as described in the section “**Design Effect**” on page 7646.  $\hat{P}_c$  is the proportion estimate for level  $c$ ,  $\widehat{\text{Var}}(\hat{P}_c)$  is the variance of the estimate,  $f$  is the overall sampling fraction, and  $n$  is the number of observations in the sample. The factor  $(1 - f)$  is included only for Taylor series variance estimation (**VARMETHOD=TAYLOR**) when you specify the **RATE=** or **TOTAL=** option. See the section “**Design Effect**” on page 7646 for details.

If you specify the **CHISQ(MODIFIED)** or **LRCHISQ(MODIFIED)** option, the design correction is computed by using null hypothesis proportions instead of proportion estimates. By default, null hypothesis proportions are equal proportions for all levels of the one-way table. Alternatively, you can specify null proportion values in the **TESTP=** option. The modified design correction  $D_0$  is computed from null hypothesis proportions as

$$D_0 = \sum_c (1 - P_c^0) \text{Deff}_0(\hat{P}_c) / (C - 1)$$

where

$$\begin{aligned} \text{Deff}_0(\hat{P}_c) &= \widehat{\text{Var}}(\hat{P}_c) / \text{Var}_{\text{srs}}(P_c^0) \\ &= \widehat{\text{Var}}(\hat{P}_c) / \left( (1 - f) P_c^0 (1 - P_c^0) / (n - 1) \right) \end{aligned}$$

The null hypothesis proportion  $P_c^0$  equals  $1/C$  for equal proportions (the default), or  $P_c^0$  equals the null proportion that you specify for level  $c$  if you use the **TESTP=** option.

**Second-Order Test** The second-order (Satterthwaite) Rao-Scott chi-square statistic for the goodness-of-fit test is computed as

$$Q_{RS2} = Q_{RS1} / (1 + \hat{a}^2)$$

where  $Q_{RS1}$  is the first-order Rao-Scott chi-square statistic described in the section “**First-Order Test**” on page 7652 and  $\hat{a}^2$  is the second-order design correction described in the section “**Second-Order Design Correction**” on page 7654. For details, see Rao and Scott (1979, 1981); Rao and Thomas (1989).

Under the null hypothesis, the second-order Rao-Scott chi-square  $Q_{RS2}$  approximately follows a chi-square distribution with  $(C - 1)/(1 + \hat{a}^2)$  degrees of freedom. The corresponding  $F$  statistic is

$$F_{RS2} = Q_{RS2} / (C - 1)$$

which has an  $F$  distribution with  $(C - 1)/(1 + \hat{a}^2)$  and  $\kappa(C - 1)/(1 + \hat{a}^2)$  degrees of freedom under the null hypothesis (Thomas and Rao 1984, 1987). The value of  $\kappa$  is the degrees of freedom for the variance estimator, which depends on the sample design and the variance estimation method. The section “**Degrees of Freedom**” on page 7645 describes the computation of  $\kappa$ .

**Second-Order Design Correction** The second-order (Satterthwaite) design correction for one-way tables is computed from the eigenvalues of the estimated design effects matrix  $\hat{\Delta}$ , which are known as *generalized design effects*. The design effects matrix is computed as

$$\hat{\Delta} = (n - 1)/(1 - f) \left( \text{Cov}_{\text{srs}}(\hat{\mathbf{P}})^{-1} \widehat{\text{Cov}}(\hat{\mathbf{P}}) \right)$$

where  $\text{Cov}_{\text{srs}}(\hat{\mathbf{P}})$  is the covariance under multinomial sampling (*srs* with replacement) and  $\widehat{\text{Cov}}(\hat{\mathbf{P}})$  is the covariance matrix of the first  $(C - 1)$  proportion estimates. See Rao and Scott (1979, 1981) and Rao and Thomas (1989) for details.

By default, the *srs* covariance matrix is computed from the proportion estimates as

$$\text{Cov}_{\text{srs}}(\hat{\mathbf{P}}) = \text{Diag}(\hat{\mathbf{P}}) - \hat{\mathbf{P}} \hat{\mathbf{P}}'$$

where  $\hat{\mathbf{P}}$  is an array of  $(C - 1)$  proportion estimates. If you specify the **CHISQ(MODIFIED)** or **LRCHISQ(MODIFIED)** option, the *srs* covariance matrix is computed from the null hypothesis proportions  $\mathbf{P}_0$  as

$$\text{Cov}_{\text{srs}}(\mathbf{P}_0) = \text{Diag}(\mathbf{P}_0) - \mathbf{P}_0 \mathbf{P}_0'$$

where  $\mathbf{P}_0$  is an array of  $(C - 1)$  null hypothesis proportions. The null hypothesis proportions equal  $1/C$  by default. If you use the **TESTP=** option to specify null hypothesis proportions,  $\mathbf{P}_0$  is an array of  $(C - 1)$  proportions that you specify.

The second-order design correction is computed as

$$\hat{a}^2 = \left( \sum_{c=1}^{C-1} d_c^2 / (C - 1) \bar{d}^2 \right) - 1$$

where  $d_c$  are the eigenvalues of the design effects matrix  $\hat{\Delta}$  and  $\bar{d}$  is the average of the eigenvalues.

### Two-Way Tables

For two-way tables, the **CHISQ** option provides a Rao-Scott (design-based) test of association between the row and column variables. PROC SURVEYFREQ provides a first-order Rao-Scott chi-square test by default. If you specify the **CHISQ(SECONDORDER)** option, PROC SURVEYFREQ provides a second-order (Satterthwaite) Rao-Scott chi-square test.

**First-Order Test** The first-order Rao-Scott chi-square statistic is computed as

$$Q_{RS1} = Q_P / D$$

where  $Q_P$  is the Pearson chi-square based on the estimated totals and  $D$  is the design correction described in the section “**First-Order Design Correction**” on page 7655. See Rao and Scott (1979, 1984, 1987) for details.

For a two-way tables with  $R$  rows and  $C$  columns, the Pearson chi-square is computed as

$$Q_P = (n/\hat{N}) \sum_r \sum_c (\hat{N}_{rc} - E_{rc})^2 / E_{rc}$$

where  $n$  is the sample size,  $\widehat{N}$  is the estimated overall total,  $\widehat{N}_{rc}$  is the estimated total for table cell  $(r, c)$ , and  $E_{rc}$  is the expected total for table cell  $(r, c)$  under the null hypothesis of no association,

$$E_{rc} = \widehat{N}_r \cdot \widehat{N}_{\cdot c} / \widehat{N}$$

Under the null hypothesis of no association, the first-order Rao-Scott chi-square  $Q_{RS1}$  approximately follows a chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom. A better approximation can be obtained by the  $F$  statistic,

$$F_1 = Q_{RS1} / (R - 1)(C - 1)$$

which has an  $F$  distribution with  $(R - 1)(C - 1)$  and  $\kappa(R - 1)(C - 1)$  degrees of freedom under the null hypothesis (Thomas and Rao 1984, 1987). The value of  $\kappa$  is the degrees of freedom for the variance estimator, which depends on the sample design and the variance estimation method. The section “[Degrees of Freedom](#)” on page 7645 describes the computation of  $\kappa$ .

**First-Order Design Correction** By default for a first-order test, PROC SURVEYFREQ computes the design correction from proportion estimates. If you specify the [CHISQ\(MODIFIED\)](#) or [LRCHISQ\(MODIFIED\)](#) option for a first-order test, the procedure computes the design correction from null hypothesis proportions.

Second-order tests, which you request by specifying the [CHISQ\(SECONDORDER\)](#) or [LRCHISQ\(SECONDORDER\)](#) option, are computed by applying both first-order and second-order design corrections to the weighted chi-square statistic. For second-order tests for two-way tables, PROC SURVEYFREQ always uses null hypothesis proportions to compute both the first-order and second-order design corrections.

The first-order design correction  $D$  that is based on proportion estimates is computed as

$$D = \left( \sum_r \sum_c (1 - \widehat{P}_{rc}) \text{Deff}(\widehat{P}_{rc}) - \sum_r (1 - \widehat{P}_{r\cdot}) \text{Deff}(\widehat{P}_{r\cdot}) - \sum_c (1 - \widehat{P}_{\cdot c}) \text{Deff}(\widehat{P}_{\cdot c}) \right) / (R - 1)(C - 1)$$

where

$$\begin{aligned} \text{Deff}(\widehat{P}_{rc}) &= \widehat{\text{Var}}(\widehat{P}_{rc}) / \text{Var}_{\text{srs}}(\widehat{P}_{rc}) \\ &= \text{Var}(\widehat{P}_{rc}) / \left( (1 - f) \widehat{P}_{rc} (1 - \widehat{P}_{rc}) / (n - 1) \right) \end{aligned}$$

as described in the section “[Design Effect](#)” on page 7646.  $\widehat{P}_{rc}$  is the estimate of the proportion in table cell  $(r, c)$ ,  $\widehat{\text{Var}}(\widehat{P}_{rc})$  is the variance of the estimate,  $f$  is the overall sampling fraction, and  $n$  is the number of observations in the sample. The factor  $(1 - f)$  is included only for Taylor series variance estimation ([VARMETHOD=TAYLOR](#)) when you specify the [RATE=](#) or [TOTAL=](#) option. See the section “[Design Effect](#)” on page 7646 for details.

The design effects for the estimate of the proportion in row  $r$  and the estimate of the proportion in column  $c$  ( $\text{Deff}(\widehat{P}_{r\cdot})$  and  $\text{Deff}(\widehat{P}_{\cdot c})$ , respectively) are computed in the same way.

If you specify the **CHISQ(MODIFIED)** or **LRCHISQ(MODIFIED)** option for a first-order Rao-Scott test, or if you request a second-order test for a two-way table (**CHISQ(SECONDORDER)** or **LRCHISQ(SECONDORDER)**), the procedure computes the design correction from the null hypothesis cell proportions instead of the estimated cell proportions. For two-way tables, the null hypothesis cell proportions are computed as the products of the corresponding row and column proportion estimates. The modified design correction  $D_0$  (based on null hypothesis proportions) is computed as

$$D_0 = \left( \sum_r \sum_c (1 - P_{rc}^0) \text{Deff}_0(\hat{P}_{rc}) - \sum_r (1 - \hat{P}_{r\cdot}) \text{Deff}(\hat{P}_{r\cdot}) - \sum_c (1 - \hat{P}_{\cdot c}) \text{Deff}(\hat{P}_{\cdot c}) \right) / (R - 1)(C - 1)$$

where

$$P_{rc}^0 = \hat{P}_{r\cdot} \times \hat{P}_{\cdot c}$$

and

$$\begin{aligned} \text{Deff}_0(\hat{P}_{rc}) &= \widehat{\text{Var}}(\hat{P}_{rc}) / \text{Var}_{\text{srs}}(P_{rc}^0) \\ &= \widehat{\text{Var}}(\hat{P}_{rc}) / ((1 - f) P_{rc}^0 (1 - P_{rc}^0) / (n - 1)) \end{aligned}$$

**Second-Order Test** The second-order (Satterthwaite) Rao-Scott chi-square statistic for two-way tables is computed as

$$Q_{RS2} = Q_{RS1} / (1 + \hat{a}^2)$$

where  $Q_{RS1}$  is the first-order Rao-Scott chi-square statistic described in the section “**First-Order Test**” on page 7654 and  $\hat{a}^2$  is the second-order design correction described in the section “**Second-Order Design Correction**” on page 7656. See Rao and Scott (1979, 1981) and Rao and Thomas (1989) for details.

Under the null hypothesis, the second-order Rao-Scott chi-square  $Q_{RS2}$  approximately follows a chi-square distribution with  $(R - 1)(C - 1)/(1 + \hat{a}^2)$  degrees of freedom. The corresponding  $F$  statistic is

$$F_{RS2} = Q_{RS2} (1 + \hat{a}^2) / (R - 1)(C - 1)$$

which has an  $F$  distribution with  $(R - 1)(C - 1)/(1 + \hat{a}^2)$  and  $\kappa(R - 1)(C - 1)/(1 + \hat{a}^2)$  degrees of freedom under the null hypothesis (Thomas and Rao 1984, 1987). The value of  $\kappa$  is the degrees of freedom for the variance estimator, which depends on the sample design and the variance estimation method. The section “**Degrees of Freedom**” on page 7645 describes the computation of  $\kappa$ .

**Second-Order Design Correction** The second-order (Satterthwaite) design correction for two-way tables is computed from the eigenvalues of the estimated design effects matrix  $\hat{\Delta}$ , which are known as *generalized design effects*. The design effects matrix is defined as

$$\hat{\Delta} = (n - 1)/(1 - f) \left( \text{Cov}_{\text{srs}}(\hat{\mathbf{P}})^{-1} \mathbf{H} \widehat{\text{Cov}}(\hat{\mathbf{P}}) \mathbf{H}' \right)$$

where  $\widehat{\text{Cov}}(\hat{\mathbf{P}})$  is the covariance matrix of the  $R \times C$  proportion estimates and  $\text{Cov}_{\text{srs}}(\hat{\mathbf{P}})$  is the covariance under multinomial sampling (*srs* with replacement). See Rao and Scott (1979, 1981) and Rao and Thomas (1989) for details.

The second-order design correction is computed from the design effects matrix  $\hat{\Delta}$  as

$$\hat{a}^2 = \left( \sum_{i=1}^K d_c^2 / K \bar{d}^2 \right) - 1$$

where  $K = (R - 1)(C - 1)$ ,  $d_c$  are the eigenvalues of  $\hat{\Delta}$ , and  $\bar{d}$  is the average eigenvalue.

The *srs* covariance matrix is computed as

$$\text{Cov}_{\text{srs}}(\hat{\mathbf{P}}) = \hat{\mathbf{P}}_r \otimes \hat{\mathbf{P}}_c$$

where  $\hat{\mathbf{P}}_r$  is an  $(R - 1) \times (R - 1)$  matrix that is constructed from the array of  $(R - 1)$  row proportion estimates  $\hat{\mathbf{p}}_r$  as

$$\hat{\mathbf{P}}_r = \text{Diag}(\hat{\mathbf{p}}_r) - \hat{\mathbf{p}}_r \hat{\mathbf{p}}_r'$$

Similarly,  $\hat{\mathbf{P}}_c$  is a  $(C - 1) \times (C - 1)$  matrix that is constructed from the array of  $(C - 1)$  column proportion estimates  $\hat{\mathbf{p}}_c$  as

$$\hat{\mathbf{P}}_c = \text{Diag}(\hat{\mathbf{p}}_c) - \hat{\mathbf{p}}_c \hat{\mathbf{p}}_c'$$

The  $(R - 1)(C - 1) \times (R - 1)(C - 1)$  matrix  $\mathbf{H}$  is computed as

$$\mathbf{H} = \mathbf{J}_r \otimes \mathbf{J}_c - (\hat{\mathbf{p}}_r \mathbf{l}_r') \otimes \mathbf{J}_c - \mathbf{J}_r \otimes (\hat{\mathbf{p}}_c \mathbf{l}_c')$$

where  $\mathbf{J}_r = (\mathbf{I}_{(R-1)} | \mathbf{0})$ ,  $\mathbf{J}_c = (\mathbf{I}_{(C-1)} | \mathbf{0})$ ,  $\mathbf{l}_r$  is an  $(R \times 1)$  array of ones, and  $\mathbf{l}_c$  is an  $(C \times 1)$  array of ones. See Rao and Scott (1979, p. 61) for details.

### Rao-Scott Likelihood Ratio Chi-Square Test

The Rao-Scott likelihood ratio chi-square test is a design-adjusted version of the likelihood ratio test, which involves ratios of observed and expected frequencies. For details about design-adjusted chi-square tests, see Lohr (2010, Section 10.3.2), Rao and Scott (1981, 1984, 1987); Thomas, Singh, and Roberts (1996).

PROC SURVEYFREQ provides a first-order Rao-Scott likelihood ratio test by default. If you specify the **LRCHISQ(SECONDORDER)** option, PROC SURVEYFREQ provides a second-order (Satterthwaite) likelihood ratio chi-square test.

The procedure computes the Rao-Scott likelihood ratio test by applying design adjustments to the weighted likelihood ratio statistic that is based on estimated totals. This computation is identical to the Rao-Scott chi-square test computation except that it uses the likelihood ratio statistic  $G^2$  in place of the Pearson chi-square statistic  $Q_P$ . See the section “**Rao-Scott Chi-Square Test**” on page 7652 for details.

#### One-Way Tables

For one-way tables, the LRCHISQ option provides a Rao-Scott (design-based) goodness-of-fit test for one-way tables. By default, this is a test for the null hypothesis of equal proportions. If you specify null hypothesis proportions in the **TESTP=** option, the goodness-of-fit test uses the specified proportions.

The Rao-Scott likelihood ratio test uses the likelihood ratio statistic that is based on the estimated totals,

$$G^2 = 2 (n / \hat{N}) \sum_c \hat{N}_c \ln (\hat{N}_c / E_c)$$

where  $n$  is the sample size,  $\widehat{N}$  is the estimated overall total,  $\widehat{N}_c$  is the estimated total for level  $c$ , and  $E_c$  is the expected total for level  $c$  under the null hypothesis. For the null hypothesis of equal proportions, the expected total for each level equals

$$E_c = \widehat{N} / C$$

For specified null proportions, the expected total for level  $c$  equals

$$E_c = \widehat{N} \times P_c^0$$

where  $P_c^0$  is the null proportion that you specify for level  $c$ .

The computation of the Rao-Scott likelihood ratio test for one-way tables uses  $G^2$  in place of  $Q_P$  in the Rao-Scott chi-square test computation and is otherwise identical to the chi-square test computation. See the sections “[First-Order Test](#)” on page 7652 and “[Second-Order Test](#)” on page 7653 for details.

If you specify the **LRCHISQ(MODIFIED)** option, PROC SURVEYFREQ computes the design corrections by using null hypothesis proportions instead of proportion estimates. By default, null hypothesis proportions are equal proportions for all levels of the one-way table. Alternatively, you can specify null proportion values in the **TESTP=** option.

### Two-Way Tables

For two-way tables, the **LRCHISQ** option provides a Rao-Scott (design-based) test of association between the row and column variables.

The Rao-Scott likelihood ratio test uses the likelihood ratio statistic that is based on the estimated totals,

$$G^2 = 2(n/\widehat{N}) \sum_r \sum_c \widehat{N}_{rc} \ln(\widehat{N}_{rc} / E_{rc})$$

where  $n$  is the sample size,  $\widehat{N}$  is the estimated overall total,  $\widehat{N}_{rc}$  is the estimated total for table cell  $(r, c)$ , and  $E_{rc}$  is the expected total for cell  $(r, c)$  under the null hypothesis of no association. The expected total for cell  $(r, c)$  equals

$$E_{rc} = \widehat{N}_r \cdot \widehat{N}_{\cdot c} / \widehat{N}$$

The computation of the Rao-Scott likelihood ratio test for two-way tables uses  $G^2$  in place of  $Q_P$  in the Rao-Scott chi-square test computation and is otherwise identical to the chi-square test computation. See the sections “[First-Order Test](#)” on page 7654 and “[Second-Order Test](#)” on page 7656 for details.

By default for a first-order test, PROC SURVEYFREQ computes the design correction from proportion estimates. If you specify the **LRCHISQ(MODIFIED)** option for a first-order test, the procedure computes the design correction from null hypothesis proportions.

Second-order tests, which you request by specifying the **LRCHISQ(SECONDORDER)** option, are computed by applying both first-order and second-order design corrections to the weighted likelihood ratio statistic. For second-order tests for two-way tables, PROC SURVEYFREQ always uses null hypothesis proportions to compute both the first-order and second-order design corrections.

## Wald Chi-Square Test

PROC SURVEYFREQ provides two Wald chi-square tests for independence of the row and column variables in a two-way table: a Wald chi-square test based on the difference between observed and expected weighted cell frequencies, and a Wald log-linear chi-square test based on the log odds ratios. These statistics test for independence of the row and column variables in two-way tables, taking into account the complex survey design. For information about Wald statistics and their applications to categorical data analysis, see Bedrick (1983); Koch, Freeman, and Freeman (1975); Wald (1943).

For these two tests, PROC SURVEYFREQ computes the generalized Wald chi-square statistic, the corresponding Wald  $F$  statistic, and also an adjusted Wald  $F$  statistic for tables larger than  $2 \times 2$ . Under the null hypothesis of independence, the Wald chi-square statistic approximately follows a chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom for large samples. However, it has been shown that this test can perform poorly in terms of actual significance level and power, especially for tables with a large number of cells or for samples with a relatively small number of clusters. See Thomas and Rao (1984, 1985) and Lohr (2010) for more information. See Felligi (1980) and Hidiroglou, Fuller, and Hickman (1980) for information about the adjusted Wald  $F$  statistic. Thomas and Rao (1984) found that the adjusted Wald  $F$  statistic provides a more stable test than the chi-square statistic, although its power can be low when the number of sample clusters is not large. See also Korn and Graubard (1990) and Thomas, Singh, and Roberts (1996).

If you specify the **WCHISQ** option in the TABLES statement, PROC SURVEYFREQ computes a Wald test for independence in the two-way table based on the differences between the observed (weighted) cell frequencies and the expected frequencies.

Under the null hypothesis of independence of the row and column variables, the expected cell frequencies are computed as

$$E_{rc} = \hat{N}_r \cdot \hat{N}_{\cdot c} / \hat{N}$$

where  $\hat{N}_r$  is the estimated total for row  $r$ ,  $\hat{N}_{\cdot c}$  is the estimated total for column  $c$ , and  $\hat{N}$  is the estimated overall total, as described in the section “[Expected Weighted Frequency](#)” on page 7647. The null hypothesis that the population weighted frequencies equal the expected frequencies can be expressed as

$$H_0: Y_{rc} - N_{rc} - E_{rc} = 0$$

for all  $r = 1, \dots, (R - 1)$  and  $c = 1, \dots, (C - 1)$ . This null hypothesis can be stated equivalently in terms of cell proportions, with the expected cell proportions computed as the products of the marginal row and column proportions.

The generalized Wald chi-square statistic  $Q_W$  is computed as

$$Q_W = \hat{Y}' (\mathbf{H} \hat{\mathbf{V}}(\hat{\mathbf{N}}) \mathbf{H}')^{-1} \hat{Y}$$

where  $\hat{Y}$  is an array of  $(R - 1)(C - 1)$  differences between the observed and expected weighted frequencies  $(\hat{N}_{rc} - E_{rc})$ , and  $(\mathbf{H} \hat{\mathbf{V}}(\hat{\mathbf{N}}) \mathbf{H}')$  estimates the variance of  $\hat{Y}$ .

$\hat{\mathbf{V}}(\hat{\mathbf{N}})$  is the covariance matrix of the estimates  $\hat{N}_{rc}$ , and its computation is described in the section “[Covariance of Totals](#)” on page 7633.

$\mathbf{H}$  is an  $(R - 1)(C - 1)$  by  $RC$  matrix that contains the partial derivatives of the elements of  $\hat{\mathbf{Y}}$  with respect to the elements of  $\hat{\mathbf{N}}$ . The elements of  $\mathbf{H}$  are computed as follows, where  $a$  denotes a row different from row  $r$ , and  $b$  denotes a column different from column  $c$ :

$$\partial \hat{Y}_{rc} / \partial \hat{N}_{rc} = 1 - \left( \hat{N}_{r\cdot} + \hat{N}_{\cdot c} - \hat{N}_{\cdot c} \hat{N}_{r\cdot} / \hat{N} \right) / \hat{N}$$

$$\partial \hat{Y}_{rc} / \partial \hat{N}_{ac} = - \left( \hat{N}_{r\cdot} - \hat{N}_{r\cdot} \hat{N}_{\cdot c} / \hat{N} \right) / \hat{N}$$

$$\partial \hat{Y}_{rc} / \partial \hat{N}_{rb} = - \left( \hat{N}_{\cdot c} - \hat{N}_{r\cdot} \hat{N}_{\cdot c} / \hat{N} \right) / \hat{N}$$

$$\partial \hat{Y}_{rc} / \partial \hat{Y}_{ab} = \hat{N}_{r\cdot} \hat{N}_{\cdot c} / \hat{N}^2$$

Under the null hypothesis of independence, the statistic  $Q_W$  approximately follows a chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom for large samples.

PROC SURVEYFREQ computes the Wald  $F$  statistic as

$$F_W = Q_W / (R - 1)(C - 1)$$

Under the null hypothesis of independence,  $F_W$  approximately follows an  $F$  distribution with  $(R - 1)(C - 1)$  numerator degrees of freedom. The denominator degrees of freedom are the degrees of freedom for the variance estimator and depend on the sample design and the variance estimation method. The section “Degrees of Freedom” on page 7645 describes the computation of the denominator degrees of freedom. Alternatively, you can specify the denominator degrees of freedom with the `DF=` option in the TABLES statement.

For tables larger than  $2 \times 2$ , PROC SURVEYFREQ also computes the adjusted Wald  $F$  statistic as

$$F_{Adj\_W} = Q_W (s - k + 1) / (ks)$$

where  $k = (R - 1)(C - 1)$ , and  $s$  is the degrees of freedom, which are computed as described in the section “Degrees of Freedom” on page 7645. Alternatively, you can specify the value of  $s$  with the `DF=` option in the TABLES statement. Note that for  $2 \times 2$  tables,  $k = (R - 1)(C - 1) = 1$ , and therefore the adjusted Wald  $F$  statistic equals the (unadjusted) Wald  $F$  statistic, with the same numerator and denominator degrees of freedom.

Under the null hypothesis,  $F_{Adj\_W}$  approximately follows an  $F$  distribution with  $k$  numerator degrees of freedom and  $(s - k + 1)$  denominator degrees of freedom.

### Wald Log-Linear Chi-Square Test

If you specify the `WLLCHISQ` option in the TABLES statement, PROC SURVEYFREQ computes a Wald test for independence based on the log odds ratios. See the section “Wald Chi-Square Test” on page 7659 for more information about Wald tests.

For a two-way table of  $R$  rows and  $C$  columns, the Wald log-linear test is based on the  $(R - 1)(C - 1)$ -dimensional array of elements  $\hat{Y}_{rc}$ ,

$$\hat{Y}_{rc} = \log \hat{N}_{rc} - \log \hat{N}_{rC} - \log \hat{N}_{RC} + \log \hat{N}_{RC}$$

where  $\hat{N}_{rc}$  is the estimated total for table cell  $(r, c)$ . The null hypothesis of independence between the row and column variables can be expressed as  $H_0: Y_{rc} = 0$  for all  $r = 1, \dots, (R - 1)$  and  $c = 1, \dots, (C - 1)$ . This null hypothesis can be stated equivalently in terms of cell proportions.

The generalized Wald log-linear chi-square statistic is computed as

$$Q_L = \hat{\mathbf{Y}}' \hat{\mathbf{V}}(\hat{\mathbf{Y}})^{-1} \hat{\mathbf{Y}}$$

where  $\hat{\mathbf{Y}}$  is the  $(R - 1)(C - 1)$ -dimensional array of the  $\hat{Y}_{rc}$ , and  $\hat{\mathbf{V}}(\hat{\mathbf{Y}})$  estimates the variance of  $\hat{\mathbf{Y}}$ ,

$$\hat{\mathbf{V}}(\hat{\mathbf{Y}}) = \mathbf{A} \mathbf{D}^{-1} \hat{\mathbf{V}}(\hat{\mathbf{N}}) \mathbf{D}^{-1} \mathbf{A}'$$

where  $\hat{\mathbf{V}}(\hat{\mathbf{N}})$  is the covariance matrix of the estimates  $\hat{N}_{rc}$ , which is computed as described in the section “Covariance of Totals” on page 7633.  $\mathbf{D}$  is a diagonal matrix with the estimated totals  $\hat{N}_{rc}$  on the diagonal, and  $\mathbf{A}$  is the  $(R - 1)(C - 1)$  by  $RC \times RC$  linear contrast matrix.

Under the null hypothesis of independence, the statistic  $Q_L$  approximately follows a chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom for large samples.

PROC SURVEYFREQ computes the Wald log-linear  $F$  statistic as

$$F_L = Q_L / (R - 1)(C - 1)$$

Under the null hypothesis of independence,  $F_L$  approximately follows an  $F$  distribution with  $(R - 1)(C - 1)$  numerator degrees of freedom. PROC SURVEYFREQ computes the denominator degrees of freedom as described in the section “Degrees of Freedom” on page 7645. Alternatively, you can specify the denominator degrees of freedom with the **DF=** option in the TABLES statement.

For tables larger than  $2 \times 2$ , PROC SURVEYFREQ also computes the adjusted Wald log-linear  $F$  statistic as

$$F_{Adj\_L} = Q_L (s - k + 1) / (ks)$$

where  $k = (R - 1)(C - 1)$ , and  $s$  is the denominator degrees of freedom, which is computed as described in the section “Degrees of Freedom” on page 7645. Alternatively, you can specify the value of  $s$  with the **DF=** option in the TABLES statement. Note that for  $2 \times 2$  tables,  $k = (R - 1)(C - 1) = 1$ , and therefore the adjusted Wald  $F$  statistic equals the (unadjusted) Wald  $F$  statistic, with the same numerator and denominator degrees of freedom.

Under the null hypothesis,  $F_{Adj\_L}$  approximately follows an  $F$  distribution with  $k$  numerator degrees of freedom and  $(s - k + 1)$  denominator degrees of freedom.

---

## Output Data Sets

You can use the Output Delivery System to create a SAS data set from any piece of PROC SURVEYFREQ output. See the section “ODS Table Names” on page 7668 and [Example 90.3](#) for more information.

PROC SURVEYFREQ also provides an output data set that stores the replicate weights for BRR or jackknife variance estimation and an output data set that stores the jackknife coefficients for jackknife variance estimation.

## Replicate Weight Output Data Set

If you specify the `OUTWEIGHTS= method-option` for `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE`, PROC SURVEYFREQ stores the replicate weights in an output data set. The `OUTWEIGHTS=` output data set contains all observations from the `DATA=` input data set that are valid (used in the analysis). A valid observation must have a positive value of the `WEIGHT` variable. A valid observations must also have nonmissing values of the `STRATA` and `CLUSTER` variables unless you specify the `MISSING` option in the PROC SURVEYFREQ statement. See the section “Data Summary Table” on page 7663 for details about valid observations.

The `OUTWEIGHTS=` data set contains the following variables:

- all variables in the `DATA=` input data set
- `RepWt_1`, `RepWt_2`, . . . , `RepWt_n`, which are the replicate weight variables, where `n` is the total number of replicates in the analysis

Each replicate weight variable contains the replicate weights for the corresponding replicate. Replicate weights equal zero for those observations not included in the replicate.

After the procedure creates and stores replicate weights for a particular input data set and survey design, you can use them again in subsequent analyses, either in PROC SURVEYFREQ or in another survey procedure. You use a `REPWEIGHTS` statement to provide replicate weights to the procedure.

## Jackknife Coefficient Output Data Set

If you specify the `OUTJKCOEFS= method-option` for `VARMETHOD=JACKKNIFE`, PROC SURVEYFREQ stores the jackknife coefficients in an output data set. The `OUTJKCOEFS=` output data set contains one observation for each replicate. The `OUTJKCOEFS=` data set contains the following variables:

- `Replicate`, which is the replicate number for the jackknife coefficient
- `JKCoefficient`, which is the jackknife coefficient
- `DonorStratum`, which is the stratum of the PSU that was deleted to construct the replicate, if you specify a `STRATA` statement

After the procedure creates jackknife coefficients for a particular input data set and survey design, you can use the `OUTJKCOEFS= method-option` to store these coefficients and then use them again in subsequent analyses, either in PROC SURVEYFREQ or in another survey procedure. You use the `JKCOEFS=` option in the `REPWEIGHTS` statement to provide jackknife coefficients for the procedure.

---

## Displayed Output

### Data Summary Table

The “Data Summary” table provides information about the input data set and the sample design. PROC SURVEYFREQ displays this table unless you specify the **NOSUMMARY** option in the PROC SURVEYFREQ statement.

The “Data Summary” table displays the total number of valid observations. To be considered *valid*, an observation must have a nonmissing, positive sampling weight value if you specify a **WEIGHT** statement. If you do not specify the **MISSING** option, a valid observation must also have nonmissing values for all **STRATA** and **CLUSTER** variables. The number of valid observations can differ from the number of nonmissing observations for an individual table request, which the procedure displays in the frequency or crosstabulation tables. See the section “Missing Values” on page 7627 for more information.

PROC SURVEYFREQ displays the following information in the “Data Summary” table:

- Number of Strata, if you specify a **STRATA** statement
- Number of Clusters, if you specify a **CLUSTER** statement
- Number of Observations, which is the total number of valid observations
- Sum of Weights, which is the sum over all valid observations, if you specify a **WEIGHT** or **REPWEIGHTS** statement

### Stratum Information Table

If you specify the **LIST** option in the **STRATA** statement, PROC SURVEYFREQ displays a “Stratum Information” table. This table provides the following information for each stratum:

- Stratum Index, which is a sequential stratum identification number
- **STRATA** variables, which list the levels of **STRATA** variables for the stratum
- Number of Observations, which is the number of valid observations in the stratum
- Population Total for the stratum, if you specify the **TOTAL=** option
- Sampling Rate for the stratum, if you specify the **TOTAL=** or **RATE=** option. If you specify the **TOTAL=** option, the sampling rate is based on the number of valid observations in the stratum.
- Number of Clusters, which is the number of clusters in the stratum, if you specify a **CLUSTER** statement

## Variance Estimation Table

If you specify the `VARMETHOD=BRR`, `VARMETHOD=JACKKNIFE`, or `NOMCAR` option in the PROC SURVEYFREQ statement, the procedure displays a “Variance Estimation” table. If you do not specify any of these options, the procedure creates a “Variance Estimation” table but does not display it. You can store this nondisplayed table in an output data set by using the Output Delivery System (ODS). See the section “ODS Table Names” on page 7668 for more information.

The “Variance Estimation” table provides the following information:

- Method, which is the variance estimation method—Taylor Series, Balanced Repeated Replication, or Jackknife
- Replicate Weights input data set name, if you provide replicate weights with a `REPWEIGHTS` statement
- Number of Replicates, for `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE`
- Hadamard Data Set name, if you specify the `HADAMARD= method-option` for `VARMETHOD=BRR`
- Fay Coefficient, if you specify the `FAY method-option` for `VARMETHOD=BRR`
- Missing Levels Included (MISSING), if you specify the `MISSING` option
- Missing Levels Included (NOMCAR), if you specify the `NOMCAR` option

## Hadamard Matrix

If you specify the `PRINTH method-option` for `VARMETHOD=BRR`, PROC SURVEYFREQ displays the Hadamard matrix used to construct replicates for BRR variance estimation. If you provide a Hadamard matrix with the `HADAMARD= method-option` for `VARMETHOD=BRR` but the procedure does not use the entire matrix, the procedure displays only the rows and columns that are actually used to construct replicates.

## One-Way Frequency Tables

PROC SURVEYFREQ displays one-way frequency tables for all one-way table requests in the `TABLES` statements, unless you specify the `NOPRINT` option in the `TABLES` statement. A one-way table shows the sample frequency distribution of a single variable, and provides estimates for its population distribution in terms of totals and proportions.

If you request a one-way table without specifying options, PROC SURVEYFREQ displays the following information for each level of the variable:

- Frequency count, which is the number of sample observations in the level
- Weighted Frequency, which estimates the population total for the level
- Standard Deviation of Weighted Frequency
- Percent, which estimates the population proportion for the level
- Standard Error of Percent

The one-way table displays weighted frequencies if your analysis includes a **WEIGHT** or **REPWEIGHTS** statement, or if you specify the **WTFREQ** option in the **TABLES** statement.

The one-way table also displays the Frequency Missing, which is the number of observations with missing values.

You can suppress the frequency counts by specifying the **NOFREQ** option in the **TABLES** statement. Also, the **NOWT** option suppresses the weighted frequencies and their standard deviations. The **NOPERCENT** option suppresses the percentages and their standard errors. The **NOSTD** option suppresses the standard errors of the percentages and the standard deviations of the weighted frequencies. The **NOTOTAL** option suppresses the total row of the one-way table.

**PROC SURVEYFREQ** optionally displays the following information in a one-way table:

- Variance of Weighted Frequency, if you specify the **VARWT** option
- Confidence Limits for Weighted Frequency, if you specify the **CLWT** option
- Coefficient of Variation for Weighted Frequency, if you specify the **CVWT** option
- Test Percent, if you specify the **TESTP=** option
- Variance of Percent, if you specify the **VAR** option
- Confidence Limits for Percent, if you specify the **CL** option
- Coefficient of Variation for Percent, if you specify the **CV** option
- Design Effect for Percent, if you specify the **DEFF** option

## Crosstabulation Tables

**PROC SURVEYFREQ** displays all table requests in the **TABLES** statements, unless you specify the **NOPRINT** option in the **TABLES** statement. For two-way to multiway crosstabulation tables, the values of the last variable in the table request form the table columns. The values of the next-to-last variable form the rows. Each level (or combination of levels) of the other variables forms one layer. **PROC SURVEYFREQ** produces a separate two-way crosstabulation table for each layer of a multiway table.

For each layer, the crosstabulation table displays the row and column variable names and values (levels). Each two-way table lists levels of the column variable within each level of the row variable.

By default, the procedure displays all levels of the column variable within each level of the row variables, including any column variable levels with zero frequency for that row. For multiway tables, the procedure displays all levels of the row variable for each layer of the table by default, including any row levels with zero frequency for that layer. You can suppress the display of zero frequency levels by specifying the **NOSPARE** option.

If you request a crosstabulation table without specifying options, the table displays the following information for each combination of variable levels (table cell):

- Frequency, which is the number of sample observations in the table cell
- Weighted Frequency, which estimates the population total for the table cell

- Standard Deviation of Weighted Frequency
- Percent, which estimates the population proportion for the table cell
- Standard Error of Percent

The two-way table displays weighted frequencies if your analysis includes a **WEIGHT** or **REPWEIGHTS** statement, or if you specify the **WTFREQ** option in the **TABLES** statement.

The two-way table also displays the Frequency Missing, which is the number of observations with missing values.

You can suppress the frequency counts by specifying the **NOFREQ** option in the **TABLES** statement. Also, the **NOWT** option suppresses the weighted frequencies and their standard deviations. The **NOPERCENT** option suppresses all percentages and their standard errors. The **NOCELLPERCENT** option suppresses overall cell percentages and their standard errors, but displays any other percentages (and standard errors) that you request, such as row or column percentages. The **NOSTD** option suppresses the standard errors of the percentages and the standard deviations of the weighted frequencies. The **NOTOTAL** option suppresses the row totals and column totals, as well as the overall total.

PROC SURVEYFREQ optionally displays the following information in a two-way table:

- Expected Weighted Frequency, if you specify the **EXPECTED** option
- Variance of Weighted Frequency, if you specify the **VARWT** option
- Confidence Limits for Weighted Frequency, if you specify the **CLWT** option
- Coefficient of Variation for Weighted Frequency, if you specify the **CVWT** option
- Variance of Percent, if you specify the **VAR** option
- Confidence Limits for Percent, if you specify the **CL** option
- Coefficient of Variation for Percent, if you specify the **CV** option
- Design Effect for Percent, if you specify the **DEFF** option
- Row Percent, which estimates the population proportion of the row total, if you specify the **ROW** option
- Standard Error of Row Percent, if you specify the **ROW** option
- Variance of Row Percent, if you specify the **VAR** option and the **ROW** option
- Confidence Limits for Row Percent, if you specify the **CL** option and the **ROW** option
- Coefficient of Variation for Row Percent, if you specify the **CV** option and the **ROW** option
- Design Effect for Row Percent, if you specify the **ROW(DEFF)** option
- Column Percent, which estimates the population proportion of the column total, if you specify the **COLUMN** option
- Standard Error of Column Percent, if you specify the **COLUMN** option

- Variance of Column Percent, if you specify the **VAR** option and the **COLUMN** option
- Confidence Limits for Column Percent, if you specify the **CL** option and the **COLUMN** option
- Coefficient of Variation for Column Percent, if you specify the **CV** option and the **COLUMN** option
- Design Effects for Column Percent, if you specify the **COLUMN(DEFF)** option

## Statistical Tests

If you specify the **CHISQ** option for the Rao-Scott chi-square test or the **LRCHISQ** option for the Rao-Scott likelihood ratio chi-square test, PROC SURVEYFREQ displays the following information:

- Pearson Chi-Square, if you specify the **CHISQ** option
- Likelihood Ratio Chi-Square, if you specify the **LRCHISQ** option
- Design Correction
- Rao-Scott Chi-Square, by default or if you specify the **FIRSTORDER** option
- First-Order Chi-Square, if you specify the **SECONDORDER** option
- Second-Order Chi-Square, if you specify the **SECONDORDER** option
- DF, which is the degrees of freedom for the chi-square test
- Pr > ChiSq, which is the  $p$ -value for the chi-square test
- F Value
- Num DF, which is the numerator degrees of freedom for F
- Den DF, which is the denominator degrees of freedom for F
- Pr > F, which is the  $p$ -value for the  $F$  test

If you specify the **WCHISQ** option for the Wald chi-square test or the **WLLCHISQ** option for the Wald log-linear chi-square test, PROC SURVEYFREQ displays the following information:

- Wald Chi-Square, if you specify the **WCHISQ** option
- Wald Log-Linear Chi-Square, if you specify the **WLLCHISQ** option
- F Value
- Num DF, which is the numerator degrees of freedom for F
- Den DF, which is the denominator degrees of freedom for F
- Pr > F, which is the  $p$ -value for the  $F$  test
- Adjusted F Value, for tables larger than  $2 \times 2$

- Num DF, which is the numerator degrees of freedom for Adjusted F
- Den DF, which is the denominator degrees of freedom for Adjusted F
- Pr > Adj F, which is the  $p$ -value for the Adjusted  $F$  test

## Risks and Risk Difference

If you specify the **RISK** option in the TABLES statement for a  $2 \times 2$  table, PROC SURVEYFREQ displays “Column 1 Risk Estimates” and “Column 2 Risk Estimates” tables. You can display only column 1 or column 2 risks by specifying the **RISK1** or **RISK2** option, respectively.

The “Risk Estimates” table displays the following information for Row 1, Row 2, Total, and Difference:

- Row, which identifies the risk as Row 1, Row 2, Total, or Difference
- Risk estimate
- Standard Error
- Confidence Limits

In the “Column 1 Risk Estimates” table, the row 1 risk is the column 1 percentage of row 1. The row 2 risk is the column 1 percentage of row 2, and the total risk is the column 1 percentage of the entire table. The risk difference is the row 1 risk minus the row 2 risk. In the “Column 2 Risk Estimates” table, these computations are based on column 2.

## Odds Ratio and Relative Risks

If you specify the **OR** option in the TABLES statement for a  $2 \times 2$  table, PROC SURVEYFREQ displays the “Odds Ratio” table. This table includes the following information:

- Statistic, which identifies the statistic as the Odds Ratio, the Column 1 Relative Risk, or the Column 2 Relative Risk
- Estimate
- Confidence Limits

---

## ODS Table Names

PROC SURVEYFREQ assigns a name to each table that it creates. You can use these names to refer to tables when you use the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, “Using the Output Delivery System.” See Example 90.3 for examples of storing PROC SURVEYFREQ tables as output data sets.

Table 90.8 lists the ODS table names together with their descriptions and the options required to produce the tables.

**Table 90.8** ODS Tables Produced by PROC SURVEYFREQ

| ODS Table Name     | Description                     | Statement         | Option                                              |
|--------------------|---------------------------------|-------------------|-----------------------------------------------------|
| ChiSq              | Chi-square test                 | TABLES            | CHISQ                                               |
| ChiSq1             | Modified chi-square test        | TABLES            | CHISQ(MODIFIED)                                     |
| CrossTabs          | Crosstabulation table           | TABLES            | <i>n</i> -way table request, <i>n</i> > 1           |
| HadamardMatrix     | Hadamard matrix                 | PROC              | VARMETHOD=BRR(PRINTH)                               |
| LRChiSq            | Likelihood ratio test           | TABLES            | LRCHISQ                                             |
| LRChiSq1           | Modified likelihood ratio test  | TABLES            | LRCHISQ(MODIFIED)                                   |
| OddsRatio          | Odds ratio and relative risks   | TABLES            | OR (2 × 2 table)                                    |
| OneWay             | One-way frequency table         | PROC<br>or TABLES | No TABLES statement<br>One-way table request        |
| Risk1              | Column 1 risk estimates         | TABLES            | RISK or RISK1 (2 × 2 table)                         |
| Risk2              | Column 2 risk estimates         | TABLES            | RISK or RISK2 (2 × 2 table)                         |
| StrataInfo         | Stratum information             | STRATA            | LIST                                                |
| Summary            | Data summary                    | PROC              | Default                                             |
| TableSummary       | Table summary (not displayed)   | TABLES            | Default                                             |
| VarianceEstimation | Variance estimation             | PROC              | VARMETHOD=BRR,<br>VARMETHOD=JACKKNIFE,<br>or NOMCAR |

| WLLChiSq           | Wald log-linear chi-square test | TABLES            | WLLCHISQ (two-way table)                            |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

When ODS Graphics is enabled, you can request specific plots with the PLOTS= option in the TABLES statement. To produce a weighted frequency plot, you must specify the WTFREQPLOT *plot-request* in the PLOTS= option. By default, PROC SURVEYFREQ produces all other plots that are associated with the analyses that you request in the TABLES statement. You can suppress default plots and request specific plots by using the PLOTS(ONLY)= option. See the description of the PLOTS= option for more information.

PROC SURVEYFREQ assigns a name to each graph that it creates with ODS Graphics. You can use these names to refer to the graphs. Table 90.9 lists the names of the graphs that PROC SURVEYFREQ generates together with their descriptions, their PLOTS= options (*plot-requests*), and the TABLES statement options that are required to produce the graphs.

**Table 90.9** ODS Graphs Produced by PROC SURVEYFREQ

| ODS Graph Name | Description             | PLOTS= Option | TABLES Statement Option             |
|----------------|-------------------------|---------------|-------------------------------------|
| WtFreqPlot     | Weighted frequency plot | WTFREQPLOT    | Any table request                   |
| ORPlot         | Odds ratio plot         | ODDSRATIOPLOT | OR ( $h \times 2 \times 2$ table)   |
| RelRiskPlot    | Relative risk plot      | RELRIKSPLOT   | OR ( $h \times 2 \times 2$ table)   |
| RiskDiffPlot   | Risk difference plot    | RISKDIFFPLOT  | RISK ( $h \times 2 \times 2$ table) |

## Examples: SURVEYFREQ Procedure

### Example 90.1: Two-Way Tables

This example uses the SIS\_Survey data set from the section “Getting Started: SURVEYFREQ Procedure” on page 7588. The data set contains results from a customer satisfaction survey for a student information system (SIS).

The following PROC SURVEYFREQ statements request a two-way table for Department by Response and customize the crosstabulation table display:

```

title 'Student Information System Survey';
proc surveyfreq data=SIS_Survey;
 tables Department * Response / cv deff nowt nostd nototal;
 strata State NewUser / list;
 cluster School;
 weight SamplingWeight;
run;

```

The TABLES statement requests a two-way table of Department by Response. The CV option requests coefficients of variation for the percentage estimates. The DEFF option requests design effects for the percentage estimates. The NOWT option suppresses display of the weighted frequencies, and the NOSTD option suppresses display of standard errors for the estimates. The NOTOTAL option suppresses the row totals, column totals, and overall totals.

The STRATA, CLUSTER, and WEIGHT statements provide sample design information for the procedure, so that the analysis is done according to the sample design used for the survey. The STRATA statement names the variables State and NewUser, which identify the first-stage strata. The LIST option in the STRATA statement requests a “Stratum Information” table. The CLUSTER statement names the variable School, which identifies the clusters (primary sampling units). The WEIGHT statement names the sampling weight variable.

Output 90.1.1 displays the “Data Summary” and “Stratum Information” tables produced by PROC SURVEYFREQ. The “Stratum Information” table lists the six strata in the survey and shows the number of observations and the number of clusters (schools) in each stratum.

**Output 90.1.1** Data Summary and Stratum Information

```

Student Information System Survey

The SURVEYFREQ Procedure

Data Summary

Number of Strata 6
Number of Clusters 370
Number of Observations 1850
Sum of Weights 38899.6482

Stratum Information

Stratum Index State NewUser Number of Number of
 State NewUser Obs Clusters

1 GA Renewal Customer 315 63
2 GA New Customer 355 71
3 NC Renewal Customer 280 56
4 NC New Customer 420 84
5 SC Renewal Customer 210 42
6 SC New Customer 270 54

```

Output 90.1.2 displays the two-way table of Department by Response. According to the TABLES statement options that are specified, this two-way table includes coefficients of variation and design effects for the percentage estimates, and it does not show the weighted frequencies or the standard errors of the estimates. It also does not show the row, column, and overall totals.

**Output 90.1.2** Two-Way Table of Department by Response

```

Table of Department by Response

Department Response Frequency Percent CV for Design
 State Frequency Percent Percent Effect

Faculty Very Unsatisfied 209 13.4987 0.0865 2.1586
Faculty Unsatisfied 203 13.0710 0.0868 2.0962
Faculty Neutral 346 22.4127 0.0629 2.1157
Faculty Satisfied 254 16.2006 0.0806 2.3232
Faculty Very Satisfied 98 6.2467 0.1362 2.2842

Admin/Guidance Very Unsatisfied 95 3.6690 0.1277 1.1477
Admin/Guidance Unsatisfied 123 4.6854 0.1060 1.0211
Admin/Guidance Neutral 235 9.1838 0.0700 0.9166
Admin/Guidance Satisfied 201 7.7305 0.0756 0.8848
Admin/Guidance Very Satisfied 86 3.3016 0.1252 0.9892

```

The following PROC SURVEYFREQ statements request a two-way table of Department by Response that includes row percentages, and also a Wald chi-square test of association between the two table variables:

```

title 'Student Information System Survey';
proc surveyfreq data=SIS_Survey nosummary;
 tables Department * Response / row nowt wchisq;
 strata State NewUser;
 cluster School;
 weight SamplingWeight;
run;

```

Output 90.1.3 displays the two-way table. The row percentages show the distribution of Response for Department = 'Faculty' and for Department = 'Admin/Guidance'. This is equivalent to a domain (subpopulation) analysis of Response, where the domains are Department = 'Faculty' and Department = 'Admin/Guidance'.

Output 90.1.4 displays the Wald chi-square test of association between Department and Response. The Wald chi-square is 11.44, and the corresponding adjusted  $F$  value is 2.84 with a  $p$ -value of 0.0243. This indicates a significant association between department (faculty or admin/guidance) and satisfaction with the student information system.

**Output 90.1.3** Table of Department by Response with Row Percentages

| Student Information System Survey |                  |           |         |                       |                |                           |

**Example 90.2: Multiway Tables (Domain Analysis)**

Continuing to use the SIS\_Survey data set from the section “Getting Started: SURVEYFREQ Procedure” on page 7588, this example shows how to produce multiway tables. The following PROC SURVEYFREQ statements request a table of Department by SchoolType by Response for the student information system survey:

```

title 'Student Information System Survey';
proc surveyfreq data=SIS_Survey;
 tables Department * SchoolType * Response
 SchoolType * Response;
 strata State NewUser;
 cluster School;
 weight SamplingWeight;
run;

```

The TABLES statement requests a multiway table with SchoolType as the row variable, Response as the column variable, and Department as the layer variable. This request produces a separate two-way table of SchoolType by Response for each level of the variable Department. The TABLES statement also requests a two-way table of SchoolType by Response, which totals the multiway table over both levels of Department. As in the previous examples, the STRATA, CLUSTER, and WEIGHT statements provide sample design information, so that the analysis will be done according to the design used for this survey.

Output 90.2.1 displays the multiway table produced by PROC SURVEYFREQ, which includes a table of SchoolType by Response for Department = ‘Faculty’ and for Department = ‘Admin/Guidance’. This is equivalent to a domain (subpopulation) analysis of SchoolType by Response, where the domains are Department = ‘Faculty’ and Department = ‘Admin/Guidance’.

## Example 90.3: Output Data Sets

PROC SURVEYFREQ uses the Output Delivery System (ODS) to create output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality. By using ODS, you can create a SAS data set from any piece of PROC SURVEYFREQ output. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

When selecting tables for ODS output data sets, you refer to tables by their ODS table names. Each table created by PROC SURVEYFREQ is assigned a name. See the section “ODS Table Names” on page 7668 for a list of the table names provided by PROC SURVEYFREQ.

To save the one-way table of Response from Figure 90.3 in an output data set, use an ODS OUTPUT statement as follows:

```
proc surveyfreq data=SIS_Survey;
 tables Response / cl nowt;
 ods output OneWay=ResponseTable;
 strata State NewUser;
 cluster School;
 weight SamplingWeight;
run;
```

Output 90.3.1 displays the output data set ResponseTable, which contains the one-way table of Response. This data set has six observations, and each of these observations corresponds to a row of the one-way table. The first five observations correspond to the five levels of Response, as they are ordered in the one-way table display, and the last observation corresponds to the overall total, which is the last row of the one-way table. The data set ResponseTable includes a variable corresponding to each column of the one-way table. For example, the variable Percent contains the percentage estimates, and the variables LowerCL and UpperCL contain the lower and upper confidence limits for the percentage estimates.

**Output 90.3.1** ResponseTable Output Data Set

| Obs | Table          | Response         | Frequency | Percent | StdErr | LowerCL | UpperCL |

| 2   | Table Response | Unsatisfied      | 326       | 17.7564 | 1.2712 | 15.2566 | 20.2562 |
| 3   | Table Response | Neutral          | 581       | 31.5965 | 1.5795 | 28.4904 | 34.7026 |
| 4   | Table Response | Satisfied        | 455       | 23.9311 | 1.4761 | 21.0285 | 26.8338 |
| 5   | Table Response | Very Satisfied   | 184       | 9.5483  | 0.9523 | 7.6756  | 11.4210 |
| 6   | Table Response | .                | 1850      | 100.000 | —      | —       | —       |

PROC SURVEYFREQ also creates a table summary that is not displayed. Some of the information in this table is similar to that contained in the “Data Summary” table, but the table summary describes the data that are used to analyze the specified table, while the data summary describes the entire input data set. Due to missing values, for example, the number of observations (or strata or clusters) used to analyze a particular table can differ from the number of observations (or strata or clusters) reported for the input data set in the “Data Summary” table. See the section “Missing Values” on page 7627 for more details. If you request confidence limits, the “Table Summary” table also contains the degrees of freedom and the *t*-value used to compute the confidence limits.

The following statements store the nondisplayed “Table Summary” table in the output data set ResponseSummary:

```
proc surveyfreq data=SIS_Survey;
 tables Response / cl nowt;
 ods output TableSummary=ResponseSummary;
 strata State NewUser;
 cluster School;
 weight SamplingWeight;
run;
```

Output 90.3.2 displays the output data set ResponseSummary.

**Output 90.3.2** ResponseSummary Output Data Set

| Obs | Table          | Number of Observations | Number of Strata | Number of Clusters | Degrees of Freedom | t Percentile |
|-----|----------------|------------------------|------------------|--------------------|--------------------|--------------|
| 1   | Table Response | 1850                   | 6                | 370                | 364                | 1.966503     |

## Overview: SURVEYLOGISTIC Procedure

Categorical responses arise extensively in sample survey. Common examples of responses include the following:

- binary: for example, attended graduate school or not
- ordinal: for example, mild, moderate, and severe pain
- nominal: for example, ABC, NBC, CBS, FOX TV network viewed at a certain hour

Logistic regression analysis is often used to investigate the relationship between such discrete responses and a set of explanatory variables. For a description of logistic regression for sample survey data, see Binder (1981, 1983); Roberts, Rao, and Kumar (1987); Skinner, Holt, and Smith (1989); Morel (1989); Lehtonen and Pahkinen (1995).

For binary response models, the response of a sampling unit can take a specified value or not (for example, attended graduate school or not). Suppose  $\mathbf{x}$  is a row vector of explanatory variables and  $\pi$  is the response probability to be modeled. The linear logistic model has the form

$$\text{logit}(\pi) \equiv \log\left(\frac{\pi}{1-\pi}\right) = \alpha + \mathbf{x}\boldsymbol{\beta}$$

where  $\alpha$  is the intercept parameter and  $\boldsymbol{\beta}$  is the vector of slope parameters.

The logistic model shares a common feature with the more general class of generalized linear models—namely, that a function  $g = g(\mu)$  of the expected value,  $\mu$ , of the response variable is assumed to be linearly related to the explanatory variables. Since  $\mu$  implicitly depends on the stochastic behavior of the response, and since the explanatory variables are assumed to be fixed, the function  $g$  provides the link between the random (stochastic) component and the systematic (deterministic) component of the response variable. For this reason, Nelder and Wedderburn (1972) refer to  $g(\cdot)$  as a link function. One advantage of the logit function over other link functions is that differences on the logistic scale are interpretable regardless

of whether the data are sampled prospectively or retrospectively (McCullagh and Nelder 1989, Chapter 4). Other link functions that are widely used in practice are the probit function and the complementary log-log function. The SURVEYLOGISTIC procedure enables you to choose one of these link functions, resulting in fitting a broad class of binary response models of the form

$$g(\pi) = \alpha + \mathbf{x}\boldsymbol{\beta}$$

For ordinal response models, the response  $Y$  of an individual or an experimental unit might be restricted to one of a usually small number of ordinal values, denoted for convenience by  $1, \dots, D, D + 1$  ( $D \geq 1$ ). For example, pain severity can be classified into three response categories as 1=mild, 2=moderate, and 3=severe. The SURVEYLOGISTIC procedure fits a common slopes cumulative model, which is a parallel lines regression model based on the cumulative probabilities of the response categories rather than on their individual probabilities. The cumulative model has the form

$$g(\Pr(Y \leq d | \mathbf{x})) = \alpha_d + \mathbf{x}\boldsymbol{\beta}, \quad 1 \leq d \leq D$$

where  $\alpha_1, \dots, \alpha_k$  are  $k$  intercept parameters and  $\boldsymbol{\beta}$  is the vector of slope parameters. This model has been considered by many researchers. Aitchison and Silvey (1957) and Ashford (1959) employ a probit scale and provide a maximum likelihood analysis; Walker and Duncan (1967) and Cox and Snell (1989) discuss the use of the log-odds scale. For the log-odds scale, the cumulative logit model is often referred to as the *proportional odds* model.

For nominal response logistic models, where the  $D + 1$  possible responses have no natural ordering, the logit model can also be extended to a *generalized logit* model, which has the form

$$\log \left( \frac{\Pr(Y = i | \mathbf{x})}{\Pr(Y = D + 1 | \mathbf{x})} \right) = \alpha_i + \mathbf{x}\boldsymbol{\beta}_i, \quad i = 1, \dots, D$$

where the  $\alpha_1, \dots, \alpha_D$  are  $D$  intercept parameters and the  $\boldsymbol{\beta}_1, \dots, \boldsymbol{\beta}_D$  are  $D$  vectors of parameters. These models were introduced by McFadden (1974) as the *discrete choice* model, and they are also known as *multinomial* models.

The SURVEYLOGISTIC procedure fits linear logistic regression models for discrete response survey data by the method of maximum likelihood. For statistical inferences, PROC SURVEYLOGISTIC incorporates complex survey sample designs, including designs with stratification, clustering, and unequal weighting.

The maximum likelihood estimation is carried out with either the Fisher scoring algorithm or the Newton-Raphson algorithm. You can specify starting values for the parameter estimates. The logit link function in the ordinal logistic regression models can be replaced by the probit function or the complementary log-log function.

Odds ratio estimates are displayed along with parameter estimates. You can also specify the change in the explanatory variables for which odds ratio estimates are desired.

Variances of the regression parameters and odds ratios are computed by using either the Taylor series (linearization) method or replication (resampling) methods to estimate sampling errors of estimators based on complex sample designs (Binder 1983; Särndal, Swensson, and Wretman 1992; Wolter 2007; Rao, Wu, and Yue 1992).

The SURVEYLOGISTIC procedure enables you to specify categorical variables (also known as CLASS variables) as explanatory variables. It also enables you to specify interaction terms in the same way as in the LOGISTIC procedure.

Like many procedures in SAS/STAT software that allow the specification of CLASS variables, the SURVEYLOGISTIC procedure provides a CONTRAST statement for specifying customized hypothesis tests concerning the model parameters. The CONTRAST statement also provides estimation of individual rows of contrasts, which is particularly useful for obtaining odds ratio estimates for various levels of the CLASS variables.

## Getting Started: SURVEYLOGISTIC Procedure

The SURVEYLOGISTIC procedure is similar to the LOGISTIC procedure and other regression procedures in the SAS System. See Chapter 54, “The LOGISTIC Procedure,” for general information about how to perform logistic regression by using SAS. PROC SURVEYLOGISTIC is designed to handle sample survey data, and thus it incorporates the sample design information into the analysis.

The following example illustrates how to use PROC SURVEYLOGISTIC to perform logistic regression for sample survey data.

In the customer satisfaction survey example in the section “Getting Started: SURVEYSELECT Procedure” on page 8021 of Chapter 95, “The SURVEYSELECT Procedure,” an Internet service provider conducts a customer satisfaction survey. The survey population consists of the company’s current subscribers from four states: Alabama (AL), Florida (FL), Georgia (GA), and South Carolina (SC). The company plans to select a sample of customers from this population, interview the selected customers and ask their opinions on customer service, and then make inferences about the entire population of subscribers from the sample data. A stratified sample is selected by using the probability proportional to size (PPS) method. The sample design divides the customers into strata depending on their types (‘Old’ or ‘New’) and their states (AL, FL, GA, SC). There are eight strata in all. Within each stratum, customers are selected and interviewed by using the PPS with replacement method, where the size variable is Usage. The stratified PPS sample contains 192 customers. The data are stored in the SAS data set SampleStrata. Figure 91.1 displays the first 10 observations of this data set.

**Figure 91.1** Stratified PPS Sample (First 10 Observations)

| Obs                                                                                | State | Type | Customer ID | Rating                | Usage | Sampling Weight |
| 1                                                                                  | AL    | New  | 24394278    | Neutral               | 13.17 | 26.358          |
| 2                                                                                  | AL    | New  | 64798692    | Extremely Unsatisfied | 15.53 | 22.352          |
| 3                                                                                  | AL    | New  | 75375074    | Unsatisfied           | 99.11 | 3.501           |
| 4                                                                                  | AL    | New  | 262831809   | Neutral               | 5.40  | 64.228          |
| 5                                                                                  | AL    | New  | 294428658   | Extremely Satisfied   | 1.17  | 297.488         |
| 6                                                                                  | AL    | New  | 336222949   | Unsatisfied           | 38.69 | 8.970           |
| 7                                                                                  | AL    | New  | 351929023   | Extremely Satisfied   | 2.72  | 127.475         |
| 8                                                                                  | AL    | New  | 366142640   | Satisfied             | 2.61  | 132.958         |
| 9                                                                                  | AL    | New  | 371478614   | Neutral               | 14.36 | 24.173          |
| 10                                                                                 | AL    | New  | 477172230   | Neutral               | 4.06  | 85.489          |

In the SAS data set `SampleStrata`, the variable `CustomerID` uniquely identifies each customer. The variable `State` contains the state of the customer's address. The variable `Type` equals 'Old' if the customer has subscribed to the service for more than one year; otherwise, the variable `Type` equals 'New'. The variable `Usage` contains the customer's average monthly service usage, in hours. The variable `Rating` contains the customer's responses to the survey. The sample design uses an unequal probability sampling method, with the sampling weights stored in the variable `SamplingWeight`.

The following SAS statements fit a cumulative logistic model between the satisfaction levels and the Internet usage by using the stratified PPS sample:

```

title 'Customer Satisfaction Survey';
proc surveylogistic data=SampleStrata;
 strata state type/list;
 model Rating (order=internal) = Usage;
 weight SamplingWeight;
run;

```

The PROC SURVEYLOGISTIC statement invokes the SURVEYLOGISTIC procedure. The STRATA statement specifies the stratification variables `State` and `Type` that are used in the sample design. The LIST option requests a summary of the stratification. In the MODEL statement, `Rating` is the response variable and `Usage` is the explanatory variable. The ORDER=internal is used for the response variable `Rating` to ask the procedure to order the response levels by using the internal numerical value (1–5) instead of the formatted character value. The WEIGHT statement specifies the variable `SamplingWeight` that contains the sampling weights.

The results of this analysis are shown in the following figures.

**Figure 91.2** Stratified PPS Sample, Model Information

| Weight Variable              | SamplingWeight          | Sampling Weight |
| Model                        | Cumulative Logit        |                 |
| Optimization Technique       | Fisher's Scoring        |                 |
| Variance Adjustment          | Degrees of Freedom (DF) |                 |

PROC SURVEYLOGISTIC first lists the following model fitting information and sample design information in Figure 91.2:

- The link function is the logit of the cumulative of the lower response categories.
- The Fisher scoring optimization technique is used to obtain the maximum likelihood estimates for the regression coefficients.
- The response variable is Rating, which has five response levels.
- The stratification variables are State and Type.
- There are eight strata in the sample.
- The weight variable is SamplingWeight.
- The **variance adjustment method** used for the regression coefficients is the default degrees of freedom adjustment.

Figure 91.3 lists the number of observations in the data set and the number of observations used in the analysis. Since there is no missing value in this example, observations in the entire data set are used in the analysis. The sums of weights are also reported in this table.

**Figure 91.3** Stratified PPS Sample, Number of Observations

|                             |          |
|-----------------------------|----------|
| Number of Observations Read | 192      |
| Number of Observations Used | 192      |
| Sum of Weights Read         | 11326.25 |
| Sum of Weights Used         | 11326.25 |

The “Response Profile” table in Figure 91.4 lists the five response levels, their ordered values, and their total frequencies and total weights for each category. Due to the ORDER=INTERNAL option for the response variable Rating, the category “Extremely Unsatisfied” has the Ordered Value 1, the category “Unsatisfied” has the Ordered Value 2, and so on.

**Figure 91.4** Stratified PPS Sample, Response Profile

| Response Profile |                       |                 |              |
|------------------|-----------------------|-----------------|--------------|
| Ordered Value    | Rating                | Total Frequency | Total Weight |
| 1                | Extremely Unsatisfied | 58              | 2368.8598    |
| 2                | Unsatisfied           | 47              | 1606.9657    |
| 3                | Neutral               | 44              | 2594.3564    |
| 4                | Satisfied             | 35              | 1898.5839    |
| 5                | Extremely Satisfied   | 8               | 2857.4848    |

Probabilities modeled are cumulated over the lower Ordered Values.

Figure 91.5 displays the output of the stratification summary. There are a total of eight strata, and each stratum is defined by the customer types within each state. The table also shows the number of customers within each stratum.

**Figure 91.5** Stratified PPS Sample, Stratification Summary

| Stratum Information |       |      |       |
|---------------------|-------|------|-------|
| Stratum Index       | State | Type | N Obs |
| 1                   | AL    | New  | 24    |
| 2                   |       | Old  | 23    |
| 3                   | FL    | New  | 25    |
| 4                   |       | Old  | 22    |
| 5                   | GA    | New  | 25    |
| 6                   |       | Old  | 24    |
| 7                   | SC    | New  | 24    |
| 8                   |       | Old  | 25    |

Figure 91.6 shows the chi-square test for testing the proportional odds assumption. The test is highly significant, which indicates that the cumulative logit model might not adequately fit the data.

**Figure 91.6** Stratified PPS Sample, Testing the Proportional Odds Assumption

| Score Test for the Proportional Odds Assumption |    |            |
|-------------------------------------------------|----|------------|
| Chi-Square                                      | DF | Pr > ChiSq |
| 617.8597                                        | 3  | <.0001     |

Figure 91.7 shows the iteration algorithm converged to obtain the MLE for this example. The “Model Fit Statistics” table contains the Akaike information criterion (AIC), the Schwarz criterion (SC), and the negative of twice the log likelihood ( $-2 \log L$ ) for the intercept-only model and the fitted model. AIC and SC can be used to compare different models, and the ones with smaller values are preferred.

**Figure 91.7** Stratified PPS Sample, Model Fitting Information

| Model Convergence Status                      |                |                          |
|-----------------------------------------------|----------------|--------------------------|
| Convergence criterion (GCONV=1E-8) satisfied. |                |                          |
| Model Fit Statistics                          |                |                          |
| Criterion                                     | Intercept Only | Intercept and Covariates |

## Syntax: SURVEYLOGISTIC Procedure

The following statements are available in the SURVEYLOGISTIC procedure:

```

PROC SURVEYLOGISTIC < options > ;
 BY variables ;
 CLASS variable < (v-options) > < variable < (v-options) > ... > < / v-options > ;
 CLUSTER variables ;
 CONTRAST 'label' effect values < , ... effect values > < / options > ;
 DOMAIN variables < variable*variable variable*variable*variable ... > ;
 EFFECT name = effect-type (variables < / options >) ;
 ESTIMATE < 'label' > estimate-specification < / options > ;
 FREQ variable ;
 LSMEANS < model-effects > < / options > ;
 LSMESTIMATE model-effect lsmestimate-specification < / options > ;
 MODEL events/trials = < effects < / options > > ;
 MODEL variable < (v-options) > = < effects > < / options > ;
 OUTPUT < OUT=SAS-data-set > < options > < / option > ;
 REPWEIGHTS variables < / options > ;
 SLICE model-effect < / options > ;
 STORE < OUT= > item-store-name < / LABEL='label' > ;
 STRATA variables < / option > ;
 < label: > TEST equation1 < , ... , equationk > < / options > ;
 UNITS independent1 = list1 < ... independentk = listk > < / option > ;
 WEIGHT variable ;

```

The PROC SURVEYLOGISTIC and MODEL statements are required.

The CLASS, CLUSTER, CONTRAST, EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, REPWEIGHTS, SLICE, STRATA, TEST statements can appear multiple times. You should use only one of each following statements: MODEL, WEIGHT, STORE, OUTPUT, and UNITS.

The CLASS statement (if used) must precede the MODEL statement, and the CONTRAST statement (if used) must follow the MODEL statement.

The rest of this section provides detailed syntax information for each of the preceding statements, except the EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, SLICE, STORE statements. These statements are also available in many other procedures. Summary descriptions of functionality and syntax for these statements are shown in this chapter, and full documentation about them is available in Chapter 19, “Shared Concepts and Topics.”

The syntax descriptions begin with the PROC SURVEYLOGISTIC statement; the remaining statements are covered in alphabetical order.

## PROC SURVEYLOGISTIC Statement

**PROC SURVEYLOGISTIC** < options > ;

The PROC SURVEYLOGISTIC statement invokes the SURVEYLOGISTIC procedure. Optionally, it identifies input data sets, controls the ordering of the response levels, and specifies the variance estimation method. The PROC SURVEYLOGISTIC statement is required.

Table 91.1 summarizes the options available in the PROC SURVEYLOGISTIC statement.

**Table 91.1** PROC SURVEYLOGISTIC Statement Options

| Option     | Description                                                      |
|------------|------------------------------------------------------------------|
| ALPHA=     | Sets the confidence level for confidence limits                  |
| DATA=      | Names the SAS data set containing the data to be analyze         |
| INEST=     | Names the SAS data set that contains initial estimates           |
| MISSING    | Treats missing values as a nonmissing category                   |
| NAMELEN=   | Specifies the length of effect names                             |
| NOMCAR     | Treats missing values as <i>not missing completely at random</i> |
| NOSORT     | Suppresses the internal sorting process                          |
| ORDER=     | Specifies the sort order                                         |
| RATE=      | Specifies the sampling rate                                      |
| TOTAL=     | Specifies the total number of primary sampling units             |
| VARMETHOD= | Specifies the variance estimation method                         |

### ALPHA=*value*

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of  $\alpha$  produces  $100(1 - \alpha)\%$  confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

### DATA=*SAS-data-set*

names the SAS data set containing the data to be analyzed. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

### INEST=*SAS-data-set*

names the SAS data set that contains initial estimates for all the parameters in the model. BY-group processing is allowed in setting up the INEST= data set. See the section “[INEST= Data Set](#)” on page 7733 for more information.

### MISSING

treats missing values as a valid (nonmissing) category for all categorical variables, which include [CLASS](#), [STRATA](#), [CLUSTER](#), and [DOMAIN](#) variables.

By default, if you do not specify the MISSING option, an observation is excluded from the analysis if it has a missing value. For more information, see the section “[Missing Values](#)” on page 7723.

**NAMELEN=*n***

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

**NOMCAR**

requests that the procedure treat missing values in the variance computation as *not missing completely at random* (NOMCAR) for Taylor series variance estimation. When you specify the NOMCAR option, PROC SURVEYLOGISTIC computes variance estimates by analyzing the nonmissing values as a domain or subpopulation, where the entire population includes both nonmissing and missing domains. See the section “Missing Values” on page 7723 for more details.

By default, PROC SURVEYLOGISTIC completely excludes an observation from analysis if that observation has a missing value, unless you specify the MISSING option. Note that the NOMCAR option has no effect on a classification variable when you specify the MISSING option, which treats missing values as a valid nonmissing level.

The NOMCAR option applies only to Taylor series variance estimation. The replication methods, which you request with the VARMETHOD=BRR and VARMETHOD=JACKKNIFE options, do not use the NOMCAR option.

**NOSORT**

suppresses the internal sorting process to shorten the computation time if the data set is presorted by the STRATA and CLUSTER variables. By default, the procedure sorts the data by the STRATA variables if you use the STRATA statement; then the procedure sorts the data by the CLUSTER variables within strata. If your data are already stored by the order of STRATA and CLUSTER variables, then you can specify this option to omit this sorting process to reduce the usage of computing resources, especially when your data set is very large. However, if you specify this NOSORT option while your data are not presorted by STRATA and CLUSTER variables, then any changes in these variables creates a new stratum or cluster.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of the response variable. This option, except for ORDER=FREQ, also determines the sort order for the levels of CIUSTER and DOMAIN variables and controls STRATA variable levels in the “Stratum Information” table. By default, ORDER=INTERNAL. However, if an ORDER= option is specified after the response variable, in the MODEL statement, it overrides this option for the response variable. This option does not affect the ordering of the CLASS variable levels; see the ORDER= option in the CLASS statement for more information.

**RATE=*value* | SAS-data-set****R=*value* | SAS-data-set**

specifies the sampling rate as a nonnegative *value*, or specifies an input data set that contains the stratum sampling rates. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the RATE= option for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option.

If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of PSUs selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative *value* for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 7734 for more details.

The *value* in the RATE= option or the values of `_RATE_` in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYLOGISTIC converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

If you do not specify the TOTAL= or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= and RATE= options.

**TOTAL=***value* | *SAS-data-set*

**N=***value* | *SAS-data-set*

specifies the total number of primary sampling units in the study population as a positive *value*, or specifies an input data set that contains the stratum population totals. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the TOTAL= option for BRR or jackknife variance estimation, which you request with the `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE` option.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 7734 for more details.

If you do not specify the TOTAL= or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= and RATE= options.

**VARMETHOD=BRR** <(method-options)>

**VARMETHOD=JACKKNIFE** | **JK** <(method-options)>

**VARMETHOD=TAYLOR**

specifies the variance estimation method. `VARMETHOD=TAYLOR` requests the Taylor series method, which is the default if you do not specify the `VARMETHOD=` option or the `REPWEIGHTS` statement. `VARMETHOD=BRR` requests variance estimation by balanced repeated replication (BRR), and `VARMETHOD=JACKKNIFE` requests variance estimation by the delete-1 jackknife method.

For `VARMETHOD=BRR` and `VARMETHOD=JACKKNIFE` you can specify *method-options* in parentheses. [Table 91.2](#) summarizes the available *method-options*.

**Table 91.2** Variance Estimation Options

| <b>VARMETHOD=</b> | <b>Variance Estimation Method</b> | <i>Method-Options</i>                                                                                                          |
|-------------------|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| BRR               | Balanced repeated replication     | FAY <i>&lt;=value&gt;</i><br>HADAMARD= <i>SAS-data-set</i><br>OUTWEIGHTS= <i>SAS-data-set</i><br>PRINTH<br>REPS= <i>number</i> |
| JACKKNIFE         | Jackknife                         | OUTJKCOEFS= <i>SAS-data-set</i><br>OUTWEIGHTS= <i>SAS-data-set</i>                                                             |
| TAYLOR            | Taylor series linearization       | None                                                                                                                           |

*Method-options* must be enclosed in parentheses following the method keyword. For example:

```
varmethod=BRR (reps=60 outweights=myReplicateWeights)
```

The following values are available for the VARMETHOD= option:

**BRR** *<(method-options)>*

requests **balanced repeated replication** (BRR) variance estimation. The BRR method requires a stratified sample design with two primary sampling units (PSUs) per stratum. See the section “**Balanced Repeated Replication (BRR) Method**” on page 7740 for more information.

You can specify the following *method-options* in parentheses following VARMETHOD=BRR:

**FAY** *<=value>*

requests **Fay’s method**, a modification of the BRR method, for variance estimation. See the section “**Fay’s BRR Method**” on page 7741 for more information.

You can specify the *value* of the Fay coefficient, which is used in converting the original sampling weights to replicate weights. The Fay coefficient must be a nonnegative number less than 1. By default, the value of the Fay coefficient equals 0.5.

**HADAMARD**=*SAS-data-set*

**H**=*SAS-data-set*

names a SAS data set that contains the **Hadamard matrix** for BRR replicate construction. If you do not provide a Hadamard matrix with the HADAMARD= *method-option*, PROC SURVEYLOGISTIC generates an appropriate Hadamard matrix for replicate construction. See the sections “**Balanced Repeated Replication (BRR) Method**” on page 7740 and “**Hadamard Matrix**” on page 7743 for details.

If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the HADAMARD= *method-option*.

In the HADAMARD= input data set, each variable corresponds to a column of the Hadamard matrix, and each observation corresponds to a row of the matrix. You can use any variable names in the HADAMARD= data set. All values in the data set must equal either 1 or -1. You must ensure that the matrix you provide is indeed a Hadamard matrix—that is,  $\mathbf{A}'\mathbf{A} = R\mathbf{I}$ , where  $\mathbf{A}$  is the Hadamard matrix of dimension  $R$  and  $\mathbf{I}$  is an identity matrix. PROC SURVEYLOGISTIC does not check the validity of the Hadamard matrix that you provide.

The HADAMARD= input data set must contain at least  $H$  variables, where  $H$  denotes the number of first-stage strata in your design. If the data set contains more than  $H$  variables, the procedure uses only the first  $H$  variables. Similarly, the HADAMARD= input data set must contain at least  $H$  observations.

If you do not specify the REPS= *method-option*, then the number of replicates is taken to be the number of observations in the HADAMARD= input data set. If you specify the number of replicates—for example, REPS=*nreps*—then the first *nreps* observations in the HADAMARD= data set are used to construct the replicates.

You can specify the PRINTH option to display the Hadamard matrix that the procedure uses to construct replicates for BRR.

#### **OUTWEIGHTS=SAS-data-set**

names a SAS data set that contains replicate weights. See the section “Balanced Repeated Replication (BRR) Method” on page 7740 for information about replicate weights. See the section “Replicate Weights Output Data Set” on page 7751 for more details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= *method-option* is not available when you provide replicate weights with the REPWEIGHTS statement.

#### **PRINTH**

displays the Hadamard matrix.

When you provide your own Hadamard matrix with the HADAMARD= *method-option*, only the rows and columns of the Hadamard matrix that are used by the procedure are displayed. See the sections “Balanced Repeated Replication (BRR) Method” on page 7740 and “Hadamard Matrix” on page 7743 for details.

The PRINTH *method-option* is not available when you provide replicate weights with the REPWEIGHTS statement because the procedure does not use a Hadamard matrix in this case.

#### **REPS=number**

specifies the number of replicates for BRR variance estimation. The value of *number* must be an integer greater than 1.

If you do not provide a Hadamard matrix with the HADAMARD= *method-option*, the number of replicates should be greater than the number of strata

and should be a multiple of 4. See the section “Balanced Repeated Replication (BRR) Method” on page 7740 for more information. If a Hadamard matrix cannot be constructed for the REPS= value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the REPS= value that you specify.

If you provide a Hadamard matrix with the HADAMARD= *method-option*, the value of REPS= must not be less than the number of rows in the Hadamard matrix. If you provide a Hadamard matrix and do not specify the REPS= *method-option*, the number of replicates equals the number of rows in the Hadamard matrix.

If you do not specify the REPS= or HADAMARD= *method-option* and do not include a REPWEIGHTS statement, the number of replicates equals the smallest multiple of 4 that is greater than the number of strata.

If you provide replicate weights with the REPWEIGHTS statement, the procedure does not use the REPS= *method-option*. With a REPWEIGHTS statement, the number of replicates equals the number of REPWEIGHTS variables.

#### JACKKNIFE | JK <(method-options)>

requests variance estimation by the delete-1 jackknife method. See the section “Jackknife Method” on page 7742 for details. If you provide replicate weights with a REPWEIGHTS statement, VARMETHOD=JACKKNIFE is the default variance estimation method.

You can specify the following *method-options* in parentheses following VARMETHOD=JACKKNIFE:

##### **OUTJKCOEFS=SAS-data-set**

names a SAS data set that contains jackknife coefficients. See the section “Jackknife Method” on page 7742 for information about jackknife coefficients. See the section “Jackknife Coefficients Output Data Set” on page 7751 for more details about the contents of the OUTJKCOEFS= data set.

##### **OUTWEIGHTS=SAS-data-set**

names a SAS data set that contains replicate weights. See the section “Jackknife Method” on page 7742 for information about replicate weights. See the section “Replicate Weights Output Data Set” on page 7751 for more details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= *method-option* is not available when you provide replicate weights with the REPWEIGHTS statement.

#### TAYLOR

requests Taylor series variance estimation. This is the default method if you do not specify the VARMETHOD= option or a REPWEIGHTS statement. See the section “Taylor Series (Linearization)” on page 7739 for more information.

---

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC SURVEYLOGISTIC to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the SURVEYLOGISTIC procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid domain (subpopulation) analysis, where the total number of units in the subpopulation is not known with certainty. You should use the DOMAIN statement to obtain domain analysis. For more information about subpopulation analysis for sample survey data, see Cochran (1977).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

**CLASS** *variable* <(v-options)> <*variable* <(v-options)> ... > </v-options> ;

The CLASS statement names the classification variables to be used in the analysis. The CLASS statement must precede the MODEL statement. You can specify various *v-options* for each variable by enclosing them in parentheses after the variable name. You can also specify global *v-options* for the CLASS statement by placing them after a slash (/). Global *v-options* are applied to all the variables specified in the CLASS statement. However, individual CLASS variable *v-options* override the global *v-options*.

**CPREFIX=** *n*

specifies that, at most, the first *n* characters of a CLASS variable name be used in creating names for the corresponding dummy variables. The default is  $32 - \min(32, \max(2, f))$ , where *f* is the formatted length of the CLASS variable.

**DESCENDING**

**DESC**

reverses the sort order of the classification variable.

**LPREFIX= *n***

specifies that, at most, the first *n* characters of a CLASS variable label be used in creating labels for the corresponding dummy variables.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the order in which to sort the levels of the classification variables.

This option applies to the levels for all classification variables, except when you use the (default) ORDER=FORMATTED option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

| Value of ORDER=  | Levels Sorted By                                                                                                                       |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DATA</b>      | Order of appearance in the input data set                                                                                              |
| <b>FORMATTED</b> | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| <b>FREQ</b>      | Descending frequency count; levels with the most observations come first in the order                                                  |
| <b>INTERNAL</b>  | Unformatted value                                                                                                                      |

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent. For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**PARAM=keyword**

specifies the parameterization method for the classification variable or variables. Design matrix columns are created from CLASS variables according to the following coding schemes; the default is PARAM=EFFECT.

|                          |                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------|
| EFFECT                   | specifies effect coding                                                                               |
| GLM                      | specifies less-than-full-rank, reference cell coding; this option can be used only as a global option |
| ORDINAL                  | specifies the cumulative parameterization for an ordinal CLASS variable                               |
| POLYNOMIAL   POLY        | specifies polynomial coding                                                                           |
| REFERENCE   REF          | specifies reference cell coding                                                                       |
| ORTHEFFECT               | orthogonalizes PARAM=EFFECT                                                                           |
| ORTHORDINAL   ORTHOTHERM | orthogonalizes PARAM=ORDINAL                                                                          |
| ORTHPOLY                 | orthogonalizes PARAM=POLYNOMIAL                                                                       |
| ORTHREF                  | orthogonalizes PARAM=REFERENCE                                                                        |

If PARAM=ORTHPOLY or PARAM=POLY, and the CLASS levels are numeric, then the ORDER= option in the CLASS statement is ignored, and the internal, unformatted values are used.

EFFECT, POLYNOMIAL, REFERENCE, ORDINAL, and their orthogonal parameterizations are full rank. The REF= option in the CLASS statement determines the reference level for EFFECT, REFERENCE, and their orthogonal parameterizations.

Parameter names for a CLASS predictor variable are constructed by concatenating the CLASS variable name with the CLASS levels. However, for the POLYNOMIAL and orthogonal parameterizations, parameter names are formed by concatenating the CLASS variable name and keywords that reflect the parameterization.

**REFERENCE=** 'level' | keyword

**REF=** 'level' | keyword

specifies the reference level for PARAM=EFFECT or PARAM=REFERENCE. For an individual (but not a global) variable REF= *option*, you can specify the *level* of the variable to use as the reference level. For a global or individual variable REF= *option*, you can use one of the following *keywords*. The default is REF=LAST.

|       |                                                 |
|-------|-------------------------------------------------|
| FIRST | designates the first ordered level as reference |
| LAST  | designates the last ordered level as reference  |

---

## CLUSTER Statement

**CLUSTER** *variables* ;

The CLUSTER statement names variables that identify the clusters in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If you provide replicate weights for BRR or jackknife variance estimation with the REPWEIGHTS statement, you do not need to specify a CLUSTER statement.

If your sample design has clustering at multiple stages, you should identify only the first-stage clusters (primary sampling units (PSUs)), in the CLUSTER statement. See the section “Primary Sampling Units (PSUs)” on page 7734 for more information.

The CLUSTER *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

When determining levels of a CLUSTER variable, an observation with missing values for this CLUSTER variable is excluded, unless you specify the MISSING option. For more information, see the section “Missing Values” on page 7723.

You can use multiple CLUSTER statements to specify cluster variables. The procedure uses variables from all CLUSTER statements to create clusters.

## CONTRAST Statement

**CONTRAST** *'label'* *row-description* <, ..., *row-description* </ options>> ;

where a *row-description* is defined as follows:

*effect values* <, ..., *effect values*>

The CONTRAST statement provides a mechanism for obtaining customized hypothesis tests. It is similar to the CONTRAST statement in PROC LOGISTIC and PROC GLM, depending on the coding schemes used with any classification variables involved.

The CONTRAST statement enables you to specify a matrix,  $\mathbf{L}$ , for testing the hypothesis  $\mathbf{L}\boldsymbol{\theta} = 0$ , where  $\boldsymbol{\theta}$  is the parameter vector. You must be familiar with the details of the model parameterization that PROC SURVEYLOGISTIC uses (for more information, see the [PARAM=](#) option in the section “[CLASS Statement](#)” on page 7697). Optionally, the CONTRAST statement enables you to estimate each row,  $\mathbf{l}_i\boldsymbol{\theta}$ , of  $\mathbf{L}\boldsymbol{\theta}$  and test the hypothesis  $\mathbf{l}_i\boldsymbol{\theta} = 0$ . Computed statistics are based on the asymptotic chi-square distribution of the Wald statistic.

There is no limit to the number of CONTRAST statements that you can specify, but they must appear after the [MODEL](#) statement.

The following parameters can be specified in the CONTRAST statement:

- label* identifies the contrast on the output. A label is required for every contrast specified, and it must be enclosed in quotes.
- effect* identifies an effect that appears in the MODEL statement. The name INTERCEPT can be used as an effect when one or more intercepts are included in the model. You do not need to include all effects that are included in the MODEL statement.
- values* are constants that are elements of the  $\mathbf{L}$  matrix associated with the effect. To correctly specify your contrast, it is crucial to know the ordering of parameters within each effect and the variable levels associated with any parameter. The “Class Level Information” table shows the ordering of levels within variables. The E option, described later in this section, enables you to verify the proper correspondence of *values* to parameters.

The rows of  $\mathbf{L}$  are specified in order and are separated by commas. Multiple degree-of-freedom hypotheses can be tested by specifying multiple *row-descriptions*. For any of the full-rank parameterizations, if an effect is not specified in the CONTRAST statement, all of its coefficients in the  $\mathbf{L}$  matrix are set to 0. If too many values are specified for an effect, the extra ones are ignored. If too few values are specified, the remaining ones are set to 0.

When you use effect coding (by default or by specifying [PARAM=EFFECT](#) in the CLASS statement), all parameters are directly estimable (involve no other parameters).

For example, suppose an effect that is coded CLASS variable A has four levels. Then there are three parameters ( $\alpha_1, \alpha_2, \alpha_3$ ) that represent the first three levels, and the fourth parameter is represented by

$$-\alpha_1 - \alpha_2 - \alpha_3$$

To test the first versus the fourth level of A, you would test

$$\alpha_1 = -\alpha_1 - \alpha_2 - \alpha_3$$

or, equivalently,

$$2\alpha_1 + \alpha_2 + \alpha_3 = 0$$

which, in the form  $\mathbf{L}\boldsymbol{\theta} = 0$ , is

$$\begin{bmatrix} 2 & 1 & 1 \end{bmatrix} \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} = 0$$

Therefore, you would use the following CONTRAST statement:

```
contrast '1 vs. 4' A 2 1 1;
```

To contrast the third level with the average of the first two levels, you would test

$$\frac{\alpha_1 + \alpha_2}{2} = \alpha_3$$

or, equivalently,

$$\alpha_1 + \alpha_2 - 2\alpha_3 = 0$$

Therefore, you would use the following CONTRAST statement:

```
contrast '1&2 vs. 3' A 1 1 -2;
```

Other CONTRAST statements are constructed similarly. For example:

```
contrast '1 vs. 2' A 1 -1 0;
contrast '1&2 vs. 4' A 3 3 2;
contrast '1&2 vs. 3&4' A 2 2 0;
contrast 'Main Effect' A 1 0 0,
 A 0 1 0,
 A 0 0 1;
```

When you use the less-than-full-rank parameterization (by specifying `PARAM=GLM` in the `CLASS` statement), each row is checked for estimability. If `PROC SURVEYLOGISTIC` finds a contrast to be nonestimable, it displays missing values in corresponding rows in the results. `PROC SURVEYLOGISTIC` handles missing level combinations of classification variables in the same manner as `PROC LOGISTIC`. Parameters corresponding to missing level combinations are not included in the model. This convention can affect the way in which you specify the `L` matrix in your `CONTRAST` statement. If the elements of `L` are not specified for an effect that contains a specified effect, then the elements of the specified effect are distributed over the levels of the higher-order effect just as the `LOGISTIC` procedure does for its `CONTRAST` and `ESTIMATE` statements. For example, suppose that the model contains effects `A` and `B` and their interaction `A*B`. If you specify a `CONTRAST` statement involving `A` alone, the `L` matrix contains nonzero terms for both `A` and `A*B`, since `A*B` contains `A`.

The degrees of freedom is the number of linearly independent constraints implied by the `CONTRAST` statement—that is, the rank of `L`.

You can specify the following options after a slash (/):

**ALPHA=***value*

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of  $\alpha$  produces  $100(1 - \alpha)\%$  confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

**E**

requests that the **L** matrix be displayed.

**ESTIMATE=***keyword*

requests that each individual contrast (that is, each row,  $\mathbf{l}_i\boldsymbol{\beta}$ , of  $\mathbf{L}\boldsymbol{\beta}$ ) or exponentiated contrast ( $e^{\mathbf{l}_i\boldsymbol{\beta}}$ ) be estimated and tested. PROC SURVEYLOGISTIC displays the point estimate, its standard error, a Wald confidence interval, and a Wald chi-square test for each contrast. The significance level of the confidence interval is controlled by the ALPHA= option. You can estimate the contrast or the exponentiated contrast ( $e^{\mathbf{l}_i\boldsymbol{\beta}}$ ), or both, by specifying one of the following *keywords*:

|      |                                                                              |
|------|------------------------------------------------------------------------------|
| PARM | specifies that the contrast itself be estimated                              |
| EXP  | specifies that the exponentiated contrast be estimated                       |
| BOTH | specifies that both the contrast and the exponentiated contrast be estimated |

**SINGULAR=***value*

tunes the estimability checking. If  $\mathbf{v}$  is a vector, define  $\text{ABS}(\mathbf{v})$  to be the largest absolute value of the elements of  $\mathbf{v}$ . For a row vector  $\mathbf{l}$  of the matrix **L**, define

$$c = \begin{cases} \text{ABS}(\mathbf{l}) & \text{if } \text{ABS}(\mathbf{l}) > 0 \\ 1 & \text{otherwise} \end{cases}$$

If  $\text{ABS}(\mathbf{l} - \mathbf{I}\mathbf{H})$  is greater than  $c*\textit{value}$ , then  $\mathbf{l}\boldsymbol{\beta}$  is declared nonestimable. The **H** matrix is the Hermite form matrix  $\mathbf{I}_0^{-1}\mathbf{I}_0$ , where  $\mathbf{I}_0^{-1}$  represents a generalized inverse of the information matrix  $\mathbf{I}_0$  of the null model. The *value* must be between 0 and 1; the default is  $10^{-4}$ .

## DOMAIN Statement

**DOMAIN** *variables* < *variable\*variable variable\*variable\*variable ...* > ;

The DOMAIN statement requests analysis for domains (subpopulations) in addition to analysis for the entire study population. The DOMAIN statement names the variables that identify domains, which are called domain variables.

It is common practice to compute statistics for domains. The formation of these domains might be unrelated to the sample design. Therefore, the sample sizes for the domains are random variables. Use a DOMAIN statement to incorporate this variability into the variance estimation.

Note that a DOMAIN statement is different from a BY statement. In a BY statement, you treat the sample sizes as fixed in each subpopulation, and you perform analysis within each BY group independently. See the section “[Domain Analysis](#)” on page 7744 for more details.

Use the DOMAIN statement on the entire data set to perform a domain analysis. Creating a new data set from a single domain and analyzing that with PROC SURVEYLOGISTIC yields inappropriate estimates of variance.

A domain variable can be either character or numeric. The procedure treats domain variables as categorical variables. If a variable appears by itself in a DOMAIN statement, each level of this variable determines a domain in the study population. If two or more variables are joined by asterisks (\*), then every possible combination of levels of these variables determines a domain. The procedure performs a descriptive analysis within each domain that is defined by the domain variables.

When determining levels of a DOMAIN variable, an observation with missing values for this DOMAIN variable is excluded, unless you specify the **MISSING** option. For more information, see the section “Missing Values” on page 7723.

The formatted values of the domain variables determine the categorical variable levels. Thus, you can use formats to group values into levels. See the **FORMAT** procedure in the *Base SAS Procedures Guide* and the **FORMAT** statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

---

## EFFECT Statement

**EFFECT** *name=effect-type (variables < / options >)* ;

The **EFFECT** statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “GLM Parameterization of Classification Variables and Effects” on page 383 in Chapter 19, “Shared Concepts and Topics.”

You can specify the following *effect-types*:

|                          |                                                                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>COLLECTION</b>        | is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.       |
| <b>LAG</b>               | is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.                                                                           |
| <b>MULTIMEMBER   MM</b>  | is a multimember classification effect whose levels are determined by one or more variables that appear in a <b>CLASS</b> statement.                                                                      |
| <b>POLYNOMIAL   POLY</b> | is a multivariate polynomial effect in the specified numeric variables.                                                                                                                                   |
| <b>SPLINE</b>            | is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables. |

Table 91.3 summarizes the *options* available in the **EFFECT** statement.

**Table 91.3** EFFECT Statement Options

| Option                            | Description                                                                   |
|-----------------------------------|-------------------------------------------------------------------------------|
| <b>Collection Effects Options</b> |                                                                               |
| <b>DETAILS</b>                    | Displays the constituents of the collection effect                            |
| <b>Lag Effects Options</b>        |                                                                               |
| <b>DESIGNROLE=</b>                | Names a variable that controls to which lag design an observation is assigned |

Table 91.3 continued

| Option                             | Description                                                                                                                                          |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| DETAILS                            | Displays the lag design of the lag effect                                                                                                            |
| NLAG=                              | Specifies the number of periods in the lag                                                                                                           |
| PERIOD=                            | Names the variable that defines the period                                                                                                           |
| WITHIN=                            | Names the variable or variables that define the group within which each period is defined                                                            |
| <b>Multimember Effects Options</b> |                                                                                                                                                      |
| NOEFFECT                           | Specifies that observations with all missing levels for the multimember variables should have zero values in the corresponding design matrix columns |
| WEIGHT=                            | Specifies the weight variable for the contributions of each of the classification effects                                                            |
| <b>Polynomial Effects Options</b>  |                                                                                                                                                      |
| DEGREE=                            | Specifies the degree of the polynomial                                                                                                               |
| MDEGREE=                           | Specifies the maximum degree of any variable in a term of the polynomial                                                                             |
| STANDARDIZE=                       | Specifies centering and scaling suboptions for the variables that define the polynomial                                                              |
| <b>Spline Effects Options</b>      |                                                                                                                                                      |
| BASIS=                             | Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion                                              |
| DEGREE=                            | Specifies the degree of the spline transformation                                                                                                    |
| KNOTMETHOD=                        | Specifies how to construct the knots for spline effects                                                                                              |

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “EFFECT Statement” on page 393 in Chapter 19, “Shared Concepts and Topics.”

## ESTIMATE Statement

```
ESTIMATE <'label'> estimate-specification <(divisor=n)>
 < , ... <'label'> estimate-specification <(divisor=n)> >
 </options> ;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form  $L\beta$ . You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 91.4 summarizes the options available in the ESTIMATE statement.

**Table 91.4** ESTIMATE Statement Options

| Option                                                     | Description                                                                     |
|------------------------------------------------------------|---------------------------------------------------------------------------------|
| <b>Construction and Computation of Estimable Functions</b> |                                                                                 |
| DIVISOR=                                                   | Specifies a list of values to divide the coefficients                           |
| NOFILL                                                     | Suppresses the automatic fill-in of coefficients for higher-order effects       |
| SINGULAR=                                                  | Tunes the estimability checking difference                                      |
| <b>Degrees of Freedom and <math>p</math>-values</b>        |                                                                                 |
| ADJUST=                                                    | Determines the method for multiple comparison adjustment of estimates           |
| ALPHA= $\alpha$                                            | Determines the confidence level ( $1 - \alpha$ )                                |
| LOWER                                                      | Performs one-sided, lower-tailed inference                                      |
| STEPDOWN                                                   | Adjusts multiplicity-corrected $p$ -values further in a step-down fashion       |
| TESTVALUE=                                                 | Specifies values under the null hypothesis for tests                            |
| UPPER                                                      | Performs one-sided, upper-tailed inference                                      |
| <b>Statistical Output</b>                                  |                                                                                 |
| CL                                                         | Constructs confidence limits                                                    |
| CORR                                                       | Displays the correlation matrix of estimates                                    |
| COV                                                        | Displays the covariance matrix of estimates                                     |
| E                                                          | Prints the <b>L</b> matrix                                                      |
| JOINT                                                      | Produces a joint $F$ or chi-square test for the estimable functions             |
| SEED=                                                      | Specifies the seed for computations that depend on random numbers               |
| <b>Generalized Linear Modeling</b>                         |                                                                                 |
| CATEGORY=                                                  | Specifies how to construct estimable functions with multinomial data            |
| EXP                                                        | Exponentiates and displays estimates                                            |
| ILINK                                                      | Computes and displays estimates and standard errors on the inverse linked scale |

For details about the syntax of the ESTIMATE statement, see the section “ESTIMATE Statement” on page 437 in Chapter 19, “Shared Concepts and Topics.”

## FREQ Statement

**FREQ** *variable* ;

The *variable* in the FREQ statement identifies a variable that contains the frequency of occurrence of each observation. PROC SURVEYLOGISTIC treats each observation as if it appears  $n$  times, where  $n$  is the value of the FREQ variable for the observation. If it is not an integer, the frequency value is truncated to

an integer. If the frequency value is less than 1 or missing, the observation is not used in the model fitting. When the FREQ statement is not specified, each observation is assigned a frequency of 1.

If you use the `events/trials` syntax in the MODEL statement, the FREQ statement is not allowed because the event and trial variables represent the frequencies in the data set.

If you use the FREQ statement and specify the `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE` option to estimate the variance, then you must identify the primary sampling units with a CLUSTER statement unless you also provide replicate weights with a REPWEIGHTS statement.

---

## LSMEANS Statement

**LSMEANS** < *model-effects* > < / *options* > ;

The LSMEANS statement computes and compares least squares means (LS-means) of fixed effects. LS-means are *predicted margins*—that is, they estimate the marginal means over a hypothetical balanced population.

Table 91.5 summarizes available options in the LSMEANS statement.

**Table 91.5** LSMEANS Statement Options

| Option                                          | Description                                                                                 |
|-------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b> |                                                                                             |
| AT                                              | Modifies the covariate value in computing LS-means                                          |
| BYLEVEL                                         | Computes separate margins                                                                   |
| DIFF                                            | Requests differences of LS-means                                                            |
| OM=                                             | Specifies the weighting scheme for LS-means computation as determined by the input data set |
| SINGULAR=                                       | Tunes estimability checking                                                                 |
| <b>Degrees of Freedom and <i>p</i>-values</b>   |                                                                                             |
| ADJUST=                                         | Determines the method for multiple-comparison adjustment of LS-means differences            |
| ALPHA= $\alpha$                                 | Determines the confidence level $(1 - \alpha)$                                              |
| STEPDOWN                                        | Adjusts multiple-comparison <i>p</i> -values further in a step-down fashion                 |
| <b>Statistical Output</b>                       |                                                                                             |
| CL                                              | Constructs confidence limits for means and mean differences                                 |
| CORR                                            | Displays the correlation matrix of LS-means                                                 |
| COV                                             | Displays the covariance matrix of LS-means                                                  |
| E                                               | Prints the <b>L</b> matrix                                                                  |
| LINES                                           | Produces a “Lines” display for pairwise LS-means differences                                |
| MEANS                                           | Prints the LS-means                                                                         |
| PLOTS=                                          | Requests graphs of means and mean comparisons                                               |
| SEED=                                           | Specifies the seed for computations that depend on random numbers                           |

---

Table 91.5 *continued*

| Option                             | Description                                                                                                       |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Generalized Linear Modeling</b> |                                                                                                                   |
| EXP                                | Exponentiates and displays estimates of LS-means or LS-means differences                                          |
| ILINK                              | Computes and displays estimates and standard errors of LS-means (but not differences) on the inverse linked scale |
| ODDSRATIO                          | Reports (simple) differences of least squares means in terms of odds ratios if permitted by the link function     |

For details about the syntax of the LSMEANS statement, see the section “LSMEANS Statement” on page 453 of Chapter 19, “Shared Concepts and Topics.”

## LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
 < , ... <'label'> values <divisor=n> >
 </options> ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 91.6 summarizes the options available in the LSMESTIMATE statement.

Table 91.6 LSMESTIMATE Statement Options

| Option                                              | Description                                                                         |
|-----------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b>     |                                                                                     |
| AT                                                  | Modifies covariate values in computing LS-means                                     |
| BYLEVEL                                             | Computes separate margins                                                           |
| DIVISOR=                                            | Specifies a list of values to divide the coefficients                               |
| OM=                                                 | Specifies the weighting scheme for LS-means computation as determined by a data set |
| SINGULAR=                                           | Tunes estimability checking                                                         |
| <b>Degrees of Freedom and <math>p</math>-values</b> |                                                                                     |
| ADJUST=                                             | Determines the method for multiple-comparison adjustment of LS-means differences    |
| ALPHA= $\alpha$                                     | Determines the confidence level ( $1 - \alpha$ )                                    |
| LOWER                                               | Performs one-sided, lower-tailed inference                                          |
| STEPDOWN                                            | Adjusts multiple-comparison $p$ -values further in a step-down fashion              |
| TESTVALUE=                                          | Specifies values under the null hypothesis for tests                                |
| UPPER                                               | Performs one-sided, upper-tailed inference                                          |

Table 91.6 *continued*

| Option                             | Description                                                                                                       |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Statistical Output</b>          |                                                                                                                   |
| CL                                 | Constructs confidence limits for means and mean differences                                                       |
| CORR                               | Displays the correlation matrix of LS-means                                                                       |
| COV                                | Displays the covariance matrix of LS-means                                                                        |
| E                                  | Prints the <b>L</b> matrix                                                                                        |
| ELSM                               | Prints the <b>K</b> matrix                                                                                        |
| JOINT                              | Produces a joint <i>F</i> or chi-square test for the LS-means and LS-means differences                            |
| SEED=                              | Specifies the seed for computations that depend on random numbers                                                 |
| <b>Generalized Linear Modeling</b> |                                                                                                                   |
| CATEGORY=                          | Specifies how to construct estimable functions with multinomial data                                              |
| EXP                                | Exponentiates and displays LS-means estimates                                                                     |
| ILINK                              | Computes and displays estimates and standard errors of LS-means (but not differences) on the inverse linked scale |

For details about the syntax of the LSMESTIMATE statement, see the section “[LSMESTIMATE Statement](#)” on page 470 in Chapter 19, “[Shared Concepts and Topics](#).”

## MODEL Statement

**MODEL** *events/trials* = < *effects* </ *options* >> ;

**MODEL** *variable* <( *v-options*) > = < *effects* > </ *options* > ;

The MODEL statement names the response variable and the explanatory effects, including covariates, main effects, interactions, and nested effects; see the section “[Specification of Effects](#)” on page 3324 of Chapter 42, “[The GLM Procedure](#),” for more information. If you omit the explanatory variables, the procedure fits an intercept-only model. [Model options](#) can be specified after a slash (/).

Two forms of the MODEL statement can be specified. The first form, referred to as *single-trial* syntax, is applicable to binary, ordinal, and nominal response data. The second form, referred to as *events/trials* syntax, is restricted to the case of binary response data. The single-trial syntax is used when each observation in the DATA= data set contains information about only a single trial, such as a single subject in an experiment. When each observation contains information about multiple binary-response trials, such as the counts of the number of subjects observed and the number responding, then events/trials syntax can be used.

In the events/trials syntax, you specify two variables that contain count data for a binomial experiment. These two variables are separated by a slash. The value of the first variable, *events*, is the number of positive responses (or events), and it must be nonnegative. The value of the second variable, *trials*, is the number of trials, and it must not be less than the value of *events*.

In the single-trial syntax, you specify one variable (on the left side of the equal sign) as the response variable. This variable can be character or numeric. [Options](#) specific to the response variable can be specified immediately after the response variable with parentheses around them.

For both forms of the MODEL statement, explanatory *effects* follow the equal sign. Variables can be either continuous or classification variables. Classification variables can be character or numeric, and they must be declared in the CLASS statement. When an effect is a classification variable, the procedure enters a set of coded columns into the design matrix instead of directly entering a single column containing the values of the variable.

## Response Variable Options

You specify the following options by enclosing them in parentheses after the response variable:

### DESCENDING

#### DESC

reverses the order of response categories. If both the DESCENDING and the [ORDER=](#) options are specified, PROC SURVEYLOGISTIC orders the response categories according to the ORDER= option and then reverses that order. See the section “[Response Level Ordering](#)” on page 7724 for more detail.

#### EVENT=*'category'* | *keyword*

specifies the event category for the binary response model. PROC SURVEYLOGISTIC models the probability of the event category. The EVENT= option has no effect when there are more than two response categories. You can specify the value (formatted if a format is applied) of the event category in quotes or you can specify one of the following keywords. The default is EVENT=FIRST.

FIRST                    designates the first ordered category as the event

LAST                     designates the last ordered category as the event

One of the most common sets of response levels is  $\{0,1\}$ , with 1 representing the event for which the probability is to be modeled. Consider the example where Y takes the values 1 and 0 for event and nonevent, respectively, and Exposure is the explanatory variable. To specify the value 1 as the event category, use the following MODEL statement:

```
model Y(event='1') = Exposure;
```

### ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of the response variable. By default, ORDER=INTERNAL. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent.

When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format,

| Value of ORDER= | Levels Sorted By                                                                                                                       |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------|
| DATA            | Order of appearance in the input data set                                                                                              |
| FORMATTED       | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| FREQ            | Descending frequency count; levels with the most observations come first in the order                                                  |
| INTERNAL        | Unformatted value                                                                                                                      |

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**REFERENCE=**'category' | keyword

**REF=**'category' | keyword

specifies the reference category for the generalized logit model and the binary response model. For the generalized logit model, each nonreference category is contrasted with the reference category. For the binary response model, specifying one response category as the reference is the same as specifying the other response category as the event category. You can specify the value (formatted if a format is applied) of the reference category in quotes or you can specify one of the following keywords. The default is REF=LAST.

FIRST            designates the first ordered category as the reference

LAST             designates the last ordered category as the reference

## Model Options

Model options can be specified after a slash (/). [Table 91.7](#) summarizes the options available in the MODEL statement.

**Table 91.7** MODEL Statement Options

| Option                               | Description                                                                                                            |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Model Specification Options</b>   |                                                                                                                        |
| LINK=                                | Specifies link function                                                                                                |
| NOINT                                | Suppresses intercept(s)                                                                                                |
| OFFSET=                              | Specifies offset variable                                                                                              |
| <b>Convergence Criterion Options</b> |                                                                                                                        |
| ABSFCNV=                             | Specifies absolute function convergence criterion                                                                      |
| FCNV=                                | Specifies relative function convergence criterion                                                                      |
| GCONV=                               | Specifies relative gradient convergence criterion                                                                      |
| XCONV=                               | Specifies relative parameter convergence criterion                                                                     |
| MAXITER=                             | Specifies maximum number of iterations                                                                                 |
| NOCHECK                              | Suppresses checking for infinite parameters                                                                            |
| RIDGING=                             | Specifies technique used to improve the log-likelihood function when its value is worse than that of the previous step |
| SINGULAR=                            | Specifies tolerance for testing singularity                                                                            |

Table 91.7 (continued)

| Option                                               | Description                                                         |
|------------------------------------------------------|---------------------------------------------------------------------|
| TECHNIQUE=                                           | Specifies iterative algorithm for maximization                      |
| <b>Options for Adjustment to Variance Estimation</b> |                                                                     |
| VADJUST=                                             | Chooses variance estimation adjustment method                       |
| <b>Options for Confidence Intervals</b>              |                                                                     |
| ALPHA=                                               | Specifies $\alpha$ for the $100(1 - \alpha)\%$ confidence intervals |
| CLPARM                                               | Computes confidence intervals for parameters                        |
| CLODDS                                               | Computes confidence intervals for odds ratios                       |
| <b>Options for Display of Details</b>                |                                                                     |
| CORRB                                                | Displays correlation matrix                                         |
| COVB                                                 | Displays covariance matrix                                          |
| EXPB                                                 | Displays exponentiated values of estimates                          |
| ITPRINT                                              | Displays iteration history                                          |
| NODUMMYPRINT                                         | Suppresses “Class Level Information” table                          |
| PARMLABEL                                            | Displays parameter labels                                           |
| RSQUARE                                              | Displays generalized $R^2$                                          |
| STB                                                  | Displays standardized estimates                                     |

The following list describes these options:

**ABSFCNV=value**

specifies the absolute function convergence criterion. Convergence requires a small change in the log-likelihood function in subsequent iterations:

$$|l^{(i)} - l^{(i-1)}| < value$$

where  $l^{(i)}$  is the value of the log-likelihood function at iteration  $i$ . See the section “Convergence Criteria” on page 7731.

**ALPHA=value**

sets the level of significance  $\alpha$  for  $100(1 - \alpha)\%$  confidence intervals for regression parameters or odds ratios. The value  $\alpha$  must be between 0 and 1. By default,  $\alpha$  is equal to the value of the ALPHA= option in the PROC SURVEYLOGISTIC statement, or  $\alpha = 0.05$  if the ALPHA= option is not specified. This option has no effect unless confidence limits for the parameters or odds ratios are requested.

**CLODDS**

requests confidence intervals for the odds ratios. Computation of these confidence intervals is based on individual Wald tests. The confidence coefficient can be specified with the ALPHA= option.

See the section “Wald Confidence Intervals for Parameters” on page 7745 for more information.

**CLPARM**

requests confidence intervals for the parameters. Computation of these confidence intervals is based on the individual Wald tests. The confidence coefficient can be specified with the ALPHA= option.

See the section “Wald Confidence Intervals for Parameters” on page 7745 for more information.

**CORRB**

displays the correlation matrix of the parameter estimates.

**COVB**

displays the covariance matrix of the parameter estimates.

**EXPB****EXPEST**

displays the exponentiated values ( $e^{\hat{\theta}_i}$ ) of the parameter estimates  $\hat{\theta}_i$  in the “Analysis of Maximum Likelihood Estimates” table for the logit model. These exponentiated values are the estimated odds ratios for the parameters corresponding to the continuous explanatory variables.

**FCONV=value**

specifies the relative function convergence criterion. Convergence requires a small relative change in the log-likelihood function in subsequent iterations:

$$\frac{|l^{(i)} - l^{(i-1)}|}{|l^{(i-1)}| + 1\text{E-}6} < \text{value}$$

where  $l^{(i)}$  is the value of the log likelihood at iteration  $i$ . See the section “Convergence Criteria” on page 7731 for details.

**GCONV=value**

specifies the relative gradient convergence criterion. Convergence requires that the normalized prediction function reduction is small:

$$\frac{\mathbf{g}^{(i)'} \mathbf{I}^{(i)} \mathbf{g}^{(i)}}{|l^{(i)}| + 1\text{E-}6} < \text{value}$$

where  $l^{(i)}$  is the value of the log-likelihood function,  $\mathbf{g}^{(i)}$  is the gradient vector, and  $\mathbf{I}^{(i)}$  the (expected) information matrix. All of these functions are evaluated at iteration  $i$ . This is the default convergence criterion, and the default value is 1E–8. See the section “Convergence Criteria” on page 7731 for details.

**ITPRINT**

displays the iteration history of the maximum-likelihood model fitting. The ITPRINT option also displays the last evaluation of the gradient vector and the final change in the  $-2 \log L$ .

**LINK=keyword****L=keyword**

specifies the link function that links the response probabilities to the linear predictors. You can specify one of the following keywords. The default is LINK=LOGIT.

**CLOGLOG** specifies the complementary log-log function. PROC SURVEYLOGISTIC fits the binary complementary log-log model for binary response and fits the cumulative complementary log-log model when there are more than two response categories. Aliases: CCLOGLOG, CCLL, CUMCLOGLOG.

**GLOGIT** specifies the generalized logit function. PROC SURVEYLOGISTIC fits the generalized logit model where each nonreference category is contrasted with the reference category. You can use the response variable option REF= to specify the reference category.

|        |                                                                                                                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOGIT  | specifies the cumulative logit function. PROC SURVEYLOGISTIC fits the binary logit model when there are two response categories and fits the cumulative logit model when there are more than two response categories. Aliases: CLOGIT, CUMLOGIT.                                 |
| PROBIT | specifies the inverse standard normal distribution function. PROC SURVEYLOGISTIC fits the binary probit model when there are two response categories and fits the cumulative probit model when there are more than two response categories. Aliases: NORMIT, CPROBIT, CUMPROBIT. |

See the section “[Link Functions and the Corresponding Distributions](#)” on page 7727 for details.

**MAXITER=*n***

specifies the maximum number of iterations to perform. By default, MAXITER=25. If convergence is not attained in *n* iterations, the displayed output created by the procedure contains results that are based on the last maximum likelihood iteration.

**NOCHECK**

disables the checking process to determine whether maximum likelihood estimates of the regression parameters exist. If you are sure that the estimates are finite, this option can reduce the execution time when the estimation takes more than eight iterations. For more information, see the section “[Existence of Maximum Likelihood Estimates](#)” on page 7731.

**NODUMMYPRINT**

suppresses the “Class Level Information” table, which shows how the design matrix columns for the CLASS variables are coded.

**NOINT**

suppresses the intercept for the binary response model or the first intercept for the ordinal response model.

**OFFSET=*name***

names the offset variable. The regression coefficient for this variable is fixed at 1.

**PARMLABEL**

displays the labels of the parameters in the “Analysis of Maximum Likelihood Estimates” table.

**RIDGING=ABSOLUTE | RELATIVE | NONE**

specifies the technique used to improve the log-likelihood function when its value in the current iteration is less than that in the previous iteration. If you specify the RIDGING=ABSOLUTE option, the diagonal elements of the negative (expected) Hessian are inflated by adding the ridge value. If you specify the RIDGING=RELATIVE option, the diagonal elements are inflated by a factor of 1 plus the ridge value. If you specify the RIDGING=NONE option, the crude line search method of taking half a step is used instead of ridging. By default, RIDGING=RELATIVE.

**RSQUARE**

requests a generalized  $R^2$  measure for the fitted model.

For more information, see the section “[Generalized Coefficient of Determination](#)” on page 7733.

**SINGULAR=***value*

specifies the tolerance for testing the singularity of the Hessian matrix (Newton-Raphson algorithm) or the expected value of the Hessian matrix (Fisher scoring algorithm). The Hessian matrix is the matrix of second partial derivatives of the log likelihood. The test requires that a pivot for sweeping this matrix be at least this *value* times a norm of the matrix. Values of the SINGULAR= option must be numeric. By default, SINGULAR= $10^{-12}$ .

**STB**

displays the standardized estimates for the parameters for the continuous explanatory variables in the “Analysis of Maximum Likelihood Estimates” table. The standardized estimate of  $\theta_i$  is given by  $\hat{\theta}_i/(s/s_i)$ , where  $s_i$  is the total sample standard deviation for the  $i$ th explanatory variable and

$$s = \begin{cases} \pi/\sqrt{3} & \text{Logistic} \\ 1 & \text{Normal} \\ \pi/\sqrt{6} & \text{Extreme-value} \end{cases}$$

For the intercept parameters and parameters associated with a CLASS variable, the standardized estimates are set to missing.

**TECHNIQUE=FISHER | NEWTON****TECH=FISHER | NEWTON**

specifies the optimization technique for estimating the regression parameters. NEWTON (or NR) is the Newton-Raphson algorithm and FISHER (or FS) is the Fisher scoring algorithm. Both techniques yield the same estimates, but the estimated covariance matrices are slightly different except for the case where the LOGIT link is specified for binary response data. The default is TECHNIQUE=FISHER. If the LINK=GLOGIT option is specified, then Newton-Raphson is the default and only available method. See the section “[Iterative Algorithms for Model Fitting](#)” on page 7729 for details.

**VADJUST=DF****VADJUST=MOREL** < (*Morel-options*) >**VADJUST=NONE**

specifies an [adjustment to the variance estimation](#) for the regression coefficients.

By default, PROC SURVEYLOGISTIC uses the degrees of freedom adjustment VADJUST=DF.

If you do not want to use any variance adjustment, you can specify the VADJUST=NONE option. You can specify the VADJUST=MOREL option for the variance adjustment proposed by Morel (1989).

You can specify the following *Morel-options* within parentheses after the VADJUST=MOREL option:

**ADJBOUND=** $\phi$ 

sets the upper bound coefficient  $\phi$  in the variance adjustment. This upper bound must be positive. By default, the procedure uses  $\phi = 0.5$ . See the section “[Adjustments to the Variance Estimation](#)” on page 7740 for more details on how this upper bound is used in the variance estimation.

**DEFFBOUND=** $\delta$ 

sets the lower bound of the estimated design effect in the variance adjustment. This lower bound must be positive. By default, the procedure uses  $\delta = 1$ . See the section “[Adjustments to the Variance Estimation](#)” on page 7740 for more details about how this lower bound is used in the variance estimation.

**XCONV=value**

specifies the relative parameter convergence criterion. Convergence requires a small relative parameter change in subsequent iterations:

$$\max_j |\delta_j^{(i)}| < value$$

where

$$\delta_j^{(i)} = \begin{cases} \theta_j^{(i)} - \theta_j^{(i-1)} & |\theta_j^{(i-1)}| < 0.01 \\ \frac{\theta_j^{(i)} - \theta_j^{(i-1)}}{\theta_j^{(i-1)}} & \text{otherwise} \end{cases}$$

and  $\theta_j^{(i)}$  is the estimate of the  $j$ th parameter at iteration  $i$ . See the section “Convergence Criteria” on page 7731 for details.

## OUTPUT Statement

**OUTPUT** < **OUT=SAS-data-set** > < options > < / option > ;

The OUTPUT statement creates a new SAS data set that contains all the variables in the input data set and, optionally, the estimated linear predictors and their standard error estimates, the estimates of the cumulative or individual response probabilities, and the confidence limits for the cumulative probabilities. Formulas for the statistics are given in the section “Linear Predictor, Predicted Probability, and Confidence Limits” on page 7749.

If you use the single-trial syntax, the data set also contains a variable named `_LEVEL_`, which indicates the level of the response that the given row of output is referring to. For example, the value of the cumulative probability variable is the probability that the response variable is as large as the corresponding value of `_LEVEL_`. For details, see the section “OUT= Data Set in the OUTPUT Statement” on page 7750.

The estimated linear predictor, its standard error estimate, all predicted probabilities, and the confidence limits for the cumulative probabilities are computed for all observations in which the explanatory variables have no missing values, even if the response is missing. By adding observations with missing response values to the input data set, you can compute these statistics for new observations, or for settings of the explanatory variables not present in the data, without affecting the model fit.

Table 91.8 summarizes the options available in the OUTPUT statement.

**Table 91.8** OUTPUT Statement Options

| Option     | Description                                                            |
|------------|------------------------------------------------------------------------|
| ALPHA=     | Sets the level of significance                                         |
| LOWER      | Names the variable that contains the lower confidence limits           |
| OUT=       | Names the output data set                                              |
| PREDICTED  | Names the variable that contains the predicted probabilities           |
| PREDPROBS= | Requests predicted probabilities                                       |
| STDXBETA=  | Names the variable that contains the standard error estimates          |
| UPPER      | Names the variable that contains the upper confidence limits           |
| XBETA=     | Names the variable that contains the estimates of the linear predictor |

You can specify the following options in the OUTPUT statement:

**LOWER | L=name**

names the variable that contains the lower confidence limits for  $\pi$ , where  $\pi$  is the probability of the event response if events/trials syntax or the single-trial syntax with binary response is specified;  $\pi$  is cumulative probability (that is, the probability that the response is less than or equal to the value of `_LEVEL_`) for a cumulative model; and  $\pi$  is the individual probability (that is, the probability that the response category is represented by the value of `_LEVEL_`) for the generalized logit model. See the [ALPHA=](#) option for information about setting the confidence level.

**OUT=SAS-data-set**

names the output data set. If you omit the OUT= option, the output data set is created and given a default name by using the `DATAn` convention.

The statistic options in the OUTPUT statement specify the statistics to be included in the output data set and name the new variables that contain the statistics.

**PREDICTED | P=name**

names the variable that contains the predicted probabilities. For the events/trials syntax or the single-trial syntax with binary response, it is the predicted event probability. For a cumulative model, it is the predicted cumulative probability (that is, the probability that the response variable is less than or equal to the value of `_LEVEL_`); and for the generalized logit model, it is the predicted individual probability (that is, the probability of the response category represented by the value of `_LEVEL_`).

**PREDPROBS=(keywords)**

requests individual, cumulative, or cross validated predicted probabilities. Descriptions of the *keywords* are as follows.

**INDIVIDUAL | I** requests the predicted probability of each response level. For a response variable *Y* with three levels, 1, 2, and 3, the individual probabilities are  $\Pr(Y=1)$ ,  $\Pr(Y=2)$ , and  $\Pr(Y=3)$ .

**CUMULATIVE | C** requests the cumulative predicted probability of each response level. For a response variable *Y* with three levels, 1, 2, and 3, the cumulative probabilities are  $\Pr(Y \leq 1)$ ,  $\Pr(Y \leq 2)$ , and  $\Pr(Y \leq 3)$ . The cumulative probability for the last response level always has the constant value of 1. For generalized logit models, the cumulative predicted probabilities are not computed and are set to missing.

**CROSSVALIDATE | XVALIDATE | X** requests the cross validated individual predicted probability of each response level. These probabilities are derived from the leave-one-out principle; that is, dropping the data of one subject and reestimating the parameter estimates. PROC SURVEYLOGISTIC uses a less expensive one-step approximation to compute the parameter estimates. This option is valid only for binary response models; for nominal and ordinal models, the cross validated probabilities are not computed and are set to missing.

See the section “[Details of the PREDPROBS= Option](#)” on page 7717 at the end of this section for further details.

**STDXBETA=***name*

names the variable that contains the standard error estimates of **XBETA** (the definition of which follows).

**UPPER | U=***name*

names the variable that contains the upper confidence limits for  $\pi$ , where  $\pi$  is the probability of the event response if events/trials syntax or single-trial syntax with binary response is specified;  $\pi$  is cumulative probability (that is, the probability that the response is less than or equal to the value of `_LEVEL_`) for a cumulative model; and  $\pi$  is the individual probability (that is, the probability that the response category is represented by the value of `_LEVEL_`) for the generalized logit model. See the **ALPHA=** option for information about setting the confidence level.

**XBETA=***name*

names the variable that contains the estimates of the linear predictor  $\alpha_i + \mathbf{x}\boldsymbol{\beta}$ , where  $i$  is the corresponding ordered value of `_LEVEL_`.

You can specify the following option in the OUTPUT statement after a slash (/):

**ALPHA=***value*

sets the level of significance  $\alpha$  for  $100(1 - \alpha)\%$  confidence limits for the appropriate response probabilities. The value  $\alpha$  must be between 0 and 1. By default,  $\alpha$  is equal to the value of the **ALPHA=** option in the PROC SURVEYLOGISTIC statement, or 0.05 if the ALPHA= option is not specified.

### Details of the PREDPROBS= Option

You can request any of the three given types of predicted probabilities. For example, you can request both the individual predicted probabilities and the cross validated probabilities by specifying **PREDPROBS=(I X)**.

When you specify the **PREDPROBS=** option, two automatic variables `_FROM_` and `_INTO_` are included for the single-trial syntax and only one variable, `_INTO_`, is included for the events/trials syntax. The `_FROM_` variable contains the formatted value of the observed response. The variable `_INTO_` contains the formatted value of the response level with the largest individual predicted probability.

If you specify **PREDPROBS=INDIVIDUAL**, the OUTPUT data set contains  $k$  additional variables representing the individual probabilities, one for each response level, where  $k$  is the maximum number of response levels across all BY groups. The names of these variables have the form `IP_`*xxx*, where *xxx* represents the particular level. The representation depends on the following situations:

- If you specify the events/trials syntax, *xxx* is either Event or Nonevent. Thus, the variable that contains the event probabilities is named `IP_Event` and the variable containing the nonevent probabilities is named `IP_Nonevent`.
- If you specify the single-trial syntax with more than one BY group, *xxx* is 1 for the first ordered level of the response, 2 for the second ordered level of the response, and so forth, as given in the “Response Profile” table. The variable that contains the predicted probabilities  $\Pr(Y=1)$  is named `IP_1`, where  $Y$  is the response variable. Similarly, `IP_2` is the name of the variable containing the predicted probabilities  $\Pr(Y=2)$ , and so on.
- If you specify the single-trial syntax with no BY-group processing, *xxx* is the left-justified formatted value of the response level (the value can be truncated so that `IP_`*xxx* does not exceed 32 characters).

For example, if  $Y$  is the response variable with response levels ‘None,’ ‘Mild,’ and ‘Severe,’ the variables representing individual probabilities  $\Pr(Y=\text{‘None’})$ ,  $\Pr(Y=\text{‘Mild’})$ , and  $\Pr(Y=\text{‘Severe’})$  are named `IP_None`, `IP_Mild`, and `IP_Severe`, respectively.

If you specify `PREDPROBS=CUMULATIVE`, the OUTPUT data set contains  $k$  additional variables that represent the cumulative probabilities, one for each response level, where  $k$  is the maximum number of response levels across all BY groups. The names of these variables have the form `CP_xxx`, where `xxx` represents the particular response level. The naming convention is similar to that given by `PREDPROBS=INDIVIDUAL`. The `PREDPROBS=CUMULATIVE` values are the same as those output by the `PREDICT=keyword`, but they are arranged in variables in each output observation rather than in multiple output observations.

If you specify `PREDPROBS=CROSSVALIDATE`, the OUTPUT data set contains  $k$  additional variables representing the cross validated predicted probabilities of the  $k$  response levels, where  $k$  is the maximum number of response levels across all BY groups. The names of these variables have the form `XP_xxx`, where `xxx` represents the particular level. The representation is the same as that given by `PREDPROBS=INDIVIDUAL`, except that for the events/trials syntax there are four variables for the cross validated predicted probabilities instead of two:

`XP_EVENT_R1E` is the cross validated predicted probability of an event when a current event trial is removed.

`XP_NONEVENT_R1E` is the cross validated predicted probability of a nonevent when a current event trial is removed.

`XP_EVENT_R1N` is the cross validated predicted probability of an event when a current nonevent trial is removed.

`XP_NONEVENT_R1N` is the cross validated predicted probability of a nonevent when a current nonevent trial is removed.

---

## REPWEIGHTS Statement

**REPWEIGHTS** *variables* </ options > ;

The `REPWEIGHTS` statement names variables that provide replicate weights for BRR or jackknife variance estimation, which you request with the `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE` option in the `PROC SURVEYLOGISTIC` statement. If you do not provide replicate weights for these methods by using a `REPWEIGHTS` statement, then the procedure constructs replicate weights for the analysis. See the sections “Balanced Repeated Replication (BRR) Method” on page 7740 and “Jackknife Method” on page 7742 for information about replicate weights.

Each `REPWEIGHTS` variable should contain the weights for a single replicate, and the number of replicates equals the number of `REPWEIGHTS` variables. The `REPWEIGHTS` variables must be numeric, and the variable values must be nonnegative numbers.

If you provide replicate weights with a `REPWEIGHTS` statement, you do not need to specify a `CLUSTER` or `STRATA` statement. If you use a `REPWEIGHTS` statement and do not specify the `VARMETHOD=` option in the `PROC SURVEYLOGISTIC` statement, the procedure uses `VARMETHOD=JACKKNIFE` by default.

If you specify a **REPWEIGHTS** statement but do not include a **WEIGHT** statement, the procedure uses the average of replicate weights of each observation as the observation's weight.

You can specify the following options in the **REPWEIGHTS** statement after a slash (/):

**DF=***df*

specifies the degrees of freedom for the analysis. The value of *df* must be a positive number. By default, the degrees of freedom equals the number of **REPWEIGHTS** variables.

**JKCOEFS=***value*

specifies a **jackknife coefficient** for **VARMETHOD=JACKKNIFE**. The coefficient *value* must be a nonnegative number. See the section “**Jackknife Method**” on page 7742 for details about jackknife coefficients.

You can use this option to specify a single value of the jackknife coefficient, which the procedure uses for all replicates. To specify different coefficients for different replicates, use the **JKCOEFS=values** or **JKCOEFS=SAS-data-set** option.

**JKCOEFS=***values*

specifies jackknife coefficients for **VARMETHOD=JACKKNIFE**, where each coefficient corresponds to an individual replicate that is identified by a **REPWEIGHTS** variable. You can separate *values* with blanks or commas. The coefficient *values* must be nonnegative numbers. The number of *values* must equal the number of replicate weight variables named in the **REPWEIGHTS** statement. List these values in the same order in which you list the corresponding replicate weight variables in the **REPWEIGHTS** statement.

See the section “**Jackknife Method**” on page 7742 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the **JKCOEFS=SAS-data-set** option. To specify a single jackknife coefficient for all replicates, use the **JKCOEFS=value** option.

**JKCOEFS=SAS-data-set**

names a SAS data set that contains the jackknife coefficients for **VARMETHOD=JACKKNIFE**. You provide the jackknife coefficients in the **JKCOEFS=** data set variable **JKCoefficient**. Each coefficient value must be a nonnegative number. The observations in the **JKCOEFS=** data set should correspond to the replicates that are identified by the **REPWEIGHTS** variables. Arrange the coefficients or observations in the **JKCOEFS=** data set in the same order in which you list the corresponding replicate weight variables in the **REPWEIGHTS** statement. The number of observations in the **JKCOEFS=** data set must not be less than the number of **REPWEIGHTS** variables.

See the section “**Jackknife Method**” on page 7742 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the **JKCOEFS=values** option. To specify a single jackknife coefficient for all replicates, use the **JKCOEFS=value** option.

---

## SLICE Statement

**SLICE** *model-effect* </ options > ;

The **SLICE** statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the LSMEANS statement, which are summarized in Table 19.21. For details about the syntax of the SLICE statement, see the section “SLICE Statement” on page 498 in Chapter 19, “Shared Concepts and Topics.”

## STORE Statement

```
STORE <OUT=>item-store-name </ LABEL='label'> ;
```

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “STORE Statement” on page 501 in Chapter 19, “Shared Concepts and Topics.”

## STRATA Statement

```
STRATA variables </ option> ;
```

The STRATA statement specifies variables that form the strata in a stratified sample design. The combinations of categories of STRATA variables define the strata in the sample.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section “Specification of Population Totals and Sampling Rates” on page 7734 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with the REPWEIGHTS statement, you do not need to specify a STRATA statement.

The STRATA variables are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the STRATA variables determine the levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

When determining levels of a STRATA variable, an observation with missing values for this STRATA variable is excluded, unless you specify the MISSING option. For more information, see the section “Missing Values” on page 7723.

You can use multiple STRATA statements to specify stratum variables.

You can specify the following option in the STRATA statement after a slash (/):

### LIST

displays a “Stratum Information” table, which includes values of the STRATA variables and the number of observations, number of clusters, population total, and sampling rate for each stratum. See the section “Stratum Information” on page 7754 for more details.

---

## TEST Statement

`< label: > TEST equation1 <, equation2, ... > </ option > ;`

The TEST statement tests linear hypotheses about the regression coefficients. The Wald test is used to jointly test the null hypotheses ( $H_0: \mathbf{L}\boldsymbol{\theta} = \mathbf{c}$ ) specified in a single TEST statement. When  $\mathbf{c} = \mathbf{0}$  you should specify a CONTRAST statement instead.

Each *equation* specifies a linear hypothesis (a row of the  $\mathbf{L}$  matrix and the corresponding element of the  $\mathbf{c}$  vector); multiple *equations* are separated by commas. The label, which must be a valid SAS name, is used to identify the resulting output and should always be included. You can submit multiple TEST statements.

The form of an *equation* is as follows:

`term < ± term ... > < = ± term < ± term ... >>`

where *term* is a parameter of the model, or a constant, or a constant times a parameter. For a binary response model, the intercept parameter is named INTERCEPT; for an ordinal response model, the intercept parameters are named INTERCEPT, INTERCEPT2, INTERCEPT3, and so on. When no equal sign appears, the expression is set to 0. The following illustrates possible uses of the TEST statement:

```
proc surveylogistic;
 model y= a1 a2 a3 a4;
 test1: test intercept + .5 * a2 = 0;
 test2: test intercept + .5 * a2;
 test3: test a1=a2=a3;
 test4: test a1=a2, a2=a3;
run;
```

Note that the first and second TEST statements are equivalent, as are the third and fourth TEST statements.

You can specify the following option in the TEST statement after a slash (/):

### PRINT

displays intermediate calculations in the testing of the null hypothesis  $H_0: \mathbf{L}\boldsymbol{\theta} = \mathbf{c}$ . This includes  $\mathbf{L}\widehat{\mathbf{V}}(\hat{\boldsymbol{\theta}})\mathbf{L}'$  bordered by  $(\mathbf{L}\hat{\boldsymbol{\theta}} - \mathbf{c})$  and  $[\mathbf{L}\widehat{\mathbf{V}}(\hat{\boldsymbol{\theta}})\mathbf{L}']^{-1}$  bordered by  $[\mathbf{L}\widehat{\mathbf{V}}(\hat{\boldsymbol{\theta}})\mathbf{L}']^{-1}(\mathbf{L}\hat{\boldsymbol{\theta}} - \mathbf{c})$ , where  $\hat{\boldsymbol{\theta}}$  is the pseudo-estimator of  $\boldsymbol{\theta}$  and  $\widehat{\mathbf{V}}(\hat{\boldsymbol{\theta}})$  is the estimated covariance matrix of  $\hat{\boldsymbol{\theta}}$ .

For more information, see the section “Testing Linear Hypotheses about the Regression Coefficients” on page 7745.

---

## UNITS Statement

`UNITS independent1 = list1 <... independentk = listk > </ option > ;`

The UNITS statement enables you to specify units of change for the continuous explanatory variables so that customized odds ratios can be estimated. An estimate of the corresponding odds ratio is produced for each unit of change specified for an explanatory variable. The UNITS statement is ignored for CLASS variables. If the CLODDS option is specified in the MODEL statement, the corresponding confidence limits for the odds ratios are also displayed.

The term *independent* is the name of an explanatory variable, and *list* represents a list of units of change, separated by spaces, that are of interest for that variable. Each unit of change in a list has one of the following forms:

- *number*
- SD or -SD
- *number* \* SD

where *number* is any nonzero number and SD is the sample standard deviation of the corresponding independent variable. For example,  $X = -2$  requests an odds ratio that represents the change in the odds when the variable  $X$  is decreased by two units.  $X = 2*SD$  requests an estimate of the change in the odds when  $X$  is increased by two sample standard deviations.

You can specify the following option in the UNITS statement after a slash (/):

**DEFAULT=*list***

gives a list of units of change for all explanatory variables that are not specified in the UNITS statement. Each unit of change can be in any of the forms described previously. If the DEFAULT= option is not specified, PROC SURVEYLOGISTIC does not produce customized odds ratio estimates for any explanatory variable that is not listed in the UNITS statement.

For more information, see the section “Odds Ratio Estimation” on page 7745.

## WEIGHT Statement

**WEIGHT** *variable* ;

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric, and the sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “Missing Values” on page 7723 for more information. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

If you do not specify a WEIGHT statement but provide replicate weights with a REPWEIGHTS statement, PROC SURVEYLOGISTIC uses the average of replicate weights of each observation as the observation’s weight.

If you do not specify a WEIGHT statement or a REPWEIGHTS statement, PROC SURVEYLOGISTIC assigns all observations a weight of one.

---

## Details: SURVEYLOGISTIC Procedure

---

### Missing Values

If you have missing values in your survey data for any reason, such as nonresponse, this can compromise the quality of your survey results. If the respondents are different from the nonrespondents with regard to a survey effect or outcome, then survey estimates might be biased and cannot accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. After data collection is complete, you can use imputation to replace missing values with acceptable values, and/or you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYLOGISTIC. For more information, see Cochran (1977); Kalton and Kaspyzyk (1986); Brick and Kalton (1996).

If an observation has a missing value or a nonpositive value for the **WEIGHT** or **FREQ** variable, then that observation is excluded from the analysis.

An observation is also excluded if it has a missing value for any design (**STRATA**, **CLUSTER**, or **DOMAIN**) variable, unless you specify the **MISSING** option in the PROC SURVEYLOGISTIC statement. If you specify the **MISSING** option, the procedure treats missing values as a valid (nonmissing) category for all categorical variables.

By default, if an observation contains missing values for the response, offset, or any explanatory variables used in the independent effects, the observation is excluded from the analysis. This treatment is based on the assumption that the missing values are missing completely at random (MCAR). However, this assumption is not true sometimes. For example, evidence from other surveys might suggest that observations with missing values are systematically different from observations without missing values. If you believe that missing values are not missing completely at random, then you can specify the **NOMCAR** option to include these observations with missing values in the dependent variable and the independent variables in the variance estimation.

Whether or not the **NOMCAR** option is used, observations with missing or invalid values for **WEIGHT**, **FREQ**, **STRATA**, **CLUSTER**, or **DOMAIN** variables are always excluded, unless the **MISSING** option is also specified.

When you specify the **NOMCAR** option, the procedure treats observations with and without missing values for variables in the regression model as two different domains, and it performs a domain analysis in the domain of nonmissing observations.

If you use a **REPWEIGHTS** statement, all **REPWEIGHTS** variables must contain nonmissing values.

## Model Specification

### Response Level Ordering

Response level ordering is important because, by default, PROC SURVEYLOGISTIC models the probabilities of response levels with lower *Ordered Values*. Ordered Values, displayed in the “Response Profile” table, are assigned to response levels in ascending sorted order. That is, the lowest response level is assigned Ordered Value 1, the next lowest is assigned Ordered Value 2, and so on. For example, if your response variable  $Y$  takes values in  $\{1, \dots, D + 1\}$ , then the functions of the response probabilities modeled with the cumulative model are

$$\text{logit}(\Pr(Y \leq i|\mathbf{x})), i = 1, \dots, D$$

and for the generalized logit model they are

$$\log \left( \frac{\Pr(Y = i|\mathbf{x})}{\Pr(Y = D + 1|\mathbf{x})} \right), i = 1, \dots, D$$

where the highest Ordered Value  $Y = D + 1$  is the reference level. You can change these default functions by specifying the **EVENT=**, **REF=**, **DESCENDING**, or **ORDER=** response variable options in the MODEL statement.

For binary response data with event and nonevent categories, the procedure models the function

$$\text{logit}(p) = \log \left( \frac{p}{1 - p} \right)$$

where  $p$  is the probability of the response level assigned to Ordered Value 1 in the “Response Profiles” table. Since

$$\text{logit}(p) = -\text{logit}(1 - p)$$

the effect of reversing the order of the two response levels is to change the signs of  $\alpha$  and  $\beta$  in the model  $\text{logit}(p) = \alpha + \mathbf{x}\beta$ .

If your event category has a higher Ordered Value than the nonevent category, the procedure models the nonevent probability. You can use response variable options to model the event probability. For example, suppose the binary response variable  $Y$  takes the values 1 and 0 for event and nonevent, respectively, and **Exposure** is the explanatory variable. By default, the procedure assigns Ordered Value 1 to response level  $Y=0$ , and Ordered Value 2 to response level  $Y=1$ . Therefore, the procedure models the probability of the nonevent (Ordered Value=1) category. To model the event probability, you can do the following:

- Explicitly state which response level is to be modeled by using the response variable option **EVENT=** in the MODEL statement:

```
model Y(event='1') = Exposure;
```

- Specify the response variable option **DESCENDING** in the MODEL statement:

```
model Y(descending)=Exposure;
```

- Specify the response variable option **REF=** in the MODEL statement as the nonevent category for the response variable. This option is most useful when you are fitting a generalized logit model.

```
model Y(ref='0') = Exposure;
```

- Assign a format to Y such that the first formatted value (when the formatted values are put in sorted order) corresponds to the event. For this example, Y=1 is assigned formatted value 'event' and Y=0 is assigned formatted value 'nonevent.' Since **ORDER= FORMATTED** by default, Ordered Value 1 is assigned to response level Y=1 so the procedure models the event.

```
proc format;
 value Disease 1='event' 0='nonevent';
run;

proc surveylogistic;
 format Y Disease.;
 model Y=Exposure;
run;
```

## CLASS Variable Parameterization

Consider a model with one **CLASS** variable A with four levels: 1, 2, 5, and 7. Details of the possible choices for the **PARAM=** option follow.

**EFFECT** Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of  $-1$ . For instance, if the reference level is 7 (**REF=7**), the design matrix columns for A are as follows.

| Design Matrix |    |    |    |
|---------------|----|----|----|
| A             | A1 | A2 | A5 |
| 1             | 1  | 0  | 0  |
| 2             | 0  | 1  | 0  |
| 5             | 0  | 0  | 1  |
| 7             | -1 | -1 | -1 |

For **CLASS** main effects that use the **EFFECT** coding scheme, individual parameters correspond to the difference between the effect of each nonreference level and the average over all four levels.

**GLM** As in **PROC GLM**, four columns are created to indicate group membership. The design matrix columns for A are as follows.

| Design Matrix |    |    |    |    |
|---------------|----|----|----|----|
| A             | A1 | A2 | A5 | A7 |
| 1             | 1  | 0  | 0  | 0  |
| 2             | 0  | 1  | 0  | 0  |
| 5             | 0  | 0  | 1  | 0  |
| 7             | 0  | 0  | 0  | 1  |

For CLASS main effects that use the GLM coding scheme, individual parameters correspond to the difference between the effect of each level and the last level.

**ORDINAL**

Three columns are created to indicate group membership of the higher levels of the effect. For the first level of the effect (which for A is 1), all three dummy variables have a value of 0. The design matrix columns for A are as follows.

| Design Matrix |    |    |    |
|---------------|----|----|----|
| A             | A2 | A5 | A7 |
| 1             | 0  | 0  | 0  |
| 2             | 1  | 0  | 0  |
| 5             | 1  | 1  | 0  |
| 7             | 1  | 1  | 1  |

The first level of the effect is a control or baseline level.

For CLASS main effects that use the ORDINAL coding scheme, the first level of the effect is a control or baseline level; individual parameters correspond to the difference between effects of the current level and the preceding level. When the parameters for an ordinal main effect have the same sign, the response effect is monotonic across the levels.

**POLYNOMIAL | POLY** Three columns are created. The first represents the linear term ( $x$ ), the second represents the quadratic term ( $x^2$ ), and the third represents the cubic term ( $x^3$ ), where  $x$  is the level value. If the CLASS levels are not numeric, they are translated into 1, 2, 3, ... according to their sort order. The design matrix columns for A are as follows.

| Design Matrix |        |        |        |
|---------------|--------|--------|--------|
| A             | APOLY1 | APOLY2 | APOLY3 |
| 1             | 1      | 1      | 1      |
| 2             | 2      | 4      | 8      |
| 5             | 5      | 25     | 125    |
| 7             | 7      | 49     | 343    |

**REFERENCE | REF** Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of 0. For instance, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

| Design Matrix |    |    |    |
|---------------|----|----|----|
| A             | A1 | A2 | A5 |
| 1             | 1  | 0  | 0  |
| 2             | 0  | 1  | 0  |
| 5             | 0  | 0  | 1  |
| 7             | 0  | 0  | 0  |

For CLASS main effects that use the REFERENCE coding scheme, individual parameters correspond to the difference between the effect of each nonreference level and the reference level.

**ORTHEFFECT** The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=EFFECT. The design matrix columns for A are as follows.

| Design Matrix |          |          |          |
|---------------|----------|----------|----------|
| A             | AOEFF1   | AOEFF2   | AOEFF3   |
| 1             | 1.41421  | -0.81650 | -0.57735 |
| 2             | 0.00000  | 1.63299  | -0.57735 |
| 5             | 0.00000  | 0.00000  | 1.73205  |
| 7             | -1.41421 | -0.81649 | -0.57735 |

**ORTHORDINAL** | **ORTHOTHERM** The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=ORDINAL. The design matrix columns for A are as follows.

| Design Matrix |          |          |          |
|---------------|----------|----------|----------|
| A             | AOORD1   | AOORD2   | AOORD3   |
| 1             | -1.73205 | 0.00000  | 0.00000  |
| 2             | 0.57735  | -1.63299 | 0.00000  |
| 5             | 0.57735  | 0.81650  | -1.41421 |
| 7             | 0.57735  | 0.81650  | 1.41421  |

**ORTHPOLY** The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=POLY. The design matrix columns for A are as follows.

| Design Matrix |         |         |         |
|---------------|---------|---------|---------|
| A             | AOPOLY1 | AOPOLY2 | AOPOLY5 |

**ORTHREF** The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=REFERENCE. The design matrix columns for A are as follows.

| Design Matrix |          |          |          |
|---------------|----------|----------|----------|
| A             | AOREF1   | AOREF2   | AOREF3   |
| 1             | 1.73205  | 0.00000  | 0.00000  |
| 2             | -0.57735 | 1.63299  | 0.00000  |
| 5             | -0.57735 | -0.81650 | 1.41421  |
| 7             | -0.57735 | -0.81650 | -1.41421 |

## Link Functions and the Corresponding Distributions

Four link functions are available in the SURVEYLOGISTIC procedure. The logit function is the default. To specify a different link function, use the **LINK=** option in the MODEL statement. The link functions and the corresponding distributions are as follows:

- The **logit** function

$$g(p) = \log\left(\frac{p}{1-p}\right)$$

is the inverse of the cumulative logistic distribution function, which is

$$F(x) = \frac{1}{1 + e^{-x}}$$

- The **probit** (or normit) function

$$g(p) = \Phi^{-1}(p)$$

is the inverse of the cumulative standard normal distribution function, which is

$$F(x) = \Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{1}{2}z^2} dz$$

Traditionally, the probit function includes an additive constant 5, but throughout PROC SURVEYLOGISTIC, the terms probit and normit are used interchangeably, previously defined as  $g(p)$ .

- The **complementary log-log** function

$$g(p) = \log(-\log(1-p))$$

is the inverse of the cumulative extreme-value function (also called the Gompertz distribution), which is

$$F(x) = 1 - e^{-e^x}$$

- The **generalized logit** function extends the binary logit link to a vector of levels  $(\pi_1, \dots, \pi_{k+1})$  by contrasting each level with a fixed level

$$g(\pi_i) = \log\left(\frac{\pi_i}{\pi_{k+1}}\right) \quad i = 1, \dots, k$$

The variances of the normal, logistic, and extreme-value distributions are not the same. Their respective means and variances are

| Distribution  | Mean      | Variance  |
|---------------|-----------|-----------|
| Normal        | 0         | 1         |
| Logistic      | 0         | $\pi^2/3$ |
| Extreme-value | $-\gamma$ | $\pi^2/6$ |

where  $\gamma$  is the Euler constant. In comparing parameter estimates that use different link functions, you need to take into account the different scalings of the corresponding distributions and, for the complementary log-log function, a possible shift in location. For example, if the fitted probabilities are in the neighborhood of 0.1 to 0.9, then the parameter estimates from using the logit link function should be about  $\pi/\sqrt{3} \approx 1.8$  larger than the estimates from the probit link function.

## Model Fitting

### Determining Observations for Likelihood Contributions

If you use the events/trials syntax, each observation is split into two observations. One has the response value 1 with a frequency equal to the value of the *events* variable. The other observation has the response value 2 and a frequency equal to the value of (*trials* – *events*). These two observations have the same explanatory variable values and the same WEIGHT values as the original observation.

For either the single-trial or the events/trials syntax, let  $j$  index all observations. In other words, for the single-trial syntax,  $j$  indexes the actual observations. And, for the events/trials syntax,  $j$  indexes the observations after splitting (as described previously). If your data set has 30 observations and you use the single-trial syntax,  $j$  has values from 1 to 30; if you use the events/trials syntax,  $j$  has values from 1 to 60.

Suppose the response variable in a cumulative response model can take on the ordered values  $1, \dots, k, k + 1$ , where  $k$  is an integer  $\geq 1$ . The likelihood for the  $j$ th observation with ordered response value  $y_j$  and explanatory variables vector (row vectors)  $\mathbf{x}_j$  is given by

$$L_j = \begin{cases} F(\alpha_1 + \mathbf{x}_j \boldsymbol{\beta}) & y_j = 1 \\ F(\alpha_i + \mathbf{x}_j \boldsymbol{\beta}) - F(\alpha_{i-1} + \mathbf{x}_j \boldsymbol{\beta}) & 1 < y_j = i \leq k \\ 1 - F(\alpha_k + \mathbf{x}_j \boldsymbol{\beta}) & y_j = k + 1 \end{cases}$$

where  $F(\cdot)$  is the logistic, normal, or extreme-value distribution function;  $\alpha_1, \dots, \alpha_k$  are ordered intercept parameters; and  $\boldsymbol{\beta}$  is the slope parameter vector.

For the generalized logit model, letting the  $k + 1$ st level be the reference level, the intercepts  $\alpha_1, \dots, \alpha_k$  are unordered and the slope vector  $\boldsymbol{\beta}_i$  varies with each logit. The likelihood for the  $j$ th observation with ordered response value  $y_j$  and explanatory variables vector  $\mathbf{x}_j$  (row vectors) is given by

$$L_j = \Pr(Y = y_j | \mathbf{x}_j) = \begin{cases} \frac{e^{\alpha_i + \mathbf{x}_j \boldsymbol{\beta}_i}}{1 + \sum_{i=1}^k e^{\alpha_i + \mathbf{x}_j \boldsymbol{\beta}_i}} & 1 \leq y_j = i \leq k \\ \frac{1}{1 + \sum_{i=1}^k e^{\alpha_i + \mathbf{x}_j \boldsymbol{\beta}_i}} & y_j = k + 1 \end{cases}$$

### Iterative Algorithms for Model Fitting

Two iterative maximum likelihood algorithms are available in PROC SURVEYLOGISTIC to obtain the pseudo-estimate  $\hat{\boldsymbol{\theta}}$  of the model parameter  $\boldsymbol{\theta}$ . The default is the Fisher scoring method, which is equivalent to fitting by iteratively reweighted least squares. The alternative algorithm is the Newton-Raphson method. Both algorithms give the same parameter estimates; the covariance matrix of  $\hat{\boldsymbol{\theta}}$  is estimated in the section “Variance Estimation” on page 7738. For a generalized logit model, only the Newton-Raphson technique is available. You can use the `TECHNIQUE=` option in the MODEL statement to select a fitting algorithm.

**Iteratively Reweighted Least Squares Algorithm (Fisher Scoring)**

Let  $Y$  be the response variable that takes values  $1, \dots, k, k+1$  ( $k \geq 1$ ). Let  $j$  index all observations and  $Y_j$  be the value of response for the  $j$ th observation. Consider the multinomial variable  $\mathbf{Z}_j = (Z_{1j}, \dots, Z_{kj})'$  such that

$$Z_{ij} = \begin{cases} 1 & \text{if } Y_j = i \\ 0 & \text{otherwise} \end{cases}$$

and  $Z_{(k+1)j} = 1 - \sum_{i=1}^k Z_{ij}$ . With  $\pi_{ij}$  denoting the probability that the  $j$ th observation has response value  $i$ , the expected value of  $\mathbf{Z}_j$  is  $\boldsymbol{\pi}_j = (\pi_{1j}, \dots, \pi_{kj})'$ , and  $\pi_{(k+1)j} = 1 - \sum_{i=1}^k \pi_{ij}$ . The covariance matrix of  $\mathbf{Z}_j$  is  $\mathbf{V}_j$ , which is the covariance matrix of a multinomial random variable for one trial with parameter vector  $\boldsymbol{\pi}_j$ . Let  $\boldsymbol{\theta}$  be the vector of regression parameters—for example,  $\boldsymbol{\theta} = (\alpha_1, \dots, \alpha_k, \boldsymbol{\beta})'$  for cumulative logit model. Let  $\mathbf{D}_j$  be the matrix of partial derivatives of  $\boldsymbol{\pi}_j$  with respect to  $\boldsymbol{\theta}$ . The estimating equation for the regression parameters is

$$\sum_j \mathbf{D}'_j \mathbf{W}_j (\mathbf{Z}_j - \boldsymbol{\pi}_j) = \mathbf{0}$$

where  $\mathbf{W}_j = w_j f_j \mathbf{V}_j^{-1}$ , and  $w_j$  and  $f_j$  are the WEIGHT and FREQ values of the  $j$ th observation.

With a starting value of  $\boldsymbol{\theta}^{(0)}$ , the pseudo-estimate of  $\boldsymbol{\theta}$  is obtained iteratively as

$$\boldsymbol{\theta}^{(i+1)} = \boldsymbol{\theta}^{(i)} + \left( \sum_j \mathbf{D}'_j \mathbf{W}_j \mathbf{D}_j \right)^{-1} \sum_j \mathbf{D}'_j \mathbf{W}_j (\mathbf{Z}_j - \boldsymbol{\pi}_j)$$

where  $\mathbf{D}_j$ ,  $\mathbf{W}_j$ , and  $\boldsymbol{\pi}_j$  are evaluated at the  $i$ th iteration  $\boldsymbol{\theta}^{(i)}$ . The expression after the plus sign is the step size. If the log likelihood evaluated at  $\boldsymbol{\theta}^{(i+1)}$  is less than that evaluated at  $\boldsymbol{\theta}^{(i)}$ , then  $\boldsymbol{\theta}^{(i+1)}$  is recomputed by step-halving or ridging. The iterative scheme continues until convergence is obtained—that is, until  $\boldsymbol{\theta}^{(i+1)}$  is sufficiently close to  $\boldsymbol{\theta}^{(i)}$ . Then the maximum likelihood estimate of  $\boldsymbol{\theta}$  is  $\hat{\boldsymbol{\theta}} = \boldsymbol{\theta}^{(i+1)}$ .

By default, starting values are zero for the slope parameters, and starting values are the observed cumulative logits (that is, logits of the observed cumulative proportions of response) for the intercept parameters. Alternatively, the starting values can be specified with the **INEST=** option in the PROC SURVEYLOGISTIC statement.

**Newton-Raphson Algorithm**

Let

$$\mathbf{g} = \sum_j w_j f_j \frac{\partial l_j}{\partial \boldsymbol{\theta}}$$

$$\mathbf{H} = \sum_j -w_j f_j \frac{\partial^2 l_j}{\partial \boldsymbol{\theta}^2}$$

be the gradient vector and the Hessian matrix, where  $l_j = \log L_j$  is the log likelihood for the  $j$ th observation. With a starting value of  $\boldsymbol{\theta}^{(0)}$ , the pseudo-estimate  $\hat{\boldsymbol{\theta}}$  of  $\boldsymbol{\theta}$  is obtained iteratively until convergence is obtained:

$$\boldsymbol{\theta}^{(i+1)} = \boldsymbol{\theta}^{(i)} + \mathbf{H}^{-1} \mathbf{g}$$

where  $\mathbf{H}$  and  $\mathbf{g}$  are evaluated at the  $i$ th iteration  $\boldsymbol{\theta}^{(i)}$ . If the log likelihood evaluated at  $\boldsymbol{\theta}^{(i+1)}$  is less than that evaluated at  $\boldsymbol{\theta}^{(i)}$ , then  $\boldsymbol{\theta}^{(i+1)}$  is recomputed by step-halving or ridging. The iterative scheme continues until convergence is obtained—that is, until  $\boldsymbol{\theta}^{(i+1)}$  is sufficiently close to  $\boldsymbol{\theta}^{(i)}$ . Then the maximum likelihood estimate of  $\boldsymbol{\theta}$  is  $\hat{\boldsymbol{\theta}} = \boldsymbol{\theta}^{(i+1)}$ .

## Convergence Criteria

Four convergence criteria are allowed: `ABSFCONV=`, `FCONV=`, `GCONV=`, and `XCONV=`. If you specify more than one convergence criterion, the optimization is terminated as soon as one of the criteria is satisfied. If none of the criteria is specified, the default is `GCONV=1E-8`.

## Existence of Maximum Likelihood Estimates

The likelihood equation for a logistic regression model does not always have a finite solution. Sometimes there is a nonunique maximum on the boundary of the parameter space, at infinity. The existence, finiteness, and uniqueness of pseudo-estimates for the logistic regression model depend on the patterns of data points in the observation space (Albert and Anderson 1984; Santner and Duffy 1986).

Consider a binary response model. Let  $Y_j$  be the response of the  $i$ th subject, and let  $\mathbf{x}_j$  be the row vector of explanatory variables (including the constant 1 associated with the intercept). There are three mutually exclusive and exhaustive types of data configurations: complete separation, quasi-complete separation, and overlap.

**Complete separation**                      There is a complete separation of data points if there exists a vector  $\mathbf{b}$  that correctly allocates all observations to their response groups; that is,

$$\begin{cases} \mathbf{x}_j \mathbf{b} > 0 & Y_j = 1 \\ \mathbf{x}_j \mathbf{b} < 0 & Y_j = 2 \end{cases}$$

This configuration gives nonunique infinite estimates. If the iterative process of maximizing the likelihood function is allowed to continue, the log likelihood diminishes to zero, and the dispersion matrix becomes unbounded.

**Quasi-complete separation**            The data are not completely separable, but there is a vector  $\mathbf{b}$  such that

$$\begin{cases} \mathbf{x}_j \mathbf{b} \geq 0 & Y_j = 1 \\ \mathbf{x}_j \mathbf{b} \leq 0 & Y_j = 2 \end{cases}$$

and equality holds for at least one subject in each response group. This configuration also yields nonunique infinite estimates. If the iterative process of maximizing the likelihood function is allowed to continue, the dispersion matrix becomes unbounded and the log likelihood diminishes to a nonzero constant.

**Overlap**                                      If neither complete nor quasi-complete separation exists in the sample points, there is an overlap of sample points. In this configuration, the pseudo-estimates exist and are unique.

Complete separation and quasi-complete separation are problems typically encountered with small data sets. Although complete separation can occur with any type of data, quasi-complete separation is not likely with truly continuous explanatory variables.

The SURVEYLOGISTIC procedure uses a simple empirical approach to recognize the data configurations that lead to infinite parameter estimates. The basis of this approach is that any convergence method of maximizing the log likelihood must yield a solution that gives complete separation, if such a solution exists. In maximizing the log likelihood, there is no checking for complete or quasi-complete separation if convergence is attained in eight or fewer iterations. Subsequent to the eighth iteration, the probability of the observed response is computed for each observation. If the probability of the observed response is one for all observations, there is a complete separation of data points and the iteration process is stopped. If the complete separation of data has not been determined and an observation is identified to have an extremely large probability ( $\geq 0.95$ ) of the observed response, there are two possible situations. First, there is overlap in the data set, and the observation is an atypical observation of its own group. The iterative process, if allowed to continue, stops when a maximum is reached. Second, there is quasi-complete separation in the data set, and the asymptotic dispersion matrix is unbounded. If any of the diagonal elements of the dispersion matrix for the standardized observations vectors (all explanatory variables standardized to zero mean and unit variance) exceeds 5,000, quasi-complete separation is declared and the iterative process is stopped. If either complete separation or quasi-complete separation is detected, a warning message is displayed in the procedure output.

Checking for quasi-complete separation is less foolproof than checking for complete separation. The **NOCHECK** option in the MODEL statement turns off the process of checking for infinite parameter estimates. In cases of complete or quasi-complete separation, turning off the checking process typically results in the procedure failing to converge.

## Model Fitting Statistics

Suppose the model contains  $s$  explanatory effects. For the  $j$ th observation, let  $\hat{\pi}_j$  be the estimated probability of the observed response. The three criteria displayed by the SURVEYLOGISTIC procedure are calculated as follows:

- $-2 \log$  likelihood:

$$-2 \text{ Log L} = -2 \sum_j w_j f_j \log(\hat{\pi}_j)$$

where  $w_j$  and  $f_j$  are the weight and frequency values, respectively, of the  $j$ th observation. For binary response models that use the events/trials syntax, this is equivalent to

$$-2 \text{ Log L} = -2 \sum_j w_j f_j \{r_j \log(\hat{\pi}_j) + (n_j - r_j) \log(1 - \hat{\pi}_j)\}$$

where  $r_j$  is the number of events,  $n_j$  is the number of trials, and  $\hat{\pi}_j$  is the estimated event probability.

- Akaike information criterion:

$$\text{AIC} = -2 \text{ Log L} + 2p$$

where  $p$  is the number of parameters in the model. For cumulative response models,  $p = k + s$ , where  $k$  is the total number of response levels minus one, and  $s$  is the number of explanatory effects. For the generalized logit model,  $p = k(s + 1)$ .

- Schwarz criterion:

$$SC = -2 \text{Log } L + p \log\left(\sum_j f_j\right)$$

where  $p$  is the number of parameters in the model. For cumulative response models,  $p = k + s$ , where  $k$  is the total number of response levels minus one, and  $s$  is the number of explanatory effects. For the generalized logit model,  $p = k(s + 1)$ .

The  $-2 \log$  likelihood statistic has a chi-square distribution under the null hypothesis (that all the explanatory effects in the model are zero), and the procedure produces a  $p$ -value for this statistic. The AIC and SC statistics give two different ways of adjusting the  $-2 \log$  likelihood statistic for the number of terms in the model and the number of observations used.

### Generalized Coefficient of Determination

Cox and Snell (1989, pp. 208–209) propose the following generalization of the coefficient of determination to a more general linear model:

$$R^2 = 1 - \left\{ \frac{L(\mathbf{0})}{L(\hat{\boldsymbol{\theta}})} \right\}^{\frac{2}{n}}$$

where  $L(\mathbf{0})$  is the likelihood of the intercept-only model,  $L(\hat{\boldsymbol{\theta}})$  is the likelihood of the specified model, and  $n$  is the sample size. The quantity  $R^2$  achieves a maximum of less than 1 for discrete models, where the maximum is given by

$$R_{\max}^2 = 1 - \{L(\mathbf{0})\}^{\frac{2}{n}}$$

Nagelkerke (1991) proposes the following adjusted coefficient, which can achieve a maximum value of 1:

$$\tilde{R}^2 = \frac{R^2}{R_{\max}^2}$$

Properties and interpretation of  $R^2$  and  $\tilde{R}^2$  are provided in Nagelkerke (1991). In the “Testing Global Null Hypothesis: BETA=0” table,  $R^2$  is labeled as “RSquare” and  $\tilde{R}^2$  is labeled as “Max-rescaled RSquare.” Use the **RSQUARE** option to request  $R^2$  and  $\tilde{R}^2$ .

### INEST= Data Set

You can specify starting values for the iterative algorithm in the **INEST=** data set.

The **INEST=** data set contains one observation for each **BY** group. The **INEST=** data set must contain the intercept variables (named **Intercept** for binary response models and **Intercept**, **Intercept2**, **Intercept3**, and so forth, for ordinal response models) and all explanatory variables in the **MODEL** statement. If **BY** processing is used, the **INEST=** data set should also include the **BY** variables, and there must be one observation for each **BY** group. If the **INEST=** data set also contains the **\_TYPE\_** variable, only observations with **\_TYPE\_** value ‘**PARMS**’ are used as starting values.

---

## Survey Design Information

### Specification of Population Totals and Sampling Rates

To include a finite population correction (*fpc*) in Taylor series variance estimation, you can input either the sampling rate or the population total by using the `RATE=` or `TOTAL=` option in the PROC SURVEYLOGISTIC statement. (You cannot specify both of these options in the same PROC SURVEYLOGISTIC statement.) The `RATE=` and `TOTAL=` options apply only to Taylor series variance estimation. The procedure does not use a finite population correction for BRR or jackknife variance estimation.

If you do not specify the `RATE=` or `TOTAL=` option, the Taylor series variance estimation does not include a finite population correction. For fairly small sampling fractions, it is appropriate to ignore this correction. See Cochran (1977) and Kish (1965) for more information.

If your design has multiple stages of selection and you are specifying the `RATE=` option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the `TOTAL=` option for a multistage design, you should input the total number of PSUs in the study population. See the section “Primary Sampling Units (PSUs)” on page 7734 for more details.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you can use the `RATE=value` or `TOTAL=value` option. If your sample design is stratified with different sampling rates or population totals in different strata, use the `RATE=SAS-data-set` or `TOTAL=SAS-data-set` option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the `DATA=` option.

The secondary data set must contain all the stratification variables listed in the STRATA statement and all the variables in the BY statement. If there are formats associated with the STRATA variables and the BY variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the `TOTAL=SAS-data-set` option, the secondary data set must have a variable named `_TOTAL_` that contains the stratum population totals. Or if you specify the `RATE=SAS-data-set` option, the secondary data set must have a variable named `_RATE_` that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of `_TOTAL_` or `_RATE_` for that stratum and ignores the rest.

The *value* in the `RATE=` option or the values of `_RATE_` in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYLOGISTIC converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

If you specify the `TOTAL=value` option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

### Primary Sampling Units (PSUs)

When you have clusters, or primary sampling units (PSUs), in your sample design, the procedure estimates variance from the variation among PSUs when the Taylor series variance method is used. See the section “Taylor Series (Linearization)” on page 7739 for more information.

BRR or jackknife variance estimation methods draw multiple replicates (or subsamples) from the full sample by following a specific resampling scheme. These subsamples are constructed by deleting PSUs from the full sample.

If you use a **REPWEIGHTS** statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a **CLUSTER** statement. Otherwise, you should specify a **CLUSTER** statement whenever your design includes clustering at the first stage of sampling. If you do not specify a **CLUSTER** statement, then PROC SURVEYLOGISTIC treats each observation as a PSU.

---

## Logistic Regression Models and Parameters

The SURVEYLOGISTIC procedure fits a logistic regression model and estimates the corresponding regression parameters. Each model uses the link function you specified in the **LINK=** option in the MODEL statement. There are four types of model you can use with the procedure: cumulative logit model, complementary log-log model, probit model, and generalized logit model.

### Notation

Let  $Y$  be the response variable with categories  $1, 2, \dots, D, D + 1$ . The  $p$  covariates are denoted by a  $p$ -dimension row vector  $\mathbf{x}$ .

For a stratified clustered sample design, each observation is represented by a row vector,  $(w_{hij}, \mathbf{y}'_{hij}, y_{hij(D+1)}, \mathbf{x}_{hij})$ , where

- $h = 1, 2, \dots, H$  is the stratum index
- $i = 1, 2, \dots, n_h$  is the cluster index within stratum  $h$
- $j = 1, 2, \dots, m_{hi}$  is the unit index within cluster  $i$  of stratum  $h$
- $w_{hij}$  denotes the sampling weight
- $\mathbf{y}_{hij}$  is a  $D$ -dimensional column vector whose elements are indicator variables for the first  $D$  categories for variable  $Y$ . If the response of the  $j$ th unit of the  $i$ th cluster in stratum  $h$  falls in category  $d$ , the  $d$ th element of the vector is one, and the remaining elements of the vector are zero, where  $d = 1, 2, \dots, D$ .
- $y_{hij(D+1)}$  is the indicator variable for the  $(D + 1)$  category of variable  $Y$
- $\mathbf{x}_{hij}$  denotes the  $k$ -dimensional row vector of explanatory variables for the  $j$ th unit of the  $i$ th cluster in stratum  $h$ . If there is an intercept, then  $x_{hij1} \equiv 1$ .
- $\tilde{n} = \sum_{h=1}^H n_h$  is the total number of clusters in the sample
- $n = \sum_{h=1}^H \sum_{i=1}^{n_h} m_{hi}$  is the total sample size

The following notations are also used:

- $f_h$  denotes the sampling rate for stratum  $h$
- $\boldsymbol{\pi}_{hij}$  is the expected vector of the response variable:

$$\begin{aligned}\boldsymbol{\pi}_{hij} &= E(\mathbf{y}_{hij}|\mathbf{x}_{hij}) \\ &= (\pi_{hij1}, \pi_{hij2}, \dots, \pi_{hijD})' \\ \pi_{hij(D+1)} &= E(y_{hij(D+1)}|\mathbf{x}_{hij})\end{aligned}$$

Note that  $\pi_{hij(D+1)} = 1 - \mathbf{1}'\boldsymbol{\pi}_{hij}$ , where  $\mathbf{1}$  is a  $D$ -dimensional column vector whose elements are 1.

## Logistic Regression Models

If the response categories of the response variable  $Y$  can be restricted to a number of ordinal values, you can fit cumulative probabilities of the response categories with a cumulative logit model, a complementary log-log model, or a probit model. Details of cumulative logit models (or proportional odds models) can be found in McCullagh and Nelder (1989). If the response categories of  $Y$  are nominal responses without natural ordering, you can fit the response probabilities with a generalized logit model. Formulation of the generalized logit models for nominal response variables can be found in Agresti (2002). For each model, the procedure estimates the model parameter  $\boldsymbol{\theta}$  by using a pseudo-log-likelihood function. The procedure obtains the pseudo-maximum likelihood estimator  $\hat{\boldsymbol{\theta}}$  by using iterations described in the section “[Iterative Algorithms for Model Fitting](#)” on page 7729 and estimates its variance described in the section “[Variance Estimation](#)” on page 7738.

### Cumulative Logit Model

A cumulative logit model uses the **logit** function

$$g(t) = \log\left(\frac{t}{1-t}\right)$$

as the link function.

Denote the cumulative sum of the expected proportions for the first  $d$  categories of variable  $Y$  by

$$F_{hijd} = \sum_{r=1}^d \pi_{hijr}$$

for  $d = 1, 2, \dots, D$ . Then the cumulative logit model can be written as

$$\log\left(\frac{F_{hijd}}{1-F_{hijd}}\right) = \alpha_d + \mathbf{x}_{hij}\boldsymbol{\beta}$$

with the model parameters

$$\begin{aligned}\boldsymbol{\beta} &= (\beta_1, \beta_2, \dots, \beta_k)' \\ \boldsymbol{\alpha} &= (\alpha_1, \alpha_2, \dots, \alpha_D)', \quad \alpha_1 < \alpha_2 < \dots < \alpha_D \\ \boldsymbol{\theta} &= (\boldsymbol{\alpha}', \boldsymbol{\beta}')'\end{aligned}$$

**Complementary Log-Log Model**

A complementary log-log model uses the **complementary log-log** function

$$g(t) = \log(-\log(1 - t))$$

as the link function. Denote the cumulative sum of the expected proportions for the first  $d$  categories of variable  $Y$  by

$$F_{hijd} = \sum_{r=1}^d \pi_{hijr}$$

for  $d = 1, 2, \dots, D$ . Then the complementary log-log model can be written as

$$\log(-\log(1 - F_{hijd})) = \alpha_d + \mathbf{x}_{hij} \boldsymbol{\beta}$$

with the model parameters

$$\begin{aligned} \boldsymbol{\beta} &= (\beta_1, \beta_2, \dots, \beta_k)' \\ \boldsymbol{\alpha} &= (\alpha_1, \alpha_2, \dots, \alpha_D)', \quad \alpha_1 < \alpha_2 < \dots < \alpha_D \\ \boldsymbol{\theta} &= (\boldsymbol{\alpha}', \boldsymbol{\beta}')' \end{aligned}$$

**Probit Model**

A probit model uses the **probit** (or normit) function, which is the inverse of the cumulative standard normal distribution function,

$$g(t) = \Phi^{-1}(t)$$

as the link function, where

$$\Phi(t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^t e^{-\frac{1}{2}z^2} dz$$

Denote the cumulative sum of the expected proportions for the first  $d$  categories of variable  $Y$  by

$$F_{hijd} = \sum_{r=1}^d \pi_{hijr}$$

for  $d = 1, 2, \dots, D$ . Then the probit model can be written as

$$F_{hijd} = \Phi(\alpha_d + \mathbf{x}_{hij} \boldsymbol{\beta})$$

with the model parameters

$$\begin{aligned} \boldsymbol{\beta} &= (\beta_1, \beta_2, \dots, \beta_k)' \\ \boldsymbol{\alpha} &= (\alpha_1, \alpha_2, \dots, \alpha_D)', \quad \alpha_1 < \alpha_2 < \dots < \alpha_D \\ \boldsymbol{\theta} &= (\boldsymbol{\alpha}', \boldsymbol{\beta}')' \end{aligned}$$

### Generalized Logit Model

For nominal response, a generalized logit model is to fit the ratio of the expected proportion for each response category over the expected proportion of a reference category with a logit link function.

Without loss of generality, let category  $D + 1$  be the reference category for the response variable  $Y$ . Denote the expected proportion for the  $d$ th category by  $\pi_{hij d}$  as in the section “Notation” on page 7735. Then the generalized logit model can be written as

$$\log \left( \frac{\pi_{hij d}}{\pi_{hij(D+1)}} \right) = \mathbf{x}_{hij} \boldsymbol{\beta}_d$$

for  $d = 1, 2, \dots, D$ , with the model parameters

$$\begin{aligned} \boldsymbol{\beta}_d &= (\beta_{d1}, \beta_{d2}, \dots, \beta_{dk})' \\ \boldsymbol{\theta} &= (\boldsymbol{\beta}'_1, \boldsymbol{\beta}'_2, \dots, \boldsymbol{\beta}'_D)' \end{aligned}$$

### Likelihood Function

Let  $g(\cdot)$  be a link function such that

$$\boldsymbol{\pi} = \mathbf{g}(\mathbf{x}, \boldsymbol{\theta})$$

where  $\boldsymbol{\theta}$  is a column vector for regression coefficients. The pseudo-log likelihood is

$$l(\boldsymbol{\theta}) = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} \left( (\log(\boldsymbol{\pi}_{hij}))' \mathbf{y}_{hij} + \log(\pi_{hij(D+1)}) y_{hij(D+1)} \right)$$

Denote the pseudo-estimator as  $\hat{\boldsymbol{\theta}}$ , which is a solution to the estimating equations:

$$\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} \mathbf{D}_{hij} \left( \text{diag}(\boldsymbol{\pi}_{hij}) - \boldsymbol{\pi}_{hij} \boldsymbol{\pi}'_{hij} \right)^{-1} (\mathbf{y}_{hij} - \boldsymbol{\pi}_{hij}) = \mathbf{0}$$

where  $\mathbf{D}_{hij}$  is the matrix of partial derivatives of the link function  $\mathbf{g}$  with respect to  $\boldsymbol{\theta}$ .

To obtain the pseudo-estimator  $\hat{\boldsymbol{\theta}}$ , the procedure uses iterations with a starting value  $\boldsymbol{\theta}^{(0)}$  for  $\boldsymbol{\theta}$ . See the section “Iterative Algorithms for Model Fitting” on page 7729 for more details.

---

### Variance Estimation

Due to the variability of characteristics among items in the population, researchers apply scientific sample designs in the sample selection process to reduce the risk of a distorted view of the population, and they make inferences about the population based on the information from the sample survey data. In order to make statistically valid inferences for the population, they must incorporate the sample design in the data analysis.

The SURVEYLOGISTIC procedure fits linear logistic regression models for discrete response survey data by using the maximum likelihood method. In the variance estimation, the procedure uses the Taylor series

(linearization) method or replication (resampling) methods to estimate sampling errors of estimators based on complex sample designs, including designs with stratification, clustering, and unequal weighting (Binder 1981, 1983; Roberts, Rao, and Kumar 1987; Skinner, Holt, and Smith 1989; Binder and Roberts 2003; Morel 1989; Lehtonen and Pahkinen 1995; Woodruff 1971; Fuller 1975; Särndal, Swensson, and Wretman 1992; Fuller 2009; Wolter 2007; Rust 1985; Dippo, Fay, and Morganstein 1984; Rao and Shao 1999; Rao, Wu, and Yue 1992; Rao and Shao 1996).

You can use the `VARMETHOD=` option to specify a variance estimation method to use. By default, the Taylor series method is used. However, replication methods have recently gained popularity for estimating variances in complex survey data analysis. One reason for this popularity is the relative simplicity of replication-based estimates, especially for nonlinear estimators; another is that modern computational capacity has made replication methods feasible for practical survey analysis.

Replication methods draw multiple replicates (also called subsamples) from a full sample according to a specific resampling scheme. The most commonly used resampling schemes are the *balanced repeated replication* (BRR) method and the *jackknife* method. For each replicate, the original weights are modified for the PSUs in the replicates to create replicate weights. The parameters of interest are estimated by using the replicate weights for each replicate. Then the variances of parameters of interest are estimated by the variability among the estimates derived from these replicates. You can use the `REPWEIGHTS` statement to provide your own replicate weights for variance estimation.

The following sections provide details about how the variance-covariance matrix of the estimated regression coefficients is estimated for each variance estimation method.

### Taylor Series (Linearization)

The Taylor series (linearization) method is the most commonly used method to estimate the covariance matrix of the regression coefficients for complex survey data. It is the default variance estimation method used by PROC SURVEYLOGISTIC.

Using the notation described in the section “Notation” on page 7735, the estimated covariance matrix of model parameters  $\hat{\theta}$  by the Taylor series method is

$$\widehat{V}(\hat{\theta}) = \widehat{Q}^{-1} \widehat{G} \widehat{Q}^{-1}$$

where

$$\begin{aligned} \widehat{Q} &= \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} \widehat{D}_{hij} \left( \text{diag}(\hat{\boldsymbol{\pi}}_{hij}) - \hat{\boldsymbol{\pi}}_{hij} \hat{\boldsymbol{\pi}}'_{hij} \right)^{-1} \widehat{D}'_{hij} \\ \widehat{G} &= \frac{n-1}{n-p} \sum_{h=1}^H \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot}) (\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot})' \\ \mathbf{e}_{hi\cdot} &= \sum_{j=1}^{m_{hi}} w_{hij} \widehat{D}_{hij} \left( \text{diag}(\hat{\boldsymbol{\pi}}_{hij}) - \hat{\boldsymbol{\pi}}_{hij} \hat{\boldsymbol{\pi}}'_{hij} \right)^{-1} (\mathbf{y}_{hij} - \hat{\boldsymbol{\pi}}_{hij}) \\ \bar{\mathbf{e}}_{h\cdot\cdot} &= \frac{1}{n_h} \sum_{i=1}^{n_h} \mathbf{e}_{hi\cdot} \end{aligned}$$

and  $\mathbf{D}_{hij}$  is the matrix of partial derivatives of the link function  $g$  with respect to  $\boldsymbol{\theta}$  and  $\widehat{D}_{hij}$  and the response probabilities  $\hat{\boldsymbol{\pi}}_{hij}$  are evaluated at  $\hat{\boldsymbol{\theta}}$ .

If you specify the `TECHNIQUE=NEWTON` option in the `MODEL` statement to request the **Newton-Raphson algorithm**, the matrix  $\widehat{\mathbf{Q}}$  is replaced by the negative (expected) Hessian matrix when the estimated covariance matrix  $\widehat{\mathbf{V}}(\widehat{\boldsymbol{\theta}})$  is computed.

### Adjustments to the Variance Estimation

The factor  $(n - 1)/(n - p)$  in the computation of the matrix  $\widehat{\mathbf{G}}$  reduces the small sample bias associated with using the estimated function to calculate deviations (Morel 1989; Hidioglou, Fuller, and Hickman 1980). For simple random sampling, this factor contributes to the degrees-of-freedom correction applied to the residual mean square for ordinary least squares in which  $p$  parameters are estimated. By default, the procedure uses this adjustment in Taylor series variance estimation. It is equivalent to specifying the `VADJUST=DF` option in the `MODEL` statement. If you do not want to use this multiplier in the variance estimation, you can specify the `VADJUST=NONE` option in the `MODEL` statement to suppress this factor.

In addition, you can specify the `VADJUST=MOREL` option to request an adjustment to the variance estimator for the model parameters  $\widehat{\boldsymbol{\theta}}$ , introduced by Morel (1989):

$$\widehat{\mathbf{V}}(\widehat{\boldsymbol{\theta}}) = \widehat{\mathbf{Q}}^{-1}\widehat{\mathbf{G}}\widehat{\mathbf{Q}}^{-1} + \kappa\lambda\widehat{\mathbf{Q}}^{-1}$$

where for given nonnegative constants  $\delta$  and  $\phi$ ,

$$\begin{aligned}\kappa &= \max\left(\delta, p^{-1}\text{tr}\left(\widehat{\mathbf{Q}}^{-1}\widehat{\mathbf{G}}\right)\right) \\ \lambda &= \min\left(\phi, \frac{p}{\bar{n} - p}\right)\end{aligned}$$

The adjustment  $\kappa\lambda\widehat{\mathbf{Q}}^{-1}$  does the following:

- reduces the small sample bias reflected in inflated Type I error rates
- guarantees a positive-definite estimated covariance matrix provided that  $\widehat{\mathbf{Q}}^{-1}$  exists
- is close to zero when the sample size becomes large

In this adjustment,  $\kappa$  is an estimate of the design effect, which has been bounded below by the positive constant  $\delta$ . You can use `DEFFBOUND= $\delta$`  in the `VADJUST=MOREL` option in the `MODEL` statement to specify this lower bound; by default, the procedure uses  $\delta = 1$ . The factor  $\lambda$  converges to zero when the sample size becomes large, and  $\lambda$  has an upper bound  $\phi$ . You can use `ADJBOUND= $\phi$`  in the `VADJUST=MOREL` option in the `MODEL` statement to specify this upper bound; by default, the procedure uses  $\phi = 0.5$ .

### Balanced Repeated Replication (BRR) Method

The balanced repeated replication (BRR) method requires that the full sample be drawn by using a stratified sample design with two primary sampling units (PSUs) per stratum. Let  $H$  be the total number of strata. The total number of replicates  $R$  is the smallest multiple of 4 that is greater than  $H$ . However, if you prefer a larger number of replicates, you can specify the `REPS=number` option. If a *number*  $\times$  *number* Hadamard matrix cannot be constructed, the number of replicates is increased until a Hadamard matrix becomes available.

Each replicate is obtained by deleting one PSU per stratum according to the corresponding **Hadamard matrix** and adjusting the original weights for the remaining PSUs. The new weights are called replicate weights.

Replicates are constructed by using the first  $H$  columns of the  $R \times R$  **Hadamard matrix**. The  $r$ th ( $r = 1, 2, \dots, R$ ) replicate is drawn from the full sample according to the  $r$ th row of the Hadamard matrix as follows:

- If the  $(r, h)$  element of the Hadamard matrix is 1, then the first PSU of stratum  $h$  is included in the  $r$ th replicate and the second PSU of stratum  $h$  is excluded.
- If the  $(r, h)$  element of the Hadamard matrix is  $-1$ , then the second PSU of stratum  $h$  is included in the  $r$ th replicate and the first PSU of stratum  $h$  is excluded.

Note that the “first” and “second” PSUs are determined by data order in the input data set. Thus, if you reorder the data set and perform the same analysis by using BRR method, you might get slightly different results, because the contents in each replicate sample might change.

The replicate weights of the remaining PSUs in each half-sample are then doubled to their original weights. For more details about the BRR method, see Wolter (2007) and Lohr (2010).

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the **VARMETHOD=BRR(PRINTH)** *method-option*. If you provide a Hadamard matrix by specifying the **VARMETHOD=BRR(HADAMARD=)** *method-option*, then the replicates are generated according to the provided Hadamard matrix.

You can use the **VARMETHOD=BRR(OUTWEIGHTS=)** *method-option* to save the replicate weights into a SAS data set.

Let  $\hat{\theta}$  be the estimated regression coefficients from the full sample for  $\theta$ , and let  $\hat{\theta}_r$  be the estimated regression coefficient from the  $r$ th replicate by using replicate weights. PROC SURVEYLOGISTIC estimates the covariance matrix of  $\hat{\theta}$  by

$$\widehat{V}(\hat{\theta}) = \frac{1}{R} \sum_{r=1}^R (\hat{\theta}_r - \hat{\theta}) (\hat{\theta}_r - \hat{\theta})'$$

with  $H$  degrees of freedom, where  $H$  is the number of strata.

## Fay's BRR Method

Fay's method is a modification of the **BRR** method, and it requires a stratified sample design with two primary sampling units (PSUs) per stratum. The total number of replicates  $R$  is the smallest multiple of 4 that is greater than the total number of strata  $H$ . However, if you prefer a larger number of replicates, you can specify the **REPS=** *method-option*.

For each replicate, Fay's method uses a Fay coefficient  $0 \leq \epsilon < 1$  to impose a perturbation of the original weights in the full sample that is gentler than using only half-samples, as in the traditional BRR method. The Fay coefficient  $0 \leq \epsilon < 1$  can be set by specifying the **FAY =  $\epsilon$**  *method-option*. By default,  $\epsilon = 0.5$  if the **FAY** *method-option* is specified without providing a value for  $\epsilon$  (Judkins 1990; Rao and Shao 1999). When  $\epsilon = 0$ , Fay's method becomes the traditional **BRR** method. For more details, see Dippo, Fay, and Morganstein (1984); Fay (1984, 1989); Judkins (1990).

Let  $H$  be the number of strata. Replicates are constructed by using the first  $H$  columns of the  $R \times R$  Hadamard matrix, where  $R$  is the number of replicates,  $R > H$ . The  $r$ th ( $r = 1, 2, \dots, R$ ) replicate is created from the full sample according to the  $r$ th row of the Hadamard matrix as follows:

- If the  $(r, h)$  element of the Hadamard matrix is 1, then the full sample weight of the first PSU in stratum  $h$  is multiplied by  $\epsilon$  and the full sample weight of the second PSU is multiplied by  $2 - \epsilon$  to obtain the  $r$ th replicate weights.
- If the  $(r, h)$  element of the Hadamard matrix is  $-1$ , then the full sample weight of the first PSU in stratum  $h$  is multiplied by  $2 - \epsilon$  and the full sample weight of the second PSU is multiplied by  $\epsilon$  to obtain the  $r$ th replicate weights.

You can use the `VARMETHOD=BRR(OUTWEIGHTS=)` *method-option* to save the replicate weights into a SAS data set.

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the `VARMETHOD=BRR(PRINTH)` *method-option*. If you provide a Hadamard matrix by specifying the `VARMETHOD=BRR(HADAMARD=)` *method-option*, then the replicates are generated according to the provided Hadamard matrix.

Let  $\hat{\theta}$  be the estimated regression coefficients from the full sample for  $\theta$ . Let  $\hat{\theta}_r$  be the estimated regression coefficient obtained from the  $r$ th replicate by using replicate weights. PROC SURVEYLOGISTIC estimates the covariance matrix of  $\hat{\theta}$  by

$$\widehat{V}(\hat{\theta}) = \frac{1}{R(1 - \epsilon)^2} \sum_{r=1}^R (\hat{\theta}_r - \hat{\theta}) (\hat{\theta}_r - \hat{\theta})'$$

with  $H$  degrees of freedom, where  $H$  is the number of strata.

## Jackknife Method

The jackknife method of variance estimation deletes one PSU at a time from the full sample to create replicates. The total number of replicates  $R$  is the same as the total number of PSUs. In each replicate, the sample weights of the remaining PSUs are modified by the jackknife coefficient  $\alpha_r$ . The modified weights are called replicate weights.

The jackknife coefficient and replicate weights are described as follows.

**Without Stratification** If there is no stratification in the sample design (no `STRATA` statement), the jackknife coefficients  $\alpha_r$  are the same for all replicates:

$$\alpha_r = \frac{R - 1}{R} \quad \text{where } r = 1, 2, \dots, R$$

Denote the original weight in the full sample for the  $j$ th member of the  $i$ th PSU as  $w_{ij}$ . If the  $i$ th PSU is included in the  $r$ th replicate ( $r = 1, 2, \dots, R$ ), then the corresponding replicate weight for the  $j$ th member of the  $i$ th PSU is defined as

$$w_{ij}^{(r)} = w_{ij} / \alpha_r$$

**With Stratification** If the sample design involves stratification, each stratum must have at least two PSUs to use the jackknife method.

Let stratum  $\tilde{h}_r$  be the stratum from which a PSU is deleted for the  $r$ th replicate. Stratum  $\tilde{h}_r$  is called the *donor stratum*. Let  $n_{\tilde{h}_r}$  be the total number of PSUs in the donor stratum  $\tilde{h}_r$ . The jackknife coefficients are defined as

$$\alpha_r = \frac{n_{\tilde{h}_r} - 1}{n_{\tilde{h}_r}} \quad \text{where } r = 1, 2, \dots, R$$

Denote the original weight in the full sample for the  $j$ th member of the  $i$ th PSU as  $w_{ij}$ . If the  $i$ th PSU is included in the  $r$ th replicate ( $r = 1, 2, \dots, R$ ), then the corresponding replicate weight for the  $j$ th member of the  $i$ th PSU is defined as

$$w_{ij}^{(r)} = \begin{cases} w_{ij} & \text{if } i\text{th PSU is not in the donor stratum } \tilde{h}_r \\ w_{ij}/\alpha_r & \text{if } i\text{th PSU is in the donor stratum } \tilde{h}_r \end{cases}$$

You can use the `VARMETHOD=JACKKNIFE(OUTJKCOEFS=)` *method-option* to save the jackknife coefficients into a SAS data set and use the `VARMETHOD=JACKKNIFE(OUTWEIGHTS=)` *method-option* to save the replicate weights into a SAS data set.

If you provide your own replicate weights with a `REPWEIGHTS` statement, then you can also provide corresponding jackknife coefficients with the `JKCOEFS=` option.

Let  $\hat{\theta}$  be the estimated regression coefficients from the full sample for  $\theta$ . Let  $\hat{\theta}_r$  be the estimated regression coefficient obtained from the  $r$ th replicate by using replicate weights. PROC SURVEYLOGISTIC estimates the covariance matrix of  $\hat{\theta}$  by

$$\widehat{V}(\hat{\theta}) = \sum_{r=1}^R \alpha_r (\hat{\theta}_r - \hat{\theta}) (\hat{\theta}_r - \hat{\theta})'$$

with  $R - H$  degrees of freedom, where  $R$  is the number of replicates and  $H$  is the number of strata, or  $R - 1$  when there is no stratification.

### Hadamard Matrix

A Hadamard matrix  $\mathbf{H}$  is a square matrix whose elements are either 1 or -1 such that

$$\mathbf{H}\mathbf{H}' = k\mathbf{I}$$

where  $k$  is the dimension of  $\mathbf{H}$  and  $\mathbf{I}$  is the identity matrix of order  $k$ . The order  $k$  is necessarily 1, 2, or a positive integer that is a multiple of 4.

For example, the following matrix is a Hadamard matrix of dimension  $k = 8$ :

$$\begin{matrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 & 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 & 1 & -1 & -1 & 1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & -1 & 1 & -1 & -1 & 1 & -1 & 1 \\ 1 & 1 & -1 & -1 & -1 & -1 & 1 & 1 \\ 1 & -1 & -1 & 1 & -1 & 1 & 1 & -1 \end{matrix}$$

## Domain Analysis

A **DOMAIN** statement requests that the procedure perform logistic regression analysis for each domain.

For a domain  $\Omega$ , let  $I_\Omega$  be the corresponding indicator variable:

$$I_\Omega(h, i, j) = \begin{cases} 1 & \text{if observation } (h, i, j) \text{ belongs to } \Omega \\ 0 & \text{otherwise} \end{cases}$$

Let

$$v_{hij} = w_{hij} I_\Omega(h, i, j) = \begin{cases} w_{hij} & \text{if observation } (h, i, j) \text{ belongs to } \Omega \\ 0 & \text{otherwise} \end{cases}$$

The regression in domain  $\Omega$  uses  $v$  as the weight variable.

## Hypothesis Testing and Estimation

### Score Statistics and Tests

To understand the general form of the score statistics, let  $\mathbf{g}(\boldsymbol{\theta})$  be the vector of first partial derivatives of the log likelihood with respect to the parameter vector  $\boldsymbol{\theta}$ , and let  $\mathbf{H}(\boldsymbol{\theta})$  be the matrix of second partial derivatives of the log likelihood with respect to  $\boldsymbol{\theta}$ . That is,  $\mathbf{g}(\boldsymbol{\theta})$  is the gradient vector, and  $\mathbf{H}(\boldsymbol{\theta})$  is the Hessian matrix. Let  $\mathbf{I}(\boldsymbol{\theta})$  be either  $-\mathbf{H}(\boldsymbol{\theta})$  or the expected value of  $-\mathbf{H}(\boldsymbol{\theta})$ . Consider a null hypothesis  $H_0$ . Let  $\hat{\boldsymbol{\theta}}$  be the MLE of  $\boldsymbol{\theta}$  under  $H_0$ . The chi-square score statistic for testing  $H_0$  is defined by

$$\mathbf{g}'(\hat{\boldsymbol{\theta}})\mathbf{I}^{-1}(\hat{\boldsymbol{\theta}})\mathbf{g}(\hat{\boldsymbol{\theta}})$$

It has an asymptotic  $\chi^2$  distribution with  $r$  degrees of freedom under  $H_0$ , where  $r$  is the number of restrictions imposed on  $\boldsymbol{\theta}$  by  $H_0$ .

### Testing the Parallel Lines Assumption

For an ordinal response, PROC SURVEYLOGISTIC performs a test of the parallel lines assumption. In the displayed output, this test is labeled “Score Test for the Equal Slopes Assumption” when the **LINK=** option is **NORMIT** or **CLOGLOG**. When **LINK=LOGIT**, the test is labeled as “Score Test for the Proportional Odds Assumption” in the output. This section describes the methods used to calculate the test.

For this test, the number of response levels,  $D + 1$ , is assumed to be strictly greater than 2. Let  $Y$  be the response variable taking values  $1, \dots, D, D + 1$ . Suppose there are  $k$  explanatory variables. Consider the general cumulative model without making the parallel lines assumption:

$$g(\Pr(Y \leq d \mid \mathbf{x})) = (\mathbf{1}, \mathbf{x})\boldsymbol{\theta}_d, \quad 1 \leq d \leq D$$

where  $g(\cdot)$  is the link function, and  $\boldsymbol{\theta}_d = (\alpha_d, \beta_{d1}, \dots, \beta_{dk})'$  is a vector of unknown parameters consisting of an intercept  $\alpha_d$  and  $k$  slope parameters  $\beta_{k1}, \dots, \beta_{kd}$ . The parameter vector for this general cumulative model is

$$\boldsymbol{\theta} = (\boldsymbol{\theta}'_1, \dots, \boldsymbol{\theta}'_D)'$$

Under the null hypothesis of parallelism  $H_0: \beta_{1i} = \beta_{2i} = \dots = \beta_{Di}, 1 \leq i \leq k$ , there is a single common slope parameter for each of the  $s$  explanatory variables. Let  $\beta_1, \dots, \beta_k$  be the common slope parameters. Let  $\hat{\alpha}_1, \dots, \hat{\alpha}_D$  and  $\hat{\beta}_1, \dots, \hat{\beta}_k$  be the MLEs of the intercept parameters and the common slope parameters. Then, under  $H_0$ , the MLE of  $\theta$  is

$$\hat{\theta} = (\hat{\theta}'_1, \dots, \hat{\theta}'_D)' \quad \text{with} \quad \hat{\theta}_d = (\hat{\alpha}_d, \hat{\beta}_1, \dots, \hat{\beta}_k)', \quad 1 \leq d \leq D$$

and the chi-square score statistic  $\mathbf{g}'(\hat{\theta})\mathbf{I}^{-1}(\hat{\theta})\mathbf{g}(\hat{\theta})$  has an asymptotic chi-square distribution with  $k(D - 1)$  degrees of freedom. This tests the parallel lines assumption by testing the equality of separate slope parameters simultaneously for all explanatory variables.

### Wald Confidence Intervals for Parameters

Wald confidence intervals are sometimes called normal confidence intervals. They are based on the asymptotic normality of the parameter estimators. The  $100(1 - \alpha)\%$  Wald confidence interval for  $\theta_j$  is given by

$$\hat{\theta}_j \pm z_{1-\alpha/2} \hat{\sigma}_j$$

where  $z_{1-\alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the standard normal distribution,  $\hat{\theta}_j$  is the pseudo-estimate of  $\theta_j$ , and  $\hat{\sigma}_j$  is the standard error estimate of  $\hat{\theta}_j$  in the section “Variance Estimation” on page 7738.

### Testing Linear Hypotheses about the Regression Coefficients

Linear hypotheses for  $\theta$  are expressed in matrix form as

$$H_0: \mathbf{L}\theta = \mathbf{c}$$

where  $\mathbf{L}$  is a matrix of coefficients for the linear hypotheses and  $\mathbf{c}$  is a vector of constants. The vector of regression coefficients  $\theta$  includes slope parameters as well as intercept parameters. The Wald chi-square statistic for testing  $H_0$  is computed as

$$\chi^2_W = (\mathbf{L}\hat{\theta} - \mathbf{c})'[\mathbf{L}\hat{\mathbf{V}}(\hat{\theta})\mathbf{L}']^{-1}(\mathbf{L}\hat{\theta} - \mathbf{c})$$

where  $\hat{\mathbf{V}}(\hat{\theta})$  is the estimated covariance matrix in the section “Variance Estimation” on page 7738. Under  $H_0$ ,  $\chi^2_W$  has an asymptotic chi-square distribution with  $r$  degrees of freedom, where  $r$  is the rank of  $\mathbf{L}$ .

### Odds Ratio Estimation

Consider a dichotomous response variable with outcomes *event* and *nonevent*. Let a dichotomous risk factor variable  $X$  take the value 1 if the risk factor is present and 0 if the risk factor is absent. According to the logistic model, the log odds function,  $g(X)$ , is given by

$$g(X) \equiv \log\left(\frac{\Pr(\text{event} | X)}{\Pr(\text{nonevent} | X)}\right) = \beta_0 + \beta_1 X$$

The odds ratio  $\psi$  is defined as the ratio of the odds for those with the risk factor ( $X = 1$ ) to the odds for those without the risk factor ( $X = 0$ ). The log of the odds ratio is given by

$$\log(\psi) \equiv \log(\psi(X = 1, X = 0)) = g(X = 1) - g(X = 0) = \beta_1$$

The parameter,  $\beta_1$ , associated with  $X$  represents the change in the log odds from  $X = 0$  to  $X = 1$ . So the odds ratio is obtained by simply exponentiating the value of the parameter associated with the risk factor. The odds ratio indicates how the odds of *event* change as you change  $X$  from 0 to 1. For instance,  $\psi = 2$  means that the odds of an event when  $X = 1$  are twice the odds of an event when  $X = 0$ .

Suppose the values of the dichotomous risk factor are coded as constants  $a$  and  $b$  instead of 0 and 1. The odds when  $X = a$  become  $\exp(\beta_0 + a\beta_1)$ , and the odds when  $X = b$  become  $\exp(\beta_0 + b\beta_1)$ . The odds ratio corresponding to an increase in  $X$  from  $a$  to  $b$  is

$$\psi = \exp[(b - a)\beta_1] = [\exp(\beta_1)]^{b-a} \equiv [\exp(\beta_1)]^c$$

Note that for any  $a$  and  $b$  such that  $c = b - a = 1$ ,  $\psi = \exp(\beta_1)$ . So the odds ratio can be interpreted as the change in the odds for any increase of one unit in the corresponding risk factor. However, the change in odds for some amount other than one unit is often of greater interest. For example, a change of one pound in body weight might be too small to be considered important, while a change of 10 pounds might be more meaningful. The odds ratio for a change in  $X$  from  $a$  to  $b$  is estimated by raising the odds ratio estimate for a unit change in  $X$  to the power of  $c = b - a$ , as shown previously.

For a polytomous risk factor, the computation of odds ratios depends on how the risk factor is parameterized. For illustration, suppose that **Race** is a risk factor with four categories: White, Black, Hispanic, and Other.

For the effect parameterization scheme (PARAM=EFFECT) with White as the reference group, the design variables for **Race** are as follows.

| Race     | Design Variables |       |       |
|----------|------------------|-------|-------|
|          | $X_1$            | $X_2$ | $X_3$ |
| Black    | 1                | 0     | 0     |
| Hispanic | 0                | 1     | 0     |
| Other    | 0                | 0     | 1     |
| White    | -1               | -1    | -1    |

The log odds for Black is

$$\begin{aligned} g(\text{Black}) &= \beta_0 + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) \\ &= \beta_0 + \beta_1 \end{aligned}$$

The log odds for White is

$$\begin{aligned} g(\text{White}) &= \beta_0 + \beta_1(X_1 = -1) + \beta_2(X_2 = -1) + \beta_3(X_3 = -1) \\ &= \beta_0 - \beta_1 - \beta_2 - \beta_3 \end{aligned}$$

Therefore, the log odds ratio of Black versus White becomes

$$\begin{aligned} \log(\psi(\text{Black, White})) &= g(\text{Black}) - g(\text{White}) \\ &= 2\beta_1 + \beta_2 + \beta_3 \end{aligned}$$

For the reference cell parameterization scheme (PARAM=REF) with White as the reference cell, the design variables for race are as follows.

| Race     | Design Variables |       |       |
|----------|------------------|-------|-------|
|          | $X_1$            | $X_2$ | $X_3$ |
| Black    | 1                | 0     | 0     |
| Hispanic | 0                | 1     | 0     |
| Other    | 0                | 0     | 1     |
| White    | 0                | 0     | 0     |

The log odds ratio of Black versus White is given by

$$\begin{aligned}
 \log(\psi(\text{Black}, \text{White})) &= g(\text{Black}) - g(\text{White}) \\
 &= (\beta_0 + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0)) - \\
 &\quad (\beta_0 + \beta_1(X_1 = 0) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0)) \\
 &= \beta_1
 \end{aligned}$$

For the GLM parameterization scheme (PARAM=GLM), the design variables are as follows.

| Race     | Design Variables |       |       |       |
|----------|------------------|-------|-------|-------|
|          | $X_1$            | $X_2$ | $X_3$ | $X_4$ |
| Black    | 1                | 0     | 0     | 0     |
| Hispanic | 0                | 1     | 0     | 0     |
| Other    | 0                | 0     | 1     | 0     |
| White    | 0                | 0     | 0     | 1     |

The log odds ratio of Black versus White is

$$\begin{aligned}
 \log(\psi(\text{Black}, \text{White})) &= g(\text{Black}) - g(\text{White}) \\
 &= (\beta_0 + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) + \beta_4(X_4 = 0)) - \\
 &\quad (\beta_0 + \beta_1(X_1 = 0) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) + \beta_4(X_4 = 1)) \\
 &= \beta_1 - \beta_4
 \end{aligned}$$

Consider the hypothetical example of heart disease among race in Hosmer and Lemeshow (2000, p. 51). The entries in the following contingency table represent counts.

| Disease Status | Race  |       |          |       |
|----------------|-------|-------|----------|-------|
|                | White | Black | Hispanic | Other |
| Present        | 5     | 20    | 15       | 10    |
| Absent         | 20    | 10    | 10       | 10    |

The computation of odds ratio of Black versus White for various parameterization schemes is shown in Table 91.9.

**Table 91.9** Odds Ratio of Heart Disease Comparing Black to White

| PARAM= | Parameter Estimates |                 |                 |                 | Odds Ratio Estimates                          |
|--------|---------------------|-----------------|-----------------|-----------------|-----------------------------------------------|
|        | $\hat{\beta}_1$     | $\hat{\beta}_2$ | $\hat{\beta}_3$ | $\hat{\beta}_4$ |                                               |
| EFFECT | 0.7651              | 0.4774          | 0.0719          |                 | $\exp(2 \times 0.7651 + 0.4774 + 0.0719) = 8$ |
| REF    | 2.0794              | 1.7917          | 1.3863          |                 | $\exp(2.0794) = 8$                            |
| GLM    | 2.0794              | 1.7917          | 1.3863          | 0.0000          | $\exp(2.0794) = 8$                            |

Since the log odds ratio ( $\log(\psi)$ ) is a linear function of the parameters, the Wald confidence interval for  $\log(\psi)$  can be derived from the parameter estimates and the estimated covariance matrix. Confidence intervals for the odds ratios are obtained by exponentiating the corresponding confidence intervals for the log odds ratios. In the displayed output of PROC SURVEYLOGISTIC, the “Odds Ratio Estimates” table contains the odds ratio estimates and the corresponding 95% Wald confidence intervals computed by using the covariance matrix in the section “Variance Estimation” on page 7738. For continuous explanatory variables, these odds ratios correspond to a unit increase in the risk factors.

To customize odds ratios for specific units of change for a continuous risk factor, you can use the UNITS statement to specify a list of relevant units for each explanatory variable in the model. Estimates of these customized odds ratios are given in a separate table. Let  $(L_j, U_j)$  be a confidence interval for  $\log(\psi)$ . The corresponding lower and upper confidence limits for the customized odds ratio  $\exp(c\beta_j)$  are  $\exp(cL_j)$  and  $\exp(cU_j)$ , respectively, (for  $c > 0$ ); or  $\exp(cU_j)$  and  $\exp(cL_j)$ , respectively, (for  $c < 0$ ). You use the CLODDS option in the MODEL statement to request confidence intervals for the odds ratios.

For a generalized logit model, odds ratios are computed similarly, except  $D$  odds ratios are computed for each effect, corresponding to the  $D$  logits in the model.

### Rank Correlation of Observed Responses and Predicted Probabilities

The predicted mean score of an observation is the sum of the Ordered Values (shown in the “Response Profile” table) minus one, weighted by the corresponding predicted probabilities for that observation; that is, the predicted mean score is  $\sum_{d=1}^{D+1} (d-1)\hat{\pi}_d$ , where  $D+1$  is the number of response levels and  $\hat{\pi}_d$  is the predicted probability of the  $d$ th (ordered) response.

A pair of observations with different observed responses is said to be *concordant* if the observation with the lower ordered response value has a lower predicted mean score than the observation with the higher ordered response value. If the observation with the lower ordered response value has a higher predicted mean score than the observation with the higher ordered response value, then the pair is *discordant*. If the pair is neither concordant nor discordant, it is a *tie*. Enumeration of the total numbers of concordant and discordant pairs is carried out by categorizing the predicted mean score into intervals of length  $D/500$  and accumulating the corresponding frequencies of observations.

Let  $N$  be the sum of observation frequencies in the data. Suppose there are a total of  $t$  pairs with different responses,  $n_c$  of them are concordant,  $n_d$  of them are discordant, and  $t - n_c - n_d$  of them are tied. PROC SURVEYLOGISTIC computes the following four indices of rank correlation for assessing the predictive ability of a model:

$$c = (n_c + 0.5(t - n_c - n_d))/t$$

$$\text{Somers' } D = (n_c - n_d)/t$$

$$\text{Goodman-Kruskal Gamma} = (n_c - n_d)/(n_c + n_d)$$

$$\text{Kendall's Tau-}a = (n_c - n_d)/(0.5N(N - 1))$$

Note that  $c$  also gives an estimate of the area under the receiver operating characteristic (ROC) curve when the response is binary (Hanley and McNeil 1982).

For binary responses, the predicted mean score is equal to the predicted probability for Ordered Value 2. As such, the preceding definition of concordance is consistent with the definition used in previous releases for the binary response model.

## Linear Predictor, Predicted Probability, and Confidence Limits

This section describes how predicted probabilities and confidence limits are calculated by using the pseudo-estimates (MLEs) obtained from PROC SURVEYLOGISTIC. For a specific example, see the section “Getting Started: SURVEYLOGISTIC Procedure” on page 7685. Predicted probabilities and confidence limits can be output to a data set with the OUTPUT statement.

### Cumulative Response Models

For a row vector of explanatory variables  $\mathbf{x}$ , the linear predictor

$$\eta_i = g(\text{Pr}(Y \leq i | \mathbf{x})) = \alpha_i + \mathbf{x}\boldsymbol{\beta}, \quad 1 \leq i \leq k$$

is estimated by

$$\hat{\eta}_i = \hat{\alpha}_i + \mathbf{x}\hat{\boldsymbol{\beta}}$$

where  $\hat{\alpha}_i$  and  $\hat{\boldsymbol{\beta}}$  are the MLEs of  $\alpha_i$  and  $\boldsymbol{\beta}$ . The estimated standard error of  $\eta_i$  is  $\hat{\sigma}(\hat{\eta}_i)$ , which can be computed as the square root of the quadratic form  $(1, \mathbf{x}')\hat{\mathbf{V}}_b(1, \mathbf{x}')$ , where  $\hat{\mathbf{V}}_b$  is the estimated covariance matrix of the parameter estimates. The asymptotic  $100(1 - \alpha)\%$  confidence interval for  $\eta_i$  is given by

$$\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i)$$

where  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$  percentile point of a standard normal distribution.

The predicted value and the  $100(1 - \alpha)\%$  confidence limits for  $\text{Pr}(Y \leq i | \mathbf{x})$  are obtained by back-transforming the corresponding measures for the linear predictor.

| Link    | Predicted Probability       | $100(1 - \alpha)$ Confidence Limits                                    |
|---------|-----------------------------|------------------------------------------------------------------------|
| LOGIT   | $1/(1 + e^{-\hat{\eta}_i})$ | $1/(1 + e^{-\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i)})$ |
| PROBIT  | $\Phi(\hat{\eta}_i)$        | $\Phi(\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i))$        |
| CLOGLOG | $1 - e^{-e^{\hat{\eta}_i}}$ | $1 - e^{-e^{\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i)}}$ |

## Generalized Logit Model

For a vector of explanatory variables  $\mathbf{x}$ , let  $\pi_i$  denote the probability of obtaining the response value  $i$ :

$$\pi_i = \begin{cases} \frac{\pi_{k+1} e^{\alpha_i + \mathbf{x}\boldsymbol{\beta}_i}}{1 + \sum_{j=1}^k e^{\alpha_j + \mathbf{x}\boldsymbol{\beta}_j}} & 1 \leq i \leq k \\ 1 & i = k + 1 \end{cases}$$

By the *delta method*,

$$\sigma^2(\pi_i) = \left( \frac{\partial \pi_i}{\partial \boldsymbol{\theta}} \right)' \mathbf{V}(\boldsymbol{\theta}) \frac{\partial \pi_i}{\partial \boldsymbol{\theta}}$$

A 100(1- $\alpha$ )% confidence level for  $\pi_i$  is given by

$$\hat{\pi}_i \pm z_{\alpha/2} \hat{\sigma}(\hat{\pi}_i)$$

where  $\hat{\pi}_i$  is the estimated expected probability of response  $i$  and  $\hat{\sigma}(\hat{\pi}_i)$  is obtained by evaluating  $\sigma(\pi_i)$  at  $\boldsymbol{\theta} = \hat{\boldsymbol{\theta}}$ .

## Output Data Sets

You can use the Output Delivery System (ODS) to create a SAS data set from any piece of PROC SURVEYLOGISTIC output. See the section “ODS Table Names” on page 7757 for more information. For a more detailed description of using ODS, see Chapter 20, “Using the Output Delivery System.”

PROC SURVEYLOGISTIC also provides an **OUTPUT** statement to create a data set that contains estimated linear predictors, the estimates of the cumulative or individual response probabilities, and their confidence limits.

If you use BRR or jackknife variance estimation, PROC SURVEYLOGISTIC provides an output data set that stores the replicate weights and an output data set that stores the jackknife coefficients for jackknife variance estimation.

### OUT= Data Set in the OUTPUT Statement

The OUT= data set in the **OUTPUT** statement contains all the variables in the input data set along with statistics you request by using *keyword=name* options or the PREDPROBS= option in the OUTPUT statement. In addition, if you use the single-trial syntax and you request any of the XBETA=, STDXBETA=, PREDICTED=, LCL=, and UCL= options, the OUT= data set contains the automatic variable `_LEVEL_`. The value of `_LEVEL_` identifies the response category upon which the computed values of XBETA=, STDXBETA=, PREDICTED=, LCL=, and UCL= are based.

When there are more than two response levels, only variables named by the XBETA=, STDXBETA=, PREDICTED=, LOWER=, and UPPER= options and the variables given by PREDPROBS=(INDIVIDUAL CUMULATIVE) have their values computed; the other variables have missing values. If you fit a generalized logit model, the cumulative predicted probabilities are not computed.

When there are only two response categories, each input observation produces one observation in the OUT= data set.

If there are more than two response categories and you specify only the PREDPROBS= option, then each input observation produces one observation in the OUT= data set. However, if you fit an ordinal (cumulative) model and specify options other than the PREDPROBS= options, each input observation generates as many output observations as one fewer than the number of response levels, and the predicted probabilities and their confidence limits correspond to the cumulative predicted probabilities. If you fit a generalized logit model and specify options other than the PREDPROBS= options, each input observation generates as many output observations as the number of response categories; the predicted probabilities and their confidence limits correspond to the probabilities of individual response categories.

For observations in which only the response variable is missing, values of the XBETA=, STDXBETA=, PREDICTED=, UPPER=, LOWER=, and PREDPROBS= options are computed even though these observations do not affect the model fit. This enables, for instance, predicted probabilities to be computed for new observations.

### Replicate Weights Output Data Set

If you specify the OUTWEIGHTS= *method-option* for VARMETHOD=BRR or VARMETHOD=JACKKNIFE, PROC SURVEYLOGISTIC stores the replicate weights in an output data set. The OUTWEIGHTS= output data set contains all observations from the DATA= input data set that are valid (used in the analysis). (A valid observation is an observation that has a positive value of the WEIGHT variable. Valid observations must also have nonmissing values of the STRATA and CLUSTER variables, unless you specify the MISSING option.)

The OUTWEIGHTS= data set contains the following variables:

- all variables in the DATA= input data set
- RepWt\_1, RepWt\_2, . . . , RepWt\_n, which are the replicate weight variables

where  $n$  is the total number of replicates in the analysis. Each replicate weight variable contains the replicate weights for the corresponding replicate. Replicate weights equal zero for those observations not included in the replicate.

After the procedure creates replicate weights for a particular input data set and survey design, you can use the OUTWEIGHTS= *method-option* to store these replicate weights and then use them again in subsequent analyses, either in PROC SURVEYLOGISTIC or in the other survey procedures. You can use the REPWEIGHTS statement to provide replicate weights for the procedure.

### Jackknife Coefficients Output Data Set

If you specify the OUTJKCOEFS= *method-option* for VARMETHOD=JACKKNIFE, PROC SURVEYLOGISTIC stores the jackknife coefficients in an output data set. The OUTJKCOEFS= output data set contains one observation for each replicate. The OUTJKCOEFS= data set contains the following variables:

- Replicate, which is the replicate number for the jackknife coefficient
- JKCoefficient, which is the jackknife coefficient
- DonorStratum, which is the stratum of the PSU that was deleted to construct the replicate, if you specify a STRATA statement

After the procedure creates jackknife coefficients for a particular input data set and survey design, you can use the `OUTJKCOEFS=` *method-option* to store these coefficients and then use them again in subsequent analyses, either in PROC SURVEYLOGISTIC or in the other survey procedures. You can use the `JKCOEFS=` option in the `REPWEIGHTS` statement to provide jackknife coefficients for the procedure.

---

## Displayed Output

The SURVEYLOGISTIC procedure produces output that is described in the following sections.

Output that is generated by the `EFFECT`, `ESTIMATE`, `LSMEANS`, `LSMESTIMATE`, and `SLICE` statements are not listed below. For information about the output that is generated by these statements, see the corresponding sections of Chapter 19, “[Shared Concepts and Topics](#).”

## Model Information

By default, PROC SURVEYLOGISTIC displays the following information in the “Model Information” table:

- name of the input Data Set
- name and label of the Response Variable if the single-trial syntax is used
- number of Response Levels
- name of the Events Variable if the events/trials syntax is used
- name of the Trials Variable if the events/trials syntax is used
- name of the Offset Variable if the `OFFSET=` option is specified
- name of the Frequency Variable if the `FREQ` statement is specified
- name(s) of the Stratum Variable(s) if the `STRATA` statement is specified
- total Number of Strata if the `STRATA` statement is specified
- name(s) of the Cluster Variable(s) if the `CLUSTER` statement is specified
- total Number of Clusters if the `CLUSTER` statement is specified
- name of the Weight Variable if the `WEIGHT` statement is specified
- Variance Adjustment method
- Upper Bound `ADJBOUND` parameter used in the `VADJUST=MOREL(ADJBOUND= )` option
- Lower Bound `DEFFBOUND` parameter used in the `VADJUST=MOREL(DEFFBOUND= )` option
- whether FPC (finite population correction) is used

## Variance Estimation

By default, PROC SURVEYLOGISTIC displays the following variance estimation information in the “Variance Estimation” table:

- Method, which is the variance estimation method
- Variance Adjustment method
- Upper Bound ADJBOUND parameter specified in the `VADJUST=MOREL(ADJBOUND= )` option
- Lower Bound DEFFBOUND parameter specified in the `VADJUST=MOREL(DEFFBOUND= )` option
- whether FPC (finite population correction) is used
- Number of Replicates, if you specify the `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE` option
- Number of Replicates Used, if you specify the `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE` option and some of the replicates are excluded due to unattained convergence
- Hadamard Data Set name, if you specify the `VARMETHOD=BRR(HADAMARD=) method-option`
- Fay Coefficient, if you specify the `VARMETHOD=BRR(FAY) method-option`
- Replicate Weights input data set name, if you use a `REPWEIGHTS` statement
- whether Missing Levels are created for categorical variables by the `MISSING` option
- whether observations with Missing Values are included in the analysis by the `NOMCAR` option

## Data Summary

By default, PROC SURVEYLOGISTIC displays the following information for the entire data set:

- Number of Observations read from the input data set
- Number of Observations used in the analysis

If there is a `DOMAIN` statement, PROC SURVEYLOGISTIC also displays the following:

- Number of Observations in the current domain
- Number of Observations not in the current domain

If there is a `FREQ` statement, PROC SURVEYLOGISTIC also displays the following:

- Sum of Frequencies of all the observations read from the input data set
- Sum of Frequencies of all the observations used in the analysis

If there is a WEIGHT statement, PROC SURVEYLOGISTIC also displays the following:

- Sum of Weights of all the observations read from the input data set
- Sum of Weights of all the observations used in the analysis
- Sum of Weights of all the observations in the current domain, if DOMAIN statement is also specified.

## Response Profile

By default, PROC SURVEYLOGISTIC displays a “Response Profile” table, which gives, for each response level, the ordered value (an integer between one and the number of response levels, inclusive); the value of the response variable if the single-trial syntax is used or the values “EVENT” and “NO EVENT” if the events/trials syntax is used; the count or frequency; and the sum of weights if the WEIGHT statement is specified.

## Class Level Information

If you use a CLASS statement to name classification variables, PROC SURVEYLOGISTIC displays a "Class Level Information" table. This table contains the following information for each classification variable:

- Class, which lists each CLASS variable name
- Value, which lists the values of the classification variable. The values are separated by a white space character; therefore, to avoid confusion, you should not include a white space character within a classification variable value.
- Design Variables, which lists the parameterization used for the classification variables

## Stratum Information

When you specify the LIST option in the STRATA statement, PROC SURVEYLOGISTIC displays a "Stratum Information" table, which provides the following information for each stratum:

- Stratum Index, which is a sequential stratum identification number
- STRATA variable(s), which lists the levels of STRATA variables for the stratum
- Population Total, if you specify the TOTAL= option
- Sampling Rate, if you specify the TOTAL= or RATE= option. If you specify the TOTAL= option, the sampling rate is based on the number of nonmissing observations in the stratum.
- N Obs, which is the number of observations
- number of Clusters, if you specify a CLUSTER statement

## Maximum Likelihood Iteration History

The “Maximum Likelihood Iterative Phase” table gives the iteration number, the step size (in the scale of 1.0, 0.5, 0.25, and so on) or the ridge value,  $-2 \log$  likelihood, and parameter estimates for each iteration. Also displayed are the last evaluation of the gradient vector and the last change in the  $-2 \log$  likelihood. You need to use the ITPRINT option in the MODEL statement to obtain this table.

## Score Test

The “Score Test” table displays the score test result for testing the parallel lines assumption, if an ordinal response model is fitted. If LINK=CLOGLOG or LINK=PROBIT, this test is labeled “Score Test for the Parallel Slopes Assumption.” The proportion odds assumption is a special case of the parallel lines assumption when LINK=LOGIT. In this case, the test is labeled “Score Test for the Proportional Odds Assumption.”

## Model Fit Statistics

By default, PROC SURVEYLOGISTIC displays the following information in the “Model Fit Statistics” table:

- “Model Fit Statistics” and “Testing Global Null Hypothesis: BETA=0” tables, which give the various criteria ( $-2 \log L$ , AIC, SC) based on the likelihood for fitting a model with intercepts only and for fitting a model with intercepts and explanatory variables. If you specify the NOINT option, these statistics are calculated without considering the intercept parameters. The third column of the table gives the chi-square statistics and  $p$ -values for the  $-2 \log L$  statistic and for the Score statistic. These test the joint effect of the explanatory variables included in the model. The Score criterion is always missing for the models identified by the first two columns of the table. Note also that the first two rows of the Chi-Square column are always missing, since tests cannot be performed for AIC and SC.
- generalized  $R^2$  measures for the fitted model if you specify the RSQUARE option in the MODEL statement

## Type III Analysis of Effects

PROC SURVEYLOGISTIC displays the “Type III Analysis of Effects” table if the model contains an effect involving a CLASS variable. This table gives the degrees of freedom, the Wald Chi-square statistic, and the  $p$ -value for each effect in the model.

## Analysis of Maximum Likelihood Estimates

By default, PROC SURVEYLOGISTIC displays the following information in the “Analysis of Maximum Likelihood Estimates” table:

- the degrees of freedom for Wald chi-square test
- maximum likelihood estimate of the parameter
- estimated standard error of the parameter estimate, computed as the square root of the corresponding diagonal element of the estimated covariance matrix

- Wald chi-square statistic, computed by squaring the ratio of the parameter estimate divided by its standard error estimate
- $p$ -value of the Wald chi-square statistic with respect to a chi-square distribution with one degree of freedom
- standardized estimate for the slope parameter, given by  $\hat{\beta}_i / (s/s_i)$ , where  $s_i$  is the total sample standard deviation for the  $i$ th explanatory variable and

$$s = \begin{cases} \pi/\sqrt{3} & \text{logistic} \\ 1 & \text{normal} \\ \pi/\sqrt{6} & \text{extreme-value} \end{cases}$$

You need to specify the STB option in the MODEL statement to obtain these estimates. Standardized estimates of the intercept parameters are set to missing.

- value of  $(e^{\hat{\beta}_i})$  for each slope parameter  $\beta_i$  if you specify the EXPB option in the MODEL statement. For continuous variables, this is equivalent to the estimated odds ratio for a one-unit change.
- label of the variable (if space permits) if you specify the PARMLABEL option in the MODEL statement. Due to constraints on the line size, the variable label might be suppressed in order to display the table in one panel. Use the SAS system option LINESIZE= to specify a larger line size to accommodate variable labels. A shorter line size can break the table into two panels, allowing labels to be displayed.

### Odds Ratio Estimates

The “Odds Ratio Estimates” table displays the odds ratio estimates and the corresponding 95% Wald confidence intervals. For continuous explanatory variables, these odds ratios correspond to a unit increase in the risk factors.

### Association of Predicted Probabilities and Observed Responses

The “Association of Predicted Probabilities and Observed Responses” table displays measures of association between predicted probabilities and observed responses, which include a breakdown of the number of pairs with different responses, and four rank correlation indexes: Somers’  $D$ , Goodman-Kruskal Gamma, and Kendall’s Tau- $a$ , and  $c$ .

### Wald Confidence Interval for Parameters

The “Wald Confidence Interval for Parameters” table displays confidence intervals for all the parameters if you use the CLPARM option in the MODEL statement.

### Wald Confidence Interval for Odds Ratios

The “Wald Confidence Interval for Odds Ratios” table displays confidence intervals for all the odds ratios if you use the CLODDS option in the MODEL statement.

## Estimated Covariance Matrix

PROC SURVEYLOGISTIC displays the following information in the “Estimated Covariance Matrix” table:

- estimated covariance matrix of the parameter estimates if you use the COVB option in the MODEL statement
- estimated correlation matrix of the parameter estimates if you use the CORRB option in the MODEL statement

## Linear Hypotheses Testing Results

The “Linear Hypothesis Testing” table gives the result of the Wald test for each TEST statement (if specified).

## Hadamard Matrix

If you specify the `VARMETHOD=BRR(PRINTH)` *method-option* in the PROC SURVEYLOGISTIC statement, the procedure displays the Hadamard matrix.

When you provide a Hadamard matrix with the `VARMETHOD=BRR(HADAMARD=)` *method-option*, the procedure displays only used rows and columns of the Hadamard matrix.

---

## ODS Table Names

PROC SURVEYLOGISTIC assigns a name to each table it creates; these names are listed in Table 91.10. You can use these names to refer the table when using the Output Delivery System (ODS) to select tables and create output data sets. The EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements also create tables, which are not listed in Table 91.10. For information about these tables, see the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 91.10** ODS Tables Produced by PROC SURVEYLOGISTIC

| ODS Table Name    | Description                                                   | Statement | Option                            |
|-------------------|---------------------------------------------------------------|-----------|-----------------------------------|
| Association       | Association of predicted probabilities and observed responses | MODEL     | Default                           |
| ClassLevelInfo    | Class variable levels and design variables                    | MODEL     | Default<br>(with CLASS variables) |
| CLOddsWald        | Wald’s confidence limits for odds ratios                      | MODEL     | CLODDS                            |
| CLparmWald        | Wald’s confidence limits for parameters                       | MODEL     | CLPARAM                           |
| ContrastCoeff     | L matrix from CONTRAST                                        | CONTRAST  | E                                 |
| ContrastEstimate  | Estimates from CONTRAST                                       | CONTRAST  | ESTIMATE=                         |
| ContrastTest      | Wald test for CONTRAST                                        | CONTRAST  | Default                           |
| ConvergenceStatus | Convergence status                                            | MODEL     | Default                           |

Table 91.10 continued

| ODS Table Name      | Description                                                                                                         | Statement | Option                            |
|---------------------|---------------------------------------------------------------------------------------------------------------------|-----------|-----------------------------------|
| CorrB               | Estimated correlation matrix of parameter estimators                                                                | MODEL     | CORRB                             |
| CovB                | Estimated covariance matrix of parameter estimators                                                                 | MODEL     | COVB                              |
| CumulativeModelTest | Test of the cumulative model assumption                                                                             | MODEL     | (Ordinal response)                |
| DomainSummary       | Domain summary                                                                                                      | DOMAIN    | Default                           |
| FitStatistics       | Model fit statistics                                                                                                | MODEL     | Default                           |
| GlobalTests         | Test for global null hypothesis                                                                                     | MODEL     | Default                           |
| HadamardMatrix      | Hadamard matrix                                                                                                     | PROC      | PRINTH                            |
| IterHistory         | Iteration history                                                                                                   | MODEL     | ITPRINT                           |
| LastGradient        | Last evaluation of gradient                                                                                         | MODEL     | ITPRINT                           |
| Linear              | Linear combination                                                                                                  | PROC      | Default                           |
| LogLikeChange       | Final change in the log likelihood                                                                                  | MODEL     | ITPRINT                           |
| ModelInfo           | Model information                                                                                                   | PROC      | Default                           |
| NObs                | Number of observations                                                                                              | PROC      | Default                           |
| OddsEst             | Adjusted odds ratios                                                                                                | UNITS     | Default                           |
| OddsRatios          | Odds ratios                                                                                                         | MODEL     | Default                           |
| ParameterEstimates  | Maximum likelihood estimates of model parameters                                                                    | MODEL     | Default                           |
| RSquare             | R-square                                                                                                            | MODEL     | RSQUARE                           |
| ResponseProfile     | Response profile                                                                                                    | PROC      | Default                           |
| StrataInfo          | Stratum information                                                                                                 | STRATA    | LIST                              |
| TestPrint1          | $L[\text{cov}(\mathbf{b})]L'$ and $L\mathbf{b} - \mathbf{c}$                                                        | TEST      | PRINT                             |
| TestPrint2          | $G\text{inv}(L[\text{cov}(\mathbf{b})]L')$ and $G\text{inv}(L[\text{cov}(\mathbf{b})]L')(L\mathbf{b} - \mathbf{c})$ | TEST      | PRINT                             |
| TestStmts           | Linear hypotheses testing results                                                                                   | TEST      | Default                           |
| Type3               | Type III tests of effects                                                                                           | MODEL     | Default<br>(with CLASS variables) |
| VarianceEstimation  | Variance estimation                                                                                                 | PROC      | Default                           |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

When ODS Graphics is enabled, then the ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements can produce plots that are associated with their analyses. For information about these plots, see the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

---

## Examples: SURVEYLOGISTIC Procedure

---

### Example 91.1: Stratified Cluster Sampling

A market research firm conducts a survey among undergraduate students at a certain university to evaluate three new Web designs for a commercial Web site targeting undergraduate students at the university.

The sample design is a stratified sample where the strata are students' classes. Within each class, 300 students are randomly selected by using simple random sampling without replacement. The total number of students in each class in the fall semester of 2001 is shown in the following table:

| Class         | Enrollment |
|---------------|------------|
| 1 - Freshman  | 3,734      |
| 2 - Sophomore | 3,565      |
| 3 - Junior    | 3,903      |
| 4 - Senior    | 4,196      |

This total enrollment information is saved in the SAS data set Enrollment by using the following SAS statements:

```
proc format;
 value Class
 1='Freshman' 2='Sophomore'
 3='Junior' 4='Senior';
run;

data Enrollment;
 format Class Class.;
 input Class _TOTAL_;
 datalines;
1 3734
2 3565
3 3903
4 4196
;
```

In the data set Enrollment, the variable `_TOTAL_` contains the enrollment figures for all classes. They are also the population size for each stratum in this example.

Each student selected in the sample evaluates one randomly selected Web design by using the following scale:

|   |                   |
|---|-------------------|
| 1 | Dislike very much |
| 2 | Dislike           |
| 3 | Neutral           |
| 4 | Like              |
| 5 | Like very much    |

The survey results are collected and shown in the following table, with the three different Web designs coded as A, B, and C.

| Evaluation of New Web Designs |        |               |    |    |    |    |
|-------------------------------|--------|---------------|----|----|----|----|
| Strata                        | Design | Rating Counts |    |    |    |    |
|                               |        | 1             | 2  | 3  | 4  | 5  |
| Freshman                      | A      | 10            | 34 | 35 | 16 | 15 |
|                               | B      | 5             | 6  | 24 | 30 | 25 |
|                               | C      | 11            | 14 | 20 | 34 | 21 |
| Sophomore                     | A      | 19            | 12 | 26 | 18 | 25 |
|                               | B      | 10            | 18 | 32 | 23 | 26 |
|                               | C      | 15            | 22 | 34 | 9  | 20 |
| Junior                        | A      | 8             | 21 | 23 | 26 | 22 |
|                               | B      | 1             | 4  | 15 | 33 | 47 |
|                               | C      | 16            | 19 | 30 | 23 | 12 |
| Senior                        | A      | 11            | 14 | 24 | 33 | 18 |
|                               | B      | 8             | 15 | 25 | 30 | 22 |
|                               | C      | 2             | 34 | 30 | 18 | 16 |

The survey results are stored in a SAS data set WebSurvey by using the following SAS statements:

```
proc format;
 value Design 1='A' 2='B' 3='C';
 value Rating
 1='dislike very much'
 2='dislike'
 3='neutral'
 4='like'
 5='like very much';
run;

data WebSurvey;
 format Class Class. Design Design. Rating Rating.;
 do Class=1 to 4;
 do Design=1 to 3;
 do Rating=1 to 5;
 input Count @@;
 output;
 end;
 end;
 end;
end;
```

```

datalines;
10 34 35 16 15 8 21 23 26 22 5 10 24 30 21
 1 14 25 23 37 11 14 20 34 21 16 19 30 23 12
19 12 26 18 25 11 14 24 33 18 10 18 32 23 17
 8 15 35 30 12 15 22 34 9 20 2 34 30 18 16
;

data WebSurvey;
 set WebSurvey;
 if Class=1 then Weight=3734/300;
 if Class=2 then Weight=3565/300;
 if Class=3 then Weight=3903/300;
 if Class=4 then Weight=4196/300;
run;

```

The data set WebSurvey contains the variables Class, Design, Rating, Count, and Weight. The variable class is the stratum variable, with four strata: freshman, sophomore, junior, and senior. The variable Design specifies the three new Web designs: A, B, and C. The variable Rating contains students' evaluations of the new Web designs. The variable counts gives the frequency with which each Web design received each rating within each stratum. The variable weight contains the sampling weights, which are the reciprocals of selection probabilities in this example.

Output 91.1.1 shows the first 20 observations of the data set.

**Output 91.1.1** Web Design Survey Sample (First 20 Observations)

| Obs | Class     | Design | Rating            | Count | Weight  |
|-----|-----------|--------|-------------------|-------|---------|
| 1   | Freshman  | A      | dislike very much | 10    | 12.4467 |
| 2   | Freshman  | A      | dislike           | 34    | 12.4467 |
| 3   | Freshman  | A      | neutral           | 35    | 12.4467 |
| 4   | Freshman  | A      | like              | 16    | 12.4467 |
| 5   | Freshman  | A      | like very much    | 15    | 12.4467 |
| 6   | Freshman  | B      | dislike very much | 8     | 12.4467 |
| 7   | Freshman  | B      | dislike           | 21    | 12.4467 |
| 8   | Freshman  | B      | neutral           | 23    | 12.4467 |
| 9   | Freshman  | B      | like              | 26    | 12.4467 |
| 10  | Freshman  | B      | like very much    | 22    | 12.4467 |
| 11  | Freshman  | C      | dislike very much | 5     | 12.4467 |
| 12  | Freshman  | C      | dislike           | 10    | 12.4467 |
| 13  | Freshman  | C      | neutral           | 24    | 12.4467 |
| 14  | Freshman  | C      | like              | 30    | 12.4467 |
| 15  | Freshman  | C      | like very much    | 21    | 12.4467 |
| 16  | Sophomore | A      | dislike very much | 1     | 11.8833 |
| 17  | Sophomore | A      | dislike           | 14    | 11.8833 |
| 18  | Sophomore | A      | neutral           | 25    | 11.8833 |
| 19  | Sophomore | A      | like              | 23    | 11.8833 |
| 20  | Sophomore | A      | like very much    | 37    | 11.8833 |

The following SAS statements perform the logistic regression:

```
proc surveylogistic data=WebSurvey total=Enrollment;
 stratum Class;
 freq Count;
 class Design;
 model Rating (order=internal) = design;
 weight Weight;
run;
```

The PROC SURVEYLOGISTIC statement invokes the procedure. The TOTAL= option specifies the data set Enrollment, which contains the population totals in the strata. The population totals are used to calculate the finite population correction factor in the variance estimates. The response variable Rating is in the ordinal scale. A cumulative logit model is used to investigate the responses to the Web designs. In the MODEL statement, rating is the response variable, and Design is the effect in the regression model. The ORDER=INTERNAL option is used for the response variable Rating to sort the ordinal response levels of Rating by its internal (numerical) values rather than by the formatted values (for example, 'like very much'). Because the sample design involves stratified simple random sampling, the STRATA statement is used to specify the stratification variable Class. The WEIGHT statement specifies the variable Weight for sampling weights.

The sample and analysis summary is shown in [Output 91.1.2](#). There are five response levels for the Rating, with 'dislike very much' as the lowest ordered value. The regression model is modeling lower cumulative probabilities by using logit as the link function. Because the TOTAL= option is used, the finite population correction is included in the variance estimation. The sampling weight is also used in the analysis.

#### Output 91.1.2 Web Design Survey, Model Information

| The SURVEYLOGISTIC Procedure |                         |
|------------------------------|-------------------------|
| Model Information            |                         |

**Output 91.1.2** *continued*

| Response Profile |                   |                 |              |
|------------------|-------------------|-----------------|--------------|
| Ordered Value    | Rating            | Total Frequency | Total Weight |
| 1                | dislike very much | 116             | 1489.0733    |
| 2                | dislike           | 227             | 2933.0433    |
| 3                | neutral           | 338             | 4363.3767    |
| 4                | like              | 283             | 3606.8067    |
| 5                | like very much    | 236             | 3005.7000    |

Probabilities modeled are cumulated over the lower Ordered Values.

In [Output 91.1.3](#), the score chi-square for testing the proportional odds assumption is 98.1957, which is highly significant. This indicates that the cumulative logit model might not adequately fit the data.

**Output 91.1.3** Web Design Survey, Testing the Proportional Odds Assumption

| Score Test for the Proportional Odds Assumption |    |            |
|-------------------------------------------------|----|------------|
| Chi-Square                                      | DF | Pr > ChiSq |
| 98.1957                                         | 6  | <.0001     |

An alternative model is to use the generalized logit model with the LINK=GLOGIT option, as shown in the following SAS statements:

```
proc surveylogistic data=WebSurvey total=Enrollment;
 stratum Class;
 freq Count;
 class Design;
 model Rating (ref='neutral') = Design /link=glogit;
 weight Weight;
run;
```

The REF='neutral' option is used for the response variable Rating to indicate that all other response levels are referenced to the level 'neutral.' The option LINK=GLOGIT option requests that the procedure fit a generalized logit model.

The summary of the analysis is shown in [Output 91.1.4](#), which indicates that the generalized logit model is used in the analysis.

**Example 91.2: The Medical Expenditure Panel Survey (MEPS)**

The U.S. Department of Health and Human Services conducts the Medical Expenditure Panel Survey (MEPS) to produce national and regional estimates of various aspects of health care. The MEPS has a complex sample design that includes both stratification and clustering. The sampling weights are adjusted for nonresponse and raked with respect to population control totals from the Current Population Survey. See the MEPS Survey Background (2006) and Machlin, Yu, and Zodet (2005) for details.

In this example, the 1999 full-year consolidated data file HC-038 (MEPS HC-038, 2002) from the MEPS is used to investigate the relationship between medical insurance coverage and the demographic variables. The data can be downloaded directly from the Agency for Healthcare Research and Quality (AHRQ) Web site at [http://www.meps.ahrq.gov/mepsweb/data\\_stats/download\\_data\\_files\\_detail.jsp?cboPufNumber=HC-038](http://www.meps.ahrq.gov/mepsweb/data_stats/download_data_files_detail.jsp?cboPufNumber=HC-038) in either ASCII format or SAS transport format. The Web site includes a detailed description of the data as well as the SAS program used to access and format it.

For this example, the SAS transport format data file for HC-038 is downloaded to 'C:H38.ssp' on a Windows-based PC. The instructions on the Web site lead to the following SAS statements for creating

a SAS data set MEPS, which contains only the sample design variables and other variables necessary for this analysis.

```

proc format;
 value racex
 -9 = 'NOT ASCERTAINED'
 -8 = 'DK'
 -7 = 'REFUSED'
 -1 = 'INAPPLICABLE'
 1 = 'AMERICAN INDIAN'
 2 = 'ALEUT, ESKIMO'
 3 = 'ASIAN OR PACIFIC ISLANDER'
 4 = 'BLACK'
 5 = 'WHITE'
 91 = 'OTHER'
 ;
 value sex
 -9 = 'NOT ASCERTAINED'
 -8 = 'DK'
 -7 = 'REFUSED'
 -1 = 'INAPPLICABLE'
 1 = 'MALE'
 2 = 'FEMALE'
 ;
 value povcat9h
 1 = 'NEGATIVE OR POOR'
 2 = 'NEAR POOR'
 3 = 'LOW INCOME'
 4 = 'MIDDLE INCOME'
 5 = 'HIGH INCOME'
 ;
 value inscov9f
 1 = 'ANY PRIVATE'
 2 = 'PUBLIC ONLY'
 3 = 'UNINSURED'
 ;
run;

libname mylib '';
filename in1 'H38.SSP';
proc xcopy in=in1 out=mylib import;
run;

data meps;
 set mylib.H38;
 label racex= sex= inscov99= povcat99=
 varstr99= varpsu99= perwt99f= totexp99=;
 format racex racex. sex sex.
 povcat99 povcat9h. inscov99 inscov9f.;
 keep inscov99 sex racex povcat99 varstr99
 varpsu99 perwt99f totexp99;
run;

```

There are a total of 24,618 observations in this SAS data set. Each observation corresponds to a person in the survey. The stratification variable is VARSTR99, which identifies the 143 strata in the sample. The variable VARPSU99 identifies the 460 PSUs in the sample. The sampling weights are stored in the variable PERWT99F. The response variable is the health insurance coverage indicator variable, INSCOV99, which has three values:

- 
- 1 The person had any private insurance coverage any time during 1999
  - 2 The person had only public insurance coverage during 1999
  - 3 The person was uninsured during all of 1999
- 

The demographic variables include gender (SEX), race (RACEX), and family income level as a percent of the poverty line (POVCAT99). The variable RACEX has five categories:

- 
- 1 American Indian
  - 2 Aleut, Eskimo
  - 3 Asian or Pacific Islander
  - 4 Black
  - 5 White
- 

The variable POVCAT99 is constructed by dividing family income by the applicable poverty line (based on family size and composition), with the resulting percentages grouped into five categories:

- 
- 1 Negative or poor (less than 100%)
  - 2 Near poor (100% to less than 125%)
  - 3 Low income (125% to less than 200%)
  - 4 Middle income (200% to less than 400%)
  - 5 High income (greater than or equal to 400%)
- 

The data set also contains the total health care expenditure in 1999, TOTEXP99, which is used as a covariate in the analysis.

Output 91.2.1 displays the first 30 observations of this data set.

**Output 91.2.1** 1999 Full-Year MEPS (First 30 Observations)

| O  | S      | R     | P                | I           | T           | P    | V        | V   |    |

The following SAS statements fit a generalized logit model for the 1999 full-year consolidated MEPS data:

```
proc surveylogistic data=meps;
 stratum VARSTR99;
 cluster VARPSU99;
 weight PERWT99F;
 class SEX RACEX POVCAT99;
 model INSCOV99 = TOTEXP99 SEX RACEX POVCAT99 / link=glogit;
run;
```

The STRATUM statement specifies the stratification variable VARSTR99. The CLUSTER statement specifies the PSU variable VARPSU99. The WEIGHT statement specifies the sample weight variable PERWT99F. The demographic variables SEX, RACEX, and POV99 are listed in the CLASS statement to indicate that they are categorical independent variables in the MODEL statement. In the MODEL statement, the response variable is INSCOV99, and the independent variables are TOTEXP99 along with the selected demographic variables. The LINK= option requests that the procedure fit the generalized logit model because the response variable INSCOV99 has nominal responses.

The results of this analysis are shown in the following outputs.

PROC SURVEYLOGISTIC lists the model fitting information and sample design information in [Output 91.2.2](#).

**Output 91.2.2** MEPS, Model Information

| The SURVEYLOGISTIC Procedure |                         |
|------------------------------|-------------------------|
| Model Information            |                         |
| Data Set                     | WORK.MEPS               |
| Response Variable            | INSCOV99                |
| Number of Response Levels    | 3                       |
| Stratum Variable             | VARSTR99                |
| Number of Strata             | 143                     |
| Cluster Variable             | VARPSU99                |
| Number of Clusters           | 460                     |
| Weight Variable              | PERWT99F                |
| Model                        | Generalized Logit       |
| Optimization Technique       | Newton-Raphson          |
| Variance Adjustment          | Degrees of Freedom (DF) |

[Output 91.2.3](#) displays the number of observations and the total of sampling weights both in the data set and used in the analysis. Only the observations with positive person-level weight are used in the analysis. Therefore, 1,053 observations with zero person-level weights were deleted.

**Output 91.2.3** MEPS, Number of Observations

|                             |          |
|-----------------------------|----------|
| Number of Observations Read | 24618    |
| Number of Observations Used | 23565    |
| Sum of Weights Read         | 2.7641E8 |
| Sum of Weights Used         | 2.7641E8 |

[Output 91.2.4](#) lists the three insurance coverage levels for the response variable INSCOV99. The “UNINSURED” category is used as the reference category in the model.

**Output 91.2.4** MEPS, Response Profile

| Response Profile |             |                 |              |
|------------------|-------------|-----------------|--------------|
| Ordered Value    | INSCOV99    | Total Frequency | Total Weight |
| 1                | ANY PRIVATE | 16130           | 204403997    |
| 2                | PUBLIC ONLY | 4241            | 41809572     |
| 3                | UNINSURED   | 3194            | 30197198     |

Logits modeled use INSCOV99='UNINSURED' as the reference category.

Output 91.2.5 shows the parameterization in the regression model for each categorical independent variable.

**Output 91.2.5** MEPS, Classification Levels

| Class Level Information |                           |    |                  |    |    |  |
|-------------------------|---------------------------|----|------------------|----|----|--|
| Class                   | Value                     |    | Design Variables |    |    |  |
| SEX                     | FEMALE                    | 1  |                  |    |    |  |

|                         | WHITE                     | -1 | -1               | -1 | -1 |  |
| POVCAT99                | HIGH INCOME               | 1  | 0                | 0  | 0  |  |
|                         | LOW INCOME                | 0  | 1                | 0  | 0  |  |
|                         | MIDDLE INCOME             | 0  | 0                | 1  | 0  |  |
|                         | NEAR POOR                 | 0  | 0                | 0  | 1  |  |
|                         | NEGATIVE OR POOR          | -1 | -1               | -1 | -1 |  |

Output 91.2.6 displays the parameter estimates and their standard errors.

Output 91.2.7 displays the odds ratio estimates and their standard errors.

For example, after adjusting for the effects of sex, race, and total health care expenditures, a person with high income is estimated to be 11.595 times more likely than a poor person to choose private health care insurance over no insurance, but only 0.274 times as likely to choose public health insurance over no insurance.

Output 91.2.6 MEPS, Parameter Estimates

## Overview: SURVEYMEANS Procedure

The SURVEYMEANS procedure estimates characteristics of a survey population by using statistics computed from a survey sample. It enables you to estimate statistics such as means, totals, proportions, quantiles, geometric means, and ratios. PROC SURVEYMEANS also provides domain analysis, which computes estimates for subpopulations or domains. The procedure also estimates variances and confidence limits and performs  $t$  tests for these statistics. PROC SURVEYMEANS uses either the Taylor series (linearization) method or replication (subsampling) methods to estimate sampling errors of estimators based on complex sample designs. The sample design can be a complex survey sample design with stratification, clustering, and unequal weighting. For more information, see Fuller (2009); Lohr (2010); Särndal, Swensson, and Wretman (1992); Wolter (2007).

---

## Getting Started: SURVEYMEANS Procedure

This section demonstrates how you can use the SURVEYMEANS procedure to produce descriptive statistics from sample survey data. For a complete description of PROC SURVEYMEANS, see the section “Syntax: SURVEYMEANS Procedure” on page 7785. The section “Examples: SURVEYMEANS Procedure” on page 7839 provides more complicated examples to illustrate the applications of PROC SURVEYMEANS.

---

## Simple Random Sampling

This example illustrates how you can use PROC SURVEYMEANS to estimate population means and proportions from sample survey data. The study population is a junior high school with a total of 4,000 students in grades 7, 8, and 9. Researchers want to know how much these students spend weekly for ice cream, on average, and what percentage of students spend at least \$10 weekly for ice cream.

To answer these questions, 40 students were selected from the entire student population by using simple random sampling (SRS). Selection by simple random sampling means that all students have an equal chance of being selected and no student can be selected more than once. Each student selected for the sample was asked how much he or she spends for ice cream per week, on average. The SAS data set IceCream saves the responses of the 40 students:

```
data IceCream;
 input Grade Spending @@;
 if (Spending < 10) then Group='less';
 else Group='more';
 datalines;
7 7 7 7 8 12 9 10 7 1 7 10 7 3 8 20 8 19 7 2
7 2 9 15 8 16 7 6 7 6 7 6 9 15 8 17 8 14 9 8
9 8 9 7 7 3 7 12 7 4 9 14 8 18 9 9 7 2 7 1
7 4 7 11 9 8 8 10 8 13 7 2 9 6 9 11 7 2 7 9
;
```

The variable Grade contains a student's grade. The variable Spending contains a student's response regarding how much he spends per week for ice cream, in dollars. The variable Group is created to indicate

whether a student spends at least \$10 weekly for ice cream: Group='more' if a student spends at least \$10, or Group='less' if a student spends less than \$10.

You can use PROC SURVEYMEANS to produce estimates for the entire student population, based on this random sample of 40 students:

```

title1 'Analysis of Ice Cream Spending';
title2 'Simple Random Sample Design';
proc surveymeans data=IceCream total=4000;
 var Spending Group;
run;

```

The PROC SURVEYMEANS statement invokes the procedure. The TOTAL=4000 option specifies the total number of students in the study population, or school. The procedure uses this total to adjust variance estimates for the effects of sampling from a finite population. The VAR statement names the variables to analyze, Spending and Group.

Figure 92.1 displays the results from this analysis. There are a total of 40 observations used in the analysis. The “Class Level Information” table lists the two levels of the variable Group. This variable is a character variable, and so PROC SURVEYMEANS provides a categorical analysis for it, estimating the relative frequency or proportion for each level. If you want a categorical analysis for a numeric variable, you can name that variable in the CLASS statement.

**Figure 92.1** Analysis of Ice Cream Spending

| Statistics                     |        |           |          |                      |                 |            |
| Variable                       | Level  | N         | Mean     | Std Error<br>of Mean | 95% CL for Mean |            |
| Spending                       |        | 40        | 8.750000 | 0.845139             | 7.04054539      | 10.4594546 |
| Group                          | less   | 23        | 0.575000 | 0.078761             | 0.41568994      | 0.7343101  |
|                                | more   | 17        | 0.425000 | 0.078761             | 0.26568994      | 0.5843101  |

The “Statistics” table displays the estimates for each analysis variable. By default, PROC SURVEYMEANS displays the number of observations, the estimate of the mean, its standard error, and the 95% confidence limits for the mean. You can obtain other statistics by specifying the corresponding *statistic-keywords* in the PROC SURVEYMEANS statement.

The estimate of the average weekly ice cream expense is \$8.75 for students at this school. The standard error of this estimate is \$0.85, and the 95% confidence interval for weekly ice cream expense is from \$7.04 to \$10.46. The analysis variable Group is a character variable, and so PROC SURVEYMEANS analyzes it as categorical, estimating the relative frequency or proportion for each level or category. These estimates are displayed in the Mean column of the “Statistics” table. It is estimated that 57.5% of all students spend less than \$10 weekly on ice cream, while 42.5% of the students spend at least \$10 weekly. The standard error of each estimate is 7.9%.

---

## Stratified Sampling

Suppose that the sample of students described in the previous section was actually selected by using stratified random sampling. In stratified sampling, the study population is divided into nonoverlapping strata, and samples are selected from each stratum independently.

The list of students in this junior high school was stratified by grade, yielding three strata: grades 7, 8, and 9. A simple random sample of students was selected from each grade. Table 92.1 shows the total number of students in each grade.

**Table 92.1** Number of Students by Grade

| Grade | Number of Students |
|-------|--------------------|
| 7     | 1,824              |
| 8     | 1,025              |
| 9     | 1,151              |
| Total | 4,000              |

To analyze this stratified sample, you need to provide the population totals for each stratum to PROC SURVEYMEANS. The SAS data set StudentTotals contains the information from Table 92.1:

```
data StudentTotals;
 input Grade _total_;
 datalines;
7 1824
8 1025
9 1151
;
```

The variable Grade is the stratum identification variable, and the variable \_TOTAL\_ contains the total number of students for each stratum. PROC SURVEYMEANS requires you to use the variable name \_TOTAL\_ for the stratum population totals.

The procedure uses the stratum population totals to adjust variance estimates for the effects of sampling from a finite population. If you do not provide population totals or sampling rates, then the procedure assumes

that the proportion of the population in the sample is very small, and the computation does not involve a finite population correction.

In a stratified sample design, when the sampling rates in the strata are unequal, you need to use sampling weights to reflect this information in order to produce an unbiased mean estimator. In this example, the appropriate sampling weights are reciprocals of the probabilities of selection. You can use the following DATA step to create the sampling weights:

```
data IceCream;
 set IceCream;
 if Grade=7 then Prob=20/1824;
 if Grade=8 then Prob=9/1025;
 if Grade=9 then Prob=11/1151;
 Weight=1/Prob;
run;
```

When you use PROC SURVEYSELECT to select your sample, the procedure creates these sampling weights for you.

The following SAS statements perform the stratified analysis of the survey data:

```
title1 'Analysis of Ice Cream Spending';
title2 'Stratified Sample Design';
proc surveymeans data=IceCream total=StudentTotals;
 stratum Grade / list;
 var Spending Group;
 weight Weight;
run;
```

The PROC SURVEYMEANS statement invokes the procedure. The DATA= option names the SAS data set IceCream as the input data set to be analyzed. The TOTAL= option names the data set StudentTotals as the input data set that contains the stratum population totals. Comparing this to the analysis in the section “[Simple Random Sampling](#)” on page 7779, notice that the TOTAL=StudentTotals option is used here instead of the TOTAL=4000 option. In this stratified sample design, the population totals are different for different strata, and so you need to provide them to PROC SURVEYMEANS in a SAS data set.

The STRATA statement identifies the stratification variable Grade. The LIST option in the STRATA statement requests that the procedure display stratum information. The WEIGHT statement tells the procedure that the variable Weight contains the sampling weights.

[Figure 92.2](#) displays information about the input data set. There are three strata in the design and 40 observations in the sample. The categorical variable Group has two levels, ‘less’ and ‘more.’

[Figure 92.3](#) displays information for each stratum. The table displays a stratum index and the values of the STRATA variable. The stratum index identifies each stratum by a sequentially assigned number. For each stratum, the table gives the population total (total number of students), the sampling rate, and the sample size. The stratum sampling rate is the ratio of the number of students in the sample to the number of students in the population for that stratum. The table also lists each analysis variable and the number of stratum observations for that variable. For categorical variables, the table lists each level and the number of sample observations in that level.

```

Figure 92.4 shows the following:

- The estimate of average weekly ice cream expense is \$9.14 for students in this school, with a standard error of \$0.53, and a 95% confidence interval from \$8.06 to \$10.22.
- An estimate of 54.5% of all students spend less than \$10 weekly on ice cream, and 45.5% spend more, with a standard error of 5.8%.

## Output Data Sets

PROC SURVEYMEANS uses the Output Delivery System (ODS) to create output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

For example, to save the “Statistics” table shown in Figure 92.4 in the previous section in an output data set, you use the ODS OUTPUT statement as follows:

```
title1 'Analysis of Ice Cream Spending';
title2 'Stratified Sample Design';
proc surveymeans data=IceCream total=StudentTotals;
 stratum Grade / list;
 var Spending Group;
 weight Weight;
 ods output Statistics=MyStat;
run;
```

The statement

```
ods output Statistics=MyStat;
```

requests that the “Statistics” table that appears in Figure 92.4 be placed in a SAS data set MyStat.

The PRINT procedure displays observations of the data set MyStat:

```
proc print data=MyStat;
run;
```

Figure 92.5 displays the data set MyStat. The section “ODS Table Names” on page 7838 gives the complete list of tables produced by PROC SURVEYMEANS.

**Figure 92.5** Output Data Set MyStat

| 2                                                          | Group    | less         | 23 | 0.544555 | 0.058424 | 0.42617678      | 0.6629323       |
| 3                                                          | Group    | more         | 17 | 0.455445 | 0.058424 | 0.33706769      | 0.5738232       |

## Syntax: SURVEYMEANS Procedure

The following statements are available in the SURVEYMEANS procedure:

```

PROC SURVEYMEANS < options > < statistic-keywords > ;
 BY variables ;
 CLASS variables ;
 CLUSTER variables ;
 DOMAIN variables < variable*variable variable*variable*variable ... > < / option > ;
 POSTSTRATA variables / PSTOTAL= < option > ;
 POSTSTRATA variables / PSPCT= < option > ;
 RATIO < 'label' > variables / variables ;
 REPWEIGHTS variables < / options > ;
 STRATA variables < / option > ;
 VAR variables ;
 WEIGHT variable ;

```

The PROC SURVEYMEANS statement invokes the procedure. It optionally names the input data sets, specifies statistics for the procedure to compute, and specifies the variance estimation method. The PROC SURVEYMEANS statement is required.

The VAR statement identifies the variables to be analyzed. The CLASS statement identifies numeric variables that are to be analyzed as categorical variables. The STRATA statement lists the variables that form the strata in a stratified sample design. The CLUSTER statement specifies cluster identification variables in a clustered sample design. The DOMAIN statement lists the variables that define domains for subpopulation analysis. The RATIO statement requests ratio analysis for means or proportions of analysis variables. The WEIGHT statement names the sampling weight variable. The POSTSTRATA statement lists the variables that are used to form poststrata for poststratification. The REPWEIGHTS statement names replicate weight variables for BRR or jackknife variance estimation. You can use a BY statement with PROC SURVEYMEANS to obtain separate analyses for groups defined by the BY variables.

All statements can appear multiple times except the PROC SURVEYMEANS statement, POSTSTRATA statement, and WEIGHT statement, which can appear only once.

The rest of this section gives detailed syntax information for the BY, CLASS, CLUSTER, DOMAIN, POSTSTRATA, RATIO, REPWEIGHTS, STRATA, VAR, and WEIGHT statements in alphabetical order after the description of the PROC SURVEYMEANS statement.

## PROC SURVEYMEANS Statement

**PROC SURVEYMEANS** < options > *statistic-keywords* ;

The PROC SURVEYMEANS statement invokes the SURVEYMEANS procedure. In this statement, you identify the data set to be analyzed, specify the variance estimation method, and provide sample design information. The DATA= option names the input data set to be analyzed. The VARMETHOD= option specifies the variance estimation method, which is the Taylor series method by default. For Taylor series variance estimation, you can include a finite population correction factor in the analysis by providing either the sampling rate or population total with the RATE= or TOTAL= option. If your design is stratified, with different sampling rates or totals for different strata, then you can input these stratum rates or totals in a SAS data set that contains the stratification variables.

In the PROC SURVEYMEANS statement, you also can use *statistic-keywords* to specify statistics, such as population mean and population total, for the procedure to compute. You can also request data set summary information and sample design information.

Table 92.2 summarizes the options available in the PROC SURVEYMEANS statement.

**Table 92.2** PROC SURVEYMEANS Statement Options

| Option      | Description                                                                    |
|-------------|--------------------------------------------------------------------------------|
| ALPHA=      | Sets the confidence level for confidence limits                                |
| DATA=       | Specifies the SAS data set to be analyzed                                      |
| MISSING     | Treats missing values as a valid                                               |
| NOMCAR      | Computes variance estimates by analyzing the nonmissing values as a domain     |
| NONSYMCL    | Requests nonsymmetric confidence limits for quantiles                          |
| NOPARSE     | Suppresses the display of analysis variables with zero frequency               |
| ORDER=      | Specifies the order in which to report the values of the categorical variables |
| PERCENTILE= | Specifies percentiles that you want the procedure to compute                   |
| QUANTILE=   | Specifies quantiles that you want the procedure to compute                     |
| RATE=       | Specifies the sampling rate                                                    |
| STACKING    | Produces the output data sets by using a stacking table structure              |
| TOTAL=      | Specifies the total number of primary sampling units                           |
| VARMETHOD=  | Specifies the variance estimation method                                       |

You can specify the following options in the PROC SURVEYMEANS statement:

### ALPHA= $\alpha$

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of  $\alpha$  produces  $100(1 - \alpha)\%$  confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

**DATA=SAS-data-set**

specifies the SAS data set to be analyzed by PROC SURVEYMEANS. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

**MISSING**

treats missing values as a valid (nonmissing) category for all categorical variables, which include CLASS, STRATA, CLUSTER, DOMAIN, and POSTSTRATA variables.

By default, if you do not specify the MISSING option, an observation is excluded from the analysis if it has a missing value. For more information, see the section “Missing Values” on page 7804.

**NOMCAR**

requests that the procedure treat missing values in the variance computation as *not missing completely at random* (NOMCAR) for Taylor series variance estimation. When you specify the NOMCAR option, PROC SURVEYMEANS computes variance estimates by analyzing the nonmissing values as a domain (subpopulation), where the entire population includes both nonmissing and missing domains. See the section “Missing Values” on page 7804 for more details.

By default, PROC SURVEYMEANS completely excludes an observation from analysis if that observation has a missing value, unless you specify the MISSING option for categorical variables. Note that the NOMCAR option has no effect on a categorical variable when you specify the MISSING option, which treats missing values as a valid nonmissing level.

The NOMCAR option applies only to Taylor series variance estimation. The replication methods, which you request with the VARMETHOD=BRR and VARMETHOD=JACKKNIFE options, do not use the NOMCAR option.

The NOMCAR option is not available for geometric means or poststratification.

**NONSYMCL**

requests nonsymmetric confidence limits for quantiles when you request quantiles with PERCENTILE= or QUANTILE= option. See the section “Confidence Limits” on page 7818 for more details. This option applies only to the default VARMETHOD=TAYLOR option.

**NOSPARE**

suppresses the display of analysis variables with zero frequency. By default, the procedure displays all continuous variables and all levels of categorical variables.

**ORDER=DATA | FORMATTED | INTERNAL**

specifies the order in which the values of the categorical variables are to be reported.

This option also determines the sort order for the levels of CIUSTER and DOMAIN variables and controls STRATA variable levels in the “Stratum Information” table.

The following shows how PROC SURVEYMEANS interprets values of the ORDER= option:

|           |                                                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| DATA      | orders values according to their order in the input data set.                                                                                       |
| FORMATTED | orders values by their formatted values. This order is operating environment dependent. By default, the order is ascending.                         |
| INTERNAL  | orders values by their unformatted values, which yields the same order that the SORT procedure does. This order is operating environment dependent. |

By default, ORDER=INTERNAL. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent.

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

#### PERCENTILE=(*values*)

specifies percentiles you want the procedure to compute. You can separate values with blanks or commas. Each value must be between 0 and 100. You can also use the *statistic-keywords* DECILES, MEDIAN, Q1, Q3, and QUARTILES to request common percentiles.

PROC SURVEYMEANS uses Woodruff's method (Dorfman and Valliant 1993; Särndal, Swensson, and Wretman 1992; Francisco and Fuller 1991) to estimate the variances of quantiles. See the section "Quantiles" on page 7817 for more details.

#### QUANTILE=(*values*)

specifies quantiles you want the procedure to compute. You can separate values with blanks or commas. Each value must be between 0 and 1. You can also use the *statistic-keywords* DECILES, MEDIAN, Q1, Q3, and QUARTILES to request common quantiles.

PROC SURVEYMEANS uses Woodruff's method (Dorfman and Valliant 1993; Särndal, Swensson, and Wretman 1992; Francisco and Fuller 1991) to estimate the variances of quantiles. See the section "Quantiles" on page 7817 for more details.

#### RATE=*value* | SAS-data-set

#### R=*value* | SAS-data-set

specifies the sampling rate as a nonnegative *value*, or specifies an input data set that contains the stratum sampling rates. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the RATE= option for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option.

If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of PSUs selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative *value* for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section "Specification of Population Totals and Sampling Rates" on page 7805 for more details.

The *value* in the RATE= option or the values of \_RATE\_ in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYMEANS converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

If you do not specify the TOTAL= or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= and RATE= options.

#### STACKING

requests that the procedure produce the output data sets by using a stacking table structure, which was the default before SAS 9. The new default is to produce a rectangular table structure in the output data sets.

A rectangular structure creates one observation for each analysis variable in the data set. A stacking structure creates only one observation in the output data set for all analysis variables.

The STACKING option affects the following tables:

- Domain
- Ratio
- Statistics
- StrataInfo

See the section “[Rectangular and Stacking Structures in an Output Data Set](#)” on page 7831 for more details.

**TOTAL=***value* | *SAS-data-set*

**N=***value* | *SAS-data-set*

specifies the total number of primary sampling units in the study population as a positive *value*, or specifies an input data set that contains the stratum population totals. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the TOTAL= option for BRR or jackknife variance estimation, which you request with the [VARMETHOD=BRR](#) or [VARMETHOD=JACKKNIFE](#) option.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 7805 for more details.

If you do not specify the TOTAL= or [RATE=](#) option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= and RATE= options.

*statistic-keywords*

specifies the statistics for the procedure to compute. If you do not specify any *statistic-keywords*, PROC SURVEYMEANS computes the NOBS, MEAN, STDERR, and CLM statistics by default.

The statistics produced depend on the type of the analysis variable. If you name a numeric variable in the CLASS statement, then the procedure analyzes that variable as a categorical variable. The procedure always analyzes character variables as categorical. See the section “[CLASS Statement](#)” on page 7796 for more information.

PROC SURVEYMEANS computes MIN, MAX, and RANGE for numeric variables but not for categorical variables. For numeric variables, the keyword MEAN produces the mean, but for categorical variables it produces the proportion in each category or level. Also, for categorical variables, the keyword NOBS produces the number of observations for each variable level, and the keyword NMISS produces the number of missing observations for each level. If you request the keyword NCLUSTER for a categorical variable, PROC SURVEYMEANS displays for each level the number of clusters with observations in that level. PROC SURVEYMEANS computes SUMWGT in the same way for both categorical and numeric variables, as the sum of the weights over all nonmissing observations.

PROC SURVEYMEANS performs univariate analysis, analyzing each variable separately. Thus the number of nonmissing and missing observations might not be the same for all analysis variables. See the section “[Missing Values](#)” on page 7804 for more information.

The following statistics are available for ratios (which you request with a **RATIO** statement): N, NCLU, SUMWGT, RATIO, STDERR, DF, T, PROBT, and CLM, as shown in the following list. If no statistics are requested, the procedure computes the ratio and its standard error by default.

The valid *statistic-keywords* are as follows:

|           |                                                                                                                                                                |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ALL       | all available statistics except those associated with geometric means                                                                                          |
| ALLGEO    | all available statistics associated with geometric means                                                                                                       |
| CLM       | 100(1 - $\alpha$ )% two-sided confidence limits for the MEAN, where $\alpha$ is determined by the <b>ALPHA=</b> option; the default is $\alpha = 0.05$         |
| CLSUM     | 100(1 - $\alpha$ )% two-sided confidence limits for the SUM, where $\alpha$ is determined by the <b>ALPHA=</b> option; the default is $\alpha = 0.05$          |
| CV        | coefficient of variation for MEAN                                                                                                                              |
| CVSUM     | coefficient of variation for SUM                                                                                                                               |
| DECILES   | the 10th, the 20th, . . . , and the 90th percentiles including their standard errors and confidence limits                                                     |
| DF        | degrees of freedom for the <i>t</i> test                                                                                                                       |
| GEOMEAN   | geometric mean of a numeric variable that contains positive values                                                                                             |
| GMCLM     | 100(1 - $\alpha$ )% two-sided confidence limits for the GEOMEAN, where $\alpha$ is determined by the <b>ALPHA=</b> option; the default is $\alpha = 0.05$      |
| GMSTDERR  | standard error of the GEOMEAN. When you request GEOMEAN, the procedure computes GMSTDERR by default.                                                           |
| LCLM      | 100(1 - $\alpha$ )% one-sided lower confidence limit for the MEAN, where $\alpha$ is determined by the <b>ALPHA=</b> option; the default is $\alpha = 0.05$    |
| LCLSUM    | 100(1 - $\alpha$ )% one-sided lower confidence limit for the SUM, where $\alpha$ is determined by the <b>ALPHA=</b> option; the default is $\alpha = 0.05$     |
| LGMCLM    | 100(1 - $\alpha$ )% one-sided lower confidence limit for the GEOMEAN, where $\alpha$ is determined by the <b>ALPHA=</b> option; the default is $\alpha = 0.05$ |
| MAX       | maximum value                                                                                                                                                  |
| MEAN      | mean for a numeric variable, or the proportion in each category for a categorical variable                                                                     |
| MEDIAN    | median for a numeric variable                                                                                                                                  |
| MIN       | minimum value                                                                                                                                                  |
| NCLUSTER  | number of clusters                                                                                                                                             |
| NMISS     | number of missing observations                                                                                                                                 |
| NOBS      | number of nonmissing observations                                                                                                                              |
| Q1        | lower quartile                                                                                                                                                 |
| Q3        | upper quartile                                                                                                                                                 |
| QUARTILES | lower quartile (25%th percentile), median (50%th percentile), and upper quartile (75%th percentile), including their standard errors and confidence limits     |

|        |                                                                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| RANGE  | range, MAX–MIN                                                                                                                                          |
| STD    | standard deviation of the SUM. When you request SUM, the procedure computes STD by default.                                                             |
| STDERR | standard error of the MEAN or RATIO. When you request MEAN or RATIO, the procedure computes STDERR by default.                                          |
| SUM    | weighted sum, $\sum w_i y_i$ , or estimated population total when the appropriate sampling weights are used                                             |
| SUMWGT | sum of the weights, $\sum w_i$                                                                                                                          |
| T      | $t$ -value and its corresponding $p$ -value with DF degrees of freedom for $H_0 : \theta = 0$ , where $\theta$ is a requested statistic                 |
| UCLM   | 100(1 – $\alpha$ )% one-sided upper confidence limit for the MEAN, where $\alpha$ is determined by the ALPHA= option; the default is $\alpha = 0.05$    |
| UCLSUM | 100(1 – $\alpha$ )% one-sided upper confidence limit for the SUM, where $\alpha$ is determined by the ALPHA= option; the default is $\alpha = 0.05$     |
| UGMCLM | 100(1 – $\alpha$ )% one-sided upper confidence limit for the GEOMEAN, where $\alpha$ is determined by the ALPHA= option; the default is $\alpha = 0.05$ |
| VAR    | variance of the MEAN or RATIO                                                                                                                           |
| VARSUM | variance of the SUM                                                                                                                                     |

See the section “Statistical Computations” on page 7807 for details about how PROC SURVEYMEANS computes these statistics.

**VARMETHOD=BRR** <(method-options)>

**VARMETHOD=JACKKNIFE** | **JK** <(method-options)>

**VARMETHOD=TAYLOR**

specifies the variance estimation method. VARMETHOD=TAYLOR requests the Taylor series method, which is the default if you do not specify the VARMETHOD= option or the REPWEIGHTS statement. VARMETHOD=BRR requests variance estimation by balanced repeated replication (BRR), and VARMETHOD=JACKKNIFE requests variance estimation by the delete-1 jackknife method.

For VARMETHOD=BRR and VARMETHOD=JACKKNIFE you can specify *method-options* in parentheses. Table 92.3 summarizes the available *method-options*.

**Table 92.3** Variance Estimation Options

| <b>VARMETHOD=</b> | <b>Variance Estimation Method</b> | <i>Method-Options</i>                                                                              |
|-------------------|-----------------------------------|----------------------------------------------------------------------------------------------------|
| BRR               | Balanced repeated replication     | DFADJ<br>FAY <=value><br>HADAMARD=SAS-data-set<br>OUTWEIGHTS=SAS-data-set<br>PRINTH<br>REPS=number |
| JACKKNIFE         | Jackknife                         | DFADJ<br>OUTJKCOEFS=SAS-data-set<br>OUTWEIGHTS=SAS-data-set                                        |
| TAYLOR            | Taylor series linearization       | None                                                                                               |

*Method-options* must be enclosed in parentheses following the method keyword. For example:

```
varmethod=BRR (reps=60 outweights=myReplicateWeights)
```

The following values are available for the VARMETHOD= option:

#### **BRR** <(method-options)>

requests **balanced repeated replication** (BRR) variance estimation. The BRR method requires a stratified sample design with two primary sampling units (PSUs) per stratum. See the section “**Balanced Repeated Replication (BRR) Method**” on page 7824 for more information.

You can specify the following *method-options* in parentheses following VARMETHOD=BRR:

#### **DFADJ**

computes the degrees of freedom as the number of nonmissing strata for an analysis variable. The degrees of freedom for VARMETHOD=BRR equal the number of strata, which by default is based on all valid observations in the data set. But if you specify the *DFADJ method-option*, PROC SURVEYMEANS does not count any empty strata that are due to all observations containing missing values for an analysis variable.

See the section “**Degrees of Freedom**” on page 7810 for more information. See the section “**Data and Sample Design Summary**” on page 7832 for details about valid observations.

The *DFADJ method-option* has no effect on categorical variables when you specify the **MISSING** option, which treats missing values as a valid nonmissing level.

The *DFADJ method-option* cannot be used when you provide replicate weights with a **REPWEIGHTS** statement. When you use a **REPWEIGHTS** statement, the degrees of freedom equal the number of **REPWEIGHTS** variables (or replicates), unless you specify an alternative value in the **DF=** option in the **REPWEIGHTS** statement.

#### **FAY** <=value>

requests **Fay’s method**, a modification of the **BRR** method, for variance estimation. See the section “**Fay’s BRR Method**” on page 7825 for more information.

You can specify the *value* of the Fay coefficient, which is used in converting the original sampling weights to replicate weights. The Fay coefficient must be a nonnegative number less than 1. By default, the value of the Fay coefficient equals 0.5.

#### **HADAMARD**=SAS-data-set

#### **H**=SAS-data-set

names a SAS data set that contains the **Hadamard matrix** for BRR replicate construction. If you do not provide a Hadamard matrix with the

HADAMARD= *method-option*, PROC SURVEYMEANS generates an appropriate Hadamard matrix for replicate construction. See the sections “Balanced Repeated Replication (BRR) Method” on page 7824 and “Hadamard Matrix” on page 7827 for details.

If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the HADAMARD= *method-option*.

In the HADAMARD= input data set, each variable corresponds to a column of the Hadamard matrix, and each observation corresponds to a row of the matrix. You can use any variable names in the HADAMARD= data set. All values in the data set must equal either 1 or -1. You must ensure that the matrix you provide is indeed a Hadamard matrix—that is,  $\mathbf{A}'\mathbf{A} = R\mathbf{I}$ , where  $\mathbf{A}$  is the Hadamard matrix of dimension  $R$  and  $\mathbf{I}$  is an identity matrix. PROC SURVEYMEANS does not check the validity of the Hadamard matrix that you provide.

The HADAMARD= input data set must contain at least  $H$  variables, where  $H$  denotes the number of first-stage strata in your design. If the data set contains more than  $H$  variables, the procedure uses only the first  $H$  variables. Similarly, the HADAMARD= input data set must contain at least  $H$  observations.

If you do not specify the REPS= *method-option*, then the number of replicates is taken to be the number of observations in the HADAMARD= input data set. If you specify the number of replicates—for example, REPS= $nreps$ —then the first  $nreps$  observations in the HADAMARD= data set are used to construct the replicates.

You can specify the PRINTH option to display the Hadamard matrix that the procedure uses to construct replicates for BRR.

#### **OUTWEIGHTS=SAS-data-set**

names a SAS data set that contains replicate weights. See the section “Balanced Repeated Replication (BRR) Method” on page 7824 for information about replicate weights. See the section “Replicate Weights Output Data Set” on page 7829 for more details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= *method-option* is not available when you provide replicate weights with the REPWEIGHTS statement.

#### **PRINTH**

displays the Hadamard matrix.

When you provide your own Hadamard matrix with the HADAMARD= *method-option*, only the rows and columns of the Hadamard matrix that are used by the procedure are displayed. See the sections “Balanced Repeated Replication (BRR) Method” on page 7824 and “Hadamard Matrix” on page 7827 for details.

The PRINTH *method-option* is not available when you provide replicate weights with the REPWEIGHTS statement because the procedure does not use a Hadamard matrix in this case.

**REPS=*number***

specifies the number of replicates for BRR variance estimation. The value of *number* must be an integer greater than 1.

If you do not provide a Hadamard matrix with the HADAMARD= *method-option*, the number of replicates should be greater than the number of strata and should be a multiple of 4. See the section “Balanced Repeated Replication (BRR) Method” on page 7824 for more information. If a Hadamard matrix cannot be constructed for the REPS= value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the REPS= value that you specify.

If you provide a Hadamard matrix with the HADAMARD= *method-option*, the value of REPS= must not be less than the number of rows in the Hadamard matrix. If you provide a Hadamard matrix and do not specify the REPS= *method-option*, the number of replicates equals the number of rows in the Hadamard matrix.

If you do not specify the REPS= or HADAMARD= *method-option* and do not include a REPWEIGHTS statement, the number of replicates equals the smallest multiple of 4 that is greater than the number of strata.

If you provide replicate weights with the REPWEIGHTS statement, the procedure does not use the REPS= *method-option*. With a REPWEIGHTS statement, the number of replicates equals the number of REPWEIGHTS variables.

**JACKKNIFE | JK <(method-options)>**

requests variance estimation by the delete-1 jackknife method. See the section “Jackknife Method” on page 7826 for details. If you provide replicate weights with a REPWEIGHTS statement, VARMETHOD=JACKKNIFE is the default variance estimation method.

You can specify the following *method-options* in parentheses following VARMETHOD=JACKKNIFE:

**DFADJ**

computes the degrees of freedom as the number of nonmissing strata for an analysis variable. The degrees of freedom for VARMETHOD=JACKKNIFE equal the number of clusters (or number of observations if there is no clusters) minus the number of strata (or one if there is no strata). By default, the number of strata is based on all valid observations in the data set. But if you specify the DFADJ *method-option*, PROC SURVEYMEANS does not count any empty strata that are due to all observations containing missing values for an analysis variable.

See the section “Degrees of Freedom” on page 7810 for more information. See the section “Data and Sample Design Summary” on page 7832 for details about valid observations.

The DFADJ *method-option* has no effect on categorical variables when you specify the MISSING option, which treats missing values as a valid nonmissing level.

The DFADJ *method-option* cannot be used when you provide replicate weights with a REPWEIGHTS statement. When you use a REPWEIGHTS statement, the degrees of freedom equal the number of REPWEIGHTS variables (or replicates), unless you specify an alternative value in the DF= option in the REPWEIGHTS statement.

**OUTJKCOEFS=SAS-data-set**

names a SAS data set that contains jackknife coefficients. See the section “Jackknife Method” on page 7826 for information about jackknife coefficients. See the section “Jackknife Coefficients Output Data Set” on page 7830 for more details about the contents of the OUTJKCOEFS= data set.

**OUTWEIGHTS=SAS-data-set**

names a SAS data set that contains replicate weights. See the section “Jackknife Method” on page 7826 for information about replicate weights. See the section “Replicate Weights Output Data Set” on page 7829 for more details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= *method-option* is not available when you provide replicate weights with the REPWEIGHTS statement.

**TAYLOR**

requests Taylor series variance estimation. This is the default method if you do not specify the VARMETHOD= option or a REPWEIGHTS statement. See the section “Taylor Series Method” on page 7809 for more information.

---

## BY Statement

**BY variables ;**

You can specify a BY statement with PROC SURVEYMEANS to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the SURVEYMEANS procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid domain (subpopulation) analysis, where the total number of units in the subpopulation is not known with certainty. You should use the DOMAIN statement to obtain domain analysis. For more information about subpopulation analysis for sample survey data, see Cochran (1977).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

## CLASS Statement

**CLASS** *variables* ;

The CLASS statement names variables to be analyzed as categorical variables. For categorical variables, PROC SURVEYMEANS estimates the proportion in each category or level, instead of the overall mean. PROC SURVEYMEANS always analyzes character variables as categorical. If you want categorical analysis for a numeric variable, you must include that variable in the CLASS statement.

The CLASS *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLASS variables determine the categorical variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

When determining levels of a CLASS variable, an observation with missing values for this CLASS variable is excluded, unless you specify the MISSING option. For more information, see the section “Missing Values” on page 7804.

You can use multiple CLASS statements to specify categorical variables.

When you specify classification variables, you can use the SAS system option SUMSIZE= to limit (or to specify) the amount of memory that is available for data analysis. See the chapter on SAS system options in *SAS System Options: Reference* for a description of the SUMSIZE= option.

## CLUSTER Statement

**CLUSTER** *variables* ;

The CLUSTER statement names variables that identify the clusters in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If you provide replicate weights for BRR or jackknife variance estimation with the REPWEIGHTS statement, you do not need to specify a CLUSTER statement.

If your sample design has clustering at multiple stages, you should identify only the first-stage clusters (primary sampling units (PSUs)), in the CLUSTER statement. See the section “Primary Sampling Units (PSUs)” on page 7806 for more information.

The CLUSTER *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

When determining levels of a CLUSTER variable, an observation with missing values for this CLUSTER variable is excluded, unless you specify the MISSING option. For more information, see the section “Missing Values” on page 7804.

You can use multiple CLUSTER statements to specify cluster variables. The procedure uses variables from all CLUSTER statements to create clusters.

---

## DOMAIN Statement

**DOMAIN** *variables* < *variable\*variable variable\*variable\*variable . . .* > < / *option* > ;

The DOMAIN statement requests analysis for domains (subpopulations) in addition to analysis for the entire study population. The DOMAIN statement names the variables that identify domains, which are called domain variables.

It is common practice to compute statistics for domains. The formation of these domains might be unrelated to the sample design. Therefore, the sample sizes for the domains are random variables. Use a DOMAIN statement to incorporate this variability into the variance estimation.

Note that a DOMAIN statement is different from a BY statement. In a BY statement, you treat the sample sizes as fixed in each subpopulation, and you perform analysis within each BY group independently. See the section “Domain Analysis” on page 7806 for more details.

Use the DOMAIN statement on the entire data set to perform a domain analysis. Creating a new data set from a single domain and analyzing that with PROC SURVEYMEANS yields inappropriate estimates of variance.

A domain variable can be either character or numeric. The procedure treats domain variables as categorical variables. If a variable appears by itself in a DOMAIN statement, each level of this variable determines a domain in the study population. If two or more variables are joined by asterisks (\*), then every possible combination of levels of these variables determines a domain. The procedure performs a descriptive analysis within each domain that is defined by the domain variables.

When determining levels of a DOMAIN variable, an observation with missing values for this DOMAIN variable is excluded, unless you specify the MISSING option. For more information, see the section “Missing Values” on page 7804.

The formatted values of the domain variables determine the categorical variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

You can specify the following option in the DOMAIN statement after a slash (/):

### DFADJ

computes the degrees of freedom by using the number of non-empty strata for an analysis variable in a domain.

In a domain analysis, it is possible that some strata contain no sampling units for a specific domain. Or some strata in the domain might be empty due to missing values. By default, the procedure counts these empty strata when computing the degrees of freedom.

However, if you specify the DFADJ option, the procedure excludes any empty strata when computing the degrees of freedom. Prior to SAS 9.2, the procedure excluded empty strata by default.

See the section “Degrees of Freedom” on page 7810 for more information. See the section “Data and Sample Design Summary” on page 7832 for details about valid observations.

The DFADJ option has no effect on categorical variables when you specify the MISSING option, which treats missing values as a valid nonmissing level.

## POSTSTRATA Statement

**POSTSTRATA** *variables* / **PSTOTAL=** *< option >* ;

**POSTSTRATA** *variables* / **PSPCT=** *< option >* ;

The POSTSTRATA statement names variables that form the poststrata to adjust the sampling weight for analyzing the survey. The combinations of categories of POSTSTRATA variables define the poststrata in the sample.

The POSTSTRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the POSTSTRATA *variables* determine the categorical levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

You must specify either poststratification totals or poststratification proportions, but not both, in the POSTSTRATA statement after a slash (/).

**PSTOTAL=***SAS-data-set* | *values*

**POSTTOTAL=***SAS-data-set* | *values*

**PSCONTROL=***SAS-data-set* | *values*

specifies an input data set that contains the poststratum totals or specifies the population poststratum totals as positive *values*. The SURVEYMEANS procedure uses this information to compute weight adjustment for poststratification.

You can provide poststratification totals by specifying **PSTOTAL=***SAS-data-set*, which names a SAS data set that contains the poststratification variables and the poststratum totals. This data set is called the *poststratum total data set*.

A poststratum total data set must contain all the poststratification variables that are listed in the POSTSTRATA statement and all the variables listed in the BY statement. If there are formats associated with the POSTSTRATA variables and the BY variables, then the formats in the poststratum

total data set for these variables must be consistent with those in the **DATA=** data set in the PROC SURVEYMEANS statement.

A poststratum total data set must have a variable named **\_PSTOTAL\_** that contains the poststratum totals. The value of **\_PSTOTAL\_** must be positive.

When poststratum levels are easy to identify, their corresponding poststratum totals can be specified as a list of positive numbers.

**ORDER=FORMATTED** is used to order the levels of poststratum levels.

You can separate *values* in the **PSTOTAL=** option with blanks or commas. The number of *values* must equal the number of poststrata in the data. List the *values* in the order of the corresponding poststratum level. The sum of the *values* should equal the total sampling weights.

**PSPCT=SAS-data-set | values**

**POSTPCT=SAS-data-set | values**

specifies an input data set that contains the population poststratum proportions or specifies the population poststratum proportions as positive *values*. The SURVEYMEANS procedure uses this information to compute weight adjustment for poststratification.

You can provide poststratification proportions by specifying **POSTPCT=SAS-data-set**, which names a SAS data set that contains the poststratification variables and the poststratum poststratification. This data set is called the *poststratum proportion data set*.

A poststratum proportion data set must contain all the poststratification variables that are listed in the POSTSTRATA statement and all the variables listed in the BY statement. If there are formats associated with the POSTSTRATA variables and the BY variables, then the formats in the poststratum proportion data set for these variables must be consistent with those in the **DATA=** data set in the PROC SURVEYMEANS statement.

A poststratum proportion data set must have a variable named **\_PSPCT\_** that contains the poststratum proportions. The value of **\_PSPCT\_** must be positive.

You can provide poststratum proportions either as positive decimal numbers between 0 and 1 for all poststrata or as positive percentages that must be less than 100 for all poststrata. If any value of the proportions is greater than 1, the procedure treats all proportions as percentages instead of decimal numbers.

When poststratum levels are easy to identify, their corresponding poststratum proportions can be specified as a list of positive numbers.

**ORDER=FORMATTED** is used to order the levels of poststratum levels.

You can separate *values* in the **POSTPCT=** option with blanks or commas. The number of *values* must equal the number of poststrata in the data. List the *values* in the order of the corresponding poststratum level.

If you provide the proportions as decimal numbers, then the sum of these values over all poststrata must be 1.

If you provide the proportions as percentages, then the sum of these percentages over all poststrata must be 100.

You can also optionally specify the following option to create an output data set to store the poststratification weights.

**OUTPSWGT=SAS-data-set**

**OUT=SAS-data-set**

names a SAS data set to contain poststratification weights. See the section “Poststratification” on page 7820 for information about poststratification weights.

If you also specify an **OUTWEIGHTS=** *method-option* for **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** in the **PROC SURVEYMEANS** statement, the **OUTPSWGT=** option is ignored. The poststratification weights for the full sample and the replication weights adjusted for poststratification are stored in the **OUTWEIGHTS=** data set.

See the section “Poststratification Weights Output Data Set” on page 7830 for more information about the contents of the **OUTPSWGT=** data set and the section “Replicate Weights Output Data Set” on page 7829 for more information about the contents of the **OUTWEIGHTS=** data set.

## RATIO Statement

**RATIO** < 'label' > *variables / variables* ;

The **RATIO** statement requests ratio analysis for means or proportions of analysis variables. A ratio statement names the variables whose means are used as numerators or denominators in a ratio. Variables that appear before the slash (/) are called *numerator variables* and are used as numerators. Variables that appear after the slash (/) are called *denominator variables* and are used as denominators. These *variables* can be any number of analysis variables, either continuous or categorical, except those named in the **BY**, **CLUSTER**, **STRATA**, **DOMAIN**, **POSTSTRATA**, **REPWEIGHTS**, and **WEIGHT** statements.

You can optionally specify a label for each **RATIO** statement to identify the ratios in the output. Labels must be enclosed in single quotes.

The computation of ratios depends on whether the numerator and denominator variables are continuous or categorical.

For continuous variables, ratios are calculated from the variable means. For example, for continuous variables X, Y, Z, and T, the following **RATIO** statement requests that the procedure analyze the ratios  $\bar{x}/\bar{z}$ ,  $\bar{x}/\bar{t}$ ,  $\bar{y}/\bar{z}$ , and  $\bar{y}/\bar{t}$ :

```
ratio x y / z t;
```

If a continuous variable appears as both a numerator and a denominator variable, the ratio of this variable to itself is ignored.

For categorical variables, ratios are calculated with the proportions for the categories. For example, if the categorical variable Gender has the values ‘Male’ and ‘Female,’ with the proportions  $p_m = \text{Pr}(\text{Gender}=\text{‘Male’})$  and  $p_f = \text{Pr}(\text{Gender}=\text{‘Female’})$ , and Y is a continuous variable, then the following **RATIO** statement requests that the procedure analyze the ratios  $p_m/p_f$ ,  $p_f/p_m$ ,  $\bar{y}/p_m$ , and  $\bar{y}/p_f$ :

```
ratio Gender y / Gender;
```

If a categorical variable appears as both a numerator and denominator variable, then the ratios of the proportions for all categories are computed, except the ratio of each category to itself.

You can have more than one RATIO statement. Each RATIO statement produces ratios independently by using its own numerator and denominator variables. Each RATIO statement also produces its own ratio analysis table.

Available statistics for a ratio are as follows:

- N, number of observations used to compute the ratio
- NCLU, number of clusters
- SUMWGT, sum of weights
- RATIO, ratio
- STDERR, standard error of ratio
- VAR, variance of ratio
- T, *t*-value of ratio
- PROBT, *p*-value of *t*
- DF, degrees of freedom of *t*
- CLM, two-sided confidence limits for ratio
- UCLM, one-sided upper confidence limit for ratio
- LCLM, one-sided lower confidence limit for ratio

The procedure calculates these statistics based on the *statistic-keywords* that you specify in the PROC SURVEYMEANS statement. If a *statistic-keyword* is not appropriate for a RATIO statement, that *statistic-keyword* is ignored for the ratios. If no valid statistics are requested for a RATIO statement, the procedure computes the ratio and its standard error by default.

When the means or proportions for the numerator and denominator variables in a ratio are calculated, an observation is excluded if it has a missing value for a continuous numerator or denominator variable. The procedure also excludes an observation with a missing value for a categorical numerator or denominator variable unless you specify the **MISSING** option.

When the denominator for a ratio is zero, then the value of the ratio is displayed as ‘-Infy’, ‘Infy’, or a missing value, depending on whether the numerator is negative, positive, or zero, respectively, and the corresponding internal value is the special missing value ‘.M’, the special missing value ‘.I’, or the usual missing value, respectively.

---

## REPWEIGHTS Statement

**REPWEIGHTS** *variables* </ options > ;

The REPWEIGHTS statement names variables that provide replicate weights for BRR or jackknife variance estimation, which you request with the **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** option in the PROC SURVEYMEANS statement. If you do not provide replicate weights for these methods by using a

REPWEIGHTS statement, then the procedure constructs replicate weights for the analysis. See the sections “Balanced Repeated Replication (BRR) Method” on page 7824 and “Jackknife Method” on page 7826 for information about replicate weights.

Each REPWEIGHTS variable should contain the weights for a single replicate, and the number of replicates equals the number of REPWEIGHTS variables. The REPWEIGHTS variables must be numeric, and the variable values must be nonnegative numbers.

If you provide replicate weights with a REPWEIGHTS statement, you do not need to specify a CLUSTER or STRATA statement. If you use a REPWEIGHTS statement and do not specify the VARMETHOD= option in the PROC SURVEYMEANS statement, the procedure uses VARMETHOD=JACKKNIFE by default.

If you specify a REPWEIGHTS statement but do not include a WEIGHT statement, the procedure uses the average of replicate weights of each observation as the observation’s weight.

You can specify the following options in the REPWEIGHTS statement after a slash (/):

**DF=*df***

specifies the degrees of freedom for the analysis. The value of *df* must be a positive number. By default, the degrees of freedom equals the number of REPWEIGHTS variables.

**JKCOEFS=*value***

specifies a jackknife coefficient for VARMETHOD=JACKKNIFE. The coefficient *value* must be a nonnegative number. See the section “Jackknife Method” on page 7826 for details about jackknife coefficients.

You can use this option to specify a single value of the jackknife coefficient, which the procedure uses for all replicates. To specify different coefficients for different replicates, use the JKCOEFS=*values* or JKCOEFS=*SAS-data-set* option.

**JKCOEFS=*values***

specifies jackknife coefficients for VARMETHOD=JACKKNIFE, where each coefficient corresponds to an individual replicate that is identified by a REPWEIGHTS variable. You can separate *values* with blanks or commas. The coefficient *values* must be nonnegative numbers. The number of *values* must equal the number of replicate weight variables named in the REPWEIGHTS statement. List these values in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement.

See the section “Jackknife Method” on page 7826 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the JKCOEFS=*SAS-data-set* option. To specify a single jackknife coefficient for all replicates, use the JKCOEFS=*value* option.

**JKCOEFS=*SAS-data-set***

names a SAS data set that contains the jackknife coefficients for VARMETHOD=JACKKNIFE. You provide the jackknife coefficients in the JKCOEFS= data set variable JKCoefficient. Each coefficient value must be a nonnegative number. The observations in the JKCOEFS= data set should correspond to the replicates that are identified by the REPWEIGHTS variables. Arrange the coefficients or observations in the JKCOEFS= data set in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement. The number of observations in the JKCOEFS= data set must not be less than the number of REPWEIGHTS variables.

See the section “Jackknife Method” on page 7826 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the `JKCOEFS=values` option. To specify a single jackknife coefficient for all replicates, use the `JKCOEFS=value` option.

---

## STRATA Statement

**STRATA** *variables* </ option > ;

The STRATA statement specifies variables that form the strata in a stratified sample design. The combinations of categories of STRATA variables define the strata in the sample.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section “Specification of Population Totals and Sampling Rates” on page 7805 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with the `REPWEIGHTS` statement, you do not need to specify a STRATA statement.

The STRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the STRATA variables determine the levels. Thus, you can use formats to group values into levels. See the `FORMAT` procedure in the *Base SAS Procedures Guide* and the `FORMAT` statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

When determining levels of a STRATA variable, an observation with missing values for this STRATA variable is excluded, unless you specify the `MISSING` option. For more information, see the section “Missing Values” on page 7804.

You can use multiple STRATA statements to specify stratum variables.

You can specify the following option in the STRATA statement after a slash (/):

### LIST

displays a “Stratum Information” table, which includes values of the STRATA variables and the number of observations, number of clusters, population total, and sampling rate for each stratum. See the section “Stratum Information” on page 7833 for more details.

---

## VAR Statement

**VAR** *variables* ;

The VAR statement names the variables to be analyzed.

A *variable* in the VAR statement should not appear in any of the `BY`, `CLUSTER`, `DOMAIN`, `POSTSTRATA`, `REPWEIGHTS`, `STRATA`, and `WEIGHT` statements.

If you want a categorical analysis for a numeric variable, you must also name that variable in the `CLASS` statement. For categorical variables, PROC SURVEYMEANS estimates the proportion in each category or level, instead of the overall mean. Character variables are always analyzed as categorical variables. See the section “CLASS Statement” on page 7796 for more information.

When you specify a variable in a `RATIO` statement but not in a VAR statement, PROC SURVEYMEANS includes this variable as an analysis variable.

If you do not specify a VAR statement, then PROC SURVEYMEANS analyzes all variables in the DATA= input data set, except those named in the BY, CLUSTER, DOMAIN, POSTSTRATA, REPWEIGHTS, STRATA, and WEIGHT statements.

---

## WEIGHT Statement

**WEIGHT** *variable* ;

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric, and the sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “Missing Values” on page 7804 for more information. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

If you do not specify a WEIGHT statement but provide replicate weights with a REPWEIGHTS statement, PROC SURVEYMEANS uses the average of replicate weights of each observation as the observation’s weight.

If you do not specify a WEIGHT statement or a REPWEIGHTS statement, PROC SURVEYMEANS assigns all observations a weight of one.

---

## Details: SURVEYMEANS Procedure

---

### Missing Values

If you have missing values in your survey data for any reason, such as nonresponse, this can compromise the quality of your survey results. If the respondents are different from the nonrespondents with regard to a survey effect or outcome, then survey estimates might be biased and cannot accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. After data collection is complete, you can use imputation to replace missing values with acceptable values, and/or you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYMEANS. For more information, see Cochran (1977); Kalton and Kaspyzyk (1986); Brick and Kalton (1996).

If an observation has a missing value or a nonpositive value for the WEIGHT variable, then that observation is excluded from the analysis.

An observation is also excluded from the analysis if it has a missing value for any design (STRATA, CLUSTER, DOMAIN, or POSTSTRATA) variable, unless you specify the MISSING option in the PROC SURVEYMEANS statement. If you specify the MISSING option, the procedure treats missing values as a valid (nonmissing) category for all categorical variables.

By default, when computing statistics for an analysis variable, PROC SURVEYMEANS omits observations with missing values for that analysis variable. The procedure computes statistics for each variable based only on observations that have nonmissing values for that variable. This treatment is based on the assumption that the missing values are missing completely at random (MCAR). However, this assumption is sometimes

not true. For example, evidence from other surveys might suggest that observations with missing values are systematically different from observations without missing values. If you believe that missing values are not missing completely at random, then you can specify the **NOMCAR** option to let variance estimation include these observations with missing values in the analysis variables.

Whether or not you specify the **NOMCAR** option, the procedure always excludes observations with missing or invalid values for the **WEIGHT**, **STRATA**, **CLUSTER**, and **DOMAIN** variables, unless you specify the **MISSING** option.

When you specify the **NOMCAR** option, the procedure treats observations with and without missing values for analysis variables as two different domains, and it performs a domain analysis in the domain of nonmissing observations.

The procedure performs univariate analysis and analyzes each **VAR** variable separately. Thus, the number of missing observations might be different for different variables. You can specify the keyword **NMISS** in the **PROC SURVEYMEANS** statement to display the number of missing values for each analysis variable in the “Statistics” table.

When you specify a **RATIO** statement, the procedure excludes any observation that has a missing value for a continuous numerator or denominator variable. The procedure also excludes an observation with a missing value for a categorical numerator or denominator variable unless you specify the **MISSING** option.

If you use a **REPWEIGHTS** statement, all **REPWEIGHTS** variables must contain nonmissing values.

## Survey Data Analysis

### Specification of Population Totals and Sampling Rates

To include a finite population correction (*fpc*) in Taylor series variance estimation, you can input either the sampling rate or the population total by using the **RATE=** or **TOTAL=** option in the **PROC SURVEYMEANS** statement. (You cannot specify both of these options in the same **PROC SURVEYMEANS** statement.) The **RATE=** and **TOTAL=** options apply only to Taylor series variance estimation. The procedure does not use a finite population correction for **BRR** or jackknife variance estimation.

If you do not specify the **RATE=** or **TOTAL=** option, the Taylor series variance estimation does not include a finite population correction. For fairly small sampling fractions, it is appropriate to ignore this correction. For more information, see Cochran (1977); Kish (1965).

If your design has multiple stages of selection and you are specifying the **RATE=** option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the **TOTAL=** option for a multistage design, you should input the total number of PSUs in the study population. See the section “**Primary Sampling Units (PSUs)**” on page 7806 for more details.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you can use the **RATE=value** or **TOTAL=value** option. If your sample design is stratified with different sampling rates or population totals in different strata, use the **RATE=SAS-data-set** or **TOTAL=SAS-data-set** option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the **DATA=** option.

The secondary data set must contain all the stratification variables listed in the STRATA statement and all the variables in the BY statement. If there are formats associated with the STRATA variables and the BY variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the TOTAL=*SAS-data-set* option, the secondary data set must have a variable named `_TOTAL_` that contains the stratum population totals. Or if you specify the RATE=*SAS-data-set* option, the secondary data set must have a variable named `_RATE_` that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of `_TOTAL_` or `_RATE_` for that stratum and ignores the rest.

The *value* in the RATE= option or the values of `_RATE_` in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYMEANS converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

If you specify the TOTAL=*value* option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

### Primary Sampling Units (PSUs)

When you have clusters, or primary sampling units (PSUs), in your sample design, the procedure estimates variance from the variation among PSUs when the Taylor series variance method is used. See the section “Variance and Standard Error of the Mean” on page 7809 and the section “Variance and Standard Deviation of the Total” on page 7812 for more information.

BRR or jackknife variance estimation methods draw multiple replicates (or subsamples) from the full sample by following a specific resampling scheme. These subsamples are constructed by deleting PSUs from the full sample.

If you use a `REPWEIGHTS` statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a `CLUSTER` statement. Otherwise, you should specify a `CLUSTER` statement whenever your design includes clustering at the first stage of sampling. If you do not specify a `CLUSTER` statement, then PROC SURVEYMEANS treats each observation as a PSU.

### Domain Analysis

It is common practice to compute statistics for domains (subpopulations), in addition to computing statistics for the entire study population. Analysis for domains that uses the entire sample is called *domain analysis* (also called subgroup analysis, subpopulation analysis, or subdomain analysis). The formation of these subpopulations of interest might be unrelated to the sample design. Therefore, the sample sizes for the subpopulations might actually be random variables.

Use a `DOMAIN` statement to incorporate this variability into the variance estimation. Note that using a `BY` statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, where the total number of units in the subpopulation is not known with certainty.

For more detailed information about domain analysis, see Kish (1965).

## Statistical Computations

The SURVEYMEANS procedure uses the Taylor series (linearization) method or replication (resampling) methods to estimate sampling errors of estimators based on complex sample designs. For more information, see Fuller (2009); Wolter (2007); Lohr (2010); Kalton (1983); Hidiroglou, Fuller, and Hickman (1980); Fuller et al. (1989); Lee, Forthoffer, and Lorimor (1989); Cochran (1977); Kish (1965); Hansen, Hurwitz, and Madow (1953); Rust (1985); Dippo, Fay, and Morganstein (1984); Rao and Shao (1999); Rao, Wu, and Yue (1992); Rao and Shao (1996). You can use the `VARMETHOD=` option to specify a variance estimation method to use. By default, the Taylor series method is used.

The Taylor series method obtains a linear approximation for the estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Woodruff 1971; Fuller 1975). When there are clusters, or PSUs, in the sample design, the procedure estimates variance from the variation among PSUs. When the design is stratified, the procedure pools stratum variance estimates to compute the overall variance estimate. For  $t$  tests of the estimates, the degrees of freedom equal the number of clusters minus the number of strata in the sample design.

For a multistage sample design, the Taylor series estimation depends only on the first stage of the sample design. Therefore, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling. This variance estimation method assumes that the first-stage sampling fraction is small, or that the first-stage sample is drawn with replacement, as it often is in practice.

Quite often in complex surveys, respondents have unequal weights, which reflect unequal selection probabilities and adjustments for nonresponse. In such surveys, the appropriate sampling weights must be used to obtain valid estimates for the study population.

However, replication methods have recently gained popularity for estimating variances in complex survey data analysis. One reason for this popularity is the relative simplicity of replication-based estimates, especially for nonlinear estimators; another is that modern computational capacity has made replication methods feasible for practical survey analysis.

Replication methods draw multiple replicates (also called subsamples) from a full sample according to a specific resampling scheme. The most commonly used resampling schemes are the *balanced repeated replication* (BRR) method and the *jackknife* method. For each replicate, the original weights are modified for the PSUs in the replicates to create replicate weights. The population parameters of interest are estimated by using the replicate weights for each replicate. Then the variances of parameters of interest are estimated by the variability among the estimates derived from these replicates. You can use a `REPWEIGHTS` statement to provide your own replicate weights for variance estimation. For more information about using replication methods to analyze sample survey data, see the section “Replication Methods for Variance Estimation” on page 7824.

## Definitions and Notation

For a stratified clustered sample design, together with the sampling weights, the sample can be represented by an  $n \times (P + 1)$  matrix

$$\begin{aligned} (\mathbf{w}, \mathbf{Y}) &= (w_{hij}, \mathbf{y}_{hij}) \\ &= (w_{hij}, y_{hij}^{(1)}, y_{hij}^{(2)}, \dots, y_{hij}^{(P)}) \end{aligned}$$

where

- $h = 1, 2, \dots, H$  is the stratum index
- $i = 1, 2, \dots, n_h$  is the cluster index within stratum  $h$
- $j = 1, 2, \dots, m_{hi}$  is the unit index within cluster  $i$  of stratum  $h$
- $p = 1, 2, \dots, P$  is the analysis variable number, with a total of  $P$  variables
- $n = \sum_{h=1}^H \sum_{i=1}^{n_h} m_{hi}$  is the total number of observations in the sample
- $w_{hij}$  denotes the sampling weight for unit  $j$  in cluster  $i$  of stratum  $h$
- $y_{hij} = (y_{hij}^{(1)}, y_{hij}^{(2)}, \dots, y_{hij}^{(P)})$  are the observed values of the analysis variables for unit  $j$  in cluster  $i$  of stratum  $h$ , including both the values of numerical variables and the values of indicator variables for levels of categorical variables.

For a categorical variable  $C$ , let  $l$  denote the number of levels of  $C$ , and denote the level values as  $c_1, c_2, \dots, c_l$ . Let  $y^{(q)}$  ( $q \in \{1, 2, \dots, P\}$ ) be an indicator variable for the category  $C = c_k$  ( $k = 1, 2, \dots, l$ ) with the observed value in unit  $j$  in cluster  $i$  of stratum  $h$ :

$$y_{hij}^{(q)} = I_{\{C=c_k\}}(h, i, j) = \begin{cases} 1 & \text{if } C_{hij} = c_k \\ 0 & \text{otherwise} \end{cases}$$

Note that the indicator variable  $y_{hij}^{(q)}$  is set to missing when  $C_{hij}$  is missing. Therefore, the total number of analysis variables,  $P$ , is the total number of numerical variables plus the total number of levels of all categorical variables.

The sampling rate  $f_h$  for stratum  $h$ , which is used in Taylor series variance estimation, is the fraction of first-stage units (PSUs) selected for the sample. You can use the TOTAL= or RATE= option to input population totals or sampling rates. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 7805 for details. If you input stratum totals, PROC SURVEYMEANS computes  $f_h$  as the ratio of the stratum sample size to the stratum total. If you input stratum sampling rates, PROC SURVEYMEANS uses these values directly for  $f_h$ . If you do not specify the TOTAL= or RATE= option, then the procedure assumes that the stratum sampling rates  $f_h$  are negligible, and a finite population correction is not used when computing variances. Replication methods specified by the [VARMETHOD=BRR](#) or the [VARMETHOD=JACKKNIFE](#) option do not use this finite population correction  $f_h$ .

## Mean

When you specify the keyword MEAN, the procedure computes the estimate of the mean (mean per element) from the survey data. Also, the procedure computes the mean by default if you do not specify any *statistic-keywords* in the PROC SURVEYMEANS statement.

PROC SURVEYMEANS computes the estimate of the mean as

$$\hat{Y} = \left( \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij} \right) / w_{..}$$

where

$$w_{\dots} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij}$$

is the sum of the weights over all observations in the sample.

## Variance and Standard Error of the Mean

When you specify the keyword `STDERR`, the procedure computes the standard error of the mean. Also, the procedure computes the standard error by default if you specify the keyword `MEAN`, or if you do not specify any *statistic-keywords* in the `PROC SURVEYMEANS` statement. The keyword `VAR` requests the variance of the mean.

### Taylor Series Method

When you use `VARMETHOD=TAYLOR`, or by default if you do not specify the `VARMETHOD=` option, `PROC SURVEYMEANS` uses the Taylor series method to estimate the variance of the mean  $\widehat{Y}$ . The procedure computes the estimated variance as

$$\widehat{V}(\widehat{Y}) = \sum_{h=1}^H \widehat{V}_h(\widehat{Y})$$

where, if  $n_h > 1$ , then

$$\begin{aligned} \widehat{V}_h(\widehat{Y}) &= \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (e_{hi\cdot} - \bar{e}_{h\cdot\cdot})^2 \\ e_{hi\cdot} &= \left( \sum_{j=1}^{m_{hi}} w_{hij} (y_{hij} - \widehat{Y}) \right) / w_{\dots} \\ \bar{e}_{h\cdot\cdot} &= \left( \sum_{i=1}^{n_h} e_{hi\cdot} \right) / n_h \end{aligned}$$

and if  $n_h = 1$ , then

$$\widehat{V}_h(\widehat{Y}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

### Replication Methods

When you specify `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE`, the procedure computes the variance  $\widehat{V}(\widehat{Y})$  with replication methods by using the variability among replicate estimates to estimate the overall variance. See the section “Replication Methods for Variance Estimation” on page 7824 for more details.

**Standard Error**

The standard error of the mean is the square root of the estimated variance.

$$\text{StdErr}(\hat{Y}) = \sqrt{\hat{V}(\hat{Y})}$$

**t Test for the Mean**

If you specify the keyword T, PROC SURVEYMEANS computes the  $t$ -value for testing that the population mean equals zero,  $H_0 : \bar{Y} = 0$ . The test statistic equals

$$t(\hat{Y}) = \hat{Y} / \text{StdErr}(\hat{Y})$$

The two-sided  $p$ -value for this test is

$$\text{Prob}(|T| > |t(\hat{Y})|)$$

where  $T$  is a random variable with the  $t$  distribution with  $df$  degrees of freedom.

**Degrees of Freedom**

PROC SURVEYMEANS computes degrees of freedom  $df$  to obtain the  $100(1 - \alpha)\%$  confidence limits for means, proportions, totals, ratios, and other statistics. The degrees of freedom computation depends on the variance estimation method that you request. Missing values can affect the degrees of freedom computation. See the section “Missing Values” on page 7804 for details.

**Taylor Series Variance Estimation**

For the Taylor series method, PROC SURVEYMEANS calculates the degrees of freedom for the  $t$  test as the number of clusters minus the number of strata. If there are no clusters, then the degrees of freedom equal the number of observations minus the number of strata. If the design is not stratified, then the degrees of freedom equal the number of PSUs minus one.

If all observations in a stratum are excluded from the analysis due to missing values, then that stratum is called an *empty stratum*. Empty strata are not counted in the total number of strata for the table. Similarly, empty clusters and missing observations are not included in the total counts of cluster and observations that are used to compute the degrees of freedom for the analysis.

If you specify the MISSING option, missing values are treated as valid nonmissing levels for a categorical variable and are included in computing degrees of freedom. If you specify the NOMCAR option for Taylor series variance estimation, observations with missing values for an analysis variable are included in computing degrees of freedom.

**Replicate-Based Variance Estimation**

When there is a REPWEIGHTS statement, the degrees of freedom equal the number of REPWEIGHTS variables, unless you specify an alternative in the DF= option in a REPWEIGHTS statement.

For BRR or jackknife variance estimation without a REPWEIGHT statement, by default PROC SURVEYMEANS computes the degrees of freedom by using all valid observations in the input data set. A valid observation is an observation that has a positive value of the WEIGHT variable and nonmissing values of the STRATA and CLUSTER variables unless you specify the MISSING option. See the section “Data and Sample Design Summary” on page 7832 for details about valid observations.

For BRR variance estimation (including [Fay's method](#)) without a REPWEIGHTS statement, PROC SURVEYMEANS calculates the degrees of freedom as the number of strata. PROC SURVEYMEANS bases the number of strata on all valid observations in the data set, unless you specify the *DFADJ method-option* for `VARMETHOD=BRR`. When you specify the DFADJ option, the procedure computes the degrees of freedom as the number of nonmissing strata for an analysis variable. This excludes any empty strata that occur when observations with missing values of that analysis variable are removed.

For jackknife variance estimation without a REPWEIGHTS statement, PROC SURVEYMEANS calculates the degrees of freedom as the number of clusters (or number of observations if there are no clusters) minus the number of strata (or one if there are no strata). For jackknife variance estimation, PROC SURVEYMEANS bases the number of strata and clusters on all valid observations in the data set, unless you specify the *DFADJ method-option* for `VARMETHOD=JACKKNIFE`. When you specify the DFADJ option, the procedure computes the degrees of freedom from the number of nonmissing strata and clusters for an analysis variable. This excludes any empty strata or clusters that occur when observations with missing values of an analysis variable are removed.

The procedure displays the degrees of freedom for the  $t$  test if you specify the keyword DF in the PROC SURVEYMEANS statement.

## Confidence Limits for the Mean

If you specify the keyword CLM, the procedure computes two-sided confidence limits for the mean. Also, the procedure includes the confidence limits by default if you do not specify any *statistic-keywords* in the PROC SURVEYMEANS statement.

The confidence coefficient is determined by the value of the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits. The confidence limits are computed as

$$\hat{Y} \pm \text{StdErr}(\hat{Y}) \cdot t_{df, \alpha/2}$$

where  $\hat{Y}$  is the estimate of the mean,  $\text{StdErr}(\hat{Y})$  is the standard error of the mean, and  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the  $t$  distribution with  $df$  calculated as in the section "[t Test for the Mean](#)" on page 7810.

If you specify the keyword UCLM, the procedure computes the one-sided upper  $100(1 - \alpha)\%$  confidence limit for the mean:

$$\hat{Y} + \text{StdErr}(\hat{Y}) \cdot t_{df, \alpha}$$

If you specify the keyword LCLM, the procedure computes the one-sided lower  $100(1 - \alpha)\%$  confidence limit for the mean:

$$\hat{Y} - \text{StdErr}(\hat{Y}) \cdot t_{df, \alpha}$$

## Coefficient of Variation

If you specify the keyword CV, PROC SURVEYMEANS computes the coefficient of variation, which is the ratio of the standard error of the mean to the estimated mean:

$$cv(\bar{Y}) = \text{StdErr}(\bar{Y}) / \bar{Y}$$

If you specify the keyword CVSUM, PROC SURVEYMEANS computes the coefficient of variation for the estimated total, which is the ratio of the standard deviation of the sum to the estimated total:

$$cv(Y) = \text{Std}(\hat{Y}) / \hat{Y}$$

## Proportions

If you specify the keyword MEAN for a categorical variable, PROC SURVEYMEANS estimates the proportion, or relative frequency, for each level of the categorical variable. If you do not specify any *statistic-keywords* in the PROC SURVEYMEANS statement, the procedure estimates the proportions for levels of the categorical variables, together with their standard errors and confidence limits.

The procedure estimates the proportion in level  $c_k$  for variable  $C$  as

$$\hat{p} = \frac{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij}^{(q)}}{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij}}$$

where  $y_{hij}^{(q)}$  is the value of the indicator function for level  $C = c_k$ , defined in the section “Definitions and Notation” on page 7807, and  $y_{hij}^{(q)}$  equals 1 if the observed value of variable  $C$  equals  $c_k$ , and  $y_{hij}^{(q)}$  equals 0 otherwise. Since the proportion estimator is actually an estimator of the mean for an indicator variable, the procedure computes its variance and standard error according to the method outlined in the section “Variance and Standard Error of the Mean” on page 7809. Similarly, the procedure computes confidence limits for proportions as in the section “Confidence Limits for the Mean” on page 7811.

## Total

If you specify the keyword SUM, the procedure computes the estimate of the population total from the survey data. The estimate of the total is the weighted sum over the sample:

$$\hat{Y} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij}$$

For a categorical variable level,  $\hat{Y}$  estimates its total frequency in the population.

## Variance and Standard Deviation of the Total

When you specify the keyword STD or the keyword SUM, the procedure estimates the standard deviation of the total. The keyword VARSUM requests the variance of the total.

### Taylor Series Method

When you use `VARMETHOD=TAYLOR`, or by default, PROC SURVEYMEANS uses the Taylor series method to estimate the variance of the total as

$$\hat{V}(\hat{Y}) = \sum_{h=1}^H \hat{V}_h(\hat{Y})$$

where, if  $n_h > 1$ , then

$$\widehat{V}_h(\widehat{Y}) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (y_{hi\cdot} - \bar{y}_{h\cdot\cdot})^2$$

$$y_{hi\cdot} = \sum_{j=1}^{m_{hi}} w_{hij} y_{hij}$$

$$\bar{y}_{h\cdot\cdot} = \left( \sum_{i=1}^{n_h} y_{hi\cdot} \right) / n_h$$

and if  $n_h = 1$ , then

$$\widehat{V}_h(\widehat{Y}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

### Replication Methods

When you specify `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE` option, the procedure computes the variance  $\widehat{V}(\widehat{Y})$  with replication methods by measuring the variability among the estimates derived from these replicates. See the section “Replication Methods for Variance Estimation” on page 7824 for more details.

### Standard Deviation

The standard deviation of the total equals

$$\text{Std}(\widehat{Y}) = \sqrt{\widehat{V}(\widehat{Y})}$$

### Confidence Limits for the Total

If you specify the keyword `CLSUM`, the procedure computes confidence limits for the total. The confidence coefficient is determined by the value of the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence limits. The confidence limits are computed as

$$\widehat{Y} \pm \text{Std}(\widehat{Y}) \cdot t_{df, \alpha/2}$$

where  $\widehat{Y}$  is the estimate of the total,  $\text{Std}(\widehat{Y})$  is the estimated standard deviation, and  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the  $t$  distribution with  $df$  calculated as described in the section “*t* Test for the Mean” on page 7810.

If you specify the keyword `UCLSUM`, the procedure computes the one-sided upper  $100(1 - \alpha)\%$  confidence limit for the sum:

$$\widehat{Y} + \text{Std}(\widehat{Y}) \cdot t_{df, \alpha}$$

If you specify the keyword `LCLSUM`, the procedure computes the one-sided lower  $100(1 - \alpha)\%$  confidence limit for the sum:

$$\widehat{Y} - \text{Std}(\widehat{Y}) \cdot t_{df, \alpha}$$

## Ratio

When you use a **RATIO** statement, the procedure produces statistics requested by the *statistic-keywords* in the PROC SURVEYMEANS statement.

Suppose that you want to calculate the ratio of variable  $Y$  to variable  $X$ . Let  $x_{hij}$  be the value of variable  $X$  for the  $j$ th member in cluster  $i$  in the  $h$ th stratum.

The ratio of  $Y$  to  $X$  is

$$\widehat{R} = \frac{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij}}{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} x_{hij}}$$

PROC SURVEYMEANS uses the Taylor series method to estimate the variance of the ratio  $\widehat{R}$  as

$$\widehat{V}(\widehat{R}) = \sum_{h=1}^H \widehat{V}_h(\widehat{R})$$

where, if  $n_h > 1$ , then

$$\begin{aligned} \widehat{V}_h(\widehat{R}) &= \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (g_{hi\cdot} - \bar{g}_{h\cdot\cdot})^2 \\ g_{hi\cdot} &= \frac{\sum_{j=1}^{m_{hi}} w_{hij} (y_{hij} - x_{hij} \widehat{R})}{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} x_{hij}} \\ \bar{g}_{h\cdot\cdot} &= \left( \sum_{i=1}^{n_h} g_{hi\cdot} \right) / n_h \end{aligned}$$

and if  $n_h = 1$ , then

$$\widehat{V}_h(\widehat{R}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

The standard error of the ratio is the square root of the estimated variance:

$$\text{StdErr}(\widehat{R}) = \sqrt{\widehat{V}(\widehat{R})}$$

When the denominator for a ratio is zero, then the value of the ratio is displayed as ‘-Infy’, ‘Infy’, or a missing value, depending on whether the numerator is negative, positive, or zero, respectively; and the corresponding internal value is the special missing value ‘.M’, the special missing value ‘.I’, or the usual missing value, respectively.

## Domain Statistics

When you use a **DOMAIN** statement to request a domain analysis, the procedure computes the requested statistics for each domain.

For a domain  $D$ , let  $I_D$  be the corresponding indicator variable:

$$I_D(h, i, j) = \begin{cases} 1 & \text{if observation } (h, i, j) \text{ belongs to } D \\ 0 & \text{otherwise} \end{cases}$$

Let

$$v_{hij} = w_{hij} I_D(h, i, j) = \begin{cases} w_{hij} & \text{if observation } (h, i, j) \text{ belongs to } D \\ 0 & \text{otherwise} \end{cases}$$

The requested statistics for variable  $y$  in domain  $D$  are computed by using the new weights  $v$ .

**Domain Mean**

The estimated mean of  $y$  in the domain  $D$  is

$$\widehat{Y}_D = \left( \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} v_{hij} y_{hij} \right) / v_{\dots}$$

where

$$v_{\dots} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} v_{hij}$$

The variance of  $\widehat{Y}_D$  is estimated by

$$\widehat{V}(\widehat{Y}_D) = \sum_{h=1}^H \widehat{V}_h(\widehat{Y}_D)$$

where, if  $n_h > 1$ , then

$$\begin{aligned} \widehat{V}_h(\widehat{Y}_D) &= \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (r_{hi\cdot} - \bar{r}_{h\cdot\cdot})^2 \\ r_{hi\cdot} &= \left( \sum_{j=1}^{m_{hi}} v_{hij} (y_{hij} - \widehat{Y}_D) \right) / v_{\dots} \\ \bar{r}_{h\cdot\cdot} &= \left( \sum_{i=1}^{n_h} r_{hi\cdot} \right) / n_h \end{aligned}$$

and if  $n_h = 1$ , then

$$\widehat{V}_h(\widehat{Y}_D) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

**Domain Total**

The estimated total in domain  $D$  is

$$\widehat{Y}_D = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} v_{hij} y_{hij}$$

and its estimated variance is

$$\widehat{V}(\widehat{Y}_D) = \sum_{h=1}^H \widehat{V}_h(\widehat{Y}_D)$$

where, if  $n_h > 1$ , then

$$\begin{aligned} \widehat{V}_h(\widehat{Y}_D) &= \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (z_{hi\cdot} - \bar{z}_{h\cdot\cdot})^2 \\ z_{hi\cdot} &= \sum_{j=1}^{m_{hi}} v_{hij} z_{hij} \\ \bar{z}_{h\cdot\cdot} &= \left( \sum_{i=1}^{n_h} z_{hi\cdot} \right) / n_h \end{aligned}$$

and if  $n_h = 1$ , then

$$\widehat{V}_h(\widehat{Y}_D) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

**Domain Ratio**

The estimated ratio of  $Y$  to  $X$  in domain  $D$  is

$$\widehat{R}_D = \frac{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} v_{hij} y_{hij}}{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} v_{hij} x_{hij}}$$

and its estimated variance is

$$\widehat{V}(\widehat{R}_D) = \sum_{h=1}^H \widehat{V}_h(\widehat{R}_D)$$

where, if  $n_h > 1$ , then

$$\begin{aligned} \widehat{V}_h(\widehat{R}_D) &= \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (g_{hi\cdot} - \bar{g}_{h\cdot\cdot})^2 \\ g_{hi\cdot} &= \frac{\sum_{j=1}^{m_{hi}} v_{hij} (y_{hij} - x_{hij} \widehat{R}_D)}{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} v_{hij} x_{hij}} \\ \bar{g}_{h\cdot\cdot} &= \left( \sum_{i=1}^{n_h} g_{hi\cdot} \right) / n_h \end{aligned}$$

and if  $n_h = 1$ , then

$$\widehat{V}_h(\widehat{R}_D) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

### Quantiles

Let  $Y$  be the variable of interest in a complex survey. Denote  $F(t) = \Pr(Y \leq t)$  as the cumulative distribution for  $Y$ . For  $0 < p < 1$ , the  $p$ th quantile of the population cumulative distribution function is

$$Y_p = \inf\{y : F(y) \geq p\}$$

#### Estimate of Quantile

Let  $\{y_{hij}, w_{hij}\}$  be the observed values for variable  $Y$  associated with sampling weights, where  $(h, i, j)$  are the stratum index, cluster index, and member index, respectively, as shown in the section “Definitions and Notation” on page 7807. Let  $y_{(1)} < y_{(2)} < \dots < y_{(d)}$  denote the sample order statistics for variable  $Y$ .

An estimate of quantile  $Y_p$  is

$$\hat{Y}_p = \begin{cases} y_{(1)} & \text{if } p < \hat{F}(y_{(1)}) \\ y_{(k)} + \frac{p - \hat{F}(y_{(k)})}{\hat{F}(y_{(k+1)}) - \hat{F}(y_{(k)})} (y_{(k+1)} - y_{(k)}) & \text{if } \hat{F}(y_{(k)}) \leq p < \hat{F}(y_{(k+1)}) \\ y_{(d)} & \text{if } p = 1 \end{cases}$$

where  $\hat{F}(t)$  is the estimated cumulative distribution for  $Y$ :

$$\hat{F}(t) = \frac{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} I(y_{hij} \leq t)}{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij}}$$

and  $I(\cdot)$  is the indicator function.

#### Standard Error

When you use `VARMETHOD=TAYLOR`, or by default if you do not specify the `VARMETHOD=` option, PROC SURVEYMEANS uses Woodruff’s method (Dorfman and Valliant 1993; Särndal, Swensson, and Wretman 1992; Francisco and Fuller 1991) to estimate the variances of quantiles. This method first constructs a confidence interval on a quantile. Then it uses the width of the confidence interval to estimate the standard error of a quantile.

In order to estimate the variance for  $\hat{Y}_p$ , first the procedure estimates the variance of the estimated distribution function  $\hat{F}(\hat{Y}_p)$  by

$$\hat{V}(\hat{F}(\hat{Y}_p)) = \sum_{h=1}^H \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (d_{hi\cdot} - \bar{d}_{h\cdot})^2$$

where

$$d_{hi\cdot} = \left( \sum_{j=1}^{m_{hi}} w_{hij} (I(y_{hij} \leq \hat{Y}_p) - \hat{F}(\hat{Y}_p)) \right) / w_{\dots}$$

$$\bar{d}_{h\cdot} = \left( \sum_{i=1}^{n_h} d_{hi\cdot} \right) / n_h$$

Then  $100(1 - \alpha)\%$  confidence limits for  $\hat{F}(\hat{Y}_p)$  can be constructed by

$$(\hat{p}_L, \hat{p}_U) = \left( \hat{F}(\hat{Y}_p) - t_{df, \alpha/2} \sqrt{\hat{V}(\hat{F}(\hat{Y}_p))}, \quad \hat{F}(\hat{Y}_p) + t_{df, \alpha/2} \sqrt{\hat{V}(\hat{F}(\hat{Y}_p))} \right)$$

where  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the  $t$  distribution with  $df$  degrees of freedom, described in the section “[Degrees of Freedom](#)” on page 7810.

When  $(\hat{p}_L, \hat{p}_U)$  is out of the range of  $[0, 1]$ , the procedure does not compute the standard error.

The  $\hat{p}_L$ th quantile is defined as

$$\hat{Y}_{\hat{p}_L} = \begin{cases} y_{(1)} & \text{if } \hat{p}_L < \hat{F}(y_{(1)}) \\ y_{(k_L)} + \frac{\hat{p}_L - \hat{F}(y_{(k_L)})}{\hat{F}(y_{(k_L+1)}) - \hat{F}(y_{(k_L)})} (y_{(k_L+1)} - y_{(k_L)}) & \text{if } \hat{F}(y_{(k_L)}) \leq \hat{p}_L < \hat{F}(y_{(k_L+1)}) \\ y_{(d)} & \text{if } \hat{p}_L = 1 \end{cases}$$

and the  $\hat{p}_U$ th quantile is defined as

$$\hat{Y}_{\hat{p}_U} = \begin{cases} y_{(1)} & \text{if } \hat{p}_U < \hat{F}(y_{(1)}) \\ y_{(k_U)} + \frac{\hat{p}_U - \hat{F}(y_{(k_U)})}{\hat{F}(y_{(k_U+1)}) - \hat{F}(y_{(k_U)})} (y_{(k_U+1)} - y_{(k_U)}) & \text{if } \hat{F}(y_{(k_U)}) \leq \hat{p}_U < \hat{F}(y_{(k_U+1)}) \\ y_{(d)} & \text{if } \hat{p}_U = 1 \end{cases}$$

The standard error of  $\hat{Y}_p$  then is estimated by

$$\text{sd}(\hat{Y}_p) = \frac{\hat{Y}_{\hat{p}_U} - \hat{Y}_{\hat{p}_L}}{2t_{df, \alpha/2}}$$

where  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the  $t$  distribution with  $df$  degrees of freedom.

When you use the replication method, PROC SURVEYMEANS uses the usual variance estimates for a quantile as described in the section “[Replication Methods for Variance Estimation](#)” on page 7824. However, you should proceed cautiously because this variance estimator can have poor properties (Dorfman and Valliant 1993).

### Confidence Limits

Symmetric  $100(1 - \alpha)\%$  confidence limits are computed as

$$\left( \hat{Y}_p - \text{sd}(\hat{Y}_p) \cdot t_{df, \alpha/2}, \quad \hat{Y}_p + \text{sd}(\hat{Y}_p) \cdot t_{df, \alpha/2} \right)$$

If you specify the `NONSYMCL` option in the SURVEYMEANS statement when you use `VARMETHOD=TAYLOR` option, the procedure computes  $100(1 - \alpha)\%$  nonsymmetric confidence limits:

$$\left( \hat{Y}_{\hat{p}_L}, \quad \hat{Y}_{\hat{p}_U} \right)$$

### Geometric Mean

For a continuous variable  $Y$  that has positive values, the SURVEYMEANS procedure can compute its geometric mean and associated standard error and confidence limits. To request these statistics, you can specify *statistic-keywords* such as GEOMEAN, GEOSTDERR, and GEOMLCLM.

The geometric mean of  $Y$  from a sample is computed as

$$\begin{aligned} \widehat{Y}_G &= \left( \prod_{h=1}^H \prod_{i=1}^{n_h} \prod_{j=1}^{m_{hi}} y_{hij}^{w_{hij}} \right)^{\frac{1}{w_{\dots}}} \\ &= \exp \left( \frac{1}{w_{\dots}} \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} \ln(y_{hij}) \right) \end{aligned}$$

where

$$w_{\dots} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij}$$

is the sum of the weights over all observations in the data set.

When you use the Taylor series method, the variance estimation for the geometric mean is computed as

$$\widehat{V}(\widehat{Y}_G) = \left(\widehat{Y}_G\right)^2 \sum_{h=1}^H \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (r_{hi\cdot} - \bar{r}_{h\cdot})^2$$

where

$$\begin{aligned} r_{hi\cdot} &= \left( \sum_{j=1}^{m_{hi}} w_{hij} (\ln(y_{hij}) - \ln(\widehat{Y}_G)) \right) / w_{\dots} \\ \bar{r}_{h\cdot} &= \left( \sum_{i=1}^{n_h} r_{hi\cdot} \right) / n_h \end{aligned}$$

The standard error of the geometric mean is the square root of the estimated variance:

$$\text{StdErr}(\widehat{Y}_G) = \sqrt{\widehat{V}(\widehat{Y}_G)}$$

The confidence limits for the geometric means are computed based on the confidence limits for the log transformation of the  $Y$  variable as

$$\left( \exp(\ln(\widehat{Y}_G) - \gamma), \quad \exp(\ln(\widehat{Y}_G) + \gamma) \right)$$

where

$$\gamma = t_{df, \alpha/2} * \text{StdErr}(\widehat{Y}_G) / \widehat{Y}_G$$

and  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the  $t$  distribution, with  $df$  calculated as in the section “*t* Test for the Mean” on page 7810.

If you use replication methods to estimate the variance by specifying `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE`, the procedure computes the variance of a geometric means  $\widehat{V}_R(\widehat{Y}_G)$  by using the variability among replicate estimates to estimate the overall variance. See the section “*Replication Methods for Variance Estimation*” on page 7824 for more information.

Then the standard error is the square root of the estimated variance:

$$\text{StdErr}_R(\widehat{Y}_G) = \sqrt{\widehat{V}_R(\widehat{Y}_G)}$$

The confidence limits for the geometric means are computed based on the confidence limits for the log transformation of the variable  $Y$  as

$$\left( \exp(\ln(\widehat{Y}_G) - \lambda), \quad \exp(\ln(\widehat{Y}_G) + \lambda) \right)$$

where

$$\lambda = t_{df, \alpha/2} * \text{StdErr}_R(\widehat{Y}_G) / \widehat{Y}_G$$

and  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the  $t$  distribution, with  $df$  calculated as in the section “*t* Test for the Mean” on page 7810.

## Poststratification

After a probability sample is drawn and survey data are collected, researchers sometimes want to stratify the sample according to auxiliary information about the sampled population. This process is often called *poststratification*.

When poststratification is done properly, it can improve efficiency. It can also be used to adjust the sampling weights such that the marginal distribution of the sampling weights is in agreement with known auxiliary information from other resources, such as the census. The adjusted weight is often called the *poststratification weight*. It is quite common for researchers to use poststratification techniques in survey data analysis.

Poststratification is also used by epidemiologists, who frequently analyze health survey data. They often compute statistics based on a process called *direct standardization*, a form of poststratification. For example, certain diseases, such as cancer, are more common among older populations. Therefore, to compare the prevalence rates among geographic regions that are populated with different age groups, it is necessary to make adjustments according to such demographic categories and to compute relative prevalence rates of the diseases.

For more information about poststratification, see Fuller (2009); Lohr (2010); Wolter (2007); Rao, Yung, and Hidiroglou (2002).

After you provide the population controls for each poststratum that is defined by the poststratification variables, the SURVEYMEANS procedure creates the poststratification weights accordingly. Then the procedure computes statistics that you request by using poststratification weights.

You can save the poststratification weights in an `OUTPSWGT=` data to be used in subsequent analyses.

For a select sample, let  $p = 1, 2, \dots, P$  be the poststratum index; let  $Z_1, Z_2, \dots, Z_P$  be the population totals for each corresponding poststratum; and let  $I_p$  be a corresponding indicator variable for the poststratum  $p$  defined by

$$I_p(h, i, j) = \begin{cases} 1 & \text{if observation } (h, i, j) \text{ belongs to } p\text{th poststratum} \\ 0 & \text{otherwise} \end{cases}$$

Denote the total sum of original weights in the sample for each poststratum as

$$\psi_p = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} I_p(h, i, j)$$

Then the poststratification weight for the observation  $(h, i, j)$  is

$$\tilde{w}_{hij} = w_{hij} \frac{Z_p}{\psi_p}$$

The SURVEYMEANS procedure computes statistics by using the poststratification weights  $\tilde{w}_{hij}$  instead of the original weights  $w_{hij}$ .

The standard error and confidence intervals of computed statistics are based on the estimated variance, using either a replication method or the Taylor series method.

### **Replication Methods**

When you specify `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE`, PROC SURVEYMEANS computes the variance of a statistic by using replication methods, as described in the section “[Replication Methods for Variance Estimation](#)” on page 7824. However, with poststratification, an extra step is needed to adjust the weights.

First, PROC SURVEYMEANS constructs a replicate and computes appropriate replicate weights for the replicate. Then, by using the poststratification control totals, the procedure adjusts these replicate weights in the same way as described previously for constructing the poststratification weights for the full sample. Finally, PROC SURVEYMEANS computes the estimate for a desired statistics by using the poststratification weights that are adjusted from the replicate weights in the current replicate. Then the final variance is estimated by the variability among replicate estimates, as described in the section “[Replication Methods for Variance Estimation](#)” on page 7824.

**Taylor Series Method**

When you specify `VARMETHOD=TAYLOR`, or by default when you do not specify the `VARMETHOD=` option, PROC SURVEYMEANS uses the Taylor series method to estimate the variances of requested statistics.

**Variance of the Mean** The mean of variable  $Y$  under poststratification is

$$\hat{Y}_{PS} = \left( \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \tilde{w}_{hij} y_{hij} \right) / \tilde{w}_{\dots}$$

where

$$\tilde{w}_{\dots} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \tilde{w}_{hij}$$

is the sum of the poststratification weights over all observations in the sample.

For each poststratum  $p = 1, 2, \dots, P$ , let the mean of variable  $Y$  in each poststratum be

$$\hat{Y}^{(p)} = \left( \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} I_p(h, i, j) \tilde{w}_{hij} y_{hij} \right) / \tilde{w}_{\dots}^{(p)}$$

where

$$\tilde{w}_{\dots}^{(p)} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} I_p(h, i, j) \tilde{w}_{hij}$$

is the total of the poststratification weights in poststratum  $p$ .

For observation  $(h, i, j)$ , let  $p$  be the poststratum to which it belongs. Let

$$\tilde{y}_{hij} = y_{hij} - \hat{Y}^{(p)}$$

PROC SURVEYMEANS estimates the variance of  $\hat{Y}_{PS}$  as

$$\hat{V}(\hat{Y}_{PS}) = \sum_{h=1}^H \hat{V}_h$$

where, if  $n_h > 1$ , then

$$\hat{V}_h = \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (e_{hi\cdot} - \bar{e}_{h\cdot\cdot})^2$$

$$e_{hi\cdot} = \left( \sum_{j=1}^{m_{hi}} \tilde{w}_{hij} \tilde{y}_{hij} \right) / \tilde{w}_{h\cdot\cdot}$$

$$\bar{e}_{h\cdot\cdot} = \left( \sum_{i=1}^{n_h} e_{hi\cdot} \right) / n_h$$

and if  $n_h = 1$ , then

$$\hat{V}_h = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

**Variance of the Ratio** Suppose you want to calculate the ratio of variable Y to variable X. Let  $x_{hij}$  and  $y_{hij}$  be the values of variable X and variable Y, respectively, for observation  $(h, i, j)$ .

The ratio of Y to X after poststratification is

$$\hat{R}_{PS} = \frac{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \tilde{w}_{hij} y_{hij}}{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \tilde{w}_{hij} x_{hij}}$$

where  $\tilde{w}_{hij}$  is the poststratification weight for observation  $(h, i, j)$ .

Let

$$\tilde{y}_{hij} = y_{hij} - \hat{Y}^{(p)}$$

$$\tilde{x}_{hij} = x_{hij} - \hat{X}^{(p)}$$

where  $\hat{Y}^{(p)}$  and  $\hat{X}^{(p)}$  are the means of variable Y and variable X, respectively, in poststratum  $p$ .

The variance of  $\hat{R}_{PS}$  is estimated by

$$\hat{V}(\hat{R}_{PS}) = \sum_{h=1}^H \hat{V}_h(\hat{R}_{PS})$$

where, if  $n_h > 1$ , then

$$\hat{V}_h(\hat{R}_{PS}) = \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (g_{hi\cdot} - \bar{g}_{h\cdot\cdot})^2$$

$$g_{hi\cdot} = \frac{\sum_{j=1}^{m_{hi}} \tilde{w}_{hij} (\tilde{y}_{hij} - \tilde{x}_{hij} \hat{R}_{PS})}{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \tilde{w}_{hij} x_{hij}}$$

$$\bar{g}_{h\cdot\cdot} = \left( \sum_{i=1}^{n_h} g_{hi\cdot} \right) / n_h$$

and if  $n_h = 1$ , then

$$\hat{V}_h(\hat{R}_{PS}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

## Replication Methods for Variance Estimation

Recently replication methods have gained popularity for estimating variances in complex survey data analysis. One reason for this popularity is the relative simplicity of replication-based estimates, especially for nonlinear estimators; another is that modern computational capacity has made replication methods feasible for practical survey analysis. For more information, see Lohr (2010); Wolter (2007); Rust (1985); Dippo, Fay, and Morganstein (1984); Rao and Shao (1999); Rao, Wu, and Yue (1992); Rao and Shao (1996).

Replication methods draw multiple replicates (also called subsamples) from a full sample according to a specific resampling scheme. The most commonly used resampling schemes are the *balanced repeated replication* (BRR) method and the *jackknife* method. For each replicate, the original weights are modified for the PSUs in the replicates to create replicate weights. The statistics of interest are estimated by using the replicate weights for each replicate. Then the variances of parameters of interest are estimated by the variability among the estimates derived from these replicates. You can use the `REPWEIGHTS` statement to provide your own replicate weights for variance estimation.

### Balanced Repeated Replication (BRR) Method

The balanced repeated replication (BRR) method requires that the full sample be drawn by using a stratified sample design with two primary sampling units (PSUs) per stratum. Let  $H$  be the total number of strata. The total number of replicates  $R$  is the smallest multiple of 4 that is greater than  $H$ . However, if you prefer a larger number of replicates, you can specify the `REPS=number` option. If a  $number \times number$  Hadamard matrix cannot be constructed, the number of replicates is increased until a Hadamard matrix becomes available.

Each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix and adjusting the original weights for the remaining PSUs. The new weights are called replicate weights.

Replicates are constructed by using the first  $H$  columns of the  $R \times R$  Hadamard matrix. The  $r$ th ( $r = 1, 2, \dots, R$ ) replicate is drawn from the full sample according to the  $r$ th row of the Hadamard matrix as follows:

- If the  $(r, h)$  element of the Hadamard matrix is 1, then the first PSU of stratum  $h$  is included in the  $r$ th replicate and the second PSU of stratum  $h$  is excluded.
- If the  $(r, h)$  element of the Hadamard matrix is  $-1$ , then the second PSU of stratum  $h$  is included in the  $r$ th replicate and the first PSU of stratum  $h$  is excluded.

Note that the “first” and “second” PSUs are determined by data order in the input data set. Thus, if you reorder the data set and perform the same analysis by using BRR method, you might get slightly different results, because the contents in each replicate sample might change.

The replicate weights of the remaining PSUs in each half-sample are then doubled to their original weights. For more details about the BRR method, see Wolter (2007) and Lohr (2010).

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the `VARMETHOD=BRR(PRINTH)` *method-option*. If you provide a Hadamard matrix by specifying the `VARMETHOD=BRR(HADAMARD=)` *method-option*, then the replicates are generated according to the provided Hadamard matrix.

You can use the `VARMETHOD=BRR(OUTWEIGHTS=)` *method-option* to save the replicate weights into a SAS data set.

Suppose that  $\theta$  is a population parameter of interest. Let  $\hat{\theta}$  be the estimate from the full sample for  $\theta$ . Let  $\hat{\theta}_r$  be the estimate from the  $r$ th replicate subsample by using replicate weights. PROC SURVEYMEANS estimates the variance of  $\hat{\theta}$  by

$$\widehat{V}(\hat{\theta}) = \frac{1}{R} \sum_{r=1}^R (\hat{\theta}_r - \hat{\theta})^2$$

with  $H$  degrees of freedom, where  $H$  is the number of strata.

If a parameter cannot be computed from one or more replicates, then the variance estimate is computed by using those replicates from which the parameter can be estimated. For example, suppose the parameter is a ratio. If a replicate  $r$  contains observations such that the denominator of the ratio is zero, then the ratio cannot be computed from replicate  $r$ . In this case, the BRR variance estimate is computed as

$$\widehat{V}(\hat{\theta}) = \frac{1}{R'} \sum_{r=1}^{R'} (\hat{\theta}_r - \hat{\theta})^2$$

where the summation is over the replicates where the parameter  $\theta$  can be computed, and  $R'$  is the number of those replicates.

## Fay's BRR Method

Fay's method is a modification of the BRR method, and it requires a stratified sample design with two primary sampling units (PSUs) per stratum. The total number of replicates  $R$  is the smallest multiple of 4 that is greater than the total number of strata  $H$ . However, if you prefer a larger number of replicates, you can specify the `REPS=` *method-option*.

For each replicate, Fay's method uses a Fay coefficient  $0 \leq \epsilon < 1$  to impose a perturbation of the original weights in the full sample that is gentler than using only half-samples, as in the traditional BRR method. The Fay coefficient  $0 \leq \epsilon < 1$  can be set by specifying the `FAY =  $\epsilon$`  *method-option*. By default,  $\epsilon = 0.5$  if the `FAY` *method-option* is specified without providing a value for  $\epsilon$  (Judkins 1990; Rao and Shao 1999). When  $\epsilon = 0$ , Fay's method becomes the traditional BRR method. For more details, see Dippo, Fay, and Morganstein (1984); Fay (1984, 1989); Judkins (1990).

Let  $H$  be the number of strata. Replicates are constructed by using the first  $H$  columns of the  $R \times R$  Hadamard matrix, where  $R$  is the number of replicates,  $R > H$ . The  $r$ th ( $r = 1, 2, \dots, R$ ) replicate is created from the full sample according to the  $r$ th row of the Hadamard matrix as follows:

- If the  $(r, h)$  element of the Hadamard matrix is 1, then the full sample weight of the first PSU in stratum  $h$  is multiplied by  $\epsilon$  and the full sample weight of the second PSU is multiplied by  $2 - \epsilon$  to obtain the  $r$ th replicate weights.

- If the  $(r, h)$  element of the Hadamard matrix is  $-1$ , then the full sample weight of the first PSU in stratum  $h$  is multiplied by  $2 - \epsilon$  and the full sample weight of the second PSU is multiplied by  $\epsilon$  to obtain the  $r$ th replicate weights.

You can use the `VARMETHOD=BRR(OUTWEIGHTS=)` *method-option* to save the replicate weights into a SAS data set.

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the `VARMETHOD=BRR(PRINTH)` *method-option*. If you provide a Hadamard matrix by specifying the `VARMETHOD=BRR(HADAMARD=)` *method-option*, then the replicates are generated according to the provided Hadamard matrix.

Suppose that  $\theta$  is a population parameter of interest. Let  $\hat{\theta}$  be the estimate from the full sample for  $\theta$ . Let  $\hat{\theta}_r$  be the estimate from the  $r$ th replicate subsample by using replicate weights. PROC SURVEYMEANS estimates the variance of  $\hat{\theta}$  by

$$\widehat{V}(\hat{\theta}) = \frac{1}{R(1 - \epsilon)^2} \sum_{r=1}^R (\hat{\theta}_r - \hat{\theta})^2$$

with  $H$  degrees of freedom, where  $H$  is the number of strata.

## Jackknife Method

The jackknife method of variance estimation deletes one PSU at a time from the full sample to create replicates. The total number of replicates  $R$  is the same as the total number of PSUs. In each replicate, the sample weights of the remaining PSUs are modified by the jackknife coefficient  $\alpha_r$ . The modified weights are called replicate weights.

The jackknife coefficient and replicate weights are described as follows.

**Without Stratification** If there is no stratification in the sample design (no `STRATA` statement), the jackknife coefficients  $\alpha_r$  are the same for all replicates:

$$\alpha_r = \frac{R - 1}{R} \quad \text{where } r = 1, 2, \dots, R$$

Denote the original weight in the full sample for the  $j$ th member of the  $i$ th PSU as  $w_{ij}$ . If the  $i$ th PSU is included in the  $r$ th replicate ( $r = 1, 2, \dots, R$ ), then the corresponding replicate weight for the  $j$ th member of the  $i$ th PSU is defined as

$$w_{ij}^{(r)} = w_{ij} / \alpha_r$$

**With Stratification** If the sample design involves stratification, each stratum must have at least two PSUs to use the jackknife method.

Let stratum  $\tilde{h}_r$  be the stratum from which a PSU is deleted for the  $r$ th replicate. Stratum  $\tilde{h}_r$  is called the *donor stratum*. Let  $n_{\tilde{h}_r}$  be the total number of PSUs in the donor stratum  $\tilde{h}_r$ . The jackknife coefficients are defined as

$$\alpha_r = \frac{n_{\tilde{h}_r} - 1}{n_{\tilde{h}_r}} \quad \text{where } r = 1, 2, \dots, R$$

Denote the original weight in the full sample for the  $j$ th member of the  $i$ th PSU as  $w_{ij}$ . If the  $i$ th PSU is included in the  $r$ th replicate ( $r = 1, 2, \dots, R$ ), then the corresponding replicate weight for the  $j$ th member of the  $i$ th PSU is defined as

$$w_{ij}^{(r)} = \begin{cases} w_{ij} & \text{if } i\text{th PSU is not in the donor stratum } \tilde{h}_r \\ w_{ij}/\alpha_r & \text{if } i\text{th PSU is in the donor stratum } \tilde{h}_r \end{cases}$$

You can use the `VARMETHOD=JACKKNIFE(OUTJKCOEFS=)` *method-option* to save the jackknife coefficients into a SAS data set and use the `VARMETHOD=JACKKNIFE(OUTWEIGHTS=)` *method-option* to save the replicate weights into a SAS data set.

If you provide your own replicate weights with a `REPWEIGHTS` statement, then you can also provide corresponding jackknife coefficients with the `JKCOEFS=` option.

Suppose that  $\theta$  is a population parameter of interest. Let  $\hat{\theta}$  be the estimate from the full sample for  $\theta$ . Let  $\hat{\theta}_r$  be the estimate from the  $r$ th replicate subsample by using replicate weights. PROC SURVEYMEANS estimates the variance of  $\hat{\theta}$  by

$$\widehat{V}(\hat{\theta}) = \sum_{r=1}^R \alpha_r (\hat{\theta}_r - \hat{\theta})^2$$

with  $R - H$  degrees of freedom, where  $R$  is the number of replicates and  $H$  is the number of strata, or  $R - 1$  when there is no stratification.

## Hadamard Matrix

A Hadamard matrix  $\mathbf{H}$  is a square matrix whose elements are either 1 or  $-1$  such that

$$\mathbf{H}\mathbf{H}' = k\mathbf{I}$$

where  $k$  is the dimension of  $\mathbf{H}$  and  $\mathbf{I}$  is the identity matrix of order  $k$ . The order  $k$  is necessarily 1, 2, or a positive integer that is a multiple of 4.

For example, the following matrix is a Hadamard matrix of dimension  $k = 8$ :

$$\begin{matrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 & 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 & 1 & -1 & -1 & 1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & -1 & 1 & -1 & -1 & 1 & -1 & 1 \\ 1 & 1 & -1 & -1 & -1 & -1 & 1 & 1 \\ 1 & -1 & -1 & 1 & -1 & 1 & 1 & -1 \end{matrix}$$

---

## Computational Resources

Due to the complex nature of survey data analysis, the SURVEYMEANS procedure usually requires more memory than an analysis by the MEANS procedure for the same analysis variables. PROC SURVEYMEANS requires memory resources to keep a copy of each unique value of the STRATUM, CLUSTER, and DOMAIN variables in addition to the memory needed for the categorical analysis variables and other computations.

The estimated memory needed by the SURVEYMEANS procedure is described as follows.

Let:

- $T_{\text{str}}$  be the total number of STRATUM variables
- $L_{\text{str}}(t)$  be the number of unique values for the  $t$ th STRATUM variable, where  $t = 1, 2, \dots, T_{\text{str}}$
- $H$  be the total number of strata
- $T_{\text{clu}}$  be the total number of CLUSTER variables
- $L_{\text{clu}}(t)$  be the number of unique values for the  $t$ th CLUSTER variable, where  $t = 1, 2, \dots, T_{\text{clu}}$
- $T_{\text{dom}}$  be the total number of DOMAIN variables in a domain (you might have multiple domains defined in a DOMAIN statement)
- $L_{\text{dom}}(t)$  be the number of unique values for the  $t$ th DOMAIN variable, where  $t = 1, 2, \dots, T_{\text{dom}}$
- $D$  be the total number of domains
- $T_{\text{cont}}$  be the total number of continuous analysis variables
- $T_{\text{clas}}$  be the total number of categorical analysis variables (CLASS variable)
- $L_{\text{clas}}(t)$  be the number of unique values for the  $t$ th CLASS variable, where  $t = 1, 2, \dots, T_{\text{clas}}$
- $T_{\text{ratio}}$  be the total number of ratios
- $T_{\text{pctl}}$  be the total number of percentiles
- $c$  be a constant on the order of 32 bytes (64 for 64-bit architectures) plus the maximum combined unformatted and formatted length among all the STRATUM, CLUSTER, DOMAIN, and CLASS variables

If all combinations of levels of categorical variables exist, the maximum potential memory (in bytes) requirements for the analysis is estimated by

$$c * P * Q + 2000 * (H + 1) * (D + 1) * Q$$

where

$$P = \prod_{t=1}^{T_{\text{str}}} L_{\text{str}}(t) \prod_{t=1}^{T_{\text{clu}}} L_{\text{clu}}(t) \prod_{t=1}^{T_{\text{dom}}} L_{\text{dom}}(t)$$

$$Q = T_{\text{cont}} + \sum_{t=1}^{T_{\text{clas}}} L_{\text{clas}}(t) + T_{\text{ratio}} + T_{\text{pctl}}$$

A relatively small amount of memory, compared to the memory usage described in the preceding calculation, is also needed for the analysis.

When the data-dependent memory usage overwhelms what is available in the computer system, the procedure might open one or more utility files to complete the analysis. This process can be controlled by the SAS system option `SUMSIZE=`, which sets the memory threshold where utility file operations begin. For best results, set `SUMSIZE=` to be less than the amount of real memory that is likely to be available for the task. See the chapter on SAS system options in *SAS System Options: Reference* for a description of the `SUMSIZE=` option.

If PROC SURVEYMEANS reports that there is insufficient memory, increase `SUMSIZE=`. A `SUMSIZE=` value greater than `MEMSIZE=` has no effect. Therefore, you might also need to increase `MEMSIZE=`.

The `MEMSIZE` option can be specified at system invocation, on the SAS command line, or in a configuration file. However, the `MEMSIZE` system option is not available in some operating environments. See the *SAS Companion* for your operating environment for more information and for the syntax specification.

To report a procedure's memory consumption, you can use the `FULLSTIMER` option. The syntax is described in the *SAS Companion* for your operating environment.

Also see the *SAS System Options: Reference* for more information about how to adjust your computation resource parameters for your operating environment.

For additional information about the memory usage for categorical variables, see the section “Computational Resources” in the chapter “The MEANS Procedure” in the *Base SAS Procedures Guide: Statistical Procedures*.

## Output Data Sets

You can use the Output Delivery System to create a SAS data set from any piece of PROC SURVEYMEANS output. See the section “ODS Table Names” on page 7838 for more information.

PROC SURVEYMEANS also provides an output data set that stores the replicate weights for BRR or jackknife variance estimation and an output data set that stores the jackknife coefficients for jackknife variance estimation.

### Replicate Weights Output Data Set

If you specify the `OUTWEIGHTS= method-option` for `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE`, PROC SURVEYMEANS stores the replicate weights in an output data set. The `OUTWEIGHTS=` output data set contains all observations from the `DATA=` input data set that are valid (used in the analysis). (A valid observation is an observation that has a positive value of the `WEIGHT` variable. Valid observations must also have nonmissing values of the `STRATA` and `CLUSTER` variables, unless you specify the `MISSING` option. See the section “Data and Sample Design Summary” on page 7832 for details about valid observations.)

The `OUTWEIGHTS=` data set contains the following variables:

- all variables in the `DATA=` input data set
- `RepWt_1`, `RepWt_2`, . . . , `RepWt_n`, which are the replicate weight variables

where  $n$  is the total number of replicates in the analysis. Each replicate weight variable contains the replicate weights for the corresponding replicate. Replicate weights equal zero for those observations not included in the replicate.

After the procedure creates replicate weights for a particular input data set and survey design, you can use the `OUTWEIGHTS= method-option` to store these replicate weights and then use them again in subsequent analyses, either in PROC SURVEYMEANS or in the other survey procedures. You can use the `REPWEIGHTS` statement to provide replicate weights for the procedure.

### Jackknife Coefficients Output Data Set

If you specify the `OUTJKCOEFS= method-option` for `VARMETHOD=JACKKNIFE`, PROC SURVEYMEANS stores the jackknife coefficients in an output data set. The `OUTJKCOEFS=` output data set contains one observation for each replicate. The `OUTJKCOEFS=` data set contains the following variables:

- Replicate, which is the replicate number for the jackknife coefficient
- JKCoefficient, which is the jackknife coefficient
- DonorStratum, which is the stratum of the PSU that was deleted to construct the replicate, if you specify a `STRATA` statement

After the procedure creates jackknife coefficients for a particular input data set and survey design, you can use the `OUTJKCOEFS= method-option` to store these coefficients and then use them again in subsequent analyses, either in PROC SURVEYMEANS or in the other survey procedures. You can use the `JKCOEFS=` option in the `REPWEIGHTS` statement to provide jackknife coefficients for the procedure.

### Poststratification Weights Output Data Set

If you specify the `OUTPSWGT=` option in the `POSTSTRATA` statement, PROC SURVEYMEANS stores the poststratification weights in an output data set. The `OUTPSWGT=` output data set contains all observations from the `DATA=` input data set that are valid (used in the analysis). (A valid observation is an observation that has a positive value of the `WEIGHT` variable. Valid observations must also have non-missing values of the `STRATA` and `CLUSTER` variables, unless you specify the `MISSING` option. See the section “Data and Sample Design Summary” on page 7832 for more information about valid observations.)

For `VARMETHOD=TAYLOR`, the `OUTPSWGT=` data set contains the following variables:

- all variables in the `DATA=` input data set
- `_PSWt_`, which contains poststratification weights

For `VARMETHOD=BRR` and `VARMETHOD=JACKKNIFE`, the `OUTPSWGT=` option is the same `OUTWEIGHTS= method-option` that you specify in the PROC SURVEYMEANS statement, except that it also contains the variable `_PSWt_`, which contains poststratification weights for the full sample. The replication weights, adjusted for poststratification, are stored in the `OUTWEIGHTS=` data set. See the section “Replicate Weights Output Data Set” on page 7829 for the contents of the `OUTWEIGHTS=` data set.

However, if you also specify an `OUTWEIGHTS= method-option` in the PROC SURVEYMEANS statement and use a different data set name, the data set in `OUTPSWGT=` option is ignored.

If you provide your own replicate weights by using a `REPWEIGHTS` statement for `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE`, the poststratification replicate weights replace the original replicate weights in the `OUTPSWGT=` data set.

## Rectangular and Stacking Structures in an Output Data Set

When you use an ODS output statement to create SAS data sets for certain tables in PROC SURVEYMEANS, there are two possible types of table structure for the output data sets: *rectangular* and *stacking*. A rectangular structure creates one observation for each analysis variable in the data set. A stacking structure creates only one observation in the output data set for all analysis variables.

Before SAS 9, the stacking table structure, similar to the table structure in PROC MEANS, was the default in PROC SURVEYMEANS. Since SAS 9, the new default is to produce a rectangular table in the output data sets. You can use the **STACKING** option to request that the procedure produce the output data sets by using a stacking table structure.

The STACKING option affects the following tables:

- Domain
- Ratio
- Statistics
- StrataInfo

Figure 92.6 and Figure 92.7 shows these two structures for analyzing the following data set:

```
data new;
 input sex$ x;
 datalines;
M 12
F 5
M 13
F 23
F 11
;
```

The following statements request the default rectangular structure of the output data set for the statistics table:

```
proc surveymeans data=new mean;
 ods output statistics=rectangle;
run;

proc print data=rectangle;
run;
```

Figure 92.6 shows the rectangular structure.

**Figure 92.6** Rectangular Structure in the Output Data Set

| Rectangular Structure in the Output Data Set |             |              |           |          |
|----------------------------------------------|-------------|--------------|-----------|----------|
| Obs                                          | Var<br>Name | Var<br>Level | Mean      | StdErr   |
| 1                                            | x           |              | 12.800000 | 2.905168 |
| 2                                            | sex         | F            | 0.600000  | 0.244949 |
| 3                                            | sex         | M            | 0.400000  | 0.244949 |

The following statements specify the **STACKING** option to request that the output data set have a stacking structure:

```
proc surveymeans data=new mean stacking;
 ods output statistics=stacking;
run;

proc print data=stacking;
run;
```

Figure 92.7 shows the stacking structure of the output data set for the statistics table requested by the **STACKING** option.

**Figure 92.7** Stacking Structure in the Output Data Set Requested by the **STACKING** option

| Stacking Structure in the Output Data Set |              |           |            |              |            |
|-------------------------------------------|--------------|-----------|------------|--------------|------------|
| Obs                                       | x            | x_Mean    | x_StdErr   | sex_F        | sex_F_Mean |
| 1                                         | x            | 12.800000 | 2.905168   | sex=F        | 0.600000   |
| Obs                                       | sex_F_StdErr | sex_M     | sex_M_Mean | sex_M_StdErr |            |
| 1                                         | 0.244949     | sex=M     | 0.400000   | 0.244949     |            |

---

## Displayed Output

The SURVEYMEANS procedure produces output that is described in the following sections.

### Data and Sample Design Summary

The “Data Summary” table provides information about the input data set and the sample design. This table displays the total number of valid observations, where an observation is considered *valid* if it has nonmissing values for all procedure variables other than the analysis variables—that is, for all specified

**STRATA**, **CLUSTER**, **DOMAIN**, **POSTSTRATA**, and **WEIGHT** variables. This number might differ from the number of nonmissing observations for an individual analysis variable, which the procedure displays in the “Statistics” table. See the section “Missing Values” on page 7804 for more information.

PROC SURVEYMEANS displays the following information in the “Data Summary” table:

- Number of Strata, if you specify a STRATA statement
- Number of Poststrata, if you specify a POSTSTRATA statement
- Number of Clusters, if you specify a CLUSTER statement
- Number of Observations, which is the total number of valid observations
- Sum of Weights, which is the sum over all valid observations, if you specify a WEIGHT statement

### Class Level Information

If you use a **CLASS** statement to name classification variables for categorical analysis, or if you list any character variables in the VAR statement, then PROC SURVEYMEANS displays a “Class Level Information” table. This table contains the following information for each classification variable:

- Class Variable, which lists each CLASS variable name
- Levels, which is the number of values or levels of the classification variable
- Values, which lists the values of the classification variable. The values are separated by a white space character; therefore, to avoid confusion, you should not include a white space character within a classification variable value.

### Stratum Information

If you specify the **LIST** option in the STRATA statement, PROC SURVEYMEANS displays a “Stratum Information” table. This table displays the number of valid observations in each stratum, as well as the number of nonmissing stratum observations for each analysis variable. The “Stratum Information” table provides the following for each stratum:

- Stratum Index, which is a sequential stratum identification number
- STRATA variable(s), which lists the levels of STRATA variables for the stratum
- Population Total, if you specify the **TOTAL=** option
- Sampling Rate, if you specify the **TOTAL=** or **RATE=** option. If you specify the **TOTAL=** option, the sampling rate is based on the number of valid observations in the stratum.
- N Obs, which is the number of valid observations
- Variable, which lists each analysis variable name
- Levels, which identifies each level for categorical variables

- N, which is the number of nonmissing observations for the analysis variable
- Clusters, which is the number of clusters, if you specify a **CLUSTER** statement

## Variance Estimation

If the variance method is not Taylor series or if the **NOMCAR** option is used, by default, PROC SURVEYMEANS displays the following variance estimation specifications in the “Variance Estimation” table:

- Method, which is the variance estimation method
- Replicate Weights Data Set, which is the name of the SAS data set that contains the replicate weights
- Number of Replicates, which is the number of replicates if you specify the **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** option
- Hadamard Data Set, which is the name of the SAS data set for the HADAMARD matrix if you specify the **VARMETHOD=BRR(HADAMARD=)** *method-option*
- Fay Coefficient, which is the value of the FAY coefficient if you specify the **VARMETHOD=BRR(FAY)** *method-option*
- Missing Levels Included (MISSING), if you specify the **MISSING** option
- Missing Levels Included (NOMCAR), if you specify the **NOMCAR** option

## Statistics

The “Statistics” table displays all of the statistics that you request with *statistic-keywords* in the PROC SURVEYMEANS statement, except DECILES, MEDIAN, Q1, Q3, and QUARTILES, which are displayed in the “Quantiles” table. If you do not specify any *statistic-keywords*, then by default this table displays the following information for each analysis variable: the sample size, the mean, the standard error of the mean, and the confidence limits for the mean. The “Statistics” table can contain the following information for each analysis variable, depending on which *statistic-keywords* you request:

- Variable name
- Variable Label
- Level, which identifies each level for categorical variables
- N, which is the number of nonmissing observations
- N Miss, which is the number of missing observations
- Minimum
- Maximum
- Range

- Number of Clusters
- Sum of Weights
- DF, which is the degrees of freedom for the  $t$  test
- Mean
- Std Error of Mean, which is the standard error of the mean
- Var of Mean, which is the variance of the mean
- $t$  Value, for testing  $H_0$  : population MEAN = 0
- $\text{Pr} > |t|$ , which is the two-sided  $p$ -value for the  $t$  test
- $100(1 - \alpha)\%$  CL for Mean, which are two-sided confidence limits for the mean
- $100(1 - \alpha)\%$  Upper CL for Mean, which is a one-sided upper confidence limit for the mean
- $100(1 - \alpha)\%$  Lower CL for Mean, which is a one-sided lower confidence limit for the mean
- Coeff of Variation, which is the coefficient of variation for the mean
- Sum
- Std Dev, which is the standard deviation of the sum
- Var of Sum, which is the variance of the sum
- $100(1 - \alpha)\%$  CL for Sum, which are two-sided confidence limits for the sum
- $100(1 - \alpha)\%$  Upper CL for Sum, which is a one-sided upper confidence limit for the sum
- $100(1 - \alpha)\%$  Lower CL for Sum, which is a one-sided lower confidence limit for the Sum
- Coeff of Variation for sum, which is the coefficient of variation for the sum

## Quantiles

The “Quantiles” table displays all the quantiles that you request with either *statistic-keywords* such as DECILES, MEDIAN, Q1, Q3, and QUARTILES, or the `PERCENTILE=` option, or the `QUANTILE=` option in the PROC SURVEYMEANS statement.

The “Quantiles” table contains the following information for each quantile:

- Variable name
- Variable Label
- Percentile, which is the requested quantile in the format of %
- Percentile Label, which is the corresponding common name for a percentile if it exists—for example, *Median* for 50th percentile

- Estimate, which is the estimate for a requested quantile with respect to the population distribution
- Std Error, which is the standard error of the quantile
- $100(1 - \alpha)\%$  Confidence Limits, which are two-sided confidence limits for the quantile

## Domain Analysis

If you specify a **DOMAIN** statement, the procedure displays domain statistics in a “Domain Analysis” table. A “Domain Analysis” table displays all the requested statistics for each level of the domain request. The procedure produces a separate “Domain Analysis” for each separate domain request. For example, the **DOMAIN** statement

```
domain A B*C*D A*C C;
```

specifies four domain requests:

- A: all the levels of A
- C: all the levels of C
- A\*C: all the interactive levels of A and C
- B\*C\*D: all the interactive levels of B, C, and D

The procedure displays four “Domain Analysis” tables, one for each domain definition. If you use an **ODS OUTPUT** statement to create an output data set for domain analysis, the output data set contains a variable **Domain** whose values are these domain definitions. It contains all the columns in the “Statistics” table plus columns of domain variable values.

## Ratio Analysis

The “Ratio Analysis” table displays statistics for all the ratios that you request in the **RATIO** statement. If you do not specify any *statistic-keywords* in the **PROC SURVEYMEANS** statement, then by default this table displays the ratios and standard errors. The “Ratio Analysis” table can contain the following information for each ratio, depending on which *statistic-keywords* you request:

- Numerator, which identifies the numerator variable of the ratio
- Denominator, which identifies the denominator variable of the ratio
- N, which is the number of observations used in the ratio analysis
- number of Clusters
- Sum of Weights
- DF, which is the degrees of freedom for the *t* test
- Ratio
- Std Err of Ratio, which is the standard error of the ratio

- Var, which is the variance of the ratio
- $t$  Value, for testing  $H_0$  : population RATIO = 0
- $\Pr > |t|$ , which is the two-sided  $p$ -value for the  $t$  test
- $100(1 - \alpha)\%$  CL for Ratio, which are two-sided confidence limits for the Ratio
- Upper  $100(1 - \alpha)\%$  CL for Ratio, which are one-sided upper confidence limits for the Ratio
- Lower  $100(1 - \alpha)\%$  CL for Ratio, which are one-sided lower confidence limits for the Ratio

When you use the ODS OUTPUT statement to create an output data set, if you use labels for your RATIO statement, these labels are saved in the variable Ratio Statement in the output data set.

### Domain Ratio Analysis

If you specify a DOMAIN statement with a RATIO statement, the procedure displays domain ratios in a “Domain Ratio Analysis” table. A “Domain Ratio Analysis” table displays all the ratio statistics for each level of the domain request. It contains all the columns in the “Ratio Analysis” table plus columns of domain variable values.

### Hadamard Matrix

If you specify the `VARMETHOD=BRR(PRINTH)` *method-option* in the PROC SURVEYMEANS statement, PROC SURVEYMEANS displays the Hadamard matrix that is used to construct replicates for BRR variance estimation.

If you provide a Hadamard matrix with the `VARMETHOD=BRR(HADAMARD=)` *method-option* but the procedure does not use the entire matrix, the procedure displays only the rows and columns that are actually used to construct replicates.

### Geometric Means

The “Geometric Means” table displays all the statistics related to geometric mean that you request with *statistic-keywords* in the PROC SURVEYMEANS statement. The “Geometric Means” table can contain the following information for each analysis variable, depending on which *statistic-keywords* you request:

- Variable Name
- Variable Label
- Geometric Mean
- Std Error of Geometric Mean
- $100(1 - \alpha)\%$  CL for Geometric Mean, which are two-sided confidence limits for the geometric mean
- $100(1 - \alpha)\%$  Lower CL for Geometric Mean, which is a one-sided lower confidence limit for the geometric mean
- $100(1 - \alpha)\%$  Upper CL for Geometric Mean, which is a one-sided upper confidence limit for the geometric mean

## Domain Geometric Means

If you specify a **DOMAIN** statement and request any statistics related to geometric mean with *statistic-keywords* in the PROC SURVEYMEANS statement, the procedure displays these statistics for each domain level in a “Domain Geometric Means” table. It contains all the columns in the “Geometric Means” table plus columns of domain variable values.

## ODS Table Names

PROC SURVEYMEANS assigns a name to each table it creates; these names are listed in Table 92.4. You can use these names to refer to tables when you use the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 92.4** ODS Tables Produced by PROC SURVEYMEANS

| ODS Table Name     | Description                                      | Statement                      | Option                                        |
|--------------------|--------------------------------------------------|--------------------------------|-----------------------------------------------|
| ClassVarInfo       | Class level information                          | <b>CLASS</b>                   | Default                                       |
| Domain             | Statistics in domains                            | <b>DOMAIN</b>                  | Default                                       |
| DomainRatio        | Statistics for ratios in domains                 | <b>DOMAIN</b> and <b>RATIO</b> | Default                                       |
| DomainGeoMeans     | Statistics related to geometric means in domains | <b>PROC</b> and <b>DOMAIN</b>  | <b>Keywords</b>                               |
| GeoMeans           | Statistics related to geometric means            | <b>PROC</b>                    | <b>Keywords</b>                               |
| HadamardMatrix     | Hadamard matrix                                  | <b>PROC</b>                    | <b>PRINTH</b>                                 |
| Ratio              | Statistics for ratios                            | <b>RATIO</b>                   | Default                                       |
| Quantiles          | Quantiles                                        | <b>PROC</b>                    | Default                                       |
| Statistics         | Statistics                                       | <b>PROC</b>                    | Default                                       |
| StrataInfo         | Stratum information                              | <b>STRATA</b>                  | <b>LIST</b>                                   |
| Summary            | Data summary                                     | <b>PROC</b>                    | Default                                       |
| VarianceEstimation | Variance estimation                              | <b>PROC</b>                    | <b>VARMETHOD=JK   BRR</b><br>or <b>NOMCAR</b> |

For example, the following statements create an output data set MyStrata, which contains the “StrataInfo” table, and an output data set MyStat, which contains the “Statistics” table for the ice cream study discussed in the section “Stratified Sampling” on page 7781:

```

title1 'Analysis of Ice Cream Spending';
proc surveymeans data=IceCream total=StudentTotals;
 strata Grade / list;
 var Spending Group;
 weight Weight;
 ods output
 StrataInfo = MyStrata
 Statistics = MyStat;
run;

```

## Examples: SURVEYMEANS Procedure

The section “Getting Started: SURVEYMEANS Procedure” on page 7779 contains examples of analyzing data from simple random sampling and stratified simple random sample designs. This section provides more examples that illustrate how to use PROC SURVEYMEANS.

### Example 92.1: Stratified Cluster Sample Design

Consider the example in the section “Stratified Sampling” on page 7781. The study population is a junior high school with a total of 4,000 students in grades 7, 8, and 9. Researchers want to know how much these students spend weekly for ice cream, on the average, and what percentage of students spend at least \$10 weekly for ice cream.

The example in the section “Stratified Sampling” on page 7781 assumes that the sample of students was selected using a stratified simple random sample design. This example shows analysis based on a more complex sample design.

Suppose that every student belongs to a study group and that study groups are formed within each grade level. Each study group contains between two and four students. Table 92.5 shows the total number of study groups for each grade.

**Table 92.5** Study Groups and Students by Grade

| Grade | Number of Study Groups | Number of Students |
|-------|------------------------|--------------------|
| 7     | 608                    | 1,824              |
| 8     | 252                    | 1,025              |
| 9     | 403                    | 1,151              |
| Total | 1263                   | 4,000              |

It is quicker and more convenient to collect data from students in the same study group than to collect data from students individually. Therefore, this study uses a stratified clustered sample design. The primary sampling units, or clusters, are study groups. The list of all study groups in the school is stratified by grade level. From each grade level, a sample of study groups is randomly selected, and all students in each selected study group are interviewed. The sample consists of eight study groups from the 7th grade, three groups from the 8th grade, and five groups from the 9th grade.

The SAS data set IceCreamStudy saves the responses of the selected students:

```
data IceCreamStudy;
 input Grade StudyGroup Spending @@;
 if (Spending < 10) then Group='less';
 else Group='more';
 datalines;
7 34 7 7 34 7 7 412 4 9 27 14
7 34 2 9 230 15 9 27 15 7 501 2
9 230 8 9 230 7 7 501 3 8 59 20
7 403 4 7 403 11 8 59 13 8 59 17
```

```

8 143 12 8 143 16 8 59 18 9 235 9
8 143 10 9 312 8 9 235 6 9 235 11
9 312 10 7 321 6 8 156 19 8 156 14
7 321 3 7 321 12 7 489 2 7 489 9
7 78 1 7 78 10 7 489 2 7 156 1
7 78 6 7 412 6 7 156 2 9 301 8
;

```

In the data set `IceCreamStudy`, the variable `Grade` contains a student's grade. The variable `StudyGroup` identifies a student's study group. It is possible for students from different grades to have the same study group number because study groups are sequentially numbered within each grade. The variable `Spending` contains a student's response regarding how much he spends per week for ice cream, in dollars. The variable `GROUP` indicates whether a student spends at least \$10 weekly for ice cream. It is not necessary to store the data in order of grade and study group.

The SAS data set `StudyGroup` is created to provide PROC SURVEYMEANS with the sample design information shown in [Table 92.5](#):

```

data StudyGroups;
 input Grade _total_;
 datalines;
7 608
8 252
9 403
;

```

The variable `Grade` identifies the strata, and the variable `_TOTAL_` contains the total number of study groups in each stratum. As discussed in the section “[Specification of Population Totals and Sampling Rates](#)” on page 7805, the population totals stored in the variable `_TOTAL_` should be expressed in terms of the primary sampling units (PSUs), which are study groups in this example. Therefore, the variable `_TOTAL_` contains the total number of study groups for each grade, rather than the total number of students.

In order to obtain unbiased estimates, you create sampling weights by using the following SAS statements:

```

data IceCreamStudy;
 set IceCreamStudy;
 if Grade=7 then Prob=8/608;
 if Grade=8 then Prob=3/252;
 if Grade=9 then Prob=5/403;
 Weight=1/Prob;
run;

```

The sampling weights are the reciprocals of the probabilities of selections. The variable `Weight` contains the sampling weights. Because the sampling design is clustered and all students from each selected cluster are interviewed, the sampling weights equal the inverse of the cluster (or study group) selection probabilities.

The following SAS statements perform the analysis for this sample design:

```

title1 'Analysis of Ice Cream Spending';
proc surveymeans data=IceCreamStudy total=StudyGroups;
 strata Grade / list;
 cluster StudyGroup;
 var Spending Group;
 weight Weight;
run;

```

[Output 92.1.1](#) provides information about the sample design and the input data set. There are three strata in the sample design, and the sample contains 16 clusters and 40 observations. The variable `Group` has two levels, 'less' and 'more.'

**Output 92.1.1** Data Summary and Class Information

| Analysis of Ice Cream Spending |        |           |
|--------------------------------|--------|-----------|
| The SURVEYMEANS Procedure      |        |           |
| Data Summary                   |        |           |
| Number of Strata               |        | 3         |
| Number of Clusters             |        | 16        |
| Number of Observations         |        | 40        |
| Sum of Weights                 |        | 3162.6    |
| Class Level Information        |        |           |
| Class                          |        |           |
| Variable                       | Levels | Values    |
| Group                          | 2      | less more |

[Output 92.1.2](#) displays information for each stratum. Since the primary sampling units in this design are study groups, the population totals shown in [Output 92.1.2](#) are the total numbers of study groups for each stratum or grade. This differs from [Output 92.3](#), which provides the population totals in terms of students since students were the primary sampling units for that design. [Output 92.1.2](#) also displays the number of clusters for each stratum and analysis variable.

## Output 92.1.2 Stratum Information

| Stratum Information |       |                  |               |       |                |           |
|---------------------|-------|------------------|---------------|-------|----------------|-----------|

| Variable   | Level | N  | Mean     | Std Error<br>of Mean | 95% CL for Mean |            |
| Spending   |       | 40 | 8.923860 | 0.650859             | 7.51776370      | 10.3299565 |
| Group      | less  | 23 | 0.561437 | 0.056368             | 0.43966057      | 0.6832130  |
|            | more  | 17 | 0.438563 | 0.056368             | 0.31678698      | 0.5603394  |

**Example 92.2: Domain Analysis**

Suppose that you are studying profiles of 800 top-performing companies to provide information about their impact on the economy. You are also interested in the company profiles within each market type. A sample of 66 companies is selected with unequal probability across market types. However, market type is not included in the sample design. Thus, the number of companies within each market type is a random variable in your sample. To obtain statistics within each market type, you should use domain analysis. The data of the 66 companies are saved in the following data set:

```

data Company;
 length Type $14;
 input Type$ Asset Sale Value Profit Employee Weight;
 datalines;

;

For each company in your sample, the variables are defined as follows:

- Type identifies the type of market for the company.
- Asset contains the company's assets, in millions of dollars.
- Sale contains sales, in millions of dollars.
- Value contains the market value of the company, in millions of dollars.
- Profit contains the profit, in millions of dollars.

- Employee contains the number of employees, in thousands.
- Weight contains the sampling weight.

The following SAS statements use PROC SURVEYMEANS to perform the domain analysis, estimating means, and other statistics for the overall population and also for the subpopulations (or domain) defined by market type. The DOMAIN statement specifies Type as the domain variable:

```

title 'Top Companies Profile Study';
proc surveymeans data=Company total=800 mean sum;
 var Asset Sale Value Profit Employee;
 weight Weight;
 domain Type;
run;

```

Output 92.2.1 shows that there are 66 observations in the sample. The sum of the sampling weights equals 799.8, which is close to the total number of companies in the study population.

**Output 92.2.1** Company Profile Study

| Top Companies Profile Study |             |                      |         |             |

### Example 92.3: Ratio Analysis

Suppose you are interested in the profit per employee and the sale per employee among the 800 top-performing companies in the data in the previous example. The following SAS statements illustrate how you can use PROC SURVEYMEANS to estimate these ratios:

```

title 'Ratio Analysis in Top Companies Profile Study';
proc surveymeans data=Company total=800 ratio;
 var Profit Sale Employee;
 weight Weight;
 ratio Profit Sale / Employee;
run;

```

The RATIO statement requests the ratio of the profit and the sales to the number of employees.

Output 92.3.1 shows the estimated ratios and their standard errors. Because the profit and the sales figures are in millions of dollars, and the employee numbers are in thousands, the profit per employee is estimated as \$5,120 with a standard error of \$1,059, and the sales per employee are \$114,332 with a standard error of \$20,503.

**Output 92.3.1** Estimate Ratios

| Ratio Analysis in Top Companies Profile Study |             |            |           |
|-----------------------------------------------|-------------|------------|-----------|
| The SURVEYMEANS Procedure                     |             |            |           |
| Ratio Analysis                                |             |            |           |
| Numerator                                     | Denominator | Ratio      | Std Err   |
| Sale                                          | Employee    | 114.332497 | 20.502742 |
| Profit                                        | Employee    | 5.119698   | 1.058939  |

### Example 92.4: Analyzing Survey Data with Missing Values

As described in the section “Missing Values” on page 7804, the SURVEYMEANS procedure excludes an observation from the analysis if it has a missing value for the analysis variable or a nonpositive value for the WEIGHT variable.

However, if there is evidence indicating that the nonrespondents are different from the respondents for your study, you can use the NOMCAR option to compute descriptive statistics among respondents while still counting the number of nonrespondents.

We use the ice cream example in the section “Stratified Sampling” on page 7781 to illustrate how to perform similar analysis when there are missing values.

Suppose that some of the students failed to provide the amounts spent on ice cream, as shown in the following data set, IceCream:

```

data IceCream;
 input Grade Spending @@;
 if Grade=7 then Prob=20/1824;
 if Grade=8 then Prob=9/1025;
 if Grade=9 then Prob=11/1151;
 Weight=1/Prob;
 datalines;
7 7 7 7 8 . 9 10 7 . 7 10 7 3 8 20 8 19 7 2
7 . 9 15 8 16 7 6 7 6 7 6 9 15 8 17 8 14 9 .
9 8 9 7 7 3 7 12 7 4 9 14 8 18 9 9 7 2 7 1
7 4 7 11 9 8 8 . 8 13 7 . 9 . 9 11 7 2 7 9
;

data StudentTotals;
 input Grade _total_;
 datalines;
7 1824
8 1025
9 1151
;

```

Considering the possibility that those students who did not respond spend differently than those students who did respond, you can use the NOMCAR option to request the analysis to treat the respondents as a domain rather than exclude the nonrespondents.

The following SAS statements produce the desired analysis:

```

title 'Analysis of Ice Cream Spending';
proc surveymeans data=IceCream total=StudentTotals nomcar mean sum;
 strata Grade;
 var Spending;
 weight Weight;
run;

```

Output 92.4.1 summarizes the analysis including the variance estimation method.

#### Output 92.4.1 Analysis of Incomplete Ice Cream Data Excluding Observations with Missing Values

| Analysis of Ice Cream Spending |               |
|--------------------------------|---------------|
| The SURVEYMEANS Procedure      |               |
| Data Summary                   |               |
| Number of Strata               | 3             |
| Number of Observations         | 40            |
| Sum of Weights                 | 4000          |
| Variance Estimation            |               |
| Method                         | Taylor Series |
| Missing Values                 | NOMCAR        |

Output 92.4.2 shows the mean and total estimates when treating respondents as a domain in the student population. Although the point estimates are the same as the analysis without the NOMCAR option, for this particular example, the variance estimations are slightly higher when you assume that the missingness is not completely at random.

**Output 92.4.2** Analysis of Incomplete Ice Cream Data Excluding Observations with Missing Values

| Variable | Statistics |                      |       |             |
|----------|------------|----------------------|-------|-------------|
|          | Mean       | Std Error<br>of Mean | Sum   | Std Dev     |
| Spending | 9.770542   | 0.652347             | 32139 | 3515.126876 |

### Example 92.5: Variance Estimation Using Replication Methods

In order to improve service, the San Francisco Municipal Railway (MUNI) conducts a survey to estimate passenger’s average waiting time for MUNI’s subway system.

The study uses a stratified cluster sample design. Each MUNI subway line is a stratum. The subway lines included in the study are ‘J-Church,’ ‘K-Ingleside,’ ‘L-Taraval,’ ‘M-Ocean View,’ ‘N-Judah,’ and the street car ‘F-Market & Wharves.’ The MUNI vehicles in service for these lines during a day are primary sampling units. Within each stratum, two vehicles (PSUs) are randomly selected. Then the waiting times of passengers for a selected MUNI vehicle are collected.

Table 92.6 shows the number of passengers that are interviewed in each of the selected MUNI vehicles.

**Table 92.6** The Sample of the MUNI Waiting Time Study

| MUNI Line          | Vehicle | Number of Passengers |
|--------------------|---------|----------------------|
| F-Market & Wharves | 1       | 65                   |

The collected data are saved in the SAS data set MUNISURVEY. The variable Line indicates which MUNI line a passenger is riding. The variable vehicle identifies the vehicle that a passenger is boarding. The variable

Waittime is the time (in minutes) that a passenger waited. The variable weight contains the sampling weights, which are determined by selection probabilities within each stratum.

Output 92.5.1 displays the first 10 observations of the data set MUNIsurvey.

**Output 92.5.1** First 10 Observations in the Data Set from the MUNI Subway Survey

| MUNI Subway Passenger Waiting Time Survey Data |                    |         |           |          |        |
|------------------------------------------------|--------------------|---------|-----------|----------|--------|

| 7                                              | F-Market & Wharves | 1       | 7         | 7        | 59     |
| 8                                              | F-Market & Wharves | 1       | 8         | 5        | 59     |
| 9                                              | F-Market & Wharves | 1       | 9         | 16       | 59     |
| 10                                             | F-Market & Wharves | 1       | 10        | 5        | 59     |

Using the VARMETHOD=BRR option, the following SAS statements analyze the MUNI subway survey by using the BRR method to estimate the variance:

```

title 'MUNI Passenger Waiting Time Analysis Using BRR';
proc surveymeans data=MUNIsurvey mean varmethod=brr mean clm;
 strata line;
 cluster vehicle;
 var waittime;
 weight weight;
run;

```

The STRATUM variable is line, which corresponds to MUNI lines. The two clusters within each stratum are identified by the variable vehicle. The sampling weights are stored in the variable weight. The mean and confident limits for passenger waiting time (in minutes) are requested statistics.

Output 92.5.2 summarizes the data and indicates that the variance estimation method is BRR with 8 replicates.

**Output 92.5.2** MUNI Passenger Waiting Time Analysis Using the BRR Method

| MUNI Passenger Waiting Time Analysis Using BRR |        |
|------------------------------------------------|--------|
| The SURVEYMEANS Procedure                      |        |
| Data Summary                                   |        |
| Number of Strata                               | 6      |
| Number of Clusters                             | 12     |
| Number of Observations                         | 1937   |
| Sum of Weights                                 | 143040 |
| Variance Estimation                            |        |
| Method                                         | BRR    |
| Number of Replicates                           | 8      |

Output 92.5.3 reports that the average passenger waiting time for a MUNI vehicle is 7.33 minutes, with an estimated standard of 0.24 minutes, using the BRR method. The 95% confident limits for the mean are estimated as 6.75 to 7.91 minutes.

**Output 92.5.3** MUNI Passenger Waiting Time Analysis Using the BRR Method

| Statistics |          |                      |                       |
|------------|----------|----------------------|-----------------------|
| Variable   | Mean     | Std Error<br>of Mean | 95% CL for Mean       |
| waittime   | 7.333012 | 0.237557             | 6.75172983 7.91429366 |

Alternatively, the variance can be estimated using the jackknife method if the VARMETHOD=JACKKNIFE option is used. The following SAS statements analyze the MUNI subway survey by using the jackknife method to estimate the variance:

```

title 'MUNI Passenger Waiting Time Analysis Using Jackknife';
proc surveymeans data=MUNISURVEY mean varmethod=jackknife mean clm;
 strata line;
 cluster vehicle;
 var waittime;
 weight weight;
run;

```

Output 92.5.4 summarizes the data and indicates that the variance estimation method is jackknife with 12 replicates.

**Output 92.5.4** MUNI Passenger Waiting Time Analysis Using the Jackknife Method

| MUNI Passenger Waiting Time Analysis Using Jackknife |           |
|------------------------------------------------------|-----------|
| The SURVEYMEANS Procedure                            |           |
| Data Summary                                         |           |
| Number of Strata                                     | 6         |
| Number of Clusters                                   | 12        |
| Number of Observations                               | 1937      |
| Sum of Weights                                       | 143040    |
| Variance Estimation                                  |           |
| Method                                               | Jackknife |
| Number of Replicates                                 | 12        |

Output 92.5.5 reports the statistics computed using the jackknife method. Although the average passenger waiting time remains the same (7.33 minutes), the standard error is slightly smaller 0.23 minutes when the jackknife method is used, as opposed to 0.24 minutes when the BRR method is used. The 95% confidence limits are between 6.76 and 7.90 minutes when the jackknife method is used.

**Output 92.5.5** MUNI Passenger Waiting Time Analysis Using the Jackknife Method

| Statistics |          |                      |                       |
|------------|----------|----------------------|-----------------------|
| Variable   | Mean     | Std Error<br>of Mean | 95% CL for Mean       |
| waittime   | 7.333012 | 0.232211             | 6.76481105 7.90121244 |

## Overview: SURVEYPHREG Procedure

The SURVEYPHREG procedure performs regression analysis based on the Cox proportional hazards model for sample survey data. Cox’s semiparametric model is widely used in the analysis of survival data to estimate hazard rates when adequate explanatory variables are available. The procedure provides design-based variance estimates, confidence intervals, and hypothesis tests concerning the parameters and model effects. See Chapter 3, “Introduction to Statistical Modeling with SAS/STAT Software,” and Chapter 14, “Introduction to Survey Procedures,” for an introduction to the basic concepts of survey data analysis; see Chapter 13, “Introduction to Survival Analysis Procedures,” for an introduction to the basic concepts of survival analysis.

The survival time of each member of a finite population is assumed to follow its own hazard function,  $\lambda_i(t)$ , expressed as

$$\lambda_i(t) = \lambda(t; \mathbf{Z}_i(t)) = \lambda_0(t) \exp(\mathbf{Z}_i'(t)\boldsymbol{\beta})$$

where  $\lambda_0(t)$  is an arbitrary and unspecified baseline hazard function,  $\mathbf{Z}_i(t)$  is the vector of explanatory variables for the  $i$ th population unit at time  $t$ , and  $\boldsymbol{\beta}$  is the vector of unknown regression parameters.

The finite population regression parameter  $\boldsymbol{\beta}_N$  is defined as the maximizer of the partial log likelihood when the entire finite population is observed. The SURVEYPHREG procedure produces a sample-based estimate  $\hat{\boldsymbol{\beta}}$  of the proportional hazards regression parameters  $\boldsymbol{\beta}_N$  for the finite population by maximizing the partial pseudo-log-likelihood  $l_\pi(\boldsymbol{\beta}; \mathbf{Z}_i(t), t_i)$  based on observed covariates  $\mathbf{Z}_i(t)$  and observed survival time  $t_i$ . The procedure also produces an estimate of the sampling variance  $V(\hat{\boldsymbol{\beta}}|\mathcal{F}_N)$ , which assumes that the values of

the finite population  $\mathcal{F}_N$  are fixed. For statistical inference, PROC SURVEYPHREG incorporates complex survey sample designs, including designs with stratification, clustering, and unequal weighting.

The procedure also allows time-dependent explanatory variables. An explanatory variable is time-dependent if its value for any given individual can change over time. Time-dependent variables have many useful applications in survival analysis. You can include time-dependent variables such as blood pressure or blood chemistry measures that vary with time during the course of a study. You can also use time-dependent variables to test the validity of the proportional hazards model.

Several optimization techniques are available in SURVEYPHREG to maximize the log likelihood. Hazard ratio estimates can also be obtained along with parameter estimates. Sampling errors of the regression parameters and hazard ratios are computed by using either the Taylor series (linearization) method or one of the replication (resampling) methods that are based on complex sample designs (Binder 1983; Wolter 2007; Särndal, Swensson, and Wretman 1992; Binder 1992; Lohr 2010; Fuller 2009). These variance estimators essentially assume the finite population as fixed and estimate the variability due to the random sample selection mechanism.

The remaining sections of this chapter contain information about how to use PROC SURVEYPHREG, information about the underlying statistical methodology, and some applications of the procedure. The section “[Getting Started: SURVEYPHREG Procedure](#)” on page 7857 introduces PROC SURVEYPHREG with an example. The section “[Syntax: SURVEYPHREG Procedure](#)” on page 7861 describes the syntax of the procedure. The section “[Details: SURVEYPHREG Procedure](#)” on page 7884 summarizes the statistical techniques employed in PROC SURVEYPHREG. The section “[Examples: SURVEYPHREG Procedure](#)” on page 7913 includes some additional examples of useful applications. Experienced SAS/STAT software users might decide to proceed to the “Syntax” section, while other users might choose to read both the “Getting Started” and “Examples” sections before proceeding to “Syntax” and “Details.”

---

## Getting Started: SURVEYPHREG Procedure

This section uses a data set that is obtained by stratified random sampling from a simulated finite population to illustrate some of the basic features of PROC SURVEYPHREG.

Suppose the library system for a small county wants to study the length of time that books are borrowed over a specified study period, adjusting for the age of the borrower and accounting for the fact that some books are never returned. Suppose there are 10 branch libraries in the county. Assume that a list of 11,617 (simulated) transactions is available for the study period October 1, 2008, to December 31, 2008, and assume that this list can be used as the sampling frame. A stratified random sample with replacement is used to select 100 transactions, where branch libraries are the strata. The total number of transactions within branches range from 510 to 2,011 for the study period. The total sample size of 100 transactions is allocated proportionally across branches based on the number of transactions. For each selected transaction, telephone interviews were conducted to find out additional characteristics of the borrower. The data set LibrarySurvey contains the following variables for all units (transactions) in the sample:

- Branch, the library branch from which the book was borrowed
- SampleWeight, the survey sampling weight for the transaction
- CheckOut, the date the book was borrowed

- CheckIn, the date the book was returned, with a missing value if the book was not returned by December 31, 2008
- Age, the age of the borrower

```

PROC SURVEYPHREG can be used to estimate the regression parameters of a proportional hazards model and the design-based variance of the estimated coefficients. The design-based variance is useful when the finite population is considered fixed, as in this example. See Lohr (2010) and Särndal, Swensson, and Wretman (1992) for details.

The following statements request a proportional hazards regression of lenBorrow on Age with Returned as the censor indicator. A transaction is considered to be censored if its check-in date is missing. The WEIGHT statement specifies the sampling weight variable (SamplingWeight), and the STRATA statement specifies the stratification variable (Branch).

```

proc surveypHreg data = LibrarySurvey;
 weight SamplingWeight;
 strata Branch;
 model lenBorrow*Returned(0) = Age;
run;

```

Summary information about the model, number of observations, survey design, censored values, and variance estimation method are shown in [Output 93.1](#). The “Model Information” table summarizes the model you fit. The “Number of Observations” table displays the number of observations read and used by the procedure. This table also displays the sum of weights read and used. The sum of weights read (11,616.79) can be used as an estimator of the population size, and the sum of weights used can be used as an estimator of the respondent size in the population. The “Design Summary” table displays survey design information such as stratification and clustering. This example implements a stratified design with 10 strata. The “Censored Summary” and “Weighted Censored Summary” tables display the (weighted) number of censored and event units. Weighted counts can be used as estimators of the corresponding finite population quantities. For example, [Output 93.1](#) shows that 10% of the sampled units are censored and an estimated 10.05% of the population units are censored.

Figure 93.1 continued

| Summary of the Weighted Number of Event and Censored Values |               |          |                  |
|-------------------------------------------------------------|---------------|----------|------------------|
| Total                                                       | Event         | Censored | Percent Censored |
| 11616.79                                                    | 10449.22      | 1167.57  | 10.05            |
| Variance Estimation                                         |               |          |                  |
| Method                                                      | Taylor Series |          |                  |

Parameter estimates and their standard errors are shown in [Output 93.2](#). The estimated regression coefficient is highly significant with a value of 0.062, indicating a positive association between age and the length of time books are borrowed (recall that these are simulated data). In this example, the procedure uses the STRATA and WEIGHT statements to incorporate stratification and unequal weighting, respectively, into variance estimation. The degrees of freedom are calculated as the number of sampling units (100) minus the number of strata (10). Note that the estimated variance reported in [Output 93.2](#) ignores the finite population correction (*fpc*). You can use the TOTAL= or RATE= option in the PROC statement to include an *fpc* in your variance estimator.

## Syntax: SURVEYPHREG Procedure

The following statements are available in the SURVEYPHREG procedure. Items within < > are optional.

```

PROC SURVEYPHREG < options > ;
 BY variables ;
 CLASS variable < (options) > < ... variable < (options) > > < / options > ;
 CLUSTER variables ;
 DOMAIN variables < variable* variable variable* variable* variable ... > ;
 ESTIMATE < 'label' > estimate-specification < / options > ;
 FREQ variable ;
 LSMEANS < model-effects > < / options > ;
 LSMESTIMATE model-effect lsmestimate-specification < / options > ;
 MODEL response < * censor(list) > = effects < / options > ;
 NLOPTIONS < options > ;
 OUTPUT < OUT=SAS-data-set > < keyword=name ... keyword=name > < / options > ;
 Programming statements ;
 REPWEIGHTS variables < / options > ;
 SLICE model-effect < / options > ;
 STRATA variables < / option > ;
 STORE < OUT= > item-store-name < / LABEL='label' > ;
 TEST < model-effects > < / options > ;
 WEIGHT variable ;

```

The PROC SURVEYPHREG and MODEL statements are required. The CLASS statement, if present, must precede the MODEL statement.

The MODEL statement specifies the analysis model. The CLASS statement specifies the categorical variables. The STRATA statement lists the variables that form the strata in a stratified sample design. The CLUSTER statement specifies cluster identification variables in a clustered sample design. The WEIGHT statement names the sampling weight variable. The NLOPTIONS statement specifies the optimization techniques. The REPWEIGHTS statement names replicate weight variables for BRR or jackknife variance estimation. The DOMAIN statement lists the variables that define domains for subpopulation analysis. The BY statement requests completely separate analyses of groups defined by the BY variables.

The rest of this section provides detailed syntax information for each statement, beginning with the PROC SURVEYPHREG statement. The remaining statements are covered in alphabetical order.

The ESTIMATE, LSMEANS, LSMESTIMATE, SLICE, STORE, and TEST statements are also available in other procedures. Summary descriptions of functionality and syntax for these statements are provided in this chapter, and you can find full documentation about them in Chapter 19, “[Shared Concepts and Topics](#).”

## PROC SURVEYPHREG Statement

**PROC SURVEYPHREG** <options> ;

The PROC SURVEYPHREG statement invokes the SURVEYPHREG procedure. It also identifies the data set to be analyzed. Table 93.1 summarizes the options available in the PROC SURVEYPHREG statement.

**Table 93.1** PROC SURVEYPHREG Statement Options

| Option     | Description                                                                    |
|------------|--------------------------------------------------------------------------------|
| DATA=      | Names the input SAS data set                                                   |
| MISSING    | Treats missing values as a valid category                                      |
| NOPRINT    | Suppresses all displayed output                                                |
| NOMCAR     | Uses missing observations specified as <i>not missing completely at random</i> |
| ORDER=     | Specifies the sort order of CLASS variables                                    |
| RATE=      | Specifies the sampling rate                                                    |
| TOTAL=     | Specifies the total number of primary sampling units                           |
| VARMETHOD= | Specifies the variance estimation method                                       |

You can specify the following options in the PROC SURVEYPHREG statement:

### DATA=SAS-data-set

names the SAS data set that contains the data to be analyzed. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

### MISSING

treats missing values as a valid (nonmissing) category for all categorical variables, which include CLASS, STRATA, CLUSTER, and DOMAIN variables. By default, if you do not specify the MISSING option, an observation is excluded from the analysis if it has a missing value for any of these categorical variables. For more information, see the section “Missing Values” on page 7893.

### NOPRINT

suppresses all displayed output. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “Using the Output Delivery System,” for more information.

### NOMCAR

includes observations with missing values of the analysis variables that are specified in the MODEL statement as *not missing completely at random* (NOMCAR) for Taylor series variance estimation. When you specify the NOMCAR option, PROC SURVEYPHREG computes variance estimates by analyzing the nonmissing values as a domain (subpopulation), where the entire population includes both nonmissing and missing domains. See the section “Missing Values” on page 7893 for details.

By default, PROC SURVEYPHREG excludes an observation from analyses (and the corresponding variance computations) if that observation has a missing value for any of the variables in the MODEL statement. Note that if you specify the MISSING option for classification variables, then the procedure treats the missing values as a valid nonmissing level.

The NOMCAR option applies only to Taylor series variance estimation. The replication methods, which you request with the VARMETHOD=BRR and VARMETHOD=JACKKNIFE options, do not use the NOMCAR option.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of the classification variables (which are specified in the **CLASS** statement). This option applies to the levels for all classification variables, except when you use the (default) **ORDER=FORMATTED** option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The **ORDER=** option can take the following values:

| Value of <b>ORDER=</b> | Levels Sorted By                                                                                                                       |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DATA</b>            | Order of appearance in the input data set                                                                                              |
| <b>FORMATTED</b>       | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| <b>FREQ</b>            | Descending frequency count; levels with the most observations come first in the order                                                  |
| <b>INTERNAL</b>        | Unformatted value                                                                                                                      |

By default, **ORDER=FORMATTED**. For **ORDER=FORMATTED** and **ORDER=INTERNAL**, the sort order is machine-dependent. For more information about sort order, see the chapter on the **SORT** procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**RATE=***value* | *SAS-data-set*

**R=***value* | *SAS-data-set*

specifies the sampling rate as a nonnegative *value*, or identifies an input data set that gives the stratum sampling rates in a variable named `_RATE_`. PROC SURVEYPHREG uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the **RATE=** option for BRR or jackknife variance estimation, which you request with the **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** option.

If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of primary sampling units (PSUs) that are selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative *value* for the **RATE=** option. If your design is stratified with different sampling rates in different strata, then you should name a SAS data set that contains the stratification variables and the stratum sampling rates. See the section “[Population Totals and Sampling Rates](#)” on page 7892 for details.

The sampling rate *value* must be a nonnegative number. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYPHREG converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

If you do not specify the **RATE=** or **TOTAL=** option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the **TOTAL=** option and the **RATE=** option in the same PROC SURVEYPHREG statement.

**TOTAL=***value* | *SAS-data-set*

**N=***value* | *SAS-data-set*

specifies the total number of primary sampling units (PSUs) in the study population as a positive *value*, or identifies an input data set that gives the stratum population totals in a variable named `_TOTAL_`. PROC SURVEYPHREG uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the TOTAL= option for BRR or jackknife variance estimation, which you request with the **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** option.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option, which refers to the total number of PSUs in each stratum. If your sample design is stratified with different population totals in different strata, then you should name a SAS data set that contains the stratification variables and the stratum totals. See the section “Population Totals and Sampling Rates” on page 7892 for details.

If you do not specify the TOTAL= or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option in the same PROC SURVEYPHREG statement.

**VARMETHOD=BRR** < (*method-options*) > | **JACKKNIFE** < (*method-options*) > | **TAYLOR**

specifies the variance estimation method. **VARMETHOD=TAYLOR** requests the Taylor series method, which is the default if you do not specify the VARMETHOD= option or a **REPWEIGHTS** statement. **VARMETHOD=BRR** requests variance estimation by balanced repeated replication (BRR), and **VARMETHOD=JACKKNIFE** requests variance estimation by the delete-1 jackknife method.

For **VARMETHOD=BRR** and **VARMETHOD=JACKKNIFE**, you can specify *method-options* in parentheses following the variance method name. Table 93.2 summarizes the available *method-options*.

**Table 93.2** Variance Estimation Options

| <b>VARMETHOD=</b> | <b>Variance Estimation Method</b> | <i>Method-Options</i>                                                                                                                                                                 |
|-------------------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BRR               | Balanced repeated replication     | <b>CENTER=FULLSAMPLE</b>   <b>REPLICATES</b><br><b>FAY</b> <= <i>value</i> ><br><b>HADAMARD=SAS-data-set</b><br><b>OUTWEIGHTS=SAS-data-set</b><br><b>PRINTH</b><br><b>REPS=number</b> |
| JACKKNIFE         | Jackknife                         | <b>CENTER=FULLSAMPLE</b>   <b>REPLICATES</b><br><b>OUTJKCOEFS=SAS-data-set</b><br><b>OUTWEIGHTS=SAS-data-set</b>                                                                      |
| TAYLOR            | Taylor series linearization       | None                                                                                                                                                                                  |

The following values are available for the VARMETHOD= option:

**BRR** < (*method-options*) >

requests variance estimation by balanced repeated replication (BRR). The BRR method requires a stratified sample design with two primary sampling units (PSUs) in each stratum. If you specify the VARMETHOD=BRR option, you must also specify a STRATA statement unless you provide replicate weights with a REPWEIGHTS statement. See the section “Balanced Repeated Replication (BRR) Method” on page 7896 for details.

You can specify the following *method-options* in parentheses after the VARMETHOD=BRR option:

**CENTER=FULLSAMPLE | REPLICATES**

defines how to compute the deviations for the BRR method. CENTER=FULLSAMPLE is the default, which computes the deviations of the replicate estimates from the full sample estimate. Alternatively, you can specify CENTER=REPLICATES to compute the deviations of the replicate estimates from the average of the replicate estimates. See the section “Balanced Repeated Replication (BRR) Method” on page 7896 for details.

**FAY** < =*value* >

requests Fay’s method, which is a modification of the BRR method. See the section “Fay’s BRR Method” on page 7898 for details.

You can specify the *value* of the Fay coefficient, which is used in converting the original sampling weights to replicate weights. The Fay coefficient must be a nonnegative number less than 1. By default, the value of the Fay coefficient equals 0.5.

**HADAMARD=***SAS-data-set*

**H=***SAS-data-set*

names a SAS data set that contains the Hadamard matrix for BRR replicate construction. If you do not provide a Hadamard matrix with the HADAMARD= *method-option*, PROC SURVEYPHREG generates an appropriate Hadamard matrix for replicate construction. See the sections “Balanced Repeated Replication (BRR) Method” on page 7896 and “Hadamard Matrix” on page 7898 for details.

If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the HADAMARD= *method-option*.

In the HADAMARD= input data set, each variable corresponds to a column of the Hadamard matrix, and each observation corresponds to a row of the matrix. You can use any variable names in the HADAMARD= data set. All values in the data set must equal either 1 or –1. You must ensure that the matrix you provide is indeed a Hadamard matrix—that is,  $\mathbf{A}'\mathbf{A} = \mathbf{R}\mathbf{I}$ , where  $\mathbf{A}$  is the Hadamard matrix of dimension  $R$  and  $\mathbf{I}$  is an identity matrix. PROC SURVEYPHREG does not check the validity of the Hadamard matrix that you provide.

The HADAMARD= input data set must contain at least  $H$  variables, where  $H$  denotes the number of first-stage strata in your design. If the data set contains more than  $H$  variables, PROC SURVEYPHREG uses only the first  $H$  variables. Similarly, the HADAMARD= input data set must contain at least  $H$  observations.

If you do not specify the REPS= *method-option*, then the number of replicates is taken to be the number of observations in the HADAMARD= input data set. If you specify the number of replicates—for example, REPS=*nreps*—then the first *nreps* observations in the HADAMARD= data set are used to construct the replicates.

You can specify the PRINTH *method-option* to display the Hadamard matrix that the procedure uses to construct replicates for BRR.

#### **OUTWEIGHTS=SAS-data-set**

names an output SAS data set to store the replicate weights that PROC SURVEYPHREG creates for BRR variance estimation. See the section “Balanced Repeated Replication (BRR) Method” on page 7896 for information about replicate weights. See the section “Replicate Weights Output Data Set” on page 7908 for details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= *method-option* is not available when you provide replicate weights with a REPWEIGHTS statement.

#### **PRINTH**

displays the Hadamard matrix used to construct replicates for BRR. When you provide the Hadamard matrix in the HADAMARD= *method-option*, PROC SURVEYPHREG displays only the rows and columns that are actually used to construct replicates. See the sections “Balanced Repeated Replication (BRR) Method” on page 7896 and “Hadamard Matrix” on page 7898 for more information.

The PRINTH *method-option* is not available when you provide replicate weights with a REPWEIGHTS statement because the procedure does not use a Hadamard matrix in this case.

#### **REPS=number**

specifies the number of replicates for BRR variance estimation. The value of *number* must be an integer greater than 1.

If you do not provide a Hadamard matrix with the HADAMARD= *method-option*, the number of replicates should be greater than the number of strata and should be a multiple of 4. See the section “Balanced Repeated Replication (BRR) Method” on page 7896 for more information. If a Hadamard matrix cannot be constructed for the REPS= value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the REPS= value that you specify.

If you provide a Hadamard matrix with the HADAMARD= *method-option*, the value of REPS= must not be less than the number of rows in the Hadamard matrix. If you provide a Hadamard matrix and do not specify the REPS= *method-option*, the number of replicates equals the number of rows in the Hadamard matrix.

If you do not specify the REPS= or HADAMARD= *method-option* and do not include a **REPWEIGHTS** statement, the number of replicates equals the smallest multiple of 4 that is greater than the number of strata.

If you provide replicate weights with a **REPWEIGHTS** statement, the procedure does not use the REPS= *method-option*. With a **REPWEIGHTS** statement, the number of replicates equals the number of **REPWEIGHTS** variables.

### **JACKKNIFE | JK** <(method-options)>

requests variance estimation by the delete-1 jackknife method. See the section “[Jackknife Method](#)” on page 7899 for details. If you provide replicate weights with a **REPWEIGHTS** statement, **VARMETHOD=JACKKNIFE** is the default variance estimation method. The **JACKKNIFE** method requires at least two primary sampling units (PSUs) in each stratum for stratified designs unless you provide replicate weights with a **REPWEIGHTS** statement.

You can specify the following *method-options* in parentheses following **VARMETHOD=JACKKNIFE**:

#### **CENTER=FULLSAMPLE | REPLICATES**

defines how to compute the deviations for the jackknife method. **CENTER=FULLSAMPLE** is the default, which computes the deviations of the replicate estimates from the full sample estimate. Alternatively, you can specify **CENTER=REPLICATES** to compute the deviations of the replicate estimates from the average of the replicate estimates. See the section “[Jackknife Method](#)” on page 7899 for details.

#### **OUTWEIGHTS=SAS-data-set**

names an output SAS data set that contains replicate weights. See the section “[Jackknife Method](#)” on page 7899 for information about replicate weights. See the section “[Replicate Weights Output Data Set](#)” on page 7908 for more details about the contents of the **OUTWEIGHTS=** data set.

The **OUTWEIGHTS=** *method-option* is not available when you provide replicate weights with the **REPWEIGHTS** statement.

#### **OUTJKCOEFS=SAS-data-set**

names an output SAS data set that contains [jackknife coefficients](#). See the section “[Jackknife Coefficients Output Data Set](#)” on page 7909 for more details about the contents of the **OUTJKCOEFS=** data set.

### **TAYLOR**

requests [Taylor series](#) variance estimation. This is the default method if you do not specify the **VARMETHOD=** option or a **REPWEIGHTS** statement. See the section “[Taylor Series Linearization](#)” on page 7895 for more information.

---

## **BY Statement**

**BY variables ;**

You can specify a **BY** statement with **PROC SURVEYPHREG** to obtain separate analyses of observations in groups that are defined by the **BY** variables. When a **BY** statement appears, the procedure expects the input data set to be sorted in order of the **BY** variables. If you specify more than one **BY** statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the SURVEYPHREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a domain (subpopulation) analysis, where the total number of units in the subpopulation is not known at the time the survey is designed. For such an analysis use the DOMAIN statement.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

```
CLASS variable <(options)> ... <variable <(options)>> </options> ;
```

The CLASS statement names the classification variables to be used as explanatory variables in the analysis. The CLASS statement must precede the MODEL statement. Most *options* can be specified either as individual variable *options* or as global *options*. You can specify *options* for each variable by enclosing the options in parentheses after the variable name. You can also specify global *options* for the CLASS statement by placing the *options* after a slash (/). Global *options* are applied to all the variables specified in the CLASS statement. If you specify more than one CLASS statement, the global *options* specified in any one CLASS statement apply to all CLASS statements. However, individual CLASS variable *options* override the global *options*. The following *options* are available:

### DESCENDING

#### DESC

reverses the sort order of the classification variable. If both the DESCENDING and ORDER= options are specified, PROC SURVEYPHREG orders the categories according to the ORDER= option and then reverses that order.

### MISSING

treats missing values (“.”, “.A”, ..., “.Z” for numeric variables and blanks for character variables) as valid values for the CLASS variable.

### ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of classification variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option can be useful when you use the CONTRAST statement. By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent. When ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

The following table shows how PROC SURVEYPHREG interprets values of the ORDER= option.

| Value of ORDER= | Levels Sorted By                                                                                                                         |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------|
| DATA            | Order of appearance in the input data set                                                                                                |
| FORMATTED       | External formatted values, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) values |
| FREQ            | Descending frequency count; levels with more observations come earlier in the order                                                      |
| INTERNAL        | Unformatted value                                                                                                                        |

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**PARAM=keyword**

specifies the parameterization method for the classification variable or variables. You can specify any of the *keywords* shown in the following table;

Design matrix columns are created from CLASS variables according to the corresponding coding schemes:

| Value of PARAM=           | Coding                                                                                              |
|---------------------------|-----------------------------------------------------------------------------------------------------|
| EFFECT                    | Effect coding                                                                                       |
| GLM                       | Less-than-full-rank reference cell coding (this <i>keyword</i> can be used only in a global option) |
| ORDINAL<br>THERMOMETER    | Cumulative parameterization for an ordinal CLASS variable                                           |
| POLYNOMIAL<br>POLY        | Polynomial coding                                                                                   |
| REFERENCE<br>REF          | Reference cell coding                                                                               |
| ORTHEFFECT                | Orthogonalizes PARAM=EFFECT coding                                                                  |
| ORTHORDINAL<br>ORTHOTHERM | Orthogonalizes PARAM=ORDINAL coding                                                                 |
| ORTHPOLY                  | Orthogonalizes PARAM=POLYNOMIAL coding                                                              |
| ORTHREF                   | Orthogonalizes PARAM=REFERENCE coding                                                               |

All parameterizations are full rank, except for the GLM parameterization. The REF= option in the CLASS statement determines the reference level for EFFECT and REFERENCE coding and for their orthogonal parameterizations. It also indirectly determines the reference level for a singular GLM parameterization through the order of levels.

If PARAM=ORTHPOLY or PARAM=POLY and the classification variable is numeric, then the ORDER= option in the CLASS statement is ignored, and the internal unformatted values are used. See

the section “Other Parameterizations” on page 387 of Chapter 19, “Shared Concepts and Topics,” for further details.

**REF=** *'level' | keyword*

specifies the reference level for **PARAM=EFFECT**, **PARAM=REFERENCE**, and their orthogonalizations. For **PARAM=GLM**, the **REF=** option specifies a level of the classification variable to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the linear estimates with a singular parameterization.

For an individual variable **REF=** option (but not for a global **REF=** option), you can specify the *level* of the variable to use as the reference level. Specify the formatted value of the variable if a format is assigned. For a global or individual variable **REF=** option, you can use one of the following *keywords*. The default is **REF=LAST**.

**FIRST**     designates the first ordered level as reference.

**LAST**      designates the last ordered level as reference.

**TRUNCATE**< *=n* >

specifies the length *n* of **CLASS** variable values to use in determining **CLASS** variable levels. The default is to use the full formatted length of the **CLASS** variable. If you specify **TRUNCATE** without the length *n*, the first 16 characters of the formatted values are used. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases before SAS 9. The **TRUNCATE** option is available only as a global option.

## CLUSTER Statement

**CLUSTER** *variables* ;

The **CLUSTER** statement names variables that identify the first-stage clusters in a clustered sample design. First-stage clusters are also known as primary sampling units (PSUs). The combinations of categories of **CLUSTER** variables define the clusters in the sample. If there is a **STRATA** statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should specify only the first-stage clusters (PSUs) in the **CLUSTER** statement. See the section “Specifying the Sample Design” on page 7891 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with a **REPWEIGHTS** statement, you do not need to specify a **CLUSTER** statement.

The **CLUSTER variables** are one or more variables in the **DATA=** input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. The formatted values of the **CLUSTER** variables determine the **CLUSTER** variable levels. Thus, you can use formats to group values into levels. See the discussion of the **FORMAT** procedure in the *Base SAS Procedures Guide* and the discussions of the **FORMAT** statement and SAS formats in *SAS Formats and Informats: Reference*.

You can use multiple **CLUSTER** statements to specify **CLUSTER** variables. The procedure uses variables from all **CLUSTER** statements to create clusters. Cluster variables must not occur in the **CLASS** statement.

---

## DOMAIN Statement

**DOMAIN** *variables* < *variable\** *variable* *variable\** *variable\** *variable* ... > ;

The DOMAIN statement requests analysis for domains (subpopulations), in addition to analysis for the entire study population. The DOMAIN statement names the variables that identify domains, which are called domain variables.

It is common practice to compute statistics for domains. The formation of these domains might not be known at the design stage. Therefore, the sample sizes for the domains are often random. Use a DOMAIN statement to incorporate this variability into the variance estimation.

Note that a DOMAIN statement is different from a BY statement. In a BY statement, you treat the sample sizes as fixed in each subpopulation, and you perform analysis within each BY group independently.

Use the DOMAIN statement on the entire data set to perform a domain analysis. Creating a new data set from a single domain and analyzing that with PROC SURVEYPHREG yields inappropriate estimates of variance.

A domain variable can be either character or numeric. The procedure treats domain variables as categorical variables. If a variable appears by itself in a DOMAIN statement, each level of this variable determines a domain in the study population. If two or more variables are joined by asterisks (\*), then every possible combination of levels of these variables determines a domain. The procedure performs a descriptive analysis within each domain that is defined by the domain variables. Domain variables must not occur in the CLASS statement.

The formatted values of the domain variables determine the categorical variable levels. Thus, you can use formats to group values into levels. For more information, see the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in the *SAS Formats and Informats: Reference*.

---

## ESTIMATE Statement

**ESTIMATE** < '*label*' > *estimate-specification* < (*divisor*=*n*) >  
 < , ... < '*label*' > *estimate-specification* < (*divisor*=*n*) > >  
 < / *options* > ;

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form  $\mathbf{L}\boldsymbol{\beta}$ . You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 93.3 summarizes the options available in the ESTIMATE statement.

**Table 93.3** ESTIMATE Statement Options

| Option                                                     | Description                                                               |
|------------------------------------------------------------|---------------------------------------------------------------------------|
| <b>Construction and Computation of Estimable Functions</b> |                                                                           |
| DIVISOR=                                                   | Specifies a list of values to divide the coefficients                     |
| NOFILL                                                     | Suppresses the automatic fill-in of coefficients for higher-order effects |
| SINGULAR=                                                  | Tunes the estimability checking difference                                |
| <b>Degrees of Freedom and <math>p</math>-values</b>        |                                                                           |
| ADJUST=                                                    | Determines the method for multiple comparison adjustment of estimates     |
| ALPHA= $\alpha$                                            | Determines the confidence level ( $1 - \alpha$ )                          |
| LOWER                                                      | Performs one-sided, lower-tailed inference                                |
| STEPDOWN                                                   | Adjusts multiplicity-corrected $p$ -values further in a step-down fashion |
| TESTVALUE=                                                 | Specifies values under the null hypothesis for tests                      |
| UPPER                                                      | Performs one-sided, upper-tailed inference                                |
| <b>Statistical Output</b>                                  |                                                                           |
| CL                                                         | Constructs confidence limits                                              |
| CORR                                                       | Displays the correlation matrix of estimates                              |
| COV                                                        | Displays the covariance matrix of estimates                               |
| E                                                          | Prints the $L$ matrix                                                     |
| JOINT                                                      | Produces a joint $F$ or chi-square test for the estimable functions       |
| SEED=                                                      | Specifies the seed for computations that depend on random numbers         |

For details about the syntax of the ESTIMATE statement, see the section “ESTIMATE Statement” on page 437 in Chapter 19, “Shared Concepts and Topics.”

## FREQ Statement

**FREQ** *variable* ;

The FREQ statement names a numeric *variable* that provides a frequency for each observation in the input data set. PROC SURVEYPHREG treats each observation as if it appears  $n$  times, where  $n$  is the value of the FREQ variable for the observation. If not an integer, the frequency value is truncated to an integer. If the frequency value is missing, the observation is not used in the analysis. The FREQ statement allows one frequency variable.

If you use the FREQ statement and request the jackknife or BRR variance estimator by specifying the VARMETHOD=JACKKNIFE or VARMETHOD=BRR option in the PROC SURVEYPHREG statement, then you must identify the primary sampling units with a CLUSTER statement unless you also provide replicate weights with a REPWEIGHTS statement.

## LSMEANS Statement

**LSMEANS** < model-effects > < / options > ;

The LSMEANS statement computes and compares least squares means (LS-means) of fixed effects. LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs.

Table 93.4 summarizes the options available in the LSMEANS statement.

**Table 93.4** LSMEANS Statement Options

| Option                                          | Description                                                                                 |
|-------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b> |                                                                                             |
| AT                                              | Modifies the covariate value in computing LS-means                                          |
| BYLEVEL                                         | Computes separate margins                                                                   |
| DIFF                                            | Requests differences of LS-means                                                            |
| OM=                                             | Specifies the weighting scheme for LS-means computation as determined by the input data set |
| SINGULAR=                                       | Tunes estimability checking                                                                 |
| <b>Degrees of Freedom and <i>p</i>-values</b>   |                                                                                             |
| ADJUST=                                         | Determines the method for multiple-comparison adjustment of LS-means differences            |
| ALPHA= $\alpha$                                 | Determines the confidence level ( $1 - \alpha$ )                                            |
| STEPDOWN                                        | Adjusts multiple-comparison <i>p</i> -values further in a step-down fashion                 |
| <b>Statistical Output</b>                       |                                                                                             |
| CL                                              | Constructs confidence limits for means and mean differences                                 |
| CORR                                            | Displays the correlation matrix of LS-means                                                 |
| COV                                             | Displays the covariance matrix of LS-means                                                  |
| E                                               | Prints the <b>L</b> matrix                                                                  |
| LINES                                           | Produces a “Lines” display for pairwise LS-means differences                                |
| MEANS                                           | Prints the LS-means                                                                         |
| PLOTS=                                          | Requests graphs of means and mean comparisons                                               |
| SEED=                                           | Specifies the seed for computations that depend on random numbers                           |

For details about the syntax of the LSMEANS statement, see the section “LSMEANS Statement” on page 453 in Chapter 19, “Shared Concepts and Topics.”

## LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
 <,...<'label'> values <divisor=n>>
 </options>;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 93.5 summarizes the options available in the LSMESTIMATE statement.

**Table 93.5** LSMESTIMATE Statement Options

| Option                                          | Description                                                                            |
|-------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b> |                                                                                        |
| AT                                              | Modifies covariate values in computing LS-means                                        |
| BYLEVEL                                         | Computes separate margins                                                              |
| DIVISOR=                                        | Specifies a list of values to divide the coefficients                                  |
| OM=                                             | Specifies the weighting scheme for LS-means computation as determined by a data set    |
| SINGULAR=                                       | Tunes estimability checking                                                            |
| <b>Degrees of Freedom and <i>p</i>-values</b>   |                                                                                        |
| ADJUST=                                         | Determines the method for multiple-comparison adjustment of LS-means differences       |
| ALPHA= $\alpha$                                 | Determines the confidence level ( $1 - \alpha$ )                                       |
| LOWER                                           | Performs one-sided, lower-tailed inference                                             |
| STEPDOWN                                        | Adjusts multiple-comparison <i>p</i> -values further in a step-down fashion            |
| TESTVALUE=                                      | Specifies values under the null hypothesis for tests                                   |
| UPPER                                           | Performs one-sided, upper-tailed inference                                             |
| <b>Statistical Output</b>                       |                                                                                        |
| CL                                              | Constructs confidence limits for means and mean differences                            |
| CORR                                            | Displays the correlation matrix of LS-means                                            |
| COV                                             | Displays the covariance matrix of LS-means                                             |
| E                                               | Prints the <b>L</b> matrix                                                             |
| ELSM                                            | Prints the <b>K</b> matrix                                                             |
| JOINT                                           | Produces a joint <i>F</i> or chi-square test for the LS-means and LS-means differences |
| SEED=                                           | Specifies the seed for computations that depend on random numbers                      |

For details about the syntax of the LSMESTIMATE statement, see the section “LSMESTIMATE Statement” on page 470 in Chapter 19, “Shared Concepts and Topics.”

## MODEL Statement

**MODEL** *response* < \* *censor (list)* > = *effects* < / *options* > ;

The MODEL statement identifies the variable to be used as the failure time variable, the optional censoring variable, and the explanatory effects, including covariates, main effects, and interactions; see the section “Specification of Effects” on page 3324 of Chapter 42, “The GLM Procedure,” for more information. A note of caution: specifying the effect T\*A in the MODEL statement, where T is the time variable and A is a CLASS variable, does not make the effect time-dependent. You must specify exactly one MODEL statement.

The MODEL statement allows one response variable. In the MODEL statement, the failure time variable precedes the equal sign. This can optionally be followed by an asterisk, the name of the censoring variable, and a list of censoring values (separated by blanks or commas if there is more than one) enclosed in parentheses. If the censoring variable takes on one of these values, the corresponding failure time is considered to be censored. The variables following the equal sign are the explanatory variables (sometimes called independent variables or covariates) for the model.

The censoring variable must be numeric. The failure time variable must contain nonnegative values. Any observation with a negative failure time is excluded from the analysis, as is any observation with a missing value for any of the variables listed in the MODEL statement. See “Missing Values” on page 7893 for details.

Table 93.6 summarizes the options available in the MODEL statement, which can be specified after a slash (/).

**Table 93.6** MODEL Statement Options

| Option     | Description                                                                  |
|------------|------------------------------------------------------------------------------|
| ALPHA=     | Specifies $\alpha$ for the 100(1 - $\alpha$ )% confidence limits             |
| CLPARM     | Computes confidence limits for regression parameters                         |
| COVB       | Displays covariance matrix                                                   |
| DF=        | Specifies the denominator degrees of freedom                                 |
| HESS       | Displays the Hessian matrix                                                  |
| INVHESS    | Displays the inverse of the Hessian matrix                                   |
| RISKLIMITS | Computes confidence limits for the exponentials of the regression parameters |
| SERATIO=   | Computes the ratio of two standard errors for the regression coefficients    |
| SINGULAR=  | Specifies tolerance for testing singularity                                  |
| TIES=      | Specifies the method of handling ties in failure times                       |
| VADJUST=   | Specifies a variance adjustment factor                                       |
| VARRATIO=  | Computes the ratio of two variances for the regression coefficients          |

**ALPHA= $\alpha$** 

sets the level of the confidence limits for the estimated regression parameters and the hazard ratios. The value of *alpha* must be between 0 and 1, and the default is 0.05. A confidence level of  $\alpha$  produces  $100(1 - \alpha)\%$  confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

The ALPHA= option has no effect unless the CLPARM or RISKLIMITS option is also specified.

**CLPARM**

produces confidence limits for regression parameters of Cox proportional hazards models. The confidence coefficient can be specified with the ALPHA= option. Classification main effects that use parameterizations other than REF, EFFECT, or GLM are ignored. See “Confidence Intervals” on page 7905 for details.

**COVB**

displays the estimated covariance matrix of the parameter estimates.

**DF=value | keyword**

specifies the denominator degrees of freedom for hypothesis tests and the degrees of freedom to use for confidence limits. If a *value* is specified, it must be a nonnegative number. By default, PROC SURVEYPHREG computes the degrees of freedom as described in the section “Degrees of Freedom” on page 7901. Instead of a *value*, you can specify one of the following key words:

**NONE**

specifies the denominator degrees of freedom to be infinite. Use this option if you want to compute chi-square tests and normal confidence intervals. This option is applicable to both the Taylor series linearization and the replication methods.

**PARMADJ**

computes the denominator degrees of freedom as the number of clusters (or observations if no CLUSTER statement is specified) minus the number of strata (or one if no STRATA statement is specified) minus the number of nonsingular parameters plus one in the model. This option can be useful if you are fitting a model with many parameters relative to the number of clusters minus the number of strata. See Korn and Graubard (1999, section 5.2) for further details. This option is applicable only for the Taylor series linearization method.

**ALLREPS**

computes the denominator degrees of freedom for replication methods by using the total number of replicate samples. By default, PROC SURVEYPHREG computes the denominator degrees of freedom based on the number of replicate samples used. See “Degrees of Freedom” on page 7901 for details.

**HESS**

displays the last evaluation of the Hessian matrix.

**INVHESS**

displays the inverse of the Hessian matrix that is evaluated at the estimated regression parameters.

**RISKLIMITS****RL**

produces confidence limits for hazard ratios and related quantities. See the section “[Hazard Ratios](#)” on page 7905 for details. The confidence coefficient can be specified with the **ALPHA=** option. Great care needs to be taken with any interpretation of the estimates and their confidence limits if interaction effects are involved in the model or if parameterizations other than REF, EFFECT, or GLM are used.

**SERATIO=ALL | MODEL | IND**

computes the ratio of two standard errors for the regression parameters. The standard error in the numerator uses the complete design information that you specify. You can specify the following options to compute different standard errors for the denominator:

**ALL**

requests both MODEL and IND standard error ratios.

**MODEL**

computes the standard errors in the denominator as the square root of the diagonals of the inverse Hessian matrix evaluated at the estimated regression parameters. See the section “[Variance Ratios and Standard Error Ratios](#)” on page 7902 for more information.

**IND**

computes the standard errors in the denominator by ignoring stratification and clustering. See the section “[Variance Ratios and Standard Error Ratios](#)” on page 7902 for more information.

**SINGULAR=value**

specifies the singularity criterion for determining linear dependencies in the set of explanatory variables. The default value is  $10^{-12}$ .

**TIES=method**

specifies how to handle ties in the failure time. The available *methods* are as follows:

**BRESLOW**

uses the approximate partial likelihood of Breslow (1974). This is the default value.

**EFRON**

uses the approximate partial likelihood of Efron (1977).

If there are no ties, both methods result in the same likelihood and yield identical estimates. The default, TIES=BRESLOW, is the most efficient method when there are no ties.

**VADJUST=DF | PARMADJ | NONE | AVGREPSS**

specifies variance adjustment factors. You can use the following key words:

**DF****PARMADJ**

requests degrees of freedom adjustment  $(n - 1)/(n - p)$  in the computation of the matrix **G** for the Taylor series linearization [variance estimation](#). By default, VADJUST=DF.

**NONE**

excludes the degrees of freedom adjustment  $(n - 1)/(n - p)$  from the computation of the matrix **G** for the Taylor series linearization [variance estimation](#).

**AVGREPSS**

use the average sum of squares from all the usable replicate samples for the unusable replicates. This option is applicable only for the jackknife replication method. AVGREPSS multiplies the default jackknife variance estimator by the factor  $R/R_a$ , where  $R_a$  is the number of usable replicates and  $R$  is the total number of replicates. See the section “[Variance Adjustment Factors](#)” on page 7902 for details.

**VARRATIO=ALL | MODEL | IND**

computes the ratio of two variances for the regression parameters. The variance in the numerator uses the complete design information. You can specify the following options to compute different variances for the denominator:

**ALL**

requests both MODEL and IND variance ratios.

**MODEL**

computes the variances in the denominator as the diagonals of the inverse Hessian matrix evaluated at the estimated regression parameters. See the section “[Variance Ratios and Standard Error Ratios](#)” on page 7902 for more information.

**IND**

computes the variances in the denominator by ignoring stratification and clustering. See the section “[Variance Ratios and Standard Error Ratios](#)” on page 7902 for more information.

**NLOPTIONS Statement**

**NLOPTIONS** < options > ;

The NLOPTIONS statement specifies details of the nonlinear optimization used by PROC SURVEYPHREG to maximize the log likelihood function. By default, the procedure uses the Newton-Raphson optimization technique. For more information about the NLOPTIONS statement, see the section “[NLOPTIONS Statement](#)” on page 482 in Chapter 19, “[Shared Concepts and Topics](#).”

**OUTPUT Statement**

**OUTPUT** < OUT=SAS-data-set > < keyword=name . . . keyword=name > < / options > ;

The OUTPUT statement creates a new SAS data set that contains statistics that are calculated for each observation unit. These statistics can include the estimated linear predictor ( $\mathbf{z}'_j \hat{\boldsymbol{\beta}}$ ) and its standard error, residuals, and influence statistics. In addition, this data set includes all the variables from the DATA= input data set.

Only score residuals are available in the OUTPUT data set if the model contains a time-dependent variable that is defined by means of programming statements.

The following list explains specifications in the OUTPUT statement:

**OUT=SAS-data-set**

names the output data set. If you omit the OUT= option, the OUTPUT data set is named by using the DATA*n* convention. See the section “[OUT= Data Set for the OUTPUT statement](#)” on page 7908 for more information.

*keyword=name*

specifies the statistics to include in the OUTPUT data set and names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), and optionally an equal sign with either a variable or a list of variables in parentheses to contain the statistics. If you specify a keyword without a variable name, then the procedure uses default names. The keywords that accept a list of variables are RESSCH, RESSCO, and WTRESSCH. For these keywords, you can specify as many names in *name* as the number of explanatory variables in the MODEL statement. If you specify *k* names and *k* is less than the total number of explanatory variables, only the first *k* names are taken from the list; the procedure assigns default names for the rest of the statistics. The keywords and the corresponding statistics are as follows:

**ATRISK**

specifies the number of subjects at risk at the observation time  $\tau_j$ .

**RESDEV**

specifies the deviance residual  $\hat{D}_j$ . This is a transform of the martingale residual to achieve a more symmetric distribution.

**RESMART**

specifies the martingale residual  $\hat{M}_j$ . The residual at the observation time  $\tau_j$  can be interpreted as the difference over  $[0, \tau_j]$  in the observed number of events minus the expected number of events given by the model.

**RESSCH**

specifies the Schoenfeld residuals. These residuals are useful in assessing the proportional hazards assumption.

**RESSCO**

specifies the score residuals. These residuals are a decomposition of the first partial derivative of the log likelihood. They can be used to assess the leverage that is exerted by each subject in the parameter estimation. They are also useful in constructing design-based variance estimators.

**STDXBETA**

specifies the standard error of the estimated linear predictor,  $\sqrt{\mathbf{z}'_j \hat{\mathbf{V}}(\hat{\boldsymbol{\beta}}|F) \mathbf{z}_j}$ .

**WTATRISK**

specifies the weighted number of subjects at risk at the observation time  $\tau_j$ .

**XBETA**

specifies the estimate of the linear predictor,  $\mathbf{z}'_j \hat{\boldsymbol{\beta}}$ .

## Programming Statements

Programming statements are used to create or modify the values of the explanatory variables in the MODEL statement. They are especially useful in fitting models with time-dependent explanatory variables. Programming statements can also be used to create explanatory variables that are not time-dependent. PROC SURVEYPHREG programming statements cannot be used to create or modify the values of the response variable, the censoring variable, the frequency variable, the weight variable, the class variables, the strata variables, the cluster variables, or the domain variables.

The following DATA step statements are available in PROC SURVEYPHREG:

```

ABORT;
ARRAY arrayname < [dimensions] > < $ > < variables-and-constants >;
CALL name < (expression < , expression ... >) >;
DELETE;
DO < variable = expression < TO expression > < BY expression > >
 < , expression < TO expression > < BY expression > > ...
 < WHILE expression > < UNTIL expression >;
END;
GOTO statement-label;
IF expression;
IF expression THEN program-statement;
 ELSE program-statement;
variable = expression;
variable + expression;
LINK statement-label;
PUT < variable > < = > ...;
RETURN;
SELECT < (expression) >;
STOP;
SUBSTR(variable, index, length)= expression;
WHEN (expression)program-statement;
 OTHERWISE program-statement;

```

By default, the PUT statement in PROC SURVEYPHREG writes results to the Output window instead of the Log window. If you want the results of the PUT statements to go to the Log window, add the following statement before the PUT statement:

```
FILE LOG;
```

DATA step functions are also available. Use these programming statements the same way you use them in the DATA step. For detailed information, see the *SAS Functions and CALL Routines: Reference*.

Consider the following example of using programming statements in PROC SURVEYPHREG. Suppose blood pressure is measured at multiple times during the course of a study that investigates the effect of blood pressure on some survival time. By treating the blood pressure as a time-dependent explanatory variable, you can use the value of the most recent blood pressure at each specific point of time in the modeling process rather than using the initial blood pressure or the final blood pressure. The values of the following variables are recorded for each patient, if they are available. Otherwise, the variables contain missing values.

|        |                                                     |
|--------|-----------------------------------------------------|
| Time   | survival time                                       |
| Censor | censoring indicator (with 0 as the censoring value) |
| BP0    | blood pressure on entry to the study                |
| T1     | time 1                                              |
| BP1    | blood pressure at T1                                |
| T2     | time 2                                              |
| BP2    | blood pressure at T2                                |
| WT     | design weight                                       |
| PSU    | identification of primary sampling units            |

The following programming statements create a variable BP. At each time T, the value of BP is the blood pressure reading for that time, if available. Otherwise, it is the last blood pressure reading.

```
proc surveyphreg;
 weight WT;
 model Time*Censor(0)=BP;
 cluster PSU;
 BP = BP0;
 if Time>=T1 and T1^=. then BP=BP1;
 if Time>=T2 and T2^=. then BP=BP2;
run;
```

---

## REPWEIGHTS Statement

**REPWEIGHTS** *variables* *</ options >* ;

The REPWEIGHTS statement names variables that provide replicate weights for BRR or jackknife variance estimation, which you request with the **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** option in the PROC SURVEYPHREG statement. If you do not provide replicate weights for these methods by using a REPWEIGHTS statement, then PROC SURVEYPHREG constructs replicate weights for the analysis. See the sections “Balanced Repeated Replication (BRR) Method” on page 7896 and “Jackknife Method” on page 7899 for more information.

Each REPWEIGHTS variable should contain the weights for a single replicate, and the number of replicates equals the number of REPWEIGHTS variables. The REPWEIGHTS variables must be numeric, and the variable values must be nonnegative numbers.

If you provide replicate weights with a REPWEIGHTS statement, you do not need to specify a **CLUSTER** or **STRATA** statement. If you use a REPWEIGHTS statement and do not specify the **VARMETHOD=** option in the PROC SURVEYPHREG statement, the procedure uses **VARMETHOD=JACKKNIFE** by default.

If you specify a REPWEIGHTS statement but do not include a **WEIGHT** statement, PROC SURVEYPHREG uses the average of each observation’s replicate weights as the observation’s weight.

You can specify the following options in the REPWEIGHTS statement after a slash (/):

**DF=***df*

specifies the degrees of freedom for the analysis. The value of *df* must be a positive number. See the section “Degrees of Freedom” on page 7901 for details.

PROC SURVEYPHREG also use the DF= value in computing the denominator degrees of freedom for the *F* statistics in Wald type tests and confidence intervals.

**JKCOEFS=***jackknife-coefficient-specification*

specifies jackknife coefficients for **VARMETHOD=JACKKNIFE**. The default value for the jackknife coefficient is  $(R - 1)/R$ , where *R* is the total number of replicates. You can specify an alternative value with one of the following three forms:

**JKCOEFS=***value*

specifies a single jackknife coefficient for all replicates. The coefficient *value* must be a non-negative number.

**JKCOEFS=**(*values*)

specifies jackknife coefficients for **VARMETHOD=JACKKNIFE**, where each coefficient corresponds to an individual replicate identified by a REPWEIGHTS variable. You can separate *values* with blanks or commas. The coefficient *values* must be nonnegative numbers. The number of *values* must equal the number of replicate weight variables named in the REPWEIGHTS statement. List these values in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement.

**JKCOEFS=***SAS-data-set*

names a SAS data set that contains the jackknife coefficients for **VARMETHOD=JACKKNIFE**. You provide the jackknife coefficients in the JKCOEFS= data set variable JKCoefficient. Each coefficient value must be a nonnegative number. The observations in the JKCOEFS= data set should correspond to the replicates that are identified by the REPWEIGHTS variables. Arrange the coefficients or observations in the JKCOEFS= data set in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement. The number of observations in the JKCOEFS= data set must not be less than the number of REPWEIGHTS variables.

See the section “Jackknife Method” on page 7899 for details about jackknife coefficients.

---

## SLICE Statement

**SLICE** *model-effect* < / *options* > ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the LSMEANS statement, which are summarized in Table 19.21. For details about the syntax of the SLICE statement, see the section “SLICE Statement” on page 498 in Chapter 19, “Shared Concepts and Topics.”

---

## STORE Statement

**STORE** < **OUT=** > *item-store-name* < / **LABEL=** 'label' > ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “STORE Statement” on page 501 in Chapter 19, “Shared Concepts and Topics.”

---

## STRATA Statement

**STRATA** *variables* < / *option* > ;

The STRATA statement names variables that form the strata in a stratified sample design. The combinations of levels of STRATA variables define the strata in the sample, where strata are nonoverlapping subgroups that were sampled independently.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section “Specifying the Sample Design” on page 7891 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with a REPWEIGHTS statement, you do not need to specify a STRATA statement.

The STRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. The formatted values of the STRATA variables determine the STRATA variable levels. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in the *SAS Formats and Informats: Reference*. Strata variables must not occur in the CLASS statement.

The STRATA statement in PROC SURVEYPHREG is different from the STRATA statement in PROC PHREG (Chapter 67, “The PHREG Procedure”). PROC PHREG fits different baseline hazard functions in different strata, which is useful if the proportional hazards assumption is not satisfied.

You can specify the following option in the STRATA statement after a slash (/):

### LIST

displays a “Stratum Information” table, which lists all strata together with the corresponding values of the STRATA variables. This table provides the number of observations and the number of clusters in each stratum, as well as the sampling fraction if you specify the RATE= or TOTAL= option.

---

## TEST Statement

**TEST** < *model-effects* > < / *options* > ;

The TEST statement enables you to perform  $F$  tests for model effects that test Type I, Type II, or Type III hypotheses. See Chapter 15, “The Four Types of Estimable Functions,” for details about the construction of Type I, II, and III estimable functions.

Table 93.7 summarizes the options available in the TEST statement.

**Table 93.7** TEST Statement Options

| Option    | Description                                                |
|-----------|------------------------------------------------------------|
| CHISQ     | Requests chi-square tests                                  |
| DDF=      | Specifies denominator degrees of freedom for fixed effects |
| E         | Requests Type I, Type II, and Type III coefficients        |
| E1        | Requests Type I coefficients                               |
| E2        | Requests Type II coefficients                              |
| E3        | Requests Type III coefficients                             |
| HTYPE=    | Indicates the type of hypothesis test to perform           |
| INTERCEPT | Adds a row that corresponds to the overall intercept       |

For details about the syntax of the TEST statement, see the section “TEST Statement” on page 502 in Chapter 19, “Shared Concepts and Topics.”

## WEIGHT Statement

**WEIGHT** *variable* ;

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric, and the sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “Missing Values” on page 7893 for more information. The WEIGHT statement allows one weight variable.

If you do not specify a WEIGHT statement but provide replicate weights with a REPWEIGHTS statement, PROC SURVEYPHREG uses the average of each observation’s replicate weights as the observation’s weight.

If you specify neither a WEIGHT statement nor a REPWEIGHTS statement, PROC SURVEYPHREG assigns all observations a weight of one.

## Details: SURVEYPHREG Procedure

### Notation and Estimation

Let  $U = \{1, 2, \dots, N\}$  be the set of indices and let  $\mathcal{F}_N$  be the set of values for a finite population of size  $N$ . The survival time of each member of the finite population is assumed to follow its own hazard function,  $\lambda_i(t)$ , expressed as

$$\lambda_i(t) = \lambda(t; \mathbf{Z}_i(t)) = \lambda_0(t) \exp(\mathbf{Z}_i'(t)\boldsymbol{\beta})$$

where  $\lambda_0(t)$  is an arbitrary and unspecified baseline hazard function,  $\mathbf{Z}_i(t)$  is the vector of explanatory variables for the  $i$ th unit at time  $t$ , and  $\boldsymbol{\beta}$  is the vector of unknown regression parameters that are associated with the explanatory variables. The vector  $\boldsymbol{\beta}$  is assumed to be the same for all individuals.

The partial likelihood function introduced by Cox (1972, 1975) eliminates the unknown baseline hazard  $\lambda_0(t)$  and accounts for censored survival times. If the entire population is observed, then this partial likelihood can be used to estimate  $\boldsymbol{\beta}$ . Let  $\boldsymbol{\beta}_N$  be the desired estimator. Assuming a working model with uncorrelated responses,  $\boldsymbol{\beta}_N$  is obtained by maximizing the partial log likelihood,

$$l(\boldsymbol{\beta}) = \sum_{i \in U} \log \left\{ L(\boldsymbol{\beta}; \mathbf{Z}_i(t), t_i) \right\}$$

with respect to  $\boldsymbol{\beta}$ , where  $L(\boldsymbol{\beta}; \mathbf{Z}_i(t), t_i)$  is Cox's partial likelihood function.

Assume that probability sample  $A$  is selected from the finite population  $U$  and  $\pi_i$  is the selection probability for unit  $i$ . Further assume that covariates  $\mathbf{Z}_i(t)$  and survival time  $t_i$  are available for every unit in the sample  $A$ . An estimator of the finite population log likelihood is

$$l_\pi(\boldsymbol{\beta}) = \sum_{i \in A} \pi_i^{-1} \log \left\{ L(\boldsymbol{\beta}; \mathbf{Z}_i(t), t_i) \right\}$$

See “Partial Likelihood Function for the Cox Model” on page 7890 for more details.

A sample-based estimator  $\hat{\boldsymbol{\beta}}$  for the finite population quantity  $\boldsymbol{\beta}_N$  can be obtained by maximizing the partial pseudo-log-likelihood  $l_\pi(\boldsymbol{\beta}; \mathbf{Z}_i(t), t_i)$  with respect to  $\boldsymbol{\beta}$ . The design-based variance for  $\hat{\boldsymbol{\beta}}$  is obtained by assuming the set of finite population values  $\mathcal{F}_N$  as fixed. For more information about maximum pseudo-likelihood estimators and other inferential approaches for survey data, see Kish and Frankel (1974); Godambe and Thompson (1986); Pfeiffermann (1993), Korn and Graubard (1999, chapter 3), Chambers and Skinner (2003, chapter 2), and Fuller (2009, section 6.5). Maximum pseudo-likelihood estimators and their properties for Cox's proportional hazards model for survey data are discussed in Binder (1990, 1992); Lin and Wei (1989); Lin (2000); Boudreau and Lawless (2006).

Without loss of generality, the rest of this section uses indices for stratified clustered designs. For a stratified clustered sample design, observations are represented by a matrix

$$(\mathbf{w}, \mathbf{t}, \mathbf{\Delta}, \mathbf{Z}) = (w_{hij}, t_{hij}, \Delta_{hij}, \mathbf{z}_{hij})$$

where

- $\mathbf{w}$  denotes the vector of sampling weights
- $\mathbf{t}$  denotes the event time variable
- $\mathbf{\Delta}$  denotes the event indicator
- $\mathbf{Z}$  denotes the  $n \times p$  matrix of auxiliary information
- $h = 1, 2, \dots, H$  is the stratum index
- $i = 1, 2, \dots, n_h$  is the cluster index within stratum  $h$
- $j = 1, 2, \dots, m_{hi}$  is the unit index within cluster  $i$  of stratum  $h$
- $p$  is the total number of parameters
- $n = \sum_{h=1}^H \sum_{i=1}^{n_h} m_{hi}$  is the total number of observations in the sample
- $y_{hij}(t) = I(t_{hij} \geq t)$ , where  $I(\cdot)$  is an indicator function
- $n_{hij}(t) = I(t_{hij} \leq t)$ , where  $I(\cdot)$  is an indicator function

Let  $\sum_B = \sum_{(h,i,j) \in B}$  denote the summation over the set of indices such that the observation unit  $j$  in PSU  $i$  and stratum  $h$  belongs to the index set  $B$ . Typically,  $B$  is the set of all population indices that are in the sample, the risk set, or the set of all units with a failure.

The first-stage sampling rate (fraction of PSUs selected for the sample) is denoted by  $f_h$ . The first-stage sampling rate is used in Taylor series variance estimation. You can specify the stratum sampling rates with the `RATE=` option. Or if you specify population totals with the `TOTAL=` option, PROC SURVEYFREQ computes  $f_h$  as the ratio of stratum sample size to the stratum total, in terms of PSUs. See the section “Population Totals and Sampling Rates” on page 7892 for details. If you do not specify the `RATE=` option or the `TOTAL=` option, then the procedure assumes that the stratum sampling rates  $f_h$  are negligible and does not use a finite population correction when computing variances.

## Failure Time Distribution

Let  $T$  be a nonnegative random variable that represents the failure time of an individual from a homogeneous superpopulation. The survival distribution function (also known as the survivor function) of  $T$  is written as

$$S(t) = \Pr(T \geq t)$$

A mathematically equivalent way of specifying the distribution of  $T$  is through its hazard function. The hazard function  $\lambda(t)$  specifies the instantaneous failure rate at  $t$ . If  $T$  is a continuous random variable,  $\lambda(t)$  is expressed as

$$\lambda(t) = \lim_{\Delta t \rightarrow 0^+} \frac{\Pr(t \leq T < t + \Delta t \mid T \geq t)}{\Delta t} = \frac{f(t)}{S(t)}$$

where  $f(t)$  is the probability density function of  $T$ .

## Time and CLASS Variables Usage

The following DATA step creates an artificial data set, `Test`, to be used in this section. There are six variables in `Test`: the variable `T` contains the failure times; the variable `Status` is the censoring indicator variable with the value 1 for an uncensored failure time and the value 0 for a censored time; the variable `A` is a categorical variable with values 1, 2, and 3 representing three different categories; the variable `MirrorT` is an exact copy of `T`; the variable `W` is the observation weight; and the variable `S` is the strata indicator.

```
data Test;
 input T Status A W S @@;
 MirrorT = T;
 datalines;
23 1 1 10 1 7 0 1 20 2
23 1 1 10 1 10 1 1 20 2
20 0 1 10 1 13 0 1 20 2
24 1 1 10 1 10 1 1 20 2
18 1 2 10 1 6 1 2 20 2
18 0 2 10 1 6 1 2 20 2
13 0 2 10 1 13 1 2 20 2

 9 1 2 10 1 15 1 2 20 2
 3 1 2 10 1 14 0 3 20 2
 6 1 1 10 1 13 1 2 20 2
;

```

### Time Variable on the Right Side of the MODEL Statement

The time variable cannot be used explicitly as an explanatory effect in the MODEL statement. The following statements produce an error message:

```

proc surveypreg data=Test;
 weight W;
 strata S;
 class A;
 model T*Status(0)=T*A;
run;

```

To use the time variable as an explanatory effect, replace T by MirrorT as an effect, which is an exact copy of T, as in the following statements:

```

proc surveypreg data=Test;
 weight W;
 strata S;
 class A;
 model T*Status(0)=A*MirrorT;
run;

```

Note that neither T\*A nor MirrorT\*A in the MODEL statement is time-dependent. The results of fitting this model are shown in Figure 93.3.

**Figure 93.3** T\*A Effect

| The SURVEYPHREG Procedure                |    |            |                   |         |         |                 |

### CLASS Variables and Programming Statements

In PROC SURVEYPHREG, the levels of CLASS variables are determined by the CLASS statement and the input data and are not affected by user-supplied programming statements. Consider the following state-

ments, which produce the results in Figure 93.4. Variable A is declared as a CLASS variable in the CLASS statement.

```
proc surveypHreg data=Test;
 weight W;
 strata S;
 class A;
 model T*Status(0)=A;
run;
```

Figure 93.4 shows the parameters that correspond to A and their respective regression coefficients estimates.

**Figure 93.4** Design Variable and Regression Coefficient Estimates

| The SURVEYPHREG Procedure                |        |           |                |         |         |              |
|------------------------------------------|--------|-----------|----------------|---------|---------|--------------|
| Class Level Information                  |        |           |                |         |         |              |
| Class                                    | Levels | Values    |                |         |         |              |
| A                                        | 3      | 1         | 2              | 3       |         |              |
| Analysis of Maximum Likelihood Estimates |        |           |                |         |         |              |
| Parameter                                | DF     | Estimate  | Standard Error | t Value | Pr >  t | Hazard Ratio |
| A 1                                      | 30     | -1.162184 | 0.655136       | -1.77   | 0.0862  | 0.313        |
| A 2                                      | 30     | -0.616962 | 0.521841       | -1.18   | 0.2464  | 0.540        |
| A 3                                      | 30     | 0         | .              | .       | .       | 1.000        |

Now consider the programming statement that attempts to change the value of the CLASS variable A as in the following specification:

```
proc surveypHreg data=Test;
 weight W;
 strata S;
 class A;
 model T*Status(0)=A;
 if A=3 then A=2;
run;
```

Results of this analysis are shown in Figure 93.5 and are identical to those in Figure 93.4. The `if A=3 then A=2` programming statement has no effect on the explanatory variable for A, which have already been determined.

**Figure 93.5** Design Variable and Regression Coefficient Estimates

| The SURVEYPHREG Procedure                |        |           |                |         |         |              |
|------------------------------------------|--------|-----------|----------------|---------|---------|--------------|
| Class Level Information                  |        |           |                |         |         |              |
| Class                                    | Levels | Values    |                |         |         |              |
| A                                        | 3      | 1         | 2              | 3       |         |              |
| Analysis of Maximum Likelihood Estimates |        |           |                |         |         |              |
| Parameter                                | DF     | Estimate  | Standard Error | t Value | Pr >  t | Hazard Ratio |
| A 1                                      | 30     | -1.162184 | 0.655136       | -1.77   | 0.0862  | 0.313        |
| A 2                                      | 30     | -0.616962 | 0.521841       | -1.18   | 0.2464  | 0.540        |
| A 3                                      | 30     | 0         | .              | .       | .       | 1.000        |

Additionally any variable used in a programming statement that has already been declared in the CLASS statement is *not* treated as a collection of the corresponding design variables. Consider the following statements:

```
proc surveypreg data=Test;
 class A;
 model T*Status(0)=A X;
 X=T*A;
run;
```

The CLASS variable A generates two design variables as explanatory variables. The variable X created by the `X=T*A` programming statement is a single time-dependent covariate whose values are evaluated using the exact values of A given in the data, not the dummy coded values that represent A. In the data set Test, A has the values of 1, 2, and 3, and these values are multiplied by the values of T to produce X. If A were a character variable with values 'Bird', 'Cat', and 'Dog', the programming statement `X=T*A` would have produced an error in the attempt to multiply a number with a character value.

**Figure 93.6** Single Time-Dependent Variable X\*A

| The SURVEYPHREG Procedure                |    |          |                |         |         |              |
|------------------------------------------|----|----------|----------------|---------|---------|--------------|
| Analysis of Maximum Likelihood Estimates |    |          |                |         |         |              |
| Parameter                                | DF | Estimate | Standard Error | t Value | Pr >  t | Hazard Ratio |
| A 1                                      | 31 | 0.158010 | 1.222654       | 0.13    | 0.8980  | 1.171        |
| A 2                                      | 31 | 0.008993 | 0.674629       | 0.01    | 0.9894  | 1.009        |
| A 3                                      | 31 | 0        | .              | .       | .       | 1.000        |
| X                                        | 31 | 0.092679 | 0.073746       | 1.26    | 0.2182  | 1.097        |

The following statements are not the same as in the preceding program. If you want to create time-dependent covariates from the values of a CLASS variable, you could use syntax like the following:

```
proc surveypHreg data=Test;
 class A;
 model T*Status(0)=A X1 X2;
 X1= T*(A=1);
 X2= T*(A=2);
run;
```

The Boolean parenthetical expressions (A=1) and (A=2) resolve to a value of 1 or 0, depending on whether the expression is true or false, respectively.

Results of this test are shown in Figure 93.7.

**Figure 93.7** Simple Test of Proportional Hazards Assumption

| The SURVEYPHREG Procedure                |    |           |                |         |         |              |
|------------------------------------------|----|-----------|----------------|---------|---------|--------------|
| Analysis of Maximum Likelihood Estimates |    |           |                |         |         |              |
| Parameter                                | DF | Estimate  | Standard Error | t Value | Pr >  t | Hazard Ratio |
| A 1                                      | 31 | -0.007655 | 1.284875       | -0.01   | 0.9953  | 0.992        |
| A 2                                      | 31 | -0.881383 | 1.834533       | -0.48   | 0.6343  | 0.414        |
| A 3                                      | 31 | 0         | .              | .       | .       | 1.000        |
| X1                                       | 31 | -0.155220 | 0.172914       | -0.90   | 0.3763  | 0.856        |
| X2                                       | 31 | 0.011554  | 0.198796       | 0.06    | 0.9540  | 1.012        |

In general, when your model contains a categorical explanatory variable that is time-dependent, it might be necessary to use hardcoded dummy variables to represent the categories of the categorical variable.

## Partial Likelihood Function for the Cox Model

Let  $t_{(1)} < t_{(2)} < \dots < t_{(K)}$  denote the  $K$  distinct, ordered event times. Let  $d_k$  denote the multiplicity of failures at  $t_{(k)}$ ; that is,  $d_k$  is the size of the set  $\mathcal{D}_k$  of individuals that fail at  $t_{(k)}$ . Let  $w_{hij}$  be the weight associated with the  $j$ th observation unit in the  $i$ th cluster in stratum  $h$ . Using this notation, the pseudo-likelihood functions used in PROC SURVEYPHREG to estimate  $\beta_N$  are described in the following sections.

### Continuous Time Scale

Let  $\mathcal{R}_k$  denote the risk set just before the  $k$ th ordered event time  $t_{(k)}$ .

The Breslow likelihood is expressed as

$$L_{\text{Breslow}}(\beta) = \prod_{k=1}^K \frac{\exp(\beta' \sum_{\mathcal{D}_k} w_{hij} \mathbf{Z}_{hij}(t))}{\left\{ \sum_{\mathcal{R}_k} w_{hij} \exp(\beta' \mathbf{Z}_{hij}(t)) \right\}^{\sum_{\mathcal{D}_k} w_{hij}}}$$

The Efron likelihood is expressed as

$$L_{\text{Efron}}(\boldsymbol{\beta}) = \prod_{k=1}^K \frac{\exp(\boldsymbol{\beta}' \sum_{\mathcal{D}_k} w_{hij} \mathbf{Z}_{hij}(t))}{\{\phi(\boldsymbol{\beta}, \mathbf{Z}, \mathbf{w}, k)\}^{\frac{1}{d_k}} \sum_{\mathcal{D}_k} w_{hij}}$$

where  $\phi(\boldsymbol{\beta}, \mathbf{Z}, \mathbf{w}, k)$  is

$$\phi(\boldsymbol{\beta}, \mathbf{Z}, \mathbf{w}, k) = \prod_{l=1}^{d_k} \left\{ \sum_{\mathcal{R}_k} w_{hij} \exp(\boldsymbol{\beta}' \mathbf{Z}_{hij}(t)) - \frac{l-1}{d_k} \sum_{\mathcal{D}_k} w_{hij} \exp(\boldsymbol{\beta}' \mathbf{Z}_{hij}(t)) \right\}$$

## Specifying the Sample Design

PROC SURVEYPHREG produces statistics that are based on the sample design used to obtain the survey data. PROC SURVEYPHREG can be used for single-stage or multistage designs, with or without stratification, and with or without unequal weighting. To analyze your survey data with PROC SURVEYPHREG, you need to provide sample design information for the procedure. This information can include design (or variance) strata, clusters, and sampling weights. You provide sample design information with the **STRATA**, **CLUSTER**, and **WEIGHT** statements, and with the **RATE=** or **TOTAL=** option in the PROC SURVEYPHREG statement.

If you provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a **STRATA** or **CLUSTER** statement. Otherwise, you should specify **STRATA** and **CLUSTER** statements whenever your design includes stratification and clustering.

When there are clusters (PSUs) in the sample design, the procedure estimates variance by using the PSUs, as described in the section “[Variance Estimation](#)” on page 7895. For a multistage sample design, PROC SURVEYPHREG uses only the first stage of the sample design for variance estimation. So, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling.

### Stratification

If your sample design is stratified at the first stage of sampling, use the **STRATA** statement to name the variables that form the strata. The combinations of categories of **STRATA** variables define the strata in the sample, where strata are nonoverlapping subgroups that were sampled independently. If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the **STRATA** statement.

If you use a **REPWEIGHTS** statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a **STRATA** statement. Otherwise, you should specify a **STRATA** statement whenever your design includes stratification. If you do not specify a **STRATA** statement or a **REPWEIGHTS** statement, then PROC SURVEYPHREG assumes there is no stratification at the first stage. In other words, in this case, the procedure assumes that all observation units are in the same stratum.

### Clustering

If your sample design selects clusters at the first stage of sampling, use the **CLUSTER** statement to name the variables that identify the first-stage clusters, which are also called primary sampling units (PSUs). The combinations of categories of **CLUSTER** variables define the clusters in the sample. If there is a **STRATA**

statement, clusters are nested within strata. If your sample design has clustering at multiple stages, you should specify only the first-stage clusters (PSUs) in the CLUSTER statement. PROC SURVEYPHREG assumes that each cluster that is defined by the CLUSTER statement variables represents a PSU in the sample.

If you use a REPWEIGHTS statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a CLUSTER statement. Otherwise, you should specify a CLUSTER statement whenever your design includes clustering at the first stage of sampling. If you do not specify a CLUSTER statement, then PROC SURVEYPHREG treats each observation as a PSU.

## Weighting

If your sample design includes unequal weighting, use the WEIGHT statement to name the variable that contains the sampling weights. Sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “Missing Values” on page 7893 for more information.

If you do not specify a WEIGHT statement but include a REPWEIGHTS statement, PROC SURVEYPHREG uses the average of each observation’s replicate weights as the observation’s weight. If you specify neither a WEIGHT statement nor a REPWEIGHTS statement, PROC SURVEYPHREG assumes all observations have a weight of one.

## Population Totals and Sampling Rates

To include a finite population correction (*fpc*) in Taylor series variance estimation, you can input either the sampling rate or the population total by using the RATE= or TOTAL= option in the PROC SURVEYPHREG statement. You cannot specify both of these options in the same PROC SURVEYPHREG statement. The RATE= and TOTAL= options apply only to Taylor series variance estimation. The procedure does not use a finite population correction for BRR or jackknife variance estimation.

If you do not specify the RATE= or TOTAL= option, the Taylor series variance estimation does not include a finite population correction. For fairly small sampling fractions, this correction is often ignored. See Cochran (1977) and Kish (1965) for more information.

If your design has multiple stages of selection and you are specifying the RATE= option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the TOTAL= option for a multistage design, you should input the total number of PSUs in the study population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you can use the RATE=*value* or TOTAL=*value* option. If your sample design is stratified with different sampling rates or population totals in different strata, use the RATE=*SAS-data-set* or TOTAL=*SAS-data-set* option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the DATA= option.

The secondary data set must contain all the stratification variables listed in the STRATA statement and all the variables in the BY statement. Furthermore, the BY groups must appear in the same order as in the primary data set. If there are formats associated with the STRATA variables and the BY variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the TOTAL=*SAS-data-set* option, the secondary data set must have a variable named `_TOTAL_` that contains the stratum population

totals. If you specify the `RATE=SAS-data-set` option, the secondary data set must have a variable named `_RATE_` that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, the procedure uses the first value of `_TOTAL_` or `_RATE_` for that stratum and ignores the rest.

The *value* in the `RATE=` option or the values of `_RATE_` in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYPHREG converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

If you specify the `TOTAL=value` option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

---

## Missing Values

Missing values in your survey data can compromise the quality of your survey results. Some missing values for survey data are because of nonresponses. An observation whose response to every survey item is available is called a *complete respondent*, and an observation whose response to one or more survey items are missing is called an *incomplete respondent*. If the complete respondents are different from the incomplete respondents with regard to a survey effect or outcome, then survey estimates will be biased and will not accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. After data collection is complete, you can use imputation to replace missing values with acceptable values, and you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYPHREG. For more details, see Cochran (1977); Kalton and Kaspyzyk (1986); Brick and Kalton (1996).

### WEIGHT Variable

If an observation has a missing value or a nonpositive value for the `WEIGHT` variable, then PROC SURVEYPHREG excludes that observation from the analysis.

### REPWEIGHTS Variables

If you provide replicate weights with a `REPWEIGHTS` statement for BRR or jackknife variance estimation, all `REPWEIGHTS` variable values must be nonmissing. Similarly, if you provide jackknife coefficients with the `JKCOEFS=` option in the `REPWEIGHTS` statement, all values of the `JKCoefficient` variable must be nonmissing. The procedure does not perform the analysis when any replicate weight or jackknife coefficient value is missing.

### CLASS, STRATA, CLUSTER, and DOMAIN Variables

An observation is excluded from the analysis if it has a missing value for any `CLASS`, `STRATA`, `CLUSTER`, or `DOMAIN` variable, unless you specify the `MISSING` option in the PROC SURVEYPHREG statement. If you specify the `MISSING` option, the procedure treats missing values as a valid (nonmissing) category for all categorical variables, which include `STRATA` variables, `CLUSTER` variables, `CLASS` variables, and `DOMAIN` variables.

## Analysis Variables

By default, PROC SURVEYPHREG excludes an observation from the likelihood estimation and all associated analyses if the observation has a missing value for any of the variables in the **MODEL** statement, unless you specify the **MISSING** or **NOMCAR** option in the PROC SURVEYPHREG statement. When the procedure excludes observations with missing values from analyses, it displays the total frequency of observations used in the “NObs” table.

If you specify time-dependent covariates by using **programming statements**, the procedure computes the values of the covariates for all observations in the risk set at every event time. If an observation contains missing values for any of the time-dependent covariates at a given event time, then the observation is not used at that event time. However, that same observation can be used at some other event times where it contains no missing values. Therefore, an observation with missing time-dependent covariates can be used at some event times but ignored at other event times, depending on whether any of the corresponding time-dependent covariates are missing.

If you specify the **MISSING** option, the procedure treats missing levels as a valid (nonmissing) level for each categorical analysis variable.

If you specify the **NOMCAR** option for Taylor series variance estimation, the procedure includes observations with missing values of analysis variables in the variance computations.

## The NOMCAR Option

When you specify the **NOMCAR** option, PROC SURVEYPHREG computes variance estimates by analyzing the nonmissing values for variables in the regression model as a domain or subpopulation, where the entire population includes both nonmissing and missing domains. By default, if an observation contains missing values for the dependent variable or for any variable used in the independent effects, the observation is excluded from the analysis. See the section “**Missing Values**” on page 7893 for more information.

Note that the **NOMCAR** option has no effect on categorical predictors when you specify the **MISSING** option, which treats missing values as a valid nonmissing level. The **NOMCAR** option does not affect the inclusion of observations with missing values of the **WEIGHT**, **FREQ**, **CLUSTER**, **STRATA**, or **DOMAIN** variables. Observations with missing values of the **WEIGHT** and **FREQ** variables are always excluded from the analysis. Observations with missing values of the **CLUSTER**, **DOMAIN**, or **STRATA** variables are excluded unless you specify the **MISSING** option.

The **NOMCAR** option applies only to Taylor series variance estimation. The replication methods, which you request with the **VARMETHOD=BRR** and **VARMETHOD=JACKKNIFE** options, do not use the **NOMCAR** option.

## Degrees of Freedom

PROC SURVEYPHREG computes degrees of freedom to compute confidence limits and  $F$  statistics. The degrees of freedom computation depends on the variance estimation method that you request. See the section “**Degrees of Freedom**” on page 7901 for details. Missing values can affect the degrees of freedom computation.

### **Taylor Series Variance Estimation**

The degrees of freedom can depend on the number of clusters, the number of strata, and the number of observations. For Taylor series variance estimation, these numbers are based on the observations included

in the analysis. These numbers do not count observations that are excluded from the analysis due to missing values. If all values in a stratum are excluded from the analysis as missing values, then that stratum is called an *empty stratum*. Empty strata are not counted in the total number of strata for the analysis. Similarly, empty clusters and missing observations are not included in the totals counts of clusters and observations that are used to compute the degrees of freedom for the analysis.

If you specify the **MISSING** option, missing values are treated as valid nonmissing levels and are included in computing degrees of freedom. If you specify the **NOMCAR** option for Taylor series variance estimation, observations with missing values for variables in the regression model are included in computing degrees of freedom.

### Replicate-Based Variance Estimation

For BRR or jackknife variance estimation, by default PROC SURVEYPHREG computes the degrees of freedom by using all valid observations in the input data set. A valid observation is an observation that has a positive value of the **WEIGHT** variable and nonmissing values of the **STRATA** and **CLUSTER** variables unless you specify the **MISSING** option.

---

## Variance Estimation

PROC SURVEYPHREG uses the Taylor series method or replication (resampling) methods to estimate sampling errors of estimators that are based on complex sample designs (Fuller 1975; Särndal, Swensson, and Wretman 1992; Wolter 2007; Rust 1985; Dippo, Fay, and Morganstein 1984; Rao and Shao 1999, 1996; and Binder 1992). You can use the **VARMETHOD=** option in the PROC statement to specify the variance estimation method. By default, PROC SURVEYPHREG uses the Taylor series method.

However, replication methods have recently gained popularity for estimating variances in complex survey data analysis. One reason for this popularity is the relative simplicity of replication-based estimates, especially for nonlinear estimators; another is that modern computational capacity has made replication methods feasible for practical survey analysis.

Replication methods draw multiple replicates (also called subsamples) from a full sample according to a specific resampling scheme. The most commonly used resampling schemes are the *balanced repeated replication* (BRR) method and the *jackknife* method. For each replicate, the original weights are modified for the PSUs in the replicates to create replicate weights. The parameters of interest are estimated by using the replicate weights for each replicate. Then the variances of parameters of interest are estimated by the variability among the estimates derived from these replicates. The procedure automatically creates replicate weights based on the replication method you specify; alternatively you can use the **REPWEIGHTS** statement to provide your own replicate weights for variance estimation.

The following sections provide details about how the variance-covariance matrix of the estimated regression coefficients is estimated for each variance estimation method.

### Taylor Series Linearization

The Taylor series linearization method is the default variance estimation method used by PROC SURVEYPHREG. See the section “**Notation and Estimation**” on page 7884 for definitions of the notation used in this section. Let

$$S^{(r)}(\boldsymbol{\beta}, t) = \sum_A w_{hij} y_{hij}(t) \exp(\boldsymbol{\beta}' \mathbf{Z}_{hij}(t)) \mathbf{Z}_{hij}^{\otimes r}(t)$$

where  $r = 0, 1$ . Let  $A$  be the set of indices in the selected sample. Let

$$\mathbf{a}^{\otimes r} = \begin{cases} \mathbf{a}\mathbf{a}' & , r = 1 \\ I_{\dim(\mathbf{a})} & , r = 0 \end{cases}$$

and let  $I_{\dim(\mathbf{a})}$  be the identity matrix of appropriate dimension.

Let  $\bar{\mathbf{Z}}(\boldsymbol{\beta}, t) = \frac{S^{(1)}(\boldsymbol{\beta}, t)}{S^{(0)}(\boldsymbol{\beta}, t)}$ . The score residual for the  $(h, i, j)$  subject is

$$\begin{aligned} \mathbf{L}_{hij}(\boldsymbol{\beta}) &= \Delta_{hij} \left\{ \mathbf{Z}_{hij}(t_{hij}) - \bar{\mathbf{Z}}(\boldsymbol{\beta}, t_{hij}) \right\} \\ &\quad - \sum_{(h', i', j') \in A} \Delta_{h'i'j'} \frac{w_{h'i'j'} Y_{hij}(t_{h'i'j'}) \exp(\boldsymbol{\beta}' \mathbf{Z}_{hij}(t_{h'i'j'}))}{S^{(0)}(\boldsymbol{\beta}, t_{h'i'j'})} \left\{ \mathbf{Z}_{hij}(t_{h'i'j'}) - \bar{\mathbf{Z}}(\boldsymbol{\beta}, t_{h'i'j'}) \right\} \end{aligned}$$

For TIES=EFRON, the computation of the score residuals is modified to comply with the Efron partial likelihood. See the section “Residuals” on page 7906 for more information.

The Taylor series estimate of the covariance matrix of  $\hat{\boldsymbol{\beta}}$  is

$$\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) = \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}}) \mathbf{G} \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})$$

where  $\mathcal{I}(\hat{\boldsymbol{\beta}})$  is the observed information matrix and the  $p \times p$  matrix  $\mathbf{G}$  is defined as

$$\mathbf{G} = \frac{n-1}{n-p} \sum_{h=1}^H \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (\mathbf{e}_{hi+} - \bar{\mathbf{e}}_{h..})' (\mathbf{e}_{hi+} - \bar{\mathbf{e}}_{h..})$$

The observed residuals, their sums and means are defined as follows:

$$\begin{aligned} \mathbf{e}_{hij} &= w_{hij} \mathbf{L}_{hij}(\hat{\boldsymbol{\beta}}) \\ \mathbf{e}_{hi+} &= \sum_{j=1}^{m_{hi}} \mathbf{e}_{hij} \\ \bar{\mathbf{e}}_{h..} &= \frac{1}{n_h} \sum_{i=1}^{n_h} \mathbf{e}_{hi+} \end{aligned}$$

The factor  $(n-1)/(n-p)$  in the computation of the matrix  $\mathbf{G}$  reduces the small sample bias that is associated with using the estimated function to calculate deviations (Fuller et al. (1989), pp. 77–81). For simple random sampling, this factor contributes to the degrees of freedom correction applied to the residual mean square for ordinary least squares in which  $p$  parameters are estimated. By default, the procedure uses this adjustment in the variance estimation. If you do not want to use this multiplier in the variance estimator, then specify the VADJUST=NONE option in the MODEL statement.

### Balanced Repeated Replication (BRR) Method

The balanced repeated replication (BRR) method requires that the full sample be drawn by using a stratified sample design with two primary sampling units (PSUs) per stratum. The BRR method constructs half-sample replicates by deleting one PSU per stratum according to a Hadamard matrix and doubling the original

weight of the other PSU in that stratum. Let  $H$  be the total number of strata. The total number of replicates  $R$  is the smallest multiple of 4 that is greater than  $H$ . However, if you prefer a larger number of replicates, you can specify the `REPS= $n$  method-option`. If a  $n \times n$  Hadamard matrix cannot be constructed, the number of replicates is increased until a Hadamard matrix becomes available.

Each replicate is obtained by deleting one PSU per stratum according to a corresponding Hadamard matrix and adjusting the original weights for the remaining PSUs. The new weights are called replicate weights.

Replicates are constructed by using the first  $H$  columns of the  $R \times R$  Hadamard matrix. The  $r$ th ( $r = 1, 2, \dots, R$ ) replicate is drawn from the full sample according to the  $r$ th row of the Hadamard matrix as follows:

- If the  $(r, h)$  element of the Hadamard matrix is 1, then the first PSU of stratum  $h$  is included in the  $r$ th replicate and the second PSU of stratum  $h$  is excluded.
- If the  $(r, h)$  element of the Hadamard matrix is  $-1$ , then the second PSU of stratum  $h$  is included in the  $r$ th replicate and the first PSU of stratum  $h$  is excluded.

The replicate weights of the remaining PSUs in each half sample are then doubled to their original weights. For more detail about the BRR method, see Wolter (2007) and Lohr (2010).

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can display the Hadamard matrix by specifying the `VARMETHOD=BRR(PRINTH) method-option`. If you provide a Hadamard matrix by specifying the `VARMETHOD=BRR(HADAMARD=) method-option`, then the replicates are generated according to the provided Hadamard matrix. You can use the `VARMETHOD=BRR(OUTWEIGHTS=) method-option` to store the replicate weights in a SAS data set.

Let  $\hat{\beta}$  be the estimated proportional hazards regression coefficients from the full sample, and let  $\hat{\beta}_r$  be the estimated proportional hazards regression coefficients from the  $r$ th replicate by using replicate weights. PROC SURVEYPHREG estimates the covariance matrix of  $\hat{\beta}$  by

$$\widehat{V}(\hat{\beta}) = \frac{1}{R} \sum_{r=1}^R (\hat{\beta}_r - \hat{\beta}) (\hat{\beta}_r - \hat{\beta})'$$

with  $H$  degrees of freedom, where  $H$  is the number of strata.

If you specify the `CENTER=REPLICATES method-option`, then PROC SURVEYPHREG computes the covariance matrix of  $\hat{\beta}$  by

$$\widehat{V}(\hat{\beta}) = \frac{1}{R} \sum_{r=1}^R (\hat{\beta}_r - \overline{\hat{\beta}}_r) (\hat{\beta}_r - \overline{\hat{\beta}}_r)'$$

where  $\overline{\hat{\beta}}_r$  is the average of the replicate estimates as follows:

$$\overline{\hat{\beta}}_r = \frac{1}{R} \sum_{r=1}^R \hat{\beta}_r$$

If one or more components of  $\hat{\beta}_r$  cannot be calculated for some replicates, then the variance estimate is computed by using only the replicates for which the proportional hazards regression coefficients can

be estimated. Estimability and nonconvergence are the two most common reasons why  $\hat{\beta}_r$  might not be available for a replicate sample even if  $\hat{\beta}$  is defined for the full sample. Let  $R_a$  be the number of replicates where  $\hat{\beta}_r$  is available, and let  $R - R_a$  be the number of replicates where  $\hat{\beta}_r$  is not available. Without loss of generality, assume that  $\hat{\beta}_r$  is available only for the first  $R_a$  replicates; then the BRR variance estimator is

$$\widehat{V}(\hat{\beta}) = \frac{1}{R_a} \sum_{r=1}^{R_a} (\hat{\beta}_r - \hat{\beta})(\hat{\beta}_r - \hat{\beta})'$$

with degrees of freedom equal to the minimum of  $H$  and  $R_a$ , where  $H$  is the number of strata. Alternatively, you can use the `FAY=method-option` to request Fay's BRR method, as discussed in the following section.

### Fay's BRR Method

The traditional BRR method constructs half-sample replicates by deleting one PSU per stratum according to a Hadamard matrix and doubling the original weight of the other PSU. Fay's BRR method uses the Fay coefficient,  $\epsilon$  ( $0 \leq \epsilon < 1$ ), and instead of deleting one PSU per stratum, it multiplies the original weight by the coefficient  $\epsilon$ . The original weight of the remaining PSU in that stratum is multiplied by  $2 - \epsilon$ . PROC SURVEYPHREG uses  $\epsilon = 0.5$  as the default value; alternatively, you can specify a value for  $\epsilon$  with the `FAY=method-option`. When  $\epsilon = 0$ , Fay's method becomes the traditional BRR method. For more details, see Dipppo, Fay, and Morganstein (1984); Fay (1984, 1989); Judkins (1990). Because the traditional BRR method uses only half of the total sample in every replicate, several replicate estimators ( $\hat{\beta}_r$ ) might be undefined even when the full sample estimator ( $\hat{\beta}$ ) is defined. Fay's BRR method is especially useful for this situation because it uses all the sampled units in every replicate.

Let  $\hat{\beta}$  be the estimated proportional hazards regression coefficients from the full sample, and let  $\hat{\beta}_r$  be the estimated regression coefficients that are obtained from the  $r$ th replicate by using replicate weights. PROC SURVEYPHREG estimates the covariance matrix of  $\hat{\beta}$  by

$$\widehat{V}(\hat{\beta}) = \frac{1}{R(1-\epsilon)^2} \sum_{r=1}^R (\hat{\beta}_r - \hat{\beta})(\hat{\beta}_r - \hat{\beta})'$$

with  $H$  degrees of freedom, where  $H$  is the number of strata.

### Hadamard Matrix

PROC SURVEYPHREG uses a Hadamard matrix to construct replicates for BRR variance estimation. You can provide a Hadamard matrix for replicate construction by using the `HADAMARD=method-option` for `VARMETHOD=BRR`. Otherwise, PROC SURVEYPHREG generates an appropriate Hadamard matrix. You can display the Hadamard matrix by specifying the `PRINTH method-option`.

A Hadamard matrix  $\mathbf{A}$  of dimension  $R$  is a square matrix that has all elements equal to 1 or  $-1$  such that  $\mathbf{A}'\mathbf{A} = R\mathbf{I}$ , where  $\mathbf{I}$  is an identity matrix of appropriate order. The dimension of a Hadamard matrix must equal 1, 2, or a multiple of 4.

For example, the following matrix is a Hadamard matrix of dimension  $k = 8$ :

$$\begin{matrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 & 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 & 1 & -1 & -1 & 1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & -1 & 1 & -1 & -1 & 1 & -1 & 1 \\ 1 & 1 & -1 & -1 & -1 & -1 & 1 & 1 \\ 1 & -1 & -1 & 1 & -1 & 1 & 1 & -1 \end{matrix}$$

For BRR replicate construction, the dimension of the Hadamard matrix must be at least  $H$ , where  $H$  denotes the number of first-stage strata in your design. If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the `HADAMARD=method-option`. You must ensure that the matrix that you provide is actually a Hadamard matrix; PROC SURVEYPHREG does not check the validity of your Hadamard matrix.

See the section “Balanced Repeated Replication (BRR) Method” on page 7896 for details about how the Hadamard matrix is used to construct replicates for BRR variance estimation.

## Jackknife Method

The jackknife method of variance estimation deletes one PSU at a time from the full sample to create replicates. This method is also known as the delete-1 jackknife method because it deletes exactly one PSU in every replicate. The total number of replicates  $R$  is the same as the total number of PSUs. In each replicate, the sampling weights of the remaining PSUs are modified by the *jackknife coefficient*  $\alpha_r$ . The modified weights are called replicate weights.

Let PSU  $i$  in stratum  $h_r$  be omitted for the  $r$ th replicate; then the jackknife coefficient and replicate weights are computed as

$$\alpha_r = \begin{cases} \frac{n_{hr}-1}{n_{hr}} & \text{for a stratified design} \\ \frac{R-1}{R} & \text{for designs without stratification} \end{cases}$$

and

$$w_{hij}^{(r)} = \begin{cases} w_{hij} & \text{if observation unit } j \text{ is not in donor stratum } h_r \\ 0 & \text{if observation unit } j \text{ is in PSU } i \text{ of donor stratum } h_r \\ w_{hij}/\alpha_r & \text{if observation unit } j \text{ is not in PSU } i \text{ but in donor stratum } h_r \end{cases}$$

You can use the `VARMETHOD=JACKKNIFE(OUTJKCOEFS=)` *method-option* to store the jackknife coefficients in a SAS data set and use the `VARMETHOD=JACKKNIFE(OUTWEIGHTS=)` *method-option* to store the replicate weights in a SAS data set.

If you provide your own replicate weights with a `REPWEIGHTS` statement, then you can also provide corresponding jackknife coefficients with the `JKCOEFS=` option. If you provide replicate weights with a `REPWEIGHTS` statement but do not provide jackknife coefficients, then the procedure uses  $(R - 1)/R$  as the default jackknife coefficient for every replicate, where  $R$  is the total number of replicates.

Let  $\hat{\beta}$  be the estimated proportional hazards regression coefficients from the full sample, and let  $\hat{\beta}_r$  be the estimated regression coefficients for the  $r$ th replicate. PROC SURVEYPHREG estimates the covariance matrix of  $\hat{\beta}$  by

$$\widehat{V}(\hat{\beta}) = \sum_{r=1}^R \alpha_r (\hat{\beta}_r - \hat{\beta}) (\hat{\beta}_r - \hat{\beta})'$$

with  $R - H$  degrees of freedom, where  $R$  is the number of replicates and  $H$  is the number of strata, or  $R - 1$  when there is no stratification.

If you specify the `CENTER=REPLICATES` *method-option*, then PROC SURVEYPHREG computes the covariance matrix of  $\hat{\beta}$  by

$$\widehat{V}(\hat{\beta}) = \sum_{r=1}^R \alpha_r (\hat{\beta}_r - \overline{\hat{\beta}_r}) (\hat{\beta}_r - \overline{\hat{\beta}_r})'$$

where  $\overline{\hat{\beta}_r}$  is the average of the replicate estimates as follows:

$$\overline{\hat{\beta}_r} = \frac{1}{R} \sum_{r=1}^R \hat{\beta}_r$$

If one or more components of  $\hat{\beta}_r$  cannot be calculated for some replicates, then the variance estimator uses only the replicates for which the proportional hazards regression coefficients can be estimated. Estimability and nonconvergence are two common reasons why  $\hat{\beta}_r$  might not be available for a replicate sample even if  $\hat{\beta}$  is defined for the full sample. Let  $R_a$  be the number of replicates where  $\hat{\beta}_r$  are available, and let  $R - R_a$  be the number of replicates where  $\hat{\beta}_r$  are not available. Without loss of generality, assume that  $\hat{\beta}_r$  is available only for the first  $R_a$  replicates; then the jackknife variance estimator is

$$\widehat{V}(\hat{\beta}) = \sum_{r=1}^{R_a} \alpha_r (\hat{\beta}_r - \hat{\beta}) (\hat{\beta}_r - \hat{\beta})'$$

with  $R_a - H$  degrees of freedom, where  $H$  is the number of strata. Alternatively, you can use the `VADJUST=AVGREPSS` option in the MODEL statement to use the average sum of squares for the invalid replicate samples. See “[Variance Adjustment Factors](#)” on page 7902 for details.

## Degrees of Freedom

PROC SURVEYPHREG uses the degrees of freedom of the variance estimator to obtain  $t$  confidence limits and Wald type  $F$  tests. PROC SURVEYPHREG computes the degrees of freedom based on the variance estimation method and the sample design. Alternatively, you can specify the degrees of freedom in the **DF=** option in the **MODEL** statement.

For Taylor series variance estimation, PROC SURVEYPHREG calculates the degrees of freedom ( $df$ ) as the number of clusters minus the number of strata. If the **CLUSTER** statement is not specified, then the procedure treats each observation as a cluster. If the **STRATA** statement is not specified, then the procedure assumes that all observations are in the same stratum. These numbers are based on the observations included in the analysis. These numbers do not count observations that are excluded from the analysis due to missing values. See the section “Missing Values” on page 7893 for details. If you specify the **MISSING** option in the **CLASS** statement, missing values are treated as valid nonmissing levels and are included in computing degrees of freedom. If you specify the **NOMCAR** option for Taylor series variance estimation, observations with missing values of the analysis variables are included in computing the degrees of freedom.

If you provide replicate weights with a **REPWEIGHTS** statement, the degrees of freedom is equal the number of replicates used, which is the number of **REPWEIGHTS** variables that provide replicate estimates. Alternatively, you can specify the degrees of freedom in the **DF=** option in the **REPWEIGHTS** or **MODEL** statement.

For BRR variance estimation (when you do not use a **REPWEIGHTS** statement), PROC SURVEYPHREG calculates the degrees of freedom as the number of strata. PROC SURVEYPHREG bases the number of strata on all valid observations in the data set. If some replicate samples are not usable in the sense that these replicate samples cannot be used for parameter estimation (say, for nonconvergence or inestimability), then  $df$  equals the minimum of the number of strata and the number of replicates used. Alternatively, you can use the **DF=ALLREPS** option in the **MODEL** statement to specify that  $df$  equals the number of strata.

For jackknife variance estimation (when you do not use a **REPWEIGHTS** statement), PROC SURVEYPHREG calculates the degrees of freedom as the number of clusters minus the number of strata. If the **CLUSTER** statement is not specified, then the procedure treats each observation as a cluster. If the **STRATA** statement is not specified, then the procedure assumes that all observations are in the same stratum. For jackknife variance estimation, PROC SURVEYPHREG bases the number of strata and clusters on all valid observations in the data set. If some replicate samples are not usable in the sense that these replicate samples cannot be used for parameter estimation (say, for nonconvergence or inestimability), then  $df$  equals the number of clusters (or observations if no **CLUSTER** statement is specified) minus the number of strata (or one in if no **STRATA** statement is specified) minus the number of replicate samples that are not used. Alternatively, you can use the **DF=ALLREPS** option in the **MODEL** statement to specify that  $df$  equals the number of clusters minus the number of strata.

## Variance Adjustment Factors

PROC SURVEYPHREG provides options for adjustment of the default variance estimators. VADJUST=NONE and VADJUST=DF are available for the Taylor series linearization variance estimator. VADJUST=AVGREPSS is available for the jackknife replication variance estimators.

For models with large number of parameters, it is reasonable to adjust the Taylor series linearized variance estimator by the number of estimable parameters in the analysis model. Fuller et al. (1989, pp. 77–81) use an adjustment factor  $(n - 1)/(n - p)$  to estimate the linearized variance for regression coefficients, where  $n$  is the total number of observation units and  $p$  is the number of estimable parameters in the analysis model. By default, PROC SURVEYPHREG uses this adjustment in the computation of the matrix  $\mathbf{G}$  for the Taylor series linearization **variance estimation**. If you do not want to use this adjustment, then specify VADJUST=NONE.

Variance adjustment factors can be useful for replication variance estimations, especially if some replicate samples are not usable. A replicate sample might not provide useful parameter estimates (replicate estimates) for reasons such as nonconvergence of the optimization or inestimability of some parameters in that subsample. For example, consider the **jackknife variance estimator** with  $R$  replicates. Suppose that only  $R_a (< R)$  replicates are used to obtain replicate estimates and  $R - R_a$  replicates cannot be used due to, say, nonconvergence of the optimization. Without loss of generality, assume that the first  $R_a$  replicates are used. By default SURVEYPHREG uses

$$\widehat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) = \sum_{r=1}^{R_a} \alpha_r (\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}}) (\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}})'$$

as the jackknife variance estimator. An alternative estimator is

$$\begin{aligned} \widehat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) &= \sum_{r=1}^{R_a} \alpha_r (\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}}) (\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}})' + (R - R_a) \left\{ \frac{1}{R_a} \sum_{r=1}^{R_a} \alpha_r (\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}}) (\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}})' \right\} \\ &= \frac{R}{R_a} \sum_{r=1}^{R_a} \alpha_r (\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}}) (\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}})' \end{aligned}$$

which uses the average replicate sum of squares for the  $R - R_a$  unusable replicate samples. If you specify the VADJUST=AVGREPSS option, PROC SURVEYPHREG uses the second variance estimator for the jackknife replication method. Note that you can specify the **FAY method-option** for the BRR method to avoid nonconvergence of the optimization or inestimability of some parameters in subsamples.

## Variance Ratios and Standard Error Ratios

PROC SURVEYPHREG provides options to compute different variance ratios and standard error ratios.

If you specify the VARRATIO=MODEL option, then the procedure computes the variance ratio of the estimated regression parameter  $\hat{\beta}_j$  as  $\frac{\widehat{V}(\hat{\beta}_j)}{\widehat{V}_M(\hat{\beta}_j)}$ , where  $\widehat{V}(\hat{\beta}_j)$ , the estimated variance of  $\hat{\beta}_j$ , uses the complete design information and  $\widehat{V}_M(\hat{\beta}_j)$  is the  $j$ th diagonal element of the observed information matrix  $\mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})$ .

If you specify the VARRATIO=IND option, then the procedure computes the variance ratio of the estimated regression parameter  $\hat{\beta}_j$  as  $\frac{\widehat{V}(\hat{\beta}_j)}{\widehat{V}_{\text{IND}}(\hat{\beta}_j)}$ , where  $\widehat{V}(\hat{\beta}_j)$ , the estimated variance of  $\hat{\beta}_j$ , uses the complete design information and  $\widehat{V}_{\text{IND}}(\hat{\beta}_j)$  is the  $j$ th diagonal element of  $\widehat{V}_{\text{IND}}(\hat{\boldsymbol{\beta}})$ .  $\widehat{V}_{\text{IND}}(\hat{\boldsymbol{\beta}})$  is the sandwich variance

estimator, which ignores the strata and the clusters and is computed as

$$\hat{V}_{\text{IND}}(\hat{\beta}) = \mathcal{I}^{-1}(\hat{\beta}) \left\{ \frac{n}{n-1} (1-f) \sum_h \sum_i \sum_j (e_{hij} - \bar{e}_{\dots})' (e_{hij} - \bar{e}_{\dots}) \right\} \mathcal{I}^{-1}(\hat{\beta})$$

where  $e_{hij}$  are the weighted score residuals,  $f$  is the overall sampling fraction, and  $n$  is the number of observation units. The three sums are over the observation units ( $j$ ) across the PSUs ( $i$ ) and the strata ( $h$ ).

For Taylor series variance estimation, PROC SURVEYPHREG determines the value of  $f$ , the overall sampling fraction, based on the **RATE=** or **TOTAL=** option. If you do not specify either of these options, PROC SURVEYPHREG assumes that the value of  $f$  is negligible and does not use a finite population correction in the analysis. If you specify **RATE=value**, PROC SURVEYPHREG uses *value* as the overall sampling fraction  $f$ . If you specify **TOTAL=value**, PROC SURVEYPHREG computes  $f$  as the ratio of the number of PSUs in the sample to the specified total.

If you specify stratum sampling rates by using the **RATE=SAS-data-set** option, then PROC SURVEYPHREG computes stratum totals based on these stratum sampling rates and the number of sample PSUs in each stratum. The procedure sums the stratum totals to form the overall total and then computes  $f$  as the ratio of the number of sample PSUs to the overall total. Alternatively, if you specify stratum totals with the **TOTAL=SAS-data-set** option, then PROC SURVEYPHREG sums these totals to compute the overall total. The overall sampling fraction  $f$  is then computed as the ratio of the number of sample PSUs to the overall total.

The replication methods do not use the finite population correction factor  $(1 - f)$  in the denominator.

Standard error ratios are computed as the square root of the variance ratios.

---

## Domain Analysis

*Domain analysis* refers to the computation of statistics for domains (subpopulations). Formation of subpopulations can be unrelated to the sample design, and so the domain sample sizes can actually be random variables. Domain analysis takes this variability into account to compute variance estimates for estimated model parameters. Domain analysis is also known as subgroup analysis, subpopulation analysis, and subdomain analysis. For more information about domain analysis, see Lohr (2010); Särndal, Swensson, and Wretman (1992); Cochran (1977).

To request domain analysis with PROC SURVEYPHREG, use the **DOMAIN** statement. If your domains are formed by more than one variable, you can specify **DomainVariable\_1 \* DomainVariable\_2** in the **DOMAIN** statement. If you use the **DOMAIN** statement, the procedure performs separate analyses for all domains, in addition to the overall analysis.

Including the domain variables in a **DOMAIN** statement request provides a different analysis from that obtained by using a **BY** statement, which provides completely separate analyses of the **BY** groups. The **BY** statement can also be used to analyze the data set by subgroups, but it is critical to note that this does *not* account for random sample sizes that often occur for domain analyses. The **BY** statement is appropriate only when the number of units in each subgroup is known with certainty. For example, the **BY** statement can be used to obtain stratum level estimates when you have fixed sample sizes for the strata. When the subgroup sample size is random, include the domain variables in **DOMAIN** statement.

## Hypothesis Tests, Confidence Intervals, and Residuals

### Testing the Global Null Hypothesis

The following statistics can be used to test the global null hypothesis  $H_0: \boldsymbol{\beta} = \mathbf{0}$ . Let  $d$  be the number of clusters (or observations) minus the number of strata (or one) and  $p$  be the number of estimable parameters in the analysis model.

The likelihood ratio test is expressed as

$$\chi_{LR}^2 = 2 \left[ \log \{L(\hat{\boldsymbol{\beta}})\} - \log \{L(\mathbf{0})\} \right]$$

where  $L(\cdot)$  denotes the partial pseudo-likelihood described in “[Partial Likelihood Function for the Cox Model](#)” on page 7890. The  $p$ -value is computed by using a chi-square distribution with  $p$  degrees of freedom. The usual assumptions required for a likelihood ratio test do not hold for the pseudo-likelihood that is used by PROC SURVEYPHREG, leading to other methods for testing the global null hypothesis, such as the Wald test discussed below.

Wald’s test is expressed as

$$W_F = \left( \frac{d - p + 1}{dp} \right) \hat{\boldsymbol{\beta}}' \left[ \widehat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) \right]^{-1} \hat{\boldsymbol{\beta}}$$

The  $p$ -value is computed by using an  $F$  distribution with  $(p, d)$  degrees of freedom. For the Taylor series linearization method, the `DF=PARMADJ` option in the MODEL statement computes the  $p$ -value by using an  $F$  distribution with  $(p, d - p + 1)$  degrees of freedom.

If you specify the `DF=NONE` option in the MODEL statement, then the procedure computes

$$W_{\chi^2} = \hat{\boldsymbol{\beta}}' \left[ \widehat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) \right]^{-1} \hat{\boldsymbol{\beta}}$$

and the  $p$ -value is computed by using a chi-square distribution with  $p$  degrees of freedom.

### Model Fit Statistics

Suppose the model contains  $p$  estimable parameters. Then the following two criteria are displayed for model fit statistics:

- $-2 \log$  likelihood:

$$-2 \text{ Log L} = -2 \log(L(\hat{\boldsymbol{\beta}}))$$

where  $L(\cdot)$  is a partial pseudo-likelihood function for the corresponding `TIES=` option as described in the section “[Partial Likelihood Function for the Cox Model](#)” on page 7890, and  $\hat{\boldsymbol{\beta}}$  is the maximum pseudo-log-likelihood estimate of the proportional hazards regression coefficients.

- Akaike’s information criterion (AIC):

$$\text{AIC} = -2 \text{ Log L} + 2p$$

The AIC statistics gives a different way of adjusting the  $-2 \log$  likelihood statistic for the number of estimable parameters in the model.

## Contrasts

For a testable hypothesis  $H_0: \mathbf{L}\boldsymbol{\beta} = 0$ , the Wald  $F$  statistic is computed as

$$F_{\text{Wald}} = \frac{(\mathbf{L}^* \hat{\boldsymbol{\beta}})' (\mathbf{L}^* \hat{\mathbf{V}} \mathbf{L}^*)^{-1} (\mathbf{L}^* \hat{\boldsymbol{\beta}})}{\text{rank}(\mathbf{L})}$$

where  $\mathbf{L}$  is a contrast vector or matrix that you specify,  $\boldsymbol{\beta}$  is the vector of regression parameters,  $\hat{\boldsymbol{\beta}}$  is the estimated regression coefficients,  $\hat{\mathbf{V}}$  is the estimated covariance matrix of  $\hat{\boldsymbol{\beta}}$ ,  $\text{rank}(\mathbf{L})$  is the rank of  $\mathbf{L}$ , and  $\mathbf{L}^*$  is a matrix such that

- $\mathbf{L}^*$  has the same number of columns as  $\mathbf{L}$
- $\mathbf{L}^*$  has full row rank
- the rank of  $\mathbf{L}^*$  equals the rank of the  $\mathbf{L}$  matrix
- all rows of  $\mathbf{L}^*$  are estimable functions
- the Wald  $F$  statistic computed by using the  $\mathbf{L}^*$  matrix is equivalent to the Wald  $F$  statistic computed by using the  $\mathbf{L}$  matrix with any row deleted that is a linear combination of previous rows

If  $\mathbf{L}$  is a full-rank matrix and all rows of  $\mathbf{L}$  are estimable functions, then  $\mathbf{L}^*$  is the same as  $\mathbf{L}$ . It is possible that  $\mathbf{L}$  matrix cannot be constructed for a given set of linear contrasts, in which case the contrasts are not testable.

If the **DF=NONE** option in the MODEL statement is specified, then the procedure performs a chi-square significance test.

## Confidence Intervals

By default, the SURVEYPHREG procedure computes  $t$  confidence limits for the estimated regression coefficients. Alternatively, you can specify the **DF=NONE** option in the MODEL statement to request standard normal confidence intervals. The  $t$  confidence interval for a linear combination  $\mathbf{L}'\boldsymbol{\beta}$  of the regression coefficients is computed as

$$\left( \mathbf{L}'\hat{\boldsymbol{\beta}} \pm t_{df, \alpha/2} \sqrt{\mathbf{L}'\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})\mathbf{L}} \right)$$

where  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile point of the  $t$  distribution with  $df$  degrees of freedom. See the section “**Degrees of Freedom**” on page 7901 for more information about  $df$ . If you use the **DF=NONE** option in the MODEL statement, then the procedure uses the  $100(1 - \alpha/2)$  percentile point of the standard normal distribution.

## Hazard Ratios

The hazard ratio for a quantitative effect with regression coefficient  $\beta_j = \mathbf{e}'_j \boldsymbol{\beta}$  is defined as  $\exp(\beta_j)$ , where  $\mathbf{e}_j$  denotes the  $j$ th unit vector. In general, a log-hazard ratio can be written as  $\mathbf{L}'\boldsymbol{\beta}$ , a linear combination of the regression coefficients, and the hazard ratio  $\exp(\mathbf{L}'\boldsymbol{\beta})$  is obtained by replacing  $\mathbf{e}_j$  with  $\mathbf{l}$ .

The confidence intervals for hazard ratios are obtained by exponentiating the confidence limits of the corresponding linear combination. Thus, the  $100(1 - \alpha)$  confidence limits are

$$\exp\left(\mathbf{e}'_j \hat{\boldsymbol{\beta}} \pm t_{df, \alpha/2} \sqrt{\mathbf{e}'_j \hat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) \mathbf{e}_j}\right)$$

where  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile point of the  $t$  distribution with  $df$  degrees of freedom. See the section “[Degrees of Freedom](#)” on page 7901 for more information about  $df$ . If you use the `DF=NONE` option in the MODEL statement, then the procedure uses the  $100(1 - \alpha/2)$  percentile point of the standard normal distribution.

## Residuals

This section describes the computation of residuals (RESMART, RESDEV, RESSCH, and RESSCO in the OUTPUT statement). See the section “[Notation and Estimation](#)” on page 7884 for definition of notation that is used in this section. The residuals are calculated based on the `TIES=` option in the MODEL statement.

### **TIES=BRESLOW**

This is the default option. Let

$$S^{(r)}(\boldsymbol{\beta}, t) = \sum_A w_{hij} y_{hij}(t) \exp(\boldsymbol{\beta}' \mathbf{Z}_{hij}(t)) \mathbf{Z}_{hij}^{\otimes r}(t)$$

$$\bar{\mathbf{Z}}(\boldsymbol{\beta}, t) = \frac{S^{(1)}(\boldsymbol{\beta}, t)}{S^{(0)}(\boldsymbol{\beta}, t)}$$

where  $r = 0, 1$ ; and  $A$  be the set of indices in the selected sample.

Further let

$$\begin{aligned} d\Lambda_0(\boldsymbol{\beta}, t) &= \sum_A \frac{w_{hij} dn_{hij}(t)}{S^{(0)}(\boldsymbol{\beta}, t)} \\ dM_{hij}(\boldsymbol{\beta}, t) &= dn_{hij}(t) - y_{hij}(t) \exp(\boldsymbol{\beta}' \mathbf{Z}_{hij}(t)) d\Lambda_0(\boldsymbol{\beta}, t) \end{aligned}$$

The martingale residual at  $t$  is defined as

$$\begin{aligned} \hat{M}_{hij}(t) &= \int_0^t dM_{hij}(\hat{\boldsymbol{\beta}}, \tau) \\ &= n_{hij}(t) - \int_0^t y_{hij}(\tau) \exp(\hat{\boldsymbol{\beta}}' \mathbf{Z}_{hij}(\tau)) d\Lambda_0(\hat{\boldsymbol{\beta}}, \tau) \end{aligned}$$

Here  $\hat{M}_{hij}(t)$  estimates the difference over  $(0, t]$  between the observed number of events for the  $(h, i, j)$  observation unit and a conditional expected number of events. The quantity  $\hat{M}_{hij} \equiv \hat{M}_{hij}(\infty)$  is referred to as the martingale residual for the  $(h, i, j)$  observation unit. For the Cox model with no time-dependent explanatory variables, the martingale residual for the  $(h, i, j)$  unit with observation time  $t_{(h,i,j)}$  and event status  $\Delta_{(h,i,j)}$  is

$$\hat{M}_{(h,i,j)} = \Delta_{(h,i,j)} - e^{\hat{\boldsymbol{\beta}}' \mathbf{Z}_{(h,i,j)}} \int_0^{t_{(h,i,j)}} d\Lambda_0(\hat{\boldsymbol{\beta}}, s)$$

The deviance residual  $D_{hij}$  for the  $(h, i, j)$  observation unit is a transformation of the corresponding martingale residuals,

$$D_{hij} = \text{sign}(\hat{M}_{hij}) \sqrt{2 \left[ -\hat{M}_{hij} - n_{hij}(\infty) \log \left( \frac{n_{hij}(\infty) - \hat{M}_{hij}}{n_{hij}(\infty)} \right) \right]}$$

The square root shrinks large negative martingale residuals, while the logarithmic transformation expands martingale residuals that are close to unity. As such, the deviance residuals are more symmetrically distributed around zero than the martingale residuals. For the Cox model, the deviance residual reduces to the form

$$D_{hij} = \text{sign}(\hat{M}_{hij}) \sqrt{2[-\hat{M}_{hij} - \Delta_{hij} \log(\Delta_{hij} - \hat{M}_{hij})]}$$

The Schoenfeld (1982) residual vector is calculated on a per-event-time basis. At the  $k$ th event time  $t_{hij,k}$  of the  $(h, i, j)$  observation unit, the Schoenfeld residual

$$\hat{U}_{hij}(t_{hij,k}) = \mathbf{Z}_{hij}(t_{hij,k}) - \bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, t_{hij,k})$$

is the difference between the observed covariate vector for the  $(h, i, j)$  observation unit and the average of the covariate vectors over the risk set at  $t_{hij,k}$ . Under the proportional hazards assumption, the Schoenfeld residuals have the sample path of a random walk; therefore, they are useful in assessing time trend or lack of proportionality.

The score process for the  $(h, i, j)$  subject at time  $t$  is

$$\mathbf{L}_{hij}(\boldsymbol{\beta}, t) = \int_0^t [\mathbf{Z}_{hij}(\tau) - \bar{\mathbf{Z}}(\boldsymbol{\beta}, \tau)] dM_{hij}(\boldsymbol{\beta}, \tau)$$

The vector  $\hat{\mathbf{L}}_{hij} \equiv \mathbf{L}_{hij}(\hat{\boldsymbol{\beta}}, \infty)$  is the score residual for the  $(h, i, j)$  observation unit.

The score residuals are a decomposition of the first partial derivative of the log likelihood. They are useful in assessing the influence of each subject on individual parameter estimates. They also play an important role in the computation of the variance estimators.

### TIES=EFRON

For TIES=EFRON, the preceding computation is modified to comply with the Efron partial likelihood. For a given uncensored time  $t$ , let  $\delta_{hij}(t) = 1$  if  $t$  is an event time for the  $(h, i, j)$  observation, and 0 otherwise. Let  $d(t) = \sum_{hij \in A} \delta_{hij}(t)$ , which is the number of observation units that have an event at  $t$ . For  $1 \leq l \leq d(t)$ , let

$$\begin{aligned} S^{(r)}(\boldsymbol{\beta}, l, t) &= \sum_A w_{hij} y_{hij}(t) \left\{ 1 - \frac{l-1}{d(t)} \delta_{hij}(t) \right\} \exp(\boldsymbol{\beta}' \mathbf{Z}_{hij}(t)) \mathbf{Z}_{hij}^{\otimes r}(t) \\ \bar{\mathbf{Z}}(\boldsymbol{\beta}, l, t) &= \frac{S^{(1)}(\boldsymbol{\beta}, l, t)}{S^{(0)}(\boldsymbol{\beta}, l, t)} \\ d\Lambda_0(\boldsymbol{\beta}, l, t) &= \sum_A \frac{w_{hij} d n_{hij}(t)}{S^{(0)}(\boldsymbol{\beta}, l, t)} \\ dM_{hij}(\boldsymbol{\beta}, l, t) &= d n_{hij}(t) - y_{hij}(t) \left( 1 - \delta_{hij}(t) \frac{l-1}{d(t)} \right) \exp(\boldsymbol{\beta}' \mathbf{Z}_{hij}(t)) d\Lambda_0(\boldsymbol{\beta}, l, t) \end{aligned}$$

where  $r = 0, 1$ , and  $A$  are the set of indices in the selected sample.

The martingale residual at  $t$  for the  $(h, i, j)$  observation unit is defined as

$$\begin{aligned}\hat{M}_{hij}(t) &= \int_0^t \frac{1}{d(\tau)} \sum_{l=1}^{d(\tau)} dM_{hij}(\hat{\beta}, l, \tau) \\ &= n_{hij}(t) - \int_0^t \frac{1}{d(\tau)} \sum_{l=1}^{d(\tau)} y_{hij}(\tau) \left(1 - \delta_{hij}(\tau) \frac{l-1}{d(\tau)}\right) \exp\left(\hat{\beta}' \mathbf{Z}_{hij}(\tau)\right) d\Lambda_0(\hat{\beta}, l, \tau)\end{aligned}$$

Deviance residuals are computed by using the same transform on the corresponding martingale residuals as in TIES=BRESLOW.

The Schoenfeld residual vector for the  $(h, i, j)$  observation unit at event time  $t_{hij,k}$  is

$$\hat{\mathbf{U}}_{hij}(t_{hij,k}) = \mathbf{Z}_{hij}(t_{hij,k}) - \frac{1}{d(t_{hij,k})} \sum_{l=1}^{d(t_{hij,k})} \bar{\mathbf{Z}}(\hat{\beta}, l, t_{hij,k})$$

The score process for the  $(h, i, j)$  observation unit at time  $t$  is

$$\mathbf{L}_{hij}(\beta, t) = \int_0^t \frac{1}{d(\tau)} \sum_{l=1}^{d(\tau)} \left(\mathbf{Z}_{hij}(\tau) - \bar{\mathbf{Z}}(\beta, l, \tau)\right) dM_{hij}(\beta, l, \tau)$$

## Output Data Sets

You can use the Output Delivery System to create a SAS data set from any piece of PROC SURVEYPHREG output. See the section “ODS Table Names” on page 7912 for more information. PROC SURVEYPHREG also provides an output data set to store observation-level statistics, an output data set to store the replicate weights for BRR or jackknife variance estimation, and an output data set to store the jackknife coefficients for jackknife variance estimation.

### OUT= Data Set for the OUTPUT statement

The **OUTPUT** statement can be used to store observation-level statistics, such as the predicted values and their standard errors, the (weighted) number of observation units at risk, martingale residuals, Schoenfeld residuals, score residuals, and deviance residuals. See the section “Residuals” on page 7906 for details about how these statistics are calculated.

### Replicate Weights Output Data Set

If you specify the **OUTWEIGHTS=** *method-option* for **VARMETHOD=BRR** or **JACKKNIFE**, PROC SURVEYPHREG stores the replicate weights in an output data set. The **OUTWEIGHTS=** output data set contains all observations that are used in the analysis or all valid observations in the **DATA=** input data set. See the section “Missing Values” on page 7893 for details about valid observations.

The OUTWEIGHTS= data set contains the following variables:

- all variables in the DATA= input data set
- RepWt\_1, RepWt\_2, . . . , RepWt\_R, which are the replicate weight variables, where R is the total number of replicates in the analysis

Each replicate weight variable contains the replicate weights for the corresponding replicate. Replicate weights equal zero for those observations not included in the replicate.

After the procedure creates replicate weights for a particular input data set and survey design, you can use the OUTWEIGHTS= *method-option* to store these replicate weights and then use them again in subsequent analyses, either in PROC SURVEYPHREG or in the other survey procedures. You can use a REPWEIGHTS statement to provide replicate weights for the procedure.

### Jackknife Coefficients Output Data Set

If you specify the OUTJKCOEFS= *method-option* for VARMETHOD=JACKKNIFE, PROC SURVEYPHREG stores the jackknife coefficients in an output data set. The OUTJKCOEFS= output data set contains one observation for each replicate. The OUTJKCOEFS= data set contains the following variables:

- Replicate, which is the replicate number for the jackknife coefficient
- JKCoefficient, which is the jackknife coefficient for the replicate
- DonorStratum, which is the stratum of the PSU that was deleted to construct the replicate, if you specify a STRATA statement

After the procedure creates jackknife coefficients for a particular input data set and survey design, you can use the OUTJKCOEFS= *method-option* to store these coefficients and then use them again in subsequent analyses, either in PROC SURVEYPHREG or in the other survey procedures. You can use the JKCOEFS= option in the REPWEIGHTS statement to provide jackknife coefficients for the procedure.

---

## Displayed Output

If you use the NOPRINT option in the PROC SURVEYPHREG statement, the procedure does not display any output. Otherwise, PROC SURVEYPHREG displays results of the analysis in a collection of tables.

### Model Information

The “Model Information” table displays the two-level name of the input data set, the name and label of the failure time variable, the name and label of the censoring variable and the values that indicate censored times, the model, the name and label of the FREQ variable, the name and label of the WEIGHT variable, the name and label of the STRATA variables, the name and label of the CLUSTER variables, and the method of handling ties in the failure time for the Cox model. The ODS name of the “Model Information” table is “ModelInfo.”

## Number of Observations

The “Number of Observations” table displays the number of observations that are read and used, the sum of frequencies read and used, the sum of weights read and used, and the weighted sum of frequencies that are read and used in the analysis. The ODS name of the “Number of Observations” table is “NObs.”

## Summary of the Number of Event and Censored Values

The “Summary of the Number of Event and Censored Values” table displays the number of events and censored values. The ODS name of the “Summary of the Number of Event and Censored Values” table is “CensoredSummary.”

## Summary of the Weighted Number of Event and Censored Values

The “Summary of the Weighted Number of Event and Censored Values” table displays the weighted number of events and censored values. The ODS name of the “Summary of the Weighted Number of Event and Censored Values” table is “WeightedCensoredSummary.”

## Class Level Information

The “Class Level Information” table is displayed when there are CLASS variables in the model. The table lists the categories of every CLASS variable that is used in the model and the corresponding design variable values. The ODS name of the “Class Level Information” table is “ClassLevelInfo.”

## Design Summary Table

The “Design Summary” table provides information about the sample design. The table displays the total number of strata that are read and used, and the total number of clusters read and used. The table is displayed only if you specify a STRATA or CLUSTER statement. The ODS name of the “Design Summary” table is “DesignSummary.”

## Stratum Information Table

If you specify the LIST option in the STRATA statement, PROC SURVEYPHREG displays a “Stratum Information” table. The ODS name of the “Stratum Information Table” is “StrataInfo.” This table provides the following information for each stratum:

- Stratum Index, which is a sequential stratum identification number
- STRATA variables, which list the levels of STRATA variables for the stratum
- Number of Observations, which is the number of observations used in the stratum
- Population Total for the stratum, if you specify the TOTAL= option
- Sampling Rate for the stratum, if you specify the TOTAL= or RATE= option. If you specify the TOTAL= option, the sampling rate is based on the number of valid observations in the stratum.
- Number of Clusters, which is the number of clusters in the stratum, if you specify a CLUSTER statement

## Convergence Status

The “Convergence Status” table displays the convergence status of the optimization routine. The procedure displays this table only when you specify the NLOPTIONS statement. The ODS name of the “Convergence Status” table is “ConvergenceStatus.”

## Model Fit Statistics

The “Model Fit Statistics” table displays the values of  $-2 \log$  likelihood and the AIC for the null model and the fitted model. The ODS name of the “Model Fit Statistics” table is “FitStatistics.”

## Testing Global Null Hypothesis: BETA=0

The “Testing Global Null Hypothesis: BETA=0” table displays results of the likelihood ratio test and the Wald test for testing the hypothesis that all parameters are zero. The ODS name of the “Testing Global Null Hypothesis: BETA=0” table is “GlobalTests.”

## Analysis of Maximum Likelihood Estimates

The “Analysis of Maximum Likelihood Estimates” table displays the denominator degrees of freedom, which is computed as described in the section “Degrees of Freedom” on page 7901; the maximum likelihood estimate of the parameter; the estimated standard error, computed as the square root of the corresponding diagonal element of the estimated covariance matrix; the  $t$  statistic, computed as the parameter estimate divided by the standard error; the  $p$ -value of the  $t$  statistic with respect to a  $t$  distribution with denominator degrees of freedom; and the hazard ratio estimate. The  $t$  confidence limits for the parameter estimates and estimated hazard ratios are displayed if you specify the CLPARM or RISKLIMITS option in the MODEL statement. You can specify the DF=NONE option in the MODEL statement to request  $p$ -values and confidence intervals from a standard normal distribution. If you specify the VARRATIO=ALL | MODEL | IND option in the MODEL statement, then the variance ratios for model or independence (or both) are displayed. If you specify the SERATIO=ALL | MODEL | IND option in the MODEL statement, then the standard error ratios for model or independence (or both) are displayed.

The ODS name of the “Analysis of Maximum Likelihood Estimates” table is “ParameterEstimates.”

## Covariance Matrix

The “Covariance Matrix” table is displayed if you specify the COVB option in the MODEL statement. The table contains the estimated covariance matrix for the parameter estimates. The ODS name of the “Covariance Matrix” table is “CovB.”

## Hessian Matrix

The “Hessian Matrix” table is displayed if you specify the HESS option in the MODEL statement. The table contains the Hessian matrix that is evaluated at the estimated regression parameters. The ODS name of the “Hessian Matrix” table is “Hessian.”

## Inverse Hessian Matrix

The “Inverse Hessian Matrix” table is displayed if you specify the INVHESS option in the MODEL statement. The table contains the inverse of the Hessian matrix evaluated at the estimated regression parameters. The ODS name of the “Inverse Hessian Matrix” table is “InvHessian.”

## Variance Estimation Table

The “Variance Estimation” table provides the following information:

- Method, which is the variance estimation method—Taylor Series, Balanced Repeated Replication, or Jackknife
- Replicate Weights input data set name, if you provide replicate weights with a `REPWEIGHTS` statement
- Number of Replicates, for `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE`
- Hadamard Data Set name, if you specify the `HADAMARD= method-option` for `VARMETHOD=BRR`
- Fay Coefficient, if you specify the `FAY method-option` for `VARMETHOD=BRR`
- Missing Values Included (MISSING), if you specify the `MISSING` option
- Missing Values Included (NOMCAR), if you specify the `NOMCAR` option
- Missing Values Excluded, if you have missing values and you do not specify the `NOMCAR` option

## Hadamard Matrix

If you specify the `PRINTH method-option` for `VARMETHOD=BRR`, PROC SURVEYPHREG displays the Hadamard matrix that is used to construct replicates for BRR variance estimation. If you provide a Hadamard matrix with the `HADAMARD= method-option` for `VARMETHOD=BRR` but the procedure does not use the entire matrix, the procedure displays only the rows and columns that are actually used to construct replicates. The ODS name of the “Hadamard Matrix” table is “HadamardMatrix.”

---

## ODS Table Names

PROC SURVEYPHREG assigns a name to each table it creates. You can use this name to refer to the table when using the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, “Using the Output Delivery System.” Table 93.8 lists the table names, along with the corresponding analysis options.

**Table 93.8** ODS Tables Produced by PROC SURVEYPHREG

| ODS Table Name    | Description                                | Statement / Option |
|-------------------|--------------------------------------------|--------------------|
| CensoredSummary   | Summary of event and censored observations | Default            |
| ClassLevelInfo    | CLASS variable levels                      | CLASS              |
| ConvergenceStatus | Convergence status                         | NLOPTIONS / PALL   |
| CovB              | Covariance of parameter estimates          | MODEL / COVB       |
| DesignSummary     | Design summary                             | STRATA or CLUSTER  |
| FitStatistics     | Model fit statistics                       | Default            |
| GlobalTests       | Tests of the global null hypothesis        | Default            |

Table 93.8 *continued*

| ODS Table Name          | Description                                                   | Statement / Option    |
|-------------------------|---------------------------------------------------------------|-----------------------|
| Hadamard                | Hadamard matrix                                               | VARMETHOD=BRR(PRINTH) |
| Hessian                 | Observed Hessian matrix                                       | MODEL / HESSIAN       |
| InvHessian              | Inverse of the observed Hessian matrix                        | MODEL / INVHESS       |
| IterHist                | Iteration history                                             | NLOPTIONS / PHISTORY  |
| ModelInfo               | Model information                                             | Default               |
| NObs                    | Number of observations                                        | Default               |
| ParameterEstimates      | Maximum likelihood Estimates of model parameters              | Default               |
| ParameterEstimatesStart | Initial parameter values for optimization                     | NLOPTIONS / PALL      |
| StrataInfo              | Stratum information                                           | STRATA / LIST         |
| VarianceEstimation      | Variance estimation                                           | Default               |
| WeightedCensoredSummary | Summary of weighted number of event and censored observations | WEIGHT                |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

When ODS Graphics is enabled, the ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements can produce plots that are associated with their analyses. For information about these plots, see the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

## Examples: SURVEYPHREG Procedure

### Example 93.1: Analysis of Clustered Data

When experimental units are naturally or artificially clustered, failure times of experimental units within a cluster are correlated. Lee, Wei, and Amato (1992) estimate the regression parameters in the Cox model by maximizing a partial likelihood function under an independent working correlation assumption and estimate

the variance of the estimated regression coefficients by using a robust sandwich variance estimator that accounts for the intracluster dependence.

The Diabetic Retinopathy Study (DRS) is a randomized, controlled clinical trial of more than 1,700 patients across 15 medical centers. One objective of this study was to determine if photocoagulation treatment delays the occurrence of blindness. One eye of each patient was randomly assigned to treatment and the other eye to control. See [Example 67.11](#) in Chapter 67, “The PHREG Procedure,” for more information about the data set and a similar analysis; see <http://www.nei.nih.gov/neitrials/static/study62.asp> for more information about the DRS.

Each patient is a cluster that contributes two observations to the input data set, one for each eye. The following variables are available:

- ID, patient’s identification
- Time, failure time
- Status, event indicator (0=censored, and 1=uncensored)
- Treatment, treatment received (1=laser photocoagulation, and 0=otherwise)
- DiabeticType, type of diabetes (0=juvenile onset with age of onset at 20 or under, and 1= adult onset with age of onset over 20)

The following DATA step creates the data set Blind, which represents 197 diabetic patients from the DRS:

```
data Blind;
 input ID Time Status DiabeticType Treatment @@;
 datalines;

;
```

The following SAS statements request a proportional hazards regression of Time on Treatment, DiabeticType, and the Treatment × DiabeticType interaction, with Status as the censoring indicator. The CLUSTER statement indicates the observations that came from the same patient.

```
proc surveypreg data=Blind;
 model Time*Status(0) = Treatment DiabeticType Treatment*DiabeticType;
 cluster id;
run;
```

Output 93.1.1 displays some summary information. There are 394 observations and 197 patients (clusters). Almost 61% of the observations are censored. The  $p$ -values for the null model are less than 0.0001 for both the likelihood ratio test and the Wald test (Output 93.1.2), which indicates that the survival time is highly dependent on Treatment and DiabeticType. In this example, the likelihood ratio statistic has a chi-square distribution with 3 degrees of freedom and the Wald statistics has the  $F$  distribution with the numerator degrees of freedom 3 and the denominator degrees of freedom 196. The denominator degrees of freedom are calculated as the number of clusters (197) minus one.

**Output 93.1.1** Summary Information

| Wald                                   | 11.3872        | 3      | 196    | <.0001  |

Output 93.1.3 displays parameter estimates, standard errors,  $t$  statistics, denominator degrees of freedom,  $p$ -values, and hazard ratios. In this example data set, Treatment and Treatment  $\times$  DiabeticType interaction

are significant with  $p$ -values 0.023 and 0.006, respectively. Since the model contains Treatment  $\times$  DiabeticType interaction, the exponential of the estimated regression coefficient is not the hazard ratio. Use the ESTIMATE statement to calculate the hazard ratios.

### Example 93.2: Stratification, Clustering, and Unequal Weights

This example uses a data set from the National Health and Nutrition Examination Survey I (NHANES I) Epidemiologic Followup Study (NHEFS). The NHEFS is a national longitudinal survey that is conducted by the National Center for Health Statistics, the National Institute on Aging, and some other agencies of the Public Health Service in the United States. Some important objectives of this survey are to determine the relationships between clinical, nutritional, and behavioral factors; to determine mortality and hospital utilizations; and to monitor changes in risk factors for the initial cohort that represents the NHANES I population. A cohort of size 14,407, which includes all persons 25 to 74 years old who completed a medical examination at NHANES I in 1971–1975, was selected for the NHEFS. Personal interviews were conducted for every selected unit during the first wave of data collection from the year 1982 to 1984. Follow-up studies were conducted in 1986, 1987, and 1992. In the year 1986, only nondeceased persons 55 to 74 years old (as reported in the base year survey) were interviewed. The 1987 and 1992 NHEFS contain the entire nondeceased NHEFS cohort. Vital and tracing status data, interview data, health care facility stay data, and mortality data for all four waves are available for public use. See <http://www.cdc.gov/nchs/nhanes/nhefs/nhefs.htm> for more information about the survey and the data sets.

For illustration purposes, 1,018 observations from the 1987 NHEFS public use interview data are used to create the data set cancer. The observations are obtained from 10 strata that contain 596 PSUs. The sum of observation weights for these selected units is over 19 million. Observation weights range from 359 to 129,359 with a mean of 18,747.69 and a median of 11,414. Several observation weights have large values; therefore it is reasonable to rescale the observation weights to facilitate the optimization routine. Different scaling techniques are proposed in the literature. For example, Binder (1992) uses scaled weights such that the sum of weights over the sampled units is one. Without loss of generality, the analysis weights in this example are obtained by dividing each observation weight by a large number (130,000). Because of this rescaling, you must be careful interpreting some results from PROC SURVEYPHREG.

The following variables are used in this example:

- ObsNo, unit identification
- Strata, stratum identification
- PSU, identification for primary sampling units
- ObservationWt, sampling weight associated with each unit
- AnalysisWt, obtained from the sampling weights by dividing each ObservationWt by 130,000
- Smoke, smoking status (–1 = not applicable, 1 = never smoked, 2 = current or former smoker in 1982–1984 follow-up, and 3 = current or former smoker in 1987 follow-up)
- Age, the event-time variable, defined as follows:
  - age of the subject when the first cancer was reported for subjects with reported cancer
  - age of the subject at death for deceased subjects without reported cancer
  - age of the subject as reported in 1987 follow-up (this value is used for nondeceased subjects who never reported cancer)
  - age of the subject for the entry year 1971–1975 survey if the subject has cancer (or is deceased) but the date of incident is not reported
- Cancer, cancer indicator (1 = cancer reported, 0 = cancer not reported)
- BodyWeight, body weight of the subject as reported in the 1987 follow-up, or an imputed body weight based on the subject’s age in the entry year 1971–1975 survey

The following SAS statements create the data set cancer. Note that BodyWeight for a few observations (8%) is imputed based on Age by using a deterministic regression imputation model (Särndal and Lundström (2005, chapter 12)). The imputed values are treated as observed values in this example. In other words, this example treats the data set Cancer as the observed data set.

Suppose you want to study the occurrence of cancer for the base year survey population and its relation to smoking status and body weight. The following statements request a proportional hazards regression of Age on BodyWeight and Smoke with Cancer as the censor indicator. The STRATA, CLUSTER, and WEIGHT statements identify the variance strata, PSUs, and analysis weights respectively. The CLASS statement specifies that Smoke is a categorical variable, and the MODEL statement provides information about the analysis model. The TIES= option in the MODEL statement requests the Efron likelihood to handle tied events. If you do not specify the TIES= option in the MODEL statement, then the procedure uses the Breslow likelihood. The PHISTORY option in the NLOPTIONS statement is used to display the iteration history table. The ESTIMATE statement computes a contrast between subjects who are reported as current (or former) smokers and the others. The EXP option in the ESTIMATE statement requests that the linear contrast be estimated in the exponential scale, which is the hazard ratio. The TEST statement requests the Type 3 test for each effect that is specified in the MODEL statement.

```
proc surveypHreg data = cancer;
 strata strata;
 cluster psu;
 weight analysiswt;
 class smoke;
 model age*cancer(0) = bodyweight smoke / ties = efron;
 nloptions phistory;
 estimate smoke 0.5 0.5 -0.5 -0.5 / exp;
 test ;
run;
```

Some summary statistics are shown in [Output 93.2.1](#). The “Model Information” table contains information about the model such as the names for the dependent and censoring variables, and the likelihood. The “Number of Observations” table displays the number of observations and the sum of weights. A total of 1,018 observations are read from the Cancer data set, but one observation is not used in the analysis because it has a zero sampling weight. The sum of weights is 146.81, which gives an estimated population size of 19,085,105 ( $= 146.8085 \times 130,000$ ). Note that the estimated population size would be 19,085,151 if you use the sampling weights (ObservationWt) instead of the analysis weights (AnalysisWt). The difference is due to the rounding errors in AnalysisWt. For simplicity, analysis weights are rounded at the fifth decimal place. The “Design Summary” table shows that there are 596 PSUs and 10 strata. From the censored summary tables, 11.7% subjects in the sample have reported cancer and an estimated 11.6% subjects in the study population have cancer. The “Variance Estimation” table shows that the Taylor series linearization variance estimation method is used and the observation units with missing values are excluded from the analysis. Note that the only missing unit in this data set has a zero sampling weight and hence it is not included in the analysis.

The “Iteration History” table in [Output 93.2.2](#) shows that the procedure converged after four iterations. The “Objective Function” column contains the value of the likelihood after every iteration. The “Objective Function Change” column measures the change in the objective function between iterations; however, this is not the monitored convergence criterion. The SURVEYPHREG procedure monitors several features simultaneously to determine whether to stop an optimization.

**Output 93.2.2** Iteration History

| Maximum Likelihood Iteration History |              |               |            |                       |                   |                                |       |                                  |

Estimates for proportional hazards regression coefficients and their standard errors are shown in [Output 93.2.3](#). The categorical variable Smoke has four levels, and GLM parameterization is used by PROC SURVEYPHREG. You can use the PARAM= option in the CLASS statement to specify other types of parameterizations. The estimated regression coefficient for BodyWeight is 0.012 with a standard error of 0.003. The degrees of freedom for the *t* test are equal to the number of PSUs (596) minus the number of strata (10). The “Estimates” table displays the estimated contrast and the corresponding hypothesis test. The estimated value for the contrast is -0.75. The estimated hazard for the nonsmokers is 0.47 times the estimated hazard for the current or former smokers. In this example data set, the contrast of interest is not significant at 0.05 levels. The “Type III Tests of Model Effects” table displays the Type 3 analysis. The effect variable Smoke has four levels. The F Value for Smoke is 1.49 with three numerator degrees of freedom and 586 denominator degrees of freedom.

**Example 93.3: Domain Analysis**

This example uses a data set from the NHANES I Epidemiologic Followup Study (NHEFS); see [Example 93.2](#) for more information about the NHEFS.

For illustration purposes, 1,891 observations from the 1992 NHEFS vital and tracing status data set are used to estimate the regression coefficients of a proportional hazards model. The observations are obtained from 22 strata; each stratum contains either two or three primary sampling units. The sum of observation weights for these selected units is almost 103 million. Observation weights range from 1,498 to 470,154 with a mean of 54,457.11 and a median of 45,246. The following variables are used in this example. Although this example uses the observation weights directly, Binder (1992) suggests that a scaled version of the observation weights would be useful to improve the performance of the optimization routine.

The following variables are created in the data set mortality:

- ID, unit identification
- VARSTRATA, stratum identification
- VARPSU, identification for primary sampling units
- SWEIGHT, sampling weight associated with each unit
- AGE, the subject's reported age at the 1992 interview if the subject was alive at that time; otherwise, the subject's age at death
- VITALSTATUS, vital status of subject in 1992 (1 = alive, 3 = dead, 4 = unknown, 5 = traced alive with direct subject contact, 6 = traced alive without direct subject contact)
- POVARIND, indicator for poverty area where subject's household was located at NHANES I (1971–1975) exam, (1 = poverty area, 2 = non-poverty area)
- GENDER, (1 = male, 2 = female)

Suppose you want to estimate the hazard function for mortality time after adjusting for the poverty area indicator in the base year survey population. The following SAS statements request a proportional hazards regression of age (AGE) on poverty indicator (POVARIND):

```

proc surveypHreg data = mortality nomcar;
 class povarind;
 strata varstrata;
 cluster varpsu;
 weight sweight;
 model age*vitalstatus(1 4 5 6) = povarind;
 domain gender;
run;

```

Subjects with VITALSTATUS 1, 4, 5, or 6 are considered alive. The CLASS statement specifies that POVARIND is a categorical variable, the WEIGHT statement identifies the sampling weights, the STRATA statement identifies variance strata, and the CLUSTER statement identifies variance PSUs. The DOMAIN statement requests three separate analyses: for the overall data set, the male subpopulation, and the female subpopulation respectively. There are 223 observation units with missing values on age. All the units with missing age have vital status 1, 4, 5, or 6. Therefore, these subjects are considered to be alive in the current survey year 1992. Age for every observation unit in the base year survey was known from 1971–1975 NHANES I. One reasonable approach is to determine the age of these 223 units based on their age from the NHANES I data set. However, for illustration purposes, this example does not include the observation units with missing age when estimating the regression coefficients. Instead, an analysis of just the set of respondents is requested by specifying the NOMCAR option in the PROC SURVEYPHREG statement. This option uses a variance estimator that accounts for the random size of the set of respondents.

Output 93.3.1 shows summary statistics for the overall analysis. A total of 1,891 observations are read from the input DATA= data set, but only 1,668 observations are used in the analysis. The remaining 223 observations have missing values in the variable age. The respondent data set represents almost 89.5 million units in the population. There are 22 strata and 55 clusters. Although only 57% observation units in the sample are alive, an estimated 69% observation units in the population are alive. This difference is reasonable because selection probabilities for observation units are not the same. If you do not use the sampling weights, then your sample-based estimators might be biased for the corresponding finite population quantities. The “Variance Estimation” table indicates that the NOMCAR option is used for variance estimation.

Output 93.3.2 displays the estimated regression coefficients and their standard errors. Poverty index has two levels, and only one level is estimable. By default, PROC SURVEYPHREG estimates the first level (POVARIND 1) and assigns a zero value for the second level. The estimated regression coefficient is 0.385 with a standard error of 0.078. The estimated hazard for the poverty areas is 1.47 times higher than the estimated hazard for the non-poverty areas. The degrees of freedom are equal to the number of PSUs (55) minus the number of strata (22).

Output 93.3.3 shows that 813 observation units in the sample are male, and they account for over 42.6 million males in the base year survey population. Approximately half of these observation units in the sample are censored, and an estimated 64.5% observation units are censored for the male subpopulation.

**Example 93.4: Variance Estimation by Using Replicate Weights**

Consider the data set LibrarySurvey from “Getting Started: SURVEYPHREG Procedure” on page 7857. The selected sample contains 100 transactions from ten branch libraries. A set of replicate weights and jackknife coefficients are created by randomly assigning observation units in disjoint groups of nearly equal size within each stratum. A total of 46 different groups are created. The data set LibraryRepWeights is

similar to the data set LibrarySurvey except that it also contains replicate weights repwt\_1 to repwt\_46. Each column of replicate weights is obtained by deleting one group of observations and adjusting the sampling weights for the other groups in that stratum (Rust 1985).

The data set LibraryJKCOEF contains the jackknife coefficient for every replicate sample. The variable replicate denotes the replicate number, donorstratum denotes the stratum identification for that replicate, and jkcoefficient denotes the jackknife coefficient for that replicate sample.

```

data LibrarySurvey;
 set LibrarySurvey;
 randomorder = ranuni(12345);
run;
proc sort data = LibrarySurvey out = LibrarySurvey;
 by Branch randomorder;
run;
data LibrarySurvey;
 set LibrarySurvey;
 array nGroup{10} (2 2 2 4 4 4 4 8 8 8);
 GroupPSU = mod(_N_, nGroup{Branch});
 drop randomorder nGroup1 nGroup2 nGroup3 nGroup4
 nGroup5 nGroup6 nGroup7 nGroup8 nGroup9 nGroup10;
run;

proc surveymeans data = LibrarySurvey varmethod = jk
 (outweights = LibraryRepWeights outjkcoefs = LibraryJKCOEF);
 weight SamplingWeight;
 strata Branch;
 cluster GroupPSU;
 var Age;
run;

```

It is not necessary to provide replicate weights to compute jackknife variance estimates using the SURVEYPHREG procedure. If you do not specify the replicate weights, then the procedure creates replicate weights for you. For this illustration, assume that LibraryRepWeights and LibraryJKCOEF are the only two data sets available for analysis.

The following SAS statements request a proportional hazards regression of lenBorrow on Age. The variable Returned is the censor indicator, and the value 0 indicates a censored observation. The WEIGHT statement specifies the sampling weight variable, and the REPWEIGHTS statement specifies replicate weight variables RepWt\_1 to RepWt\_46. The JKCOEFS= option in the REPWEIGHTS statement specifies the jackknife coefficient for each replicate sample. The VARMETHOD= option in the MODEL statement requests the jackknife variance estimation method. A STRATA statement is not required when the REPWEIGHTS statement is specified.

```

proc surveypHreg data = LibraryRepWeights varmethod = jk;
 weight SamplingWeight;
 repweights RepWt_: / jkcoefs = LibraryJKCOEF;
 model lenBorrow*Returned(0) = Age;
run;

```

Output 93.4.1 displays some summary information. The “Number of Observations,” “Censored Summary,” and “Weighted Censored Summary” tables are exactly the same as in the example discussed in “Getting Started: SURVEYPHREG Procedure” on page 7857. The “Variance Estimation” table displays information about the variance estimation, such as the name of the variance estimation method and the number of replicate samples.

**Output 93.4.1** Summary Statistics for Overall Analysis

| Number of Replicates                                        |          |                        | 46        |                  |

Output 93.4.2 shows that the estimated regression coefficient is 0.0616 with a standard error of 0.009. The denominator degrees of freedom (46) for the *t* test is equal to the number of replicates used. Note that the estimated proportional hazards regression coefficient is the same as the estimated proportional hazards regression coefficient in the example in “Getting Started: SURVEYPHREG Procedure” on page 7857, but the standard error and the denominator degrees of freedom are different. This is not surprising because these two examples use the same estimator to estimate the regression coefficients but different estimators to estimate the variance.

**Output 93.4.2** Inferences Based on Survey Design for Overall Analysis

## Example 93.5: A Test of the Proportional Hazards Assumption by Using the Programming Statements

You can use programming statements in PROC SURVEYPHREG to create time-dependent covariates to test the proportional hazards assumption for complex survey data. Consider the data set mortality from Example 93.3. The data set contains 1,891 observations from the 1992 NHANES I Epidemiologic Followup study (NHEFS) vital and tracing status.

Suppose you want to fit a proportional hazards model to this data and construct a test for the proportional hazards assumption on gender. The following statements request a proportional hazards regression of age on gender and x, where the time-dependent covariate x is created using the programming statements. The explanatory variable x assumes the value of the time variable age for the male subgroup. The variable vitalstatus is the censor indicator, and a value of 1, 4, 5, or 6 indicates a censored observation. The WEIGHT statement specifies the sampling weight, and the CLASS statement specifies that gender is a classification variable.

```
proc surveypHreg data = mortality nomcar;
 class gender;
 strata varstrata;
 cluster varpsu;
 weight sweight;
 model age*vitalstatus(1 4 5 6) = gender x;
 x = age*(gender=1);
run;
```

Output 93.5.1 displays some summary information. The “Number of Observations,” “Censored Summary,” and “Weighted Censored Summary” tables are exactly the same as in the example discussed in “Example 93.3: Domain Analysis” on page 7921.

### Output 93.5.1 Data Summary, Censored Summary, and Information about Variance Estimation

| The SURVEYPHREG Procedure                                   |          |          |                  |  |

| Number of Observations Read                                 |          | 1891     |                  |  |
| Number of Observations Used                                 |          | 1891     |                  |  |
| Sum of Weights Read                                         |          | 1.0298E8 |                  |  |
| Sum of Weights Used                                         |          | 1.0298E8 |                  |  |
| Summary of the Number of Event and Censored Values          |          |          |                  |  |
| Total                                                       | Event    | Censored | Percent Censored |  |
| 1891                                                        | 717      | 1174     | 62.08            |  |
| Summary of the Weighted Number of Event and Censored Values |          |          |                  |  |
| Total                                                       | Event    | Censored | Percent Censored |  |
| 1.0298E8                                                    | 27650348 | 75328323 | 73.15            |  |

**Output 93.5.1** *continued*

| Variance Estimation |               |
|---------------------|---------------|
| Method              | Taylor Series |
| Missing Values      | NOMCAR        |

**Output 93.5.2** displays the estimated regression coefficients and their standard errors. The variable gender has two levels, and only one level is estimable. By default, PROC SURVEYPHREG estimates the first level (GENDER 1) and assigns a zero value for the second level. The estimated regression coefficient is 1.61 with a standard error of 0.71. The estimated regression coefficient for  $x$  is  $-0.02$  with a standard error of 0.01. The  $t$  statistic for  $x$  is  $-1.55$  with a  $p$ -value of 0.13 on 33 degrees of freedom. This test suggests that an interaction between the time variable age and gender is not significant. Therefore, there is little evidence of an exponential trend over time in the hazard ratio for gender.

**Output 93.5.2** Parameter Estimates

| Analysis of Maximum Likelihood Estimates |    |             |                |         |         |              |

## Overview: SURVEYREG Procedure

The SURVEYREG procedure performs regression analysis for sample survey data. This procedure can handle complex survey sample designs, including designs with stratification, clustering, and unequal weighting. The procedure fits linear models for survey data and computes regression coefficients and their variance-covariance matrix. The procedure also provides significance tests for the model effects and for any specified estimable linear functions of the model parameters. Using the regression model, the procedure can compute predicted values for the sample survey data.

PROC SURVEYREG uses elementwise regression to compute the regression coefficient estimators by generalized least squares estimation. The procedure assumes that the regression coefficients are the same across strata and primary sampling units (PSUs). To estimate the variance-covariance matrix for the regression coefficients, PROC SURVEYREG uses either the Taylor series (linearization) method or replication (resampling) methods to estimate sampling errors of estimators, based on complex sample designs. For details see Woodruff (1971); Fuller (1975); Särndal, Swensson, and Wretman (1992); Wolter (2007); Rust (1985); Dippo, Fay, and Morganstein (1984); Rao and Shao (1999); Rao, Wu, and Yue (1992); and Rao and Shao (1996).

---

## Getting Started: SURVEYREG Procedure

This section demonstrates how you can use PROC SURVEYREG to perform a regression analysis for sample survey data. For a complete description of the usage of PROC SURVEYREG, see the section “[Syntax: SURVEYREG Procedure](#)” on page 7942. The section “[Examples: SURVEYREG Procedure](#)” on page 7985 provides more detailed examples that illustrate the applications of PROC SURVEYREG.

---

## Simple Random Sampling

Suppose that, in a junior high school, there are a total of 4,000 students in grades 7, 8, and 9. You want to know how household income and the number of children in a household affect students’ average weekly spending for ice cream.

In order to answer this question, you draw a sample by using simple random sampling from the student population in the junior high school. You randomly select 40 students and ask them their average weekly expenditure for ice cream, their household income, and the number of children in their household. The answers from the 40 students are saved as the following SAS data set `IceCream`:

```
data IceCream;
 input Grade Spending Income Kids @@;
 datalines;
7 7 39 2 7 7 38 1 8 12 47 1
9 10 47 4 7 1 34 4 7 10 43 2
7 3 44 4 8 20 60 3 8 19 57 4
7 2 35 2 7 2 36 1 9 15 51 1
8 16 53 1 7 6 37 4 7 6 41 2
7 6 39 2 9 15 50 4 8 17 57 3
```

```

8 14 46 2 9 8 41 2 9 8 41 1
9 7 47 3 7 3 39 3 7 12 50 2
7 4 43 4 9 14 46 3 8 18 58 4
9 9 44 3 7 2 37 1 7 1 37 2
7 4 44 2 7 11 42 2 9 8 41 2
8 10 42 2 8 13 46 1 7 2 40 3
9 6 45 1 9 11 45 4 7 2 36 1
7 9 46 1
;

```

In the data set `IceCream`, the variable `Grade` indicates a student's grade. The variable `Spending` contains the dollar amount of each student's average weekly spending for ice cream. The variable `Income` specifies the household income, in thousands of dollars. The variable `Kids` indicates how many children are in a student's family.

The following PROC SURVEYREG statements request a regression analysis:

```

title1 'Ice Cream Spending Analysis';
title2 'Simple Random Sample Design';
proc surveyreg data=IceCream total=4000;
 class Kids;
 model Spending = Income Kids / solution;
run;

```

The PROC SURVEYREG statement invokes the procedure. The `TOTAL=4000` option specifies the total in the population from which the sample is drawn. The `CLASS` statement requests that the procedure use the variable `Kids` as a classification variable in the analysis. The `MODEL` statement describes the linear model that you want to fit, with `Spending` as the dependent variable and `Income` and `Kids` as the independent variables. The `SOLUTION` option in the `MODEL` statement requests that the procedure output the regression coefficient estimates.

Figure 94.1 displays the summary of the data, the summary of the fit, and the levels of the classification variable `Kids`. The "Fit Statistics" table displays the denominator degrees of freedom, which are used in  $F$  tests and  $t$  tests in the regression analysis.

**Figure 94.1** Summary of Data

|                                                     |           |

| Kids                    | 4      | 1 2 3 4 |

Figure 94.2 displays the tests for model effects. The effect Income is significant in the linear regression model, while the effect Kids is not significant at the 5% level.

Figure 94.2 Testing Effects in the Regression

| Tests of Model Effects |        |         |        |
|------------------------|--------|---------|--------|
| Effect                 | Num DF | F Value | Pr > F |
| Model                  | 4      | 119.15  | <.0001 |
| Intercept              | 1      | 153.32  | <.0001 |
| Income                 | 1      | 324.45  | <.0001 |
| Kids                   | 3      | 0.92    | 0.4385 |

NOTE: The denominator degrees of freedom for the F tests is 39.

The regression coefficient estimates and their standard errors and associated  $t$  tests are displayed in Figure 94.3.

Figure 94.3 Regression Coefficients

| Estimated Regression Coefficients |            |                |         |         |
|-----------------------------------|------------|----------------|---------|---------|
| Parameter                         | Estimate   | Standard Error | t Value | Pr >  t |
| Intercept                         | -26.084677 | 2.46720403     | -10.57  | <.0001  |
| Income                            | 0.775330   | 0.04304415     | 18.01   | <.0001  |
| Kids 1                            | 0.897655   | 1.12352876     | 0.80    | 0.4292  |
| Kids 2                            | 1.494032   | 1.24705263     | 1.20    | 0.2381  |
| Kids 3                            | -0.513181  | 1.33454891     | -0.38   | 0.7027  |
| Kids 4                            | 0.000000   | 0.00000000     | .       | .       |

NOTE: The denominator degrees of freedom for the  $t$  tests is 39.  
Matrix X'X is singular and a generalized inverse was used to solve the normal equations. Estimates are not unique.

## Stratified Sampling

Suppose that the previous student sample is actually drawn using a stratified sample design. The strata are grades in the junior high school: 7, 8, and 9. Within strata, simple random samples are selected. Table 94.1 provides the number of students in each grade.

**Table 94.1** Students in Grades

| Grade        | Number of Students |
|--------------|--------------------|
| 7            | 1,824              |
| 8            | 1,025              |
| 9            | 1,151              |
| <b>Total</b> | <b>4,000</b>       |

In order to analyze this sample by using PROC SURVEYREG, you need to input the stratification information by creating a SAS data set with the information in Table 94.1. The following SAS statements create such a data set called StudentTotals:

```
data StudentTotals;
 input Grade _TOTAL_;
 datalines;
7 1824
8 1025
9 1151
;
```

The variable Grade is the stratification variable, and the variable \_TOTAL\_ contains the total numbers of students in each stratum in the survey population. PROC SURVEYREG requires you to use the keyword \_TOTAL\_ as the name of the variable that contains the population total information.

In a stratified sample design, when the sampling rates in the strata are unequal, you need to use sampling weights to reflect this information. For this example, the appropriate sampling weights are the reciprocals of the probabilities of selection. You can use the following DATA step to create the sampling weights:

```
data IceCream;
 set IceCream;
 if Grade=7 then Prob=20/1824;
 if Grade=8 then Prob=9/1025;
 if Grade=9 then Prob=11/1151;
 Weight=1/Prob;
run;
```

If you use PROC SURVEYSELECT to select your sample, PROC SURVEYSELECT creates these sampling weights for you.

The following statements demonstrate how you can fit a linear model while incorporating the sample design information (stratification):

```

title1 'Ice Cream Spending Analysis';
title2 'Stratified Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
 strata Grade /list;
 class Kids;
 model Spending = Income Kids / solution;
 weight Weight;
run;

```

Comparing these statements to those in the section “[Simple Random Sampling](#)” on page 7935, you can see how the TOTAL=StudentTotals option replaces the previous TOTAL=4000 option.

The STRATA statement specifies the stratification variable Grade. The LIST option in the STRATA statement requests that the stratification information be included in the output. The WEIGHT statement specifies the weight variable.

[Figure 94.4](#) summarizes the data information, the sample design information, and the fit information. Note that, due to the stratification, the denominator degrees of freedom for  $F$  tests and  $t$  tests are 37, which is different from the analysis in [Figure 94.1](#).

**Figure 94.4** Summary of the Regression

|                                                     |         |

| The SURVEYREG Procedure                             |         |
| Regression Analysis for Dependent Variable Spending |         |
| Data Summary                                        |         |
| Number of Observations                              | 40      |
| Sum of Weights                                      | 4000.0  |
| Weighted Mean of Spending                           | 9.14130 |
| Weighted Sum of Spending                            | 36565.2 |
| Design Summary                                      |         |
| Number of Strata                                    | 3       |
| Fit Statistics                                      |         |
| R-square                                            | 0.8219  |
| Root MSE                                            | 2.4185  |
| Denominator DF                                      | 37      |

For each stratum, [Figure 94.5](#) displays the value of identifying variables, the number of observations (sample size), the total population size, and the calculated sampling rate or fraction.

**Figure 94.5** Stratification and Classification Information

| Stratum Information |       |       |                  |               |
|---------------------|-------|-------|------------------|---------------|
| Stratum Index       | Grade | N Obs | Population Total | Sampling Rate |
| 1                   | 7     | 20    | 1824             | 1.10%         |
| 2                   | 8     | 9     | 1025             | 0.88%         |
| 3                   | 9     | 11    | 1151             | 0.96%         |

| Class Level Information |        |        |       |
|-------------------------|--------|--------|-------|
| Class Variable          | Levels | Values |       |
| Kids                    | 4      | 1      | 2 3 4 |

Figure 94.6 displays the tests for the significance of model effects under the stratified sample design. The Income effect is strongly significant, while the Kids effect is not significant at the 5% level.

**Figure 94.6** Testing Effects

| Tests of Model Effects |        |         |        |
|------------------------|--------|---------|--------|
| Effect                 | Num DF | F Value | Pr > F |
| Model                  | 4      | 124.85  | <.0001 |
| Intercept              | 1      | 150.95  | <.0001 |
| Income                 | 1      | 326.89  | <.0001 |
| Kids                   | 3      | 0.99    | 0.4081 |

NOTE: The denominator degrees of freedom for the F tests is 37.

The regression coefficient estimates for the stratified sample, along with their standard errors and associated  $t$  tests, are displayed in Figure 94.7.

**Figure 94.7** Regression Coefficients

| Estimated Regression Coefficients |            |                |         |         |
|-----------------------------------|------------|----------------|---------|---------|
| Parameter                         | Estimate   | Standard Error | t Value | Pr >  t |
| Intercept                         | -26.086882 | 2.44108058     | -10.69  | <.0001  |
| Income                            | 0.776699   | 0.04295904     | 18.08   | <.0001  |
| Kids 1                            | 0.888631   | 1.07000634     | 0.83    | 0.4116  |
| Kids 2                            | 1.545726   | 1.20815863     | 1.28    | 0.2087  |
| Kids 3                            | -0.526817  | 1.32748011     | -0.40   | 0.6938  |
| Kids 4                            | 0.000000   | 0.00000000     | .       | .       |

NOTE: The denominator degrees of freedom for the t tests is 37.  
Matrix X'WX is singular and a generalized inverse was used to solve the normal equations. Estimates are not unique.

You can request other statistics and tests by using PROC SURVEYREG. You can also analyze data from a more complex sample design. The remainder of this chapter provides more detailed information.

---

## Output Data Sets

You can use the OUTPUT statement to create a new SAS data set that contains the estimated linear predictors and their standard error estimates, the residuals from the linear regression, and the confidence limits for the predictors. See the section “[OUTPUT Statement](#)” on page 7960 for more details.

You can use the Output Delivery System (ODS) to create SAS data sets that capture the outputs from PROC SURVEYREG. For more information about ODS, see Chapter 20, “[Using the Output Delivery System.](#)”

For example, to save the “ParameterEstimates” table ([Figure 94.7](#)) in the previous section in an output data set, you use the ODS OUTPUT statement as follows:

```

title1 'Ice Cream Spending Analysis';
title2 'Stratified Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
 strata Grade /list;
 class Kids;
 model Spending = Income Kids / solution;
 weight Weight;
 ods output ParameterEstimates = MyParmEst;
run;

```

The statement

```
ods output ParameterEstimates = MyParmEst;
```

requests that the “ParameterEstimates” table that appears in [Figure 94.7](#) be placed into a SAS data set MyParmEst.

The PRINT procedure displays observations of the data set MyParmEst:

```
proc print data=MyParmEst;
run;
```

Figure 94.8 displays the observations in the data set MyParmEst. The section “ODS Table Names” on page 7983 gives the complete list of the tables produced by PROC SURVEYREG.

**Figure 94.8** The Data Set MyParmEst

## Syntax: SURVEYREG Procedure

The following statements are available in the SURVEYREG procedure:

```
PROC SURVEYREG < options > ;
 BY variables ;
 CLASS variables ;
 CLUSTER variables ;
 CONTRAST 'label' effect values < ... effect values > < / options > ;
 DOMAIN variables < variable*variable variable*variable*variable ... > ;
 EFFECT name = effect-type (variables < / options >) ;
 ESTIMATE < 'label' > estimate-specification < / options > ;
 LSMEANS < model-effects > < / options > ;
 LSMESTIMATE model-effect lsmestimate-specification < / options > ;
 MODEL dependent = < effects > < / options > ;
 OUTPUT < keyword < =variable-name > ... keyword < =variable-name > > < / option > ;
 REPWEIGHTS variables < / options > ;
 SLICE model-effect < / options > ;
 STORE < OUT= > item-store-name < / LABEL='label' > ;
 STRATA variables < / options > ;
 TEST < model-effects > < / options > ;
 WEIGHT variable ;
```

The PROC SURVEYREG and MODEL statements are required. If your model contains classification effects, you must list the classification variables in a CLASS statement, and the CLASS statement must pre-

cede the MODEL statement. If you use a CONTRAST statement or an ESTIMATE statement, the MODEL statement must precede the CONTRAST or ESTIMATE statement.

The rest of this section provides detailed syntax information for each of the preceding statements, except the EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, SLICE, STORE, and TEST statements. These statements are also available in many other procedures. Summary descriptions of functionality and syntax for these statements are shown in this chapter, and full documentation about them is available in Chapter 19, “Shared Concepts and Topics.”

The CLASS, CLUSTER, CONTRAST, EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, REPWEIGHTS, SLICE, STRATA, TEST statements can appear multiple times. You should use only one of each of the following statements: MODEL, WEIGHT, STORE, and OUTPUT.

The syntax descriptions begin with the PROC SURVEYREG statement; the remaining statements are covered in alphabetical order.

---

## PROC SURVEYREG Statement

**PROC SURVEYREG** < options > ;

The PROC SURVEYREG statement invokes the SURVEYREG procedure. It optionally names the input data sets and specifies the variance estimation method.

Table 94.2 summarizes the options available in the PROC SURVEYREG statement.

**Table 94.2** PROC SURVEYREG Statement Options

| Option     | Description                                                                               |
|------------|-------------------------------------------------------------------------------------------|
| ALPHA=     | Sets the confidence level                                                                 |
| DATA=      | Specifies the SAS data set to be analyzed                                                 |
| MISSING    | Treats missing values as a nonmissing                                                     |
| NOMCAR     | Treats missing values as <i>not missing completely at random</i>                          |
| ORDER=     | Specifies the sort order                                                                  |
| RATE=      | Specifies the sampling rate                                                               |
| TOTAL=     | Specifies the total number of primary sampling units                                      |
| TRUNCATE   | Specifies class levels using no more than the first 16 characters of the formatted values |
| VARMETHOD= | Specifies the variance estimation method                                                  |

You can specify the following options in the PROC SURVEYREG statement:

### **ALPHA=** $\alpha$

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of  $\alpha$  produces  $100(1 - \alpha)\%$  confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

**DATA=SAS-data-set**

specifies the SAS data set to be analyzed by PROC SURVEYREG. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

**MISSING**

treats missing values as a valid (nonmissing) category for all categorical variables, which include **CLASS**, **STRATA**, **CLUSTER**, and **DOMAIN** variables.

By default, if you do not specify the MISSING option, an observation is excluded from the analysis if it has a missing value. For more information, see the section “Missing Values” on page 7964.

**NOMCAR**

requests that the procedure treat missing values in the variance computation as *not missing completely at random* (NOMCAR) for Taylor series variance estimation. When you specify the NOMCAR option, PROC SURVEYREG computes variance estimates by analyzing the nonmissing values as a domain or subpopulation, where the entire population includes both nonmissing and missing domains. See the section “Missing Values” on page 7964 for more details.

By default, PROC SURVEYREG completely excludes an observation from analysis if that observation has a missing value, unless you specify the MISSING option. Note that the NOMCAR option has no effect on a classification variable when you specify the MISSING option, which treats missing values as a valid nonmissing level.

The NOMCAR option applies only to Taylor series variance estimation. The replication methods, which you request with the **VARMETHOD=BRR** and **VARMETHOD=JACKKNIFE** options, do not use the NOMCAR option.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of the classification variables (which are specified in the **CLASS** statement).

This option also determines the sort order for the levels of **DOMAIN** variables.

This option applies to the levels for all classification variables, except when you use the (default) **ORDER=FORMATTED** option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

| Value of ORDER=  | Levels Sorted By                                                                                                                       |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DATA</b>      | Order of appearance in the input data set                                                                                              |
| <b>FORMATTED</b> | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| <b>FREQ</b>      | Descending frequency count; levels with the most observations come first in the order                                                  |
| <b>INTERNAL</b>  | Unformatted value                                                                                                                      |

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the

sort order is machine-dependent. For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**RATE=***value* | *SAS-data-set*

**R=***value* | *SAS-data-set*

specifies the sampling rate as a nonnegative *value*, or specifies an input data set that contains the stratum sampling rates. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the RATE= option for BRR or jackknife variance estimation, which you request with the **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** option.

If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of PSUs selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative *value* for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 7965 for more details.

The *value* in the RATE= option or the values of `_RATE_` in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYREG converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you do not specify the **TOTAL=** or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the **TOTAL=** and RATE= options.

**TOTAL=***value* | *SAS-data-set*

**N=***value* | *SAS-data-set*

specifies the total number of primary sampling units in the study population as a positive *value*, or specifies an input data set that contains the stratum population totals. The procedure uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the TOTAL= option for BRR or jackknife variance estimation, which you request with the **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** option.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 7965 for more details.

If you do not specify the **TOTAL=** or **RATE=** option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the **TOTAL=** and **RATE=** options.

**TRUNCATE**

specifies that class levels should be determined using no more than the first 16 characters of the formatted values of the CLASS, STRATA, and CLUSTER variables. When formatted values are longer than 16 characters, you can use this option in order to revert to the levels as determined in releases before SAS 9.

**VARMETHOD=BRR** <(method-options)>

**VARMETHOD=JACKKNIFE** | **JK** <(method-options)>

**VARMETHOD=TAYLOR**

specifies the variance estimation method. **VARMETHOD=TAYLOR** requests the Taylor series method, which is the default if you do not specify the **VARMETHOD=** option or the **REPWEIGHTS** statement. **VARMETHOD=BRR** requests variance estimation by balanced repeated replication (BRR), and **VARMETHOD=JACKKNIFE** requests variance estimation by the delete-1 jackknife method.

For **VARMETHOD=BRR** and **VARMETHOD=JACKKNIFE** you can specify *method-options* in parentheses. Table 94.3 summarizes the available *method-options*.

**Table 94.3** Variance Estimation Options

| <b>VARMETHOD=</b> | <b>Variance Estimation Method</b> | <i>Method-Options</i>                                                                     |
|-------------------|-----------------------------------|-------------------------------------------------------------------------------------------|
| BRR               | Balanced repeated replication     | FAY <=value><br>HADAMARD=SAS-data-set<br>OUTWEIGHTS=SAS-data-set<br>PRINTH<br>REPS=number |
| JACKKNIFE         | Jackknife                         | OUTJKCOEFS=SAS-data-set<br>OUTWEIGHTS=SAS-data-set                                        |
| TAYLOR            | Taylor series linearization       | None                                                                                      |

*Method-options* must be enclosed in parentheses following the method keyword. For example:

```
varmethod=BRR(reps=60 outweights=myReplicateWeights)
```

The following values are available for the **VARMETHOD=** option:

**BRR** <(method-options)>

requests **balanced repeated replication** (BRR) variance estimation. The BRR method requires a stratified sample design with two primary sampling units (PSUs) per stratum. See the section “**Balanced Repeated Replication (BRR) Method**” on page 7971 for more information.

You can specify the following *method-options* in parentheses following **VARMETHOD=BRR**:

**FAY** <=value>

requests **Fay’s method**, a modification of the BRR method, for variance estimation. See the section “**Fay’s BRR Method**” on page 7972 for more information.

You can specify the *value* of the Fay coefficient, which is used in converting the original sampling weights to replicate weights. The Fay coefficient must be a nonnegative number less than 1. By default, the value of the Fay coefficient equals 0.5.

**HADAMARD=SAS-data-set****H=SAS-data-set**

names a SAS data set that contains the [Hadamard matrix](#) for BRR replicate construction. If you do not provide a Hadamard matrix with the `HADAMARD= method-option`, PROC SURVEYREG generates an appropriate Hadamard matrix for replicate construction. See the sections “[Balanced Repeated Replication \(BRR\) Method](#)” on page 7971 and “[Hadamard Matrix](#)” on page 7973 for details.

If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the `HADAMARD= method-option`.

In the `HADAMARD=` input data set, each variable corresponds to a column of the Hadamard matrix, and each observation corresponds to a row of the matrix. You can use any variable names in the `HADAMARD=` data set. All values in the data set must equal either 1 or -1. You must ensure that the matrix you provide is indeed a Hadamard matrix—that is,  $\mathbf{A}'\mathbf{A} = R\mathbf{I}$ , where  $\mathbf{A}$  is the Hadamard matrix of dimension  $R$  and  $\mathbf{I}$  is an identity matrix. PROC SURVEYREG does not check the validity of the Hadamard matrix that you provide.

The `HADAMARD=` input data set must contain at least  $H$  variables, where  $H$  denotes the number of first-stage strata in your design. If the data set contains more than  $H$  variables, the procedure uses only the first  $H$  variables. Similarly, the `HADAMARD=` input data set must contain at least  $H$  observations.

If you do not specify the `REPS= method-option`, then the number of replicates is taken to be the number of observations in the `HADAMARD=` input data set. If you specify the number of replicates—for example, `REPS=nreps`—then the first  $nreps$  observations in the `HADAMARD=` data set are used to construct the replicates.

You can specify the `PRINTH` option to display the Hadamard matrix that the procedure uses to construct replicates for BRR.

**OUTWEIGHTS=SAS-data-set**

names a SAS data set that contains replicate weights. See the section “[Balanced Repeated Replication \(BRR\) Method](#)” on page 7971 for information about replicate weights. See the section “[Replicate Weights Output Data Set](#)” on page 7978 for more details about the contents of the `OUTWEIGHTS=` data set.

The `OUTWEIGHTS= method-option` is not available when you provide replicate weights with the `REPWEIGHTS` statement.

**PRINTH**

displays the Hadamard matrix.

When you provide your own Hadamard matrix with the `HADAMARD= method-option`, only the rows and columns of the Hadamard matrix that

are used by the procedure are displayed. See the sections “Balanced Repeated Replication (BRR) Method” on page 7971 and “Hadamard Matrix” on page 7973 for details.

The PRINTH *method-option* is not available when you provide replicate weights with the REPWEIGHTS statement because the procedure does not use a Hadamard matrix in this case.

**REPS=*number***

specifies the number of replicates for BRR variance estimation. The value of *number* must be an integer greater than 1.

If you do not provide a Hadamard matrix with the HADAMARD= *method-option*, the number of replicates should be greater than the number of strata and should be a multiple of 4. See the section “Balanced Repeated Replication (BRR) Method” on page 7971 for more information. If a Hadamard matrix cannot be constructed for the REPS= value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the REPS= value that you specify.

If you provide a Hadamard matrix with the HADAMARD= *method-option*, the value of REPS= must not be less than the number of rows in the Hadamard matrix. If you provide a Hadamard matrix and do not specify the REPS= *method-option*, the number of replicates equals the number of rows in the Hadamard matrix.

If you do not specify the REPS= or HADAMARD= *method-option* and do not include a REPWEIGHTS statement, the number of replicates equals the smallest multiple of 4 that is greater than the number of strata.

If you provide replicate weights with the REPWEIGHTS statement, the procedure does not use the REPS= *method-option*. With a REPWEIGHTS statement, the number of replicates equals the number of REPWEIGHTS variables.

**JACKKNIFE | JK <(method-options)>**

requests variance estimation by the delete-1 jackknife method. See the section “Jackknife Method” on page 7972 for details. If you provide replicate weights with a REPWEIGHTS statement, VARMETHOD=JACKKNIFE is the default variance estimation method.

You can specify the following *method-options* in parentheses following VARMETHOD=JACKKNIFE:

**OUTJKCOEFS=*SAS-data-set***

names a SAS data set that contains jackknife coefficients. See the section “Jackknife Method” on page 7972 for information about jackknife coefficients. See the section “Jackknife Coefficients Output Data Set” on page 7978 for more details about the contents of the OUTJKCOEFS= data set.

**OUTWEIGHTS=SAS-data-set**

names a SAS data set that contains replicate weights. See the section “[Jackknife Method](#)” on page 7972 for information about replicate weights. See the section “[Replicate Weights Output Data Set](#)” on page 7978 for more details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= *method-option* is not available when you provide replicate weights with the [REPWEIGHTS](#) statement.

**TAYLOR**

requests Taylor series variance estimation. This is the default method if you do not specify the [VARMETHOD=](#) option or a [REPWEIGHTS](#) statement. See the section “[Taylor Series \(Linearization\)](#)” on page 7970 for more information.

---

## BY Statement

**BY variables ;**

You can specify a BY statement with PROC SURVEYREG to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the SURVEYREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid domain (subpopulation) analysis, where the total number of units in the subpopulation is not known with certainty. You should use the DOMAIN statement to obtain domain analysis. For more information about subpopulation analysis for sample survey data, see Cochran (1977).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

**CLASS** *variables* ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

**NOTE:** Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the PROC SURVEYREG statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the ORDER= option in the PROC SURVEYREG statement.

You can use multiple CLASS statements to specify classification variables.

---

## CLUSTER Statement

**CLUSTER** *variables* ;

The CLUSTER statement names variables that identify the clusters in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If you provide replicate weights for BRR or jackknife variance estimation with the REPWEIGHTS statement, you do not need to specify a CLUSTER statement.

If your sample design has clustering at multiple stages, you should identify only the first-stage clusters (primary sampling units (PSUs)), in the CLUSTER statement. See the section “Primary Sampling Units (PSUs)” on page 7966 for more information.

The CLUSTER *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

When determining levels of a CLUSTER variable, an observation with missing values for this CLUSTER variable is excluded, unless you specify the MISSING option. For more information, see the section “Missing Values” on page 7964.

You can use multiple CLUSTER statements to specify cluster variables. The procedure uses variables from all CLUSTER statements to create clusters.

Prior to SAS 9, clusters were determined by using no more than the first 16 characters of the formatted values. If you want to revert to this previous behavior, you can use the TRUNCATE option in the PROC SURVEYREG statement.

## CONTRAST Statement

**CONTRAST** *'label'* effect values *</ options >* ;

**CONTRAST** *'label'* effect values *< . . . effect values >* *</ options >* ;

The CONTRAST statement provides custom hypothesis tests for linear combinations of the regression parameters  $H_0: \mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ , where  $\mathbf{L}$  is the vector or matrix you specify and  $\boldsymbol{\beta}$  is the vector of regression parameters. Thus, to use this feature, you must be familiar with the details of the model parameterization used by PROC SURVEYREG. For information about the parameterization, see the section “GLM Parameterization of Classification Variables and Effects” on page 383 in Chapter 19, “Shared Concepts and Topics.”

Each term in the MODEL statement, called an *effect*, is a variable or a combination of variables. You can specify an effect with a variable name or a special notation by using variable names and operators. For more details about how to specify an effect, see the section “Specification of Effects” on page 3324 in Chapter 42, “The GLM Procedure.”

For each CONTRAST statement, PROC SURVEYREG computes Wald’s  $F$  test. The procedure displays this value with the degrees of freedom, and identifies it with the contrast label. The numerator degrees of freedom for Wald’s  $F$  test equal  $\text{rank}(\mathbf{L})$ . The denominator degrees of freedom equal the number of clusters (or the number of observations if there is no CLUSTER statement) minus the number of strata. Alternatively, you can use the **DF=** option in the MODEL statement to specify the denominator degrees of freedom.

You can specify any number of CONTRAST statements, but they must appear after the MODEL statement.

In the CONTRAST statement,

|               |                                                                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>label</i>  | identifies the contrast in the output. A label is required for every contrast specified. Labels must be enclosed in single quotes.                                                                                         |
| <i>effect</i> | identifies an effect that appears in the MODEL statement. You can use the INTERCEPT keyword as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the MODEL statement. |
| <i>values</i> | are constants that are elements of $\mathbf{L}$ associated with the effect.                                                                                                                                                |

You can specify the following options in the CONTRAST statement after a slash (/):

### **E**

displays the entire coefficient  $\mathbf{L}$  vector or matrix.

### **NOFILL**

requests no filling in higher-order effects. When you specify only certain portions of  $\mathbf{L}$ , by default PROC SURVEYREG constructs the remaining elements from the context. (For more information, see the section “Specification of ESTIMATE Expressions” on page 3345 in Chapter 42, “The GLM Procedure.”)

When you specify the NOFILL option, PROC SURVEYREG does not construct the remaining portions and treats the vector or matrix  $\mathbf{L}$  as it is defined in the CONTRAST statement.

**SINGULAR=value**

tunes the estimability checking. If  $\mathbf{v}$  is a vector, define  $\text{ABS}(\mathbf{v})$  to be the largest absolute value of the elements of  $\mathbf{v}$ . For a row vector  $\mathbf{l}$  of the matrix  $\mathbf{L}$ , define

$$c = \begin{cases} \text{ABS}(\mathbf{l}) & \text{if } \text{ABS}(\mathbf{l}) > 0 \\ 1 & \text{otherwise} \end{cases}$$

If  $\text{ABS}(\mathbf{l} - \mathbf{lH})$  is greater than  $c \cdot \text{value}$ , then  $\mathbf{l}\boldsymbol{\beta}$  is declared nonestimable. Here,  $\mathbf{H}$  is the matrix  $(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{X}$ . The *value* must be between 0 and 1; the default is  $10^{-7}$ .

As stated previously, the CONTRAST statement enables you to perform hypothesis tests  $H_0: \mathbf{L}\boldsymbol{\beta} = 0$ .

If the  $\mathbf{L}$  matrix contains more than one contrast, then you can separate the rows of the  $\mathbf{L}$  matrix with commas.

For example, for the model

```
proc surveyreg;
 class A B;
 model Y=A B;
run;
```

with A at 5 levels and B at 2 levels, the parameter vector is

$$(\mu \ \alpha_1 \ \alpha_2 \ \alpha_3 \ \alpha_4 \ \alpha_5 \ \beta_1 \ \beta_2)$$

To test the hypothesis that the pooled A linear and A quadratic effect is zero, you can use the following  $\mathbf{L}$  matrix:

$$\mathbf{L} = \begin{bmatrix} 0 & -2 & -1 & 0 & 1 & 2 & 0 & 0 \\ 0 & 2 & -1 & -2 & -1 & 2 & 0 & 0 \end{bmatrix}$$

The corresponding CONTRAST statement is

```
contrast 'A Linear & Quadratic'
 a -2 -1 0 1 2,
 a 2 -1 -2 -1 2;
```

## DOMAIN Statement

**DOMAIN** *variables* < *variable\*variable variable\*variable\*variable ...* > ;

The DOMAIN statement requests analysis for domains (subpopulations) in addition to analysis for the entire study population. The DOMAIN statement names the variables that identify domains, which are called domain variables.

It is common practice to compute statistics for domains. The formation of these domains might be unrelated to the sample design. Therefore, the sample sizes for the domains are random variables. Use a DOMAIN statement to incorporate this variability into the variance estimation.

Note that a DOMAIN statement is different from a BY statement. In a BY statement, you treat the sample sizes as fixed in each subpopulation, and you perform analysis within each BY group independently. See the section “[Domain Analysis](#)” on page 7976 for more details.

Use the DOMAIN statement on the entire data set to perform a domain analysis. Creating a new data set from a single domain and analyzing that with PROC SURVEYREG yields inappropriate estimates of variance.

A domain variable can be either character or numeric. The procedure treats domain variables as categorical variables. If a variable appears by itself in a DOMAIN statement, each level of this variable determines a domain in the study population. If two or more variables are joined by asterisks (\*), then every possible combination of levels of these variables determines a domain. The procedure performs a descriptive analysis within each domain that is defined by the domain variables.

When determining levels of a DOMAIN variable, an observation with missing values for this DOMAIN variable is excluded, unless you specify the MISSING option. For more information, see the section “Missing Values” on page 7964.

The formatted values of the domain variables determine the categorical variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

---

## EFFECT Statement

**EFFECT** *name=effect-type (variables < / options>);*

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “GLM Parameterization of Classification Variables and Effects” on page 383 in Chapter 19, “Shared Concepts and Topics.”

You can specify the following *effect-types*:

|                          |                                                                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>COLLECTION</b>        | is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.       |
| <b>LAG</b>               | is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.                                                                           |
| <b>MULTIMEMBER   MM</b>  | is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.                                                                             |
| <b>POLYNOMIAL   POLY</b> | is a multivariate polynomial effect in the specified numeric variables.                                                                                                                                   |
| <b>SPLINE</b>            | is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables. |

Table 94.4 summarizes the *options* available in the EFFECT statement.

**Table 94.4** EFFECT Statement Options

| Option                            | Description                                        |
|-----------------------------------|----------------------------------------------------|
| <b>Collection Effects Options</b> |                                                    |
| DETAILS                           | Displays the constituents of the collection effect |

Table 94.4 continued

| Option                             | Description                                                                                                                                          |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Lag Effects Options</b>         |                                                                                                                                                      |
| DESIGNROLE=                        | Names a variable that controls to which lag design an observation is assigned                                                                        |
| DETAILS                            | Displays the lag design of the lag effect                                                                                                            |
| NLAG=                              | Specifies the number of periods in the lag                                                                                                           |
| PERIOD=                            | Names the variable that defines the period                                                                                                           |
| WITHIN=                            | Names the variable or variables that define the group within which each period is defined                                                            |
| <b>Multimember Effects Options</b> |                                                                                                                                                      |
| NOEFFECT                           | Specifies that observations with all missing levels for the multimember variables should have zero values in the corresponding design matrix columns |
| WEIGHT=                            | Specifies the weight variable for the contributions of each of the classification effects                                                            |
| <b>Polynomial Effects Options</b>  |                                                                                                                                                      |
| DEGREE=                            | Specifies the degree of the polynomial                                                                                                               |
| MDEGREE=                           | Specifies the maximum degree of any variable in a term of the polynomial                                                                             |
| STANDARDIZE=                       | Specifies centering and scaling suboptions for the variables that define the polynomial                                                              |
| <b>Spline Effects Options</b>      |                                                                                                                                                      |
| BASIS=                             | Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion                                              |
| DEGREE=                            | Specifies the degree of the spline transformation                                                                                                    |
| KNOTMETHOD=                        | Specifies how to construct the knots for spline effects                                                                                              |

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “EFFECT Statement” on page 393 in Chapter 19, “Shared Concepts and Topics.”

## ESTIMATE Statement

```
ESTIMATE <'label'> estimate-specification <(divisor=n)>
 < , ... <'label'> estimate-specification <(divisor=n)> >
 </ options > ;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form  $\mathbf{L}\boldsymbol{\beta}$ . You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 94.5 summarizes the options available in the ESTIMATE statement.

**Table 94.5** ESTIMATE Statement Options

| Option                                                     | Description                                                               |
|------------------------------------------------------------|---------------------------------------------------------------------------|
| <b>Construction and Computation of Estimable Functions</b> |                                                                           |
| DIVISOR=                                                   | Specifies a list of values to divide the coefficients                     |
| NOFILL                                                     | Suppresses the automatic fill-in of coefficients for higher-order effects |
| SINGULAR=                                                  | Tunes the estimability checking difference                                |
| <b>Degrees of Freedom and <math>p</math>-values</b>        |                                                                           |
| ADJUST=                                                    | Determines the method for multiple comparison adjustment of estimates     |
| ALPHA= $\alpha$                                            | Determines the confidence level ( $1 - \alpha$ )                          |
| LOWER                                                      | Performs one-sided, lower-tailed inference                                |
| STEPDOWN                                                   | Adjusts multiplicity-corrected $p$ -values further in a step-down fashion |
| TESTVALUE=                                                 | Specifies values under the null hypothesis for tests                      |
| UPPER                                                      | Performs one-sided, upper-tailed inference                                |
| <b>Statistical Output</b>                                  |                                                                           |
| CL                                                         | Constructs confidence limits                                              |
| CORR                                                       | Displays the correlation matrix of estimates                              |
| COV                                                        | Displays the covariance matrix of estimates                               |
| E                                                          | Prints the <b>L</b> matrix                                                |
| JOINT                                                      | Produces a joint $F$ or chi-square test for the estimable functions       |
| SEED=                                                      | Specifies the seed for computations that depend on random numbers         |

For details about the syntax of the ESTIMATE statement, see the section “ESTIMATE Statement” on page 437 in Chapter 19, “Shared Concepts and Topics.”

## LSMEANS Statement

```
LSMEANS < model-effects > < / options > ;
```

The LSMEANS statement computes and compares least squares means (LS-means) of fixed effects. LS-means are *predicted margins*—that is, they estimate the marginal means over a hypothetical balanced population.

Table 94.6 summarizes available options in the LSMEANS statement.

**Table 94.6** LSMEANS Statement Options

| Option                                              | Description                                                                                 |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b>     |                                                                                             |
| AT                                                  | Modifies the covariate value in computing LS-means                                          |
| BYLEVEL                                             | Computes separate margins                                                                   |
| DIFF                                                | Requests differences of LS-means                                                            |
| OM=                                                 | Specifies the weighting scheme for LS-means computation as determined by the input data set |
| SINGULAR=                                           | Tunes estimability checking                                                                 |
| <b>Degrees of Freedom and <math>p</math>-values</b> |                                                                                             |
| ADJUST=                                             | Determines the method for multiple-comparison adjustment of LS-means differences            |
| ALPHA= $\alpha$                                     | Determines the confidence level $(1 - \alpha)$                                              |
| STEPDOWN                                            | Adjusts multiple-comparison $p$ -values further in a step-down fashion                      |
| <b>Statistical Output</b>                           |                                                                                             |
| CL                                                  | Constructs confidence limits for means and mean differences                                 |
| CORR                                                | Displays the correlation matrix of LS-means                                                 |
| COV                                                 | Displays the covariance matrix of LS-means                                                  |
| E                                                   | Prints the L matrix                                                                         |
| LINES                                               | Produces a “Lines” display for pairwise LS-means differences                                |
| MEANS                                               | Prints the LS-means                                                                         |
| PLOTS=                                              | Requests graphs of means and mean comparisons                                               |
| SEED=                                               | Specifies the seed for computations that depend on random numbers                           |

For details about the syntax of the LSMEANS statement, see the section “LSMEANS Statement” on page 453 of Chapter 19, “Shared Concepts and Topics.”

## LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
 < , ... <'label'> values <divisor=n> >
 </options> ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 94.7 summarizes the options available in the LSMESTIMATE statement.

**Table 94.7** LSMESTIMATE Statement Options

| Option                                          | Description                                                                            |
|-------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b> |                                                                                        |
| AT                                              | Modifies covariate values in computing LS-means                                        |
| BYLEVEL                                         | Computes separate margins                                                              |
| DIVISOR=                                        | Specifies a list of values to divide the coefficients                                  |
| OM=                                             | Specifies the weighting scheme for LS-means computation as determined by a data set    |
| SINGULAR=                                       | Tunes estimability checking                                                            |
| <b>Degrees of Freedom and <i>p</i>-values</b>   |                                                                                        |
| ADJUST=                                         | Determines the method for multiple-comparison adjustment of LS-means differences       |
| ALPHA= $\alpha$                                 | Determines the confidence level ( $1 - \alpha$ )                                       |
| LOWER                                           | Performs one-sided, lower-tailed inference                                             |
| STEPDOWN                                        | Adjusts multiple-comparison <i>p</i> -values further in a step-down fashion            |
| TESTVALUE=                                      | Specifies values under the null hypothesis for tests                                   |
| UPPER                                           | Performs one-sided, upper-tailed inference                                             |
| <b>Statistical Output</b>                       |                                                                                        |
| CL                                              | Constructs confidence limits for means and mean differences                            |
| CORR                                            | Displays the correlation matrix of LS-means                                            |
| COV                                             | Displays the covariance matrix of LS-means                                             |
| E                                               | Prints the <b>L</b> matrix                                                             |
| ELSM                                            | Prints the <b>K</b> matrix                                                             |
| JOINT                                           | Produces a joint <i>F</i> or chi-square test for the LS-means and LS-means differences |
| SEED=                                           | Specifies the seed for computations that depend on random numbers                      |

For details about the syntax of the LSMESTIMATE statement, see the section “LSMESTIMATE Statement” on page 470 in Chapter 19, “Shared Concepts and Topics.”

## MODEL Statement

**MODEL** *dependent* = < effects > < / options > ;

The MODEL statement specifies the dependent (response) variable and the independent (regressor) variables or effects. The dependent variable must be numeric. Each term in a MODEL statement, called an *effect*, is a variable or a combination of variables. You can specify an effect with a variable name or with special notation by using variable names and operators. For more information about how to specify an effect, see the section “Specification of Effects” on page 3324 in Chapter 42, “The GLM Procedure.”

Only one MODEL statement is allowed for each PROC SURVEYREG statement. If you specify more than one MODEL statement, the procedure uses the first model and ignores the rest.

Table 94.8 summarizes the options available in the MODEL statement.

**Table 94.8** MODEL Statement Options

| Option    | Description                                                         |
|-----------|---------------------------------------------------------------------|
| ADJRSQ    | Compute the adjusted multiple R-square                              |
| ANOVA     | Produces the ANOVA table                                            |
| CLPARM    | Requests confidence limits                                          |
| COVB      | Displays the estimated covariance matrix                            |
| DEFF      | Displays design effects                                             |
| DF=       | Specifies the denominator degrees of freedom                        |
| I         | Displays the inverse or the generalized inverse of the $X'X$ matrix |
| NOINT     | Omits the intercept                                                 |
| PARMLABEL | Displays the labels of the parameters                               |
| SINGULAR= | Tunes the estimability checking                                     |
| SOLUTION  | Displays parameter estimates                                        |
| STB       | Displays standardized parameter estimates                           |
| VADJUST=  | Specifies whether to use degrees of freedom adjustment              |
| X         | Displays the $X'X$ matrix, or the $X'WX$ matrix                     |

You can specify the following options in the MODEL statement after a slash (/):

#### **ADJRSQ**

requests the procedure compute the adjusted multiple R-square.

#### **ANOVA**

requests the ANOVA table be produced in the output. By default, the ANOVA table is not printed in the output.

#### **CLPARM**

requests confidence limits for the parameter estimates. The SURVEYREG procedure determines the confidence coefficient by using the **ALPHA=** option, which by default equals 0.05 and produces 95% confidence bounds. The CLPARM option also requests confidence limits for all the estimable linear functions of regression parameters in the **ESTIMATE** statements.

Note that when there is a **CLASS** statement, you need to use the **SOLUTION** option with the CLPARM option to obtain the parameter estimates and their confidence limits.

#### **COVB**

displays the estimated covariance matrix of the estimated regression estimates.

#### **DEFF**

displays design effects for the regression coefficient estimates.

**DF=value**

specifies the denominator degrees of freedom for the  $F$  tests and the degrees of freedom for the  $t$  tests. For details about the default denominator degrees of freedom, see the section “Denominator Degrees of Freedom” on page 7974 for details.

**I | INVERSE**

displays the inverse or the generalized inverse of the  $X'X$  matrix. When there is a WEIGHT variable, the procedure displays the inverse or the generalized inverse of the  $X'WX$  matrix, where  $W$  is the diagonal matrix constructed from WEIGHT variable values.

**NOINT**

omits the intercept from the model.

**PARMLABEL**

displays the labels of the parameters in the “Estimated Regression Coefficients” table, if the effect contains a single continuous variable that has a label.

**SINGULAR=value**

tunes the estimability checking. If  $\mathbf{v}$  is a vector, define  $ABS(\mathbf{v})$  to be the largest absolute value of the elements of  $\mathbf{v}$ . For a row vector  $\mathbf{l}$  of the matrix  $L$ , define

$$c = \begin{cases} ABS(\mathbf{l}) & \text{if } ABS(\mathbf{l}) > 0 \\ 1 & \text{otherwise} \end{cases}$$

If  $ABS(\mathbf{l} - \mathbf{IH})$  is greater than  $c*value$ , then  $\mathbf{l}\beta$  is declared nonestimable. Here,  $\mathbf{H}$  is the matrix  $(X'X)^{-1}X'X$ . The *value* must be between 0 and 1; the default is  $10^{-4}$ .

**SOLUTION**

displays a solution to the normal equations, which are the parameter estimates. The SOLUTION option is useful only when you use a CLASS statement. If you do not specify a CLASS statement, PROC SURVEYREG displays parameter estimates by default. But if you specify a CLASS statement, PROC SURVEYREG does not display parameter estimates unless you also specify the SOLUTION option.

**STB**

produces standardized regression coefficients. A standardized regression coefficient is computed by dividing a parameter estimate by the ratio of the sample standard deviation of the dependent variable to the sample standard deviation of the regressor.

**VADJUST=DF | NONE**

specifies whether to use degrees of freedom adjustment  $(n - 1)/(n - p)$  in the computation of the matrix  $G$  for the variance estimation. If you do not specify the VADJUST= option, by default, PROC SURVEYREG uses the degrees-of-freedom adjustment that is equivalent to the VARADJ=DF option. If you do not want to use this variance adjustment, you can specify the VADJUST=NONE option.

**X | XPX**

displays the  $X'X$  matrix, or the  $X'WX$  matrix when there is a WEIGHT variable, where  $W$  is the diagonal matrix constructed from WEIGHT variable values. The X option also displays the crossproducts vector  $X'y$  or  $X'Wy$ .

## OUTPUT Statement

```
OUTPUT < OUT=SAS-data-set > < keyword < =variable-name > . . . keyword < =variable-name > >
< / option > ;
```

The OUTPUT statement creates a new SAS data set that contains all the variables in the input data set and, optionally, the estimated linear predictors and their standard error estimates, the residuals from the linear regression, and the confidence limits for the predictors.

You can specify the following options in the OUTPUT statement:

### **OUT=SAS-data-set**

gives the name of the new output data set. By default, the procedure uses the DATA*n* convention to name the new data set.

### *keyword* < =*variable-name* >

specifies the statistics to include in the output data set and names the new variables that contain the statistics. You can specify a keyword for each desired statistic (see the following list of keywords). Optionally, you can name a statistic by providing a variable name followed an equal sign to contain the statistic. For example,

```
output out=myOutDataSet p=myPredictor;
```

creates a SAS data set myOutDataSet that contains the predicted values in the variable myPredictor.

The keywords allowed and the statistics they represent are as follows:

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LCLM   L             | lower bound of a $100(1 - \alpha)\%$ confidence interval for the expected value (mean) of the predicted value. The $\alpha$ level is equal to the value of the ALPHA= option in the OUTPUT statement or, if this option is not specified, to the ALPHA= option in the PROC SURVEYREG statement. If neither of these options is set, then $\alpha = 0.05$ by default, resulting in the lower bound for a 95% confidence interval. If no variable name is given for this keyword, the default variable name is _LCLM_. |
| PREDICTED   PRED   P | predicted values. If no variable name is given for this keyword, the default variable name is _PREDICTED_.                                                                                                                                                                                                                                                                                                                                                                                                           |
| RESIDUAL   R         | residuals, calculated as ACTUAL – PREDICTED. If no variable name is given for this keyword, the default variable name is _RESIDUAL_.                                                                                                                                                                                                                                                                                                                                                                                 |
| STDP   STD           | standard error of the mean predicted value. If no variable name is given for this keyword, the default variable name is _STD_.                                                                                                                                                                                                                                                                                                                                                                                       |
| UCLM   U             | upper bound of a $100(1 - \alpha)\%$ confidence interval for the expected value (mean) of the predicted value. The $\alpha$ level is equal to the value of the ALPHA= option in the OUTPUT statement or, if this option is not specified, to the ALPHA= option in the PROC SURVEYREG statement. If neither of these options is set, then $\alpha = 0.05$ by default, resulting in the upper bound for a 95% confidence interval. If no variable name is given for this keyword, the default variable name is _UCLM_. |

The following option is available in the OUTPUT statement and is specified after a slash (/):

**ALPHA= $\alpha$** 

specifies the level of significance  $\alpha$  for  $100(1 - \alpha)\%$  confidence intervals. By default,  $\alpha$  is equal to the value of the **ALPHA=** option in the PROC SURVEYREG statement or 0.05 if that option is not specified. You can use values between 0 and 1.

---

## REPWEIGHTS Statement

**REPWEIGHTS** *variables* *</ options >* ;

The REPWEIGHTS statement names variables that provide replicate weights for BRR or jackknife variance estimation, which you request with the **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** option in the PROC SURVEYREG statement. If you do not provide replicate weights for these methods by using a REPWEIGHTS statement, then the procedure constructs replicate weights for the analysis. See the sections “Balanced Repeated Replication (BRR) Method” on page 7971 and “Jackknife Method” on page 7972 for information about replicate weights.

Each REPWEIGHTS variable should contain the weights for a single replicate, and the number of replicates equals the number of REPWEIGHTS variables. The REPWEIGHTS variables must be numeric, and the variable values must be nonnegative numbers.

If you provide replicate weights with a REPWEIGHTS statement, you do not need to specify a **CLUSTER** or **STRATA** statement. If you use a REPWEIGHTS statement and do not specify the **VARMETHOD=** option in the PROC SURVEYREG statement, the procedure uses **VARMETHOD=JACKKNIFE** by default.

If you specify a REPWEIGHTS statement but do not include a **WEIGHT** statement, the procedure uses the average of replicate weights of each observation as the observation’s weight.

You can specify the following options in the REPWEIGHTS statement after a slash (/):

**DF=*df***

specifies the degrees of freedom for the analysis. The value of *df* must be a positive number. By default, the degrees of freedom equals the number of REPWEIGHTS variables.

**JKCOEFS=*value***

specifies a jackknife coefficient for **VARMETHOD=JACKKNIFE**. The coefficient *value* must be a nonnegative number. See the section “Jackknife Method” on page 7972 for details about jackknife coefficients.

You can use this option to specify a single value of the jackknife coefficient, which the procedure uses for all replicates. To specify different coefficients for different replicates, use the **JKCOEFS=values** or **JKCOEFS=SAS-data-set** option.

**JKCOEFS=*values***

specifies jackknife coefficients for **VARMETHOD=JACKKNIFE**, where each coefficient corresponds to an individual replicate that is identified by a REPWEIGHTS variable. You can separate *values* with blanks or commas. The coefficient *values* must be nonnegative numbers. The number of *values* must equal the number of replicate weight variables named in the REPWEIGHTS statement. List these values in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement.

See the section “Jackknife Method” on page 7972 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the `JKCOEFS=SAS-data-set` option. To specify a single jackknife coefficient for all replicates, use the `JKCOEFS=value` option.

#### **JKCOEFS=SAS-data-set**

names a SAS data set that contains the jackknife coefficients for `VARMETHOD=JACKKNIFE`. You provide the jackknife coefficients in the `JKCOEFS=` data set variable `JKCoefficient`. Each coefficient value must be a nonnegative number. The observations in the `JKCOEFS=` data set should correspond to the replicates that are identified by the `REPWEIGHTS` variables. Arrange the coefficients or observations in the `JKCOEFS=` data set in the same order in which you list the corresponding replicate weight variables in the `REPWEIGHTS` statement. The number of observations in the `JKCOEFS=` data set must not be less than the number of `REPWEIGHTS` variables.

See the section “[Jackknife Method](#)” on page 7972 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the `JKCOEFS=values` option. To specify a single jackknife coefficient for all replicates, use the `JKCOEFS=value` option.

## **SLICE Statement**

**SLICE** *model-effect* < / options > ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the `LSMEANS` statement, which are summarized in [Table 19.21](#). For details about the syntax of the SLICE statement, see the section “[SLICE Statement](#)” on page 498 in Chapter 19, “[Shared Concepts and Topics](#).”

## **STORE Statement**

**STORE** < **OUT=** > *item-store-name* < / **LABEL=** 'label' > ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “[STORE Statement](#)” on page 501 in Chapter 19, “[Shared Concepts and Topics](#).”

## **STRATA Statement**

**STRATA** *variables* < / options > ;

The STRATA statement specifies variables that form the strata in a stratified sample design. The combinations of categories of STRATA variables define the strata in the sample.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 7965 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with the **REPWEIGHTS** statement, you do not need to specify a STRATA statement.

The STRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the STRATA variables determine the levels. Thus, you can use formats to group values into levels. See the **FORMAT** procedure in the *Base SAS Procedures Guide* and the **FORMAT** statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

When determining levels of a STRATA variable, an observation with missing values for this STRATA variable is excluded, unless you specify the **MISSING** option. For more information, see the section “**Missing Values**” on page 7964.

You can use multiple STRATA statements to specify stratum variables.

You can specify the following options in the STRATA statement after a slash (/):

#### **LIST**

displays a “Stratum Information” table, which includes values of the STRATA variables and the number of observations, number of clusters, population total, and sampling rate for each stratum. See the section “**Stratum Information**” on page 7980 for more details.

#### **NOCOLLAPSE**

prevents the procedure from collapsing (combining) strata that have only one sampling unit for the Taylor series variance estimation. By default, the procedure **collapses** strata that contain only one sampling unit for the Taylor series method. See the section “**Stratum Collapse**” on page 7968 for details.

---

## **TEST Statement**

**TEST** < *model-effects* > < / *options* > ;

The TEST statement enables you to perform *F* tests for model effects that test Type I, Type II, or Type III hypotheses. See Chapter 15, “**The Four Types of Estimable Functions**,” for details about the construction of Type I, II, and III estimable functions.

Table 94.9 summarizes the options available in the TEST statement.

**Table 94.9** TEST Statement Options

| <b>Option</b>    | <b>Description</b>                                         |
|------------------|------------------------------------------------------------|
| <b>CHISQ</b>     | Requests chi-square tests                                  |
| <b>DDF=</b>      | Specifies denominator degrees of freedom for fixed effects |
| <b>E</b>         | Requests Type I, Type II, and Type III coefficients        |
| <b>E1</b>        | Requests Type I coefficients                               |
| <b>E2</b>        | Requests Type II coefficients                              |
| <b>E3</b>        | Requests Type III coefficients                             |
| <b>HTYPE=</b>    | Indicates the type of hypothesis test to perform           |
| <b>INTERCEPT</b> | Adds a row that corresponds to the overall intercept       |

For details about the syntax of the TEST statement, see the section “TEST Statement” on page 502 in Chapter 19, “Shared Concepts and Topics.”

---

## WEIGHT Statement

**WEIGHT** *variable* ;

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric, and the sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “Missing Values” on page 7964 for more information. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

If you do not specify a WEIGHT statement but provide replicate weights with a REPWEIGHTS statement, PROC SURVEYREG uses the average of replicate weights of each observation as the observation’s weight.

If you do not specify a WEIGHT statement or a REPWEIGHTS statement, PROC SURVEYREG assigns all observations a weight of one.

---

## Details: SURVEYREG Procedure

---

### Missing Values

If you have missing values in your survey data for any reason, such as nonresponse, this can compromise the quality of your survey results. If the respondents are different from the nonrespondents with regard to a survey effect or outcome, then survey estimates might be biased and cannot accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. After data collection is complete, you can use imputation to replace missing values with acceptable values, and/or you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYREG. For more information, see Cochran (1977); Kalton and Kaspyzyk (1986); Brick and Kalton (1996).

If an observation has a missing value or a nonpositive value for the WEIGHT variable, then that observation is excluded from the analysis.

An observation is also excluded from the analysis if it has a missing value for any design (STRATA, CLUSTER, or DOMAIN) variable, unless you specify the MISSING option in the PROC SURVEYREG statement. If you specify the MISSING option, the procedure treats missing values as a valid (nonmissing) category for all categorical variables.

By default, if an observation contains missing values for the dependent variable or for any variable used in the independent effects, the observation is excluded from the analysis. This treatment is based on the assumption that the missing values are missing completely at random (MCAR). However, this assumption sometimes is not true. For example, evidence from other surveys might suggest that observations with missing values are systematically different from observations without missing values. If you believe that missing values are not missing completely at random, then you can specify the NOMCAR option to include these

observations with missing values in the dependent variable and the independent variables in the variance estimation.

Whether or not you specify the **NOMCAR** option, the procedure always excludes observations with missing or invalid values for the **WEIGHT**, **STRATA**, **CLUSTER**, and **DOMAIN** variables, unless you specify the **MISSING** option.

When you specify the **NOMCAR** option, the procedure treats observations with and without missing values for variables in the regression model as two different domains, and it performs a domain analysis in the domain of nonmissing observations.

If you use a **REPWEIGHTS** statement, all **REPWEIGHTS** variables must contain nonmissing values.

## Survey Design Information

### Specification of Population Totals and Sampling Rates

To include a finite population correction (*fpc*) in Taylor series variance estimation, you can input either the sampling rate or the population total by using the **RATE=** or **TOTAL=** option in the **PROC SURVEYREG** statement. (You cannot specify both of these options in the same **PROC SURVEYREG** statement.) The **RATE=** and **TOTAL=** options apply only to Taylor series variance estimation. The procedure does not use a finite population correction for **BRR** or jackknife variance estimation.

If you do not specify the **RATE=** or **TOTAL=** option, the Taylor series variance estimation does not include a finite population correction. For fairly small sampling fractions, it is appropriate to ignore this correction. See Cochran (1977) and Kish (1965) for more information.

If your design has multiple stages of selection and you are specifying the **RATE=** option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the **TOTAL=** option for a multistage design, you should input the total number of PSUs in the study population. See the section “**Primary Sampling Units (PSUs)**” on page 7966 for more details.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you can use the **RATE=value** or **TOTAL=value** option. If your sample design is stratified with different sampling rates or population totals in different strata, use the **RATE=SAS-data-set** or **TOTAL=SAS-data-set** option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the **DATA=** option.

The secondary data set must contain all the stratification variables listed in the **STRATA** statement and all the variables in the **BY** statement. If there are formats associated with the **STRATA** variables and the **BY** variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the **TOTAL=SAS-data-set** option, the secondary data set must have a variable named **\_TOTAL\_** that contains the stratum population totals. Or if you specify the **RATE=SAS-data-set** option, the secondary data set must have a variable named **\_RATE\_** that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of **\_TOTAL\_** or **\_RATE\_** for that stratum and ignores the rest.

The *value* in the **RATE=** option or the values of **\_RATE\_** in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage

form as a number between 1 and 100, and PROC SURVEYREG converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the `TOTAL=value` option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

### Primary Sampling Units (PSUs)

When you have clusters, or primary sampling units (PSUs), in your sample design, the procedure estimates variance from the variation among PSUs when the Taylor series variance method is used. See the section “Variance Estimation” on page 7969 for more information.

BRR or jackknife variance estimation methods draw multiple replicates (or subsamples) from the full sample by following a specific resampling scheme. These subsamples are constructed by deleting PSUs from the full sample.

If you use a `REPWEIGHTS` statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a `CLUSTER` statement. Otherwise, you should specify a `CLUSTER` statement whenever your design includes clustering at the first stage of sampling. If you do not specify a `CLUSTER` statement, then PROC SURVEYREG treats each observation as a PSU.

## Computational Details

### Notation

For a stratified clustered sample design, observations are represented by an  $n \times (p + 2)$  matrix

$$(\mathbf{w}, \mathbf{y}, \mathbf{X}) = (w_{hij}, y_{hij}, \mathbf{x}_{hij})$$

where

- $\mathbf{w}$  denotes the sampling weight vector
- $\mathbf{y}$  denotes the dependent variable
- $\mathbf{X}$  denotes the  $n \times p$  design matrix. (When an effect contains only classification variables, the columns of  $\mathbf{X}$  that correspond this effect contain only 0s and 1s; no reparameterization is made.)
- $h = 1, 2, \dots, H$  is the stratum index
- $i = 1, 2, \dots, n_h$  is the cluster index within stratum  $h$
- $j = 1, 2, \dots, m_{hi}$  is the unit index within cluster  $i$  of stratum  $h$
- $p$  is the total number of parameters (including an intercept if the `INTERCEPT` effect is included in the `MODEL` statement)
- $n = \sum_{h=1}^H \sum_{i=1}^{n_h} m_{hi}$  is the total number of observations in the sample

Also,  $f_h$  denotes the sampling rate for stratum  $h$ . You can use the `TOTAL=` or `RATE=` option to input population totals or sampling rates. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 7965 for details. If you input stratum totals, PROC SURVEYREG computes  $f_h$  as the ratio of the stratum sample size to the stratum total. If you input stratum sampling rates, PROC SURVEYREG uses these values directly for  $f_h$ . If you do not specify the `TOTAL=` or `RATE=` option, then the procedure assumes that the stratum sampling rates  $f_h$  are negligible, and a finite population correction is not used when computing variances.

## Regression Coefficients

PROC SURVEYREG solves the normal equations  $\mathbf{X}'\mathbf{W}\mathbf{X}\boldsymbol{\beta} = \mathbf{X}'\mathbf{W}\mathbf{y}$  by using a modified sweep routine that produces a generalized (g2) inverse  $(\mathbf{X}'\mathbf{W}\mathbf{X})^-$  and a solution (Pringle and Rayner 1971)

$$\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{W}\mathbf{X})^- \mathbf{X}'\mathbf{W}\mathbf{y}$$

where  $\mathbf{W}$  is the diagonal matrix constructed from `WEIGHT` variable values.

For models with class variables, there are more design matrix columns than there are degrees of freedom ( $df$ ) for the effect. Thus, there are linear dependencies among the columns. In this case, the parameters are not estimable; there is an infinite number of least squares solutions. PROC SURVEYREG uses a generalized (g2) inverse to obtain values for the estimates. The solution values are not displayed unless you specify the `SOLUTION` option in the `MODEL` statement. The solution has the characteristic that estimates are zero whenever the design column for that parameter is a linear combination of previous columns. (In strict terms, the solution values should not be called estimates.) With this full parameterization, hypothesis tests are constructed to test linear functions of the parameters that are estimable.

## Design Effect

If you specify the `DEFF` option in the `MODEL` statement, PROC SURVEYREG calculates the design effects for the regression coefficients. The design effect of an estimate is the ratio of the actual variance to the variance computed under the assumption of simple random sampling:

$$\text{DEFF} = \frac{\text{variance under the sample design}}{\text{variance under simple random sampling}}$$

See Kish (1965, p. 258) for more details. PROC SURVEYREG computes the numerator as described in the section “[Variance Estimation](#)” on page 7969. And the denominator is computed under the assumption that the sample design is simple random sampling, with no stratification and no clustering.

To compute the variance under the assumption of simple random sampling, PROC SURVEYREG calculates the sampling rate as follows. If you specify both sampling weights and sampling rates (or population totals) for the analysis, then the sampling rate under simple random sampling is calculated as

$$f_{\text{SRS}} = n / w_{..}$$

where  $n$  is the sample size and  $w_{..}$  (the sum of the weights over all observations) estimates the population size. If the sum of the weights is less than the sample size,  $f_{\text{SRS}}$  is set to zero. If you specify sampling rates for the analysis but not sampling weights, then PROC SURVEYREG computes the sampling rate under simple random sampling as the average of the stratum sampling rates:

$$f_{\text{SRS}} = \frac{1}{H} \sum_{h=1}^H f_h$$

If you do not specify sampling rates (or population totals) for the analysis, then the sampling rate under simple random sampling is assumed to be zero:

$$f_{\text{SRS}} = 0$$

## Stratum Collapse

If there is only one sampling unit in a stratum, then PROC SURVEYREG cannot estimate the variance for this stratum for the Taylor series method. To estimate stratum variances, by default the procedure collapses, or combines, those strata that contain only one sampling unit. If you specify the **NOCOLLAPSE** option in the STRATA statement, PROC SURVEYREG does not collapse strata and uses a variance estimate of zero for any stratum that contains only one sampling unit.

Note that stratum collapse only applies to Taylor series variance estimation (the default method, also specified by **VARMETHOD=TAYLOR**). The procedure does not collapse strata for BRR or jackknife variance estimation, which you request with the **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** option.

If you do not specify the **NOCOLLAPSE** option for the Taylor series method, PROC SURVEYREG collapses strata according to the following rules. If there are multiple strata that contain only one sampling unit each, then the procedure collapses, or combines, all these strata into a new pooled stratum. If there is only one stratum with a single sampling unit, then PROC SURVEYREG collapses that stratum with the preceding stratum, where strata are ordered by the **STRATA** variable values. If the stratum with one sampling unit is the first stratum, then the procedure combines it with the following stratum.

If you specify stratum sampling rates by using the **RATE=SAS-data-set** option, PROC SURVEYREG computes the sampling rate for the new pooled stratum as the weighted average of the sampling rates for the collapsed strata. See the section “Computational Details” on page 7966 for details. If the specified sampling rate equals 0 for any of the collapsed strata, then the pooled stratum is assigned a sampling rate of 0. If you specify stratum totals by using the **TOTAL=SAS-data-set** option, PROC SURVEYREG combines the totals for the collapsed strata to compute the sampling rate for the new pooled stratum.

## Sampling Rate of the Pooled Stratum from Collapse

Assuming that PROC SURVEYREG collapses single-unit strata  $h_1, h_2, \dots, h_c$  into the pooled stratum, the procedure calculates the sampling rate for the pooled stratum as

$$f_{\text{Pooled Stratum}} = \begin{cases} 0 & \text{if any of } f_{h_l} = 0 \text{ where } l = 1, 2, \dots, c \\ \left( \sum_{l=1}^c n_{h_l} f_{h_l}^{-1} \right)^{-1} \sum_{l=1}^c n_{h_l} & \text{otherwise} \end{cases}$$

## Analysis of Variance (ANOVA)

PROC SURVEYREG produces an analysis of variance table for the model specified in the **MODEL** statement. This table is identical to the one produced by the GLM procedure for the model. PROC SURVEYREG computes ANOVA table entries by using the sampling weights, but not the sample design information about stratification and clustering.

The degrees of freedom (*df*) displayed in the ANOVA table are the same as those in the ANOVA table produced by PROC GLM. The Total DF is the total degrees of freedom used to obtain the regression coefficient

estimates. The Total DF equals the total number of observations minus 1 if the model includes an intercept. If the model does not include an intercept, the Total DF equals the total number of observations. The Model DF equals the degrees of freedom for the effects in the MODEL statement, not including the intercept. The Error DF equals the Total DF minus the Model DF.

### Multiple R-Square

PROC SURVEYREG computes a multiple R-square for the weighted regression as

$$R^2 = 1 - \frac{SS_{error}}{SS_{total}}$$

where  $SS_{error}$  is the error sum of squares in the ANOVA table

$$SS_{error} = \mathbf{r}'\mathbf{W}\mathbf{r}$$

and  $SS_{total}$  is the total sum of squares

$$SS_{total} = \begin{cases} \mathbf{y}'\mathbf{W}\mathbf{y} & \text{if no intercept} \\ \mathbf{y}'\mathbf{W}\mathbf{y} - \left( \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij} \right)^2 / w_{\dots} & \text{otherwise} \end{cases}$$

where  $w_{\dots}$  is the sum of the sampling weights over all observations.

### Adjusted R-Square

If you specify the **ADJRSQ** option in the MODEL statement, PROC SURVEYREG computes an multiple R-square adjusted as the weighted regression as

$$ADJRSQ = \begin{cases} 1 - \frac{n(1 - R^2)}{n - p} & \text{if no intercept} \\ 1 - \frac{(n - 1)(1 - R^2)}{n - p} & \text{otherwise} \end{cases}$$

where  $R^2$  is the multiple R-square.

### Root Mean Square Errors

PROC SURVEYREG computes the square root of mean square errors as

$$\sqrt{MSE} = \sqrt{n SS_{error} / (n - p) w_{\dots}}$$

where  $w_{\dots}$  is the sum of the sampling weights over all observations.

---

## Variance Estimation

PROC SURVEYREG uses the Taylor series method or replication (resampling) methods to estimate sampling errors of estimators based on complex sample designs (Fuller 2009; Woodruff 1971; Fuller 1975;

Fuller et al. 1989; Särndal, Swensson, and Wretman 1992; Wolter 2007; Rust 1985; Dippo, Fay, and Morganstein 1984; Rao and Shao 1999; Rao, Wu, and Yue 1992; Rao and Shao 1996). You can use the **VARMETHOD=** option to specify a variance estimation method to use. By default, the Taylor series method is used. However, replication methods have recently gained popularity for estimating variances in complex survey data analysis. One reason for this popularity is the relative simplicity of replication-based estimates, especially for nonlinear estimators; another is that modern computational capacity has made replication methods feasible for practical survey analysis.

Replication methods draw multiple replicates (also called subsamples) from a full sample according to a specific resampling scheme. The most commonly used resampling schemes are the *balanced repeated replication* (BRR) method and the *jackknife* method. For each replicate, the original weights are modified for the PSUs in the replicates to create replicate weights. The parameters of interest are estimated by using the replicate weights for each replicate. Then the variances of parameters of interest are estimated by the variability among the estimates derived from these replicates. You can use the **REPWEIGHTS** statement to provide your own replicate weights for variance estimation.

The following sections provide details about how the variance-covariance matrix of the estimated regression coefficients is estimated for each variance estimation method.

### Taylor Series (Linearization)

The Taylor series (linearization) method is the most commonly used method to estimate the covariance matrix of the regression coefficients for complex survey data. It is the default variance estimation method used by PROC SURVEYREG.

Use the notation described in the section “**Notation**” on page 7966 to denote the residuals from the linear regression as

$$\mathbf{r} = \mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}$$

with  $r_{hij}$  as its elements. Let the  $p \times p$  matrix  $\mathbf{G}$  be defined as

$$\mathbf{G} = \frac{n-1}{n-p} \sum_{h=1}^H \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot})' (\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot})$$

where

$$\mathbf{e}_{hij} = w_{hij} r_{hij} \mathbf{x}_{hij}$$

$$\mathbf{e}_{hi\cdot} = \sum_{j=1}^{m_{hi}} \mathbf{e}_{hij}$$

$$\bar{\mathbf{e}}_{h\cdot\cdot} = \frac{1}{n_h} \sum_{i=1}^{n_h} \mathbf{e}_{hi\cdot}$$

The Taylor series estimate of the covariance matrix of  $\hat{\boldsymbol{\beta}}$  is

$$\widehat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1} \mathbf{G} (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}$$

The factor  $(n - 1)/(n - p)$  in the computation of the matrix  $\mathbf{G}$  reduces the small sample bias associated with using the estimated function to calculate deviations (Hidiroglou, Fuller, and Hickman 1980). For simple random sampling, this factor contributes to the degrees of freedom correction applied to the residual mean square for ordinary least squares in which  $p$  parameters are estimated. By default, the procedure use this adjustment in the variance estimation. If you do not want to use this multiplier in variance estimation, you can specify the `VADJUST=NONE` option in the `MODEL` statement to suppress this factor.

### Balanced Repeated Replication (BRR) Method

The balanced repeated replication (BRR) method requires that the full sample be drawn by using a stratified sample design with two primary sampling units (PSUs) per stratum. Let  $H$  be the total number of strata. The total number of replicates  $R$  is the smallest multiple of 4 that is greater than  $H$ . However, if you prefer a larger number of replicates, you can specify the `REPS=number` option. If a  $number \times number$  Hadamard matrix cannot be constructed, the number of replicates is increased until a Hadamard matrix becomes available.

Each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix and adjusting the original weights for the remaining PSUs. The new weights are called replicate weights.

Replicates are constructed by using the first  $H$  columns of the  $R \times R$  Hadamard matrix. The  $r$ th ( $r = 1, 2, \dots, R$ ) replicate is drawn from the full sample according to the  $r$ th row of the Hadamard matrix as follows:

- If the  $(r, h)$  element of the Hadamard matrix is 1, then the first PSU of stratum  $h$  is included in the  $r$ th replicate and the second PSU of stratum  $h$  is excluded.
- If the  $(r, h)$  element of the Hadamard matrix is  $-1$ , then the second PSU of stratum  $h$  is included in the  $r$ th replicate and the first PSU of stratum  $h$  is excluded.

Note that the “first” and “second” PSUs are determined by data order in the input data set. Thus, if you reorder the data set and perform the same analysis by using BRR method, you might get slightly different results, because the contents in each replicate sample might change.

The replicate weights of the remaining PSUs in each half-sample are then doubled to their original weights. For more details about the BRR method, see Wolter (2007) and Lohr (2010).

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the `VARMETHOD=BRR(PRINTH)` *method-option*. If you provide a Hadamard matrix by specifying the `VARMETHOD=BRR(HADAMARD=)` *method-option*, then the replicates are generated according to the provided Hadamard matrix.

You can use the `VARMETHOD=BRR(OUTWEIGHTS=)` *method-option* to save the replicate weights into a SAS data set.

Let  $\hat{\boldsymbol{\beta}}$  be the estimated regression coefficients from the full sample for  $\boldsymbol{\beta}$ , and let  $\hat{\boldsymbol{\beta}}_r$  be the estimated regression coefficient from the  $r$ th replicate by using replicate weights. PROC SURVEYREG estimates the covariance matrix of  $\hat{\boldsymbol{\beta}}$  by

$$\widehat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) = \frac{1}{R} \sum_{r=1}^R (\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}}) (\hat{\boldsymbol{\beta}}_r - \hat{\boldsymbol{\beta}})'$$

with  $H$  degrees of freedom, where  $H$  is the number of strata.

## Fay's BRR Method

Fay's method is a modification of the BRR method, and it requires a stratified sample design with two primary sampling units (PSUs) per stratum. The total number of replicates  $R$  is the smallest multiple of 4 that is greater than the total number of strata  $H$ . However, if you prefer a larger number of replicates, you can specify the `REPS=method-option`.

For each replicate, Fay's method uses a Fay coefficient  $0 \leq \epsilon < 1$  to impose a perturbation of the original weights in the full sample that is gentler than using only half-samples, as in the traditional BRR method. The Fay coefficient  $0 \leq \epsilon < 1$  can be set by specifying the `FAY =  $\epsilon$  method-option`. By default,  $\epsilon = 0.5$  if the `FAY method-option` is specified without providing a value for  $\epsilon$  (Judkins 1990; Rao and Shao 1999). When  $\epsilon = 0$ , Fay's method becomes the traditional BRR method. For more details, see Dipbo, Fay, and Morganstein (1984); Fay (1984, 1989); Judkins (1990).

Let  $H$  be the number of strata. Replicates are constructed by using the first  $H$  columns of the  $R \times R$  Hadamard matrix, where  $R$  is the number of replicates,  $R > H$ . The  $r$ th ( $r = 1, 2, \dots, R$ ) replicate is created from the full sample according to the  $r$ th row of the Hadamard matrix as follows:

- If the  $(r, h)$  element of the Hadamard matrix is 1, then the full sample weight of the first PSU in stratum  $h$  is multiplied by  $\epsilon$  and the full sample weight of the second PSU is multiplied by  $2 - \epsilon$  to obtain the  $r$ th replicate weights.
- If the  $(r, h)$  element of the Hadamard matrix is  $-1$ , then the full sample weight of the first PSU in stratum  $h$  is multiplied by  $2 - \epsilon$  and the full sample weight of the second PSU is multiplied by  $\epsilon$  to obtain the  $r$ th replicate weights.

You can use the `VARMETHOD=BRR(OUTWEIGHTS=) method-option` to save the replicate weights into a SAS data set.

By default, an appropriate Hadamard matrix is generated automatically to create the replicates. You can request that the Hadamard matrix be displayed by specifying the `VARMETHOD=BRR(PRINTH) method-option`. If you provide a Hadamard matrix by specifying the `VARMETHOD=BRR(HADAMARD=) method-option`, then the replicates are generated according to the provided Hadamard matrix.

Let  $\hat{\beta}$  be the estimated regression coefficients from the full sample for  $\beta$ . Let  $\hat{\beta}_r$  be the estimated regression coefficient obtained from the  $r$ th replicate by using replicate weights. PROC SURVEYREG estimates the covariance matrix of  $\hat{\beta}$  by

$$\widehat{V}(\hat{\beta}) = \frac{1}{R(1 - \epsilon)^2} \sum_{r=1}^R (\hat{\beta}_r - \hat{\beta}) (\hat{\beta}_r - \hat{\beta})'$$

with  $H$  degrees of freedom, where  $H$  is the number of strata.

## Jackknife Method

The jackknife method of variance estimation deletes one PSU at a time from the full sample to create replicates. The total number of replicates  $R$  is the same as the total number of PSUs. In each replicate, the sample weights of the remaining PSUs are modified by the jackknife coefficient  $\alpha_r$ . The modified weights are called replicate weights.

The jackknife coefficient and replicate weights are described as follows.

**Without Stratification** If there is no stratification in the sample design (no **STRATA** statement), the jackknife coefficients  $\alpha_r$  are the same for all replicates:

$$\alpha_r = \frac{R-1}{R} \quad \text{where } r = 1, 2, \dots, R$$

Denote the original weight in the full sample for the  $j$ th member of the  $i$ th PSU as  $w_{ij}$ . If the  $i$ th PSU is included in the  $r$ th replicate ( $r = 1, 2, \dots, R$ ), then the corresponding replicate weight for the  $j$ th member of the  $i$ th PSU is defined as

$$w_{ij}^{(r)} = w_{ij}/\alpha_r$$

**With Stratification** If the sample design involves stratification, each stratum must have at least two PSUs to use the jackknife method.

Let stratum  $\tilde{h}_r$  be the stratum from which a PSU is deleted for the  $r$ th replicate. Stratum  $\tilde{h}_r$  is called the *donor stratum*. Let  $n_{\tilde{h}_r}$  be the total number of PSUs in the donor stratum  $\tilde{h}_r$ . The jackknife coefficients are defined as

$$\alpha_r = \frac{n_{\tilde{h}_r} - 1}{n_{\tilde{h}_r}} \quad \text{where } r = 1, 2, \dots, R$$

Denote the original weight in the full sample for the  $j$ th member of the  $i$ th PSU as  $w_{ij}$ . If the  $i$ th PSU is included in the  $r$ th replicate ( $r = 1, 2, \dots, R$ ), then the corresponding replicate weight for the  $j$ th member of the  $i$ th PSU is defined as

$$w_{ij}^{(r)} = \begin{cases} w_{ij} & \text{if } i\text{th PSU is not in the donor stratum } \tilde{h}_r \\ w_{ij}/\alpha_r & \text{if } i\text{th PSU is in the donor stratum } \tilde{h}_r \end{cases}$$

You can use the **VARMETHOD=JACKKNIFE(OUTJKCOEFS=)** *method-option* to save the jackknife coefficients into a SAS data set and use the **VARMETHOD=JACKKNIFE(OUTWEIGHTS=)** *method-option* to save the replicate weights into a SAS data set.

If you provide your own replicate weights with a **REPWEIGHTS** statement, then you can also provide corresponding jackknife coefficients with the **JKCOEFS=** option.

Let  $\hat{\beta}$  be the estimated regression coefficients from the full sample for  $\beta$ . Let  $\hat{\beta}_r$  be the estimated regression coefficient obtained from the  $r$ th replicate by using replicate weights. PROC SURVEYREG estimates the covariance matrix of  $\hat{\beta}$  by

$$\widehat{V}(\hat{\beta}) = \sum_{r=1}^R \alpha_r (\hat{\beta}_r - \hat{\beta}) (\hat{\beta}_r - \hat{\beta})'$$

with  $R-H$  degrees of freedom, where  $R$  is the number of replicates and  $H$  is the number of strata, or  $R-1$  when there is no stratification.

## Hadamard Matrix

A Hadamard matrix **H** is a square matrix whose elements are either 1 or  $-1$  such that

$$\mathbf{H}\mathbf{H}' = k\mathbf{I}$$

where  $k$  is the dimension of  $\mathbf{H}$  and  $\mathbf{I}$  is the identity matrix of order  $k$ . The order  $k$  is necessarily 1, 2, or a positive integer that is a multiple of 4.

For example, the following matrix is a Hadamard matrix of dimension  $k = 8$ :

```

1 1 1 1 1 1 1 1
1 -1 1 -1 1 -1 1 -1
1 1 -1 -1 1 1 -1 -1
1 -1 -1 1 1 -1 -1 1
1 1 1 1 -1 -1 -1 -1
1 -1 1 -1 -1 1 -1 1
1 1 -1 -1 -1 -1 1 1
1 -1 -1 1 -1 1 1 -1

```

## Degrees of Freedom

PROC SURVEYREG produces tests for the significance of model effects, regression parameters, estimable functions specified in the **ESTIMATE** statement, and contrasts specified in the **CONTRAST** statement. It computes all these tests taking into account the sample design. The degrees of freedom for these tests differ from the degrees of freedom for the ANOVA table, which does not consider the sample design.

### Denominator Degrees of Freedom

The denominator  $df$  refers to the denominator degrees of freedom for  $F$  tests and to the degrees of freedom for  $t$  tests in the analysis.

For the **Taylor series** method, the denominator  $df$  equals the number of clusters minus the actual number of strata. If there are no clusters, the denominator  $df$  equals the number of observations minus the actual number of strata. The *actual number of strata* equals the following:

- one, if there is no **STRATA** statement
- the number of strata in the sample, if there is a **STRATA** statement but the procedure does not collapse any strata
- the number of strata in the sample after collapsing, if there is a **STRATA** statement and the procedure collapses strata that have only one sampling unit

Alternatively, you can specify your own denominator  $df$  by using the **DF=** option in the **MODEL** statement.

For the **BRR** method (including **Fay's method**) without a **REPWEIGHTS** statement, the denominator  $df$  equals the number of strata.

For the **jackknife** method without a **REPWEIGHTS** statement, the denominator  $df$  is equal to the number of replicates minus the *actual number of strata*.

When there is a **REPWEIGHTS** statement, the denominator  $df$  equals the number of **REPWEIGHTS** variables, unless you specify an alternative in the **DF=** option in a **REPWEIGHTS** statement.

### Numerator Degrees of Freedom

The numerator *df* refers to the numerator degrees of freedom for the Wald *F* statistic associated with an effect or with a contrast. The procedure computes the Wald *F* statistic for an effect as a Type III test; that is, the test has the following properties:

- The hypothesis for an effect does not involve parameters of other effects except for containing effects (which it must involve to be estimable).
- The hypotheses to be tested are invariant to the ordering of effects in the model.

See the section “Testing Effects” on page 7975 for more information. The numerator *df* for the Wald *F* statistic for a contrast is the rank of the **L** matrix that defines the contrast.

## Testing

### Testing Effects

For each effect in the model, PROC SURVEYREG computes an **L** matrix such that every element of **Lβ** is estimable; the **L** matrix has the maximum possible rank that is associated with the effect. To test the effect, the procedure uses the Wald *F* statistic for the hypothesis  $H_0: \mathbf{L}\boldsymbol{\beta} = 0$ . The Wald *F* statistic equals

$$F_{\text{Wald}} = \frac{(\mathbf{L}\hat{\boldsymbol{\beta}})'(\mathbf{L}'\hat{\mathbf{V}}\mathbf{L})^{-1}(\mathbf{L}\hat{\boldsymbol{\beta}})}{\text{rank}(\mathbf{L}'\hat{\mathbf{V}}\mathbf{L})}$$

with numerator degrees of freedom equal to  $\text{rank}(\mathbf{L}'\hat{\mathbf{V}}\mathbf{L})$ .

In the Taylor series method, the denominator degrees of freedom is equal to the number of clusters minus the number of strata (unless you specify the denominator degrees of freedom with the **DF=** option in the MODEL statement). For details about denominator degrees of freedom in replication methods, see the section “Denominator Degrees of Freedom” on page 7974. It is possible that the **L** matrix cannot be constructed for an effect, in which case that effect is not testable. For more information about how the matrix **L** is constructed, see the discussion in Chapter 15, “The Four Types of Estimable Functions.”

You can use the TEST statement to perform *F* tests that test Type I, Type II, or Type III hypotheses. For details about the syntax of the TEST statement, see the section “TEST Statement” on page 502 of Chapter 19, “Shared Concepts and Topics.”

### Contrasts

You can use the CONTRAST statement to perform custom hypothesis tests. If the hypothesis is testable in the univariate case, the Wald *F* statistic for  $H_0: \mathbf{L}\boldsymbol{\beta} = 0$  is computed as

$$F_{\text{Wald}} = \frac{(\mathbf{L}_{\text{Full}}\hat{\boldsymbol{\beta}})'(\mathbf{L}'_{\text{Full}}\hat{\mathbf{V}}\mathbf{L}_{\text{Full}})^{-1}(\mathbf{L}_{\text{Full}}\hat{\boldsymbol{\beta}})}{\text{rank}(\mathbf{L})}$$

where  $\mathbf{L}$  is the contrast vector or matrix you specify,  $\boldsymbol{\beta}$  is the vector of regression parameters,  $\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}\mathbf{X}'\mathbf{W}\mathbf{Y}$ ,  $\widehat{\mathbf{V}}$  is the estimated covariance matrix of  $\hat{\boldsymbol{\beta}}$ ,  $\text{rank}(\mathbf{L})$  is the rank of  $\mathbf{L}$ , and  $\mathbf{L}_{\text{Full}}$  is a matrix such that

- $\mathbf{L}_{\text{Full}}$  has the same number of columns as  $\mathbf{L}$
- $\mathbf{L}_{\text{Full}}$  has full row rank
- the rank of  $\mathbf{L}_{\text{Full}}$  equals the rank of the  $\mathbf{L}$  matrix
- all rows of  $\mathbf{L}_{\text{Full}}$  are estimable functions
- the Wald  $F$  statistic computed using the  $\mathbf{L}_{\text{Full}}$  matrix is equivalent to the Wald  $F$  statistic computed by using the  $\mathbf{L}$  matrix with any row deleted that is a linear combination of previous rows

If  $\mathbf{L}$  is a full-rank matrix and all rows of  $\mathbf{L}$  are estimable functions, then  $\mathbf{L}_{\text{Full}}$  is the same as  $\mathbf{L}$ . It is possible that  $\mathbf{L}_{\text{Full}}$  matrix cannot be constructed for contrasts in a CONTRAST statement, in which case the contrasts are not testable.

---

## Domain Analysis

A **DOMAIN** statement requests that the procedure perform regression analysis for each domain.

For a domain  $D$ , let  $I_D$  be the corresponding indicator variable:

$$I_D(h, i, j) = \begin{cases} 1 & \text{if observation } (h, i, j) \text{ belongs to domain } D \\ 0 & \text{otherwise} \end{cases}$$

Let

$$v_{hij} = w_{hij} I_D(h, i, j) = \begin{cases} w_{hij} & \text{if observation } (h, i, j) \text{ belongs to domain } D \\ 0 & \text{otherwise} \end{cases}$$

The regression in domain  $D$  uses  $v$  as the weight variable.

---

## Computational Resources

Due to the complex nature of survey data analysis, the SURVEYREG procedure requires more memory than an analysis of the same regression model by the GLM procedure. For details about the amount of memory related to the modeling, see the section “[Computational Resources](#)” on page 3379 in Chapter 42, “[The GLM Procedure](#).”

The memory needed by the SURVEYREG procedure to handle the survey design is described as follows.

Let

- $H$  be the total number of strata
- $n_c$  be the total number of clusters in your sample across all  $H$  strata, if you specify a **CLUSTER** statement
- $p$  be the total number of parameters in the model

The memory needed (in bytes) is

$$48H + 8pH + 4p(p + 1)H$$

For a cluster sample, the additional memory needed (in bytes) is

$$48H + 8pH + 4p(p + 1)H + 4p(p + 1)n_c + 16n_c$$

The SURVEYREG procedure also uses other small amounts of additional memory. However, when you have a large number of clusters or strata, or a large number of parameters in your model, the memory described previously dominates the total memory required by the procedure.

## Output Data Sets

You can use the Output Delivery System (ODS) to create a SAS data set from any piece of PROC SURVEYREG output. See the section “[ODS Table Names](#)” on page 7983 for more information. For a more detailed description of using ODS, see Chapter 20, “[Using the Output Delivery System](#).”

PROC SURVEYREG also provides an **OUTPUT** statement to create a data set that contains estimated linear predictors and their standard error estimates, the residuals from the linear regression, and the confidence limits for the predictors.

If you use BRR or jackknife variance estimation, PROC SURVEYREG provides an output data set that stores the replicate weights and an output data set that stores the jackknife coefficients for jackknife variance estimation.

### OUT= Data Set Created by the OUTPUT Statement

The **OUTPUT** statement produces an output data set that contains the following:

- all original data from the SAS data set input to PROC SURVEYREG
- the new variables corresponding to the diagnostic measures specified with statistics keywords in the **OUTPUT** statement (**PREDICTED=**, **RESIDUAL=**, and so on)

When any independent variable in the analysis (including all classification variables) is missing for an observation, then all new variables that correspond to diagnostic measures are missing for the observation in the output data set.

When a dependent variable in the analysis is missing for an observation, then the residual variable that corresponds to **R** is also missing in the output data set. However, the variables corresponding to **LCLM**, **P**, **STDP**, and **UCLM** are not missing.

## Replicate Weights Output Data Set

If you specify the `OUTWEIGHTS= method-option` for `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE`, PROC SURVEYREG stores the replicate weights in an output data set. The `OUTWEIGHTS=` output data set contains all observations from the `DATA=` input data set that are valid (used in the analysis). (A valid observation is an observation that has a positive value of the `WEIGHT` variable. Valid observations must also have nonmissing values of the `STRATA` and `CLUSTER` variables, unless you specify the `MISSING` option.)

The `OUTWEIGHTS=` data set contains the following variables:

- all variables in the `DATA=` input data set
- `RepWt_1`, `RepWt_2`, . . . , `RepWt_n`, which are the replicate weight variables

where  $n$  is the total number of replicates in the analysis. Each replicate weight variable contains the replicate weights for the corresponding replicate. Replicate weights equal zero for those observations not included in the replicate.

After the procedure creates replicate weights for a particular input data set and survey design, you can use the `OUTWEIGHTS= method-option` to store these replicate weights and then use them again in subsequent analyses, either in PROC SURVEYREG or in the other survey procedures. You can use the `REPWEIGHTS` statement to provide replicate weights for the procedure.

## Jackknife Coefficients Output Data Set

If you specify the `OUTJKCOEFS= method-option` for `VARMETHOD=JACKKNIFE`, PROC SURVEYREG stores the jackknife coefficients in an output data set. The `OUTJKCOEFS=` output data set contains one observation for each replicate. The `OUTJKCOEFS=` data set contains the following variables:

- `Replicate`, which is the replicate number for the jackknife coefficient
- `JKCoefficient`, which is the jackknife coefficient
- `DonorStratum`, which is the stratum of the PSU that was deleted to construct the replicate, if you specify a `STRATA` statement

After the procedure creates jackknife coefficients for a particular input data set and survey design, you can use the `OUTJKCOEFS= method-option` to store these coefficients and then use them again in subsequent analyses, either in PROC SURVEYREG or in the other survey procedures. You can use the `JKCOEFS=` option in the `REPWEIGHTS` statement to provide jackknife coefficients for the procedure.

---

## Displayed Output

The SURVEYREG procedure produces output that is described in the following sections.

Output that is generated by the `EFFECT`, `ESTIMATE`, `LSMEANS`, `LSMESTIMATE`, and `SLICE` statements is not listed below. For information about the output that is generated by these statements, see the corresponding sections of Chapter 19, “[Shared Concepts and Topics](#).”

## Data Summary

By default, PROC SURVEYREG displays the following information in the “Data Summary” table:

- Number of Observations, which is the total number of observations used in the analysis, excluding observations with missing values
- Sum of Weights, if you specify a WEIGHT statement
- Mean of the dependent variable in the MODEL statement, or Weighted Mean if you specify a WEIGHT statement
- Sum of the dependent variable in the MODEL statement, or Weighted Sum if you specify a WEIGHT statement

## Design Summary

When you specify a CLUSTER statement or a STRATA statement, the procedure displays a “Design Summary” table, which provides the following sample design information:

- Number of Strata, if you specify a STRATA statement
- Number of Strata Collapsed, if the procedure collapses strata
- Number of Clusters, if you specify a CLUSTER statement
- Overall Sampling Rate used to calculate the design effect, if you specify the DEFF option in the MODEL statement

## Domain Summary

By default, PROC SURVEYREG displays the following information in the “Domain Summary” table:

- Number of Observations, which is the total number of observations used in the analysis
- total number of observations in the current domain
- total number of observations not in the current domain
- Sum of Weights for the observations in the current domain, if you specify a WEIGHT statement

## Fit Statistics

By default, PROC SURVEYREG displays the following regression statistics in the “Fit Statistics” table:

- R-square for the regression
- Root MSE, which is the square root of the mean square error
- Denominator DF, which is the denominator degrees of freedom for the  $F$  tests and also the degrees of freedom for the  $t$  tests produced by the procedure

## Variance Estimation

If the variance method is not Taylor series (see the section “Variance Estimation” on page 7969) or if the `NOMCAR` option is used, by default, PROC SURVEYREG displays the following variance estimation information in the “Variance Estimation” table:

- Method, which is the variance estimation method
- Number of Replicates, if you specify the `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE` option
- Hadamard Data Set name, if you specify the `VARMETHOD=BRR(HADAMARD=)` *method-option*
- Fay Coefficient, if you specify the `VARMETHOD=BRR(FAY)` *method-option*
- Replicate Weights input data set name, if you provide replicate weights with a `REPWEIGHTS` statement
- Missing Levels, which indicates whether missing levels of categorical variables are included by the `MISSING` option
- Missing Values, which indicates whether observations with missing values are included in the analysis by the `NOMCAR` option

## Stratum Information

When you specify the `LIST` option in the `STRATA` statement, PROC SURVEYREG displays a “Stratum Information” table, which provides the following information for each stratum:

- Stratum Index, which is a sequential stratum identification number
- `STRATA` variable(s), which lists the levels of `STRATA` variables for the stratum
- Population Total, if you specify the `TOTAL=` option
- Sampling Rate, if you specify the `TOTAL=` option or the `RATE=` option. If you specify the `TOTAL=` option, the sampling rate is based on the number of nonmissing observations in the stratum.
- N Obs, which is the number of observations
- number of Clusters, if you specify a `CLUSTER` statement
- Collapsed, which has the value ‘Yes’ if the stratum is collapsed with another stratum before analysis

If PROC SURVEYREG collapses strata, the “Stratum Information” table also displays stratum information for the new, collapsed stratum. The new stratum has a Stratum Index of 0 and is labeled ‘Pooled.’

## Class Level Information

If you use a CLASS statement to name classification variables, PROC SURVEYREG displays a “Class Level Information” table. This table contains the following information for each classification variable:

- Class Variable, which lists each CLASS variable name
- Levels, which is the number of values or levels of the classification variable
- Values, which lists the values of the classification variable. The values are separated by a white space character; therefore, to avoid confusion, you should not include a white space character within a classification variable value.

## X'X Matrix

If you specify the XPX option in the MODEL statement, PROC SURVEYREG displays the  $X'X$  matrix. When there is a WEIGHT variable, the procedure displays the  $X'WX$  matrix. This option also displays the crossproducts vector  $X'y$  or  $X'Wy$ , where  $y$  is the response vector (dependent variable).

## Inverse Matrix of X'X

If you specify the INVERSE option in the MODEL statement, PROC SURVEYREG displays the inverse or the generalized inverse of the  $X'X$  matrix. When there is a WEIGHT variable, the procedure displays the inverse or the generalized inverse of the  $X'WX$  matrix.

## ANOVA for Dependent Variable

If you specify the ANOVA option in the model statement, PROC SURVEYREG displays an analysis of variance table for the dependent variable. This table is identical to the ANOVA table displayed by the GLM procedure.

## Tests of Model Effects

By default, PROC SURVEYREG displays a “Tests of Model Effects” table, which provides Wald’s  $F$  test for each effect in the model. The table contains the following information for each effect:

- Effect, which is the effect name
- Num DF, which is the numerator degrees of freedom for Wald’s  $F$  test
- F Value, which is Wald’s  $F$  statistic
- Pr > F, which is the significance probability corresponding to the F Value

A footnote displays the denominator degrees of freedom, which is the same for all effects.

## Estimated Regression Coefficients

PROC SURVEYREG displays the “Estimated Regression Coefficients” table by default when there is no CLASS statement. Also, the procedure displays this table when you specify a CLASS statement and also specify the SOLUTION option in the MODEL statement. This table contains the following information for each regression parameter:

- Parameter, which identifies the effect or regressor variable
- Estimate, which is the estimate of the regression coefficient
- Standardized Estimate, which is the standardized regression coefficient
- Standard Error, which is the standard error of the estimate
- t Value, which is the  $t$  statistic for testing  $H_0: \text{Parameter} = 0$
- Pr > |t|, which is the two-sided significance probability corresponding to the t Value
- Pr > |t|, which is the two-sided significance probability corresponding to the t Value

## Covariance of Estimated Regression Coefficients

When you specify the COVB option in the MODEL statement, PROC SURVEYREG displays the “Covariance of Estimated Regression Coefficients” matrix.

## Coefficients of Contrast

When you specify the E option in a CONTRAST statement, PROC SURVEYREG displays a “Coefficients of Contrast” table for the contrast. You can use this table to check the coefficients you specified in the CONTRAST statement. Also, this table gives a note for a nonestimable contrast.

## Analysis of Contrasts

If you specify a CONTRAST statement, PROC SURVEYREG produces an “Analysis of Contrasts” table, which displays Wald’s  $F$  test for the contrast. If you use more than one CONTRAST statement, the procedure displays all results in the same table. The “Analysis of Contrasts” table contains the following information for each contrast:

- Contrast, which is the label of the contrast
- Num DF, which is the numerator degrees of freedom for Wald’s  $F$  test
- F Value, which is Wald’s  $F$  statistic for testing  $H_0: \text{Contrast} = 0$
- Pr > F, which is the significance probability corresponding to the F Value

## Hadamard Matrix

If you specify the `VARMETHOD=BRR(PRINTH)` *method-option* in the PROC SURVEYREG statement, the procedure displays the Hadamard matrix.

When you provide a Hadamard matrix with the `VARMETHOD=BRR(HADAMARD=)` *method-option* but the procedure does not use the entire matrix, the procedure displays only the rows and columns that are actually used to construct replicates.

---

## ODS Table Names

PROC SURVEYREG assigns a name to each table it creates; these names are listed in Table 94.10. You can use these names to refer to tables when you use the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

To improve the consistency among procedures, tables that are generated by the ESTIMATE statements are changed slightly in appearance and formatting compared to releases prior to SAS/STAT 9.22. However, the statistics in the “Estimates” table remain unchanged. The “Coef” table replaces the previous “EstimateCoef” table that displays the L matrix coefficients of an estimable function of the parameters.

The EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements also create tables, which are not listed in Table 94.10. For information about these tables, see the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

**Table 94.10** ODS Tables Produced by PROC SURVEYREG

| ODS Table Name     | Description                                     | Statement        | Option   |
|--------------------|-------------------------------------------------|------------------|----------|
| ANOVA              | ANOVA for dependent variable                    | MODEL            | ANOVA    |
| ClassVarInfo       | Class level information                         | CLASS            | Default  |
| ContrastCoef       | Coefficients of contrast                        | CONTRAST         | E        |
| Contrasts          | Analysis of contrasts                           | CONTRAST         | Default  |
| CovB               | Covariance of estimated regression coefficients | MODEL            | COVB     |
| DataSummary        | Data summary                                    | PROC             | Default  |
| DesignSummary      | Design summary                                  | STRATA   CLUSTER | Default  |
| DomainSummary      | Domain summary                                  | DOMAIN           | Default  |
| Effects            | Tests of model effects                          | MODEL            | Defect   |
| FitStatistics      | Fit statistics                                  | MODEL            | Default  |
| HadamardMatrix     | Hadamard matrix                                 | PROC             | PRINTH   |
| InvXPX             | Inverse matrix of $X'X$                         | MODEL            | I        |
| ParameterEstimates | Estimated regression coefficients               | MODEL            | SOLUTION |
| StrataInfo         | Stratum information                             | STRATA           | LIST     |
| VarianceEstimation | Variance estimation                             | PROC             | Default  |
| XPX                | $X'X$ matrix                                    | MODEL            | XPX      |

By referring to the names of such tables, you can use the ODS OUTPUT statement to place one or more of these tables in output data sets.

For example, the following statements create an output data set MyStrata, which contains the “StrataInfo” table, an output data set MyParmEst, which contains the “ParameterEstimates” table, and an output data set Cov, which contains the “CovB” table for the ice cream study discussed in the section “Stratified Sampling” on page 7938:

```

title1 'Ice Cream Spending Analysis';
title2 'Stratified Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
 strata Grade /list;
 class Kids;
 model Spending = Income Kids / solution covb;
 weight Weight;
 ods output StrataInfo = MyStrata
 ParameterEstimates = MyParmEst
 CovB = Cov;
run;

```

Note that the option CovB is specified in the MODEL statement in order to produce the covariance matrix table.

---

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

When ODS Graphics is enabled, the ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements can produce plots that are associated with their analyses. For information about these plots, see the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

---

## Examples: SURVEYREG Procedure

---

### Example 94.1: Simple Random Sampling

This example investigates the relationship between the labor force participation rate (LFPR) of women in 1968 and 1972 in large cities in the United States. A simple random sample of 19 cities is drawn from a total of 200 cities. For each selected city, the LFPRs are recorded and saved in a SAS data set Labor. In the following DATA step, LFPR in 1972 is contained in the variable LFPR1972, and the LFPR in 1968 is identified by the variable LFPR1968:

```
data Labor;
 input City $ 1-16 LFPR1972 LFPR1968;
 datalines;
New York .45 .42
Los Angeles .50 .50
Chicago .52 .52
Philadelphia .45 .45
Detroit .46 .43
San Francisco .55 .55
Boston .60 .45
Pittsburgh .49 .34
St. Louis .35 .45
Connecticut .55 .54
Washington D.C. .52 .42
Cincinnati .53 .51
Baltimore .57 .49
Newark .53 .54
Minn/St. Paul .59 .50
Buffalo .64 .58
Houston .50 .49
Patterson .57 .56
Dallas .64 .63
;
```

Assume that the LFPRs in 1968 and 1972 have a linear relationship, as shown in the following model:

$$\text{LFPR1972} = \beta_0 + \beta_1 * \text{LFPR1968} + \text{error}$$

You can use PROC SURVEYREG to obtain the estimated regression coefficients and estimated standard errors of the regression coefficients. The following statements perform the regression analysis:

```
title 'Study of Labor Force Participation Rates of Women';
proc surveyreg data=Labor total=200;
 model LFPR1972 = LFPR1968;
run;
```

Here, the TOTAL=200 option specifies the finite population total from which the simple random sample of 19 cities is drawn. You can specify the same information by using the sampling rate option RATE=0.095 (19/200=.095).

Output 94.1.1 summarizes the data information and the fit information.

**Output 94.1.1** Summary of Regression Using Simple Random Sampling

| Study of Labor Force Participation Rates of Women   |          |
|-----------------------------------------------------|----------|
| The SURVEYREG Procedure                             |          |
| Regression Analysis for Dependent Variable LFPR1972 |          |
| Data Summary                                        |          |
| Number of Observations                              | 19       |
| Mean of LFPR1972                                    | 0.52684  |
| Sum of LFPR1972                                     | 10.01000 |
| Fit Statistics                                      |          |
| R-square                                            | 0.3970   |
| Root MSE                                            | 0.05657  |
| Denominator DF                                      | 18       |

Output 94.1.2 presents the significance tests for the model effects and estimated regression coefficients. The  $F$  tests and  $t$  tests for the effects in the model are also presented in these tables.

**Output 94.1.2** Regression Coefficient Estimates

| Tests of Model Effects                                          |            |                |         |         |
|-----------------------------------------------------------------|------------|----------------|---------|---------|
| Effect                                                          | Num DF     | F Value        | Pr > F  |         |
| Model                                                           | 1          | 13.84          | 0.0016  |         |
| Intercept                                                       | 1          | 4.63           | 0.0452  |         |
| LFPR1968                                                        | 1          | 13.84          | 0.0016  |         |
| NOTE: The denominator degrees of freedom for the F tests is 18. |            |                |         |         |
| Estimated Regression Coefficients                               |            |                |         |         |
| Parameter                                                       | Estimate   | Standard Error | t Value | Pr >  t |
| Intercept                                                       | 0.20331056 | 0.09444296     | 2.15    | 0.0452  |
| LFPR1968                                                        | 0.65604048 | 0.17635810     | 3.72    | 0.0016  |
| NOTE: The denominator degrees of freedom for the t tests is 18. |            |                |         |         |

From the regression performed by PROC SURVEYREG, you obtain a positive estimated slope for the linear relationship between the LFPR in 1968 and the LFPR in 1972. The regression coefficients are all significant at the 5% level. The effects Intercept and LFPR1968 are significant in the model at the 5% level. In this example, the  $F$  test for the overall model without intercept is the same as the effect LFPR1968.

## Example 94.2: Cluster Sampling

This example illustrates the use of regression analysis in a simple random cluster sample design. The data are from Särndal, Swensson, and Wretman (1992, p. 652). A total of 284 Swedish municipalities are grouped into 50 clusters of neighboring municipalities. Five clusters with a total of 32 municipalities are randomly selected. The results from the regression analysis in which clusters are used in the sample design are compared to the results of a regression analysis that ignores the clusters. The linear relationship between the population in 1975 and in 1985 is investigated.

The 32 selected municipalities in the sample are saved in the data set `Municipalities`:

```
data Municipalities;
 input Municipality Cluster Population85 Population75;
 datalines;
205 37 5 5
206 37 11 11
207 37 13 13
208 37 8 8
209 37 17 19
6 2 16 15
7 2 70 62
8 2 66 54
9 2 12 12
10 2 60 50
94 17 7 7
95 17 16 16
96 17 13 11
97 17 12 11
98 17 70 67
99 17 20 20
100 17 31 28
101 17 49 48
276 50 6 7
277 50 9 10
278 50 24 26
279 50 10 9
280 50 67 64
281 50 39 35
282 50 29 27
283 50 10 9
284 50 27 31
52 10 7 6
53 10 9 8
54 10 28 27
55 10 12 11
56 10 107 108
;
```

The variable `Municipality` identifies the municipalities in the sample; the variable `Cluster` indicates the cluster to which a municipality belongs; and the variables `Population85` and `Population75` contain the municipality populations in 1985 and in 1975 (in thousands), respectively. A regression analysis is performed by PROC SURVEYREG with a `CLUSTER` statement:

```

title1 'Regression Analysis for Swedish Municipalities';
title2 'Cluster Sampling';
proc surveyreg data=Municipalities total=50;
 cluster Cluster;
 model Population85=Population75;
run;

```

The TOTAL=50 option specifies the total number of clusters in the sampling frame.

Output 94.2.1 displays the data and design summary. Since the sample design includes clusters, the procedure displays the total number of clusters in the sample in the “Design Summary” table.

**Output 94.2.1** Regression Analysis for Cluster Sampling

|                                                         |           |
|---------------------------------------------------------|-----------|
| Regression Analysis for Swedish Municipalities          |           |
| Cluster Sampling                                        |           |
| The SURVEYREG Procedure                                 |           |
| Regression Analysis for Dependent Variable Population85 |           |
| Data Summary                                            |           |
| Number of Observations                                  | 32        |
| Mean of Population85                                    | 27.50000  |
| Sum of Population85                                     | 880.00000 |
| Design Summary                                          |           |
| Number of Clusters                                      | 5         |

Output 94.2.2 displays the fit statistics and regression coefficient estimates. In the “Estimated Regression Coefficients” table, the estimated slope for the linear relationship is 1.05, which is significant at the 5% level; but the intercept is not significant. This suggests that a regression line crossing the original can be established between populations in 1975 and in 1985.

**Output 94.2.2** Regression Analysis for Cluster Sampling

|                |        |
|----------------|--------|
| Fit Statistics |        |
| R-square       | 0.9860 |
| Root MSE       | 3.0488 |
| Denominator DF | 4      |

**Output 94.2.2** *continued*

| Estimated Regression Coefficients |            |                |         |         |
|-----------------------------------|------------|----------------|---------|---------|
| Parameter                         | Estimate   | Standard Error | t Value | Pr >  t |
| Intercept                         | -0.0191292 | 0.89204053     | -0.02   | 0.9839  |
| Population75                      | 1.0546253  | 0.05167565     | 20.41   | <.0001  |

NOTE: The denominator degrees of freedom for the t tests is 4.

The CLUSTER statement is necessary in PROC SURVEYREG in order to incorporate the sample design. If you do not specify a CLUSTER statement in the regression analysis, as in the following statements, the standard deviation of the regression coefficients are incorrectly estimated.

```

title1 'Regression Analysis for Swedish Municipalities';
title2 'Simple Random Sampling';
proc surveyreg data=Municipalities total=284;
 model Population85=Population75;
run;

```

The analysis ignores the clusters in the sample, assuming that the sample design is a simple random sampling. Therefore, the TOTAL= option specifies the total number of municipalities, which is 284.

Output 94.2.3 displays the regression results ignoring the clusters. Compared to the results in Output 94.2.2, the regression coefficient estimates are the same. However, without using clusters, the regression coefficients have a smaller variance estimate, as in Output 94.2.3. By using clusters in the analysis, the estimated regression coefficient for effect Population75 is 1.05, with the estimated standard error 0.05, as displayed in Output 94.2.2; without using the clusters, the estimate is 1.05, but with the estimated standard error 0.04, as displayed in Output 94.2.3. To estimate the variance of the regression coefficients correctly, you should include the clustering information in the regression analysis.

**Output 94.2.3** Regression Analysis for Simple Random Sampling

| Regression Analysis for Swedish Municipalities<br>Simple Random Sampling |           |
|--------------------------------------------------------------------------|-----------|
| The SURVEYREG Procedure                                                  |           |
| Regression Analysis for Dependent Variable Population85                  |           |
| Data Summary                                                             |           |
| Number of Observations                                                   | 32        |
| Mean of Population85                                                     | 27.50000  |
| Sum of Population85                                                      | 880.00000 |

**Output 94.2.3** *continued*

| Fit Statistics                                                  |            |                |         |         |
|-----------------------------------------------------------------|------------|----------------|---------|---------|
| R-square                                                        |            |                | 0.9860  |         |
| Root MSE                                                        |            |                | 3.0488  |         |
| Denominator DF                                                  |            |                | 31      |         |
| Estimated Regression Coefficients                               |            |                |         |         |
| Parameter                                                       | Estimate   | Standard Error | t Value | Pr >  t |
| Intercept                                                       | -0.0191292 | 0.67417606     | -0.03   | 0.9775  |
| Population75                                                    | 1.0546253  | 0.03668414     | 28.75   | <.0001  |
| NOTE: The denominator degrees of freedom for the t tests is 31. |            |                |         |         |

**Example 94.3: Regression Estimator for Simple Random Sample**

By using auxiliary information, you can construct regression estimators to provide more accurate estimates of population characteristics. With ESTIMATE statements in PROC SURVEYREG, you can specify a regression estimator as a linear function of the regression parameters to estimate the population total. This example illustrates this application by using the data set Municipalities from [Example 94.2](#).

In this sample, a linear model between the Swedish populations in 1975 and in 1985 is established:

$$\text{Population85} = \alpha + \beta * \text{Population75} + \text{error}$$

Assuming that the total population in 1975 is known to be 8200 (in thousands), you can use the ESTIMATE statement to predict the 1985 total population by using the following statements:

```

title1 'Regression Analysis for Swedish Municipalities';
title2 'Estimate Total Population';
proc surveyreg data=Municipalities total=50;
 cluster Cluster;
 model Population85=Population75;
 estimate '1985 population' Intercept 284 Population75 8200;
run;

```

Since each observation in the sample is a municipality and there is a total of 284 municipalities in Sweden, the coefficient for Intercept ( $\alpha$ ) in the ESTIMATE statement is 284 and the coefficient for Population75 ( $\beta$ ) is the total population in 1975 (8.2 million).

[Output 94.3.1](#) displays the regression results and the estimation of the total population. By using the linear model, you can predict the total population in 1985 to be 8.64 million, with a standard error of 0.26 million.

**Output 94.3.1** Use the Regression Estimator to Estimate the Population Total

| Regression Analysis for Swedish Municipalities<br>Estimate Total Population |          |                |    |         |         |
|-----------------------------------------------------------------------------|----------|----------------|----|---------|---------|
| The SURVEYREG Procedure                                                     |          |                |    |         |         |
| Regression Analysis for Dependent Variable Population85                     |          |                |    |         |         |
|                                                                             | Estimate |                |    |         |         |
| Label                                                                       | Estimate | Standard Error | DF | t Value | Pr >  t |
| 1985 population                                                             | 8642.49  | 258.56         | 4  | 33.43   | <.0001  |

**Example 94.4: Stratified Sampling**

This example illustrates the use of the SURVEYREG procedure to perform a regression in a stratified sample design. Consider a population of 235 farms producing corn in Nebraska and Iowa. You are interested in the relationship between corn yield (CornYield) and total farm size (FarmArea).

Each state is divided into several regions, and each region is used as a stratum. Within each stratum, a simple random sample with replacement is drawn. A total of 19 farms is selected by using a stratified simple random sample. The sample size and population size within each stratum are displayed in Table 94.11.

**Table 94.11** Number of Farms in Each Stratum

| Stratum      | State    | Region | Number of Farms |           |
|--------------|----------|--------|-----------------|-----------|
|              |          |        | Population      | Sample    |
| 1            | Iowa     | 1      | 100             | 3         |
| 2            |          | 2      | 50              | 5         |
| 3            |          | 3      | 15              | 3         |
| 4            | Nebraska | 1      | 30              | 6         |
| 5            |          | 2      | 40              | 2         |
| <b>Total</b> |          |        | <b>235</b>      | <b>19</b> |

Three models for the data are considered:

- Model I — Common intercept and slope:

$$\text{Corn Yield} = \alpha + \beta * \text{Farm Area}$$

- Model II — Common intercept, different slope:

$$\text{Corn Yield} = \begin{cases} \alpha + \beta_{\text{Iowa}} * \text{Farm Area} & \text{if the farm is in Iowa} \\ \alpha + \beta_{\text{Nebraska}} * \text{Farm Area} & \text{if the farm is in Nebraska} \end{cases}$$

- Model III — Different intercept and different slope:

$$\text{Corn Yield} = \begin{cases} \alpha_{\text{Iowa}} + \beta_{\text{Iowa}} * \text{Farm Area} & \text{if the farm is in Iowa} \\ \alpha_{\text{Nebraska}} + \beta_{\text{Nebraska}} * \text{Farm Area} & \text{if the farm is in Nebraska} \end{cases}$$

Data from the stratified sample are saved in the SAS data set Farms. In the data set Farms, the variable Weight represents the sampling weight. In the following DATA step, the sampling weights are the reciprocals of selection probabilities:

```
data Farms;
 input State $ Region FarmArea CornYield Weight;
 datalines;
Iowa 1 100 54 33.333

;
```

The information about population size in each stratum is saved in the SAS data set StratumTotals:

```
data StratumTotals;
 input State $ Region _TOTAL_;
 datalines;
Iowa 1 100
Iowa 2 50
Iowa 3 15
Nebraska 1 30
Nebraska 2 40
;
```

Using the sample data from the data set Farms and the control information data from the data set StratumTotals, you can fit Model I by using PROC SURVEYREG with the following statements:

```

title1 'Analysis of Farm Area and Corn Yield';
title2 'Model I: Same Intercept and Slope';
proc surveyreg data=Farms total=StratumTotals;
 strata State Region / list;
 model CornYield = FarmArea / covB;
 weight Weight;
run;

```

Output 94.4.1 displays the data summary and stratification information fitting Model I. The sampling rates are automatically computed by the procedure based on the sample sizes and the population totals in strata.

| FarmArea                          | 0.2126576  | 0.04560949     | 4.66    | 0.0004  |

NOTE: The denominator degrees of freedom for the t tests is 14.

| Covariance of Estimated Regression Coefficients |              |              |
|-------------------------------------------------|--------------|--------------|
|                                                 | Intercept    | FarmArea     |
| Intercept                                       | 28.300381277 | -0.146471538 |
| FarmArea                                        | -0.146471538 | 0.0020802259 |

Alternatively, you can assume that the linear relationship between corn yield (CornYield) and farm area (FarmArea) is different among the states (Model II). In order to analyze the data by using this model, you create auxiliary variables FarmAreaNE and FarmAreaIA to represent farm area in different states:

$$\text{FarmAreaNE} = \begin{cases} 0 & \text{if the farm is in Iowa} \\ \text{FarmArea} & \text{if the farm is in Nebraska} \end{cases}$$

$$\text{FarmAreaIA} = \begin{cases} \text{FarmArea} & \text{if the farm is in Iowa} \\ 0 & \text{if the farm is in Nebraska} \end{cases}$$

The following statements create these variables in a new data set called FarmsByState and use PROC SURVEYREG to fit Model II:

```
data FarmsByState;
 set Farms;
 if State='Iowa' then do;
 FarmAreaIA=FarmArea;
 FarmAreaNE=0;
 end;
```

```

else do;
 FarmAreaIA=0;
 FarmAreaNE=FarmArea;
end;
run;

```

The following statements perform the regression by using the new data set FarmsByState. The analysis uses the auxiliary variables FarmAreaIA and FarmAreaNE as the regressors:

```

title1 'Analysis of Farm Area and Corn Yield';
title2 'Model II: Same Intercept, Different Slopes';
proc surveyreg data=FarmsByState total=StratumTotals;
 strata State Region;
 model CornYield = FarmAreaIA FarmAreaNE / covB;
 weight Weight;
run;

```

Output 94.4.3 displays the fit statistics and parameter estimates. The estimated slope parameters for each state are quite different from the estimated slope in Model I. The results from the regression show that Model II fits these data better than Model I.

**Output 94.4.3** Regression Results from Fitting Model II

| Analysis of Farm Area and Corn Yield                            |              |                |              |         |
|-----------------------------------------------------------------|--------------|----------------|--------------|---------|
| Model II: Same Intercept, Different Slopes                      |              |                |              |         |

| FarmAreaNE                                                      | -0.079908772 | 0.0006501109   | 0.0006227496 |         |

For Model III, different intercepts are used for the linear relationship in two states. The following statements illustrate the use of the NOINT option in the MODEL statement associated with the CLASS statement to fit Model III:

```

title1 'Analysis of Farm Area and Corn Yield';
title2 'Model III: Different Intercepts and Slopes';
proc surveyreg data=FarmsByState total=StratumTotals;
 strata State Region;
 class State;
 model CornYield = State FarmAreaIA FarmAreaNE / noint covB solution;
 weight Weight;
run;

```

The model statement includes the classification effect State as a regressor. Therefore, the parameter estimates for effect State present the intercepts in two states.

Output 94.4.4 displays the regression results for fitting Model III, including parameter estimates, and covariance matrix of the regression coefficients. The estimated covariance matrix shows a lack of correlation between the regression coefficients from different states. This suggests that Model III might be the best choice for building a model for farm area and corn yield in these two states.

However, some statistics remain the same under different regression models—for example, Weighted Mean of CornYield. These estimators do not rely on the particular model you use.

#### Output 94.4.4 Regression Results for Fitting Model III

**Example 94.5: Regression Estimator for Stratified Sample**

This example uses the corn yield data set FARMS from Example 94.4 to illustrate how to construct a regression estimator for a stratified sample design.

As in Example 94.3, by incorporating auxiliary information into a regression estimator, the procedure can produce more accurate estimates of the population characteristics that are of interest. In this example, the sample design is a stratified sample design. The auxiliary information is the total farm areas in regions of each state, as displayed in Table 94.12. You want to estimate the total corn yield by using this information under the three linear models given in Example 94.4.

**Table 94.12** Information for Each Stratum

| Stratum      | State    | Number of Farms |            | Sample    | Total Farm Area |
|--------------|----------|-----------------|------------|-----------|-----------------|
|              |          | Region          | Population |           |                 |
| 1            | Iowa     | 1               | 100        | 3         | 13,200          |
| 2            |          | 2               | 50         | 5         |                 |
| 3            |          | 3               | 15         | 3         |                 |
| 4            | Nebraska | 1               | 30         | 6         | 8,750           |
| 5            |          | 2               | 40         | 2         |                 |
| <b>Total</b> |          |                 | <b>235</b> | <b>19</b> | <b>21,950</b>   |

The regression estimator to estimate the total corn yield under Model I can be obtained by using PROC SURVEYREG with an ESTIMATE statement:

```

title1 'Estimate Corn Yield from Farm Size';
title2 'Model I: Same Intercept and Slope';
proc surveyreg data=Farms total=StratumTotals;
 strata State Region / list;
 class State Region;
 model CornYield = FarmArea State*Region /solution;
 weight Weight;
 estimate 'Estimate of CornYield under Model I'
 INTERCEPT 235 FarmArea 21950
 State*Region 100 50 15 30 40 /e;
run;

```

To apply the constraint in each stratum that the weighted total number of farms equals to the total number of farms in the stratum, you can include the strata as an effect in the MODEL statement, effect State\*Region. Thus, the CLASS statement must list the STRATA variables, State and Region, as classification variables. The following ESTIMATE statement specifies the regression estimator, which is a linear function of the regression parameters:

```
estimate 'Estimate of CornYield under Model I'
 INTERCEPT 235 FarmArea 21950
 State*Region 100 50 15 30 40 /e;
```

This linear function contains the total for each explanatory variable in the model. Because the sampling units are farms in this example, the coefficient for Intercept in the ESTIMATE statement is the total number of farms (235); the coefficient for FarmArea is the total farm area listed in Table 94.12 (21950); and the coefficients for effect State\*Region are the total number of farms in each strata (as displayed in Table 94.12).

Output 94.5.1 displays the results of the ESTIMATE statement. The regression estimator for the total of CornYield in Iowa and Nebraska is 7464 under Model I, with a standard error of 927.

**Output 94.5.1** Regression Estimator for the Total of CornYield under Model I

| Estimate Corn Yield from Farm Size<br>Model I: Same Intercept and Slope |          |                |    |         |
|-------------------------------------------------------------------------|----------|----------------|----|---------|
| The SURVEYREG Procedure                                                 |          |                |    |         |
| Regression Analysis for Dependent Variable CornYield                    |          |                |    |         |
| Estimate                                                                |          |                |    |         |
| Label                                                                   | Estimate | Standard Error | DF | t Value |
| Estimate of CornYield under Model I                                     | 7463.52  | 926.84         | 14 | 8.05    |
| Estimate                                                                |          |                |    |         |
| Label                                                                   | Pr >  t  |                |    |         |
| Estimate of CornYield under Model I                                     | <.0001   |                |    |         |

Under Model II, a regression estimator for totals can be obtained by using the following statements:

```
title1 'Estimate Corn Yield from Farm Size';
title2 'Model II: Same Intercept, Different Slopes';
proc surveyreg data=FarmsByState total=StratumTotals;
 strata State Region;
 class State Region;
 model CornYield = FarmAreaIA FarmAreaNE
 state*region /solution;
 weight Weight;
 estimate 'Total of CornYield under Model II'
 INTERCEPT 235 FarmAreaIA 13200 FarmAreaNE 8750
 State*Region 100 50 15 30 40 /e;
run;
```

In this model, you also need to include strata as a fixed effect in the MODEL statement. Other regressors are the auxiliary variables FarmAreaIA and FarmAreaNE (defined in Example 94.4). In the following ESTIMATE statement, the coefficient for Intercept is still the total number of farms; and the coefficients for FarmAreaIA and FarmAreaNE are the total farm area in Iowa and Nebraska, respectively, as displayed in Table 94.12. The total number of farms in each strata are the coefficients for the strata effect:

```
estimate 'Total of CornYield under Model II'
 INTERCEPT 235 FarmAreaIA 13200 FarmAreaNE 8750
 State*Region 100 50 15 30 40 /e;
```

Output 94.5.2 displays that the results of the regression estimator for the total of corn yield in two states under Model II is 7580 with a standard error of 859. The regression estimator under Model II has a slightly smaller standard error than under Model I.

**Output 94.5.2** Regression Estimator for the Total of CornYield under Model II

| Estimate Corn Yield from Farm Size                   |          |                |    |         |         |
|------------------------------------------------------|----------|----------------|----|---------|---------|
| Model II: Same Intercept, Different Slopes           |          |                |    |         |         |
| The SURVEYREG Procedure                              |          |                |    |         |         |
| Regression Analysis for Dependent Variable CornYield |          |                |    |         |         |
|                                                      | Estimate |                |    |         |         |
| Label                                                | Estimate | Standard Error | DF | t Value | Pr >  t |
| Total of CornYield under Model II                    | 7580.49  | 859.18         | 14 | 8.82    | <.0001  |

Finally, you can apply Model III to the data and estimate the total corn yield. Under Model III, you can also obtain the regression estimators for the total corn yield for each state. Three ESTIMATE statements are used in the following statements to create the three regression estimators:

```
title1 'Estimate Corn Yield from Farm Size';
title2 'Model III: Different Intercepts and Slopes';
proc surveyreg data=FarmsByState total=StratumTotals;
 strata State Region;
 class State Region;
 model CornYield = state FarmAreaIA FarmAreaNE
 State*Region /noint solution;
 weight Weight;
 estimate 'Total CornYield in Iowa under Model III'
 State 165 0 FarmAreaIA 13200 FarmAreaNE 0
 State*region 100 50 15 0 0 /e;
 estimate 'Total CornYield in Nebraska under Model III'
 State 0 70 FarmAreaIA 0 FarmAreaNE 8750
 State*Region 0 0 0 30 40 /e;
 estimate 'Total CornYield in both states under Model III'
 State 165 70 FarmAreaIA 13200 FarmAreaNE 8750
 State*Region 100 50 15 30 40 /e;
run;
```

The fixed effect State is added to the MODEL statement to obtain different intercepts in different states, by using the NOINT option. Among the ESTIMATE statements, the coefficients for explanatory variables are different depending on which regression estimator is estimated. For example, in the ESTIMATE statement

```
estimate 'Total CornYield in Iowa under Model III'
 State 165 0 FarmAreaIA 13200 FarmAreaNE 0
 State*region 100 50 15 0 0 /e;
```

the coefficients for the effect State are 165 and 0, respectively. This indicates that the total number of farms in Iowa is 165 and the total number of farms in Nebraska is 0, because the estimation is the total corn yield in Iowa only. Similarly, the total numbers of farms in three regions in Iowa are used for the coefficients of the strata effect State\*Region, as displayed in Table 94.12. Output 94.5.3 displays the results from the three regression estimators by using Model III. Since the estimations are independent in each state, the total corn yield from both states is equal to the sum of the estimated total of corn yield in Iowa and Nebraska,  $6246 + 1334 = 7580$ . This regression estimator is the same as the one under Model II. The variance of regression estimator of the total corn yield in both states is the sum of variances of regression estimators for total corn yield in each state. Therefore, it is not necessary to use Model III to obtain the regression estimator for the total corn yield unless you need to estimate the total corn yield for each individual state.

**Output 94.5.3** Regression Estimator for the Total of CornYield under Model III

| Estimate Corn Yield from Farm Size                   |          |                |    |         |
|------------------------------------------------------|----------|----------------|----|---------|
| Model III: Different Intercepts and Slopes           |          |                |    |         |
| The SURVEYREG Procedure                              |          |                |    |         |
| Regression Analysis for Dependent Variable CornYield |          |                |    |         |
| Estimate                                             |          |                |    |         |
| Label                                                | Estimate | Standard Error | DF | t Value |
| Total CornYield in Iowa under Model III              | 6246.11  | 851.27         | 14 | 7.34    |
| Estimate                                             |          |                |    |         |
| Label                                                | Pr >  t  |                |    |         |
| Total CornYield in Iowa under Model III              | <.0001   |                |    |         |

## Example 94.6: Stratum Collapse

In a stratified sample, it is possible that some strata might have only one sampling unit. When this happens, PROC SURVEYREG collapses the strata that contain a single sampling unit into a pooled stratum. For more detailed information about stratum collapse, see the section “Stratum Collapse” on page 7968.

Suppose that you have the following data:

```

data Sample;
 input Stratum X Y W;
 datalines;
10 0 0 5
10 1 1 5
11 1 1 10
11 1 2 10
12 3 3 16
33 4 4 45
14 6 7 50
12 3 4 16
;

```

The variable `Stratum` is again the stratification variable, the variable `X` is the independent variable, and the variable `Y` is the dependent variable. You want to regress `Y` on `X`. In the data set `Sample`, both `Stratum=33` and `Stratum=14` contain one observation. By default, PROC SURVEYREG collapses these strata into one pooled stratum in the regression analysis.

To input the finite population correction information, you create the SAS data set `StratumTotals`:

```

data StratumTotals;
 input Stratum _TOTAL_;
 datalines;
10 10
11 20
12 32
33 40
33 45
14 50
15 .
66 70
;

```

The variable `Stratum` is the stratification variable, and the variable `_TOTAL_` contains the stratum totals. The data set `StratumTotals` contains more strata than the data set `Sample`. Also in the data set `StratumTotals`, more than one observation contains the stratum totals for `Stratum=33`:

```

33 40
33 45

```

PROC SURVEYREG allows this type of input. The procedure simply ignores strata that are not present in the data set `Sample`; for the multiple entries of a stratum, the procedure uses the first observation. In this example, `Stratum=33` has the stratum total `_TOTAL_=40`.

The following SAS statements perform the regression analysis:

```

title1 'Stratified Sample with Single Sampling Unit in Strata';
title2 'With Stratum Collapse';
proc surveyreg data=Sample total=StratumTotals;
 strata Stratum/list;
 model Y=X;
 weight W;
run;

```

Output 94.6.1 shows that there are a total of five strata in the input data set and two strata are collapsed into a pooled stratum. The denominator degrees of freedom is 4, due to the collapse (see the section “Denominator Degrees of Freedom” on page 7974).

**Output 94.6.1** Summary of Data and Regression

| Stratified Sample with Single Sampling Unit in Strata<br>With Stratum Collapse |           |
|--------------------------------------------------------------------------------|-----------|
| The SURVEYREG Procedure                                                        |           |
| Regression Analysis for Dependent Variable Y                                   |           |
| Data Summary                                                                   |           |
| Number of Observations                                                         | 8         |
| Sum of Weights                                                                 | 157.00000 |
| Weighted Mean of Y                                                             | 4.31210   |
| Weighted Sum of Y                                                              | 677.00000 |
| Design Summary                                                                 |           |
| Number of Strata                                                               | 5         |
| Number of Strata Collapsed                                                     | 2         |
| Fit Statistics                                                                 |           |
| R-square                                                                       | 0.9564    |
| Root MSE                                                                       | 0.5111    |
| Denominator DF                                                                 | 4         |

Output 94.6.2 displays the stratification information, including stratum collapse. Under the column Collapsed, the fourth stratum (Stratum=14) and the fifth (Stratum=33) are marked as ‘Yes,’ which indicates that these two strata are collapsed into the pooled stratum (Stratum Index=0). The sampling rate for the pooled stratum is 2% (see the section “Sampling Rate of the Pooled Stratum from Collapse” on page 7968).

Output 94.6.3 displays the parameter estimates and the tests of the significance of the model effects.

**Output 94.6.2** Stratification Information

| Stratum Information |           |         |       |                  |               |
|---------------------|-----------|---------|-------|------------------|---------------|
| Stratum Index       | Collapsed | Stratum | N Obs | Population Total | Sampling Rate |
| 1                   |           | 10      | 2     | 10               | 20.0%         |
| 2                   |           | 11      | 2     | 20               | 10.0%         |
| 3                   |           | 12      | 2     | 32               | 6.25%         |
| 4                   | Yes       | 14      | 1     | 50               | 2.00%         |
| 5                   | Yes       | 33      | 1     | 40               | 2.50%         |
| 0                   | Pooled    |         | 2     | 90               | 2.22%         |

NOTE: Strata with only one observation are collapsed into the stratum with Stratum Index "0".

**Output 94.6.3** Parameter Estimates and Effect Tests

| Tests of Model Effects |        |         |        |
|------------------------|--------|---------|--------|
| Effect                 | Num DF | F Value | Pr > F |
| Model                  | 1      | 173.01  | 0.0002 |
| Intercept              | 1      | 0.00    | 0.9961 |
| X                      | 1      | 173.01  | 0.0002 |

NOTE: The denominator degrees of freedom for the F tests is 4.

| Estimated Regression Coefficients |            |                |         |         |
|-----------------------------------|------------|----------------|---------|---------|
| Parameter                         | Estimate   | Standard Error | t Value | Pr >  t |
| Intercept                         | 0.00179469 | 0.34306373     | 0.01    | 0.9961  |
| X                                 | 1.12598708 | 0.08560466     | 13.15   | 0.0002  |

NOTE: The denominator degrees of freedom for the t tests is 4.

Alternatively, if you prefer not to collapse strata with a single sampling unit, you can specify the NOCOLLAPSE option in the STRATA statement:

```

title1 'Stratified Sample with Single Sampling Unit in Strata';
title2 'Without Stratum Collapse';
proc surveyreg data=Sample total=StratumTotals;
 strata Stratum/list nocollapse;
 model Y = X;
 weight W;
run;

```

Output 94.6.4 does not contain the stratum collapse information displayed in Output 94.6.1, and the denominator degrees of freedom are 3 instead of 4.

#### Output 94.6.4 Summary of Data and Regression

| Stratified Sample with Single Sampling Unit in Strata<br>Without Stratum Collapse |           |
|-----------------------------------------------------------------------------------|-----------|
| The SURVEYREG Procedure                                                           |           |
| Regression Analysis for Dependent Variable Y                                      |           |
| Data Summary                                                                      |           |
| Number of Observations                                                            | 8         |
| Sum of Weights                                                                    | 157.00000 |
| Weighted Mean of Y                                                                | 4.31210   |
| Weighted Sum of Y                                                                 | 677.00000 |
| Design Summary                                                                    |           |
| Number of Strata                                                                  | 5         |
| Fit Statistics                                                                    |           |
| R-square                                                                          | 0.9564    |
| Root MSE                                                                          | 0.5111    |
| Denominator DF                                                                    | 3         |

In Output 94.6.5, although the fourth stratum and the fifth stratum contain only one observation, no stratum collapse occurs.

#### Output 94.6.5 Stratification Information

| Stratum Information |         |       |                  |               |  |
|---------------------|---------|-------|------------------|---------------|--|
| Stratum Index       | Stratum | N Obs | Population Total | Sampling Rate |  |
| 1                   | 10      | 2     | 10               | 20.0%         |  |
| 2                   | 11      | 2     | 20               | 10.0%         |  |
| 3                   | 12      | 2     | 32               | 6.25%         |  |
| 4                   | 14      | 1     | 50               | 2.00%         |  |
| 5                   | 33      | 1     | 40               | 2.50%         |  |

As a result of not collapsing strata, the standard error estimates of the parameters, shown in Output 94.6.6, are different from those in Output 94.6.3, as are the tests of the significance of model effects.

**Output 94.6.6** Parameter Estimates and Effect Tests

| Tests of Model Effects |        |         |        |
|------------------------|--------|---------|--------|
| Effect                 | Num DF | F Value | Pr > F |
| Model                  | 1      | 347.27  | 0.0003 |
| Intercept              | 1      | 0.00    | 0.9962 |
| X                      | 1      | 347.27  | 0.0003 |

NOTE: The denominator degrees of freedom for the F tests is 3.

| Estimated Regression Coefficients |            |                |         |         |
|-----------------------------------|------------|----------------|---------|---------|
| Parameter                         | Estimate   | Standard Error | t Value | Pr >  t |
| Intercept                         | 0.00179469 | 0.34302581     | 0.01    | 0.9962  |
| X                                 | 1.12598708 | 0.06042241     | 18.64   | 0.0003  |

NOTE: The denominator degrees of freedom for the t tests is 3.

**Example 94.7: Domain Analysis**

Recall the example in the section “Getting Started: SURVEYREG Procedure” on page 7935, which analyzed a stratified simple random sample from a junior high school to examine how household income and the number of children in a household affect students’ average weekly spending for ice cream. You can use the same sample to analyze the average weekly spending among male and female students. Because student gender is unrelated to the design of the sample, this kind of analysis is called domain analysis (subgroup analysis).

This example shows how you can use PROC SURVEYREG to perform domain analysis. The data set follows:

```
data IceCreamDataDomain;
 input Grade Spending Income Gender$ @@;
 datalines;
7 7 39 M 7 7 38 F 8 12 47 F
9 10 47 M 7 1 34 M 7 10 43 M
7 3 44 M 8 20 60 F 8 19 57 M
7 2 35 M 7 2 36 F 9 15 51 F
8 16 53 F 7 6 37 F 7 6 41 M
7 6 39 M 9 15 50 M 8 17 57 F
8 14 46 M 9 8 41 M 9 8 41 F
9 7 47 F 7 3 39 F 7 12 50 M
7 4 43 M 9 14 46 F 8 18 58 M
9 9 44 F 7 2 37 F 7 1 37 M
7 4 44 M 7 11 42 M 9 8 41 M
8 10 42 M 8 13 46 F 7 2 40 F
9 6 45 F 9 11 45 M 7 2 36 F
7 9 46 F
;
```

```

data IceCreamDataDomain;
 set IceCreamDataDomain;
 if Grade=7 then Prob=20/1824;
 if Grade=8 then Prob=9/1025;
 if Grade=9 then Prob=11/1151;
 Weight=1/Prob;
run;

```

In the data set `IceCreamDataDomain`, the variable `Grade` indicates a student's grade, which is the stratification variable. The variable `Spending` contains the dollar amount of each student's average weekly spending for ice cream. The variable `Income` specifies the household income, in thousands of dollars. The variable `Gender` indicates a student's gender. The sampling weights are created by using the reciprocals of the probabilities of selection, as follows:

```

data StudentTotals;
 input Grade _TOTAL_;
 datalines;
7 1824
8 1025
9 1151
;

```

In the data set `StudentTotals`, the variable `Grade` is the stratification variable, and the variable `_TOTAL_` contains the total numbers of students in the strata in the survey population.

The following statements demonstrate how you can analyze the relationship between spending and income among male and female students:

```

title1 'Ice Cream Spending Analysis';
title2 'Domain Analysis by Gender';
proc surveyreg data=IceCreamDataDomain total=StudentTotals;
 strata Grade;
 model Spending = Income;
 domain Gender;
 weight Weight;
run;

```

Output 94.7.1 gives a summary of the domains.

### Output 94.7.1 Domain Analysis Summary

|                                                  |         |

| Domain Regression Analysis for Variable Spending                |            |                   |         |         |
| Estimated Regression Coefficients                               |            |                   |         |         |
| Parameter                                                       | Estimate   | Standard<br>Error | t Value | Pr >  t |
| Intercept                                                       | -23.751681 | 2.30795437        | -10.29  | <.0001  |
| Income                                                          | 0.735366   | 0.04757001        | 15.46   | <.0001  |
| NOTE: The denominator degrees of freedom for the t tests is 37. |            |                   |         |         |
| Ice Cream Spending Analysis<br>Domain Analysis by Gender        |            |                   |         |         |
| The SURVEYREG Procedure                                         |            |                   |         |         |
| Gender=M                                                        |            |                   |         |         |
| Domain Regression Analysis for Variable Spending                |            |                   |         |         |
| Estimated Regression Coefficients                               |            |                   |         |         |
| Parameter                                                       | Estimate   | Standard<br>Error | t Value | Pr >  t |
| Intercept                                                       | -23.213291 | 2.13361241        | -10.88  | <.0001  |
| Income                                                          | 0.729419   | 0.04589801        | 15.89   | <.0001  |
| NOTE: The denominator degrees of freedom for the t tests is 37. |            |                   |         |         |

For this particular example, the effect Income is significant for both models built within subgroups of male and female students, and the models are quite similar. In many other cases, regression models vary from subgroup to subgroup.

## Example 94.8: Compare Domain Statistics

This example is a continuation of [Example 94.7](#) in which domain analyses for male and female students were performed. Suppose that you are now interested in estimating the gender domain means of weekly ice cream spending (that is, the average spending for males and females, respectively). You can use the SURVEYMEANS procedure to produce these domain statistics by using the following statements:

```
proc surveymeans data=IceCreamDataDomain total=StudentTotals;
 strata Grade;
 var spending;
 domain Gender;
 weight Weight;
run;
```

Output 94.8.1 shows the estimated spending among male and female students.

**Output 94.8.1** Estimated Domain Means

| The SURVEYMEANS Procedure |          |    |          |                      |
|---------------------------|----------|----|----------|----------------------|
| Domain Analysis: Gender   |          |    |          |                      |
| Gender                    | Variable | N  | Mean     | Std Error<br>of Mean |
| F                         | Spending | 19 | 9.376111 | 1.077927             |
| M                         | Spending | 21 | 8.923052 | 1.003423             |

| Domain Analysis: Gender |          |                 |            |  |
|-------------------------|----------|-----------------|------------|--|
| Gender                  | Variable | 95% CL for Mean |            |  |
| F                       | Spending | 7.19202418      | 11.5601988 |  |
| M                       | Spending | 6.88992385      | 10.9561807 |  |

You can also use PROC SURVEYREG to estimate these domain means. The benefit of this alternative approach is that PROC SURVEYREG provides more tools for additional analysis, such as domain means comparisons in a LSMEANS statement.

Suppose that you want to test whether there is a significant difference for the ice cream spending between male and female students. You can use the following statements to perform the test:

```

title1 'Ice Cream Spending Analysis';
title2 'Compare Domain Statistics';
proc surveyreg data=IceCreamDataDomain total=StudentTotals;
 strata Grade;
 class Gender;
 model Spending = Gender / vadjust=none;
 lsmeans Gender / diff;
 weight Weight;
run;

```

The variable Gender is used as a model effect. The `VADJUST=NONE` option is used to produce variance estimates for domain means that are identical to those produced by PROC SURVEYMEANS. The `LSMEANS` statement requests that PROC SURVEYREG estimate the average spending in each gender group. The `DIFF` option requests that the procedure compute the difference among domain means.

Output 94.8.2 displays the estimated weekly spending on ice cream among male and female students, respectively, and their standard errors. Female students spend \$9.38 per week on average, and male students spend \$8.92 per week on average. These domain means, including their standard errors, are identical to those in Output 94.8.1 which are produced by PROC SURVEYMEANS.

**Output 94.8.2** Domain Means between Gender

| Ice Cream Spending Analysis                         |          |                |    |         |         |
|-----------------------------------------------------|----------|----------------|----|---------|---------|
| Compare Domain Statistics                           |          |                |    |         |         |
| The SURVEYREG Procedure                             |          |                |    |         |         |
| Regression Analysis for Dependent Variable Spending |          |                |    |         |         |
| Gender Least Squares Means                          |          |                |    |         |         |
| Gender                                              | Estimate | Standard Error | DF | t Value | Pr >  t |
| F                                                   | 9.3761   | 1.0779         | 37 | 8.70    | <.0001  |
| M                                                   | 8.9231   | 1.0034         | 37 | 8.89    | <.0001  |

Output 94.8.3 shows the estimated difference for weekly ice cream spending between the two gender groups. The female students spend \$0.45 more than male students on average, and the difference is not statistically significant based on the  $t$  test.

**Output 94.8.3** Domain Means Comparison

| Differences of Gender Least Squares Means |         |          |                |    |         |         |
|-------------------------------------------|---------|----------|----------------|----|---------|---------|
| Gender                                    | _Gender | Estimate | Standard Error | DF | t Value | Pr >  t |
| F                                         | M       | 0.4531   | 1.7828         | 37 | 0.25    | 0.8008  |

If you want to investigate whether there is any significant difference in ice cream spending among grades, you can use the following similar statements to compare:

```

title1 'Ice Cream Spending Analysis';
title2 'Compare Domain Statistics';
ods graphics on;
proc surveyreg data=IceCreamDataDomain total=StudentTotals;
 strata Grade;
 class Grade;
 model Spending = Grade / vadjust=none;
 lsmeans Grade / diff plots=(diff meanplot(cl));
 weight Weight;
run;
ods graphics off;

```

The Grade is specified in the CLASS statement to be used as an effect in the MODEL statement. The DIFF option in the LSMEANS statement requests that the procedure compute the difference among the domain means for the effect Grade. The ODS GRAPHICS statement enables ODS to create graphics. The PLOTS=(DIFF MEANPLOT(CL)) option requests two graphics: the domain means plot “MeanPlot” and their pairwise difference plot “DiffPlot”. The CL suboption requests the “MeanPlot” to display confidence. For information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.”

Output 94.8.4 shows the estimated weekly spending on ice cream for students within each grade. Students in Grade 7 spend the least, only \$5.00 per week. Students in Grade 8 spend the most, \$15.44 per week. Students in Grade 9 spend a little less at \$10.09 per week.

**Output 94.8.4** Domain Means among Grades

Output 94.8.7 plots the comparisons that are shown in Output 94.8.6.

**Output 94.8.7** Plot of Pairwise Comparisons of Spending among Grades

In Output 94.8.7, the spending for each grade is shown in the background grid on both axes. Comparisons for each pair of domain means are shown by colored bars at intersections of these grids. The length of each bar represents the width of the confidence intervals for the corresponding difference between domain means. The significance of these pairwise comparisons are indicated in the plot by whether these bars cross the 45-degree background dash-line across the plot. Since none of the three bars cross the dash-line, all pairwise comparisons are significant, as shown in Output 94.8.6.

## Example 94.9: Variance Estimate Using the Jackknife Method

This example uses the stratified sample from the section “Getting Started: SURVEYREG Procedure” on page 7935 to illustrate how to estimate the variances with replication methods.

As shown in the section “Stratified Sampling” on page 7938, the sample is saved in the SAS data set IceCream. The variable Grade that indicates a student’s grade is the stratification variable. The variable Spending contains the dollar amount of each student’s average weekly spending for ice cream. The variable

Income specifies the household income, in thousands of dollars. The variable Kids indicates how many children are in a student's family. The variable Weight contains sampling weights.

In this example, we use the jackknife method to estimate the variance, saving the replicate weights generated by the procedure into a SAS data set:

```

title1 'Ice Cream Spending Analysis';
title2 'Use the Jackknife Method to Estimate the Variance';
proc surveyreg data=IceCream
 varmethod=JACKKNIFE(outweights=JKWeights);
 strata Grade;
 class Kids;
 model Spending = Income Kids / solution;
 weight Weight;
run;

```

The `VARMETHOD=JACKKNIFE` option requests the procedure to estimate the variance by using the jackknife method. The `OUTWEIGHTS=JKWeights` option provides a SAS data set named JKWeights that contains the replicate weights used in the computation.

Output 94.9.1 shows the summary of the data and the variance estimation method. There are a total of 40 replicates generated by the procedure.

#### Output 94.9.1 Variance Estimation Using the Jackknife Method

|                                                     |           |

| Kids 2                            | 1.545726   | 1.25598146     | 1.23    | 0.2262  |
| Kids 3                            | -0.526817  | 1.42555453     | -0.37   | 0.7138  |
| Kids 4                            | 0.000000   | 0.00000000     | .       | .       |

NOTE: The denominator degrees of freedom for the t tests is 37.  
 Matrix X'WX is singular and a generalized inverse was used to solve the normal equations. Estimates are not unique.

Output 94.9.3 prints the first 6 observation in the output data set JKWeights, which contains the replicate weights.

The data set JKWeights contains all the variable in the data set IceCream, in addition to the replicate weights variables named RepWt\_1, RepWt\_2, ..., RepWt\_40.

For example, the first observation (student) from stratum Grade=7 is deleted to create the first replicate. Therefore, stratum Grade=7 is the donor stratum for the first replicate, and the corresponding replicate weights are saved in the variable RepWt\_1.

Because the first observation is deleted in the first replicate, RepWt\_1=0 for the first observation. For observations from strata other than the donor stratum Grade=7, their replicate weights remain the same as in the variable Weight, while the rest of the observations in stratum Grade=7 are multiplied by the reciprocal of the corresponding jackknife coefficient, 0.95 for the first replicate.

**Output 94.9.3** The Jackknife Replicate Weights for the First 6 Observations

| The Jackknife Weights for the First 6 Obs |          |          |          |          |          |          |          |          |          |         |

## Overview: SURVEYSELECT Procedure

The SURVEYSELECT procedure provides a variety of methods for selecting probability-based random samples. The procedure can select a simple random sample or can sample according to a complex multistage sample design that includes stratification, clustering, and unequal probabilities of selection. With probability sampling, each unit in the survey population has a known, positive probability of selection. This property of probability sampling avoids selection bias and enables you to use statistical theory to make valid inferences from the sample to the survey population.

To select a sample with PROC SURVEYSELECT, you input a SAS data set that contains the sampling frame, which is the list of units from which the sample is to be selected. The sampling units can be individual observations or groups of observations (clusters). You also specify the selection method, the desired sample size or sampling rate, and other selection parameters. PROC SURVEYSELECT selects the sample and produces an output data set that contains the selected units, their selection probabilities, and their sampling weights. When you select a sample in multiple stages, you invoke the procedure separately for each stage of selection, inputting the frame and selection parameters for each current stage.

PROC SURVEYSELECT provides methods for both equal probability sampling and probability proportional to size (PPS) sampling. In equal probability sampling, each unit in the sampling frame, or in a stratum, has the same probability of being selected for the sample. In PPS sampling, a unit's selection probability is proportional to its size measure. For details about probability sampling methods, see Lohr (2010); Kish (1965, 1987); Kalton (1983); Cochran (1977).

PROC SURVEYSELECT provides the following equal probability sampling methods:

- simple random sampling (without replacement)
- unrestricted random sampling (with replacement)
- systematic random sampling
- sequential random sampling
- Bernoulli sampling

This procedure also provides Poisson sampling and the following probability proportional to size (PPS) sampling methods:

- PPS sampling without replacement
- PPS sampling with replacement
- PPS systematic sampling
- PPS algorithms for selecting two units per stratum
- sequential PPS sampling with minimum replacement

The procedure uses fast, efficient algorithms for these sample selection methods. Thus, it performs well even for large input data sets or sampling frames.

PROC SURVEYSELECT can perform stratified sampling by selecting samples independently within strata, which are nonoverlapping subgroups of the survey population. Stratification controls the distribution of the sample size in the strata. It is widely used in practice toward meeting a variety of survey objectives. For example, with stratification you can ensure adequate sample sizes for subgroups of interest, including small subgroups, or you can use stratification toward improving the precision of the overall estimates. When you use a systematic or sequential selection method, PROC SURVEYSELECT can also sort by control variables within strata for the additional control of implicit stratification.

For stratified sampling, PROC SURVEYSELECT provides survey design methods to allocate the total sample size among the strata. Available allocation methods include proportional, Neyman, and optimal allocation. Optimal allocation maximizes the estimation precision within the available resources, taking into account stratum sizes, costs, and variances.

PROC SURVEYSELECT provides replicated sampling, where the total sample is composed of a set of replicates, and each replicate is selected in the same way. You can use replicated sampling to study variable nonsampling errors, such as variability in the results obtained by different interviewers. You can also use replication to estimate standard errors for combined sample estimates and to perform a variety of other resampling and simulation tasks.

---

## Getting Started: SURVEYSELECT Procedure

In this example, an Internet service provider conducts a customer satisfaction survey. The survey population consists of the company's current subscribers. The company plans to select a sample of customers from this population, interview the selected customers, and then make inferences about the entire survey population from the sample data.

The SAS data set `Customers` contains the sampling frame, which is the list of units in the survey population. The sample of customers will be selected from this sampling frame. The data set `Customers` is constructed from the company's customer database. It contains one observation for each customer, with a total of 13,471 observations.

The following PROC PRINT statements display the first 10 observations of the data set Customers and produce Figure 95.1:

```
title1 'Customer Satisfaction Survey';
title2 'First 10 Observations';
proc print data=Customers(obs=10);
run;
```

**Figure 95.1** Customers Data Set (First 10 Observations)

| Customer Satisfaction Survey |             |       |      |       |  |
|------------------------------|-------------|-------|------|-------|--|
| First 10 Observations        |             |       |      |       |  |
| Obs                          | CustomerID  | State | Type | Usage |  |
| 1                            | 416-87-4322 | AL    | New  | 839   |  |
| 2                            | 288-13-9763 | GA    | Old  | 224   |  |
| 3                            | 339-00-8654 | GA    | Old  | 2451  |  |
| 4                            | 118-98-0542 | GA    | New  | 349   |  |
| 5                            | 421-67-0342 | FL    | New  | 562   |  |
| 6                            | 623-18-9201 | SC    | New  | 68    |  |
| 7                            | 324-55-0324 | FL    | Old  | 137   |  |
| 8                            | 832-90-2397 | AL    | Old  | 1563  |  |
| 9                            | 586-45-0178 | GA    | New  | 615   |  |
| 10                           | 801-24-5317 | SC    | New  | 728   |  |

In the SAS data set Customers, the variable CustomerID uniquely identifies each customer. The variable State contains the state of the customer's address. The company has customers in four states: Georgia (GA), Alabama (AL), Florida (FL), and South Carolina (SC). The variable Type equals 'Old' if the customer has subscribed to the service for more than one year; otherwise, the variable Type equals 'New'. The variable Usage contains the customer's average monthly service usage, in minutes.

The following sections illustrate the use of PROC SURVEYSELECT for probability sampling with three different designs for the customer satisfaction survey. All three designs are one-stage, with customers as the sampling units. The first design is simple random sampling without stratification. In the second design, customers are stratified by state and type, and the sample is selected by simple random sampling within strata. In the third design, customers are sorted within strata by usage, and the sample is selected by systematic random sampling within strata.

---

## Simple Random Sampling

The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set by using simple random sampling:

```
title1 'Customer Satisfaction Survey';
title2 'Simple Random Sampling';
proc surveyselect data=Customers method=srs n=100
 out=SampleSRS;
run;
```

The PROC SURVEYSELECT statement invokes the procedure. The DATA= option names the SAS data set Customers as the input data set from which to select the sample. The METHOD=SRS option specifies simple random sampling as the sample selection method. In simple random sampling, each unit has an equal probability of selection, and sampling is without replacement. Without-replacement sampling means that a unit cannot be selected more than once. The N= option specifies a sample size of 100 customers. The OUT= option stores the sample in the SAS data set named SampleSRS.

Figure 95.2 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A sample of 100 customers is selected from the data set Customers by simple random sampling. With simple random sampling and no stratification in the sample design, the selection probability is the same for all units in the sample. In this sample, the selection probability for each customer equals 0.007423, which is the sample size (100) divided by the population size (13,471). The sampling weight equals 134.71 for each customer in the sample, where the weight is the inverse of the selection probability. If you specify the STATS option, PROC SURVEYSELECT includes the selection probabilities and sampling weights in the output data set. (This information is always included in the output data set for more complex designs.)

The random number seed is 39647. PROC SURVEYSELECT uses this number as the initial seed for random number generation. Because the SEED= option is not specified in the PROC SURVEYSELECT statement, the seed value is obtained by using the time of day from the computer's clock. You can specify SEED=39647 to reproduce this sample.

**Figure 95.2** Sample Selection Summary

| Customer Satisfaction Survey<br>Simple Random Sampling |                        |
|--------------------------------------------------------|------------------------|
| The SURVEYSELECT Procedure                             |                        |
| Selection Method                                       | Simple Random Sampling |
| Input Data Set                                         | CUSTOMERS              |
| Random Number Seed                                     | 39647                  |
| Sample Size                                            | 100                    |
| Selection Probability                                  | 0.007423               |
| Sampling Weight                                        | 134.71                 |
| Output Data Set                                        | SAMPLESRS              |

The sample of 100 customers is stored in the SAS data set SampleSRS. PROC SURVEYSELECT does not display this output data set. The following PROC PRINT statements display the first 20 observations of SampleSRS:

```

title1 'Customer Satisfaction Survey';
title2 'Sample of 100 Customers, Selected by SRS';
title3 '(First 20 Observations)';
proc print data=SampleSRS(obs=20);
run;

```

Figure 95.3 displays the first 20 observations of the output data set SampleSRS, which contains the sample of customers. This data set includes all the variables from the DATA= input data set Customers. If you do not want to include all variables, you can use the ID statement to specify which variables to copy from the input data set to the output (sample) data set.

**Figure 95.3** Customer Sample (First 20 Observations)

## Stratified Sampling

In this section, stratification is added to the sample design for the customer satisfaction survey. The sampling frame, which is the list of all customers, is stratified by State and Type. This divides the sampling frame into nonoverlapping subgroups formed from the values of the State and Type variables. Samples are then selected independently within the strata.

PROC SURVEYSELECT requires that the input data set be sorted by the STRATA variables. The following PROC SORT statements sort the Customers data set by the stratification variables State and Type:

```
proc sort data=Customers;
 by State Type;
run;
```

The following PROC FREQ statements display the crosstabulation of the Customers data set by State and Type:

```
title1 'Customer Satisfaction Survey';
title2 'Strata of Customers';
proc freq data=Customers;
 tables State*Type;
run;
```

Figure 95.4 presents the table of State by Type for the 13,471 customers. There are four states and two levels of Type, forming a total of eight strata.

**Figure 95.4** Stratification of Customers by State and Type

|                                | 65.81 | 34.19 |        |
|                                | 19.63 | 17.89 |        |
| -----+-----+-----+-----+-----+ |       |       |        |
| Total                          | 8580  | 4891  | 13471  |
|                                | 63.69 | 36.31 | 100.00 |

The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set according to the stratified sample design:

```

title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling';
proc surveyselect data=Customers method=srs n=15
 seed=1953 out=SampleStrata;
 strata State Type;
run;

```

The STRATA statement names the stratification variables State and Type. In the PROC SURVEYSELECT statement, the METHOD=SRS option specifies simple random sampling. The N= option specifies a sample size of 15 customers for each stratum. If you want to specify different sample sizes for different strata, you can use the N=SAS-*data-set* option to name a secondary data set that contains the stratum sample sizes. The SEED= option specifies 1953 as the initial seed for random number generation.

Figure 95.5 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A total of 120 customers are selected.

| Strata Variables                                    | State<br>Type          |
| Input Data Set                                      | CUSTOMERS              |
| Random Number Seed                                  | 1953                   |
| Stratum Sample Size                                 | 15                     |
| Number of Strata                                    | 8                      |
| Total Sample Size                                   | 120                    |
| Output Data Set                                     | SAMPLESTRATA           |

The following PROC PRINT statements display the first 30 observations of the output data set SampleStrata:

```

title1 'Customer Satisfaction Survey';
title2 'Sample Selected by Stratified Design';
title3 '(First 30 Observations)';
proc print data=SampleStrata(obs=30);
run;

```

Figure 95.6 displays the first 30 observations of the output data set SampleStrata, which contains the sample of 120 customers, 15 customers from each of the eight strata. The variable SelectionProb contains the selection probability for each customer in the sample. Because customers are selected with equal probability within strata in this design, the selection probability equals the stratum sample size (15) divided by the stratum population size. The selection probabilities differ from stratum to stratum because the stratum population sizes differ. The selection probability for each customer in the first stratum (State='AL' and Type='New') is 0.012116, and the selection probability for customers in the second stratum is 0.021246. The variable SamplingWeight contains the sampling weights, which are computed as inverse selection probabilities.

## Stratified Sampling with Control Sorting

The next sample design for the customer satisfaction survey uses stratification by State and also control sorting by Type and Usage within State. After stratification and control sorting, customers are selected by systematic random sampling within strata. Selection by systematic sampling, together with control sorting before selection, spreads the sample uniformly over the range of type and usage values within each stratum (state). The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set according to this design:

```

title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling with Control Sorting';
proc surveyselect data=Customers method=sys rate=.02
 seed=1234 out=SampleControl;
 strata State;
 control Type Usage;
run;

```

The STRATA statement names the stratification variable State. The CONTROL statement names the control variables Type and Usage. In the PROC SURVEYSELECT statement, the METHOD=SYS option requests systematic random sampling. The RATE= option specifies a sampling rate of 2% for each stratum. The SEED= option specifies the initial seed for random number generation.

Figure 95.7 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A sample of 271 customers is selected by using systematic random sampling within strata determined by State. The sampling frame Customers is sorted by control variables Type and Usage within strata. The type of sorting is serpentine, which is the default when SORT=NEST is not specified. See the section “Sorting by CONTROL Variables” on page 8057 for a description of serpentine sorting. The sorted data set replaces the input data set. (To leave the input data set unsorted and store the sorted input data in another data set, use the OUTSORT= option.) The output data set SampleControl contains the sample of customers.

## Syntax: SURVEYSELECT Procedure

The following statements are available in the SURVEYSELECT procedure:

```
PROC SURVEYSELECT options ;
 CONTROL variables ;
 FREQ variable ;
 ID variables ;
 SAMPLINGUNIT | CLUSTER variables </ options > ;
 SIZE variable ;
 STRATA variables </ options > ;
```

The **PROC SURVEYSELECT** statement invokes the SURVEYSELECT procedure. Optionally, it identifies input and output data sets. It also specifies the selection method, the sample size, and other sample design parameters. The **PROC SURVEYSELECT** statement is required.

The **SIZE** statement identifies the variable that contains the size measures of the sampling units. This statement is required for any probability proportional to size (PPS) selection method unless you specify the **PPS** option in the **SAMPLINGUNIT** statement.

The remaining statements are optional. The **STRATA** statement identifies a variable or set of variables that stratify the input data set. When you specify a **STRATA** statement, **PROC SURVEYSELECT** selects samples independently from the strata that are formed by the **STRATA** variables. The **STRATA** statement also provides options to allocate the total sample size among the strata.

The **SAMPLINGUNIT** statement identifies a variable or set of variables that group the input data set observations into sampling units (clusters). Sampling units are nested within strata. When you specify a **SAMPLINGUNIT** statement, **PROC SURVEYSELECT** selects clusters instead of individual observations.

The **CONTROL** statement identifies variables for ordering units within strata. It can be used for systematic and sequential sampling methods. The **ID** statement identifies variables to copy from the input data set to the output data set of selected units.

The **FREQ** statement identifies a variable that contains the frequency of occurrence for each observation. The **FREQ** statement is available only for sample allocation when no sample is selected, which you can request by specifying the **ALLOC=** and **NOSAMPLE** options in the **STRATA** statement.

The rest of this section gives detailed syntax information for the **CONTROL**, **FREQ**, **ID**, **SAMPLINGUNIT**, **SIZE**, and **STRATA** statements in alphabetical order after the description of the **PROC SURVEYSELECT** statement.

---

## PROC SURVEYSELECT Statement

```
PROC SURVEYSELECT options ;
```

The **PROC SURVEYSELECT** statement invokes the SURVEYSELECT procedure. Optionally, it identifies input and output data sets. If you do not name a **DATA=** input data set, the procedure selects the sample from the most recently created SAS data set. If you do not name an **OUT=** output data set to contain the sample of selected units, the procedure still creates an output data set and names it according to the **DATA<sub>n</sub>** convention.

The PROC SURVEYSELECT statement also specifies the sample selection method, the sample size, and other sample design parameters.

If you do not specify a selection method, PROC SURVEYSELECT uses simple random sampling (**METHOD=SRS**) by default unless you specify a **SIZE** statement or the **PPS** option in the **SAMPLINGUNIT** statement. If you do specify a **SIZE** statement (or the **PPS** option), PROC SURVEYSELECT uses probability proportional to size selection without replacement (**METHOD=PPS**) by default. See the description of the **METHOD=** option for more information.

You must specify the sample size or sampling rate except when you request Poisson sampling (**METHOD=POISSON**), request a method that selects two units from each stratum (**METHOD=PPS\_BREWER** or **METHOD=PPS\_MURTHY**), or specify the **MARGIN=** option in the **STRATA** statement for sample allocation. You can use the **SAMPSIZE=*n*** option to specify the sample size, or you can use the **SAMPSIZE=SAS-data-set** option to name a secondary input data set that contains stratum sample sizes.

You can also provide stratum sampling rates, minimum size measures, maximum size measures, and certainty size measures in the secondary input data set. See the descriptions of the **SAMPSIZE=**, **SAMPRATE=**, **MINSIZE=**, **MAXSIZE=**, **CERTSIZE=**, and **CERTSIZE=P=** options for more information. You can name only one secondary input data set in each invocation of the procedure. See the section “Secondary Input Data Set” on page 8071 for details.

Table 95.1 summarizes the *options* available in the PROC SURVEYSELECT statement. Descriptions of the *options* follow in alphabetical order.

**Table 95.1** PROC SURVEYSELECT Statement Options

| Option                            | Description                                                        |
|-----------------------------------|--------------------------------------------------------------------|
| <b>Input and Output Data Sets</b> |                                                                    |
| <b>DATA=</b>                      | Names the input SAS data set                                       |
| <b>OUT=</b>                       | Names the output SAS data set that contains the sample             |
| <b>OUTSORT=</b>                   | Names an output SAS data set that stores the sorted input data set |
| <b>Selection Method</b>           |                                                                    |
| <b>METHOD=</b>                    | Specifies the sample selection method                              |
| <b>Sample Size</b>                |                                                                    |
| <b>SAMPSIZE=</b>                  | Specifies the sample size                                          |
| <b>SELECTALL</b>                  | Selects all stratum units when the sample size exceeds the total   |
| <b>Sampling Rate</b>              |                                                                    |
| <b>SAMPRATE=</b>                  | Specifies the sampling rate                                        |
| <b>NMIN=</b>                      | Specifies the minimum stratum sample size                          |
| <b>NMAX=</b>                      | Specifies the maximum stratum sample size                          |
| <b>Replicated Sampling</b>        |                                                                    |
| <b>REPS=</b>                      | Specifies the number of sample replicates                          |
| <b>Size Measures</b>              |                                                                    |
| <b>MINSIZE=</b>                   | Specifies the minimum size measure                                 |
| <b>MAXSIZE=</b>                   | Specifies the maximum size measure                                 |
| <b>CERTSIZE=</b>                  | Specifies the certainty size measure                               |
| <b>CERTSIZE=P=</b>                | Specifies the certainty proportion                                 |

Table 95.1 *continued*

| Option                          | Description                                               |
|---------------------------------|-----------------------------------------------------------|
| <b>Control Sorting</b>          |                                                           |
| <b>SORT=</b>                    | Specifies the type of sorting                             |
| <b>Random Number Generation</b> |                                                           |
| <b>SEED=</b>                    | Specifies the initial seed                                |
| <b>RANUNI</b>                   | Requests the RANUNI random number generator               |
| <b>Displayed Output</b>         |                                                           |
| <b>NOPRINT</b>                  | Suppresses the display of all output                      |
| <b>OUT= Data Set Contents</b>   |                                                           |
| <b>JTPROBS</b>                  | Includes joint probabilities of selection                 |
| <b>OUTALL</b>                   | Includes all observations from the DATA= input data set   |
| <b>OUTHITS</b>                  | Includes a distinct copy of each selected unit            |
| <b>OUTSEED</b>                  | Includes the initial seed for each stratum                |
| <b>OUTSIZE</b>                  | Includes additional design and sampling frame information |
| <b>STATS</b>                    | Includes selection probabilities and sampling weights     |

You can specify the following *options* in the PROC SURVEYSELECT statement:

### **CERTSIZE**

requests certainty selection, where the certainty size values are provided in the secondary input data set. Use the CERTSIZE option when you have already named the secondary data set in another option, such as the **SAMPSIZE=SAS-data-set** option. See the section “Secondary Input Data Set” on page 8071 for details.

The CERTSIZE option is available for **METHOD=PPS** and **METHOD=PPS\_SAMPFORD**. The CERTSIZE option is not available with the **SAMPLINGUNIT** statement.

In certainty selection, PROC SURVEYSELECT automatically selects all sampling units that have size measures greater than or equal to the stratum certainty size values. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method that is specified in the **METHOD=** option.

You provide the stratum certainty size values in the secondary input data set variable **\_CERTSIZE\_**. Each certainty size value must be a positive number. The variable **Certain** in the **OUT=** data set identifies the certainty selections, which have selection probabilities equal to 1.

If you want to specify a single certainty size value for all strata, you can use the **CERTSIZE=certain** option.

### **CERTSIZE=certain**

specifies the certainty size value, which must be a positive number. PROC SURVEYSELECT automatically selects all sampling units that have size measures greater than or equal to the value *certain*. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method that is specified in the **METHOD=** option.

The **CERTSIZE=** option is available for **METHOD=PPS** and **METHOD=PPS\_SAMPFORD**. The **CERTSIZE=** option is not available with the **SAMPLINGUNIT** statement.

The variable **Certain** in the **OUT=** data set identifies the certainty selections, which have selection probabilities equal to 1.

If you request a stratified sample design with the **STRATA** statement and specify the **CERTSIZE=certain** option, PROC SURVEYSELECT uses the value *certain* for all strata. If you do not want to use the same certainty size for all strata, use the **CERTSIZE=SAS-data-set** option to specify a certainty size value for each stratum.

#### **CERTSIZE=SAS-data-set**

names a SAS data set that contains certainty size values for the strata. PROC SURVEYSELECT automatically selects all sampling units that have size measures greater than or equal to the stratum certainty size values. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method that is specified in the **METHOD=** option.

The **CERTSIZE=** option is available for **METHOD=PPS** and **METHOD=PPS\_SAMPFORD**. The **CERTSIZE=** option is not available with the **SAMPLINGUNIT** statement.

You provide the stratum certainty size values in the **CERTSIZE=** data set variable **\_CERTSIZE\_**. Each certainty size value must be a positive number. The variable **Certain** in the **OUT=** data set identifies the certainty selections, which have selection probabilities equal to 1.

The **CERTSIZE=** input data set should contain all the **STRATA** variables, with the same type and length as in the **DATA=** data set. The **STRATA** groups should appear in the same order in the **CERTSIZE=** data set as in the **DATA=** data set. The **CERTSIZE=** data set must include a variable named **\_CERTSIZE\_** that contains the certainty size value for each stratum. The **CERTSIZE=** data set is a secondary input data set. See the section “**Secondary Input Data Set**” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

If you want to specify a single certainty size value for all strata, you can use the **CERTSIZE=certain** option.

#### **CERTSIZE=P**

requests certainty proportion selection, where the stratum certainty proportions are provided in the secondary input data set. Use the **CERTSIZE=P** option when you have already named the secondary data set in another option, such as the **SAMPSIZE=SAS-data-set** option. See the section “**Secondary Input Data Set**” on page 8071 for details.

The **CERTSIZE=P** option is available for **METHOD=PPS** and **METHOD=PPS\_SAMPFORD**. The **CERTSIZE=P** option is not available with the **SAMPLINGUNIT** statement.

In certainty proportion selection, PROC SURVEYSELECT automatically selects all sampling units that have size measures greater than or equal to the stratum certainty proportion of the total stratum size. The procedure repeats this process with the remaining units until no more certainty units are selected. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method that is specified in the **METHOD=** option.

You provide the stratum certainty proportions in the secondary input data set variable **\_CERTP\_**. Each certainty proportion must be a positive number. You can specify a proportion value as a number between 0 and 1. Or you can specify a proportion value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

The variable **Certain** in the **OUT=** data set identifies the certainty selections, which have selection probabilities equal to 1.

If you want to specify a single certainty proportion for all strata, you can use the **CERTSIZE=P=p** option.

**CERTSIZE=P= $\rho$** 

specifies the certainty proportion. PROC SURVEYSELECT automatically selects all sampling units that have size measures greater than or equal to the proportion  $\rho$  of the total stratum size. The procedure repeats this process with the remaining units until no more certainty units are selected. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method that is specified in the **METHOD=** option.

The CERTSIZE=P= option is available for **METHOD=PPS** and **METHOD=PPS\_SAMPFORD**. The CERTSIZE=P= option is not available with the **SAMPLINGUNIT** statement.

The value of the certainty proportion  $\rho$  must be a positive number. You can specify  $\rho$  as a number between 0 and 1. Or you can specify  $\rho$  in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

The variable **Certain** in the **OUT=** data set identifies the certainty selections, which have selection probabilities equal to 1.

If you request a stratified sample design with the **STRATA** statement and specify the CERTSIZE=P= $\rho$  option, PROC SURVEYSELECT uses the certainty proportion  $\rho$  for all strata. If you do not want to use the same certainty proportion for all strata, use the **CERTSIZE=P=SAS-data-set** option to specify a certainty proportion for each stratum.

**CERTSIZE=P=SAS-data-set**

names a SAS data set that contains certainty proportions for the strata. PROC SURVEYSELECT automatically selects all sampling units with size measures greater than or equal to the certainty proportion of the total stratum size. The procedure repeats this process with the remaining units until no more certainty units are selected. After identifying the certainty units, PROC SURVEYSELECT selects the remainder of the sample according to the method that is specified in the **METHOD=** option.

The CERTSIZE=P= option is available for **METHOD=PPS** and **METHOD=PPS\_SAMPFORD**. The CERTSIZE=P= option is not available with the **SAMPLINGUNIT** statement.

You provide the stratum certainty proportions in the CERTSIZE=P= data set variable **\_CERTP\_**. Each certainty proportion must be a positive number. You can specify a proportion value as a number between 0 and 1. Or you can specify a proportion value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

The variable **Certain** in the **OUT=** data set identifies the certainty selections, which have selection probabilities equal to 1.

The CERTSIZE=P= input data set should contain all the **STRATA** variables, with the same type and length as in the **DATA=** data set. The **STRATA** groups should appear in the same order in the CERTSIZE=P= data set as in the **DATA=** data set. The CERTSIZE=P= data set must include a variable named **\_CERTP\_** that contains the certainty proportion for each stratum. The CERTSIZE=P= data set is a secondary input data set. See the section “**Secondary Input Data Set**” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

If you want to specify a single certainty proportion for all strata, you can use the **CERTSIZE=P= $\rho$**  option.

**DATA=SAS-data-set**

names the SAS data set from which PROC SURVEYSELECT selects the sample. If you omit the DATA= option, the procedure uses the most recently created SAS data set. In sampling terminology, the input data set is the *sampling frame* (the list of units from which the sample is selected).

By default, the procedure uses input data set observations as sampling units and selects a sample of these units. Alternatively, you can use the **SAMPLINGUNIT** statement to define sampling units as groups of observations (clusters).

**JTPROBS**

includes joint probabilities of selection in the OUT= output data set. This option is available for the following probability proportional to size selection methods: **METHOD=PPS**, **METHOD=PPS\_SAMPFORD**, and **METHOD=PPS\_WR**. By default, PROC SURVEYSELECT outputs joint selection probabilities for **METHOD=PPS\_BREWER** and **METHOD=PPS\_MURTHY**, which select two units per stratum.

For details about computation of joint selection probabilities for a particular sampling method, see the method description in the section “[Sample Selection Methods](#)” on page 8058. For more information about the contents of the output data set, see the section “[Sample Output Data Set](#)” on page 8072.

**MAXSIZE**

requests adjustment of size measures according to the stratum maximum size values provided in the secondary input data set. Use the MAXSIZE option when you have already named the secondary input data set in another option, such as the **SAMPSIZE=SAS-data-set** option. See the section “[Secondary Input Data Set](#)” on page 8071 for details.

The MAXSIZE option is available when you use size measures for any PPS selection method and also include a **STRATA** statement. You provide size measures by specifying the **SIZE** statement or the **PPS** option in the **SAMPLINGUNIT** statement.

You provide the stratum maximum size values in the secondary input data set variable **\_MAXSIZE\_**. Each maximum size value must be a positive number.

When a size measure exceeds the specified maximum value for its stratum, PROC SURVEYSELECT adjusts the size measure downward to equal the maximum size value. If your sampling units are individual observations, the variable **AdjustedSize** in the OUT= data set contains the adjusted size measures.

If you use a **SAMPLINGUNIT** statement to define sampling units (clusters), then the procedure applies the MAXSIZE adjustment to the sampling unit size. The sampling unit size equals the number of observations in the sampling unit if you specify the **PPS** option, or the sum of the observation size measures if you specify a **SIZE** statement. The output data set variable **UnitSize** contains the adjusted sampling unit size measures.

If you want to specify a single maximum size value for all strata, you can use the **MAXSIZE=max** option.

**MAXSIZE=max**

specifies the maximum size value. The value of *max* must be a positive number.

When a size measure exceeds the value *max*, PROC SURVEYSELECT adjusts the size measure downward to equal *max*. If your sampling units are individual observations, the variable **AdjustedSize** in the OUT= data set contains the adjusted size measures.

If you use a **SAMPLINGUNIT** statement to define sampling units (clusters), then the procedure applies the **MAXSIZE** adjustment to the sampling unit size. The sampling unit size equals the number of observations in the sampling unit if you specify the **PPS** option, or the sum of the observation size measures if you specify a **SIZE** statement. The output data set variable **UnitSize** contains the adjusted sampling unit size measures.

The **MAXSIZE=***max* option is available when you use size measures for any PPS selection method. You provide size measures by specifying the **SIZE** statement or the **PPS** option in the **SAMPLINGUNIT** statement.

If you request a stratified sample design with the **STRATA** statement and specify the **MAXSIZE=***max* option, PROC SURVEYSELECT uses the maximum size *max* for all strata. If you do not want to use the same maximum size for all strata, use the **MAXSIZE=***SAS-data-set* option to specify a maximum size value for each stratum.

#### **MAXSIZE=***SAS-data-set*

names a SAS data set that contains maximum size values for the strata. You provide the stratum maximum size values in the **MAXSIZE=** data set variable **\_MAXSIZE\_**. Each maximum size value must be a positive number.

The **MAXSIZE=***SAS-data-set* option is available when you use size measures for any PPS selection method and also include a **STRATA** statement. You provide size measures by specifying the **SIZE** statement or the **PPS** option in the **SAMPLINGUNIT** statement.

When a size measure exceeds the maximum size value for its stratum, PROC SURVEYSELECT adjusts the size measure downward to equal the maximum size value. If your sampling units are individual observations, the variable **AdjustedSize** in the **OUT=** data set contains the adjusted size measures.

If you use a **SAMPLINGUNIT** statement to define sampling units (clusters), then the procedure applies the **MAXSIZE** adjustment to the sampling unit size. The sampling unit size equals the number of observations in the sampling unit if you specify the **PPS** option, or the sum of the observation size measures if you specify a **SIZE** statement. The output data set variable **UnitSize** contains the adjusted sampling unit size measures.

The **MAXSIZE=** input data set should contain all the **STRATA** variables, with the same type and length as in the **DATA=** data set. The **STRATA** groups should appear in the same order in the **MAXSIZE=** data set as in the **DATA=** data set. The **MAXSIZE=** data set must include a variable named **\_MAXSIZE\_** that contains the maximum size value for each stratum. The **MAXSIZE=** data set is a secondary input data set. See the section “**Secondary Input Data Set**” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

If you want to specify a single maximum size value for all strata, you can use the **MAXSIZE=***max* option.

#### **METHOD=***name*

##### **M=***name*

specifies the method for sample selection.

If you do not specify the **METHOD=** option, PROC SURVEYSELECT uses simple random sampling (**METHOD=****SRS**) by default unless you specify a **SIZE** statement or the **PPS** option in the **SAMPLINGUNIT** statement. If you do specify a **SIZE** statement (or the **PPS** option), PROC SURVEYSELECT uses probability proportional to size selection without replacement (**METHOD=****PPS**) by default.

The following values are available for the METHOD= option:

### **BERNOULLI**

requests Bernoulli sampling, which consists of  $N$  independent selection trials, each with constant inclusion probability  $\pi$ , where  $N$  is the total number of sampling units in the stratum or data set. The sample size is not fixed but is a random variable. See the section “[Bernoulli Sampling](#)” on page 8061 for details.

When you specify METHOD=BERNOULLI, you must provide the sampling rate (inclusion probability  $\pi$ ) by using the SAMPRATE= option. For stratified sampling (which you request with the STRATA statement), you can specify the same sampling rate for each stratum with the SAMPRATE= $r$  option. Or you can specify different sampling rates for different strata by using the SAMPRATE=(*values*) or SAMPRATE=SAS-data-set option.

Because Bernoulli sampling is based on a specified inclusion probability instead of a fixed sample size, METHOD=BERNOULLI does not use the SAMPSIZE= option. Also, the ALLOC= option in the STRATA statement (which allocates the total sample size among strata) is not available with METHOD=BERNOULLI.

### **POISSON**

requests Poisson sampling. A generalization of Bernoulli sampling, Poisson sampling consists of  $N$  independent selection trials with a separate inclusion probability specified for each unit, where  $N$  is the total number of sampling units in the stratum or data set. The sample size is not fixed but is a random variable. See the section “[Poisson Sampling](#)” on page 8062 for details.

You must provide inclusion probabilities for Poisson sampling in the SIZE variable. The probability values should be between 0 and 1. If a value of the SIZE variable is missing, nonpositive, or greater than 1, PROC SURVEYSELECT omits the observation from sample selection.

Because Poisson sampling is based on specified inclusion probabilities instead of a fixed sample size, METHOD=POISSON does not use the SAMPSIZE= option. Also, the ALLOC= option in the STRATA statement (which allocates the total sample size among strata) is not available with METHOD=POISSON.

The SAMPLINGUNIT statement is not available with METHOD=POISSON.

When METHOD=POISSON is specified with the SAMPRATE= option and without a SIZE statement, PROC SURVEYSELECT uses METHOD=BERNOULLI.

### **PPS**

requests selection with probability proportional to size and without replacement. See the section “[PPS Sampling without Replacement](#)” on page 8062 for details. If you specify METHOD=PPS, you must name a size measure variable in the SIZE statement or specify the PPS option in the SAMPLINGUNIT statement.

### **PPS\_BREWER | BREWER**

requests selection according to Brewer’s method. Brewer’s method selects two units from each stratum with probability proportional to size and without replacement. See the section “[Brewer’s PPS Method](#)” on page 8066 for details. If you specify METHOD=PPS\_BREWER, you must name a size measure variable in the SIZE statement or specify the PPS option in the SAMPLINGUNIT statement. You do not need to specify the sample size with the SAMPSIZE= option because Brewer’s method selects two units from each stratum.

**PPS\_MURTHY | MURTHY**

requests selection according to Murthy's method. Murthy's method selects two units from each stratum with probability proportional to size and without replacement. See the section “[Murthy's PPS Method](#)” on page 8066 for details. If you specify `METHOD=PPS_MURTHY`, you must name a size measure variable in the `SIZE` statement or specify the `PPS` option in the `SAMPLINGUNIT` statement. You do not need to specify the sample size with the `SAMPsize=` option because Murthy's method selects two units from each stratum.

**PPS\_SAMPFORD | SAMPFORD**

requests selection according to Sampford's method. Sampford's method selects units with probability proportional to size and without replacement. See the section “[Sampford's PPS Method](#)” on page 8067 for details. If you specify `METHOD=PPS_SAMPFORD`, you must name a size measure variable in the `SIZE` statement or specify the `PPS` option in the `SAMPLINGUNIT` statement.

**PPS\_SEQ | CHROMY**

requests sequential selection with probability proportional to size and with minimum replacement. This method is also known as Chromy's method. See the section “[PPS Sequential Sampling](#)” on page 8064 for details. If you specify `METHOD=PPS_SEQ`, you must name a size measure variable in the `SIZE` statement or specify the `PPS` option in the `SAMPLINGUNIT` statement.

**PPS\_SYS**

requests systematic selection with probability proportional to size. See the section “[PPS Systematic Sampling](#)” on page 8064 for details. If you specify `METHOD=PPS_SYS`, you must name a size measure variable in the `SIZE` statement or specify the `PPS` option in the `SAMPLINGUNIT` statement.

**PPS\_WR**

requests selection with probability proportional to size and with replacement. See the section “[PPS Sampling with Replacement](#)” on page 8064 for details. If you specify `METHOD=PPS_WR`, you must name a size measure variable in the `SIZE` statement or specify the `PPS` option in the `SAMPLINGUNIT` statement.

**SEQ**

requests sequential selection according to Chromy's method. If you specify `METHOD=SEQ` and do not specify a `SIZE` statement (or the `PPS` option in the `SAMPLINGUNIT` statement), PROC SURVEYSELECT uses sequential zoned selection with equal probability and without replacement. See the section “[Sequential Random Sampling](#)” on page 8060 for details.

If you specify `METHOD=SEQ` and also specify a `SIZE` statement (or the `PPS` option in the `SAMPLINGUNIT` statement), PROC SURVEYSELECT uses `METHOD=PPS_SEQ`, which is sequential selection with probability proportional to size and with minimum replacement. See the section “[PPS Sequential Sampling](#)” on page 8064 for more information.

**SRS**

requests simple random sampling, which is selection with equal probability and without replacement. See the section “[Simple Random Sampling](#)” on page 8059 for details. `METHOD=SRS` is the default if you do not specify the `METHOD=` option and also do not specify a `SIZE` statement (or the `PPS` option in the `SAMPLINGUNIT` statement).

**SYS**

requests systematic random sampling. If you specify `METHOD=SYS` and do not specify a `SIZE` statement (or the `PPS` option in the `SAMPLINGUNIT` statement), PROC SURVEYSELECT uses systematic selection with equal probability. See the section “Systematic Random Sampling” on page 8060 for more information.

If you specify `METHOD=SYS` and also specify a `SIZE` statement (or the `PPS` option in the `SAMPLINGUNIT` statement), PROC SURVEYSELECT uses `METHOD=PPS_SYS`, which is systematic selection with probability proportional to size. See the section “PPS Systematic Sampling” on page 8064 for details.

**URS**

requests unrestricted random sampling, which is selection with equal probability and with replacement. See the section “Unrestricted Random Sampling” on page 8059 for details.

**MINSIZE**

requests adjustment of size measures according to the stratum minimum size values provided in the secondary input data set. Use the `MINSIZE` option when you have already named the secondary input data set in another option, such as the `SAMPsize=SAS-data-set` option. See the section “Secondary Input Data Set” on page 8071 for details.

The `MINSIZE` option is available when you use size measures for any PPS selection method and also include a `STRATA` statement. You provide size measures by specifying the `SIZE` statement or the `PPS` option in the `SAMPLINGUNIT` statement.

You provide the stratum minimum size values in the secondary input data set variable `_MINSIZE_`. Each minimum size value must be a positive number.

When a size measure is less than the specified minimum value for its stratum, PROC SURVEYSELECT adjusts the size measure upward to equal the minimum size value. If your sampling units are individual observations, the variable `AdjustedSize` in the `OUT=` data set contains the adjusted size measures.

If you use a `SAMPLINGUNIT` statement to define sampling units (clusters), then the procedure applies the `MINSIZE` adjustment to the sampling unit size. The sampling unit size equals the number of observations in the sampling unit if you specify the `PPS` option, or the sum of the observation size measures if you specify a `SIZE` statement. The output data set variable `UnitSize` contains the adjusted sampling unit size measures.

If you want to specify a single minimum size value for all strata, you can use the `MINSIZE=min` option.

**MINSIZE=min**

specifies the minimum size value. The value of *min* must be a positive number.

When a size measure is less than the value *min*, PROC SURVEYSELECT adjusts the size measure upward to equal *min*. If your sampling units are individual observations, the variable `AdjustedSize` in the `OUT=` data set contains the adjusted size measures.

If you use a `SAMPLINGUNIT` statement to define sampling units (clusters), then the procedure applies the `MINSIZE` adjustment to the sampling unit size. The sampling unit size equals the number of observations in the sampling unit if you specify the `PPS` option, or the sum of the observation size

measures if you specify a [SIZE](#) statement. The output data set variable `UnitSize` contains the adjusted sampling unit size measures.

The `MINSIZE=min` option is available when you use size measures for any PPS selection method. You provide size measures by specifying the [SIZE](#) statement or the [PPS](#) option in the [SAMPLINGUNIT](#) statement.

If you request a stratified sample design with the [STRATA](#) statement and specify the `MINSIZE=min` option, PROC SURVEYSELECT uses the minimum size *min* for all strata. If you do not want to use the same minimum size for all strata, use the `MINSIZE=SAS-data-set` option to specify a minimum size value for each stratum.

#### **MINSIZE=*SAS-data-set***

names a SAS data set that contains minimum size values for the strata. You provide the stratum minimum size values in the `MINSIZE=` data set variable `_MINSIZE_`. Each minimum size value must be a positive number.

The `MINSIZE=SAS-data-set` option is available when you use size measures for any PPS selection method and also include a [STRATA](#) statement. You provide size measures by specifying the [SIZE](#) statement or the [PPS](#) option in the [SAMPLINGUNIT](#) statement.

When a size measure is less than the minimum size value for its stratum, PROC SURVEYSELECT adjusts the size measure upward to equal the minimum size measure. If your sampling units are individual observations, the variable `AdjustedSize` in the `OUT=` data set contains the adjusted size measures.

If you use a [SAMPLINGUNIT](#) statement to define sampling units (clusters), then the procedure applies the `MINSIZE` adjustment to the sampling unit size. The sampling unit size equals the number of observations in the sampling unit if you specify the [PPS](#) option, or the sum of the observation size measures if you specify a [SIZE](#) statement. The output data set variable `UnitSize` contains the adjusted sampling unit size measures.

The `MINSIZE=` input data set should contain all the [STRATA](#) variables, with the same type and length as in the `DATA=` data set. The [STRATA](#) groups should appear in the same order in the `MINSIZE=` data set as in the `DATA=` data set. The `MINSIZE=` data set must include a variable named `_MINSIZE_` that contains the minimum size measure for each stratum. The `MINSIZE=` data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

If you want to specify a single minimum size value for all strata, you can use the `MINSIZE=min` option.

#### **NMAX=*n***

specifies the maximum stratum sample size *n* for the [SAMPRATE=](#) option. When you specify the [SAMPRATE=](#) option, PROC SURVEYSELECT calculates the stratum sample size by multiplying the total number of units in the stratum by the specified sampling rate. If this sample size is greater than the value `NMAX=n`, then PROC SURVEYSELECT selects only *n* units.

The maximum sample size *n* must be a positive integer. The `NMAX=` option is available only with the [SAMPRATE=](#) option, which can be used with equal probability selection methods ([METHOD=SRS](#), [METHOD=URS](#), [METHOD=SYS](#), and [METHOD=SEQ](#)). The `NMAX=` option is not available with [METHOD=BERNOULLI](#), where the [SAMPRATE=](#) option specifies the constant inclusion probability.

**NMIN=*n***

specifies the minimum stratum sample size  $n$  for the **SAMPRATE=** option. When you specify the **SAMPRATE=** option, PROC SURVEYSELECT calculates the stratum sample size by multiplying the total number of units in the stratum by the specified sampling rate. If this sample size is less than the value **NMIN= $n$** , then PROC SURVEYSELECT selects  $n$  units.

The minimum sample size  $n$  must be a positive integer. The **NMIN=** option is available only with the **SAMPRATE=** option, which can be used with equal probability selection methods (**METHOD=SRS**, **METHOD=URS**, **METHOD=SYS**, and **METHOD=SEQ**). The **NMIN=** option is not available with **METHOD=BERNOULLI**, where the **SAMPRATE=** option specifies the constant inclusion probability.

**NOPRINT**

suppresses the display of all output. You can use the **NOPRINT** option when you want only to create an output data set. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, “Using the Output Delivery System.”

**OUT=*SAS-data-set***

names the output data set that contains the sample. If you omit the **OUT=** option, the data set is named **DATA $n$** , where  $n$  is the smallest integer that makes the name unique.

The output data set contains the units that are selected for the sample, in addition to design information and selection statistics, depending on the selection method and output options that you request. See descriptions of the options **JTPROBS**, **OUTALL**, **OUTHITS**, **OUTSEED**, **OUTSIZE**, and **STATS**, which specify information to include in the output data set. See the section “Sample Output Data Set” on page 8072 for details about the contents of the output data set.

By default, the output data set contains only those units that are selected for the sample. To include all observations from the input data set in the output data set, use the **OUTALL** option.

By default, the output data set includes one copy of each selected unit, even when a unit is selected more than once, which can occur when you use with-replacement or with-minimum-replacement selection methods. For with-replacement or with-minimum-replacement selection methods, the output data set includes a variable **NumberHits** that records the number of hits (selections) for each unit. To include a distinct copy of each selection in the output data set when the same unit is selected more than once, use the **OUTHITS** option.

If you specify the **NOSAMPLE** option in the **STRATA** statement, PROC SURVEYFREQ allocates the total sample size among the strata but does not select the sample. In this case, the **OUT=** data set contains the allocated sample sizes. See the section “Allocation Output Data Set” on page 8075 for details.

**OUTALL**

includes all observations from the **DATA=** input data set in the **OUT=** output data set. By default, the output data set includes only those units selected for the sample. When you specify the **OUTALL** option, the output data set includes all observations from the input data set and also contains a variable that indicates each observation’s selection status. The variable **Selected** equals 1 for an observation that is selected for the sample, and equals 0 for an observation that is not selected. For information about the contents of the output data set, see the section “Sample Output Data Set” on page 8072.

The **OUTALL** option is available for equal probability selection methods (**METHOD=SRS**, **METHOD=URS**, **METHOD=SYS**, **METHOD=SEQ**, and **METHOD=BERNOULLI**). The **OUTALL** option is also available for **METHOD=POISSON**.

**OUTHITS**

includes a distinct copy of each selected unit in the **OUT=** output data set when the same sampling unit is selected more than once. By default, the output data set contains a single copy of each unit selected, even when a unit is selected more than once, and the variable `NumberHits` records the number of hits (selections) for each unit. If you specify the **OUTHITS** option, the output data set contains  $m$  copies of a sampling unit for which `NumberHits` equals  $m$ . For example, with the **OUTHITS** option a unit that is selected three times is represented by three copies in the output data set.

A sampling unit can be selected more than once by with-replacement and with-minimum-replacement selection methods, which include **METHOD=URS**, **METHOD=PPS\_WR**, **METHOD=PPS\_SYS**, and **METHOD=PPS\_SEQ**. The **OUTHITS** option is available for these selection methods.

See the section “[Sample Output Data Set](#)” on page 8072 for details about the contents of the output data set.

**OUTSEED**

includes the initial seed for each stratum in the **OUT=** output data set. The variable `InitialSeed` contains the stratum initial seeds. See the section “[Sample Output Data Set](#)” on page 8072 for details about the contents of the output data set.

To reproduce the same sample for any stratum in a subsequent execution of PROC SURVEYSELECT, you can specify the same stratum initial seed with the **SEED=SAS-data-set** option, along with the same sample selection parameters. See the section “[Random Number Generation](#)” on page 8058 for more information.

The “[Sample Selection Summary](#)” table displays the initial random number seed for the entire sample selection, which is the same as the initial seed for the first stratum when the design is stratified. To reproduce the entire sample, you can specify this same seed value in the **SEED=** option, along with the same sample selection parameters.

Beginning in SAS/STAT 12.1, PROC SURVEYSELECT uses the Mersenne-Twister random number generator by default. In previous releases, PROC SURVEYSELECT used the RANUNI random number generator, which you can now request by specifying the **RANUNI** option. To reproduce samples that PROC SURVEYSELECT selected in releases prior to SAS/STAT 12.1, specify the **RANUNI** option with the **SEED=** option (for the same input data set and sample selection parameters).

**OUTSIZE**

includes additional design and sampling frame information in the **OUT=** output data set.

If you use a **STRATA** statement, the **OUTSIZE** option provides stratum-level values in the output data set. Otherwise, the **OUTSIZE** option provides overall values.

The **OUTSIZE** option includes the sample size or sampling rate in the output data set, depending on whether you specify the **SAMPSIZE=** option or the **SAMPRATE=** option, respectively. For PPS selection methods, the **OUTSIZE** option includes the total size measure in the output data set. If you do not provide size measures, or if you specify a **SAMPLINGUNIT** statement, the **OUTSIZE** option includes the total number of sampling units.

If you request size measure adjustment or certainty selection, the **OUTSIZE** option includes the following information in the output data set: the minimum size measure if you specify the **MINSIZE=** option, the maximum size measure if you specify the **MAXSIZE=** option, the certainty size measure if you specify the **CERTSIZE=** option, and the certainty proportion if you specify the **CERTSIZE=P=** option.

For **METHOD=BERNOULLI**, the **OUTSIZE** option includes the following information in the output data set: total number of sampling units, selection probability (sampling rate), expected sample size, and actual sample size. See the section “[Bernoulli Sampling](#)” on page 8061 for descriptions of these statistics.

For more information about the contents of the output data set, see the section “[Sample Output Data Set](#)” on page 8072.

#### **OUTSORT=SAS-data-set**

names an output data set to store the sorted input data set. This option is available when you specify a **CONTROL** statement to sort the **DATA=** input data set for systematic or sequential selection methods (**METHOD=SYS**, **METHOD=PPS\_SYS**, **METHOD=SEQ**, and **METHOD=PPS\_SEQ**).

If you specify **CONTROL** variables but do not name an output data set with the **OUTSORT=** option, then the sorted data set replaces the input data set.

#### **RANUNI**

requests uniform random number generation by the method of Fishman and Moore (1982), which PROC SURVEYSELECT used in releases prior to SAS/STAT 12.1. This is the same random number generator that the RANUNI function provides.

Beginning in SAS/STAT 12.1, PROC SURVEYSELECT uses the Mersenne-Twister random number generator by default. Developed by Matsumoto and Nishimura (1998), the Mersenne-Twister random number generator has a very long period and good statistical properties. This is the random number generator that the RAND function provides for the uniform distribution.

See the section “[Random Number Generation](#)” on page 8058 for details, and see *SAS Functions and CALL Routines: Reference* for information about the RANUNI and RAND functions.

You can specify the RANUNI option with the **SEED=** option to reproduce samples that PROC SURVEYSELECT selected in releases prior to SAS/STAT 12.1. To reproduce a sample by using the RANUNI and **SEED=** options, you must also specify the same input data set and sample selection parameters.

#### **REPS=nreps**

specifies the number of sample replicates. The value of *nreps* must be a positive integer.

When you specify the **REPS=** option, PROC SURVEYSELECT selects *nreps* independent samples, each with the same sample size or sampling rate and the same sample design that you request. The variable Replicate in the **OUT=** data set contains the sample replicate number.

You can use replicated sampling to provide a simple method of variance estimation for any form of statistic, and also to evaluate variable nonsampling errors such as interviewer differences. For information about replicated sampling, see Lohr (2010); Wolter (2007); Kish (1965, 1987); Kalton (1983). You can also use the **REPS=** option to perform a variety of other resampling and simulation tasks. See Cassell (2007) for more information.

#### **SAMPRATE=r**

#### **RATE=r**

specifies the sampling rate, which is the proportion of units to select for the sample. The sampling rate *r* must be a positive number. You can specify *r* as a number between 0 and 1. Or you can specify

$r$  in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

The SAMPRATE= option is available only for equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, METHOD=SEQ, and METHOD=BERNOULLI). For systematic random sampling (METHOD=SYS), PROC SURVEYSELECT uses the inverse of the sampling rate  $r$  as the selection interval. See the section “Systematic Random Sampling” on page 8060 for details. For Bernoulli sampling (METHOD=BERNOULLI), PROC SURVEYSELECT uses the sampling rate  $r$  as the inclusion probability. See the section “Bernoulli Sampling” on page 8061 for details. For the other equal probability selection methods, PROC SURVEYSELECT converts the sampling rate  $r$  to the sample size before selection by multiplying the total number of units in the stratum or frame by the sampling rate and rounding up to the nearest integer.

If you request a stratified sample design with the STRATA statement and specify the SAMPRATE= $r$  option, PROC SURVEYSELECT uses the sampling rate  $r$  for each stratum. If you do not want to use the same sampling rate for each stratum, use the SAMPRATE=(values) option or the SAMPRATE=SAS-data-set option to specify a sampling rate for each stratum.

#### **SAMPRATE=(values)**

#### **RATE=(values)**

specifies stratum sampling rates, where the stratum sampling rate is the proportion of units to select from the stratum. You can separate values with blanks or commas. The number of SAMPRATE= values must equal the number of strata in the input data set.

List the stratum sampling rate values in the order in which the strata appear in the input data set. When you use the SAMPRATE=(values) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

Each stratum sampling rate value must be a nonnegative. You can specify a rate value as a number between 0 and 1. Or you can specify a rate value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

To select a sample from a stratum, the value of the stratum sampling rate must be positive. If you specify a stratum sampling rate of 0, then PROC SURVEYSELECT does not select a sample from the stratum. This has the effect of subsetting the input data set before sample selection; the stratum that you omit is not included in the sampling frame or represented in the sample.

The SAMPRATE= option is available only for equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, METHOD=SEQ, and METHOD=BERNOULLI). For systematic random sampling (METHOD=SYS), PROC SURVEYSELECT uses the inverse of the stratum sampling rate as the stratum selection interval. See the section “Systematic Random Sampling” on page 8060 for details. For Bernoulli sampling (METHOD=BERNOULLI), PROC SURVEYSELECT uses the stratum sampling rate as the inclusion probability for the stratum. See the section “Bernoulli Sampling” on page 8061 for details. For the other equal probability selection methods, PROC SURVEYSELECT converts the stratum sampling rate to the stratum sample size before selection by multiplying the total number of units in the stratum by the sampling rate and rounding up to the nearest integer.

**SAMPRATE=SAS-data-set**

**RATE=SAS-data-set**

names a SAS data set that contains stratum sampling rates, where the stratum sampling rate is the proportion of units to select from the stratum. The SAMPRATE= data set should include a variable `_RATE_` that contains the stratum sampling rates.

Each sampling rate value must be a nonnegative number. You can specify a rate value as a number between 0 and 1. Or you can specify a rate value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

To select a sample from a stratum, the value of the stratum sampling rate must be positive. If you specify a stratum sampling rate of 0, then PROC SURVEYSELECT does not select a sample from the stratum. This has the effect of subsetting the input data set before sample selection; the stratum that you omit is not included in the sampling frame or represented in the sample.

The SAMPRATE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the SAMPRATE= data set as in the DATA= data set.

The SAMPRATE= option is available only for equal probability selection methods ([METHOD=SRS](#), [METHOD=URS](#), [METHOD=SYS](#), [METHOD=SEQ](#), and [METHOD=BERNOULLI](#)). For systematic random sampling ([METHOD=SYS](#)), PROC SURVEYSELECT uses the inverse of the stratum sampling rate as the stratum selection interval. See the section “[Systematic Random Sampling](#)” on page 8060 for details. For Bernoulli sampling ([METHOD=BERNOULLI](#)), PROC SURVEYSELECT uses the stratum sampling rate as the inclusion probability for the stratum. See the section “[Bernoulli Sampling](#)” on page 8061 for details. For the other equal probability selection methods, PROC SURVEYSELECT converts the stratum sampling rate to the stratum sample size before selection by multiplying the total number of units in the stratum by the sampling rate and rounding up to the nearest integer.

**SAMPsize=*n***

**N=*n***

specifies the sample size, which is the number of units to select for the sample. The sample size *n* must be a positive integer. For selection methods that select without replacement, the sample size *n* must not exceed the number of units in the input data set.

If you do not specify a [SAMPLINGUNIT](#) statement, then your sampling units are observations, and PROC SURVEYSELECT selects *n* observations. If you use a [SAMPLINGUNIT](#) statement to define sampling units as groups of observations (clusters), then the procedure selects *n* clusters.

If you specify the SAMPsize=*n* option and request stratified selection with the [STRATA](#) statement, PROC SURVEYSELECT selects *n* units from each stratum unless you also specify the [ALLOC=](#) option in the [STRATA](#) statement to allocate the total sample size among the strata.

If you specify the [ALLOC=](#) option in the [STRATA](#) statement and the SAMPsize=*n* option, PROC SURVEYSELECT allocates the total sample size *n* among the strata according to the allocation method that you request. See the section “[Sample Size Allocation](#)” on page 8067 for details. If you specify the [MARGIN=](#) option with the [ALLOC=](#) option in the [STRATA](#) statement, PROC SURVEYSELECT determines the stratum sample sizes that provide the requested margin of error for the allocation. Therefore, you cannot use the SAMPsize= option with the [MARGIN=](#) option.

For methods that select without replacement, the sample size  $n$  must not exceed the number of units in any stratum. If you do not want to select the same number of units from each stratum, use the **SAMPSIZE=(values)** option or the **SAMPSIZE=SAS-data-set** option to specify a sample size for each stratum.

For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units available in the stratum. If you specify the **SELECTALL** option, PROC SURVEYSELECT selects all stratum units when the stratum sample size exceeds the number of units in the stratum.

### **SAMPSIZE=(values)**

#### **N=(values)**

specifies stratum sample sizes, where the stratum sample size is the number of units to select from the stratum. You can separate *values* with blanks or commas. The number of SAMPSIZE= values must equal the number of strata in the input data set.

List the stratum sample size values in the order in which the strata appear in the input data set. When you use the SAMPSIZE=(values) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

Each stratum sample size value must be a nonnegative integer. To select a sample from a stratum, the value of the stratum sample size must be positive. If you specify a stratum sample size of 0, then PROC SURVEYSELECT does not select a sample from the stratum. This has the effect of subsetting the input data set before sample selection; the stratum that you omit is not included in the sampling frame or represented in the sample.

For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units available in the stratum. If you specify the **SELECTALL** option, PROC SURVEYSELECT selects all stratum units when the stratum sample size exceeds the number of units in the stratum.

### **SAMPSIZE=SAS-data-set**

#### **N=SAS-data-set**

names a SAS data set that contains stratum sample sizes, where the stratum sample size is the number of units to select from the stratum. The SAMPSIZE= input data set should include a variable named `_NSIZE_` or `SampleSize` that contains the stratum sample sizes.

Each stratum sample size value must be a nonnegative integer. To select a sample from a stratum, the value of the stratum sample size must be positive. If you specify a stratum sample size of 0, then PROC SURVEYSELECT does not select a sample from the stratum. This has the effect of subsetting the input data set before sample selection; the stratum that you omit is not included in the sampling frame or represented in the sample.

The SAMPSIZE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the SAMPSIZE= data set as in the DATA= data set. The SAMPSIZE= data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units available in the stratum. If you specify the **SELECTALL** option, PROC SURVEYSELECT selects all stratum units when the stratum sample size exceeds the number of units in the stratum.

**SEED**

indicates that stratum-level initial seeds are included in the secondary input data set. Use the SEED option when you have already named the secondary input data set in another option, such as the `SAMPsize=SAS-data-set` option. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

You provide the stratum initial seeds in the secondary input data set variable named `_SEED_` or `InitialSeed`. The initial seeds must be positive integers.

See the description of the `SEED=SAS-data-set` option for more information about initial seeds for random number generation.

**SEED=number**

specifies the initial seed for random number generation. The SEED= value must be a positive integer. If you do not specify the SEED= option, or if the SEED= value is negative or 0, PROC SURVEYSELECT uses the time of day from the computer’s clock to obtain the initial seed. See the section “[Random Number Generation](#)” on page 8058 for more information.

If you request a stratified sample design with the STRATA statement, you can use the `SEED=SAS-data-set` option to specify an initial seed for each stratum. Otherwise, PROC SURVEYSELECT generates random numbers continuously across strata from the random number stream initialized by the SEED= value.

You can use the `OUTSEED` option to include the stratum initial seeds in the output data set.

Whether or not you specify the SEED= option, PROC SURVEYSELECT displays the value of the initial seed in the “Sample Selection Summary” table. If you need to reproduce the same sample in a subsequent execution of PROC SURVEYSELECT, you can specify this same seed value in the SEED= option, along with the same sample selection parameters, and PROC SURVEYSELECT will reproduce the sample.

Beginning in SAS/STAT 12.1, PROC SURVEYSELECT uses the Mersenne-Twister random number generator by default. In previous releases, PROC SURVEYSELECT used the RANUNI random number generator, which you can now request by specifying the `RANUNI` option. To reproduce samples that PROC SURVEYSELECT selected in releases prior to SAS/STAT 12.1, use the `RANUNI` option with the SEED= option (for the same input data set and sample selection parameters).

**SEED=SAS-data-set**

names a SAS data set that contains initial seeds for the strata. You provide the stratum seeds in the SEED= input data set variable `_SEED_` or `InitialSeed`.

The initial seed values must be positive integers. If the initial seed value for the first stratum is not a positive integer, PROC SURVEYSELECT uses the time of day from the computer’s clock to obtain the initial seed. If the initial seed value for a subsequent stratum is not a positive integer, PROC SURVEYSELECT continues to use the random number stream already initialized by the seed for the previous stratum. See the section “[Sample Selection Methods](#)” on page 8058 for more information.

The SEED= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the SEED= data set as in the DATA= data set. The SEED= data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

You can use the `OUTSEED` option to include the stratum initial seeds in the output data set.

Whether or not you specify the SEED= option, PROC SURVEYSELECT displays the value of the initial seed in the “Sample Selection Summary” table. If you need to reproduce the same sample in a subsequent execution of PROC SURVEYSELECT, you can specify this same seed value in the SEED= option, along with the same sample selection parameters, and PROC SURVEYSELECT will reproduce the sample.

If you specify initial seeds by strata with the SEED=*SAS-data-set* option, you can reproduce the same sample in a subsequent execution of PROC SURVEYSELECT by specifying these same stratum initial seeds, along with the same sample selection parameters. If you need to reproduce the same sample for only a subset of the strata, you can use the same initial seeds for those strata in the subset.

Beginning in SAS/STAT 12.1, PROC SURVEYSELECT uses the Mersenne-Twister random number generator by default. In previous releases, PROC SURVEYSELECT used the RANUNI random number generator, which you can now request by specifying the RANUNI option. To reproduce samples that PROC SURVEYSELECT selected in releases prior to SAS/STAT 12.1, use the RANUNI option with the SEED= option (for the same input data set and sample selection parameters).

### SELECTALL

requests that PROC SURVEYSELECT select all stratum units when the stratum sample size exceeds the total number of units in the stratum. By default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units in the stratum, unless you are using a with-replacement selection method.

The SELECTALL option is available for the following without-replacement selection methods: METHOD=SRS, METHOD=SYS, METHOD=SEQ, METHOD=PPS, and METHOD=PPS\_SAMPFORD.

The SELECTALL option is not available for with-replacement selection methods, with-minimum-replacement methods, or those PPS methods that select two units per stratum.

### SORT=NEST | SERP

specifies the type of sorting by CONTROL variables. The option SORT=NEST requests nested sorting, and SORT=SERP requests hierarchic serpentine sorting. The default is SORT=SERP. See the section “[Sorting by CONTROL Variables](#)” on page 8057 for descriptions of serpentine and nested sorting. Where there is only one CONTROL variable, the two types of sorting are equivalent.

The SORT= option is available when you specify a CONTROL statement for systematic or sequential selection methods (METHOD=SYS, METHOD=PPS\_SYS, METHOD=SEQ, and METHOD=PPS\_SEQ). When you specify a CONTROL statement, PROC SURVEYSELECT sorts the input data set by the CONTROL variables within strata before selecting the sample.

The SORT= option and the CONTROL statement are not available with a SAMPLINGUNIT statement. See the descriptions of the CONTROL and SAMPLINGUNIT statements for more information.

When you specify a CONTROL statement, you can also use the OUTSORT= option to name an output data set that contains the sorted input data set. Otherwise, if you do not specify the OUTSORT= option, the sorted data set replaces the input data set.

### STATS

includes the selection probability and sampling weight in the OUT= output data set for equal probability selection methods when you do not specify a STRATA statement. By default, the output data set does not include these values for equal probability selection methods unless you specify a STRATA statement. The STATS option applies to the following selection methods: METHOD=SRS, METHOD=URS, METHOD=SYS, METHOD=SEQ, and METHOD=BERNOULLI.

In addition to the selection probability and sampling weight, the **STATS** option includes the following statistics in the output data set for **METHOD=BERNOULLI**: total number of sampling units, expected sample size, actual sample size, and adjusted sampling weight. See the section “[Bernoulli Sampling](#)” on page 8061 for more information.

For PPS selection methods, the output data set contains selection probabilities and sampling weights by default. The **STATS** option has no effect for PPS methods.

For more information about the contents of the output data set, see the section “[Sample Output Data Set](#)” on page 8072.

## CONTROL Statement

**CONTROL** *variables* ;

The **CONTROL** statement names variables for sorting the input data set before sample selection. The **CONTROL** variables can be character or numeric. If you also specify a **STRATA** statement, **PROC SURVEYSELECT** sorts by **CONTROL** variables within strata.

Control sorting is available for systematic and sequential selection methods (**METHOD=SYS**, **METHOD=PPS\_SYS**, **METHOD=SEQ**, and **METHOD=PPS\_SEQ**). Ordering the sampling units before systematic or sequential selection can provide additional control over the distribution of the sample.

Control sorting is not available when you use a **SAMPLINGUNIT** statement, which defines groups of observations as units (clusters) for sample selection. See the description of the **SAMPLINGUNIT** statement for information about ordering clusters before systematic or sequential selection.

By default (or if you specify the **SORT=SERP** option in the **PROC SURVEYSELECT** statement), **PROC SURVEYSELECT** uses hierarchic serpentine sorting by the **CONTROL** variables. If you specify the **SORT=NEST** option, the procedure uses nested sorting. For more information about serpentine and nested sorting, see the section “[Sorting by CONTROL Variables](#)” on page 8057.

You can use the **OUTSORT=** option in the **PROC SURVEYSELECT** statement to name an output data set that contains the sorted input data set. If you do not specify the **OUTSORT=** option when you use the **CONTROL** statement, then the sorted data set replaces the input data set.

## FREQ Statement

**FREQ** *variable* ;

The **FREQ** statement names a numeric variable that contains the frequency of occurrence of each observation. If you use a **FREQ** statement, **PROC SURVEYSELECT** assumes that an observation represents  $n$  observations, where  $n$  is the value of the **FREQ** variable for the observation. The **FREQ** statement is not available when you specify a **SAMPLINGUNIT** statement.

The **FREQ** statement is available only for sample allocation when no sample is selected, which you can request by specifying the **ALLOC=** and **NOSAMPLE** options in the **STRATA** statement. The **ALLOC=** option requests allocation of the total sample size among the strata, and the **NOSAMPLE** option requests that no sample be selected after allocation. When you specify the **NOSAMPLE** option, the procedure computes stratum sample sizes according to the allocation method that you request, but does not select the

sample. See the sections “Allocation Options” on page 8052 and “Sample Size Allocation” on page 8067 for details.

The sum of the FREQ variable values (frequencies) represents the total number of sampling units. The sum of the frequencies in a stratum represents the total number of sampling units in the stratum. When you use a FREQ statement, the sample size allocation is based on the expanded total and stratum frequencies.

Values of the FREQ variable must be nonmissing and nonnegative. If a value of the FREQ variable is 0, PROC SURVEYSELECT ignores the observation. If a value of the FREQ variable is not an integer, PROC SURVEYSELECT uses only the integer portion as the frequency of the observation.

## ID Statement

**ID** *variables* ;

The ID statement names one or more variables from the **DATA=** input data set to include in the **OUT=** output data set of selected units. If there is no ID statement, PROC SURVEYSELECT includes all variables from the input data set in the output data set. The ID variables can be either character or numeric.

## SAMPLINGUNIT | CLUSTER Statement

**SAMPLINGUNIT | CLUSTER** *variables* < / options > ;

The SAMPLINGUNIT statement names variables that identify the sampling units as groups of observations (clusters). The combinations of categories of SAMPLINGUNIT variables define the sampling units. If there is a STRATA statement, sampling units are nested within strata.

When you use a SAMPLINGUNIT statement to define units (clusters), PROC SURVEYSELECT selects a sample of these units by using the selection method and design parameters that you specify in the PROC SURVEYSELECT statement. If you do not use a SAMPLINGUNIT statement, then PROC SURVEYSELECT uses the input data set observations as sampling units by default.

The SAMPLINGUNIT variables are one or more variables in the **DATA=** input data set. These variables can be either character or numeric. The formatted values of the SAMPLINGUNIT variables determine the SAMPLINGUNIT variable levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference* for more information.

You can use a SAMPLINGUNIT statement with any equal probability selection method or PPS selection method. The SAMPLINGUNIT statement is not available for Poisson sampling (**METHOD=POISSON**).

If you specify the **PPS** option in the SAMPLINGUNIT statement and do not specify a **SIZE** statement, then the procedure computes sampling unit size as the number of observations in the sampling unit. If you specify a **SIZE** statement with a SAMPLINGUNIT statement, then the procedure computes sampling unit size by summing the size measures of all observations in the sampling unit.

By default, PROC SURVEYSELECT sorts the input data set by the SAMPLINGUNIT variables within strata before sample selection. This groups the observations into sampling units and orders the sampling units by the SAMPLINGUNIT variables. If you do not want the procedure to sort the input data set by the SAMPLINGUNIT variables, then specify the **PRESORTED** option in the SAMPLINGUNIT statement. By

using the **PRESORTED** option, you can provide the order of the sampling units for systematic and sequential selection methods. The **CONTROL** statement is not available with the **SAMPLINGUNIT** statement.

Note that the **SAMPLINGUNIT** statement defines groups of observations (clusters) to use as sampling units, and **PROC SURVEYSELECT** selects a sample of these units. When you use a **SAMPLINGUNIT** statement, **PROC SURVEYSELECT** does not select samples of observations from within the sampling units (clusters). To select independent samples within groups, use the **STRATA** statement.

You can specify the following *options* in the **SAMPLINGUNIT** statement after a slash (/):

### **PPS**

computes a sampling unit's size measure as the number of observations in the sampling unit. The procedure then uses these size measures to select a sample according to the PPS selection method that you specify with the **METHOD=** option in the **PROC SURVEYSELECT** statement.

This option has no effect when you specify a **SIZE** statement. When you specify a **SIZE** statement, the procedure computes sampling unit size by summing the size measures of all observations that belong to the sampling unit.

### **PRESORTED**

requests that **PROC SURVEYSELECT** not sort the input data set by the **SAMPLINGUNIT** variables within strata. By default, the procedure sorts the input data set by the **SAMPLINGUNIT** variables, which groups the observations into sampling units and orders the units by the **SAMPLINGUNIT** variables.

The **PRESORTED** option enables you to provide the order of the sampling units. For systematic and sequential selection methods, ordering provides additional control over the distribution of the sample and gives some benefits of proportionate stratification. Systematic and sequential methods include **METHOD=SYS**, **METHOD=PPS\_SYS**, **METHOD=SEQ**, and **METHOD=PPS\_SEQ**. See the descriptions of these methods in the section “Sample Selection Methods” on page 8058 for more information.

When you specify the **PRESORTED** option, the procedure treats the sampling unit groups as **NOTSORTED**. Like the **BY** statement option **NOTSORTED**, this does not mean that the data are unsorted by the **SAMPLINGUNIT** variables, but rather that the data are arranged in groups (according to values of the **SAMPLINGUNIT** variables) and that these groups are not necessarily in alphabetical or increasing numeric order. For more information about the **BY** statement **NOTSORTED** option, see *SAS Language Reference: Concepts*.

## **SIZE Statement**

**SIZE** *variable* ;

The **SIZE** statement names one and only one variable that contains size measures that are used for PPS selection. The **SIZE** variable must be numeric.

If you specify a **SAMPLINGUNIT** statement with a **SIZE** statement, the procedure computes a sampling unit's size by summing the size measures of all observations that belong to the sampling unit. Alternatively, if you specify the **PPS** option in the **SAMPLINGUNIT** statement and do not use a **SIZE** statement, the procedure computes sampling unit size as the number of observations in the sampling unit.

When the value of a sampling unit's size measure is missing or nonpositive, that sampling unit is excluded from the sample selection. See the section “[Missing Values](#)” on page 8056 for more information.

You can adjust the size measure values by using the `MAXSIZE=` option, the `MINSIZE=` option, or both of these options in the `PROC SURVEYSELECT` statement.

All PPS selection methods require size measures, which you can provide by specifying a `SIZE` statement (or by specifying the `PPS` option in the `SAMPLINGUNIT` statement). PPS selection methods include the following: `METHOD=PPS`, `METHOD=PPS_BREWER`, `METHOD=PPS_MURTHY`, `METHOD=PPS_SAMPFORD`, `METHOD=PPS_SEQ`, `METHOD=PPS_SYS`, and `METHOD=PPS_WR`. For details about how size measures are used in sample selection, see the descriptions of PPS selection methods in the section “[Sample Selection Methods](#)” on page 8058.

Note that a sampling unit's size measure, which you provide for PPS selection by specifying a `SIZE` statement, is not the same as the *sample size*. The sample size is the number of units to select for the sample; you specify the sample size with the `SAMPSIZE=` option in the `PROC SURVEYSELECT` statement.

For `METHOD=POISSON`, the variable that is specified in the `SIZE` statement provides inclusion probabilities for Poisson sampling. See the section “[Poisson Sampling](#)” on page 8062 for details. When the value of the `SIZE` variable is missing, nonpositive, or greater than 1, the sampling unit is not included in the sample selection.

## STRATA Statement

**STRATA** *variables* </ *options* > ;

The `STRATA` statement names variables that partition the input data set into nonoverlapping subgroups (strata). The combinations of levels of `STRATA` variables define the strata. `PROC SURVEYSELECT` then selects independent samples from these strata, according to the selection method and design parameters that you specify in the `PROC SURVEYSELECT` statement. For information about the use of stratification in sample design, see Lohr (2010); Kalton (1983); Kish (1965, 1987); Cochran (1977).

The `STRATA` variables are one or more variables in the `DATA=` input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. The formatted values of the `STRATA` variables determine the `STRATA` variable levels. Thus, you can use formats to group values into levels. See the `FORMAT` procedure in the *Base SAS Procedures Guide* and the `FORMAT` statement and SAS formats in *SAS Formats and Informats: Reference*.

The `STRATA` variables function much like `BY` variables, and `PROC SURVEYSELECT` expects the input data set to be sorted in order of the `STRATA` variables.

If you specify a `CONTROL` statement, or if you specify `METHOD=PPS`, the input data set must be sorted in ascending order by the `STRATA` variables. This means you cannot use the `STRATA` option `NOTSORTED` or `DESCENDING` when you specify a `CONTROL` statement or `METHOD=PPS`.

If your input data set is not sorted by the `STRATA` variables in ascending order, use one of the following alternatives:

- Sort the data by using the `SORT` procedure with the `STRATA` variables in a `BY` statement.
- Specify the `NOTSORTED` or `DESCENDING` option in the `STRATA` statement (when you do not specify a `CONTROL` statement or `METHOD=PPS`). The `NOTSORTED` option does not mean that the

data are unsorted but rather that the data are arranged in groups (according to values of the STRATA variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index on the STRATA variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

## Allocation Options

The STRATA options request allocation of the total sample size among the strata. You can use the ALLOC= option to specify the allocation method. Available allocation methods include proportional allocation (ALLOC=PROP), optimal allocation (ALLOC=OPTIMAL), and Neyman allocation (ALLOC=NEYMAN). See the section “Sample Size Allocation” on page 8067 for details about these methods.

Instead of requesting that PROC SURVEYSELECT compute the sample allocation, you can provide the allocation proportions by using the ALLOC=(values) option or the ALLOC=SAS-data-set option. Then PROC SURVEYSELECT allocates the total sample size among the strata according to the proportions that you provide. Allocation proportions are relative stratum sample sizes,  $n_h/n$ , where  $n_h$  is the stratum  $h$  sample size and  $n$  is the total sample size.

You can use the SAMPSIZE= option in the PROC SURVEYSELECT statement to specify the total sample size to be allocated among the strata. Alternatively, you can specify the desired margin of error in the MARGIN= option, and the procedure determines the stratum sample sizes that are required to achieve that margin. See the section “Specifying the Margin of Error” on page 8069 for details.

When you request sample allocation, by default PROC SURVEYSELECT computes the allocation of the total sample size among the strata and then selects the sample. If you specify the NOSAMPLE option, the procedure computes the allocation but does not select the sample. In this case the OUT= output data set contains the stratum sample sizes that are computed according to the specified allocation method. See the section “Allocation Output Data Set” on page 8075 for details.

You can use the ALLOC= option with any selection method except METHOD=PPS\_BREWER and METHOD=PPS\_MURTHY, which select two units from each stratum.

Table 95.2 summarizes the options available in the STRATA statement. Descriptions of the options follow in alphabetical order.

**Table 95.2** STRATA Statement Options for Sample Allocation

| Option         | Description                                   |
|----------------|-----------------------------------------------|
| ALLOC=name     | Specifies the allocation method               |
| ALLOC=(values) | Provides allocation proportions               |
| ALLOCMIN=      | Specifies the minimum sample size per stratum |
| ALPHA=         | Specifies the confidence level                |
| COST=          | Provides stratum costs                        |
| MARGIN=        | Specifies the margin of error                 |
| NOSAMPLE       | Allocates but does not select the sample      |
| STATS          | Displays additional allocation statistics     |
| VAR=           | Provides stratum variances                    |

You can specify the following *options* in the STRATA statement after a slash (/):

**ALLOC=*name***

specifies the method for allocating the total sample size among the strata. The following values for *name* are available:

**PROPORTIONAL | PROP**

requests proportional allocation, which allocates the total sample size in proportion to the stratum sizes, where the stratum size is the number of sampling units in the stratum. See the section “[Proportional Allocation](#)” on page 8068 for details.

**OPTIMAL | OPT**

requests optimal allocation, which allocates the total sample size among the strata in proportion to stratum sizes, stratum variances, and stratum costs. See the section “[Optimal Allocation](#)” on page 8068 for more information. If you specify ALLOC=OPTIMAL, you must provide the stratum variances with the [VAR=\(values\)](#), [VAR=SAS-data-set](#), or [VAR](#) option. You must provide the stratum costs with the [COST=\(values\)](#), [COST=SAS-data-set](#), or [COST](#) option.

**NEYMAN**

requests Neyman allocation, which allocates the total sample size among the strata in proportion to the stratum sizes and variances. See the section “[Neyman Allocation](#)” on page 8069 for more information. If you specify ALLOC=NEYMAN, you must provide the stratum variances with the [VAR=\(values\)](#), [VAR=SAS-data-set](#), or [VAR](#) option.

**ALLOC=(*values*)**

lists stratum allocation proportions. You can separate *values* with blanks or commas.

Each allocation proportion specifies the percent of the total sample size to allocate to the corresponding stratum. The number of ALLOC= values must equal the number of strata in the input data set. The sum of the allocation proportions must equal 1.

Each allocation proportion must be a positive number. You can specify each value as a number between 0 and 1. Or you can specify a value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

List the allocation proportions in the order in which the strata appear in the input data set. If you use the ALLOC=(*values*) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

**ALLOC=*SAS-data-set***

names a SAS data set that contains stratum allocation proportions. You provide the stratum allocation proportions in the ALLOC= data set variable `_ALLOC_`.

Each allocation proportion specifies the percent of the total sample size to allocate to the corresponding stratum. The sum of the allocation proportions must equal 1.

Each allocation proportion must be a positive number. You can specify the value as a number between 0 and 1. Or you can specify the value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

The ALLOC= data set should contain all the STRATA variables, with the same type and length as in the DATA= input data set. The STRATA groups should appear in the same order in the ALLOC= data set as in the DATA= data set. The ALLOC= data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary data set in each invocation of the procedure.

**ALLOCMIN=*n***

specifies the minimum sample size to allocate to a stratum. When you specify ALLOCMIN=*n*, PROC SURVEYSELECT allocates at least *n* sampling units to each stratum. If you do not specify the ALLOCMIN= option, PROC SURVEYSELECT allocates at least one sampling unit to each stratum by default.

The minimum stratum sample size *n* must be a positive integer. The ALLOCMIN value *n* times the number of strata should not exceed the total sample size to be allocated. For without-replacement selection methods, the ALLOCMIN value should not exceed the number of sampling units in any stratum.

**ALPHA= $\alpha$** 

specifies the level of the confidence interval for the [MARGIN=](#) determination of stratum sample sizes. See the section “[Specifying the Margin of Error](#)” on page 8069 for details.

The value of  $\alpha$  must be between 0 and 1; the default is 0.05. A confidence level of  $\alpha$  produces a  $100(1 - \alpha)\%$  confidence interval. The default of ALPHA=0.05 produces a 95% confidence interval.

**COST**

indicates that stratum costs are included in the secondary input data set. Use the COST option when you have already named the secondary input data set in another option, such as the [VAR=SAS-data-set](#) option. You provide the stratum costs in the secondary input data set variable `_COST_`.

A stratum cost represents the per-unit cost (the survey cost of a single unit in the stratum). Each stratum cost must be a positive number. Cost values are required if you specify the [ALLOC=OPTIMAL](#) option.

**COST=(*values*)**

specifies stratum costs, which are required if you specify the [ALLOC=OPTIMAL](#) option. You can separate *values* with blanks or commas.

A stratum cost represents the per-unit cost (the survey cost of a single unit in the stratum). Each stratum cost must be a positive number.

The number of COST= values must equal the number of strata in the input data set. List the stratum costs in the order in which the strata appear in the input data set. If you use the COST=*values* option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED option in the STRATA statement.

**COST=SAS-data-set**

names a SAS data set that contains the stratum costs. You provide the stratum costs in the COST= data set variable `_COST_`.

A stratum cost represents the per-unit cost (the survey cost of a single unit in the stratum). Each stratum cost must be a positive number. Stratum costs are required if you specify the [ALLOC=OPTIMAL](#) option.

The COST= data set should contain all the STRATA variables, with the same type and length as in the DATA= input data set. The STRATA groups should appear in the same order in the COST= data set as in the DATA= data set. The COST= data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

### **MARGIN=***value*

specifies the desired margin of error for estimating the overall mean from the stratified sample. When you specify the MARGIN= option, PROC SURVEYSELECT determines the stratum sample sizes required to achieve this margin for the allocation method or proportions that you specify in the ALLOC= option. See the section “[Specifying the Margin of Error](#)” on page 8069 for details.

The MARGIN= *value* must be a positive number. When you specify the MARGIN= option, you must also provide the stratum variances in the VAR=(*values*), VAR=*SAS-data-set*, or VAR option.

You can use the ALPHA= option to set the level of the confidence interval that the MARGIN= computation uses. The default of ALPHA=0.05 specifies a 95% confidence interval.

You can request the MARGIN= option for any allocation method (proportional, optimal, or Neyman) or for allocation proportions that you provide (ALLOC=(*values*) or ALLOC=*SAS-data-set*). When you use the MARGIN= option, you cannot specify a total sample size in the SAMPSIZE= option in the PROC SURVEYSELECT statement.

### **NOSAMPLE**

requests that PROC SURVEYSELECT allocate the total sample size among the strata but not select the sample. When you specify the NOSAMPLE option, the OUT= output data set contains the stratum sample sizes that PROC SURVEYSELECT computes. See the section “[Allocation Output Data Set](#)” on page 8075 for details.

### **STATS**

displays statistics for the sample allocation. If you specify the MARGIN= option, the STATS option displays the expected margin of error for the allocation. See the section “[Specifying the Margin of Error](#)” on page 8069 for details. If you request ALLOC=OPTIMAL or ALLOC=NEYMAN without the MARGIN= option, the STATS option displays the expected variance, which is computed from the stratum variances that you provide and the allocated stratum sample sizes. If you request ALLOC=OPTIMAL, the STATS option also displays the total stratum cost, which is computed from the stratum costs that you provide and the allocated stratum sample sizes.

### **VAR**

indicates that stratum variances are included in the secondary input data set. Use the VAR option when you have already named the secondary input data set in another option, such as the COST=*SAS-data-set* option. You provide the stratum variances in the secondary input data set variable `_VAR_`.

Each stratum variance must be a positive number. Stratum variances are required if you specify the ALLOC=OPTIMAL, ALLOC=NEYMAN, or MARGIN= option.

### **VAR=(*values*)**

lists stratum variances, which are required if you specify the ALLOC=OPTIMAL, ALLOC=NEYMAN, or MARGIN= option. You can separate *values* with blanks or commas.

Each stratum variance must be a positive number. The number of VAR= values must equal the number of strata in the input data set. List the stratum variances in the order in which the strata appear in the

input data set. If you use the `VAR=(values)` option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the `DESCENDING` or `NOTSORTED` option in the STRATA statement.

**VAR=SAS-data-set**

names a SAS data set that contains the stratum variances. You provide the stratum variances in the `VAR=` data set variable `_VAR_`.

Each stratum variance must be a positive number. Stratum variances are required if you specify the `ALLOC=OPTIMAL`, `ALLOC=NEYMAN`, or `MARGIN=` option.

The `VAR=` data set should contain all the STRATA variables, with the same type and length as in the `DATA=` input data set. The STRATA groups should appear in the same order in the `VAR=` data set as in the `DATA=` data set. The `VAR=` data set is a secondary input data set. See the section “[Secondary Input Data Set](#)” on page 8071 for details. You can name only one secondary input data set in each invocation of the procedure.

---

## Details: SURVEYSELECT Procedure

---

### Missing Values

PROC SURVEYSELECT treats missing values of `STRATA` and `SAMPLINGUNIT` variables like any other STRATA or SAMPLINGUNIT variable value. The missing values form a separate, valid variable level.

When you use a `FREQ` statement for sample size allocation, all values of the frequency variable must be nonmissing. If there is a missing or nonpositive frequency, PROC SURVEYSELECT does not perform the allocation.

When you specify a `SIZE` variable, any sampling units that have missing or nonpositive size measures are excluded from the sample selection. The procedure provides a log note that reports the number of observations omitted due to missing or nonpositive size measures.

If you do not use a `SAMPLINGUNIT` statement with the `SIZE` statement, your sampling units are input data set observations, and observations that have missing or nonpositive size measures are excluded from the sample selection. If you do use a `SAMPLINGUNIT` statement with the `SIZE` statement, the procedure computes sampling unit size by summing the size measures of all observations in the unit. When summing the observation size measures, the procedure omits any observations that have missing or nonpositive size measures. If the size of an entire sampling unit is missing or nonpositive, the procedure excludes that unit from the sample selection. When a sampling unit is selected, the output data set includes all observations that belong to the selected unit, regardless of whether an observation’s size measure is missing.

If you provide stratum-level design or allocation information in a secondary input data set, the variable values should be nonmissing. For example, if a stratum value of `_NSIZE_` (or `SampleSize`) in the `SAMPSIZE=` secondary input data set is missing or negative, PROC SURVEYSELECT cannot select a sample from the stratum. The procedure gives an error message and skips the stratum. Similarly, if other secondary data

set variables have missing values for a stratum, a sample cannot be selected from the stratum. These variables include `_NRATE_`, `_MINSIZE_`, `_MAXSIZE_`, `_CERTSIZE_`, and `_CERTP_`. Additionally, if any of the sample allocation variables in the secondary input data set have missing or nonpositive values, PROC SURVEYSELECT cannot compute the sample allocation. Variables that provide information for allocation include `_ALLOC_`, `_VAR_`, and `_COST_`. See the section “Secondary Input Data Set” on page 8071 for details.

---

## Sorting by CONTROL Variables

If you specify a `CONTROL` statement, PROC SURVEYSELECT sorts the input data set by the CONTROL variables before selecting the sample. If you also specify a `STRATA` statement, the procedure sorts by CONTROL variables within strata. Sorting by CONTROL variables is available for systematic and sequential selection methods, which include `METHOD=SYS`, `METHOD=PPS_SYS`, `METHOD=SEQ`, and `METHOD=PPS_SEQ`. Sorting provides additional control over the distribution of the sample and gives some benefits of proportionate stratification.

Control sorting is not available when you use a `SAMPLINGUNIT` statement, which defines groups of observations as units (clusters) for sample selection. See the description of the `SAMPLINGUNIT` statement for information about ordering clusters before systematic or sequential selection.

When you specify a `CONTROL` statement, the sorted data set replaces the input data set by default. Alternatively, you can use the `OUTSORT=` option to name an output data set that contains the sorted input data set.

PROC SURVEYSELECT provides two types of sorting: hierarchic serpentine sorting and nested sorting. By default (or if you specify the `SORT=SERP` option), the procedure uses serpentine sorting. If you specify the `SORT=NEST` option, then the procedure sorts by the CONTROL variables according to nested sorting. These two types of sorting are equivalent when there is only one CONTROL variable.

If you request nested sorting, PROC SURVEYSELECT sorts observations in the same order as PROC SORT does for an ascending sort by the CONTROL variables. See the chapter “The SORT Procedure” in the *Base SAS Procedures Guide* for more information. PROC SURVEYSELECT sorts within strata if you also specify a `STRATA` statement. The procedure first arranges the input observations in ascending order of the first CONTROL variable. Then within each level of the first control variable, the procedure arranges the observations in ascending order of the second CONTROL variable. This continues for all CONTROL variables that are specified.

In hierarchic serpentine sorting, PROC SURVEYSELECT sorts by the first CONTROL variable in ascending order. Then within the first level of the first CONTROL variable, the procedure sorts by the second CONTROL variable in ascending order. Within the second level of the first CONTROL variable, the procedure sorts by the second CONTROL variable in descending order. Sorting by the second CONTROL variable continues to alternate between ascending and descending sorting throughout all levels of the first CONTROL variable. If there is a third CONTROL variable, the procedure sorts by that variable within levels formed from the first two CONTROL variables, again alternating between ascending and descending sorting. This continues for all CONTROL variables that are specified. This sorting algorithm minimizes the change from one observation to the next with respect to the CONTROL variable values, thus making nearby observations more similar. For more information about serpentine sorting, see Chromy (1979) and Williams and Chromy (1980).

---

## Random Number Generation

The probability sampling methods provided by PROC SURVEYSELECT use random numbers in their selection algorithms, as described in the following sections and in the references cited. PROC SURVEYSELECT uses a uniform random number function to generate streams of pseudo-random numbers from an initial starting point, or *seed*. You can use the **SEED=** option to specify the initial seed. If you do not specify the **SEED=** option, PROC SURVEYSELECT uses the time of day from the computer's clock to obtain the initial seed. See the description of the **SEED=** option for details about specifying initial seeds for strata, storing stratum seeds in the output data set, and reproducing samples.

Beginning in SAS/STAT 12.1, PROC SURVEYSELECT uses the Mersenne-Twister random number generator by default. The Mersenne-Twister generator (Matsumoto and Nishimura 1998) has a very long period ( $2^{19937} - 1$ ) and very good statistical properties. The algorithm is a twisted generalized feedback shift register. This is the same random number generator that the RAND function provides for the uniform distribution. See *SAS Functions and CALL Routines: Reference* for more information.

In previous releases, PROC SURVEYSELECT used the RANUNI random number generator, which you can now request by specifying the **RANUNI** option. This uniform random number generator is based on the method of Fishman and Moore (1982), which uses a prime modulus multiplicative generator with modulus  $2^{31}$  and multiplier 397,204,094. This is the same uniform random number generator that the RANUNI function provides. For more information about the RANUNI function, see *SAS Functions and CALL Routines: Reference*.

To reproduce samples that PROC SURVEYSELECT selected in releases prior to SAS/STAT 12.1, you can use the **RANUNI** option with the **SEED=** option (for the same input data set and selection parameters).

---

## Sample Selection Methods

PROC SURVEYSELECT provides a variety of methods for selecting probability-based random samples. With probability sampling, each unit in the survey population has a known, positive probability of selection. This property of probability sampling avoids selection bias and enables you to use statistical theory to make valid inferences from the sample to the survey population. For more information about probability sampling, see Lohr (2010); Kish (1965, 1987); Kalton (1983); Cochran (1977).

In equal probability sampling, each unit in the sampling frame, or in a stratum, has the same probability of being selected for the sample. PROC SURVEYSELECT provides the following methods that select units with equal probability: simple random sampling, unrestricted random sampling, systematic random sampling, sequential random sampling, and Bernoulli sampling. In simple random sampling, units are selected *without replacement*, which means that a unit cannot be selected more than once. Both systematic and sequential equal probability sampling are also without replacement. In unrestricted random sampling, units are selected *with replacement*, which means that a unit can be selected more than once. In with-replacement sampling, the *number of hits* refers to the number of times a unit is selected.

In probability proportional to size (PPS) sampling, a unit's selection probability is proportional to its size measure. PROC SURVEYSELECT provides the following methods that select units with probability proportional to size (PPS): PPS sampling without replacement, PPS sampling with replacement, PPS systematic sampling, PPS sequential sampling, Brewer's method, Murthy's method, and Sampford's method. PPS sampling is often used in cluster sampling, where you select clusters (or groups of sampling units) of varying

size in the first stage of selection. For example, clusters might be schools, hospitals, or geographical areas, and the final sampling units might be students, patients, or citizens. Cluster sampling can provide efficiencies in frame construction and other survey operations. For more information, see Lohr (2010); Kalton (1983); Kish (1965), in addition to the other references cited in the following sections.

The following sections give detailed descriptions of the sample selection methods available in PROC SURVEYSELECT. In these sections,  $n_h$  denotes the sample size (the number of units in the sample) for stratum  $h$ , and  $N_h$  denotes the population size (number of units in the population) for stratum  $h$ , for  $h = 1, 2, \dots, H$ . When the sample design is not stratified,  $n$  denotes the sample size, and  $N$  denotes the population size. For PPS sampling,  $M_{hi}$  represents the size measure for unit  $i$  in stratum  $h$ ,  $M_h$  is the total of all size measures for the population of stratum  $h$ , and  $Z_{hi} = M_{hi}/M_h$  is the relative size of unit  $i$  in stratum  $h$ .

### Simple Random Sampling

The method of simple random sampling (**METHOD=SRS**) selects units with equal probability and without replacement. Each possible sample of  $n$  different units out of  $N$  has the same probability of being selected. The selection probability for each individual unit equals  $n/N$ . When you request stratified sampling with a **STRATA** statement, PROC SURVEYSELECT selects samples independently within strata. The selection probability for a unit in stratum  $h$  equals  $n_h/N_h$  for stratified simple random sampling.

By default, PROC SURVEYSELECT uses Floyd's ordered hash table algorithm for simple random sampling. This algorithm is fast, efficient, and appropriate for large data sets. See Bentley and Floyd (1987) and Bentley and Knuth (1986) for details.

If there is not enough memory available for Floyd's algorithm, PROC SURVEYSELECT switches to the sequential algorithm of Fan, Muller, and Rezucha (1962), which requires less memory but might require more time to select the sample. When PROC SURVEYSELECT uses the alternative sequential algorithm, it writes a note to the log. To request the sequential algorithm, even if enough memory is available for Floyd's algorithm, you can specify **METHOD=SRS2** in the PROC SURVEYSELECT statement.

### Unrestricted Random Sampling

The method of unrestricted random sampling (**METHOD=URS**) selects units with equal probability and with replacement. Because units are selected with replacement, a unit can be selected for the sample more than once. The expected number of hits (selections) for each unit equals  $n/N$  when sampling without stratification. For stratified sampling, the expected number of hits for a unit in stratum  $h$  equals  $n_h/N_h$ . Note that the expected number of hits exceeds 1 when the sample size  $n$  is greater than the population size  $N$ .

For unrestricted random sampling, by default, the output data set contains a single copy of each unit selected, even when a unit is selected more than once, and the variable **NumberHits** records the number of hits (selections) for each unit. If you specify the **OUTHITS** option, the output data set contains  $m$  copies of a sampling unit for which **NumberHits** equals  $m$ . For example, with the **OUTHITS** option a unit that is selected three times is represented by three copies in the output data set. For information about the contents of the output data set, see the section “**Sample Output Data Set**” on page 8072.

## Systematic Random Sampling

The method of systematic random sampling (**METHOD=SYS**) selects units at a fixed interval throughout the sampling frame or stratum after a random start. If you specify the sample size (or the stratum sample sizes) with the **SAMPSIZE=** option, PROC SURVEYSELECT uses a fractional interval to provide exactly the specified sample size. The interval equals  $N/n$ , or  $N_h/n_h$  for stratified sampling. The selection probability for each unit equals  $n/N$ , or  $n_h/N_h$  for stratified sampling. If you specify the sampling rate (or the stratum sampling rates) with the **SAMPRATE=** option, PROC SURVEYSELECT uses the inverse of the rate as the interval for systematic selection. The selection probability for each unit equals the specified rate.

Systematic random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum at equal intervals, thus providing implicit stratification. You can use the **CONTROL** statement to order the input data set by the CONTROL variables before sample selection. If you also use a **STRATA** statement, PROC SURVEYSELECT sorts by the CONTROL variables within strata. If you do not specify a CONTROL statement, PROC SURVEYSELECT applies systematic selection to the observations in the order in which they appear in the input data set.

## Sequential Random Sampling

If you specify the **METHOD=SEQ** option and do not include a **SIZE** statement, PROC SURVEYSELECT uses the equal probability version of Chromy's method for sequential random sampling. This method selects units sequentially with equal probability and without replacement. See Chromy (1979) and Williams and Chromy (1980) for details. See the section "PPS Sequential Sampling" on page 8064 for a description of Chromy's PPS selection method.

Sequential random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum, thus providing implicit stratification according to the order of units in the frame or stratum. You can use the **CONTROL** statement to sort the input data set by the CONTROL variables before sample selection. If you also use a **STRATA** statement, PROC SURVEYSELECT sorts by the CONTROL variables within strata. By default (or if you specify the **SORT=SERP** option), the procedure uses hierarchic serpentine ordering for sorting. If you specify the **SORT=NEST** option, the procedure uses nested sorting. See the section "Sorting by CONTROL Variables" on page 8057 for descriptions of serpentine and nested sorting. If you do not specify a CONTROL statement, PROC SURVEYSELECT applies sequential selection to the observations in the order in which they appear in the input data set.

Following Chromy's method of sequential selection, PROC SURVEYSELECT randomly chooses a starting unit from the entire stratum (or frame, if the design is not stratified). With this unit as the first one, the procedure treats the stratum units as a closed loop. This is done so that all pairwise (joint) selection probabilities are positive and an unbiased variance estimator can be obtained. The procedure numbers units sequentially from the random start to the end of the stratum and then continues from the beginning of the stratum until all units are numbered.

Beginning with the randomly chosen starting unit, PROC SURVEYSELECT accumulates the expected number of selections (hits), where the expected number of selections  $E(S_{hi})$  equals  $n_h/N_h$  for all units  $i$  in stratum  $h$ . The procedure computes

$$I_{hi} = \text{Int}\left(\sum_{j=1}^i E(S_{hj})\right) = \text{Int}(in_h/N_h)$$

$$F_{hi} = \text{Frac}\left(\sum_{j=1}^i E(S_{hj})\right) = \text{Frac}(in_h/N_h)$$

where  $\text{Int}(\cdot)$  denotes the integer part of the number, and  $\text{Frac}(\cdot)$  denotes the fractional part.

Considering each unit sequentially, Chromy's method determines whether unit  $i$  is selected by comparing the total number of selections for the first  $(i - 1)$  units,

$$T_{h(i-1)} = \sum_{j=1}^{i-1} S_{hj}$$

with the value of  $I_{h(i-1)}$ .

If  $T_{h(i-1)} = I_{h(i-1)}$ , Chromy's method determines whether or not unit  $i$  is selected as follows. If  $F_{hi} = 0$  or  $F_{h(i-1)} > F_{hi}$ , then unit  $i$  is selected with certainty. Otherwise, unit  $i$  is selected with probability

$$(F_{hi} - F_{h(i-1)}) / (1 - F_{h(i-1)})$$

If  $T_{h(i-1)} = (I_{h(i-1)} + 1)$ , Chromy's method determines whether or not unit  $i$  is selected as follows. If  $F_{hi} = 0$  or  $F_{hi} > F_{h(i-1)}$ , then the unit is not selected. Otherwise, unit  $i$  is selected with probability

$$F_{hi} / F_{h(i-1)}$$

## Bernoulli Sampling

Bernoulli sampling, which you request by specifying the `METHOD=BERNOULLI` option, is an equal probability selection method for which the total sample size is not fixed. PROC SURVEYSELECT performs an independent random selection trial for each of the  $N$  sampling units in the input data set by using the constant inclusion probability (sampling rate) that you specify. You can specify a single value of the inclusion probability  $\pi$  to use for all  $N$  sampling units, or you can specify separate stratum-level values of  $\pi_h$  to use for the  $N_h$  units in each stratum.

You provide the inclusion probability (or probabilities) by specifying the `SAMPRATE=` option. For stratified sampling (which you request with the `STRATA` statement), you can specify the same sampling rate for each stratum by using the `SAMPRATE=r` option. Or you can specify different sampling rates for different strata by using the `SAMPRATE=(values)` or `SAMPRATE=SAS-data-set` option.

In Bernoulli sampling, the sample size  $n$  (number of units selected) is not fixed; it is a random variable that has a binomial distribution with parameters  $N$  and  $\pi$ . The possible values of  $n$  range from 0 to  $N$ . The expected value of the sample size is  $\pi N$  (or  $\pi_h N_h$  for stratified sampling), and the variance of the sample size is  $\pi(1 - \pi)N$ .

For Bernoulli sampling, the selection probability is the inclusion probability that you specify by using the `SAMPRATE=` option. PROC SURVEYSELECT computes the sampling weight as the inverse of the selection probability, which is  $1/\pi$ . For Bernoulli sampling, the procedure also computes an adjusted sampling weight as the ratio of the total number of sampling units to the actual sample size,  $N/n$  (or  $N_h/n_h$  for stratified sampling). The joint selection probability for any two distinct units is  $\pi^2$ . See Särndal, Swensson, and Wretman (1992) for more information.

You can specify the `STATS` option to include the following information in the `OUT=` output data set for `METHOD=BERNOULLI`: total number of sampling units, selection probability, expected sample size, actual sample size, sampling weight, and adjusted sampling weight.

## Poisson Sampling

Poisson sampling, which you request by specifying the `METHOD=POISSON` option, is an unequal probability sampling method for which the total sample size is not fixed. A generalization of Bernoulli sampling, Poisson sampling also consists of independent random selection trials for the  $N$  sampling units in the input data set, but the sampling units can have different inclusion probabilities. You provide inclusion probabilities for Poisson sampling in the variable that you specify in the `SIZE` statement.

The expected value of the sample size for Poisson sampling is  $\sum_i \pi_i$ , where  $\pi_i$  is the inclusion probability for sampling unit  $i$ . The variance of the sample size is  $\sum_i \pi_i(1 - \pi_i)$ .

For Poisson sampling, the selection probability for unit  $i$  is the inclusion probability  $\pi_i$  that you specify by using the `SIZE` statement. PROC SURVEYSELECT computes the sampling weight for unit  $i$  as the inverse of the selection probability, which is  $1/\pi_i$ . The joint selection probability for any two distinct units  $i$  and  $j$  is  $\pi_i \pi_j$  for Poisson sampling. See Särndal, Swensson, and Wretman (1992) for more information.

## PPS Sampling without Replacement

If you specify the `METHOD=PPS` option, PROC SURVEYSELECT selects units with probability proportional to size and without replacement. The selection probability for unit  $i$  in stratum  $h$  equals  $n_h Z_{hi}$ , where  $n_h$  is the sample size for stratum  $h$ , and  $Z_{hi}$  is the relative size of unit  $i$  in stratum  $h$ . The relative size equals  $M_{hi}/M_{h\cdot}$ , which is the ratio of the size measure for unit  $i$  in stratum  $h$  ( $M_{hi}$ ) to the total of all size measures for stratum  $h$  ( $M_{h\cdot}$ ).

Because selection probabilities cannot exceed 1, the relative size for each unit must not exceed  $1/n_h$  for `METHOD=PPS`. This requirement can be expressed as  $Z_{hi} \leq 1/n_h$ , or equivalently,  $M_{hi} \leq M_{h\cdot}/n_h$ . If your size measures do not meet this requirement, you can adjust the size measures by using the `MAXSIZE=` or `MINSIZE=` option. Or you can request certainty selection for the larger units by using the `CERTSIZE=` or `CERTSIZE=P=` option. Alternatively, you can use a selection method that does not have this relative size restriction, such as PPS with minimum replacement (`METHOD=PPS_SEQ`).

PROC SURVEYSELECT uses the Hanurav-Vijayan algorithm for PPS selection without replacement. Hanurav (1967) introduced this algorithm for the selection of two units per stratum, and Vijayan (1968) generalized it for the selection of more than two units. The algorithm enables computation of joint selection probabilities and provides joint selection probability values that usually ensure nonnegativity and stability of the Sen-Yates-Grundy variance estimator. For details, see Fox (1989); Golmant (1990); Watts (1991).

Notation in the remainder of this section drops the stratum subscript  $h$  for simplicity, but selection is still done independently within strata if you specify a stratified design. For a stratified design,  $n$  now denotes the sample size for the current stratum,  $N$  denotes the stratum population size, and  $M_i$  denotes the size measure for unit  $i$  in the stratum. If the design is not stratified, this notation applies to the entire sampling frame.

According to the Hanurav-Vijayan algorithm, PROC SURVEYSELECT first orders units within the stratum in ascending order by size measure, so that  $M_1 \leq M_2 \leq \dots \leq M_N$ . Then the procedure selects the PPS sample of  $n$  observations as follows:

1. The procedure randomly chooses one of the integers  $1, 2, \dots, n$  with probability  $\theta_1, \theta_2, \dots, \theta_n$ , where

$$\theta_i = n(Z_{N-n+i+1} - Z_{N-n+i})(T + iZ_{N-n+1})/T$$

where  $Z_j = M_j/M$  and

$$T = \sum_{j=1}^{N-n} Z_j$$

By definition,  $Z_{N+1} = 1/n$  to ensure that  $\sum_{i=1}^n \theta_i = 1$ .

2. If  $i$  is the integer selected in step 1, the procedure includes the last  $(n - i)$  units of the stratum in the sample, where the units are ordered by size measure as described previously. The procedure then selects the remaining  $i$  units according to steps 3 through 6.
3. The procedure defines new normed size measures for the remaining  $(N - n + i)$  stratum units that were not selected in steps 1 and 2:

$$Z_j^* = \begin{cases} Z_j/(T + iZ_{N-n+1}) & \text{for } j = 1, \dots, N - n + 1 \\ Z_{N-n+1}/(T + iZ_{N-n+1}) & \text{for } j = N - n + 2, \dots, N - n + i \end{cases}$$

4. The procedure selects the next unit from the first  $(N - n + 1)$  stratum units with probability proportional to  $a_j(1)$ , where

$$\begin{aligned} a_1(1) &= iZ_1^* \\ a_j(1) &= iZ_j^* \prod_{k=1}^{j-1} (1 - (i - 1) P_k) \quad \text{for } j = 2, \dots, N - n + 1 \end{aligned}$$

and

$$P_k = M_k/(M_{k+1} + M_{k+2} + \dots + M_{N-n+i})$$

5. If stratum unit  $j_1$  is the unit selected in step 4, then the procedure selects the next unit from units  $(j_1 + 1)$  through  $(N - n + 2)$  with probability proportional to  $a_j(2, j_1)$ , where

$$\begin{aligned} a_{j_1+1}(2, j_1) &= (i - 1)Z_{j_1+1}^* \\ a_j(2, j_1) &= (i - 1)Z_j^* \prod_{k=j_1+1}^{j-1} (1 - (i - 2)P_k) \quad \text{for } j = j_1 + 2, \dots, N - n + 2 \end{aligned}$$

6. The procedure repeats step 5 until all  $n$  sample units are selected.

If you specify the **JTPROBS** option, PROC SURVEYSELECT computes the joint selection probabilities for all pairs of selected units in each stratum. The joint selection probability for units  $i$  and  $j$  in the stratum equals

$$P_{(ij)} = \sum_{r=1}^n \theta_r K_{ij}^{(r)}$$

where

$$K_{ij} = \begin{cases} 1 & N - n + r < i \leq N - 1 \\ rZ_{N-n+1}/(T + rZ_{N-n+1}) & N - n < i \leq N - n + r, \quad j > N - n + r \\ rZ_i/(T + rZ_{N-n+1}) & 1 \leq i \leq N - n, \quad j > N - n + r \\ \pi_{ij}^{(r)} & j \leq N - n + r \end{cases}$$

$$\pi_{ij}^{(r)} = \frac{r(r - 1)}{2} P_i Z_j \prod_{k=1}^{i-1} (1 - P_k)$$

$$P_k = M_k/(M_{k+1} + M_{k+2} + \dots + M_{N-n+r})$$

## PPS Sampling with Replacement

If you specify the `METHOD=PPS_WR` option, PROC SURVEYSELECT selects units with probability proportional to size and with replacement. The procedure makes  $n_h$  independent random selections from the stratum of  $N_h$  units, selecting with probability  $Z_{hi} = M_{hi}/M_h$ . Because units are selected with replacement, a unit can be selected for the sample more than once. The expected number of hits (selections) for unit  $i$  in stratum  $h$  equals  $n_h Z_{hi}$ . If you specify the `JTPROBS` option, PROC SURVEYSELECT computes the joint expected number of hits for all pairs of selected units in each stratum. The joint expected number of hits for units  $i$  and  $j$  in stratum  $h$  equals

$$P_{h(ij)} = \begin{cases} n_h(n_h - 1)Z_{hi}Z_{hj} & \text{for } j \neq i \\ n_h(n_h - 1)Z_{hi}Z_{hi}/2 & \text{for } j = i \end{cases}$$

## PPS Systematic Sampling

If you specify the `METHOD=PPS_SYS` option, PROC SURVEYSELECT selects units by systematic random sampling with probability proportional to size. Systematic sampling selects units at a fixed interval throughout the stratum or sampling frame after a random start. PROC SURVEYSELECT uses a fractional interval to provide exactly the specified sample size. The interval equals  $M_h/n_h$  for stratified sampling and  $M/n$  for sampling without stratification. Depending on the sample size and the values of the size measures, it might be possible for a unit to be selected more than once. The expected number of hits (selections) for unit  $i$  in stratum  $h$  equals  $n_h M_{hi}/M_h = n_h Z_{hi}$ . See Cochran (1977, pp. 265–266) and Madow (1949) for details.

Systematic random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum at equal intervals, thus providing implicit stratification. You can use the `CONTROL` statement to order the input data set by the `CONTROL` variables before sample selection. If you also use a `STRATA` statement, PROC SURVEYSELECT sorts by the `CONTROL` variables within strata. If you do not specify a `CONTROL` statement, PROC SURVEYSELECT applies systematic selection to the observations in the order in which they appear in the input data set.

## PPS Sequential Sampling

If you specify the `METHOD=PPS_SEQ` option, PROC SURVEYSELECT uses Chromy's method of sequential random sampling. See Chromy (1979) and Williams and Chromy (1980) for details. Chromy's method selects units sequentially with probability proportional to size and with minimum replacement. Selection *with minimum replacement* means that the actual number of hits for a unit can equal the integer part of the expected number of hits for that unit, or the next largest integer. This can be compared to selection *without replacement*, where each unit can be selected only once, so the number of hits can equal 0 or 1. The other alternative is selection *with replacement*, where there is no restriction on the number of hits for each unit, so the number of hits can equal  $0, 1, \dots, n_h$ , where  $n_h$  is the stratum sample size.

Sequential random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum, thus providing implicit stratification according to the order of units in the frame or stratum. You can use the `CONTROL` statement to sort the input data set by the `CONTROL` variables before sample selection. If you also use a `STRATA` statement, PROC SURVEYSELECT sorts by the `CONTROL` variables within strata. By default (or if you specify the `SORT=SERP` option), the procedure uses hierarchic

serpentine ordering to sort the sampling frame by the CONTROL variables within strata. If you specify the **`SORT=NEST`** option, the procedure uses nested sorting. See the section “**Sorting by CONTROL Variables**” on page 8057 for descriptions of serpentine and nested sorting. If you do not specify a CONTROL statement, PROC SURVEYSELECT applies sequential selection to the observations in the order in which they appear in the input data set.

According to Chromy’s method of sequential selection, PROC SURVEYSELECT first chooses a starting unit randomly from the entire stratum, with probability proportional to size. The procedure uses this unit as the first one and treats the stratum observations as a closed loop. This is done so that all pairwise (joint) expected number of hits are positive and an unbiased variance estimator can be obtained. The procedure numbers observations sequentially from the random start to the end of the stratum and then continues from the beginning of the stratum until all units are numbered.

Beginning with the randomly chosen starting unit, Chromy’s method partitions the ordered stratum sampling frame into  $n_h$  zones of equal size. There is one selection from each zone and a total of  $n_h$  hits (selections), although fewer than  $n_h$  distinct units might be selected. Beginning with the random start, the procedure accumulates the expected number of hits and computes

$$E(S_{hi}) = n_h Z_{hi}$$

$$I_{hi} = \text{Int}\left(\sum_{j=1}^i E(S_{hj})\right)$$

$$F_{hi} = \text{Frac}\left(\sum_{j=1}^i E(S_{hj})\right)$$

where  $E(S_{hi})$  represents the expected number of hits for unit  $i$  in stratum  $h$ ,  $\text{Int}(\cdot)$  denotes the integer part of the number, and  $\text{Frac}(\cdot)$  denotes the fractional part.

Considering each unit sequentially, Chromy’s method determines the actual number of hits for unit  $i$  by comparing the total number of hits for the first  $(i - 1)$  units,

$$T_{h(i-1)} = \sum_{j=1}^{i-1} S_{hj}$$

with the value of  $I_{h(i-1)}$ .

If  $T_{h(i-1)} = I_{h(i-1)}$ , Chromy’s method determines the total number of hits for the first  $i$  units as follows. If  $F_{hi} = 0$  or  $F_{h(i-1)} > F_{hi}$ , then  $T_{hi} = I_{hi}$ . Otherwise,  $T_{hi} = I_{hi} + 1$  with probability

$$(F_{hi} - F_{h(i-1)}) / (1 - F_{h(i-1)})$$

And the number of hits for unit  $i$  equals  $T_{hi} - T_{h(i-1)}$ .

If  $T_{h(i-1)} = (I_{h(i-1)} + 1)$ , Chromy’s method determines the total number of hits for the first  $i$  units as follows. If  $F_{hi} = 0$ , then  $T_{hi} = I_{hi}$ . If  $F_{hi} > F_{h(i-1)}$ , then  $T_{hi} = I_{hi} + 1$ . Otherwise,  $T_{hi} = I_{hi} + 1$  with probability

$$F_{hi} / F_{h(i-1)}$$

### Brewer's PPS Method

Brewer's method (`METHOD=PPS_BREWER`) selects two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit  $i$  in stratum  $h$  equals  $2M_{hi}/M_h = 2Z_{hi}$ . (Because selection probabilities cannot exceed 1, the relative size for each unit,  $Z_{hi}$ , must not exceed  $1/2$ .)

Brewer's algorithm first selects a unit with probability

$$\frac{Z_{hi}(1 - Z_{hi})}{D_h(1 - 2Z_{hi})}$$

where

$$D_h = \sum_{i=1}^{N_h} \frac{Z_{hi}(1 - Z_{hi})}{1 - 2Z_{hi}}$$

Then a second unit is selected from the remaining units with probability

$$\frac{Z_{hj}}{1 - Z_{hi}}$$

where unit  $i$  is the first unit selected. The joint selection probability for units  $i$  and  $j$  in stratum  $h$  equals

$$P_{h(ij)} = \frac{2Z_{hi}Z_{hj}}{D_h} \left( \frac{1 - Z_{hi} - Z_{hj}}{(1 - 2Z_{hi})(1 - 2Z_{hj})} \right)$$

See Cochran (1977, pp. 261–263) and Brewer (1963) for details. Brewer's method yields the same selection probabilities and joint selection probabilities as Durbin's method. See Cochran (1977) and Durbin (1967) for details.

### Murthy's PPS Method

Murthy's method (`METHOD=PPS_MURTHY`) selects two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit  $i$  in stratum  $h$  equals

$$P_{hi} = Z_{hi}(1 + K_h - (Z_{hi}/(1 - Z_{hi})))$$

where  $Z_{hi} = M_{hi}/M_h$  and

$$K_h = \sum_{j=1}^{N_h} (Z_{hj}/(1 - Z_{hj}))$$

Murthy's algorithm first selects a unit with probability  $Z_{hi}$ . Then a second unit is selected from the remaining units with probability  $Z_{hj}/(1 - Z_{hi})$ , where unit  $i$  is the first unit selected. The joint selection probability for units  $i$  and  $j$  in stratum  $h$  equals

$$P_{h(ij)} = Z_{hi}Z_{hj} \left( \frac{2 - Z_{hi} - Z_{hj}}{(1 - Z_{hi})(1 - Z_{hj})} \right)$$

See Cochran (1977, pp. 263–265) and Murthy (1957) for details.

## Sampford's PPS Method

Sampford's method (METHOD=PPS\_SAMPFORD) is an extension of Brewer's method that selects more than two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit  $i$  in stratum  $h$  equals  $n_h M_{hi} / M_h = n_h Z_{hi}$ . (Because selection probabilities cannot exceed 1, the relative size for each unit,  $Z_{hi}$ , must not exceed  $1/n_h$ .)

Sampford's method first selects a unit from stratum  $h$  with probability  $Z_{hi}$ . Then subsequent units are selected with probability proportional to

$$\lambda_{hi} = Z_{hi} / (1 - n_h Z_{hi})$$

and with replacement. If the same unit appears more than once in the sample of size  $n_h$ , then Sampford's algorithm rejects that sample and selects a new sample. The sample is accepted if it contains  $n_h$  distinct units.

If you specify the JTPROBS option, PROC SURVEYSELECT computes the joint selection probabilities for all pairs of selected units in each stratum. The joint selection probability for units  $i$  and  $j$  in stratum  $h$  equals

$$P_{h(ij)} = K_h \lambda_{hi} \lambda_{hj} \sum_{t=2}^{n_h} \left( [t - n_h (Z_{hi} + Z_{hj})] L_{h,(n_h-t)}(\bar{ij}) \right) / n_h^{t-2}$$

where

$$K_h = 1 / \sum_{t=1}^{n_h} (t L_{h,(n_h-t)} / n_h^t)$$

$$L_{h,m} = \sum_{S_h(m)} \lambda_{hi_1} \lambda_{hi_2} \cdots \lambda_{hi_m}$$

and  $S_h(m)$  denotes all possible samples of size  $m$ , for  $m = 1, 2, \dots, N_h$ . The sum  $L_{h,m}(\bar{ij})$  is defined similarly to  $L_{h,m}$  but sums over all possible samples of size  $m$  that do not include units  $i$  and  $j$ . See Cochran (1977, pp. 262–263) and Sampford (1967) for details.

## Sample Size Allocation

If you specify the ALLOC= option in the STRATA statement, PROC SURVEYSELECT allocates the total sample size among the strata according to the method that you request. PROC SURVEYSELECT provides proportional allocation (ALLOC=PROP), optimal allocation (ALLOC=OPTIMAL), and Neyman allocation (ALLOC=NEYMAN). For more information about these allocation methods, see Lohr (2010); Kish (1965); Cochran (1977). You can also directly provide the allocation proportions by using the ALLOC=(values) option or the ALLOC=SAS-data-set option. Then PROC SURVEYSELECT allocates the sample size among the strata according to the proportions that you provide. Allocation proportions are the relative stratum sample sizes,  $n_h/n$ , where  $n_h$  is the sample size for stratum  $h$  and  $n$  is the total sample size.

You can use the SAMPSIZE= $n$  option in the PROC SURVEYSELECT statement to specify the total sample size to allocate among the strata. Or you can specify the desired margin of error in the MARGIN= option in the STRATA statement, and PROC SURVEYSELECT computes the stratum sample sizes necessary to achieve that margin of error for the allocation method that you request. See the section “Specifying the Margin of Error” on page 8069 for details.

## Proportional Allocation

When you specify the `ALLOC=PROP` option in the `STRATA` statement, PROC SURVEYSELECT allocates the total sample size among the strata in proportion to the stratum sizes, where the stratum size is the number of sampling units in the stratum. The allocation proportion of the total sample size for stratum  $h$  equals

$$f_h^* = N_h/N$$

where  $N_h$  is the number of sampling units in stratum  $h$  and  $N$  is the total number of sampling units for all strata. If you specify the total sample size  $n$  in the `SAMPsize=` option in the `PROC SURVEYSELECT` statement, the procedure computes the target sample size for stratum  $h$  as

$$n_h^* = f_h^* \times n$$

The target sample size values,  $n_h^*$ , might not be integers, but the stratum sample sizes are required to be integers. PROC SURVEYSELECT uses a rounding algorithm to convert the  $n_h^*$  to integer values  $n_h$  and maintain the requested total sample size  $n$ . The rounding algorithm includes the restriction that all values of  $n_h$  must be at least 1, so that at least one unit is selected from each stratum. If you specify a minimum stratum sample size  $n_{min}$  in the `ALLOCmin=` option in the `STRATA` statement, then all values of  $n_h$  are required to be at least  $n_{min}$ . For without-replacement selection methods, PROC SURVEYSELECT also requires that each stratum sample size must not exceed the total number of sampling units in the stratum,  $n_h \leq N_h$ . If a target stratum sample size exceeds the number of units in the stratum, PROC SURVEYSELECT allocates the maximum number of units,  $N_h$ , to the stratum, and then allocates the remaining total sample size proportionally among the remaining strata.

PROC SURVEYSELECT provides the target allocation proportions  $f_h^*$  in the output data set variable `AllocProportion`. The variable `ActualProportion` contains the actual proportions for the allocated sample sizes  $n_h$ . For stratum  $h$ , the actual proportion is computed as

$$f_h = n_h/n$$

where  $n_h$  is the allocated sample size for stratum  $h$  and  $n$  is the total sample size. The actual proportions  $f_h$  can differ from the target allocation proportions  $f_h^*$  due to rounding, the requirement that  $n_h \geq 1$  (or  $n_h \geq n_{min}$ ), and the requirement that  $n_h \leq N_h$  for without-replacement selection methods.

## Optimal Allocation

When you specify the `ALLOC=OPTIMAL` option in the `STRATA` statement, PROC SURVEYSELECT allocates the total sample size among the strata in proportion to stratum sizes, stratum costs, and stratum variances. You provide the stratum costs and variances by using the `COST=` and `VAR=` options, respectively.

Optimal allocation minimizes the overall variance for a specified cost, or equivalently minimizes the overall cost for a specified variance. For details, see Lohr (2010); Cochran (1977); Kish (1965). For optimal allocation, PROC SURVEYSELECT computes the proportion of the total sample size for stratum  $h$  as

$$f_h^* = \frac{N_h S_h}{\sqrt{C_h}} / \sum_{i=1}^H \frac{N_i S_i}{\sqrt{C_i}}$$

where  $N_h$  is the number of sampling units in stratum  $h$ ,  $S_h$  is the standard deviation within stratum  $h$ ,  $C_h$  is the unit cost within stratum  $h$ , and  $H$  is the total number of strata.

If you specify the total sample size  $n$  in the `SAMPsize=` option in the `PROC SURVEYSELECT` statement, the procedure computes the target sample size for stratum  $h$  as

$$n_h^* = f_h^* \times n$$

As described in the section “Proportional Allocation” on page 8068, the values of  $n_h^*$  are converted to integer sample sizes  $n_h$  by using a rounding algorithm that requires the sum of the stratum sample sizes to equal  $n$ . The final stratum sample sizes  $n_h$  are also required to be at least 1, or at least  $n_{min}$  if you specify a minimum stratum sample size in the `ALLOCmin=` option in the `STRATA` statement. For without-replacement selection methods, the final sample sizes cannot exceed the stratum sizes.

## Neyman Allocation

When you specify the `ALLOC=NEYMAN` option in the `STRATA` statement, `PROC SURVEYSELECT` allocates the total sample size among the strata in proportion to stratum sizes and stratum variances. Neyman allocation is a special case of optimal allocation (described in the section “Optimal Allocation” on page 8068), where the costs per unit are the same for all strata. For Neyman allocation, the proportion of the total sample size for stratum  $h$  is computed as

$$f_h^* = N_h S_h / \sum_{i=1}^H N_i S_i$$

If you specify the total sample size  $n$  in the `SAMPsize=` option in the `PROC SURVEYSELECT` statement, the procedure computes the target sample size for stratum  $h$  as  $n_h^* = f_h^* \times n$ . The  $n_h^*$  are converted to integer sample sizes  $n_h$  by using a rounding algorithm that requires the sum of the stratum sizes to equal  $n$ . The final sample sizes  $n_h$  are required to be at least 1, or at least  $n_{min}$  if you specify a minimum sample size in the `ALLOCmin=` option in the `STRATA` statement. For without-replacement selection methods, the final sample sizes must not exceed the stratum sizes.

## Specifying the Margin of Error

Instead of specifying the total sample size to allocate among the strata, you can specify the desired margin of error for estimating the overall mean from the stratified sample. Based on the requested allocation method and the stratum variances that you provide, `PROC SURVEYSELECT` computes the stratum sample sizes that are required to achieve this margin of error. You specify the margin of error in the `MARGIN=` option in the `STRATA` statement, and you provide stratum variances in the `VAR=` option. You can use the `MARGIN=` option with any allocation method (proportional, optimal, or Neyman) or with allocation proportions that you provide (`ALLOC=(values)` or `ALLOC=SAS-data-set`).

The margin of error  $e$  is the half-width of the  $100(1 - \alpha)\%$  confidence interval for the overall mean based on the stratified sample,

$$e = z_{\alpha/2} \times \sqrt{\text{Var}(\bar{y}_{str})}$$

where  $\text{Var}(\bar{y}_{str})$  is the variance of the estimate of the mean from the stratified sample and  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the standard normal distribution. You can specify the value of  $\alpha$  in the `ALPHA=` option in the `STRATA` statement. By default, `PROC SURVEYSELECT` uses a 95% confidence interval (`ALPHA=0.05`).

For the specified margin of error  $e$ , PROC SURVEYSELECT computes the target stratum sample sizes  $n_h^*$  for without-replacement selection methods as

$$n_h^* = f_h^* \left( \sum_{i=1}^H N_i^2 S_i^2 / f_i^* \right) / \left( (eN/z_{\alpha/2})^2 + \sum_{i=1}^H N_i S_i^2 \right)$$

where  $N_i$  is the number of sampling units in stratum  $i$ ,  $S_i^2$  is the variance within stratum  $i$ ,  $N$  is the total number of sampling units for all strata, and  $H$  is the total number of strata.

The values of  $f_h^*$  are the stratum allocation proportions, which PROC SURVEYSELECT computes according to the allocation method that you request. See the sections “[Proportional Allocation](#)” on page 8068, “[Optimal Allocation](#)” on page 8068, and “[Neyman Allocation](#)” on page 8069 for details.

For with-replacement selection methods, PROC SURVEYSELECT computes the target stratum sample sizes as

$$n_h^* = f_h^* \left( \sum_{i=1}^H N_i^2 S_i^2 / f_i^* \right) / (eN/z_{\alpha/2})^2$$

See Lohr (2010, p. 91), Cochran (1977, Chapter 5), and Arkin (1984, Chapter 10) for more information.

The target sample size values  $n_h^*$  might not be integers, but the stratum sample sizes are required to be integers. PROC SURVEYSELECT rounds all fractional target sample sizes up to integer sample sizes. If you specify a minimum stratum sample size  $n_{min}$  in the `ALLOCMIN=` option in the `STRATA` statement, then all stratum sample sizes  $n_h$  are required to be at least  $n_{min}$ .

For without-replacement selection methods, a stratum sample size cannot exceed the number of units in the stratum. If a target stratum sample size does exceed the number of units in the stratum, the procedure sets  $n_h = N_h$  for that stratum, removes the stratum from the variance computation (because it contributes nothing to the sampling error), revises the allocation proportions  $f_h^*$  for the remaining strata, and computes the stratum sample sizes again. If a stratum sample size equals the number of units in its stratum, the procedure also removes that stratum from the variance computation and revises the sample sizes for the remaining strata. See Cochran (1977, p. 104) and Arkin (1984, p. 176) for details.

When you specify the `STATS` option with the `MARGIN=` option in the `STRATA` statement, PROC SURVEYSELECT displays the expected margin of error for the sample allocation. The expected margin of error (for the overall mean based on the stratified sample) is computed from the stratum sizes ( $N_i$ ), the stratum variances that you provide ( $S_i^2$ ), and the allocated stratum sample sizes that the procedure computes ( $n_i$ ). For without-replacement selection methods, the expected margin of error is

$$e = z_{\alpha/2} \times \frac{1}{N} \sqrt{\sum_{i=1}^H \frac{N_i^2 S_i^2}{n_i} \left(1 - \frac{n_i}{N}\right)}$$

For with-replacement selection methods, the expected margin of error is

$$e = z_{\alpha/2} \times \frac{1}{N} \sqrt{\sum_{i=1}^H \frac{N_i^2 S_i^2}{n_i}}$$

The expected margin of error should be less than or equal to the value specified in the `MARGIN=` option. Any difference between the expected margin and the specified value is due to rounding the target stratum sample sizes up to integer values and increasing stratum sample sizes to equal the required minimum value (`ALLOCMIN=`).

## Secondary Input Data Set

The primary input data set for PROC SURVEYSELECT is the `DATA=` data set, which contains the list of units from which the sample is selected. You can use a secondary input data set to provide stratum-level design and selection information, such as sample sizes or rates, certainty size values, or stratum costs. This secondary input data set is sometimes called the `SAMPSIZE=` input data set. You can provide stratum sample sizes in the `_NSIZE_` (or `SampleSize`) variable in the `SAMPSIZE=` data set.

The secondary input data set must contain all the `STRATA` variables, with the same type and length as in the `DATA=` data set. The `STRATA` groups should appear in the same order in the secondary data set as in the `DATA=` data set. You can name only one secondary data set in each invocation of the procedure.

You must name the secondary input data set in the appropriate `PROC SURVEYSELECT` or `STRATA` option, and use the designated variable name to provide the stratum-level values. For example, if you want to provide stratum-level costs for sample allocation, you name the secondary data set in the `COST=SAS-data-set` option in the `STRATA` statement. The data set must include the stratum costs in a variable named `_COST_`. You can use the secondary input data set for more than one option if it is appropriate for your design. For example, the secondary data set can include both stratum costs and stratum variances, which are required for optimal allocation (`ALLOC=OPTIMAL`).

Instead of using a separate secondary input data set, you can include secondary information in the `DATA=` data set along with the sampling frame. When you include secondary information in the `DATA=` data set, name the `DATA=` data set in the appropriate options, and include the required variables in the `DATA=` data set.

Table 95.3 lists the available secondary data set variables, together with their descriptions and the corresponding options.

**Table 95.3** PROC SURVEYSELECT Secondary Data Set Variables

| Variable                | Description           | Statement           | Option                   |
|-------------------------|-----------------------|---------------------|--------------------------|
| <code>_ALLOC_</code>    | Allocation proportion | <code>STRATA</code> | <code>ALLOC=</code>      |
| <code>_CERTP_</code>    | Certainty proportion  | <code>PROC</code>   | <code>CERTSIZE=P=</code> |
| <code>_CERTSIZE_</code> | Certainty size        | <code>PROC</code>   | <code>CERTSIZE=</code>   |
| <code>_COST_</code>     | Cost                  | <code>STRATA</code> | <code>COST=</code>       |
| <code>_MAXSIZE_</code>  | Maximum size          | <code>PROC</code>   | <code>MAXSIZE=</code>    |

## Sample Output Data Set

PROC SURVEYSELECT selects a sample and creates a SAS data set that contains the sample of selected units, unless you specify the **NOSAMPLE** option in the **STRATA** statement. If you specify the **NOSAMPLE** option, PROC SURVEYSELECT allocates the total sample size among the strata but does not select the sample. When you specify the **NOSAMPLE** option, the output data set contains the allocated sample sizes. See the section “Allocation Output Data Set” on page 8075 for details.

You can specify the name of the sample output data set in the **OUT=** option in the PROC SURVEYSELECT statement. If you omit the **OUT=** option, the data set is named **DATA $n$** , where  $n$  is the smallest integer that makes the name unique.

The output data set contains the units that are selected for the sample. These units are either observations or groups of observations (clusters) that you define by specifying the **SAMPLINGUNIT** statement. If you do not specify the **SAMPLINGUNIT** statement to define units (clusters), then PROC SURVEYSELECT uses observations as sampling units by default.

By default, the output data set contains only those units that are selected for the sample. But if you specify the **OUTALL** option, the output data set includes all observations from the input data set and also contains a variable that indicates each observation’s selection status. The variable **Selected** equals 1 for an observation selected for the sample, and equals 0 for an observation not selected. The **OUTALL** option is available for equal probability selection methods.

By default, the output data set contains a single copy of each selected unit, even if the unit is selected more than once, and the variable **NumberHits** records the number of hits (selections) for each unit. A unit can be selected more than once if you use a with-replacement or with-minimum-replacement selection method (**METHOD=URS**, **METHOD=PPS\_WR**, **METHOD=PPS\_SYS**, or **METHOD=PPS\_SEQ**). If you specify the **OUTHITS** option, the output data set includes a distinct copy of each selected unit in the output data set. For example, with the **OUTHITS** option a unit that is selected three times is represented by three copies in the output data set.

The output data set also contains design information and selection statistics, depending on the selection method and output options you specify. The output data set can include the following variables:

- **Selected**, which indicates whether or not the observation is selected for the sample. This variable is included if you specify the **OUTALL** option. **Selected** equals 1 for an observation that is selected for the sample, or 0 for an observation that is not selected.
- **STRATA** variables, which you specify in the **STRATA** statement.
- **Replicate**, which is the sample replicate number. This variable is included when you request replicated sampling with the **REPS=** option.
- **SAMPLINGUNIT (CLUSTER)** variables, which you specify in the **SAMPLINGUNIT** statement.
- **ID** variables, which you name in the **ID** statement.
- **CONTROL** variables, which you specify in the **CONTROL** statement.

- Zone, which is the selection zone. This variable is included for `METHOD=PPS_SEQ`.
- SIZE variable, which you specify in the `SIZE` statement.
- AdjustedSize, which is the adjusted size measure. This variable is included if you request adjusted sizes with the `MINSIZE=` or `MAXSIZE=` option when your sampling units are observations.
- UnitSize, which is the sampling unit (or cluster) size measure. This variable is included if you specify the `SAMPLINGUNIT` statement.
- Certain, which indicates certainty selection. This variable is included if you specify the `CERTSIZE=` or `CERTSIZE=P=` option. Certain equals 1 for units that are included with certainty because their size measures exceed the certainty size value or the certainty proportion; otherwise, Certain equals 0.
- NumberHits, which is the number of hits (selections). This variable is included for selection methods that are with replacement or with minimum replacement (`METHOD=URS`, `METHOD=PPS_WR`, `METHOD=PPS_SYS`, and `METHOD=PPS_SEQ`).

The output data set includes the following variables if you request a PPS selection method or if you specify the `STATS` option in the PROC SURVEYSELECT statement for other methods:

- ExpectedHits, which is the expected number of hits (selections). This variable is included for selection methods that are with replacement or with minimum replacement, where the same unit can be selected more than once (`METHOD=URS`, `METHOD=PPS_WR`, `METHOD=PPS_SYS`, and `METHOD=PPS_SEQ`).
- SelectionProb, which is the probability of selection. This variable is included for selection methods that are without replacement.
- SamplingWeight, which is the sampling weight. This variable equals the inverse of ExpectedHits or SelectionProb.

If you specify the `STATS` or `OUTSIZE` option for `METHOD=BERNOULLI`, the output data set contains the following variables. If you specify a `STRATA` statement, the output data set includes stratum-level values of these variables; otherwise, the output data set includes overall values.

- Total, which is the total number of sampling units
- SelectionProb, which is the selection probability that you specify by using the `SAMPRATE=` option
- ExpectedN, which is the expected value of the sample size
- SampleSize, which is the actual sample size

If you specify the `STATS` option for `METHOD=BERNOULLI`, the output data set also contains the following variable:

- AdjSamplingWeight, which is the adjusted sampling weight

For `METHOD=PPS_BREWER` and `METHOD=PPS_MURTHY`, which select two units from each stratum with probability proportional to size, the output data set contains the following variable:

- `JtSelectionProb`, which is the joint probability of selection for the two units selected from the stratum.

If you specify the `JTPROBS` option to compute joint probabilities of selection for `METHOD=PPS` or `METHOD=PPS_SAMPFORD`, then the output data set contains the following variables:

- `Unit`, which is an identification variable that numbers the selected units sequentially within each stratum.
- `JtProb_1`, `JtProb_2`, `JtProb_3`, ..., where the variable `JtProb_1` contains the joint probability of selection for the current unit and unit 1. Similarly, `JtProb_2` contains the joint probability of selection for the current unit and unit 2, and so on.

If you specify the `JTPROBS` option for `METHOD=PPS_WR`, then the output data set contains the following variables:

- `Unit`, which is an identification variable that numbers the selected units sequentially within each stratum.
- `JtHits_1`, `JtHits_2`, `JtHits_3`, ..., where the variable `JtHits_1` contains the joint expected number of hits for the current unit and unit 1. Similarly, `JtHits_2` contains the joint expected number of hits for the current unit and unit 2, and so on.

If you specify the `OUTSIZE` option, the output data set contains the following variables. If you specify a `STRATA` statement, the output data set includes stratum-level values of these variables; otherwise, the output data set includes overall values.

- `MinimumSize`, which is the minimum size measure specified with the `MINSIZE=` option. This variable is included if you specify the `MINSIZE=` option.
- `MaximumSize`, which is the maximum size measure specified with the `MAXSIZE=` option. This variable is included if you specify the `MAXSIZE=` option.
- `CertaintySize`, which is the certainty size measure specified with the `CERTSIZE=` option. This variable is included if you specify the `CERTSIZE=` option.
- `CertaintyProp`, which is the certainty proportion specified with the `CERTSIZE=P=` option. This variable is included if you specify the `CERTSIZE=P=` option.
- `Total`, which is the total number of sampling units in the stratum. This variable is included if there is no `SIZE` statement, or if you specify a `SAMPLINGUNIT` statement.
- `TotalSize`, which is the total of size measures in the stratum. This variable is included if there is a `SIZE` statement, or if you specify the `PPS` option in the `SAMPLINGUNIT` statement.

- TotalAdjSize, which is the total of adjusted size measures in the stratum. This variable is included if you request adjusted sizes with the `MAXSIZE=` or `MINSIZE=` option.
- SamplingRate, which is the sampling rate. This variable is included if you specify the `SAMPRATE=` option.
- SampleSize, which is the sample size. This variable is included if you specify the `SAMPSIZE=` option, or if you specify `METHOD=PPS_BREWER` or `METHOD=PPS_MURTHY`, which selects two units from each stratum.

If you specify the `OUTSEED` option, the output data set contains the following variable:

- InitialSeed, which is the initial seed for the stratum.

If you specify the `ALLOC=` option in the `STRATA` statement, the output data set contains the following variables:

- Total, which is the total number of sampling units in the stratum.
- Variance, which is the stratum variance. This variable is included if you specify the `VAR`, `VAR=(values)`, or `VAR=SAS-data-set` option for the `ALLOC=OPTIMAL`, `ALLOC=NEYMAN`, or `MARGIN=` allocation option.
- Cost, which is the stratum cost. This variable is included if you specify the `COST`, `COST=(values)`, or `COST=SAS-data-set` option for `ALLOC=OPTIMAL`.
- AllocProportion, which is the target allocation proportion (the proportion of the total sample size to allocate to the stratum). PROC SURVEYSELECT computes this proportion by using the specified allocation method.
- SampleSize, which is the sample size allocated to the stratum.
- ActualProportion, which is the actual proportion allocated to the stratum. The value of ActualProportion equals the allocated stratum sample size divided by the total sample size. This value can differ from the target AllocProportion due to rounding and other restrictions. See the section “Sample Size Allocation” on page 8067 for details.

---

## Allocation Output Data Set

When you specify the `NOSAMPLE` option in the `STRATA` statement, PROC SURVEYSELECT allocates the total sample size among the strata but does not select the sample. In this case, the `OUT=` data set contains the allocated sample sizes.

You can specify the name of the allocation output data set with the `OUT=` option in the PROC SURVEYSELECT statement. If you omit the `OUT=` option, the data set is named `DATAn`, where `n` is the smallest integer that makes the name unique.

The allocation output data set contains one observation for each stratum. The data set can include the following variables:

- STRATA variables, which you specify in the **STRATA** statement.
- Total, which is the total number of sampling units in the stratum.
- Variance, which is the stratum variance. This variable is included if you specify the **VAR**, **VAR=(values)**, or **VAR=SAS-data-set** option for the **ALLOC=OPTIMAL**, **ALLOC=NEYMAN**, or **MARGIN=** allocation option.
- Cost, which is the stratum cost. This variable is included if you specify the **COST**, **COST=(values)**, or **COST=SAS-data-set** option for **ALLOC=OPTIMAL**.
- AllocProportion, which is the target allocation proportion (the proportion of the total sample size to allocate to the stratum). PROC SURVEYSELECT computes this proportion by using the specified allocation method.
- SampleSize, which is the sample size allocated to the stratum.
- ActualProportion, which is the actual proportion allocated to the stratum. The value of ActualProportion equals the allocated stratum sample size divided by the total sample size. This value can differ from the target AllocProportion due to rounding and other restrictions. See the section “Sample Size Allocation” on page 8067 for details.

---

## Displayed Output

By default, PROC SURVEYSELECT displays two tables that summarize the sample selection: the “Sample Selection Method” table and the “Sample Selection Summary” table.

If you request sample allocation but no sample selection, PROC SURVEYSELECT displays two tables that summarize the allocation: the “Sample Allocation Method” table and the “Sample Allocation Summary” table.

You can suppress display of these tables by specifying the **NOPRINT** option.

PROC SURVEYSELECT creates an output data set that contains the units that are selected for the sample. Or if you request sample allocation but no sample selection, PROC SURVEYSELECT creates an output data set that contains the sample size allocation results. (See the sections “Sample Output Data Set” on page 8072 and “Allocation Output Data Set” on page 8075 for information about these output data sets.) The procedure does not display the output data set that it creates. Use PROC PRINT, PROC REPORT, or any other SAS reporting tool to display the output data set.

PROC SURVEYSELECT displays the following information in the “Sample Selection Method” table:

- Selection Method
- Sampling Unit Variables, if you specify a **SAMPLINGUNIT** statement
- Size Measure variable, if you specify a **SIZE** statement

- Size Measure: Number of Observations, if you specify the `PPS` option in the `SAMPLINGUNIT` statement and do not specify a `SIZE` statement
- Minimum Size Measure, if you specify the `MINSIZE=` option
- Maximum Size Measure, if you specify the `MAXSIZE=` option
- Certainty Size Measure, if you specify the `CERTSIZE=` option
- Certainty Proportion, if you specify the `CERTSIZE=P=` option
- Strata Variables, if you specify a `STRATA` statement
- Control Variables, if you specify a `CONTROL` statement
- Control Sorting (Serpentine or Nested), if you specify a `CONTROL` statement
- Allocation (Proportional, Neyman, Optimal, or Input), if you specify the `ALLOC=` option in the `STRATA` statement
- Margin of Error, if you specify the `MARGIN=` option in the `STRATA` statement
- Confidence Level, if you specify the `ALPHA=` option in the `STRATA` statement

PROC SURVEYSELECT displays the following information in the “Sample Selection Summary” table:

- Input Data Set name
- Sorted Data Set name, if you specify the `OUTSORT=` option
- Random Number Seed
- Sample Size or Stratum Sample Size, if you specify the `SAMPSIZE=n` option
- Sample Size Data Set, if you specify the `SAMPSIZE=SAS-data-set` option
- Sampling Rate or Stratum Sampling Rate, if you specify the `SAMPRATE=r` option for `METHOD=SRS`, `METHOD=URS`, `METHOD=SYS`, or `METHOD=SEQ`.
- Selection Probability or Stratum Selection Probability, if you specify the `SAMPRATE=r` option for `METHOD=BERNOULLI`
- Sampling Rate Data Set, if you specify the `SAMPRATE=SAS-data-set` option
- Minimum Sample Size or Stratum Minimum Sample Size, if you specify the `NMIN=` option with the `SAMPRATE=` option
- Maximum Sample Size or Stratum Maximum Sample Size, if you specify the `NMAX=` option with the `SAMPRATE=` option
- Allocation Input Data Set name, if you specify the `ALLOC=SAS-data-set` option in the `STRATA` statement
- Variance Input Data Set name, if you specify the `VAR=SAS-data-set` option in the `STRATA` statement

- Cost Input Data Set name, if you specify the `COST=SAS-data-set` option in the `STRATA` statement
- Selection Probability, if you specify `METHOD=SRS`, `METHOD=SYS`, or `METHOD=SEQ` and do not specify a `SIZE` statement or a `STRATA` statement
- Expected Number of Hits, if you specify `METHOD=URS` and do not specify a `STRATA` statement
- Total Number of Units, if you specify `METHOD=BERNOULLI` or `METHOD=POISSON` and do not specify a `STRATA` statement
- Expected Sample Size, if you specify `METHOD=BERNOULLI` or `METHOD=POISSON` and do not specify a `STRATA` statement
- Sample Size, if you specify `METHOD=BERNOULLI` or `METHOD=POISSON` and do not specify a `STRATA` statement
- Sampling Weight, if you specify an equal probability selection method (`METHOD=SRS`, `METHOD=URS`, `METHOD=SYS`, `METHOD=SEQ`, or `METHOD=BERNOULLI`) and do not specify a `STRATA` statement
- Adjusted Sampling Weight, if you specify `METHOD=BERNOULLI` and do not specify a `STRATA` statement
- Number of Strata, if you specify a `STRATA` statement
- Stratum Minimum Sample Size, if you specify the `ALLOCMIN=` option in the `STRATA` statement
- Number of Replicates, if you specify the `REPS=` option
- Total Sample Size, if you specify a `STRATA` statement or the `REPS=` option
- Expected Margin of Error, if you specify the `STATS` option with the `MARGIN=` option in the `STRATA` statement
- Expected Variance, if you specify the `STATS` option without the `MARGIN=` option in the `STRATA` statement for `ALLOC=OPTIMAL` or `ALLOC=NEYMAN`
- Total Stratum Costs, if you specify the `STATS` option with `ALLOC=OPTIMAL` in the `STRATA` statement
- Output Data Set name

If you specify the `NOSAMPLE` option in the `STRATA` statement, PROC SURVEYSELECT allocates the total sample among the strata but does not select the sample. When you specify the `NOSAMPLE` option, PROC SURVEYSELECT displays the “Sample Allocation Method” table and the “Sample Allocation Summary” table. The “Sample Allocation Method” table includes the following information:

- Allocation (Proportional, Neyman, Optimal, or Input)
- Margin of Error, if you specify the `MARGIN=` option in the `STRATA` statement
- Confidence Level, if you specify the `ALPHA=` option in the `STRATA` statement
- Sampling Unit Variables, if you specify a `SAMPLINGUNIT` statement

- Strata Variables
- Frequency Variable
- Selection Method, if you specify the `METHOD=` option

PROC SURVEYSELECT displays the following information in the “Sample Allocation Summary” table.

- Input Data Set name
- Allocation Input Data Set name, if you specify the `ALLOC=SAS-data-set` option in the `STRATA` statement
- Variance Input Data Set name, if you specify the `VAR=SAS-data-set` option in the `STRATA` statement
- Cost Input Data Set name, if you specify the `COST=SAS-data-set` option in the `STRATA` statement
- Number of Strata
- Stratum Minimum Sample Size, if you specify the `ALLOCMIN=` option in the `STRATA` statement
- Total Sample Size
- Expected Margin of Error, if you specify the `STATS` option with the `MARGIN=` option in the `STRATA` statement
- Expected Variance, if you specify the `STATS` option without the `MARGIN=` option in the `STRATA` statement for `ALLOC=OPTIMAL` or `ALLOC=NEYMAN`
- Total Stratum Costs, if you specify the `STATS` option with `ALLOC=OPTIMAL` in the `STRATA` statement
- Allocation Output Data Set name

---

## ODS Table Names

PROC SURVEYSELECT assigns a name to each table that it creates. You can use these names to refer to tables when you use the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, “Using the Output Delivery System.” Table 95.4 lists the table names.

**Table 95.4** ODS Tables Produced by PROC SURVEYSELECT

| ODS Table Name | Description               | Statement | Option   |
|----------------|---------------------------|-----------|----------|
| Method         | Sample selection method   | PROC      | Default  |
| Method         | Sample allocation method  | STRATA    | NOSAMPLE |
| Summary        | Sample selection summary  | PROC      | Default  |
| Summary        | Sample allocation summary | STRATA    | NOSAMPLE |

---

## Examples: SURVEYSELECT Procedure

---

### Example 95.1: Replicated Sampling

This example uses the Customers data set from the section “Getting Started: SURVEYSELECT Procedure” on page 8021. The data set Customers contains an Internet service provider’s current subscribers, and the service provider wants to select a sample from this population for a customer satisfaction survey.

This example illustrates replicated sampling, which selects multiple samples from the survey population according to the same design. You can use replicated sampling to provide a simple method of variance estimation, or to evaluate variable nonsampling errors such as interviewer differences. For information about replicated sampling, see Lohr (2010); Wolter (2007); Kish (1965, 1987); Kalton (1983).

This design includes four replicates, each with a sample size of 50 customers. The sampling frame is stratified by State and sorted by Type and Usage within strata. Customers are selected by sequential random sampling with equal probability within strata. The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set by using this design:

```
title1 'Customer Satisfaction Survey';
title2 'Replicated Sampling';
proc surveyselect data=Customers method=seq n=(8 12 20 10)
 reps=4 seed=40070 ranuni out=SampleRep;
 strata State;
 control Type Usage;
run;
```

The STRATA statement names the stratification variable State. The CONTROL statement names the control variables Type and Usage.

In the PROC SURVEYSELECT statement, the METHOD=SEQ option requests sequential random sampling. The REPS= option specifies four replicates of this sample. The N=(8 12 20 10) option lists the stratum sample sizes for each replicate. The N= option lists the stratum sample sizes in the same order as the strata appear in the Customers data set, which has been sorted by State. The sample size of eight customers corresponds to the first stratum, State = ‘AL’. The sample size 12 corresponds to the next stratum, State = ‘FL’, and so on.

The SEED= option specifies 40070 as the initial seed for random number generation. The RANUNI option requests random number generation by the RANUNI generator, which PROC SURVEYSELECT used in releases prior to SAS/STAT 12.1. (Beginning in SAS/STAT 12.1, PROC SURVEYSELECT uses the Mersenne-Twister random number generator by default.) You can specify the RANUNI option with the SEED= option to reproduce samples that PROC SURVEYSELECT selected in releases prior to SAS/STAT 12.1. To reproduce a sample by using the RANUNI and SEED= options, you must also specify the same input data set and sample selection parameters.

**Output 95.1.1** displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A total of 200 customers is selected in four replicates. PROC SURVEYSELECT selects each replicate by using sequential random sampling within strata determined by State. The sampling frame Customers is sorted by the control variables Type and Usage within strata, according to hierarchic serpentine sorting. The output data set SampleRep contains the sample.

### Output 95.1.1 Sample Selection Summary

| Customer Satisfaction Survey |                                                      |
|------------------------------|------------------------------------------------------|
| Replicated Sampling          |                                                      |
| The SURVEYSELECT Procedure   |                                                      |
| Selection Method             | Sequential Random Sampling<br>With Equal Probability |
| Strata Variable              | State                                                |
| Control Variables            | Type<br>Usage                                        |
| Control Sorting              | Serpentine                                           |
| Input Data Set               | CUSTOMERS                                            |
| Random Number Seed           | 40070                                                |
| Number of Strata             | 4                                                    |
| Number of Replicates         | 4                                                    |
| Total Sample Size            | 200                                                  |
| Output Data Set              | SAMPLEREP                                            |

The following PROC PRINT statements display the selected customers for the first stratum, State = 'AL', from the output data set SampleRep:

```

title1 'Customer Satisfaction Survey';
title2 'Sample Selected by Replicated Design';
title3 '(First Stratum)';
proc print data=SampleRep;
 where State = 'AL';
run;

```

**Output 95.1.2** displays the 32 sample customers of the first stratum (State = 'AL') from the output data set SampleRep, which includes the entire sample of 200 customers. The variable SelectionProb contains the selection probability, and SamplingWeight contains the sampling weight. Because customers are selected with equal probability within strata in this design, all customers in the same stratum have the same selection probability. These selection probabilities and sampling weights apply to a single replicate, and the variable Replicate contains the sample replicate number.

## Output 95.1.2 Customer Sample (First Stratum)

| Customer Satisfaction Survey<br>Sample Selected by Replicated Design<br>(First Stratum) |       |           |             |      |       |                |                 |

## Example 95.2: PPS Selection of Two Units per Stratum

This example describes hospital selection for a survey by using PROC SURVEYSELECT. A state health agency plans to conduct a statewide survey of a variety of different hospital services. The agency plans to select a probability sample of individual discharge records within hospitals by using a two-stage sample design. First-stage units are hospitals, and second-stage units are patient discharges during the study period. Hospitals are stratified first according to geographic region and then by rural/urban type and size of hospital. Two hospitals are selected from each stratum with probability proportional to size.

The data set HospitalFrame contains all hospitals in the first geographical region of the state:

```
data HospitalFrame;
 input Hospital$ Type$ SizeMeasure @@;
 if (SizeMeasure < 20) then Size='Small ';
 else if (SizeMeasure < 50) then Size='Medium';
 else Size='Large ';
 datalines;
034 Rural 0.870 107 Rural 1.316
079 Rural 2.127 223 Rural 3.960
236 Rural 5.279 165 Rural 5.893
086 Rural 0.501 141 Rural 11.528
042 Urban 3.104 124 Urban 4.033
006 Urban 4.249 261 Urban 4.376
195 Urban 5.024 190 Urban 10.373
038 Urban 17.125 083 Urban 40.382
259 Urban 44.942 129 Urban 46.702
133 Urban 46.992 218 Urban 48.231
026 Urban 61.460 058 Urban 65.931
119 Urban 66.352
;
```

In the SAS data set HospitalFrame, the variable Hospital identifies the hospital. The variable Type equals 'Urban' if the hospital is located in an urban area, and 'Rural' otherwise. The variable SizeMeasure contains the hospital's size measure, which is constructed from past data on service utilization for the hospital together with the desired sampling rates for each service. This size measure reflects the amount of relevant survey information expected from the hospital. See Drummond et al. (1982) for details about this type of size measure. The variable Size equals 'Small', 'Medium', or 'Large', depending on the value of the hospital's size measure.

The following PROC PRINT statements display the data set Hospital Frame and produce [Output 95.2.1](#):

```
title1 'Hospital Utilization Survey';
title2 'Sampling Frame, Region 1';
proc print data=HospitalFrame;
run;
```

## Output 95.2.1 Sampling Frame

| 21                                                      | 026      | Urban | 61.460       | Large  |
| 22                                                      | 058      | Urban | 65.931       | Large  |
| 23                                                      | 119      | Urban | 66.352       | Large  |

The following PROC SURVEYSELECT statements select a probability sample of hospitals from the HospitalFrame data set by using a stratified design with PPS selection of two units from each stratum:

```

title1 'Hospital Utilization Survey';
title2 'Stratified PPS Sampling';
proc surveyselect data=HospitalFrame method=pps_brewer
 seed=48702 out=SampleHospitals;
 size SizeMeasure;
 strata Type Size notsorted;
run;

```

The STRATA statement names the stratification variables Type and Size. The NOTSORTED option specifies that observations with the same STRATA variable values are grouped together but are not necessarily sorted in alphabetical or increasing numerical order. In the HospitalFrame data set, Size = 'Small' precedes Size = 'Medium'.

In the PROC SURVEYSELECT statement, the METHOD=PPS\_BREWER option requests sample selection by Brewer's method, which selects two units per stratum with probability proportional to size. The SEED= option specifies 48702 as the initial seed for random number generation. The SIZE statement names SizeMeasure as the size measure variable. It is not necessary to specify the sample size with the N= option, because Brewer's method always selects two units from each stratum.

Output 95.2.2 displays the output from PROC SURVEYSELECT. A total of eight hospitals were selected from the four strata. The data set SampleHospitals contains the selected hospitals.

The variable SelectionProb contains the selection probability for each hospital in the sample. The variable JtSelectionProb contains the joint probability of selection for the two sample hospitals in the same stratum. The variable SamplingWeight contains the sampling weight component for this first stage of the design. The final-stage weight components, which correspond to patient record selection within hospitals, can be multiplied by the hospital weight components to obtain the overall sampling weights.

### Example 95.3: PPS (Dollar-Unit) Sampling

A small company wants to audit employee travel expenses in an effort to improve the expense reporting procedure and possibly reduce expenses. The company does not have resources to examine all expense reports and wants to use statistical sampling to objectively select expense reports for audit.

The data set `TravelExpense` contains the dollar amount of all employee travel expense transactions during the past month:

```
data TravelExpense;
 input ID$ Amount @@;
 if (Amount < 500) then Level='1_Low ';
 else if (Amount > 1500) then Level='3_High';
 else Level='2_Avg ';
 datalines;
110 237.18 002 567.89 234 118.50
743 74.38 411 1287.23 782 258.10
216 325.36 174 218.38 568 1670.80
302 134.71 285 2020.70 314 47.80
139 1183.45 775 330.54 425 780.10
506 895.80 239 620.10 011 420.18
672 979.66 142 810.25 738 670.85
192 314.58 243 87.50 263 1893.40
496 753.30 332 540.65 486 2580.35
614 230.56 654 185.60 308 688.43
784 505.14 017 205.48 162 650.42
289 1348.34 691 30.50 545 2214.80
517 940.35 382 217.85 024 142.90
478 806.90 107 560.72
;
```

In the SAS data set `TravelExpense`, the variable `ID` identifies the travel expense report. The variable `Amount` contains the dollar amount of the reported expense. The variable `Level` equals '1\_Low', '2\_Avg', or '3\_High', depending on the value of `Amount`.

In the sample design for this audit, expense reports are stratified by `Level`. This ensures that each of these expense levels is included in the sample and also permits a disproportionate allocation of the sample, selecting proportionately more of the expense reports from the higher levels. Within strata, the sample of expense reports is selected with probability proportional to the amount of the expense, thus giving a greater chance of selection to larger expenses. In auditing terms, this is known as monetary-unit sampling. See Wilburn (1984) for details.

`PROC SURVEYSELECT` requires that the input data set be sorted by the `STRATA` variables. The following `PROC SORT` statements sort the `TravelExpense` data set by the stratification variable `Level`.

```
proc sort data=TravelExpense;
 by Level;
run;
```

Output 95.3.1 displays the sampling frame data set `TravelExpense`, which contains 41 observations.

**Output 95.3.1** Sampling Frame

| Travel Expense Audit |     |         |        |
|----------------------|-----|---------|--------|

| 36                   | 107 | 560.72  | 2_Avg  |
| 37                   | 568 | 1670.80 | 3_High |
| 38                   | 285 | 2020.70 | 3_High |
| 39                   | 263 | 1893.40 | 3_High |
| 40                   | 486 | 2580.35 | 3_High |
| 41                   | 545 | 2214.80 | 3_High |

The following PROC SURVEYSELECT statements select a probability sample of expense reports from the TravelExpense data set by using the stratified design with PPS selection within strata:

```

title1 'Travel Expense Audit';
title2 'Stratified PPS (Dollar-Unit) Sampling';
proc surveyselect data=TravelExpense method=pps n=(6 10 4)
 seed=47279 out=AuditSample;
 size Amount;
 strata Level;
run;

```

The STRATA statement names the stratification variable Level. The SIZE statement specifies the size measure variable Amount. In the PROC SURVEYSELECT statement, the METHOD=PPS option requests sample selection with probability proportional to size and without replacement. The N=(6 10 4) option specifies the stratum sample sizes, listing the sample sizes in the same order as the strata appear in the TravelExpense data set. The sample size of 6 corresponds to the first stratum, Level = '1\_Low'; the sample size of 10 corresponds to the second stratum, Level = '2\_Avg'; and 4 corresponds to the last stratum, Level = '3\_High'. The SEED= option specifies 47279 as the initial seed for random number generation.

Output 95.3.2 displays the output from PROC SURVEYSELECT. A total of 20 expense reports are selected for audit. The data set AuditSample contains the sample of travel expense reports.

#### Output 95.3.2 Sample Selection Summary

| Travel Expense Audit                  |                          |
|---------------------------------------|--------------------------|
| Stratified PPS (Dollar-Unit) Sampling |                          |
| The SURVEYSELECT Procedure            |                          |
| Selection Method                      | PPS, Without Replacement |
| Size Measure                          | Amount                   |
| Strata Variable                       | Level                    |
| Input Data Set                        | TRAVELEXPENSE            |

**Example 95.4: Proportional Allocation**

This example uses the Customers data set from the section “Getting Started: SURVEYSELECT Procedure” on page 8021. The data set Customers contains an Internet service provider’s current subscribers, and the service provider wants to select a sample from this population for a customer satisfaction survey. This example illustrates proportional allocation, which allocates the total sample size among the strata in proportion to the strata sizes.

The section “Getting Started: SURVEYSELECT Procedure” on page 8021 gives an example of stratified sampling, where the list of customers is stratified by State and Type. Figure 95.4 displays the strata in a table of State by Type for the 13,471 customers. There are four states and two levels of Type, forming a total of eight strata. A sample of 15 customers was selected from each stratum by using the following PROC SURVEYSELECT statements:

```

title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling';
proc surveyselect data=Customers method=srs n=15
 seed=1953 out=SampleStrata;
 strata State Type;
run;

```

The STRATA statement names the stratification variables State and Type. In the PROC SURVEYSELECT statement, the N= option specifies a sample size of 15 customers for each stratum.

Instead of specifying the number of customers to select from each stratum, you can specify the total sample size and request allocation of the total sample size among the strata. The following PROC SURVEYSELECT statements request proportional allocation, which allocates the total sample size in proportion to the stratum sizes:

```

title1 'Customer Satisfaction Survey';
title2 'Proportional Allocation';
proc surveyselect data=Customers n=1000
 out=SampleSizes;
 strata State Type / alloc=prop nosample;
run;

```

The STRATA statement names the stratification variables State and Type. In the STRATA statement, the ALLOC=PROP option requests proportional allocation. The NOSAMPLE option requests that no sample be selected after the procedure computes the sample size allocation. In the PROC SURVEYSELECT statement, the N= option specifies a total sample size of 1000 customers to be allocated among the strata.

Output 95.4.1 displays the output from PROC SURVEYSELECT, which summarizes the sample allocation. The total sample size of 1000 is allocated among the eight strata by using proportional allocation. The allocated sample sizes are stored in the SAS data set SampleSizes.

**Output 95.4.1** Proportional Allocation Summary

| Customer Satisfaction Survey<br>Proportional Allocation |                               |
|---------------------------------------------------------|-------------------------------|
| The SURVEYSELECT Procedure                              |                               |
| Allocation<br>Strata Variables                          | Proportional<br>State<br>Type |
| Input Data Set                                          | CUSTOMERS                     |
| Number of Strata                                        | 8                             |
| Total Sample Size                                       | 1000                          |
| Allocation Output Data Set                              | SAMPLESIZES                   |

The following PROC PRINT statements display the allocation output data set SampleSizes, which is shown in Output 95.4.2:

```

title1 'Customer Satisfaction Survey';
title2 'Proportional Allocation';
proc print data=SampleSizes;
run;

```

**Output 95.4.2** Stratum Sample Sizes

| 7                                                       | SC    | New  | 1684  | 0.12501             | 125            | 0.125                |
| 8                                                       | SC    | Old  | 875   | 0.06495             | 65             | 0.065                |

The output data set `SampleSizes` includes one observation for each of the eight strata, which are identified by the stratification variables `State` and `Type`. The variable `Total` contains the number of sampling units in the stratum, and the variable `AllocProportion` contains the proportion of the total sample size to allocate to the stratum. The variable `SampleSize` contains the allocated stratum sample size. For the first stratum (`State='AL'` and `Type='New'`), the total number of sampling units is 1238 customers, the allocation proportion is 0.09190, and the allocated sample size is 92 customers. The sum of the allocated sample sizes equals the requested total sample size of 1000 customers.

The output data set also includes the variable `ActualProportion`, which contains actual stratum proportions of the total sample size. The actual proportion for a stratum equals the stratum sample size divided by the total sample size. For the first stratum (`State='AL'` and `Type='New'`), the actual proportion is 0.092, while the allocation proportion is 0.09190. The target sample sizes computed from the allocation proportions are often not integers, and PROC SURVEYSELECT uses a rounding algorithm to obtain integer sample sizes and maintain the requested total sample size. Due to rounding and other restrictions, the actual proportions can differ from the target allocation proportions. See the section “[Sample Size Allocation](#)” on page 8067 for details.

If you want to use the allocated sample sizes in a later invocation of PROC SURVEYSELECT, you can name the allocation data set in the `N=SAS-data-set` option, as shown in the following PROC SURVEYSELECT statements:

```

title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling';
proc surveyselect data=Customers method=srs n=SampleSizes
 seed=1953 out=SampleStrata;
 strata State Type;
run;

```

### Overview: TPSPLINE Procedure

The TPSPLINE procedure uses the penalized least squares method to fit a nonparametric regression model. It computes thin-plate smoothing splines to approximate smooth multivariate functions observed with noise. The TPSPLINE procedure allows great flexibility in the possible form of the regression surface. In particular, PROC TPSPLINE makes no assumptions of a parametric form for the model. The generalized cross validation (GCV) function can be used to select the amount of smoothing.

The TPSPLINE procedure complements the methods provided by the standard SAS regression procedures such as the GLM, REG, and NLIN procedures. These procedures can handle most situations in which you

specify the regression model and the model is known up to a fixed number of parameters. However, when you have no prior knowledge about the model, or when you know that the data cannot be represented by a model with a fixed number of parameters, you can use the TPSPLINE procedure to model the data.

The TPSPLINE procedure uses the penalized least squares method to fit the data with a flexible model in which the number of effective parameters can be as large as the number of unique design points. Hence, as the sample size increases, the model space also increases, enabling the thin-plate smoothing spline to fit more complicated situations.

The main features of the TPSPLINE procedure are as follows:

- provides penalized least squares estimates
- supports the use of multidimensional data
- supports multiple SCORE statements
- fits both semiparametric models and nonparametric models
- provides options for handling large data sets
- supports multiple dependent variables
- enables you to choose a particular model by specifying the model degrees of freedom or smoothing parameter
- produces graphs with ODS Graphics

---

## Penalized Least Squares Estimation

Penalized least squares estimation provides a way to balance fitting the data closely and avoiding excessive roughness or rapid variation. A penalized least squares estimate is a surface that minimizes the penalized squared error over the class of all surfaces that satisfy sufficient regularity conditions.

Define  $\mathbf{x}_i$  as a  $d$ -dimensional covariate vector from an  $n \times d$  matrix  $\mathbf{X}$ ,  $\mathbf{z}_i$  as a  $p$ -dimensional covariate vector, and  $y_i$  as the observation associated with  $(\mathbf{x}_i, \mathbf{z}_i)$ . Assuming that the relation between  $\mathbf{z}_i$  and  $y_i$  is linear but the relation between  $\mathbf{x}_i$  and  $y_i$  is unknown, you can fit the data by using a semiparametric model as follows:

$$y_i = f(\mathbf{x}_i) + \mathbf{z}_i \boldsymbol{\beta} + \epsilon_i$$

where  $f$  is an unknown function that is assumed to be reasonably smooth,  $\epsilon_i, i = 1, \dots, n$ , are independent, zero-mean random errors, and  $\boldsymbol{\beta}$  is a  $p$ -dimensional unknown parameter vector.

This model consists of two parts. The  $\mathbf{z}_i \boldsymbol{\beta}$  is the parametric part of the model, and the  $\mathbf{z}_i$  are the regression variables. The  $f(\mathbf{x}_i)$  is the nonparametric part of the model, and the  $\mathbf{x}_i$  are the smoothing variables. The ordinary least squares method estimates  $f(\mathbf{x}_i)$  and  $\boldsymbol{\beta}$  by minimizing the quantity:

$$\frac{1}{n} \sum_{i=1}^n (y_i - f(\mathbf{x}_i) - \mathbf{z}_i \boldsymbol{\beta})^2$$

However, the functional space of  $f(\mathbf{x})$  is so large that you can always find a function  $f$  that interpolates the data points. In order to obtain an estimate that fits the data well and has some degree of smoothness, you can use the penalized least squares method.

The penalized least squares function is defined as

$$S_\lambda(f) = \frac{1}{n} \sum_{i=1}^n (y_i - f(\mathbf{x}_i) - \mathbf{z}_i \boldsymbol{\beta})^2 + \lambda J_2(f)$$

where  $J_2(f)$  is the penalty on the roughness of  $f$  and is defined, in most cases, as the integral of the square of the second derivative of  $f$ .

The first term measures the goodness of fit and the second term measures the smoothness associated with  $f$ . The  $\lambda$  term is the smoothing parameter, which governs the tradeoff between smoothness and goodness of fit. When  $\lambda$  is large, it more heavily penalizes rougher fits. Conversely, a small value of  $\lambda$  puts more emphasis on the goodness of fit.

The estimate  $f_\lambda$  is selected from a reproducing kernel Hilbert space, and it can be represented as a linear combination of a sequence of basis functions. Hence, the final estimates of  $f$  can be written as

$$\hat{f}_\lambda(\mathbf{x}_i) = \theta_0 + \sum_{j=1}^d \theta_j \mathbf{x}_{i,j} + \sum_{j=1}^p \delta_j B_j(\mathbf{x}_j)$$

where  $B_j$  is the basis function, which depends on where the data  $\mathbf{x}_i$  are located, and  $\boldsymbol{\theta} = \{\theta_0, \dots, \theta_d\}$  and  $\boldsymbol{\delta} = \{\delta_1, \dots, \delta_p\}$  are the coefficients that need to be estimated.

For a fixed  $\lambda$ , the coefficients  $(\boldsymbol{\theta}, \boldsymbol{\delta}, \boldsymbol{\beta})$  can be estimated by solving an  $n \times n$  system.

The smoothing parameter can be chosen by minimizing the generalized cross validation (GCV) function.

If you write

$$\hat{\mathbf{y}} = \mathbf{A}(\lambda)\mathbf{y}$$

then  $\mathbf{A}(\lambda)$  is referred to as the *hat* or *smoothing* matrix, and the GCV function  $\text{GCV}(\lambda)$  is defined as

$$\text{GCV}(\lambda) = \frac{(1/n)\|(\mathbf{I} - \mathbf{A}(\lambda))\mathbf{y}\|^2}{[(1/n)\text{tr}(\mathbf{I} - \mathbf{A}(\lambda))]^2}$$

---

## PROC TPSPLINE with Large Data Sets

The calculation of the penalized least squares estimate is computationally intensive. The amount of memory and CPU time needed for the analysis depends on the number of unique design points, which corresponds to the number of unknown parameters to be estimated.

You can specify the `D=` option in the `MODEL` statement to reduce the number of unknown parameters. The option groups design points by the specified range (see the `D=` option on page 8114).

`PROC TPSPLINE` selects one design point from the group and treats all observations in the group as replicates of that design point. Calculation of the thin-plate smoothing spline estimates is based on the reprocessed data. The way to choose the design point from a group depends on the order of the data. Hence, different orders of input data might result in different estimates.

By combining several design points into one, this option reduces the number of unique design points, thereby approximating the original data. The value you specify for the `D=` option determines the width of the range used to group the data.

---

## Getting Started: TPSPLINE Procedure

The following example demonstrates how you can use the `TPSPLINE` procedure to fit a semiparametric model.

Suppose that  $y$  is a continuous variable and  $x_1$  and  $x_2$  are two explanatory variables of interest. To fit a bivariate thin-plate spline model, you can use a `MODEL` statement similar to that used in many regression procedures in the SAS System:

```
proc tpspline;
 model y = (x1 x2);
run;
```

The `TPSPLINE` procedure can fit semiparametric models; the parentheses in the preceding `MODEL` statement separate the smoothing variables from the regression variables. The following statements illustrate this syntax:

```
proc tpspline;
 model y = z1 (x1 x2);
run;
```

This model assumes a linear relation with  $z_1$  and an unknown functional relation with  $x_1$  and  $x_2$ .

If you want to fit several responses by using the same explanatory variables, you can save computation time by using the multiple responses feature in the `MODEL` statement. For example, if  $y_1$  and  $y_2$  are two response variables, the following `MODEL` statement can be used to fit two models. Separate analyses are then performed for each response variable.

```
proc tpspline;
 model y1 y2 = (x1 x2);
run;
```

The following example illustrates the use of PROC TPSPLINE. The data are from Bates et al. (1987).

```
data Measure;
 input x1 x2 y @@;
 datalines;

The data set Measure contains three variables x1, x2, and y. Suppose that you want to fit a surface by using the variables x1 and x2 to model the response y. The variables x1 and x2 are spaced evenly on a  $[-1 \times 1] \times [-1 \times 1]$  square, and the response y is generated by adding a random error to a function  $f(x_1, x_2)$ . The raw data are plotted in three-dimensional scatter plot by using the G3D procedure. In order to visualize those replicates, half of the data are shifted a little bit by adding a small value (0.001) to x1 values, as in the following statements:

```
data Measure1;
 set Measure;
run;

proc sort data=Measure1;
 by x2 x1;
run;
```

```

data Measure1;
 set Measure1;
 if mod(_N_, 2) = 0 then x1=x1+0.001;
run;

proc g3d data=Measure1;
 scatter x2*x1=y /size=.5
 zmin=9 zmax=21
 zticknum=4;
 title "Raw Data";
run;

```

Figure 96.1 displays the raw data.

**Figure 96.1** Plot of Data Set MEASURE

The following statements invoke the TPSPLINE procedure, to analyze the Measure data set as input. In the MODEL statement, the x1 and x2 variables are listed as smoothing variables. The LOGNLAMBDA= option specifies that PROC TPSPLINE examine a list of models with  $\log_{10}(n\lambda)$  ranging from -4 to -2.5. The OUTPUT statement creates the data set estimate to contain the predicted values and the 95% upper and lower confidence limits from the best model selected by the GCV criterion.

```
ods graphics on;
proc tpspline data=Measure;
 model y=(x1 x2) /lognlambda=(-4 to -2.5 by 0.1);
 output out=estimate pred uclm lclm;
run;

proc print data=estimate;
run;
```

When ODS Graphics is enabled, PROC TPSPLINE produces several default plots. One of the default plots is the contour plot of the fitted surface, shown in Figure 96.2. The surface exhibits nonlinear patterns along the directions of both predictors.

**Figure 96.2** Fitted Surface from PROC TPSPLINE

Figure 96.3 shows the “Criterion Plot” that provides a graphical display of the GCV selection process. Three sets of values are shown in the plot: the specified smoothing values and their GCV values, the examined smoothing values and their GCV values during the optimization process, and the best smoothing parameter and its GCV value. The final thin-plate smoothing spline estimate is based on  $\log_{10}(n\lambda) = -3.4762$ , which minimizes the GCV.

**Figure 96.3** The GCV Criterion by  $\log_{10}(n\lambda)$

Figure 96.4 shows that the data set Measure contains 50 observations with 25 unique design points. The final model contains no parametric regression terms and two smoothing variables. The order of the derivative in the penalty is 2 by default, and the dimension of polynomial space is 3. See the section “Computational Formulas” on page 8117 for definitions.

Figure 96.4 also lists the GCV values along with the supplied values of  $\log_{10}(n\lambda)$ . The value that minimizes the GCV function is  $-3.5$  among the given list of  $\log_{10}(n\lambda)$ .

The residual sum of squares from the fitted model is 0.246110, and the model degrees of freedom are 24.593203. The standard deviation, defined as  $\text{RSS}/(\text{tr}(\mathbf{I} - \mathbf{A}))$ , is 0.098421. The predictions and 95% confidence limits are displayed in Figure 96.5.

| 50       | 1.0  | 1.0  | 15.9014 | 15.8761 | 15.7402 | 16.0120 |

You can also use the `TEMPLATE` and `SGRENDER` procedures to create a perspective plot for visualizing the fitted surface. Because the data in the data set `Measure` are very sparse, the fitted surface is not smooth. To produce a smoother surface, the following statements generate the data set `pred` in order to obtain a finer grid. The `LOGNLAMBDA0=` option requests that `PROC TPSPLINE` fit a model with a fixed  $\log_{10}(n\lambda)$  value of  $-3.4762$ . The `SCORE` statement evaluates the fitted surface at those new design points.

```

data pred;
 do x1=-1 to 1 by 0.1;
 do x2=-1 to 1 by 0.1;
 output;
 end;
 end;
run;

proc tpspline data=measure;
 model y=(x1 x2)/lognlambda0=-3.4762;
 score data=pred out=predy;
run;

proc template;
 define statgraph surface;
 dynamic _X _Y _Z _T;
 begingraph /designheight=360;
 entrytitle _T;
 layout overlay3d/rotate=120 cube=false xaxisopts=(label="x1")
 yaxisopts=(label="x2") zaxisopts=(label="P_y");
 surfaceplotparm x=_X y=_Y z=_Z;
 endlayout;
 endgraph;
end;
run;

proc sgrender data=predy template=surface;
 dynamic _X='x1' _Y='x2' _Z='P_y'
 _T='Plot of Fitted Surface on a Fine Grid';
run;

```

The surface plot based on the finer grid is displayed in [Figure 96.6](#). The plot indicates that a parametric model with quadratic terms of  $x_1$  and  $x_2$  provides a reasonable fit to the data.

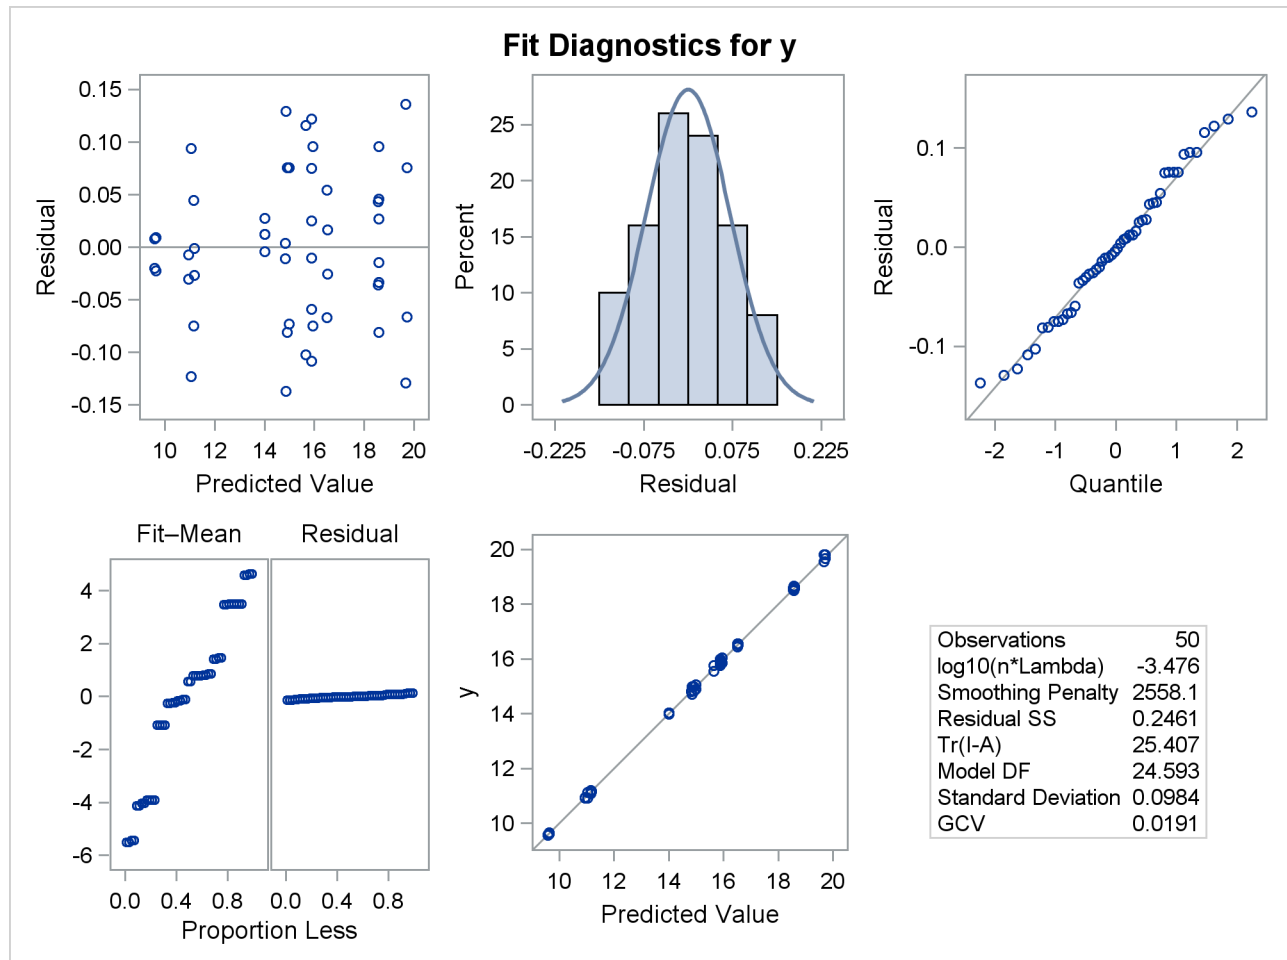

**Figure 96.6** Plot of TPSPLINE Fit

[Figure 96.7](#) shows a panel of fit diagnostics for the selected model that indicate a reasonable fit:

- The predicted values closely approximate the observed values.
- The residuals are approximately normally distributed and do not show obvious systematic patterns.
- The [RFPLOT](#) shows that much variation in the response variable is addressed by the fit and only a little remains in the residuals.

Figure 96.7 Fit Diagnostics

## Syntax: TPSPLINE Procedure

The following statements are available in the TPSPLINE procedure:

```

PROC TPSPLINE < options > ;
 MODEL dependents = < variables > (variables) < / options > ;
 SCORE DATA=SAS-data-set OUT=SAS-data-set < keyword ... keyword > ;
 OUTPUT < OUT=SAS-data-set > keyword ... keyword ;
 BY variables ;
 FREQ variable ;
 ID variables ;

```

The syntax in PROC TPSPLINE is similar to that of other regression procedures in the SAS System. The PROC TPSPLINE and MODEL statements are required. The SCORE statement can appear multiple times; all other statements appear no more than once.

The statements available for PROC TPSPLINE are described in alphabetical order after the description of the PROC TPSPLINE statement.

## PROC TPSPLINE Statement

**PROC TPSPLINE** < options > ;

The PROC TPSPLINE statement invokes the TPSPLINE procedure. Table 96.1 summarizes the options available in the TPSPLINE statement.

**Table 96.1** PROC TPSPLINE Statement Options

| Option       | Description                                               |
|--------------|-----------------------------------------------------------|
| <b>DATA=</b> | Specifies the SAS data set to be read                     |
| <b>PLOTS</b> | Controls the plots that are produced through ODS Graphics |

You can specify the following options:

**DATA=SAS-data-set**

specifies the SAS data set to be read by PROC TPSPLINE. The default value is the most recently created data set.

**PLOTS** < (global-plot-options) > <= plot-request < (options) > >

**PLOTS** < (global-plot-options) > <= (plot-request < (options) > <...plot-request < (options) > > >

controls the plots that are produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=none
plots=residuals(smooth)
plots(unpack)=diagnostics
plots(only)=(fit residualHistogram)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc tpspline;
 model y = (x);
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC TPSPLINE produces a default set of plots. The following table lists the plots that are produced.

**Table 96.2** Graphs Produced

| Plot            | Conditional on:                                                |
|-----------------|----------------------------------------------------------------|
| ContourFitPanel | LAMBDA= or LOGNLAMBDA= option specified in the MODEL statement |
| ContourFit      | Model with two predictors                                      |

Table 96.2 continued

| Plot             | Conditional On                                                 |
|------------------|----------------------------------------------------------------|
| CriterionPlot    | Multiple values for the smoothing parameter                    |
| DiagnosticsPanel | Unconditional                                                  |
| ResidualBySmooth | LAMBDA= or LOGNLAMBDA= option specified in the MODEL statement |
| ResidualPanel    | Unconditional                                                  |
| FitPanel         | LAMBDA= or LOGNLAMBDA= option specified in the MODEL statement |
| FitPlot          | Model with one predictor                                       |
| ScorePlot        | One or more SCORE statements and a model with one predictor    |

For models with multiple dependent variables, separate plots are produced for each dependent variable. For models in which multiple smoothing parameters are specified with the LAMBDA= or LOGNLAMBDA= option in the MODEL statement, the plots are produced for the selected model only.

## Global Plot Options

The *global-plot-options* apply to all relevant plots generated by the TPSPLINE procedure, unless they are overridden by a *specific-plot-option*. The following *global-plot-options* are supported by the TPSPLINE procedure:

### ONLY

suppresses the default plots. Only the plots specifically requested are produced.

### UNPACK

suppresses paneling. By default, multiple plots can appear in some output panels. Specify UNPACK to get each plot individually. You can specify PLOTS(UNPACK) to unpack the default plots. You can also specify UNPACK as a suboption with the CONTOURFITPANEL, DIAGNOSTICS, FITPANEL, RESIDUALS and RESIDUALSBYSMOOTH options.

## Plot Requests

You can specify the following specific *plot-requests* and controls for them:

### ALL

produces all plots appropriate for the particular analysis. You can specify other options with ALL; for example, to request that all plots be produced and that only the residual plots be unpacked, specify PLOTS=(ALL RESIDUALS(UNPACK)).

### CONTOURFIT <(OBS=*contour-options*)>

produces a contour plot of the fitted surface overlaid with a scatter plot of the data for models with two predictors. You can use the following *contour-options* to control how the observations are displayed:

### GRADIENT

displays observations as circles colored by the observed response. The same color gradient is used to display the fitted surface and the observations. Observations where the predicted response is close to the observed response have similar colors—the greater the contrast between the color of an observation and the surface, the larger the residual is at that point. OBS=GRADIENT is the default if you do not specify any *contour-options*.

**NONE**

suppresses the observations.

**OUTLINE**

displays observations as circles with a border but with a completely transparent fill.

**OUTLINEGRADIENT**

is the same as `OBS=GRADIENT` except that a border is shown around each observation. This option is useful for identifying the location of observations where the residuals are small, because at these points the color of the observations and the color of the surface are indistinguishable.

**CONTOURFITPANEL <(options)>**

produces panels of contour plots overlaid with a scatter plot of the data for each smoothing parameter specified in the `LAMBDA=` or `LOGNLAMBDA=` option in the `MODEL` statement, for models with two predictors. If you do not specify the `LAMBDA=` or `LOGNLAMBDA=` option or if the model does not have two predictors, then this plot is not produced. Each panel contains at most six plots, and multiple panels are used when there are more than six smoothing parameters in the `LAMBDA=` or `LOGNLAMBDA=` option. The following *options* are available:

**OBS=contour-options**

specifies how the observations are displayed. See *contour-options* for the `CONTOURFIT` option for details.

**UNPACK**

suppresses paneling.

**CRITERIONPLOT | CRITERION <(NOPATH)>**

displays a scatter plot of the value of the GCV criterion versus the smoothing parameter value for all smoothing parameter values examined in the selection process. This plot is not produced when you specify one smoothing parameter with either the `LAMBDA0=` or `LOGNLAMBDA0=` option in the `MODEL` statement. When you supply a list of values for the smoothing parameter with the `LAMBDA=` or `LOGNLAMBDA=` option and PROC TPSPLINE obtains the optimal smoothing parameter by minimizing the GCV criterion, then the plot contains the supplied list of smoothing values and the optimal smoothing parameter in addition to the values examined during the optimization process. You can use the `NOPATH` suboption to disable the display of the optimization path in the plot in this case.

**DIAGNOSTICSPANEL | DIAGNOSTICS <(UNPACK)>**

produces a summary panel of fit diagnostics that consists of the following:

- residuals versus the predicted values
- a histogram of the residuals
- a normal quantile plot of the residuals
- a “Residual-Fit” (RF) plot that consists of side-by-side quantile plots of the centered fit and the residuals
- response values versus the predicted values

You can request the five plots in this panel as individual plots by specifying the `UNPACK` option. You can also request individual plots in the panel by name without having to unpack the panel. The fit diagnostics panel is produced by default whenever ODS Graphics is enabled.

**FITPANEL** < (*options*) >

produces panels of plots that show the fitted TPSPLINE curve overlaid on a scatter plot of the input data for each smoothing parameter specified in the **LAMBDA=** or **LOGNLAMBDA=** option in the MODEL statement. If you do not specify the **LAMBDA=** or **LOGNLAMBDA=** option or the model has more than one predictor, then this plot is not produced. Each panel contains at most six plots, and multiple panels are used when there are more than six smoothing parameters in the **LAMBDA=** or **LOGNLAMBDA=** option. The following *options* are available:

**CLM**

includes a confidence band at the significance level specified in the **ALPHA=** option in the MODEL statement in each plot in the panels.

**UNPACK**

suppresses paneling.

**FITPLOT | FIT** < (**CLM**) >

produces a scatter plot of the input data with the fitted TPSPLINE curve overlaid for models with a single predictor. If the **CLM** option is specified, then a confidence band at the significance level specified in the **ALPHA=** option in the MODEL statement is included in the plot.

**NONE**

suppresses all plots.

**OBSERVEDBYPREDICTED**

produces a scatter plot of the dependent variable values by the predicted values.

**QQPLOT | QQ**

produces a normal quantile plot of the residuals.

**RESIDUALBYSMOOTH** < (**SMOOTH**) >

produces, for each predictor, panels of plots that show the residuals of the TPSPLINE fit versus the predictor for each smoothing parameter specified in the **LAMBDA=** or **LOGNLAMBDA=** option in the MODEL statement. If you do not specify the **LAMBDA=** or **LOGNLAMBDA=** option, then this plot is not produced. Each panel contains at most six plots, and multiple panels are used when there are more than six smoothing parameters in the **LAMBDA=** or **LOGNLAMBDA=** option in the MODEL statement. The **SMOOTH** option displays a nonparametric fit line in each plot in the panel. The type of nonparametric fit and the options used are controlled by the underlying template for this plot. In the standard template that is provided, the nonparametric smooth is specified to be a loess fit that corresponds to the default options of PROC LOESS, except that the **PRESEARCH** suboption in the **SELECT** statement is always used. It is important to note that the loess fit that is shown in each of the residual plots is computed independently of the smoothing spline fit that is used to obtain the residuals.

**RESIDUALBYPREDICTED**

produces a scatter plot of the residuals by the predicted values.

**RESIDUALHISTOGRAM**

produces a histogram of the residuals.

**RESIDUALPANEL | RESIDUALS** <(options)>

produces panels of the residuals versus the predictors in the model. Each panel contains at most six plots, and multiple panels are used when there are more than six predictors in the model.

The following *options* are available:

**SMOOTH**

displays a nonparametric fit line in each plot in the panel. The type of nonparametric fit and the options used are controlled by the underlying template for this plot. In the standard template that is provided, the nonparametric smooth is specified to be a loess fit that corresponds to the default options of PROC LOESS, except that the PRESEARCH suboption in the SELECT statement is always used. It is important to note that the loess fit that is shown in each of the residual plots is computed independently of the smoothing spline fit that is used to obtain the residuals.

**UNPACK**

suppresses paneling.

**RFPLOT | RF**

produces a “Residual-Fit” (RF) plot that consists of side-by-side quantile plots of the centered fit and the residuals. This plot “shows how much variation in the data is explained by the fit and how much remains in the residuals” (Cleveland 1993).

**SCOREPLOT | SCORE**

produces a scatter plot of the scored values at the score points for each SCORE statement. SCORE plots are not produced for models with more than one predictor.

**BY Statement**

**BY** *variables* ;

You can specify a BY statement with PROC TPSPLINE to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the TPSPLINE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## FREQ Statement

**FREQ** *variable* ;

If one variable in your input data set represents the frequency of occurrence for other values in the observation, specify the variable's name in a FREQ statement. PROC TPSPLINE treats the data as if each observation appears  $n$  times, where  $n$  is the value of the FREQ variable for the observation. If the value of the FREQ variable is less than one, the observation is not used in the analysis. Only the integer portion of the value is used.

---

## ID Statement

**ID** *variables* ;

The ID statement is optional, and more than one ID statement can be used. If variables are specified in the ID statement, their values are displayed in tooltips to identify observations in the plots produced by PROC TPSPLINE.

---

## MODEL Statement

**MODEL** *dependent-variables* = < *regression-variables* > (*smoothing-variables*)< / *options* > ;

The MODEL statement specifies the dependent variables, the independent regression variables, which are listed with no parentheses, and the independent smoothing variables, which are listed inside parentheses.

The regression variables are optional. At least one smoothing variable is required, and it must be listed after the regression variables. No variables can be listed in both the regression variable list and the smoothing variable list.

If you specify more than one dependent variable, PROC TPSPLINE calculates a thin-plate smoothing spline estimate for each dependent variable by using the regression variables and smoothing variables specified on the right side.

If you specify regression variables, PROC TPSPLINE fits a semiparametric model by using the regression variables as the linear part of the model.

Table 96.3 summarizes the options available in the MODEL statement.

**Table 96.3** MODEL Statement Options

| Option       | Description                                                                              |
|--------------|------------------------------------------------------------------------------------------|
| ALPHA=       | Specifies the significance level                                                         |
| DF=          | Specifies the degrees of freedom                                                         |
| DISTANCE=    | Defines a range in which points are treated as replicates                                |
| LAMBDA0=     | Specifies the smoothing parameter                                                        |
| LAMBDA=      | Specifies a set of values for the $\lambda$ parameter                                    |
| LOGNLAMBDA0= | Specifies the smoothing parameter on the $\log_{10}(n\lambda)$ scale                     |
| LOGNLAMBDA=  | Specifies a set of values for the $\lambda$ parameter on the $\log_{10}(n\lambda)$ scale |
| M=           | Specifies the order of the derivative                                                    |
| RANGE=       | Specifies the range for smoothing values to be evaluated                                 |

You can specify the following options in the MODEL statement:

**ALPHA=number**

specifies the significance level  $\alpha$  of the confidence limits on the final thin-plate smoothing spline estimate when you request confidence limits to be included in the output data set. Specify *number* as a value between 0 and 1. The default value is 0.05. See the section “OUTPUT Statement” on page 8116 for more information about the OUTPUT statement.

**DF=df**

specifies the degrees of freedom of the thin-plate smoothing spline estimate, defined as

$$df = \text{tr}(\mathbf{A}(\lambda))$$

where  $\mathbf{A}(\lambda)$  is the *hat* matrix. Specify *df* as a value between zero and the number of unique design points  $n_q$ . Smaller *df* values cause more penalty on the roughness and thus smoother fits.

**DISTANCE=number**

**D=number**

defines a range such that if the  $L_\infty$  distance between two data points  $(\mathbf{x}_i, \mathbf{z}_i)$  and  $(\mathbf{x}_j, \mathbf{z}_j)$  satisfies

$$\|\mathbf{x}_i - \mathbf{x}_j\|_\infty \leq D/2$$

then these data points are treated as replicates, where  $\mathbf{x}_i$  are the smoothing variables and  $\mathbf{z}_i$  are the regression variables.

You can use the DISTANCE= option to reduce the number of unique design points by treating nearby data as replicates. This can be useful when you have a large data set. Larger DISTANCE= option values cause fewer  $n_q$  points. The default value is 0.

PROC TPSPLINE uses the DISTANCE= value to group points as follows: The data are first sorted by the smoothing variables in the order in which they appear in the MODEL statement. The first point in the sorted data becomes the first unique point. Subsequent points have their values set equal to that point until the first point where the maximum distance in one dimension is larger than  $D/2$ . This point becomes the next unique point, and so on. Because of this sequential processing, the set of unique points differs depending on the order of the smoothing variables in the MODEL statement.

For example, with a model that has two smoothing variables ( $x_1$ ,  $x_2$ ), the data are first sorted by  $x_1$  and  $x_2$  (in that order), and then uniqueness is assessed sequentially. The first point in the sorted data  $x_1 = (x_{1_1}, x_{2_1})$  becomes the first unique point,  $u_1 = (u_{1_1}, u_{2_1})$ . Subsequent points  $x_i = (x_{1_i}, x_{2_i})$  are set equal to  $u_1$  until the algorithm comes to a point with  $\max(|x_{1_i} - u_{1_1}|, |x_{2_i} - u_{2_1}|) > D/2$ . This point becomes the second unique point  $u_2$ , and data sorting proceeds from there.

**LAMBDA0=number**

specifies the smoothing parameter,  $\lambda_0$ , to be used in the thin-plate smoothing spline estimate. By default, PROC TPSPLINE uses the  $\lambda$  parameter that minimizes the GCV function for the final fit. The LAMBDA0= value must be positive. Larger  $\lambda_0$  values cause smoother fits.

**LAMBDA=list-of-values**

specifies a set of values for the  $\lambda$  parameter. PROC TPSPLINE returns a GCV value for each  $\lambda$  point that you specify. You can use the LAMBDA= option to study the GCV function curve for a set of values for  $\lambda$ . All values listed in the LAMBDA= option must be positive.

**LOGNLAMBDA0=number**

**LOGNL0=number**

specifies the smoothing parameter  $\lambda_0$  on the  $\log_{10}(n\lambda)$  scale. If you specify both the LOGNL0= and LAMBDA0= options, only the value provided by the LOGNL0= option is used. Larger  $\log_{10}(n\lambda_0)$  values cause smoother fits. By default, PROC TPSPLINE uses the  $\lambda$  parameter that minimizes the GCV function for the estimate.

**LOGNLAMBDA=list-of-values**

**LOGNL=list-of-values**

specifies a set of values for the  $\lambda$  parameter on the  $\log_{10}(n\lambda)$  scale. PROC TPSPLINE returns a GCV value for each  $\lambda$  point that you specify. You can use the LOGNLAMBDA= option to study the GCV function curve for a set of  $\lambda$  values. If you specify both the LOGNL= and LAMBDA= options, only the list of values provided by the LOGNL= option is used.

In some cases, the LOGNL= option might be preferred over the LAMBDA= option. Because the LAMBDA= value must be positive, a small change in that value can result in a major change in the GCV value. If you instead specify  $\lambda$  on the  $\log_{10}(n\lambda)$  scale, the allowable range is enlarged to include negative values. Thus, the GCV function is less sensitive to changes in LOGNLAMBDA.

The DF= option, LAMBDA0= option, and LOGNLAMBDA0= option all specify exact smoothness of a nonparametric fit. If you want to fit a model with specified smoothness, the DF= option is preferable to the other two options because  $(0, n_q)$ , the range of  $df$ , is much smaller in length than  $(0, \infty)$  of  $\lambda$  and  $(-\infty, \infty)$  of  $\log_{10}(n\lambda)$ .

**M=number**

specifies the order of the derivative in the penalty term. The *number* must be a positive integer. The default value is  $\max(2, \text{int}(d/2) + 1)$ , where  $d$  is the number of smoothing variables.

**RANGE=(lower, upper)**

specifies that on the  $\log_{10}(n\lambda)$  scale only smoothing values greater than or equal to *lower* and less than or equal to *upper* be evaluated to minimize the GCV function.

## OUTPUT Statement

**OUTPUT** **OUT**=SAS-data-set < keyword ... keyword > ;

The OUTPUT statement creates a new SAS data set that contains diagnostic measures calculated after fitting the model.

All the variables in the original data set are included in the new data set, along with variables created by specifying *keywords* in the OUTPUT statement. These new variables contain the values of a variety of statistics and diagnostic measures that are calculated for each observation in the data set. If no *keyword* is present, the data set contains only the original data set and predicted values.

Details about the specifications in the OUTPUT statement are as follows.

### **OUT**=SAS-data-set

specifies the name of the new data set to contain the diagnostic measures. This specification is required.

### *keyword*

specifies the statistics to include in the output data set. The names of the new variables that contain the statistics are formed by using a prefix of one or more characters to identify the statistic, followed by an underscore (\_), followed by the dependent variable name.

For example, suppose that you have two dependent variables—say, *y1* and *y2*—and you specify the keywords PRED, ADIAG, and UCLM. The output SAS data set will contain the following variables:

- P\_y1 and P\_y2
- ADIAG\_y1 and ADIAG\_y2
- UCLM\_y1 and UCLM\_y2

The keywords and the statistics they represent are as follows:

|           |                                                                                                                                                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RESID   R | residual values, calculated as fitted values subtracted from the observed response values: $y - \hat{y}$ . The default prefix is R_.                                                                                                                                              |
| PRED      | predicted values. The default prefix is P_.                                                                                                                                                                                                                                       |
| STD       | standard error of the mean predicted value. The default prefix is STD_.                                                                                                                                                                                                           |
| UCLM      | upper limit of the Bayesian confidence interval for the expected value of the dependent variables. By default, PROC TPSPLINE computes 95% confidence limits. The default prefix is UCLM_.                                                                                         |
| LCLM      | lower limit of the Bayesian confidence interval for the expected value of the dependent variables. By default, PROC TPSPLINE computes 95% confidence limits. The default prefix is LCLM_.                                                                                         |
| ADIAG     | diagonal element of the hat matrix associated with the observation. The default prefix is ADIAG_.                                                                                                                                                                                 |
| COEF      | coefficients arranged in the order of $(\theta_0, \theta_1, \dots, \theta_d, \delta_1, \dots, \delta_{n_q})$ , where $n_q$ is the number of unique data points. This option can be used only when there is only one dependent variable in the model. The default prefix is COEF_. |

---

## SCORE Statement

**SCORE DATA=SAS-data-set OUT=SAS-data-set < keyword . . . keyword > ;**

The SCORE statement calculates predicted statistics for a new data set. If you have multiple data sets to predict, you can specify multiple SCORE statements. You must use a SCORE statement for each data set.

You can request diagnostic measures that are calculated for each observation in the SCORE data set. The new data set contains all the variables in the SCORE data set in addition to the requested variables. If no *keyword* is present, the data set contains only the predicted values.

The following keywords must be specified in the SCORE statement:

**DATA=SAS-data-set**

specifies the input SAS data set that contains the smoothing variables  $\mathbf{x}$  and regression variables  $\mathbf{z}$ . The predicted response ( $\hat{y}$ ) value is computed for each  $(\mathbf{x}, \mathbf{z})$  pair. The data set must include all independent variables specified in the MODEL statement.

**OUT=SAS-data-set**

specifies the name of the SAS data set to contain the predictions.

*keyword*

specifies the statistics to include in the output data set for the current SCORE statement. The names of the new variables that contain the statistics are formed by using a prefix of one or more characters to identify the statistic, followed by an underscore ( $\_$ ), followed by the dependent variable name. The keywords and the statistics they represent are as follows:

|      |                                                                                                                                                              |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRED | predicted values                                                                                                                                             |
| STD  | standard error of the mean predicted value                                                                                                                   |
| UCLM | upper limit of the Bayesian confidence interval for the expected value of the dependent variables. By default, PROC TPSPLINE computes 95% confidence limits. |
| LCLM | lower limit of the Bayesian confidence interval for the expected value of the dependent variables. By default, PROC TPSPLINE computes 95% confidence limits. |

## Details: TPSPLINE Procedure

---

### Computational Formulas

The theoretical foundations for the thin-plate smoothing spline are described in Duchon (1976, 1977) and Meinguet (1979). Further results and applications are given in: Wahba and Wendelberger (1980); Hutchinson and Bischof (1983); Seaman and Hutchinson (1985).

Suppose that  $\mathcal{H}_m$  is a space of functions whose partial derivatives of total order  $m$  are in  $L_2(E^d)$ , where  $E^d$  is the domain of  $\mathbf{x}$ .

Now, consider the data model

$$y_i = f(\mathbf{x}_i) + \epsilon_i, i = 1, \dots, n$$

where  $f \in \mathcal{H}_m$ .

Using the notation from the section “[Penalized Least Squares Estimation](#)” on page 8096, for a fixed  $\lambda$ , estimate  $f$  by minimizing the penalized least squares function

$$\frac{1}{n} \sum_{i=1}^n (y_i - f(\mathbf{x}_i) - \mathbf{z}_i \boldsymbol{\beta})^2 + \lambda J_m(f)$$

$\lambda J_m(f)$  is the penalty term to enforce smoothness on  $f$ . There are several ways to define  $J_m(f)$ . For the thin-plate smoothing spline, with  $\mathbf{x} = (x_1, \dots, x_d)$  of dimension  $d$ , define  $J_m(f)$  as

$$J_m(f) = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \sum \frac{m!}{\alpha_1! \cdots \alpha_d!} \left( \frac{\partial^m f}{\partial x_1^{\alpha_1} \cdots \partial x_d^{\alpha_d}} \right)^2 dx_1 \cdots dx_d$$

where  $\sum_i \alpha_i = m$ . Under this definition,  $J_m(f)$  gives zero penalty to some functions. The space that is spanned by the set of polynomials that contribute zero penalty is called the polynomial space. The dimension of the polynomial space  $M$  is a function of dimension  $d$  and order  $m$  of the smoothing penalty,  $M = \binom{m+d-1}{d}$ .

Given the condition that  $2m > d$ , the function that minimizes the penalized least squares criterion has the form

$$\hat{f}(\mathbf{x}) = \sum_{j=1}^M \theta_j \phi_j(\mathbf{x}) + \sum_{i=1}^n \delta_i \eta_{md}(\|\mathbf{x} - \mathbf{x}_i\|)$$

where  $\boldsymbol{\theta}$  and  $\boldsymbol{\delta}$  are vectors of coefficients to be estimated. The  $M$  functions  $\phi_j$  are linearly independent polynomials that span the space of functions for which  $J_m(f)$  is zero. The basis functions  $\eta_{md}$  are defined as

$$\eta_{md}(r) = \begin{cases} \frac{(-1)^{m+1+d/2}}{2^{2m-1} \pi^{d/2} (m-1)! (m-d/2)!} r^{2m-d} \log(r) & \text{if } d \text{ is even} \\ \frac{\Gamma(d/2-m)}{2^{2m} \pi^{d/2} (m-1)!} r^{2m-d} & \text{if } d \text{ is odd} \end{cases}$$

When  $d = 2$  and  $m = 2$ , then  $M = \binom{3}{2} = 3$ ,  $\phi_1(\mathbf{x}) = 1$ ,  $\phi_2(\mathbf{x}) = x_1$ , and  $\phi_3(\mathbf{x}) = x_2$ .  $J_m(f)$  is as follows:

$$J_2(f) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left( \left( \frac{\partial^2 f}{\partial x_1^2} \right)^2 + 2 \left( \frac{\partial^2 f}{\partial x_1 \partial x_2} \right)^2 + \left( \frac{\partial^2 f}{\partial x_2^2} \right)^2 \right) dx_1 dx_2$$

For the sake of simplicity, the formulas and equations that follow assume  $m = 2$ . See Wahba (1990) and Bates et al. (1987) for more details.

Duchon (1976) showed that  $f_\lambda$  can be represented as

$$f_\lambda(\mathbf{x}_i) = \theta_0 + \sum_{j=1}^d \theta_j \mathbf{x}_{i j} + \sum_{j=1}^n \delta_j E_2(\mathbf{x}_i - \mathbf{x}_j)$$

where  $E_2(\mathbf{s}) = \frac{1}{2^{3\pi}} \|\mathbf{s}\|^2 \log(\|\mathbf{s}\|)$  for  $d = 2$ . For derivations of  $E_2(\mathbf{s})$  for other values of  $d$ , see Villalobos and Wahba (1987).

If you define  $\mathbf{K}$  with elements  $\mathbf{K}_{ij} = E_2(\mathbf{x}_i - \mathbf{x}_j)$  and  $\mathbf{T}$  with elements  $\mathbf{T}_{ij} = (\mathbf{X}_{ij})$ , the goal is to find vectors of coefficients  $\boldsymbol{\beta}$ ,  $\boldsymbol{\theta}$ , and  $\boldsymbol{\delta}$  that minimize

$$S_\lambda(\boldsymbol{\beta}, \boldsymbol{\theta}, \boldsymbol{\delta}) = \frac{1}{n} \|\mathbf{y} - \mathbf{T}\boldsymbol{\theta} - \mathbf{K}\boldsymbol{\delta} - \mathbf{Z}\boldsymbol{\beta}\|^2 + \lambda \boldsymbol{\delta}'\mathbf{K}\boldsymbol{\delta}$$

A unique solution is guaranteed if the matrix  $\mathbf{T}$  is of full rank and  $\boldsymbol{\delta}'\mathbf{K}\boldsymbol{\delta} \geq 0$ .

If  $\boldsymbol{\alpha} = \begin{pmatrix} \boldsymbol{\theta} \\ \boldsymbol{\beta} \end{pmatrix}$  and  $\mathbf{X} = (\mathbf{T} \ \mathbf{Z})$ , the expression for  $S_\lambda$  becomes

$$\frac{1}{n} \|\mathbf{y} - \mathbf{X}\boldsymbol{\alpha} - \mathbf{K}\boldsymbol{\delta}\|^2 + \lambda \boldsymbol{\delta}'\mathbf{K}\boldsymbol{\delta}$$

The coefficients  $\boldsymbol{\alpha}$  and  $\boldsymbol{\delta}$  can be obtained by solving

$$\begin{aligned} (\mathbf{K} + n\lambda\mathbf{I}_n)\boldsymbol{\delta} + \mathbf{X}\boldsymbol{\alpha} &= \mathbf{y} \\ \mathbf{X}'\boldsymbol{\delta} &= \mathbf{0} \end{aligned}$$

To compute  $\boldsymbol{\alpha}$  and  $\boldsymbol{\delta}$ , let the QR decomposition of  $\mathbf{X}$  be

$$\mathbf{X} = (\mathbf{Q}_1 \ \mathbf{Q}_2) \begin{pmatrix} \mathbf{R} \\ \mathbf{0} \end{pmatrix}$$

where  $(\mathbf{Q}_1 \ \mathbf{Q}_2)$  is an orthogonal matrix and  $\mathbf{R}$  is an upper triangular, with  $\mathbf{X}'\mathbf{Q}_2 = \mathbf{0}$  (Dongarra et al. 1979).

Since  $\mathbf{X}'\boldsymbol{\delta} = \mathbf{0}$ ,  $\boldsymbol{\delta}$  must be in the column space of  $\mathbf{Q}_2$ . Therefore,  $\boldsymbol{\delta}$  can be expressed as  $\boldsymbol{\delta} = \mathbf{Q}_2\boldsymbol{\gamma}$  for a vector  $\boldsymbol{\gamma}$ . Substituting  $\boldsymbol{\delta} = \mathbf{Q}_2\boldsymbol{\gamma}$  into the preceding equation and multiplying through by  $\mathbf{Q}_2'$  gives

$$\mathbf{Q}_2'(\mathbf{K} + n\lambda\mathbf{I})\mathbf{Q}_2\boldsymbol{\gamma} = \mathbf{Q}_2'\mathbf{y}$$

or

$$\boldsymbol{\delta} = \mathbf{Q}_2\boldsymbol{\gamma} = \mathbf{Q}_2[\mathbf{Q}_2'(\mathbf{K} + n\lambda\mathbf{I})\mathbf{Q}_2]^{-1}\mathbf{Q}_2'\mathbf{y}$$

The coefficient  $\boldsymbol{\alpha}$  can be obtained by solving

$$\mathbf{R}\boldsymbol{\alpha} = \mathbf{Q}_1'[\mathbf{y} - (\mathbf{K} + n\lambda\mathbf{I})\boldsymbol{\delta}]$$

The influence matrix  $\mathbf{A}(\lambda)$  is defined as

$$\hat{\mathbf{y}} = \mathbf{A}(\lambda)\mathbf{y}$$

and has the form

$$\mathbf{A}(\lambda) = \mathbf{I} - n\lambda\mathbf{Q}_2[\mathbf{Q}_2'(\mathbf{K} + n\lambda\mathbf{I})\mathbf{Q}_2]^{-1}\mathbf{Q}_2'$$

Similar to the regression case, if you consider the trace of  $\mathbf{A}(\lambda)$  as the degrees of freedom for the model and the trace of  $(\mathbf{I} - \mathbf{A}(\lambda))$  as the degrees of freedom for the error, the estimate  $\sigma^2$  can be represented as

$$\hat{\sigma}^2 = \frac{\text{RSS}(\lambda)}{\text{tr}(\mathbf{I} - \mathbf{A}(\lambda))}$$

where  $\text{RSS}(\lambda)$  is the residual sum of squares. Theoretical properties of these estimates have not yet been published. However, good numerical results in simulation studies have been described by several authors. For more information, see O'Sullivan and Wong (1987); Nychka (1986a, b, 1988); Hall and Titterton (1987).

## Confidence Intervals

Viewing the spline model as a Bayesian model, Wahba (1983) proposed Bayesian confidence intervals for smoothing spline estimates as

$$\hat{f}_\lambda(\mathbf{x}_i) \pm z_{\alpha/2} \sqrt{\hat{\sigma}^2 a_{ii}(\lambda)}$$

where  $a_{ii}(\lambda)$  is the  $i$ th diagonal element of the  $\mathbf{A}(\lambda)$  matrix and  $z_{\alpha/2}$  is the  $1 - \alpha/2$  quantile of the standard normal distribution. The confidence intervals are interpreted as intervals “across the function” as opposed to pointwise intervals.

For SCORE data sets, the hat matrix  $\mathbf{A}(\lambda)$  is not available. To compute the Bayesian confidence interval for a new point  $\mathbf{x}_{\text{new}}$ , let

$$\mathbf{S} = \mathbf{X}, \quad \mathbf{M} = \mathbf{K} + n\lambda\mathbf{I}$$

and let  $\boldsymbol{\xi}$  be an  $n \times 1$  vector with  $i$ th entry

$$\eta_{md}(\|\mathbf{x}_{\text{new}} - \mathbf{x}_i\|)$$

When  $d = 2$  and  $m = 2$ ,  $\xi_i$  is computed with

$$E_2(\mathbf{x}_i - \mathbf{x}_{\text{new}}) = \frac{1}{2^3 \pi} \|\mathbf{x}_i - \mathbf{x}_{\text{new}}\|^2 \log(\|\mathbf{x}_i - \mathbf{x}_{\text{new}}\|)$$

$\boldsymbol{\phi}$  is a vector of evaluations of  $\mathbf{x}_{\text{new}}$  by the polynomials that span the functional space where  $J_m(f)$  is zero. The details for  $\mathbf{X}$ ,  $\mathbf{K}$ , and  $E_2$  are discussed in the previous section. Wahba (1983) showed that the Bayesian posterior variance of  $\mathbf{x}_{\text{new}}$  satisfies

$$n\lambda \text{Var}(\mathbf{x}_{\text{new}}) = \boldsymbol{\phi}'(\mathbf{S}'\mathbf{M}^{-1}\mathbf{S})^{-1}\boldsymbol{\phi} - 2\boldsymbol{\phi}'\mathbf{d}_\xi - \boldsymbol{\xi}'\mathbf{c}_\xi$$

where

$$\begin{aligned} \mathbf{c}_\xi &= (\mathbf{M}^{-1} - \mathbf{M}^{-1}\mathbf{S}(\mathbf{S}'\mathbf{M}^{-1}\mathbf{S})^{-1}\mathbf{S}'\mathbf{M}^{-1})\boldsymbol{\xi} \\ \mathbf{d}_\xi &= (\mathbf{S}'\mathbf{M}^{-1}\mathbf{S})^{-1}\mathbf{S}'\mathbf{M}^{-1}\boldsymbol{\xi} \end{aligned}$$

Suppose that you fit a spline estimate that consists of a true function  $f$  and a random error term  $\epsilon_i$  to experimental data. In repeated experiments, it is likely that about  $100(1 - \alpha)\%$  of the confidence intervals cover the corresponding true values, although some values are covered every time and other values are not covered by the confidence intervals most of the time. This effect is more pronounced when the true surface or surface has small regions of particularly rapid change.

## Smoothing Parameter

The quantity  $\lambda$  is called the smoothing parameter, which controls the balance between the goodness of fit and the smoothness of the final estimate.

A large  $\lambda$  heavily penalizes the  $m$ th derivative of the function, thus forcing  $f^{(m)}$  close to 0. A small  $\lambda$  places less of a penalty on rapid change in  $f^{(m)}(\mathbf{x})$ , resulting in an estimate that tends to interpolate the data points.

The smoothing parameter greatly affects the analysis, and it should be selected with care. One method is to perform several analyses with different values for  $\lambda$  and compare the resulting final estimates.

A more objective way to select the smoothing parameter  $\lambda$  is to use the “leave-out-one” cross validation function, which is an approximation of the predicted mean squares error. A generalized version of the leave-out-one cross validation function is proposed by Wahba (1990) and is easy to calculate. This generalized cross validation (GCV) function is defined as

$$\text{GCV}(\lambda) = \frac{(1/n)\|(\mathbf{I} - \mathbf{A}(\lambda))\mathbf{y}\|^2}{[(1/n)\text{tr}(\mathbf{I} - \mathbf{A}(\lambda))]^2}$$

The justification for using the GCV function to select  $\lambda$  relies on asymptotic theory. Thus, you cannot expect good results for very small sample sizes or when there is not enough information in the data to separate the model from the error component. Simulation studies suggest that for independent and identically distributed Gaussian noise, you can obtain reliable estimates of  $\lambda$  for  $n$  greater than 25 or 30. Note that, even for large values of  $n$  (say,  $n \geq 50$ ), in extreme Monte Carlo simulations there might be a small percentage of unwarranted extreme estimates in which  $\hat{\lambda} = 0$  or  $\hat{\lambda} = \infty$  (Wahba 1983). Generally, if  $\sigma^2$  is known to within an order of magnitude, the occasional extreme case can be readily identified. As  $n$  gets larger, the effect becomes weaker.

The GCV function is fairly robust against nonhomogeneity of variances and non-Gaussian errors (Villalobos and Wahba 1987). Andrews (1988) has provided favorable theoretical results when variances are unequal. However, this selection method is likely to give unsatisfactory results when the errors are highly correlated.

The GCV value might be suspect when  $\lambda$  is extremely small because computed values might become indistinguishable from zero. In practice, calculations with  $\lambda = 0$  or  $\lambda$  near 0 can cause numerical instabilities that result in an unsatisfactory solution. Simulation studies have shown that a  $\lambda$  with  $\log_{10}(n\lambda) > -8$  is small enough that the final estimate based on this  $\lambda$  almost interpolates the data points. A GCV value based on a  $\lambda \leq 10^{-8}$  might not be accurate.

---

## ODS Table Names

PROC TPSPLINE assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. [Table 96.4](#) lists these names. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 96.4** ODS Tables Produced by PROC TPSPLINE

| ODS Table Name | Description                    | Statement | Option             |
|----------------|--------------------------------|-----------|--------------------|
| DataSummary    | Data summary                   | PROC      | Default            |
| FitSummary     | Fit parameters and fit summary | PROC      | Default            |
| FitStatistics  | Model fit statistics           | PROC      | Default            |
| GCVFunction    | GCV table                      | MODEL     | LOGNLAMBDA, LAMBDA |

By referring to the names of such tables, you can use the ODS OUTPUT statement to place one or more of these tables in output data sets.

For example, the following statements create an output data set named `FitStats` which contains the `FitStatistics` table, an output data set named `DataInfo` which contains the `DataSummary` table, an output data set named `ModelInfo` which contains the `FitSummary` table, and an output data set named `GCVFunc` which contains the `GCVFunction` table.

```
proc tpspline data=Melanoma;
 model Incidences=Year /LOGNLAMBDA=(-4 to 0 by 0.2);
 ods output FitStatistics = FitStats
 DataSummary = DataInfo
 FitSummary = ModelInfo
 GCVFunction = GCVFunc;
run;
```

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the `ODS GRAPHICS ON` statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

You can reference every graph produced through ODS Graphics with a name. [Table 96.5](#) lists the names of the graphs, along with the relevant `PLOTS=` options.

**Table 96.5** Graphs Produced by PROC TPSPLINE

| ODS Graph Name      | Plot Description                                                              | PLOTS Option        |

## Examples: TPSPLINE Procedure

### Example 96.1: Partial Spline Model Fit

This example analyzes the data set `Measure` that was introduced in the section “Getting Started: TPSPLINE Procedure” on page 8098. That analysis determined that the final estimated surface can be represented by a quadratic function for one or both of the independent variables. This example illustrates how you can use PROC TPSPLINE to fit a partial spline model. The data set `Measure` is fit by using the following model:

$$y = \beta_0 + \beta_1 x_1 + \beta x_1^2 + f(x_2)$$

The model has a parametric component (associated with the  $x_1$  variable) and a nonparametric component (associated with the  $x_2$  variable). The following statements fit a partial spline model:

```
data Measure;
 set Measure;
 x1sq = x1*x1;
run;

data pred;
 do x1=-1 to 1 by 0.1;
 do x2=-1 to 1 by 0.1;
 x1sq = x1*x1;
 output;
 end;
 end;
run;

proc tpspline data= measure;
 model y = x1 x1sq (x2);
 score data = pred out = predy;
run;
```

Output 96.1.1 displays the results from these statements.

**Output 96.1.1** Output from PROC TPSPLINE

| Raw Data                                  |          |
|-------------------------------------------|----------|
| The TPSPLINE Procedure                    |          |
| Dependent Variable: y                     |          |
| Summary of Input Data Set                 |          |
| Number of Non-Missing Observations        | 50       |
| Number of Missing Observations            | 0        |
| Unique Smoothing Design Points            | 5        |
| Summary of Final Model                    |          |
| Number of Regression Variables            | 2        |
| Number of Smoothing Variables             | 1        |
| Order of Derivative in the Penalty        | 2        |
| Dimension of Polynomial Space             | 4        |
| Summary Statistics<br>of Final Estimation |          |
| log10(n*Lambda)                           | -2.2374  |
| Smoothing Penalty                         | 205.3461 |
| Residual SS                               | 8.5821   |
| Tr(I-A)                                   | 43.1534  |
| Model DF                                  | 6.8466   |
| Standard Deviation                        | 0.4460   |
| GCV                                       | 0.2304   |

As displayed in [Output 96.1.1](#), there are five unique design points for the smoothing variable  $x_2$  and two regression variables in the model  $(x_1, x_1^2)$ . The dimension of the polynomial space is the number of columns in  $(\{1, x_1, x_1^2, x_2\}) = 4$ . The standard deviation of the estimate is much larger than the one based on the model with both  $x_1$  and  $x_2$  as smoothing variables (0.445954 compared to 0.098421). One of the many possible explanations might be that the number of unique design points of the smoothing variable is too small to warrant an accurate estimate for  $f(x_2)$ .

The following statements produce a surface plot for the partial spline model by using the surface template that is defined in the section “Getting Started: TPSPLINE Procedure” on page 8098.

```
proc sgrender data=predy template=surface;
 dynamic _X='x1' _Y='x2' _Z='P_y' _T='Plot of Fitted Surface on a Fine Grid';
run;
```

The surface displayed in [Output 96.1.2](#) is similar to the one estimated by using the full nonparametric model (displayed in [Output 96.2](#) and [Output 96.6](#)).

**Output 96.1.2** Plot of PROC TPSPLINE Fit from the Partial Spline Model

---

## Example 96.2: Spline Model with Higher-Order Penalty

This example continues the analysis of the data set `Measure` to illustrate how you can use PROC TPSPLINE to fit a spline model with a higher-order penalty term. Spline models with high-order penalty terms move low-order polynomial terms into the polynomial space. Hence, there is no penalty for these terms, and they can vary without constraint.

As shown in the previous analyses, the final model for the data set `Measure` must include quadratic terms for both  $x_1$  and  $x_2$ . This example fits the following model:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_1^2 + \beta_3 x_2 + \beta_4 x_2^2 + \beta_5 x_1 x_2 + f(x_1, x_2)$$

The model includes quadratic terms for both variables, although it differs from the usual linear model. The nonparametric term  $f(x_1, x_2)$  explains the variation of the data that is unaccounted for by a simple quadratic surface.

To modify the order of the derivative in the penalty term, specify the `M=` option. The following statements specify the option `M=3` in order to include the quadratic terms in the polynomial space:

```
data Measure;
 set Measure;
 x1sq = x1*x1;
 x2sq = x2*x2;
 x1x2 = x1*x2;
run;

proc tpspline data= Measure;
 model y = (x1 x2) / m=3;
 score data = pred out = predy;
run;
```

Output 96.2.1 displays the results from these statements.

**Output 96.2.1** Output from PROC TPSPLINE with M=3

The model contains six terms in the polynomial space is the number of columns in  $(\{1, x_1, x_1^2, x_1x_2, x_2, x_2^2\}) = 6$ . Compare Output 96.2.1 with Output 96.1.1: the  $\log_{10}(n\lambda)$  value and the smoothing penalty differ significantly. In general, these terms are not directly comparable for different models. The final estimate based on this model is close to the estimate based on the model by using the default, M=2.

In the following statements, the REG procedure fits a quadratic surface model to the data set Measure:

```
proc reg data= Measure;
 model y = x1 x1sq x2 x2sq x1x2;
run;
```

The results are displayed in [Output 96.2.2](#).

**Output 96.2.2** Quadratic Surface Model: The REG Procedure

The REG procedure produces slightly different results. To fit a similar model with PROC TPSPLINE, you can use a MODEL statement that specifies the degrees of freedom with the DF= option. You can also use a large value for the LOGNLAMBDA0= option to force a parametric model fit.

Because there is one degree of freedom for each of the terms intercept, x1, x2, x1sq, x2sq, and x1x2, the DF=6 option is used as follows:

```
proc tpspline data=measure;
 model y=(x1 x2) /m=3 df=6 lognlambda=(-4 to 1 by 0.5);
 score data = pred
 out = predy;
run;
```

The fit statistics are displayed in [Output 96.2.3](#).

Output 96.2.4 shows the GCV values for the list of supplied  $\log_{10}(n\lambda)$  values in addition to the fitted model with fixed degrees of freedom 6. The fitted model has a larger GCV value than all other examined models.

**Output 96.2.4** Criterion Plot

The final estimate is based on 6.000330 degrees of freedom because there are already 6 degrees of freedom in the polynomial space and the search range for  $\lambda$  is not large enough (in this case, setting DF=6 is equivalent to setting  $\lambda = \infty$ ).

The standard deviation and RSS (Output 96.2.3) are close to the sum of squares for the error term and the root MSE from the linear regression model (Output 96.2.2), respectively.

For this model, the optimal  $\log_{10}(n\lambda)$  is around  $-3.8$ , which produces a standard deviation estimate of 0.096765 (see Output 96.2.1) and a GCV value of 0.016051, while the model that specifies DF=6 results in a  $\log_{10}(n\lambda)$  larger than 1 and a GCV value larger than 0.23074. The nonparametric model, based on the GCV, should provide better prediction, but the linear regression model can be more easily interpreted.

## Example 96.3: Multiple Minima of the GCV Function

The data in this example represent the deposition of sulfate (SO<sub>4</sub>) at 179 sites in the 48 contiguous states of the United States in 1990. Each observation records the latitude and longitude of the site in addition to the SO<sub>4</sub> deposition at the site measured in grams per square meter ( $g/m^2$ ).

You can use PROC TPSPLINE to fit a surface that reflects the general trend and that reveals underlying features of the data, which are shown in the following DATA step:

```
data so4;
 input latitude longitude so4 @@;
 datalines;
32.45833 87.24222 1.403 34.28778 85.96889 2.103
33.07139 109.86472 0.299 36.07167 112.15500 0.304
31.95056 112.80000 0.263 33.60500 92.09722 1.950
34.17944 93.09861 2.168 36.08389 92.58694 1.578

... more lines ...

43.87333 104.19222 0.306 44.91722 110.42028 0.210
45.07611 72.67556 2.646
;

data pred;
 do latitude = 25 to 47 by 1;
 do longitude = 68 to 124 by 1;
 output;
 end;
 end;
run;
```

The preceding statements create the SAS data set so4 and the data set pred in order to make predictions on a regular grid. The following statements fit a surface for SO<sub>4</sub> deposition:

```
ods graphics on;
proc tpspline data=so4 plots(only)=criterion;
 model so4 = (latitude longitude) /lognlambda=(-6 to 1 by 0.1);
 score data=pred out=prediction1;
run;
```

Partial output from these statements is displayed in [Output 96.3.1](#) and [Output 96.3.2](#).

Output 96.3.3 displays the CriterionPlot of the GCV function versus  $\log_{10}(n\lambda)$ .

**Output 96.3.3** GCV Function of SO<sub>4</sub> Data Set

The GCV function has two minima. PROC TPSPLINE locates the global minimum at 0.277005. The plot also displays a local minimum located around  $-2.56$ . The TPSPLINE procedure might not always find the global minimum, although it did in this case. If there is a predetermined search range based on prior knowledge, you can use the **RANGE=** option to narrow the search range in order to find a desired smoothing value. For example, if you believe a better smoothing parameter should be within the  $(-4, -2)$  range, you can obtain the model with  $\log_{10}(n\lambda) = -2.56$  with the following statements.

```
proc tpspline data=so4;
 model so4 = (latitude longitude) / range=(-4,-2);
 score data=pred out=prediction2;
run;
```

Output 96.3.4 displays the output from PROC TPSPLINE with a specified search range from the smoothing parameter.

**Output 96.3.4** Output from PROC TPSPLINE for Data Set SO<sub>4</sub> with  $\log_{10}(n\lambda) = -2.56$

The smoothing penalty in Output 96.3.4 is much larger than that displayed in Output 96.3.2. The estimate in Output 96.3.2 uses a large  $\lambda$  value; therefore, the surface is smoother than the estimate by using  $\log_{10}(n\lambda) = -2.56$  (Output 96.3.4).

The estimate based on  $\log_{10}(n\lambda) = -2.56$  has a larger value of degrees of freedom, and it has a much smaller standard deviation.

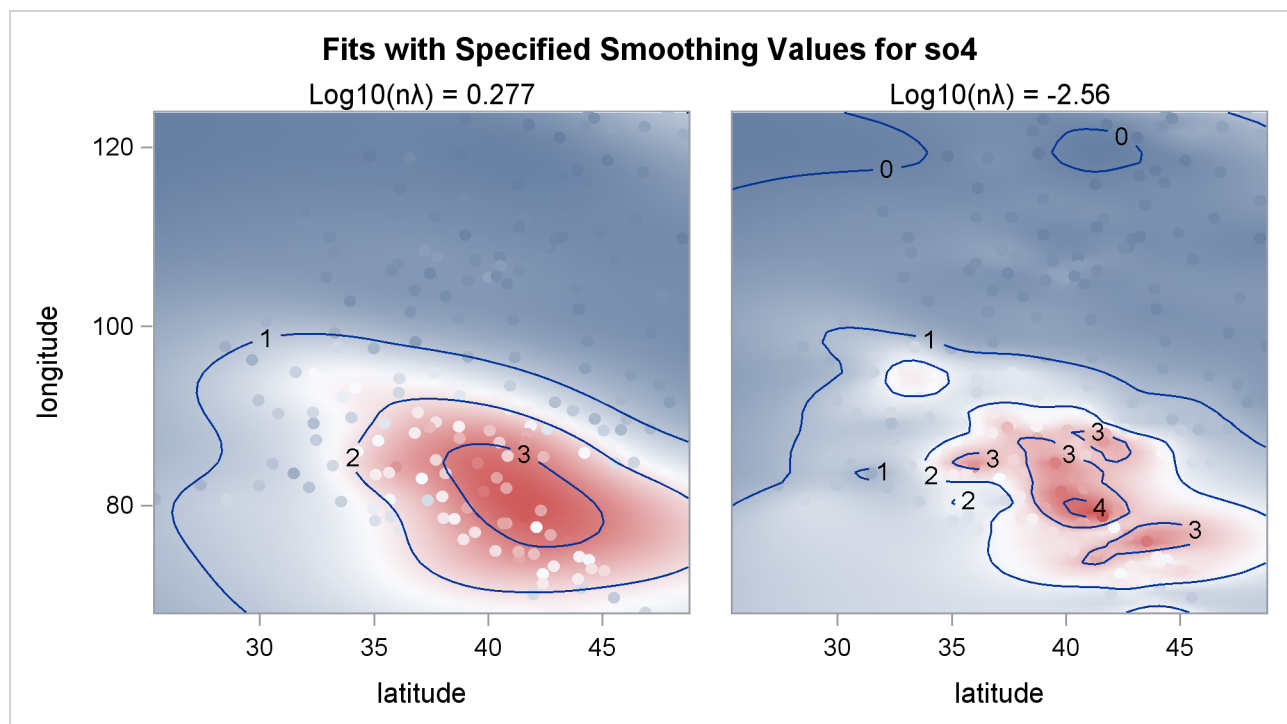

However, a smaller standard deviation in nonparametric regression does not necessarily mean that the estimate is good: a small  $\lambda$  value always produces an estimate closer to the data and, therefore, a smaller standard deviation.

When ODS Graphics is enabled, you can compare the two fits by supplying 0.277 and  $-2.56$  to the `LOGN-LAMBDA=` option:

```
proc tpspline data=so4;
 model so4 = (latitude longitude) / lognlambda=(0.277 -2.56);
run;
```

**Output 96.3.5** shows the contour surfaces of two models with the two minima. The fit that corresponds to the global minimum 0.277 shows a smoother fit that captures the general structure in the data set. The fit at the local minimum  $-2.56$  is a rougher fit that captures local details. The response values are also displayed as circles with the same color gradient by the default `GRADIENT contour-option`. The contrast between the predicted and observed  $\text{SO}_4$  deposition is greater for the smoother fit than for the other one, which means the smoother fit has larger absolute residual values.

**Output 96.3.5** Panel of Contour Fit Plots by 0.277 and  $-2.56$

The residuals for the two fits can be visualized in `RESIDUALBYSMOOTH` panels. **Output 96.3.6** is a panel of plots of residuals against smoothing variable Latitude. **Output 96.3.7** is a panel of plots of residuals against smoothing variable Longitude. Both panels show that the residuals from the model with the global minimum are larger in absolute values than the ones from the local minimum. This is expected, since the optimal model achieves the smallest GCV value by significantly increasing the smoothness of fit and sacrificing a little in the goodness of fit.

**Output 96.3.6** Panel of Residuals by Latitude Plots

**Output 96.3.7** Panel of Residuals by Longitude Plots

In summary, the fit with  $\log_{10}(n\lambda) = 0.277$  represents the underlying surface, while the fit with the  $\log_{10}(n\lambda) = -2.56$  overfits the data and captures the additional noise component.

## Example 96.4: Large Data Set Application

This example illustrates how you can use the `D=` option to decrease the computation time needed by the TPSPLINE procedure. Although the `D=` option can be helpful in decreasing computation time for large data sets, it might produce unexpected results when used with small data sets.

The following statements generate the data set large:

```
data large;
 do x=-5 to 5 by 0.02;
 y=5*sin(3*x)+1*rannor(57391);
 output;
 end;
run;
```

The data set large contains 501 observations with one independent variable `x` and one dependent variable `y`. The following statements invoke PROC TPSPLINE to produce a thin-plate smoothing spline estimate and the associated 99% confidence interval. The output statistics are saved in the data set fit1.

```
proc tpspline data=large;
 model y =(x) /lognlambda=(-5 to -1 by 0.2) alpha=0.01;
 output out=fit1 pred lclm uclm;
run;
```

The results from this MODEL statement are displayed in [Output 96.4.1](#).

**Output 96.4.1** Output from PROC TPSPLINE without the `D=` Option

The following statements specify an identical model, but with the additional specification of the `D=` option. The estimates are obtained by treating nearby points as replicates.

```
proc tpspline data=large;
 model y =(x) /lognlambda=(-5 to -1 by 0.2) d=0.05 alpha=0.01;
 output out=fit2 pred lclm uclm;
run;
```

The output is displayed in Output 96.4.2.

**Output 96.4.2** Output from PROC TPSPLINE with the D= Option

The difference between the two estimates is minimal. However, the CPU time for the second MODEL statement is only about 1/7 of the CPU time used in the first model fit.

The following statements produce a plot for comparison of the two estimates:

```

data fit2;
 set fit2;
 P1_y = P_y;
 LCLM1_y = LCLM_y;
 UCLM1_y = UCLM_y;
 drop P_y LCLM_y UCLM_y;
run;

proc sort data=fit1;
 by x y;
run;

proc sort data=fit2;
 by x y;
run;

data comp;
 merge fit1 fit2;
 by x y;
 label p1_y ="Yhat1" p_y="Yhat0"
 lclm_y ="Lower CL"
 uclm_y ="Upper CL";
run;

proc sgplot data=comp;
 title "Comparison of Two Estimates";
 title2 "with and without the D= Option";

 yaxis label="Predicted y Values";
 xaxis label="x";

 band x=x lower=lclm_y upper=uclm_y /name="range"
 legendlabel="99% CI of Predicted y without D=";
 series x=x y=P_y/ name="P_y" legendlabel="Predicted y without D="
 lineattrs=graphfit(thickness=1px pattern=shortdash);
 series x=x y=P1_y/ name="P1_y" legendlabel="Predicted y with D="

```

```

lineattrs=graphfit(thickness=1px color=red);
discretelegend "range" "P_y" "Pl_y";
run;

```

The estimates from fit1 and fit2 are displayed in [Output 96.4.3](#) with the 99% confidence interval from the fit1 output data set.

**Output 96.4.3** Comparison of Two PROC TPSPLINE Fits with and without the D= Option

## Example 96.5: Computing a Bootstrap Confidence Interval

This example illustrates how you can construct a bootstrap confidence interval by using the multiple responses feature in PROC TPSPLINE.

Numerous epidemiological observations have indicated that exposure to solar radiation is an important factor in the etiology of melanoma. The following data present age-adjusted melanoma incidences for 37 years from the Connecticut Tumor Registry (Houghton, Flannery, and Viola 1980). The data are analyzed by Ramsay and Silverman (1997).

```

data melanoma;
 input year incidences @@;
 datalines;
1936 0.9 1937 0.8 1938 0.8 1939 1.3
1940 1.4 1941 1.2 1942 1.7 1943 1.8
1944 1.6 1945 1.5 1946 1.5 1947 2.0
1948 2.5 1949 2.7 1950 2.9 1951 2.5
1952 3.1 1953 2.4 1954 2.2 1955 2.9
1956 2.5 1957 2.6 1958 3.2 1959 3.8
1960 4.2 1961 3.9 1962 3.7 1963 3.3
1964 3.7 1965 3.9 1966 4.1 1967 3.8
1968 4.7 1969 4.4 1970 4.8 1971 4.8
1972 4.8
;

```

The variable incidences records the number of melanoma cases per 100,000 people for the years 1936 to 1972. The following model fits the data and requests a 90% Bayesian confidence interval along with the estimate:

```

ods graphics on;
proc tpspline data=melanoma plots(only)=(criterionplot fitplot(clm));
 model incidences = (year) /alpha = 0.1;
 output out = result pred uclm lclm;
run;

```

The output is displayed in [Output 96.5.1](#)

**Output 96.5.1** Output from PROC TPSPLINE for the MELANOMA Data

The estimated curve is displayed with 90% confidence interval bands in [Output 96.5.2](#). The number of melanoma incidences exhibits a periodic pattern and increases over the years. The periodic pattern is related to sunspot activity and the accompanying fluctuations in solar radiation.

**Output 96.5.2** PROC TPSPLINE Estimate and 90% Confidence Interval of Data Set MELANOMA

Wang and Wahba (1995) compare several bootstrap confidence intervals to Bayesian confidence intervals for smoothing splines. Both bootstrap and Bayesian confidence intervals are across-the-curve intervals, not pointwise intervals. They concluded that bootstrap confidence intervals work as well as Bayesian intervals concerning average coverage probability. Additionally, bootstrap confidence intervals appear to be better for small sample sizes. Based on their simulation, the “percentile- $t$  interval” bootstrap interval performs better than the other types of bootstrap intervals.

Suppose that  $\hat{f}_\lambda$  and  $\hat{\sigma}$  are the estimates of  $f$  and  $\sigma$  from the data. Assume that  $f_\lambda$  is the “true”  $f$ , and generate the bootstrap sample as

$$y_i^* = \hat{f}_\lambda(\mathbf{x}_i) + \epsilon_i^*, \quad i = 1, \dots, n$$

where  $\epsilon^* = (\epsilon_1^*, \dots, \epsilon_n^*)' \sim N(0, \hat{\sigma}\mathbf{I})$ . Denote  $f_\lambda^*(\mathbf{x}_i)$  as the random variable of the bootstrap estimate at  $\mathbf{x}_i$ . Repeat this process  $K$  times, so that at each point  $\mathbf{x}_i$ , you have  $K$  bootstrap estimates  $\hat{f}_\lambda^*(\mathbf{x}_i)$  or  $K$  realizations of  $f_\lambda^*(\mathbf{x}_i)$ . For each fixed  $\mathbf{x}_i$ , consider the statistic  $D_i^*$ , which is similar to the Student’s  $t$  statistic,

$$D_i^* = \left( f_\lambda^*(\mathbf{x}_i) - \hat{f}_\lambda(\mathbf{x}_i) \right) / \hat{\sigma}_i^*$$

where  $\hat{\sigma}_i^*$  is the estimate of  $\hat{\sigma}$  based on the  $i$ th bootstrap sample.

Suppose  $\chi_{\alpha/2}$  and  $\chi_{1-\alpha/2}$  are the lower and upper  $\alpha/2$  points, respectively, of the empirical distribution of  $D_i^*$ . The  $(1 - \alpha)100\%$  bootstrap confidence interval is defined as

$$\left( \hat{f}_\lambda(\mathbf{x}_i) - \chi_{1-\alpha/2}\hat{\sigma}, \hat{f}_\lambda(\mathbf{x}_i) - \chi_{\alpha/2}\hat{\sigma} \right)$$

Bootstrap confidence intervals are easy to interpret and can be used with any distribution. However, because they require  $K$  model fits, their construction is computationally intensive.

The feature of multiple dependent variables in PROC TPSPLINE enables you to fit multiple models with the same independent variables. The procedure calculates the matrix decomposition part of the calculations only once, regardless of the number of dependent variables in the model. These calculations are responsible for most of the computing time used by the TPSPLINE procedure. This feature is particularly useful when you need to generate a bootstrap confidence interval.

To construct a bootstrap confidence interval, perform the following tasks:

- Fit the data by using PROC TPSPLINE and obtain estimates  $\hat{f}_\lambda(\mathbf{x}_i)$  and  $\hat{\sigma}$ .
- Generate  $K$  bootstrap samples based on  $\hat{f}_\lambda(\mathbf{x}_i)$  and  $\hat{\sigma}$ .
- Fit the  $K$  bootstrap samples with the TPSPLINE procedure to obtain estimates of  $\hat{f}_\lambda^*(\mathbf{x}_i)$  and  $\hat{\sigma}_i^*$ .
- Compute  $D_i^*$  and the values  $\chi_{\alpha/2}$  and  $\chi_{1-\alpha/2}$ .

The following statements illustrate this process:

```
proc tpspline data=melanoma plots(only)=fitplot(clm);
 model incidences = (year) /alpha = 0.1;
 output out=result pred uclm lclm;
run;
```

The output from the initial PROC TPSPLINE analysis is displayed in [Output 96.5.3](#). The data set result contains the predicted values and confidence limits from the analysis.

**Output 96.5.3** Output from PROC TPSPLINE for the MELANOMA Data

| GCV                                                           | 0.0888  |

The following statements illustrate how you can obtain a bootstrap confidence interval for the Melanoma data set. The following statements create the data set bootstrap. The observations are created with information from the preceding PROC TPSPLINE execution; as displayed in [Output 96.5.3](#),  $\hat{\sigma} = 0.232823$ . The values of  $\hat{f}_{\hat{\lambda}}(x_i)$  are stored in the data set result in the variable P\_incidence.

```

data bootstrap;
 set result;
 array y{1070} y1-y1070;
 do i=1 to 1070;
 y{i} = p_incidences + 0.232823*rannor(123456789);
 end;
 keep y1-y1070 p_incidences year;
run;

ods listing close;
proc tpspline data=bootstrap plots=none;
 ods output FitStatistics=FitResult;
 id p_incidences;
 model y1-y1070 = (year);
 output out=result2;
run;
ods listing;

```

The DATA step generates 1,070 bootstrap samples based on the previous estimate from PROC TPSPLINE. For this data set, some of the bootstrap samples result in  $\lambda$ s (selected by the GCV function) that cause problematic behavior. Thus, an additional 70 bootstrap samples are generated.

The ODS listing destination is closed before PROC TPSPLINE is invoked. The PLOTS=NONE option suppresses all graphical output. The model fits all the  $y_1 \dots y_{1070}$  variables as dependent variables, and the models are fit for all bootstrap samples simultaneously. The output data set result2 contains the variables year,  $y_1 \dots y_{1070}$ ,  $p_{y_1} \dots p_{y_{1070}}$ , and p\_incidences.

The ODS OUTPUT statement writes the FitStatistics table to the data set FitResult. The data set FitResult contains the two variables Parameter and Value. The FitResult data set is used in subsequent calculations for  $D_i^*$ .

In the data set FitResult, there are 63 estimates with a standard deviation of zero, suggesting that the estimates provide perfect fits of the data and are caused by  $\hat{\lambda}$ s that are approximately equal to zero. For small sample sizes, there is a positive probability that the  $\lambda$  chosen by the GCV function will be zero (Wang and Wahba 1995).

In the following steps, these cases are removed from the bootstrap samples as “bad” samples: they represent failure of the GCV function.

The following SAS statements manipulate the data set FitResult, retaining the standard deviations for all bootstrap samples and merging FitResult with the data set result2, which contains the estimates for bootstrap samples. In the final data set boot, the  $D_i^*$  statistics are calculated.

```

data FitResult;
 set FitResult;
 if Parameter="Standard Deviation";
 keep Value;
run;

proc transpose data=FitResult out=sd prefix=sd;

data result2;
 if _N_ = 1 then set sd;
 set result2;
run;

```

```

data boot;
 set result2;
 array y{1070} p_y1-p_y1070;
 array sd{1070} sd1-sd1070;
 do i=1 to 1070;
 if sd{i} > 0 then do;
 d = (y{i} - P_incidences)/sd{i};
 obs = _N_;
 output;
 end;
 end;
 keep d obs P_incidences year;
run;

```

The following SAS statements retain the first 1,000 bootstrap samples and calculate the values  $\chi_{\alpha/2}$  and  $\chi_{1-\alpha/2}$  with  $\alpha = 0.1$ .

```

proc sort data=boot;
 by obs;
run;

data boot;
 set boot;
 by obs;
 retain n;

 if first.obs then n=1;
 else n=n+1;
 if n > 1000 then delete;
run;

proc sort data=boot;
 by obs d;
run;

data chi1 chi2 ;
 set boot;
 if (_N_ = (obs-1)*1000+50) then output chi1;
 if (_N_ = (obs-1)*1000+950) then output chi2;
run;

proc sort data=result;
 by year;
run;

proc sort data=chi1;
 by year;
run;

proc sort data=chi2;
 by year;
run;

```

```

data result;
 merge result
 chi1(rename=(d=chi05))
 chi2(rename=(d=chi95));
 keep year incidences P_incidences lower upper
 LCLM_incidences UCLM_incidences;

 lower = -chi95*0.232823 + P_incidences;
 upper = -chi05*0.232823 + P_incidences;

 label lower="Lower 90% CL (Bootstrap)"
 upper="Upper 90% CL (Bootstrap)"
 lclm_incidences="Lower 90% CL (Bayesian)"
 uclm_incidences="Upper 90% CL (Bayesian)";
run;

```

The data set result contains the variables year and incidences, the PROC TPSPLINE estimate P\_incidences, and the 90% Bayesian and 90% bootstrap confidence intervals.

The following statements produce [Output 96.5.4](#):

```

proc sgplot data=result;
 title "Age-adjusted Melanoma Incidence for 37 Years";

 xaxis label="year";
 yaxis label="Incidences";

 band x=year lower=lclm_incidences upper=uclm_incidences/name="bayesian"
 legendlabel="90% Bayesian CI of Predicted incidences"
 fillattrs=(color=red);
 band x=year lower=lower upper=upper/name="bootstrap"
 legendlabel="90% Bootstrap CI of Predicted incidences"
 transparency=0.05;
 scatter x=year y=incidences/name="obs" legendlabel="incidences";
 series x=year y=p_incidences/name="pred"
 legendlabel="predicted values of incidences"
 lineattrs=graphfit(thickness=1px);

 discretelegend "bayesian" "bootstrap" "obs" "pred";
run;

ods graphics off;

```

[Output 96.5.4](#) displays the plot of the variable incidences, the predicted values, and the Bayesian and bootstrap confidence intervals.

The plot shows that the bootstrap confidence interval is similar to the Bayesian confidence interval. However, the Bayesian confidence interval is symmetric around the estimates, while the bootstrap confidence interval is not.

**Output 96.5.4** Comparison of Bayesian and Bootstrap Confidence Interval for Data Set MELANOMA

## Overview: TRANSREG Procedure

The TRANSREG (transformation regression) procedure fits linear models, optionally with smooth, spline, Box-Cox, and other nonlinear transformations of the variables. You can use PROC TRANSREG to fit a curve through a scatter plot or fit multiple curves, one for each level of a classification variable. You can also constrain the functions to be parallel or monotone or have the same intercept. PROC TRANSREG can be used to code experimental designs and classification variables prior to their use in other analyses.

The TRANSREG procedure fits many types of linear models, including the following:

- ordinary regression and ANOVA
- metric and nonmetric conjoint analysis (Green and Wind 1975; de Leeuw, Young, and Takane 1976)
- linear models with Box-Cox (1964) transformations of the dependent variables
- regression with a smooth (Reinsch 1967), spline (de Boor 1978; van Rijckevorsel 1982), monotone spline (Winsberg and Ramsay 1980), or penalized B-spline (Eilers and Marx 1996) fit function
- metric and nonmetric vector and ideal point preference mapping (Carroll 1972)
- simple, multiple, and multivariate regression with variable transformations (Young, de Leeuw, and Takane 1976; Winsberg and Ramsay 1980; Breiman and Friedman 1985)
- redundancy analysis (Stewart and Love 1968) with variable transformations (Israels 1984)
- canonical correlation analysis with variable transformations (van der Burg and de Leeuw 1983)
- response surface regression (Meyers 1976; Khuri and Cornell 1987) with variable transformations

The data set can contain variables measured on nominal, ordinal, interval, and ratio scales (Siegel 1956). You can specify any mix of these variable types for the dependent and independent variables. PROC TRANSREG can do the following:

- transform nominal variables by scoring the categories to minimize squared error (Fisher 1938), or treat nominal variables as classification variables
- transform ordinal variables by monotonically scoring the ordered categories so that order is weakly preserved (adjacent categories can be merged) and squared error is minimized. Ties can be optimally untied or left tied (Kruskal 1964). Ordinal variables can also be transformed to ranks.
- transform interval and ratio scale of measurement variables linearly or nonlinearly with spline (de Boor 1978; van Rijckevorsel 1982), monotone spline (Winsberg and Ramsay 1980), penalized B-spline (Eilers and Marx 1996), smooth (Reinsch 1967), or Box-Cox (Box and Cox 1964) transformations. In addition, logarithmic, exponential, power, logit, and inverse trigonometric sine transformations are available.

Transformations produced by the PROC TRANSREG multiple regression algorithm, requesting spline transformations, are often similar to transformations produced by the ACE smooth regression method of Breiman and Friedman (1985). However, ACE does not explicitly optimize a loss function (de Leeuw 1986), while PROC TRANSREG explicitly minimizes a squared-error criterion.

PROC TRANSREG extends the ordinary general linear model by providing optimal variable transformations that are iteratively derived. PROC TRANSREG iterates until convergence, alternating two major steps: finding least squares estimates of the model parameters given the current scoring of the data, and finding least squares estimates of the scoring parameters given the current set of model parameters. This is called the method of alternating least squares (Young 1981).

For more background on alternating least squares optimal scaling methods and transformation regression methods, see Young, de Leeuw, and Takane (1976); Winsberg and Ramsay (1980); Young (1981); Gifi (1990); Schiffman, Reynolds, and Young (1981); van der Burg and de Leeuw (1983); Israels (1984); Breiman and Friedman (1985); Hastie and Tibshirani (1986). (These are just a few of the many relevant sources.)

---

## Getting Started: TRANSREG Procedure

This section provides several examples that illustrate a few of the more basic features of PROC TRANSREG.

---

### Fitting a Curve through a Scatter Plot

PROC TRANSREG can fit curves through data and detect nonlinear relationships among variables. This example uses a subset of the data from an experiment in which nitrogen oxide emissions from a single cylinder engine are measured for various combinations of fuel and equivalence ratio (Brinkman 1981). This gas data set is available from the Sashelp library. The following step creates a subset of the data for analysis:

```
title 'Gasoline and Emissions Data';

data gas;
 set sashelp.gas;
 if fuel in ('Ethanol', '82rongas', 'Gasohol');
run;
```

The next step fits a spline or curve through the data and displays the regression results. For information about splines and knots, see the sections “Smoothing Splines” on page 8263, “Linear and Nonlinear Regression Functions” on page 8250, “Simultaneously Fitting Two Regression Functions” on page 8254, and “Using Splines and Knots” on page 8233, as well as [Example 97.1](#). The following statements produce [Figure 97.1](#):

```
ods graphics on;

* Request a Spline Transformation of Equivalence Ratio;
proc transreg data=Gas solve ss2 plots=(transformation obp residuals);
 model identity(nox) = spline(EqRatio / nknots=4);
 where fuel in ('Ethanol', '82rongas', 'Gasohol');
run;
```

The **SOLVE** algorithm option, or *a-option*, requests a direct solution for both the transformation and the parameter estimates. For many models, PROC TRANSREG with the SOLVE *a-option* can produce exact results without iteration. The **SS2** (Type II sums of squares) *a-option* requests regression and ANOVA results. The **PLOTS=** option requests plots of the variable transformations, a plot of the observed values by the predicted values, and a plot of the residuals. The dependent variable NOx was specified with an **IDENTITY** transformation, which means that it will not be transformed, just as in ordinary regression. The independent variable EqRatio, in contrast, is transformed by using a cubic spline with four knots. The **NKNOTS=** option is known as a transformation option, or *t-option*. Graphical results are enabled when ODS Graphics is enabled. The results are shown in Figure 97.1 through Figure 97.5.

**Figure 97.1** Iteration, ANOVA, and Regression Results

PROC TRANSREG increases the squared multiple correlation from the original value of 0.00917 to 0.82429. Iteration 0 shows the fit before the data are transformed, and iteration 1 shows the fit after the transformation, which was directly solved for in the initial iteration. The change values for iteration 0 show the change from the original EqRatio variable to the transformed EqRatio variable. For this model, no improvement on the initial solution is possible, so in iteration 1, all change values are zero. The ANOVA and regression results show that you are fitting a model with 7 model parameters, 4 knots plus a degree 3 or cubic spline. The overall model fit is identical to the test for the spline transformation, since there is only one term in the model besides the intercept, and the results are significant at the 0.0001 level. The transformations are shown next in Figure 97.2.

Figure 97.2 Transformations

The transformation plots show the identity transformation of NO<sub>x</sub> and the nonlinear spline transformation of EqRatio. These plots are requested with the `PLOTS=TRANSFORMATION` option. The plot on the left shows that NO<sub>x</sub> is unchanged, which is always the case with the `IDENTITY` transformation. In contrast, the spline transformation of EqRatio is nonlinear. It is this nonlinear transformation of EqRatio that accounts for the increase in fit that is shown in the iteration history table.

Figure 97.3 Residuals

The residuals plot in Figure 97.3 shows the residuals as a function of the transformed independent variable.

The “Spline Regression Fit” plot in Figure 97.4 displays the nonlinear regression function plotted through the original data, along with 95% confidence and prediction limits. This plot clearly shows that nitrous oxide emissions are largest in the middle range of equivalence ratio, 0.08 to 1.0, and are much lower for the extreme values of equivalence ratio, such as around 0.6 and 1.2.

**Figure 97.4** Fitting a Curve through a Scatter Plot

This plot is produced by default when ODS Graphics is enabled and when there is an IDENTITY dependent variable and one non-CLASS independent variable. The plot consists of an ordinary scatter plot of NOx plotted as a function of EqRatio. It also contains the predicted values of NOx, which are a function of the spline transformation of EqRatio (or TEqRatio shown previously), and are plotted as a function of EqRatio. Similarly, it contains confidence limits based on NOx and TEqRatio.

The “Observed by Predicted” values plot in Figure 97.5 displays the dependent variable plotted as a function of the regression predicted values along with a linear regression line, which for this plot always has a slope of 1. This plot was requested with the OBP or OBSERVEDBYPREDICTED suboption in the PLOTS= option. The residual differences between the transformed data and the regression line show how well the nonlinearly transformed data fit a linear-regression model. The residuals look mostly random; however, they are larger for larger values of NOx, suggesting that maybe this is not the optimal model. You can also see this by examining the fit of the function through the original scatter plot in Figure 97.4. Near the

middle of the function, the residuals are much larger. You can refit the model, this time requesting separate functions for each type of fuel. You can request the original scatter plot, without any regression information and before the variables are transformed, by specifying the SCATTER suboption in the PLOTS= option.

**Figure 97.5** Observed by Predicted

These next statements fit an additive model with separate functions for each of the different fuels. The statements produce [Figure 97.6](#) through [Figure 97.9](#).

```
* Separate Curves and Intercepts;
proc transreg data=Gas solve ss2 additive plots=(transformation obp);
 model identity(nox) = class(Fuel / zero=none) |
 spline(EqRatio / nknots=4 after);
run;
```

The **ADDITIVE** *a-option* requests an additive model, where the regression coefficients are absorbed into the transformations, and so the final regression coefficients are all one. The specification **CLASS(Fuel / ZERO=NONE)** recodes fuel into a set of three binary variables, one for each of the three fuels in this data set. The vertical bar between the **CLASS** and **SPLINE** specifications request both main effects and interactions. For this model, it requests both a separate intercept and a separate spline function for each fuel. The original

two variables, Fuel and EqRatio, are replaced by six variables—three binary intercept terms and three spline variables. The three spline variables are zero when their corresponding intercept binary variable is zero, and nonzero otherwise. The nonzero parts are optimally transformed by the analysis. The *AFTER t-option* specified with the SPLINE transformation specifies that the four knots should be selected independently for each of the three spline transformations, *after* EqRatio is crossed with the CLASS variable. Alternatively, and by default, the knots are chosen by examining EqRatio before it is crossed with the CLASS variable, and the same knots are used for all three transformations. The results are shown in Figure 97.6.

ZERO=SUM and ZERO=NONE coefficient tests are not exact when there are iterative transformations. Those tests are performed holding all transformations fixed, and so are generally liberal.

The first iteration history table in Figure 97.6 shows that PROC TRANSREG increases the squared multiple correlation from the original value of 0.18543 to 0.95870. The remaining iteration histories pertain to PROC TRANSREG's process of comparing models to test hypotheses. The important thing to look for is convergence in all of the tables.

Figure 97.7 Transformations

The transformations, shown in Figure 97.7, show that for all three groups, the transformation of EqRatio is approximately quadratic.

**Figure 97.8** Fitting Curves through a Scatter Plot

The fit plot, shown in [Figure 97.8](#), shows that there are in fact three distinct functions in the data. The increase in fit over the previous model comes from individually fitting each group instead of providing an aggregate fit.

Figure 97.9 Observed by Predicted

The residuals in the observed by predicted plot displayed in [Figure 97.9](#) are much better for this analysis.

You could fit a model that is “in between” the two models shown previously. This next model provides for separate intercepts for each group, but calls for a common function. There are still three functions, one per group, but their shapes are the same, and they are equidistant or parallel. This model is requested by omitting the vertical bar so that separate intercepts are requested, but not separate curves within each group. The following statements fit the separate intercepts model and create [Figure 97.10](#):

```
* Separate Intercepts;
proc transreg data=Gas solve ss2 additive;
 model identity(nox) = class(Fuel / zero=none)
 spline(EqRatio / nknots=4);
run;
```

The ANOVA table and fit plot are shown in [Figure 97.10](#).

**Figure 97.10** Separate Intercepts Only

**Figure 97.10** continued

Now, squared multiple correlation is 0.9005, which is smaller than the model with the unconstrained separate curves, but larger than the model with only one curve. Because of the restrictions on the shapes, these curves do not track the data as well as the previous model. However, this model is more parsimonious with many fewer parameters.

There are other ways to fit curves through scatter plots in PROC TRANSREG. For example, you could use smoothing splines or penalized B-splines, as is illustrated next. The following statements fit separate curves through each group by using penalized B-splines and produce Figure 97.11:

```
* Separate Curves and Intercepts with Penalized B-Splines;
proc transreg data=Gas ss2 plots=transformation lprefix=0;
 model identity(nox) = class(Fuel / zero=none) * pbspline(EqRatio);
run;
```

This example asks for a separate penalized B-spline transformation, **PBSPLINE**, of equivalence ratio for each type of fuel. The **LPREFIX=0** *a-option* is specified in the PROC statement so that zero characters of the **CLASS** variable name (Fuel) are used in constructing the labels for the coded variables. The result is label components like “Ethanol” instead of the more redundant “Fuel Ethanol”. The results of this analysis are shown in Figure 97.11.

**Figure 97.11** Penalized B-Splines

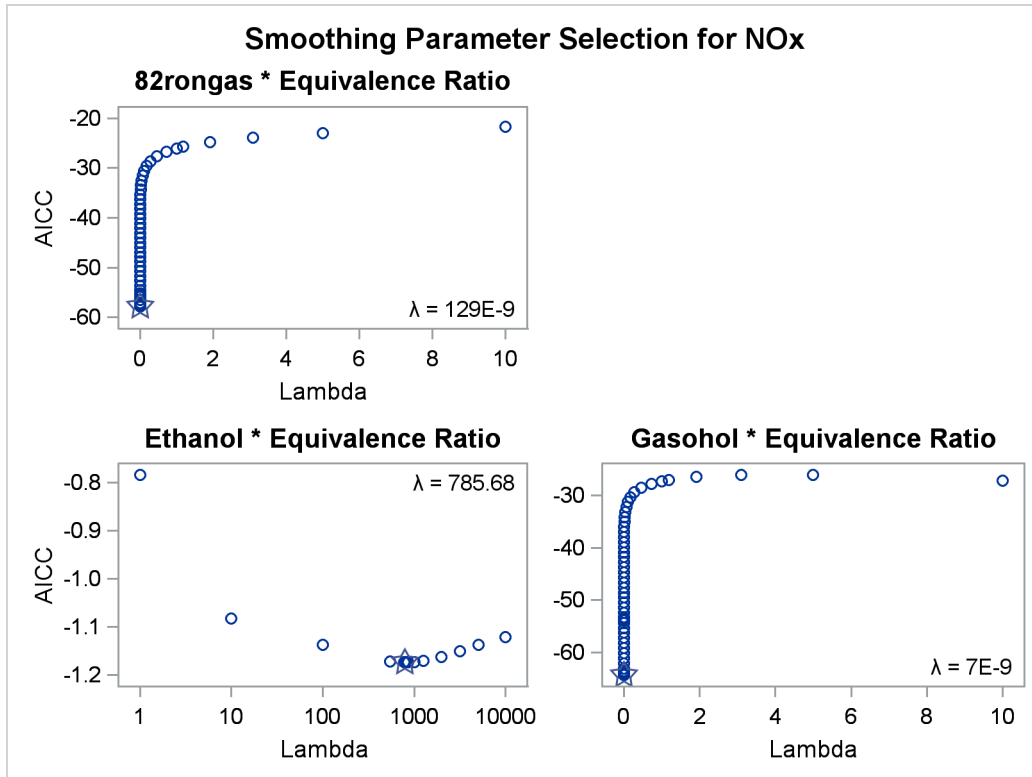

Figure 97.11 continued

With penalized B-splines, the degrees of freedom are based on the trace of the transformation hat matrix and are typically not integers. The first panel of plots shows AICC as a function of lambda, the smoothing parameter. The smoothing parameter is automatically chosen, and since the smoothing parameters range from essentially 0 to almost 800, it is clear that some functions are smoother than others. The plots of the criterion (AICC in this example) as a function of lambda use a linear scale for the horizontal axis when the range of lambdas is small, as in the first and third plot, and a log scale when the range is large, as in the second plot. The transformation for equivalence ratio for Ethanol required more smoothing than for the other two fuels. All three have an overall quadratic shape, but for Ethanol, the function more closely follows the smaller variations in the data. You could get similar results with `SPLINE` by using more knots.

For other examples of curve fitting by using PROC TRANSREG, see the sections “Smoothing Splines” on page 8263, “Linear and Nonlinear Regression Functions” on page 8250, “Simultaneously Fitting Two Regression Functions” on page 8254, and “Using Splines and Knots” on page 8233, as well as Example 97.3. These examples include cases where multiple curves are fit through scatter plots with multiple groups. Special cases include linear models with separate slopes and separate intercepts. Many constraints on the slopes, curves, and intercepts are possible.

## Main-Effects ANOVA

This example shows how to use PROC TRANSREG to code and fit a main-effects ANOVA model. PROC TRANSREG has very extensive and versatile options for coding or creating so-called dummy variables. PROC TRANSREG is commonly used to code classification variables before they are used for analysis

in other procedures. See the sections “Using the DESIGN Output Option” on page 8331 and “Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO” on page 8335. In this example, the input data set contains the dependent variables *y*, factors *x1* and *x2*, and 12 observations. PROC TRANSREG can be useful for coding even before running procedures with a CLASS statement because of its detailed options that enable you to control how the coded variable names and labels are constructed. The following statements perform a main-effects ANOVA and display the results in Figure 97.12 and Figure 97.13:

```

title 'Introductory Main-Effects ANOVA Example';

data a;
 input y x1 $ x2 $;
 datalines;
8 a a
7 a a
4 a b

2 c b
;

* Fit a main-effects ANOVA model with 1, 0, -1 coding;
proc transreg ss2;
 model identity(y) = class(x1 x2 / effects);
 output coefficients replace;
run;

* Display TRANSREG output data set;
proc print label;
 format intercept -- x2a 5.2;
run;

```

The *SS2 a-option* requests results based on Type II sums of squares. The simple ANOVA model is fit by designating *y* as an **IDENTITY** variable, which specifies no transformation. The independent variables are specified with a **CLASS** expansion, which replaces them with coded variables. There are  $(3-1)+(2-1) = 3$  coded variables created by the CLASS specification, since the two CLASS variables have 3 and 2 different values or levels. In this case, the **EFFECTS t-option** is specified. This option requests an *effects coding* (displayed in Figure 97.13), which is also called a deviations from means or 0, 1, -1 coding. The **OUTPUT** statement requests an output data set with the data and coded variables. The **COEFFICIENTS** output option, or *o-option*, adds the parameter estimates and marginal means to the data set. The **REPLACE o-option** specifies that the transformed variables should replace the original variables in the output data set. The output data set variable names are the same as the original variable name. In an example like this, there are no nonlinear transformations; the transformed variables are the same as the original variables. The **REPLACE o-option** is used to eliminate unnecessary and redundant transformed variables from the output data set. The results of the PROC TRANSREG step are shown in Figure 97.12.

| 11                                      | SCORE    | ROW11  | 5 | 1.00      | -1.00 | -1.00 | -1.00 | c  | b  |
| 12                                      | SCORE    | ROW12  | 2 | 1.00      | -1.00 | -1.00 | -1.00 | c  | b  |
| 13                                      | M COEFFI | y      | . | 4.67      | 0.83  | -1.67 | 1.83  |    |    |
| 14                                      | MEAN     | y      | . | .         | 5.50  | 3.00  | 6.50  |    |    |

The output data set has three kinds of observations, identified by values of `_TYPE_` as follows:

- When `_TYPE_='SCORE'`, the observation contains the following information about the dependent and independent variables:
  - `y` is the original dependent variable.
  - `x1` and `x2` are the independent classification variables, and the `Intercept` through `x2 a` columns contain the main-effects design matrix that PROC TRANSREG creates. The variable names are `Intercept`, `x1a`, `x1b`, and `x2a`. Their labels are shown in the listing.
- When `_TYPE_='M COEFFI'`, the observation contains coefficients of the final linear model (parameter estimates).
- When `_TYPE_='MEAN'`, the observation contains the marginal means.

The observations with `_TYPE_='SCORE'` form the score or data partition of the output data set, and the observations with `_TYPE_='M COEFFI'` and `_TYPE_='MEAN'` form the output statistics partition of the output data set.

---

## Syntax: TRANSREG Procedure

The following statements are available in the TRANSREG procedure:

```

PROC TRANSREG < DATA=SAS-data-set>
 < PLOTS=(plot-requests)>
 < OUTTEST=SAS-data-set> < a-options> < o-options> ;
MODEL < transform(dependents </ t-options>)>
 < transform(dependents </ t-options>)...=>
 transform(independents </ t-options>)
 < transform(independents </ t-options>)... > </ a-options> ;
OUTPUT < OUT=SAS-data-set> < o-options> ;
ID variables ;
FREQ variable ;
WEIGHT variable ;
BY variables ;

```

To use PROC TRANSREG, you need both the PROC TRANSREG and MODEL statements. To produce an OUT= output data set, the OUTPUT statement is required. PROC TRANSREG enables you to specify the same options in more than one statement. All of the MODEL statement *a-options* (algorithm options) and all of the OUTPUT statement *o-options* (output options) can also be specified in the PROC TRANSREG statement. You can abbreviate all *a-options*, *o-options*, and *t-options* (transformation options) to their first three letters. This is a special feature of PROC TRANSREG and is not generally true of other SAS/STAT procedures. See [Table 97.1](#) for a list of options available in the PROC TRANSREG statement.

The PROC TRANSREG statement starts the TRANSREG procedure. Optionally, this statement identifies an input and an OUTTEST= data set, specifies the algorithm and other computational details, requests displayed output, and controls the contents of the OUT= data set (which is created with the OUTPUT statement). The DATA= and OUTTEST= options can appear only in the PROC TRANSREG statement. All *a-options* and *o-options* are described in the sections on either the MODEL or OUTPUT statement, in which these options can also be specified.

The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC TRANSREG statement. The remaining statements are described in alphabetical order.

---

### PROC TRANSREG Statement

```

PROC TRANSREG < DATA=SAS-data-set>
 < PLOTS=(plot-requests)>
 < OUTTEST=SAS-data-set> < a-options> < o-options> ;

```

The PROC TRANSREG statement invokes the TRANSREG procedure. Optionally, this statement identifies an input and an OUTTEST= data set, specifies the algorithm and other computational details, requests displayed output, and controls the contents of the OUT= data set (which is created with the OUTPUT statement). The DATA=, OUTTEST=, and PLOTS= options can appear only in the PROC TRANSREG statement. [Table 97.1](#) summarizes the options available in the PROC TRANSREG statement. The *a-options* are also available in the MODEL statement, and the *o-options* are also available in the OUTPUT statement.

**Table 97.1** Options Available in the PROC TRANSREG Statement

| Option                                               | Description                                    |
|------------------------------------------------------|------------------------------------------------|
| <b>Data Set Options (PROC Statement)</b>             |                                                |
| DATA=                                                | Specifies input SAS data set                   |
| OUTTEST=                                             | Specifies output test statistics data set      |
| <b>ODS Graphics (PROC Statement)</b>                 |                                                |
| PLOTS=                                               | Specifies ODS Graphics selection               |
| <b>Input Control (PROC or MODEL)</b>                 |                                                |
| REITERATE                                            | Restarts the iterations                        |
| TYPE=                                                | Specifies input observation type               |
| <b>Method and Iterations (PROC or MODEL)</b>         |                                                |
| CCONVERGE=                                           | Specifies minimum criterion change             |
| CONVERGE=                                            | Specifies minimum data change                  |
| MAXITER=                                             | Specifies maximum number of iterations         |
| METHOD=                                              | Specifies iterative algorithm                  |
| NCAN=                                                | Specifies number of canonical variables        |
| NSR                                                  | Specifies no restrictions on smoothing models  |
| SINGULAR=                                            | Specifies singularity criterion                |
| SOLVE                                                | Attempts direct solution instead of iteration  |
| <b>Missing Data Handling (PROC or MODEL)</b>         |                                                |
| INDIVIDUAL                                           | Fits each model individually (METHOD=MORALS)   |
| MONOTONE=                                            | Includes monotone special missing values       |
| NOMISS                                               | Excludes observations with missing values      |
| UNTIE=                                               | Unties special missing values                  |
| <b>Intercept and CLASS Variables (PROC or MODEL)</b> |                                                |
| CPREFIX=                                             | Specifies CLASS coded variable name prefix     |
| LPREFIX=                                             | Specifies CLASS coded variable label prefix    |
| NOINT                                                | Specifies no intercept or centering            |
| ORDER=                                               | Specifies order of CLASS variable levels       |
| REFERENCE=                                           | Controls output of reference levels            |
| SEPARATORS=                                          | Controls CLASS coded variable label separators |
| <b>Control Displayed Output (PROC or MODEL)</b>      |                                                |
| ALPHA=                                               | Specifies confidence limits alpha              |
| CL                                                   | Displays parameter estimate confidence limits  |
| DETAIL                                               | Displays model specification details           |
| HISTORY                                              | Displays iteration histories                   |
| NOPRINT                                              | Suppresses displayed output                    |
| PBOXCOXTABLE                                         | Prints the Box-Cox log likelihood table        |
| RSQUARE                                              | Displays the R square                          |
| SHORT                                                | Suppresses the iteration histories             |
| SS2                                                  | Displays regression results                    |
| TEST                                                 | Displays ANOVA table                           |
| TSUFFIX=                                             | Shortens transformed variable labels           |

Table 97.1 *continued*

| Option                                                         | Description                                     |
|----------------------------------------------------------------|-------------------------------------------------|
| UTILITIES                                                      | Displays conjoint part-worth utilities          |
| <b>Standardization (PROC or MODEL)</b>                         |                                                 |
| ADDITIVE                                                       | Fits additive model                             |
| NOZEROCONSTANT                                                 | Does not zero constant variables                |
| TSTANDARD=                                                     | Specifies transformation standardization        |
| <b>Predicted Values, Residuals, Scores (PROC or OUTPUT)</b>    |                                                 |
| CANONICAL                                                      | Outputs canonical scores                        |
| CLI                                                            | Outputs individual confidence limits            |
| CLM                                                            | Outputs mean confidence limits                  |
| DESIGN=                                                        | Specifies design matrix coding                  |
| DREPLACE                                                       | Replaces dependent variables                    |
| IREPLACE                                                       | Replaces independent variables                  |
| LEVERAGE                                                       | Outputs leverage                                |
| NORESTOREMISSING                                               | Does not restore missing values                 |
| NOSCORES                                                       | Suppresses output of scores                     |
| PREDICTED                                                      | Outputs predicted values                        |
| REDUNDANCY=                                                    | Outputs redundancy variables                    |
| REPLACE                                                        | Replaces all variables                          |
| RESIDUALS                                                      | Outputs residuals                               |
| <b>Output Data Set Coefficients (PROC or OUTPUT)</b>           |                                                 |
| COEFFICIENTS                                                   | Outputs coefficients                            |
| COORDINATES=                                                   | Outputs ideal point coordinates                 |
| MEANS                                                          | Outputs marginal means                          |
| MREDUNDANCY                                                    | Outputs redundancy analysis coefficients        |
| <b>Output Data Set Variable Name Prefixes (PROC or OUTPUT)</b> |                                                 |
| ADPREFIX=                                                      | Specifies dependent variable approximations     |
| AIPREFIX=                                                      | Specifies independent variable approximations   |
| CDPREFIX=                                                      | Specifies canonical dependent variables         |
| CILPREFIX=                                                     | Specifies conservative individual lower CL      |
| CIPREFIX=                                                      | Specifies canonical independent variables       |
| CIUPREFIX=                                                     | Specifies conservative-individual-upper CL      |
| CMLPREFIX=                                                     | Specifies conservative-mean-lower CL            |
| CMUPREFIX=                                                     | Specifies conservative-mean-upper CL            |
| DEPENDENT=                                                     | Specifies METHOD=MORALS untransformed dependent |
| LILPREFIX=                                                     | Specifies liberal-individual-lower CL           |
| LIUPREFIX=                                                     | Specifies liberal-individual-upper CL           |
| LMLPREFIX=                                                     | Specifies liberal-mean-lower CL                 |
| LMUPREFIX=                                                     | Specifies liberal-mean-upper CL                 |
| PPREFIX=                                                       | Specifies predicted values                      |
| RDPREFIX=                                                      | Specifies residuals                             |
| RPREFIX=                                                       | Specifies redundancy variables                  |
| TDPREFIX=                                                      | Specifies transformed dependents                |

Table 97.1 *continued*

| Option                                   | Description                                        |
|------------------------------------------|----------------------------------------------------|

| <b>Macros Variables (PROC or OUTPUT)</b> |                                                    |
| MACRO                                    | Creates macro variables                            |
| <b>Other Options (PROC or OUTPUT)</b>    |                                                    |
| APPROXIMATIONS                           | Outputs dependent and independent approximations   |
| CCC                                      | Outputs canonical correlation coefficients         |
| CEC                                      | Outputs canonical elliptical point coordinates     |
| CPC                                      | Outputs canonical point coordinates                |
| CQC                                      | Outputs canonical quadratic point coordinates      |
| DAPPROXIMATIONS                          | Outputs approximations to transformed dependents   |
| IAPPROXIMATIONS                          | Outputs approximations to transformed independents |
| MEC                                      | Outputs elliptical point coordinates               |
| MPC                                      | Outputs point coordinates                          |
| MQC                                      | Outputs quadratic point coordinates                |
| MRC                                      | Outputs multiple regression coefficients           |

**DATA=SAS-data-set**

specifies the SAS data set to be analyzed. If you do not specify the DATA= option, PROC TRANSREG uses the most recently created SAS data set. The data set must be an ordinary SAS data set; it cannot be a special TYPE= data set.

**OUTTEST=SAS-data-set**

specifies an output data set to contain hypothesis tests results. When you specify the OUTTEST= option, the data set contains ANOVA results. When you specify the SS2 *a-option*, regression tables are also output. When you specify the UTILITIES *o-option*, conjoint analysis part-worth utilities are also output. For more information about the OUTTEST= data set, see the section “OUTTEST= Output Data Set” on page 8313.

**PLOTS <(global-plot-options)> <= plot-request <(options)>>****PLOTS <(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>>**

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=none
plots=(residuals transformation)
plots(unpack)=boxcox
plots(unpack)=(transformation boxcox(p=0))
plots=(residuals(unpack) transformation(dep unpk) boxcox(t rmse))
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc transreg plots=all;
 model identity(y) = pbspline(x);
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled, but you do not specify the PLOTS= option, then PROC TRANSREG produces a default set of plots. The fit, scatter, residual, and observed-by-predicted plots are available with [METHOD=MORALS](#) and also with [METHOD=UNIVARIATE](#) when there is only one dependent variable. When no method is specified and there is more than one dependent variable, and when regression plots are requested, the default method is set to [METHOD=MORALS](#). When there is more than one dependent variable, when [METHOD=](#) is not specified, or when [METHOD=MORALS](#) is specified and [PLOTS=ALL](#) is specified, the plots that are produced might be different from those you would see with [METHOD=UNIVARIATE](#) and [PLOTS=ALL](#). Certain plots appear by default when ODS Graphics is enabled and certain combinations of options are specified. The Box-Cox  $F = t^2$  and log-likelihood plots appear when a [BOXCOX](#) dependent variable transformation is specified. The regression fit plot appears for models with a single dependent variable that is not transformed (for example, [IDENTITY\(y\)](#)), a single quantitative independent variable that might or might not be transformed, and at most one [CLASS](#) independent variable. Preference mapping plots appear when the [COORDINATES o-option](#) is used.

The global plot options include the following:

## **INTERPOLATE**

### **INT**

uses observations that are excluded from the analysis for interpolation in the fit and transformation plots. By default, observations with zero weight are excluded from all plots. These include observations with a zero, negative, or missing weight or frequency and observations excluded due to missing and invalid values. You can specify [PLOTS\(INTERPOLATE\)=\(plot-requests\)](#) to include some of these observations in the plots. You might want to use this option, for example, with sparse data sets to show smoother functions over the range of the data (see the section “[The PLOTS\(INTERPOLATE\) Option](#)” on page 8340). Observations with missing values in [CLASS](#) variables are excluded from the plots even when [PLOTS\(INTERPOLATE\)](#) is specified.

### **ONLY**

### **ONL**

suppresses the default plots. Only plots specifically requested are displayed.

## **UNPACKPANEL**

### **UNPACK**

### **UNP**

suppresses paneling. By default, multiple plots can appear in some output panels. Specify [UNPACKPANEL](#) to get each plot in a separate panel. You can specify [PLOTS\(UNPACKPANEL\)](#) to unpack the default plots. You can also specify [UNPACKPANEL](#) as a suboption with [TRANSFORMATION](#), [RESIDUALS](#), [PBSPLINE](#), and [BOXCOX](#).

The plot requests include the following:

**ALL**

produces all appropriate plots. You can specify other options with ALL; for example, to request all plots and unpack only the residuals, specify PLOTS=(ALL RES(UNP)).

**BOXCOX** <(options)>

**BOX** <(options)>

requests a display of the results of the Box-Cox transformation. These results are displayed by default when there is a Box-Cox transformation. The BOXCOX plot request has the following options:

**P=*n***

adds  $t$  or  $F = t^2$  curves to the legend for the functions where  $p(t) < n$ , where  $t$  is the  $t$  statistic corresponding to the optimal lambda. You can specify P=0 to suppress the legend and P=1 to see all curves in the legend. The default value comes from the BOXCOX(variable / ALPHA=p) specification, which by default is 0.05.

**RMSE**

**RMS**

plots the root mean square error as a function of lambda.

**T**

plots  $t$  statistics rather than  $F = t^2$  statistics.

**UNPACKPANEL**

**UNPACK**

**UNP**

plots the  $t$  or  $F = t^2$  and log-likelihood plots in separate panels.

**FIT** <(options)>

requests a regression fit plot. This plot is produced by default whenever it is appropriate. It is produced when the dependent variable is specified with the IDENTITY *transform*, and when there is one quantitative independent variable (for example, IDENTITY for linear fit, SPLINE or one of the other transformations for a nonlinear fit, or PSPLINE) and at most one CLASS variable. When there is a CLASS variable, separate fits are produced within levels based on your model. You would specify the FIT plot request only to specify a FIT option or with the ONLY global plot option. The FIT plot request has the following options:

**FORMULA**

**FOR**

displays the fit function as an equation in regression fit plots. This option is valid when a fit plot is produced and either an IDENTITY *transform* or a PSPLINE *expansion* with degree less than ten and no knots is specified for a single independent variable. When this option is specified, you can output the formula to a data set by using the ods output **formula**=SAS-data-set statement. This is the formula, complete with Unicode specifications for polynomials, that is used in the fit plot template to make the formula.

**NOCLM**

suppresses the confidence limits in regression fit plots.

**NOCLI**

suppresses the individual prediction limits in regression fit plots.

**NOOBS**

suppresses the observations showing only the fit function and optionally the confidence and prediction limits.

**NONE**

suppresses all plots.

**OBSERVEDBYPREDICTED****OBP****OBS**

plots the transformed dependent variable as a function of the regression predicted values.

**PBSPLINE <(UNPACKPANEL)>****PBS <(UNPACK)>**

requests the penalized B-spline criterion plots. You would specify the PBSPLINE plot request only to specify a PBSPLINE option or with the ONLY global plot option. The PBSPLINE plot request has the following option:

**UNPACKPANEL****UNPACK****UNP**

plots each criterion plot in a separate panel.

**PREFMAP****PRE**

plots ideal point or vector preference mapping results when either two **IDENTITY** or two **POINT** independent variables are specified along with the **COORDINATES** option.

**RESIDUALS <(options)>****RES <(options)>**

plots the residuals as a function of each of the transformed independent variables, except coded **CLASS** variables. The RESIDUALS plot request has the following options:

**CLASS****CLA**

plots the residuals as a function of each of the transformed independent variables, including coded **CLASS** variables. Note that the **ALL** plot request, which you use to request all plots, specifies the RESIDUALS plot request without the **CLASS** option.

**UNPACKPANEL****UNPACK****UNP**

plots the residuals in separate plots, not several per panel.

**SMOOTH****SMO**

adds a LOESS smooth function to the residuals plots.

**SCATTER****SCA**

plots the scatter plot of observed data, before the transformations, for models with a single quantitative dependent variable, a single quantitative independent variable, and at most one CLASS independent variable.

**TRANSFORMATION** <(options)>**TRA** <(options)>

plots the variable transformations. The TRANSFORMATION plot request has the following options:

**DEPENDENTS****DEP**

plots only the dependent variable transformations.

**INDEPENDENTS****IND**

plots only the independent variable transformations.

**UNPACKPANEL****UNPACK****UNP**

plots the transformations in separate plots, not several per panel.

**BY Statement**

**BY** *variables* ;

You can specify a BY statement with PROC TRANSREG to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.

- Specify the NOTSORTED or DESCENDING option in the BY statement for the TRANSREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## FREQ Statement

**FREQ** *variable* ;

If one variable in the input data set represents the frequency of occurrence for other values in the observation, specify the variable's name in a FREQ statement. PROC TRANSREG then treats the data set as if each observation appeared  $n$  times, where  $n$  is the value of the FREQ variable for the observation. Noninteger values of the FREQ variable are truncated to the largest integer less than the FREQ value. The observation is used in the analysis only if the value of the FREQ statement variable is greater than or equal to 1.

---

## ID Statement

**ID** *variables* ;

The ID statement includes additional character or numeric variables in the **OUT=** data set. The variables must be contained in the input data set. The first variable is used to label points in PREFMAP plots. These variables are also used in some plots as tip variables.

---

## MODEL Statement

```
MODEL < transform(dependents </ t-options>)>
 < transform(dependents </ t-options>)...=>
 transform(independents </ t-options>)
 < transform(independents </ t-options>)... > </ a-options> ;
```

The MODEL statement specifies the dependent and independent variables (*dependents* and *independents*, respectively) and specifies the transformation (*transform*) to apply to each variable. Only one MODEL statement can appear in PROC TRANSREG. The *t-options* are transformation options, and the *a-options* are algorithm options. The *t-options* provide details for the transformation; these depend on the *transform* chosen. The *t-options* are listed after a slash in the parentheses that enclose the variable list (either *dependents* or *independents*). The *a-options* control the algorithm used, details of iteration, details of how the intercept and coded variables are generated, and displayed output details. The *a-options* are listed after the entire model specification (the *dependents*, *independents*, transformations, and *t-options*) and after a slash. You can also specify the algorithm options in the PROC TRANSREG statement. When you specify the

**DESIGN** *o-option*, *dependents* and an equal sign are not required. The operators \*, |, and @ from the GLM procedure are available for interactions with the **CLASS** expansion and the **IDENTITY** transformation. They are used as follows:

```

Class(a * b ...
 c | d ...
 e | f ... @ n)
Identity(a * b ...
 c | d ...
 e | f ... @ n)

```

In addition, transformations and spline expansions can be crossed with classification variables as follows:

```

transform(var) * class(group)
transform(var) | class(group)

```

See the section “Types of Effects” on page 3325 in Chapter 42, “The GLM Procedure,” for a description of the @, \*, and | operators and see the section “Model Statement Usage” on page 8220 for information about how to use these operators in PROC TRANSREG. Note that nesting is not implemented in PROC TRANSREG.

The next three sections discuss the transformations available (*transforms*) (see the section “Families of Transformations” on page 8183), the transformation options (*t-options*) (see the section “Transformation Options (t-options)” on page 8190), and the algorithm options (*a-options*) (see the section “Algorithm Options (a-options)” on page 8200).

## Families of Transformations

In the MODEL statement, *transform* specifies a transformation in one of the following five families:

|                               |                                                                                                                                                                                                                                                                              |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Variable expansions           | preprocess the specified variables, replacing them with more variables.                                                                                                                                                                                                      |
| Nonoptimal transformations    | preprocess the specified variables, replacing each one with a single new nonoptimal, nonlinear transformation.                                                                                                                                                               |
| Nonlinear fit transformations | preprocess the specified variable, replacing it with a smooth transformation, fitting one or more nonlinear functions through a scatter plot.                                                                                                                                |
| Optimal transformations       | replace the specified variables with new, iteratively derived optimal transformation variables that fit the specified model better than the original variable (except for contrived cases where the transformation fits the model exactly as well as the original variable). |
| Other transformations         | are the <b>IDENTITY</b> and <b>SSPLINE</b> transformations. These do not fit into the preceding categories.                                                                                                                                                                  |

The transformations and expansions listed in [Table 97.2](#) are available in the MODEL statement.

**Table 97.2** Transformation Families

| Transformation                       | Description                         |
|--------------------------------------|-------------------------------------|
| <b>Variable Expansions</b>           |                                     |
| BSPLINE                              | B-spline basis                      |
| CLASS                                | set of coded variables              |
| EPOINT                               | elliptical response surface         |
| POINT                                | circular response surface & PREFMAP |
| PSPLINE                              | piecewise polynomial basis          |
| QPOINT                               | quadratic response surface          |
| <b>Nonoptimal Transformations</b>    |                                     |
| ARSIN                                | inverse trigonometric sine          |
| EXP                                  | exponential                         |
| LOG                                  | logarithm                           |
| LOGIT                                | logit                               |
| POWER                                | raises variables to specified power |
| RANK                                 | transforms to ranks                 |
| <b>Nonlinear Fit Transformations</b> |                                     |
| BOXCOX                               | Box-Cox                             |
| PBSPLINE                             | penalized B-splines                 |
| SMOOTH                               | noniterative smoothing spline       |
| <b>Optimal Transformations</b>       |                                     |
| LINEAR                               | linear                              |
| MONOTONE                             | monotonic, ties preserved           |
| MSPLINE                              | monotonic B-spline                  |
| OPSCORE                              | optimal scoring                     |
| SPLINE                               | B-spline                            |
| UNTIE                                | monotonic, ties not preserved       |
| <b>Other Transformations</b>         |                                     |
| IDENTITY                             | identity, no transformation         |
| SSPLINE                              | iterative smoothing spline          |

You can use any transformation with either dependent or independent variables (except the **SMOOTH** and **PBSPLINE** transformations, which can be used only with independent variables, and **BOXCOX**, which can be used only with dependent variables). However, the variable expansions are usually more appropriate for independent variables.

The *transform* is followed by a variable (or list of variables) enclosed in parentheses. Here is an example:

```
model log(y) = class(x);
```

This example finds a **LOG** transformation of *y* and performs a **CLASS** expansion of *x*. Optionally, depending on the *transform*, the parentheses can also contain *t-options*, which follow the variables and a slash. Here is an example:

```
model identity(y) = spline(x1 x2 / nknots=3);
```

The preceding statement finds **SPLINE** transformations of *x1* and *x2*. The **NKNOTS=** *t-option* used with the **SPLINE** transformation specifies three knots. The **identity(y)** transformation specifies that *y* is not to be transformed.

The rest of this section provides syntax details for members of the five families of transformations listed at the beginning of this section. The *t-options* are discussed in the section “Transformation Options (t-options)” on page 8190.

## Variable Expansions

PROC TRANSREG performs variable expansions before iteration begins. Variable expansions expand the original variables into a typically larger set of new variables. The original variables are those that are listed in parentheses after *transform*, and they are sometimes referred to by the name of the *transform*. For example, in `CLASS(x1 x2)`, `x1` and `x2` are sometimes referred to as CLASS expansion variables or simply CLASS variables, and the expanded variables are referred to as coded or sometimes “dummy” variables. Similarly, in `POINT(Dim1 Dim2)`, `Dim1` and `Dim2` are sometimes referred to as POINT variables.

The resulting variables are not transformed by the iterative algorithms after the initial preprocessing. Observations with missing values for these types of variables are excluded from the analysis.

The `POINT`, `EPOINT`, and `QPOINT` variable expansions are used in preference mapping analyses (also called PREFMAP, external unfolding, ideal point regression) (Carroll 1972) and for response surface regressions. These three expansions create circular, elliptical, and quadratic response or preference surfaces (see the section “Point Models” on page 8294 and Example 97.6). The `CLASS` variable expansion is used for main-effects ANOVA.

The following list provides syntax and details for the variable expansion *transforms*.

### BSPLINE

#### BSP

expands each variable to a B-spline basis. You can specify the `DEGREE=`, `KNOTS=`, `NKNOTS=`, and `EVENLY=` *t-options* with the BSPLINE expansion. When `DEGREE=n` (3 by default) with *k* knots (0 by default),  $n + k + 1$  variables are created. In addition, the original variable appears in the `OUT=` data set before the `ID` variables. For example, `bspline(x)` expands `x` into `x_0 x_1 x_2 x_3` and outputs `x` as well. The `x_:` variables contain the B-spline basis vectors (which are the same basis vectors that the `SPLINE` and `MSPLINE` transformations use internally). The columns of the BSPLINE expansion sum to a column of ones, so an implicit intercept model is fit when the BSPLINE expansion is specified. If you specify the BSPLINE expansion for more than one variable, the model is less than full rank. Variables specified in a BSPLINE expansion must be numeric, and they are typically continuous. See the sections “SPLINE and MSPLINE Transformations” on page 8300 and “SPLINE, BSPLINE, and PSPLINE Comparisons” on page 8302 for more information about B-splines.

### CLASS

#### CLA

expands the variables to a set of coded or “dummy” variables. PROC TRANSREG uses the values of the formatted variables to determine class membership. The specification `class(x1 x2)` fits a simple main-effects model, `class(x1 | x2)` fits a main-effects and interactions model, and `class(x1|x2|x3|x4@2 x1*x2*x3)` fits a model with all main effects, all two-way interactions, and one three-way interaction. Variables specified with the CLASS expansion can be either character or numeric; numeric variables should be discrete. See the section “ANOVA Codings” on page 8270 for more information about CLASS variables. See the section “Model Statement Usage” on page 8220 for information about how to use the operators @, \*, and | in PROC TRANSREG.

**EPOINT****EPO**

expands the variables for an elliptical response surface regression or for an elliptical ideal point regression. Specify the **COORDINATES** *o-option* to output PREFMAP ideal elliptical point model coordinates to the **OUT=** data set. Each axis of the ellipse (or ellipsoid) is oriented in the same direction as one of the variables. The EPOINT expansion creates a new variable for each original variable. The value of each new variable is the square of each observed value for the corresponding original variable. The regression analysis then uses both sets of variables (original and squared). Variables specified with the EPOINT expansion must be numeric, and they are typically continuous. See the section “**Point Models**” on page 8294 and **Example 97.6** for more information about point models.

**POINT****POI**

expands the variables for a circular response surface regression or for a circular ideal point regression. Specify the **COORDINATES** *o-option* to output PREFMAP ideal point model coordinates to the **OUT=** data set. The POINT expansion creates a new variable having a value for each observation that is the sum of squares of all the POINT variables. This new variable is added to the set of variables and is used in the regression analysis. For more information about ideal point regression, see Carroll (1972). Variables specified with the POINT expansion must be numeric, and they are typically continuous. See the section “**Point Models**” on page 8294 and **Example 97.6** for more information about point models.

**PSPLINE****PSP**

expands each variable to a piecewise polynomial basis. You can specify the **DEGREE=**, **KNOTS=**, **NKNOTS=**, and **EVENLY** *t-options* with PSPLINE. When **DEGREE=n** (3 by default) with *k* knots (0 by default),  $n + k$  variables are created. In addition, the original variable appears in the **OUT=** data set before the **ID** variables. For example, **pspline(x / nknots=1)** expands *x* into  $x_1$   $x_2$   $x_3$   $x_4$  and outputs *x* as well. Unlike BSPLINE, an intercept is not implicit in the columns of PSPLINE. Variables specified with the PSPLINE expansion must be numeric, and they are typically continuous. See the sections “**SPLINE, BSPLINE, and PSPLINE Comparisons**” on page 8302 and “**Using Splines and Knots**” on page 8233 for more information about splines. Also see Smith (1979) for a good introduction to piecewise polynomial splines.

**QPOINT****QPO**

expands the variables for a quadratic response surface regression or for a quadratic ideal point regression. Specify the **COORDINATES** *o-option* to output PREFMAP quadratic ideal point model coordinates to the **OUT=** data set. For *m* QPOINT variables,  $m(m + 1)/2$  new variables are created containing the squares and crossproducts of the original variables. The regression analysis uses both sets (original and crossed). Variables specified with the QPOINT expansion must be numeric, and they are typically continuous. See the section “**Point Models**” on page 8294 and **Example 97.6** for more information about point models.

## Nonoptimal Transformations

The nonoptimal transformations, like the variable expansions, are computed before the iterative algorithm begins. Nonoptimal transformations create a single new transformed variable that replaces the original variable. The new variable is not transformed by the subsequent iterative algorithms (except for a possible linear transformation with missing value estimation). The following list provides syntax and details for nonoptimal variable transformations.

### ARSIN

#### ARS

finds an inverse trigonometric sine transformation. Variables specified in the ARSIN *transform* must be numeric and in the interval  $(-1.0 \leq x \leq 1.0)$ , and they are typically continuous.

### EXP

exponentiates variables ( $x$  is transformed to  $a^x$ ). To specify the value of  $a$ , use the **PARAMETER=** *t-option*. By default,  $a$  is the mathematical constant  $e = 2.718\dots$ . Variables specified with the EXP *transform* must be numeric, and they are typically continuous.

### LOG

transforms variables to logarithms ( $x$  is transformed to  $\log_a(x)$ ). To specify the base of the logarithm, use the **PARAMETER=** *t-option*. The default is a natural logarithm with base  $e = 2.718\dots$ . Variables specified with the LOG *transform* must be numeric and positive, and they are typically continuous.

### LOGIT

finds a logit transformation on the variables. The logit of  $x$  is  $\log(x/(1-x))$ . Unlike other transformations, LOGIT does not have a three-letter abbreviation. Variables specified with the LOGIT *transform* must be numeric and in the interval  $(0.0 < x < 1.0)$ , and they are typically continuous.

### POWER

#### POW

raises variables to a specified power ( $x$  is transformed to  $x^a$ ). You must specify the power parameter  $a$  by specifying the **PARAMETER=** *t-option* following the variables. Here is an example:

```
power(variable / parameter=number)
```

You can use POWER for squaring variables (PARAMETER=2), reciprocal transformations (PARAMETER=-1), square roots (PARAMETER=0.5), and so on. Variables specified with the POWER *transform* must be numeric, and they are typically continuous.

### RANK

#### RAN

transforms variables to ranks. Ranks are averaged within ties. The smallest input value is assigned the smallest rank. Variables specified in the RANK *transform* must be numeric.

## Nonlinear Fit Transformations

Nonlinear fit transformations, like nonoptimal transformations, are computed before the iterative algorithm begins. Nonlinear fit transformations create a single new transformed variable that replaces the original variable and provides one or more smooth functions through a scatter plot. The new variable is not transformed by the subsequent iterative algorithms. The nonlinear fit transformations, unlike the nonoptimal

transformations, use information in the other variables in the model to find the transformations. The nonlinear fit transformations, unlike the optimal transformations, do not minimize a squared-error criterion. The following list provides syntax and details for nonoptimal variable transformations.

## BOXCOX

### BOX

finds a Box-Cox (1964) transformation of the specified variables. The BOXCOX transformation can be used only with dependent variables. The `ALPHA=`, `CLL=`, `CONVENIENT`, `GEOMETRICMEAN`, `LAMBDA=`, and `PARAMETER=` *t-options* can be used with the BOXCOX transformation. Variables specified in the BOXCOX *transform* must be numeric, and they are typically continuous. See the section “[Box-Cox Transformations](#)” on page 8222 and [Example 97.2](#) for more information about Box-Cox transformations.

## PBSPLINE

### PBS

is a noniterative penalized B-spline transformation (Eilers and Marx 1996). The PBSPLINE transformation can be used only with independent variables. By default with PBSPLINE, a cubic spline is fit with 100 evenly spaced knots, three evenly spaced exterior knots, and a difference matrix of order three (`DEGREE=3` `NKNOTS=100` `EVENLY=3` `PARAMETER=3`). Variables specified in the PBSPLINE *transform* must be numeric, and they are typically continuous. See the section “[Penalized B-Splines](#)” on page 8260 and [Example 97.3](#) for more information about penalized B-splines.

## SMOOTH

### SMO

is a noniterative smoothing spline transformation (Reinsch 1967). You can specify the smoothing parameter with either the `SM=` or the `PARAMETER=` *t-option*. The default smoothing parameter is `SM=0`. The SMOOTH transformation can be used only with independent variables. Variables specified with the SMOOTH *transform* must be numeric, and they are typically continuous. See the sections “[Smoothing Splines](#)” on page 8263 and “[Smoothing Splines Changes and Enhancements](#)” on page 8267 for more information about smoothing splines.

## Optimal Transformations

Optimal transformations are iteratively derived. Missing values for these types of variables can be optimally estimated (see the section “[Missing Values](#)” on page 8289). The following list provides syntax and details for optimal transformations.

## LINEAR

### LIN

finds an optimal linear transformation of each variable. For variables with no missing values, the transformed variable is the same as the original variable. For variables with missing values, the transformed nonmissing values have a different scale and origin than the original values. Variables specified in the LINEAR *transform* must be numeric. See the section “[OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations](#)” on page 8298 for more information about optimal scaling.

**MONOTONE****MON**

finds a monotonic transformation of each variable, with the restriction that ties are preserved. The Kruskal (1964) secondary least squares monotonic transformation is used. This transformation weakly preserves order and category membership (ties). Variables specified with the **MONOTONE** *transform* must be numeric, and they are typically discrete. See the section “**OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations**” on page 8298 for more information about optimal scaling.

**MSPLINE****MSP**

finds a monotonically increasing B-spline transformation with monotonic coefficients (de Boor 1978; de Leeuw 1986) of each variable. You can specify the **DEGREE=**, **KNOTS=**, **NKNOTS=**, and **EVENLY=** *t-options* with **MSPLINE**. By default, PROC TRANSREG fits a quadratic spline with no knots. Variables specified with the **MSPLINE** *transform* must be numeric, and they are typically continuous. See the section “**SPLINE and MSPLINE Transformations**” on page 8300 for more information about monotone splines.

**OPSCORE****OPS**

finds an optimal scoring of each variable. The **OPSCORE** transformation assigns scores to each class (level) of the variable. The Fisher (1938) optimal scoring method is used. Variables specified with the **OPSCORE** *transform* can be either character or numeric; numeric variables should be discrete. See the sections “**Character OPSCORE Variables**” on page 8293 and “**OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations**” on page 8298 for more information about optimal scaling.

**SPLINE****SPL**

finds a B-spline transformation (de Boor 1978) of each variable. By default, PROC TRANSREG fits a cubic spline with no knots. You can specify the **DEGREE=**, **KNOTS=**, **NKNOTS=**, and **EVENLY=** *t-options* with **SPLINE**. Variables specified with the **SPLINE** *transform* must be numeric, and they are typically continuous. See the sections “**SPLINE and MSPLINE Transformations**” on page 8300, “**Specifying the Number of Knots**” on page 8301, and “**SPLINE, BSPLINE, and PSPLINE Comparisons**” on page 8302, and “**Using Splines and Knots**” on page 8233 for more information about splines.

**UNTIE****UNT**

finds a monotonic transformation of each variable without the restriction that ties are preserved. PROC TRANSREG uses the Kruskal (1964) primary least squares monotonic transformation method. This transformation weakly preserves order but not category membership (it might untie some previously tied values). Variables specified with the **UNTIE** *transform* must be numeric, and they are typically discrete. See the section “**OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations**” on page 8298 for more information about optimal scaling.

## Other Transformations

### IDENTITY

#### IDE

specifies variables that are not changed by the iterations. Typically, the IDENTITY transformation is used with a simple variable list, such as `identity(x1-x5)`. However, you can also specify interaction terms. For example, `identity(x1 | x2)` creates  $x_1$ ,  $x_2$ , and the product  $x_1*x_2$ ; and `identity(x1 | x2 | x3)` creates  $x_1$ ,  $x_2$ ,  $x_1*x_2$ ,  $x_3$ ,  $x_1*x_3$ ,  $x_2*x_3$ , and  $x_1*x_2*x_3$ . See the section “Model Statement Usage” on page 8220 for information about how to use the operators @, \*, and | in PROC TRANSREG. Variables specified in the IDENTITY *transform* must be numeric.

The IDENTITY transformation is used for variables when no transformation and no missing data estimation are desired. However, the REFLECT *t-option*, the ADDITIVE *a-option*, and the TSTANDARD=Z, and TSTANDARD=CENTER options can linearly transform all variables, including IDENTITY variables, after the iterations. Observations with missing values in IDENTITY variables are excluded from the analysis, and no optimal scores are computed for missing values in IDENTITY variables.

### SSPLINE

#### SSP

finds an iterative smoothing spline transformation of each variable. The SSPLINE transformation does not generally minimize squared error. You can specify the smoothing parameter with either the SM= *t-option* or the PARAMETER= *t-option*. The default smoothing parameter is SM=0. Variables specified with the SSPLINE *transform* must be numeric, and they are typically continuous.

## Transformation Options (t-options)

If you use a nonoptimal, nonlinear fit, optimal, or other transformation, you can use *t-options*, which specify additional details of the transformation. The *t-options* are specified within the parentheses that enclose variables and are listed after a slash. You can use *t-options* with both the dependent and the independent variables. Here is an example of using just one *t-option*:

```
proc transreg;
 model identity(y)=spline(x / nknots=3);
 output;
run;
```

The preceding statements find an optimal variable transformation (SPLINE) of the independent variable, and they use a *t-option* to specify the number of knots (NKNOTS=). The following is a more complex example:

```
proc transreg;
 model mspline(y / nknots=3)=class(x1 x2 / effects);
 output;
run;
```

These statements find a monotone spline transformation (MSPLINE with three knots) of the dependent variable and perform a CLASS expansion with effects coding of the independents.

Table 97.3 summarizes the *t-options* available in the MODEL statement.

**Table 97.3** Transformation Options

| Option                           | Description                                     |
|----------------------------------|-------------------------------------------------|
| <b>Nonoptimal Transformation</b> |                                                 |
| ORIGINAL                         | Uses original mean and variance                 |
| <b>Parameter Specification</b>   |                                                 |
| PARAMETER=                       | Specifies miscellaneous parameters              |
| SM=                              | Specifies smoothing parameter                   |
| <b>Penalized B-Spline</b>        |                                                 |
| AIC                              | Uses Akaike's information criterion             |
| AICC                             | Uses corrected AIC                              |
| CV                               | Uses cross validation criterion                 |
| GCV                              | Uses generalized cross validation criterion     |
| LAMBDA=                          | Specifies smoothing parameter list or range     |
| RANGE                            | Specifies a LAMBDA= range, not a list           |
| SBC                              | Uses Schwarz's Bayesian criterion               |
| <b>Spline</b>                    |                                                 |
| DEGREE=                          | Specifies the degree of the spline              |
| EVENLY=                          | Spaces the knots evenly                         |
| EXKNOTS=                         | Specifies exterior knots                        |
| KNOTS=                           | Specifies the interior knots or break points    |
| NKNOTS=                          | Creates <i>n</i> knots                          |
| <b>CLASS Variable</b>            |                                                 |
| CPREFIX=                         | Specifies CLASS coded variable name prefix      |
| DEVIATIONS                       | Specifies a deviations-from-means coding        |
| EFFECTS                          | Specifies a deviations-from-means coding        |
| LPREFIX=                         | Specifies CLASS coded variable label prefix     |
| ORDER=                           | Specifies order of CLASS variable levels        |
| ORTHOGONAL                       | Specifies an orthogonal-contrast coding         |
| SEPARATORS=                      | Specifies CLASS coded variable label separators |
| STANDORTH                        | Specifies a standardized-orthogonal coding      |
| ZERO=                            | Controls reference levels                       |
| <b>Box-Cox</b>                   |                                                 |
| ALPHA=                           | Specifies confidence interval alpha             |
| CLL=                             | Specifies convenient lambda list                |
| CONVENIENT                       | Uses a convenient lambda                        |
| GEOMETRICMEAN                    | Scales transformation using geometric mean      |
| LAMBDA=                          | Specifies power parameter list                  |

Table 97.3 continued

| Option                 | Description                                    |
|------------------------|------------------------------------------------|
| <b>Other t-options</b> |                                                |
| AFTER                  | Specifies operations occur after the expansion |
| CENTER                 | Specifies center before the analysis begins    |
| NAME=                  | Renames variables                              |
| REFLECT                | Reflects the variable around the mean          |
| TSTANDARD=             | Specifies transformation standardization       |
| Z                      | Standardizes before the analysis begins        |

The following sections discuss the *t-options* available for nonoptimal, nonlinear fit, optimal, and other transformations.

### Nonoptimal Transformation t-options

#### ORIGINAL

#### ORI

matches the variable's final mean and variance to the mean and variance of the original variable. By default, the mean and variance are based on the transformed values. The ORIGINAL *t-option* is available for all of the nonoptimal transformations.

### Parameter t-options

#### PARAMETER=*number*

#### PAR=*number*

specifies the transformation parameter. The PARAMETER= *t-option* is available for the BOXCOX, EXP, LOG, POWER, SMOOTH, SSPLINE, and PBSPLINE transformations. For BOXCOX, the parameter is the value to add to each value of the variable before a Box-Cox transformation. For EXP, the parameter is the value to be exponentiated; for LOG, the parameter is the base value; and for POWER, the parameter is the power. For SMOOTH and SSPLINE, the parameter is the raw smoothing parameter. (See the SM= option for an alternative way to specify the smoothing parameter.) The default for the PARAMETER= *t-option* for the BOXCOX transformation is 0 and for the LOG and EXP transformations is  $e = 2.718\dots$ . The default parameter for SMOOTH and SSPLINE is computed from SM=0. For the POWER transformation, you must specify the PARAMETER= *t-option*; there is no default. For PBSPLINE, the parameter is the order of the difference matrix, which provides some control over the smoothness of the transformation. The default order parameter with PBSPLINE is the maximum of the DEGREE= *t-option*, and 1. With PBSPLINE, the default is DEGREE=3 and PARAMETER=3, which works well for most problems.

#### SM=*n*

specifies a smoothing parameter in the range 0 to 100, just like PROC GLOT uses. For example, SM=50 in PROC TRANSREG is equivalent to I=SM50 in the SYMBOL statement with PROC GLOT. You can specify the SM= *t-option* only with the SMOOTH and SSPLINE transformations. The smoothness of the function increases as the value of the smoothing parameter increases. By default, SM=0.

## Spline t-options

The following *t-options* are available with the **SPLINE**, **MSPLINE** and **PBSPLINE** transformations and with the **PSPLINE** and **BSPLINE** expansions.

### **DEGREE=*n***

#### **DEG=*n***

specifies the degree of the spline transformation. The degree must be a nonnegative integer. The defaults are **DEGREE=3** for **SPLINE**, **PSPLINE**, and **BSPLINE** variables and **DEGREE=2** for **MSPLINE** variables.

The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

### **EVENLY<=*n*>**

#### **EVE<=*n*>**

is used with the **NKNOTS=** *t-option* to space the knots evenly. The differences between adjacent knots are constant.

If you specify **NKNOTS=*k*** and **EVENLY**, *k* knots are created at

$$\text{minimum} + i((\text{maximum} - \text{minimum}) / (k + 1))$$

for  $i = 1, \dots, k$ . Here is an example:

```
spline(x / nknots=2 evenly)
```

When the variable *x* has a minimum of 4 and a maximum of 10, then the two interior knots are 6 and 8. Without the **EVENLY** *t-option*, the **NKNOTS=** *t-option* places knots at percentiles, so the knots are not evenly spaced. By default for the **BSPLINE** expansion and the **SPLINE** and **MSPLINE** transformations, the smaller exterior knots are all the same and all just a little smaller than the minimum. Similarly, by default, the larger exterior knots are all the same and all just a little larger than the maximum. However, if you specify **EVENLY=*n***, then the *n* exterior knots are evenly spaced as well. The number of exterior knots must be greater than or equal to the degree. You can specify values larger than the degree when you want to interpolate slightly beyond the range or your data. The exterior knots must be less than the minimum or greater than the maximum; hence the knots across all sets are not precisely equally spaced. For example, with data ranging from 0 to 10, and with **EVENLY=3** and **NKNOTS=4**, the first exterior knots are  $-4.000000000001$ ,  $-2.000000000001$ , and  $-0.000000000001$ , the interior knots are 2, 4, 6, and 8, and the second exterior knots are  $10.000000000001$ ,  $12.000000000001$ , and  $14.000000000001$ .

With the **BSPLINE** and **PSPLINE** expansions and the **SPLINE** and **MSPLINE** transformations, evenly spaced knots are not the default. With the **PBSPLINE** transformation, evenly spaced interior and exterior knots are the default. If you want unevenly spaced knots with **PBSPLINE**, you must use the **KNOTS=** *t-option*.

### **EXKNOTS=number-list**

#### **EXK=number-list**

specifies exterior knots for **SPLINE** and **MSPLINE** transformations and **BSPLINE** expansions. Usually, this *t-option* is not needed; PROC TRANSREG automatically picks suitable exterior knots. The only time you need to use this option is when you want to ensure that the exact same basis is used for

different splines, such as when you apply coefficients from one spline transformation to a variable in a different data set (see the section “[Scoring Spline Variables](#)” on page 8245).

Specify one or two values. If the minimum EXKNOTS= value is less than the minimum data value, it is used as the exterior knot. If the maximum EXKNOTS= value is greater than the maximum data value, it is used as the exterior knot. Otherwise these values are ignored. When EXKNOTS= is specified with the [CENTER](#) or [Z](#) *t-options*, the knots apply to the original variable, not to the centered or standardized variable.

The B-spline transformations and expansions use a knot list consisting of exterior knots (values just smaller than the minimum), the specified (interior) knots, and exterior knots (values just larger than the minimum). You can use the [DETAIL](#) *a-option* to see all of these knots. If you use different exterior knots, you get different but equivalent B-spline bases. You can specify exterior knots in either the [KNOTS=](#) or [EXKNOTS=](#) *t-options*; however, for the [BSPLINE](#) expansion, the [KNOTS=](#) *t-option* creates extra all-zero basis columns, whereas the [EXKNOTS=](#) *t-option* gives you the correct basis. See the [EVENLY=](#) *t-option* for an alternative way to specify exterior knots.

**KNOTS=***number-list* | *n* TO *m* BY *p*

**KNO=***number-list* | *n* TO *m* BY *p*

specifies the interior knots or break points. By default, there are no knots. The first time you specify a value in the knot list, it indicates a discontinuity in the *n*th (from [DEGREE=\*n\*](#)) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the (*n* – 1) derivative of the transformation function at the value of the knot. Knots can be repeated any number of times for decreasing smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the [KNOTS=](#) *t-option* with the [NKNOTS=](#) *t-option*. You should keep the number of knots small (see the section “[Specifying the Number of Knots](#)” on page 8301).

**NKNOTS=***n*

**NKN=***n*

creates *n* knots, the first at the 100/(*n* + 1) percentile, the second at the 200/(*n* + 1) percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if [NKNOTS=3](#), knots are placed at the 25th percentile, the median, and the 75th percentile. You can use the [EVENLY=](#) *t-option* along with [NKNOTS=](#) to get evenly spaced knots. By default, with the [BSPLINE](#) and [PSPLINE](#) expansions and the [SPLINE](#) and [MSPLINE](#) transformations, [NKNOTS=0](#). By default, with the [PBSPLINE](#) transformation, [NKNOTS=100](#).

The value specified for the [NKNOTS=](#) *t-option* must be  $\geq 0$ .

You cannot use the [NKNOTS=](#) *t-option* with the [KNOTS=](#) *t-option*.

You should keep the number of knots small (see the section “[Specifying the Number of Knots](#)” on page 8301).

## Penalized B-Spline *t-options*

The following *t-options* are available with the [PBSPLINE](#) transformation.

**AIC**

specifies that the procedure should select the smoothing parameter,  $\lambda$ , that minimizes the (Akaike 1973) information criterion (AIC). By default, the (AICC) criterion is minimized.

**AICC**

specifies that the procedure should select the smoothing parameter,  $\lambda$ , that minimizes the corrected Akaike information criterion (Hurvich, Simonoff, and Tsai 1998). This is the default criterion unless the **AIC**, **CV**, **GCV**, or **SBC** *t-option* is specified.

**CV**

specifies that the procedure should select the smoothing parameter,  $\lambda$ , that minimizes the cross validation criterion (CV). By default, the (AICC) criterion is minimized.

**GCV**

specifies that the procedure should select the smoothing parameter,  $\lambda$ , that minimizes the generalized cross validation criterion (Craven and Wahba 1979). By default, the (AICC) criterion is minimized.

**LAMBDA=***number-list*

**LAM=***number-list*

specifies a list of penalized B-spline smoothing parameters. By default, PROC TRANSREG considers lambdas in the range 0 to 1E6. Alternatively, you can specify the **RANGE** *t-option* with **LAMBDA=**, such as **LAMBDA=1E3 1E5 RANGE**, to only consider lambdas in a narrower range. Note that the algorithm might not actually evaluate the criterion at the minimum and maximum if it does not have to. In particular, it avoids evaluating the criterion at **LAMBDA=0** (no smoothing) unless it is the only **LAMBDA=** value specified. You can also specify a list of lambdas, such as **LAMBDA=1 TO 10**, and the procedure selects the best lambda from the list. In all cases, the lambda that minimizes the specified criterion (or **AICC** by default) is chosen.

**RANGE****RAN**

specifies that the **LAMBDA=** *t-option* specifies two lambdas that define a range of values, from which an optimal lambda is selected. By default, PROC TRANSREG considers lambdas in the range 0 to 1E6.

**SBC**

specifies that the procedure should select the smoothing parameter,  $\lambda$ , that minimizes Schwarz's Bayesian criterion (Schwarz 1978; Judge et al. 1980). By default, the (AICC) criterion is minimized.

**Class Variable t-options**

**CPREFIX=***n* | *number-list*

**CPR=***n* | *number-list*

specifies the number of first characters of a **CLASS** expansion variable's name to use in constructing names for coded variables. When you specify **CPREFIX=** as an *a-option* or an *o-option*, it specifies the default for all **CLASS** variables. When you specify **CPREFIX=** as a *t-option*, it overrides the default only for selected variables. A different **CPREFIX=** value can be specified for each **CLASS** variable by specifying the **CPREFIX=number-list** *t-option*, like the **ZERO=formatted-value** *t-option*.

**DEVIATIONS****DEV**

requests a deviations-from-means coding of **CLASS** variables. The coded design matrix has values of 0, 1, and -1 for reference levels. This coding is referred to as “deviations-from-means,” “effects,” “center-point,” or “full-rank” coding. For example, here is the coding for two-, three-, four-, and five-level factors:

|   | Number of Levels |       |    |      |    |    |      |    |    |
|---|------------------|-------|----|------|----|----|------|----|----|
|   | Two              | Three |    | Four |    |    | Five |    |    |
| a | 1                | 1     | 0  | 1    | 0  | 0  | 1    | 0  | 0  |
| b | -1               | 0     | 1  | 0    | 1  | 0  | 0    | 1  | 0  |
| c |                  | -1    | -1 | 0    | 0  | 1  | 0    | 0  | 1  |
| d |                  |       |    | -1   | -1 | -1 | 0    | 0  | 0  |
| e |                  |       |    |      |    |    | -1   | -1 | -1 |

**EFFECTS****EFF**

See the **DEVIATIONS** *t-option*.

**LPREFIX=*n*** | *number-list*

**LPR=*n*** | *number-list*

specifies the number of first characters of a **CLASS** expansion variable’s label (or name if no label is specified) to use in constructing labels for the coded variables. When you specify **LPREFIX=** as an *a-option* or an *o-option*, it specifies the default for all **CLASS** variables. When you specify **LPREFIX=** as a *t-option*, it overrides the default only for selected variables. A different **LPREFIX=** value can be specified for each **CLASS** variable by specifying the **LPREFIX=number-list** *t-option*, like the **ZERO=formatted-value** *t-option*.

**ORDER=DATA** | **FREQ** | **FORMATTED** | **INTERNAL**

**ORD=DAT** | **FRE** | **FOR** | **INT**

specifies the order in which the **CLASS** variable levels are to be reported. The default is **ORDER=INTERNAL**. For **ORDER=FORMATTED** and **ORDER=INTERNAL**, the sort order is machine dependent. When you specify **ORDER=** as an *a-option* or an *o-option*, it specifies the default ordering for all **CLASS** variables. When you specify **ORDER=** as a *t-option*, it overrides the default ordering only for selected variables. You can specify a different **ORDER=** value for each **CLASS** specification.

**ORTHOGONAL****ORT**

requests an orthogonal-contrast coding of **CLASS** variables. For example, here is the orthogonal-contrast coding for two-, three-, four-, and five-level factors:

|   | Number of Levels |       |    |      |    |    |      |    |    |
|---|------------------|-------|----|------|----|----|------|----|----|
|   | Two              | Three |    | Four |    |    | Five |    |    |
| a | 1                | 1     | -1 | 1    | -1 | -1 | 1    | -1 | -1 |
| b | -1               | 0     | 2  | 0    | 2  | -1 | 0    | 2  | -1 |
| c |                  | -1    | -1 | 0    | 0  | 3  | 0    | 0  | 3  |
| d |                  |       |    | -1   | -1 | -1 | 0    | 0  | 0  |
| e |                  |       |    |      |    |    | -1   | -1 | -1 |

The sum of the coded values within each column is zero, all columns within a factor are orthogonal, and the *i*th column represents a contrast between the *i*th level and the combination of all preceding

levels and the last level. The  $X$  matrix is orthogonal and  $X'X$  is diagonal with this coding only if the experimental design is orthogonal.

**SEPARATORS=**'string-1' < 'string-2' >

**SEP=**'string-1' < 'string-2' >

specifies separators for creating **CLASS** expansion variable labels. By default, SEPARATORS=' ' \* ' ("blank" and "blank asterisk blank"). When you specify SEPARATORS= as an *a-option* or an *o-option*, it specifies the default separators for all **CLASS** variables. When you specify SEPARATORS= as a *t-option*, it overrides the default only for selected variables. You can specify a different SEPARATORS= value for each **CLASS** specification.

## STANDORTH

### STA

### ORTHEFFECT

requests a standardized-orthogonal coding of **CLASS** variables. For example, here is the standardized-orthogonal coding for two-, three-, four-, and five-level factors:

|   | Number of Levels |       |       |       |       |       |       |       |       |       |
|---|------------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
|   | Two              | Three |       | Four  |       |       | Five  |       |       |       |
| a | 1                | 1.22  | -0.71 | 1.41  | -0.82 | -0.58 | 1.58  | -0.91 | -0.65 | -0.50 |
| b | -1               | 0.00  | 1.41  | 0.00  | 1.63  | -0.58 | 0.00  | 1.83  | -0.65 | -0.50 |
| c |                  | -1.22 | -0.71 | 0.00  | 0.00  | 1.73  | 0.00  | 0.00  | 1.94  | -0.50 |
| d |                  |       |       | -1.41 | -0.82 | -0.58 | 0.00  | 0.00  | 0.00  | 2.00  |
| e |                  |       |       |       |       |       | -1.58 | -0.91 | -0.65 | -0.50 |

The sum of the coded values within each column is zero, the sum of squares of the coded values within each column is equal to the number of levels, all columns within a factor are orthogonal, and the *i*th column represents a contrast between the *i*th level and the combination of all preceding levels and the last level. The  $X$  matrix is orthogonal and  $X'X$  is diagonal ( $X'X = nI$ , the number of observations times an identity matrix) with this coding only if the experimental design is orthogonal.

**ZERO=FIRST | LAST | NONE | SUM**

**ZER=FIR | LAS | NON | SUM**

**ZERO=**'formatted-value' < 'formatted-value' ... >

is used with **CLASS** variables. The default is ZERO=LAST.

The specification CLASS(variable / ZERO=FIRST) sets to missing the coded variable for the first of the sorted categories, implying a zero coefficient for that category.

The specification CLASS(variable / ZERO=LAST) sets to missing the coded variable for the last of the sorted categories, implying a zero coefficient for that category.

The specification CLASS(variable / ZERO='formatted-value') sets to missing the coded variable for the category with a formatted value that matches 'formatted-value', implying a zero coefficient for that category. With ZERO=formatted-value, the first formatted value applies to the first variable in the specification, the second formatted value applies to the next variable that was not previously mentioned, and so on. For example, `class(a a*b b b*c c / zero='x' 'y' 'z')` specifies that the reference level for a is 'x', for b is 'y', and for c is 'z'. With ZERO='formatted-value', the procedure first looks for exact matches between the formatted values and the specified value. If none are found, leading blanks are stripped from both and the values are compared again. If zero or two or more matches are found, warnings are issued.

The specifications ZERO=FIRST, ZERO=LAST, and ZERO='formatted-value' are used for reference cell models. The Intercept parameter estimate is the marginal mean for the reference cell, and the other marginal means are obtained by adding the intercept to the coded variable coefficients.

The specification CLASS(variable / ZERO=NONE) sets to missing none of the coded variables. The columns of the expansion sum to a column of ones, so an implicit intercept model is fit. If you specify ZERO=NONE for more than one variable, the model is less than full rank. In the model `model identity(y) = class(x / zero=none)`, the coefficients are cell means.

The specification CLASS(variable / ZERO=SUM) sets to missing none of the coded variables, and the coefficients for the coded variables created from the variable sum to 0. This creates a less-than-full-rank model, but the coefficients are uniquely determined due to the sum-to-zero constraint.

In the presence of iterative transformations, hypothesis tests for ZERO=NONE and ZERO=SUM levels are not exact; they are liberal because a model with an explicit intercept is fit inside the iterations. There is no provision for adjusting the transformations while setting to 0 a parameter that is redundant given the explicit intercept and the other parameters.

## Box-Cox t-options

The following *t-options* are available only with the BOXCOX transformation of the dependent variable (see the section “Box-Cox Transformations” on page 8222 and Example 97.2).

### ALPHA= $\rho$

#### ALP= $\rho$

specifies the Box-Cox alpha for the confidence interval for the power parameter. By default, ALPHA=0.05.

### CLL=*number-list*

specifies the Box-Cox convenient lambda list. When the confidence interval for the power parameter includes one of the values in this list, PROC TRANSREG reports it and can optionally use the convenient power parameter instead of the more optimal power parameter. The default is CLL=1.0 0.0 0.5 -1.0 -0.5 2.0 -2.0 3.0 -3.0. By default, a linear transformation is preferred over log, square root, inverse, inverse square root, quadratic, inverse quadratic, cubic, and inverse cubic. If you specify the CONVENIENT *t-option*, then PROC TRANSREG uses the first convenient power parameter in the list that is in the confidence interval. For example, if the optimal power parameter is 0.25 and 0.0 is in the confidence interval but not 1.0, then the convenient power parameter is 0.0.

### CONVENIENT

#### CON

specifies that a power parameter from the CLL= *t-option* list is to be used for the final transformation instead of the LAMBDA= *t-option* value if a CLL= value is in the confidence interval. See the CLL= *t-option* for more information about its usage.

### GEOMETRICMEAN

#### GEO

divides the Box-Cox transformation by  $\bar{y}^{\lambda-1}$ , where  $\bar{y}$  is the geometric mean of the variable to be transformed. This form of the Box-Cox transformation essentially converts the transformation back to original units, and hence it permits direct comparison of the residual sums of squares for models with different power parameters.

**LAMBDA=***number-list*

**LAM=***number-list*

specifies a list of Box-Cox power parameters. The default is LAMBDA=−3 TO 3 BY 0.25. PROC TRANSREG tries each power parameter in the list and picks the best one. However, when the **CONVENIENT** *t-option* is specified, PROC TRANSREG chooses a convenient value from the confidence interval instead of the optimal value. For example, if the optimal power parameter is 0.25 and 0.0 is in the confidence interval but not 1.0, then the convenient power parameter 0.0 (log transformation) is chosen instead of the more optimal parameter 0.25. See the **CLL=** *t-option* for more information about its usage.

## Other t-options

**AFTER**

**AFT**

requests that certain operations occur after the expansion. This *t-option* affects the **NKNOTS=** *t-option* when the **SPLINE** or **MSPLINE** transformation is crossed with a **CLASS** specification. For example, if the original spline variable (1 2 3 4 5 6 7 8 9) is expanded into the three variables (1 2 3 0 0 0 0 0 0), (0 0 0 4 5 6 0 0 0), and (0 0 0 0 0 0 7 8 9), then, by default, **NKNOTS=1** would use the overall median of 5 as the knot for all three variables. When you specify the **AFTER** *t-option*, the knots for the three variables are 2, 5, and 8. Note that the structural zeros are ignored when the internal knot list is created, but they are not ignored for the exterior knots.

You can also specify the **AFTER** *t-option* with the **RANK**, **SMOOTH**, and **PBSPLINE** transformations. The following specifications compute ranks and smooth transformations within groups, after crossing, ignoring the structural zeros:

```
class(x / zero=none) | rank(z / after)
class(x / zero=none) | smooth(z / after)
```

**CENTER**

**CEN**

centers the variables before the analysis begins (in contrast to the **TSTANDARD=CENTER** option, which centers after the analysis ends). The **CENTER** *t-option* can be used instead of running PROC STANDARD before PROC TRANSREG (see the section “Centering” on page 8336). When the **KNOTS=** *t-option* is specified with **CENTER**, the knots apply to the original variable, not to the centered variable. PROC TRANSREG centers the knots.

**NAME=***(variable-list)*

**NAM=***(variable-list)*

renames variables as they are used in the MODEL statement. This *t-option* lets you use a variable more than once.

For example, if x is a character variable, then the following step stores both the original character variable x and a numeric variable xc that contains category numbers in the **OUT=** data set:

```
proc transreg data=a;
 model identity(y) = opscore(x / name=(xc));
 output;
 id x;
run;
```

With the **CLASS** and **IDENTITY** transformations, which can contain interaction effects, the first name applies to the first variable in the specification, the second name applies to the next variable that was not previously mentioned, and so on. For example, `identity(a a * b b b * c c / name=(g h i))` specifies that the new name for **a** is **g**, for **b** is **h**, and for **c** is **i**. The same assignment is used for the (not useful) specification `identity(a a b b c c / name=(g h i))`. For all *transforms* other than **CLASS** and **IDENTITY** (all those in which interactions are not supported), repeated variables are not handled specially. For example, `spline(a a b b c c / name=(a g b h c i))` creates six variables: a copy of **a** named **a**, another copy of **a** named **g**, a copy of **b** named **b**, another copy of **b** named **h**, a copy of **c** named **c**, and another copy of **c** named **i**.

**REFLECT****REF**

reflects the transformation

$$y = -(y - \bar{y}) + \bar{y}$$

after the iterations are completed and before the final standardization and results calculations. This *t-option* is particularly useful with the dependent variable in a conjoint analysis. When the dependent variable consists of ranks with the most preferred combination assigned 1.0, the **REFLECT** *t-option* reflects the transformation so that positive utilities mean high preference. (See [Example 97.4](#).)

**TSTANDARD=CENTER | NOMISS | ORIGINAL | Z****TST=CEN | NOM | ORI | Z**

specifies the standardization of the transformed variables for the hypothesis tests and in the **OUT=** data set (see the section “[Centering](#)” on page 8336). By default, **TSTANDARD=ORIGINAL**. When you specify **TSTANDARD=** as an *a-option* or an *o-option*, it determines the default standardization for all variables. When you specify **TSTANDARD=** as a *t-option*, it overrides the default standardization only for selected variables. You can specify a different **TSTANDARD=** value for each transformation. For example, to perform a redundancy analysis with standardized dependent variables, specify the following:

```
model identity(y1-y4 / tstandard=z) = identity(x1-x10);
```

**Z**

centers and standardizes the variables to variance one before the analysis begins (in contrast to the **TSTANDARD=Z** option, which standardizes after the analysis ends). The **Z** *t-option* can be used instead of running **PROC STANDARD** before **PROC TRANSREG** (see the section “[Centering](#)” on page 8336). When the **KNOTS=** *t-option* is specified with **Z**, the knots apply to the original variable, not to the standardized variable. **PROC TRANSREG** standardizes the knots.

**Algorithm Options (a-options)**

This section discusses the options that can appear in the **PROC TRANSREG** or **MODEL** statement as *a-options*. They are listed after the entire model specification and after a slash. Here is an example:

```

proc transreg;
 model spline(y / nknots=3)=log(x1 x2 / parameter=2)
 / nomiss maxiter=50;
 output;
run;

```

In the preceding statements, **NOMISS** and **MAXITER=** are *a-options*. (**SPLINE** and **LOG** are *transforms*, and **NKNOTS=** and **PARAMETER=** are *t-options*.) The statements find a spline transformation with 3 knots on *y* and a base 2 logarithmic transformation on *x1* and *x2*. The **NOMISS** *a-option* excludes all observations with missing values, and the **MAXITER=** *a-option* specifies the maximum number of iterations.

Table 97.4 summarizes the *a-options* available in the PROC TRANSREG or MODEL statement.

**Table 97.4** Options Available in the PROC TRANSREG or MODEL Statement

| Option                               | Description                                     |
|--------------------------------------|-------------------------------------------------|
| <b>Input Control</b>                 |                                                 |
| REITERATE                            | Restarts iterations                             |
| TYPE=                                | Specifies input observation type                |
| <b>Method and Iterations</b>         |                                                 |
| CCONVERGE=                           | Specifies minimum criterion change              |
| CONVERGE=                            | Specifies minimum data change                   |
| MAXITER=                             | Specifies maximum number of iterations          |
| METHOD=                              | Specifies iterative algorithm                   |
| NCAN=                                | Specifies number of canonical variables         |
| NSR                                  | Specifies no restrictions on smoothing models   |
| SINGULAR=                            | Specifies singularity criterion                 |
| SOLVE                                | Attempts direct solution instead of iteration   |
| <b>Missing Data Handling</b>         |                                                 |
| INDIVIDUAL                           | Fits each model individually (METHOD=MORALS)    |
| MONOTONE=                            | Includes monotone special missing values        |
| NOMISS                               | Excludes observations with missing values       |
| UNTIE=                               | Unties special missing values                   |
| <b>Intercept and CLASS Variables</b> |                                                 |
| CPREFIX=                             | Specifies CLASS coded variable name prefix      |
| LPREFIX=                             | Specifies CLASS coded variable label prefix     |
| NOINT                                | Specifies no intercept or centering             |
| ORDER=                               | Specifies order of CLASS variable levels        |
| REFERENCE=                           | Controls output of reference levels             |
| SEPARATORS=                          | Specifies CLASS coded variable label separators |
| <b>Control Displayed Output</b>      |                                                 |
| ALPHA=                               | Specifies confidence limits alpha               |
| CL                                   | Displays parameter estimate confidence limits   |
| DETAIL                               | Displays model specification details            |
| HISTORY                              | Displays iteration histories                    |
| NOPRINT                              | Suppresses displayed output                     |
| PBOXCOXTABLE                         | Prints the Box-Cox log likelihood table         |

Table 97.4 continued

| Option                 | Description                              |
|------------------------|------------------------------------------|
| RSQUARE                | Displays the R square                    |
| SHORT                  | Suppresses the iteration histories       |
| SS2                    | Displays regression results              |
| TEST                   | Displays ANOVA table                     |
| TSUFFIX=               | Shortens transformed variable labels     |
| UTILITIES              | Displays conjoint part-worth utilities   |
| <b>Standardization</b> |                                          |
| ADDITIVE               | Fits additive model                      |
| NOZEROCONSTANT         | Does not zero constant variables         |
| TSTANDARD=             | Specifies transformation standardization |

The following list provides details about these *a-options*. The *a-options* are available in the PROC TRANSREG or MODEL statement.

**ADDITIVE****ADD**

creates an additive model by multiplying the values of each independent variable (after the **TSTANDARD=** standardization) by that variable's corresponding multiple regression coefficient. This process scales the independent variables so that the predicted-values variable for the final dependent variable is simply the sum of the final independent variables. An additive model is a univariate multiple regression model. As a result, the **ADDITIVE a-option** is not valid if **METHOD=CANALS**, or if **METHOD=REDUNDANCY** or **METHOD=UNIVARIATE** with more than one dependent variable.

**ALPHA=number****ALP=number**

specifies the level of significance for all of the confidence limits. By default, ALPHA=0.05.

**CCONVERGE=n****CCO=n**

specifies the minimum change in the criterion being optimized (squared multiple correlation for **METHOD=MORALS** and **METHOD=UNIVARIATE**, average squared multiple correlation for **METHOD=REDUNDANCY**, average squared canonical correlation for **METHOD=CANALS**) that is required to continue iterating. By default, CCONVERGE=0.0.

**CL**

requests confidence limits on the parameter estimates in the displayed output.

**CONVERGE=n****CON=n**

specifies the minimum average absolute change in standardized variable scores that is required to continue iterating. By default, CONVERGE=0.00001. Average change is computed over only those variables that can be transformed by the iterations; that is, all **LINEAR**, **OPSCORE**, **MONOTONE**, **UNTIE**, **SPLINE**, **MSPLINE**, and **SSPLINE** variables and nonoptimal transformation variables with missing values.

**CPREFIX=*n*****CPR=*n***

specifies the number of first characters of a **CLASS** expansion variable's name to use in constructing names for coded variables. Coded variable names are constructed from the first *n* characters of the **CLASS** expansion variable's name and the first  $32 - n$  characters of the formatted **CLASS** expansion variable's value. For example, if the variable **ClassVariable** has values 1, 2, and 3, then, by default, the coded variables are named **ClassVariable1**, **ClassVariable2**, and **ClassVariable3**. However, with **CPREFIX=5**, the coded variables are named **Class1**, **Class2**, and **Class3**. When **CPREFIX=0**, coded variable names are created entirely from the **CLASS** expansion variable's formatted values. Valid values range from  $-1$  to  $31$ , where  $-1$  indicates the default calculation and  $0$  to  $31$  are the number of prefix characters to use. The default,  $-1$ , sets *n* to  $32 - \min(32, \max(2, fl))$ , where *fl* is the format length. When you specify **CPREFIX=** as an *a-option* or an *o-option*, it specifies the default for all **CLASS** variables. When you specify **CPREFIX=** as a *t-option*, it overrides the default only for selected variables.

**DETAIL****DET**

reports on details of the model specification. For example, it reports the knots and coefficients for splines, reference levels for **CLASS** variables, Box-Cox results, the smoothing parameter, and so on. The **DETAIL** option can take two optional suboptions, **NOCOEFFICIENTS** and **NOKNOTS** (or **NOC** and **NOK**). To suppress knots from the details listing, specify **DETAIL(NOKNOTS)**. To suppress coefficients from the details listing, specify **DETAIL(NOCOEFFICIENTS)**. To suppress both knots and coefficients from the details listing, specify **DETAIL(NOKNOTS NOCOEFFICIENTS)**.

**SOLVE****SOL****DUMMY****DUM**

provides a canonical initialization. When there are no monotonicity constraints, when there is at most one canonical variable in each set, and when there is enough available memory, **PROC TRANSREG** (with the **SOLVE a-option**) can usually directly solve for the optimal solution in only one iteration. The initialization iteration is number 0, which is slower and uses more memory than other iterations. However, for some models, specifying the **SOLVE a-option** can greatly decrease the amount of time required to find the optimal transformations. During iteration 0, each variable is replaced by an expanded variable and the model is fit to the larger, expanded set of variables. For example, an **OPSCORE** variable is expanded into coded (or "dummy") variables, as if **CLASS** were specified, and a **SPLINE** variable is expanded into a B-spline basis, as if **BSPLINE** were specified. Then for each expanded variable, the results of iteration zero are constructed by multiplying the expanded basis times the  $\beta$  subvector to get the optimal transformation. This *a-option* can be useful even in models where a direct solution is not possible, because it provides good initial transformations of all the variables.

**HISTORY****HIS**

displays the iteration histories even when the **NOPRINT a-option** is specified.

**INDIVIDUAL****IND**

fits each model for each dependent variable individually. This means, for example, that when INDIVIDUAL is specified, missing values in one dependent variable will not cause that observation to be deleted for the other models with the other dependent variables. In contrast, by default, missing values in any variable in any model can cause the observation to be deleted for all models. The INDIVIDUAL *a-option* can be specified only with **METHOD=MORALS**.

This *a-option* also affects the order of the output. By default, the number of observations table is printed once at the beginning of the output. With INDIVIDUAL, a number of observations table appears for each model.

**LPREFIX=*n*****LPR=*n***

specifies the number of first characters of a **CLASS** expansion variable's label (or name if no label is specified) to use in constructing labels for coded variables. Coded variable labels are constructed from the first *n* characters of the CLASS expansion variable's name and the first 127 – Argument*n* characters of the formatted CLASS expansion variable's value. Valid values range from –1 to 127. Values of 0 to 127 specify the number of name or label characters to use. The default is –1, which specifies that PROC TRANSREG should pick a value depending on the length of the prefix and the formatted class value. When you specify LPREFIX= as an *a-option* or an *o-option*, it determines the default for all CLASS variables. When you specify LPREFIX= as a *t-option*, it overrides the default only for selected variables.

**MAXITER=*n*****MAX=*n***

specifies the maximum number of iterations (see the section “Controlling the Number of Iterations” on page 8290). By default, MAXITER=30. You can specify MAXITER=0 to save time when no transformations are requested.

**METHOD=CANALS | MORALS | REDUNDANCY | UNIVARIATE****MET=CAN | MOR | RED | UNI**

specifies the iterative algorithm. By default, METHOD=UNIVARIATE, unless you specify options that cannot be handled by the UNIVARIATE algorithm. Specifically, the default is METHOD=MORALS for the following situations:

- if you specify **LINEAR**, **OPSCORE**, **MONOTONE**, **UNTIE**, **SPLINE**, **MSPLINE**, or **SSPLINE** transformations for the independent variables
- if you specify the **ADDITIVE** *a-option* with more than one dependent variable
- if you specify the **IAPPROXIMATIONS** *o-option*
- if you specify the **INDIVIDUAL** *a-option*
- if ODS Graphics is enabled, regression plots are produced, and there is more than one dependent variable

**CANALS**

specifies canonical correlation with alternating least squares. This jointly transforms all dependent and independent variables to maximize the average of the first *n* squared canonical correlations, where *n* is the value of the **NCAN=** *a-option*.

- MORALS** specifies multiple optimal regression with alternating least squares. This transforms each dependent variable, along with the set of independent variables, to maximize the squared multiple correlation.
- REDUNDANCY** jointly transforms all dependent and independent variables to maximize the average of the squared multiple correlations (see the section “[Redundancy Analysis](#)” on page 8295).
- UNIVARIATE** transforms each dependent variable to maximize the squared multiple correlation, while the independent variables are not transformed.

**MONOTONE=***two-letters*

**MON=***two-letters*

specifies the first and last special missing value in the list of those special missing values to be estimated with within-variable order and category constraints. By default, there are no order constraints on missing value estimates. The *two-letters* value must consist of two letters in alphabetical order. For example, MONOTONE=DF means that the estimate of .D must be less than or equal to the estimate of .E, which must be less than or equal to the estimate of .F; no order constraints are placed on estimates of .\_, .A through .C, and .G through .Z. For details, see the section “[Missing Values](#)” on page 8289.

**NCAN=***n*

**NCA=***n*

specifies the number of canonical variables to use in the METHOD=CANALS algorithm. By default, NCAN=1. The value of the NCAN= *a-option* must be  $\geq 1$ .

When canonical coefficients and coordinates are included in the OUT= data set, the NCAN= *a-option* also controls the number of rows of the canonical coefficient matrices in the data set. If you specify an NCAN= value larger than the minimum of the number of dependent variables and the number of independent variables, PROC TRANSREG displays a warning and sets the NCAN= *a-option* to the maximum value.

**NOINT**

**NOI**

omits the intercept from the OUT= data set and suppresses centering of data. You cannot specify the NOINT *a-option* with iterative transformations since there is no provision for optimal scaling without an intercept. The NOINT *a-option* can be specified only when there is no implicit intercept and when all of the data in a BY group absolutely will not change during the iterations.

**NOMISS**

**NOM**

excludes all observations with missing values from the analysis, but does not exclude them from the OUT= data set. If you omit the NOMISS *a-option*, PROC TRANSREG simultaneously computes the optimal transformations of the nonmissing values and estimates the missing values that minimize squared error. For details, see the section “[Missing Values](#)” on page 8289.

Casewise deletion of observations with missing values occurs when the NOMISS *a-option* is specified, when there are missing values in expansions, when there are missing values in METHOD=UNIVARIATE independent variables, when there are weights less than or equal to 0, or when there are frequencies less than 1. Excluded observations are output with a blank value for the \_TYPE\_ variable, and they have a weight of 0. They do not contribute to the analysis but are scored and transformed as *supplementary* or *passive* observations.

See the section “[Passive Observations](#)” on page 8294 for more information about excluded observations.

## **NOPRINT**

### **NOP**

suppresses the display of all output unless you specify the [HISTORY](#) *a-option*. The **NOPRINT** *a-option* without the [HISTORY](#) *a-option* disables the Output Delivery System (ODS), including ODS Graphics, for the duration of the procedure run. The **NOPRINT** *a-option* with the [HISTORY](#) *a-option* disables all output except the iteration history, again including ODS Graphics, for the duration of the procedure run. For more information, see Chapter 20, “[Using the Output Delivery System](#).”

## **NOZEROCONSTANT**

### **NOZERO**

### **NOZ**

specifies that constant variables are expected and should not be zeroed. By default, constant variables are zeroed. This option is useful when PROC TRANSREG is used to code experimental designs for discrete choice models (see the section “[Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO](#)” on page 8335). When these designs are very large, it might be more efficient to use the [DESIGN=\*n\*](#) *a-option*. It might be that attributes are constant within a block of *n* observations, so you need to specify the **NOZEROCONSTANT** *a-option* to get the correct results. You can specify this option in the PROC TRANSREG, MODEL, and OUTPUT statements.

## **NSR**

specifies that no restrictions are placed on the use of [SMOOTH](#) and [SSPLINE](#) and the ordinary least squares is used to find the coefficients and predicted values. By default, only certain types of models can be specified with [SMOOTH](#) and ordinary least squares is not used to find the coefficients and predicted values. See the section “[Smoothing Splines Changes and Enhancements](#)” on page 8267 for more information about the **NSR** option and smooth transformations.

## **ORDER=DATA | FREQ | FORMATTED | INTERNAL**

### **ORD=DAT | FRE | FOR | INT**

specifies the order in which the [CLASS](#) variable levels are to be reported. The default is **ORDER=INTERNAL**. For **ORDER=FORMATTED** and **ORDER=INTERNAL**, the sort order is machine dependent. When you specify **ORDER=** as an *a-option* or an *o-option*, it determines the default ordering for all [CLASS](#) variables. When you specify **ORDER=** as a *t-option*, it overrides the default ordering only for selected variables.

|                  |                                                                                      |
|------------------|--------------------------------------------------------------------------------------|
| <b>DATA</b>      | sorts by order of appearance in the input data set.                                  |
| <b>FORMATTED</b> | sorts by formatted value.                                                            |
| <b>FREQ</b>      | sorts by descending frequency count; levels with the most observations appear first. |
| <b>INTERNAL</b>  | sorts by unformatted value.                                                          |

## **PBOXCOXTABLE**

**PBO**

prints the Box-Cox table with the log likelihood displayed as a function of lambda. The important information in this table is displayed in the Box-Cox plot, so when ODS Graphics is enabled and the plot is produced, the table is not produced by default. When ODS Graphics is not enabled or when the plot is not produced, the table is produced by default. Specify the PBOXCOXTABLE option if you want to see the table in addition to the plot.

**REFERENCE=NONE | MISSING | ZERO****REF=NON | MIS | ZER**

specifies how reference levels of **CLASS** variables are to be treated. The options are REFERENCE=NONE, the default, in which reference levels are suppressed; REFERENCE=MISSING, in which reference levels are displayed and output with missing values; and REFERENCE=ZERO, in which reference levels are displayed and output with zeros. You can specify the REFERENCE= option in the PROC TRANSREG, MODEL, or OUTPUT statement, and you can specify it independently for the **OUT=** data set and the displayed output. When you specify it in only one statement, it sets the option for both the displayed output and the **OUT=** data set.

**REITERATE****REI**

enables PROC TRANSREG to use previous transformations as starting points. The REITERATE *a-option* affects only variables that are iteratively transformed (specified as **LINEAR**, **OPSCORE**, **MONOTONE**, **UNTIE**, **SPLINE**, **MSPLINE**, and **SSPLINE**). For iterative transformations, the REITERATE *a-option* requests a search in the input data set for a variable that consists of the value of the **TDPREFIX=** or **TIPREFIX=** *o-option* followed by the original variable name. If such a variable is found, it is used to provide the initial values for the first iteration. The final transformation is a member of the transformation family defined by the original variable, not the transformation family defined by the initialization variable. See the section “Using the REITERATE Algorithm Option” on page 8291 for more information about the REITERATE option.

**RSQUARE****RSQ**

prints a table with only the model R square.

**SEPARATORS='string-1' <'string-2'>****SEP='string-1' <'string-2'>**

specifies separators for creating **CLASS** expansion variable labels. By default, SEPARATORS=' ' \* ' (“blank” and “blank asterisk blank”). The first value is used to separate variable names and values in interactions. The second value is used to separate interaction components. For example, the label for the coded variable for the A=1 and B=2 cell is, by default, 'A 1 \* B 2'. If SEPARATORS='=' 'x' is specified, then the label is 'A=1xB=2'. When you specify SEPARATORS= as an *a-option* or an *o-option*, it determines the default separators for all **CLASS** variables. When you specify SEPARATORS= as a *t-option*, it overrides the default only for selected variables.

**SHORT****SHO**

suppresses the iteration histories.

**SINGULAR=*n*****SIN=*n***

specifies the largest value within rounding error of zero. By default, SINGULAR=1E-12. PROC TRANSREG uses the value of the SINGULAR= *a-option* for checking  $1 - R^2$  when constructing full-rank matrices of predictor variables, checking denominators before dividing, and so on. PROC TRANSREG computes the regression coefficients by sweeping with rational pivoting.

**SS2**

produces a regression table based on Type II sums of squares. Tests of the contribution of each transformation to the overall model are displayed and output to the OUTTEST= data set when you specify the OUTTEST= option. When you specify the SS2 *a-option*, the TEST *a-option* is automatically specified for you. See the section “Hypothesis Tests” on page 8303 for more information about the TEST and SS2 options. You can suppress the variable labels in the regression tables by specifying the NOLABEL option in the OPTIONS statement.

**TEST****TES**

generates an ANOVA table. PROC TRANSREG tests the null hypothesis that the vector of scoring coefficients for all of the transformations is zero. See the section “Hypothesis Tests” on page 8303 for more information about the TEST option.

**TSUFFIX=*n*****TSU=*n***

specifies the number of characters in “Transformation” to append to variable labels for transformed variables. By default, all characters are used.

**TSTANDARD=CENTER | NOMISS | ORIGINAL | Z****TST=CEN | NOM | ORI | Z**

specifies the standardization of the transformed variables for the hypothesis tests and in the OUT= data set. By default, TSTANDARD=ORIGINAL. When you specify TSTANDARD= as an *a-option* or an *o-option*, it determines the default standardization for all variables. When you specify TSTANDARD= as a *t-option*, it overrides the default standardization only for selected variables.

**CENTER** centers the output variables to mean zero, but the variances are the same as the variances of the input variables.

**NOMISS** sets the means and variances of the transformed variables in the OUT= data set, computed over all output values that correspond to nonmissing values in the input data set, to the means and variances computed from the nonmissing observations of the original variables. The TSTANDARD=NOMISS specification is useful with missing data. When a variable is linearly transformed, the final variable contains the original nonmissing values and the missing value estimates. In other words, the nonmissing values are unchanged. If your data have no missing values, TSTANDARD=NOMISS and TSTANDARD=ORIGINAL produce the same results.

**ORIGINAL** sets the means and variances of the transformed variables to the means and variances of the original variables. This is the default.

**Z** standardizes the variables to mean zero, variance one.

The final standardization is affected by other options. If you also specify the **ADDITIVE** *a-option*, the **TSTANDARD=** option specifies an intermediate step in computing the final means and variances. The final independent variables, along with their means and standard deviations, are scaled by the regression coefficients, creating an additive model with all coefficients equal to one.

For nonoptimal variable transformations, the means and variances of the original variables are actually the means and variances of the nonlinearly transformed variables, unless you specify the **ORIGINAL** nonoptimal *t-option* in the MODEL statement. For example, if a variable *x* with no missing values is specified as **LOG**, then, by default, the final transformation of *x* is simply the log of *x*, not the log of *x* standardized to the mean of *x* and variance of *x*.

**TYPE=**'text'|name

**TYP=**'text'|name

specifies the valid value for the `_TYPE_` variable in the input data set. If PROC TRANSREG finds an input `_TYPE_` variable, it uses only observations with a `_TYPE_` value that matches the **TYPE=** value. This enables a PROC TRANSREG **OUT=** data set containing coefficients to be used as input to PROC TRANSREG without requiring a WHERE statement to exclude the coefficients. If a `_TYPE_` variable is not in the data set, all observations are used. The default is **TYPE='SCORE'**, so if you do not specify the **TYPE=** *a-option*, only observations with `_TYPE_='SCORE'` are used. Do not confuse this *a-option* with the data set **TYPE=** option. The **DATA=** data set must be an ordinary SAS data set.

PROC TRANSREG displays a note when it reads observations with blank values of `_TYPE_`, but it does not automatically exclude those observations. Data sets created by the TRANSREG and PRINQUAL procedures have blank `_TYPE_` values for those observations that were excluded from the analysis due to nonpositive weights, nonpositive frequencies, or missing data. When these observations are read again, they are excluded for the same reason that they were excluded from their original analysis, not because their `_TYPE_` value is blank.

**UNTIE=**two-letters

**UNT=**two-letters

specifies the first and last special missing values in the list of those special missing values that are to be estimated with within-variable order constraints but no category constraints. The *two-letters* value must consist of two letters in alphabetical order. By default, there are category constraints but no order constraints on special missing value estimates. For details, see the sections “[Missing Values](#)” on page 8289 and “[Optimal Scaling](#)” on page 8298.

## UTILITIES

### UTI

produces a table of the part-worth utilities from a conjoint analysis. Utilities, their standard errors, and the relative importance of each factor are displayed and output to the **OUTTEST=** data set when you specify the **OUTTEST=** option. When you specify the UTILITIES *a-option*, the **TEST** *a-option* is automatically specified for you. See [Example 97.4](#) and [Example 97.5](#) for more information about conjoint analysis.

## OUTPUT Statement

**OUTPUT** **OUT**=SAS-data-set < o-options > ;

The OUTPUT statement creates a new SAS data set that contains coefficients, marginal means, and information about the original and transformed variables. The information about original and transformed variables composes the score partition of the data set; observations have `_TYPE_='SCORE'`. The coefficients and marginal means compose the coefficient partition of the data set; observations have `_TYPE_='M COEFFI'` or `_TYPE_='MEAN'`. Other values of `_TYPE_` are possible; for details, see “`_TYPE_` and `_NAME_` Variables” later in this chapter. For details about data set structure, see the section “Output Data Set” on page 8305. To specify the name of the output data set, use the **OUT=** option.

### **OUT**=SAS-data-set

specifies the output data set for the data, transformed data, predicted values, residuals, scores, coefficients, and so on. When you use an OUTPUT statement but do not use the **OUT=** specification, PROC TRANSREG creates a data set and uses the `DATAn` convention. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

To control the contents of the data set and variable names, use one or more of the *o-options*. You can also specify these options in the PROC TRANSREG statement.

## Output Options (o-options)

Table 97.5 summarizes the options available in the OUTPUT statement. These options include the **OUT=** option and all of the *o-options*. Many of the statistics created in the OUTPUT statement are exactly the same as statistics created by PROC REG. More details are given in the sections “Predicted and Residual Values” on page 6708, “Model Fit and Diagnostic Statistics” on page 6715 in Chapter 79, “The REG Procedure,” and Chapter 4, “Introduction to Regression Procedures.”

**Table 97.5** Options Available in the OUTPUT Statement

| Option                                     | Description                          |
|--------------------------------------------|--------------------------------------|
| <b>Identify output data set</b>            |                                      |
| <b>OUT=</b>                                | Outputs data set                     |
| <b>Predicted Values, Residuals, Scores</b> |                                      |
| <b>CANONICAL</b>                           | Outputs canonical scores             |
| <b>CLI</b>                                 | Outputs individual confidence limits |
| <b>CLM</b>                                 | Outputs mean confidence limits       |
| <b>DESIGN=</b>                             | Specifies design matrix coding       |
| <b>DREPLACE</b>                            | Replaces dependent variables         |
| <b>IREPLACE</b>                            | Replaces independent variables       |
| <b>LEVERAGE</b>                            | Outputs leverage                     |
| <b>NORESTOREMISSING</b>                    | Does not restore missing values      |
| <b>NOSCORES</b>                            | Suppresses output of scores          |
| <b>PREDICTED</b>                           | Outputs predicted values             |
| <b>REDUNDANCY=</b>                         | Outputs redundancy variables         |
| <b>REPLACE</b>                             | Replaces all variables               |
| <b>RESIDUALS</b>                           | Outputs residuals                    |

Table 97.5 *continued*

| Option                                        | Description                                        |
|-----------------------------------------------|----------------------------------------------------|
| <b>Output Data Set Coefficients</b>           |                                                    |
| COEFFICIENTS                                  | Outputs coefficients                               |
| COORDINATES=                                  | Outputs ideal point coordinates                    |
| MEANS                                         | Outputs marginal means                             |
| MREDUNDANCY                                   | Outputs redundancy analysis coefficients           |
| <b>Output Data Set Variable Name Prefixes</b> |                                                    |
| ADPREFIX=                                     | Specifies dependent variable approximations        |
| AIPREFIX=                                     | Specifies independent variable approximations      |
| CDPREFIX=                                     | Specifies canonical dependent variables            |
| CILPREFIX=                                    | Specifies conservative individual lower CL         |
| CIPREFIX=                                     | Specifies canonical independent variables          |
| CIUPREFIX=                                    | Specifies conservative-individual-upper CL         |
| CMLPREFIX=                                    | Specifies conservative-mean-lower CL               |
| CMUPREFIX=                                    | Specifies conservative-mean-upper CL               |
| DEPENDENT=                                    | Specifies METHOD=MORALS untransformed dependent    |
| LILPREFIX=                                    | Specifies liberal-individual-lower CL              |

For the coefficients partition, the **COEFFICIENTS**, **COORDINATES**, and **MEANS** *o-options* provide the coefficients that are appropriate for your model. For more explicit control of the coefficient partition, use the options that control details and prefixes. The following list provides details about these options.

**ADPREFIX=***name***ADP=***name*

specifies a prefix for naming the dependent variable predicted values. The default is ADPREFIX=P when you specify the **PREDICTED** *o-option*; otherwise, it is ADPREFIX=A. When you specify the ADPREFIX= *o-option*, the **PREDICTED** *o-option* is automatically specified for you. The ADPREFIX= *o-option* is the same as the **PPREFIX=** *o-option*.

**AIPREFIX=***name***AIP=***name*

specifies a prefix for naming the independent variable approximations. The default is AIPREFIX=A. When you specify the AIPREFIX= *o-option*, the **IAPPROXIMATIONS** *o-option* is automatically specified for you.

**APPROXIMATIONS****APPROX****APP**

is equivalent to specifying both the **DAPPROXIMATIONS** and the **IAPPROXIMATIONS** *o-options*. If you specify **METHOD=UNIVARIATE**, then the **APPROXIMATIONS** *o-option* specifies only the **DAPPROXIMATIONS** *o-option*.

**CANONICAL****CAN**

outputs canonical variables to the **OUT=** data set. When you specify **METHOD=CANALS**, the **CANONICAL** *o-option* is automatically specified for you. The **CDPREFIX=** *o-option* specifies a prefix for naming the dependent canonical variables (default Cand), and the **CIPREFIX=** *o-option* specifies a prefix for naming the independent canonical variables (default Cani).

**CCC**

outputs canonical correlation coefficients to the **OUT=** data set.

**CDPREFIX=***name***CDP=***name*

provides a prefix for naming the canonical dependent variables. The default is CDPREFIX=Cand. When you specify the CDPREFIX= *o-option*, the **CANONICAL** *o-option* is automatically specified for you.

**CEC**

outputs canonical elliptical point model coordinates to the **OUT=** data set.

**CILPREFIX=***name***CIL=***name*

specifies a prefix for naming the conservative-individual-lower confidence limits. The default prefix is CIL. When you specify the CILPREFIX= *o-option*, the **CLI** *o-option* is automatically specified for you.

**CIPREFIX=***name***CIP=***name*

provides a prefix for naming the canonical independent variables. The default is CIPREFIX=Cani. When you specify the CIPREFIX= *o-option*, the **CANONICAL** *o-option* is automatically specified for you.

**CIUPREFIX=***name***CIU=***name*

specifies a prefix for naming the conservative-individual-upper confidence limits. The default prefix is CIU. When you specify the CIUPREFIX= *o-option*, the **CLI** *o-option* is automatically specified for you.

**CLI**

outputs individual confidence limits to the **OUT=** data set. The names of the confidence limits variables are constructed from the original dependent variable names and the prefixes specified in the following *o-options*: **LILPREFIX=** (default LIL for liberal individual lower), **CILPREFIX=** (default CIL for conservative individual lower), **LIUPREFIX=** (default LIU for liberal individual upper), and **CIUPREFIX=** (default CIU for conservative individual upper). When there are no monotonicity constraints, the liberal and conservative limits are the same.

**CLM**

outputs mean confidence limits to the **OUT=** data set. The names of the confidence limits variables are constructed from the original dependent variable names and the prefixes specified in the following *o-options*: **LMLPREFIX=** (default LML for liberal mean lower), **CMLPREFIX=** (default CML for conservative mean lower), **LMUPREFIX=** (default LMU for liberal mean upper), and **CMUPREFIX=** (default CMU for conservative mean upper). When there are no monotonicity constraints, the liberal and conservative limits are the same.

**CMLPREFIX=***name***CML=***name*

specifies a prefix for naming the conservative-mean-lower confidence limits. The default prefix is CML. When you specify the CMLPREFIX= *o-option*, the **CLM** *o-option* is automatically specified for you.

**CMUPREFIX=***name***CMU=***name*

specifies a prefix for naming the conservative-mean-upper confidence limits. The default prefix is CMU. When you specify the CMUPREFIX= *o-option*, the **CLM** *o-option* is automatically specified for you.

**COEFFICIENTS****COE**

outputs either multiple regression coefficients or raw canonical coefficients to the **OUT=** data set. If you specify **METHOD=CANALS** (in the MODEL or PROC TRANSREG statement), then the **COEFFICIENTS** *o-option* outputs the first *n* canonical variables, where *n* is the value of the **NCAN=** *a-option* (specified in the MODEL or PROC TRANSREG statement). Otherwise, the **COEFFICIENTS** *o-option* includes multiple regression coefficients in the **OUT=** data set. In addition, when you specify the **CLASS** expansion for any independent variable, the **COEFFICIENTS** *o-option* also outputs marginal means.

**COORDINATES**<=*n*>**COO**<=*n*>

outputs either ideal point or vector model coordinates for preference mapping to the **OUT=** data set. When **METHOD=CANALS**, these coordinates are computed from canonical coefficients; otherwise, the coordinates are computed from multiple regression coefficients. For details, see the section “[Point Models](#)” on page 8294.

When ODS Graphics is enabled and vector model coordinates are requested, a plot is produced with points for each row and vectors for each column. If the vectors are plotted based on the actual computed coordinates, then often the vectors are short. A better graphical display is produced when the vectors are stretched. The absolute lengths of each vector can optionally be changed by specifying **COORDINATES=*n***. Then the vector coordinates are all multiplied by *n*. Usually, *n* is a value such as 2, 2.5, or 3. The default is 2.5. Specify **COORDINATES=1** if you want to see the vectors without any stretching. The relative lengths of the different vectors are important and interpretable, and these are preserved by the stretching.

**CPC**

outputs canonical point model coordinates to the **OUT=** data set.

**CQC**

outputs canonical quadratic point model coordinates to the **OUT=** data set.

**DAPPROXIMATIONS****DAP**

outputs the approximations of the transformed dependent variables to the **OUT=** data set. These are the target values for the optimal transformations. With **METHOD=UNIVARIATE** and **METHOD=MORALS**, the dependent variable approximations are the ordinary predicted values from the linear model. The names of the approximation variables are constructed from the **ADPREFIX= *o-option*** (default A) and the original dependent variable names. For ordinary predicted values, use the **PREDICTED *o-option*** instead of the **DAPPROXIMATIONS *o-option***, since the **PREDICTED *o-option*** uses a more relevant prefix (“P” instead of “A”) and a more relevant variable label suffix (“Predicted Values” instead of “Approximations”).

**DESIGN**<=*n*>**DES**<=*n*>

specifies that your primary goal is design matrix coding, not analysis. Specifying the **DESIGN *o-option*** makes the procedure run faster. The **DESIGN *o-option*** sets the default method to **UNIVARIATE** and the default **MAXITER=** value to zero. It suppresses computing the regression coefficients, unless they are needed for some other option. Furthermore, when the **DESIGN *o-option*** is specified, the **MODEL** statement is not required to have an equal sign. When no **MODEL** statement equal sign is specified, all variables are considered independent variables, all options that require dependent variables are ignored, and the **IREPLACE *o-option*** is automatically specified for you.

You can use **DESIGN=*n*** for coding very large data sets, where *n* is the number of observations to code at one time. For example, to code a data set with a large number of observations, you can specify **DESIGN=100** or **DESIGN=1000** to process the data set in blocks of 100 or 1000 observations. If you specify the **DESIGN *o-option*** rather than **DESIGN=*n***, PROC TRANSREG tries to process all observations at once, which might not work with very large data sets. Specify the **NOZEROCONSTANT *a-option*** with **DESIGN=*n*** to ensure that constant variables within blocks are not zeroed. See the sections “[Using the DESIGN Output Option](#)” on page 8331 and “[Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO](#)” on page 8335 for more information about the **DESIGN** option.

**DEPENDENT=***name*

**DEP=***name*

specifies the untransformed dependent variable for **OUT=** data sets with **METHOD=MORALS** when there is more than one dependent variable. The default is **DEPENDENT=\_DEPEND\_**.

**DREPLACE**

**DRE**

replaces the original dependent variables with the transformed dependent variables in the **OUT=** data set. The names of the transformed variables in the **OUT=** data set correspond to the names of the original dependent variables in the input data set. By default, both the original dependent variables and the transformed dependent variables (with names constructed from the **TDPREFIX=** (default T) *o-option* and the original dependent variable names) are included in the **OUT=** data set.

**IAPPROXIMATIONS**

**IAP**

outputs the approximations of the transformed independent variables to the **OUT=** data set. These are the target values for the optimal transformations. The names of the approximation variables are constructed from the **AIPREFIX=** *o-option* (default A) and the original independent variable names. When you specify the **AIPREFIX=** *o-option*, the **IAPPROXIMATIONS** *o-option* is automatically specified for you. The **IAPPROXIMATIONS** *o-option* is not valid when **METHOD=UNIVARIATE**.

**IREPLACE**

**IRE**

replaces the original independent variables with the transformed independent variables in the **OUT=** data set. The names of the transformed variables in the **OUT=** data set correspond to the names of the original independent variables in the input data set. By default, both the original independent variables and the transformed independent variables (with names constructed from the **TIPREFIX=** *o-option* (default T) and the original independent variable names) are included in the **OUT=** data set.

**LEVERAGE<=***name***>**

**LEV<=***name***>**

creates a variable with the specified name in the **OUT=** data set that contains leverages. Specifying the **LEVERAGE** *o-option* is equivalent to specifying **LEVERAGE=Leverage**.

**LILPREFIX=***name*

**LIL=***name*

specifies a prefix for naming the liberal-individual-lower confidence limits. The default prefix is LIL. When you specify the **LILPREFIX=** *o-option*, the **CLI** *o-option* is automatically specified for you.

**LIUPREFIX=***name*

**LIU=***name*

specifies a prefix for naming the liberal-individual-upper confidence limits. The default prefix is LIU. When you specify the **LIUPREFIX=** *o-option*, the **CLI** *o-option* is automatically specified for you.

**LMLPREFIX=***name***LML=***name*

specifies a prefix for naming the liberal-mean-lower confidence limits. The default prefix is LML. When you specify the LMLPREFIX= *o-option*, the **CLM** *o-option* is automatically specified for you.

**LMUPREFIX=***name***LMU=***name*

specifies a prefix for naming the liberal-mean-upper confidence limits. The default prefix is LMU. When you specify the LMUPREFIX= *o-option*, the **CLM** *o-option* is automatically specified for you.

**MACRO**(*keyword=name. . .*)**MAC**(*keyword=name. . .*)

creates macro variables. Most of the options available within the MACRO *o-option* are rarely needed. By default, PROC TRANSREG creates a macro variable named `_TrgInd` with a complete list of independent variables created by the procedure. When PROC TRANSREG is being used for design matrix creation prior to running a procedure without a CLASS statement, this macro provides a convenient way to use the results from PROC TRANSREG. For example, a PROC LOGISTIC step that uses a design matrix coded by PROC TRANSREG can use the following MODEL statement:

```
model y=&_trgind;
```

PROC TRANSREG, also by default, creates a macro variable named `_TrgIndN`, which contains the number of variables in the `_TrgInd` list. These macro variables can be used in an ARRAY statement as follows:

```
array indvars[&_trgindn] &_trgind;
```

See the sections “Using the DESIGN Output Option” on page 8331 and “Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO” on page 8335 for examples of using the default macro variables.

The available *keywords* are as follows.

**DN=***name* specifies the name of a macro variable that contains the number of dependent variables. By default, a macro variable named `_TrgDepN` is created. This is the number of variables in the DL= list and the number of macro variables created by the DV= and DE= specifications.

**IN=***name* specifies the name of a macro variable that contains the number of independent variables. By default, a macro variable named `_TrgIndN` is created. This is the number of variables in the IL= list and the number of macro variables created by the IV= and IE= specifications.

**DL=***name* specifies the name of a macro variable that contains the list of the dependent variables. By default, a macro variable named `_TrgDep` is created. These are the variable names of the final transformed variables in the OUT= data set. For example, if there are three dependent variables, `y1–y3`, then `_TrgDep` contains, by default, `Ty1 Ty2 Ty3` (or `y1 y2 y3` if you specify the REPLACE *o-option*).

**IL=name** specifies the name of a macro variable that contains the list of the independent variables. By default, a macro variable named `_TrgInd` is created. These are the variable names of the final transformed variables in the `OUT=` data set. For example, if there are three independent variables, `x1–x3`, then `_TrgInd` contains, by default, `Tx1 Tx2 Tx3` (or `x1 x2 x3` if you specify the `REPLACE o-option`).

**DV=prefix** specifies a prefix for creating a list of macro variables, each of which contains one dependent variable name. For example, if there are three dependent variables, `y1–y3`, and you specify `macro (dv=Dep)`, then three macro variables, `Dep1`, `Dep2`, and `Dep3`, are created, containing `Ty1`, `Ty2`, and `Ty3`, respectively (or `y1`, `y2`, and `y3` if you specify the `REPLACE o-option`). By default, no list is created.

**IV=prefix** specifies a prefix for creating a list of macro variables, each of which contains one independent variable name. For example, if there are three independent variables, `x1–x3`, and you specify `macro (iv=Ind)`, then three macro variables, `Ind1`, `Ind2`, and `Ind3`, are created, containing `Tx1`, `Tx2`, and `TX3`, respectively (or `x1`, `x2`, and `x3` if you specify the `REPLACE o-option`). By default, no list is created.

**DE=prefix** specifies a prefix for creating a list of macro variables, each of which contains one dependent variable effect. This list shows the origin of each model term. Each effect consists of two or more parts, and each part consists of a value in 32 columns followed by a blank. For example, if you specify `macro (de=d)`, then a macro variable `d1` is created for `identity(y)`. The `d1` macro variable is shown next, wrapped onto two lines:

```

4 TY
IDENTITY Y

```

The first part is the number of parts (4), the second part is the transformed variable name, the third part is the transformation, and the last part is the input variable name. By default, no list is created.

**IE=prefix** specifies a prefix for creating a list of macro variables, each of which contains one independent variable effect. This list shows the origin of each model term. Each effect consists of two or more parts, and each part consists of a value in 32 columns followed by a blank. For example, if you specify `macro (ie=I)`, then three macro variables, `I1`, `I2`, and `I3`, are created for `class(x1 | x2)` when both `x1` and `x2` have values of 1 and 2. These macro variables are shown next, with extra white space removed:

```

5 Tx11 CLASS x1 1
5 Tx21 CLASS x2 1
8 Tx11x21 CLASS x1 1 CLASS x2 1

```

For `CLASS` variables, the formatted level appears after the variable name. The first two effects are the main effects, and the last is the interaction term. By default, no list is created.

**MEANS****MEA**

outputs marginal means for **CLASS** variable expansions to the **OUT=** data set.

**MEC**

outputs multiple regression elliptical point model coordinates to the **OUT=** data set.

**MPC**

outputs multiple regression point model coordinates to the **OUT=** data set.

**MQC**

outputs multiple regression quadratic point model coordinates to the **OUT=** data set.

**MRC**

outputs multiple regression coefficients to the **OUT=** data set.

**MREDUNDANCY****MRE**

outputs multiple redundancy analysis coefficients to the **OUT=** data set.

**NORESTOREMISSING****NORESTORE****NOR**

specifies that missing values should not be restored when the **OUT=** data set is created. By default, the coded **CLASS** variable contains a row of missing values for observations in which the **CLASS** variable is missing. When you specify the **NORESTOREMISSING** *o-option*, these observations contain a row of zeros instead. This is useful when PROC TRANSREG is used to code experimental designs for discrete choice models and there is a constant alternative indicated by a missing value.

**NOSCORES****NOS**

excludes original variables, transformed variables, predicted values, residuals, and scores from the **OUT=** data set. You can use the **NOSCORES** *o-option* with various other options to create an **OUT=** data set that contains only a coefficient partition (for example, a data set consisting entirely of coefficients and coordinates).

**PREDICTED****PRE****P**

outputs predicted values, which for **METHOD=UNIVARIATE** and **METHOD=MORALS** are the ordinary predicted values from the linear model, to the **OUT=** data set. The names of the predicted values' variables are constructed from the **PPREFIX=** *o-option* (default **P**) and the original dependent variable names. When you specify the **PPREFIX=** *o-option*, the **PREDICTED** *o-option* is automatically specified for you.

**PPREFIX=name**

**PDPREFIX=name**

**PDP=name**

specifies a prefix for naming the dependent variable predicted values. The default is **PPREFIX=P** when you specify the **PREDICTED** *o-option*; otherwise, it is **PPREFIX=A**. When you specify the **PPREFIX=** *o-option*, the **PREDICTED** *o-option* is automatically specified for you. The **PPREFIX=** *o-option* is the same as the **ADPREFIX=** *o-option*.

**RDPREFIX=***name*

**RDP=***name*

specifies a prefix for naming the residual (dependent) variables to the **OUT=** data set. The default is **RDPREFIX=R**. When you specify the **RDPREFIX=** *o-option*, the **RESIDUALS** *o-option* is automatically specified for you.

**REDUNDANCY**< **=STANDARDIZE** | **UNSTANDARDIZE** >

**RED**< **=STA** | **UNS** >

outputs redundancy variables to the **OUT=** data set, either standardized or unstandardized. Specifying the **REDUNDANCY** *o-option* is the same as specifying **REDUNDANCY=STANDARDIZE**. The results of the **REDUNDANCY** *o-option* depends on the **TSTANDARD=** option. You must specify **TSTANDARD=Z** to get results based on standardized data. The **TSTANDARD=** option controls how the data that go into the redundancy analysis are scaled, and **REDUNDANCY=STANDARDIZE|UNSTANDARDIZE** controls how the redundancy variables are scaled. The **REDUNDANCY** *o-option* is automatically specified for you when you specify the **METHOD=REDUNDANCY** *a-option*. The **RPREFIX=** *o-option* specifies a prefix (default Red) for naming the redundancy variables.

**REFERENCE=NONE** | **MISSING** | **ZERO**

**REF=NON** | **MIS** | **ZER**

specifies how reference levels of **CLASS** variables are to be treated. The options are **REFERENCE=NONE**, the default, in which reference levels are suppressed; **REFERENCE=MISSING**, in which reference levels are displayed and output with missing values; and **REFERENCE=ZERO**, in which reference levels are displayed and output with zeros. You can specify the **REFERENCE=** option in the **PROC TRANSREG**, **MODEL**, or **OUTPUT** statement, and you can specify it independently for the **OUT=** data set and the displayed output. When you specify it in only one statement, it sets the option for both the displayed output and the **OUT=** data set.

**REPLACE**

**REP**

is equivalent to specifying both the **DREPLACE** and the **IREPLACE** *o-options*.

**RESIDUALS**

**RES**

**R**

outputs the differences between the transformed dependent variables and their predicted values. The names of the residual variables are constructed from the **RDPREFIX=** *o-option* (default R) and the original dependent variable names.

**RPREFIX=***name*

**RPR=***name*

provides a prefix for naming the redundancy variables. The default is **RPREFIX=Red**. When you specify the **RPREFIX=** *o-option*, the **REDUNDANCY** *o-option* is automatically specified for you.

**TDPREFIX=***name*

**TDP=***name*

specifies a prefix for naming the transformed dependent variables. By default, **TDPREFIX=T**. The **TDPREFIX=** *o-option* is ignored when you specify the **DREPLACE** *o-option*.

**TIPREFIX**=*name*

**TIP**=*name*

specifies a prefix for naming the transformed independent variables. By default, TIPREFIX=T. The TIPREFIX= *o-option* is ignored when you specify the IREPLACE *o-option*.

## WEIGHT Statement

**WEIGHT** *variable* ;

When you use a WEIGHT statement, a weighted residual sum of squares is minimized. The WEIGHT statement has no effect on degrees of freedom or number of observations, but the weights affect most other calculations. The observation is used in the analysis only if the value of the WEIGHT statement variable is greater than 0.

## Details: TRANSREG Procedure

### Model Statement Usage

```
MODEL < transform(dependents </ t-options>)>
 < transform(dependents </ t-options>)...=>
 transform(independents </ t-options>)
 < transform(independents </ t-options>)... > </ a-options> ;
```

Here are some examples of model statements:

- linear regression

```
model identity(y) = identity(x);
```

- a linear model with a nonlinear regression function

```
model identity(y) = spline(x / nknots=5);
```

- multiple regression

```
model identity(y) = identity(x1-x5);
```

- multiple regression with nonlinear transformations

```
model spline(y / nknots=3) = spline(x1-x5 / nknots=3);
```

- multiple regression with nonlinear but monotone transformations

```
model mspline(y / nknots=3) = mspline(x1-x5 / nknots=3);
```

- multivariate multiple regression

```
model identity(y1-y4) = identity(x1-x5);
```

- canonical correlation

```
model identity(y1-y4) = identity(x1-x5) / method=canals;
```

- redundancy analysis

```
model identity(y1-y4) = identity(x1-x5) / method=redundancy;
```

- preference mapping, vector model (Carroll 1972)

```
model identity(Attrib1-Attrib3) = identity(Dim1-Dim2);
```

- preference mapping, ideal point model (Carroll 1972)

```
model identity(Attrib1-Attrib3) = point(Dim1-Dim2);
```

- preference mapping, ideal point model, elliptical (Carroll 1972)

```
model identity(Attrib1-Attrib3) = epoint(Dim1-Dim2);
```

- preference mapping, ideal point model, quadratic (Carroll 1972)

```
model identity(Attrib1-Attrib3) = qpoint(Dim1-Dim2);
```

- metric conjoint analysis

```
model identity(Subj1-Subj50) = class(a b c d e f / zero=sum);
```

- nonmetric conjoint analysis

```
model monotone(Subj1-Subj50) = class(a b c d e f / zero=sum);
```

- main effects, two-way interaction

```
model identity(y) = class(a|b);
```

- less-than-full-rank model—main effects and two-way interaction are constrained to sum to zero

```
model identity(y) = class(a|b / zero=sum);
```

- main effects and all two-way interactions

```
model identity(y) = class(a|b|c@2);
```

- main effects and all two- and three-way interactions

```
model identity(y) = class(a|b|c);
```

- main effects and only the b\*c two-way interaction

```
model identity(y) = class(a b c b*c);
```

- seven main effects, three two-way interactions

```
model identity(y) = class(a b c d e f g a*b a*c a*d);
```

- deviations-from-means (effects or (1, 0, -1)) coding, with an a reference level of '1' and a b reference level of '2'

```
model identity(y) = class(a|b / deviations zero='1' '2');

---

## Box-Cox Transformations

Box-Cox (1964) transformations are used to find potentially nonlinear transformations of a dependent variable. The Box-Cox transformation has the form

$$\begin{array}{ll} (y^\lambda - 1)/\lambda & \lambda \neq 0 \\ \log(y) & \lambda = 0 \end{array}$$

This family of transformations of the positive dependent variable  $y$  is controlled by the parameter  $\lambda$ . Transformations linearly related to square root, inverse, quadratic, cubic, and so on are all special cases. The limit

as  $\lambda$  approaches 0 is the log transformation. More generally, Box-Cox transformations of the following form can be fit:

$$\begin{aligned} ((y + c)^\lambda - 1)/(\lambda g) & \quad \lambda \neq 0 \\ \log(y + c)/g & \quad \lambda = 0 \end{aligned}$$

By default,  $c = 0$ . The parameter  $c$  can be used to rescale  $y$  so that it is strictly positive. By default,  $g = 1$ . Alternatively,  $g$  can be  $\bar{y}^{\lambda-1}$ , where  $\bar{y}$  is the geometric mean of  $y$ .

The **BOXCOX** transformation in PROC TRANSREG can be used to perform a Box-Cox transformation of the dependent variable. You can specify a list of power parameters by using the **LAMBDA=** *t-option*. By default, **LAMBDA=** -3 TO 3 BY 0.25. The procedure chooses the optimal power parameter by using a maximum likelihood criterion (Draper and Smith 1981, pp. 225–226). You can specify the **PARAMETER=**  $c$  transformation option when you want to shift the values of  $y$ , usually to avoid negatives. To divide by  $\bar{y}^{\lambda-1}$ , specify the **GEOMETRICMEAN** *t-option*.

Here are three examples of using the **LAMBDA=** *t-option*:

```
model BoxCox(y / lambda=0) = identity(x1-x5);
model BoxCox(y / lambda=-2 to 2 by 0.1) = identity(x1-x5);
model BoxCox(y) = identity(x1-x5);
```

Here is the first example:

```
model BoxCox(y / lambda=0) = identity(x1-x5);
```

**LAMBDA=0** specifies a Box-Cox transformation with a power parameter of 0. Since a single value of 0 was specified for **LAMBDA=**, there is no difference between the following models:

```
model BoxCox(y / lambda=0) = identity(x1-x5);
model log(y) = identity(x1-x5);
```

Here is the second example:

```
model BoxCox(y / lambda=-2 to 2 by 0.1) = identity(x1-x5);
```

**LAMBDA=** specifies a list of power parameters. PROC TRANSREG tries each power parameter in the list and picks the best transformation. A maximum likelihood approach (Draper and Smith 1981, pp. 225–226) is used. With Box-Cox transformations, PROC TRANSREG finds the transformation before the usual iterations begin. Note that this is quite different from PROC TRANSREG's usual approach of iteratively finding optimal transformations with ordinary and alternating least squares. It is analogous to **SMOOTH** and **PBSPLINE**, which also find transformations before the iterations begin based on a criterion other than least squares.

Here is the third example:

```
model BoxCox(y) = identity(x1-x5);
```

The default **LAMBDA=** list of -3 TO 3 BY 0.25 is used.

The procedure prints the optimal power parameter, a confidence interval on the power parameter (based on the **ALPHA=** *t-option*), a “convenient” power parameter (selected from the **CLL=** *t-option* list), and the log likelihood for each power parameter tried (see [Example 97.2](#)).

To illustrate how Box-Cox transformations work, data were generated from the model

$$y = e^{x+\epsilon}$$

where  $\epsilon \sim N(0, 1)$ . The transformed data can be fit with a linear model

$$\log(y) = x + \epsilon$$

The following statements produce [Figure 97.14](#) through [Figure 97.15](#):

```
title 'Basic Box-Cox Example';

data x;
 do x = 1 to 8 by 0.025;
 y = exp(x + normal(7));
 output;
 end;
run;

ods graphics on;

title2 'Default Options';

proc transreg data=x test;
 model BoxCox(y) = identity(x);
run;
```

Figure 97.14 Basic Box-Cox Example, Default Output

Figure 97.14 shows that PROC TRANSREG correctly selects the log transformation  $\lambda = 0$ , with a narrow confidence interval. The  $F = t^2$  plot shows that  $F$  is at its largest in the vicinity of the optimal Box-Cox transformation.

The rest of the output, which contains the ANOVA results, is shown in Figure 97.15.

|                                                                                                                              | Root MSE       | 1.04285        | R-Square    | 0.7906  |           |
|                                                                                                                              | Dependent Mean | 4.49653        | Adj R-Sq    | 0.7899  |           |
|                                                                                                                              | Coeff Var      | 23.19225       | Lambda      | 0.0000  |           |

This next example uses several options. The `LAMBDA=` *t-option* specifies power parameters sparsely from  $-2$  to  $-0.5$  and  $0.5$  to  $2$  just to get the general shape of the log-likelihood function in that region. Between  $-0.5$  and  $0.5$ , more power parameters are tried. The `CONVENIENT` *t-option* is specified so that if a power parameter like  $\lambda = 1$  or  $\lambda = 0$  is found in the confidence interval, it is used instead of the optimal power parameter. `PARAMETER=2` is specified to add 2 to each  $y$  before performing the transformations. `ALPHA=0.00001` specifies a wide confidence interval.

These next statements perform the Box-Cox analysis and produce Figure 97.16 and Figure 97.17:

```

title2 'Several Options Demonstrated';

proc transreg data=x ss2 details
 plots=(transformation(dependent) scatter
 observedbypredicted);
 model BoxCox(y / lambda=-2 -1 -0.5 to 0.5 by 0.05 1 2
 convenient parameter=2 alpha=0.00001) =
 identity(x);
run;

```

**Figure 97.16** Basic Box-Cox Example, Several Options Demonstrated

The results in [Figure 97.16](#) and [Figure 97.17](#) show that the optimal power parameter is  $-0.1$ , but  $0$  is in the confidence interval, and hence a log transformation is chosen. The actual Box-Cox transformation, the original scatter plot, and observed by predicted values plot are shown in [Figure 97.17](#).

The above statistics are not adjusted for the fact that the dependent variable was transformed and so are generally liberal.

Figure 97.17 continued

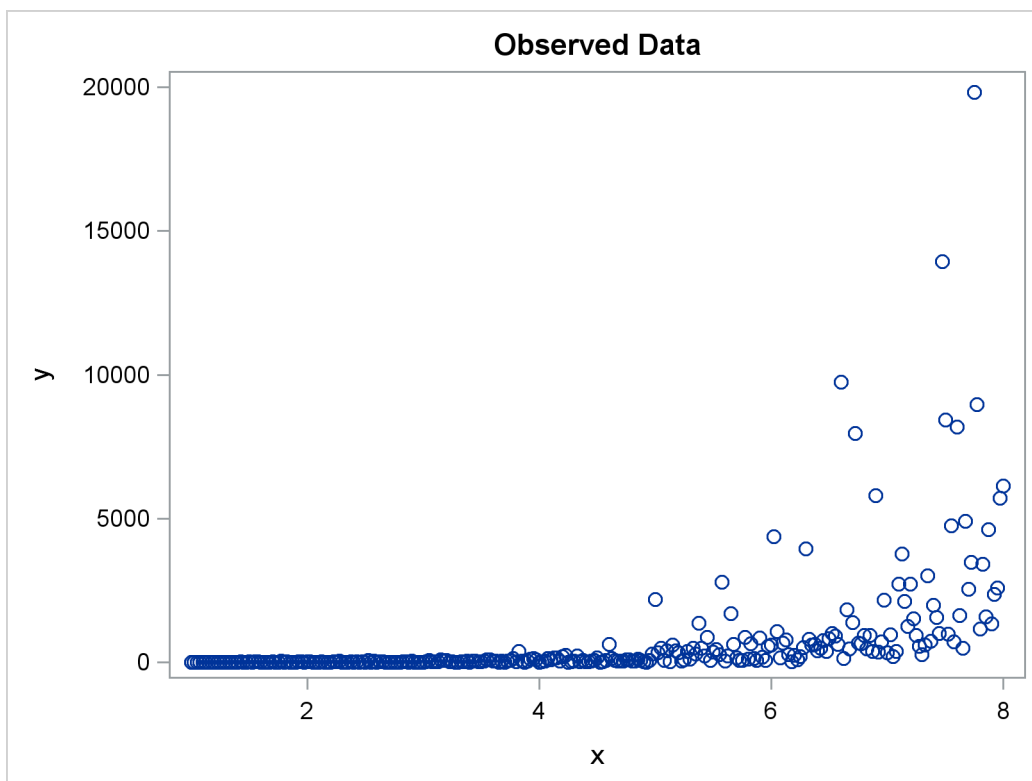

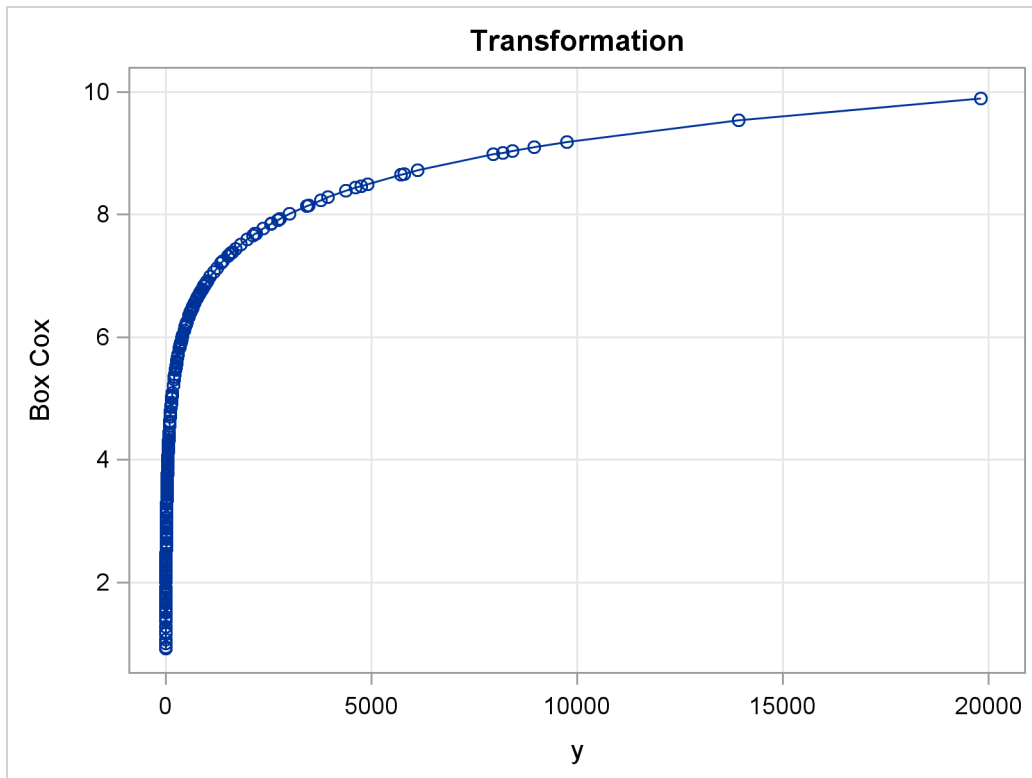

Figure 97.17 continued

The next example shows how to find a Box-Cox transformation without an independent variable. This seeks to normalize the univariate histogram. This example generates 500 random observations from a lognormal distribution. In addition, a constant variable  $z$  is created that is all zero. This is because PROC TRANSREG requires some independent variable to be specified, even if it is constant. Two options are specified in the PROC TRANSREG statement. `MAXITER=0` is specified because the Box-Cox transformation is performed before any iterations are begun. No iterations are needed since no other work is required. The `NOZERO-CONSTANT` *a-option* (which can be abbreviated `NOZ`) is specified so that PROC TRANSREG does not print any warnings when it encounters the constant independent variable. The MODEL statement asks for a Box-Cox transformation of  $y$  and an IDENTITY transformation (which does nothing) of the constant variable  $z$ . Finally, PROC UNIVARIATE is run to show a histogram of the original variable  $y$ , and the Box-Cox transformation,  $T_y$ . The following statements fit the univariate Box-Cox model and produce Figure 97.18:

```

title 'Univariate Box-Cox';

data x;
 call streaminit(17);
 z = 0;
 do i = 1 to 500;
 y = rand('lognormal');
 output;
 end;
run;

proc transreg maxiter=0 nozeroconstant;
 model BoxCox(y) = identity(z);
 output;
run;

proc univariate noprint;
 histogram y ty;
run;

```

The PROC TRANSREG results in Figure 97.18 show that zero is chosen for lambda, so a log transformation is chosen. The first histogram shows that the original data are skewed, but a log transformation makes the data appear much more nearly normal.

**Figure 97.18** Box-Cox with No Independent Variable

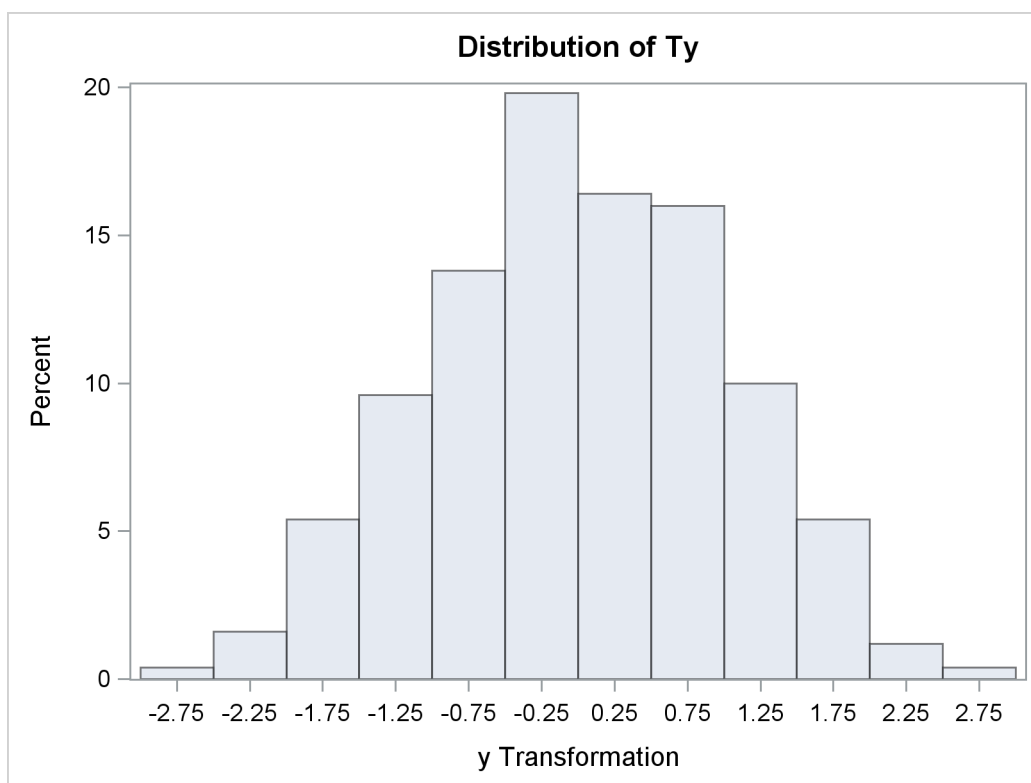

Figure 97.18 continued

## Using Splines and Knots

This section illustrates some properties of splines. *Splines* are curves, and they are usually required to be continuous and smooth. Splines are usually defined as piecewise polynomials of degree  $n$  with function values and first  $n - 1$  derivatives that agree at the points where they join. The abscissa or X-axis values of the join points are called *knots*. The term “spline” is also used for polynomials (splines with no knots) and piecewise polynomials with more than one discontinuous derivative. Splines with no knots are generally smoother than splines with knots, which are generally smoother than splines with multiple discontinuous derivatives. Splines with few knots are generally smoother than splines with many knots; however, increasing the number of knots usually increases the fit of the spline function to the data. Knots give the curve freedom to bend to more closely follow the data. See Smith (1979) for an excellent introduction to splines.

In this section, an artificial data set is created with a variable  $y$  that is a discontinuous function of  $x$ . (See Figure 97.20.) Notice that the function has four unconnected parts, each of which is a curve. Notice too that there is an overall quadratic trend—that is, ignoring the shapes of the individual curves, at first the  $y$  values tend to decrease as  $x$  increases, then  $y$  values tend to increase. While these artificial data are clearly not realistic, their distinct pattern helps illustrate how splines work. The following statements create the data set, fit a simple linear regression model, and produce Figure 97.19 through Figure 97.20:

```

title 'An Illustration of Splines and Knots';

* Create in y a discontinuous function of x.;

data a;
 x = -0.000001;
 do i = 0 to 199;
 if mod(i, 50) = 0 then do;
 c = ((x / 2) - 5)**2;
 if i = 150 then c = c + 5;
 y = c;
 end;
 x = x + 0.1;
 y = y - sin(x - c);
 output;
 end;
run;

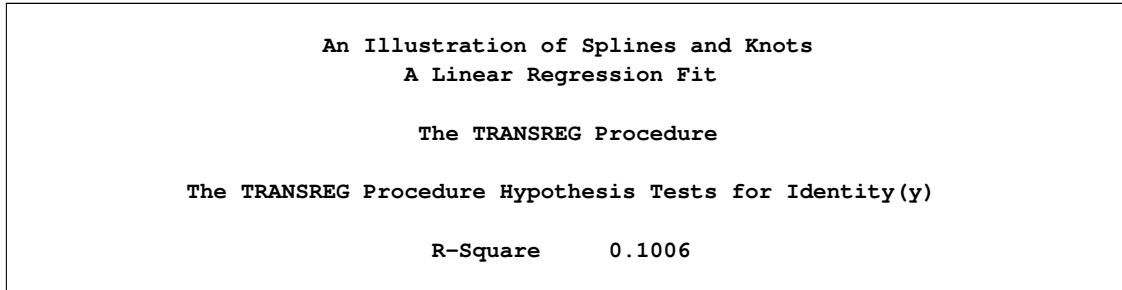

ods graphics on;

title2 'A Linear Regression Fit';
proc transreg data=a plots=scatter rsquare;
 model identity(y) = identity(x);
run;

```

The R square for the linear regression is 0.1006. The linear fit results in Figure 97.19 show the predicted values of y given x. It can clearly be seen in Figure 97.19 that the linear regression model is not appropriate for these data.

**Figure 97.19** A Linear Regression Fit

**Figure 97.19** continued

**Figure 97.20** The Original Scatter Plot

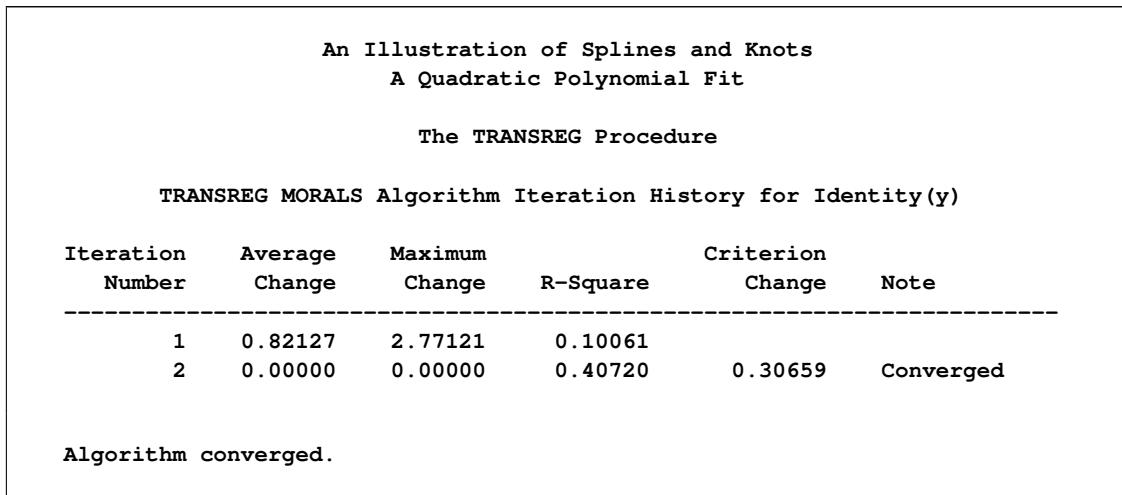

The next PROC TRANSREG step finds a degree-two spline transformation with no knots, which is a quadratic polynomial. The spline is a weighted sum of a single constant, a single straight line, and a single quadratic curve. The following statements perform the quadratic analysis and produce Figure 97.21:

```
title2 'A Quadratic Polynomial Fit';

proc transreg data=A;
 model identity(y)=spline(x / degree=2);
run;
```

The R square in Figure 97.21 increases from 0.10061, which is the linear fit value from before, to 0.40720. The plot shows that the quadratic regression function does not fit any of the individual curves well, but it does follow the overall trend in the data. Since the overall trend is quadratic, if you were to fit a degree-three spline with no knots (not shown) would increase R square by only a small amount.

**Figure 97.21** A Quadratic Polynomial Fit

**Figure 97.21** continued

The next step uses the default degree of three, for a piecewise cubic polynomial, and requests knots at the known break points,  $x=5$ , 10, and 15. This requests a spline that is continuous, has continuous first and second derivatives, and has a third derivative that is discontinuous at 5, 10, and 15. The spline is a weighted sum of a single constant, a single straight line, a single quadratic curve, a cubic curve for the portion of  $x$  less than 5, a different cubic curve for the portion of  $x$  between 5 and 10, a different cubic curve for the portion of  $x$  between 10 and 15, and another cubic curve for the portion of  $x$  greater than 15. The following statements fit the spline model and produce [Figure 97.22](#):

```
title2 'A Cubic Spline Fit with Knots at X=5, 10, 15';

proc transreg data=a;
 model identity(y) = spline(x / knots=5 10 15);
run;
```

The new R square in [Figure 97.22](#) is 0.61730. The plot shows that the spline is less smooth than the quadratic polynomial and follows the data more closely than the quadratic polynomial.

Figure 97.22 continued

The same model could be fit with a DATA step and PROC REG, as follows:

```

data b; /* A is the data set used by transreg */
 set a(keep=x y);
 x1=x; /* x */
 x2=x**2; /* x squared */
 x3=x**3; /* x cubed */
 x4=(x> 5)*((x-5)**3); /* change in x**3 after 5 */
 x5=(x>10)*((x-10)**3); /* change in x**3 after 10 */
 x6=(x>15)*((x-15)**3); /* change in x**3 after 15 */
run;

proc reg;
 model y=x1-x6;
run; quit;

```

The output from these previous statements is not displayed. The assignment statements and comments show how you can construct terms that can be used to fit the same model.

In the next step, each knot is repeated three times, so the first, second, and third derivatives are discontinuous at  $x=5$ , 10, and 15, but the spline is continuous at the knots. The spline is a weighted sum of the following:

- a single constant
- a line for the portion of  $x$  less than 5
- a quadratic curve for the portion of  $x$  less than 5
- a cubic curve for the portion of  $x$  less than 5
- a different line for the portion of  $x$  between 5 and 10
- a different quadratic curve for the portion of  $x$  between 5 and 10
- a different cubic curve for the portion of  $x$  between 5 and 10
- a different line for the portion of  $x$  between 10 and 15
- a different quadratic curve for the portion of  $x$  between 10 and 15
- a different cubic curve for the portion of  $x$  between 10 and 15
- another line for the portion of  $x$  greater than 15
- another quadratic curve for the portion of  $x$  greater than 15
- another cubic curve for the portion of  $x$  greater than 15

The spline is continuous since there is not a separate constant or separate intercept in the formula for the spline for each knot. The following statements perform this analysis and produce [Figure 97.23](#):

```
title3 'First - Third Derivatives Discontinuous at X=5, 10, 15';

proc transreg data=a;
 model identity(y) = spline(x / knots=5 5 5 10 10 10 15 15 15);
run;
```

Now the R square in [Figure 97.23](#) is 0.95542, and the spline closely follows the data, except at the knots.

Figure 97.23 continued

The same model could be fit with a DATA step and PROC REG, as follows:

```

data b;
 set a(keep=x y);
 x1=x; /* x */
 x2=x**2; /* x squared */
 x3=x**3; /* x cubed */
 x4=(x>5) * (x-5); /* change in x after 5 */
 x5=(x>10) * (x-10); /* change in x after 10 */
 x6=(x>15) * (x-15); /* change in x after 15 */
 x7=(x>5) * ((x-5)**2); /* change in x**2 after 5 */
 x8=(x>10) * ((x-10)**2); /* change in x**2 after 10 */
 x9=(x>15) * ((x-15)**2); /* change in x**2 after 15 */
 x10=(x>5) * ((x-5)**3); /* change in x**3 after 5 */
 x11=(x>10) * ((x-10)**3); /* change in x**3 after 10 */
 x12=(x>15) * ((x-15)**3); /* change in x**3 after 15 */
run;

proc reg;
 model y=x1-x12;
run; quit;

```

The output from these previous statements is not displayed. The assignment statements and comments show how you can construct terms that can be used to fit the same model.

Each knot is repeated four times in the next step. Now the spline function is discontinuous at the knots, and it can follow the data more closely. The following statements perform this analysis and produce [Figure 97.24](#):

```

title3 'Discontinuous Function and Derivatives';

proc transreg data=a;
 model identity(y) = spline(x / knots=5 5 5 5 10 10 10 10
 15 15 15 15);
run;

```

Now the R square in [Figure 97.24](#) is 0.99254. In this step, each separate curve is approximated by a cubic polynomial (with no knots within the separate polynomials). (Note, however, that the separate functions are connected in the plot, because PROC TRANSREG cannot currently produce separate functions for a model like this. Usually, you would use a CLASS variable to get separate functions.)

| Iteration<br>Number                                                                                                            | Average<br>Change | Maximum<br>Change | R-Square | Criterion<br>Change | Note      |
| 1                                                                                                                              | 0.90271           | 3.29184           | 0.10061  |                     |           |
| 2                                                                                                                              | 0.00000           | 0.00000           | 0.99254  | 0.89193             | Converged |

Algorithm converged.

Figure 97.24 continued

To solve this problem with a DATA step and PROC REG, you would need to create all of the variables in the preceding DATA step (the B data set for the piecewise polynomial with discontinuous third derivatives), plus the following three variables:

```
x13=(x > 5); /* intercept change after 5 */
x14=(x > 10); /* intercept change after 10 */
x15=(x > 15); /* intercept change after 15 */
```

The next two examples use the `NKNOTS=` *t-option* to specify the number of knots but not their location. `NKNOTS=4` places knots at the quintiles, whereas `NKNOTS=9` places knots at the deciles. The spline and its first two derivatives are continuous. The following statements produce [Figure 97.25](#) and [Figure 97.26](#):

```
title3 'Four Knots';

proc transreg data=a;
 model identity(y) = spline(x / nknots=4);
run;

title3 'Nine Knots';

proc transreg data=a;
 model identity(y) = spline(x / nknots=9);
run;
```

The R-square values displayed in [Figure 97.25](#) and [Figure 97.26](#) are 0.74450 and 0.95256, respectively. Even though the knots are not optimally placed, the spline can closely follow the data with `NKNOTS=9`.

Figure 97.26 continued

## Scoring Spline Variables

This section shows you how to find spline transformations of variables in one data set and apply the same transformations to variables in another data set. This is illustrated with artificial data. In these data sets, the variable  $y$  is approximately a linear function of nonlinear transformations of the variables  $x$ ,  $w$ , and  $z$ . The model is fit using data set  $X$ , and those results are used to score data set  $Z$ . The following statements create the two data sets:

```

title 'An Illustration of Splines and Knots';
title2 'Scoring Spline Variables';

data x;
 do i = 1 to 5000;
 w = normal(7);
 x = normal(7);
 z = normal(7);
 y = w * w + log(5 + x) + sin(z) + normal(7);
 output;
 end;
run;

```

```

data z;
 do i = 1 to 5000;
 w = normal(1);
 x = normal(1);
 z = normal(1);
 y = w * w + log(5 + x) + sin(z) + normal(1);
 output;
 end;
run;

```

First, you run PROC TRANSREG to fit the transformation regression model asking for spline transformations of the three independent variables. You must use the `EXKNOTS= t-option`, because you need to use the same knots, both interior and exterior, with both data sets. By default, the exterior knots will be different if the minima and maxima are different in the two data sets, so you get the wrong results if you do not specify the `EXKNOTS= t-option` with values less than the minima and greater than the maxima of the six `x`, `y`, and `w` variables. If the ranges in all three pairs were different, you would need separate spline transformation for each variable with different knot and exterior knot specifications. The following statements fit the spline model:

```

proc transreg data=x solve details ss2;
 ods output splinecoef=c;
 model identity(y) = spline(w x z / knots=-1.5 to 1.5 by 0.5
 exknots=-5 5);
 output out=d;
run;

```

The results of this step are not displayed. The nonprinting “SplineCoef” table is output to a SAS data set. This data set contains the coefficients that were used to get the spline transformations and can be used to transform variables in other data sets. These coefficients are also in the details table. However, in the “SplineCoef” table, they are in a form directly suitable for use with PROC SCORE.

The next step reads the second input data set, `Z`, and generates an output data set with the B-spline basis for each of the variables:

```

proc transreg data=z design;
 model bspl(w x z / knots=-1.5 to 1.5 by 0.5 exknots=-5 5);
 output out=b;
run;

```

Note that the same interior and exterior knots are used in both of the previous steps. The next three steps score the B-spline bases created in the previous step by using the coefficients generated in the first PROC TRANSREG step. PROC SCORE is run once for each `SPLINE` variable in the statements that follow:

```

proc score data=b score=c out=o1(rename=(spline=bw w=nw));
 var w;;
run;

proc score data=b score=c out=o2(rename=(spline=bx x=nx));
 var x;;
run;

proc score data=b score=c out=o3(rename=(spline=bz z=nz));
 var z;;
run;

```

The following steps merge the three transformations with the original data and plot the results:

```

data all;
 merge d(keep=w x z tw tx tz) o1(keep=nw bw)
 o2(keep=nx bx) o3(keep=nz bz);
run;

proc template;
 define statgraph twobytwo;
 begingraph;
 layout lattice / rows=2 columns=2;
 layout overlay;
 seriesplot y=tw x=w / connectorder=xaxis;
 seriesplot y=bw x=nw / connectorder=xaxis;
 endlayout;
 layout overlay;
 seriesplot y=tx x=x / connectorder=xaxis;
 seriesplot y=bx x=nx / connectorder=xaxis;
 endlayout;
 layout overlay;
 seriesplot y=tz x=z / connectorder=xaxis;
 seriesplot y=bz x=nz / connectorder=xaxis;
 endlayout;
 endlayout;
 endgraph;
 end;
run;

proc sgrender data=all template=twobytwo;
run;

```

The plots in [Figure 97.27](#) show that the two transformations for each variable, original and scored, are the same function. The two functions in each plot are on top of each other and are indistinguishable. Furthermore, PROC TRANSREG found the functional forms that were used to generate the data: quadratic for w, log for x, and sine for z.

Figure 97.27 Scoring Spline Variables Example

The next statements show how to run PROC TRANSREG, output the interior and exterior knots to an output data set with ODS, extract the knots, and use them in a DATA step to re-create the B-spline basis that PROC TRANSREG makes. In practice, you would never need to use a DATA step to make the B-spline basis since PROC TRANSREG does it automatically. The following statements show how you could do it yourself:

```
data x;
 input x @@;
 datalines;
1 2 3 4 5 6 7 8 9 10
;

ods output details=d;
proc transreg details design;
 model bspline(x / nkn=3);
 output out=y;
run;
```

```

%let k = 0;
data d;
 set d;
 length d $ 20;
 retain d ' ';
 if description ne ' ' then d = description;
 if d = 'Degree' then call symput('d', compress(formattedvalue));
 if d = 'Number of Knots'
 then call symput('k', compress(formattedvalue));
 if index(d, 'Knots') and not index(d, 'Number');
 keep d numericvalue;
run;

%let nkn = %eval(&d * 2 + &k); /* total number of knots */
%let nb = %eval(&d + 1 + &k); /* number of cols in basis */

proc transpose data=d out=k(drop=_name_) prefix=Knot;
run;

proc print; format k: 20.16;
run;

data b(keep=x:);
 if _n_ = 1 then set k; /* read knots from transreg */
 array k[&nkn] knot1-knot&nkn; /* knots */
 array b[&nb] x_0 - x_%eval(&nb - 1); /* basis */
 array w[%eval(2 * &d)]; /* work */
 set x;
 do i = 1 to &nb; b[i] = 0; end;

 * find the index of first knot greater than current data value;
 do ki = 1 to &nkn while(k[ki] le x); end;
 kki = ki - &d - 1;

 * make the basis;
 b[1 + kki] = 1;
 do j = 1 to &d;
 w[&d + j] = k[ki + j - 1] - x;
 w[j] = x - k[ki - j];
 s = 0;
 do i = 1 to j;
 t = w[&d + i] + w[j + 1 - i];
 if t ne 0.0 then t = b[i + kki] / t;
 b[i + kki] = s + w[&d + i] * t;
 s = w[j + 1 - i] * t;
 end;
 b[j + 1 + kki] = s;
 end;
run;

proc compare data=y(keep=x:) compare=b
 criterion=1e-12 note nosummary;
 title3 "should be no differences";
run;

```

The output from these steps is not shown. There are several things to note about the DATA step. It produces the same basis as PROC TRANSREG only because it uses exactly the same interior and exterior knots. The exterior knots (0.999999999999 and 10.000000000001) are just slightly smaller than 1 (the minimum in  $x$ ) and just slightly greater than 10 (the maximum in  $x$ ). Both exterior knots appear in the list three times, because a cubic (degree 3) polynomial was requested. The complete knot list is: 0.999999999999 0.999999999999 0.999999999999 3 6 8 10.000000000001 10.000000000001 10.000000000001. The exterior knots do not have any particular interpretation, but they are needed by the algorithm to construct the proper basis. The construction method computes differences between each value and the nearby knots. The algorithm that makes the B-spline basis is not very obvious, particularly compared to the polynomial spline basis. However, the B-spline basis is much better behaved numerically than a polynomial-spline basis, so that is why it is used.

---

## Linear and Nonlinear Regression Functions

This section shows how to use PROC TRANSREG in simple regression (one dependent variable and one independent variable) to find the optimal regression line, a nonlinear but monotone regression function, and a nonlinear and nonmonotone regression function. To find a linear regression function, specify the **IDENTITY** transformation of the independent variable. For a monotone curve, specify the **MSPLINE** transformation of the independent variable. To relax the monotonicity constraint, specify the **SPLINE** transformation. You can get more flexibility in spline functions by specifying knots. The more knots you specify, the more freedom the function has to follow minor variations in the data. This example uses artificial data. While these artificial data are clearly not realistic, their distinct pattern helps illustrate how splines work. The following statements generate the data and produce [Figure 97.28](#) through [Figure 97.31](#):

```

title 'Linear and Nonlinear Regression Functions';

* Generate an Artificial Nonlinear Scatter Plot;
data a;
 do i = 1 to 500;
 x = i / 2.5;
 y = -((x/50)-1.5)**2 + sin(x/8) + sqrt(x)/5 + 2*log(x) + cos(x);
 x = x / 21;
 if y > 2 then output;
 end;
run;

ods graphics on;
ods select fitplot(persist);

title2 'Linear Regression';

proc transreg data=a;
 model identity(y)=identity(x);
run;

title2 'A Monotone Regression Function';

```

```

run;

title2 'A Nonlinear Regression Function';

proc transreg data=a;
 model identity(y)=spline(x / nknots=9);
run;

title2 'A Nonlinear Regression Function, 100 Knots';

proc transreg data=a;
 model identity(y)=spline(x / nknots=100);
run;

ods select all;

```

Figure 97.28 Linear Regression

Figure 97.29 A Monotone Regression Function

Figure 97.30 A Nonlinear Regression Function

**Figure 97.31** A Less-Smooth Nonlinear Regression Function

The squared correlation is only 0.15 for the linear regression in Figure 97.28. Clearly, a simple linear regression model is not appropriate for these data. By relaxing the constraints placed on the regression line, the proportion of variance accounted for increases from 0.15 (linear) to 0.61 (monotone in Figure 97.29) to 0.90 (nonlinear but smooth in Figure 97.30) to almost 1.0 with 100 knots (nonlinear and not very smooth in Figure 97.28). Relaxing the linearity constraint permits the regression function to bend and more closely follow the right portion of the scatter plot. Relaxing the monotonicity constraint permits the regression function to follow the periodic portion of the left side of the plot more closely. The nonlinear **MSPLINE** transformation is a quadratic spline with knots at the deciles. The first nonlinear nonmonotonic **SPLINE** transformation is a cubic spline with knots at the deciles.

Different knots and different degrees would produce slightly different results. The two nonlinear regression functions could be closely approximated by simpler piecewise linear regression functions. The monotone function could be approximated by a two-piece line with a single knot at the elbow. The first nonmonotone function could be approximated by a six-piece function with knots at the five elbows.

With this type of problem (one dependent variable with no missing values that is not transformed and one independent variable that is nonlinearly transformed), PROC TRANSREG always iterates exactly twice (although only one iteration is necessary). The first iteration reports the R square for the linear regression line and finds the optimal transformation of  $x$ . Since the data change in the first iteration, a second iteration is performed, which reports the R square for the final nonlinear regression function, and zero data change. The predicted values, which are a linear function of the optimal transformation of  $x$ , contain the  $Y$  coordinates for the nonlinear regression function. The variance of the predicted values divided by the variance of  $y$  is the R square for the fit of the nonlinear regression function. When  $x$  is monotonically transformed, the transformation of  $x$  is always monotonically increasing, but the predicted values increase if the correlation is positive and decrease for negative correlations.

## Simultaneously Fitting Two Regression Functions

One application of ordinary multiple regression is fitting two or more regression lines through a single scatter plot. With PROC TRANSREG, this application can easily be generalized to fit separate or parallel curves. To illustrate, consider a data set with two groups and a group membership variable *g* that has the value 1 for one group and 2 for the other group. The data set also has a continuous independent variable *x* and a continuous dependent variable *y*. When *g* is crossed with *x*, the variables *g1x* and *g2x* both have a large partition of zeros. For this reason, the `KNOTS= t-option` is specified instead of the `NKNOTS= t-option`. (The latter would put a number of knots in the partition of zeros.) The following example generates an artificial data set with two curves. While these artificial data are clearly not realistic, their distinct pattern helps illustrate how fitting simultaneous regression functions works. The following statements generate data and show how PROC TRANSREG fits lines, curves, and monotone curves through a scatter plot:

```

title 'Separate Curves, Separate Intercepts';

data a;
 do x = -2 to 3 by 0.025;
 g = 1;
 y = 8*(x*x + 2*cos(x*6)) + 15*normal(7654321);
 output;
 g = 2;
 y = 4*(-x*x + 4*sin(x*4)) - 40 + 15*normal(7654321);
 output;
 end;
run;

ods graphics on;
ods select fitplot(persist);

title 'Parallel Lines, Separate Intercepts';

proc transreg data=a solve;
 model identity(y)=class(g) identity(x);
run;

title 'Parallel Monotone Curves, Separate Intercepts';

proc transreg data=a;
 model identity(y)=class(g) mspline(x / knots=-1.5 to 2.5 by 0.5);
run;

title 'Parallel Curves, Separate Intercepts';

proc transreg data=a solve;
 model identity(y)=class(g) spline(x / knots=-1.5 to 2.5 by 0.5);
run;

title 'Separate Slopes, Same Intercept';

```

```

proc transreg data=a;
 model identity(y)=class(g / zero=none) * identity(x);
run;

title 'Separate Monotone Curves, Same Intercept';

proc transreg data=a;
 model identity(y) = class(g / zero=none) *
 mspline(x / knots=-1.5 to 2.5 by 0.5);
run;

title 'Separate Curves, Same Intercept';

proc transreg data=a solve;
 model identity(y) = class(g / zero=none) *
 spline(x / knots=-1.5 to 2.5 by 0.5);
run;

title 'Separate Slopes, Separate Intercepts';

proc transreg data=a;
 model identity(y) = class(g / zero=none) | identity(x);
run;

title 'Separate Monotone Curves, Separate Intercepts';

proc transreg data=a;
 model identity(y) = class(g / zero=none) |
 mspline(x / knots=-1.5 to 2.5 by 0.5);
run;

title 'Separate Curves, Separate Intercepts';

proc transreg data=a solve;
 model identity(y) = class(g / zero=none) |
 spline(x / knots=-1.5 to 2.5 by 0.5);
run;
ods select all;

```

The previous statements produce [Figure 97.32](#) through [Figure 97.40](#). Only the fit plots are generated and displayed.

## Penalized B-Splines

You can use penalized B-splines (Eilers and Marx 1996) to fit a smooth curve through a scatter plot with an automatic selection of the smoothing parameter. See [Example 97.3](#) for an example. With penalized B-splines, you can find a transformation that minimizes any of the following criteria: **CV**, **GCV**, **AIC**, **AICC**, or **SBC**. These criteria are all functions of  $\lambda$ . For many problems, all of these criteria produce nearly identical results. However, for some problems, the choice of criterion can have a large effect. When the default results are not satisfactory, try the other criteria. Information criteria such as AIC and AICC are defined in different ways in the statistical literature, and these differences can be seen in different SAS procedures. Typically, the definitions differ only by a positive (additive or multiplicative) constant, so they are equivalent, and each of the definitions of the same criterion produces the same selection of  $\lambda$ . The definitions that PROC TRANSREG uses match the definitions that PROC REG uses. The penalized B-spline matrices, statistics, and criteria are defined as follows:

|                                                                                                           |                                                 |
|-----------------------------------------------------------------------------------------------------------|-------------------------------------------------|
| $n$                                                                                                       | number of observations                          |
| $y$                                                                                                       | dependent variable                              |
| $\mathbf{W}$                                                                                              | diagonal matrix of observation weights          |
| $w_i$                                                                                                     | weight for the $i$ th observation               |
| $\mathbf{B}$                                                                                              | B-spline basis for the independent variable     |
| $\lambda$                                                                                                 | nonnegative smoothing parameter                 |
| $\mathbf{D}$                                                                                              | difference matrix, penalizes lack of smoothness |
| $\mathbf{H} = \mathbf{B}(\mathbf{B}'\mathbf{W}\mathbf{B} + \lambda\mathbf{D}'\mathbf{D})^{-1}\mathbf{B}'$ | hat matrix                                      |

|                                                                        |                                                   |
|------------------------------------------------------------------------|---------------------------------------------------|
| $h_{ii}$                                                               | $i$ th diagonal element of $\mathbf{H}$           |
| $\hat{\mathbf{y}} = \mathbf{H}\mathbf{y}$                              | penalized B-spline transformation of $\mathbf{y}$ |
| $\text{SSE} = \sum_{i=1}^n w_i (y_i - \hat{y}_i)^2$                    | error sum of squares                              |
| $t = \sum_{i=1}^n w_i h_{ii}$                                          | weighted trace of $\mathbf{H}$                    |
| $\sum_{i=1}^n w_i \left( \frac{y_i - \hat{y}_i}{1 - h_{ii}} \right)^2$ | CV - cross validation criterion                   |
| $\sum_{i=1}^n w_i \left( \frac{y_i - \hat{y}_i}{n - t} \right)^2$      | GCV - generalized cross validation criterion      |
| $n \log(\text{SSE}/n) + 2t$                                            | AIC - Akaike's information criterion              |
| $1 + \log(\text{SSE}/n) + \frac{2(t + 1)}{n - t - 2}$                  | AICC - corrected AIC (default)                    |
| $n \log(\text{SSE}/n) + t \log(n)$                                     | SBC - Schwarz's Bayesian criterion                |

For more information about constructing the B-spline basis, see “[SPLINE and MSPLINE Transformations](#)” on page 8300 and the section “[Using Splines and Knots](#)” on page 8233. The nonzero elements of  $\mathbf{D}$ , order 1 are (1 -1), order 2 are (1 -2 1), order 3 (the default) are (1 -3 3 -1), order 4 are (1 -4 6 -4 1), and so on. The nonzero elements for each order are made from the nonzero elements from the preceding order by subtraction:  $\mathbf{d}'_{i+1} = (\mathbf{d}'_i \ 0) - (0 \ \mathbf{d}'_i)$ . Within an order, the first nonzero element of row  $i$  is in column  $i$ —that is, each row of  $\mathbf{D}$  is made from the preceding row by shifting the nonzero elements to the right one position. For example, with  $k = 4$  knots, order  $o = 3$ , and degree  $d = 3$ ,  $\mathbf{D}$  is the  $((d + 1 + k - o) \times (d + 1 + k))$  matrix:

$$\begin{bmatrix} 1 & -3 & 3 & -1 & 0 & 0 & 0 & 0 \\ 0 & 1 & -3 & 3 & -1 & 0 & 0 & 0 \\ 0 & 0 & 1 & -3 & 3 & -1 & 0 & 0 \\ 0 & 0 & 0 & 1 & -3 & 3 & -1 & 0 \\ 0 & 0 & 0 & 0 & 1 & -3 & 3 & -1 \end{bmatrix} \text{ where } \begin{array}{c} 1 \quad -1 \quad 0 \\ - \quad 0 \quad 1 \quad -1 \\ \hline 1 \quad -2 \quad 1 \quad 0 \\ - \quad 0 \quad 1 \quad -2 \quad 1 \\ \hline 1 \quad -3 \quad 3 \quad -1 \end{array}$$

The weighted trace of the hat matrix,  $t = \sum_{i=1}^n w_i h_{ii}$ , provides an estimate of the number of parameters needed to find the transformation and is used in  $df$  calculations. Note, however, that in some cases, particularly with error-free or nearly error-free data, this value can be *much* larger than you might expect. You might be able to directly create a function by using [SPLINE](#) or [BSPLINE](#) with many fewer parameters that fits essentially just as well as the penalized B-spline function.

By default with [PBSPLINE](#), a cubic spline is fit with 100 evenly spaced knots, three evenly spaced exterior knots, and a difference matrix of order three. Options are specified as follows: [PBSPLINE\(x / DEGREE=3 NKNOTS=100 EVENLY=3 PARAMETER=3\)](#). By default, PROC TRANSREG searches for an optimal

lambda in the range 0 to 1E6 by using parabolic interpolation and Brent's (Brent 1973; Press et al. 1989) method. Alternatively, you can specify a lambda range or a list of lambdas by using the **LAMBDA=** option. Be aware, however, **LAMBDA=0** and values near zero might cause numerical problems including floating point errors. Also be aware that larger lambdas might cause numerical problems—for example, the error sum of squares for the model,  $\Sigma(y - \hat{y})^2$ , might be greater than the total sum of squares,  $\Sigma(y - \bar{y})^2$ —implying that the model with the transformation fits less well than simply predicting by using the mean. When this happens, you will see this message: ERROR: Degenerate transformation with PBSPLINE.

You can fit a single curve through a scatter plot ( $y \times x$ ) as follows:

```
model identity(y) = pbspline(x);
```

Alternatively, you can fit multiple curves through a scatter plot, one for each level of Group, as follows:

```
model identity(y) = class(group / zero=none) * pbspline(x);
```

There are several options for how the smoothing parameter,  $\lambda$ , is chosen. Usually, you do not specify the smoothing parameter,  $\lambda$ , and you let PROC TRANSREG choose  $\lambda$  for you by minimizing one of the information or cross validation criteria. By default, PROC TRANSREG first considers ranges defined by  $\lambda = 0$  and  $\lambda = 1, 10, 100, 1000, 10,000, 100,000, 1,000,000$ . If it finds a range that includes the minimum, it stops and does not consider larger  $\lambda$  values. Then it performs further searches in that range. For example, if the initial evaluations at  $\lambda = 1$  and  $\lambda = 10$  show that there is at least a local minimum in the range 0 to 10, then larger values are not considered. Note that the zero smoothing case,  $\lambda = 0$ , provides a boundary on the range even though the criterion is not evaluated at  $\lambda = 0$ . The criterion is not evaluated at  $\lambda = 0$  unless **LAMBDA=0** is the only value specified. Also note that the default approach is not the same as specifying the options **LAMBDA=0 1E6 RANGE**. When a range of values is specified, along with the **RANGE t-option**, PROC TRANSREG does not try to find smaller ranges based on powers of 10.

PROC TRANSREG avoids evaluating the criterion for **LAMBDA=** values at or near zero unless you force it to consider them. This is because zero smoothing is rarely interesting and the results are numerically unstable. Values of  $\lambda$  at or near zero often result in predicted values that are far outside the range of the data, particularly with interpolation and  $x$  values that do not appear in the data set. Also, zero smoothing is prone to numerical problems including floating point errors. This is particularly true when there is a small number of observations, a large number of knots, a high degree, or a perfect or near perfect fit. If you force PROC TRANSREG to evaluate the criterion at or near  $\lambda = 0$ , you can easily get bad results.

Note that when some observations appear more than once, such as when you have the kind of data where you can use a **FREQ** statement, then you should consider directly specifying lambda based on a preliminary analysis, ignoring the frequencies. Alternatively, specify a range of  $\lambda$  values, such as **LAMBDA=0.1 1E6 RANGE**, that steers  $\lambda$  away from values near zero. With the default lambda list, a cross validation criterion does not perform well in choosing a smoothing parameter with replicated data. Leaving one observation out of the computations changes the frequency for that observation from one positive integer to the next smaller positive integer, so in some sense, the point corresponding to that observation is never really left out of any computations. The resulting fit will be undersmoothed unless you specify a larger  $\lambda$ .

---

## Smoothing Splines

You can use PROC TRANSREG to plot and output to a SAS data set the same smoothing spline function that the GPLOT procedure creates. You request a smoothing spline transformation by specifying **SMOOTH** in the MODEL statement. The smoothing parameter can be specified with either the **SM=** or the **PARAMETER=** *o-option*. The results are saved in the independent variable transformation (for example, Tx, when the independent variable is x) and the predicted values variable (for example, Py, when the dependent variable is y).

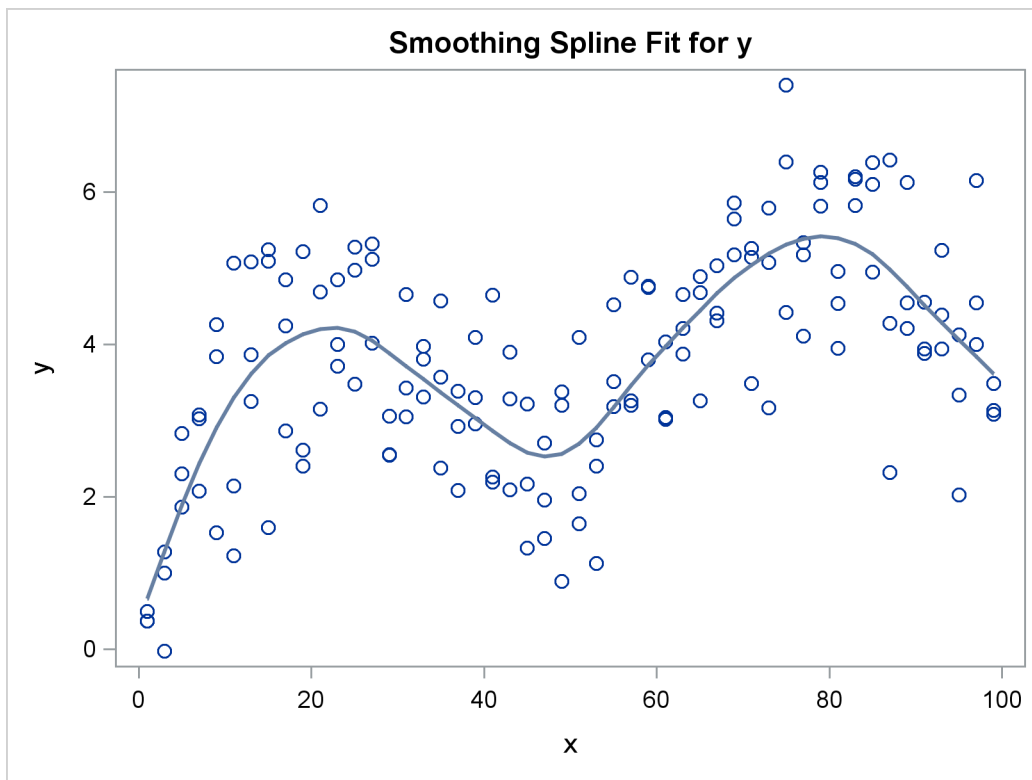

You can display the smoothing spline by using PROC TRANSREG and ODS Graphics (as shown in Figure 97.41). The following statements produce Figure 97.41:

```
title h=1.5 'Smoothing Splines';

ods graphics on;

data x;
 do x = 1 to 100 by 2;
 do rep = 1 to 3;
 y = log(x) + sin(x / 10) + normal(7);
 output;
 end;
 end;
run;

proc transreg;
 model identity(y) = smooth(x / sm=50);
 output p;
run;
```

**Figure 97.41** Smoothing Spline Displayed with ODS Graphics

You can also use PROC GPLOT to verify that the two procedures produce the same results. The PROC GPLOT plot request `y * x = 1` displays the data as stars. The specification `y * x = 2` with `I=SM50` requests the smooth curve through the scatter plot. It is overlaid with `Py * x = 3`, which displays with large dots the smooth function created by PROC TRANSREG. The results of the following step are not displayed:

```
proc gplot;
 axis1 minor=none label=(angle=90 rotate=0);
 axis2 minor=none;
 symbol1 color=blue v=circle i=none; /* data */
 symbol2 color=blue v=none i=sm50; /* gplot's smooth */
 symbol3 color=red v=dot i=none; /* transreg's smooth */
 plot y*x=1 y*x=2 py*x=3 / overlay haxis=axis2 vaxis=axis1 frame;
run; quit;
```

You can plot multiple nonlinear functions, one for each of several groups as defined by the levels of a **CLASS** variable. When you cross a **SMOOTH** variable with a **CLASS** variable, specify `ZERO=NONE` with the **CLASS** expansion. The following statements create artificial data and produce Figure 97.42:

```
title2 'Two Groups';

data x;
 do x = 1 to 100;
 Group = 1;
 do rep = 1 to 3;
 y = log(x) + sin(x / 10) + normal(7);
 end;
 end;
```

```

 output;
 end;
 group = 2;
 do rep = 1 to 3;
 y = -log(x) + cos(x / 10) + normal(7);
 output;
 end;
end;
run;

proc transreg ss2 data=x;
 model identity(y) = class(group / zero=none) *
 smooth(x / sm=50);

 output p;
run;

```

The ANOVA table in Figure 97.42 shows the overall model fit. The degrees of freedom are based on the trace of the transformation hat matrix, and are typically not integers. The “Smooth Transformation” table reports the degrees of freedom for each term, which includes an intercept for each group; the regression coefficients, which are always 1 with smoothing splines; the 0 to 100 smoothing parameter (like the one PROC GPLOT uses); the actual computed smoothing parameter; and the name and label for each term.

Figure 97.42 continued

The **SMOOTH** transformation is valid only with independent variables. Typically, it is used only, as in the two preceding examples, in models with a single dependent variable, a single independent variable, and optionally, a single classification variable that is crossed with the independent variable. The various standardization options such as **TSTANDARD=**, **CENTER**, **Z**, and **REFLECT** are by default not permitted when the **SMOOTH** transformation is part of the model.

The **SMOOTH** transformation can also be used in other ways, but only when you specify the **NSR** *a-option*. (See the section “[Smoothing Splines Changes and Enhancements](#)” on page 8267.) When you specify the **NSR** *a-option*, and there are multiple independent variables designated as **SMOOTH**, **PROC TRANSREG**

tries to smooth the  $i$ th independent variable by using the  $i$ th dependent variable as a target. When there are more independent variables than dependent variables, the last dependent variable is reused as often as is necessary. For example, consider the following statements:

```
proc transreg nsr;
 model identity(y1-y3) = smooth(x1-x5);
run;
```

Smoothing is based on the pairs  $(y_1, x_1)$ ,  $(y_2, x_2)$ ,  $(y_3, x_3)$ ,  $(y_3, x_4)$ , and  $(y_3, x_5)$ .

The SMOOTH transformation is a noniterative transformation. The smoothing of each variable occurs before the iterations begin. In contrast, SSPLINE provides an iterative smoothing spline transformation. It does not generally minimize squared error; hence, divergence is possible with SSPLINE.

## Smoothing Splines Changes and Enhancements

How the results of the transformation are processed in PROC TRANSREG has changed with SAS 9.2. In particular, some aspects of the syntax along the coefficients and predicted values have changed. The new behavior was required to make the smoothing splines work properly with ODS Graphics and to make SMOOTH work consistently with the new PBSPLINE (penalized B-spline; see the section “Penalized B-Splines” on page 8260) capabilities. However, you can use the new NSR *a-option*, if you want the old functionality. Here are two typical uses of the SMOOTH transformation:

```
proc transreg;
 model identity(y) = smooth(x / sm=50);
 output p;
run;

proc transreg;
 model identity(y) = class(group / zero=none) * smooth(x / sm=50);
 output p;
run;
```

For the first model, the variable  $x$  is smoothly transformed by using a smoothing parameter of  $SM=50$ , and the results are stored in the transformed variable  $Tx$ . The second model has two groups of observations corresponding to  $group=1$  and  $Group=2$ . Separate curves are fit through each group. The results for the first group are stored in the transformed variable  $TGroup1x$ , and the results for the second group are stored in the transformed variable  $TGroup2x$ . The predicted values are stored in  $Py$ . In the first case,  $Py = Tx$ , and in the second case,  $Py = TGroup1x + TGroup2x$ . These represent the two standard usages of the SMOOTH transformation, and you can use ODS Graphics to display fit plots with a single or multiple smooth functions. For the first model, which is the most typical usage, the syntax has not changed, nor has the transformed variable. For the second model, the syntax has slightly changed, but the transformed variables have not. The details of the syntax changes are discussed later in this section. The primary change involves what happens after the SMOOTH transformation is found. Now, by default, ordinary least squares (OLS) is no longer used to find the coefficients when there are smooth transformations, and in the iteration history table the OLS R square is no longer produced.

Here is some background for the change. The first three of the four models shown next have much in common:

```

model identity(y) = smooth(x / sm=50);
model identity(y) = rank(x);
model identity(y) = log(x);
model identity(y) = spline(x);

```

Before SAS 9.2, the **SMOOTH**, **RANK**, and **LOG** transformations all requested that PROC TRANSREG preprocess the data, nonlinearly transforming  $x$  before using OLS to fit a model to the preprocessed results. All of these first three transformations of  $x$  are nonoptimal in the sense that none of them is based in any way on the OLS regression model that follows the preprocessing of the data. In contrast, the fourth model requests a spline transformation. In this model, both the nonlinear transformation and the final regression model seek to minimize the same OLS criterion. Some PROC TRANSREG transformations, such as **SPLINE**, **MSPLINE**, **OPSCORE**, **MONOTONE**, and so on, seek to minimize squared error, whereas others, such as **SMOOTH**, **LOG**, **EXP**, and **RANK**, do not. For the latter, the data are simply preprocessed before analysis. There is a philosophical difference, however, between **SMOOTH** and the nonoptimal transformations. The **SMOOTH** and **PBSPLINE** transformations use the dependent variable and a model (but not OLS) to compute the transformation, whereas **LOG**, **EXP**, **RANK**, and the other nonoptimal transformations do not. A log transformation, for example, would be the same, regardless of context, whereas the **SMOOTH** and **PBSPLINE** transformations depend on the model.

The principal change to **SMOOTH** in PROC TRANSREG with SAS 9.2 involves making PROC TRANSREG aware of the underlying smoothing spline model. This makes **SMOOTH** and **PBSPLINE** perform similarly, and less like **LOG**, **EXP**, **RANK**, and the other nonoptimal transformations. Previously, if you specified **SMOOTH** and then examined the regression coefficients, you would probably get an intercept very close to but not exactly 0, and the remaining coefficients would be very close to but not exactly 1. This is because PROC TRANSREG was using OLS to find the coefficients. This has changed. Now, PROC TRANSREG recognizes that the **SMOOTH** transformation has an implicit intercept (see the section “**Implicit and Explicit Intercepts**” on page 8294); hence there is no separate intercept. Furthermore, now the other parameters are exactly 1, which are the correct parameters for the non-OLS smoothing spline model. Hence, the predicted values are now the sum of the transformed variables. When there is no **CLASS** variable, the predicted values exactly match the transformed variable. The **SMOOTH** transformation is no longer a form of preprocessing; it now changes the nature of the model from OLS to a true smoothing-spline model. If you still want the old behavior, preprocessing and then OLS, you can get the old default functionality by specifying the **NSR a-option**.

The new, default functionality assumes that you either want to fit a smooth function through the data or fit separate functions, one for each level of a **CLASS** variable. It also recognizes the smoothing-spline model as a model with an implicit intercept. For these reasons, the syntax for models with a **CLASS** variable has slightly changed, as is shown next:

```

proc transreg nsr; /* old */
 model identity(y) = class(group / zero=none) |
 smooth(x / after sm=50);

 output p;
run;

proc transreg; /* new */
 model identity(y) = class(group / zero=none) *
 smooth(x / sm=50);

 output p;
run;

```

Previously, the **AFTER** *t-option* was required when you wanted to fit separate and independent functions within each group. This *t-option* specifies that PROC TRANSREG should find the smoothing spline transformations *after* it crosses the independent variable with the CLASS variable. Previously, by default, PROC TRANSREG found an overall smooth transformation and then crossed it with the CLASS variable, which is probably not what you want. You can still specify the **AFTER** *t-option*, but now it is assumed with CLASS \* SMOOTH. If you specify **AFTER** without the **NSR** *a-option*, PROC TRANSREG suppresses the note that **AFTER** is assumed. It does not affect the model. If you do not want **AFTER** to be in effect by default, you must specify the **NSR** *a-option*. Also previously, you typically needed to specify the vertical bar instead of the asterisk to cross the CLASS and SMOOTH variables. The difference is that the bar adds both crossed variables and separate group intercepts to the model, whereas the asterisk adds only the crossed variables to the model. Since the SMOOTH transformation is now recognized as providing an implicit intercept, you should use the asterisk and not the vertical bar.

The default behavior of the SMOOTH transformation needed to change for several reasons. SMOOTH was originally provided as nothing more than a way to get PROC GPLOT's smoothing splines into an output data set in the transformed variables. However, with new enhancements to PROC TRANSREG such as ODS Graphics and PBSPLINE, the old method for SMOOTH did not fit well. The old method produced predicted values that were not the correct values to plot in order to show the smoothing spline fit. Now, with this change, ODS Graphics can always plot the predicted values. PBSPLINE and SMOOTH are similar in spirit, and for both, OLS results are not truly appropriate. Before SAS 9.2, PROC TRANSREG fit linear models, linear models with nonlinearly preprocessed variables, and linear models with optimal nonlinear transformations that minimized squared error. Now it also has the ability to fit non-OLS models for scatter plot smoothing.

One aspect of the SMOOTH transformation has unconditionally changed with SAS 9.2. Previously, PROC TRANSREG did not evaluate the effective degrees of freedom by examining the trace of the transformation hat matrix. It simply used the number of categories in the *df* calculations, which for continuous variables is the number of observations. This made it impossible to get a sensible ANOVA test for the overall fit. With SAS 9.2, the degrees of freedom are always based on the trace. This *df* change also affects the **SSPLINE** transformation, which finds a smooth transformation by using the same algorithm as SMOOTH. The difference is that the SMOOTH transformation occurs once, as an analysis preprocessing step, whereas **SSPLINE** transformations occur iteratively and in the body of the alternating least squares algorithm.

---

## Iteration History Changes and Enhancements

With SAS 9.2, PROC TRANSREG no longer always prints an iteration history table by default, and in some cases, the table it prints is not the same as it was previously. This change is due to the increasing use of PROC TRANSREG with transformations that are not based on alternating least squares. Here is some background for the change. PROC TRANSREG's processing can be divided into three steps. In the first step, the data are read and certain transformations, such as **SMOOTH**, **PBSPLINE**, **BOXCOX**, **RANK**, **LOG** and the other nonoptimal transformations, are performed. These transformations are not based on OLS. In the second step, the alternating least squares iterations are performed according to **METHOD=UNIVARIATE**, **MORALS**, **REDUNDANCY**, or **CANALS**. It is in the second step that the alternating least squares transformations (**SPLINE**, **MSPLINE**, **MONOTONE**, **OPSCORE**, **LINEAR**, and **UNTIE**) are iteratively found. In the third step, the results are displayed. In some cases, the results are appropriately based on using the method of OLS applied to the optimally transformed variables. In other cases, such as with smoothing splines and penalized B-splines, OLS-based results are not appropriate. Furthermore, for many of these types of models, nothing changes in the iterations, so the computations needed to realize that nothing changes are not needed, nor is the iteration history table.

With SAS 9.2, the iteration history is not printed for models where it is known that nothing will change in the iterations. Suppose the **NOMISS** option is specified or there are no missing data. If **METHOD=UNIVARIATE**, if there are no iterative transformations (**SPLINE**, **MSPLINE**, **MONOTONE**, **OPSCORE**, **LINEAR**, and **UNTIE**), and if the **MAXITER=** option is not specified, then by default, an iteration history table is not produced. If you want to see an iteration history, there are many things you can do, such as specifying **MAXITER=**, changing the method to **MORALS**, or changing **IDENTITY** to **LINEAR**.

With models with smoothing splines or penalized B-splines, the iteration history will not contain an R square. This is because the iterations are based on the method of alternating least squares, but the smoothing splines and penalized B-splines are not based on a least squares model. Hence, an ordinary R square in the iterations, based on a computed intercept, which is typically not exactly zero, and a computed slope, which is typically not exactly one, will not be exactly the same as the correct R square, which is based on an intercept and slope of zero and one. The final reported results include the correct R square in the fit statistics table after the ANOVA table. If you want to see only the correct R square from the results, without the iteration history, you can specify the new **RSQUARE** option.

---

## ANOVA Codings

This section illustrates several different codings of classification variables and hence several different ways of fitting two-way ANOVA models to some data. Each example fits an ANOVA model, displays the ANOVA table and parameter estimates, and displays the coded design matrix. Note throughout that the ANOVA tables and R squares are identical for all of the models, showing that the codings are equivalent. For each model, the parameter estimates are stated as a function of the cell means. The formulas are appropriate for a design such as this one, which is balanced and orthogonal (every level and every pair of levels occurs equally often). They will not work with unequal frequencies. Since this data set has  $3 \times 2 = 6$  cells, the full-rank codings all have six parameters. The following statements create the input data set, and display it in Figure 97.43:

```

title 'Two-Way ANOVA Models';

data x;
 input a b @@;
 do i = 1 to 2; input y @@; output; end;
 drop i;
 datalines;
1 1 16 14 1 2 15 13
2 1 1 9 2 2 12 20
3 1 14 8 3 2 18 20
;

proc print label;
run;

```

The next model is a deviations-from-means model. This coding is also called effects coding. The default reference cell is the last cell (3,2). The following statements produce [Figure 97.48](#) and [Figure 97.49](#):

```
proc transreg data=x ss2 short;
 title2 'Deviations from Means, (3,2) Reference Cell';
 model identity(y) = class(a | b / deviations);
 output replace;
run;

proc print label;
run;
```

The sum of the regression table DF's, minus one for the intercept, will be greater than the model df when there are ZERO=SUM constraints.

The parameter estimates are

$$\begin{aligned}
\hat{\mu} &= \bar{y} = 13.3333 \\
\hat{\alpha}_1 &= (\bar{y}_{11} + \bar{y}_{12})/2 - \bar{y} = (15 + 14)/2 - 13.3333 = 1.1667 \\
\hat{\alpha}_2 &= (\bar{y}_{21} + \bar{y}_{22})/2 - \bar{y} = (5 + 16)/2 - 13.3333 = -2.8333 \\
\hat{\alpha}_3 &= (\bar{y}_{31} + \bar{y}_{32})/2 - \bar{y} = (11 + 19)/2 - 13.3333 = 1.6667 \\
\hat{\beta}_1 &= (\bar{y}_{11} + \bar{y}_{21} + \bar{y}_{31})/3 - \bar{y} = (15 + 5 + 11)/3 - 13.3333 = -3 \\
\hat{\beta}_2 &= (\bar{y}_{12} + \bar{y}_{22} + \bar{y}_{32})/3 - \bar{y} = (14 + 16 + 19)/3 - 13.3333 = 3 \\
\hat{\gamma}_{11} &= \bar{y}_{11} - (\bar{y} + \hat{\alpha}_1 + \hat{\beta}_1) = 15 - (13.3333 + 1.1667 + -3) = 3.5 \\
\hat{\gamma}_{12} &= \bar{y}_{12} - (\bar{y} + \hat{\alpha}_1 + \hat{\beta}_2) = 14 - (13.3333 + 1.1667 + 3) = -3.5 \\
\hat{\gamma}_{21} &= \bar{y}_{21} - (\bar{y} + \hat{\alpha}_2 + \hat{\beta}_1) = 5 - (13.3333 + -2.8333 + -3) = -2.5 \\
\hat{\gamma}_{22} &= \bar{y}_{22} - (\bar{y} + \hat{\alpha}_2 + \hat{\beta}_2) = 16 - (13.3333 + -2.8333 + 3) = 2.5 \\
\hat{\gamma}_{31} &= \bar{y}_{31} - (\bar{y} + \hat{\alpha}_3 + \hat{\beta}_1) = 11 - (13.3333 + 1.6667 + -3) = -1 \\
\hat{\gamma}_{32} &= \bar{y}_{32} - (\bar{y} + \hat{\alpha}_3 + \hat{\beta}_2) = 19 - (13.3333 + 1.6667 + 3) = 1
\end{aligned}$$

The constraints are

$$\alpha_1 + \alpha_2 + \alpha_3 \equiv \beta_1 + \beta_2 \equiv 0$$

$$\gamma_{11} + \gamma_{12} \equiv \gamma_{21} + \gamma_{22} \equiv \gamma_{31} + \gamma_{32} \equiv \gamma_{11} + \gamma_{21} + \gamma_{31} \equiv \gamma_{12} + \gamma_{22} + \gamma_{32} \equiv 0$$

Only four of the five interaction constraints are needed. The fifth constraint is implied by the other four. (Given a  $2 \times 3$  table with four marginal sum-to-zero constraints, you can freely fill in only two cells. The values in the other four cells are determined from the first two cells and the constraints.) A full-rank model has six estimable parameters. This less-than-full-rank model has one parameter for the intercept, two for

the first main effect (plus one more as determined by the first constraint), one for the second main effect (plus one more as determined by the second constraint), and two for the interactions (plus four more as determined by the next four constraints). Six of the twelve parameters are determined given the other six and the constraints. Notice that  $\hat{\mu}$ ,  $\hat{\alpha}_1$ ,  $\hat{\alpha}_2$ ,  $\hat{\beta}_1$ ,  $\hat{\gamma}_{11}$ , and  $\hat{\gamma}_{21}$  match the corresponding estimates from the effects coding.

The next model is a reference cell model, but this time the reference cell is the first cell (1,1). The following statements produce [Figure 97.52](#) and [Figure 97.53](#):

```
proc transreg data=x ss2 short;
 title2 'Reference Cell Model, (1,1) Reference Cell';
 model identity(y) = class(a | b / zero=first);
 output replace;
run;

proc print label;
run;
```

The next model is a deviations-from-means model, but this time the reference cell is the first cell (1,1). This coding is also called effects coding. The following statements produce [Figure 97.54](#) and [Figure 97.55](#):

```
proc transreg data=x ss2 short;
 title2 'Deviations from Means, (1,1) Reference Cell';
 model identity(y) = class(a | b / deviations zero=first);
 output replace;
run;

proc print label;
run;
```

The parameter estimates are

$$\begin{aligned}\hat{\mu} &= \bar{y} = 13.3333 \\ \hat{\alpha}_1 &= (((\bar{y}_{11} + \bar{y}_{12}) - (\bar{y}_{31} + \bar{y}_{32}))/4) \times \sqrt{2/3} \\ &= (((15 + 14) - (11 + 19))/4) \times \sqrt{2/3} = -0.2041 \\ \hat{\alpha}_2 &= (((\bar{y}_{21} + \bar{y}_{22}) - (\bar{y}_{11} + \bar{y}_{12} + \bar{y}_{31} + \bar{y}_{32})/2)/6) \times \sqrt{6/3} \\ &= (((5 + 16) - (15 + 14 + 11 + 19)/2)/6) \times \sqrt{6/3} = -2.0035 \\ \hat{\beta}_1 &= (((\bar{y}_{11} + \bar{y}_{21} + \bar{y}_{31}) - (\bar{y}_{12} + \bar{y}_{22} + \bar{y}_{32}))/6) \times \sqrt{2/2} \\ &= (((15 + 5 + 11) - (14 + 16 + 19))/6) \times \sqrt{2/2} = -3 \\ \hat{\gamma}_{11} &= ((\bar{y}_{11} - \bar{y}_{12} - \bar{y}_{31} + \bar{y}_{32})/4) \times \sqrt{2/3} \times \sqrt{2/2} \\ &= ((15 - 14 - 11 + 19)/4) \times \sqrt{2/3} \times \sqrt{2/2} = 1.8371 \\ \hat{\gamma}_{21} &= (((-\bar{y}_{11} + \bar{y}_{12} - \bar{y}_{31} + \bar{y}_{32})/2 + (\bar{y}_{21} - \bar{y}_{22}))/6) \times \sqrt{6/3} \times \sqrt{2/2} \\ &= (((-15 + 14 - 11 + 19)/2 + (5 - 16))/6) \times \sqrt{6/3} \times \sqrt{2/2} = -1.7678\end{aligned}$$

The numerators in the square roots are sums of squares of the coded values for the unstandardized-orthogonal codings, and the denominators are the numbers of levels. These terms convert the estimates from the orthogonal contrast coding to the standardized-orthogonal coding. The term  $\sqrt{2/2}$ , which is 1 and could be dropped, is included in the preceding formulas to show the general pattern. Notice the regression tables for the orthogonal-contrast coding and the standardized-orthogonal coding. Some of the coefficients are different, but the rest of the table is the same since the coded variables for the two models differ only by a constant.

## Missing Values

PROC TRANSREG can estimate missing values, with or without category or monotonicity constraints, so that the regression model fit is optimized. Several approaches to missing data handling are provided. All observations with missing values in **IDENTITY**, **CLASS**, **POINT**, **EPOINT**, **QPOINT**, **SMOOTH**, **PBSPLINE**, **PSPLINE**, and **BSPLINE** variables are excluded from the analysis. When **METHOD=UNIVARIATE** (specified in the PROC TRANSREG or MODEL statement), observations with missing values in any of the independent variables are excluded from the analysis. When you specify the **NOMISS** *a-option*, observations with missing values in the other analysis variables are excluded. Otherwise, missing data are estimated, and the variable means are the initial estimates.

You can specify the **LINEAR**, **OPSCORE**, **MONOTONE**, **UNTIE**, **SPLINE**, **MSPLINE**, **SSPLINE**, **LOG**, **LOGIT**, **POWER**, **ARSIN**, **BOXCOX**, **RANK**, and **EXP** transformations in any combination with nonmissing values, ordinary missing values, and special missing values, as long as the nonmissing values in each variable have positive variance. No category or order restrictions are placed on the estimates of ordinary missing values. You can force missing value estimates within a variable to be identical by using special missing values (see “DATA Step Processing” in *SAS Language Reference: Concepts*). You can specify up to 27 categories of missing values, in which within-category estimates must be the same, by coding the missing values with **.\_** and **.A** through **.Z**.

You can also specify an ordering of some missing value estimates. You can use the **MONOTONE=** *a-option* in the PROC TRANSREG or MODEL statement to indicate a range of special missing values (a subset of the list from **.A** to **.Z**) with estimates that must be weakly ordered within each variable in which they appear. For example, if **MONOTONE=AI**, the nine classes, **.A**, **.B**, . . . , **.I**, are monotonically scored and optimally scaled just as **MONOTONE** transformation values are scored. In this case, category but not order restrictions are placed on the missing values **.\_** and **.J** through **.Z**. You can also use the **UNTIE=** *a-option* (in the PROC TRANSREG or MODEL statement) to indicate a range of special missing values with estimates that must be weakly ordered within each variable in which they appear but can be untied.

The missing value estimation facilities enable you to have partitioned or mixed-type variables. For example, a variable can be considered part nominal and part ordinal. Nominal classes of otherwise ordinal variables are coded with special missing values. This feature can be useful with survey research. The class “unfamiliar with the product” in the variable “Rate your preference for ‘Brand X’ on a 1 to 9 scale, or if you are unfamiliar with the product, check ‘unfamiliar with the product’” is an example. You can code “unfamiliar with the product” as a special missing value, such as **.A**. The 1s to 9s can be monotonically transformed, while no monotonic restrictions are placed on the quantification of the “unfamiliar with the product” class.

A variable specified for a **LINEAR** transformation, with special missing values and ordered categorical missing values, can be part interval, part ordinal, and part nominal. A variable specified for a **MONOTONE** transformation can have two independent ordinal parts. A variable specified for an **UNTIE** transformation can have an ordered categorical part and an ordered part without category restrictions. Many other mixes are possible.

---

## Missing Values, UNTIE, and Hypothesis Tests

PROC TRANSREG can estimate missing data and monotonically transform variables while untying tied values. Estimates of ordinary missing values (**.**) are all permitted to be different. Analyses with **UNTIE** transformations, the **UNTIE=** *a-option*, and ordinary missing data estimation are all prone to degeneracy

problems. Consider the following example. A perfect fit is found by collapsing all observations except the one with two missing values into a single value in  $y$  and  $x_1$ . The following statements produce Figure 97.60:

```

title 'Missing Data';

data x;

Generally, the use of ordinary missing data estimation, the UNTIE transformation, and the UNTIE= *a-option* should be avoided, particularly with hypothesis tests. With these options, parameters are estimated based on only a single observation, and they can exert tremendous influence over the results. Each of these parameters has one model degree of freedom associated with it, so small or zero error degrees of freedom can also be a problem.

## Controlling the Number of Iterations

Several *a-options* in the PROC TRANSREG or MODEL statement control the number of iterations performed. Iteration terminates when any one of the following conditions is satisfied:

- The number of iterations equals the value of the `MAXITER=` *a-option*.

- The average absolute change in variable scores from one iteration to the next is less than the value of the `CONVERGE= a-option`.
- The criterion change is less than the value of the `CCONVERGE= a-option`.

You can specify negative values for either convergence *a-option* if you want to define convergence only in terms of the other option. The criterion change can become negative when the data have converged, so it is numerically impossible, within machine precision, to increase the criterion. Usually, a negative criterion change is the result of very small amounts of rounding error, since the algorithms are (usually) convergent. However, there are cases where a negative criterion change is a sign of divergence, which is not necessarily an error. When you specify an `SSPLINE` transformation or the `REITERATE` or `SOLVE a-option`, divergence is perfectly normal.

When there are no monotonicity constraints and there is only one canonical variable in each set, PROC TRANSREG (with the `SOLVE a-option`) can usually find the optimal solution in only one iteration. (There are no monotonicity constraints when none of the following is specified: `MONOTONE`, `MSPLINE`, or `UNTIE` transformation or the `UNTIE=` or `MONOTONE= a-option`. There is only one canonical variable in each set when `METHOD=MORALS` or `METHOD=UNIVARIATE`, or when `METHOD=REDUNDANCY` with only one dependent variable, or when `METHOD=CANALS` and `NCAN=1`.)

The initialization iteration is number 0. When there are no monotonicity constraints and there is only one canonical variable in each set, the next iteration shows no change, and iteration stops. At least two iterations (0 and 1) are performed with the `SOLVE a-option` even if nothing changes in iteration 0. The `MONOTONE`, `MSPLINE`, and `UNTIE` variables are not transformed by the canonical initialization. Note that divergence with the `SOLVE a-option`, particularly in the second iteration, is not an error. The initialization iteration is slower and uses more memory than other iterations. However, for many models, specifying the `SOLVE a-option` can greatly decrease the amount of time required to find the optimal transformations.

You can increase the number of iterations to ensure convergence by increasing the value of the `MAXITER= a-option` and decreasing the value of the `CONVERGE= a-option`. Since the average absolute change in standardized variable scores seldom decreases below  $1E-11$ , you should not specify a value for the `CONVERGE= a-option` less than  $1E-8$  or  $1E-10$ . Most of the data changes occur during the first few iterations, but the data can still change after 50 or even 100 iterations. You can try different combinations of values for the `CONVERGE=` and `MAXITER= a-options` to ensure convergence without extreme overiteration. If the data do not converge with the default specifications, try `CONVERGE=1E-8` and `MAXITER=50`, or `CONVERGE=1E-10` and `MAXITER=200`. Note that you can specify the `REITERATE a-option` to start iterating where the previous analysis stopped.

---

## Using the REITERATE Algorithm Option

You can use the `REITERATE a-option` to perform additional iterations when PROC TRANSREG stops before the data have adequately converged. For example, suppose that you execute the following step:

```
proc transreg data=a;
 model mspline(y) = mspline(x1-x5);
 output out=b coefficients;
run;
```

If the transformations do not converge in the default 30 iterations, you can perform more iterations without repeating the first 30 iterations, as follows:

```
proc transreg data=b reiterate;
 model mspline(y) = mspline(x1-x5);
 output out=b coefficients;
run;
```

Note that a WHERE statement is not necessary to exclude the coefficient observations. They are automatically excluded because their `_TYPE_` value is not SCORE.

You can also use the REITERATE *a-option* to specify starting values other than the original values for the transformations. Providing alternate starting points might help avoid local optima. Here are two examples:

```
proc transreg data=a;
 model rank(y) = rank(x1-x5);
 output out=b;
run;

proc transreg data=b reiterate;
 /* Use ranks as the starting point. */
 model mspline(y) = mspline(x1-x5);
 output out=c coefficients;
run;

data b;
 set a;
 array tx[6] ty tx1-tx5;
 do j = 1 to 6;
 tx[j] = normal(7);
 end;
run;

proc transreg data=b reiterate;
 /* Use a random starting point. */
 model mspline(y) = mspline(x1-x5);
 output out=c coefficients;
run;
```

Note that divergence with the REITERATE *a-option*, particularly in the second iteration, is not an error since the initial transformation is not required to be a valid member of the transformation family. When you specify the REITERATE *a-option*, the iteration does not terminate when the criterion change is negative during the first 10 iterations.

---

## Avoiding Constant Transformations

There are times when the optimal scaling produces a constant transformed variable. This can happen with the MONOTONE, UNTIE, and MSPLINE transformations when the target is negatively correlated with the original input variable. It can happen with all transformations when the target is uncorrelated with the original input variable. When this happens, the procedure modifies the target to avoid a constant transformation. This strategy avoids certain nonoptimal solutions.

If the transformation is monotonic and a constant transformed variable results, the procedure multiplies the target by  $-1$  and tries the optimal scaling again. If the transformation is not monotonic or if the multiplication by  $-1$  did not help, the procedure tries using a random target. If the transformation is still constant, the

previous nonconstant transformation is retained. When a constant transformation is avoided by any strategy, this message is displayed: “A constant transformation was avoided for *name*.”

With extreme collinearity, small amounts of rounding error might interact with the instability of the coefficients to produce target vectors that are not positively correlated with the original scaling. If a regression coefficient for a variable is zero, the formula for the target for that variable contains a zero divide. In a multiple regression model, after many iterations, one independent variable can be scaled the same way as the current scaling of the dependent variable, so the other independent variables have coefficients of zero. When the constant transformation warning appears, you should interpret your results with extreme caution, and recheck your model.

---

## Constant Variables

Constant and almost constant variables are zeroed and ignored. When constant variables are expected and should not be zeroed, specify the `NOZEROCONSTANT` *a-option*.

---

## Character OPSCORE Variables

Character `OPSCORE` variables are replaced by a numeric variable containing category numbers before the iterations, and the character values are discarded. Only the first eight characters are considered in determining category membership. If you want the original character variable in the output data set, give it a different name in the `OPSCORE` specification (`OPSCORE(x / name=(x2))`) and name the original variable in the `ID` statement (`ID x;`).

---

## Convergence and Degeneracies

When you specify the `SSPLINE` transformation, divergence is normal. The rest of this section assumes that you did not specify `SSPLINE`. For all the methods available in `PROC TRANSREG`, the algorithms are convergent, in terms of both the criterion being optimized and the parameters being estimated. The value of the criterion being maximized (squared multiple correlation, average squared multiple correlation, or average squared canonical correlation) can, theoretically, never decrease from one iteration to the next. The values of the parameters being solved for (the scores and weights of the transformed variables) become stable after sufficient iteration.

In practice, the criterion being maximized can decrease with overiteration. When the statistic has very nearly reached its maximum, further iterations might report a decrease in the criterion in the last few decimal places. This is a normal result of very small amounts of rounding error. By default, iteration terminates when this occurs because, by default, `CCONVERGE=0.0`. Specifying `CCONVERGE=-1`, an impossible change, turns off this check for convergence.

Even though the algorithms are convergent, they might not converge to a global optimum. Also, under extreme circumstances, the solution might degenerate. Because two points always form a straight line, the algorithms sometimes try to reach this degenerate optimum. This sometimes occurs when one observation is an ordinal outlier (when one observation has the extreme rank on all variables). The algorithm can reach an optimal solution that ties all other categories producing two points. Similar results can occur when there

are many missing values. More generally, whenever there are very few constraints on the scoring of one or more points, degeneracies can be a problem. In a well-behaved analysis, the maximum data change, average data change, and criterion change all decrease at a rapid rate with each iteration. When the rate of change increases for several iterations, the solution might be degenerating.

---

## Implicit and Explicit Intercepts

Depending on several options, the model intercept is nonzero, zero, or implicit, or there is no intercept. Ordinarily, the model contains an explicit nonzero intercept, and the Intercept variable in the `OUT=` data set contains ones. When `TSTANDARD=CENTER` or `TSTANDARD=Z` is specified, the model contains an explicit, zero intercept and the Intercept variable contains zeros. When `METHOD=CANALS`, the model is fit with centered variables and the Intercept variable is set to missing.

If you specify `CLASS` with `ZERO=NONE` or `BSPLINE` for one or more independent variables, and `TSTANDARD=NOMISS` or `TSTANDARD=ORIGINAL` (the default), an implicit intercept model is fit. The intercept is implicit in a set of the independent variables since there exists a set of independent variables the sum of which is a column of ones. All statistics are mean corrected. The implicit intercept is not an option; it is implied by the model. Specifying `SMOOTH` or `PBSPLINE` also implies an implicit intercept model.

With `METHOD=CANALS`, the Intercept variable contains the *canonical intercept* for canonical coefficients observations:  $\hat{\beta}_0 = \bar{y}'\hat{\alpha} - \bar{x}'\hat{\beta}$  where  $\mathbf{Y}\hat{\alpha} \approx \mathbf{X}\hat{\beta}$ .

---

## Passive Observations

Observations can be excluded from the analysis for several reasons; these include zero weight; zero frequency; missing values in variables designated `IDENTITY`, `CLASS`, `POINT`, `EPOINT`, `QPOINT`, `SMOOTH`, `PBSPLINE`, `PSPLINE`, or `BSPLINE`; and missing values with the `NOMISS a-option` specified. These observations are passive in that they do not contribute to determining transformations, R square, sums of squares, degrees of freedom, and so on. However, some information can be computed for them. For example, if no independent variable values are missing, predicted values and redundancy variable values can both be computed. Residuals can be computed for observations with a nonmissing dependent and nonmissing predicted value. Canonical variables for dependent variables can be computed when no dependent variables are missing; canonical variables for independent variables can be computed when no independent variables are missing, and so on. Passive observations in the `OUT=` data set have a blank value for `_TYPE_`.

---

## Point Models

The expanded set of independent variables generated from the `POINT`, `EPOINT`, and `QPOINT` expansions can be used to perform ideal point regressions (Carroll 1972) and compute ideal point coordinates for plotting in a biplot (Gabriel 1981). The three types of ideal point coordinates can all be described as transformed coefficients. Assume that  $m$  independent variables are specified in one of the three point expansions. Let  $\mathbf{b}'$  be a  $1 \times m$  row vector of coefficients for these variables and one of the dependent variables. Let  $\mathbf{R}$  be a matrix created from the coefficients of the extra variables. When coordinates are requested with the `MPC`, `MEC`, or `MQC o-option`,  $\mathbf{b}'$  and  $\mathbf{R}$  are created from multiple regression coefficients. When coordinates are requested with the `CPC`, `CEC`, or `CQC o-option`,  $\mathbf{b}'$  and  $\mathbf{R}$  are created from canonical coefficients.

If you specify the **POINT** expansion in the **MODEL** statement, **R** is an  $m \times m$  identity matrix times the coefficient for the sums of squares (**\_ISSQ\_**) variable. If you specify the **EPOINT** expansion, **R** is an  $m \times m$  diagonal matrix of coefficients from the squared variables. If you specify the **QPOINT** expansion, **R** is an  $m \times m$  symmetric matrix of coefficients from the squared variables on the diagonal and crossproduct variables off the diagonal. The **MPC**, **MEC**, **MQC**, **CPC**, **CEC**, and **CQC** ideal point coordinates are defined as  $-0.5\mathbf{b}'\mathbf{R}^{-1}$ . When **R** is singular, the ideal point coordinates are infinitely far away and are set to missing, so you should try a simpler version of the model. The version that is simpler than the **POINT** model is the vector model, where no extra variables are created. In the vector model, designate all independent variables as **IDENTITY**. Then draw vectors from the origin to the **COEFFICIENTS** points.

Typically, when you request ideal point coordinates, the **MODEL** statement should consist of a single transformation for the dependent variables (usually **IDENTITY**, **MONOTONE**, or **MSPLINE**) and a single expansion for the independent variables (one of **POINT**, **EPOINT**, or **QPOINT**).

---

## Redundancy Analysis

Redundancy analysis (Stewart and Love 1968) is a principal component analysis of multivariate regression predicted values. These first steps show the redundancy analysis results produced by **PROC TRANSREG**. The specification **TSTANDARD=Z** sets all variables to mean zero and variance one. **METHOD=REDUNDANCY** specifies redundancy analysis and outputs the redundancy variables to the **OUT=** data set. The **MREDUNDANCY** *o-option* outputs two sets of redundancy analysis coefficients to the **OUT=** data set.

The following statements produce [Figure 97.61](#):

The `_TYPE_='SCORE'` observations of the Red1–Red3 variables contain the redundancy variables. The nonmissing “M REDUND” values are coefficients for predicting the redundancy variables from the independent variables. The nonmissing “R REDUND” values are coefficients for predicting the independent variables from the redundancy variables.

The next steps show how to generate the same results manually. The data set is standardized, predicted values are computed, and principal components of the predicted values are computed. The following statements produce the redundancy variables, shown in Figure 97.62:

```
proc standard data=x out=std m=0 s=1;
 title2 'Manually Generate Redundancy Variables';
run;

proc reg noprint data=std;
 model y1-y3 = x1-x4;
 output out=p p=ay1-ay3;
run; quit;

proc princomp data=p cov noprint std out=p;
 var ay1-ay3;
run;

proc print data=p(keep=Prin:);
 format _numeric_ 4.1;
run;
```

## Optimal Scaling

An alternating least squares optimal scaling algorithm can be divided into two major stages. The first major stage estimates the parameters of the linear model. These parameters are used to create the predicted values or target for each variable that can be transformed. Each target minimizes squared error (as explained in the discussion of the algorithms in *SAS Technical Report R-108*). The definition of the target depends on many factors, such as whether a variable is independent or dependent, which algorithm is used (for example, regression, redundancy, CANALS, or principal components), and so on. The definition of the target is independent of the transformation family you specify for the variable. However, the target values for a variable typically do not fit the prescribed transformation family for the variable. They might not have the right category structure; they might not have the right order; they might not be a linear combination of the columns of a B-spline basis; and so on.

The second major stage is optimal scaling. Optimal scaling can be defined as a possibly constrained, least squares regression problem. When you specify an optimal transformation, or when missing data are estimated for any variable, the full representation of the variable is not simply a vector; it is a matrix with more than one column. The optimal scaling phase finds the vector that is a linear combination of the columns of this matrix that is closest to the target (in terms of minimum squared error), among those that do not violate any of the constraints imposed by the transformation family. Optimal scaling methods are independent of the data analysis method that generated the target. In all cases, optimal scaling can be accomplished by creating a design matrix based on the original scaling of the variable and the transformation family specified for that variable. The optimally scaled variable is a linear combination of the columns of the design matrix. The coefficients of the linear combination are found by using (possibly constrained) least squares. Many optimal scaling problems are solved without actually constructing design and projection matrices. The next two sections describe the algorithms used by PROC TRANSREG for optimal scaling. The first section discusses optimal scaling for **OPSCORE**, **MONOTONE**, **UNTIE**, and **LINEAR** transformations, including how missing values are handled. The second section addresses **SPLINE** and **MSPLINE** transformations.

## OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations

Two vectors of information are needed to produce the optimally scaled variable: the initial variable scaling vector  $x$  and the target vector  $y$ . For convenience, both vectors are first sorted on the values of the initial scaling vector. If you request an **UNTIE** transformation, the target vector is sorted within ties in the initial

scaling vector. The normal SAS collating sequence for missing and nonmissing values is used. Sorting simply permits the constraints to be specified in terms of relationships among adjoining coefficients. The sorting process partitions  $x$  and  $y$  into missing and nonmissing parts  $(x'_m x'_n)'$ , and  $(y'_m y'_n)'$ .

Next, PROC TRANSREG determines category membership. Every ordinary missing value (.) forms a separate category. (Three ordinary missing values form three categories.) Every special missing value within the range specified in the UNTIE= *a-option* forms a separate category. (If UNTIE= BC and there are three .B and two .C missing values, five categories are formed from them.) For all other special missing values, a separate category is formed for each different value. (If there are four .A missing values, one category is formed from them.)

Each distinct nonmissing value forms a separate category for OPSCORE and MONOTONE transformations (1 1 1 2 2 3 form three categories). Each nonmissing value forms a separate category for all other transformations (1 1 1 2 2 3 form six categories). When category membership is determined, category means are computed. Here is an example:

```

x: (. . .A .A .B 1 1 1 2 2 3 3 3 4)'
y: (5 6 2 4 2 1 2 3 4 6 4 5 6 7)'

OPSCORE and
MONOTONE means: (5 6 3 2 2 5 5 7)'
other means: (5 6 3 2 1 2 3 4 6 4 5 6 7)'

```

The category means are the coefficients of a category indicator design matrix. The category means are the Fisher (1938) optimal scores. For MONOTONE and UNTIE transformations, order constraints are imposed on the category means for the nonmissing partition by merging categories that are out of order. The algorithm checks upward until an order violation is found, and then averages downward until the order violation is averaged away. (The average of  $\bar{x}_1$  computed from  $n_1$  observations and  $\bar{x}_2$  computed from  $n_2$  observations is  $(n_1\bar{x}_1 + n_2\bar{x}_2)/(n_1 + n_2)$ .) The MONOTONE algorithm (Kruskal 1964, secondary approach to ties) for this example with means for the nonmissing values  $(2\ 5\ 5\ 7)'$  would do the following checks:  $2 < 5$ : OK,  $5 = 5$ : OK,  $5 < 7$ : OK. The means are in the proper order, so no work is needed.

The UNTIE transformation (Kruskal 1964, primary approach to ties) uses the same algorithm on the means of the nonmissing values  $(1\ 2\ 3\ 4\ 6\ 4\ 5\ 6\ 7)'$  but with different results for this example:  $1 < 2$ : OK,  $2 < 3$ : OK,  $3 < 4$ : OK,  $4 < 6$ : OK,  $6 > 4$ : average 6 and 4 and replace 6 and 4 by the average. The new means of the nonmissing values are  $(1\ 2\ 3\ 4\ 5\ 5\ 6\ 7)'$ . The check resumes:  $4 < 5$ : OK,  $5 = 5$ : OK,  $5 = 5$ : OK,  $5 < 6$ : OK,  $6 < 7$ : OK. If some of the special missing values are ordered, the upward-checking, downward-averaging algorithm is applied to them also, independently of the other missing and nonmissing partitions. When the means conform to any required category or order constraints, an optimally scaled vector is produced from the means. The following example results from a MONOTONE transformation:

```

x: (. . .A .A .B 1 1 1 2 2 3 3 3 4)'
y: (5 6 2 4 2 1 2 3 4 6 4 5 6 7)'
result: (5 6 3 3 2 2 2 2 5 5 5 5 5 7)'

```

The upward-checking, downward-averaging algorithm is equivalent to creating a category indicator design matrix, solving for least squares coefficients with order constraints, and then computing the linear combination of design matrix columns.

For the optimal transformation LINEAR and for nonoptimal transformations, missing values are handled as just described. The nonmissing target values are regressed onto the matrix defined by the nonmissing initial

scaling values and an intercept. In this example, the target vector  $y_n = (1\ 2\ 3\ 4\ 6\ 4\ 5\ 6\ 7)'$  is regressed onto the design matrix

$$\begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 2 & 2 & 3 & 3 & 3 & 4 \end{bmatrix}'$$

Although only a linear transformation is performed, the effect of a linear regression optimal scaling is not eliminated by the later standardization step (unless the variable has no missing values). In the presence of missing values, the linear regression is necessary to minimize squared error.

## SPLINE and MSPLINE Transformations

The missing portions of variables subjected to **SPLINE** or **MSPLINE** transformations are handled the same way as for **OPSCORE**, **MONOTONE**, **UNTIE**, and **LINEAR** transformations (see the previous section). The nonmissing partition is handled by first creating a B-spline basis of the specified degree with the specified knots for the nonmissing partition of the initial scaling vector and then regressing the target onto the basis. The optimally scaled vector is a linear combination of the B-spline basis vectors. Ordinary least squares regression coefficients are used. An algorithm for generating the B-spline basis is given in de Boor (1978, pp. 134–135). B-splines are both a computationally accurate and efficient way of constructing a basis for piecewise polynomials; however, they are not the most natural method of describing splines.

Consider an initial scaling vector  $x = (1\ 2\ 3\ 4\ 5\ 6\ 7\ 8\ 9)'$  and a degree-three spline with interior knots at 3.5 and 6.5. The B-spline basis for the transformation is the left matrix, and the natural piecewise polynomial spline basis is the right matrix.

| B-Spline Basis                                                                                                                                                                                                                                                                                                                                                                                                | Piecewise Polynomial Splines                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\begin{bmatrix} 1.000 & 0.000 & 0.000 & 0.000 & 0 & 0 \\ 0.216 & 0.608 & 0.167 & 0.009 & 0 & 0 \\ 0.008 & 0.458 & 0.461 & 0.073 & 0 & 0 \\ 0 & 0.172 & 0.585 & 0.241 & 0.001 & 0 \\ 0 & 0.037 & 0.463 & 0.463 & 0.037 & 0 \\ 0 & 0.001 & 0.241 & 0.585 & 0.172 & 0 \\ 0 & 0 & 0.073 & 0.461 & 0.458 & 0.008 \\ 0 & 0 & 0.009 & 0.167 & 0.608 & 0.216 \\ 0 & 0 & 0.000 & 0.000 & 0.000 & 1.000 \end{bmatrix}$ | $\begin{bmatrix} 1 & 1 & 1 & 1 & 0 & 0 \\ 1 & 2 & 4 & 8 & 0 & 0 \\ 1 & 3 & 9 & 27 & 0 & 0 \\ 1 & 4 & 16 & 64 & 0.125 & 0 \\ 1 & 5 & 25 & 125 & 3.375 & 0 \\ 1 & 6 & 36 & 216 & 15.625 & 0 \\ 1 & 7 & 49 & 343 & 42.875 & 0.125 \\ 1 & 8 & 64 & 512 & 91.125 & 3.375 \\ 1 & 9 & 81 & 729 & 166.375 & 15.625 \end{bmatrix}$ |

The two matrices span the same column space. The natural basis has an intercept, a linear term, a quadratic term, a cubic term, and two more terms since there are two interior knots. These terms are generated (for knot  $k$  and  $x$  element  $x$ ) by the formula  $(x - k)^3 \times I_{(x > k)}$ . The indicator variable  $I_{(x > k)}$  evaluates to 1.0 if  $x$  is greater than  $k$  and to 0.0 otherwise. If knot  $k$  had been repeated, there would be a  $(x - k)^2 \times I_{(x > k)}$  term also. Notice that the fifth column makes no contribution to the curve before 3.5, makes zero contribution at 3.5 (the transformation is continuous), and makes an increasing contribution beyond 3.5. The same pattern of results holds for the last term with knot 6.5. The coefficient of the fifth column represents the change in the cubic portion of the curve after 3.5. The coefficient of the sixth column represents the change in the cubic portion of the curve after 6.5.

The numbers in the B-spline basis do not have a simple interpretation like the numbers in the natural piecewise polynomial basis. The B-spline basis has a diagonally banded structure. The band shifts one column to the right after every knot. The number of entries in each row that can potentially be nonzero is one greater than the degree. The elements within a row always sum to one. The B-spline basis is accurate because of the smallness of the numbers and the lack of extreme collinearity inherent in the natural polynomials. B-splines are efficient because PROC TRANSREG can take advantage of the sparseness of the B-spline basis when it accumulates crossproducts. The number of required multiplications and additions to accumulate the crossproduct matrix does not increase with the number of knots but does increase with the degree of the spline, so it is much more computationally efficient to increase the number of knots than to increase the degree of the polynomial.

MSPLINE transformations are handled like SPLINE transformations except that constraints are placed on the coefficients to ensure monotonicity. When the coefficients of the B-spline basis are monotonically increasing, the transformation is monotonically increasing. When the polynomial degree is two or less, monotone coefficient splines, integrated splines (Winsberg and Ramsay 1980), and the general class of all monotone splines are equivalent.

---

## Specifying the Number of Knots

Keep the number of knots small (usually less than 10, although you can specify more). A degree-three spline with nine knots, one at each decile, can closely follow a large variety of curves. Each spline transformation of degree  $p$  with  $q$  knots fits a model with  $p + q$  parameters. The total number of parameters should be much less than the number of observations. Usually in regression analyses, it is recommended that there be at least five or ten observations for each parameter in order to get stable results. For example, when spline transformations of degree three with nine knots are requested for six variables, the number of observations in the data set should be at least 5 or 10 times 72 (since  $6 \times (3 + 9)$  is the total number of parameters). The overall model can also have a parameter for the intercept and one or more parameters for each nonspline variable in the model.

Increasing the number of knots gives the spline more freedom to bend and follow the data. Increasing the degree also gives the spline more freedom, but to a lesser extent. Specifying a large number of knots is much better than increasing the degree beyond three.

When you specify `NKNOTS= $q$`  for a variable with  $n$  observations, then each of the  $q + 1$  segments of the spline contains  $n/(q + 1)$  observations on the average. When you specify `KNOTS=number-list`, make sure that there is a reasonable number of observations in each interval.

The following statements find a cubic polynomial transformation of  $x$  and no transformation of  $y$ :

```
proc transreg;
 model identity(y)=spline(x);
 output;
run;
```

The following statements find a cubic-spline transformation for  $x$  that consists of the weighted sum of a single constant, a single straight line, a quadratic curve for the portion of the variable less than 3.0, a different quadratic curve for the portion greater than 3.0 (since the 3.0 knot is repeated), and a different cubic curve for each of the intervals: (minimum to 1.5), (1.5 to 2.4), (2.4 to 3.0), (3.0 to 4.0), and (4.0 to maximum):

```
proc transreg;
 model identity(y)=spline(x / knots=1.5 2.4 3.0 3.0 4.0);
 output;
run;
```

The transformation is continuous everywhere, its first derivative is continuous everywhere, its second derivative is continuous everywhere except at 3.0, and its third derivative is continuous everywhere except at 1.5, 2.4, 3.0, and 4.0.

The following statements find a quadratic spline transformation that consists of a polynomial  $x_t = b_0 + b_1x + b_2x^2$  for the range ( $x < 3.0$ ) and a completely different polynomial  $x_t = b_3 + b_4x + b_5x^2$  for the range ( $x > 3.0$ ):

```
proc transreg;
 model identity(y)=spline(x / knots=3 3 3 degree=2);
 output;
run;
```

The two curves are not required to be continuous at 3.0.

The following statements categorize  $y$  into 10 intervals and find a step-function transformation:

```
proc transreg;
 model identity(y)=spline(x / degree=0 nknots=9);
 output;
run;
```

One aspect of this transformation family is unlike all other optimal transformation families. The initial scaling of the data does not fit the restrictions imposed by the transformation family. This is because the initial variable can be continuous, but a discrete step-function transformation is sought. Zero-degree spline variables are categorized before the first iteration.

The following statements find a continuous, piecewise linear transformation of  $x$ :

```
proc transreg;
 model identity(y)=spline(x / degree=1 nknots=8);
 output;
run;
```

---

## SPLINE, BSPLINE, and PSPLINE Comparisons

**SPLINE** is a transformation. It takes a variable as input and produces a transformed variable as output. Internally, with **SPLINE**, a B-spline basis is used to find the transformation, which is a linear combination of the columns of the B-spline basis. However, with **SPLINE**, the basis is not made available in any output.

**BSPLINE** is an expansion. It takes a variable as input and produces more than one variable as output. The output variables are the same B-spline basis that is used internally by **SPLINE**.

**PSPLINE** is an expansion. It takes a variable as input and produces more than one variable as output. The difference between **PSPLINE** and **BSPLINE** is that **PSPLINE** produces a piecewise polynomial, whereas **BSPLINE** produces a B-spline. A matrix consisting of a piecewise polynomial basis and an intercept spans the same space as the B-spline matrix, but the basis vectors are quite different. The numbers in the piecewise

polynomials can get quite large; the numbers in the B-spline basis range between 0 and 1. There are many more zeros in the B-spline basis.

Interchanging SPLINE, BSPLINE, and PSPLINE should have no effect on the fit of the overall model except for the fact that PSPLINE is much more prone to numerical problems. Similarly, interchanging a CLASS expansion and an OPSCORE transformation should have no effect on the fit of the overall model.

---

## Hypothesis Tests

PROC TRANSREG has a set of options for testing hypotheses in models with a single dependent variable. The **TEST** *a-option* produces an ANOVA table. It tests the null hypothesis that the vector of coefficients for all of the transformations is zero. The **SS2** *a-option* produces a regression table with Type II tests of the contribution of each transformation to the overall model. In some cases, exact tests are provided; in other cases, the tests are approximate, liberal, or conservative.

There are two reasons why it is typically not appropriate to test hypotheses by using the output from PROC TRANSREG as input to other procedures such as the REG procedure. First, PROC REG has no way of determining how many degrees of freedom were used for each transformation. Second, the Type II sums of squares for the tests of the individual regression coefficients are not correct for the transformation regression model because PROC REG, as it evaluates the effect of each variable, cannot change the transformations of the other variables. PROC TRANSREG uses the correct degrees of freedom and sums of squares.

In an ordinary univariate linear model, there is one parameter for each independent variable, including the intercept. In the transformation regression model, many of the “variables” are used internally in the bases for the transformations. Each basis column has one parameter or *scoring* coefficient, and each linearly independent column has one model degree of freedom associated with it. Coefficients applied to transformed variables, *model coefficients*, do not enter into the degrees-of-freedom calculations. They are byproducts of the standardizations and can be absorbed into the transformations by specifying the **ADDITIVE** *a-option*. The word *parameter* is reserved for model and scoring coefficients that have a degree of freedom associated with them.

For expansions, there is one model parameter for each variable created by the expansion (except for all missing **CLASS** columns and expansions that have an implicit intercept). Each **IDENTITY** variable has one model parameter. If there are  $m$  **POINT** variables, they expand to  $m + 1$  variables and hence have  $m + 1$  model parameters. For  $m$  **EPOINT** variables, there are  $2m$  model parameters. For  $m$  **QPOINT** variables, there are  $m(m + 3)/2$  model parameters. If a variable with  $m$  categories is designated **CLASS**, there are  $m - 1$  parameters. For **BSPLINE** and **PSPLINE** variables of **DEGREE**= $n$  with **NKNOTS**= $k$ , there are  $n + k$  parameters. Note that one of the  $n + k + 1$  **BSPLINE** columns and one of the  $m$  **CLASS**(variable / **ZERO**=**NONE**) columns are not counted due to the implicit intercept.

There are scoring parameters for missing values in nonexcluded observations. Each ordinary missing value (.) has one scoring parameter. Each different special missing value (.\_ and .A through .Z) within each variable has one scoring parameter. Missing values specified in the **UNTIE**= and **MONOTONE**= options follow the rules for **UNTIE** and **MONOTONE** transformations, which are described later in this chapter.

For all nonoptimal transformations (**LOG**, **LOGIT**, **ARSIN**, **POWER**, **EXP**, **RANK**, **BOXCOX**), there is one parameter per variable in addition to any missing value scoring parameters.

For **SPLINE**, **OPSCORE**, and **LINEAR** transformations, the number of scoring parameters is the number of basis columns that are used internally to find the transformations minus 1 for the intercept. The number of

scoring parameters for SPLINE variables is the same as the number of model parameters for BSPLINE and PSPLINE variables. If DEGREE= $n$  and NKNOTS= $k$ , there are  $n + k$  scoring parameters. The number of scoring parameters for OPSCORE, SMOOTH, and SSPLINE variables is the same as the number of model parameters for CLASS variables. If there are  $m$  categories, there are  $m - 1$  scoring parameters. There is one parameter for each LINEAR variable. For SPLINE, OPSCORE, LINEAR, MONOTONE, UNTIE, and MSPLINE transformations, missing value scoring parameters are computed as described previously with the nonoptimal transformations.

The number of scoring parameters for MONOTONE, UNTIE, and MSPLINE transformations is less precise than for SPLINE, OPSCORE, and LINEAR transformations. One way of handling a MONOTONE transformation is to treat it as if it were the same as an OPSCORE transformation. If there are  $m$  categories, there are  $m - 1$  potential scoring parameters. However, there are typically fewer than  $m - 1$  unique parameter estimates, since some of those  $m - 1$  scoring parameter estimates might be tied during the optimal scaling to impose the order constraints. Imposing ties on the scoring parameter estimates is equivalent to fitting a model with fewer parameters. So there are two available scoring parameter counts:  $m - 1$  and a smaller number that is determined during the analysis. Using  $m - 1$  as the model degrees of freedom for MONOTONE variables (treating OPSCORE and MONOTONE transformations the same way) is *conservative*, since the MONOTONE scoring parameter estimates are more restricted than the OPSCORE scoring parameter estimates. Using the smaller count (the number of scoring parameter estimates that are different, minus 1 for the intercept) in the model degrees of freedom is *liberal*, since the data and the model together are being used to determine the number of parameters. PROC TRANSREG reports tests that use both liberal and conservative degrees of freedom to provide lower and upper bounds on the “true”  $p$ -values.

For the UNTIE transformation, the conservative scoring parameter count is the number of distinct observations, whereas the liberal scoring parameter count is the number of scoring parameter estimates that are different, minus 1 for the intercept. Hence, when you specify UNTIE, conservative tests have zero error degrees of freedom unless there are replicated observations.

For MSPLINE variables of DEGREE= $n$  and NKNOTS= $k$ , the conservative scoring parameter count is  $n + k$ , whereas the liberal parameter count is the number of scoring parameter estimates that are different, minus 1 for the intercept. A liberal degrees of freedom of 1 does not necessarily imply a linear transformation. It implies only that  $n$  plus  $k$  minus the number of ties imposed equals 1. An example of a one-degree-of-freedom nonlinear transformation is a two-piece linear transformation in which the slope of one piece is 0.

The number of scoring parameters is determined during each iteration. After the last iteration, enough information is available for the TEST *a-option* to produce an ANOVA table that reports the overall fit of the model. If you specify the SS2 *a-option*, further iterations are necessary to test the contribution of each transformation to the overall model.

The liberal tests do not compensate for overparameterization. For example, requesting a spline transformation with  $k$  knots when a linear transformation will suffice results in “liberal” tests that are actually conservative because too many degrees of freedom are being used for the transformations. To avoid this problem, use as few knots as possible.

In ordinary multiple regression, an  $F$  test of the null hypothesis that the coefficient for variable  $x_j$  is zero can be constructed by comparing two linear models. One model is the full model with all parameters, and the other is a reduced model that has all parameters except the parameter for variable  $x_j$ . The difference between the model sum of squares for the full model and the model sum of squares for the reduced model is the Type II sum of squares for the test of the null hypothesis that the coefficient for variable  $x_j$  is 0. The numerator of the  $F$  test has one degree of freedom. The mean square error for the full model is the denominator of the

$F$  test of variable  $x_j$ . Note that the estimates of the coefficients for the two models are not usually the same. When variable  $x_j$  is removed, the coefficients for the other variables change to compensate for the removal of  $x_j$ . In a transformation regression model, the transformations of the other variables must be permitted to change and the numerator degrees of freedom are not always ones. It is not correct to simply let the model coefficients for the transformed variables change and apply the new model coefficients to the old transformations computed with the old scoring parameter estimates. In a transformation regression model, further iteration is needed to test each transformation, because all the scoring parameter estimates for other variables must be permitted to change to test the effect of variable  $x_j$ . This can be quite time-consuming for a large model if the *SOLVE a-option* cannot be used to solve directly for the transformations.

---

## Output Data Set

The OUT= output data set can contain a great deal of information; however, in most cases, the output data set contains a small portion of the entire range of available information.

### Output Data Set Examples

This section provides three brief examples, illustrating some typical OUT= output data sets. See the section “Output Data Set Contents” on page 8310 for a complete list of the contents of the OUT= data set.

The first example shows the output data set from a two-way ANOVA model. The following statements produce Figure 97.65:

The `_TYPE_` variable indicates observation type: score, multiple regression coefficient (parameter estimates), and marginal means. The `_NAME_` variable contains the default observation labels, “ROW1”, “ROW2”, and so on, and contains the dependent variable name (y) for the remaining observations. If you specify an `ID` statement, `_NAME_` contains the values of the first ID variable for score observations. The y variable is the dependent variable, Py contains the predicted values, Ry contains the residuals, and the variables Intercept through x1ax2a contain the design matrix. The x1 and x2 variables are the original CLASS variables.

The next example shows the contents of the output data set from fitting a curve through a scatter plot. The following statements produce [Figure 97.66](#):

```

title 'Output Data Set for Curve Fitting Example';

data a;
 do x = 1 to 100;
 y = log(x) + sin(x / 10) + normal(7);
 output;
 end;
run;

proc transreg;
 model identity(y) = spline(x / nknots=9);
 output predicted out=b;
run;

proc contents position;
 ods select position;
run;

```

**Figure 97.66** Predicted Values Example Output Data Set Contents

| 4                                         | Ty            | Num  | 8   | y Transformation         |
| 5                                         | Py            | Num  | 8   | y Predicted Values       |
| 6                                         | Intercept     | Num  | 8   | Intercept                |
| 7                                         | x             | Num  | 8   |                          |
| 8                                         | TIntercept    | Num  | 8   | Intercept Transformation |
| 9                                         | Tx            | Num  | 8   | x Transformation         |

The `OUT=` data set contains `_TYPE_` and `_NAME_` variables. Since no coefficients or coordinates are requested, all observations are `_TYPE_='SCORE'`. The `y` variable is the original dependent variable, `Ty` is the transformed dependent variable, `Py` contains the predicted values, `x` is the original independent variable, and `Tx` is the transformed independent variable. The data set also contains an `Intercept` and transformed intercept `TIntercept` variable. (In this case, the transformed intercept is the same as the intercept. However, if you specify the `TSTANDARD=` and `ADDITIVE` options, these are not always the same.)

The following example shows the results from specifying `METHOD=MORALS` when there is more than one dependent variable:

```
title 'METHOD=MORALS Output Data Set Example';

data x;
 input y1 y2 x1 $ x2 $;
 datalines;
11 1 a a
10 4 b a
 5 2 a b
 5 9 b b
 4 3 c c
 3 6 b a
 1 8 a b
;

* Fit Reference Cell Two-Way ANOVA Model;
proc transreg data=x noprint solve;
 model spline(y1 y2) = opscore(x1 x2 / name=(n1 n2));
 output coefficients predicted residuals;
 id x1 x2;
run;

* Print the Results;
proc print;
run;

proc contents position;
 ods select position;
run;
```

These statements produce [Figure 97.67](#).

If you specify **METHOD=MORALS** with multiple dependent variables, PROC TRANSREG performs separate univariate analyses and stacks the results in the **OUT=** data set. For this example, the results of the first analysis are in the partition designated by **\_DEPVAR\_='Spline(y1)'** and the results of the second analysis are in the partition designated by **\_DEPVAR\_='Spline(y2)'**, which are the transformation and dependent variable names. Each partition has **\_TYPE\_='SCORE'** observations for the variables and a **\_TYPE\_='M COEFFI'** observation for the coefficients. In this example, an **ID** variable is specified, so the **\_NAME\_** variable contains the formatted values of the first **ID** variable. Since both dependent variables have to go into the same column, the dependent variable is given a new name, **\_DEPEND\_**. The dependent variable transformation is named **T\_DEPEND\_**, the predicted values variable is named **P\_DEPEND\_**, and the residuals variable is named **R\_DEPEND\_**.

The independent variables are character **OPSCORE** variables. By default, PROC TRANSREG replaces character **OPSCORE** variables with category numbers and discards the original character variables. To avoid this, the input variables are renamed from **x1** and **x2** to **n1** and **n2** and the original **x1** and **x2** are added to the data set as **ID** variables. The **n1** and **n2** variables contain the initial values for the **OPSCORE** transformations, and the **Tn1** and **Tn2** variables contain optimal scores. The data set also contains an **Intercept** and transformed intercept **TIntercept** variable. The regression coefficients are in the transformation columns, which also contain the variables to which they apply.

## Output Data Set Contents

Table 97.7 summarizes the various matrices that can result from PROC TRANSREG processing and that appear in the **OUT=** data set. The exact contents of an **OUT=** data set depends on many options.

**Table 97.7** PROC TRANSREG OUT= Data Set Contents

| <b>_TYPE_</b> | <b>Contents</b>                        | <b>Options, Default Prefix</b>       |
|---------------|----------------------------------------|--------------------------------------|
| SCORE         | dependent variables                    | DREPLACE not specified               |
| SCORE         | independent variables                  | IREPLACE not specified               |
| SCORE         | transformed dependent variables        | default, TDPREFIX=T                  |
| SCORE         | transformed independent variables      | default, TIPREFIX=T                  |
| SCORE         | predicted values                       | PREDICTED, PPREFIX=P                 |
| SCORE         | residuals                              | RESIDUALS, RDPREFIX=R                |
| SCORE         | leverage                               | LEVERAGE, LEVERAGE=Leverage          |

| SCORE         | independent variables approximations   | IAPPROXIMATIONS, AIPREFIX=A          |
| M COEFFI      | multiple regression coefficients       | COEFFICIENTS, MRC                    |
| C COEFFI      | canonical coefficients                 | COEFFICIENTS, CCC                    |
| MEAN          | marginal means                         | COEFFICIENTS, MEANS                  |
| M REDUND      | multiple redundancy coefficients       | MREDUNDANCY                          |
| R REDUND      | multiple redundancy coefficients       | MREDUNDANCY                          |
| M POINT       | point coordinates                      | COORDINATES or MPC, POINT            |
| M EPOINT      | elliptical point coordinates           | COORDINATES or MEC, EPOINT           |
| M QPOINT      | quadratic point coordinates            | COORDINATES or MQC, QPOINT           |
| C POINT       | canonical point coordinates            | COORDINATES or CPC, POINT            |
| C EPOINT      | canonical elliptical point coordinates | COORDINATES or CEC, EPOINT           |
| C QPOINT      | canonical quadratic point coordinates  | COORDINATES or CQC, QPOINT           |

The independent and dependent variables are created from the original input data. Several potential differences exist between these variables and the actual input data. An intercept variable can be added, new variables can be added for POINT, EPOINT, QPOINT, CLASS, IDENTITY, PSPLINE, and BSPLINE variables, and category numbers are substituted for character OPSCORE variables. These matrices are not always what is input to the first iteration. After the expanded data set is stored for inclusion in the output data set, several things happen to the data before they are input to the first iteration: column means are substituted for missing values; zero-degree SPLINE and MSPLINE variables are transformed so that the iterative algorithms get step-function data as input, which conform to the zero-degree transformation family restrictions; and the nonoptimal transformations are performed.

**Details for the UNIVARIATE Method**

When you specify `METHOD=UNIVARIATE` (in the `MODEL` or `PROC TRANSREG` statement), `PROC TRANSREG` can perform several analyses, one for each dependent variable. While each dependent variable can be transformed, their independent variables are not transformed. The `OUT=` data set optionally contains all of the `_TYPE_='SCORE'` observations, optionally followed by coefficients or coordinates.

**Details for the MORALS Method**

When you specify `METHOD=MORALS` (in the `MODEL` or `PROC TRANSREG` statement), successive analyses are performed, one for each dependent variable. Each analysis transforms one dependent variable and the entire set of the independent variables. All information for the first dependent variable (scores then, optionally, coefficients) appears first. Then all information for the second dependent variable (scores then, optionally, coefficients) appears next. This arrangement is repeated for all dependent variables.

**Details for the CANALS and REDUNDANCY Methods**

For `METHOD=CANALS` and `METHOD=REDUNDANCY` (specified in either the `MODEL` or `PROC TRANSREG` statement), one analysis is performed that simultaneously transforms all dependent and independent variables. The `OUT=` data set optionally contains all of the `_TYPE_='SCORE'` observations, optionally followed by coefficients or coordinates.

**Variable Names**

As shown in the preceding examples, some variables in the output data set directly correspond to input variables, and some are created. All original optimal and nonoptimal transformation variable names are unchanged.

The names of the `POINT`, `QPOINT`, and `EPOINT` expansion variables are also left unchanged, but new variables are created. When independent `POINT` variables are present, the sum-of-squares variable `_ISSQ_` is added to the output data set. For each `EPOINT` and `QPOINT` variable, a new squared variable is created by appending “\_2”. For example, `Dim1` and `Dim2` are expanded into `Dim1`, `Dim2`, `Dim1_2`, and `Dim2_2`. In addition, for each pair of `QPOINT` variables, a new crossproduct variable is created by combining the two names—for example, `Dim1Dim2`.

The names of the `CLASS` variables are constructed from original variable names and levels. Lengths are controlled by the `CPREFIX= a-option`. For example, when `x1` and `x2` both have values of 'a' and 'b', `CLASS(x1 | x2 / ZERO=NONE)` creates `x1` main-effect variable names `x1a` `x1b`, `x2` main-effect variable names `x2a` `x2b`, and interaction variable names `x1ax2a` `x1ax2b` `x1bx2a` `x1bx2b`.

`PROC TRANSREG` then uses these variable names when creating the transformed, predicted, and residual variable names by affixing the relevant prefix and dropping extra characters if necessary.

**METHOD=MORALS Variable Names**

When you specify `METHOD=MORALS` and only one dependent variable is present, the output data set is structured exactly as if `METHOD=REDUNDANCY` (see the section “[Details for the CANALS and REDUNDANCY Methods](#)” on page 8312). When more than one dependent variable is present, the dependent variables are output in the variable `_DEPEND_`, transformed dependent variables are output in the variable `T_DEPEND_`, predicted values are output in the variable `P_DEPEND_`, and residuals are output in the variable `R_DEPEND_`. You can partition the data set into `BY` groups, one per dependent variable, by referring to the character variable `_DEPVAR_`, which contains the original dependent variable names and transformations.

**Duplicate Variable Names**

When the same name is generated from multiple variables in the **OUT=** data set, new names are created by appending '2', '3', or '4', and so on, until a unique name is created. For 32-character names, the last character is replaced with a numeric suffix until a unique name is created. For example, if there are two output variables that otherwise would be named *x*, then *x* and *x2* are created instead. If there are two output variables that otherwise would be named *ThisIsAThirtyTwoCharacterVarName*, then *ThisIsAThirtyTwoCharacterVarName* and *ThisIsAThirtyTwoCharacterVarNam2* are created instead.

**OUTTEST= Output Data Set**

The **OUTTEST=** data set contains hypothesis test results. The **OUTTEST=** data set always contains ANOVA results. When you specify the **SS2** *a-option*, regression tables are also output. When you specify the **UTILITIES** *a-option*, conjoint analysis part-worth utilities are also output. The **OUTTEST=** data set has the following variables:

|                    |                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>_DEPVAR_</b>    | is a 42-character variable that contains the dependent variable transformation and name.                                                                                                                                                                                                                                                                                                            |
| <b>_TYPE_</b>      | is an 8-character variable that contains the table type. The first character is “U” for univariate or “M” for multivariate. The second character is blank. The third character is “A” for ANOVA, “2” for Type II sum of squares, or “U” for <b>UTILITIES</b> . The fourth character is blank. The fifth character is “L” for liberal tests, “C” for conservative tests, or “U” for the usual tests. |
| <b>Title</b>       | is an 80-character variable that contains the table title.                                                                                                                                                                                                                                                                                                                                          |
| <b>Variable</b>    | is a 42-character variable that contains the independent variable transformations and names for regression tables and blanks for ANOVA tables.                                                                                                                                                                                                                                                      |
| <b>Coefficient</b> | contains the multiple regression coefficients for regression tables and underscore special missing values for ANOVA tables.                                                                                                                                                                                                                                                                         |
| <b>Statistic</b>   | is a 24-character variable that contains the names for statistics in other variables, such as <b>Value</b> .                                                                                                                                                                                                                                                                                        |
| <b>Value</b>       | contains multivariate test statistics and all other information that does not fit in one of the other columns including R square, dependent mean, adjusted R square, and coefficient of variation. Whenever <b>Value</b> is not an underscore special missing value, the <b>Statistic</b> variable describes the contents of the <b>Value</b> variable.                                             |
| <b>NumDF</b>       | contains numerator degrees of freedom for <i>F</i> tests.                                                                                                                                                                                                                                                                                                                                           |
| <b>DenDF</b>       | contains denominator degrees of freedom for <i>F</i> tests.                                                                                                                                                                                                                                                                                                                                         |
| <b>SSq</b>         | contains sums of squares.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>MeanSquare</b>  | contains mean squares.                                                                                                                                                                                                                                                                                                                                                                              |
| <b>F</b>           | contains <i>F</i> statistics.                                                                                                                                                                                                                                                                                                                                                                       |
| <b>NumericP</b>    | contains the <i>p</i> -value for the <i>F</i> statistic, stored in a numeric variable.                                                                                                                                                                                                                                                                                                              |
| <b>P</b>           | is a 9-character variable that contains the formatted <i>p</i> -value for the <i>F</i> statistic, including the appropriate ~, <=, >=, or blank symbols.                                                                                                                                                                                                                                            |
| <b>LowerLimit</b>  | contains lower confidence limits on the parameter estimates.                                                                                                                                                                                                                                                                                                                                        |

|            |                                                                                                                                                   |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| UpperLimit | contains upper confidence limits on the parameter estimates.                                                                                      |
| StdError   | contains standard errors. For <b>SS2</b> and <b>UTILITIES</b> tables, standard errors are output for each coefficient with one degree of freedom. |
| Importance | contains the relative importance of each factor for <b>UTILITIES</b> tables.                                                                      |
| Label      | is a 256-character variable that contains variable labels.                                                                                        |

There are several possible tables in the **OUTTEST=** data set corresponding to combinations of univariate and multivariate tests; ANOVA and regression results; and liberal, conservative, and the usual tests. Each table is composed of only a subset of the variables. Numeric variables contain underscore special missing values when they are not a column in a table. Ordinary missing values (.) appear in variables that are part of a table when a nonmissing value cannot be produced. For example, the *F* is missing for a test with zero degrees of freedom.

---

## Computational Resources

This section provides information about the computational resources required to use PROC TRANSREG.

Let

- $n$  = number of observations
- $q$  = number of expanded independent variables
- $r$  = number of expanded dependent variables
- $k$  = maximum spline degree
- $p$  = maximum number of knots

More than  $56(q + r)$  plus the maximum of the data matrix size, the optimal scaling work space, and the covariance matrix size bytes of array space are required. The data matrix size is  $8n(q + r)$  bytes. The optimal scaling work space requires less than  $8(6n + (p + k + 2)(p + k + 11))$  bytes. The covariance matrix size is  $4(q + r)(q + r + 1)$  bytes.

PROC TRANSREG tries to store the original and transformed data in memory. If there is not enough memory, a utility data set is used, potentially resulting in a large increase in execution time. The amount of memory for the preceding data formulas is an underestimate of the amount of memory needed to handle most problems. These formulas give the absolute minimum amount of memory required. If a utility data set is used, and if memory can be used with perfect efficiency, then roughly the amount of memory stated previously is needed. In reality, most problems require at least two or three times the minimum.

PROC TRANSREG sorts the data once. The sort time is roughly proportional to  $(q + r)n^{3/2}$ .

One regression analysis per iteration is required to compute model parameters (or two canonical correlation analyses per iteration for **METHOD=CANALS**). The time required to accumulate the crossproducts matrix is roughly proportional to  $n(q + r)^2$ . The time required to compute the regression coefficients is roughly proportional to  $q^3$ .

Each optimal scaling is a multiple regression problem, although some transformations are handled with faster special-case algorithms. The number of regressors for the optimal scaling problems depends on the

original values of the variable and the type of transformation. For each monotone spline transformation, an unknown number of multiple regressions is required to find a set of coefficients that satisfies the constraints. The B-spline basis is generated twice for each `SPLINE` and `MSPLINE` transformation for each iteration. The time required to generate the B-spline basis is roughly proportional to  $nk^2$ .

---

## Unbalanced ANOVA without CLASS Variables

This section illustrates that an analysis of variance model can be formulated as a simple regression model with optimal scoring. The purpose of the example is to explain one aspect of how PROC TRANSREG works, not to propose an alternative way of performing an analysis of variance.

Finding the overall fit of a large, unbalanced analysis of variance model can be handled as an optimal scoring problem without creating large, sparse design matrices. For example, consider an unbalanced full main-effects and interactions ANOVA model with six factors. Assume that a SAS data set is created with factor-level indicator variables `c1` through `c6` and dependent variable `y`. If each factor level consists of nonblank single characters, you can create a cell indicator in a DATA step with the statement as follows:

```
x=compress(c1||c2||c3||c4||c5||c6);
```

The following statements optimally score `x` (by using the `OPSCORE` transformation) and do not transform `y`:

```
proc transreg;
 model identity(y)=opscore(x);
 output;
run;
```

The final R square reported is the R square for the full analysis of variance model. This R square is the same R square that would be reported by both of the following PROC GLM steps:

```
proc glm;
 class x;
 model y=x;
run;

proc glm;
 class c1-c6;
 model y=c1|c2|c3|c4|c5|c6;
run;
```

PROC TRANSREG optimally scores the classes of `x`, within the space of a single variable with values linearly related to the cell means, so the full ANOVA problem is reduced to a simple regression problem with an optimal independent variable. PROC TRANSREG requires only one iteration to find the optimal scoring of `x` but, by default, performs a second iteration, which reports no data changes.

## Hypothesis Tests for Simple Univariate Models

If the dependent variable has one parameter (`IDENTITY`, `LINEAR` with no missing values, and so on) and if there are no monotonicity constraints, PROC TRANSREG fits univariate models, which can also be fit with a DATA step and PROC REG. This is illustrated with the following artificial data set:

```
data htex;
 do i = 0.5 to 10 by 0.5;
 x1 = log(i);
 x2 = sqrt(i) + sin(i);
 x3 = 0.05 * i * i + cos(i);
 y = x1 - x2 + x3 + 3 * normal(7);
 x1 = x1 + normal(7);
 x2 = x2 + normal(7);
 x3 = x3 + normal(7);
 output;
 end;
run;
```

Both PROC TRANSREG and PROC REG are run to fit the same polynomial regression model as follows:

```
proc transreg data=htex ss2 short;
 title 'Fit a Polynomial Regression Model with PROC TRANSREG';
 model identity(y) = spline(x1);
run;

data htex2;
 set htex;
 x1_1 = x1;
 x1_2 = x1 * x1;
 x1_3 = x1 * x1 * x1;
run;

proc reg;
 title 'Fit a Polynomial Regression Model with PROC REG';
 model y = x1_1 - x1_3;
run; quit;
```

The ANOVA and regression tables from PROC TRANSREG are displayed in [Figure 97.68](#). The ANOVA and regression tables from PROC REG are displayed in [Figure 97.69](#). The `SHORT` *a-option* is specified with PROC TRANSREG to suppress the iteration history.

The PROC TRANSREG regression table differs in several important ways from the parameter estimate table produced by PROC REG. The REG procedure displays standard errors and  $t$  statistics. PROC TRANSREG displays Type II sums of squares, mean squares, and  $F$  statistics. The difference is because the numerator degrees of freedom are not always 1, so  $t$  tests are not uniformly appropriate. When the degrees of freedom for variable  $x_j$  is 1, the following relationships hold between the standard errors ( $s_{\beta_j}$ ) and the Type II sums of squares ( $SS_j$ ):

$$s_{\beta_j} = (\hat{\beta}_j^2 / F_j)^{1/2}$$

and

$$SS_j = \hat{\beta}_j^2 \times \text{MSE} / s_{\beta_j}^2$$

PROC TRANSREG does not provide tests of the individual terms that go into the transformation. (However, it could if **BSPLINE** or **PSPLINE** had been specified instead of **SPLINE**.) The test of **spline(x1)** is the same as the test of the overall model. The intercepts are different due to the different numbers of variables and their standardizations.

In the next example, both  $x_1$  and  $x_2$  are transformed in the first PROC TRANSREG step, and PROC TRANSREG is used instead of a DATA step to create the polynomials for PROC REG. Both PROC TRANSREG and PROC REG fit the same polynomial regression model. The following statements run PROC TRANSREG and PROC REG and produce Figure 97.70 and Figure 97.71:

```

title 'Two-Variable Polynomial Regression';

proc transreg data=htex ss2 solve;
 model identity(y) = spline(x1 x2);
run;

proc transreg noprint data=htex maxiter=0;
 /* Use PROC TRANSREG to prepare input to PROC REG */
 model identity(y) = pspline(x1 x2);
 output out=htex2;
run;

proc reg data=htex2;
 model y = x1_1-x1_3 x2_1-x2_3;
 test x1_1, x1_2, x1_3;
 test x2_1, x2_2, x2_3;
run; quit;

```

Univariate Regression Table Based on the Usual Degrees of Freedom

| Variable   | DF | Coefficient | Type II Sum of Squares | Mean Square | F Value | Pr > F |
|------------|----|-------------|------------------------|-------------|---------|--------|
| Intercept  | 1  | 3.5437125   | 35.2282                | 35.2282     | 2.47    | 0.1400 |
| Spline(x1) | 3  | 0.3644562   | 4.5682                 | 1.5227      | 0.11    | 0.9546 |
| Spline(x2) | 3  | -1.3551738  | 32.9112                | 10.9704     | 0.77    | 0.5315 |

There are three iteration histories: one for the overall model and two for the two independent variables. The first PROC TRANSREG iteration history shows the R square of 0.17287 for the fit of the overall model. The second is for the following model:

```
model identity(y) = spline(x2);
```

This model excludes `spline(x1)`. The third iteration history is for the following model:

```
model identity(y) = spline(x1);
```

This model excludes `spline(x2)`. The difference between the first and second R square times the total sum of squares is the model sum of squares for `spline(x1)`:

$$(0.17287 - 0.15249) \times 224.143800 = 4.568165$$

The difference between the first and third R square times the total sum of squares is the model sum of squares for `spline(x2)`:

$$(0.17287 - 0.02604) \times 224.143800 = 32.911247$$

Figure 97.71 displays the PROC REG results. The TEST statement in PROC REG tests the null hypothesis that the vector of parameters for `x1_1 x1_2 x1_3` is zero. This is the same test as the `spline(x1)` test used by PROC TRANSREG. Similarly, the PROC REG test that the vector of parameters for `x2_1 x2_2 x2_3` is zero is the same as the PROC TRANSREG `SPLINE(x2)` test. So for models with no monotonicity constraints and no dependent variable transformations, PROC TRANSREG provides little more than a different packaging of standard least squares methodology.

## Hypothesis Tests with Monotonicity Constraints

Now consider a model with monotonicity constraints. This model has no counterpart in PROC REG. The following statements fit a monotone-spline model and produce Figure 97.72:

```

title 'Monotone Splines';

proc transreg data=htex ss2 short;
 model identity(y) = mspline(x1-x3 / nknots=3);
run;

```

The *SHORT a-option* is specified to suppress the iteration histories. Two ANOVA tables are displayed—one by using liberal degrees of freedom and one by using conservative degrees of freedom. All sums of squares and the R squares are the same for both tables. What differs are the degrees of freedom and statistics that use degrees of freedom. The liberal test has 8 model degrees of freedom and 11 error degrees of freedom, whereas the conservative test has 15 model degrees of freedom and only 4 error degrees of freedom. The “true” *p*-value is between 0.8462 and 0.9997, so clearly you would fail to reject the null hypothesis. Unfortunately, results are not always this clear. (See Figure 97.72.)

## Hypothesis Tests with Dependent Variable Transformations

PROC TRANSREG can also provide approximate tests of hypotheses when the dependent variable is transformed, but the output is more complicated. When a dependent variable has more than one degree of freedom, the problem becomes multivariate. Hypothesis tests are performed in the context of a multivariate linear model with the number of dependent variables equal to the number of scoring parameters for the dependent variable transformation. The transformation regression model with a dependent variable transformation differs from the usual multivariate linear model in two important ways. First, the usual assumption of multivariate normality is always violated. This fact is simply ignored. This is one reason why all hypothesis tests in the presence of a dependent variable transformation should be considered approximate at best. Multivariate normality is assumed even though it is known that the assumption is violated.

The second difference concerns the usual multivariate test statistics: Pillai's trace, Wilks' lambda, Hotelling-Lawley trace, and Roy's greatest root. The first three statistics are defined in terms of all the squared canonical correlations. Here, there is only one linear combination (the transformation), and hence only one squared canonical correlation of interest, which is equal to the R square. It might seem that Roy's greatest root, which uses only the largest squared canonical correlation, is the only statistic of interest. Unfortunately, Roy's greatest root is very liberal and provides only a lower bound on the  $p$ -value. Approximate upper bounds are provided by adjusting the other three statistics for the one linear combination case. Wilks' lambda, Pillai's trace, and Hotelling-Lawley trace are a conservative adjustment of the usual statistics.

These statistics are normally defined in terms of the squared canonical correlations, which are the eigenvalues of the matrix  $\mathbf{H}(\mathbf{H} + \mathbf{E})^{-1}$ , where  $\mathbf{H}$  is the hypothesis sum-of-squares matrix and  $\mathbf{E}$  is the error sum-of-squares matrix. Here the R square is used for the first eigenvalue, and all other eigenvalues are set to 0 since only one linear combination is used. Degrees of freedom are computed assuming that all linear

combinations contribute to the lambda and trace statistics, so the  $F$  tests for those statistics are conservative. The  $p$ -values for the liberal and conservative statistics provide approximate lower and upper bounds on  $p$ . In practice, the adjusted Pillai's trace is very conservative—perhaps too conservative to be useful. Wilks' lambda is less conservative, and the Hotelling-Lawley trace seems to be the least conservative. The conservative statistics and the liberal Roy's greatest root provide a bound on the true  $p$ -value. Unfortunately, they sometimes report a bound of 0.0001 and 1.0000.

The following example has a dependent variable transformation and produces [Figure 97.73](#):

```
title 'Transform Dependent and Independent Variables';

proc transreg data=htex ss2 solve short;
 model spline(y) = spline(x1-x3);
run;
```

The univariate results match Roy's greatest root results. Clearly, the proper action is to fail to reject the null hypothesis. However, as stated previously, results are not always this clear.

The Wilks' Lambda, Pillai's Trace, and Hotelling-Lawley Trace statistics are a conservative adjustment of the normal statistics. Roy's Greatest Root is liberal. These statistics are normally defined in terms of the squared canonical correlations which are the eigenvalues of the matrix  $H \cdot \text{inv}(H+E)$ . Here the R-Square is used for the first eigenvalue and all other eigenvalues are set to zero since only one linear combination is used. Degrees of freedom are computed assuming all linear combinations contribute to the Lambda and Trace statistics, so the F tests for those statistics are conservative. The p values for the liberal and conservative statistics provide approximate lower and upper bounds on p. A liberal test statistic with conservative degrees of freedom and a conservative test statistic with liberal degrees of freedom yield at best an approximate p value, which is indicated by a "~" before the p value.

These statistics are adjusted in the same way as the multivariate statistics above.

## Hypothesis Tests with One-Way ANOVA

One-way ANOVA models are fit with either an explicit or implicit intercept. In implicit intercept models, the ANOVA table of PROC TRANSREG is the correct table for a model with an intercept, and the regression table is the correct table for a model that does not have a separate explicit intercept. The PROC TRANSREG implicit intercept ANOVA table matches the PROC REG table when the NOINT *a-option* is not specified, and the PROC TRANSREG implicit intercept regression table matches the PROC REG table when the NOINT *a-option* is specified. The following statements illustrate this relationship and produce Figure 97.74:

```

Figure 97.74 continued

NOTE: Model is not full rank. Least-squares solutions for the parameters are not unique. Some statistics will be misleading. A reported DF of 0 or B means that the estimate is biased.

NOTE: The following parameters have been set to 0, since the variables are a linear combination of other variables as shown.

$$xc = \text{Intercept} - xa - xb$$

Parameter Estimates

| Variable  | Label     | DF | Parameter Estimate | Standard Error | t Value | Pr >  t |

## Using the DESIGN Output Option

This example uses PROC TRANSREG and the DESIGN *o-option* to prepare an input data set with classification variables for the LOGISTIC procedure. The DESIGN *o-option* specifies that the goal is design matrix creation, not analysis. When you specify DESIGN, dependent variables are not required. The DEVIATIONS (or EFFECTS) *t-option* requests a deviations-from-means (1, 0, -1) coding of the classification variables, which is the same coding the CATMOD procedure uses. PROC TRANSREG automatically creates a macro variable `&_TrgInd` that contains the list of independent variables created. This macro is used in the PROC LOGISTIC MODEL statement. (See Figure 97.75.) For comparison, the same analysis is also performed with PROC CATMOD. The following statements create Figure 97.75:

```

title 'Using PROC TRANSREG to Create a Design Matrix';

data a;
 do y = 1, 2;
 do a = 1 to 4;
 do b = 1 to 3;
 w = ceil(uniform(1) * 10 + 10);
 output;
 end;
 end;
 end;
run;

proc transreg data=a design;
 model class(a b / deviations);
 id y w;
 output out=coded;
run;

proc print;
 title2 'PROC TRANSREG Output Data Set';
run;

title2 'PROC LOGISTIC with Classification Variables';

proc logistic;
 freq w;
 model y = &_trgind;
run;

title2 'PROC CATMOD Should Produce the Same Results';

proc catmod data=a;
 model y = a b;
 weight w;
run;

```

## Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO

A discrete choice experiment is constructed consisting of four product brands, each available at three different prices, \$1.49, \$1.99, \$2.49. In addition, each choice set contains a constant “other” alternative available at \$1.49. In the fifth choice set, price is constant. PROC TRANSREG is used to code the design, and the PHREG procedure fits the multinomial logit choice model (not shown). See [http://support.sas.com/resources/papers/tnote/tnote\\_marketresearch.html](http://support.sas.com/resources/papers/tnote/tnote_marketresearch.html) (Kuhfeld 2005) for more information about discrete choice modeling and the multinomial logit model; look for the latest “Discrete Choice” report. The following statements produce Figure 97.76:

```

title 'Choice Model Coding';

data design;
 array p[4];
 input p1-p4 @@;
 set = _n_;
 do brand = 1 to 4;
 price = p[brand];
 output;
 end;
 brand = .; price = 1.49; output; /* constant alternative */
 keep set brand price;
 datalines;

1.99 1.99 1.49 2.49 1.99 2.49 1.99 1.99 1.49 2.49 1.99 2.49
;

proc transreg data=design design norestoremissing nozeroconstant;
 model class(brand / zero=none) identity(price);
 output out=coded;
 by set;
run;

proc print data=coded(firstobs=21 obs=25);
 var set brand &_trgind;
run;

```

In the interest of space, only the fifth choice set is displayed in Figure 97.76.

Figure 97.76 The Fifth Choice Set

| Choice Model Coding |     |       |        |        |        |        |       |
|---------------------|-----|-------|--------|--------|--------|--------|-------|
| Obs                 | set | brand | brand1 | brand2 | brand3 | brand4 | price |
| 21                  | 5   | 1     | 1      | 0      | 0      | 0      | 1.49  |
| 22                  | 5   | 2     | 0      | 1      | 0      | 0      | 1.49  |
| 23                  | 5   | 3     | 0      | 0      | 1      | 0      | 1.49  |
| 24                  | 5   | 4     | 0      | 0      | 0      | 1      | 1.49  |
| 25                  | 5   | .     | 0      | 0      | 0      | 0      | 1.49  |

For the constant alternative (Brand = .), the brand coding is a row of zeros due to the **NORESTOREMISSING** *o-option*, and Price is a constant \$1.49 (instead of 0) due to the **NOZEROCONSTANT**.

The data set was coded by choice set (BY set;). This is a small problem. With very large problems, it might be necessary to restrict the number of observations that are coded at one time so that the procedure uses less time and memory. Coding by choice set is one option. When coding is performed after the data are merged in, coding by subject and choice set combinations is another option. Alternatively, you can specify **DESIGN=n**, where *n* is the number of observations to code at one time. For example, you can specify **DESIGN=100** or **DESIGN=1000** to process the data set in blocks of 100 or 1000 observations. Specify the **NOZEROCONSTANT** *a-option* to ensure that constant variables within blocks are not zeroed. When you specify **DESIGN=n**, or perform coding after the data are merged in, specify the dependent variable and any other variables needed for analysis as **ID** variables.

---

## Centering

You can use transformation options to center and standardize the variables in several ways. For example, the following **MODEL** statement creates three independent variables,  $x$ ,  $x^2$ , and  $x^3$ :

```
model identity(y) = pspline(x);
```

The variables are not centered.

When the **CENTER** *t-option* is specified, as in the following statement, the independent variable is centered before squaring and cubing:

```
model identity(y) = pspline(x / center);
```

The three independent variables are  $x - \bar{x}$ ,  $(x - \bar{x})^2$ , and  $(x - \bar{x})^3$ .

Since operations such as squaring occur after the centering, the resulting variables are not always centered. The **CENTER** *t-option* is particularly useful with polynomials since centering before squaring and cubing can help reduce collinearity and numerical problems. For example, if one of your variables is year, with values all greater than 1900, squaring and cubing without centering first will create variables that are all essentially perfectly correlated.

When the `TSTANDARD=CENTER` *t-option* is specified, as in the following model, the three independent variables are squared and cubed and then centered:

```
model identity(y) = pspline(x / tstandard=center);
```

The three independent variables are  $x - \bar{x}$ ,  $x^2 - \overline{x^2}$ , and  $x^3 - \overline{x^3}$ .

You can specify both the `CENTER` and `TSTANDARD=CENTER` *t-options* to center the variables, then square and cube them, and then center the results, as in the following statement:

```
model identity(y) = pspline(x / center tstandard=center);
```

The three independent variables are  $x - \bar{x}$ ,  $(x - \bar{x})^2 - \overline{(x - \bar{x})^2}$ , and  $(x - \bar{x})^3 - \overline{(x - \bar{x})^3}$ .

## Displayed Output

The display options control the amount of displayed output. The displayed output can contain the following:

- an iteration history and convergence status table (by default when there are iterations)
- an ANOVA table when the `TEST`, `SS2`, or `UTILITIES` *a-option* is specified
- a regression table when the `SS2` *a-option* is specified
- conjoint analysis part-worth utilities when the `UTILITIES` *a-option* is specified
- model details when the `DETAIL` *a-option* is specified
- a multivariate ANOVA table when the dependent variable is transformed and the `TEST` or `SS2` *a-option* is specified
- a multivariate regression table when the dependent variable is transformed and it is specified
- liberal and conservative ANOVA, multivariate ANOVA, regression, and multivariate regression tables when there is a `MONOTONE`, `UNTIE`, or `MSPLINE` transformation and the `TEST` or `SS2` *a-option* is specified

## ODS Table Names

PROC TRANSREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 97.8. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 97.8** ODS Tables Produced by PROC TRANSREG

| ODS Table Name | Description                    | Statement & Option                        |

\*1. Liberal and conservative test tables are produced when a **MONOTONE**, **UNTIE**, or **MSPLINE** transformation is requested.

\*2. Multivariate tables are produced when the dependent variable is iteratively transformed.

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

Some graphs are produced by default; other graphs are produced by using statements and options. You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC TRANSREG generates are listed in Table 97.9, along with the required statements and options.

**Table 97.9** Graphs Produced by PROC TRANSREG

| ODS Graph Name      | Plot Description                                 | Statement & Option                                                                                                      |

## The PLOTS(INTERPOLATE) Option

This section illustrates one use of the PLOTS(INTERPOLATE) option for use with ODS Graphics. The data set has two groups of observations,  $c = 1$  and  $c = 2$ . Each group is sparse, having only five observations, so the plots of the transformations and fit functions are not smooth. A second DATA step adds additional observations to the data set, over the range of  $x$ , with  $y$  missing. These observations do not contribute to the analysis, but they are used in computations of transformed and predicted values. The resulting plots are much smoother in the latter case than in the former. The other results of the analysis are the same. The following statements produce [Figure 97.77](#) and [Figure 97.78](#):

```

title 'Smoother Interpolation with PLOTS(INTERPOLATE)';

data a;
 input c y x;
 output;

1 2 2
1 4 3
1 6 4
1 7 5
2 3 1
2 4 2
2 5 3
2 4 4
2 5 5
;

ods graphics on;

proc transreg data=a plots=(tran fit) ss2;
 model ide(y) = pbs(x) * class(c / zero=none);
run;

data b;
 set a end=eof;
 output;
 if eof then do;
 y = .;
 do x = 1 to 5 by 0.05;
 c = 1; output;
 c = 2; output;
 end;
 end;
run;

proc transreg data=b plots(interpolate)=(tran fit) ss2;
 model ide(y) = pbs(x) * class(c / zero=none);
run;

```

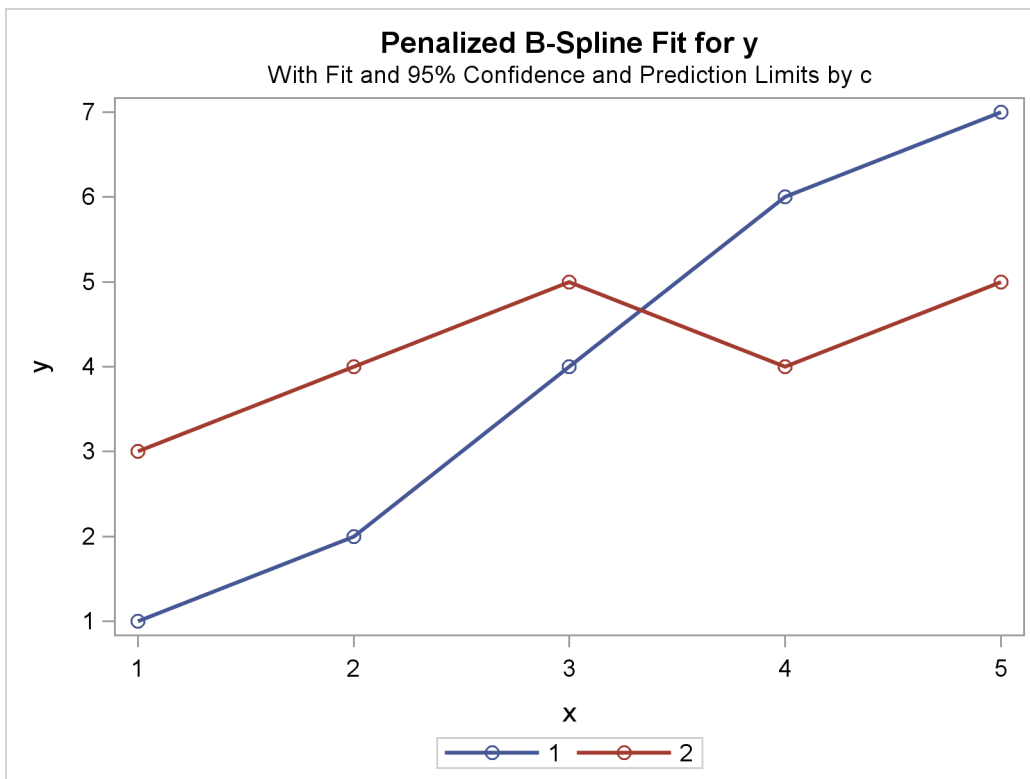

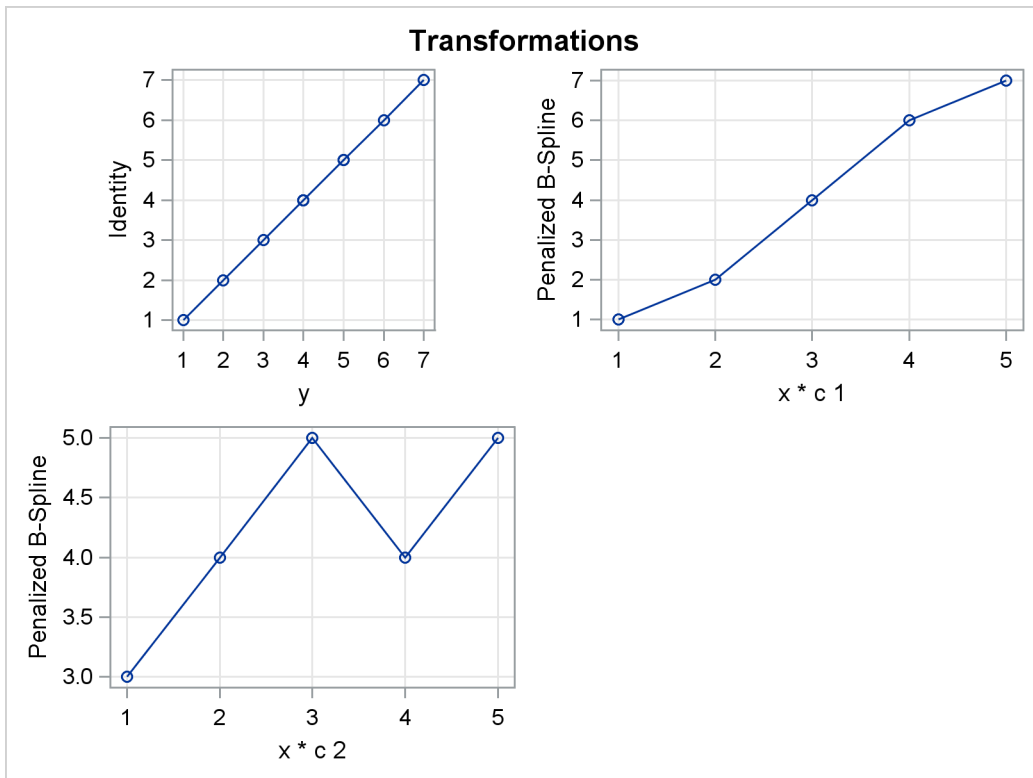

The results with no interpolation are shown in Figure 97.77. The transformation and fit functions are not at all smooth. The results with interpolation are shown in Figure 97.78. The transformation and fit functions are smooth in Figure 97.78, because there are intermediate points to plot.

## Examples: TRANSREG Procedure

### Example 97.1: Transformation Regression of Exhaust Emissions Data

In this example, the data are from an experiment in which nitrogen oxide emissions from a single cylinder engine are measured for various combinations of fuel, compression ratio, and equivalence ratio. The data are provided by Brinkman (1981). This gas data set is available from the Sashelp library.

The equivalence ratio and nitrogen oxide variables are continuous and numeric, so spline transformations of these variables are requested. The spline transformation of the dependent variable is restricted to be monotonic. Each spline is degree three with nine knots (one at each decile) in order to give PROC TRANSREG a great deal of freedom in finding transformations. The compression ratio variable has only five discrete values, so an optimal scoring is requested with monotonicity constraints. The character variable Fuel is nominal, so it is optimally scored without any monotonicity constraints. Observations with missing values are excluded with the *NOMISS a-option*.

```
ods graphics on;

title 'Gasoline Example';
title2 'Iteratively Estimate NOx, CpRatio, EqRatio, and Fuel';

* Fit the Nonparametric Model;
proc transreg data=sashelp.Gas solve test nomiss plots=all;
 ods exclude where=(_path_ ? 'MV');
 model mspline(NOx / nknots=9) = spline(EqRatio / nknots=9)
 monotone(CpRatio) opscore(Fuel);
run;
```

The TRANSREG Procedure Hypothesis Tests for Mspline(NOx)  
Nitrogen Oxide

Univariate ANOVA Table Based on the Usual Degrees of Freedom

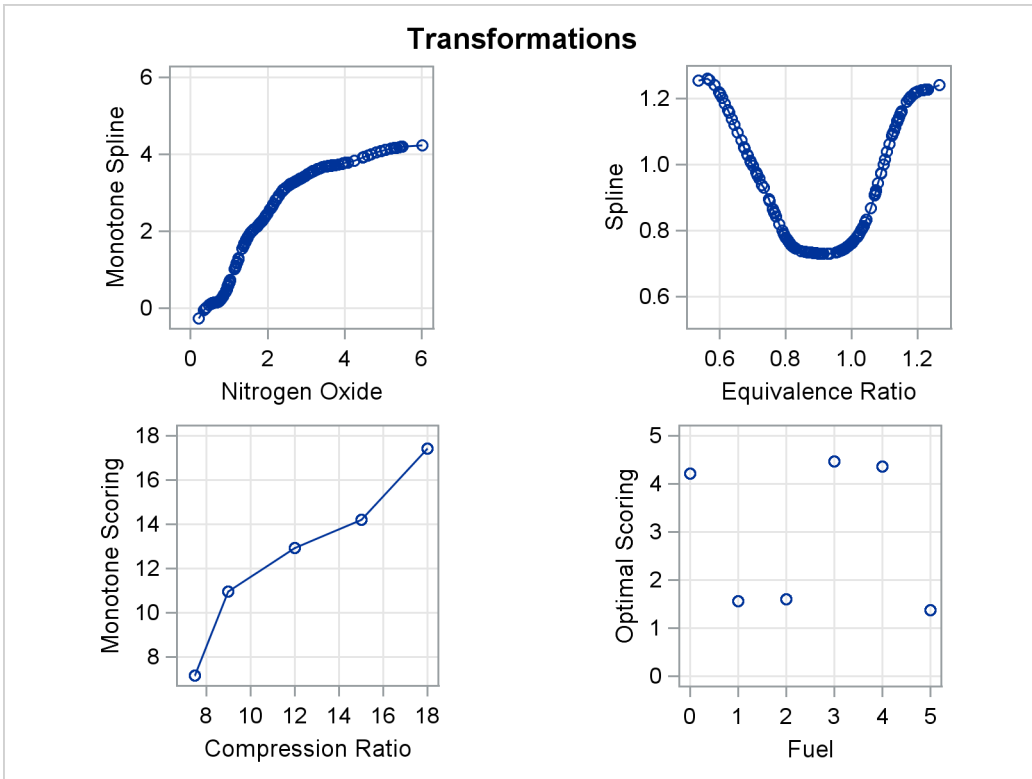

| Source          | DF  | Sum of Squares | Mean Square | F Value | Liberal p |
|-----------------|-----|----------------|-------------|---------|-----------|
| Model           | 21  | 326.0176       | 15.52465    | 161.35  | >= <.0001 |
| Error           | 147 | 14.1443        | 0.09622     |         |           |
| Corrected Total | 168 | 340.1619       |             |         |           |

The above statistics are not adjusted for the fact that the dependent variable was transformed and so are generally liberal.

Output 97.1.1 continued

## Output 97.1.1 continued

The squared multiple correlation for the initial model is approximately 0.05. PROC TRANSREG increases the R square to over 0.95 by transforming the variables. The transformation plots show how each variable is transformed. The transformation of compression ratio (TCpRatio) is nearly linear. The transformation of equivalence ratio (TEqRatio) is nearly parabolic. It can be seen from this plot that the optimal transformation of equivalence ratio is nearly uncorrelated with the original scoring. This suggests that the large increase in R square is due to this transformation. The transformation of nitrogen oxide (TNOx) is similar to a log transformation. The final plot shows the transformed dependent variable plotted as a function of the predicted values. This plot is reasonably linear, showing that the nonlinearities in the data are being accounted for fairly well by the TRANSREG model.

These results suggest the parametric model

$$\log(\text{NOx}) = b_0 + b_1 \times \text{EqRatio} + b_2 \times \text{EqRatio}^2 + b_3 \times \text{CpRatio} \\ + \sum_j b_j \text{class}_j(\text{Fuel}) + \text{error}$$

You can perform this analysis with PROC TRANSREG. The following statements produce [Output 97.1.2](#):

```

title2 'Now fit log(NOx) = b0 + b1*EqRatio + b2*EqRatio**2 +';
title3 'b3*CpRatio + Sum b(j)*Fuel(j) + Error';

*-Fit the Parametric Model Suggested by the Nonparametric Analysis-;
proc transreg data=sashelp.Gas solve ss2 short nomiss plots=all;
 model log(NOx) = pspline(EqRatio / deg=2) identity(CpRatio)
 opscore(Fuel);
run;

```

Output 97.1.2 continued

Output 97.1.2 *continued*

The **LOG** transformation computes the natural log. The **PSPLINE** expansion expands EqRatio into a linear term, EqRatio, and a squared term, EqRatio<sup>2</sup>. An identity transformation of CpRatio and an optimal scoring of Fuel is requested. These should provide a good parametric operationalization of the optimal transformations. The final model has an R square of 0.91 (smaller than before since the model has fewer parameters, but still quite good).

---

## Example 97.2: Box-Cox Transformations

This example shows Box-Cox transformations with a yarn failure data set. For more information about Box-Cox transformations, including using a Box-Cox transformation in a model with no independent variable, to normalize the distribution of the data, see the section “Box-Cox Transformations” on page 8222. In this example, a simple 3<sup>3</sup> design was used to study the effects of different factors on the failure of a yarn manufacturing process. The design factors are as follows:

- the length of test specimens of yarn, with levels of 250, 300, and 350 mm
- the amplitude of the loading cycle, with levels of 8, 9, and 10 mmd
- the load with levels of 40, 45, and 50 grams

The measured response was time (in cycles) until failure. However, you could just as well have measured the inverse of time until failure (in other words, the failure rate). Hence, the correct metric with which to analyze the response is not apparent. You can use PROC TRANSREG to find an optimum power transformation for the analysis. The following statements create the input SAS data set:

```

title 'Yarn Strength';

proc format;
 value a -1 = 8 0 = 9 1 = 10;
 value l -1 = 250 0 = 300 1 = 350;
 value o -1 = 40 0 = 45 1 = 50;
run;

data yarn;
 input Fail Amplitude Length Load @@;
 format amplitude a. length l. load o.;
 label fail = 'Time in Cycles until Failure';
 datalines;
674 -1 -1 -1 370 -1 -1 0 292 -1 -1 1 338 0 -1 -1
266 0 -1 0 210 0 -1 1 170 1 -1 -1 118 1 -1 0
 90 1 -1 1 1414 -1 0 -1 1198 -1 0 0 634 -1 0 1
1022 0 0 -1 620 0 0 0 438 0 0 1 442 1 0 -1
332 1 0 0 220 1 0 1 3636 -1 1 -1 3184 -1 1 0
2000 -1 1 1 1568 0 1 -1 1070 0 1 0 566 0 1 1
1140 1 1 -1 884 1 1 0 360 1 1 1
;

```

PROC TRANSREG is run to find the Box-Cox transformation. The lambda list is  $-2$  TO  $2$  BY  $0.05$ , which produces 81 lambdas, and a convenient lambda is requested. This many power parameters makes a nice graphical display with plenty of detail around the confidence interval. In the interest of space, only part of this table is displayed. The independent variables are designated with the QPOINT expansion. QPOINT, for quadratic point model, gets its name from PROC TRANSREG's ideal point modeling capabilities, which process variables for a response surface analysis. What QPOINT does is create a set of independent variables consisting of the following: the  $m$  original variables (Length Amplitude Load), the  $m$  original variables squared (Length\_2 Amplitude\_2 Load\_2), and the  $m \times (m - 1)/2 = 3$  pairs of products between the  $m$  variables (LengthAmplitude LengthLoad AmplitudeLoad). The following statements produce Output 97.2.1:

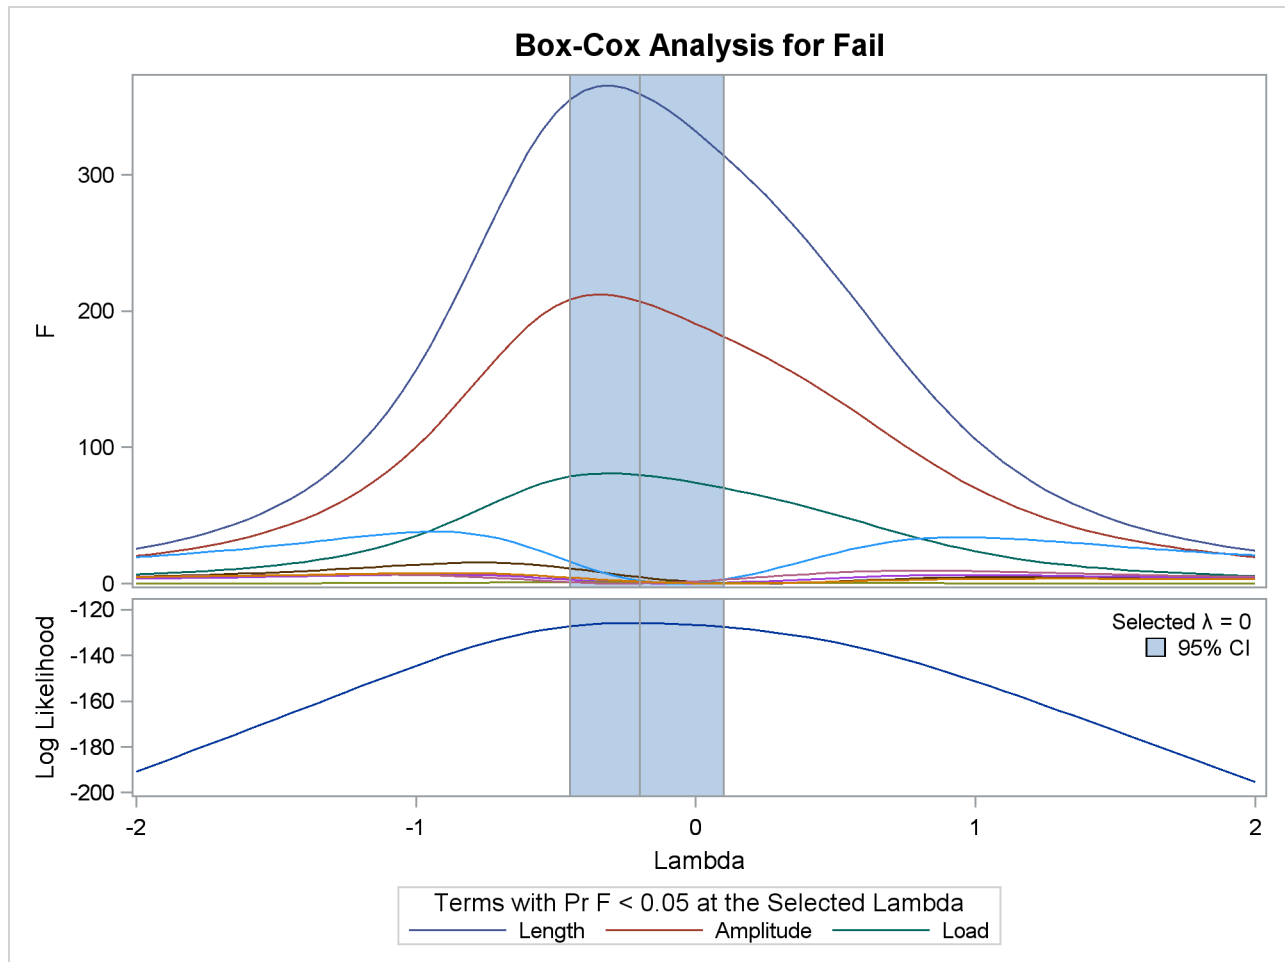

```

ods graphics on;

proc transreg details data=yarn ss2
 plots=(transformation(dependent) obp);
 model BoxCox(fail / convenient lambda=-2 to 2 by 0.05) =
 qpoint(length amplitude load);
run;

```

Output 97.2.1 Box-Cox Yarn Data

Output 97.2.1 continued

```

Dependent Variable BoxCox(Fail)
Time in Cycles until Failure

The above statistics are not adjusted for the fact that the dependent variable was transformed and so are generally liberal.

Output 97.2.1 continued

## Output 97.2.1 continued

The optimal power parameter is  $-0.20$ , but since  $0.0$  is in the confidence interval, and since the **CONVE-NIENT** *t-option* was specified, the procedure chooses a log transformation. The  $F = t^2$  plot shows in the vicinity of the optimal Box-Cox transformation, the parameters for the three original variables (Length Amplitude Load), particularly Length, are significant and the others become essentially zero.

### Example 97.3: Penalized B-Spline

The ENSO data set contains measurements of monthly averaged atmospheric pressure differences between Easter Island and Darwin, Australia, for a period of 168 months (National Institute of Standards and Technology 1998). The ENSO data set is available from the Sashelp library.

You can fit a curve through these data by using a penalized B-spline (Eilers and Marx 1996) function and the following statements:

```

title 'Atmospheric Pressure Changes Between'
 'Easter Island & Darwin, Australia';
ods graphics on;

proc transreg data=sashelp.enso;
 model identity(pressure) = pbspline(year);
run;

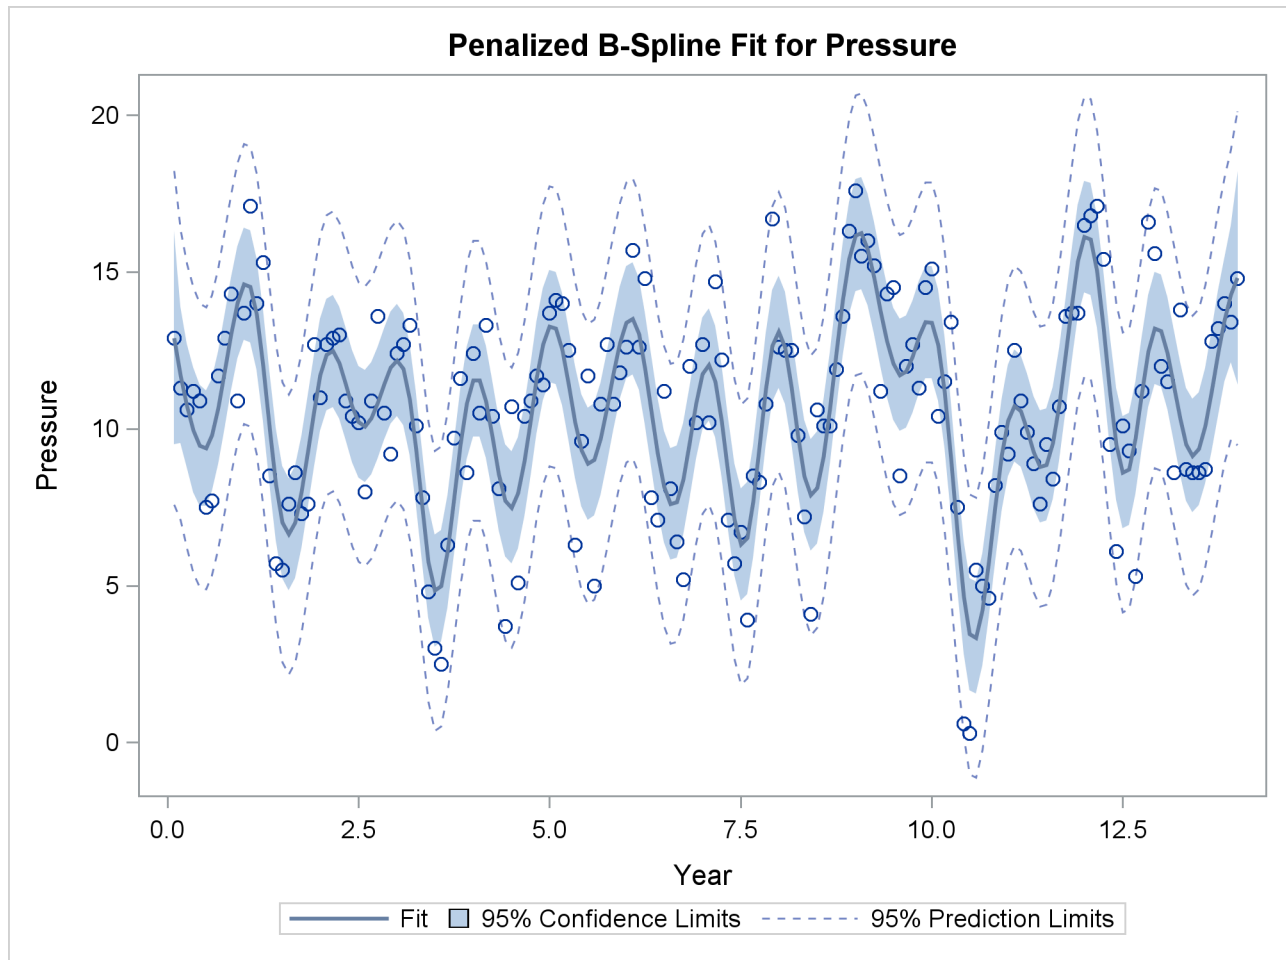

```

The dependent variable Pressure is specified along with an **IDENTITY** transformation, so Pressure is analyzed as is, with no transformations. The independent variable Year is specified with a **PBSPLINE** transformation, so a penalized B-spline model is fit. By default, a **DEGREE=3** B-spline basis is used along with 100 evenly spaced knots and three evenly spaced exterior knots on each side of the data. The penalized spline function is typically much smoother than you would get by using a **SPLINE** transformation or a **BSPLINE** expansion since changes in the coefficients of the basis are penalized to make a smoother fit. The output is shown next in [Output 97.3.1](#).

**Output 97.3.1** Change in Atmospheric Pressure, AICC

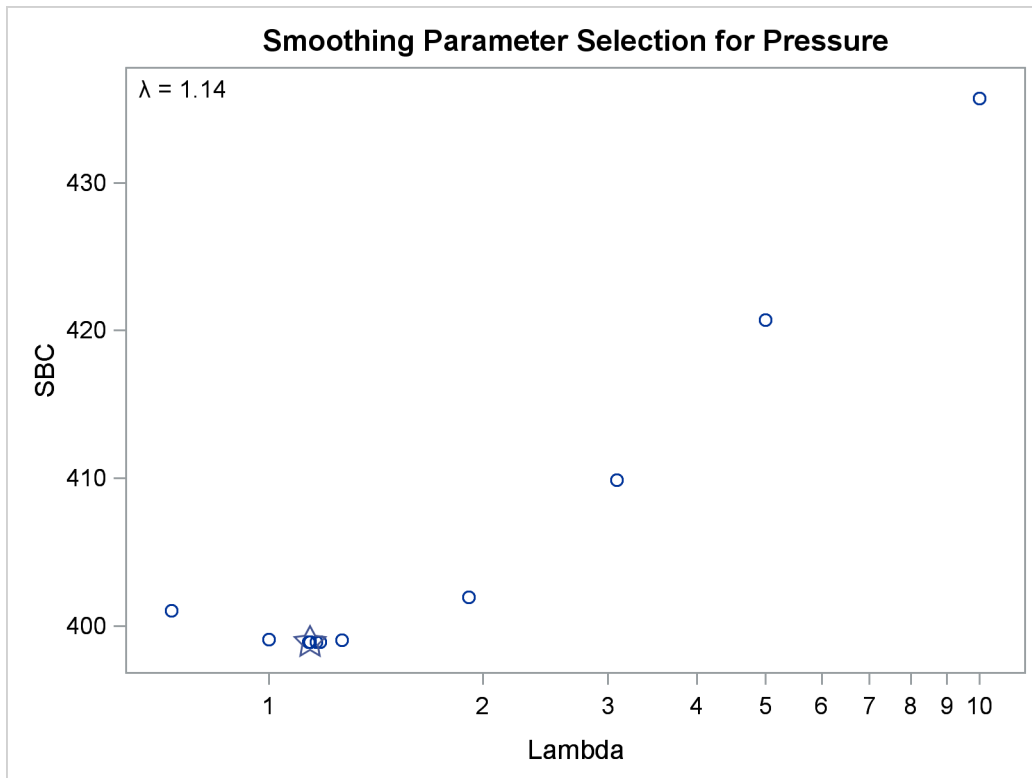

Output 97.3.1 continued

The results show a yearly cycle of pressure change. The procedure chose a smoothing parameter of  $\lambda = 0.709$ . With data such as these, with many peaks and valleys, it might be useful to perform another analysis, this time asking for a smoother plot. The Schwarz Bayesian criterion (SBC) is sometimes a better choice than the default criterion when you want a smoother plot. The following PROC TRANSREG step requests a penalized B-spline analysis minimizing the SBC criterion:

```
proc transreg data=sashelp.enso;
 model identity(pressure) = pbspline(year / sbc);
run;
```

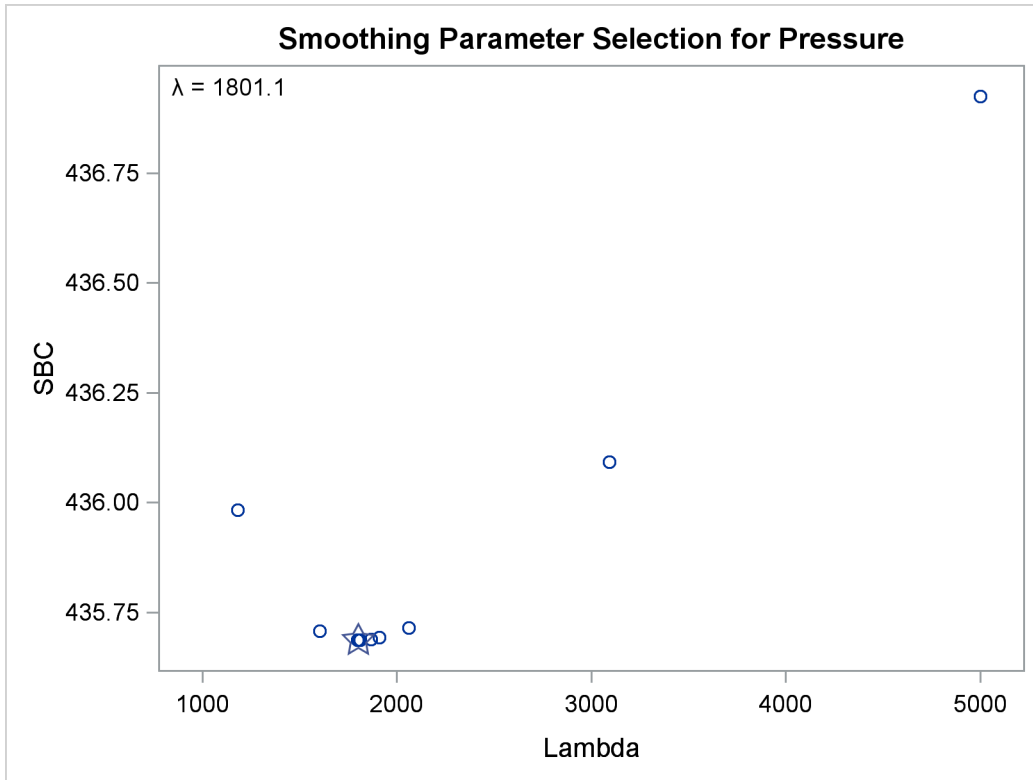

The plot of SBC as a function of  $\lambda$  is shown in [Output 97.3.2](#).

**Output 97.3.2** Change in Atmospheric Pressure, SBC

The fit plot (not shown) is essentially the same as the one shown in [Output 97.3.1](#) due to the similar choice of smoothing parameters:  $\lambda = 0.709$  versus  $\lambda = 1.14$ . You can analyze these data again, this time forcing PROC TRANSREG to consider only larger smoothing parameters. The specification `LAMBDA=2 10000 RANGE` eliminates from consideration the two lambdas that you previously saw and considers only  $2 \leq \lambda \leq 10,000$ . The following statements produce [Output 97.3.3](#):

```
proc transreg data=sashelp.enso;
 model identity(pressure) = pbspline(year / sbc lambda=2 10000 range);
run;
```

**Output 97.3.3** Change in Atmospheric Pressure, SBC, Lambda > 1

Output 97.3.3 continued

The results clearly show that there is a local minimum in the  $SBC(\lambda)$  function at  $\lambda = 1801.1$ . Using this lambda results in a much smoother regression function with a longer cycle than you saw previously. This second cycle can be identified as the periodic warming of the Pacific Ocean known as “El Niño.” The  $SBC(\lambda)$  function has at least two minima since there are at least two trends in the data. In the first analysis, PROC TRANSREG found what is probably the globally optimal solution, and in the second set of analyses, with a little nudging away from the global optimum, it found a very interesting locally optimal solution.

You can specify a list of lambdas to see SBC as a function of lambda over the range that includes both minima as follows:

```
proc transreg data=sashelp.enso;
 model identity(pressure) = pbspline(year / sbc lambda=.1 .5 1 5
 10 50 100 500 to 2500 by 500);
run;
```

The plot of SBC as a function of  $\lambda$  is shown in Output 97.3.4.

**Output 97.3.4** Change in Atmospheric Pressure, SBC, Over the Range of Both Minima

### Example 97.4: Nonmetric Conjoint Analysis of Tire Data

This example uses PROC TRANSREG to perform a nonmetric conjoint analysis of tire preference data. Conjoint analysis decomposes rank-ordered evaluation judgments of products or services into components based on qualitative product attributes. For each level of each attribute of interest, a numerical “part-worth utility” value is computed. The sum of the part-worth utilities for each product is an estimate of the utility for that product. The goal is to compute part-worth utilities such that the product utilities are as similar as possible to the original rank ordering. (This example is a greatly simplified introductory example.)

The stimuli for the experiment are 18 hypothetical tires. The stimuli represent different brands (Goodstone, Pirogi, Machismo),<sup>1</sup> prices (\$69.99, \$74.99, \$79.99), expected tread life (50,000, 60,000, 70,000 miles), and road hazard insurance plans (Yes, No). There are  $3 \times 3 \times 3 \times 2 = 54$  possible combinations. From these, 18 combinations are selected that form an efficient experimental design for a main-effects model. The combinations are then ranked from 1 (most preferred) to 18 (least preferred). In this simple example, there is one set of rankings. A real conjoint study would have many more.

First, the FORMAT procedure is used to specify the meanings of the factor levels, which are entered as numbers in the DATA step along with the ranks. PROC TRANSREG is used to perform the conjoint analysis. A maximum of 50 iterations is requested. The specification `monotone(Rank / reflect)` in the MODEL statement requests that the dependent variable Rank should be monotonically transformed and reflected so that positive utilities mean high preference. The variables Brand, Price, Life, and Hazard are

<sup>1</sup>In real conjoint experiments, real brand names would be used.

designated as **CLASS** variables, and the part-worth utilities are constrained by **ZERO=SUM** to sum to zero within each factor. The **UTILITIES** *a-option* displays the conjoint analysis results.

The importance column of the utilities table shows that price is the most important attribute in determining preference (57%), followed by expected tread life (18%), brand (15%), and road hazard insurance (10%). Looking at the utilities table for the maximum part-worth utility within each attribute, you see from the results that the most preferred combination is Pirogi brand tires, at \$69.99, with a 70,000-mile expected tread life and road hazard insurance. This product is not actually in the data set. The sum of the part-worth utilities for this combination is as follows:

$$20.64 = 9.50 + 1.90 + 5.87 + 2.41 + 0.96$$

The following statements produce [Output 97.4.1](#).

```

## Example 97.5: Metric Conjoint Analysis of Tire Data

This example, which is more detailed than the previous one, uses PROC TRANSREG to perform a metric conjoint analysis of tire preference data. Conjoint analysis can be used to decompose preference ratings of products or services into components based on qualitative product attributes. For each level of each attribute of interest, a numerical “part-worth utility” value is computed. The sum of the part-worth utilities for each product is an estimate of the utility for that product. The goal is to compute part-worth utilities such that the product utilities are as similar as possible to the original ratings. Metric conjoint analysis, as shown in this example, fits an ordinary linear model directly to data assumed to be measured on an interval scale. Nonmetric conjoint analysis, as shown in [Example 97.4](#), finds an optimal monotonic transformation of original data before fitting an ordinary linear model to the transformed data.

This example has three parts. In the first part, an experimental design is created. In the second part, a DATA step creates descriptions of the stimuli for the experiment. The third part of the example performs the conjoint analyses.

The stimuli for the experiment are 18 hypothetical tires. The stimuli represent different brands (Goodstone, Pirogi, Machismo),<sup>2</sup> prices (\$69.99, \$74.99, \$79.99), expected tread life (50,000, 60,000, 70,000 miles), and road hazard insurance plans (Yes, No).

For a conjoint study such as this, you need to create an experimental design with 3 three-level factors, 1 two-level factor, and 18 combinations or *runs*. The easiest way to get this design is with the %MktEx autocall macro. The %MktEx macro requires you to specify the number of levels of each of the four factors, followed by N=18, the number of runs. Specifying a random number seed, while not strictly necessary, helps ensure that the design is reproducible. The %MktLab macro assigns the actual factor names instead of the default names x1, x2, and so on, and it assigns formats to the factor levels. The %MktEval macro helps you evaluate the design. It shows how correlated or independent the factors are, how often each factor level appears in the design, how often each pair occurs for every factor pair, and how often each product profile or run occurs in the design. See [http://support.sas.com/resources/papers/tnote/tnote\\_marketresearch.html](http://support.sas.com/resources/papers/tnote/tnote_marketresearch.html) (Kuhfeld 2005) for more information about experimental design and conjoint analysis; look for the latest “Conjoint Analysis” report. The following statements create, evaluate, and display the design:

```

title 'Tire Study, Experimental Design';

proc format;
 value BrandF
 1 = 'Goodstone'
 2 = 'Pirogi '
 3 = 'Machismo ';
 value PriceF
 1 = '$69.99'
 2 = '$74.99'
 3 = '$79.99';
 value LifeF
 1 = '50,000'
 2 = '60,000'
 3 = '70,000';
 value HazardF

```

<sup>2</sup>In real conjoint experiments, real brand names would be used.

```

1 = 'Yes'
2 = 'No ';

run;

%mktext(3 3 3 2, n=18, seed=448)

%mktlab(vars=Brand Price Life Hazard, out=sasuser.TireDesign,
statements=format Brand BrandF9. Price PriceF9.
Life LifeF6. Hazard HazardF3.)

%mkteval;

proc print data=sasuser.TireDesign;
run;

```

The %MktEx macro (Kuhfeld 2005) output displayed in [Output 97.5.1](#) shows you that the design is 100% efficient, which means it is orthogonal and balanced. The %MktEval macro output displayed in [Output 97.5.2](#) shows you that all of the factors are uncorrelated or orthogonal, the design is balanced (each level occurs once), and every pair of factor levels occurs equally often (again showing that the design is orthogonal). The *n*-way frequencies show that each product profile occurs once (there are no duplicates). The design is shown in [Output 97.5.3](#). The design is automatically randomized (the profiles were sorted into a random order and the original levels are randomly reassigned). Orthogonality, balance, randomization, and other design concepts are discussed in detail in Kuhfeld (2005), in the “Experimental Design, Efficiency, Coding, and Choice Designs” report.

The %MktEx macro requires SAS/STAT, SAS/QC, and SAS/IML software. Alternatively, you can make a design for this experiment using the %MktDes macro, which requires only SAS/STAT and SAS/QC software. The %MktDes macro contains a small subset of the functionality of the %MktEx macro. It can be used as follows:

```
%mktdes(factors=Brand=3 Price=3 Life=3 Hazard=2, n=18)
```

The results of this step are not shown or used.

Next, the questionnaires are printed and given to the subjects, who are asked to rate the tires.

The following statements produce [Output 97.5.4](#):

```

data _null_;
 title;
 set sasuser.TireDesign;
 file print;
 if mod(_n_,4) eq 1 then do;
 put _page_;
 put +55 'Subject _____';
 end;
 length hazardstring $ 7.;
 if put(hazard, hazardf3.) = 'Yes'
 then hazardstring = 'with';
 else hazardstring = 'without';

 s = 3 + (_n_ >= 10);
 put // _n_ +(-1) ') For your next tire purchase, '
 'how likely are you to buy this product?'
 // +s Brand 'brand tires at ' Price +(-1) ', '
 / +s 'with a ' Life 'tread life guarantee, '
 / +s 'and ' hazardstring 'road hazard insurance.'
 // +s 'Definitely Would Definitely Would'
 / +s 'Not Purchase Purchase'
 // +s '1 2 3 4 5 6 7 8 9 ';
run;

```

This output in [Output 97.5.4](#) is abbreviated in the interest of conserving space; the statements actually produce stimuli for all combinations.

**Output 97.5.4** Conjoint Analysis, Stimuli Descriptions

| Machismo brand tires at \$74.99,<br>with a 50,000 tread life guarantee,<br>and without road hazard insurance. |   |   |   |   |                              |   |   |   |  |
| Definitely Would<br>Not Purchase                                                                              |   |   |   |   | Definitely Would<br>Purchase |   |   |   |  |
| 1                                                                                                             | 2 | 3 | 4 | 5 | 6                            | 7 | 8 | 9 |  |

The third part of the example performs the conjoint analyses. The DATA step reads the data. Only the ratings are entered, one row per subject. Real conjoint studies have many more subjects than five. The TRANSPOSE procedure transposes this (5 × 18) data set into an (18 × 5) data set that can be merged with the factor level data set sasuser.TireDesign. The next DATA step does the merge. The PRINT procedure displays the input data set.

PROC TRANSREG fits the five individual conjoint models, one for each subject. The UTILITIES *a-option* displays the conjoint analysis results. The SHORT *a-option* suppresses the iteration histories, OUTTEST=UTILS creates an output data set with all of the conjoint results, and the SEPARATORS= option requests that the labels constructed for each category contain two blanks between the variable name and the level value. The ODS SELECT statement is used to limit the displayed output. The MODEL statement specifies IDENTITY for the ratings, which specifies a metric conjoint analysis—the ratings are not transformed. The variables Brand, Price, Life, and Hazard are designated as CLASS variables, and the part-worth utilities are constrained to sum to zero within each factor.

The following statements produce [Output 97.5.5](#):

```

title 'Tire Study, Data Entry, Preprocessing';

data Results;
 input (c1-c18) (1.);
 datalines;

* Fit Each Subject Individually;
proc transreg data=Both utilities short outtest=utils separators=' ';
 ods select TestsNote FitStatistics Utilities;
 model identity(Subj1-Subj5) =
 class(Brand Price Life Hazard / zero=sum);
run;

```

The output contains two tables per subject, one with overall fit statistics and one with the conjoint analysis results.

The next steps summarize the results. Three tables are displayed, showing the following: all of the importance values, the average importance, and the part-worth utilities. The first DATA step selects the importance information from the UTILS data set. The final assignment statement stores just the variable name from the label, relying on the fact that the separator is two blanks. PROC TRANSPOSE creates the data set of importances, one row per subject, and PROC PRINT displays the results. The MEANS procedure displays the average importance of each attribute across the subjects. The next DATA step selects the part-worth utilities information from the UTILS data set. PROC TRANSPOSE creates the data set of utilities, one row per subject, and PROC PRINT displays the results. The following statements produce [Output 97.5.6](#):

Based on the importance values, price is the most important attribute for some of the respondents, but expected tread life is most important for others. On the average, price is most important, followed by expected tread life and brand. Road hazard insurance is less important. Each of the brands is preferred by some of the respondents. All respondents preferred a lower price over a higher price, a longer tread life, and road hazard insurance.

---

### Example 97.6: Preference Mapping of Automobile Data

This example uses PROC TRANSREG to perform a preference mapping (PREFMAP) analysis (Carroll 1972) of automobile preference data after a PROC PRINQUAL principal component analysis. The PREFMAP analysis is a response surface regression that locates ideal points for each dependent variable in a space defined by the independent variables.

The data are ratings obtained from 25 judges of their preference for each of 17 automobiles. The ratings were made on a scale of zero (very weak preference) to nine (very strong preference). These judgments were made in 1980 about that year's products. There are two character variables that indicate the manufacturer and model of the automobile. The data set also contains three ratings: miles per gallon (MPG), projected reliability (Reliability), and quality of the ride (Ride). These ratings are on a scale of one (bad) to five (good). PROC PRINQUAL creates an `OUT=` data set containing standardized principal component scores (Prin1 and Prin2), along with the `ID` variables Model, MPG, Reliability, and Ride.

While this data set contains all of the information needed for the subsequent preference mapping, you can make slightly more informative plots by adding new variable labels to the principal component score variables. The default labels are 'Component 1', 'Component 2', and so on. These are by necessity rather generic since they are created before any data are read, and they must be appropriate across BY groups when a BY variable is specified. In contrast, the MDPREF plot in PROC PRINQUAL has axis labels of the form 'Component 1 (43.54%)' and 'Component 2 (23.4%)' that show the proportion of variance accounted for

by each component. You can create an output data set from the MDPREF plot by using the ODS OUTPUT statement and then use only the label information from it to reset the labels in the output data set from PROC PRINQUAL. In the DATA PLOT step, the SET statement for the MD data set is specified before the SET statement for the PRESULTS data set. The `if 0` ensures that no data are actually read from it, but nevertheless the properties of the Prin1 and Prin2 variables including the variable labels are set based on the properties of those variables in the MD data set.

The first PROC TRANSREG step fits univariate regression models for MPG and Reliability. All variables are designated **IDENTITY**. A vector drawn in the plot of Prin1 and Prin2 from the origin to the point defined by an attribute's regression coefficients approximately shows how the autos differ on that attribute. See Carroll (1972) for more information. The Prin1 and Prin2 columns of the TResult1 **OUT=** data set contain the automobile coordinates (`_Type_='SCORE'` observations) and endpoints of the MPG and Reliability vectors (`_Type_='M COEFFI'` observations).

The second PROC TRANSREG step fits a univariate regression model with Ride designated **IDENTITY**, and Prin1 and Prin2 designated **POINT**. The **POINT** expansion creates an additional independent variable `_ISSQ_`, which contains the sum of Prin1 squared and Prin2 squared. The **OUT=** data set TResult2 contains no `_Type_='SCORE'` observations, only ideal point (`_Type_='M POINT'`) coordinates for Ride. The coordinates of both the vectors and the ideal points are output by specifying **COORDINATES** in the OUTPUT statement in PROC TRANSREG.

A vector model is used for MPG and Reliability because perfectly efficient and reliable automobiles do not exist in the data set. The ideal points for MPG and Reliability are far removed from the plot of the automobiles. It is more likely that an ideal point for quality of the ride is in the plot, so an ideal point model is used for the ride variable. See Carroll (1972) and Schiffman, Reynolds, and Young (1981) for discussions of the vector model and point models (including the **EPOINT** and **QPOINT** versions of the point model that are not used in this example). For the vector model, the default coordinates stretch factor of 2.5 was used. This extends the vectors by a factor of 2.5 from their standard lengths, making a better graphical display. Sometimes the default vectors are short and near the origin, and they look better when they are extended.

R-Square 0.5086

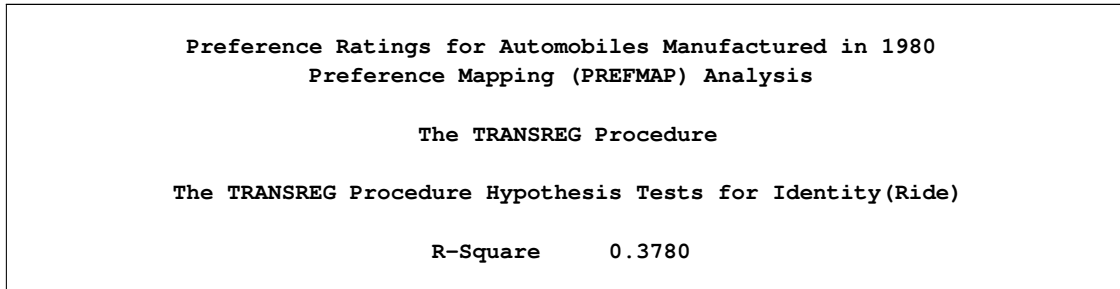

```

**Output 97.6.3** continued

The ideal point for Ride in [Output 97.6.4](#) is in the top, just right of the center of the plot. Automobiles near the Ride ideal point tend to have a better ride than automobiles far away. It can be seen from the R squares that none of these ratings perfectly fits the model, so all of the interpretations are approximate.

**Output 97.6.4** Preference Mapping Ideal Point Plot

**Output 97.6.4** continued

The Ride point is a “negative-negative” ideal point. The point models assume that small ratings mean the object (automobile) is similar to the rating name and large ratings imply dissimilarity to the rating name. Because the opposite scoring is used, the interpretation of the Ride point must be reversed to a negative

ideal point (bad ride). However, the coefficient for the `_ISSQ_` variable in [Output 97.6.5](#) is negative, so the interpretation is reversed again, back to the original interpretation.

## Overview: TREE Procedure

The TREE procedure reads a data set created by the CLUSTER or VARCLUS procedure and produces a tree diagram (also known as a *dendrogram* or *phenogram*), which displays the results of a hierarchical clustering analysis as a tree structure. The TREE procedure uses the data set to produce a diagram of the tree structure in the style of Johnson (1967), with the root at the top. Alternatively, the diagram can be oriented horizontally, with the root at the left. Any numeric variable in the output data set can be used to specify the heights of the clusters. PROC TREE can also create an output data set that contains a variable to indicate the disjoint clusters at a specified level in the tree.

Tree diagrams are discussed in the context of cluster analysis by Duran and Odell (1974); Hartigan (1975); Everitt (1980). Knuth (1973) provides a general treatment of tree diagrams in computer programming.

The literature on tree diagrams contains a mixture of botanical and genealogical terminology. The objects that are clustered are *leaves*. The cluster that contains all objects is the *root*. A cluster that contains at least two objects but not all of them is a *branch*. The general term for leaves, branches, and roots is *node*. If a cluster A is the union of clusters B and C, then A is the *parent* of B and C, and B and C are *children* of A. A leaf is thus a node with no children, and a root is a node with no parent. If every cluster has at most two children, the tree diagram is a *binary tree*. The CLUSTER procedure always produces binary trees. The VARCLUS procedure can produce tree diagrams with clusters that have many children.

---

## Getting Started: TREE Procedure

The TREE procedure creates tree diagrams from a SAS data set that contains the tree structure. You can create this type of data set with the CLUSTER or VARCLUS procedure. See Chapter 31, “The CLUSTER Procedure,” and Chapter 100, “The VARCLUS Procedure,” for more information.

In the following example, the VARCLUS procedure is used to divide a set of variables into hierarchical clusters and to create the SAS data set that contains the tree structure. The TREE procedure then generates the tree diagrams.

The following data, from Hand et al. (1994), represent the amount of protein consumed from nine food groups for each of 25 European countries. The nine food groups are red meat (RedMeat), white meat (WhiteMeat), eggs (Eggs), milk (Milk), fish (Fish), cereal (Cereal), starch (Starch), nuts (Nuts), and fruits and vegetables (FruVeg).

The following SAS statements create the data set Protein:

```

data Protein;
 input Country $15. RedMeat WhiteMeat Eggs Milk
 Fish Cereal Starch Nuts FruVeg;
 datalines;

;

```

The data set Protein contains the character variable Country and the nine numeric variables that represent the food groups. The \$15. in the INPUT statement specifies that the variable Country is a character variable with a length of 15.

The following statements cluster the variables in the data set Protein:

```

ods graphics on;

proc varclus data=Protein outtree=Tree centroid maxclusters=4
 plots=dendrogram(vertical height=ncl);
 var RedMeat--FruVeg;
run;

```

The OUTTREE= option creates an output data set named Tree to contain the tree structure. The CENTROID option specifies the centroid clustering method, and the MAXCLUSTERS= option specifies that the largest number of clusters desired is four. The VAR statement specifies that all numeric variables (RedMeat—FruVeg) are used by the procedure. Since ODS Graphics is enabled, PROC VARCLUS creates a dendrogram, which is displayed in [Figure 98.1](#). The option `plots=dendrogram(vertical height=ncl)` specifies a vertical dendrogram with the number of clusters on the vertical axis. The default is a horizontal dendrogram with, for this cluster analysis, the proportion of variance explained on the horizontal axis.

**Figure 98.1** Dendrogram from PROC VARCLUS and ODS Graphics

The output data set `Tree`, created by the `OUTTREE=` option in the previous statements, contains the following variables:

|                         |                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------|
| <code>_NAME_</code>     | the name of the cluster                                                                       |
| <code>_PARENT_</code>   | the parent of the cluster                                                                     |
| <code>_NCL_</code>      | the number of clusters                                                                        |
| <code>_VAREXP_</code>   | the amount of variance explained by the cluster                                               |
| <code>_PROPOR_</code>   | the proportion of variance explained by the clusters at the current level of the tree diagram |
| <code>_MINPRO_</code>   | the minimum proportion of variance explained by a cluster                                     |
| <code>_MAXEIGEN_</code> | the maximum second eigenvalue of a cluster                                                    |

**Figure 98.2** Graphical Tree Diagram from PROC TREE

The following statements use PROC TREE to produce tree diagrams of the clusters created by PROC VARCLUS:

```
proc tree data=tree;
run;
```

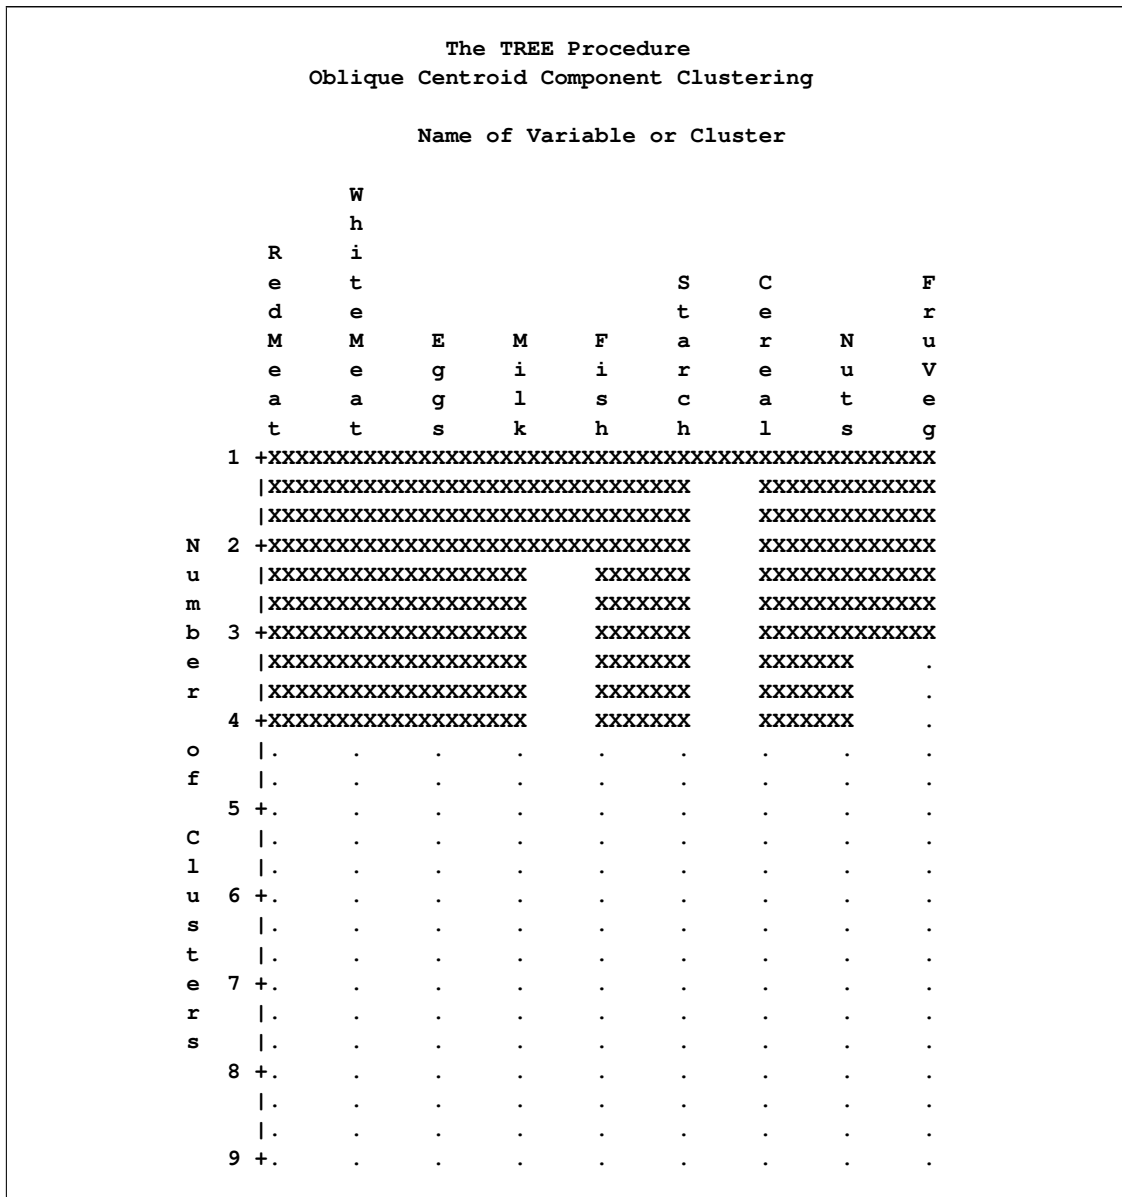

```
proc tree data=tree lineprinter;
run;
```

PROC TREE is invoked twice. In the first invocation, the tree diagram is presented using the default graphical output. In the second invocation, the LINEPRINTER option specifies line printer output.

Figure 98.2 displays the default graphical representation of the tree diagram. Figure 98.3 displays the same information as Figure 98.2 by using line printer output.

**Figure 98.3** Line Printer Representation of the Tree Diagram

In each diagram the name of the cluster is displayed on the horizontal axis and the number of clusters is displayed on the vertical (height) axis.

As you look up from the bottom of either diagram, clusters are progressively joined until a single, all-encompassing cluster is formed at the top (or root) of the tree. Clusters exist at each level of the diagram. For example, at the level where the diagram indicates three clusters, the clusters are as follows:

- Cluster 1: RedMeat WhiteMeat Eggs Milk
- Cluster 2: Fish Starch
- Cluster 3: Cereal Nuts FruVeg

As you proceed up the diagram one level, the number of clusters is two:

- Cluster 1: RedMeat WhiteMeat Eggs Milk Fish Starch
- Cluster 2: Cereal Nuts FruVeg

The following statements illustrate how you can specify the numeric variable that defines the height of each node (cluster) in the tree:

```
axis1 order=(0 to 1 by 0.2);
proc tree data=Tree horizontal haxis=axis1;
 height _PROPOR_;
run;
```

The ORDER= option in the AXIS1 statement (see *SAS/GRAPH: Reference*) specifies the data values in the order in which they are to appear on the axis. The HORIZONTAL option in the PROC TREE statement orients the tree diagram horizontally. The HAXIS= option specifies that the AXIS1 statement be used to customize the appearance of the horizontal axis. The HEIGHT statement specifies the variable \_PROPOR\_ (the proportion of variance explained) as the height variable.

The resulting tree diagram is shown in [Figure 98.4](#).

**Figure 98.4** Horizontal Tree Diagram with `_PROPOR_` as the HEIGHT Variable

As you look from left to right in the diagram, objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the right (or root) of the tree.

Clusters exist at each level of the diagram, represented by horizontal line segments. Each vertical line segment represents a point where leaves and branches are connected into progressively larger clusters.

For example, three clusters are formed at the leftmost point along the axis where three horizontal line segments exist. At that point, where a vertical line segment connects the Cereal-Nuts and FruVeg clusters, the proportion of variance explained is about 0.6 (`_PROPOR_ = 0.6`). At the next clustering level the variables Fish and Starch are clustered with variables RedMeat through Milk, resulting in a total of two clusters. The proportion of variance explained is about 0.45 at that point.

---

## Syntax: TREE Procedure

The following statements are available in the TREE procedure:

```

PROC TREE < options > ;
 NAME variables ;
 HEIGHT variable ;
 PARENT variables ;
 BY variables ;
 COPY variables ;
 FREQ variable ;
 ID variable ;

```

If the input data set has been created by CLUSTER or VARCLUS, the only statement required is the PROC TREE statement. The BY, COPY, FREQ, HEIGHT, ID, NAME, and PARENT statements are described after the PROC TREE statement.

---

## PROC TREE Statement

```

PROC TREE < options > ;

```

The PROC TREE statement invokes the TREE procedure.

Table 98.1 summarizes the options available in the PROC TREE statement.

**Table 98.1** PROC TREE Statement Options

| Option                  | Description                                                   |
|-------------------------|---------------------------------------------------------------|
| <b>Data Sets</b>        |                                                               |
| DATA=                   | specifies input data set                                      |
| DOCK=                   | specifies that small clusters not be counted in OUT= data set |
| LEVEL=                  | defines disjoint cluster in OUT= data set                     |
| NCLUSTERS=              | specifies number of clusters in OUT= data set                 |
| OUT=                    | specifies output data set                                     |
| ROOT=                   | displays root of a subtree                                    |
| <b>Cluster Heights</b>  |                                                               |
| HEIGHT=                 | specifies variable for the height axis                        |
| DISSIMILAR              | specifies that height values indicate dissimilarity           |
| SIMILAR                 | specifies that height values indicate similarity              |
| <b>Horizontal Trees</b> |                                                               |
| HORIZONTAL              | specifies that height axis be horizontal                      |
| <b>Sort Order</b>       |                                                               |
| DESCENDING              | reverses sort order                                           |
| SORT                    | sorts children by HEIGHT variable                             |
| <b>Displayed Output</b> |                                                               |
| INC=                    | specifies increment between tick values                       |

Table 98.1 *continued*

| Option                       | Description                                                |
|------------------------------|------------------------------------------------------------|
| LINEPRINTER                  | displays tree by using line printer graphics               |
| LIST                         | displays all nodes in tree                                 |
| MAXHEIGHT=                   | specifies maximum value on axis                            |
| MINHEIGHT=                   | specifies minimum value on axis                            |
| NOPRINT                      | suppresses display of tree                                 |
| NTICK=                       | specifies number of tick intervals                         |
| <b>Graphics</b>              |                                                            |
| CFRAME=                      | specifies color of the frame                               |
| DESCRIPTION=                 | specifies catalog description                              |
| GOUT=                        | specifies catalog name                                     |
| HAXIS=                       | customizes horizontal axis                                 |
| HORDISPLAY=                  | displays horizontal tree with leaves on right              |
| HPAGES=                      | specifies number of pages to expand tree horizontally      |
| LINES=                       | specifies line color and thickness, dots at nodes          |
| NAME=                        | specifies name of graph in catalog                         |
| VAXIS=                       | customizes vertical axis                                   |
| VPAGES=                      | specifies number of pages to expand tree vertically        |
| <b>Line Printer Graphics</b> |                                                            |
| PAGES=                       | specifies number of pages                                  |
| POS=                         | specifies number of column positions                       |
| SPACES=                      | specifies number of spaces between objects                 |
| TICKPOS=                     | specifies number of column positions between ticks         |
| FILLCHAR=                    | specifies fill character between unjoined leaves           |
| JOINCHAR=                    | specifies character displayed between joined leaves        |
| LEAFCHAR=                    | specifies character representing clusters with no children |
| TREECHAR=                    | specifies character representing clusters with children    |

**CFRAME=***color*

specifies a color for the frame, which is the rectangle bounded by the axes.

**DATA=***SAS-data-set*

specifies the input data set that defines the tree. If you omit the DATA= option, the most recently created SAS data set is used.

**DESCENDING****DES**

reverses the sort order for the SORT option.

**DESCRIPTION=***entry-description*

specifies a description for the graph in the GOUT= catalog. The default is “Proc Tree Graph Output.”

**DISSIMILAR****DIS**

specifies that the values of the HEIGHT variable are dissimilarities; that is, a large height value means that the clusters are very dissimilar or far apart.

If neither the SIMILAR nor the DISSIMILAR option is specified, PROC TREE attempts to infer from the data whether the height values are similarities or dissimilarities. If PROC TREE cannot tell this from the data, it issues an error message and does not display a tree diagram.

**DOCK=*n***

causes observations in the OUT= data set that have a frequency of *n* or less to be given missing values for the output variables CLUSTER and CLUSNAME. If the NCLUSTERS= option is also specified, DOCK= also prevents clusters with a frequency of *n* or less from being counted toward the number of clusters requested by the NCLUSTERS= option. By default, DOCK=0.

**FILLCHAR='c'****FC='c'**

specifies the character displayed between leaves that are not joined into a cluster. The character should be enclosed in single quotes. The default is a blank. The LINEPRINTER option must also be specified.

**GOUT=< libref.>member-name**

specifies the catalog in which the generated graph is stored. The default is Work.Gseg.

**HAXIS=AXIS*n***

specifies that the AXIS*n* statement be used to customize the appearance of the horizontal axis.

**HEIGHT=*name*****H=*name***

specifies certain conventional variables to be used for the height axis of the tree diagram. For many situations, the only option you need is the HEIGHT= option. Valid values for *name* and their meanings are as follows:

|            |                                                                                                                                        |
|------------|----------------------------------------------------------------------------------------------------------------------------------------|
| HEIGHT   H | specifies the <code>_HEIGHT_</code> variable.                                                                                          |
| LENGTH   L | defines the height of each node as its path length from the root. This can also be interpreted as the number of ancestors of the node. |
| MODE   M   | specifies the <code>_MODE_</code> variable.                                                                                            |
| NCL   N    | specifies the <code>_NCL_</code> (number of clusters) variable.                                                                        |
| RSQ   R    | specifies the <code>_RSQ_</code> variable.                                                                                             |

See also the section “[HEIGHT Statement](#)” on page 8408. The HEIGHT statement can specify any variable in the input data set to be used for the height axis. In rare cases, you might need to specify either the DISSIMILAR option or the SIMILAR option.

**HORDISPLAY=RIGHT**

specifies that the graph be oriented horizontally with the leaf nodes on the right side, when the HORIZONTAL option is also specified. By default, the leaf nodes are on the left side.

**HORIZONTAL****HOR**

displays the tree diagram with the height axis oriented horizontally. The leaf nodes are on the side specified in the HORDISPLAY= option. If you do not specify the HORIZONTAL option, the height axis is vertical, with the root at the top. When the tree takes up more than one page, horizontal orientation can make the tree diagram considerably easier to read.

**HPAGES=*n1***

specifies that the original graph be enlarged to cover *n1* pages. If you also specify the VPAGES=*n2* option, the original graph is enlarged to cover  $n1 \times n2$  graphs. For example, if HPAGES=2 and VPAGES=3, then the original graph is generated, followed by  $2 \times 3 = 6$  more graphs. In these six graphs, the original is enlarged by a factor of 2 in the horizontal direction and by a factor of 3 in the vertical direction. The graphs are generated in left-to-right and top-to-bottom order.

**INC=*n***

specifies the increment between tick values on the height axis. If the HEIGHT variable is \_NCL\_, the default is usually 1, although a different value can be specified for consistency with other options. For any other HEIGHT variable, the default is some power of 10 times 1, 2, 2.5, or 5.

**JOINCHAR='c'****JC='c'**

specifies the character displayed between leaves that are joined into a cluster. The character should be enclosed in single quotes. The default is 'X'. The LINEPRINTER option must also be specified.

**LEAFCHAR='c'****LC='c'**

specifies the character used to represent clusters that have no children. The character should be enclosed in single quotes. The default is a period. The LINEPRINTER option must also be specified.

**LEVEL=*n***

specifies the level of the tree that defines disjoint clusters for the OUT= data set. The LEVEL= option also causes only clusters between the root and a height of *n* to be displayed. The clusters in the output data set are those that exist at a height of *n* on the tree diagram. For example, if the HEIGHT variable is \_NCL\_ (number of clusters) and LEVEL=5 is specified, then the OUT= data set contains five disjoint clusters. If the HEIGHT variable is \_RSQ\_ (R square) and LEVEL=0.9 is specified, then the OUT= data set contains the smallest number of clusters that yields an R square of at least 0.9.

**LINEPRINTER**

specifies that the tree diagram be displayed using line printer graphics.

**LINES=( < COLOR=*color* > < WIDTH=*n* > < DOTS > )**

specifies the color and the thickness of the lines of the tree, and whether a dot is drawn at each leaf node. If the frame and the lines are specified to be the same color, PROC TREE selects a different color for the lines.

**LIST**

lists all the nodes in the tree, displaying the height, parent, and children of each node.

**MAXHEIGHT=*n*****MAXH=*n***

specifies the maximum value displayed on the height axis.

**MINHEIGHT=*n*****MINH=*n***

specifies the minimum value displayed on the height axis.

**NAME=*name***

specifies the entry name for the generated graph in the GOUT= catalog. Each time another graph is generated with the same name, the name is modified by appending a number to make it unique.

**NCLUSTERS=*n*****NCL=*n*****N=*n***

specifies the number of clusters desired in the OUT= data set. The number of clusters obtained might not equal the number specified if (1) there are fewer than *n* leaves in the tree, (2) there are more than *n* unconnected trees in the data set, (3) a multiway tree does not contain a level with the specified number of clusters, or (4) the DOCK= option eliminates too many clusters.

The NCLUSTERS= option uses the `_NCL_` variable to determine the order in which the clusters are formed. If there is no `_NCL_` variable, the height variable (as determined by the HEIGHT statement or HEIGHT= option) is used instead.

**NTICK=*n***

specifies the number of tick intervals on the height axis. The default depends on the values of other options.

**NOPRINT**

suppresses the display of the tree. Specify the NOPRINT option if you want only to create an OUT= data set.

**OUT=*SAS-data-set***

creates an output data set that contains one observation for each object in the tree or subtree being processed and variables called CLUSTER and CLUSNAME that show cluster membership at any specified level in the tree. If you specify the OUT= option, you must also specify either the NCLUSTERS= or LEVEL= option in order to define the output partition level. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

**PAGES=*n***

specifies the number of pages over which the tree diagram (from root to leaves) is to extend. The default is 1. The LINEPRINTER option must also be specified.

**POS=*n***

specifies the number of column positions on the height axis. The default depends on the value of the PAGES= option, the orientation of the tree diagram, and the values specified by the PAGESIZE= and LINESIZE= options. The LINEPRINTER option must also be specified.

**ROOT='name'**

specifies the value of the NAME statement variable for the root of a subtree to be displayed if you do not want to display the entire tree. If you also specify the OUT= option, the output data set contains only objects that belong to the subtree specified by the ROOT= option.

**SIMILAR****SIM**

specifies that the values of the HEIGHT variable represent similarities; that is, a large height value means that the clusters are very similar or close together.

If neither the SIMILAR nor the DISSIMILAR option is specified, PROC TREE attempts to infer from the data whether the height values are similarities or dissimilarities. If PROC TREE cannot tell this from the data, it issues an error message and does not display a tree diagram.

**SORT**

sorts the children of each node by the HEIGHT variable, in the order of cluster formation. See the DESCENDING option for details.

**SPACES=s****S=s**

specifies the number of spaces between objects in the output. The default depends on the number of objects, the orientation of the tree diagram, and the values specified by the PAGESIZE= and LINE-SIZE= options. The LINEPRINTER option must also be specified.

**TICKPOS=n**

specifies the number of column positions per tick interval on the height axis. The default value is usually between 5 and 10, although a different value can be specified for consistency with other options.

**TREECHAR='c'****TC='c'**

specifies the character used to represent clusters with children. The character should be enclosed in single quotes. The default is 'X'. The LINEPRINTER option must also be specified.

**VAXIS=AXISn**

specifies that the AXISn statement be used to customize the appearance of the vertical axis.

**VPAGES=n2**

specifies that the original graph be enlarged to cover  $n2$  pages. If you also specify the HPAGES= $n1$  option, the original graph is enlarged to cover  $n1 \times n2$  pages. For example, if HPAGES=2 and VPAGES=3, then the original graph is generated, followed by  $2 \times 3 = 6$  more graphs. In these six graphs, the original is enlarged by a factor of 2 in the horizontal direction and by a factor of 3 in the vertical direction. The graphs are generated in left-to-right and top-to-bottom order.

---

## BY Statement

**BY variables ;**

You can specify a BY statement with PROC TREE to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the TREE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## COPY Statement

**COPY variables ;**

The COPY statement specifies one or more character or numeric variables to be copied to the OUT= data set.

---

## FREQ Statement

**FREQ variable ;**

The FREQ statement specifies one numeric variable that tells how many clustering observations belong to the cluster. If the FREQ statement is omitted, PROC TREE uses the variable `_FREQ_` to specify the number of observations per cluster. If neither the FREQ statement nor the `_FREQ_` variable is present, each leaf is assumed to represent one clustering observation, and the frequency for each internal node is found by summing the frequencies of its children.

---

## HEIGHT Statement

**HEIGHT** *variable* ;

The HEIGHT statement specifies the name of a numeric variable to define the height of each node (cluster) in the tree. The height variable can also be specified by the HEIGHT= option in the PROC TREE statement. If both the HEIGHT statement and the HEIGHT= option are omitted, PROC TREE uses the variable `_HEIGHT_`. If the data set does not contain `_HEIGHT_`, PROC TREE uses the variable `_NCL_`. If `_NCL_` is not present either, the height of each node is defined to be its path length from the root.

---

## ID Statement

**ID** *variable* ;

The ID variable is used to identify the objects (leaves) in the tree on the output. The ID variable can be a character or numeric variable of any length. If the ID statement is omitted, the variable in the NAME statement is used instead. If both the ID and NAME statements are omitted, PROC TREE uses the variable `_NAME_`. If the `_NAME_` variable is not found in the data set, PROC TREE issues an error message and stops. The ID variable is copied to the OUT= data set.

---

## NAME Statement

**NAME** *variable* ;

The NAME statement specifies a character or numeric variable that identifies the node represented by each observation. The NAME statement variable and the PARENT statement variable jointly define the tree structure. If the NAME statement is omitted, PROC TREE uses the variable `_NAME_`. If the `_NAME_` variable is not found in the data set, PROC TREE issues an error message and stops.

---

## PARENT Statement

**PARENT** *variable* ;

The PARENT statement specifies a character or numeric variable that identifies the node in the tree that is the parent of each observation. The PARENT statement variable must have the same formatted length as the NAME statement variable. If the PARENT statement is omitted, PROC TREE uses the variable `_PARENT_`. If the `_PARENT_` variable is not found in the data set, PROC TREE issues an error message and stops.

---

## Details: TREE Procedure

---

### Missing Values

An observation with a missing value for the NAME statement variable is omitted from processing. If the PARENT statement variable has a missing value but the NAME statement variable is present, the observation is treated as the root of a tree. A data set can contain several roots and, hence, several trees.

Missing values of the HEIGHT variable are set to upper or lower bounds determined from the nonmissing values under the assumption that the heights are monotonic with respect to the tree structure.

Missing values of the FREQ variable are inferred from nonmissing values where possible; otherwise, they are treated as zero.

---

### Output Data Set

The OUT= data set contains one observation for each leaf in the tree or subtree being processed. The variables are as follows:

- the BY variables, if any
- the ID variable, or the NAME statement variable if the ID statement is not used
- the COPY variables
- a numeric variable CLUSTER that takes values from 1 to  $c$ , where  $c$  is the number of disjoint clusters. The cluster to which the first observation belongs is given the number 1, the cluster to which the next observation belongs that does not belong to cluster 1 is given the number 2, and so on.
- a character variable CLUSNAME that gives the value of the NAME statement variable of the cluster to which the observation belongs

The CLUSTER and CLUSNAME variables are missing if the corresponding leaf has a nonpositive frequency.

---

### Displayed Output

The displayed output from the TREE procedure includes the following:

- the names of the objects in the tree
- the height axis
- the tree diagram.

The leaves of the tree diagram are displayed at the bottom of the graph. Horizontal lines connect the leaves into branches, while the topmost horizontal line indicates the root.

If the `LINEPRINTER` option is specified, the root (the cluster that contains all the objects) is indicated by a solid line of the character specified by the `TREECHAR=` option (the default character is 'X'). At each level of the tree, clusters are shown by unbroken lines of the `TREECHAR=` symbol with the `FILLCHAR=` symbol (the default is a blank) separating the clusters. The `LEAFCHAR=` symbol (the default character is a period) represents single-member clusters.

By default, the tree diagram is oriented with the height axis vertical and the object names at the top of the diagram. If the `HORIZONTAL` option is specified, then the height axis is horizontal and the object names are on the left.

---

## ODS Table Names

`PROC TREE` assigns a name to each table it creates. You can use table names to refer to tables when using the Output Delivery System (ODS) to select tables and create output data sets. The name of `PROC TREE`'s only table is listed in Table 98.2. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

**Table 98.2** ODS Tables Produced by `PROC TREE`

| ODS Table Name | Description                      | Statement | Option |
|----------------|----------------------------------|-----------|--------|
| TreeListing    | Listing of all nodes in the tree | PROC      | LIST   |

---

## Examples: TREE Procedure

---

### Example 98.1: Mammals' Teeth

The following statements produce a data set that contains the numbers of different kinds of teeth for a variety of mammals:

```
data teeth;
 title 'Mammals' Teeth';
 input mammal & $16. v1-v8 @@;
 label v1='Right Top Incisors'
 v2='Right Bottom Incisors'
 v3='Right Top Canines'
 v4='Right Bottom Canines'

```

The following statements use the CLUSTER procedure to cluster the mammals by average linkage and use ODS Graphics and the TREE procedure to produce a horizontal tree diagram that uses the average-linkage distance as its height axis:

```
ods graphics on;

proc cluster method=average std pseudo noeigen outtree=tree;
 id mammal;
 var v1-v8;
run;

proc tree horizontal;
run;

```

Output 98.1.1 displays the information about how the clusters are joined. For example, the cluster history shows that the mammals ‘Wolf’ and ‘Bear’ form cluster 29, which is merged with ‘Raccoon’ to form cluster 11.

### Output 98.1.1 Output from PROC CLUSTER

Output 98.1.2 shows the tree diagram produced by PROC CLUSTER.

**Output 98.1.2** Dendrogram from PROC CLUSTER

Output 98.1.3 shows the corresponding tree diagram produced by PROC TREE.

**Output 98.1.3** Tree Diagram of Mammal Teeth Clusters

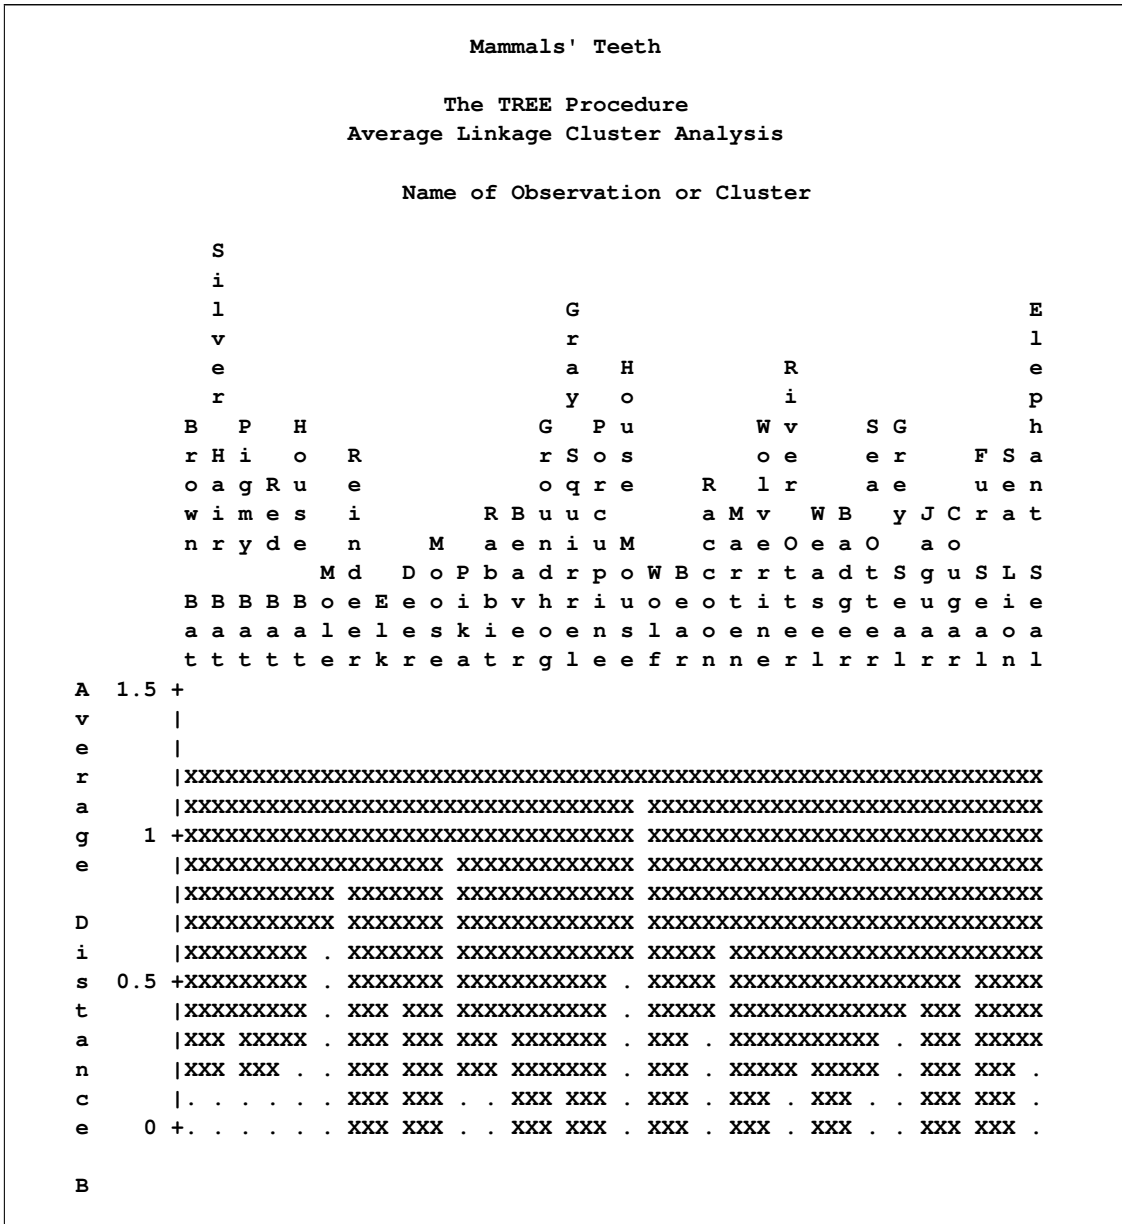

As you view the diagram in [Output 98.1.3](#) from left to right, objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the right (or root) of the tree. Clusters exist at each level of the diagram, and every vertical line connects leaves and branches into progressively larger clusters. For example, the five bats form a cluster at the 0.6 level, while the next cluster consists only of the mole. The mammals ‘Reindeer’, ‘Elk’, ‘Deer’, and ‘Moose’ form the next cluster at the 0.6 level, the mammals ‘Pika’ through ‘House Mouse’ are in the fourth cluster, the mammals ‘Wolf’, ‘Bear’, and ‘Raccoon’ form the fifth cluster, and the last cluster contains the mammals ‘Marten’ through ‘Elephant Seal’.

The following statements create the same tree with line printer graphics in a vertical orientation:

```
proc tree lineprinter;
run;
```

The tree is displayed in [Output 98.1.4](#).

**Output 98.1.4** PROC TREE with the LINEPRINTER Option

As you look up from the bottom of the diagram, objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the top (or root) of the root. Clusters exist at each level of the diagram. For example, the unbroken line of Xs at the leftmost side of the 0.6 level indicates that the five bats have formed a cluster. The next cluster is represented by a period because it contains only one mammal, 'Mole'. The mammals 'Reindeer', 'Elk', 'Deer', and 'Moose' form the next cluster, indicated by Xs again. The mammals 'Pika' through 'House Mouse' are in the fourth cluster. The mammals 'Wolf', 'Bear', and 'Raccoon' form the fifth cluster, while the last cluster contains the mammals 'Marten' through 'Elephant Seal'.

The next statements sort the clusters at each branch in order of formation and use the number of clusters as the height axis:

```
proc tree sort height=n horizontal;
run;
```

The resulting tree is displayed in [Output 98.1.5](#).

**Output 98.1.5** PROC TREE with SORT and HEIGHT= Options

Because the CLUSTER procedure always produces binary trees, the number of internal (root and branch) nodes in the tree is one less than the number of leaves. Therefore 31 clusters are formed from the 32 mammals in the input data set. These are represented by the 31 vertical line segments in the tree diagram, each at a different value along the horizontal axis.

As you examine the tree from left to right, the first vertical line segment is where 'Beaver' and 'Groundhog' are clustered and the number of clusters is 31. The next cluster is formed from 'Gray Squirrel' and 'Porcupine'. The third contains 'Wolf' and 'Bear'. Note how the tree graphically displays the clustering order information that was presented in tabular form by the CLUSTER procedure in [Output 98.1.1](#).

The same clusters as in [Output 98.1.3](#) and [Output 98.1.4](#) can be seen at the six-cluster level of the tree diagram in [Output 98.1.5](#), although the SORT and HEIGHT= options make them appear in a different order.

The following statements create these six clusters and save the result in the output data set part:

```
proc tree noprint out=part nclusters=6;
 id mammal;
 copy v1-v8;
run;

proc sort;
 by cluster;
run;
```

PROC TREE with the NOPRINT option displays no output but creates an output data set that indicates the cluster to which each observation belongs at the six-cluster level in the tree. The following statements print the data set part, with the results shown in [Output 98.1.6](#):

```
proc print label uniform;
 id mammal;
 var v1-v8;
 format v1-v8 1.;
 by cluster;
run;
```

**Output 98.1.6** PROC TREE OUT= Data Set
