{i=1}^{n} (x_{ij} - \bar{x}_j)(x_{ik} - \bar{x}_k)$$

The matrix $\mathbf{S}$ can also be computed as

$$s_{jk} = \frac{1}{n(n-1)} \sum_{i=2}^{n} \sum_{h=1}^{i-1} (x_{ij} - x_{hj})(x_{ik} - x_{hk})$$

Let $\mathbf{W} = (w_{jk})$ be the pooled within-cluster covariance matrix, q be the number of clusters, n_c be the number of observations in the cth cluster, and

$$d''_{ic} = \begin{cases} 1 & \text{if observation } i \text{ is in cluster } c \\ 0 & \text{otherwise} \end{cases}$$

The matrix $\mathbf{W}$ is normally defined as

$$w_{jk} = \frac{1}{n-q} \sum_{c=1}^{q} \sum_{i=1}^{n} d''_{ic}(x_{ij} - \bar{x}_{cj})(x_{ik} - \bar{x}_{ck})$$

where $\bar{x}_{cj}$ is the mean of the jth variable in cluster c. Let

$$d'_{ih} = \begin{cases} \frac{1}{n_c} & \text{if observations } i \text{ and } h \text{ are in cluster } c \\ 0 & \text{otherwise} \end{cases}$$

The matrix $\mathbf{W}$ can also be computed as

$$w_{jk} = \frac{1}{n-q} \sum_{i=2}^{n} \sum_{h=1}^{i-1} d'_{ih}(x_{ij} - x_{hj})(x_{ik} - x_{hk})$$

If the clusters are not known, d'_{ih} cannot be determined. However, an approximation to $\mathbf{W}$ can be obtained by using instead

$$d_{ih} = \begin{cases} 1 & \text{if } \sum_{j=1}^{v} \sum_{k=1}^{v} m_{jk}(x_{ij} - x_{hj})(x_{ik} - x_{hk}) \le u^2 \\ 0 & \text{otherwise} \end{cases}$$

where u is an appropriately chosen value and $\mathbf{M} = (m_{jk})$ is an appropriate metric. Let $\mathbf{A} = (a_{jk})$ be defined as

$$a_{jk} = \frac{\sum_{i=2}^{n} \sum_{h=1}^{i-1} d_{ih}(x_{ij} - x_{hj})(x_{ik} - x_{hk})}{2 \sum_{i=2}^{n} \sum_{h=1}^{i-1} d_{ih}}$$

If all of the following conditions hold, $\mathbf{A}$ equals $\mathbf{W}$:

- All within-cluster distances in the metric $\mathbf{M}$ are less than or equal to u.
- All between-cluster distances in the metric $\mathbf{M}$ are greater than u.
- All clusters have the same number of members n_c.

If the clusters are of unequal size, $\mathbf{A}$ gives more weight to large clusters than $\mathbf{W}$ does, but this discrepancy should be of little importance if the population within-cluster covariance matrices are equal. There might be large differences between $\mathbf{A}$ and $\mathbf{W}$ if the cutoff u does not discriminate between pairs in the same cluster and pairs in different clusters. Lack of discrimination might occur for one of the following reasons:

- The clusters are not well separated.
- The metric $\mathbf{M}$ or the cutoff u is not chosen appropriately.

In the former case, little can be done to remedy the problem. The remaining question concerns how to choose $\mathbf{M}$ and u. Consider $\mathbf{M}$ first. The best choice for $\mathbf{M}$ is $\mathbf{W}^{-1}$, but $\mathbf{W}$ is not known. The solution is to use an iterative algorithm:

1. Obtain an initial estimate of **A**, such as the identity or the total-sample covariance matrix. See the INITIAL= option in the PROC ACECLUS statement for more information.
2. Let **M** equal $\mathbf{A}^{-1}$.
3. Recompute **A** by using the preceding formula.
4. Repeat steps 2 and 3 until the estimate stabilizes.

Convergence is assessed by comparing values of **A** on successive iterations. Let $\mathbf{A}_i$ be the value of **A** on the ith iteration and $\mathbf{A}_0$ be the initial estimate of **A**. Let **Z** be a user-specified $v \times v$ matrix. See the METRIC= option in the PROC ACECLUS statement for more information. The convergence measure is

$$e_i = \frac{1}{v} \parallel \mathbf{Z}'(\mathbf{A}_i - \mathbf{A}_{i-1})\mathbf{Z} \parallel$$

where $\parallel \cdots \parallel$ indicates the Euclidean norm—that is, the square root of the sum of the squares of the elements of the matrix. In PROC ACECLUS, **Z** can be the identity or an inverse factor of **S** or diag(**S**). Iteration stops when e_i falls below a user-specified value. See the CONVERGE= option or the MAXITER= option in the PROC ACECLUS statement for more information.

The remaining question of how to choose u has no simple answer. In practice, you must try several different values. PROC ACECLUS provides four different ways of specifying u:

- You can specify a constant value for u. This method is useful if the initial estimate of **A** is quite good. See the ABSOLUTE option and the THRESHOLD= option in the PROC ACECLUS statement for more information.
- You can specify a threshold value $t > 0$ that is multiplied by the root mean square distance between observations in the current metric on each iteration to give u. Thus, the value of u changes from iteration to iteration. This method is appropriate if the initial estimate of **A** is poor. See the THRESHOLD= option in the PROC ACECLUS statement for more information.
- You can specify a value p, $0 < p < 1$, to be transformed into a distance u such that approximately a proportion p of the pairwise Mahalanobis distances between observations in a random sample from a multivariate normal distribution will be less than u in repeated sampling. The transformation can be computed only if the number of observations exceeds the number of variables, preferably by at least 10 percent. This method also requires a good initial estimate of **A**. See the PROPORTION= option and the ABSOLUTE option in the PROC ACECLUS statement for more information.
- You can specify a value p, $0 < p < 1$, to be transformed into a value t that is then multiplied by $1/\sqrt{2v}$ times the root mean square distance between observations in the current metric on each iteration to yield u. The value of u changes from iteration to iteration. This method can be used with a poor initial estimate of **A**. See the PROPORTION= option in the PROC ACECLUS statement for more information.

In most cases, the analysis should begin with the last method, using values of p between 0.5 and 0.01 and using the full covariance matrix as the initial estimate of **A**.

Proportions p are transformed to distances t by using the formula

$$t^2 = 2v \left\{ \left[F^{-1}_{v,n-v}(p) \right]^{\frac{n-v}{n-1}} \right\}$$

where $F^{-1}_{v,n-v}$ is the quantile (inverse cumulative distribution) function of an F random variable with v and $n - v$ degrees of freedom. The squared Mahalanobis distance between a single pair of observations sampled from a multivariate normal distribution is distributed as $2v$ times an F random variable with v and $n - v$ degrees of freedom. The distances between two pairs of observations are correlated if the pairs have an observation in common. The quantile function is raised to the power given in the preceding formula to compensate approximately for the correlations among distances between pairs of observations that share a member. Monte Carlo studies indicate that the approximation is acceptable if the number of observations exceeds the number of variables by at least 10 percent.

If $\mathbf{A}$ becomes singular, step 2 in the iterative algorithm cannot be performed because $\mathbf{A}$ cannot be inverted. In this case, let $\mathbf{Z}$ be the matrix as defined in discussing the convergence measure, and let $\mathbf{Z}'\mathbf{A}\mathbf{Z} = \mathbf{R}'\mathbf{\Lambda}\mathbf{R}$, where $\mathbf{R}'\mathbf{R} = \mathbf{R}\mathbf{R}' = \mathbf{I}$ and $\mathbf{\Lambda} = (\lambda_{jk})$ is diagonal. Let $\mathbf{\Lambda}^* = (\lambda^*_{jk})$ be a diagonal matrix, where $\lambda^*_{jj} = \max(\lambda_{jj}, g \text{ trace}(\mathbf{\Lambda}))$, and $0 < g < 1$ is a user-specified singularity criterion (see the SINGULAR= option in the PROC ACECLUS statement for more information). Then $\mathbf{M}$ is computed as $\mathbf{Z}\mathbf{R}'(\mathbf{\Lambda}^*)^{-1}\mathbf{R}\mathbf{Z}'$.

The ACECLUS procedure differs from the method used by Art, Gnanadesikan, and Kettenring (1982) in several respects:

- The Art, Gnanadesikan, and Kettenring method uses the identity matrix as the initial estimate, whereas the ACECLUS procedure enables you to specify any symmetric matrix as the initial estimate and defaults to the total-sample covariance matrix. The default initial estimate in PROC ACECLUS is chosen to yield invariance under nonsingular linear transformations of the data but might sometimes obscure clusters that become apparent if the identity matrix is used.
- The Art, Gnanadesikan, and Kettenring method carries out all computations with SSCP matrices, whereas the ACECLUS procedure uses estimated covariance matrices because covariances are easier to interpret than crossproducts.
- The Art, Gnanadesikan, and Kettenring method uses the m pairs with the smallest distances to form the new estimate at each iteration, where m is specified by the user, whereas the ACECLUS procedure uses all pairs closer than a given cutoff value. Kettenring (1984) says that the m-closest-pairs method seems to give the user more direct control. PROC ACECLUS uses a distance cutoff because it yields a slight decrease in computer time and because in some cases, such as widely separated spherical clusters, the results are less sensitive to the choice of distance cutoff than to the choice of m. Much research remains to be done on this issue.
- The Art, Gnanadesikan, and Kettenring method uses a different convergence measure. Let $\mathbf{A}_i$ be computed on each iteration by using the m-closest-pairs method, and let $\mathbf{B}_i = \mathbf{A}^{-1}_{i-1}\mathbf{A}_i - \mathbf{I}$, where $\mathbf{I}$ is the identity matrix. The convergence measure is equivalent to trace$(\mathbf{B}^2_i)$.

Analyses of Fisher's (1936) iris data, consisting of measurements of petal and sepal length and width for 50 specimens from each of three iris species, are summarized in Table 22.1. The number of misclassified observations out of 150 is given for four clustering methods:

- k-means as implemented in PROC FASTCLUS with MAXC=3, MAXITER=99, and CONV=0
- Ward's minimum variance method as implemented in PROC CLUSTER
- average linkage on Euclidean distances as implemented in PROC CLUSTER
- the centroid method as implemented in PROC CLUSTER

Each hierarchical analysis is followed by the TREE procedure with NCL=3 to determine cluster assignments at the three-cluster level. Clusters with 20 or fewer observations are discarded by using the DOCK=20 option. The observations in a discarded cluster are considered unclassified.

Each method is applied to the following data:

- the raw data
- the data standardized to unit variance by the STANDARD procedure
- two standardized principal components accounting for 95 percent of the standardized variance and having an identity total-sample covariance matrix, computed by the PRINCOMP procedure with the STD option
- four standardized principal components having an identity total-sample covariance matrix, computed by PROC PRINCOMP with the STD option
- the data transformed by PROC ACECLUS, using seven different settings of the PROPORTION= (P=) option
- four canonical variables having an identity pooled within-species covariance matrix, computed using the CANDISC procedure

Theoretically, the best results should be obtained by using the canonical variables from PROC CANDISC. PROC ACECLUS yields results comparable to those from PROC CANDISC for values of the PROPORTION= option ranging from 0.005 to 0.02. At PROPORTION=0.04, average linkage and the centroid method show some deterioration, but k-means and Ward's method continue to produce excellent classifications. At larger values of the PROPORTION= option, all methods perform poorly, although no worse than with four standardized principal components.

Table 22.1 Number of Misclassified and Unclassified Observations Using Fisher's (1936) Iris Data

Data	Clustering Method			
	k-means	Ward's	Average Linkage	Centroid
raw data	16*	16*	25 + 12**	14*
standardized data	25	26	33+4	33+4
two standardized principal components	29	31	30+9	27+32
four standardized principal components	39	27	32+7	45+11
transformed by ACECLUS P=0.32	39	10+9	7+25	
transformed by ACECLUS P=0.16	39	18+9	7+19	7+26
transformed by ACECLUS P=0.08	19	9	3+13	5+16
transformed by ACECLUS P=0.04	4	5	1+19	3+12
transformed by ACECLUS P=0.02	4	3	3	3
transformed by ACECLUS P=0.01	4	4	3	4
transformed by ACECLUS P=0.005	4	4	4	4
canonical variables	3	5	4	4+1

* A single number represents misclassified observations with no unclassified observations.

** Where two numbers are separated by a plus sign, the first is the number of misclassified observations; the second is the number of unclassified observations.

This example demonstrates the following:

- PROC ACECLUS can produce results as good as those from the optimal transformation.
- PROC ACECLUS can be useful even when the within-cluster covariance matrices are moderately heterogeneous.
- The choice of the distance cutoff as specified by the PROPORTION= or the THRESHOLD= option is important, and several values should be tried.
- Commonly used transformations such as standardization and principal components can produce poor classifications.

Although experience with the Art, Gnanadesikan, and Kettenring and PROC ACECLUS methods is limited, the results so far suggest that these methods help considerably more often than they hinder the subsequent cluster analysis, especially with normal-mixture techniques such as k-means and Ward's minimum variance method.

Getting Started: ACECLUS Procedure

The following example demonstrates how you can use the ACECLUS procedure to obtain approximate estimates of the pooled within-cluster covariance matrix and to compute canonical variables

for subsequent analysis. You use PROC ACECLUS to preprocess data before you cluster it by using the FASTCLUS or CLUSTER procedure.

Suppose you want to determine whether national figures for birth rates, death rates, and infant death rates can be used to determine certain types or categories of countries. You want to perform a cluster analysis to determine whether the observations can be formed into groups suggested by the data. Previous studies indicate that the clusters computed from this type of data can be elongated and elliptical. Thus, you need to perform a linear transformation on the raw data before the cluster analysis.

The following data[1] from Rouncefield (1995) are the birth rates, death rates, and infant death rates for 97 countries. The following statements create the SAS data set Poverty:

```
data poverty;
   input Birth Death InfantDeath Country $15. @@;
   datalines;
24.7  5.7  30.8 Albania         12.5 11.9  14.4 Bulgaria
13.4 11.7  11.3 Czechoslovakia    12 12.4   7.6 Former_E._Germa

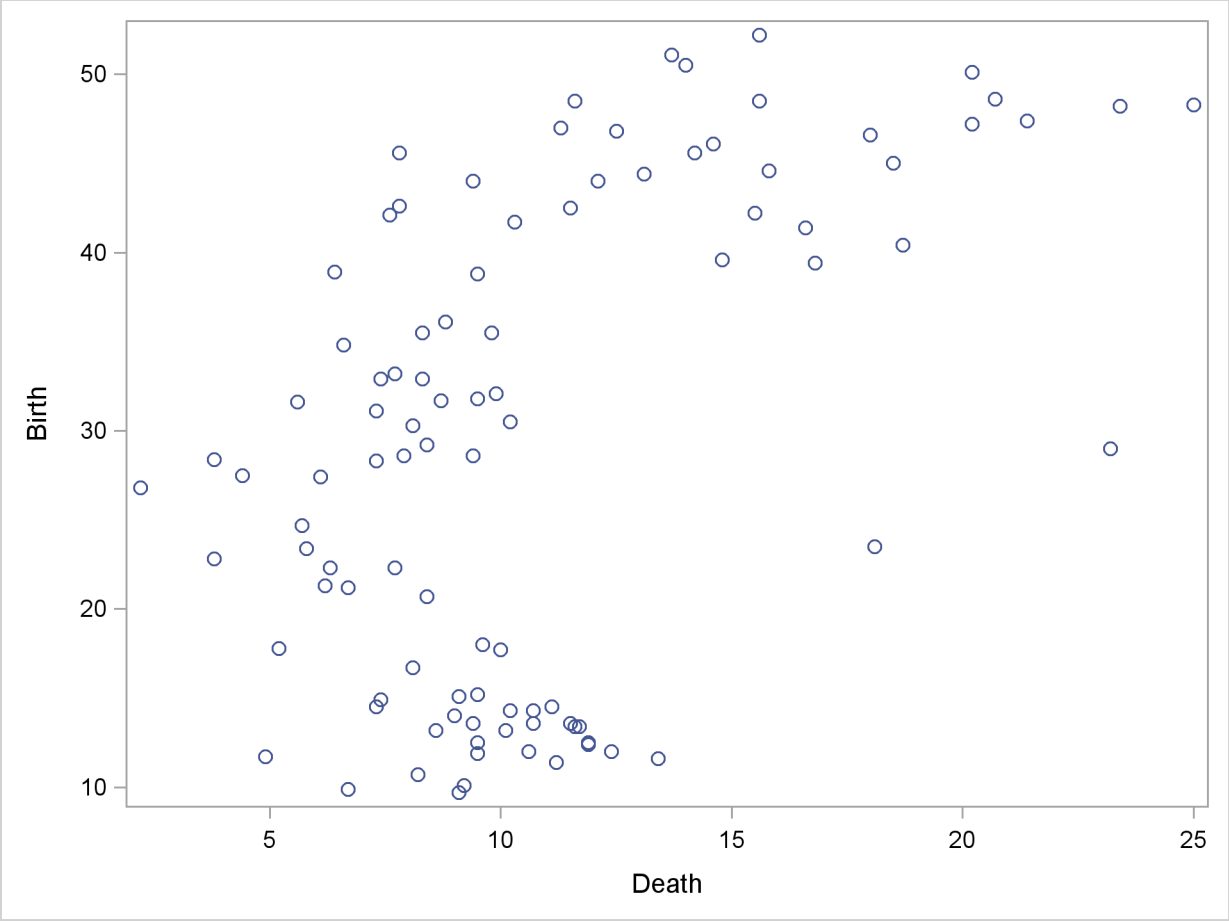
;
```



The data set Poverty contains the character variable Country and the numeric variables Birth, Death, and InfantDeath, which represent the birth rate per thousand, death rate per thousand, and infant death rate per thousand, respectively. The \$15. in the INPUT statement specifies that the variable Country is a character variable with a length of 15. The double trailing at sign (@@) in the INPUT statement specifies that observations are input from each line until all values have been read.

It is often useful when beginning a cluster analysis to look at the data graphically. The following statements use the SGPLOT procedure to make a scatter plot of the variables Birth and Death.

```
proc sgplot data=poverty;
   scatter x=Death y=Birth;
run;
```

The plot, displayed in Figure 22.1, indicates the difficulty of dividing the points into clusters. Plots of the other variable pairs (not shown) display similar characteristics. The clusters that comprise these data might be poorly separated and elongated. Data with poorly separated or elongated clusters must be transformed.

Figure 22.1 Scatter Plot of Original Poverty Data: Birth Rate versus Death Rate

If you know the within-cluster covariances, you can transform the data to make the clusters spherical. However, since you do not know what the clusters are, you cannot calculate exactly the within-cluster covariance matrix. The ACECLUS procedure estimates the within-cluster covariance matrix to transform the data, even when you have no knowledge of cluster membership or the number of clusters.

The following statements perform the ACECLUS procedure transformation by using the SAS data set Poverty:

```
proc aceclus data=poverty out=ace proportion=.03;
   var Birth Death InfantDeath;
run;
```

The OUT= option creates an output data set called Ace to contain the canonical variable scores. The PROPORTION= option specifies that approximately 3 percent of the pairs are included in the estimation of the within-cluster covariance matrix. The VAR statement specifies that the variables Birth, Death, and InfantDeath are used in computing the canonical variables.

The results of this analysis are displayed in Figure 22.2 through Figure 22.5.

Figure 22.2 displays the number of observations, the number of variables, and the settings for the PROPORTION and CONVERGE options. The PROPORTION option is set at 0.03, as specified in the previous statements. The CONVERGE parameter is set at its default value of 0.001. Figure 22.2 next displays the means, standard deviations, and sample covariance matrix of the analytical variables.

Figure 22.2 Means, Standard Deviations, and Covariance Matrix from the ACECLUS Procedure

The ACECLUS Procedure

Approximate Covariance Estimation for Cluster Analysis

Observations	97	Proportion	0.0300
Variables	3	Converge	0.00100

Means and Standard Deviations

Variable	Mean	Standard Deviation
Birth	29.2299	13.5467
Death	10.8361	4.6475
InfantDeath	54.9010	45.9926

COV: Total Sample Covariances

	Birth	Death	InfantDeath
Birth	183.512951	30.610056	534.794969
Death	30.610056	21.599205	139.925900
InfantDeath	534.794969	139.925900	2115.317811

The type of matrix used for the initial within-cluster covariance estimate is displayed in Figure 22.3. In this example, that initial estimate is the full covariance matrix. The threshold value that corresponds to the PROPORTION=0.03 setting is given as 0.292815.

Figure 22.3 Table of Iteration History from the ACECLUS Procedure

Initial Within-Cluster Covariance Estimate = Full Covariance Matrix

Threshold = 0.292815

Figure 22.3 *continued*

Iteration History

Iteration	RMS Distance	Distance Cutoff	Pairs Within Cutoff	Convergence Measure
1	2.449	0.717	385.0	0.552025
2	12.534	3.670	446.0	0.008406
3	12.851	3.763	521.0	0.009655
4	12.882	3.772	591.0	0.011193
5	12.716	3.723	628.0	0.008784
6	12.821	3.754	658.0	0.005553
7	12.774	3.740	680.0	0.003010
8	12.631	3.699	683.0	0.000676

Algorithm converged.

Figure 22.3 displays the iteration history. For each iteration, PROC ACECLUS displays the following measures:

- root mean square distance between all pairs of observations
- distance cutoff for including pairs of observations in the estimate of within-cluster covariances (equal to RMS*Threshold)
- number of pairs within the cutoff
- convergence measure

Figure 22.4 displays the approximate within-cluster covariance matrix and the table of eigenvalues from the canonical analysis. The first column of the eigenvalues table contains numbers for the eigenvectors. The next column of the table lists the eigenvalues of Inv(ACE)*(COV-ACE).

Figure 22.4 Approximate Within-Cluster Covariance Estimates

ACE: Approximate Covariance Estimate Within Clusters

	Birth	Death	InfantDeath
Birth	5.94644949	-0.63235725	6.28151537
Death	-0.63235725	2.33464129	1.59005857
InfantDeath	6.28151537	1.59005857	35.10327233

Eigenvalues of Inv(ACE)*(COV-ACE)

	Eigenvalue	Difference	Proportion	Cumulative
1	63.5500	54.7313	0.8277	0.8277
2	8.8187	4.4038	0.1149	0.9425
3	4.4149		0.0575	1.0000

The next three columns of the eigenvalue table (Figure 22.4) display measures of the relative size and importance of the eigenvalues. The first column lists the difference between each eigenvalue and its successor. The last two columns display the individual and cumulative proportions that each eigenvalue contributes to the total sum of eigenvalues.

The raw and standardized canonical coefficients are displayed in Figure 22.5. The coefficients are standardized by multiplying the raw coefficients with the standard deviation of the associated variable. The ACECLUS procedure uses these standardized canonical coefficients to create the transformed canonical variables, which are the linear transformations of the original input variables, Birth, Death, and InfantDeath.

Figure 22.5 Raw and Standardized Canonical Coefficients from the ACECLUS Procedure

Eigenvectors (Raw Canonical Coefficients)

	Can1	Can2	Can3
Birth	0.125610	0.457037	0.003875
Death	0.108402	0.163792	0.663538
InfantDeath	0.134704	-.133620	-.046266

Standardized Canonical Coefficients

	Can1	Can2	Can3
Birth	1.70160	6.19134	0.05249
Death	0.50380	0.76122	3.08379
InfantDeath	6.19540	-6.14553	-2.12790

The following statements invoke the CLUSTER procedure, using the SAS data set Ace created in the previous ACECLUS procedure:

```
proc cluster data=ace outtree=tree noprint method=ward;
   var can1 can2 can3 ;
   copy Birth--Country;
run;
```

The OUTTREE= option creates the output SAS data set Tree that is used in subsequent statements to draw a tree diagram. The NOPRINT option suppresses the display of the output. The METHOD= option specifies Ward's minimum-variance clustering method.

The VAR statement specifies that the canonical variables computed in the ACECLUS procedure are used in the cluster analysis. The COPY statement specifies that all the variables from the SAS data set Poverty (Birth—Country) are added to the output data set Tree.

The following statements use the TREE procedure to create an output SAS data set called New. The NCLUSTERS= option specifies the number of clusters desired in the SAS data set New. The NOPRINT option suppresses the display of the output.

```
proc tree data=tree out=new nclusters=3 noprint;
   copy Birth Death InfantDeath can1 can2 ;
   id Country;
run;
```

The COPY statement copies the canonical variables Can1 and Can2 (computed in the preceding ACECLUS procedure) and the original analytical variables Birth, Death, and InfantDeath into the output SAS data set New.

The following statements invoke the SGPLOT procedure, using the SAS data set created by PROC TREE:

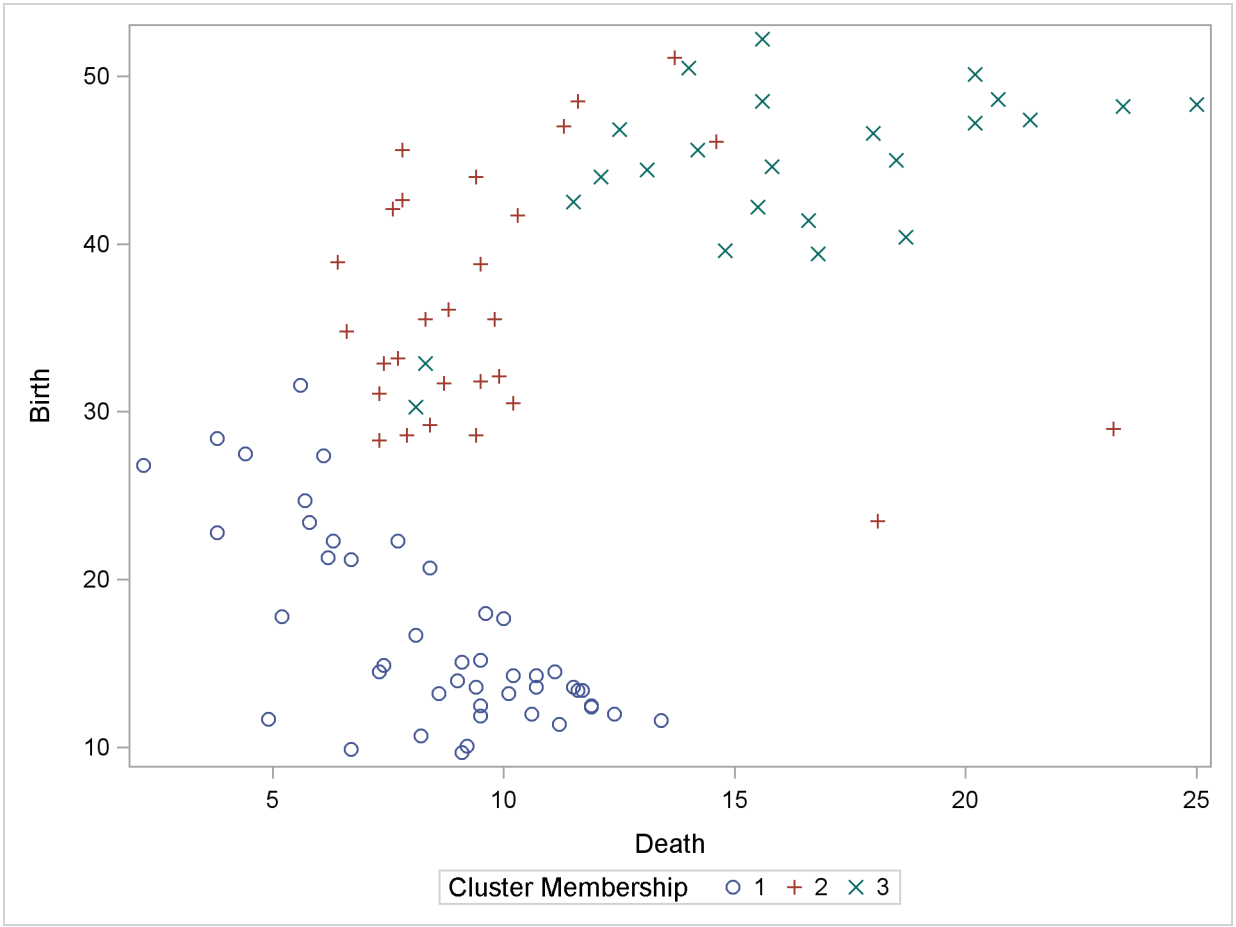
```
proc sgplot data=new;
   scatter y=Birth x= Death / group= cluster;
   keylegend / title= "Cluster Membership";
run;
proc sgplot data=new;
   scatter y=can2 x=can1 / group= cluster;
   keylegend / title= "Cluster Membership";
run;
```

The first PROC SGPLOT statement requests a scatter plot of the two variables Birth and Death, using the variable CLUSTER as the identification variable.

The second PROC SGPLOT statement requests a plot of the two canonical variables, using the value of the variable CLUSTER as the identification variable.

Figure 22.6 and Figure 22.7 display the separation of the clusters when three clusters are calculated.

Figure 22.6 Scatter Plot of Poverty Data, Identified by Cluster



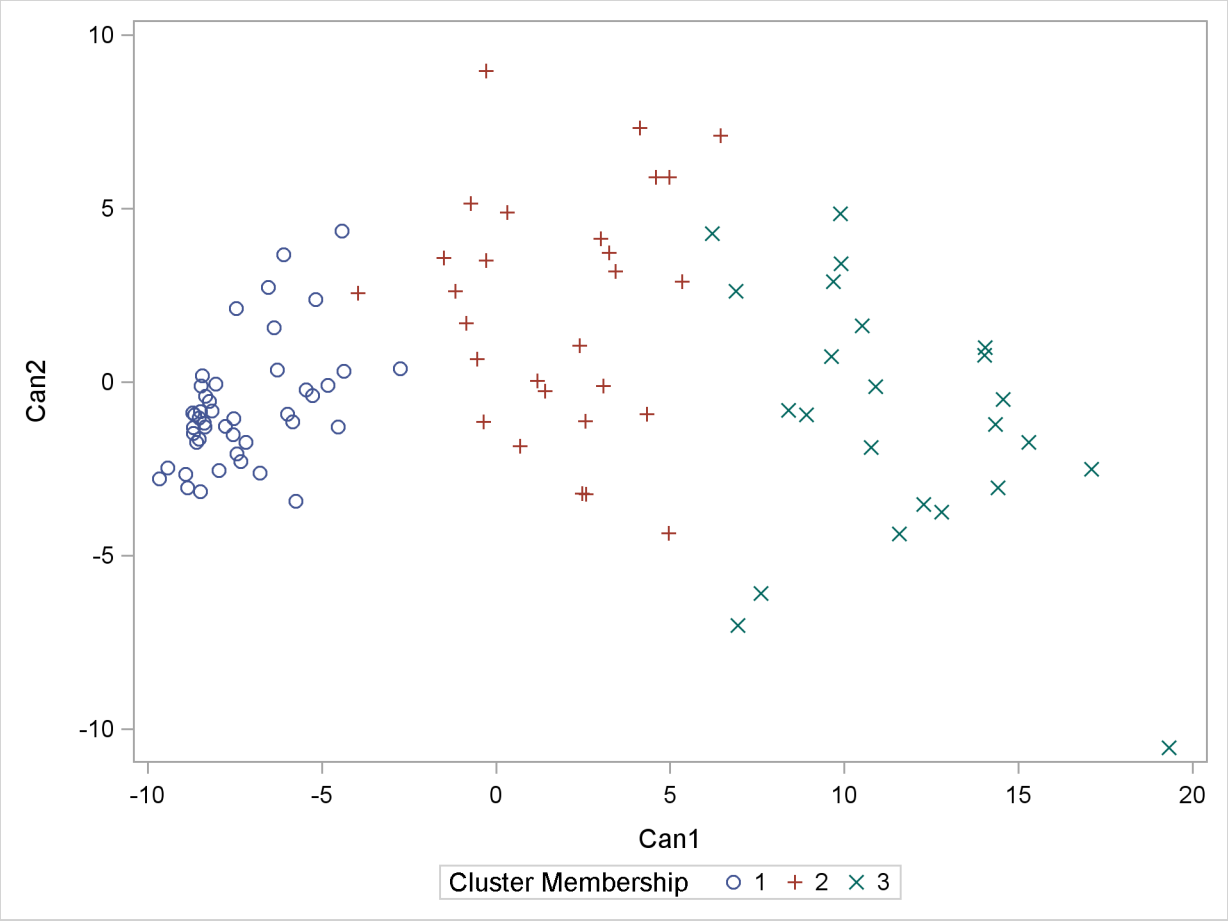


Figure 22.7 Scatter Plot of Canonical Variables

Syntax: ACECLUS Procedure

The following statements are available in the ACECLUS procedure:

PROC ACECLUS PROPORTION=*p* | **THRESHOLD=***t* < *options* > **;**
BY *variables* **;**
FREQ *variable* **;**
VAR *variables* **;**
WEIGHT *variable* **;**

Usually you need only the VAR statement in addition to the required PROC ACECLUS statement. The optional BY, FREQ, VAR, and WEIGHT statements are described in alphabetical order after the PROC ACECLUS statement.

PROC ACECLUS Statement

PROC ACECLUS PROPORTION=*p* | **THRESHOLD=***t* < *options* > **;**

The PROC ACECLUS statement starts the ACECLUS procedure. The options available with the PROC ACECLUS statement are summarized in Table 22.2 and discussed in the following sections. Note that, if you specify the METHOD=COUNT option, you must specify either the PROPORTION= or the MPAIRS= option. Otherwise, you must specify either the PROPORTION= or THRESHOLD= option.

Table 22.2 Summary of PROC ACECLUS Statement Options

Options	Description
Specify clustering options	
METHOD=	specifies the clustering method
MPAIRS=	specifies number of pairs for estimating within-cluster covariance (when you specify the option METHOD=COUNT)
PROPORTION=	specifies proportion of pairs for estimating within-cluster covariance
THRESHOLD=	specifies the threshold for including pairs in the estimation of the within-cluster covariance
Specify input and output data sets	
DATA=	specifies input data set name
OUT=	specifies output data set name
OUTSTAT=	specifies output data set name containing various statistics
Specify iteration options	
ABSOLUTE	uses absolute instead of relative threshold
CONVERGE=	specifies convergence criterion
INITIAL=	specifies initial estimate of within-cluster covariance matrix
MAXITER=	specifies maximum number of iterations
METRIC=	specifies metric in which computations are performed
SINGULAR=	specifies singularity criterion
Specify canonical analysis options	
N=	specifies number of canonical variables
PREFIX=	specifies prefix for naming canonical variables
Control displayed output	
NOPRINT	suppresses the display of the output
PP	produces PP-plot of distances between pairs from last iteration
QQ	produces QQ-plot of power transformation of distances between pairs from last iteration
SHORT	omits all output except for iteration history and eigenvalue table

The following list provides details about the options. The list is in alphabetical order.

ABSOLUTE

causes the THRESHOLD= value or the threshold computed from the PROPORTION= option to be treated absolutely rather than relative to the root mean square distance between observations. Use the ABSOLUTE option only when you are confident that the initial estimate of the within-cluster covariance matrix is close to the final estimate, such as when the INITIAL= option specifies a data set created by a previous execution of PROC ACECLUS by using the OUTSTAT= option.

CONVERGE=*c*

specifies the convergence criterion. By default, CONVERGE= 0.001. Iteration stops when the convergence measure falls below the value specified by the CONVERGE= option or when the iteration limit as specified by the MAXITER= option is exceeded, whichever happens first.

DATA=*SAS-data-set*

specifies the SAS data set to be analyzed. By default, PROC ACECLUS uses the most recently created SAS data set.

INITIAL=*name*

specifies the matrix for the initial estimate of the within-cluster covariance matrix. Valid values for *name* are as follows:

DIAGONAL | D
: uses the diagonal matrix of sample variances as the initial estimate of the within-cluster covariance matrix.

FULL | F
: uses the total-sample covariance matrix as the initial estimate of the within-cluster covariance matrix.

IDENTITY | I
: uses the identity matrix as the initial estimate of the within-cluster covariance matrix.

INPUT=*SAS-data-set*
: specifies a SAS data set from which to obtain the initial estimate of the within-cluster covariance matrix. The data set can be TYPE=CORR, COV, UCORR, UCOV, SSCP, or ACE, or it can be an ordinary SAS data set. See Appendix A, "Special SAS Data Sets," for descriptions of CORR, COV, UCORR, UCOV, and SSCP data sets. See the section "Output Data Sets" on page 680 for a description of ACE data sets.

  If you do not specify the INITIAL= option, the default is the matrix specified by the METRIC= option. If neither the INITIAL= nor the METRIC= option is specified, INITIAL=FULL is used if there are enough observations to obtain a nonsingular total-sample covariance matrix; otherwise, INITIAL=DIAGONAL is used.

MAXITER=*n*

specifies the maximum number of iterations. By default, MAXITER=10.

METHOD=COUNT | C | THRESHOLD | T

specifies the clustering method. The METHOD=THRESHOLD option requests a method (also the default) that uses all pairs closer than a given cutoff value to form the estimate at each iteration. The METHOD=COUNT option requests a method that uses a number of pairs, m, with the smallest distances to form the estimate at each iteration.

METRIC=*name*

specifies the metric in which the computations are performed, implies the default value for the INITIAL= option, and specifies the matrix $\mathbf{Z}$ used in the formula for the convergence measure e_i and for checking singularity of the $\mathbf{A}$ matrix. Valid values for *name* are as follows:

DIAGONAL | D	uses the diagonal matrix of sample variances diag($\mathbf{S}$) and sets $\mathbf{Z} = \text{diag}(\mathbf{S})^{-\frac{1}{2}}$, where the superscript $-\frac{1}{2}$ indicates an inverse factor.
FULL | F	uses the total-sample covariance matrix $\mathbf{S}$ and sets $\mathbf{Z} = \mathbf{S}^{-\frac{1}{2}}$.
IDENTITY | I	uses the identity matrix $\mathbf{I}$ and sets $\mathbf{Z} = \mathbf{I}$.

If you do not specify the METRIC= option, METRIC=FULL is used if there are enough observations to obtain a nonsingular total-sample covariance matrix; otherwise, METRIC=DIAGONAL is used.

The option METRIC= is rather technical. It affects the computations in a variety of ways, but for well-conditioned data the effects are subtle. For most data sets, the METRIC= option is not needed.

MPAIRS=*m*

specifies the number of pairs to be included in the estimation of the within-cluster covariance matrix when METHOD=COUNT is requested. The values of m must be greater than 0 but less than or equal to $(totfq \times (totfq-1))/2$, where *totfq* is the sum of nonmissing frequencies specified in the FREQ statement. If there is no FREQ statement, *totfq* equals the number of total nonmissing observations.

N=*n*

specifies the number of canonical variables to be computed. The default is the number of variables analyzed. N=0 suppresses the canonical analysis.

NOPRINT

suppresses the display of all output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, "Using the Output Delivery System."

OUT=*SAS-data-set*

creates an output SAS data set that contains all the original data as well as the canonical variables having an estimated within-cluster covariance matrix equal to the identity matrix. If you want to create a permanent SAS data set, you must specify a two-level name. See *SAS Language Reference: Concepts* for more information about permanent SAS data sets.

OUTSTAT=*SAS-data-set*

specifies a TYPE=ACE output SAS data set that contains means, standard deviations, number of observations, covariances, estimated within-cluster covariances, eigenvalues, and canonical coefficients. If you want to create a permanent SAS data set, you must specify a two-level name. See *SAS Language Reference: Concepts* for more information about permanent SAS data sets.

PROPORTION=*p*

PERCENT=*p*

P=*p*

specifies the percentage of pairs to be included in the estimation of the within-cluster covariance matrix. The value of p must be greater than 0. If p is greater than or equal to 1, it is interpreted as a percentage and divided by 100; PROPORTION=0.02 and PROPORTION=2 are equivalent. When you specify METHOD=THRESHOLD, a threshold value is computed from the PROPORTION= option under the assumption that the observations are sampled from a multivariate normal distribution.

When you specify METHOD=COUNT, the number of pairs, m, is computed from PROPORTION=p as

$$m = \text{floor}\left(\frac{p}{2} \times totfq \times (totfq - 1)\right)$$

where *totfq* is the number of total nonmissing observations.

PP

produces a PP probability plot of distances between pairs of observations computed in the last iteration.

PREFIX=*name*

specifies a prefix for naming the canonical variables. By default the names are Can1, Can2, ..., CANN. If you specify PREFIX=ABC, the variables are named ABC1, ABC2, ABC3, and so on. The number of characters in the prefix plus the number of digits required to designate the variables should not exceed the name length defined by the VALIDVARNAME= system option. For more information about the VALIDVARNAME= system option, see *SAS Language Reference: Dictionary*.

QQ

produces a QQ probability plot of a power transformation of the distances between pairs of observations computed in the last iteration. **CAUTION:** The QQ plot can require an enormous amount of computer time.

SHORT

omits all items from the standard output except for the iteration history and the eigenvalue table.

SINGULAR=*g*

SING=*g*

specifies a singularity criterion $0 < g < 1$ for the total-sample covariance matrix $\mathbf{S}$ and the approximate within-cluster covariance estimate $\mathbf{A}$. The default is SINGULAR=1E−4.

THRESHOLD=*t*

T=*t*

specifies the threshold for including pairs of observations in the estimation of the within-cluster covariance matrix. A pair of observations is included if the Euclidean distance between them is less than or equal to t times the root mean square distance computed over all pairs of observations.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC ACECLUS to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for PROC ACECLUS. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

If you specify the INITIAL=INPUT= option and the INITIAL=INPUT= data set does not contain any of the BY variables, the entire INITIAL=INPUT= data set provides the initial value for the matrix **A** for each BY group in the DATA= data set.

If the INITIAL=INPUT= data set contains some but not all of the BY variables, or if some BY variables do not have the same type or length in the INITIAL=INPUT= data set as in the DATA= data set, then PROC ACECLUS displays an error message and stops.

If all the BY variables appear in the INITIAL=INPUT= data set with the same type and length as in the DATA= data set, then each BY group in the INITIAL=INPUT= data set provides the initial value for **A** for the corresponding BY group in the DATA= data set. All BY groups in the DATA= data set must also appear in the INITIAL= INPUT= data set. The BY groups in the INITIAL=INPUT= data set must be in the same order as in the DATA= data set. If you specify NOTSORTED in the BY statement, identical BY groups must occur in the same order in both data sets. If you do not specify NOTSORTED, some BY groups can appear in the INITIAL= INPUT= data set, but not in the DATA= data set; such BY groups are not used in the analysis.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the *Base SAS Procedures Guide.*

FREQ Statement

FREQ *variable* **;**

If a variable in your data set represents the frequency of occurrence for the observation, include the name of that variable in the FREQ statement. The procedure then treats the data set as if each observation appears n times, where n is the value of the FREQ variable for the observation. If a value of the FREQ variable is not integral, it is truncated to the largest integer not exceeding the given value. Observations with FREQ values less than one are not included in the analysis. The total number of observations is considered equal to the sum of the FREQ variable.

VAR Statement

VAR *variables* **;**

The VAR statement specifies the numeric variables to be analyzed. If the VAR statement is omitted, all numeric variables not specified in other statements are analyzed.

WEIGHT Statement

WEIGHT *variable* **;**

If you want to specify relative weights for each observation in the input data set, place the weights in a variable in the data set and specify that variable name in a WEIGHT statement. This is often done when the variance associated with each observation is different and the values of the weight variable are proportional to the reciprocals of the variances. The values of the WEIGHT variable can be nonintegral and are not truncated. An observation is used in the analysis only if the value of the WEIGHT variable is greater than zero.

The WEIGHT and FREQ statements have a similar effect, except in calculating the divisor of the **A** matrix.

Details: ACECLUS Procedure

Missing Values

Observations with missing values are omitted from the analysis and are given missing values for canonical variable scores in the OUT= data set.

Output Data Sets

OUT= Data Set

The OUT= data set contains all the variables in the original data set plus new variables containing the canonical variable scores. The N= option determines the number of new variables. The OUT= data set is not created if N=0. The names of the new variables are formed by concatenating the value given by the PREFIX= option (or the prefix CAN if the PREFIX= option is not specified) and the numbers 1, 2, 3, and so on. The OUT= data set can be used as input to PROC CLUSTER or PROC FASTCLUS. The cluster analysis should be performed on the canonical variables, not on the original variables.

OUTSTAT= Data Set

The OUTSTAT= data set is a TYPE=ACE data set containing the following variables:

- the BY variables, if any
- the two new character variables, _TYPE_ and _NAME_
- the variables analyzed—that is, those in the VAR statement, or, if there is no VAR statement, all numeric variables not listed in any other statement

Each observation in the new data set contains some type of statistic as indicated by the _TYPE_ variable. The values of the _TYPE_ variable are as follows:

MEAN	mean of each variable
STD	standard deviation of each variable
N	number of observations on which the analysis is based. This value is the same for each variable.
SUMWGT	sum of the weights if a WEIGHT statement is used. This value is the same for each variable.
COV	covariances between each variable and the variable named by the _NAME_ variable. The number of observations with _TYPE_=COV is equal to the number of variables being analyzed.
ACE	estimated within-cluster covariances between each variable and the variable named by the _NAME_ variable. The number of observations with _TYPE_=ACE is equal to the number of variables being analyzed.
EIGENVAL	eigenvalues of INV(ACE)*(COV−ACE). If the N= option requests fewer than the maximum number of canonical variables, only the specified number of eigenvalues are produced, with missing values filling out the observation.

RAWSCORE — raw canonical coefficients.

To obtain the canonical variable scores, these coefficients should be multiplied by the raw data centered by means obtained from the observation with _TYPE_='MEAN'.

SCORE — standardized canonical coefficients. The _NAME_ variable contains the name of the corresponding canonical variable as constructed from the PREFIX= option. The number of observations with _TYPE_=SCORE equals the number of canonical variables computed.

To obtain the canonical variable scores, these coefficients should be multiplied by the standardized data, using means obtained from the observation with _TYPE_='MEAN' and standard deviations obtained from the observation with _TYPE_='STD'.

The OUTSTAT= data set can be used in the following conditions:

- to initialize another execution of PROC ACECLUS
- to compute canonical variable scores with the SCORE procedure
- as input to the FACTOR procedure, specifying METHOD=SCORE, to rotate the canonical variables

Computational Resources

Let

n = number of observations

v = number of variables

i = number of iterations

Memory

The memory in bytes required by PROC ACECLUS is approximately

$$8(2n(v+1)+21v+5v^2)$$

bytes. If you request the PP or QQ option, an additional $4n(n-1)$ bytes are needed.

Time

The time required by PROC ACECLUS is roughly proportional to

$$2nv^2+10v^3+i\left(\frac{n^2v}{2}+nv^2+5v^3\right)$$

Displayed Output

Unless the SHORT option is specified, the ACECLUS procedure displays the following items:

- Means and Standard Deviations of the input variables
- the **S** matrix, labeled COV: Total Sample Covariances
- the name or value of the matrix used for the Initial Within-Cluster Covariance Estimate
- the Threshold value if the PROPORTION= option is specified

For each iteration, PROC ACECLUS displays the following items:

- the Iteration number
- RMS Distance, the root mean square distance between all pairs of observations
- the Distance Cutoff (u) for including pairs of observations in the estimate of the within-cluster covariances, which equals the RMS distance times the threshold
- the number of Pairs Within Cutoff
- the Convergence Measure (e_i) as specified by the METRIC= option

If the SHORT option is not specified, PROC ACECLUS also displays the **A** matrix, labeled ACE: Approximate Covariance Estimate Within Clusters.

The ACECLUS procedure displays a table of eigenvalues from the canonical analysis containing the following items:

- Eigenvalues of Inv(ACE)*(COV−ACE)
- the Difference between successive eigenvalues
- the Proportion of variance explained by each eigenvalue
- the Cumulative proportion of variance explained

If the SHORT option is not specified, PROC ACECLUS displays the following items:

- the Eigenvectors or raw canonical coefficients
- the standardized eigenvectors or standard canonical coefficients

ODS Table Names

PROC ACECLUS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 22.3 ODS Tables Produced by PROC ACECLUS

ODS Table Name	Description	Statement	Option
ConvergenceStatus	Convergence status	PROC	default
DataOptionInfo	Data and option information	PROC	default
Eigenvalues	Eigenvalues of Inv(ACE)*(COV–ACE)	PROC	default
Eigenvectors	Eigenvectors (raw canonical coefficients)	PROC	default
InitWithin	Initial within-cluster covariance estimate	PROC	INITIAL=INPUT
IterHistory	Iteration history	PROC	default
SimpleStatistics	Simple statistics	PROC	default
StdCanCoef	Standardized canonical coefficients	PROC	default
Threshold	Threshold value	PROC	PROPORTION=
TotSampleCov	Total sample covariances	PROC	default
Within	Approximate covariance estimate within clusters	PROC	default

Example: ACECLUS Procedure

Example 22.1: Transformation and Cluster Analysis of Fisher Iris Data

The iris data published by Fisher (1936) have been widely used for examples in discriminant analysis and cluster analysis. The sepal length, sepal width, petal length, and petal width are measured in millimeters on 50 iris specimens from each of three species, *Iris setosa, I. versicolor,* and *I. virginica*. Mezzich and Solomon (1980) discuss a variety of cluster analyses of the iris data.

In this example PROC ACECLUS is used to transform the data, and the clustering is performed by PROC FASTCLUS. Compare this with the example in Chapter 34, "The FASTCLUS Procedure." The results from the FREQ procedure display fewer misclassifications when PROC ACECLUS is used. The following statements produce Output 22.1.1 through Output 22.1.5.

```

Overview: ANOVA Procedure

The ANOVA procedure performs *analysis of variance* (ANOVA) for balanced data from a wide variety of experimental designs. In analysis of variance, a continuous response variable, known as a *dependent variable*, is measured under experimental conditions identified by classification variables, known as *independent variables*. The variation in the response is assumed to be due to effects in the classification, with random error accounting for the remaining variation.

The ANOVA procedure is one of several procedures available in SAS/STAT software for analysis of variance. The ANOVA procedure is designed to handle balanced data (that is, data with equal numbers of observations for every combination of the classification factors), whereas the GLM procedure can analyze both balanced and unbalanced data. Because PROC ANOVA takes into account the special structure of a balanced design, it is faster and uses less storage than PROC GLM for balanced data.

Use PROC ANOVA for the analysis of balanced data only, with the following exceptions: one-way analysis of variance, Latin square designs, certain partially balanced incomplete block designs, completely nested (hierarchical) designs, and designs with cell frequencies that are proportional to each other and are also proportional to the background population. These exceptions have designs in which the factors are all orthogonal to each other.

For further discussion, see Searle (1971, p. 138). PROC ANOVA works for designs with block diagonal $\mathbf{X}'\mathbf{X}$ matrices where the elements of each block all have the same value. The procedure partially tests this requirement by checking for equal cell means. However, this test is imperfect: some designs that cannot be analyzed correctly might pass the test, and designs that can be analyzed correctly might not pass. If your design does not pass the test, PROC ANOVA produces a warning message to tell you that the design is unbalanced and that the ANOVA analyses might not be valid; if your design is not one of the special cases described here, then you should use PROC GLM instead. Complete validation of designs is not performed in PROC ANOVA since this would require the whole $\mathbf{X}'\mathbf{X}$ matrix; if you're unsure about the validity of PROC ANOVA for your design, you should use PROC GLM.

CAUTION: If you use PROC ANOVA for analysis of unbalanced data, you must assume responsibility for the validity of the results.

The ANOVA procedure automatically produces graphics as part of its ODS output. For general information about ODS graphics, see the section "ODS Graphics" on page 729 and Chapter 21, "Statistical Graphics Using ODS."

Getting Started: ANOVA Procedure

The following examples demonstrate how you can use the ANOVA procedure to perform analyses of variance for a one-way layout and a randomized complete block design.

One-Way Layout with Means Comparisons

A one-way analysis of variance considers one treatment factor with two or more treatment levels. The goal of the analysis is to test for differences among the means of the levels and to quantify these differences. If there are two treatment levels, this analysis is equivalent to a t test comparing two group means.

The assumptions of analysis of variance (Steel and Torrie 1980) are that treatment effects are additive and experimental errors are independently random with a normal distribution that has mean zero and constant variance.

The following example studies the effect of bacteria on the nitrogen content of red clover plants. The treatment factor is bacteria strain, and it has six levels. Five of the six levels consist of five different *Rhizobium trifolii* bacteria cultures combined with a composite of five *Rhizobium meliloti* strains. The sixth level is a composite of the five *Rhizobium trifolii* strains with the composite of the *Rhizobium meliloti*. Red clover plants are inoculated with the treatments, and nitrogen content is later measured in milligrams. The data are derived from an experiment by Erdman (1946) and are analyzed in Chapters 7 and 8 of Steel and Torrie (1980). The following DATA step creates the SAS data set Clover:

```
title1 'Nitrogen Content of Red Clover Plants';
data Clover;
   input Strain $ Nitrogen @@;
   datalines;
3DOK1  19.4 3DOK1  32.6 3DOK1  27.0 3DOK1  32.1 3DOK1  33.0
3DOK5  17.7 3DOK5  24.8 3DOK5  27.9 3DOK5  25.2 3DOK5  24.3
3DOK4  17.0 3DOK4  19.4 3DOK4   9.1 3DOK4  11.9 3DOK4  15.8
3DOK7  20.7 3DOK7  21.0 3DOK7  20.5 3DOK7  18.8 3DOK7  18.6
3DOK13 14.3 3DOK13 14.4 3DOK13 11.8 3DOK13 11.6 3DOK13 14.2
COMPOS 17.3 COMPOS 19.4 COMPOS 19.1 COMPOS 16.9 COMPOS 20.8
;
```

The variable Strain contains the treatment levels, and the variable Nitrogen contains the response. The following statements produce the analysis.

```
proc anova data = Clover;
   class strain;
   model Nitrogen = Strain;
run;
```

The classification variable is specified in the CLASS statement. Note that, unlike the GLM procedure, PROC ANOVA does not allow continuous variables on the right-hand side of the model. Figure 23.1 and Figure 23.2 display the output produced by these statements.

Figure 23.1 Class Level Information

```
                    Nitrogen Content of Red Clover Plants

                              The ANOVA Procedure

                            Class Level Information

          Class          Levels    Values

          Strain              6    3DOK1 3DOK13 3DOK4 3DOK5 3DOK7 COMPOS

                     Number of Observations Read          30
                     Number of Observations Used          30
```

The "Class Level Information" table shown in Figure 23.1 lists the variables that appear in the CLASS statement, their levels, and the number of observations in the data set.

Figure 23.2 displays the ANOVA table, followed by some simple statistics and tests of effects.

Figure 23.2 ANOVA Table

```
                    Nitrogen Content of Red Clover Plants

                              The ANOVA Procedure

Dependent Variable: Nitrogen

                                        Sum of
 Source                       DF        Squares    Mean Square   F Value   Pr > F

 Model                         5     847.046667     169.409333     14.37   <.0001

 Error                        24     282.928000      11.788667

 Corrected Total              29    1129.974667

             R-Square     Coeff Var      Root MSE    Nitrogen Mean

             0.749616      17.26515      3.433463         19.88667

 Source                       DF       Anova SS    Mean Square   F Value   Pr > F

 Strain                        5    847.0466667    169.4093333     14.37   <.0001
```

The degrees of freedom (DF) column should be used to check the analysis results. The model degrees of freedom for a one-way analysis of variance are the number of levels minus 1; in this case, $6 - 1 = 5$. The Corrected Total degrees of freedom are always the total number of observations minus one; in this case $30 - 1 = 29$. The sum of Model and Error degrees of freedom equal the Corrected Total.

The overall F test is significant ($F = 14.37$, $p < 0.0001$), indicating that the model as a whole

accounts for a significant portion of the variability in the dependent variable. The F test for Strain is significant, indicating that some contrast between the means for the different strains is different from zero. Notice that the Model and Strain F tests are identical, since Strain is the only term in the model.

The F test for Strain ($F = 14.37, p < 0.0001$) suggests that there are differences among the bacterial strains, but it does not reveal any information about the nature of the differences. Mean comparison methods can be used to gather further information. The interactivity of PROC ANOVA enables you to do this without re-running the entire analysis. After you specify a model with a MODEL statement and execute the ANOVA procedure with a RUN statement, you can execute a variety of statements (such as MEANS, MANOVA, TEST, and REPEATED) without PROC ANOVA recalculating the model sum of squares.

The following command requests means of the Strain levels with Tukey's studentized range procedure.

```
means strain / tukey;
```

Results of Tukey's procedure are shown in Figure 23.3.

Figure 23.3 Tukey's Multiple Comparisons Procedure

Nitrogen Content of Red Clover Plants

The ANOVA Procedure

Tukey's Studentized Range (HSD) Test for Nitrogen

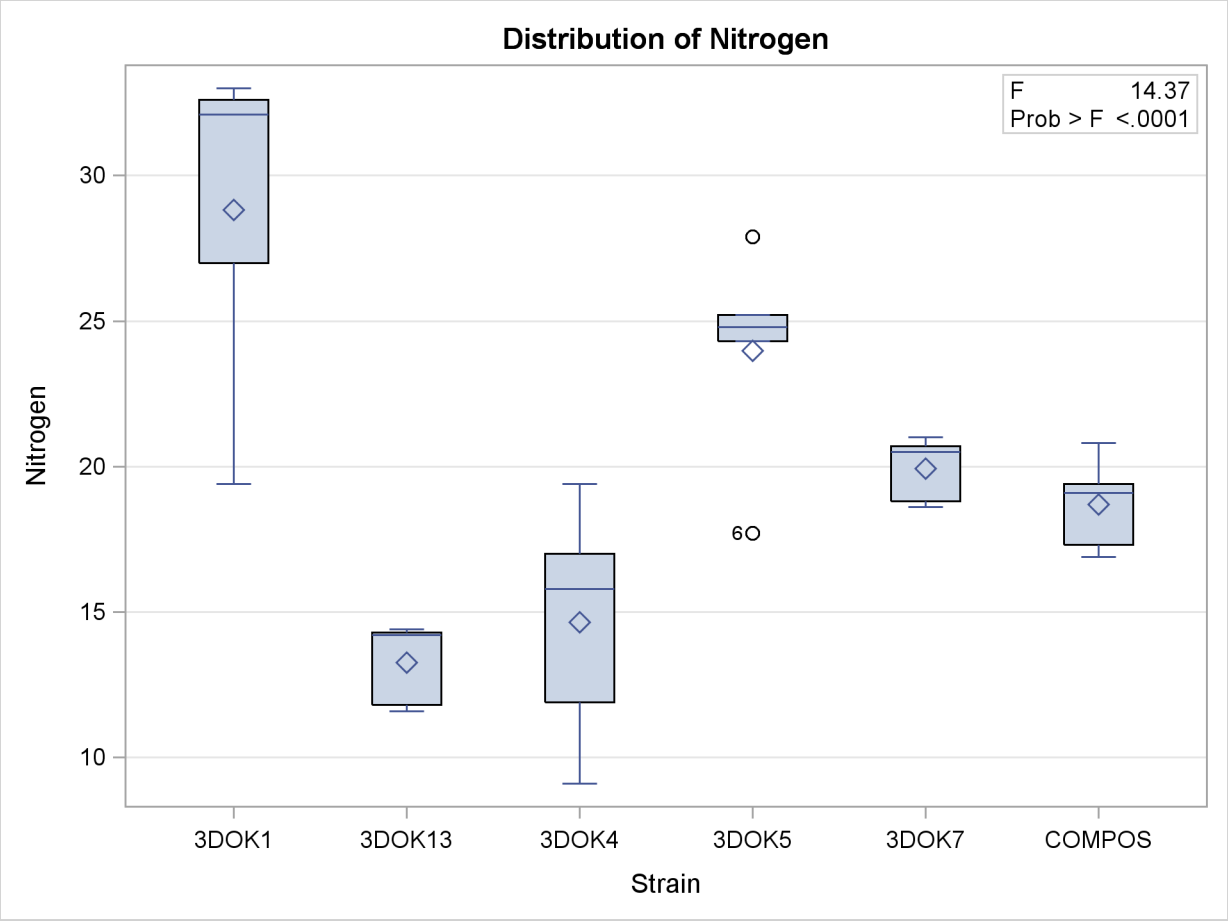
Alpha	0.05
Error Degrees of Freedom	24
Error Mean Square	11.78867
Critical Value of Studentized Range	4.37265
Minimum Significant Difference	6.7142

Means with the same letter are not significantly different.

Tukey Grouping	Mean	N	Strain
A	28.820	5	3DOK1
A			
B A	23.980	5	3DOK5
B			
B C	19.920	5	3DOK7
B C			
B C	18.700	5	COMPOS
C			
C	14.640	5	3DOK4
C			
C	13.260	5	3DOK13

Examples of implications of the multiple comparisons results are as follows:

- Strain 3DOK1 fixes significantly more nitrogen than all but 3DOK5.
- While 3DOK5 is not significantly different from 3DOK1, it is also not significantly better than all the rest, though it is better than the bottom two groups.



Although the experiment has succeeded in separating the best strains from the worst, more experimentation is required in order to clearly distinguish the very best strain.

If you enable ODS Graphics, ANOVA also displays by default a plot that enables you to visualize the distribution of nitrogen content for each treatment. The following statements, which are the same as the previous analysis but with ODS graphics enabled, additionally produce Figure 23.4.

```
ods graphics on;
proc anova data = Clover;
   class strain;
   model Nitrogen = Strain;
run;
ods graphics off;
```

When you specify the ODS GRAPHICS statement and fit a one-way analysis of variance model, the ANOVA procedure output includes a box plot of the dependent variable values within each classification level of the independent variable. For general information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS." For specific information about the graphics available in the ANOVA procedure, see the section "ODS Graphics" on page 729.

Figure 23.4 Box Plot of Nitrogen Content for each Treatment

Randomized Complete Block with One Factor

This example illustrates the use of PROC ANOVA in analyzing a randomized complete block design. Researchers are interested in whether three treatments have different effects on the yield and worth of a particular crop. They believe that the experimental units are not homogeneous. So, a blocking factor is introduced that allows the experimental units to be homogeneous within each block. The three treatments are then randomly assigned within each block.

The data from this study are input into the SAS data set RCB:

```
title1 'Randomized Complete Block';
data RCB;
   input Block Treatment $ Yield Worth @@;
   datalines;
1 A 32.6 112   1 B 36.4 130   1 C 29.5 106
2 A 42.7 139   2 B 47.1 143   2 C 32.9 112
3 A 35.3 124   3 B 40.1 134   3 C 33.6 116
;
```

The variables Yield and Worth are continuous response variables, and the variables Block and Treatment are the classification variables. Because the data for the analysis are balanced, you can use PROC ANOVA to run the analysis.

The statements for the analysis are

```
proc anova data=RCB;
   class Block Treatment;
   model Yield Worth=Block Treatment;
run;
```

The Block and Treatment effects appear in the CLASS statement. The MODEL statement requests an analysis for each of the two dependent variables, Yield and Worth.

Figure 23.5 shows the "Class Level Information" table.

Figure 23.5 Class Level Information

```
                    Randomized Complete Block

                       The ANOVA Procedure

                     Class Level Information

                Class          Levels    Values

                Block               3    1 2 3

                Treatment           3    A B C

              Number of Observations Read           9
              Number of Observations Used           9
```

The "Class Level Information" table lists the number of levels and their values for all effects specified in the CLASS statement. The number of observations in the data set are also displayed. Use this information to make sure that the data have been read correctly.

The overall ANOVA table for Yield in Figure 23.6 appears first in the output because it is the first response variable listed on the left side in the MODEL statement.

Figure 23.6 Overall ANOVA Table for Yield

Randomized Complete Block

The ANOVA Procedure

Dependent Variable: Yield

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	4	225.2777778	56.3194444	8.94	0.0283
Error	4	25.1911111	6.2977778		
Corrected Total	8	250.4688889			

R-Square	Coeff Var	Root MSE	Yield Mean
0.899424	6.840047	2.509537	36.68889

The overall F statistic is significant ($F = 8.94$, $p = 0.0283$), indicating that the model as a whole accounts for a significant portion of the variation in Yield and that you can proceed to evaluate the tests of effects.

The degrees of freedom (DF) are used to ensure correctness of the data and model. The Corrected Total degrees of freedom are one less than the total number of observations in the data set; in this case, $9-1 = 8$. The Model degrees of freedom for a randomized complete block are $(b-1)+(t-1)$, where b =number of block levels and t =number of treatment levels. In this case, this formula leads to $(3-1)+(3-1) = 4$ model degrees of freedom.

Several simple statistics follow the ANOVA table. The R-Square indicates that the model accounts for nearly 90% of the variation in the variable Yield. The coefficient of variation (C.V.) is listed along with the Root MSE and the mean of the dependent variable. The Root MSE is an estimate of the standard deviation of the dependent variable. The C.V. is a unitless measure of variability.

The tests of the effects shown in Figure 23.7 are displayed after the simple statistics.

Figure 23.7 Tests of Effects for Yield

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Block	2	98.1755556	49.0877778	7.79	0.0417
Treatment	2	127.1022222	63.5511111	10.09	0.0274

For Yield, both the Block and Treatment effects are significant ($F = 7.79$, $p = 0.0417$ and $F = 10.09$, $p = 0.0274$, respectively) at the 95% level. From this you can conclude that blocking is useful for this variable and that some contrast between the treatment means is significantly different from zero.

Figure 23.8 shows the ANOVA table, simple statistics, and tests of effects for the variable Worth.

Figure 23.8 ANOVA Table for Worth

Randomized Complete Block

The ANOVA Procedure

Dependent Variable: Worth

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	4	1247.333333	311.833333	8.28	0.0323
Error	4	150.666667	37.666667		
Corrected Total	8	1398.000000			

R-Square	Coeff Var	Root MSE	Worth Mean
0.892227	4.949450	6.137318	124.0000

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Block	2	354.6666667	177.3333333	4.71	0.0889
Treatment	2	892.6666667	446.3333333	11.85	0.0209

The overall F test is significant ($F = 8.28$, $p = 0.0323$) at the 95% level for the variable Worth. The Block effect is not significant at the 0.05 level but is significant at the 0.10 confidence level ($F = 4.71$, $p = 0.0889$). Generally, the usefulness of blocking should be determined before the analysis. However, since there are two dependent variables of interest, and Block is significant for one of them (Yield), blocking appears to be generally useful. For Worth, as with Yield, the effect of Treatment is significant ($F = 11.85$, $p = 0.0209$).

Issuing the following command produces the Treatment means.

```
    means Treatment;
run;
```

Figure 23.9 displays the treatment means and their standard deviations for both dependent variables.

Figure 23.9 Means of Yield and Worth

```
                          Randomized Complete Block

```

Syntax: ANOVA Procedure

The following statements are available in PROC ANOVA.

PROC ANOVA < *options* > ;
  CLASS *variables* < / *option* > ;
  MODEL *dependents=effects* < / *options* > ;
  ABSORB *variables* ;
  BY *variables* ;
  FREQ *variable* ;
  MANOVA < *test-options* >< / *detail-options* > ;
  MEANS *effects* < / *options* > ;
  REPEATED *factor-specification* < / *options* > ;
  TEST < **H=***effects* > **E=***effect* ;

The PROC ANOVA, CLASS, and MODEL statements are required, and they must precede the first RUN statement. The CLASS statement must precede the MODEL statement. If you use the ABSORB, FREQ, or BY statement, it must precede the first RUN statement. The MANOVA, MEANS, REPEATED, and TEST statements must follow the MODEL statement, and they can be specified in any order. These four statements can also appear after the first RUN statement.

Table 23.1 summarizes the function of each statement (other than the PROC statement) in the ANOVA procedure:

Table 23.1 Statements in the ANOVA Procedure

Statement	Description
ABSORB	absorbs classification effects in a model
BY	specifies variables to define subgroups for the analysis
CLASS	declares classification variables
FREQ	specifies a frequency variable
MANOVA	performs a multivariate analysis of variance
MEANS	computes and compares means
MODEL	defines the model to be fit

Table 23.1 *continued*

Statement	Description
REPEATED	performs multivariate and univariate repeated measures analysis of variance
TEST	constructs tests that use the sums of squares for effects and the error term you specify

PROC ANOVA Statement

PROC ANOVA < *options* > **;**

The PROC ANOVA statement starts the ANOVA procedure.

You can specify the following options in the PROC ANOVA statement:

DATA=*SAS-data-set*
names the SAS data set used by the ANOVA procedure. By default, PROC ANOVA uses the most recently created SAS data set.

MANOVA
requests the multivariate mode of eliminating observations with missing values. If any of the dependent variables have missing values, the procedure eliminates that observation from the analysis. The MANOVA option is useful if you use PROC ANOVA in interactive mode and plan to perform a multivariate analysis.

MULTIPASS
requests that PROC ANOVA reread the input data set, when necessary, instead of writing the values of dependent variables to a utility file. This option decreases disk space usage at the expense of increased execution times and is useful only in rare situations where disk space is at an absolute premium.

NAMELEN=*n*
specifies the length of effect names to be *n* characters long, where *n* is a value between 20 and 200 characters. The default length is 20 characters.

NOPRINT
suppresses the normal display of results. The NOPRINT option is useful when you want to create only the output data set with the procedure. Note that this option temporarily disables the Output Delivery System

(ODS); see Chapter 20, "Using the Output Delivery System," for more information.

ORDER=DATA | FORMATTED | FREQ | INTERNAL
specifies the sorting order for the levels of the classification variables (specified in the CLASS statement). This ordering determines which parameters in the model correspond to each level in the data. Note that the ORDER= option applies to the levels for all classification variables. The exception is the default ORDER=FORMATTED for numeric variables for which you

have supplied no explicit format. In this case, the levels are ordered by their internal value. Note that this represents a change from previous releases for how classification levels are ordered. In releases previous to Version 8, numeric classification levels with no explicit format were ordered by their BEST12. formatted values, and in order to revert to the previous ordering you can specify this format explicitly for the affected classification variables. The change was implemented because the former default behavior for ORDER=FORMATTED often resulted in levels not being ordered numerically and usually required the user to intervene with an explicit format or ORDER=INTERNAL to get the more natural ordering.

The following table shows how PROC ANOVA interprets values of the ORDER= option.

Value of ORDER=	Levels Sorted By
DATA	order of appearance in the input data set
FORMATTED	external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

OUTSTAT=*SAS-data-set*

names an output data set that contains sums of squares, degrees of freedom, F statistics, and probability levels for each effect in the model. If you use the CANONICAL option in the MANOVA statement and do not use an M= specification in the MANOVA statement, the data set also contains results of the canonical analysis. See the section "Output Data Set" on page 724 for more information.

PLOTS=NONE

controls the plots produced through ODS Graphics. When ODS Graphics is enabled, the ANOVA procedure can display a grouped box-plot of the input data with groups defined by an effect in the model. Such a plot is produced by default if you have a one-way model, with only a single classification variable, or if you use a MEANS statement. Specify the PLOTS=NONE option in order to prevent these plots from being produced when ODS Graphics is enabled.

ABSORB Statement

ABSORB *variables* **;**

Absorption is a computational technique that provides a large reduction in time and memory requirements for certain types of models. The *variables* are one or more variables in the input data set.

For a main effect variable that does not participate in interactions, you can absorb the effect by naming it in an ABSORB statement. This means that the effect can be adjusted out before the construction and solution of the rest of the model. This is particularly useful when the effect has a large number of levels.

Several variables can be specified, in which case each one is assumed to be nested in the preceding variable in the ABSORB statement.

NOTE: When you use the ABSORB statement, the data set (or each BY group, if a BY statement appears) must be sorted by the variables in the ABSORB statement. Including an absorbed variable in the CLASS list or in the MODEL statement might produce erroneous sums of squares. If the ABSORB statement is used, it must appear before the first RUN statement or it is ignored.

When you use an ABSORB statement and also use the INT option in the MODEL statement, the procedure ignores the option but produces the uncorrected total sum of squares (SS) instead of the corrected total SS.

See the section "Absorption" on page 2507 in Chapter 39, "The GLM Procedure," for more information.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC ANOVA to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. The *variables* are one or more variables in the input data set.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the ANOVA procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in base SAS software).

Since sorting the data changes the order in which PROC ANOVA reads observations, the sorting order for the levels of the classification variables might be affected if you have also specified the ORDER=DATA option in the PROC ANOVA statement.

If the BY statement is used, it must appear before the first RUN statement or it is ignored. When you use a BY statement, the interactive features of PROC ANOVA are disabled.

When both a BY and an ABSORB statement are used, observations must be sorted first by the variables in the BY statement, and then by the variables in the ABSORB statement.

For more information about the BY statement, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *SAS Procedures Guide*.

CLASS Statement

CLASS *variables* < / *option* > **;**

The CLASS statement names the classification variables to be used in the model. Typical classification variables are TREATMENT, SEX, RACE, GROUP, and REPLICATION. The CLASS statement is required, and it must appear before the MODEL statement.

By default, classification levels are determined from the entire formatted values of the CLASS variables. Note that this represents a slight change from previous releases in the way in which classification levels are determined. In releases prior to Version 9, classification levels were determined by using no more than the first 16 characters of the formatted values. If you wish to revert to this previous behavior you can use the TRUNCATE option on the CLASS statement. In any case, you can use formats to group values into levels.

See the discussion of the FORMAT procedure in the *SAS Procedures Guide* and the discussions for the FORMAT statement and SAS formats in *SAS Language Reference: Concepts*.

You can specify the following option in the CLASS statement after a slash(/):

TRUNCATE
specifies that classification levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option in order to revert to the levels as determined in releases previous to Version 9.

FREQ Statement

FREQ *variable* **;**

The FREQ statement names a variable that provides frequencies for each observation in the DATA= data set. Specifically, if n is the value of the FREQ variable for a given observation, then that observation is used n times.

The analysis produced by using a FREQ statement reflects the expanded number of observations. For example, means and total degrees of freedom reflect the expanded number of observations. You can produce the same analysis (without the FREQ statement) by first creating a new data set that contains the expanded number of observations. For example, if the value of the FREQ variable is 5 for the first observation, the first 5 observations in the new data set would be identical. Each observation in the old data set would be replicated n_i times in the new data set, where n_i is the value of the FREQ variable for that observation.

If the value of the FREQ variable is missing or is less than 1, the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

If the FREQ statement is used, it must appear before the first RUN statement or it is ignored.

MANOVA Statement

MANOVA < *test-options* > < *detail-options* > **;**

If the MODEL statement includes more than one dependent variable, you can perform multivariate analysis of variance with the MANOVA statement. The *test-options* define which effects to test, while the *detail-options* specify how to execute the tests and what results to display.

When a MANOVA statement appears before the first RUN statement, PROC ANOVA enters a multivariate mode with respect to the handling of missing values; in addition to observations with missing independent variables, observations with *any* missing dependent variables are excluded from the analysis. If you want to use this mode of handling missing values but do not need any multivariate analyses, specify the MANOVA option in the PROC ANOVA statement.

Test Options

You can specify the following options in the MANOVA statement as *test-options* in order to define which multivariate tests to perform.

H=*effects* | **INTERCEPT** | **_ALL_**

specifies effects in the preceding model to use as hypothesis matrices. For each SSCP matrix $\mathbf{H}$ associated with an effect, the H= specification computes an analysis based on the characteristic roots of $\mathbf{E}^{-1}\mathbf{H}$, where $\mathbf{E}$ is the matrix associated with the error effect. The characteristic roots and vectors are displayed, along with the Hotelling-Lawley trace, Pillai's trace, Wilks' lambda, and Roy's greatest root. By default, these statistics are tested with approximations based on the F distribution. To test them with exact (but computationally intensive) calculations, use the MSTAT=EXACT option.

Use the keyword INTERCEPT to produce tests for the intercept. To produce tests for all effects listed in the MODEL statement, use the keyword _ALL_ in place of a list of effects.

For background and further details, see the section "Multivariate Analysis of Variance" on page 2531 in Chapter 39, "The GLM Procedure."

E=*effect*

specifies the error effect. If you omit the E= specification, the ANOVA procedure uses the error SSCP (residual) matrix from the analysis.

M=*equation,...,equation* | **(***row-of-matrix,...,row-of-matrix***)**

specifies a transformation matrix for the dependent variables listed in the MODEL statement. The equations in the M= specification are of the form

$$c_1 \times \textit{dependent-variable} \quad \pm \quad c_2 \times \textit{dependent-variable}$$
$$\cdots \quad \pm \quad c_n \times \textit{dependent-variable}$$

where the c_i values are coefficients for the various *dependent-variables*. If the value of a given c_i is 1, it can be omitted; in other words $1 \times Y$ is the same as Y. Equations should involve two or more dependent variables. For sample syntax, see the section "Examples" on page 708.

Alternatively, you can input the transformation matrix directly by entering the elements of the matrix with commas separating the rows, and parentheses surrounding the matrix. When this alternate form of input is used, the number of elements in each row must equal the number of dependent variables. Although these combinations actually represent the columns of the **M** matrix, they are displayed by rows.

When you include an M= specification, the analysis requested in the MANOVA statement is carried out for the variables defined by the equations in the specification, not the original dependent variables. If you omit the M= option, the analysis is performed for the original dependent variables in the MODEL statement.

If an M= specification is included without either the MNAMES= or the PREFIX= option, the variables are labeled MVAR1, MVAR2, and so forth by default.

For further information, see the section "Multivariate Analysis of Variance" on page 2531 in Chapter 39, "The GLM Procedure."

MNAMES=*names*
provides names for the variables defined by the equations in the M= specification. Names in the list correspond to the M= equations or the rows of the **M** matrix (as it is entered).

PREFIX=*name*
is an alternative means of identifying the transformed variables defined by the M= specification. For example, if you specify PREFIX=DIFF, the transformed variables are labeled DIFF1, DIFF2, and so forth.

Detail Options

You can specify the following options in the MANOVA statement after a slash as *detail-options*:

CANONICAL
produces a canonical analysis of the **H** and **E** matrices (transformed by the **M** matrix, if specified) instead of the default display of characteristic roots and vectors.

MSTAT=FAPPROX

MSTAT=EXACT
specifies the method of evaluating the multivariate test statistics. The default is MSTAT=FAPPROX, which specifies that the multivariate tests are evaluated by using the usual approximations based on the F distribution, as discussed in the "Multivariate Tests" section in Chapter 4, "Introduction to Regression Procedures." Alternatively, you can specify MSTAT=EXACT to compute exact p-values for three of the four tests (Wilks' lambda, the Hotelling-Lawley trace, and Roy's greatest root) and an improved F-approximation for the fourth (Pillai's trace). While MSTAT=EXACT provides better control of the significance probability for the tests, especially for Roy's Greatest Root, computations for the exact

p-values can be appreciably more demanding, and are in fact infeasible for large problems (many dependent variables). Thus, although MSTAT=EXACT is more accurate for most data, it is not the default method. For more information about the results of MSTAT=EXACT, see the section "Multivariate Analysis of Variance" on page 2531 in Chapter 39, "The GLM Procedure."

ORTH

requests that the transformation matrix in the M= specification of the MANOVA statement be orthonormalized by rows before the analysis.

PRINTE

displays the error SSCP matrix **E**. If the **E** matrix is the error SSCP (residual) matrix from the analysis, the partial correlations of the dependent variables given the independent variables are also produced.

For example, the statement

```
manova / printe;
```

displays the error SSCP matrix and the partial correlation matrix computed from the error SSCP matrix.

PRINTH

displays the hypothesis SSCP matrix **H** associated with each effect specified by the H= specification.

SUMMARY

produces analysis-of-variance tables for each dependent variable. When no **M** matrix is specified, a table is produced for each original dependent variable from the MODEL statement; with an **M** matrix other than the identity, a table is produced for each transformed variable defined by the **M** matrix.

Examples

The following statements give several examples of using a MANOVA statement.

```
proc anova;
   class A B;
   model Y1-Y5=A B(A);
   manova h=A e=B(A) / printh printe;
   manova h=B(A) / printe;
   manova h=A e=B(A) m=Y1-Y2,Y2-Y3,Y3-Y4,Y4-Y5
          prefix=diff;

   manova h=A e=B(A) m=(1 -1  0  0  0,
                        0  1 -1  0  0,
                        0  0  1 -1  0,
                        0  0  0  1 -1) prefix=diff;
run;
```

The first MANOVA statement specifies A as the hypothesis effect and B(A) as the error effect. As a result of the PRINTH option, the procedure displays the hypothesis SSCP matrix associated with the A effect; and, as a result of the PRINTE option, the procedure displays the error SSCP matrix associated with the B(A) effect.

The second MANOVA statement specifies B(A) as the hypothesis effect. Since no error effect is specified, PROC ANOVA uses the error SSCP matrix from the analysis as the **E** matrix. The PRINTE option displays this **E** matrix. Since the **E** matrix is the error SSCP matrix from the analysis, the partial correlation matrix computed from this matrix is also produced.

The third MANOVA statement requests the same analysis as the first MANOVA statement, but the analysis is carried out for variables transformed to be successive differences between the original dependent variables. The PREFIX=DIFF specification labels the transformed variables as DIFF1, DIFF2, DIFF3, and DIFF4.

Finally, the fourth MANOVA statement has the identical effect as the third, but it uses an alternative form of the M= specification. Instead of specifying a set of equations, the fourth MANOVA statement specifies rows of a matrix of coefficients for the five dependent variables.

As a second example of the use of the M= specification, consider the following:

```
proc anova;
   class group;
   model dose1-dose4=group / nouni;
   manova h = group
          m = -3*dose1 -   dose2 +   dose3 + 3*dose4,
                 dose1 -   dose2 -   dose3 +   dose4,
                -dose1 + 3*dose2 - 3*dose3 +   dose4
          mnames = Linear Quadratic Cubic
          / printe;
run;
```

The M= specification gives a transformation of the dependent variables dose1 through dose4 into orthogonal polynomial components, and the MNAMES= option labels the transformed variables as LINEAR, QUADRATIC, and CUBIC, respectively. Since the PRINTE option is specified and the default residual matrix is used as an error term, the partial correlation matrix of the orthogonal polynomial components is also produced.

For further information, see the section "Multivariate Analysis of Variance" on page 2531 in Chapter 39, "The GLM Procedure."

MEANS Statement

MEANS *effects* < / *options* > ;

PROC ANOVA can compute means of the dependent variables for any effect that appears on the right-hand side in the MODEL statement.

You can use any number of MEANS statements, provided that they appear after the MODEL statement. For example, suppose A and B each have two levels. Then, if you use the following statements

```
proc anova;
   class A B;
   model Y=A B A*B;
   means A B / tukey;
   means A*B;
run;
```

means, standard deviations, and Tukey's multiple comparison tests are produced for each level of the main effects A and B, and just the means and standard deviations for each of the four combinations of levels for A*B. Since multiple comparisons options apply only to main effects, the single MEANS statement

```
means A B A*B / tukey;
```

produces the same results.

Options are provided to perform multiple comparison tests for only main effects in the model. PROC ANOVA does not perform multiple comparison tests for interaction terms in the model; for multiple comparisons of interaction terms, see the LSMEANS statement in Chapter 39, "The GLM Procedure."

Table 23.2 summarizes categories of options available in the MEANS statement.

Table 23.2 Options Available in the MEANS Statement

Task	Available options
Perform multiple comparison tests	BON
	DUNCAN
	DUNNETT
	DUNNETTL
	DUNNETTU
	GABRIEL
	GT2
	LSD
	REGWQ
	SCHEFFE
	SIDAK
	SMM
Perform multiple comparison tests	SNK
	T
	TUKEY
	WALLER

Table 23.2 *continued*

Task	Available options
Specify additional details for multiple comparison tests	ALPHA= CLDIFF CLM E= KRATIO= LINES NOSORT
Test for homogeneity of variances	HOVTEST
Compensate for heterogeneous variances	WELCH

Descriptions of these options follow. For a further discussion of these options, see the section "Multiple Comparisons" on page 2514 in Chapter 39, "The GLM Procedure."

ALPHA=*p*

specifies the level of significance for comparisons among the means. By default, ALPHA=0.05. You can specify any value greater than 0 and less than 1.

BON

performs Bonferroni *t* tests of differences between means for all main effect means in the MEANS statement. See the CLDIFF and LINES options, which follow, for a discussion of how the procedure displays results.

CLDIFF

presents results of the BON, GABRIEL, SCHEFFE, SIDAK,SMM, GT2, T, LSD, and TUKEY options as confidence intervals for all pairwise differences between means, and the results of the DUNNETT, DUNNETTU, and DUNNETTL options as confidence intervals for differences with the control. The CLDIFF option is the default for unequal cell sizes unless the DUNCAN, REGWQ, SNK, or WALLER option is specified.

CLM

presents results of the BON, GABRIEL, SCHEFFE, SIDAK,SMM, T, and LSD options as intervals for the mean of each level of the variables specified in the MEANS statement. For all options except GABRIEL, the intervals are confidence intervals for the true means. For the GABRIEL option, they are *comparison intervals* for comparing means pairwise: in this case, if the intervals corresponding to two means overlap, the difference between them is insignificant according to Gabriel's method.

DUNCAN

performs Duncan's multiple range test on all main effect means given in the MEANS statement. See the LINES option for a discussion of how the procedure displays results.

DUNNETT <(*formatted-control-values***)>**

performs Dunnett's two-tailed *t* test, testing if any treatments are significantly different from a single control for all main effects means in the MEANS statement.

To specify which level of the effect is the control, enclose the formatted value in quotes in parentheses after the keyword. If more than one effect is specified in the MEANS statement, you can use a list of control values within the parentheses. By default, the first level of the effect is used as the control. For example,

```
means a / dunnett('CONTROL');
```

where CONTROL is the formatted control value of A. As another example,

```
means a b c / dunnett('CNTLA' 'CNTLB' 'CNTLC');
```

where CNTLA, CNTLB, and CNTLC are the formatted control values for A, B, and C, respectively.

DUNNETTL <(*formatted-control-value*)>

performs Dunnett's one-tailed *t* test, testing if any treatment is significantly less than the control. Control level information is specified as described previously for the DUNNETT option.

DUNNETTU <(*formatted-control-value*)>

performs Dunnett's one-tailed *t* test, testing if any treatment is significantly greater than the control. Control level information is specified as described previously for the DUNNETT option.

E=*effect*

specifies the error mean square used in the multiple comparisons. By default, PROC ANOVA uses the residual Mean Square (MS). The effect specified with the E= option must be a term in the model; otherwise, the procedure uses the residual MS.

GABRIEL

performs Gabriel's multiple-comparison procedure on all main effect means in the MEANS statement. See the CLDIFF and LINES options for discussions of how the procedure displays results.

GT2

see the SMM option.

HOVTEST

HOVTEST=BARTLETT

HOVTEST=BF

HOVTEST=LEVENE <(TYPE=ABS | SQUARE)>

HOVTEST=OBRIEN <(W=*number*)>

requests a homogeneity of variance test for the groups defined by the MEANS effect. You can optionally specify a particular test; if you do not specify a test, Levene's test (Levene 1960) with TYPE=SQUARE is computed. Note that this option is ignored unless your MODEL statement specifies a simple one-way model.

The HOVTEST=BARTLETT option specifies Bartlett's test (Bartlett 1937), a modification of the normal-theory likelihood ratio test.

The HOVTEST=BF option specifies Brown and Forsythe's variation of Levene's test (Brown and Forsythe 1974).

The HOVTEST=LEVENE option specifies Levene's test (Levene 1960), which is widely considered to be the standard homogeneity of variance test. You can use the TYPE= option in parentheses to specify whether to use the absolute residuals (TYPE=ABS) or the squared residuals (TYPE=SQUARE) in Levene's test. The default is TYPE=SQUARE.

The HOVTEST=OBRIEN option specifies O'Brien's test (O'Brien 1979), which is basically a modification of HOVTEST=LEVENE(TYPE=SQUARE). You can use the W= option in parentheses to tune the variable to match the suspected kurtosis of the underlying distribution. By default, W=0.5, as suggested by O'Brien (1979, 1981).

See the section "Homogeneity of Variance in One-Way Models" on page 2526 in Chapter 39, "The GLM Procedure," for more details on these methods. Example 39.10 in the same chapter illustrates the use of the HOVTEST and WELCH options in the MEANS statement in testing for equal group variances.

KRATIO=*value*

specifies the Type 1/Type 2 error seriousness ratio for the Waller-Duncan test. Reasonable values for KRATIO are 50, 100, and 500, which roughly correspond for the two-level case to ALPHA levels of 0.1, 0.05, and 0.01. By default, the procedure uses the default value of 100.

LINES

presents results of the BON, DUNCAN, GABRIEL, REGWQ, SCHEFFE, SIDAK,SMM, GT2, SNK, T, LSD TUKEY, and WALLER options by listing the means in descending order and indicating nonsignificant subsets by line segments beside the corresponding means. The LINES option is appropriate for equal cell sizes, for which it is the default. The LINES option is also the default if the DUNCAN, REGWQ, SNK, or WALLER option is specified, or if there are only two cells of unequal size. If the cell sizes are unequal, the harmonic mean of the cell sizes is used, which might lead to somewhat liberal tests if the cell sizes are highly disparate. The LINES option cannot be used in combination with the DUNNETT, DUNNETTL, or DUNNETTU option. In addition, the procedure has a restriction that no more than 24 overlapping groups of means can exist. If a mean belongs to more than 24 groups, the procedure issues an error message. You can either reduce the number of levels of the variable or use a multiple comparison test that allows the CLDIFF option rather than the LINES option.

LSD

see the T option.

NOSORT

prevents the means from being sorted into descending order when the CLDIFF or CLM option is specified.

REGWQ

performs the Ryan-Einot-Gabriel-Welsch multiple range test on all main effect means in the MEANS statement. See the LINES option for a discussion of how the procedure displays results.

SCHEFFE

performs Scheffé's multiple-comparison procedure on all main effect means in the MEANS statement. See the CLDIFF and LINES options for discussions of how the procedure displays results.

SIDAK

performs pairwise t tests on differences between means with levels adjusted according to Sidak's inequality for all main effect means in the MEANS statement. See the CLDIFF and LINES options for discussions of how the procedure displays results.

SMM

GT2

performs pairwise comparisons based on the studentized maximum modulus and Sidak's uncorrelated-t inequality, yielding Hochberg's GT2 method when sample sizes are unequal, for all main effect means in the MEANS statement. See the CLDIFF and LINES options for discussions of how the procedure displays results.

SNK

performs the Student-Newman-Keuls multiple range test on all main effect means in the MEANS statement. See the LINES option for a discussion of how the procedure displays results.

T

LSD

performs pairwise t tests, equivalent to Fisher's least-significant-difference test in the case of equal cell sizes, for all main effect means in the MEANS statement. See the CLDIFF and LINES options for discussions of how the procedure displays results.

TUKEY

performs Tukey's studentized range test (HSD) on all main effect means in the MEANS statement. (When the group sizes are different, this is the Tukey-Kramer test.) See the CLDIFF and LINES options for discussions of how the procedure displays results.

WALLER

performs the Waller-Duncan k-ratio t test on all main effect means in the MEANS statement. See the KRATIO= option for information about controlling details of the test, and see the LINES option for a discussion of how the procedure displays results.

WELCH

requests Welch's (1951) variance-weighted one-way ANOVA. This alternative to the usual analysis of variance for a one-way model is robust to the assumption of equal within-group variances. This option is ignored unless your MODEL statement specifies a simple one-way model.

Note that using the WELCH option merely produces one additional table consisting of Welch's ANOVA. It does not affect all of the other tests displayed by the ANOVA procedure, which still require the assumption of equal variance for exact validity.

See the section "Homogeneity of Variance in One-Way Models" on page 2526 in Chapter 39, "The GLM Procedure," for more details on Welch's ANOVA. Example 39.10 in the same

chapter illustrates the use of the HOVTEST and WELCH options in the MEANS statement in testing for equal group variances.

MODEL Statement

MODEL *dependents=effects* < / *options* > **;**

The MODEL statement names the dependent variables and independent effects. The syntax of effects is described in the section "Specification of Effects" on page 720. For any model effect involving classification variables (interactions as well as main effects), the number of levels cannot exceed 32,767. If no independent effects are specified, only an intercept term is fit. This tests the hypothesis that the mean of the dependent variable is zero. All variables in effects that you specify in the MODEL statement must appear in the CLASS statement because PROC ANOVA does not allow for continuous effects.

You can specify the following options in the MODEL statement; they must be separated from the list of independent effects by a slash.

INTERCEPT

INT

displays the hypothesis tests associated with the intercept as an effect in the model. By default, the procedure includes the intercept in the model but does not display associated tests of hypotheses. Except for producing the uncorrected total SS instead of the corrected total SS, the INT option is ignored when you use an ABSORB statement.

NOUNI

suppresses the display of univariate statistics. You typically use the NOUNI option with a multivariate or repeated measures analysis of variance when you do not need the standard univariate output. The NOUNI option in a MODEL statement does not affect the univariate output produced by the REPEATED statement.

REPEATED Statement

REPEATED *factor-specification* < / *options* > **;**

When values of the dependent variables in the MODEL statement represent repeated measurements on the same experimental unit, the REPEATED statement enables you to test hypotheses about the measurement factors (often called *within-subject factors*), as well as the interactions of within-subject factors with independent variables in the MODEL statement (often called *between-subject factors*). The REPEATED statement provides multivariate and univariate tests as well as hypothesis tests for a variety of single-degree-of-freedom contrasts. There is no limit to the number of within-subject factors that can be specified. For more details, see the section "Repeated Measures Analysis of Variance" on page 2532 in Chapter 39, "The GLM Procedure."

The REPEATED statement is typically used for handling repeated measures designs with one repeated response variable. Usually, the variables on the left-hand side of the equation in the MODEL statement represent one repeated response variable.

This does not mean that only one factor can be listed in the REPEATED statement. For example, one repeated response variable (hemoglobin count) might be measured 12 times (implying variables Y1 to Y12 on the left-hand side of the equal sign in the MODEL statement), with the associated within-subject factors treatment and time (implying two factors listed in the REPEATED statement). See the section "Examples" on page 719 for an example of how PROC ANOVA handles this case.

Designs with two or more repeated response variables can, however, be handled with the IDENTITY transformation; see Example 39.9 in Chapter 39, "The GLM Procedure," for an example of analyzing a doubly-multivariate repeated measures design.

When a REPEATED statement appears, the ANOVA procedure enters a multivariate mode of handling missing values. If any values for variables corresponding to each combination of the within-subject factors are missing, the observation is excluded from the analysis.

The simplest form of the REPEATED statement requires only a *factor-name*. With two repeated factors, you must specify the *factor-name* and number of levels (*levels*) for each factor. Optionally, you can specify the actual values for the levels (*level-values*), a *transformation* that defines single-degree-of freedom contrasts, and *options* for additional analyses and output. When more than one within-subject factor is specified, *factor-names* (and associated level and transformation information) must be separated by a comma in the REPEATED statement. These terms are described in the following section, "Syntax Details."

Syntax Details

You can specify the following terms in the REPEATED statement.

factor-specification

The *factor-specification* for the REPEATED statement can include any number of individual factor specifications, separated by commas, of the following form:

factor-name levels < (level-values) > < transformation >

where

factor-name names a factor to be associated with the dependent variables. The name should not be the same as any variable name that already exists in the data set being analyzed and should conform to the usual conventions of SAS variable names.

When specifying more than one factor, list the dependent variables in the MODEL statement so that the within-subject factors defined in the REPEATED statement are nested; that is, the first factor defined in the REPEATED statement should be the one with values that change least frequently.

levels specifies the number of levels associated with the factor being defined. When there is only one within-subject factor, the number of levels is equal to the number of dependent variables. In this case, *levels* is optional. When more than one within-subject factor is defined, however, *levels* is required, and the product of the number of levels of all the factors must equal the number of dependent variables in the MODEL statement.

(level-values) specifies values that correspond to levels of a repeated-measures factor. These values are used to label output; they are also used as spacings for constructing orthogonal polynomial contrasts if you specify a POLYNOMIAL transformation. The number of level values specified must correspond to the number of levels for that factor in the REPEATED statement. Enclose the *level-values* in parentheses.

The following *transformation* keywords define single-degree-of-freedom contrasts for factors specified in the REPEATED statement. Since the number of contrasts generated is always one less than the number of levels of the factor, you have some control over which contrast is omitted from the analysis by which transformation you select. The only exception is the IDENTITY transformation; this transformation is not composed of contrasts, and it has the same degrees of freedom as the factor has levels. By default, the procedure uses the CONTRAST transformation.

CONTRAST<(*ordinal-reference-level*)>
generates contrasts between levels of the factor and a reference level. By default, the procedure uses the last level; you can optionally specify a reference level in parentheses after the keyword CONTRAST. The reference level corresponds to the ordinal value of the level rather than the level value specified. For example, to generate contrasts between the first level of a factor and the other levels, use

```
contrast(1)
```

HELMERT generates contrasts between each level of the factor and the mean of subsequent levels.

IDENTITY generates an identity transformation corresponding to the associated factor. This transformation is *not* composed of contrasts; it has n degrees of freedom for an n-level factor, instead of $n - 1$. This can be used for doubly-multivariate repeated measures.

MEAN<(*ordinal-reference-level*)>
generates contrasts between levels of the factor and the mean of all other levels of the factor. Specifying a reference level eliminates the contrast between that level and the mean. Without a reference level, the contrast involving the last level is omitted. See the CONTRAST transformation for an example.

POLYNOMIAL generates orthogonal polynomial contrasts. Level values, if provided, are used as spacings in the construction of the polynomials; otherwise, equal spacing is assumed.

PROFILE generates contrasts between adjacent levels of the factor.

For examples of the transformation matrices generated by these contrast transformations, see the section "Repeated Measures Analysis of Variance" on page 2532 in Chapter 39, "The GLM Procedure."

You can specify the following options in the REPEATED statement after a slash:

CANONICAL
performs a canonical analysis of the **H** and **E** matrices corresponding to the transformed variables specified in the REPEATED statement.

MSTAT=FAPPROX

MSTAT=EXACT
specifies the method of evaluating the multivariate test statistics. The default is MSTAT=FAPPROX, which specifies that the multivariate tests are evaluated by using the usual approximations based on the F distribution, as discussed in the "Multivariate Tests" section in Chapter 4, "Introduction to Regression Procedures." Alternatively, you can specify MSTAT=EXACT to compute exact p-values for three of the four tests (Wilks' lambda, the Hotelling-Lawley trace, and Roy's greatest root) and an improved F-approximation for the fourth (Pillai's trace). While MSTAT=EXACT provides better control of the significance probability for the tests, especially for Roy's Greatest Root, computations for the exact p-values can be appreciably more demanding, and are in fact infeasible for large problems (many dependent variables). Thus, although MSTAT=EXACT is more accurate for most data, it is not the default method. For more information about the results of MSTAT=EXACT, see the section "Multivariate Analysis of Variance" on page 2531 in Chapter 39, "The GLM Procedure."

NOM
displays only the results of the univariate analyses.

NOU
displays only the results of the multivariate analyses.

PRINTE
displays the **E** matrix for each combination of within-subject factors, as well as partial correlation matrices for both the original dependent variables and the variables defined by the transformations specified in the REPEATED statement. In addition, the PRINTE option provides sphericity tests for each set of transformed variables. If the requested transformations are not orthogonal, the PRINTE option also provides a sphericity test for a set of orthogonal contrasts.

PRINTH
displays the **H** (SSCP) matrix associated with each multivariate test.

PRINTM
displays the transformation matrices that define the contrasts in the analysis. PROC ANOVA always displays the **M** matrix so that the transformed variables are defined by the rows, not the columns, of the displayed **M** matrix. In other words, PROC ANOVA actually displays $\mathbf{M}'$.

PRINTRV
produces the characteristic roots and vectors for each multivariate test.

SUMMARY
produces analysis-of-variance tables for each contrast defined by the within-subjects factors. Along with tests for the effects of the independent variables specified in the MODEL statement, a term labeled MEAN tests the hypothesis that the overall mean of the contrast is zero.

Examples

When specifying more than one factor, list the dependent variables in the MODEL statement so that the within-subject factors defined in the REPEATED statement are nested; that is, the first factor defined in the REPEATED statement should be the one with values that change least frequently. For example, assume that three treatments are administered at each of four times, for a total of twelve dependent variables on each experimental unit. If the variables are listed in the MODEL statement as Y1 through Y12, then the following REPEATED statement

```
repeated trt 3, time 4;
```

implies the following structure:

	Dependent Variables											
	Y1	Y2	Y3	Y4	Y5	Y6	Y7	Y8	Y9	Y10	Y11	Y12
Value of trt	1	1	1	1	2	2	2	2	3	3	3	3
Value of time	1	2	3	4	1	2	3	4	1	2	3	4

The REPEATED statement always produces a table like the preceding one.

For more information about repeated measures analysis and about using the REPEATED statement, see the section "Repeated Measures Analysis of Variance" on page 2532 in Chapter 39, "The GLM Procedure."

TEST Statement

TEST < **H=** *effects* > **E=** *effect* **;**

Although an F value is computed for all SS in the analysis by using the residual MS as an error term, you can request additional F tests that use other effects as error terms. You need a TEST statement when a nonstandard error structure (as in a split plot) exists.

CAUTION: The ANOVA procedure does not check any of the assumptions underlying the F statistic. When you specify a TEST statement, you assume sole responsibility for the validity of the F statistic produced. To help validate a test, you might want to use the GLM procedure with the RANDOM statement and inspect the expected mean squares. In the GLM procedure, you can also use the TEST option in the RANDOM statement.

You can use as many TEST statements as you want, provided that they appear after the MODEL statement.

You can specify the following terms in the TEST statement.

H=*effects* specifies which effects in the preceding model are to be used as hypothesis (numerator) effects.

E=*effect* specifies one, and only one, effect to use as the error (denominator) term. The **E=** specification is required.

The following example uses two TEST statements and is appropriate for analyzing a split-plot design.

```
proc anova;
   class a b c;
   model y=a|b(a)|c;
   test h=a e=b(a);
   test h=c a*c e=b*c(a);
run;
```

Details: ANOVA Procedure

Specification of Effects

In SAS analysis-of-variance procedures, the variables that identify levels of the classifications are called *classification variables*, and they are declared in the CLASS statement. Classification variables are also called *categorical*, *qualitative*, *discrete*, or *nominal variables*. The values of a classification variable are called *levels*. Classification variables can be either numeric or character. This is in contrast to the *response* (or *dependent*) *variables*, which are continuous. Response variables must be numeric.

The analysis-of-variance model specifies *effects*, which are combinations of classification variables used to explain the variability of the dependent variables in the following manner:

- Main effects are specified by writing the variables by themselves in the CLASS statement: `A B C`. Main effects used as independent variables test the hypothesis that the mean of the dependent variable is the same for each level of the factor in question, ignoring the other independent variables in the model.
- Crossed effects (interactions) are specified by joining the CLASS variables with asterisks in the MODEL statement: `A*B A*C A*B*C`. Interaction terms in a model test the hypothesis that the effect of a factor does not depend on the levels of the other factors in the interaction.

- Nested effects are specified by following a main effect or crossed effect with a CLASS variable or list of CLASS variables enclosed in parentheses in the MODEL statement. The main effect or crossed effect is nested within the effects listed in parentheses: B(A) C*D(A B). Nested effects test hypotheses similar to interactions, but the levels of the nested variables are not the same for every combination within which they are nested.

The general form of an effect can be illustrated by using the CLASS variables A, B, C, D, E, and F:

A ∗ B ∗ C(D E F)

The crossed list should come first, followed by the nested list in parentheses. Note that no asterisks appear within the nested list or immediately before the left parenthesis.

Main Effects Models

For a three-factor main effects model with A, B, and C as the factors and Y as the dependent variable, the necessary statements are

```
proc anova;
   class A B C;
   model Y=A B C;
run;
```

Models with Crossed Factors

To specify interactions in a factorial model, join effects with asterisks as described previously. For example, these statements specify a complete factorial model, which includes all the interactions:

```
proc anova;
   class A B C;
   model Y=A B C A*B A*C B*C A*B*C;
run;
```

Bar Notation

You can shorten the specifications of a full factorial model by using bar notation. For example, the preceding statements can also be written

```
proc anova;
   class A B C;
   model Y=A|B|C;
run;
```

When the bar (|) is used, the expression on the right side of the equal sign is expanded from left to right by using the equivalents of rules 2–4 given in Searle (1971, p. 390). The variables on the right- and left-hand sides of the bar become effects, and the cross of them becomes an effect. Multiple bars are permitted. For instance, A | B | C is evaluated as follows:

$$\begin{aligned} \text{A | B | C} &\rightarrow \{\text{ A | B }\}\text{ | C} \\ &\rightarrow \{\text{ A B A*B }\}\text{ | C} \\ &\rightarrow \text{A B A*B C A*C B*C A*B*C} \end{aligned}$$

You can also specify the maximum number of variables involved in any effect that results from bar evaluation by specifying that maximum number, preceded by an @ sign, at the end of the bar effect. For example, the specification A | B | C@2 results in only those effects that contain two or fewer variables; in this case, A B A*B C A*C and B*C.

The following table gives more examples of using the bar and at operators.

A | C(B)	is equivalent to	A C(B) A*C(B)
A(B) | C(B)	is equivalent to	A(B) C(B) A*C(B)
A(B) | B(D E)	is equivalent to	A(B) B(D E)
A | B(A) | C	is equivalent to	A B(A) C A*C B*C(A)
A | B(A) | C@2	is equivalent to	A B(A) C A*C
A | B | C | D@2	is equivalent to	A B A*B C A*C B*C D A*D B*D C*D

Consult the section "Specification of Effects" on page 2488 in Chapter 39, "The GLM Procedure," for further details on bar notation.

Nested Models

Write the effect that is nested within another effect first, followed by the other effect in parentheses. For example, if A and B are main effects and C is nested within A and B (that is, the levels of C that are observed are not the same for each combination of A and B), the statements for PROC ANOVA are

```
proc anova;
   class A B C;
   model y=A B C(A B);
run;
```

The identity of a level is viewed within the context of the level of the containing effects. For example, if City is nested within State, then the identity of City is viewed within the context of State.

The distinguishing feature of a nested specification is that nested effects never appear as main effects. Another way of viewing nested effects is that they are effects that pool the main effect with the interaction of the nesting variable.

See the "Automatic Pooling" section, which follows.

Models Involving Nested, Crossed, and Main Effects

Asterisks and parentheses can be combined in the MODEL statement for models involving nested and crossed effects:

```
proc anova;
   class A B C;
   model Y=A B(A) C(A) B*C(A);
run;
```

Automatic Pooling

In line with the general philosophy of the GLM procedure, there is no difference between the statements

```
model Y=A B(A);
```

and

```
model Y=A A*B;
```

The effect B becomes a nested effect by virtue of the fact that it does not occur as a main effect. If B is not written as a main effect in addition to participating in A*B, then the sum of squares that is associated with B is pooled into A*B.

This feature allows the automatic pooling of sums of squares. If an effect is omitted from the model, it is automatically pooled with all the higher-level effects containing the CLASS variables in the omitted effect (or within-error). This feature is most useful in split-plot designs.

Using PROC ANOVA Interactively

PROC ANOVA can be used interactively. After you specify a model in a MODEL statement and run PROC ANOVA with a RUN statement, a variety of statements (such as MEANS, MANOVA, TEST, and REPEATED) can be executed without PROC ANOVA recalculating the model sum of squares.

the section "Syntax: ANOVA Procedure" on page 701 describes which statements can be used interactively. You can execute these interactive statements individually or in groups by following the single statement or group of statements with a RUN statement. Note that the MODEL statement cannot be repeated; the ANOVA procedure allows only one MODEL statement.

If you use PROC ANOVA interactively, you can end the procedure with a DATA step, another PROC step, an ENDSAS statement, or a QUIT statement. The syntax of the QUIT statement is

```
quit;
```

When you use PROC ANOVA interactively, additional RUN statements do not end the procedure but tell PROC ANOVA to execute additional statements.

When a WHERE statement is used with PROC ANOVA, it should appear before the first RUN statement. The WHERE statement enables you to select only certain observations for analysis

without using a subsetting DATA step. For example, the statement `where group ne 5` omits observations with GROUP=5 from the analysis. See *SAS Language Reference: Dictionary* for details about this statement.

When a BY statement is used with PROC ANOVA, interactive processing is not possible; that is, once the first RUN statement is encountered, processing proceeds for each BY group in the data set, and no further statements are accepted by the procedure.

Interactivity is also disabled when there are different patterns of missing values among the dependent variables. For details, see the section "Missing Values," which follows.

Missing Values

For an analysis involving one dependent variable, PROC ANOVA uses an observation if values are nonmissing for that dependent variable and for all the variables used in independent effects.

For an analysis involving multiple dependent variables without the MANOVA or REPEATED statement, or without the MANOVA option in the PROC ANOVA statement, a missing value in one dependent variable does not eliminate the observation from the analysis of other nonmissing dependent variables. For an analysis with the MANOVA or REPEATED statement, or with the MANOVA option in the PROC ANOVA statement, the ANOVA procedure requires values for all dependent variables to be nonmissing for an observation before the observation can be used in the analysis.

During processing, PROC ANOVA groups the dependent variables by their pattern of missing values across observations so that sums and cross products can be collected in the most efficient manner.

If your data have different patterns of missing values among the dependent variables, interactivity is disabled. This could occur when some of the variables in your data set have missing values and either of the following conditions obtain:

- You do not use the MANOVA option in the PROC ANOVA statement.
- You do not use a MANOVA or REPEATED statement before the first RUN statement.

Output Data Set

The OUTSTAT= option in the PROC ANOVA statement produces an output data set that contains the following:

- the BY variables, if any
- _TYPE_, a new character variable. This variable has the value 'ANOVA' for observations corresponding to sums of squares; it has the value 'CANCORR', 'STRUCTUR', or 'SCORE' if a canonical analysis is performed through the MANOVA statement and no M= matrix is specified.

- _SOURCE_, a new character variable. For each observation in the data set, _SOURCE_ contains the name of the model effect from which the corresponding statistics are generated.
- _NAME_, a new character variable. The variable _NAME_ contains the name of one of the dependent variables in the model or, in the case of canonical statistics, the name of one of the canonical variables (CAN1, CAN2, and so on).
- four new numeric variables, SS, DF, F, and PROB, containing sums of squares, degrees of freedom, F values, and probabilities, respectively, for each model or contrast sum of squares generated in the analysis. For observations resulting from canonical analyses, these variables have missing values.
- if there is more than one dependent variable, then variables with the same names as the dependent variables represent
  - for _TYPE_='ANOVA', the crossproducts of the hypothesis matrices
  - for _TYPE_='CANCORR', canonical correlations for each variable
  - for _TYPE_='STRUCTUR', coefficients of the total structure matrix
  - for _TYPE_='SCORE', raw canonical score coefficients

The output data set can be used to perform special hypothesis tests (for example, with the IML procedure in SAS/IML software), to reformat output, to produce canonical variates (through the SCORE procedure), or to rotate structure matrices (through the FACTOR procedure).

Computational Method

Let $\mathbf{X}$ represent the $n \times p$ design matrix. The columns of $\mathbf{X}$ contain only 0s and 1s. Let $\mathbf{Y}$ represent the $n \times 1$ vector of dependent variables.

In the GLM procedure, $\mathbf{X}'\mathbf{X}$, $\mathbf{X}'\mathbf{Y}$, and $\mathbf{Y}'\mathbf{Y}$ are formed in main storage. However, in the ANOVA procedure, only the diagonals of $\mathbf{X}'\mathbf{X}$ are computed, along with $\mathbf{X}'\mathbf{Y}$ and $\mathbf{Y}'\mathbf{Y}$. Thus, PROC ANOVA saves a considerable amount of storage as well as time. The memory requirements for PROC ANOVA are asymptotically linear functions of n^2 and nr, where n is the number of dependent variables and r the number of independent parameters.

The elements of $\mathbf{X}'\mathbf{Y}$ are cell totals, and the diagonal elements of $\mathbf{X}'\mathbf{X}$ are cell frequencies. Since PROC ANOVA automatically pools omitted effects into the next higher-level effect containing the names of the omitted effect (or within-error), a slight modification to the rules given by Searle (1971, p. 389) is used.

1. PROC ANOVA computes the sum of squares for each effect as if it is a main effect. In other words, for each effect, PROC ANOVA squares each cell total and divides by its cell frequency. The procedure then adds these quantities together and subtracts the correction factor for the mean (total squared over N).
2. For each effect involving two CLASS variable names, PROC ANOVA subtracts the SS for any main effect with a name that is contained in the two-factor effect.

3. For each effect involving three CLASS variable names, PROC ANOVA subtracts the SS for all main effects and two-factor effects with names that are contained in the three-factor effect. If effects involving four or more CLASS variable names are present, the procedure continues this process.

Displayed Output

PROC ANOVA first displays a table that includes the following:

- the name of each variable in the CLASS statement
- the number of different values or Levels of the CLASS variables
- the Values of the CLASS variables
- the Number of observations in the data set and the number of observations excluded from the analysis because of missing values, if any

PROC ANOVA then displays an analysis-of-variance table for each dependent variable in the MODEL statement. This table breaks down the Total Sum of Squares for the dependent variable into the portion attributed to the Model and the portion attributed to Error. It also breaks down the Mean Square term, which is the Sum of Squares divided by the degrees of freedom (DF). The analysis-of-variance table also lists the following:

- the Mean Square for Error (MSE), which is an estimate of σ^2, the variance of the true errors
- the F Value, which is the ratio produced by dividing the Mean Square for the Model by the Mean Square for Error. It tests how well the model as a whole (adjusted for the mean) accounts for the dependent variable's behavior. This F test is a test of the null hypothesis that all parameters except the intercept are zero.
- the significance probability associated with the F statistic, labeled "Pr > F"
- R-Square, R^2, which measures how much variation in the dependent variable can be accounted for by the model. The R^2 statistic, which can range from 0 to 1, is the ratio of the sum of squares for the model divided by the sum of squares for the corrected total. In general, the larger the R^2 value, the better the model fits the data.
- C.V., the coefficient of variation, which is often used to describe the amount of variation in the population. The C.V. is 100 times the standard deviation of the dependent variable divided by the Mean. The coefficient of variation is often a preferred measure because it is unitless.
- Root MSE, which estimates the standard deviation of the dependent variable. Root MSE is computed as the square root of Mean Square for Error, the mean square of the error term.
- the Mean of the dependent variable

For each effect (or source of variation) in the model, PROC ANOVA then displays the following:

- DF, degrees of freedom
- Anova SS, the sum of squares, and the associated Mean Square
- the F Value for testing the hypothesis that the group means for that effect are equal
- Pr > F, the significance probability value associated with the F Value

When you specify a TEST statement, PROC ANOVA displays the results of the requested tests. When you specify a MANOVA statement and the model includes more than one dependent variable, PROC ANOVA produces these additional statistics:

- the characteristic roots and vectors of $\mathbf{E}^{-1}\mathbf{H}$ for each $\mathbf{H}$ matrix
- the Hotelling-Lawley trace
- Pillai's trace
- Wilks' lambda
- Roy's greatest root

See Example 39.6 in Chapter 39, "The GLM Procedure," for an example of the MANOVA results. These MANOVA tests are discussed in Chapter 4, "Introduction to Regression Procedures."

ODS Table Names

PROC ANOVA assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 23.3. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 23.3 ODS Tables Produced by PROC ANOVA

ODS Table Name	Description	Statement / Option
AltErrTests	Anova tests with error other than MSE	TEST /E=
Bartlett	Bartlett's homogeneity of variance test	MEANS / HOVTEST=BARTLETT
CLDiffs	Multiple comparisons of pairwise differences	MEANS / CLDIFF or DUNNETT or (Unequal cells and not LINES)
CLDiffsInfo	Information for multiple comparisons of pairwise differences	MEANS / CLDIFF or DUNNETT or (Unequal cells and not LINES)

Table 23.3 *continued*

ODS Table Name	Description	Statement / Option
CLMeans	Multiple comparisons of means with confidence/comparison interval	MEANS / CLM with (BON or GABRIEL or SCHEFFE or SIDAK or SMM or T or LSD)
CLMeansInfo	Information for multiple comparisons of means with confidence/comparison interval	MEANS / CLM
CanAnalysis	Canonical analysis	(MANOVA or REPEATED) / CANONICAL
CanCoef	Canonical coefficients	(MANOVA or REPEATED) / CANONICAL
CanStructure	Canonical structure	(MANOVA or REPEATED) / CANONICAL
CharStruct	Characteristic roots and vectors	(MANOVA / not CANONICAL) or (REPEATED / PRINTRV)
ClassLevels	Classification variable levels	CLASS statement
DependentInfo	Simultaneously analyzed dependent variables	default when there are multiple dependent variables with different patterns of missing values
Epsilons	Greenhouse-Geisser and Huynh-Feldt epsilons	REPEATED statement
ErrorSSCP	Error SSCP matrix	(MANOVA or REPEATED) / PRINTE
FitStatistics	R-Square, C.V., Root MSE, and dependent mean	default
HOVFTest	Homogeneity of variance ANOVA	MEANS / HOVTEST
HypothesisSSCP	Hypothesis SSCP matrix	(MANOVA or REPEATED) / PRINTE
MANOVATransform	Multivariate transformation matrix	MANOVA / M=
MCLines	Multiple comparisons LINES output	MEANS / LINES or ((DUNCAN or WALLER or SNK or REGWQ) and not(CLDIFF or CLM)) or (Equal cells and not CLDIFF)
MCLinesInfo	Information for multiple comparison LINES output	MEANS / LINES or ((DUNCAN or WALLER or SNK or REGWQ) and not (CLDIFF or CLM)) or (Equal cells and not CLDIFF)
MCLinesRange	Ranges for multiple range MC tests	MEANS / LINES or ((DUNCAN or WALLER or SNK or REGWQ) and not (CLDIFF or CLM)) or (Equal cells and not CLDIFF)
Means	Group means	MEANS statement

Tests	Summary ANOVA for specified MANOVA H= effects	MANOVA / H= SUMMARY
Welch	Welch's ANOVA	MEANS / WELCH

ODS Graphics

This section describes the use of ODS for creating statistical graphs with the ANOVA procedure. To request these graphs you must specify the ODS GRAPHICS statement with an appropriate model, as discussed in the following. For more information about the ODS GRAPHICS statement, see Chapter 21, "Statistical Graphics Using ODS."

When the ODS Graphics are in effect, if you specify a one-way analysis of variance model, with just one independent classification variable, or if you use a MEANS statement, then the ANOVA procedure will produce a grouped box plot of the response values versus the classification levels. For an example of the box plot, see the section "One-Way Layout with Means Comparisons" on page 693.

ODS Graph Names

PROC ANOVA produces a single graph, the name of which you can use for referencing it in ODS. The name is listed in Table 23.4.

To request this graph you must specify the ODS GRAPHICS statement. For more information about the ODS GRAPHICS statement, see Chapter 21, "Statistical Graphics Using ODS."

Table 23.4 ODS Graphic Produced by PROC ANOVA

ODS Graph Name	Plot Description
BoxPlot	Box plot of observed response values by classification levels

Examples: ANOVA Procedure

Example 23.1: Randomized Complete Block With Factorial Treatment Structure

This example uses statements for the analysis of a randomized block with two treatment factors occurring in a factorial structure. The data, from Neter, Wasserman, and Kutner (1990, p. 941), are from an experiment examining the effects of codeine and acupuncture on post-operative dental pain in male subjects. Both treatment factors have two levels. The codeine levels are a codeine capsule or a sugar capsule. The acupuncture levels are two inactive acupuncture points or two active acupuncture points. There are four distinct treatment combinations due to the factorial treatment structure. The 32 subjects are assigned to eight blocks of four subjects each based on an assessment of pain tolerance.

The data for the analysis are balanced, so PROC ANOVA is used. The data are as follows:

```
title1 'Randomized Complete Block With Two Factors';
data PainRelief;
   input PainLevel Codeine Acupuncture Relief @@;
   datalines;
1 1 1 0.0  1 2 1 0.5  1 1 2 0.6  1 2 2 1.2
2 1 1 0.3  2 2 1 0.6  2 1 2 0.7  2 2 2 1.3
3 1 1 0.4  3 2 1 0.8  3 1 2 0.8  3 2 2 1.6
4 1 1 0.4  4 2 1 0.7  4 1 2 0.9  4 2 2 1.5
5 1 1 0.6  5 2 1 1.0  5 1 2 1.5  5 2 2 1.9
6 1 1 0.9  6 2 1 1.4  6 1 2 1.6  6 2 2 2.3
7 1 1 1.0  7 2 1 1.8  7 1 2 1.7  7 2 2 2.1
8 1 1 1.2  8 2 1 1.7  8 1 2 1.6  8 2 2 2.4
;
```

The variable PainLevel is the blocking variable, and Codeine and Acupuncture represent the levels of the two treatment factors. The variable Relief is the pain relief score (the higher the score, the more relief the patient has).

The following statements invokes PROC ANOVA. The blocking variable and treatment factors appear in the CLASS statement. The bar between the treatment factors Codeine and Acupuncture adds their main effects as well as their interaction Codeine*Acupuncture to the model.

```
proc anova data=PainRelief;
   class PainLevel Codeine Acupuncture;
   model Relief = PainLevel Codeine|Acupuncture;
run;
```

The results from the analysis are shown in Output 23.1.1, Output 23.1.2, and Output 23.1.3.

Output 23.1.1 Class Level Information

Randomized Complete Block With Two Factors

The ANOVA Procedure

Class Level Information

Class	Levels	Values
PainLevel	8	1 2 3 4 5 6 7 8
Codeine	2	1 2
Acupuncture	2	1 2

Number of Observations Read	32
Number of Observations Used	32

Output 23.1.2 ANOVA Table

Randomized Complete Block With Two Factors

The ANOVA Procedure

Dependent Variable: Relief

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	10	11.33500000	1.13350000	78.37	<.0001
Error	21	0.30375000	0.01446429		
Corrected Total	31	11.63875000			

R-Square	Coeff Var	Root MSE	Relief Mean
0.973902	10.40152	0.120268	1.156250

The Class Level Information and ANOVA table are shown in Output 23.1.1 and Output 23.1.2. The classification level information summarizes the structure of the design. It is good to check these consistently in search of errors in the DATA step. The overall F test is significant, indicating that the model accounts for a significant amount of variation in the dependent variable.

Output 23.1.3 Tests of Effects

Source	DF	Anova SS	Mean Square	F Value	Pr > F
PainLevel	7	5.59875000	0.79982143	55.30	<.0001
Codeine	1	2.31125000	2.31125000	159.79	<.0001
Acupuncture	1	3.38000000	3.38000000	233.68	<.0001
Codeine*Acupuncture	1	0.04500000	0.04500000	3.11	0.0923

Output 23.1.3 shows tests of the effects. The blocking effect is significant; hence, it is useful. The interaction between codeine and acupuncture is significant at the 90% level but not at the 95% level. The significance level of this test should be determined before the analysis. The main effects of both treatment factors are highly significant.

Example 23.2: Alternative Multiple Comparison Procedures

The following is a continuation of the first example in the section "One-Way Layout with Means Comparisons" on page 693. You are studying the effect of bacteria on the nitrogen content of red clover plants, and the analysis of variance shows a highly significant effect. The following statements create the data set and compute the analysis of variance as well as Tukey's multiple comparisons test for pairwise differences between bacteria strains; the results are shown in Figure 23.1, Figure 23.2, and Figure 23.3

```
title1 'Nitrogen Content of Red Clover Plants';
data Clover;
   input Strain $ Nitrogen @@;
   datalines;
3DOK1  19.4 3DOK1  32.6 3DOK1  27.0 3DOK1  32.1 3DOK1  33.0
3DOK5  17.7 3DOK5  24.8 3DOK5  27.9 3DOK5  25.2 3DOK5  24.3
3DOK4  17.0 3DOK4  19.4 3DOK4   9.1 3DOK4  11.9 3DOK4  15.8
3DOK7  20.7 3DOK7  21.0 3DOK7  20.5 3DOK7  18.8 3DOK7  18.6
3DOK13 14.3 3DOK13 14.4 3DOK13 11.8 3DOK13 11.6 3DOK13 14.2
COMPOS 17.3 COMPOS 19.4 COMPOS 19.1 COMPOS 16.9 COMPOS 20.8
;

proc anova data=Clover;
   class Strain;
   model Nitrogen = Strain;
   means Strain / tukey;
run;
```

The interactivity of PROC ANOVA enables you to submit further MEANS statements without rerunning the entire analysis. For example, the following command requests means of the Strain levels with Duncan's multiple range test and the Waller-Duncan k-ratio t test.

```
   means Strain / duncan waller;
run;
```

Results of the Waller-Duncan k-ratio t test are shown in Output 23.2.1.

Output 23.2.1 Waller-Duncan K-ratio t Test

Nitrogen Content of Red Clover Plants

The ANOVA Procedure

Waller-Duncan K-ratio t Test for Nitrogen

Kratio	100
Error Degrees of Freedom	24
Error Mean Square	11.78867

The Waller-Duncan k-ratio t test is a multiple range test. Unlike Tukey's test, this test does not operate on the principle of controlling Type I error. Instead, it compares the Type I and Type II error rates based on Bayesian principles (Steel and Torrie 1980).

The Waller Grouping column in Output 23.2.1 shows which means are significantly different. From this test, you can conclude the following:

- The mean nitrogen content for strain 3DOK1 is higher than the means for all other strains.
- The mean nitrogen content for strain 3DOK5 is higher than the means for COMPOS, 3DOK4, and 3DOK13.
- The mean nitrogen content for strain 3DOK7 is higher than the means for 3DOK4 and 3DOK13.
- The mean nitrogen content for strain COMPOS is higher than the mean for 3DOK13.
- Differences between all other means are not significant based on this sample size.

Output 23.2.2 shows the results of Duncan's multiple range test. Duncan's test is a result-guided test that compares the treatment means while controlling the comparison-wise error rate. You should use this test for planned comparisons only (Steel and Torrie 1980). The results and conclusions for this example are the same as for the Waller-Duncan k-ratio t test. This is not always the case.

Output 23.2.2 Duncan's Multiple Range Test

```
                    Alpha                          0.05

If you only perform the LSD tests when the overall model F test is significant, then this is called Fisher's protected LSD test. Note that the LSD tests should be used for planned comparisons.

The TUKEY tests shown in Output 23.2.4 find fewer significant differences than the other three tests. This is not unexpected, as the TUKEY test controls the Type I experimentwise error rate. For a complete discussion of multiple comparison methods, see the section "Multiple Comparisons" on page 2514 in Chapter 39, "The GLM Procedure."

Output 23.2.4 Tukey's Studentized Range Test

Alpha	0.05
Error Degrees of Freedom	24
Error Mean Square	11.78867

Example 23.3: Split Plot

In some experiments, treatments can be applied only to groups of experimental observations rather than separately to each observation. When there are two nested groupings of the observations on the basis of treatment application, this is known as a *split plot design*. For example, in integrated circuit fabrication it is of interest to see how different manufacturing methods affect the characteristics of individual chips. However, much of the manufacturing process is applied to a relatively large wafer of material, from which many chips are made. Additionally, a chip's position within a wafer might also affect chip performance. These two groupings of chips—by wafer and by position-within-wafer—might form the *whole plots* and the *subplots*, respectively, of a split plot design for integrated circuits.

The following statements produce an analysis for a split-plot design. The CLASS statement includes the variables Block, A, and B, where B defines subplots within BLOCK*A whole plots. The MODEL statement includes the independent effects Block, A, Block*A, B, and A*B. The TEST statement asks for an F test of the A effect that uses the Block*A effect as the error term. The following statements produce Output 23.3.1 and Output 23.3.2:

```
title1 'Split Plot Design';
data Split;
   input Block 1 A 2 B 3 Response;
   datalines;
142 40.0
141 39.5
112 37.9
111 35.4
121 36.7
122 38.2
132 36.4
131 34.8
221 42.7
222 41.6
212 40.3
211 41.6
241 44.5
242 47.6
231 43.6
232 42.8
;

proc anova data=Split;
   class Block A B;
   model Response = Block A Block*A B A*B;
   test h=A e=Block*A;
run;
```

Output 23.3.1 Class Level Information and ANOVA Table

Split Plot Design

The ANOVA Procedure

Class Level Information

Class	Levels	Values
Block	2	1 2
A	4	1 2 3 4
B	2	1 2

Number of Observations Read	16
Number of Observations Used	16

Split Plot Design

The ANOVA Procedure

Dependent Variable: Response

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	11	182.0200000	16.5472727	7.85	0.0306
Error	4	8.4300000	2.1075000		
Corrected Total	15	190.4500000			

R-Square	Coeff Var	Root MSE	Response Mean
0.955736	3.609007	1.451723	40.22500

First, notice that the overall F test for the model is significant.

Output 23.3.2 Tests of Effects

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Block	1	131.1025000	131.1025000	62.21	0.0014
A	3	40.1900000	13.3966667	6.36	0.0530
Block*A	3	6.9275000	2.3091667	1.10	0.4476
B	1	2.2500000	2.2500000	1.07	0.3599
A*B	3	1.5500000	0.5166667	0.25	0.8612

Tests of Hypotheses Using the Anova MS for Block*A as an Error Term

Source	DF	Anova SS	Mean Square	F Value	Pr > F
A	3	40.19000000	13.39666667	5.80	0.0914

The effect of Block is significant. The effect of A is not significant: look at the F test produced by the TEST statement, not at the F test produced by default. Neither the B nor A*B effects are significant. The test for Block*A is irrelevant, as this is simply the main-plot error.

Example 23.4: Latin Square Split Plot

The data for this example is taken from Smith (1951). A Latin square design is used to evaluate six different sugar beet varieties arranged in a six-row (Rep) by six-column (Column) square. The data are collected over two harvests. The variable Harvest then becomes a split plot on the original Latin square design for whole plots. The following statements produce Output 23.4.1, Output 23.4.2, and Output 23.4.3:

```
title1 'Sugar Beet Varieties';
title3 'Latin Square Split-Plot Design';
data Beets;
   do Harvest=1 to 2;
      do Rep=1 to 6;
         do Column=1 to 6;
            input Variety Y @;
            output;
            end;
         end;
      end;
   datalines;
3 19.1 6 18.3 5 19.6 1 18.6 2 18.2 4 18.5

Error	25	7.4484722	0.2979389		
Corrected Total	71	106.3631944			

R-Square	Coeff Var	Root MSE	Y Mean
0.929971	3.085524	0.545838	17.69028

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Rep	5	4.32069444	0.86413889	2.90	0.0337
Column	5	1.57402778	0.31480556	1.06	0.4075
Variety	5	20.61902778	4.12380556	13.84	<.0001
Column*Rep*Variety	20	3.25444444	0.16272222	0.55	0.9144
Harvest	1	60.68347222	60.68347222	203.68	<.0001
Rep*Harvest	5	7.71736111	1.54347222	5.18	0.0021
Variety*Harvest	5	0.74569444	0.14913889	0.50	0.7729

First, note from Output 23.4.2 that the overall model is significant.

Output 23.4.3 Tests of Effects

Tests of Hypotheses Using the Anova MS for Column*Rep*Variety as an Error Term

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Rep	5	4.32069444	0.86413889	5.31	0.0029
Column	5	1.57402778	0.31480556	1.93	0.1333
Variety	5	20.61902778	4.12380556	25.34	<.0001

Tests of Hypotheses Using the Anova MS for Rep*Harvest as an Error Term

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Harvest	1	60.68347222	60.68347222	39.32	0.0015

Output 23.4.3 shows that the effects for Rep and Harvest are significant, while the Column effect is not. The average Ys for the six different Varietys are significantly different. For these four tests, look at the output produced by the two TEST statements, not at the usual ANOVA procedure output. The Variety*Harvest interaction is not significant. All other effects in the default output should either be tested by using the results from the TEST statements or are irrelevant as they are only error terms for portions of the model.

Example 23.5: Strip-Split Plot

In this example, four different fertilizer treatments are laid out in vertical strips, which are then split into subplots with different levels of calcium. Soil type is stripped across the split-plot experiment, and the entire experiment is then replicated three times. The dependent variable is the yield of winter barley. The data come from the notes of G. Cox and A. Rotti.

The input data are the 96 values of Y, arranged so that the calcium value (Calcium) changes most rapidly, then the fertilizer value (Fertilizer), then the Soil value, and, finally, the Rep value. Values are shown for Calcium (0 and 1); Fertilizer (0, 1, 2, 3); Soil (1, 2, 3); and Rep (1, 2, 3, 4). The following example produces Output 23.5.1, Output 23.5.2, Output 23.5.3, and Output 23.5.4.

```
title1 'Strip-split Plot';
data Barley;
   do Rep=1 to 4;
      do Soil=1 to 3; /* 1=d 2=h 3=p */
         do Fertilizer=0 to 3;
            do Calcium=0,1;
               input Yield @;
               output;
            end;
         end;
      end;
   end;

The ANOVA Procedure

Dependent Variable: Yield

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	95	31.89149583	0.33569996	.	.
Error	0	0.00000000	.		
Corrected Total	95	31.89149583			

R-Square	Coeff Var	Root MSE	Yield Mean
1.000000	.	.	5.427292

Output 23.5.2 *continued*

Source	DF	Anova SS	Mean Square	F Value	Pr > F
Rep	3	6.27974583	2.09324861	.	.
Fertilizer	3	7.22127083	2.40709028	.	.
Rep*Fertilizer	9	6.08211250	0.67579028	.	.
Calcium	1	0.27735000	0.27735000	.	.
Calcium*Fertilizer	3	1.96395833	0.65465278	.	.
Rep*Calcium(Fertili)	12	1.76705833	0.14725486	.	.
Soil	2	1.92658958	0.96329479	.	.
Rep*Soil	6	1.66761042	0.27793507	.	.
Soil*Fertilizer	6	0.68828542	0.11471424	.	.
Rep*Soil*Fertilizer	18	1.58698125	0.08816563	.	.
Soil*Calcium	2	0.04493125	0.02246562	.	.
Soil*Calcium*Fertili	6	0.18936042	0.03156007	.	.
Rep*Soil*Calc(Ferti)	24	2.19624167	0.09151007	.	.

Notice in Output 23.5.2 that the default tests against the residual error rate are all unavailable. This is because the Soil*Calcium*Rep(Fertilizer) term in the model takes up all the degrees of freedom, leaving none for estimating the residual error rate. This is appropriate in this case since the TEST statements give the specific error terms appropriate for testing each effect. Output 23.5.3 displays the output produced by the various TEST statements. The only significant effect is the Calcium*Fertilizer interaction.

Output 23.5.3 Tests of Effects

Tests of Hypotheses Using the Anova MS for Rep*Fertilizer as an Error Term

Output 23.5.4 Results of MEANS statement

Level of Fertilizer	N	Yield Mean	Yield Std Dev
0	24	5.18416667	0.48266395
1	24	5.12916667	0.38337082
2	24	5.75458333	0.53293265
3	24	5.64125000	0.63926801

Level of Calcium	N	Yield Mean	Yield Std Dev
0	48	5.48104167	0.54186141
1	48	5.37354167	0.61565219

Level of Soil	N	Yield Mean	Yield Std Dev
1	32	5.54312500	0.55806369
2	32	5.51093750	0.62176315
3	32	5.22781250	0.51825224

Level of Calcium	Level of Fertilizer	N	Yield Mean	Yield Std Dev
0	0	12	5.34666667	0.45029956
0	1	12	5.08833333	0.44986530
0	2	12	5.62666667	0.44707806
0	3	12	5.86250000	0.52886027
1	0	12	5.02166667	0.47615569
1	1	12	5.17000000	0.31826233
1	2	12	5.88250000	0.59856077
1	3	12	5.42000000	0.68409197

Output 23.5.4 shows the results of the MEANS statement, displaying for various effects and combinations of effects, as requested. You can examine the Calcium*Fertilizer means to understand the interaction better.

In this example, you could reduce memory requirements by omitting the Soil*Calcium*Rep(Fertilizer) effect from the model in the MODEL statement. This effect then becomes the ERROR effect, and you can omit the last TEST statement in the statements shown

earlier. The test for the Soil*Calcium effect is then given in the Analysis of Variance table in the top portion of output. However, for all other tests, you should look at the results from the TEST statement. In large models, this method might lead to significant reductions in memory requirements.

Overview: BOXPLOT Procedure

The BOXPLOT procedure creates side-by-side box-and-whiskers plots of measurements organized in groups. A box-and-whiskers plot displays the mean, quartiles, and minimum and maximum observations for a group. Throughout this chapter, this type of plot, which can contain one or more box-and-whiskers plots, is referred to as a *box plot*.

The PLOT statement of the BOXPLOT procedure produces a box plot. You can specify more than one PLOT statement to produce multiple box plots. You can use options in the PLOT statement to do the following:

- control the style of the box-and-whiskers plots
- specify one of several methods for calculating quantile statistics (percentiles)
- add block legends and symbol markers to reveal stratification in data
- display vertical and horizontal reference lines
- control axis values and labels
- overlay the box plot with plots of additional variables
- control the layout and appearance of the plot

The INSET and INSETGROUP statements produce boxes or tables (referred to as *insets*) of summary statistics or other data on a box plot. An INSET statement produces an inset of statistics pertaining to the entire box plot. An INSETGROUP statement produces an inset containing statistics calculated separately for each group. An INSET or INSETGROUP statement by itself does not produce a display; it must be used with a PLOT statement.

You can use options in an INSET or INSETGROUP statement to control insets in these ways:

- specify the position of the inset
- specify a header for the inset
- specify graphical enhancements, such as background colors, text colors, text height, text font, and drop shadows

The BOXPLOT procedure can produce two kinds of graphical output:

- traditional graphics
- ODS Statistical Graphics output, supported on an experimental basis for SAS 9.2

PROC BOXPLOT produces traditional graphics box plots by default. These graphs are saved in graphics catalogs. Their appearance is controlled by the SAS/GRAPH GOPTIONS, AXIS, and SYMBOL statements (as described in *SAS/GRAPH: Reference*) and numerous specialized PLOT statement options.

ODS Statistical Graphics (or ODS Graphics for short) is an extension to the Output Delivery System (ODS) that is invoked when you use the ODS GRAPHICS statement prior to your procedure statements. An ODS graph is produced in ODS output (not a graphics catalog), and the details of its appearance and layout are controlled by ODS styles and templates rather than by SAS/GRAPH statements and procedure options. See Chapter 21, "Statistical Graphics Using ODS," for a thorough discussion of ODS Graphics.

Prior to SAS 9.2, the box plots produced by PROC BOXPLOT were extremely basic by default. Producing attractive graphical output required the careful selection of colors, fonts, and other elements, which were specified via SAS/GRAPH statements and PLOT statement options. Beginning with SAS 9.2, the default appearance of box plots is governed by the prevailing ODS style, which automatically produces attractive, consistent output. You can also specify the NOGSTYLE system option to prevent the ODS style from affecting the appearance of traditional graphs.

See the section "Getting Started: BOXPLOT Procedure" on page 751 for examples producing box plots via the traditional graphics system and ODS Graphics.

Getting Started: BOXPLOT Procedure

This section introduces the BOXPLOT procedure with simple examples demonstrating commonly used options. Complete syntax for the BOXPLOT procedure is presented in the section "Syntax: BOXPLOT Procedure" on page 759, and advanced examples are presented in the section "Examples: BOXPLOT Procedure" on page 812.

Creating Box Plots from Raw Data

A petroleum company uses a turbine to heat water into steam that is pumped into the ground to make oil less viscous and easier to extract. This process occurs 20 times daily, and the amount of power (in kilowatts) used to heat the water to the desired temperature is recorded. The following statements create a SAS data set called Turbine that contains the power output measurements for 10 nonconsecutive days:

```
data Turbine;
   informat Day date7.;
   format Day date5.;
   label KWatts='Average Power Output';
   input Day @;
   do i=1 to 10;
      input KWatts @;
      output;
      end;
   drop i;
   datalines;

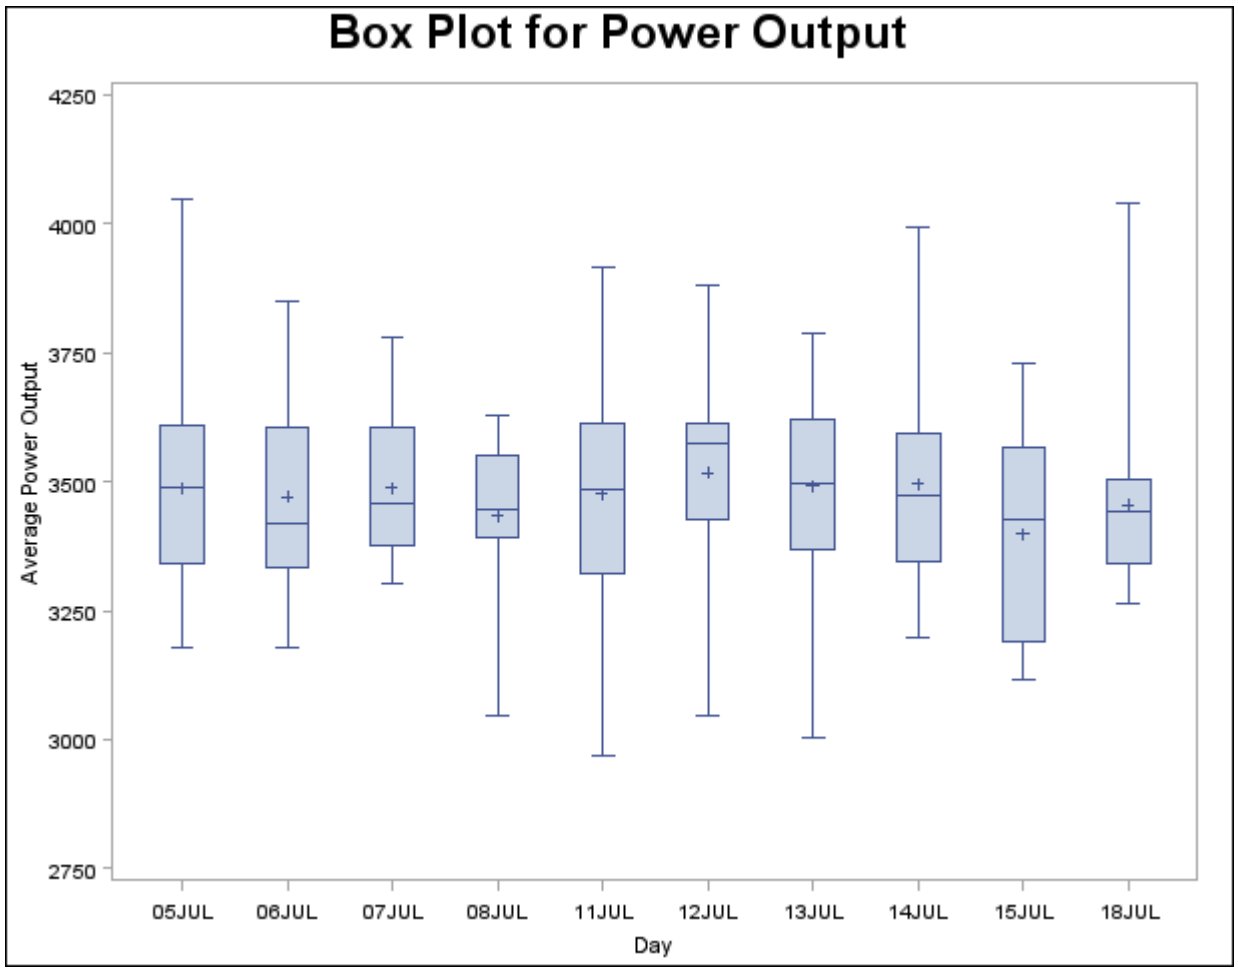
18JUL94 3421 3381 4040 3467 3475 3285 3619 3325 3317 3472
18JUL94 3296 3501 3366 3492 3367 3619 3550 3263 3355 3510
;
run;
```



In the data set Turbine, each observation contains the date and the power output for a single heating. The first 20 observations contain the outputs for the first day, the second 20 observations contain the outputs for the second day, and so on. Because the variable Day classifies the observations into groups, it is referred to as the *group variable*. The variable KWatts contains the output measurements and is referred to as the *analysis variable*.

The following statements create a box plot showing the distribution of power output for each day:

```
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day;
run;
```

The input data set Turbine is specified with the DATA= option in the PROC BOXPLOT statement. The PLOT statement requests a box-and-whiskers plot for each group of data. After the keyword PLOT, you specify the analysis variable (in this case, KWatts), followed by an asterisk and the group variable (Day). The box plot is shown in Figure 24.1.

Figure 24.1 Box Plot for Power Output Data

The box plot displayed in Figure 24.1 represents summary statistics for the analysis variable KWatts. Each of the 10 box-and-whiskers plots describes the variable KWatts for a particular day. The plot elements and the statistics they represent are as follows:

- The length of the box represents the interquartile range (the distance between the 25th and 75th percentiles).
- The symbol in the box interior represents the group mean.
- The horizontal line in the box interior represents the group median.
- The vertical lines (called *whiskers*) issuing from the box extend to the group minimum and maximum values.

Creating Box Plots from Summary Data

The previous example illustrates how you can create box plots from raw data. However, in some applications the data are provided as summary statistics. This example illustrates how you can use the BOXPLOT procedure with data of this type.

The following statements create the data set Oilsum, which provides the data from the preceding example in summarized form:

```
data Oilsum;
   input Day KWattsL KWatts1 KWattsX KWattsM
             KWatts3 KWattsH KWattsS KWattsN;
   informat Day date7. ;
   format Day date5. ;
   label Day    ='Date of Measurement'
         KWattsL='Minimum Power Output'
         KWatts1='25th Percentile'
         KWattsX='Average Power Output'
         KWattsM='Median Power Output'
         KWatts3='75th Percentile'
         KWattsH='Maximum Power Output'
         KWattsS='Standard Deviation of Power Output'
         KWattsN='Group Sample Size';
   datalines;
05JUL94 3180 3340.0 3487.40 3490.0 3610.0 4050 220.3 20
06JUL94 3179 3333.5 3471.65 3419.5 3605.0 3849 210.4 20
07JUL94 3304 3376.0 3488.30 3456.5 3604.5 3781 147.0 20
08JUL94 3045 3390.5 3434.20 3447.0 3550.0 3629 157.6 20
11JUL94 2968 3321.0 3475.80 3487.0 3611.5 3916 258.9 20
12JUL94 3047 3425.5 3518.10 3576.0 3615.0 3881 211.6 20
13JUL94 3002 3368.5 3492.65 3495.5 3621.5 3787 193.8 20
14JUL94 3196 3346.0 3496.40 3473.5 3592.5 3994 212.0 20
15JUL94 3115 3188.5 3398.50 3426.0 3568.5 3731 199.2 20
18JUL94 3263 3340.0 3456.05 3444.0 3505.5 4040 173.5 20
;
run;
```

Oilsum contains exactly one observation for each group. Note that, as in the previous example, the groups are indexed by the variable Day. A listing of Oilsum is shown in Figure 24.2.

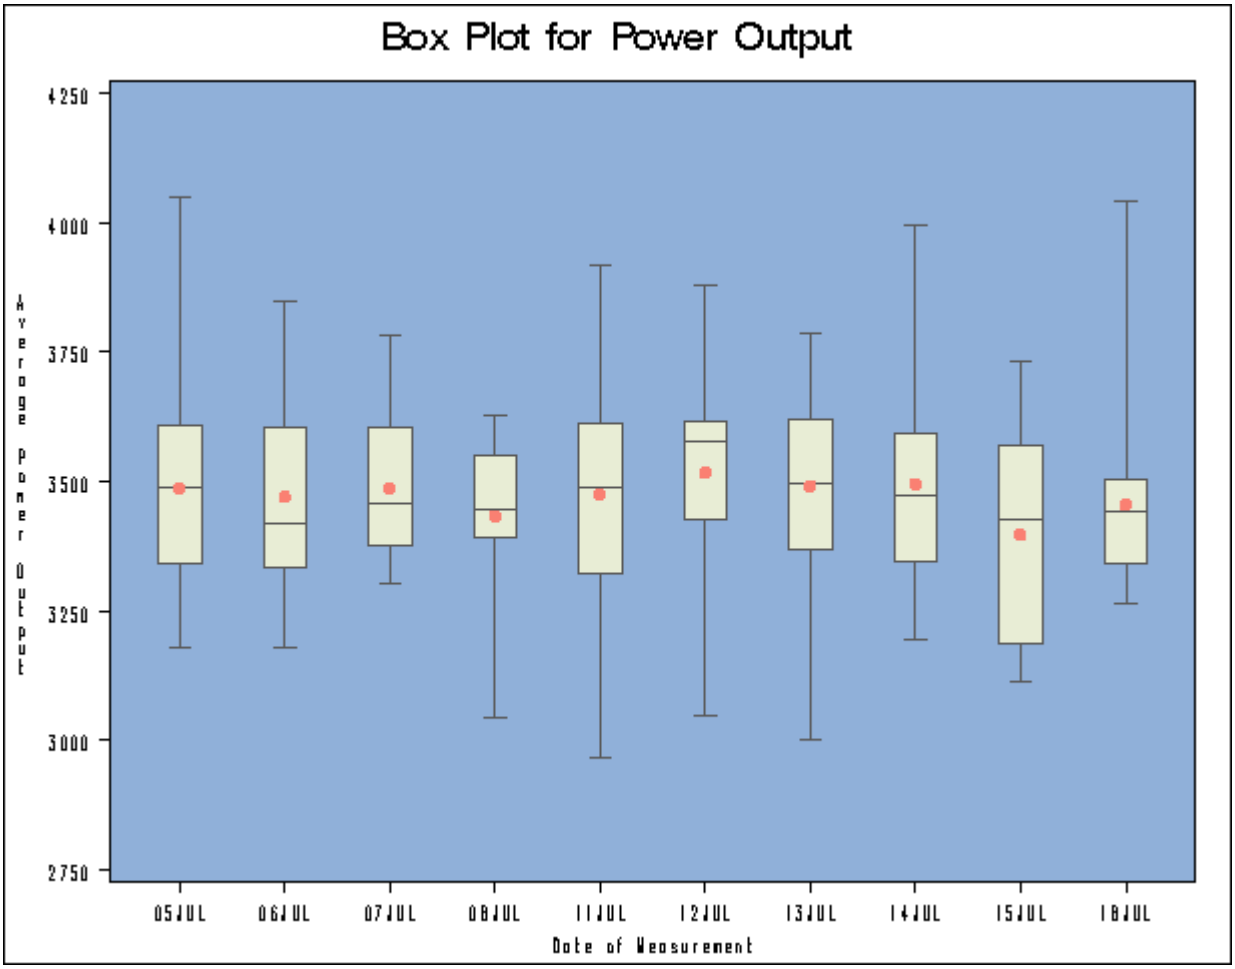
Figure 24.2 The Summary Data Set Oilsum

Box Plot for Power Output

Day	KWatts L	KWatts1	KWattsX	KWatts M	KWatts3	KWatts H	KWatts S	KWatts N
05JUL	3180	3340.0	3487.40	3490.0	3610.0	4050	220.3	20
06JUL	3179	3333.5	3471.65	3419.5	3605.0	3849	210.4	20
07JUL	3304	3376.0	3488.30	3456.5	3604.5	3781	147.0	20
08JUL	3045	3390.5	3434.20	3447.0	3550.0	3629	157.6	20
11JUL	2968	3321.0	3475.80	3487.0	3611.5	3916	258.9	20
12JUL	3047	3425.5	3518.10	3576.0	3615.0	3881	211.6	20
13JUL	3002	3368.5	3492.65	3495.5	3621.5	3787	193.8	20
14JUL	3196	3346.0	3496.40	3473.5	3592.5	3994	212.0	20
15JUL	3115	3188.5	3398.50	3426.0	3568.5	3731	199.2	20
18JUL	3263	3340.0	3456.05	3444.0	3505.5	4040	173.5	20

There are eight summary variables in Oilsum:

- KWattsL contains the group minima (low values).
- KWatts1 contains the 25th percentile (first quartile) for each group.
- KWattsX contains the group means.
- KWattsM contains the group medians.
- KWatts3 contains the 75th percentile (third quartile) for each group.
- KWattsH contains the group maxima (high values).
- KWattsS contains the group standard deviations.
- KWattsN contains the group sizes.



You can use this data set as input to the BOXPLOT procedure by specifying it with the HISTORY= option in the PROC BOXPLOT statement. Detailed requirements for HISTORY= data sets are presented in the section "HISTORY= Data Set" on page 794.

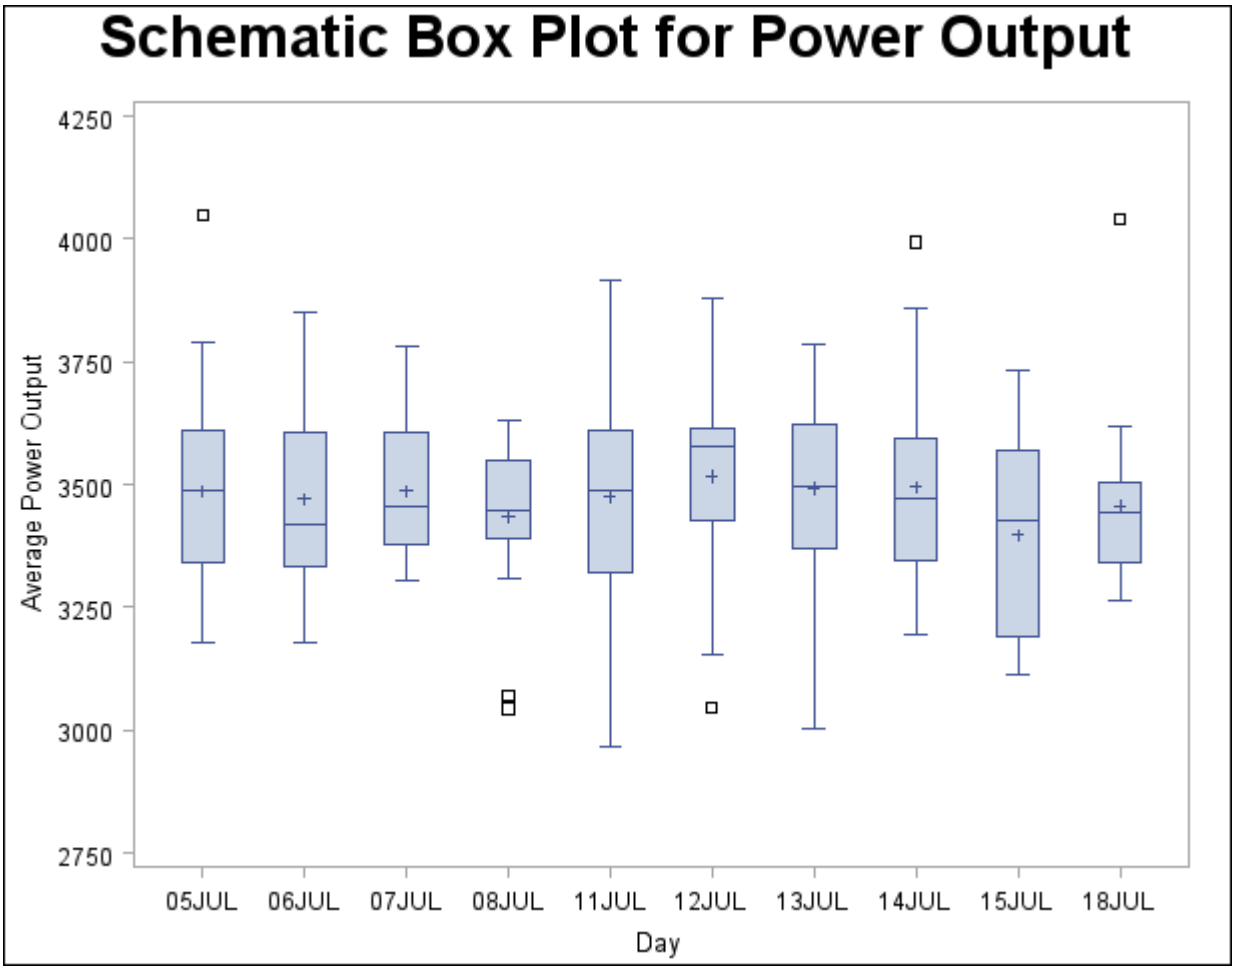
The following statements produce a box plot of the summary data from the Oilsum data set:

```
options nogstyle;
title 'Box Plot for Power Output';
symbol value=dot color=salmon;
proc boxplot history=Oilsum;
   plot KWatts*Day / cframe   = vligb
                     cboxes   = dagr
                     cboxfill = ywh;
run;
options gstyle;
goptions reset=symbol;
```

The NOGSTYLE system option causes PROC BOXPLOT to ignore ODS styles when producing the box plot. Instead, the SYMBOL statement and options specified after the slash (/) in the PLOT statement control its appearance. The GSTYLE system option restores the use of ODS styles for subsequent high-resolution graphics output. For more information about SYMBOL statements, see *SAS/GRAPH: Reference*. The resulting box plot is shown in Figure 24.3.

Figure 24.3 High-Resolution Box Plot with NOGSTYLE

Saving Summary Data with Outliers



In a *schematic* box plot, outlier values within a group are plotted as separate points beyond the whiskers of the box-and-whiskers plot. See the section "Styles of Box Plots" on page 796 and the description of the BOXSTYLE= option on page 773 for a complete description of schematic box plots.

The following statements use the BOXSTYLE= option to produce a schematic box plot of the data from the Turbine data set. The OUTBOX= option creates a summary data set named OilSchematic.

```
title 'Schematic Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day / boxstyle = schematic
                     outbox   = OilSchematic;
run;
```

The schematic box plot is shown in Figure 24.4. Note the outliers plotted with squares for several of the groups.

Figure 24.4 Schematic Box Plot of Power Output

Whereas the Oilsum data set from the section "Creating Box Plots from Summary Data" on page 754 contains a *variable* for each summary statistic and one observation per group, the OUTBOX= data set OilSchematic contains one *observation* for each summary statistic in each group. The _TYPE_ variable identifies the statistic and the _VALUE_ variable contains its value. In addition, the OilSchematic data set contains an observation recording each outlier value for each group. Figure 24.5 shows a partial listing of the OilSchematic data set.

Figure 24.5 The Summary Data Set OilSchematic

Schematic Box Plot for Power Output

Day	_VAR_	_TYPE_	_VALUE_
05JUL	KWatts	N	20.00
05JUL	KWatts	MIN	3180.00
05JUL	KWatts	Q1	3340.00
05JUL	KWatts	MEAN	3487.40
05JUL	KWatts	MEDIAN	3490.00
05JUL	KWatts	Q3	3610.00
05JUL	KWatts	MAX	4050.00
05JUL	KWatts	STDDEV	220.26
05JUL	KWatts	HIWHISKR	3789.00
05JUL	KWatts	HIGH	4050.00
06JUL	KWatts	N	20.00
06JUL	KWatts	MIN	3179.00
06JUL	KWatts	Q1	3333.50
06JUL	KWatts	MEAN	3471.65
06JUL	KWatts	MEDIAN	3419.50
06JUL	KWatts	Q3	3605.00
06JUL	KWatts	MAX	3849.00
06JUL	KWatts	STDDEV	210.43
07JUL	KWatts	N	20.00
07JUL	KWatts	MIN	3304.00
07JUL	KWatts	Q1	3376.00
07JUL	KWatts	MEAN	3488.30
07JUL	KWatts	MEDIAN	3456.50
07JUL	KWatts	Q3	3604.50
07JUL	KWatts	MAX	3781.00
07JUL	KWatts	STDDEV	147.02
08JUL	KWatts	N	20.00
08JUL	KWatts	MIN	3045.00
08JUL	KWatts	Q1	3390.50
08JUL	KWatts	MEAN	3434.20
08JUL	KWatts	MEDIAN	3447.00
08JUL	KWatts	Q3	3550.00
08JUL	KWatts	MAX	3629.00
08JUL	KWatts	STDDEV	157.64
08JUL	KWatts	LOWHISKR	3309.00
08JUL	KWatts	LOW	3070.00
08JUL	KWatts	LOW	3045.00
11JUL	KWatts	N	20.00
11JUL	KWatts	MIN	2968.00
11JUL	KWatts	Q1	3321.00

Observations with the _TYPE_ variable values “HIGH” and “LOW” contain outlier values. If you want to use a summary data set to re-create a schematic box plot, you *must* create an OUTBOX= data set in order to save the outlier data.

Syntax: BOXPLOT Procedure

The syntax for the BOXPLOT procedure is as follows:

PROC BOXPLOT *options* ;
BY *variables* ;
ID *variables* ;
INSET *keywords* < */options* > ;
INSETGROUP *keywords* < */ options* > ;
PLOT *analysis-variable*group-variable* < *(block-variables)* > < *=symbol-variable* > < */ options* > ;

Both the PROC BOXPLOT and PLOT statements are required. You can specify any number of PLOT statements within a single PROC BOXPLOT invocation.

PROC BOXPLOT Statement

PROC BOXPLOT *options* ;

The PROC BOXPLOT statement starts the BOXPLOT procedure. The following options can appear in the PROC BOXPLOT statement.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an ANNOTATE= type data set, as described in *SAS/GRAPH: Reference*, which enhances high-resolution box plots requested in subsequent PLOT statements.

BOX=*SAS-data-set*

names an input data set containing group summary statistics and outlier values. Typically, this data set is created as an OUTBOX= data set in a previous run of PROC BOXPLOT. Each group summary statistic or outlier value is recorded in a separate observation in a BOX= data set, so there are multiple observations per group. You cannot use a BOX= data set together with a DATA= or HISTORY= data set. If you do not specify one of these input data sets, the procedure uses the most recently created SAS data set as a DATA= data set.

DATA=*SAS-data-set*

names an input data set containing raw data to be analyzed. You cannot use a DATA= data set together with a BOX= or HISTORY= data set. If you do not specify one of these input data sets, the procedure uses the most recently created SAS data set as a DATA= data set.

GOUT=< *libref.* >*output catalog*

specifies the SAS catalog in which to save high-resolution graphics output that is produced by the BOXPLOT procedure. If you omit the libref, PROC BOXPLOT looks for the catalog in the temporary library called WORK and creates the catalog if it does not exist.

HISTORY=*SAS-data-set*
HIST=*SAS-data-set*
names an input data set containing group summary statistics. Typically, this data set is created as an OUTHISTORY= data set in a previous run of PROC BOXPLOT, but it can also be created using a SAS summarization procedure such as the MEANS procedure. The HISTORY= data set can contain only one observation for each value of the group variable. You cannot use a HISTORY= data set with a DATA= or BOX= data set. If you do not specify one of these three input data sets, PROC BOXPLOT uses the most recently created data set as a DATA= data set.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC BOXPLOT to obtain separate box plots for each group defined by the levels of the BY variables. When you specify a BY statement, the input data set must be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the BOXPLOT procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the *Base SAS Procedures Guide.*

ID Statement

ID *variables* **;**

The ID statement specifies variables used to identify observations. The ID variables must be variables in the input data set.

If you specify the keyword SCHEMATICID or SCHEMATICIDFAR with the BOXSTYLE= option, the value of an ID variable is used to label each extreme observation. When you specify a BOX= data set, the label values come from the variable _ID_, if it is present in the data set. When you specify a DATA= or HISTORY= input data set, or a BOX= data set that does not contain the variable _ID_, the labels come from the first variable listed in the ID statement. If ID statement is specified, the outliers are not labeled.

INSET Statement

INSET *keywords* < / options > **;**

Each PLOT statement in the BOXPLOT procedure is followed by a series of zero or more INSET and INSETGROUP statements. Each INSET statement in that series produces one inset in the box plot produced by the preceding PLOT statement. If the box plot occupies multiple panels, the inset appears on each panel.

The data requested using the *keywords* are displayed in the order in which they are specified. Summary statistics requested with an INSET statement are calculated using the observations in all groups.

keywords identify summary statistics or other data to be displayed in the inset. By default, inset statistics are identified with appropriate labels, and numeric values are printed using appropriate formats. However, you can provide customized labels and formats. You provide the customized label by specifying the *keyword* for that statistic followed by an equal sign (=) and the label in quotes. Labels can have up to 24 characters. You provide the numeric format in parentheses after the *keyword*. Note that if you specify both a label and a format for a statistic, the label must appear before the format.

The available keywords are listed in Table 24.1.

options control the appearance of the inset. Table 24.2 lists all the options in the INSET statement. Complete descriptions for each option follow.

Table 24.1 INSET Statement Keywords

Keyword	Description
DATA=	(label, value) pairs from *SAS-data-set*
MEAN	mean of all observations
MIN	minimum observed value
MAX	maximum observed value
NMIN	minimum group size
NMAX	maximum group size
NOBS	number of observations in box plot
STDDEV	pooled standard deviation

The DATA= keyword specifies a SAS data set containing (label, value) pairs to be displayed in an inset. The data set must contain the variables _LABEL_ and _VALUE_. _LABEL_ is a character variable of up to 24 characters whose values provide labels for inset entries. _VALUE_ can be character or numeric, and provides values displayed in the inset. The label and value from each observation in the DATA= data set occupy one line in the inset.

The *pooled standard deviation* requested with the STDDEV keyword is defined as

$$s_p = \sqrt{\frac{\sum_{i=1}^{N} s_i^2 (n_i - 1)}{\sum_{i=1}^{N} (n_i - 1)}}$$

where N is the number of groups, n_i is the size of the ith group, and s_i^2 is the variance of the ith group.

Table 24.2 INSET Statement Options

Option	Description
CFILL=*color* | BLANK	specifies color of inset background
CFILLH=*color*	specifies color of inset header background
CFRAME=*color*	specifies color of inset frame
CHEADER=*color*	specifies color of inset header text
CSHADOW=*color*	specifies color of inset drop shadow
CTEXT=*color*	specifies color of inset text
DATA	specifies data units for POSITION=(x, y) coordinates
FONT=*font*	specifies font of inset text
FORMAT=*format*	specifies format of values in inset
HEADER='*string*'	specifies inset header text
HEIGHT=*value*	specifies height of inset and header text
NOFRAME	suppresses frame around inset
POSITION=*position*	specifies position of inset
REFPOINT=BR|BL|TR|TL	specifies reference point of inset positioned with POSITION=(x, y) coordinates

Following are descriptions of the options that you can specify in the INSET statement after a slash (/).

CFILL=*color* **| BLANK**

specifies the color of the inset background (including the header background if you do not specify the CFILLH= option).

If you do not specify the CFILL= option, then by default the background is empty. This means that items that overlap the inset (such as box-and-whiskers plots or reference lines) show through the inset. If you specify any value for the CFILL= option, then overlapping items no longer show through the inset. Specify CFILL=BLANK to leave the background uncolored and also to prevent items from showing through the inset.

CFILLH=*color*

specifies the color of the header background. By default, if you do not specify a CFILLH= color, the CFILL= color is used.

CFRAME=*color*

specifies the color of the frame around the inset. By default, the frame is the same color as the axis of the plot.

CHEADER=*color*

specifies the color of the header text. By default, if you do not specify a CHEADER= color, the INSET statement CTEXT= color is used.

CSHADOW=*color*

CS=*color*

specifies the color of the drop shadow. If you do not specify the CSHADOW= option, a drop shadow is not displayed.

CTEXT=*color*

CT=*color*

specifies the color of the text in the inset. By default, the inset text color is the same as the other text in the box plot.

DATA

specifies that data coordinates be used in positioning the inset with the POSITION= option. The DATA option is available only when you specify POSITION= (x, y), and it must be placed immediately after the coordinates (x, y). See the entry for the POSITION= option.

FONT=*font*

specifies the font of the text.

FORMAT=*format*

specifies a format for all the values displayed in an inset. If you specify a format for a particular statistic, then this format overrides the format you specified with the FORMAT= option.

HEADER='*string***'**

specifies the header text. The *string* can be up to 40 characters. If you do not specify the HEADER= option, no header line appears in the inset.

HEIGHT=*value*

specifies the height of the inset and header text.

NOFRAME

suppresses the frame drawn around the inset.

POSITION=*position*

POS=*position*

determines the position of the inset. The *position* can be a compass point keyword, a margin keyword, or a pair of coordinates (x, y). You can specify coordinates in axis percent units or axis data units. For more information, see the section "Positioning Insets" on page 800. By default, POSITION=NW, which positions the inset in the upper-left (northwest) corner of the plot.

REFPOINT=BR | BL | TR | TL

RP=BR | BL | TR | TL

specifies the reference point for an inset that is positioned by a pair of coordinates with the POSITION= option. Use the REFPOINT= option with POSITION= coordinates. The REFPOINT= option specifies which corner of the inset frame you want positioned at coordinates (x, y). The keywords BL, BR, TL, and TR represent bottom left, bottom right, top left, and top right, respectively. The default is REFPOINT=BL.

If you specify the position of the inset as a compass point or margin keyword, the REFPOINT= option is ignored.

INSETGROUP Statement

INSETGROUP *keywords* < / options > **;**

Each PLOT statement in the BOXPLOT procedure is followed by a series of zero or more INSET and INSETGROUP statements. Each INSETGROUP statement in that series displays statistics associated with individual groups in the box plot produced by the preceding PLOT statement. No more than two INSETGROUP statements can be associated with a given PLOT statement: one that displays group statistics above the box plot and one that displays group statistics below it. The data requested using the *keywords* are displayed in the order in which they are specified.

keywords identify summary statistics to be displayed in the insets. By default, inset statistics are identified with appropriate labels, and numeric values are printed using appropriate formats. However, you can provide customized labels and formats. You provide the customized label by specifying the *keyword* for that statistic followed by an equal sign (=) and the label in quotes. Labels can have up to 24 characters. You provide the numeric format in parentheses after the *keyword*. Note that if you specify both a label and a format for a statistic, the label must appear before the format. The keywords are listed in Table 24.3.

options control the appearance of the insets. Table 24.4 lists all the options in the INSETGROUP statement. Complete descriptions for each option follow.

Table 24.3 INSETGROUP Statement Keywords

Keyword	Description
MEAN	group mean
MIN	group minimum value
MAX	group maximum value
N	number of observations in group
NHIGH	number of outliers above upper fence
NLOW	number of outliers below lower fence
NOUT	total number of outliers in group
Q1	first quartile of group values
Q2	second quartile of group values
Q3	third quartile of group values
RANGE	range of group values
STDDEV	group standard deviation

Table 24.4 lists the options available in the INSETGROUP statement.

Table 24.4 INSETGROUP Statement Options

Option	Description
CFILL=*color* | BLANK	specifies color of inset background
CFILLH=*color*	specifies color of inset header background
CFRAME=*color*	specifies color of inset frame
CHEADER=*color*	specifies color of inset header text
CTEXT=*color*	specifies color of inset text
FONT=*font*	specifies font of inset text
FORMAT=*format*	specifies format of values in inset
HEADER='*string*'	specifies inset header text
HEIGHT=*value*	specifies height of inset and header text
NOFRAME	suppresses frame around inset
POSITION=*position*	specifies position of inset

Following are descriptions of the options that you can specify in the INSETGROUP statement after a slash (/).

CFILL=*color*

specifies the color of the inset background (including the header background if you do not specify the CFILLH= option). If you do not specify the CFILL= option, then by default the background is empty.

CFILLH=*color*

specifies the color of the header background. By default, if you do not specify a CFILLH= color, the CFILL= color is used.

CFRAME=*color*

specifies the color of the frame around the inset. By default, the frame is the same color as the axis of the plot.

CHEADER=*color*

specifies the color of the header text. By default, if you do not specify a CHEADER= color, the CTEXT= color is used.

CTEXT=*color*

CT=*color*

specifies the color of the inset text. By default, the inset text color is the same as the other text in the plot.

FONT=*font*

specifies the font of the inset text. By default, the font is SIMPLEX.

FORMAT=*format*

specifies a format for all the values displayed in an inset. If you specify a format for a particular statistic, then this format overrides the format you specified with the FORMAT= option.

HEADER='*string*'

specifies the header text. The *string* can be up to 40 characters. If you do not specify the HEADER= option, no header line appears in the inset.

HEIGHT=*value*

specifies the height of the inset and header text.

NOFRAME

suppresses the frame drawn around the inset.

POSITION=*position*

POS=*position*

determines the position of the inset. Valid positions are TOP, TOPOFF, AXIS, and BOTTOM. By default, POSITION=TOP.

Position Keyword	Description
TOP	top of plot, immediately above axis frame
TOPOFF	top of plot, offset from axis frame
AXIS	bottom of plot, immediately above horizontal axis
BOTTOM	bottom of plot, below horizontal axis label

PLOT Statement

PLOT *(analysis-variables)*group-variable* <*(block-variables)*> <*=symbol-variable*> </ *options* > ;

You can specify multiple PLOT statements after the PROC BOXPLOT statement. The components of the PLOT statement are as follows:

analysis-variables identify one or more variables to be analyzed. An analysis variable is required. If you specify more than one analysis variable, enclose the list in parentheses. For example, the following statements request distinct box plots for the variables Weight, Length, and Width:

```
proc boxplot data=Summary;
   plot (Weight Length Width)*Day;
run;
```

group-variable specifies the variable that identifies groups in the data. The group variable is required. In the preceding PLOT statement, Day is the group variable.

block-variables specify optional variables that group the data into blocks of consecutive groups. These blocks are labeled in a legend, and each block variable provides one level of labels in the legend.

symbol-variable specifies an optional variable whose levels (unique values) determine the symbol marker used to plot the means. Distinct symbol markers are displayed for points corresponding to the various levels of the symbol variable. You can specify the symbol markers with SYMBOL*n* statements (refer to *SAS/GRAPH: Reference* for complete details).

options enhance the appearance of the box plot, request additional analyses, save results in data sets, and so on. Complete descriptions of each option follow.

Table 24.5 lists all options in the PLOT statement by function.

PLOT Statement Options

Table 24.5 PLOT Statement Options

Option	Description
Options for Controlling Box Appearance	
BOXCONNECT=	connects features of adjacent box-and-whiskers plots with line segments
BOXSTYLE=	specifies style of box-and-whiskers plots
BOXWIDTH=	specifies width of box-and-whiskers plots
BOXWIDTHSCALE=	specifies that widths of box-and-whiskers plots vary proportionately to group size

Table 24.5 *continued*

Option	Description
CBOXES=	specifies color for outlines of box-and-whiskers plots
CBOXFILL=	specifies fill color for interior of box-and-whiskers plots
IDCOLOR=	specifies outlier symbol color in schematic box-and-whiskers plots
IDCTEXT=	specifies outlier label color in schematic box-and-whiskers plots
IDFONT=	specifies outlier label font in schematic box-and-whiskers plots
IDHEIGHT=	specifies outlier label height in schematic box-and-whiskers plots
IDSYMBOL=	specifies outlier symbol in schematic box-and-whiskers plots
LBOXES=	specifies line types for outlines of box-and-whiskers plots
NOSERIFS	eliminates serifs from whiskers of box-and-whiskers plots
NOTCHES	specifies that box-and-whiskers plots be notched
PCTLDEF=	specifies percentile definition used for box-and-whiskers plots
Options for Plotting and Labeling Points	
ALLLABEL=	labels means of box-and-whiskers plots
CLABEL=	specifies color for labels requested with ALLLABEL= option
CCONNECT=	specifies color for line segments requested with BOXCONNECT= option
LABELANGLE=	specifies angle for labels requested with ALLLABEL= option
SYMBOLLEGEND=	specifies LEGEND statement for levels of symbol variable
SYMBOLORDER=	specifies order in which symbols are assigned for levels of symbol variable
Reference Line Options	
CHREF=	specifies color for lines requested by HREF= option
CVREF=	specifies color for lines requested by VREF= option
FRONTREF	draws reference lines in front of boxes
HREF=	requests reference lines perpendicular to horizontal axis
HREFLABELS=	specifies labels for HREF= lines
HREFLABPOS=	specifies position of HREFLABELS= labels
LHREF=	specifies line type for HREF= lines
LVREF=	specifies line type for VREF= lines
NOBYREF	specifies that reference line information in a data set be applied uniformly to plots created for all BY groups
VREF=	requests reference lines perpendicular to vertical axis
VREFLABELS=	specifies labels for VREF= lines
VREFLABPOS=	specifies position of VREFLABELS= labels
Block Variable Legend Options	
BLOCKLABELPOS=	specifies position of label for block variable legend

Table 24.5 *continued*

Option	Description
BLOCKLABTYPE=	specifies text size of block variable legend
BLOCKPOS=	specifies vertical position of block variable legend
BLOCKREP	repeats identical consecutive labels in block variable legend
CBLOCKLAB=	specifies colors for filling frames enclosing block variable labels
CBLOCKVAR=	specifies colors for filling background of block variable legend
Axis and Axis Label Options	
CAXIS=	specifies color for axis lines and tick marks
CFRAME=	specifies fill color for frame for plot area
CONTINUOUS	produces horizontal axis for continuous group variable values (traditional graphics only)
CTEXT=	specifies color for tick mark values and axis labels
HAXIS=	specifies major tick mark values for horizontal axis
HEIGHT=	specifies height of axis label and axis legend text
HMINOR=	specifies number of minor tick marks between major tick marks on horizontal axis
HOFFSET=	specifies length of offset at both ends of horizontal axis
NOHLABEL	suppresses horizontal axis label
NOTICKREP	specifies that only first occurrence of repeated, adjacent character group values be labeled on horizontal axis
NOVANGLE	requests vertical axis labels that are strung out vertically
SKIPHLABELS=	specifies thinning factor for tick mark labels on horizontal axis
TURNHLABELS	requests horizontal tick labels that are strung out vertically
VAXIS=	specifies major tick mark values for vertical axis
VFORMAT=	specifies format for vertical axis tick marks
VMINOR=	specifies number of minor tick marks between major tick marks on vertical axis
VOFFSET=	specifies length of offset at both ends of vertical axis
VZERO	forces origin to be included in vertical axis
WAXIS=	specifies width of axis lines
Input Data Set Options	
MISSBREAK	specifies that a missing value between identical character group values signify the start of a new group
Output Data Set Options	
OUTBOX=	produces an output data set containing group summary statistics and outlier values
OUTHISTORY=	produces an output data set containing group summary statistics

Table 24.5 *continued*

Option	Description
Graphical Enhancement Options	
ANNOTATE=	specifies annotate data set that adds features to box plot
BWSLEGEND	displays a legend identifying the function of group size specified with BOXWIDTHSCALE= option
DESCRIPTION=	specifies string that appears in description field of PROC GREPLAY master menu for high-resolution graphics box plot
FONT=	specifies font for labels and legends on plots
HORIZONTAL	requests a horizontal box plot with ODS Graphics
HTML=	specifies URLs to be associated with box-and-whiskers plots
NAME=	specifies name that appears in name field of PROC GREPLAY master menu for high-resolution graphics box plot
NLEGEND	requests legend displaying group sizes
OUTHIGHHTML=	specifies URLs to be associated with high outliers on box-and-whiskers plots
OUTLOWHTML=	specifies URLs to be associated with low outliers on box-and-whiskers plots
PAGENUM=	specifies form of label used in pagination
PAGENUMPOS=	specifies position of page number requested with PAGENUM= option
Grid Options	
CGRID=	specifies color for grid requested with ENDGRID or GRID option
ENDGRID	adds grid after last box-and-whiskers plot
GRID	adds grid to box plot
LENDGRID=	specifies line type for grid requested with ENDGRID option
LGRID=	specifies line type for grid requested with GRID option
WGRID=	specifies width of grid lines
Plot Layout Options	
INTERVAL=	specifies natural time interval between consecutive group positions when time, date, or datetime format is associated with numeric group variable
INTSTART=	specifies first major tick mark value on horizontal axis when date, time, or datetime format is associated with numeric group variable
MAXPANELS=	specifies maximum number of panels used for box plot
NOCHART	suppresses creation of box plot
NOFRAME	suppresses frame for plot area
NPANELPOS=	specifies number of group positions per panel
REPEAT	repeats last group position on panel as first group position of next panel

Table 24.5 *continued*

Option	Description
TOTPANELS=	specifies number of panels to be used to display box plot
Overlay Options	
CCOVERLAY=	specifies colors for line segments connecting points on overlays
COVERLAY=	specifies colors for points on overlays
LOVERLAY=	specifies line types for line segments connecting points on overlays
NOOVERLAYLEGEND	suppresses overlay legend
OVERLAY=	specifies variables to be plotted on overlays
OVERLAYHTML=	specifies URLs to be associated with overlay plot points
OVERLAYID=	specifies labels for overlay plot points
OVERLAYLEGLAB=	specifies label for overlay legend
OVERLAYSYM=	specifies symbols used for overlays
OVERLAYSYMHT=	specifies heights for overlay symbols
WOVERLAY=	specifies widths for line segments connecting points on overlays
Clipping Options	
CCLIP=	specifies color for plot symbol for clipped points
CLIPFACTOR=	determines extent to which extreme values are clipped
CLIPLEGEND=	specifies text for clipping legend
CLIPLEGPOS=	specifies position of clipping legend
CLIPSUBCHAR	specifies substitution character for CLIPLEGEND= text
CLIPSYMBOL=	specifies plot symbol for clipped points
CLIPSYMBOLHT=	specifies symbol marker height for clipped points
COVERLAYCLIP=	specifies color for clipped points on overlays
OVERLAYCLIPSYM=	specifies symbol for clipped points on overlays
OVERLAYCLIPSYMHT=	specifies symbol height for clipped points on overlays
Options for Box Plots Produced Using Styles	
BLOCKVAR=	groups block legends whose backgrounds are filled with colors from style
BOXES=	groups boxes whose outlines are draw with colors from style
BOXFILL=	groups boxes that are filled with colors from style

Following are explanations of the options you can specify in the PLOT statement after a slash (/).

ALLLABEL=VALUE | (*variable***)**
labels the point plotted for the mean of each box-and-whiskers plot with its VALUE or with the value of a *variable* in the input data set.

ANNOTATE=*SAS-data-set*
specifies an ANNOTATE= type data set, as described in *SAS/GRAPH: Reference*.

BLOCKLABELPOS=ABOVE | LEFT

specifies the position of a block variable label in the block legend. The keyword ABOVE places the label immediately above the legend, and LEFT places the label to the left of the legend. Use the keyword LEFT with labels that are short enough to fit in the margin of the plot; otherwise, they are truncated. The default keyword is ABOVE.

BLOCKLABTYPE=SCALED | TRUNCATED

BLOCKLABTYPE=*height*

specifies how lengthy block variable values are treated when there is insufficient space to display them in the block legend. If you specify BLOCKLABTYPE=SCALED, the values are uniformly reduced in height so that they fit. If you specify BLOCKLABTYPE=TRUNCATED, lengthy values are truncated on the right until they fit. You can also specify a text height in vertical percent screen units for the values. By default, lengthy values are not displayed. For more information, see the section "Displaying Blocks of Data" on page 805.

BLOCKPOS=*n*

specifies the vertical position of the legend for the values of the block variables. Values of *n* and the corresponding positions are as follows. By default, BLOCKPOS=1.

n	Legend Position
1	top of plot, offset from axis frame
2	top of plot, immediately above axis frame
3	bottom of plot, immediately above horizontal axis
4	bottom of plot, below horizontal axis label

BLOCKREP

specifies that block variable values for all groups be displayed. By default, only the first block variable value in any block is displayed, and repeated block variable values are not displayed.

BLOCKVAR=*variable* | **(***variable-list***)**

specifies variables whose values are used to assign colors for filling the background of the legend associated with block variables. A list of BLOCKVAR= variables must be enclosed in parentheses. BLOCKVAR= variables are matched with block variables by their order in the respective variable lists. While the values of a CBLOCKVAR= variable are color names, values of a BLOCKVAR= variable are used to group block legends for assigning fill colors from the ODS style. Block legends with the same BLOCKVAR= variable value are filled with the same color.

BOXCONNECT=MEAN | MEDIAN | MAX | MIN | Q1 | Q3

BOXCONNECT

specifies that the points in adjacent box-and-whiskers plots representing group means, medians, maximum values, minimum values, first quartiles, or third quartiles be connected with line segments. If the BOXCONNECT option is specified without a keyword identifying the points to be connected, group means are connected. By default, no points are connected.

BOXES=(*variable*)

specifies a variable whose values are used to assign colors for the outlines of box-and-whiskers plots. While the values of a CBOXES= variable are color names, values of the BOXES= variable are used to group box-and-whiskers plots for assigning outline colors from the ODS style. The outlines of box-and-whiskers plots of groups with the same BOXES= variable value are drawn using the same color.

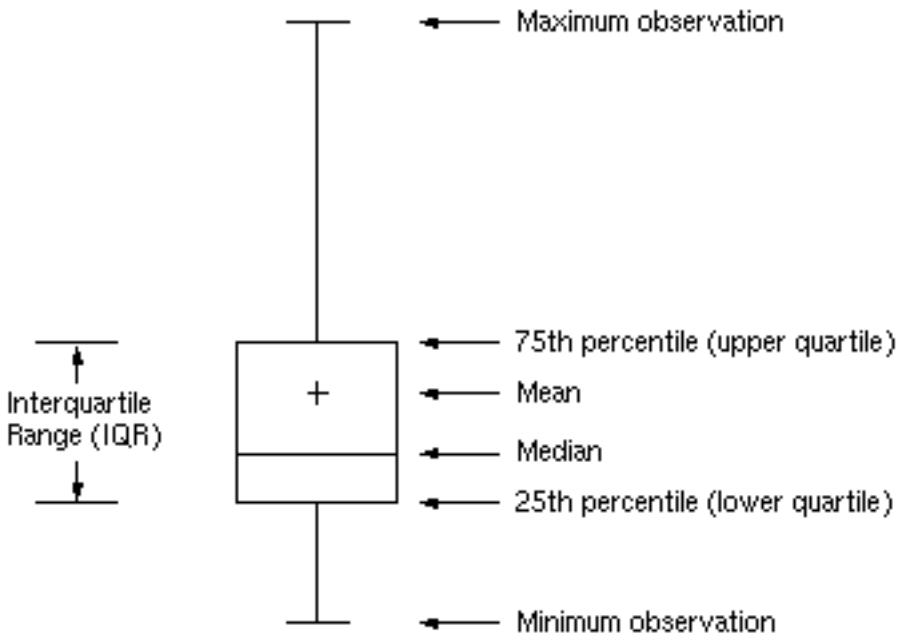
BOXFILL=(*variable*)

specifies a variable whose values are used to assign fill colors for box-and-whiskers plots. While the values of a CBOXFILL= variable are color names, values of the BOXFILL= variable are used to group box-and-whiskers plots for assigning fill colors from the ODS style. Box-and-whiskers plots of groups with the same BOXFILL= variable value are filled with the same color.

BOXSTYLE=*keyword*

specifies the style of the box-and-whiskers plots displayed. If you specify BOXSTYLE=SKELETAL, the whiskers are drawn from the edges of the box to the extreme values of the group. This plot is sometimes referred to as a skeletal box-and-whiskers plot. By default, the whiskers are drawn with serifs. You can specify the NOSERIFS option to draw the whiskers without serifs.

In the following descriptions, the terms *fence* and *far fence* refer to the distance from the first and third quartiles (25th and 75th percentiles, respectively), expressed in terms of the interquartile range (IQR). For example, the lower fence is located at $1.5 \times$ IQR below the 25th percentile; the upper fence is located at $1.5 \times$ IQR above the 75th percentile. Similarly, the lower far fence is located at $3 \times$ IQR below the 25th percentile; the upper far fence is located at $3 \times$ IQR above the 75th percentile.



If you specify BOXSTYLE=SCHEMATIC, a whisker is drawn from the upper edge of the box to the largest observed value within the upper fence, and another is drawn from the lower edge of the box to the smallest observed value within the lower fence. Serifs are added to the whiskers by default. Observations outside the fences are identified with a special symbol; you can specify the shape and color for this symbol with the IDSYMBOL= and IDCOLOR= options. The default symbol is a square. This type of plot corresponds to the schematic box-and-whiskers plot described in Chapter 2 of Tukey (1977). See Figure 24.8 and the discussion in the section "Styles of Box Plots" on page 796 for more information.

If you specify BOXSTYLE=SCHEMATICID, a schematic box-and-whiskers plot is displayed in which an ID variable value is used to label the symbol marking each observation outside the upper and lower fences. A BOX= data set can contain a variable named _ID_ that is used as the ID variable. Otherwise, the first variable listed in the ID statement provides the labels.

If you specify BOXSTYLE=SCHEMATICIDFAR, a schematic box-and-whiskers plot is displayed in which the value of the ID variable is used to label the symbol marking each observation outside the lower and upper far fences. Observations between the fences and the far fences are identified with a symbol but are not labeled with the ID variable.

Figure 24.6 illustrates the elements of a skeletal box-and-whiskers plot.

Figure 24.6 Skeletal Box-and-Whiskers Plot

The skeletal style of the box-and-whiskers plot shown in Figure 24.6 is the default.

BOXWIDTH=*value*

specifies the width (in horizontal percent screen units) of the box-and-whiskers plots.

BOXWIDTHSCALE=*value*

specifies that the box-and-whiskers plot width is to vary proportionately to a particular function of the group size n. The function is determined by the *value*.

If you specify a positive value, the widths are proportional to n^{value}. In particular, if you specify BOXWIDTHSCALE=1, the widths are proportional to the group size. If you specify BOXWIDTHSCALE=0.5, the widths are proportional to $\sqrt{n}$, as described by McGill, Tukey, and Larsen (1978). If you specify BOXWIDTHSCALE=0, the widths are proportional to $\log(n)$. See Example 24.4 for an illustration of the BOXWIDTHSCALE= option.

You can specify the BWSLEGEND option to display a legend identifying the function of n used to determine the box-and-whiskers plot widths.

By default, the box widths are constant.

BWSLEGEND

displays a legend identifying the function of group size n specified with the BOXWIDTHSCALE= option. No legend is displayed if all group sizes are equal. The BWSLEGEND option is not applicable unless you also specify the BOXWIDTHSCALE= option.

CAXIS=*color*

CAXES=*color*

CA=*color*

specifies the color for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement.

CBLOCKLAB=*color* | **(***color-list***)**

specifies fill colors for the frames that enclose the block variable labels in a block legend. By default, these areas are not filled. Colors in the CBLOCKLAB= list are matched with block variables in the order in which they appear in the PLOT statement.

CBLOCKVAR=*variable* | **(***variable-list***)**

specifies variables whose values are colors for filling the background of the legend associated with block variables. CBLOCKVAR= variables are matched with block variables by their order in the respective variable lists. Each CBLOCKVAR= variable must be a character variable of no more than eight characters in the input data set, and its values must be valid SAS/GRAPH color names (refer to *SAS/GRAPH: Reference* for complete details). A list of CBLOCKVAR= variables must be enclosed in parentheses.

The procedure matches the CBLOCKVAR= variables with block variables in the order specified. That is, each block legend is filled with the color value of the CBLOCKVAR= variable of the first observation in each block. In general, values of the *i*th CBLOCKVAR= variable are used to fill the block of the legend corresponding to the *i*th block variable.

By default, fill colors are not used for the block variable legend. The CBLOCKVAR= option is available only when block variables are used in the PLOT statement.

CBOXES=*color* | **(***variable***)**

specifies the colors for the outlines of the box-and-whiskers plots created with the PLOT statement. You can use one of the following approaches:

- You can specify CBOXES=*color* to provide a single outline color for all the box-and-whiskers plots.
- You can specify CBOXES=*(variable)* to provide a distinct outline color for each box-and-whiskers plot as the value of the variable. The variable must be a character variable of up to eight characters in the input data set, and its values must be valid SAS/GRAPH color names (refer to *SAS/GRAPH: Reference* for complete details). The outline color of the plot displayed for a particular group is the value of the variable in the observations corresponding to this group. Note that if there are multiple observations per group in the input data set, the values of the variable should be identical for all the observations in a given group.

CBOXFILL=*color* | **(***variable***)**

specifies the interior fill colors for the box-and-whiskers plots. You can use one of the following approaches:

- You can specify CBOXFILL=*color* to provide a single color for all of the box-and-whiskers plots.

- You can specify CBOXFILL=*(variable)* to provide a distinct color for each box-and-whiskers plot as the value of the variable. The variable must be a character variable of up to eight characters in the input data set, and its values must be valid SAS/GRAPH color names (or the value EMPTY, which you can use to suppress color filling). Refer to *SAS/GRAPH: Reference* for complete details. The interior color of the box displayed for a particular group is the value of the variable in the observations corresponding to this group. Note that if there are multiple observations per group in the input data set, the values of the variable should be identical for all the observations in a given group.

By default, the interiors are not filled.

CCLIP=*color*

specifies a color for the plotting symbol that is specified with the CLIPSYMBOL= option to mark clipped values. The default color is the color specified in the COLOR= option in the SYMBOL1 statement.

CCONNECT=*color*

specifies the color for line segments connecting points on the plot. The default color is the color specified in the COLOR= option in the SYMBOL1 statement. This option is not applicable unless you also specify the BOXCONNECT= option.

CCOVERLAY=(*color-list***)**

specifies the colors for line segments connecting points on overlay plots. Colors in the CCOVERLAY= list are matched with variables in the corresponding positions in the OVERLAY= list. By default, points are connected by line segments of the same color as the plotted points. You can specify the value NONE to suppress the line segments connecting points of an overlay plot.

CFRAME=*color*

specifies the color for filling the rectangle enclosed by the axes and the frame. By default, this area is not filled. The CFRAME= option cannot be used in conjunction with the NOFRAME option.

CGRID=*color*

specifies the color for the grid requested by the ENDGRID or GRID option. By default, the grid is the same color as the axes.

CHREF=*color*

specifies the color for the lines requested by the HREF= option.

CLABEL=*color*

specifies the color for labels produced by the ALLLABEL= option. The default color is the CTEXT= color.

CLIPFACTOR=*factor*

requests clipping of extreme values on the box plot. The *factor* that you specify determines the extent to which these values are clipped, and it must be greater than 1.

For examples of the CLIPFACTOR= option, see Figure 24.17 and Figure 24.18. Related clipping options are CCLIP=, CLIPLEGEND=, CLIPLEGPOS=, CLIPSUBCHAR=, and CLIPSYMBOL=.

CLIPLEGEND='*label***'**
specifies the *label* for the legend that indicates the number of clipped boxes when the CLIPFACTOR= option is used. The *label* must be no more than 16 characters and must be enclosed in quotes. For an example, see Figure 24.18.

CLIPLEGPOS= TOP | BOTTOM
specifies the position for the legend that indicates the number of clipped boxes when the CLIPFACTOR= option is used. The keyword TOP or BOTTOM positions the legend at the top or bottom of the chart, respectively. Do not specify CLIPLEGPOS=TOP together with the BLOCKPOS=1 or BLOCKPOS=2 option. By default, CLIPLEGPOS=BOTTOM.

CLIPSUBCHAR='*character***'**
specifies a substitution character (such as '#') for the label provided with the CLIPLEGEND= option. The substitution character is replaced with the number of boxes that are clipped. For example, suppose that the following statements produce a chart in which three boxes are clipped:

```
proc boxplot data=Pistons;
   plot Diameter*Hour /
      clipfactor  = 1.5
      cliplegend  = 'Boxes clipped=#'
      clipsubchar = '#' ;
run;
```

Then the clipping legend displayed on the chart will be "Boxes clipped=3".

CLIPSYMBOL=*symbol*
specifies a plot symbol used to identify clipped points on the chart and in the legend when the CLIPFACTOR= option is used. You should use this option in conjunction with the CLIPFACTOR= option. The default *symbol* is CLIPSYMBOL=SQUARE.

CLIPSYMBOLHT=*value*
specifies the height for the symbol marker used to identify clipped points on the chart when the CLIPFACTOR= option is used. The default is the height specified with the H= option in the SYMBOL statement.

For general information about clipping options, refer to the section "Clipping Extreme Values" on page 807.

CONTINUOUS
specifies that numeric group variable values be treated as continuous values. By default, the values of a numeric group variable are considered discrete values unless the HAXIS= option is specified. **NOTE:** The CONTINUOUS option is not supported for ODS Graphics output. For more information, see the discussion in the section "Continuous Group Variables" on page 798.

COVERLAY=(*color-list***)**
specifies the colors used to plot overlay variables. Colors in the COVERLAY= list are matched with variables in the corresponding positions in the OVERLAY= list.

COVERLAYCLIP=*color*
specifies the color used to plot clipped values on overlay plots when the CLIPFACTOR= option is used.

CTEXT=*color*
specifies the color for tick mark values and axis labels. The default color is the color specified in the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color*
specifies the color for the lines requested by the VREF= option.

DESCRIPTION='*string*'
DES='*string*'
specifies a description of a box plot produced with high-resolution graphics. The description appears in the PROC GREPLAY master menu and can be no longer than 256 characters. The default description is the analysis variable name.

ENDGRID
adds a grid to the rightmost portion of the plot, beginning with the first labeled major tick mark position that follows the last box-and-whiskers plot. You can use the HAXIS= option to force space to be added to the horizontal axis.

FONT=*font*
specifies a font for labels and legends. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the GOPTIONS statement. Refer to *SAS/GRAPH: Reference* for more information about the GOPTIONS statement.

FRONTREF
draws reference lines specified with the HREF= and VREF= options in front of box-and-whiskers plots. By default, reference lines are drawn behind the box-and-whiskers plots and can be obscured by filled boxes.

GRID
adds a grid to the box plot. Grid lines are horizontal lines positioned at labeled major tick marks, and they cover the length and height of the plotting area.

HAXIS=*value-list*
HAXIS=AXIS*n*
specifies tick mark values for the horizontal (group) axis. If the group variable is numeric, the values must be numeric and equally spaced. If the group variable is character, values must be quoted strings of up to 16 characters. Optionally, you can specify an axis name defined in a previous AXIS statement. Refer to *SAS/GRAPH: Reference* for more information about the AXIS statement.

If you are producing traditional graphics, specifying the HAXIS= option with a numeric group variable causes the group variable values to be treated as continuous values. For more information, see the description of the CONTINUOUS option and the discussion in the section "Continuous Group Variables" on page 798. Numeric values can be given in an explicit

or implicit list. If a date, time, or datetime format is associated with a numeric group variable, SAS datetime literals can be used. Examples of HAXIS= lists follow:

- haxis=0 2 4 6 8 10
- haxis=0 to 10 by 2
- haxis='LT12A' 'LT12B' 'LT12C' 'LT15A' 'LT15B' 'LT15C'
- haxis='20MAY88'D to '20AUG88'D by 7
- haxis='01JAN88'D to '31DEC88'D by 30

If the group variable is numeric, the HAXIS= list must span the group variable values. If the group variable is character, the HAXIS= list must include all of the group variable values. You can add group positions to the box plot by specifying HAXIS= values that are not group variable values.

If you specify a large number of HAXIS= values, some of these can be thinned to avoid collisions between tick mark labels. To avoid thinning, use one of the following methods.

- Shorten values of the group variable by eliminating redundant characters. For example, if your group variable has values LOT1, LOT2, LOT3, and so on, you can use the SUBSTR function in a DATA step to eliminate LOT from each value, and you can modify the horizontal axis label to indicate that the values refer to lots.
- Use the TURNHLABELS option to turn the labels vertically.
- Use the NPANELPOS= option to force fewer group positions per panel.

HEIGHT=*value*

specifies the height (in vertical screen percent units) of the text for axis labels and legends. This value takes precedence over the HTEXT= value specified in the GOPTIONS statement. This option is recommended for use with fonts specified with the FONT= option or with the FTEXT= option in the GOPTIONS statement. Refer to *SAS/GRAPH: Reference* for complete information about the GOPTIONS statement.

HMINOR=*n*

HM=*n*

specifies the number of minor tick marks between major tick marks on the horizontal axis. Minor tick marks are not labeled. The default is HMINOR=0.

HOFFSET=*value*

specifies the length (in percent screen units) of the offset at both ends of the horizontal axis. You can eliminate the offset by specifying HOFFSET=0.

HORIZONTAL

Experimental

produces a horizontal box plot, with group variable values on the vertical axis and analysis variable values on the horizontal axis. The HORIZONTAL option is supported only with ODS Graphics.

HREF=*value-list*

HREF=*SAS-data-set*

draws reference lines perpendicular to the horizontal (group) axis on the box plot. You can use this option in the following ways:

- You can specify the values for the lines with an HREF= list. If the group variable is numeric, the values must be numeric. If the group variable is character, the values must be quoted strings of up to 16 characters. If the group variable is formatted, the values must be given as internal values. Examples of HREF= values follow:

```
href=5
href=5 10 15 20 25 30
href='Shift 1' 'Shift 2' 'Shift 3'
```

- You can specify reference line values as the values of a variable named _REF_ in an HREF= data set. The type and length of _REF_ must match those of the group variable specified in the PLOT statement. Optionally, you can provide labels for the lines as values of a variable named _REFLAB_, which must be a character variable of up to 16 characters. If you want distinct reference lines to be displayed in plots for different analysis variables specified in the PLOT statement, you must include a character variable named _VAR_, whose values are the analysis variable names. If you do not include the variable _VAR_, all of the lines are displayed in all of the plots. Each observation in an HREF= data set corresponds to a reference line. If BY variables are used in the input data set, the same BY variable structure must be used in the reference line data set unless you specify the NOBYREF option.

Unless the CONTINUOUS or HAXIS= option is specified, numeric group variable values are treated as discrete values, and only HREF= values matching these discrete values are valid. Other values are ignored.

HREFLABELS='*label1*' **...**'*labeln*'

HREFLABEL='*label1*' **...**'*labeln*'

HREFLAB='*label1*' **...**'*labeln*'

specifies labels for the reference lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of the HREFLABEL= label, as described in the following table. By default, n=2.

HREFLABPOS=	Label Position
1	along top of plot area
2	staggered from top to bottom of plot area
3	along bottom of plot area
4	staggered from bottom to top of plot area

HTML=*variable*

specifies uniform resource locators (URLs) as values of the specified character variable (or formatted values of a numeric variable). These URLs are associated with box-and-whiskers plots when graphics output is directed into HTML. The value of the HTML= variable should be the same for each observation with a given value of the group variable.

IDCOLOR=*color*

specifies the color of the symbol marker used to identify outliers in schematic box-and-whiskers plots (that is, when you specify the keyword SCHEMATIC, SCHEMATICID, or SCHEMATICIDFAR with the BOXSTYLE= option). The default color is the color specified with the CBOXES= option.

IDCTEXT=*color*

specifies the color for the text used to label outliers when you specify the keyword SCHEMATICID or SCHEMATICIDFAR with the BOXSTYLE= option. The default value is the color specified with the CTEXT= option.

IDFONT=*font*

specifies the font for the text used to label outliers when you specify the keyword SCHEMATICID or SCHEMATICIDFAR with the BOXSTYLE= option. The default font is SIMPLEX.

IDHEIGHT=*value*

specifies the height for the text used to label outliers when you specify the keyword SCHEMATICID or SCHEMATICIDFAR with the BOXSTYLE= option. The default value is the height specified with the HTEXT= option in the GOPTIONS statement. Refer to *SAS/GRAPH: Reference* for complete information about the GOPTIONS statement.

IDSYMBOL=*symbol*

specifies the symbol marker used to identify outliers in schematic box plots. The default symbol is SQUARE.

INTERVAL=DAY | DTDAY | HOUR | MINUTE | MONTH | QTR | SECOND

specifies the natural time interval between consecutive group positions when a time, date, or datetime format is associated with a numeric group variable. By default, the INTERVAL= option uses the number of group positions per panel (screen or page) that you specify with the NPANELPOS= option. The default time interval keywords for various time formats are shown in the following table.

Format	Default Keyword	Format	Default Keyword
DATE	DAY	MONYY	MONTH
DATETIME	DTDAY	TIME	SECOND
DDMMYY	DAY	TOD	SECOND
HHMM	HOUR	WEEKDATE	DAY
HOUR	HOUR	WORDDATE	DAY
MMDDYY	DAY	YYMMDD	DAY
MMSS	MINUTE	YYQ	QTR

You can use the INTERVAL= option to modify the effect of the NPANELPOS= option, which specifies the number of group positions per panel. The INTERVAL= option enables you to match the scale of the horizontal axis to the scale of the group variable without having to associate a different format with the group variable.

For example, suppose that your formatted group values span an overall time interval of 100 days and a DATETIME format is associated with the group variable. Since the default interval for the DATETIME format is DTDAY and since NPANELPOS=25 by default, the plot is displayed with four panels.

Now, suppose that your data span an overall time interval of 100 hours and a DATETIME format is associated with the group variable. The plot for these data is created in a single panel, but the data occupy only a small fraction of the plot since the scale of the data (hours) does not match that of the horizontal axis (days). If you specify INTERVAL=HOUR, the horizontal axis is scaled for 25 hours, matching the scale of the data, and the plot is displayed with four panels.

You should use the INTERVAL= option only in conjunction with the CONTINUOUS or HAXIS= option, which produces a horizontal axis of continuous group variable values. For more information, see the descriptions of the CONTINUOUS and HAXIS= options, and the discussion in the section "Continuous Group Variables" on page 798.

INTSTART=*value*

specifies the starting value for a numeric horizontal axis when a date, time, or datetime format is associated with the group variable. If the value specified is greater than the first group variable value, this option has no effect.

LABELANGLE=*angle*

specifies the angle at which labels requested with the ALLLABEL= option are drawn. A positive angle rotates the labels counterclockwise; a negative angle rotates them clockwise. By default, labels are oriented horizontally.

LBOXES=*linetype*

LBOXES=(*variable***)**

specifies the line types for the outlines of the box-and-whiskers plots. You can use one of the following approaches:

- You can specify LBOXES=*linetype* to provide a single linetype for all of the box-and-whiskers plots.
- You can specify LBOXES=*(variable)* to provide a distinct line type for each box-and-whiskers plot. The variable must be a numeric variable in the input data set, and its values must be valid SAS/GRAPH linetype values (numbers ranging from 1 to 46). The line type for the plot displayed for a particular group is the value of the variable in the observations corresponding to this group. Note that if there are multiple observations per group in the input data set, the values of the variable should be identical for all of the observations in a given group.

The default value is 1, which produces solid lines. Refer to the description of the SYMBOL statement in *SAS/GRAPH: Reference* for more information about valid linetypes.

LENDGRID=*linetype*

specifies the line type for the grid requested with the ENDGRID option. The default value is 1, which produces a solid line. If you use the LENDGRID= option, you do not need to specify the ENDGRID option. Refer to the description of the SYMBOL statement in *SAS/GRAPH: Reference* for more information about valid linetypes.

LGRID=*linetype*

specifies the line type for the grid requested with the GRID option. The default value is 1, which produces a solid line. If you use the LGRID= option, you do not need to specify the GRID option. Refer to the description of the SYMBOL statement in *SAS/GRAPH: Reference* for more information about valid linetypes.

LHREF=*linetype*

LH=*linetype*

specifies the line type for reference lines requested with the HREF= option. The default value is 2, which produces a dashed line. Refer to the description of the SYMBOL statement in *SAS/GRAPH: Reference* for more information about valid linetypes.

LOVERLAY=(*linetypes***)**

specifies line types for the line segments connecting points on overlay plots. Line types in the LOVERLAY= list are matched with variables in the corresponding positions in the OVERLAY= list.

LVREF=*linetype*

LV=*linetype*

specifies the line type for reference lines requested by the VREF= option. The default value is 2, which produces a dashed line. Refer to the description of the SYMBOL statement in *SAS/GRAPH: Reference* for more information about valid linetypes.

MAXPANELS=*n*

specifies the maximum number of panels used to display a box plot. By default, $n = 20$.

MISSBREAK

determines how groups are formed when observations are read from a DATA= data set and a character group variable is provided. When you specify the MISSBREAK option, observations with missing values of the group variable are not processed. Furthermore, the next observation with a nonmissing value of the group variable is treated as the beginning observation of a new group even if this value is identical to the most recent nonmissing group value. In other words, by specifying the option MISSBREAK and by inserting an observation with a missing group variable value into a group of consecutive observations with the same group variable value, you can split the group into two distinct groups of observations.

By default (that is, when you omit the MISSBREAK option), observations with missing values of the group variable are not processed, and all remaining observations with the same consecutive value of the group variable are treated as a single group.

NAME='*string*'

specifies a name for the box plot, not more than eight characters, that appears in the PROC GREPLAY master menu.

NLEGEND

requests a legend displaying group sizes. If the size is the same for each group, that number is displayed. Otherwise, the minimum and maximum group sizes are displayed.

NOBYREF

specifies that the reference line information in an HREF= or VREF= data set be applied uniformly to box plots created for all the BY groups in the input data set. If you specify the NOBYREF option, you do not need to provide BY variables in the reference line data set. By default, you must provide BY variables.

NOCHART

suppresses the creation of the box plot. You typically specify the NOCHART option when you are using the procedure to compute group summary statistics and save them in an output data set.

NOFRAME

suppresses the default frame drawn around the plot.

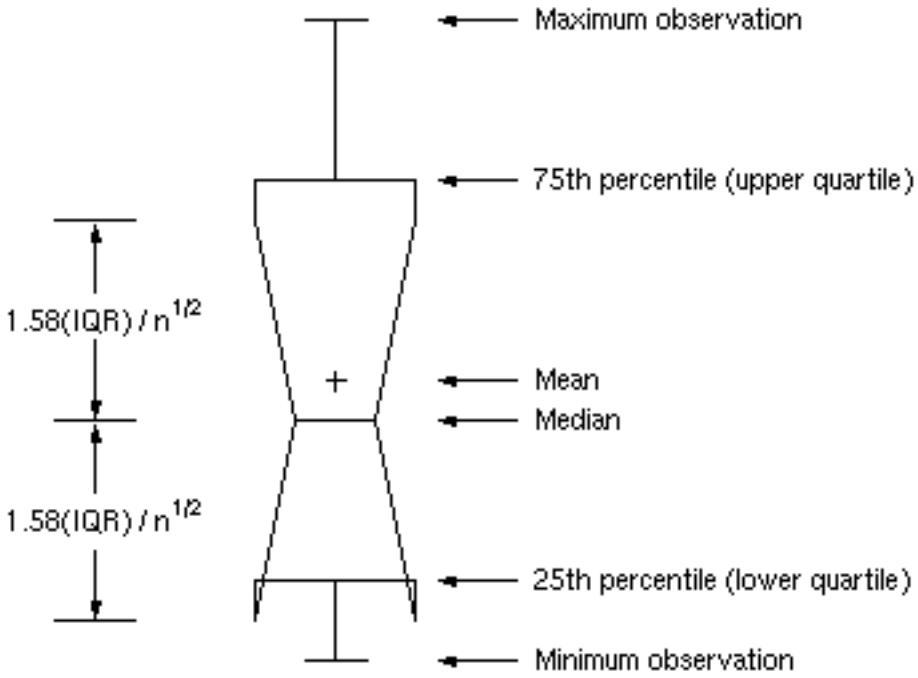
NOHLABEL

suppresses the label for the horizontal (group) axis. Use the NOHLABEL option when the meaning of the axis is evident from the tick mark labels, such as when a date format is associated with the group variable.

NOOVERLAYLEGEND

suppresses the legend for overlay plots that is displayed by default when the OVERLAY= option is specified.

NOSERIFS



eliminates serifs from the whiskers of box-and-whiskers plots.

NOTCHES

specifies that box-and-whiskers plots be notched. The endpoints of the notches are located at the median plus and minus $1.58(\mathrm{IQR}/\sqrt{n})$, where IQR is the interquartile range and n is the group size. The medians (central lines) of two box-and-whiskers plots are significantly different at approximately the 0.95 confidence level if the corresponding notches do not overlap.

Refer to McGill, Tukey, and Larsen (1978) for more information. Figure 24.7 illustrates the NOTCHES option. Notice the folding effect at the bottom, which happens when the endpoint of a notch is beyond its corresponding quartile. This situation typically occurs when the group size is small.

Figure 24.7 Box Plot: The NOTCHES Option

NOTICKREP

applies to character-valued group variables and specifies that only the first occurrence of repeated, adjacent group values be labeled on the horizontal axis.

NOVANGLE

requests that the vertical axis label be strung out vertically.

NPANELPOS=*n*

NPANEL=*n*

specifies the number of group positions per panel. You typically specify the NPANELPOS= option to display more box-and-whiskers plots on a panel than the default number, which is $n = 25$.

You can specify a positive or negative number for n. The absolute value of n must be at least 5. If n is positive, the number of positions is adjusted so that it is approximately equal to n and so that all panels display approximately the same number of group positions. If n is negative, no balancing is done, and each panel (except possibly the last) displays approximately $|n|$ positions. In this case, the approximation is due only to axis scaling.

You can use the INTERVAL= option to change the effect of the NPANELPOS= option when a date or time format is associated with the group variable. The INTERVAL= option enables you to match the scale of the horizontal axis to the scale of the group variable without having to associate a different format with the group variable.

OUTBOX=*SAS-data-set*

creates an output data set that contains group summary statistics and outlier values for a box

plot. You can use an OUTBOX= data set as a BOX= input data set in a subsequent run of the procedure. See the section "OUTBOX= Data Set" on page 791 for details.

OUTHIGHHTML=*variable*
specifies a variable whose values are URLs to be associated with outlier points above the upper fence on a schematic box plot when graphics output is directed into HTML.

OUTHISTORY=*SAS-data-set*
creates an output data set that contains the group summary statistics. You can use an OUTHISTORY= data set as a HISTORY= input data set in a subsequent run of the procedure. See the section "OUTHISTORY= Data Set" on page 792 for details.

OUTLOWHTML=*variable*
specifies a variable whose values are URLs to be associated with outlier points below the lower fence on a schematic box plot when graphics output is directed into HTML.

OVERLAY=(*variable-list***)**
specifies variables to be plotted as overlays on the box plot. One value for each overlay variable is plotted at each group position. If there are multiple observations with the same group variable value in the input data set, the overlay variable values from the first observation in each group are plotted. By default, the points in an overlay plot are connected with line segments.

OVERLAYCLIPSYM=*symbol*
specifies the symbol used to plot clipped values on overlay plots when the CLIPFACTOR= option is used.

OVERLAYCLIPSYMHT=*value*
specifies the height for the symbol used to plot clipped values on overlay plots when the CLIPFACTOR= option is used.

OVERLAYHTML=(*variable-list***)**
specifies variables whose values are URLs to be associated with points on overlay plots when graphics output is directed into HTML. Variables in the OVERLAYHTML= list are matched with variables in the corresponding positions in the OVERLAY= list.

OVERLAYID=(*variable-list***)**
specifies variables whose formatted values are used to label points on overlays. Variables in the OVERLAYID= list are matched with variables in the corresponding positions in the OVERLAY= list. The value of the OVERLAYID= variable should be the same for each observation with a given value of the group variable.

OVERLAYLEGLAB='*label***'**
specifies the label displayed to the left of the overlay legend produced by the OVERLAY= option. The label can be up to 16 characters and must be enclosed in quotes. The default label is "Overlays:".

OVERLAYSYM=(*symbol-list***)**
specifies symbols used to plot overlay variables. Symbols in the OVERLAYSYM= list are matched with variables in the corresponding positions in the OVERLAY= list.

OVERLAYSYMHT=(*value-list*)

specifies the heights of symbols used to plot overlay variables. Symbol heights in the OVERLAYSYMHT= list are matched with variables in the corresponding positions in the OVERLAY= list.

PAGENUM=‘*string*’

specifies the form of the label used for pagination. The string can be up to 16 characters, and it must include one or two occurrences of the substitution character ‘#’. The first ‘#’ is replaced with the page number, and the optional second ‘#’ is replaced with the total number of pages.

The PAGENUM= option is useful when you are working with a large number of groups, resulting in multiple pages of output. For example, suppose that each of the following PLOT statements produces multiple pages:

```
proc boxplot data=Pistons;
   plot Diameter*Hour / pagenum='Page #';
   plot Diameter*Hour / pagenum='Page # of #';
   plot Diameter*Hour / pagenum='#/#';
run;
```

The third page produced by the first statement would be labeled “Page 3”. The third page produced by the second statement would be labeled “Page 3 of 5”. The third page produced by the third statement would be labeled “3/5”.

By default, no page number is displayed.

PAGENUMPOS=TL | TR | BL | BR | TL100 | TR100 | BL0 | BR0

specifies where to position the page number requested with the PAGENUM= option. The keywords TL, TR, BL, and BR correspond to the positions top left, top right, bottom left, and bottom right, respectively. You can use the TL100 and TR100 keywords to ensure that the page number appears at the very top of a page when a title is displayed. The BL0 and BR0 keywords ensure that the page number appears at the very bottom of a page when footnotes are displayed.

The default value is BR.

PCTLDEF=*index*

specifies one of five definitions used to calculate percentiles in the construction of box-and-whiskers plots. The index can be 1, 2, 3, 4, or 5. The five corresponding percentile definitions are discussed in the section “Percentile Definitions” on page 797. The default index is 5.

REPEAT

REP

specifies that the horizontal axis of a plot that spans multiple panels be arranged so that the last group position on a panel is repeated as the first group position on the next panel. The REPEAT option facilitates cutting and pasting panels together. When a SAS DATETIME format is associated with the group variable, the REPEAT option is the default.

SKIPHLABELS=*n*

SKIPHLABEL=*n*

specifies the number *n* of consecutive tick mark labels, beginning with the second tick mark label, that are thinned (not displayed) on the horizontal (group) axis. For example, specifying SKIPHLABEL=1 causes every other label to be skipped. Specifying SKIPHLABEL=2 causes the second and third labels to be skipped, the fifth and sixth labels to be skipped, and so forth.

The default value of the SKIPHLABELS= option is the smallest value *n* for which tick mark labels do not collide. A specified *n* will be overridden to avoid collision. To reduce thinning, you can use the TURNHLABELS option.

SYMBOLLEGEND=LEGEND*n*

SYMBOLLEGEND=NONE

controls the legend for the levels of a symbol variable (see Example 24.1). You can specify SYMBOLLEGEND=LEGEND*n*, where *n* is the number of a LEGEND statement defined previously. You can specify SYMBOLLEGEND=NONE to suppress the default legend. Refer to *SAS/GRAPH: Reference* for more information about the LEGEND statement.

SYMBOLORDER=DATA | INTERNAL | FORMATTED

SYMORD=DATA | INTERNAL | FORMATTED

specifies the order in which symbols are assigned for levels of the symbol variable. The DATA keyword assigns symbols to values in the order in which values appear in the input data set. The INTERNAL keyword assigns symbols based on sorted order of internal values of the symbol variable, and the FORMATTED keyword assigns them based on sorted formatted values. The default value is FORMATTED.

TOTPANELS=*n*

specifies the total number of panels to be used to display the plot. This option overrides the NPANEL= option.

TURNHLABELS

TURNHLABEL

turns the major tick mark labels for the horizontal (group) axis so that they are arranged vertically. By default, labels are arranged horizontally.

Note that arranging the labels vertically might leave insufficient vertical space on the panel for a plot.

VAXIS=*value-list*

VAXIS=AXIS*n*

specifies major tick mark values for the vertical axis of a box plot. The values must be listed in increasing order, must be evenly spaced, and must span the range of values displayed in the plot. You can specify the values with an explicit list or with an implicit list, as shown in the following example:

```
proc boxplot;
   plot Width*Hour / vaxis=0 2 4 6 8;
   plot Width*Hour / vaxis=0 to 8 by 2;
run;
```

You can also specify a previously defined AXIS statement with the VAXIS= option.

VFORMAT=*format*

specifies a format to be used for displaying tick mark labels on the vertical axis of the box plot.

VMINOR=*n*

VM=*n*

specifies the number of minor tick marks between major tick marks on the vertical axis. Minor tick marks are not labeled. By default, VMINOR=0.

VOFFSET=*value*

specifies the length in percent screen units of the offset at the ends of the vertical axis.

VREF=*value-list*

VREF=*SAS-data-set*

draws reference lines perpendicular to the vertical axis. You can use this option in the following ways:

- Specify the values for the lines with a VREF= list:

  ```
  vref=20
  vref=20 40 80
  ```

- Specify the values for the lines as the values of a numeric variable named _REF_ in a VREF= data set. Optionally, you can provide labels for the lines as values of a variable named _REFLAB_, which must be a character variable of up to 16 characters. If you want distinct reference lines to be displayed in plots for different analysis variables specified in the PLOT statement, you must include a character variable named _VAR_, whose values are the names of the analysis variables. If you do not include the variable _VAR_, all of the lines are displayed in all of the plots. Each observation in the VREF= data set corresponds to a reference line. If BY variables are used in the input data set, the same BY-variable structure must be used in the VREF= data set unless you specify the NOBYREF option.

VREFLABELS='*label1*' **...** '*labeln*'

VREFLABEL='*label1*' **...** '*labeln*'

VREFLAB='*label1*' **...** '*labeln*'

specifies labels for the reference lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of the VREFLABEL= label, as described in the following table. By default, *n=1*.

n	Label Position
1	left-justified in plot area
2	right-justified in plot area
3	left-justified in right margin

VZERO
forces the origin to be included in the vertical axis for a box plot.

WAXIS=*n*
specifies the width in pixels for the axis and frame lines. By default, *n=1*.

WGRID=*n*
specifies the width in pixels for grid lines requested with the ENDGRID and GRID options. By default, *n=1*.

WOVERLAY=(*value-list***)**
specifies the widths in pixels for the line segments connecting points on overlay plots. Widths in the WOVERLAY= list are matched with variables in the corresponding positions in the OVERLAY= list. By default, all overlay widths are 1.

Details: BOXPLOT Procedure

Summary Statistics Represented by Box Plots

Table 24.6 lists the summary statistics represented in each box-and-whiskers plot.

Table 24.6 Summary Statistics Represented by Box Plots

Group Summary Statistic	Feature of Box-and-Whiskers Plot
maximum	endpoint of upper whisker
third quartile (75th percentile)	upper edge of box
median (50th percentile)	line inside box
mean	symbol marker
first quartile (25th percentile)	lower edge of box
minimum	endpoint of lower whisker

Note that you can request different box plot styles, as discussed in the section "Styles of Box Plots" on page 796, and as illustrated in Example 24.2.

Output Data Sets

OUTBOX= Data Set

The OUTBOX= data set saves group summary statistics and outlier values. The following variables can be saved:

- the group variable
- the variable _VAR_, containing the analysis variable name
- the variable _TYPE_, identifying features of box-and-whiskers plots
- the variable _VALUE_, containing values of box-and-whiskers plot features
- the variable _ID_, containing labels for outliers
- the variable _HTML_, containing URLs associated with plot features

_ID_ is included in the OUTBOX= data set only if the keyword SCHEMATICID or SCHEMATICIDFAR is specified with the BOXSTYLE= option. _HTML_ is present only if one or more of the HTML=, OUTHIGHHTML=, and OUTLOWHTML= options are specified.

Each observation in an OUTBOX= data set records the value of a single feature of one group's box-and-whiskers plot, such as its mean. The _TYPE_ variable identifies the feature whose value is recorded in _VALUE_. Table 24.7 lists valid _TYPE_ variable values.

Table 24.7 Valid _TYPE_ Values in an OUTBOX= Data Set

TYPE	Description
N	group size
MIN	minimum group value
Q1	group first quartile
MEDIAN	group median
MEAN	group mean
Q3	group third quartile
MAX	group maximum value
STDDEV	group standard deviation
LOW	low outlier value
HIGH	high outlier value
LOWHISKR	low whisker value, if different from MIN
HIWHISKR	high whisker value, if different from MAX
FARLOW	low far outlier value
FARHIGH	high far outlier value

Additionally, the following variables, if specified, are included:

- block variables
- symbol variable
- BY variables
- ID variables

OUTHISTORY= Data Set

The OUTHISTORY= data set saves group summary statistics. The following variables are saved:

- the group variable
- group minimum variables named by *analysis-variable* suffixed with *L*
- group first-quartile variables named by *analysis-variable* suffixed with *1*
- group mean variables named by *analysis-variable* suffixed with *X*
- group median variables named by *analysis-variable* suffixed with *M*
- group third-quartile variables named by *analysis-variable* suffixed with *3*
- group maximum variables named by *analysis-variable* suffixed with *H*
- group standard deviation variables named by *analysis-variable* suffixed with *S*
- group size variables named by *analysis-variable* suffixed with *N*

If an analysis variable name has the maximum length of 32 characters, PROC BOXPLOT forms summary statistic names from its first 16 characters, its last 15 characters, and the appropriate suffix.

Subgroup summary variables are created for each analysis variable specified in the PLOT statement. For example, consider the following statements:

```
proc boxplot data=Steel;
   plot (Width Diameter)*Lot / outhistory=Summary;
run;
```

The data set Summary contains variables named Lot, WidthL, Width1, WidthM, WidthX, Width3, WidthH, WidthS, WidthN, DiameterL, Diameter1, DiameterM, DiameterX, Diameter3, DiameterH, DiameterS, and DiameterN.

Additionally, the following variables, if specified, are included:

- BY variables
- block variables
- symbol variable
- ID variables

Note that an OUTHISTORY= data set does not contain outlier values, and therefore cannot be used, in general, to save a schematic box plot. You can use an OUTBOX= data set to save a schematic box plot summary.

Input Data Sets

DATA= Data Set

You can read analysis variable measurements from a data set specified with the DATA= option in the PROC BOXPLOT statement. Each analysis variable specified in the PLOT statement must be a SAS variable in the data set. This variable provides measurements that are organized into groups indexed by the group variable. The group variable, specified in the PLOT statement, must also be a SAS variable in the DATA= data set. Each observation in a DATA= data set must contain a value for each analysis variable and a value for the group variable. If the ith group contains n_i measurements, there should be n_i consecutive observations for which the value of the group variable is the index of the ith group. For example, if each group contains 20 items and there are 30 groups, the DATA= data set should contain 600 observations. Other variables that can be read from a DATA= data set include the following:

- block variables
- symbol variable
- BY variables
- ID variables

BOX= Data Set

You can read group summary statistics and outlier information from a BOX= data set specified in the PROC BOXPLOT statement. This enables you to reuse OUTBOX= data sets that have been created in previous runs of the BOXPLOT procedure to reproduce schematic box plots.

A BOX= data set must contain the following variables:

- the group variable
- _VAR_, containing the analysis variable name
- _TYPE_, identifying features of box-and-whiskers plots
- _VALUE_, containing values of those features

Each observation in a BOX= data set records the value of a single feature of one group's box-and-whiskers plot, such as its mean. Consequently, a BOX= data set contains multiple observations per group. These must appear consecutively in the BOX= data set.

The _TYPE_ variable identifies the feature whose value is recorded in a given observation. The following table lists valid _TYPE_ variable values.

Table 24.8 Valid _TYPE_ Values in a BOX= Data Set

TYPE	Description
N	group size
MIN	group minimum value
Q1	group first quartile
MEDIAN	group median
MEAN	group mean
Q3	group third quartile
MAX	group maximum value
STDDEV	group standard deviation
LOW	low outlier value
HIGH	high outlier value
LOWHISKR	low whisker value, if different from MIN
HIWHISKR	high whisker value, if different from MAX
FARLOW	low far outlier value
FARHIGH	high far outlier value

The features identified by _TYPE_ values N, MIN, Q1, MEDIAN, MEAN, Q3, and MAX are required for each group.

Other variables that can be read from a BOX= data set include the following:

- the variable _ID_, containing labels for outliers
- the variable _HTML_, containing URLs to be associated with features on box plots
- block variables
- symbol variable
- BY variables
- ID variables

When you specify the keyword SCHEMATICID or SCHEMATICIDFAR with the BOXSTYLE= option, values of _ID_ are used as outlier labels. If _ID_ does not exist in the BOX= data set, the values of the first variable listed in the ID statement are used.

HISTORY= Data Set

You can read group summary statistics from a HISTORY= data set specified in the PROC BOXPLOT statement. This enables you to reuse OUTHISTORY= data sets that have been created in previous runs of the BOXPLOT procedure or to read output data sets created with SAS summarization procedures, such as PROC UNIVARIATE.

Note that a HISTORY= data set does *not* contain outlier information. Therefore, in general you cannot reproduce a schematic box plot from summary statistics saved in an OUTHISTORY= data set. To save and reproduce schematic box plots, use OUTBOX= and BOX= data sets.

A HISTORY= data set must contain the following:

- the group variable
- a group minimum variable for each analysis variable
- a group first-quartile variable for each analysis variable
- a group median variable for each analysis variable
- a group mean variable for each analysis variable
- a group third-quartile variable for each analysis variable
- a group maximum variable for each analysis variable
- a group standard deviation variable for each analysis variable
- a group size variable for each analysis variable

The names of the group summary statistics variables must be the analysis variable name concatenated with the following special suffix characters.

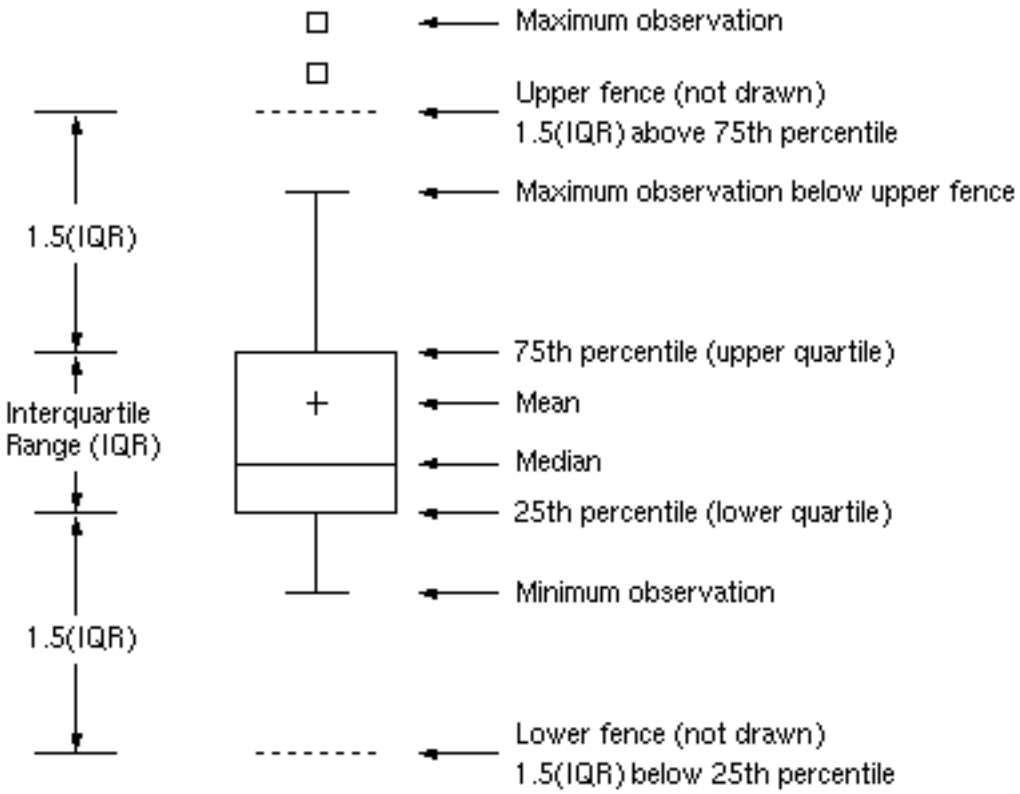
Group Summary Statistic	Suffix Character
group minimum	L
group first quartile	1
group median	M
group mean	X
group third quartile	3
group maximum	H
group standard deviation	S
group size	N

For example, consider the following statements:

```
proc boxplot history=Summary;
   plot (Weight Yieldstrength) * Batch;
run;
```

The data set Summary must include the variables Batch, WeightL, Weight1, WeightM, WeightX, Weight3, WeightH, WeightS, WeightN, YieldstrengthL, Yieldstrength1, YieldstrengthM, YieldstrengthX, Yieldstrength3, YieldstrengthH, YieldstrengthS, and YieldstrengthN.

Note that if you specify an analysis variable whose name contains the maximum of 32 characters, the summary variable names must be formed from the first 16 characters and the last 15 characters of the analysis variable name, suffixed with the appropriate character.



These other variables can be read from a HISTORY= data set:

- block variables
- symbol variable
- BY variables
- ID variables

Styles of Box Plots

A box-and-whiskers plot is displayed for the measurements in each group on the box plot. The *skeletal* style of the box-and-whiskers plot shown in Figure 24.6 is the default. You can produce a *schematic* box plot by specifying the BOXSTYLE=SCHEMATIC option in the PLOT statement. Figure 24.8 illustrates a typical schematic box plot and the locations of the fences (which are not displayed in actual output). See the description of the BOXSTYLE= option on page 773 for complete details.

Figure 24.8 Schematic Box-and-Whiskers Plot

You can draw connecting lines between adjacent box-and-whiskers plots by using the BOXCONNECT=*keyword* option. For example, BOXCONNECT=MEAN connects the points representing the means of adjacent groups. Other available keywords are MIN, Q1, MEDIAN, Q3, and

MAX. Specifying BOXCONNECT without a keyword is equivalent to specifying BOXCONNECT=MEAN. You can specify the color for the connecting lines with the CCONNECT= option.

Percentile Definitions

You can use the PCTLDEF= option to specify one of five definitions for computing quantile statistics (percentiles). Suppose that n is the number of nonmissing values for a variable and that $x_1, x_2, \ldots, x_n$ represent the ordered values of the analysis variable. For the tth percentile, set $p = t/100$.

For the following definitions numbered 1, 2, 3, and 5, express np as

$$np = j + g$$

where j is the integer part of np, and g is the fractional part of np. For definition 4, let

$$(n+1)p = j + g$$

The tth percentile (call it y) can be defined as follows:

PCTLDEF=1 weighted average at x_{np}

$$y = (1-g)x_j + gx_{j+1}$$

where x_0 is taken to be x_1.

PCTLDEF=2 observation numbered closest to np

$$y = x_i$$

where i is the integer part of $np + 1/2$ if $g \neq 1/2$. If $g = 1/2$, then $y = x_j$ if j is even, or $y = x_{j+1}$ if j is odd.

PCTLDEF=3 empirical distribution function

$$y = x_j \text{ if } g = 0$$

$$y = x_{j+1} \text{ if } g > 0$$

PCTLDEF=4 weighted average aimed at $x_{p(n+1)}$

$$y = (1-g)x_j + gx_{j+1}$$

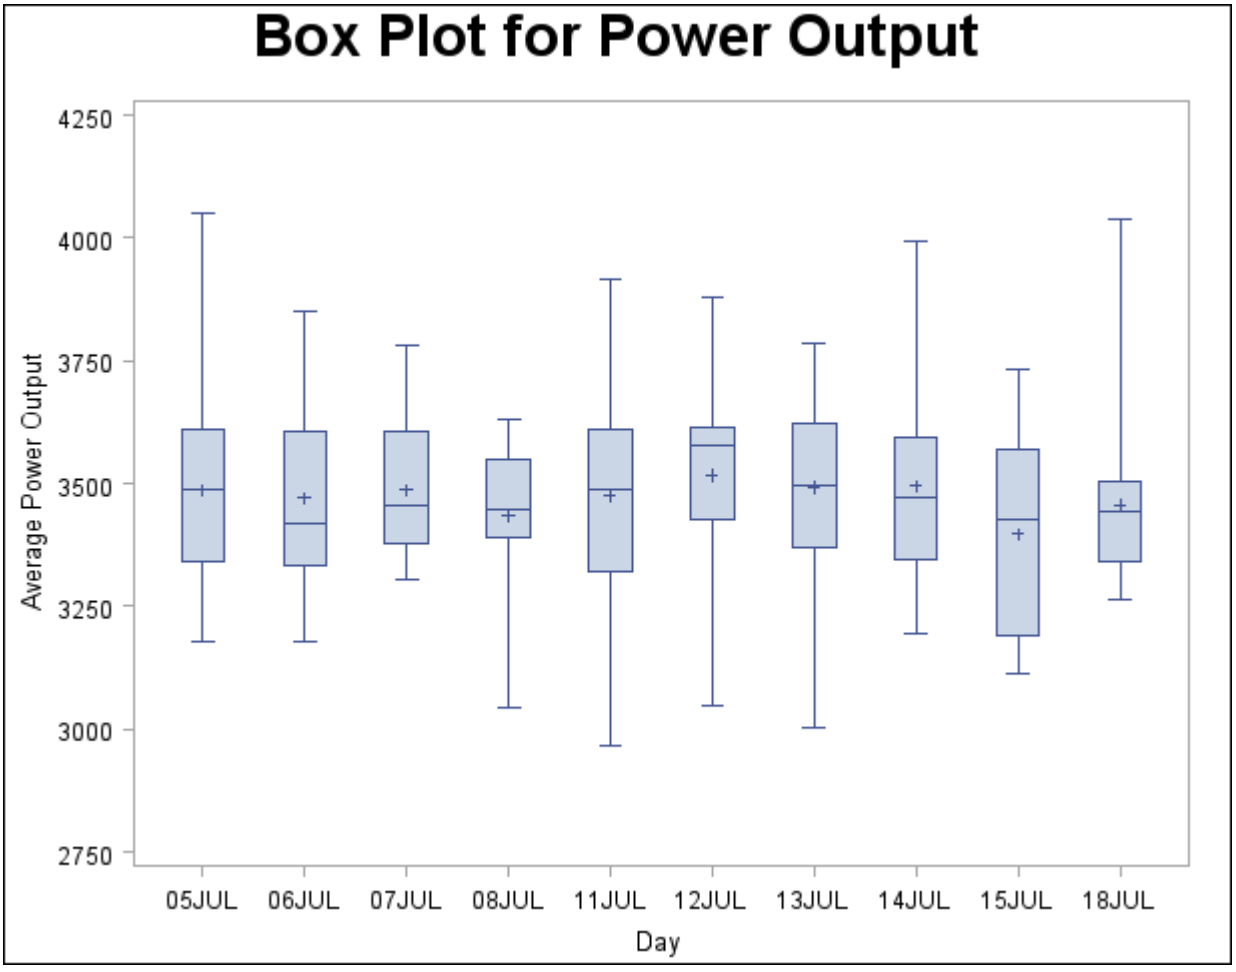
where x_{n+1} is taken to be x_n.

PCTLDEF=5 empirical distribution function with averaging

$$y = (x_j + x_{j+1})/2 \text{ if } g = 0$$

$$y = x_{j+1} \text{ if } g > 0$$

Missing Values



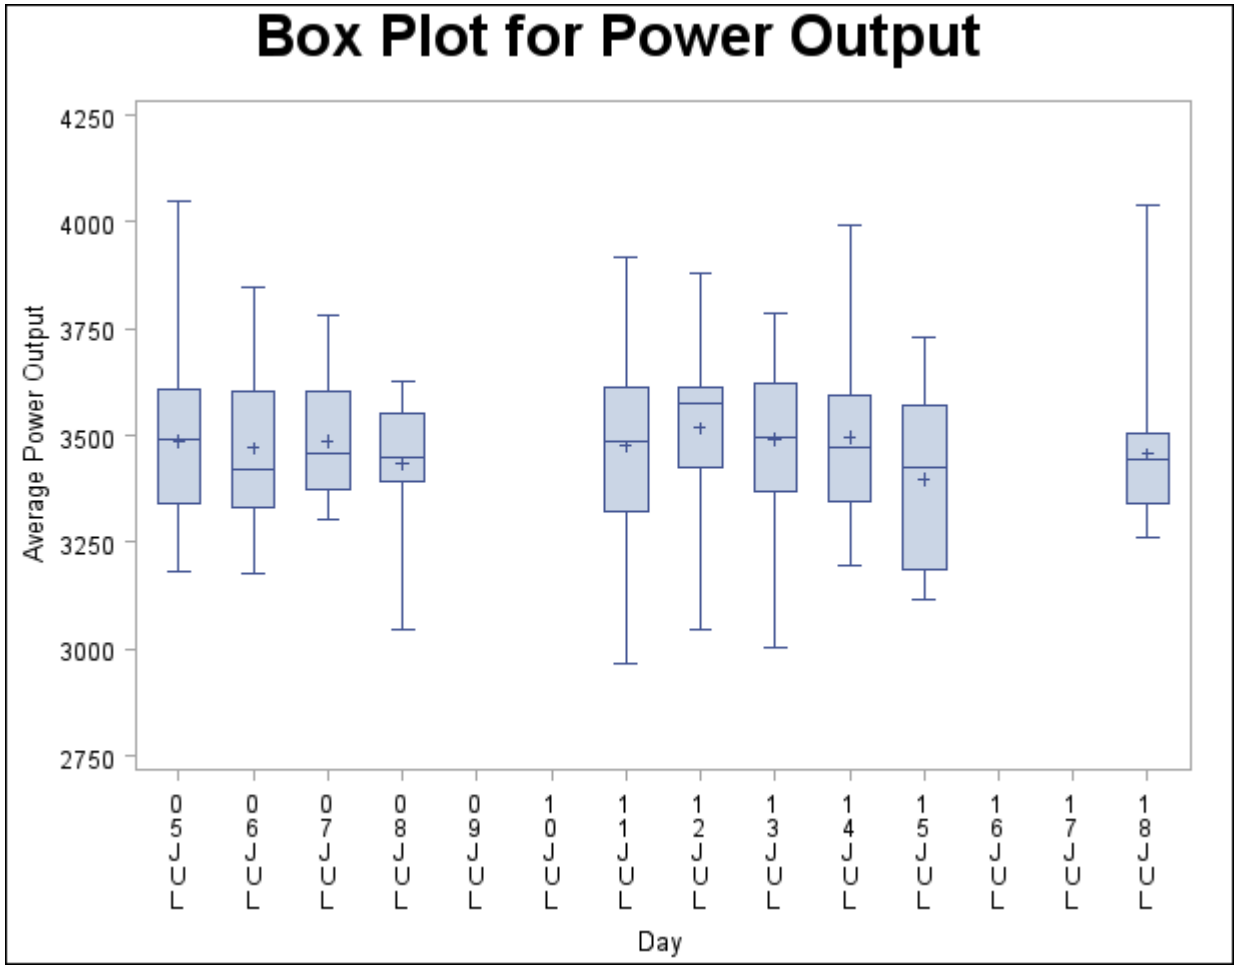
An observation read from an input data set is not analyzed if the value of the group variable is missing. For a particular analysis variable, an observation read from a DATA= data set is not analyzed if the value of the analysis variable is missing.

Continuous Group Variables

By default, the PLOT statement treats numerical group variable values as *discrete* values and spaces the boxes evenly on the plot. The following statements produce the box plot in Figure 24.9:

```
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day;
run;
```

Figure 24.9 Box Plot with Discrete Group Variable



The labels on the horizontal axis in Figure 24.9 do not represent 10 consecutive days, but the box-and-whiskers plots are evenly spaced.

In order to treat the group variable as *continuous*, you can specify the CONTINUOUS or HAXIS= option when producing traditional graphics. Either option produces a box plot with a horizontal axis scaled for continuous group variable values. (ODS Graphics does not support a continuous group axis.)

The following statements produce the plot shown in Figure 24.10. The TURNHLABEL option orients the horizontal axis labels vertically so there is room to display them all.

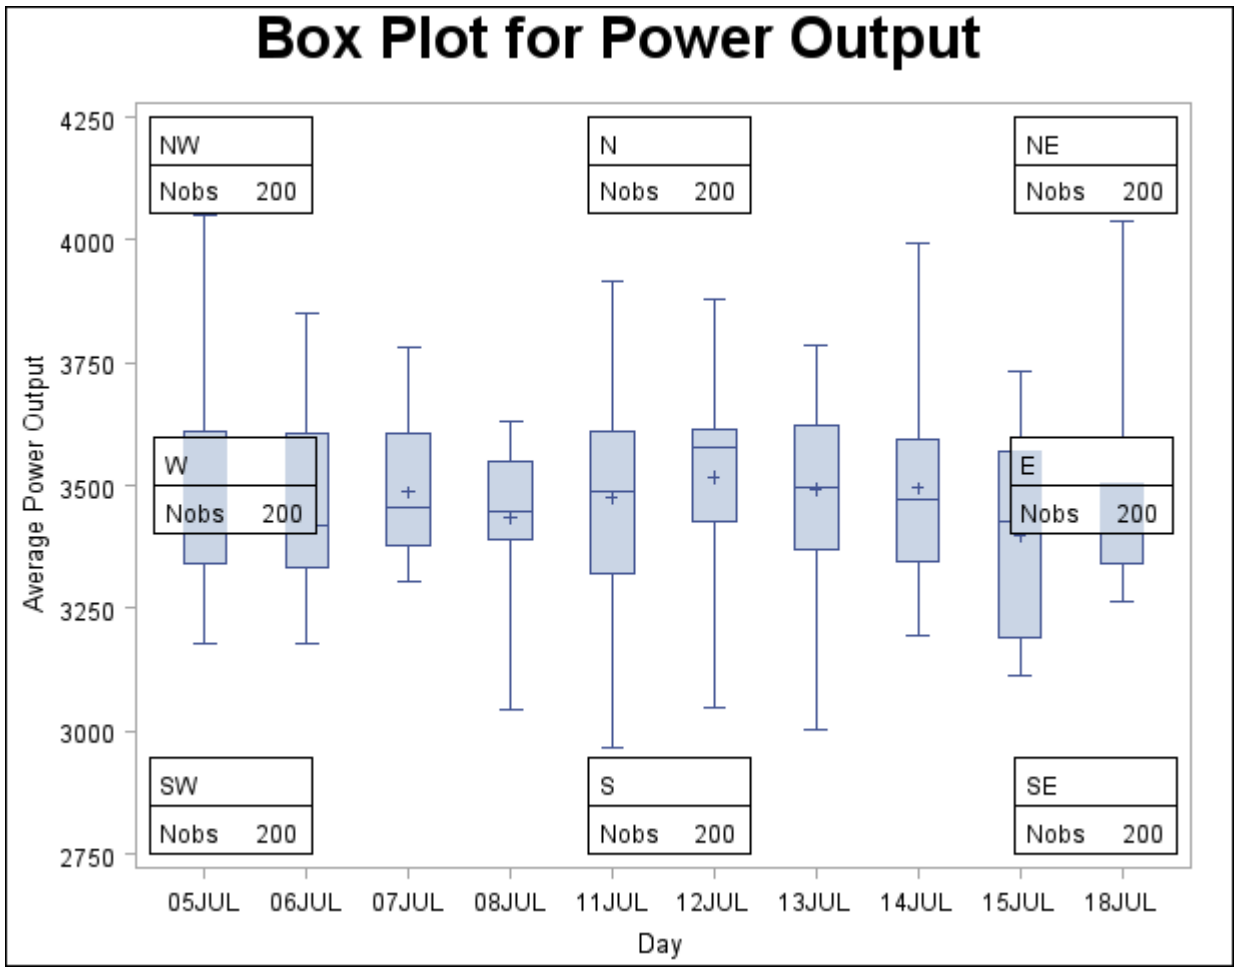
```
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day / turnhlabel
                     continuous;
run;
```

Figure 24.10 Box Plot with Continuous Group Variable

Note that the tick values on the horizontal axis represent consecutive days and that no box-and-whiskers plots are displayed for days when no turbine data were collected.

Positioning Insets

This section provides details on three different methods of positioning INSET boxes by using the POSITION= option. With the POSITION= option, you can specify the following:



- compass points
- keywords for margin positions
- coordinates in data units or percent axis units

Positioning the Inset Using Compass Points

You can specify the eight compass points (N, NE, E, SE, S, SW, W, and NW) as keywords for the POSITION= option. The default inset position is NW. The following statements create the display in Figure 24.11, which illustrates all eight compass positions:

```
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day;
   inset nobs / height=2.5 cfill=blank header='NW' pos=nw;
   inset nobs / height=2.5 cfill=blank header='N ' pos=n ;
   inset nobs / height=2.5 cfill=blank header='NE' pos=ne;
   inset nobs / height=2.5 cfill=blank header='E ' pos=e ;
   inset nobs / height=2.5 cfill=blank header='SE' pos=se;
   inset nobs / height=2.5 cfill=blank header='S ' pos=s ;
   inset nobs / height=2.5 cfill=blank header='SW' pos=sw;
   inset nobs / height=2.5 cfill=blank header='W ' pos=w ;
run;
```

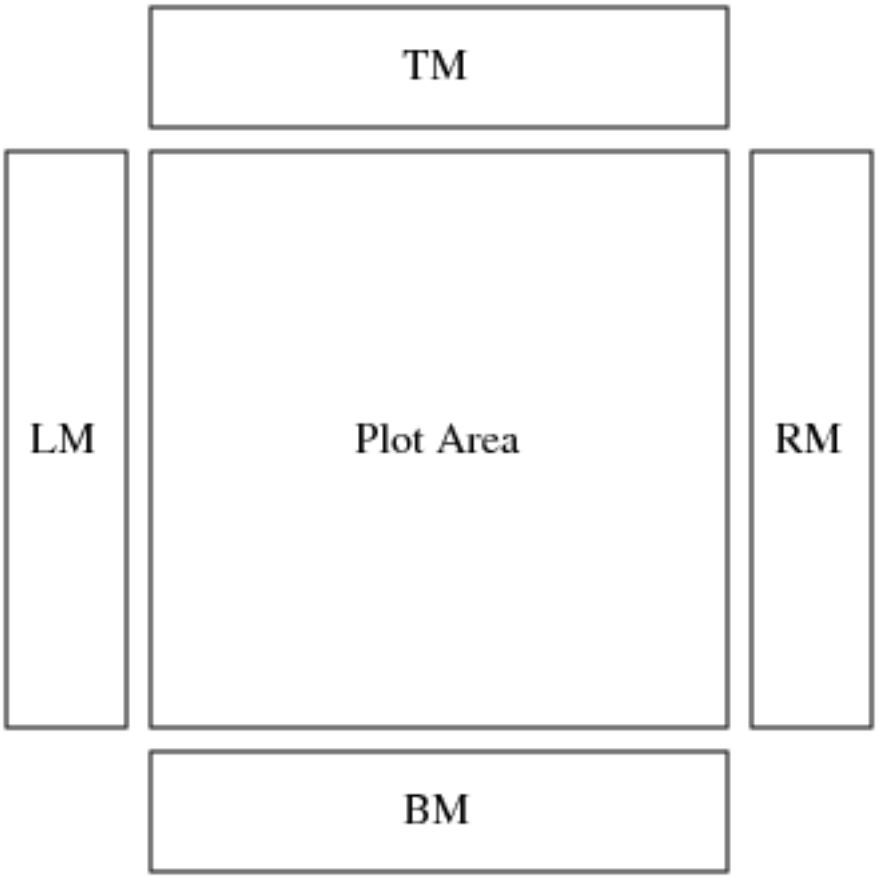


Figure 24.11 Insets Positioned Using Compass Points

Positioning the Inset in the Margins

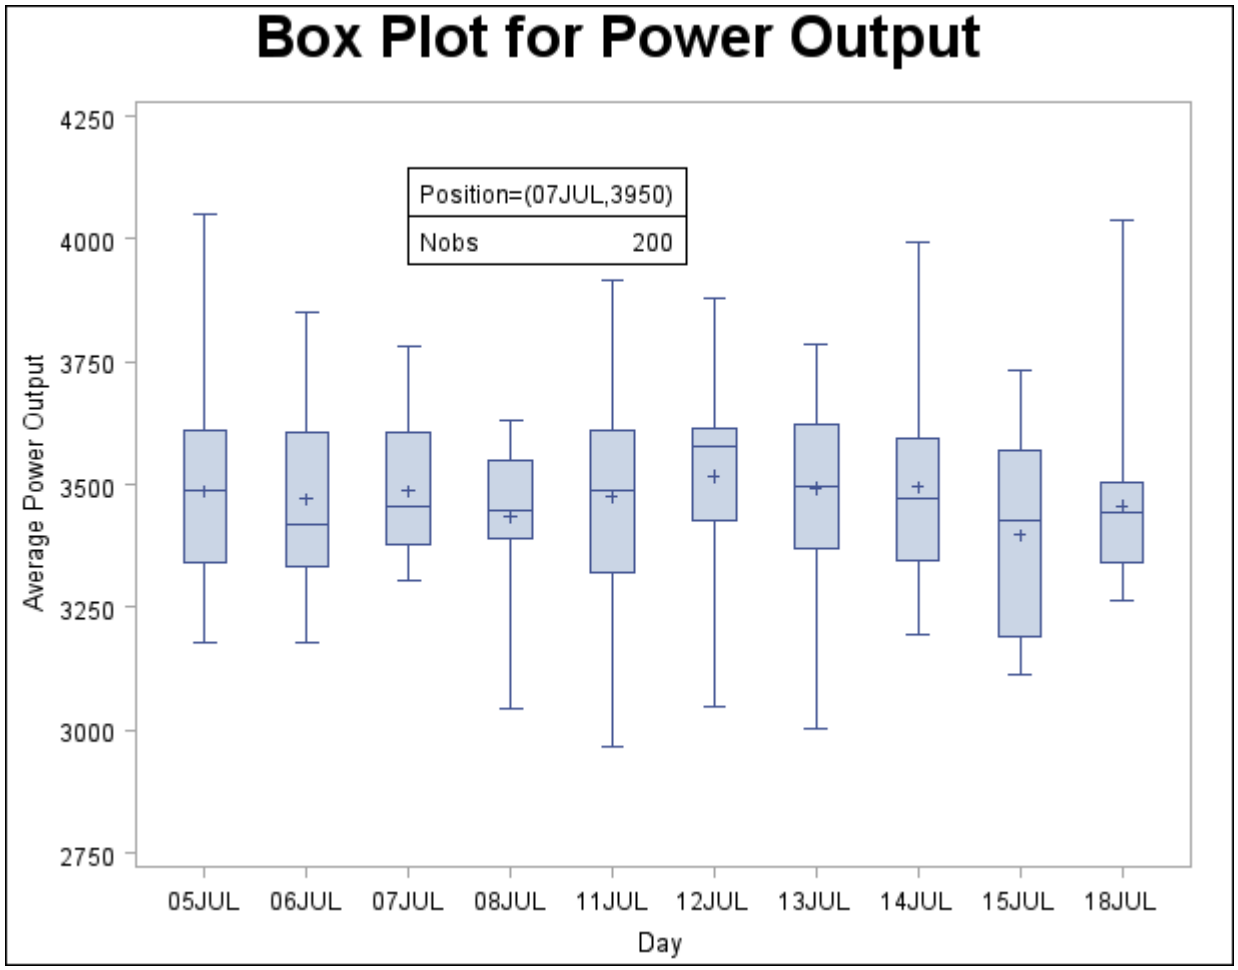
You can also use the INSET statement to position an inset in one of the four margins surrounding the plot area by using the margin keyword LM, RM, TM, or BM, as illustrated in Figure 24.12.

Figure 24.12 Positioning Insets in the Margins

For an example of an inset placed in the top margin, see Output 24.1.1. Margin positions are recommended for insets containing a large number of statistics. If you attempt to display a lengthy inset in the interior of the plot, it is likely that the inset will collide with the data display.

Positioning the Inset Using Coordinates

You can also specify the position of an inset with coordinates by using the POSITION= (x, y) option. You can specify coordinates in axis percent units (the default) or in axis data units.



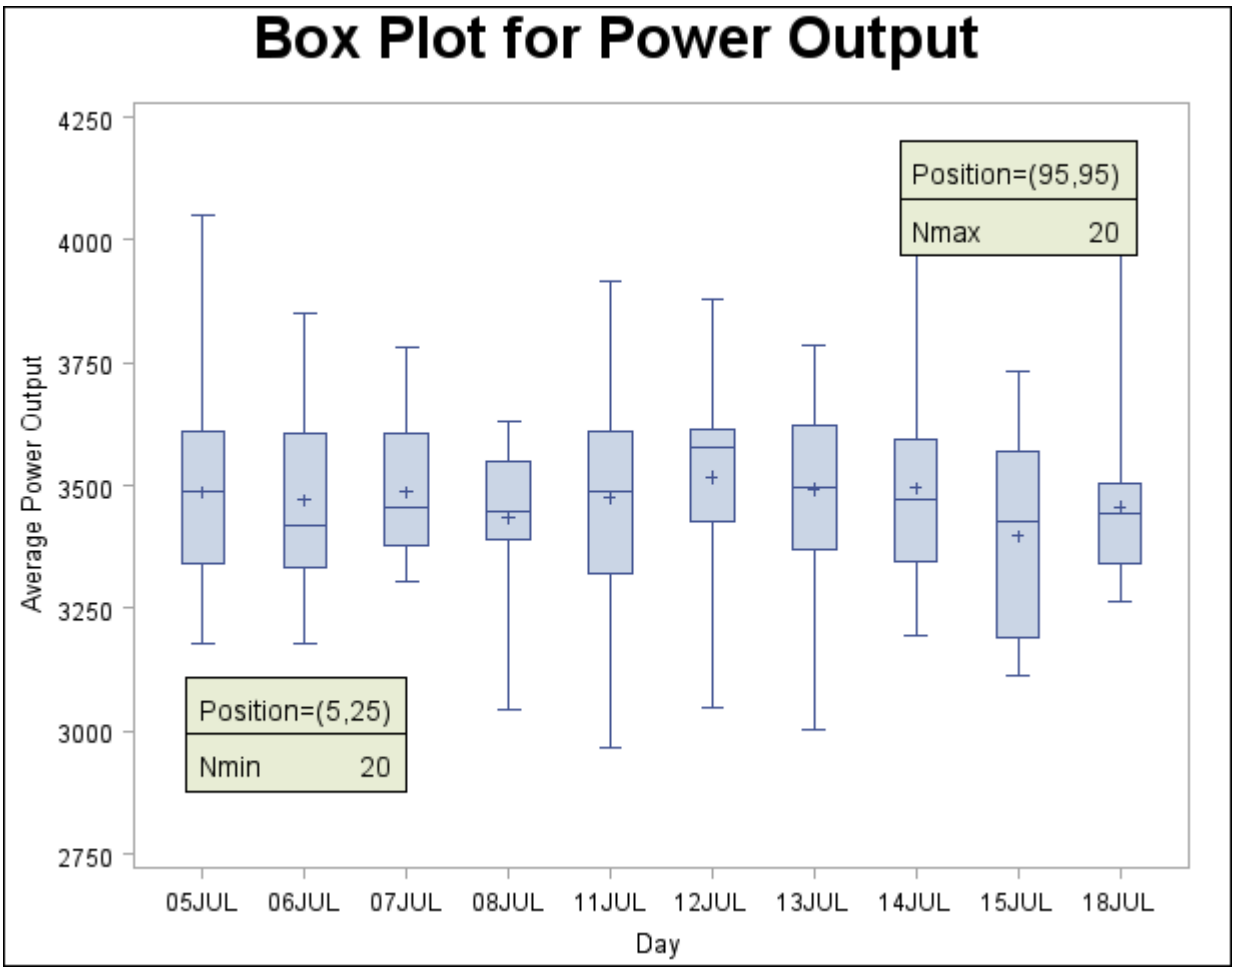
Data Unit Coordinates

If you specify the DATA option immediately following the coordinates, the inset is positioned using axis data units. For example, the following statements place the bottom-left corner of the inset at 07JUL on the horizontal axis and 3950 on the vertical axis:

```
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day;
   inset nobs /
      header   = 'Position=(07JUL,3950)'
      position = ('07JUL94'd, 3950) data;
run;
```

The box plot is displayed in Figure 24.13. By default, the specified coordinates determine the position of the bottom-left corner of the inset. You can change this reference point with the REFPOINT= option, as in the next example.

Figure 24.13 Inset Positioned Using Data Unit Coordinates



Axis Percent Unit Coordinates

If you do not use the DATA option, the inset is positioned using axis percent units. The coordinates of the bottom-left corner of the display are $(0, 0)$, while the coordinates of the top-right corner are $(100, 100)$. For example, the following statements create a box plot with two insets, both positioned using coordinates in axis percent units:

```
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day;
   inset nmin / position = (5,25)
                header   = 'Position=(5,25)'
                height   = 3
                cfill    = ywh
                refpoint = tl;
   inset nmax / position = (95,95)
                header   = 'Position=(95,95)'
                height   = 3
                cfill    = ywh
                refpoint = tr;
run;
```

The display is shown in Figure 24.14. Notice that the REFPOINT= option is used to determine which corner of the inset is placed at the coordinates specified with the POSITION= option. The first inset has REFPOINT=TL, so the top-left corner of the inset is positioned 5% of the way across the horizontal axis and 25% of the way up the vertical axis. The second inset has REFPOINT=TR, so the top-right corner of the inset is positioned 95% of the way across the horizontal axis and 95% of the way up the vertical axis. Note also that coordinates in axis percent units must be *between* 0 and 100.

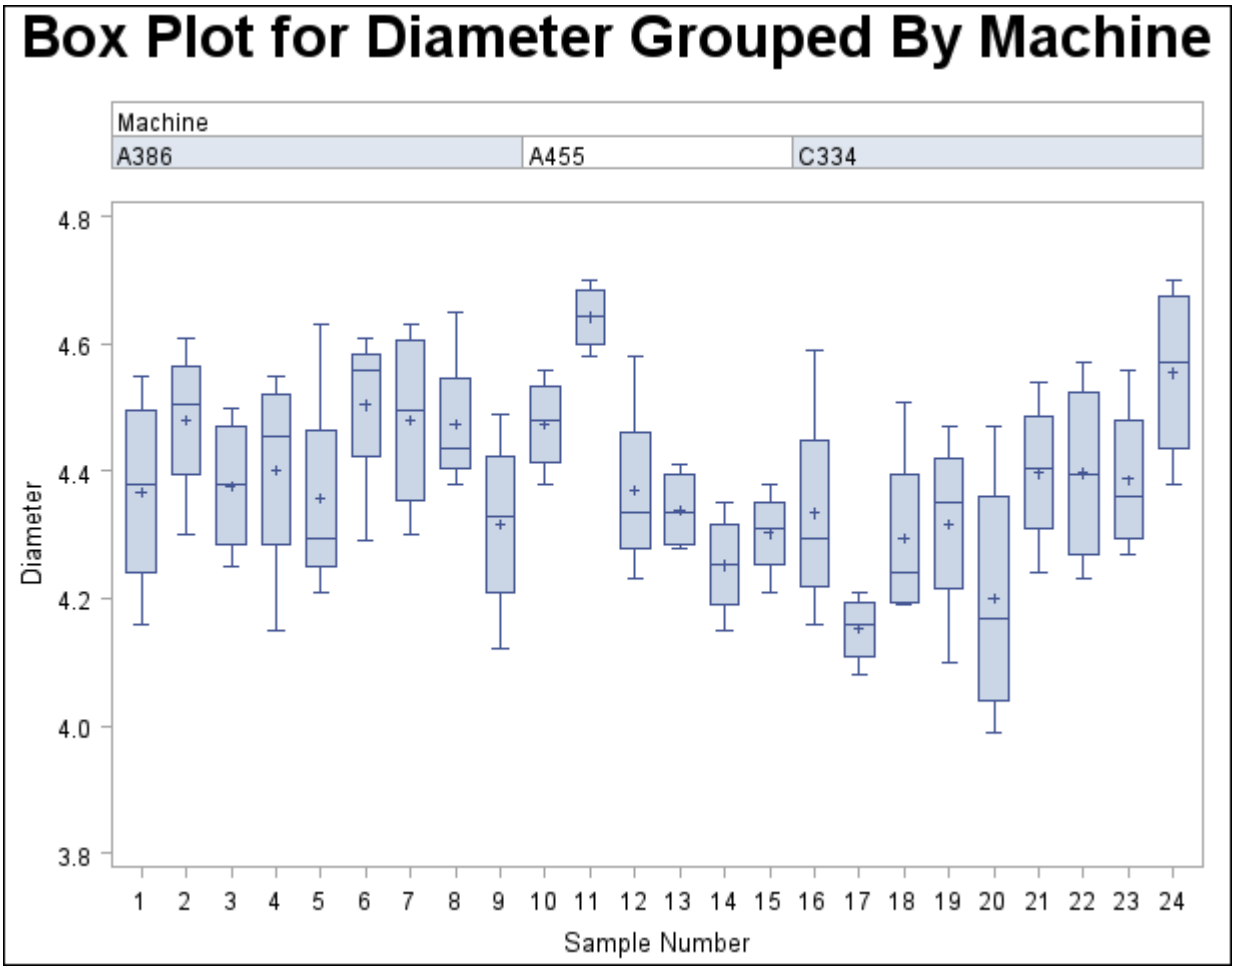
Figure 24.14 Inset Positioned Using Axis Percent Unit Coordinates

Displaying Blocks of Data

To display data organized in blocks of consecutive observations, specify one or more *block variables* in parentheses after the group variable in the PLOT statement. The block variables must be variables in the input data set. The BOXPLOT procedure displays a legend identifying blocks of consecutive observations with identical values of the block variables. The legend displays one track of values for each block variable containing formatted values of the block variable.

The values of a block variable must be the same for all observations with the same value of the group variable. In other words, groups must be nested within blocks determined by block variables.

The following statements create a SAS data set containing diameter measurements for a part produced on three different machines:



```
data Parts;
   length Machine $ 4;
   input Sample Machine $ @;
   do i= 1 to 4;
      input Diam @;
      output;
   end;
   drop i;
 datalines;
 1  A386  4.32 4.55 4.16 4.44
 2  A386  4.49 4.30 4.52 4.61
 3  A386  4.44 4.32 4.25 4.50
 4  A386  4.55 4.15 4.42 4.49
 5  A386  4.21 4.30 4.29 4.63
 6  A386  4.56 4.61 4.29 4.56
 7  A386  4.63 4.30 4.41 4.58
 8  A386  4.38 4.65 4.43 4.44
 9  A386  4.12 4.49 4.30 4.36
10  A455  4.45 4.56 4.38 4.51
11  A455  4.62 4.67 4.70 4.58
12  A455  4.33 4.23 4.34 4.58
13  A455  4.29 4.38 4.28 4.41
14  A455  4.15 4.35 4.28 4.23
15  A455  4.21 4.30 4.32 4.38
16  C334  4.16 4.28 4.31 4.59
17  C334  4.14 4.18 4.08 4.21
18  C334  4.51 4.20 4.28 4.19
19  C334  4.10 4.33 4.37 4.47
20  C334  3.99 4.09 4.47 4.25
21  C334  4.24 4.54 4.43 4.38
22  C334  4.23 4.48 4.31 4.57
23  C334  4.27 4.40 4.32 4.56
24  C334  4.70 4.65 4.49 4.38
;
```

The following statements create a box plot for the measurements in the Parts data set grouped into blocks by the block variable Machine:

```
title 'Box Plot for Diameter Grouped By Machine';
proc boxplot data=Parts;
   plot Diam*Sample (Machine);
   label Sample  = 'Sample Number'
         Machine = 'Machine'
         Diam    = 'Diameter';
run;
```

Note the LABEL statement used to provide labels for the axes and for the block legend. The plot is shown in Figure 24.15.

Figure 24.15 Box Plot Using a Block Variable

The unique consecutive values of Machine (A386, A455, and C334) are displayed in a legend above the plot. That is the default location of the block legend. You can control the position of the block legend with the BLOCKPOS= option. See the BLOCKPOS= option on page 772 for details.

By default, block variable values that are too long to fit into the available space in a block legend are not displayed. You can specify the BLOCKLABTYPE= option to display lengthy labels. Specify BLOCKLABTYPE=SCALED to scale down the text size of the values so they all fit. Use BLOCKLABTYPE=TRUNCATED to truncate lengthy values. You can also use BLOCKLABTYPE=*height*

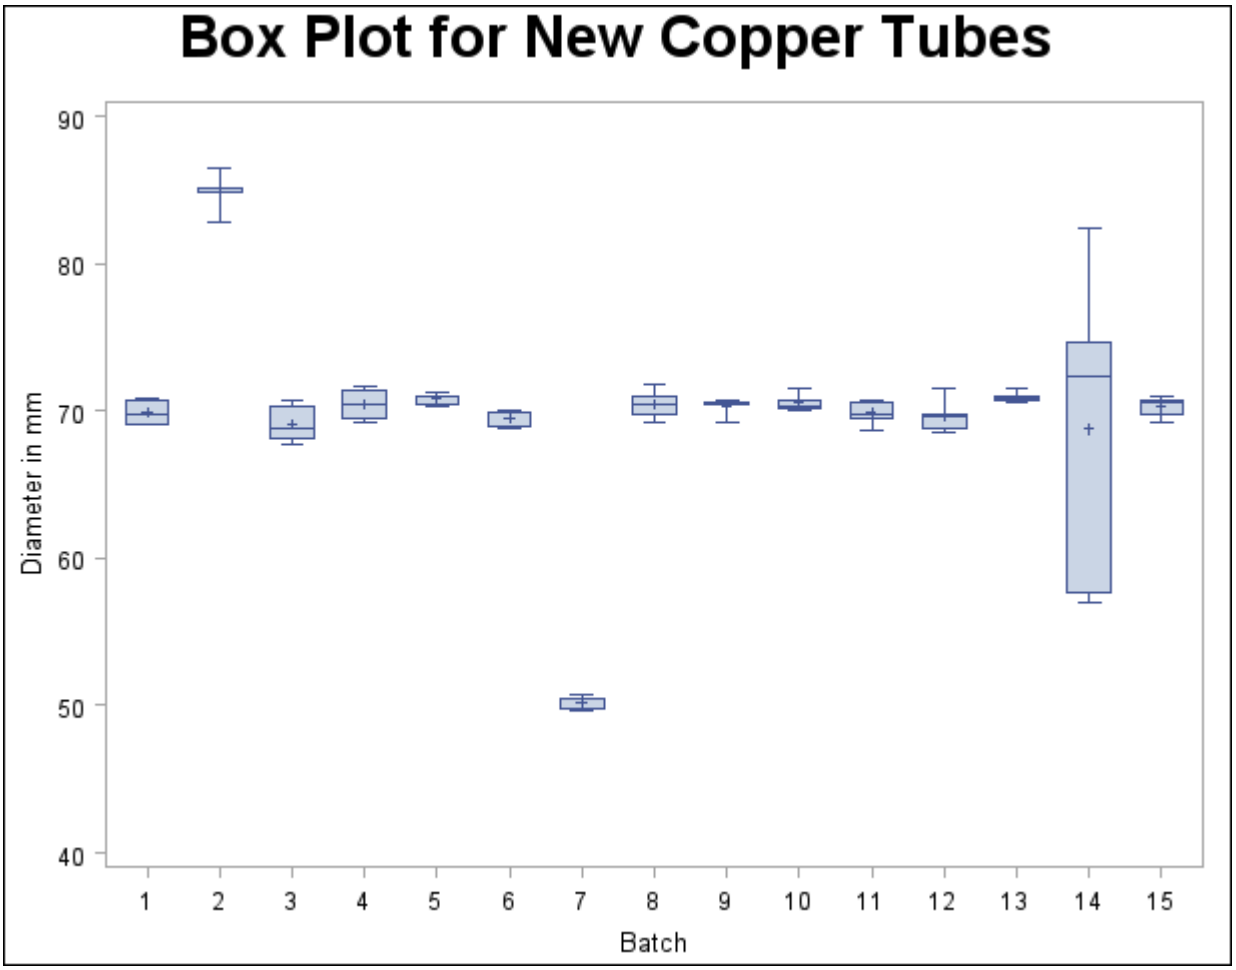
to specify a text height in vertical percent screen units for the values.

You can control the position of legend labels with the BLOCKLABELPOS= option. Valid BLOCKLABELPOS= values are ABOVE (the default, as shown in Figure 24.15) and LEFT.

Clipping Extreme Values

By default a box plot's vertical axis is scaled to accommodate all the values in all groups. If the variation between groups is large with respect to the variation within groups, or if some groups contain extreme outlier values, the vertical axis scale can become so large that the box-and-whiskers plots are compressed. In such cases, you can clip the extreme values to produce a more readable plot, as illustrated in the following example.

A company produces copper tubing. The diameter measurements (in millimeters) for 15 batches of five tubes each are provided in the data set Newtubes:



```
data Newtubes;
   label Diameter='Diameter in mm';
   do Batch = 1 to 15;
      do  i = 1 to 5;
         input Diameter @@;
         output;
      end;
   end;
datalines;
69.13  69.83  70.76  69.13  70.81
85.06  82.82  84.79  84.89  86.53
67.67  70.37  68.80  70.65  68.20
71.71  70.46  71.43  69.53  69.28
71.04  71.04  70.29  70.51  71.29
69.01  68.87  69.87  70.05  69.85
50.72  50.49  49.78  50.49  49.69
69.28  71.80  69.80  70.99  70.50
70.76  69.19  70.51  70.59  70.40
70.16  70.07  71.52  70.72  70.31
68.67  70.54  69.50  69.79  70.76
68.78  68.55  69.72  69.62  71.53
70.61  70.75  70.90  71.01  71.53

70.54  69.82  70.71  71.05  69.24
;
run;
```

The following statements create a box plot of the tube diameters:

```
title  'Box Plot for New Copper Tubes' ;
proc boxplot data=Newtubes;
   plot Diameter*Batch;
run;
```

The box plot is shown in Figure 24.16.

Figure 24.16 Compressed Box Plots

Note that the diameters in batch 2 are significantly larger, and those in batch 7 significantly smaller, than those in most of the other batches. The default vertical axis scaling causes the box-and-whiskers plots to be compressed.

You can produce a more useful box plot by specifying the CLIPFACTOR=*factor* option, where *factor* is a value greater than one. Clipping is applied as follows:

1. The mean of the first quartile values ($\overline{Q1}$) and the mean of the third quartile values ($\overline{Q3}$) are computed across all groups.
2. The following values define the clipping range:

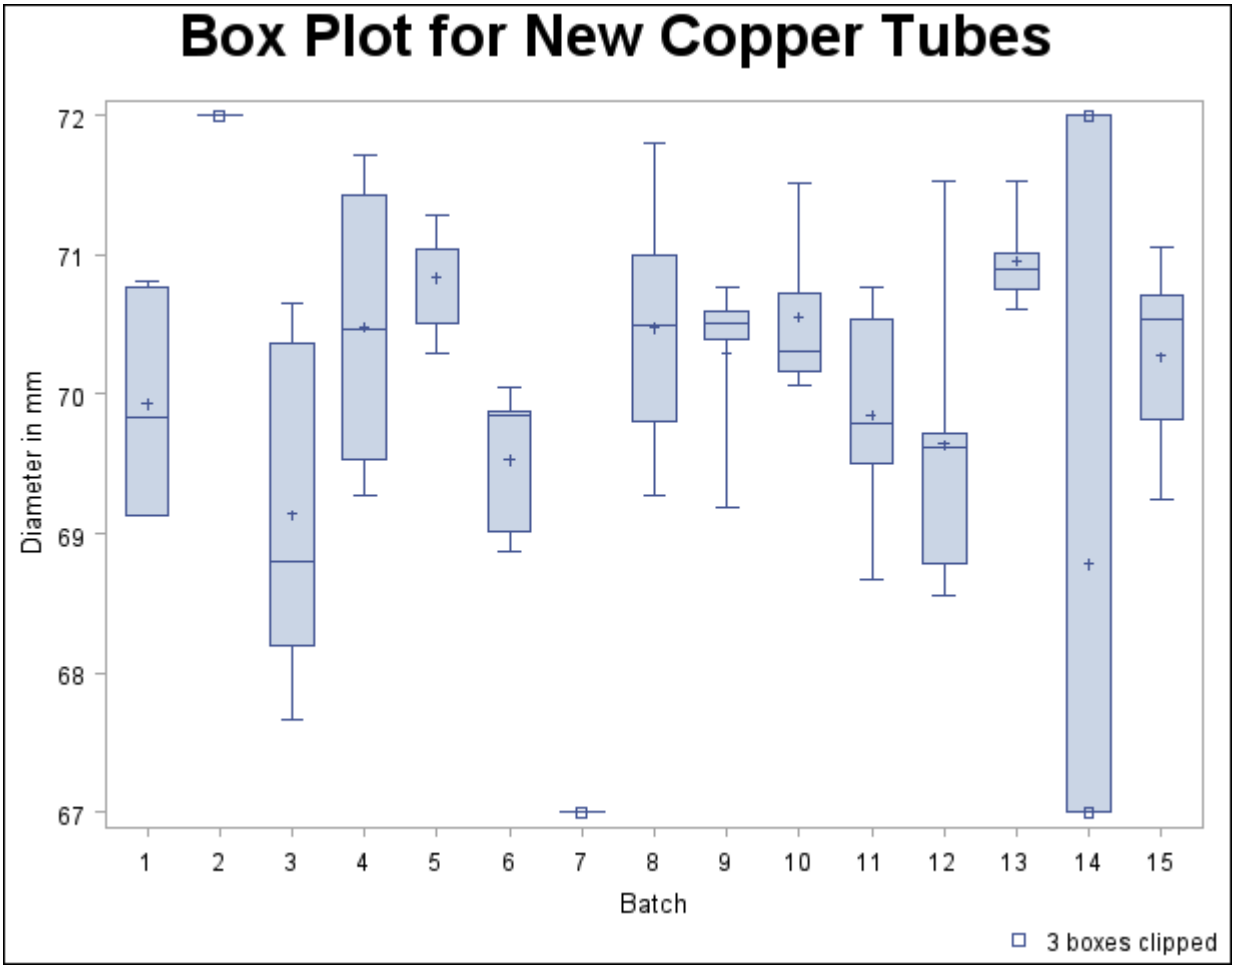
   $$y_{\max} = \overline{Q1} + (\overline{Q3} - \overline{Q1}) \times factor$$

   and

   $$y_{\min} = \overline{Q3} - (\overline{Q3} - \overline{Q1}) \times factor$$

   Any statistic greater than $y_{\max}$ or less than $y_{\min}$ is ignored during vertical axis scaling.

NOTE:



- Clipping is applied only to the plotted statistics and not to the statistics saved in an output data set.
- A special symbol is used for clipped points (the default symbol is a square), and a legend is added to the chart indicating the number of boxes that were clipped.

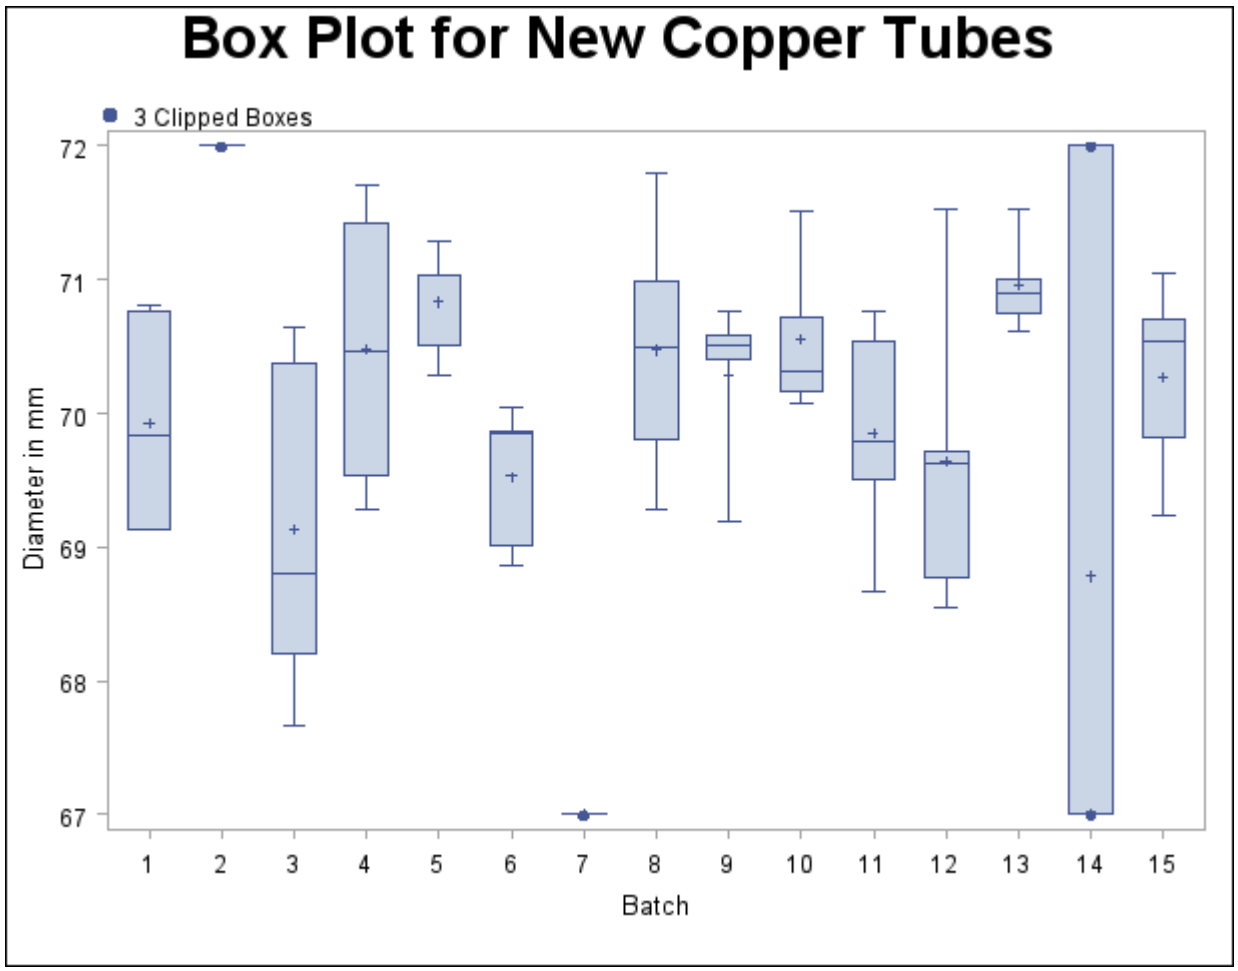
The following statements use a clipping factor of 1.5 to create a box plot of the same data plotted in Figure 24.16:

```
title  'Box Plot for New Copper Tubes' ;
proc boxplot data=Newtubes;
   plot Diameter*Batch /
      clipfactor = 1.5;
run;
```

The clipped box plot is shown in Figure 24.17.

Figure 24.17 Box Plot with Clip Factor of 1.5

In Figure 24.17 the extreme values are clipped, making the box plot more readable. The box-and-whiskers plots for batches 2 and 7 are clipped completely, while the plot for batch 14 is clipped at both the top and bottom. Clipped points are marked with a square, and a clipping legend is added at the lower right of the display.



Other clipping options are available, as illustrated by the following statements:

```
title  'Box Plot for New Copper Tubes' ;
proc boxplot data=Newtubes;
   plot Diameter*Batch /
      clipfactor  = 1.5
      clipsymbol  = dot
      cliplegpos  = top
      cliplegend  = '# Clipped Boxes'
      clipsubchar = '#';
run;
```

Specifying CLIPSYMBOL=DOT marks the clipped points with a dot instead of the default square. Specifying CLIPLEGPOS=TOP positions the clipping legend at the top of the chart. The options CLIPLEGEND='# Clipped Boxes' and CLIPSUBCHAR='#' request the clipping legend "3 Clipped Boxes".

Figure 24.18 shows the modified box plot.

Figure 24.18 Box Plot Using Clipping Options

For more information about clipping options, see the appropriate entries in the section "PLOT Statement Options" on page 767.

ODS Graphics (Experimental)

The BOXPLOT procedure supports ODS Graphics on an experimental basis in SAS 9.2. To use ODS Graphics to produce box plots you must specify the ODS GRAPHICS statement prior to the PROC BOXPLOT statement. For more information about ODS Graphics, see Chapter 21, "Statistical Graphics Using ODS."

The appearance of a box plot produced using ODS Graphics is determined by the style associated with the ODS destination where the graph is produced. PLOT statement options used to control the appearance of traditional high-resolution graphs are ignored for ODS Graphics output.

When producing ODS graphical displays, the PLOT statement assigns a name to each graph it creates. You can use this name to reference the graph when using ODS. The name is listed in Table 24.9.

Table 24.9 ODS Graphics Produced by PROC BOXPLOT

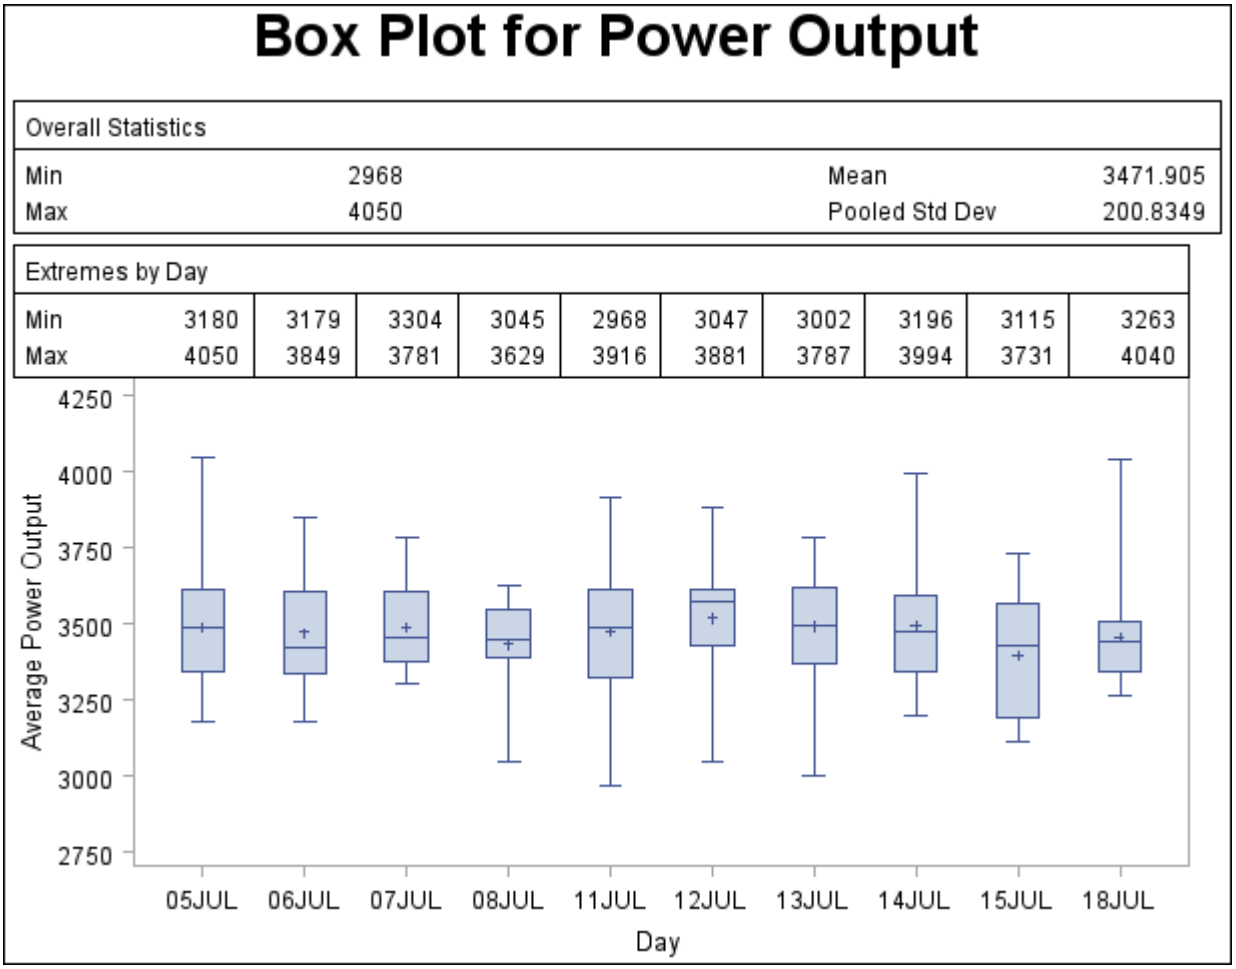
ODS Graph Name	Plot Description
Boxplot	box-and-whiskers plots for groups

Examples: BOXPLOT Procedure

This section provides advanced examples of the PLOT statement.

Example 24.1: Displaying Summary Statistics in a Box Plot

This example demonstrates how you can use the INSET and INSETGROUP statements to include tables of summary statistics in your box plots. The following statements produce a box plot of the Turbine data set from the section "Getting Started: BOXPLOT Procedure" on page 751, augmented with insets containing summary statistics:



```
title 'Box Plot for Power Output';
proc boxplot data=Turbine;
   plot KWatts*Day;
   inset min mean max stddev /
      header = 'Overall Statistics'
      pos    = tm;
   insetgroup min max /
      header = 'Extremes by Day';
run;
```

The INSET statement produces an inset of overall summary statistics. The keywords listed before the slash (/) request the minimum, mean, maximum, and standard deviation computed over all days. The POS=TM option places the inset in the top margin of the plot.

The INSETGROUP statement produces an inset containing statistics calculated for each group separately. The MIN and MAX keywords request the minimum and maximum observations from each day, respectively.

The resulting plot is shown in Output 24.1.1.

Output 24.1.1 Box Plot with Insets

Example 24.2: Using Box Plots to Compare Groups

In this example a box plot is used to compare the delay times of airline flights during the Christmas holidays with the delay times prior to the holiday period. The following statements create a data set named Times with the delay times in minutes for 25 flights each day. When a flight is canceled, the delay is recorded as a missing value.

```
data Times;
   informat Day date7. ;
   format   Day date7. ;
   input Day @ ;
   do Flight=1 to 25;
      input Delay @ ;
      output;
      end;
datalines;
16DEC88   4  12   2   2  18   5   6  21   0   0
          0  14   3   .   2   3   5   0   6  19
          7   4   9   5  10
17DEC88   1  10   3   3   0   1   5   0   .   .
          1   5   7   1   7   2   2  16   2   1
          3   1  31   5   0
18DEC88   7   8   4   2   3   2   7   6  11   3
          2   7   0   1  10   2   3  12   8   6
          2   7   2   4   5
19DEC88  15   6   9   0  15   7   1   1   0   2
          5   6   5  14   7  20   8   1  14   3
         10   0   1  11   7
20DEC88   2   1   0   4   4   6   2   2   1   4
          1  11   .   1   0   6   5   5   4   2
          2   6   6   4   0
21DEC88   2   6   6   2   7   7   5   2   5   0
          9   2   4   2   5   1   4   7   5   6
          5   0   4  36  28
22DEC88   3   7  22   1  11  11  39  46   7  33
         19  21   1   3  43  23   9   0  17  35
         50   0   2   1   0
23DEC88   6  11   8  35  36  19  21   .   .   4
          6  63  35   3  12  34   9   0  46   0
          0  36   3   0  14
24DEC88  13   2  10   4   5  22  21  44  66  13
          8   3   4  27   2  12  17  22  19  36
          9  72   2   4   4
25DEC88   4  33  35   0  11  11  10  28  34   3
         24   6  17   0   8   5   7  19   9   7
         21  17  17   2   6
26DEC88   3   8   8   2   7   7   8   2   5   9
          2   8   2  10  16   9   5  14  15   1
         12   2   2  14  18
;
run;
```

In the following statements, the MEANS procedure is used to count the number of canceled flights for each day. This information is then added to the data set Times.

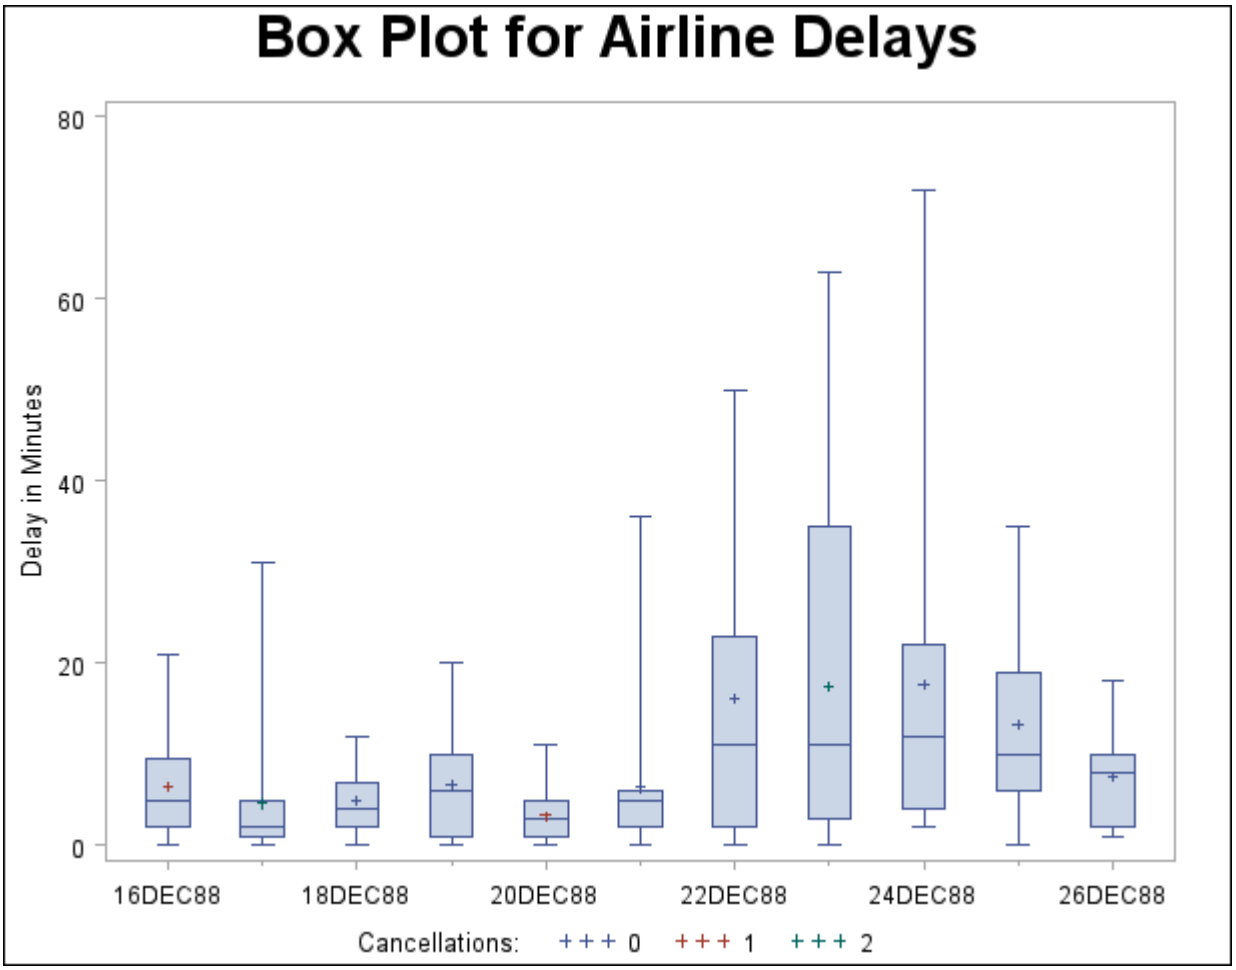
```
proc means data=Times noprint;
   var Delay;
   by Day;
   output out=Cancel nmiss=ncancel;

data Times;
   merge Times Cancel;
   by Day;
run;
```

The following statements create a data set named Weather containing information about possible causes for delays, and then merge this data set with the data set Times:

```
data Weather;
   informat Day date7. ;
   format   Day date7. ;
   length Reason $ 16 ;
input Day Flight Reason & ;
datalines;
16DEC88  8   Fog
17DEC88  18  Snow Storm
17DEC88  23  Sleet
21DEC88  24  Rain
21DEC88  25  Rain
22DEC88  7   Mechanical
22DEC88  15  Late Arrival
24DEC88  9   Late Arrival
24DEC88  22  Late Arrival
;
run;

data Times;
   merge Times Weather;
   by Day Flight;
run;
```



The following statements create a box plot for the complete set of data:

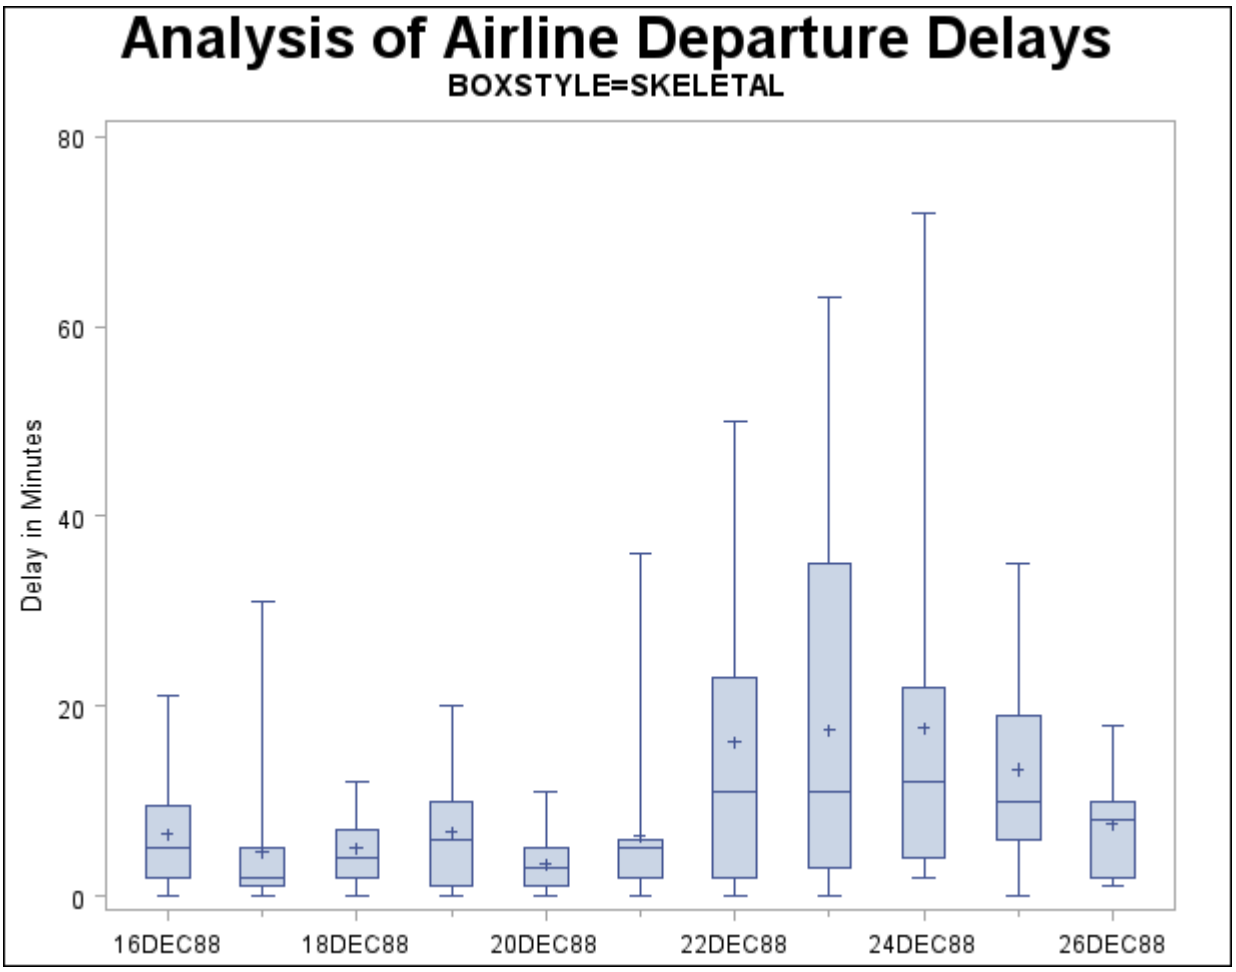
```
symbol1 v=plus;
symbol2 v=square;
symbol3 v=triangle;
title 'Box Plot for Airline Delays';
proc boxplot data=Times;
   plot Delay*Day = ncancel /
       nohlabel
       symbollegend = legend1;
   legend1 label = ('Cancellations:');
   label Delay = 'Delay in Minutes';
run;
goptions reset=symbol;
```

The level of the *symbol variable* ncancel determines the symbol marker for each group mean, and the SYMBOLLEGEND= option controls the appearance of the legend for the symbols. The NOHLA-

BEL option suppresses the horizontal axis label. The resulting box plot is shown in Output 24.2.1.

Output 24.2.1 Box Plot for Airline Data

The delay distributions from December 22 through December 25 are drastically different from the delay distributions during the pre-holiday period. Both the mean delay and the variability of the delays are much greater during the holiday period.



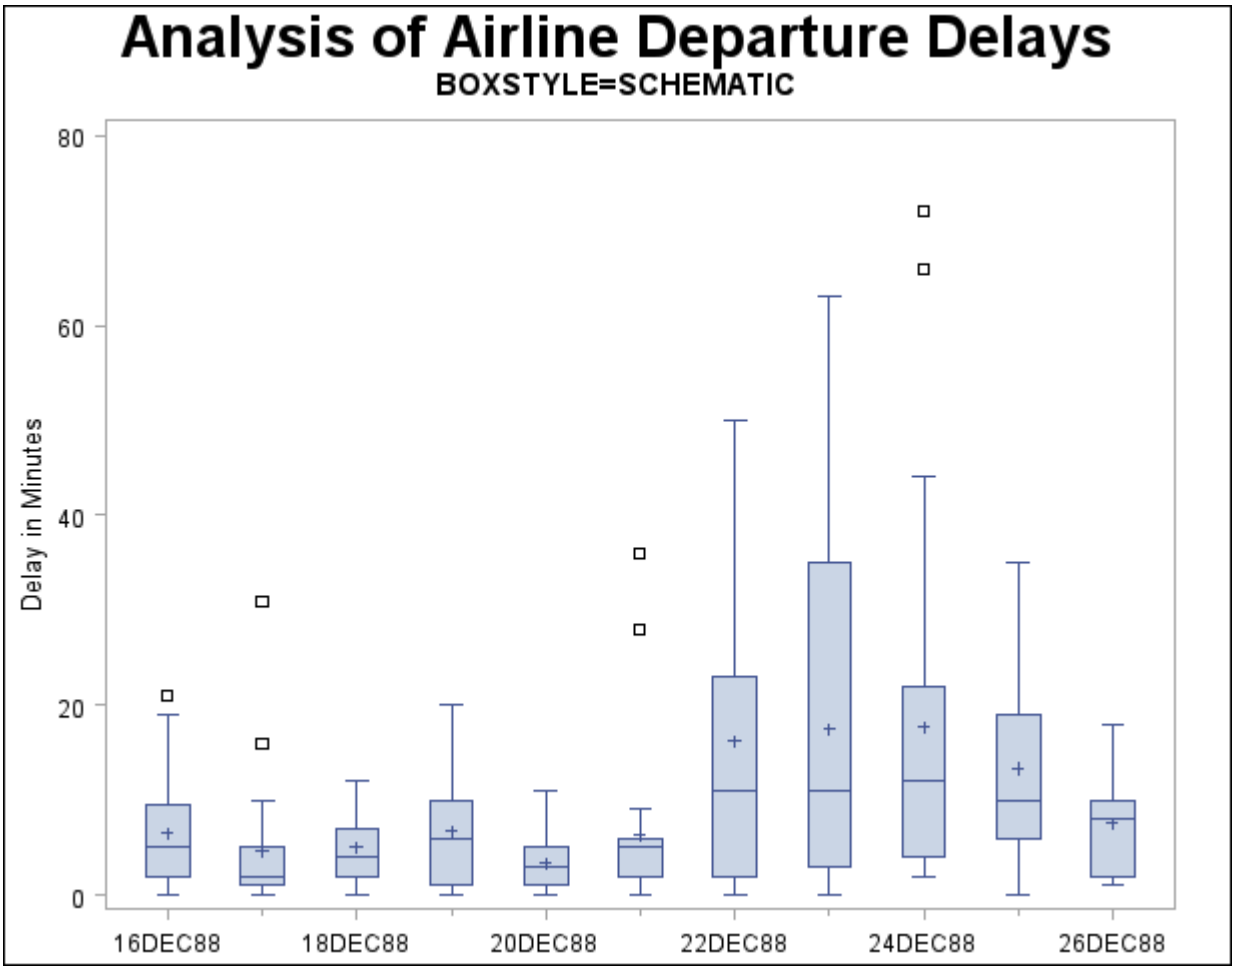
Example 24.3: Creating Various Styles of Box-and-Whiskers Plots

This example uses the flight delay data of the preceding example to illustrate how you can create box plots with various styles of box-and-whiskers plots. The following statements create a plot that displays skeletal box-and-whiskers plots:

```
title 'Analysis of Airline Departure Delays';
title2 'BOXSTYLE=SKELETAL';
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = skeletal
      nohlabel;
   label Delay = 'Delay in Minutes';
run;
```

In a skeletal box-and-whiskers plot, the whiskers are drawn from the quartiles to the extreme values of the group. The skeletal box plot is the default style, so you can also produce a skeletal box plot by omitting the BOXSTYLE= option. Output 24.3.1 shows the skeletal box plot.

Output 24.3.1 BOXSTYLE=SKELETAL

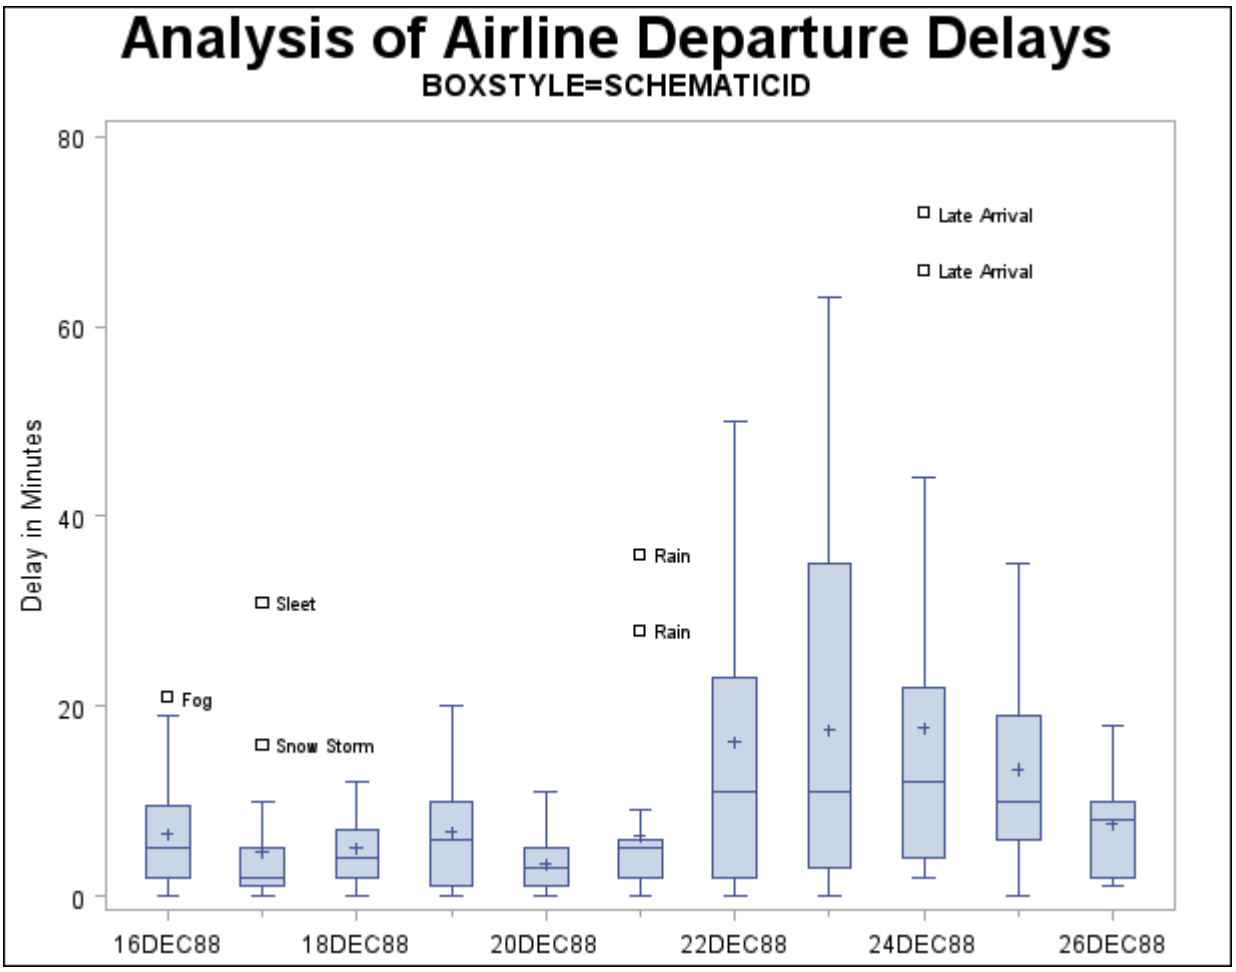


The following statements request a schematic box:

```
title 'Analysis of Airline Departure Delays';
title2 'BOXSTYLE=SCHEMATIC';
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = schematic
      nohlabel;
   label Delay = 'Delay in Minutes';
run;
```

When you specify BOXSTYLE=SCHEMATIC, the whiskers are drawn to the most extreme points in the group that lie within the *fences*. The *upper fence* is defined as the third quartile (represented by the upper edge of the box) plus 1.5 times the interquartile range (IQR). The *lower fence* is defined as the first quartile (represented by the lower edge of the box) minus 1.5 times the interquartile range. Observations outside the fences are identified with a special symbol. The default symbol is a square, and you can specify the shape and color for this symbol with the IDSYMBOL= and IDCOLOR= options. Serifs are added to the whiskers by default. For further details, see the entry for the BOXSTYLE= option on page 773. The plot is shown in Output 24.3.2.

Output 24.3.2 BOXSTYLE=SCHEMATIC

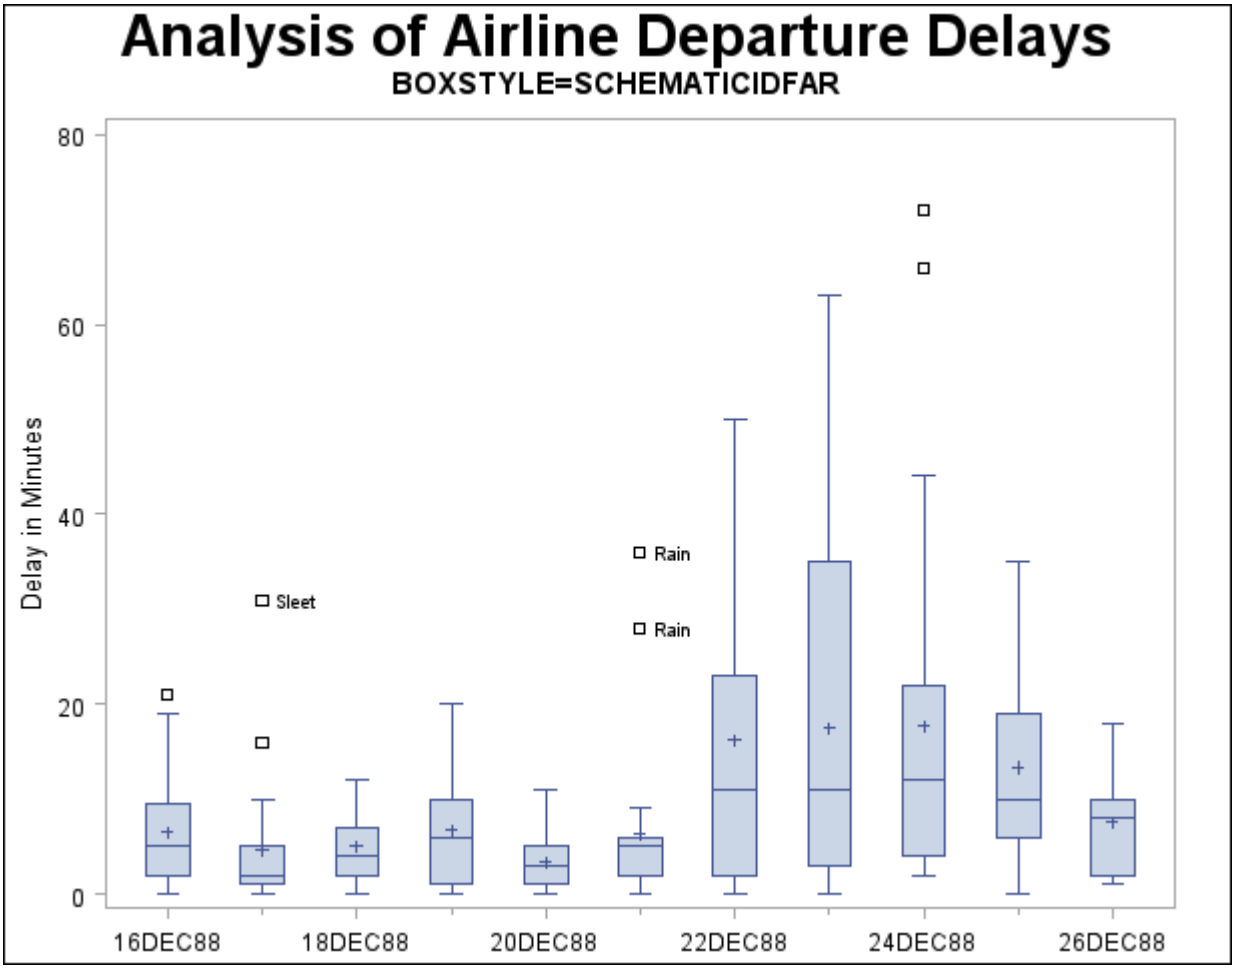


The following statements create a schematic box plot in which the observations outside the fences are labeled:

```
title 'Analysis of Airline Departure Delays';
title2 'BOXSTYLE=SCHEMATICID';
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = schematicid
      nohlabel;
   id Reason;
   label Delay = 'Delay in Minutes';
run;
```

If you specify BOXSTYLE=SCHEMATICID, schematic box-and-whiskers plots are created and the value of the first ID variable (in this case, Reason) is used to label each observation outside the fences. The box plot is shown in Output 24.3.3.

Output 24.3.3 BOXSTYLE=SCHEMATICID



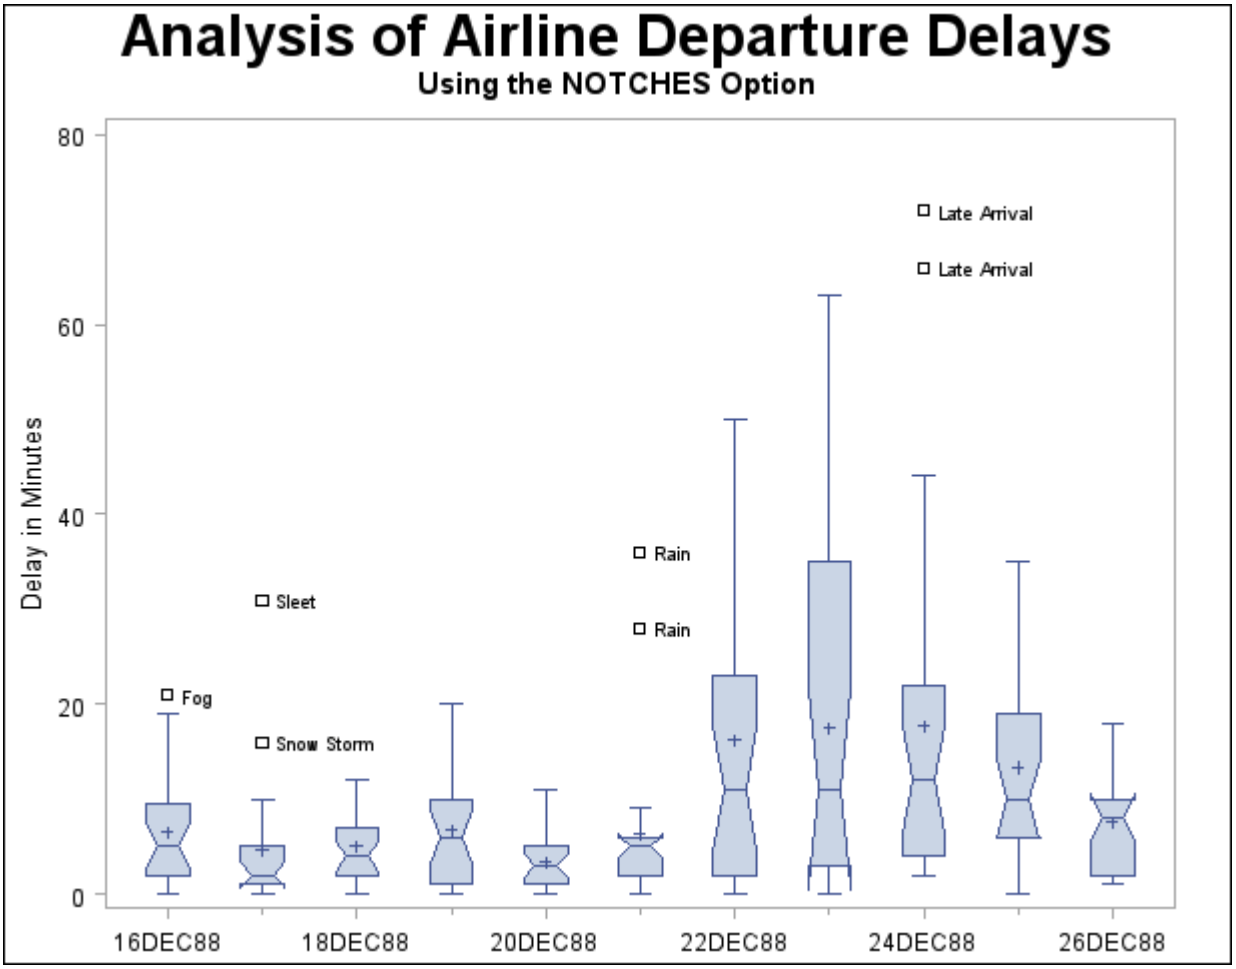
The following statements create a box plot with schematic box-and-whiskers plots in which only the extreme observations outside the fences are labeled:

```
title 'Analysis of Airline Departure Delays';
title2 'BOXSTYLE=SCHEMATICIDFAR';
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = schematicidfar
      nohlabel;
   id Reason;
   label Delay = 'Delay in Minutes';
run;
```

If you specify BOXSTYLE=SCHEMATICIDFAR, the value of the first ID variable is used to label each observation outside the lower and upper *far fences*. The lower and upper far fences are located 3×IQR below the 25th percentile and 3×IQR above the 75th percentile, respectively. Observations between the fences and the far fences are identified with a symbol but are not labeled. The box plot is shown in Output 24.3.4.

Output 24.3.4 BOXSTYLE=SCHEMATICIDFAR

Other options for controlling the display of high-resolution graphics box plots include the BOXWIDTH=, BOXWIDTHSCALE=, CBOXES=, CBOXFILL=, and LBOXES= options.



Example 24.4: Creating Notched Box-and-Whiskers Plots

The following statements use the flight delay data of Example 24.1 to create box-and-whiskers plots with notches:

```
title 'Analysis of Airline Departure Delays';
title2 'Using the NOTCHES Option';
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = schematicid
      nohlabel
      notches;
   id Reason;
   label Delay = 'Delay in Minutes';
run;
```

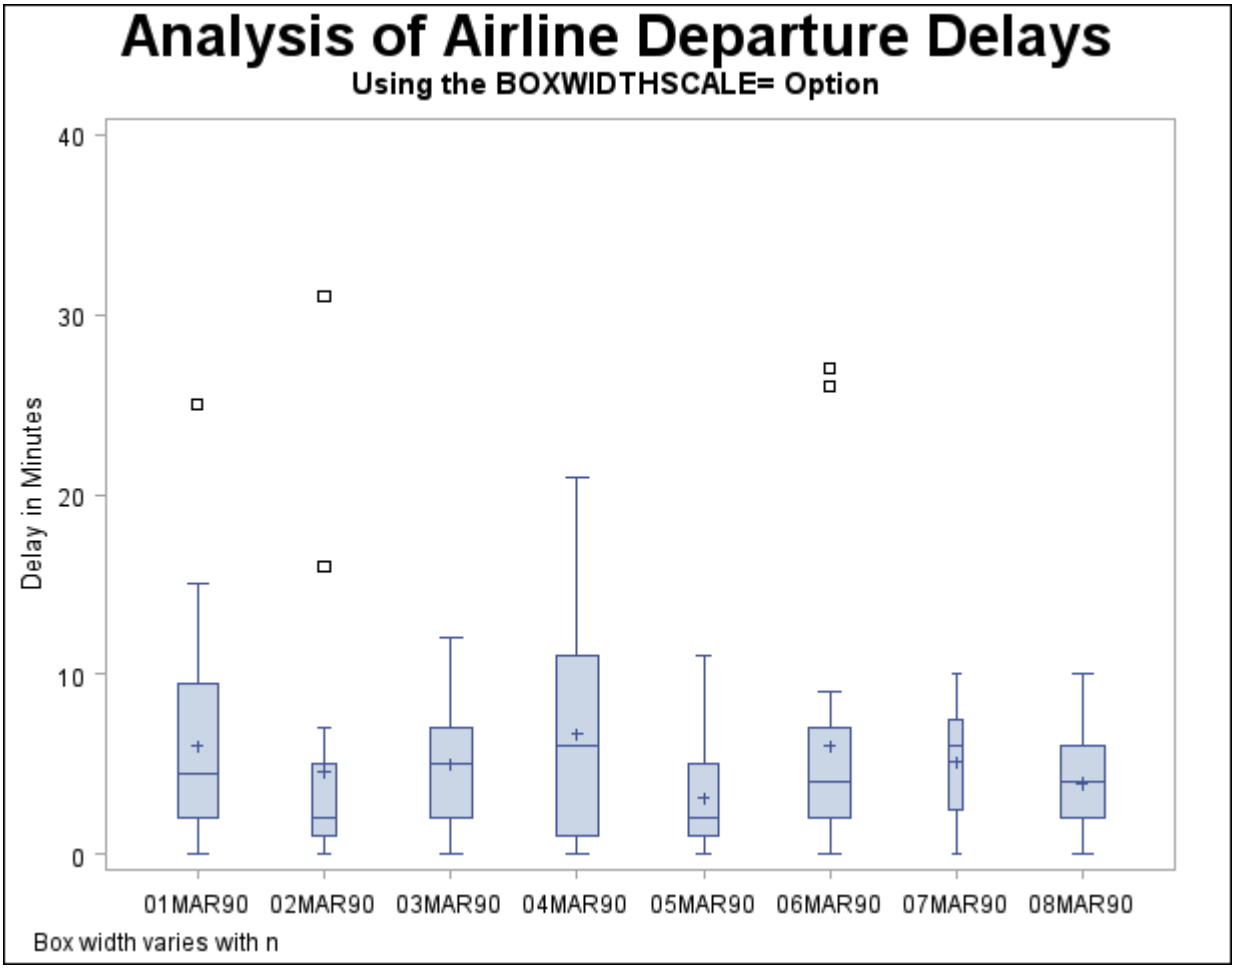
The notches, requested with the NOTCHES option, measure the significance of the difference between two medians. The medians of two box plots are significantly different at approximately the 0.95 confidence level if the corresponding notches do not overlap. For example, in Output 24.4.1, the median for December 20 is significantly different from the median for December 24.

Output 24.4.1 Notched Side-by-Side Box-and-Whiskers Plots

Example 24.5: Creating Box-and-Whiskers Plots with Varying Widths

This example shows how to create a box plot with box-and-whiskers plots whose widths vary proportionately with the group size. The following statements create a SAS data set named Times2 that contains flight departure delays (in minutes) recorded daily for eight consecutive days:

```
data Times2;
     label Delay = 'Delay in Minutes';
     informat Day date7. ;
     format   Day date7. ;
     input Day @ ;
     do Flight=1 to 25;
        input Delay @ ;
        output;
        end;
datalines;
01MAR90   12  4   2   2  15   8   0  11   0   0
           0 12   3   .   2   3   5   0   6  25
           7  4   9   5  10
02MAR90   1   .   3   .   0   1   5   0   .   .
          1   5   7   .   7   2   2  16   2   1
          3   1  31   .   0
03MAR90   6   8   4   2   3   2   7   6  11   3
          2   7   0   1  10   2   5  12   8   6
          2   7   2   4   5
04MAR90  12   6   9   0  15   7   1   1   0   2
          5   6   5  14   7  21   8   1  14   3
         11   0   1  11   7
05MAR90   2   1   0   4   .   6   2   2   1   4
          1  11   .   1   0   .   5   5   .   2
          3   6   6   4   0
06MAR90   8   6   5   2   9   7   4   2   5   1
          2   2   4   2   5   1   3   9   7   8
          1   0   4  26  27
07MAR90   9   6   6   2   7   8   .   .  10   8
          0   2   4   3   .   .   .   7   .   6
          4   0   .   .   .
08MAR90   1   6   6   2   8   8   5   3   5   0
          8   2   4   2   5   1   6   4   5  10
          2   0   4   1   1
run;
```



The following statements create a box plot with varying box widths:

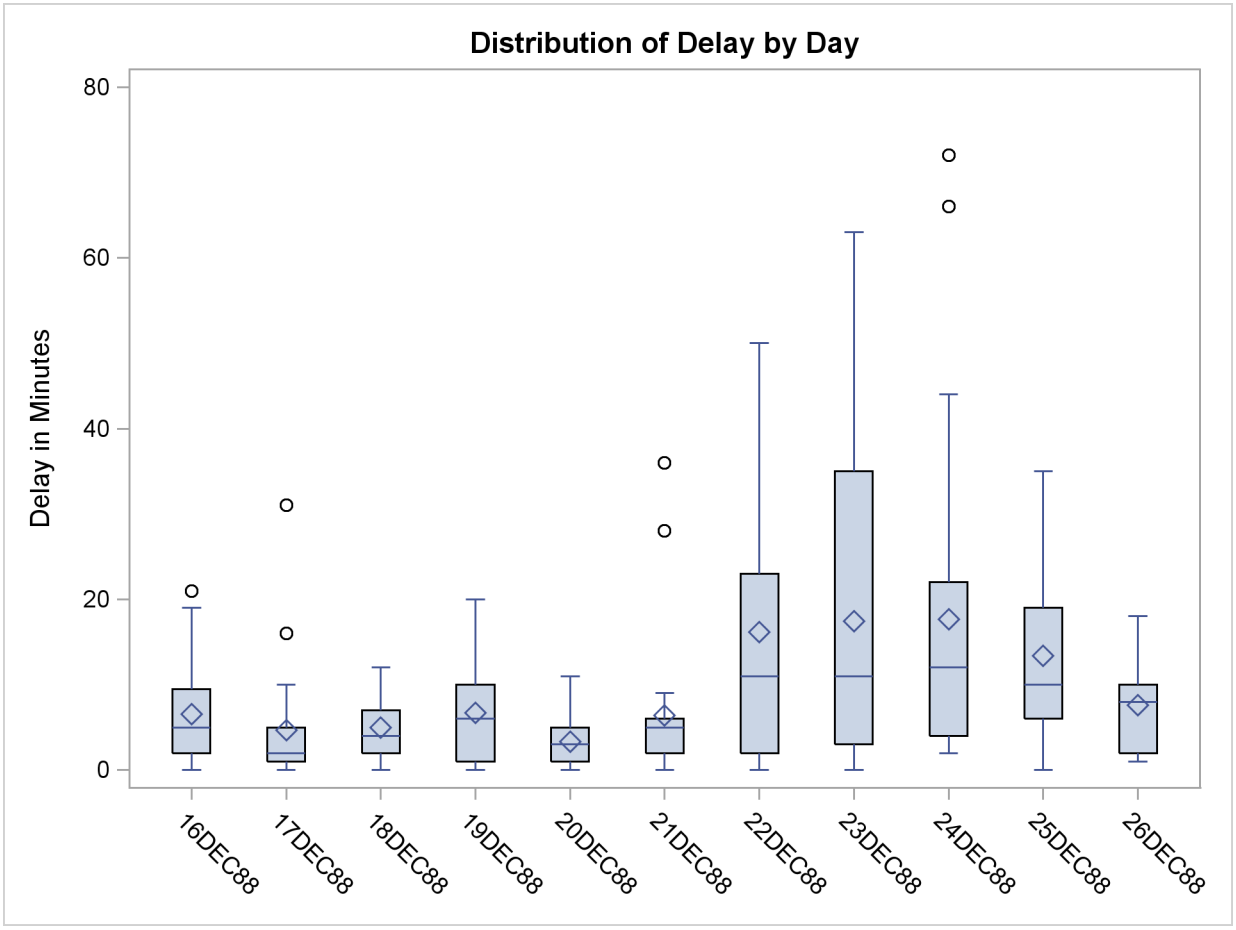
```
title 'Analysis of Airline Departure Delays';
title2 'Using the BOXWIDTHSCALE= Option';
proc boxplot data=Times2;
   plot Delay*Day /
      nohlabel
      boxstyle      = schematic
      boxwidthscale = 1
      bwslegend;
run;
```

The BOXWIDTHSCALE=*value* option specifies that the widths of the box-and-whiskers plots vary in proportion to a particular function of the group size n. The function is determined by *value* and is identified on the box plot with a legend if the BWSLEGEND option is specified. The BOXWIDTHSCALE= option is useful in situations where the group sizes vary widely.

Output 24.5.1 shows the resulting box plot.

Output 24.5.1 Box Plot with Box-and-Whiskers Plots of Varying Widths

Example 24.6: Creating Box-and-Whiskers Plots Using ODS Graphics (Experimental)



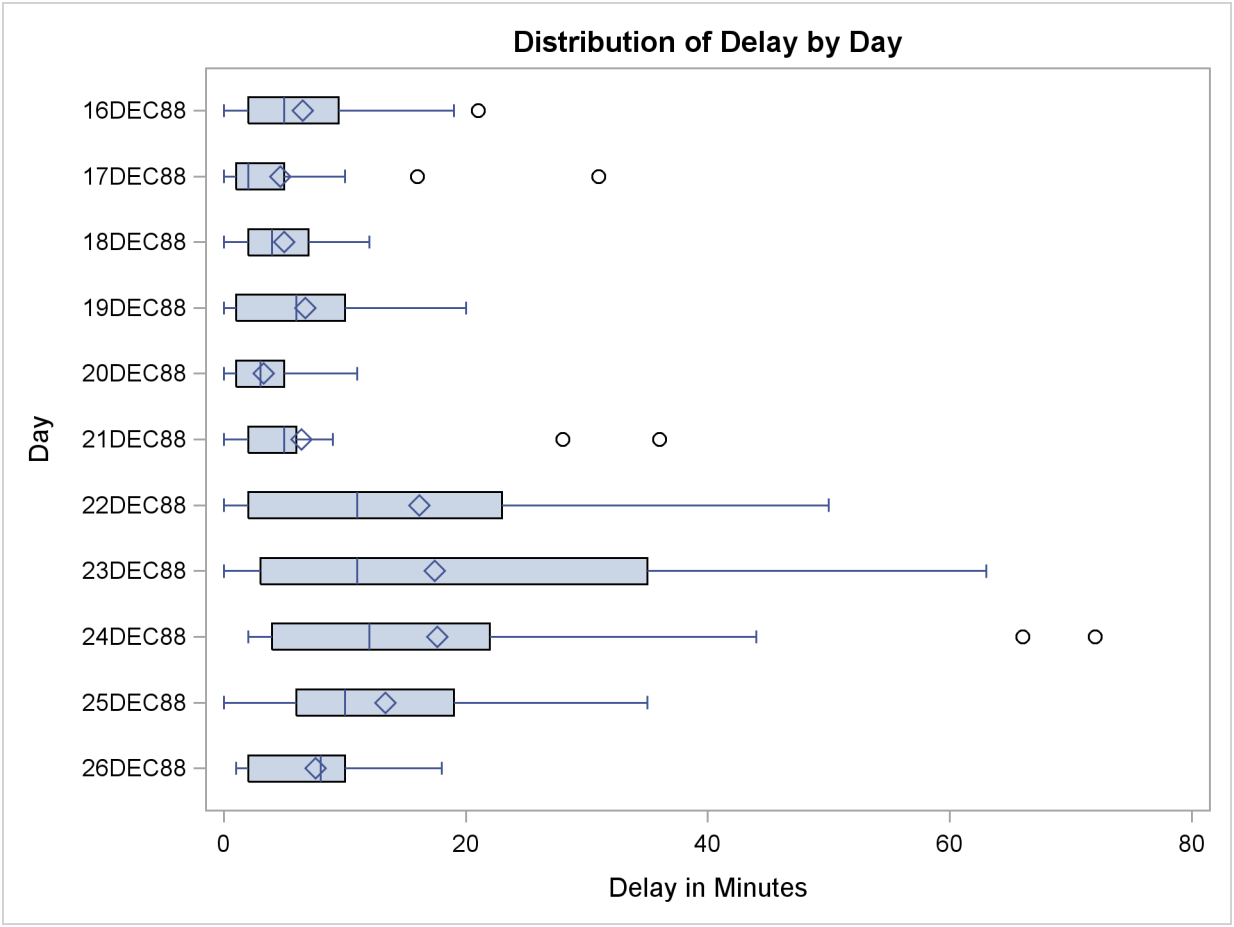
The BOXPLOT procedure supports ODS Graphics on an experimental basis for SAS 9.2.

The following statements use ODS Graphics to produce a box plot of the flight delay data from Example 24.2. You invoke ODS Graphics with the ODS GRAPHICS ON statement.

```
ods graphics on;
title 'Box Plot for Airline Delays';
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = schematic
      nohlabel;
   label Delay = 'Delay in Minutes';
run;
```

The resulting box plot is shown in Output 24.6.1.

Output 24.6.1 Box Plot Produced Using ODS Graphics



ODS graphical displays, like traditional high-resolution graphs in SAS 9.2, are controlled by the ODS style currently in effect for the output destination where the box plots are produced. However, unlike high-resolution graphs, ODS graphs are unaffected by GOPTIONS and SYMBOL statements, and by PLOT statement options used to specify colors, fonts, and other features affecting box plot appearance. Options such as BOXSTYLE= and NOHLABEL *are* honored by the PLOT statement when producing ODS graphical output.

The following statements use the HORIZONTAL option, which is supported only by ODS Graphics, to produce a horizontal box plot:

```
title 'Box Plot for Airline Delays';
proc boxplot data=Times;
   plot Delay*Day /
      boxstyle = schematic
      horizontal;
   label Delay = 'Delay in Minutes';
run;
ods graphics off;
```

The horizontal box plot is shown in Output 24.6.2.

Output 24.6.2 Horizontal Box Plot

Overview: CALIS Procedure

Structural equation modeling is an important statistical tool in economics and behavioral sciences. Structural equations express relationships among several variables that can be either directly observed variables (manifest variables) or unobserved hypothetical variables (latent variables). For an introduction to latent variable models, refer to Loehlin (1987), Bollen (1989b), Everitt (1984), or Long (1983); and for manifest variables, refer to Fuller (1987).

In structural models, as opposed to functional models, all variables are taken to be random rather than having fixed levels. For maximum likelihood (default) and generalized least squares estimation in PROC CALIS, the random variables are assumed to have an approximately multivariate normal distribution. Nonnormality, especially high kurtosis, can produce poor estimates and grossly incorrect standard errors and hypothesis tests, even in large samples. Consequently, the assumption of normality is much more important than in models with nonstochastic exogenous variables. You should remove outliers and consider transformations of nonnormal variables before using PROC CALIS with maximum likelihood (default) or generalized least squares estimation. If the number of observations is sufficiently large, Browne's asymptotically distribution-free (ADF) estimation method can be used.

You can use the CALIS procedure to estimate parameters and test hypotheses for constrained and unconstrained problems in the following:

- multiple and multivariate linear regression
- linear measurement-error models
- path analysis and causal modeling
- simultaneous equation models with reciprocal causation
- exploratory and confirmatory factor analysis of any order
- canonical correlation
- a wide variety of other (non)linear latent variable models

The parameters are estimated using the following criteria:

- unweighted least squares (ULS)
- generalized least squares (GLS, with optional weight matrix input)
- maximum likelihood (ML, for multivariate normal data)
- weighted least squares (WLS, ADF, with optional weight matrix input)
- diagonally weighted least squares (DWLS, with optional weight matrix input)

The default weight matrix for generalized least squares estimation is the sample covariance or correlation matrix. The default weight matrix for weighted least squares estimation is an estimate of the asymptotic covariance matrix of the sample covariance or correlation matrix. In this case, weighted least squares estimation is equivalent to Browne's (1982, 1984) asymptotic distribution-free estimation. The default weight matrix for diagonally weighted least squares estimation is an estimate of the asymptotic variances of the input sample covariance or correlation matrix. You can also use an input data set to specify the weight matrix in GLS, WLS, and DWLS estimation.

Estimation methods implemented in PROC CALIS do not exhaust all alternatives in the field. For example, partial least squares (PLS) is not implemented. See the section "Estimation Criteria" on page 923 for details about estimation criteria used in PROC CALIS. Note that there is a SAS/STAT procedure called PROC PLS, which employs the partial least squares technique but for a class of models different from those of PROC CALIS. For general path analysis or structural equation model with latent variables you should consider using PROC CALIS.

You can specify the model in several ways:

- If you have a set of structural equations to describe the model, you can use an equation-type LINEQS statement similar to that originally developed by Bentler (1985).
- You can specify simple path models by using an easily formulated list-type RAM statement similar to that originally developed by McArdle (McArdle and McDonald 1984).

- You can do a constrained (confirmatory) first-order factor analysis or component analysis by using the FACTOR statement.
- You can analyze a broad family of matrix models by using COSAN and MATRIX statements that are similar to the COSAN program of McDonald and Fraser (McDonald 1978, 1980). It enables you to specify complex matrix models including nonlinear equation models and higher-order factor models.

You can specify linear and nonlinear equality and inequality constraints on the parameters with several different statements, depending on the type of input. Lagrange multiplier test indices are computed for simple constant and equality parameter constraints and for active boundary constraints. General equality and inequality constraints can be formulated using programming statements. For more information, see the section "SAS Programming Statements" on page 903.

PROC CALIS offers a variety of methods for the automatic generation of initial values for the optimization process:

- two-stage least squares estimation
- instrumental variable factor analysis
- approximate factor analysis
- ordinary least squares estimation
- McDonald's (McDonald and Hartmann 1992) method

In many common applications, these initial values prevent computational problems and save computer time.

Because numerical problems can occur in the (non)linearly constrained optimization process, the CALIS procedure offers several optimization algorithms:

- Levenberg-Marquardt algorithm (Moré, 1978)
- trust-region algorithm (Gay 1983)
- Newton-Raphson algorithm with line search
- ridge-stabilized Newton-Raphson algorithm
- various quasi-Newton and dual quasi-Newton algorithms: Broyden-Fletcher-Goldfarb-Shanno and Davidon-Fletcher-Powell, including a sequential quadratic programming algorithm for processing nonlinear equality and inequality constraints
- various conjugate gradient algorithms: automatic restart algorithm of Powell (1977), Fletcher-Reeves, Polak-Ribiere, and conjugate descent algorithm of Fletcher (1980)

The quasi-Newton and conjugate gradient algorithms can be modified by several line-search methods. All of the optimization techniques can impose simple boundary and general linear constraints on the parameters. Only the dual quasi-Newton algorithm is able to impose general nonlinear equality and inequality constraints.

The procedure creates an OUTRAM= output data set that completely describes the model (except for program statements) and also contains parameter estimates. This data set can be used as input for another execution of PROC CALIS. Small model changes can be made by editing this data set, so you can exploit the old parameter estimates as starting values in a subsequent analysis. An OUTEST= data set contains information about the optimal parameter estimates (parameter estimates, gradient, Hessian, projected Hessian and Hessian of Lagrange function for constrained optimization, the information matrix, and standard errors). The OUTEST= data set can be used as an INEST= data set to provide starting values and boundary and linear constraints for the parameters. An OUTSTAT= data set contains residuals and, for exploratory factor analysis, the rotated and unrotated factor loadings.

Automatic variable selection (using only those variables from the input data set that are used in the model specification) is performed in connection with the RAM and LINEQS input statements or when these models are recognized in an input model file. Also in these cases, the covariances of the exogenous manifest variables are recognized as given constants. With the PREDET option, you can display the predetermined pattern of constant and variable elements in the predicted model matrix before the minimization process starts. For more information, see the section "Automatic Variable Selection" on page 942 and the section "Exogenous Manifest Variables" on page 943.

PROC CALIS offers an analysis of linear dependencies in the information matrix (approximate Hessian matrix) that might be helpful in detecting unidentified models. You also can save the information matrix and the approximate covariance matrix of the parameter estimates (inverse of the information matrix), together with parameter estimates, gradient, and approximate standard errors, in an output data set for further analysis.

PROC CALIS does not provide the analysis of multiple samples with different sample size or a generalized algorithm for missing values in the data. However, the analysis of multiple samples with equal sample size can be performed by the analysis of a moment supermatrix containing the individual moment matrices as block diagonal submatrices.

The new experimental procedure TCALIS is now available. Except for the COSAN model specification, PROC TCALIS supports almost all model specification methods that are available in the CALIS procedure. In addition, there are many new features in PROC TCALIS, including a PATH statement that enables you to specify models by using a path-like syntax, an MSTRUCT statement that enables you to specify patterned covariance structures directly, multiple-group analysis, enhanced mean and covariance structure analysis, a priori parametric function testing, effect analysis with standard error estimates, and more. For more information, see Chapter 88, "The TCALIS Procedure (Experimental)."

The CALIS procedure uses ODS Graphics to create graphs as part of its output. High-quality residual histograms are available in PROC CALIS. See Chapter 21, "Statistical Graphics Using ODS," for general information about ODS Graphics. See the section "ODS Graphics" on page 970 and the PLOTS= option on page 864 for specific information about the statistical graphics available with the CALIS procedure.

Structural Equation Models

The Generalized COSAN Model

PROC CALIS can analyze matrix models of the form

$$\mathbf{C} = \mathbf{F}_1\mathbf{P}_1\mathbf{F}_1' + \cdots + \mathbf{F}_m\mathbf{P}_m\mathbf{F}_m'$$

where $\mathbf{C}$ is a symmetric correlation or covariance matrix, each matrix $\mathbf{F}_k$, $k = 1, \ldots, m$, is the product of $n(k)$ matrices $\mathbf{F}_{k_1}, \ldots, \mathbf{F}_{k_{n(k)}}$, and each matrix $\mathbf{P}_k$ is symmetric; that is,

$$\mathbf{F}_k = \mathbf{F}_{k_1} \cdots \mathbf{F}_{k_{n(k)}} \qquad \text{and} \quad \mathbf{P}_k = \mathbf{P}_k', \quad k = 1, \ldots, m$$

The matrices $\mathbf{F}_{k_j}$ and $\mathbf{P}_k$ in the model are parameterized by the matrices $\mathbf{G}_{k_j}$ and $\mathbf{Q}_k$

$$\mathbf{F}_{k_j} = \begin{cases} \mathbf{G}_{k_j} \\ \mathbf{G}_{k_j}^{-1} \\ (\mathbf{I} - \mathbf{G}_{k_j})^{-1} \end{cases} \qquad j = 1, \ldots, n(k) \qquad \text{and} \qquad \mathbf{P}_k = \begin{cases} \mathbf{Q}_k \\ \mathbf{Q}_k^{-1} \end{cases}$$

where you can specify the type of matrix desired.

The matrices $\mathbf{G}_{k_j}$ and $\mathbf{Q}_k$ can contain the following:

- constant values
- parameters to be estimated
- values computed from parameters via programming statements

The parameters can be summarized in a parameter vector $\mathbf{X} = (x_1, \ldots, x_t)$. For a given covariance or correlation matrix $\mathbf{C}$, PROC CALIS computes the unweighted least squares (ULS), generalized least squares (GLS), maximum likelihood (ML), weighted least squares (WLS), or diagonally weighted least squares (DWLS) estimates of the vector $\mathbf{X}$.

Some Special Cases of the Generalized COSAN Model

Original COSAN (Covariance Structure Analysis) Model (McDonald 1978, 1980)

Covariance structure:

$$\mathbf{C} = \mathbf{F}_1 \cdots \mathbf{F}_n\mathbf{P}\mathbf{F}_n' \cdots \mathbf{F}_1'$$

Reticular Action Model—RAM (McArdle 1980; McArdle and McDonald 1984)

Structural equation model:

$$\mathbf{v} = \mathbf{A}\mathbf{v} + \mathbf{u}$$

where $\mathbf{A}$ is a matrix of coefficients, and $\mathbf{v}$ and $\mathbf{u}$ are vectors of random variables. The variables in $\mathbf{v}$ and $\mathbf{u}$ can be manifest or latent variables. The endogenous variables corresponding to the components in $\mathbf{v}$ are expressed as a linear combination of the remaining variables and a residual component in $\mathbf{u}$ with covariance matrix $\mathbf{P}$.

Covariance structure:

$$\mathbf{C} = \mathbf{J}(\mathbf{I} - \mathbf{A})^{-1}\mathbf{P}((\mathbf{I} - \mathbf{A})^{-1})'\mathbf{J}'$$

with selection matrix $\mathbf{J}$ and

$$\mathbf{C} = \mathcal{E}\{\mathbf{J}\mathbf{v}\mathbf{v}'\mathbf{J}'\} \qquad \text{and} \qquad \mathbf{P} = \mathcal{E}\{\mathbf{u}\mathbf{u}'\}$$

LINEQS (Linear Equations) Model (Bentler and Weeks 1980)

Structural equation model:

$$\eta = \beta\eta + \gamma\xi$$

where β and γ are coefficient matrices, and η and ξ are vectors of random variables. The components of η correspond to the endogenous variables; the components of ξ correspond to the exogenous variables and to error variables. The variables in η and ξ can be manifest or latent variables. The endogenous variables in η are expressed as a linear combination of the remaining endogenous variables, the exogenous variables in ξ, and a residual component in ξ. The coefficient matrix β describes the relationships among the endogenous variables of η, and $I - \beta$ should be nonsingular. The coefficient matrix γ describes the relationships between the endogenous variables of η and the exogenous and error variables of ξ.

Covariance structure:

$$\mathbf{C} = \mathbf{J}(\mathbf{I} - \mathbf{B})^{-1}\mathbf{\Gamma}\mathbf{\Phi}\mathbf{\Gamma}'((\mathbf{I} - \mathbf{B})^{-1})'\mathbf{J}'$$

with selection matrix $\mathbf{J}$, $\mathbf{\Phi} = \mathcal{E}\{\xi\xi'\}$, and

$$\mathbf{B} = \begin{pmatrix} \beta & 0 \\ 0 & 0 \end{pmatrix} \qquad \text{and} \qquad \mathbf{\Gamma} = \begin{pmatrix} \gamma \\ \mathbf{I} \end{pmatrix}$$

Keesling-Wiley-Jöreskog LISREL (Linear Structural Relationship) Model (Keesling 1972; Wiley 1973; Jöreskog 1973)

Structural equation model and measurement models:

$$\eta = \mathbf{B}\eta + \mathbf{\Gamma}\xi + \zeta \quad , \qquad \mathbf{y} = \mathbf{\Lambda}_y\eta + \varepsilon \quad , \qquad \mathbf{x} = \mathbf{\Lambda}_x\xi + \delta$$

where η and ξ are vectors of latent variables (factors), and $\mathbf{x}$ and $\mathbf{y}$ are vectors of manifest variables. The components of η correspond to endogenous latent variables; the components of ξ correspond to exogenous latent variables. The endogenous and exogenous latent variables are connected by a system of linear equations (the structural model) with coefficient matrices $\mathbf{B}$ and $\mathbf{\Gamma}$ and an error vector ζ. It is assumed that matrix $\mathbf{I} - \mathbf{B}$ is nonsingular. The random vectors $\mathbf{y}$ and $\mathbf{x}$ correspond to manifest variables that are related to the latent variables η and ξ by two systems of linear equations (the measurement model) with coefficients $\mathbf{\Lambda}_y$ and $\mathbf{\Lambda}_x$ and with measurement errors ε and δ.

Covariance structure:

$$\begin{aligned} \mathbf{C} &= \mathbf{J}(\mathbf{I}-\mathbf{A})^{-1}\mathbf{P}((\mathbf{I}-\mathbf{A})^{-1})'\mathbf{J}' \\ A &= \begin{pmatrix} 0 & 0 & \mathbf{\Lambda}_y & 0 \\ 0 & 0 & 0 & \mathbf{\Lambda}_x \\ 0 & 0 & \mathbf{B} & \mathbf{\Gamma} \\ 0 & 0 & 0 & 0 \end{pmatrix} \quad \text{and} \quad P = \begin{pmatrix} \mathbf{\Theta}_{\boldsymbol{\varepsilon}} & & & \\ & \mathbf{\Theta}_{\boldsymbol{\delta}} & & \\ & & \mathbf{\Psi} & \\ & & & \mathbf{\Phi} \end{pmatrix} \end{aligned}$$

with selection matrix $\mathbf{J}$, $\mathbf{\Phi} = \mathcal{E}\{\boldsymbol{\xi}\boldsymbol{\xi}'\}$, $\mathbf{\Psi} = \mathcal{E}\{\boldsymbol{\zeta}\boldsymbol{\zeta}'\}$, $\mathbf{\Theta}_\delta = \mathcal{E}\{\boldsymbol{\delta}\boldsymbol{\delta}'\}$, and $\mathbf{\Theta}_\varepsilon = \mathcal{E}\{\boldsymbol{\varepsilon}\boldsymbol{\varepsilon}'\}$.

Higher-Order Factor Analysis Models

First-order model:

$$\mathbf{C} = \mathbf{F}_1\mathbf{P}_1\mathbf{F}_1' + \mathbf{U}_1^2$$

Second-order model:

$$\mathbf{C} = \mathbf{F}_1\mathbf{F}_2\mathbf{P}_2\mathbf{F}_2'\mathbf{F}_1' + \mathbf{F}_1\mathbf{U}_2^2\mathbf{F}_1' + \mathbf{U}_1^2$$

First-Order Autoregressive Longitudinal Factor Model

Example of McDonald (1980): $k = 3$: Occasions of Measurement; $n = 3$: Variables (Tests); $m = 2$: Common Factors

$$\begin{aligned} \mathbf{C} &= \mathbf{F}_1\mathbf{F}_2\mathbf{F}_3\mathbf{L}\mathbf{F}_3^{-1}\mathbf{F}_2^{-1}\mathbf{P}(\mathbf{F}_2^{-1})'(\mathbf{F}_3^{-1})'\mathbf{L}'\mathbf{F}_3'\mathbf{F}_2'\mathbf{F}_1' + \mathbf{U}^2 \\ F_1 &= \begin{pmatrix} B_1 & & \\ & B_2 & \\ & & B_3 \end{pmatrix}, \quad F_2 = \begin{pmatrix} I_2 & & \\ & D_2 & \\ & & D_2 \end{pmatrix}, \quad F_3 = \begin{pmatrix} I_2 & & \\ & I_2 & \\ & & D_3 \end{pmatrix} \\ L &= \begin{pmatrix} I_2 & o & o \\ I_2 & I_2 & o \\ I_2 & I_2 & I_2 \end{pmatrix}, \quad P = \begin{pmatrix} I_2 & & \\ & S_2 & \\ & & S_3 \end{pmatrix}, \quad U = \begin{pmatrix} U_{11} & U_{12} & U_{13} \\ U_{21} & U_{22} & U_{23} \\ U_{31} & U_{32} & U_{33} \end{pmatrix} \\ S_2 &= I_2 - D_2^2 \quad , \qquad S_3 = I_2 - D_3^2 \end{aligned}$$

For more information about this model, see Example 25.6.

A Structural Equation Example

This example from Wheaton et al. (1977) illustrates the relationships among the RAM, LINEQS, and LISREL models. Different structural models for these data are in Jöreskog and Sörbom (1985) and in Bentler (1985, p. 28). The data set contains covariances among six (manifest) variables collected from 932 people in rural regions of Illinois:

Variable 1: V1, y_1 : Anomie 1967

Variable 2: V2, y_2 : Powerlessness 1967

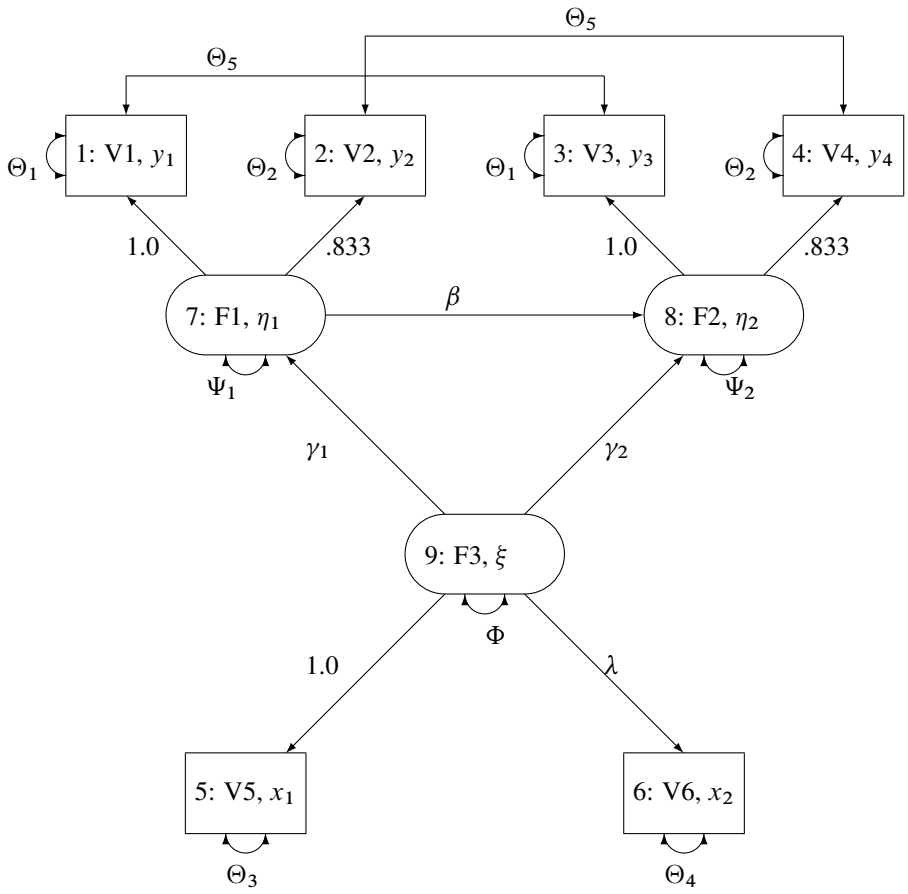
Variable 3: V3, y_3 : Anomie 1971

Variable 4: V4, y_4 : Powerlessness 1971

Variable 5: V5, x_1 : Education (years of schooling)

Variable 6: V6, x_2 : Duncan's Socioeconomic Index (SEI)

It is assumed that anomie and powerlessness are indicators of an alienation factor and that education and SEI are indicators for a socioeconomic status (SES) factor. Hence, the analysis contains three latent variables:



Variable 7: F1, η_1 : Alienation 1967

Variable 8: F2, η_2 : Alienation 1971

Variable 9: F3, ξ_1 : Socioeconomic Status (SES)

The following path diagram shows the structural model used in Bentler (1985, p. 29) and slightly modified in Jöreskog and Sörbom (1985, p. 56). In this notation for the path diagram, regression coefficients between the variables are indicated as one-headed arrows. Variances and covariances among the variables are indicated as two-headed arrows. Indicating error variances and covariances as two-headed arrows with the same source and destination (McArdle 1988; McDonald 1985) is helpful in transforming the path diagram to RAM model list input for the CALIS procedure.

Figure 25.1 Path Diagram of Stability and Alienation Example

Variables in Figure 25.1 are as follows:

Variable 1: V1, y_1 : Anomie 1967

Variable 2: V2, y_2 : Powerlessness 1967

Variable 3: V3, y_3 : Anomie 1971

Variable 4: V4, y_4 : Powerlessness 1971

Variable 5: V5, x_1 : Education (years of schooling)

Variable 6: V6, x_2 : Duncan's Socioeconomic Index (SEI)

Variable 7: F1, η_1 : Alienation 1967

Variable 8: F2, η_2 : Alienation 1971

Variable 9: F3, ξ_1 : Socioeconomic Status (SES)

LINEQS Model

The vector $\boldsymbol{\eta}$ contains the six endogenous manifest variables V1, ..., V6 and the two endogenous latent variables F1 and F2. The vector $\boldsymbol{\xi}$ contains the exogenous error variables E1, ..., E6, D1, and D2 and the exogenous latent variable F3. The path diagram corresponds to the following set of structural equations of the LINEQS model:

$$\begin{aligned}
V1 &= 1.000F1 + E1 \\
V2 &= 0.833F1 + E2 \\
V3 &= 1.000F2 + E3 \\
V4 &= 0.833F2 + E4 \\
V5 &= 1.000F3 + E5 \\
V6 &= \lambda F3 + E6 \\
F1 &= \gamma_1 F3 + D1 \\
F2 &= \beta F1 + \gamma_2 F3 + D2
\end{aligned}$$

This gives the matrices $\boldsymbol{\beta}$, $\boldsymbol{\gamma}$, and $\boldsymbol{\Phi}$ in the LINEQS model:

$$\boldsymbol{\beta} = \begin{pmatrix}
o & o & o & o & o & o & 1.000 & o \\
o & o & o & o & o & o & 0.833 & o \\
o & o & o & o & o & o & o & 1.000 \\
o & o & o & o & o & o & o & 0.833 \\
o & o & o & o & o & o & o & o \\
o & o & o & o & o & o & o & o \\
o & o & o & o & o & o & o & o \\
o & o & o & o & o & o & \beta & o
\end{pmatrix}, \quad
\boldsymbol{\gamma} = \begin{pmatrix}
1 & o & o & o & o & o & o & o & o \\
o & 1 & o & o & o & o & o & o & o \\
o & o & 1 & o & o & o & o & o & o \\
o & o & o & 1 & o & o & o & o & o \\
o & o & o & o & 1 & o & o & o & 1.000 \\
o & o & o & o & o & 1 & o & o & \lambda \\
o & o & o & o & o & o & 1 & o & \gamma_1 \\
o & o & o & o & o & o & o & 1 & \gamma_2
\end{pmatrix}$$

$$\boldsymbol{\Phi} = \begin{pmatrix}
\theta_1 & o & \theta_5 & o & o & o & o & o & o \\
o & \theta_2 & o & \theta_5 & o & o & o & o & o \\
\theta_5 & o & \theta_1 & o & o & o & o & o & o \\
o & \theta_5 & o & \theta_2 & o & o & o & o & o \\
o & o & o & o & \theta_3 & o & o & o & o \\
o & o & o & o & o & \theta_4 & o & o & o \\
o & o & o & o & o & o & \psi_1 & o & o \\
o & o & o & o & o & o & o & \psi_2 & o \\
o & o & o & o & o & o & o & o & \phi
\end{pmatrix}$$

The LINEQS model input specification of this example for the CALIS procedure is given in the section "LINEQS Model Specification" on page 841.

RAM Model

The vector **v** contains the six manifest variables v_1 =V1, ..., v_6 =V6 and the three latent variables v_7 =F1, v_8 =F2, v_9 =F3. The vector **u** contains the corresponding error variables u_1 =E1, ..., u_6 =E6 and u_7 =D1, u_8 =D2, u_9 =D3. The path diagram corresponds to the following set of

structural equations of the RAM model:

$$
\begin{aligned}
v_1 &= 1.000v_7 + u_1 \\
v_2 &= 0.833v_7 + u_2 \\
v_3 &= 1.000v_8 + u_3 \\
v_4 &= 0.833v_8 + u_4 \\
v_5 &= 1.000v_9 + u_5 \\
v_6 &= \lambda v_9 + u_6 \\
v_7 &= \gamma_1 v_9 + u_7 \\
v_8 &= \beta v_7 + \gamma_2 v_9 + u_8 \\
v_9 &= u_9
\end{aligned}
$$

This gives the matrices **A** and **P** in the RAM model:

$$
\mathbf{A} = \begin{pmatrix}
o & o & o & o & o & o & 1.000 & o & o \\
o & o & o & o & o & o & 0.833 & o & o \\
o & o & o & o & o & o & o & 1.000 & o \\
o & o & o & o & o & o & o & 0.833 & o \\
o & o & o & o & o & o & o & o & 1.000 \\
o & o & o & o & o & o & o & o & \lambda \\
o & o & o & o & o & o & o & o & \gamma_1 \\
o & o & o & o & o & o & \beta & o & \gamma_2 \\
o & o & o & o & o & o & o & o & o
\end{pmatrix}
$$

$$
\mathbf{P} = \begin{pmatrix}
\theta_1 & o & \theta_5 & o & o & o & o & o & o \\
o & \theta_2 & o & \theta_5 & o & o & o & o & o \\
\theta_5 & o & \theta_1 & o & o & o & o & o & o \\
o & \theta_5 & o & \theta_2 & o & o & o & o & o \\
o & o & o & o & \theta_3 & o & o & o & o \\
o & o & o & o & o & \theta_4 & o & o & o \\
o & o & o & o & o & o & \psi_1 & o & o \\
o & o & o & o & o & o & o & \psi_2 & o \\
o & o & o & o & o & o & o & o & \phi
\end{pmatrix}
$$

The RAM model input specification of this example for the CALIS procedure is given in the section "RAM Model Specification" on page 842.

LISREL Model

The vector **y** contains the four endogenous manifest variables y_1 =V1, ..., y_4 =V4, and the vector **x** contains the exogenous manifest variables x_1 =V5 and x_2 =V6. The vector $\boldsymbol{\varepsilon}$ contains the error variables ε_1 =E1, ..., ε_4 =E4 corresponding to **y**, and the vector $\boldsymbol{\delta}$ contains the error variables δ_1 =E5 and δ_2 =E6 corresponding to **x**. The vector $\boldsymbol{\eta}$ contains the endogenous latent variables (factors) η_1 =F1 and η_2 =F2, while the vector $\boldsymbol{\xi}$ contains the exogenous latent variable (factor) ξ_1 =F3. The vector $\boldsymbol{\zeta}$ contains the errors ζ_1 =D1 and ζ_2 =D2 in the equations (disturbance terms)

corresponding to $\boldsymbol{\eta}$. The path diagram corresponds to the following set of structural equations of the LISREL model:

$$
\begin{aligned}
y_1 &= 1.000\eta_1 + \epsilon_1 \\
y_2 &= 0.833\eta_1 + \epsilon_2 \\
y_3 &= 1.000\eta_2 + \epsilon_3 \\
y_4 &= 0.833\eta_2 + \epsilon_4 \\
x_1 &= 1.000\xi_1 + \delta_1 \\
x_2 &= \lambda\xi_1 + \delta_2 \\
\eta_1 &= \gamma_1\xi_1 + \zeta_1 \\
\eta_2 &= \beta\eta_1 + \gamma_2\xi_1 + \zeta_2
\end{aligned}
$$

This gives the matrices $\boldsymbol{\Lambda}_y$, $\boldsymbol{\Lambda}_x$, $\mathbf{B}$, $\boldsymbol{\Gamma}$, and $\boldsymbol{\Phi}$ in the LISREL model:

$$
\boldsymbol{\Lambda}_y = \begin{pmatrix} 1.000 & o \\ 0.833 & o \\ o & 1.000 \\ o & 0.833 \end{pmatrix}, \boldsymbol{\Lambda}_x = \begin{pmatrix} 1. \\ \lambda \end{pmatrix}, \mathbf{B} = \begin{pmatrix} o & o \\ \beta & o \end{pmatrix}, \boldsymbol{\Gamma} = \begin{pmatrix} \gamma_1 \\ \gamma_2 \end{pmatrix}
$$

$$
\boldsymbol{\Theta}_\varepsilon^2 = \begin{pmatrix} \theta_1 & o & \theta_5 & o \\ o & \theta_2 & o & \theta_5 \\ \theta_5 & o & \theta_1 & o \\ o & \theta_5 & o & \theta_2 \end{pmatrix}, \boldsymbol{\Theta}_\delta^2 = \begin{pmatrix} \theta_3 & o \\ \theta_4 & o \end{pmatrix}, \boldsymbol{\Psi} = \begin{pmatrix} \psi_1 & o \\ o & \psi_2 \end{pmatrix}, \boldsymbol{\Phi} = (\phi)
$$

The CALIS procedure does not provide a LISREL model input specification. However, any model that can be specified by the LISREL model can also be specified by using the LINEQS, RAM, or COSAN model specifications in PROC CALIS.

Getting Started: CALIS Procedure

Statements in the CALIS procedure are used for various purposes:

- PROC CALIS statement invokes the procedure.
- Main model specification statements: LINEQS, RAM, FACTOR, and COSAN. These statements define the model type and specify the main model.
- Subsidiary model specification statements: STD, COV, VARNAMES, MATRIX, and PARAMETERS. These statements define additional parameters and model features that supplement to the main model specification. The usage of these statements depends on the model type specified in the main model statement. See the section "The Model Type and Related Statements" on page 840 for more details.

- Statements for constraining parameters: BOUNDS, LINCON, and NLINCON. The SAS programming statements can also be used to constrain parameters. See the section "Constrained Estimation" on page 845 for more details.
- General data processing statements: BY, VAR, PARTIAL, FREQ, and WEIGHT. The usages of these statements are common to other SAS procedures.
- Other statements: The STRUCTEQ statement is used for defining "structural equations" in the model. The NLOPTIONS statement is used for fine-tuning the optimization techniques for the analysis. The SAS programming statements are used for computing dependent parametric functions that are useful for model specification or setting up constraints in the model.

The Model Type and Related Statements

There are four sets of statements available in the CALIS procedure to specify a model. Each set represents a model type supported by the CALIS procedure. For the LINEQS model with linear equations input, you can specify the following statements:

LINEQS *analysis model in equations notation*;
  STD *variance pattern*;
  COV *covariance pattern*;
  PARAMETERS *parameter names from programming statements*;

For the RAM model, you can specify the following statements:

RAM *analysis model in list notation*;
  VARNAMES *names of latent and error variables*;
  PARAMETERS *parameter names from programming statements*;

For the (confirmatory) factor model, you can specify the following statements:

FACTOR *options*;
  MATRIX *definition of matrix elements*;
  VARNAMES *names of latent and residual variables*;
  PARAMETERS *parameter names from programming statements*;

For the COSAN model, you can specify the following statements:

COSAN *analysis model in matrix notation*;
  MATRIX *definition of matrix elements* ;
  VARNAMES *names of additional variables* ;
  PARAMETERS *parameter names from programming statements*;

You can also specify a model by using an INRAM= data set, which is usually a version of an OUTRAM= data set produced by a previous PROC CALIS analysis (and possibly modified). If no INRAM= data set is specified, you must use one of the four main model specification statements that defines the analysis model: LINEQS, RAM, FACTOR, or COSAN.

LISREL model input is not directly supported in PROC CALIS. However, with careful constructions you can use either the LINEQS, RAM, or COSAN model input to specify a LISREL model equivalently.

In the following sections, each model type supported by the CALIS procedure is discussed in more details.

LINEQS Model Specification

By using notation similar to that originally developed by Bentler for his EQS program, you can also describe the model by a set of linear equations combined with variance and covariance specifications. The displayed output can be in either equation form or matrix form.

The following statements define the structural model of the alienation example as a LINEQS model:

```
lineqs
     V1 =          F1                    + E1,
     V2 =    .833 F1                     + E2,
     V3 =          F2                    + E3,
     V4 =    .833 F2                     + E4,
     V5 =          F3                    + E5,
     V6 = Lamb (.5) F3                   + E6,
     F1 = Gam1(-.5) F3                   + D1,
     F2 = Beta (.5) F1 + Gam2(-.5) F3 + D2;
std
     E1-E6 = The1-The2 The1-The4 (6 * 3.),
     D1-D2 = Psi1-Psi2 (2 * 4.),
     F3    = Phi (6.) ;
cov
     E1 E3 = The5 (.2),
     E4 E2 = The5 (.2);
```

The LINEQS statement shows the equations in the section "LINEQS Model" on page 837, except that in this case the coefficients to be estimated can be followed (optionally) by the initial value to use in the optimization process. If you do not specify initial values for the parameters in a LINEQS statement, PROC CALIS tries to assign these values automatically. The endogenous variables used on the left side can be manifest variables (with names that must be defined by the input data set) or latent variables (which must have names starting with F). The variables used on the right side can be manifest variables, latent variables (with names that must start with an F), or error variables (which must have names starting with an E or D). Commas separate the equations. The coefficients to be estimated are indicated by names. If no name is used, the coefficient is constant, either equal to a specified number or, if no number is used, equal to 1. The VAR statement in Bentler's notation is replaced here by the STD statement, because the VAR statement in PROC CALIS defines the subset of manifest variables in the data set to be analyzed. The variable names used in the STD or COV statement must be exogenous (that is, they should not occur on the left side of any equation). The STD and COV statements define the diagonal and off-diagonal elements in the $\mathbf{\Phi}$ matrix. The parameter specifications in the STD and COV statements are separated by commas. Using k variable names on the left of an equal sign in a COV statement means that the parameter list on the right side refers to all $k(k-1)/2$ distinct variable pairs in the $\mathbf{\Phi}$ matrix. Identical coefficient names indicate parameters constrained to be equal. You can also use prefix names to specify those parameters for which you do not need a precise name in any parameter constraint.

See the section "LINEQS Model Statement" on page 881 for more information about the precise syntax rules for a LINEQS statement.

RAM Model Specification

The RAM model enables a path diagram to be transcribed into a RAM statement in list form. The displayed output from the RAM statement is in matrix or list form.

The following statement defines the structural model of the alienation example as a RAM model:

```
ram
     1   1  7  1.       ,
     1   2  7  .833     ,
     1   3  8  1.       ,
     1   4  8  .833     ,
     1   5  9  1.       ,
     1   6  9  .5    Lamb ,
     1   7  9  -.5   Gam1 ,
     1   8  7  .5    Beta ,
     1   8  9  -.5   Gam2 ,
     2   1  1  3.    The1 ,
     2   2  2  3.    The2 ,
     2   3  3  3.    The1 ,
     2   4  4  3.    The2 ,
     2   5  5  3.    The3 ,
     2   6  6  3.    The4 ,
     2   1  3  .2    The5 ,
     2   2  4  .2    The5 ,
     2   7  7  4.    Psi1 ,
     2   8  8  4.    Psi2 ,
     2   9  9  6.    Phi ;
```

You must assign numbers to the nodes in the path diagram. In the path diagram of Figure 25.1, the boxes corresponding to the six manifest variables V1, ..., V6 are assigned the number of the variable in the covariance matrix (1, ..., 6); the circles corresponding to the three latent variables F1, F2, and F3 are given the numbers 7, 8, and 9. The path diagram contains 20 paths between the nine nodes; nine of the paths are one-headed arrows and eleven are two-headed arrows.

The RAM statement contains a list of items separated by commas. Each item corresponds to an arrow in the path diagram. The first entry in each item is the number of arrow heads (matrix number), the second entry shows where the arrow points to (row number), the third entry shows where the arrow comes from (column number), the fourth entry gives the (initial) value of the coefficient, and the fifth entry assigns a name if the path represents a parameter rather than a constant. If you specify the fifth entry as a parameter name, then the fourth list entry can be omitted, since PROC CALIS tries to assign an initial value to this parameter.

See the section "RAM Model Statement" on page 899 for more information about the RAM statement.

COSAN Model Specification

You specify the model for a generalized COSAN analysis with a COSAN statement and one or more MATRIX statements. The COSAN statement determines the name, dimension, and type (identity, diagonal, symmetric, upper, lower, general, inverse, and so forth) of each matrix in the model. You can specify the values of the constant elements in each matrix and give names and initial values to

the elements that are to be estimated as parameters or functions of parameters by using MATRIX statements. The resulting displayed output is in matrix form.

The following statements define the structural model of the alienation example as a COSAN model:

```
cosan J(9, Ide) * A(9, Gen, Imi) * P(9, Sym);
matrix A
          [ ,7] = 1. .833  5 * 0. Beta (.5) ,
          [ ,8] = 2 * 0.  1.  .833 ,
          [ ,9] = 4 * 0.  1.  Lamb Gam1-Gam2 (.5 2 * -.5);
matrix P
          [1,1] = The1-The2 The1-The4 (6 * 3.) ,
          [7,7] = Psi1-Psi2 Phi (2 * 4. 6.) ,
          [3,1] = The5 (.2) ,
          [4,2] = The5 (.2) ;
```

The matrix model specified in the COSAN statement is the RAM model

$$\mathbf{C} = \mathbf{J}(\mathbf{I} - \mathbf{A})^{-1}\mathbf{P}((\mathbf{I} - \mathbf{A})^{-1})'\mathbf{J}'$$

with selection matrix **J** and

$$\mathbf{C} = \mathcal{E}\{\mathbf{J}\mathbf{v}\mathbf{v}'\mathbf{J}'\}, \qquad \mathbf{P} = \mathcal{E}\{\mathbf{u}\mathbf{u}'\}$$

The COSAN statement must contain only the matrices up to the central matrix **P** because of the symmetry of each matrix term in a COSAN model. Each matrix name is followed by one to three arguments in parentheses. The first argument is the number of columns. The second and third arguments are optional, and they specify the form of the matrix. The selection matrix **J** in the RAM model is specified by the 6×9 identity (IDE) (sub)matrix **J** because the first six variables in vector **v** correspond to the six manifest variables in the data set. The 9×9 parameter matrix **A** has a general (GEN) form and is used as $(\mathbf{I} - \mathbf{A})^{-1}$ in the analysis, as indicated by the identity-minus-inverse (IMI) argument. The central 9×9 matrix P is specified as a symmetric (SYM) matrix.

The MATRIX statement for matrix **A** specifies the values in columns 7, 8, and 9, which correspond to the three latent variables F1, F2, and F3, in accordance with the RAM model. The other columns of **A** are assumed to be zero. The initial values for the parameter elements in **A** are chosen as in the path diagram to be

$$\lambda = \beta = 0.5, \qquad \gamma_1 = \gamma_2 = -0.5$$

In accordance with matrix **P** of the RAM model and the path model, the nine diagonal elements of matrix **P** are parameters with initial values

$$\theta_1 = \theta_2 = \theta_3 = \theta_4 = 3, \quad \psi_1 = \psi_2 = 4, \quad \phi = 6$$

There are also two off-diagonal elements in each triangle of **P** that are constrained to be equal, and they have an initial value of 0.2.

See the section "COSAN Model Statement" on page 873 for more information about the COSAN statement.

FACTOR Model Specification

You can specify the FACTOR statement to compute factor loadings **F** and unique variances **U** of an exploratory or confirmatory first-order factor (or component) analysis. By default, the factor correlation matrix **P** is an identity matrix.

$$\mathbf{C} = \mathbf{F}\mathbf{F}' + \mathbf{U}, \quad \mathbf{U} = diag$$

For a first-order confirmatory factor analysis, you can use MATRIX statements to define elements in the matrices **F**, **P**, and **U** of the more general model

$$\mathbf{C} = \mathbf{F}\mathbf{P}\mathbf{F}' + \mathbf{U}, \quad \mathbf{P} = \mathbf{P}', \quad \mathbf{U} = diag$$

To perform a component analysis, specify the COMPONENT option to constrain the matrix **U** to a zero matrix; that is, the model is replaced by

$$\mathbf{C} = \mathbf{F}\mathbf{F}'$$

Note that the rank of $\mathbf{F}\mathbf{F}'$ is equal to the number m of components in **F**, and if m is smaller than the number of variables in the moment matrix **C**, the matrix of predicted model values is singular and maximum likelihood estimates for **F** cannot be computed. You should compute ULS estimates in this case.

The HEYWOOD option constrains the diagonal elements of **U** to be nonnegative; that is, the model is replaced by

$$\mathbf{C} = \mathbf{F}\mathbf{F}' + \mathbf{U}^2, \quad \mathbf{U} = diag$$

If the factor loadings are unconstrained, they can be orthogonally rotated by one of the following methods:

- principal axes rotation
- quartimax
- varimax
- equamax
- parsimax

The most common approach to factor analysis consists of two steps:

1. Obtain estimates for factor loadings and unique variances.
2. Apply an orthogonal or oblique rotation method.

PROC CALIS enables you to specify general linear and nonlinear equality and inequality constraints by using the LINCON and NLINCON statements. You can specify the NLINCON statement to estimate orthogonal or oblique rotated factor loadings; refer to Browne and Du Toit (1992). Unlike PROC FACTOR, PROC CALIS currently does not provide standard errors for the rotated factor loadings.

PROC CALIS also computes the factor score regression coefficients for the final factor solution.

For default (exploratory) factor analysis, PROC CALIS computes initial estimates. If you use a MATRIX statement together with a FACTOR model specification, initial values are generally computed by McDonald's (McDonald and Hartmann 1992) method or are set by the START= option. See the section "FACTOR Model Statement" on page 877 and Example 25.3 for more information about the FACTOR statement.

Constrained Estimation

- Simple equality constraints, $x_i = c_i$, $c_i = const$, and $x_i = x_j$, can be defined in each model by specifying constants or using the same name for parameters constrained to be equal.
- BOUNDS statement: You can specify boundary constraints, $l_i \le x_i \le u_i$, l_i, $u_i = const$, with the BOUNDS statement for the COSAN, LINEQS, and RAM models and in connection with an INRAM= data set. There might be serious convergence problems if negative values appear in the diagonal locations (variances) of the central model matrices during the minimization process. You can use the BOUNDS statement to constrain these parameters to have nonnegative values.
- LINCON statement: You can specify general linear equality and inequality constraints of the parameter estimates with the LINCON statement or by using an INEST= data set. The variables listed in the LINCON statements must be (a subset of) the model parameters. All optimization methods can be used with linear constraints.
- NLINCON statement: You can specify general nonlinear equality and inequality constraints of the parameter estimates with the NLINCON statement. The syntax of the NLINCON statement is almost the same as that for the BOUNDS statement with the exception that the BOUNDS statement can contain only names of the model parameters. However, the variables listed in the NLINCON statement can be defined by programming statements. Only the quasi-Newton optimization method can be used when there are nonlinear constraints.
- Reparameterizing the model: Complex linear equality and inequality constraints can be defined by means of programming statements similar to those used in the DATA step. In this case, some of the parameters x_i are not elements of the matrices $\mathbf{G}_{kj}$ and $\mathbf{Q}_k$ but are instead defined in a PARAMETERS statement. Elements of the model matrices can then be computed by programming statements as functions of parameters in the PARAMETERS statement. This approach is similar to the classical COSAN program of McDonald, implemented by Fraser (McDonald 1978, 1980). One advantage of the CALIS procedure is that you need not supply code for the derivatives of the specified functions. The analytic derivatives of the user-written functions are computed automatically by PROC CALIS. The specified functions must be continuous and have continuous first-order partial derivatives. See the section "SAS Programming Statements" on page 903 and the section "Constrained Estimation by

Using Program Code" on page 955 for more information about imposing linear and nonlinear restrictions on parameters by using programming statements.

Although much effort has been made to implement reliable and numerically stable optimization methods, no practical algorithm exists that can always find the global optimum of a nonlinear function, especially when there are nonlinear constraints.

Syntax: CALIS Procedure

The following statements are available in PROC CALIS:

PROC CALIS < *options* > ;
LINEQS *model equations* ;
STD *variance pattern* ;
COV *covariance pattern* ;
RAM *model list* ;
VARNAMES *variables* ;
FACTOR < *options* > ;
COSAN *matrix model* ;
MATRIX *matrix elements* ;
PARAMETERS *parameters* ;
STRUCTEQ *variables* ;
BOUNDS *boundary constraints* ;
LINCON *linear constraints* ;
NLINCON *nonlinear constraints* ;
NLOPTIONS *optimization options* ;
BY *variables* ;
VAR *variables* ;
PARTIAL *variables* ;
FREQ *variable* ;
WEIGHT *variable* ;
SAS programming statements ;

- If no INRAM= data set is specified, one of the four statements that define the input form of the analysis model, LINEQS, RAM, FACTOR, or COSAN, must be used.
- The MATRIX statement can be used multiple times for the same or different matrices along with a COSAN or FACTOR statement. If the MATRIX statement is used multiple times for the same matrix, later definitions override earlier ones.
- The STD and COV statements can be used only with the LINEQS model statement.
- You can formulate a generalized COSAN model by using a COSAN statement. MATRIX statements can be used to define the elements of a matrix used in the COSAN statement. The input notation resembles the COSAN program of McDonald and Fraser (McDonald 1978, 1980).

- The RAM statement uses a simple list input that is especially suitable for describing McArdle's RAM analysis model (McArdle 1980; McArdle and McDonald 1984) for causal and path analysis problems.
- The LINEQS statement formulates the analysis model by means of a system of linear equations similar to Bentler's (1989) EQS program notation. The STD and COV statements can be used to define the variances and covariances corresponding to elements of matrix $\mathbf{\Phi}$ in the LINEQS model.
- A FACTOR statement can be used to compute a first-order exploratory or confirmatory factor (or component) analysis. The analysis of a simple exploratory factor analysis model performed by PROC CALIS is not as efficient as one performed by the FACTOR procedure. The CALIS procedure is designed for more general structural problems, and it needs significantly more computation time for a simple unrestricted factor or component analysis than PROC FACTOR does.
- You can add SAS programming statements to impose linear or nonlinear constraints on the parameters if you specify the model by means of a COSAN, LINEQS, or RAM statement. The PARAMETERS statement defines additional parameters that are needed as independent variables in your program code and that belong to the set of parameters to be estimated. Variable names used in the program code should differ from the preceding statement names. The code should respect the syntax rules of SAS statements usually used in the DATA step. See the section "SAS Programming Statements" on page 903 for more information.
- The BOUNDS statement can be used to specify simple lower and upper boundary constraints for the parameters.
- You can specify general linear equality and inequality constraints with the LINCON statement (or via an INEST= data set). The NLINCON statement can be used to specify general nonlinear equality and inequality constraints by referring to nonlinear functions defined by programming statements.
- The VAR, PARTIAL, WEIGHT, FREQ, and BY statements can be used in the same way as in other procedures, such as the FACTOR or PRINCOMP procedure. You can select a subset of the input variables to analyze with the VAR statement. The PARTIAL statement defines a set of input variables that are chosen as partial variables for the analysis of a matrix of partial correlations or covariances. The BY statement specifies groups in which separate covariance structure analyses are performed.

The following sections describe the PROC CALIS statement and then describe the other statements in alphabetical order.

PROC CALIS Statement

PROC CALIS < *options* > **;**

The options available with the PROC CALIS statement are listed in the following table and then are described in alphabetical order.

Table 25.1 Options Available in the PROC CALIS Statement

Option	Description
Data Set Options	
DATA=	specifies the input data set
INEST=	inputs the initial values and constraints
INRAM=	inputs the model specifications
INWGT=	specifies the input weight matrix
OUTEST=	outputs the covariance matrix of estimates
OUTJAC	outputs the Jacobian into the OUTEST= data set
OUTRAM=	outputs the model specifications
OUTSTAT=	outputs the statistical results
OUTWGT=	outputs the weight matrix
Data Processing	
AUGMENT	analyzes augmented moment matrix
COVARIANCE	analyzes covariance matrix
EDF=	defines the number of observations by the error degrees of freedom
NOBS=	defines the number of observations
NOINT	analyzes uncorrected moments
RDF=	specifies regression degrees of freedom for modifying the number of observations
RIDGE	specifies ridge factor for the covariance matrix
UCORR	analyzes uncorrected correlation matrix
UCOV	analyzes uncorrected covariance matrix
VARDEF=	specifies the method for computing the variance divisor
Estimation Methods	
ASYCOV=	specifies the formula for computing asymptotic covariances
DFREDUCE=	reduces the degrees of freedom for model fit chi-square test
G4=	specifies the algorithm for computing standard errors
METHOD=	specifies the estimation method
NODIAG	excludes the diagonal elements of the covariance matrix from model fitting
WPENALTY=	specifies the penalty weight to fit correlations
WRIDGE=	specifies the ridge factor for weight matrix
Statistical Analysis	
ALPHAECV=	specifies the α level for computing the confidence interval of ECV (Browne and Cudeck 1993)

Table 25.1 *continued*

Option	Description
ALPHARMS=	specifies the α level for computing the confidence interval of RMSEA (Steiger and Lind 1980)
BIASKUR	computes the skewness and kurtosis without bias corrections
KURTOSIS	computes and displays kurtosis
MODIFICATION	computes modification indices
NOMOD	suppresses modification indices
NOSTDERR	suppresses standard error computations
PCOVES	displays the covariance matrix of estimates
PDETERM	computes the determination coefficients
PLATCOV	computes the latent variable covariances and score coefficients
PREDET	displays predetermined moment matrix
RESIDUAL=	specifies the type of residuals being computed
SIMPLE	prints univariate statistics
SLMW=	specifies the probability limit for Wald tests
STDERR	computes the standard errors
TOTEFF	displays total and indirect effects
ODS Graphics	
PLOTS=	specifies ODS Graphics selection
Control Display Output	
NOPRINT	suppresses the displayed output
PALL	displays all output (ALL)
PCORR	displays analyzed and estimated moment matrix
PESTIM	prints parameter estimates
PINITIAL	prints initial pattern and values
PJACPAT	displays structure of variable and constant elements of the Jacobian matrix
PRIMAT	displays output in matrix form
PRINT	adds default displayed output
PRIVEC	displays output in vector form
PSHORT	reduces default output (SHORT)
PSUMMARY	displays fit summary only (SUMMARY)
PWEIGHT	displays the weight matrix
Optimization Techniques	
FCONV=	specifies the objective function convergence criterion
GCONV=	specifies the gradient convergence criterion
INSTEP=	specifies the initial step length (RADIUS=, SALPHA=)
LINESEARCH=	specifies the line-search method
LSPRECISION=	specifies the line-search precision (SPRECISION=)
MAXFUNC=	specifies the maximum number of function calls
MAXITER=	specifies the maximum number of iterations
TECHNIQUE=	specifies the minimization method
UPDATE=	specifies the update technique

Table 25.1 *continued*

Option	Description
Numerical Properties	
ASINGULAR=	specifies the absolute singularity information matrix
COVSING=	specifies the singularity tolerance of information matrix
MSINGULAR=	specifies the relative M singularity of information matrix
SINGULAR=	specifies the singularity criterion
VSINGULAR=	specifies the relative V singularity of information matrix
Miscellaneous	
DEMPHAS=	emphasizes the diagonal entries
FDCODE	uses numeric derivatives for programming code
HESSALG=	specifies the algorithm for computing the Hessian
NOADJDF	requests no degrees of freedom adjustment be made for active constraints
RANDOM=	specifies the seed for randomly generated initial values
START=	specifies the constant for the initial values

Options for General Output Display

Some output display control options enable or disable more than a single display. These are general output display control options, which include the PALL, PRINT, PSHORT, PSUMMARY, and NOPRINT options. If the NOPRINT option is not specified, a default set of output is displayed. The PRINT and PALL options add more output to the default set of output, while the PSHORT and PSUMMARY options reduce from the set of default output.

The relationships of the general output display control options (excluding the NOPRINT option) with other specific options or displays are summarized in the following table.

Output Options	PALL	PRINT	default	PSHORT	PSUMMARY
fit indices	*	*	*	*	*
linear dependencies	*	*	*	*	*
iteration history	*	*	*	*	
model matrices	*	*	*	*	
PESTIM	*	*	*	*	
PREDET	*	(*)	(*)	(*)	
PINITIAL	*	*	*		
SIMPLE	*	*	*		
STDERR	*	*	*		
RESIDUAL	*	*			
KURTOSIS	*	*			
PLATCOV	*	*			
TOTEFF	*	*			
PCORR	*				
MODIFICATION	*				
PWEIGHT	*				
PCOVES					
PDETERM					
PJACPAT					
PRIMAT					
PRIVEC					

Each "*" in the table represents a specific display or a set of displays enabled by the general output display control option. For example, if you specify the PSUMMARY option, the fit indices and the linear dependencies of parameter estimates (if present) will be shown in the printed output. With the PSHORT option, iteration history and model matrices will also be printed. In addition, the PESTIM option and the PREDET option are also enabled by the PSHORT option. Entries with "(*)" represent specific conditions that enable the PREDET option. See the PREDET option for more details.

Alphabetical Listing of Options with the PROC CALIS Statement

ALPHAECV=α

specifies the significance level for a $1-\alpha$ confidence interval, $0 \leq \alpha \leq 1$, for the Browne and Cudeck (1993) expected cross validation index (ECVI). The default value is $\alpha = 0.1$, which corresponds to a 90% confidence interval for the ECVI.

ALPHARMS=α

specifies the significance level for a $1-\alpha$ confidence interval, $0 \leq \alpha \leq 1$, for the Steiger and Lind (1980) root mean squared error of approximation (RMSEA) coefficient (refer to Browne and Du Toit 1992). The default value is $\alpha = 0.1$, which corresponds to a 90% confidence interval for the RMSEA.

ASINGULAR | ASING=*r*

specifies an absolute singularity criterion r, $r > 0$, for the inversion of the information matrix, which is needed to compute the covariance matrix. The following singularity criterion is used:

$$|d_{j,j}| \leq \max(ASING, VSING * |H_{j,j}|, MSING * \max(|H_{1,1}|, \ldots, |H_{n,n}|))$$

In the preceding criterion, $d_{j,j}$ is the diagonal pivot of the matrix, and *VSING* and *MSING* are the specified values of the VSINGULAR= and MSINGULAR= options. The default value for *ASING* is the square root of the smallest positive double-precision value. Note that, in many cases, a normalized matrix $\mathbf{D}^{-1}\mathbf{H}\mathbf{D}^{-1}$ is decomposed, and the singularity criteria are modified correspondingly.

ASYCOV | ASC=*name*

specifies the formula for asymptotic covariances used in the weight matrix $\mathbf{W}$ for WLS and DWLS estimation. The ASYCOV option is effective only if METHOD=WLS or METHOD=DWLS and no INWGT= input data set is specified. The following formulas are implemented:

BIASED — Browne's (1984) formula (3.4)
biased asymptotic covariance estimates; the resulting weight matrix is at least positive semidefinite. This is the default for analyzing a covariance matrix.

UNBIASED — Browne's (1984) formula (3.8)
asymptotic covariance estimates corrected for bias; the resulting weight matrix can be indefinite (that is, can have negative eigenvalues), especially for small N.

CORR — Browne and Shapiro's (1986) formula (3.2), which is identical to DeLeeuw's (1983) formulas (2, 3, 4)
the asymptotic variances of the diagonal elements are set to the reciprocal of the value r specified by the WPENALTY= option (default: $r = 100$). This formula is the default for analyzing a correlation matrix.

CAUTION: Using the WLS and DWLS methods with the ASYCOV=CORR option means that you are fitting a correlation (rather than a covariance) structure. Since the fixed diagonal of a correlation matrix for some models does not contribute to the model's degrees of freedom, you can specify the DFREDUCE=*i* option to reduce the degrees of freedom by the number of manifest variables used in the model. See the section "Counting the Degrees of Freedom" on page 956 for more information.

AUGMENT | AUG

analyzes the augmented correlation or covariance matrix. Using the AUG option is equivalent to specifying UCORR (NOINT but not COV) or UCOV (NOINT and COV) for a data set that

is augmented by an intercept variable INTERCEPT that has constant values equal to 1. The variable INTERCEP can be used instead of the default INTERCEPT only if you specify the SAS option OPTIONS VALIDVARNAME=V6. The dimension of an augmented matrix is one higher than that of the corresponding correlation or covariance matrix. The AUGMENT option is effective only if the data set does not contain a variable called INTERCEPT and if you specify the UCOV, UCORR, or NOINT option.

CAUTION: The INTERCEPT variable is included in the moment matrix as the variable with number $n + 1$. Using the RAM model statement assumes that the first n variable numbers correspond to the n manifest variables in the input data set. Therefore, specifying the AUGMENT option assumes that the numbers of the latent variables used in the RAM or path model have to start with number $n + 2$.

BIASKUR

computes univariate skewness and kurtosis by formulas uncorrected for bias. See the section "Measures of Multivariate Kurtosis" on page 938 for more information.

COVARIANCE | COV

analyzes the covariance matrix instead of the correlation matrix. By default, PROC CALIS (like the FACTOR procedure) analyzes a correlation matrix. If the DATA= input data set is a valid TYPE=CORR data set (containing a correlation matrix and standard deviations), using the COV option means that the covariance matrix is computed and analyzed.

COVSING=*r*

specifies a nonnegative threshold r, which determines whether the eigenvalues of the information matrix are considered to be zero. If the inverse of the information matrix is found to be singular (depending on the VSINGULAR=, MSINGULAR=, ASINGULAR=, or SINGULAR= option), a generalized inverse is computed using the eigenvalue decomposition of the singular matrix. Those eigenvalues smaller than r are considered to be zero. If a generalized inverse is computed and you do not specify the NOPRINT option, the distribution of eigenvalues is displayed.

DATA=*SAS-data-set*

specifies an input data set that can be an ordinary SAS data set or a specially structured TYPE=CORR, TYPE=COV, TYPE=UCORR, TYPE=UCOV, TYPE=SSCP, or TYPE=FACTOR SAS data set, as described in the section "Input Data Sets" on page 909. If the DATA= option is omitted, the most recently created SAS data set is used.

DEMPHAS | DE=*r*

changes the initial values of all parameters that are located on the diagonals of the central model matrices by the relationship

$$diag_{new} = r(|diag_{old}| + 1)$$

The initial values of the diagonal elements of the central matrices should always be nonnegative to generate positive-definite predicted model matrices in the first iteration. By using values of $r > 1$, such as $r = 2, r = 10, \ldots$, you can increase these initial values to produce predicted model matrices with high positive eigenvalues in the first iteration. The DEMPHAS= option is effective independently of the way the initial values are set; that is, it changes the initial values set in the model specification as well as those set by an INRAM= data set and

those automatically generated for RAM, LINEQS, or FACTOR model statements. It also affects the initial values set by the START= option, which uses, by default, DEMPHAS=100 if a covariance matrix is analyzed and DEMPHAS=10 for a correlation matrix.

DFREDUCE | DFRED=*i*

reduces the degrees of freedom of the χ^2 test by i. In general, the number of degrees of freedom is the number of elements of the lower triangle of the predicted model matrix $\mathbf{C}$, $n(n+1)/2$, minus the number of parameters, t. If the NODIAG option is used, the number of degrees of freedom is additionally reduced by n. Because negative values of i are allowed, you can also increase the number of degrees of freedom by using this option. If the DFREDUCE= or NODIAG option is used in a correlation structure analysis, PROC CALIS does not additionally reduce the degrees of freedom by the number of constant elements in the diagonal of the predicted model matrix, which is otherwise done automatically. See the section "Counting the Degrees of Freedom" on page 956 for more information.

EDF | DFE=*n*

makes the effective number of observations $n + i$, where i is 0 if the NOINT, UCORR, or UCOV option is specified without the AUGMENT option or where i is 1 otherwise. You can also use the NOBS= option to specify the number of observations.

FCONV | FTOL=*r*

specifies the relative function convergence criterion. The optimization process is terminated when the relative difference of the function values of two consecutive iterations is smaller than the specified value of r; that is,

$$\frac{|f(x^{(k)}) - f(x^{(k-1)})|}{\max(|f(x^{(k-1)})|, FSIZE)} \leq r$$

where $FSIZE$ can be defined by the FSIZE= option in the NLOPTIONS statement.

The default value is $r = 10^{-FDIGITS}$, where $FDIGITS$ either can be specified in the NLOPTIONS statement or is set by default to $-\log_{10}(\epsilon)$, where ϵ is the machine precision.

FDCODE

replaces the analytic derivatives of the programming statements by numeric derivatives (finite-difference approximations). In general, this option is needed only when you have programming statements that are too difficult for the built-in function compiler to differentiate analytically. For example, if the program code for the nonlinear constraints contains many arrays and many DO loops with array processing, the built-in function compiler can require too much time and memory to compute derivatives of the constraints with respect to the parameters. In this case, the Jacobian matrix of constraints is computed numerically by using finite-difference approximations. The FDCODE option does not modify the kind of derivatives specified with the HESSALG= option.

G4=*i*

specifies the algorithm to compute the approximate covariance matrix of parameter estimates used for computing the approximate standard errors and modification indices when the information matrix is singular. If the number of parameters t used in the model you analyze is smaller than the value of i, the time-expensive Moore-Penrose (G4) inverse of the singular information matrix is computed by eigenvalue decomposition. Otherwise, an inexpensive

pseudo (G1) inverse is computed by sweeping. By default, $i = 60$. For more details, see the section "Estimation Criteria" on page 923.

GCONV | GTOL=*r*

specifies the relative gradient convergence criterion (see the ABSGCONV= option on page 892 for the absolute gradient convergence criterion).

Termination of all techniques (except the CONGRA technique) requires the normalized predicted function reduction to be small,

$$\frac{[g(x^{(k)})]'[\mathbf{G}^{(k)}]^{-1}g(x^{(k)})}{\max(|f(x^{(k)})|, FSIZE)} \leq r$$

where $FSIZE$ can be defined by the FSIZE= option in the NLOPTIONS statement. For the CONGRA technique (where a reliable Hessian estimate $\mathbf{G}$ is not available),

$$\frac{\| g(x^{(k)}) \|_2^2 \quad \| s(x^{(k)}) \|_2}{\| g(x^{(k)}) - g(x^{(k-1)}) \|_2 \max(|f(x^{(k)})|, FSIZE)} \leq r$$

is used. The default value is $r = 10^{-8}$.

Note that prior to SAS 6.11, the GCONV= option specified the absolute gradient convergence criterion.

HESSALG | HA = 1 | 2 | 3 | 4 | 5 | 6 | 11

specifies the algorithm used to compute the (approximate) Hessian matrix when TECHNIQUE=LEVMAR and NEWRAP, to compute approximate standard errors of the parameter estimates, and to compute Lagrange multipliers. There are different groups of algorithms available:

- analytic formulas: HA=*1,2,3,4,11*
- finite-difference approximation: HA=*5,6*
- dense storage: HA=*1,2,3,4,5,6*
- sparse storage: HA=*11*

If the Jacobian is more than 25% dense, the dense analytic algorithm, HA= 1, is used by default. The HA= 1 algorithm is faster than the other dense algorithms, but it needs considerably more memory for large problems than HA= 2,3,4. If the Jacobian is more than 75% sparse, the sparse analytic algorithm, HA= 11, is used by default. The dense analytic algorithm HA= 4 corresponds to the original COSAN algorithm; you are advised not to specify HA= 4 due to its very slow performance. If there is not enough memory available for the dense analytic algorithm HA= 1 and you must specify HA= 2 or HA= 3, it might be more efficient to use one of the quasi-Newton or conjugate-gradient optimization techniques since Levenberg-Marquardt and Newton-Raphson optimization techniques need to compute the Hessian matrix in each iteration. For approximate standard errors and modification indices, the Hessian matrix has to be computed at least once, regardless of the optimization technique.

The algorithms HA= 5 and HA= 6 compute approximate derivatives by using forward-difference formulas. The HA= 5 algorithm corresponds to the analytic HA= 1: it is faster

than HA= 6, but it needs much more memory. The HA= 6 algorithm corresponds to the analytic HA= 2: it is slower than HA= 5, but it needs much less memory.

Test computations of large sparse problems show that the sparse algorithm HA= 11 can be up to 10 times faster than HA= 1 (and needs much less memory).

INEST | INVAR | ESTDATA=*SAS-data-set*

specifies an input data set that contains initial estimates for the parameters used in the optimization process and can also contain boundary and general linear constraints on the parameters. If the model did not change too much, you can specify an OUTEST= data set from a previous PROC CALIS analysis. The initial estimates are taken from the values of the PARMS observation.

INRAM=*SAS-data-set*

specifies an input data set that contains in RAM list form all information needed to specify an analysis model. The INRAM= data set is described in the section "Input Data Sets" on page 909. Typically, this input data set is an OUTRAM= data set (possibly modified) from a previous PROC CALIS analysis. If you use an INRAM= data set to specify the analysis model, you cannot use the model specification statement COSAN, MATRIX, RAM, LINEQS, STD, COV, FACTOR, or VARNAMES, but you can use the BOUNDS and PARAMETERS statements and programming statements. If the INRAM= option is omitted, you must define the analysis model with a COSAN, RAM, LINEQS, or FACTOR statement.

INSTEP=*r*

For highly nonlinear objective functions, such as the EXP function, the default initial radius of the trust-region algorithms TRUREG, DBLDOG, and LEVMAR or the default step length of the line-search algorithms can produce arithmetic overflows. If this occurs, specify decreasing values of $0 < r < 1$ such as INSTEP=1E−1, INSTEP=1E−2, INSTEP=1E−4, ..., until the iteration starts successfully.

- For trust-region algorithms (TRUREG, DBLDOG, and LEVMAR), the INSTEP option specifies a positive factor for the initial radius of the trust-region. The default initial trust-region radius is the length of the scaled gradient, and it corresponds to the default radius factor of $r = 1$.
- For line-search algorithms (NEWRAP, CONGRA, and QUANEW), INSTEP specifies an upper bound for the initial step length for the line search during the first five iterations. The default initial step length is $r = 1$.

For releases prior to SAS 6.11, specify the SALPHA= and RADIUS= options. For more details, see the section "Computational Problems" on page 958.

INWGT=*SAS-data-set*

specifies an input data set that contains the weight matrix **W** used in generalized least squares (GLS), weighted least squares (WLS, ADF), or diagonally weighted least squares (DWLS) estimation. If the weight matrix **W** defined by an INWGT= data set is not positive-definite, it can be ridged by using the WRIDGE= option. See the section "Estimation Criteria" on page 923 for more information. If no INWGT= data set is specified, default settings for the weight matrices are used in the estimation process. The INWGT= data set is described in the section "Input Data Sets" on page 909. Typically, this input data set is an OUTWGT= data set from a previous PROC CALIS analysis.

KURTOSIS | KU

computes and displays univariate kurtosis and skewness, various coefficients of multivariate kurtosis, and the numbers of observations that contribute most to the normalized multivariate kurtosis. See the section "Measures of Multivariate Kurtosis" on page 938 for more information. Using the KURTOSIS option implies the SIMPLE display option. This information is computed only if the DATA= data set is a raw data set, and it is displayed by default if the PRINT option is specified. The multivariate LS kappa and the multivariate mean kappa are displayed only if you specify METHOD=WLS and the weight matrix is computed from an input raw data set. All measures of skewness and kurtosis are corrected for the mean. If an intercept variable is included in the analysis, the measures of multivariate kurtosis do not include the intercept variable in the corrected covariance matrix, as indicated by a displayed message. Using the BIASKUR option displays the biased values of univariate skewness and kurtosis.

LINESEARCH | LIS | SMETHOD | SM=*i*

specifies the line-search method for the CONGRA, QUANEW, and NEWRAP optimization techniques. Refer to Fletcher (1980) for an introduction to line-search techniques. The value of i can be $1, \ldots, 8$; the default is $i = 2$.

LIS=1 specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is similar to one used by the Harwell subroutine library.

LIS=2 specifies a line-search method that needs more function calls than gradient calls for quadratic and cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option.

LIS=3 specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option.

LIS=4 specifies a line-search method that needs the same number of function and gradient calls for stepwise extrapolation and cubic interpolation.

LIS=5 specifies a line-search method that is a modified version of LIS=4.

LIS=6 specifies golden section line search (Polak 1971), which uses only function values for linear approximation.

LIS=7 specifies bisection line search (Polak 1971), which uses only function values for linear approximation.

LIS=8 specifies Armijo line-search technique (Polak 1971), which uses only function values for linear approximation.

LSPRECISION | LSP=*r*

SPRECISION | SP=*r*

specifies the degree of accuracy that should be obtained by the line-search algorithms LIS=2 and LIS=3. Usually an imprecise line search is inexpensive and successful. For more difficult optimization problems, a more precise and more expensive line search might be necessary

(Fletcher 1980, p. 22). The second (default for NEWRAP, QUANEW, and CONGRA) and third line-search methods approach exact line search for small LSPRECISION= values. If you have numerical problems, you should decrease the LSPRECISION= value to obtain a more precise line search. The default LSPRECISION= values are displayed in the following table.

TECH=	UPDATE=	LSP Default
QUANEW	DBFGS, BFGS	$r = 0.4$
QUANEW	DDFP, DFP	$r = 0.06$
CONGRA	all	$r = 0.1$
NEWRAP	no update	$r = 0.9$

For more details, refer to Fletcher (1980, pp. 25–29).

MAXFUNC | MAXFU=*i*

specifies the maximum number i of function calls in the optimization process. The default values are displayed in the following table.

TECH=	MAXFUNC Default
LEVMAR, NEWRAP, NRRIDG, TRUREG	i=125
DBLDOG, QUANEW	i=500
CONGRA	i=1000

The default is used if you specify MAXFUNC=0. The optimization can be terminated only after completing a full iteration. Therefore, the number of function calls that are actually performed can exceed the number that is specified by the MAXFUNC= option.

MAXITER | MAXIT=*i* < *n* >

specifies the maximum number i of iterations in the optimization process. The default values are displayed in the following table.

TECH=	MAXITER Default
LEVMAR, NEWRAP, NRRIDG, TRUREG	i=50
DBLDOG, QUANEW	i=200
CONGRA	i=400

The default is used if you specify MAXITER=0 or if you omit the MAXITER option.

The optional second value n is valid only for TECH=QUANEW with nonlinear constraints. It specifies an upper bound n for the number of iterations of an algorithm and reduces the violation of nonlinear constraints at a starting point. The default is n=20. For example, specifying

```
maxiter= . 0
```

means that you do not want to exceed the default number of iterations during the main optimization process and that you want to suppress the feasible-point algorithm for nonlinear constraints.

METHOD | MET=*name*

specifies the method of parameter estimation. Valid values for *name* are as follows:

ML | M | MAX	performs normal-theory maximum likelihood parameter estimation. The ML method requires a nonsingular covariance or correlation matrix. This is the default method.
GLS | G	performs generalized least squares parameter estimation. If no INWGT= data set is specified, the GLS method uses the inverse sample covariance or correlation matrix as weight matrix **W**. Therefore, METHOD=GLS requires a nonsingular covariance or correlation matrix.
WLS | W | ADF	performs weighted least squares parameter estimation. If no INWGT= data set is specified, the WLS method uses the inverse matrix of estimated asymptotic covariances of the sample covariance or correlation matrix as the weight matrix **W**. In this case, the WLS estimation method is equivalent to Browne's (1982, 1984) asymptotically distribution-free estimation. The WLS method requires a nonsingular weight matrix.
DWLS | D	performs diagonally weighted least squares parameter estimation. If no INWGT= data set is specified, the DWLS method uses the inverse diagonal matrix of asymptotic variances of the input sample covariance or correlation matrix as the weight matrix **W**. The DWLS method requires a nonsingular diagonal weight matrix.
ULS | LS | U	performs unweighted least squares parameter estimation.
LSML | LSM | LSMAX	performs unweighted least squares followed by normal-theory maximum likelihood parameter estimation.
LSGLS | LSG	performs unweighted least squares followed by generalized least squares parameter estimation.
LSWLS | LSW | LSADF	performs unweighted least squares followed by weighted least squares parameter estimation.
LSDWLS | LSD	performs unweighted least squares followed by diagonally weighted least squares parameter estimation.
NONE | NO	uses no estimation method. This option is suitable for checking the validity of the input information and for displaying the model matrices and initial values.

The default estimation method is maximum likelihood (METHOD=ML), assuming a multivariate normal distribution of the observed variables. The two-stage estimation methods METHOD=LSML, METHOD=LSGLS, METHOD=LSWLS, and METHOD=LSDWLS first compute unweighted least squares estimates of the model parameters and their residuals. Afterward, these estimates are used as initial values for the optimization process to compute maximum likelihood, generalized least squares, weighted least squares, or diagonally weighted least squares parameter estimates. You can do the same thing by using an OUTRAM= data set with least squares estimates as an INRAM= data set for a further analysis

to obtain the second set of parameter estimates. This strategy is also discussed in the section "Use of Optimization Techniques" on page 945. For more details, see the section "Estimation Criteria" on page 923.

MODIFICATION | MOD

computes and displays Lagrange multiplier test indices for constant parameter constraints, equality parameter constraints, and active boundary constraints, as well as univariate and multivariate Wald test indices. The modification indices are not computed in the case of unweighted or diagonally weighted least squares estimation.

The Lagrange multiplier test (Bentler 1986; Lee 1985; Buse 1982) provides an estimate of the χ^2 reduction that results from dropping the constraint. For constant parameter constraints and active boundary constraints, the approximate change of the parameter value is displayed also. You can use this value to obtain an initial value if the parameter is allowed to vary in a modified model. For more information, see the section "Modification Indices" on page 953.

MSINGULAR | MSING=*r*

specifies a relative singularity criterion r, $r > 0$, for the inversion of the information matrix, which is needed to compute the covariance matrix. The following singularity criterion is used:

$$|d_{j,j}| \leq \max(ASING, VSING * |H_{j,j}|, MSING * \max(|H_{1,1}|, \ldots, |H_{n,n}|))$$

where $d_{j,j}$ is the diagonal pivot of the matrix, and *ASING* and *VSING* are the specified values of the ASINGULAR= and VSINGULAR= options, respectively. If you do not specify the SINGULAR= option, the default value for *MSING* is 1E−12; otherwise, the default value is 1E−4 * SINGULAR. Note that, in many cases, a normalized matrix $\mathbf{D}^{-1}\mathbf{H}\mathbf{D}^{-1}$ is decomposed, and the singularity criteria are modified correspondingly.

NOADJDF

turns off the automatic adjustment of degrees of freedom when there are active constraints in the analysis. When the adjustment is in effect, most fit statistics and the associated probability levels will be affected. This option should be used when the researcher believes that the active constraints observed in the current sample will have little chance to occur in repeated sampling.

NOBS=*nobs*

specifies the number of observations. If the DATA= input data set is a raw data set, *nobs* is defined by default to be the number of observations in the raw data set. The NOBS= and EDF= options override this default definition. You can use the RDF= option to modify the *nobs* specification. If the DATA= input data set contains a covariance, correlation, or scalar product matrix, you can specify the number of observations either by using the NOBS=, EDF=, and RDF= options in the PROC CALIS statement or by including a _TYPE_='N' observation in the DATA= input data set.

NODIAG | NODI

omits the diagonal elements of the analyzed correlation or covariance matrix from the fit function. This option is useful only for special models with constant error variables. The NODIAG option does not allow fitting of those parameters that contribute to the diagonal of the estimated moment matrix. The degrees of freedom are automatically reduced by n. A

simple example for the usefulness of the NODIAG option is the fit of the first-order factor model, $\mathbf{S} = \mathbf{FF}' + \mathbf{U}^2$. In this case, you do not have to estimate the diagonal matrix of unique variances $\mathbf{U}^2$ that are fully determined by $diag(\mathbf{S} - \mathbf{FF}')$.

NOINT

specifies that no intercept be used in computing covariances and correlations; that is, covariances or correlations are not corrected for the mean. You can specify this option (or UCOV or UCORR) to analyze mean structures in an uncorrected moment matrix—that is, to compute intercepts in systems of structured linear equations (see Example 25.2). The term NOINT is misleading in this case because an uncorrected covariance or correlation matrix is analyzed containing a constant (intercept) variable that is used in the analysis model. The degrees of freedom used in the variance divisor (specified by the VARDEF= option) and some of the assessment of the fit function (see the section "Assessment of Fit" on page 928) depend on whether an intercept variable is included in the model (the intercept is used in computing the corrected covariance or correlation matrix or is used as a variable in the uncorrected covariance or correlation matrix to estimate mean structures) or not included (an uncorrected covariance or correlation matrix is used that does not contain a constant variable).

NOMOD

does not compute modification indices. The NOMOD option is useful in connection with the PALL option because it saves computing time.

NOPRINT | NOP

suppresses the displayed output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, "Using the Output Delivery System."

NOSTDERR | NOSE

specifies that standard errors should not be computed. Standard errors are not computed for unweighted least squares (ULS) or diagonally weighted least squares (DWLS) estimation. In general, standard errors are computed even if the STDERR display option is not used (for file output).

OUTEST | OUTVAR=*SAS-data-set*

creates an output data set containing the parameter estimates, their gradient, Hessian matrix, and boundary and linear constraints. For METHOD=ML, METHOD=GLS, and METHOD=WLS, the OUTEST= data set also contains the information matrix, the approximate covariance matrix of the parameter estimates ((generalized) inverse of information matrix), and approximate standard errors. If linear or nonlinear equality or active inequality constraints are present, the Lagrange multiplier estimates of the active constraints, the projected Hessian, and the Hessian of the Lagrange function are written to the data set. The OUTEST= data set also contains the Jacobian if the OUTJAC option is used.

The OUTEST= data set is described in the section "OUTEST= SAS-data-set" on page 913. If you want to create a permanent SAS data set, you must specify a two-level name. Refer to the chapter titled "SAS Data Files" in *SAS Language Reference: Concepts* for more information about permanent data sets.

OUTJAC
writes the Jacobian matrix, if it has been computed, to the OUTEST= data set. This is useful when the information and Jacobian matrices need to be computed for other analyses.

OUTRAM=*SAS-data-set*
creates an output data set containing the model information for the analysis, the parameter estimates, and their standard errors. An OUTRAM= data set can be used as an input INRAM= data set in a subsequent analysis by PROC CALIS. The OUTRAM= data set also contains a set of fit indices; it is described in more detail in the section "OUTRAM= SAS-data-set" on page 917. If you want to create a permanent SAS data set, you must specify a two-level name. Refer to the chapter titled "SAS Data Files" in *SAS Language Reference: Concepts* for more information about permanent data sets.

OUTSTAT=*SAS-data-set*
creates an output data set containing the BY-group variables, the analyzed covariance or correlation matrices, and the predicted and residual covariance or correlation matrices of the analysis. You can specify the correlation or covariance matrix in an OUTSTAT= data set as an input DATA= data set in a subsequent analysis by PROC CALIS. The OUTSTAT= data set is described in the section "OUTSTAT= SAS-data-set" on page 920. If the model contains latent variables, this data set also contains the predicted covariances between latent and manifest variables and the latent variable score regression coefficients (see the PLATCOV option on page 864). If the FACTOR statement is used, the OUTSTAT= data set also contains the rotated and unrotated factor loadings, the unique variances, the matrix of factor correlations, the transformation matrix of the rotation, and the matrix of standardized factor loadings.

You can use the latent variable score regression coefficients with PROC SCORE to compute latent variable or factor scores. For details, see the section "Latent Variable Scores" on page 937.

If you want to create a permanent SAS data set, you must specify a two-level name. Refer to the chapter titled "SAS Data Files" in *SAS Language Reference: Concepts* for more information about permanent data sets.

OUTWGT=*SAS-data-set*
creates an output data set containing the weight matrix $\mathbf{W}$ used in the estimation process. You cannot create an OUTWGT= data set with an unweighted least squares or maximum likelihood estimation. The fit function in GLS, WLS (ADF), and DWLS estimation contains the inverse of the (Cholesky factor of the) weight matrix $\mathbf{W}$ written in the OUTWGT= data set. The OUTWGT= data set contains the weight matrix to which the WRIDGE= and the WPENALTY= options are applied. An OUTWGT= data set can be used as an input INWGT= data set in a subsequent analysis by PROC CALIS. The OUTWGT= data set is described in the section "OUTWGT= SAS-data-set" on page 922. If you want to create a permanent SAS data set, you must specify a two-level name. Refer to the chapter titled "SAS Data Files" in *SAS Language Reference: Concepts* for more information about permanent data sets.

PALL | ALL

displays all optional output except the output generated by the PCOVES, PDETERM, PJACPAT, and PRIVEC options.

CAUTION: The PALL option includes the very expensive computation of the modification indices. If you do not really need modification indices, you can save computing time by specifying the NOMOD option in addition to the PALL option.

PCORR | CORR

displays the (corrected or uncorrected) covariance or correlation matrix that is analyzed and the predicted model covariance or correlation matrix.

PCOVES | PCE

displays the following:

- the information matrix (crossproduct Jacobian)
- the approximate covariance matrix of the parameter estimates (generalized inverse of the information matrix)
- the approximate correlation matrix of the parameter estimates

The covariance matrix of the parameter estimates is not computed for the ULS and DWLS estimation methods. This displayed output is not included in the output generated by the PALL option.

PDETERM | PDE

displays three coefficients of determination: the determination of all equations (DETAE), the determination of the structural equations (DETSE), and the determination of the manifest variable equations (DETMV). These determination coefficients are intended to be global means of the squared multiple correlations for different subsets of model equations and variables. The coefficients are displayed only when you specify a RAM or LINEQS model, but they are displayed for all five estimation methods: ULS, GLS, ML, WLS, and DWLS.

You can use the STRUCTEQ statement to define which equations are structural equations. If you do not use the STRUCTEQ statement, PROC CALIS uses its own default definition to identify structural equations.

The term "structural equation" is not defined in a unique way. The LISREL program defines the structural equations by the user-defined BETA matrix. In PROC CALIS, the default definition of a structural equation is an equation that has a dependent left-side variable that appears at least once on the right side of another equation, or an equation that has at least one right-side variable that is the left-side variable of another equation. Therefore, PROC CALIS sometimes identifies more equations as structural equations than the LISREL program does.

If the model contains structural equations, PROC CALIS also displays the "Stability Coefficient of Reciprocal Causation"—that is, the largest eigenvalue of the $\mathbf{BB}'$ matrix, where $\mathbf{B}$ is the causal coefficient matrix of the structural equations. These coefficients are computed as in the LISREL VI program of Jöreskog and Sörbom (1985). This displayed output is not included in the output generated by the PALL option.

PESTIM | PES
displays the parameter estimates. In some cases, this includes displaying the standard errors and t values.

PINITIAL | PIN
displays the input model matrices and the vector of initial values.

PJACPAT | PJP
displays the structure of variable and constant elements of the Jacobian matrix. This displayed output is not included in the output generated by the PALL option.

PLATCOV | PLC
displays the following:

- the estimates of the covariances among the latent variables
- the estimates of the covariances between latent and manifest variables
- the latent variable score regression coefficients

The estimated covariances between latent and manifest variables and the latent variable score regression coefficients are written to the OUTSTAT= data set. You can use the score coefficients with PROC SCORE to compute factor scores. For details, see the section "Latent Variable Scores" on page 937.

PLOTS <(*global-plot-options*)> = *plot-request* <(*options*)>
PLOTS <(*global-plot-options*)> = (*plot-request* <(*options*)> <... *plot-request* <(*options*)> >)
specifies the ODS graphical plots. Currently, the only available ODS graphical plots in PROC CALIS are for residual distributions. Also, when the residual histograms are requested, the bar charts of residual tallies are suppressed. To display these bar charts with the residual histograms, you must use the RESIDUAL(TALLY) option.

When you specify only one *plot-request*, you can omit the parentheses around the *plot-request*. For example:

```
plots=all
plots=residuals
```

You must enable ODS Graphics before requesting plots; for example:

```
ods graphics on;

proc calis plots=residuals;
run;

ods graphics off;
```

For more information about the ODS GRAPHICS statement, see Chapter 21, "Statistical Graphics Using ODS."

The following table shows the available *plot-requests*:

Plot-request	Plot Description
ALL	all available plots
NONE	no ODS graphical plots
RESIDUALS	distribution of residuals

PREDET | PRE

displays the pattern of variable and constant elements of the predicted moment matrix that is predetermined by the analysis model. It is especially helpful in finding manifest variables that are not used or that are used as exogenous variables in a complex model specified in the COSAN statement. Those entries of the predicted moment matrix for which the model generates variable (rather than constant) elements are displayed as missing values. This output is displayed even without specifying the PREDET option if the model generates constant elements in the predicted model matrix different from those in the analysis moment matrix and if you specify at least the PSHORT amount of displayed output.

If the analyzed matrix is a correlation matrix (containing constant elements of 1s in the diagonal) and the model generates a predicted model matrix with q constant (rather than variable) elements in the diagonal, the degrees of freedom are automatically reduced by q. The output generated by the PREDET option displays those constant diagonal positions. If you specify the DFREDUCE= or NODIAG option, this automatic reduction of the degrees of freedom is suppressed. See the section "Counting the Degrees of Freedom" on page 956 for more information.

PRIMAT | PMAT

displays parameter estimates, approximate standard errors, and t values in matrix form if you specify the analysis model in the RAM or LINEQS statement. When a COSAN statement is used, this occurs by default.

PRINT | PRI

adds the options KURTOSIS, RESIDUAL, PLATCOV, and TOTEFF to the default output.

PRIVEC | PVEC

displays parameter estimates, approximate standard errors, the gradient, and t values in vector form. The values are displayed with more decimal places. This displayed output is not included in the output generated by the PALL option.

PSHORT | SHORT | PSH

excludes the output produced by the PINITIAL, SIMPLE, and STDERR options from the default output.

PSUMMARY | SUMMARY | PSUM

displays the fit assessment table and the ERROR, WARNING, and NOTE messages.

PWEIGHT | PW

displays the weight matrix $\mathbf{W}$ used in the estimation. The weight matrix is displayed after the WRIDGE= and WPENALTY= options are applied to it.

RADIUS=*r*

is an alias for the INSTEP= option for Levenberg-Marquardt minimization.

RANDOM =*i*

specifies a positive integer as a seed value for the pseudo-random number generator to generate initial values for the parameter estimates for which no other initial value assignments in the model definitions are made. Except for the parameters in the diagonal locations of the central matrices in the model, the initial values are set to random numbers in the range

$0 \leq r \leq 1$. The values for parameters in the diagonals of the central matrices are random numbers multiplied by 10 or 100. For more information, see the section "Initial Estimates" on page 941.

RDF | DFR=*n*

makes the effective number of observations the actual number of observations minus the RDF= value. The degree of freedom for the intercept should not be included in the RDF= option. If you use PROC CALIS to compute a regression model, you can specify RDF= *number-of-regressor-variables* to get approximate standard errors equal to those computed by PROC REG.

RESIDUAL | RES <(TALLY | TALLIES)> <= NORM | VARSTAND | ASYSTAND>

displays the raw and normalized residual covariance matrices, the rank order of the largest residuals, and the bar charts of residual tallies. This information is displayed by default when you specify the PRINT option.

Three types of normalized or standardized residual matrices can be chosen with the RESIDUAL= specification:

RESIDUAL= NORM	normalized residuals
RESIDUAL= VARSTAND | VARSTD	variance standardized residuals
RESIDUAL= ASYSTAND | ASYMSTD	asymptotically standardized residuals

When ODS graphical plots of residuals are also requested, the bar charts of residual tallies are suppressed. They are replaced with high-quality graphical histograms showing residual distributions. If you still want to display the bar charts in this situation, use the RESIDUAL(TALLY) or RESIDUAL(TALLY)= option.

For more details, see the section "Assessment of Fit" on page 928.

RIDGE<=*r***>**

defines a ridge factor r for the diagonal of the moment matrix $\mathbf{S}$ that is analyzed. The matrix $\mathbf{S}$ is transformed to

$$\mathbf{S} \longrightarrow \tilde{\mathbf{S}} = \mathbf{S} + r(diag(\mathbf{S}))$$

If you do not specify r in the RIDGE option, PROC CALIS tries to ridge the moment matrix $\mathbf{S}$ so that the smallest eigenvalue is about 10^{-3}.

CAUTION: The moment matrix in the OUTSTAT= output data set does not contain the ridged diagonal.

SALPHA=*r*

is an alias for the INSTEP= option for line-search algorithms.

SIMPLE | S

displays means, standard deviations, skewness, and univariate kurtosis if available. This information is displayed when you specify the PRINT option. If you specify the UCOV, UCORR, or NOINT option, the standard deviations are not corrected for the mean. If the KURTOSIS option is specified, the SIMPLE option is set by default.

SINGULAR | SING=*r*

specifies the singularity criterion r, $0 < r < 1$, used, for example, for matrix inversion. The default value is the square root of the relative machine precision or, equivalently, the square root of the largest double-precision value that, when added to 1, results in 1.

SLMW=*r*

specifies the probability limit used for computing the stepwise multivariate Wald test. The process stops when the univariate probability is smaller than r. The default value is $r = 0.05$.

SPRECISION | SP=*r*

is an alias for the LSPRECISION= option.

START=*r*

In general, this option is needed only in connection with the COSAN model statement, and it specifies a constant r as an initial value for all the parameter estimates for which no other initial value assignments in the pattern definitions are made. Start values in the diagonal locations of the central matrices are set to $100|r|$ if a COV or UCOV matrix is analyzed and $10|r|$ if a CORR or UCORR matrix is analyzed. The default value is $r = 0.5$. Unspecified initial values in a FACTOR, RAM, or LINEQS model are usually computed by PROC CALIS. If none of the initialization methods are able to compute all starting values for a model specified by a FACTOR, RAM, or LINEQS statement, then the start values of parameters that could not be computed are set to r, $10|r|$, or $100|r|$. If the DEMPHAS= option is used, the initial values of the diagonal elements of the central model matrices are multiplied by the value specified in the DEMPHAS= option. For more information, see the section "Initial Estimates" on page 941.

STDERR | SE

displays approximate standard errors if estimation methods other than unweighted least squares (ULS) or diagonally weighted least squares (DWLS) are used (and the NOSTDERR option is not specified). If you specify neither the STDERR nor the NOSTDERR option, the standard errors are computed for the OUTRAM= data set. This information is displayed by default when you specify the PRINT option.

TECHNIQUE | TECH=*name*

OMETHOD | OM=*name*

specifies the optimization technique. Valid values for *name* are as follows:

CONGRA | CG chooses one of four different conjugate-gradient optimization algorithms, which can be more precisely defined with the UPDATE= option and modified with the LINESEARCH= option. The conjugate-gradient techniques need only $O(t)$ memory compared to the $O(t^2)$ memory for the other three techniques, where t is the number of parameters. On the other hand, the conjugate-gradient techniques are significantly slower than other optimization techniques and should be used only when memory is insufficient for more efficient techniques. When you choose this option, UPDATE=PB by default. This is the default optimization technique if there are more than 400 parameters to estimate.

DBLDOG | DD performs a version of double-dogleg optimization, which uses the gradient to update an approximation of the Cholesky factor of the Hessian. This technique is, in many ways, very similar to the dual quasi-Newton method, but it does not use line search. The implementation is based on Dennis and Mei (1979) and Gay (1983).

LEVMAR | LM | MARQUARDT performs a highly stable but, for large problems, memory- and time-consuming Levenberg-Marquardt optimization technique, a slightly improved variant of the Moré (1978) implementation. This is the default optimization technique if there are fewer than 40 parameters to estimate.

NEWRAP | NRA performs a usually stable but, for large problems, memory- and time-consuming Newton-Raphson optimization technique. The algorithm combines a line-search algorithm with ridging, and it can be modified with the LINESEARCH= option. Prior to SAS 6.11, this option invokes the NRRIDG option.

NRRIDG | NRR | NR | NEWTON performs a usually stable but, for large problems, memory- and time-consuming Newton-Raphson optimization technique. This algorithm does not perform a line search. Since TECH=NRRIDG uses an orthogonal decomposition of the approximate Hessian, each iteration of TECH=NRRIDG can be slower than that of TECH=NEWRAP, which works with Cholesky decomposition. However, usually TECH=NRRIDG needs fewer iterations than TECH=NEWRAP.

QUANEW | QN chooses one of four different quasi-Newton optimization algorithms that can be more precisely defined with the UPDATE= option and modified with the LINESEARCH= option. If boundary constraints are used, these techniques sometimes converge slowly. When you choose this option, UPDATE=DBFGS by default. If nonlinear constraints are specified in the NLINCON statement, a modification of Powell's (1982a, 1982b) VMCWD algorithm is used, which is a sequential quadratic programming (SQP) method. This algorithm can be modified by specifying VERSION=1, which replaces the update of the Lagrange multiplier estimate vector μ to the original update of Powell (1978a, 1978b) that is used in the VF02AD algorithm. This can be helpful for applications with linearly dependent active constraints. The QUANEW technique is the default optimization technique if there are nonlinear constraints specified or if there are more than 40 and fewer than 400 parameters to estimate. The QUANEW algorithm uses only first-order derivatives of the objective function and, if available, of the nonlinear constraint functions.

TRUREG | TR performs a usually very stable but, for large problems, memory- and time-consuming trust-region optimization technique. The algorithm is implemented similar to Gay (1983) and Moré and Sorensen (1983).

NONE | NO does not perform any optimization. This option is similar to METHOD=NONE, but TECH=NONE also computes and displays residuals and goodness of fit statistics. If you

specify METHOD=ML, METHOD=LSML, METHOD=GLS, METHOD=LSGLS, METHOD=WLS, or METHOD=LSWLS, this option enables computing and displaying (if the display options are specified) of the standard error estimates and modification indices corresponding to the input parameter estimates.

Since there is no single nonlinear optimization algorithm available that is clearly superior (in terms of stability, speed, and memory) for all applications, different types of optimization techniques are provided in the CALIS procedure. Each technique can be modified in various ways. The default optimization technique for fewer than 40 parameters ($t < 40$) is TECHNIQUE=LEVMAR. For $40 \leq t < 400$, TECHNIQUE=QUANEW is the default method, and for $t \geq 400$, TECHNIQUE=CONGRA is the default method. For more details, see the section "Use of Optimization Techniques" on page 945. You can specify the following set of options in the PROC CALIS statement or in the NLOPTIONS statement.

TOTEFF | TE
computes and displays total effects and indirect effects.

UCORR
analyzes the uncorrected correlation matrix instead of the correlation matrix corrected for the mean. Using the UCORR option is equivalent to specifying the NOINT option but not the COV option.

UCOV
analyzes the uncorrected covariance matrix instead of the covariance matrix corrected for the mean. Using the UCOV option is equivalent to specifying both the COV and NOINT options. You can specify this option to analyze mean structures in an uncorrected covariance matrix—that is, to compute intercepts in systems of linear structural equations (see Example 25.2).

UPDATE | UPD=*name*
specifies the update method for the quasi-Newton or conjugate-gradient optimization technique.

For TECHNIQUE=CONGRA, the following updates can be used:

PB performs the automatic restart update method of Powell (1977) and Beale (1972). This is the default.

FR performs the Fletcher-Reeves update (Fletcher 1980, p. 63).

PR performs the Polak-Ribiere update (Fletcher 1980, p. 66).

CD performs a conjugate-descent update of Fletcher (1987).

For TECHNIQUE=DBLDOG, the following updates (Fletcher 1987) can be used:

DBFGS performs the dual Broyden-Fletcher-Goldfarb-Shanno (BFGS) update of the Cholesky factor of the Hessian matrix. This is the default.

DDFP performs the dual Davidon-Fletcher-Powell (DFP) update of the Cholesky factor of the Hessian matrix.

For TECHNIQUE=QUANEW, the following updates (Fletcher 1987) can be used:

BFGS performs original BFGS update of the inverse Hessian matrix. This is the default for earlier releases.

DFP performs the original DFP update of the inverse Hessian matrix.

DBFGS performs the dual BFGS update of the Cholesky factor of the Hessian matrix. This is the default.

DDFP performs the dual DFP update of the Cholesky factor of the Hessian matrix.

VARDEF= DF | N | WDF | WEIGHT | WGT

specifies the divisor used in the calculation of covariances and standard deviations. The default value is VARDEF=DF. The values and associated divisors are displayed in the following table, where $i = 0$ if the NOINT option is used and $i = 1$ otherwise and where k is the number of partial variables specified in the PARTIAL statement. Using an intercept variable in a mean structure analysis, by specifying the AUGMENT option, includes the intercept variable in the analysis. In this case, $i = 1$. When a WEIGHT statement is used, w_j is the value of the WEIGHT variable in the jth observation, and the summation is performed only over observations with positive weight.

Value	Description	Divisor
DF	degrees of freedom	$N - k - i$
N	number of observations	N
WDF	sum of weights DF	$\sum_j^N w_j - k - i$
WEIGHT | WGT	sum of weights	$\sum_j^N w_j$

VSINGULAR | VSING=*r*

specifies a relative singularity criterion r, $r > 0$, for the inversion of the information matrix, which is needed to compute the covariance matrix. The following singularity criterion is used:

$$|d_{j,j}| \leq \max(ASING, VSING * |H_{j,j}|, MSING * \max(|H_{1,1}|, \ldots, |H_{n,n}|))$$

where $d_{j,j}$ is the diagonal pivot of the matrix, and *ASING* and *MSING* are the specified values of the ASINGULAR= and MSINGULAR= options. If you do not specify the SINGULAR= option, the default value for *VSING* is 1E−8; otherwise, the default value is SINGULAR. Note that in many cases a normalized matrix $\mathbf{D}^{-1}\mathbf{H}\mathbf{D}^{-1}$ is decomposed, and the singularity criteria are modified correspondingly.

WPENALTY | WPEN=*r*

specifies the penalty weight $r \geq 0$ for the WLS and DWLS fit of the diagonal elements of a correlation matrix (constant 1s). The criterion for weighted least squares estimation of a correlation structure is

$$\mathbf{F}_{WLS} = \sum_{i=2}^{n} \sum_{j=1}^{i-1} \sum_{k=2}^{n} \sum_{l=1}^{k-1} w^{ij,kl}(s_{ij} - c_{ij})(s_{kl} - c_{kl}) + r \sum_{i}^{n} (s_{ii} - c_{ii})^2$$

where r is the penalty weight specified by the WPENALTY=r option and the $w^{ij,kl}$ are the elements of the inverse of the reduced $(n(n-1)/2) \times (n(n-1)/2)$ weight matrix that

contains only the nonzero rows and columns of the full weight matrix **W**. The second term is a penalty term to fit the diagonal elements of the correlation matrix. The default value is 100. The reciprocal of this value replaces the asymptotic variance corresponding to the diagonal elements of a correlation matrix in the weight matrix **W**, and it is effective only with the ASYCOV=CORR option. The often used value $r = 1$ seems to be too small in many cases to fit the diagonal elements of a correlation matrix properly. The default WPENALTY= value emphasizes the importance of the fit of the diagonal elements in the correlation matrix. You can decrease or increase the value of r if you want to decrease or increase the importance of the diagonal elements fit. This option is effective only with the WLS or DWLS estimation method and the analysis of a correlation matrix. See the section "Estimation Criteria" on page 923 for more details.

WRIDGE=*r*

defines a ridge factor r for the diagonal of the weight matrix **W** used in GLS, WLS, or DWLS estimation. The weight matrix **W** is transformed to

$$\mathbf{W} \longrightarrow \tilde{\mathbf{W}} = \mathbf{W} + r(diag(\mathbf{W}))$$

The WRIDGE= option is applied to the weight matrix as follows:

- before the WPENALTY= option is applied to it
- before the weight matrix is written to the OUTWGT= data set
- before the weight matrix is displayed

BOUNDS Statement

BOUNDS *constraint* < , *constraint* . . . > **;**

where *constraint* represents

< *number operator* > *parameter-list* < *operator number* >

You can use the BOUNDS statement to define boundary constraints for any parameter that has its name specified in a MATRIX, LINEQS, STD, COV, or RAM statement or that is used in the model of an INRAM= data set. Valid operators are <=, <, >=, >, and = or, equivalently, LE, LT, GE, GT, and EQ. The following is an example of the BOUNDS statement:

```
bounds         0.   <= a1-a9 x    <= 1. ,
              -1.   <= c2-c5              ,
                       b1-b10 y   >= 0. ;
```

You must separate boundary constraints with a comma, and you can specify more than one BOUNDS statement. The feasible region for a parameter is the intersection of all boundary constraints specified for that parameter; if a parameter has a maximum lower boundary constraint larger than its minimum upper bound, the parameter is set equal to the minimum of the upper bounds.

If you need to compute the values of the upper or lower bounds, create a TYPE=EST data set containing _TYPE_='UPPERBD' or _TYPE_='LOWERBD' observations and use it as an INEST= or INVAR= input data set in a later PROC CALIS run.

The BOUNDS statement can contain only parameter names and numerical constants. You cannot use the names of variables created in SAS programming statements.

The active set strategies made available in PROC CALIS cannot realize the strict inequality constraints < or >. For example, you cannot specify **BOUNDS x > 0;** to prevent infinite values for $y = log(x)$. Use **BOUNDS x > 1E-8;** instead.

If the CALIS procedure encounters negative diagonal elements in the central model matrices during the minimization process, serious convergence problems can occur. You can use the BOUNDS statement to constrain these parameters to nonnegative values. Using negative values in these locations can lead to a smaller χ^2 value but uninterpretable estimates.

BY Statement

BY *variables* **;**

You can specify a BY statement with PROC CALIS to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the CALIS procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the *Base SAS Procedures Guide*.

COSAN Model Statement

COSAN *matrix_term* < + *matrix_term*. . . > **;**

where *matrix_term* represents
matrix_definition < ∗ *matrix_definition* . . . >
and *matrix_definition* represents
matrix_name (column_number < *,general_form* < *,transformation* >> *)*

The COSAN statement constructs the symmetric matrix model for the covariance analysis mentioned earlier (see the section "The Generalized COSAN Model" on page 832):

$$\mathbf{C} = \mathbf{F}_1\mathbf{P}_1\mathbf{F}_1' + \cdots + \mathbf{F}_m\mathbf{P}_m\mathbf{F}_m',$$

$$\mathbf{F}_k = \mathbf{F}_{k_1}\cdots\mathbf{F}_{k_{n(k)}}, \qquad \text{and} \quad \mathbf{P}_k = \mathbf{P}_k', \quad k = 1,\ldots,m$$

$$\mathbf{F}_{k_j} = \begin{cases} \mathbf{G}_{k_j} \\ \mathbf{G}_{k_j}^{-1} \\ (\mathbf{I}-\mathbf{G}_{k_j})^{-1} \end{cases} \quad j = 1,\ldots,n(k), \qquad \text{and} \qquad \mathbf{P}_k = \begin{cases} \mathbf{Q}_k \\ \mathbf{Q}_k^{-1} \end{cases}$$

You can specify only one COSAN statement with each PROC CALIS statement. The COSAN statement contains m *matrix_term*s corresponding to the generalized COSAN formula. The *matrix_term*s are separated by plus signs (+) according to the addition of the terms within the model.

Each *matrix_term* of the COSAN statement contains the definitions of the first $n(k)+1$ matrices, $\mathbf{F}_{k_j}$ and $\mathbf{P}_k$, separated by asterisks (*) according to the multiplication of the matrices within the term. The matrices $\mathbf{F}_k'$ of the right-hand-side product are redundant and are not specified within the COSAN statement.

Each *matrix_definition* consists of the name of the matrix (*matrix_name*), followed in parentheses by the number of columns of the matrix (*column_number*) and, optionally, one or two matrix properties, separated by commas, describing the form of the matrix.

The number of rows of the first matrix in each term is defined by the input correlation or covariance matrix. You can reorder and reduce the variables in the input moment matrix by using the VAR statement. The number of rows of the other matrices within the term is defined by the number of columns of the preceding matrix.

The first matrix property is indicated by *general_form*, which describes the general form of the matrix in the model. You can choose one of the following specifications of the first matrix property. The default first matrix property is GEN.

IDE specifies an identity matrix; if the matrix is not square, this specification describes an identity submatrix followed by a rectangular zero submatrix.

ZID specifies an identity matrix; if the matrix is not square, this specification describes a rectangular zero submatrix followed by an identity submatrix.

DIA specifies a diagonal matrix; if the matrix is not square, this specification describes a diagonal submatrix followed by a rectangular zero submatrix.

ZDI specifies a diagonal matrix; if the matrix is not square, this specification describes a rectangular zero submatrix followed by a diagonal submatrix.

LOW specifies a lower triangular matrix; the matrix can be rectangular.

UPP specifies an upper triangular matrix; the matrix can be rectangular.

SYM specifies a symmetric matrix; the matrix cannot be rectangular.

GEN specifies a general rectangular matrix (default).

The second matrix property is indicated by *transformation*, which describes the kind of inverse matrix transformation. If the second matrix property is omitted, no transformation is applied to the matrix.

INV uses the inverse of the matrix.

IMI uses the inverse of the difference between the identity and the matrix.

You cannot specify a nonsquare parameter matrix as an INV or IMI model matrix. Specifying a matrix of type DIA, ZDI, UPP, LOW, or GEN is not necessary if you do not use the *unspecified location* list in the corresponding MATRIX statements. After PROC CALIS processes the corresponding MATRIX statements, the matrix type DIA, ZDI, UPP, LOW, or GEN is recognized from the pattern of possibly nonzero elements. If you do not specify the first matrix property and you use the *unspecified location* list in a corresponding MATRIX statement, the matrix is recognized as a GEN matrix. You can also generate an IDE or ZID matrix by specifying a DIA, ZDI, or IMI matrix and by using MATRIX statements that define the pattern structure. However, PROC CALIS would be unable to take advantage of the fast algorithms that are available for IDE and ZID matrices in this case.

For example, to specify a second-order factor analysis model

$$\mathbf{S} = \mathbf{F}_1\mathbf{F}_2\mathbf{P}_2\mathbf{F}_2'\mathbf{F}_1' + \mathbf{F}_1\mathbf{U}_2^2\mathbf{F}_1' + \mathbf{U}_1^2$$

with $m_1 = 3$ first-order factors and $m_2 = 2$ second-order factors and with $n = 9$ variables, you can use the following COSAN statement:

```
cosan F1(3) * F2(2) * P2(2,SYM)+F1(3) * U2(3,DIA) * I1(3,IDE)
      +U1(9,DIA) * I2(9,IDE)
```

COV Statement

COV *assignment* < , *assignment . . .* > **;**

where *assignment* represents *variables* < ∗ *variables2* >> = *pattern-definition*

The COV statement tells which covariances are parameters to estimate and which are fixed. The COV statement can be used only with the LINEQS statement. The COV statement differs from the STD statement only in the meaning of the left-hand-side *variables* list. You can specify only one COV statement with each LINEQS statement. The COV statement defines the off-diagonal

elements of the central model matrix $\mathbf{\Phi}$. These elements correspond to the covariances of the exogenous variables and to the error covariances of the endogenous variables. Elements that are not defined are assumed to be zero. The *assignment*s in the COV statement must be separated by commas.

The *variables* list on the left-hand side of the equal sign should contain only names of variables that do not appear on the left-hand side of an equation in the LINEQS statement—that is, exogenous, error, and disturbance variables.

The *pattern-definition* on the right-hand side is similar to that used in the MATRIX statement. Each list element on the right-hand side defines the covariance of a pair of variables in the list on the left-hand side. A name on the right-hand side can be followed by a number inside parentheses that gives the initial value. A number on the right-hand side means that the corresponding covariance of the variable on the left-hand side is fixed. If the right-hand-side list is longer than the left-hand-side variable list, the right-hand-side list is shortened to the length of the variable list. If the right-hand-side list is shorter than the variable list, the right-hand-side list is filled with repetitions of the last item in the list.

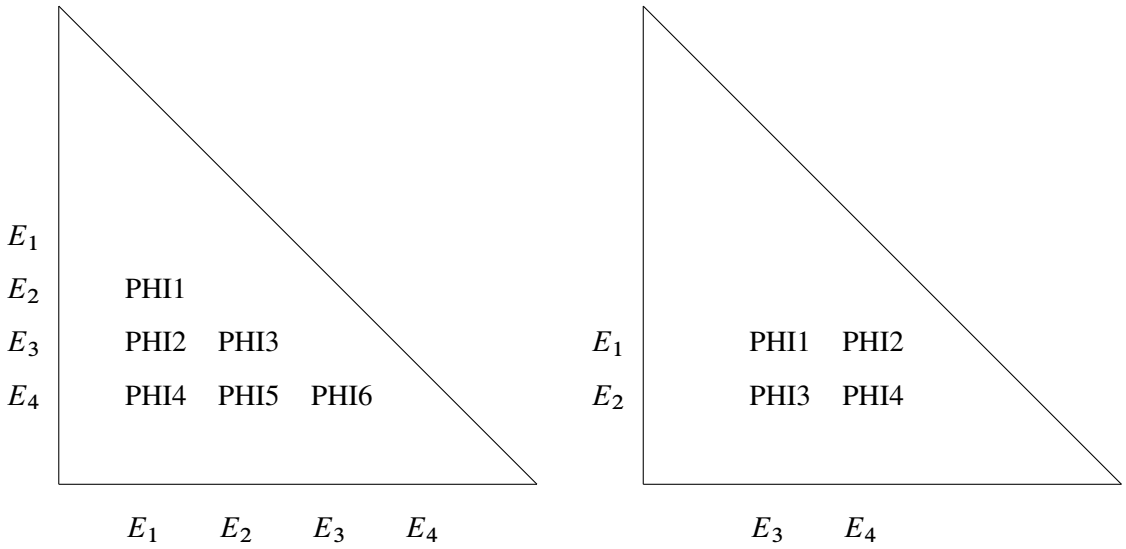
You can use one of two alternatives to refer to parts of $\mathbf{\Phi}$. The first alternative uses only one variable list and refers to all distinct pairs of variables within the list. The second alternative uses two variable lists separated by an asterisk and refers to all pairs of variables among the two lists.

Within-List Covariances

Using k variable names in the *variables* list on the left-hand side of an equal sign in a COV statement means that the parameter list (*pattern-definition*) on the right-hand side refers to all $k(k-1)/2$ distinct variable pairs in the below-diagonal part of the $\mathbf{\Phi}$ matrix. Order is very important. The order relation between the left-hand-side variable pairs and the right-hand-side parameter list is illustrated by the following example:

```
COV E1-E4 = PHI1-PHI6 ;
```

This is equivalent to the following specification:



```
COV E2 E1 = PHI1,
    E3 E1 = PHI2, E3 E2 = PHI3,
    E4 E1 = PHI4, E4 E2 = PHI5, E4 E3 = PHI6;
```

The symmetric elements are generated automatically. When you use prefix names on the right-hand sides, you do not have to count the exact number of parameters. For example,

```
COV E1-E4 = PHI: ;
```

generates the same list of parameter names if the prefix PHI is not used in a previous statement. This is illustrated in the left panel of Figure 25.2. Integers starting from 1 are appended to the prefix PHI to form the parameter names for each of the within-list covariances.

Figure 25.2 Within-List and Between-List Covariances

Between-List Covariances

Using k_1 and k_2 variable names in the two lists (separated by an asterisk) on the left-hand side of an equal sign in a COV statement means that the parameter list on the right-hand side refers to all $k_1 \times k_2$ distinct variable pairs in the $\mathbf{\Phi}$ matrix. Order is very important. The order relation between the left-hand-side variable pairs and the right-hand-side parameter list is illustrated by the following example:

```
COV E1 E2 * E3 E4 = PHI1-PHI4 ;
```

This is equivalent to the following specification:

```
COV  E1 E3 = PHI1, E1 E4 = PHI2,
     E2 E3 = PHI3, E2 E4 = PHI4;
```

The symmetric elements are generated automatically. Using prefix names on the right-hand sides lets you achieve the same purpose without counting the number of parameters. That is,

```
COV  E1 E2 * E3 E4 = PHI: ;
```

This is illustrated in the right panel of Figure 25.2. Integers starting from 1 are appended to the prefix PHI to form the parameter names for each of the between-list covariances.

FACTOR Model Statement

FACTOR < *options* > **;**

You can use the FACTOR statement to specify an exploratory or confirmatory first-order factor analysis of the given covariance or correlation matrix $\mathbf{C}$,

$$\mathbf{C} = \mathbf{F}\mathbf{F}' + \mathbf{U}, \quad \mathbf{U} = diag$$

or

$$\mathbf{C} = \mathbf{F}\mathbf{P}\mathbf{F}' + \mathbf{U}, \quad \mathbf{P} = \mathbf{P}'$$

where $\mathbf{U}$ is a diagonal matrix and $\mathbf{P}$ is symmetric. Within this section, n denotes the number of manifest variables corresponding to the rows and columns of matrix $\mathbf{C}$, and m denotes the number of latent variables (factors or components) corresponding to the columns of the loading matrix $\mathbf{F}$.

You can specify only one FACTOR statement with each PROC CALIS statement. You can specify higher-order factor analysis problems by using a COSAN model specification. PROC CALIS requires more computing time and memory than PROC FACTOR because it is designed for more general structural estimation problems and is unable to exploit the special properties of the unconstrained factor analysis model.

For default (exploratory) factor analysis, PROC CALIS computes initial estimates for factor loadings and unique variances by an algebraic method of approximate factor analysis. If you use a MATRIX statement together with a FACTOR model specification, initial values are computed by McDonald's (McDonald and Hartmann 1992) method (if possible). For details, see "Using the FACTOR and MATRIX Statements" on page 879. If neither of the two methods is appropriate, the initial values are set by the START= option.

The unrestricted factor analysis model is not identified because any orthogonal rotated factor loading matrix $\tilde{\mathbf{F}} = \mathbf{F}\boldsymbol{\Theta}$ is equivalent to the result $\mathbf{F}$,

$$\mathbf{C} = \tilde{\mathbf{F}}\tilde{\mathbf{F}}' + \mathbf{U}, \qquad \tilde{\mathbf{F}} = \mathbf{F}\boldsymbol{\Theta}, \quad \text{where} \quad \boldsymbol{\Theta}'\boldsymbol{\Theta} = \boldsymbol{\Theta}\boldsymbol{\Theta}' = \mathbf{I}$$

To obtain an identified factor solution, the FACTOR statement imposes zero constraints on the $m(m-1)/2$ elements in the upper triangle of $\mathbf{F}$ by default.

The following options are available in the FACTOR statement.

COMPONENT | COMP

computes a component analysis instead of a factor analysis (the diagonal matrix $\mathbf{U}$ in the model is set to 0). Note that the rank of $\mathbf{F}\mathbf{F}'$ is equal to the number m of components in $\mathbf{F}$. If m is smaller than the number of variables in the moment matrix $\mathbf{C}$, the matrix of predicted model values is singular and maximum likelihood estimates for $\mathbf{F}$ cannot be computed. You should compute ULS estimates in this case.

HEYWOOD | HEY

constrains the diagonal elements of **U** to be nonnegative; in other words, the model is replaced by

$$\mathbf{C} = \mathbf{F}\mathbf{F}' + \mathbf{U}^2, \quad \mathbf{U} = diag$$

N=*m*

specifies the number of first-order factors or components. The number m of factors should not exceed the number n of variables in the covariance or correlation matrix analyzed. For the saturated model, $m = n$, the COMP option should generally be specified for $\mathbf{U} = 0$; otherwise, $df < 0$. For $m = 0$ no factor loadings are estimated, and the model is $\mathbf{C} = \mathbf{U}$, with $\mathbf{U} = diag$. By default, $m = 1$.

NORM < = KAISER | NONE >

Kaiser-normalizes the rows of the factor pattern for rotation. NORM=KAISER, which is the default, has exactly the same effect as NORM. You can turn off the normalization by NORM=NONE.

RCONVERGE=*p*

RCONV=*p*

specifies the convergence criterion for rotation cycles. The option is applicable to rotation by using either the QUARTIMAX, VARIMAX, EQUAMAX, or PARSIMAX method in the ROTATE= option. Rotation stops when the scaled change of the simplicity function value is less than the RCONVERGE= value. The default convergence criterion is

$$|f_{new} - f_{old}|/K < \epsilon$$

where f_{new} and f_{old} are simplicity function values of the current cycle and the previous cycle, respectively, $K = max(1, |f_{old}|)$ is a scaling factor, and ϵ is 1E–9 by default and is modified by the RCONVERGE= value.

RITER=*n*

specifies the maximum number of cycles n for factor rotation by using either the QUARTIMAX, VARIMAX, EQUAMAX, or PARSIMAX method in the ROTATE= option. The default n is the maximum between 10 times the number of variables and 100.

ROTATE | R=*name*

specifies an orthogonal rotation. By default, ROTATE=NONE. The possible values for *name* are as follows:

PRINCIPAL | PC specifies a principal axis rotation. If ROTATE=PRINCIPAL is used with a factor rather than a component model, the following rotation is performed:

$$\mathbf{F}_{new} = \mathbf{F}_{old}\mathbf{T}, \quad \text{with} \quad \mathbf{F}'_{old}\mathbf{F}_{old} = \mathbf{T}\mathbf{\Lambda}\mathbf{T}'$$

where the columns of matrix $\mathbf{T}$ contain the eigenvectors of $\mathbf{F}'_{old}\mathbf{F}_{old}$.

QUARTIMAX | Q specifies quartimax rotation.

VARIMAX | V specifies varimax rotation.

EQUAMAX | E specifies equamax rotation.

PARSIMAX | P specifies parsimax rotation.

NONE performs no rotation (default).

Using the FACTOR and MATRIX Statements

You can specify the MATRIX statement and the FACTOR statement to compute a confirmatory first-order factor or component analysis. You can define the elements of the matrices **F**, **P**, and **U** of the oblique model,

$$\mathbf{C} = \mathbf{FPF}' + \mathbf{U}^2, \quad \mathbf{P} = \mathbf{P}', \quad \mathbf{U} = diag$$

To specify the structure for matrix **F**, **P**, or **U**, you have to refer to the matrix _F_ , _P_ , or _U_ in the MATRIX statement. Matrix names automatically set by PROC CALIS always start with an underscore. As you name your own matrices or variables, you should avoid leading underscores.

The default matrix forms are as follows:

_F_ lower triangular matrix (0 upper triangle for problem identification, removing rotational invariance)

_P_ identity matrix (constant)

_U_ diagonal matrix

For details about specifying the elements in matrices, see the section "MATRIX Statement" on page 883. If you are using at least one MATRIX statement in connection with a FACTOR model statement, you can also use the BOUNDS or PARAMETERS statement and programming statements to constrain the parameters named in the MATRIX statement. Initial estimates are computed by McDonald's (McDonald and Hartmann 1992) method. McDonald's method of computing initial values works better if you scale the factors by setting the factor variances to 1 rather than by setting the loadings of the reference variables equal to 1.

FREQ Statement

FREQ *variable* **;**

If one variable in your data set represents the frequency of occurrence for the other values in the observation, specify the variable's name in a FREQ statement. PROC CALIS then treats the data set as if each observation appears n_i times, where n_i is the value of the FREQ variable for observation i. Only the integer portion of the value is used. If the value of the FREQ variable is less than 1 or is missing, that observation is not included in the analysis. The total number of observations is considered to be the sum of the FREQ values when the procedure computes significance probabilities. You can use only one FREQ statement with each PROC CALIS statement.

LINCON Statement

LINCON *constraint* < , *constraint* ... > **;**

where *constraint* represents one of the following:

- *number operator linear-term*
- *linear-term operator number*

and *linear-term* is

< + | − >< *coefficient* * > *parameter* << + | − >< *coefficient* * > *parameter* ... >

The LINCON statement specifies a set of linear equality or inequality constraints of the form

$$\sum_{j=1}^{n} a_{ij} x_j \leq b_i, \quad i = 1, \ldots, m$$

The constraints must be separated by commas. Each linear constraint i in the statement consists of a linear combination $\sum_j a_{ij} x_j$ of a subset of the n parameters x_j, $j = 1, \ldots, n$, and a constant value b_i separated by a comparison operator. Valid operators are <=, <, >=, >, and = or, equivalently, LE, LT, GE, GT, and EQ. PROC CALIS cannot enforce the strict inequalities < or >. Note that the coefficients a_{ij} in the linear combination must be constant numbers and must be followed by an asterisk and the name of a parameter (for example, listed in the PARMS, STD, or COV statement). The following is an example of the LINCON statement that sets a linear constraint on parameters x1 and x2:

```
lincon       x1 + 3 * x2 <= 1;
```

Although you can easily express boundary constraints in LINCON statements, for many applications it is much more convenient to specify both the BOUNDS and LINCON statements in the same PROC CALIS call.

The LINCON statement can contain only parameter names, operators, and numerical constants. If you need to compute the values of the coefficients a_{ij} or right-hand sides b_i, you can run a preliminary DATA step and create a TYPE=EST data set containing _TYPE_='LE', _TYPE_='GE', or _TYPE_='EQ' observations, and then specify this data set as an INEST= or INVAR= data set in a subsequent PROC CALIS run.

LINEQS Model Statement

LINEQS *equation* < , *equation* . . . > **;**

where *equation* represents

dependent = *term* < + *term* . . . >

and each *term* represents one of the following:

- *coefficient-name* < *(number)* > *variable-name*
- *prefix-name* < *(number)* > *variable-name*
- < *number* > *variable-name*

The LINEQS statement defines the following LINEQS model:

$$\begin{aligned} \boldsymbol{\eta} &= \boldsymbol{\beta}\boldsymbol{\eta} + \boldsymbol{\gamma}\boldsymbol{\xi} \\ \mathbf{C} &= \mathbf{J}(\mathbf{I}-\mathbf{B})^{-1}\boldsymbol{\Gamma}\boldsymbol{\Phi}\boldsymbol{\Gamma}'((\mathbf{I}-\mathbf{B})^{-1})'\mathbf{J}' \end{aligned}$$

You can specify only one LINEQS statement with each PROC CALIS statement. There are some differences from Bentler's notation in choosing the variable names. The length of each variable name is restricted to eight characters. The names of the manifest variables are defined in the DATA= input data set. The VAR statement can be used to select a subset of manifest variables in the DATA= input data set to analyze. You do not need to use a V prefix for manifest variables in the LINEQS statement, nor do you need to use a numerical suffix in any variable name. The names of the latent variables must start with the prefix letter F (for Factor); the names of the residuals must start with the prefix letters E (for Error) or D (for Disturbance). The trailing part of the variable name can contain letters or digits. The prefix letter E is used for the errors of the manifest variables, and the prefix letter D is used for the disturbances of the latent variables. The names of the manifest variables in the DATA= input data set can start with F, E, or D, but these names should not coincide with the names of latent or error variables used in the model. The left-hand side (that is, endogenous *dependent* variable) of each equation should be either a manifest variable of the data set or a latent variable with prefix letter F. The left-hand-side variable should not appear on the right-hand side of the same equation; this means that matrix $\boldsymbol{\beta}$ should not have a nonzero diagonal element. Each equation should contain, at most, one E or D variable.

The equations must be separated by a comma. The order of the equations is arbitrary. The displayed output generally contains equations and terms in an order different from that of the input.

Coefficients to estimate are indicated in the equations by a name preceding the independent variable's name. The coefficient's name can be followed by a number inside parentheses indicating the initial value for this coefficient. A number preceding the independent variable's name indicates a constant coefficient. If neither a coefficient name nor a number precedes the independent variable's name, a constant coefficient of 1 is assumed.

If the initial value of a parameter is not specified in the equation, the initial value is chosen in one of the following ways:

- If you specify the RANDOM= option in the PROC CALIS statement, the variable obtains a randomly generated initial value r, such that $0 \leq r \leq 1$. The uninitialized parameters in the

diagonals of the central model matrices are given the nonnegative random values r multiplied by 10, 100, or the value specified in the DEMPHAS= option.

- If the RANDOM= option is not used, PROC CALIS tries to estimate the initial values.
- If the initial values cannot be estimated, the value of the START= option is used as an initial value.

In Bentler's notation, estimated coefficients are indicated by asterisks. Referring to a parameter in Bentler's notation requires the specification of two variable names that correspond to the row and column of the position of the parameter in the matrix. Specifying the estimated coefficients by parameter names makes it easier to impose additional constraints with code. You do not need any additional statements to express equality constraints. Simply specify the same name for parameters that should have equal values.

If your model contains many unconstrained parameters and it is too cumbersome to find different parameter names, you can specify all those parameters by the same prefix name. A prefix is a short name followed by a colon. The CALIS procedure then generates a parameter name by appending an integer suffix to this prefix name. The prefix name should have no more than five or six characters so that the generated parameter name is not longer than eight characters. To avoid unintentional equality constraints, the prefix names should not coincide with explicitly defined parameter names.

For example, consider the following model described in the section "Specifying a Second-Order Factor-Analysis Model" on page 885:

$$\mathbf{S} = \mathbf{F}_1\mathbf{F}_2\mathbf{P}_2\mathbf{F}_2'\mathbf{F}_1' + \mathbf{F}_1\mathbf{U}_2^2\mathbf{F}_1' + \mathbf{U}_1^2$$

You can fit this model by using the LINEQS and STD statements:

```
lineqs
       V1 = X1 F1 + E1,
       V2 = X2 F1 + E2,
       V3 = X3 F1 + E3,
       V4 = X4 F2 + E4,
       V5 = X5 F2 + E5,
       V6 = X6 F2 + E6,
       V7 = X7 F3 + E7,
       V8 = X8 F3 + E8,
       V9 = X9 F3 + E9,
       F1 = Y1 F4 + D1,
       F2 = Y1 F4 + Y2 F5 + D2,
       F3 = Y2 F5 + D3;

std
       E1-E9 = 9 * U:,
       D1-D3 = 3 * V:,
       F4 F5 = 2 * P;
run;
```

MATRIX Statement

MATRIX *matrix-name* < *location* > = *list* < , *location* = *list* . . . > **;**

You can specify one or more MATRIX statements with a COSAN or FACTOR statement. A MATRIX statement specifies which elements of the matrix are constant and which are parameters. You can also assign values to the constant elements and initial values for the parameters. The input notation resembles that used in the COSAN program of McDonald and Fraser (personal communication), except that in PROC CALIS, parameters are distinguished from constants by giving parameters names instead of by using positive and negative integers.

A MATRIX statement cannot be used for an IDE or ZID matrix. For all other types of matrices, each element is assumed to be a constant of 0 unless a MATRIX statement specifies otherwise. Hence, there must be at least one MATRIX statement for each matrix mentioned in the COSAN statement except for IDE and ZID matrices. There can be more than one MATRIX statement for a given matrix. If the same matrix element is given different definitions, later definitions override earlier definitions.

At the start, all elements of each model matrix, except IDE or ZID matrices, are set equal to 0.

Description of *location*:

There are several ways to specify the starting *location* and continuation direction of a *list* with $n+1$, $n \geq 0$, elements within the parameter matrix.

[*i* , *j*] The *list* elements correspond to the diagonally continued matrix elements [*i*,*j*], [*i*+1,*j*+1], . . . , [*i*+*n*,*j*+*n*]. The number of elements is defined by the length of the list and eventually terminated by the matrix boundaries. If the list contains just one element (constant or variable), then it is assigned to the matrix element [*i*,*j*].

[*i* ,] The *list* elements correspond to the horizontally continued matrix elements [*i*,*j*], [*i*,*j*+1], . . . , [*i*,*j*+*n*], where the starting column *j* is the diagonal position for a DIA, ZDI, or UPP matrix and is the first column for all other matrix types. For a SYM matrix, the list elements refer only to the matrix elements in the lower triangle. For a DIA or ZDI matrix, only one list element is accepted.

[, *j*] The *list* elements correspond to the vertically continued matrix elements [*i*,*j*], [*i*+1, *j*], . . . , [*i*+*n*,*j*], where the starting row *i* is equal to the diagonal position for a DIA, ZDI, SYM, or LOW matrix and is the first row for each other matrix type. For a SYM matrix, the list elements refer only to the matrix elements in the lower triangle. For a DIA or ZDI matrix, only one list element is accepted.

[,] unspecified location: The *list* is allocated to all valid matrix positions (except for a ZDI matrix) starting at the element [1,1] and continuing rowwise. The only valid matrix positions for a DIA or ZDI matrix are the diagonal elements; for an UPP or LOW matrix, the valid positions are the elements above or below the diagonal; and for a symmetric matrix, the valid positions are the elements in the lower triangle since the other triangle receives the symmetric allocation automatically. This *location* definition differs from the definitions with specified pattern locations in one important respect: if the number

of elements in the *list* is smaller than the number of valid matrix elements, the list is repeated in the allocation process until all valid matrix elements are filled.

Omitting the left-hand-side term is equivalent to using [,] for an *unspecified location*.

Description of *list*:

The *list* contains numeric values or parameter names, or both, that are assigned to a list of matrix elements starting at a specified position and proceeding in a specified direction. A real number r in the list defines the corresponding matrix element as a constant element with this value. The notation $n * r$ generates n values of r in the list. A name in the list defines the corresponding matrix element as a parameter to be estimated. You can use numbered name lists (X1-X10) or the asterisk notation (5 *X means five occurrences of the parameter X). If a sublist of n_1 names inside a *list* is followed by a list of $n_2 \leq n_1$ real values inside parentheses, the last n_2 parameters in the name sublist are given the initial values mentioned inside the parentheses. For example, the *list*

```
0. 1. A2-A5 (1.4 1.9 2.5) 5.
```

specifies that the first two matrix elements (specified by the *location* to the left of the equal sign) are constants with values 0 and 1. The next element is parameter A2 with no specified initial value. The next three matrix elements are the variable parameters A3, A4, and A5 with initial values 1.4, 1.9, and 2.5, respectively. The next matrix element is specified by the seventh list element to be the constant 5.

If your model contains many unconstrained parameters and it is too cumbersome to find different parameter names, you can specify all those parameters by the same prefix name. A prefix is a short name followed by a colon. The CALIS procedure generates a parameter name by appending an integer suffix to this prefix name. The prefix name should have no more than five or six characters so that the generated parameter name is not longer than eight characters. For example, if the prefix A (the parameter A1) is already used once in a *list*, the previous example would be identical to

```
0. 1. 4 * A: (1.4 1.9 2.5) 5.
```

To avoid unintentional equality constraints, the prefix names should not coincide with explicitly defined parameter names.

If you do not assign initial values to the parameters (listed in parentheses following a name sublist within the pattern list), PROC CALIS assigns initial values as follows:

- If the PROC CALIS statement contains a START=r option, each uninitialized parameter is given the initial value r. The uninitialized parameters in the diagonals of the central model matrices are given the initial value $10|r|$, $100|r|$, or $|r|$ multiplied by the value specified in the DEMPHAS= option.
- If the PROC CALIS statement contains a RANDOM=i option, each uninitialized parameter is given a random initial value $0 \leq r \leq 1$. The uninitialized parameters in the diagonals of the central model matrices are given the random values multiplied by 10, 100, or the value specified in the DEMPHAS= option.
- Otherwise, the initial value is set corresponding to START=0.5.

Specifying a Second-Order Factor-Analysis Model

For example, to specify a confirmatory second-order factor analysis model

$$\mathbf{S} = \mathbf{F}_1\mathbf{F}_2\mathbf{P}_2\mathbf{F}_2'\mathbf{F}_1' + \mathbf{F}_1\mathbf{U}_2^2\mathbf{F}_1' + \mathbf{U}_1^2$$

with $m_1 = 3$ first-order factors, $m_2 = 2$ second-order factors, and $n = 9$ variables and the following matrix pattern,

$$\mathbf{F}_1 = \begin{pmatrix} X_1 & 0 & 0 \\ X_2 & 0 & 0 \\ X_3 & 0 & 0 \\ 0 & X_4 & 0 \\ 0 & X_5 & 0 \\ 0 & X_6 & 0 \\ 0 & 0 & X_7 \\ 0 & 0 & X_8 \\ 0 & 0 & X_9 \end{pmatrix}, \quad \mathbf{U}_1 = \begin{pmatrix} U_1 & & & & & & & & \\ & U_2 & & & & & & & \\ & & U_3 & & & & & & \\ & & & U_4 & & & & & \\ & & & & U_5 & & & & \\ & & & & & U_6 & & & \\ & & & & & & U_7 & & \\ & & & & & & & U_8 & \\ & & & & & & & & U_9 \end{pmatrix}$$

$$\mathbf{F}_2 = \begin{pmatrix} Y_1 & 0 \\ Y_1 & Y_2 \\ 0 & Y_2 \end{pmatrix}, \quad \mathbf{P}_2 = \begin{pmatrix} P & 0 \\ 0 & P \end{pmatrix}, \quad \mathbf{U}_2 = \begin{pmatrix} V_1 & & \\ & V_2 & \\ & & V_3 \end{pmatrix}$$

you can specify the following COSAN and MATRIX statements:

```
cosan f1(3) * f2(2) * p2(2,dia) + f1(3) * u2(3,dia) * i1(3,ide)
      + u1(9,dia) * i2(9,ide);
matrix f1
         [ ,1]= x1-x3,
         [ ,2]= 3 * 0 x4-x6,
         [ ,3]= 6 * 0 x7-x9;
matrix u1
         [1,1]=u1-u9;
matrix f2
         [ ,1]= 2 * y1,
         [ ,2]= 0. 2 * y2;
matrix u2 = 3 * v:;
matrix p2 = 2 * p;
run;
```

The matrix pattern includes several equality constraints. Two loadings in the first and second factor of $\mathbf{F}_2$ (parameter names Y1 and Y2) and the two factor correlations in the diagonal of matrix $\mathbf{P}_2$ (parameter name P) are constrained to be equal. There are many other ways to specify the same model. See Figure 25.3 for the path diagram of this model.

The MATRIX statement can also be used with the FACTOR model statement. See "Using the FACTOR and MATRIX Statements" on page 879 for the usage.

NLINCON Statement

NLINCON | **NLC** *constraint* < , *constraint . . .* > **;**

where *constraint* represents one of the following:

- *number operator variable-list number operator*
- *variable-list operator number*
- *number operator variable-list*

You can specify nonlinear equality and inequality constraints with the NLINCON or NLC statement. The QUANEW optimization subroutine is used when you specify nonlinear constraints by using the NLINCON statement.

The syntax of the NLINCON statement is similar to that of the BOUNDS statement, except that the NLINCON statement must contain the names of variables that are defined in the programming statements and are defined as continuous functions of parameters in the model. They must not be confused with the variables in the data set.

As with the BOUNDS statement, one- or two-sided constraints are allowed in the NLINCON statement; equality constraints must be one-sided. Valid operators are <=, <, >=, >, and = or, equivalently, LE, LT, GE, GT, and EQ.

PROC CALIS cannot enforce the strict inequalities < or > but instead treats them as <= and >=, respectively. The listed nonlinear constraints must be separated by commas. The following is an example of the NLINCON statement that constrains the nonlinear parametric function $x_1 * x_1 + u_1$, which is defined in a programming statement, to a fixed value of 1:

```
nlincon    xx = 1;
xx = x1 * x1 + u1;
```

Note that x1 and u1 are parameters defined in the model. The following three NLINCON statements, which require xx1, xx2, and xx3 to be between 0 and 10, are equivalent:

```
nlincon  0. <= xx1-xx3,
               xx1-xx3 <= 10;
nlincon 0. <= xx1-xx3 <= 10.;
nlincon 10. >= xx1-xx3 >= 0.;
```

NLOPTIONS Statement

NLOPTIONS *option(s)* **;**

Many options that are available in PROC NLP can now be specified for the optimization subroutines in PROC CALIS by using the NLOPTIONS statement. The NLOPTIONS statement provides more displayed and file output on the results of the optimization process, and it permits the same set of termination criteria as in PROC NLP. These are more technical options that you might not need to

specify in most cases. The available options are summarized in Table 25.2 through Table 25.4, and the options are described in detail in the following three sections.

Table 25.2 Options Documented in the PROC CALIS Statement

Option	Description
Estimation Methods	
G4=*i*	specifies the algorithm for computing standard errors
Optimization Techniques	
FCONV=*r*	specifies the relative change function convergence criterion
GCONV=*r*	specifies the relative gradient convergence criterion
INSTEP=*r*	specifies the initial step length (SALPHA=, RADIUS=)
LINESEARCH=*i*	specifies the line-search method
LSPRECISION=*r*	specifies the line-search precision
MAXFUNC=*i*	specifies the maximum number of function calls
MAXITER=*i* <*n*>	specifies the maximum number of iterations
TECHNIQUE=*name*	specifies the minimization method
UPDATE=*name*	specifies the update technique
Miscellaneous Options	
ASINGULAR=*r*	specifies the absolute singularity criterion for inversion of the information matrix
COVSING=*r*	specifies the singularity tolerance of the information matrix
MSINGULAR=*r*	specifies the relative M singularity criterion for inversion of the information matrix
SINGULAR=*r*	specifies the singularity criterion for inversion of the Hessian
VSINGULAR=*r*	specifies the relative V singularity criterion for inversion of the information matrix

Table 25.3 Termination Criteria Options

Option	Description
Options Used by All Techniques	
ABSCONV=*r*	specifies the absolute function convergence criterion
MAXFUNC=*i*	specifies the maximum number of function calls
MAXITER=*i* <*n*>	specifies the maximum number of iterations
MAXTIME=*r*	specifies the maximum CPU time
MINITER=*i*	specifies the minimum number of iterations
Options for Unconstrained and Linearly Constrained Techniques	
ABSFCONV=*r* <*n*>	specifies the absolute change function convergence criterion
ABSGCONV=*r* <*n*>	specifies the absolute gradient convergence criterion
ABSXCONV=*r* <*n*>	specifies the absolute change parameter convergence criterion
FCONV=*r* <*n*>	specifies the relative change function convergence criterion
FCONV2=*r* <*n*>	specifies the function convergence criterion

Table 25.3 *continued*

Option	Description
FDIGITS=*r*	specifies the precision in computation of the objective function
FSIZE=*r*	specifies the parameter for FCONV= and GCONV=
GCONV=*r* <*n*>	specifies the relative gradient convergence criterion
GCONV2=*r* <*n*>	specifies the relative gradient convergence criterion
XCONV=*r* <*n*>	specifies the relative change parameter convergence criterion
XSIZE=*r*	specifies the parameter for XCONV=
Options for Nonlinearly Constrained Techniques	
ABSGCONV=*r* <*n*>	specifies the maximum absolute gradient of Lagrange function criterion
FCONV2=*r* <*n*>	specifies the predicted objective function reduction criterion
GCONV=*r* <*n*>	specifies the normalized predicted objective function reduction criterion

Table 25.4 Miscellaneous Options

Option	Description
Options for the Approximate Covariance Matrix of Parameter Estimates	
CFACTOR=*r*	specifies the scalar factor for standard errors
NOHLF	uses the Hessian of the objective function for standard errors
Options for Additional Displayed Output	
PALL	displays the initial and final optimization values
PCRPJAC	displays the approximate Hessian matrix
PHESSIAN	displays the Hessian matrix
PHISTORY	displays the optimization history
PINIT	displays the initial values and derivatives
PNLCJAC	displays the Jacobian matrix of nonlinear constraints
PRINT	displays the results of the optimization process
Additional Options for Optimization Techniques	
DAMPSTEP< =*r* >	controls the initial line-search step size
HESCAL=*n*	specifies the scaling version of Hessian or Jacobian
LCDEACT=*r*	specifies the Lagrange multiplier threshold of constraint
LCEPSILON=*r*	specifies the range for boundary and linear constraints
LCSINGULAR=*r*	specifies the QR decomposition linear dependence criterion
NOEIGNUM	suppresses the computation of matrices
RESTART=*i*	specifies the restart algorithm with a steepest descent direction
VERSION=1 | 2	specifies the quasi-Newton optimization technique version

Options Documented in the PROC CALIS Statement

The following options are the same as in the PROC CALIS statement and are documented in the section "PROC CALIS Statement" on page 848.

Estimation Method Option

G4=*i*

specifies the method for computing the generalized (G2 or G4) inverse of a singular matrix needed for the approximate covariance matrix of parameter estimates. This option is valid only for applications where the approximate covariance matrix of parameter estimates is found to be singular.

Optimization Technique Options

FCONV | FTOL=*r*

specifies the relative function convergence criterion. For more details, see the section "Termination Criteria Options" on page 890.

GCONV | GTOL=*r*

specifies the relative gradient convergence criterion. For more details, see the section "Termination Criteria Options" on page 890.

INSTEP | SALPHA | RADIUS=*r*

restricts the step length of an optimization algorithm during the first iterations.

LINESEARCH | LIS=*i*

specifies the line-search method for the CONGRA, QUANEW, and NEWRAP optimization techniques.

LSPRECISION | LSP=*r*

specifies the degree of accuracy that should be obtained by the line-search algorithms LIS=2 and LIS=3.

MAXFUNC | MAXFU=*i*

specifies the maximum number i of function calls in the optimization process. For more details, see the section "Termination Criteria Options" on page 890.

MAXITER | MAXIT=*i* < *n* >

specifies the maximum number i of iterations in the optimization process. For more details, see the section "Termination Criteria Options" on page 890.

TECHNIQUE | TECH=*name*

OMETHOD | OM=*name*

specifies the optimization technique.

UPDATE | UPD=*name*

specifies the update method for the quasi-Newton or conjugate-gradient optimization technique.

Miscellaneous Options

ASINGULAR | ASING=*r*
specifies an absolute singularity criterion r, $r > 0$, for the inversion of the information matrix, which is needed to compute the approximate covariance matrix of parameter estimates.

COVSING=*r*
specifies a nonnegative threshold r, $r > 0$, that decides whether the eigenvalues of the information matrix are considered to be zero. This option is valid only for applications where the approximate covariance matrix of parameter estimates is found to be singular.

MSINGULAR | MSING=*r*
specifies a relative singularity criterion r, $r > 0$, for the inversion of the information matrix, which is needed to compute the approximate covariance matrix of parameter estimates.

SINGULAR | SING =*r*
specifies the singularity criterion r, $0 \leq r \leq 1$, that is used for the inversion of the Hessian matrix. The default value is 1E−8.

VSINGULAR | VSING=*r*
specifies a relative singularity criterion r, $r > 0$, for the inversion of the information matrix, which is needed to compute the approximate covariance matrix of parameter estimates.

Termination Criteria Options

Let x^* be the point at which the objective function $f(\cdot)$ is optimized, and let $x^{(k)}$ be the parameter values attained at the kth iteration. All optimization techniques stop at the kth iteration if at least one of a set of termination criteria is satisfied. The specified termination criteria should enable termination in an area of sufficient size around x^*. You can avoid termination respective to any of the following function, gradient, or parameter criteria by setting the corresponding option to zero. There is a default set of termination criteria for each optimization technique; most of these default settings make the criteria ineffective for termination. PROC CALIS might have problems due to rounding errors (especially in derivative evaluations) that prevent an optimizer from satisfying strong termination criteria.

Note that PROC CALIS also terminates if the point $x^{(k)}$ is fully constrained by linearly independent active linear or boundary constraints, and all Lagrange multiplier estimates of active inequality constraints are greater than a small negative tolerance.

The following options are available only in the NLOPTIONS statement (except for FCONV, GCONV, MAXFUNC, and MAXITER), and they affect the termination criteria.

Options Used by All Optimization Techniques

ABSCONV | ABSTOL=*r*
specifies an absolute function convergence criterion.

- For minimization, termination requires

$$f^{(k)} = f(x^{(k)}) \leq ABSCONV$$

- For maximization, termination requires

$$f^{(k)} = f(x^{(k)}) \geq ABSCONV$$

The default value of ABSCONV is as follows:

- for minimization, the negative square root of the largest double-precision value
- for maximization, the positive square root of the largest double-precision value

MAXFUNC | MAXFU=*i*

requires the number of function calls to be no larger than i. The default values are listed in the following table.

TECH=	MAXFUNC Default
LEVMAR, NEWRAP, NRRIDG, TRUREG	i=125
DBLDOG, QUANEW	i=500
CONGRA	i=1000

The default is used if you specify MAXFUNC=0. The optimization can be terminated only after completing a full iteration. Therefore, the number of function calls that are actually performed can exceed the number that is specified by the MAXFUNC= option.

MAXITER | MAXIT= *i <n>*

requires the number of iterations to be no larger than i. The default values are listed in the following table.

TECH=	MAXITER Default
LEVMAR, NEWRAP, NRRIDG, TRUREG	i=50
DBLDOG, QUANEW	i=200
CONGRA	i=400

The default is used if you specify MAXITER=0 or you omit the MAXITER option.

The optional second value n is valid only for TECH=QUANEW with nonlinear constraints. It specifies an upper bound n for the number of iterations of an algorithm and reduces the violation of nonlinear constraints at a starting point. The default value is n=20. For example, specifying `MAXITER= . 0` means that you do not want to exceed the default number of iterations during the main optimization process and that you want to suppress the feasible-point algorithm for nonlinear constraints.

MAXTIME=*r*

requires the CPU time to be no larger than r. The default value of the MAXTIME= option is the largest double floating-point number on your computer.

MINITER | MINIT=*i*

specifies the minimum number of iterations. The default value is $i = 0$.

The ABSCONV=, MAXITER=, MAXFUNC=, and MAXTIME= options are useful for dividing a time-consuming optimization problem into a series of smaller problems by using the OUTEST= and INEST= data sets.

Options for Unconstrained and Linearly Constrained Optimization Techniques

ABSFCONV | ABSFTOL=*r* < *n* >

specifies the absolute function convergence criterion. Termination requires a small change of the function value in successive iterations,

$$|f(x^{(k-1)}) - f(x^{(k)})| \leq r$$

The default value is $r = 0$. The optional integer value n determines the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

ABSGCONV | ABSGTOL=*r* < *n* >

specifies the absolute gradient convergence criterion. Termination requires the maximum absolute gradient element to be small,

$$\max_j |g_j^{(k)}| \leq r$$

The default value is *r*=1E−5. The optional integer value n determines the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

NOTE: In some applications, the small default value of the ABSGCONV= criterion is too difficult to satisfy for some of the optimization techniques.

ABSXCONV | ABSXTOL=*r* < *n* >

specifies the absolute parameter convergence criterion. Termination requires a small Euclidean distance between successive parameter vectors,

$$\| x^{(k)} - x^{(k-1)} \|_2 \leq r$$

The default value is $r = 0$. The optional integer value n determines the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

FCONV | FTOL=*r* < *n* >

specifies the relative function convergence criterion. Termination requires a small relative change of the function value in successive iterations,

$$\frac{|f(x^{(k)}) - f(x^{(k-1)})|}{\max(|f(x^{(k-1)})|, FSIZE)} \leq r$$

where $FSIZE$ is defined by the FSIZE= option. The default value is $r = 10^{-FDIGITS}$, where $FDIGITS$ either is specified or is set by default to $-log_{10}(\epsilon)$, where ϵ is the machine precision. The optional integer value n determines the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

FCONV2 | FTOL2=*r* < *n* >

specifies another function convergence criterion. For least squares problems, termination requires a small predicted reduction

$$df^{(k)} \approx f(x^{(k)}) - f(x^{(k)} + s^{(k)})$$

of the objective function.

The predicted reduction

$$\begin{aligned} df^{(k)} &= -g^{(k)'}s^{(k)} - \frac{1}{2}s^{(k)'}G^{(k)}s^{(k)} \\ &= -\frac{1}{2}s^{(k)'}g^{(k)} \\ &\leq r \end{aligned}$$

is computed by approximating the objective function f by the first two terms of the Taylor series and substituting the Newton step

$$s^{(k)} = -G^{(k)-1}g^{(k)}$$

The FCONV2 criterion is the unscaled version of the GCONV criterion. The default value is $r = 0$. The optional integer value n determines the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

FDIGITS=*r*

specifies the number of accurate digits in evaluations of the objective function. Fractional values such as FDIGITS=4.7 are allowed. The default value is $r = -log_{10}\epsilon$, where ϵ is the machine precision. The value of r is used for the specification of the default value of the FCONV= option.

FSIZE=*r*

specifies the $FSIZE$ parameter of the relative function and relative gradient termination criteria. The default value is $r = 0$. See the FCONV= and GCONV= options for details.

GCONV | GTOL=*r* **<** *n* **>**

specifies the relative gradient convergence criterion. For all techniques except the CONGRA technique, termination requires that the normalized predicted function reduction be small,

$$\frac{[g^{(k)}]'[G^{(k)}]^{-1}g^{(k)}}{\max(|f(x^{(k)})|, FSIZE)} \leq r$$

where $FSIZE$ is defined by the FSIZE= option. For the CONGRA technique (where a reliable Hessian estimate $\mathbf{G}$ is not available),

$$\frac{\| g^{(k)} \|_2^2 \quad \| s^{(k)} \|_2}{\| g^{(k)} - g^{(k-1)} \|_2 \max(|f(x^{(k)})|, FSIZE)} \leq r$$

is used. The default value is r=1E−8. The optional integer value n determines the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

NOTE: The default setting for the GCONV= option sometimes leads to early termination far from the location of the optimum. This is especially true for the special form of this criterion used in the CONGRA optimization.

GCONV2 | GTOL2=*r* **<** *n* **>**

specifies another relative gradient convergence criterion. For least squares problems and the

TRUREG, LEVMAR, NRRIDG, and NEWRAP techniques, the criterion of Browne (1982) is used,

$$\max_j \frac{|g_j^{(k)}|}{\sqrt{f(x^{(k)})G_{j,j}^{(k)}}} \leq r$$

This criterion is not used by the other techniques. The default value is $r = 0$. The optional integer value n determines the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

XCONV | XTOL=*r* **<** *n* **>**

specifies the relative parameter convergence criterion. Termination requires a small relative parameter change in subsequent iterations,

$$\frac{\max_j |x_j^{(k)} - x_j^{(k-1)}|}{\max(|x_j^{(k)}|, |x_j^{(k-1)}|, XSIZE)} \leq r$$

The default value is $r = 0$. The optional integer value n determines the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

XSIZE=*r*

specifies the $XSIZE$ parameter of the relative function and relative gradient termination criteria. The default value is $r = 0$. See the XCONV= option for details.

Options for Nonlinearly Constrained Techniques

The non-NMSIMP algorithms available for nonlinearly constrained optimization (currently only TECH=QUANEW) do not monotonically reduce either the value of the objective function or some kind of merit function that combines objective and constraint functions. Furthermore, the algorithm uses the watchdog technique with backtracking (Chamberlain et al., 1982). Therefore, no termination criteria are implemented that are based on the values (x or f) of successive iterations. In addition to the criteria used by all optimization techniques, only three more termination criteria are currently available, and they are based on the Lagrange function:

$$L(x, \lambda) = f(x) - \sum_{i=1}^{m} \lambda_i c_i(x)$$

and its gradient

$$\nabla_x L(x, \lambda) = g(x) - \sum_{i=1}^{m} \lambda_i \nabla_x c_i(x)$$

Here, m denotes the total number of constraints, $g = g(x)$ denotes the gradient of the objective function, and λ denotes the m vector of Lagrange multipliers. The Kuhn-Tucker conditions require that the gradient of the Lagrange function is zero at the optimal point (x^*, λ^*):

$$\nabla_x L(x^*, \lambda^*) = 0$$

The termination criteria available for nonlinearly constrained optimization follow.

ABSGCONV | ABSGTOL=*r* < *n* >
specifies that termination requires the maximum absolute gradient element of the Lagrange function to be small,

$$\max_j |\{\nabla_x L(x^{(k)}, \lambda^{(k)})\}_j| \leq r$$

The default value is r=1E−5. The optional integer value n determines the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

FCONV2 | FTOL2=*r* < *n* >
specifies that termination requires the predicted objective function reduction to be small:

$$|g(x^{(k)})s(x^{(k)})| + \sum_{i=1}^{m} |\lambda_i c_i| \leq r$$

The default value is r=1E−6. This is the criterion used by the programs VMCWD and VF02AD (Powell 1982b). The optional integer value n determines the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

GCONV | GTOL=*r* < *n* >
specifies that termination requires the normalized predicted objective function reduction to be small:

$$\frac{|g(x^{(k)})s(x^{(k)})| + \sum_{i=1}^{m} |\lambda_i c_i(x^{(k)})|}{\max(|f(x^{(k)})|, FSIZE)} \leq r$$

where $FSIZE$ is defined by the FSIZE= option. The default value is r=1E−8. The optional integer value n determines the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

Miscellaneous Options

Options for the Approximate Covariance Matrix of Parameter Estimates

CFACTOR=*r*
specifies the scalar factor for the covariance matrix of parameter estimates. The scalar $r \geq 0$ replaces the default value c/NM. For more details, see the section "Approximate Standard Errors" on page 928.

NOHLF
specifies that the Hessian matrix of the objective function (rather than the Hessian matrix of the Lagrange function) be used for computing the approximate covariance matrix of parameter estimates and, therefore, the approximate standard errors.

It is theoretically not correct to use the NOHLF option. However, since most implementations use the Hessian matrix of the objective function and not the Hessian matrix of the Lagrange function for computing approximate standard errors, the NOHLF option can be used to compare the results.

Options for Additional Displayed Output

PALL | ALL
displays information about the starting values and final values of the optimization process.

PCRPJAC | PJTJ
displays the approximate Hessian matrix. If general linear or nonlinear constraints are active at the solution, the projected approximate Hessian matrix is also displayed.

PHESSIAN | PHES
displays the Hessian matrix. If general linear or nonlinear constraints are active at the solution, the projected Hessian matrix is also displayed.

PHISTORY | PHIS
displays the optimization history. The PHISTORY option is set automatically if the PALL or PRINT option is set.

PINIT | PIN
displays the initial values and derivatives (if available). The PINIT option is set automatically if the PALL option is set.

PNLCJAC
displays the Jacobian matrix of nonlinear constraints specified by the NLINCON statement. The PNLCJAC option is set automatically if the PALL option is set.

PRINT | PRI
displays the results of the optimization process, such as parameter estimates and constraints.

Options for Fine-Tuning Optimization Techniques

DAMPSTEP | DS *<=r>*
specifies that the initial step-size value $\alpha^{(0)}$ for each line search (used by the QUANEW, CONGRA, or NEWRAP technique) cannot be larger than r times the step-size value used in the former iteration. If the factor r is not specified, the default value is $r = 2$. The DAMPSTEP option can prevent the line-search algorithm from repeatedly stepping into regions where some objective functions are difficult to compute or where they can lead to floating-point overflows during the computation of objective functions and their derivatives. The DAMPSTEP<=*r*> option can prevent time-costly function calls during line searches with very small step sizes α of objective functions. For more information about setting the start values of each line search, see the section "Restricting the Step Length" on page 952.

HESCAL | HS = 0 | 1 | 2 | 3
specifies the scaling version of the Hessian or crossproduct Jacobian matrix used in NRRIDG, TRUREG, LEVMAR, NEWRAP, or DBLDOG optimization. If HS is not equal to zero, the first iteration and each restart iteration set the diagonal scaling matrix $\mathbf{D}^{(0)} = diag(d_i^{(0)})$:

$$d_i^{(0)} = \sqrt{\max(|\mathbf{G}_{i,i}^{(0)}|, \epsilon)}$$

where $\mathbf{G}^{(0)}_{i,i}$ are the diagonal elements of the Hessian or crossproduct Jacobian matrix. In every other iteration, the diagonal scaling matrix $\mathbf{D}^{(0)} = diag(d_i^{(0)})$ is updated depending on the HS option:

HS=0 specifies that no scaling is done.

HS=1 specifies the Moré (1978) scaling update:

$$d_i^{(k+1)} = \max(d_i^{(k)}, \sqrt{\max(|\mathbf{G}^{(k)}_{i,i}|, \epsilon)})$$

HS=2 specifies the Dennis, Gay, and Welsch (1981) scaling update:

$$d_i^{(k+1)} = \max(0.6 * d_i^{(k)}, \sqrt{\max(|\mathbf{G}^{(k)}_{i,i}|, \epsilon)})$$

HS=3 specifies that d_i is reset in each iteration:

$$d_i^{(k+1)} = \sqrt{\max(|\mathbf{G}^{(k)}_{i,i}|, \epsilon)}$$

In the preceding equations, ϵ is the relative machine precision. The default is HS=1 for LEVMAR minimization and HS=0 otherwise. Scaling of the Hessian or crossproduct Jacobian can be time-consuming in the case where general linear constraints are active.

LCDEACT | LCD=*r*

specifies a threshold r for the Lagrange multiplier that decides whether an active inequality constraint remains active or can be deactivated. For maximization, r must be greater than zero; for minimization, r must be smaller than zero. The default is

$$r = \pm \min(0.01, \max(0.1 * ABSGCONV, 0.001 * gmax^{(k)}))$$

where "+" stands for maximization, "−" stands for minimization, $ABSGCONV$ is the value of the absolute gradient criterion, and $gmax^{(k)}$ is the maximum absolute element of the (projected) gradient $g^{(k)}$ or $Z'g^{(k)}$.

LCEPSILON | LCEPS | LCE=*r*

specifies the range r, $r \geq 0$, for active and violated boundary and linear constraints. If the point $x^{(k)}$ satisfies the condition

$$|\sum_{j=1}^{n} a_{ij} x_j^{(k)} - b_i| \leq r * (|b_i| + 1)$$

the constraint i is recognized as an active constraint. Otherwise, the constraint i is either an inactive inequality or a violated inequality or equality constraint. The default value is r=1E−8. During the optimization process, the introduction of rounding errors can force PROC NLP to increase the value of r by factors of 10. If this happens, it is indicated by a message displayed in the log.

LCSINGULAR | LCSING | LCS=*r*

specifies a criterion r, $r \geq 0$, used in the update of the QR decomposition that decides whether an active constraint is linearly dependent on a set of other active constraints. The default is r=1E−8. The larger r becomes, the more the active constraints are recognized as being linearly dependent.

NOEIGNUM

suppresses the computation and displayed output of the determinant and the inertia of the Hessian, crossproduct Jacobian, and covariance matrices. The inertia of a symmetric matrix are the numbers of negative, positive, and zero eigenvalues. For large applications, the NOEIGNUM option can save computer time.

RESTART | REST=*i*

specifies that the QUANEW or CONGRA algorithm is restarted with a steepest descent/ascent search direction after at most i iterations, $i > 0$. Default values are as follows:

- CONGRA: UPDATE=PB: restart is done automatically so specification of i is not used.
- CONGRA: UPDATE≠PB: $i = \min(10n, 80)$, where n is the number of parameters.
- QUANEW: i is the largest integer available.

VERSION | VS = 1 | 2

specifies the version of the quasi-Newton optimization technique with nonlinear constraints.

VS=1 specifies the update of the μ vector as in Powell (1978a, 1978b) (update like VF02AD).

VS=2 specifies the update of the μ vector as in Powell (1982a, 1982b) (update like VMCWD).

The default is VS=2.

PARAMETERS Statement

PARAMETERS | PARMS *parameter(s)* << = > *number(s)* >
<< , > *parameter(s)* << = > *number(s)* > . . . > ;

The PARAMETERS statement defines additional parameters that are not elements of a model matrix to use in your own programming statements. You can specify more than one PARAMETERS statement with each PROC CALIS statement. The *parameters* can be followed by an equal sign and a number list. The values of the *numbers* list are assigned as initial values to the preceding parameters in the *parameters* list. For example, each of the following statements assigns the initial values ALPHA=.5 and BETA=-.5 for the parameters used in programming statements:

```
parameters alfa beta=.5 -.5;
parameters alfa beta (.5 -.5);
parameters alfa beta .5 -.5;
parameters alfa=.5 beta (-.5);
```

The number of parameters and the number of values does not have to match. When there are fewer values than parameter names, either the RANDOM= or START= option is used. When there are more values than parameter names, the extra values are dropped. Parameters listed in the PARAMETERS statement can be assigned initial values by programming statements or by the START= or RANDOM= option in the PROC CALIS statement.

CAUTION: The OUTRAM= and INRAM= data sets do not contain any information about the PARAMETERS statement or additional programming statements.

PARTIAL Statement

PARTIAL *variables* **;**

If you want the analysis to be based on a partial correlation or covariance matrix, use the PARTIAL statement to list the variables used to partial out the variables in the analysis. You can specify only one PARTIAL statement with each PROC CALIS statement.

RAM Model Statement

RAM *list-entry* < , *list-entry* . . . > **;**

where *list-entry* represents
matrix-number row-number column-number < *value* > < *parameter-name* >

The RAM statement defines the elements of the symmetric RAM matrix model

$$\mathbf{v} = \mathbf{A}\mathbf{v} + \mathbf{u}$$

in the form of a list type input (McArdle and McDonald 1984).

The covariance structure is given by

$$\mathbf{C} = \mathbf{J}(\mathbf{I} - \mathbf{A})^{-1}\mathbf{P}((\mathbf{I} - \mathbf{A})^{-1})'\mathbf{J}'$$

with selection matrix $\mathbf{J}$ and

$$\mathbf{C} = \mathcal{E}\{\mathbf{J}\mathbf{v}\mathbf{v}'\mathbf{J}'\}, \qquad \mathbf{P} = \mathcal{E}\{\mathbf{u}\mathbf{u}'\}$$

You can specify only one RAM statement with each PROC CALIS statement. Using the RAM statement requires that the first n variable numbers in the path diagram and in the vector v correspond to the numbers of the n manifest variables of the given covariance or correlation matrix. If you are not sure what the order of the manifest variables in the DATA= data set is, use a VAR statement to specify the order of these observed variables. Using the AUGMENT option includes the INTERCEPT variable as a manifest variable with number $n + 1$ in the RAM model. In this case, latent variables have to start with $n + 2$. The box of each manifest variable in the path diagram is assigned the number of the variable in the covariance or correlation matrix.

The selection matrix **J** is always a rectangular identity (IDE) matrix, and it does not have to be specified in the RAM statement.

A constant matrix element is defined in a RAM statement by a *list-entry* with four numbers. You define a parameter element by three or four numbers followed by a name for the parameter. Separate the list entries with a comma. Each *list-entry* in the RAM statement corresponds to a path in the diagram, as follows:

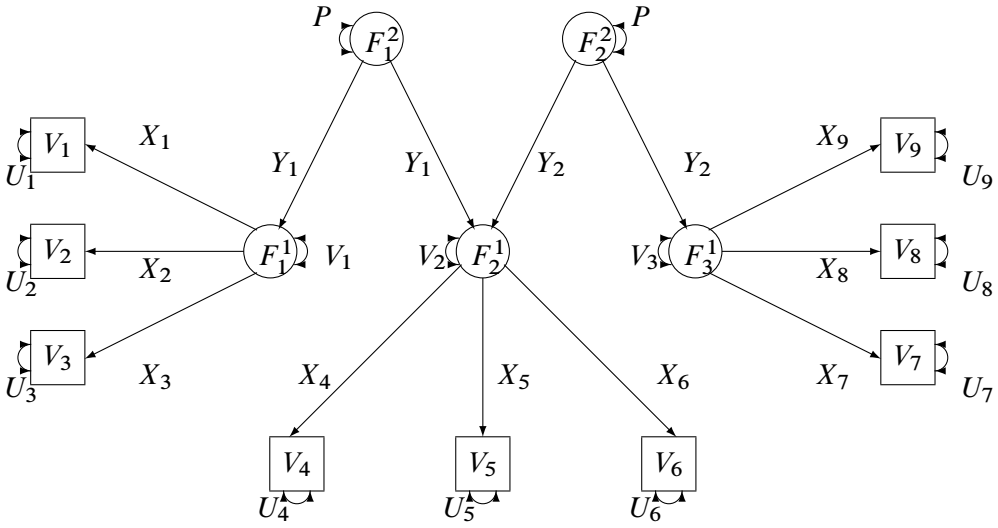
- The first number in each list entry (*matrix-number*) is the number of arrowheads of the path, which is the same as the number of the matrix in the RAM model (1 := **A** , 2 := **P**).
- The second number in each list entry (*row-number*) is the number of the node in the diagram to which the path points, which is the same as the row number of the matrix element.
- The third number in each list entry (*column-number*) is the number of the node in the diagram from which the path originates, which is the same as the column number of the matrix element.
- The fourth number (*value*) gives the (initial) value of the path coefficient. If you do not specify a fifth *list-entry*, this number specifies a constant coefficient; otherwise, this number specifies the initial value of this parameter. It is not necessary to specify the fourth item. If you specify neither the fourth nor the fifth item, the constant is set to 1 by default. If the fourth item (*value*) is not specified for a parameter, PROC CALIS tries to compute an initial value for this parameter.
- If the path coefficient is a parameter rather than a constant, then a fifth item in the list entry (*parameter-name*) is required to assign a name to the parameter. Using the same name for different paths constrains the corresponding coefficients to be equal.

If the initial value of a parameter is not specified in the list, the initial value is chosen in one of the following ways:

- If the PROC CALIS statement contains a RANDOM=i option, then the parameter obtains a randomly generated initial value r, such that $0 \leq r \leq 1$. The uninitialized parameters in the diagonals of the central model matrices are given the random values r multiplied by 10, 100, or the value specified in the DEMPHAS= option.
- If the RANDOM= option is not used, PROC CALIS tries to estimate the initial values.
- If the initial values cannot be estimated, the value of the START= option is used as an initial value.

If your model contains many unconstrained parameters and it is too cumbersome to find different parameter names, you can specify all those parameters by the same prefix name. A prefix is a short name followed by a colon. The CALIS procedure then generates a parameter name by appending an integer suffix to this prefix name. The prefix name should have no more than five or six characters so that the generated parameter name is not longer than eight characters. To avoid unintentional equality constraints, the prefix names should not coincide with explicitly defined parameter names.

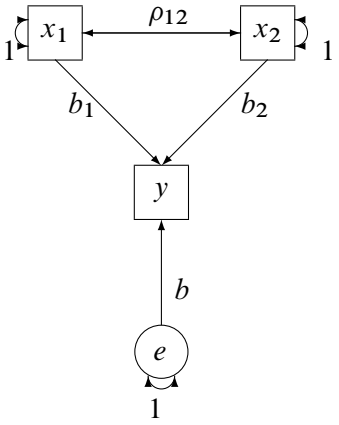
For example, consider the following model described in the section "Specifying a Second-Order Factor-Analysis Model" on page 885:



$$\mathbf{S} = \mathbf{F}_1\mathbf{F}_2\mathbf{P}_2\mathbf{F}_2'\mathbf{F}_1' + \mathbf{F}_1\mathbf{U}_2^2\mathbf{F}_1' + \mathbf{U}_1^2$$

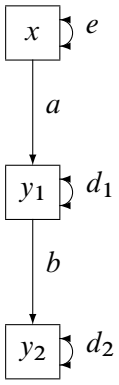
You can fit this model by using the following RAM model statement:

```
ram
   1  1 10    x1,
   1  2 10    x2,
   1  3 10    x3,
   1  4 11    x4,
   1  5 11    x5,
   1  6 11    x6,
   1  7 12    x7,
   1  8 12    x8,
   1  9 12    x9,
   1 10 13    y1,
   1 11 13    y1,
   1 11 14    y2,
   1 12 14    y2,
   2  1  1    u:,
   2  2  2    u:,
   2  3  3    u:,
   2  4  4    u:,
   2  5  5    u:,
   2  6  6    u:,
   2  7  7    u:,
   2  8  8    u:,
   2  9  9    u:,
   2 10 10    v:,
   2 11 11    v:,
   2 12 12    v:,
   2 13 13    p ,
   2 14 14    p ;
run;
```



The confirmatory second-order factor analysis model corresponds to the path diagram displayed in Figure 25.3.

Figure 25.3 Path Diagram of Second-Order Factor Analysis Model



There is a very close relationship between the RAM model algebra and the specification of structural linear models by path diagrams. See Figure 25.4 for an example.

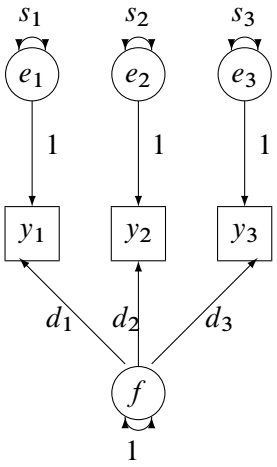


Figure 25.4 Examples of RAM Nomography

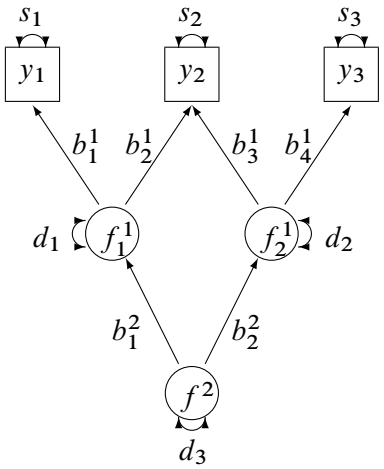

1. Multiple Regression

2. Chain Simplex

3. First-Order Factor Analysis

4. Second-Order Factor Analysis

Refer to McArdle (1980) for the interpretation of the models displayed in Figure 25.4.

SAS Programming Statements

This section lists the programming statements used to express the linear and nonlinear constraints on the parameters and documents the differences between programming statements in PROC CALIS and program statements in the DATA step. The very different use of the ARRAY statement by PROC CALIS is also discussed. Most of the programming statements that can be used in the SAS DATA step also can be used in PROC CALIS. Refer to *SAS Language Reference: Dictionary* for a description of the SAS programming statements. You can specify the following SAS programming

statements to compute parameter constraints with the CALIS procedure:

ABORT;
CALL *name* < **(** *expression* < **,** *expression . . .* > **)** >**;**
DELETE;
DO < *variable* **=** *expression*
< **TO** *expression* > < **BY** *expression* >
< **,** *expression* < **TO** *expression* > < **BY** *expression* > . . . >
>
< **WHILE** *expression* > < **UNTIL** *expression* >**;**
END;
GOTO *statement-label***;**
IF *expression***;**
IF *expression* **THEN** *program-statement***;**
ELSE *program-statement***;**
variable **=** *expression***;**
variable **+** *expression***;**
LINK *statement-label***;**
PUT < *variable* > < **=** > < *...* >**;**
RETURN;
SELECT < **(** *expression* **)** >**;**
STOP;
SUBSTR(*variable, index, length* **)=** *expression***;**
WHEN (*expression* **)** *program-statement***;**
OTHERWISE *program-statement***;**

For the most part, the SAS programming statements work the same as they do in the SAS DATA step as documented in *SAS Language Reference: Concepts*. However, there are several differences that should be noted.

- The ABORT statement does not allow any arguments.
- The DO statement does not allow a character index variable. Thus,

  ```
  do I=1,2,3;
  ```

  is supported; however,

  ```
  do I='A','B','C';
  ```

  is not valid in PROC CALIS, although it is supported in the DATA step.
- The PUT statement, used mostly for program debugging in PROC CALIS, supports only some of the features of the DATA step PUT statement, and it has some new features that the DATA step PUT statement does not have:
  - The CALIS procedure PUT statement does not support line pointers, factored lists, iteration factors, overprinting, _INFILE_, the colon (:) format modifier, or $.
  - The CALIS procedure PUT statement does support expressions enclosed in parentheses. For example, the following statement displays the square root of x:

```
put (sqrt(x));
```

– The CALIS procedure PUT statement supports the print item _PDV_ to display a formatted listing of all variables in the program. For example, the following statement displays a much more readable listing of the variables than the _ALL_ print item:

```
put _pdv_ ;
```

- The WHEN and OTHERWISE statements allow more than one target statement. That is, DO/END groups are not necessary for multiple WHEN statements. For example, the following syntax is valid:

```
select;
   when ( expression1 ) statement1;
                        statement2;
   when ( expression2 ) statement3;
                        statement4;
end;
```

You can specify one or more PARMS statements to define parameters used in the programming statements that are not defined in the model matrices (MATRIX, RAM, LINEQS, STD, or COV statement).

Parameters that are used only on the right-hand side of your programming statements are called independent, and parameters that are used at least once on the left-hand side of an equation in the program code are called dependent parameters. The dependent parameters are used only indirectly in the minimization process. They should be fully defined as functions of the independent parameters. The independent parameters are included in the set **X** of parameters used in the minimization. Be sure that all independent parameters used in your programming statements are somehow connected to elements of the model matrices. Otherwise the minimization function does not depend on those independent parameters, and the parameters vary without control (since the corresponding derivative is the constant 0). You also can specify the PARMS statement to set the initial values of all independent parameters used in the programming statements that are not defined as elements of model matrices.

ARRAY Statement

ARRAY *arrayname* < *dimensions* >< $ >< *variables and constants* > **;**

The ARRAY statement is similar to, but not the same as, the ARRAY statement in the DATA step. The ARRAY statement is used to associate a name with a list of variables and constants. The array name can then be used with subscripts in the program to refer to the items in the list.

The ARRAY statement supported by PROC CALIS does not support all the features of the DATA step ARRAY statement. With PROC CALIS, the ARRAY statement cannot be used to give initial values to array elements. Implicit indexing variables cannot be used; all array references must have explicit subscript expressions. Only exact array dimensions are allowed; lower-bound specifications are not supported. A maximum of six dimensions is allowed.

On the other hand, the ARRAY statement supported by PROC CALIS does allow both variables and constants to be used as array elements. Constant array elements cannot be changed. Both the dimension specification and the list of elements are optional, but at least one must be given. When the list of elements is not given or fewer elements than the size of the array are listed, array variables are created by suffixing element numbers to the array name to complete the element list.

STD Statement

STD *assignment* < *, assignment . . .* > **;**

where *assignment* represents
variables = *pattern-definition*

The STD statement tells which variances are parameters to estimate and which are fixed. The STD statement can be used only with the LINEQS statement. You can specify only one STD statement with each LINEQS model statement. The STD statement defines the diagonal elements of the central model matrix $\mathbf{\Phi}$. These elements correspond to the variances of the exogenous variables and to the error variances of the endogenous variables. Elements that are not defined are assumed to be zero.

Each *assignment* consists of a variable list (*variables*) on the left-hand side and a pattern list (*pattern-definition*) on the right-hand side of an equal sign. The *assignments* in the STD statement must be separated by commas. The *variables* list on the left-hand side of the equal sign should contain only names of variables that do not appear on the left-hand side of an equation in the LINEQS statement—that is, exogenous, error, and disturbance variables.

The *pattern-definition* on the right-hand side is similar to that used in the MATRIX statement. Each list element on the right-hand side defines the variance of the variable on the left-hand side in the same list position. A name on the right-hand side means that the corresponding variance is a parameter to estimate. A name on the right-hand side can be followed by a number inside parentheses that gives the initial value. A number on the right-hand side means that the corresponding variance of the variable on the left-hand side is fixed. If the right-hand-side list is longer than the left-hand-side variable list, the right-hand-side list is shortened to the length of the variable list. If the right-hand-side list is shorter than the variable list, the right-hand-side list is filled with repetitions of the last item in the list.

The right-hand side can also contain prefixes. A prefix is a short name followed by a colon. The CALIS procedure then generates a parameter name by appending an integer suffix to this prefix name. The prefix name should have no more than five or six characters so that the generated parameter name is not longer than eight characters. To avoid unintentional equality constraints, the prefix names should not coincide with explicitly defined parameter names. For example, if the prefix A is not used in any previous statement, the STD statement

```
std E1-E6=6 * A: (6 * 3.) ;
```

defines the six error variances as free parameters A1, . . . , A6, all with starting values of 3.

STRUCTEQ Statement

STRUCTEQ *variable* < *variable . . .* > **;**

The STRUCTEQ statement is used to list the dependent variables of the structural equations. This statement is ignored if you omit the PDETERM option. This statement is useful because the term *structural equation* is not defined in a unique way, and PROC CALIS has difficulty identifying the structural equations.

If LINEQS statements are used, the names of the left-hand-side (dependent) variables of those equations to be treated as structural equations should be listed in the STRUCTEQ statement.

If the RAM statement is used, variable names in the STRUCTEQ statements depend on the VARNAMES statement:

- If the VARNAMES statement is used, variable names must correspond to those in the VARNAMES statement.
- If the VARNAMES statement is not used, variable names must correspond to the names of manifest variables or latent (F) variables.

The STRUCTEQ statement also defines the names of variables used in the causal coefficient matrix of the structural equations, **B**, for computing the *Stability Coefficient of Reciprocal Causation* (the largest eigenvalue of the $\mathbf{BB}'$ matrix). If the PROC CALIS option PDETERM is used without the STRUCTEQ statement, the structural equations are defined as described in the PDETERM option. See the PROC CALIS option PDETERM on page 863 for more details.

VAR Statement

VAR *variables* **;**

The VAR statement lists the numeric variables to be analyzed. If the VAR statement is omitted, all numeric variables not mentioned in other statements are analyzed. You can use the VAR statement to ensure that the manifest variables appear in correct order for use in the RAM statement. Only one VAR statement can be used with each PROC CALIS statement. If you do not use all manifest variables when you specify the model with a RAM or LINEQS statement, PROC CALIS does automatic variable selection. For more information, see the section "Automatic Variable Selection" on page 942.

VARNAMES Statement

VARNAMES | **VNAMES** *assignment* < , *assignment* . . . > **;**

where *assignment* represents
matrix-id variable-names or *matrix-name* = *matrix-name*

Use the VARNAMES statement in connection with the RAM, COSAN, or FACTOR model statement to allocate names to latent variables including error and disturbance terms. This statement is not needed if you are using the LINEQS statement.

In connection with the RAM model statement, the *matrix-id* must be specified by the integer number as it is used in the RAM list input (1 for matrix **A**, 2 for matrix **P**). Because the first variables of matrix **A** correspond to the manifest variables in the input data set, you can specify names only for the latent variables following the manifest variables in the rows of **A**. For example, in the RAM notation of the alienation example, you can specify the latent variables by names F1, F2, F3 and the error variables by names E1, . . . , E6, D1, D2, D3 with the following statement:

```
vnames 1  F1-F3,
       2  E1-E6 D1-D3;
```

If the RAM model statement is not accompanied by a VNAMES statement, default variable names are assigned using the prefixes "F", "E", and "D" with numerical suffixes: latent variables are F1, F2, . . . , and error variables are E1, E2, ...

The *matrix-id* must be specified by its name when used with the COSAN or FACTOR statement. The *variable-names* following the matrix name correspond to the columns of this matrix. The variable names corresponding to the rows of this matrix are set automatically by the following rules:

- If it is the first matrix of any term, the row variable names are the names of the manifest variables.
- If it is the central symmetric matrix of any term, the row variable names are the same as the column variable names of the same matrix.
- For any other matrices, the row variable names are the same as the column variable names of the preceding matrix.

You also can use the second kind of name assignment in connection with a COSAN statement. Two matrix names separated by an equal sign allocate the column names of one matrix to the column names of the other matrix. This assignment assumes that the column names of at least one of the two matrices are already allocated. For example, in the COSAN notation of the alienation example, you can specify the variable names by using the following statements to allocate names to the columns of **J**, **A**, and **P**:

```
vnames  J  V1-V6 F1-F3 ,
        A =J ,
        P  E1-E6 D1-D3 ;
```

WEIGHT Statement

WEIGHT *variable* **;**

To compute weighted covariances or correlations, specify the name of the weighting variable in a WEIGHT statement. This is often done when the error variance associated with each observation is different and the values of the weight variable are proportional to the reciprocals of the variances. You can use only one WEIGHT statement with each PROC CALIS statement. The WEIGHT and FREQ statements have a similar effect, except the WEIGHT statement does not alter the number of observations unless VARDEF=WGT or VARDEF=WDF. An observation is used in the analysis only if the WEIGHT variable is greater than 0 and is not missing.

Details: CALIS Procedure

Input Data Sets

You can use four different kinds of input data sets in the CALIS procedure, and you can use them simultaneously. The DATA= data set contains the data to be analyzed, and it can be an ordinary SAS data set containing raw data or a special TYPE=COV, TYPE=UCOV, TYPE=CORR, TYPE=UCORR, TYPE=SYMATRIX, TYPE=SSCP, or TYPE=FACTOR data set containing previously computed statistics. The INEST= data set specifies an input data set that contains initial estimates for the parameters used in the optimization process, and it can also contain boundary and general linear constraints on the parameters. If the model does not change too much, you can use an OUTEST= data set from a previous PROC CALIS analysis; the initial estimates are taken from the values of the PARMS observation. The INRAM= data set names a third input data set that contains all information needed to specify the analysis model in RAM list form (except for user-written program statements). Often the INRAM= data set can be the OUTRAM= data set from a previous PROC CALIS analysis. See the section "OUTRAM= SAS-data-set" on page 917 for the structure of both OUTRAM= and INRAM= data sets. Using the INWGT= data set enables you to read in the weight matrix **W** that can be used in generalized least squares, weighted least squares, or diagonally weighted least squares estimation.

DATA= SAS-data-set

A TYPE=COV, TYPE=UCOV, TYPE=CORR, or TYPE=UCORR data set can be created by the CORR procedure or various other procedures. It contains means, standard deviations, the sample size, the covariance or correlation matrix, and possibly other statistics depending on which procedure is used.

If your data set has many observations and you plan to run PROC CALIS several times, you can save computer time by first creating a TYPE=COV, TYPE=UCOV, TYPE=CORR, or TYPE=UCORR

data set and using it as input to PROC CALIS. For example, assuming that PROC CALIS is first run with an OUTRAM=MOD option, you can run the following statements:

```
* create TYPE=COV data set;
proc corr cov nocorr data=raw outp=cov(type=cov);
run;
* analysis using correlations;
proc calis data=cov inram=mod;
run;
* analysis using covariances;
proc calis cov data=cov inram=mod;
run;
```

Most procedures automatically set the TYPE= option of an output data set appropriately. However, the CORR procedure sets TYPE=CORR unless an explicit TYPE= option is used. Thus, (TYPE=COV) is needed in the preceding PROC CORR request, since the output data set is a covariance matrix. If you use a DATA step with a SET statement to modify this data set, you must declare the TYPE=COV, TYPE=UCOV, TYPE=CORR, or TYPE=UCORR attribute in the new data set.

You can use a VAR statement with PROC CALIS when reading a TYPE=COV, TYPE=UCOV, TYPE=CORR, TYPE=UCORR, or TYPE=SSCP data set to select a subset of the variables or change the order of the variables.

CAUTION: Problems can arise from using the CORR procedure when there are missing data. By default, PROC CORR computes each covariance or correlation from all observations that have values present for the pair of variables involved ("pairwise deletion"). The resulting covariance or correlation matrix can have negative eigenvalues. A correlation or covariance matrix with negative eigenvalues is recognized as a singular matrix in PROC CALIS, and you cannot compute (default) generalized least squares or maximum likelihood estimates. You can specify the RIDGE option to ridge the diagonal of such a matrix to obtain a positive-definite data matrix. If the NOMISS option is used with the CORR procedure, observations with any missing values are completely omitted from the calculations ("listwise deletion"), and there is no possibility of negative eigenvalues (but still a chance for a singular matrix).

PROC CALIS can also create a TYPE=COV, TYPE=UCOV, TYPE=CORR, or TYPE=UCORR data set that includes all the information needed for repeated analyses. If the data set DATA=RAW does not contain missing values, the following statements should give the same PROC CALIS results as the previous example:

```
* using correlations;
proc calis data=raw outstat=cov inram=mod;
run;
* using covariances;
proc calis cov data=cov inram=mod;
run;
```

You can create a TYPE=COV, TYPE=UCOV, TYPE=CORR, TYPE=UCORR, or TYPE=SSCP data set in a DATA step. Be sure to specify the TYPE= option in parentheses after the data set name in the DATA statement, and include the _TYPE_ and _NAME_ variables. If you want to analyze the covariance matrix but your DATA= data set is a TYPE=CORR or TYPE=UCORR data set, you

should include an observation with _TYPE_=STD giving the standard deviation of each variable. If you specify the COV option, PROC CALIS analyzes the recomputed covariance matrix:

```
data correl(type=corr);
   input _type_ $ _name_ $ X1-X3;
   datalines;
std   .   4.  2.  8.
corr  X1  1.0  .   .
corr  X2   .7 1.0  .
corr  X3   .5  .4 1.0
;
proc calis cov inram=model;
run;
```

If you want to analyze the UCOV or UCORR matrix but your DATA= data set is a TYPE=COV or TYPE=CORR data set, you should include observations with _TYPE_=STD and _TYPE_=MEAN giving the standard deviation and mean of each variable.

INEST= SAS-data-set

You can use the INEST= (or INVAR= or ESTDATA=) input data set to specify the initial values of the parameters used in the optimization and to specify boundary constraints and the more general linear constraints that can be imposed on these parameters.

The variables of the INEST= data set must correspond to the following variables:

- a character variable _TYPE_ that indicates the type of the observation
- *n* numeric variables with the parameter names used in the specified PROC CALIS model
- the BY variables that are used in a DATA= input data set
- a numeric variable _RHS_ (right-hand side) (needed only if linear constraints are used)
- additional variables with names corresponding to constants used in the programming statements

The content of the _TYPE_ variable defines the meaning of the observation of the INEST= data set. PROC CALIS recognizes observations with the following _TYPE_ specifications.

PARMS — specifies initial values for parameters that are defined in the model statements of PROC CALIS. The _RHS_ variable is not used. Additional variables can contain the values of constants that are referred to in programming statements. At the beginning of each run of PROC CALIS, the values of the constants are read from the PARMS observation initializing the constants in the program statements.

UPPERBD | UB — specifies upper bounds with nonmissing values. The use of a missing value indicates that no upper bound is specified for the parameter. The _RHS_ variable is not used.

LOWERBD | LB specifies lower bounds with nonmissing values. The use of a missing value indicates that no lower bound is specified for the parameter. The _RHS_ variable is not used.

LE | <= | < specifies the linear constraint $\sum_j a_{ij}x_j \leq b_i$. The n parameter values contain the coefficients a_{ij}, and the _RHS_ variable contains the right-hand-side b_i. The use of a missing value indicates a zero coefficient a_{ij}.

GE | >= | > specifies the linear constraint $\sum_j a_{ij}x_j \geq b_i$. The n parameter values contain the coefficients a_{ij}, and the _RHS_ variable contains the right-hand-side b_i. The use of a missing value indicates a zero coefficient a_{ij}.

EQ | = specifies the linear constraint $\sum_j a_{ij}x_j = b_i$. The n parameter values contain the coefficients a_{ij}, and the _RHS_ variable contains the right-hand-side b_i. The use of a missing value indicates a zero coefficient a_{ij}.

The constraints specified in the INEST=, INVAR=, or ESTDATA= data set are added to the constraints specified in BOUNDS and LINCON statements.

You can use an OUTEST= data set from a PROC CALIS run as an INEST= data set in a new run. However, be aware that the OUTEST= data set also contains the boundary and general linear constraints specified in the previous run of PROC CALIS. When you are using this OUTEST= data set without changes as an INEST= data set, PROC CALIS adds the constraints from the data set to the constraints specified by a BOUNDS and LINCON statement. Although PROC CALIS automatically eliminates multiple identical constraints, you should avoid specifying the same constraint a second time.

INRAM= SAS-data-set

This data set is usually created in a previous run of PROC CALIS. It is useful if you want to reanalyze a problem in a different way, such as by using a different estimation method. You can alter an existing OUTRAM= data set, either in the DATA step or using the FSEDIT procedure, to create the INRAM= data set describing a modified model. For more details on the INRAM= data set, see the section "OUTRAM= SAS-data-set" on page 917.

In the case of a RAM or LINEQS analysis of linear structural equations, the OUTRAM= data set always contains the variable names of the model specified. These variable names and the model specified in the INRAM= data set are the basis of the automatic variable selection algorithm performed after reading the INRAM= data set.

INWGT= SAS-data-set

This data set enables you to specify a weight matrix other than the default matrix for the generalized, weighted, and diagonally weighted least squares estimation methods. The specification of any INWGT= data set for unweighted least squares or maximum likelihood estimation is ignored. For generalized and diagonally weighted least squares estimation, the INWGT= data set must contain a _TYPE_ and a _NAME_ variable as well as the manifest variables used in the analysis. The value of the _NAME_ variable indicates the row index i of the weight w_{ij}. For weighted least squares, the INWGT= data set must contain _TYPE_, _NAME_, _NAM2_, and _NAM3_ variables as well as the

manifest variables used in the analysis. The values of the _NAME_, _NAM2_, and _NAM3_ variables indicate the three indices i, j, k of the weight $w_{ij,kl}$. You can store information other than the weight matrix in the INWGT= data set, but only observations with _TYPE_=WEIGHT are used to specify the weight matrix $\mathbf{W}$. This property enables you to store more than one weight matrix in the INWGT= data set. You can then run PROC CALIS with each of the weight matrices by changing only the _TYPE_ observation in the INWGT= data set with an intermediate DATA step.

For more details on the INWGT= data set, see the section "OUTWGT= SAS-data-set" on page 922.

Output Data Sets

OUTEST= SAS-data-set

The OUTEST= (or OUTVAR=) data set is of TYPE=EST and contains the final parameter estimates, the gradient, the Hessian, and boundary and linear constraints. For METHOD=ML, METHOD=GLS, and METHOD=WLS, the OUTEST= data set also contains the approximate standard errors, the information matrix (crossproduct Jacobian), and the approximate covariance matrix of the parameter estimates ((generalized) inverse of the information matrix). If there are linear or nonlinear equality or active inequality constraints at the solution, the OUTEST= data set also contains Lagrange multipliers, the projected Hessian matrix, and the Hessian matrix of the Lagrange function.

The OUTEST= data set can be used to save the results of an optimization by PROC CALIS for another analysis with either PROC CALIS or another SAS procedure. Saving results to an OUTEST= data set is advised for expensive applications that cannot be repeated without considerable effort.

The OUTEST= data set contains the BY variables, two character variables _TYPE_ and _NAME_, t numeric variables corresponding to the parameters used in the model, a numeric variable _RHS_ (right-hand side) that is used for the right-hand-side value b_i of a linear constraint or for the value $f = f(x)$ of the objective function at the final point x^* of the parameter space, and a numeric variable _ITER_ that is set to zero for initial values, set to the iteration number for the OUTITER output, and set to missing for the result output.

The _TYPE_ observations in Table 25.5 are available in the OUTEST= data set, depending on the request.

Table 25.5 _TYPE_ Observations in the OUTEST= Data Set

TYPE	Description
ACTBC	If there are active boundary constraints at the solution x^*, three observations indicate which of the parameters are actively constrained, as follows.

NAME	Description
GE	indicates the active lower bounds
LE	indicates the active upper bounds
EQ	indicates the active masks

Table 25.5 *continued*

TYPE	Description
COV	contains the approximate covariance matrix of the parameter estimates; used in computing the approximate standard errors.
COVRANK	contains the rank of the covariance matrix of the parameter estimates.
CRPJ_LF	contains the Hessian matrix of the Lagrange function (based on CRPJAC).
CRPJAC	contains the approximate Hessian matrix used in the optimization process. This is the inverse of the information matrix.
EQ	If linear constraints are used, this observation contains the ith linear constraint $\sum_j a_{ij}x_j = b_i$. The parameter variables contain the coefficients a_{ij}, $j = 1, \ldots, n$, the _RHS_ variable contains b_i, and _NAME_=ACTLC or _NAME_=LDACTLC.
GE	If linear constraints are used, this observation contains the ith linear constraint $\sum_j a_{ij}x_j \geq b_i$. The parameter variables contain the coefficients a_{ij}, $j = 1, \ldots, n$, and the _RHS_ variable contains b_i. If the constraint i is active at the solution x^*, then _NAME_=ACTLC or _NAME_=LDACTLC.
GRAD	contains the gradient of the estimates.
GRAD_LF	contains the gradient of the Lagrange function. The _RHS_ variable contains the value of the Lagrange function.
HESSIAN	contains the Hessian matrix.
HESS_LF	contains the Hessian matrix of the Lagrange function (based on HESSIAN).
INFORMAT	contains the information matrix of the parameter estimates (only for METHOD=ML, METHOD=GLS, or METHOD=WLS).
INITIAL	contains the starting values of the parameter estimates.
JACNLC	contains the Jacobian of the nonlinear constraints evaluated at the final estimates.
JACOBIAN	contains the Jacobian matrix (only if the OUTJAC option is used).
LAGM BC	contains Lagrange multipliers for masks and active boundary constraints.

NAME	Description
GE	indicates the active lower bounds
LE	indicates the active upper bounds
EQ	indicates the active masks

Table 25.5 *continued*

TYPE	Description
LAGM LC	contains Lagrange multipliers for linear equality and active inequality constraints in pairs of observations containing the constraint number and the value of the Lagrange multiplier.

NAME	Description
LEC_NUM	number of the linear equality constraint
LEC_VAL	corresponding Lagrange multiplier value
LIC_NUM	number of the linear inequality constraint
LIC_VAL	corresponding Lagrange multiplier value

LAGM NLC	contains Lagrange multipliers for nonlinear equality and active inequality constraints in pairs of observations containing the constraint number and the value of the Lagrange multiplier.

NAME	Description
NLEC_NUM	number of the nonlinear equality constraint
NLEC_VAL	corresponding Lagrange multiplier value
NLIC_NUM	number of the linear inequality constraint
NLIC_VAL	corresponding Lagrange multiplier value

LE	If linear constraints are used, this observation contains the ith linear constraint $\sum_j a_{ij}x_j \leq b_i$. The parameter variables contain the coefficients a_{ij}, $j = 1, \ldots, n$, and the _RHS_ variable contains b_i. If the constraint i is active at the solution x^*, then _NAME_=ACTLC or _NAME_=LDACTLC.
LOWERBD | LB	If boundary constraints are used, this observation contains the lower bounds. Those parameters not subjected to lower bounds contain missing values. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.
NACTBC	All parameter variables contain the number n_{abc} of active boundary constraints at the solution x^*. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.
NACTLC	All parameter variables contain the number n_{alc} of active linear constraints at the solution x^* that are recognized as linearly independent. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.

Table 25.5 *continued*

TYPE	Description
NLC_EQ NLC_GE NLC_LE	contains values and residuals of nonlinear constraints. The _NAME_ variable is described as follows. **_NAME_ — Description** NLC — inactive nonlinear constraint NLCACT — linear independent active nonlinear constr. NLCACTLD — linear dependent active nonlinear constr.
NLDACTBC	contains the number of active boundary constraints at the solution x^* that are recognized as linearly dependent. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.
NLDACTLC	contains the number of active linear constraints at the solution x^* that are recognized as linearly dependent. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.
NOBS	contains the number of observations.
PARMS	contains the final parameter estimates. The _RHS_ variable contains the value of the objective function.
PCRPJ_LF	contains the projected Hessian matrix of the Lagrange function (based on CRPJAC).
PHESS_LF	contains the projected Hessian matrix of the Lagrange function (based on HESSIAN).
PROJCRPJ	contains the projected Hessian matrix (based on CRPJAC).
PROJGRAD	If linear constraints are used in the estimation, this observation contains the $n-n_{act}$ values of the projected gradient $g_Z = Z'g$ in the variables corresponding to the first $n - n_{act}$ parameters. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.
PROJHESS	contains the projected Hessian matrix (based on HESSIAN).
SIGSQ	contains the scalar factor of the covariance matrix of the parameter estimates.
STDERR	contains approximate standard errors (only for METHOD=ML, METHOD=GLS, or METHOD=WLS).
TERMINAT	The _NAME_ variable contains the name of the termination criterion.

Table 25.5 *continued*

TYPE	Description
UPPERBD | UB	If boundary constraints are used, this observation contains the upper bounds. Those parameters not subjected to upper bounds contain missing values. The _RHS_ variable contains a missing value, and the _NAME_ variable is blank.

If the technique specified by the TECH= option cannot be performed (for example, no feasible initial values can be computed, or the function value or derivatives cannot be evaluated at the starting point), the OUTEST= data set might contain only some of the observations (usually only the PARMS and GRAD observations).

OUTRAM= SAS-data-set

The OUTRAM= data set is of TYPE=RAM and contains the model specification and the computed parameter estimates. This data set is intended to be reused as an INRAM= data set to specify good initial values in a subsequent analysis by PROC CALIS.

The OUTRAM= data set contains the following variables:

- the BY variables, if any
- the character variable _TYPE_, which takes the values MODEL, ESTIM, VARNAME, METHOD, and STAT
- six additional variables whose meaning depends on the _TYPE_ of the observation

Each observation with _TYPE_=MODEL defines one matrix in the generalized COSAN model. The additional variables are as follows.

Table 25.6 Additional Variables When _TYPE_=MODEL

Variable	Contents
NAME	name of the matrix (character)
MATNR	number for the term and matrix in the model (numeric)
ROW	matrix row number (numeric)
COL	matrix column number (numeric)
ESTIM	first matrix type (numeric)
STDERR	second matrix type (numeric)

If the generalized COSAN model has only one matrix term, the _MATNR_ variable contains only the number of the matrix in the term. If there is more than one term, then it is the term number multiplied by 10,000 plus the matrix number (assuming that there are no more than 9,999 matrices specified in the COSAN model statement).

Each observation with _TYPE_=ESTIM defines one element of a matrix in the generalized COSAN model. The variables are used as follows.

Table 25.7 Additional Variables When _TYPE_=ESTIM

Variable	Contents
NAME	name of the parameter (character)
MATNR	term and matrix location of parameter (numeric)
ROW	row location of parameter (numeric)
COL	column location of parameter (numeric)
ESTIM	parameter estimate or constant value (numeric)
STDERR	standard error of estimate (numeric)

For constants rather than estimates, the _STDERR_ variable is 0. The _STDERR_ variable is missing for ULS and DWLS estimates if NOSTDERR is specified or if the approximate standard errors are not computed.

Each observation with _TYPE_=VARNAME defines a column variable name of a matrix in the generalized COSAN model.

The observations with _TYPE_=METHOD and _TYPE_=STAT are not used to build the model. The _TYPE_=METHOD observation contains the name of the estimation method used to compute the parameter estimates in the _NAME_ variable. If METHOD=NONE is not specified, the _ESTIM_ variable of the _TYPE_=STAT observations contains the information summarized in Table 25.8 (described in the section "Assessment of Fit" on page 928).

Table 25.8 _ESTIM_ Contents for _TYPE_=STAT

NAME	_ESTIM_
N	sample size
NPARM	number of parameters used in the model
DF	degrees of freedom
N_ACT	number of active boundary constraints for ML, GLS, and WLS estimation
FIT	fit function
GFI	goodness of fit index (GFI)
AGFI	adjusted GFI for degrees of freedom
RMR	root mean square residual
SRMR	standardized root mean square residual
PGFI	parsimonious GFI of Mulaik et al. (1989)
CHISQUAR	overall χ^2
P_CHISQ	probability $> \chi^2$
CHISQNUL	null (baseline) model χ^2
RMSEAEST	Steiger and Lind's (1980) RMSEA index estimate
RMSEALOB	lower range of RMSEA confidence interval
RMSEAUPB	upper range of RMSEA confidence interval
P_CLOSFT	Browne and Cudeck's (1993) probability of close fit
ECVI_EST	Browne and Cudeck's (1993) ECV index estimate

Table 25.8 *continued*

NAME	_ESTIM_
ECVI_LOB	lower range of ECVI confidence interval
ECVI_UPB	upper range of ECVI confidence interval
COMPFITI	Bentler's (1989) comparative fit index
ADJCHISQ	adjusted χ^2 for elliptic distribution
P_ACHISQ	probability corresponding adjusted χ^2
RLSCHISQ	reweighted least squares χ^2 (only ML estimation)
AIC	Akaike's information criterion
CAIC	Bozdogan's consistent information criterion
SBC	Schwarz's Bayesian criterion
CENTRALI	McDonald's centrality criterion
PARSIMON	Parsimonious index of James, Mulaik, and Brett
ZTESTWH	z test of Wilson and Hilferty
BB_NONOR	Bentler-Bonett (1980) nonnormed index ρ
BB_NORMD	Bentler-Bonett (1980) normed index Δ
BOL_RHO1	Bollen's (1986) normed index ρ_1
BOL_DEL2	Bollen's (1989a) nonnormed index Δ_2
CNHOELT	Hoelter's critical N index

You can edit the OUTRAM= data set to use its contents for initial estimates in a subsequent analysis by PROC CALIS, perhaps with a slightly changed model. But you should be especially careful for _TYPE_=MODEL when changing matrix types. The codes for the two matrix types are listed in Table 25.9.

Table 25.9 Matrix Type Codes

Code	First Matrix Type	Description
1:	IDE	identity matrix
2:	ZID	zero matrix concatenated by an identity matrix
3:	DIA	diagonal matrix
4:	ZDI	zero matrix concatenated by a diagonal matrix
5:	LOW	lower triangular matrix
6:	UPP	upper triangular matrix
7:		temporarily not used
8:	SYM	symmetric matrix
9:	GEN	general-type matrix
10:	BET	identity minus general-type matrix
11:	PER	selection matrix
12:		first matrix ($\mathbf{J}$) in LINEQS model statement
13:		second matrix ($\boldsymbol{\beta}$) in LINEQS model statement
14:		third matrix ($\boldsymbol{\gamma}$) in LINEQS model statement
Code	**Second Matrix Type**	**Description**
0:		noninverse model matrix
1:	INV	inverse model matrix
2:	IMI	"identity minus inverse" model matrix

OUTSTAT= SAS-data-set

The OUTSTAT= data set is similar to the TYPE=COV, TYPE=UCOV, TYPE=CORR, or TYPE=UCORR data set produced by the CORR procedure. The OUTSTAT= data set contains the following variables:

- the BY variables, if any
- two character variables, _TYPE_ and _NAME_
- the variables analyzed—that is, those in the VAR statement, or if there is no VAR statement, all numeric variables not listed in any other statement but used in the analysis. (**CAUTION:** Using the LINEQS or RAM model statements selects variables automatically.)

The OUTSTAT= data set contains the following information (when available):

- the mean and standard deviation
- the skewness and kurtosis (if the DATA= data set is a raw data set and the KURTOSIS option is specified)
- the number of observations
- if the WEIGHT statement is used, sum of the weights
- the correlation or covariance matrix to be analyzed
- the predicted correlation or covariance matrix
- the standardized or normalized residual correlation or covariance matrix
- if the model contains latent variables, the predicted covariances between latent and manifest variables, and the latent variable (or factor) score regression coefficients (see the PLATCOV display option on page 864)

In addition, if the FACTOR model statement is used, the OUTSTAT= data set contains the following:

- the unrotated factor loadings, the unique variances, and the matrix of factor correlations
- the rotated factor loadings and the transformation matrix of the rotation
- the matrix of standardized factor loadings

Each observation in the OUTSTAT= data set contains some type of statistic as indicated by the _TYPE_ variable. The values of the _TYPE_ variable are given in Table 25.10.

Table 25.10 _TYPE_ Observations in the OUTSTAT= Data Set

TYPE	Contents
MEAN	means
STD	standard deviations
USTD	uncorrected standard deviations
SKEWNESS	univariate skewness
KURTOSIS	univariate kurtosis
N	sample size
SUMWGT	sum of weights (if WEIGHT statement is used)
COV	covariances analyzed
CORR	correlations analyzed
UCOV	uncorrected covariances analyzed
UCORR	uncorrected correlations analyzed
ULSPRED	ULS predicted model values
GLSPRED	GLS predicted model values
MAXPRED	ML predicted model values
WLSPRED	WLS predicted model values
DWLSPRED	DWLS predicted model values
ULSNRES	ULS normalized residuals
GLSNRES	GLS normalized residuals
MAXNRES	ML normalized residuals
WLSNRES	WLS normalized residuals
DWLSNRES	DWLS normalized residuals
ULSSRES	ULS variance standardized residuals
GLSSRES	GLS variance standardized residuals
MAXSRES	ML variance standardized residuals
WLSSRES	WLS variance standardized residuals
DWLSSRES	DWLS variance standardized residuals
ULSASRES	ULS asymptotically standardized residuals
GLSASRES	GLS asymptotically standardized residuals
MAXASRES	ML asymptotically standardized residuals
WLSASRES	WLS asymptotically standardized residuals
DWLSASRS	DWLS asymptotically standardized residuals
UNROTATE	unrotated factor loadings
FCORR	matrix of factor correlations
UNIQUE_V	unique variances
TRANSFOR	transformation matrix of rotation
LOADINGS	rotated factor loadings
STD_LOAD	standardized factor loadings
LSSCORE	latent variable (or factor) score regression coefficients for ULS method
SCORE	latent variable (or factor) score regression coefficients other than ULS method

The _NAME_ variable contains the name of the manifest variable corresponding to each row for the covariance, correlation, predicted, and residual matrices and contains the name of the latent variable in case of factor regression scores. For other observations, _NAME_ is blank.

The unique variances and rotated loadings can be used as starting values in more difficult and constrained analyses.

If the model contains latent variables, the OUTSTAT= data set also contains the latent variable score regression coefficients and the predicted covariances between latent and manifest variables. You can use the latent variable score regression coefficients with PROC SCORE to compute latent variable or factor scores. For details, see the section "Latent Variable Scores" on page 937.

If the analyzed matrix is a (corrected or uncorrected) covariance rather than a correlation matrix, the _TYPE_=STD or _TYPE_=USTD observation is not included in the OUTSTAT= data set. In this case, the standard deviations can be obtained from the diagonal elements of the covariance matrix. Dropping the _TYPE_=STD or _TYPE_=USTD observation prevents PROC SCORE from standardizing the observations before computing the factor scores.

OUTWGT= SAS-data-set

You can create an OUTWGT= data set that is of TYPE=WEIGHT and contains the weight matrix used in generalized, weighted, or diagonally weighted least squares estimation. The *inverse* of the weight matrix is used in the corresponding fit function. The OUTWGT= data set contains the weight matrix to which the WRIDGE= and the WPENALTY= options are applied. For unweighted least squares or maximum likelihood estimation, no OUTWGT= data set can be written. The last weight matrix used in maximum likelihood estimation is the predicted model matrix (observations with _TYPE_=MAXPRED) that is included in the OUTSTAT= data set.

For generalized and diagonally weighted least squares estimation, the weight matrices $\mathbf{W}$ of the OUTWGT= data set contain all elements w_{ij}, where the indices i and j correspond to all manifest variables used in the analysis. Let $varnam_i$ be the name of the ith variable in the analysis. In this case, the OUTWGT= data set contains n observations with variables as displayed in the following table.

Table 25.11 Contents of OUTWGT= Data Set for GLS and DWLS Estimation

Variable	Contents
TYPE	WEIGHT (character)
NAME	name of variable $varnam_i$ (character)
$varnam_1$	weight w_{i1} for variable $varnam_1$ (numeric)
$\vdots$	$\vdots$
$varnam_n$	weight w_{in} for variable $varnam_n$ (numeric)

For weighted least squares estimation, the weight matrix $\mathbf{W}$ of the OUTWGT= data set contains only the nonredundant elements $w_{ij,kl}$. In this case, the OUTWGT= data set contains $n(n+1)(2n+1)/6$ observations with variables as in the following table.

Table 25.12 Contents of OUTWGT= Data Set for WLS Estimation

Variable	Contents
TYPE	WEIGHT (character)
NAME	name of variable $varnam_i$ (character)
NAM2	name of variable $varnam_j$ (character)
NAM3	name of variable $varnam_k$ (character)
$varnam_1$	weight $w_{ij,k1}$ for variable $varnam_1$ (numeric)
⋮	⋮
$varnam_n$	weight $w_{ij,kn}$ for variable $varnam_n$ (numeric)

Symmetric redundant elements are set to missing values.

Missing Values

If the DATA= data set contains raw data (rather than a covariance or correlation matrix), observations with missing values for any variables in the analysis are omitted from the computations. If a covariance or correlation matrix is read, missing values are allowed as long as every pair of variables has at least one nonmissing value.

Estimation Criteria

The following five estimation methods are available in PROC CALIS:

- unweighted least squares (ULS)
- generalized least squares (GLS)
- normal-theory maximum likelihood (ML)
- weighted least squares (WLS, ADF)
- diagonally weighted least squares (DWLS)

An INWGT= data set can be used to specify other than the default weight matrices $\mathbf{W}$ for GLS, WLS, and DWLS estimation.

PROC CALIS do not exhaust all estimation methods in the field. As mentioned in the section "Overview: CALIS Procedure" on page 828, partial least squares (PLS) is not implemented. The PLS method is developed under less restrictive statistical assumptions. It circumvents some computational and theoretical problems encountered by the existing estimation methods in PROC CALIS. However, PLS estimates are less efficient in general. When the statistical assumptions of PROC

CALIS are tenable (for example, large sample size, correct distributional assumptions, etc.), ML, GLS, or WLS methods yield better estimates than the PLS method. Note that there is a SAS/STAT procedure called PROC PLS, which employs the partial least squares technique but for a class of models different from those of PROC CALIS. For example, in a PROC CALIS model each latent variable is typically associated with only a subset of manifest variables (predictor or outcome variables). However, in PROC PLS latent variables are not prescribed with subsets of manifest variables. Rather, they are extracted from linear combinations of all manifest predictor variables. Therefore, for general path analysis with latent variables you should consider using PROC CALIS.

In each estimation method, the parameter vector is estimated iteratively by a nonlinear optimization algorithm that optimizes a goodness of fit function F. When n denotes the number of manifest variables, $\mathbf{S}$ denotes the given sample covariance or correlation matrix for a sample with size N, and $\mathbf{C}$ denotes the predicted moment matrix, then the fit function for unweighted least squares estimation is

$$F_{ULS} = 0.5Tr[(\mathbf{S} - \mathbf{C})^2]$$

For normal-theory generalized least squares estimation, the function is

$$F_{GLS} = 0.5Tr[(\mathbf{S}^{-1}(\mathbf{S} - \mathbf{C}))^2]$$

For normal-theory maximum likelihood estimation, the function is

$$F_{ML} = Tr(\mathbf{S}\mathbf{C}^{-1}) - n + ln(det(\mathbf{C})) - ln(det(\mathbf{S}))$$

The first three functions can be expressed by the generalized weighted least squares criterion (Browne 1982):

$$F_{GWLS} = 0.5Tr[(\mathbf{W}^{-1}(\mathbf{S} - \mathbf{C}))^2]$$

For unweighted least squares, the weight matrix $\mathbf{W}$ is chosen as the identity matrix $\mathbf{I}$; for generalized least squares, the default weight matrix $\mathbf{W}$ is the sample covariance matrix $\mathbf{S}$; and for normal-theory maximum likelihood, $\mathbf{W}$ is the iteratively updated predicted moment matrix $\mathbf{C}$. The values of the normal-theory maximum likelihood function F_{ML} and the generally weighted least squares criterion F_{GWLS} with $\mathbf{W} = \mathbf{C}$ are asymptotically equivalent.

The goodness of fit function that is minimized in weighted least squares estimation is

$$F_{WLS} = Vec(s_{ij} - c_{ij})'\mathbf{W}^{-1}Vec(s_{ij} - c_{ij})$$

where $Vec(s_{ij} - c_{ij})$ denotes the vector of the $n(n+1)/2$ elements of the lower triangle of the symmetric matrix $\mathbf{S} - \mathbf{C}$, and $\mathbf{W} = (w_{ij,kl})$ is a positive-definite symmetric matrix with $n(n+1)/2$ rows and columns.

If the moment matrix **S** is considered as a covariance rather than a correlation matrix, the default setting of $\mathbf{W} = (w_{ij,kl})$ is the consistent but biased estimators of the asymptotic covariances $\sigma_{ij,kl}$ of the sample covariance s_{ij} with the sample covariance s_{kl}, as defined in the following:

$$w_{ij,kl} = s_{ij,kl} - s_{ij}s_{kl}$$

where

$$s_{ij,kl} = \frac{1}{N}\sum_{r=1}^{N}(z_{ri} - \bar{z}_i)(z_{rj} - \bar{z}_j)(z_{rk} - \bar{z}_k)(z_{rl} - \bar{z}_l)$$

The formula of the asymptotic covariances of uncorrected covariances (using the UCOV or NOINT option) is a straightforward generalization of this expression.

The resulting weight matrix **W** is at least positive semidefinite (except for rounding errors). Using the ASYCOV option, you can use Browne's (1984, formula (3.8)) unbiased estimators

$$\begin{aligned} w_{ij,kl} &= \frac{N(N-1)}{(N-2)(N-3)}(s_{ij,kl} - s_{ij}s_{kl}) \\ &\quad -\frac{N}{(N-2)(N-3)}(s_{ik}s_{jl} + s_{il}s_{jk} - \frac{2}{N-1}s_{ij}s_{kl}) \end{aligned}$$

There is no guarantee that this weight matrix is positive semidefinite. However, the second part is of order $O(N^{-1})$ and does not destroy the positive semidefinite first part for sufficiently large N. For a large number of independent observations, default settings of the weight matrix **W** result in asymptotically distribution-free parameter estimates with unbiased standard errors and a correct χ^2 test statistic (Browne 1982, 1984).

If the moment matrix **S** is a correlation (rather than a covariance) matrix, the default setting of $\mathbf{W} = (w_{ij,kl})$ is the estimators of the asymptotic covariances $\sigma_{ij,kl}$ of the correlations $\mathbf{S} = (s_{ij})$ (Browne and Shapiro 1986; DeLeeuw 1983)

$$\begin{aligned} w_{ij,kl} &= r_{ij,kl} - \frac{1}{2}r_{ij}(r_{ii,kl} + r_{jj,kl}) - \frac{1}{2}r_{kl}(r_{kk,ij} + r_{ll,ij}) \\ &\quad +\frac{1}{4}r_{ij}r_{kl}(r_{ii,kk} + r_{ii,ll} + r_{jj,kk} + r_{jj,ll}) \end{aligned}$$

where

$$r_{ij,kl} = \frac{s_{ij,kl}}{\sqrt{s_{ii}s_{jj}s_{kk}s_{ll}}}$$

The asymptotic variances of the diagonal elements of a correlation matrix are 0. Therefore, the weight matrix computed by Browne and Shapiro's formula is always singular. In this case the goodness of fit function for weighted least squares estimation is modified to

$$F_{WLS} = \sum_{i=2}^{n}\sum_{j=1}^{i-1}\sum_{k=2}^{n}\sum_{l=1}^{k-1} w^{ij,kl}(s_{ij} - c_{ij})(s_{kl} - c_{kl}) + r\sum_{i}^{n}(s_{ii} - c_{ii})^2$$

where r is the penalty weight specified by the WPENALTY=r option and the $w^{ij,kl}$ are the elements of the inverse of the reduced $(n(n-1)/2)\times(n(n-1)/2)$ weight matrix that contains only the nonzero rows and columns of the full weight matrix $\mathbf{W}$. The second term is a penalty term to fit the diagonal elements of the moment matrix $\mathbf{S}$. The default value of $r = 100$ can be decreased or increased by the WPENALTY= option. The often used value of $r = 1$ seems to be too small in many cases to fit the diagonal elements of a correlation matrix properly. If your model does not fit the diagonal of the moment matrix $\mathbf{S}$, you can specify the NODIAG option to exclude the diagonal elements from the fit function.

Storing and inverting the huge weight matrix $\mathbf{W}$ in WLS estimation needs considerable computer resources. A compromise is found by implementing the DWLS method that uses only the diagonal of the weight matrix $\mathbf{W}$ from the WLS estimation in the minimization function

$$F_{DWLS} = Vec(s_{ij} - c_{ij})' diag(\mathbf{W})^{-1} Vec(s_{ij} - c_{ij})$$

The statistical properties of DWLS estimates are still not known.

In generalized, weighted, or diagonally weighted least squares estimation, you can change from the default settings of weight matrices $\mathbf{W}$ by using an INWGT= data set. Because the diagonal elements $w_{ii,kk}$ of the weight matrix $\mathbf{W}$ are interpreted as asymptotic variances of the sample covariances or correlations, they cannot be negative. The CALIS procedure requires a positive-definite weight matrix that has positive diagonal elements.

Relationships among Estimation Criteria

The five estimation functions, F_{ULS}, F_{GLS}, F_{ML}, F_{WLS}, and F_{DWLS}, belong to the following two groups:

- The functions F_{ULS}, F_{GLS}, and F_{ML} take into account all n^2 elements of the symmetric residual matrix $\mathbf{S} - \mathbf{C}$. This means that the off-diagonal residuals contribute twice to F, as lower and as upper triangular elements.
- The functions F_{WLS} and F_{DWLS} take into account only the $n(n+1)/2$ lower triangular elements of the symmetric residual matrix $\mathbf{S} - \mathbf{C}$. This means that the off-diagonal residuals contribute to F only once.

The F_{DWLS} function used in PROC CALIS differs from that used by the LISREL 7 program. Formula (1.25) of the LISREL 7 manual (Jöreskog and Sörbom 1988, p. 23) shows that LISREL groups the F_{DWLS} function in the first group by taking into account all n^2 elements of the symmetric residual matrix $\mathbf{S} - \mathbf{C}$.

- Relationship between DWLS and WLS:
  PROC CALIS: The F_{DWLS} and F_{WLS} estimation functions deliver the same results for the special case that the weight matrix $\mathbf{W}$ used by WLS estimation is a diagonal matrix.
  LISREL 7: This is not the case.

- Relationship between DWLS and ULS:
  LISREL 7: The F_{DWLS} and F_{ULS} estimation functions deliver the same results for the special case that the diagonal weight matrix **W** used by DWLS estimation is an identity matrix (contains only 1s).
  PROC CALIS: To obtain the same results with F_{DWLS} and F_{ULS} estimation, set the diagonal weight matrix **W** used in DWLS estimation to

$$w_{ik,ik} = \begin{cases} 1. & \text{if } i = k \\ 0.5 & \text{otherwise} \end{cases}$$

  Because the reciprocal elements of the weight matrix are used in the goodness of fit function, the off-diagonal residuals are weighted by a factor of 2.

Testing Rank Deficiency in the Approximate Covariance Matrix

The inverse of the information matrix (or approximate Hessian matrix) is used for the covariance matrix of the parameter estimates, which is needed for the computation of approximate standard errors and modification indices. The numerical condition of the information matrix (computed as the crossproduct $\mathbf{J}'\mathbf{J}$ of the Jacobian matrix **J**) can be very poor in many practical applications, especially for the analysis of unscaled covariance data. The following four-step strategy is used for the inversion of the information matrix.

1. The inversion (usually of a normalized matrix $\mathbf{D}^{-1}\mathbf{H}\mathbf{D}^{-1}$) is tried using a modified form of the Bunch and Kaufman (1977) algorithm, which allows the specification of a different singularity criterion for each pivot. The following three criteria for the detection of rank loss in the information matrix are used to specify thresholds:

   - *ASING* specifies absolute singularity.
   - *MSING* specifies relative singularity depending on the whole matrix norm.
   - *VSING* specifies relative singularity depending on the column matrix norm.

   If no rank loss is detected, the inverse of the information matrix is used for the covariance matrix of parameter estimates, and the next two steps are skipped.

2. The linear dependencies among the parameter subsets are displayed based on the singularity criteria.

3. If the number of parameters t is smaller than the value specified by the G4= option (the default value is 60), the Moore-Penrose inverse is computed based on the eigenvalue decomposition of the information matrix. If you do not specify the NOPRINT option, the distribution of eigenvalues is displayed, and those eigenvalues that are set to zero in the Moore-Penrose inverse are indicated. You should inspect this eigenvalue distribution carefully.

4. If PROC CALIS did not set the right subset of eigenvalues to zero, you can specify the COVSING= option to set a larger or smaller subset of eigenvalues to zero in a further run of PROC CALIS.

Approximate Standard Errors

Except for unweighted and diagonally weighted least squares estimation, approximate standard errors can be computed as the diagonal elements of the matrix

$$\frac{c}{NM}\mathbf{H}^{-1}, \quad \text{where}$$

$$NM = \begin{cases} (N-1) & \text{if the CORR or COV matrix is analyzed} \\ & \text{or the intercept variable is not used in the model} \\ N & \text{if the UCORR or UCOV matrix is analyzed} \\ & \text{and the intercept variable is not used in the model} \end{cases}$$

The matrix $\mathbf{H}$ is the approximate Hessian matrix of F evaluated at the final estimates, $c = 1$ for the WLS estimation method, $c = 2$ for the GLS and ML method, and N is the sample size. If a given correlation or covariance matrix is singular, PROC CALIS offers two ways to compute a generalized inverse of the information matrix and, therefore, two ways to compute approximate standard errors of implicitly constrained parameter estimates, t values, and modification indices. Depending on the G4= specification, either a Moore-Penrose inverse or a G2 inverse is computed. The expensive Moore-Penrose inverse computes an estimate of the null space by using an eigenvalue decomposition. The cheaper G2 inverse is produced by sweeping the linearly independent rows and columns and zeroing out the dependent ones. The information matrix, the approximate covariance matrix of the parameter estimates, and the approximate standard errors are not computed in the cases of unweighted or diagonally weighted least squares estimation.

Assessment of Fit

This section contains a collection of formulas used in computing indices to assess the goodness of fit by PROC CALIS. The following notation is used:

- N for the sample size
- n for the number of manifest variables
- t for the number of parameters to estimate
- $NM = \begin{cases} (N-1) & \text{if the CORR or COV matrix is analyzed} \\ & \text{or the intercept variable is not used in the model} \\ N & \text{if the UCORR or UCOV matrix is analyzed} \\ & \text{and the intercept variable is not used in the model} \end{cases}$
- df for the degrees of freedom
- $\boldsymbol{\gamma} = \mathbf{X}$ for the t vector of optimal parameter estimates
- $\mathbf{S} = (s_{ij})$ for the $n \times n$ input COV, CORR, UCOV, or UCORR matrix
- $\mathbf{C} = (c_{ij}) = \hat{\boldsymbol{\Sigma}} = \boldsymbol{\Sigma}(\hat{\boldsymbol{\gamma}})$ for the predicted model matrix

- $\mathbf{W}$ for the weight matrix ($\mathbf{W} = \mathbf{I}$ for ULS, $\mathbf{W} = \mathbf{S}$ for default GLS, and $\mathbf{W} = \mathbf{C}$ for ML estimates)
- $\mathbf{U}$ for the $n^2 \times n^2$ asymptotic covariance matrix of sample covariances
- $\Phi(x|\lambda, df)$ for the cumulative distribution function of the noncentral chi-squared distribution with noncentrality parameter λ

The following notation is for indices that support testing nested models by a χ^2 difference test:

- f_0 for the function value of the independence model
- df_0 for the degrees of freedom of the independence model
- $f_{min} = F$ for the function value of the fitted model
- $df_{min} = df$ for the degrees of freedom of the fitted model

The degrees of freedom df_{min} and the number of parameters t are adjusted automatically when there are active constraints in the analysis. The computation of many fit statistics and indices are affected. You can turn off the automatic adjustment by using the NOADJDF option. See the section "Counting the Degrees of Freedom" on page 956 for more information.

Residuals

PROC CALIS computes four types of residuals and writes them to the OUTSTAT= data set.

- **Raw Residuals**

  $$Res = \mathbf{S} - \mathbf{C}, Res_{ij} = s_{ij} - c_{ij}$$

  The raw residuals are displayed whenever the PALL, PRINT, or RESIDUAL option is specified.

- **Variance Standardized Residuals**

  $$VSRes_{ij} = \frac{s_{ij} - c_{ij}}{\sqrt{s_{ii} s_{jj}}}$$

  The variance standardized residuals are displayed when you specify the following:

  – the PALL, PRINT, or RESIDUAL option and METHOD=NONE, METHOD=ULS, or METHOD=DWLS
  – RESIDUAL=VARSTAND

  The variance standardized residuals are equal to those computed by the EQS 3 program (Bentler 1989).

- **Asymptotically Standardized Residuals**

$$ASRes_{ij} = \frac{s_{ij} - c_{ij}}{\sqrt{v_{ij,ij}}}, \quad \text{where}$$

$$v_{ij,ij} = diag(\mathbf{U} - \mathbf{J}Cov(\boldsymbol{\gamma})\mathbf{J}')_{ij}$$

The matrix $\mathbf{J}$ is the $n^2 \times t$ Jacobian matrix $d\,\boldsymbol{\Sigma}/d\,\boldsymbol{\gamma}$, and $Cov(\boldsymbol{\gamma})$ is the $t \times t$ asymptotic covariance matrix of parameter estimates (the inverse of the information matrix). Asymptotically standardized residuals are displayed when one of the following conditions is met:

  - The PALL, PRINT, or RESIDUAL option is specified, and METHOD=ML, METHOD=GLS, or METHOD=WLS, and the expensive information and Jacobian matrices are computed for some other reason.
  - RESIDUAL= ASYSTAND is specified.

The asymptotically standardized residuals are equal to those computed by the LISREL 7 program (Jöreskog and Sörbom 1988) except for the denominator NM in the definition of matrix $\mathbf{U}$.

- **Normalized Residuals**

$$NRes_{ij} = \frac{s_{ij} - c_{ij}}{\sqrt{u_{ij,ij}}}$$

where the diagonal elements $u_{ij,ij}$ of the $n^2 \times n^2$ asymptotic covariance matrix $\mathbf{U}$ of sample covariances are defined for the following methods.

  - **GLS** as $u_{ij,ij} = \frac{1}{NM}(s_{ii}s_{jj} + s_{ij}^2)$
  - **ML** as $u_{ij,ij} = \frac{1}{NM}(c_{ii}c_{jj} + c_{ij}^2)$
  - **WLS** as $u_{ij,ij} = \frac{1}{NM}w_{ij,ij}$

Normalized residuals are displayed when one of the following conditions is met:

  - The PALL, PRINT, or RESIDUAL option is specified, and METHOD=ML, METHOD=GLS, or METHOD=WLS, and the expensive information and Jacobian matrices are **not** computed for some other reason.
  - RESIDUAL=NORM is specified.

The normalized residuals are equal to those computed by the LISREL VI program (Jöreskog and Sörbom 1985) except for the definition of the denominator NM in matrix $\mathbf{U}$.

For estimation methods that are not BGLS estimation methods (Browne 1982, 1984), such as METHOD=NONE, METHOD=ULS, or METHOD=DWLS, the assumption of an asymptotic covariance matrix $\mathbf{U}$ of sample covariances does not seem to be appropriate. In this case, the normalized residuals should be replaced by the more relaxed variance standardized residuals. Computation of asymptotically standardized residuals requires computing the Jacobian and information matrices. This is computationally very expensive and is done only if the Jacobian matrix has to be computed for some other reason—that is, if at least one of the following items is true:

- The default, PRINT, or PALL displayed output is requested, and neither the NOMOD nor NOSTDERR option is specified.
- Either the MODIFICATION (included in PALL), PCOVES, or STDERR (included in default, PRINT, and PALL output) option is requested or RESIDUAL=ASYSTAND is specified.
- The LEVMAR or NEWRAP optimization technique is used.
- An OUTRAM= data set is specified without using the NOSTDERR option.
- An OUTEST= data set is specified without using the NOSTDERR option.

Since normalized residuals use an overestimate of the asymptotic covariance matrix of residuals (the diagonal of **U**), the normalized residuals cannot be larger than the asymptotically standardized residuals (which use the diagonal of $\mathbf{U} - \mathbf{J}Cov(\boldsymbol{\gamma})\mathbf{J}'$).

Together with the residual matrices, the values of the average residual, the average off-diagonal residual, and the rank order of the largest values are displayed. The distribution of the normalized and standardized residuals is displayed also.

Goodness of Fit Indices Based on Residuals

The following items are computed for all five kinds of estimation: ULS, GLS, ML, WLS, and DWLS. All these indices are written to the OUTRAM= data set. The goodness of fit (GFI), adjusted goodness of fit (AGFI), and root mean square residual (RMR) are computed as in the LISREL VI program of Jöreskog and Sörbom (1985).

- **Goodness of Fit Index**
  The goodness of fit index for the ULS, GLS, and ML estimation methods is

  $$GFI = 1 - \frac{Tr((\mathbf{W}^{-1}(\mathbf{S} - \mathbf{C}))^2)}{Tr((\mathbf{W}^{-1}\mathbf{S})^2)}$$

  but for WLS and DWLS estimation, it is

  $$GFI = 1 - \frac{Vec(s_{ij} - c_{ij})'\mathbf{W}^{-1}Vec(s_{ij} - c_{ij})}{Vec(s_{ij})'\mathbf{W}^{-1}Vec(s_{ij})}$$

  where $\mathbf{W} = diag$ for DWLS estimation, and $Vec(s_{ij} - c_{ij})$ denotes the vector of the $n(n+1)/2$ elements of the lower triangle of the symmetric matrix $\mathbf{S} - \mathbf{C}$. For a constant weight matrix **W**, the goodness of fit index is 1 minus the ratio of the minimum function value and the function value before any model has been fitted. The GFI should be between 0 and 1. The data probably do not fit the model if the GFI is negative or much larger than 1.
- **Adjusted Goodness of Fit Index**
  The AGFI is the GFI adjusted for the degrees of freedom of the model

  $$AGFI = 1 - \frac{n(n+1)}{2df}(1 - GFI)$$

The AGFI corresponds to the GFI in replacing the total sum of squares by the mean sum of squares.

CAUTION:

- Large n and small df can result in a negative AGFI. For example, GFI= 0.90, $n = 19$, and $df = 2$ result in an AGFI of -8.5.
- AGFI is not defined for a saturated model, due to division by $df = 0$.
- AGFI is not sensitive to losses in df.

The AGFI should be between 0 and 1. The data probably do not fit the model if the AGFI is negative or much larger than 1. For more information, refer to Mulaik et al. (1989).

- **Root Mean Square Residual**
  The RMR is the root of the mean of the squared residuals:

$$RMR = \sqrt{\frac{2}{n(n+1)} \sum_{i}^{n} \sum_{j}^{i} (s_{ij} - c_{ij})^2}$$

- **Standardized Root Mean Square Residual**
  The SRMR is the root of the mean of the squared standardized residuals:

$$SRMR = \sqrt{\frac{2}{n(n+1)} \sum_{i}^{n} \sum_{j}^{i} \frac{(s_{ij} - c_{ij})^2}{s_{ii} s_{jj}}}$$

- **Parsimonious Goodness of Fit Index**
  The PGFI (Mulaik et al. 1989) is a modification of the GFI that takes the parsimony of the model into account:

$$PGFI = \frac{df_{min}}{df_0} GFI$$

The PGFI uses the same parsimonious factor as the parsimonious normed Bentler-Bonett index (James, Mulaik, and Brett 1982).

Goodness of Fit Indices Based on the χ^2

The following items are transformations of the overall χ^2 value and in general depend on the sample size N. These indices are not computed for ULS or DWLS estimates.

- **Uncorrected χ^2**
  The overall χ^2 measure is the optimum function value F multiplied by $N - 1$ if a CORR or COV matrix is analyzed, or multiplied by N if a UCORR or UCOV matrix is analyzed. This gives the likelihood ratio test statistic for the null hypothesis that the predicted matrix $\mathbf{C}$ has the specified model structure against the alternative that $\mathbf{C}$ is unconstrained. The χ^2 test is valid only if the observations are independent and identically distributed, the analysis is based

on the nonstandardized sample covariance matrix **S**, and the sample size N is sufficiently large (Browne 1982; Bollen 1989b; Jöreskog and Sörbom 1985). For ML and GLS estimates, the variables must also have an approximately multivariate normal distribution. The notation Prob>Chi**2 means "the probability under the null hypothesis of obtaining a greater χ^2 statistic than that observed."

$$\chi^2 = NM * F$$

where F is the function value at the minimum.

- **χ_0^2 Value of the Independence Model**
  The χ_0^2 value of the independence model

  $$\chi_0^2 = NM * f_0$$

  and the corresponding degrees of freedom df_0 can be used (in large samples) to evaluate the gain of explanation by fitting the specific model (Bentler 1989).

- **RMSEA Index (Steiger and Lind 1980)**
  The Steiger and Lind (1980) root mean squared error approximation (RMSEA) coefficient is

  $$\epsilon_\alpha = \sqrt{\max(\frac{F}{df} - \frac{1}{NM}, 0)}$$

  The lower and upper limits of the confidence interval are computed using the cumulative distribution function of the noncentral chi-squared distribution $\Phi(x|\lambda, df) = \alpha$, with $x = NM * F$, λ_L satisfying $\Phi(x|\lambda_L, df) = 1 - \frac{\alpha}{2}$, and λ_U satisfying $\Phi(x|\lambda_U, df) = \frac{\alpha}{2}$:

  $$(\epsilon_{\alpha_L}; \epsilon_{\alpha_U}) = (\sqrt{\frac{\lambda_L}{NM * df}}; \sqrt{\frac{\lambda_U}{NM * df}})$$

  Refer to Browne and Du Toit (1992) for more details. The size of the confidence interval is defined by the option ALPHARMS=α, $0 \leq \alpha \leq 1$. The default is $\alpha = 0.1$, which corresponds to the 90% confidence interval for the RMSEA.

- **Probability for Test of Close Fit (Browne and Cudeck 1993)**
  The traditional exact χ^2 test hypothesis $H_0: \epsilon_\alpha = 0$ is replaced by the null hypothesis of close fit $H_0: \epsilon_\alpha \leq 0.05$ and the exceedance probability P is computed as

  $$P = 1 - \Phi(x|\lambda^*, df)$$

  where $x = NM * F$ and $\lambda^* = 0.05^2 * NM * df$. The null hypothesis of close fit is rejected if P is smaller than a prespecified level (for example, $P < 0.05$).

- **Expected Cross Validation Index (Browne and Cudeck 1993)**
  For GLS and WLS, the estimator c of the ECVI is linearly related to AIC:

  $$c = F(\mathbf{S}, \mathbf{C}) + \frac{2t}{NM}$$

  For ML estimation, c_{ML} is used.

  $$c_{ML} = F_{ML}(\mathbf{S}, \mathbf{C}) + \frac{2t}{NM - n - 1}$$

The confidence interval $(c_L; c_U)$ for c is computed using the cumulative distribution function $\Phi(x|\lambda, df)$ of the noncentral chi-squared distribution,

$$(c_L; c_U) = (\frac{\lambda_L + nnt}{NM}; \frac{\lambda_U + nnt}{NM})$$

with $nnt = n(n+1)/2 + t$, $x = NM * F$, $\Phi(x|\lambda_U, df) = 1 - \frac{\alpha}{2}$, and $\Phi(x|\lambda_L, df) = \frac{\alpha}{2}$. The confidence interval $(c_L^*; c_U^*)$ for c_{ML} is

$$(c_L^*; c_U^*) = (\frac{\lambda_L^* + nnt}{NM - n - 1}); \frac{\lambda_U^* + nnt}{NM - n - 1})$$

where $nnt = n(n+1)/2+t$, $x = (NM-n-1)*F$, $\Phi(x|\lambda_U^*, df) = \frac{\alpha}{2}$ and $\Phi(x|\lambda_L^*, df) = 1 - \frac{\alpha}{2}$. Refer to Browne and Cudeck (1993) for details. The size of the confidence interval is defined by the option ALPHAECV=α, $0 \leq \alpha \leq 1$. The default is $\alpha = 0.1$, which corresponds to the 90% confidence interval for the ECVI.

- **Comparative Fit Index (Bentler 1989)**

$$CFI = 1 - \frac{\max(NM * f_{min} - df_{min}, 0)}{\max(NM * f_0 - df_0, 0)}$$

- **Adjusted χ^2 Value (Browne 1982)**
  If the variables are n-variate elliptic rather than normal and have significant amounts of multivariate kurtosis (leptokurtic or platykurtic), the χ^2 value can be adjusted to

$$\chi^2_{ell} = \frac{\chi^2}{\eta_2}$$

  where η_2 is the multivariate relative kurtosis coefficient.

- **Normal Theory Reweighted LS χ^2 Value**
  This index is displayed only if METHOD=ML. Instead of the function value F_{ML}, the reweighted goodness of fit function F_{GWLS} is used,

$$\chi^2_{GWLS} = NM * F_{GWLS}$$

  where F_{GWLS} is the value of the function at the minimum.

- **Akaike's Information Criterion (AIC) (Akaike 1974; Akaike 1987)**
  This is a criterion for selecting the best model among a number of candidate models. The model that yields the smallest value of AIC is considered the best.

$$AIC = \chi^2 - 2df$$

- **Consistent Akaike's Information Criterion (CAIC) (Bozdogan 1987)**
  This is another criterion, similar to AIC, for selecting the best model among alternatives. The model that yields the smallest value of CAIC is considered the best. CAIC is preferred by some people to AIC or the χ^2 test.

$$CAIC = \chi^2 - (ln(N) + 1)df$$

- **Schwarz's Bayesian Criterion (SBC) (Schwarz 1978; Sclove 1987)**
  This is another criterion, similar to AIC, for selecting the best model. The model that yields the smallest value of SBC is considered the best. SBC is preferred by some people to AIC or the χ^2 test.

  $$SBC = \chi^2 - ln(N)df$$

- **McDonald's Measure of Centrality (McDonald 1989)**

  $$CENT = exp(-\frac{(\chi^2 - df)}{2N})$$

- **Parsimonious Normed Fit Index (James, Mulaik, and Brett 1982)**
  The PNFI is a modification of Bentler-Bonett's normed fit index that takes parsimony of the model into account,

  $$PNFI = \frac{df_{min}}{df_0}\frac{(f_0 - f_{min})}{f_0}$$

  The PNFI uses the same parsimonious factor as the parsimonious GFI of Mulaik et al. (1989).

- **Z-Test (Wilson and Hilferty 1931)**
  The Z-test of Wilson and Hilferty assumes an n-variate normal distribution:

  $$Z = \frac{\sqrt[3]{\frac{\chi^2}{df}} - (1 - \frac{2}{9df})}{\sqrt{\frac{2}{9df}}}$$

  Refer to McArdle (1988) and Bishop, Fienberg, and Holland (1977, p. 527) for an application of the Z-test.

- **Nonnormed Coefficient (Bentler and Bonett 1980)**

  $$\rho = \frac{f_0/df_0 - f_{min}/df_{min}}{f_0/df_0 - 1/NM}$$

  Refer to Tucker and Lewis (1973) for details.

- **Normed Coefficient (Bentler and Bonett 1980)**

  $$\Delta = \frac{f_0 - f_{min}}{f_0}$$

  Mulaik et al. (1989) recommend the parsimonious weighted form PNFI.

- **Normed Index ρ_1 (Bollen 1986)**

  $$\rho_1 = \frac{f_0/df_0 - f_{min}/df_{min}}{f_0/df_0}$$

  ρ_1 is always less than or equal to 1; $\rho_1 < 0$ is unlikely in practice. Refer to the discussion in Bollen (1989a) for details.

- **Nonnormed Index Δ_2 (Bollen 1989a)**

$$\Delta_2 = \frac{f_0 - f_{min}}{f_0 - \frac{df}{NM}}$$

is a modification of Bentler and Bonett's Δ that uses df and "lessens the dependence" on N. Refer to the discussion in Bollen (1989b). Δ_2 is identical to Mulaik et al.'s (1989) IFI2 index.

- **Critical N Index (Hoelter 1983)**

$$CN = \frac{\chi^2_{crit}}{F} + 1$$

where χ^2_{crit} is the critical chi-square value for the given df degrees of freedom and probability $\alpha = 0.05$, and F is the value of the estimation criterion (minimization function). Refer to Bollen (1989b, p. 277) for details. Hoelter (1983) suggests that CN should be at least 200; however, Bollen (1989b) notes that the CN value might lead to an overly pessimistic assessment of fit for small samples.

Squared Multiple Correlation

The following are measures of the squared multiple correlation for manifest and endogenous variables and are computed for all five estimation methods: ULS, GLS, ML, WLS, and DWLS. These coefficients are computed as in the LISREL VI program of Jöreskog and Sörbom (1985). The DETAE, DETSE, and DETMV determination coefficients are intended to be global means of the squared multiple correlations for different subsets of model equations and variables. These coefficients are displayed only when you specify the PDETERM option with a RAM or LINEQS model.

- **R^2 Values Corresponding to Endogenous Variables**

$$R^2_i = 1 - \frac{\widehat{var(\boldsymbol{\xi}_i)}}{\widehat{var(\boldsymbol{\eta}_i)}}$$

- **Total Determination of All Equations**

$$DETAE = 1 - \frac{det(\hat{\boldsymbol{\Theta}}, \hat{\boldsymbol{\Psi}})}{det(\widehat{Cov(y, x, \boldsymbol{\eta})})}$$

- **Total Determination of the Structural Equations**

$$DETSE = 1 - \frac{det(\hat{\boldsymbol{\Psi}})}{det(\widehat{Cov(\boldsymbol{\eta})})}$$

- **Total Determination of the Manifest Variables**

$$DETMV = 1 - \frac{det(\hat{\boldsymbol{\Theta}})}{det(\mathbf{S})}$$

CAUTION: In the LISREL program, the structural equations are defined by specifying the BETA matrix. In PROC CALIS, a structural equation has a dependent left-hand-side variable that appears at least once on the right-hand side of another equation, or the equation has at least one right-hand-side variable that is the left-hand-side variable of another equation. Therefore, PROC CALIS sometimes identifies more equations as structural equations than the LISREL program does.

Latent Variable Scores

Although latent variable or factor scores are unobserved, they can be estimated after you fit your model using PROC CALIS. Latent variable or factor scores are estimated as linear combinations of observed variables, weighted by the latent variable (factor) score regression coefficients.

To display the latent variable (factor) score regression coefficients in the PROC CALIS output, you can use the PLATCOV option. You can also save these coefficients in an output data set by using the OUTSTAT= option. These coefficients can then be used by the SCORE procedure to compute the latent variable (factor) scores.

To summarize, do the following if you need to compute latent variable (factor) scores for each observation by using the SCORE procedure:

- Create an output data set with the OUTSTAT= option in the PROC CALIS statement.
- Use the SCORE procedure with both the raw data and the OUTSTAT= data set.

For example, you can use the following statements to compute the latent variable (factor) scores, which are stored in the OUT= data set named "**scores**":

```
proc calis data=raw outstat=ostat;
   lineqs
      v1 = a1 f1 + e1,
      v2 = a2 f1 + e2,
      v3 = a3 f1 + e3;
   std
      f1 = 1.,
      e1-e3 = evar1-evar3;
run;

proc score data=raw score=ostat out=scores;
run;
```

If you analyze a correlation or covariance matrix in PROC CALIS, the original raw data must be used in the PROC SCORE procedure, as shown in the following statements:

```
proc corr data=raw out=correl;
run;

proc calis data=correl outstat=ostat;
   lineqs
      v1 = a1 f1 + e1,
      v2 = a2 f1 + e2,
      v3 = a3 f1 + e3;
   std
      f1 = 1.,
      e1-e3 = evar1-evar3;
run;

proc score data=raw score=ostat out=scores;
run;
```

For a more detailed example, see Example 76.1 in Chapter 76, "The SCORE Procedure." Although the FACTOR procedure is used in that example, it is also applicable to the CALIS procedure. Essentially, an OUTSTAT= data set containing the latent variable or factor score regression coefficients, either from PROC FACTOR or PROC CALIS, is used with the raw data in the SCORE procedure to create the latent variable or factor scores.

Measures of Multivariate Kurtosis

In many applications, the manifest variables are not even approximately multivariate normal. If this happens to be the case with your data set, the default generalized least squares and maximum likelihood estimation methods are not appropriate, and you should compute the parameter estimates and their standard errors by an asymptotically distribution-free method, such as the WLS estimation method. If your manifest variables are multivariate normal, then they have a zero relative multivariate kurtosis, and all marginal distributions have zero kurtosis (Browne 1982). If your DATA= data set contains raw data, PROC CALIS computes univariate skewness and kurtosis and a set of multivariate kurtosis values. By default, the values of univariate skewness and kurtosis are corrected for bias (as in PROC UNIVARIATE), but using the BIASKUR option enables you to compute the uncorrected values also. The values are displayed when you specify the PROC CALIS statement option KURTOSIS.

- **Corrected Variance for Variable z_j**

$$\sigma_j^2 = \frac{1}{N-1}\sum_i^N (z_{ij} - \bar{z}_j)^2$$

- **Corrected Univariate Skewness for Variable z_j**

$$\gamma_{1(j)} = \frac{N}{(N-1)(N-2)} \frac{\sum_i^N (z_{ij} - \bar{z}_j)^3}{\sigma_j^3}$$

- **Uncorrected Univariate Skewness for Variable z_j**

$$\gamma_{1(j)} = \frac{N \sum_i^N (z_{ij} - \bar{z}_j)^3}{\sqrt{N[\sum_i^N (z_{ij} - \bar{z}_j)^2]^3}}$$

- **Corrected Univariate Kurtosis for Variable z_j**

$$\gamma_{2(j)} = \frac{N(N+1)}{(N-1)(N-2)(N-3)} \frac{\sum_i^N (z_{ij} - \bar{z}_j)^4}{\sigma_j^4} - \frac{3(N-1)^2}{(N-2)(N-3)}$$

- **Uncorrected Univariate Kurtosis for Variable z_j**

$$\gamma_{2(j)} = \frac{N\sum_i^N (z_{ij} - \bar{z}_j)^4}{[\sum_i^N (z_{ij} - \bar{z}_j)^2]^2} - 3$$

- **Mardia's Multivariate Kurtosis**

$$\gamma_2 = \frac{1}{N}\sum_i^N [(z_i - \bar{z})' S^{-1} (z_i - \bar{z})]^2 - n(n+2)$$

- **Relative Multivariate Kurtosis**

$$\eta_2 = \frac{\gamma_2 + n(n+2)}{n(n+2)}$$

- **Normalized Multivariate Kurtosis**

$$\kappa_0 = \frac{\gamma_2}{\sqrt{8n(n+2)/N}}$$

- **Mardia-Based Kappa**

$$\kappa_1 = \frac{\gamma_2}{n(n+2)}$$

- **Mean Scaled Univariate Kurtosis**

$$\kappa_2 = \frac{1}{3n}\sum_j^n \gamma_{2(j)}$$

- **Adjusted Mean Scaled Univariate Kurtosis**

$$\kappa_3 = \frac{1}{3n}\sum_{j}^{n}\gamma^*_{2(j)}$$

with

$$\gamma^*_{2(j)} = \begin{cases} \gamma_{2(j)} & , \quad if \quad \gamma_{2(j)} > \frac{-6}{n+2} \\ \frac{-6}{n+2} & , \quad \text{otherwise} \end{cases}$$

If variable Z_j is normally distributed, the uncorrected univariate kurtosis $\gamma_{2(j)}$ is equal to 0. If Z has an n-variate normal distribution, Mardia's multivariate kurtosis γ_2 is equal to 0. A variable Z_j is called *leptokurtic* if it has a positive value of $\gamma_{2(j)}$ and is called *platykurtic* if it has a negative value of $\gamma_{2(j)}$. The values of κ_1, κ_2, and κ_3 should not be smaller than a lower bound (Bentler 1985):

$$\hat{\kappa} \geq \frac{-2}{n+2}$$

PROC CALIS displays a message if this happens.

If weighted least squares estimates (METHOD=WLS or METHOD=ADF) are specified and the weight matrix is computed from an input raw data set, the CALIS procedure computes two more measures of multivariate kurtosis.

- **Multivariate Mean Kappa**

$$\kappa_4 = \frac{1}{m}\sum_{i}^{n}\sum_{j}^{i}\sum_{k}^{j}\sum_{l}^{k}\hat{\kappa}_{ij,kl} - 1$$

where

$$\hat{\kappa}_{ij,kl} = \frac{s_{ij,kl}}{s_{ij}s_{kl} + s_{ik}s_{jl} + s_{il}s_{jk}}$$

and $m = n(n+1)(n+2)(n+3)/24$ is the number of elements in the vector $s_{ij,kl}$ (Bentler 1985).

- **Multivariate Least Squares Kappa**

$$\kappa_5 = \frac{s_4' s_2}{s_2' s_2} - 1$$

where

$$s_{ij,kl} = \frac{1}{N}\sum_{r=1}^{N}(z_{ri} - \bar{z}_i)(z_{rj} - \bar{z}_j)(z_{rk} - \bar{z}_k)(z_{rl} - \bar{z}_l)$$

s_4 is the vector of the $s_{ij,kl}$, and s_2 is the vector of the elements in the denominator of $\hat{\kappa}$ (Bentler 1985).

The occurrence of significant nonzero values of Mardia's multivariate kurtosis γ_2 and significant amounts of some of the univariate kurtosis values $\gamma_{2(j)}$ indicate that your variables are not multivariate normal distributed. Violating the multivariate normality assumption in (default) generalized least squares and maximum likelihood estimation usually leads to the wrong approximate standard errors and incorrect fit statistics based on the χ^2 value. In general, the parameter estimates are more stable against violation of the normal distribution assumption. For more details, refer to Browne (1974, 1982, 1984).

Initial Estimates

Each optimization technique requires a set of initial values for the parameters. To avoid local optima, the initial values should be as close as possible to the globally optimal solution. You can check for local optima by running the analysis with several different sets of initial values; the RANDOM= option in the PROC CALIS statement is useful in this regard.

- RAM and LINEQS: There are several default estimation methods available in PROC CALIS for initial values of parameters in a linear structural equation model specified by a RAM or LINEQS model statement, depending on the form of the specified model.
  - two-stage least squares estimation
  - instrumental variable method (Hägglund 1982; Jennrich 1987)
  - approximative factor analysis method
  - ordinary least squares estimation
  - estimation method of McDonald (McDonald and Hartmann 1992)
- FACTOR: For default (exploratory) factor analysis, PROC CALIS computes initial estimates for factor loadings and unique variances by an algebraic method of approximate factor analysis. If you use a MATRIX statement together with a FACTOR model specification, initial values are computed by McDonald's (McDonald and Hartmann 1992) method if possible. McDonald's method of computing initial values works better if you scale the factors by setting the factor variances to 1 rather than setting the loadings of the reference variables equal to 1. If neither of the two methods seems to be appropriate, the initial values are set by the START= option.
- COSAN: For the more general COSAN model, there is no default estimation method for the initial values. In this case, the START= or RANDOM= option can be used to set otherwise unassigned initial values.

Poor initial values can cause convergence problems, especially with maximum likelihood estimation. You should not specify a constant initial value for all parameters since this would produce a singular predicted model matrix in the first iteration. Sufficiently large positive diagonal elements in the central matrices of each model matrix term provide a nonnegative definite initial predicted model matrix. If maximum likelihood estimation fails to converge, it might help to use METHOD=LSML, which uses the final estimates from an unweighted least squares analysis as initial estimates for

maximum likelihood. Or you can fit a slightly different but better-behaved model and produce an OUTRAM= data set, which can then be modified in accordance with the original model and used as an INRAM= data set to provide initial values for another analysis.

If you are analyzing a covariance or scalar product matrix, be sure to take into account the scales of the variables. The default initial values might be inappropriate when some variables have extremely large or small variances.

Automatic Variable Selection

You can use the VAR statement to reorder the variables in the model and to delete the variables not used. Using the VAR statement saves memory and computation time. If a linear structural equation model that uses the RAM or LINEQS statement (or an INRAM= data set specifying a RAM or LINEQS model) does not use all the manifest variables given in the input DATA= data set, PROC CALIS automatically deletes those manifest variables not used in the model.

In some special circumstances, the automatic variable selection performed for the RAM and LINEQS statements might be inappropriate—for example, if you are interested in modification indices connected to some of the variables that are not used in the model. You can include such manifest variables as exogenous variables in the analysis by specifying constant zero coefficients.

For example, the first three steps in a stepwise regression analysis of the Werner blood chemistry data (Jöreskog and Sörbom 1988, p. 111) can be performed as follows:

```
proc calis data=dixon method=gls nobs=180 print mod;
   lineqs y=0 x1+0 x2+0 x3+0 x4+0 x5+0 x6+0 x7+e;
   std    e=var;
run;
proc calis data=dixon method=gls nobs=180 print mod;
   lineqs y=g1 x1+0 x2+0 x3+0 x4+0 x5+0 x6+0 x7+e;
   std    e=var;
run;
proc calis data=dixon method=gls nobs=180 print mod;
   lineqs y=g1 x1+0 x2+0 x3+0 x4+0 x5+g6 x6+0 x7+e;
   std    e=var;
run;
```

Using the COSAN statement does not automatically delete those variables from the analysis that are not used in the model. You can use the output of the predetermined values in the predicted model matrix (PREDET option) to detect unused variables. Variables that are not used in the model are indicated by 0 in the rows and columns of the predetermined predicted model matrix.

Exogenous Manifest Variables

If there are exogenous manifest variables in the linear structural equation model, then there is a one-to-one relationship between the given covariances and corresponding estimates in the central model matrix (**P** or **Φ**). In general, using exogenous manifest variables reduces the degrees of freedom since the corresponding sample correlations or covariances are not part of the exogenous information provided for the parameter estimation. See the section "Counting the Degrees of Freedom" on page 956 for more information.

If you specify a RAM or LINEQS model statement, or if such a model is recognized in an INRAM= data set, those elements in the central model matrices that correspond to the exogenous manifest variables are reset to the sample values after computing covariances or correlations within the current BY group.

The COSAN statement does not automatically set the covariances in the central model matrices that correspond to manifest exogenous variables.

You can use the output of the predetermined values in the predicted model matrix (PREDET option) that correspond to manifest exogenous variables to see which of the manifest variables are exogenous variables and to help you set the corresponding locations of the central model matrices with their covariances.

The following two examples show how different the results of PROC CALIS can be if manifest variables are considered as either endogenous or exogenous variables. (See Figure 25.5.) In both examples, a correlation matrix **S** is tested against an identity model matrix **C**; that is, no parameter is estimated. The following three runs of the first example (specified by the COSAN, LINEQS, and RAM statements) consider the two variables y and x as endogenous variables:

```
title2 'Data: FULLER (1987, p.18)';
data corn;
   input y x;
   datalines;
 86  70
115  97
 90  53
 86  64
110  95
 91  64
 99  50
 96  70
 99  94
104  69
 96  51
;
```

```
title3 'Endogenous Y and X';
proc calis data=corn;
   cosan corr(2,ide);
run;
proc calis data=corn;
   lineqs
          y=ey,
          x=ex;
   std    ey ex=2 * 1;
run;
proc calis data=corn;
   ram
       1  1  3  1.,
       1  2  4  1.,
       2  3  3  1.,
       2  4  4  1.;
run;
```

The following two runs of the second example (specified by the LINEQS and RAM statements) consider y and x as exogenous variables:

```
title3 'Exogenous Y and X';
proc calis data=corn;
   std y x=2 * 1;
run;
proc calis data=corn;
   ram
       2  1  1  1.,
       2  2  2  1.;
run;
```

Figure 25.5 Exogenous and Endogenous Variables

Exogenous x, y Endogenous x, y

The LINEQS and the RAM model statements set the covariances (correlations) of exogenous manifest variables in the estimated model matrix and automatically reduce the degrees of freedom.

Use of Optimization Techniques

No algorithm for optimizing general nonlinear functions exists that will always find the global optimum for a general nonlinear minimization problem in a reasonable amount of time. Since no single optimization technique is invariably superior to others, PROC CALIS provides a variety of optimization techniques that work well in various circumstances. However, you can devise problems for which none of the techniques in PROC CALIS will find the correct solution. All optimization techniques in PROC CALIS use $O(n^2)$ memory except the conjugate gradient methods, which use only $O(n)$ of memory and are designed to optimize problems with many parameters.

The PROC CALIS statement NLOPTIONS can be especially helpful for tuning applications with nonlinear equality and inequality constraints on the parameter estimates. Some of the options available in NLOPTIONS might also be invoked as PROC CALIS options. The NLOPTIONS statement can specify almost the same options as the SAS/OR NLP procedure.

Nonlinear optimization requires the repeated computation of the following:

- the function value (optimization criterion)
- the gradient vector (first-order partial derivatives)
- for some techniques, the (approximate) Hessian matrix (second-order partial derivatives)
- values of linear and nonlinear constraints
- the first-order partial derivatives (Jacobian) of nonlinear constraints

For the criteria used by PROC CALIS, computing the gradient takes more computer time than computing the function value, and computing the Hessian takes *much* more computer time and memory than computing the gradient, especially when there are many parameters to estimate. Unfortunately, optimization techniques that do not use the Hessian usually require many more iterations than techniques that do use the (approximate) Hessian, and so they are often slower. Techniques that do not use the Hessian also tend to be less reliable (for example, they might terminate at local rather than global optima).

The available optimization techniques are displayed in Table 25.13 and can be chosen by the TECH=*name* option.

Table 25.13 Optimization Techniques

TECH=	Optimization Technique
LEVMAR	Levenberg-Marquardt method
TRUREG	Trust-region method
NEWRAP	Newton-Raphson method with line search
NRRIDG	Newton-Raphson method with ridging
QUANEW	Quasi-Newton methods (DBFGS, DDFP, BFGS, DFP)
DBLDOG	Double-dogleg method (DBFGS, DDFP)
CONGRA	Conjugate gradient methods (PB, FR, PR, CD)

Table 25.14 shows, for each optimization technique, which derivatives are needed (first-order or second-order) and what kind of constraints (boundary, linear, or nonlinear) can be imposed on the parameters.

Table 25.14 Derivatives Needed and Constraints Allowed

	Derivatives		Constraints		
TECH=	**First Order**	**Second Order**	**Boundary**	**Linear**	**Nonlinear**
LEVMAR	x	x	x	x	-
TRUREG	x	x	x	x	-
NEWRAP	x	x	x	x	-
NRRIDG	x	x	x	x	-
QUANEW	x	-	x	x	x
DBLDOG	x	-	x	x	-
CONGRA	x	-	x	x	-

The Levenberg-Marquardt, trust-region, and Newton-Raphson techniques are usually the most reliable, work well with boundary and general linear constraints, and generally converge after a few iterations to a precise solution. However, these techniques need to compute a Hessian matrix in each iteration. For HESSALG=1, this means that you need about $4(n(n+1)/2)t$ bytes of work memory (n = the number of manifest variables, t = the number of parameters to estimate) to store the Jacobian and its crossproduct. With HESSALG=2 or HESSALG=3, you do not need this work memory, but the use of a utility file increases execution time. Computing the approximate Hessian in each iteration can be very time- and memory-consuming, especially for large problems (more than 60 or 100 parameters, depending on the computer used). For large problems, a quasi-Newton technique, especially with the BFGS update, can be far more efficient.

For a poor choice of initial values, the Levenberg-Marquardt method seems to be more reliable.

If memory problems occur, you can use one of the conjugate gradient techniques, but they are generally slower and less reliable than the methods that use second-order information.

There are several options to control the optimization process. First of all, you can specify various termination criteria. You can specify the GCONV= option to specify a relative gradient termination criterion. If there are active boundary constraints, only those gradient components that correspond to inactive constraints contribute to the criterion. When you want very precise parameter estimates, the GCONV= option is useful. Other criteria that use relative changes in function values or parameter estimates in consecutive iterations can lead to early termination when active constraints cause small steps to occur. The small default value for the FCONV= option helps prevent early termination. Using the MAXITER= and MAXFUNC= options enables you to specify the maximum number of iterations and function calls in the optimization process. These limits are especially useful in combination with the INRAM= and OUTRAM= options; you can run a few iterations at a time, inspect the results, and decide whether to continue iterating.

Nonlinearly Constrained QN Optimization

The algorithm used for nonlinearly constrained quasi-Newton optimization is an efficient modification of Powell's (1978a, 1978b, 1982a, 1982b) *Variable Metric Constrained WatchDog* (VMCWD) algorithm. A similar but older algorithm (VF02AD) is part of the Harwell library. Both VMCWD and VF02AD use Fletcher's VE02AD algorithm (also part of the Harwell library) for positive-definite quadratic programming. The PROC CALIS QUANEW implementation uses a quadratic programming subroutine that updates and downdates the approximation of the Cholesky factor when the active set changes. The nonlinear QUANEW algorithm is not a feasible-point algorithm, and the value of the objective function need not decrease (minimization) or increase (maximization) monotonically. Instead, the algorithm tries to reduce a linear combination of the objective function and constraint violations, called the *merit function*.

The following are similarities and differences between this algorithm and VMCWD:

- A modification of this algorithm can be performed by specifying VERSION=1, which replaces the update of the Lagrange vector μ with the original update of Powell (1978a, 1978b), which is used in VF02AD. This can be helpful for some applications with linearly dependent active constraints.
- If the VERSION= option is not specified or VERSION=2 is specified, the evaluation of the Lagrange vector μ is performed in the same way as Powell (1982a, 1982b) describes.
- Instead of updating an approximate Hessian matrix, this algorithm uses the dual BFGS (or DFP) update that updates the Cholesky factor of an approximate Hessian. If the condition of the updated matrix gets too bad, a restart is done with a positive diagonal matrix. At the end of the first iteration after each restart, the Cholesky factor is scaled.
- The Cholesky factor is loaded into the quadratic programming subroutine, automatically ensuring positive-definiteness of the problem. During the quadratic programming step, the Cholesky factor of the projected Hessian matrix $\mathbf{Z}_k'\mathbf{G}\mathbf{Z}_k$ and the QT decomposition are updated simultaneously when the active set changes. Refer to Gill et al. (1984) for more information.
- The line-search strategy is very similar to that of Powell (1982a, 1982b). However, this algorithm does not call for derivatives during the line search; hence, it generally needs fewer derivative calls than function calls. The VMCWD algorithm always requires the same number of derivative and function calls. It was also found in several applications of VMCWD that Powell's line-search method sometimes uses steps that are too long during the first iterations. In those cases, you can use the INSTEP= option specification to restrict the step length α of the first iterations.
- Also the watchdog strategy is similar to that of Powell (1982a, 1982b). However, this algorithm does not return automatically after a fixed number of iterations to a former better point. A return here is further delayed if the observed function reduction is close to the expected function reduction of the quadratic model.
- Although Powell's termination criterion still is used (as FCONV2), the QUANEW implementation uses two additional termination criteria (GCONV and ABSGCONV).

This algorithm is automatically invoked when you specify the NLINCON statement. The nonlinear QUANEW algorithm needs the Jacobian matrix of the first-order derivatives (constraints normals) of the constraints

$$(\nabla c_i) = (\frac{\partial c_i}{\partial x_j}), \quad i = 1, \ldots, nc, j = 1, \ldots, n$$

where nc is the number of nonlinear constraints for a given point x.

You can specify two update formulas with the UPDATE= option:

- UPDATE=DBFGS performs the dual BFGS update of the Cholesky factor of the Hessian matrix. This is the default.
- UPDATE=DDFP performs the dual DFP update of the Cholesky factor of the Hessian matrix.

This algorithm uses its own line-search technique. All options and parameters (except the INSTEP= option) controlling the line search in the other algorithms do not apply here. In several applications, large steps in the first iterations are troublesome. You can specify the INSTEP= option to impose an upper bound for the step size α during the first five iterations. The values of the LCSINGULAR=, LCEPSILON=, and LCDEACT= options, which control the processing of linear and boundary constraints, are valid only for the quadratic programming subroutine used in each iteration of the nonlinear constraints QUANEW algorithm.

Optimization and Iteration History

The optimization and iteration histories are displayed by default because it is important to check for possible convergence problems.

The optimization history includes the following summary of information about the initial state of the optimization:

- the number of constraints that are active at the starting point, or more precisely, the number of constraints that are currently members of the working set. If this number is followed by a plus sign, there are more active constraints, of which at least one is temporarily released from the working set due to negative Lagrange multipliers.
- the value of the objective function at the starting point
- if the (projected) gradient is available, the value of the largest absolute (projected) gradient element
- for the TRUREG and LEVMAR subroutines, the initial radius of the trust-region around the starting point

The optimization history ends with some information concerning the optimization result:

- the number of constraints that are active at the final point, or more precisely, the number of constraints that are currently members of the working set. If this number is followed by a plus sign, there are more active constraints, of which at least one is temporarily released from the working set due to negative Lagrange multipliers.

- the value of the objective function at the final point
- if the (projected) gradient is available, the value of the largest absolute (projected) gradient element
- other information specific to the optimization technique

The iteration history generally consists of one line of displayed output containing the most important information for each iteration. The _LIST_ variable (see the section "SAS Programming Statements" on page 903) also enables you to display the parameter estimates and the gradient in some or all iterations.

The iteration history always includes the following (the words in parentheses are the column header output):

- the iteration number (Iter)
- the number of iteration restarts (rest)
- the number of function calls (nfun)
- the number of active constraints (act)
- the value of the optimization criterion (optcrit)
- the difference between adjacent function values (difcrit)
- the maximum of the absolute gradient components corresponding to inactive boundary constraints (maxgrad)

An apostrophe trailing the number of active constraints indicates that at least one of the active constraints is released from the active set due to a significant Lagrange multiplier.

For the Levenberg-Marquardt technique (LEVMAR), the iteration history also includes the following information:

- An asterisk trailing the iteration number means that the computed Hessian approximation is singular and consequently ridged with a positive lambda value. If all or the last several iterations show a singular Hessian approximation, the problem is not sufficiently identified. Thus, there are other locally optimal solutions that lead to the same optimum function value for different parameter values. This implies that standard errors for the parameter estimates are not computable without the addition of further constraints.
- the value of the Lagrange multiplier (lambda); this is 0 if the optimum of the quadratic function approximation is inside the trust-region (a trust-region-scaled Newton step can be performed) and is greater than 0 when the optimum of the quadratic function approximation is located at the boundary of the trust-region (the scaled Newton step is too long to fit in the trust-region and a quadratic constraint optimization is performed). Large values indicate optimization difficulties. For a nonsingular Hessian matrix, the value of lambda should go to 0 during the last iterations, indicating that the objective function can be well approximated by a quadratic function in a small neighborhood of the optimum point. An increasing lambda value often indicates problems in the optimization process.

- the value of the ratio ρ (rho) between the actually achieved difference in function values and the predicted difference in the function values on the basis of the quadratic function approximation. Values much less than 1 indicate optimization difficulties. The value of the ratio ρ indicates the goodness of the quadratic function approximation; in other words, $\rho << 1$ means that the radius of the trust-region has to be reduced. A fairly large value of ρ means that the radius of the trust region need not be changed. And a value close to or larger than 1 means that the radius can be increased, indicating a good quadratic function approximation.

For the Newton-Raphson technique (NRRIDG), the iteration history also includes the following information:

- the value of the ridge parameter. This is 0 when a Newton step can be performed, and it is greater than 0 when either the Hessian approximation is singular or a Newton step fails to reduce the optimization criterion. Large values indicate optimization difficulties.
- the value of the ratio ρ (rho) between the actually achieved difference in function values and the predicted difference in the function values on the basis of the quadratic function approximation. Values much less than 1.0 indicate optimization difficulties.

For the Newton-Raphson with line-search technique (NEWRAP), the iteration history also includes the following information:

- the step size α (alpha) computed with one of the line-search algorithms
- the slope of the search direction at the current parameter iterate. For minimization, this value should be significantly negative. Otherwise, the line-search algorithm has difficulty reducing the function value sufficiently.

For the trust-region technique (TRUREG), the iteration history also includes the following information:

- An asterisk after the iteration number means that the computed Hessian approximation is singular and consequently ridged with a positive lambda value.
- the value of the Lagrange multiplier (lambda). This value is zero when the optimum of the quadratic function approximation is inside the trust-region (a trust-region-scaled Newton step can be performed) and is greater than zero when the optimum of the quadratic function approximation is located at the boundary of the trust-region (the scaled Newton step is too long to fit in the trust-region and a quadratically constrained optimization is performed). Large values indicate optimization difficulties. As in Gay (1983), a negative lambda value indicates the special case of an indefinite Hessian matrix (the smallest eigenvalue is negative in minimization).
- the value of the radius Δ of the trust-region. Small trust-region radius values combined with large lambda values in subsequent iterations indicate optimization problems.

For the quasi-Newton (QUANEW) and conjugate gradient (CONGRA) techniques, the iteration history also includes the following information:

- the step size (alpha) computed with one of the line-search algorithms
- the descent of the search direction at the current parameter iterate. This value should be significantly smaller than 0. Otherwise, the line-search algorithm has difficulty reducing the function value sufficiently.

Frequent update restarts (rest) of a quasi-Newton algorithm often indicate numerical problems related to required properties of the approximate Hessian update, and they decrease the speed of convergence. This can happen particularly if the ABSGCONV= termination criterion is too small—that is, when the requested precision cannot be obtained by quasi-Newton optimization. Generally, the number of automatic restarts used by conjugate gradient methods is much higher.

For the nonlinearly constrained quasi-Newton technique, the iteration history also includes the following information:

- the maximum value of all constraint violations,

$$\text{conmax} = \max(|c_i(x)| : c_i(x) < 0)$$

- the value of the predicted function reduction used with the GCONV and FCONV2 termination criteria,

$$\text{pred} = |g(x^{(k)})s(x^{(k)})| + \sum_{i=1}^{m} |\lambda_i c_i(x^{(k)})|$$

- the step size α of the quasi-Newton step. Note that this algorithm works with a special line-search algorithm.
- the maximum element of the gradient of the Lagrange function,

$$\begin{aligned} \text{lfgmax} &= \nabla_x L(x^{(k)}, \lambda^{(k)}) \\ &= \nabla_x f(x^{(k)}) - \sum_{i=1}^{m} \lambda_i^{(k)} \nabla_x c_i(x^{(k)}) \end{aligned}$$

For the double-dogleg technique, the iteration history also includes the following information:

- the parameter λ of the double-dogleg step. A value $\lambda = 0$ corresponds to the full (quasi) Newton step.
- the slope of the search direction at the current parameter iterate. For minimization, this value should be significantly negative.

Line-Search Methods

In each iteration k, the (dual) quasi-Newton, hybrid quasi-Newton, conjugate gradient, and Newton-Raphson minimization techniques use iterative line-search algorithms that try to optimize a linear, quadratic, or cubic approximation of the nonlinear objective function f of n parameters x along a feasible descent search direction $s^{(k)}$

$$f(x^{(k+1)}) = f(x^{(k)} + \alpha^{(k)} s^{(k)})$$

by computing an approximately optimal scalar $\alpha^{(k)} > 0$. Since the outside iteration process is based only on the approximation of the objective function, the inside iteration of the line-search algorithm does not have to be perfect. Usually, it is satisfactory that the choice of α significantly reduces (in a minimization) the objective function. Criteria often used for termination of line-search algorithms are the Goldstein conditions (Fletcher 1987).

Various line-search algorithms can be selected by using the LIS= option. The line-search methods LIS=1, LIS=2, and LIS=3 satisfy the left-hand-side and right-hand-side Goldstein conditions (refer to Fletcher 1987). When derivatives are available, the line-search methods LIS=6, LIS=7, and LIS=8 try to satisfy the right-hand-side Goldstein condition; if derivatives are not available, these line-search algorithms use only function calls.

The line-search method LIS=2 seems to be superior when function evaluation consumes significantly less computation time than gradient evaluation. Therefore, LIS=2 is the default value for Newton-Raphson, (dual) quasi-Newton, and conjugate gradient optimizations.

Restricting the Step Length

Almost all line-search algorithms use iterative extrapolation techniques that can easily lead to feasible points where the objective function f is no longer defined (resulting in indefinite matrices for ML estimation) or is difficult to compute (resulting in floating-point overflows). Therefore, PROC CALIS provides options that restrict the step length or trust-region radius, especially during the first main iterations.

The inner product $g's$ of the gradient g and the search direction s is the slope of $f(\alpha) = f(x + \alpha s)$ along the search direction s with step length α. The default starting value $\alpha^{(0)} = \alpha^{(k,0)}$ in each line-search algorithm ($\min_{\alpha>0} f(x + \alpha s)$) during the main iteration k is computed in three steps.

1. Use either the difference $df = |f^{(k)} - f^{(k-1)}|$ of the function values during the last two consecutive iterations or the final step-size value α^- of the previous iteration $k-1$ to compute a first value $\alpha_1^{(0)}$.

   - Using the DAMPSTEP<=*r*> option:

     $$\alpha_1^{(0)} = \min(1, r\alpha^-)$$

     The initial value for the new step length can be no larger than r times the final step length α^- of the previous iteration. The default is $r = 2$.

- Not using the DAMPSTEP option:

$$\alpha_1^{(0)} = \begin{cases} step & \text{if } 0.1 \leq step \leq 10 \\ 10 & \text{if } step > 10 \\ 0.1 & \text{if } step < 0.1 \end{cases}$$

with

$$step = \begin{cases} df/|g's| & \text{if } |g's| \geq \epsilon \max(100df, 1) \\ 1 & \text{otherwise} \end{cases}$$

This value of $\alpha_1^{(0)}$ can be too large and can lead to a difficult or impossible function evaluation, especially for highly nonlinear functions such as the EXP function.

2. During the first five iterations, the second step enables you to reduce $\alpha_1^{(0)}$ to a smaller starting value $\alpha_2^{(0)}$ using the INSTEP=r option:

$$\alpha_2^{(0)} = \min(\alpha_1^{(0)}, r)$$

After more than five iterations, $\alpha_2^{(0)}$ is set to $\alpha_1^{(0)}$.

3. The third step can further reduce the step length by

$$\alpha_3^{(0)} = \min(\alpha_2^{(0)}, \min(10, u))$$

where u is the maximum length of a step inside the feasible region.

The INSTEP=r option lets you specify a smaller or larger radius of the trust region used in the first iteration by the trust-region, double-dogleg, and Levenberg-Marquardt algorithms. The default initial trust-region radius is the length of the scaled gradient (Moré 1978). This step corresponds to the default radius factor of $r = 1$. This choice is successful in most practical applications of the TRUREG, DBLDOG, and LEVMAR algorithms. However, for bad initial values used in the analysis of a covariance matrix with high variances, or for highly nonlinear constraints (such as using the EXP function) in your programming code, the default start radius can result in arithmetic overflows. If this happens, you can try decreasing values of INSTEP=r, $0 < r < 1$, until the iteration starts successfully. A small factor r also affects the trust-region radius of the next steps because the radius is changed in each iteration by a factor $0 < c \leq 4$ depending on the ρ ratio. Reducing the radius corresponds to increasing the ridge parameter λ that produces smaller steps directed closer toward the gradient direction.

Modification Indices

While fitting structural models, you might want to modify the specified model in order to do the following:

- reduce the χ^2 value significantly
- reduce the number of parameters to estimate without increasing the χ^2 value too much

If you specify the MODIFICATION or MOD option, PROC CALIS computes and displays a default set of modification indices:

- **Univariate Lagrange multiplier test indices** for most elements in the model matrices that are constrained to *equal constants*. These are second-order approximations of the decrease in the χ^2 value that would result from allowing the constant matrix element to vary. Besides the value of the Lagrange multiplier, the corresponding probability ($df = 1$) and the approximate change of the parameter value (should the constant be changed to a parameter) are displayed. If allowing the constant to be a free estimated parameter would result in a singular information matrix, the string 'sing' is displayed instead of the Lagrange multiplier index. Not all elements in the model matrices should be allowed to vary; the diagonal elements of the inverse matrices in the RAM or LINEQS model must be constant ones. The univariate Lagrange multipliers are displayed at the constant locations of the model matrices.

- **Univariate Wald test indices** for those matrix elements that correspond to *parameter estimates* in the model. These are second-order approximations of the increase in the χ^2 value that would result from constraining the parameter to a 0 constant. The univariate Wald test indices are the same as the squared t values that are displayed together with the parameter estimates and standard errors. The univariate Wald test indices are displayed at the parameter locations of the model matrices.

- **Univariate Lagrange multiplier test indices** that are second-order approximations of the decrease in the χ^2 value that would result from the release of *equality constraints*. Multiple equality constraints containing $n > 2$ parameters are tested successively in n steps, each assuming the release of one of the equality-constrained parameters. The expected change of the parameter values of the separated parameter and the remaining parameter cluster are displayed, too.

- **Univariate Lagrange multiplier test indices** for releasing *active boundary constraints* specified by the BOUNDS statement

- **Stepwise multivariate Wald test indices** for constraining estimated parameters to 0 are computed and displayed. In each step, the parameter that would lead to the smallest increase in the multivariate χ^2 value is set to 0. Besides the multivariate χ^2 value and its probability, the univariate increments are also displayed. The process stops when the univariate probability is smaller than the specified value in the SLMW= option.

All of the preceding tests are approximations. You can often get more accurate tests by actually fitting different models and computing likelihood ratio tests. For more details about the Wald and the Lagrange multiplier test, refer to MacCallum (1986), Buse (1982), Bentler (1986), or Lee (1985).

Note that, for large model matrices, the computation time for the default modification indices can considerably exceed the time needed for the minimization process.

The modification indices are not computed for unweighted least squares or diagonally weighted least squares estimation.

CAUTION: Modification indices are not computed if the model matrix is an identity matrix (IDE or ZID), a selection matrix (PER), or the first matrix **J** in the LINEQS model. If you want to display the modification indices for such a matrix, you should specify the matrix as another type; for example,

specify an identity matrix used in the COSAN statement as a diagonal matrix with constant diagonal elements of 1.

Constrained Estimation by Using Program Code

The CALIS procedure offers a very flexible way to constrain parameter estimates. You can use your own programming statements to express special properties of the parameter estimates. This tool is also present in McDonald's COSAN implementation but is considerably easier to use in the CALIS procedure. PROC CALIS is able to compute analytic first- and second-order derivatives that you would have to specify using the COSAN program. There are also three PROC CALIS statements you can use:

- the BOUNDS statement, to specify simple bounds on the parameters used in the optimization process
- the LINCON statement, to specify general linear equality and inequality constraints on the parameters used in the optimization process
- the NLINCON statement, to specify general nonlinear equality and inequality constraints on the parameters used in the optimization process. The variables listed in the NLINCON statement must be specified in the program code.

There are some traditional ways to enforce parameter constraints by using parameter transformations (McDonald 1980).

- **One-sided boundary constraints:** For example, the parameter q_k should be at least as large (or at most as small) as a given constant value a (or b),

  $$q_k \geq a \qquad \text{or} \qquad q_k \leq b$$

  This inequality constraint can be expressed as an equality constraint

  $$q_k = a + x_j^2 \qquad \text{or} \qquad q_k = b - x_j^2$$

  in which the fundamental parameter x_j is unconstrained.

- **Two-sided boundary constraints:** For example, the parameter q_k should be located between two given constant values a and b, $a < b$,

  $$a \leq q_k \leq b$$

  This inequality constraint can be expressed as an equality constraint

  $$q_k = a + (b - a)\frac{exp(x_j)}{1 + exp(x_j)}$$

  in which the fundamental parameter x_j is unconstrained.

- **One-sided order constraints:** For example, the parameters $q_1, \ldots, q_k$ should be ordered in the form

  $$q_1 \leq q_2, \quad q_1 \leq q_3, \quad \ldots, \quad q_1 \leq q_k$$

  These inequality constraints can be expressed as a set of equality constraints

  $$q_1 = x_1, \quad q_2 = x_1 + x_2^2, \quad \ldots, \quad q_k = x_1 + x_k^2$$

  in which the fundamental parameters $x_1, \ldots, x_k$ are unconstrained.

- **Two-sided order constraints:** For example, the parameters $q_1, \ldots, q_k$ should be ordered in the form

  $$q_1 \leq q_2 \leq q_3 \leq \ldots \leq q_k$$

  These inequality constraints can be expressed as a set of equality constraints

  $$q_1 = x_1, \quad q_2 = q_1 + x_2^2, \quad \ldots, \quad q_k = q_{k-1} + x_k^2$$

  in which the fundamental parameters $x_1, \ldots, x_k$ are unconstrained.

- **Linear equation constraints:** For example, the parameters q_1, q_2, q_3 should be linearly constrained in the form

  $$q_1 + q_2 + q_3 = a$$

  which can be expressed in the form of three explicit equations in which the fundamental parameters x_1 and x_2 are unconstrained:

  $$q_1 = x_1, \quad q_2 = x_2, \quad q_3 = a - x_1 - x_2$$

Refer to McDonald (1980) and Browne (1982) for further notes on reparameterizing techniques. If the optimization problem is not too large to apply the Levenberg-Marquardt or Newton-Raphson algorithm, boundary constraints should be requested by the BOUNDS statement rather than by reparameterizing code. If the problem is so large that you must use a quasi-Newton or conjugate gradient algorithm, reparameterizing techniques might be more efficient than the BOUNDS statement.

Counting the Degrees of Freedom

In a regression problem, the number of degrees of freedom for the error estimate is the number of observations in the data set minus the number of parameters. The NOBS=, DFR= (RDF=), and DFE= (EDF=) options refer to degrees of freedom in this sense. However, these values are not related to the degrees of freedom of a test statistic used in a covariance or correlation structure analysis. The NOBS=, DFR=, and DFE= options should be used in PROC CALIS to specify only the effective number of observations in the input DATA= data set.

In general, the number of degrees of freedom in a covariance or correlation structure analysis is defined as the difference between the number of nonredundant values q in the observed $n \times n$

correlation or covariance matrix **S** and the number t of free parameters **X** used in the fit of the specified model, $df = q - t$. Both values, q and t, are counted differently in different situations by PROC CALIS.

The number of nonredundant values q is generally equal to the number of lower triangular elements in the $n \times n$ moment matrix **S** including all diagonal elements, minus a constant c dependent upon special circumstances,

$$q = n(n+1)/2 - c$$

The number c is evaluated by adding the following quantities:

- If you specify a linear structural equation model containing exogenous manifest variables by using the RAM or LINEQS statement, PROC CALIS adds to c the number of variances and covariances among these manifest exogenous variables, which are automatically set in the corresponding locations of the central model matrices (see the section "Exogenous Manifest Variables" on page 943).
- If you specify the DFREDUCE=i option, PROC CALIS adds the specified number i to c. The number i can be a negative integer.
- If you specify the NODIAG option to exclude the fit of the diagonal elements of the data matrix **S**, PROC CALIS adds the number n of diagonal elements to c.
- If all the following conditions hold, then PROC CALIS adds to c the number of the diagonal locations:
  - NODIAG and DFREDUC= options are not specified.
  - A correlation structure is being fitted.
  - The predicted correlation matrix contains constants on the diagonal.

In some complicated models, especially those use programming statements, PROC CALIS might not be able to detect all the constant predicted values. In such cases, you must specify the DFREDUCE= option to get the correct degrees of freedom.

The number t is the number of different parameter names used in constructing the model if you do not use programming statements to impose constraints on the parameters. Using programming statements in general introduces two kinds of parameters:

- independent parameters, which are used only on the right-hand side of the expressions
- dependent parameters, which are used at least once on the left-hand side of the expressions

The independent parameters belong to the parameters involved in the estimation process, whereas the dependent parameters are fully defined by the programming statements and can be computed from the independent parameters. In this case, the number t is the number of different parameter names used in the model specification, but not used in the programming statements, plus the number of independent parameters. The independent parameters and their initial values can be defined in a model specification statement or in a PARMS statement.

The degrees of freedom are automatically increased by the number of active constraints in the solution. Similarly, the number of parameters are decreased by the number of active constraints. This affects the computation of many fit statistics and indices. Refer to Dijkstra (1992) for a discussion of the validity of statistical inferences with active boundary constraints. If the researcher believes that the active constraints will have a small chance of occurrence in repeated sampling, it might be more suitable to turn off the automatic adjustment by using the NOADJDF option.

Computational Problems

First Iteration Overflows

Analyzing a covariance matrix including high variances in the diagonal and using bad initial estimates for the parameters can easily lead to arithmetic overflows in the first iterations of the minimization algorithm. The line-search algorithms that work with cubic extrapolation are especially sensitive to arithmetic overflows. If this occurs with quasi-Newton or conjugate gradient minimization, you can specify the INSTEP= option to reduce the length of the first step. If an arithmetic overflow occurs in the first iteration of the Levenberg-Marquardt algorithm, you can specify the INSTEP= option to reduce the trust-region radius of the first iteration. You also can change the minimization technique or the line-search method. If none of these help, you should consider the following:

- scaling the covariance matrix
- providing better initial values
- changing the model

No Convergence of Minimization Process

If convergence does not occur during the minimization process, perform the following tasks.

- If there are *negative variance estimates* in the diagonal locations of the central model matrices, you can do the following:
  - Specify the BOUNDS statement to obtain nonnegative variance estimates.
  - Specify the HEYWOOD option, if the FACTOR model statement is specified.
- Change the estimation method to obtain a better set of initial estimates. For example, if you use METHOD=ML, you can do the following:
  - Change to METHOD=LSML.
  - Run some iterations with METHOD=DWLS or METHOD=GLS, write the results in an OUTRAM= data set, and use the results as initial values specified by an INRAM= data set in a second run with METHOD=ML.

- Change the optimization technique. For example, if you use the default TECH=LEVMAR, you can do the following:
  - Change to TECH=QUANEW or TECH=NEWRAP.
  - Run some iterations with TECH=CONGRA, write the results in an OUTRAM= data set, and use the results as initial values specified by an INRAM= data set in a second run with a different TECH= technique.
- Change or modify the update technique or the line-search algorithm, or both, when using TECH=QUANEW or TECH=CONGRA. For example, if you use the default update formula and the default line-search algorithm, you can do the following:
  - Change the update formula with the UPDATE= option.
  - Change the line-search algorithm with the LIS= option.
  - Specify a more precise line search with the LSPRECISION= option, if you use LIS=2 or LIS=3.
- Add more iterations and function calls by using the MAXIT= and MAXFU= options.
- Change the initial values. For many categories of model specifications done by the LINEQS, RAM, or FACTOR model, PROC CALIS computes an appropriate set of initial values automatically. However, for some of the model specifications (for example, structural equations with latent variables on the left-hand side and manifest variables on the right-hand side), PROC CALIS can generate very obscure initial values. In these cases, you have to set the initial values yourself.
  - Increase the initial values of the parameters located at the diagonal of central matrices in one of the following ways:
    - manually, by setting the values in the model specification
    - automatically, by using the DEMPHAS= option
  - Use a slightly different, but more stable, model to obtain preliminary estimates.
  - Use additional information to specify initial values, such as by using other SAS software like the FACTOR, REG, SYSLIN, and MODEL (SYSNLIN) procedures for the modified, unrestricted model case.

Unidentified Model

The parameter vector $\mathbf{x}$ in the covariance structure model

$$\mathbf{C} = \mathbf{C}(\mathbf{x})$$

is said to be identified in a parameter space G, if

$$\mathbf{C}(\mathbf{x}) = \mathbf{C}(\tilde{\mathbf{x}}), \quad \tilde{\mathbf{x}} \in G$$

implies $\mathbf{x} = \tilde{\mathbf{x}}$. The parameter estimates that result from an unidentified model can be very far from the parameter estimates of a very similar but identified model. They are usually machine dependent. Do not use parameter estimates of an unidentified model as initial values for another run of PROC CALIS.

Singular Predicted Model Matrix

You can easily specify models with singular predicted model matrices, such as by fixing diagonal elements of central matrices to 0. In such cases, you cannot compute maximum likelihood estimates (the ML function value F is not defined). Since singular predicted model matrices can also occur temporarily in the minimization process, PROC CALIS tries in such cases to change the parameter estimates so that the predicted model matrix becomes positive-definite. In such cases, the following message is displayed:

```
NOTE: Parameter set changed.
```

This process does not always work well, especially if there are fixed instead of variable diagonal elements in the central model matrices. A famous example where you cannot compute ML estimates is a component analysis with fewer components than given manifest variables. See the section "FACTOR Model Statement" on page 877 for more details. If you continue to get a singular predicted model matrix after changing initial values and optimization techniques, then your model is perhaps specified so that ML estimates cannot be computed.

Saving Computing Time

For large models, the most computing time is needed to compute the modification indices. If you do not really need the Lagrange multipliers or multiple Wald test indices (the univariate Wald test indices are the same as the t values), using the NOMOD option can save a considerable amount of computing time.

Central Matrices with Negative Eigenvalues

A covariance matrix cannot have negative eigenvalues, since a negative eigenvalue means that some linear combination of the variables has negative variance. PROC CALIS displays a warning if a central model matrix has negative eigenvalues but does not actually compute the eigenvalues. Sometimes this warning can be triggered by 0 or very small positive eigenvalues that appear negative because of numerical error. If you want to be sure that the central model matrix you are fitting can be considered to be a variance-covariance matrix, you can use the SAS/IML command *VAL=EIGVAL(U)* to compute the vector *VAL* of eigenvalues of matrix **U**.

Negative R^2 Values

The estimated squared multiple correlations R^2 of the endogenous variables are computed using the estimated error variances

$$R_i^2 = 1 - \frac{\widehat{var(\zeta_i)}}{\widehat{var(\eta_i)}}$$

If the model is a poor fit, it is possible that $\widehat{var(\zeta_i)} > \widehat{var(\eta_i)}$, which results in $R_i^2 < 0$.

Displayed Output

The output displayed by PROC CALIS depends on the statement used to specify the model. Since an analysis requested by the LINEQS or RAM statement implies the analysis of a structural equation model, more statistics can be computed and displayed than for a covariance structure analysis following the generalized COSAN model requested by the COSAN statement. The displayed output resulting from use of the FACTOR statement includes all the COSAN displayed output as well as more statistics displayed only when you specify the FACTOR statement. Since the displayed output by using the RAM statement differs only in its form from that generated by the LINEQS statement, in this section distinctions are made between COSAN and LINEQS output only.

The unweighted least squares and diagonally weighted least squares estimation methods do not provide a sufficient statistical basis to provide the following output (neither displayed nor written to an OUTEST= data set):

- most of the fit indices
- approximate standard errors
- normalized or asymptotically standardized residuals
- modification indices
- information matrix
- covariance matrix of parameter estimates

The notation $\mathbf{S} = (s_{ij})$ is used for the analyzed covariance or correlation matrix, $\mathbf{C} = (c_{ij})$ for the predicted model matrix, $\mathbf{W}$ for the weight matrix (for example, $\mathbf{W} = \mathbf{I}$ for ULS, $\mathbf{W} = \mathbf{S}$ for GLS, $\mathbf{W} = \mathbf{C}$ for ML estimates), $\mathbf{X}$ for the vector of optimal parameter estimates, n for the number of manifest variables, t for the number of parameter estimates, and N for the sample size.

The output of PROC CALIS includes the following:

- COSAN and LINEQS: List of the matrices and their properties specified by the generalized COSAN model if you specify at least the PSHORT option.
- LINEQS: List of manifest variables that are not used in the specified model and that are automatically omitted from the analysis. Note that there is no automatic variable reduction with the COSAN or FACTOR statement. If necessary, you should use the VAR statement in these cases.
- LINEQS: List of the endogenous and exogenous variables specified by the LINEQS, STD, and COV statements if you specify at least the PSHORT option.
- COSAN: Initial values of the parameter matrices indicating positions of constants and parameters. The output, or at least the default output, is displayed if you specify the PINITIAL option.

- LINEQS: The set of structural equations containing the initial values and indicating constants and parameters, and output of the initial error variances and covariances. The output, or at least the default output, is displayed if you specify the PINITIAL option.
- COSAN and LINEQS: The weight matrix **W** is displayed if GLS, WLS, or DWLS estimation is used and you specify the PWEIGHT or PALL option.
- COSAN and LINEQS: General information about the estimation problem: number of observations (N), number of manifest variables (n), amount of independent information in the data matrix (information, $n(n+1)/2$), number of terms and matrices in the specified generalized COSAN model, and number of parameters to be estimated (parameters, t). If there are no exogenous manifest variables, the difference between the amount of independent information ($n(n+1)/2$) and the number of requested estimates (t) is equal to the degrees of freedom (df). A necessary condition for a model to be identified is that the degrees of freedom are nonnegative. The output, or at least the default output, is displayed if you specify the SIMPLE option.
- COSAN and LINEQS: Mean and Std Dev (standard deviation) of each variable if you specify the SIMPLE option, as well as skewness and kurtosis if the DATA= data set is a raw data set and you specify the KURTOSIS option.
- COSAN and LINEQS: Various coefficients of multivariate kurtosis and the numbers of observations that contribute most to the normalized multivariate kurtosis if the DATA= data set is a raw data set and the KURTOSIS option, or you specify at least the PRINT option. See the section "Measures of Multivariate Kurtosis" on page 938 for more information.
- COSAN and LINEQS: Covariance or correlation matrix to be analyzed and the value of its determinant if you specify the output option PCORR or PALL. A 0 determinant indicates a singular data matrix. In this case, the generalized least squares estimates with default weight matrix **S** and maximum likelihood estimates cannot be computed.
- LINEQS: If exogenous manifest variables in the linear structural equation model are specified, then there is a one-to-one relationship between the given covariances and corresponding estimates in the central model matrix Φ or P. The output indicates which manifest variables are recognized as exogenous—that is, for which variables the entries in the central model matrix are set to fixed parameters. The output, or at least the default output, is displayed if you specify the PINITIAL option.
- COSAN and LINEQS: Vector of parameter names, initial values, and corresponding matrix locations, also indicating dependent parameter names used in your programming statements that are not allocated to matrix locations and have no influence on the fit function. The output, or at least the default output, is displayed if you specify the PINITIAL option.
- COSAN and LINEQS: The pattern of variable and constant elements of the predicted moment matrix that is predetermined by the analysis model is displayed if there are significant differences between constant elements in the predicted model matrix and the data matrix and you specify at least the PSHORT option. It is also displayed if you specify the PREDET option. The output indicates the differences between constant values in the predicted model matrix and the data matrix that is analyzed.
- COSAN and LINEQS: Special features of the optimization technique chosen if you specify at least the PSHORT option.

- COSAN and LINEQS: Optimization history if at least the PSHORT option is specified. For more details, see the section "Use of Optimization Techniques" on page 945.
- COSAN and LINEQS: Specific output requested by options in the NLOPTIONS statement; for example, parameter estimates, gradient, gradient of Lagrange function, constraints, Lagrange multipliers, projected gradient, Hessian, projected Hessian, Hessian of Lagrange function, Jacobian of nonlinear constraints.
- COSAN and LINEQS: The predicted model matrix and its determinant, if you specify the output option PCORR or PALL.
- COSAN and LINEQS: Residual and normalized residual matrix if you specify the RESIDUAL, or at least the PRINT option. The variance standardized or asymptotically standardized residual matrix can be displayed also. The average residual and the average off-diagonal residual are also displayed. See the section "Assessment of Fit" on page 928 for more details.
- COSAN and LINEQS: Rank order of the largest normalized residuals if you specify the RESIDUAL, or at least the PRINT option.
- COSAN and LINEQS: Bar chart of the normalized residuals if you specify the RESIDUAL, or at least the PRINT option.
- COSAN and LINEQS: Value of the fit function F. See the section "Estimation Criteria" on page 923 for more details. This output can be suppressed only by the NOPRINT option.
- COSAN and LINEQS: Goodness of fit index (GFI), adjusted goodness of fit index (AGFI), and root mean square residual (RMR) (Jöreskog and Sörbom 1985). See the section "Assessment of Fit" on page 928 for more details. This output can be suppressed only by the NOPRINT option.
- COSAN and LINEQS: Parsimonious goodness of fit index (PGFI) of Mulaik et al. (1989). See the section "Assessment of Fit" on page 928 for more detail. This output can be suppressed only by the NOPRINT option.
- COSAN and LINEQS: Overall χ^2, df, and Prob>Chi**2 if the METHOD= option is not ULS or DWLS. The χ^2 measure is the optimum function value F multiplied by $(N-1)$ if a CORR or COV matrix is analyzed or multiplied by N if a UCORR or UCOV matrix is analyzed; χ^2 measures the likelihood ratio test statistic for the null hypothesis that the predicted matrix $\mathbf{C}$ has the specified model structure against the alternative that $\mathbf{C}$ is unconstrained. The notation Prob>Chi**2 means "the probability under the null hypothesis of obtaining a greater χ^2 statistic than that observed." This output can be suppressed only by the NOPRINT option.
- COSAN and LINEQS: If METHOD= is not ULS or DWLS, the χ_0^2 value of the independence model and the corresponding degrees of freedom can be used (in large samples) to evaluate the gain of explanation by fitting the specific model (Bentler 1989). See the section "Assessment of Fit" on page 928 for more detail. This output can be suppressed only by the NOPRINT option.
- COSAN and LINEQS: If METHOD= is not ULS or DWLS, the value of the Steiger and Lind (1980) root mean squared error of approximation (RMSEA) coefficient and the lower and upper limits of the confidence interval. The size of the confidence interval is defined by the

option ALPHARMS=α, $0 \leq \alpha \leq 1$. The default is $\alpha = 0.1$, which corresponds to a 90% confidence interval. See the section "Assessment of Fit" on page 928 for more detail. This output can be suppressed only by the NOPRINT option.

- COSAN and LINEQS: If the value of the METHOD= option is not ULS or DWLS, the value of the *probability of close fit* (Browne and Cudeck 1993). See the section "Assessment of Fit" on page 928 for more detail. This output can be suppressed only by the NOPRINT option.
- COSAN and LINEQS: If the value of the METHOD= option is not ULS or DWLS, the value of the Browne and Cudeck (1993) expected cross validation (ECVI) index and the lower and upper limits of the confidence interval. The size of the confidence interval is defined by the option ALPHAECV=α, $0 \leq \alpha \leq 1$. The default is $\alpha = 0.1$, which corresponds to a 90% confidence interval. See the section "Assessment of Fit" on page 928 for more detail. This output can be suppressed only by the NOPRINT option.
- COSAN and LINEQS: If the value of the METHOD= option is not ULS or DWLS, Bentler's (1989) comparative fit index. See the section "Assessment of Fit" on page 928 for more detail. This output can be suppressed only by the NOPRINT option.
- COSAN and LINEQS: If you specify METHOD=ML or METHOD=GLS, the χ^2 value and corresponding probability adjusted by the relative kurtosis coefficient η_2, which should be a close approximation of the χ^2 value for elliptically distributed data (Browne 1982). See the section "Assessment of Fit" on page 928 for more detail. This output can be suppressed only by the NOPRINT option.
- COSAN and LINEQS: The normal theory reweighted LS χ^2 value is displayed if METHOD= ML. Instead of the function value F_{ML}, the reweighted goodness of fit function F_{GWLS} is used. See the section "Assessment of Fit" on page 928 for more detail.
- COSAN and LINEQS: Akaike's information criterion if the value of the METHOD= option is not ULS or DWLS. See the section "Assessment of Fit" on page 928 for more detail. This output can be suppressed only by the NOPRINT option.
- COSAN and LINEQS: Bozdogan's (1987) consistent information criterion, CAIC. See the section "Assessment of Fit" on page 928 for more detail. This output can be suppressed only by the NOPRINT option.
- COSAN and LINEQS: Schwarz's Bayesian criterion (SBC) if the value of the METHOD= option is not ULS or DWLS (Schwarz 1978). See the section "Assessment of Fit" on page 928 for more detail. This output can be suppressed only by the NOPRINT option.
- COSAN and LINEQS: If the value of the METHOD= option is not ULS or DWLS, the following fit indices based on the overall χ^2 value are displayed:
  - McDonald's (McDonald 1989) measure of centrality
  - Parsimonious index of James, Mulaik, and Brett (1982)
  - Z-test of Wilson and Hilferty (1931)
  - Bentler and Bonett's (1980) nonnormed coefficient
  - Bentler and Bonett's (1980) normed coefficient
  - Bollen's (1986) normed index ρ_1
  - Bollen's (1989a) nonnormed index Δ_2

See the section "Assessment of Fit" on page 928 for more detail. This output can be suppressed only by the NOPRINT option.

- COSAN and LINEQS: Hoelter's (1983) critical N index is displayed (Bollen 1989b, p. 277). See the section "Assessment of Fit" on page 928 for more detail. This output can be suppressed only by the NOPRINT option.
- COSAN and LINEQS: Equations of linear dependencies among the parameters used in the model specification if the information matrix is recognized as singular at the final solution.
- COSAN: Model matrices containing the parameter estimates. Except for ULS or DWLS estimates, the approximate standard errors and t values are also displayed. This output is displayed if you specify the PESTIM option or at least the PSHORT option.
- LINEQS: Linear equations containing the parameter estimates. Except for ULS and DWLS estimates, the approximate standard errors and t values are also displayed. This output is displayed if you specify the PESTIM option, or at least the PSHORT option.
- LINEQS: Variances and covariances of the exogenous variables. This output is displayed if you specify the PESTIM option, or at least the PSHORT option.
- LINEQS: Linear equations containing the standardized parameter estimates. This output is displayed if you specify the PESTIM option, or at least the PSHORT option.
- LINEQS: Table of correlations among the exogenous variables. This output is displayed if you specify the PESTIM option, or at least the PSHORT option.
- LINEQS: Correlations among the exogenous variables. This output is displayed if you specify the PESTIM option, or at least the PSHORT option.
- LINEQS: Squared multiple correlations table, which displays the error variances of the endogenous variables. These are the diagonal elements of the predicted model matrix. Also displayed is the Total Variance and the R^2 values corresponding to all endogenous variables. See the section "Assessment of Fit" on page 928 for more detail. This output is displayed if you specify the PESTIM option, or at least the PSHORT option.
- LINEQS: If you specify the PDETERM or the PALL option, the total determination of all equations (DETAE), the total determination of the structural equations (DETSE), and the total determination of the manifest variables (DETMV) are displayed. See the section "Assessment of Fit" on page 928 for more detail. If one of the determinants in the formulas is 0, the corresponding coefficient is displayed as a missing value. If there are structural equations, PROC CALIS also displays the stability coefficient of reciprocal causation—that is, the largest eigenvalue of the $\mathbf{BB}'$ matrix, where $\mathbf{B}$ is the causal coefficient matrix of the structural equations.
- LINEQS: The matrix of estimated covariances among the latent variables if you specify the PLATCOV option, or at least the PRINT option.
- LINEQS: The matrix of estimated covariances between latent and manifest variables used in the model if you specify the PLATCOV option, or at least the PRINT option.

- LINEQS and FACTOR: The matrix **FSR** of latent variable scores regression coefficients if you specify the PLATCOV option, or at least the PRINT option. The **FSR** matrix is a generalization of Lawley and Maxwell's (1971, p. 109) factor scores regression matrix,

  $$\mathbf{FSR} = \mathbf{C}_{yx}\mathbf{C}_{xx}^{-1}$$

  where $\mathbf{C}_{xx}$ is the $n \times n$ predicted model matrix. (predicted covariances among manifest variables) and $\mathbf{C}_{yx}$ is the $n_{lat} \times n$ matrix of the predicted covariances between latent and manifest variables. You can multiply the manifest observations by this matrix to estimate the scores of the latent variables used in your model.

- LINEQS: The matrix **TEF** of total effects if you specify the TOTEFF option, or at least the PRINT option. For the LINEQS model, the matrix of total effects is

  $$\mathbf{TEF} = (\mathbf{I} - \boldsymbol{\beta})^{-1}\boldsymbol{\gamma} - (\mathbf{O} : \mathbf{I})$$

  (For the LISREL model, refer to Jöreskog and Sörbom 1985.) The matrix of indirect effects is displayed also.

- FACTOR: The matrix of rotated factor loadings and the orthogonal transformation matrix if you specify the ROTATE= and PESTIM options, or at least the PSHORT option.

- FACTOR: Standardized (rotated) factor loadings, variance estimates of endogenous variables, R^2 values, correlations among factors, and factor scores regression matrix, if you specify the PESTIM option, or at least the PSHORT option. The determination of manifest variables is displayed only if you specify the PDETERM option.

- COSAN and LINEQS: Univariate Lagrange multiplier and Wald test indices are displayed in matrix form if you specify the MODIFICATION (or MOD) or PALL option. Those matrix locations that correspond to constants in the model in general contain three values: the value of the Lagrange multiplier, the corresponding probability ($df = 1$), and the estimated change of the parameter value should the constant be changed to a parameter. If allowing the constant to be an estimated parameter would result in a singular information matrix, the string 'sing' is displayed instead of the Lagrange multiplier index. Those matrix locations that correspond to parameter estimates in the model contain the Wald test index and the name of the parameter in the model. See the section "Modification Indices" on page 953 for more detail.

- COSAN and LINEQS: Univariate Lagrange multiplier test indices for releasing equality constraints if you specify the MODIFICATION (or MOD) or PALL option. See the section "Modification Indices" on page 953 for more detail.

- COSAN and LINEQS: Univariate Lagrange multiplier test indices for releasing active boundary constraints specified by the BOUNDS statement if you specify the MODIFICATION (or MOD) or PALL option. See the section "Modification Indices" on page 953 for more detail.

- COSAN and LINEQS: If the MODIFICATION (or MOD) or PALL option is specified, the stepwise multivariate Wald test for constraining estimated parameters to zero constants is performed as long as the univariate probability is larger than the value specified in the PMW= option (default PMW=0.05). See the section "Modification Indices" on page 953 for more detail.

ODS Table Names

PROC CALIS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

Table 25.15 ODS Tables Produced by PROC CALIS

ODS Table Name	Model[1]	Description	Option[2]
AddParms	C, F, L, R	Additional parameters in the PARAMETERS statement	PINITIAL or default
AsymStdRes	C, F, L, R	Asymptotically standardized residual matrix	RESIDUAL= or PRINT
AveAsymStdRes	C, F, L, R	Average absolute asymptotically standardized residuals	RESIDUAL= or PRINT
AveNormRes	C, F, L, R	Average absolute normalized residuals	RESIDUAL= or PRINT
AveRawRes	C, F, L, R	Average absolute raw residuals	RESIDUAL= or PRINT
AveVarStdRes	C, F, L, R	Average absolute variance standardized residuals	RESIDUAL= or PRINT
ContKurtosis	C, F, L, R	Contributions to kurtosis	KURTOSIS or PRINT
ConvergenceStatus	C, F, L, R	Convergence status	PSHORT
CorrExog	L	Correlations among exogenous variables	PESTIM or PSHORT
CorrParm	C, F, L, R	Correlations among parameter estimates	PCOVES and default
CovMat	C, F, L, R	Assorted covariance matrices	PCOVES and default
DependParms	C, F, L, R	Dependent parameters (if specified by programming statements)	PRIVEC and default
Determination	L, F, R	Coefficients of determination	PDETERM and default
DistAsymStdRes	C, F, L, R	Distribution of asymptotically standardized residuals	RESIDUAL= or PRINT
DistNormRes	C, F, L, R	Distribution of normalized residuals	RESIDUAL= or PRINT
DistVarStdRes	C, F, L, R	Distribution of variance standardized residuals	RESIDUAL= or PRINT
Eigenvalues	C, F, L, R	Eigenvalues of the approximate Hessian matrix	PCOVES[3] and default
EndogenousVar	L	Endogenous variables	PESTIM or PSHORT
EstCovExog	L	Estimated covariances among exogenous variables	PESTIM or PSHORT
Estimates	C, F, L, R	Vector of estimates	PRIVEC
EstLatentEq	L	Estimated latent variable equations	PESTIM or PSHORT
EstManifestEq	L	Estimated manifest variable equations	PESTIM or PSHORT
EstParms	C, F	Estimated parameter matrix	PESTIM or PSHORT
EstVarExog	L	Estimated variances of exogenous variables	PESTIM or PSHORT
ExogenousVar	L	List of exogenous variables	PESTIM or PSHORT
FactCorrExog	F	Correlations among factors	PESTIM or PSHORT

Table 25.15 *continued*

ODS Table Name	Model[1]	Description	Option[2]
FactScoreCoef	F	Factor score regression coefficients	PESTIM or PSHORT
Fit	C, F, L, R	Fit statistics	PSUMMARY
GenModInfo	C, F, L, R	General modeling information	PSIMPLE or default
Gradient	C, F, L, R	First partial derivatives (Gradient)	PRIVEC and default
InCorr	C, F, L, R	Input correlation matrix	PCORR or PALL
InCorrDet	C, F, L, R	Determinant of the input correlation matrix	PCORR or PALL
InCov	C, F, L, R	Input covariance matrix	PCORR or PALL
InCovDet	C, F, L, R	Determinant of the input covariance matrix	PCORR or PALL
InCovExog	L	Input covariances among exogenous variables	PESTIM or PSHORT
IndirectEffects	L, R	Indirect effects	TOTEFF or PRINT

InitEstimates	C, F, L, R	Initial vector of parameter estimates	PINITIAL or default
InitParms	C, F	Initial matrix of parameter estimates	PINITIAL or default
InitParms	L, R	Initial matrix of parameter estimates	PRIMAT and default
InitRAMEstimates	R	Initial RAM estimates	PESTIM or PSHORT
InLatentEq	L	Input latent variable equations	PESTIM or PSHORT
InManifestEq	L	Input manifest variable equations	PESTIM or PSHORT
InSymmetric	C, F, L, R	Input symmetric matrix (SYMATRIX data type)	PCORR or PALL
InVarExog	L	Input variances of exogenous variables	PESTIM or PSHORT
IterHist	C, F, L, R	Iteration history	PSHORT
IterStart	C, F, L, R	Iteration start	PSHORT
IterStop	C, F, L, R	Iteration stop	PSHORT
Jacobian	C, F, L, R	Jacobi column pattern	PJACPAT
Kurtosis	C, F, L, R	Kurtosis, with raw data input	KURTOSIS or PRINT
LagrangeBoundary	C, F, L, R	Lagrange, releasing active boundary constraints	MODIFICATION[4] or PALL
LagrangeEquality	C, F, L, R	Lagrange, releasing equality constraints	MODIFICATION or PALL
LatentScoreCoef	L, R	Latent variable regression score coefficients	PLATCOV or PRINT
ModelStatement	C, F, L, R	Model summary	PSHORT
ModIndices	C, F, L, R	Lagrange multiplier and Wald test statistics	MODIFICATION or PALL
NormRes	C, F, L, R	Normalized residual matrix	RESIDUAL= or PRINT
PredetElements	C, F, L, R	Predetermined elements	PREDET or PALL
PredModel	C, F, L, R	Predicted model matrix	PCORR or PALL
PredModelDet	C, F, L, R	Predicted model determinant	PCORR or PALL
PredMomentLatent	L, R	Predicted latent variable moments	PLATCOV or PRINT
PredMomentManLat	L, R	Predicted manifest and latent variable moments	PLATCOV or PRINT
ProblemDescription	C, F, L, R	Problem description	PSHORT
RAMCorrExog	R	Correlations among exogenous variables	PESTIM or PSHORT

Table 25.15 *continued*

ODS Table Name	Model[1]	Description	Option[2]
RAMEstimates	R	RAM final estimates	PESTIM, or PSHORT
RAMStdEstimates	R	Standardized estimates	PESTIM, or PSHORT
RankAsymStdRes	C, F, L, R	Ranking of the largest asymptotically standardized residuals	RESIDUAL= or PRINT
RankLagrange	C, F, L, R	Ranking of the largest Lagrange indices	RESIDUAL= or PRINT
RankNormRes	C, F, L, R	Ranking of the largest normalized residuals	RESIDUAL= or PRINT
RankRawRes	C, F, L, R	Ranking of the largest raw residuals	RESIDUAL= or PRINT
RankVarStdRes	C, F, L, R	Ranking of the largest variance standardized residuals	RESIDUAL= or PRINT
RawRes	C, F, L, R	Raw residual matrix	RESIDUAL= or PRINT
RotatedLoadings	F	Rotated loadings, with ROTATE= option in FACTOR statement	PESTIM or PSHORT
Rotation	F	Rotation matrix, with ROTATE= option in FACTOR statement	PESTIM or PSHORT
SetCovExog	L, R	Set covariance parameters for manifest exogenous variables	PINITIAL or default
SimpleStatistics	C, F, L, R	Simple statistics, with raw data input	SIMPLE or default
SqMultCorr	F, L, R	Squared multiple correlations	PESTIM or PSHORT
Stability	L, R	Stability of reciprocal causation	PDETERM and default
StdErrs	C, F, L, R	Vector of standard errors	PRIVEC and default
StdLatentEq	L	Standardized latent variable equations	PESTIM or PSHORT
StdLoadings	F	Standardized factor loadings	PESTIM or PSHORT
StdManifestEq	L	Standardized manifest variable equations	PESTIM or PSHORT
StructEq	L, R	Variables in the structural equations	PDETERM and default
SumSqDif	C, F, L, R	Sum of squared differences of pre-determined elements	PREDET or PALL
TotalEffects	L, R	Total effects	TOTEFF or PRINT
tValues	C, F, L, R	Vector of t values	PRIVEC and default
VarSelection	L, R	Manifest variables, if not all are used, selected for modeling	default
VarStdRes	C, F, L, R	Variance standardized residual matrix	RESIDUAL= or PRINT
WaldTest	C, F, L, R	Wald test	MODIFICATION or PALL
Weights	C, F, L, R	Weight matrix	PWEIGHT[5] or PALL
WeightsDet	C, F, L, R	Determinant of the weight matrix	PWEIGHT[5] or PALL

1. Most CALIS output tables are specific to the model statement used. Keys: C: COSAN model, F: FACTOR model, L: LINEQS model, R: RAM model.

2. The printing options PALL, PRINT, "default," PSHORT, and PSUMM form hierarchical levels of output control, with PALL including all the output enabled by the options at the lower levels, and so on. The "default" option means that NOPRINT is not specified. Therefore, in the table, for example, if PSHORT is the printing option for an output, PALL, PRINT, or "default" will also enable the same output printing.

3. The eigenvalues are printed only when there are negative eigenvalues in the approximate Hessian matrix.

4. The printing of LagrangeBoundary is effective only if you have set some boundary constraints for parameters.

5. The printing of Weights or WeightsDet is effective only if your estimation method uses the weight matrix (for example, WLS or LSWLS).

ODS Graphics

To request graphics with PROC CALIS, you must first enable ODS Graphics by specifying the **ods graphics on** statement. See Chapter 21, "Statistical Graphics Using ODS," for more information. The names of the graphs that PROC CALIS generates are listed in Table 25.16, along with the required statements and options.

Table 25.16 ODS Graphics Produced by PROC CALIS

ODS Graph Name	Plot Description	PLOTS= Option
AsymStdResidualHistogram	Asymptotically standardized residuals	PLOTS=RESIDUALS and RESIDUAL=ASYMSTD; METHOD= is not ULS or DWLS
NormResidualHistogram	Normalized residuals	PLOTS=RESIDUALS and RESIDUAL=NORM
RawResidualHistogram	Raw residuals	PLOTS=RESIDUALS
VarStdResidualHistogram	Variance standardized residuals	PLOTS=RESIDUALS and RESIDUAL=VARSTD

Examples: CALIS Procedure

Example 25.1: Path Analysis: Stability of Alienation

The following covariance matrix from Wheaton et al. (1977) has served to illustrate the performance of several implementations for the analysis of structural equation models. Two different models have been analyzed by an early implementation of LISREL and are mentioned in Jöreskog (1978). You can also find a more detailed discussion of these models in the LISREL VI manual (Jöreskog and Sörbom 1985).

A slightly modified model for this covariance matrix is included in the EQS 2.0 manual (Bentler 1985, p. 28). The path diagram of this model is displayed in Figure 25.1. The same model is reanalyzed here by PROC CALIS. However, for the analysis with the EQS implementation, the last variable (V6) is rescaled by a factor of 0.1 to make the matrix less ill-conditioned. Since the Levenberg-Marquardt or Newton-Raphson optimization technique is used with PROC CALIS, rescaling the data matrix is not necessary and, therefore, is not done here. The results reported here reflect the estimates based on the original covariance matrix.

The DATA step and the CALIS model specification are shown as follows:

```
data Wheaton(TYPE=COV);
title "Stability of Alienation";
title2 "Data Matrix of WHEATON, MUTHEN, ALWIN & SUMMERS (1977)";
   _type_ = 'cov'; input _name_ $ v1-v6;

      e1 e3 = The5 (.2),
      e4 e2 = The5 (.2);
run;

ods graphics off;
```

The COV option in the PROC CALIS statement requests the analysis of the covariance matrix. Without the COV option, the correlation matrix would be computed and analyzed. Since no METHOD= option has been used, maximum likelihood estimates are computed by default. The TECH=NR option requests the Newton-Raphson optimization method. The PALL option produces the almost complete set of displayed output, as displayed in Output 25.1.1 through Output 25.1.23. Note that, when you specify the PALL option, you can produce large amounts of output. The PALL option is used in this example to show how you can get a wide spectrum of useful information from PROC CALIS.

PROC CALIS can produce a high-quality residual histogram that is useful for showing the distribution of residuals. To request the residual histogram, you must first enable ODS Graphics by specifying the **ods graphics on** statement, as shown in the preceding code before the PROC CALIS statement. Then, the residual histogram is requested by the **plots=residuals** option in the PROC CALIS statement.

Output 25.1.1 displays the model specification in matrix terms, followed by the lists of endogenous and exogenous variables. Output 25.1.2 displays equations and initial parameter estimates. You can use these output to ensure that the desired model is being analyzed.

```

General modeling information, descriptive statistics, and the input covariance matrix are displayed in Output 25.1.3. Because the input data set contains only the covariance matrix, the means of the manifest variables are assumed to be zero. Note that this has no impact on the estimation, unless a mean structure model is being analyzed.

PROC CALIS examines whether each element in the moment matrix is modeled by the parameters defined in the model. If an element is not structured by the model parameters, it is predetermined by its observed value. This occurs, for example, when there are exogenous manifest variables in the

model. If present, the predetermined values of the elements are displayed. In the current example, the '.' displayed for all elements in the predicted moment matrix (Output 25.1.5) indicates that there are no predetermined elements in the model.

PROC CALIS can perform a detailed residual analysis. Large residuals might indicate misspecification of the model. In Output 25.1.9, raw residuals are reported and ranked. Because of the differential scaling of the variables, it is usually more useful to examine the standardized residuals instead. In Output 25.1.10, for example, the table for the 10 largest asymptotically standardized residuals is displayed. The model performs the poorest concerning the variable v5 and its covariance with v2, v1, and v3. This might suggest a misspecification of the model equation for v5. However, because the model fit is quite good, such a possible misspecification is not a serious concern in the analysis.

The histogram of the asymptotically standardized residuals is displayed in Output 25.1.11, which also shows the normal and kernel approximations. The residual distribution looks quite symmetrical. It shows a small to medium departure from the normal distribution, as evidenced by the discrepancies between the kernel and the normal distribution curves.

Output 25.1.11 Distribution of Asymptotically Standardized Residuals

Output 25.1.12 displays the equations and parameter estimates. Each parameter estimate is displayed with its standard error and the corresponding *t* ratio. As a general rule, a *t* ratio larger than 2 represents a statistically significant departure from 0. From these results, it is observed that both f1 (Alienation 1967) and f2 (Alienation 1971) are regressed negatively on f3 (Socioeconomic Status), and f1 has a positive effect on f2. The estimates and significance tests for the variance and covariance of the exogenous variables are also displayed.

e2	e4	The5	0.90580	0.12167	7.44

The measurement scale of variables is often arbitrary. Therefore, it can be useful to look at the standardized equations produced by PROC CALIS. Output 25.1.13 displays the standardized equations and predicted moments. From the standardized structural equations for f1 and f2, you can conclude that SES (f3) has a larger impact on earlier Alienation (f1) than on later Alienation (f3). The squared multiple correlation for each equation is also shown in Output 25.1.13. These correlations indicate the proportion of systematic variance in the equations. Finally, correlations among the exogenous variables are shown.

Output 25.1.13 Standardized Solutions

Manifest Variable Equations with Standardized Estimates

```
        v1      =   0.8348 f1   +  0.5505 e1
        v2      =   0.7846 f1   +  0.6200 e2
        v3      =   0.8450 f2   +  0.5348 e3
        v4      =   0.7968 f2   +  0.6043 e4
        v5      =   0.8297 f3   +  0.5581 e5
        v6      =   0.6508*f3   +  0.7593 e6
                        Lamb
```

Latent Variable Equations with Standardized Estimates

```
f1      =  -0.5626*f3   +  0.8268 d1
                Gam1
f2      =   0.5692*f1   + -0.2064*f3   +  0.7080 d2
                Beta           Gam2
```

Squared Multiple Correlations

	Variable	Error Variance	Total Variance	R-Square

Correlations Among Exogenous Variables

Var1	Var2	Parameter	Estimate
e1	e3	The5	0.25106
e2	e4	The5	0.25197

The predicted covariances among the latent variables and between the observed and the latent variables are displayed in Output 25.1.14.

Output 25.1.14 Predicted Moments

Predicted Moments of Latent Variables

	f1	f2	f3
f1	8.296026985	5.924364730	-4.167911571
f2	5.924364730	9.007870649	-4.065656060
f3	-4.167911571	-4.065656060	6.616317547

Output 25.1.14 *continued*

Predicted Moments between Manifest and Latent Variables

	f1	f2	f3
v1	8.29602698	5.92436473	−4.16791157
v2	6.91059048	4.93499582	−3.47187034
v3	5.92436473	9.00787065	−4.06565606
v4	4.93499582	7.50355625	−3.38669150
v5	−4.16791157	−4.06565606	6.61631755
v6	−22.37688158	−21.82788734	35.52199986

For interpreting the model, these predicted moments are not as useful as the main results shown previously. However, these predicted moments can be useful for further analysis. For example, they can be useful in constructing bootstrap "populations" for resampling. Another use of these moments is to compute the latent variable score regression coefficients. PROC CALIS computes these coefficients automatically, as shown in Output 25.1.15.

Output 25.1.15 Latent Variable Score Regression Coefficients

Latent Variable Score Regression Coefficients

		f1	f2	f3
v1	Anomie (1967)	0.4131113567	0.0482681051	−.0521264408
v2	Anomie (1971)	0.3454029627	0.0400143300	−.0435560637
v3	Education	0.0526632293	0.4306175653	−.0399927539
v4	Powerlessness (1967)	0.0437036855	0.3600452776	−.0334000265
v5	Powerlessness (1971)	−.0749215200	−.0639697183	0.5057060770
v6	Occupational Status Index	−.0046390513	−.0039609288	0.0313127184

In Output 25.1.15, each latent variable is expressed as a linear combination of the observed variables. By computing these linear combinations for each individual, you can estimate the latent variable scores. See Chapter 76, "The SCORE Procedure," for more information about the creation of latent variable scores.

The total effects and indirect effects of the exogenous variables are displayed in Output 25.1.16. These results supplement to those shown in the linear equations in Output 25.1.12, which shows only the direct effects of predictor variables on outcome variables. Total, direct, and indirect effects have the following simple relationship:

$$\text{Total Effect} = \text{Direct Effect} + \text{Indirect Effect}$$

To illustrate, consider the relationships between latent factor f3 and variables v1–v4. In the linear equations shown in Output 25.1.12, latent factor f3 does not have direct effects on variables v1–v4. This does not mean that f3 has no effects on these variables at all. As shown in the first table of Output 25.1.16, latent factor f3 indeed has nonzero total effects on all variables, including variables v1–v4. In the next table that shows indirect effects, latent factor f3, again, has nonzero indirect effects on variables v1–v4, and these effects are identical to the total effects. Because the sum of

direct and indirect effects is the total effect, this means that the effects of f3 on v1–v4 are all *indirect*. Similar decomposition of effects can be made for other relationships. For example, while f1 has a total effect of 1.0 on v1, it has no indirect effect on v1. This means that all the effect of f1 on v1 is *direct*, which is also shown in an equation in Output 25.1.12. Finally, consider the effects of f3 on f2. In Output 25.1.16, latent factor f3 has nonzero total effect (−0.6145) and indirect effect (−0.3736) on f2, and these two effects are not identical. The difference of these two effects is the direct effect −0.2409, as shown in an equation in Output 25.1.12.

Output 25.1.16 Total and Indirect Effects

PROC CALIS can display Lagrange multiplier and Wald statistics for model modifications. Modification indices are displayed for each parameter matrix, as shown in Output 25.1.17 through Output 25.1.22. Only the Lagrange multiplier statistics have significance levels and approximate changes of values displayed. The significance level of the Wald statistic for a given parameter is the same as that shown in the equation output. An insignificant *p*-value for a Wald statistic means that the corresponding parameter can be dropped from the model without significantly worsening the fit of the model.

A significant *p*-value for a Lagrange multiplier test indicates that the model would achieve a better fit if the corresponding parameter were free. To aid in determining significant results, PROC CALIS displays the rank order of the 10 largest Lagrange multiplier statistics. For example, [E5:E2] in the _PHI_ matrix is associated with the largest Lagrange multiplier statistic; the associated *p*-value is 0.0067. This means that adding a parameter for the covariance between E5 and E2 will lead to a significantly better fit of the model. However, adding parameters indiscriminately can result in specification errors. An overfitted model might not perform well with future samples. As always, the decision to add parameters should be accompanied by consideration and knowledge of the ap-

plication area.

When you specify equality constraints, PROC CALIS displays Lagrange multiplier tests for releasing the constraints, as shown in Output 25.1.23. In the current example, none of the three constraints achieve a p-value smaller than 0.05. This means that releasing the constraints might not lead to a significantly better fit of the model. Therefore, all constraints are retained in the model.

The current model is specified using the LINEQS, STD, and COV statements. As discussed in the section "Getting Started: CALIS Procedure" on page 839, you can also specify the same model by using other specification methods. In the following statements, equivalent COSAN and RAM specifications of the current model are shown. These two specifications would give essentially the same estimation results for the model specified using the LINEQS model statements.

```
proc calis cov data=Wheaton tech=nr edf=931;
   Cosan J(9, Ide) * A(9, Gen, Imi) * P(9, Sym);

Example 25.2: Simultaneous Equations with Intercept

The demand-and-supply food example of Kmenta (1971, pp. 565, 582) is used to illustrate the use of PROC CALIS for the estimation of intercepts and coefficients of simultaneous equations. The model is specified by two simultaneous equations containing two endogenous variables Q and P and three exogenous variables D, F, and Y,

$$Q_t(demand) = \alpha_1 + \beta_1 P_t + \gamma_1 D_t$$

$$Q_t(supply) = \alpha_2 + \beta_2 P_t + \gamma_2 F_t + \gamma_3 Y_t$$

for $t = 1, \ldots, 20$.

The LINEQS statement requires that each endogenous variable appear on the left-hand side of exactly one equation. Instead of analyzing the system

$$\mathbf{B}^*\boldsymbol{\eta} = \boldsymbol{\Gamma}\boldsymbol{\xi} + \boldsymbol{\zeta}$$

PROC CALIS analyzes the equivalent system

$$\boldsymbol{\eta} = \mathbf{B}\boldsymbol{\eta} + \boldsymbol{\Gamma}\boldsymbol{\xi} + \boldsymbol{\zeta}$$

with $\mathbf{B}^* = \mathbf{I} - \mathbf{B}$. This requires that one of the preceding equations be solved for P_t. Solving the second equation for P_t yields

$$P_t = \frac{1}{\beta_2} Q_t - \frac{\alpha_2}{\beta_2} - \frac{\gamma_2}{\beta_2} F_t - \frac{\gamma_3}{\beta_2} Y_t$$

You can estimate the intercepts of a system of simultaneous equations by applying PROC CALIS to the uncorrected covariance (UCOV) matrix of the data set that is augmented by an additional constant variable with the value 1. In the following statements, the uncorrected covariance matrix is augmented by an additional variable INTERCEPT by using the AUGMENT option. The PROC CALIS statement contains the options UCOV and AUG to compute and analyze an augmented UCOV matrix from the input data set FOOD.

Example 25.3: Second-Order Confirmatory Factor Analysis

A second-order confirmatory factor analysis model is applied to a correlation matrix of Thurstone reported by McDonald (1985). Using the LINEQS statement, the three-term second-order factor analysis model is specified in equations notation. The first-order loadings for the three factors, f1, f2, and f3, each refer to three variables, X1-X3, X4-X6, and X7-X9. One second-order factor, f4, reflects the correlations among the three first-order factors. The second-order factor correlation matrix P is defined as a 1×1 identity matrix. Choosing the second-order uniqueness matrix U2 as a diagonal matrix with parameters U21-U23 gives an unidentified model. To compute identified maximum likelihood estimates, the matrix U2 is defined as a 3×3 identity matrix. The following statements generate results that are partially displayed in Output 25.3.1 through Output 25.3.4:

To compute McDonald's unidentified model, you would have to change the STD and BOUNDS statements to include three more parameters:

```
std
   F4      = 1.,
   E1-E9   = U11-U19,
   E10-E12 = U21-U23;
bounds
   0. <= U11-U19,
   0. <= U21-U23;
```

The unidentified model is indicated in the output by an analysis of the linear dependencies in the approximate Hessian matrix (not shown). Because the information matrix is singular, standard errors are computed based on a Moore-Penrose inverse. The results computed by PROC CALIS differ from those reported by McDonald (1985). In the case of an unidentified model, the parameter estimates are not unique.

To specify the identified model by using the COSAN model statement, you can use the following statements:

```
proc calis data=Thurst method=max edf=212 pestim se;
   cosan F1(3) * F2(1) * P(1,Ide) + F1(3) * U2(3,Ide) + U1(9,Dia);
   matrix F1
          [ ,1] = X1-X3,
          [ ,2] = 3 * 0. X4-X6,
          [ ,3] = 6 * 0. X7-X9;
   matrix F2
          [ ,1] = X10-X12;
   matrix U1
          [1,1] = U11-U19;
   bounds
          0. <= U11-U19;
run;
```

Because PROC CALIS cannot compute initial estimates for a model specified by the general COSAN statement, this analysis might require more iterations than one that uses the LINEQS statement, depending on the precision of the processor.

Example 25.4: Linear Relations among Factor Loadings

In this example, a confirmatory factor-analysis model with linear constraints on loadings is specified by the COSAN statement. SAS programming statements are used to set the constraints. In the context of the current example, the differences between fitting covariance structures and correlation structures will also be discussed.

The correlation matrix of six variables from Kinzer and Kinzer (N=326) is used by Guttman (1957) as an example that yields an approximate simplex. McDonald (1980) uses this data set as an example of factor analysis where he supposes that the loadings of the second factor are linear functions of the loadings on the first factor. Let **B** be the factor loading matrix containing the two factors and six variables so that

$$\mathbf{B} = \begin{pmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \\ b_{31} & b_{32} \\ b_{41} & b_{42} \\ b_{51} & b_{52} \\ b_{61} & b_{62} \end{pmatrix}$$

and

$$b_{j2} = \alpha + \beta b_{j1}, \quad j = 1, \ldots, 6$$

The correlation structures are represented by

$$\mathbf{P} = \mathbf{B}\mathbf{B}' + \Psi$$

where $\Psi = \text{diag}(\psi_{11}, \psi_{22}, \psi_{33}, \psi_{44}, \psi_{55}, \psi_{66})$ represents the diagonal matrix of unique variances for the variables.

With parameters α and β being unconstrained, McDonald (1980) has fitted an underidentified model with seven degrees of freedom. Browne (1982) imposes the following identification condition:

$$\beta = -1$$

In this example, Browne's identification condition is imposed. The following statements specify the confirmatory factor model:

```
Data Kinzer(TYPE=CORR);
Title "Data Matrix of Kinzer & Kinzer, see GUTTMAN (1957)";
   _TYPE_ = 'CORR'; INPUT _NAME_ $ var1-var6;
   Datalines;
var1  1.00   .     .     .     .
var2   .51  1.00   .     .     .
var3   .46   .51  1.00   .     .
var4   .46   .47   .54  1.00   .
var5   .40   .39   .49   .57  1.00   .
var6   .33   .39   .47   .45   .56  1.00
  ;

proc calis data=Kinzer method=max nobs=326 nose;
   cosan B(2,Gen) * I(2,Ide) + U(6,Ide) * PSI(6,DIA);
   matrix B
          [ ,1]= b11 b21 b31 b41 b51 b61,
          [ ,2]= b12 b22 b32 b42 b52 b62;
   matrix Psi
          [1,1]= psi1-psi6;
   parameters alpha = .5;
   /* SAS Programming Statements */
   b12  = alpha - b11;
   b22  = alpha - b21;
   b32  = alpha - b31;
   b42  = alpha - b41;
   b52  = alpha - b51;
   b62  = alpha - b61;
   vnames B  Fact1 Fact2,
          I  Fact1 Fact2,
          U  var1-var6,
          PSI var1-var6;
run;
```

In the COSAN statement, you specify the model matrices for the correlation structures. Matrix **B** is the 6×2 factor loading matrix. Matrix **I** is a fixed 2×2 identity matrix, representing the factor variances and covariances. In the next term, matrix **U** is a 6×6 identity matrix, appearing there only because it makes the specification conform to the format of the generalized COSAN model. The **PSI** matrix is the matrix for variances and covariances for errors. The matrix specification in the COSAN statement realizes the following matrix model:

$$\mathbf{P} = \mathbf{BIB}' + \mathbf{U}\Psi\mathbf{U}' = \mathbf{BB}' + \Psi$$

which is the intended correlation structures.
