Example 40.11: Exact Poisson Regression

The following data, taken from Cox and Snell (1989, pp. 10–11), consists of the number, Notready, of ingots that are not ready for rolling, out of Total tested, for several combinations of heating time and soaking time:

```
data ingots;
  input Heat Soak Notready Total @@;
  lnTotal= log(Total);
  datalines;
7 1.0 0 10 14 1.0 0 31 27 1.0 1 56 51 1.0 3 13
7 1.7 0 17 14 1.7 0 43 27 1.7 4 44 51 1.7 0 1
7 2.2 0 7 14 2.2 2 33 27 2.2 0 21 51 2.2 0 1
7 2.8 0 12 14 2.8 0 31 27 2.8 1 22 51 4.0 0 1
7 4.0 0 9 14 4.0 0 19 27 4.0 1 16
;
```

The following invocation of PROC GENMOD fits an asymptotic (unconditional) Poisson regression model to the data. The variable Notready is specified as the response variable, and the continuous predictors Heat and Soak are defined in the CLASS statement as categorical predictors that use reference coding. Specifying the offset variable as lnTotal enables you to model the ratio Notready/Total.

```
proc genmod data=ingots;
  class Heat Soak / param=ref;
  model Notready=Heat Soak / offset=lnTotal dist=poisson link=log;
  exact Heat Soak / joint estimate;
  exactoptions statustime=10;
run;
```

The EXACT statement is specified to additionally fit an exact conditional Poisson regression model. Specifying the lnTotal offset variable models the ratio Notready/Total; in this case, the Total variable contains the largest possible response value for each observation. The JOINT option produces a joint test for the significance of the covariates, along with the usual marginal tests. The ESTIMATE option produces exact parameter estimates for the covariates. The STATUSTIME=10 option is specified in the EXACTOPTIONS statement for monitoring the progress of the results; this example can take several minutes to complete due to the JOINT option. If you run out of memory, see the SAS Companion for your system for information about how to increase the available memory.

The “Criteria For Assessing Goodness Of Fit” table is displayed in [Output 40.11.1](#). Comparing the deviance of 10.9363 to an asymptotic chi-square distribution with 11 degrees of freedom, you find that the p -value is 0.449. This indicates that the specified model fits the data reasonably well.

Output 40.11.1 Unconditional Goodness of Fit Criteria

The GENMOD Procedure			
Criteria For Assessing Goodness Of Fit			
Criterion	DF	Value	Value/DF
Deviance	11	10.9363	0.9942
Scaled Deviance	11	10.9363	0.9942
Pearson Chi-Square	11	9.3722	0.8520
Scaled Pearson X2	11	9.3722	0.8520
Log Likelihood		-7.2408	
Full Log Likelihood		-12.9038	
AIC (smaller is better)		41.8076	
AICC (smaller is better)		56.2076	
BIC (smaller is better)		49.3631	

From the “Analysis Of Parameter Estimates” table in [Output 40.11.2](#), you can see that only two of the Heat parameters are deemed significant. Looking at the standard errors, you can see that the unconditional analysis had convergence difficulties with the Heat=7 parameter (Standard Error=264324.6), which means you cannot fit this unconditional Poisson regression model to this data.

Output 40.11.2 Unconditional Maximum Likelihood Parameter Estimates

Analysis Of Maximum Likelihood Parameter Estimates						
Parameter	DF	Estimate	Standard Error	Wald	95% Confidence Limits	Wald Chi-Square
Intercept	1	-1.5700	1.1657	-3.8548	0.7147	1.81
Heat	7	-27.6129	264324.6	-518094	518039.0	0.00
Heat	14	-3.0107	1.0025	-4.9756	-1.0458	9.02
Heat	27	-1.7180	0.7691	-3.2253	-0.2106	4.99
Soak	1	-0.2454	1.1455	-2.4906	1.9998	0.05
Soak	1.7	0.5572	1.1217	-1.6412	2.7557	0.25
Soak	2.2	0.4079	1.2260	-1.9951	2.8109	0.11
Soak	2.8	-0.1301	1.4234	-2.9199	2.6597	0.01
Scale	0	1.0000	0.0000	1.0000	1.0000	

Analysis Of Maximum Likelihood Parameter Estimates		
Parameter		Pr > ChiSq
Intercept		0.1780
Heat	7	0.9999
Heat	14	0.0027
Heat	27	0.0255
Soak	1	0.8304
Soak	1.7	0.6193
Soak	2.2	0.7394
Soak	2.8	0.9272
Scale		

NOTE: The scale parameter was held fixed.

Following the output from the asymptotic analysis, the exact conditional Poisson regression results are displayed, as shown in [Output 40.11.3](#).

Output 40.11.3 Exact Tests

The GENMOD Procedure				
Exact Conditional Analysis				
Exact Conditional Tests				
Effect	Test	Statistic	--- p-Value ---	
			Exact	Mid
Joint	Score	18.3665	0.0137	0.0137
	Probability	1.294E-6	0.0471	0.0471
Heat	Score	15.8259	0.0023	0.0022
	Probability	0.000175	0.0063	0.0062
Soak	Score	1.4612	0.8683	0.8646
	Probability	0.00735	0.8176	0.8139

The Joint test in the “Conditional Exact Tests” table in [Output 40.11.3](#) is produced by specifying the **JOINT** option in the **EXACT** statement. The p -values for this test indicate that the parameters for Heat and Soak are jointly significant as explanatory effects in the model. If the Heat variable is the only explanatory variable in your model, then the rows of this table labeled as “Heat” show the joint significance of all the Heat effect parameters in that reduced model. In this case, a model that contains only the Heat parameters still explains a significant amount of the variability; however, you can see that a model that contains only the Soak parameters would not be significant.

The “Exact Parameter Estimates” table in [Output 40.11.4](#) displays parameter estimates and tests of significance for the levels of the CLASS variables. Again, the Heat=7 parameter has some difficulties; however, in the exact analysis, a *median unbiased estimate* is computed for the parameter instead of a maximum likelihood estimate. The confidence limits show that the Heat variable contains some explanatory power, while the categorical Soak variable is insignificant and can be dropped from the model.

Output 40.11.4 Exact Parameter Estimates

Exact Parameter Estimates						
Parameter		Estimate	Standard Error	95% Confidence Limits		Two-sided p-Value
Heat	7	-2.7552*	.	-Infinity	-0.7864	0.0199
Heat	14	-3.0255	1.0128	-5.7450	-0.6194	0.0113
Heat	27	-1.7846	0.8065	-3.6779	0.2260	0.0844
Soak	1	-0.3231	1.1717	-2.8673	3.6754	1.0000
Soak	1.7	0.5375	1.1284	-1.8056	4.4588	1.0000
Soak	2.2	0.4035	1.2347	-2.5785	4.5054	1.0000
Soak	2.8	-0.1661	1.4214	-4.5490	4.2168	1.0000

NOTE: * indicates a median unbiased estimate.

NOTE: If you want to make predictions from the exact results, you can obtain an estimate for the intercept parameter by specifying the INTERCEPT keyword in the EXACT statement. You should also remove the JOINT option to reduce the amount of time and memory consumed.

Overview: GLIMMIX Procedure

The GLIMMIX procedure fits statistical models to data with correlations or nonconstant variability and where the response is not necessarily normally distributed. These models are known as generalized linear mixed models (GLMM).

GLMMs, like linear mixed models, assume normal (Gaussian) random effects. Conditional on these random effects, data can have any distribution in the exponential family. The exponential family comprises many of the elementary discrete and continuous distributions. The binary, binomial, Poisson, and negative binomial distributions, for example, are discrete members of this family. The normal, beta, gamma, and chi-square distributions are representatives of the continuous distributions in this family. In the absence of random effects, the GLIMMIX procedure fits generalized linear models (fit by the GENMOD procedure).

GLMMs are useful for the following applications:

- estimating trends in disease rates
- modeling CD4 counts in a clinical trial over time
- modeling the proportion of infected plants on experimental units in a design with randomly selected treatments or randomly selected blocks
- predicting the probability of high ozone levels in counties
- modeling skewed data over time
- analyzing customer preference
- joint modeling of multivariate outcomes

Such data often display correlations among some or all observations as well as nonnormality. The correlations can arise from repeated observation of the same sampling units, shared random effects in an experimental design, spatial (temporal) proximity, multivariate observations, and so on.

The GLIMMIX procedure does not fit hierarchical models with nonnormal random effects. With the GLIMMIX procedure you select the distribution of the response variable conditional on normally distributed random effects.

For more information about the differences between the GLIMMIX procedure and SAS procedures that specialize in certain subsets of the GLMM models, see the section “[PROC GLIMMIX Contrasted with Other SAS Procedures](#)” on page 2920.

Basic Features

The GLIMMIX procedure enables you to specify a generalized linear mixed model and to perform confirmatory inference in such models. The syntax is similar to that of the MIXED procedure and includes **CLASS**, **MODEL**, and **RANDOM** statements. For instructions on how to specify PROC MIXED REPEATED effects with PROC GLIMMIX, see the section “[Comparing the GLIMMIX and MIXED Procedures](#)” on page 3101. The following are some of the basic features of PROC GLIMMIX.

- **SUBJECT=** and **GROUP=** options, which enable blocking of variance matrices and parameter heterogeneity
- choice of linearization approach or integral approximation by quadrature or Laplace method for mixed models with nonlinear random effects or nonnormal distribution
- choice of linearization about expected values or expansion about current solutions of best linear unbiased predictors
- flexible covariance structures for random and residual random effects, including variance components, unstructured, autoregressive, and spatial structures
- **CONTRAST**, **ESTIMATE**, **LSMEANS**, and **LSMESTIMATE** statements, which produce hypothesis tests and estimable linear combinations of effects
- **NLOPTIONS** statement, which enables you to exercise control over the numerical optimization. You can choose techniques, update methods, line search algorithms, convergence criteria, and more. Or, you can choose the default optimization strategies selected for the particular class of model you are fitting.
- computed variables with SAS programming statements inside of PROC GLIMMIX (except for variables listed in the **CLASS** statement). These computed variables can appear in the **MODEL**, **RANDOM**, **WEIGHT**, or **FREQ** statement.
- grouped data analysis
- user-specified link and variance functions
- choice of model-based variance-covariance estimators for the fixed effects or empirical (sandwich) estimators to make analysis robust against misspecification of the covariance structure and to adjust for small-sample bias
- joint modeling for multivariate data. For example, you can model binary and normal responses from a subject jointly and use random effects to relate (fuse) the two outcomes.
- multinomial models for ordinal and nominal outcomes
- univariate and multivariate low-rank mixed model smoothing

Assumptions

The primary assumptions underlying the analyses performed by PROC GLIMMIX are as follows:

- If the model contains random effects, the distribution of the data conditional on the random effects is known. This distribution is either a member of the exponential family of distributions or one of the supplementary distributions provided by the GLIMMIX procedure. In models without random effects, the unconditional (marginal) distribution is assumed to be known for maximum likelihood estimation, or the first two moments are known in the case of quasi-likelihood estimation.

- The conditional expected value of the data takes the form of a linear mixed model after a monotonic transformation is applied.
- The problem of fitting the GLMM can be cast as a singly or doubly iterative optimization problem. The objective function for the optimization is a function of either the actual log likelihood, an approximation to the log likelihood, or the log likelihood of an approximated model.

For a model containing random effects, the GLIMMIX procedure, by default, estimates the parameters by applying pseudo-likelihood techniques as in Wolfinger and O’Connell (1993) and Breslow and Clayton (1993). In a model without random effects (GLM models), PROC GLIMMIX estimates the parameters by maximum likelihood, restricted maximum likelihood, or quasi-likelihood. See the section “[Singly or Doubly Iterative Fitting](#)” on page 3104 about when the GLIMMIX procedure applies noniterative, singly and doubly iterative algorithms, and the section “[Default Estimation Techniques](#)” on page 3106 about the default estimation methods. You can also fit generalized linear mixed models by maximum likelihood where the marginal distribution is numerically approximated by the Laplace method (`METHOD=LAPLACE`) or by adaptive Gaussian quadrature (`METHOD=QUAD`).

Once the parameters have been estimated, you can perform statistical inferences for the fixed effects and covariance parameters of the model. Tests of hypotheses for the fixed effects are based on Wald-type tests and the estimated variance-covariance matrix. The `COVTEST` statement enables you to perform inferences about covariance parameters based on likelihood ratio tests.

PROC GLIMMIX uses the Output Delivery System (ODS) for displaying and controlling the output from SAS procedures. ODS enables you to convert any of the output from PROC GLIMMIX into a SAS data set. See the section “[ODS Table Names](#)” on page 3113 for more information.

The GLIMMIX procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the statistical graphics available with the GLIMMIX procedure, see the `PLOTS` options in the `PROC GLIMMIX` and `LSMEANS` statements.

Notation for the Generalized Linear Mixed Model

This section introduces the mathematical notation used throughout the chapter to describe the generalized linear mixed model (GLMM). See the section “[Details: GLIMMIX Procedure](#)” on page 3047 for a description of the fitting algorithms and the mathematical-statistical details.

The Basic Model

Suppose \mathbf{Y} represents the $(n \times 1)$ vector of observed data and $\boldsymbol{\gamma}$ is a $(r \times 1)$ vector of random effects. Models fit by the GLIMMIX procedure assume that

$$E[\mathbf{Y}|\boldsymbol{\gamma}] = g^{-1}(\mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma})$$

where $g(\cdot)$ is a differentiable monotonic link function and $g^{-1}(\cdot)$ is its inverse. The matrix \mathbf{X} is an $(n \times p)$ matrix of rank k , and \mathbf{Z} is an $(n \times r)$ design matrix for the random effects. The random effects are assumed to be normally distributed with mean $\mathbf{0}$ and variance matrix \mathbf{G} .

The GLMM contains a linear mixed model inside the inverse link function. This model component is referred to as the linear predictor,

$$\eta = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma}$$

The variance of the observations, conditional on the random effects, is

$$\text{Var}[\mathbf{Y}|\boldsymbol{\gamma}] = \mathbf{A}^{1/2}\mathbf{R}\mathbf{A}^{1/2}$$

The matrix \mathbf{A} is a diagonal matrix and contains the variance functions of the model. The variance function expresses the variance of a response as a function of the mean. The GLIMMIX procedure determines the variance function from the `DIST=` option in the `MODEL` statement or from the user-supplied variance function (see the section “[Implied Variance Functions](#)” on page 3043). The matrix \mathbf{R} is a variance matrix specified by the user through the `RANDOM` statement. If the conditional distribution of the data contains an additional scale parameter, it is either part of the variance functions or part of the \mathbf{R} matrix. For example, the gamma distribution with mean μ has the variance function $a(\mu) = \mu^2$ and $\text{Var}[Y|\boldsymbol{\gamma}] = \mu^2\phi$. If your model calls for G-side random effects only (see the next section), the procedure models $\mathbf{R} = \phi\mathbf{I}$, where \mathbf{I} is the identity matrix. [Table 41.19](#) identifies the distributions for which $\phi \equiv 1$.

G-Side and R-Side Random Effects and Covariance Structures

The GLIMMIX procedure distinguishes two types of random effects. Depending on whether the parameters of the covariance structure for random components in your model are contained in \mathbf{G} or in \mathbf{R} , the procedure distinguishes between “G-side” and “R-side” random effects. The associated covariance structures of \mathbf{G} and \mathbf{R} are similarly termed the G-side and R-side covariance structure, respectively. R-side effects are also called “residual” effects. Simply put, if a random effect is an element of $\boldsymbol{\gamma}$, it is a G-side effect and you are modeling the G-side covariance structure; otherwise, you are modeling the R-side covariance structure of the model. Models without G-side effects are also known as marginal (or population-averaged) models. Models fit with the GLIMMIX procedure can have none, one, or more of each type of effect.

Note that an R-side effect in the GLIMMIX procedure is equivalent to a `REPEATED` effect in the `MIXED` procedure. The R-side covariance structure in the GLIMMIX procedure is the covariance structure that you would formulate with the `REPEATED` statement in the `MIXED` procedure. In the GLIMMIX procedure all random effects and their covariance structures are specified through the `RANDOM` statement. See the section “[Comparing the GLIMMIX and MIXED Procedures](#)” on page 3101 for a comparison of the GLIMMIX and MIXED procedures.

The columns of \mathbf{X} are constructed from effects listed on the right side in the `MODEL` statement. Columns of \mathbf{Z} and the variance matrices \mathbf{G} and \mathbf{R} are constructed from the `RANDOM` statement.

The \mathbf{R} matrix is by default the scaled identity matrix, $\mathbf{R} = \phi\mathbf{I}$. The scale parameter ϕ is set to one if the distribution does not have a scale parameter, such as in the case of the binary, binomial, Poisson, and exponential distribution (see [Table 41.19](#)). To specify a different \mathbf{R} matrix, use the `RANDOM` statement with the `_RESIDUAL_` keyword or the `RESIDUAL` option. For example, to specify that the Time effect for each patient is an R-side effect with a first-order autoregressive covariance structure, use the `RESIDUAL` option:

```
random time / type=ar(1) subject=patient residual;
```

To add a multiplicative overdispersion parameter, use the `_RESIDUAL_` keyword:

```
random _residual_;
```

You specify the link function $g(\cdot)$ with the `LINK=` option in the `MODEL` statement or with programming statements. You specify the variance function that controls the matrix \mathbf{A} with the `DIST=` option in the `MODEL` statement or with programming statements.

Unknown quantities subject to estimation are the fixed-effects parameter vector $\boldsymbol{\beta}$ and the covariance parameter vector $\boldsymbol{\theta}$ that comprises all unknowns in \mathbf{G} and \mathbf{R} . The random effects $\boldsymbol{\gamma}$ are not parameters of the model in the sense that they are not estimated. The vector $\boldsymbol{\gamma}$ is a vector of random variables. The solutions for $\boldsymbol{\gamma}$ are predictors of these random variables.

Relationship with Generalized Linear Models

Generalized linear models (Nelder and Wedderburn 1972; McCullagh and Nelder 1989) are a special case of GLMMs. If $\boldsymbol{\gamma} = \mathbf{0}$ and $\mathbf{R} = \phi\mathbf{I}$, the GLMM reduces to either a generalized linear model (GLM) or a GLM with overdispersion. For example, if \mathbf{Y} is a vector of Poisson variables so that \mathbf{A} is a diagonal matrix containing $E[\mathbf{Y}] = \boldsymbol{\mu}$ on the diagonal, then the model is a Poisson regression model for $\phi = 1$ and overdispersed relative to a Poisson distribution for $\phi > 1$. Because the Poisson distribution does not have an extra scale parameter, you can model overdispersion by adding the following statement to your GLIMMIX program:

```
random _residual_;
```

If the only random effect is an overdispersion effect, PROC GLIMMIX fits the model by (restricted) maximum likelihood and not by one of the methods specific to GLMMs.

PROC GLIMMIX Contrasted with Other SAS Procedures

The GLIMMIX procedure generalizes the MIXED and GENMOD procedures in two important ways. First, the response can have a nonnormal distribution. The MIXED procedure assumes that the response is normally (Gaussian) distributed. Second, the GLIMMIX procedure incorporates random effects in the model and so allows for subject-specific (conditional) and population-averaged (marginal) inference. The GENMOD procedure allows only for marginal inference.

The GLIMMIX and MIXED procedure are closely related; see the syntax and feature comparison in the section “Comparing the GLIMMIX and MIXED Procedures” on page 3101. The remainder of this section compares the GLIMMIX procedure with the GENMOD, NLMIXED, LOGISTIC, and CATMOD procedures.

The GENMOD procedure fits generalized linear models for independent data by maximum likelihood. It can also handle correlated data through the marginal GEE approach of Liang and Zeger (1986) and Zeger and Liang (1986). The GEE implementation in the GENMOD procedure is a marginal method that does not incorporate random effects. The GEE estimation in the GENMOD procedure relies on R-side covariances only, and the unknown parameters in \mathbf{R} are estimated by the method of moments. The GLIMMIX procedure allows G-side random effects and R-side covariances. PROC GLIMMIX can fit marginal (GEE-type) models, but the covariance parameters are not estimated by the method of moments. The parameters are estimated by likelihood-based techniques. When the GLIMMIX and GENMOD procedures fit a generalized

linear model where the distribution contains a scale parameter, such as the normal, gamma, inverse Gaussian, or negative binomial distribution, the scale parameter is reported in the “Parameter Estimates” table. For some distributions, the parameterization of this parameter differs. See the section “[Scale and Dispersion Parameters](#)” on page 3050 for details about how the GLIMMIX procedure parameterizes the log-likelihood functions and information about how the reported quantities differ between the two procedures.

Many of the fit statistics and tests in the GENMOD procedure are based on the likelihood. In a GLMM it is not always possible to derive the log likelihood of the data. Even if the log likelihood is tractable, it might be computationally infeasible. In some cases, the objective function must be constructed based on a substitute model. In other cases, only the first two moments of the marginal distribution can be approximated. Consequently, obtaining likelihood-based tests and statistics is difficult for many generalized linear mixed models. The GLIMMIX procedure relies heavily on linearization and Taylor-series techniques to construct Wald-type test statistics and confidence intervals. Likelihood ratio tests and confidence intervals for covariance parameters are available in the GLIMMIX procedure through the [COVTEST](#) statement.

The NLMIXED procedure fits nonlinear mixed models where the conditional mean function is a general nonlinear function. The class of generalized linear mixed models is a special case of the nonlinear mixed models; hence some of the models you can fit with PROC NLMIXED can also be fit with the GLIMMIX procedure. The NLMIXED procedure relies by default on approximating the marginal log likelihood through adaptive Gaussian quadrature. In the GLIMMIX procedure, maximum likelihood estimation by adaptive Gaussian quadrature is available with the [METHOD=QUAD](#) option in the [PROC GLIMMIX](#) statement. The default estimation methods thus differ between the NLMIXED and GLIMMIX procedures, because adaptive quadrature is possible for only a subset of the models available with the GLIMMIX procedure. If you choose [METHOD=LAPLACE](#) or [METHOD=QUAD\(QPOINTS=1\)](#) in the [PROC GLIMMIX](#) statement for a generalized linear mixed model, the GLIMMIX procedure performs maximum likelihood estimation based on a Laplace approximation of the marginal log likelihood. This is equivalent to the [QPOINTS=1](#) option in the NLMIXED procedure.

The LOGISTIC and CATMOD procedures also fit generalized linear models; PROC LOGISTIC accommodates the independence case only. Binary, binomial, multinomial models for ordered data, and generalized logit models that can be fit with PROC LOGISTIC can also be fit with the GLIMMIX procedure. The diagnostic tools and capabilities specific to such data implemented in the LOGISTIC procedure go beyond the capabilities of the GLIMMIX procedure.

Getting Started: GLIMMIX Procedure

Logistic Regressions with Random Intercepts

Researchers investigated the performance of two medical procedures in a multicenter study. They randomly selected 15 centers for inclusion. One of the study goals was to compare the occurrence of side effects for the procedures. In each center n_A patients were randomly selected and assigned to procedure “A,” and n_B patients were randomly assigned to procedure “B.” The following DATA step creates the data set for the analysis:

```

data multicenter;
  input center group$ n sideeffect;
  datalines;
1  A  32  14
1  B  33  18
2  A  30   4
2  B  28   8
3  A  23  14
3  B  24   9
4  A  22   7
4  B  22  10
5  A  20   6
5  B  21  12
6  A  19   1
6  B  20   3
7  A  17   2
7  B  17   6
8  A  16   7
8  B  15   9
9  A  13   1
9  B  14   5
10 A  13   3
10 B  13   1
11 A  11   1
11 B  12   2
12 A  10   1
12 B   9   0
13 A   9   2
13 B   9   6
14 A   8   1
14 B   8   1
15 A   7   1
15 B   8   0
;

```

The variable `group` identifies the two procedures, `n` is the number of patients who received a given procedure in a particular center, and `sideeffect` is the number of patients who reported side effects.

If Y_{iA} and Y_{iB} denote the number of patients in center i who report side effects for procedures A and B , respectively, then—for a given center—these are independent binomial random variables. To model the probability of side effects for the two drugs, π_{iA} and π_{iB} , you need to account for the fixed group effect and the random selection of centers. One possibility is to assume a model that relates group and center effects linearly to the logit of the probabilities:

$$\log \left\{ \frac{\pi_{iA}}{1 - \pi_{iA}} \right\} = \beta_0 + \beta_A + \gamma_i$$

$$\log \left\{ \frac{\pi_{iB}}{1 - \pi_{iB}} \right\} = \beta_0 + \beta_B + \gamma_i$$

In this model, $\beta_A - \beta_B$ measures the difference in the logits of experiencing side effects, and the γ_i are independent random variables due to the random selection of centers. If you think of β_0 as the overall intercept in the model, then the γ_i are random intercept adjustments. Observations from the same center receive the same adjustment, and these vary randomly from center to center with variance $\text{Var}[\gamma_i] = \sigma_c^2$.

Because π_{iA} is the conditional mean of the sample proportion, $E[Y_{iA}/n_{iA}|\gamma_i] = \pi_{iA}$, you can model the sample proportions as binomial ratios in a generalized linear mixed model. The following statements request this analysis under the assumption of normally distributed center effects with equal variance and a logit link function:

```
proc glimmix data=multicenter;
  class center group;
  model sideeffect/n = group / solution;
  random intercept / subject=center;
run;
```

The **PROC GLIMMIX** statement invokes the procedure. The **CLASS** statement instructs the procedure to treat the variables `center` and `group` as classification variables. The **MODEL** statement specifies the response variable as a sample proportion by using the *events/trials* syntax. In terms of the previous formulas, `sideeffect/n` corresponds to Y_{iA}/n_{iA} for observations from group A and to Y_{iB}/n_{iB} for observations from group B. The **SOLUTION** option in the **MODEL** statement requests a listing of the solutions for the fixed-effects parameter estimates. Note that because of the *events/trials* syntax, the GLIMMIX procedure defaults to the binomial distribution, and that distribution’s default link is the logit link. The **RANDOM** statement specifies that the linear predictor contains an intercept term that randomly varies at the level of the center effect. In other words, a random intercept is drawn separately and independently for each center in the study.

The results of this analysis are shown in [Figure 41.1](#)–[Figure 41.9](#).

The “Model Information Table” in [Figure 41.1](#) summarizes important information about the model you fit and about aspects of the estimation technique.

Figure 41.1 Model Information

The GLIMMIX Procedure	
Model Information	
Data Set	WORK.MULTICENTER
Response Variable (Events)	sideeffect
Response Variable (Trials)	n
Response Distribution	Binomial
Link Function	Logit
Variance Function	Default
Variance Matrix Blocked By	center
Estimation Technique	Residual PL
Degrees of Freedom Method	Containment

PROC GLIMMIX recognizes the variables `sideeffect` and `n` as the numerator and denominator in the *events/trials* syntax, respectively. The distribution—conditional on the random center effects—is binomial. The marginal variance matrix is block-diagonal, and observations from the same center form the blocks. The default estimation technique in generalized linear mixed models is residual pseudo-likelihood with a subject-specific expansion (**METHOD=RSPL**).

The “Class Level Information” table lists the levels of the variables specified in the **CLASS** statement and the ordering of the levels. The “Number of Observations” table displays the number of observations read and used in the analysis ([Figure 41.2](#)).

Figure 41.2 Class Level Information and Number of Observations

Class Level Information	
Class	Levels Values
center	15 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
group	2 A B
Number of Observations Read 30	
Number of Observations Used 30	
Number of Events 155	
Number of Trials 503	

There are two variables listed in the **CLASS** statement. The center variable has fifteen levels, and the group variable has two levels. Because the response is specified through the *events/trial* syntax, the “Number of Observations” table also contains the total number of events and trials used in the analysis.

The “Dimensions” table lists the size of relevant matrices (Figure 41.3).

Figure 41.3 Dimensions

Dimensions	
G-side Cov. Parameters	1
Columns in X	3
Columns in Z per Subject	1
Subjects (Blocks in V)	15
Max Obs per Subject	2

There are three columns in the **X** matrix, corresponding to an intercept and the two levels of the group variable. For each subject (center), the **Z** matrix contains only an intercept column.

The “Optimization Information” table provides information about the methods and size of the optimization problem (Figure 41.4).

Figure 41.4 Optimization Information

Optimization Information	
Optimization Technique	Dual Quasi-Newton
Parameters in Optimization	1
Lower Boundaries	1
Upper Boundaries	0
Fixed Effects	Profiled
Starting From	Data

The default optimization technique for generalized linear mixed models with binomial data is the quasi-Newton method. Because a residual likelihood technique is used to compute the objective function, only the covariance parameters participate in the optimization. A lower boundary constraint is placed on the variance component for the random center effect. The solution for this variance cannot be less than zero.

The “Iteration History” table displays information about the progress of the optimization process. After the initial optimization, the GLIMMIX procedure performed 15 updates before the convergence criterion was met (Figure 41.5). At convergence, the largest absolute value of the gradient was near zero. This indicates that the process stopped at an extremum of the objective function.

Figure 41.5 Iteration History and Convergence Status

Iteration History						
Iteration	Restarts	Subiterations	Objective Function	Change	Max Gradient	
0	0	5	79.688580269	0.11807224	7.851E-7	
1	0	3	81.294622554	0.02558021	8.209E-7	
2	0	2	81.438701534	0.00166079	4.061E-8	
3	0	1	81.444083567	0.00006263	2.311E-8	
4	0	1	81.444265216	0.00000421	0.000025	
5	0	1	81.444277364	0.00000383	0.000023	
6	0	1	81.444266322	0.00000348	0.000021	
7	0	1	81.44427636	0.00000316	0.000019	
8	0	1	81.444267235	0.00000287	0.000017	
9	0	1	81.444275529	0.00000261	0.000016	
10	0	1	81.44426799	0.00000237	0.000014	
11	0	1	81.444274843	0.00000216	0.000013	
12	0	1	81.444268614	0.00000196	0.000012	
13	0	1	81.444274277	0.00000178	0.000011	
14	0	1	81.444269129	0.00000162	9.772E-6	
15	0	0	81.444273808	0.00000000	9.102E-6	

Convergence criterion (PCONV=1.11022E-8) satisfied.

The “Fit Statistics” table lists information about the fitted model (Figure 41.6).

Figure 41.6 Fit Statistics

Fit Statistics	
-2 Res Log Pseudo-Likelihood	81.44
Generalized Chi-Square	30.69
Gener. Chi-Square / DF	1.10

Twice the negative of the residual log likelihood in the final pseudo-model equaled 81.44. The ratio of the generalized chi-square statistic and its degrees of freedom is close to 1. This is a measure of the residual variability in the marginal distribution of the data.

The “Covariance Parameter Estimates” table displays estimates and asymptotic estimated standard errors for all covariance parameters (Figure 41.7).

Figure 41.7 Covariance Parameter Estimates

Covariance Parameter Estimates			
Cov Parm	Subject	Estimate	Standard Error
Intercept	center	0.6176	0.3181

The variance of the random center intercepts on the logit scale is estimated as $\hat{\sigma}_c^2 = 0.6176$.

The “Parameter Estimates” table displays the solutions for the fixed effects in the model (Figure 41.8).

Figure 41.8 Parameter Estimates

Solutions for Fixed Effects						
Effect	group	Estimate	Standard Error	DF	t Value	Pr > t
Intercept		-0.8071	0.2514	14	-3.21	0.0063
group	A	-0.4896	0.2034	14	-2.41	0.0305
group	B	0

Because of the fixed-effects parameterization used in the GLIMMIX procedure, the “Intercept” effect is an estimate of $\beta_0 + \beta_B$, and the “A” group effect is an estimate of $\beta_A - \beta_B$, the log odds ratio. The associated estimated probabilities of side effects in the two groups are

$$\hat{\pi}_A = \frac{1}{1 + \exp\{0.8071 + 0.4896\}} = 0.2147$$

$$\hat{\pi}_B = \frac{1}{1 + \exp\{0.8071\}} = 0.3085$$

There is a significant difference between the two groups ($p = 0.0305$).

The “Type III Tests of Fixed Effect” table displays significance tests for the fixed effects in the model (Figure 41.9).

Figure 41.9 Type III Tests of Fixed Effects

Type III Tests of Fixed Effects				
Effect	Num DF	Den DF	F Value	Pr > F
group	1	14	5.79	0.0305

Because the group effect has only two levels, the p -value for the effect is the same as in the “Parameter Estimates” table, and the “ F Value” is the square of the “ t Value” shown there.

You can produce the estimates of the average logits in the two groups and their predictions on the scale of the data with the `LSMEANS` statement in PROC GLIMMIX:

```
ods select lsmeans;
proc glimmix data=multicenter;
  class center group;
  model sideeffect/n = group / solution;
  random intercept / subject=center;
  lsmeans group / cl ilink;
run;
```

The `LSMEANS` statement requests the least squares means of the group effect on the logit scale. The `CL` option requests their confidence limits. The `ILINK` option adds estimates, standard errors, and confidence limits on the mean (probability) scale (Figure 41.10).

Figure 41.10 Least Squares Means

The GLIMMIX Procedure								
group Least Squares Means								
group	Estimate	Standard Error	DF	t Value	Pr > t	Alpha	Lower	Upper
A	-1.2966	0.2601	14	-4.99	0.0002	0.05	-1.8544	-0.7388
B	-0.8071	0.2514	14	-3.21	0.0063	0.05	-1.3462	-0.2679
group Least Squares Means								
group	Mean	Standard Error Mean	Lower Mean	Upper Mean				
A	0.2147	0.04385	0.1354	0.3233				
B	0.3085	0.05363	0.2065	0.4334				

The “Estimate” column displays the least squares mean estimate on the logit scale, and the “Mean” column represents its mapping onto the probability scale. The “Lower” and “Upper” columns are 95% confidence limits for the logits in the two groups. The “Lower Mean” and “Upper Mean” columns are the corresponding confidence limits for the probabilities of side effects. These limits are obtained by inversely linking the confidence bounds on the linear scale, and thus are not symmetric about the estimate of the probabilities.

Syntax: GLIMMIX Procedure

The following statements are available in the GLIMMIX procedure:

```

PROC GLIMMIX < options > ;
  BY variables ;
  CLASS variable < (REF= option) > ... < variable < (REF= option) > > < / global-options > ;
  CODE < options > ;

  Programming statements ;

```

The **CLASS**, **CONTRAST**, **COVTEST**, **EFFECT**, **ESTIMATE**, **LSMEANS**, **LSMESTIMATE**, **RANDOM** and **SLICE** statements and the **programming statements** can appear multiple times. The **PROC GLIMMIX** and **MODEL** statements are required, and the **MODEL** statement must appear after the **CLASS** statement if a **CLASS** statement is included. The **EFFECT** statements must appear before the **MODEL** statement.

The **SLICE** statement is also available in many other procedures. A summary description of functionality and syntax for this statement is given in this chapter. You can find full documentation in the section “**SLICE Statement**” on page 498 of Chapter 19, “**Shared Concepts and Topics**.”

PROC GLIMMIX Statement

```

PROC GLIMMIX < options > ;

```

The **PROC GLIMMIX** statement invokes the **GLIMMIX** procedure. [Table 41.1](#) summarizes the options available in the **PROC GLIMMIX** statement. These and other options in the **PROC GLIMMIX** statement are then described fully in alphabetical order.

Table 41.1 PROC GLIMMIX Statement Options

Option	Description
Basic Options	
DATA=	Specifies the input data set
METHOD=	Determines estimation method
NOFIT	Does not fit the model
NOPROFILE	Includes scale parameter in optimization
NOREML	Determines computation of scale parameters in GLM models
ORDER=	Determines the sort order of CLASS variables
OUTDESIGN	Writes X and/or Z matrices to a SAS data set
PROFILE	Profile scale parameters from the optimization
Displayed Output	
ASYCORR	Displays the asymptotic correlation matrix of the covariance parameter estimates
ASYCOV	Displays the asymptotic covariance matrix of the covariance parameter estimates
GRADIENT	Displays the gradient of the objective function with respect to the parameter estimates
HESSIAN	Displays the Hessian matrix
ITDETAILS	Adds estimates and gradients to the “Iteration History”
NAMELEN=	Specifies the length of long effect names
NOBSDETAIL	Shows data exclusions
NOCLPRINT	Suppresses “Class Level Information” completely or in part
ODDSRATIO	Requests odds ratios
PLOTS	Produces ODS statistical graphics
SUBGRADIENT	Writes subject-specific gradients to a SAS data set
Optimization Options	
MAXOPT=	Specifies the number of optimizations
Computational Options	
CHOLESKY	Constructs and solves mixed model equations using the Cholesky root of the G matrix
EMPIRICAL	Computes empirical (“sandwich”) estimators
EXPHESSIAN	Uses the expected Hessian matrix to compute the covariance matrix of nonprofiled parameters
INFOCRIT	Affects the computation of information criteria
INITGLM	Uses fixed-effects starting values via generalized linear model
INITITER=	Sets the number of initial GLM steps
NOBOUND	Unbounds the covariance parameter estimates
NOINITGLM	Does not use fixed-effects starting values via generalized linear model
SCORING=	Applies Fisher scoring where applicable
SCOREMOD	Bases the Hessian matrix in GLMMs on a modified scoring algorithm

Table 41.1 *continued*

Option	Description
Singularity Tolerances	
ABSPCONV=	Determines the absolute parameter estimate convergence criterion for PL
FDIGITS=	Specifies significant digits in computing objective function
PCONV=	Specifies the relative parameter estimate convergence criterion for PL
SINGCHOL=	Tunes singularity for Cholesky decompositions
SINGRES=	Tunes singularity for the residual variance
SINGULAR=	Tunes general singularity criterion
Debugging Output	
LIST	Lists model program and variables

You can specify the following options in the PROC GLIMMIX statement.

ABSPCONV=*r*

specifies an absolute parameter estimate convergence criterion for doubly iterative estimation methods. For such methods, the GLIMMIX procedure by default examines the *relative* change in parameter estimates between optimizations (see PCONV=). The purpose of the ABSPCONV= criterion is to stop the process when the *absolute* change in parameter estimates is less than the tolerance criterion *r*. The criterion is based on fixed effects and covariance parameters.

Note that this convergence criterion does not affect the convergence criteria applied within any individual optimization. In order to change the convergence behavior within an optimization, you can change the ABSPCONV=, ABSFCONV=, ABSGCONV=, ABSXCONV=, FCONV=, or GCONV= option in the NLOPTIONS statement.

ASYCORR

produces the asymptotic correlation matrix of the covariance parameter estimates. It is computed from the corresponding asymptotic covariance matrix (see the description of the ASYCOV option, which follows).

ASYCOV

requests that the asymptotic covariance matrix of the covariance parameter estimates be displayed. By default, this matrix is the observed inverse Fisher information matrix, which equals $m\mathbf{H}^{-1}$, where \mathbf{H} is the Hessian (second derivative) matrix of the objective function. The factor *m* equals 1 in a GLM and equals 2 in a GLMM.

When you use the SCORING= option and PROC GLIMMIX converges without stopping the scoring algorithm, the procedure uses the expected Hessian matrix to compute the covariance matrix instead of the observed Hessian. Regardless of whether a scoring algorithm is used or the number of scoring iterations has been exceeded, you can request that the asymptotic covariance matrix be based on the expected Hessian with the EXPHESSIAN option in the PROC GLIMMIX statement. If a residual scale parameter is profiled from the likelihood equation, the asymptotic covariance matrix is adjusted for the presence of this parameter; details of this adjustment process are found in Wolfinger, Tobias, and Sall (1994) and in the section “Estimated Precision of Estimates” on page 3056.

CHOLESKY**CHOL**

requests that the mixed model equations be constructed and solved by using the Cholesky root of the \mathbf{G} matrix. This option applies only to estimation methods that involve mixed model equations. The Cholesky root algorithm has greater numerical stability but also requires more computing resources. When the estimated \mathbf{G} matrix is not positive definite during a particular function evaluation, PROC GLIMMIX switches to the Cholesky algorithm for that evaluation and returns to the regular algorithm if $\hat{\mathbf{G}}$ becomes positive definite again. When the CHOLESKY option is in effect, the procedure applies the algorithm all the time.

DATA=SAS-data-set

names the SAS data set to be used by PROC GLIMMIX. The default is the most recently created data set.

EMPIRICAL<=CLASSICAL | HC0>**EMPIRICAL<=DF | HC1>****EMPIRICAL<=MBN<(mbn-options)>>****EMPIRICAL<=ROOT | HC2>****EMPIRICAL<=FIRORES | HC3>****EMPIRICAL<=FIROEEQ<(r)>>**

requests that the covariance matrix of the parameter estimates be computed as one of the asymptotically consistent estimators, known as *sandwich* or *empirical* estimators. The name stems from the layering of the estimator. An empirically based estimate of the inverse variance of the parameter estimates (the “meat”) is wrapped by the model-based variance estimate (the “bread”).

Empirical estimators are useful for obtaining inferences that are not sensitive to the choice of the covariance model. In nonmixed models, they can help, for example, to allay the effects of variance heterogeneity on the tests of fixed effects. Empirical estimators can coarsely be grouped into likelihood-based and residual-based estimators. The distinction arises from the components used to construct the “meat” and “bread” of the estimator. If you specify the EMPIRICAL option without further qualifiers, the GLIMMIX procedure computes the classical sandwich estimator in the appropriate category.

Likelihood-Based Estimator

Let $\mathbf{H}(\boldsymbol{\alpha})$ denote the second derivative matrix of the log likelihood for some parameter vector $\boldsymbol{\alpha}$, and let $\mathbf{g}_i(\boldsymbol{\alpha})$ denote the gradient of the log likelihood with respect to $\boldsymbol{\alpha}$ for the i th of m independent sampling units. The gradient for the entire data is $\sum_{i=1}^m \mathbf{g}_i(\boldsymbol{\alpha})$. A sandwich estimator for the covariance matrix of $\hat{\boldsymbol{\alpha}}$ can then be constructed as (White 1982)

$$\mathbf{H}(\hat{\boldsymbol{\alpha}})^{-1} \left(\sum_{i=1}^m \mathbf{g}_i(\hat{\boldsymbol{\alpha}}) \mathbf{g}_i(\hat{\boldsymbol{\alpha}})' \right) \mathbf{H}(\hat{\boldsymbol{\alpha}})^{-1}$$

If you fit a mixed model by maximum likelihood with Laplace or quadrature approximation (METHOD=LAPLACE, METHOD=QUAD), the GLIMMIX procedure constructs this likelihood-based estimator when you choose EMPIRICAL=CLASSICAL. If you choose EMPIRICAL=MBN, the likelihood-based sandwich estimator is further adjusted (see the section “[Design-Adjusted MBN](#)”).

Estimator” on page 3079 for details). Because Laplace and quadrature estimation in GLIMMIX includes the fixed-effects parameters and the covariance parameters in the optimization, this empirical estimator adjusts the covariance matrix of both types of parameters. The following empirical estimators are not available with `METHOD=LAPLACE` or with `METHOD=QUAD`: `EMPIRICAL=DF`, `EMPIRICAL=ROOT`, `EMPIRICAL=FIRORES`, and `EMPIRICAL=FIROEEQ`.

Residual-Based Estimators

For a general model, let \mathbf{Y} denote the response with mean $\boldsymbol{\mu}$ and variance $\boldsymbol{\Sigma}$, and let \mathbf{D} be the matrix of first derivatives of $\boldsymbol{\mu}$ with respect to the fixed effects $\boldsymbol{\beta}$. The classical sandwich estimator (Huber 1967; White 1980) is

$$\hat{\boldsymbol{\Omega}} \left(\sum_{i=1}^m \hat{\mathbf{D}}_i' \hat{\boldsymbol{\Sigma}}_i^{-1} \mathbf{e}_i \mathbf{e}_i' \hat{\boldsymbol{\Sigma}}_i^{-1} \hat{\mathbf{D}}_i \right) \hat{\boldsymbol{\Omega}}$$

where $\boldsymbol{\Omega} = (\mathbf{D}'\boldsymbol{\Sigma}^{-1}\mathbf{D})^{-1}$, $\mathbf{e}_i = y_i - \hat{\boldsymbol{\mu}}_i$, and m denotes the number of independent sampling units.

Since the expected value of $\mathbf{e}_i \mathbf{e}_i'$ does not equal $\boldsymbol{\Sigma}_i$, the classical sandwich estimator is biased, particularly if m is small. The estimator tends to underestimate the variance of $\hat{\boldsymbol{\beta}}$. The `EMPIRICAL=DF`, `ROOT`, `FIRORES`, `FIROEEQ`, and `MBN` estimators are bias-corrected sandwich estimators. The `DF` estimator applies a simple sample size adjustment. The `ROOT`, `FIRORES`, and `FIROEEQ` estimators are based on Taylor series approximations applied to residuals and estimating equations. For uncorrelated data, the `EMPIRICAL=FIRORES` estimator can be motivated as a jackknife estimator.

In the case of a linear regression model, the various estimators reduce to the *heteroscedasticity-consistent covariance matrix* estimators (HCMM) of White (1980) and MacKinnon and White (1985). The classical estimator, HC0, was found to perform poorly in small samples. Based on simulations in regression models, MacKinnon and White (1985) and Long and Ervin (2000) strongly recommend the HC3 estimator. The sandwich estimators computed by the GLIMMIX procedure can be viewed as an extension of the HC0—HC3 estimators of MacKinnon and White (1985) to accommodate nonnormal data and correlated observations.

The `MBN` estimator, introduced as a residual-based estimator (Morel 1989; Morel, Bokossa, and Neerchal 2003), applies an additive adjustment to the residual crossproduct. It is controlled by three suboptions. The valid *mbn-options* are as follows: a sample size adjustment is applied when the `DF` suboption is in effect. The `NODF` suboption suppresses this component of the adjustment. The lower bound of the design effect parameter $0 \leq r \leq 1$ can be specified with the `R=` option. The magnitude of Morel’s δ parameter is partly determined with the `D=` option ($d \geq 1$).

For details about the general expression for the residual-based estimators and their relationship, see the section “Empirical Covariance (“Sandwich”) Estimators” on page 3078. The `MBN` estimator and its parameters are explained for residual- and likelihood-based estimators in the section “Design-Adjusted MBN Estimator” on page 3079.

The `EMPIRICAL=DF` estimator applies a simple, multiplicative correction factor to the classical estimator (Hinkley 1977). This correction factor is

$$c = \begin{cases} m/(m-k) & m > k \\ 1 & \text{otherwise} \end{cases}$$

where k is the rank of \mathbf{X} , and m equals the sum of all frequencies when PROC GLIMMIX is in GLM mode and equals the number of subjects in GLMM mode. For example, the following statements fit an overdispersed GLM:

```
proc glimmix empirical;
  model y = x;
  random _residual_;
run;
```

PROC GLIMMIX is in GLM mode, and the individual observations are the independent sampling units from which the sandwich estimator is constructed. If you use a **SUBJECT=** effect in the **RANDOM** statement, however, the procedure fits the model in GLMM mode and the subjects represent the sampling units in the construction of the sandwich estimator. In other words, the following statements fit a GEE-type model with independence working covariance structure and subjects (clusters) defined by the levels of ID:

```
proc glimmix empirical;
  class id;
  model y = x;
  random _residual_ / subject=id type=vc;
run;
```

See the section “[GLM Mode or GLMM Mode](#)” on page 3067 for information about how the GLIMMIX procedure determines the estimation mode.

The **EMPIRICAL=ROOT** estimator is based on the residual approximation in Kauermann and Carroll (2001), and the **EMPIRICAL=FIRORES** estimator is based on the approximation in Mancl and DeRouen (2001). The Kauermann and Carroll estimator requires the inverse square root of a nonsymmetric matrix. This square root matrix is obtained from the singular value decomposition in PROC GLIMMIX, and thus this sandwich estimator is computationally more demanding than others. In the linear regression case, the Mancl-DeRouen estimator can be motivated as a jackknife estimator, based on the “leave-one-out” estimates of $\hat{\beta}$; see MacKinnon and White (1985) for details.

The **EMPIRICAL=FIROEEQ** estimator is based on approximating an unbiased estimating equation (Fay and Graubard 2001). It is computationally less demanding than the estimator of Kauermann and Carroll (2001) and, in certain balanced cases, gives identical results. The optional number $0 \leq r < 1$ is chosen to provide an upper bound on the correction factor. The default value for r is 0.75.

When you specify the **EMPIRICAL** option with a residual-based estimator, PROC GLIMMIX adjusts all standard errors and test statistics involving the fixed-effects parameters.

Sampling Units

Computation of an empirical variance estimator requires that the data can be processed by independent sampling units. This is always the case in GLMs. In this case, m , the number of independent units, equals the sum of the frequencies used in the analysis (see “Number of Observations” table). In GLMMs, empirical estimators can be computed only if the data comprise more than one subject as per the “Dimensions” table. See the section “[Processing by Subjects](#)” on page 3082 for information about how the GLIMMIX procedure determines whether the data can be processed by subjects. If a GLMM comprises only a single subject for a particular BY group, the model-based variance estimator is used instead of the empirical estimator, and a message is written to the log.

EXPHESSIAN

requests that the expected Hessian matrix be used in computing the covariance matrix of the nonprofiled parameters. By default, the GLIMMIX procedure uses the observed Hessian matrix in computing the asymptotic covariance matrix of covariance parameters in mixed models and the covariance matrix of fixed effects in models without random effects. The EXPHESSIAN option is ignored if the (conditional) distribution is not a member of the exponential family or is unknown. It is also ignored in models for nominal data.

FDIGITS=*r*

specifies the number of accurate digits in evaluations of the objective function. Fractional values are allowed. The default value is $r = -\log_{10} \epsilon$, where ϵ is the machine precision. The value of r is used to compute the interval size for the computation of finite-difference approximations of the derivatives of the objective function. It is also used in computing the default value of the FCONV= option in the NLOPTIONS statement.

GRADIENT

displays the gradient of the objective function with respect to the parameter estimates in the “Covariance Parameter Estimates” table and/or the “Parameter Estimates” table.

HESSIAN**HESS****H**

displays the Hessian matrix of the optimization.

INFOCRIT=NONE | PQ | Q**IC=NONE | PQ | Q**

determines the computation of information criteria in the “Fit Statistics” table. The GLIMMIX procedure computes various information criteria that typically apply a penalty to the (possibly restricted) log likelihood, log pseudo-likelihood, or log quasi-likelihood that depends on the number of parameters and/or the sample size. If IC=NONE, these criteria are suppressed in the “Fit Statistics” table. This is the default for models based on pseudo-likelihoods.

The AIC, AICC, BIC, CAIC, and HQIC fit statistics are various information criteria. AIC and AICC represent Akaike’s information criteria (Akaike 1974) and a small sample bias corrected version thereof (for AICC, see Hurvich and Tsai 1989; Burnham and Anderson 1998). BIC represents Schwarz’s Bayesian criterion (Schwarz 1978). Table 41.2 gives formulas for the criteria.

Table 41.2 Information Criteria

Criterion	Formula	Reference
AIC	$-2\ell + 2d$	Akaike (1974)
AICC	$-2\ell + 2dn^*/(n^* - d - 1)$	Hurvich and Tsai (1989) Burnham and Anderson (1998)
HQIC	$-2\ell + 2d \log \log n$	Hannan and Quinn (1979)
BIC	$-2\ell + d \log n$	Schwarz (1978)
CAIC	$-2\ell + d(\log n + 1)$	Bozdogan (1987)

Here, ℓ denotes the maximum value of the (possibly restricted) log likelihood, log pseudo-likelihood, or log quasi-likelihood, d is the dimension of the model, and n , n^* reflect the size of the data.

The IC=PQ option requests that the penalties include the number of fixed-effects parameters, when estimation in models with random effects is based on a residual (restricted) likelihood. For **METHOD=MSPL**, **METHOD=MMPL**, **METHOD=LAPLACE**, and **METHOD=QUAD**, IC=Q and IC=PQ produce the same results. IC=Q is the default for linear mixed models with normal errors, and the resulting information criteria are identical to the IC option in the MIXED procedure.

The quantities d , n , and n^* depend on the model and IC= option in the following way:

GLM: IC=Q and IC=PQ options have no effect on the computation.

- d equals the number of parameters in the optimization whose solutions do not fall on the boundary or are otherwise constrained. The scale parameter is included, if it is part of the optimization. If you use the **PARMS** statement to place a hold on a scale parameter, that parameter does not count toward d .
- n equals the sum of the frequencies (f) for maximum likelihood and quasi-likelihood estimation and $f - \text{rank}(\mathbf{X})$ for restricted maximum likelihood estimation.
- n^* equals n , unless $n < d + 2$, in which case $n^* = d + 2$.

GLMM, IC=Q:

- d equals the number of effective covariance parameters—that is, covariance parameters whose solution does not fall on the boundary. For estimation of an unrestricted objective function (**METHOD=MMPL**, **METHOD=MSPL**, **METHOD=LAPLACE**, **METHOD=QUAD**), this value is incremented by $\text{rank}(\mathbf{X})$.
- n equals the effective number of subjects as displayed in the “Dimensions” table, unless this value equals 1, in which case n equals the number of levels of the first G-side **RANDOM** effect specified. If the number of effective subjects equals 1 and there are no G-side random effects, n is determined as

$$n = \begin{cases} f - \text{rank}(\mathbf{X}) & \text{METHOD} = \text{RMPL}, \text{METHOD} = \text{RSPL} \\ f & \text{otherwise} \end{cases}$$

where f is the sum of frequencies used.

- n^* equals f or $f - \text{rank}(\mathbf{X})$ (for **METHOD=RMPL** and **METHOD=RSPL**), unless this value is less than $d + 2$, in which case $n^* = d + 2$.

GLMM, IC=PQ: For **METHOD=MSPL**, **METHOD=MMPL**, **METHOD=LAPLACE**, and **METHOD=QUAD**, the results are the same as for IC=Q. For **METHOD=RSPL** and **METHOD=RMPL**, d equals the number of effective covariance parameters plus $\text{rank}(\mathbf{X})$, and $n = n^*$ equals $f - \text{rank}(\mathbf{X})$. The formulas for the information criteria thus agree with Verbeke and Molenberghs (2000, Table 6.7, p. 74) and Vonesh and Chinchilli (1997, p. 263).

INITGLM

requests that the estimates from a generalized linear model fit (a model without random effects) be used as the starting values for the generalized linear mixed model. This option is the default for **METHOD=LAPLACE** and **METHOD=QUAD**.

INITITER=number

specifies the maximum number of iterations used when a generalized linear model is fit initially to derive starting values for the fixed effects; see the **INITGLM** option. By default, the initial fit involves at most four iteratively reweighted least squares updates. You can change the upper limit of initial iterations with *number*. If the model does not contain random effects, this option has no effect.

ITDETAILS

adds parameter estimates and gradients to the “Iteration History” table.

LIST

requests that the model program and variable lists be displayed. This is a debugging feature and is not normally needed. When you use programming statements to define your statistical model, this option enables you to examine the complete set of statements submitted for processing. See the section “Programming Statements” for more details about how to use SAS statements with the GLIMMIX procedure.

MAXLMMUPDATE=number**MAXOPT=number**

specifies the maximum number of optimizations for doubly iterative estimation methods based on linearizations. After each optimization, a new pseudo-model is constructed through a Taylor series expansion. This step is known as the linear mixed model update. The **MAXLMMUPDATE** option limits the number of updates and thereby limits the number of optimizations. If this option is not specified, *number* is set equal to the value specified in the **MAXITER=** option in the **NLOPTIONS** statement. If no **MAXITER=** value is given, *number* defaults to 20.

METHOD=RSPL**METHOD=MSPL****METHOD=RMPL****METHOD=MMPL****METHOD=LAPLACE****METHOD=QUAD**< (*quad-options*) >

specifies the estimation method in a generalized linear mixed model (GLMM). The default is **METHOD=RSPL**.

Pseudo-Likelihood

Estimation methods ending in “PL” are pseudo-likelihood techniques. The first letter of the **METHOD=** identifier determines whether estimation is based on a residual likelihood (“R”) or a maximum likelihood (“M”). The second letter identifies the expansion locus for the underlying approximation. Pseudo-likelihood methods for generalized linear mixed models can be cast in terms of Taylor series expansions (linearizations) of the GLMM. The expansion locus of the expansion is either the vector of random effects solutions (“S”) or the mean of the random effects (“M”). The expansions are also referred to as the “S”ubject-specific and “M”arginal expansions. The abbreviation “PL” identifies the method as a pseudo-likelihood technique.

Residual methods account for the fixed effects in the construction of the objective function, which reduces the bias in covariance parameter estimates. Estimation methods involving Taylor series create pseudo-data for each optimization. Those data are transformed to have zero mean in a residual

method. While the covariance parameter estimates in a residual method are the maximum likelihood estimates for the transformed problem, the fixed-effects estimates are (estimated) generalized least squares estimates. In a likelihood method that is not residual based, both the covariance parameters and the fixed-effects estimates are maximum likelihood estimates, but the former are known to have greater bias. In some problems, residual likelihood estimates of covariance parameters are unbiased.

For more information about linearization methods for generalized linear mixed models, see the section “[Pseudo-likelihood Estimation Based on Linearization](#)” on page 3054.

Maximum Likelihood with Laplace Approximation

If you choose `METHOD=LAPLACE` with a generalized linear mixed model, PROC GLIMMIX approximates the marginal likelihood by using Laplace’s method. Twice the negative of the resulting log-likelihood approximation is the objective function that the procedure minimizes to determine parameter estimates. Laplace estimates typically exhibit better asymptotic behavior and less small-sample bias than pseudo-likelihood estimators. On the other hand, the class of models for which a Laplace approximation of the marginal log likelihood is available is much smaller compared to the class of models to which PL estimation can be applied.

To determine whether Laplace estimation can be applied in your model, consider the marginal distribution of the data in a mixed model

$$\begin{aligned} p(\mathbf{y}) &= \int p(\mathbf{y}|\boldsymbol{\gamma}) p(\boldsymbol{\gamma}) d\boldsymbol{\gamma} \\ &= \int \exp\{\log\{p(\mathbf{y}|\boldsymbol{\gamma})\} + \log\{p(\boldsymbol{\gamma})\}\} d\boldsymbol{\gamma} \\ &= \int \exp\{nf(\mathbf{y}, \boldsymbol{\gamma})\} d\boldsymbol{\gamma} \end{aligned}$$

The function $f(\mathbf{y}, \boldsymbol{\gamma})$ plays an important role in the Laplace approximation: it is a function of the joint distribution of the data and the random effects (see the section “[Maximum Likelihood Estimation Based on Laplace Approximation](#)” on page 3059). In order to construct a Laplace approximation, PROC GLIMMIX requires a conditional log-likelihood $\log\{p(\mathbf{y}|\boldsymbol{\gamma})\}$ as well as the distribution of the G-side random effects. The random effects are always assumed to be normal with zero mean and covariance structure determined by the `RANDOM` statement. The conditional distribution is determined by the `DIST=` option of the `MODEL` statement or the default associated with a particular response type. Because a valid conditional distribution is required, R-side random effects are not permitted for `METHOD=LAPLACE` in the GLIMMIX procedure. In other words, the GLIMMIX procedure requires for `METHOD=LAPLACE` conditional independence without R-side overdispersion or covariance structure.

Because the marginal likelihood of the data is approximated numerically, certain features of the marginal distribution are not available—for example, you cannot display a marginal variance-covariance matrix. Also, the procedure includes both the fixed-effects parameters and the covariance parameters in the optimization for Laplace estimation. Consequently, this setting imposes some restrictions with respect to available options for Laplace estimation. [Table 41.3](#) lists the options that are assumed for `METHOD=LAPLACE`, and [Table 41.4](#) lists the options that are not compatible with this estimation method.

The section “[Maximum Likelihood Estimation Based on Laplace Approximation](#)” contains details about Laplace estimation in PROC GLIMMIX.

Maximum Likelihood with Adaptive Quadrature

If you choose `METHOD=QUAD` in a generalized linear mixed model, the GLIMMIX procedure approximates the marginal log likelihood with an adaptive Gauss-Hermite quadrature. Compared to `METHOD=LAPLACE`, the models for which parameters can be estimated by quadrature are further restricted. In addition to the conditional independence assumption and the absence of R-side covariance parameters, it is required that models suitable for `METHOD=QUAD` can be processed by subjects. (See the section “[Processing by Subjects](#)” on page 3082 about how the GLIMMIX procedure determines whether the data can be processed by subjects.) This in turn requires that all `RANDOM` statements have `SUBJECT=` effects and in the case of multiple `SUBJECT=` effects that these form a containment hierarchy.

In a containment hierarchy each effect is contained by another effect, and the effect contained by all is considered “the” effect for subject processing. For example, the `SUBJECT=` effects in the following statements form a containment hierarchy:

```
proc glimmix;
  class A B block;
  model y = A B A*B;
  random intercept / subject=block;
  random intercept / subject=A*block;
run;
```

The block effect is contained in the `A*block` interaction and the data are processed by block. The `SUBJECT=` effects in the following statements do not form a containment hierarchy:

```
proc glimmix;
  class A B block;
  model y = A B A*B;
  random intercept / subject=block;
  random block      / subject=A;
run;
```

The section “[Maximum Likelihood Estimation Based on Adaptive Quadrature](#)” on page 3062 contains important details about the computations involved with quadrature approximations. The section “[Aspects Common to Adaptive Quadrature and Laplace Approximation](#)” on page 3064 contains information about issues that apply to Laplace and adaptive quadrature, such as the computation of the prediction variance matrix and the determination of starting values.

You can specify the following *quad-options* for `METHOD=QUAD` in parentheses:

EBDETAILS

reports details about the empirical Bayes suboptimization process should this suboptimization fail.

EBSSFRAC=*r*

specifies the step-shortening fraction to be used while computing empirical Bayes estimates of the random effects. The default value is $r = 0.8$, and it is required that $r > 0$.

EBSSTOL=*r*

specifies the objective function tolerance for determining the cessation of step shortening while computing empirical Bayes estimates of the random effects, $r \geq 0$. The default value is $r=1E-8$.

EBSTEPS=*n*

specifies the maximum number of Newton steps for computing empirical Bayes estimates of random effects, $n \geq 0$. The default value is $n=50$.

EBSUBSTEPS=*n*

specifies the maximum number of step shortenings for computing empirical Bayes estimates of random effects. The default value is $n=20$, and it is required that $n \geq 0$.

EBTOL=*r*

specifies the convergence tolerance for empirical Bayes estimation, $r \geq 0$. The default value is $r = \epsilon \times 1E4$, where ϵ is the machine precision. This default value equals approximately $1E-12$ on most machines.

INITPL=*number*

requests that adaptive quadrature commence after performing up to *number* pseudo-likelihood updates. The initial pseudo-likelihood (PL) steps (METHOD=MSPL) can be useful to provide good starting values for the quadrature algorithm. If you choose *number* large enough so that the initial PL estimation converges, the process is equivalent to starting a quadrature from the PL estimates of the fixed-effects and covariance parameters. Because this also makes available the PL random-effects solutions, the adaptive step of the quadrature that determines the number of quadrature points can take this information into account.

Note that you can combine the INITPL option with the NOINITGLM option in the PROC GLIMMIX statement to define a precise path for starting value construction to the GLIMMIX procedure. For example, the following statement generates starting values in these steps:

```
proc glimmix method=quad(initpl=5);
```

1. A GLM without random effects is fit initially to obtain as starting values for the fixed effects. The INITITER= option in the PROC GLIMMIX statement controls the number of iterations in this step.
2. Starting values for the covariance parameters are then obtained by MIVQUE0 estimation (Goodnight 1978a), using the fixed-effects parameter estimates from step 1.
3. With these values up to five pseudo-likelihood updates are computed.
4. The PL estimates for fixed-effects, covariance parameters, and the solutions for the random effects are then used to determine the number of quadrature points and used as the starting values for the quadrature.

The first step (GLM fixed-effects estimates) is omitted, if you modify the previous statement as follows:

```
proc glimmix method=quad(initpl=5) noinitglm;
```

The NOINITGLM option is the default of the pseudo-likelihood methods you select with the METHOD= option.

QCHECK

performs an adaptive recalculation of the objective function ($-2 \log$ likelihood) at the solution. The increment of the quadrature points, starting from the number of points used in the optimization, follows the same rules as the determination of the quadrature point sequence at the starting values (see the QFAC= and QMAX= suboptions). For example, the following statement estimates the parameters based on a quadrature with seven nodes in each dimension:

```
proc glimmix method=quad(qpoints=7 qcheck);
```

Because the default search sequence is 1, 3, 5, 7, 9, 11, 21, 31, the QCHECK option computes the $-2 \log$ likelihood at the converged solution for 9, 11, 21, and 31 quadrature points and reports relative differences to the converged value and among successive values. The ODS table produced by this option is named “QuadCheck.”

CAUTION: This option is useful to diagnose the sensitivity of the likelihood approximation at the solution. It does **not** diagnose the stability of the solution under changes in the number of quadrature points. For example, if increasing the number of points from 7 to 9 does not alter the objective function, this does not imply that a quadrature with 9 points would arrive at the same parameter estimates as a quadrature with 7 points.

QFAC=*r*

determines the step size for the quadrature point sequence. If the GLIMMIX procedure determines the quadrature nodes adaptively, the log likelihoods are computed for nodes in a pre-determined sequence. If N_{min} and N_{max} denote the values from the QMIN= and QMAX= suboptions, respectively, the sequence for values less than 11 is constructed in increments of 2 starting at N_{min} . Values greater than 11 are incremented in steps of r . The default value is $r=10$. The default sequence, without specifying the QMIN=, QMAX=, or QFAC= option, is thus 1, 3, 5, 7, 9, 11, 21, 31. By contrast, the following statement evaluates the sequence 8, 10, 30, 50:

```
proc glimmix method=quad(qmin=8, qmax=51, qfac=20);
```

QMAX=*n*

specifies an upper bound for the number of quadrature points. The default is $n=31$.

QMIN=*n*

specifies a lower bound for the number of quadrature points. The default is $n=1$ and the value must be less than the QMAX= value.

QPOINTS=*n*

determines the number of quadrature points in each dimension of the integral. Note that if there are r random effects for each subject, the GLIMMIX procedure evaluates n^r conditional log likelihoods for each observation to compute one value of the objective function. Increasing the number of quadrature nodes can substantially increase the computational burden. If you choose QPOINTS=1, the quadrature approximation reduces to the Laplace approximation. If you do not specify the number of quadrature points, it is determined adaptively by increasing the number of nodes at the starting values. See the section “[Aspects Common to Adaptive Quadrature and Laplace Approximation](#)” on page 3064 for details.

QTOL=*r*

specifies a relative tolerance criterion for the successive evaluation of log likelihoods for different numbers of quadrature points. When the GLIMMIX procedure determines the number of quadrature points adaptively, the number of nodes are increased until the QMAX=*n* limit is reached or until two successive evaluations of the log likelihood have a relative change of less than *r*. In the latter case, the lesser number of quadrature nodes is used for the optimization.

The EBSSFRAC, EBSSTOL, EBSTEPS, EBSUBSTEPS, and EBTOL suboptions affect the suboptimization that leads to the empirical Bayes estimates of the random effects. Under normal circumstances, there is no reason to change from the default values. When the sub-optimizations fail, the optimization process can come to a halt. If the EBDDETAILS option is in effect, you might be able to determine why the suboptimization fails and then adjust these values accordingly.

The QMIN, QMAX, QTOL, and QFAC suboptions determine the quadrature point search sequence for the adaptive component of estimation.

As for METHOD=LAPLACE, certain features of the marginal distribution are not available because the marginal likelihood of the data is approximated numerically. For example, you cannot display a marginal variance-covariance matrix. Also, the procedure includes both the fixed-effects and covariance parameters in the optimization for quadrature estimation. Consequently, this setting imposes some restrictions with respect to available options. Table 41.3 lists the options that are assumed for METHOD=QUAD and METHOD=LAPLACE, and Table 41.4 lists the options that are not compatible with these estimation methods.

Table 41.3 Defaults for METHOD=LAPLACE and METHOD=QUAD

Statement	Option
PROC GLIMMIX	NOPROFILE
PROC GLIMMIX	INITGLM
MODEL	NOCENTER

Table 41.4 Options Incompatible with METHOD=LAPLACE and METHOD=QUAD

Statement	Option
PROC GLIMMIX	EXPHESSIAN
PROC GLIMMIX	SCOREMOD
PROC GLIMMIX	SCORING
PROC GLIMMIX	PROFILE
MODEL	DDFM=KENWARDROGER
MODEL	DDFM=SATTERTHWAITE
MODEL	STDcoef
RANDOM	RESIDUAL
RANDOM _RESIDUAL_	All R-side random effects
RANDOM	V
RANDOM	VC
RANDOM	VCI
RANDOM	VCORR
RANDOM	VI

In addition to the options displayed in Table 41.4, the **NOBOUND** option in the **PROC GLIMMIX** and the **NOBOUND** option in the **PARMS** statements are not available with **METHOD=QUAD**. Unbounding the covariance parameter estimates is possible with **METHOD=LAPLACE**, however.

No Random Effects Present

If the model does not contain G-side random effects or contains only a single overdispersion component, then the model belongs to the family of (overdispersed) generalized linear models if the distribution is known or the quasi-likelihood models for independent data if the distribution is not known. The GLIMMIX procedure then estimates model parameters by the following techniques:

- normally distributed data: residual maximum likelihood
- nonnormal data: maximum likelihood
- data with unknown distribution: quasi-likelihood

The **METHOD=** specification then has only an effect with respect to the divisor used in estimating the overdispersion component. With a residual method, the divisor is $f - k$, where f denotes the sum of the frequencies and k is the rank of **X**. Otherwise, the divisor is f .

NAMELEN=number

specifies the length to which long effect names are shortened. The default and minimum value is 20.

NOBOUND

requests the removal of boundary constraints on covariance and scale parameters in mixed models. For example, variance components have a default lower boundary constraint of 0, and the **NOBOUND** option allows their estimates to be negative.

The **NOBOUND** option cannot be used for adaptive quadrature estimation with **METHOD=QUAD**. The scaling of the quadrature abscissas requires an inverse Cholesky root that is possibly not well defined when the **G** matrix of the mixed model is negative definite or indefinite. The Laplace approximation (**METHOD=LAPLACE**) is not subject to this limitation.

NOBSDetail

adds detailed information to the “Number of Observations” table to reflect how many observations were excluded from the analysis and for which reason.

NOCLPRINT<=number>

suppresses the display of the “Class Level Information” table, if you do not specify *number*. If you specify *number*, only levels with totals that are less than *number* are listed in the table.

NOFIT

suppresses fitting of the model. When the **NOFIT** option is in effect, **PROC GLIMMIX** produces the “Model Information,” “Class Level Information,” “Number of Observations,” and “Dimensions” tables. These can be helpful to gauge the computational effort required to fit the model. For example, the “Dimensions” table informs you as to whether the GLIMMIX procedure processes the data by subjects, which is typically more computationally efficient than processing the data as a single subject. See the section “[Processing by Subjects](#)” for more information.

If you request a radial smooth with knot selection by k -d tree methods, **PROC GLIMMIX** also computes the knot locations of the smoother. You can then examine the knots without fitting the model.

This enables you to try out different knot construction methods and bucket sizes. See the [KNOT-METHOD=KDTREE](#) option (and its suboptions) of the [RANDOM](#) statement.

If you combine the [NOFIT](#) option with the [OUTDESIGN](#) option, you can write the **X** and/or **Z** matrix of your model to a SAS data set without fitting the model.

NOINITGLM

requests that the starting values for the fixed effects not be obtained by first fitting a generalized linear model. This option is the default for the pseudo-likelihood estimation methods and for the linear mixed model. For the pseudo-likelihood methods, starting values can be implicitly defined based on an initial pseudo-data set derived from the data and the link function. For linear mixed models, starting values for the fixed effects are not necessary. The [NOINITGLM](#) option is useful in conjunction with the [INITPL=](#) suboption of [METHOD=QUAD](#) in order to perform initial pseudo-likelihood steps prior to an adaptive quadrature.

NOITPRINT

suppresses the display of the “Iteration History” table.

NOPROFILE

includes the scale parameter ϕ into the optimization for models that have such a parameter (see [Table 41.19](#)). By default, the [GLIMMIX](#) procedure profiles scale parameters from the optimization in mixed models. In generalized linear models, scale parameters are not profiled.

NOREML

determines the denominator for the computation of the scale parameter in a GLM for normal data and for overdispersion parameters. By default, the [GLIMMIX](#) procedure computes the scale parameter for the normal distribution as

$$\hat{\phi} = \sum_{i=1}^n \frac{f_i (y_i - \hat{y}_i)^2}{f - k}$$

where k is the rank of **X**, f_i is the frequency associated with the i th observation, and $f = \sum f_i$. Similarly, the overdispersion parameter in an overdispersed GLM is estimated by the ratio of the Pearson statistic and $(f - k)$. If the [NOREML](#) option is in effect, the denominators are replaced by f , the sum of the frequencies. In a GLM for normal data, this yields the maximum likelihood estimate of the error variance. For this case, the [NOREML](#) option is a convenient way to change from [REML](#) to [ML](#) estimation.

In [GLMM](#) models fit by pseudo-likelihood methods, the [NOREML](#) option changes the estimation method to the nonresidual form. See the [METHOD=](#) option for the distinction between residual and nonresidual estimation methods.

ODDSRATIO

OR

requests that odds ratios be added to the output when applicable. Odds ratios and their confidence limits are reported only for models with logit, cumulative logit, or generalized logit link. Specifying the [ODDSRATIO](#) option in the [PROC GLIMMIX](#) statement has the same effect as specifying the [ODDSRATIO](#) option in the [MODEL](#) statement and in all [LSMEANS](#) statements. Note that the [ODDSRATIO](#) option in the [MODEL](#) statement has several suboptions that enable you to construct customized odds ratios. These suboptions are available only through the [MODEL](#) statement. For details about the interpretation and computation of odds and odds ratios with the [GLIMMIX](#) procedure, see the section “Odds and Odds Ratio Estimation” on page 3090.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of the classification variables (which are specified in the **CLASS** statement). This ordering determines which parameters in the model correspond to each level in the data, so the **ORDER=** option can be useful when you use **CONTRAST** or **ESTIMATE** statements. This option applies to the levels for all classification variables, except when you use the (default) **ORDER=FORMATTED** option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The **ORDER=** option can take the following values:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, **ORDER=FORMATTED**. For **ORDER=FORMATTED** and **ORDER=INTERNAL**, the sort order is machine-dependent.

When the response variable appears in a **CLASS** statement, the **ORDER=** option in the **PROC GLIMMIX** statement applies to its sort order. Specification of a *response-option* in the **MODEL** statement overrides the **ORDER=** option in the **PROC GLIMMIX** statement. For example, in the following statements the sort order of the *wheeze* variable is determined by the formatted value (default):

```
proc glimmix order=data;
  class city;
  model wheeze = city age / dist=binary s;
run;
```

The **ORDER=** option in the **PROC GLIMMIX** statement has no effect on the sort order of the *wheeze* variable because it does not appear in the **CLASS** statement. However, in the following statements the sort order of the *wheeze* variable is determined by the order of appearance in the input data set because the response variable appears in the **CLASS** statement:

```
proc glimmix order=data;
  class city wheeze;
  model wheeze = city age / dist=binary s;
run;
```

For more information about sort order, see the chapter on the **SORT** procedure in the *Base SAS Procedures Guide* and the discussion of **BY**-group processing in *SAS Language Reference: Concepts*.

OUTDESIGN< (*options*) > < =SAS-data-set >

creates a data set that contains the contents of the **X** and **Z** matrix. If the data are processed by subjects as shown in the “Dimensions” table, then the **Z** matrix saved to the data set corresponds to a single subject. By default, the GLIMMIX procedure includes in the OUTDESIGN data set the **X** and **Z** matrix (if present) and the variables in the input data set. You can specify the following *options* in parentheses to control the contents of the OUTDESIGN data set:

NAMES

produces tables associating columns in the OUTDESIGN data set with fixed-effects parameter estimates and random-effects solutions.

NOMISS

excludes from the OUTDESIGN data set observations that were not used in the analysis.

NOVAR

excludes from the OUTDESIGN data set variables from the input data set. Variables listed in the **BY** and **ID** statements and variables needed for identification of **SUBJECT=** effects are always included in the OUTDESIGN data set.

X< =*prefix* >

saves the contents of the **X** matrix. The optional *prefix* is used to name the columns. The default naming prefix is “_X”.

Z< =*prefix* >

saves the contents of the **Z** matrix. The optional *prefix* is used to name the columns. The default naming prefix is “_Z”.

The order of the observations in the OUTDESIGN data set is the same as the order of the input data set. If you do not specify a data set with the OUTDESIGN option, the procedure uses the **DATA=** convention to name the data set.

PCONV=*r*

specifies the parameter estimate convergence criterion for doubly iterative estimation methods. The GLIMMIX procedure applies this criterion to fixed-effects estimates and covariance parameter estimates. Suppose $\hat{\psi}_i^{(u)}$ denotes the estimate of the *i*th parameter at the *u*th optimization. The procedure terminates the doubly iterative process if the largest value

$$2 \times \frac{|\hat{\psi}_i^{(u)} - \hat{\psi}_i^{(u-1)}|}{|\hat{\psi}_i^{(u)}| + |\hat{\psi}_i^{(u-1)}|}$$

is less than *r*. To check an absolute convergence criteria as well, you can set the **ABSPCONV=** option in the PROC GLIMMIX statement. The default value for *r* is 1E8 times the machine epsilon, a product that equals about 1E–8 on most machines.

Note that this convergence criterion does not affect the convergence criteria applied within any individual optimization. In order to change the convergence behavior within an optimization, you can use the **ABSCONV=**, **ABSFCONV=**, **ABSGCONV=**, **ABSXCONV=**, **FCONV=**, or **GCONV=** option in the **NLOPTIONS** statement.

PLOTS <(global-plot-options)> <= plot-request <(options)>>

PLOTS <(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>>
requests that the GLIMMIX procedure produce statistical graphics via ODS Graphics.

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc glimmix data=plants;
  class Block Type;
  model StemLength = Block Type;
  lsmeans type / diff=control plots=controlplot;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

For examples of the basic statistical graphics produced by the GLIMMIX procedure and aspects of their computation and interpretation, see the section “[ODS Graphics](#)” on page 3115 in this chapter. You can also request statistical graphics for least squares means through the **PLOTS** option in the **LSMEANS** statement, which gives you more control over the display compared to the **PLOTS** option in the **PROC GLIMMIX** statement.

Global Plot Options

The *global-plot-options* apply to all relevant plots generated by the GLIMMIX procedure. The *global-plot-options* supported by the GLIMMIX procedure are as follows:

OBSNO

uses the data set observation number to identify observations in tooltips, provided that the observation number can be determined. Otherwise, the number displayed in tooltips is the index of the observation as it is used in the analysis within the BY group.

UNPACKPANEL

UNPACK

displays each graph separately. (By default, some graphs can appear together in a single panel.)

Specific Plot Options

The following listing describes the specific plots and their options.

ALL

requests that all plots appropriate for the analysis be produced. In models with G-side random effects, residual plots are based on conditional residuals (by using the BLUPs of random effects) on the linear (linked) scale. Plots of least squares means differences are produced for **LSMEANS** statements without options that would contradict such a display.

ANOMPLOT**ANOM**

requests an analysis of means display in which least squares means are compared against an average least squares mean (Ott 1967; Nelson 1982, 1991, 1993). See the **DIFF=** option in the **LSMEANS** statement for the computation of this average. Least squares mean ANOM plots are produced only for those fixed effects that are listed in **LSMEANS** statements that have options that do not contradict the display. For example, if you request ANOM plots with the **PLOTS=** option in the **PROC GLIMMIX** statement, the following **LSMEANS** statements produce analysis of mean plots for effects A and C:

```
lsmeans A / diff=anom;
lsmeans B / diff;
lsmeans C;
```

The **DIFF** option in the second **LSMEANS** statement implies all pairwise differences.

When differences against the average LS-mean are adjusted for multiplicity with the **ADJUST=NELSON** option in the **LSMEANS** statement, the ANOMPLOT display is adjusted accordingly.

BOXPLOT <(boxplot-options)>

requests box plots for the effects in your model that consist of classification effects only. Note that these effects can involve more than one classification variable (interaction and nested effects), but cannot contain any continuous variables. By default, the **BOXPLOT** request produces box plots of (conditional) residuals for the qualifying effects in the **MODEL** and **RANDOM** statements. See the discussion of the *boxplot-options* in a later section for information about how to tune your box plot request.

CONTROLPLOT**CONTROL**

requests a display in which least squares means are visually compared against a reference level. LS-mean control plots are produced only for those fixed effects that are listed in **LSMEANS** statements that have options that do not contradict with the display. For example, the following statements produce control plots for effects A and C if you specify **PLOTS=CONTROL** in the **PROC GLIMMIX** statement:

```
lsmeans A / diff=control('1');
lsmeans B / diff;
lsmeans C;
```

The **DIFF** option in the second **LSMEANS** statement implies all pairwise differences.

When differences against a control level are adjusted for multiplicity with the **ADJUST=** option in the **LSMEANS** statement, the control plot display is adjusted accordingly.

DIFFPLOT< (*diffplot-options*) >

DIFFOGRAM < (*diffplot-options*) >

DIFF< (*diffplot-options*) >

requests a display of all pairwise least squares mean differences and their significance. When constructed from arithmetic means, the display is also known as a “mean-mean scatter plot” (Hsu 1996; Hsu and Peruggia 1994). For each comparison a line segment, centered at the LS-means in the pair, is drawn. The length of the segment corresponds to the projected width of a confidence interval for the least squares mean difference. Segments that fail to cross the 45-degree reference line correspond to significant least squares mean differences.

If you specify the **ADJUST=** option in the **LSMEANS** statement, the lengths of the line segments are adjusted for multiplicity.

LS-mean difference plots are produced only for those fixed effects listed in **LSMEANS** statements that have options that do not conflict with the display. For example, the following statements request differences against a control level for the A effect, all pairwise differences for the B effect, and the least squares means for the C effect:

```
lsmeans A / diff=control('1');
lsmeans B / diff;
lsmeans C;
```

The **DIFF=** type in the first statement contradicts a display of all pairwise differences. Difference plots are produced only for the B and C effects if you specify **PLOTS=DIFF** in the **PROC GLIMMIX** statement.

You can specify the following *diffplot-options*. The **ABS** and **NOABS** options determine the positioning of the line segments in the plot. When the **ABS** option is in effect (this is the default) all line segments are shown on the same side of the reference line. The **NOABS** option separates comparisons according to the sign of the difference. The **CENTER** option marks the center point for each comparison. This point corresponds to the intersection of two least squares means. The **NOLINES** option suppresses the display of the line segments that represent the confidence bounds for the differences of the least squares means. The **NOLINES** option implies the **CENTER** option. The default is to draw line segments in the upper portion of the plot area without marking the center point.

MEANPLOT< (*meanplot-options*) >

requests a display of the least squares means of effects specified in **LSMEANS** statements. The following *meanplot-options* affect the display. Upper and lower confidence limits are plotted when the **CL** option is used. When the **CLBAND** option is in effect, confidence limits are shown as bands and the means are connected. By default, least squares means are not joined by lines. You can achieve that effect with the **JOIN** or **CONNECT** option. Least squares means are displayed in the same order in which they appear in the “Least Squares Means” table. You can change that order for plotting purposes with the **ASCENDING** and **DESCENDING** options. The **ILINK** option requests that results be displayed on the inverse linked (the data) scale.

Note that there is also a **MEANPLOT** suboption of the **PLOTS=** option in the **LSMEANS** statement. In addition to the *meanplot-options* just described, you can also specify classification effects that give you more control over the display of interaction means through the **PLOTBY=** and **SLICEBY=** options. To display interaction means, you typically want to use the **MEANPLOT** option in the **LSMEANS** statement. For example, the next statement requests a plot in

which the levels of A are placed on the horizontal axis and the means that belong to the same level of B are joined by lines:

```
lsmeans A*B / plot=meanplot(sliceby=b join);
```

NONE

requests that no plots be produced.

ODDSRATIO <(oddsratioplot-options)>

requests a display of odds ratios and their confidence limits when the link function permits the computation of odds ratios (see the **ODDSRATIO** option in the **MODEL** statement). Possible suboptions of the **ODDSRATIO** plot request are described below under the heading “Odds Ratio Plot Options.”

RESIDUALPANEL<(residualplot-options)>

requests a paneled display constructed from raw residuals. The panel consists of a plot of the residuals against the linear predictor or predicted mean, a histogram with normal density overlaid, a *Q-Q* plot, and a box plot of the residuals. The *residualplot-options* enable you to specify which type of residual is being graphed. These are further discussed below under the heading “Residual Plot Options.”

STUDENTPANEL<(residualplot-options)>

requests a paneled display constructed from studentized residuals. The same panel organization is applied as for the **RESIDUALPANEL** plot type.

PEARSONPANEL<(residualplot-options)>

requests a paneled display constructed from Pearson residuals. The same panel organization is applied as for the **RESIDUALPANEL** plot type.

Residual Plot Options

The *residualplot-options* apply to the **RESIDUALPANEL**, **STUDENTPANEL**, and **PEARSONPANEL** displays. The primary function of these options is to control which type of a residual to display. The four types correspond to *keyword-options* as for output statistics in the **OUTPUT** statement. The *residualplot-options* take on the following values:

BLUP

CONDITIONAL

uses the predictors of the random effects in computing the residual.

ILINK

NONLINEAR

computes the residual on the inverse linked scale (the data scale).

NOBLUP

MARGINAL

does not use the predictors of the random effects in computing the residual.

NOILINK**LINEAR**

computes the residual on the linked scale.

UNPACK

produces separate plots from the elements of the panel.

You can list a plot request one or more times with different options. For example, the following statements request a panel of marginal raw residuals, individual plots generated from a panel of the conditional raw residuals, and a panel of marginal studentized residuals:

```
ods graphics on;
proc glimmix plots=(ResidualPanel(marginal)
                   ResidualPanel(unpack conditional)
                   StudentPanel(marginal));
```

The default is to compute conditional residuals on the linear scale if the model contains G-side random effects (BLUP NOILINK). Not all combinations of the BLUP/NOBLUP and ILINK/NOILINK suboptions are possible for all residual types and models. For details, see the description of output statistics for the **OUTPUT** statement. Pearson residuals are always displayed against the linear predictor; all other residuals are graphed versus the linear predictor if the NOILINK suboption is in effect (default), and against the corresponding prediction on the mean scale if the ILINK option is in effect. See [Table 41.14](#) for a definition of the residual quantities and exclusions.

Box Plot Options

The *boxplot-options* determine whether box plots are produced for residuals or for residuals and observed values, and for which model effects the box plots are constructed. The available *boxplot-options* are as follows:

BLOCK**BLOCKLEGEND**

displays levels of up to four classification variables of the box plot effect by using block legends instead of axis tick values.

BLUP**CONDITIONAL**

constructs box plots from conditional residuals—that is, residuals that use the estimated BLUPs of random effects.

FIXED

produces box plots for all fixed effects (**MODEL** statement) consisting entirely of classification variables.

GROUP

produces box plots for all **GROUP=** effects in **RANDOM** statements consisting entirely of classification variables.

ILINK**NONLINEAR**

computes the residual on the scale of the data (the inverse linked scale).

NOBLUP**MARGINAL**

constructs box plots from marginal residuals.

NOILINK**LINEAR**

computes the residual on the linked scale.

NPANELPOS=*number*

specifies the number of box positions on the graphic and provides the capability to break a box plot into multiple graphics. If *number* is negative, no balancing of the number of boxes takes place and *number* is the maximum number of boxes per graphic. If *number* is positive, the number of boxes per graphic is balanced. For example, suppose that variable A has 125 levels. The following statements request that the number of boxes per plot results be balanced and result in six plots with 18 boxes each and one plot with 17 boxes:

```
ods graphics on;
proc glimmix plots=boxplot (npanelpos=20);
  class A;
  model y = A;
run;
```

If *number* is zero (this is the default), all levels of the effect are displayed in a single plot.

OBSERVED

adds box plots of the observed data for the selected effects.

PEARSON

constructs box plots from Pearson residuals rather than from the default residuals.

PSEUDO

adds box plots of the pseudo-data for the selected effects. This option is available only for the pseudo-likelihood estimation methods that construct pseudo-data.

RANDOM

produces box plots for all effects in **RANDOM** statements that consist entirely of classification variables. This does not include effects specified in the **GROUP=** or **SUBJECT=** option of the **RANDOM** statements.

RAW

constructs box plots from raw residuals (observed minus predicted).

STUDENT

constructs box plots from studentized residuals rather than from the default residuals.

SUBJECT

produces box plots for all **SUBJECT=** effects in **RANDOM** statements consisting entirely of classification variables.

USEINDEX

uses as the horizontal axis label the index of the effect level, rather than the formatted value(s). For classification variables with many levels or model effects that involve multiple classification variables, the formatted values identifying the effect levels might take up too much space as axis tick values, leading to extensive thinning. The **USEINDEX** option replaces tick values constructed from formatted values with the internal level number.

By default, box plots of residuals are constructed from the raw conditional residuals (on the linked scale) in linear mixed models and from Pearson residuals in all other models. Note that not all combinations of the **BLUP/NOBLUP** and **ILINK/NOILINK** suboptions are possible for all residual types and models. For details, see the description of output statistics for the **OUTPUT** statement.

Odds Ratio Plot Options

The *oddsratioplot-options* determine the display of odds ratios and their confidence limits. The computation of the odds ratios follows the **ODDSRATIO** option in the **MODEL** statement. The available *oddsratioplot-options* are as follows:

LOGBASE= 2 | E | 10

log-scales the odds ratio axis.

NPANELPOS=*n*

provides the capability to break an odds ratio plot into multiple graphics having at most $|n|$ odds ratios per graphic. If n is positive, then the number of odds ratios per graphic is balanced. If n is negative, then no balancing of the number of odds ratios takes place. For example, suppose you want to display 21 odds ratios. Then **NPANELPOS=20** displays two plots, the first with 11 and the second with 10 odds ratios, and **NPANELPOS=-20** displays 20 odds ratios in the first plot and a single odds ratio in the second. If $n=0$ (this is the default), then all odds ratios are displayed in a single plot.

ORDER=ASCENDING | DESCENDING

displays the odds ratios in sorted order. By default the odds ratios are displayed in the order in which they appear in the “Odds Ratio Estimates” table.

RANGE=(*< min >* *<, max >*) | CLIP

specifies the range of odds ratios to display. If you specify **RANGE=CLIP**, then the confidence intervals are clipped and the range contains the minimum and maximum odds ratios. By default the range of view captures the extent of the odds ratio confidence intervals.

STATS

adds the numeric values of the odds ratio and its confidence limits to the graphic.

PROFILE

requests that scale parameters be profiled from the optimization, if possible. This is the default for generalized linear mixed models. In generalized linear models with normally distributed data, you can use the PROFILE option to request profiling of the residual variance.

SCOREMOD

requests that the Hessian matrix in GLMMs be based on a modified scoring algorithm, provided that PROC GLIMMIX is in scoring mode when the Hessian is evaluated. The procedure is in scoring mode during iteration, if the optimization technique requires second derivatives, the SCORING=*n* option is specified, and the iteration count has not exceeded *n*. The procedure also computes the expected (scoring) Hessian matrix when you use the EXPHESSIAN option in the PROC GLIMMIX statement.

The SCOREMOD option has no effect if the SCORING= or EXPHESSIAN option is not specified. The nature of the SCOREMOD modification to the expected Hessian computation is shown in Table 41.21, in the section “Pseudo-likelihood Estimation Based on Linearization” on page 3054. The modification can improve the convergence behavior of the GLMM compared to standard Fisher scoring and can provide a better approximation of the variability of the covariance parameters. For more details, see the section “Estimated Precision of Estimates” on page 3056.

SCORING=*number*

requests that Fisher scoring be used in association with the estimation method up to iteration *number*. By default, no scoring is applied. When you use the SCORING= option and PROC GLIMMIX converges without stopping the scoring algorithm, the procedure uses the expected Hessian matrix to compute approximate standard errors for the covariance parameters instead of the observed Hessian. If necessary, the standard errors of the covariance parameters as well as the output from the ASYCOV and ASYCORR options are adjusted.

If scoring stopped prior to convergence and you want to use the expected Hessian matrix in the computation of standard errors, use the EXPHESSIAN option in the PROC GLIMMIX statement.

Scoring is not possible in models for nominal data. It is also not possible for GLMs with unknown distribution or for those outside the exponential family. If you perform quasi-likelihood estimation, the GLIMMIX procedure is always in scoring mode and the SCORING= option has no effect. See the section “Quasi-likelihood for Independent Data” for a description of the types of models where GLIMMIX applies quasi-likelihood estimation.

The SCORING= option has no effect for optimization methods that do not involve second derivatives. See the TECHNIQUE= option in the NLOPTIONS statement and the section “Choosing an Optimization Algorithm” on page 494 in Chapter 19, “Shared Concepts and Topics,” for details about first- and second-order algorithms.

SINGCHOL=*number*

tunes the singularity criterion in Cholesky decompositions. The default is 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

SINGRES=*number*

sets the tolerance for which the residual variance is considered to be zero. The default is 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

SINGULAR=number

tunes the general singularity criterion applied by the GLIMMIX procedure in divisions and inversions. The default is 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

STARTGLM

is an alias of the [INITGLM](#) option.

SUBGRADIENT< =SAS-data-set >**SUBGRAD< =SAS-data-set >**

creates a data set with information about the gradient of the objective function. The contents and organization of the SUBGRADIENT= data set depend on the type of model. The following paragraphs describe the SUBGRADIENT= data set for the two major estimation modes. See the section “[GLM Mode or GLMM Mode](#)” on page 3067 for details about the estimation modes of the GLIMMIX procedure.

GLMM Mode

If the GLIMMIX procedure operates in GLMM mode, the SUBGRADIENT= data set contains as many observations as there are usable subjects in the analysis. The maximum number of usable subjects is displayed in the “Dimensions” table. Gradient information is not written to the data set for subjects who do not contribute valid observations to the analysis. Note that the objective function in the “Iteration History” table is in terms of the $-2 \log$ (residual, pseudo-) likelihood. The gradients in the SUBGRADIENT= data set are gradients of that objective function.

The gradients are evaluated at the final solution of the estimation problem. If the GLIMMIX procedure fails to converge, then the information in the SUBGRADIENT= data set corresponds to the gradient evaluated at the last iteration or optimization.

The number of gradients saved to the SUBGRADIENT= data set equals the number of parameters in the optimization. For example, with [METHOD=LAPLACE](#) or [METHOD=QUAD](#) the fixed-effects parameters and the covariance parameters take part in the optimization. The order in which the gradients appear in the data set equals the order in which the gradients are displayed when the [ITDETAILS](#) option is in effect: gradients for fixed-effects parameters precede those for covariance parameters, and gradients are not reported for singular columns in the $X'X$ matrix. In models where the residual variance is profiled from the optimization, a subject-specific gradient is not reported for the residual variance. To decompose this gradient by subjects, add the [NOPROFILE](#) option in the [PROC GLIMMIX](#) statement. When the subject-specific gradients in the SUBGRADIENT= data set are summed, the totals equal the values reported by the [GRADIENT](#) option.

GLM Mode

When you fit a generalized linear model (GLM) or a GLM with overdispersion, the SUBGRADIENT= data set contains the observation-wise gradients of the negative log-likelihood function with respect to the parameter estimates. Note that this corresponds to the objective function in GLMs as displayed in the “Iteration History” table. However, the gradients displayed in the “Iteration History” for GLMs—when the [ITDETAILS](#) option is in effect—are possibly those of the centered and scaled coefficients. The gradients reported in the “Parameter Estimates” table and in the SUBGRADIENT= data set are gradients with respect to the uncentered and unscaled coefficients.

The gradients are evaluated at the final estimates. If the model does not converge, the gradients contain missing values. The gradients appear in the SUBGRADIENT= data set in the same order as in the “Parameter Estimates” table, with singular columns removed.

The variables from the input data set are added to the SUBGRADIENT= data set in GLM mode. The data set is organized in the same way as the input data set; observations that do not contribute to the analysis are transferred to the SUBGRADIENT= data set, but gradients are calculated only for observations that take part in the analysis. If you use an ID statement, then only the variables in the ID statement are transferred to the SUBGRADIENT= data set.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC GLIMMIX to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the GLIMMIX procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

Since sorting the data changes the order in which PROC GLMMIX reads observations, the sort order for the levels of the CLASS variables might be affected if you have also specified ORDER=DATA in the PROC GLIMMIX statement. This, in turn, affects specifications in the CONTRAST, ESTIMATE, or LSMESTIMATE statement.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CLASS Statement

CLASS *variable* <(REF= *option*)> ... <*variable* <(REF= *option*)>> </ *global-options* > ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

NOTE: Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the ORDER= option in the PROC GLIMMIX statement. You can specify the following REF= option to indicate how the levels of an individual classification variable are to be ordered by enclosing it in parentheses after the variable name:

REF= 'level' | FIRST | LAST

specifies a level of the classification variable to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the estimates with PROC GLIMMIX's singular parameterization. You can specify the *level* of the variable to use as the reference level; specify a value that corresponds to the formatted value of the variable if a format is assigned. Alternatively, you can specify REF=FIRST to designate that the first ordered level serve as the reference, or REF=LAST to designate that the last ordered level serve as the reference. To specify that REF=FIRST or REF=LAST be used for all classification variables, use the REF= *global-option* after the slash (/) in the CLASS statement.

You can specify the following *global-options* in the CLASS statement after a slash (/):

REF=FIRST | LAST

specifies a level of all classification variables to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the estimates with PROC GLIMMIX's singular parameterization. Specify REF=FIRST to designate that the first ordered level for each classification variable serve as the reference. Specify REF=LAST to designate that the last ordered level serve as the reference. This option applies to all the variables specified in the CLASS statement. To specify different reference levels for different classification variables, use REF= options for individual variables.

TRUNCATE

specifies that class levels be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

CODE Statement

CODE < options > ;

The CODE statement enables you to write SAS DATA step code for computing predicted values of the fitted model either to a file or to a catalog entry. This code can then be included in a DATA step to score new data.

Table 41.5 summarizes the *options* available in the CODE statement.

Table 41.5 CODE Statement Options

Option	Description
CATALOG=	Names the catalog entry where the generated code is saved
DUMMIES	Retains the dummy variables in the data set
ERROR	Computes the error function
FILE=	Names the file where the generated code is saved
FORMAT=	Specifies the numeric format for the regression coefficients
GROUP=	Specifies the group identifier for array names and statement labels
IMPUTE	Imputes predicted values for observations with missing or invalid covariates
LINESIZE=	Specifies the line size of the generated code
LOOKUP=	Specifies the algorithm for looking up CLASS levels
RESIDUAL	Computes residuals

For details about the syntax of the CODE statement, see the section “CODE Statement” on page 390 in Chapter 19, “Shared Concepts and Topics.”

CONTRAST Statement

```

CONTRAST 'label' contrast-specification
    <, contrast-specification> <, ... >
    </ options> ;

```

The CONTRAST statement provides a mechanism for obtaining custom hypothesis tests. It is patterned after the CONTRAST statement in PROC MIXED and enables you to select an appropriate inference space (McLean, Sanders, and Stroup 1991). The GLIMMIX procedure gives you greater flexibility in entering contrast coefficients for random effects, however, because it permits the usual *value*-oriented positional syntax for entering contrast coefficients, as well as a level-oriented syntax that simplifies entering coefficients for interaction terms and is designed to work with constructed effects that are defined through the experimental EFFECT statement. The differences between the traditional and new-style coefficient syntax are explained in detail in the section “Positional and Nonpositional Syntax for Contrast Coefficients” on page 3097.

You can test the hypothesis $\mathbf{L}'\boldsymbol{\phi} = \mathbf{0}$, where $\mathbf{L}' = [\mathbf{K}' \mathbf{M}']$ and $\boldsymbol{\phi}' = [\boldsymbol{\beta}' \boldsymbol{\gamma}']$, in several inference spaces. The inference space corresponds to the choice of \mathbf{M} . When $\mathbf{M} = \mathbf{0}$, your inferences apply to the entire population from which the random effects are sampled; this is known as the *broad* inference space. When all elements of \mathbf{M} are nonzero, your inferences apply only to the observed levels of the random effects. This is known as the *narrow* inference space, and you can also choose it by specifying all of the random effects as fixed. The GLM procedure uses the narrow inference space. Finally, by zeroing portions of \mathbf{M} corresponding to selected main effects and interactions, you can choose *intermediate* inference spaces. The broad inference space is usually the most appropriate; it is used when you do not specify random effects in the CONTRAST statement.

In the CONTRAST statement,

<i>label</i>	identifies the contrast in the table. A label is required for every contrast specified. Labels can be up to 200 characters and must be enclosed in quotes.
<i>contrast-specification</i>	identifies the fixed effects and random effects and their coefficients from which the L matrix is formed. The syntax representation of a <i>contrast-specification</i> is <code>< fixed-effect values ... > random-effect values ... ></code>
<i>fixed-effect</i>	identifies an effect that appears in the MODEL statement. The keyword INTERCEPT can be used as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the MODEL statement.
<i>random-effect</i>	identifies an effect that appears in the RANDOM statement. The first random effect must follow a vertical bar (); however, random effects do not have to be specified.
<i>values</i>	are constants that are elements of the L matrix associated with the fixed and random effects. There are two basic methods of specifying the entries of the L matrix. The traditional representation—also known as the positional syntax—relies on entering coefficients in the position they assume in the L matrix. For example, in the following statements the elements of L associated with the b main effect receive a 1 in the first position and a -1 in the second position:

```
class a b;
model y = a b a*b;
contrast 'B at A2' b 1 -1 a*b 0 0 1 -1;
```

The elements associated with the interaction receive a 1 in the third position and a -1 in the fourth position. In order to specify coefficients correctly for the interaction term, you need to know how the levels of a and b vary in the interaction, which is governed by the order of the variables in the **CLASS** statement. The nonpositional syntax is designed to make it easier to enter coefficients for interactions and is necessary to enter coefficients for effects constructed with the experimental **EFFECT** statement. In square brackets you enter the coefficient followed by the associated levels of the **CLASS** variables. If B has two and A has three levels, the previous **CONTRAST** statement, by using nonpositional syntax for the interaction term, becomes

```
contrast 'B at A2' b 1 -1 a*b [1, 2 1] [-1, 2 2];
```

It assigns value 1 to the interaction where A is at level 2 and B is at level 1, and it assigns -1 to the interaction where both classification variables are at level 2. The comma separating the entry for the **L** matrix from the level indicators is optional. Further details about the nonpositional contrast syntax and its use with constructed effects can be found in the section “[Positional and Nonpositional Syntax for Contrast Coefficients](#)” on page 3097. Nonpositional syntax is available only for fixed-effects coefficients.

The rows of **L'** are specified in order and are separated by commas. The rows of the **K'** component of **L'** are specified on the left side of the vertical bars (|). These rows test the fixed effects and are, therefore, checked for estimability. The rows of the **M'** component of **L'** are specified on the right side of the vertical bars. They test the random effects, and no estimability checking is necessary.

If PROC GLIMMIX finds the fixed-effects portion of the specified contrast to be nonestimable (see the `SINGULAR=` option), then it displays missing values for the test statistics.

If the elements of **L** are not specified for an effect that contains a specified effect, then the elements of the unspecified effect are automatically “filled in” over the levels of the higher-order effect. This feature is designed to preserve estimability for cases where there are complex higher-order effects. The coefficients for the higher-order effect are determined by equitably distributing the coefficients of the lower-level effect as in the construction of least squares means. In addition, if the intercept is specified, it is distributed over all classification effects that are not contained by any other specified effect. If an effect is not specified and does not contain any specified effects, then all of its coefficients in **L** are set to 0. You can override this behavior by specifying coefficients for the higher-order effect.

If too many values are specified for an effect, the extra ones are ignored; if too few are specified, the remaining ones are set to 0. If no random effects are specified, the vertical bar can be omitted; otherwise, it must be present. If a `SUBJECT` effect is used in the `RANDOM` statement, then the coefficients specified for the effects in the `RANDOM` statement are equitably distributed across the levels of the `SUBJECT` effect. You can use the `E` option to see exactly what **L** matrix is used.

PROC GLIMMIX handles missing level combinations of classification variables similarly to PROC GLM and PROC MIXED. These procedures delete fixed-effects parameters corresponding to missing levels in order to preserve estimability. However, PROC MIXED and PROC GLIMMIX do not delete missing level combinations for random-effects parameters, because linear combinations of the random-effects parameters are always estimable. These conventions can affect the way you specify your `CONTRAST` coefficients.

The `CONTRAST` statement computes the statistic

$$F = \frac{\begin{bmatrix} \hat{\beta} \\ \hat{\gamma} \end{bmatrix}' \mathbf{L}(\mathbf{L}'\mathbf{C}\mathbf{L})^{-1}\mathbf{L}' \begin{bmatrix} \hat{\beta} \\ \hat{\gamma} \end{bmatrix}}{r}$$

where $r = \text{rank}(\mathbf{L}'\mathbf{C}\mathbf{L})$, and approximates its distribution with an F distribution unless `DDFM=NONE`. If you select `DDFM=NONE` as the degrees-of-freedom method in the `MODEL` statement, and if you do not assign degrees of freedom to the contrast with the `DF=` option, then PROC GLIMMIX computes the test statistic $r \times F$ and approximates its distribution with a chi-square distribution. In the expression for F , **C** is an estimate of $\text{Var}[\hat{\beta}, \hat{\gamma} - \boldsymbol{\gamma}]$; see the section “[Estimated Precision of Estimates](#)” on page 3056 and the section “[Aspects Common to Adaptive Quadrature and Laplace Approximation](#)” on page 3064 for details about the computation of **C** in a generalized linear mixed model.

The numerator degrees of freedom in the F approximation and the degrees of freedom in the chi-square approximation are equal to r . The denominator degrees of freedom are taken from the “Tests of Fixed Effects” table and correspond to the final effect you list in the `CONTRAST` statement. You can change the denominator degrees of freedom by using the `DF=` option.

You can specify the following options in the `CONTRAST` statement after a slash (/).

BYCATEGORY

BYCAT

requests that in models for nominal data (generalized logit models) the contrasts not be combined across response categories but reported separately for each category. For example, assume that the response variable `Style` is multinomial with three (unordered) categories. The following GLIMMIX statements fit a generalized logit model relating the preferred style of instruction to school and educational program effects:

```

proc glimmix data=school;
  class School Program;
  model Style(order=data) = School Program / s ddfm=none
                                dist=multinomial link=glogit;

  freq Count;
  contrast 'School 1 vs. 2' school 1 -1;
  contrast 'School 1 vs. 2' school 1 -1 / bycat;
run;

```

The first contrast compares school effects in all categories. This is a two-degrees-of-freedom contrast because there are two nonredundant categories. The second CONTRAST statement produces two single-degree-of-freedom contrasts, one for each nonreference Style category.

The BYCATEGORY option has no effect unless your model is a generalized (mixed) logit model.

CHISQ

requests that chi-square tests be performed for all contrasts in addition to any F tests. A chi-square statistic equals its corresponding F statistic times the numerator degrees of freedom, and these same degrees of freedom are used to compute the p -value for the chi-square test. This p -value will always be less than that for the F test, because it effectively corresponds to an F test with infinite denominator degrees of freedom.

DF=number

specifies the denominator degrees of freedom for the F test. For the degrees of freedom methods [DDFM=BETWITHIN](#), [DDFM=CONTAIN](#), and [DDFM=RESIDUAL](#), the default is the denominator degrees of freedom taken from the “Tests of Fixed Effects” table and corresponds to the final effect you list in the CONTRAST statement. For [DDFM=NONE](#), infinite denominator degrees of freedom are assumed by default, and for [DDFM=SATTERTHWAITE](#) and [DDFM=KENWARDROGER](#), the denominator degrees of freedom are computed separately for each contrast.

E

requests that the **L** matrix coefficients for the contrast be displayed.

GROUP coeffs

sets up random-effect contrasts between different groups when a [GROUP=](#) variable appears in the [RANDOM](#) statement. By default, CONTRAST statement coefficients on random effects are distributed equally across groups. If you enter a multiple row contrast, you can also enter multiple rows for the GROUP coefficients. If the number of GROUP coefficients is less than the number of contrasts in the CONTRAST statement, the GLIMMIX procedure cycles through the GROUP coefficients. For example, the following two statements are equivalent:

```

contrast 'Trt 1 vs 2 @ x=0.4' trt 1 -1 0 | x 0.4,
                                trt 1 0 -1 | x 0.4,
                                trt 1 -1 0 | x 0.5,
                                trt 1 0 -1 | x 0.5 /
                                group 1 -1, 1 0 -1, 1 -1, 1 0 -1;

contrast 'Trt 1 vs 2 @ x=0.4' trt 1 -1 0 | x 0.4,
                                trt 1 0 -1 | x 0.4,
                                trt 1 -1 0 | x 0.5,
                                trt 1 0 -1 | x 0.5 /
                                group 1 -1, 1 0 -1;

```

SINGULAR=number

tunes the estimability checking. If \mathbf{v} is a vector, define $\text{ABS}(\mathbf{v})$ to be the largest absolute value of the elements of \mathbf{v} . If $\text{ABS}(\mathbf{K}' - \mathbf{K}'\mathbf{T})$ is greater than $c*\text{number}$ for any row of \mathbf{K}' in the contrast, then $\mathbf{K}'\boldsymbol{\beta}$ is declared nonestimable. Here, \mathbf{T} is the Hermite form matrix $(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{X}$, and c is $\text{ABS}(\mathbf{K}')$, except when it equals 0, and then c is 1. The value for *number* must be between 0 and 1; the default is 1E-4.

SUBJECT coeffs

sets up random-effect contrasts between different subjects when a **SUBJECT=** variable appears in the **RANDOM** statement. By default, **CONTRAST** statement coefficients on random effects are distributed equally across subjects. Listing subject coefficients for multiple row **CONTRAST** statements follows the same rules as for **GROUP** coefficients.

COVTEST Statement

COVTEST < 'label' > < test-specification > < / options > ;

The **COVTEST** statement provides a mechanism to obtain statistical inferences for the covariance parameters. Significance tests are based on the ratio of (residual) likelihoods or pseudo-likelihoods. Confidence limits and bounds are computed as Wald or likelihood ratio limits. You can specify multiple **COVTEST** statements.

The likelihood ratio test is obtained by fitting the model subject to the constraints imposed by the *test-specification*. The test statistic is formed as twice the difference of the (possibly restricted) log (pseudo-) likelihoods of the full and the reduced models. Note that fitting the null model does not necessarily require fewer computer resources compared to fitting the full model. The optimization settings for refitting the model are the same as for the full model and can be controlled with the **NLOPTIONS** statement.

Common questions in mixed modeling are whether variance components are zero, whether random effects are independent, and whether rows (columns) can be added or removed from an unstructured covariance matrix. When the parameters under the null hypothesis fall on the boundary of the parameter space, the distribution of the likelihood ratio statistic can be a complicated mixture of distributions. In certain situations it is known to be a relatively straightforward mixture of central chi-square distributions. When the **GLIMMIX** procedure recognizes the model and hypothesis as a case for which the mixture is readily available, the *p*-value of the likelihood ratio test is determined accordingly as a linear combination of central chi-square probabilities. The **Note** column in the “Likelihood Ratio Tests for Covariance Parameters” table along with the table’s footnotes informs you about when mixture distributions are used in the calculation of *p*-values. You can find important statistical and computational details about likelihood ratio testing of covariance parameters with the **GLIMMIX** procedure in the section “Statistical Inference for Covariance Parameters” on page 3068.

In generalized linear mixed models that depend on pseudo-data, the **GLIMMIX** procedure fits the null model for a test of covariance parameters to the final pseudo-data of the converged optimization.

Table 41.6 summarizes the options available in the COVTEST statement.

Table 41.6 COVTEST Statement Options

Option	Description
Test specification	
TESTDATA=	Reads in covariance parameter values from a SAS data set
GENERAL	Provides a general facility to test linear combinations of covariance parameters
Covariance Test Options	
CL	Requests confidence limits for the covariance parameter estimates
CLASSICAL	Computes the likelihood ratio test p -value using the classical method
DF=	Specifies the degrees of freedom
ESTIMATES	Displays the estimates of the covariance parameters under the null hypothesis
MAXITER=	Limits the number of iterations
PARMS	Displays the values of the covariance parameters under the null hypothesis
RESTART	Specifies that starting values for the covariance parameters
TOLERANCE=	Sets the tolerance level of the parameter space boundary
WALD	Produces Wald Z tests
WGHT=	Supplies weights for the computation of p -values

Test Specification

The *test-specification* in the COVTEST statement draws on keywords that represent a particular null hypothesis, lists or data sets of parameter values, or general contrast specifications. Valid keywords are as follows:

GLM INDEP	tests the model against a null model of complete independence. All G-side covariance parameters are eliminated and the R-side covariance structure is reduced to a diagonal structure.
DIAGG	tests for a diagonal \mathbf{G} matrix by constraining off-diagonal elements in \mathbf{G} to zero. The R-side structure is not modified.
DIAGR CINDEP	tests for conditional independence by reducing the R-side covariance structure to diagonal form. The G-side structure is not modified.
HOMOGENEITY	tests homogeneity of covariance parameters across groups by imposing equality constraints. For example, the following statements fit a one-way model with heterogeneous variances and test whether the model could be reduced to a one-way analysis with the same variance across groups:

```
proc glimmix;
  class A;
  model y = a;
  random _residual_ / group=A;
  covtest 'common variance' homogeneity;
run;
```

See [Example 41.9](#) for an application with groups and unstructured covariance matrices.

START INITIAL	compares the final estimates to the starting values of the covariance parameter estimates. This option is useful, for example, if you supply starting values in the PARMs statement and want to test whether the optimization produced significantly better values. In GLMMs based on pseudo-data, the likelihoods that use the starting and the final values are based on the final pseudo-data.
ZEROG	tests whether the G matrix can be reduced to a zero matrix. This eliminates all G-side random effects from the model.

Only a single keyword is permitted in the COVTEST statement. To test more complicated hypotheses, you can formulate tests with the following specifications.

TESTDATA=*data-set*

TDATA=*data-set*

reads in covariance parameter values from a SAS data set. The data set should contain the numerical variable Estimate or numerical variables named Covpi. The GLIMMIX procedure associates the values for Covpi with the *i*th covariance parameter.

For data sets containing the numerical variable Estimate, the GLIMMIX procedure fixes the *i*th covariance parameter value at the value of the *i*th observation in the data set. A missing value indicates not to fix the particular parameter. PROC GLIMMIX performs one likelihood ratio test for the TESTDATA= data set.

For data sets containing numerical variables named Covpi, the procedure performs one likelihood ratio test for each observation in the TESTDATA= data set. You do not have to specify a Covpi variable for every covariance parameter. If the value for the variable is not missing, PROC GLIMMIX fixes the associated covariance parameter in the null model. Consider the following statements:

```
data TestDataSet;
  input covp1 covp2 covp3;
  datalines;
. 0 .
0 0 .
. 0 0
0 0 0
;

proc glimmix method=mspl;
  class subject x;
  model y = x age x*age;
  random intercept age / sub=subject type=un;
  covtest testdata=TestDataSet;
run;
```

Because the **G** matrix is a (2 × 2) unstructured matrix, the first observation of the TestDataSet corresponds to zeroing the covariance between the random intercept and the random slope. When the reduced model is fit, the variances of the intercept and slope are reestimated. The second observation reduces the model to one with only a random slope in age. The third reduces the model to a random intercept model. The last observation eliminates the **G** matrix altogether.

Note that the tests associated with the first and last set of covariance parameters in TestDataSet can also be obtained by using keywords:

```

proc glimmix;
  class subject x;
  model y = x age x*age;
  random intercept age / sub=subject type=un;
  covtest DiagG;
  covtest GLM;
run;

```

value-list

supplies a list of values at which to fix the covariance parameters. A missing value in the list indicates that the covariance parameter is not fixed. If the list is shorter than the number of covariance parameters, missing values are assumed for all parameters not specified. The COVTEST statements that test the random intercept and random slope in the previous example are as follows:

```

proc glimmix;
  class subject x;
  model y = x age x*age;
  random intercept age / sub=subject type=un;
  covtest 0 0;
  covtest . 0 0;
run;

```

GENERAL *coefficients* < ,*coefficients* > < ,... >

CONTRAST *coefficients* < ,*coefficients* > < ,... >

provides a general facility to test linear combinations of covariance parameters. You can specify one or more sets of coefficients. The position of a coefficient in the list corresponds to the position of the parameter in the “Covariance Parameter Estimates” table. The linear combination of covariance parameters that is implied by each set of coefficients is tested against zero. If the list of coefficients is shorter than the number of covariance parameters, a zero coefficient is assumed for the remaining parameters.

For example, in a heterogeneous variance model with four groups, the following statements test the simultaneous hypothesis $H: \sigma_1^2 = \sigma_2^2, \sigma_3^2 = \sigma_4^2$:

```

proc glimmix;
  class A;
  model y = a;
  random _residual_ / group=A;
  covtest 'pair-wise homogeneity'
    general 1 -1 0 0,
           0 0 1 -1;
run;

```

In a repeated measures study with four observations per subject, the COVTEST statement in the following example tests whether the four correlation parameters are identical:

```

proc glimmix;
  class subject drug time;
  model y = drug time drug*time;
  random _residual_ / sub=subject type=unr;
  covtest 'Homogeneous correlation'
    general 0 0 0 0 1 -1          ,
            0 0 0 0 1  0 -1      ,
            0 0 0 0 1  0  0 -1   ,
            0 0 0 0 1  0  0  0 -1 ,
            0 0 0 0 1  0  0  0  0 -1;
run;

```

Notice that the variances (the first four covariance parameters) are allowed to vary. The null model for this test is thus a heterogeneous compound symmetry model.

The degrees of freedom associated with these general linear hypotheses are determined as the rank of the matrix \mathbf{LL}' , where \mathbf{L} is the $k \times q$ matrix of coefficients and q is the number of covariance parameters. Notice that the coefficients in a row do not have to sum to zero. The following statement tests $H: \theta_1 = 3\theta_2, \theta_3 = 0$:

```

covtest general 1 -3, 0 0 1;

```

Covariance Test Options

You can specify the following options in the COVTEST statement after a slash (/).

CL<(suboptions)>

requests confidence limits or bounds for the covariance parameter estimates. These limits are displayed as extra columns in the “Covariance Parameter Estimates” table.

The following suboptions determine the computation of confidence bounds and intervals. See the section “[Statistical Inference for Covariance Parameters](#)” on page 3068 for details about constructing likelihood ratio confidence limits for covariance parameters with PROC GLIMMIX.

ALPHA=*number*

determines the confidence level for constructing confidence limits for the covariance parameters. The value of *number* must be between 0 and 1, the default is 0.05, and the confidence level is $1 - \textit{number}$.

LOWERBOUND

LOWER

requests lower confidence bounds.

TYPE=*method*

determines how the GLIMMIX procedure constructs confidence limits for covariance parameters. The valid methods are PLR (or PROFILE), ELR (or ESTIMATED), and WALD.

TYPE=PLR (TYPE=PROFILE) requests confidence bounds by inversion of the profile (restricted) likelihood ratio (PLR). If θ is the parameter of interest, L denotes the likelihood (possibly restricted and possibly a pseudo-likelihood), and θ_2 is the vector of the remaining (nuisance) parameters, then the profile likelihood is defined as

$$L(\theta_2|\tilde{\theta}) = \sup_{\theta_2} L(\tilde{\theta}, \theta_2)$$

for a given value $\tilde{\theta}$ of θ . If $L(\hat{\theta})$ is the overall likelihood evaluated at the estimates $\hat{\theta}$, the $(1 - \alpha) \times 100\%$ confidence region for θ satisfies the inequality

$$2 \left\{ L(\hat{\theta}) - L(\theta_2|\tilde{\theta}) \right\} \leq \chi_{1,(1-\alpha)}^2$$

where $\chi_{1,(1-\alpha)}^2$ is the cutoff from a chi-square distribution with one degree of freedom and α probability to its right. If a residual scale parameter ϕ is profiled from the estimation, and θ is expressed in terms of a ratio with ϕ during estimation, then profile likelihood confidence limits are constructed for the ratio of the parameter with the residual variance. A column showing the ratio estimates is added to the “Covariance Parameter Estimates” table in this case. To obtain profile likelihood ratio limits for the parameters, rather than their ratios, and for the residual variance, use the NOPROFILE option in the PROC GLIMMIX statement. Also note that METHOD=LAPLACE or METHOD=QUAD implies the NOPROFILE option.

The TYPE=ELR (TYPE=ESTIMATED) option constructs bounds from the estimated likelihood (Pawitan 2001), where nuisance parameters are held fixed at the (restricted) maximum (pseudo-) likelihood estimates of the model. Estimated likelihood intervals are computationally less demanding than profile likelihood intervals, but they do not take into account the variability of the nuisance parameters or the dependence among the covariance parameters. See the section “Statistical Inference for Covariance Parameters” on page 3068 for a geometric interpretation and comparison of ELR versus PLR confidence bounds. A $(1 - \alpha) \times 100\%$ confidence region based on the estimated likelihood is defined by the inequality

$$2 \left\{ L(\hat{\theta}) - L(\tilde{\theta}, \hat{\theta}_2) \right\} \leq \chi_{1,(1-\alpha)}^2$$

where $L(\tilde{\theta}, \hat{\theta}_2)$ is the likelihood evaluated at $\tilde{\theta}$ and the component of $\hat{\theta}$ that corresponds to θ_2 . Estimated likelihood ratio intervals tend to perform well when the correlations between the parameter of interest and the nuisance parameters is small. Their coverage probabilities can fall short of the nominal coverage otherwise. You can display the correlation matrix of the covariance parameter estimates with the ASYCORR option in the PROC GLIMMIX statement.

If you choose TYPE=PLR or TYPE=ELR, the GLIMMIX procedure reports the right-tail probability of the associated single-degree-of-freedom likelihood ratio test along with the confidence bounds. This helps you diagnose whether solutions to the inequality could be found. If the reported probability exceeds α , the associated bound does not meet the inequality. This might occur, for example, when the parameter space is bounded and the likelihood at the boundary values has not dropped by a sufficient amount to satisfy the test inequality.

The TYPE=WALD method requests confidence limits based on the Wald-type statistic $Z_\theta = \hat{\theta}/\text{ease}(\hat{\theta})$, where ease is the estimated asymptotic standard error of the covariance parameter. For parameters that have a lower boundary constraint of zero, a Satterthwaite approximation is

used to construct limits of the form

$$\frac{v\hat{\theta}}{\chi_{v,1-\alpha/2}^2} \leq \theta \leq \frac{v\hat{\theta}}{\chi_{v,\alpha/2}^2}$$

where $v = 2Z^2$, and the denominators are quantiles of the χ^2 distribution with v degrees of freedom. See Milliken and Johnson (1992) and Burdick and Graybill (1992) for similar techniques. For all other parameters, Wald Z-scores and normal quantiles are used to construct the limits. Such limits are also provided for variance components if you specify the **NOBOUND** option in the **PROC GLIMMIX** statement or the **PARMS** statement.

UPPERBOUND

UPPER

requests upper confidence bounds.

If you do not specify any suboptions, the default is to compute two-sided Wald confidence intervals with confidence level $1 - \alpha = 0.95$.

CLASSICAL

requests that the p -value of the likelihood ratio test be computed by the classical method. If $\hat{\lambda}$ is the realized value of the test statistic in the likelihood ratio test,

$$p = \Pr(\chi_v^2 \geq \hat{\lambda})$$

where v is the degrees of freedom of the hypothesis.

DF=value-list

enables you to supply degrees of freedom v_1, \dots, v_k for the computation of p -values from chi-square mixtures. The mixture weights w_1, \dots, w_k are supplied with the **WGHT=** option. If no weights are specified, an equal weight distribution is assumed. If $\hat{\lambda}$ is the realized value of the test statistic in the likelihood ratio test, PROC GLIMMIX computes the p -value as (Shapiro 1988)

$$p = \sum_{i=1}^k w_i \Pr(\chi_{v_i}^2 \geq \hat{\lambda})$$

Note that $\chi_0^2 \equiv 0$ and that mixture weights are scaled to sum to one. If you specify more weights than degrees of freedom in *value-list*, the rank of the hypothesis (DF column) is substituted for the missing degrees of freedom.

Specifying a single value v for *value-list* without giving mixture weights is equivalent to computing the p -value as

$$p = \Pr(\chi_v^2 \geq \hat{\lambda})$$

For example, the following statements compute the p -value based on a chi-square distribution with one degree of freedom:

```

proc glimmix noprofile;
  class A sub;
  model score = A;
  random _residual_ / type=ar(1) subject=sub;
  covtest 'ELR low' 30.62555 0.7133361 / df=1;
run;

```

The DF column of the COVTEST output will continue to read 2 regardless of the DF= specification, however, because the DF column reflects the rank of the hypothesis and equals the number of constraints imposed on the full model.

ESTIMATES

EST

displays the estimates of the covariance parameters under the null hypothesis. Specifying the ESTIMATES option in one COVTEST statement has the same effect as specifying the option in every COVTEST statement.

MAXITER=*number*

limits the number of iterations when you are refitting the model under the null hypothesis to *number* iterations. If the null model does not converge before the limit is reached, no *p*-values are produced.

PARMS

displays the values of the covariance parameters under the null hypothesis. This option is useful if you supply multiple sets of parameter values with the TESTDATA= option. Specifying the PARMS option in one COVTEST statement has the same effect as specifying the option in every COVTEST statement.

RESTART

specifies that starting values for the covariance parameters for the null model are obtained by the same mechanism as starting values for the full models. For example, if you do not specify a PARMS statement, the RESTART option computes MIVQUE(0) estimates under the null model (Goodnight 1978a). If you provide starting values with the PARMS statement, the starting values for the null model are obtained by applying restrictions to the starting values for the full model.

By default, PROC GLIMMIX obtains starting values by applying null model restrictions to the converged estimates of the full model. Although this is computationally expedient, the method does not always lead to good starting values for the null model, depending on the nature of the model and hypothesis. In particular, when you receive a warning about parameters not specified under H_0 falling on the boundary, the RESTART option can be useful.

TOLERANCE=*r*

Values within tolerance $r \geq 0$ of the boundary of the parameter space are considered on the boundary when PROC GLIMMIX examines estimates of nuisance parameters under H_0 and determines whether mixture weights and degrees of freedom can be obtained. In certain cases, when parameters not specified under the null hypothesis are on boundaries, the asymptotic distribution of the likelihood ratio statistic is not a mixture of chi-squares (see, for example, case 8 in Self and Liang 1987). The default for *r* is 1E4 times the machine epsilon; this product is approximately 1E-12 on most computers.

WALD

produces Wald Z tests for the covariance parameters based on the estimates and asymptotic standard errors in the “Covariance Parameter Estimates” table.

WGHT=value-list

enables you to supply weights for the computation of p -values from chi-square mixtures. See the **DF=** option for details. Mixture weights are scaled to sum to one.

EFFECT Statement

EFFECT *effect-specification* ;

The experimental EFFECT statement enables you to construct special collections of columns for **X** or **Z** matrices in your model. These collections are referred to as *constructed effects* to distinguish them from the usual model effects formed from continuous or classification variables.

For details about the syntax of the EFFECT statement and how columns of constructed effects are computed, see the section “EFFECT Statement” on page 393 of Chapter 19, “Shared Concepts and Topics.” For specific details concerning the use of the EFFECT statement with the GLIMMIX procedure, see the section “Notes on the EFFECT Statement” on page 3096.

ESTIMATE Statement

ESTIMATE *'label'* *contrast-specification* <(divisor= n)>
<, *'label'* *contrast-specification* <(divisor= n)>> <, ... >
</ *options* > ;

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. As in the **CONTRAST** statement, the basic element of the ESTIMATE statement is the *contrast-specification*, which consists of **MODEL** and G-side random effects and their coefficients. Specifically, a *contrast-specification* takes the form

$$\langle \text{fixed-effect values} \dots \rangle \langle | \text{random-effect values} \dots \rangle$$

Based on the *contrast-specifications* in your ESTIMATE statement, PROC GLIMMIX constructs the matrix $\mathbf{L}' = [\mathbf{K}' \ \mathbf{M}']$, as in the **CONTRAST** statement, where **K** is associated with the fixed effects and **M** is associated with the G-side random effects. The GLIMMIX procedure supports nonpositional syntax for the coefficients of fixed effects in the ESTIMATE statement. For details see the section “Positional and Nonpositional Syntax for Contrast Coefficients” on page 3097.

PROC GLIMMIX then produces for each row l of \mathbf{L}' an approximate t test of the hypothesis $H: \mathbf{l}\phi = 0$, where $\phi = [\beta' \ \gamma']'$. You can also obtain multiplicity-adjusted p -values and confidence limits for multirow estimates with the **ADJUST=** option. The output from multiple ESTIMATE statements is organized as follows. Results from unadjusted estimates are reported first in a single table, followed by separate tables for each of the adjusted estimates. Results from all ESTIMATE statements are combined in the “Estimates” ODS table.

Note that multirow estimates are permitted. Unlike the **CONTRAST** statement, you need to specify a *'label'* for every row of the multirow estimate, because PROC GLIMMIX produces one test per row. PROC

GLIMMIX selects the degrees of freedom to match those displayed in the “Type III Tests of Fixed Effects” table for the final effect you list in the ESTIMATE statement. You can modify the degrees of freedom by using the `DF=` option. If you select `DDFM=NONE` and do not modify the degrees of freedom by using the `DF=` option, PROC GLIMMIX uses infinite degrees of freedom, essentially computing approximate z tests. If PROC GLIMMIX finds the fixed-effects portion of the specified estimate to be nonestimable, then it displays “Non-est” for the estimate entry.

Table 41.7 summarizes the options available in the ESTIMATE statement.

Table 41.7 ESTIMATE Statement Options

Option	Description
Construction and Computation of Estimable Functions	
<code>DIVISOR=</code>	Specifies a list of values to divide the coefficients
<code>GROUP</code>	Sets up random-effect contrasts between different groups
<code>SINGULAR=</code>	Tunes the estimability checking difference
<code>SUBJECT</code>	Sets up random-effect contrasts between different subjects
Degrees of Freedom and p-values	
<code>ADJDFE=</code>	Determines denominator degrees of freedom when p -values and confidence limits are adjusted for multiple comparisons
<code>ADJUST=</code>	Determines the method for multiple comparison adjustment of estimates
<code>ALPHA=α</code>	Determines the confidence level ($1 - \alpha$)
<code>DF=</code>	Assigns a specific value to degrees of freedom for tests and confidence limits
<code>LOWER</code>	Performs one-sided, lower-tailed inference
<code>STEPDOWN</code>	Adjusts multiplicity-corrected p -values further in a step-down fashion
<code>UPPER</code>	Performs one-sided, upper-tailed inference
Statistical Output	
<code>CL</code>	Constructs t -type confidence limits
<code>E</code>	Prints the L matrix
Generalized Linear Modeling	
<code>BYCATEGORY=</code>	Reports estimates separately for each category for models with nominal data
<code>EXP</code>	Displays exponentiated estimates
<code>ILINK</code>	Computes and displays estimates and standard errors on the inverse linked scale

ADJDFE=SOURCE

ADJDFE=ROW

specifies how denominator degrees of freedom are determined when p -values and confidence limits are adjusted for multiple comparisons with the `ADJUST=` option. When you do not specify the `ADJDFE=` option, or when you specify `ADJDFE=SOURCE`, the denominator degrees of freedom for multiplicity-adjusted results are the denominator degrees of freedom for the final effect listed in the ESTIMATE statement from the “Type III Tests of Fixed Effects” table.

The ADJDFE=ROW setting is useful if you want multiplicity adjustments to take into account that denominator degrees of freedom are not constant across estimates. This can be the case, for example, when the DDFM=SATTERTHWAITE or DDFM=KENWARDROGER degrees-of-freedom method is in effect.

ADJUST=BON**ADJUST=SCHEFFE****ADJUST=SIDAK****ADJUST=SIMULATE**< (*simoptions*) >**ADJUST=T**

requests a multiple comparison adjustment for the p -values and confidence limits for the estimates. The adjusted quantities are produced in addition to the unadjusted quantities. Adjusted confidence limits are produced if the CL or ALPHA= option is in effect. For a description of the adjustments, see Chapter 42, “The GLM Procedure,” and Chapter 61, “The MULTTEST Procedure,” and the documentation for the ADJUST= option in the LSMEANS statement. The ADJUST= option is ignored for generalized logit models.

If the STEPDOWN option is in effect, the p -values are further adjusted in a step-down fashion.

ALPHA=number

requests that a t -type confidence interval be constructed with confidence level $1 - \text{number}$. The value of *number* must be between 0 and 1; the default is 0.05. If DDFM=NONE and you do not specify degrees of freedom with the DF= option, PROC GLIMMIX uses infinite degrees of freedom, essentially computing a z interval.

BYCATEGORY**BYCAT**

requests that in models for nominal data (generalized logit models) estimates be reported separately for each category. In contrast to the BYCATEGORY option in the CONTRAST statement, an ESTIMATE statement in a generalized logit model does not distribute coefficients by response category, because ESTIMATE statements always correspond to single rows of the **L** matrix.

For example, assume that the response variable Style is multinomial with three (unordered) categories. The following GLIMMIX statements fit a generalized logit model relating the preferred style of instruction to school and educational program effects:

```
proc glimmix data=school;
  class School Program;
  model Style(order=data) = School Program / s ddfm=none
                                dist=multinomial link=glogit;

  freq Count;
  estimate 'School 1 vs. 2' school 1 -1 / bycat;
  estimate 'School 1 vs. 2' school 1 -1;
run;
```

The first ESTIMATE statement compares school effects separately for each nonredundant category. The second ESTIMATE statement compares the school effects for the first non-reference category.

The BYCATEGORY option has no effect unless your model is a generalized (mixed) logit model.

CL

requests that *t*-type confidence limits be constructed. If **DDFM=NONE** and you do not specify degrees of freedom with the **DF=** option, PROC GLIMMIX uses infinite degrees of freedom, essentially computing a *z* interval. The confidence level is 0.95 by default. These intervals are adjusted for multiplicity when you specify the **ADJUST=** option.

DF=number

specifies the degrees of freedom for the *t* test and confidence limits. The default is the denominator degrees of freedom taken from the “Type III Tests of Fixed Effects” table and corresponds to the final effect you list in the ESTIMATE statement.

DIVISOR=value-list

specifies a list of values by which to divide the coefficients so that fractional coefficients can be entered as integer numerators. If you do not specify *value-list*, a default value of 1.0 is assumed. Missing values in the *value-list* are converted to 1.0.

If the number of elements in *value-list* exceeds the number of rows of the estimate, the extra values are ignored. If the number of elements in *value-list* is less than the number of rows of the estimate, the last value in *value-list* is copied forward.

If you specify a row-specific divisor as part of the specification of the estimate row, this value multiplies the corresponding divisor implied by the *value-list*. For example, the following statement divides the coefficients in the first row by 8, and the coefficients in the third and fourth row by 3:

```
estimate 'One vs. two'   A 2 -2 (divisor=2),
         'One vs. three' A 1  0 -1      ,
         'One vs. four'  A 3  0  0 -3    ,
         'One vs. five'  A 1  0  0  0 -1 / divisor=4,.,3;
```

Coefficients in the second row are not altered.

E

requests that the **L** matrix coefficients be displayed.

EXP

requests exponentiation of the estimate. When you model data with the logit, cumulative logit, or generalized logit link functions, and the estimate represents a log odds ratio or log cumulative odds ratio, the EXP option produces an odds ratio. See “Odds and Odds Ratio Estimation” on page 3090 for important details about the computation and interpretation of odds and odds ratio results with the GLIMMIX procedure. If you specify the **CL** or **ALPHA=** option, the (adjusted) confidence bounds are also exponentiated.

GROUP coeffs

sets up random-effect contrasts between different groups when a **GROUP=** variable appears in the **RANDOM** statement. By default, ESTIMATE statement coefficients on random effects are distributed equally across groups. If you enter a multirow estimate, you can also enter multiple rows for the GROUP coefficients. If the number of GROUP coefficients is less than the number of contrasts in the ESTIMATE statement, the GLIMMIX procedure cycles through the GROUP coefficients. For example, the following two statements are equivalent:

```

estimate 'Trt 1 vs 2 @ x=0.4' trt 1 -1 0 | x 0.4,
         'Trt 1 vs 3 @ x=0.4' trt 1 0 -1 | x 0.4,
         'Trt 1 vs 2 @ x=0.5' trt 1 -1 0 | x 0.5,
         'Trt 1 vs 3 @ x=0.5' trt 1 0 -1 | x 0.5 /
         group 1 -1, 1 0 -1, 1 -1, 1 0 -1;

estimate 'Trt 1 vs 2 @ x=0.4' trt 1 -1 0 | x 0.4,
         'Trt 1 vs 3 @ x=0.4' trt 1 0 -1 | x 0.4,
         'Trt 1 vs 2 @ x=0.5' trt 1 -1 0 | x 0.5,
         'Trt 1 vs 3 @ x=0.5' trt 1 0 -1 | x 0.5 /
         group 1 -1, 1 0 -1;

```

ILINK

requests that the estimate and its standard error are also reported on the scale of the mean (the inverse linked scale). PROC GLIMMIX computes the value on the mean scale by applying the inverse link to the estimate. The interpretation of this quantity depends on the *fixed-effect values* and *random-effect values* specified in your ESTIMATE statement and on the link function. In a model for binary data with logit link, for example, the following statements compute

$$\frac{1}{1 + \exp\{-(\alpha_1 - \alpha_2)\}}$$

where α_1 and α_2 are the fixed-effects solutions associated with the first two levels of the classification effect A:

```

proc glimmix;
  class A;
  model y = A / dist=binary link=logit;
  estimate 'A one vs. two' A 1 -1 / ilink;
run;

```

This quantity is not the difference of the probabilities associated with the two levels,

$$\pi_1 - \pi_2 = \frac{1}{1 + \exp\{-\beta_0 - \alpha_1\}} - \frac{1}{1 + \exp\{-\beta_0 - \alpha_2\}}$$

The standard error of the inversely linked estimate is based on the delta method. If you also specify the **CL** option, the GLIMMIX procedure computes confidence limits for the estimate on the mean scale. In multinomial models for nominal data, the limits are obtained by the delta method. In other models they are obtained from the inverse link transformation of the confidence limits for the estimate. The **ILINK** option is specific to an ESTIMATE statement.

LOWER**LOWERTAILED**

requests that the *p*-value for the *t* test be based only on values less than the test statistic. A two-tailed test is the default. A lower-tailed confidence limit is also produced if you specify the **CL** or **ALPHA=** option.

Note that for **ADJUST=SCHEFFE** the one-sided adjusted confidence intervals and one-sided adjusted *p*-values are the same as the corresponding two-sided statistics, because this adjustment is based on only the right tail of the *F* distribution.

SINGULAR=number

tunes the estimability checking as documented for the **CONTRAST** statement.

STEPDOWN< (*step-down-options*) >

requests that multiplicity adjustments for the p -values of estimates be further adjusted in a step-down fashion. Step-down methods increase the power of multiple testing procedures by taking advantage of the fact that a p -value will never be declared significant unless all smaller p -values are also declared significant. Note that the **STEPDOWN** adjustment combined with **ADJUST=BON** corresponds to the methods of Holm (1979) and “Method 2” of Shaffer (1986); this is the default. Using step-down-adjusted p -values combined with **ADJUST=SIMULATE** corresponds to the method of Westfall (1997).

If the degrees-of-freedom method is **DDFM=KENWARDROGER** or **DDFM=SATTERTHWAITE**, then step-down-adjusted p -values are produced only if the **ADJDFE=ROW** option is in effect.

Also, the **STEPDOWN** option affects only p -values, not confidence limits. For **ADJUST=SIMULATE**, the generalized least squares hybrid approach of Westfall (1997) is employed to increase Monte Carlo accuracy.

You can specify the following *step-down-options* in parentheses after the **STEPDOWN** option.

MAXTIME=n

specifies the time (in seconds) to spend computing the maximal logically consistent sequential subsets of equality hypotheses for **TYPE=LOGICAL**. The default is **MAXTIME=60**. If the **MAXTIME** value is exceeded, the adjusted tests are not computed. When this occurs, you can try increasing the **MAXTIME** value. However, note that there are common multiple comparisons problems for which this computation requires a huge amount of time—for example, all pairwise comparisons between more than 10 groups. In such cases, try to use **TYPE=FREE** (the default) or **TYPE=LOGICAL(n)** for small n .

ORDER=PVALUE**ORDER=ROWS**

specifies the order in which the step-down tests are performed. **ORDER=PVALUE** is the default, with estimates being declared significant only if all estimates with smaller (unadjusted) p -values are significant. If you specify **ORDER=ROWS**, then significances are evaluated in the order in which they are specified in the syntax.

REPORT

specifies that a report on the step-down adjustment be displayed, including a listing of the sequential subsets (Westfall 1997) and, for **ADJUST=SIMULATE**, the step-down simulation results.

TYPE=LOGICAL< (n) >**TYPE=FREE**

If you specify **TYPE=LOGICAL**, the step-down adjustments are computed by using maximal logically consistent sequential subsets of equality hypotheses (Shaffer 1986; Westfall 1997). Alternatively, for **TYPE=FREE**, sequential subsets are computed ignoring logical constraints. The **TYPE=FREE** results are more conservative than those for **TYPE=LOGICAL**, but they can be much more efficient to produce for many estimates. For example, it is not feasible to take logical constraints between all pairwise comparisons of more than about 10 groups. For this reason, **TYPE=FREE** is the default.

However, you can reduce the computational complexity of taking logical constraints into account by limiting the depth of the search tree used to compute them, specifying the optional depth parameter as a number n in parentheses after `TYPE=LOGICAL`. As with `TYPE=FREE`, results for `TYPE=LOGICAL(n)` are conservative relative to the true `TYPE=LOGICAL` results, but even for `TYPE=LOGICAL(0)` they can be appreciably less conservative than `TYPE=FREE` and they are computationally feasible for much larger numbers of estimates. If you do not specify n or if $n = -1$, the full search tree is used.

SUBJECT *coeffs*

sets up random-effect contrasts between different subjects when a `SUBJECT=` variable appears in the `RANDOM` statement. By default, `ESTIMATE` statement coefficients on random effects are distributed equally across subjects. Listing subject coefficients for an `ESTIMATE` statement with multiple rows follows the same rules as for `GROUP` coefficients.

UPPER

UPPERTAILED

requests that the p -value for the t test be based only on values greater than the test statistic. A two-tailed test is the default. An upper-tailed confidence limit is also produced if you specify the `CL` or `ALPHA=` option.

Note that for `ADJUST=SCHEFFE` the one-sided adjusted confidence intervals and one-sided adjusted p -values are the same as the corresponding two-sided statistics, because this adjustment is based on only the right tail of the F distribution.

FREQ Statement

FREQ *variable* ;

The *variable* in the `FREQ` statement identifies a numeric variable in the data set or one computed through `PROC GLIMMIX` programming statements that contains the frequency of occurrence for each observation. `PROC GLIMMIX` treats each observation as if it appears f times, where f is the value of the `FREQ` variable for the observation. If it is not an integer, the frequency value is truncated to an integer. If the frequency value is less than 1 or missing, the observation is not used in the analysis. When the `FREQ` statement is not specified, each observation is assigned a frequency of 1.

The analysis produced by using a `FREQ` statement reflects the expanded number of observations. For an example of a `FREQ` statement in a model with random effects, see [Example 41.11](#) in this chapter.

ID Statement

ID *variables* ;

The `ID` statement specifies which quantities to include in the `OUT=` data set from the `OUTPUT` statement in addition to any statistics requested in the `OUTPUT` statement. If no `ID` statement is given, the `GLIMMIX` procedure includes all variables from the input data set in the `OUT=` data set. Otherwise, only the variables listed in the `ID` statement are included. Automatic variables such as `_LINF_`, `_MU_`, `_VARIANCE_`, etc. are not transferred to the `OUT=` data set unless they are listed in the `ID` statement.

The ID statement can be used to transfer computed quantities that depend on the model to an output data set. In the following example, two sets of Hessian weights are computed in a gamma regression with a noncanonical link. The covariance matrix for the fixed effects can be constructed as the inverse of $\mathbf{X}'\mathbf{W}\mathbf{X}$. \mathbf{W} is a diagonal matrix of the w_{ei} or w_{oi} , depending on whether the expected or observed Hessian matrix is desired, respectively.

```
proc glimmix;
  class group age;
  model cost = group age / s error=gamma link=pow(0.5);
  output out=gmxout pred=pred;
  id _variance_ wei woi;
  vpmu = 2*_mu_;
  if (_mu_ > 1.0e-8) then do;
    gpmu = 0.5 * (_mu_**(-0.5));
    gppmu = -0.25 * (_mu_**(-1.5));
    wei = 1/(_phi_*_variance_*gpmu*gpmu);
    woi = wei + (cost-_mu_) *
          (_variance_*gppmu + vpmu*gpmu) /
          (_variance_*_variance_*gpmu*gpmu*gpmu*_phi_);
  end;
run;
```

The variables `_VARIANCE_` and `_MU_` and other symbols are predefined by PROC GLIMMIX and can be used in programming statements. For rules and restrictions, see the section “Programming Statements” on page 3042.

LSMEANS Statement

LSMEANS *fixed-effects* </ options > ;

The LSMEANS statement computes least squares means (LS-means) of fixed effects. As in the GLM and the MIXED procedures, LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs. The \mathbf{L} matrix constructed to compute them is the same as the \mathbf{L} matrix formed in PROC GLM; however, the standard errors are adjusted for the covariance parameters in the model. Least squares means computations are not supported for multinomial models.

Each LS-mean is computed as $\mathbf{L}\hat{\boldsymbol{\beta}}$, where \mathbf{L} is the coefficient matrix associated with the least squares mean and $\hat{\boldsymbol{\beta}}$ is the estimate of the fixed-effects parameter vector. The approximate standard error for the LS-mean is computed as the square root of $\mathbf{L}\widehat{\text{Var}}[\hat{\boldsymbol{\beta}}]\mathbf{L}'$. The approximate variance matrix of the fixed-effects estimates depends on the estimation method.

LS-means are constructed on the linked scale—that is, the scale on which the model effects are additive. For example, in a binomial model with logit link, the least squares means are predicted population margins of the logits.

LS-means can be computed for any effect in the MODEL statement that involves only CLASS variables. You can specify multiple effects in one LSMEANS statement or in multiple LSMEANS statements, and all LSMEANS statements must appear after the MODEL statement. As in the ESTIMATE statement, the \mathbf{L} matrix is tested for estimability, and if this test fails, PROC GLIMMIX displays “Non-est” for the LS-means entries.

Assuming the LS-mean is estimable, PROC GLIMMIX constructs an approximate t test to test the null hypothesis that the associated population quantity equals zero. By default, the denominator degrees of freedom for this test are the same as those displayed for the effect in the “Type III Tests of Fixed Effects” table. If the `DDFM=SATTERTHWAITE` or `DDFM=KENWARDROGER` option is specified in the `MODEL` statement, PROC GLIMMIX determines degrees of freedom separately for each test, unless the `DDF=` option overrides it for a particular effect. See the `DDFM=` option for more information. Table 41.8 summarizes options available in the LSMEANS statement. All LSMEANS options are subsequently discussed in alphabetical order.

Table 41.8 LSMEANS Statement Options

Option	Description
Construction and Computation of LS-Means	
<code>AT</code>	Modifies covariate value in computing LS-means
<code>BYLEVEL</code>	Computes separate margins
<code>DIFF</code>	Requests differences of LS-means
<code>OM</code>	Specifies weighting scheme for LS-mean computation as determined by the input data set
<code>SINGULAR=</code>	Tunes estimability checking
<code>SLICE=</code>	Partitions F tests (simple effects)
<code>SLICEDIFF=</code>	Requests simple effects differences
<code>SLICEDIFFTYPE</code>	Determines the type of simple difference
Degrees of Freedom and P-values	
<code>ADJDFE=</code>	Determines whether to compute row-wise denominator degrees of freedom with <code>DDFM=SATTERTHWAITE</code> or <code>DDFM=KENWARDROGER</code>
<code>ADJUST=</code>	Determines the method for multiple comparison adjustment of LS-mean differences
<code>ALPHA=α</code>	Determines the confidence level ($1 - \alpha$)
<code>DF=</code>	Assigns specific value to degrees of freedom for tests and confidence limits
<code>STEPDOWN</code>	Adjusts multiple comparison p -values further in a step-down fashion
Statistical Output	
<code>CL</code>	Constructs confidence limits for means and or mean differences
<code>CORR</code>	Displays correlation matrix of LS-means
<code>COV</code>	Displays covariance matrix of LS-means
<code>E</code>	Prints the L matrix
<code>ILINK</code>	Applies the inverse link transform to the LS-Means (not differences) and produces the standard errors on the inverse linked scale
<code>LINES</code>	Produces “Lines” display for pairwise LS-mean differences
<code>ODDS</code>	Reports odds of levels of fixed effects if permissible by the link function
<code>ODDSRATIO</code>	Reports (simple) differences of least squares means in terms of odds ratios if permissible by the link function
<code>PLOTS=</code>	Requests ODS statistical graphics of means and mean comparisons

You can specify the following options in the LSMEANS statement after a slash (/).

ADJDFE=ROW

ADJDFE=SOURCE

specifies how denominator degrees of freedom are determined when p -values and confidence limits are adjusted for multiple comparisons with the **ADJUST=** option. When you do not specify the **ADJDFE=** option, or when you specify **ADJDFE=SOURCE**, the denominator degrees of freedom for multiplicity-adjusted results are the denominator degrees of freedom for the LS-mean effect in the “Type III Tests of Fixed Effects” table. When you specify **ADJDFE=ROW**, the denominator degrees of freedom for multiplicity-adjusted results correspond to the degrees of freedom displayed in the DF column of the “Differences of Least Squares Means” table.

The **ADJDFE=ROW** setting is particularly useful if you want multiplicity adjustments to take into account that denominator degrees of freedom are not constant across LS-mean differences. This can be the case, for example, when the **DDFM=SATTERTHWAITE** or **DDFM=KENWARDROGER** degrees-of-freedom method is in effect.

In one-way models with heterogeneous variance, combining certain **ADJUST=** options with the **ADJDFE=ROW** option corresponds to particular methods of performing multiplicity adjustments in the presence of heteroscedasticity. For example, the following statements fit a heteroscedastic one-way model and perform Dunnett’s T3 method (Dunnett 1980), which is based on the studentized maximum modulus (**ADJUST=SMM**):

```
proc glimmix;
  class A;
  model y = A / ddfm=satterth;
  random _residual_ / group=A;
  lsmeans A / adjust=smm adjdfe=row;
run;
```

If you combine the **ADJDFE=ROW** option with **ADJUST=SIDAK**, the multiplicity adjustment corresponds to the T2 method of Tamhane (1979), while **ADJUST=TUKEY** corresponds to the method of Games-Howell (Games and Howell 1976). Note that **ADJUST=TUKEY** gives the exact results for the case of fractional degrees of freedom in the one-way model, but it does not take into account that the degrees of freedom are subject to variability. A more conservative method, such as **ADJUST=SMM**, might protect the overall error rate better.

Unless the **ADJUST=** option is specified in the LSMEANS statement, the **ADJDFE=** option has no effect.

ADJUST=BON

ADJUST=DUNNETT

ADJUST=NELSON

ADJUST=SCHEFFE

ADJUST=SIDAK

ADJUST=SIMULATE< (*simoptions*) >

ADJUST=SMM | **GT2**

ADJUST=TUKEY

requests a multiple comparison adjustment for the p -values and confidence limits for the differences of LS-means. The adjusted quantities are produced in addition to the unadjusted quantities. By default, PROC GLIMMIX performs all pairwise differences. If you specify **ADJUST=DUNNETT**, the

procedure analyzes all differences with a control level. If you specify ADJUST=NELSON, ANOM differences are taken. The ADJUST= option implies the DIFF option, unless the SLICEDIFF= option is specified.

The BON (Bonferroni) and SIDAK adjustments involve correction factors described in Chapter 42, “The GLM Procedure,” and Chapter 61, “The MULTTEST Procedure;” also see Westfall and Young (1993) and Westfall et al. (1999). When you specify ADJUST=TUKEY and your data are unbalanced, PROC GLIMMIX uses the approximation described in Kramer (1956) and identifies the adjustment as “Tukey-Kramer” in the results. Similarly, when you specify ADJUST=DUNNETT or ADJUST=NELSON and the LS-means are correlated, the GLIMMIX procedure uses the factor-analytic covariance approximation described in Hsu (1992) and identifies the adjustment in the results as “Dunnett-Hsu” or “Nelson-Hsu,” respectively. The approximation derives an approximate “effective sample sizes” for which exact critical values are computed. Note that computing the exact adjusted p -values and critical values for unbalanced designs can be computationally intensive, in particular for ADJUST=NELSON. A simulation-based approach, as specified by the ADJUST=SIM option, while nondeterministic, can provide inferences that are sufficiently accurate in much less time. The preceding references also describe the SCHEFFE and SMM adjustments.

Nelson’s adjustment applies only to the analysis of means (Ott 1967; Nelson 1982, 1991, 1993), where LS-means are compared against an average LS-mean. It does not apply to all pairwise differences of least squares means, or to slice differences that you specify with the SLICEDIFF= option. See the DIFF=ANOM option for more details regarding the analysis of means with the GLIMMIX procedure.

The SIMULATE adjustment computes adjusted p -values and confidence limits from the simulated distribution of the maximum or maximum absolute value of a multivariate t random vector. All covariance parameters, except the residual scale parameter, are fixed at their estimated values throughout the simulation, potentially resulting in some underdispersion. The simulation estimates q , the true $(1 - \alpha)$ quantile, where $1 - \alpha$ is the confidence coefficient. The default α is 0.05, and you can change this value with the ALPHA= option in the LSMEANS statement.

The number of samples is set so that the tail area for the simulated q is within γ of $1 - \alpha$ with $100(1 - \epsilon)\%$ confidence. In equation form,

$$\Pr(|F(\hat{q}) - (1 - \alpha)| \leq \gamma) = 1 - \epsilon$$

where \hat{q} is the simulated q and F is the true distribution function of the maximum; see Edwards and Berry (1987) for details. By default, $\gamma = 0.005$ and $\epsilon = 0.01$, placing the tail area of \hat{q} within 0.005 of 0.95 with 99% confidence. The ACC= and EPS= *simoptions* reset γ and ϵ , respectively, the NSAMP= *simoption* sets the sample size directly, and the SEED= *simoption* specifies an integer used to start the pseudo-random number generator for the simulation. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer clock. For additional descriptions of these and other simulation options, see the section “LSMEANS Statement” on page 3293 in Chapter 42, “The GLM Procedure.”

If the STEPDOWN option is in effect, the p -values are further adjusted in a step-down fashion. For certain options and data, this adjustment is exact under an iid $N(0, \sigma^2)$ model for the dependent variable, in particular for the following:

- for ADJUST=DUNNETT when the means are uncorrelated
- for ADJUST=TUKEY with STEPDOWN(TYPE=LOGICAL) when the means are balanced and uncorrelated.

The first case is a consequence of the nature of the successive step-down hypotheses for comparisons with a control; the second employs an extension of the maximum studentized range distribution appropriate for partition hypotheses (Royen 1989). Finally, for `STEPDOWN(TYPE=FREE)`, `ADJUST=TUKEY` employs the Royen (1989) extension in such a way that the resulting p -values are conservative.

ALPHA=number

requests that a t -type confidence interval be constructed for each of the LS-means with confidence level $1 - \text{number}$. The value of *number* must be between 0 and 1; the default is 0.05.

AT variable=value

AT (variable-list)=(value-list)

AT MEANS

enables you to modify the values of the covariates used in computing LS-means. By default, all covariate effects are set equal to their mean values for computation of standard LS-means. The AT option enables you to assign arbitrary values to the covariates. Additional columns in the output table indicate the values of the covariates.

If there is an effect containing two or more covariates, the AT option sets the effect equal to the product of the individual means rather than the mean of the product (as with standard LS-means calculations). The AT MEANS option sets covariates equal to their mean values (as with standard LS-means) and incorporates this adjustment to crossproducts of covariates.

As an example, consider the following invocation of PROC GLIMMIX:

```
proc glimmix;
  class A;
  model Y = A x1 x2 x1*x2;
  lsmeans A;
  lsmeans A / at means;
  lsmeans A / at x1=1.2;
  lsmeans A / at (x1 x2)=(1.2 0.3);
run;
```

For the first two LSMEANS statements, the LS-means coefficient for x_1 is \bar{x}_1 (the mean of x_1) and for x_2 is \bar{x}_2 (the mean of x_2). However, for the first LSMEANS statement, the coefficient for x_1*x_2 is $\bar{x}_1\bar{x}_2$, but for the second LSMEANS statement, the coefficient is $\bar{x}_1 \times \bar{x}_2$. The third LSMEANS statement sets the coefficient for x_1 equal to 1.2 and leaves it at \bar{x}_2 for x_2 , and the final LSMEANS statement sets these values to 1.2 and 0.3, respectively.

Even if you specify a **WEIGHT** variable, the unweighted covariate means are used for the covariate coefficients if there is no AT specification. If you specify the AT option, **WEIGHT** or **FREQ** variables are taken into account as follows. The weighted covariate means are then used for the covariate coefficients for which no explicit AT values are given, or if you specify AT MEANS. Observations that do not contribute to the analysis because of a missing dependent variable are included in computing the covariate means. You should use the **E** option in conjunction with the AT option to check that the modified LS-means coefficients are the ones you want.

The AT option is disabled if you specify the **BYLEVEL** option.

BYLEVEL

requests that separate margins be computed for each level of the LSMEANS effect.

The standard LS-means have equal coefficients across classification effects. The BYLEVEL option changes these coefficients to be proportional to the observed margins. This adjustment is reasonable when you want your inferences to apply to a population that is not necessarily balanced but has the margins observed in the input data set. In this case, the resulting LS-means are actually equal to raw means for fixed-effects models and certain balanced random-effects models, but their estimated standard errors account for the covariance structure that you have specified. If a **WEIGHT** statement is specified, PROC GLIMMIX uses weighted margins to construct the LS-means coefficients.

If the **AT** option is specified, the BYLEVEL option disables it.

CL

requests that *t*-type confidence limits be constructed for each of the LS-means. If **DDFM=NONE**, then PROC GLIMMIX uses infinite degrees of freedom for this test, essentially computing a *z* interval. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option. If you specify an **ADJUST=** option, then the confidence limits are adjusted for multiplicity, but if you also specify **STEPDOWN**, then only *p*-values are step-down adjusted, not the confidence limits.

CORR

displays the estimated correlation matrix of the least squares means as part of the “Least Squares Means” table.

COV

displays the estimated covariance matrix of the least squares means as part of the “Least Squares Means” table.

DF=number

specifies the degrees of freedom for the *t* test and confidence limits. The default is the denominator degrees of freedom taken from the “Type III Tests of Fixed Effects” table corresponding to the LS-means effect.

DIFF<=difftype>**PDIFF<=difftype>**

requests that differences of the LS-means be displayed. The optional *difftype* specifies which differences to produce, with possible values ALL, ANOM, CONTROL, CONTROLL, and CONTROLU. The ALL value requests all pairwise differences, and it is the default. The CONTROL *difftype* requests differences with a control, which, by default, is the first level of each of the specified LSMEANS effects.

The ANOM value requests differences between each LS-mean and the average LS-mean, as in the *analysis of means* (Ott 1967). The average is computed as a weighted mean of the LS-means, the weights being inversely proportional to the diagonal entries of the

$$\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}'$$

matrix. If LS-means are nonestimable, this design-based weighted mean is replaced with an equally weighted mean. Note that the ANOM procedure in SAS/QC software implements both tables and graphics for the analysis of means with a variety of response types. For one-way designs and normal data with identity link, the DIFF=ANOM computations are equivalent to the results of PROC ANOM.

If the LS-means being compared are uncorrelated, exact adjusted p -values and critical values for confidence limits can be computed in the analysis of means; see Nelson (1982, 1991, 1993); Guirguis and Tobias (2004) as well as the documentation for the `ADJUST=NELSON` option.

To specify which levels of the effects are the controls, list the quoted formatted values in parentheses after the `CONTROL` keyword. For example, if the effects A, B, and C are classification variables, each having two levels, 1 and 2, the following LSMEANS statement specifies the (1,2) level of A*B and the (2,1) level of B*C as controls:

```
lsmeans A*B B*C / diff=control('1' '2' '2' '1');
```

For multiple effects, the results depend upon the order of the list, and so you should check the output to make sure that the controls are correct.

Two-tailed tests and confidence limits are associated with the `CONTROL difftype`. For one-tailed results, use either the `CONTROLL` or `CONTROLU difftype`. The `CONTROLL difftype` tests whether the noncontrol levels are significantly smaller than the control; the upper confidence limits for the control minus the noncontrol levels are considered to be infinity and are displayed as missing. Conversely, the `CONTROLU difftype` tests whether the noncontrol levels are significantly larger than the control; the upper confidence limits for the noncontrol levels minus the control are considered to be infinity and are displayed as missing.

If you want to perform multiple comparison adjustments on the differences of LS-means, you must specify the `ADJUST=` option.

The differences of the LS-means are displayed in a table titled “Differences of Least Squares Means.”

E

requests that the **L** matrix coefficients for the LSMEANS effects be displayed.

ILINK

requests that estimates and their standard errors in the “Least Squares Means” table also be reported on the scale of the mean (the inverse linked scale). The `ILINK` option is specific to an LSMEANS statement. If you also specify the `CL` option, the GLIMMIX procedure computes confidence intervals for the predicted means by applying the inverse link transform to the confidence limits on the linked (linear) scale. Standard errors on the inverse linked scale are computed by the delta method.

The GLIMMIX procedure applies the inverse link transform to the LS-mean reported in the Estimate column. In a logistic model, for example, this implies that the value reported as the inversely linked estimate corresponds to a predicted probability that is based on an average estimable function (the estimable function that produces the LS-mean on the linear scale). To compute average predicted probabilities, you can average the results from applying the `ILINK` option in the `ESTIMATE` statement for suitably chosen estimable functions.

LINES

presents results of comparisons between all pairs of least squares means by listing the means in descending order and indicating nonsignificant subsets by line segments beside the corresponding LS-means. When all differences have the same variance, these comparison lines are guaranteed to accurately reflect the inferences based on the corresponding tests, made by comparing the respective p -values to the value of the `ALPHA=` option (0.05 by default). However, equal variances might not be the case for differences between LS-means. If the variances are not all the same, then the comparison

lines might be conservative, in the sense that if you base your inferences on the lines alone, you will detect fewer significant differences than the tests indicate. If there are any such differences, PROC GLIMMIX lists the pairs of means that are inferred to be significantly different by the tests but not by the comparison lines. Note, however, that in many cases, even though the variances are unequal, they are similar enough that the comparison lines accurately reflect the test inferences.

ODDS

requests that in models with logit, cumulative logit, and generalized logit link function the odds of the levels of the fixed effects are reported. If you specify the **CL** or **ALPHA=** option, confidence intervals for the odds are also computed. See the section “Odds and Odds Ratio Estimation” on page 3090 for further details about computation and interpretation of odds and odds ratios with the GLIMMIX procedure.

ODDSRATIO

OR

requests that LS-mean differences (**DIFF**, **ADJUST=** options) and simple effect comparisons (**SLICEDIFF** option) are also reported in terms of odds ratios. The **ODDSRATIO** option is ignored unless you use either the logit, cumulative logit, or generalized logit link function. If you specify the **CL** or **ALPHA=** option, confidence intervals for the odds ratios are also computed. These intervals are adjusted for multiplicity when you specify the **ADJUST=** option. See the section “Odds and Odds Ratio Estimation” on page 3090 for further details about computation and interpretation of odds and odds ratios with the GLIMMIX procedure.

OBSMARGINS

OM

specifies a potentially different weighting scheme for the computation of LS-means coefficients. The standard LS-means have equal coefficients across classification effects; however, the **OM** option changes these coefficients to be proportional to those found in the input data set. This adjustment is reasonable when you want your inferences to apply to a population that is not necessarily balanced but has the margins observed in your data.

In computing the observed margins, PROC GLIMMIX uses all observations for which there are no missing or invalid independent variables, including those for which there are missing dependent variables. Also, if you use a **WEIGHT** statement, PROC GLIMMIX computes weighted margins to construct the LS-means coefficients. If your data are balanced, the LS-means are unchanged by the **OM** option.

The **BYLEVEL** option modifies the observed-margins LS-means. Instead of computing the margins across all of the input data set, PROC GLIMMIX computes separate margins for each level of the LSMEANS effect in question. In this case the resulting LS-means are actually equal to raw means for fixed-effects models and certain balanced random-effects models, but their estimated standard errors account for the covariance structure that you have specified.

You can use the **E** option in conjunction with either the **OM** or **BYLEVEL** option to check that the modified LS-means coefficients are the ones you want. It is possible that the modified LS-means are not estimable when the standard ones are estimable, or vice versa.

PDIFF

is the same as the **DIFF** option. See the description of the **DIFF** option on page 2981.

PLOT | PLOTS<=*plot-request*<(*options*)>>**PLOT | PLOTS**<=*(plot-request*<(*options*)> <...*plot-request*<(*options*)> >)>

creates least squares means related graphs when ODS Graphics has been enabled and the plot request does not conflict with other options in the LSMEANS statement. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” For examples of the basic statistical graphics for least squares means and aspects of their computation and interpretation, see the section “Graphics for LS-Mean Comparisons” on page 3122 in this chapter.

The *options* for a specific plot request (and their suboptions) of the LSMEANS statement include those for the **PLOTS=** option in the **PROC GLIMMIX** statement. You can specify classification effects in the MEANPLOT request of the LSMEANS statement to control the display of interaction means with the **PLOTBY=** and **SLICEBY=** suboptions; these are not available in the **PLOTS=** option in the **PROC GLIMMIX** statement. Options specified in the LSMEANS statement override those in the **PLOTS=** option in the **PROC GLIMMIX** statement.

The available options and suboptions are as follows.

ALL

requests that the default plots corresponding to this LSMEANS statement be produced. The default plot depends on the options in the statement.

ANOMPLOT**ANOM**

requests an analysis of means display in which least squares means are compared to an average least squares mean. Least squares mean ANOM plots are produced only for those model effects listed in LSMEANS statements that have options that do not contradict with the display. For example, the following statements produce analysis of mean plots for effects A and C:

```
lsmeans A / diff=anom plot=anom;
lsmeans B / diff      plot=anom;
lsmeans C /           plot=anom;
```

The **DIFF** option in the second LSMEANS statement implies all pairwise differences.

CONTROLPLOT**CONTROL**

requests a display in which least squares means are visually compared against a reference level. These plots are produced only for statements with options that are compatible with control differences. For example, the following statements produce control plots for effects A and C:

```
lsmeans A / diff=control('1') plot=control;
lsmeans B / diff              plot=control;
lsmeans C                    plot=control;
```

The **DIFF** option in the second LSMEANS statement implies all pairwise differences.

DIFFPLOT<(diffplot-options)>

DIFFOGRAM<(diffplot-options)>

DIFF<(diffplot-options)>

requests a display of all pairwise least squares mean differences and their significance. The display is also known as a “mean-mean scatter plot” when it is based on arithmetic means (Hsu 1996; Hsu and Peruggia 1994). For each comparison a line segment, centered at the LS-means in the pair, is drawn. The length of the segment corresponds to the projected width of a confidence interval for the least squares mean difference. Segments that fail to cross the 45-degree reference line correspond to significant least squares mean differences.

LS-mean difference plots are produced only for statements with options that are compatible with the display. For example, the following statements request differences against a control level for the A effect, all pairwise differences for the B effect, and the least squares means for the C effect:

```
lsmeans A / diff=control('1') plot=diff;
lsmeans B / diff                plot=diff;
lsmeans C                      plot=diff;
```

The **DIFF=** type in the first statement is incompatible with a display of all pairwise differences.

You can specify the following *diffplot-options*. The **ABS** and **NOABS** options determine the positioning of the line segments in the plot. When the **ABS** option is in effect, and this is the default, all line segments are shown on the same side of the reference line. The **NOABS** option separates comparisons according to the sign of the difference. The **CENTER** option marks the center point for each comparison. This point corresponds to the intersection of two least squares means. The **NOLINES** option suppresses the display of the line segments that represent the confidence bounds for the differences of the least squares means. The **NOLINES** option implies the **CENTER** option. The default is to draw line segments in the upper portion of the plot area without marking the center point.

MEANPLOT<(meanplot-options)>

requests displays of the least squares means.

The following *meanplot-options* control the display of the least squares means.

ASCENDING

displays the least squares means in ascending order. This option has no effect if means are sliced or displayed in separate plots.

CL

displays upper and lower confidence limits for the least squares means. By default, 95% limits are drawn. You can change the confidence level with the **ALPHA=** option. Confidence limits are drawn by default if the **CL** option is specified in the LSMEANS statement.

CLBAND

displays confidence limits as bands. This option implies the **JOIN** option.

DESCENDING

displays the least squares means in descending order. This option has no effect if means are sliced or displayed in separate plots.

ILINK

requests that means (and confidence limits) are displayed on the inverse linked scale.

JOIN**CONNECT**

connects the least squares means with lines. This option is implied by the CLBAND option. If the effect contains nested variables, and a SLICEBY= effect contains classification variables that appear as crossed effects, this option is ignored.

SLICEBY=*fixed-effect*

specifies an effect by which to group the means in a single plot. For example, the following statement requests a plot in which the levels of A are placed on the horizontal axis and the means that belong to the same level of B are joined by lines:

```
lsmeans A*B / plot=meanplot(sliceby=b join);
```

Unless the LS-mean effect contains at least two classification variables, the SLICEBY= option has no effect. The *fixed-effect* does not have to be an effect in your MODEL statement, but it must consist entirely of classification variables.

PLOTBY=*fixed-effect*

specifies an effect by which to break interaction plots into separate displays. For example, the following statement requests for each level of C one plot of the A*B cell means that are associated with that level of C:

```
lsmeans A*B*C / plot=meanplot(sliceby=b plotby=c clband);
```

In each plot, levels of A are displayed on the horizontal axis, and confidence bands are drawn around the means that share the same level of B.

The PLOTBY= option has no effect unless the LS-mean effect contains at least three classification variables. The *fixed-effect* does not have to be an effect in the MODEL statement, but it must consist entirely of classification variables.

NONE

requests that no plots be produced.

When LS-mean calculations are adjusted for multiplicity by using the ADJUST= option, the plots are adjusted accordingly.

SINGULAR=*number*

tunes the estimability checking as documented for the CONTRAST statement.

SLICE=*fixed-effect*

SLICE=(fixed-effects)

specifies effects by which to partition interaction LSMEANS effects. This can produce what are known as tests of simple effects (Winer 1971). For example, suppose that $A*B$ is significant, and you want to test the effect of A for each level of B . The appropriate LSMEANS statement is

```
lsmeans A*B / slice=B;
```

This statement tests for the simple main effects of A for B , which are calculated by extracting the appropriate rows from the coefficient matrix for the $A*B$ LS-means and by using them to form an F test.

The SLICE option produces F tests that test the simultaneous equality of cell means at a fixed level of the slice effect (Schabenberger, Gregoire, and Kong 2000). You can request differences of the least squares means while holding one or more factors at a fixed level with the SLICEDIFF= option.

The SLICE option produces a table titled “Tests of Effect Slices.”

SLICEDIFF=fixed-effect**SLICEDIFF=(fixed-effects)****SIMPLEDIFF=fixed-effect****SIMPLEDIFF=(fixed-effects)**

requests that differences of simple effects be constructed and tested against zero. Whereas the SLICE option extracts multiple rows of the coefficient matrix and forms an F test, the SLICEDIFF option tests pairwise differences of these rows. This enables you to perform multiple comparisons among the levels of one factor at a fixed level of the other factor. For example, assume that, in a balanced design, factors A and B have $a = 4$ and $b = 3$ levels, respectively. Consider the following statements:

```
proc glimmix;
  class a b;
  model y = a b a*b;
  lsmeans a*b / slice=a;
  lsmeans a*b / slicediff=a;
run;
```

The first LSMEANS statement produces four F tests, one per level of A . The first of these tests is constructed by extracting the three rows corresponding to the first level of A from the coefficient matrix for the $A*B$ interaction. Call this matrix L_{a1} and its rows $l_{a1}^{(1)}$, $l_{a1}^{(2)}$, and $l_{a1}^{(3)}$. The SLICE tests the two-degrees-of-freedom hypothesis

$$H: \begin{cases} \left(l_{a1}^{(1)} - l_{a1}^{(2)} \right) \boldsymbol{\beta} = 0 \\ \left(l_{a1}^{(1)} - l_{a1}^{(3)} \right) \boldsymbol{\beta} = 0 \end{cases}$$

In a balanced design, where μ_{ij} denotes the mean response if A is at level i and B is at level j , this hypothesis is equivalent to $H: \mu_{11} = \mu_{12} = \mu_{13}$. The SLICEDIFF option considers the three rows of L_{a1} in turn and performs tests of the difference between pairs of rows. How these differences are constructed depends on the SLICEDIFFTYPE= option. By default, all pairwise differences within

the subset of \mathbf{L} are considered; in the example this corresponds to tests of the form

$$H: \left(1_{a1}^{(1)} - 1_{a1}^{(2)}\right) \boldsymbol{\beta} = 0$$

$$H: \left(1_{a1}^{(1)} - 1_{a1}^{(3)}\right) \boldsymbol{\beta} = 0$$

$$H: \left(1_{a1}^{(2)} - 1_{a1}^{(3)}\right) \boldsymbol{\beta} = 0$$

In the example, with $a = 4$ and $b = 3$, the second LSMEANS statement produces four sets of least squares means differences. Within each set, factor A is held fixed at a particular level and each set consists of three comparisons.

When the **ADJUST=** option is specified, the GLIMMIX procedure also adjusts the tests for multiplicity. The adjustment is based on the number of comparisons within each level of the **SLICEDIFF=** effect; see the **SLICEDIFFTYPE=** option. The Nelson adjustment is not available for slice differences.

SLICEDIFFTYPE<=*difftype*>

SIMPLEDIFFTYPE<=*difftype*>

determines the type of simple effect differences produced with the **SLICEDIFF=** option.

The possible values for the *difftype* are ALL, CONTROL, CONTROLL, and CONTROLU. The *difftype* ALL requests all simple effects differences, and it is the default. The *difftype* CONTROL requests the differences with a control, which, by default, is the first level of each of the specified LSMEANS effects.

To specify which levels of the effects are the controls, list the quoted formatted values in parentheses after the keyword CONTROL. For example, if the effects A, B, and C are classification variables, each having three levels (1, 2, and 3), the following LSMEANS statement specifies the (1,3) level of A*B as the control:

```
lsmeans A*B / slicediff=(A B)
                slicedifftype=control('1' '3');
```

This LSMEANS statement first produces simple effects differences holding the levels of A fixed, and then it produces simple effects differences holding the levels of B fixed. In the former case, level '3' of B serves as the control level. In the latter case, level '1' of A serves as the control.

For multiple effects, the results depend upon the order of the list, and so you should check the output to make sure that the controls are correct.

Two-tailed tests and confidence limits are associated with the CONTROL *difftype*. For one-tailed results, use either the CONTROLL or CONTROLU *difftype*. The CONTROLL *difftype* tests whether the noncontrol levels are significantly smaller than the control; the upper confidence limits for the control minus the noncontrol levels are considered to be infinity and are displayed as missing. Conversely, the CONTROLU *difftype* tests whether the noncontrol levels are significantly larger than the control; the upper confidence limits for the noncontrol levels minus the control are considered to be infinity and are displayed as missing.

STEPDOWN< (*step-down options*) >

requests that multiple comparison adjustments for the p -values of LS-mean differences be further adjusted in a step-down fashion. Step-down methods increase the power of multiple comparisons by taking advantage of the fact that a p -value will never be declared significant unless all smaller p -values are also declared significant. Note that the STEPDOWN adjustment combined with **ADJUST=BON** corresponds to the methods of Holm (1979) and “Method 2” of Shaffer (1986); this is the default. Using step-down-adjusted p -values combined with **ADJUST=SIMULATE** corresponds to the method of Westfall (1997).

If the degrees-of-freedom method is **DDFM=KENWARDROGER** or **DDFM=SATTERTHWAITE**, then step-down-adjusted p -values are produced only if the **ADJDFE=ROW** option is in effect.

Also, STEPDOWN affects only p -values, not confidence limits. For **ADJUST=SIMULATE**, the generalized least squares hybrid approach of Westfall (1997) is employed to increase Monte Carlo accuracy.

You can specify the following *step-down options* in parentheses:

MAXTIME= n

specifies the time (in seconds) to spend computing the maximal logically consistent sequential subsets of equality hypotheses for **TYPE=LOGICAL**. The default is **MAXTIME=60**. If the **MAXTIME** value is exceeded, the adjusted tests are not computed. When this occurs, you can try increasing the **MAXTIME** value. However, note that there are common multiple comparisons problems for which this computation requires a huge amount of time—for example, all pairwise comparisons between more than 10 groups. In such cases, try to use **TYPE=FREE** (the default) or **TYPE=LOGICAL(n)** for small n .

REPORT

specifies that a report on the step-down adjustment should be displayed, including a listing of the sequential subsets (Westfall 1997) and, for **ADJUST=SIMULATE**, the step-down simulation results.

TYPE=LOGICAL< (n) >**TYPE=FREE**

If you specify **TYPE=LOGICAL**, the step-down adjustments are computed by using maximal logically consistent sequential subsets of equality hypotheses (Shaffer 1986; Westfall 1997). Alternatively, for **TYPE=FREE**, sequential subsets are computed ignoring logical constraints. The **TYPE=FREE** results are more conservative than those for **TYPE=LOGICAL**, but they can be much more efficient to produce for many comparisons. For example, it is not feasible to take logical constraints between all pairwise comparisons of more than 10 groups. For this reason, **TYPE=FREE** is the default.

However, you can reduce the computational complexity of taking logical constraints into account by limiting the depth of the search tree used to compute them, specifying the optional depth parameter as a number n in parentheses after **TYPE=LOGICAL**. As with **TYPE=FREE**, results for **TYPE=LOGICAL(n)** are conservative relative to the true **TYPE=LOGICAL** results, but even for **TYPE=LOGICAL(0)** they can be appreciably less conservative than **TYPE=FREE** and they are computationally feasible for much larger numbers of comparisons. If you do not specify n or if $n = -1$, the full search tree is used.

LSMESTIMATE Statement

```
LSMESTIMATE fixed-effect <'label'> values <divisor=n>
             <,<'label'> values <divisor=n>> <,&ldots >
             </options>;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among the least squares means. In contrast to the hypotheses tested with the ESTIMATE or CONTRAST statements, the LSMESTIMATE statement enables you to form linear combinations of the least squares means, rather than linear combination of fixed-effects parameter estimates and/or random-effects solutions. Multiple-row sets of coefficients are permitted.

The computation of an LSMESTIMATE involves two coefficient matrices. Suppose that the *fixed-effect* has n_l levels. Then the LS-means are formed as $\mathbf{L}_1 \hat{\boldsymbol{\beta}}$, where \mathbf{L}_1 is a $(n_l \times p)$ coefficient matrix. The $(k \times n_l)$ coefficient matrix \mathbf{K} is formed from the *values* that you supply in the k rows of the LSMESTIMATE statement. The least squares means estimates then represent the $(k \times 1)$ vector

$$\mathbf{KL}_1 \boldsymbol{\beta} = \mathbf{L} \boldsymbol{\beta}$$

The GLIMMIX procedure supports nonpositional syntax for the coefficients (*values*) in the LSMESTIMATE statement. For details see the section “Positional and Nonpositional Syntax for Contrast Coefficients” on page 3097.

PROC GLIMMIX produces a t test for each row of coefficients specified in the LSMESTIMATE statement. You can adjust p -values and confidence intervals for multiplicity with the ADJUST= option. You can obtain an F test of single-row or multirow LSMESTIMATEs with the FTEST option.

Note that in contrast to a multirow estimate in the ESTIMATE statement, you specify only a single fixed effect in the LSMESTIMATE statement. The row labels are optional and follow the effects specification. For example, the following statements fit a split-split-plot design and compare the average of the third and fourth LS-mean of the whole-plot factor A to the first LS-mean of the factor:

```
proc glimmix;
  class a b block;
  model y = a b a*b / s;
  random int a / sub=block;
  lsmestimate A 'a1 vs avg(a3,a4)' 2 0 -1 -1 divisor=2;
run;
```

The order in which coefficients are assigned to the least squares means corresponds to the order in which they are displayed in the “Least Squares Means” table. You can use the ELSM option to see how coefficients are matched to levels of the *fixed-effect*.

The optional *divisor=n* specification enables you to assign a separate divisor to each row of the LSMESTIMATE. You can also assign divisor values through the DIVISOR= option. See the documentation that follows for the interaction between the two ways of specifying divisors.

Many options of the LSMESTIMATE statement affect the computation of least squares means—for example, the AT=, BYLEVEL, and OM options. See the documentation for the LSMEANS statement for details.

Table 41.9 summarizes the options available in the LSMESTIMATE statement.

Table 41.9 LSMESTIMATE Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies covariate values in computing LS-means
BYLEVEL	Computes separate margins
DIVISOR=	Specifies a list of values to divide the coefficients
OM=	Specifies the weighting scheme for LS-means computation as determined by a data set
SINGULAR=	Tunes estimability checking
Degrees of Freedom and p-values	
ADJDFE=	Determines denominator degrees of freedom when p -values and confidence limits are adjusted for multiple comparisons
ADJUST=	Determines the method for multiple comparison adjustment of LS-means differences
ALPHA= α	Determines the confidence level $(1 - \alpha)$
CHISQ	Requests a chi-square test in addition to the F test
DF=	Assigns a specific value to degrees of freedom for tests and confidence limits
FTEST	Produces an F test
LOWER	Performs one-sided, lower-tailed inference
STEPDOWN	Adjusts multiple comparison p -values further in a step-down fashion
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Prints the L matrix
ELSM	Prints the K matrix
JOINT	Produces a joint F or chi-square test for the LS-means and LS-means differences
Generalized Linear Modeling	
EXP	Exponentiates and displays LS-means estimates
ILINK	Computes and displays estimates and standard errors of LS-means (but not differences) on the inverse linked scale

You can specify the following options in the LSMESTIMATE statement after a slash (/).

ADJDFE=SOURCE**ADJDFE=ROW**

specifies how denominator degrees of freedom are determined when p -values and confidence limits are adjusted for multiple comparisons with the **ADJUST=** option. When you do not specify the **ADJDFE=** option, or when you specify **ADJDFE=SOURCE**, the denominator degrees of freedom for

multiplicity-adjusted results are the denominator degrees of freedom for the LS-mean effect in the “Type III Tests of Fixed Effects” table.

The `ADJDFE=ROW` setting is useful if you want multiplicity adjustments to take into account that denominator degrees of freedom are not constant across estimates. This can be the case, for example, when `DDFM=SATTERTHWAITE` or `DDFM=KENWARDROGER` is specified in the `MODEL` statement.

ADJUST=BON

ADJUST=SCHEFFE

ADJUST=SIDAK

ADJUST=SIMULATE< (*simoptions*) >

ADJUST=T

requests a multiple comparison adjustment for the p -values and confidence limits for the LS-mean estimates. The adjusted quantities are produced in addition to the unadjusted p -values and confidence limits. Adjusted confidence limits are produced if the `CL` or `ALPHA=` option is in effect. For a description of the adjustments, see Chapter 42, “The GLM Procedure,” and Chapter 61, “The MULTTEST Procedure,” as well as the documentation for the `ADJUST=` option in the `LSMEANS` statement.

Note that not all adjustment methods of the `LSMEANS` statement are available for the `LSMESTIMATE` statement. Multiplicity adjustments in the `LSMEANS` statement are designed specifically for differences of least squares means.

If you specify the `STEPDOWN` option, the p -values are further adjusted in a step-down fashion.

ALPHA=number

requests that a t -type confidence interval be constructed for each of the LS-means with confidence level $1 - \textit{number}$. The value of *number* must be between 0 and 1; the default is 0.05.

AT variable=value

AT (variable-list)=(value-list)

AT MEANS

enables you to modify the values of the covariates used in computing LS-means. See the `AT` option in the `LSMEANS` statement for details.

BYLEVEL

requests that PROC GLIMMIX compute separate margins for each level of the `LSMEANS` effect.

The standard LS-means have equal coefficients across classification effects. The `BYLEVEL` option changes these coefficients to be proportional to the observed margins. This adjustment is reasonable when you want your inferences to apply to a population that is not necessarily balanced but has the margins observed in the input data set. In this case, the resulting LS-means are actually equal to raw means for fixed-effects models and certain balanced random-effects models, but their estimated standard errors account for the covariance structure that you have specified. If a `WEIGHT` statement is specified, PROC GLIMMIX uses weighted margins to construct the LS-means coefficients.

If the `AT` option is specified, the `BYLEVEL` option disables it.

CHISQ

requests that chi-square tests be performed in addition to F tests, when you request an F test with the **FTEST** option.

CL

requests that t -type confidence limits be constructed for each of the LS-means. If **DDFM=NONE**, then PROC GLIMMIX uses infinite degrees of freedom for this test, essentially computing a z interval. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option.

CORR

displays the estimated correlation matrix of the linear combination of the least squares means.

COV

displays the estimated covariance matrix of the linear combination of the least squares means.

DF=number

specifies the degrees of freedom for the t test and confidence limits. The default is the denominator degrees of freedom taken from the “Type III Tests of Fixed Effects” table corresponding to the LS-means effect.

DIVISOR=value-list

specifies a list of values by which to divide the coefficients so that fractional coefficients can be entered as integer numerators. If you do not specify *value-list*, a default value of 1.0 is assumed. Missing values in the *value-list* are converted to 1.0.

If the number of elements in *value-list* exceeds the number of rows of the estimate, the extra values are ignored. If the number of elements in *value-list* is less than the number of rows of the estimate, the last value in *value-list* is carried forward.

If you specify a row-specific divisor as part of the specification of the estimate row, this value multiplies the corresponding value in the *value-list*. For example, the following statement divides the coefficients in the first row by 8, and the coefficients in the third and fourth row by 3:

```
lsmestimate A 'One vs. two' 8 -8 divisor=2,
              'One vs. three' 1 0 -1 ,
              'One vs. four' 3 0 0 -3 ,
              'One vs. five' 3 0 0 0 -3 / divisor=4,.,3;
```

Coefficients in the second row are not altered.

E

requests that the **L** coefficients of the estimable function be displayed. These are the coefficients that apply to the fixed-effect parameter estimates. The **E** option displays the coefficients that you would need to enter in an equivalent **ESTIMATE** statement.

ELSM

requests that the **K** matrix coefficients be displayed. These are the coefficients that apply to the LS-means. This option is useful to ensure that you assigned the coefficients correctly to the LS-means.

EXP

requests exponentiation of the least squares means estimate. When you model data with the logit link function and the estimate represents a log odds ratio, the EXP option produces an odds ratio. See the section “[Odds and Odds Ratio Estimation](#)” on page 3090 for important details concerning the computation and interpretation of odds and odds ratio results with the GLIMMIX procedure. If you specify the **CL** or **ALPHA=** option, the (adjusted) confidence limits for the estimate are also exponentiated.

FTEST< (*joint-test-options*) >**JOINT**< (*joint-test-options*) >

produces an F test that jointly tests the rows of the LSMESTIMATE against zero. If the LOWER or UPPER options are in effect or if you specify boundary values with the BOUNDS= suboption, the GLIMMIX procedure computes a simulation-based p -value for the constrained joint test. For more information about these simulation-based p -values, see the section “[Joint Hypothesis Tests with Complex Alternatives, the Chi-Bar-Square Statistic](#)” on page 451 in Chapter 19, “[Shared Concepts and Topics](#).” You can specify the following *joint-test-options* in parentheses:

ACC= γ

specifies the accuracy radius for determining the necessary sample size in the simulation-based approach of Silvapulle and Sen (2004) for tests with order restrictions. The value of γ must be strictly between 0 and 1; the default value is 0.005.

BOUNDS=*value-list*

specifies boundary values for the estimable linear function. The null value of the hypothesis is always zero. If you specify a positive boundary value z , the hypotheses are $H: \theta = 0$ vs. $H_a: \theta > 0$ with the added constraint that $\theta < z$. The same is true for negative boundary values. The alternative hypothesis is then $H_a: \theta < 0$ subject to the constraint $\theta > -|z|$. If you specify a missing value, the hypothesis is assumed to be two-sided. The BOUNDS option enables you to specify sets of one- and two-sided joint hypotheses. If all values in *value-list* are set to missing, the procedure performs a simulation-based p -value calculation for a two-sided test.

EPS= ϵ

specifies the accuracy confidence level for determining the necessary sample size in the simulation-based approach of Silvapulle and Sen (2004) for F tests with order restrictions. The value of ϵ must be strictly between 0 and 1; the default value is 0.01.

LABEL='*label*'

enables you to assign a label to the joint test that identifies the results in the “LSMFtest” table. If you do not specify a label, the first non-default label for the LSMESTIMATE rows is used to label the joint test.

NSAMP= n

specifies the number of samples for the simulation-based method of Silvapulle and Sen (2004). If n is not specified, it is constructed from the values of the ALPHA= α , the ACC= γ , and the EPS= ϵ options. With the default values for γ , ϵ , and α (0.005, 0.01, and 0.05, respectively), NSAMP=12,604 by default.

ILINK

requests that the estimate and its standard error also be reported on the scale of the mean (the inverse linked scale). PROC GLIMMIX computes the value on the mean scale by applying the inverse link to the estimate. The interpretation of this quantity depends on the coefficients that are specified in your LSMESTIMATE statement and the link function. For example, in a model for binary data with a logit link, the following LSMESTIMATE statement computes

$$q = \frac{1}{1 + \exp\{-(\tau_1 - \tau_2)\}}$$

where τ_1 and τ_2 are the least squares means associated with the first two levels of the classification effect A:

```
proc glimmix;
  class A;
  model y = A / dist=binary link=logit;
  lsmestimate A 1 -1 / ilink;
run;
```

The quantity q is not the difference of the probabilities associated with the two levels,

$$\pi_1 - \pi_2 = \frac{1}{1 + \exp\{-\tau_1\}} - \frac{1}{1 + \exp\{-\tau_2\}}$$

The standard error of the inversely linked estimate is based on the delta method. If you also specify the **CL** or **ALPHA=** option, the GLIMMIX procedure computes confidence intervals for the inversely linked estimate. These intervals are obtained by applying the inverse link to the confidence intervals on the linked scale.

JOINT< *joint-test-options* >

is an alias for the **FTEST** option.

LOWER**LOWERTAILED**

requests that the p -value for the t test be based only on values that are less than the test statistic. A two-tailed test is the default. A lower-tailed confidence limit is also produced if you specify the **CL** or **ALPHA=** option.

Note that for **ADJUST=SCHEFFE** the one-sided adjusted confidence intervals and one-sided adjusted p -values are the same as the corresponding two-sided statistics, because this adjustment is based on only the right tail of the F distribution.

If you request an F test with the **FTEST** option, then a one-sided left-tailed order restriction is applied to all estimable functions, and the corresponding chi-bar-square statistic of Silvapulle and Sen (2004) is computed in addition to the two-sided, standard F or chi-square statistic. See the description of the **FTEST** option for information about how to control the computation of the simulation-based chi-bar-square statistic.

OBSMARGINS**OM**

specifies a potentially different weighting scheme for the computation of LS-means coefficients. The standard LS-means have equal coefficients across classification effects; however, the OM option changes these coefficients to be proportional to those found in the input data set. See the **OBSMARGINS** option in the **LSMEANS** statement for further details.

SINGULAR=*number*

tunes the estimability checking as documented for the **CONTRAST** statement.

STEPDOWN< (*step-down-options*) >

requests that multiplicity adjustments for the p -values of LS-mean estimates be further adjusted in a step-down fashion. Step-down methods increase the power of multiple testing procedures by taking advantage of the fact that a p -value will never be declared significant unless all smaller p -values are also declared significant. Note that the STEPDOWN adjustment combined with **ADJUST=BON** corresponds to the Holm (1979) and “Method 2” of Shaffer (1986); this is the default. Using step-down-adjusted p -values combined with **ADJUST=SIMULATE** corresponds to the method of Westfall (1997).

If the degrees-of-freedom method is **DDFM=KENWARDROGER** or **DDFM=SATTERTHWAITE**, then step-down-adjusted p -values are produced only if the **ADJDFE=ROW** option is in effect.

Also, the STEPDOWN option affects only p -values, not confidence limits. For **ADJUST=SIMULATE**, the generalized least squares hybrid approach of Westfall (1997) is employed to increase Monte Carlo accuracy.

You can specify the following *step-down-options* in parentheses:

MAXTIME=*n*

specifies the time (in seconds) to spend computing the maximal logically consistent sequential subsets of equality hypotheses for **TYPE=LOGICAL**. The default is **MAXTIME=60**. If the **MAXTIME** value is exceeded, the adjusted tests are not computed. When this occurs, you can try increasing the **MAXTIME** value. However, note that there are common multiple comparisons problems for which this computation requires a huge amount of time—for example, all pairwise comparisons between more than 10 groups. In such cases, try to use **TYPE=FREE** (the default) or **TYPE=LOGICAL(*n*)** for small n .

ORDER=PVALUE**ORDER=ROWS**

specifies the order in which the step-down tests are performed. **ORDER=PVALUE** is the default, with LS-mean estimates being declared significant only if all LS-mean estimates with smaller (unadjusted) p -values are significant. If you specify **ORDER=ROWS**, then significances are evaluated in the order in which they are specified.

REPORT

specifies that a report on the step-down adjustment be displayed, including a listing of the sequential subsets (Westfall 1997) and, for **ADJUST=SIMULATE**, the step-down simulation results.

TYPE=LOGICAL< (*n*) >**TYPE=FREE**

If you specify **TYPE=LOGICAL**, the step-down adjustments are computed by using maximal logically consistent sequential subsets of equality hypotheses (Shaffer 1986; Westfall 1997). Alternatively, for **TYPE=FREE**, logical constraints are ignored when sequential subsets are computed. The **TYPE=FREE** results are more conservative than those for **TYPE=LOGICAL**, but they can be much more efficient to produce for many estimates. For example, it is not feasible to take logical constraints between all pairwise comparisons of more than about 10 groups. For this reason, **TYPE=FREE** is the default.

However, you can reduce the computational complexity of taking logical constraints into account by limiting the depth of the search tree used to compute them, specifying the optional depth parameter as a number *n* in parentheses after **TYPE=LOGICAL**. As with **TYPE=FREE**, results for **TYPE=LOGICAL**(*n*) are conservative relative to the true **TYPE=LOGICAL** results, but even for **TYPE=LOGICAL**(0), they can be appreciably less conservative than **TYPE=FREE**, and they are computationally feasible for much larger numbers of estimates. If you do not specify *n* or if *n* = -1, the full search tree is used.

UPPER**UPPERTAILED**

requests that the *p*-value for the *t* test be based only on values that are greater than the test statistic. A two-tailed test is the default. An upper-tailed confidence limit is also produced if you specify the **CL** or **ALPHA=** option.

Note that for **ADJUST=SCHEFFE** the one-sided adjusted confidence intervals and one-sided adjusted *p*-values are the same as the corresponding two-sided statistics, because this adjustment is based on only the right tail of the *F* distribution.

If you request a joint test with the **FTEST** option, then a one-sided right-tailed order restriction is applied to all estimable functions, and the corresponding chi-bar-square statistic of Silvapulle and Sen (2004) is computed in addition to the two-sided, standard *F* or chi-square statistic. See the **FTEST** option for information about how to control the computation of the simulation-based chi-bar-square statistic.

MODEL Statement

MODEL *response* < (*response-options*) > = < *fixed-effects* > < / *model-options* > ;

MODEL *events/trials* = < *fixed-effects* > < / *model-options* > ;

The **MODEL** statement is required and names the dependent variable and the fixed effects. The *fixed-effects* determine the **X** matrix of the model (see the section “[Notation for the Generalized Linear Mixed Model](#)” for details). The [specification of effects](#) is the same as in the **GLM** or **MIXED** procedure. In contrast to **PROC GLM**, you do not specify random effects in the **MODEL** statement. However, in contrast to **PROC GLM** and **PROC MIXED**, continuous variables on the left and right side of the **MODEL** statement can be computed through **PROC GLIMMIX programming statements**.

An intercept is included in the fixed-effects model by default. It can be removed with the **NOINT** option.

The dependent variable can be specified by using either the *response* syntax or the *events/trials* syntax. The *events/trials* syntax is specific to models for binomial data. A binomial(n, π) variable is the sum of n independent Bernoulli trials with event probability π . Each Bernoulli trial results in either an event or a nonevent (with probability $1 - \pi$). You use the *events/trials* syntax to indicate to the GLIMMIX procedure that the Bernoulli outcomes are grouped. The value of the second variable, *trials*, gives the number n of Bernoulli trials. The value of the first variable, *events*, is the number of events out of n . The values of both *events* and (*trials*–*events*) must be nonnegative and the value of *trials* must be positive. Observations for which these conditions are not met are excluded from the analysis. If the *events/trials* syntax is used, the GLIMMIX procedure defaults to the binomial distribution. The response is then the *events* variable. The *trials* variable is accounted in model fitting as an additional weight. If you use the *response* syntax, the procedure defaults to the normal distribution.

There are two sets of options in the MODEL statement. The *response-options* determine how the GLIMMIX procedure models probabilities for binary and multinomial data. The *model-options* control other aspects of model formation and inference. Table 41.10 summarizes the options available in the MODEL statement. These are subsequently discussed in detail in alphabetical order by option category.

Table 41.10 MODEL Statement Options

Option	Description
Response Variable Options	
DESCENDING	Reverses the order of response categories
EVENT=	Specifies the event category in binary models
ORDER=	Specifies the sort order for the response variable
REFERENCE=	Specifies the reference category in generalized logit models
Model Building	
DIST=	Specifies the response distribution
LINK=	Specifies the link function
NOINT	Excludes fixed-effect intercept from model
OFFSET=	Specifies the offset variable for linear predictor
Statistical Computations	
ALPHA= α	Determines the confidence level ($1 - \alpha$)
CHISQ	Requests chi-square tests
DDF=	Specifies the denominator degrees of freedom (list)
DDFM=	Specifies the method for computing denominator degrees of freedom
HTYPE=	Selects the type of hypothesis test
LWEIGHT	Determines how weights are used
NOCENTER	Suppresses centering and scaling of X columns during the estimation phase
REFLINP	Specifies a value for the linear predictor
ZETA=	Tunes sensitivity in computing Type III functions
Statistical Output	
CL	Displays confidence limits for fixed-effects parameter estimates
CORRB	Displays the correlation matrix of fixed-effects parameter estimates
COVB	Displays the covariance matrix of fixed-effects parameter estimates
COVBI	Displays the inverse covariance matrix of fixed-effects parameter estimates
E, E1, E2, E3	Displays the L matrix coefficients

Table 41.10 *continued*

Option	Description
INTERCEPT	Adds a row for the intercept to test tables
ODDSRATIO	Displays odds ratios and confidence limits
SOLUTION	Displays fixed-effects parameter estimates (and scale parameter in GLM models)
STDCOEFF	Displays standardized coefficients

Response Variable Options

Response variable options determine how the GLIMMIX procedure models probabilities for binary and multinomial data.

You can specify the following options by enclosing them in parentheses after the response variable. See the section “[Response-Level Ordering and Referencing](#)” on page 3100 for more detail and examples.

DESCENDING

DESC

reverses the order of the response categories. If both the DESCENDING and ORDER= options are specified, PROC GLIMMIX orders the response categories according to the ORDER= option and then reverses that order.

EVENT=*category* | *keyword*

specifies the event category for the binary response model. PROC GLIMMIX models the probability of the event category. The EVENT= option has no effect when there are more than two response categories. You can specify the value (formatted, if a format is applied) of the event category in quotes, or you can specify one of the following keywords:

FIRST

designates the first ordered category as the event. This is the default.

LAST

designates the last ordered category as the event.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of the response variable. When ORDER=FORMATTED (the default) for numeric variables for which you have supplied no explicit format (that is, for which there is no corresponding FORMAT statement in the current PROC GLIMMIX run or in the DATA step that created the data set), the levels are ordered by their internal (numeric) value. If you specify the ORDER= option in the MODEL statement and the ORDER= option in the PROC GLIMMIX statement, the former takes precedence. The following table shows the interpretation of the ORDER= values:

Value of ORDER=	Levels Sorted By
DATA	order of appearance in the input data set
FORMATTED	external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value

Table 41.10 continued

Value of ORDER=	Levels Sorted By
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

By default, ORDER=FORMATTED. For the FORMATTED and INTERNAL values, the sort order is machine dependent.

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

REFERENCE='category' | keyword

REF='category' | keyword

specifies the reference category for the generalized logit model and the binary response model. For the generalized logit model, each nonreference category is contrasted with the reference category. For the binary response model, specifying one response category as the reference is the same as specifying the other response category as the event category. You can specify the value (formatted if a format is applied) of the reference category in quotes, or you can specify one of the following keywords:

FIRST

designates the first ordered category as the reference category.

LAST

designates the last ordered category as the reference category. This is the default.

Model Options

ALPHA=number

requests that a *t*-type confidence interval be constructed for each of the fixed-effects parameters with confidence level $1 - \text{number}$. The value of *number* must be between 0 and 1; the default is 0.05.

CHISQ

requests that chi-square tests be performed for all specified effects in addition to the *F* tests. Type III tests are the default; you can produce the Type I and Type II tests by using the **HTYPE=** option.

CL

requests that *t*-type confidence limits be constructed for each of the fixed-effects parameter estimates. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option.

CORRB

produces the correlation matrix from the approximate covariance matrix of the fixed-effects parameter estimates.

COVB<(DETAILS)>

produces the approximate variance-covariance matrix of the fixed-effects parameter estimates $\hat{\beta}$. In a generalized linear mixed model this matrix typically takes the form $(\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}$ and can be obtained by sweeping the mixed model equations; see the section “Estimated Precision of Estimates” on

page 3056. In a model without random effects, it is obtained from the inverse of the observed or expected Hessian matrix. Which Hessian is used in the computation depends on whether the procedure is in scoring mode (see the **SCORING=** option in the **PROC GLIMMIX** statement) and whether the **EX-PHESSIAN** option is in effect. Note that if you use **EMPIRICAL=** or **DDFM=KENWARDROGER**, the matrix displayed by the **COVB** option is the empirical (sandwich) estimator or the adjusted estimator, respectively.

The **DETAILS** suboption of the **COVB** option enables you to obtain a table of statistics about the covariance matrix of the fixed effects. If an adjusted estimator is used because of the **EMPIRICAL=** or **DDFM=KENWARDROGER** option, the **GLIMMIX** procedure displays statistics for the adjusted and unadjusted estimators as well as statistics comparing them. This enables you to diagnose, for example, changes in rank (because of an insufficient number of subjects for the empirical estimator) and to assess the extent of the covariance adjustment. In addition, the **GLIMMIX** procedure then displays the unadjusted (=model-based) covariance matrix of the fixed-effects parameter estimates. For more details, see the section “Exploring and Comparing Covariance Matrices” on page 3080.

COVBI

produces the inverse of the approximate covariance matrix of the fixed-effects parameter estimates.

DDF=value-list

DF=value-list

enables you to specify your own denominator degrees of freedom for the fixed effects. The *value-list* specification is a list of numbers or missing values (.) separated by commas. The degrees of freedom should be listed in the order in which the effects appear in the “Type III Tests of Fixed Effects” table. If you want to retain the default degrees of freedom for a particular effect, use a missing value for its location in the list. For example, the statement assigns 3 denominator degrees of freedom to A and 4.7 to A*B, while those for B remain the same:

```
model Y = A B A*B / ddf=3, ., 4.7;
```

If you select a degrees-of-freedom method with the **DDFM=** option, then nonmissing, positive values in *value-list* override the degrees of freedom for the particular effect. For example, the statement assigns 3 and 6 denominator degrees of freedom in the test of the A main effect and the A*B interaction, respectively:

```
model Y = A B A*B / ddf=3, ., 6 ddfm=Satterth;
```

The denominator degrees of freedom for the test for the B effect are determined from a Satterthwaite approximation.

Note that the **DDF=** and **DDFM=** options determine the degrees of freedom in the “Type I Tests of Fixed Effects,” “Type II Tests of Fixed Effects,” and “Type III Tests of Fixed Effects” tables. These degrees of freedom are also used in determining the degrees of freedom in tests and confidence intervals from the **CONTRAST**, **ESTIMATE**, **LSMEANS**, and **LSMESTIMATE** statements. Exceptions from this rule are noted in the documentation for the respective statements.

DDFM=method

specifies the method for computing the denominator degrees of freedom for the tests of fixed effects that result from the **MODEL**, **CONTRAST**, **ESTIMATE**, **LSMEANS**, and **LSMESTIMATE** statements.

You can specify the following *methods*:

BETWITHIN

BW

assigns within-subject degrees of freedom to a fixed effect if the fixed effect changes within a subject, and between-subject degrees of freedom otherwise. This method is the default for models with only R-side random effects and a **SUBJECT=** option. Computational details can be found in the section “[Degrees of Freedom Methods](#)” on page 3075.

CONTAIN

CON

invokes the containment method to compute denominator degrees of freedom. This method is the default when the model contains G-side random effects. Computational details can be found in the section “[Degrees of Freedom Methods](#)” on page 3075.

KENWARDROGER< (FIRSTORDER) >

KENROGER< (FIRSTORDER) >

KR< (FIRSTORDER) >

applies the (prediction) standard error and degrees-of-freedom correction detailed by Kenward and Roger (1997). This approximation involves adjusting the estimated variance-covariance matrix of the fixed and random effects in a manner similar to that of Prasad and Rao (1990); Harville and Jeske (1992); Kackar and Harville (1984). Satterthwaite-type degrees of freedom are then computed based on this adjustment. Computational details can be found in the section “[Degrees of Freedom Methods](#)” on page 3075.

KENWARDROGER2

KENROGER2

KR2

applies the (prediction) standard error and degrees-of-freedom correction that are detailed by Kenward and Roger (2009). This correction further reduces the precision estimator bias for the fixed and random effects under nonlinear covariance structures. Computational details can be found in the section “[Degrees of Freedom Methods](#)” on page 3075.

NONE

specifies that no denominator degrees of freedom be applied. PROC GLIMMIX then essentially assumes that infinite degrees of freedom are available in the calculation of p -values. The p -values for t tests are then identical to p -values that are derived from the standard normal distribution. In the case of F tests, the p -values are equal to those of chi-square tests that are determined as follows: if F_{obs} is the observed value of the F test with l numerator degrees of freedom, then

$$p = \Pr\{F_{l,\infty} > F_{obs}\} = \Pr\{\chi_l^2 > lF_{obs}\}$$

Regardless of the DDFM= method, you can obtain these chi-square p -values with the [CHISQ](#) option in the MODEL statement.

RESIDUAL

RES

performs all tests by using the residual degrees of freedom, $n - \text{rank}(\mathbf{X})$, where n is the sum of the frequencies of observations or the sum of frequencies of *event/trials* pairs. This method is the default degrees of freedom method for GLMs and overdispersed GLMs.

SATTERTHWAITE

SAT

performs a general Satterthwaite approximation for the denominator degrees of freedom in a generalized linear mixed model. This method is a generalization of the techniques that are described in Giesbrecht and Burns (1985); McLean and Sanders (1988); Fai and Cornelius (1996). The method can also include estimated random effects. Computational details can be found in the section “[Degrees of Freedom Methods](#)” on page 3075.

When the asymptotic variance matrix of the covariance parameters is found to be singular, a generalized inverse is used. Covariance parameters with zero variance then do not contribute to the degrees of freedom adjustment for DDFM=SATTERTH and DDFM=KENWARDROGER, and a message is written to the log.

DISTRIBUTION=*keyword*

DIST=*keyword*

D=*keyword*

ERROR=*keyword*

E=*keyword*

specifies the built-in (conditional) probability distribution of the data. If you specify the DIST= option and you do not specify a user-defined link function, a default link function is chosen according to the following table. If you do not specify a distribution, the GLIMMIX procedure defaults to the normal distribution for continuous response variables and to the multinomial distribution for classification or character variables, unless the *events/trial* syntax is used in the MODEL statement. If you choose the *events/trial* syntax, the GLIMMIX procedure defaults to the binomial distribution.

[Table 41.11](#) lists the values of the DIST= option and the corresponding default link functions. For the case of generalized linear models with these distributions, you can find expressions for the log-likelihood functions in the section “[Maximum Likelihood](#)” on page 3047.

Table 41.11 Keyword Values of the DIST= Option

DIST=	Distribution	Default Link Function	Numeric Value
BETA	beta	logit	12
BINARY	binary	logit	4
BINOMIAL BIN B	binomial	logit	3
EXPONENTIAL EXPO	exponential	log	9
GAMMA GAM	gamma	log	5
GAUSSIAN G NORMAL N	normal	identity	1
GEOMETRIC GEOM	geometric	log	8
INVGAUSS IGAUSSIAN IG	inverse Gaussian	inverse squared (power(-2))	6
LOGNORMAL LOGN	lognormal	identity	11
MULTINOMIAL MULTI MULT	multinomial	cumulative logit	NA
NEGBINOMIAL NEGBIN NB	negative binomial	log	7
POISSON POI P	Poisson	log	2
TCENTRAL TDIST T	<i>t</i>	identity	10
BYOBS(<i>variable</i>)	multivariate	varied	NA

Note that the PROC GLIMMIX default link for the gamma or exponential distribution is not the canonical link (the reciprocal link).

The numeric value in the last column of Table 41.11 can be used in combination with DIST=BYOBS. The BYOBS(*variable*) syntax designates a variable whose value identifies the distribution to which an observation belongs. If the variable is numeric, its values must match values in the last column of Table 41.11. If the variable is not numeric, an observation's distribution is identified by the first four characters of the distribution's name in the leftmost column of the table. Distributions whose numeric value is "NA" cannot be used with DIST=BYOBS.

If the variable in BYOBS(*variable*) is a data set variable, it can also be used in the CLASS statement of the GLIMMIX procedure. For example, this provides a convenient method to model multivariate data jointly while varying fixed-effects components across outcomes. Assume that, for example, for each patient, a count and a continuous outcome were observed; the count data are modeled as Poisson data and the continuous data are modeled as gamma variates. The following statements fit a Poisson and a gamma regression model simultaneously:

```
proc sort data=yourdata;
  by patient;
run;
data yourdata;
  set yourdata;
  by patient;
  if first.patient then dist='POIS' else dist='GAMM';
run;
proc glimmix data=yourdata;
  class treatment dist;
  model y = dist treatment*dist / dist=byobs(dist);
run;
```

The two models have separate intercepts and treatment effects. To correlate the outcomes, you can share a random effect between the observations from the same patient:

```
proc glimmix data=yourdata;
  class treatment dist patient;
  model y = dist treatment*dist / dist=byobs(dist);
  random intercept / subject=patient;
run;
```

Or, you could use an R-side correlation structure:

```
proc glimmix data=yourdata;
  class treatment dist patient;
  model y = dist treatment*dist / dist=byobs(dist);
  random _residual_ / subject=patient type=un;
run;
```

Although `DIST=BYOBS(variable)` is used to model multivariate data, you only need a single response variable in PROC GLIMMIX. The responses are in “univariate” form. This allows, for example, different missing value patterns across the responses. It does, however, require that all response variables be numeric.

The default links that are assigned when `DIST=BYOBS` is in effect correspond to the respective default links in [Table 41.11](#).

When you choose `DIST=LOGNORMAL`, the GLIMMIX procedure models the logarithm of the response variable as a normal random variable. That is, the mean and variance are estimated on the logarithmic scale, assuming a normal distribution, $\log\{Y\} \sim N(\mu, \sigma^2)$. This enables you to draw on options that require a distribution in the exponential family—for example, by using a scoring algorithm in a GLM. To convert means and variances for $\log\{Y\}$ into those of Y , use the relationships

$$\begin{aligned} E[Y] &= \exp\{\mu\} \sqrt{\omega} \\ \text{Var}[Y] &= \exp\{2\mu\} \omega(\omega - 1) \\ \omega &= \exp\{\sigma^2\} \end{aligned}$$

The `DIST=T` option models the data as a shifted and scaled central t variable. This enables you to model data with heavy-tailed distributions. If Y denotes the response and X has a t_ν distribution with ν degrees of freedom, then PROC GLIMMIX models

$$Y = \mu + \sqrt{\phi} X$$

In this parameterization, Y has mean μ and variance $\phi\nu/(\nu - 2)$.

By default, $\nu = 3$. You can supply different degrees of freedom for the t variate as in the following statements:

```
proc glimmix;
  class a b;
  model y = b x b*x / dist=tcentral(9.6);
  random a;
run;
```

The GLIMMIX procedure does not accept values for the degrees of freedom parameter less than 3.0. If the t distribution is used with the `DIST=BYOBS(variable)` specification, the degrees of freedom are fixed at $\nu = 3$. For mixed models where parameters are estimated based on linearization, choosing `DIST=T` instead of `DIST=NORMAL` affects only the residual variance, which decreases by the factor $\nu/(\nu - 2)$.

Note that in SAS 9.1, the GLIMMIX procedure modeled $Y = \mu + \phi^* \sqrt{\frac{\nu-2}{\nu}} X$. The scale parameter of the parameterizations are related as $\phi = \phi^* \times \phi^* \times (\nu - 2)/\nu$.

The `DIST=BETA` option implements the parameterization of the beta distribution in Ferrari and Cribari-Neto (2004). If Y has a $\text{beta}(\alpha, \beta)$ density, so that $E[Y] = \mu = \alpha/(\alpha + \beta)$, this parameterization uses the variance function $a(\mu) = \mu(1 - \mu)$ and $\text{Var}[Y] = a(\mu)/(1 + \phi)$.

See the section “[Maximum Likelihood](#)” on page 3047 for the log likelihoods of the distributions fitted by the GLIMMIX procedure.

E

requests that Type I, Type II, and Type III L matrix coefficients be displayed for all specified effects.

E1 | EI

requests that Type I L matrix coefficients be displayed for all specified effects.

E2 | EII

requests that Type II L matrix coefficients be displayed for all specified effects.

E3 | EIII

requests that Type III L matrix coefficients be displayed for all specified effects.

HTYPE=value-list

indicates the type of hypothesis test to perform on the fixed effects. Valid entries for values in the *value-list* are 1, 2, and 3, corresponding to Type I, Type II, and Type III tests. The default value is 3. You can specify several types by separating the values with a comma or a space. The ODS table names are “Tests1,” “Tests2,” and “Tests3” for the Type I, Type II, and Type III tests, respectively.

INTERCEPT

adds a row to the tables for Type I, II, and III tests corresponding to the overall intercept.

LINK=keyword

specifies the link function in the generalized linear mixed model. The keywords and their associated built-in link functions are shown in [Table 41.12](#).

Table 41.12 Built-in Link Functions of the GLIMMIX Procedure

LINK=	Link Function	$g(\mu) = \eta =$	Numeric Value
CUMCLL CCLL	cumulative complementary log-log	$\log(-\log(1 - \pi))$	NA
CUMLOGIT CLOGIT	cumulative logit	$\log(\gamma/(1 - \pi))$	NA
CUMLOGLOG	cumulative log-log	$-\log(-\log(\pi))$	NA
CUMPROBIT CPROBIT	cumulative probit	$\Phi^{-1}(\pi)$	NA
CLOGLOG CLL	complementary log-log	$\log(-\log(1 - \mu))$	5

Table 41.12 continued

LINK=	Link Function	$g(\mu) = \eta =$	Numeric Value
GLOGIT GENLOGIT	generalized logit		NA
IDENTITY ID	identity	μ	1
LOG	log	$\log(\mu)$	4
LOGIT	logit	$\log(\mu/(1 - \mu))$	2
LOGLOG	log-log	$-\log(-\log(\mu))$	6
PROBIT	probit	$\Phi^{-1}(\mu)$	3
POWER(λ) POW(λ)	power with exponent $\lambda = \text{number}$	$\begin{cases} \mu^\lambda & \text{if } \lambda \neq 0 \\ \log(\mu) & \text{if } \lambda = 0 \end{cases}$	NA
POWERMINUS2	power with exponent -2	$1/\mu^2$	8
RECIPROCAL INVERSE	reciprocal	$1/\mu$	7
BYOBS(<i>variable</i>)	varied	varied	NA

For the probit and cumulative probit links, $\Phi^{-1}(\cdot)$ denotes the quantile function of the standard normal distribution. For the other cumulative links, π denotes a cumulative category probability. The cumulative and generalized logit link functions are appropriate only for the multinomial distribution. When you choose a cumulative link function, PROC GLIMMIX assumes that the data are ordinal. When you specify LINK=GLOGIT, the GLIMMIX procedure assumes that the data are nominal (not ordered).

The numeric value in the rightmost column of Table 41.12 can be used in conjunction with LINK=BYOBS(*variable*). This syntax designates a *variable* whose values identify the link function associated with an observation. If the variable is numeric, its values must match those in the last column of Table 41.12. If the variable is not numeric, an observation's link function is determined by the first four characters of the link's name in the first column. Those link functions whose numeric value is "NA" cannot be used with LINK=BYOBS(*variable*).

You can define your own link function through programming statements. See the section "User-Defined Link or Variance Function" on page 3043 for more information about how to specify a link function. If a user-defined link function is in effect, the specification in the LINK= option is ignored. If you specify neither the LINK= option nor a user-defined link function, then the default link function is chosen according to Table 41.11.

LWEIGHT=FIRSTORDER | FIRO

LWEIGHT=NONE

LWEIGHT=VAR

determines how weights are used in constructing the coefficients for Type I through Type III L matrices. The default is LWEIGHT=VAR, and the values of the WEIGHT variable are used in forming crossproduct matrices. If you specify LWEIGHT=FIRO, the weights incorporate the WEIGHT variable as well as the first-order weights of the linearized model. For LWEIGHT=NONE, the L matrix coefficients are based on the raw crossproduct matrix, whether a WEIGHT variable is specified or not.

NOCENTER

requests that the columns of the \mathbf{X} matrix are not centered and scaled. By default, the columns of \mathbf{X} are centered and scaled. Unless the NOCENTER option is in effect, \mathbf{X} is replaced by \mathbf{X}^* during estimation. The columns of \mathbf{X}^* are computed as follows:

- In models with an intercept, the intercept column remains the same and the j th entry in row i of \mathbf{X}^* is

$$x_{ij}^* = \frac{x_{ij} - \bar{x}_j}{\sqrt{\sum_{i=1}^n (x_{ij} - \bar{x}_j)^2}}$$

- In models without intercept, no centering takes place and the j th entry in row i of \mathbf{X}^* is

$$x_{ij}^* = \frac{x_{ij}}{\sqrt{\sum_{i=1}^n (x_{ij} - \bar{x}_j)^2}}$$

The effects of centering and scaling are removed when results are reported. For example, if the covariance matrix of the fixed effects is printed with the COVB option of the MODEL statement, the covariances are reported in terms of the original parameters, not the centered and scaled versions. If you specify the STDCOEf option, fixed-effects parameter estimates and their standard errors are reported in terms of the standardized (scaled and/or centered) coefficients in addition to the usual results in noncentered form.

NOINT

requests that no intercept be included in the fixed-effects model. An intercept is included by default.

ODDSRATIO<(odds-ratio-options)>**OR**<(odds-ratio-options)>

requests estimates of odds ratios and their confidence limits, provided the link function is the logit, cumulative logit, or generalized logit. Odds ratios are produced for the following:

- classification main effects, if they appear in the MODEL statement
- continuous variables in the MODEL statement, unless they appear in an interaction with a classification effect
- continuous variables in the MODEL statement at fixed levels of a classification effect, if the MODEL statement contains an interaction of the two
- continuous variables in the MODEL statement, if they interact with other continuous variables

You can specify the following *odds-ratio-options* to create customized odds ratio results.

AT *var-list=value-list*

specifies the reference values for continuous variables in the model. By default, the average value serves as the reference. Consider, for example, the following statements:

```
proc glimmix;
  class A;
  model y = A x A*x / dist=binary oddsratio;
run;
```

Odds ratios for A are based on differences of least squares means for which x is set to its mean. Odds ratios for x are computed by differencing two sets of least squares mean for the A factor. One set is computed at $x = \bar{x} + 1$, and the second set is computed at $x = \bar{x}$. The following MODEL statement changes the reference value for x to 3:

```
model y = A x A*x / dist=binary
          oddsratio(at x=3);
```

DIFF<=difftype>

controls the type of differences for classification main effects. By default, odds ratios compare the odds of a response for level j of a factor to the odds of the response for the last level of that factor (DIFF=LAST). The DIFF=FIRST option compares the levels against the first level, DIFF=ALL produces odds ratios based on all pairwise differences, and DIFF=NONE suppresses odds ratios for classification main effects.

LABEL

displays a label in the “Odds Ratio Estimates” table. The table describes the comparison associated with the table row.

UNIT var-list=value-list

specifies the units in which the effects of continuous variable in the model are assessed. By default, odds ratios are computed for a change of one unit from the average. Consider a model with a classification factor A with 4 levels. The following statements produce an “Odds Ratio Estimates” table with 10 rows:

```
proc glimmix;
  class A;
  model y = A x A*x / dist=binary
          oddsratio(diff=all unit x=2);
run;
```

The first $4 \times 3/2 = 6$ rows correspond to pairwise differences of levels of A. The underlying log odds ratios are computed as differences of A least squares means. In the least squares mean computation the covariate x is set to \bar{x} . The next four rows compare least squares means for A at $x = \bar{x} + 2$ and at $x = \bar{x}$. You can combine the AT and UNIT options to produce custom odds ratios. For example, the following statements produce an “Odds Ratio Estimates” table with 8 rows:

```
proc glimmix;
  class A;
  model y = A x x*z / dist=binary
          oddsratio(diff=all
                    at x = 3
                    unit x z = 2 4);
run;
```

The first $4 \times 3/2 = 6$ rows correspond to pairwise differences of levels of A. The underlying log odds ratios are computed as differences of A least squares means. In the least squares mean computation, the covariate x is set to 3, and the covariate x*z is set to $3\bar{z}$. The next odds ratio measures the effect of a change in x. It is based on differencing the linear predictor for $x = 3 + 2$

and $x^*z = (3 + 2)\bar{z}$ with the linear predictor for $x = 3$ and $x^*z = 3\bar{z}$. The last odds ratio expresses a change in z by contrasting the linear predictors based on $x = 3$ and $x^*z = 3(\bar{z} + 4)$ with the predictor based on $x = 3$ and $x^*z = 3\bar{z}$.

To compute odds and odds ratios for general estimable functions and least squares means, see the **ODDSRATIO** option in the **LSMEANS** statement and the **EXP** options in the **ESTIMATE** and **LSMESTIMATE** statements.

For important details concerning interpretation and computation of odds ratios with the GLIMMIX procedure, see the section “Odds and Odds Ratio Estimation” on page 3090.

OFFSET=variable

specifies a variable to be used as an offset for the linear predictor. An offset plays the role of a fixed effect whose coefficient is known to be 1. You can use an offset in a Poisson model, for example, when counts have been obtained in time intervals of different lengths. With a log link function, you can model the counts as Poisson variables with the logarithm of the time interval as the offset variable. The offset variable cannot appear in the **CLASS** statement or elsewhere in the **MODEL** or **RANDOM** statement.

REFLINP=r

specifies a value for the linear predictor of the reference level in the generalized logit model for nominal data. By default $r=0$.

SOLUTION

S

requests that a solution for the fixed-effects parameters be produced. Using notation from the section “Notation for the Generalized Linear Mixed Model” on page 2918, the fixed-effects parameter estimates are $\hat{\beta}$, and their (approximate) estimated standard errors are the square roots of the diagonal elements of $\widehat{\text{Var}}[\hat{\beta}]$. This matrix commonly is of the form $(\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}$ in GLMMs. You can output this approximate variance matrix with the **COVB** option. See the section “Details: GLIMMIX Procedure” on page 3047 on the construction of $\hat{\mathbf{V}}$ in the various models.

Along with the estimates and their approximate standard errors, a t statistic is computed as the estimate divided by its standard error. The degrees of freedom for this t statistic matches the one appearing in the “Type III Tests of Fixed Effects” table under the effect containing the parameter. If **DDFM=KENWARDROGER** or **DDFM=SATTERTHWAITE**, the degrees of freedom are computed separately for each fixed-effect estimate, unless you override the value for any specific effect with the **DDF=value-list** option. The “Pr > |t|” column contains the two-tailed p -value corresponding to the t statistic and associated degrees of freedom. You can use the **CL** option to request confidence intervals for the fixed-effects parameters; they are constructed around the estimate by using a radius of the standard error times a percentage point from the t distribution.

STDCOEF

reports solutions for fixed effects in terms of the standardized (scaled and/or centered) coefficients. This option has no effect when the **NOCENTER** option is specified or in models for multinomial data.

ZETA=number

tunes the sensitivity in forming Type III functions. Any element in the estimable function basis with an absolute value less than *number* is set to 0. The default is 1E–8.

NLOPTIONS Statement

NLOPTIONS < options > ;

Most models fit with the GLIMMIX procedure typically have one or more nonlinear parameters. Estimation requires nonlinear optimization methods. You can control the optimization through options in the NLOPTIONS statement.

Several estimation methods of the GLIMMIX procedure (**METHOD=RSPL**, **MSPL**, **RMPL**, **MMPL**) are doubly iterative in the following sense. The generalized linear mixed model is approximated by a linear mixed model based on current values of the covariance parameter estimates. The resulting linear mixed model is then fit, which is itself an iterative process (with some exceptions). On convergence, new covariance parameters and fixed-effects estimates are obtained and the approximated linear mixed model is updated. Its parameters are again estimated iteratively. It is thus reasonable to refer to *outer* and *inner* iterations. The outer iterations involve the repeated updates of the linear mixed models, and the inner iterations are the iterative steps that lead to parameter estimates in any given linear mixed model. The NLOPTIONS statement controls the inner iterations. The outer iteration behavior can be controlled with options in the **PROC GLIMMIX** statement, such as the **MAXLMMUPDATE=**, **PCONV=**, and **ABSPCONV=** options. If the estimation method involves a singly iterative approach, then there is no need for the outer cycling and the model is fit in a single optimization controlled by the NLOPTIONS statement (see the section “[Singly or Doubly Iterative Fitting](#)” on page 3104).

The syntax and options of the NLOPTIONS statement are described in the section “[NLOPTIONS Statement](#)” on page 482 of Chapter 19, “[Shared Concepts and Topics](#).”

Note that in a GLMM with pseudo-likelihood estimation, specifying **TECHNIQUE=NONE** has the same effect as specifying the **NOITER** option in the **PARMS** statement. If you estimate the parameters by **METHOD=LAPLACE** or **METHOD=QUAD**, **TECHNIQUE=NONE** applies to the optimization after starting values have been determined.

The GLIMMIX procedure applies the default optimization technique shown in [Table 41.13](#), depending on your model.

Table 41.13 Default Techniques

Model Family	Setting	TECHNIQUE=
GLM	DIST=NORMAL LINK=IDENTITY	NONE
GLM	otherwise	NEWRAP
GLMM	PARMS NOITER, PL	NONE
GLMM	binary data, PL	NRRIDG
GLMM	otherwise	QUANEW

OUTPUT Statement

```
OUTPUT < OUT=SAS-data-set >
  < keyword<(keyword-options)> <=name>> ...
  < keyword<(keyword-options)> <=name>> </options> ;
```

The OUTPUT statement creates a data set that contains predicted values and residual diagnostics, computed after fitting the model. By default, all variables in the original data set are included in the output data set.

You can use the ID statement to select a subset of the variables from the input data set as well as computed variables for adding to the output data set. If you reassign a data set variable through programming statements, the value of the variable from the input data set supersedes the recomputed value when observations are written to the output data set. If you list the variable in the ID statement, however, PROC GLIMMIX saves the current value of the variable after the programming statements have been executed.

For example, suppose that data set Scores contains the variables score, machine, and person. The following statements fit a model with fixed machine and random person effects. The variable score divided by 100 is assumed to follow an inverse Gaussian distribution. The (conditional) mean and residuals are saved to the data set igaussout. Because no ID statement is given, the variable score in the output data set contains the values from the input data set.

```
proc glimmix;
  class machine person;
  score = score/100;
  p = 4*_linp_;
  model score = machine / dist=invgauss;
  random int / sub=person;
  output out=igaussout pred=p resid=r;
run;
```

On the contrary, the following statements list explicitly which variables to save to the OUTPUT data set. Because the variable score is listed in the ID statement, and is (re-)assigned through programming statements, the values of score saved to the OUTPUT data set are the input values divided by 100.

```
proc glimmix;
  class machine person;
  score = score / 100;
  model score = machine / dist=invgauss;
  random int / sub=person;
  output out=igaussout pred=p resid=r;
  id machine score _xbeta_ _zgamma_;
run;
```

You can specify the following syntax elements in the OUTPUT statement before the slash (/).

OUT=SAS-data-set

specifies the name of the output data set. If the OUT= option is omitted, the procedure uses the DATA n convention to name the output data set.

keyword<(keyword-options)> <=name>

specifies a statistic to include in the output data set and optionally assigns the variable the name *name*. You can use the *keyword-options* to control which type of a particular statistic to compute. The *keyword-options* can take on the following values:

- BLUP uses the predictors of the random effects in computing the statistic.
- ILINK computes the statistic on the scale of the data.
- NOBLUP does not use the predictors of the random effects in computing the statistic.
- NOILINK computes the statistic on the scale of the link function.

The default is to compute statistics by using BLUPs on the scale of the link function (the linearized scale). For example, the following OUTPUT statements are equivalent:

```
output out=out1 pred=predicted lcl=lower;

output out=out1 pred(blup noilink)=predicted
               lcl (blup noilink)=lower;
```

If a particular combination of keyword and keyword options is not supported, the statistic is not computed and a message is produced in the SAS log.

A **keyword** can appear multiple times in the OUTPUT statement. Table 41.14 lists the keywords and the default names assigned by the GLIMMIX procedure if you do not specify a *name*. In this table, *y* denotes the observed response, and *p* denotes the linearized pseudo-data. See the section “Pseudo-likelihood Estimation Based on Linearization” on page 3054 for details on notation and the section “Notes on Output Statistics” on page 3111 for further details regarding the output statistics.

Table 41.14 Keywords for Output Statistics

Keyword	Options	Description	Expression	Name
PREDICTED	Default	Linear predictor	$\hat{\eta} = \mathbf{x}'\hat{\boldsymbol{\beta}} + \mathbf{z}'\hat{\boldsymbol{\gamma}}$	Pred
	NOBLUP	Marginal linear predictor	$\hat{\eta}_m = \mathbf{x}'\hat{\boldsymbol{\beta}}$	PredPA
	ILINK	Predicted mean	$g^{-1}(\hat{\eta})$	PredMu
	NOBLUP ILINK	Marginal mean	$g^{-1}(\hat{\eta}_m)$	PredMuPA
STDERR	Default	Standard deviation of linear predictor	$\sqrt{\text{Var}[\hat{\eta} - \mathbf{z}'\boldsymbol{\gamma}]}$	StdErr
	NOBLUP	Standard deviation of marginal linear predictor	$\sqrt{\text{Var}[\hat{\eta}_m]}$	StdErrPA
	ILINK	Standard deviation of mean	$\sqrt{\text{Var}[g^{-1}(\hat{\eta} - \mathbf{z}'\boldsymbol{\gamma})]}$	StdErr
	NOBLUP ILINK	Standard deviation of marginal mean	$\sqrt{\text{Var}[g^{-1}(\hat{\eta}_m)]}$	StdErrMuPA
RESIDUAL	Default	Residual	$r = p - \hat{\eta}$	Resid
	NOBLUP	Marginal residual	$r_m = p_m - \hat{\eta}_m$	ResidPA

Table 41.14 continued

Keyword	Options	Description	Expression	Name
	ILINK	Residual on mean scale	$r_y = y - g^{-1}(\hat{\eta})$	ResidMu
	NOBLUP ILINK	Marginal residual on mean scale	$r_{ym} = y - g^{-1}(\hat{\eta}_m)$	ResidMuPA
PEARSON	Default	Pearson-type residual	$r / \sqrt{\widehat{\text{Var}}[p \boldsymbol{y}]}$	Pearson
	NOBLUP	Marginal Pearson-type residual	$r_m / \sqrt{\widehat{\text{Var}}[p_m]}$	PearsonPA
	ILINK	Conditional Pearson-type mean residual	$r_y / \sqrt{\widehat{\text{Var}}[Y \boldsymbol{y}]}$	PearsonMu
STUDENT	Default	Studentized residual	$r / \sqrt{\widehat{\text{Var}}[r]}$	Student
	NOBLUP	Studentized marginal residual	$r_m / \sqrt{\widehat{\text{Var}}[r_m]}$	StudentPA
LCL	Default	Lower prediction limit for linear predictor		LCL
	NOBLUP	Lower confidence limit for marginal linear predictor		LCLPA
	ILINK	Lower prediction limit for mean		LCLMu
	NOBLUP ILINK	Lower confidence limit for marginal mean		LCLMuPA
UCL	Default	Upper prediction limit for linear predictor		UCL
	NOBLUP	Upper confidence limit for marginal linear predictor		UCLPA
	ILINK	Upper prediction limit for mean		UCLMu
	NOBLUP ILINK	Upper confidence limit for marginal mean		UCLMuPA
VARIANCE	Default	Conditional variance of pseudo-data	$\widehat{\text{Var}}[p \boldsymbol{y}]$	Variance
	NOBLUP	Marginal variance of pseudo-data	$\widehat{\text{Var}}[p_m]$	VariancePA
	ILINK	Conditional variance of response	$\widehat{\text{Var}}[Y \boldsymbol{y}]$	Variance_Dep
	NOBLUP ILINK	Marginal variance of response	$\widehat{\text{Var}}[Y]$	Variance_DepPA

Studentized residuals are computed only on the linear scale (scale of the link), unless the link is the identity, in which case the two scales are equal. The keywords RESIDUAL, PEARSON, STUDENT, and VARIANCE are not available with the multinomial distribution. You can use the following short-cuts to request statistics: PRED for PREDICTED, STD for STDERR, RESID for RESIDUAL, and VAR for VARIANCE. Output statistics that depend on the marginal variance $\text{Var}[Y_i]$ are not available with METHOD=LAPLACE or METHOD=QUAD.

Table 41.15 summarizes the options available in the OUTPUT statement.

Table 41.15 OUTPUT Statement Options

Option	Description
ALLSTATS	Computes all statistics
ALPHA= α	Determines the confidence level ($1 - \alpha$)
CPSEUDO	Changes the way in which marginal residuals are computed
DERIVATIVES	Adds derivatives of model quantities to the output data set
NOMISS	Outputs only observations used in the analysis
NOUNIQUE	Requests that names not be made unique
NOVAR	Requests that variables from the input data set not be added to the output data set
OBSCAT	Writes statistics to output data set only for the response level corresponding to the observed level of the observation
SYMBOLS	Adds computed variables to the output data set

You can specify the following options in the OUTPUT statement after a slash (/).

ALLSTATS

requests that all statistics are computed. If you do not use a keyword to assign a name, the GLIMMIX procedure uses the default name.

ALPHA=*number*

determines the coverage probability for two-sided confidence and prediction intervals. The coverage probability is computed as $1 - \textit{number}$. The value of *number* must be between 0 and 1; the default is 0.05.

CPSEUDO

changes the way in which marginal residuals are computed when model parameters are estimated by pseudo-likelihood methods. See the section “Notes on Output Statistics” on page 3111 for details.

DERIVATIVES

DER

adds derivatives of model quantities to the output data set. If, for example, the model fit requires the (conditional) log likelihood of the data, then the DERIVATIVES option writes for each observation the evaluations of the first and second derivatives of the log likelihood with respect to `_LNP_` and `_PHI_` to the output data set. The particular derivatives produced by the GLIMMIX procedure depend on the type of model and the estimation method.

NOMISS

requests that records be written to the output data only for those observations that were used in the analysis. By default, the GLIMMIX procedure produces output statistics for all observations in the input data set.

NOUNIQUE

requests that names not be made unique in the case of naming conflicts. By default, the GLIMMIX procedure avoids naming conflicts by assigning a unique name to each output variable. If you specify the NOUNIQUE option, variables with conflicting names are not renamed. In that case, the first variable added to the output data set takes precedence.

NOVAR

requests that variables from the input data set not be added to the output data set. This option does not apply to variables listed in the **BY** statement or to computed variables listed in the **ID** statement.

OBSCAT

requests that in models for multinomial data statistics be written to the output data set only for the response level that corresponds to the observed level of the observation.

SYMBOLS**SYM**

adds to the output data set computed variables that are defined or referenced in the program.

PARMS Statement

PARMS < (*value-list*) > ... < / *options* > ;

The PARMS statement specifies initial values for the covariance or scale parameters, or it requests a grid search over several values of these parameters in generalized linear mixed models.

The *value-list* specification can take any of several forms:

m	a single value
m_1, m_2, \dots, m_n	several values
m to n	a sequence where m equals the starting value, n equals the ending value, and the increment equals 1
m to n by i	a sequence where m equals the starting value, n equals the ending value, and the increment equals i
m_1, m_2 to m_3	mixed values and sequences

Using the PARMS Statement with a GLM

If you are fitting a GLM or a GLM with overdispersion, the scale parameters are listed at the end of the “Parameter Estimates” table in the same order as *value-list*. If you specify more than one set of initial values, PROC GLIMMIX uses only the first value listed for each parameter. Grid searches by using scale parameters are not possible for these models, because the fixed effects are part of the optimization.

Using the PARS Statement with a GLMM

If you are fitting a GLMM, the *value-list* corresponds to the parameters as listed in the “Covariance Parameter Estimates” table. Note that this order can change depending on whether a residual variance is profiled or not; see the `NOPROFILE` option in the `PROC GLIMMIX` statement.

If you specify more than one set of initial values, `PROC GLIMMIX` performs a grid search of the objective function surface and uses the best point on the grid for subsequent analysis. Specifying a large number of grid points can result in long computing times.

Options in the PARS Statement

You can specify the following options in the `PARMS` statement after a slash (/).

HOLD=*value-list*

specifies which parameter values `PROC GLIMMIX` should hold equal to the specified values. For example, the following statement constrains the first and third covariance parameters to equal 5 and 2, respectively:

```
parms (5) (3) (2) (3) / hold=1,3;
```

Covariance or scale parameters that are held fixed with the `HOLD=` option are treated as constrained parameters in the optimization. This is different from evaluating the objective function, gradient, and Hessian matrix at known values of the covariance parameters. A constrained parameter introduces a singularity in the optimization process. The covariance matrix of the covariance parameters (see the `ASYCOV` option of the `PROC GLIMMIX` statement) is then based on the projected Hessian matrix. As a consequence, the variance of parameters subjected to a `HOLD=` is zero. Such parameters do not contribute to the computation of denominator degrees of freedom with the `DDFM=KENWARDROGER` and `DDFM=SATTERTHWAITE` methods, for example. If you want to treat the covariance parameters as known, without imposing constraints on the optimization, you should use the `NOITER` option.

When you place a hold on all parameters (or when you specify the `NOITER`) option in a GLMM, you might notice that `PROC GLIMMIX` continues to produce an iteration history. Unless your model is a linear mixed model, several recomputations of the pseudo-response might be required in linearization-based methods to achieve agreement between the pseudo-data and the covariance matrix. In other words, the `GLIMMIX` procedure continues to update the fixed-effects estimates (and random-effects solutions) until convergence is achieved.

In certain models, placing a hold on covariance parameters implies that the procedure processes the parameters in the same order as if the `NOPROFILE` were in effect. This can change the order of the covariance parameters when you place a hold on one or more parameters. Models that are subject to this reordering are those with R-side covariance structures whose scale parameter could be profiled. This includes the `TYPE=CS`, `TYPE=SP`, `TYPE=AR(1)`, `TYPE=TOEP`, and `TYPE=ARMA(1,1)` covariance structures.

LOWERB=*value-list*

enables you to specify lower boundary constraints for the covariance or scale parameters. The *value-list* specification is a list of numbers or missing values (.) separated by commas. You must list the numbers in the same order that `PROC GLIMMIX` uses for the *value-list* in the `PARMS` statement, and each number corresponds to the lower boundary constraint. A missing value instructs `PROC`

GLIMMIX to use its default constraint, and if you do not specify numbers for all of the covariance parameters, PROC GLIMMIX assumes that the remaining ones are missing.

This option is useful, for example, when you want to constrain the **G** matrix to be positive definite in order to avoid the more computationally intensive algorithms required when **G** becomes singular. The corresponding statements for a random coefficients model are as follows:

```
proc glimmix;
  class person;
  model y = time;
  random int time / type=chol sub=person;
  parms / lowerb=1e-4, ., 1e-4;
run;
```

Here, the **TYPE=CHOL** structure is used in order to specify a Cholesky root parameterization for the 2×2 unstructured blocks in **G**. This parameterization ensures that the **G** matrix is nonnegative definite, and the **PARMS** statement then ensures that it is positive definite by constraining the two diagonal terms to be greater than or equal to $1E-4$.

NOBOUND

requests the removal of boundary constraints on covariance and scale parameters in mixed models. For example, variance components have a default lower boundary constraint of 0, and the **NOBOUND** option allows their estimates to be negative. See the **NOBOUND** option in the **PROC GLIMMIX** statement for further details.

NOITER

requests that no optimization of the covariance parameters be performed. This option has no effect in generalized linear models.

If you specify the **NOITER** option, PROC GLIMMIX uses the values for the covariance parameters given in the **PARMS** statement to perform statistical inferences. Note that the **NOITER** option is not equivalent to specifying a **HOLD=** value for all covariance parameters. If you use the **NOITER** option, covariance parameters are not constrained in the optimization. This prevents singularities that might otherwise occur in the optimization process.

If a residual variance is profiled, the parameter estimates can change from the initial values you provide as the residual variance is recomputed. To prevent an update of the residual variance, combine the **NOITER** option with the **NOPROFILE** option in the **PROC GLIMMIX** statements, as in the following code:

```
proc glimmix noprofile;
  class A B C rep mp sp;
  model y = A | B | C;
  random rep mp sp;
  parms (180) (200) (170) (1000) / noiter;
run;
```

When you specify the **NOITER** option in a model where parameters are estimated by pseudo-likelihood techniques, you might notice that the GLIMMIX procedure continues to produce an iteration history. Unless your model is a linear mixed model, several recomputations of the pseudo-response might be required in linearization-based methods to achieve agreement between the pseudo-

data and the covariance matrix. In other words, the GLIMMIX procedure continues to update the profiled fixed-effects estimates (and random-effects solutions) until convergence is achieved. To prevent these updates, use the `MAXLMMUPDATE=` option in the `PROC GLIMMIX` statement. Specifying the `NOITER` option in the `PARMS` statement of a GLMM with pseudo-likelihood estimation has the same effect as choosing `TECHNIQUE=NONE` in the `NLOPTIONS` statement.

If you want to base initial fixed-effects estimates on the results of fitting a generalized linear model, then you can combine the `NOITER` option with the `TECHNIQUE=` option. For example, the following statements determine the starting values for the fixed effects by fitting a logistic model (without random effects) with the Newton-Raphson algorithm:

```
proc glimmix startglm inititer=10;
  class clinic A;
  model y/n = A / link=logit dist=binomial;
  random clinic;
  parms (0.4) / noiter;
  nloptions technique=newrap;
run;
```

The initial GLM fit stops at convergence or after at most 10 iterations, whichever comes first. The pseudo-data for the linearized GLMM is computed from the GLM estimates. The variance of the Clinic random effect is held constant at 0.4 during subsequent iterations that update the fixed effects only.

If you also want to combine the GLM fixed-effects estimates with known and fixed covariance parameter values without updating the fixed effects, you can add the `MAXLMMUPDATE=0` option:

```
proc glimmix startglm inititer=10 maxlmmupdate=0;
  class clinic A;
  model y/n = A / link=logit dist=binomial;
  random clinic;
  parms (0.4) / noiter;
  nloptions technique=newrap;
run;
```

In a GLMM with parameter estimation by `METHOD=LAPLACE` or `METHOD=QUAD` the `NOITER` option also leads to an iteration history, since the fixed-effects estimates are part of the optimization and the `PARMS` statement places restrictions on only the covariance parameters.

Finally, the `NOITER` option can be useful if you want to obtain minimum variance quadratic unbiased estimates (with 0 priors), also known as MIVQUE0 estimates (Goodnight 1978a). Because MIVQUE0 estimates are starting values for covariance parameters—unless you provide (*value-list*) in the `PARMS` statement—the following statements produce MIVQUE0 mixed model estimates:

```
proc glimmix noprofile;
  class A B;
  model y = A;
  random int / subject=B;
  parms / noiter;
run;
```

PARMSDATA=SAS-data-set

PDATA=SAS-data-set

reads in covariance parameter values from a SAS data set. The data set should contain the numerical variable ESTIMATE or the numerical variables Covp1–Covp q , where q denotes the number of covariance parameters.

If the PARMSDATA= data set contains multiple sets of covariance parameters, the GLIMMIX procedure evaluates the initial objective function for each set and commences the optimization step by using the set with the lowest function value as the starting values. For example, the following SAS statements request that the objective function be evaluated for three sets of initial values:

```
data data_covp;
  input covp1-covp4;
  datalines;
  180 200 170 1000
  170 190 160 900
  160 180 150 800
;
proc glimmix;
  class A B C rep mainEU smallEU;
  model yield = A|B|C;
  random rep mainEU smallEU;
  parms / pdata=data_covp;
run;
```

Each set comprises four covariance parameters.

The order of the observations in a data set with the numerical variable Estimate corresponds to the order of the covariance parameters in the “Covariance Parameter Estimates” table. In a GLM, the PARMSDATA= option can be used to set the starting value for the exponential family scale parameter. A grid search is not conducted for GLMs if you specify multiple values.

The PARMSDATA= data set must not contain missing values.

If the GLIMMIX procedure is processing the input data set in BY groups, you can add the BY variables to the PARMSDATA= data set. If this data set is sorted by the BY variables, the GLIMMIX procedure matches the covariance parameter values to the current BY group. If the PARMSDATA= data set does not contain all BY variables, the data set is processed in its entirety for every BY group and a message is written to the log. This enables you to provide a single set of starting values across BY groups, as in the following statements:

```
data data_covp;
  input covp1-covp4;
  datalines;
  180 200 170 1000
;
```

```

proc glimmix;
  class A B C rep mainEU smallEU;
  model yield = A|B|C;
  random rep mainEU smallEU;
  parms / pdata=data_covp;
  by year;
run;

```

The same set of starting values is used for each value of the year variable.

UPPERB=*value-list*

enables you to specify upper boundary constraints on the covariance parameters. The *value-list* specification is a list of numbers or missing values (.) separated by commas. You must list the numbers in the same order that PROC GLIMMIX uses for the *value-list* in the PARMs statement, and each number corresponds to the upper boundary constraint. A missing value instructs PROC GLIMMIX to use its default constraint. If you do not specify numbers for all of the covariance parameters, PROC GLIMMIX assumes that the remaining ones are missing.

RANDOM Statement

RANDOM *random-effects* </ options > ;

Using notation from “Notation for the Generalized Linear Mixed Model” on page 2918, the RANDOM statement defines the **Z** matrix of the mixed model, the random effects in the $\boldsymbol{\gamma}$ vector, the structure of **G**, and the structure of **R**.

The **Z** matrix is constructed exactly like the **X** matrix for the fixed effects, and the **G** matrix is constructed to correspond to the effects constituting **Z**. The structures of **G** and **R** are defined by using the **TYPE=** option described on page 3028. The random effects can be classification or continuous effects, and multiple RANDOM statements are possible.

Some reserved keywords have special significance in the *random-effects* list. You can specify INTERCEPT (or INT) as a random effect to indicate the intercept. PROC GLIMMIX does not include the intercept in the RANDOM statement by default as it does in the MODEL statement. You can specify the **_RESIDUAL_** keyword (or RESID, RESIDUAL, **_RESID_**) before the option slash (/) to indicate a residual-type (R-side) random component that defines the **R** matrix. Basically, the **_RESIDUAL_** keyword takes the place of the *random-effect* if you want to specify R-side variances and covariance structures. These keywords take precedence over variables in the data set with the same name. If your data or the covariance structure requires that an effect is specified, you can use the **RESIDUAL** option to instruct the GLIMMIX procedure to model the R-side variances and covariances.

In order to add an overdispersion component to the variance function, simply specify a single residual random component. For example, the following statements fit a polynomial Poisson regression model with overdispersion. The variance function $a(\mu) = \mu$ is replaced by $\phi a(\mu)$:

```

proc glimmix;
  model count = x x*x / dist=poisson;
  random _residual_;
run;

```

Table 41.16 summarizes the options available in the RANDOM statement. All options are subsequently discussed in alphabetical order.

Table 41.16 RANDOM Statement Options

Option	Description
Construction of Covariance Structure	
GCOORD=	Determines coordinate association for G-side spatial structures with repeat levels
GROUP=	Varies covariance parameters by groups
LDATA=	Specifies a data set with coefficient matrices for TYPE= LIN
NOFULLZ	Eliminates columns in \mathbf{Z} corresponding to missing values
RESIDUAL	Designates a covariance structure as R-side
SUBJECT=	Identifies the subjects in the model
TYPE=	Specifies the covariance structure
Mixed Model Smoothing	
KNOTINFO	Displays spline knots
KNOTMAX=	Specifies the upper limit for knot construction
KNOTMETHOD	Specifies the method for constructing knots for radial smoother and penalized B-splines
KNOTMIN=	Specifies the lower limit for knot construction
Statistical Output	
ALPHA= α	Determines the confidence level ($1 - \alpha$)
CL	Requests confidence limits for predictors of random effects
G	Displays the estimated \mathbf{G} matrix
GC	Displays the Cholesky root (lower) of the estimated \mathbf{G} matrix
GCI	Displays the inverse Cholesky root (lower) of the estimated \mathbf{G} matrix
GCORR	Displays the correlation matrix that corresponds to the estimated \mathbf{G} matrix
GI	Displays the inverse of the estimated \mathbf{G} matrix
SOLUTION	Displays solutions $\hat{\boldsymbol{\gamma}}$ of the G-side random effects
V	Displays blocks of the estimated \mathbf{V} matrix
VC	Displays the lower-triangular Cholesky root of blocks of the estimated \mathbf{V} matrix
VCI	Displays the inverse Cholesky root of blocks of the estimated \mathbf{V} matrix
VCORR	Displays the correlation matrix corresponding to blocks of the estimated \mathbf{V} matrix
VI	Displays the inverse of the blocks of the estimated \mathbf{V} matrix

You can specify the following options in the RANDOM statement after a slash (/).

ALPHA=number

requests that a t -type confidence interval with confidence level $1 - \text{number}$ be constructed for the predictors of G-side random effects in this statement. The value of *number* must be between 0 and 1; the default is 0.05. Specifying the ALPHA= option implies the CL option.

CL

requests that t -type confidence limits be constructed for each of the predictors of G-side random effects in this statement. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option. The CL option implies the **SOLUTION** option.

G

requests that the estimated **G** matrix be displayed for G-side random effects associated with this RANDOM statement. PROC GLIMMIX displays blanks for values that are 0.

GC

displays the lower-triangular Cholesky root of the estimated **G** matrix for G-side random effects.

GCI

displays the inverse Cholesky root of the estimated **G** matrix for G-side random effects.

GCOORD=LAST**GCOORD=FIRST****GCOORD=MEAN**

determines how the GLIMMIX procedure associates coordinates for **TYPE=SP()** covariance structures with effect levels for G-side random effects. In these covariance structures, you specify one or more variables that identify the coordinates of a data point. The levels of classification variables, on the other hand, can occur multiple times for a particular subject. For example, in the following statements the same level of **A** can occur multiple times, and the associated values of **x** might be different:

```
proc glimmix;
  class A B;
  model y = B;
  random A / type=sp(pow) (x);
run;
```

The **GCOORD=LAST** option determines the coordinates for a level of the random effect from the last observation associated with the level. Similarly, the **GCOORD=FIRST** and **GCOORD=MEAN** options determine the coordinate from the first observation and from the average of the observations. Observations not used in the analysis are not considered in determining the first, last, or average coordinate. The default is **GCOORD=LAST**.

GCORR

displays the correlation matrix that corresponds to the estimated **G** matrix for G-side random effects.

GI

displays the inverse of the estimated **G** matrix for G-side random effects.

GROUP=effect**GRP=effect**

identifies groups by which to vary the covariance parameters. Each new level of the grouping effect produces a new set of covariance parameters. Continuous variables and computed variables are permitted as group effects. PROC GLIMMIX does not sort by the values of the continuous variable; rather, it considers the data to be from a new group whenever the value of the continuous variable changes from the previous observation. Using a continuous variable decreases execution time for

models with a large number of groups and also prevents the production of a large “Class Levels Information” table.

Specifying a GROUP effect can greatly increase the number of estimated covariance parameters, which can adversely affect the optimization process.

KNOTINFO

displays the number and coordinates of the knots as determined by the **KNOTMETHOD=** option.

KNOTMAX=number-list

provides upper limits for the values of random effects used in the construction of knots for **TYPE=RSMOOTH**. The items in *number-list* correspond to the random effects of the radial smooth. If the **KNOTMAX=** option is not specified, or if the value associated with a particular random effect is set to missing, the maximum is based on the values in the data set for **KNOTMETHOD=EQUAL** or **KNOTMETHOD=KDTREE**, and is based on the values in the knot data set for **KNOTMETHOD=DATA**.

KNOTMETHOD=KDTREE<(tree-options)>

KNOTMETHOD=EQUAL<(number-list)>

KNOTMETHOD=DATA(SAS-data-set)

determines the method of constructing knots for the radial smoother fit with the **TYPE=RSMOOTH** covariance structure and the **TYPE=PSPLINE** covariance structure.

Unless you select the **TYPE=RSMOOTH** or **TYPE=PSPLINE** covariance structure, the **KNOTMETHOD=** option has no effect. The default for **TYPE=RSMOOTH** is **KNOTMETHOD=KDTREE**. For **TYPE=PSPLINE**, only equally spaced knots are used and you can use the optional *numberlist* argument of **KNOTMETHOD=EQUAL** to determine the number of interior knots for **TYPE=PSPLINE**.

Knot Construction for TYPE=RSMOOTH

PROC GLIMMIX fits a low-rank smoother, meaning that the number of knots is considerably less than the number of observations. By default, PROC GLIMMIX determines the knot locations based on the vertices of a k -d tree (Friedman, Bentley, and Finkel 1977; Cleveland and Grosse 1991). The k -d tree is a tree data structure that is useful for efficiently determining the m nearest neighbors of a point. The k -d tree also can be used to obtain a grid of points that adapts to the configuration of the data. The process starts with a hypercube that encloses the values of the random effects. The space is then partitioned recursively by splitting cells at the median of the data in the cell for the random effect. The procedure is repeated for all cells that contain more than a specified number of points, b . The value b is called the bucket size.

The k -d tree is thus a division of the data into cells such that cells representing leaf nodes contain at most b values. You control the building of the k -d tree through the **BUCKET= tree-option**. You control the construction of knots from the cell coordinates of the tree with the other options as follows.

BUCKET=number

determines the bucket size b . A larger bucket size will result in fewer knots. For k -d trees in more than one dimension, the correspondence between bucket size and number of knots is difficult to determine. It depends on the data configuration and on other suboptions. In the multivariate case, you might need to try out different bucket sizes to obtain the desired number of knots.

The default value of *number* is 4 for univariate trees (a single random effect) and $\lfloor 0.1n \rfloor$ in the multidimensional case.

KNOTTYPE=type

specifies whether the knots are based on vertices of the tree cells or the centroid. The two possible values of *type* are VERTEX and CENTER. The default is KNOTTYPE=VERTEX. For multidimensional smoothing, such as smoothing across irregularly shaped spatial domains, the KNOTTYPE=CENTER option is useful to move knot locations away from the bounding hypercube toward the convex hull.

NEAREST

specifies that knot coordinates are the coordinates of the nearest neighbor of either the centroid or vertex of the cell, as determined by the KNOTTYPE= suboption.

TREEINFO

displays details about the construction of the *k*-d tree, such as the cell splits and the split values.

See the section “[Knot Selection](#)” on page 3085 for a detailed example of how the specification of the bucket size translates into the construction of a *k*-d tree and the spline knots.

The KNOTMETHOD=EQUAL option enables you to define a regular grid of knots. By default, PROC GLIMMIX constructs 10 knots for one-dimensional smooths and 5 knots in each dimension for smoothing in higher dimensions. You can specify a different number of knots with the optional *number-list*. Missing values in the *number-list* are replaced with the default values. A minimum of two knots in each dimension is required. For example, the following statements use a rectangular grid of 35 knots, five knots for *x1* combined with seven knots for *x2*:

```
proc glimmix;
  model y=;
  random x1 x2 / type=rsmooth knotmethod=equal(5 7);
run;
```

When you use the NOFIT option in the PROC GLIMMIX statement, the GLIMMIX procedure computes the knots but does not fit the model. This can be useful if you want to compare knot selections with different suboptions of KNOTMETHOD=KDTREE. Suppose you want to determine the number of knots based on a particular bucket size. The following statements compute and display the knots in a bivariate smooth, constructed from nearest neighbors of the vertices of a *k*-d tree with bucket size 10:

```
proc glimmix nofit;
  model y = Latitude Longitude;
  random Latitude Longitude / type=rsmooth
    knotmethod=kdtree(knottype=vertex
    nearest bucket=10) knotinfo;
run;
```

You can specify a data set that contains variables whose values give the knot coordinates with the KNOTMETHOD=DATA option. The data set must contain numeric variables with the same name as the radial smoothing *random-effects*. PROC GLIMMIX uses only the unique knot coordinates in the knot data set. This option is useful to provide knot coordinates different from those that can be produced from a *k*-d tree. For example, in spatial problems where the domain is irregularly shaped,

you might want to determine knots by a space-filling algorithm. The following SAS statements invoke the OPTEX procedure to compute 45 knots that uniformly cover the convex hull of the data locations (see *SAS/QC User's Guide* for details about the OPTEX procedure).

```
proc optex coding=none;
  model latitude longitude / noint;
  generate n=45 criterion=u method=m_fedorov;
  output out=knotdata;
run;
proc glimmix;
  model y = Latitude Longitude;
  random Latitude Longitude / type=rsmooth
        knotmethod=data (knotdata) ;
run;
```

Knot Construction for TYPE=PSPLINE

Only evenly spaced knots are supported when you fit penalized B-splines with the GLIMMIX procedure. For the **TYPE=PSPLINE** covariance structure, the *numberlist* argument specifies the number m of interior knots, the default is $m = 10$. Suppose that $x_{(1)}$ and $x_{(n)}$ denote the smallest and largest values, respectively. For a B-spline of degree d (de Boor 2001), the interior knots are supplemented with d exterior knots below $x_{(1)}$ and $\max\{1, d\}$ exterior knots above $x_{(n)}$. PROC GLIMMIX computes the location of these $m + d + \max\{1, d\}$ knots as follows. Let $\delta_x = (x_{(n)} - x_{(1)}) / (m + 1)$, then interior knots are placed at

$$x_{(1)} + j\delta_x, \quad j = 1, \dots, m$$

The exterior knots are also evenly spaced with step size δ_x and start at $x_{(1)} \pm 100$ times the machine epsilon. At least one interior knot is required.

KNOTMIN=*number-list*

provides lower limits for the values of random effects used in the construction of knots for **TYPE=RSMOOTH**. The items in *number-list* correspond to the random effects of the radial smooth. If the **KNOTMIN=** option is not specified, or if the value associated with a particular random effect is set to missing, the minimum is based on the values in the data set for **KNOTMETHOD=EQUAL** or **KNOTMETHOD=KDTREE**, and is based on the values in the knot data set for **KNOTMETHOD=DATA**.

LDATA=*SAS-data-set*

reads the coefficient matrices $\mathbf{A}_1, \dots, \mathbf{A}_q$ for the **TYPE=LIN(q)** option. You can specify the **LDATA=** data set in a sparse or dense form. In the sparse form the data set must contain the numeric variables Parm, Row, Col, and Value. The Parm variable contains the indices $i = 1, \dots, q$ of the \mathbf{A}_i matrices. The Row and Col variables identify the position within a matrix and the Value variable contains the matrix element. Values not specified for a particular row and column are set to zero. Missing values are allowed in the Value column of the **LDATA=** data set; these values are also replaced by zeros. The sparse form is particularly useful if the **A** matrices have only a few nonzero elements.

In the dense form the **LDATA=** data set contains the numeric variables Parm and Row (with the same function as above), in addition to the numeric variables Col1–Col q . If you omit one or more of the

Col1–Col q variables from the data set, zeros are assumed for the respective rows and columns of the \mathbf{A} matrix. Missing values for Col1–Col q are ignored in the dense form.

The GLIMMIX procedure assumes that the matrices $\mathbf{A}_1, \dots, \mathbf{A}_q$ are symmetric. In the sparse LDATA= form you do not need to specify off-diagonal elements in position (i, j) and (j, i) . One of them is sufficient. Row-column indices are converted in both storage forms into positions in lower triangular storage. If you specify multiple values in row ($\max\{i, j\}$ and column $\min\{i, j\}$) of a particular matrix, only the last value is used. For example, assume you are specifying elements of a 4×4 matrix. The lower triangular storage of matrix \mathbf{A}_3 defined by

```
data ldata;
  input parm row col value;
  datalines;
3  2  1  2
3  1  2  5
;
```

is

$$\begin{bmatrix} 0 & & & \\ 5 & 0 & & \\ 0 & 0 & 0 & \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

NOFULLZ

eliminates the columns in \mathbf{Z} corresponding to missing levels of random effects involving CLASS variables. By default, these columns are included in \mathbf{Z} . It is sufficient to specify the NOFULLZ option on any G-side RANDOM statement.

RESIDUAL

RSIDE

specifies that the random effects listed in this statement be R-side effects. You use the RESIDUAL option in the RANDOM statement if the nature of the covariance structure requires you to specify an effect. For example, if it is necessary to order the columns of the R-side AR(1) covariance structure by the time variable, you can use the RESIDUAL option as in the following statements:

```
class time id;
random time / subject=id type=ar(1) residual;
```

SOLUTION

S

requests that the solution $\hat{\boldsymbol{\gamma}}$ for the random-effects parameters be produced, if the statement defines G-side random effects.

The numbers displayed in the Std Err Pred column of the “Solution for Random Effects” table are not the standard errors of the $\hat{\boldsymbol{\gamma}}$ displayed in the Estimate column; rather, they are the square roots of the prediction errors $\hat{\boldsymbol{\gamma}}_i - \boldsymbol{\gamma}_i$, where $\hat{\boldsymbol{\gamma}}_i$ is the predictor of the i th random effect and $\boldsymbol{\gamma}_i$ is the i th random effect. In pseudo-likelihood methods that are based on linearization, these EBLUPs are the estimated best linear unbiased predictors in the linear mixed pseudo-model. In models fit by maximum likelihood by using the Laplace approximation or by using adaptive quadrature, the SOLUTION option displays the empirical Bayes estimates (EBE) of $\boldsymbol{\gamma}_i$.

SUBJECT=effect**SUB=effect**

identifies the subjects in your generalized linear mixed model. Complete independence is assumed across subjects. Specifying a subject effect is equivalent to nesting all other effects in the RANDOM statement within the subject effect.

Continuous variables and computed variables are permitted with the SUBJECT= option. PROC GLIMMIX does not sort by the values of the continuous variable but considers the data to be from a new subject whenever the value of the continuous variable changes from the previous observation. Using a continuous variable can decrease execution time for models with a large number of subjects and also prevents the production of a large “Class Levels Information” table.

TYPE=covariance-structure

specifies the covariance structure of **G** for G-side effects and the covariance structure of **R** for R-side effects.

Although a variety of structures are available, many applications call for either simple diagonal (TYPE=VC) or unstructured covariance matrices. The TYPE=VC (variance components) option is the default structure, and it models a different variance component for each random effect. It is recommended to model unstructured covariance matrices in terms of their Cholesky parameterization (TYPE=CHOL) rather than TYPE=UN.

If you want different covariance structures in different parts of **G**, you must use multiple RANDOM statements with different TYPE= options.

Valid values for *covariance-structure* are as follows. Examples are shown in Table 41.18.

The variances and covariances in the formulas that follow in the TYPE= descriptions are expressed in terms of generic random variables ξ_i and ξ_j . They represent the G-side random effects or the residual random variables for which the **G** or **R** matrices are constructed.

ANTE(1)

specifies a first-order ante-dependence structure (Kenward 1987; Patel 1991) parameterized in terms of variances and correlation parameters. If t ordered random variables ξ_1, \dots, ξ_t have a first-order ante-dependence structure, then each ξ_j , $j > 1$, is independent of all other ξ_k , $k < j$, given ξ_{j-1} . This Markovian structure is characterized by its inverse variance matrix, which is tridiagonal. Parameterizing an ANTE(1) structure for a random vector of size t requires $2t - 1$ parameters: variances $\sigma_1^2, \dots, \sigma_t^2$ and $t - 1$ correlation parameters $\rho_1, \dots, \rho_{t-1}$. The covariances among random variables ξ_i and ξ_j are then constructed as

$$\text{Cov} [\xi_i, \xi_j] = \sqrt{\sigma_i^2 \sigma_j^2} \prod_{k=i}^{j-1} \rho_k$$

PROC GLIMMIX constrains the correlation parameters to satisfy $|\rho_k| < 1$, $\forall k$. For variable-order ante-dependence models see Macchiavelli and Arnold (1994).

AR(1)

specifies a first-order autoregressive structure,

$$\text{Cov} [\xi_i, \xi_j] = \sigma^2 \rho^{|i^* - j^*|}$$

The values i^* and j^* are derived for the i th and j th observations, respectively, and are not necessarily the observation numbers. For example, in the following statements the values correspond to the class levels for the time effect of the i th and j th observation within a particular subject:

```

proc glimmix;
  class time patient;
  model y = x x*x;
  random time / sub=patient type=ar(1);
run;

```

PROC GLIMMIX imposes the constraint $|\rho| < 1$ for stationarity.

ARH(1)

specifies a heterogeneous first-order autoregressive structure,

$$\text{Cov}[\xi_i, \xi_j] = \sqrt{\sigma_i^2 \sigma_j^2} \rho^{|i^* - j^*|}$$

with $|\rho| < 1$. This covariance structure has the same correlation pattern as the TYPE=AR(1) structure, but the variances are allowed to differ.

ARMA(1,1)

specifies the first-order autoregressive moving-average structure,

$$\text{Cov}[\xi_i, \xi_j] = \begin{cases} \sigma^2 & i = j \\ \sigma^2 \gamma \rho^{|i^* - j^*| - 1} & i \neq j \end{cases}$$

Here, ρ is the autoregressive parameter, γ models a moving-average component, and σ^2 is a scale parameter. In the notation of Fuller (1976, p. 68), $\rho = \theta_1$ and

$$\gamma = \frac{(1 + b_1 \theta_1)(\theta_1 + b_1)}{1 + b_1^2 + 2b_1 \theta_1}$$

The example in Table 41.18 and $|b_1| < 1$ imply that

$$b_1 = \frac{\beta - \sqrt{\beta^2 - 4\alpha^2}}{2\alpha}$$

where $\alpha = \gamma - \rho$ and $\beta = 1 + \rho^2 - 2\gamma\rho$. PROC GLIMMIX imposes the constraints $|\rho| < 1$ and $|\gamma| < 1$ for stationarity, although for some values of ρ and γ in this region the resulting covariance matrix is not positive definite. When the estimated value of ρ becomes negative, the computed covariance is multiplied by $\cos(\pi d_{ij})$ to account for the negativity.

CHOL<(q)>

specifies an unstructured variance-covariance matrix parameterized through its Cholesky root. This parameterization ensures that the resulting variance-covariance matrix is at least positive semidefinite. If all diagonal values are nonzero, it is positive definite. For example, a 2×2 unstructured covariance matrix can be written as

$$\text{Var}[\boldsymbol{\xi}] = \begin{bmatrix} \theta_1 & \theta_{12} \\ \theta_{12} & \theta_2 \end{bmatrix}$$

Without imposing constraints on the three parameters, there is no guarantee that the estimated variance matrix is positive definite. Even if θ_1 and θ_2 are nonzero, a large value for θ_{12} can lead to a negative eigenvalue of $\text{Var}[\boldsymbol{\xi}]$. The Cholesky root of a positive definite matrix \mathbf{A} is a lower

triangular matrix \mathbf{C} such that $\mathbf{CC}' = \mathbf{A}$. The Cholesky root of the above 2×2 matrix can be written as

$$\mathbf{C} = \begin{bmatrix} \alpha_1 & 0 \\ \alpha_{12} & \alpha_2 \end{bmatrix}$$

The elements of the unstructured variance matrix are then simply $\theta_1 = \alpha_1^2$, $\theta_{12} = \alpha_1\alpha_{12}$, and $\theta_2 = \alpha_{12}^2 + \alpha_2^2$. Similar operations yield the generalization to covariance matrices of higher orders.

For example, the following statements model the covariance matrix of each subject as an unstructured matrix:

```
proc glimmix;
  class sub;
  model y = x;
  random _residual_ / subject=sub type=un;
run;
```

The next set of statements accomplishes the same, but the estimated \mathbf{R} matrix is guaranteed to be nonnegative definite:

```
proc glimmix;
  class sub;
  model y = x;
  random _residual_ / subject=sub type=chol;
run;
```

The GLIMMIX procedure constrains the diagonal elements of the Cholesky root to be positive. This guarantees a unique solution when the matrix is positive definite.

The optional order parameter $q > 0$ determines how many bands below the diagonal are modeled. Elements in the lower triangular portion of \mathbf{C} in bands higher than q are set to zero. If you consider the resulting covariance matrix $\mathbf{A} = \mathbf{CC}'$, then the order parameter has the effect of zeroing all off-diagonal elements that are at least q positions away from the diagonal.

Because of its good computational and statistical properties, the Cholesky root parameterization is generally recommended over a completely unstructured covariance matrix (TYPE=UN). However, it is computationally slightly more involved.

CS

specifies the compound-symmetry structure, which has constant variance and constant covariance

$$\text{Cov}[\xi_i, \xi_j] = \begin{cases} \phi + \sigma & i = j \\ \sigma & i \neq j \end{cases}$$

The compound symmetry structure arises naturally with nested random effects, such as when subsampling error is nested within experimental error. The models constructed with the following two sets of GLIMMIX statements have the same marginal variance matrix, provided σ is positive:

```

proc glimmix;
  class block A;
  model y = block A;
  random block*A / type=vc;
run;

proc glimmix;
  class block A;
  model y = block A;
  random _residual_ / subject=block*A
                    type=cs;
run;

```

In the first case, the `block*A` random effect models the G-side experimental error. Because the distribution defaults to the normal, the \mathbf{R} matrix is of form $\phi\mathbf{I}$ (see Table 41.19), and ϕ is the subsampling error variance. The marginal variance for the data from a particular experimental unit is thus $\sigma_{b*a}^2\mathbf{J} + \phi\mathbf{I}$. This matrix is of compound symmetric form.

Hierarchical random assignments or selections, such as subsampling or split-plot designs, give rise to compound symmetric covariance structures. This implies exchangeability of the observations on the subunit, leading to constant correlations between the observations. Compound symmetric structures are thus usually not appropriate for processes where correlations decline according to some metric, such as spatial and temporal processes.

Note that R-side compound-symmetry structures do not impose any constraint on σ . You can thus use an R-side `TYPE=CS` structure to emulate a variance-component model with unbounded estimate of the variance component.

CSH

specifies the heterogeneous compound-symmetry structure, which is an equi-correlation structure but allows for different variances

$$\text{Cov}[\xi_i, \xi_j] = \begin{cases} \sqrt{\sigma_i^2 \sigma_j^2} & i = j \\ \rho \sqrt{\sigma_i^2 \sigma_j^2} & i \neq j \end{cases}$$

FA(*q*)

specifies the factor-analytic structure with q factors (Jennrich and Schluchter 1986). This structure is of the form $\mathbf{\Lambda}\mathbf{\Lambda}' + \mathbf{D}$, where $\mathbf{\Lambda}$ is a $t \times q$ rectangular matrix and \mathbf{D} is a $t \times t$ diagonal matrix with t different parameters. When $q > 1$, the elements of $\mathbf{\Lambda}$ in its upper-right corner (that is, the elements in the i th row and j th column for $j > i$) are set to zero to fix the rotation of the structure.

FA0(*q*)

specifies a factor-analytic structure with q factors of the form $\text{Var}[\boldsymbol{\xi}] = \mathbf{\Lambda}\mathbf{\Lambda}'$, where $\mathbf{\Lambda}$ is a $t \times q$ rectangular matrix and t is the dimension of \mathbf{Y} . When $q > 1$, $\mathbf{\Lambda}$ is a lower triangular matrix. When $q < t$ —that is, when the number of factors is less than the dimension of the matrix—this structure is nonnegative definite but not of full rank. In this situation, you can use it to approximate an unstructured covariance matrix.

HF

specifies a covariance structure that satisfies the general Huynh-Feldt condition (Huynh and Feldt 1970). For a random vector with t elements, this structure has $t + 1$ positive parameters and covariances

$$\text{Cov}[\xi_i, \xi_j] = \begin{cases} \sigma_i^2 & i = j \\ 0.5(\sigma_i^2 + \sigma_j^2) - \lambda & i \neq j \end{cases}$$

A covariance matrix Σ generally satisfies the Huynh-Feldt condition if it can be written as $\Sigma = \tau \mathbf{1}' + \mathbf{1} \tau' + \lambda \mathbf{I}$. The preceding parameterization chooses $\tau_i = 0.5(\sigma_i^2 - \lambda)$. Several simpler covariance structures give rise to covariance matrices that also satisfy the Huynh-Feldt condition. For example, `TYPE=CS`, `TYPE=VC`, and `TYPE=UN(1)` are nested within `TYPE=HF`. You can use the `COVTEST` statement to test the HF structure against one of these simpler structures. Note also that the HF structure is nested within an unstructured covariance matrix.

The `TYPE=HF` covariance structure can be sensitive to the choice of starting values and the default `MIVQUE(0)` starting values can be poor for this structure; you can supply your own starting values with the `PARMS` statement.

LIN(q)

specifies a general linear covariance structure with q parameters. This structure consists of a linear combination of known matrices that you input with the `LDATA=` option. Suppose that you want to model the covariance of a random vector of length t , and further suppose that $\mathbf{A}_1, \dots, \mathbf{A}_q$ are symmetric ($t \times t$) matrices constructed from the information in the `LDATA=` data set. Then,

$$\text{Cov}[\xi_i, \xi_j] = \sum_{k=1}^q \theta_k [\mathbf{A}_k]_{ij}$$

where $[\mathbf{A}_k]_{ij}$ denotes the element in row i , column j of matrix \mathbf{A}_k .

Linear structures are very flexible and general. You need to exercise caution to ensure that the variance matrix is positive definite. Note that PROC GLIMMIX does not impose boundary constraints on the parameters $\theta_1, \dots, \theta_k$ of a general linear covariance structure. For example, if classification variable `A` has 6 levels, the following statements fit a variance component structure for the random effect without boundary constraints:

```
data ldata;
  retain parm 1 value 1;
  do row=1 to 6; col=row; output; end;
run;

proc glimmix data=MyData;
  class A B;
  model Y = B;
  random A / type=lin(1) ldata=ldata;
run;
```

PSPLINE<(options)>

requests that PROC GLIMMIX form a B-spline basis and fits a penalized B-spline (P-spline, Eilers and Marx 1996) with random spline coefficients. This covariance structure is available only for G-side random effects and only a single continuous random effect can be specified with TYPE=PSPLINE. As for TYPE=RSMOOTH, PROC GLIMMIX forms a modified \mathbf{Z} matrix and fits a mixed model in which the random variables associated with the columns of \mathbf{Z} are independent with a common variance. The \mathbf{Z} matrix is constructed as follows.

Denote as $\tilde{\mathbf{Z}}$ the $(n \times K)$ matrix of B-splines of degree d and denote as \mathbf{D}_r the $(K - r \times K)$ matrix of r th-order differences. For example, for $K = 5$,

$$\mathbf{D}_1 = \begin{bmatrix} 1 & -1 & 0 & 0 & 0 \\ 0 & 1 & -1 & 0 & 0 \\ 0 & 0 & 1 & -1 & 0 \\ 0 & 0 & 0 & 1 & -1 \end{bmatrix}$$

$$\mathbf{D}_2 = \begin{bmatrix} 1 & -2 & 1 & 0 & 0 \\ 0 & 1 & -2 & 1 & 0 \\ 0 & 0 & 1 & -2 & 1 \end{bmatrix}$$

$$\mathbf{D}_3 = \begin{bmatrix} 1 & -3 & 3 & -1 & 0 \\ 0 & 1 & -3 & 3 & -1 \end{bmatrix}$$

Then, the \mathbf{Z} matrix used in fitting the mixed model is the $(n \times K - r)$ matrix

$$\mathbf{Z} = \tilde{\mathbf{Z}}(\mathbf{D}'_r \mathbf{D}_r)^{-1} \mathbf{D}'_r$$

The construction of the B-spline knots is controlled with the **KNOTMETHOD=** EQUAL(m) option and the **DEGREE=** d suboption of TYPE=PSPLINE. The total number of knots equals the number m of equally spaced interior knots plus d knots at the low end and $\max\{1, d\}$ knots at the high end. The number of columns in the B-spline basis equals $K = m + d + 1$. By default, the interior knots exclude the minimum and maximum of the random-effect values and are based on $m - 1$ equally spaced intervals. Suppose $x_{(1)}$ and $x_{(n)}$ are the smallest and largest random-effect values; then interior knots are placed at

$$x_{(1)} + j(x_{(n)} - x_{(1)})/(m + 1), \quad j = 1, \dots, m$$

In addition, d evenly spaced exterior knots are placed below $x_{(1)}$ and $\max\{d, 1\}$ exterior knots are placed above $x_{(n)}$. The exterior knots are evenly spaced and start at $x_{(1)} \pm 100$ times the machine epsilon. For example, based on the defaults $d = 3$, $r = 3$, the following statements lead to 26 total knots and 21 columns in \mathbf{Z} , $m = 20$, $K = m + d + 1 = 24$, $K - r = 21$:

```
proc glimmix;
  model y = x;
  random x / type=pspline knotmethod=equal(20);
run;
```

Details about the computation and properties of B-splines can be found in de Boor (2001).

You can extend or limit the range of the knots with the `KNOTMIN=` and `KNOTMAX=` options. Table 41.17 lists some of the parameters that control this covariance type and their relationships.

Table 41.17 P-Spline Parameters

Parameter	Description
d	Degree of B-spline, default $d = 3$
r	Order of differencing in construction of \mathbf{D}_r , default $r = 3$
m	Number of interior knots, default $m = 10$
$m + d + \max\{1, d\}$	Total number of knots
$K = m + d + 1$	Number of columns in B-spline basis
$K - r$	Number of columns in \mathbf{Z}

You can specify the following *options* for `TYPE=PSPLINE`:

`DEGREE= d` specifies the degree of the B-spline. The default is $d = 3$.

`DIFFORDER= r` specifies the order of the differencing matrix \mathbf{D}_r . The default and maximum is $r = 3$.

RSMOOTH<(m | **NOLOG**)>

specifies a radial smoother covariance structure for G-side random effects. This results in an approximate low-rank thin-plate spline where the smoothing parameter is obtained by the estimation method selected with the `METHOD=` option of the `PROC GLIMMIX` statement. The smoother is based on the automatic smoother in Ruppert, Wand, and Carroll (2003, Chapter 13.4–13.5), but with a different method of selecting the spline knots. See the section “Radial Smoothing Based on Mixed Models” on page 3084 for further details about the construction of the smoother and the knot selection.

Radial smoothing is possible in one or more dimensions. A univariate smoother is obtained with a single random effect, while multiple random effects in a `RANDOM` statement yield a multivariate smoother. Only continuous random effects are permitted with this covariance structure. If n_r denotes the number of continuous random effects in the `RANDOM` statement, then the covariance structure of the random effects $\boldsymbol{\gamma}$ is determined as follows. Suppose that \mathbf{z}_i denotes the vector of random effects for the i th observation. Let $\boldsymbol{\tau}_k$ denote the $(n_r \times 1)$ vector of knot coordinates, $k = 1, \dots, K$, and K is the total number of knots. The Euclidean distance between the knots is computed as

$$d_{kp} = \|\boldsymbol{\tau}_k - \boldsymbol{\tau}_p\| = \sqrt{\sum_{j=1}^{n_r} (\tau_{jk} - \tau_{jp})^2}$$

and the distance between knots and effects is computed as

$$h_{ik} = \|\mathbf{z}_i - \boldsymbol{\tau}_k\| = \sqrt{\sum_{j=1}^{n_r} (z_{ij} - \tau_{jk})^2}$$

The \mathbf{Z} matrix for the GLMM is constructed as

$$\mathbf{Z} = \tilde{\mathbf{Z}}\boldsymbol{\Omega}^{-1/2}$$

where the $(n \times K)$ matrix $\tilde{\mathbf{Z}}$ has typical element

$$[\tilde{\mathbf{Z}}]_{ik} = \begin{cases} h_{ik}^p & n_r \text{ odd} \\ h_{ik}^p \log\{h_{ik}\} & n_r \text{ even} \end{cases}$$

and the $(K \times K)$ matrix $\mathbf{\Omega}$ has typical element

$$[\mathbf{\Omega}]_{kp} = \begin{cases} d_{kp}^p & n_r \text{ odd} \\ d_{kp}^p \log\{d_{kp}\} & n_r \text{ even} \end{cases}$$

The exponent in these expressions equals $p = 2m - n_r$, where the optional value m corresponds to the derivative penalized in the thin-plate spline. A larger value of m will yield a smoother fit. The GLIMMIX procedure requires $p > 0$ and chooses by default $m = 2$ if $n_r < 3$ and $m = n_r/2 + 1$ otherwise. The NOLOG option removes the $\log\{h_{ik}\}$ and $\log\{d_{kp}\}$ terms from the computation of the $\tilde{\mathbf{Z}}$ and $\mathbf{\Omega}$ matrices when n_r is even; this yields invariance under rescaling of the coordinates.

Finally, the components of $\boldsymbol{\gamma}$ are assumed to have equal variance σ_r^2 . The “smoothing parameter” λ of the low-rank spline is related to the variance components in the model, $\lambda^2 = f(\phi, \sigma_r^2)$. See Ruppert, Wand, and Carroll (2003) for details. If the conditional distribution does not provide a scale parameter ϕ , you can add a single R-side residual parameter.

The knot selection is controlled with the **KNOTMETHOD=** option. The GLIMMIX procedure selects knots automatically based on the vertices of a k -d tree or reads knots from a data set that you supply. See the section “[Radial Smoothing Based on Mixed Models](#)” on page 3084 for further details on radial smoothing in the GLIMMIX procedure and its connection to a mixed model formulation.

SIMPLE

is an alias for TYPE=VC.

SP(EXP)(*c-list*)

models an exponential spatial or temporal covariance structure, where the covariance between two observations depends on a distance metric d_{ij} . The *c-list* contains the names of the numeric variables used as coordinates to determine distance. For a stochastic process in R^k , there are k elements in *c-list*. If the $(k \times 1)$ vectors of coordinates for observations i and j are \mathbf{c}_i and \mathbf{c}_j , then PROC GLIMMIX computes the Euclidean distance

$$d_{ij} = \|\mathbf{c}_i - \mathbf{c}_j\| = \sqrt{\sum_{m=1}^k (c_{mi} - c_{mj})^2}$$

The covariance between two observations is then

$$\text{Cov}[\xi_i, \xi_j] = \sigma^2 \exp\{-d_{ij}/\alpha\}$$

The parameter α is *not* what is commonly referred to as the range parameter in geostatistical applications. The practical range of a (second-order stationary) spatial process is the distance $d^{(p)}$ at which the correlations fall below 0.05. For the SP(EXP) structure, this distance is $d^{(p)} = 3\alpha$. PROC GLIMMIX constrains α to be positive.

SP(GAU)(*c-list*)

models a Gaussian covariance structure,

$$\text{Cov} [\xi_i, \xi_j] = \sigma^2 \exp\{-d_{ij}^2/\alpha^2\}$$

See TYPE=SP(EXP) for the computation of the distance d_{ij} . The parameter α is related to the range of the process as follows. If the practical range $d^{(p)}$ is defined as the distance at which the correlations fall below 0.05, then $d^{(p)} = \sqrt{3}\alpha$. PROC GLIMMIX constrains α to be positive. See TYPE=SP(EXP) for the computation of the distance d_{ij} from the variables specified in *c-list*.

SP(MAT)(*c-list*)

models a covariance structure in the Matérn class of covariance functions (Matérn 1986). The covariance is expressed in the parameterization of Handcock and Stein (1993); Handcock and Wallis (1994); it can be written as

$$\text{Cov} [\xi_i, \xi_j] = \sigma^2 \frac{1}{\Gamma(\nu)} \left(\frac{d_{ij} \sqrt{\nu}}{\rho} \right)^\nu 2K_\nu \left(\frac{2d_{ij} \sqrt{\nu}}{\rho} \right)$$

The function K_ν is the modified Bessel function of the second kind of (real) order $\nu > 0$. The smoothness (continuity) of a stochastic process with covariance function in the Matérn class increases with ν . This class thus enables data-driven estimation of the smoothness properties of the process. The covariance is identical to the exponential model for $\nu = 0.5$ (TYPE=SP(EXP)(*c-list*)), while for $\nu = 1$ the model advocated by Whittle (1954) results. As $\nu \rightarrow \infty$, the model approaches the Gaussian covariance structure (TYPE=SP(GAU)(*c-list*)).

Note that the MIXED procedure offers covariance structures in the Matérn class in two parameterizations, TYPE=SP(MATERN) and TYPE=SP(MATHSW). The TYPE=SP(MAT) in the GLIMMIX procedure is equivalent to TYPE=SP(MATHSW) in the MIXED procedure.

Computation of the function K_ν and its derivatives is numerically demanding; fitting models with Matérn covariance structures can be time-consuming. Good starting values are essential.

SP(POW)(*c-list*)

models a power covariance structure,

$$\text{Cov} [\xi_i, \xi_j] = \sigma^2 \rho^{d_{ij}}$$

where $\rho \geq 0$. This is a reparameterization of the exponential structure, TYPE=SP(EXP). Specifically, $\log\{\rho\} = -1/\alpha$. See TYPE=SP(EXP) for the computation of the distance d_{ij} from the variables specified in *c-list*. When the estimated value of ρ becomes negative, the computed covariance is multiplied by $\cos(\pi d_{ij})$ to account for the negativity.

SP(POWA)(*c-list*)

models an anisotropic power covariance structure in k dimensions, provided that the coordinate list *c-list* has k elements. If c_{im} denotes the coordinate for the i th observation of the m th variable in *c-list*, the covariance between two observations is given by

$$\text{Cov} [\xi_i, \xi_j] = \sigma^2 \rho_1^{|c_{i1}-c_{j1}|} \rho_2^{|c_{i2}-c_{j2}|} \dots \rho_k^{|c_{ik}-c_{jk}|}$$

Note that for $k = 1$, TYPE=SP(POWA) is equivalent to TYPE=SP(POW), which is itself a reparameterization of TYPE=SP(EXP). When the estimated value of ρ_m becomes negative, the computed covariance is multiplied by $\cos(\pi |c_{im} - c_{jm}|)$ to account for the negativity.

SP(SPH)(*c-list*)

models a spherical covariance structure,

$$\text{Cov} [\xi_i, \xi_j] = \begin{cases} \sigma^2 \left\{ 1 - \frac{3d_{ij}}{2\alpha} + \frac{1}{2} \left(\frac{d_{ij}}{\alpha} \right)^3 \right\} & d_{ij} \leq \alpha \\ 0 & d_{ij} > \alpha \end{cases}$$

The spherical covariance structure has a true range parameter. The covariances between observations are exactly zero when their distance exceeds α . See TYPE=SP(EXP) for the computation of the distance d_{ij} from the variables specified in *c-list*.

TOEP

models a Toeplitz covariance structure. This structure can be viewed as an autoregressive structure with order equal to the dimension of the matrix,

$$\text{Cov} [\xi_i, \xi_j] = \begin{cases} \sigma^2 & i = j \\ \sigma_{|i-j|} & i \neq j \end{cases}$$

TOEP(*q*)

specifies a banded Toeplitz structure,

$$\text{Cov} [\xi_i, \xi_j] = \begin{cases} \sigma^2 & i = j \\ \sigma_{|i-j|} & |i - j| < q \end{cases}$$

This can be viewed as a moving-average structure with order equal to $q - 1$. The specification TYPE=TOEP(1) is the same as $\sigma^2 \mathbf{I}$, and it can be useful for specifying the same variance component for several effects.

TOEPH<(q)>

models a Toeplitz covariance structure. The correlations of this structure are banded as the TOEP or TOEP(*q*) structures, but the variances are allowed to vary:

$$\text{Cov} [\xi_i, \xi_j] = \begin{cases} \sigma_i^2 & i = j \\ \rho_{|i-j|} \sqrt{\sigma_i^2 \sigma_j^2} & i \neq j \end{cases}$$

The correlation parameters satisfy $|\rho_{|i-j|}| < 1$. If you specify the optional value q , the correlation parameters with $|i - j| \geq q$ are set to zero, creating a banded correlation structure. The specification TYPE=TOEPH(1) results in a diagonal covariance matrix with heterogeneous variances.

UN<(q)>

specifies a completely general (unstructured) covariance matrix parameterized directly in terms of variances and covariances,

$$\text{Cov} [\xi_i, \xi_j] = \sigma_{ij}$$

The variances are constrained to be nonnegative, and the covariances are unconstrained. This structure is not constrained to be nonnegative definite in order to avoid nonlinear constraints; however, you can use the TYPE=CHOL structure if you want this constraint to be imposed by a Cholesky factorization. If you specify the order parameter q , then PROC GLIMMIX estimates only the first q bands of the matrix, setting elements in all higher bands equal to 0.

UNR<(q)>

specifies a completely general (unstructured) covariance matrix parameterized in terms of variances and correlations,

$$\text{Cov} [\xi_i, \xi_j] = \sigma_i \sigma_j \rho_{ij}$$

where σ_i denotes the standard deviation and the correlation ρ_{ij} is zero when $i = j$ and when $|i - j| \geq q$, provided the order parameter q is given. This structure fits the same model as the TYPE=UN(q) option, but with a different parameterization. The i th variance parameter is σ_i^2 . The parameter ρ_{ij} is the correlation between the i th and j th measurements; it satisfies $|\rho_{ij}| < 1$. If you specify the order parameter q , then PROC GLIMMIX estimates only the first q bands of the matrix, setting all higher bands equal to zero.

VC

specifies standard variance components and is the default structure for both G-side and R-side covariance structures. In a G-side covariance structure, a distinct variance component is assigned to each effect. In an R-side structure TYPE=VC is usually used only to add overdispersion effects or with the GROUP= option to specify a heterogeneous variance model.

Table 41.18 Covariance Structure Examples

Description	Structure	Example
Variance Components	VC (default)	$\begin{bmatrix} \sigma_B^2 & 0 & 0 & 0 \\ 0 & \sigma_B^2 & 0 & 0 \\ 0 & 0 & \sigma_{AB}^2 & 0 \\ 0 & 0 & 0 & \sigma_{AB}^2 \end{bmatrix}$
Compound Symmetry	CS	$\begin{bmatrix} \sigma + \phi & \sigma & \sigma & \sigma \\ \sigma & \sigma + \phi & \sigma & \sigma \\ \sigma & \sigma & \sigma + \phi & \sigma \\ \sigma & \sigma & \sigma & \sigma + \phi \end{bmatrix}$
Heterogeneous CS	CSH	$\begin{bmatrix} \sigma_1^2 & \sigma_1 \sigma_2 \rho & \sigma_1 \sigma_3 \rho & \sigma_1 \sigma_4 \rho \\ \sigma_2 \sigma_1 \rho & \sigma_2^2 & \sigma_2 \sigma_3 \rho & \sigma_2 \sigma_4 \rho \\ \sigma_3 \sigma_1 \rho & \sigma_3 \sigma_2 \rho & \sigma_3^2 & \sigma_3 \sigma_4 \rho \\ \sigma_4 \sigma_1 \rho & \sigma_4 \sigma_2 \rho & \sigma_4 \sigma_3 \rho & \sigma_4^2 \end{bmatrix}$
First-Order Autoregressive	AR(1)	$\sigma^2 \begin{bmatrix} 1 & \rho & \rho^2 & \rho^3 \\ \rho & 1 & \rho & \rho^2 \\ \rho^2 & \rho & 1 & \rho \\ \rho^3 & \rho^2 & \rho & 1 \end{bmatrix}$
Heterogeneous AR(1)	ARH(1)	$\begin{bmatrix} \sigma_1^2 & \sigma_1 \sigma_2 \rho & \sigma_1 \sigma_3 \rho^2 & \sigma_1 \sigma_4 \rho^3 \\ \sigma_2 \sigma_1 \rho & \sigma_2^2 & \sigma_2 \sigma_3 \rho & \sigma_2 \sigma_4 \rho^2 \\ \sigma_3 \sigma_1 \rho^2 & \sigma_3 \sigma_2 \rho & \sigma_3^2 & \sigma_3 \sigma_4 \rho \\ \sigma_4 \sigma_1 \rho^3 & \sigma_4 \sigma_2 \rho & \sigma_4 \sigma_3 \rho & \sigma_4^2 \end{bmatrix}$
Unstructured	UN	$\begin{bmatrix} \sigma_1^2 & \sigma_{21} & \sigma_{31} & \sigma_{41} \\ \sigma_{21} & \sigma_2^2 & \sigma_{32} & \sigma_{42} \\ \sigma_{31} & \sigma_{32} & \sigma_3^2 & \sigma_{43} \\ \sigma_{41} & \sigma_{42} & \sigma_{43} & \sigma_4^2 \end{bmatrix}$

Table 41.18 continued

Description	Structure	Example
Banded Main Diagonal	UN(1)	$\begin{bmatrix} \sigma_1^2 & 0 & 0 & 0 \\ 0 & \sigma_2^2 & 0 & 0 \\ 0 & 0 & \sigma_3^2 & 0 \\ 0 & 0 & 0 & \sigma_4^2 \end{bmatrix}$
Unstructured Correlations	UNR	$\begin{bmatrix} \sigma_1^2 & \sigma_1\sigma_2\rho_{21} & \sigma_1\sigma_3\rho_{31} & \sigma_1\sigma_4\rho_{41} \\ \sigma_2\sigma_1\rho_{21} & \sigma_2^2 & \sigma_2\sigma_3\rho_{32} & \sigma_2\sigma_4\rho_{42} \\ \sigma_3\sigma_1\rho_{31} & \sigma_3\sigma_2\rho_{32} & \sigma_3^2 & \sigma_3\sigma_4\rho_{43} \\ \sigma_4\sigma_1\rho_{41} & \sigma_4\sigma_2\rho_{42} & \sigma_4\sigma_3\rho_{43} & \sigma_4^2 \end{bmatrix}$
Toeplitz	TOEP	$\begin{bmatrix} \sigma^2 & \sigma_1 & \sigma_2 & \sigma_3 \\ \sigma_1 & \sigma^2 & \sigma_1 & \sigma_2 \\ \sigma_2 & \sigma_1 & \sigma^2 & \sigma_1 \\ \sigma_3 & \sigma_2 & \sigma_1 & \sigma^2 \end{bmatrix}$
Toeplitz with Two Bands	TOEP(2)	$\begin{bmatrix} \sigma^2 & \sigma_1 & 0 & 0 \\ \sigma_1 & \sigma^2 & \sigma_1 & 0 \\ 0 & \sigma_1 & \sigma^2 & \sigma_1 \\ 0 & 0 & \sigma_1 & \sigma^2 \end{bmatrix}$
Heterogeneous Toeplitz	TOEPH	$\begin{bmatrix} \sigma_1^2 & \sigma_1\sigma_2\rho_1 & \sigma_1\sigma_3\rho_2 & \sigma_1\sigma_4\rho_3 \\ \sigma_2\sigma_1\rho_1 & \sigma_2^2 & \sigma_2\sigma_3\rho_1 & \sigma_2\sigma_4\rho_2 \\ \sigma_3\sigma_1\rho_2 & \sigma_3\sigma_2\rho_1 & \sigma_3^2 & \sigma_3\sigma_4\rho_1 \\ \sigma_4\sigma_1\rho_3 & \sigma_4\sigma_2\rho_2 & \sigma_4\sigma_3\rho_1 & \sigma_4^2 \end{bmatrix}$
Spatial Power	SP(POW)(c-list)	$\sigma^2 \begin{bmatrix} 1 & \rho^{d_{12}} & \rho^{d_{13}} & \rho^{d_{14}} \\ \rho^{d_{21}} & 1 & \rho^{d_{23}} & \rho^{d_{24}} \\ \rho^{d_{31}} & \rho^{d_{32}} & 1 & \rho^{d_{34}} \\ \rho^{d_{41}} & \rho^{d_{42}} & \rho^{d_{43}} & 1 \end{bmatrix}$
First-Order Autoregressive Moving-Average	ARMA(1,1)	$\sigma^2 \begin{bmatrix} 1 & \gamma & \gamma\rho & \gamma\rho^2 \\ \gamma & 1 & \gamma & \gamma\rho \\ \gamma\rho & \gamma & 1 & \gamma \\ \gamma\rho^2 & \gamma\rho & \gamma & 1 \end{bmatrix}$
First-Order Factor Analytic	FA(1)	$\begin{bmatrix} \lambda_1^2 + d_1 & \lambda_1\lambda_2 & \lambda_1\lambda_3 & \lambda_1\lambda_4 \\ \lambda_2\lambda_1 & \lambda_2^2 + d_2 & \lambda_2\lambda_3 & \lambda_2\lambda_4 \\ \lambda_3\lambda_1 & \lambda_3\lambda_2 & \lambda_3^2 + d_3 & \lambda_3\lambda_4 \\ \lambda_4\lambda_1 & \lambda_4\lambda_2 & \lambda_4\lambda_3 & \lambda_4^2 + d_4 \end{bmatrix}$
Huynh-Feldt	HF	$\begin{bmatrix} \sigma_1^2 & \frac{\sigma_1^2 + \sigma_2^2}{2} - \lambda & \frac{\sigma_1^2 + \sigma_3^2}{2} - \lambda \\ \frac{\sigma_2^2 + \sigma_1^2}{2} - \lambda & \sigma_2^2 & \frac{\sigma_2^2 + \sigma_3^2}{2} - \lambda \\ \frac{\sigma_3^2 + \sigma_1^2}{2} - \lambda & \frac{\sigma_3^2 + \sigma_2^2}{2} - \lambda & \sigma_3^2 \end{bmatrix}$
First-Order Ante-dependence	ANTE(1)	$\begin{bmatrix} \sigma_1^2 & \sigma_1\sigma_2\rho_1 & \sigma_1\sigma_3\rho_1\rho_2 \\ \sigma_2\sigma_1\rho_1 & \sigma_2^2 & \sigma_2\sigma_3\rho_2 \\ \sigma_3\sigma_1\rho_2\rho_1 & \sigma_3\sigma_2\rho_2 & \sigma_3^2 \end{bmatrix}$

V<=*value-list*>

requests that blocks of the estimated marginal variance-covariance matrix $V(\hat{\theta})$ be displayed in generalized linear mixed models. This matrix is based on the last linearization as described in the section “The Pseudo-model” on page 3054. You can use the *value-list* to select the subjects for which the matrix is displayed. If *value-list* is not specified, the **V** matrix for the first subject is chosen.

Note that the *value-list* refers to subjects as the processing units in the “Dimensions” table. For example, the following statements request that the estimated marginal variance matrix for the second subject be displayed:

```
proc glimmix;
  class A B;
  model y = B;
  random int / subject=A;
  random int / subject=A*B v=2;
run;
```

The subject effect for processing in this case is the **A** effect, because it is contained in the **A*B** interaction. If there is only a single subject as per the “Dimensions” table, then the **V** option displays an ($n \times n$) matrix.

See the section “Processing by Subjects” on page 3082 for how the GLIMMIX procedure determines the number of subjects in the “Dimensions” table.

The GLIMMIX procedure displays blanks for values that are 0.

VC<=*value-list*>

displays the lower-triangular Cholesky root of the blocks of the estimated $V(\hat{\theta})$ matrix. See the **V** option for the specification of *value-list*.

VCI<=*value-list*>

displays the inverse Cholesky root of the blocks of the estimated $V(\hat{\theta})$ matrix. See the **V** option for the specification of *value-list*.

VCORR<=*value-list*>

displays the correlation matrix corresponding to the blocks of the estimated $V(\hat{\theta})$ matrix. See the **V** option for the specification of *value-list*.

VI<=*value-list*>

displays the inverse of the blocks of the estimated $V(\hat{\theta})$ matrix. See the **V** option for the specification of *value-list*.

SLICE Statement

SLICE *model-effect* < / options > ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects (Winer 1971).

The SLICE statement uses most of the options of the LSMEANS statement that are summarized in Table 41.8. The options SLICEDIFF=, SLICEDIFFTYPE=, and ODDS do not apply to the SLICE statement; in the SLICE statement, the relevant options for SLICEDIFF= and SLICEDIFFTYPE= are the SLICEBY= and the DIFF= options, respectively.

For details about the syntax of the SLICE statement, see the section “SLICE Statement” on page 498 of Chapter 19, “Shared Concepts and Topics.”

STORE Statement

STORE < OUT= > *item-store-name* < / LABEL= 'label' > ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “STORE Statement” on page 501 in Chapter 19, “Shared Concepts and Topics.”

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement replaces \mathbf{R} with $\mathbf{W}^{-1/2}\mathbf{R}\mathbf{W}^{-1/2}$, where \mathbf{W} is a diagonal matrix containing the weights. Observations with nonpositive or missing weights are not included in the resulting PROC GLIMMIX analysis. If a WEIGHT statement is not included, all observations used in the analysis are assigned a weight of 1.

Programming Statements

This section lists the programming statements available in PROC GLIMMIX to compute various aspects of the generalized linear mixed model or output quantities. For example, you can compute model effects, weights, frequency, subject, group, and other variables. You can use programming statements to define the mean and variance functions. This section also documents the differences between programming statements in PROC GLIMMIX and programming statements in the SAS DATA step. The syntax of programming statements used in PROC GLIMMIX is identical to that used in the NLMIXED procedure (see Chapter 64, “The NLMIXED Procedure,” and the MODEL procedure (see the *SAS/ETS User’s Guide*). Most of the programming statements that can be used in the DATA step can also be used in the GLIMMIX procedure. See *SAS Statements: Reference* for a description of SAS programming statements. The following are valid statements:

```

ABORT;
ARRAY arrayname < [ dimensions ] > < $ > < variables-and-constants >;
CALL name < (expression < , expression ... >) >;
DELETE;
DO < variable = expression < TO expression > < BY expression > >
    < , expression < TO expression > < BY expression > > ...
    < WHILE expression > < UNTIL expression >;
END;
GOTO statement-label;
IF expression;
IF expression THEN program-statement;
    ELSE program-statement;
variable = expression;
variable + expression;
LINK statement-label;
PUT < variable > < = > ...;
RETURN;
SELECT < (expression) >;
STOP;
SUBSTR(variable, index, length)= expression;
WHEN (expression)program-statement;
    OTHERWISE program-statement;

```

For the most part, the SAS programming statements work the same as they do in the SAS DATA step, as documented in *SAS Language Reference: Concepts*. However, there are several differences:

- The ABORT statement does not allow any arguments.
- The DO statement does not allow a character index variable. Thus

```
do i = 1,2,3;
```

is supported; however, the following statement is not supported:

```
do i = 'A', 'B', 'C';
```

- The LAG function is not supported with PROC GLIMMIX.
- The PUT statement, used mostly for program debugging in PROC GLIMMIX, supports only some of the features of the DATA step PUT statement, and it has some features not available with the DATA step PUT statement:
 - The PROC GLIMMIX PUT statement does not support line pointers, factored lists, iteration factors, overprinting, `_INFILE_`, the colon (:) format modifier, or “\$”.
 - The PROC GLIMMIX PUT statement does support expressions, but the expression must be enclosed in parentheses. For example, the following statement displays the square root of `x`:

```
put (sqrt(x));
```

- The PROC GLIMMIX PUT statement supports the item `_PDV_` to display a formatted listing of all variables in the program. For example:
- ```
put _pdv_;
```
- The WHEN and OTHERWISE statements enable you to specify more than one target statement. That is, DO/END groups are not necessary for multiple statement WHENs. For example, the following syntax is valid:

```
select;
 when (exp1) stmt1;
 stmt2;
 when (exp2) stmt3;
 stmt4;
end;
```

The LINK statement is used in a program to jump immediately to the label `statement_label` and to continue program execution at that point. It is not used to specify a user-defined link function.

When coding your programming statements, you should avoid defining variables that begin with an underscore (`_`), because they might conflict with internal variables created by PROC GLIMMIX.

## User-Defined Link or Variance Function

### Implied Variance Functions

While link functions are not unique for each distribution (see [Table 41.12](#) for the default link functions), the distribution does determine the variance function  $a(\mu)$ . This function expresses the variance of an observation as a function of the mean, apart from weights, frequencies, and additional scale parameters. The implied variance functions  $a(\mu)$  of the GLIMMIX procedure are shown in [Table 41.19](#) for the supported distributions. For the binomial distribution,  $n$  denotes the number of trials in the `events/trials` syntax. For the negative binomial distribution,  $k$  denotes the scale parameter. The multiplicative scale parameter  $\phi$  is not included for the other distributions. The last column of the table indicates whether  $\phi$  has a value equal to 1.0 for the particular distribution.

**Table 41.19** Variance Functions in PROC GLIMMIX

| DIST=                     | Distribution      | Variance function         |                 |
|---------------------------|-------------------|---------------------------|-----------------|
|                           |                   | $a(\mu)$                  | $\phi \equiv 1$ |
| BETA                      | beta              | $\mu(1 - \mu)/(1 + \phi)$ | No              |
| BINARY                    | binary            | $\mu(1 - \mu)$            | Yes             |
| BINOMIAL   BIN   B        | binomial          | $\mu(1 - \mu)/n$          | Yes             |
| EXPONENTIAL   EXPO        | exponential       | $\mu^2$                   | Yes             |
| GAMMA   GAM               | gamma             | $\mu^2$                   | No              |
| GAUSSIAN   G   NORMAL   N | normal            | 1                         | No              |
| GEOMETRIC   GEOM          | geometric         | $\mu + \mu^2$             | Yes             |
| INVGAUSS   IGAUSSIAN   IG | inverse Gaussian  | $\mu^3$                   | No              |
| LOGNORMAL   LOGN          | lognormal         | 1                         | No              |
| NEGBINOMIAL   NEGBIN   NB | negative binomial | $\mu + k\mu^2$            | Yes             |
| POISSON   POI   P         | Poisson           | $\mu$                     | Yes             |
| TCENTRAL   TDIST   T      | $t$               | $v/(v - 2)$               | No              |

To change the variance function, you can use SAS programming statements and the predefined automatic variables, as outlined in the following section. Your definition of a variance function will override the **DIST=** option and its implied variance function. This has the following implication for parameter estimation with the GLIMMIX procedure. When a user-defined link is available, the distribution of the data is determined from the **DIST=** option, or the respective default for the type of response. In a GLM, for example, this enables maximum likelihood estimation. If a user-defined variance function is provided, the **DIST=** option is not honored and the distribution of the data is assumed unknown. In a GLM framework, only quasi-likelihood estimation is then available to estimate the model parameters.

### Automatic Variables

To specify your own link or variance function you can use SAS programming statements and draw on the following automatic variables:

**\_LINP\_** is the current value of the linear predictor. It equals either  $\hat{\eta} = \mathbf{x}'\hat{\boldsymbol{\beta}} + \mathbf{z}'\hat{\boldsymbol{\gamma}} + o$  or  $\hat{\eta} = \mathbf{x}'\hat{\boldsymbol{\beta}} + o$ , where  $o$  is the value of the offset variable, or 0 if no offset is specified. The estimated random effects solutions  $\hat{\boldsymbol{\gamma}}$  are used in the calculation of the linear predictor during the model fitting phase, if a linearization expands about the current values of  $\boldsymbol{\gamma}$ . During the computation of output statistics, the EBLUPs are used if statistics depend on them. For example, the following statements add the variable **p** to the output data set **glimmixout**:

```
proc glimmix;
 model y = x / dist=binary;
 random int / subject=b;
 p = 1/(1+exp(-_linp_));
 output out=glimmixout;
 id p;
run;
```

Because no output statistics are requested in the **OUTPUT** statement that depend on the random-effects solutions (BLUPs, EBEs), the value of `_LINP_` in this example equals  $x'\hat{\beta}$ . On the contrary, the following statements also request conditional residuals on the logistic scale:

```
proc glimmix;
 model y = x / dist=binary;
 random int / subject=b;
 p = 1/(1+exp(-_linp_));
 output out=glimmixout resid(blup)=r;
 id p;
run;
```

The value of `_LINP_` when computing the variable `p` is  $x'\hat{\beta} + z'\hat{\gamma}$ . To ensure that computed statistics are formed from  $x'\hat{\beta}$  and  $z'\hat{\gamma}$  terms as needed, it is recommended that you use the automatic variables `_XBETA_` and `_ZGAMMA_` instead of `_LINP_`.

|                         |                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------|
| <code>_MU_</code>       | expresses the mean of an observation as a function of the linear predictor, $\hat{\mu} = g^{-1}(\hat{\eta})$ . |
| <code>_N_</code>        | is the observation number in the sequence of the data read.                                                    |
| <code>_VARIANCE_</code> | is the estimate of the variance function, $a(\hat{\mu})$ .                                                     |
| <code>_XBETA_</code>    | equals $x'\hat{\beta}$ .                                                                                       |
| <code>_ZGAMMA_</code>   | equals $z'\hat{\gamma}$ .                                                                                      |

The automatic variable `_N_` is incremented whenever the procedure reads an observation from the data set. Observations that are not used in the analysis—for example, because of missing values or invalid weights—are counted. The counter is reset to 1 at the start of every new BY group. Only in some circumstances will `_N_` equal the actual observation number. The symbol should thus be used sparingly to avoid unexpected results.

You must observe the following syntax rules when you use the automatic variables. The `_LINP_` symbol cannot appear on the left side of programming statements; you cannot make an assignment to the `_LINP_` variable. The value of the linear predictor is controlled by the **CLASS**, **MODEL**, and **RANDOM** statements as well as the current parameter estimates and solutions. You can, however, use the `_LINP_` variable on the right side of other operations. Suppose, for example, that you want to transform the linear predictor prior to applying the inverse log link. The following statements are not valid because the linear predictor appears in an assignment:

```
proc glimmix;
 linp = sqrt(abs(_linp_));
 mu = exp(_linp_);
 model count = logtstd / dist=poisson;
run;
```

The next statements achieve the desired result:

```
proc glimmix;
 mu = exp(sqrt(abs(_linp_)));
 model count = logtstd / dist=poisson;
run;
```

If the value of the linear predictor is altered in any way through programming statements, you need to ensure that an assignment to `_MU_` follows. The assignment to variable `P` in the next set of GLIMMIX statements is without effect:

```
proc glimmix;
 p = _linp_ + rannor(454);
 model count = logtstd / dist=poisson;
run;
```

A user-defined link function is implied by expressing `_MU_` as a function of `_LNP_`. That is, if  $\mu = g^{-1}(\eta)$ , you are providing an expression for the inverse link function with programming statements. It is neither necessary nor possible to give an expression for the inverse operation,  $\eta = g(\mu)$ . The variance function is determined by expressing `_VARIANCE_` as a function of `_MU_`. If the `_MU_` variable appears in an assignment statement inside PROC GLIMMIX, the `LINK=` option of the `MODEL` statement is ignored. If the `_VARIANCE_` function appears in an assignment statement, the `DIST=` option is ignored. Furthermore, the associated variance function per Table 41.19 is not honored. In short, user-defined expressions take precedence over built-in defaults.

If you specify your own link and variance function, the assignment to `_MU_` must precede an assignment to the variable `_VARIANCE_`.

The following two sets of GLIMMIX statements yield the same parameter estimates, but the models differ statistically:

```
proc glimmix;
 class block entry;
 model y/n = block entry / dist=binomial link=logit;
run;

proc glimmix;
 class block entry;
 prob = 1 / (1+exp(- _linp_));
 mu = n * prob ;
 variance = n * prob *(1-prob);
 model y = block entry;
run;
```

The first GLIMMIX invocation models the proportion  $y/n$  as a binomial proportion with a logit link. The `DIST=` and `LINK=` options are superfluous in this case, because the GLIMMIX procedure defaults to the binomial distribution in light of the *events/trials* syntax. The logit link is that distribution's default link. The second set of GLIMMIX statements models the count variable  $y$  and takes the binomial sample size into account through assignments to the mean and variance function. In contrast to the first set of GLIMMIX statements, the distribution of  $y$  is unknown. Only its mean and variance are known. The model parameters are estimated by maximum likelihood in the first case and by quasi-likelihood in the second case.

## Details: GLIMMIX Procedure

---

### Generalized Linear Models Theory

A generalized linear model consists of the following:

- a linear predictor  $\eta = \mathbf{x}'\boldsymbol{\beta}$
- a monotonic mapping between the mean of the data and the linear predictor
- a response distribution in the exponential family of distributions

A density or mass function in this family can be written as

$$f(y) = \exp \left\{ \frac{y\theta - b(\theta)}{\phi} + c(y, f(\phi)) \right\}$$

for some functions  $b(\cdot)$  and  $c(\cdot)$ . The parameter  $\theta$  is called the natural (canonical) parameter. The parameter  $\phi$  is a scale parameter, and it is not present in all exponential family distributions. See [Table 41.19](#) for a list of distributions for which  $\phi \equiv 1$ . In the case where observations are weighted, the scale parameter is replaced with  $\phi/w$  in the preceding density (or mass function), where  $w$  is the weight associated with the observation  $y$ .

The mean and variance of the data are related to the components of the density,  $E[Y] = \mu = b'(\theta)$ ,  $\text{Var}[Y] = \phi b''(\theta)$ , where primes denote first and second derivatives. If you express  $\theta$  as a function of  $\mu$ , the relationship is known as the natural link or the canonical link function. In other words, modeling data with a canonical link assumes that  $\theta = \mathbf{x}'\boldsymbol{\beta}$ ; the effect contributions are additive on the canonical scale. The second derivative of  $b(\cdot)$ , expressed as a function of  $\mu$ , is the variance function of the generalized linear model,  $a(\mu) = b''(\theta(\mu))$ . Note that because of this relationship, the distribution determines the variance function and the canonical link function. You cannot, however, proceed in the opposite direction. If you provide a user-specified variance function, the GLIMMIX procedure assumes that only the first two moments of the response distribution are known. The full distribution of the data is then unknown and maximum likelihood estimation is not possible. Instead, the GLIMMIX procedure then estimates parameters by quasi-likelihood.

### Maximum Likelihood

The GLIMMIX procedure forms the log likelihoods of generalized linear models as

$$L(\boldsymbol{\mu}, \phi; \mathbf{y}) = \sum_{i=1}^n f_i l(\mu_i, \phi; y_i, w_i)$$

where  $l(\mu_i, \phi; y_i, w_i)$  is the log likelihood contribution of the  $i$ th observation with weight  $w_i$  and  $f_i$  is the value of the frequency variable. For the determination of  $w_i$  and  $f_i$ , see the [WEIGHT](#) and [FREQ](#) statements. The individual log likelihood contributions for the various distributions are as follows.

**Beta**

$$l(\mu_i, \phi; y_i, w_i) = \log \left\{ \frac{\Gamma(\phi/w_i)}{\Gamma(\mu\phi/w_i)\Gamma((1-\mu)\phi/w_i)} \right\} \\ + (\mu\phi/w_i - 1) \log\{y_i\} \\ + ((1-\mu)\phi/w_i - 1) \log\{1 - y_i\}$$

$\text{Var}[Y] = \mu(1-\mu)/(1+\phi)$ ,  $\phi > 0$ . See Ferrari and Cribari-Neto (2004).

**Binary**

$$l(\mu_i, \phi; y_i, w_i) = w_i(y_i \log\{\mu_i\} + (1 - y_i) \log\{1 - \mu_i\})$$

$\text{Var}[Y] = \mu(1 - \mu)$ ,  $\phi \equiv 1$ .

**Binomial**

$$l(\mu_i, \phi; y_i, w_i) = w_i(y_i \log\{\mu_i\} + (n_i - y_i) \log\{1 - \mu_i\}) \\ + w_i(\log\{\Gamma(n_i + 1)\} - \log\{\Gamma(y_i + 1)\} - \log\{\Gamma(n_i - y_i + 1)\})$$

where  $y_i$  and  $n_i$  are the *events* and *trials* in the *events/trials* syntax, and  $0 < \mu < 1$ .  
 $\text{Var}[Y/n] = \mu(1 - \mu)/n$ ,  $\phi \equiv 1$ .

**Exponential**

$$l(\mu_i, \phi; y_i, w_i) = \begin{cases} -\log\{\mu_i\} - y_i/\mu_i & w_i = 1 \\ w_i \log\left\{\frac{w_i y_i}{\mu_i}\right\} - \frac{w_i y_i}{\mu_i} - \log\{y_i \Gamma(w_i)\} & w_i \neq 1 \end{cases}$$

$\text{Var}[Y] = \mu^2$ ,  $\phi \equiv 1$ .

**Gamma**

$$l(\mu_i, \phi; y_i, w_i) = w_i \phi \log \left\{ \frac{w_i y_i \phi}{\mu_i} \right\} - \frac{w_i y_i \phi}{\mu_i} - \log\{y_i\} - \log\{\Gamma(w_i \phi)\}$$

$\text{Var}[Y] = \phi \mu^2$ ,  $\phi > 0$ .

**Geometric**

$$l(\mu_i, \phi; y_i, w_i) = y_i \log \left\{ \frac{\mu_i}{w_i} \right\} - (y_i + w_i) \log \left\{ 1 + \frac{\mu_i}{w_i} \right\} \\ + \log \left\{ \frac{\Gamma(y_i + w_i)}{\Gamma(w_i)\Gamma(y_i + 1)} \right\}$$

$\text{Var}[Y] = \mu + \mu^2$ ,  $\phi \equiv 1$ .

**Inverse Gaussian**

$$l(\mu_i, \phi; y_i, w_i) = -\frac{1}{2} \left[ \frac{w_i(y_i - \mu_i)^2}{y_i \phi \mu_i^2} + \log \left\{ \frac{\phi y_i^3}{w_i} \right\} + \log\{2\pi\} \right]$$

$\text{Var}[Y] = \phi \mu^3$ ,  $\phi > 0$ .

**“Lognormal”**

$$l(\mu_i, \phi; \log\{y_i\}, w_i) = -\frac{1}{2} \left[ \frac{w_i (\log\{y_i\} - \mu_i)^2}{\phi} + \log \left\{ \frac{\phi}{w_i} \right\} + \log\{2\pi\} \right]$$

$$\text{Var}[\log\{Y\}] = \phi, \phi > 0.$$

If you specify `DIST=LOGNORMAL` with response variable `Y`, the `GLIMMIX` procedure assumes that  $\log\{Y\} \sim N(\mu, \sigma^2)$ . Note that the preceding density is not the density of `Y`.

**Multinomial**

$$l(\mu_i, \phi; \mathbf{y}_i, w_i) = w_i \sum_{j=1}^J y_{ij} \log\{\mu_{ij}\}$$

$$\phi \equiv 1.$$

**Negative Binomial**

$$l(\mu_i, \phi; y_i, w_i) = y_i \log \left\{ \frac{k\mu_i}{w_i} \right\} - (y_i + w_i/k) \log \left\{ 1 + \frac{k\mu_i}{w_i} \right\} \\ + \log \left\{ \frac{\Gamma(y_i + w_i/k)}{\Gamma(w_i/k)\Gamma(y_i + 1)} \right\}$$

$$\text{Var}[Y] = \mu + k\mu^2, k > 0, \phi \equiv 1.$$

For a given  $k$ , the negative binomial distribution is a member of the exponential family. The parameter  $k$  is related to the scale of the data, because it is part of the variance function. However, it cannot be factored from the variance, as is the case with the  $\phi$  parameter in many other distributions. The parameter  $k$  is designated as “Scale” in the “Parameter Estimates” table of the `GLIMMIX` procedure.

**Normal (Gaussian)**

$$l(\mu_i, \phi; y_i, w_i) = -\frac{1}{2} \left[ \frac{w_i (y_i - \mu_i)^2}{\phi} + \log \left\{ \frac{\phi}{w_i} \right\} + \log\{2\pi\} \right]$$

$$\text{Var}[Y] = \phi, \phi > 0.$$

**Poisson**

$$l(\mu_i, \phi; y_i, w_i) = w_i (y_i \log\{\mu_i\} - \mu_i - \log\{\Gamma(y_i + 1)\})$$

$$\text{Var}[Y] = \mu, \phi \equiv 1.$$

**Shifted T**

$$z_i = -0.5 \log\{\phi/\sqrt{w_i}\} + \log\{\Gamma(0.5(v + 1))\} \\ - \log\{\Gamma(0.5v)\} - 0.5 \times \log\{\pi v\}$$

$$l(\mu_i, \phi; y_i, w_i) = -(v/2 + 0.5) \log \left\{ 1 + \frac{w_i (y_i - \mu_i)^2}{\phi} \right\} + z_i$$

$$\phi > 0, v > 0, \text{Var}[Y] = \phi v / (v - 2).$$

Define the parameter vector for the generalized linear model as  $\boldsymbol{\theta} = \boldsymbol{\beta}$ , if  $\phi \equiv 1$ , and as  $\boldsymbol{\theta} = [\boldsymbol{\beta}', \phi]'$  otherwise.  $\boldsymbol{\beta}$  denotes the fixed-effects parameters in the linear predictor. For the negative binomial distribution, the relevant parameter vector is  $\boldsymbol{\theta} = [\boldsymbol{\beta}', k]'$ . The gradient and Hessian of the negative log likelihood are then

$$\mathbf{g} = -\frac{\partial L(\boldsymbol{\theta}; \mathbf{y})}{\partial \boldsymbol{\theta}} \quad \mathbf{H} = -\frac{\partial^2 L(\boldsymbol{\theta}; \mathbf{y})}{\partial \boldsymbol{\theta} \partial \boldsymbol{\theta}'}$$

The GLIMMIX procedure computes the gradient vector and Hessian matrix analytically, unless your programming statements involve functions whose derivatives are determined by finite differences. If the procedure is in scoring mode,  $\mathbf{H}$  is replaced by its expected value. PROC GLIMMIX is in scoring mode when the number  $n$  of SCORING= $n$  iterations has not been exceeded and the optimization technique uses second derivatives, or when the Hessian is computed at convergence and the EXPHESSIAN option is in effect. Note that the objective function is the negative log likelihood when the GLIMMIX procedure fits a GLM model. The procedure performs a minimization problem in this case.

In models for independent data with known distribution, parameter estimates are obtained by the method of maximum likelihood. No parameters are profiled from the optimization. The default optimization technique for GLMs is the Newton-Raphson algorithm, except for Gaussian models with identity link, which do not require iterative model fitting. In the case of a Gaussian model, the scale parameter is estimated by restricted maximum likelihood, because this estimate is unbiased. The results from the GLIMMIX procedure agree with those from the GLM and REG procedure for such models. You can obtain the maximum likelihood estimate of the scale parameter with the NOREML option in the PROC GLIMMIX statement. To change the optimization algorithm, use the TECHNIQUE= option in the NLOPTIONS statement.

Standard errors of the parameter estimates are obtained from the inverse of the (observed or expected) second derivative matrix  $\mathbf{H}$ .

## Scale and Dispersion Parameters

The parameter  $\phi$  in the log-likelihood functions is a scale parameter. McCullagh and Nelder (1989, p. 29) refer to it as the dispersion parameter. With the exception of the normal distribution,  $\phi$  does not correspond to the variance of an observation, the variance of an observation in a generalized linear model is a function of  $\phi$  and  $\mu$ . In a generalized linear model (GLM mode), the GLIMMIX procedure displays the estimate of  $\phi$  as “Scale” in the “Parameter Estimates” table. Note that for some distributions this scale is different from that reported by the GENMOD procedure in its “Parameter Estimates” table. The scale reported by PROC GENMOD is sometimes a transformation of the dispersion parameter in the log-likelihood function. Table 41.19 displays the relationship between the “Scale” entries reported by the two procedures in terms of the  $\phi$  (or  $k$ ) parameter in the GLIMMIX log-likelihood functions.

**Table 41.19** Scales in Parameter Estimates Table

| Distribution      | GLIMMIX Reports                        | GENMOD Reports      |
|-------------------|----------------------------------------|---------------------|
| Beta              | $\hat{\phi}$                           | N/A                 |
| Gamma             | $\hat{\phi}$                           | $\hat{\phi}$        |
| Inverse Gaussian  | $\hat{\phi}$                           | $\sqrt{\hat{\phi}}$ |
| Negative binomial | $\hat{k}$                              | $\hat{k}$           |
| Normal            | $\hat{\phi} = \widehat{\text{Var}}[Y]$ | $\sqrt{\hat{\phi}}$ |

Note that for normal linear models, PROC GLIMMIX by default estimates the parameters by restricted maximum likelihood, whereas PROC GENMOD estimates the parameters by maximum likelihood. As a consequence, the scale parameter in the “Parameter Estimates” table of the GLIMMIX procedure coincides for these models with the mean-squared error estimate of the GLM or REG procedures. To obtain maximum likelihood estimates in a normal linear model in the GLIMMIX procedure, specify the NOREML option in the PROC GLIMMIX statement.

### Quasi-likelihood for Independent Data

Quasi-likelihood estimation uses only the first and second moment of the response. In the case of independent data, this requires only a specification of the mean and variance of your data. The GLIMMIX procedure estimates parameters by quasi-likelihood, if the following conditions are met:

- The response distribution is unknown, because of a user-specified variance function.
- There are no G-side random effects.
- There are no R-side covariance structures or at most an overdispersion parameter.

Under some mild regularity conditions, the function

$$Q(\mu_i, y_i) = \int_{y_i}^{\mu_i} \frac{y_i - t}{\phi a(t)} dt$$

known as the log quasi-likelihood of the  $i$ th observation, has some properties of a log-likelihood function (McCullagh and Nelder 1989, p. 325). For example, the expected value of its derivative is zero, and the variance of its derivative equals the negative of the expected value of the second derivative. Consequently,

$$QL(\boldsymbol{\mu}, \phi, \mathbf{y}) = \sum_{i=1}^n f_i w_i \frac{Y_i - \mu_i}{\phi a(\mu_i)}$$

can serve as the score function for estimation. Quasi-likelihood estimation takes as the gradient and “Hessian” matrix—with respect to the fixed-effects parameters  $\boldsymbol{\beta}$ —the quantities

$$\mathbf{g}_{ql} = [g_{ql,j}] = \left[ \frac{\partial QL(\boldsymbol{\mu}, \phi, \mathbf{y})}{\partial \beta_j} \right] = \mathbf{D}'\mathbf{V}^{-1}(\mathbf{Y} - \boldsymbol{\mu})/\phi$$

$$\mathbf{H}_{ql} = [h_{ql,jk}] = \left[ \frac{\partial^2 QL(\boldsymbol{\mu}, \phi, \mathbf{y})}{\partial \beta_j \partial \beta_k} \right] = \mathbf{D}'\mathbf{V}^{-1}\mathbf{D}/\phi$$

In this expression,  $\mathbf{D}$  is a matrix of derivatives of  $\boldsymbol{\mu}$  with respect to the elements in  $\boldsymbol{\beta}$ , and  $\mathbf{V}$  is a diagonal matrix containing variance functions,  $\mathbf{V} = [a(\mu_1), \dots, a(\mu_n)]$ . Notice that  $\mathbf{H}_{ql}$  is not the second derivative matrix of  $Q(\boldsymbol{\mu}, \mathbf{y})$ . Rather, it is the negative of the expected value of  $\partial \mathbf{g}_{ql} / \partial \boldsymbol{\beta}$ .  $\mathbf{H}_{ql}$  thus has the form of a “scoring Hessian.”

The GLIMMIX procedure fixes the scale parameter  $\phi$  at 1.0 by default. To estimate the parameter, add the statement

```
random _residual_;
```

The resulting estimator (McCullagh and Nelder 1989, p. 328) is

$$\hat{\phi} = \frac{1}{m} \sum_{i=1}^n f_i w_i \frac{(y_i - \hat{\mu}_i)^2}{a(\hat{\mu}_i)}$$

where  $m = f - \text{rank}\{\mathbf{X}\}$  if the **NOREML** option is in effect,  $m = f$  otherwise, and  $f$  is the sum of the frequencies.

See [Example 41.4](#) for an application of quasi-likelihood estimation with PROC GLIMMIX.

## Effects of Adding Overdispersion

You can add a multiplicative overdispersion parameter to a generalized linear model in the GLIMMIX procedure with the statement

```
random _residual_;
```

For models in which  $\phi \equiv 1$ , this effectively lifts the constraint of the parameter. In models that already contain a  $\phi$  or  $k$  scale parameter—such as the normal, gamma, or negative binomial model—the statement adds a multiplicative scalar (the overdispersion parameter,  $\phi_o$ ) to the variance function.

The overdispersion parameter is estimated from Pearson's statistic after all other parameters have been determined by (restricted) maximum likelihood or quasi-likelihood. This estimate is

$$\hat{\phi}_o = \frac{1}{\phi^p m} \sum_{i=1}^n f_i w_i \frac{(y_i - \mu_i)^2}{a(\mu_i)}$$

where  $m = f - \text{rank}\{\mathbf{X}\}$  if the **NOREML** option is in effect, and  $m = f$  otherwise, and  $f$  is the sum of the frequencies. The power  $p$  is  $-1$  for the gamma distribution and  $1$  otherwise.

Adding an overdispersion parameter does not alter any of the other parameter estimates. It only changes the variance-covariance matrix of the estimates by a certain factor. If overdispersion arises from correlations among the observations, then you should investigate more complex random-effects structures.

## Generalized Linear Mixed Models Theory

### Model or Integral Approximation

In a generalized linear model, the log likelihood is well defined, and an objective function for estimation of the parameters is simple to construct based on the independence of the data. In a GLMM, several problems must be overcome before an objective function can be computed.

- The model might be vacuous in the sense that no valid joint distribution can be constructed either in general or for a particular set of parameter values. For example, if  $\mathbf{Y}$  is an equicorrelated ( $n \times 1$ ) vector of binary responses with the same success probability and a symmetric distribution, then the lower bound on the correlation parameter depends on  $n$  and  $\pi$  (Gilliland and Schabenberger 2001). If further restrictions are placed on the joint distribution, as in Bahadur (1961), the correlation is also restricted from above.

- The dependency between mean and variance for nonnormal data places constraints on the possible correlation models that simultaneously yield valid joint distributions and a desired conditional distributions. Thus, for example, aspiring for conditional Poisson variates that are marginally correlated according to a spherical spatial process might not be possible.
- Even if the joint distribution is feasible mathematically, it still can be out of reach computationally. When data are independent, conditional on the random effects, the marginal log likelihood can in principle be constructed by integrating out the random effects from the joint distribution. However, numerical integration is practical only when the number of random effects is small and when the data have a clustered (subject) structure.

Because of these special features of generalized linear mixed models, many estimation methods have been put forth in the literature. The two basic approaches are (1) to approximate the objective function and (2) to approximate the model. Algorithms in the second category can be expressed in terms of Taylor series (linearizations) and are hence also known as linearization methods. They employ expansions to approximate the model by one based on pseudo-data with fewer nonlinear components. The process of computing the linear approximation must be repeated several times until some criterion indicates lack of further progress. Schabenberger and Gregoire (1996) list numerous algorithms based on Taylor series for the case of clustered data alone. The fitting methods based on linearizations are usually doubly iterative. The generalized linear mixed model is approximated by a linear mixed model based on current values of the covariance parameter estimates. The resulting linear mixed model is then fit, which is itself an iterative process. On convergence, the new parameter estimates are used to update the linearization, which results in a new linear mixed model. The process stops when parameter estimates between successive linear mixed model fits change only within a specified tolerance.

Integral approximation methods approximate the log likelihood of the GLMM and submit the approximated function to numerical optimization. Various techniques are used to compute the approximation: Laplace methods, quadrature methods, Monte Carlo integration, and Markov chain Monte Carlo methods. The advantage of integral approximation methods is to provide an actual objective function for optimization. This enables you to perform likelihood ratio tests among nested models and to compute likelihood-based fit statistics. The estimation process is singly iterative. The disadvantage of integral approximation methods is the difficulty of accommodating crossed random effects and multiple subject effects, and the inability to accommodate R-side covariance structures, even only R-side overdispersion. The number of random effects should be small for integral approximation methods to be practically feasible.

The advantages of linearization-based methods include a relatively simple form of the linearized model that typically can be fit based on only the mean and variance in the linearized form. Models for which the joint distribution is difficult—or impossible—to ascertain can be fit with linearization-based approaches. Models with correlated errors, a large number of random effects, crossed random effects, and multiple types of subjects are thus excellent candidates for linearization methods. The disadvantages of this approach include the absence of a true objective function for the overall optimization process and potentially biased estimates, especially for binary data when the number of observations per subject is small (see the section “[Notes on Bias of Estimators](#)” on page 3066 for further comments and considerations about the bias of estimates in generalized linear mixed models). Because the objective function to be optimized after each linearization update depends on the current pseudo-data, objective functions are not comparable across linearizations. The estimation process can fail at both levels of the double iteration scheme.

By default the GLIMMIX procedure fits generalized linear mixed models based on linearizations. The default estimation method in GLIMMIX for models containing random effects is a technique known as

restricted pseudo-likelihood (RPL) (Wolfinger and O’Connell 1993) estimation with an expansion around the current estimate of the best linear unbiased predictors of the random effects (**METHOD=RSPL**).

Two maximum likelihood estimation methods based on integral approximation are available in the GLIMMIX procedure. If you choose **METHOD=LAPLACE** in a GLMM, the GLIMMIX procedure performs maximum likelihood estimation based on a Laplace approximation of the marginal log likelihood. See the section “[Maximum Likelihood Estimation Based on Laplace Approximation](#)” on page 3059 for details about the Laplace approximation with PROC GLIMMIX. If you choose **METHOD=QUAD** in the PROC GLIMMIX statement in a generalized linear mixed model, the GLIMMIX procedure estimates the model parameters by adaptive Gauss-Hermite quadrature. See the section “[Maximum Likelihood Estimation Based on Adaptive Quadrature](#)” on page 3062 for details about the adaptive Gauss-Hermite quadrature approximation with PROC GLIMMIX.

The following subsections discuss the three estimation methods in turn. Keep in mind that your modeling possibilities are increasingly restricted in the order of these subsections. For example, in the class of generalized linear mixed models, the pseudo-likelihood estimation methods place no restrictions on the covariance structure, and Laplace estimation adds restriction with respect to the R-side covariance structure. Adaptive quadrature estimation further requires a clustered data structure—that is, the data must be processed by subjects.

**Table 41.20** Model Restrictions Depending on Estimation Method

| Method     | Restriction                                                                      |
|------------|----------------------------------------------------------------------------------|
| RSPL, RMPL | None                                                                             |
| MSPL, MMPL | None                                                                             |
| LAPLACE    | No R-side effects                                                                |
| QUAD       | No R-side effects<br>Requires SUBJECT= effect<br>Requires processing by subjects |

## Pseudo-likelihood Estimation Based on Linearization

### The Pseudo-model

Recall from the section “[Notation for the Generalized Linear Mixed Model](#)” on page 2918 that

$$E[\mathbf{Y}|\boldsymbol{\gamma}] = \mathbf{g}^{-1}(\mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma}) = \mathbf{g}^{-1}(\boldsymbol{\eta}) = \boldsymbol{\mu}$$

where  $\boldsymbol{\gamma} \sim N(\mathbf{0}, \mathbf{G})$  and  $\text{Var}[\mathbf{Y}|\boldsymbol{\gamma}] = \mathbf{A}^{1/2}\mathbf{R}\mathbf{A}^{1/2}$ . Following Wolfinger and O’Connell (1993), a first-order Taylor series of  $\boldsymbol{\mu}$  about  $\tilde{\boldsymbol{\beta}}$  and  $\tilde{\boldsymbol{\gamma}}$  yields

$$\mathbf{g}^{-1}(\boldsymbol{\eta}) \doteq \mathbf{g}^{-1}(\tilde{\boldsymbol{\eta}}) + \tilde{\boldsymbol{\Delta}}\mathbf{X}(\boldsymbol{\beta} - \tilde{\boldsymbol{\beta}}) + \tilde{\boldsymbol{\Delta}}\mathbf{Z}(\boldsymbol{\gamma} - \tilde{\boldsymbol{\gamma}})$$

where

$$\tilde{\boldsymbol{\Delta}} = \left( \frac{\partial \mathbf{g}^{-1}(\boldsymbol{\eta})}{\partial \boldsymbol{\eta}} \right)_{\tilde{\boldsymbol{\beta}}, \tilde{\boldsymbol{\gamma}}}$$

is a diagonal matrix of derivatives of the conditional mean evaluated at the expansion locus. Rearranging terms yields the expression

$$\tilde{\boldsymbol{\Delta}}^{-1}(\boldsymbol{\mu} - \mathbf{g}^{-1}(\tilde{\boldsymbol{\eta}})) + \mathbf{X}\tilde{\boldsymbol{\beta}} + \mathbf{Z}\tilde{\boldsymbol{\gamma}} \doteq \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma}$$

The left side is the expected value, conditional on  $\boldsymbol{\gamma}$ , of

$$\tilde{\mathbf{A}}^{-1}(\mathbf{Y} - g^{-1}(\tilde{\boldsymbol{\eta}})) + \mathbf{X}\tilde{\boldsymbol{\beta}} + \mathbf{Z}\tilde{\boldsymbol{\gamma}} \equiv \mathbf{P}$$

and

$$\text{Var}[\mathbf{P}|\boldsymbol{\gamma}] = \tilde{\mathbf{A}}^{-1}\mathbf{A}^{1/2}\mathbf{R}\mathbf{A}^{1/2}\tilde{\mathbf{A}}^{-1}$$

You can thus consider the model

$$\mathbf{P} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$$

which is a linear mixed model with pseudo-response  $\mathbf{P}$ , fixed effects  $\boldsymbol{\beta}$ , random effects  $\boldsymbol{\gamma}$ , and  $\text{Var}[\boldsymbol{\epsilon}] = \text{Var}[\mathbf{P}|\boldsymbol{\gamma}]$ .

### Objective Functions

Now define

$$\mathbf{V}(\boldsymbol{\theta}) = \mathbf{Z}\mathbf{G}\mathbf{Z}' + \tilde{\mathbf{A}}^{-1}\mathbf{A}^{1/2}\mathbf{R}\mathbf{A}^{1/2}\tilde{\mathbf{A}}^{-1}$$

as the marginal variance in the linear mixed pseudo-model, where  $\boldsymbol{\theta}$  is the  $(q \times 1)$  parameter vector containing all unknowns in  $\mathbf{G}$  and  $\mathbf{R}$ . Based on this linearized model, an objective function can be defined, assuming that the distribution of  $\mathbf{P}$  is known. The GLIMMIX procedure assumes that  $\boldsymbol{\epsilon}$  has a normal distribution. The maximum log pseudo-likelihood (MxPL) and restricted log pseudo-likelihood (RxPL) for  $\mathbf{P}$  are then

$$l(\boldsymbol{\theta}, \mathbf{p}) = -\frac{1}{2} \log |\mathbf{V}(\boldsymbol{\theta})| - \frac{1}{2} \mathbf{r}'\mathbf{V}(\boldsymbol{\theta})^{-1}\mathbf{r} - \frac{f}{2} \log\{2\pi\}$$

$$l_R(\boldsymbol{\theta}, \mathbf{p}) = -\frac{1}{2} \log |\mathbf{V}(\boldsymbol{\theta})| - \frac{1}{2} \mathbf{r}'\mathbf{V}(\boldsymbol{\theta})^{-1}\mathbf{r} - \frac{1}{2} \log |\mathbf{X}'\mathbf{V}(\boldsymbol{\theta})^{-1}\mathbf{X}| - \frac{f-k}{2} \log\{2\pi\}$$

with  $\mathbf{r} = \mathbf{p} - \mathbf{X}(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}\mathbf{X}'\mathbf{V}^{-1}\mathbf{p}$ .  $f$  denotes the sum of the frequencies used in the analysis, and  $k$  denotes the rank of  $\mathbf{X}$ . The fixed-effects parameters  $\boldsymbol{\beta}$  are profiled from these expressions. The parameters in  $\boldsymbol{\theta}$  are estimated by the optimization techniques specified in the **NLOPTIONS** statement. The objective function for minimization is  $-2l(\boldsymbol{\theta}, \mathbf{p})$  or  $-2l_R(\boldsymbol{\theta}, \mathbf{p})$ . At convergence, the profiled parameters are estimated and the random effects are predicted as

$$\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{X})^{-1}\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{p}$$

$$\hat{\boldsymbol{\gamma}} = \hat{\mathbf{G}}\mathbf{Z}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\hat{\mathbf{r}}$$

With these statistics, the pseudo-response and error weights of the linearized model are recomputed and the objective function is minimized again. The predictors  $\hat{\boldsymbol{\gamma}}$  are the estimated BLUPs in the approximated linear model. This process continues until the relative change between parameter estimates at two successive (outer) iterations is sufficiently small. See the **PCONV=** option in the **PROC GLIMMIX** statement for the computational details about how the GLIMMIX procedure compares parameter estimates across optimizations.

If the conditional distribution contains a scale parameter  $\phi \neq 1$  (Table 41.19), the GLIMMIX procedure profiles this parameter in GLMMs from the log pseudo-likelihoods as well. To this end define

$$\mathbf{V}(\boldsymbol{\theta}^*) = \tilde{\mathbf{A}}^{-1}\mathbf{A}^{1/2}\mathbf{R}^*\mathbf{A}^{1/2}\tilde{\mathbf{A}}^{-1} + \mathbf{Z}\mathbf{G}^*\mathbf{Z}'$$

where  $\boldsymbol{\theta}^*$  is the covariance parameter vector with  $q - 1$  elements. The matrices  $\mathbf{G}^*$  and  $\mathbf{R}^*$  are appropriately reparameterized versions of  $\mathbf{G}$  and  $\mathbf{R}$ . For example, if  $\mathbf{G}$  has a variance component structure and  $\mathbf{R} = \phi\mathbf{I}$ , then  $\boldsymbol{\theta}^*$  contains ratios of the variance components and  $\phi$ , and  $\mathbf{R}^* = \mathbf{I}$ . The solution for  $\hat{\boldsymbol{\phi}}$  is

$$\hat{\boldsymbol{\phi}} = \hat{\mathbf{r}}'\mathbf{V}(\hat{\boldsymbol{\theta}}^*)^{-1}\hat{\mathbf{r}}/m$$

where  $m = f$  for MxPL and  $m = f - k$  for RxPL. Substitution into the previous functions yields the profiled log pseudo-likelihoods,

$$\begin{aligned} l(\boldsymbol{\theta}^*, \mathbf{p}) &= -\frac{1}{2} \log |\mathbf{V}(\boldsymbol{\theta}^*)| - \frac{f}{2} \log \{\mathbf{r}'\mathbf{V}(\boldsymbol{\theta}^*)^{-1}\mathbf{r}\} - \frac{f}{2} (1 + \log\{2\pi/f\}) \\ l_R(\boldsymbol{\theta}^*, \mathbf{p}) &= -\frac{1}{2} \log |\mathbf{V}(\boldsymbol{\theta}^*)| - \frac{f-k}{2} \log \{\mathbf{r}'\mathbf{V}(\boldsymbol{\theta}^*)^{-1}\mathbf{r}\} \\ &\quad - \frac{1}{2} \log |\mathbf{X}'\mathbf{V}(\boldsymbol{\theta}^*)^{-1}\mathbf{X}| - \frac{f-k}{2} (1 + \log\{2\pi/(f-k)\}) \end{aligned}$$

Profiling of  $\phi$  can be suppressed with the **NOPROFILE** option in the **PROC GLIMMIX** statement.

Where possible, the objective function, its gradient, and its Hessian employ the sweep-based W-transformation ( Hemmerle and Hartley 1973; Goodnight 1979; Goodnight and Hemmerle 1979). Further details about the minimization process in the general linear mixed model can be found in Wolfinger, Tobias, and Sall (1994).

### Estimated Precision of Estimates

The GLIMMIX procedure produces estimates of the variability of  $\hat{\boldsymbol{\beta}}$ ,  $\hat{\boldsymbol{\theta}}$ , and estimates of the prediction variability for  $\hat{\boldsymbol{\gamma}}$ ,  $\text{Var}[\hat{\boldsymbol{\gamma}} - \boldsymbol{\gamma}]$ . Denote as  $\mathbf{S}$  the matrix

$$\mathbf{S} \equiv \widehat{\text{Var}}[\mathbf{P}|\boldsymbol{\gamma}] = \widetilde{\boldsymbol{\Delta}}^{-1}\mathbf{A}^{1/2}\mathbf{R}\mathbf{A}^{1/2}\widetilde{\boldsymbol{\Delta}}^{-1}$$

where all components on the right side are evaluated at the converged estimates. The mixed model equations (Henderson 1984) in the linear mixed (pseudo-)model are then

$$\begin{bmatrix} \mathbf{X}'\mathbf{S}^{-1}\mathbf{X} & \mathbf{X}'\mathbf{S}^{-1}\mathbf{Z} \\ \mathbf{Z}'\mathbf{S}^{-1}\mathbf{X} & \mathbf{Z}'\mathbf{S}^{-1}\mathbf{Z} + \mathbf{G}(\hat{\boldsymbol{\theta}})^{-1} \end{bmatrix} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\mathbf{S}^{-1}\mathbf{p} \\ \mathbf{Z}'\mathbf{S}^{-1}\mathbf{p} \end{bmatrix}$$

and

$$\begin{aligned} \mathbf{C} &= \begin{bmatrix} \mathbf{X}'\mathbf{S}^{-1}\mathbf{X} & \mathbf{X}'\mathbf{S}^{-1}\mathbf{Z} \\ \mathbf{Z}'\mathbf{S}^{-1}\mathbf{X} & \mathbf{Z}'\mathbf{S}^{-1}\mathbf{Z} + \mathbf{G}(\hat{\boldsymbol{\theta}})^{-1} \end{bmatrix}^{-1} \\ &= \begin{bmatrix} \hat{\boldsymbol{\Omega}} & -\hat{\boldsymbol{\Omega}}\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{Z}\mathbf{G}(\hat{\boldsymbol{\theta}}) \\ -\mathbf{G}(\hat{\boldsymbol{\theta}})\mathbf{Z}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{X}\hat{\boldsymbol{\Omega}} & \mathbf{M} + \mathbf{G}(\hat{\boldsymbol{\theta}})\mathbf{Z}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{X}\hat{\boldsymbol{\Omega}}\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{Z}\mathbf{G}(\hat{\boldsymbol{\theta}}) \end{bmatrix} \end{aligned}$$

is the approximate estimated variance-covariance matrix of  $[\hat{\boldsymbol{\beta}}', \hat{\boldsymbol{\gamma}}' - \boldsymbol{\gamma}']'$ . Here,  $\hat{\boldsymbol{\Omega}} = (\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{X})^{-1}$  and  $\mathbf{M} = (\mathbf{Z}'\mathbf{S}^{-1}\mathbf{Z} + \mathbf{G}(\hat{\boldsymbol{\theta}})^{-1})^{-1}$ .

The square roots of the diagonal elements of  $\widehat{\Omega}$  are reported in the Standard Error column of the “Parameter Estimates” table. This table is produced with the **SOLUTION** option in the **MODEL** statement. The prediction standard errors of the random-effects solutions are reported in the Std Err Pred column of the “Solution for Random Effects” table. This table is produced with the **SOLUTION** option in the **RANDOM** statement.

As a cautionary note, **C** tends to underestimate the true sampling variability of  $[\widehat{\beta}', \widehat{\gamma}']'$ , because no account is made for the uncertainty in estimating **G** and **R**. Although inflation factors have been proposed (Kackar and Harville 1984; Kass and Steffey 1989; Prasad and Rao 1990), they tend to be small for data sets that are fairly well balanced. PROC GLIMMIX does not compute any inflation factors by default. The **DDFM=KENWARDROGER** option in the **MODEL** statement prompts PROC GLIMMIX to compute a specific inflation factor (Kenward and Roger 1997), along with Satterthwaite-based degrees of freedom.

If  $\mathbf{G}(\widehat{\theta})$  is singular, or if you use the **CHOL** option of the **PROC GLIMMIX** statement, the mixed model equations are modified as follows. Let **L** denote the lower triangular matrix so that  $\mathbf{L}\mathbf{L}' = \mathbf{G}(\widehat{\theta})$ . PROC GLIMMIX then solves the equations

$$\begin{bmatrix} \mathbf{X}'\mathbf{S}^{-1}\mathbf{X} & \mathbf{X}'\mathbf{S}^{-1}\mathbf{Z}\mathbf{L} \\ \mathbf{L}'\mathbf{Z}'\mathbf{S}^{-1}\mathbf{X} & \mathbf{L}'\mathbf{Z}'\mathbf{S}^{-1}\mathbf{Z}\mathbf{L} + \mathbf{I} \end{bmatrix} \begin{bmatrix} \widehat{\beta} \\ \widehat{\tau} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\mathbf{S}^{-1}\mathbf{p} \\ \mathbf{L}'\mathbf{Z}'\mathbf{S}^{-1}\mathbf{p} \end{bmatrix}$$

and transforms  $\widehat{\tau}$  and a generalized inverse of the left-side coefficient matrix by using **L**.

The asymptotic covariance matrix of the covariance parameter estimator  $\widehat{\theta}$  is computed based on the observed or expected Hessian matrix of the optimization procedure. Consider first the case where the scale parameter  $\phi$  is not present or not profiled. Because  $\beta$  is profiled from the pseudo-likelihood, the objective function for minimization is  $f(\theta) = -2l(\theta, \mathbf{p})$  for **METHOD=MSPL** and **METHOD=MMPL** and  $f(\theta) = -2l_R(\theta, \mathbf{p})$  for **METHOD=RSPL** and **METHOD=RMPL**. Denote the observed Hessian (second derivative) matrix as

$$\mathbf{H} = \frac{\partial^2 f(\theta)}{\partial \theta \partial \theta'}$$

The GLIMMIX procedure computes the variance of  $\widehat{\theta}$  by default as  $2\mathbf{H}^{-1}$ . If the Hessian is not positive definite, a sweep-based generalized inverse is used instead. When the **EXPHESSIAN** option of the **PROC GLIMMIX** statement is used, or when the procedure is in scoring mode at convergence (see the **SCORING** option in the **PROC GLIMMIX** statement), the observed Hessian is replaced with an approximated expected Hessian matrix in these calculations.

Following Wolfinger, Tobias, and Sall (1994), define the following components of the gradient and Hessian in the optimization:

$$\begin{aligned} \mathbf{g}_1 &= \frac{\partial}{\partial \theta} \mathbf{r}'\mathbf{V}(\theta)^{-1}\mathbf{r} \\ \mathbf{H}_1 &= \frac{\partial^2}{\partial \theta \partial \theta'} \log\{\mathbf{V}(\theta)\} \\ \mathbf{H}_2 &= \frac{\partial^2}{\partial \theta \partial \theta'} \mathbf{r}'\mathbf{V}(\theta)^{-1}\mathbf{r} \\ \mathbf{H}_3 &= \frac{\partial^2}{\partial \theta \partial \theta'} \log\{|\mathbf{X}'\mathbf{V}(\theta)^{-1}\mathbf{X}|\} \end{aligned}$$

Table 41.21 gives expressions for the Hessian matrix  $\mathbf{H}$  depending on estimation method, profiling, and scoring.

**Table 41.21** Hessian Computation in GLIMMIX

| Profiling | Scoring  | MxPL                                                                                                                        | RxPL                                                                                                                                             |
|-----------|----------|-----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| No        | No       | $\mathbf{H}_1 + \mathbf{H}_2$                                                                                               | $\mathbf{H}_1 + \mathbf{H}_2 + \mathbf{H}_3$                                                                                                     |
| No        | Yes      | $-\mathbf{H}_1$                                                                                                             | $-\mathbf{H}_1 + \mathbf{H}_3$                                                                                                                   |
| No        | Modified | $-\mathbf{H}_1$                                                                                                             | $-\mathbf{H}_1 - \mathbf{H}_3$                                                                                                                   |
| Yes       | No       | $\begin{bmatrix} \mathbf{H}_1 + \mathbf{H}_2/\phi & -\mathbf{g}_2/\phi^2 \\ -\mathbf{g}'_2/\phi^2 & f/\phi^2 \end{bmatrix}$ | $\begin{bmatrix} \mathbf{H}_1 + \mathbf{H}_2/\phi + \mathbf{H}_3 & -\mathbf{g}_2/\phi^2 \\ -\mathbf{g}'_2/\phi^2 & (f - k)/\phi^2 \end{bmatrix}$ |
| Yes       | Yes      | $\begin{bmatrix} -\mathbf{H}_1 & -\mathbf{g}_2/\phi^2 \\ -\mathbf{g}'_2/\phi^2 & f/\phi^2 \end{bmatrix}$                    | $\begin{bmatrix} -\mathbf{H}_1 + \mathbf{H}_3 & -\mathbf{g}_2/\phi^2 \\ -\mathbf{g}'_2/\phi^2 & (f - k)/\phi^2 \end{bmatrix}$                    |
| Yes       | Modified | $\begin{bmatrix} -\mathbf{H}_1 & -\mathbf{g}_2/\phi^2 \\ -\mathbf{g}'_2/\phi^2 & f/\phi^2 \end{bmatrix}$                    | $\begin{bmatrix} -\mathbf{H}_1 - \mathbf{H}_3 & -\mathbf{g}_2/\phi^2 \\ -\mathbf{g}'_2/\phi^2 & (f - k)/\phi^2 \end{bmatrix}$                    |

The “Modified” expressions for the Hessian under scoring in RxPL estimation refer to a modified scoring method. In some cases, the modification leads to faster convergence than the standard scoring algorithm. The modification is requested with the SCOREMOD option in the PROC GLIMMIX statement.

Finally, in the case of a profiled scale parameter  $\phi$ , the Hessian for the  $(\theta^*, \phi)$  parameterization is converted into that for the  $\theta$  parameterization as

$$\mathbf{H}(\theta) = \mathbf{B}\mathbf{H}(\theta^*, \phi)\mathbf{B}'$$

where

$$\mathbf{B} = \begin{bmatrix} 1/\phi & 0 & \dots & 0 & 0 \\ 0 & 1/\phi & \dots & 0 & 0 \\ 0 & \dots & \dots & 1/\phi & 0 \\ -\theta_1^*/\phi & -\theta_2^*/\phi & \dots & -\theta_{q-1}^*/\phi & 1 \end{bmatrix}$$

**Subject-Specific and Population-Averaged (Marginal) Expansions**

There are two basic choices for the expansion locus of the linearization. A subject-specific (SS) expansion uses

$$\tilde{\boldsymbol{\beta}} = \hat{\boldsymbol{\beta}} \quad \tilde{\boldsymbol{\gamma}} = \hat{\boldsymbol{\gamma}}$$

which are the current estimates of the fixed effects and estimated BLUPs. The population-averaged (PA) expansion expands about the same fixed effects and the expected value of the random effects

$$\tilde{\boldsymbol{\beta}} = \hat{\boldsymbol{\beta}} \quad \tilde{\boldsymbol{\gamma}} = \mathbf{0}$$

To recompute the pseudo-response and weights in the SS expansion, the BLUPs must be computed every time the objective function in the linear mixed model is maximized. The PA expansion does not require any BLUPs. The four pseudo-likelihood methods implemented in the GLIMMIX procedure are the  $2 \times 2$  factorial combination between two expansion loci and residual versus maximum pseudo-likelihood estimation. The following table shows the combination and the corresponding values of the `METHOD=` option (PROC GLIMMIX statement); `METHOD=RSPL` is the default.

| Type of<br>PL | Expansion Locus             |                          |
|---------------|-----------------------------|--------------------------|
|               | $\hat{\boldsymbol{\gamma}}$ | $E[\boldsymbol{\gamma}]$ |
| residual      | RSPL                        | RMPL                     |
| maximum       | MSPL                        | MMPL                     |

## Maximum Likelihood Estimation Based on Laplace Approximation

### Objective Function

Let  $\boldsymbol{\beta}$  denote the vector of fixed-effects parameters and  $\boldsymbol{\theta}$  the vector of covariance parameters. For Laplace estimation in the GLIMMIX procedure,  $\boldsymbol{\theta}$  includes the G-side parameters and a possible scale parameter  $\phi$ , provided that the conditional distribution of the data contains such a scale parameter.  $\boldsymbol{\theta}^*$  is the vector of the G-side parameters.

The marginal distribution of the data in a mixed model can be expressed as

$$\begin{aligned} p(\mathbf{y}) &= \int p(\mathbf{y}|\boldsymbol{\gamma}, \boldsymbol{\beta}, \phi) p(\boldsymbol{\gamma}|\boldsymbol{\theta}^*) d\boldsymbol{\gamma} \\ &= \int \exp \{ \log \{ p(\mathbf{y}|\boldsymbol{\gamma}, \boldsymbol{\beta}, \phi) \} + \log \{ p(\boldsymbol{\gamma}|\boldsymbol{\theta}^*) \} \} d\boldsymbol{\gamma} \\ &= \int \exp \{ c_l f(\mathbf{y}, \boldsymbol{\beta}, \boldsymbol{\theta}; \boldsymbol{\gamma}) \} d\boldsymbol{\gamma} \end{aligned}$$

If the constant  $c_l$  is large, the Laplace approximation of this integral is

$$L(\boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}}, \mathbf{y}) = \left( \frac{2\pi}{c_l} \right)^{n_{\boldsymbol{\gamma}}/2} | -f''(\mathbf{y}, \boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}}) |^{-1/2} e^{c_l f(\mathbf{y}, \boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}})}$$

where  $n_{\boldsymbol{\gamma}}$  is the number of elements in  $\boldsymbol{\gamma}$ ,  $f''$  is the second derivative matrix

$$f''(\mathbf{y}, \boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}}) = \left. \frac{\partial^2 f(\mathbf{y}, \boldsymbol{\beta}, \boldsymbol{\theta}; \boldsymbol{\gamma})}{\partial \boldsymbol{\gamma} \partial \boldsymbol{\gamma}'} \right|_{\hat{\boldsymbol{\gamma}}}$$

and  $\hat{\boldsymbol{\gamma}}$  satisfies the first-order condition

$$\frac{\partial f(\mathbf{y}, \boldsymbol{\beta}, \boldsymbol{\theta}; \boldsymbol{\gamma})}{\partial \boldsymbol{\gamma}} = \mathbf{0}$$

The objective function for Laplace parameter estimation in the GLIMMIX procedure is  $-2 \log \{ L(\boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}}, \mathbf{y}) \}$ . The optimization process is singly iterative, but because  $\hat{\boldsymbol{\gamma}}$  depends on  $\hat{\boldsymbol{\beta}}$  and  $\hat{\boldsymbol{\theta}}$ , the GLIMMIX procedure solves a suboptimization problem to determine for given values of  $\hat{\boldsymbol{\beta}}$  and  $\hat{\boldsymbol{\theta}}$  the random-effects solution vector that maximizes  $f(\mathbf{y}, \boldsymbol{\beta}, \boldsymbol{\theta}; \boldsymbol{\gamma})$ .

When you have longitudinal or clustered data with  $m$  independent subjects or clusters, the vector of observations can be written as  $\mathbf{y} = [\mathbf{y}'_1, \dots, \mathbf{y}'_m]'$ , where  $\mathbf{y}_i$  is an  $n_i \times 1$  vector of observations for subject (cluster)  $i$  ( $i = 1, \dots, m$ ). In this case, assuming conditional independence such that

$$p(\mathbf{y}_i | \boldsymbol{\gamma}_i) = \prod_{j=1}^{n_i} p(y_{ij} | \boldsymbol{\gamma}_i)$$

the marginal distribution of the data can be expressed as

$$\begin{aligned} p(\mathbf{y}) &= \prod_{i=1}^m p(\mathbf{y}_i) = \prod_{i=1}^m \int p(\mathbf{y}_i | \boldsymbol{\gamma}_i) p(\boldsymbol{\gamma}_i) d\boldsymbol{\gamma}_i \\ &= \prod_{i=1}^m \int \exp\{n_i f(\mathbf{y}_i, \boldsymbol{\beta}, \boldsymbol{\theta}; \boldsymbol{\gamma}_i)\} d\boldsymbol{\gamma}_i \end{aligned}$$

where

$$\begin{aligned} n_i f(\mathbf{y}_i, \boldsymbol{\beta}, \boldsymbol{\theta}; \boldsymbol{\gamma}_i) &= \log\{p(\mathbf{y}_i | \boldsymbol{\gamma}_i) p(\boldsymbol{\gamma}_i)\} \\ &= \sum_{j=1}^{n_i} \log\{p(y_{ij} | \boldsymbol{\gamma}_i)\} + \log\{p(\boldsymbol{\gamma}_i)\} \end{aligned}$$

When the number of observations within a cluster,  $n_i$ , is large, the Laplace approximation to the  $i$ th individual's marginal probability density function is

$$\begin{aligned} p(\mathbf{y}_i | \boldsymbol{\beta}, \boldsymbol{\theta}) &= \int \exp\{n_i f(\mathbf{y}_i, \boldsymbol{\beta}, \boldsymbol{\theta}; \boldsymbol{\gamma}_i)\} d\boldsymbol{\gamma}_i \\ &= \frac{(2\pi)^{n_\gamma} / 2}{|-n_i f''(\mathbf{y}_i, \boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}}_i)|^{1/2}} \exp\{n_i f(\mathbf{y}_i, \boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}}_i)\} \end{aligned}$$

where  $n_{\boldsymbol{\gamma}_i}$  is the common dimension of the random effects,  $\boldsymbol{\gamma}_i$ . In this case, provided that the constant  $c_l = \min\{n_i\}$  is large, the Laplace approximation to the marginal log likelihood is

$$\begin{aligned} \log\{L(\boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}}, \mathbf{y})\} &= \sum_{i=1}^m \left\{ n_i f(\mathbf{y}_i, \boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}}_i) + \frac{n_{\boldsymbol{\gamma}_i}}{2} \log\{2\pi\} \right. \\ &\quad \left. - \frac{1}{2} \log |-n_i f''(\boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}}_i)| \right\} \end{aligned}$$

which serves as the objective function for the **METHOD=LAPLACE** estimator in PROC GLIMMIX.

The Laplace approximation implemented in the GLIMMIX procedure differs from that in Wolfinger (1993) and Pinheiro and Bates (1995) in important respects. Wolfinger (1993) assumed a flat prior for  $\boldsymbol{\beta}$  and expanded the integrand around  $\boldsymbol{\beta}$  and  $\boldsymbol{\gamma}$ , leaving only the covariance parameters for the overall optimization. The “fixed” effects  $\boldsymbol{\beta}$  and the random effects  $\boldsymbol{\gamma}$  are determined in a suboptimization that takes the form of a linear mixed model step with pseudo-data. The GLIMMIX procedure involves only the random effects vector  $\boldsymbol{\gamma}$  in the suboptimization. Pinheiro and Bates (1995) and Wolfinger (1993) consider a modified Laplace approximation that replaces the second derivative  $f''(\mathbf{y}, \boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}})$  with an (approximate) expected value, akin to scoring. The GLIMMIX procedure does not use an approximation to  $f''(\mathbf{y}, \boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}})$ . The **METHOD=RSPL** estimates in PROC GLIMMIX are equivalent to the estimates obtained with the modified Laplace approximation in Wolfinger (1993). The objective functions of **METHOD=RSPL** and Wolfinger (1993) differ in a constant that depends on the number of parameters.

### Asymptotic Properties and the Importance of Subjects

Suppose that the GLIMMIX procedure processes your data by subjects (see the section “Processing by Subjects” on page 3082) and let  $n_i$  denote the number of observations per subject,  $i = 1, \dots, s$ . Arguments in Vonesh (1996) show that the maximum likelihood estimator based on the Laplace approximation is a consistent estimator to order  $O_p\{\max\{1/\sqrt{s}\}, 1/\min\{n_i\}\}$ . In other words, as the number of subjects and the number of observations per subject grows, the small-sample bias of the Laplace estimator disappears. Note that the term involving the number of subjects in this maximum relates to standard asymptotic theory, and the term involving the number of observations per subject relates to the accuracy of the Laplace approximation (Vonesh 1996). In the case where random effects enter the model linearly, the Laplace approximation is exact and the requirement that  $\min\{n_i\} \rightarrow \infty$  can be dropped.

If your model is not processed by subjects but is equivalent to a subject model, the asymptotics with respect to  $s$  still apply, because the Hessian matrix of the suboptimization for  $\boldsymbol{y}$  breaks into  $s$  separate blocks. For example, the following two models are equivalent with respect to  $s$  and  $n_i$ , although only for the first model does PROC GLIMMIX process the data explicitly by subjects:

```
proc glimmix method=laplace;
 class sub A;
 model y = A;
 random intercept / subject=sub;
run;

proc glimmix method=laplace;
 class sub A;
 model y = A;
 random sub;
run;
```

The same holds, for example, for models with independent nested random effects. The following two models are equivalent, and you can derive asymptotic properties related to  $s$  and  $\min\{n_i\}$  from the model in the first run:

```
proc glimmix method=laplace;
 class A B block;
 model y = A B A*B;
 random intercept A / subject=block;
run;

proc glimmix method=laplace;
 class A B block;
 model y = A B A*B;
 random block a*block;
run;
```

The Laplace approximation requires that the dimension of the integral does not increase with the size of the sample. Otherwise the error of the likelihood approximation does not diminish with  $n_i$ . This is the case, for example, with exchangeable arrays (Shun and McCullagh 1995), crossed random effects (Shun 1997), and correlated random effects of arbitrary dimension (Raudenbush, Yang, and Yosef 2000). Results in Shun (1997), for example, show that even in this case the standard Laplace approximation has smaller bias than pseudo-likelihood estimates.

## Maximum Likelihood Estimation Based on Adaptive Quadrature

Quadrature methods, like the Laplace approximation, approximate integrals. If you choose `METHOD=QUAD` for a generalized linear mixed model, the GLIMMIX procedure approximates the marginal log likelihood with an adaptive Gauss-Hermite quadrature rule. Gaussian quadrature is particularly well suited to numerically evaluate integrals against probability measures (Lange 1999, Ch. 16). And Gauss-Hermite quadrature is appropriate when the density has kernel  $\exp\{-x^2\}$  and integration extends over the real line, as is the case for the normal distribution. Suppose that  $p(x)$  is a probability density function and the function  $f(x)$  is to be integrated against it. Then the quadrature rule is

$$\int_{-\infty}^{\infty} f(x)p(x) dx \approx \sum_{i=1}^N w_i f(x_i)$$

where  $N$  denotes the number of quadrature points, the  $w_i$  are the quadrature weights, and the  $x_i$  are the abscissas. The Gaussian quadrature chooses abscissas in areas of high density, and if  $p(x)$  is continuous, the quadrature rule is exact if  $f(x)$  is a polynomial of up to degree  $2N - 1$ . In the generalized linear mixed model the roles of  $f(x)$  and  $p(x)$  are played by the conditional distribution of the data given the random effects, and the random-effects distribution, respectively. Quadrature abscissas and weights are those of the standard Gauss-Hermite quadrature (Golub and Welsch 1969; see also Table 25.10 of Abramowitz and Stegun 1972; Evans 1993).

A numerical integration rule is called adaptive when it uses a variable step size to control the error of the approximation. For example, an adaptive trapezoidal rule uses serial splitting of intervals at midpoints until a desired tolerance is achieved. The quadrature rule in the GLIMMIX procedure is adaptive in the following sense: if you do not specify the number of quadrature points (nodes) with the `QPOINTS=` suboption of the `METHOD=QUAD` option, then the number of quadrature points is determined by evaluating the log likelihood at the starting values at a successively larger number of nodes until a tolerance is met (for more details see the text under the heading “Starting Values” in the next section). Furthermore, the GLIMMIX procedure centers and scales the quadrature points by using the empirical Bayes estimates (EBEs) of the random effects and the Hessian (second derivative) matrix from the EBE suboptimization. This centering and scaling improves the likelihood approximation by placing the abscissas according to the density function of the random effects. It is not, however, adaptiveness in the previously stated sense.

### Objective Function

Let  $\boldsymbol{\beta}$  denote the vector of fixed-effects parameters and  $\boldsymbol{\theta}$  the vector of covariance parameters. For quadrature estimation in the GLIMMIX procedure,  $\boldsymbol{\theta}$  includes the G-side parameters and a possible scale parameter  $\phi$ , provided that the conditional distribution of the data contains such a scale parameter.  $\boldsymbol{\theta}^*$  is the vector of the G-side parameters. The marginal distribution of the data for subject  $i$  in a mixed model can be expressed as

$$p(\mathbf{y}_i) = \int \cdots \int p(\mathbf{y}_i | \boldsymbol{\gamma}_i, \boldsymbol{\beta}, \phi) p(\boldsymbol{\gamma}_i | \boldsymbol{\theta}^*) d\boldsymbol{\gamma}_i$$

Suppose  $N_q$  denotes the number of quadrature points in each dimension (for each random effect) and  $r$  denotes the number of random effects. For each subject, obtain the empirical Bayes estimates of  $\boldsymbol{\gamma}_i$  as the vector  $\hat{\boldsymbol{\gamma}}_i$  that minimizes

$$-\log \{p(\mathbf{y}_i | \boldsymbol{\gamma}_i, \boldsymbol{\beta}, \phi) p(\boldsymbol{\gamma}_i | \boldsymbol{\theta}^*)\} = f(\mathbf{y}_i, \boldsymbol{\beta}, \boldsymbol{\theta}; \boldsymbol{\gamma}_i)$$

If  $\mathbf{z} = [z_1, \dots, z_{N_q}]$  are the standard abscissas for Gauss-Hermite quadrature, and  $\mathbf{z}_j^* = [z_{j1}, \dots, z_{jr}]$  is a point on the  $r$ -dimensional quadrature grid, then the centered and scaled abscissas are

$$\mathbf{a}_j^* = \hat{\boldsymbol{\gamma}}_i + 2^{1/2} f''(\mathbf{y}_i, \boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}}_i)^{-1/2} \mathbf{z}_j^*$$

As for the Laplace approximation,  $f''$  is the second derivative matrix with respect to the random effects,

$$f''(\mathbf{y}_i, \boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}}_i) = \frac{\partial^2 f(\mathbf{y}_i, \boldsymbol{\beta}, \boldsymbol{\theta}; \boldsymbol{\gamma}_i)}{\partial \boldsymbol{\gamma}_i \partial \boldsymbol{\gamma}_i'} \Big|_{\hat{\boldsymbol{\gamma}}_i}$$

These centered and scaled abscissas, along with the Gauss-Hermite quadrature weights  $\mathbf{w} = [w_1, \dots, w_{N_q}]$ , are used to construct the  $r$ -dimensional integral by a sequence of one-dimensional rules

$$\begin{aligned} p(\mathbf{y}_i) &= \int \cdots \int p(\mathbf{y}_i | \boldsymbol{\gamma}_i, \boldsymbol{\beta}, \phi) p(\boldsymbol{\gamma}_i | \boldsymbol{\theta}^*) d\boldsymbol{\gamma}_i \\ &\approx 2^{r/2} |f''(\mathbf{y}_i, \boldsymbol{\beta}, \boldsymbol{\theta}; \hat{\boldsymbol{\gamma}}_i)|^{-1/2} \\ &\quad \sum_{j_1=1}^{N_q} \cdots \sum_{j_r=1}^{N_q} \left[ p(\mathbf{y}_i | \mathbf{a}_{j^*}, \boldsymbol{\beta}, \phi) p(\mathbf{a}_{j^*} | \boldsymbol{\theta}^*) \prod_{k=1}^r w_{j_k} \exp z_{j_k}^2 \right] \end{aligned}$$

The right-hand side of this expression, properly accumulated across subjects, is the objective function for adaptive quadrature estimation in the GLIMMIX procedure.

### Quadrature or Laplace Approximation

If you select the quadrature rule with a single quadrature point, namely

```
proc glimmix method=quad(qpoints=1);
```

the results will be identical to `METHOD=LAPLACE`. Computationally, the two methods are not identical, however. `METHOD=LAPLACE` can be applied to a considerably larger class of models. For example, crossed random effects, models without subjects, or models with non-nested subjects can be handled with the Laplace approximation but not with quadrature. Furthermore, `METHOD=LAPLACE` draws on a number of computational simplifications that can increase its efficiency compared to a quadrature algorithm with a single node. For example, the Laplace approximation is possible with unbounded covariance parameter estimates (`NOBOUND` option in the `PROC GLIMMIX` statement) and can permit certain types of negative definite or indefinite  $\mathbf{G}$  matrices. The adaptive quadrature approximation with scaled abscissas typically breaks down when  $\mathbf{G}$  is not at least positive semidefinite.

As the number of random effects grows—for example, if you have nested random effects—quadrature quickly becomes computationally infeasible, due to the high dimensionality of the integral. To this end it is worthwhile to clarify the issues of dimensionality and computational effort as related to the number of quadrature nodes. Suppose that the A effect has 4 levels and consider the following statements:

```
proc glimmix method=quad(qpoints=5);
 class A id;
 model y = / dist=negbin;
 random A / subject=id;
run;
```

For each subject, computing the marginal log likelihood requires the numerical evaluation of a four-dimensional integral. As part of this evaluation  $5^4 = 625$  conditional log likelihoods need to be computed for each observation on each pass through the data. As the number of quadrature points or the number of random effects increases, this constitutes a sizable computational effort. Suppose, for example, that an additional random effect with  $b = 2$  levels is added as an interaction. The following statements then require evaluation of  $5^{(4+8)} = 244140625$  conditional log likelihoods for each observation on each pass through the data:

```
proc glimmix method=quad(qpoints=5);
 class A B id;
 model y = / dist=negbin;
 random A A*B / subject=id;
run;
```

As the number of random effects increases, Laplace approximation presents a computationally more expedient alternative.

If you wonder whether `METHOD=LAPLACE` would present a viable alternative to a model that you can fit with `METHOD=QUAD`, the “Optimization Information” table can provide some insights. The table contains as its last entry the number of quadrature points determined by PROC GLIMMIX to yield a sufficiently accurate approximation of the log likelihood (at the starting values). In many cases, a single quadrature node is sufficient, in which case the estimates are identical to those of `METHOD=LAPLACE`.

## Aspects Common to Adaptive Quadrature and Laplace Approximation

### Estimated Precision of Estimates

Denote as  $\mathbf{H}$  the second derivative matrix

$$\mathbf{H} = -\frac{\partial^2 \log\{L(\boldsymbol{\beta}, \boldsymbol{\theta}, \hat{\boldsymbol{\gamma}})\}}{\partial[\boldsymbol{\beta}, \boldsymbol{\theta}] \partial[\boldsymbol{\beta}', \boldsymbol{\theta}']}$$

evaluated at the converged solution of the optimization process. Partition its inverse as

$$\mathbf{H}^{-1} = \begin{bmatrix} \mathbf{C}(\boldsymbol{\beta}, \boldsymbol{\beta}) & \mathbf{C}(\boldsymbol{\beta}, \boldsymbol{\theta}) \\ \mathbf{C}(\boldsymbol{\theta}, \boldsymbol{\beta}) & \mathbf{C}(\boldsymbol{\theta}, \boldsymbol{\theta}) \end{bmatrix}$$

For `METHOD=LAPLACE` and `METHOD=QUAD`, the GLIMMIX procedure computes  $\mathbf{H}$  by finite forward differences based on the analytic gradient of  $\log\{L(\boldsymbol{\beta}, \boldsymbol{\theta}, \hat{\boldsymbol{\gamma}})\}$ . The partition  $\mathbf{C}(\boldsymbol{\theta}, \boldsymbol{\theta})$  serves as the asymptotic covariance matrix of the covariance parameter estimates (`ASYCOV` option in the `PROC GLIMMIX` statement). The standard errors reported in the “Covariance Parameter Estimates” table are based on the diagonal entries of this partition.

If you request an empirical standard error matrix with the `EMPIRICAL` option in the `PROC GLIMMIX` statement, a likelihood-based sandwich estimator is computed based on the subject-specific gradients of the Laplace or quadrature approximation. The sandwich estimator then replaces  $\mathbf{H}^{-1}$  in calculations following convergence.

To compute the standard errors and prediction standard errors of linear combinations of  $\boldsymbol{\beta}$  and  $\boldsymbol{\gamma}$ , PROC GLIMMIX forms an approximate prediction variance matrix for  $[\hat{\boldsymbol{\beta}}, \hat{\boldsymbol{\gamma}}]'$  from

$$\mathbf{P} = \begin{bmatrix} \mathbf{H}^{-1} & \mathbf{H}^{-1} \left( \frac{\partial \hat{\boldsymbol{\gamma}}}{\partial[\boldsymbol{\beta}, \boldsymbol{\theta}]} \right) \\ \left( \frac{\partial \hat{\boldsymbol{\gamma}}}{\partial[\boldsymbol{\beta}', \boldsymbol{\theta}']} \right) \mathbf{H}^{-1} & \boldsymbol{\Gamma}^{-1} + \left( \frac{\partial \hat{\boldsymbol{\gamma}}}{\partial[\boldsymbol{\beta}', \boldsymbol{\theta}']} \right) \mathbf{H}^{-1} \left( \frac{\partial \hat{\boldsymbol{\gamma}}}{\partial[\boldsymbol{\beta}, \boldsymbol{\theta}]} \right) \end{bmatrix}$$

where  $\boldsymbol{\Gamma}$  is the second derivative matrix from the  $\boldsymbol{\gamma}$  suboptimization that maximizes  $f(\mathbf{y}, \boldsymbol{\beta}, \boldsymbol{\theta}; \boldsymbol{\gamma})$  for given values of  $\boldsymbol{\beta}$  and  $\boldsymbol{\theta}$ . The prediction variance submatrix for the random effects is based on approximating the conditional mean squared error of prediction as in Booth and Hobert (1998). Note that even in the normal linear mixed model, the approximate conditional prediction standard errors are not identical to the prediction standard errors you obtain by inversion of the mixed model equations.

### Conditional Fit and Output Statistics

When you estimate the parameters of a mixed model by Laplace approximation or quadrature, the GLIMMIX procedure displays fit statistics related to the marginal distribution as well as the conditional distribution  $p(\mathbf{y}|\hat{\boldsymbol{\gamma}}, \hat{\boldsymbol{\beta}}, \hat{\boldsymbol{\phi}})$ . For ODS purposes, the name of the “Conditional Fit Statistics” table is “CondFitStatistics.” Because the marginal likelihood is approximated numerically for these methods, statistics based on the marginal distribution are not available. Instead of the generalized Pearson chi-square statistic in the “Fit Statistics” table, PROC GLIMMIX reports the Pearson statistic of the conditional distribution in the “Conditional Fit Statistics” table.

The unavailability of the marginal distribution also affects the set of output statistics that can be produced with `METHOD=LAPLACE` and `METHOD=QUAD`. Output statistics and statistical graphics that depend on the marginal variance of the data are not available with these estimation methods.

### User-Defined Variance Function

If you provide your own variance function, PROC GLIMMIX generally assumes that the (conditional) distribution of the data is unknown. Laplace or quadrature estimation would then not be possible. When you specify a variance function with `METHOD=LAPLACE` or `METHOD=QUAD`, the procedure assumes that the conditional distribution is normal. For example, consider the following statements to fit a mixed model to count data:

```
proc glimmix method=laplace;
 class sub;
 variance = _phi_*_mu_;
 model count = x / s link=log;
 random int / sub=sub;
run;
```

The variance function and the link suggest an overdispersed Poisson model. The Poisson distribution cannot accommodate the extra scale parameter `_PHI_`, however. In this situation, the GLIMMIX procedure fits a mixed model with random intercepts, log link function, and variance function  $\phi\mu$ , assuming that the count variable is normally distributed, given the random effects.

### Starting Values

Good starting values for the fixed effects and covariance parameters are important for Laplace and quadrature methods because the process commences with a suboptimization in which the empirical Bayes estimates of the random effects must be obtained before the optimization can get under way. Furthermore, the starting values are important for the adaptive choice of the number of quadrature points.

If you choose `METHOD=LAPLACE` or `METHOD=QUAD` and you do not provide starting values for the covariance parameters through the `PARMS` statement, the GLIMMIX procedure determines starting values in the following steps.

1. A GLM is fit initially to obtain starting values for the fixed-effects parameters. No output is produced from this stage. The number of initial iterations of this GLM fit can be controlled with the `INITITER=` option in the `PROC GLIMMIX` statement. You can suppress this step with the `NOINITGLM` option in the `PROC GLIMMIX` statement.
2. Given the fixed-effects estimates, starting values for the covariance parameters are computed by a MIVQUE0 step (Goodnight 1978a).

3. For **METHOD=QUAD** you can follow these steps with several pseudo-likelihood updates to improve on the estimates and to obtain solutions for the random effects. The number of pseudo-likelihood steps is controlled by the **INITPL=** suboption of **METHOD=QUAD**.
4. For **METHOD=QUAD**, if you do not specify the number of quadrature points with the suboptions of the **METHOD** option, the GLIMMIX procedure attempts to determine a sufficient number of points adaptively as follows. Suppose that  $N_q$  denotes the number of nodes in each dimension. If  $N_{min}$  and  $N_{max}$  denote the values from the **QMIN=** and **QMAX=** suboptions, respectively, the sequence for values less than 11 is constructed in increments of 2 starting at  $N_{min}$ . Values greater than 11 are incremented in steps of  $r$ . The default value is  $r = 10$ . The default sequence, without specifying the **QMIN=**, **QMAX=**, or **QFAC=** option, is thus 1, 3, 5, 7, 9, 11, 21, 31. If the relative difference of the log-likelihood approximation for two values in the sequence is less than the **QTOL= $t$**  value (default  $t = 0.0001$ ), the GLIMMIX procedure uses the lesser value for  $N_q$  in the subsequent optimization. If the relative difference does not fall below the tolerance  $t$  for any two subsequent values in the sequence, no estimation takes place.

### Notes on Bias of Estimators

Generalized linear mixed models are nonlinear models, and the estimation techniques rely on approximations to the log likelihood or approximations of the model. It is thus not surprising that the estimates of the covariance parameters and the fixed effects are usually not unbiased. Whenever estimates are biased, questions arise about the magnitude of the bias, its dependence on other model quantities, and the order of the bias. The order is important because it determines how quickly the bias vanishes while some aspect of the data increases. Typically, studies of asymptotic properties in models for hierarchical data suppose that the number of subjects (clusters) tends to infinity while the size of the clusters is held constant or grows at a particular rate. Note that asymptotic results so established do not extend to designs with fully crossed random effects, for example.

The following paragraphs summarize some important findings from the literature regarding the bias in covariance parameter and fixed-effects estimates with pseudo-likelihood, Laplace, and adaptive quadrature methods. The remarks draw in particular on results in Breslow and Lin (1995); Lin and Breslow (1996); Pinheiro and Chao (2006). Breslow and Lin (1995); Lin and Breslow (1996) study the “worst case” scenario of binary responses in a matched-pairs design. Their models have a variance component structure, comprising either a single variance component (a subject-specific random intercept; Breslow and Lin 1995) or a diagonal  $\mathbf{G}$  matrix (Lin and Breslow 1996). They study the bias in the estimates of the fixed-effects  $\boldsymbol{\beta}$  and the covariance parameters  $\boldsymbol{\theta}$  when the variance components are near the origin and for a canonical link function.

The matched-pairs design gives rise to a generalized linear mixed model with a cluster (subject) size of 2. Recall that the pseudo-likelihood methods rely on a linearization and a probabilistic assumption that the pseudo-data so obtained follow a normal linear mixed model. Obviously, it is difficult to imagine how the subject-specific (conditional) distribution would follow a normal linear mixed models with binary data in a cluster size of 2. The bias in the pseudo-likelihood estimator of  $\boldsymbol{\beta}$  is of order  $\|\boldsymbol{\theta}\|$ . The bias for the Laplace estimator of  $\boldsymbol{\beta}$  is of smaller magnitude; its asymptotic bias has order  $\|\boldsymbol{\theta}\|^2$ .

The Laplace methods and the pseudo-likelihood method produce biased estimators of the variance component  $\theta$  for the model considered in Breslow and Lin (1995). The order of the asymptotic bias for both estimation methods is  $\theta$ , as  $\theta$  approaches zero. Breslow and Lin (1995) comment on the fact that even with matched pairs, the bias vanishes very quickly in the binomial setting. If the conditional mean in the two

groups is equal to 0.5, then the asymptotic bias factor of the pseudo-likelihood estimator is  $1 - 1/(2n)$ , where  $n$  is the binomial denominator. This term goes to 1 quickly as  $n$  increases. This result underlines the importance of grouping binary observations into binomial responses whenever possible.

The results of Breslow and Lin (1995) and Lin and Breslow (1996) are echoed in the simulation study in Pinheiro and Chao (2006). These authors also consider adaptive quadrature in models with nested, hierarchical, random effects and show that adaptive quadrature with a sufficient number of nodes leads to nearly unbiased—or least biased—estimates. Their results also show that results for binary data cannot so easily be ported to other distributions. Even with a cluster size of 2, the pseudo-likelihood estimates of fixed effects and covariance parameters are virtually unbiased in their simulation of a Poisson GLMM. Breslow and Lin (1995) and Lin and Breslow (1996) “eschew” the residual PL version (**METHOD=RSPL**) over the maximum likelihood form (**METHOD=MSPL**). Pinheiro and Chao (2006) consider both forms in their simulation study. As expected, the residual form shows less bias than the MSPL form, for the same reasons REML estimation leads to less biased estimates compared to ML estimation in linear mixed models. The gain is modest, however; see, for example, Table 1 in Pinheiro and Chao (2006). When the variance components are small, there is a sufficient number of observations per cluster, and a reasonable number of clusters, then pseudo-likelihood methods for binary data are very useful—they provide a computational expedient alternative to numerical integration, and they allow the incorporation of R-side covariance structure into the model. Because many group randomized trials involve many observations per group and small random effects variances, Murray, Varnell, and Blitstein (2004) term questioning the use of conditional models for trials with binary outcome an “overreaction.”

---

## GLM Mode or GLMM Mode

The GLIMMIX procedure knows two basic modes of parameter estimation, and it can be important for you to understand the differences between the two modes.

In GLM mode, the data are never correlated and there can be no G-side random effects. Typical examples are logistic regression and normal linear models. When you fit a model in GLM mode, the **METHOD=** option in the PROC GLIMMIX statement has no effect. PROC GLIMMIX estimates the parameters of the model by maximum likelihood, (restricted) maximum likelihood, or quasi-likelihood, depending on the distributional properties of the model (see the section “[Default Estimation Techniques](#)” on page 3106). The “Model Information” table tells you which estimation method was applied. In GLM mode, the individual observations are considered the sampling units. This has bearing, for example, on how sandwich estimators are computed (see the **EMPIRICAL** option and the section “[Empirical Covariance \(“Sandwich”\) Estimators](#)” on page 3078).

In GLMM mode, the procedure assumes that the model contains random effects or possibly correlated errors, or that the data have a clustered structure. The parameters are then estimated by the techniques specified with the **METHOD=** option in the PROC GLIMMIX statement.

In general, adding one overdispersion parameter to a generalized linear model does not trigger the GLMM mode. For example, the model defined by the following statements is fit in GLM mode:

```
proc glimmix;
 model y = x1 x2 / dist=poisson;
 random _residual_;
run;
```

The parameters of the fixed effects are estimated by maximum likelihood, and the covariance matrix of the fixed-effects parameters is adjusted by the overdispersion parameter.

In a model with uncorrelated data you can trigger the GLMM mode by specifying a **SUBJECT=** or **GROUP=** effect in the **RANDOM** statement. For example, the following statements fit the model by using the residual pseudo-likelihood algorithm:

```
proc glimmix;
 class id;
 model y = x1 x2 / dist=poisson;
 random _residual_ / subject=id;
run;
```

If in doubt, you can determine whether a model was fit in GLM mode or GLMM mode. In GLM mode the “Covariance Parameter Estimates” table is not produced. Scale and dispersion parameters in the model appear in the “Parameter Estimates” table.

## Statistical Inference for Covariance Parameters

### The Likelihood Ratio Test

The likelihood ratio test (LRT) compares the likelihoods of two models where parameter estimates are obtained in two parameter spaces, the space  $\Omega$  and the restricted subspace  $\Omega_0$ . In the GLIMMIX procedure, the full model defines  $\Omega$  and the *test-specification* in the **COVTEST** statement determines the null parameter space  $\Omega_0$ . The likelihood ratio procedure consists of the following steps (see, for example, Bickel and Doksum 1977, p. 210):

1. Find the estimate  $\hat{\theta}$  of  $\theta \in \Omega$ . Compute the likelihood  $L(\hat{\theta})$ .
2. Find the estimate  $\hat{\theta}_0$  of  $\theta \in \Omega_0$ . Compute the likelihood  $L(\hat{\theta}_0)$ .
3. Form the likelihood ratio

$$\bar{\lambda} = \frac{L(\hat{\theta})}{L(\hat{\theta}_0)}$$

4. Find a function  $f(\bar{\lambda})$  that has a known distribution.  $f(\cdot)$  serves as the test statistic for the likelihood ratio test.

Please note the following regarding the implementation of these steps in the **COVTEST** statement of the GLIMMIX procedure.

- The function  $f(\cdot)$  in step 4 is always taken to be

$$\lambda = 2 \log \left\{ \bar{\lambda} \right\}$$

which is twice the difference between the log likelihoods for the full model and the model under the **COVTEST** restriction.

- For `METHOD=RSPL` and `METHOD=RMPL`, the test statistic is based on the restricted likelihood.
- For GLMMs involving pseudo-data, the test statistics are based on the pseudo-likelihood or the restricted pseudo-likelihood and are based on the final pseudo-data.
- The parameter space  $\Omega$  for the full model is typically not an unrestricted space. The GLIMMIX procedure imposes boundary constraints for variance components and scale parameters, for example. The specification of the subspace  $\Omega_0$  must be consistent with these full-model constraints; otherwise the test statistic  $\lambda$  does not have the needed distribution. You can remove the boundary restrictions with the `NOBOUND` option in the `PROC GLIMMIX` statement or the `NOBOUND` option in the `PARMS` statement.

### One- and Two-Sided Testing, Mixture Distributions

Consider testing the hypothesis  $H_0: \theta_i = 0$ . If  $\Omega$  is the open interval  $(0, \infty)$ , then only a one-sided alternative hypothesis is meaningful,

$$H_0: \theta_i = 0 \quad H_a: \theta_i > 0$$

This is the appropriate set of hypotheses, for example, when  $\theta_i$  is the variance of a G-side random effect. The positivity constraint on  $\Omega$  is required for valid conditional and marginal distributions of the data. Verbeke and Molenberghs (2003) refer to this situation as the constrained case.

However, if one focuses on the validity of the marginal distribution alone, then negative values for  $\theta_i$  might be permissible, provided that the marginal variance remains positive definite. In the vernacular or Verbeke and Molenberghs (2003), this is the unconstrained case. The appropriate alternative hypothesis is then two-sided,

$$H_0: \theta_i = 0 \quad H_a: \theta_i \neq 0$$

Several important issues are connected to the choice of hypotheses. The GLIMMIX procedure by default imposes constraints on some covariance parameters. For example, variances and scale parameters have a lower bound of 0. This implies a constrained setting with one-sided alternatives. If you specify the `NOBOUND` option in the `PROC GLIMMIX` statement, or the `NOBOUND` option in the `PARMS` statement, the boundary restrictions are lifted from the covariance parameters and the GLIMMIX procedure takes an unconstrained stance in the sense of Verbeke and Molenberghs (2003). The alternative hypotheses for variance components are then two-sided.

When  $H_0: \theta_i = 0$  and  $\Omega = (0, \infty)$ , the value of  $\theta_i$  under the null hypothesis is on the boundary of the parameter space. The distribution of the likelihood ratio test statistic  $\lambda$  is then nonstandard. In general, it is a mixture of distributions, and in certain special cases, it is a mixture of central chi-square distributions. Important contributions to the understanding of the asymptotic behavior of the likelihood ratio and score test statistic in this situation have been made by, for example, Self and Liang (1987); Shapiro (1988); Silvapulle and Silvapulle (1995). Stram and Lee (1994, 1995) applied the results of Self and Liang (1987) to likelihood ratio testing in the mixed model with uncorrelated errors. Verbeke and Molenberghs (2003) compared the score and likelihood ratio tests in random effects models with unstructured **G** matrix and provide further results on mixture distributions.

The GLIMMIX procedure recognizes the following special cases in the computation of  $p$ -values ( $\hat{\lambda}$  denotes the realized value of the test statistic). Notice that the probabilities of general chi-square mixture distributions do not equal linear combination of central chi-square probabilities (Davis 1977; Johnson, Kotz, and Balakrishnan 1994, Section 18.8).

1.  $\nu$  parameters are tested, and neither parameters specified under  $H_0$  nor nuisance parameters are on the boundary of the parameters space (Case 4 in Self and Liang 1987). The  $p$ -value is computed by the classical result:

$$p = \Pr\left(\chi_\nu^2 \geq \widehat{\lambda}\right)$$

2. One parameter is specified under  $H_0$  and it falls on the boundary. No other parameters are on the boundary (Case 5 in Self and Liang 1987).

$$p = \begin{cases} 1 & \widehat{\lambda} = 0 \\ 0.5 \Pr\left(\chi_1^2 \geq \widehat{\lambda}\right) & \widehat{\lambda} > 0 \end{cases}$$

Note that this implies a 50:50 mixture of a  $\chi_0^2$  and a  $\chi_1^2$  distribution. This is also Case 1 in Verbeke and Molenberghs (2000, p. 69).

3. Two parameters are specified under  $H_0$ , and one falls on the boundary. No nuisance parameters are on the boundary (Case 6 in Self and Liang 1987).

$$p = 0.5 \Pr\left(\chi_1^2 \geq \widehat{\lambda}\right) + 0.5 \Pr\left(\chi_2^2 \geq \widehat{\lambda}\right)$$

A special case of this scenario is the addition of a random effect to a model with a single random effect and unstructured covariance matrix (Case 2 in Verbeke and Molenberghs 2000, p. 70).

4. Removing  $j$  random effects from  $j + k$  uncorrelated random effects (Verbeke and Molenberghs 2003).

$$p = 2^{-j} \sum_{i=0}^j \binom{j}{i} \Pr\left(\chi_i^2 \geq \widehat{\lambda}\right)$$

Note that this case includes the case of testing a single random effects variance against zero, which leads to a 50:50 mixture of a  $\chi_0^2$  and a  $\chi_1^2$  as in 2.

5. Removing a random effect from an unstructured  $\mathbf{G}$  matrix (Case 3 in Verbeke and Molenberghs 2000, p. 71).

$$p = 0.5 \Pr\left(\chi_k^2 \geq \widehat{\lambda}\right) + 0.5 \Pr\left(\chi_{k-1}^2 \geq \widehat{\lambda}\right)$$

where  $k$  is the number of random effects (columns of  $\mathbf{G}$ ) in the full model. Case 5 in Self and Liang (1987) describes a special case.

When the GLIMMIX procedure determines that estimates of nuisance parameters (parameters not specified under  $H_0$ ) fall on the boundary, no mixture results are computed.

You can request that the procedure not use mixtures with the **CLASSICAL** option in the **COVTEST** statement. If mixtures are used, the Note column of the “Likelihood Ratio Tests of Covariance Parameters” table contains the “MI” entry. The “DF” entry is used when PROC GLIMMIX determines that the standard computation of  $p$ -values is appropriate. The “-” entry is used when the classical computation was used because the testing and model scenario does not match one of the special cases described previously.

## Handling the Degenerate Distribution

Likelihood ratio testing in mixed models invariably involves the chi-square distribution with zero degrees of freedom. The  $\chi_0^2$  random variable is degenerate at 0, and it occurs in two important circumstances. First, it is a component of mixtures, where typically the value of the test statistic is not zero. In that case, the contribution of the  $\chi_0^2$  component of the mixture to the  $p$ -value is nil. Second, a degenerate distribution of the test statistic occurs when the null model is identical to the full model—for example, if you test a hypothesis that does not impose any (new) constraints on the parameter space. The following statements test whether the **R** matrix in a variance component model is diagonal:

```
proc glimmix;
 class a b;
 model y = a;
 random b a*b;
 covtest diagR;
run;
```

Because no R-side covariance structure is specified (all random effects are G-side effects), the **R** matrix is diagonal in the full model and the **COVTEST** statement does not impose any further restriction on the parameter space. The likelihood ratio test statistic is zero. The **GLIMMIX** procedure computes the  $p$ -value as the probability to observe a value at least as large as the test statistic under the null hypothesis. Hence,

$$p = \Pr(\chi_0^2 \geq 0) = 1$$

## Wald Versus Likelihood Ratio Tests

The Wald test and the likelihood ratio tests are asymptotic tests, meaning that the distribution from which  $p$ -values are calculated for a finite number of samples draws on the distribution of the test statistic as the sample size grows to infinity. The Wald test is a simple test that is easy to compute based only on parameter estimates and their (asymptotic) standard errors. The likelihood ratio test, on the other hand, requires the likelihoods of the full model and the model reduced under  $H_0$ . It is computationally more demanding, but also provides the asymptotically more powerful and reliable test. The likelihood ratio test is almost always preferable to the Wald test, unless computational demands make it impractical to refit the model.

## Confidence Bounds Based on Likelihoods

Families of statistical tests can be inverted to produce confidence limits for parameters. The confidence region for parameter  $\theta$  is the set of values for which the corresponding test fails to reject  $H: \theta = \theta_0$ . When parameters are estimated by maximum likelihood or a likelihood-based technique, it is natural to consider the likelihood ratio test statistic for  $H$  in the test inversion. When there are multiple parameters in the model, however, you need to supply values for these nuisance parameters during the test inversion as well.

In the following, suppose that  $\theta$  is the covariance parameter vector and that one of its elements,  $\theta$ , is the parameter of interest for which you want to construct a confidence interval. The other elements of  $\theta$  are collected in the nuisance parameter vector  $\theta_2$ . Suppose that  $\hat{\theta}$  is the estimate of  $\theta$  from the overall optimization and that  $L(\hat{\theta})$  is the likelihood evaluated at that estimate. If estimation is based on pseudo-data, then  $L(\hat{\theta})$  is the pseudo-likelihood based on the final pseudo-data. If estimation uses a residual (restricted) likelihood, then  $L$  denotes the restricted maximum likelihood and  $\hat{\theta}$  is the REML estimate.

**Profile Likelihood Bounds**

The likelihood ratio test statistic for testing  $H: \theta = \theta_0$  is

$$2 \left\{ \log \left\{ L(\hat{\theta}) \right\} - \log \left\{ L(\theta_0, \hat{\theta}_2) \right\} \right\}$$

where  $\hat{\theta}_2$  is the likelihood estimate of  $\theta_2$  under the restriction that  $\theta = \theta_0$ . To invert this test, a function is defined that returns the maximum likelihood for a fixed value of  $\theta$  by seeking the maximum over the remaining parameters. This function is termed the profile likelihood (Pawitan 2001, Ch. 3.4),

$$\lambda_p = L(\theta_2|\tilde{\theta}) = \sup_{\theta_2} L(\tilde{\theta}, \theta_2)$$

In computing  $\lambda_p$ ,  $\theta$  is fixed at  $\tilde{\theta}$  and  $\theta_2$  is estimated. In mixed models, this step typically requires a separate, iterative optimization to find the estimate of  $\theta_2$  while  $\theta$  is held fixed. The  $(1 - \alpha) \times 100\%$  profile likelihood confidence interval for  $\theta$  is then defined as the set of values for  $\tilde{\theta}$  that satisfy

$$2 \left\{ \log \left\{ L(\hat{\theta}) \right\} - \log \left\{ L(\theta_2|\tilde{\theta}) \right\} \right\} \leq \chi_{1,(1-\alpha)}^2$$

The GLIMMIX procedure seeks the values  $\tilde{\theta}_l$  and  $\tilde{\theta}_u$  that mark the endpoints of the set around  $\hat{\theta}$  that satisfy the inequality. The values  $(\tilde{\theta}_l$  and  $\tilde{\theta}_u)$  are then called the  $(1 - \alpha) \times 100\%$  confidence bounds for  $\theta$ . Note that the GLIMMIX procedure assumes that the confidence region is not disjoint and relies on the convexity of  $L(\hat{\theta})$ .

It is not always possible to find values  $\tilde{\theta}_l$  and  $\tilde{\theta}_u$  that satisfy the inequalities. For example, when the parameter space is  $(0, \infty)$  and

$$2 \left\{ \log \left\{ L(\hat{\theta}) \right\} - \log \left\{ L(\theta_2|0) \right\} \right\} > \chi_{1,(1-\alpha)}^2$$

a lower bound cannot be found at the desired confidence level. The GLIMMIX procedure reports the right-tail probabilities that are achieved by the underlying likelihood ratio statistic separately for lower and upper bounds.

**Effect of Scale Parameter**

When a scale parameter  $\phi$  is eliminated from the optimization by profiling from the likelihood, some parameters might be expressed as ratios with  $\phi$  in the optimization. This is the case, for example, in variance component models. The profile likelihood confidence bounds are reported on the scale of the parameter in the overall optimization. In case parameters are expressed as ratios with  $\phi$  or functions of  $\phi$ , the column RatioEstimate is added to the “Covariance Parameter Estimates” table. If parameters are expressed as ratios with  $\phi$  and you want confidence bounds for the unscaled parameter, you can prevent profiling of  $\phi$  from the optimization with the NOPROFILE option in the PROC GLIMMIX statement, or choose estimated likelihood confidence bounds with the TYPE=ELR suboption of the CL option in the COVTEST statement. Note that the NOPROFILE option is automatically in effect with METHOD=LAPLACE and METHOD=QUAD.

**Estimated Likelihood Bounds**

Computing profile likelihood ratio confidence bounds can be computationally expensive, because of the need to repeatedly estimate  $\theta_2$  in a constrained optimization. A computationally simpler method to construct confidence bounds from likelihood-based quantities is to use the estimated likelihood (Pawitan 2001, Ch. 10.7) instead of the profile likelihood. An estimated likelihood technique replaces the nuisance parameters

in the test inversion with some other estimate. If you choose the TYPE=ELR suboption of the CL option in the COVTEST statement, the GLIMMIX procedure holds the nuisance parameters fixed at the likelihood estimates. The estimated likelihood statistic for inversion is then

$$\lambda_e = L(\tilde{\theta}, \hat{\theta}_2)$$

where  $\hat{\theta}_2$  are the elements of  $\hat{\theta}$  that correspond to the nuisance parameters. As the values of  $\tilde{\theta}$  are varied, no reestimation of  $\theta_2$  takes place. Although computationally more economical, estimated likelihood intervals do not take into account the variability associated with the nuisance parameters. Their coverage can be satisfactory if the parameter of interest is not (or only weakly) correlated with the nuisance parameters. Estimated likelihood ratio intervals can fall short of the nominal coverage otherwise.

Figure 41.11 depicts profile and estimated likelihood ratio intervals for the parameter  $\sigma$  in a two-parameter compound-symmetric model,  $\theta = [\sigma, \phi]'$ , in which the correlation between the covariance parameters is small. The elliptical shape traces the set of values for which the likelihood ratio test rejects the hypothesis of equality with the solution. The interior of the ellipse is the “acceptance” region of the test. The solid and dashed lines depict the PLR and ELR confidence limits for  $\sigma$ , respectively. Note that both confidence limits intersect the ellipse and that the ELR interval passes through the REML estimate of  $\phi$ . The PLR bounds are found as those points intersecting the ellipse, where  $\phi$  equals the constrained REML estimate.

**Figure 41.11** PLR and ELR Intervals, Small Correlation between Parameters

The major axes of the ellipse in Figure 41.11 are nearly aligned with the major axes of the coordinate system. As a consequence, the line connecting the PLR bounds passes close to the REML estimate in the full model. As a result, ELR bounds will be similar to PLR bounds. Figure 41.12 displays a different scenario, a two-parameter AR(1) covariance structure with a more substantial correlation between the AR(1) parameter ( $\rho$ ) and the residual variance ( $\phi$ ).

**Figure 41.12** PLR and ELR Intervals, Large Correlation between Parameters

The correlation between the parameters yields an acceptance region whose major axes are not aligned with the axes of the coordinate system. The ELR bound for  $\rho$  passes through the REML estimate of  $\phi$  from the full model and is much shorter than the PLR interval. The PLR interval aligns with the major axis of the acceptance region; it is the preferred confidence interval.

## Degrees of Freedom Methods

### Between-Within Degrees of Freedom Approximation

The `DDFM=BETWITHIN` option divides the residual degrees of freedom into between-subject and within-subject portions. PROC GLIMMIX then determines whether a fixed effect changes within any subject. If so, it assigns within-subject degrees of freedom to the effect; otherwise, it assigns the between-subject degrees of freedom to the effect (Schluchter and Elashoff 1990). If the GLIMMIX procedure does not process the data by subjects, the `DDFM=BETWITHIN` option has no effect. See the section “Processing by Subjects” on page 3082 for more information.

If multiple within-subject effects contain classification variables, the within-subject degrees of freedom are partitioned into components that correspond to the subject-by-effect interactions.

One exception to the preceding method is the case where you model only R-side covariation with an unstructured covariance matrix (`TYPE=UN`). In this case, all fixed effects are assigned the between-subject degrees of freedom to provide for better small-sample approximations to the relevant sampling distributions. The `DDFM=BETWITHIN` method is the default for models with only R-side random effects and a `SUBJECT=` option.

### Containment Degrees of Freedom Approximation

The `DDFM=CONTAIN` method is carried out as follows: Denote the fixed effect in question as *A* and search the G-side random effect list for the effects that *syntactically* contain *A*. For example, the effect *B(A)* contains *A*, but the effect *C* does not, even if it has the same levels as *B(A)*.

Among the random effects that contain *A*, compute their rank contributions to the  $[X \ Z]$  matrix (in order). The denominator degrees of freedom that is assigned to *A* is the smallest of these rank contributions. If no effects are found, the denominator degrees of freedom for *A* is set equal to the residual degrees of freedom,  $n - \text{rank}[X \ Z]$ . This choice of degrees of freedom is the same as for the tests performed for balanced split-plot designs and should be adequate for moderately unbalanced designs.

**NOTE:** If you have a *Z* matrix with a large number of columns, the overall memory requirements and the computing time after convergence can be substantial for the containment method. In this case, you might want to use a different degrees-of-freedom method, such as `DDFM=RESIDUAL`, `DDFM=NONE`, or `DDFM=BETWITHIN`.

### Satterthwaite Degrees of Freedom Approximation

The `DDFM=SATTERTHWAITE` option in the `MODEL` statement requests that denominator degrees of freedom in *t* tests and *F* tests be computed according to a general Satterthwaite approximation.

The general Satterthwaite approximation computed in PROC GLIMMIX for the test

$$H: \mathbf{L} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix} = \mathbf{0}$$

is based on the *F* statistic

$$F = \frac{\begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix}' \mathbf{L}' (\mathbf{LCL}')^{-1} \mathbf{L} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix}}{r}$$

where  $r = \text{rank}(\mathbf{LCL}')$  and  $\mathbf{C}$  is the approximate variance matrix of  $[\hat{\boldsymbol{\beta}}', \hat{\boldsymbol{\gamma}}' - \boldsymbol{\gamma}']'$ . See the section “Estimated Precision of Estimates” on page 3056 and the section “Aspects Common to Adaptive Quadrature and Laplace Approximation” on page 3064.

The approximation proceeds by first performing the spectral decomposition  $\mathbf{LCL}' = \mathbf{U}'\mathbf{D}\mathbf{U}$ , where  $\mathbf{U}$  is an orthogonal matrix of eigenvectors and  $\mathbf{D}$  is a diagonal matrix of eigenvalues, both of dimension  $r \times r$ . Define  $\mathbf{b}_j$  to be the  $j$ th row of  $\mathbf{UL}$ , and let

$$v_j = \frac{2(D_j)^2}{\mathbf{g}'_j \mathbf{A} \mathbf{g}_j}$$

where  $D_j$  is the  $j$ th diagonal element of  $\mathbf{D}$  and  $\mathbf{g}_j$  is the gradient of  $\mathbf{b}_j \mathbf{C} \mathbf{b}'_j$  with respect to  $\boldsymbol{\theta}$ , evaluated at  $\hat{\boldsymbol{\theta}}$ . The matrix  $\mathbf{A}$  is the asymptotic variance-covariance matrix of  $\hat{\boldsymbol{\theta}}$ , which is obtained from the second derivative matrix of the likelihood equations. You can display this matrix with the `ASYCOV` option in the `PROC GLIMMIX` statement.

Finally, let

$$E = \sum_{j=1}^r \frac{v_j}{v_j - 2} I(v_j > 2)$$

where the indicator function eliminates terms for which  $v_j \leq 2$ . The degrees of freedom for  $F$  are then computed as

$$\nu = \frac{2E}{E - \text{rank}(\mathbf{L})}$$

provided  $E > r$ ; otherwise  $\nu$  is set to 0.

In the one-dimensional case, when `PROC GLIMMIX` computes a  $t$  test, the Satterthwaite degrees of freedom for the  $t$  statistic

$$t = \frac{Y' \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix}}{Y' \mathbf{C} \mathbf{I}}$$

are computed as

$$\nu = \frac{2(Y' \mathbf{C} \mathbf{I})^2}{\mathbf{g}' \mathbf{A} \mathbf{g}}$$

where  $\mathbf{g}$  is the gradient of  $Y' \mathbf{C} \mathbf{I}$  with respect to  $\boldsymbol{\theta}$ , evaluated at  $\hat{\boldsymbol{\theta}}$ .

The calculation of Satterthwaite degrees of freedom requires extra memory to hold  $q$  matrices that are the size of the mixed model equations, where  $q$  is the number of covariance parameters. Extra computing time is also required to process these matrices. The implemented Satterthwaite method is intended to produce an accurate  $F$  approximation; however, the results can differ from those produced by `PROC GLM`. Also, the small-sample properties of this approximation have not been extensively investigated for the various models available with `PROC GLIMMIX`.

## Kenward-Roger Degrees of Freedom Approximation

The `DDFM=KENWARDROGER` option prompts PROC GLIMMIX to compute the denominator degrees of freedom in  $t$  tests and  $F$  tests by using the approximation described in Kenward and Roger (1997). For inference on the linear combination  $L\beta$  in a Gaussian linear model, they propose a scaled Wald statistic

$$F^* = \lambda F \\ = \frac{\lambda}{l} (\hat{\beta} - \beta)^T L (L^T \hat{\Phi}_A L)^{-1} L^T (\hat{\beta} - \beta),$$

where  $l = \text{rank}(L)$ ,  $\hat{\Phi}_A$  is a bias-adjusted estimator of the precision of  $\hat{\beta}$ , and  $0 < \lambda < 1$ . An appropriate  $F_{l,m}$  approximation to the sampling distribution of  $F^*$  is derived by matching the first two moments of  $F^*$  with those from the approximating  $F$  distribution and solving for the values of  $\lambda$  and  $m$ . The value of  $m$  thus derived is the Kenward-Roger degrees of freedom. The precision estimator  $\hat{\Phi}_A$  is bias-adjusted, in contrast to the conventional precision estimator  $\Phi(\hat{\sigma}) = (X'V(\hat{\sigma})^{-1}X)^{-1}$ , which is obtained by simply replacing  $\sigma$  with  $\hat{\sigma}$  in  $\Phi(\sigma)$ , the asymptotic variance of  $\hat{\beta}$ . This method uses  $\hat{\Phi}_A$  to address the fact that  $\Phi(\hat{\sigma})$  is a biased estimator of  $\Phi(\sigma)$ , and  $\Phi(\sigma)$  itself underestimates  $\text{var}(\hat{\beta})$  when  $\sigma$  is unknown. This bias-adjusted precision estimator is also discussed in Prasad and Rao (1990); Harville and Jeske (1992); Kackar and Harville (1984).

By default, the observed information matrix of the covariance parameter estimates is used in the calculations. For covariance structures that have nonzero second derivatives with respect to the covariance parameters, the Kenward-Roger covariance matrix adjustment includes a second-order term. This term can result in standard error shrinkage. Also, the resulting adjusted covariance matrix can then be indefinite and is not invariant under reparameterization. The `FIRSTORDER` suboption of the `DDFM=KENWARDROGER` option eliminates the second derivatives from the calculation of the covariance matrix adjustment. For scalar estimable functions, the resulting estimator is referred to as the Prasad-Rao estimator  $\tilde{m}^{\text{PR}}$  in Harville and Jeske (1992). You can use the `COVB(DETAILS)` option to diagnose the adjustments that PROC GLIMMIX makes to the covariance matrix of fixed-effects parameter estimates. An application with `DDFM=KENWARDROGER` is presented in Example 41.8. The following are examples of covariance structures that generally lead to nonzero second derivatives: `TYPE=ANTE(1)`, `TYPE=AR(1)`, `TYPE=ARH(1)`, `TYPE=ARMA(1,1)`, `TYPE=CHOL`, `TYPE=CSH`, `TYPE=FA0( $q$ )`, `TYPE=TOEPH`, `TYPE=UNR`, and all `TYPE=SP()` structures.

`DDFM=KENWARDROGER2` specifies an improved F approximation of the `DDFM=KENWARD-ROGER` type that uses a less biased precision estimator, as proposed by Kenward and Roger (2009). An important feature of the KR2 precision estimator is that it is invariant under reparameterization within the classes of intrinsically linear and intrinsically linear inverse covariance structures. For the invariance to hold within these two classes of covariance structures, a modified expected Hessian matrix is used in the computation of the covariance matrix of  $\sigma$ . The two cells classified as “Modified” scoring for RxPL estimation in Table 41.21 give the modified Hessian expressions for the cases where the scale parameter is profiled and not profiled. You can enforce the use of the modified expected Hessian matrix by specifying both the `EXPHESSIAN` and `SCOREMOD` options in the PROC GLIMMIX statement. Kenward and Roger (2009) note that for an intrinsically linear covariance parameterization, `DDFM=KR2` produces the same precision estimator as that obtained using `DDFM=KR(FIRSTORDER)`.

## Empirical Covariance (“Sandwich”) Estimators

### Residual-Based Estimators

The GLIMMIX procedure can compute the classical sandwich estimator of the covariance matrix of the fixed effects, as well as several bias-adjusted estimators. This requires that the model is either an (overdispersed) GLM or a GLMM that can be processed by subjects (see the section “Processing by Subjects” on page 3082).

Consider a statistical model of the form

$$\mathbf{Y} = \boldsymbol{\mu} + \boldsymbol{\epsilon}, \quad \boldsymbol{\epsilon} \sim (\mathbf{0}, \boldsymbol{\Sigma})$$

The general expression of a sandwich covariance estimator is then

$$c \times \widehat{\boldsymbol{\Omega}} \left( \sum_{i=1}^m \mathbf{A}_i \widehat{\mathbf{D}}_i' \widehat{\boldsymbol{\Sigma}}_i^{-1} \mathbf{F}_i' \mathbf{e}_i \mathbf{e}_i' \mathbf{F}_i \widehat{\boldsymbol{\Sigma}}_i^{-1} \widehat{\mathbf{D}}_i \mathbf{A}_i \right) \widehat{\boldsymbol{\Omega}}$$

where  $\mathbf{e}_i = \mathbf{y}_i - \widehat{\boldsymbol{\mu}}_i$ ,  $\boldsymbol{\Omega} = (\mathbf{D}'\boldsymbol{\Sigma}^{-1}\mathbf{D})^{-}$ .

For a GLMM estimated by one of the pseudo-likelihood techniques that involve linearization, you can make the following substitutions:  $\mathbf{Y} \rightarrow \mathbf{P}$ ,  $\boldsymbol{\Sigma} \rightarrow \mathbf{V}(\boldsymbol{\theta})$ ,  $\mathbf{D} \rightarrow \mathbf{X}$ ,  $\widehat{\boldsymbol{\mu}} \rightarrow \mathbf{X}\widehat{\boldsymbol{\beta}}$ . These matrices are defined in the section “Pseudo-likelihood Estimation Based on Linearization” on page 3054.

The various estimators computed by the GLIMMIX procedure differ in the choice of the constant  $c$  and the matrices  $\mathbf{F}_i$  and  $\mathbf{A}_i$ . You obtain the classical estimator, for example, with  $c = 1$ , and  $\mathbf{F}_i = \mathbf{A}_i$  equal to the identity matrix.

The **EMPIRICAL=ROOT** estimator of Kauermann and Carroll (2001) is based on the approximation

$$\text{Var}[\mathbf{e}_i \mathbf{e}_i'] \approx (\mathbf{I} - \mathbf{H}_i) \boldsymbol{\Sigma}_i$$

where  $\mathbf{H}_i = \mathbf{D}_i \boldsymbol{\Omega} \mathbf{D}_i' \boldsymbol{\Sigma}_i^{-1}$ . The **EMPIRICAL=FIRORES** estimator is based on the approximation

$$\text{Var}[\mathbf{e}_i \mathbf{e}_i'] \approx (\mathbf{I} - \mathbf{H}_i) \boldsymbol{\Sigma}_i (\mathbf{I} - \mathbf{H}_i')$$

of Mancl and DeRouen (2001). Finally, the **EMPIRICAL=FIROEEQ** estimator is based on approximating an unbiased estimating equation (Fay and Graubard 2001). For this estimator,  $\mathbf{A}_i$  is a diagonal matrix with entries

$$[\mathbf{A}_i]_{jj} = (1 - \min\{r, [\mathbf{Q}]_{jj}\})^{-1/2}$$

where  $\mathbf{Q} = \mathbf{D}_i' \widehat{\boldsymbol{\Sigma}}_i^{-1} \mathbf{D}_i \widehat{\boldsymbol{\Omega}}$ . The optional number  $0 \leq r < 1$  is chosen to provide an upper bound on the correction factor. For  $r = 0$ , the classical sandwich estimator results. PROC GLIMMIX chooses as default value  $r = 3/4$ . The diagonal entries of  $\mathbf{A}_i$  are then no greater than 2.

Table 41.22 summarizes the components of the computation for the GLMM based on linearization, where  $m$  denotes the number of subjects and  $k$  is the rank of  $\mathbf{X}$ .

**Table 41.22** Empirical Covariance Estimators for a Linearized GLMM

| EMPIRICAL= | $c$                                                                       | $A_i$                                                      | $F_i$                                 |
|------------|---------------------------------------------------------------------------|------------------------------------------------------------|---------------------------------------|
| CLASSICAL  | 1                                                                         | $\mathbf{I}$                                               | $\mathbf{I}$                          |
| DF         | $\begin{cases} \frac{m}{m-k} & m > k \\ 1 & \text{otherwise} \end{cases}$ | $\mathbf{I}$                                               | $\mathbf{I}$                          |
| ROOT       | 1                                                                         | $\mathbf{I}$                                               | $(\mathbf{I} - \mathbf{H}'_i)^{-1/2}$ |
| FIRORES    | 1                                                                         | $\mathbf{I}$                                               | $(\mathbf{I} - \mathbf{H}'_i)^{-1}$   |
| FIROEEQ(r) | 1                                                                         | $\text{Diag}\{(1 - \min\{r, [\mathbf{Q}]_{jj}\})^{-1/2}\}$ | $\mathbf{I}$                          |

Computation of an empirical variance estimator requires that the data can be processed by independent sampling units. This is always the case in GLMs. In this case,  $m$  equals the sum of all frequencies. In GLMMs, the empirical estimators require that the data consist of multiple subjects. In that case,  $m$  equals the number of subjects as per the “Dimensions” table. The following section discusses how the GLIMMIX procedure determines whether the data can be processed by subjects. The section “GLM Mode or GLMM Mode” on page 3067 explains how PROC GLIMMIX determines whether a model is fit in GLM mode or in GLMM mode.

### Design-Adjusted MBN Estimator

Morel (1989) and Morel, Bokossa, and Neerchal (2003) suggested a bias correction of the classical sandwich estimator that rests on an additive correction of the residual crossproducts and a sample size correction. This estimator is available with the EMPIRICAL=MBN option in the PROC GLIMMIX statement. In the notation of the previous section, the residual-based MBN estimator can be written as

$$\widehat{\Omega} \left( \sum_{i=1}^m \widehat{\mathbf{D}}'_i \widehat{\Sigma}_i^{-1} (c \mathbf{e}_i \mathbf{e}'_i + \mathbf{B}_i) \widehat{\Sigma}_i^{-1} \widehat{\mathbf{D}}_i \right) \widehat{\Omega}$$

where

- $c = (f - 1)/(f - k) \times m/(m - 1)$  or  $c = 1$  when you specify the EMPIRICAL=MBN(NODF) option
- $f$  is the sum of the frequencies
- $k$  equals the rank of  $\mathbf{X}$
- $\mathbf{B}_i = \delta_m \phi \widehat{\Sigma}_i$
- $\phi = \max \{r, \text{trace}(\widehat{\Omega} \mathbf{M}) / k^*\}$
- $\mathbf{M} = \sum_{i=1}^m \widehat{\mathbf{D}}'_i \widehat{\Sigma}_i^{-1} \mathbf{e}_i \mathbf{e}'_i \widehat{\Sigma}_i^{-1} \widehat{\mathbf{D}}_i$
- $k^* = k$  if  $m \geq k$ , otherwise  $k^*$  equals the number of nonzero singular values of  $\widehat{\Omega} \mathbf{M}$
- $\delta_m = k/(m - k)$  if  $m > (d + 1)k$  and  $\delta_m = 1/d$  otherwise
- $d \geq 1$  and  $0 \leq r \leq 1$  are parameters supplied with the *mbn-options* of the EMPIRICAL=MBN(*mbn-options*) option. The default values are  $d = 2$  and  $r = 1$ . When the NODF option is in effect, the factor  $c$  is set to 1.

Rearranging terms, the MBN estimator can also be written as an additive adjustment to a sample-size corrected classical sandwich estimator

$$c \times \widehat{\Omega} \left( \sum_{i=1}^m \widehat{D}_i' \widehat{\Sigma}_i^{-1} \mathbf{e}_i \mathbf{e}_i' \widehat{\Sigma}_i^{-1} \widehat{D}_i \right) \widehat{\Omega} + \delta_m \phi \widehat{\Omega}$$

Because  $\delta_m$  is of order  $m^{-1}$ , the additive adjustment to the classical estimator vanishes as the number of independent sampling units (subjects) increases. The parameter  $\phi$  is a measure of the design effect (Morel, Bokossa, and Neerchal 2003). Besides good statistical properties in terms of Type I error rates in small- $m$  situations, the MBN estimator also has the desirable property of recovering rank when the number of sampling units is small. If  $m < k$ , the “meat” piece of the classical sandwich estimator is essentially a sum of rank one matrices. A small number of subjects relative to the rank of  $\mathbf{X}$  can result in a loss of rank and subsequent loss of numerator degrees of freedom in tests. The additive MBN adjustment counters the rank exhaustion. You can examine the rank of an adjusted covariance matrix with the **COVB(Details)** option in the **MODEL** statement.

When the principle of the MBN estimator is applied to the likelihood-based empirical estimator, you obtain

$$\mathbf{H}(\widehat{\alpha})^{-1} \left( \sum_{i=1}^m c \mathbf{g}_i(\widehat{\alpha}) \mathbf{g}_i(\widehat{\alpha})' + \mathbf{B}_i \right) \mathbf{H}(\widehat{\alpha})^{-1}$$

where  $\mathbf{B}_i = -\delta_m \phi \mathbf{H}_i(\widehat{\alpha})$ , and  $\mathbf{H}_i(\widehat{\alpha})$  is the second derivative of the log likelihood for the  $i$ th sampling unit (subject) evaluated at the vector of parameter estimates,  $\widehat{\alpha}$ . Also,  $\mathbf{g}_i(\widehat{\alpha})$  is the first derivative of the log likelihood for the  $i$ th sampling unit. This estimator is computed if you request **EMPIRICAL=MBN** with **METHOD=LAPLACE** or **METHOD=QUAD**.

In terms of adjusting the classical likelihood-based estimator (White 1982), the likelihood MBN estimator can be written as

$$c \times \mathbf{H}(\widehat{\alpha})^{-1} \left( \sum_{i=1}^m \mathbf{g}_i(\widehat{\alpha}) \mathbf{g}_i(\widehat{\alpha})' \right) \mathbf{H}(\widehat{\alpha})^{-1} - \delta_m \phi \mathbf{H}(\widehat{\alpha})^{-1}$$

The parameter  $\phi$  is determined as

- $\phi = \max \{r, \text{trace}(-\mathbf{H}(\widehat{\alpha})^{-1} \mathbf{M}) / k^*\}$
- $\mathbf{M} = \sum_{i=1}^m \mathbf{g}_i(\widehat{\alpha}) \mathbf{g}_i(\widehat{\alpha})'$
- $k^* = k$  if  $m \geq k$ , otherwise  $k^*$  equals the number of nonzero singular values of  $-\mathbf{H}(\widehat{\alpha})^{-1} \mathbf{M}$

---

## Exploring and Comparing Covariance Matrices

If you use an empirical (sandwich) estimator with the **EMPIRICAL=** option in the **PROC GLIMMIX** statement, the procedure replaces the model-based estimator of the covariance of the fixed effects with the sandwich estimator. This affects aspects of inference, such as prediction standard errors, tests of fixed effects, estimates, contrasts, and so forth. Similarly, if you choose the **DDFM=KENWARDROGER** degrees-of-freedom method in the **MODEL** statement, **PROC GLIMMIX** adjusts the model-based covariance matrix

of the fixed effects according to Kenward and Roger (1997) or according to Kackar and Harville (1984) and Harville and Jeske (1992).

In this situation, the `COVB(Details)` option in the `MODEL` statement has two effects. The `GLIMMIX` procedure displays the (adjusted) covariance matrix of the fixed effects and the model-based covariance matrix (the ODS name of the table with the model-based covariance matrix is `CovBModelBased`). The procedure also displays a table of statistics for the unadjusted and adjusted covariance matrix and for their comparison. The ODS name of this table is `CovBDetails`.

If the model-based covariance matrix is not replaced with an adjusted estimator, the `COVB(Details)` option displays the model-based covariance matrix and provides diagnostic measures for it in the “CovB-Details” table.

The table generated by the `COVB(Details)` option consists of several sections. See [Example 41.8](#) for an application.

The trace and log determinant of covariance matrices are general scalar summaries that are sometimes used in direct comparisons, or in formulating other statistics, such as the difference of log determinants. The trace simply represents the sum of the variances of all fixed-effects parameters. If a matrix is indefinite, the determinant is reported instead of the log determinant.

The model-based and adjusted covariance matrices should have the same general makeup of eigenvalues. There should not be any negative eigenvalues, and they should have the same numbers of positive and zero eigenvalues. A reduction in rank due to the adjustment is troublesome for aspects of inference. Negative eigenvalues are listed in the table only if they occur, because a covariance matrix should be at least positive semi-definite. However, the `GLIMMIX` procedure examines the model-based and adjusted covariance matrix for negative eigenvalues. The condition numbers reported by `PROC GLIMMIX` for positive (semi-)definite matrices are computed as the ratio of the largest and smallest nonzero eigenvalue. A large condition number reflects poor conditioning of the matrix.

Matrix norms are extensions of the concept of vector norms to measure the “length” of a matrix. The Frobenius norm of an  $(n \times m)$  matrix  $\mathbf{A}$  is the direct equivalent of the Euclidean vector norm, the square root of the sum of the squared elements,

$$\|\mathbf{A}\|_F = \sqrt{\sum_{i=1}^n \sum_{j=1}^n a_{ij}^2}$$

The  $\infty$ - and 1-norms of matrix  $\mathbf{A}$  are the maximum absolute row and column sums, respectively:

$$\|\mathbf{A}\|_\infty = \max \left\{ \sum_{j=1}^m |a_{ij}| : i = 1, \dots, n \right\}$$

$$\|\mathbf{A}\|_1 = \max \left\{ \sum_{i=1}^n |a_{ij}| : j = 1, \dots, m \right\}$$

These two norms are identical for symmetric matrices.

The “Comparison” section of the “CovBDetails” table provides several statistics that set the matrices in relationship. The concordance correlation reported by the `GLIMMIX` procedure is a standardized measure

of the closeness of the model-based and adjusted covariance matrix. It is a slight modification of the covariance concordance correlation in Vonesh, Chinchilli, and Pu (1996) and Vonesh and Chinchilli (1997, Ch. 8.3). Denote as  $\mathbf{\Omega}$  the  $(p \times p)$  model-based covariance matrix and as  $\mathbf{\Omega}_a$  the adjusted matrix. Suppose that  $\mathbf{K}$  is the matrix obtained from the identity matrix of size  $p$  by replacing diagonal elements corresponding to singular rows in  $\mathbf{\Omega}$  with zeros. The lower triangular portion of  $\mathbf{\Omega}^{-1/2}\mathbf{\Omega}_a\mathbf{\Omega}^{-1/2}$  is stored in vector  $\boldsymbol{\omega}$  and the lower triangular portion of  $\mathbf{K}$  is stored in vector  $\mathbf{k}$ . The matrix  $\mathbf{\Omega}^{-1/2}$  is constructed from an eigenanalysis of  $\mathbf{\Omega}$  and is symmetric. The covariance concordance correlation is then

$$r(\boldsymbol{\omega}) = 1 - \frac{\|\boldsymbol{\omega} - \mathbf{k}\|^2}{\|\boldsymbol{\omega}\|^2 + \|\mathbf{k}\|^2}$$

This measure is 1 if  $\mathbf{\Omega} = \mathbf{\Omega}_a$ . If  $\boldsymbol{\omega}$  is orthogonal to  $\mathbf{k}$ , there is total disagreement between the model-based and the adjusted covariance matrix and  $r(\boldsymbol{\omega})$  is zero.

The discrepancy function reported by PROC GLIMMIX is computed as

$$d = \log\{|\mathbf{\Omega}|\} - \log\{|\mathbf{\Omega}_a|\} + \text{trace}\{\mathbf{\Omega}_a\mathbf{\Omega}^{-}\} - \text{rank}\{\mathbf{\Omega}\}$$

In diagnosing departures between an assumed covariance structure and  $\text{Var}[\mathbf{Y}]$ —using an empirical estimator—Vonesh, Chinchilli, and Pu (1996) find that the concordance correlation is useful in detecting gross departures and propose  $\lambda = n_s d$  to test the correctness of the assumed model, where  $n_s$  denotes the number of subjects.

## Processing by Subjects

Some mixed models can be expressed in different but mathematically equivalent ways with PROC GLIMMIX statements. While equivalent statements lead to equivalent statistical models, the data processing and estimation phase can be quite different, depending on how you write the GLIMMIX statements. For example, the particular use of the **SUBJECT=** option in the **RANDOM** statement affects data processing and estimation. Certain options are available only when the data are processed by subject, such as the **EMPIRICAL** option in the **PROC GLIMMIX** statement.

Consider a GLIMMIX model where variables **A** and **Rep** are classification variables with  $a$  and  $r$  levels, respectively. The following pairs of statements produce the same random-effects structure:

```
class Rep A;
random Rep*A;
```

```
class Rep A;
random intercept / subject=Rep*A;
```

```
class Rep A;
random Rep / subject=A;
```

```
class Rep A;
random A / subject=Rep;
```

In the first case, PROC GLIMMIX does not process the data by subjects because no **SUBJECT=** option was given. The computation of empirical covariance estimators, for example, will not be possible. The marginal variance-covariance matrix has the same block-diagonal structure as for cases 2–4, where each block consists of the observations belonging to a unique combination of **Rep** and **A**. More importantly, the dimension of the **Z** matrix of this model will be  $n \times ra$ , and **Z** will be sparse. In the second case, the **Z<sub>i</sub>** matrix for each of the  $ra$  subjects is a vector of ones.

If the data can be processed by subjects, the procedure typically executes faster and requires less memory. The differences can be substantial, especially if the number of subjects is large. Recall that fitting of generalized linear mixed models might be doubly iterative. Small gains in efficiency for any one optimization can produce large overall savings.

If you interpret the intercept as “1,” then a **RANDOM** statement with **TYPE=VC** (the default) and no **SUBJECT=** option can be converted into a statement with subject by dividing the random effect by the eventual subject effect. However, the presence of the **SUBJECT=** option does not imply processing by subject. If a **RANDOM** statement does not have a **SUBJECT=** effect, processing by subjects is not possible unless the random effect is a pure R-side overdispersion effect. In the following example, the data will not be processed by subjects, because the first **RANDOM** statement specifies a G-side component and does not use a **SUBJECT=** option:

```
proc glimmix;
 class A B;
 model y = B;
 random A;
 random B / subject=A;
run;
```

To allow processing by subjects, you can write the equivalent model with the following statements:

```
proc glimmix;
 class A B;
 model y = B;
 random int / subject=A;
 random B / subject=A;
run;
```

If you denote a variance component effect  $X$  with subject effect  $S$  as  $X-(S)$ , then the “calculus of random effects” applied to the first **RANDOM** statement reads  $A = \text{Int}^*A = \text{Int}-(A) = A-(\text{Int})$ . For the second statement there are even more equivalent formulations:  $A*B = A*B*\text{Int} = A*B-(\text{Int}) = A-(B) = B-(A) = \text{Int}-(A*B)$ .

If there are multiple subject effects, processing by subjects is possible if the effects are equal or contained in each other. Note that in the last example the  $A*B$  interaction is a random effect. The following statements give an equivalent specification to the previous model:

```
proc glimmix;
 class A B;
 model y = B;
 random int / subject=A;
 random A / subject=B;
run;
```

Processing by subjects is not possible in this case, because the two subject effects are not syntactically equal or contained in each other. The following statements depict a case where subject effects are syntactically contained:

```
proc glimmix;
 class A B;
 model y = B;
 random int / subject=A;
 random int / subject=A*B;
run;
```

The A main effect is contained in the A\*B interaction. The GLIMMIX procedure chooses as the subject effect for processing the effect that is contained in all other subject effects. In this case, the subjects are defined by the levels of A.

You can examine the “Model Information” and “Dimensions” tables to see whether the GLIMMIX procedure processes the data by subjects and which effect is used to define subjects. The “Model Information” table displays whether the marginal variance matrix is diagonal (GLM models), blocked, or not blocked. The “Dimensions” table tells you how many subjects (=blocks) there are.

Finally, nesting and crossing of interaction effects in subject effects are equivalent. The following two **RANDOM** statements are equivalent:

```
class Rep A;
random intercept / subject=Rep*A;

class Rep A;
random intercept / subject=Rep(A);
```

---

## Radial Smoothing Based on Mixed Models

The radial smoother implemented with the **TYPE=RSMOOTH** option in the **RANDOM** statement is an approximate low-rank thin-plate spline as described in Ruppert, Wand, and Carroll (2003, Chapter 13.4–13.5). The following sections discuss in more detail the mathematical-statistical connection between mixed models and penalized splines and the determination of the number of spline knots and their location as implemented in the GLIMMIX procedure.

### From Penalized Splines to Mixed Models

The connection between splines and mixed models arises from the similarity of the penalized spline fitting criterion to the minimization problem that yields the mixed model equations and solutions for  $\beta$  and  $\gamma$ . This connection is made explicit in the following paragraphs. An important distinction between classical spline fitting and its mixed model smoothing variant, however, lies in the nature of the spline coefficients. Although they address similar minimization criteria, the solutions for the spline coefficients in the GLIMMIX procedure are the solutions of random effects, not fixed effects. Standard errors of predicted values, for example, account for this source of variation.

Consider the linearized mixed pseudo-model from the section “The Pseudo-model” on page 3054,  $\mathbf{P} = \mathbf{X}\beta + \mathbf{Z}\gamma + \epsilon$ . One derivation of the mixed model equations, whose solutions are  $\hat{\beta}$  and  $\hat{\gamma}$ , is to maximize the joint density of  $f(\gamma, \epsilon)$  with respect to  $\beta$  and  $\gamma$ . This is not a true likelihood problem, because  $\gamma$  is not a parameter, but a random vector.

In the special case with  $\text{Var}[\epsilon] = \phi\mathbf{I}$  and  $\text{Var}[\gamma] = \sigma^2\mathbf{I}$ , the maximization of  $f(\gamma, \epsilon)$  is equivalent to the minimization of

$$Q(\beta, \gamma) = \phi^{-1}(\mathbf{p} - \mathbf{X}\beta - \mathbf{Z}\gamma)'(\mathbf{p} - \mathbf{X}\beta - \mathbf{Z}\gamma) + \sigma^{-2}\gamma'\gamma$$

Now consider a linear spline as in Ruppert, Wand, and Carroll (2003, p. 108),

$$p_i = \beta_0 + \beta_1 x_i + \sum_{j=1}^K \gamma_j (x_i - t_j)_+$$

where the  $\gamma_j$  denote the spline coefficients at knots  $t_1, \dots, t_K$ . The truncated line function is defined as

$$(x - t)_+ = \begin{cases} x - t & x > t \\ 0 & \text{otherwise} \end{cases}$$

If you collect the intercept and regressor  $x$  into the matrix  $\mathbf{X}$ , and if you collect the truncated line functions into the  $(n \times K)$  matrix  $\mathbf{Z}$ , then fitting the linear spline amounts to minimization of the penalized spline criterion

$$Q^*(\boldsymbol{\beta}, \boldsymbol{\gamma}) = (\mathbf{p} - \mathbf{X}\boldsymbol{\beta} - \mathbf{Z}\boldsymbol{\gamma})'(\mathbf{p} - \mathbf{X}\boldsymbol{\beta} - \mathbf{Z}\boldsymbol{\gamma}) + \lambda^2 \boldsymbol{\gamma}'\boldsymbol{\gamma}$$

where  $\lambda$  is the smoothing parameter.

Because minimizing  $Q^*(\boldsymbol{\beta}, \boldsymbol{\gamma})$  with respect to  $\boldsymbol{\beta}$  and  $\boldsymbol{\gamma}$  is equivalent to minimizing  $Q^*(\boldsymbol{\beta}, \boldsymbol{\gamma})/\phi$ , both problems lead to the same solution, and  $\lambda = \phi/\sigma$  is the smoothing parameter. The mixed model formulation of spline smoothing has the advantage that the smoothing parameter is selected “automatically.” It is a function of the covariance parameter estimates, which, in turn, are estimated according to the method you specify with the `METHOD=` option in the `PROC GLIMMIX` statement.

To accommodate nonnormal responses and general link functions, the GLIMMIX procedure uses  $\text{Var}[\boldsymbol{\epsilon}] = \phi \tilde{\boldsymbol{\Delta}}^{-1} \mathbf{A} \tilde{\boldsymbol{\Delta}}^{-1}$ , where  $\mathbf{A}$  is the matrix of variance functions and  $\boldsymbol{\Delta}$  is the diagonal matrix of mean derivatives defined earlier. The correspondence between spline smoothing and mixed modeling is then one between a weighted linear mixed model and a weighted spline. In other words, the minimization criterion that yields the estimates  $\hat{\boldsymbol{\beta}}$  and solutions  $\hat{\boldsymbol{\gamma}}$  is then

$$Q(\boldsymbol{\beta}, \boldsymbol{\gamma}) = \phi^{-1} (\mathbf{p} - \mathbf{X}\boldsymbol{\beta} - \mathbf{Z}\boldsymbol{\gamma})' \tilde{\boldsymbol{\Delta}} \mathbf{A}^{-1} \tilde{\boldsymbol{\Delta}} (\mathbf{p} - \mathbf{X}\boldsymbol{\beta} - \mathbf{Z}\boldsymbol{\gamma})' + \sigma^{-2} \boldsymbol{\gamma}'\boldsymbol{\gamma}$$

If you choose the `TYPE=RSMOOTH` covariance structure, PROC GLIMMIX chooses radial basis functions as the spline basis and transforms them to approximate a thin-plate spline as in Chapter 13.4 of Ruppert, Wand, and Carroll (2003). For computational expediency, the number of knots is chosen to be less than the number of data points. Ruppert, Wand, and Carroll (2003) recommend one knot per every four unique regressor values for one-dimensional smoothers. In the multivariate case, general recommendations are more difficult, because the optimal number and placement of knots depend on the spatial configuration of samples. Their recommendation for a bivariate smoother is one knot per four samples, but at least 20 and no more than 150 knots (Ruppert, Wand, and Carroll 2003, p. 257).

The magnitude of the variance component  $\sigma^2$  depends on the metric of the random effects. For example, if you apply radial smoothing in time, the variance changes if you measure time in days or minutes. If the solution for the variance component is near zero, then a rescaling of the random effect data can help the optimization problem by moving the solution for the variance component away from the boundary of the parameter space.

## Knot Selection

The GLIMMIX procedure computes knots for low-rank smoothing based on the vertices or centroids of a  $k$ -d tree. The default is to use the vertices of the tree as the knot locations, if you use the `TYPE=RSMOOTH` covariance structure. The construction of this tree amounts to a partitioning of the random regressor space until all partitions contain at most  $b$  observations. The number  $b$  is called the *bucket size* of the  $k$ -d tree. You can exercise control over the construction of the tree by changing the bucket size with the `BUCKET=` suboption of the `KNOTMETHOD=KDTREE` option in the `RANDOM` statement. A large bucket size leads to fewer knots, but it is not correct to assume that  $K$ , the number of knots, is simply  $\lfloor n/b \rfloor$ . The number of

vertices depends on the configuration of the values in the regressor space. Also, coordinates of the bounding hypercube are vertices of the tree. In the one-dimensional case, for example, the extreme values of the random effect are vertices.

To demonstrate how the  $k$ -d tree partitions the random-effects space based on observed data and the influence of the bucket size, consider the following example from Chapter 53, “The LOESS Procedure.” The SAS data set Gas contains the results of an engine exhaust emission study (Brinkman 1981). The covariate in this analysis, E, is a measure of the air-fuel mixture richness. The response, NOx, measures the nitric oxide concentration (in micrograms per joule, and normalized).

```
data Gas;
 input NOx E;
 format NOx E f5.3;
 datalines;
4.818 0.831
2.849 1.045
3.275 1.021
4.691 0.97
4.255 0.825
5.064 0.891
2.118 0.71
4.602 0.801
2.286 1.074
0.97 1.148
3.965 1
5.344 0.928
3.834 0.767
1.99 0.701
5.199 0.807
5.283 0.902
3.752 0.997
0.537 1.224
1.64 1.089
5.055 0.973
4.937 0.98
1.561 0.665
;
```

There are 22 observations in the data set, and the values of the covariate are unique. If you want to smooth these data with a low-rank radial smoother, you need to choose the number of knots, as well as their placement within the support of the variable E. The  $k$ -d tree construction depends on the observed values of the variable E; it is independent of the values of nitric oxide in the data. The following statements construct a tree based on a bucket size of  $b = 11$  and display information about the tree and the selected knots:

```
ods select KDtree KnotInfo;
proc glimmix data=gas nofit;
 model NOx = e;
 random e / type=rsmooth
 knotmethod=kdtree(bucket=11 treeinfo knotinfo);
run;
```

The **NOFIT** option prevents the GLIMMIX procedure from fitting the model. This option is useful if you want to investigate the knot construction for various bucket sizes. The **TREEINFO** and **KNOTINFO** suboptions of the **KNOTMETHOD=KDTREE** option request displays of the  $k$ -d tree and the knot coordinates derived from it. Construction of the tree commences by splitting the data in half. For  $b = 11$ ,  $n = 22$ , neither of the two splits contains more than  $b$  observations and the process stops. With a single split value, and the two extreme values, the tree has two terminal nodes and leads to three knots (Figure 41.13). Note that for one-dimensional problems, vertices of the  $k$ -d tree always coincide with data values.

**Figure 41.13**  $K$ -d Tree and Knots for Bucket Size 11

| The GLIMMIX Procedure  |            |             |                 |             |
|------------------------|------------|-------------|-----------------|-------------|
| kd-Tree for RSmooth(E) |            |             |                 |             |
| Node Number            | Left Child | Right Child | Split Direction | Split Value |
| 0                      | 1          | 2           | E               | 0.9280      |
| 1                      |            |             | TERMINAL        |             |
| 2                      |            |             | TERMINAL        |             |
| Radial Smoother        |            |             |                 |             |
| Knots for RSmooth(E)   |            |             |                 |             |
| Knot Number            |            | E           |                 |             |
| 1                      |            | 0.6650      |                 |             |
| 2                      |            | 0.9280      |                 |             |
| 3                      |            | 1.2240      |                 |             |

If the bucket size is reduced to  $b = 8$ , the following statements produce the tree and knots in Figure 41.14:

```
ods select KdTree KnotInfo;
proc glimmix data=gas nofit;
 model NOx = e;
 random e / type=rsmooth
 knotmethod=kdtree(bucket=8 treeinfo knotinfo);
run;
```

The initial split value of 0.9280 leads to two sets of 11 observations. In order to achieve a partition into cells that contain at most eight observations, each initial partition is split at its median one more time. Note that one split value is greater and one split value is less than 0.9280.

**Figure 41.14** K-d Tree and Knots for Bucket Size 8

| The GLIMMIX Procedure  |            |             |                 |             |
|------------------------|------------|-------------|-----------------|-------------|
| kd-Tree for RSmooth(E) |            |             |                 |             |

The split value for  $b = 11$  is also a split value for  $b = 8$ , the split values for  $b = 8$  are a subset of those for  $b = 4$ , and so forth. Figure 41.16 displays the data and the location of split values for the three cases. For a one-dimensional problem (a univariate smoother), the vertices comprise the split values and the values on the bounding interval.

You might want to move away from the boundary, in particular for an irregular data configuration or for multivariate smoothing. The `KNOTTYP=`CENTER suboption of the `KNOTMETHOD=` option chooses centroids of the leaf node cells instead of vertices. This tends to move the outer knot locations closer to the convex hull, but not necessarily to data locations. In the emission example, choosing a bucket size of  $b = 11$  and centroids as knot locations yields two knots at  $E=0.7956$  and  $E=1.076$ . If you choose the `NEAREST` suboption, then the nearest neighbor of a vertex or centroid will serve as the knot location. In this case, the knot locations are a subset of the data locations, regardless of the dimension of the smooth.

**Figure 41.16** Vertices of  $k$ -d Trees for Various Bucket Sizes

## Odds and Odds Ratio Estimation

In models with a logit, generalized logit, or cumulative logit link, you can obtain estimates of odds ratios through the `ODDSRATIO` options in the `PROC GLIMMIX`, `LSMEANS`, and `MODEL` statements. This section provides details about the computation and interpretation of the computed quantities. Note that for

these link functions the **EXP** option in the **ESTIMATE** and **LSMESTIMATE** statements also produces odds or odds ratios.

Consider first a model with a dichotomous outcome variable, linear predictor  $\eta = \mathbf{x}'\boldsymbol{\beta} + \mathbf{z}'\boldsymbol{\gamma}$ , and logit link function. Suppose that  $\eta_0$  represents the linear predictor for a condition of interest. For example, in a simple logistic regression model with  $\eta = \alpha + \beta x$ ,  $\eta_0$  might correspond to the linear predictor at a particular value of the covariate—say,  $\eta_0 = \alpha + \beta x_0$ .

The modeled probability is  $\pi = 1/(1 + \exp\{-\eta\})$ , and the odds for  $\eta = \eta_0$  are

$$\frac{\pi_0}{1 - \pi_0} = \frac{1/(1 + \exp\{-\eta_0\})}{\exp\{-\eta_0\}/(1 + \exp\{-\eta_0\})} = \exp\{\eta_0\}$$

Because  $\eta_0$  is a logit, it represents the log odds. The odds ratio  $\psi(\eta_1, \eta_0)$  is defined as the ratio of odds for  $\eta_1$  and  $\eta_0$ ,

$$\psi(\eta_1, \eta_0) = \exp\{\eta_1 - \eta_0\}$$

The odds ratio compares the odds of the outcome under the condition expressed by  $\eta_1$  to the odds under the condition expressed by  $\eta_0$ . In the preceding simple logistic regression example, this ratio equals  $\exp\{\beta(x_1 - x_0)\}$ . The exponentiation of the estimate of  $\beta$  is thus an estimate of the odds ratio comparing conditions for which  $x_1 - x_0 = 1$ . If  $x$  and  $x + 1$  represent standard and experimental conditions, for example,  $\exp\{\beta\}$  compares the odds of the outcome under the experimental condition to the odds under the standard condition. For many other types of models, odds ratios can be expressed as simple functions of parameter estimates. For example, suppose you are fitting a logistic model with a single classification effect with three levels:

```
proc glimmix;
 class A;
 model y = A / dist=binary;
run;
```

The estimated linear predictor for level  $j$  of  $A$  is  $\hat{\eta}_j = \hat{\beta} + \hat{\alpha}_j$ ,  $j = 1, 2, 3$ . Because the  $\mathbf{X}$  matrix is singular in this model due to the presence of an overall intercept, the solution for the intercept estimates  $\beta + \alpha_3$ , and the solution for the  $j$ th treatment effect estimates  $\alpha_j - \alpha_3$ . Exponentiating the solutions for  $\alpha_1$  and  $\alpha_2$  thus produces odds ratios comparing the odds for these levels against the third level of  $A$ .

Results designated as odds or odds ratios in the **GLIMMIX** procedure might reduce to simple exponentiations of solutions in the “Parameter Estimates” table, but they are computed by a different mechanism if the model contains classification variables. The computations rely on general estimable functions; for the **MODEL**, **LSMEANS**, and **LSMESTIMATE** statements, these functions are based on least squares means. This enables you to obtain odds ratio estimates in more complicated models that involve main effects and interactions, including interactions between continuous and classification variables.

In all cases, the results represent the exponentiation of a linear function of the fixed-effects parameters,  $\eta = \mathbf{l}'\boldsymbol{\beta}$ . If  $L_\eta$  and  $U_\eta$  are the confidence limits for  $\eta$  on the logit scale, confidence limits for the odds or the odds ratio are obtained as  $\exp\{L_\eta\}$  and  $\exp\{U_\eta\}$ .

## The Odds Ratio Estimates Table

This table is produced by the **ODDSRATIO** option in the **MODEL** statement. It consists of estimates of odds ratios and their confidence limits. Odds ratios are produced for the following:

- classification main effects, if they appear in the **MODEL** statement
- continuous variables in the **MODEL** statement, unless they appear in an interaction with a classification effect
- continuous variables in the **MODEL** statement at fixed levels of a classification effect, if the **MODEL** statement contains an interaction of the two.
- continuous variables in the **MODEL** statements if they interact with other continuous variables

### The Default Table

Consider the following PROC GLIMMIX statements that fit a logistic model with one classification effect, one continuous variable, and their interaction (the **ODDSRATIO** option in the **MODEL** statement requests the “Odds Ratio Estimates” table).

```
proc glimmix;
 class A;
 model y = A x A*x / dist=binary oddsratio;
run;
```

By default, odds ratios are computed as follows:

- The covariate is set to its average,  $\bar{x}$ , and the least squares means for the A effect are obtained. Suppose  $\mathbf{L}^{(1)}$  denotes the matrix of coefficients defining the estimable functions that produce the  $a$  least squares means  $\mathbf{L}\hat{\boldsymbol{\beta}}$ , and  $\mathbf{l}_j^{(1)}$  denotes the  $j$ th row of  $\mathbf{L}^{(1)}$ . Differences of the least squares means against the last level of the A factor are computed and exponentiated:

$$\begin{aligned} \psi(A_1, A_a) &= \exp \left\{ \left( \mathbf{l}_1^{(1)} - \mathbf{l}_a^{(1)} \right) \hat{\boldsymbol{\beta}} \right\} \\ \psi(A_2, A_a) &= \exp \left\{ \left( \mathbf{l}_2^{(1)} - \mathbf{l}_a^{(1)} \right) \hat{\boldsymbol{\beta}} \right\} \\ &\vdots \\ \psi(A_{a-1}, A_a) &= \exp \left\{ \left( \mathbf{l}_{a-1}^{(1)} - \mathbf{l}_a^{(1)} \right) \hat{\boldsymbol{\beta}} \right\} \end{aligned}$$

The differences are checked for estimability. Notice that this set of odds ratios can also be obtained with the following **LSMESTIMATE** statement (assuming A has five levels):

```
lsmestimate A 1 0 0 0 -1,
 0 1 0 0 -1,
 0 0 1 0 -1,
 0 0 0 1 -1 / exp cl;
```

You can also obtain the odds ratios with this **LSMEANS** statement (assuming the last level of A is coded as 5):

```
lsmeans A / diff=control('5') oddsratio cl;
```

- The odds ratios for the covariate must take into account that  $x$  occurs in an interaction with the  $A$  effect. A second set of least squares means are computed, where  $x$  is set to  $\bar{x} + 1$ . Denote the coefficients of the estimable functions for this set of least squares means as  $L^{(2)}$ . Differences of the least squares means at a given level of factor  $A$  are then computed and exponentiated:

$$\begin{aligned}\psi(A(\bar{x} + 1)_1, A(\bar{x})_1) &= \exp \left\{ \left( l_1^{(2)} - l_1^{(1)} \right) \hat{\beta} \right\} \\ \psi(A(\bar{x} + 1)_2, A(\bar{x})_2) &= \exp \left\{ \left( l_2^{(2)} - l_2^{(1)} \right) \hat{\beta} \right\} \\ &\vdots \\ \psi(A(\bar{x} + 1)_a, A(\bar{x})_a) &= \exp \left\{ \left( l_a^{(2)} - l_a^{(1)} \right) \hat{\beta} \right\}\end{aligned}$$

The differences are checked for estimability. If the continuous covariate does not appear in an interaction with the  $A$  variable, only a single odds ratio estimate related to  $x$  would be produced, relating the odds of a one-unit shift in the regressor from  $\bar{x}$ .

Suppose you fit a model that contains interactions of continuous variables, as with the following statements:

```
proc glimmix;
 class A;
 model y = A x x*z / dist=binary oddsratio;
run;
```

In the computation of the  $A$  least squares means, the continuous effects are set to their means—that is,  $\bar{x}$  and  $\bar{x}\bar{z}$ . In the computation of odds ratios for  $x$ , linear predictors are computed at  $x = \bar{x}$ ,  $x^*z = \bar{x} \times \bar{z}$  and at  $x = \bar{x} + 1$ ,  $x^*z = (\bar{x} + 1)\bar{z}$ .

### **Modifying the Default Table, Customized Odds Ratios**

Several suboptions of the `ODDSRATIO` option in the `MODEL` statement are available to obtain customized odds ratio estimates. For customized odds ratios that cannot be obtained with these suboptions, use the `EXP` option in the `ESTIMATE` or `LSMESTIMATE` statement.

The type of differences constructed when the levels of a classification factor are varied is controlled by the `DIFF=` suboption. By default, differences against the last level are taken. `DIFF=FIRST` computes differences from the first level, and `DIFF=ALL` computes odds ratios based on all pairwise differences.

For continuous variables in the model, you can change both the reference value (with the `AT` suboption) and the units of change (with the `UNIT` suboption). By default, a one-unit change from the mean of the covariate is assessed. For example, the following statements produce all pairwise differences for the  $A$  factor:

```
proc glimmix;
 class A;
 model y = A x A*x / dist=binary
 oddsratio(diff=all
 at x=4
 unit x=3);
run;
```

The covariate  $x$  is set to the reference value  $x = 4$  in the computation of the least squares means for the  $A$  odds ratio estimates. The odds ratios computed for the covariate are based on differencing this set of least squares means with a set of least squares means computed at  $x = 4 + 3$ .

## Odds or Odds Ratio

The odds ratio is the exponentiation of a difference on the logit scale,

$$\psi(\eta_1, \eta_0) = \exp\{(\mathbf{l}_1 - \mathbf{l}_0)\boldsymbol{\beta}\}$$

and  $\exp\{\mathbf{l}_1\boldsymbol{\beta}\}$  and  $\exp\{\mathbf{l}_0\boldsymbol{\beta}\}$  are the corresponding odds. If the ODDSRATIO option is specified in a suitable model in the PROC GLIMMIX statement or the individual statements that support the option, odds ratios are computed in the “Odds Ratio Estimates” table (MODEL statement), the “Differences of Least Squares Means” table (LSMEANS / DIFF), and the “Simple Effect Comparisons of Least Squares Means” table (LSMEANS / SLICEDIFF=). Odds are computed in the “Least Squares Means” table.

## Odds Ratios in Multinomial Models

The GLIMMIX procedure fits two kinds of models to multinomial data. Models with cumulative link functions apply to ordinal data, and generalized logit models are fit to nominal data. If you model a multinomial response with LINK=CUMLOGIT or LINK=GLOGIT, odds ratio results are available for these models.

In the generalized logit model, you model baseline category logits. By default, the GLIMMIX procedure chooses the last category as the reference category. If your nominal response has  $J$  categories, the baseline logit for category  $j$  is

$$\log\{\pi_j/\pi_J\} = \eta_j = \mathbf{x}'\boldsymbol{\beta}_j + \mathbf{z}'\mathbf{u}_j$$

and

$$\pi_j = \frac{\exp\{\eta_j\}}{\sum_{k=1}^J \exp\{\eta_k\}}$$

$$\eta_J = 0$$

As before, suppose that the two conditions to be compared are identified with subscripts 1 and 0. The log odds ratio of outcome  $j$  versus  $J$  for the two conditions is then

$$\log\{\psi(\eta_{j1}, \eta_{j0})\} = \log\left\{\frac{\pi_{j1}/\pi_{J1}}{\pi_{j0}/\pi_{J0}}\right\} = \log\left\{\frac{\exp\{\eta_{j1}\}}{\exp\{\eta_{j0}\}}\right\}$$

$$= \eta_{j1} - \eta_{j0}$$

Note that the log odds ratios are again differences on the scale of the linear predictor, but they depend on the response category. The GLIMMIX procedure determines the estimable functions whose differences represent log odds ratios as discussed previously but produces separate estimates for each nonreference response category.

In models for ordinal data, PROC GLIMMIX models the logits of cumulative probabilities. Thus, the estimates on the linear scale represent log cumulative odds. The cumulative logits are formed as

$$\log\left\{\frac{\Pr(Y \leq j)}{\Pr(Y > j)}\right\} = \eta_j = \alpha_j + \mathbf{x}'\boldsymbol{\beta} + \mathbf{z}'\boldsymbol{\gamma} = \alpha_j + \tilde{\eta}$$

so that the linear predictor depends on the response category only through the intercepts (cutoffs)  $\alpha_1, \dots, \alpha_{J-1}$ . The odds ratio comparing two conditions represented by linear predictors  $\eta_{j1}$  and  $\eta_{j0}$  is then

$$\psi(\eta_{j1}, \eta_{j0}) = \exp\{\eta_{j1} - \eta_{j0}\}$$

$$= \exp\{\tilde{\eta}_1 - \tilde{\eta}_0\}$$

and is independent of category.

---

## Parameterization of Generalized Linear Mixed Models

PROC GLIMMIX constructs a generalized linear mixed model according to the specifications in the **CLASS**, **MODEL**, and **RANDOM** statements. Each effect in the **MODEL** statement generates one or more columns in the matrix **X**, and each G-side effect in the **RANDOM** statement generates one or more columns in the matrix **Z**. R-side effects in the **RANDOM** statement do not generate model matrices; they serve only to index observations within subjects. This section shows how the GLIMMIX procedure builds **X** and **Z**. You can output the **X** and **Z** matrices to a SAS data set with the **OUTDESIGN=** option in the **PROC GLIMMIX** statement.

The general rules and techniques for parameterization of a linear model are given in “GLM Parameterization of Classification Variables and Effects” on page 383 of Chapter 19, “Shared Concepts and Topics.” The following paragraphs discuss how these rules differ in a mixed model, in particular, how parameterization differs between the **X** and the **Z** matrix.

### Intercept

By default, all models automatically include a column of 1s in **X** to estimate a fixed-effect intercept parameter. You can use the **NOINT** option in the **MODEL** statement to suppress this intercept. The **NOINT** option is useful when you are specifying a classification effect in the **MODEL** statement and you want the parameter estimates to be in terms of the (linked) mean response for each level of that effect, rather than in terms of a deviation from an overall mean.

By contrast, the intercept is not included by default in **Z**. To obtain a column of 1s in **Z**, you must specify in the **RANDOM** statement either the **INTERCEPT** effect or some effect that has only one level.

### Interaction Effects

Often a model includes interaction (crossed) effects. With an interaction, PROC GLIMMIX first reorders the terms to correspond to the order of the variables in the **CLASS** statement. Thus, **B\*A** becomes **A\*B** if **A** precedes **B** in the **CLASS** statement. Then, PROC GLIMMIX generates columns for all combinations of levels that occur in the data. The order of the columns is such that the rightmost variables in the cross index faster than the leftmost variables. Empty columns (which would contain all 0s) are not generated for **X**, but they are for **Z**.

See Table 19.5 in the section “GLM Parameterization of Classification Variables and Effects” on page 383 of Chapter 19, “Shared Concepts and Topics,” for an example of an interaction parameterization.

### Nested Effects

Nested effects are generated in the same manner as crossed effects. Hence, the design columns generated by the following two statements are the same (but the ordering of the columns is different):

Note that nested effects are often distinguished from interaction effects by the implied randomization structure of the design. That is, they usually indicate random effects within a fixed-effects framework. The fact that random effects can be modeled directly in the **RANDOM** statement might make the specification of nested effects in the **MODEL** statement unnecessary.

See Table 19.6 in the section “GLM Parameterization of Classification Variables and Effects” on page 383 of Chapter 19, “Shared Concepts and Topics,” for an example of the parameterization of a nested effect.

## Implications of the Non-Full-Rank Parameterization

For models with fixed effects involving classification variables, there are more design columns in  $\mathbf{X}$  constructed than there are degrees of freedom for the effect. Thus, there are linear dependencies among the columns of  $\mathbf{X}$ . In this event, all of the parameters are not estimable; there is an infinite number of solutions to the mixed model equations. The GLIMMIX procedure uses a generalized inverse (a  $g_2$ -inverse, Pringle and Rayner (1971), to obtain values for the estimates (Searle 1971). The solution values are not displayed unless you specify the **SOLUTION** option in the **MODEL** statement. The solution has the characteristic that estimates are 0 whenever the design column for that parameter is a linear combination of previous columns. With this parameterization, hypothesis tests are constructed to test linear functions of the parameters that are estimable.

Some procedures (such as the CATMOD and LOGISTIC procedures) reparameterize models to full rank by using restrictions on the parameters. PROC GLM, PROC MIXED, and PROC GLIMMIX do not reparameterize, making the hypotheses that are commonly tested more understandable. See Goodnight (1978b) for additional reasons for not reparameterizing.

## Missing Level Combinations

PROC GLIMMIX handles missing level combinations of classification variables in the same manner as PROC GLM and PROC MIXED. These procedures delete fixed-effects parameters corresponding to missing levels in order to preserve estimability. However, PROC GLIMMIX does not delete missing level combinations for random-effects parameters because linear combinations of the random-effects parameters are always predictable. These conventions can affect the way you specify your **CONTRAST** and **ESTIMATE** coefficients.

## Notes on the EFFECT Statement

Some restrictions and limitations for models that contain constructed effects are in place with the GLIMMIX procedure. Also, you should be aware of some special defaults and handling that apply only when the model contains constructed fixed and/or random effects.

- Constructed effects can be used in the **MODEL** and **RANDOM** statements but not to specify **SUBJECT=** or **GROUP=** effects.
- Computed variables are not supported in the specification of a constructed effect. All variables needed to form the collection of columns for a constructed effect must be in the data set.
- You cannot use constructed effects that comprise continuous variables or interactions with other constructed effects as the **LSMEANS** or **LSMESTIMATE** effect.
- The calculation of quantities that depend on least squares means, such as odds ratios in the “Odds Ratio Estimates” table, is not possible if the model contains fixed effects that consist of more than one constructed effects, unless all constructed effects are of spline type. For example, least squares means computations are not possible in the following model because the **MM\_AB\*cvars** effect contains two constructed effects:

```
proc glimmix;
 class A B C;
 effect MM_AB = MM(A B);
 effect cvars = COLLECTION(x1 x2 x3);
 model y = C MM_AB*cvars;
run;
```

- If the **MODEL** or **RANDOM** statement contains constructed effects, the default degrees-of-freedom method for mixed models is **DDFM=KENWARDROGER**. The containment degrees-of-freedom method (**DDFM=CONTAIN**) is not available in these models.
- If the model contains fixed spline effects, least squares means are computed at the average spline coefficients across the usable data, possibly further averaged over levels of **CLASS** variables that interact with the spline effects in the model. You can use the **AT** option in the **LSMEANS** and **LSMESTIMATE** statements to construct the splines for particular values of the covariates involved. Consider, for example, the following statements:

```
proc glimmix;
 class A;
 effect spl = spline(x);
 model y = A spl;
 lsmeans A;
 lsmeans A / at means;
 lsmeans A / at x=0.4;
run;
```

Suppose that the **spl** effect contributes seven columns  $[s_1, \dots, s_7]$  to the **X** matrix. The least squares means coefficients for the **spl** effect in the first **LSMEANS** statement are  $[\bar{s}_1, \dots, \bar{s}_7]$  with the averages taken across the observations used in the analysis. The second **LSMEANS** statement computes the spline coefficient at the average value of **x**:  $[s(\bar{x})_1, \dots, s(\bar{x})_7]$ . The final **LSMEANS** statement uses  $[s(0.4)_1, \dots, s(0.4)_7]$ . Using the **AT** option for least squares means calculations with spline effects can resolve inestimability issues.

- Using a spline effect with B-spline basis in the **RANDOM** statement is **not** the same as using a penalized B-spline (P-spline) through the **TYPE=PSPLINE** option in the **RANDOM** statement. The following statement constructs a penalized B-spline by using mixed model methodology:

```
random x / type=pspline;
```

The next set of statements defines a set of B-spline columns in the **Z** matrix with uncorrelated random effects and homogeneous variance:

```
effect bspline = spline(x);
random bspline / type=vc;
```

This does not lead to a properly penalized fit. See the documentation on **TYPE=PSPLINE** about the construction of penalties for B-splines through the covariance matrix of random effects.

## Positional and Nonpositional Syntax for Contrast Coefficients

When you define custom linear hypotheses with the **CONTRAST** or **ESTIMATE** statement, the **GLIMMIX** procedure sets up an **L** vector or matrix that conforms to the fixed-effects solutions or the fixed- and random-effects solutions. With the **LSMESTIMATE** statement, you specify coefficients of the matrix **K** that is then converted into a coefficient matrix that conforms to the fixed-effects solutions.

There are two methods for specifying the entries in a coefficient matrix (hereafter simply referred to as the **L** matrix), termed the positional and nonpositional methods. In the positional form, and this is the traditional method, you provide a list of values that occupy the elements of the **L** matrix associated with the effect in

question in the order in which the values are listed. For traditional model effects comprising continuous and classification variables, the positional syntax is simpler in some cases (main effects) and more cumbersome in others (interactions). When you work with effects constructed through the experimental **EFFECT** statement, the nonpositional syntax is essential.

Consider, for example, the following two-way model with interactions where factors A and B have three and two levels, respectively:

```
proc glimmix;
 class a b block;
 model y = a b a*b / ddfm=kr;
 random block a*block;
run;
```

To test the difference of the B levels at the second level of A with a **CONTRAST** statement (a slice), you need to assign coefficients 1 and -1 to the levels of B and to the levels of the interaction where A is at the second level. Two examples of equivalent **CONTRAST** statements by using positional and nonpositional syntax are as follows:

```
contrast 'B at A2' b 1 -1 a*b 0 0 1 -1 ;
contrast 'B at A2' b 1 -1 a*b [1 2 1] [-1 2 2];
```

Because A precedes B in the **CLASS** statement, the levels of the interaction are formed as  $\alpha_1\beta_1, \alpha_1\beta_2, \alpha_2\beta_1, \alpha_2\beta_2, \dots$ . If B precedes A in the **CLASS** statement, you need to modify the coefficients accordingly:

```
proc glimmix;
 class b a block;
 model y = a b a*b / ddfm=kr;
 random block a*block;
 contrast 'B at A2' b 1 -1 a*b 0 1 0 0 -1 ;
 contrast 'B at A2' b 1 -1 a*b [1 1 2] [-1 2 2];
 contrast 'B at A2' b 1 -1 a*b [1, 1 2] [-1, 2 2];
run;
```

You can optionally separate the **L** value entry from the level indicators with a comma, as in the last **CONTRAST** statement.

The general syntax for defining coefficients with the nonpositional syntax is as follows:

$$\text{effect-name} [\text{multiplier} <, > \text{level-values}] \dots <[\text{multiplier} <, > \text{level-values}] >$$

The first entry in square brackets is the multiplier that is applied to the elements of **L** for the effect after the *level-values* have been resolved and any necessary action forming **L** has been taken.

The *level-values* are organized in a specific form:

- The number of entries should equal the number of terms needed to construct the effect. For effects that do not contain any constructed effects, this number is simply the number of terms in the name of the effect.
- Values of continuous variables needed for the construction of the **L** matrix precede the level indicators of **CLASS** variables.
- If the effect involves constructed effects, then you need to provide as many continuous and classification variables as are needed for the effect formation. For example, if a grouping effect is defined as

```
class c;
effect v = vars(x1 x2 c);
```

then a proper nonpositional syntax would be, for example,

```
v [0.5, 0.2 0.3 3]
```

- If an effect contains both regular terms (old-style effects) and constructed effects, then the order of the coefficients is as follows: continuous values for old-style effects, class levels for **CLASS** variables in old-style effects, continuous values for constructed effects, and finally class levels needed for constructed effects.

Assume that C has four levels so that effect v contributes six elements to the **L** matrix. When PROC GLIMMIX resolves this syntax, the values 0.2 and 0.3 are assigned to the positions for x1 and x2 and a 1 is associated with the third level of C. The resulting vector is then multiplied by 0.5 to produce

```
[0.1 0.15 0 0 0.5 0]
```

Note that you enter the **levels** of the classification variables in the square brackets, not their formatted values. The ordering of the levels of **CLASS** variables can be gleaned from the “Class Level Information” table.

To specify values for continuous variables, simply give their value as one of the terms in the effect. The nonpositional syntax in the following **ESTIMATE** statement is read as “1-time the value 0.4 in the column associated with level 2 of A”

```
proc glimmix;
 class a;
 model y = a a*x / s;
 lsmeans a / e at x=0.4;
 estimate 'A2 at x=0.4' intercept 1 a 0 1 a*x [1,0.4 2] / e;
run;
```

Because the value before the comma serves as a multiplier, the same estimable function could also be constructed with the following statements:

```
estimate 'A2 at x=0.4' intercept 1 a 0 1 a*x [4, 0.1 2];
estimate 'A2 at x=0.4' intercept 1 a 0 1 a*x [2, 0.2 2];
estimate 'A2 at x=0.4' intercept 1 a 0 1 a*x [-1, -0.4 2];
```

Note that continuous variables needed to construct an effect are always listed before any **CLASS** variables.

When you work with constructed effects, the nonpositional syntax works in the same way. For example, the following model contains a classification effect and a B-spline. The first two **ESTIMATE** statements produce predicted values for level one of C when the continuous variable x takes on the values 20 and 10, respectively.

```

proc glimmix;
 class c;
 effect spl = spline(x / knotmethod=equal(5));
 model y = c spl;
 estimate 'C = 1 @ x=20' intercept 1 c 1 spl [1,20],
 'C = 1 @ x=10' intercept 1 c 1 spl [1,10];
 estimate 'Difference' spl [1,20] [-1,10];
run;

```

The GLIMMIX procedure computes the spline coefficients for the first **ESTIMATE** statement based on  $x = 20$ , and similarly in the second statement for  $x = 10$ . The third **ESTIMATE** statement computes the difference of the predicted values. Because the spline effect does not interact with the classification variable, this difference does not depend on the level of C. If such an interaction is present, you can estimate the difference in predicted values for a given level of C by using the nonpositional syntax. Because the effect C\*spl contains both old-style terms (C) and a constructed effect, you specify the values for the old-style terms before assigning values to constructed effects:

```

proc glimmix;
 class c;
 effect spl = spline(x / knotmethod=equal(5));
 model y = spl*c;
 estimate 'C2 = 1, x=20' intercept 1 c*spl [1,1 20];
 estimate 'C2 = 2, x=20' intercept 1 c*spl [1,2 20];
 estimate 'C diff at x=20' c*spl [1,1 20] [-1,2 20];
run;

```

It is recommended to add the E option to the **CONTRAST**, **ESTIMATE**, or **LSMESTIMATE** statement to verify that the L matrix is formed according to your expectations.

In any row of an **ESTIMATE** or **CONTRAST** statement you can choose positional and nonpositional syntax separately for each effect. You cannot mix the two forms of syntax for coefficients of a single effect, however. For example, the following statement is not proper because both forms of syntax are used for the interaction effect:

```

estimate 'A1B1 - A1B2' b 1 -1 a*b 0 1 [-1, 1 2];

```

---

## Response-Level Ordering and Referencing

In models for binary and multinomial data, the response-level ordering is important because it reflects the following:

- which probability is modeled with binary data
- how categories are ordered for ordinal data
- which category serves as the reference category in nominal generalized logit models (models for nominal data)

You should view the “Response Profile” table to ensure that the categories are properly arranged and that the desired outcome is modeled. In this table, response levels are arranged by *Ordered Value*. The lowest

response level is assigned Ordered Value 1, the next lowest is assigned Ordered Value 2, and so forth. In binary models, the probability modeled is the probability of the response level with the lowest Ordered Value.

You can change which probability is modeled and the Ordered Value in the “Response Profile” table with the **DESCENDING**, **EVENT=**, **ORDER=**, and **REF=** response variable options in the **MODEL** statement. See the section “Response Level Ordering” on page 4237 in Chapter 54, “The LOGISTIC Procedure,” for examples about how to use these options to affect the probability being modeled for binary data.

For multinomial models, the response-level ordering affects two important aspects. In cumulative link models the categories are assumed ordered according to their Ordered Value in the “Response Profile” table. If the response variable is a character variable or has a format, you should check this table carefully as to whether the Ordered Values reflect the correct ordinal scale.

In generalized logit models (for multinomial data with unordered categories), one response category is chosen as the reference category in the formulation of the generalized logits. By default, the linear predictor in the reference category is set to 0, and the reference category corresponds to the entry in the “Response Profile” table with the highest Ordered Value. You can affect the assignment of Ordered Values with the **DESCENDING** and **ORDER=** options in the **MODEL** statement. You can choose a different reference category with the **REF=** option. The choice of the reference category for generalized logit models affects the results. It is sometimes recommended that you choose the category with the highest frequency as the reference (see, for example, Brown and Prescott 1999, p. 160). You can achieve this with the GLIMMIX procedure by combining the **ORDER=** and **REF=** options, as in the following statements:

```
proc glimmix;
 class preference;
 model preference(order=freq ref=first) = feature price /
 dist=multinomial
 link=glogit;
 random intercept / subject=store group=preference;
run;
```

The **ORDER=FREQ** option arranges the categories by descending frequency. The **REF=FIRST** option then selects the response category with the lowest Ordered Value—the most frequent category—as the reference.

---

## Comparing the GLIMMIX and MIXED Procedures

The MIXED procedure is subsumed by the GLIMMIX procedure in the following sense:

- Linear mixed models are a special case in the family of generalized linear mixed models; a linear mixed model is a generalized linear mixed model where the conditional distribution is normal and the link function is the identity function.
- Most models that can be fit with the MIXED procedure can also be fit with the GLIMMIX procedure.

Despite this overlap in functionality, there are also some important differences between the two procedures. Awareness of these differences enables you to select the most appropriate tool in situations where you have a choice between procedures and to identify situations where a choice does not exist. Furthermore, the %GLIMMIX macro, which fits generalized linear mixed models by linearization methods, essentially calls

the MIXED procedure repeatedly. If you are aware of the syntax differences between the procedures, you can easily convert your %GLIMMIX macro statements.

Important functional differences between PROC GLIMMIX and PROC MIXED for linear models and linear mixed models include the following:

- The MIXED procedure models R-side effects through the REPEATED statement and G-side effects through the RANDOM statement. The GLIMMIX procedure models all random components of the model through the RANDOM statement. You use the `_RESIDUAL_` keyword or the RESIDUAL option in the RANDOM statement to model R-side covariance structure in the GLIMMIX procedure. For example, the PROC MIXED statement

```
repeated / subject=id type=ar(1);
```

is equivalent to the following RANDOM statement in the GLIMMIX procedure:

```
random _residual_ / subject=id type=ar(1);
```

If you need to specify an effect for levelization—for example, because the construction of the **R** matrix is order-dependent or because you need to account for missing values—the RESIDUAL option in the RANDOM statement of the GLIMMIX procedure is used to indicate that you are modeling an R-side covariance nature. For example, the PROC MIXED statements

```
class time id;
repeated time / subject=id type=ar(1);
```

are equivalent to the following PROC GLIMMIX statements:

```
class time id;
random time / subject=id type=ar(1) residual;
```

- There is generally considerable overlap in the covariance structures available through the TYPE= option in the RANDOM statement in PROC GLIMMIX and through the TYPE= options in the RANDOM and REPEATED statements in PROC MIXED. However, the Kronecker-type structures, the geometrically anisotropic spatial structures, and the GDATA= option in the RANDOM statement of the MIXED procedure are currently not supported in the GLIMMIX procedure. The MIXED procedure, on the other hand, does not support TYPE=RSMOOTH and TYPE=PSPLINE.
- For normal linear mixed models, the (default) METHOD=RSPL in PROC GLIMMIX is identical to the default METHOD=REML in PROC MIXED. Similarly, METHOD=MSPL in PROC GLIMMIX is identical for these models to METHOD=ML in PROC MIXED. The GLIMMIX procedure does not support Type I through Type III (ANOVA) estimation methods for variance component models. Also, the procedure does not have a METHOD=MIVQUE0 option, but you can produce these estimates through the NOITER option in the PARMs statement.
- The MIXED procedure solves the iterative optimization problem by means of a ridge-stabilized Newton-Raphson algorithm. With the GLIMMIX procedure, you can choose from a variety of optimization methods via the NLOPTIONS statement. The default method for most GLMMs is a quasi-Newton algorithm. A ridge-stabilized Newton-Raphson algorithm, akin to the optimization method in

the MIXED procedure, is available in the GLIMMIX procedure through the TECHNIQUE=NRRIDG option in the NLOPTIONS statement. Because of differences in the line-search methods, update methods, and the convergence criteria, you might get slightly different estimates with the two procedures in some instances. The GLIMMIX procedure, for example, monitors several convergence criteria simultaneously.

- You can produce predicted values, residuals, and confidence limits for predicted values with both procedures. The mechanics are slightly different, however. With the MIXED procedure you use the OUTPM= and OUTP= options in the MODEL statement to write statistics to data sets. With the GLIMMIX procedure you use the OUTPUT statement and indicate with keywords which “flavor” of a statistic to compute.
- The following GLIMMIX statements are not available in the MIXED procedure: COVTEST, EFFECT, FREQ, LSMESTIMATE, OUTPUT, and programming statements.
- A sampling-based Bayesian analysis as through the PRIOR statement in the MIXED procedure is not available in the GLIMMIX procedure.
- In the GLIMMIX procedure, several RANDOM statement options apply to the RANDOM statement in which they are specified. For example, the following statements in the GLIMMIX procedure request that the solution vector be printed for the A and A\*B\*C random effects and that the G matrix corresponding to the A\*B interaction random effect be displayed:

```
random a / s;
random a*b / G;
random a*b*c / alpha=0.04;
```

Confidence intervals with a 0.96 coverage probability are produced for the solutions of the A\*B\*C effect. In the MIXED procedure, the S option, for example, when specified in one RANDOM statement, applies to all RANDOM statements.

- If you select nonmissing values in the *value-list* of the DDF= option in the MODEL statement, PROC GLIMMIX uses these values to override degrees of freedom for this effect that might be determined otherwise. For example, the following statements request that the denominator degrees of freedom for tests and confidence intervals involving the A effect be set to 4:

```
proc glimmix;
 class block a b;
 model y = a b a*b / s ddf=4, ., . ddfm=satterthwaite;
 random block a*block / s;
 lsmeans a b a*b / diff;
run;
```

In the example, this applies to the “Type III Tests of Fixed Effects,” “Least Squares Means,” and “Differences of Least Squares Means” tables. In the MIXED procedure, the Satterthwaite approximation overrides the DDF= specification.

- The DDFM=BETWITHIN degrees-of-freedom method in the GLIMMIX procedure requires that the data be processed by subjects; see the section “Processing by Subjects” on page 3082.

- When you add the response variable to the **CLASS** statement, PROC GLIMMIX defaults to the multinomial distribution. Adding the response variable to the **CLASS** statement in PROC MIXED has no effect on the fitted model.
- The ODS name of the table for the solution of fixed effects is SolutionF in the MIXED procedure. In PROC GLIMMIX, the name of the table that contains fixed-effects solutions is “ParameterEstimates.” In generalized linear models, this table also contains scale parameters and overdispersion parameters. The MIXED procedure always produces a “Covariance Parameter Estimates” table. The GLIMMIX procedure produces this table only in mixed models or models with nontrivial R-side covariance structure.
- If you compute predicted values in the GLIMMIX procedure in a model with only R-side random components and missing values for the dependent variable, the predicted values will *not* be kriging predictions as is the case with the MIXED procedure.

---

## Singly or Doubly Iterative Fitting

Depending on the structure of your model, the GLIMMIX procedure determines the appropriate approach for estimating the parameters of the model. The elementary algorithms fall into three categories:

### 1. Noniterative algorithms

A closed form solution exists for all model parameters. Standard linear models with homoscedastic, uncorrelated errors can be fit with noniterative algorithms.

### 2. Singly iterative algorithms

A single optimization, consisting of one or more iterations, is performed to obtain solutions for the parameter estimates by numerical techniques. Linear mixed models for normal data can be fit with singly iterative algorithms. Laplace and quadrature estimation for generalized linear mixed models uses a singly iterative algorithm with a separate suboptimization to compute the random-effects solutions as modes of the log-posterior distribution.

### 3. Doubly iterative algorithms

A model of simpler structure is derived from the target model. The parameters of the simpler model are estimated by noniterative or singly iterative methods. Based on these new estimates, the model of simpler structure is rederived and another estimation step follows. The process continues until changes in the parameter estimates are sufficiently small between two recomputations of the simpler model or until some other criterion is met. The rederivation of the model can often be cast as a change of the response to some pseudo-data along with an update of implicit model weights.

Obviously, noniterative algorithms are preferable to singly iterative ones, which in turn are preferable to doubly iterative algorithms. Two drawbacks of doubly iterative algorithms based on linearization are that likelihood-based measures apply to the pseudo-data, not the original data, and that at the outer level the progress of the algorithm is tied to monitoring the parameter estimates. The advantage of doubly iterative algorithms, however, is to offer—at convergence—the statistical inference tools that apply to the simpler models.

The output and log messages contain information about which algorithm is employed. For a noniterative algorithm, PROC GLIMMIX produces a message that no optimization was performed. Noniterative algorithms are employed automatically for normal data with identity link.

You can determine whether a singly or doubly iterative algorithm was used, based on the “Iteration History” table and the “Convergence Status” table (Figure 41.17).

**Figure 41.17** Iteration History and Convergence Status in Singly Iterative Fit

| The GLIMMIX Procedure |          |             |                       |            |                 |
|-----------------------|----------|-------------|-----------------------|------------|-----------------|
| Iteration History     |          |             |                       |            |                 |
| Iteration             | Restarts | Evaluations | Objective<br>Function | Change     | Max<br>Gradient |
| 0                     | 0        | 4           | 83.039723731          | .          | 13.63536        |
| 1                     | 0        | 3           | 82.189661988          | 0.85006174 | 0.281308        |
| 2                     | 0        | 3           | 82.189255211          | 0.00040678 | 0.000174        |
| 3                     | 0        | 3           | 82.189255211          | 0.00000000 | 1.05E-10        |

Convergence criterion (GCONV=1E-8) satisfied.

The “Iteration History” table contains the Evaluations column that shows how many function evaluations were performed in a particular iteration. The convergence status message informs you which convergence criterion was met when the estimation process concluded. In a singly iterative fit, the criterion is one that applies to the optimization. In other words, it is one of the criteria that can be controlled with the **NLOPTIONS** statement: see the **ABSCONV=**, **ABSFCONV=**, **ABSGCONV=**, **ABSXCONV=**, **FCONV=**, or **GCONV=** option.

In a doubly iterative fit, the “Iteration History” table does not contain an Evaluations column. Instead it displays the number of iterations within an optimization (Subiterations column in Figure 41.18).

**Figure 41.18** Iteration History and Convergence Status in Doubly Iterative Fit

| Iteration History |          |               |                       |            |                 |  |
|-------------------|----------|---------------|-----------------------|------------|-----------------|--|
| Iteration         | Restarts | Subiterations | Objective<br>Function | Change     | Max<br>Gradient |  |
| 0                 | 0        | 5             | 79.688580269          | 0.11807224 | 7.851E-7        |  |
| 1                 | 0        | 3             | 81.294622554          | 0.02558021 | 8.209E-7        |  |
| 2                 | 0        | 2             | 81.438701534          | 0.00166079 | 4.061E-8        |  |
| 3                 | 0        | 1             | 81.444083567          | 0.00006263 | 2.311E-8        |  |
| 4                 | 0        | 1             | 81.444265216          | 0.00000421 | 0.000025        |  |
| 5                 | 0        | 1             | 81.444277364          | 0.00000383 | 0.000023        |  |
| 6                 | 0        | 1             | 81.444266322          | 0.00000348 | 0.000021        |  |
| 7                 | 0        | 1             | 81.44427636           | 0.00000316 | 0.000019        |  |
| 8                 | 0        | 1             | 81.444267235          | 0.00000287 | 0.000017        |  |
| 9                 | 0        | 1             | 81.444275529          | 0.00000261 | 0.000016        |  |
| 10                | 0        | 1             | 81.44426799           | 0.00000237 | 0.000014        |  |
| 11                | 0        | 1             | 81.444274843          | 0.00000216 | 0.000013        |  |
| 12                | 0        | 1             | 81.444268614          | 0.00000196 | 0.000012        |  |
| 13                | 0        | 1             | 81.444274277          | 0.00000178 | 0.000011        |  |
| 14                | 0        | 1             | 81.444269129          | 0.00000162 | 9.772E-6        |  |
| 15                | 0        | 0             | 81.444273808          | 0.00000000 | 9.102E-6        |  |

Convergence criterion (PCONV=1.11022E-8) satisfied.

The Iteration column then counts the number of optimizations. The “Convergence Status” table indicates that the estimation process concludes when a criterion is met that monitors the parameter estimates across optimization, namely the `PCONV=` or `ABSPCONV=` criterion.

You can control the optimization process with the GLIMMIX procedure through the `NLOPTIONS` statement. Its options affect the individual optimizations. In a doubly iterative scheme, these apply to all optimizations.

The default optimization techniques are `TECHNIQUE=NONE` for noniterative estimation, `TECHNIQUE=NEWRAP` for singly iterative methods in GLMs, `TECHNIQUE=NRRIDG` for pseudo-likelihood estimation with binary data, and `TECHNIQUE=QUANEW` for other mixed models.

---

## Default Estimation Techniques

Based on the structure of the model, the GLIMMIX procedure selects the estimation technique for estimating the model parameters. If you fit a generalized linear mixed model, you can change the estimation technique with the `METHOD=` option in the `PROC GLIMMIX` statement. The defaults are determined as follows:

- generalized linear model
  - normal distribution: restricted maximum likelihood
  - all other distributions: maximum likelihood

- generalized linear model with overdispersion  
Parameters ( $\beta$ ;  $\phi$ , if present) are estimated by (restricted) maximum likelihood as for generalized linear models. The overdispersion parameter is estimated from the Pearson statistic after all other parameters have been estimated.
- generalized linear mixed models  
The default technique is `METHOD=RSPL`, corresponding to maximizing the residual log pseudo-likelihood with an expansion about the current solutions of the best linear unbiased predictors of the random effects. In models for normal data with identity link, `METHOD=RSPL` and `METHOD=RMPL` are equivalent to restricted maximum likelihood estimation, and `METHOD=MSPL` and `METHOD=MMPL` are equivalent to maximum likelihood estimation. This is reflected in the labeling of statistics in the “Fit Statistics” table.

---

## Default Output

The following sections describe the output that PROC GLIMMIX produces by default. The output is organized into various tables, which are discussed in the order of appearance. Note that the contents of a table can change with the estimation method or the model being fit.

### Model Information

The “Model Information” table displays basic information about the fitted model, such as the link and variance functions, the distribution of the response, and the data set. If important model quantities—for example, the response, weights, link, or variance function—are user-defined, the “Model Information” table displays the final assignment to the respective variable, as determined from your programming statements. If the table indicates that the variance matrix is blocked by an effect, then PROC GLIMMIX processes the data by subjects. The “Dimensions” table displays the number of subjects. For more information about processing by subjects, see the section “Processing by Subjects” on page 3082. The ODS name of the “Model Information” table is ModelInfo.

### Class Level Information

The “Class Level Information” table lists the levels of every variable specified in the `CLASS` statement. You should check this information to make sure that the data are correct. You can adjust the order of the `CLASS` variable levels with the `ORDER=` option in the `PROC GLIMMIX` statement. The ODS name of the “Class Level Information” table is ClassLevels.

### Number of Observations

The “Number of Observations” table displays the number of observations read from the input data set and the number of observations used in the analysis. If you specify a `FREQ` statement, the table also displays the sum of frequencies read and used. If the *events/trials* syntax is used for the response, the table also displays the number of events and trials used in the analysis. The ODS name of the “Number of Observations” table is NObs.

## Response Profile

For binary and multinomial data, the “Response Profile” table displays the Ordered Value from which the GLIMMIX procedure determines the following:

- the probability being modeled for binary data
- the ordering of categories for ordinal data
- the reference category for generalized logit models

For each response category level, the frequency used in the analysis is reported. The section “Response-Level Ordering and Referencing” on page 3100 explains how you can use the **DESCENDING**, **EVENT=**, **ORDER=**, and **REF=** options to affect the assignment of Ordered Values to the response categories. The ODS name of the “Response Profile” table is ResponseProfile.

## Dimensions

The “Dimensions” table displays information from which you can determine the size of relevant matrices in the model. This table is useful in determining CPU time and memory requirements. For ODS purposes, the name of the “Dimensions” table is “Dimensions.”

## Optimization Information

The “Optimization Information” table displays important details about the optimization process.

The optimization technique that is displayed in the table is the technique that applies to any single optimization. For singly iterative methods that is *the* optimization method.

The number of parameters that are updated in the optimization equals the number of parameters in this table minus the number of equality constraints. The number of constraints is displayed if you fix covariance parameters with the **HOLD=** option in the **PARMS** statement. The GLIMMIX procedure also lists the number of upper and lower boundary constraints. Note that the procedure might impose boundary constraints for certain parameters, such as variance components and correlation parameters. Covariance parameters for which a **HOLD=** was issued have an upper and lower boundary equal to the parameter value.

If a residual scale parameter is profiled from the optimization, it is also shown in the “Optimization Information” table.

In a GLMM for which the parameters are estimated by one of the linearization methods, you need to initiate the process of computing the pseudo-response. This can be done based on existing estimates of the fixed effects, or by using the data themselves—possibly after some suitable adjustment—as an estimate of the initial mean. The default in PROC GLIMMIX is to use the data themselves to derive initial estimates of the mean function and to construct the pseudo-data. The “Optimization Information” table shows how the pseudo-data are determined initially. Note that this issue is separate from the determination of starting values for the covariance parameters. These are computed as minimum variance quadratic unbiased estimates (with 0 priors, MIVQUE0; Goodnight 1978a) or obtained from the *value-list* in the **PARMS** statement.

The ODS name of the table is OptInfo.

## Iteration History

The “Iteration History” table describes the progress of the estimation process. In singly iterative methods, the table displays the following:

- the iteration count, `Iteration`
- the number of restarts, `Restarts`
- the number of function evaluations, `Evaluations`
- the objective function, `Objective`
- the change in the objective function, `Change`
- the absolute value of the largest (projected) gradient, `MaxGradient`

Note that the change in the objective function is not the convergence criterion monitored by the GLIMMIX procedure. PROC GLIMMIX tracks several convergence criteria simultaneously; see the `ABSCONV=`, `ABSFCONV=`, `ABSGCONV=`, `ABSXCONV=`, `FCONV=`, or `GCONV=` option in the `NLOPTIONS` statement.

For doubly iterative estimation methods, the “Iteration History” table does not display the progress of the individual optimizations; instead, it reports on the progress of the outer iterations. Every row of the table then corresponds to an update of the linearization, the computation of a new set of pseudo-data, and a new optimization. In the listing, PROC GLIMMIX displays the following:

- the optimization count, `Iteration`
- the number of restarts, `Restarts`
- the number of iterations per optimization, `Subiterations`
- the change in the parameter estimates, `Change`
- the absolute value of the largest (projected) gradient at the end of the optimization, `MaxGradient`

By default, the change in the parameter estimates is expressed in terms of the relative `PCONV` criterion. If you request an absolute criterion with the `ABSPCONV` option of the `PROC GLIMMIX` statement, the change reflects the largest absolute difference since the last optimization.

If you specify the `ITDETAILS` option in the `PROC GLIMMIX` statement, parameter estimates and their gradients are added to the “Iteration History” table. For ODS purposes, the name of the “Iteration History” table is “IterHistory.”

## Convergence Status

The “Convergence Status” table contains a status message describing the reason for termination of the optimization. The message is also written to the log. The ODS name of the “Convergence Status” table is `ConvergenceStatus`, and you can query the nonprinting numeric variable `Status` to check for a successful optimization. This is useful in batch processing, or when processing `BY` groups, such as in simulations. Successful optimizations are indicated by the value 0 of the `Status` variable.

## Fit Statistics

The “Fit Statistics” table provides statistics about the estimated model. The first entry of the table corresponds to the negative of twice the (possibly restricted) log likelihood, log pseudo-likelihood, or log quasi-likelihood. If the estimation method permits the true log likelihood or residual log likelihood, the description of the first entry reads accordingly. Otherwise, the fit statistics are preceded by the words *Pseudo-* or *Quasi-*, for Pseudo- and Quasi-Likelihood estimation, respectively.

Note that the (residual) log pseudo-likelihood in a GLMM is the (residual) log likelihood of a linearized model. You should not compare these values across different statistical models, even if the models are nested with respect to fixed and/or G-side random effects. It is possible that between two nested models the larger model has a smaller pseudo-likelihood. For this reason, IC=NONE is the default for GLMMs fit by pseudo-likelihood methods.

See the IC= option of the PROC GLIMMIX statement and Table 41.2 for the definition and computation of the information criteria reported in the “Fit Statistics” table.

For generalized linear models, the GLIMMIX procedure reports Pearson’s chi-square statistic

$$X^2 = \sum_i \frac{w_i (y_i - \hat{\mu}_i)^2}{a(\hat{\mu}_i)}$$

where  $a(\hat{\mu}_i)$  is the variance function evaluated at the estimated mean.

For GLMMs, the procedure typically reports a generalized chi-square statistic,

$$X_g^2 = \hat{\mathbf{r}}' \mathbf{V}(\hat{\boldsymbol{\theta}}^*)^{-1} \hat{\mathbf{r}}$$

so that the ratio of  $X^2$  or  $X_g^2$  and the degrees of freedom produces the usual residual dispersion estimate.

If the R-side scale parameter  $\phi$  is not extracted from  $\mathbf{V}$ , the GLIMMIX procedure computes

$$X_g^2 = \hat{\mathbf{r}}' \mathbf{V}(\hat{\boldsymbol{\theta}})^{-1} \hat{\mathbf{r}}$$

as the generalized chi-square statistic. This is the case, for example, if R-side covariance structures are varied by a GROUP= effect or if the scale parameter is not profiled for an R-side TYPE=CS, TYPE=SP, TYPE=AR, TYPE=TOEP, or TYPE=ARMA covariance structure.

For METHOD=LAPLACE, the generalized chi-square statistic is not reported. Instead, the Pearson statistic for the conditional distribution appears in the “Conditional Fit Statistics” table.

If your model contains smooth components (such as TYPE=RSMOOTH), then the “Fit Statistics” table also displays the residual degrees of freedom of the smoother. These degrees of freedom are computed as

$$df_{smooth, res} = f - \text{trace}(\mathbf{S})$$

where  $\mathbf{S}$  is the “smoother” matrix—that is, the matrix that produces the predicted values on the linked scale.

The ODS name of the “Fit Statistics” table is FitStatistics.

## Covariance Parameter Estimates

In a GLMM, the “Covariance Parameter Estimates” table displays the estimates of the covariance parameters and their asymptotic standard errors. This table is produced only for generalized linear *mixed* models. In generalized linear models with scale parameter, or when an overdispersion parameter is present, the estimates of parameters related to the dispersion are displayed in the “Parameter Estimates” table.

The standard error of the covariance parameters is determined from the diagonal entries of the asymptotic variance matrix of the covariance parameter estimates. You can display this matrix with the `ASYCOV` option in the `PROC GLIMMIX` statement.

The ODS name of the “Covariance Parameter Estimates” table is `CovParms`.

## Type III Tests of Fixed Effects

The “Type III Tests of Fixed Effects” table contains hypothesis tests for the significance of each of the fixed effects specified in the `MODEL` statement. By default, `PROC GLIMMIX` computes these tests by first constructing a Type III `L` matrix for each effect; see Chapter 15, “The Four Types of Estimable Functions.” The `L` matrix is then used to construct the test statistic

$$F = \frac{\hat{\boldsymbol{\beta}}' \mathbf{L}' (\mathbf{LQL}')^{-1} \mathbf{L} \hat{\boldsymbol{\beta}}}{\text{rank}(\mathbf{LQL}')}$$

where the matrix `Q` depends on the estimation method and options. For example, in a GLMM, the default is  $\mathbf{Q} = (\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{X})^{-}$ , where  $\mathbf{V}(\boldsymbol{\theta})$  is the marginal variance of the pseudo-response. If you specify the `DDFM=KENWARDROGER` option, `Q` is the estimated variance matrix of the fixed effects, adjusted by the method of Kenward and Roger (1997). If the `EMPIRICAL=` option is in effect, `Q` corresponds to the selected sandwich estimator.

You can use the `HTYPE=` option in the `MODEL` statement to obtain tables of Type I (sequential) tests and Type II (adjusted) tests in addition to or instead of the table of Type III (partial) tests.

The ODS names of the “Type I Tests of Fixed Effects” through the “Type III Tests of Fixed Effects” tables are `Tests1` through `Tests3`, respectively.

## Notes on Output Statistics

Table 41.14 lists the statistics computed with the `OUTPUT` statement of the `GLIMMIX` procedure and their default names. This section provides further details about these statistics.

The distinction between prediction and confidence limits in Table 41.14 stems from the involvement of the predictors of the random effects. If the random-effect solutions (BLUPs, EBES) are involved, then the associated standard error used in computing the limits are standard errors of prediction rather than standard errors of estimation. The prediction limits are *not* limits for the prediction of a new observation.

The Pearson residuals in Table 41.14 are “Pearson-type” residuals, because the residuals are standardized by the square root of the marginal or conditional variance of an observation. Traditionally, Pearson residuals in generalized linear models are divided by the square root of the variance function. The `GLIMMIX` procedure divides by the square root of the variance so that marginal and conditional residuals have similar expressions. In other words, scale and overdispersion parameters are included.

When residuals or predicted values involve only the fixed effects part of the linear predictor (that is,  $\hat{\eta}_m = \mathbf{x}'\hat{\boldsymbol{\beta}}$ ), then all model quantities are computed based on this predictor. For example, if the variance by which to standardize a marginal residual involves the variance function, then the variance function is also evaluated at the marginal mean,  $g^{-1}(\hat{\eta}_m)$ . Thus the residuals  $p - \hat{\eta}$  and  $p_m - \hat{\eta}_m$  can also be expressed as  $(y - \mu)/\partial\mu$  and  $(y - \mu_m)/\partial\mu_m$ , respectively, where  $\partial\mu$  is the derivative with respect to the linear predictor. To construct the residual  $p - \hat{\eta}_m$  in a GLMM, you can add the value of `_ZGAMMA_` to the conditional residual  $p - \hat{\eta}$ . (The residual  $p - \hat{\eta}_m$  is computed instead of the default marginal residual when you specify the `CPSEUDO` option in the `OUTPUT` statement.) If the predictor involves the BLUPs, then all relevant expressions and evaluations involve the conditional mean  $g^{-1}(\hat{\eta})$ .

The naming convention to add “PA” to quantities not involving the BLUPs is chosen to suggest the concept of a population average. When the link function is nonlinear, these are not truly population-averaged quantities, because  $g^{-1}(\mathbf{x}'\boldsymbol{\beta})$  does not equal  $E[Y]$  in the presence of random effects. For example, if

$$\mu_i = g^{-1}(\mathbf{x}'_i\boldsymbol{\beta} + \mathbf{z}'_i\boldsymbol{\gamma}_i)$$

is the conditional mean for subject  $i$ , then

$$g^{-1}(\mathbf{x}'_i\hat{\boldsymbol{\beta}})$$

does not estimate the average response in the population of subjects but the response of the average subject (the subject for which  $\boldsymbol{\gamma}_i = \mathbf{0}$ ). For models with identity link, the average response and the response of the average subject are identical.

The GLIMMIX procedure obtains standard errors on the scale of the mean by the delta method. If the link is a nonlinear function of the linear predictor, these standard errors are only approximate. For example,

$$\text{Var}[g^{-1}(\hat{\eta}_m)] \doteq \left( \frac{\partial g^{-1}(t)}{\partial t} \Big|_{\hat{\eta}_m} \right)^2 \text{Var}[\hat{\eta}_m]$$

Confidence limits on the scale of the data are usually computed by applying the inverse link function to the confidence limits on the linked scale. The resulting limits on the data scale have the same coverage probability as the limits on the linked scale, but they are possibly asymmetric.

In generalized logit models, confidence limits on the mean scale are based on symmetric limits about the predicted mean in a category. Suppose that the multinomial response in such a model has  $J$  categories. The probability of a response in category  $i$  is computed as

$$\hat{\mu}_i = \frac{\exp\{\hat{\eta}_i\}}{\sum_{j=1}^J \exp\{\hat{\eta}_j\}}$$

The variance of  $\hat{\mu}_i$  is then approximated as

$$\text{Var}[\hat{\mu}_i] \doteq \zeta = \mathbf{v}'_i \text{Var} \begin{bmatrix} \hat{\eta}_1 & \hat{\eta}_2 & \cdots & \hat{\eta}_J \end{bmatrix} \mathbf{v}_i$$

where  $\mathbf{v}_i$  is a  $J \times 1$  vector with  $k$ th element

$$\begin{aligned} \hat{\mu}_i(1 - \hat{\mu}_i) & \quad i = k \\ -\hat{\mu}_i\hat{\mu}_k & \quad i \neq k \end{aligned}$$

The confidence limits in the generalized logit model are then obtained as

$$\hat{\mu}_i \pm t_{\nu, \alpha/2} \sqrt{\zeta}$$

where  $t_{\nu, \alpha/2}$  is the  $100 \times (1 - \alpha/2)$  percentile from a  $t$  distribution with  $\nu$  degrees of freedom. Confidence limits are truncated if they fall outside the  $[0, 1]$  interval.

## ODS Table Names

Each table created by PROC GLIMMIX has a name associated with it, and you must use this name to reference the table when you use ODS statements. These names are listed in Table 41.23.

**Table 41.23** ODS Tables Produced by PROC GLIMMIX

| Table Name        | Description                                                                                                      | Required Statement / Option                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| AsyCorr           | asymptotic correlation matrix of covariance parameters                                                           | PROC GLIMMIX ASYCORR                                                                                                                             |
| AsyCov            | asymptotic covariance matrix of covariance parameters                                                            | PROC GLIMMIX ASYCOV                                                                                                                              |

| VCorr      | correlation matrix from the blocks of the estimated <b>V</b> matrix | RANDOM / VCORR              |

The SLICE statement also creates tables, which are not listed in Table 41.23. For information about these tables, see the section “SLICE Statement” on page 498 of Chapter 19, “Shared Concepts and Topics.”

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

The following subsections provide information about the basic ODS statistical graphics produced by the GLIMMIX procedure. The graphics fall roughly into two categories: diagnostic plots and graphics for least squares means.

### ODS Graph Names

The GLIMMIX procedure does not produce graphs by default. You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC GLIMMIX generates are listed in Table 41.24, along with the required statements and options.

**Table 41.24** Graphs Produced by PROC GLIMMIX

| ODS Graph Name | Plot Description                                                | Option                                           |
|----------------|-----------------------------------------------------------------|--------------------------------------------------|
| AnomPlot       | Plot of LS-mean differences against the average LS-mean         | PLOTS=ANOMPLOT<br>LSMEANS / PLOTS=ANOMPLOT       |
| Boxplot        | Box plots of residuals and/or observed values for model effects | PLOTS=BOXPLOT                                    |
| ControlPlot    | Plot of LS-mean differences against a control level             | PLOTS=CONTROLPLOT<br>LSMEANS / PLOTS=CONTROLPLOT |
| DiffPlot       | Plot of LS-mean pairwise differences                            | PLOTS=DIFFPLOT<br>LSMEANS / PLOTS=DIFFPLOT       |

Table 41.24 *continued*

| ORPlot              | Plot of odds ratios                                | PLOTS=ODDSRATIO                            |
| PearsonBoxplot      | Box plot of Pearson residuals                      | PLOTS=PEARSONPANEL(UNPACK)                 |
| PearsonByPredicted  | Pearson residuals vs. mean                         | PLOTS=PEARSONPANEL(UNPACK)                 |
| PearsonHistogram    | Histogram of Pearson residuals                     | PLOTS=PEARSONPANEL(UNPACK)                 |
| PearsonPanel        | Panel of Pearson residuals                         | PLOTS=PEARSONPANEL                         |
| PearsonQQplot       | <i>Q-Q</i> plot of Pearson residuals               | PLOTS=PEARSONPANEL(UNPACK)                 |
| ResidualBoxplot     | Box plot of (raw) residuals                        | PLOTS=RESIDUALPANEL(UNPACK)                |
| ResidualByPredicted | Residuals vs. mean or linear predictor             | PLOTS=RESIDUALPANEL(UNPACK)                |
| ResidualHistogram   | Histogram of (raw) residuals                       | PLOTS=RESIDUALPANEL(UNPACK)                |
| ResidualPanel       | Panel of (raw) residuals                           | PLOTS=RESIDUALPANEL                        |
| ResidualQQplot      | <i>Q-Q</i> plot of (raw) residuals                 | PLOTS=RESIDUALPANEL(UNPACK)                |
| StudentBoxplot      | Box plot of studentized residuals                  | PLOTS=STUDENTPANEL(UNPACK)                 |
| StudentByPredicted  | Studentized residuals vs. mean or linear predictor | PLOTS=STUDENTPANEL(UNPACK)                 |
| StudentHistogram    | Histogram of studentized residuals                 | PLOTS=STUDENTPANEL(UNPACK)                 |
| StudentPanel        | Panel of studentized residuals                     | PLOTS=STUDENTPANEL                         |
| StudentQQplot       | <i>Q-Q</i> plot of studentized residuals           | PLOTS=STUDENTPANEL(UNPACK)                 |

When ODS Graphics is enabled, the SLICE statement can produce plots that are associated with its analysis. For information about these plots, see the section “[SLICE Statement](#)” on page 498 of Chapter 19, “[Shared Concepts and Topics](#).”

## Diagnostic Plots

### Residual Panels

There are three types of residual panels in the GLIMMIX procedure. Their makeup of four component plots is the same; the difference lies in the type of residual from which the panel is computed. Raw residuals are displayed with the `PLOTS=RESIDUALPANEL` option. Studentized residuals are displayed with the `PLOTS=STUDENTPANEL` option, and Pearson residuals with the `PLOTS=PEARSONPANEL` option. By default, conditional residuals are used in the construction of the panels if the model contains G-side random effects. For example, consider the following statements:

```
proc glimmix plots=residualpanel;
 class A;
 model y = x1 x2 / dist=Poisson;
 random int / sub=A;
run;
```

The parameters are estimated by a pseudo-likelihood method, and at the final stage pseudo-data are related to a linear mixed model with random intercepts. The residual panel is constructed from

$$r = p - \mathbf{x}'\hat{\boldsymbol{\beta}} + \mathbf{z}'\hat{\boldsymbol{\gamma}}$$

where  $p$  is the pseudo-data.

The following hypothetical data set contains yields of an industrial process. Material was available from five randomly selected vendors to produce a chemical reaction whose yield depends on two factors (pressure and temperature at 3 and 2 levels, respectively).

```
data Yields;
 input Vendor Pressure Temp Yield @@;
 datalines;
 1 1 1 10.20 1 1 2 9.48 1 2 1 9.74
 1 2 2 8.92 1 3 1 11.79 1 3 2 8.85
 2 1 1 10.43 2 1 2 10.59 2 2 1 10.29
 2 2 2 10.15 2 3 1 11.12 2 3 2 9.30
 3 1 1 6.46 3 1 2 7.34 3 2 1 9.44
 3 2 2 8.11 3 3 1 9.38 3 3 2 8.37
 4 1 1 7.36 4 1 2 9.92 4 2 1 10.99
 4 2 2 10.34 4 3 1 10.24 4 3 2 9.96
 5 1 1 11.72 5 1 2 10.60 5 2 1 11.28
 5 2 2 9.03 5 3 1 14.09 5 3 2 8.92
 ;
```

Consider a linear mixed model with a two-way factorial fixed-effects structure for pressure and temperature effects and independent, homoscedastic random effects for the vendors. The following statements fit this model and request panels of marginal and conditional residuals:

```
ods graphics on;

proc glimmix data=Yields
 plots=residualpanel(conditional marginal);
 class Vendor Pressure Temp;
 model Yield = Pressure Temp Pressure*Temp;
 random vendor;
run;

ods graphics off;
```

The suboptions of the RESIDUALPANEL request produce two panels. The panel of conditional residuals is constructed from  $y - \mathbf{x}'\hat{\boldsymbol{\beta}} - \mathbf{z}'\hat{\boldsymbol{\gamma}}$  (Figure 41.19). The panel of marginal residuals is constructed from  $y - \mathbf{x}'\hat{\boldsymbol{\beta}}$  (Figure 41.20). Note that these residuals are deviations from the observed data, because the model is a normal linear mixed model, and hence it does not involve pseudo-data. Whenever the random-effects solutions  $\hat{\boldsymbol{\gamma}}$  are involved in constructing residuals, the title of the residual graphics identifies them as conditional residuals (Figure 41.19).

**Figure 41.19** Conditional Residuals

Figure 41.20 Marginal Residuals

The predictor takes on only six values for the marginal residuals, corresponding to the combinations of three temperature and two pressure levels. The assumption of a zero mean for the vendor random effect seems justified; the marginal residuals in the upper-left plot of Figure 41.20 do not exhibit any trend. The conditional residuals in Figure 41.19 are smaller and somewhat closer to normality compared to the marginal residuals.

### Box Plots

You can produce box plots of observed data, pseudo-data, and various residuals for effects in your model that consist of classification variables. Because you might not want to produce box plots for all such effects, you can request subsets with the suboptions of the `BOXPLOT` option in the `PLOTS` option. The `BOXPLOT` request in the following `PROC GLIMMIX` statement produces box plots for the random effects—in this case, the vendor effect. By default, `PROC GLIMMIX` constructs box plots from conditional residuals. The `MARGINAL`, `CONDITIONAL`, and `OBSERVED` suboptions instruct the procedure to construct three box plots for each random effect: box plots of the observed data (Figure 41.21), the marginal residuals (Figure 41.22), and the conditional residuals (Figure 41.23).

```
ods graphics on;

proc glimmix data=Yields
 plots=boxplot(random marginal conditional observed);
 class Vendor Pressure Temp;
 model Yield = Pressure Temp Pressure*Temp;
 random vendor;
run;

ods graphics off;
```

The observed vendor means in Figure 41.21 are different; in particular, vendors 3 and 5 appear to differ from the other vendors and from each other. There is also heterogeneity of variance in the five groups. The marginal residuals in Figure 41.22 continue to show the differences in means by vendor, because vendor enters the model as a random effect. The marginal means are adjusted for vendor effects only in the sense that the vendor variance component affects the marginal variance that is involved in the generalized least squares solution for the pressure and temperature effects.

**Figure 41.21** Box Plots of Observed Values

**Figure 41.22** Box Plots of Marginal Residuals

The conditional residuals account for the vendor effects through the empirical BLUPs. The means and medians have stabilized near zero, but some heterogeneity in these residuals remains (Figure 41.23).

**Figure 41.23** Box Plots of Conditional Residuals

### Graphics for LS-Mean Comparisons

The following subsections provide information about the ODS statistical graphics for least squares means produced by the GLIMMIX procedure. Mean plots display marginal or interaction means. The diffogram, control plot, and ANOM plot display least squares mean comparisons.

#### *Mean Plots*

The following SAS statements request a plot of the Pressure×Temp means in which the pressure trends are plotted for each temperature.

```
ods graphics on;
ods select CovParms Tests3 MeanPlot;
proc glimmix data=Yields;
 class Vendor Pressure Temp;
 model Yield = Pressure Temp Pressure*Temp;
 random Vendor;
 lsmeans Pressure*Temp / plot=mean(sliceby=Temp join);
run;
ods graphics off;
```

There is a significant effect of temperature and an interaction between pressure and temperature (Figure 41.24). Notice that the pressure main effect might be masked by the interaction. Because of the interaction, temperature comparisons depend on the pressure and vice versa. The mean plot option requests a display of the Pressure  $\times$  Temp least squares means with separate trends for each temperature (Figure 41.25).

**Figure 41.24** Tests for Fixed Effects

| The GLIMMIX Procedure           |           |           |          |        |
|---------------------------------|-----------|-----------|----------|--------|
| Covariance Parameter Estimates  |           |           |          |        |
| Cov Parm                        | Estimate  |           | Standard |        |
|                                 |           |           | Error    |        |
| Vendor                          | 0.8602    |           | 0.7406   |        |
| Residual                        | 1.1039    |           | 0.3491   |        |
| Type III Tests of Fixed Effects |           |           |          |        |
| Effect                          | Num<br>DF | Den<br>DF | F Value  | Pr > F |
| Pressure                        | 2         | 20        | 1.42     | 0.2646 |
| Temp                            | 1         | 20        | 6.48     | 0.0193 |
| Pressure*Temp                   | 2         | 20        | 3.82     | 0.0393 |

The interaction between the two effects is evident in the lack of parallelism in Figure 41.25. The masking of the pressure main effect can be explained by slopes of different sign for the two trends. Based on these results, inferences about the pressure effects are conducted for a specific temperature. For example, Figure 41.26 is produced by adding the following statement:

```
lsmeans pressure*temp / slicediff=temp slice=temp;
```

**Figure 41.25** Interaction Plot for Pressure x Temperature

**Figure 41.26** Pressure Comparisons at a Given Temperature

| The GLIMMIX Procedure                                                  |          |           |           |                   |        |         |         |

| Temp 2                                                                 | 2        | 3         | 0.2300    | 0.6645            | 20     | 0.35    | 0.7329  |

The slope differences are evident by the change in sign for comparisons within temperature 1 and within temperature 2. There is a significant effect of pressure at temperature 1 ( $p = 0.0179$ ), but not at temperature 2 ( $p = 0.7508$ ).

### ***Pairwise Difference Plot (Diffogram)***

Graphical displays of LS-means-related analyses consist of plots of all pairwise differences (DiffPlot), plots of differences against a control level (ControlPlot), and plots of differences against an overall average (AnomPlot). The following data set is from an experiment to investigate how snapdragons grow in various soils (Stenstrom 1940). To eliminate the effect of local fertility variations, the experiment is run in blocks, with each soil type sampled in each block. See the “Examples” section of Chapter 42, “The GLM Procedure,” for an in-depth analysis of these data.

```

data plants;
 input Type $ @;
 do Block = 1 to 3;
 input StemLength @;
 output;
 end;
 datalines;
Clarion 32.7 32.3 31.5
Clinton 32.1 29.7 29.1
Knox 35.7 35.9 33.1
ONeill 36.0 34.2 31.2
Compost 31.8 28.0 29.2
Wabash 38.2 37.8 31.9
Webster 32.5 31.1 29.7
;

```

The following statements perform the analysis of the experiment with the GLIMMIX procedure:

```

ods graphics on;
ods select LSMeans DiffPlot;

proc glimmix data=plants order=data plots=Diffogram;
 class Block Type;
 model StemLength = Block Type;
 lsmeans Type;
run;

ods graphics off;

```

The `PLOTS=` option in the `PROC GLIMMIX` statement requests that plots of pairwise least squares means differences are produced for effects that are listed in corresponding `LSMEANS` statements. This is the `Type` effect.

The Type LS-means are shown in Figure 41.27. Note that the order in which the levels appear corresponds to the order in which they were read from the data set. This was accomplished with the `ORDER=DATA` option in the `PROC GLIMMIX` statement.

**Figure 41.27** Least Squares Means for Type Effect

| The GLIMMIX Procedure    |          |                |    |         |         |
|--------------------------|----------|----------------|----|---------|---------|
| Type Least Squares Means |          |                |    |         |         |
| Type                     | Estimate | Standard Error | DF | t Value | Pr >  t |
| Clarion                  | 32.1667  | 0.7405         | 12 | 43.44   | <.0001  |
| Clinton                  | 30.3000  | 0.7405         | 12 | 40.92   | <.0001  |
| Knox                     | 34.9000  | 0.7405         | 12 | 47.13   | <.0001  |
| ONeill                   | 33.8000  | 0.7405         | 12 | 45.64   | <.0001  |
| Compost                  | 29.6667  | 0.7405         | 12 | 40.06   | <.0001  |
| Wabash                   | 35.9667  | 0.7405         | 12 | 48.57   | <.0001  |
| Webster                  | 31.1000  | 0.7405         | 12 | 42.00   | <.0001  |

Because there are seven levels of Type in this analysis, there are  $7(6 - 1)/2 = 21$  pairwise comparisons among the least squares means. The comparisons are performed in the following fashion: the first level of Type is compared against levels 2 through 7; the second level of Type is compared against levels 3 through 7; and so forth.

The default difference plot for these data is shown in Figure 41.28. The display is also known as a “mean-mean scatter plot” (Hsu 1996; Hsu and Peruggia 1994). It contains 21 lines rotated by 45 degrees counterclockwise, and a reference line (dashed 45-degree line). The  $(x, y)$  coordinate for the center of each line corresponds to the two least squares means being compared. Suppose that  $\hat{\eta}_i$  and  $\hat{\eta}_j$  denote the  $i$ th and  $j$ th least squares mean, respectively, for the effect in question, where  $i < j$  according to the ordering of the effect levels. If the ABS option is in effect, which is the default, the line segment is centered at  $(\min\{\hat{\eta}_i, \hat{\eta}_j\}, \max\{\hat{\eta}_i, \hat{\eta}_j\})$ . Take, for example, the comparison of “Clarion” and “Compost” types. The respective estimates of their LS-means are  $\hat{\eta}_{.1} = 32.1667$  and  $\hat{\eta}_{.5} = 29.6667$ . The center of the line segment for  $H_0: \eta_{.1} = \eta_{.5}$  is placed at  $(29.6667, 32.1667)$ .

The length of the line segment for the comparison between means  $i$  and  $j$  corresponds to the width of the confidence interval for the difference  $\eta_i - \eta_j$ . This length is adjusted for the rotation in the plot. As a consequence, comparisons whose confidence interval covers zero cross the 45-degree reference line. These are the nonsignificant comparisons. Lines associated with significant comparisons do not touch or cross the reference line. Because these data are balanced, the estimated standard errors of all pairwise comparisons are identical, and the widths of the line segments are the same.

Figure 41.28 LS-Means Plot of Pairwise Differences

The background grid of the difference plot is drawn at the values of the least squares means for the seven type levels. These grid lines are used to find a particular comparison by intersection. Also, the labels of the grid lines indicate the ordering of the least squares means.

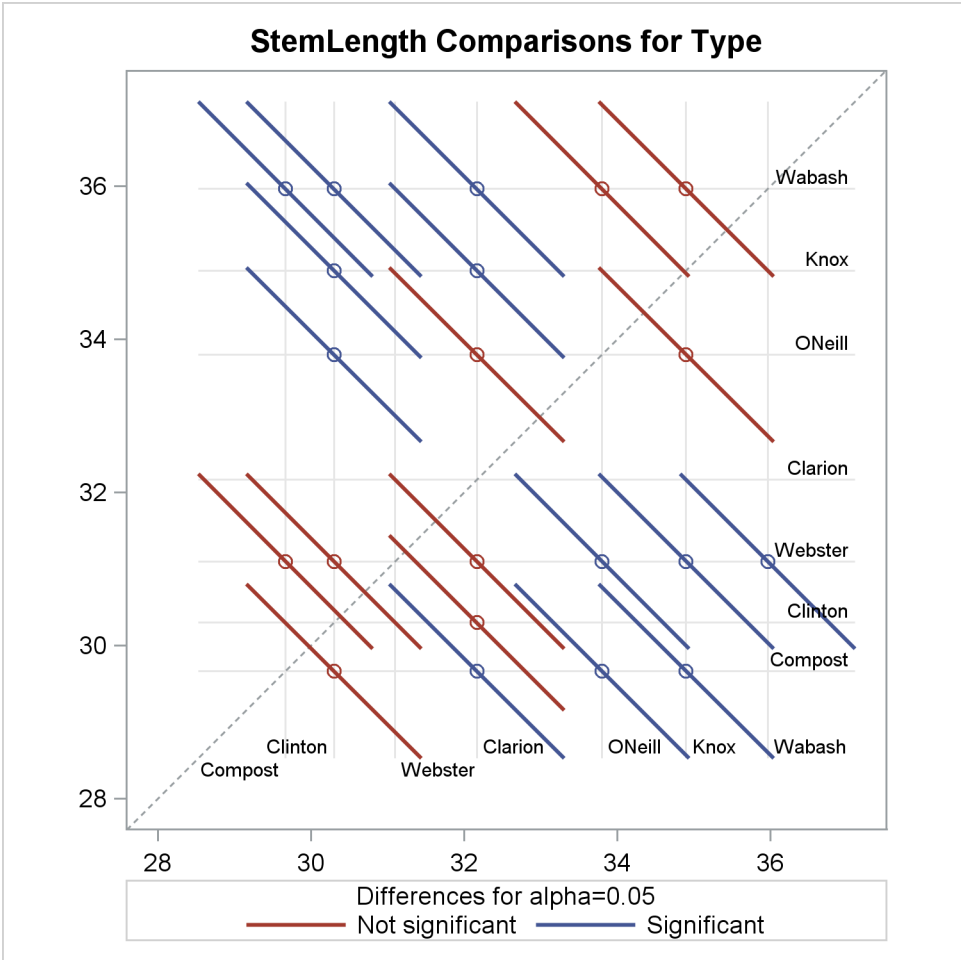

In the next set of statements, the NOABS and CENTER suboptions of the PLOTS=DIFFOGRAM option in the LSMEANS statement modify the appearance of the diffogram:

```
ods graphics on;
proc glimmix data=plants order=data;
 class Block Type;
 model StemLength = Block Type;
 lsmeans Type / plots=diffogram(noabs center);
run;
ods graphics off;
```

The NOABS suboption of the difference plot changes the way in which the GLIMMIX procedure places the line segments (Figure 41.29). If the NOABS suboption is in effect, the line segment is centered at the point  $(\hat{\eta}_{.i}, \hat{\eta}_{.j})$ ,  $i < j$ . For example, the center of the line segment for a comparison of “Clarion” and “Compost” types is centered at  $(\hat{\eta}_{.1}, \hat{\eta}_{.5}) = (32.1667, 29.6667)$ . Whether a line segment appears above or below the reference line depends on the magnitude of the least squares means and the order of their appearance in the “Least Squares Means” table. The CENTER suboption places a marker at the intersection of the least squares means.

Because the ABS option places lines on the same side of the 45-degree reference, it can help to visually discover groups of significant and nonsignificant differences. On the other hand, when the number of levels in the effect is large, the display can get crowded. The NOABS option can then provide a more accessible resolution.

Figure 41.29 Diffogram with NOABS and CENTER Options

**Least Squares Mean Control Plot**

The following SAS statements create the same data set as before, except that one observation for Type="Knox" has been removed for illustrative purposes:

```
data plants;
 input Type $ @;
 do Block = 1 to 3;
 input StemLength @;
 output;
 end;
 datalines;
Clarion 32.7 32.3 31.5
Clinton 32.1 29.7 29.1
Knox 35.7 35.9 .
ONeill 36.0 34.2 31.2
Compost 31.8 28.0 29.2
Wabash 38.2 37.8 31.9
Webster 32.5 31.1 29.7
;
```

The following statements request control plots for effects in **LSMEANS** statements with compatible option:

```
ods graphics on;
ods select Diffs ControlPlot;

proc glimmix data=plants order=data plots=ControlPlot;
 class Block Type;
 model StemLength = Block Type;
 lsmeans Type / diff=control('Clarion') adjust=dunnett;
run;

ods graphics off;
```

The **LSMEANS** statement for the Type effect is compatible; it requests comparisons of Type levels against "Clarion," adjusted for multiplicity with Dunnett's method. Because "Clarion" is the first level of the effect, the **LSMEANS** statement is equivalent to

```
lsmeans type / diff=control adjust=dunnett;
```

The "Differences of Type Least Squares Means" table in [Figure 41.30](#) shows the six comparisons between Type levels and the control level.

**Figure 41.30** Least Squares Means Differences

| The GLIMMIX Procedure                        |         |          |                |    |         |         |        |

| Differences of Type Least Squares Means      |         |          |                |    |         |         |        |
| Adjustment for Multiple Comparisons: Dunnett |         |          |                |    |         |         |        |
| Type                                         | _Type   | Estimate | Standard Error | DF | t Value | Pr >  t | Adj P  |
| Clinton                                      | Clarion | -1.8667  | 1.0937         | 11 | -1.71   | 0.1159  | 0.3936 |
| Knox                                         | Clarion | 2.7667   | 1.2430         | 11 | 2.23    | 0.0479  | 0.1854 |
| ONeill                                       | Clarion | 1.6333   | 1.0937         | 11 | 1.49    | 0.1635  | 0.5144 |
| Compost                                      | Clarion | -2.5000  | 1.0937         | 11 | -2.29   | 0.0431  | 0.1688 |
| Wabash                                       | Clarion | 3.8000   | 1.0937         | 11 | 3.47    | 0.0052  | 0.0236 |
| Webster                                      | Clarion | -1.0667  | 1.0937         | 11 | -0.98   | 0.3504  | 0.8359 |

The two rightmost columns of the table give the unadjusted and multiplicity-adjusted  $p$ -values. At the 5% significance level, both “Knox” and “Wabash” differ significantly from “Clarion” according to the unadjusted tests. After adjusting for multiplicity, only “Wabash” has a least squares mean significantly different from the control mean. Note that the standard error for the comparison involving “Knox” is larger than that for other comparisons because of the reduced sample size for that soil type.

In the plot of control differences a horizontal line is drawn at the value of the “Clarion” least squares mean. Vertical lines emanating from this reference line terminate in the least squares means for the other levels (Figure 41.31).

The dashed upper and lower horizontal reference lines are the upper and lower decision limits for tests against the control level. If a vertical line crosses the upper or lower decision limit, the corresponding least squares mean is significantly different from the LS-mean in the control group. If the data had been balanced, the UDL and LDL would be straight lines, because all estimates  $\hat{\eta}_i - \hat{\eta}_j$  would have had the same standard error. The limits for the comparison between “Knox” and “Clarion” are wider than for other comparisons, because of the reduced sample size for the “Knox” soil type.

**Figure 41.31** LS-Means Plot of Differences against a Control

The significance level of the decision limits is determined from the `ALPHA=` level in the `LSMEANS` statement. The default are 95% limits. If you choose one-sided comparisons with `DIFF=CONTROL` or `DIFF=CONTROLU` in the `LSMEANS` statement, only one of the decision limits is drawn.

### Analysis of Means (ANOM) Plot

The analysis of means in PROC GLIMMIX compares least squares means not by contrasting them against each other as with all pairwise differences or control differences. Instead, the least squares means are compared against an average value. Consequently, there are  $k$  comparisons for a factor with  $k$  levels. The following statements request ANOM differences for the Type least squares means (Figure 41.32) and plots the differences (Figure 41.33):

```
ods graphics on;
ods select Diffs AnomPlot;
proc glimmix data=plants order=data plots=AnomPlot;
 class Block Type;
 model StemLength = Block Type;
 lsmeans Type / diff=anom;
run;
ods graphics off;
```

Figure 41.32 ANOM LS-Mean Differences

| The GLIMMIX Procedure                   |       |          |                |    |         |         |
|-----------------------------------------|-------|----------|----------------|----|---------|---------|
| Differences of Type Least Squares Means |       |          |                |    |         |         |
| Type                                    | _Type | Estimate | Standard Error | DF | t Value | Pr >  t |
| Clarion                                 | Avg   | -0.2635  | 0.7127         | 11 | -0.37   | 0.7186  |
| Clinton                                 | Avg   | -2.1302  | 0.7127         | 11 | -2.99   | 0.0123  |
| Knox                                    | Avg   | 2.5032   | 0.9256         | 11 | 2.70    | 0.0205  |
| O'Neill                                 | Avg   | 1.3698   | 0.7127         | 11 | 1.92    | 0.0809  |
| Compost                                 | Avg   | -2.7635  | 0.7127         | 11 | -3.88   | 0.0026  |
| Wabash                                  | Avg   | 3.5365   | 0.7127         | 11 | 4.96    | 0.0004  |
| Webster                                 | Avg   | -1.3302  | 0.7127         | 11 | -1.87   | 0.0888  |

At the 5% level, the “Clarion,” “O’Neill,” and “Webster” soil types are not significantly different from the average. Note that the artificial lack of balance introduced previously reduces the precision of the ANOM comparison for the “Knox” soil type.

Figure 41.33 LS-Means Analysis of Means (ANOM) Plot

The reference line in the ANOM plot is drawn at the average. Vertical lines extend from this reference line upward or downward, depending on the magnitude of the least squares means compared to the reference value. This enables you to quickly see which levels perform above and below the average. The horizontal reference lines are 95% upper and lower decision limits. If a vertical line crosses the limits, you conclude that the least squares mean is significantly different (at the 5% significance level) from the average. You can adjust the comparisons for multiplicity by adding the `ADJUST=NELSON` option in the `LSMEANS` statement.

---

## Examples: GLIMMIX Procedure

---

### Example 41.1: Binomial Counts in Randomized Blocks

In the context of spatial prediction in generalized linear models, Gotway and Stroup (1997) analyze data from an agronomic field trial. Researchers studied 16 varieties (entries) of wheat for their resistance to infestation by the Hessian fly. They arranged the varieties in a randomized complete block design on an  $8 \times 8$  grid. Each  $4 \times 4$  quadrant of that arrangement constitutes a block.

The outcome of interest was the number of damaged plants ( $Y_{ij}$ ) out of the total number of plants growing on the unit ( $n_{ij}$ ). The two subscripts identify the block ( $i = 1, \dots, 4$ ) and the entry ( $j = 1, \dots, 16$ ). The following SAS statements create the data set. The variables `lat` and `lng` denote the coordinate of an experimental unit on the  $8 \times 8$  grid.

```
data HessianFly;
 label Y = 'No. of damaged plants'
 n = 'No. of plants';
 input block entry lat lng n Y @@;
 datalines;

## Analysis as a GLM

If infestations are independent among experimental units, and all plants within a unit have the same propensity for infestation, then the  $Y_{ij}$  are binomial random variables. The first model considered is a standard generalized linear model for independent binomial counts:

```
proc glimmix data=HessianFly;
 class block entry;
 model y/n = block entry / solution;
run;
```

The **PROC GLIMMIX** statement invokes the procedure. The **CLASS** statement instructs the GLIMMIX procedure to treat both block and entry as classification variables. The **MODEL** statement specifies the response variable and the fixed effects in the model. PROC GLIMMIX constructs the **X** matrix of the model from the terms on the right side of the **MODEL** statement. The GLIMMIX procedure supports two kinds of syntax for the response variable. This example uses the *events/trials* syntax. The variable *y* represents the number of successes (*events*) out of *n* Bernoulli *trials*. When the *events/trials* syntax is used, the GLIMMIX procedure automatically selects the binomial distribution as the response distribution. Once the distribution is determined, the procedure selects the link function for the model. The default link for binomial data is the logit link. The preceding statements are thus equivalent to the following statements:

```
proc glimmix data=HessianFly;
 class block entry;
 model y/n = block entry / dist=binomial link=logit solution;
run;
```

The **SOLUTION** option in the **MODEL** statement requests that solutions for the fixed effects (parameter estimates) be displayed.

The “Model Information” table describes the model and methods used in fitting the statistical model (Output 41.1.1).

The GLIMMIX procedure recognizes that this is a model for uncorrelated data (variance matrix is diagonal) and that parameters can be estimated by maximum likelihood. The default degrees-of-freedom method to denominator degrees of freedom for *F* tests and *t* tests is the RESIDUAL method. This corresponds to choosing  $f - \text{rank}(\mathbf{X})$  as the degrees of freedom, where *f* is the sum of the frequencies used in the analysis. You can change the degrees of freedom method with the **DDFM=** option in the **MODEL** statement.

**Output 41.1.1** Model Information in GLM Analysis

| The GLIMMIX Procedure      |                    |
|----------------------------|--------------------|
| Model Information          |                    |
| Data Set                   | WORK.HESSIANFLY    |
| Response Variable (Events) | Y                  |
| Response Variable (Trials) | n                  |
| Response Distribution      | Binomial           |
| Link Function              | Logit              |
| Variance Function          | Default            |
| Variance Matrix            | Diagonal           |
| Estimation Technique       | Maximum Likelihood |
| Degrees of Freedom Method  | Residual           |

The “Class Level Information” table lists the levels of the variables specified in the **CLASS** statement and the ordering of the levels (Output 41.1.2). The “Number of Observations” table displays the number of observations read and used in the analysis.

**Output 41.1.2** Class Level Information and Number of Observations

| Class Level Information        |                                           |
|--------------------------------|-------------------------------------------|
| Class                          | Levels Values                             |
| block                          | 4 1 2 3 4                                 |
| entry                          | 16 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 |
| Number of Observations Read 64 |                                           |
| Number of Observations Used 64 |                                           |
| Number of Events 396           |                                           |
| Number of Trials 736           |                                           |

The “Dimensions” table lists the size of relevant matrices (Output 41.1.3).

**Output 41.1.3** Model Dimensions Information in GLM Analysis

| Dimensions             |    |
|------------------------|----|
| Columns in X           | 21 |
| Columns in Z           | 0  |
| Subjects (Blocks in V) | 1  |
| Max Obs per Subject    | 64 |

Because of the absence of G-side random effects in this model, there are no columns in the **Z** matrix. The 21 columns in the **X** matrix comprise the intercept, 4 columns for the block effect and 16 columns for the entry effect. Because no **RANDOM** statement with a **SUBJECT=** option was specified, the **GLIMMIX** procedure does not process the data by subjects (see the section “Processing by Subjects” on page 3082 for details about subject processing).

The “Optimization Information” table provides information about the methods and size of the optimization problem (Output 41.1.4).

**Output 41.1.4** Optimization Information in GLM Analysis

| Optimization Information   |                |
|----------------------------|----------------|
| Optimization Technique     | Newton-Raphson |
| Parameters in Optimization | 19             |
| Lower Boundaries           | 0              |
| Upper Boundaries           | 0              |
| Fixed Effects              | Not Profiled   |

With few exceptions, models fit with the GLIMMIX procedure require numerical methods for parameter estimation. The default optimization method for (overdispersed) GLM models is the Newton-Raphson algorithm. In this example, the optimization involves 19 parameters, corresponding to the number of linearly independent columns of the  $X'X$  matrix.

The “Iteration History” table shows that the procedure converged after 3 iterations and 13 function evaluations (Output 41.1.5). The Change column measures the change in the objective function between iterations; however, this is not the monitored convergence criterion. The GLIMMIX procedure monitors several features simultaneously to determine whether to stop an optimization.

**Output 41.1.5** Iteration History in GLM Analysis

| Iteration History |          |             |                    |            |              |
|-------------------|----------|-------------|--------------------|------------|--------------|
| Iteration         | Restarts | Evaluations | Objective Function | Change     | Max Gradient |
| 0                 | 0        | 4           | 134.13393738       | .          | 4.899609     |
| 1                 | 0        | 3           | 132.85058236       | 1.28335502 | 0.206204     |
| 2                 | 0        | 3           | 132.84724263       | 0.00333973 | 0.000698     |
| 3                 | 0        | 3           | 132.84724254       | 0.00000009 | 3.029E-8     |

Convergence criterion (GCONV=1E-8) satisfied.

The “Fit Statistics” table lists information about the fitted model (Output 41.1.6). The  $-2$  Log Likelihood values are useful for comparing nested models, and the information criteria AIC, AICC, BIC, CAIC, and HQIC are useful for comparing nonnested models. On average, the ratio between the Pearson statistic and its degrees of freedom should equal one in GLMs. Values larger than one indicate overdispersion. With a ratio of 2.37, these data appear to exhibit more dispersion than expected under a binomial model with block and varietal effects.

**Output 41.1.6** Fit Statistics in GLM Analysis

| Fit Statistics           |        |
|--------------------------|--------|
| $-2$ Log Likelihood      | 265.69 |
| AIC (smaller is better)  | 303.69 |
| AICC (smaller is better) | 320.97 |
| BIC (smaller is better)  | 344.71 |
| CAIC (smaller is better) | 363.71 |
| HQIC (smaller is better) | 319.85 |
| Pearson Chi-Square       | 106.74 |
| Pearson Chi-Square / DF  | 2.37   |

The “Parameter Estimates” table displays the maximum likelihood estimates (Estimate), standard errors, and  $t$  tests for the hypothesis that the estimate is zero (Output 41.1.7).

**Output 41.1.7** Parameter Estimates in GLM Analysis

| Parameter Estimates |       |       |          |                |    |         |         |
|---------------------|-------|-------|----------|----------------|----|---------|---------|
| Effect              | block | entry | Estimate | Standard Error | DF | t Value | Pr >  t |
| Intercept           |       |       | -1.2936  | 0.3908         | 45 | -3.31   | 0.0018  |
| block               | 1     |       | -0.05776 | 0.2332         | 45 | -0.25   | 0.8055  |
| block               | 2     |       | -0.1838  | 0.2303         | 45 | -0.80   | 0.4289  |
| block               | 3     |       | -0.4420  | 0.2328         | 45 | -1.90   | 0.0640  |
| block               | 4     |       | 0        | .              | .  | .       | .       |
| entry               |       | 1     | 2.9509   | 0.5397         | 45 | 5.47    | <.0001  |
| entry               |       | 2     | 2.8098   | 0.5158         | 45 | 5.45    | <.0001  |
| entry               |       | 3     | 2.4608   | 0.4956         | 45 | 4.97    | <.0001  |
| entry               |       | 4     | 1.5404   | 0.4564         | 45 | 3.38    | 0.0015  |
| entry               |       | 5     | 2.7784   | 0.5293         | 45 | 5.25    | <.0001  |
| entry               |       | 6     | 2.0403   | 0.4889         | 45 | 4.17    | 0.0001  |
| entry               |       | 7     | 2.3253   | 0.4966         | 45 | 4.68    | <.0001  |
| entry               |       | 8     | 1.3006   | 0.4754         | 45 | 2.74    | 0.0089  |
| entry               |       | 9     | 1.5605   | 0.4569         | 45 | 3.42    | 0.0014  |
| entry               |       | 10    | 2.3058   | 0.5203         | 45 | 4.43    | <.0001  |
| entry               |       | 11    | 1.4957   | 0.4710         | 45 | 3.18    | 0.0027  |
| entry               |       | 12    | 1.5068   | 0.4767         | 45 | 3.16    | 0.0028  |
| entry               |       | 13    | -0.6296  | 0.6488         | 45 | -0.97   | 0.3370  |
| entry               |       | 14    | 0.4460   | 0.5126         | 45 | 0.87    | 0.3889  |
| entry               |       | 15    | 0.8342   | 0.4698         | 45 | 1.78    | 0.0826  |
| entry               |       | 16    | 0        | .              | .  | .       | .       |

The “Type III Tests of Fixed Effect” table displays significance tests for the two fixed effects in the model (Output 41.1.8).

**Output 41.1.8** Type III Tests of Block and Entry Effects in GLM Analysis

| Type III Tests of Fixed Effects |        |        |         |        |
|---------------------------------|--------|--------|---------|--------|
| Effect                          | Num DF | Den DF | F Value | Pr > F |
| block                           | 3      | 45     | 1.42    | 0.2503 |
| entry                           | 15     | 45     | 6.96    | <.0001 |

These tests are Wald-type tests, not likelihood ratio tests. The entry effect is clearly significant in this model with a  $p$ -value of <0.0001, indicating that the 16 wheat varieties are not equally susceptible to infestation by the Hessian fly.

**Analysis with Random Block Effects**

There are several possible reasons for the overdispersion noted in Output 41.1.6 (Pearson ratio = 2.37). The data might not follow a binomial distribution, one or more important effects might not have been accounted for in the model, or the data might be positively correlated. If important fixed effects have been omitted,

then you might need to consider adding them to the model. Because this is a designed experiment, it is reasonable not to expect further effects apart from the block and entry effects that represent the treatment and error control design structure. The reasons for the overdispersion must lie elsewhere.

If overdispersion stems from correlations among the observations, then the model should be appropriately adjusted. The correlation can have multiple sources. First, it might not be the case that the plants within an experimental unit responded independently. If the probability of infestation of a particular plant is altered by the infestation of a neighboring plant within the same unit, the infestation counts are not binomial and a different probability model should be used. A second possible source of correlations is the lack of independence of experimental units. Even if treatments were assigned to units at random, they might not respond independently. Shared spatial soil effects, for example, can be the underlying factor. The following analyses take these spatial effects into account.

First, assume that the environmental effects operate at the scale of the blocks. By making the block effects random, the marginal responses will be correlated due to the fact that observations within a block share the same random effects. Observations from different blocks will remain uncorrelated, in the spirit of separate randomizations among the blocks. The next set of statements fits a generalized linear mixed model (GLMM) with random block effects:

```
proc glimmix data=HessianFly;
 class block entry;
 model y/n = entry / solution;
 random block;
run;
```

Because the conditional distribution—conditional on the block effects—is binomial, the marginal distribution will be overdispersed relative to the binomial distribution. In contrast to adding a multiplicative scale parameter to the variance function, treating the block effects as random changes the estimates compared to a model with fixed block effects.

In the presence of random effects and a conditional binomial distribution, PROC GLIMMIX does not use maximum likelihood for estimation. Instead, the GLIMMIX procedure applies a restricted (residual) pseudo-likelihood algorithm (Output 41.1.9). The “restricted” attribute derives from the same rationale by which restricted (residual) maximum likelihood methods for linear mixed models attain their name; the likelihood equations are adjusted for the presence of fixed effects in the model to reduce bias in covariance parameter estimates.

#### Output 41.1.9 Model Information in GLMM Analysis

| The GLIMMIX Procedure      |                 |
|----------------------------|-----------------|
| Model Information          |                 |
| Data Set                   | WORK.HESSIANFLY |
| Response Variable (Events) | Y               |
| Response Variable (Trials) | n               |
| Response Distribution      | Binomial        |
| Link Function              | Logit           |
| Variance Function          | Default         |
| Variance Matrix            | Not blocked     |
| Estimation Technique       | Residual PL     |
| Degrees of Freedom Method  | Containment     |

The “Class Level Information” and “Number of Observations” tables are as before (Output 41.1.10).

**Output 41.1.10** Class Level Information and Number of Observations

| Class                       |  | Levels | Values                                 |
|-----------------------------|--|--------|----------------------------------------|
| block                       |  | 4      | 1 2 3 4                                |
| entry                       |  | 16     | 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 |
| Number of Observations Read |  |        | 64                                     |
| Number of Observations Used |  |        | 64                                     |
| Number of Events            |  |        | 396                                    |
| Number of Trials            |  |        | 736                                    |

The “Dimensions” table indicates that there is a single G-side parameter, the variance of the random block effect (Output 41.1.11). The “Dimensions” table has changed from the previous model (compare Output 41.1.11 to Output 41.1.3). Note that although the block effect has four levels, only a single variance component is estimated. The Z matrix has four columns, however, corresponding to the four levels of the block effect. Because no SUBJECT= option is used in the RANDOM statement, the GLIMMIX procedure treats these data as having arisen from a single subject with 64 observations.

**Output 41.1.11** Model Dimensions Information in GLMM Analysis

| Dimensions             |    |
|------------------------|----|
| G-side Cov. Parameters | 1  |
| Columns in X           | 17 |
| Columns in Z           | 4  |
| Subjects (Blocks in V) | 1  |
| Max Obs per Subject    | 64 |

The “Optimization Information” table indicates that a quasi-Newton method is used to solve the optimization problem. This is the default optimization method for GLMM models (Output 41.1.12).

**Output 41.1.12** Optimization Information in GLMM Analysis

| Optimization Information   |                   |
|----------------------------|-------------------|
| Optimization Technique     | Dual Quasi-Newton |
| Parameters in Optimization | 1                 |
| Lower Boundaries           | 1                 |
| Upper Boundaries           | 0                 |
| Fixed Effects              | Profiled          |
| Starting From              | Data              |

In contrast to the Newton-Raphson method, the quasi-Newton method does not require second derivatives. Because the covariance parameters are not unbounded in this example, the procedure enforces a lower boundary constraint (zero) for the variance of the block effect, and the optimization method is changed to a dual quasi-Newton method. The fixed effects are profiled from the likelihood equations in this model. The resulting optimization problem involves only the covariance parameters.

The “Iteration History” table appears to indicate that the procedure converged after four iterations (Output 41.1.13). Notice, however, that this table has changed slightly from the previous analysis (see Output 41.1.5). The Evaluations column has been replaced by the Subiterations column, because the GLIMMIX procedure applied a doubly iterative fitting algorithm. The entire process consisted of five optimizations, each of which was iterative. The initial optimization required four iterations, the next one required three iterations, and so on.

**Output 41.1.13** Iteration History in GLMM Analysis

| Iteration History                                   |          |               |                       |            |                 |  |
|-----------------------------------------------------|----------|---------------|-----------------------|------------|-----------------|--|
| Iteration                                           | Restarts | Subiterations | Objective<br>Function | Change     | Max<br>Gradient |  |
| 0                                                   | 0        | 4             | 173.28473428          | 0.81019251 | 0.000197        |  |
| 1                                                   | 0        | 3             | 181.66726674          | 0.17550228 | 0.000739        |  |
| 2                                                   | 0        | 2             | 182.20789493          | 0.00614874 | 7.018E-6        |  |
| 3                                                   | 0        | 1             | 182.21315596          | 0.00004386 | 1.213E-8        |  |
| 4                                                   | 0        | 0             | 182.21317662          | 0.00000000 | 3.349E-6        |  |
| Convergence criterion (PCONV=1.11022E-8) satisfied. |          |               |                       |            |                 |  |

The “Fit Statistics” table shows information about the fit of the GLMM (Output 41.1.14). The log likelihood reported in the table is not the residual log likelihood of the data. It is the residual log likelihood for an approximated model. The generalized chi-square statistic measures the residual sum of squares in the final model, and the ratio with its degrees of freedom is a measure of variability of the observation about the mean model.

**Output 41.1.14** Fit Statistics in GLMM Analysis

| Fit Statistics               |        |
|------------------------------|--------|
| -2 Res Log Pseudo-Likelihood | 182.21 |
| Generalized Chi-Square       | 107.96 |
| Gener. Chi-Square / DF       | 2.25   |

The variance of the random block effects is rather small (Output 41.1.15).

**Output 41.1.15** Estimated Covariance Parameters and Approximate Standard Errors

| Covariance Parameter Estimates |          |                |
|--------------------------------|----------|----------------|
| Cov Parm                       | Estimate | Standard Error |
| block                          | 0.01116  | 0.03116        |

If the environmental effects operate on a spatial scale smaller than the block size, the random block model does not provide a suitable adjustment. From the coarse layout of the experimental area, it is not surprising that random block effects alone do not account for the overdispersion in the data. Adding a random component to a generalized linear model is different from adding a multiplicative overdispersion component, for example, via the PSCALE option in PROC GENMOD or a

```
random _residual_;
```

statement in PROC GLIMMIX. Such overdispersion components do not affect the parameter estimates, only their standard errors. A genuine random effect, on the other hand, affects both the parameter estimates and their standard errors (compare Output 41.1.16 to Output 41.1.7).

**Output 41.1.16** Parameter Estimates for Fixed Effects in GLMM Analysis

| Solutions for Fixed Effects |       |          |                |    |         |         |
|-----------------------------|-------|----------|----------------|----|---------|---------|
| Effect                      | entry | Estimate | Standard Error | DF | t Value | Pr >  t |
| Intercept                   |       | -1.4637  | 0.3738         | 3  | -3.92   | 0.0296  |
| entry                       | 1     | 2.9609   | 0.5384         | 45 | 5.50    | <.0001  |
| entry                       | 2     | 2.7807   | 0.5138         | 45 | 5.41    | <.0001  |
| entry                       | 3     | 2.4339   | 0.4934         | 45 | 4.93    | <.0001  |

| entry                       | 12    | 1.5075   | 0.4752         | 45 | 3.17    | 0.0027  |
| entry                       | 13    | -0.5955  | 0.6475         | 45 | -0.92   | 0.3626  |
| entry                       | 14    | 0.4573   | 0.5111         | 45 | 0.89    | 0.3758  |
| entry                       | 15    | 0.8683   | 0.4682         | 45 | 1.85    | 0.0702  |
| entry                       | 16    | 0        | .              | .  | .       | .       |

**Output 41.1.17** Type III Test of Entry in GLMM Analysis

| Type III Tests of Fixed Effects |           |           |         |        |
|---------------------------------|-----------|-----------|---------|--------|
| Effect                          | Num<br>DF | Den<br>DF | F Value | Pr > F |
| entry                           | 15        | 45        | 6.90    | <.0001 |

Because the block variance component is small, the Type III test for the variety effect in [Output 41.1.17](#) is affected only very little compared to the GLM ([Output 41.1.8](#)).

### Analysis with Smooth Spatial Trends

You can also consider these data in an observational sense, where the covariation of the observations is subject to modeling. Rather than deriving model components from the experimental design alone, environmental effects can be modeled by adjusting the mean and/or correlation structure. Gotway and Stroup (1997) and Schabenberger and Pierce (2002) supplant the coarse block effects with smooth-scale spatial components.

The model considered by Gotway and Stroup (1997) is a marginal model in that the correlation structure is modeled through residual-side (R-side) random components. This exponential covariance model is fit with the following statements:

```
proc glimmix data=HessianFly;
 class entry;
 model y/n = entry / solution ddfm=contain;
 random _residual_ / subject=intercept type=sp(exp) (lng lat);
run;
```

Note that the block effects have been removed from the statements. The keyword `_RESIDUAL_` in the `RANDOM` statement instructs the GLIMMIX procedure to model the **R** matrix. Here, **R** is to be modeled as an exponential covariance structure matrix. The `SUBJECT=INTERCEPT` option means that all observations are considered correlated. Because the random effects are residual-type (R-side) effects, there are no columns in the **Z** matrix for this model ([Output 41.1.18](#)).

**Output 41.1.18** Model Dimension Information in Marginal Spatial Analysis

| The GLIMMIX Procedure    |    |
|--------------------------|----|
| Dimensions               |    |
| R-side Cov. Parameters   | 2  |
| Columns in X             | 17 |
| Columns in Z per Subject | 0  |
| Subjects (Blocks in V)   | 1  |
| Max Obs per Subject      | 64 |

In addition to the fixed effects, the GLIMMIX procedure now profiles one of the covariance parameters, the variance of the exponential covariance model (Output 41.1.19). This reduces the size of the optimization problem. Only a single parameter is part of the optimization, the “range” (SP(EXP)) of the spatial process.

**Output 41.1.19** Optimization Information in Spatial Analysis

| Optimization Information   |                   |
|----------------------------|-------------------|
| Optimization Technique     | Dual Quasi-Newton |
| Parameters in Optimization | 1                 |
| Lower Boundaries           | 1                 |
| Upper Boundaries           | 0                 |
| Fixed Effects              | Profiled          |
| Residual Variance          | Profiled          |
| Starting From              | Data              |

The practical range of a spatial process is that distance at which the correlation between data points has decreased to at most 0.05. The parameter reported by the GLIMMIX procedure as SP(EXP) in Output 41.1.20 corresponds to one-third of the practical range. The practical range in this process is  $3 \times 0.9052 = 2.7156$ . Correlations extend beyond a single experimental unit, but they do not appear to exist on the scale of the block size.

**Output 41.1.20** Estimates of Covariance Parameters

| Covariance Parameter Estimates |           |          |                |
|--------------------------------|-----------|----------|----------------|
| Cov Parm                       | Subject   | Estimate | Standard Error |
| SP (EXP)                       | Intercept | 0.9052   | 0.4404         |
| Residual                       |           | 2.5315   | 0.6974         |

The sill of the spatial process, the variance of the underlying residual effect, is estimated as 2.5315.

**Output 41.1.21** Type III Test of Entry Effect in Spatial Analysis

| Type III Tests of Fixed Effects |        |        |         |        |
|---------------------------------|--------|--------|---------|--------|
| Effect                          | Num DF | Den DF | F Value | Pr > F |
| entry                           | 15     | 48     | 3.60    | 0.0004 |

The *F* value for the entry effect has been sharply reduced compared to the previous analyses. The smooth spatial variation accounts for some of the variation among the varieties (Output 41.1.21).

In this example three models were considered for the analysis of a randomized block design with binomial outcomes. If data are correlated, a standard generalized linear model often will indicate overdispersion

relative to the binomial distribution. Two courses of action are considered in this example to address this overdispersion. First, the inclusion of G-side random effects models the correlation indirectly; it is induced through the sharing of random effects among responses from the same block. Second, the R-side spatial covariance structure models covariation directly. In generalized linear (mixed) models these two modeling approaches can lead to different inferences, because the models have different interpretation. The random block effects are modeled on the linked (logit) scale, and the spatial effects were modeled on the mean scale. Only in a linear mixed model are the two scales identical.

---

## Example 41.2: Mating Experiment with Crossed Random Effects

McCullagh and Nelder (1989, Ch. 14.5) describe a mating experiment—conducted by S. Arnold and P. Verell at the University of Chicago, Department of Ecology and Evolution—involving two geographically isolated populations of mountain dusky salamanders. One goal of the experiment was to determine whether barriers to interbreeding have evolved in light of the geographical isolation of the populations. In this case, matings within a population should be more successful than matings between the populations. The experiment conducted in the summer of 1986 involved 40 animals, 20 rough butt (R) and 20 whiteside (W) salamanders, with equal numbers of males and females. The animals were grouped into two sets of R males, two sets of R females, two sets of W males, and two sets of W females, so that each set comprised five salamanders. Each set was mated against one rough butt and one whiteside set, creating eight crossings. Within the pairings of sets, each female was paired to three male animals. The salamander mating data have been used by a number of authors; see, for example, McCullagh and Nelder (1989); Schall (1991); Karim and Zeger (1992); Breslow and Clayton (1993); Wolfinger and O’Connell (1993); Shun (1997).

The following DATA step creates the data set for the analysis.

The first observation, for example, indicates that rough butt female 1 was paired in the laboratory on day 4 of the experiment with rough butt male 1, and the pair mated. On the same day rough butt female 7 was paired with whiteside male 8, but the pairing did not result in mating of the animals.

The model adopted by many authors for these data comprises fixed effects for gender and population, their interaction, and male and female random effects. Specifically, let  $\pi_{RR}$ ,  $\pi_{RW}$ ,  $\pi_{WR}$ , and  $\pi_{WW}$  denote the mating probabilities between the populations, where the first subscript identifies the female partner of the pair. Then, you model

$$\log \left\{ \frac{\pi_{kl}}{1 - \pi_{kl}} \right\} = \tau_{kl} + \gamma_f + \gamma_m \quad k, l \in \{R, W\}$$

where  $\gamma_f$  and  $\gamma_m$  are independent random variables representing female and male random effects (20 each), and  $\tau_{kl}$  denotes the average logit of mating between females of population  $k$  and males of population  $l$ .

The following statements fit this model by pseudo-likelihood:

```
proc glimmix data=salamander;
 class fpop fnum mpop mnum;
 model mating(event='1') = fpop|mpop / dist=binary;
 random fpop*fnum mpop*mnum;
 lsmeans fpop*mpop / ilink;
run;
```

The response variable is the two-level variable `mating`. Because it is coded as zeros and ones, and because PROC GLIMMIX models by default the probability of the first level according to the response-level ordering, the `EVENT='1'` option instructs PROC GLIMMIX to model the probability of a successful mating. The distribution of the mating variable, conditional on the random effects, is binary.

The `fpop*fnum` effect in the `RANDOM` statement creates a random intercept for each female animal. Because `fpop` and `fnum` are `CLASS` variables, the effect has 20 levels (10 `rb` and 10 `ws` females). Similarly, the `mpop*mnum` effect creates the random intercepts for the male animals. Because no `TYPE=` is specified in the `RANDOM` statement, the covariance structure defaults to `TYPE=VC`. The random effects and their levels are independent, and each effect has its own variance component. Because the conditional distribution of the data, conditioned on the random effects, is binary, no extra scale parameter ( $\phi$ ) is added.

The `LSMEANS` statement requests least squares means for the four levels of the `fpop*mpop` effect, which are estimates of the cell means in the  $2 \times 2$  classification of female and male populations. The `ILINK` option in the `LSMEANS` statement requests that the estimated means and standard errors are also reported on the scale of the data. This yields estimates of the four mating probabilities,  $\pi_{RR}$ ,  $\pi_{RW}$ ,  $\pi_{WR}$ , and  $\pi_{WW}$ .

The “Model Information” table displays general information about the model being fit (Output 41.2.1).

**Output 41.2.1** Analysis of Mating Experiment with Crossed Random Effects

| The GLIMMIX Procedure     |                 |
|---------------------------|-----------------|
| Model Information         |                 |
| Data Set                  | WORK.SALAMANDER |
| Response Variable         | mating          |
| Response Distribution     | Binary          |
| Link Function             | Logit           |
| Variance Function         | Default         |
| Variance Matrix           | Not blocked     |
| Estimation Technique      | Residual PL     |
| Degrees of Freedom Method | Containment     |

The response variable `mating` follows a binary distribution (conditional on the random effects). Hence, the mean of the data is an event probability,  $\pi$ , and the logit of this probability is linearly related to the linear predictor of the model. The variance function is the default function that is implied by the distribution,  $a(\pi) = \pi(1 - \pi)$ . The variance matrix is not blocked, because the GLIMMIX procedure does not process the data by subjects (see the section “Processing by Subjects” on page 3082 for details). The estimation technique is the default method for GLMMs, residual pseudo-likelihood (`METHOD=RSPL`), and degrees of freedom for tests and confidence intervals are determined by the containment method.

The “Class Level Information” table in Output 41.2.2 lists the levels of the variables listed in the `CLASS` statement, as well as the order of the levels.

**Output 41.2.2** Class Level Information and Number of Observations

| Class Level Information     |        |                      |
|-----------------------------|--------|----------------------|
| Class                       | Levels | Values               |
| fpop                        | 2      | rb ws                |
| fnum                        | 10     | 1 2 3 4 5 6 7 8 9 10 |
| mpop                        | 2      | rb ws                |
| mnum                        | 10     | 1 2 3 4 5 6 7 8 9 10 |
| Number of Observations Read |        | 120                  |
| Number of Observations Used |        | 120                  |

Note that there are two female populations and two male populations; also, the variables fnum and mnum have 10 levels each. As a consequence, the effects fpop\*fnum and mpop\*mnum identify the 20 females and males, respectively. The effect fpop\*mpop identifies the four mating types.

The “Response Profile Table,” which is displayed for binary or multinomial data, lists the levels of the response variable and their order (Output 41.2.3). With binary data, the table also provides information about which level of the response variable defines the event. Because of the EVENT='1' response variable option in the MODEL statement, the probability being modeled is that of the higher-ordered value.

**Output 41.2.3** Response Profiles

| Response Profile |        |                 |
|------------------|--------|-----------------|
| Ordered Value    | mating | Total Frequency |
| 1                | 0      | 50              |
| 2                | 1      | 70              |

The GLIMMIX procedure is modeling the probability that mating='1'.

There are two covariance parameters in this model, the variance of the fpop\*fnum effect and the variance of the mpop\*mnum effect (Output 41.2.4). Both parameters are modeled as G-side parameters. The nine columns in the **X** matrix comprise the intercept, two columns each for the levels of the fpop and mpop effects, and four columns for their interaction. The **Z** matrix has 40 columns, one for each animal. Because the data are not processed by subjects, PROC GLIMMIX assumes the data consist of a single subject (a single block in **V**).

**Output 41.2.4** Model Dimensions Information

| Dimensions             |     |
|------------------------|-----|
| G-side Cov. Parameters | 2   |
| Columns in X           | 9   |
| Columns in Z           | 40  |
| Subjects (Blocks in V) | 1   |
| Max Obs per Subject    | 120 |

The “Optimization Information” table displays basic information about the optimization (Output 41.2.5). The default technique for GLMMs is the quasi-Newton method. There are two parameters in the optimization, which correspond to the two variance components. The 17 fixed effects parameters are not part of the optimization. The initial optimization computes pseudo-data based on the response values in the data set rather than from estimates of a generalized linear model fit.

**Output 41.2.5** Optimization Information

| Optimization Information   |                             |
|----------------------------|-----------------------------|
| Optimization Technique     | Newton-Raphson with Ridging |
| Parameters in Optimization | 2                           |
| Lower Boundaries           | 2                           |
| Upper Boundaries           | 0                           |
| Fixed Effects              | Profiled                    |
| Starting From              | Data                        |

The GLIMMIX procedure performs eight optimizations after the initial optimization (Output 41.2.6). That is, following the initial pseudo-data creation, the pseudo-data were updated eight more times and a total of nine linear mixed models were estimated.

**Output 41.2.6** Iteration History and Convergence Status

| Iteration History |          |               |                       |            |                 |
|-------------------|----------|---------------|-----------------------|------------|-----------------|

| 0                 | 0        | 4             | 537.09173501          | 2.00000000 | 1.719E-8        |
| 1                 | 0        | 3             | 544.12516903          | 0.66319780 | 1.14E-8         |
| 2                 | 0        | 2             | 545.89139118          | 0.13539318 | 1.609E-6        |
| 3                 | 0        | 2             | 546.10489538          | 0.01742065 | 5.89E-10        |
| 4                 | 0        | 1             | 546.13075146          | 0.00212475 | 9.654E-7        |
| 5                 | 0        | 1             | 546.13374731          | 0.00025072 | 1.346E-8        |
| 6                 | 0        | 1             | 546.13409761          | 0.00002931 | 1.84E-10        |
| 7                 | 0        | 0             | 546.13413861          | 0.00000000 | 4.285E-6        |

Convergence criterion (PCONV=1.11022E-8) satisfied.

The “Covariance Parameter Estimates” table lists the estimates for the two variance components and their estimated standard errors (Output 41.2.7). The heterogeneity (in the logit of the mating probabilities) among the females is considerably larger than the heterogeneity among the males.

**Output 41.2.7** Estimated Covariance Parameters and Approximate Standard Errors

| Covariance Parameter Estimates |          |                |
|--------------------------------|----------|----------------|
| Cov Parm                       | Estimate | Standard Error |
| fpop*fnum                      | 1.4099   | 0.8871         |
| mpop*mnum                      | 0.08963  | 0.4102         |

The “Type III Tests of Fixed Effects” table indicates a significant interaction between the male and female populations (Output 41.2.8). A comparison in the logits of mating success in pairs with R females and W females depends on whether the male partner in the pair is the same species. The “fpop\*mpop Least Squares Means” table shows this effect more clearly (Output 41.2.9).

**Output 41.2.8** Tests of Main Effects and Interaction

| Type III Tests of Fixed Effects |        |        |         |        |
|---------------------------------|--------|--------|---------|--------|
| Effect                          | Num DF | Den DF | F Value | Pr > F |
| fpop                            | 1      | 18     | 2.86    | 0.1081 |
| mpop                            | 1      | 17     | 4.71    | 0.0444 |
| fpop*mpop                       | 1      | 81     | 9.61    | 0.0027 |

**Output 41.2.9** Interaction Least Squares Means

| fpop*mpop Least Squares Means |      |          |                |    |         |         |        |                     |

| rb                            | rb   | 1.1629   | 0.5961         | 81 | 1.95    | 0.0545  | 0.7619 | 0.1081              |
| rb                            | ws   | 0.7839   | 0.5729         | 81 | 1.37    | 0.1750  | 0.6865 | 0.1233              |
| ws                            | rb   | -1.4119  | 0.6143         | 81 | -2.30   | 0.0241  | 0.1959 | 0.09678             |
| ws                            | ws   | 1.0151   | 0.5871         | 81 | 1.73    | 0.0876  | 0.7340 | 0.1146              |

In a pairing with a male rough butt salamander, the logit drops sharply from 1.1629 to  $-1.4119$  when the male is paired with a whiteside female instead of a female from its own population. The corresponding estimated probabilities of mating success are  $\hat{\pi}_{RR} = 0.7619$  and  $\hat{\pi}_{WR} = 0.1959$ . If the same comparisons are made in pairs with whiteside males, then you also notice a drop in the logit if the female comes from a different population, 1.0151 versus 0.7839. The change is considerably less, though, corresponding to mating probabilities of  $\hat{\pi}_{WW} = 0.7340$  and  $\hat{\pi}_{RW} = 0.6865$ . Whiteside females appear to be successful with their own population. Whiteside males appear to succeed equally well with female partners of the two populations.

This insight into the factor-level comparisons can be amplified by graphing the least squares mean comparisons and by subsetting the differences of least squares means. This is accomplished with the following statements:

```
ods graphics on;
ods select DiffPlot SliceDiffs;
proc glimmix data=salamander;
 class fpop fnum mpop mnum;
 model mating(event='1') = fpop|mpop / dist=binary;
 random fpop*fnum mpop*mnum;
 lsmeans fpop*mpop / plots=diffplot;
 lsmeans fpop*mpop / slicediff=(mpop fpop);
run;
ods graphics off;
```

The `PLOTS=DIFFPLOT` option in the first `LSMEANS` statement requests a comparison plot that displays the result of all pairwise comparisons (Output 41.2.10). The `SLICEDIFF=(mpop fpop)` option requests differences of simple effects.

The comparison plot in Output 41.2.10 is also known as a mean-mean scatter plot (Hsu 1996). Each solid line in the plot corresponds to one of the possible  $4 \times 3/2 = 6$  unique pairwise comparisons. The line is centered at the intersection of two least squares means, and the length of the line segments corresponds to the width of a 95% confidence interval for the difference between the two least squares means. The length of the segment is adjusted for the rotation. If a line segment crosses the dashed 45-degree line, the comparison between the two factor levels is not significant; otherwise, it is significant. The horizontal and vertical axes of the plot are drawn in least squares means units, and the grid lines are placed at the values of the least squares means.

The six pairs of least squares means comparisons separate into two sets of three pairs. Comparisons in the first set are significant; comparisons in the second set are not significant. For the significant set, the female partner in one of the pairs is a whiteside salamander. For the nonsignificant comparisons, the male partner in one of the pairs is a whiteside salamander.

**Output 41.2.10** LS-Means Diffogram

The “Simple Effect Comparisons” tables show the results of the `SLICEDIFF=` option in the second `LSMEANS` statement (Output 41.2.11).

**Output 41.2.11** Simple Effect Comparisons

| Simple Effect Comparisons of fpop*mpop Least Squares Means By mpop |      |       |          |                |    |         |         |

The first table of simple effect comparisons holds fixed the level of the mpop factor and compares the levels of the fpop factor. Because there is only one possible comparison for each male population, there are two entries in the table. The first entry compares the logits of mating probabilities when the male partner is a rough butt, and the second entry applies when the male partner is from the whiteside population. The second table of simple effects comparisons applies the same logic, but holds fixed the level of the female partner in the pair. Note that these four comparisons are a subset of all six possible comparisons, eliminating those where both factors are varied at the same time. The simple effect comparisons show that there is no difference in mating probabilities if the male partner is a whiteside salamander, or if the female partner is a rough butt. Rough butt females also appear to mate indiscriminately.

### Example 41.3: Smoothing Disease Rates; Standardized Mortality Ratios

Clayton and Kaldor (1987, Table 1) present data on observed and expected cases of lip cancer in the 56 counties of Scotland between 1975 and 1980. The expected number of cases was determined by a separate multiplicative model that accounted for the age distribution in the counties. The goal of the analysis is to estimate the county-specific log-relative risks, also known as standardized mortality ratios (SMR).

If  $Y_i$  is the number of incident cases in county  $i$  and  $E_i$  is the expected number of incident cases, then the ratio of observed to expected counts,  $Y_i/E_i$ , is the standardized mortality ratio. Clayton and Kaldor (1987) assume there exists a relative risk  $\lambda_i$  that is specific to each county and is a random variable. Conditional on  $\lambda_i$ , the observed counts are independent Poisson variables with mean  $E_i \lambda_i$ .

An elementary mixed model for  $\lambda_i$  specifies only a random intercept for each county, in addition to a fixed intercept. Breslow and Clayton (1993), in their analysis of these data, also provide a covariate that measures the percentage of employees in agriculture, fishing, and forestry. The expanded model for the region-specific relative risk in Breslow and Clayton (1993) is

$$\lambda_i = \exp\{\beta_0 + \beta_1 x_i/10 + \gamma_i\}, \quad i = 1, \dots, 56$$

where  $\beta_0$  and  $\beta_1$  are fixed effects, and the  $\gamma_i$  are county random effects.

The following DATA step creates the data set lipcancer. The expected number of cases is based on the observed standardized mortality ratio for counties with lip cancer cases, and based on the expected counts reported by Clayton and Kaldor (1987, Table 1) for the counties without cases. The sum of the expected counts then equals the sum of the observed counts.

Because the mean of the Poisson variates, conditional on the random effects, is  $\mu_i = E_i \lambda_i$ , applying a log link yields

$$\log\{\mu_i\} = \log\{E_i\} + \beta_0 + \beta_1 x_i / 10 + \gamma_i$$

The term  $\log\{E_i\}$  is an offset, a regressor variable whose coefficient is known to be one. Note that it is assumed that the  $E_i$  are known; they are not treated as random variables.

The following statements fit this model by residual pseudo-likelihood:

```

proc glimmix data=lipcancer;
 class county;
 x = employment / 10;
 logn = log(expCount);
 model observed = x / dist=poisson offset=logn
 solution ddfm=none;

 random county;
 SMR_pred = 100*exp(_zgamma_ + _xbeta_);
 id employment SMR SMR_pred;
 output out=glimmixout;
run;

```

The offset is created with the assignment statement

```
logn = log(expCount);
```

and is associated with the linear predictor through the **OFFSET=** option in the **MODEL** statement. The statement

```
x = employment / 10;
```

transforms the covariate measuring percentage of employment in agriculture, fisheries, and forestry to agree with the analysis of Breslow and Clayton (1993). The **DDFM=NONE** option in the **MODEL** statement requests chi-square tests and  $z$  tests instead of the default  $F$  tests and  $t$  tests by setting the denominator degrees of freedom in tests of fixed effects to  $\infty$ .

The statement

```
SMR_pred = 100*exp(_zgamma_ + _xbeta_);
```

calculates the fitted standardized mortality rate. Note that the offset variable does not contribute to the exponentiated term.

The **OUTPUT** statement saves results of the calculations to the output data set `glimmixout`. The **ID** statement specifies that only the listed variables are written to the output data set.

The GLIMMIX procedure displays in the “Model Information” table that the offset variable was computed with programming statements and the final assignment statement from your GLIMMIX statements (Output 41.3.1). There are two columns in the **X** matrix, corresponding to the intercept and the regressor  $x/10$ . There are 56 columns in the **Z** matrix, however, one for each observation in the data set (Output 41.3.1).

The optimization involves only a single covariance parameter, the variance of the county effect (Output 41.3.2). Because this parameter is a variance, the GLIMMIX procedure imposes a lower boundary constraint; the solution for the variance is bounded by zero from below.

### Output 41.3.2 Optimization Information in Poisson GLMM

| Optimization Information   |                   |
|----------------------------|-------------------|
| Optimization Technique     | Dual Quasi-Newton |
| Parameters in Optimization | 1                 |
| Lower Boundaries           | 1                 |
| Upper Boundaries           | 0                 |
| Fixed Effects              | Profiled          |
| Starting From              | Data              |

Following the initial creation of pseudo-data and the fit of a linear mixed model, the procedure goes through five more updates of the pseudo-data, each associated with a separate optimization (Output 41.3.3). Although the objective function in each optimization is the negative of twice the restricted maximum likelihood for that pseudo-data, there is no guarantee that across the outer iterations the objective function decreases in subsequent optimizations. In this example, minus twice the residual maximum likelihood at convergence takes on its smallest value at the initial optimization and increases in subsequent optimizations.

### Output 41.3.3 Iteration History in Poisson GLMM

| Iteration History                                   |          |               |                       |            |                 |  |

| Convergence criterion (PCONV=1.11022E-8) satisfied. |          |               |                       |            |                 |  |

The “Covariance Parameter Estimates” table in Output 41.3.4 shows the estimate of the variance of the region-specific log-relative risks. There is significant county-to-county heterogeneity in risks. If the covariate were removed from the analysis, as in Clayton and Kaldor (1987), the heterogeneity in county-specific risks would increase. (The fitted SMRs in Table 6 of Breslow and Clayton (1993) were obtained without the covariate  $x$  in the model.)

**Output 41.3.4** Estimated Covariance Parameters in Poisson GLMM

| Covariance Parameter Estimates |          |                   |
|--------------------------------|----------|-------------------|
| Cov<br>Parm                    | Estimate | Standard<br>Error |
| county                         | 0.3567   | 0.09869           |

The “Solutions for Fixed Effects” table displays the estimates of  $\beta_0$  and  $\beta_1$  along with their standard errors and test statistics (Output 41.3.5). Because of the DDFM=NONE option in the MODEL statement, PROC GLIMMIX assumes that the degrees of freedom for the  $t$  tests of  $H_0: \beta_j = 0$  are infinite. The  $p$ -values correspond to probabilities under a standard normal distribution. The covariate measuring employment percentages in agriculture, fisheries, and forestry is significant. This covariate might be a surrogate for the exposure to sunlight, an important risk factor for lip cancer.

**Output 41.3.5** Fixed-Effects Parameter Estimates in Poisson GLMM

| Solutions for Fixed Effects |          |                   |       |         |         |
|-----------------------------|----------|-------------------|-------|---------|---------|
| Effect                      | Estimate | Standard<br>Error | DF    | t Value | Pr >  t |
| Intercept                   | -0.4406  | 0.1572            | Infty | -2.80   | 0.0051  |
| x                           | 0.6799   | 0.1409            | Infty | 4.82    | <.0001  |

You can examine the quality of the fit of this model with various residual plots. A panel of studentized residuals is requested with the following statements:

```
ods graphics on;
ods select StudentPanel;

proc glimmix data=lipcancer plots=studentpanel;
 class county;
 x = employment / 10;
 logn = log(expCount);
 model observed = x / dist=poisson offset=logn s ddfm=none;
 random county;
run;

ods graphics off;
```

The graph in the upper-left corner of the panel displays studentized residuals plotted against the linear predictor (Output 41.3.6). The default of the GLIMMIX procedure is to use the estimated BLUPs in the construction of the residuals and to present them on the linear scale, which in this case is the logarithmic scale. You can change the type of the computed residual with the TYPE= suboptions of each paneled display. For example, the option PLOTS=STUDENTPANEL(TYPE=NOBLUP) would request a paneled display of the marginal residuals on the linear scale.

Output 41.3.6 Panel of Studentized Residuals

The graph in the upper-right corner of the panel shows a histogram with overlaid normal density. A Q-Q plot and a box plot are shown in the lower cells of the panel.

The following statements produce a graph of the observed and predicted standardized mortality ratios (Output 41.3.7):

```
proc template;
 define statgraph scatter;
 BeginGraph;
 layout overlayequated / yaxisopts=(label='Predicted SMR')
 xaxisopts=(label='Observed SMR')
 equatetype=square;
 lineparm y=0 slope=1 x=0 /
 lineattrs = GraphFit(pattern=dash)
 extend = true;
 scatterplot y=SMR_pred x=SMR /
 markercharacter = employment;
 endlayout;
 EndGraph;
end;
run;
proc sgrender data=glimmixout template=scatter;
run;
```

In **Output 41.3.7**, fitted SMRs tend to be larger than the observed SMRs for counties with small observed SMR and smaller than the observed SMRs for counties with high observed SMR.

**Output 41.3.7** Observed and Predicted SMRs; Data Labels Indicate Covariate Values

To demonstrate the impact of the random effects adjustment to the log-relative risks, the following statements fit a Poisson regression model (a GLM) by maximum likelihood:

```
proc glimmix data=lipcancer;
 x = employment / 10;
 logn = log(expCount);
 model observed = x / dist=poisson offset=logn
 solution ddfm=none;
 SMR_pred = 100*exp(_zgamma_ + _xbeta_);
 id employment SMR SMR_pred;
 output out=glimmixout;
run;
```

The GLIMMIX procedure defaults to maximum likelihood estimation because these statements fit a generalized linear model with nonnormal distribution. As a consequence, the SMRs are county specific only to the extent that the risks vary with the value of the covariate. But risks are no longer adjusted based on county-to-county heterogeneity in the observed incidence count.

Because of the absence of random effects, the GLIMMIX procedure recognizes the model as a generalized linear model and fits it by maximum likelihood (Output 41.3.8). The variance matrix is diagonal because the observations are uncorrelated.

**Output 41.3.8** Model Information in Poisson GLM

| The GLIMMIX Procedure     |                       |
|---------------------------|-----------------------|
| Model Information         |                       |
| Data Set                  | WORK.LIPCANCER        |
| Response Variable         | observed              |
| Response Distribution     | Poisson               |
| Link Function             | Log                   |
| Variance Function         | Default               |
| Offset Variable           | logn = log(expCount); |
| Variance Matrix           | Diagonal              |
| Estimation Technique      | Maximum Likelihood    |
| Degrees of Freedom Method | None                  |

The “Dimensions” table shows that there are no G-side random effects in this model and no R-side scale parameter either (Output 41.3.9).

**Output 41.3.9** Model Dimensions Information in Poisson GLM

| Dimensions             |    |
|------------------------|----|
| Columns in X           | 2  |
| Columns in Z           | 0  |
| Subjects (Blocks in V) | 1  |
| Max Obs per Subject    | 56 |

Because this is a GLM, the GLIMMIX procedure defaults to the Newton-Raphson algorithm, and the fixed effects (intercept and slope) comprise the parameters in the optimization (Output 41.3.10). (The default optimization technique for a GLM is the Newton-Raphson method.)

**Output 41.3.10** Optimization Information in Poisson GLM

| Optimization Information   |                |
|----------------------------|----------------|
| Optimization Technique     | Newton-Raphson |
| Parameters in Optimization | 2              |
| Lower Boundaries           | 0              |
| Upper Boundaries           | 0              |
| Fixed Effects              | Not Profiled   |

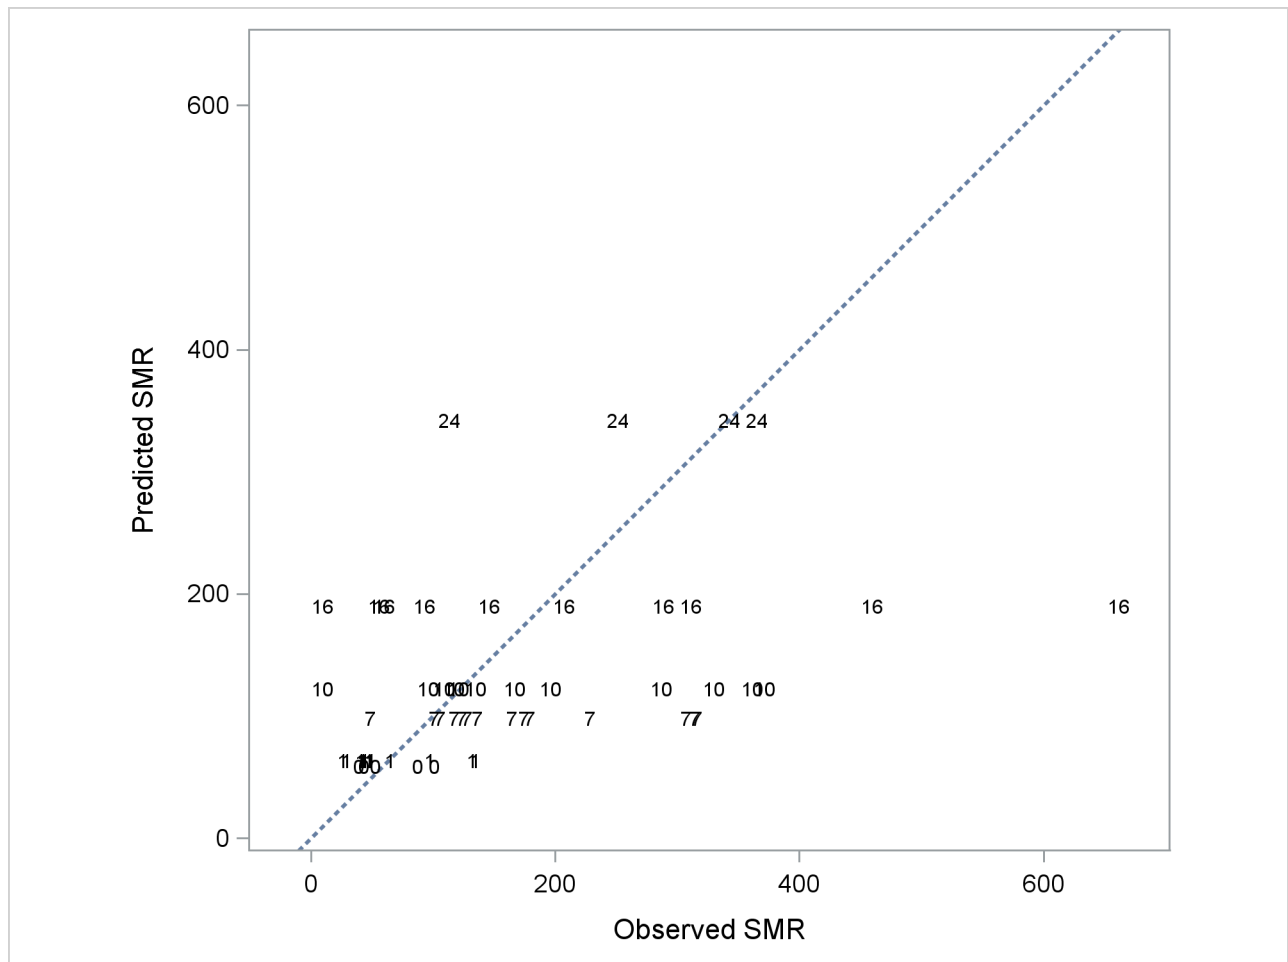

The estimates of  $\beta_0$  and  $\beta_1$  have changed from the previous analysis. In the GLMM, the estimates were  $\hat{\beta}_0 = -0.4406$  and  $\hat{\beta}_1 = 0.6799$  (Output 41.3.11).

**Output 41.3.11** Parameter Estimates in Poisson GLM

| Parameter Estimates |          |                |       |         |         |
|---------------------|----------|----------------|-------|---------|---------|
| Effect              | Estimate | Standard Error | DF    | t Value | Pr >  t |
| Intercept           | -0.5419  | 0.06951        | Infty | -7.80   | <.0001  |
| x                   | 0.7374   | 0.05954        | Infty | 12.38   | <.0001  |

More importantly, without the county-specific adjustments through the best linear unbiased predictors of the random effects, the predicted SMRs are the same for all counties with the same percentage of employees in agriculture, fisheries, and forestry (Output 41.3.12).

**Output 41.3.12** Observed and Predicted SMRs in Poisson GLM

## Example 41.4: Quasi-likelihood Estimation for Proportions with Unknown Distribution

Wedderburn (1974) analyzes data on the incidence of leaf blotch (*Rhynchosporium secalis*) on barley.

The data represent the percentage of leaf area affected in a two-way layout with 10 barley varieties at nine sites. The following DATA step converts these data to proportions, as analyzed in McCullagh and Nelder (1989, Ch. 9.2.4). The purpose of the analysis is to make comparisons among the varieties, adjusted for site effects.

```

data blotch;
 array p{9} pct1-pct9;
 input variety pct1-pct9;
 do site = 1 to 9;
 prop = p{site}/100;
 output;
 end;
 drop pct1-pct9;
 datalines;
1 0.05 0.00 1.25 2.50 5.50 1.00 5.00 5.00 17.50
2 0.00 0.05 1.25 0.50 1.00 5.00 0.10 10.00 25.00
3 0.00 0.05 2.50 0.01 6.00 5.00 5.00 5.00 42.50
4 0.10 0.30 16.60 3.00 1.10 5.00 5.00 5.00 50.00
5 0.25 0.75 2.50 2.50 2.50 5.00 50.00 25.00 37.50
6 0.05 0.30 2.50 0.01 8.00 5.00 10.00 75.00 95.00
7 0.50 3.00 0.00 25.00 16.50 10.00 50.00 50.00 62.50
8 1.30 7.50 20.00 55.00 29.50 5.00 25.00 75.00 95.00
9 1.50 1.00 37.50 5.00 20.00 50.00 50.00 75.00 95.00
10 1.50 12.70 26.25 40.00 43.50 75.00 75.00 75.00 95.00
;

```

Little is known about the distribution of the leaf area proportions. The outcomes are not binomial proportions, because they do not represent the ratio of a count over a total number of Bernoulli trials. However, because the mean proportion  $\mu_{ij}$  for variety  $j$  on site  $i$  must lie in the interval  $[0, 1]$ , you can commence the analysis with a model that treats Prop as a “pseudo-binomial” variable:

$$\begin{aligned}
 E[\text{Prop}_{ij}] &= \mu_{ij} \\
 \mu_{ij} &= 1/(1 + \exp\{-\eta_{ij}\}) \\
 \eta_{ij} &= \beta_0 + \alpha_i + \tau_j \\
 \text{Var}[\text{Prop}_{ij}] &= \phi\mu_{ij}(1 - \mu_{ij})
 \end{aligned}$$

Here,  $\eta_{ij}$  is the linear predictor for variety  $j$  on site  $i$ ,  $\alpha_i$  denotes the  $i$ th site effect, and  $\tau_j$  denotes the  $j$ th barley variety effect. The logit of the expected leaf area proportions is linearly related to these effects. The variance function of the model is that of a binomial( $n, \mu_{ij}$ ) variable, and  $\phi$  is an overdispersion parameter. The moniker “pseudo-binomial” derives not from the pseudo-likelihood methods used to estimate the parameters in the model, but from treating the response variable as if it had first and second moment properties akin to a binomial random variable.

The model is fit in the GLIMMIX procedure with the following statements:

```
proc glimmix data=blotch;
 class site variety;
 model prop = site variety / link=logit dist=binomial;
 random _residual_;
 lsmeans variety / diff=control('1');
run;
```

The **MODEL** statement specifies the distribution as binomial and the logit link. Because the variance function of the binomial distribution is  $a(\mu) = \mu(1 - \mu)$ , you use the statement

```
random _residual_;
```

to specify the scale parameter  $\phi$ . The **LSMEANS** statement requests estimates of the least squares means for the barley variety. The **DIFF=CONTROL('1')** option requests tests of least squares means differences against the first variety.

The “Model Information” table in [Output 41.4.1](#) describes the model and methods used in fitting the statistical model. It is assumed here that the data are binomial proportions.

**Output 41.4.1** Model Information in Pseudo-binomial Analysis

| The GLIMMIX Procedure     |                    |
|---------------------------|--------------------|
| Model Information         |                    |
| Data Set                  | WORK.BLOTCH        |
| Response Variable         | prop               |
| Response Distribution     | Binomial           |
| Link Function             | Logit              |
| Variance Function         | Default            |
| Variance Matrix           | Diagonal           |
| Estimation Technique      | Maximum Likelihood |
| Degrees of Freedom Method | Residual           |

The “Class Level Information” table in [Output 41.4.2](#) lists the number of levels of the Site and Variety effects and their values. All 90 observations read from the data are used in the analysis.

**Output 41.4.2** Class Levels and Number of Observations

| Class Level Information     |        |                      |
|-----------------------------|--------|----------------------|
| Class                       | Levels | Values               |
| site                        | 9      | 1 2 3 4 5 6 7 8 9    |
| variety                     | 10     | 1 2 3 4 5 6 7 8 9 10 |
| Number of Observations Read |        | 90                   |
| Number of Observations Used |        | 90                   |

In [Output 41.4.3](#), the “Dimensions” table shows that the model does not contain G-side random effects. There is a single covariance parameter, which corresponds to  $\phi$ . The “Optimization Information” table shows that the optimization comprises 18 parameters ([Output 41.4.3](#)). These correspond to the 18 nonsingular columns of the  $\mathbf{X}'\mathbf{X}$  matrix.

**Output 41.4.3** Model Fit in Pseudo-binomial Analysis

| Dimensions             |    |

| CAIC (smaller is better) | 156.15 |
| HQIC (smaller is better) | 111.30 |
| Pearson Chi-Square       | 6.39   |
| Pearson Chi-Square / DF  | 0.09   |

There are significant site and variety effects in this model based on the approximate Type III  $F$  tests ([Output 41.4.4](#)).

**Output 41.4.4** Tests of Site and Variety Effects in Pseudo-binomial Analysis

| Type III Tests of Fixed Effects |           |           |         |        |
|---------------------------------|-----------|-----------|---------|--------|
| Effect                          | Num<br>DF | Den<br>DF | F Value | Pr > F |
| site                            | 8         | 72        | 18.25   | <.0001 |
| variety                         | 9         | 72        | 13.85   | <.0001 |

[Output 41.4.5](#) displays the Variety least squares means for this analysis. These are obtained by averaging

$$\text{logit}(\hat{\mu}_{ij}) = \hat{\eta}_{ij}$$

across the sites. In other words, LS-means are computed on the linked scale where the model effects are additive. Note that the least squares means are ordered by variety. The estimate of the expected proportion of infected leaf area for the first variety is

$$\hat{\mu}_{.,1} = \frac{1}{1 + \exp\{4.38\}} = 0.0124$$

and that for the last variety is

$$\hat{\mu}_{.,10} = \frac{1}{1 + \exp\{0.127\}} = 0.468$$

**Output 41.4.5** Variety Least Squares Means in Pseudo-binomial Analysis

| variety Least Squares Means |          |                |    |         |         |
|-----------------------------|----------|----------------|----|---------|---------|
| variety                     | Estimate | Standard Error | DF | t Value | Pr >  t |
| 1                           | -4.3800  | 0.5643         | 72 | -7.76   | <.0001  |
| 2                           | -4.2300  | 0.5383         | 72 | -7.86   | <.0001  |
| 3                           | -3.6906  | 0.4623         | 72 | -7.98   | <.0001  |
| 4                           | -3.3319  | 0.4239         | 72 | -7.86   | <.0001  |
| 5                           | -2.7653  | 0.3768         | 72 | -7.34   | <.0001  |
| 6                           | -2.0089  | 0.3320         | 72 | -6.05   | <.0001  |
| 7                           | -1.8095  | 0.3228         | 72 | -5.61   | <.0001  |
| 8                           | -1.0380  | 0.2960         | 72 | -3.51   | 0.0008  |
| 9                           | -0.8800  | 0.2921         | 72 | -3.01   | 0.0036  |
| 10                          | -0.1270  | 0.2808         | 72 | -0.45   | 0.6523  |

Because of the ordering of the least squares means, the differences against the first variety are also ordered from smallest to largest (Output 41.4.6).

**Output 41.4.6** Variety Differences against the First Variety

| Differences of variety Least Squares Means |          |          |                |    |         |         |

| 6                                          | 1        | 2.3712   | 0.6090         | 72 | 3.89    | 0.0002  |
| 7                                          | 1        | 2.5705   | 0.6065         | 72 | 4.24    | <.0001  |
| 8                                          | 1        | 3.3420   | 0.6015         | 72 | 5.56    | <.0001  |
| 9                                          | 1        | 3.5000   | 0.6013         | 72 | 5.82    | <.0001  |
| 10                                         | 1        | 4.2530   | 0.6042         | 72 | 7.04    | <.0001  |

This analysis depends on your choice for the variance function that was implied by the binomial distribution. You can diagnose the distributional assumption by examining various graphical diagnostics measures. The following statements request a panel display of the Pearson-type residuals:

```
ods graphics on;
ods select PearsonPanel;
proc glimmix data=blotch plots=pearsonpanel;
 class site variety;
 model prop = site variety / link=logit dist=binomial;
 random _residual_;
run;
ods graphics off;
```

Output 41.4.7 clearly indicates that the chosen variance function is not appropriate for these data. As  $\mu$  approaches zero or one, the variability in the residuals is less than that implied by the binomial variance function.

**Output 41.4.7** Panel of Pearson-Type Residuals in Pseudo-binomial Analysis

To remedy this situation, McCullagh and Nelder (1989) consider instead the variance function

$$\text{Var}[\text{Prop}_{ij}] = \mu_{ij}^2(1 - \mu_{ij})^2$$

Imagine two varieties with  $\mu_i = 0.1$  and  $\mu_k = 0.5$ . Under the binomial variance function, the variance of the proportion for variety  $k$  is 2.77 times larger than that for variety  $i$ . Under the revised model this ratio increases to  $2.77^2 = 7.67$ .

The analysis of the revised model is obtained with the next set of GLIMMIX statements. Because you need to model a variance function that does not correspond to any of the built-in distributions, you need to supply a function with an assignment to the automatic variable `_VARIANCE_`. The GLIMMIX procedure then considers the distribution of the data as unknown. The corresponding estimation technique is quasi-likelihood. Because this model does not include an extra scale parameter, you can drop the `RANDOM _RESIDUAL_` statement from the analysis.

```
ods graphics on;
ods select ModelInfo FitStatistics LSMeans DiffS PearsonPanel;
proc glimmix data=blotch plots=pearsonpanel;
 class site variety;
 variance = _mu_**2 * (1-_mu_)**2;
 model prop = site variety / link=logit;
 lsmeans variety / diff=control('1');
run;
ods graphics off;
```

The “Model Information” table in [Output 41.4.8](#) now displays the distribution as “Unknown,” because of the assignment made in the GLIMMIX statements to `_VARIANCE_`. The table also shows the expression evaluated as the variance function.

**Output 41.4.8** Model Information in Quasi-likelihood Analysis

| The GLIMMIX Procedure     |                       |
|---------------------------|-----------------------|
| Model Information         |                       |
| Data Set                  | WORK.BLOTCH           |
| Response Variable         | prop                  |
| Response Distribution     | Unknown               |
| Link Function             | Logit                 |
| Variance Function         | _mu_**2 * (1-_mu_)**2 |
| Variance Matrix           | Diagonal              |
| Estimation Technique      | Quasi-Likelihood      |
| Degrees of Freedom Method | Residual              |

The fit statistics of the model are now expressed in terms of the log quasi-likelihood. It is computed as

$$\sum_{i=1}^9 \sum_{j=1}^{10} \int_{y_{ij}}^{\mu_{ij}} \frac{y_{ij} - t}{t^2(1-t)^2} dt$$

Twice the negative of this sum equals  $-85.74$ , which is displayed in the “Fit Statistics” table ([Output 41.4.9](#)).

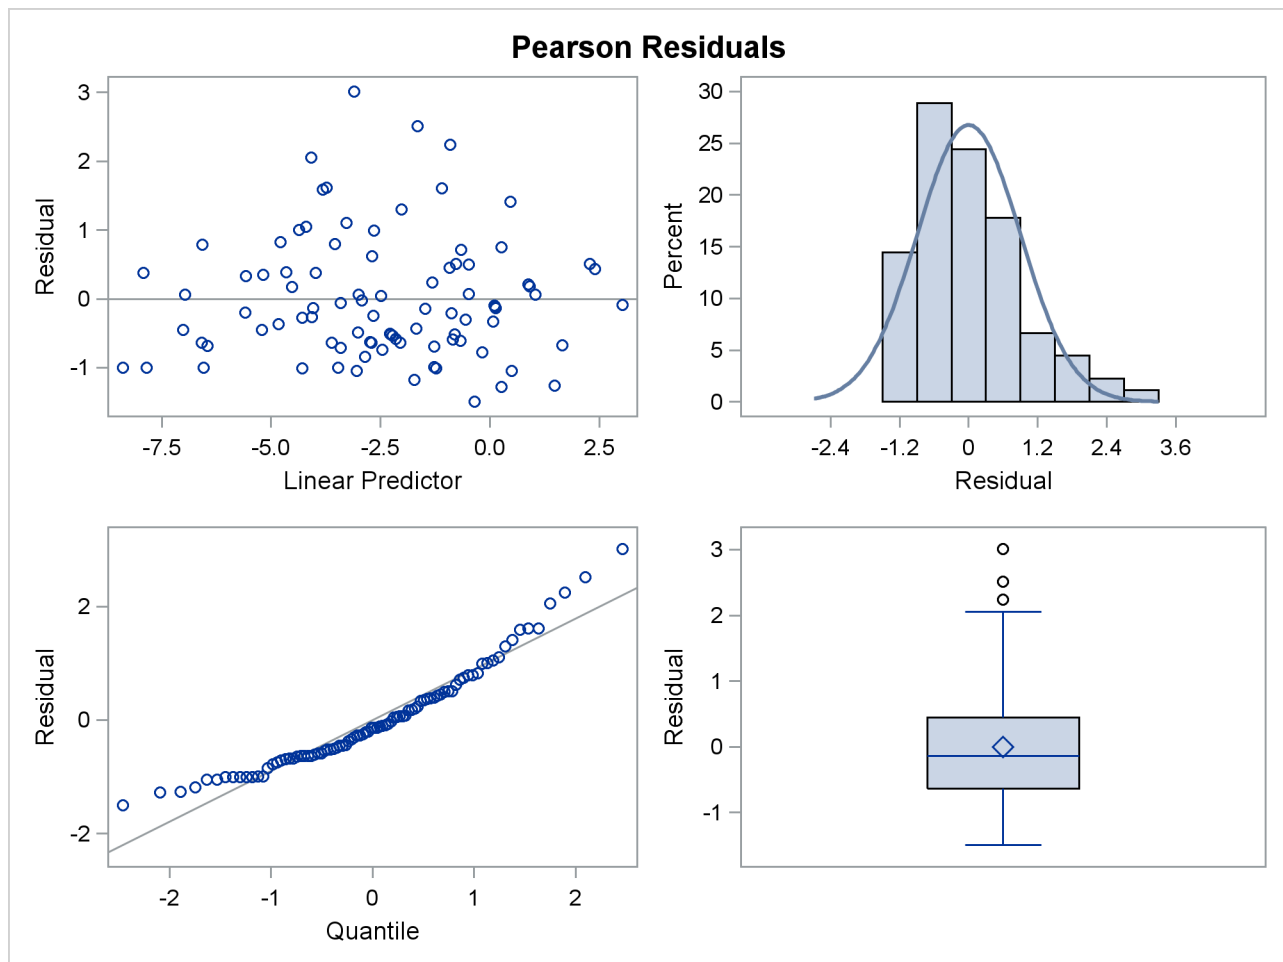

The scaled Pearson statistic is now 0.99. Inclusion of an extra scale parameter  $\phi$  would have little or no effect on the results.

**Output 41.4.9** Fit Statistics in Quasi-likelihood Analysis

| Fit Statistics                 |        |
|--------------------------------|--------|
| -2 Log Quasi-Likelihood        | -85.74 |
| Quasi-AIC (smaller is better)  | -49.74 |
| Quasi-AICC (smaller is better) | -40.11 |
| Quasi-BIC (smaller is better)  | -4.75  |
| Quasi-CAIC (smaller is better) | 13.25  |
| Quasi-HQIC (smaller is better) | -31.60 |
| Pearson Chi-Square             | 71.17  |
| Pearson Chi-Square / DF        | 0.99   |

The panel of Pearson-type residuals now shows a much more adequate distribution for the residuals and a reduction in the number of outlying residuals (Output 41.4.10).

**Output 41.4.10** Panel of Pearson-Type Residuals (Quasi-likelihood)

The least squares means are no longer ordered in size by variety (Output 41.4.11). For example,  $\text{logit}(\hat{\mu}_{.1}) > \text{logit}(\hat{\mu}_{.2})$ . Under the revised model, the second variety has a greater percentage of its leaf area covered by blotch, compared to the first variety. Varieties 5 and 6 and varieties 8 and 9 show similar reversal in ranking.

**Output 41.4.11** Variety Least Squares Means in Quasi-likelihood Analysis

| variety Least Squares Means |          |                |    |         |         |
|-----------------------------|----------|----------------|----|---------|---------|
| variety                     | Estimate | Standard Error | DF | t Value | Pr >  t |
| 1                           | -4.0453  | 0.3333         | 72 | -12.14  | <.0001  |
| 2                           | -4.5126  | 0.3333         | 72 | -13.54  | <.0001  |
| 3                           | -3.9664  | 0.3333         | 72 | -11.90  | <.0001  |
| 4                           | -3.0912  | 0.3333         | 72 | -9.27   | <.0001  |
| 5                           | -2.6927  | 0.3333         | 72 | -8.08   | <.0001  |
| 6                           | -2.7167  | 0.3333         | 72 | -8.15   | <.0001  |
| 7                           | -1.7052  | 0.3333         | 72 | -5.12   | <.0001  |
| 8                           | -0.7827  | 0.3333         | 72 | -2.35   | 0.0216  |
| 9                           | -0.9098  | 0.3333         | 72 | -2.73   | 0.0080  |
| 10                          | -0.1580  | 0.3333         | 72 | -0.47   | 0.6369  |

Interestingly, the standard errors are constant among the LS-means (Output 41.4.11) and among the LS-means differences (Output 41.4.12). This is due to the fact that for the logit link

$$\frac{\partial \mu}{\partial \eta} = \mu(1 - \mu)$$

which cancels with the square root of the variance function in the estimating equations. The analysis is thus orthogonal.

**Output 41.4.12** Variety Differences in Quasi-likelihood Analysis

| Differences of variety Least Squares Means |          |          |                |    |         |         |
|--------------------------------------------|----------|----------|----------------|----|---------|---------|

## Example 41.5: Joint Modeling of Binary and Count Data

Clustered data arise when multiple observations are collected on the same sampling or experimental unit. Often, these multiple observations refer to the same attribute measured at different points in time or space. This leads to repeated measures, longitudinal, and spatial data, which are special forms of multivariate data. A different class of multivariate data arises when the multiple observations refer to different attributes.

The data set `hernio`, created in the following `DATA` step, provides an example of a bivariate outcome variable. It reflects the condition and length of hospital stay for 32 herniorrhaphy patients. These data are based on data given by Mosteller and Tukey (1977) and reproduced in Hand et al. (1994, pp. 390, 391). The data set that follows does not contain all the covariates given in these sources. The response variables are `leave` and `los`; these denote the condition of the patient upon leaving the operating room and the length of hospital stay after the operation (in days). The variable `leave` takes on the value one if a patient experiences a routine recovery, and the value zero if postoperative intensive care was required. The binary variable `OKstatus` distinguishes patients based on their postoperative physical status (“1” implies better status).

```

data hernio;
 input patient age gender$ OKstatus leave los;
 datalines;
 1 78 m 1 0 9
 2 60 m 1 0 4
 3 68 m 1 1 7
 4 62 m 0 1 35
 5 76 m 0 0 9
 6 76 m 1 1 7
 7 64 m 1 1 5
 8 74 f 1 1 16
 9 68 m 0 1 7
 10 79 f 1 0 11
 11 80 f 0 1 4
 12 48 m 1 1 9
 13 35 f 1 1 2
 14 58 m 1 1 4
 15 40 m 1 1 3
 16 19 m 1 1 4
 17 79 m 0 0 3
 18 51 m 1 1 5
 19 57 m 1 1 8
 20 51 m 0 1 8
 21 48 m 1 1 3
 22 48 m 1 1 5
 23 66 m 1 1 8
 24 71 m 1 0 2
 25 75 f 0 0 7
 26 2 f 1 1 0
 27 65 f 1 0 16
 28 42 f 1 0 3
 29 54 m 1 0 2
 30 43 m 1 1 3
 31 4 m 1 1 3
 32 52 m 1 1 8
 ;

```

While the response variable `los` is a Poisson count variable, the response variable `leave` is a binary variable. You can perform separate analysis for the two outcomes, for example, by fitting a logistic model for the operating room exit condition and a Poisson regression model for the length of hospital stay. This, however, would ignore the correlation between the two outcomes. Intuitively, you would expect that the length of postoperative hospital stay is longer for those patients who had more tenuous exit conditions.

The following DATA step converts the data set `hernio` from the multivariate form to the univariate form. In the multivariate form the responses are stored in separate variables. The GLIMMIX procedure requires the univariate data structure.

```
data hernio_uv;
 length dist $7;
 set hernio;
 response = (leave=1);
 dist = "Binary";
 output;
 response = los;
 dist = "Poisson";
 output;
 keep patient age OKstatus response dist;
run;
```

This DATA step expands the 32 observations in the data set `hernio` into 64 observations, stacking two observations per patient. The character variable `dist` identifies the distribution that is assumed for the respective observations within a patient. The first observation for each patient corresponds to the binary response.

The following GLIMMIX statements fit a logistic regression model with two regressors (`age` and `OKStatus`) to the binary observations:

```
proc glimmix data=hernio_uv(where=(dist="Binary"));
 model response(event='1') = age OKStatus / s dist=binary;
run;
```

The `EVENT=('1')` response option requests that PROC GLIMMIX model the probability  $\Pr(\text{leave} = 1)$ —that is, the probability of routine recovery. The fit statistics and parameter estimates for this univariate analysis are shown in [Output 41.5.1](#). The coefficient for the age effect is negative ( $-0.07725$ ) and marginally significant at the 5% level ( $p = 0.0491$ ). The negative sign indicates that the probability of routine recovery decreases with age. The coefficient for the `OKStatus` variable is also negative. Its large standard error and the  $p$ -value of 0.7341 indicate, however, that this regressor is not significant.

**Output 41.5.1** Univariate Logistic Regression

| The GLIMMIX Procedure |                          |                |    |         |         |
|-----------------------|--------------------------|----------------|----|---------|---------|
| Fit Statistics        |                          |                |    |         |         |
|                       | -2 Log Likelihood        |                |    |         | 32.77   |
|                       | AIC (smaller is better)  |                |    |         | 38.77   |
|                       | AICC (smaller is better) |                |    |         | 39.63   |
|                       | BIC (smaller is better)  |                |    |         | 43.17   |
|                       | CAIC (smaller is better) |                |    |         | 46.17   |
|                       | HQIC (smaller is better) |                |    |         | 40.23   |
|                       | Pearson Chi-Square       |                |    |         | 30.37   |
|                       | Pearson Chi-Square / DF  |                |    |         | 1.05    |
| Parameter Estimates   |                          |                |    |         |         |
| Effect                | Estimate                 | Standard Error | DF | t Value | Pr >  t |
| Intercept             | 5.7694                   | 2.8245         | 29 | 2.04    | 0.0503  |
| age                   | -0.07725                 | 0.03761        | 29 | -2.05   | 0.0491  |
| OKstatus              | -0.3516                  | 1.0253         | 29 | -0.34   | 0.7341  |

Based on the univariate logistic regression analysis, you would probably want to revisit the model, examine other regressor variables, test for gender effects and interactions, and so forth. The two-regressor model is sufficient for this example. It is illustrative to trace the relative importance of the two regressors through various types of models.

The next statements fit the same regressors to the count data:

```
proc glimmix data=hernio_uv(where=(dist="Poisson"));
 model response = age OKStatus / s dist=Poisson;
run;
```

For this response, both regressors appear to make significant contributions at the 5% significance level (Output 41.5.2). The sign of the coefficient seems appropriate; the length of hospital stay should increase with patient age and be shorter for patients with better preoperative health. The magnitude of the scaled Pearson statistic (4.48) indicates, however, that there is considerable overdispersion in this model. This could be due to omitted variables or an improper distributional assumption. The importance of preoperative health status, for example, can change with a patient's age, which could call for an interaction term.

**Output 41.5.2** Univariate Poisson Regression

| age                   | 0.01525                  | 0.004454       | 29 | 3.42    | 0.0019  |
| OKstatus              | -0.3301                  | 0.1562         | 29 | -2.11   | 0.0433  |

You can also model both responses jointly. The following statements request a multivariate analysis:

```
proc glimmix data=hernio_uv;
 class dist;
 model response(event='1') = dist dist*age dist*OKstatus /
 noint s dist=byobs(dist);
run;
```

The `DIST=BYOBS` option in the `MODEL` statement instructs the GLIMMIX procedure to examine the variable `dist` in order to identify the distribution of an observation. The variable can be character or numeric. See the `DIST=` option of the `MODEL` statement for a list of the numeric codes for the various distributions that are compatible with the `DIST=BYOBS` formulation. Because no `LINK=` option is specified, the link functions are chosen as the default links that correspond to the respective distributions. In this case, the logit link is applied to the binary observations and the log link is applied to the Poisson outcomes. The `dist` variable is also listed in the `CLASS` statement, which enables you to use interaction terms in the `MODEL` statement to vary the regression coefficients by response distribution. The `NOINT` option is used here so that the parameter estimates of the joint model are directly comparable to those in [Output 41.5.1](#) and [Output 41.5.2](#).

The “Fit Statistics” and “Parameter Estimates” tables of this bivariate estimation process are shown in [Output 41.5.3](#).

| OKstatus*dist            | Poisson | -0.3301  | 0.1562         | 58 | -2.11   | 0.0389  |

The “Fit Statistics” table now contains a separate column for each response distribution, as well as an overall contribution. Because the model does not specify any random effects or R-side correlations, the log likelihoods are additive. The parameter estimates and their standard errors in this joint model are identical to those in [Output 41.5.1](#) and [Output 41.5.2](#). The *p*-values reflect the larger “sample size” in the joint analysis. Note that the coefficients would be different from the separate analyses if the *dist* variable had not been used to form interactions with the model effects.

There are two ways in which the correlations between the two responses for the same patient can be incorporated. You can induce them through shared random effects or model the dependency directly. The following statements fit a model that induces correlation:

```
proc glimmix data=hernio_uv;
 class patient dist;
 model response(event='1') = dist dist*age dist*OKstatus /
 noint s dist=byobs(dist);
 random int / subject=patient;
run;
```

Notice that the *patient* variable has been added to the **CLASS** statement and as the **SUBJECT=** effect in the **RANDOM** statement.

The “Fit Statistics” table in [Output 41.5.4](#) no longer has separate columns for each response distribution, because the data are not independent. The log (pseudo-)likelihood does not factor into additive component that correspond to distributions. Instead, it factors into components associated with subjects.

| OKstatus*dist                  | Poisson | -0.1856  | 0.3020         | 29 | -0.61   | 0.5435  |

The estimate of the variance of the random patient intercept is 0.2990, and the estimated standard error of this variance component estimate is 0.1116. There appears to be significant patient-to-patient variation in the intercepts. The estimates of the fixed effects as well as their estimated standard errors have changed from the bivariate-independence analysis (see [Output 41.5.3](#)). When the length of hospital stay and the postoperative condition are modeled jointly, the preoperative health status (variable OKStatus) no longer appears significant. Compare this result to [Output 41.5.3](#); in the separate analyses the initial health status was a significant predictor of the length of hospital stay. A further joint analysis of these data would probably remove this predictor from the model entirely.

A joint model of the second kind, where correlations are modeled directly, is fit with the following GLIMMIX statements:

```
proc glimmix data=hernio_uv;
 class patient dist;
 model response(event='1') = dist dist*age dist*OKstatus /
 noint s dist=byobs(dist);
 random _residual_ / subject=patient type=chol;
run;
```

Instead of a shared G-side random effect, an R-side covariance structure is used to model the correlations. It is important to note that this is a marginal model that models covariation on the scale of the data. The previous model involves the  $Z\mathbf{y}$  random components inside the linear predictor.

The `_RESIDUAL_` keyword instructs PROC GLIMMIX to model the R-side correlations. Because of the `SUBJECT=PATIENT` option, data from different patients are independent, and data from a single patient follow the covariance model specified with the `TYPE=` option. In this case, a generally unstructured  $2 \times 2$  covariance matrix is modeled, but in its Cholesky parameterization. This ensures that the resulting covariance matrix is at least positive semidefinite and stabilizes the numerical optimizations.

The “Covariance Parameter Estimates” table in [Output 41.5.5](#) contains three entries for this model, corresponding to a  $(2 \times 2)$  covariance matrix for each patient. The Cholesky root of the  $\mathbf{R}$  matrix is

$$\mathbf{L} = \begin{bmatrix} 1.0162 & 0 \\ 0.3942 & 2.0819 \end{bmatrix}$$

so that the covariance matrix can be obtained as

$$\mathbf{LL}' = \begin{bmatrix} 1.0162 & 0 \\ 0.3942 & 2.0819 \end{bmatrix} \begin{bmatrix} 1.0162 & 0.3942 \\ 0 & 2.0819 \end{bmatrix} = \begin{bmatrix} 1.0326 & 0.4005 \\ 0.4005 & 4.4897 \end{bmatrix}$$

This is not the covariance matrix of the data, however, because the variance functions need to be accounted for.

The  $p$ -values in the “Solutions for Fixed Effects” table indicate the same pattern of significance and non-significance as in the conditional model with random patient intercepts.

---

## Example 41.6: Radial Smoothing of Repeated Measures Data

This example of a repeated measures study is taken from Diggle, Liang, and Zeger (1994, p. 100). The data consist of body weights of 27 cows, measured at 23 unequally spaced time points over a period of approximately 22 months. Following Diggle, Liang, and Zeger (1994), one animal is removed from the analysis, one observation is removed according to their Figure 5.7, and the time is shifted to start at 0 and is measured in 10-day increments. The design is a  $2 \times 2$  factorial, and the factors are the infection of an animal with *M. paratuberculosis* and whether the animal is receiving iron dosing.

The following DATA steps create the data and arrange them in univariate format.

```

data times;
 input time1-time23;

The mean response profiles of the cows are not of particular interest; what matters are inferences about the Iron effect, the Infection effect, and their interaction. Nevertheless, the body weight of the cows changes over the 22-month period, and you need to account for these changes in the analysis. A reasonable approach is to apply the approximate low-rank smoother to capture the trends over time. This approach frees you from having to stipulate a parametric model for the response trajectories over time. In addition, you can test hypotheses about the smoothing parameter; for example, whether it should be varied by treatment.

The following statements fit a model with a  $2 \times 2$  factorial treatment structure and smooth trends over time, choosing the Newton-Raphson algorithm with ridging for the optimization:

```

proc glimmix data=cows;
 t2 = tpoint / 100;
 class cow iron infection;
 model weight = iron infection iron*infection tpoint;
 random t2 / type=rsmooth subject=cow
 knotmethod=kdtree(bucket=100 knotinfo);
 output out=gmxout pred(blup)=pred;
 nloptions tech=newrap;
run;

```

The continuous time effect appears in both the **MODEL** statement (tpoint) and the **RANDOM** statement (t2). Because the variance of the radial smoothing component depends on the temporal metric, the time scale was rescaled for the **RANDOM** effect to move the parameter estimate away from the boundary. The knots of the radial smoother are selected as the vertices of a  $k$ -d tree. Specifying **BUCKET=100** sets the bucket size of the tree to  $b = 100$ . Because measurements at each time point are available for 26 (or 25) cows, this groups approximately four time points in a single bucket. The **KNOTINFO** keyword of the **KNOTMETHOD=** option requests a printout of the knot locations for the radial smoother. The **OUTPUT** statement saves the predictions of the mean of each observations to the data set gmxout. Finally, the **TECH=NEWRAP** option in the **NLOPTIONS** statement specifies the Newton-Raphson algorithm for the optimization technique.

The “Class Level Information” table lists the number of levels of the Cow, Iron, and Infection effects (Output 41.6.1).

**Output 41.6.1** Model Information and Class Levels in Repeated Measures Analysis

The “Radial Smoother Knots for RSmooth(t2)” table displays the knots computed from the vertices of the t2 *k*-d tree (Output 41.6.2). Notice that knots are spaced unequally and that the extreme time points are among the knot locations. The “Number of Observations” table shows that one observation was not used in the analysis. The 12th observation for cow 4 has a missing value.

**Output 41.6.2** Knot Information and Number of Observations

| Radial Smoother<br>Knots for<br>RSmooth(t2) |         |     |
|---------------------------------------------|---------|-----|
| Knot<br>Number                              | t2      |     |
| 1                                           | 0       |     |
| 2                                           | 0.04400 |     |

| 7                                           | 0.5050  |     |
| 8                                           | 0.6010  |     |
| 9                                           | 0.6590  |     |
| Number of Observations Read                 |         | 598 |
| Number of Observations Used                 |         | 597 |

The “Dimensions” table shows that the model contains only two covariance parameters, the G-side variance of the spline coefficients ( $\sigma^2$ ) and the R-side scale parameter ( $\phi$ , [Output 41.6.3](#)). For each subject (cow), there are nine columns in the  $\mathbf{Z}$  matrix, one per knot location. The GLIMMIX procedure processes these data by subjects (cows).

**Output 41.6.3** Dimensions Information in Repeated Measures Analysis

| Dimensions               |    |
|--------------------------|----|
| G-side Cov. Parameters   | 1  |
| R-side Cov. Parameters   | 1  |
| Columns in X             | 10 |
| Columns in Z per Subject | 9  |
| Subjects (Blocks in V)   | 26 |
| Max Obs per Subject      | 23 |

The “Optimization Information” table displays information about the optimization process. Because fixed effects and the residual scale parameter can be profiled from the optimization, the iterative algorithm involves only a single covariance parameter, the variance of the spline coefficients ([Output 41.6.4](#)).

**Output 41.6.4** Optimization Information in Repeated Measures Analysis

| Optimization Information   |                |
|----------------------------|----------------|
| Optimization Technique     | Newton-Raphson |
| Parameters in Optimization | 1              |
| Lower Boundaries           | 1              |
| Upper Boundaries           | 0              |
| Fixed Effects              | Profiled       |
| Residual Variance          | Profiled       |
| Starting From              | Data           |

After 11 iterations, the optimization process terminates ([Output 41.6.5](#)). In this case, the absolute gradient convergence criterion was met.

**Output 41.6.5** Iteration History and Convergence Status

| Iteration History |          |             |                    |              |              |
|-------------------|----------|-------------|--------------------|--------------|--------------|
| Iteration         | Restarts | Evaluations | Objective Function | Change       | Max Gradient |
| 0                 | 0        | 4           | -1302.549272       | .            | 20.33682     |

Convergence criterion (ABSGCONV=0.00001) satisfied.

The generalized chi-square statistic in the “Fit Statistics” table is small for this model (Output 41.6.6). There is very little residual variation. The radial smoother is associated with 433.55 residual degrees of freedom, computed as 597 minus the trace of the smoother matrix.

**Output 41.6.6** Fit Statistics in Repeated Measures Analysis

| Fit Statistics           |          |
|--------------------------|----------|
| -2 Res Log Likelihood    | -1886.29 |
| AIC (smaller is better)  | -1882.29 |
| AICC (smaller is better) | -1882.27 |
| BIC (smaller is better)  | -1879.77 |
| CAIC (smaller is better) | -1877.77 |
| HQIC (smaller is better) | -1881.56 |
| Generalized Chi-Square   | 0.47     |
| Gener. Chi-Square / DF   | 0.00     |
| Radial Smoother df(res)  | 433.55   |

The “Covariance Parameter Estimates” table in Output 41.6.7 displays the estimates of the covariance parameters. The variance of the random spline coefficients is estimated as  $\hat{\sigma}^2 = 0.5961$ , and the scale parameter (=residual variance) estimate is  $\hat{\phi} = 0.0008$ .

**Output 41.6.7** Estimated Covariance Parameters

| Covariance Parameter Estimates |         |          |                |
|--------------------------------|---------|----------|----------------|
| Cov Parm                       | Subject | Estimate | Standard Error |
| Var[RSmooth(t2)]               | cow     | 0.5961   | 0.08144        |
| Residual                       |         | 0.000800 | 0.000059       |

The “Type III Tests of Fixed Effects” table displays  $F$  tests for the fixed effects in the `MODEL` statement (Output 41.6.8). There is a strong infection effect as well as the absence of an interaction between infection with *M. paratuberculosis* and iron dosing. It is important to note, however, that the interpretation of these tests rests on the assumption that the random effects in the mixed model have zero mean; in this case, the radial smoother coefficients.

**Output 41.6.8** Tests of Fixed Effects

| Type III Tests of Fixed Effects |        |        |         |        |
|---------------------------------|--------|--------|---------|--------|
| Effect                          | Num DF | Den DF | F Value | Pr > F |
| iron                            | 1      | 358    | 3.59    | 0.0588 |
| infection                       | 1      | 358    | 21.16   | <.0001 |
| iron*infection                  | 1      | 358    | 0.09    | 0.7637 |
| tpoint                          | 1      | 358    | 53.88   | <.0001 |

A graph of the observed data and fitted profiles in the four groups is produced with the following statements (Output 41.6.9):

```
data plot;
 set gmxout;
 length group $26;
 if (iron=0) and (infection=0) then group='Control Group (n=4)';
 else if (iron=1) and (infection=0) then group='Iron - No Infection (n=3)';
 else if (iron=0) and (infection=1) then group='No Iron - Infection (n=9)';
 else group = 'Iron - Infection (n=10)';
run;
proc sort data=plot; by group cow;
run;

proc sgpanel data=plot noautolegend;
 title 'Radial Smoothing With Cow-Specific Trends';
 label tpoint='Time' weight='log(Weight)';
 panelby group / columns=2 rows=2;
 scatter x=tpoint y=weight;
 series x=tpoint y=pred / group=cow lineattrs=GraphFit;
run;
```

Output 41.6.9 Observed and Predicted Profiles

The trends are quite smooth, and you can see how the radial smoother adapts to the cow-specific profile. This is the reason for the small scale parameter estimate,  $\hat{\phi} = 0.008$ . Comparing the panels at the top to the panels at the bottom of [Output 41.6.9](#) reveals the effect of Infection. A comparison of the panels on the left to those on the right indicates the weak Iron effect.

The smoothing parameter in this analysis is related to the covariance parameter estimates. Because there is only one radial smoothing variance component, the amount of smoothing is the same in all four treatment groups. To test whether the smoothing parameter should be varied by group, you can refine the analysis of the previous model. The following statements fit the same general model, but they vary the covariance parameters by the levels of the Iron\*Infection interaction. This is accomplished with the **GROUP=** option in the **RANDOM** statement.

```
ods select OptInfo FitStatistics CovParms;
proc glimmix data=cows;
 t2 = tpoint / 100;
 class cow iron infection;
 model weight = iron infection iron*infection tpoint;
 random t2 / type=rsmooth
 subject=cow
 group=iron*infection
 knotmethod=kdtree(bucket=100);
 nloptions tech=newrap;
run;
```

All observations that have the same value combination of the Iron and Infection effects share the same covariance parameter. As a consequence, you obtain different smoothing parameters result in the four groups.

In [Output 41.6.10](#), the “Optimization Information” table shows that there are now four covariance parameters in the optimization, one spline coefficient variance for each group.

| Var[RSmooth(t2)]               | cow     | iron*infection | 1 0 | 0.4904   | 0.2195         |
| Var[RSmooth(t2)]               | cow     | iron*infection | 1 1 | 0.7105   | 0.1409         |
| Residual                       |         |                |     | 0.000807 | 0.000060       |

Varying this variance component by groups has changed the  $-2$  Res Log Likelihood from  $-1886.29$  to  $-1887.95$  (Output 41.6.10). The difference, 1.66, can be viewed (asymptotically) as the realization of a chi-square random variable with three degrees of freedom. The difference is not significant ( $p = 0.64586$ ). The “Covariance Parameter Estimates” table confirms that the estimates of the spline coefficient variance are quite similar in the four groups, ranging from 0.4788 to 0.7105.

Finally, you can apply a different technique for varying the temporal trends among the cows. From Output 41.6.9 it appears that an assumption of parallel trends within groups might be reasonable. In other words, you can fit a model in which the “overall” trend over time in each group is modeled nonparametrically, and this trend is shifted up or down to capture the behavior of the individual cow. You can accomplish this with the following statements:

```
ods select FitStatistics CovParms;
proc glimmix data=cows;
 t2 = tpoint / 100;
 class cow iron infection;
 model weight = iron infection iron*infection tpoint;
 random t2 / type=rsmooth
 subject=iron*infection
 knotmethod=kdtree(bucket=100);
 random intercept / subject=cow;
 output out=gmxout pred(blup)=pred;
 nloptions tech=newrap;
run;
```

There are now two subject effects in this analysis. The first **RANDOM** statement applies the radial smoothing and identifies the experimental conditions as the subject. For each condition, a separate realization of the random spline coefficients is obtained. The second **RANDOM** statement adds a random intercept to the trend for each cow. This random intercept results in the parallel shift of the trends over time.

Results from this analysis are shown in [Output 41.6.11](#).

**Output 41.6.11** Analysis with Parallel Shifts

| Residual                       |                | 0.001976 | 0.000121       |

Because the parallel shift model is not nested within either one of the previous models, the models cannot be compared with a likelihood ratio test. However, you can draw on the other fit statistics.

All statistics indicate that this model does not fit the data as well as the initial model that varies the spline coefficients by cow. The Pearson chi-square statistic is more than twice as large as in the previous model, indicating much more residual variation in the fit. On the other hand, this model generates only four sets of spline coefficients, one for each treatment group, and thus retains more residual degrees of freedom.

The “Covariance Parameter Estimates” table in [Output 41.6.11](#) displays the solutions for the covariance parameters. The estimate of the variance of the spline coefficients is not that different from the estimate obtained in the first model (0.5961). The residual variance, however, has more than doubled.

Using similar SAS statements as previously, you can produce a plot of the observed and predicted profiles ([Output 41.6.12](#)).

The parallel shifts of the nonparametric smooths are clearly visible in [Output 41.6.12](#). In the groups receiving only iron or only an infection, the parallel lines assumption holds quite well. In the control group and the group receiving iron and the infection, the parallel shift assumption does not hold as well. Two of the profiles in the iron-only group are nearly indistinguishable.

Output 41.6.12 Observed and Predicted Profiles

This example demonstrates that mixed model smoothing techniques can be applied not only to achieve scatter plot smoothing, but also to longitudinal or repeated measures data. You can then use the **SUBJECT=** option in the **RANDOM** statement to obtain independent sets of spline coefficients for different subjects, and the **GROUP=** option in the **RANDOM** statement to vary the degree of smoothing across groups. Also, radial smoothers can be combined with other random effects. For the data considered here, the appropriate model is one with a single smoothing parameter for all treatment group and cow-specific spline coefficients.

## Example 41.7: Isotonic Contrasts for Ordered Alternatives

Dose response studies often focus on testing for monotone increasing or decreasing behavior in the mean values of the dependent variable. Hirotsu and Srivastava (2000) demonstrate one approach by using data that originally appeared in Moriguchi (1976). The data, which follow, consist of ferrite cores subjected to four increasing temperatures. The response variable is the magnetic force of each core.

```
data FerriteCores;
 do Temp = 1 to 4;
 do rep = 1 to 5; drop rep;
 input MagneticForce @@;
 output;
 end;
 end;
 datalines;
10.8 9.9 10.7 10.4 9.7
10.7 10.6 11.0 10.8 10.9
11.9 11.2 11.0 11.1 11.3
11.4 10.7 10.9 11.3 11.7
;
```

It is of interest to test whether the magnetic force of the cores rises monotonically with temperature. The approach of Hirotsu and Srivastava (2000) depends on the lower confidence limits of the *isotonic contrasts* of the force means at each temperature, adjusted for multiplicity. The corresponding isotonic contrast compares the average of a particular group and the preceding groups with the average of the succeeding groups. You can compute adjusted confidence intervals for isotonic contrasts by using the `LSMESTIMATE` statement.

The following statements request an analysis of the `FerriteCores` data as a one-way design and multiplicity-adjusted lower confidence limits for the isotonic contrasts. For the multiplicity adjustment, the `LSMESTIMATE` statement employs simulation, which provides adjusted  $p$ -values and lower confidence limits that are exact up to Monte Carlo error.

```
proc glimmix data=FerriteCores;
 class Temp;
 model MagneticForce = Temp;
 lsestimate Temp
 'avg(1:1)<avg(2:4)' -3 1 1 1 divisor=3,
 'avg(1:2)<avg(3:4)' -1 -1 1 1 divisor=2,
 'avg(1:3)<avg(4:4)' -1 -1 -1 3 divisor=3
 / adjust=simulate(seed=1) cl upper;
 ods select LSMestimates;
run;
```

The results are shown in [Output 41.7.1](#).

| Temp                                   | avg(1:2) < avg(3:4) | 0.3337    | Infty     |  |  |
| Temp                                   | avg(1:3) < avg(4:4) | -0.02291  | Infty     |  |  |

With an adjusted  $p$ -value of 0.001, the magnetic force at the first temperature is significantly less than the average of the other temperatures. Likewise, the average of the first two temperatures is significantly less than the average of the last two ( $p = 0.0009$ ). However, the magnetic force at the last temperature is not significantly greater than the average magnetic force of the others ( $p = 0.0625$ ). These results indicate a significant monotone increase over the first three temperatures, but not across all four temperatures.

**Example 41.8: Adjusted Covariance Matrices of Fixed Effects**

The following data are from Pothoff and Roy (1964) and consist of growth measurements for 11 girls and 16 boys at ages 8, 10, 12, and 14. Some of the observations are suspect (for example, the third observation for person 20); however, all of the data are used here for comparison purposes.

```
data pr;
 input child gender$ y1 y2 y3 y4;
 array yy y1-y4;
 do time=1 to 4;
 age = time*2 + 6;
 y = yy{time};
 output;
 end;
 drop y1-y4;
```

```

```

Jennrich and Schluchter (1986) analyze these data with various models for the fixed effects and the covariance structure. The strategy here is to fit a growth curve model for the boys and girls and to account for subject-to-subject variation through G-side random effects. In addition, serial correlation among the observations within each child is accounted for by a time series process. The data are assumed to be Gaussian, and their  $-2$  restricted log likelihood is minimized to estimate the model parameters.

The following statements fit a mixed model in which a separate growth curve is assumed for each gender:

```

proc glimmix data=pr;
 class child gender time;
 model y = gender age gender*age / covb(details) ddfm=kr;
 random intercept age / type=chol sub=child;
 random time / subject=child type=ar(1) residual;
 ods select ModelInfo CovB CovBModelBased CovBDetails;
run;

```

The growth curve for an individual child differs from the gender-specific trend because of a random intercept and a random slope. The two G-side random effects are assumed to be correlated. Their unstructured covariance matrix is parameterized in terms of the Cholesky root to guarantee a positive (semi-)definite estimate. An AR(1) covariance structure is modeled for the observations over time for each child. Notice the **RESIDUAL** option in the second **RANDOM** statement. It identifies this as an R-side random effect.

The **DDFM=KR** option requests that the covariance matrix of the fixed-effect parameter estimates and denominator degrees of freedom for  $t$  and  $F$  tests are determined according to Kenward and Roger (1997). This is reflected in the “Model Information” table (Output 41.8.1).

**Output 41.8.1** Model Information with DDFM=KR

| The GLIMMIX Procedure       |                               |
|-----------------------------|-------------------------------|
| Model Information           |                               |
| Data Set                    | WORK.PR                       |
| Response Variable           | y                             |
| Response Distribution       | Gaussian                      |
| Link Function               | Identity                      |
| Variance Function           | Default                       |
| Variance Matrix Blocked By  | child                         |
| Estimation Technique        | Restricted Maximum Likelihood |
| Degrees of Freedom Method   | Kenward-Roger                 |
| Fixed Effects SE Adjustment | Kenward-Roger                 |

The **COVB** option in the **MODEL** statement requests that the covariance matrix used for inference about fixed effects in this model is displayed; this is the Kenward-Roger-adjusted covariance matrix. The **DE-TAILS** suboption requests that the unadjusted covariance matrix is also displayed (Output 41.8.2). In addition, a table of diagnostic measures for the covariance matrices is produced.

**Output 41.8.2** Model-Based and Adjusted Covariance Matrix

| Model Based Covariance Matrix for Fixed Effects (Unadjusted) |        |     |          |         |      |          |          |      |

Determinant and inversion results apply to the nonsingular partitions of the covariance matrices.

The “Diagnostics for Covariance Matrices” table in [Output 41.8.2](#) consists of several sections. The trace and log determinant of covariance matrices are general scalar summaries that are sometimes used in direct comparisons, or in formulating further statistics, such as the difference of log determinants. The trace simply represents the sum of the variances of all fixed-effects parameters.

The two matrices have the same number of positive and zero eigenvalues; hence they are of the same rank. There are no negative eigenvalues; hence the matrices are positive semi-definite.

The “Comparisons” section of the table provides several statistics that set the matrices in relationship. The statistics enable you to assess the extent to which the adjustment affected the model-based matrix. If the two matrices are identical, the concordance correlation equals 1, the discrepancy function and the Frobenius norm of the differences equal 0, and the trace of the adjusted and the (generalized) inverse of the model-based matrix equals the rank. See the section “[Exploring and Comparing Covariance Matrices](#)” on page 3080 for computational details regarding these statistics. With increasing discrepancy between the matrices, the difference norm and discrepancy function increase, the concordance correlation falls below 1, and the trace deviates from the rank. In this particular example, there is strong agreement between the two matrices; the adjustment to the covariance matrix associated with  $DDFM=KR$  is only slight. It is noteworthy, however, that the trace of the adjusted covariance matrix falls short of the trace of the unadjusted one. Indeed, from [Output 41.8.2](#) you can see that the diagonal elements of the adjusted covariance matrices are uniformly smaller than those of the model-based covariance matrix.

Standard error “shrinkage” for the Kenward-Roger covariance adjustment is due to the term  $-0.25\mathbf{R}_{ij}$  in equation (3) of Kenward and Roger (1997), which is nonzero for covariance structures with second derivatives, such as the `TYPE=ANTE(1)`, `TYPE=AR(1)`, `TYPE=ARH(1)`, `TYPE=ARMA(1,1)`, `TYPE=CHOL`, `TYPE=CSH`, `TYPE=FA0(q)`, `TYPE=TOEPH`, and `TYPE=UNR` structures and all `TYPE=SP()` structures.

For covariance structures that are linear in the parameters,  $\mathbf{R}_{ij} = \mathbf{0}$ . You can add the `FIRSTORDER` suboption to the `DDFM=KR` option to request that second derivative matrices  $\mathbf{R}_{ij}$  are excluded from computing the covariance matrix adjustment. The resulting covariance adjustment is that of Kackar and Harville (1984) and Harville and Jeske (1992). This estimator is denoted as  $\tilde{m}^{\circledast}$  in Harville and Jeske (1992) and is referred to there as the Prasad-Rao estimator after related work by Prasad and Rao (1990). This standard error adjustment is guaranteed to be positive (semi-)definite. The following statements fit the model with the Kackar-Harville-Jeske estimator and compare model-based and adjusted covariance matrices:

```
proc glimmix data=pr;
 class child gender time;
 model y = gender age gender*age / covb(details)
 ddfm=kr(firstorder);
 random intercept age / type=chol sub=child;
 random time / subject=child type=ar(1) residual;
 ods select ModelInfo CovB CovBDetails;
run;
```

The standard error adjustment is reflected in the “Model Information” table (Output 41.8.3).

**Output 41.8.3** Model Information with DDFM=KR(FIRSTORDER)

| The GLIMMIX Procedure       |                                  |
|-----------------------------|----------------------------------|

|                                                      | Trace(Adjusted Inv(MBased))  |                 | 4.0352   |

Determinant and inversion results apply to the nonsingular partitions of the covariance matrices.

The “Comparisons” statistics show that the model-based and adjusted covariance matrix of the fixed-effects parameter estimates are very similar. The concordance correlation is near 1, the discrepancy is near zero, and the trace is very close to the number of positive eigenvalues. This is due to the balanced nature of these repeated measures data. Shrinkage of standard errors, however, can not occur with the Kacker-Harville-Jeske estimator.

## Example 41.9: Testing Equality of Covariance and Correlation Matrices

Fisher's iris data are widely used in multivariate statistics. They comprise measurements in millimeters of four flower attributes, the length and width of sepals and petals for 50 specimens from each of three species, *Iris setosa*, *I. versicolor*, and *I. virginica* (Fisher 1936).

When modeling multiple attributes from the same specimen, correlations among measurements from the same flower must be taken into account. Unstructured covariance matrices are common in this multivariate setting. Species comparisons can focus on comparisons of mean response, but comparisons of the variation and covariation are also of interest. In this example, the equivalence of covariance and correlation matrices among the species are examined.

The iris data set is available in the `Sashelp` library. The following step displays the first 10 observations of the iris data in multivariate format—that is, each observation contains multiple response variables. The `DATA` step that follows creates a data set in univariate form, where each observation corresponds to a single response variable. This is the form needed by the `GLIMMIX` procedure.

```
proc print data=Sashelp.iris(obs=10);
run;
```

**Output 41.9.1** Fisher (1936) Iris Data

```
data iris_univ;
 set sashelp.iris;
 retain id 0;
 array y (4) SepalLength SepalWidth PetalLength PetalWidth;
 id+1;
 do var=1 to 4;
 response = y{var};
 output;
 end;
 drop SepalLength SepalWidth PetalLength PetalWidth;
run;
```

The following `GLIMMIX` statements fit a model with separate unstructured covariance matrices for each species:

```
ods select FitStatistics CovParms CovTests;
proc glimmix data=iris_univ;
 class species var id;
 model response = species*var;
 random _residual_ / type=un group=species subject=id;
 covtest homogeneity;
run;
```

The mean function is modeled as a cell-means model that allows for different means for each species and outcome variable. The covariances are modeled directly (R-side) rather than through random effects. The ID variable identifies the individual plant, so that responses from different plants are independent. The **GROUP=SPECIES** option varies the parameters of the unstructured covariance matrix by species. Hence, this model has 30 covariance parameters: 10 unique parameters for a  $(4 \times 4)$  covariance matrix for each of three species.

The **COVTEST** statement requests a test of homogeneity—that is, it tests whether varying the covariance parameters by the group effect provides a significantly better fit compared to a model in which different groups share the same parameter.

#### Output 41.9.2 Fit Statistics for Analysis of Fisher’s Iris Data

| The GLIMMIX Procedure    |         |
|--------------------------|---------|
| Fit Statistics           |         |
| -2 Res Log Likelihood    | 2812.89 |
| AIC (smaller is better)  | 2872.89 |
| AICC (smaller is better) | 2876.23 |
| BIC (smaller is better)  | 2963.21 |
| CAIC (smaller is better) | 2993.21 |
| HQIC (smaller is better) | 2909.58 |
| Generalized Chi-Square   | 588.00  |
| Gener. Chi-Square / DF   | 1.00    |

The “Fit Statistics” table shows the  $-2$  restricted (residual) log likelihood in the full model and other fit statistics (Output 41.9.2). The “ $-2$  Res Log Likelihood” sets the benchmark against which a model with homogeneity constraint is compared. Output 41.9.3 displays the 30 covariance parameters in this model.

There appear to be substantial differences among the covariance parameters from different groups. For example, the residual variability of the petal length of the three species is 12.4249, 26.6433, and 40.4343, respectively. The homogeneity hypothesis restricts these variances to be equal and similarly for the other covariance parameters. The results from the **COVTEST** statement are shown in Output 41.9.4.

**Output 41.9.3** Covariance Parameters Varied by Species (TYPE=UN)

| Covariance Parameter Estimates |         |                    |          |                |  |

**Output 41.9.4** Likelihood Ratio Test of Homogeneity

| Tests of Covariance Parameters<br>Based on the Restricted Likelihood |    |                 |        |            |      |
|----------------------------------------------------------------------|----|-----------------|--------|------------|------|
| Label                                                                | DF | -2 Res Log Like | ChiSq  | Pr > ChiSq | Note |
| Homogeneity                                                          | 20 | 2959.55         | 146.66 | <.0001     | DF   |

DF: P-value based on a chi-square with DF degrees of freedom.

Denote as  $\mathbf{R}_k$  the covariance matrix for species  $k = 1, 2, 3$  with elements  $\sigma_{ijk}$ . In processing the **COVTEST** hypothesis  $H_0: \mathbf{R}_1 = \mathbf{R}_2 = \mathbf{R}_3$ , the GLIMMIX procedure fits a model that satisfies the constraints

$$\begin{aligned}\sigma_{111} &= \sigma_{112} = \sigma_{113} \\ \sigma_{211} &= \sigma_{212} = \sigma_{213} \\ \sigma_{231} &= \sigma_{232} = \sigma_{233} \\ &\vdots \\ \sigma_{441} &= \sigma_{442} = \sigma_{443}\end{aligned}$$

where  $\sigma_{ijk}$  is the covariance between the  $i$ th and  $j$ th variable for the  $k$ th species. The  $-2$  restricted log likelihood of this restricted model is 2959.55 (Output 41.9.4). The change of 146.66 compared to the full model is highly significant. There is sufficient evidence to reject the notion of equal covariance matrices among the three iris species.

Equality of covariance matrices implies equality of correlation matrices, but the reverse is not true. Fewer constraints are needed to equate correlations because the diagonal entries of the covariance matrices are free to vary. In order to test the equality of the correlation matrices among the three species, you can parameterize the unstructured covariance matrix in terms of the correlations and use a **COVTEST** statement with general contrasts, as shown in the following statements:

```
ods select FitStatistics CovParms CovTests;
proc glimmix data=iris_univ;
 class species var id;
 model response = species*var;
 random _residual_ / type=unr group=species subject=id;
 covtest 'Equal Covariance Matrices' homogeneity;
 covtest 'Equal Correlation Matrices' general

run;
```

The `TYPE=UNR` structure is a reparameterization of `TYPE=UN`. The models provide the same fit, as seen by comparison of the “Fit Statistics” tables in [Output 41.9.2](#) and [Output 41.9.5](#). The covariance parameters are ordered differently, however. In each group, the four variances precede the six correlations ([Output 41.9.5](#)). The first `COVTEST` statement tests the homogeneity hypothesis in terms of the UNR parameterization, and the result is identical to the test in [Output 41.9.4](#). The second `COVTEST` statement restricts the correlations to be equal across groups. If  $\rho_{ijk}$  is the correlation between the  $i$ th and  $j$ th variable for the  $k$ th species, the 12 restrictions are

$$\rho_{211} = \rho_{212} = \rho_{213}$$

$$\rho_{311} = \rho_{312} = \rho_{313}$$

$$\rho_{321} = \rho_{322} = \rho_{323}$$

$$\rho_{411} = \rho_{412} = \rho_{413}$$

$$\rho_{421} = \rho_{422} = \rho_{423}$$

$$\rho_{431} = \rho_{432} = \rho_{433}$$

The `ESTIMATES` option in the `COVTEST` statement requests that the GLIMMIX procedure display the covariance parameter estimates in the restricted model ([Output 41.9.5](#)).

**Output 41.9.5** Fit Statistics, Covariance Parameters (TYPE=UNR), and Likelihood Ratio Tests for Equality of Covariance and Correlation Matrices

DF: P-value based on a chi-square with DF degrees of freedom.

The result of the homogeneity test is identical to that in [Output 41.9.4](#). The hypothesis of equality of the correlation matrices is also rejected with a chi-square value of 63.49 and a  $p$ -value of  $< 0.0001$ . Notice, however, that the chi-square statistic is smaller than in the test of homogeneity due to the smaller number of restrictions imposed on the full model. The estimate of the common correlation matrix in the restricted model is

$$\begin{bmatrix} 1 & 0.561 & 0.683 & 0.384 \\ 0.561 & 1 & 0.402 & 0.498 \\ 0.683 & 0.402 & 1 & 0.522 \\ 0.384 & 0.498 & 0.522 & 1 \end{bmatrix}$$

---

### Example 41.10: Multiple Trends Correspond to Multiple Extrema in Profile Likelihoods

Observations for a period of 168 months for the “Southern Oscillation Index,” measurements of monthly averaged atmospheric pressure differences between Easter Island and Darwin, Australia (Kahaner, Moler, and Nash 1989, Ch. 11.9; National Institute of Standards and Technology 1998) is available in the data set ENSO in the Sashelp library. These data are also used as an example in Chapter 53, “The LOESS Procedure.” The following statements print the first 10 observations of this data set in [Output 41.10.1](#).

```
proc print data=Sashelp.enso(obs=10);
run;
```

**Output 41.10.1** El Niño Southern Oscillation Data

| Obs | Month | Year    | Pressure |
|-----|-------|---------|----------|
| 1   | 1     | 0.08333 | 12.9     |
| 2   | 2     | 0.16667 | 11.3     |
| 3   | 3     | 0.25000 | 10.6     |
| 4   | 4     | 0.33333 | 11.2     |
| 5   | 5     | 0.41667 | 10.9     |
| 6   | 6     | 0.50000 | 7.5      |
| 7   | 7     | 0.58333 | 7.7      |
| 8   | 8     | 0.66667 | 11.7     |
| 9   | 9     | 0.75000 | 12.9     |
| 10  | 10    | 0.83333 | 14.3     |

Differences in atmospheric pressure create wind, and the differences recorded in the data set ENSO drive the trade winds in the southern hemisphere. Such time series often do not consist of a single trend or cycle. In this particular case, there are at least two known cycles that reflect the annual weather pattern and a longer cycle that represents the periodic warming of the Pacific Ocean (El Niño).

To estimate the trend in these data by using mixed model technology, you can apply a mixed model smoothing technique such as `TYPE=RSMOOTH` or `TYPE=PSPLINE`. The following statements fit a radial smoother to the ENSO data and obtain profile likelihoods for a series of values for the variance of the random spline coefficients:

```
data tdata;
 do covp1=0,0.0005,0.05,0.1,0.2,0.5,
 1,2,3,4,5,6,8,10,15,20,50,
 75,100,125,140,150,160,175,
 200,225,250,275,300,350;
 output;
 end;
run;

ods select FitStatistics CovParms CovTests;
proc glimmix data=sashelp.enso noprofile;
 model pressure = year;
 random year / type=rsmooth knotmethod=equal(50);
 parms (2) (10);
 covtest tdata=tdata / parms;
 ods output covtests=ct;
run;
```

The `tdata` data set contains value for the variance of the radial smoother variance for which the profile likelihood of the model is to be computed. The profile likelihood is obtained by setting the radial smoother variance at the specified value and estimating all other parameters subject to that constraint.

Because the model contains a residual variance and you need to specify nonzero values for the first covariance parameter, the `NOPROFILE` is added to the `PROC GLIMMIX` statements. If the residual variance is profiled from the estimation, you cannot fix covariance parameters at a given value, because they would be reexpressed during model fitting in terms of ratios with the profiled (and changing) variance.

The `PARMS` statement determines starting values for the covariance parameters for fitting the (full) model. The `PARMS` option in the `COVTEST` statement requests that the input parameters be added to the output and the output data set. This is useful for subsequent plotting of the profile likelihood function.

The “Fit Statistics” table displays the  $-2$  restricted log likelihood of the model (897.76, [Output 41.10.2](#)). The estimate of the variance of the radial smoother coefficients is 3.5719.

The “Test of Covariance Parameters” table displays the  $-2$  restricted log likelihood for each observation in the `tdata` set. Because the `tdata` data set specifies values for only the first covariance parameter, the second covariance parameter is free to vary and the values for  $-2$  Res Log Like are profile likelihoods. Notice that for a number of values of `CovP1` the chi-square statistic is missing in this table. For these values the  $-2$  Res Log Like is *smaller* than that of the full model. The model did not converge to a global minimum of the negative restricted log likelihood.

### Output 41.10.2 REML and Profile Likelihood Analysis

DF: P-value based on a chi-square with DF degrees of freedom.  
MI: P-value based on a mixture of chi-squares.

The following statements plot the  $-2$  restricted profile log likelihood (Output 41.10.3):

```
proc sgplot data=ct;
 series y=objective x=covp1;
run;
```

**Output 41.10.3** –2 Restricted Profile Log Likelihood for Smoothing Variance

The local minimum at which the optimization stopped is clearly visible, as are a second local minimum near zero and the global minimum near 180.

The observed and predicted pressure differences that correspond to the three minima are shown in [Output 41.10.4](#). These results were produced with the following statements:

```
proc glimmix data=sashelp.enso;
 model pressure = year;
 random year / type=rsmooth knotmethod=equal(50);
 parms (0) (10);
 output out=gmxout1 pred=pred1;
run;
proc glimmix data=sashelp.enso;
 model pressure = year;
 random year / type=rsmooth knotmethod=equal(50);
 output out=gmxout2 pred=pred2;
 parms (2) (10);
run;
proc glimmix data=sashelp.enso;
 model pressure = year;
 random year / type=rsmooth knotmethod=equal(50);
 output out=gmxout3 pred=pred3;
 parms (200) (10);
run;
```

```

data plotthis; merge gmxout1 gmxout2 gmxout3;
run;
proc sgplot data=plotthis;
 scatter x=year y=Pressure;
 series x=year y=pred1 /
 lineattrs = (pattern=solid thickness=2)
 legendlabel = "Var[RSmooth] = 0.0005"
 name = "pred1";
 series x=year y=pred2 /
 lineattrs = (pattern=dot thickness=2)
 legendlabel = "Var[RSmooth] = 3.5719"
 name = "pred2";
 series x=year y=pred3 /
 lineattrs = (pattern=dash thickness=2)
 legendlabel = "Var[RSmooth] = 186.71"
 name = "pred3";
 keylegend "pred1" "pred2" "pred3" / across=2;
run;

```

Output 41.10.4 Observed and Predicted Pressure Differences

The one-year cycle ( $\hat{\sigma}_r^2 = 186.71$ ) and the El Niño cycle ( $\hat{\sigma}_r^2 = 3.5719$ ) are clearly visible. Notice that a larger smoother variance results in larger BLUPs and hence larger adjustments to the fixed-effects model. A large smoother variance thus results in a more wiggly fit. The third local minimum at  $\hat{\sigma}_r^2 = 0.0005$  applies only very small adjustments to the linear regression between pressure and time, creating slight curvature.

---

### Example 41.11: Maximum Likelihood in Proportional Odds Model with Random Effects

The data for this example are taken from Gilmour, Anderson, and Rae (1987) and concern the foot shape of 2,513 lambs that represent 34 sires. The foot shape of the animals was scored in three ordered categories. The following DATA step lists the data in multivariate form, where each observation corresponds to a sire and contains the outcomes for the three response categories in the variables k1, k2, and k3. For example, for the first sire the first foot shape category was observed for 52 of its offspring, foot shape category 2 was observed for 25 lambs, and none of its offspring was rated in foot shape category 3. The variables yr, b1, b2, and b3 represent contrasts of fixed effects.

```

data foot_mv;
 input yr b1 b2 b3 k1 k2 k3;
 sire = _n_;
 datalines;
1 1 0 0 52 25 0
1 1 0 0 49 17 1
1 1 0 0 50 13 1
1 1 0 0 42 9 0
1 1 0 0 74 15 0
1 1 0 0 54 8 0
1 1 0 0 96 12 0
1 -1 1 0 57 52 9
1 -1 1 0 55 27 5
1 -1 1 0 70 36 4
1 -1 1 0 70 37 3
1 -1 1 0 82 21 1
1 -1 1 0 75 19 0
1 -1 -1 0 17 12 10
1 -1 -1 0 13 23 3
1 -1 -1 0 21 17 3
-1 0 0 1 37 41 23
-1 0 0 1 47 24 12
-1 0 0 1 46 25 9
-1 0 0 1 79 32 11
-1 0 0 1 50 23 5
-1 0 0 1 63 18 8
-1 0 0 -1 30 20 9
-1 0 0 -1 31 33 3
-1 0 0 -1 28 18 4
-1 0 0 -1 42 27 4
-1 0 0 -1 35 22 2
-1 0 0 -1 33 18 3
-1 0 0 -1 35 17 4
-1 0 0 -1 26 13 2

```

```

-1 0 0 -1 37 15 2
-1 0 0 -1 36 14 1
-1 0 0 -1 63 20 3
-1 0 0 -1 41 8 1
;

```

In order to analyze these data as multinomial data with PROC GLIMMIX, the data need to be arranged in univariate form. The following DATA step creates three observations from each record in data set foot\_mv and stores the category counts in the variable count:

```

data footshape; set foot_mv;
 array k{3};
 do Shape = 1 to 3;
 count = k{Shape};
 output;
 end;
 drop k:;
run;

```

Because the sires were selected at random, a model for the three-category response with fixed regression effects for yr, b1–b3, and with random sire effects is considered. Because the response categories are ordered, a proportional odds model is chosen (McCullagh 1980). Gilmour, Anderson, and Rae (1987) consider various analyses for these data. The following GLIMMIX statements fit a model with probit link for the cumulative probabilities by maximum likelihood where the marginal log likelihood is approximated by adaptive quadrature:

```

proc glimmix data=footshape method=quad;
 class sire;
 model Shape = yr b1 b2 b3 / s link=cumprobit dist=multinomial;
 random int / sub=sire s cl;
 ods output Solutionr=solr;
 freq count;
run;

```

The number of observations that share a particular response and covariate pattern (variable count) is used in the FREQ statement. The S and CL options request solutions for the sire effects. These are output to the data set solr for plotting.

The “Model Information” table shows that the parameters are estimated by maximum likelihood and that the marginal likelihood is approximated by Gauss-Hermite quadrature (Output 41.11.1).

| 2                                                                                                                                 | 2     | 731                      |
| 3                                                                                                                                 | 3     | 146                      |
|                                                                                                                                   |       |                          |
| The GLIMMIX procedure is modeling the probabilities of levels of Shape having lower Ordered Values in the Response Profile table. |       |                          |

The distribution of the data is multinomial with ordered categories. The ordering is implied by the choice of a link function for the cumulative probabilities. Because a frequency variable is specified, the number of observations as well as the number of frequencies is displayed. Observations with zero frequency—that is, foot shape categories that were not observed for a particular sire are not used in the analysis. The “Response Profile Table” shows the ordering of the response variable and gives a breakdown of the frequencies by category.

**Output 41.11.2** Information about the Size of the Optimization Problem

| Dimensions               |    |
|--------------------------|----|

| Parameters in Optimization | 7                 |
| Lower Boundaries           | 1                 |
| Upper Boundaries           | 0                 |
| Fixed Effects              | Not Profiled      |
| Starting From              | GLM estimates     |
| Quadrature Points          | 1                 |

With `METHOD=QUAD`, the “Dimensions” and “Optimization Information” tables are particularly important, because for this estimation methods both fixed effects and covariance parameters participate in the optimization (Output 41.11.2). For GLM models the optimization involves the fixed effects and possibly a single scale parameter. For mixed models the fixed effects are typically profiled from the optimization. Laplace and quadrature estimations are exceptions to these rules. Consequently, there are seven parameters in this optimization, corresponding to six fixed effects and one variance component. The variance component has a lower bound of 0. Also, because the fixed effects are part of the optimizations, PROC GLIMMIX initially performs a few GLM iterations to obtain starting values for the fixed effects. You can control the number of initial iterations with the `INITITER=` option in the PROC GLIMMIX statement.

The last entry in the “Optimization Information” table shows that—at the starting values—PROC GLIMMIX determined that a single quadrature point is sufficient to approximate the marginal log likelihood with the required accuracy. This approximation is thus identical to the Laplace method that is available with `METHOD=LAPLACE`.

For `METHOD=LAPLACE` and `METHOD=QUAD`, the GLIMMIX procedure produces fit statistics based on the conditional and marginal distribution (Output 41.11.3). Within the limits of the numeric likelihood approximation, the information criteria shown in the “Fit Statistics” table can be used to compare models, and the  $-2$  log likelihood can be used to compare among nested models (nested with respect to fixed effects and/or the covariance parameters).

**Output 41.11.3** Marginal and Conditional Fit Statistics

| Fit Statistics                              |         |
|---------------------------------------------|---------|
| -2 Log Likelihood                           | 3870.12 |

| Fit Statistics for Conditional Distribution |         |
| -2 log L(Shape   r. effects)                | 3807.62 |

The variance of the sire effect is estimated as 0.04849 with estimated asymptotic standard error of 0.01673 (Output 41.11.4). Based on the magnitude of the estimate relative to the standard error, one might conclude that there is significant sire-to-sire variability. Because parameter estimation is based on maximum likelihood, a formal test of the hypothesis of no sire variability is possible. The category cutoffs for the cumulative probabilities are 0.3781 and 1.6435. Except for b3, all fixed effects contrasts are significant.

#### Output 41.11.4 Parameter Estimates

| b3                             |           | -0.09887 | 0.06508        | 2478 | -1.52          | 0.1289  |

A likelihood ratio test for the sire variability can be carried out by adding a **COVTEST** statement to the PROC GLIMMIX statements (Output 41.11.5):

```
ods select FitStatistics CovParms Covtests;
proc glimmix data=footshape method=quad;
 class sire;
 model Shape = yr b1 b2 b3 / link=cumprobit dist=multinomial;
 random int / sub=sire;
 covtest GLM;
 freq count;
run;
```

The statement

```
covtest GLM;
```

compares the fitted model to a generalized linear model for independent data by removing the sire variance component from the model. Equivalently, you can specify

```
covtest 0;
```

which compares the fitted model against one where the sire variance is fixed at zero.

**Output 41.11.5** Likelihood Ratio Test for Sire Variance

| The GLIMMIX Procedure                                     |         |             |                |            |         |

| MI: P-value based on a mixture of chi-squares.            |         |             |                |            |         |

The  $-2$  Log Likelihood in the reduced model without the sire effect is 3915.29. Compared to the corresponding marginal fit statistic in the full model (3870.12), this results in a chi-square statistic of 45.17. Because the variance component for the sire effect has a natural lower bound of zero, PROC GLIMMIX performs the likelihood ratio test as a one-sided test. As indicated by the note, the  $p$ -value for this test is computed from a mixture of chi-square distributions, applying the results of Self and Liang (1987). There is significant evidence that the model without sire random effects does not fit the data as well.

In studies of heritability, one is often interested to rank individuals according to some measure of “breeding value.” The following statements display the empirical Bayes estimates of the sire effects from ML estimation by quadrature along with prediction standard error bars (Output 41.11.6):

```
proc sort data=solr;
 by Estimate;
run;
data solr; set solr;
 length sire $2;
 obs = _n_;
 sire = left(substr(Subject,6,2));
run;
proc sgplot data=solr;
 scatter x=obs y=estimate /
 markerchar = sire
 yerrorupper = upper
 yerrorlower = lower;
```

```

axis grid label='Sire Rank' values=(1 5 10 15 20 25 30);
axis grid label='Predicted Sire Effect';
run;

```

**Output 41.11.6** Ranked Predicted Sire Effects and Prediction Standard Errors

### Example 41.12: Fitting a Marginal (GEE-Type) Model

A marginal GEE-type model for clustered data is a model for correlated data that is specified through a mean function, a variance function, and a “working” covariance structure. Because the assumed covariance structure can be wrong, the covariance matrix of the parameter estimates is not based on the model alone. Rather, one of the empirical (“sandwich”) estimators is used to make inferences robust against the choice of working covariance structure. PROC GLIMMIX can fit marginal models by using R-side random effects and drawing on the distributional specification in the **MODEL** statement to derive the link and variance functions. The **EMPIRICAL=** option in the **PROC GLIMMIX** statement enables you to choose one of a number of empirical covariance estimators.

The data for this example are from Thall and Vail (1990) and reflect the number of seizures of patients suffering from epileptic episodes. After an eight-week period without treatment, patients were observed four times in two-week intervals during which they received a placebo or the drug Progabide in addition to other therapy. These data are also analyzed in [Example 40.7](#) of Chapter 40, “The **GENMOD** Procedure.”

The following DATA step creates the data set seizures. The variable id identifies the subjects in the study, and the variable trt identifies whether a subject received the placebo (trt = 0) or the drug Progabide (trt = 1). The variable x1 takes on value 0 for the baseline measurement and 1 otherwise.

The model fit initially with the following PROC GLIMMIX statements is a Poisson generalized linear model with effects for an intercept, the baseline measurement, the treatment, and their interaction:

```

proc glimmix data=seizures;
 model cnt = x1 trt x1*trt / dist=poisson offset=ltime
 ddfm=none s;
run;

```

The `DDFM=NONE` option is chosen in the `MODEL` statement to produce chi-square and  $z$  tests instead of  $F$  and  $t$  tests.

Because the initial pretreatment time period is four times as long as the subsequent measurement intervals, an offset variable is used to standardize the counts. If  $Y_{ij}$  denotes the number of seizures of subject  $i$  in time interval  $j$  of length  $t_j$ , then  $Y_{ij}/t_j$  is the number of seizures per time unit. Modeling the average number per time unit with a log link leads to  $\log\{E[Y_{ij}/t_j]\} = \mathbf{x}'\boldsymbol{\beta}$  or  $\log\{E[Y_{ij}]\} = \mathbf{x}'\boldsymbol{\beta} + \log\{t_j\}$ . The logarithm of time (variable `ltime`) thus serves as an offset. Suppose that  $\beta_0$  denotes the intercept,  $\beta_1$  the effect of `x1`, and  $\beta_2$  the effect of `trt`. Then  $\exp\{\beta_0\}$  is the expected number of seizures per week in the placebo group at baseline. The corresponding numbers in the treatment group are  $\exp\{\beta_0 + \beta_2\}$  at baseline and  $\exp\{\beta_0 + \beta_1 + \beta_2\}$  for postbaseline visits.

The “Model Information” table shows that the parameters in this Poisson model are estimated by maximum likelihood (Output 41.12.1). In addition to the default link and variance function, the variable `ltime` is used as an offset.

**Output 41.12.1** Model Information in Poisson GLM

Because this is a generalized linear model, the large value for the ratio of the Pearson chi-square statistic and its degrees of freedom is indicative of a model shortcoming. The data are considerably more dispersed than is expected under a Poisson model. There could be many reasons for this overdispersion—for example, a misspecified mean model, data that might not be Poisson distributed, an incorrect variance function, and correlations among the observations. Because these data are repeated measurements, the presence of correlations among the observations from the same subject is a likely contributor to the overdispersion.

The following PROC GLIMMIX statements fit a marginal model with correlations. The model is a marginal one, because no G-side random effects are specified on which the distribution could be conditioned. The choice of the id variable as the **SUBJECT** effect indicates that observations from different IDs are uncorre-

lated. Observations from the same ID are assumed to follow a compound symmetry (equicorrelation) model. The **EMPIRICAL** option in the **PROC GLIMMIX** statement requests the classical sandwich estimator as the covariance estimator for the fixed effects:

```
proc glimmix data=seizures empirical;
 class id;
 model cnt = x1 trt x1*trt / dist=poisson offset=ltime
 ddfm=none covb s;
 random _residual_ / subject=id type=cs vcorr;
run;
```

The “Model Information” table shows that the parameters are now estimated by residual pseudo-likelihood (compare [Output 41.12.3](#) and [Output 41.12.1](#)). And in this fact lies the main difference between fitting marginal models with PROC GLIMMIX and with GEE methods as per Liang and Zeger (1986), where parameters of the working correlation matrix are estimated by the method of moments.

**Output 41.12.3** Model Information in Marginal Model

| The GLIMMIX Procedure       |                      |
|-----------------------------|----------------------|

## Example 41.13: Response Surface Comparisons with Multiplicity Adjustments

Koch et al. (1990) present data for a multicenter clinical trial testing the efficacy of a respiratory drug in patients with respiratory disease. Within each of two centers, patients were randomly assigned to a placebo (P) or an active (A) treatment. Prior to treatment and at four follow-up visits, patient status was recorded in one of five ordered categories (0=terrible, 1=poor, ..., 4=excellent). The following DATA step creates the SAS data set `clinical` for this study.

```
data Clinical;
 do Center = 1, 2;
 do Gender = 'F', 'M';
 do Drug = 'A', 'P';
```

```

 input nPatient @@;
 do iPatient = 1 to nPatient;
 input ID Age (t0-t4) (1.) @@;

Westfall and Tobias (2007) define as the measure of efficacy the average of the ratings at the final two visits and model this average as a function of drug, baseline assessment score, and age. Hence, in their model, the expected efficacy for drug  $d \in A, P$  can be written as

$$E[Y_d] = \beta_{0d} + \beta_{1d}t + \beta_{2d}a$$

where  $t$  is the baseline (pretreatment) assessment score and  $a$  is the patient's age at baseline. The age range for these data extends from 11 to 68 years. Suppose that the scientific question of interest is the comparison of the two response surfaces at a set of values  $S_t \times S_a = \{0, 1, 2, 3, 4\} \times S_a$ . In other words, you want to know for which values of the covariates the average response differs significantly between the treatment group and the placebo group. If the set of ages of interest is  $\{10, 13, 16, \dots, 70\}$ , then this involves  $5 \times 21 = 105$  comparisons, a massive multiple testing problem. The large number of comparisons and the

fact that the set  $S_a$  is chosen somewhat arbitrarily require the application of multiplicity corrections in order to protect the familywise Type I error across the comparisons.

When testing hypotheses that have logical restrictions, the power of multiplicity corrected tests can be increased by taking the restrictions into account. Logical restrictions exist, for example, when not all hypotheses in a set can be simultaneously true. Westfall and Tobias (2007) extend the truncated closed testing procedure (TCTP) of Royen (1989) for pairwise comparisons in ANOVA to general contrasts. Their work is also an extension of the S2 method of Shaffer (1986); see also Westfall (1997). These methods are all *monotonic* in the (unadjusted)  $p$ -values of the individual tests, in the sense that if  $p_j < p_i$  then the multiple test will never retain  $H_j$  while rejecting  $H_i$ . In terms of multiplicity-adjusted  $p$ -values  $\tilde{p}_j$ , monotonicity means that if  $p_j < p_i$ , then  $\tilde{p}_j < \tilde{p}_i$ .

### Analysis as Normal Data with Averaged Endpoints

In order to apply the extended TCTP procedure of Westfall and Tobias (2007) to the problem of comparing response surfaces in the clinical trial, the following convenience macro is helpful to generate the comparisons for the `ESTIMATE` statement in PROC GLIMMIX:

```
%macro Contrast (from,to,byA,byT) ;
 %let nCmp = 0;
 %do age = &from %to %to %by &byA;
 %do t0 = 0 %to 4 %by &byT;
 %let nCmp = %eval(&nCmp+1);
 %end;
 %end;
 %let iCmp = 0;
 %do age = &from %to %to %by &byA;
 %do t0 = 0 %to 4 %by &byT;
 %let iCmp = %eval(&iCmp+1);
 "%trim(%left(&age)) %trim(%left(&t0))"
 drug 1 -1
 drug*age &age -&age
 drug*t0 &t0 -&t0
 %if (&iCmp < &nCmp) %then %do; , %end;
 %end;
 %end;
%mend;
```

The following GLIMMIX statements fit the model to the data and compute the 105 contrasts that compare the placebo to the active response at 105 points in the two-dimensional regressor space:

```
proc glimmix data=clinical;
 t = (t3+t4)/2;
 class drug;
 model t = drug t0 age drug*age drug*t0;
 estimate %contrast (10,70,3,1)
 / adjust=simulate(seed=1)
 stepdown(type=logical);
 ods output Estimates=EstStepDown;
run;
```

Note that only a single `ESTIMATE` statement is used. Each of the 105 comparisons is one comparison in the multirow statement. The `ADJUST` option in the `ESTIMATE` statement requests multiplicity-adjusted

$p$ -values. The extended TCTP method is applied by specifying the `STEPDOWN(TYPE=LOGICAL)` option to compute step-down-adjusted  $p$ -values where logical constraints among the hypotheses are taken into account. The results from the `ESTIMATE` statement are saved to a data set for subsequent processing. Note also that the response, the average of the ratings at the final two visits, is computed with programming statements in PROC GLIMMIX.

The following statements print the 20 most significant estimated differences (Output 41.13.1):

```
proc sort data=EstStepDown;
 by Probt;
run;
proc print data=EstStepDown(obs=20);
 var Label Estimate StdErr Probt AdjP;
run;
```

**Output 41.13.1** The First 20 Observations of the Estimates Data Set

| Obs | Label | Estimate | StdErr | Probt  | AdjP   |
|-----|-------|----------|--------|--------|--------|
| 1   | 37 2  | 0.8310   | 0.2387 | 0.0007 | 0.0071 |

| 10  | 37 3  | 0.7252   | 0.2602 | 0.0063 | 0.0201 |
| 11  | 43 3  | 0.8258   | 0.2982 | 0.0066 | 0.0201 |
| 12  | 28 2  | 0.6800   | 0.2461 | 0.0068 | 0.0215 |
| 13  | 55 2  | 1.1329   | 0.4202 | 0.0082 | 0.0239 |
| 14  | 46 3  | 0.8761   | 0.3265 | 0.0085 | 0.0239 |
| 15  | 34 3  | 0.6749   | 0.2532 | 0.0089 | 0.0257 |
| 16  | 43 1  | 1.0374   | 0.3991 | 0.0107 | 0.0329 |
| 17  | 46 1  | 1.0877   | 0.4205 | 0.0111 | 0.0329 |
| 18  | 49 3  | 0.9264   | 0.3591 | 0.0113 | 0.0329 |
| 19  | 40 1  | 0.9871   | 0.3827 | 0.0113 | 0.0329 |
| 20  | 58 2  | 1.1832   | 0.4615 | 0.0118 | 0.0329 |

Notice that the adjusted  $p$ -values (Adj $p$ ) are larger than the unadjusted  $p$ -values, as expected. Also notice that several comparisons share the same adjusted  $p$ -values. This is a result of the monotonicity of the extended TCTP method.

In order to compare the step-down-adjusted  $p$ -values to adjusted  $p$ -values that do not use step-down methods, replace the `ESTIMATE` statement in the previous statements with the following:

```
estimate %contrast2(10,70,3,1) / adjust=simulate(seed=1);
ods output Estimates=EstAdjust;
```

The following GLIMMIX invocations create output data sets named EstAdjust and EstUnAdjust that contain (non-step-down-) adjusted and unadjusted  $p$ -values:

```
proc glimmix data=clinical;
 t = (t3+t4)/2;
 class drug;
 model t = drug t0 age drug*age drug*t0;
 estimate %contrast(10,70,3,1)
 / adjust=simulate(seed=1);
 ods output Estimates=EstAdjust;
run;
proc glimmix data=clinical;
 t = (t3+t4)/2;
 class drug;
 model t = drug t0 age drug*age drug*t0;
 estimate %contrast(10,70,3,1);
 ods output Estimates=EstUnAdjust;
run;
```

Output 41.13.2 shows a comparison of the significant comparisons ( $p < 0.05$ ) based on unadjusted, adjusted, and step-down (TCTP) adjusted  $p$ -values. Clearly, the unadjusted results indicate the most significant results, but without protecting the Type I error rate for the group of tests. The adjusted  $p$ -values (filled circles) lead to a much smaller region in which the response surfaces between treatment and placebo are significantly different. The increased power of the TCTP procedure (open circles) over the standard multiplicity adjustment—without sacrificing Type I error protection—can be seen in the considerably larger region covered by the open circles.

Output 41.13.2 Comparison of Significance Regions

### Ordinal Repeated Measure Analysis

The outcome variable in this clinical trial is an ordinal rating of patients in categories 0=terrible, 1=poor, 2=fair, 3=good, and 4=excellent. Furthermore, the observations from repeat visits for the same patients are likely correlated. The previous analysis removes the repeated measures aspect by defining efficacy as the average score at the final two visits. These averages are not normally distributed, however. The response surfaces for the two study arms can also be compared based on a model for ordinal data that takes correlation into account through random effects. Keeping with the theme of the previous analysis, the focus here for illustrative purposes is on the final two visits, and the pretreatment assessment score serves as a covariate in the model.

The following DATA step rearranges the data from the third and fourth on-treatment visits in univariate form with separate observations for the visits by patient:

```
data clinical_uv;
 set clinical;
 array time{2} t3-t4;
 do i=1 to 2; rating = time{i}; output; end;
run;
```

The basic model for the analysis is a proportional odds model with cumulative logit link (McCullagh 1980) and  $J = 5$  categories. In this model, separate intercepts (cutoffs) are modeled for the first  $J - 1 = 4$  cumulative categories and the intercepts are monotonically increasing. This guarantees ordering of the cumulative probabilities and nonnegative category probabilities. Using the same covariate structure as in the previous analysis, the probability to observe a rating in at most category  $k \leq 4$  is

$$\Pr(Y_d \leq k) = \frac{1}{1 + \exp\{-\eta_{kd}\}}$$

$$\eta_{kd} = \alpha_k + \beta_{0d} + \beta_{1d}t + \beta_{2d}a$$

Because only the intercepts are dependent on the category, contrasts comparing regression coefficients can be formulated in standard fashion. To accommodate the random and covariance structure of the repeated measures model, a random intercept  $\gamma_i$  is applied to the observations for each patient:

$$\Pr(Y_{id} \leq k) = \frac{1}{1 + \exp\{-\eta_{ikd}\}}$$

$$\eta_{ikd} = \alpha_k + \beta_{0d} + \beta_{1d}t + \beta_{2d}a + \gamma_i$$

$$\gamma_i \sim \text{iid } N(0, \sigma_\gamma^2)$$

The shared random effect of the two observations creates a marginal correlation. Note that the random effects do not depend on category.

The following GLIMMIX statements fit this ordinal repeated measures model by maximum likelihood via the Laplace approximation and compute TCTP-adjusted  $p$ -values for the 105 estimates:

```
proc glimmix data=clinical_uv method=laplace;
 class center id drug;
 model rating = drug t0 age drug*age drug*t0 /
 dist=multinomial link=cumlogit;
 random intercept / subject=id(center);
 covtest 0;
 estimate %contrast(10,70,3,1)
 / adjust=simulate(seed=1)
 stepdown(type=logical);
 ods output Estimates=EstStepDownMulti;
run;
```

The combination of `DIST=MULTINOMIAL` and `LINK=CUMLOGIT` requests the proportional odds model. The `SUBJECT=` effect nests patient IDs within centers, because patient IDs in the data set `clinical` are not unique within centers. (Specifying `SUBJECT=ID*CENTER` would have the same effect.) The `COVTEST` statement requests a likelihood ratio test for the significance of the random patient effect.

The estimate of the variance component for the random patient effect is substantial (Output 41.13.3), but so is its standard error.

### Output 41.13.3 Model and Covariance Parameter Information

| MI: P-value based on a mixture of chi-squares.            |                       |             |                |            |      |

The likelihood ratio test provides a better picture of the significance of the variance component. The difference in the  $-2$  log likelihoods is 57.6, highly significant even if one does not apply the Self and Liang (1987) correction that halves the  $p$ -value in this instance.

The results for the 20 most significant estimates are requested with the following statements and shown in Output 41.13.4:

```
proc sort data=EstStepDownMulti;
 by Probt;
run;
proc print data=EstStepDownMulti(obs=20);
 var Label Estimate StdErr Probt AdjP;
run;
```

The  $p$ -values again show the “repeat” pattern corresponding to the monotonicity of the step-down procedure.

**Output 41.13.4** The First 20 Estimates in the Ordinal Analysis

| 20  | 46 1  | -3.4718  | 1.4187 | 0.0160 | 0.0448 |

As previously, the comparisons were also performed with standard  $p$ -value adjustment via simulation. Output 41.13.5 displays the components of the regressor space in which the response surfaces differ significantly ( $p < 0.05$ ) between the two treatment arms. As before, the most significant differences occur with unadjusted  $p$ -values at the cost of protecting only the individual Type I error rate. The standard multiplicity adjustment has considerably less power than the TCTP adjustment.

**Output 41.13.5** Comparison of Significance Regions, Ordinal Analysis

### Example 41.14: Generalized Poisson Mixed Model for Overdispersed Count Data

Overdispersion is the condition by which data appear more dispersed than is expected under a reference model. For count data, the reference models are typically based on the binomial or Poisson distributions. Among the many reasons for overdispersion are an incorrect model, an incorrect distributional specification, incorrect variance functions, positive correlation among the observations, and so forth. In short, correcting an overdispersion problem, if it exists, requires the appropriate remedy. Adding an R-side scale parameter to multiply the variance function is not necessarily the adequate correction. For example, Poisson-distributed data appear overdispersed relative to a Poisson model with regressors when an important regressor is omitted.

If the reference model for count data is Poisson, a number of alternative model formulations are available to increase the dispersion. For example, zero-inflated models add a proportion of zeros (usually from a Bernoulli process) to the zeros of a Poisson process. Hurdle models are two-part models where zeros and nonzeros are generated by different stochastic processes. Zero-inflated and hurdle models are described in detail by Cameron and Trivedi (1998) and cannot be fit with the GLIMMIX procedure. See Section 15.5 in Littell et al. (2006) for examples of using the NLMIXED procedure to fit zero-inflated and hurdle models.

An alternative approach is to derive from the reference distribution a probability distribution that exhibits increased dispersion. By mixing a Poisson process with a gamma distribution for the Poisson parameter, for example, the negative binomial distribution results, which is thus overdispersed relative to the Poisson.

Joe and Zhu (2005) show that the generalized Poisson distribution can also be motivated as a Poisson mixture and hence provides an alternative to the negative binomial (NB) distribution. Like the NB, the generalized Poisson distribution has a scale parameter. It is heavier in the tails than the NB distribution and easily reduces to the standard Poisson. Joe and Zhu (2005) discuss further comparisons between these distributions.

The probability mass function of the generalized Poisson is given by

$$p(y) = \frac{\alpha}{y!} (\alpha + \xi y)^{y-1} \exp \{-\alpha - \xi y\}$$

where  $y = 0, 1, 2, \dots$ ,  $\alpha > 0$ , and  $0 \leq \xi < 1$  (Joe and Zhu 2005). Notice that for  $\xi = 0$  the mass function of the standard Poisson distribution with mean  $\alpha$  results. The mean and variance of  $Y$  in terms of the parameters  $\alpha$  and  $\xi$  are given by

$$E[Y] = \frac{\alpha}{1 - \xi} = \mu$$

$$\text{Var}[Y] = \frac{\alpha}{(1 - \xi)^3} = \frac{\mu}{(1 - \xi)^2}$$

The log likelihood of the generalized Poisson can thus be written in terms of the mean  $\mu$  and scale parameter  $\xi$  as

$$l(\mu, \xi; y) = \log \{\mu(1 - \xi)\} + (y - 1) \log \{\mu - \xi(\mu - y)\} - (\mu - \xi(\mu - y)) - \log \{\Gamma(y + 1)\}$$

The data in the following DATA step are simulated counts. For each of  $i = 1, \dots, 30$  subjects a randomly varying number  $n_i$  of observations were drawn from a count regression model with a single covariate and excess zeros (compared to a Poisson distribution).

```

The following PROC GLIMMIX statements fit a standard Poisson regression model with random intercepts by maximum likelihood. The marginal likelihood of the data is approximated by adaptive quadrature (METHOD=QUAD).

```

proc glimmix data=counts method=quad;
 class sub;
 model y = x / link=log s dist=poisson;
 random int / subject=sub;
run;

```

Output 41.14.1 displays various informational items about the model and the estimation process.

The “Model Information” table shows that the parameters are estimated by ML with quadrature. Using the starting values for fixed effects and covariance parameters that the GLIMMIX procedure generates by default, the procedure determined that five quadrature nodes provide a sufficiently accurate approximation of the marginal log likelihood (“Optimization Information” table). The iterative estimation process converges after nine iterations.

The table of conditional fit statistics displays the sum of the independent contributions to the conditional –2 log likelihood (854.47) and the Pearson statistics for the conditional distribution (Output 41.14.2).

The departure of the scaled Pearson statistic from 1.0 is fairly pronounced in this case (1.97). If one deems it to far from 1.0, however, the conclusion has to be that the conditional variation is not properly specified. This could be due to an incorrect variance function, for example. The “Solutions for Fixed Effects” table shows the estimates of the slope and intercept in this model along with their standard errors and tests of significance. Note that the slope in this model is highly significant. The variance of the random subject-specific intercepts is estimated as 1.1959.

To fit the generalized Poisson distribution to these data, you cannot draw on the built-in distributions. Instead, the variance function and the log likelihood are computed directly with PROC GLIMMIX programming statements. The **CLASS**, **MODEL**, and **RANDOM** statements in the following PROC GLIMMIX program are as before, except for the omission of the **DIST=** option in the **MODEL** statement:

```
proc glimmix data=counts method=quad;
 class sub;
 model y = x / link=log s;
 random int / subject=sub;
 xi = (1 - 1/exp(_phi_));
 variance = _mu_ / (1-xi)/(1-xi);
```

```

if (_mu=.) or (_linp_ = .) then _logl_ = .;
else do;
 mustar = _mu_ - xi*(_mu_ - y);
 if (mustar < 1E-12) or (_mu_*(1-xi) < 1e-12) then
 logl = -1E20;
 else do;
 logl = log(_mu_*(1-xi)) + (y-1)*log(mustar) -
 mustar - lgamma(y+1);
 end;
end;
run;

```

The assignments to the variables xi and the reserved symbols `_VARIANCE_` and `_LOGL_` define the variance function and the log likelihood. Because the scale parameter of the generalized Poisson distribution has the range  $0 < \xi < 1$ , and the scale parameter `_PHI_` in the GLIMMIX procedure is bounded only from below (by 0), a reparameterization is applied so that  $\phi = 0 \Leftrightarrow \xi = 0$  and  $\xi$  approaches 1 as  $\phi$  increases. The statements preceding the calculation of the actual log likelihood are intended to prevent floating-point exceptions and to trap missing values.

Output 41.14.3 displays information about the model and estimation process. The “Model Information” table shows that the distribution is not a built-in distribution and echoes the expression for the user-specified variance function. As in the case of the Poisson model, the GLIMMIX procedure determines that five quadrature points are sufficient for accurate estimation of the marginal log likelihood at the starting values. The estimation process converges after 11 iterations.

The achieved  $-2 \log$  likelihood is lower than in the Poisson model (compare “Fit Statistics” tables in [Output 41.14.4](#) and [Output 41.14.1](#)). The scaled Pearson statistic is now less than 1.0. The fixed slope estimate remains significant at the 5% level, but the test statistics are not as large as in the Poisson model, partly because the generalized Poisson model permits more variation.

Based on the large difference in the  $-2 \log$  likelihoods between the Poisson and generalized Poisson models, you conclude that a mixed model based on the latter provides a better fit to these data. From the “Covariance Parameter Estimates” table in [Output 41.14.4](#), you can see that the estimate of the scale parameter is  $\hat{\phi} = 0.6401$  and is considerably larger than 0, taking into account its standard error. The hypothesis  $H: \phi = 0$ , which articulates that a Poisson model fits the data as well as the generalized Poisson model, can be formally tested with a likelihood ratio test. Adding the following statement to the previous PROC GLIMMIX run compares the model to one in which the variance of the random intercepts (the first covariance parameter) is not constrained and the scale parameter is fixed at zero:

```
covtest 'H: phi = 0' . 0 / est;
```

This **COVTEST** statement produces [Output 41.14.5](#).

**Output 41.14.5** Likelihood Ratio Test for Poisson Assumption

| Tests of Covariance Parameters<br>Based on the Likelihood |    |             |        |            |                    |          |      |
|-----------------------------------------------------------|----|-------------|--------|------------|--------------------|----------|------|
| Label                                                     | DF | -2 Log Like | ChiSq  | Pr > ChiSq | ---Estimates H0--- |          | Note |
|                                                           |    |             |        |            | Est1               | Est2     |      |
| H:phi = 0                                                 | 1  | 854.47      | 144.64 | <.0001     | 1.1959             | 1.11E-12 | MI   |

MI: P-value based on a mixture of chi-squares.

Note that the  $-2 \log$  Like reported in [Output 41.14.5](#) agrees with the value reported in the “Fit Statistics” table for the Poisson model ([Output 41.14.2](#)) and that the estimate of the random intercept under the null hypothesis agrees with the “Covariance Parameter Estimates” table in [Output 41.14.2](#). Because the null hypothesis places the parameter  $\phi$  (or  $\xi$ ) on the boundary of the parameter space, a mixture correction is applied in the  $p$ -value calculation. Because of the magnitude of the likelihood ratio statistic (144.64), this correction has no effect on the displayed  $p$ -value.

## Example 41.15: Comparing Multiple B-Splines

This example uses simulated data to demonstrate the use of the nonpositional syntax (see the section “[Positional and Nonpositional Syntax for Contrast Coefficients](#)” on page 3097 for details) in combination with the experimental `EFFECT` statement to produce interesting predictions and comparisons in models containing fixed spline effects. Consider the data in the following `DATA` step. Each of the 100 observations for the continuous response variable `y` is associated with one of two groups.

```
data spline;
 input group y @@;
 x = _n_;
 datalines;
1 -.020 1 0.199 2 -1.36 1 -.026
2 -.397 1 0.065 2 -.861 1 0.251

1 5.253 2 3.024 2 2.403 1 5.498
;
```

The following statements produce a scatter plot of the response variable by group ([Output 41.15.1](#)):

```
proc sgplot data=spline;
 scatter y=y x=x / group=group name="data";
 keylegend "data" / title="Group";
run;
```

**Output 41.15.1** Scatter Plot of Observed Data by Group

The trends in the two groups exhibit curvature, but the type of curvature is not the same in the groups. Also, there appear to be ranges of  $x$  values where the groups are similar and areas where the point scatters separate. To model the trends in the two groups separately and with flexibility, you might want to allow for some smooth trends in  $x$  that vary by group. Consider the following PROC GLIMMIX statements:

```
proc glimmix data=spline outdesign=x;
 class group;
 effect spl = spline(x);
 model y = group spl*group / s noint;
 output out=gmxout pred=p;
run;
```

The **EFFECT** statement defines a constructed effect named `spl` by expanding the `x` into a spline with seven columns. The `group` main effect creates separate intercepts for the groups, and the interaction of the `group` variable with the spline effect creates separate trends. The **NOINT** option suppresses the intercept. This is not necessary and is done here only for convenience of interpretation. The **OUTPUT** statement computes predicted values.

The “Parameter Estimates” table contains the estimates of the group-specific “intercepts,” the spline coefficients varied by group, and the residual variance (“Scale,” [Output 41.15.2](#)).

**Output 41.15.2** Parameter Estimates in Two-Group Spline Model

| The GLIMMIX Procedure |     |       |          |                |    |         |         |

| spl*group             | 7   | 2     | 0        | .              | .  | .       | .       |
| Scale                 |     |       | 0.07352  | 0.01121        | .  | .       | .       |

Because the B-spline coefficients for an observation sum to 1 and the model contains group-specific constants, the last spline coefficient in each group is zero. In other words, you can achieve exactly the same fit with the `MODEL` statement

```
model y = spl*group / noint;
```

or

```
model y = spl*group;
```

The following statements graph the observed and fitted values in the two groups (Output 41.15.3):

```
proc sgplot data=gmxout;
 series y=p x=x / group=group name="fit";
 scatter y=y x=x / group=group;
 keylegend "fit" / title="Group";
run;
```

**Output 41.15.3** Observed and Predicted Values by Group

Suppose that you are interested in estimating the mean response at particular values of  $x$  and in performing comparisons of predicted values. The following program uses `ESTIMATE` statements with nonpositional syntax to accomplish this:

```
proc glimmix data=spline;
 class group;
 effect spl = spline(x);
 model y = group spl*group / s noint;
 estimate 'Group 1, x=20' group 1 group*spl [1,1 20] / e;
 estimate 'Group 2, x=20' group 0 1 group*spl [1,2 20];
 estimate 'Diff at x=20 ' group 1 -1 group*spl [1,1 20] [-1,2 20];
run;
```

The first **ESTIMATE** statement predicts the mean response at  $x = 20$  in group 1. The **E** option requests the coefficient vector for this linear combination of the parameter estimates. The coefficient for the group effect is entered with positional (standard) syntax. The coefficients for the **group\*spl** effect are formed based on nonpositional syntax. Because this effect comprises the interaction of a standard effect (**group**) with a constructed effect, the values and levels for the standard effect must precede those for the constructed effect. A similar statement produces the predicted mean at  $x = 20$  in group 2.

The GLIMMIX procedure interprets the syntax

```
group*spl [1,2 20]
```

as follows: construct the spline basis at  $x = 20$  as appropriate for group 2; then multiply the resulting coefficients for these columns of the **L** matrix with 1.

The final **ESTIMATE** statement represents the difference between the predicted values; it is a group comparison at  $x = 20$ .

#### Output 41.15.4 Coefficients from First ESTIMATE Statement

| The GLIMMIX Procedure     |     |       |        |
|---------------------------|-----|-------|--------|
| Coefficients for Estimate |     |       |        |
| Group 1, x=20             |     |       |        |
| Effect                    | spl | group | Row1   |
| group                     |     | 1     | 1      |
| group                     |     | 2     |        |
| spl*group                 | 1   | 1     | 0.0021 |
| spl*group                 | 1   | 2     |        |
| spl*group                 | 2   | 1     | 0.3035 |
| spl*group                 | 2   | 2     |        |
| spl*group                 | 3   | 1     | 0.619  |
| spl*group                 | 3   | 2     |        |
| spl*group                 | 4   | 1     | 0.0754 |
| spl*group                 | 4   | 2     |        |
| spl*group                 | 5   | 1     |        |
| spl*group                 | 5   | 2     |        |
| spl*group                 | 6   | 1     |        |
| spl*group                 | 6   | 2     |        |
| spl*group                 | 7   | 1     |        |
| spl*group                 | 7   | 2     |        |

The “Coefficients” table shows how the value 20 supplied in the **ESTIMATE** statement was expanded into the appropriate spline basis (Output 41.15.4). There is no significant difference between the group means at  $x = 20$  ( $p = 0.8346$ , Output 41.15.5).

## Output 41.15.5 Results from ESTIMATE Statements

| Estimates     |          |                |    |         |         |
|---------------|----------|----------------|----|---------|---------|
| Label         | Estimate | Standard Error | DF | t Value | Pr >  t |
| Group 1, x=20 | 0.6915   | 0.09546        | 86 | 7.24    | <.0001  |
| Group 2, x=20 | 0.7175   | 0.07953        | 86 | 9.02    | <.0001  |
| Diff at x=20  | -0.02602 | 0.1243         | 86 | -0.21   | 0.8346  |

The group comparisons you can achieve in this way are comparable to slices of interaction effects with classification effects. There are, however, no preset number of levels at which to perform the comparisons because  $x$  is continuous. If you add further  $x$  values for the comparisons, a multiplicity correction is in order to control the familywise Type I error. The following statements compare the groups at values  $x = 0, 5, 10, \dots, 80$  and compute simulation-based step-down-adjusted  $p$ -values. The results appear in [Output 41.15.6](#). (The numeric results for simulation-based  $p$ -value adjustments depend slightly on the value of the random number seed.)

```
ods select Estimates;
proc glimmix data=spline;
 class group;
 effect spl = spline(x);
 model y = group spl*group / s;
 estimate 'Diff at x= 0' group 1 -1 group*spl [1,1 0] [-1,2 0],
 'Diff at x= 5' group 1 -1 group*spl [1,1 5] [-1,2 5],
 'Diff at x=10' group 1 -1 group*spl [1,1 10] [-1,2 10],
 'Diff at x=15' group 1 -1 group*spl [1,1 15] [-1,2 15],
 'Diff at x=20' group 1 -1 group*spl [1,1 20] [-1,2 20],
 'Diff at x=25' group 1 -1 group*spl [1,1 25] [-1,2 25],

There are significant differences at the low end and high end of the  $x$  range. Notice that without the multiplicity adjustment you would have concluded at the 0.05 level that the groups are significantly different at  $x = 10$ . At the 0.05 level, the groups separate significantly for  $x < 10$  and  $x > 40$ .

### Example 41.16: Diallel Experiment with Multimember Random Effects

Cockerham and Weir (1977) apply variance component models in the analysis of reciprocal crosses. In these experiments, it is of interest to separate genetically determined variation from variation determined by parentage. This example analyzes the data for the diallel experiment in Cockerham and Weir (1977, Appendix C). A diallel is a mating design that consists of all possible crosses of a set of parental lines. It includes reciprocal crossings, but not self-crossings.

The basic model for a cross is  $Y_{ijk} = \beta + \alpha_{ij} + \epsilon_{ijk}$ , where  $Y_{ijk}$  is the observation for offspring  $k$  from maternal parent  $i$  and paternal parent  $j$ . The various models in Cockerham and Weir (1977) are different decompositions of the term  $\alpha_{ij}$ , the total effect that is due to the parents. Their “bio model” (model (c)) decomposes  $\alpha_{ij}$  into

$$\alpha_{ij} = \eta_i + \eta_j + \mu_i + \phi_j + (\eta\eta)_{ij} + \kappa_{ij}$$

where  $\eta_i$  and  $\eta_j$  are contributions of the female and male parents, respectively. The term  $(\eta\eta)_{ij}$  captures the interaction between maternal and paternal effects. In contrast to usual interaction effects, this term must obey a symmetry because of the reciprocals:  $(\eta\eta)_{ij} = (\eta\eta)_{ji}$ . The terms  $\mu_i$  and  $\phi_j$  in the decomposition are extranuclear maternal and paternal effects, and the remaining interactions are captured by the  $\kappa_{ij}$  term.

The following DATA step creates a SAS data set for the diallel example in Appendix C of Cockerham and Weir (1977):

```

data diallel;
 label time = 'Flowering time in days';
 do p = 1 to 8;
 do m = 1 to 8;
 if (m ne p) then do;
 sym = trim(left(min(m,p))) || ',' || trim(left(max(m,p)));
 do block = 1 to 2;
 input time @@;

;

```

The observations represent mean flowering times of *Nicotiana rustica* (Aztec tobacco) from crosses of inbred varieties grown in two blocks. The variables *p* and *m* identify the eight paternal and maternal lines, respectively. The variable *sym* is used to model the interaction between the parents, subject to the symmetry condition  $(\eta\eta)_{ij} = (\eta\eta)_{ji}$ . For example, the first two observations, 14.4 and 16.2 days, represent the observations from blocks 1 and 2 where paternal line 1 was crossed with maternal line 2.

The following PROC GLIMMIX statements fit the “bio model” in Cockerham and Weir (1977):

```

proc glimmix data=diallel outdesign(z)=zmat;
 class block sym p m;
 effect line = mm(p m);
 model time = block;
 random line sym p m p*m;
run;

```

The **EFFECT** statement defines the nuclear parental contributions as a multimember effect based on the **CLASS** variables *p* and *m*. Each observation has two nonzero entries in the design matrix for the effect that identifies the paternal and maternal lines. The terms in the **RANDOM** statement model the variance components as follows: *line*  $\rightarrow \sigma_n^2$ , *sym*  $\rightarrow \sigma_{(\eta\eta)}^2$ , *p*  $\rightarrow \sigma_\phi^2$ , *m*  $\rightarrow \sigma_\mu^2$ , *p\*m*  $\rightarrow \sigma_\kappa^2$ . The **OUTDESIGN=** option in the **PROC GLIMMIX** statement writes the **Z** matrix to the SAS data set *zmat*. The **EFFECT** statement alleviates the need for complex coding, as in Section 2.3 of Saxton (2004).

**Output 41.16.1** displays the “Class Level Information” table of the diallel model. Because the interaction terms are symmetric, there are only  $8 \times 7/2 = 28$  levels for the 8 lines. The estimates of the variance components and the residual variance in **Output 41.16.1** agree with the results in Table 7 of Cockerham and Weir (1977).

**Output 41.16.1** Class Levels and Covariance Parameter Estimates in Diallel Example

## Example 41.17: Linear Inference Based on Summary Data

The GLIMMIX procedure has facilities for multiplicity-adjusted inference through the ADJUST= and STEPDOWN options in the ESTIMATE, LSMEANS, and LSMESTIMATE statements. You can employ these facilities to test linear hypotheses among parameters even in situations where the quantities were obtained outside the GLIMMIX procedure. This example demonstrates the process. The basic idea is to prepare a data set containing the estimates of interest and a data set containing their covariance matrix. These are then passed to the GLIMMIX procedure, preventing updating of the parameters, essentially moving directly into the post-processing stage as if estimates with this covariance matrix had been produced by the GLIMMIX procedure.

The final documentation example in Chapter 63, “The NLIN Procedure,” discusses a nonlinear first-order compartment pharmacokinetic model for theophylline concentration. The data are derived by collapsing and averaging the subject-specific data from Pinheiro and Bates (1995) in a particular—yet unimportant—way that leads to two groups for comparisons. The following DATA step creates these data:

```

In terms of two fixed treatment groups, the nonlinear model for these data can be written as

$$C_{it} = \frac{Dk_{e_i}k_{a_i}}{Cl_i(k_{a_i} - k_{e_i})} [\exp(-k_{e_i}t) - \exp(-k_{a_i}t)] + \epsilon_{it}$$

where  $C_{it}$  is the observed concentration in group  $i$  at time  $t$ ,  $D$  is the dose of theophylline,  $k_{e_i}$  is the elimination rate constant in group  $i$ ,  $k_{a_i}$  is the absorption rate in group  $i$ ,  $Cl_i$  is the clearance in group  $i$ , and  $\epsilon_{it}$  denotes the model error. Because the rates and the clearance must be positive, you can parameterize the model in terms of log rates and the log clearance:

$$\begin{aligned} Cl_i &= \exp\{\beta_{1i}\} \\ k_{a_i} &= \exp\{\beta_{2i}\} \\ k_{e_i} &= \exp\{\beta_{3i}\} \end{aligned}$$

In this parameterization the model contains six parameters, and the rates and clearance vary by group. The following PROC NLIN statements fit the model and obtain the group-specific parameter estimates:

```
proc nlin data=theop outest=cov;
 parms beta1_1=-3.22 beta2_1=0.47 beta3_1=-2.45
 beta1_2=-3.22 beta2_2=0.47 beta3_2=-2.45;
 if (group=1) then do;
 cl = exp(beta1_1);
 ka = exp(beta2_1);
 ke = exp(beta3_1);
 end; else do;
 cl = exp(beta1_2);
 ka = exp(beta2_2);
 ke = exp(beta3_2);
 end;
 mean = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/cl/(ka-ke);
 model conc = mean;
 ods output ParameterEstimates=ests;
run;
```

The conditional programming statements determine the clearance, elimination, and absorption rates depending on the value of the group variable. The OUTEST= option in the PROC NLIN statement saves estimates and their covariance matrix to the data set cov. The ODS OUTPUT statement saves the “Parameter Estimates” table to the data set ests.

Output 41.17.1 displays the analysis of variance table and the parameter estimates from this NLIN run. Note that the confidence levels in the “Parameter Estimates” table are based on 92 degrees of freedom, corresponding to the residual degrees of freedom in the analysis of variance table.

**Output 41.17.1** Analysis of Variance and Parameter Estimates for Nonlinear Model

The following DATA step extracts the part of the cov data set that contains the covariance matrix of the parameter estimates in Output 41.17.1 and renames the variables as Col1–Col6. Output 41.17.2 shows the result of the DATA step.

```
data covb;
 set cov(where=(_type_='COVB'));
 rename beta1_1=col1 beta2_1=col2 beta3_1=col3
 beta1_2=col4 beta2_2=col5 beta3_2=col6;
 row = _n_;
 Parm = 1;
 keep parm row beta:;
run;

proc print data=covb;
run;
```

**Output 41.17.2** Covariance Matrix of NLIN Parameter Estimates

| 6   | 0.000000  | 0.000000  | 0.000000  | 0.015785  | -0.019996 | 0.026172  | 6   | 1    |

The reason for this transformation of the data is to use the resulting data set to define a covariance structure in PROC GLIMMIX. The following statements reconstitute a model in which the parameter estimates from PROC NLIN are the observations and in which the covariance matrix of the “observations” matches the covariance matrix of the NLIN parameter estimates:

```
proc glimmix data=ests order=data;
 class Parameter;
 model Estimate = Parameter / noint df=92 s;
 random _residual_ / type=lin(1) ldata=covb v;
 parms (1) / noiter;
 lsmeans parameter / cl;
 lsmestimate Parameter
 'beta1 eq. across groups' 1 0 0 -1,
 'beta2 eq. across groups' 0 1 0 0 -1,
 'beta3 eq. across groups' 0 0 1 0 0 -1 /
 adjust=bon stepdown ftest(label='Homogeneity');
run;
```

In other words, you are using PROC GLIMMIX to set up a linear statistical model

$$Y = I\alpha + \epsilon$$

$$\epsilon \sim (0, A)$$

where the covariance matrix  $A$  is given by

$$A = \begin{bmatrix} 0.007 & -0.005 & 0.010 & 0 & 0 & 0 \\ -0.005 & 0.018 & -0.011 & 0 & 0 & 0 \\ 0.010 & -0.011 & 0.016 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0.011 & -0.009 & 0.016 \\ 0 & 0 & 0 & -0.009 & 0.039 & -0.019 \\ 0 & 0 & 0 & 0.016 & -0.019 & 0.026 \end{bmatrix}$$

The generalized least squares estimate for  $\alpha$  in this saturated model reproduces the observations:

$$\begin{aligned} \hat{\alpha} &= (I'A^{-1}I)^{-1} I'A^{-1}y \\ &= (A^{-1})^{-1} A^{-1}y \\ &= y \end{aligned}$$

The `ORDER=DATA` option in the `PROC GLIMMIX` statement requests that the sort order of the Parameter variable be identical to the order in which it appeared in the “Parameter Estimates” table of the NLIN procedure (Output 41.17.1). The `MODEL` statement uses the Estimate and Parameter variables from that table to form a model in which the **X** matrix is the identity; hence the `NOINT` option. The `DF=92` option sets the degrees of freedom equal to the value used in the NLIN procedure. The `RANDOM` statement specifies a linear covariance structure with a single component and supplies the values for the structure through the `LDATA=` data set. This structure models the covariance matrix as  $\text{Var}[\mathbf{Y}] = \theta\mathbf{A}$ , where the **A** matrix is given previously. Essentially, the `TYPE=LIN(1)` structure forces an unstructured covariance matrix onto the data. To make this work, the parameter  $\theta$  is held fixed at 1 in the `PARMS` statement.

Output 41.17.3 displays the parameter estimates and least squares means for this model. Note that estimates and least squares means are identical, since the **X** matrix is the identity. Also, the confidence limits agree with the values reported by PROC NLIN (see Output 41.17.1).

**Output 41.17.3** Parameter Estimates and LS-Means from Summary Data

The **LSMESTIMATE** statement specifies three linear functions. These set equal the  $\beta$  parameters from the groups. The step-down Bonferroni adjustment requests a multiplicity adjustment for the family of three tests. The **FTEST** option requests a joint test of the three estimable functions; it is a global test of parameter homogeneity across groups.

[Output 41.17.5](#) displays the result from the **LSMESTIMATE** statement. The joint test is highly significant ( $F = 30.52$ ,  $p < 0.0001$ ). From the  $p$ -values associated with the individual rows of the estimates, you can see that the lack of homogeneity is due to group differences for  $\beta_1$ , the log clearance.

**Output 41.17.5** Test of Parameter Homogeneity across Groups

An alternative method to set up this model is given by the following statements, where the data set `pdata` contains the covariance parameters:

```
random _residual_ / type=un;
parms / pdata=pdata noiter
```

The following DATA step creates an appropriate `PDATA=` data set from the data set `covb` constructed earlier:

```
data pdata;
 set covb;
 array col{6};
 do i=1 to _n_;
 estimate = col{i};
 output;
 end;
 keep estimate;
run;
```

## Overview: GLM Procedure

The GLM procedure uses the method of least squares to fit general linear models. Among the statistical methods available in PROC GLM are regression, analysis of variance, analysis of covariance, multivariate analysis of variance, and partial correlation.

PROC GLM analyzes data within the framework of general linear models. PROC GLM handles models relating one or several continuous dependent variables to one or several independent variables. The independent variables can be either *classification* variables, which divide the observations into discrete groups, or *continuous* variables. Thus, the GLM procedure can be used for many different analyses, including the following:

- simple regression

- multiple regression
- analysis of variance (ANOVA), especially for unbalanced data
- analysis of covariance
- response surface models
- weighted regression
- polynomial regression
- partial correlation
- multivariate analysis of variance (MANOVA)
- repeated measures analysis of variance

---

## PROC GLM Features

The following list summarizes the features in PROC GLM:

- PROC GLM enables you to specify any degree of interaction (crossed effects) and nested effects. It also provides for polynomial, continuous-by-class, and continuous-nesting-class effects.
- Through the concept of estimability, the GLM procedure can provide tests of hypotheses for the effects of a linear model regardless of the number of missing cells or the extent of confounding. PROC GLM displays the sum of squares (SS) associated with each hypothesis tested and, upon request, the form of the estimable functions employed in the test. PROC GLM can produce the general form of all estimable functions.
- The **REPEATED** statement enables you to specify effects in the model that represent repeated measurements on the same experimental unit for the same response, providing both univariate and multivariate tests of hypotheses.
- The **RANDOM** statement enables you to specify random effects in the model; expected mean squares are produced for each Type I, Type II, Type III, Type IV, and contrast mean square used in the analysis. Upon request,  $F$  tests that use appropriate mean squares or linear combinations of mean squares as error terms are performed.
- The **ESTIMATE** statement enables you to specify an  $\mathbf{L}$  vector for estimating a linear function of the parameters  $\mathbf{L}\boldsymbol{\beta}$ .
- The **CONTRAST** statement enables you to specify a contrast vector or matrix for testing the hypothesis that  $\mathbf{L}\boldsymbol{\beta} = 0$ . When specified, the contrasts are also incorporated into analyses that use the **MANOVA** and **REPEATED** statements.
- The **MANOVA** statement enables you to specify both the hypothesis effects and the error effect to use for a multivariate analysis of variance.

- PROC GLM can create an output data set containing the input data set in addition to predicted values, residuals, and other diagnostic measures.
- PROC GLM can be used interactively. After you specify and fit a model, you can execute a variety of statements without recomputing the model parameters or sums of squares.
- For analysis involving multiple dependent variables but not the **MANOVA** or **REPEATED** statements, a missing value in one dependent variable does not eliminate the observation from the analysis for other dependent variables. PROC GLM automatically groups together those variables that have the same pattern of missing values within the data set or within a BY group. This ensures that the analysis for each dependent variable brings into use all possible observations.
- The GLM procedure automatically produces graphs as part of its ODS output. For general information about ODS Graphics, see the section “**ODS Graphics**” on page 3388 and Chapter 21, “**Statistical Graphics Using ODS**.”

---

## PROC GLM Contrasted with Other SAS Procedures

As described previously, PROC GLM can be used for many different analyses and has many special features not available in other SAS procedures. However, for some types of analyses, other procedures are available. As discussed in the sections “**PROC GLM for Unbalanced ANOVA**” on page 3269 and “**PROC GLM for Quadratic Least Squares Regression**” on page 3272, sometimes these other procedures are more efficient than PROC GLM. The following procedures perform some of the same analyses as PROC GLM:

|          |                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ANOVA    | performs analysis of variance for balanced designs. The ANOVA procedure is generally more efficient than PROC GLM for these designs.                                                                                 |
| MIXED    | fits mixed linear models by incorporating covariance structures in the model fitting process. Its <b>RANDOM</b> and <b>REPEATED</b> statements are similar to those in PROC GLM but offer different functionalities. |
| NESTED   | performs analysis of variance and estimates variance components for nested random models. The <b>NESTED</b> procedure is generally more efficient than PROC GLM for these models.                                    |
| NPAR1WAY | performs nonparametric one-way analysis of rank scores. This can also be done using the <b>RANK</b> procedure and PROC GLM.                                                                                          |
| REG      | performs simple linear regression. The <b>REG</b> procedure allows several <b>MODEL</b> statements and gives additional regression diagnostics, especially for detection of collinearity.                            |
| RSREG    | performs quadratic response surface regression, and canonical and ridge analysis. The <b>RSREG</b> procedure is generally recommended for data from a response surface experiment.                                   |

|         |                                                                                                                                                                                                              |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TTEST   | compares the means of two groups of observations. Also, tests for equality of variances for the two groups are available. The TTEST procedure is usually more efficient than PROC GLM for this type of data. |
| VARCOMP | estimates variance components for a general linear model.                                                                                                                                                    |

---

## Getting Started: GLM Procedure

---

### PROC GLM for Unbalanced ANOVA

*Analysis of variance*, or ANOVA, typically refers to partitioning the variation in a variable's values into variation between and within several groups or classes of observations. The GLM procedure can perform simple or complicated ANOVA for balanced or unbalanced data.

This example discusses the analysis of variance for the unbalanced  $2 \times 2$  data shown in [Table 42.1](#). The experimental design is a full factorial, in which each level of one treatment factor occurs at each level of the other treatment factor. Note that there is only one value for the cell with A='A2' and B='B2'. Since one cell contains a different number of values from the other cells in the table, this is an unbalanced design.

**Table 42.1** Unbalanced Two-Way Data

|    | A1     | A2     |
|----|--------|--------|
| B1 | 12, 14 | 20, 18 |
| B2 | 11, 9  | 17     |

The following statements read the data into a SAS data set and then invoke PROC GLM to produce the analysis.

```

title 'Analysis of Unbalanced 2-by-2 Factorial';
data exp;
 input A $ B $ Y @@;
 datalines;
A1 B1 12 A1 B1 14 A1 B2 11 A1 B2 9
A2 B1 20 A2 B1 18 A2 B2 17
;

proc glm data=exp;
 class A B;
 model Y=A B A*B;
run;

```

Both treatments are listed in the **CLASS** statement because they are classification variables. A\*B denotes the interaction of the A effect and the B effect. The results are shown in [Figure 42.1](#) and [Figure 42.2](#).

**Figure 42.1** Class Level Information

| Analysis of Unbalanced 2-by-2 Factorial |        |        |
|-----------------------------------------|--------|--------|
| The GLM Procedure                       |        |        |
| Class Level Information                 |        |        |
| Class                                   | Levels | Values |
| A                                       | 2      | A1 A2  |
| B                                       | 2      | B1 B2  |
| Number of Observations Read             |        | 7      |
| Number of Observations Used             |        | 7      |

Figure 42.1 displays information about the classes as well as the number of observations in the data set. Figure 42.2 shows the ANOVA table, simple statistics, and tests of effects.

| Source                                  | DF       | Type I SS      | Mean Square | F Value  | Pr > F |
| A                                       | 1        | 80.04761905    | 80.04761905 | 40.02    | 0.0080 |
| B                                       | 1        | 11.26666667    | 11.26666667 | 5.63     | 0.0982 |
| A*B                                     | 1        | 0.40000000     | 0.40000000  | 0.20     | 0.6850 |

Figure 42.2 continued

| Source | DF | Type III SS | Mean Square | F Value | Pr > F |
|--------|----|-------------|-------------|---------|--------|
| A      | 1  | 67.60000000 | 67.60000000 | 33.80   | 0.0101 |
| B      | 1  | 10.00000000 | 10.00000000 | 5.00    | 0.1114 |
| A*B    | 1  | 0.40000000  | 0.40000000  | 0.20    | 0.6850 |

The degrees of freedom can be used to check your data. The Model degrees of freedom for a  $2 \times 2$  factorial design with interaction are  $(ab - 1)$ , where  $a$  is the number of levels of A and  $b$  is the number of levels of B; in this case,  $(2 \times 2 - 1) = 3$ . The Corrected Total degrees of freedom are always one less than the number of observations used in the analysis; in this case,  $7 - 1 = 6$ .

The overall  $F$  test is significant ( $F = 15.29$ ,  $p = 0.0253$ ), indicating strong evidence that the means for the four different A×B cells are different. You can further analyze this difference by examining the individual tests for each effect.

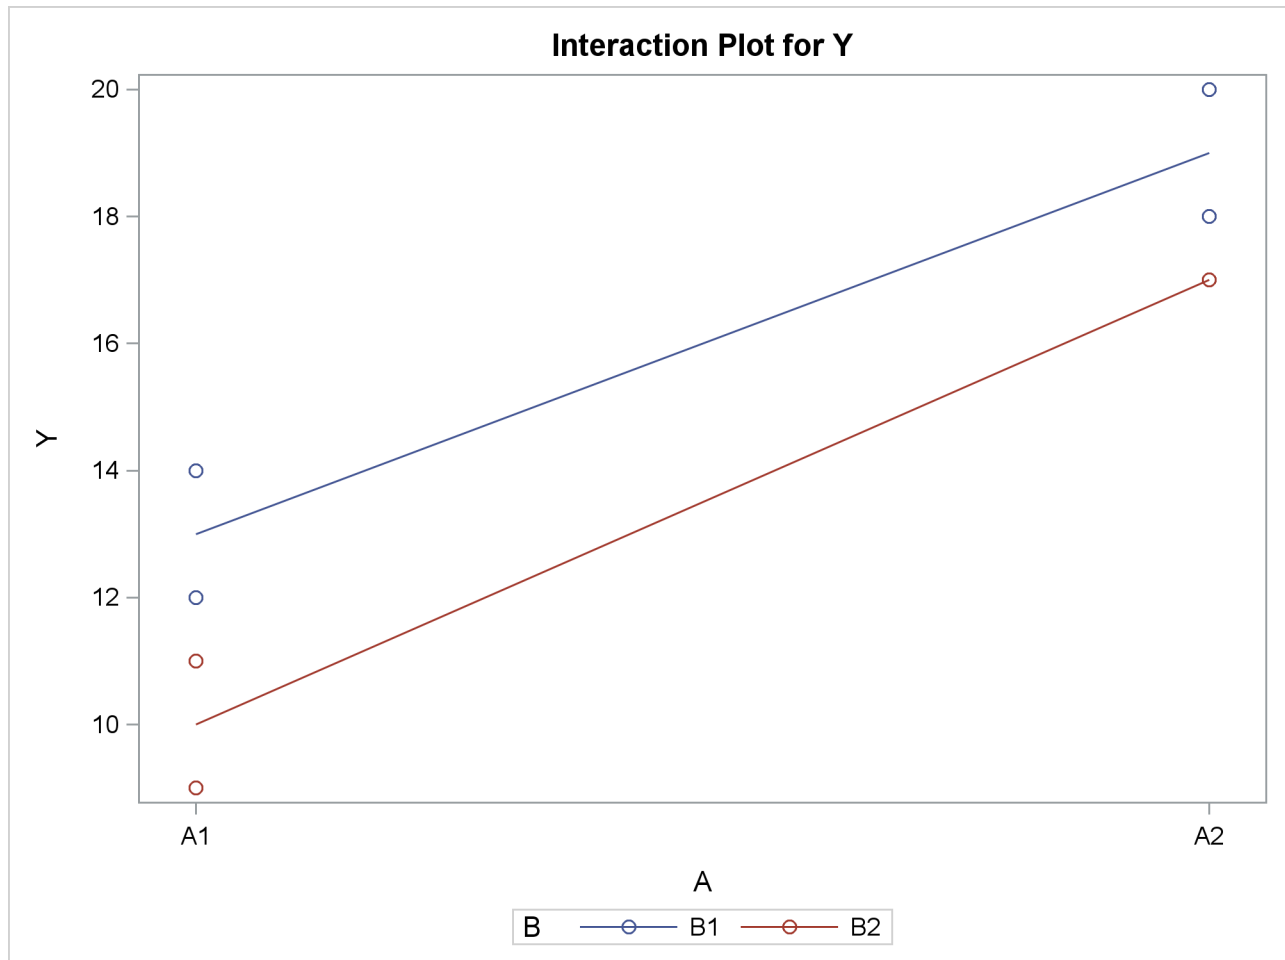

Four types of estimable functions of parameters are available for testing hypotheses in PROC GLM. For data with no missing cells, the Type III and Type IV estimable functions are the same and test the same hypotheses that would be tested if the data were balanced. Type I and Type III sums of squares are typically not equal when the data are unbalanced; Type III sums of squares are preferred in testing effects in unbalanced cases because they test a function of the underlying parameters that is independent of the number of observations per treatment combination.

According to a significance level of 5% ( $\alpha = 0.05$ ), the A\*B interaction is not significant ( $F = 0.20$ ,  $p = 0.6850$ ). This indicates that the effect of A does not depend on the level of B and vice versa. Therefore, the tests for the individual effects are valid, showing a significant A effect ( $F = 33.80$ ,  $p = 0.0101$ ) but no significant B effect ( $F = 5.00$ ,  $p = 0.1114$ ).

If ODS Graphics is enabled, GLM also displays by default an interaction plot for this analysis. The following statements, which are the same as in the previous analysis but with ODS Graphics enabled, additionally produce Figure 42.3.

```
ods graphics on;
proc glm data=exp;
 class A B;
 model Y=A B A*B;
run;
ods graphics off;
```

Figure 42.3 Plot of Y by A and B

The insignificance of the A\*B interaction is reflected in the fact that two lines in Figure 42.3 are nearly parallel. For more information about the graphics that GLM can produce, see the section “ODS Graphics” on page 3388.

## PROC GLM for Quadratic Least Squares Regression

In polynomial regression, the values of a dependent variable (also called a response variable) are described or predicted in terms of polynomial terms involving one or more independent or explanatory variables. An example of quadratic regression in PROC GLM follows. These data are taken from Draper and Smith (1966, p. 57). Thirteen specimens of 90/10 Cu-Ni alloys are tested in a corrosion-wheel setup in order to examine corrosion. Each specimen has a certain iron content. The wheel is rotated in salt sea water at 30 ft/sec for 60 days. Weight loss is used to quantify the corrosion. The `fe` variable represents the iron content, and the `loss` variable denotes the weight loss in milligrams/square decimeter/day in the following DATA step.

```
title 'Regression in PROC GLM';
data iron;
 input fe loss @@;
```

```

datalines;
0.01 127.6 0.48 124.0 0.71 110.8 0.95 103.9
1.19 101.5 0.01 130.1 0.48 122.0 1.44 92.3
0.71 113.1 1.96 83.7 0.01 128.0 1.44 91.4
1.96 86.2
;

```

The SGSCATTER procedure is used in the following statements to request a scatter plot of the response variable versus the independent variable.

```

ods graphics on;
proc sgscatter data=iron;
 plot loss*fe;
run;
ods graphics off;

```

The plot in Figure 42.4 displays a strong negative relationship between iron content and corrosion resistance, but it is not clear whether there is curvature in this relationship.

**Figure 42.4** Plot of Observed Corrosion Resistance by Iron Content

The following statements fit a quadratic regression model to the data. This enables you to estimate the linear relationship between iron content and corrosion resistance and to test for the presence of a quadratic component. The intercept is automatically fit unless the **NOINT** option is specified.

```
proc glm data=iron;
 model loss=fe fe*fe;
run;
```

The **CLASS** statement is omitted because a regression line is being fitted. Unlike PROC REG, PROC GLM allows polynomial terms in the **MODEL** statement.

PROC GLM first displays preliminary information, shown in Figure 42.5, telling you that the GLM procedure has been invoked and stating the number of observations in the data set. If the model involves classification variables, they are also listed here, along with their levels.

**Figure 42.5** Data Information

| Regression in PROC GLM      |    |
|-----------------------------|----|
| The GLM Procedure           |    |
| Number of Observations Read | 13 |
| Number of Observations Used | 13 |

Figure 42.6 shows the overall ANOVA table and some simple statistics. The degrees of freedom can be used to check that the model is correct and that the data have been read correctly. The Model degrees of freedom for a regression is the number of parameters in the model minus 1. You are fitting a model with three parameters in this case,

$$\text{loss} = \beta_0 + \beta_1 \times (\text{fe}) + \beta_2 \times (\text{fe})^2 + \text{error}$$

so the degrees of freedom are  $3 - 1 = 2$ . The Corrected Total degrees of freedom are always one less than the number of observations used in the analysis.

**Figure 42.6** ANOVA Table

| Regression in PROC GLM   |    |                |             |         |        |
|--------------------------|----|----------------|-------------|---------|--------|
| The GLM Procedure        |    |                |             |         |        |
| Dependent Variable: loss |    |                |             |         |        |
| Source                   | DF | Sum of Squares | Mean Square | F Value | Pr > F |
| Model                    | 2  | 3296.530589    | 1648.265295 | 164.68  | <.0001 |
| Error                    | 10 | 100.086334     | 10.008633   |         |        |
| Corrected Total          | 12 | 3396.616923    |             |         |        |

Figure 42.6 continued

| R-Square | Coeff Var | Root MSE | loss Mean |
|----------|-----------|----------|-----------|
| 0.970534 | 2.907348  | 3.163642 | 108.8154  |

The R square indicates that the model accounts for 97% of the variation in LOSS. The coefficient of variation (Coeff Var), Root MSE (Mean Square for Error), and mean of the dependent variable are also listed.

The overall  $F$  test is significant ( $F = 164.68$ ,  $p < 0.0001$ ), indicating that the model as a whole accounts for a significant amount of the variation in LOSS. Thus, it is appropriate to proceed to testing the effects.

Figure 42.7 contains tests of effects and parameter estimates. The latter are displayed by default when the model contains only continuous variables.

Figure 42.7 Tests of Effects and Parameter Estimates

| Source | DF | Type I SS   | Mean Square | F Value | Pr > F |
|--------|----|-------------|-------------|---------|--------|
| fe     | 1  | 3293.766690 | 3293.766690 | 329.09  | <.0001 |
| fe*fe  | 1  | 2.763899    | 2.763899    | 0.28    | 0.6107 |

| Source | DF | Type III SS | Mean Square | F Value | Pr > F |
|--------|----|-------------|-------------|---------|--------|
| fe     | 1  | 356.7572421 | 356.7572421 | 35.64   | 0.0001 |
| fe*fe  | 1  | 2.7638994   | 2.7638994   | 0.28    | 0.6107 |

  

| Parameter | Estimate    | Standard Error | t Value | Pr >  t |
|-----------|-------------|----------------|---------|---------|
| Intercept | 130.3199337 | 1.77096213     | 73.59   | <.0001  |
| fe        | -26.2203900 | 4.39177557     | -5.97   | 0.0001  |
| fe*fe     | 1.1552018   | 2.19828568     | 0.53    | 0.6107  |

The  $t$  tests provided are equivalent to the Type III  $F$  tests. The quadratic term is not significant ( $p = 0.6107$ ) and thus can be removed from the model; the linear term is significant ( $p < 0.0001$ ). This suggests that there is indeed a straight-line relationship between loss and fe.

Finally, if ODS Graphics is enabled, PROC GLM also displays by default a scatter plot of the original data, as in Figure 42.4, with the quadratic fit overlaid. The following statements, which are the same as the previous analysis but with ODS Graphics enabled, additionally produce Figure 42.8.

```
ods graphics on;
proc glm data=iron;
 model loss=fe fe*fe;
run;
ods graphics off;
```

**Figure 42.8** Plot of Observed and Fit Corrosion Resistance by Iron Content, Quadratic Model

The insignificance of the quadratic term in the model is reflected in the fact that the fit is nearly linear.

Fitting the model without the quadratic term provides more accurate estimates for  $\beta_0$  and  $\beta_1$ . PROC GLM allows only one **MODEL** statement per invocation of the procedure, so the **PROC GLM** statement must be issued again. The following statements are used to fit the linear model.

```
proc glm data=iron;
 model loss=fe;
run;
```

Figure 42.9 displays the output produced by these statements. The linear term is still significant ( $F = 352.27$ ,  $p < 0.0001$ ). The estimated model is now

$$\text{loss} = 129.79 - 24.02 \times \text{fe}$$

**Figure 42.9** Linear Model Output

| Regression in PROC GLM   |             |                |             |           |        |

## Syntax: GLM Procedure

The following statements are available in the GLM procedure:

```

PROC GLM < options > ;
 CLASS variable < (REF= option) > ... < variable < (REF= option) > > < / global-options > ;
 MODEL dependent-variables = independent-effects < / options > ;
 ABSORB variables ;
 BY variables ;
 CODE < options > ;
 FREQ variable ;
 ID variables ;
 WEIGHT variable ;
 CONTRAST 'label' effect values < ... effect values > < / options > ;
 ESTIMATE 'label' effect values < ... effect values > < / options > ;
 LSMEANS effects < / options > ;
 MANOVA < test-options > < / detail-options > ;
 MEANS effects < / options > ;
 OUTPUT < OUT=SAS-data-set > keyword=names < ... keyword=names > < / option > ;
 RANDOM effects < / options > ;
 REPEATED factor-specification < / options > ;
 STORE < OUT= > item-store-name < / LABEL='label' > ;
 TEST < H=effects > E=effect < / options > ;

```

Although there are numerous statements and options available in PROC GLM, many applications use only a few of them. Often you can find the features you need by looking at an example or by quickly scanning through this section.

To use PROC GLM, the **PROC GLM** and **MODEL** statements are required. You can specify only one **MODEL** statement (in contrast to the REG procedure, for example, which allows several **MODEL** statements in the same PROC REG run). If your model contains classification effects, the classification variables must be listed in a **CLASS** statement, and the **CLASS** statement must appear before the **MODEL** statement. In addition, if you use a **CONTRAST** statement in combination with a **MANOVA**, **RANDOM**, **REPEATED**, or **TEST** statement, the **CONTRAST** statement must be entered first in order for the contrast to be included in the **MANOVA**, **RANDOM**, **REPEATED**, or **TEST** analysis.

Table 42.2 summarizes the positional requirements for the statements in the GLM procedure.

**Table 42.2** Positional Requirements for PROC GLM Statements

| <b>Statement</b> | <b>Must Precede...</b>                                | <b>Must Follow...</b>                 |
|------------------|-------------------------------------------------------|---------------------------------------|
| ABSORB           | First RUN statement                                   |                                       |
| BY               | First RUN statement                                   |                                       |
| CLASS            | MODEL statement                                       |                                       |
| CONTRAST         | MANOVA, REPEATED,<br>or RANDOM statement              | MODEL statement                       |
| ESTIMATE         |                                                       | MODEL statement                       |
| FREQ             | First RUN statement                                   |                                       |
| ID               | First RUN statement                                   |                                       |
| LSMEANS          |                                                       | MODEL statement                       |
| MANOVA           |                                                       | CONTRAST or<br>MODEL statement        |
| MEANS            |                                                       | MODEL statement                       |
| MODEL            | CONTRAST, ESTIMATE,<br>LSMEANS, or MEANS<br>statement | CLASS statement                       |
| OUTPUT           |                                                       | MODEL statement                       |
| RANDOM           |                                                       | CONTRAST or<br>MODEL statement        |
| REPEATED         |                                                       | CONTRAST, MODEL,<br>or TEST statement |
| TEST             | MANOVA or<br>REPEATED statement                       | MODEL statement                       |
| WEIGHT           | First RUN statement                                   |                                       |

Table 42.3 summarizes the function of each statement (other than the PROC statement) in the GLM procedure.

**Table 42.3** Statements in the GLM Procedure

| <b>Statement</b> | <b>Description</b>                                                                                                                           |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| ABSORB           | Absorbs classification effects in a model                                                                                                    |
| BY               | Specifies variables to define subgroups for the analysis                                                                                     |
| CLASS            | Declares classification variables                                                                                                            |
| CODE             | Requests that the procedure write SAS DATA step code to a file or catalog entry for computing predicted values according to the fitted model |
| CONTRAST         | Constructs and tests linear functions of the parameters                                                                                      |
| ESTIMATE         | Estimates linear functions of the parameters                                                                                                 |
| FREQ             | Specifies a frequency variable                                                                                                               |
| ID               | Identifies observations on output                                                                                                            |
| LSMEANS          | Computes least squares (marginal) means                                                                                                      |
| MANOVA           | Performs a multivariate analysis of variance                                                                                                 |

**Table 42.3** *continued*

| <b>Statement</b> | <b>Description</b>                                                                                      |
|------------------|---------------------------------------------------------------------------------------------------------|
| MEANS            | Computes and optionally compares arithmetic means                                                       |
| MODEL            | Defines the model to be fit                                                                             |
| OUTPUT           | Requests an output data set containing diagnostics for each observation                                 |
| RANDOM           | Declares certain effects to be random and computes expected mean squares                                |
| REPEATED         | Performs multivariate and univariate repeated measures analysis of variance                             |
| STORE            | Requests that the procedure save the context and results of the statistical analysis into an item store |
| TEST             | Constructs tests that use the sums of squares for effects and the error term you specify                |
| WEIGHT           | Specifies a variable for weighting observations                                                         |

The rest of this section provides detailed syntax information for each of these statements, beginning with the `PROC GLM` statement. The remaining statements are covered in alphabetical order.

The `STORE` and `CODE` statements are also used by many other procedures. A summary description of functionality and syntax for these statements is also shown after the `PROC GLM` statement in alphabetical order, but you can find full documentation about them in the section “`STORE Statement`” on page 501 of Chapter 19, “Shared Concepts and Topics.”

---

## PROC GLM Statement

**PROC GLM** *< options >* ;

The `PROC GLM` statement invokes the GLM procedure. [Table 42.4](#) summarizes the options available in the `PROC GLM` statement.

**Table 42.4** PROC GLM Statement Options

| <b>Option</b> | <b>Description</b>                                                                         |
|---------------|--------------------------------------------------------------------------------------------|
| ALPHA=        | Specifies the level of significance for confidence intervals                               |
| DATA=         | Names the SAS data set used by the GLM procedure                                           |
| MANOVA        | Requests the multivariate mode of eliminating observations with missing values             |
| MULTIPASS     | Requests that the input data set be reread when necessary, instead of using a utility file |
| NAMELEN=      | Specifies the length of effect names                                                       |
| NOPRINT       | Suppresses the normal display of results                                                   |
| ORDER=        | Specifies the order in which to sort classification variables                              |
| OUTSTAT=      | Names an output data set for information and statistics on each model effect               |
| PLOTS         | Controls the plots produced through ODS Graphics                                           |

You can specify the following options in the PROC GLM statement.

**ALPHA= $p$**

specifies the level of significance  $p$  for  $100(1 - p)\%$  confidence intervals. The value must be between 0 and 1; the default value of  $p = 0.05$  results in 95% intervals. This value is used as the default confidence level for limits computed by the following options.

| Statement | Options               |
|-----------|-----------------------|
| LSMEANS   | CL                    |
| MEANS     | CLM CLDIFF            |
| MODEL     | CLI CLM CLPARM        |
| OUTPUT    | UCL= LCL= UCLM= LCLM= |

You can override the default in each of these cases by specifying the ALPHA= option for each statement individually.

**DATA=*SAS-data-set***

names the SAS data set used by the GLM procedure. By default, PROC GLM uses the most recently created SAS data set.

**MANOVA**

requests the multivariate mode of eliminating observations with missing values. If any of the dependent variables have missing values, the procedure eliminates that observation from the analysis. The MANOVA option is useful if you use PROC GLM in interactive mode and plan to perform a multivariate analysis.

**MULTIPASS**

requests that PROC GLM reread the input data set when necessary, instead of writing the necessary values of dependent variables to a utility file. This option decreases disk space usage at the expense of increased execution times, and is useful only in rare situations where disk space is at an absolute premium.

**NAMELEN= $n$**

specifies the length of effect names in tables and output data sets to be  $n$  characters long, where  $n$  is a value between 20 and 200 characters. The default length is 20 characters.

**NOPRINT**

suppresses the normal display of results. The NOPRINT option is useful when you want only to create one or more output data sets with the procedure. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “Using the Output Delivery System,” for more information.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of the classification variables (which are specified in the CLASS statement). This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option can be useful when you specify the CONTRAST or ESTIMATE statement.

This option applies to the levels for all classification variables, except when you use the (default) ORDER=FORMATTED option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

| Value of ORDER=  | Levels Sorted By                                                                                                                       |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DATA</b>      | Order of appearance in the input data set                                                                                              |
| <b>FORMATTED</b> | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| <b>FREQ</b>      | Descending frequency count; levels with the most observations come first in the order                                                  |
| <b>INTERNAL</b>  | Unformatted value                                                                                                                      |

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent.

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

#### **OUTSTAT=SAS-data-set**

names an output data set that contains sums of squares, degrees of freedom,  $F$  statistics, and probability levels for each effect in the model, as well as for each **CONTRAST** that uses the overall residual or error mean square (MSE) as the denominator in constructing the  $F$  statistic. If you use the **CANONICAL** option in the **MANOVA** statement and do not use an **M=** specification in the **MANOVA** statement, the data set also contains results of the canonical analysis.

See the section “Output Data Sets” on page 3382 for more information.

**PLOTS** <(global-plot-options)> <= plot-request <(options)>>

**PLOTS** <(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>>

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses from around the plot request. For example:

```
PLOTS=NONE
PLOTS=(DIAGNOSTICS RESIDUALS)
PLOTS (UNPACK) =RESIDUALS
PLOT=MEANPLOT (CLBAND)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc glm data=iron;
 model loss=fe fe*fe;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC GLM produces a default set of plots, which might be different for different models, as discussed in the following.

- If you specify a one-way analysis of variance model, with just one **CLASS** variable, the GLM procedure produces a grouped box plot of the response values versus the **CLASS** levels. For an example of the box plot, see the section “[One-Way Layout with Means Comparisons](#)” on page 904.
- If you specify a two-way analysis of variance model, with just two **CLASS** variables, the GLM procedure produces an interaction plot of the response values, with horizontal position representing one **CLASS** variable and marker style representing the other; and with predicted response values connected by lines representing the two-way analysis. For an example of the interaction plot, see the section “[PROC GLM for Unbalanced ANOVA](#)” on page 3269.
- If you specify a model with a single continuous predictor, the GLM procedure produces a fit plot of the response values versus the covariate values, with a curve representing the fitted relationship and a band representing the confidence limits for individual mean values. For an example of the fit plot, see the section “[PROC GLM for Quadratic Least Squares Regression](#)” on page 3272.
- If you specify a model with two continuous predictors and no **CLASS** variables, the GLM procedure produces a contour fit plot, overlaying a scatter plot of the data and a contour plot of the predicted surface.
- If you specify an analysis of covariance model, with one or two **CLASS** variables and one continuous variable, the GLM procedure produces an analysis of covariance plot of the response values versus the covariate values, with lines representing the fitted relationship within each classification level. For an example of the analysis of covariance plot, see [Example 42.4](#).
- If you specify an **LSMEANS** statement with the **PDIF** option, the GLM procedure produces a plot appropriate for the type of LS-means comparison. For **PDIF**=ALL (which is the default if you specify only **PDIF**), the procedure produces a diffogram, which displays all pairwise LS-means differences and their significance. The display is also known as a “mean-mean scatter plot” (Hsu 1996). For **PDIF**=CONTROL, the procedure produces a display of each noncontrol LS-mean compared to the control LS-mean, with two-sided confidence intervals for the comparison. For **PDIF**=CONTROL and **PDIF**=CONTROLU a similar display is produced, but with one-sided confidence intervals. Finally, for the **PDIF**=ANOM option, the procedure produces an “analysis of means” plot, comparing each LS-mean to the average LS-mean.
- If you specify a **MEANS** statement, the GLM procedure produces a grouped box plot of the response values versus the effect for which means are being calculated.

The global plot options include the following:

**MAXPOINTS=NONE** | *number*

specifies that plots with elements that require processing of more than *number* points be suppressed. The default is MAXPOINTS=5000. This limit is ignored if you specify MAXPOINTS=NONE.

**ONLY**

suppresses the default plots. Only plots specifically requested are displayed.

**UNPACKPANEL****UNPACK**

suppresses paneling. By default, multiple plots can appear in some output panels. Specify UNPACKPANEL to get each plot in a separate panel. You can specify PLOTS(UNPACKPANEL) to just unpack the default plots. You can also specify UNPACKPANEL as a suboption with DIAGNOSTICS and RESIDUALS.

The following individual plots and plot options are available. If you specify only one *plot*, then you can omit the parentheses.

**ALL**

produces all appropriate plots. You can specify other options with ALL; for example, to request all plots and unpack just the residuals, specify: PLOTS=(ALL RESIDUALS(UNPACK)).

**ANCOVAPLOT<(CLM CLI LIMITS)>**

modifies the analysis of covariance plot produced by default when you have an analysis of covariance model, with one or two CLASS variables and one continuous variable. By default the plot does not show confidence limits around the predicted values. The PLOTS=ANCOVAPLOT(CLM) option adds limits for the expected predicted values, and PLOTS=ANCOVAPLOT(CLI) adds limits for new predictions. Use PLOTS=ANCOVAPLOT(LIMITS) to add both kinds of limits.

**ANOMPLOT**

requests an analysis of means display, in which least squares means are compared against an average least squares mean (Ott 1967; Nelson 1982, 1991, 1993). LS-mean ANOM plots are produced only if you also specify PDIFF=ANOM or ADJUST=NELSON in the LSMEANS statement, and in this case they are produced by default.

**BOXPLOT<(NPANELPOS=*n*)>**

modifies the plot produced by default for the model effect in a one-way analysis of variance model, or for an effect specified in the MEANS statement. Suppose the effect has  $m$  levels. By default, or if you specify PLOTS=BOXPLOT(NPANELPOS=0), all  $m$  levels of the effect are displayed in a single plot. Specifying a nonzero value of  $n$  will result in  $P$  panels, where  $P$  is the integer part of  $m/n + 1$ . If  $n > 0$ , then the levels will be approximately balanced across the  $P$  panels; whereas if  $n < 0$ , precisely  $|n|$  levels will be displayed on each panel except possibly the last.

**CONTOURFIT<(OBS=*obs-options*)>**

modifies the contour fit plot produced by default when you have a model involving only two continuous predictors. The plot displays a contour plot of the predicted surface overlaid with a scatter plot of the observed data. You can use the following *obs-options* to control how the observations are displayed:

**OBS=GRADIENT**

specifies that observations are displayed as circles colored by the observed response. The same color gradient is used to display the fitted surface and the observations. Observations where the predicted response is close to the observed response have similar colors: the

greater the contrast between the color of an observation and the surface, the larger the residual is at that point.

**OBS=NONE**

suppresses the observations.

**OBS=OUTLINE**

specifies that observations are displayed as circles with a border but with a completely transparent fill.

**OBS=OUTLINEGRADIENT**

is the same as OBS=GRADIENT except that a border is shown around each observation. This option is useful to identify the location of observations where the residuals are small, since at these points the color of the observations and the color of the surface are indistinguishable. OBS=OUTLINEGRADIENT is the default if you do not specify any *obs-options*.

**CONTROLPLOT**

requests a display in which least squares means are compared against a reference level. LS-mean control plots are produced only when you specify **PDIFF=CONTROL** or **ADJUST=DUNNETT** in the **LSMEANS** statement, and in this case they are produced by default.

**DIAGNOSTICS<(LABEL UNPACK)>**

requests that a panel of summary diagnostics for the fit be displayed. The panel displays scatter plots of residuals, absolute residuals, studentized residuals, and observed responses by predicted values; studentized residuals by leverage; Cook's *D* by observation; a Q-Q plot of residuals; a residual histogram; and a residual-fit spread plot. The LABEL option displays labels on observations satisfying  $RSTUDENT > 2$ ,  $LEVERAGE > 2p/n$ , and on the Cook's *D* plot,  $COOKSD > 4/n$ , where  $n$  is the number of observations used in fitting the model, and  $p$  is the number of parameters in the model. The label is the first ID variable if the ID statement is specified; otherwise, it is the observation number. The UNPACK option unpanels the diagnostic display and produces the series of individual plots that form the paneled display.

**DIFFPLOT<(ABS NOABS CENTER NOLINES)>**

modifies the plot produced by an **LSMEANS** statement with the **PDIFF=ALL** option (or just **PDIFF**, since ALL is the default argument). The ABS and NOABS options determine the positioning of the line segments in the plot. When the ABS option is in effect, and this is the default, all line segments are shown on the same side of the reference line. The NOABS option separates comparisons according to the sign of the difference. The CENTER option marks the center point for each comparison. This point corresponds to the intersection of two least squares means. The NOLINES option suppresses the display of the line segments that represent the confidence bounds for the differences of the least squares means. The NOLINES option implies the CENTER option. The default is to draw line segments in the upper portion of the plot area without marking the center point.

**FITPLOT<(NOCLM NOCLI NOLIMITS)>**

modifies the fit plot produced by default when you have a model with a single continuous predictor. By default the plot includes confidence limits for both the expected predicted values and individual new predictions. The **PLOTS=FITPLOT(NOCLM)** option removes the limits on the expected values and the **PLOTS=FITPLOT(NOCLI)** option removes the limits on new predictions. The **PLOTS=FITPLOT(NOLIMITS)** option removes both kinds of confidence limits.

**INTPLOT<(CLM CLI LIMITS)>**

modifies the interaction plot produced by default when you have a two-way analysis of variance model, with just two **CLASS** variables. By default the plot does not show confidence limits around the predicted values. The **PLOTS=INTPLOT(CLM)** option adds limits for the expected predicted values and **PLOTS=INTPLOT(CLI)** adds limits for new predictions. Use **PLOTS=INTPLOT(LIMITS)** to add both kinds of limits.

**MEANPLOT<(CL CLBAND CONNECT ASCENDING DESCENDING)>**

modifies the grouped box plot produced by an **MEANS** statement. Upper and lower confidence limits are plotted when the **CL** option is used. When the **CLBAND** option is in effect, confidence limits are shown as bands and the means are connected. By default, means are not joined by lines. You can achieve that effect with the **CONNECT** option. Means are displayed in the same order as they appear in the “Means” table. You can change that order for plotting with the **ASCENDING** and **DESCENDING** options.

**NONE**

specifies that no graphics be displayed.

**RESIDUALS<(SMOOTH UNPACK)>**

requests that scatter plots of the residuals against each continuous covariate be displayed. The **SMOOTH** option overlays a Loess smooth on each residual plot. Note that if a **WEIGHT** variable is specified, then it is not used to weight the smoother. See Chapter 53, “[The LOESS Procedure](#),” for more information. The **UNPACK** option unpanels the residual display and produces a series of individual plots that form the paneled display.

**ABSORB Statement**

**ABSORB** *variables* ;

Absorption is a computational technique that provides a large reduction in time and memory requirements for certain types of models. The *variables* are one or more variables in the input data set.

For a main-effect variable that does not participate in interactions, you can absorb the effect by naming it in an **ABSORB** statement. This means that the effect can be adjusted out before the construction and solution of the rest of the model. This is particularly useful when the effect has a large number of levels.

Several variables can be specified, in which case each one is assumed to be nested in the preceding variable in the **ABSORB** statement.

**NOTE:** When you use the **ABSORB** statement, the data set (or each **BY** group, if a **BY** statement appears) must be sorted by the variables in the **ABSORB** statement. The GLM procedure cannot produce predicted values or least squares means (LS-means) or create an output data set of diagnostic values if an **ABSORB** statement is used. If the **ABSORB** statement is used, it must appear before the first **RUN** statement; otherwise, it is ignored.

When you use an **ABSORB** statement and also use the **INT** option in the **MODEL** statement, the procedure ignores the option but computes the uncorrected total sum of squares (SS) instead of the corrected total sums of squares.

See the section “[Absorption](#)” on page 3343 for more information.

---

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC GLM to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the GLM procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

Since sorting the data changes the order in which PROC GLM reads observations, the sort order for the levels of the classification variables might be affected if you also specify **ORDER=DATA** in the **PROC GLM** statement. This, in turn, affects specifications in the **CONTRAST** and **ESTIMATE** statements.

If you specify the BY statement, it must appear before the first RUN statement; otherwise, it is ignored. When you use a BY statement, the interactive features of PROC GLM are disabled.

When both the BY and **ABSORB** statements are used, observations must be sorted first by the variables in the BY statement, and then by the variables in the **ABSORB** statement.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

**CLASS** *variable* < (**REF=** *option*) > . . . < *variable* < (**REF=** *option*) > > < / *global-options* > ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the **MODEL** statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

**NOTE:** Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the **FORMAT** procedure in the *Base SAS Procedures Guide* and the discussions of the **FORMAT** statement and SAS formats in *SAS*

*Formats and Informats: Reference.* You can adjust the order of CLASS variable levels with the **ORDER=** option in the **PROC GLM** statement.

The GLM procedure displays a table that summarizes the CLASS variables and their levels. You can use this table to check the ordering of levels and, hence, of the corresponding parameters for main effects. If you need to check the ordering of parameters for interaction effects, use the E option in the **MODEL**, **CONTRAST**, **ESTIMATE**, or **LSMEANS** statement. See the section “Parameterization of PROC GLM Models” on page 3327 for more information.

You can specify the following **REF=** option to indicate how the levels of an individual classification variable are to be ordered by enclosing it in parentheses after the variable name:

**REF= 'level' | FIRST | LAST**

specifies a level of the classification variable to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the estimates with PROC GLM’s singular parameterization. You can specify the *level* of the variable to use as the reference level; specify a value that corresponds to the formatted value of the variable if a format is assigned. Alternatively, you can specify **REF=FIRST** to designate that the first ordered level serve as the reference, or **REF=LAST** to designate that the last ordered level serve as the reference. To specify that **REF=FIRST** or **REF=LAST** be used for all classification variables, use the **REF= global-option** after the slash (/) in the CLASS statement.

You can specify the following *global-options* in the CLASS statement after a slash (/):

**REF=FIRST | LAST**

specifies a level of all classification variables to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the estimates with PROC GLM’s singular parameterization. Specify **REF=FIRST** to designate that the first ordered level for each classification variable serve as the reference. Specify **REF=LAST** to designate that the last ordered level serve as the reference. This option applies to all the variables specified in the CLASS statement. To specify different reference levels for different classification variables, use **REF=** options for individual variables.

**TRUNCATE**

specifies that class levels be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

---

## CODE Statement

**CODE** < options > ;

The CODE statement enables you to write SAS DATA step code for computing predicted values of the fitted model either to a file or to a catalog entry. This code can then be included in a DATA step to score new data.

Table 42.5 summarizes the *options* available in the CODE statement.

**Table 42.5** CODE Statement Options

| Option    | Description                                                                  |
|-----------|------------------------------------------------------------------------------|
| CATALOG=  | Names the catalog entry where the generated code is saved                    |
| DUMMIES   | Retains the dummy variables in the data set                                  |
| ERROR     | Computes the error function                                                  |
| FILE=     | Names the file where the generated code is saved                             |
| FORMAT=   | Specifies the numeric format for the regression coefficients                 |
| GROUP=    | Specifies the group identifier for array names and statement labels          |
| IMPUTE    | Imputes predicted values for observations with missing or invalid covariates |
| LINESIZE= | Specifies the line size of the generated code                                |
| LOOKUP=   | Specifies the algorithm for looking up CLASS levels                          |
| RESIDUAL  | Computes residuals                                                           |

For details about the syntax of the CODE statement, see the section “CODE Statement” on page 390 in Chapter 19, “Shared Concepts and Topics.”

## CONTRAST Statement

**CONTRAST** *'label'* effect values < . . . effect values > < / options > ;

The CONTRAST statement enables you to perform custom hypothesis tests by specifying an **L** vector or matrix for testing the univariate hypothesis  $L\beta = 0$  or the multivariate hypothesis  $LBM = 0$ . Thus, to use this feature you must be familiar with the details of the model parameterization that PROC GLM uses. For more information, see the section “Parameterization of PROC GLM Models” on page 3327. All of the elements of the **L** vector might be given, or if only certain portions of the **L** vector are given, the remaining elements are constructed by PROC GLM from the context (in a manner similar to rule 4 discussed in the section “Construction of Least Squares Means” on page 3363).

There is no limit to the number of CONTRAST statements you can specify, but they must appear after the MODEL statement. In addition, if you use a CONTRAST statement and a MANOVA, REPEATED, or TEST statement, appropriate tests for contrasts are carried out as part of the MANOVA, REPEATED, or TEST analysis. If you use a CONTRAST statement and a RANDOM statement, the expected mean square of the contrast is displayed. As a result of these additional analyses, the CONTRAST statement must appear before the MANOVA, REPEATED, RANDOM, or TEST statement.

In the CONTRAST statement,

|               |                                                                                                                                                                                                                                       |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>label</i>  | identifies the contrast on the output. A label is required for every contrast specified. Labels must be enclosed in quotes.                                                                                                           |
| <i>effect</i> | identifies an effect that appears in the MODEL statement, or the INTERCEPT effect. The INTERCEPT effect can be used when an intercept is fitted in the model. You do not need to include all effects that are in the MODEL statement. |
| <i>values</i> | are constants that are elements of the <b>L</b> vector associated with the effect.                                                                                                                                                    |

You can specify the following options in the CONTRAST statement after a slash (/).

**E**

displays the entire **L** vector. This option is useful in confirming the ordering of parameters for specifying **L**.

**E=effect**

specifies an error term, which must be one of the effects in the model. The procedure uses this effect as the denominator in *F* tests in univariate analysis. In addition, if you use a **MANOVA** or **REPEATED** statement, the procedure uses the effect specified by the **E=** option as the basis of the **E** matrix. By default, the procedure uses the overall residual or error mean square (MSE) as an error term.

**ETYPE=*n***

specifies the type (1, 2, 3, or 4, corresponding to a Type I, II, III, or IV test, respectively) of the **E=** effect. If the **E=** option is specified and the **ETYPE=** option is not, the procedure uses the highest type computed in the analysis.

**SINGULAR=*number***

tunes the estimability checking. If  $\text{ABS}(\mathbf{L} - \mathbf{LH}) > C \times \text{number}$  for any row in the contrast, then **L** is declared nonestimable. **H** is the  $(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{X}$  matrix, and *C* is  $\text{ABS}(\mathbf{L})$  except for rows where **L** is zero, and then it is 1. The default value for the **SINGULAR=** option is  $10^{-4}$ . Values for the **SINGULAR=** option must be between 0 and 1.

As stated previously, the **CONTRAST** statement enables you to perform custom hypothesis tests. If the hypothesis is testable in the univariate case,  $SS(H_0: \mathbf{L}\boldsymbol{\beta} = 0)$  is computed as

$$(\mathbf{Lb})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{Lb})$$

where  $\mathbf{b} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y}$ . This is the sum of squares displayed on the analysis-of-variance table.

For multivariate testable hypotheses, the usual multivariate tests are performed using

$$\mathbf{H} = \mathbf{M}'(\mathbf{LB})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{LB})\mathbf{M}$$

where  $\mathbf{B} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{Y}$  and **Y** is the matrix of multivariate responses or dependent variables. The degrees of freedom associated with the hypothesis are equal to the row rank of **L**. The sum of squares computed in this situation is equivalent to the sum of squares computed using an **L** matrix with any row deleted that is a linear combination of previous rows.

Multiple-degrees-of-freedom hypotheses can be specified by separating the rows of the **L** matrix with commas.

For example, for the model

```
proc glm;
 class A B;
 model Y=A B;
run;
```

with A at 5 levels and B at 2 levels, the parameter vector is

$$(\mu \ \alpha_1 \ \alpha_2 \ \alpha_3 \ \alpha_4 \ \alpha_5 \ \beta_1 \ \beta_2)$$

To test the hypothesis that the pooled A linear and A quadratic effect is zero, you can use the following **L** matrix:

$$\mathbf{L} = \begin{bmatrix} 0 & -2 & -1 & 0 & 1 & 2 & 0 & 0 \\ 0 & 2 & -1 & -2 & -1 & 2 & 0 & 0 \end{bmatrix}$$

The corresponding CONTRAST statement is

```
contrast 'A LINEAR & QUADRATIC'
 a -2 -1 0 1 2,
 a 2 -1 -2 -1 2;
```

If the first level of A is a control level and you want a test of control versus others, you can use this statement:

```
contrast 'CONTROL VS OTHERS' a -1 0.25 0.25 0.25 0.25;
```

See the following discussion of the **ESTIMATE** statement and the section “Specification of **ESTIMATE Expressions**” on page 3345 for rules on specification, construction, distribution, and estimability in the **CONTRAST** statement.

## ESTIMATE Statement

```
ESTIMATE 'label' effect values <... effect values> </ options > ;
```

The **ESTIMATE** statement enables you to estimate linear functions of the parameters by multiplying the vector **L** by the parameter estimate vector **b**, resulting in **Lb**. All of the elements of the **L** vector might be given, or, if only certain portions of the **L** vector are given, the remaining elements are constructed by PROC GLM from the context (in a manner similar to rule 4 discussed in the section “Construction of Least Squares Means” on page 3363).

The linear function is checked for estimability. The estimate **Lb**, where  $\mathbf{b} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y}$ , is displayed along with its associated standard error,  $\sqrt{\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}'s^2}$ , and *t* test. If you specify the **CLPARM** option in the **MODEL** statement (see page 3311), confidence limits for the true value are also displayed.

There is no limit to the number of **ESTIMATE** statements that you can specify, but they must appear after the **MODEL** statement. In the **ESTIMATE** statement,

|               |                                                                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>label</i>  | identifies the estimate on the output. A label is required for every contrast specified. Labels must be enclosed in quotes.                                                                                                                                                    |
| <i>effect</i> | identifies an effect that appears in the <b>MODEL</b> statement, or the <b>INTERCEPT</b> effect. The <b>INTERCEPT</b> effect can be used as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the <b>MODEL</b> statement. |
| <i>values</i> | are constants that are the elements of the <b>L</b> vector associated with the preceding effect. For example,                                                                                                                                                                  |

```
estimate 'A1 VS A2' A 1 -1;
```

forms an estimate that is the difference between the parameters estimated for the first and second levels of the CLASS variable A.

You can specify the following options in the ESTIMATE statement after a slash (/):

**DIVISOR=***number*

specifies a value by which to divide all coefficients so that fractional coefficients can be entered as integer numerators. For example, you can use

```
estimate '1/3(A1+A2) - 2/3A3' a 1 1 -2 / divisor=3;
```

instead of

```
estimate '1/3(A1+A2) - 2/3A3' a 0.33333 0.33333 -0.66667;
```

**E**

displays the entire **L** vector. This option is useful in confirming the ordering of parameters for specifying **L**.

**SINGULAR=***number*

tunes the estimability checking. If  $ABS(\mathbf{L} - \mathbf{LH}) > C \times \text{number}$ , then the **L** vector is declared nonestimable. **H** is the  $(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{X}$  matrix, and **C** is  $ABS(\mathbf{L})$  except for rows where **L** is zero, and then it is 1. The default value for the SINGULAR= option is  $10^{-4}$ . Values for the SINGULAR= option must be between 0 and 1.

See also the section “Specification of ESTIMATE Expressions” on page 3345.

## FREQ Statement

**FREQ** *variable* ;

The FREQ statement names a variable that provides frequencies for each observation in the DATA= data set. Specifically, if  $n$  is the value of the FREQ variable for a given observation, then that observation is used  $n$  times.

The analysis produced using a FREQ statement reflects the expanded number of observations. For example, means and total degrees of freedom reflect the expanded number of observations. You can produce the same analysis (without the FREQ statement) by first creating a new data set that contains the expanded number of observations. For example, if the value of the FREQ variable is 5 for the first observation, the first 5 observations in the new data set are identical. Each observation in the old data set is replicated  $n_i$  times in the new data set, where  $n_i$  is the value of the FREQ variable for that observation.

If the value of the FREQ variable is missing or is less than 1, the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

If you specify the FREQ statement, it must appear before the first RUN statement or it is ignored.

---

## ID Statement

**ID** *variables* ;

When predicted values are requested as a **MODEL** statement option, values of the variables given in the ID statement are displayed beside each observed, predicted, and residual value for identification. Although there are no restrictions on the length of ID variables, PROC GLM might truncate the number of values listed in order to display them on one line. The GLM procedure displays a maximum of five ID variables.

If you specify the ID statement, it must appear before the first RUN statement or it is ignored.

---

## LSMEANS Statement

**LSMEANS** *effects* </ *options* > ;

Table 42.6 summarizes the options available in the LSMEANS statement.

**Table 42.6** LSMEANS Statement Options

| Option     | Description                                                                      |
|------------|----------------------------------------------------------------------------------|
| ADJUST=    | Requests a multiple comparison adjustment                                        |
| ALPHA=     | Specifies the level of significance                                              |
| AT         | Enables you to modify the values of the covariates                               |
| BYLEVEL    | Processes the OM data set by each level of the LS-mean effect                    |
| CL         | Requests confidence limits                                                       |
| COV        | Includes variances and covariances of the LS-means                               |
| E          | Displays the coefficients of the linear functions                                |
| E=         | Specifies an effect in the model to use as an error term                         |
| ETYPE=     | Specifies the type of the E= effect                                              |
| LINES      | Uses connecting lines to indicate nonsignificantly different subsets of LS-means |
| NOPRINT    | Suppresses the normal display of results                                         |
| OBSMARGINS | Specifies a potentially different weighting scheme                               |
| OUT=       | Creates an output data set                                                       |
| PDIFF      | Requests that <i>p</i> -values for differences                                   |
| SLICE=     | Specifies effects within which to test for differences                           |
| SINGULAR=  | Tunes the estimability checking                                                  |
| STDERR     | Produces the standard error                                                      |
| TDIFF      | Produces the <i>t</i> values                                                     |

---

Least squares means (LS-means) are computed for each *effect* listed in the LSMEANS statement. You can specify only classification effects in the LSMEANS statement—that is, effects that contain only classification variables. You can also specify options to perform multiple comparisons. In contrast to the **MEANS** statement, the LSMEANS statement performs multiple comparisons on interactions as well as main effects.

LS-means are *predicted population margins*; that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to

balanced designs. Each LS-mean is computed as  $L/b$  for a certain column vector  $L$ , where  $b$  is the vector of parameter estimates—that is, the solution of the normal equations. For further information, see the section “Construction of Least Squares Means” on page 3363.

Multiple effects can be specified in one LSMEANS statement, or multiple LSMEANS statements can be used, but they must all appear after the **MODEL** statement. For example:

```
proc glm;
 class A B;
 model Y=A B A*B;
 lsmeans A B A*B;
run;
```

LS-means are displayed for each level of the A, B, and A\*B effects.

You can specify the following options in the LSMEANS statement after a slash (/):

**ADJUST=BON**

**ADJUST=DUNNETT**

**ADJUST=NELSON**

**ADJUST=SCHEFFE**

**ADJUST=SIDAK**

**ADJUST=SIMULATE** <(simoptions)>

**ADJUST=SMM** | **GT2**

**ADJUST=TUKEY**

**ADJUST=T**

requests a multiple comparison adjustment for the  $p$ -values and confidence limits for the differences of LS-means. The **ADJUST=** option modifies the results of the **TDIFF** and **PDIFF** options; thus, if you omit the **TDIFF** or **PDIFF** option then the **ADJUST=** option implies **PDIFF**. By default, PROC GLM analyzes all pairwise differences. If you specify **ADJUST=DUNNETT**, PROC GLM analyzes all differences with a control level. If you specify the **ADJUST=NELSON** option, PROC GLM analyzes all differences with the average LS-mean. The default is **ADJUST=T**, which really signifies no adjustment for multiple comparisons.

The **BON** (Bonferroni) and **SIDAK** adjustments involve correction factors described in the section “Multiple Comparisons” on page 3349 and in Chapter 61, “The **MULTTEST** Procedure.” When you specify **ADJUST=TUKEY** and your data are unbalanced, PROC GLM uses the approximation described in Kramer (1956) and identifies the adjustment as “Tukey-Kramer” in the results. Similarly, when you specify either **ADJUST=DUNNETT** or the **ADJUST=NELSON** option and the LS-means are correlated, PROC GLM uses the factor-analytic covariance approximation described in Hsu (1992) and identifies the adjustment in the results as “Dunnett-Hsu” or “Nelson-Hsu,” respectively. The preceding references also describe the **SCHEFFE** and **SMM** adjustments.

The **SIMULATE** adjustment computes the adjusted  $p$ -values from the simulated distribution of the maximum or maximum absolute value of a multivariate  $t$  random vector. The simulation estimates  $q$ , the true  $(1 - \alpha)$  quantile, where  $1 - \alpha$  is the confidence coefficient. The default  $\alpha$  is the value of the **ALPHA=** option in the **PROC GLM** statement or 0.05 if that option is not specified. You can change this value with the **ALPHA=** option in the **LSMEANS** statement.

The number of samples for the **SIMULATE** adjustment is set so that the tail area for the simulated  $q$  is within a certain *accuracy radius*  $\gamma$  of  $1 - \alpha$  with an *accuracy confidence* of  $100(1 - \epsilon)\%$ . In equation

form,

$$P(|F(\hat{q}) - (1 - \alpha)| \leq \gamma) = 1 - \epsilon$$

where  $\hat{q}$  is the simulated  $q$  and  $F$  is the true distribution function of the maximum; see Edwards and Berry (1987) for details. By default,  $\gamma = 0.005$  and  $\epsilon = 0.01$ , so that the tail area of  $\hat{q}$  is within 0.005 of 0.95 with 99% confidence.

You can specify the following *simoptions* in parentheses after the ADJUST=SIMULATE option.

**ACC=value**

specifies the target accuracy radius  $\gamma$  of a  $100(1-\epsilon)\%$  confidence interval for the true probability content of the estimated  $(1-\alpha)$  quantile. The default value is ACC=0.005. Note that, if you also specify the CVADJUST *simoption*, then the actual accuracy radius will probably be substantially less than this target.

**CVADJUST**

specifies that the quantile should be estimated by the control variate adjustment method of Hsu and Nelson (1998) instead of simply as the quantile of the simulated sample. Specifying the CVADJUST option typically has the effect of significantly reducing the accuracy radius  $\gamma$  of a  $100 \times (1 - \epsilon)\%$  confidence interval for the true probability content of the estimated  $(1 - \alpha)$  quantile. The control-variate-adjusted quantile estimate takes roughly twice as long to compute, but it is typically much more accurate than the sample quantile.

**EPS=value**

specifies the value  $\epsilon$  for a  $100 \times (1 - \epsilon)\%$  confidence interval for the true probability content of the estimated  $(1 - \alpha)$  quantile. The default value for the accuracy confidence is 99%, corresponding to EPS=0.01.

**NSAMP=n**

specifies the sample size for the simulation. By default,  $n$  is set based on the values of the target accuracy radius  $\gamma$  and accuracy confidence  $100 \times (1 - \epsilon)\%$  for an interval for the true probability content of the estimated  $(1 - \alpha)$  quantile. With the default values for  $\gamma$ ,  $\epsilon$ , and  $\alpha$  (0.005, 0.01, and 0.05, respectively), NSAMP=12604 by default.

**REPORT**

specifies that a report on the simulation should be displayed, including a listing of the parameters, such as  $\gamma$ ,  $\epsilon$ , and  $\alpha$ , as well as an analysis of various methods for estimating or approximating the quantile.

**SEED=number**

specifies an integer used to start the pseudo-random number generator for the simulation. If you do not specify a seed, or specify a value less than or equal to zero, the seed is by default generated from reading the time of day from the computer's clock.

**THREADS**

specifies that the computational work for the simulation be divided into parallel threads, where the number of threads is the value of the SAS system option CPUCOUNT=. For large simulations (as specified directly using the NSAMP= *simoption* or indirectly using the ACC= or EPS= *simoptions*), parallel processing can markedly speed up the computation of adjusted  $p$ -values and confidence intervals. However, because the parallel processing has different pseudo-random number streams, the precise results are different from the default ones, which are

computed in sequence rather than in parallel. This option overrides the SAS system option `THREADS | NOTTHREADS`.

### **NOTTHREADS**

specifies that the computational work for the simulation be performed in sequence rather than in parallel. `NOTTHREADS` is the default. This option overrides the SAS system option `THREADS | NOTTHREADS`.

### **ALPHA=*p***

specifies the level of significance  $p$  for  $100(1 - p)\%$  confidence intervals. This option is useful only if you also specify the `CL` option, and, optionally, the `PDIFF` option. By default,  $p$  is equal to the value of the `ALPHA=` option in the `PROC GLM` statement or 0.05 if that option is not specified. This value is used to set the endpoints for confidence intervals for the individual means as well as for differences between means.

### **AT *variable = value***

### **AT (*variable-list*) = (*value-list*)**

### **AT MEANS**

enables you to modify the values of the covariates used in computing LS-means. By default, all covariate effects are set equal to their mean values for computation of standard LS-means. The `AT` option enables you to set the covariates to whatever values you consider interesting. For more information, see the section “[Setting Covariate Values](#)” on page 3364.

### **BYLEVEL**

requests that `PROC GLM` process the `OM` data set by each level of the LS-mean effect in question. For more details, see the entry for the `OM` option in this section.

### **CL**

requests confidence limits for the individual LS-means. If you specify the `PDIFF` option, confidence limits for differences between means are produced as well. You can control the confidence level with the `ALPHA=` option. Note that, if you specify an `ADJUST=` option, the confidence limits for the differences are adjusted for multiple inference but the confidence intervals for individual means are **not** adjusted.

### **COV**

includes variances and covariances of the LS-means in the output data set specified in the `OUT=` option in the `LSMEANS` statement. Note that this is the covariance matrix for the LS-means themselves, not the covariance matrix for the differences between the LS-means, which is used in the `PDIFF` computations. If you omit the `OUT=` option, the `COV` option has no effect. When you specify the `COV` option, you can specify only one effect in the `LSMEANS` statement.

### **E**

displays the coefficients of the linear functions used to compute the LS-means.

### **E=*effect***

specifies an effect in the model to use as an error term. The procedure uses the mean square for the *effect* as the error mean square when calculating estimated standard errors (requested with the `STDERR` option) and probabilities (requested with the `STDERR`, `PDIFF`, or `TDIFF` option). Unless you specify `STDERR`, `PDIFF` or `TDIFF`, the `E=` option is ignored. By default, if you specify the `STDERR`, `PDIFF`, or `TDIFF` option and do not specify the `E=` option, the procedure uses the error mean square for calculating standard errors and probabilities.

**ETYPE=*n***

specifies the type (1, 2, 3, or 4, corresponding to a Type I, II, III, or IV test, respectively) of the **E=** effect. If you specify the **E=** option but not the **ETYPE=** option, the highest type computed in the analysis is used. If you omit the **E=** option, the **ETYPE=** option has no effect.

**LINES**

presents results of comparisons between all pairs of means (specified by the **PDIFF=ALL** option) by listing the means in descending order and indicating nonsignificant subsets by line segments beside the corresponding means. When all differences have the same variance, these comparison lines are guaranteed to accurately reflect the inferences based on the corresponding tests, made by comparing the respective *p*-values to the value of the **ALPHA=** option (0.05 by default). However, equal variances are rarely the case for differences between LS-means. If the variances are not all the same, then the comparison lines might be conservative, in the sense that if you base your inferences on the lines alone, you will detect fewer significant differences than the tests indicate. If there are any such differences, a note is appended to the table that lists the pairs of means that are inferred to be significantly different by the tests but not by the comparison lines. Note, however, that in many cases, even though the variances are unbalanced, they are near enough that the comparison lines in fact accurately reflect the test inferences.

**NOPRINT**

suppresses the normal display of results from the LSMEANS statement. This option is useful when an output data set is created with the **OUT=** option in the LSMEANS statement.

**OBSMARGINS****OM**

specifies a potentially different weighting scheme for computing LS-means coefficients. The standard LS-means have equal coefficients across classification effects; however, the **OM** option changes these coefficients to be proportional to those found in the input data set. For more information, see the section “[Changing the Weighting Scheme](#)” on page 3365.

The **BYLEVEL** option modifies the observed-margins LS-means. Instead of computing the margins across the entire data set, the procedure computes separate margins for each level of the LS-mean effect in question. The resulting LS-means are actually equal to raw means in this case. If you specify the **BYLEVEL** option, it disables the **AT** option.

**OUT=SAS-data-set**

creates an output data set that contains the values, standard errors, and, optionally, the covariances (see the **COV** option) of the LS-means.

For more information, see the section “[Output Data Sets](#)” on page 3382.

**PDIFF< =difftype >**

requests that *p*-values for differences of the LS-means be produced. The optional *difftype* specifies which differences to display. Possible values for *difftype* are ALL, CONTROL, CONTROLL, CONTROLU, and ANOM. The ALL value requests all pairwise differences, and it is the default. The CONTROL value requests the differences with a control that, by default, is the first level of each of the specified LS-mean effects. The ANOM value requests differences between each LS-mean and the average LS-mean, as in the *analysis of means* (Ott 1967). The average is computed as a weighted mean of the LS-means, the weights being inversely proportional to the variances. Note that the ANOM procedure in SAS/QC software implements both tables and graphics for the analysis of means with a

variety of response types. For one-way designs, the PDIFF=ANOM computations are equivalent to the results of PROC ANOM. See the section “Analysis of Means: Comparing Each Treatments to the Average” on page 3355 for more details.

To specify which levels of the effects are the controls, list the quoted formatted values in parentheses after the keyword CONTROL. For example, if the effects A, B, and C are CLASS variables, each having two levels, '1' and '2', the following LSMEANS statement specifies the '1' '2' level of A\*B and the '2' '1' level of B\*C as controls:

```
lsmeans A*B B*C / pdiff=control('1' '2', '2' '1');
```

For multiple-effect situations such as this one, the ordering of the list is significant, and you should check the output to make sure that the controls are correct.

Two-tailed tests and confidence limits are associated with the CONTROL difftype. For one-tailed results, use either the CONTROLL or CONTROLU difftype.

- PDIFF=CONTROLL tests whether the noncontrol levels are less than the control; you declare a noncontrol level to be significantly less than the control if the associated upper confidence limit for the noncontrol level minus the control is less than zero, and you ignore the associated lower confidence limits (which are set to minus infinity).
- PDIFF=CONTROLU tests whether the noncontrol levels are greater than the control; you declare a noncontrol level to be significantly greater than the control if the associated lower confidence limit for the noncontrol level minus the control is greater than zero, and you ignore the associated upper confidence limits (which are set to infinity).

The default multiple comparisons adjustment for each *difftype* is shown in the following table.

| <i>difftype</i> | Default ADJUST= |
|-----------------|-----------------|
| Not specified   | T               |
| ALL             | TUKEY           |
| CONTROL         |                 |
| CONTROLL        | DUNNETT         |
| CONTROLU        |                 |
| ANOM            | NELSON          |

If no *difftype* is specified, the default for the ADJUST= option is T (that is, no adjustment); for PDIFF=ALL, ADJUST=TUKEY is the default; for PDIFF=CONTROL, PDIFF=CONTROLL, or PDIFF=CONTROLU, the default value for the ADJUST= option is DUNNETT. For PDIFF=ANOM, ADJUST=NELSON is the default. If there is a conflict between the PDIFF= and ADJUST= options, the ADJUST= option takes precedence.

For example, in order to compute one-sided confidence limits for differences with a control, adjusted according to Dunnett's procedure, the following statements are equivalent:

```
lsmeans Treatment / pdiff=controll c1;
lsmeans Treatment / pdiff=controll c1 adjust=dunnett;
```

**SLICE**=*fixed-effect*

**SLICE**=(*fixed-effects*)

specifies effects within which to test for differences between interaction LS-mean effects. This can produce what are known as tests of simple effects (Winer 1971). For example, suppose that A\*B is significant and you want to test for the effect of A within each level of B. The appropriate LSMEANS statement is

```
lsmeans A*B / slice=B;
```

This statement tests for the simple main effects of A for B, which are calculated by extracting the appropriate rows from the coefficient matrix for the A\*B LS-means and using them to form an  $F$  test as performed by the **CONTRAST** statement.

**SINGULAR**=*number*

tunes the estimability checking. If  $ABS(\mathbf{L} - \mathbf{LH}) > C \times \text{number}$  for any row, then  $\mathbf{L}$  is declared nonestimable.  $\mathbf{H}$  is the  $(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{X}$  matrix, and  $C$  is  $ABS(\mathbf{L})$  except for rows where  $\mathbf{L}$  is zero, and then it is 1. The default value for the SINGULAR= option is  $10^{-4}$ . Values for the SINGULAR= option must be between 0 and 1.

**STDERR**

produces the standard error of the LS-means and the probability level for the hypothesis  $H_0: \text{LS-mean} = 0$ .

**TDIFF**

produces the  $t$  values for all hypotheses  $H_0: \text{LS-mean}(i) = \text{LS-mean}(j)$  and the corresponding probabilities.

---

## MANOVA Statement

**MANOVA** < *test-options* > < *detail-options* > ;

If the **MODEL** statement includes more than one dependent variable, you can perform multivariate analysis of variance with the MANOVA statement. The *test-options* define which effects to test, while the *detail-options* specify how to execute the tests and what results to display. [Table 42.7](#) summarizes the options available in the MANOVA statement.

**Table 42.7** MANOVA Statement Options

| Option              | Description                                                   |
|---------------------|---------------------------------------------------------------|
| <b>Test Options</b> |                                                               |
| H=                  | Specifies hypothesis effects                                  |
| E=                  | Specifies the error effect                                    |
| M=                  | Specifies a transformation matrix for the dependent variables |
| MNAMES=             | Provides names for the transformed variables                  |

Table 42.7 continued

| Option                | Description                                                         |
|-----------------------|---------------------------------------------------------------------|
| PREFIX=               | Alternatively identifies the transformed variables                  |
| <b>Detail Options</b> |                                                                     |
| CANONICAL             | Displays a canonical analysis of the <b>H</b> and <b>E</b> matrices |
| ETYPE=                | Specifies the type of the <b>E</b> matrix                           |
| HTYPE=                | Specifies the type of the <b>H</b> matrix                           |
| MSTAT=                | Specifies the method of evaluating the multivariate test statistics |
| ORTH                  | Orthogonalizes the rows of the transformation matrix                |
| PRINTE                | Displays the error SSCP matrix <b>E</b>                             |
| PRINTH                | Displays the hypothesis SSCP matrix <b>H</b>                        |
| SUMMARY               | Produces analysis-of-variance tables for each dependent variable    |

When a MANOVA statement appears before the first RUN statement, PROC GLM enters a multivariate mode with respect to the handling of missing values; in addition to observations with missing independent variables, observations with *any* missing dependent variables are excluded from the analysis. If you want to use this mode of handling missing values and do not need any multivariate analyses, specify the **MANOVA** option in the **PROC GLM** statement.

If you use both the **CONTRAST** and **MANOVA** statements, the **MANOVA** statement must appear after the **CONTRAST** statement.

## Test Options

The following options can be specified in the **MANOVA** statement as *test-options* in order to define which multivariate tests to perform.

### **H=effects** | **INTERCEPT** | **\_ALL\_**

specifies effects in the preceding model to use as hypothesis matrices. For each **H** matrix (the SSCP matrix associated with an effect), the **H=** specification displays the characteristic roots and vectors of  $\mathbf{E}^{-1}\mathbf{H}$  (where **E** is the matrix associated with the error effect), along with the Hotelling-Lawley trace, Pillai's trace, Wilks' lambda, and Roy's greatest root. By default, these statistics are tested with approximations based on the *F* distribution. To test them with exact (but computationally intensive) calculations, use the **MSTAT=EXACT** option.

Use the keyword **INTERCEPT** to produce tests for the intercept. To produce tests for all effects listed in the **MODEL** statement, use the keyword **\_ALL\_** in place of a list of effects.

For background and further details, see the section “**Multivariate Analysis of Variance**” on page 3366.

### **E=effect**

specifies the error effect. If you omit the **E=** specification, the GLM procedure uses the error SSCP (residual) matrix from the analysis.

### **M=equation,...,equation** | (*row-of-matrix,...,row-of-matrix*)

specifies a transformation matrix for the dependent variables listed in the **MODEL** statement. The

equations in the M= specification are of the form

$$c_1 \times \text{dependent-variable} \pm c_2 \times \text{dependent-variable} \\ \dots \pm c_n \times \text{dependent-variable}$$

where the  $c_i$  values are coefficients for the various *dependent-variables*. If the value of a given  $c_i$  is 1, it can be omitted; in other words  $1 \times Y$  is the same as  $Y$ . Equations should involve two or more dependent variables. For sample syntax, see the section “[Examples](#)” on page 3302.

Alternatively, you can input the transformation matrix directly by entering the elements of the matrix with commas separating the rows and parentheses surrounding the matrix. When this alternate form of input is used, the number of elements in each row must equal the number of dependent variables. Although these combinations actually represent the columns of the M matrix, they are displayed by rows.

When you include an M= specification, the analysis requested in the MANOVA statement is carried out for the variables defined by the equations in the specification, not the original dependent variables. If you omit the M= option, the analysis is performed for the original dependent variables in the [MODEL](#) statement.

If an M= specification is included without either the [MNames=](#) or [PREFIX=](#) option, the variables are labeled MVAR1, MVAR2, and so forth, by default. For further information, see the section “[Multivariate Analysis of Variance](#)” on page 3366.

**MNames=names**

provides names for the variables defined by the equations in the M= specification. Names in the list correspond to the M= equations or to the rows of the M matrix (as it is entered).

**PREFIX=name**

is an alternative means of identifying the transformed variables defined by the M= specification. For example, if you specify PREFIX=DIFF, the transformed variables are labeled DIFF1, DIFF2, and so forth.

## Detail Options

You can specify the following options in the MANOVA statement after a slash (/) as *detail-options*.

**CANONICAL**

displays a canonical analysis of the H and E matrices (transformed by the M matrix, if specified) instead of the default display of characteristic roots and vectors.

**ETYPE=n**

specifies the type (1, 2, 3, or 4, corresponding to a Type I, II, III, or IV test, respectively) of the E matrix, the SSCP matrix associated with the E= effect. You need this option if you use the E= specification to specify an error effect other than residual error and you want to specify the type of sums of squares used for the effect. If you specify ETYPE=n, the corresponding test must have been performed in the [MODEL](#) statement, either by options SSn, En, or the default Type I and Type III tests. By default, the procedure uses an ETYPE= value corresponding to the highest type (largest n) used in the analysis.

**HTYPE=*n***

specifies the type (1, 2, 3, or 4, corresponding to a Type I, II, III, or IV test, respectively) of the **H** matrix. See the **ETYPE=** option for more details.

**MSTAT=FAPPROX | EXACT**

specifies the method of evaluating the multivariate test statistics. The default is **MSTAT=FAPPROX**, which specifies that the multivariate tests are evaluated using the usual approximations based on the *F* distribution, as discussed in the section “Multivariate Tests” in Chapter 4, “[Introduction to Regression Procedures](#).” Alternatively, you can specify **MSTAT=EXACT** to compute exact *p*-values for three of the four tests (Wilks’ lambda, the Hotelling-Lawley trace, and Roy’s greatest root) and an improved *F* approximation for the fourth (Pillai’s trace). While **MSTAT=EXACT** provides better control of the significance probability for the tests, especially for Roy’s greatest root, computations for the exact *p*-values can be appreciably more demanding, and are in fact infeasible for large problems (many dependent variables). Thus, although **MSTAT=EXACT** is more accurate for most data, it is not the default method. For more information about the results of **MSTAT=EXACT**, see the section “[Multivariate Analysis of Variance](#)” on page 3366.

**ORTH**

requests that the transformation matrix in the **M=** specification of the MANOVA statement be orthonormalized by rows before the analysis.

**PRINTE**

displays the error SSCP matrix **E**. If the **E** matrix is the error SSCP (residual) matrix from the analysis, the partial correlations of the dependent variables given the independent variables are also produced.

For example, the statement

```
manova / printe;
```

displays the error SSCP matrix and the partial correlation matrix computed from the error SSCP matrix.

**PRINTH**

displays the hypothesis SSCP matrix **H** associated with each effect specified by the **H=** specification.

**SUMMARY**

produces analysis-of-variance tables for each dependent variable. When no **M** matrix is specified, a table is displayed for each original dependent variable from the **MODEL** statement; with an **M** matrix other than the identity, a table is displayed for each transformed variable defined by the **M** matrix.

**Examples**

The following statements provide several examples of using a **MANOVA** statement.

```
proc glm;
 class A B;
 model Y1-Y5=A B(A) / nouni;
 manova h=A e=B(A) / printh printe htype=1 etype=1;
 manova h=B(A) / printe;
 manova h=A e=B(A) m=Y1-Y2, Y2-Y3, Y3-Y4, Y4-Y5
 prefix=diff;
```

```

manova h=A e=B(A) m=(1 -1 0 0 0,
 0 1 -1 0 0,
 0 0 1 -1 0,
 0 0 0 1 -1) prefix=diff;

run;

```

Since this **MODEL** statement requests no options for type of sums of squares, the procedure uses Type I and Type III sums of squares. The first **MANOVA** statement specifies A as the hypothesis effect and B(A) as the error effect. As a result of the **PRINTH** option, the procedure displays the hypothesis SSCP matrix associated with the A effect; and, as a result of the **PRINTE** option, the procedure displays the error SSCP matrix associated with the B(A) effect. The option **HTYPE=1** specifies a Type I H matrix, and the option **ETYPE=1** specifies a Type I E matrix.

The second **MANOVA** statement specifies B(A) as the hypothesis effect. Since no error effect is specified, PROC GLM uses the error SSCP matrix from the analysis as the E matrix. The **PRINTE** option displays this E matrix. Since the E matrix is the error SSCP matrix from the analysis, the partial correlation matrix computed from this matrix is also produced.

The third **MANOVA** statement requests the same analysis as the first **MANOVA** statement, but the analysis is carried out for variables transformed to be successive differences between the original dependent variables. The option **PREFIX=DIFF** labels the transformed variables as DIFF1, DIFF2, DIFF3, and DIFF4.

Finally, the fourth **MANOVA** statement has the identical effect as the third, but it uses an alternative form of the **M=** specification. Instead of specifying a set of equations, the fourth **MANOVA** statement specifies rows of a matrix of coefficients for the five dependent variables.

As a second example of the use of the **M=** specification, consider the following:

```

proc glm;
 class group;
 model dose1-dose4=group / nouni;
 manova h = group
 m = -3*dose1 - dose2 + dose3 + 3*dose4,
 dose1 - dose2 - dose3 + dose4,
 -dose1 + 3*dose2 - 3*dose3 + dose4
 mnames = Linear Quadratic Cubic
 / printe;

run;

```

The **M=** specification gives a transformation of the dependent variables dose1 through dose4 into orthogonal polynomial components, and the **MNAMES=** option labels the transformed variables LINEAR, QUADRATIC, and CUBIC, respectively. Since the **PRINTE** option is specified and the default residual matrix is used as an error term, the partial correlation matrix of the orthogonal polynomial components is also produced.

---

## MEANS Statement

**MEANS** *effects* *</ options >* ;

Within each group corresponding to each effect specified in the **MEANS** statement, PROC GLM computes the arithmetic means and standard deviations of all continuous variables in the model (both dependent and

independent). You can specify only classification effects in the MEANS statement—that is, effects that contain only classification variables.

Note that the arithmetic means are not adjusted for other effects in the model; for adjusted means, see the section “LSMEANS Statement” on page 3293.

If you use a WEIGHT statement, PROC GLM computes weighted means; see the section “Weighted Means” on page 3363.

You can also specify options to perform multiple comparisons. However, the MEANS statement performs multiple comparisons only for main-effect means; for multiple comparisons of interaction means, see the section “LSMEANS Statement” on page 3293.

You can use any number of MEANS statements, provided that they appear after the MODEL statement. For example, suppose A and B each have two levels. Then, if you use the statements

```
proc glm;
 class A B;
 model Y=A B A*B;
 means A B / tukey;
 means A*B;
run;
```

the means, standard deviations, and Tukey’s multiple comparisons tests are displayed for each level of the main effects A and B, and just the means and standard deviations are displayed for each of the four combinations of levels for A\*B. Since multiple comparisons tests apply only to main effects, the single MEANS statement

```
means A B A*B / tukey;
```

produces the same results.

PROC GLM does not compute means for interaction effects containing continuous variables. Thus, if you have the model

```
class A;
model Y=A X A*X;
```

then the effects X and A\*X cannot be used in the MEANS statement. However, if you specify the effect A in the means statement

```
means A;
```

then PROC GLM, by default, displays within-A arithmetic means of both Y and X. You can use the DEONLY option to display means of only the dependent variables.

```
means A / deonly;
```

If you use a WEIGHT statement, PROC GLM computes weighted means and estimates their variance as inversely proportional to the corresponding sum of weights (see the section “Weighted Means” on page 3363). However, note that the statistical interpretation of multiple comparison tests for weighted means is not well understood. See the section “Multiple Comparisons” on page 3349 for formulas. Table 42.8 summarizes the options available in the MEANS statement.

**Table 42.8** MEANS Statement Options

| Option                                                          | Description                                                                                                     |
|-----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Modify output</b>                                            |                                                                                                                 |
| DEONLY                                                          | Displays only means for the dependent variables                                                                 |
| <b>Perform multiple comparison tests</b>                        |                                                                                                                 |
| BON                                                             | Performs Bonferroni $t$ tests                                                                                   |
| DUNCAN                                                          | Performs Duncan's multiple range test                                                                           |
| DUNETT                                                          | Performs Dunnett's two-tailed $t$ test                                                                          |
| DUNETTL                                                         | Performs Dunnett's lower one-tailed $t$ test                                                                    |
| DUNETTU                                                         | Performs Dunnett's upper one-tailed $t$ test                                                                    |
| GABRIEL                                                         | Performs Gabriel's multiple-comparison procedure                                                                |
| REGWQ                                                           | Performs the Ryan-Einot-Gabriel-Welsch multiple range test                                                      |
| SCHEFFE                                                         | Performs Scheffé's multiple-comparison procedure                                                                |
| SIDAK                                                           | Performs pairwise $t$ tests on differences between means                                                        |
| SMM or GT2                                                      | Performs pairwise comparisons based on the studentized maximum modulus and Sidak's uncorrelated- $t$ inequality |
| SNK                                                             | Performs the Student-Newman-Keuls multiple range test                                                           |
| T or LSD                                                        | Performs pairwise $t$ tests                                                                                     |
| TUKEY                                                           | Performs Tukey's studentized range test (HSD)                                                                   |
| WALLER                                                          | Performs the Waller-Duncan $k$ -ratio $t$ test                                                                  |
| <b>Specify additional details for multiple comparison tests</b> |                                                                                                                 |
| ALPHA=                                                          | Specifies the level of significance                                                                             |
| CLDIFF                                                          | Presents confidence intervals for all pairwise differences between means                                        |
| CLM                                                             | Presents results as intervals for the mean of each level of the variables                                       |
| E=                                                              | Specifies the error mean square used in the multiple comparisons                                                |
| ETYPE=                                                          | Specifies the type of mean square for the error effect                                                          |
| HTYPE=                                                          | Specifies the MS type for the hypothesis MS                                                                     |
| KRATIO=                                                         | Specifies the Type 1/Type 2 error seriousness ratio                                                             |
| LINES                                                           | Lists the means in descending order and indicating nonsignificant subsets by line segments                      |
| NOSORT                                                          | Prevents the means from being sorted into descending order                                                      |
| <b>Test for homogeneity of variances</b>                        |                                                                                                                 |
| HOVTEST                                                         | Requests a homogeneity of variance test                                                                         |
| <b>Compensate for heterogeneous variances</b>                   |                                                                                                                 |
| WELCH                                                           | Requests the variance-weighted one-way ANOVA of Welch (1951)                                                    |

The options available in the MEANS statement are described in the following list.

**ALPHA=**

ALPHA= $p$  specifies the level of significance for comparisons among the means. By default,  $p$  is equal to the value of the ALPHA= option in the PROC GLM statement or 0.05 if that option is not specified. You can specify any value greater than 0 and less than 1.

**BON**

performs Bonferroni  $t$  tests of differences between means for all main-effect means in the MEANS statement. See the **CLDIFF** and **LINES** options for a discussion of how the procedure displays results.

**CLDIFF**

presents results of the **BON**, **GABRIEL**, **SCHEFFE**, **SIDAK**, **SMM**, **GT2**, **T**, **LSD**, and **TUKEY** options as confidence intervals for all pairwise differences between means, and the results of the **DUNNETT**, **DUNNETTU**, and **DUNNETTL** options as confidence intervals for differences with the control. The **CLDIFF** option is the default for unequal cell sizes unless the **DUNCAN**, **REGWQ**, **SNK**, or **WALLER** option is specified.

**CLM**

presents results of the **BON**, **GABRIEL**, **SCHEFFE**, **SIDAK**, **SMM**, **T**, and **LSD** options as intervals for the mean of each level of the variables specified in the MEANS statement. For all options except **GABRIEL**, the intervals are confidence intervals for the true means. For the **GABRIEL** option, they are *comparison intervals* for comparing means pairwise: in this case, if the intervals corresponding to two means overlap, then the difference between them is insignificant according to Gabriel's method.

**DEPONLY**

displays only means for the dependent variables. By default, PROC GLM produces means for all continuous variables, including continuous independent variables.

**DUNCAN**

performs Duncan's multiple range test on all main-effect means given in the MEANS statement. See the **LINES** option for a discussion of how the procedure displays results.

**DUNNETT** <(formatted-control-values)>

performs Dunnett's two-tailed  $t$  test, testing if any treatments are significantly different from a single control for all main-effect means in the MEANS statement.

To specify which level of the effect is the control, enclose the formatted value in quotes and parentheses after the keyword. If more than one effect is specified in the MEANS statement, you can use a list of control values within the parentheses. By default, the first level of the effect is used as the control. For example:

```
means A / dunnnett('CONTROL');
```

where CONTROL is the formatted control value of A. As another example:

```
means A B C / dunnnett('CNTLA' 'CNTLB' 'CNTLC');
```

where CNTLA, CNTLB, and CNTLC are the formatted control values for A, B, and C, respectively.

**DUNNETTL** <(formatted-control-value)>

performs Dunnett's one-tailed  $t$  test, testing if any treatment is significantly less than the control. Control level information is specified as described for the **DUNNETT** option.

**DUNNETTU** < (*formatted-control-value*) >

performs Dunnett's one-tailed *t* test, testing if any treatment is significantly greater than the control. Control level information is specified as described for the **DUNNETT** option.

**E=effect**

specifies the error mean square used in the multiple comparisons. By default, PROC GLM uses the overall residual or error mean square (MS). The effect specified with the E= option must be a term in the model; otherwise, the procedure uses the residual MS.

**ETYPE=*n***

specifies the type of mean square for the error effect. When you specify E=*effect*, you might need to indicate which type (1, 2, 3, or 4) of MS is to be used. The *n* value must be one of the types specified in or implied by the **MODEL** statement. The default MS type is the highest type used in the analysis.

**GABRIEL**

performs Gabriel's multiple-comparison procedure on all main-effect means in the MEANS statement. See the **CLDIFF** and **LINES** options for discussions of how the procedure displays results.

**GT2**

See the **SMM** option.

**HOVTEST****HOVTEST=BARTLETT****HOVTEST=BF****HOVTEST=LEVENE** < ( **TYPE= ABS | SQUARE** ) >**HOVTEST=OBRIEN** < ( **W=number** ) >

requests a homogeneity of variance test for the groups defined by the MEANS effect. You can optionally specify a particular test; if you do not specify a test, Levene's test (Levene 1960) with TYPE=SQUARE is computed. Note that this option is ignored unless your **MODEL** statement specifies a simple one-way model.

The HOVTEST=BARTLETT option specifies Bartlett's test (Bartlett 1937), a modification of the normal-theory likelihood ratio test.

The HOVTEST=BF option specifies Brown and Forsythe's variation of Levene's test (Brown and Forsythe 1974).

The HOVTEST=LEVENE option specifies Levene's test (Levene 1960), which is widely considered to be the standard homogeneity of variance test. You can use the TYPE= option in parentheses to specify whether to use the absolute residuals (TYPE=ABS) or the squared residuals (TYPE=SQUARE) in Levene's test. TYPE=SQUARE is the default.

The HOVTEST=OBRIEN option specifies O'Brien's test (O'Brien 1979), which is basically a modification of HOVTEST=LEVENE(TYPE=SQUARE). You can use the W= option in parentheses to tune the variable to match the suspected kurtosis of the underlying distribution. By default, W=0.5, as suggested by O'Brien (1979, 1981).

See the section "Homogeneity of Variance in One-Way Models" on page 3362 for more details on these methods. [Example 42.10](#) illustrates the use of the HOVTEST and **WELCH** options in the MEANS statement in testing for equal group variances and adjusting for unequal group variances in a one-way ANOVA.

**HTYPE=*n***

specifies the MS type for the hypothesis MS. The HTYPE= option is needed only when the **WALLER** option is specified. The default HTYPE= value is the highest type used in the model.

**KRATIO=*value***

specifies the Type 1/Type 2 error seriousness ratio for the Waller-Duncan test. Reasonable values for the KRATIO= option are 50, 100, 500, which roughly correspond for the two-level case to **ALPHA** levels of 0.1, 0.05, and 0.01, respectively. By default, the procedure uses the value of 100.

**LINES**

presents results of the **BON**, **DUNCAN**, **GABRIEL**, **REGWQ**, **SCHEFFE**, **SIDAK**, **SMM**, **GT2**, **SNK**, **T**, **LSD**, **TUKEY**, and **WALLER** options by listing the means in descending order and indicating nonsignificant subsets by line segments beside the corresponding means. The **LINES** option is appropriate for equal cell sizes, for which it is the default. The **LINES** option is also the default if the **DUNCAN**, **REGWQ**, **SNK**, or **WALLER** option is specified, or if there are only two cells of unequal size. The **LINES** option cannot be used in combination with the **DUNNETT**, **DUNNETTL**, or **DUNNETTU** option. In addition, the procedure has a restriction that no more than 24 overlapping groups of means can exist. If a mean belongs to more than 24 groups, the procedure issues an error message. You can either reduce the number of levels of the variable or use a multiple comparison test that allows the **CLDIFF** option rather than the **LINES** option.

**NOTE:** If the cell sizes are unequal, the harmonic mean of the cell sizes is used to compute the critical ranges. This approach is reasonable if the cell sizes are not too different, but it can lead to liberal tests if the cell sizes are highly disparate. In this case, you should not use the **LINES** option for displaying multiple comparisons results; use the **TUKEY** and **CLDIFF** options instead.

**LSD**

See the **T** option.

**NOSORT**

prevents the means from being sorted into descending order when the **CLDIFF** or **CLM** option is specified.

**REGWQ**

performs the Ryan-Einot-Gabriel-Welsch multiple range test on all main-effect means in the **MEANS** statement. See the **LINES** option for a discussion of how the procedure displays results.

**SCHEFFE**

performs Scheffé's multiple-comparison procedure on all main-effect means in the **MEANS** statement. See the **CLDIFF** and **LINES** options for discussions of how the procedure displays results.

**SIDAK**

performs pairwise *t* tests on differences between means with levels adjusted according to Sidak's inequality for all main-effect means in the **MEANS** statement. See the **CLDIFF** and **LINES** options for discussions of how the procedure displays results.

**SMM****GT2**

performs pairwise comparisons based on the studentized maximum modulus and Sidak's uncorrelated-*t* inequality, yielding Hochberg's GT2 method when sample sizes are unequal, for all main-effect means in the **MEANS** statement. See the **CLDIFF** and **LINES** options for discussions of how the procedure displays results.

**SNK**

performs the Student-Newman-Keuls multiple range test on all main-effect means in the MEANS statement. See the [LINES](#) option for discussions of how the procedure displays results.

**T****LSD**

performs pairwise *t* tests, equivalent to Fisher's least significant difference test in the case of equal cell sizes, for all main-effect means in the MEANS statement. See the [CLDIFF](#) and [LINES](#) options for discussions of how the procedure displays results.

**TUKEY**

performs Tukey's studentized range test (HSD) on all main-effect means in the MEANS statement. (When the group sizes are different, this is the Tukey-Kramer test.) See the [CLDIFF](#) and [LINES](#) options for discussions of how the procedure displays results.

**WALLER**

performs the Waller-Duncan *k*-ratio *t* test on all main-effect means in the MEANS statement. See the [KRATIO=](#) and [HTYPE=](#) options for information about controlling details of the test, and the [LINES](#) option for a discussion of how the procedure displays results.

**WELCH**

requests the variance-weighted one-way ANOVA of Welch (1951). This alternative to the usual analysis of variance for a one-way model is robust to the assumption of equal within-group variances. This option is ignored unless your [MODEL](#) statement specifies a simple one-way model.

Note that using the [WELCH](#) option merely produces one additional table consisting of Welch's ANOVA. It does not affect all of the other tests displayed by the GLM procedure, which still require the assumption of equal variance for exact validity.

See the section "Homogeneity of Variance in One-Way Models" on page 3362 for more details on Welch's ANOVA. [Example 42.10](#) illustrates the use of the [HOVTEST](#) and [WELCH](#) options in the MEANS statement in testing for equal group variances and adjusting for unequal group variances in a one-way ANOVA.

---

## MODEL Statement

**MODEL** *dependent-variables = independent-effects* </ options > ;

The MODEL statement names the dependent variables and independent effects. The syntax of effects is described in the section "[Specification of Effects](#)" on page 3324. For any model effect involving classification variables (interactions as well as main effects), the number of levels cannot exceed 32,767. If no independent effects are specified, only an intercept term is fit. You can specify only one MODEL statement (in contrast to the REG procedure, for example, which allows several MODEL statements in the same PROC REG run).

[Table 42.9](#) summarizes the options available in the MODEL statement.

**Table 42.9** MODEL Statement Options

| Option                                         | Description                                                                                |
|------------------------------------------------|--------------------------------------------------------------------------------------------|
| <b>Produce effect size information</b>         |                                                                                            |
| EFFECTSIZE                                     | Adds measures of effect size to each analysis of variance table                            |
| <b>Produce tests for the intercept</b>         |                                                                                            |
| INTERCEPT                                      | Produces the hypothesis tests associated with the intercept                                |
| <b>Omit the intercept parameter from model</b> |                                                                                            |
| NOINT                                          | Omits the intercept parameter from the model                                               |
| <b>Produce parameter estimates</b>             |                                                                                            |
| SOLUTION                                       | Produces parameter estimates                                                               |
| <b>Produce tolerance analysis</b>              |                                                                                            |
| TOLERANCE                                      | Displays the tolerances used in the SWEEP routine                                          |
| <b>Suppress univariate tests and output</b>    |                                                                                            |
| NOUNI                                          | Suppresses the display of univariate statistics                                            |
| <b>Display estimable functions</b>             |                                                                                            |
| E                                              | Displays the general form of all estimable functions                                       |
| E1                                             | Displays the Type I estimable functions and computes sums of squares                       |
| E2                                             | Displays the Type II estimable functions and computes sums of squares                      |
| E3                                             | Displays the Type III estimable functions and computes sums of squares                     |
| E4                                             | Displays the Type IV estimable functions computes sums of squares                          |
| ALIASING                                       | Specifies that the estimable functions should be displayed as an <i>aliasing structure</i> |
| <b>Control hypothesis tests performed</b>      |                                                                                            |
| SS1                                            | Displays Type I sum of squares                                                             |
| SS2                                            | Displays Type II sum of squares                                                            |
| SS3                                            | Displays Type III sum of squares                                                           |
| SS4                                            | Displays Type IV sum of squares                                                            |
| <b>Produce confidence intervals</b>            |                                                                                            |
| ALPHA=                                         | Specifies the level of significance                                                        |
| CLI                                            | Produces confidence limits for individual predicted values                                 |
| CLM                                            | Produces confidence limits for a mean predicted value                                      |
| CLPARM                                         | Produces confidence limits for the parameter estimates                                     |
| <b>Display predicted and residual values</b>   |                                                                                            |
| P                                              | Displays observed, predicted, and residual values                                          |
| <b>Display intermediate calculations</b>       |                                                                                            |
| INVERSE                                        | Displays the augmented inverse (or generalized inverse) $X'X$ matrix                       |
| XPX                                            | Displays the augmented $X'X$ crossproducts matrix                                          |
| <b>Tune sensitivity</b>                        |                                                                                            |
| SINGULAR=                                      | Tunes the sensitivity of the regression routine to linear dependencies                     |
| ZETA=                                          | Tunes the sensitivity of the check for estimability for Type III and Type IV functions     |

The options available in the MODEL statement are described in the following list.

**ALIASING**

specifies that the estimable functions should be displayed as an *aliasing structure*, for which each row says which linear combination of the parameters is estimated by each estimable function; also, this option adds a column of the same information to the table of parameter estimates, giving for each parameter the expected value of the estimate associated with that parameter. This option is most useful in fractional factorial experiments that can be analyzed without a **CLASS** statement.

**ALPHA= $p$** 

specifies the level of significance  $p$  for  $100(1 - p)\%$  confidence intervals. By default,  $p$  is equal to the value of the **ALPHA=** option in the **PROC GLM** statement, or 0.05 if that option is not specified. You can use values between 0 and 1.

**CLI**

produces confidence limits for individual predicted values for each observation. The CLI option is ignored if the **CLM** option is also specified.

**CLM**

produces confidence limits for a mean predicted value for each observation.

**CLPARM**

produces confidence limits for the parameter estimates (if the **SOLUTION** option is also specified) and for the results of all **ESTIMATE** statements.

**E**

displays the general form of all estimable functions. This is useful for determining the order of parameters when you are writing **CONTRAST** and **ESTIMATE** statements.

**E1**

displays the Type I estimable functions for each effect in the model and computes the corresponding sums of squares.

**E2**

displays the Type II estimable functions for each effect in the model and computes the corresponding sums of squares.

**E3**

displays the Type III estimable functions for each effect in the model and computes the corresponding sums of squares.

**E4**

displays the Type IV estimable functions for each effect in the model and computes the corresponding sums of squares.

**EFFECTSIZE**

adds measures of effect size to each analysis of variance table displayed by the procedure, except for those displayed by the **TEST** option in the **RANDOM** statement, by **CONTRAST** and **TEST** statements with the **E=** option, and by **MANOVA** and **REPEATED** statements. The effect size measures include the intraclass correlation and both estimates and confidence intervals for the noncentrality for the  $F$  test, as well as for the semipartial and partial correlation ratios. For more information about the computation and interpretation of these measures, see the section “Effect Size Measures for  $F$  Tests in GLM” on page 3338.

**INTERCEPT****INT**

produces the hypothesis tests associated with the intercept as an effect in the model. By default, the procedure includes the intercept in the model but does not display associated tests of hypotheses. Except for producing the uncorrected total sum of squares instead of the corrected total sum of squares, the INT option is ignored when you use an **ABSORB** statement.

**INVERSE****I**

displays the augmented inverse (or generalized inverse)  $X'X$  matrix:

$$\begin{bmatrix} (X'X)^{-} & (X'X)^{-}X'y \\ y'X(X'X)^{-} & y'y - y'X(X'X)^{-}X'y \end{bmatrix}$$

The upper-left corner is the generalized inverse of  $X'X$ , the upper-right corner is the parameter estimates, and the lower-right corner is the error sum of squares.

**NOINT**

omits the intercept parameter from the model. The NOINT option is ignored when you use an **ABSORB** statement.

**NOUNI**

suppresses the display of univariate statistics. You typically use the NOUNI option with a multivariate or repeated measures analysis of variance when you do not need the standard univariate results. The NOUNI option in a MODEL statement does not affect the univariate output produced by the **REPEATED** statement.

**P**

displays observed, predicted, and residual values for each observation that does not contain missing values for independent variables. The Durbin-Watson statistic is also displayed when the P option is specified. The PRESS statistic is also produced if either the **CLM** or **CLI** option is specified.

**SINGULAR=*number***

tunes the sensitivity of the regression routine to linear dependencies in the design. If a diagonal pivot element is less than  $C \times \textit{number}$  as PROC GLM sweeps the  $X'X$  matrix, the associated design column is declared to be linearly dependent with previous columns, and the associated parameter is zeroed.

The  $C$  value adjusts the check to the relative scale of the variable. The  $C$  value is equal to the corrected sum of squares for the variable, unless the corrected sum of squares is 0, in which case  $C$  is 1. If you specify the **NOINT** option but not the **ABSORB** statement, PROC GLM uses the uncorrected sum of squares instead.

The default value of the SINGULAR= option,  $10^{-7}$ , might be too small, but this value is necessary in order to handle the high-degree polynomials used in the literature to compare regression routines.

**SOLUTION**

produces a solution to the normal equations (parameter estimates). PROC GLM displays a solution by default when your model involves no classification variables, so you need this option only if you want to see the solution for models with classification effects.

**SS1**

displays the sum of squares associated with Type I estimable functions for each effect. These are also displayed by default.

**SS2**

displays the sum of squares associated with Type II estimable functions for each effect.

**SS3**

displays the sum of squares associated with Type III estimable functions for each effect. These are also displayed by default.

**SS4**

displays the sum of squares associated with Type IV estimable functions for each effect.

**TOLERANCE**

displays the tolerances used in the SWEEP routine. The tolerances are of the form C/USS or C/CSS, as described in the discussion of the **SINGULAR=** option. The tolerance value for the intercept is not divided by its uncorrected sum of squares.

**XPX**

displays the augmented  $X'X$  crossproducts matrix:

$$\begin{bmatrix} X'X & X'y \\ y'X & y'y \end{bmatrix}$$

**ZETA=value**

tunes the sensitivity of the check for estimability for Type III and Type IV functions. Any element in the estimable function basis with an absolute value less than the ZETA= option is set to zero. The default value for the ZETA= option is  $10^{-8}$ .

Although it is possible to generate data for which this absolute check can be defeated, the check suffices in most practical examples. Additional research is needed in order to make this check relative rather than absolute.

---

## OUTPUT Statement

**OUTPUT** < **OUT=SAS-data-set** > *keyword=names* < . . . *keyword=names* > < *option* > ;

The OUTPUT statement creates a new SAS data set that saves diagnostic measures calculated after fitting the model. At least one specification of the form *keyword=names* is required.

All the variables in the original data set are included in the new data set, along with variables created in the OUTPUT statement. These new variables contain the values of a variety of diagnostic measures that are calculated for each observation in the data set. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

Details on the specifications in the OUTPUT statement follow.

**keyword=names**

specifies the statistics to include in the output data set and provides names to the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable or variables to contain the statistic.

In the output data set, the first variable listed after a keyword in the OUTPUT statement contains that statistic for the first dependent variable listed in the MODEL statement; the second variable contains the statistic for the second dependent variable in the MODEL statement, and so on. The list of variables following the equal sign can be shorter than the list of dependent variables in the MODEL statement. In this case, the procedure creates the new names in order of the dependent variables in the MODEL statement. See the section “Examples” on page 3315.

The keywords allowed and the statistics they represent are as follows:

**COOKD**

Cook’s  $D$  influence statistic

**COVRATIO**

standard influence of observation on covariance of parameter estimates

**DFFITS**

standard influence of observation on predicted value

**H**

leverage,  $h_i = x_i(\mathbf{X}'\mathbf{X})^{-1}x_i'$

**LCL**

lower bound of a  $100(1 - p)\%$  confidence interval for an individual prediction. The  $p$ -level is equal to the value of the ALPHA= option in the OUTPUT statement or, if this option is not specified, to the ALPHA= option in the PROC GLM statement. If neither of these options is set, then  $p = 0.05$  by default, resulting in the lower bound for a 95% confidence interval. The interval also depends on the variance of the error, as well as the variance of the parameter estimates. For the corresponding upper bound, see the UCL keyword.

**LCLM**

lower bound of a  $100(1 - p)\%$  confidence interval for the expected value (mean) of the predicted value. The  $p$ -level is equal to the value of the ALPHA= option in the OUTPUT statement or, if this option is not specified, to the ALPHA= option in the PROC GLM statement. If neither of these options is set, then  $p = 0.05$  by default, resulting in the lower bound for a 95% confidence interval. For the corresponding upper bound, see the UCLM keyword.

**PREDICTED | P**

predicted values

**PRESS**

residual for the  $i$ th observation that results from dropping it and predicting it on the basis of all other observations. This is the residual divided by  $(1 - h_i)$ , where  $h_i$  is the leverage, defined previously.

**RESIDUAL | R**

residuals, calculated as ACTUAL – PREDICTED

**RSTUDENT**

a studentized residual with the current observation deleted

**STDI**

standard error of the individual predicted value

**STDP**

standard error of the mean predicted value

**STDR**

standard error of the residual

**STUDENT**

studentized residuals, the residual divided by its standard error

**UCL**

upper bound of a  $100(1 - p)\%$  confidence interval for an individual prediction. The  $p$ -level is equal to the value of the **ALPHA=** option in the OUTPUT statement or, if this option is not specified, to the **ALPHA=** option in the PROC GLM statement. If neither of these options is set, then  $p = 0.05$  by default, resulting in the upper bound for a 95% confidence interval. The interval also depends on the variance of the error, as well as the variance of the parameter estimates. For the corresponding lower bound, see the **LCL** keyword.

**UCLM**

upper bound of a  $100(1 - p)\%$  confidence interval for the expected value (mean) of the predicted value. The  $p$ -level is equal to the value of the **ALPHA=** option in the OUTPUT statement or, if this option is not specified, to the **ALPHA=** option in the PROC GLM statement. If neither of these options is set, then  $p = 0.05$  by default, resulting in the upper bound for a 95% confidence interval. For the corresponding lower bound, see the **LCLM** keyword.

**OUT=SAS-data-set**

gives the name of the new data set. By default, the procedure uses the  $DATA_n$  convention to name the new data set.

The following option is available in the OUTPUT statement and is specified after a slash (/):

**ALPHA= $p$** 

specifies the level of significance  $p$  for  $100(1 - p)\%$  confidence intervals. By default,  $p$  is equal to the value of the **ALPHA=** option in the PROC GLM statement or 0.05 if that option is not specified. You can use values between 0 and 1.

See Chapter 4, “Introduction to Regression Procedures,” and the section “Influence Statistics” on page 6717 in Chapter 79, “The REG Procedure,” for details on the calculation of these statistics.

**Examples**

The following statements show the syntax for creating an output data set with a single dependent variable.

```

proc glm;
 class a b;
 model y=a b a*b;
 output out=new p=yhat r=resid stdr=eresid;
run;

```

These statements create an output data set named `new`. In addition to all the variables from the original data set, `new` contains the variable `yhat`, with values that are predicted values of the dependent variable `y`; the variable `resid`, with values that are the residual values of `y`; and the variable `eresid`, with values that are the standard errors of the residuals.

The following statements show a situation with five dependent variables.

```

proc glm;
 by group;
 class a;
 model y1-y5=a x(a);
 output out=pout predicted=py1-py5;
run;

```

The data set `pout` contains five new variables, `py1` through `py5`. The values of `py1` are the predicted values of `y1`; the values of `py2` are the predicted values of `y2`; and so on.

For more information about the data set produced by the `OUTPUT` statement, see the section “[Output Data Sets](#)” on page 3382.

## RANDOM Statement

**RANDOM** *effects* *</ options >* ;

When some model effects are random (that is, assumed to be sampled from a normal population of effects), you can specify these effects in the `RANDOM` statement in order to compute the expected values of mean squares for various model effects and contrasts and, optionally, to perform random effects analysis of variance tests. You can use as many `RANDOM` statements as you want, provided that they appear after the `MODEL` statement. If you use a `CONTRAST` statement with a `RANDOM` statement and you want to obtain the expected mean squares for the contrast hypothesis, you must enter the `CONTRAST` statement before the `RANDOM` statement.

**NOTE:** PROC GLM uses only the information pertaining to expected mean squares when you specify the `TEST` option in the `RANDOM` statement and, even then, only in the extra  $F$  tests produced by the `RANDOM` statement. Other features in the GLM procedure—including the results of the `LSMEANS` and `ESTIMATE` statements—assume that all effects are fixed, so that all tests and estimability checks for these statements are based on a fixed-effects model, even when you use a `RANDOM` statement. Therefore, you should use the `MIXED` procedure to compute tests involving these features that take the random effects into account; see the section “[PROC GLM versus PROC MIXED for Random-Effects Analysis](#)” on page 3375 and Chapter 59, “[The MIXED Procedure](#),” for more information.

When you use the `RANDOM` statement, by default the GLM procedure produces the Type III expected mean squares for model effects and for contrasts specified before the `RANDOM` statement in the program statements. In order to obtain expected values for other types of mean squares, you need to specify which

types of mean squares are of interest in the **MODEL** statement. See the section “[Computing Type I, II, and IV Expected Mean Squares](#)” on page 3378 for more information.

The list of effects in the **RANDOM** statement should contain one or more of the pure classification effects specified in the **MODEL** statement (that is, main effects, crossed effects, or nested effects involving only classification variables). The coefficients corresponding to each effect specified are assumed to be normally and independently distributed with common variance. Levels in different effects are assumed to be independent.

You can specify the following options in the **RANDOM** statement after a slash (/):

#### **Q**

displays all quadratic forms in the fixed effects that appear in the expected mean squares. For some designs, such as large mixed-level factorials, the **Q** option might generate a substantial amount of output.

#### **TEST**

performs hypothesis tests for each effect specified in the model, using appropriate error terms as determined by the expected mean squares.

**CAUTION:** PROC GLM does not automatically declare interactions to be random when the effects in the interaction are declared random. For example,

```
random a b / test;
```

does not produce the same expected mean squares or tests as

```
random a b a*b / test;
```

To ensure correct tests, you need to list all random interactions and random main effects in the **RANDOM** statement.

See the section “[Random-Effects Analysis](#)” on page 3375 for more information about the calculation of expected mean squares and tests and on the similarities and differences between the GLM and MIXED procedures. See Chapter 5, “[Introduction to Analysis of Variance Procedures](#),” and Chapter 59, “[The MIXED Procedure](#),” for more information about random effects.

---

## **REPEATED Statement**

```
REPEATED factor-specification </ options > ;
```

When values of the dependent variables in the **MODEL** statement represent repeated measurements on the same experimental unit, the **REPEATED** statement enables you to test hypotheses about the measurement factors (often called *within-subject factors*) as well as the interactions of within-subject factors with independent variables in the **MODEL** statement (often called *between-subject factors*). The **REPEATED** statement provides multivariate and univariate tests as well as hypothesis tests for a variety of single-degree-of-freedom contrasts. There is no limit to the number of within-subject factors that can be specified.

The **REPEATED** statement is typically used for handling repeated measures designs with one repeated response variable. Usually, the variables on the left-hand side of the equation in the **MODEL** statement

represent one repeated response variable. This does not mean that only one factor can be listed in the REPEATED statement. For example, one repeated response variable (hemoglobin count) might be measured 12 times (implying variables Y1 to Y12 on the left-hand side of the equal sign in the MODEL statement), with the associated within-subject factors treatment and time (implying two factors listed in the REPEATED statement). See the section “Examples” on page 3321 for an example of how PROC GLM handles this case.

Designs with two or more repeated response variables can, however, be handled with the IDENTITY transformation; see the description of this transformation in the following section, and see Example 42.9 for an example of analyzing a doubly multivariate repeated measures design.

When a REPEATED statement appears, the GLM procedure enters a multivariate mode of handling missing values. If any values for variables corresponding to each combination of the within-subject factors are missing, the observation is excluded from the analysis.

If you use a CONTRAST or TEST statement with a REPEATED statement, you must enter the CONTRAST or TEST statement before the REPEATED statement.

The simplest form of the REPEATED statement requires only a *factor-name*. With two repeated factors, you must specify the *factor-name* and number of levels (*levels*) for each factor. Optionally, you can specify the actual values for the levels (*level-values*), a *transformation* that defines single-degree-of-freedom contrasts, and *options* for additional analyses and output. When you specify more than one within-subject factor, the *factor-names* (and associated level and transformation information) must be separated by a comma in the REPEATED statement.

These terms are described in the following section, “Syntax Details.”

## Syntax Details

Table 42.10 summarizes the options available in the REPEATED statement.

**Table 42.10** REPEATED Statement Options

| Option    | Description                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------|
| CANONICAL | Performs a canonical analysis of the <b>H</b> and <b>E</b> matrices                                    |
| HTYPE=    | Specifies the type of the <b>H</b> matrix used for analysis                                            |
| MEAN      | Generates the overall arithmetic means of the within-subject variables                                 |
| MSTAT=    | Specifies the method of evaluating the test statistics                                                 |
| NOM       | Displays only univariate analyses results                                                              |
| NOU       | Displays only multivariate analyses results                                                            |
| PRINTE    | Displays <b>E</b> and partial correlation matrices for multivariate tests, and prints sphericity tests |
| PRINTH    | Displays the <b>H</b> matrices for multivariate tests                                                  |
| PRINTM    | Displays the transformation matrices that define tested contrasts                                      |
| PRINTRV   | Displays characteristic roots and vectors for multivariate tests                                       |
| SUMMARY   | Produces analysis-of-variance tables for univariate tests                                              |
| UEPSDEF=  | Specifies the <i>F</i> test adjustment for univariate tests                                            |

You can specify the following terms in the REPEATED statement.

*factor-specification*

The *factor-specification* for the REPEATED statement can include any number of individual factor specifications, separated by commas, of the following form:

*factor-name levels* < (*level-values*) > < *transformation* >

where

*factor-name* names a factor to be associated with the dependent variables. The name should not be the same as any variable name that already exists in the data set being analyzed and should conform to the usual conventions of SAS variable names.

When specifying more than one factor, list the dependent variables in the **MODEL** statement so that the within-subject factors defined in the REPEATED statement are nested; that is, the first factor defined in the REPEATED statement should be the one with values that change least frequently.

*levels* gives the number of levels associated with the factor being defined. When there is only one within-subject factor, the number of levels is equal to the number of dependent variables. In this case, *levels* is optional. When more than one within-subject factor is defined, however, *levels* is required, and the product of the number of levels of all the factors must equal the number of dependent variables in the **MODEL** statement.

(*level-values*) gives values that correspond to levels of a repeated-measures factor. These values are used to label output and as spacings for constructing orthogonal polynomial contrasts if you specify a **POLYNOMIAL** transformation. The number of values specified must correspond to the number of levels for that factor in the REPEATED statement. Enclose the *level-values* in parentheses.

The following *transformation* keywords define single-degree-of-freedom contrasts for factors specified in the REPEATED statement. Since the number of contrasts generated is always one less than the number of levels of the factor, you have some control over which contrast is omitted from the analysis by which transformation you select. The only exception is the **IDENTITY** transformation; this transformation is not composed of contrasts and has the same degrees of freedom as the factor has levels. By default, the procedure uses the **CONTRAST** transformation.

**CONTRAST**< (*ordinal-reference-level*) >

generates contrasts between levels of the factor and a reference level. By default, the procedure uses the last level as the reference level; you can optionally specify a reference level in parentheses after the keyword **CONTRAST**. The reference level corresponds to the ordinal value of the level rather than the level value specified. For example, to generate contrasts between the first level of a factor and the other levels, use

**contrast** (1)

**HELMERT**

generates contrasts between each level of the factor and the mean of subsequent levels.

**IDENTITY**

generates an identity transformation corresponding to the associated factor. This transformation is *not* composed of contrasts; it has  $n$  degrees of freedom for an  $n$ -level factor, instead of  $n - 1$ . This can be used for doubly multivariate repeated measures.

**MEAN**

`<(ordinal-reference-level)>` generates contrasts between levels of the factor and the mean of all other levels of the factor. Specifying a reference level eliminates the contrast between that level and the mean. Without a reference level, the contrast involving the last level is omitted. See the CONTRAST transformation for an example.

**POLYNOMIAL**

generates orthogonal polynomial contrasts. Level values, if provided, are used as spacings in the construction of the polynomials; otherwise, equal spacing is assumed.

**PROFILE**

generates contrasts between adjacent levels of the factor.

You can specify the following options in the REPEATED statement after a slash (/).

**CANONICAL**

performs a canonical analysis of the **H** and **E** matrices corresponding to the transformed variables specified in the REPEATED statement.

**HTYPE= $n$** 

specifies the type of the **H** matrix used in the multivariate tests and the type of sums of squares used in the univariate tests. See the **HTYPE=** option in the specifications for the **MANOVA** statement for further details.

**MEAN**

generates the overall arithmetic means of the within-subject variables.

**MSTAT=FAPPROX | EXACT**

specifies the method of evaluating the test statistics for the multivariate analysis. The default is **MSTAT=FAPPROX**, which specifies that the multivariate tests are evaluated using the usual approximations based on the  $F$  distribution, as discussed in the section “Multivariate Tests” in Chapter 4, “Introduction to Regression Procedures.” Alternatively, you can specify **MSTAT=EXACT** to compute exact  $p$ -values for three of the four tests (Wilks’ lambda, the Hotelling-Lawley trace, and Roy’s greatest root) and an improved  $F$  approximation for the fourth (Pillai’s trace). While **MSTAT=EXACT** provides better control of the significance probability for the tests, especially for Roy’s greatest root, computations for the exact  $p$ -values can be appreciably more demanding, and are in fact infeasible for large problems (many dependent variables). Thus, although **MSTAT=EXACT** is more accurate for most data, it is not the default method. For more information about the results of **MSTAT=EXACT**, see the section “Multivariate Analysis of Variance” on page 3366.

**NOM**

displays only the results of the univariate analyses.

**NOU**

displays only the results of the multivariate analyses.

**PRINTE**

displays the **E** matrix for each combination of within-subject factors, as well as partial correlation matrices for both the original dependent variables and the variables defined by the transformations specified in the REPEATED statement. In addition, the PRINTE option provides sphericity tests for each set of transformed variables. If the requested transformations are not orthogonal, the PRINTE option also provides a sphericity test for a set of orthogonal contrasts.

**PRINTH**

displays the **H** (SSCP) matrix associated with each multivariate test.

**PRINTM**

displays the transformation matrices that define the contrasts in the analysis. PROC GLM always displays the **M** matrix so that the transformed variables are defined by the rows, not the columns, of the displayed **M** matrix. In other words, PROC GLM actually displays  $M'$ .

**PRINTRV**

displays the characteristic roots and vectors for each multivariate test.

**SUMMARY**

produces analysis-of-variance tables for each contrast defined by the within-subject factors. Along with tests for the effects of the independent variables specified in the MODEL statement, a term labeled MEAN tests the hypothesis that the overall mean of the contrast is zero.

**UEPSDEF=unbiased-epsilon-definition**

specifies the type of adjustment for the univariate  $F$  test that is displayed in addition to the Greenhouse-Geisser adjustment. The default is UEPSDEF=HFL, corresponding to the corrected form of the Huynh-Feldt adjustment (Huynh and Feldt 1976; Lecoutre 1991). Other alternatives are UEPSDEF=HF, the uncorrected Huynh-Feldt adjustment (the only available method in previous releases of SAS/STAT software), and UEPSDEF=CM, the adjustment of Chi et al. (2012). See the section “[Hypothesis Testing in Repeated Measures Analysis](#)” on page 3370 for details about these adjustments.

**Examples**

When specifying more than one factor, list the dependent variables in the MODEL statement so that the within-subject factors defined in the REPEATED statement are nested; that is, the first factor defined in the REPEATED statement should be the one with values that change least frequently. For example, assume that three treatments are administered at each of four times, for a total of twelve dependent variables on each experimental unit. If the variables are listed in the MODEL statement as Y1 through Y12, then the REPEATED statement in

```
proc glm;
 class group;
 model Y1-Y12=group / nouni;
 repeated trt 3, time 4;
run;
```

implies the following structure:

|               | Dependent Variables |    |    |    |    |    |    |    |    |     |     |     |
|---------------|---------------------|----|----|----|----|----|----|----|----|-----|-----|-----|
|               | Y1                  | Y2 | Y3 | Y4 | Y5 | Y6 | Y7 | Y8 | Y9 | Y10 | Y11 | Y12 |
| Value of trt  | 1                   | 1  | 1  | 1  | 2  | 2  | 2  | 2  | 3  | 3   | 3   | 3   |
| Value of time | 1                   | 2  | 3  | 4  | 1  | 2  | 3  | 4  | 1  | 2   | 3   | 4   |

The REPEATED statement always produces a table like the preceding one. For more information, see the section “[Repeated Measures Analysis of Variance](#)” on page 3367.

---

## STORE Statement

**STORE** <OUT=>*item-store-name* </ LABEL='label'> ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “[STORE Statement](#)” on page 501 in Chapter 19, “[Shared Concepts and Topics](#).”

---

## TEST Statement

**TEST** <H=*effects*> E=*effect* </ options> ;

By default, for each sum of squares in the analysis an  $F$  value is computed that uses the residual MS as an error term. Use a TEST statement to request additional  $F$  tests that use other effects as error terms. You need a TEST statement when a nonstandard error structure (as in a split-plot design) exists. Note, however, that this might not be appropriate if the design is unbalanced, since in most unbalanced designs with nonstandard error structures, mean squares are not necessarily independent with equal expectations under the null hypothesis.

**CAUTION:** The GLM procedure does not check any of the assumptions underlying the  $F$  statistic. When you specify a TEST statement, you assume sole responsibility for the validity of the  $F$  statistic produced. To help validate a test, you can use the [RANDOM](#) statement and inspect the expected mean squares, or you can use the [TEST](#) option of the [RANDOM](#) statement.

You can use as many TEST statements as you want, provided that they appear after the [MODEL](#) statement.

You can specify the following terms in the TEST statement.

### H=*effects*

specifies which effects in the preceding model are to be used as hypothesis (numerator) effects.

### E=*effect*

specifies one, and only one, effect to use as the error (denominator) term. The E= specification is required.

By default, the sum of squares type for all hypothesis sum of squares and error sum of squares is the highest type computed in the model. If the hypothesis type or error type is to be another type that was computed in the model, you should specify one or both of the following options after a slash (/).

**ETYPE=*n***

specifies the type of sum of squares to use for the error term. The type must be a type computed in the model (*n*=1, 2, 3, or 4).

**HTYPE=*n***

specifies the type of sum of squares to use for the hypothesis. The type must be a type computed in the model (*n*=1, 2, 3, or 4).

This example illustrates the TEST statement with a split-plot model:

```
proc glm;
 class a b c;
 model y=a b(a) c a*c b*c(a);
 test h=a e=b(a) / htype=1 etype=1;
 test h=c a*c e=b*c(a) / htype=1 etype=1;
run;
```

---

## WEIGHT Statement

**WEIGHT** *variable* ;

When a WEIGHT statement is used, a weighted residual sum of squares

$$\sum_i w_i (y_i - \hat{y}_i)^2$$

is minimized, where  $w_i$  is the value of the variable specified in the WEIGHT statement,  $y_i$  is the observed value of the response variable, and  $\hat{y}_i$  is the predicted value of the response variable.

If you specify the WEIGHT statement, it must appear before the first RUN statement or it is ignored.

An observation is used in the analysis only if the value of the WEIGHT statement variable is nonmissing and greater than zero.

The WEIGHT statement has no effect on degrees of freedom or number of observations, but it is used by the MEANS statement when calculating means and performing multiple comparison tests (as described in the section “MEANS Statement” on page 3303).

The normal equations used when a WEIGHT statement is present are

$$X'WX\beta = X'WY$$

where **W** is a diagonal matrix consisting of the values of the variable specified in the WEIGHT statement.

If the weights for the observations are proportional to the reciprocals of the error variances, then the weighted least squares estimates are best linear unbiased estimators (BLUE).

---

## Details: GLM Procedure

---

### Statistical Assumptions for Using PROC GLM

The basic statistical assumption underlying the least squares approach to general linear modeling is that the observed values of each dependent variable can be written as the sum of two parts: a fixed component  $x'\beta$ , which is a linear function of the independent coefficients, and a random noise, or error, component  $\epsilon$ :

$$y = x'\beta + \epsilon$$

The independent coefficients  $x$  are constructed from the model effects as described in the section “[Parameterization of PROC GLM Models](#)” on page 3327. Further, the errors for different observations are assumed to be uncorrelated with identical variances. Thus, this model can be written

$$E(Y) = \mathbf{X}\beta, \quad \text{Var}(Y) = \sigma^2 I$$

where  $Y$  is the vector of dependent variable values,  $\mathbf{X}$  is the matrix of independent coefficients,  $I$  is the identity matrix, and  $\sigma^2$  is the common variance for the errors. For multiple dependent variables, the model is similar except that the errors for different dependent variables within the same observation are not assumed to be uncorrelated. This yields a multivariate linear model of the form

$$E(Y) = \mathbf{X}B, \quad \text{Var}(\text{vec}(Y)) = \Sigma \otimes I$$

where  $Y$  and  $B$  are now matrices, with one column for each dependent variable,  $\text{vec}(Y)$  strings  $Y$  out by rows, and  $\otimes$  indicates the Kronecker matrix product.

Under the assumptions thus far discussed, the least squares approach provides estimates of the linear parameters that are unbiased and have minimum variance among linear estimators. Under the further assumption that the errors have a normal (or Gaussian) distribution, the least squares estimates are the maximum likelihood estimates and their distribution is known. All of the significance levels (“ $p$  values”) and confidence limits calculated by the GLM procedure require this assumption of normality in order to be exactly valid, although they are good approximations in many other cases.

---

### Specification of Effects

Each term in a model, called an *effect*, is a variable or combination of variables. Effects are specified with a special notation that uses variable names and operators. There are two kinds of variables: *classification* (or *CLASS*) *variables* and *continuous variables*. There are two primary operators: *crossing* and *nesting*. A third operator, the *bar operator*, is used to simplify effect specification.

In an analysis-of-variance model, independent variables must be variables that identify classification levels. In the SAS System, these are called *classification* (or *class*) *variables* and are declared in the **CLASS** statement. (They can also be called *categorical*, *qualitative*, *discrete*, or *nominal variables*.) Classification variables can be either *numeric* or *character*. The values of a classification variable are called *levels*. For example, the classification variable *Sex* has the levels “male” and “female.”

In a model, an independent variable that is not declared in the **CLASS** statement is assumed to be continuous. Continuous variables, which must be numeric, are used for response variables and covariates. For example, the heights and weights of subjects are continuous variables.

## Types of Effects

There are seven different types of effects used in the GLM procedure. In the following list, assume that A, B, C, D, and E are **CLASS** variables and that X1, X2, and Y are continuous variables:

- Regressor effects are specified by writing continuous variables by themselves: X1 X2.
- Polynomial effects are specified by joining two or more continuous variables with asterisks: X1\*X1 X1\*X2.
- Main effects are specified by writing **CLASS** variables by themselves: A B C.
- Crossed effects (interactions) are specified by joining classification variables with asterisks: A\*B B\*C A\*B\*C.
- Nested effects are specified by following a main effect or crossed effect with a classification variable or list of classification variables enclosed in parentheses. The main effect or crossed effect is nested within the effects listed in parentheses: B(A) C(B\*A) D\*E(C\*B\*A). In this example, B(A) is read “B nested within A.”
- Continuous-by-class effects are written by joining continuous variables and classification variables with asterisks: X1\*A.
- Continuous-nesting-class effects consist of continuous variables followed by a classification variable interaction enclosed in parentheses: X1(A) X1\*X2(A\*B).

One example of the general form of an effect involving several variables is

$$X1*X2*A*B*C(D*E)$$

This example contains crossed continuous terms by crossed classification terms nested within more than one classification variable. The continuous list comes first, followed by the crossed list, followed by the nesting list in parentheses. Note that asterisks can appear within the nested list but not immediately before the left parenthesis. For details on how the design matrix and parameters are defined with respect to the effects specified in this section, see the section “[Parameterization of PROC GLM Models](#)” on page 3327.

The **MODEL** statement and several other statements use these effects. Some examples of **MODEL** statements that use various kinds of effects are shown in the following table; a, b, and c represent classification variables, and y, y1, y2, x, and z represent continuous variables.

| Specification                       | Type of Model                              |
|-------------------------------------|--------------------------------------------|
| <code>model y=x;</code>             | Simple regression                          |
| <code>model y=x z;</code>           | Multiple regression                        |
| <code>model y=x x*x;</code>         | Polynomial regression                      |
| <code>model y1 y2=x z;</code>       | Multivariate regression                    |
| <code>model y=a;</code>             | One-way ANOVA                              |
| <code>model y=a b c;</code>         | Main-effects ANOVA                         |
| <code>model y=a b a*b;</code>       | Factorial ANOVA with interaction           |
| <code>model y=a b(a) c(b a);</code> | Nested ANOVA                               |
| <code>model y1 y2=a b;</code>       | Multivariate analysis of variance (MANOVA) |
| <code>model y=a x;</code>           | Analysis of covariance                     |
| <code>model y=a x(a);</code>        | Separate-slopes regression                 |
| <code>model y=a x x*a;</code>       | Homogeneity-of-slopes regression           |

## The Bar Operator

You can shorten the specification of a large factorial model by using the bar operator. For example, two ways of writing the model for a full three-way factorial model follow:

```
model Y = A B C A*B A*C B*C A*B*C;
```

```
model Y = A|B|C;
```

When the bar (|) is used, the right and left sides become effects, and the cross of them becomes an effect. Multiple bars are permitted. The expressions are expanded from left to right, using rules 2–4 given in Searle (1971, p. 390).

- Multiple bars are evaluated from left to right. For instance, A|B|C is evaluated as follows:

$$\begin{aligned}
 A|B|C &\rightarrow \{A|B\}|C \\
 &\rightarrow \{A B A*B\}|C \\
 &\rightarrow A B A*B C A*C B*C A*B*C
 \end{aligned}$$

- Crossed and nested groups of variables are combined. For example, A(B)|C(D) generates A\*C(B D), among other terms.
- Duplicate variables are removed. For example, A(C)|B(C) generates A\*B(C C), among other terms, and the extra C is removed.
- Effects are discarded if a variable occurs on both the crossed and nested parts of an effect. For instance, A(B)|B(D E) generates A\*B(B D E), but this effect is eliminated immediately.

You can also specify the maximum number of variables involved in any effect that results from bar evaluation by specifying that maximum number, preceded by an @ sign, at the end of the bar effect. For example, the

specification  $A | B | C @ 2$  would result in only those effects that contain 2 or fewer variables: in this case,  $A B A*B C A*C$  and  $B*C$ .

More examples of using the bar and at operators follow:

|                     |                  |                                   |
|---------------------|------------------|-----------------------------------|
| $A   C(B)$          | is equivalent to | $A C(B) A*C(B)$                   |
| $A(B)   C(B)$       | is equivalent to | $A(B) C(B) A*C(B)$                |
| $A(B)   B(D E)$     | is equivalent to | $A(B) B(D E)$                     |
| $A   B(A)   C$      | is equivalent to | $A B(A) C A*C B*C(A)$             |
| $A   B(A)   C @ 2$  | is equivalent to | $A B(A) C A*C$                    |
| $A   B   C   D @ 2$ | is equivalent to | $A B A*B C A*C B*C D A*D B*D C*D$ |
| $A*B(C*D)$          | is equivalent to | $A*B(C D)$                        |

---

## Using PROC GLM Interactively

You can use the GLM procedure interactively. After you specify a model with a **MODEL** statement and run PROC GLM with a **RUN** statement, you can execute a variety of statements without reinvoking PROC GLM.

The section “[Syntax: GLM Procedure](#)” on page 3278 describes which statements can be used interactively. These interactive statements can be executed singly or in groups by following the single statement or group of statements with a **RUN** statement. Note that the **MODEL** statement cannot be repeated; PROC GLM allows only one **MODEL** statement.

If you use PROC GLM interactively, you can end the GLM procedure with a **DATA** step, another PROC step, an **ENDSAS** statement, or a **QUIT** statement.

When you are using PROC GLM interactively, additional **RUN** statements do not end the procedure but tell PROC GLM to execute additional statements.

When you specify a **WHERE** statement with PROC GLM, it should appear before the first **RUN** statement. The **WHERE** statement enables you to select only certain observations for analysis without using a subsetting **DATA** step. For example, **where group ne 5** omits observations with **GROUP=5** from the analysis. See *SAS Statements: Reference* for details on this statement.

When you specify a **BY** statement with PROC GLM, interactive processing is not possible; that is, once the first **RUN** statement is encountered, processing proceeds for each **BY** group in the data set, and no further statements are accepted by the procedure.

Interactivity is also disabled when there are different patterns of missing values among the dependent variables. For details, see the section “[Missing Values](#)” on page 3379.

---

## Parameterization of PROC GLM Models

The GLM procedure constructs a linear model according to the specifications in the **MODEL** statement. Each effect generates one or more columns in a design matrix **X**. This section shows precisely how **X** is built.

## Intercept

All models include a column of 1s by default to estimate an intercept parameter  $\mu$ . You can use the `NOINT` option to suppress the intercept.

## Regression Effects

Regression effects (covariates) have the values of the variables copied into the design matrix directly. Polynomial terms are multiplied out and then installed in **X**.

## Main Effects

If a classification variable has  $m$  levels, PROC GLM generates  $m$  columns in the design matrix for its main effect. Each column is an indicator variable for one of the levels of the classification variable. The default order of the columns is the sort order of the values of their levels; this order can be controlled with the `ORDER=` option in the `PROC GLM` statement, as shown in the following table.

| Data |   | Design Matrix |    |    |    |    |    |
|------|---|---------------|----|----|----|----|----|
| A    | B | $\mu$         | A  |    | B  |    |    |
|      |   |               | A1 | A2 | B1 | B2 | B3 |
| 1    | 1 | 1             | 1  | 0  | 1  | 0  | 0  |
| 1    | 2 | 1             | 1  | 0  | 0  | 1  | 0  |
| 1    | 3 | 1             | 1  | 0  | 0  | 0  | 1  |
| 2    | 1 | 1             | 0  | 1  | 1  | 0  | 0  |
| 2    | 2 | 1             | 0  | 1  | 0  | 1  | 0  |
| 2    | 3 | 1             | 0  | 1  | 0  | 0  | 1  |

There are more columns for these effects than there are degrees of freedom for them; in other words, PROC GLM is using an over-parameterized model.

## Crossed Effects

First, PROC GLM reorders the terms to correspond to the order of the variables in the `CLASS` statement; thus, `B*A` becomes `A*B` if `A` precedes `B` in the `CLASS` statement. Then, PROC GLM generates columns for all combinations of levels that occur in the data. The order of the columns is such that the rightmost variables in the cross index faster than the leftmost variables. No columns are generated corresponding to combinations of levels that do not occur in the data.

| Data |   | Design Matrix |    |    |    |    |    |      |      |      |      |      |      |
|------|---|---------------|----|----|----|----|----|------|------|------|------|------|------|
| A    | B | $\mu$         | A  |    | B  |    |    | A*B  |      |      |      |      |      |
|      |   |               | A1 | A2 | B1 | B2 | B3 | A1B1 | A1B2 | A1B3 | A2B1 | A2B2 | A2B3 |
| 1    | 1 | 1             | 1  | 0  | 1  | 0  | 0  | 1    | 0    | 0    | 0    | 0    | 0    |
| 1    | 2 | 1             | 1  | 0  | 0  | 1  | 0  | 0    | 1    | 0    | 0    | 0    | 0    |
| 1    | 3 | 1             | 1  | 0  | 0  | 0  | 1  | 0    | 0    | 1    | 0    | 0    | 0    |
| 2    | 1 | 1             | 0  | 1  | 1  | 0  | 0  | 0    | 0    | 0    | 1    | 0    | 0    |
| 2    | 2 | 1             | 0  | 1  | 0  | 1  | 0  | 0    | 0    | 0    | 0    | 1    | 0    |
| 2    | 3 | 1             | 0  | 1  | 0  | 0  | 1  | 0    | 0    | 0    | 0    | 0    | 1    |

In this matrix, main-effects columns are not linearly independent of crossed-effect columns; in fact, the column space for the crossed effects contains the space of the main effect.

### Nested Effects

Nested effects are generated in the same manner as crossed effects. Hence, the design columns generated by the following statements are the same (but the ordering of the columns is different):

```

model y=a b(a); (B nested within A)
model y=a a*b; (omitted main effect for B)

```

The nesting operator in PROC GLM is more a notational convenience than an operation distinct from crossing. Nested effects are characterized by the property that the nested variables never appear as main effects. The order of the variables within nesting parentheses is made to correspond to the order of these variables in the CLASS statement. The order of the columns is such that variables outside the parentheses index faster than those inside the parentheses, and the rightmost nested variables index faster than the leftmost variables.

| Data |   | Design Matrix |    |    |      |      |      |      |      |      |
|------|---|---------------|----|----|------|------|------|------|------|------|
| A    | B | $\mu$         | A  |    | B(A) |      |      |      |      |      |
|      |   |               | A1 | A2 | B1A1 | B2A1 | B3A1 | B1A2 | B2A2 | B3A2 |
| 1    | 1 | 1             | 1  | 0  | 1    | 0    | 0    | 0    | 0    | 0    |
| 1    | 2 | 1             | 1  | 0  | 0    | 1    | 0    | 0    | 0    | 0    |
| 1    | 3 | 1             | 1  | 0  | 0    | 0    | 1    | 0    | 0    | 0    |
| 2    | 1 | 1             | 0  | 1  | 0    | 0    | 0    | 1    | 0    | 0    |
| 2    | 2 | 1             | 0  | 1  | 0    | 0    | 0    | 0    | 1    | 0    |
| 2    | 3 | 1             | 0  | 1  | 0    | 0    | 0    | 0    | 0    | 1    |

### Continuous-Nesting-Class Effects

When a continuous variable nests with a classification variable, the design columns are constructed by multiplying the continuous values into the design columns for the class effect.

| Data |   | Design Matrix |    |    |       |       |  |
|------|---|---------------|----|----|-------|-------|--|
| X    | A | $\mu$         | A  |    | X(A)  |       |  |
|      |   |               | A1 | A2 | X(A1) | X(A2) |  |
| 21   | 1 | 1             | 1  | 0  | 21    | 0     |  |
| 24   | 1 | 1             | 1  | 0  | 24    | 0     |  |
| 22   | 1 | 1             | 1  | 0  | 22    | 0     |  |
| 28   | 2 | 1             | 0  | 1  | 0     | 28    |  |
| 19   | 2 | 1             | 0  | 1  | 0     | 19    |  |
| 23   | 2 | 1             | 0  | 1  | 0     | 23    |  |

This model estimates a separate slope for X within each level of A.

## Continuous-by-Class Effects

Continuous-by-class effects generate the same design columns as continuous-nesting-class effects. The two models differ by the presence of the continuous variable as a regressor by itself, in addition to being a contributor to  $X*A$ .

| Data |   | Design Matrix |    |    |    |      |      |
|------|---|---------------|----|----|----|------|------|
| X    | A | $\mu$         | X  | A  |    | X*A  |      |
|      |   |               |    | A1 | A2 | X*A1 | X*A2 |
| 21   | 1 | 1             | 21 | 1  | 0  | 21   | 0    |
| 24   | 1 | 1             | 24 | 1  | 0  | 24   | 0    |
| 22   | 1 | 1             | 22 | 1  | 0  | 22   | 0    |
| 28   | 2 | 1             | 28 | 0  | 1  | 0    | 28   |
| 19   | 2 | 1             | 19 | 0  | 1  | 0    | 19   |
| 23   | 2 | 1             | 23 | 0  | 1  | 0    | 23   |

Continuous-by-class effects are used to test the homogeneity of slopes. If the continuous-by-class effect is nonsignificant, the effect can be removed so that the response with respect to  $X$  is the same for all levels of the classification variables.

## General Effects

An example that combines all the effects is

$$X1*X2*A*B*C(D E)$$

The continuous list comes first, followed by the crossed list, followed by the nested list in parentheses.

The sequencing of parameters is important to learn if you use the **CONTRAST** or **ESTIMATE** statement to compute or test some linear function of the parameter estimates.

Effects might be retitled by PROC GLM to correspond to ordering rules. For example,  $B*A(E D)$  might be retitled  $A*B(D E)$  to satisfy the following:

- Classification variables that occur outside parentheses (crossed effects) are sorted in the order in which they appear in the **CLASS** statement.
- Variables within parentheses (nested effects) are sorted in the order in which they appear in a **CLASS** statement.

The sequencing of the parameters generated by an effect can be described by which variables have their levels indexed faster:

- Variables in the crossed part index faster than variables in the nested list.
- Within a crossed or nested list, variables to the right index faster than variables to the left.

For example, suppose a model includes four effects— $A$ ,  $B$ ,  $C$ , and  $D$ —each having two levels, 1 and 2. If the **CLASS** statement is

```
class A B C D;
```

then the order of the parameters for the effect B\*A(C D), which is retitled A\*B(C D), is as follows.

```
A1B1C1D1
A1B2C1D1
A2B1C1D1
A2B2C1D1
A1B1C1D2
A1B2C1D2
A2B1C1D2
A2B2C1D2
A1B1C2D1
A1B2C2D1
A2B1C2D1
A2B2C2D1
A1B1C2D2
A1B2C2D2
A2B1C2D2
A2B2C2D2
```

Note that first the crossed effects B and A are sorted in the order in which they appear in the CLASS statement so that A precedes B in the parameter list. Then, for each combination of the nested effects in turn, combinations of A and B appear. The B effect changes fastest because it is rightmost in the (renamed) cross list. Then A changes next fastest. The D effect changes next fastest, and C is the slowest since it is leftmost in the nested list.

When numeric classification variables are used, their levels are sorted by their character format, which might not correspond to their numeric sort sequence. Therefore, it is advisable to include a format for numeric classification variables or to use the `ORDER=INTERNAL` option in the `PROC GLM` statement to ensure that levels are sorted by their internal values.

## Degrees of Freedom

For models with classification (categorical) effects, there are more design columns constructed than there are degrees of freedom for the effect. Thus, there are linear dependencies among the columns. In this event, the parameters are not jointly estimable; there is an infinite number of least squares solutions. The GLM procedure uses a generalized  $g_2$ -inverse to obtain values for the estimates; see the section “[Computational Method](#)” on page 3382 for more details. The solution values are not produced unless the `SOLUTION` option is specified in the `MODEL` statement. The solution has the characteristic that estimates are zero whenever the design column for that parameter is a linear combination of previous columns. (Strictly termed, the solution values should not be called estimates, since the parameters might not be formally estimable.) With this full parameterization, hypothesis tests are constructed to test linear functions of the parameters that are estimable.

Other procedures (such as the CATMOD procedure) reparameterize models to full rank by using certain restrictions on the parameters. PROC GLM does not reparameterize, making the hypotheses that are commonly tested more understandable. See Goodnight (1978a) for additional reasons for not reparameterizing.

PROC GLM does not actually construct the entire design matrix  $\mathbf{X}$ ; rather, a row  $x_i$  of  $\mathbf{X}$  is constructed for each observation in the data set and used to accumulate the crossproduct matrix  $\mathbf{X}'\mathbf{X} = \sum_i x_i'x_i$ .

## Hypothesis Testing in PROC GLM

See Chapter 15, “The Four Types of Estimable Functions,” for a complete discussion of the four standard types of hypothesis tests.

### Example

To illustrate the four types of tests and the principles upon which they are based, consider a two-way design with interaction based on the following data:

|   |   | B            |              |
|---|---|--------------|--------------|
|   |   | 1            | 2            |
| A | 1 | 23.5<br>23.7 | 28.7         |
|   | 2 | 8.9          | 5.6<br>8.9   |
|   | 3 | 10.3<br>12.5 | 13.6<br>14.6 |

Invoke PROC GLM and specify all the estimable functions options to examine what the GLM procedure can test. The following statements produce the summary ANOVA table displayed in Figure 42.10.

```
data example;
 input a b y @@;
 datalines;
1 1 23.5 1 1 23.7 1 2 28.7 2 1 8.9 2 2 5.6
2 2 8.9 3 1 10.3 3 1 12.5 3 2 13.6 3 2 14.6
;

proc glm;
 class a b;
 model y=a b a*b / e e1 e2 e3 e4;
run;
```

**Figure 42.10** Summary ANOVA Table from PROC GLM

| The GLM Procedure     |          |                |             |          |        |
|-----------------------|----------|----------------|-------------|----------|--------|
| Dependent Variable: y |          |                |             |          |        |
| Source                | DF       | Sum of Squares | Mean Square | F Value  | Pr > F |
| Model                 | 5        | 520.4760000    | 104.0952000 | 49.66    | 0.0011 |
| Error                 | 4        | 8.3850000      | 2.0962500   |          |        |
| Corrected Total       | 9        | 528.8610000    |             |          |        |
|                       | R-Square | Coeff Var      | Root MSE    | y Mean   |        |
|                       | 0.984145 | 9.633022       | 1.447843    | 15.03000 |        |

The following sections show the general form of estimable functions and discuss the four standard tests, their properties, and abbreviated output for the two-way crossed example.

### Estimability

Figure 42.11 is the general form of estimable functions for the example. In order to be testable, a hypothesis must be able to fit within the framework displayed here.

**Figure 42.11** General Form of Estimable Functions

| The GLM Procedure                   |     |                   |
|-------------------------------------|-----|-------------------|
| General Form of Estimable Functions |     |                   |
| Effect                              |     | Coefficients      |
| Intercept                           |     | L1                |
| a                                   | 1   | L2                |
| a                                   | 2   | L3                |
| a                                   | 3   | L1-L2-L3          |
| b                                   | 1   | L5                |
| b                                   | 2   | L1-L5             |
| a*b                                 | 1 1 | L7                |
| a*b                                 | 1 2 | L2-L7             |
| a*b                                 | 2 1 | L9                |
| a*b                                 | 2 2 | L3-L9             |
| a*b                                 | 3 1 | L5-L7-L9          |
| a*b                                 | 3 2 | L1-L2-L3-L5+L7+L9 |

If a hypothesis is estimable, the **Ls** in the preceding scheme can be set to values that match the hypothesis. All the standard tests in PROC GLM can be shown in the preceding format, with some of the **Ls** zeroed and some set to functions of other **Ls**.

The following sections show how many of the hypotheses can be tested by comparing the model sum-of-squares regression from one model to a submodel. The notation used is

$$SS(B \text{ effects} | A \text{ effects}) = SS(B \text{ effects}, A \text{ effects}) - SS(A \text{ effects})$$

where  $SS(A \text{ effects})$  denotes the regression model sum of squares for the model consisting of  $A \text{ effects}$ . This notation is equivalent to the reduction notation defined by Searle (1971) and summarized in Chapter 15, “The Four Types of Estimable Functions.”

## Type I Tests

Type I sums of squares (SS), also called *sequential sums of squares*, are the incremental improvement in error sums of squares as each effect is added to the model. They can be computed by fitting the model in steps and recording the difference in error sum of squares at each step.

| Source  | Type I SS               |
|---------|-------------------------|
| $A$     | $SS(A   \mu)$           |
| $B$     | $SS(B   \mu, A)$        |
| $A * B$ | $SS(A * B   \mu, A, B)$ |

Type I sums of squares are displayed by default because they are easy to obtain and can be used in various hand calculations to produce sum of squares values for a series of different models. Nelder (1994) and others have argued that Type I and II sums are essentially the only appropriate ones for testing ANOVA effects; however, see also the discussion of Nelder’s article, especially Rodriguez, Tobias, and Wolfinger (1995) and Searle (1995).

The Type I hypotheses have these properties:

- Type I sum of squares for all effects add up to the model sum of squares. None of the other sum of squares types have this property, except in special cases.
- Type I hypotheses can be derived from rows of the Forward-Dolittle transformation of  $\mathbf{X}'\mathbf{X}$  (a transformation that reduces  $\mathbf{X}'\mathbf{X}$  to an upper triangular matrix by row operations).
- Type I sum of squares are statistically independent of each other under the usual **assumption** that the true residual errors are independent and identically normally distributed (see page 3324).
- Type I hypotheses depend on the order in which effects are specified in the **MODEL** statement.
- Type I hypotheses are uncontaminated by parameters corresponding to effects that precede the effect being tested; however, the hypotheses usually involve parameters for effects following the tested effect in the model. For example, in the model

$$Y=A B;$$

the Type I hypothesis for B does not involve A parameters, but the Type I hypothesis for A does involve B parameters.

- Type I hypotheses are functions of the cell counts for unbalanced data; the hypotheses are not usually the same hypotheses that are tested if the data are balanced.
- Type I sums of squares are useful for polynomial models where you want to know the contribution of a term as though it had been made orthogonal to preceding effects. Thus, in polynomial models, Type I sums of squares correspond to tests of the orthogonal polynomial effects.

The Type I estimable functions and associated tests for the example are shown in Figure 42.12.

**Figure 42.12** Type I Estimable Functions and Tests

|           |     | Type I Estimable Functions |             |             |         |        |
|-----------|-----|----------------------------|-------------|-------------|---------|--------|
|           |     | -----Coefficients-----     |             |             |         |        |
| Effect    |     | a                          | b           | a*b         |         |        |
| Intercept |     | 0                          | 0           | 0           |         |        |
| a         | 1   | L2                         | 0           | 0           |         |        |
| a         | 2   | L3                         | 0           | 0           |         |        |
| a         | 3   | -L2-L3                     | 0           | 0           |         |        |
| b         | 1   | 0.1667*L2-0.1667*L3        | L5          | 0           |         |        |
| b         | 2   | -0.1667*L2+0.1667*L3       | -L5         | 0           |         |        |
| a*b       | 1 1 | 0.6667*L2                  | 0.2857*L5   | L7          |         |        |
| a*b       | 1 2 | 0.3333*L2                  | -0.2857*L5  | -L7         |         |        |
| a*b       | 2 1 | 0.3333*L3                  | 0.2857*L5   | L9          |         |        |
| a*b       | 2 2 | 0.6667*L3                  | -0.2857*L5  | -L9         |         |        |
| a*b       | 3 1 | -0.5*L2-0.5*L3             | 0.4286*L5   | -L7-L9      |         |        |
| a*b       | 3 2 | -0.5*L2-0.5*L3             | -0.4286*L5  | L7+L9       |         |        |
| Source    |     | DF                         | Type I SS   | Mean Square | F Value | Pr > F |
| a         |     | 2                          | 494.0310000 | 247.0155000 | 117.84  | 0.0003 |
| b         |     | 1                          | 10.7142857  | 10.7142857  | 5.11    | 0.0866 |
| a*b       |     | 2                          | 15.7307143  | 7.8653571   | 3.75    | 0.1209 |

### Type II Tests

The Type II tests can also be calculated by comparing the error sums of squares (SS) for subset models. The Type II SS are the reduction in error SS due to adding the term after all other terms have been added to the model except terms that contain the effect being tested. An effect is contained in another effect if it can be derived by deleting variables from the latter effect. For example, A and B are both contained in A\*B. For this model, the Type II SS are given by the reduced sums of squares as shown in the following table.

| Source       | Type II SS                 |
|--------------|----------------------------|
| <i>A</i>     | $SS(A \mid \mu, B)$        |
| <i>B</i>     | $SS(B \mid \mu, A)$        |
| <i>A * B</i> | $SS(A * B \mid \mu, A, B)$ |

Type II SS have these properties:

- Type II SS do not necessarily sum to the model SS.
- The hypothesis for an effect does not involve parameters of other effects except for containing effects (which it must involve to be estimable).
- Type II SS are invariant to the ordering of effects in the model.
- For unbalanced designs, Type II hypotheses for effects that are contained in other effects are not usually the same hypotheses that are tested if the data are balanced. The hypotheses are generally functions of the cell counts.

The Type II estimable functions and associated tests for the example are shown in Figure 42.13.

**Figure 42.13** Type II Estimable Functions and Tests

| Type II Estimable Functions |     |                      |             |             |         |        |
|-----------------------------|-----|----------------------|-------------|-------------|---------|--------|
| -----Coefficients-----      |     |                      |             |             |         |        |
| Effect                      |     | a                    | b           | a*b         |         |        |
| Intercept                   |     | 0                    | 0           | 0           |         |        |
| a                           | 1   | L2                   | 0           | 0           |         |        |
| a                           | 2   | L3                   | 0           | 0           |         |        |
| a                           | 3   | -L2-L3               | 0           | 0           |         |        |

## Type III and Type IV Tests

Type III and Type IV sums of squares (SS), sometimes referred to as *partial sums of squares*, are considered by many to be the most desirable; see Searle (1987, Section 4.6). Using PROC GLM's singular parameterization, these SS cannot, in general, be computed by comparing model SS from different models. However, they can sometimes be computed by reduction for methods that reparameterize to full rank, when such a reparameterization effectively imposes Type III linear constraints on the parameters. In PROC GLM, they are computed by constructing a hypothesis matrix  $L$  and then computing the SS associated with the hypothesis  $L\beta = 0$ . As long as there are no missing cells in the design, Type III and Type IV SS are the same.

These are properties of Type III and Type IV SS:

- The hypothesis for an effect does not involve parameters of other effects except for containing effects (which it must involve to be estimable).
- The hypotheses to be tested are invariant to the ordering of effects in the model.
- The hypotheses are the same hypotheses that are tested if there are no missing cells. They are not functions of cell counts.
- The SS do not generally add up to the model SS and, in some cases, can exceed the model SS.

The SS are constructed from the general form of estimable functions. Type III and Type IV tests are different only if the design has missing cells. In this case, the Type III tests have an orthogonality property, while the Type IV tests have a balancing property. These properties are discussed in Chapter 15, “[The Four Types of Estimable Functions](#).” For this example, since the data contain observations for all pairs of levels of A and B, Type IV tests are identical to the Type III tests that are shown in [Figure 42.14](#). (This combines tables from several pages of output.)

**Figure 42.14** Type III Estimable Functions and Tests

| Type III Estimable Functions |     |                        |            |        |
|------------------------------|-----|------------------------|------------|--------|
|                              |     | -----Coefficients----- |            |        |
| Effect                       |     | a                      | b          | a*b    |
| Intercept                    |     | 0                      | 0          | 0      |
| a                            | 1   | L2                     | 0          | 0      |

## Effect Size Measures for $F$ Tests in GLM

A significant  $F$  test in a linear model indicates that the effect of the term or contrast being tested might be real. The next thing you want to know is, How big is the effect? Various measures have been devised to give answers to this question that are comparable over different experimental designs. If you specify the experimental `EFFECTSIZE` option in the `MODEL` statement, then GLM adds to each ANOVA table estimates and confidence intervals for three different measures of effect size:

- the noncentrality parameter for the  $F$  test
- the proportion of total variation accounted for (also known as the semipartial correlation ratio or the squared semipartial correlation)
- the proportion of partial variation accounted for (also known as the full partial correlation ratio or the squared full partial correlation)

The adjectives “semipartial” and “full partial” might seem strange. They refer to how other effects are “partialed out” of the dependent variable and the effect being tested. For “semipartial” statistics, all other effects are partialled out of the effect in question, but not the dependent variable. This measures the (adjusted) effect as a proportion of the total variation in the dependent variable. On the other hand, for “full partial” statistics, all other effects are partialled out of *both* the dependent variable and the effect in question. This measures the (adjusted) effect as a proportion of only the dependent variation remaining after partialing, or in other words the partial variation. Details about the computation and interpretation of these estimates and confidence intervals are discussed in the remainder of this section.

The noncentrality parameter is directly related to the true distribution of the  $F$  statistic when the effect being tested has a non-null effect. The uniformly minimum variance unbiased estimate for the noncentrality is

$$NC_{UMVUE} = \frac{DF(DFE - 2)FValue}{DFE} - DF$$

where  $FValue$  is the observed value of the  $F$  statistic for the test and  $DF$  and  $DFE$  are the numerator and denominator degrees of freedom for the test, respectively. An alternative estimate that can be slightly biased but has a somewhat lower expected mean square error is

$$NC_{minMSE} = \frac{DF(DFE - 4)FValue}{DFE} - \frac{DF(DFE - 4)}{DFE - 2}$$

(See Perlman and Rasmussen (1975), cited in Johnson, Kotz, and Balakrishnan (1994).) A  $p \times 100\%$  lower confidence bound for the noncentrality is given by the value of NC for which  $\text{probf}(F\text{Value}, DF, DFE, NC) = p$ , where  $\text{probf}()$  is the cumulative probability function for the non-central  $F$  distribution. This result can be used to form a  $(1 - \alpha) \times 100\%$  confidence interval for the noncentrality.

The partial proportion of variation accounted for by the effect being tested is easiest to define by its natural sample estimate,

$$\hat{\eta}_{\text{partial}}^2 = \frac{SS}{SS + SSE}$$

where SSE is the sample error sum of squares. Note that  $\hat{\eta}_{\text{partial}}^2$  is actually sometimes denoted  $R_{\text{partial}}^2$  or just R square, but in this context the R square notation is reserved for the  $\hat{\eta}^2$  corresponding to the overall model, which is just the familiar R square for the model.  $\hat{\eta}_{\text{partial}}^2$  is actually a biased estimate of the true  $\eta_{\text{partial}}^2$ ; an alternative that is approximately unbiased is given by

$$\omega_{\text{partial}}^2 = \frac{SS - DF \times MSE}{SS + (N - DF)MSE}$$

where  $MSE = SSE/DFE$  is the sample mean square for error and  $N$  is the number of observations. The true  $\eta_{\text{partial}}^2$  is related to the true noncentrality parameter NC by the formula

$$\eta_{\text{partial}}^2 = \frac{NC}{NC + N}$$

This fact can be employed to transform a confidence interval for NC into one for  $\eta_{\text{partial}}^2$ . Note that some authors (Steiger and Fouladi 1997; Fidler and Thompson 2001; Smithson 2003) have published slightly different confidence intervals for  $\eta_{\text{partial}}^2$ , based on a slightly different formula for the relationship between  $\eta_{\text{partial}}^2$  and NC, apparently due to Cohen (1988). Cohen's formula appears to be approximately correct for random predictor values (Maxwell 2000), but the one given previously is correct if the predictor values are assumed fixed, as is standard for the GLM procedure.

Finally, the proportion of total variation accounted for by the effect being tested is again easiest to define by its natural sample estimate, which is known as the (*semipartial*)  $\hat{\eta}^2$  statistic,

$$\hat{\eta}^2 = \frac{SS}{SS_{\text{total}}}$$

where  $SS_{\text{total}}$  is the total sample (corrected) sum of squares, and  $SS$  is the observed sum of squares due to the effect being tested. As with  $\hat{\eta}_{\text{partial}}^2$ ,  $\hat{\eta}^2$  is actually a biased estimate of the true  $\eta^2$ ; an alternative that is approximately unbiased is the (*semipartial*)  $\omega^2$  statistic

$$\omega^2 = \frac{SS - DF \times MSE}{SS_{\text{total}} + MSE}$$

where  $MSE = SSE/DFE$  is the sample mean square for error. Whereas  $\eta_{\text{partial}}^2$  depends only on the noncentrality for its associated  $F$  test, the presence of the total sum of squares in the previous formulas indicates that

$\eta^2$  depends on the noncentralities for all effects in the model. An exact confidence interval is not available, but if you write the formula for  $\hat{\eta}^2$  as

$$\hat{\eta}^2 = \frac{SS}{SS + (SS_{total} - SS)}$$

then a conservative confidence interval can be constructed as for  $\eta_{partial}^2$ , treating  $SS_{total} - SS$  as the SSE and  $N - DF - 1$  as the DFE (Smithson 2004). This confidence interval is conservative in the sense that it implies values of the true  $\eta^2$  that are smaller than they should be.

Estimates and confidence intervals for effect sizes require some care in interpretation. For example, while the true proportions of total and partial variation accounted for are nonnegative quantities, their estimates might be less than zero. Also, confidence intervals for effect sizes are not directly related to the corresponding estimates. In particular, it is possible for the estimate to lie outside the confidence interval.

As for interpreting the actual values of effect size measures, the approximately unbiased  $\omega^2$  estimates are usually preferred for point estimates. Some authors have proposed certain ranges as indicating “small,” “medium,” and “large” effects (Cohen 1988), but general benchmarks like this depend on the nature of the data and the typical signal-to-noise ratio; they should not be expected to apply across various disciplines. For example, while an  $\omega^2$  value of 10% might be viewed as “large” for psychometric data, it can be a relatively small effect for industrial experimentation. Whatever the standard, confidence intervals for true effect sizes typically span more than one category, indicating that in small experiments, it can be difficult to make firm statements about the size of effects.

## Example

The data for this example are similar to data analyzed in Steiger and Fouladi (1997); Fidler and Thompson (2001); Smithson (2003). Consider the following hypothetical design, testing 28 men and 28 women on seven different tasks.

```
data Test;
 do Task = 1 to 7;
 do Gender = 'M', 'F';
 do i = 1 to 4;
 input Response @@;
 output;
 end;
 end;
 end;
 datalines;
7.1 2.8 3.9 3.7 6.5 6.5 6.5 6.6
7.1 5.5 4.8 2.6 3.6 5.4 5.6 4.5
7.2 4.6 4.9 4.6 3.3 5.4 2.8 1.5
5.6 6.2 5.4 6.5 5.6 2.7 3.8 2.3
2.2 5.4 5.6 8.4 1.2 2.0 4.3 4.6
9.1 4.5 7.6 4.9 4.3 7.7 6.5 7.7
4.5 3.8 5.9 6.1 1.7 2.5 4.3 2.7
;
```

This is a balanced two-way design with four replicates per cell. The following statements analyze this data. Since this is a balanced design, you can use the `SS1` option in the `MODEL` statement to display only the Type I sums of squares.

```
proc glm data=Test;
 class Gender Task;
 model Response = Gender|Task / ss1;
run;
```

The analysis of variance results are shown in Figure 42.15.

**Figure 42.15** Two-Way Analysis of Variance

| The GLM Procedure            |    |             |             |         |        |
|------------------------------|----|-------------|-------------|---------|--------|
| Dependent Variable: Response |    |             |             |         |        |
| Source                       | DF | Type I SS   | Mean Square | F Value | Pr > F |
| Gender                       | 1  | 14.40285714 | 14.40285714 | 6.00    | 0.0185 |
| Task                         | 6  | 38.15964286 | 6.35994048  | 2.65    | 0.0285 |
| Gender*Task                  | 6  | 35.99964286 | 5.99994048  | 2.50    | 0.0369 |

You can see that the two main effects as well as their interaction are all significant. Suppose you want to compare the main effect of Gender with the interaction between Gender and Task. The sums of squares for the interaction are more than twice as large, but it's not clear how experimental variability might affect this. The following statements perform the same analysis as before, but add the `EFFECTSIZE` option to the `MODEL` statement; also, with `ALPHA=0.1` option displays 90% confidence intervals, ensuring that inferences based on the  $p$ -values at the 0.05 levels will agree with the lower confidence limit.

```
proc glm data=Test;
 class Gender Task;
 model Response = Gender|Task / ss1 effectsize alpha=0.1;
run;
```

The Type I analysis of variance results with added effect size information are shown in Figure 42.16.

| Gender*Task                     | 0.2632             | 0.1385       | 0.0082                | 0.3160 |

The estimated effect sizes for Gender and the interaction all tell pretty much the same story: the effect of the interaction is appreciably greater than the effect of Gender. However, the confidence intervals suggest that this inference should be treated with some caution, since the lower confidence bound for the Gender effect is greater than the lower confidence bound for the interaction in all three cases. Follow-up testing is probably in order, using the estimated effect sizes in this preliminary study to design a large enough sample to distinguish the sizes of the effects.

## Absorption

Absorption is a computational technique used to reduce computing resource needs in certain cases. The classic use of absorption occurs when a blocking factor with a large number of levels is a term in the model.

For example, the statements

```
proc glm;
 absorb herd;
 class a b;
 model y=a b a*b;
run;
```

are equivalent to

```
proc glm;
 class herd a b;
 model y=herd a b a*b;
run;
```

The exception to the previous statements is that the Type II, Type III, or Type IV SS for HERD are not computed when HERD is absorbed.

The algorithm for absorbing variables is similar to the one used by the NESTED procedure for computing a nested analysis of variance. As each new row of  $[X|Y]$  (corresponding to the nonabsorbed independent effects and the dependent variables) is constructed, it is adjusted for the absorbed effects in a Type I fashion. The efficiency of the absorption technique is due to the fact that this adjustment can be done in one pass of the data and without solving any linear equations, assuming that the data have been sorted by the absorbed variables.

Several effects can be absorbed at one time. For example, these statements

```
proc glm;
 absorb herd cow;
 class a b;
 model y=a b a*b;
run;
```

are equivalent to

```
proc glm;
 class herd cow a b;
 model y=herd cow(herd) a b a*b;
run;
```

When you use absorption, the size of the  $X'X$  matrix is a function only of the effects in the **MODEL** statement. The effects being absorbed do not contribute to the size of the  $X'X$  matrix.

For the preceding example, a and b can be absorbed:

```
proc glm;
 absorb a b;
 class herd cow;
 model y=herd cow(herd);
run;
```

Although the sources of variation in the results are listed as

```
a b(a) herd cow(herd)
```

all types of estimable functions for herd and cow(herd) are free of a, b, and a\*b parameters.

To illustrate the savings in computing by using the **ABSORB** statement, PROC GLM is run on generated data with 1147 degrees of freedom in the model with the following statements.

```
data a;
 do herd=1 to 40;
 do cow=1 to 30;
 do treatment=1 to 3;
 do rep=1 to 2;
 y = herd/5 + cow/10 + treatment + rannor(1);
 output;
 end;
 end;
 end;
 end;
run;

proc glm data=a;
 class herd cow treatment;
 model y=herd cow(herd) treatment;
run;
```

This analysis would have required over 6 megabytes of memory for the  $X'X$  matrix had PROC GLM solved it directly. However, in the following statements, the GLM procedure needs only a  $4 \times 4$  matrix for the intercept and treatment because the other effects are absorbed.

```
proc glm data=a;
 absorb herd cow;
 class treatment;
 model y = treatment;
run;
```

These statements produce the results shown in Figure 42.17.

**Figure 42.17** Absorption of Effects

| The GLM Procedure           |        |        |     |
|-----------------------------|--------|--------|-----|

## Specification of ESTIMATE Expressions

Consider the model

$$E(Y) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3$$

The corresponding `MODEL` statement for PROC GLM is

```
model y=x1 x2 x3;
```

To estimate the difference between the parameters for  $x_1$  and  $x_2$ ,

$$\beta_1 - \beta_2 = (0 \ 1 \ -1 \ 0) \boldsymbol{\beta}, \text{ where } \boldsymbol{\beta} = (\beta_0 \ \beta_1 \ \beta_2 \ \beta_3)'$$

you can use the following `ESTIMATE` statement:

```
estimate 'B1-B2' x1 1 x2 -1;
```

To predict  $y$  at  $x_1 = 1$ ,  $x_2 = 0$ , and  $x_3 = -2$ , you can estimate

$$\beta_0 + \beta_1 - 2\beta_3 = (1 \ 1 \ 0 \ -2) \boldsymbol{\beta}$$

with the following **ESTIMATE** statement:

```
estimate 'B0+B1-2B3' intercept 1 x1 1 x3 -2;
```

Now consider models involving classification variables such as

```
model y=A B A*B;
```

with the associated parameters:

$$(\mu \ \alpha_1 \ \alpha_2 \ \alpha_3 \ \beta_1 \ \beta_2 \ \gamma_{11} \ \gamma_{12} \ \gamma_{21} \ \gamma_{22} \ \gamma_{31} \ \gamma_{32})$$

The LS-mean for the first level of **A** is  $\mathbf{L}\boldsymbol{\beta}$ , where

$$\mathbf{L} = (1 \ | \ 1 \ 0 \ 0 \ | \ 0.5 \ 0.5 \ | \ 0.5 \ 0.5 \ 0 \ 0 \ 0 \ 0)$$

You can estimate this with the following **ESTIMATE** statement:

```
estimate 'LS-mean(A1)' intercept 1 A 1 B 0.5 0.5 A*B 0.5 0.5;
```

Note in this statement that only one element of  $\mathbf{L}$  is specified following the **A** effect, even though **A** has three levels. Whenever the list of constants following an effect name is shorter than the effect's number of levels, zeros are used as the remaining constants. (If the list of constants is longer than the number of levels for the effect, the extra constants are ignored, and a warning message is displayed.)

To estimate the **A** linear effect in the preceding model, assuming equally spaced levels for **A**, you can use the following  $\mathbf{L}$ :

$$\mathbf{L} = (0 \ | \ -1 \ 0 \ 1 \ | \ 0 \ 0 \ | \ -0.5 \ -0.5 \ 0 \ 0 \ 0.5 \ 0.5)$$

The **ESTIMATE** statement for this  $\mathbf{L}$  is written as

```
estimate 'A Linear' A -1 0 1;
```

If you do not specify the elements of  $\mathbf{L}$  for an effect that contains a specified effect, then the elements of the specified effect are equally distributed over the corresponding levels of the higher-order effect. In addition, if you specify the intercept in an **ESTIMATE** or **CONTRAST** statement, it is distributed over all classification effects that are not contained by any other specified effect.

The distribution of lower-order coefficients to higher-order effect coefficients follows the same general rules as in the **LSMEANS** statement, and it is similar to that used to construct Type IV tests. In the previous example, the  $-1$  associated with  $\alpha_1$  is divided by the number  $n_{1j}$  of  $\gamma_{1j}$  parameters; then each  $\gamma_{1j}$  coefficient is set to  $-1/n_{1j}$ . The  $1$  associated with  $\alpha_3$  is distributed among the  $\gamma_{3j}$  parameters in a similar fashion. In the event that an unspecified effect contains several specified effects, only that specified effect with the most factors in common with the unspecified effect is used for distribution of coefficients to the higher-order effect.

Numerous syntactical expressions for the `ESTIMATE` statement were considered, including many that involved specifying the effect and level information associated with each coefficient. For models involving higher-level effects, the requirement of specifying level information can lead to very bulky specifications. Consequently, the simpler form of the `ESTIMATE` statement described earlier was implemented.

The syntax of this `ESTIMATE` statement puts a burden on you to know a priori the order of the parameter list associated with each effect. You can use the `ORDER=` option in the `PROC GLM` statement to ensure that the levels of the classification effects are sorted appropriately.

**NOTE:** If you use the `ESTIMATE` statement with unspecified effects, use the `E` option to make sure that the actual `L` constructed by the preceding rules is the one you intended.

## A Check for Estimability

Each `L` is checked for estimability using the relationship  $\mathbf{L} = \mathbf{LH}$ , where  $\mathbf{H} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{X}$ . The `L` vector is declared nonestimable, if for any  $i$

$$\text{ABS}(\mathbf{L}_i - (\mathbf{LH})_i) > \begin{cases} \epsilon & \text{if } \mathbf{L}_i = 0 \text{ or} \\ \epsilon \times \text{ABS}(\mathbf{L}_i) & \text{otherwise} \end{cases}$$

where  $\epsilon = 10^{-4}$  by default; you can change this with the `SINGULAR=` option. Continued fractions (like  $1/3$ ) should be specified to at least six decimal places, or the `DIVISOR` parameter should be used.

## Comparing Groups

An important task in analyzing data with classification effects is to estimate the typical response for each level of a given effect; often, you also want to compare these estimates to determine which levels are equivalent in terms of the response. You can perform this task in two ways with the `GLM` procedure: with direct, arithmetic group means; and with so-called *least squares means* (LS-means).

### Means versus LS-Means

Computing and comparing arithmetic means—either simple or weighted within-group averages of the input data—is a familiar and well-studied statistical process. This is the right approach to summarizing and comparing groups for one-way and balanced designs. However, in unbalanced designs with more than one effect, the arithmetic mean for a group might not accurately reflect the “typical” response for that group, since it does not take other effects into account.

For example, the following analysis of an unbalanced two-way design produces the ANOVA, means, and LS-means shown in [Figure 42.18](#), [Figure 42.19](#), and [Figure 42.20](#).

```
data twoway;

| 1                         | 25.6000000 |
| 2                         | 28.3333333 |
| 3                         | 34.4444444 |

No matter how you look at them, these data exhibit a strong effect due to the blocks ( $F$  test  $p < 0.0001$ ) and no significant interaction between treatments and blocks ( $F$  test  $p > 0.7$ ). But the lack of balance affects how the treatment effect is interpreted: in a main-effects-only model, there are no significant differences between the treatment means themselves (Type I  $F$  test  $p > 0.7$ ), but there are highly significant differences between the treatment means corrected for the block effects (Type III  $F$  test  $p < 0.01$ ).

LS-means are, in effect, within-group means appropriately adjusted for the other effects in the model. More precisely, they estimate the marginal means for a balanced population (as opposed to the unbalanced design). For this reason, they are also called *estimated population marginal means* by Searle, Speed, and Milliken (1980). In the same way that the Type I  $F$  test assesses differences between the arithmetic treatment means (when the treatment effect comes first in the model), the Type III  $F$  test assesses differences between the LS-means. Accordingly, for the unbalanced two-way design, the discrepancy between the Type I and Type III tests is reflected in the arithmetic treatment means and treatment LS-means, as shown in [Figure 42.19](#) and [Figure 42.20](#). See the section “[Construction of Least Squares Means](#)” on page 3363 for more on LS-means.

Note that, while the arithmetic means are always uncorrelated (under the usual [assumptions](#) for analysis of variance; see page 3324), the LS-means might not be. This fact complicates the problem of multiple comparisons for LS-means; see the following section.

## Multiple Comparisons

When comparing more than two means, an ANOVA  $F$  test tells you whether the means are significantly different from each other, but it does not tell you which means differ from which other means. Multiple-comparison procedures (MCPs), also called *mean separation tests*, give you more detailed information about the differences among the means. The goal in multiple comparisons is to compare the average effects of three or more “treatments” (for example, drugs, groups of subjects) to decide which treatments are better, which ones are worse, and by how much, while controlling the probability of making an incorrect decision. A variety of multiple-comparison methods are available with the [MEANS](#) and [LSMEANS](#) statement in the GLM procedure.

The following classification is due to Hsu (1996). Multiple-comparison procedures can be categorized in two ways: by the comparisons they make and by the strength of inference they provide. With respect to which comparisons are made, the GLM procedure offers two types:

- comparisons between all pairs of means
- comparisons between a control and all other means

The strength of inference says what can be inferred about the structure of the means when a test is significant; it is related to what type of error rate the MCP controls. MCPs available in the GLM procedure provide one of the following types of inference, in order from weakest to strongest:

- Individual: differences between means, unadjusted for multiplicity
- Inhomogeneity: means are different
- Inequalities: which means are different
- Intervals: simultaneous confidence intervals for mean differences

Methods that control only individual error rates are not true MCPs at all. Methods that yield the strongest level of inference, simultaneous confidence intervals, are usually preferred, since they enable you not only to say which means are different but also to put confidence bounds on *how much* they differ, making it easier to assess the practical significance of a difference. They are also less likely to lead nonstatisticians to the invalid conclusion that nonsignificantly different sample means imply equal population means. Interval MCPs are available for both arithmetic means and LS-means via the **MEANS** and **LSMEANS** statements, respectively.<sup>1</sup>

Table 42.12 and Table 42.13 display MCPs available in PROC GLM for all pairwise comparisons and comparisons with a control, respectively, along with associated strength of inference and the syntax (when applicable) for both the **MEANS** and the **LSMEANS** statements.

**Table 42.12** Multiple-Comparison Procedures for All Pairwise Comparisons

| Method               | Strength of Inference | Syntax  |                       |
|----------------------|-----------------------|---------|-----------------------|
|                      |                       | MEANS   | LSMEANS               |
| Student's <i>t</i>   | Individual            | T       | PDIFF ADJUST=T        |
| Duncan               | Individual            | DUNCAN  |                       |
| Student-Newman-Keuls | Inhomogeneity         | SNK     |                       |
| REGWQ                | Inequalities          | REGWQ   |                       |
| Tukey-Kramer         | Intervals             | TUKEY   | PDIFF ADJUST=TUKEY    |
| Bonferroni           | Intervals             | BON     | PDIFF ADJUST=BON      |
| Sidak                | Intervals             | SIDAK   | PDIFF ADJUST=SIDAK    |
| Scheffé              | Intervals             | SCHEFFE | PDIFF ADJUST=SCHEFFE  |
| SMM                  | Intervals             | SMM     | PDIFF ADJUST=SMM      |
| Gabriel              | Intervals             | GABRIEL |                       |
| Simulation           | Intervals             |         | PDIFF ADJUST=SIMULATE |

<sup>1</sup>The Duncan-Waller method does not fit into the preceding scheme, since it is based on the Bayes risk rather than any particular error rate.

**Table 42.13** Multiple-Comparison Procedures for Comparisons with a Control

| Method             | Strength of Inference | Syntax  |                               |
|--------------------|-----------------------|---------|-------------------------------|
|                    |                       | MEANS   | LSMEANS                       |
| Student's <i>t</i> | Individual            |         | PDIFF=CONTROL ADJUST=T        |
| Dunnett            | Intervals             | DUNNETT | PDIFF=CONTROL ADJUST=DUNNETT  |
| Bonferroni         | Intervals             |         | PDIFF=CONTROL ADJUST=BON      |
| Sidak              | Intervals             |         | PDIFF=CONTROL ADJUST=SIDAK    |
| Scheffé            | Intervals             |         | PDIFF=CONTROL ADJUST=SCHEFFE  |
| SMM                | Intervals             |         | PDIFF=CONTROL ADJUST=SMM      |
| Simulation         | Intervals             |         | PDIFF=CONTROL ADJUST=SIMULATE |

**NOTE:** One-sided Dunnett's tests are also available from the **MEANS** statement with the **DUNNETTL** and **DUNNETTU** options and from the **LSMEANS** statement with **PDIFF=CONTROLL** and **PDIFF=CONTROLU**.

A note concerning the ODS tables for the results of the **PDIFF** or **TDIFF** options in the **LSMEANS** statement: The *p/t*-values for differences are displayed in columns of the LSMeans table for **PDIFF/TDIFF=CONTROL** or **PDIFF/TDIFF=ANOM**, and for **PDIFF/TDIFF=ALL** when there are only two LS-means. Otherwise (for **PDIFF/TDIFF=ALL** when there are more than two LS-means), the *p/t*-values for differences are displayed in a separate table called Diff.

Details of these multiple comparison methods are given in the following sections.

### Pairwise Comparisons

All the methods discussed in this section depend on the standardized pairwise differences  $t_{ij} = (\bar{y}_i - \bar{y}_j)/\hat{\sigma}_{ij}$ , where the parts of this expression are defined as follows:

- *i* and *j* are the indices of two groups
- $\bar{y}_i$  and  $\bar{y}_j$  are the means or LS-means for groups *i* and *j*
- $\hat{\sigma}_{ij}$  is the square root of the estimated variance of  $\bar{y}_i - \bar{y}_j$ . For simple arithmetic means,  $\hat{\sigma}_{ij}^2 = s^2(1/n_i + 1/n_j)$ , where  $n_i$  and  $n_j$  are the sizes of groups *i* and *j*, respectively, and  $s^2$  is the mean square for error, with  $\nu$  degrees of freedom. For weighted arithmetic means,  $\hat{\sigma}_{ij}^2 = s^2(1/w_i + 1/w_j)$ , where  $w_i$  and  $w_j$  are the sums of the weights in groups *i* and *j*, respectively. Finally, for LS-means defined by the linear combinations  $\mathbf{l}'_i \mathbf{b}$  and  $\mathbf{l}'_j \mathbf{b}$  of the parameter estimates,  $\hat{\sigma}_{ij}^2 = s^2 \mathbf{l}'_i (\mathbf{X}'\mathbf{X})^{-1} \mathbf{l}_j$ .

Furthermore, all of the methods are discussed in terms of significance tests of the form

$$|t_{ij}| \geq c(\alpha)$$

where  $c(\alpha)$  is some constant depending on the significance level. Such tests can be inverted to form confidence intervals of the form

$$(\bar{y}_i - \bar{y}_j) - \hat{\sigma}_{ij}c(\alpha) \leq \mu_i - \mu_j \leq (\bar{y}_i - \bar{y}_j) + \hat{\sigma}_{ij}c(\alpha)$$

The simplest approach to multiple comparisons is to do a  $t$  test on every pair of means (the **T** option in the **MEANS** statement, **ADJUST=T** in the **LSMEANS** statement). For the  $i$ th and  $j$ th means, you can reject the null hypothesis that the population means are equal if

$$|t_{ij}| \geq t(\alpha; \nu)$$

where  $\alpha$  is the significance level,  $\nu$  is the number of error degrees of freedom, and  $t(\alpha; \nu)$  is the two-tailed critical value from a Student's  $t$  distribution. If the cell sizes are all equal to, say,  $n$ , the preceding formula can be rearranged to give

$$|\bar{y}_i - \bar{y}_j| \geq t(\alpha; \nu)s\sqrt{\frac{2}{n}}$$

the value of the right-hand side being Fisher's least significant difference (LSD).

There is a problem with repeated  $t$  tests, however. Suppose there are 10 means and each  $t$  test is performed at the 0.05 level. There are  $10(10 - 1)/2 = 45$  pairs of means to compare, each with a 0.05 probability of a type 1 error (a false rejection of the null hypothesis). The chance of making at least one type 1 error is much higher than 0.05. It is difficult to calculate the exact probability, but you can derive a pessimistic approximation by assuming that the comparisons are independent, giving an upper bound to the probability of making at least one type 1 error (the experimentwise error rate) of

$$1 - (1 - 0.05)^{45} = 0.90$$

The actual probability is somewhat less than 0.90, but as the number of means increases, the chance of making at least one type 1 error approaches 1.

If you decide to control the individual type 1 error rates for each comparison, you are controlling the individual or comparisonwise error rate. On the other hand, if you want to control the overall type 1 error rate for all the comparisons, you are controlling the experimentwise error rate. It is up to you to decide whether to control the comparisonwise error rate or the experimentwise error rate, but there are many situations in which the experimentwise error rate should be held to a small value. Statistical methods for comparing three or more means while controlling the probability of making at least one type 1 error are called *multiple-comparison procedures*.

It has been suggested that the experimentwise error rate can be held to the  $\alpha$  level by performing the overall ANOVA  $F$  test at the  $\alpha$  level and making further comparisons only if the  $F$  test is significant, as in Fisher's protected LSD. This assertion is false if there are more than three means (Einot and Gabriel 1975). Consider again the situation with 10 means. Suppose that one population mean differs from the others by such a sufficiently large amount that the power (probability of correctly rejecting the null hypothesis) of the  $F$  test is near 1 but that all the other population means are equal to each other. There will be  $9(9 - 1)/2 = 36$   $t$  tests of true null hypotheses, with an upper limit of 0.84 on the probability of at least one type 1 error. Thus, you must distinguish between the experimentwise error rate under the complete null hypothesis, in which all population means are equal, and the experimentwise error rate under a partial null hypothesis, in which some means are equal but others differ. The following abbreviations are used in the discussion:

CER      comparisonwise error rate

EERC     experimentwise error rate under the complete null hypothesis

MEER maximum experimentwise error rate under any complete or partial null hypothesis

These error rates are associated with the different **strengths of inference** discussed on page 3350: individual tests control the CER; tests for inhomogeneity of means control the EERC; tests that yield confidence inequalities or confidence intervals control the MEER. A preliminary  $F$  test controls the EERC but not the MEER.

You can control the MEER at the  $\alpha$  level by setting the CER to a sufficiently small value. The Bonferroni inequality (Miller 1981) has been widely used for this purpose. If

$$\text{CER} = \frac{\alpha}{c}$$

where  $c$  is the total number of comparisons, then the MEER is less than  $\alpha$ . Bonferroni  $t$  tests (the **BON** option in the **MEANS** statement, **ADJUST=BON** in the **LSMEANS** statement) with  $\text{MEER} < \alpha$  declare two means to be significantly different if

$$|t_{ij}| \geq t(\epsilon; \nu)$$

where

$$\epsilon = \frac{2\alpha}{k(k-1)}$$

for comparison of  $k$  means.

Šidák (1967) has provided a tighter bound, showing that

$$\text{CER} = 1 - (1 - \alpha)^{1/c}$$

also ensures that  $\text{MEER} \leq \alpha$  for any set of  $c$  comparisons. A Sidak  $t$  test (Games 1977), provided by the **SIDAK** option, is thus given by

$$|t_{ij}| \geq t(\epsilon; \nu)$$

where

$$\epsilon = 1 - (1 - \alpha)^{\frac{2}{k(k-1)}}$$

for comparison of  $k$  means.

You can use the Bonferroni additive inequality and the Sidak multiplicative inequality to control the MEER for any set of contrasts or other hypothesis tests, not just pairwise comparisons. The Bonferroni inequality can provide simultaneous inferences in any statistical application requiring tests of more than one hypothesis. Other methods discussed in this section for pairwise comparisons can also be adapted for general contrasts (Miller 1981).

Scheffé (1953, 1959) proposes another method to control the MEER for any set of contrasts or other linear hypotheses in the analysis of linear models, including pairwise comparisons, obtained with the SCHEFFE option. Two means are declared significantly different if

$$|t_{ij}| \geq \sqrt{\text{DF} \cdot F(\alpha; \text{DF}, \nu)}$$

where  $F(\alpha; \text{DF}, \nu)$  is the  $\alpha$ -level critical value of an  $F$  distribution with DF numerator degrees of freedom and  $\nu$  denominator degrees of freedom. The value of DF is  $k - 1$  for the MEANS statement, but in other statements the precise definition depends on context. For the LSMEANS statement, DF is the rank of the contrast matrix  $\mathbf{L}$  for LS-means differences. In more general contexts—for example, the ESTIMATE or LSMESTIMATE statements in PROC GLIMMIX—DF is the rank of the contrast covariance matrix  $\mathbf{L}\text{Cov}(\mathbf{b})\mathbf{L}'$ .

Scheffé's test is compatible with the overall ANOVA  $F$  test in that Scheffé's method never declares a contrast significant if the overall  $F$  test is nonsignificant. Most other multiple-comparison methods can find significant contrasts when the overall  $F$  test is nonsignificant and, therefore, suffer a loss of power when used with a preliminary  $F$  test.

Scheffé's method might be more powerful than the Bonferroni or Sidak method if the number of comparisons is large relative to the number of means. For pairwise comparisons, Sidak  $t$  tests are generally more powerful.

Tukey (1952, 1953) proposes a test designed specifically for pairwise comparisons based on the studentized range, sometimes called the "honestly significant difference test," that controls the MEER when the sample sizes are equal. Tukey (1953) and Kramer (1956) independently propose a modification for unequal cell sizes. The Tukey or Tukey-Kramer method is provided by the TUKEY option in the MEANS statement and the ADJUST=TUKEY option in the LSMEANS statement. This method has fared extremely well in Monte Carlo studies (Dunnett 1980). In addition, Hayter (1984) gives a proof that the Tukey-Kramer procedure controls the MEER for means comparisons, and Hayter (1989) describes the extent to which the Tukey-Kramer procedure has been proven to control the MEER for LS-means comparisons. The Tukey-Kramer method is more powerful than the Bonferroni, Sidak, or Scheffé method for pairwise comparisons. Two means are considered significantly different by the Tukey-Kramer criterion if

$$|t_{ij}| \geq q(\alpha; k, \nu)$$

where  $q(\alpha; k, \nu)$  is the  $\alpha$ -level critical value of a studentized range distribution of  $k$  independent normal random variables with  $\nu$  degrees of freedom.

Hochberg (1974) devised a method (the GT2 or SMM option) similar to Tukey's, but it uses the studentized maximum modulus instead of the studentized range and employs the uncorrelated  $t$  inequality of Šidák (1967). It is proven to hold the MEER at a level not exceeding  $\alpha$  with unequal sample sizes. It is generally less powerful than the Tukey-Kramer method and always less powerful than Tukey's test for equal cell sizes. Two means are declared significantly different if

$$|t_{ij}| \geq m(\alpha; c, \nu)$$

where  $m(\alpha; c, \nu)$  is the  $\alpha$ -level critical value of the studentized maximum modulus distribution of  $c$  independent normal random variables with  $\nu$  degrees of freedom and  $c = k(k - 1)/2$ .

Gabriel (1978) proposes another method (the **GABRIEL** option) based on the studentized maximum modulus. This method is applicable only to arithmetic means. It rejects if

$$\frac{|\bar{y}_i - \bar{y}_j|}{s \left( \frac{1}{\sqrt{2n_i}} + \frac{1}{\sqrt{2n_j}} \right)} \geq m(\alpha; k, \nu)$$

For equal cell sizes, Gabriel's test is equivalent to Hochberg's GT2 method. For unequal cell sizes, Gabriel's method is more powerful than GT2 but might become liberal with highly disparate cell sizes (see also Dunnett (1980)). Gabriel's test is the only method for unequal sample sizes that lends itself to a graphical representation as intervals around the means. Assuming  $\bar{y}_i > \bar{y}_j$ , you can rewrite the preceding inequality as

$$\bar{y}_i - m(\alpha; k, \nu) \frac{s}{\sqrt{2n_i}} \geq \bar{y}_j + m(\alpha; k, \nu) \frac{s}{\sqrt{2n_j}}$$

The expression on the left does not depend on  $j$ , nor does the expression on the right depend on  $i$ . Hence, you can form what Gabriel calls an  $(l, u)$ -interval around each sample mean and declare two means to be significantly different if their  $(l, u)$ -intervals do not overlap. See Hsu (1996, section 5.2.1.1) for a discussion of other methods of graphically representing all pairwise comparisons.

### **Comparing All Treatments to a Control**

One special case of means comparison is that in which the only comparisons that need to be tested are between a set of new treatments and a single control. In this case, you can achieve better power by using a method that is restricted to test only comparisons to the single control mean. Dunnett (1955) proposes a test for this situation that declares a mean significantly different from the control if

$$|t_{i0}| \geq d(\alpha; k, \nu, \rho_1, \dots, \rho_{k-1})$$

where  $\bar{y}_0$  is the control mean and  $d(\alpha; k, \nu, \rho_1, \dots, \rho_{k-1})$  is the critical value of the "many-to-one  $t$  statistic" (Miller 1981; Krishnaiah and Armitage 1966) for  $k$  means to be compared to a control, with  $\nu$  error degrees of freedom and correlations  $\rho_1, \dots, \rho_{k-1}$ ,  $\rho_i = n_i / (n_0 + n_i)$ . The correlation terms arise because each of the treatment means is being compared to the same control. Dunnett's test holds the MEER to a level not exceeding the stated  $\alpha$ .

### **Analysis of Means: Comparing Each Treatments to the Average**

*Analysis of means* (ANOM) refers to a technique for comparing group means and displaying the comparisons graphically so that you can easily see which ones are different. Means are judged as different if they are significantly different from the overall average, with significance adjusted for multiplicity. The overall average is computed as a weighted mean of the LS-means, the weights being inversely proportional to the variances. If you use the **PDIF=ANOM** option in the **LSMEANS** statement, the procedure will display the  $p$ -values (adjusted for multiplicity, by default) for tests of the differences between each LS-mean and the average LS-mean. The ANOM procedure in SAS/QC software displays both tables and graphics for the analysis of means with a variety of response types. For one-way designs, confidence intervals for **PDIF=ANOM** comparisons are equivalent to the results of PROC ANOM. The difference is that PROC GLM directly displays the confidence intervals for the differences, while the graphical output of PROC ANOM displays them as decision limits around the overall mean.

If the LS-means being compared are uncorrelated, exact adjusted  $p$ -values and critical values for confidence limits can be computed; see Nelson (1982, 1991, 1993) and Guirguis and Tobias (2004). For correlated LS-means, an approach similar to that of Hsu (1992) is employed, using a factor-analytic approximation of the correlation between the LS-means to derive approximate “effective sample sizes” for which exact critical values are computed. Note that computing the exact adjusted  $p$ -values and critical values for unbalanced designs can be computationally intensive. A simulation-based approach, as specified by the `ADJUST=SIM` option, while nondeterministic, might provide inferences that are accurate enough in much less time. See the section “Approximate and Simulation-Based Methods” on page 3356 for more details.

### Approximate and Simulation-Based Methods

Tukey’s, Dunnett’s, and Nelson’s tests are all based on the same general quantile calculation:

$$q^t(\alpha, \nu, R) = \{q \ni P(\max(|t_1|, \dots, |t_n|) > q) = \alpha\}$$

where the  $t_i$  have a joint multivariate  $t$  distribution with  $\nu$  degrees of freedom and correlation matrix  $R$ . In general, evaluating  $q^t(\alpha, \nu, R)$  requires repeated numerical calculation of an  $(n + 1)$ -fold integral. This is usually intractable, but the problem reduces to a feasible 2-fold integral when  $R$  has a certain symmetry in the case of Tukey’s test, and a *factor analytic structure* (Hsu 1992) in the case of Dunnett’s and Nelson’s tests. The  $R$  matrix has the required symmetry for exact computation of Tukey’s test in the following two cases:

- The  $t_i$ s are studentized differences between  $k(k - 1)/2$  pairs of  $k$  uncorrelated means with equal variances—that is, equal sample sizes.
- The  $t_i$ s are studentized differences between  $k(k - 1)/2$  pairs of  $k$  LS-means from a *variance-balanced* design (for example, a balanced incomplete block design).

See Hsu (1992, 1996) for more information. The  $R$  matrix has the factor analytic structure for exact computation of Dunnett’s and Nelson’s tests in the following two cases:

- if the  $t_i$ s are studentized differences between  $k - 1$  means and a control mean, all uncorrelated. (Dunnett’s one-sided methods depend on a similar probability calculation, without the absolute values.) Note that it is not required that the variances of the means (that is, the sample sizes) be equal.
- if the  $t_i$ s are studentized differences between  $k - 1$  LS-means and a control LS-mean from either a *variance-balanced* design, or a design in which the other factors are *orthogonal* to the treatment factor (for example, a randomized block design with proportional cell frequencies)

However, other important situations that do **not** result in a correlation matrix  $R$  that has the structure for exact computation are the following:

- all pairwise differences with unequal sample sizes
- differences between LS-means in many unbalanced designs

In these situations, exact calculation of  $q^t(\alpha, \nu, R)$  is intractable in general. Most of the preceding methods can be viewed as using various approximations for  $q^t(\alpha, \nu, R)$ . When the sample sizes are unequal, the

Tukey-Kramer test is equivalent to another approximation. For comparisons with a control when the correlation  $R$  does not have a factor analytic structure, Hsu (1992) suggests approximating  $R$  with a matrix  $R^*$  that does have such a structure and correspondingly approximating  $q^t(\alpha, \nu, R)$  with  $q^t(\alpha, \nu, R^*)$ . When you request Dunnett's or Nelson's test for LS-means (the `PDIF=CONTROL` and `ADJUST=DUNNETT` options or the `PDIF=ANOM` and `ADJUST=NELSON` options, respectively), the GLM procedure automatically uses Hsu's approximation when appropriate.

Finally, Edwards and Berry (1987) suggest calculating  $q^t(\alpha, \nu, R)$  by simulation. Multivariate  $t$  vectors are sampled from a distribution with the appropriate  $\nu$  and  $R$  parameters, and Edwards and Berry (1987) suggest estimating  $q^t(\alpha, \nu, R)$  by  $\hat{q}$ , the  $\alpha$  percentile of the observed values of  $\max(|t_1|, \dots, |t_n|)$ . Sufficient samples are generated for the true  $P(\max(|t_1|, \dots, |t_n|) > \hat{q})$  to be within a certain accuracy radius  $\gamma$  of  $\alpha$  with accuracy confidence  $100(1 - \epsilon)$ . You can approximate  $q^t(\alpha, \nu, R)$  by simulation for comparisons between LS-means by specifying `ADJUST=SIM` (with any `PDIF=` type). By default,  $\gamma = 0.005$  and  $\epsilon = 0.01$ , so that the tail area of  $\hat{q}$  is within 0.005 of  $\alpha$  with 99% confidence. You can use the `ACC=` and `EPS=` options with `ADJUST=SIM` to reset  $\gamma$  and  $\epsilon$ , or you can use the `NSAMP=` option to set the sample size directly. You can also control the random number sequence with the `SEED=` option.

Hsu and Nelson (1998) suggest a more accurate simulation method for estimating  $q^t(\alpha, \nu, R)$ , using a control variate adjustment technique. The same independent, standardized normal variates that are used to generate multivariate  $t$  vectors from a distribution with the appropriate  $\nu$  and  $R$  parameters are also used to generate multivariate  $t$  vectors from a distribution for which the exact value of  $q^t(\alpha, \nu, R)$  is known.  $\max(|t_1|, \dots, |t_n|)$  for the second sample is used as a control variate for adjusting the quantile estimate based on the first sample; see Hsu and Nelson (1998) for more details. The control variate adjustment has the drawback that it takes somewhat longer than the crude technique of Edwards and Berry (1987), but it typically yields an estimate that is many times more accurate. In most cases, if you are using `ADJUST=SIM`, then you should specify `ADJUST=SIM(CVADJUST)`. You can also specify `ADJUST=SIM(CVADJUST REPORT)` to display a summary of the simulation that includes, among other things, the actual accuracy radius  $\gamma$ , which should be substantially smaller than the target accuracy radius (0.005 by default).

### Multiple-Stage Tests

You can use all of the methods discussed so far to obtain simultaneous confidence intervals (Miller 1981). By sacrificing the facility for simultaneous estimation, you can obtain simultaneous tests with greater power by using multiple-stage tests (MSTs). MSTs come in both step-up and step-down varieties (Welsch 1977). The step-down methods, which have been more widely used, are available in SAS/STAT software.

Step-down MSTs first test the homogeneity of all the means at a level  $\gamma_k$ . If the test results in a rejection, then each subset of  $k - 1$  means is tested at level  $\gamma_{k-1}$ ; otherwise, the procedure stops. In general, if the hypothesis of homogeneity of a set of  $p$  means is rejected at the  $\gamma_p$  level, then each subset of  $p - 1$  means is tested at the  $\gamma_{p-1}$  level; otherwise, the set of  $p$  means is considered not to differ significantly and none of its subsets are tested. The many varieties of MSTs that have been proposed differ in the levels  $\gamma_p$  and the statistics on which the subset tests are based. Clearly, the EERC of a step-down MST is not greater than  $\gamma_k$ , and the CER is not greater than  $\gamma_2$ , but the MEER is a complicated function of  $\gamma_p$ ,  $p = 2, \dots, k$ .

With unequal cell sizes, PROC GLM uses the harmonic mean of the cell sizes as the common sample size. However, since the resulting operating characteristics can be undesirable, MSTs are recommended only for the balanced case. When the sample sizes are equal, using the range statistic enables you to arrange the means in ascending or descending order and test only contiguous subsets. But if you specify the  $F$  statistic, this shortcut cannot be taken. For this reason, only range-based MSTs are implemented. It is common practice to report the results of an MST by writing the means in such an order and drawing lines parallel

to the list of means spanning the homogeneous subsets. This form of presentation is also convenient for pairwise comparisons with equal cell sizes.

The best-known MSTs are the Duncan (the DUNCAN option) and Student-Newman-Keuls (the SNK option) methods (Miller 1981). Both use the studentized range statistic and, hence, are called *multiple range tests*. Duncan's method is often called the "new" multiple range test despite the fact that it is one of the oldest MSTs in current use.

The Duncan and SNK methods differ in the  $\gamma_p$  values used. For Duncan's method, they are

$$\gamma_p = 1 - (1 - \alpha)^{p-1}$$

whereas the SNK method uses

$$\gamma_p = \alpha$$

Duncan's method controls the CER at the  $\alpha$  level. Its operating characteristics appear similar to those of Fisher's unprotected LSD or repeated  $t$  tests at level  $\alpha$  (Petrinovich and Hardyck 1969). Since repeated  $t$  tests are easier to compute, easier to explain, and applicable to unequal sample sizes, Duncan's method is not recommended. Several published studies (for example, Carmer and Swanson (1973)) have claimed that Duncan's method is superior to Tukey's because of greater power without considering that the greater power of Duncan's method is due to its higher type 1 error rate (Einot and Gabriel 1975).

The SNK method holds the EERC to the  $\alpha$  level but does not control the MEER (Einot and Gabriel 1975). Consider ten population means that occur in five pairs such that means within a pair are equal, but there are large differences between pairs. If you make the usual sampling assumptions and also assume that the sample sizes are very large, all subset homogeneity hypotheses for three or more means are rejected. The SNK method then comes down to five independent tests, one for each pair, each at the  $\alpha$  level. Letting  $\alpha$  be 0.05, the probability of at least one false rejection is

$$1 - (1 - 0.05)^5 = 0.23$$

As the number of means increases, the MEER approaches 1. Therefore, the SNK method cannot be recommended.

A variety of MSTs that control the MEER have been proposed, but these methods are not as well known as those of Duncan and SNK. One approach (Ryan 1959, 1960; Einot and Gabriel 1975; Welsch 1977) sets

$$\gamma_p = \begin{cases} 1 - (1 - \alpha)^{p/k} & \text{for } p < k - 1 \\ \alpha & \text{for } p \geq k - 1 \end{cases}$$

You can use range statistics, leading to what is called the REGWQ method, after the authors' initials. If you assume that the sample means have been arranged in descending order from  $\bar{y}_1$  through  $\bar{y}_k$ , the homogeneity of means  $\bar{y}_i, \dots, \bar{y}_j, i < j$ , is rejected by REGWQ if

$$\bar{y}_i - \bar{y}_j \geq q(\gamma_p; p, \nu) \frac{s}{\sqrt{n}}$$

where  $p = j - i + 1$  and the summations are over  $u = i, \dots, j$  (Einot and Gabriel 1975). To ensure that the MEER is controlled, the current implementation checks whether  $q(\gamma_p; p, \nu)$  is monotonically increasing in  $p$ . If not, then a set of critical values that are increasing in  $p$  is substituted instead.

REGWQ appears to be the most powerful step-down MST in the current literature (for example, Ramsey 1978). Use of a preliminary  $F$  test decreases the power of all the other multiple-comparison methods discussed previously except for Scheffé's test.

### Bayesian Approach

Waller and Duncan (1969) and Duncan (1975) take an approach to multiple comparisons that differs from all the methods previously discussed in minimizing the Bayes risk under additive loss rather than controlling type 1 error rates. For each pair of population means  $\mu_i$  and  $\mu_j$ , null ( $H_0^{ij}$ ) and alternative ( $H_a^{ij}$ ) hypotheses are defined:

$$H_0^{ij}: \quad \mu_i - \mu_j \leq 0$$

$$H_a^{ij}: \quad \mu_i - \mu_j > 0$$

For any  $i, j$  pair, let  $d_0$  indicate a decision in favor of  $H_0^{ij}$  and  $d_a$  indicate a decision in favor of  $H_a^{ij}$ , and let  $\delta = \mu_i - \mu_j$ . The loss function for the decision on the  $i, j$  pair is

$$L(d_0 | \delta) = \begin{cases} 0 & \text{if } \delta \leq 0 \\ \delta & \text{if } \delta > 0 \end{cases}$$

$$L(d_a | \delta) = \begin{cases} -k\delta & \text{if } \delta \leq 0 \\ 0 & \text{if } \delta > 0 \end{cases}$$

where  $k$  represents a constant that you specify rather than the number of means. The loss for the joint decision involving all pairs of means is the sum of the losses for each individual decision. The population means are assumed to have a normal prior distribution with unknown variance, the logarithm of the variance of the means having a uniform prior distribution. For the  $i, j$  pair, the null hypothesis is rejected if

$$\bar{y}_i - \bar{y}_j \geq t_{BS} \sqrt{\frac{2}{n}}$$

where  $t_B$  is the Bayesian  $t$  value (Waller and Kemp 1976) depending on  $k$ , the  $F$  statistic for the one-way ANOVA, and the degrees of freedom for  $F$ . The value of  $t_B$  is a decreasing function of  $F$ , so the Waller-Duncan test (specified by the **WALLER** option) becomes more liberal as  $F$  increases.

### Recommendations

In summary, if you are interested in several individual comparisons and are not concerned about the effects of multiple inferences, you can use repeated  $t$  tests or Fisher's unprotected LSD. If you are interested in all pairwise comparisons or all comparisons with a control, you should use Tukey's or Dunnett's test, respectively, in order to make the strongest possible inferences. If you have weaker inferential requirements and, in particular, if you do not want confidence intervals for the mean differences, you should use the REGWQ method. Finally, if you agree with the Bayesian approach and Waller and Duncan's assumptions, you should use the Waller-Duncan test.

### Interpretation of Multiple Comparisons

When you interpret multiple comparisons, remember that failure to reject the hypothesis that two or more means are equal should not lead you to conclude that the population means are, in fact, equal. Failure to reject the null hypothesis implies only that the difference between population means, if any, is not large enough to be detected with the given sample size. A related point is that nonsignificance is nontransitive: that is, given three sample means, the largest and smallest might be significantly different from each other, while neither is significantly different from the middle one. Nontransitive results of this type occur frequently in multiple comparisons.

Multiple comparisons can also lead to counterintuitive results when the cell sizes are unequal. Consider four cells labeled A, B, C, and D, with sample means in the order  $A > B > C > D$ . If A and D each have two observations, and B and C each have 10,000 observations, then the difference between B and C might be significant, while the difference between A and D is not.

### Simple Effects

Suppose you use the following statements to fit a full factorial model to a two-way design:

```
data twoway;
 input A B Y @@;
 datalines;
 1 1 10.6 1 1 11.0 1 1 10.6 1 1 11.3
 1 2 -0.2 1 2 1.3 1 2 -0.2 1 2 0.2
 1 3 0.1 1 3 0.4 1 3 -0.4 1 3 1.0
 2 1 19.7 2 1 19.3 2 1 18.5 2 1 20.4
 2 2 -0.2 2 2 0.5 2 2 0.8 2 2 -0.4
 2 3 -0.9 2 3 -0.1 2 3 -0.2 2 3 -1.7
 3 1 29.7 3 1 29.6 3 1 29.0 3 1 30.2
 3 2 1.5 3 2 0.2 3 2 -1.5 3 2 1.3
 3 3 0.2 3 3 0.4 3 3 -0.4 3 3 -2.2
 ;

proc glm data=twoway;
 class A B;
 model Y = A B A*B;
run;
```

Partial results for the analysis of variance are shown in [Figure 42.21](#). The Type I and Type III results are the same because this is a balanced design.

**Figure 42.21** Two-Way Design with Significant Interaction

| The GLM Procedure     |    |             |             |         |        |

Figure 42.21 continued

| Source | DF | Type III SS | Mean Square | F Value | Pr > F |
|--------|----|-------------|-------------|---------|--------|
| A      | 2  | 219.905000  | 109.952500  | 165.11  | <.0001 |
| B      | 2  | 3206.101667 | 1603.050833 | 2407.25 | <.0001 |
| A*B    | 4  | 487.103333  | 121.775833  | 182.87  | <.0001 |

The interaction A\*B is significant, indicating that the effect of A depends on the level of B. In some cases, you might be interested in looking at the differences between predicted values across A for different levels of B. Winer (1971) calls this the *simple effects* of A. You can compute simple effects with the **LSMEANS** statement by specifying the **SLICE=** option. In this case, since the GLM procedure is interactive, you can compute the simple effects of A by submitting the following statements after the preceding statements.

```
lsmeans A*B / slice=B;
run;
```

The results are shown Figure 42.22. Note that A has a significant effect for B=1 but not for B=2 and B=3.

## Homogeneity of Variance in One-Way Models

One of the usual *assumptions* in using the GLM procedure is that the underlying errors are all uncorrelated with homogeneous variances (see page 3324). You can test this assumption in PROC GLM by using the **HOVTEST** option in the **MEANS** statement, requesting a *homogeneity of variance* test. This section discusses the computational details behind these tests. Note that the GLM procedure allows homogeneity of variance testing for simple one-way models only. Homogeneity of variance testing for more complex models is a subject of current research.

Bartlett (1937) proposes a test for equal variances that is a modification of the normal-theory likelihood ratio test (the **HOVTEST=BARTLETT** option). While Bartlett's test has accurate Type I error rates and optimal power when the underlying distribution of the data is normal, it can be very inaccurate if that distribution is even slightly nonnormal (Box 1953). Therefore, Bartlett's test is not recommended for routine use.

An approach that leads to tests that are much more robust to the underlying distribution is to transform the original values of the dependent variable to derive a *dispersion variable* and then to perform analysis of variance on this variable. The significance level for the test of homogeneity of variance is the *p*-value for the ANOVA *F* test on the dispersion variable. All of the homogeneity of variance tests available in PROC GLM except Bartlett's use this approach.

Levene's test (Levene 1960) is widely considered to be the standard homogeneity of variance test (the **HOVTEST=LEVENE** option). Levene's test is of the dispersion-variable-ANOVA form discussed previously, where the dispersion variable is either of the following:

$$\begin{aligned} z_{ij}^2 &= (y_{ij} - \bar{y}_i)^2 && \text{(TYPE=SQUARE, the default)} \\ z_{ij} &= |y_{ij} - \bar{y}_i| && \text{(TYPE=ABS)} \end{aligned}$$

O'Brien (1979) proposes a test (**HOVTEST=OBRIEN**) that is basically a modification of Levene's  $z_{ij}^2$ , using the dispersion variable

$$z_{ij}^W = \frac{(W + n_i - 2)n_i(y_{ij} - \bar{y}_i)^2 - W(n_i - 1)\sigma_i^2}{(n_i - 1)(n_i - 2)}$$

where  $n_i$  is the size of the *i*th group and  $\sigma_i^2$  is its sample variance. You can use the **W=** option in parentheses to tune O'Brien's  $z_{ij}^W$  dispersion variable to match the suspected kurtosis of the underlying distribution. The choice of the value of the **W=** option is rarely critical. By default, **W=0.5**, as suggested by O'Brien (1979, 1981).

Finally, Brown and Forsythe (1974) suggest using the absolute deviations from the group *medians*:

$$z_{ij}^{\text{BF}} = |y_{ij} - m_i|$$

where  $m_i$  is the median of the *i*th group. You can use the **HOVTEST=BF** option to specify this test.

Simulation results (Conover, Johnson, and Johnson 1981; Olejnik and Algina 1987) show that, while all of these ANOVA-based tests are reasonably robust to the underlying distribution, the Brown-Forsythe test seems best at providing power to detect variance differences while protecting the Type I error probability. However, since the within-group medians are required for the Brown-Forsythe test, it can be resource intensive if there are very many groups or if some groups are very large.

If one of these tests rejects the assumption of homogeneity of variance, you should use Welch's ANOVA instead of the usual ANOVA to test for differences between group means. However, this conclusion holds only if you use one of the robust homogeneity of variance tests (that is, not for `HOVTEST=BARTLETT`); even then, any homogeneity of variance test has too little power to be relied upon to always detect when Welch's ANOVA is appropriate. Unless the group variances are extremely different or the number of groups is large, the usual ANOVA test is relatively robust when the groups are all about the same size. As Box (1953) notes, "To make the preliminary test on variances is rather like putting to sea in a rowing boat to find out whether conditions are sufficiently calm for an ocean liner to leave port!"

Example 42.10 illustrates the use of the `HOVTEST` and `WELCH` options in the `MEANS` statement in testing for equal group variances and adjusting for unequal group variances in a one-way ANOVA.

### Weighted Means

If you specify a `WEIGHT` statement and one or more of the multiple comparisons options, the variance of the difference between weighted group means for group  $i$  and  $j$  is computed as

$$\text{MSE} \times \left( \frac{1}{w_i} + \frac{1}{w_j} \right)$$

where  $w_i$  is the sum of the weights for the observations in group  $i$ .

### Construction of Least Squares Means

To construct a least squares mean (LS-mean) for a given level of a given effect, construct a row vector  $\mathbf{L}$  according to the following rules and use it in an `ESTIMATE` statement to compute the value of the LS-mean:

1. Set all  $L_i$  corresponding to covariates (continuous variables) to their mean value.
2. Consider effects contained by the given effect. Set the  $L_i$  corresponding to levels associated with the given level equal to 1. Set all other  $L_i$  in these effects equal to 0. (See Chapter 15, "The Four Types of Estimable Functions," for a definition of *containing*.)
3. Consider the given effect. Set the  $L_i$  corresponding to the given level equal to 1. Set the  $L_i$  corresponding to other levels equal to 0.
4. Consider the effects that contain the given effect. If these effects are not nested within the given effect, then set the  $L_i$  corresponding to the given level to  $1/k$ , where  $k$  is the number of such columns. If these effects are nested within the given effect, then set the  $L_i$  corresponding to the given level to  $1/(k_1 k_2)$ , where  $k_1$  is the number of nested levels within this combination of nested effects, and  $k_2$  is the number of such combinations. For  $L_i$  corresponding to other levels, use 0.
5. Consider the other effects not yet considered. If there are no nested factors, then set all  $L_i$  corresponding to this effect to  $1/j$ , where  $j$  is the number of levels in the effect. If there are nested factors, then set all  $L_i$  corresponding to this effect to  $1/(j_1 j_2)$ , where  $j_1$  is the number of nested levels within a given combination of nested effects and  $j_2$  is the number of such combinations.

The consequence of these rules is that the sum of the Xs within any classification effect is 1. This set of Xs forms a linear combination of the parameters that is checked for estimability before it is evaluated.

For example, consider the following model:

```
proc glm;
 class A B C;
 model Y=A B A*B C Z;
 lsmeans A B A*B C;
run;
```

Assume A has 3 levels, B has 2 levels, and C has 2 levels, and assume that every combination of levels of A and B exists in the data. Assume also that Z is a continuous variable with an average of 12.5. Then the least squares means are computed by the following linear combinations of the parameter estimates:

|           | $\mu$ | A   |     |     | B   |     | A*B |     |     |     |     |     | C   |     | Z    |
|-----------|-------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|------|
|           |       | 1   | 2   | 3   | 1   | 2   | 11  | 12  | 21  | 22  | 31  | 32  | 1   | 2   |      |
| LSM( )    | 1     | 1/3 | 1/3 | 1/3 | 1/2 | 1/2 | 1/6 | 1/6 | 1/6 | 1/6 | 1/6 | 1/6 | 1/2 | 1/2 | 12.5 |
| LSM(A1)   | 1     | 1   | 0   | 0   | 1/2 | 1/2 | 1/2 | 1/2 | 0   | 0   | 0   | 0   | 1/2 | 1/2 | 12.5 |
| LSM(A2)   | 1     | 0   | 1   | 0   | 1/2 | 1/2 | 0   | 0   | 1/2 | 1/2 | 0   | 0   | 1/2 | 1/2 | 12.5 |
| LSM(A3)   | 1     | 0   | 0   | 1   | 1/2 | 1/2 | 0   | 0   | 0   | 0   | 1/2 | 1/2 | 1/2 | 1/2 | 12.5 |
| LSM(B1)   | 1     | 1/3 | 1/3 | 1/3 | 1   | 0   | 1/3 | 0   | 1/3 | 0   | 1/3 | 0   | 1/2 | 1/2 | 12.5 |
| LSM(B2)   | 1     | 1/3 | 1/3 | 1/3 | 0   | 1   | 0   | 1/3 | 0   | 1/3 | 0   | 1/3 | 1/2 | 1/2 | 12.5 |
| LSM(AB11) | 1     | 1   | 0   | 0   | 1   | 0   | 1   | 0   | 0   | 0   | 0   | 0   | 1/2 | 1/2 | 12.5 |

### Setting Covariate Values

By default, all covariate effects are set equal to their mean values for computation of standard LS-means. The **AT** option in the **LSMEANS** statement enables you to set the covariates to whatever values you consider interesting.

If there is an effect containing two or more covariates, the **AT** option sets the effect equal to the product of the individual means rather than the mean of the product (as with standard LS-means calculations). The **AT MEANS** option leaves covariates equal to their mean values (as with standard LS-means) and incorporates this adjustment to crossproducts of covariates.

As an example, the following is a model with a classification variable A and two continuous variables, x1 and x2:

```
class A;
model y = A x1 x2 x1*x2;
```

The coefficients for the continuous effects with various **AT** specifications are shown in the following table.

| Syntax                                         | x1          | x2          | x1*x2                       |
|------------------------------------------------|-------------|-------------|-----------------------------|
| <code>lsmeans A;</code>                        | $\bar{x}_1$ | $\bar{x}_2$ | $\bar{x}_1\bar{x}_2$        |
| <code>lsmeans A / at means;</code>             | $\bar{x}_1$ | $\bar{x}_2$ | $\bar{x}_1 \cdot \bar{x}_2$ |
| <code>lsmeans A / at x1=1.2;</code>            | 1.2         | $\bar{x}_2$ | $1.2 \cdot \bar{x}_2$       |
| <code>lsmeans A / at (x1 x2)=(1.2 0.3);</code> | 1.2         | 0.3         | $1.2 \cdot 0.3$             |

For the first two **LSMEANS** statements, the A LS-mean coefficient for x1 is  $\bar{x}_1$  (the mean of x1) and for x2 is  $\bar{x}_2$  (the mean of x2). However, for the first **LSMEANS** statement, the coefficient for x1\*x2 is  $\bar{x}_1\bar{x}_2$ , but for the second **LSMEANS** statement the coefficient is  $\bar{x}_1 \cdot \bar{x}_2$ . The third **LSMEANS** statement sets the coefficient for x1 equal to 1.2 and leaves that for x2 at  $\bar{x}_2$ , and the final **LSMEANS** statement sets these values to 1.2 and 0.3, respectively.

Even if you specify a **WEIGHT** variable, the unweighted covariate means are used for the covariate coefficients if there is no **AT** specification. However, if you also use an **AT** specification, then weighted covariate means are used for the covariate coefficients for which no explicit **AT** values are given, or if you specify **AT MEANS**. Also, observations with missing dependent variables are included in computing the covariate means, unless these observations form a missing cell. You can use the **E** option in conjunction with the **AT** option to check that the modified LS-means coefficients are the ones you want.

The **AT** option is disabled if you specify the **BYLEVEL** option, in which case the coefficients for the covariates are set equal to their means within each level of the LS-mean effect in question.

### Changing the Weighting Scheme

The standard LS-means have equal coefficients across classification effects; however, the **OM** option in the **LSMEANS** statement changes these coefficients to be proportional to those found in the input data set. This adjustment is reasonable when you want your inferences to apply to a population that is not necessarily balanced but has the margins observed in the original data set.

In computing the observed margins, PROC GLM uses all observations for which there are no missing independent variables, including those for which there are missing dependent variables. Also, if there is a **WEIGHT** variable, PROC GLM uses weighted margins to construct the LS-means coefficients. If the analysis data set is balanced or if you specify a simple one-way model, the LS-means will be unchanged by the **OM** option.

The **BYLEVEL** option modifies the observed-margins LS-means. Instead of computing the margins across the entire data set, PROC GLM computes separate margins for each level of the LS-mean effect in question. The resulting LS-means are actually equal to raw means in this case. The **BYLEVEL** option disables the **AT** option if it is specified.

Note that the **MIXED** procedure implements a more versatile form of the **OM** option, enabling you to specifying an alternative data set over which to compute observed margins. If you use the **BYLEVEL** option, too, then this data set is effectively the “population” over which the population marginal means are computed. See Chapter 59, “The **MIXED** Procedure,” for more information.

You might want to use the **E** option in conjunction with either the **OM** or **BYLEVEL** option to check that the modified LS-means coefficients are the ones you want. It is possible that the modified LS-means are not estimable when the standard ones are, or vice versa.

**Estimability of LS-means**

LS-means are defined as certain linear combinations of the parameters. As such, it is possible for them to be inestimable. In fact, it is possible for a pair of LS-means to be both inestimable but their difference estimable. When this happens, only the entries corresponding to the estimable difference are computed and displayed in the Diffis table. If `ADJUST=SIMULATE` is specified when there are inestimable LS-means differences, adjusted results for all differences are displayed as missing.

---

**Multivariate Analysis of Variance**

If you fit several dependent variables to the same effects, you might want to make joint tests involving parameters of several dependent variables. Suppose you have  $p$  dependent variables,  $k$  parameters for each dependent variable, and  $n$  observations. The models can be collected into one equation:

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where  $\mathbf{Y}$  is  $n \times p$ ,  $\mathbf{X}$  is  $n \times k$ ,  $\boldsymbol{\beta}$  is  $k \times p$ , and  $\boldsymbol{\epsilon}$  is  $n \times p$ . Each of the  $p$  models can be estimated and tested separately. However, you might also want to consider the joint distribution and test the  $p$  models simultaneously.

For multivariate tests, you need to make some assumptions about the errors. With  $p$  dependent variables, there are  $n \times p$  errors that are independent across observations but not across dependent variables. Assume

$$\text{vec}(\boldsymbol{\epsilon}) \sim N(\mathbf{0}, \mathbf{I}_n \otimes \boldsymbol{\Sigma})$$

where  $\text{vec}(\boldsymbol{\epsilon})$  strings  $\boldsymbol{\epsilon}$  out by rows,  $\otimes$  denotes Kronecker product multiplication, and  $\boldsymbol{\Sigma}$  is  $p \times p$ .  $\boldsymbol{\Sigma}$  can be estimated by

$$\mathbf{S} = \frac{\mathbf{e}'\mathbf{e}}{n-r} = \frac{(\mathbf{Y} - \mathbf{X}\mathbf{b})'(\mathbf{Y} - \mathbf{X}\mathbf{b})}{n-r}$$

where  $\mathbf{b} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{Y}$ ,  $r$  is the rank of the  $\mathbf{X}$  matrix, and  $\mathbf{e}$  is the matrix of residuals.

If  $\mathbf{S}$  is scaled to unit diagonals, the values in  $\mathbf{S}$  are called *partial correlations of the Ys adjusting for the Xs*. This matrix can be displayed by PROC GLM if `PRINTE` is specified as a `MANOVA` option.

The multivariate general linear hypothesis is written

$$\mathbf{L}\boldsymbol{\beta}\mathbf{M} = \mathbf{0}$$

You can form hypotheses for linear combinations across columns, as well as across rows of  $\boldsymbol{\beta}$ .

The `MANOVA` statement of the GLM procedure tests special cases where  $\mathbf{L}$  corresponds to Type I, Type II, Type III, or Type IV tests, and  $\mathbf{M}$  is the  $p \times p$  identity matrix. These tests are joint tests that the given type of hypothesis holds for all dependent variables in the model, and they are often sufficient to test all hypotheses of interest.

Finally, when these special cases are not appropriate, you can specify your own  $\mathbf{L}$  and  $\mathbf{M}$  matrices by using the `CONTRAST` statement before the `MANOVA` statement and the `M=` specification in the `MANOVA` statement, respectively. Another alternative is to use a `REPEATED` statement, which automatically generates a variety of  $\mathbf{M}$  matrices useful in repeated measures analysis of variance. See the section “`REPEATED Statement`” on page 3317 and the section “`Repeated Measures Analysis of Variance`” on page 3367 for more information.

One useful way to think of a MANOVA analysis with an  $\mathbf{M}$  matrix other than the identity is as an analysis of a set of transformed variables defined by the columns of the  $\mathbf{M}$  matrix. You should note, however, that PROC GLM always displays the  $\mathbf{M}$  matrix in such a way that the transformed variables are defined by the rows, not the columns, of the displayed  $\mathbf{M}$  matrix.

All multivariate tests carried out by the GLM procedure first construct the matrices  $\mathbf{H}$  and  $\mathbf{E}$  corresponding to the numerator and denominator, respectively, of a univariate  $F$  test:

$$\mathbf{H} = \mathbf{M}'(\mathbf{Lb})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{Lb})\mathbf{M}$$

$$\mathbf{E} = \mathbf{M}'(\mathbf{Y}'\mathbf{Y} - \mathbf{b}'(\mathbf{X}'\mathbf{X})\mathbf{b})\mathbf{M}$$

The diagonal elements of  $\mathbf{H}$  and  $\mathbf{E}$  correspond to the hypothesis and error SS for univariate tests. When the  $\mathbf{M}$  matrix is the identity matrix (the default), these tests are for the original dependent variables on the left side of the MODEL statement. When an  $\mathbf{M}$  matrix other than the identity is specified, the tests are for transformed variables defined by the columns of the  $\mathbf{M}$  matrix. These tests can be studied by requesting the SUMMARY option, which produces univariate analyses for each original or transformed variable.

Four multivariate test statistics, all functions of the eigenvalues of  $\mathbf{E}^{-1}\mathbf{H}$  (or  $(\mathbf{E} + \mathbf{H})^{-1}\mathbf{H}$ ), are constructed:

- Wilks' lambda =  $\det(\mathbf{E})/\det(\mathbf{H} + \mathbf{E})$
- Pillai's trace =  $\text{trace}(\mathbf{H}(\mathbf{H} + \mathbf{E})^{-1})$
- Hotelling-Lawley trace =  $\text{trace}(\mathbf{E}^{-1}\mathbf{H})$
- Roy's greatest root =  $\lambda$ , largest eigenvalue of  $\mathbf{E}^{-1}\mathbf{H}$

By default, all four are reported with  $p$ -values based on  $F$  approximations, as discussed in the "Multivariate Tests" section in Chapter 4, "Introduction to Regression Procedures." Alternatively, if you specify MSTAT=EXACT in the associated MANOVA or REPEATED statement,  $p$ -values for three of the four tests are computed exactly (Wilks' lambda, the Hotelling-Lawley trace, and Roy's greatest root), and the  $p$ -values for the fourth (Pillai's trace) are based on an  $F$  approximation that is more accurate than the default. See the "Multivariate Tests" section in Chapter 4, "Introduction to Regression Procedures," for more details on the exact calculations.

---

## Repeated Measures Analysis of Variance

When several measurements are taken on the same experimental unit (person, plant, machine, and so on), the measurements tend to be correlated with each other. When the measurements represent qualitatively different things, such as weight, length, and width, this correlation is best taken into account by use of multivariate methods, such as multivariate analysis of variance. When the measurements can be thought of as responses to levels of an experimental factor of interest, such as time, treatment, or dose, the correlation can be taken into account by performing a repeated measures analysis of variance.

PROC GLM provides both univariate and multivariate tests for repeated measures for one response. For an overall reference on univariate repeated measures, see Winer (1971). The multivariate approach is covered

in Cole and Grizzle (1966). For a discussion of the relative merits of the two approaches, see LaTour and Miniard (1983).

Another approach to analysis of repeated measures is via general mixed models. This approach can handle balanced as well as unbalanced or missing within-subject data, and it offers more options for modeling the within-subject covariance. The main drawback of the mixed models approach is that it generally requires iteration and, thus, might be less computationally efficient. For further details on this approach, see Chapter 59, “The MIXED Procedure,” and Wolfinger and Chang (1995).

## Organization of Data for Repeated Measure Analysis

In order to deal efficiently with the correlation of repeated measures, the GLM procedure uses the multivariate method of specifying the model, even if only a univariate analysis is desired. In some cases, data might already be entered in the univariate mode, with each repeated measure listed as a separate observation along with a variable that represents the experimental unit (subject) on which measurement is taken. Consider the following data set Old:

```
data Old;
 input Subject Group Time y;
 datalines;
 1 1 1 15
 1 1 2 19
 1 1 3 25
 2 1 1 21
 2 1 2 18
 2 1 3 17
 1 2 1 14
 1 2 2 12
 1 2 3 16
 2 2 1 11
 2 2 2 20
 2 2 3 21

 10 3 2 18
 10 3 3 16
 ;
```

There are three observations for each subject, corresponding to measurements taken at times 1, 2, and 3. These data could be analyzed using the following statements:

```
proc glm data=Old;
 class Group Subject Time;
 model y=Group Subject (Group) Time Group*Time;
 test h=Group e=Subject (Group);
run;
```

However, this analysis assumes subjects' measurements are uncorrelated across time. A repeated measures analysis does not make this assumption. It uses the following data set New:

```

data New;
 input Group y1 y2 y3;
 datalines;
1 15 19 25
1 21 18 17
2 14 12 16
2 11 20 21
2 24 15 12

 ... more lines ...

3 14 18 16
;

```

In the data set `New`, the three measurements for a subject are all in one observation. For example, the measurements for subject 1 for times 1, 2, and 3 are 15, 19, and 25, respectively. For these data, the statements for a repeated measures analysis (assuming default options) are

```

proc glm data=New;
 class Group;
 model y1-y3 = Group / nouni;
 repeated Time;
run;

```

To convert the univariate form of repeated measures data to the multivariate form, you can use a program like the following:

```

proc sort data=Old;
 by Group Subject;
run;

data New(keep=y1-y3 Group);
 array yy(3) y1-y3;
 do Time = 1 to 3;
 set Old;
 by Group Subject;
 yy(Time) = y;
 if last.Subject then return;
 end;
run;

```

Alternatively, you could use PROC TRANSPOSE to achieve the same results with a program like this one:

```

proc sort data=Old;
 by Group Subject;
run;

proc transpose out=New(rename=(_1=y1 _2=y2 _3=y3));
 by Group Subject;
 id Time;
run;

```

See the discussions in *SAS Language Reference: Concepts* for more information about rearrangement of data sets.

## Hypothesis Testing in Repeated Measures Analysis

In repeated measures analysis of variance, the effects of interest are as follows:

- between-subject effects (such as GROUP in the previous example)
- within-subject effects (such as TIME in the previous example)
- interactions between the two types of effects (such as GROUP\*TIME in the previous example)

Repeated measures analyses are distinguished from MANOVA because of interest in testing hypotheses about the within-subject effects and the within-subject-by-between-subject interactions.

For tests that involve only between-subjects effects, both the multivariate and univariate approaches give rise to the same tests. These tests are provided for all effects in the **MODEL** statement, as well as for any **CONTRAST**s specified. The ANOVA table for these tests is labeled “Tests of Hypotheses for Between Subjects Effects” in the PROC GLM results. These tests are constructed by first adding together the dependent variables in the model. Then an analysis of variance is performed on the sum divided by the square root of the number of dependent variables. For example, the statements

```
model y1-y3=group;
repeated time;
```

give a one-way analysis of variance that uses  $(Y1 + Y2 + Y3)/\sqrt{3}$  as the dependent variable for performing tests of hypothesis on the between-subject effect GROUP. Tests for between-subject effects are equivalent to tests of the hypothesis  $L\beta M = 0$ , where **M** is simply a vector of 1s.

For within-subject effects and for within-subject-by-between-subject interaction effects, the univariate and multivariate approaches yield different tests. These tests are provided for the within-subject effects and for the interactions between these effects and the other effects in the **MODEL** statement, as well as for any **CONTRAST**s specified. The univariate tests are displayed in a table labeled “Univariate Tests of Hypotheses for Within Subject Effects.” Results for multivariate tests are displayed in a table labeled “Repeated Measures Analysis of Variance.”

The multivariate tests provided for within-subjects effects and interactions involving these effects are Wilks’ lambda, Pillai’s trace, Hotelling-Lawley trace, and Roy’s greatest root. For further details on these four statistics, see the “Multivariate Tests” section in Chapter 4, “Introduction to Regression Procedures.” As an example, the statements

```
model y1-y3=group;
repeated time;
```

produce multivariate tests for the within-subject effect TIME and the interaction TIME\*GROUP.

The multivariate tests for within-subject effects are produced by testing the hypothesis  $L\beta M = 0$ , where the **L** matrix is the usual matrix corresponding to the Type I, Type II, Type III, or Type IV hypotheses test, and the **M** matrix is one of several matrices depending on the transformation that you specify in the **REPEATED** statement. These multivariate tests require that the column rank of **M** be less than or equal to the number of error degrees of freedom. Besides that, the only assumption required for valid tests is that the dependent variables in the model have a multivariate normal distribution with a common covariance matrix across the between-subject effects.

The univariate tests for within-subject effects and interactions involving these effects require some assumptions for the probabilities provided by the ordinary  $F$  tests to be correct. Specifically, these tests require certain patterns of covariance matrices, known as Type H covariances (Huynh and Feldt 1970). Data with these patterns in the covariance matrices are said to satisfy the Huynh-Feldt condition. You can test this assumption (and the Huynh-Feldt condition) by applying a sphericity test (Anderson 1958) to any set of variables defined by an orthogonal contrast transformation. Such a set of variables is known as a set of orthogonal components. When you use the `PRINTE` option in the `REPEATED` statement, this sphericity test is applied both to the transformed variables defined by the `REPEATED` statement and to a set of orthogonal components if the specified transformation is not orthogonal. It is the test applied to the orthogonal components that is important in determining whether your data have a Type H covariance structure. When there are only two levels of the within-subject effect, there is only one transformed variable, and a sphericity test is not needed. The sphericity test is labeled “Test for Sphericity” in the output.

If your data satisfy the preceding assumptions, use the usual  $F$  tests to test univariate hypotheses for the within-subject effects and associated interactions.

If your data do not satisfy the assumption of Type H covariance, an adjustment to numerator and denominator degrees of freedom can be used. Several such adjustments, based on a degrees-of-freedom adjustment factor known as  $\epsilon$  (epsilon) (Box 1954), are provided in PROC GLM. All these adjustments estimate  $\epsilon$  and then multiply the numerator and denominator degrees of freedom by this estimate before determining significance levels for the  $F$  tests. Significance levels associated with the adjusted tests are labeled “Adj Pr > F” in the output. Two such adjustments are displayed. One is the maximum likelihood estimate of Box’s  $\epsilon$  factor, which is known to be conservative, possibly very much so. The other adjustment is intended to be unbiased although possibly at the cost of being liberal. The first adjustment is labeled as the “Greenhouse-Geisser Epsilon.” It has the form

$$\hat{\epsilon}_{GG} = \frac{\text{trace}^2(\mathbf{E})/b}{\text{trace}(\mathbf{E}^2)}$$

where  $\mathbf{E}$  is the error matrix for the corresponding multivariate test and  $b$  is the degrees of freedom for the hypothesis being tested.  $\hat{\epsilon}_{GG}$  was initially proposed for use in data analysis by Greenhouse and Geisser (1959). Significance levels associated with  $F$  tests thus adjusted are labeled “G-G” in the output.

Huynh and Feldt (1976) showed that  $\hat{\epsilon}_{GG}$  tends to be biased downward (that is, conservative), especially for small samples. Alternative estimates have been proposed to overcome this conservative bias, and there are several options for which estimate to display along with  $\hat{\epsilon}_{GG}$ .

- Huynh and Feldt (1976) proposed an estimate of Box’s epsilon, constructed using estimators of its numerator and denominator that are intended to be unbiased. The Huynh-Feldt epsilon has the form of a modification of the Greenhouse-Geisser epsilon,

$$\hat{\epsilon}_{HF} = \frac{nb\hat{\epsilon}_{GG} - 2}{b(\text{DFE} - b\hat{\epsilon}_{GG})}$$

where  $n$  is the number of subjects and DFE is the degrees of freedom for error. The numerator of this estimate is precisely unbiased only when there are no between-subject effects, but  $\hat{\epsilon}_{HF}$  is still often employed even with nontrivial between-subject models; it was the only unbiased epsilon alternative in SAS/STAT releases before SAS/STAT 9.22. The Huynh-Feldt epsilon is no longer the default, but you can request it and its corresponding  $F$  test by using the `UEPSDEF=HF` option in the

**REPEATED** statement. The estimate is labeled “Huynh-Feldt Epsilon” in the PROC GLM output, and the significance levels associated with adjusted  $F$  tests are labeled “H-F.”

- Lecoutre (1991) gave the unbiased form of the numerator of Box’s epsilon when there is one between-subject effect. The correct form of Huynh and Feldt’s idea in this case is

$$\hat{\epsilon}_{\text{HFL}} = \frac{(\text{DFE} + 1)b\hat{\epsilon}_{\text{GG}} - 2}{b(\text{DFE} - b\hat{\epsilon}_{\text{GG}})}$$

More recently, Gribbin (2007) showed that  $\hat{\epsilon}_{\text{HFL}}$  applies to general between-subject models, and Chi et al. (2012) showed that it extends even to situations where the number of error degrees of freedom is less than the column rank of the within-subject contrast matrix. Thus, the Lecoutre correction of the Huynh-Feldt epsilon is displayed by default along with the Greenhouse-Geisser epsilon; you can also explicitly request it by using the **UEPSDEF=HFL** option in the **REPEATED** statement. The estimate is labeled “Huynh-Feldt-Lecoutre Epsilon” in the PROC GLM output, and the significance levels associated with adjusted  $F$  tests are labeled “H-F-L.”

- Finally, Chi et al. (2012) suggest that Box’s epsilon might be better estimated by replacing the reciprocal of an unbiased form of the denominator with an approximately unbiased form of the reciprocal itself. The resulting estimator can be written as a multiple of the corrected Huynh-Feldt epsilon  $\hat{\epsilon}_{\text{HFL}}$ ,

$$\hat{\epsilon}_{\text{CM}} = \hat{\epsilon}_{\text{HFL}}(v_a - 2)(v_a - 4)/v_a^2$$

where  $v_a = (\text{DFE} - 1) + \text{DFE}(\text{DFE} - 1)/2$ . Simulations indicate that  $\hat{\epsilon}_{\text{CM}}$  does a good job of providing accurate  $p$ -values without being either too conservative or too liberal. Over a wide range of cases, it is never much worse than any other alternative epsilon and often much better. You can request that the Chi-Muller epsilon estimate and its corresponding  $F$  test be displayed by using the **UEPSDEF=CM** option in the **REPEATED** statement. The estimate is labeled “Chi-Muller Epsilon” in the PROC GLM output, and the significance levels associated with adjusted  $F$  tests are labeled “C-M.”

Although  $\epsilon$  must be in the range of 0 to 1, the three approximately unbiased estimators can be outside this range. When any of these estimators is greater than 1, a value of 1 is used in all calculations for probabilities—in other words, the probabilities are not adjusted. Additionally, if  $\hat{\epsilon}_{\text{CM}} < 1/b$ , then the degrees of freedom are adjusted by  $1/b$  instead of  $\hat{\epsilon}_{\text{CM}}$ .

In summary, if your data do not meet the assumptions, use adjusted  $F$  tests. However, when you strongly suspect that your data might not have Type H covariance, all these univariate tests should be interpreted cautiously. In such cases, you should consider using the multivariate tests instead.

The univariate sums of squares for hypotheses involving within-subject effects can be easily calculated from the **H** and **E** matrices corresponding to the multivariate tests described in the section “**Multivariate Analysis of Variance**” on page 3366. If the **M** matrix is orthogonal, the univariate sums of squares is calculated as the trace (sum of diagonal elements) of the appropriate **H** matrix; if it is not orthogonal, PROC GLM calculates the trace of the **H** matrix that results from an orthogonal **M** matrix transformation. The appropriate error term for the univariate  $F$  tests is constructed in a similar way from the error SSCP matrix and is labeled **Error(factorname)**, where *factorname* indicates the **M** matrix that is used in the transformation.

When the design specifies more than one repeated measures factor, PROC GLM computes the **M** matrix for a given effect as the direct (Kronecker) product of the **M** matrices defined by the **REPEATED** statement if

the factor is involved in the effect or as a vector of 1s if the factor is not involved. The test for the main effect of a repeated measures factor is constructed using an **L** matrix that corresponds to a test that the mean of the observation is zero. Thus, the main effect test for repeated measures is a test that the means of the variables defined by the **M** matrix are all equal to zero, while interactions involving repeated measures effects are tests that the between-subjects factors involved in the interaction have no effect on the means of the transformed variables defined by the **M** matrix. In addition, you can specify other **L** matrices to test hypotheses of interest by using the **CONTRAST** statement, since hypotheses defined by **CONTRAST** statements are also tested in the **REPEATED** analysis. To see which combinations of the original variables the transformed variables represent, you can specify the **PRINTM** option in the **REPEATED** statement. This option displays the transpose of **M**, which is labeled as **M** in the PROC GLM results. The tests produced are the same for any choice of transformation (**M**) matrix specified in the **REPEATED** statement; however, depending on the nature of the repeated measurements being studied, a particular choice of transformation matrix, coupled with the **CANONICAL** or **SUMMARY** option, can provide additional insight into the data being studied.

## Transformations Used in Repeated Measures Analysis of Variance

As mentioned in the specifications of the **REPEATED** statement, several different **M** matrices can be generated automatically, based on the transformation that you specify in the **REPEATED** statement. Remember that both the univariate and multivariate tests that PROC GLM performs are unaffected by the choice of transformation; the choice of transformation is important only when you are trying to study the nature of a repeated measures effect, particularly with the **CANONICAL** and **SUMMARY** options. If one of these matrices does not meet your needs for a particular analysis, you might want to use the **M=** option in the **MANOVA** statement to perform the tests of interest.

The following sections describe the transformations available in the **REPEATED** statement, provide an example of the **M** matrix that is produced, and give guidelines for the use of the transformation. As in the PROC GLM output, the displayed matrix is labeled **M**. This is the **M'** matrix.

### **CONTRAST Transformation**

This is the default transformation used by the **REPEATED** statement. It is useful when one level of the repeated measures effect can be thought of as a control level against which the others are compared. For example, if five drugs are administered to each of several animals and the first drug is a control or placebo, the statements

```
proc glm;
 model d1-d5= / nouni;
 repeated drug 5 contrast(1) / summary printm;
run;
```

produce the following **M** matrix:

$$M = \begin{bmatrix} -1 & 1 & 0 & 0 & 0 \\ -1 & 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 1 & 0 \\ -1 & 0 & 0 & 0 & 1 \end{bmatrix}$$

When you examine the analysis of variance tables produced by the **SUMMARY** option, you can tell which of the drugs differed significantly from the placebo.

**POLYNOMIAL Transformation**

This transformation is useful when the levels of the repeated measure represent quantitative values of a treatment, such as dose or time. If the levels are unequally spaced, *level values* can be specified in parentheses after the number of levels in the **REPEATED** statement. For example, if five levels of a drug corresponding to 1, 2, 5, 10, and 20 milligrams are administered to different treatment groups, represented by the variable *group*, the statements

```
proc glm;
 class group;
 model r1-r5=group / noint;
 repeated dose 5 (1 2 5 10 20) polynomial / summary printm;
run;
```

produce the following **M** matrix:

$$M = \begin{bmatrix} -0.4250 & -0.3606 & -0.1674 & 0.1545 & 0.7984 \\ 0.4349 & 0.2073 & -0.3252 & -0.7116 & 0.3946 \\ -0.4331 & 0.1366 & 0.7253 & -0.5108 & 0.0821 \\ 0.4926 & -0.7800 & 0.3743 & -0.0936 & 0.0066 \end{bmatrix}$$

The **SUMMARY** option in this example provides univariate ANOVAs for the variables defined by the rows of this **M** matrix. In this case, they represent the linear, quadratic, cubic, and quartic trends for dose and are labeled *dose\_1*, *dose\_2*, *dose\_3*, and *dose\_4*, respectively.

**HELMERT Transformation**

Since the Helmert transformation compares a level of a repeated measure to the mean of subsequent levels, it is useful when interest lies in the point at which responses cease to change. For example, if four levels of a repeated measures factor represent responses to treatments administered over time to males and females, the statements

```
proc glm;
 class sex;
 model resp1-resp4=sex / noint;
 repeated trtmnt 4 helmert / canon printm;
run;
```

produce the following **M** matrix:

$$M = \begin{bmatrix} 1 & -0.33333 & -0.33333 & -0.33333 \\ 0 & 1 & -0.50000 & -0.50000 \\ 0 & 0 & 1 & -1 \end{bmatrix}$$

**MEAN Transformation**

This transformation can be useful in the same types of situations in which the **CONTRAST** transformation is useful. If you substitute the following statement for the **REPEATED** statement shown in the **CONTRAST Transformation** section,

```
repeated drug 5 mean / printm;
```

the following M matrix is produced:

$$M = \begin{bmatrix} 1 & -0.25 & -0.25 & -0.25 & -0.25 \\ -0.25 & 1 & -0.25 & -0.25 & -0.25 \\ -0.25 & -0.25 & 1 & -0.25 & -0.25 \\ -0.25 & -0.25 & -0.25 & 1 & -0.25 \end{bmatrix}$$

As with the **CONTRAST** transformation, if you want to omit a level other than the last, you can specify it in parentheses after the keyword **MEAN** in the **REPEATED** statement.

### **PROFILE Transformation**

When a repeated measure represents a series of factors administered over time, but a polynomial response is unreasonable, a profile transformation might prove useful. As an example, consider a training program in which four different methods are employed to teach students at several different schools. The repeated measure is the score on tests administered after each of the methods is completed. The statements

```
proc glm;
 class school;
 model t1-t4=school / nouni;
 repeated method 4 profile / summary nom printm;
run;
```

produce the following M matrix:

$$M = \begin{bmatrix} 1 & -1 & 0 & 0 \\ 0 & 1 & -1 & 0 \\ 0 & 0 & 1 & -1 \end{bmatrix}$$

To determine the point at which an improvement in test scores takes place, you can examine the analyses of variance for the transformed variables representing the differences between adjacent tests. These analyses are requested by the **SUMMARY** option in the **REPEATED** statement, and the variables are labeled **METHOD.1**, **METHOD.2**, and **METHOD.3**.

## **Random-Effects Analysis**

When some model effects are random (that is, assumed to be sampled from a normal population of effects), you can specify these effects in the **RANDOM** statement in order to compute the expected values of mean squares for various model effects and contrasts and, optionally, to perform random-effects analysis of variance tests.

### **PROC GLM versus PROC MIXED for Random-Effects Analysis**

Other SAS procedures that can be used to analyze models with random effects include the **MIXED** and **VARCOMP** procedures. Note that, for these procedures, the random-effects specification is an integral part of the model, affecting how both random and fixed effects are fit; for **PROC GLM**, the random effects are treated in a *post hoc* fashion after the complete fixed-effect model is fit. This distinction affects other

features in the GLM procedure, such as the results of the **LSMEANS** and **ESTIMATE** statements. These features assume that all effects are fixed, so that all tests and estimability checks for these statements are based on a fixed-effects model, even when you use a **RANDOM** statement. Standard errors for estimates and LS-means based on the fixed-effects model might be significantly smaller than those based on a true random-effects model; in fact, some functions that are estimable under a true random-effects model might not even be estimable under the fixed-effects model. Therefore, you should use the **MIXED** procedure to compute tests involving these features that take the random effects into account; see Chapter 59, “**The MIXED Procedure**,” for more information.

Note that, for balanced data, the test statistics computed when you specify the **TEST** option in the **RANDOM** statement have an exact  $F$  distribution only when the design is balanced; for unbalanced designs, the  $p$  values for the  $F$  tests are approximate. For balanced data, the values obtained by **PROC GLM** and **PROC MIXED** agree; for unbalanced data, they usually do not.

### Computation of Expected Mean Squares for Random Effects

The **RANDOM** statement in **PROC GLM** declares one or more effects in the model to be random rather than fixed. By default, **PROC GLM** displays the coefficients of the expected mean squares for all terms in the model. In addition, when you specify the **TEST** option in the **RANDOM** statement, the procedure determines what tests are appropriate and provides  $F$  ratios and probabilities for these tests.

The expected mean squares are computed as follows. Consider the model

$$Y = X_0\beta_0 + X_1\beta_1 + \cdots + X_k\beta_k + \epsilon$$

where  $\beta_0$  represents the fixed effects and  $\beta_1, \beta_2, \dots, \epsilon$  represent the random effects. Random effects are assumed to be normally and independently distributed. For any  $L$  in the row space of  $X = (X_0 | X_1 | X_2 | \cdots | X_k)$ , the expected value of the sum of squares for  $L\beta$  is

$$E(SS_L) = \beta_0' C_0' C_0 \beta_0 + SSQ(C_1)\sigma_1^2 + SSQ(C_2)\sigma_2^2 + \cdots + SSQ(C_k)\sigma_k^2 + \text{rank}(L)\sigma_\epsilon^2$$

where  $C$  is of the same dimensions as  $L$  and is partitioned as the  $X$  matrix. In other words,

$$C = (C_0 | C_1 | \cdots | C_k)$$

Furthermore,  $C = ML$ , where  $M$  is the inverse of the lower triangular Cholesky decomposition matrix of  $L(X'X)^{-1}L'$ .  $SSQ(A)$  is defined as  $\text{tr}(A'A)$ .

For the model in the following **MODEL** statement

```
model Y=A B(A) C A*C;
random B(A);
```

with  $B(A)$  declared as random, the expected mean square of each effect is displayed as

$$\text{Var}(\text{Error}) + \text{constant} \times \text{Var}(B(A)) + Q(A, C, A * C)$$

If any fixed effects appear in the expected mean square of an effect, the letter  $Q$  followed by the list of fixed effects in the expected value is displayed. The actual numeric values of the quadratic form ( $Q$  matrix) can be displayed using the **Q** option.

To determine appropriate means squares for testing the effects in the model, the **TEST** option in the **RANDOM** statement performs the following steps:

1. First, it forms a matrix of coefficients of the expected mean squares of those effects that were declared to be random.
2. Next, for each effect in the model, it determines the combination of these expected mean squares that produce an expectation that includes all the terms in the expected mean square of the effect of interest except the one corresponding to the effect of interest. For example, if the expected mean square of an effect A\*B is

$$\text{Var}(\text{Error}) + 3 \times \text{Var}(A) + \text{Var}(A * B)$$

PROC GLM determines the combination of other expected mean squares in the model that has expectation

$$\text{Var}(\text{Error}) + 3 \times \text{Var}(A)$$

3. If the preceding criterion is met by the expected mean square of a single effect in the model (as is often the case in balanced designs), the  $F$  test is formed directly. In this case, the mean square of the effect of interest is used as the numerator, the mean square of the single effect with an expected mean square that satisfies the criterion is used as the denominator, and the degrees of freedom for the test are simply the usual model degrees of freedom.
4. When more than one mean square must be combined to achieve the appropriate expectation, an approximation is employed to determine the appropriate degrees of freedom (Satterthwaite 1946). When effects other than the effect of interest are listed after the Q in the output, tests of hypotheses involving the effect of interest are not valid unless all other fixed effects involved in it are assumed to be zero. When tests such as these are performed by using the **TEST** option in the **RANDOM** statement, a note is displayed reminding you that further assumptions are necessary for the validity of these tests. Remember that although the tests are not valid unless these assumptions are made, this does not provide a basis for these assumptions to be true. The particulars of a given experiment must be examined to determine whether the assumption is reasonable.

For further theoretical discussion, see Goodnight and Speed (1978), Milliken and Johnson (1984, Chapters 22 and 23), and Hocking (1985).

### Sum-to-Zero Assumptions

The formulation and parameterization of the expected mean squares for random effects in mixed models are ongoing items of controversy in the statistical literature. Confusion arises over whether or not to assume that terms involving fixed effects sum to zero. Cornfield and Tukey (1956); Winer (1971), and others assume that they do sum to zero; Searle (1971); Hocking (1973), and others (including PROC GLM) do not.

Different assumptions about these sum-to-zero constraints can lead to different expected mean squares for certain terms, and hence to different  $F$  and  $p$  values.

For arguments in favor of not assuming that terms involving fixed effects sum to zero, see Section 9.7 of Searle (1971) and Sections 1 and 4 of McLean, Sanders, and Stroup (1991). Other references are Hartley and Searle (1969) and Searle, Casella, and McCulloch (1992).

## Computing Type I, II, and IV Expected Mean Squares

When you use the **RANDOM** statement, by default the GLM procedure produces the Type III expected mean squares for model effects and for contrasts specified before the **RANDOM** statement. In order to obtain expected values for other types of mean squares, you need to specify which types of mean squares are of interest in the **MODEL** statement. For example, in order to obtain the Type IV expected mean squares for effects in the **RANDOM** and **CONTRAST** statements, specify the **SS4** option in the **MODEL** statement. If you want both Type III and Type IV expected mean squares, specify both the **SS3** and **SS4** options in the **MODEL** statement. Since the estimable function basis is not automatically calculated for Type I and Type II SS, the **E1** (for Type I) or **E2** (for Type II) option must be specified in the **MODEL** statement in order for the **RANDOM** statement to produce the expected mean squares for the Type I or Type II sums of squares. Note that it is important to list the fixed effects first in the **MODEL** statement when requesting the Type I expected mean squares.

For example, suppose you have a two-way design with factors A and B in which the main effect for B and the interaction are random. In order to compute the Type III expected mean squares (in addition to the fixed-effect analysis), you can use the following statements:

```
proc glm;
 class A B;
 model Y = A B A*B;
 random B A*B;
run;
```

Suppose you use the **SS4** option in the **MODEL** statement, as follows:

```
proc glm;
 class A B;
 model Y = A B A*B / ss4;
 random B A*B;
run;
```

Then only the Type IV expected mean squares are computed (as well as the Type IV fixed-effect tests). For the Type I expected mean squares, you can use the following statements:

```
proc glm;
 class A B;
 model Y = A B A*B / e1;
 random B A*B;
run;
```

For each of these cases, in order to perform random-effect analysis of variance tests for each effect specified in the model, you need to specify the **TEST** option in the **RANDOM** statement, as follows:

```
proc glm;
 class A B;
 model Y = A B A*B;
 random B A*B / test;
run;
```

The GLM procedure automatically determines the appropriate error term for each test, based on the expected mean squares.

---

## Missing Values

For an analysis involving one dependent variable, PROC GLM uses an observation if values are nonmissing for that dependent variable and all the classification variables.

For an analysis involving multiple dependent variables without the [MANOVA](#) or [REPEATED](#) statement, or without the [MANOVA](#) option in the PROC GLM statement, a missing value in one dependent variable does not eliminate the observation from the analysis of other nonmissing dependent variables. On the other hand, for an analysis with the [MANOVA](#) or [REPEATED](#) statement, or with the [MANOVA](#) option in the PROC GLM statement, PROC GLM uses an observation if values are nonmissing for all dependent variables and all the variables used in independent effects.

During processing, the GLM procedure groups the dependent variables by their pattern of missing values across observations so that sums and crossproducts can be collected in the most efficient manner.

If your data have different patterns of missing values among the dependent variables, interactivity is disabled. This can occur when some of the variables in your data set have missing values and either of the following conditions obtain:

- You do not use the [MANOVA](#) option in the PROC GLM statement.
- You do not use a [MANOVA](#) or [REPEATED](#) statement before the first RUN statement.

Note that the REG procedure handles missing values differently in this case; see Chapter 79, “[The REG Procedure](#),” for more information.

---

## Computational Resources

### Memory

For large problems, most of the memory resources are required for holding the  $X'X$  matrix of the sums and crossproducts. The section “[Parameterization of PROC GLM Models](#)” on page 3327 describes how columns of the  $X$  matrix are allocated for various types of effects. For each level that occurs in the data for a combination of classification variables in a given effect, a row and a column for  $X'X$  are needed.

The following example illustrates the calculation. Suppose  $A$  has 20 levels,  $B$  has 4 levels, and  $C$  has 3 levels. Then consider the model

```
proc glm;
 class A B C;
 model Y1 Y2 Y3=A B A*B C A*C B*C A*B*C X1 X2;
run;
```

The  $X'X$  matrix (bordered by  $X'Y$  and  $Y'Y$ ) can have as many as 425 rows and columns:

|    |                        |
|----|------------------------|
| 1  | for the intercept term |
| 20 | for $A$                |
| 4  | for $B$                |

|     |                                          |
|-----|------------------------------------------|
| 80  | for A*B                                  |
| 3   | for C                                    |
| 60  | for A*C                                  |
| 12  | for B*C                                  |
| 240 | for A*B*C                                |
| 2   | for X1 and X2 (continuous variables)     |
| 3   | for Y1, Y2, and Y3 (dependent variables) |

The matrix has 425 rows and columns only if all combinations of levels occur for each effect in the model. For  $m$  rows and columns,  $8m^2$  bytes are needed for crossproducts. In this case,  $8 \cdot 425^2 = 1,445,000$  bytes, or about  $1,445,000/1024 = 1411K$ .

The required memory grows as the square of the number of columns of  $\mathbf{X}$ ; most of the memory is for the A\*B\*C interaction. Without A\*B\*C, you have 185 columns and need 268K for  $\mathbf{X}'\mathbf{X}$ . Without either A\*B\*C or A\*B, you need 86K. If A is recoded to have 10 levels, then the full model has only 220 columns and requires 378K.

The second time that a large amount of memory is needed is when Type III, Type IV, or contrast sums of squares are being calculated. This memory requirement is a function of the number of degrees of freedom of the model being analyzed and the maximum degrees of freedom for any single source. Let Rank equal the sum of the model degrees of freedom, MaxDF be the maximum number of degrees of freedom for any single source, and  $N_y$  be the number of dependent variables in the model. Then the memory requirement in bytes is 8 times

$$\begin{aligned}
 N_y \times \text{Rank} &+ (\text{Rank} \times (\text{Rank} + 1)) / 2 \\
 &+ \text{MaxDF} \times \text{Rank} \\
 &+ (\text{MaxDF} \times (\text{MaxDF} + 1)) / 2 \\
 &+ \text{MaxDF} \times N_y
 \end{aligned}$$

The first two components of this formula are for the estimable model coefficients and their variance; the rest correspond to  $\mathbf{L}$ ,  $\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}'$ , and  $\mathbf{Lb}$  in the computation of  $\text{SS}(\mathbf{L}\boldsymbol{\beta} = 0) = (\mathbf{Lb})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{Lb})$ . If the operating system enables SAS to run parallel computational threads on multiple CPUs, then GLM will attempt to allocate another  $8 \times \text{Rank} \times \text{Rank}$  bytes in order to perform these calculations in parallel. If this much memory is not available, then the estimability calculations are performed in a single thread.

Unfortunately, these quantities are not available when the  $\mathbf{X}'\mathbf{X}$  matrix is being constructed, so PROC GLM might occasionally request additional memory even after you have increased the memory allocation available to the program.

If you have a large model that exceeds the memory capacity of your computer, these are your options:

- Eliminate terms, especially high-level interactions.
- Reduce the number of levels for variables with many levels.
- Use the [ABSORB](#) statement for parts of the model that are large.

- Use the **REPEATED** statement for repeated measures variables.
- Use PROC ANOVA or PROC REG rather than PROC GLM, if your design allows.

A related limitation is that for any model effect involving classification variables (interactions as well as main effects), the number of levels cannot exceed 32,767. This is because GLM internally indexes effect levels with signed short (16-bit) integers, for which the maximum value is  $2^{15} - 1 = 32,767$ .

## CPU Time

Typically, if the GLM procedure requires a lot of CPU time, it will be for one of several reasons. Suppose that the input data has  $n$  rows (observations) and the model has  $E$  effects that together produce a design matrix  $X$  with  $m$  columns. Then if  $m$  or  $n$  is relatively large, the procedure might spend a lot of time in any of the following areas:

- collecting the sums of squares and crossproducts
- solving the normal equations
- computing the Type III tests

The time required for collecting sums and crossproducts is difficult to calculate because it is a complicated function of the model. The worst case occurs if all columns are continuous variables, involving  $nm^2/2$  multiplications and additions. If the columns are levels of a classification, then only  $m$  sums might be needed, but a significant amount of time might be spent in look-up operations. Solving the normal equations requires time for approximately  $m^3/2$  multiplications and additions, and the number of operations required to compute the Type III tests is also proportional to both  $E$  and  $m^3$ .

Suppose that you know that Type IV sums of squares are appropriate for the model you are analyzing (for example, if your design has no missing cells). You can specify the **SS4** option in your **MODEL** statement, which saves CPU time by requesting the Type IV sums of squares instead of the more computationally burdensome Type III sums of squares. This proves especially useful if you have a factor in your model that has many levels and is involved in several interactions.

If the operating system enables SAS to run parallel computational threads on multiple CPUs, then both the solution of the normal equations and the computation of Type III tests can take advantage of this to reduce the computational time for large models. In solving the normal equations, the fundamental row sweep operations (Goodnight 1979) are performed in parallel. In computing the Type III tests, both the orthogonalization for the estimable functions and the sums of squares calculation have been parallelized (if there is sufficient memory).

The reduction in computational time due to parallel processing depends on the size of the model, the number of processors, and the parallel architecture of the operating system. If the model is large enough that the overwhelming proportion of CPU time for the procedure is accounted for in solving the normal equations and/or computing the Type III tests, then you can expect a reduction in computational time approximately inversely proportional to the number of CPUs. However, as you increase the number of processors, the efficiency of this scaling can be reduced by several effects. One mitigating factor is a purely mathematical one known as “Amdahl’s law,” which is related to the fact that only part of the processing time for the procedure can be parallelized. Even taking Amdahl’s law into account, the parallelization efficiency can be reduced by cache effects related to how fast the multiple processors can access memory. See Cohen (2002)

for a discussion of these issues. For additional information about parallel processing in SAS, see the chapter on “Support for Parallel Processing” in *SAS Language Reference: Concepts*.

---

## Computational Method

Let  $\mathbf{X}$  represent the  $n \times p$  design matrix and  $\mathbf{Y}$  the  $n \times 1$  vector of dependent variables. (See the section “Parameterization of PROC GLM Models” on page 3327 for information about how  $\mathbf{X}$  is formed from your model specification.)

The normal equations  $\mathbf{X}'\mathbf{X}\boldsymbol{\beta} = \mathbf{X}'\mathbf{Y}$  are solved using a modified sweep routine that produces a generalized inverse  $(\mathbf{X}'\mathbf{X})^-$  and a solution  $\mathbf{b} = (\mathbf{X}'\mathbf{X})^- \mathbf{X}'\mathbf{y}$ . The modification is that rows and columns corresponding to diagonal elements that are found during sweeping to be zero (or within the expected level of numerical error of zero) are zeroed out. The  $(\mathbf{X}'\mathbf{X})^-$  produced by this procedure satisfies the following two equations:

$$\begin{aligned} (\mathbf{X}'\mathbf{X}) (\mathbf{X}'\mathbf{X})^- (\mathbf{X}'\mathbf{X}) &= (\mathbf{X}'\mathbf{X}) \\ (\mathbf{X}'\mathbf{X})^- (\mathbf{X}'\mathbf{X}) (\mathbf{X}'\mathbf{X})^- &= (\mathbf{X}'\mathbf{X})^- \end{aligned}$$

Pringle and Rayner (1971) call a generalized inverse with these characteristics a  $g_2$ -inverse, and this is the term usually used in SAS documentation and output. Urqhardt (1968) uses the term *reflexive g-inverse* to emphasize that  $(\mathbf{X}'\mathbf{X})^-$  is a generalized inverse of  $\mathbf{X}'\mathbf{X}$  in the same way that  $\mathbf{X}'\mathbf{X}$  is a generalized inverse of  $(\mathbf{X}'\mathbf{X})^-$ . Note that a  $g_2$ -inverse is not necessarily unique: if  $\mathbf{X}'\mathbf{X}$  is singular, then sweeping the matrix in a different order will result in a different  $g_2$ -inverse that also satisfies the two preceding equations.

For each effect in the model, a matrix  $\mathbf{L}$  is computed such that the rows of  $\mathbf{L}$  are estimable. Tests of the hypothesis  $\mathbf{L}\boldsymbol{\beta} = 0$  are then made by first computing

$$SS(\mathbf{L}\boldsymbol{\beta} = 0) = (\mathbf{L}\mathbf{b})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^- \mathbf{L}')^{-1}(\mathbf{L}\mathbf{b})$$

and then computing the associated  $F$  value by using the mean squared error.

---

## Output Data Sets

### OUT= Data Set Created by the OUTPUT Statement

The `OUTPUT` statement produces an output data set that contains the following:

- all original data from the SAS data set input to PROC GLM
- the new variables corresponding to the diagnostic measures specified with statistics keywords in the `OUTPUT` statement (`PREDICTED=`, `RESIDUAL=`, and so on)

With multiple dependent variables, a name can be specified for any of the diagnostic measures for each of the dependent variables in the order in which they occur in the `MODEL` statement.

For example, suppose that the input data set `A` contains the variables `y1`, `y2`, `y3`, `x1`, and `x2`. Then you can use the following statements:

```
proc glm data=A;
 model y1 y2 y3=x1;
 output out=out p=y1hat y2hat y3hat
 r=y1resid lclm=y1lcl uclm=y1ucl;
run;
```

The output data set out contains y1, y2, y3, x1, x2, y1hat, y2hat, y3hat, y1resid, y1lcl, and y1ucl. The variable x2 is output even though it is not used by PROC GLM. Although predicted values are generated for all three dependent variables, residuals are output for only the first dependent variable.

When any independent variable in the analysis (including all class variables) is missing for an observation, then all new variables that correspond to diagnostic measures are missing for the observation in the output data set.

When a dependent variable in the analysis is missing for an observation, then some new variables that correspond to diagnostic measures are missing for the observation in the output data set, and some are still available. Specifically, in this case, the new variables that correspond to COOKD, COVRATIO, DFFITS, PRESS, R, RSTUDENT, STDR, and STUDENT are missing in the output data set. The variables corresponding to H, LCL, LCLM, P, STDI, STDP, UCL, and UCLM are not missing.

## OUT= Data Set Created by the LSMEANS Statement

The **OUT=** option in the **LSMEANS** statement produces an output data set that contains the following:

- the unformatted values of each classification variable specified in any effect in the **LSMEANS** statement
- a new variable, **LSMEAN**, which contains the LS-mean for the specified levels of the classification variables
- a new variable, **STDERR**, which contains the standard error of the LS-mean

The variances and covariances among the LS-means are also output when the **COV** option is specified along with the **OUT=** option. In this case, only one effect can be specified in the **LSMEANS** statement, and the following variables are included in the output data set:

- new variables, **COV1**, **COV2**, ..., **COV $n$** , where  $n$  is the number of levels of the effect specified in the **LSMEANS** statement. These variables contain the covariances of each LS-mean with every other LS-mean.
- a new variable, **NUMBER**, which provides an index for each observation to identify the covariances that correspond to that observation. The covariances for the observation with **NUMBER** equal to  $n$  can be found in the variable **COV $n$** .

## OUTSTAT= Data Set

The **OUTSTAT=** option in the PROC GLM statement produces an output data set that contains the following:

- the **BY** variables, if any

- `_TYPE_`, a new character variable. `_TYPE_` can take the values ‘SS1’, ‘SS2’, ‘SS3’, ‘SS4’, or ‘CONTRAST’, corresponding to the various types of sums of squares generated, or the values ‘CANCORR’, ‘STRUCTUR’, or ‘SCORE’, if a canonical analysis is performed through the `MANOVA` statement and no `M=` matrix is specified.
- `_SOURCE_`, a new character variable. For each observation in the data set, `_SOURCE_` contains the name of the model effect or contrast label from which the corresponding statistics are generated.
- `_NAME_`, a new character variable. For each observation in the data set, `_NAME_` contains the name of one of the dependent variables in the model or, in the case of canonical statistics, the name of one of the canonical variables (`CAN1`, `CAN2`, and so forth).
- four new numeric variables: `SS`, `DF`, `F`, and `PROB`, containing sums of squares, degrees of freedom,  $F$  values, and probabilities, respectively, for each model or contrast sum of squares generated in the analysis. For observations resulting from canonical analyses, these variables have missing values.
- if there is more than one dependent variable, then variables with the same names as the dependent variables represent the following:
  - for `_TYPE_=SS1`, `SS2`, `SS3`, `SS4`, or `CONTRAST`, the crossproducts of the hypothesis matrices
  - for `_TYPE_=CANCORR`, canonical correlations for each variable
  - for `_TYPE_=STRUCTUR`, coefficients of the total structure matrix
  - for `_TYPE_=SCORE`, raw canonical score coefficients

The output data set can be used to perform special hypothesis tests (for example, with the `IML` procedure in SAS/IML software), to reformat output, to produce canonical variates (through the `SCORE` procedure), or to rotate structure matrices (through the `FACTOR` procedure).

---

## Displayed Output

The GLM procedure produces the following output by default:

- The overall analysis-of-variance table breaks down the Total Sum of Squares for the dependent variable into the portion attributed to the Model and the portion attributed to Error.
- The Mean Square term is the Sum of Squares divided by the degrees of freedom (DF).
- The Mean Square for Error is an estimate of  $\sigma^2$ , the variance of the true errors.
- The  $F$  Value is the ratio produced by dividing the Mean Square for the Model by the Mean Square for Error. It tests how well the model as a whole (adjusted for the mean) accounts for the dependent variable’s behavior. An  $F$  test is a joint test to determine that all parameters except the intercept are zero.
- A small significance probability,  $\text{Pr} > F$ , indicates that some linear function of the parameters is significantly different from zero.

- R-Square,  $R^2$ , measures how much variation in the dependent variable can be accounted for by the model. R square, which can range from 0 to 1, is the ratio of the sum of squares for the model to the corrected total sum of squares. In general, the larger the value of R square, the better the model's fit.
- Coeff Var, the coefficient of variation, which describes the amount of variation in the population, is 100 times the standard deviation estimate of the dependent variable, Root MSE (Mean Square for Error), divided by the Mean. The coefficient of variation is often a preferred measure because it is unitless.
- Root MSE estimates the standard deviation of the dependent variable (or equivalently, the error term) and equals the square root of the Mean Square for Error.
- Mean is the sample mean of the dependent variable.

These tests are used primarily in analysis-of-variance applications:

- The Type I SS (sum of squares) measures incremental sums of squares for the model as each variable is added.
- The Type III SS is the sum of squares for a balanced test of each effect, adjusted for every other effect.

These items are used primarily in regression applications:

- The Estimates for the model Parameters (the intercept and the coefficients)
- t Value is the Student's  $t$  value for testing the null hypothesis that the parameter (if it is estimable) equals zero.
- The significance level,  $\Pr > |t|$ , is the probability of getting a larger value of  $t$  if the parameter is truly equal to zero. A very small value for this probability leads to the conclusion that the independent variable contributes significantly to the model.
- The Standard Error is the square root of the estimated variance of the estimate of the true value of the parameter.

Other portions of output are discussed in the following examples.

---

## ODS Table Names

PROC GLM assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 42.14. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 42.14** ODS Tables Produced by PROC GLM

| ODS Table Name      | Description                                                                      | Statement / Option                                                                            |
|---------------------|----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| Aliasing            | Type 1,2,3,4 aliasing structure                                                  | MODEL / (E1 E2 E3 or E4) and ALIASING                                                         |
| AltErrContrasts     | ANOVA table for contrasts with alternative error                                 | CONTRAST / E=                                                                                 |
| AltErrTests         | ANOVA table for tests with alternative error                                     | TEST / E=                                                                                     |
| Bartlett            | Bartlett's homogeneity of variance test                                          | MEANS / HOVTEST=BARTLETT                                                                      |
| CLDiffs             | Multiple comparisons of pairwise differences                                     | MEANS / CLDIFF or DUNNETT or (Unequal cells and not LINES)                                    |
| CLDiffsInfo         | Information for multiple comparisons of pairwise differences                     | MEANS / CLDIFF or DUNNETT or (Unequal cells and not LINES)                                    |
| CLMeans             | Multiple comparisons of means with confidence/comparison interval                | MEANS / CLM                                                                                   |
| CLMeansInfo         | Information for multiple comparison of means with confidence/comparison interval | MEANS / CLM                                                                                   |
| CanAnalysis         | Canonical analysis                                                               | (MANOVA or REPEATED) / CANONICAL                                                              |
| CanCoef             | Canonical coefficients                                                           | (MANOVA or REPEATED) / CANONICAL                                                              |
| CanStructure        | Canonical structure                                                              | (MANOVA or REPEATED) / CANONICAL                                                              |
| CharStruct          | Characteristic roots and vectors                                                 | (MANOVA / not CANONICAL) or (REPEATED / PRINTRV)                                              |
| ClassLevels         | Classification variable levels                                                   | CLASS statement                                                                               |
| ContrastCoef        | L matrix for contrast or estimate                                                | CONTRAST / E or ESTIMATE / E                                                                  |
| Contrasts           | ANOVA table for contrasts                                                        | CONTRAST statement                                                                            |
| DependentInfo       | Simultaneously analyzed dependent variables                                      | default when there are multiple dependent variables with different patterns of missing values |
| Diff                | PDiff matrix of least squares means                                              | LSMEANS / PDIFF=ALL and more than two LS-means                                                |

| Sphericity Tests  | Sphericity tests<br>Summary ANOVA for specified                | REPEATED / PRINTE<br>MANOVA / H= SUMMARY |
| Tolerances        | $X'X$ tolerances                                               | MODEL / TOLERANCE                        |
| Welch             | Welch's ANOVA                                                  | MEANS / WELCH                            |
| XPX               | $X'X$ matrix                                                   | MODEL / XPX                              |

With the **PDIF** or **TDIF** option in the **LSMEANS** statement, the  $p/t$ -values for differences are displayed in columns of the LSMeans table for **PDIF/TDIF=CONTROL** or **PDIF/TDIF=ANOM**, and for **PDIF/TDIF=ALL** when there are only two LS-means. Otherwise (for **PDIF/TDIF=ALL** when there are more than two LS-means), the  $p/t$ -values for differences are displayed in a separate table called **Diff**.

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the **ODS GRAPHICS ON** statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

When ODS Graphics is enabled, then for particular models the GLM procedure will produce default graphics.

- If you specify a one-way analysis of variance model, with just one **CLASS** variable, the GLM procedure will produce a grouped box plot of the response values versus the **CLASS** levels. For an example of the box plot, see the section “One-Way Layout with Means Comparisons” on page 904.
- If you specify a two-way analysis of variance model, with just two **CLASS** variables, the GLM procedure will produce an interaction plot of the response values, with horizontal position representing

one **CLASS** variable and marker style representing the other; and with predicted response values connected by lines representing the two-way analysis. For an example of the interaction plot, see the section “[PROC GLM for Unbalanced ANOVA](#)” on page 3269.

- If you specify a model with a single continuous predictor, the GLM procedure will produce a fit plot of the response values versus the covariate values, with a curve representing the fitted relationship. For an example of the fit plot, see the section “[PROC GLM for Quadratic Least Squares Regression](#)” on page 3272.
- If you specify a model with a two continuous predictors and no **CLASS** variables, the GLM procedure will produce a panel of fit plots as in the single predictor case, with a plot of the response values versus one of the covariates at each of several values of the other covariate.
- If you specify an analysis of covariance model, with one or two **CLASS** variables and one continuous variable, the GLM procedure will produce an analysis of covariance plot of the response values versus the covariate values, with lines representing the fitted relationship within each classification level. For an example of the analysis of covariance plot, see [Example 42.4](#).
- If you specify an **LSMEANS** statement with the **PDIF** option, the GLM procedure will produce a plot appropriate for the type of LS-means comparison. For **PDIF=ALL** (which is the default if you specify only **PDIF**), the procedure produces a diffogram, which displays all pairwise LS-means differences and their significance. The display is also known as a “mean-mean scatter plot” (Hsu 1996). For **PDIF=CONTROL**, the procedure produces a display of each noncontrol LS-mean compared to the control LS-mean, with two-sided confidence intervals for the comparison. For **PDIF=CONTROL** and **PDIF=CONTROLU** a similar display is produced, but with one-sided confidence intervals. Finally, for the **PDIF=ANOM** option, the procedure produces an “analysis of means” plot, comparing each LS-mean to the average LS-mean.
- If you specify a **MEANS** statement, the GLM procedure will produce a grouped box plot of the response values versus the effect for which means are being calculated.

In addition to the default graphics mentioned previously, you can request plots that help you diagnose the quality of the fitted model.

- The **PLOTS=DIAGNOSTICS** option in the **PROC GLM** statement requests that a panel of summary diagnostics for the fit be displayed. The panel displays scatter plots of residuals, absolute residuals, studentized residuals, and observed responses by predicted values; studentized residuals by leverage; Cook’s *D* by observation; a Q-Q plot of residuals; a residual histogram; and a residual-fit spread plot.
- The **PLOTS=RESIDUALS** option in the **PROC GLM** statement requests scatter plots of the residuals against each continuous covariate.

## ODS Graph Names

PROC GLM assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in [Table 42.15](#).

ODS Graphics must be enabled before requesting plots. For more information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).”

**Table 42.15** Graphs Produced by PROC GLM

| ODS Graph Name      | Plot Description                                         | Option                                 |
|---------------------|----------------------------------------------------------|----------------------------------------|
| ANCOVAPlot          | Analysis of covariance plot                              | Analysis of covariance model           |

| ObservedByPredicted | Observed by predicted                                    | PLOTS=DIAGNOSTICS(UNPACK)              |
| QQPlot              | Residual Q-Q plot                                        | PLOTS=DIAGNOSTICS(UNPACK)              |
| ResidualByPredicted | Residual by predicted values                             | PLOTS=DIAGNOSTICS(UNPACK)              |
| ResidualHistogram   | Residual histogram                                       | PLOTS=DIAGNOSTICS(UNPACK)              |
| RFPlot              | RF plot                                                  | PLOTS=DIAGNOSTICS(UNPACK)              |
| RStudentByPredicted | Studentized residuals by predicted                       | PLOTS=DIAGNOSTICS(UNPACK)              |
| RStudentByLeverage  | RStudent by hat diagonals                                | PLOTS=DIAGNOSTICS(UNPACK)              |
| DiffPlot            | Plot of LS-mean pairwise differences                     | LSMEANS / PDIFF                        |
| IntPlot             | Interaction plot                                         | Two-way ANOVA model                    |
| FitPlot             | Plot of predicted response by predictor                  | Model with one continuous predictor    |
| ResidualPlots       | Plots of the residuals against each continuous covariate | PLOTS=RESIDUALS                        |

## Examples: GLM Procedure

### Example 42.1: Randomized Complete Blocks with Means Comparisons and Contrasts

This example, reported by Stenstrom (1940), analyzes an experiment to investigate how snapdragons grow in various soils. To eliminate the effect of local fertility variations, the experiment is run in blocks, with each soil type sampled in each block. Since these data are balanced, the Type I and Type III SS are the same and are equal to the traditional ANOVA SS.

First, the standard analysis is shown, followed by an analysis that uses the **SOLUTION** option and includes **MEANS** and **CONTRAST** statements. The **ORDER=DATA** option in the second **PROC GLM** statement is

used so that the ordering of coefficients in the **CONTRAST** statement can correspond to the ordering in the input data. The **SOLUTION** option requests a display of the parameter estimates, which are produced by default only if there are no **CLASS** variables. A **MEANS** statement is used to request a table of the means with two multiple-comparison procedures requested. In experiments with focused treatment questions, **CONTRAST** statements are preferable to general means comparison methods. The following statements produce Output 42.1.1 through Output 42.1.4.

```

This analysis shows that the stem length is significantly different for the different soil types. In addition, there are significant differences in stem length among the three blocks in the experiment.

The GLM procedure is invoked again, this time with the `ORDER=DATA` option. This enables you to write accurate contrast statements more easily because you know the order SAS is using for the levels of the

variable Type. The standard analysis is displayed again, this time including the tests for contrasts that you specified as well as the estimated parameters. These additional results are shown in [Output 42.1.2](#).

NOTE: The X'X matrix has been found to be singular, and a generalized inverse was used to solve the normal equations. Terms whose estimates are followed by the letter 'B' are not uniquely estimable.

The contrast label, degrees of freedom, sum of squares, Mean Square, F Value, and Pr > F are shown for each contrast requested. In this example, the contrast results indicate the following inferences, at the 5% significance level:

- The stem length of plants grown in compost soil is significantly different from the average stem length of plants grown in other soils.
- The stem length of plants grown in river soils is significantly different from the average stem length of those grown in nonriver soils.
- The average stem length of plants grown in glacial soils (Clarion and Webster types) is significantly different from the average stem length of those grown in drift soils (Knox and O'Neill types).

- Stem lengths for Clarion and Webster types are not significantly different.
- Stem lengths for Knox and O'Neill types are not significantly different.

In addition to the estimates for the parameters of the model, the results of  $t$  tests about the parameters are also displayed. The 'B' following the parameter estimates indicates that the estimates are biased and do not represent a unique solution to the normal equations.

The final two pages of output ([Output 42.1.3](#) and [Output 42.1.4](#)) present results of the Waller-Duncan and REGWQ multiple-comparison procedures. For each test, notes and information pertinent to the test are given in the output. The Type means are arranged from highest to lowest. Means with the same letter are not significantly different. For this example, while some pairs of means are significantly different, there are no clear equivalence classes among the different soils.

For an alternative method of analyzing and displaying mean differences, including high-resolution graphics, see [Example 42.3](#).

---

## Example 42.2: Regression with Mileage Data

A car is tested for gas mileage at various speeds to determine at what speed the car achieves the highest gas mileage. A quadratic model is fit to the experimental data. The following statements produce [Output 42.2.1](#) through [Output 42.2.4](#).

```

title 'Gasoline Mileage Experiment';
data mileage;
 input mph mpg @@;
 datalines;
20 15.4
30 20.2
40 25.7
50 26.2 50 26.6 50 27.4
55 .
60 24.8
;

**Output 42.2.1** *continued*

| Source  | DF | Type III SS | Mean Square | F Value | Pr > F |
|---------|----|-------------|-------------|---------|--------|
| mph     | 1  | 41.01171219 | 41.01171219 | 57.19   | 0.0016 |
| mph*mph | 1  | 26.16397541 | 26.16397541 | 36.48   | 0.0038 |

| Parameter | Estimate     | Standard Error | t Value | Pr >  t |
|-----------|--------------|----------------|---------|---------|
| Intercept | -5.985245902 | 3.18522249     | -1.88   | 0.1334  |
| mph       | 1.305245902  | 0.17259876     | 7.56    | 0.0016  |
| mph*mph   | -0.013098361 | 0.00216852     | -6.04   | 0.0038  |

The overall *F* statistic is significant. The tests of mph and mph\*mph in the Type I sums of squares show that both the linear and quadratic terms in the regression model are significant. The model fits well, with an R square of 0.97. The table of parameter estimates indicates that the estimated regression equation is

$$\text{mpg} = -5.9852 + 1.3052 \times \text{mph} - 0.0131 \times \text{mph}^2$$

| 1           | 12.69701317                                    | 17.06364257 |
| 2           | 20.01727192                                    | 22.74994119 |
| 3           | 23.87460041                                    | 26.65982582 |
| 4           | 25.44573423                                    | 27.61656085 |
| 5           | 25.44573423                                    | 27.61656085 |
| 6           | 25.44573423                                    | 27.61656085 |
| 7 *         | 24.88679308                                    | 27.47468233 |
| 8           | 23.05954977                                    | 27.29126990 |

The **P** and **CLM** options in the **MODEL** statement produce the table shown in **Output 42.2.2**. For each observation, the observed, predicted, and residual values are shown. In addition, the 95% confidence limits for a mean predicted value are shown for each observation. Note that the observation with a missing value for mph is not used in the analysis, but predicted and confidence limit values are shown.

**Output 42.2.3** Additional Results of Requesting the P and CLM Options

|                                     |             |
|-------------------------------------|-------------|
| Sum of Residuals                    | -0.00000000 |
| Sum of Squared Residuals            | 2.86852459  |
| Sum of Squared Residuals - Error SS | -0.00000000 |
| PRESS Statistic                     | 23.18107335 |
| First Order Autocorrelation         | -0.54376613 |
| Durbin-Watson D                     | 2.94425592  |

The last portion of the output listing, shown in [Output 42.2.3](#), gives some additional information about the residuals. The Press statistic gives the sum of squares of predicted residual errors, as described in Chapter 4, “[Introduction to Regression Procedures](#).” The First Order Autocorrelation and the Durbin-Watson  $D$  statistic, which measures first-order autocorrelation, are also given.

**Output 42.2.4** Plot of Mileage Data

Finally, the ODS GRAPHICS ON command in the previous statements enables ODS Graphics, which in this case produces the plot shown in [Output 42.2.4](#) of the actual and predicted values for the data, as well as a band representing the confidence limits for individual predictions. The quadratic relationship between mpg and mph is evident.

## Example 42.3: Unbalanced ANOVA for Two-Way Design with Interaction

This example uses data from Kutner (1974, p. 98) to illustrate a two-way analysis of variance. The original data source is Afifi and Azen (1972, p. 166). These statements produce [Output 42.3.1](#) and [Output 42.3.2](#).

Note the differences among the four types of sums of squares. The Type I sum of squares for drug essentially tests for differences between the expected values of the arithmetic mean response for different drugs, unadjusted for the effect of disease. By contrast, the Type II sum of squares for drug measures the differences between arithmetic means for each drug after adjusting for disease. The Type III sum of squares measures the differences between predicted drug means over a balanced drug×disease population—that is, between the LS-means for drug. Finally, the Type IV sum of squares is the same as the Type III sum of squares in this case, since there are data for every drug-by-disease combination.

No matter which sum of squares you prefer to use, this analysis shows a significant difference among the four drugs, while the disease effect and the drug-by-disease interaction are not significant. As the previous discussion indicates, Type III sums of squares correspond to differences between LS-means, so you can follow up the Type III tests with a multiple-comparison analysis of the drug LS-means. Since the GLM procedure is interactive, you can accomplish this by submitting the following statements after the previous ones that performed the ANOVA.

```
lsmeans drug / pdiff=all adjust=tukey;
run;
```

Both the LS-means themselves and a matrix of adjusted *p*-values for pairwise differences between them are displayed; see [Output 42.3.3](#) and [Output 42.3.4](#).

**Output 42.3.3** LS-Means for Unbalanced ANOVA

**Output 42.3.4** Adjusted *p*-Values for Pairwise LS-Mean Differences

| Least Squares Means for effect drug  |        |        |        |        |
|--------------------------------------|--------|--------|--------|--------|
| Pr >  t  for H0: LSMean(i)=LSMean(j) |        |        |        |        |
| Dependent Variable: y                |        |        |        |        |
| i/j                                  | 1      | 2      | 3      | 4      |
| 1                                    |        | 0.9989 | 0.0016 | 0.0107 |
| 2                                    | 0.9989 |        | 0.0011 | 0.0071 |
| 3                                    | 0.0016 | 0.0011 |        | 0.7870 |
| 4                                    | 0.0107 | 0.0071 | 0.7870 |        |

The multiple-comparison analysis shows that drugs 1 and 2 have very similar effects, and that drugs 3 and 4 are also insignificantly different from each other. Evidently, the main contribution to the significant drug effect is the difference between the 1/2 pair and the 3/4 pair.

If ODS Graphics is enabled for the previous analysis, GLM also displays three additional plots by default:

- an interaction plot for the effects of disease and drug
- a mean plot of the drug LS-means
- a plot of the adjusted pairwise differences and their significance levels

The following statements reproduce the previous analysis with ODS Graphics enabled. Additionally, the `PLOTS=MEANPLOT(CL)` option specifies that confidence limits for the LS-means should also be displayed in the mean plot. The graphical results are shown in [Output 42.3.5](#) through [Output 42.3.7](#).

```
ods graphics on;
proc glm plot=meanplot(cl);
 class drug disease;
 model y=drug disease drug*disease;
 lsmeans drug / pdiff=all adjust=tukey;
run;
ods graphics off;
```

**Output 42.3.5** Plot of Response by Drug and Disease

**Output 42.3.6** Plot of Response LS-Means for Drug

**Output 42.3.7** Plot of Response LS-Mean Differences for Drug

The significance of the drug differences is difficult to discern in the original data, as displayed in [Output 42.3.5](#), but the plot of just the LS-means and their individual confidence limits in [Output 42.3.6](#) makes it clearer. Finally, [Output 42.3.7](#) indicates conclusively that the significance of the effect of drug is due to the difference between the two drug pairs (1, 2) and (3, 4).

## Example 42.4: Analysis of Covariance

Analysis of covariance combines some of the features of both regression and analysis of variance. Typically, a continuous variable (the covariate) is introduced into the model of an analysis-of-variance experiment.

Data in the following example are selected from a larger experiment on the use of drugs in the treatment of leprosy (Snedecor and Cochran 1967, p. 422).

Variables in the study are as follows:

|               |                                             |
|---------------|---------------------------------------------|
| Drug          | two antibiotics (A and D) and a control (F) |
| PreTreatment  | a pretreatment score of leprosy bacilli     |
| PostTreatment | a posttreatment score of leprosy bacilli    |

Ten patients are selected for each treatment (Drug), and six sites on each patient are measured for leprosy bacilli.

The covariate (a pretreatment score) is included in the model for increased precision in determining the effect of drug treatments on the posttreatment count of bacilli.

The following statements create the data set, perform a parallel-slopes analysis of covariance with PROC GLM, and compute Drug LS-means. These statements produce [Output 42.4.1](#) and [Output 42.4.2](#).

```

data DrugTest;
 input Drug $ PreTreatment PostTreatment @@;
 datalines;
A 11 6 A 8 0 A 5 2 A 14 8 A 19 11
A 6 4 A 10 13 A 6 1 A 11 8 A 3 0
D 6 0 D 6 2 D 7 3 D 8 1 D 18 18
D 8 4 D 19 14 D 8 9 D 5 1 D 15 9
F 16 13 F 13 10 F 11 18 F 9 5 F 21 23
F 16 12 F 12 5 F 12 16 F 7 1 F 12 20
;

proc glm data=DrugTest;
 class Drug;
 model PostTreatment = Drug PreTreatment / solution;
 lsmeans Drug / stderr pdiff cov out=adjmeans;
run;

proc print data=adjmeans;
run;

```

**Output 42.4.1** Classes and Levels

| Error                             | 26       | 417.202597     | 16.046254   |                    |        |
| Corrected Total                   | 29       | 1288.700000    |             |                    |        |
|                                   | R-Square | Coeff Var      | Root MSE    | PostTreatment Mean |        |
|                                   | 0.676261 | 50.70604       | 4.005778    | 7.900000           |        |

This model assumes that the slopes relating posttreatment scores to pretreatment scores are parallel for all drugs. You can check this assumption by including the class-by-covariate interaction, Drug\*PreTreatment, in the model and examining the ANOVA test for the significance of this effect. This extra test is omitted in this example, but it is insignificant, justifying the equal-slopes assumption.

In [Output 42.4.3](#), the Type I SS for Drug (293.6) gives the between-drug sums of squares that are obtained for the analysis-of-variance model PostTreatment=Drug. This measures the difference between arithmetic means of posttreatment scores for different drugs, disregarding the covariate. The Type III SS for Drug (68.5537) gives the Drug sum of squares adjusted for the covariate. This measures the differences between Drug LS-means, controlling for the covariate. The Type I test is highly significant ( $p = 0.001$ ), but the Type III test is not. This indicates that, while there is a statistically significant difference between the arithmetic drug means, this difference is reduced to below the level of background noise when you take the pretreatment scores into account. From the table of parameter estimates, you can derive the least squares predictive formula model for estimating posttreatment score based on pretreatment score and drug:

$$\text{post} = \begin{cases} (-0.435 + -3.446) + 0.987 \cdot \text{pre}, & \text{if Drug=A} \\ (-0.435 + -3.337) + 0.987 \cdot \text{pre}, & \text{if Drug=D} \\ -0.435 + 0.987 \cdot \text{pre}, & \text{if Drug=F} \end{cases}$$

**Output 42.4.3** Tests and Parameter Estimates

| Source       | DF | Type I SS   | Mean Square | F Value | Pr > F |
|--------------|----|-------------|-------------|---------|--------|

Output 42.4.4 displays the LS-means, which are, in a sense, the means adjusted for the covariate. The **STDERR** option in the **LSMEANS** statement causes the standard error of the LS-means and the probability of getting a larger *t* value under the hypothesis  $H_0: \text{LS-mean} = 0$  to be included in this table as well. Specifying the **PDIF** option causes all probability values for the hypothesis  $H_0: \text{LS-mean}(i) = \text{LS-mean}(j)$  to be displayed, where the indexes *i* and *j* are numbered treatment levels.

**Output 42.4.4** LS-Means

| 3   | PostTreatment | F    | 10.1611 | 1.31592 | 3      | -0.08403 | -0.04299 | 1.73165  |

The new graphical features of PROC GLM enable you to visualize the fitted analysis of covariance model. The following statements enable ODS Graphics by specifying the ODS GRAPHICS statement and then fit an analysis-of-covariance model with LS-means for Drug.

```
ods graphics on;

proc glm data=DrugTest plot=meanplot(cl);
 class Drug;
 model PostTreatment = Drug PreTreatment;
 lsmeans Drug / pdiff;
run;

ods graphics off;
```

With graphics enabled, the GLM procedure output includes an analysis-of-covariance plot, as in [Output 42.4.6](#). The **LSMEANS** statement produces a plot of the LS-means; the SAS statements previously shown use the **PLOTS=MEANPLOT(CL)** option to add confidence limits for the individual LS-means, shown in [Output 42.4.7](#). If you also specify the **PDIFF** option in the **LSMEANS** statement, the output also includes a plot appropriate for the type of LS-mean differences computed. In this case, the default is to compare all LS-means with each other pairwise, so the plot is a “diffogram” or “mean-mean scatter plot” (Hsu 1996), as in [Output 42.4.8](#). For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the graphics available in the GLM procedure, see the section “[ODS Graphics](#)” on page 3388.

**Output 42.4.6** Analysis of Covariance Plot of PostTreatment Score by Drug and PreTreatment Score

**Output 42.4.7** LS-Means for PostTreatment Score by Drug

**Output 42.4.8** Plot of Differences between Drug LS-Means for PostTreatment Scores

The analysis of covariance plot [Output 42.4.6](#) makes it clear that the control (drug F) has higher posttreatment scores across the range of pretreatment scores, while the fitted models for the two antibiotics (drugs A and D) nearly coincide. Similarly, while the diffogram [Output 42.4.7](#) indicates that none of the LS-mean differences are significant at the 5% level, the difference between the LS-means for the two antibiotics is much closer to zero than the differences between either one and the control.

### Example 42.5: Three-Way Analysis of Variance with Contrasts

This example uses data from Cochran and Cox (1957, p. 176) to illustrate the analysis of a three-way factorial design with replication, including the use of the `CONTRAST` statement with interactions, the `OUTSTAT=` data set, and the `SLICE=` option in the `LSMEANS` statement.

The object of the study is to determine the effects of electric current on denervated muscle. The variables are as follows:

- Rep                    the replicate number, 1 or 2
- Time                  the length of time the current is applied to the muscle, ranging from 1 to 4

Current            the level of electric current applied, ranging from 1 to 4  
 Number            the number of treatments per day, ranging from 1 to 3  
 MuscleWeight      the weight of the denervated muscle

The following statements produce [Output 42.5.1](#) through [Output 42.5.4](#).

```
data muscles;
 do Rep=1 to 2;
 do Time=1 to 4;
 do Current=1 to 4;
 do Number=1 to 3;
 input MuscleWeight @@;
 output;
 end;
 end;
 end;
 end;
 datalines;
72 74 69 61 61 65 62 65 70 85 76 61
67 52 62 60 55 59 64 65 64 67 72 60
57 66 72 72 43 43 63 66 72 56 75 92
57 56 78 60 63 58 61 79 68 73 86 71
46 74 58 60 64 52 71 64 71 53 65 66
44 58 54 57 55 51 62 61 79 60 78 82
53 50 61 56 57 56 56 56 71 56 58 69
46 55 64 56 55 57 64 66 62 59 58 88
;

proc glm outstat=summary;
 class Rep Current Time Number;
 model MuscleWeight = Rep Current|Time|Number;
 contrast 'Time in Current 3'
 Time 1 0 0 -1 Current*Time 0 0 0 0 0 0 0 0 0 1 0 0 -1,
 Time 0 1 0 -1 Current*Time 0 0 0 0 0 0 0 0 0 0 1 0 -1,
 Time 0 0 1 -1 Current*Time 0 0 0 0 0 0 0 0 0 0 0 1 -1;
 contrast 'Current 1 versus 2' Current 1 -1;
 lsmeans Current*Time / slice=Current;
run;

proc print data=summary;
run;
```

The first **CONTRAST** statement examines the effects of Time within level 3 of Current. This is also called the *simple effect* of Time within Current\*Time. Note that, since there are three degrees of freedom, it is necessary to specify three rows in the **CONTRAST** statement, separated by commas. Since the parameterization that PROC GLM uses is determined in part by the ordering of the variables in the **CLASS** statement, Current is specified before Time so that the Time parameters are nested within the Current\*Time parameters; thus, the Current\*Time contrast coefficients in each row are simply the Time coefficients of that row within the appropriate level of Current.

The second **CONTRAST** statement isolates a single-degree-of-freedom effect corresponding to the difference between the first two levels of Current. You can use such a contrast in a large experiment where certain preplanned comparisons are important, but you want to take advantage of the additional error degrees of freedom available when all levels of the factors are considered.

The **LSMEANS** statement with the **SLICE=** option is an alternative way to test for the simple effect of Time within Current\*Time. In addition to listing the LS-means for each current strength and length of time, it gives a table of *F* tests for differences between the LS-means across Time within each Current level. In some cases, this can be a way to disentangle a complex interaction.

|                                  | 0.643805 | 13.05105       | 8.250712    | 63.21875          |        |

The output, shown in [Output 42.5.2](#) and [Output 42.5.3](#), indicates that the main effects for Rep, Current, and Number are significant (with *p*-values of 0.0045, <0.0001, and 0.0461, respectively), but the main effect for Time is not significant, indicating that, in general, it does not matter how long the current is applied. None of the interaction terms are significant, nor are the contrasts significant. Notice that the row in the sliced ANOVA table corresponding to level 3 of current matches the “Time in Current 3” contrast.

## Example 42.6: Multivariate Analysis of Variance

This example employs multivariate analysis of variance (MANOVA) to measure differences in the chemical characteristics of ancient pottery found at four kiln sites in Great Britain. The data are from Tubb, Parker, and Nickless (1980), as reported in Hand et al. (1994).

For each of 26 samples of pottery, the percentages of oxides of five metals are measured. The following statements create the data set and invoke the GLM procedure to perform a one-way MANOVA. Additionally, it is of interest to know whether the pottery from one site in Wales (Llanederyn) differs from the samples from other sites; a **CONTRAST** statement is used to test this hypothesis.

After the summary information, displayed in [Output 42.6.1](#), PROC GLM produces the univariate analyses for each of the dependent variables, as shown in [Output 42.6.2](#) through [Output 42.6.6](#). These analyses show that sites are significantly different for all oxides individually. You can suppress these univariate analyses by specifying the `NOUNI` option in the `MODEL` statement.

The **PRINTE** option in the **MANOVA** statement displays the elements of the error matrix, also called the Error Sums of Squares and Crossproducts matrix. (See [Output 42.6.7](#).) The diagonal elements of this matrix are the error sums of squares from the corresponding univariate analyses.

The **PRINTE** option also displays the partial correlation matrix associated with the E matrix. In this example, none of the oxides are very strongly correlated; the strongest correlation ( $r = 0.488$ ) is between magnesium oxide and calcium oxide.

## Output 42.6.7 Error SSCP Matrix and Partial Correlations

The **PRINTH** option produces the SSCP matrix for the hypotheses being tested (Site and the contrast); see [Output 42.6.8](#) and [Output 42.6.9](#). Since the Type III SS are the highest-level SS produced by PROC GLM by default, and since the **HTYPE=** option is not specified, the SSCP matrix for Site gives the Type III **H** matrix. The diagonal elements of this matrix are the model sums of squares from the corresponding univariate analyses.

Four multivariate tests are computed, all based on the characteristic roots and vectors of  $\mathbf{E}^{-1}\mathbf{H}$ . These roots and vectors are displayed along with the tests. All four tests can be transformed to variates that have  $F$  distributions under the null hypothesis. Note that the four tests all give the same results for the contrast, since it has only one degree of freedom. In this case, the multivariate analysis matches the univariate results: there is an overall difference between the chemical composition of samples from different sites, and the samples from Llanederyn are different from the average of the other sites.

## Example 42.7: Repeated Measures Analysis of Variance

This example uses data from Cole and Grizzle (1966) to illustrate a commonly occurring repeated measures ANOVA design. Sixteen dogs are randomly assigned to four groups. (One animal is removed from the analysis due to a missing value for one dependent variable.) Dogs in each group receive either morphine or trimethaphan (variable Drug) and have either depleted or intact histamine levels (variable Depleted) before receiving the drugs. The dependent variable is the blood concentration of histamine at 0, 1, 3, and 5 minutes after injection of the drug. Logarithms are applied to these concentrations to minimize correlation between the mean and the variance of the data.

The following SAS statements perform both univariate and multivariate repeated measures analyses and produce Output 42.7.1 through Output 42.7.7.

```
data dogs;
 input Drug $12. Depleted $ Histamine0 Histamine1
 Histamine3 Histamine5;
 LogHistamine0=log(Histamine0);

 model LogHistamine0--LogHistamine5 =
 Drug Depleted Drug*Depleted / nouni;
 repeated Time 4 (0 1 3 5) polynomial / summary printe;
run;

```

The **NOUNI** option in the **MODEL** statement suppresses the individual ANOVA tables for the original dependent variables. These analyses are usually of no interest in a repeated measures analysis. The **POLYNOMIAL** option in the **REPEATED** statement indicates that the transformation used to implement the repeated measures analysis is an orthogonal polynomial transformation, and the **SUMMARY** option requests that the univariate analyses for the orthogonal polynomial contrast variables be displayed. The parenthetical numbers (0 1 3 5) determine the spacing of the orthogonal polynomials used in the analysis.

#### Output 42.7.1 Summary Information about Groups

| The GLM Procedure              |                         |
|--------------------------------|-------------------------|
| Class Level Information        |                         |
| Class                          | Levels Values           |
| Drug                           | 2 Morphine Trimethaphan |
| Depleted                       | 2 N Y                   |
| Number of Observations Read 16 |                         |
| Number of Observations Used 15 |                         |

The “Repeated Measures Level Information” table gives information about the repeated measures effect; it is displayed in [Output 42.7.2](#). In this example, the within-subject (within-dog) effect is Time, which has the levels 0, 1, 3, and 5.

**Output 42.7.2** Repeated Measures Levels

| The GLM Procedure                      |                   |                   |                   |                   |
|----------------------------------------|-------------------|-------------------|-------------------|-------------------|
| Repeated Measures Analysis of Variance |                   |                   |                   |                   |
| Repeated Measures Level Information    |                   |                   |                   |                   |
| Dependent Variable                     | Log<br>Histamine0 | Log<br>Histamine1 | Log<br>Histamine3 | Log<br>Histamine5 |
| Level of Time                          | 0                 | 1                 | 3                 | 5                 |

The multivariate analyses for within-subject effects and related interactions are displayed in [Output 42.7.3](#). For the example, the first table displayed shows that the TIME effect is significant. In addition, the Time\*Drug\*Depleted interaction is significant, as shown in the fourth table. This means that the effect of Time on the blood concentration of histamine is different for the four Drug\*Depleted combinations studied.

**Output 42.7.3** Multivariate Tests of Within-Subject Effects

| MANOVA Test Criteria and Exact F Statistics for the Hypothesis of no Time Effect      |            |         |        |        |        |

Output 42.7.4 displays tests of hypotheses for between-subject (between-dog) effects. This section tests the hypotheses that the different Drugs, Depleteds, and their interactions have no effects on the dependent variables, while ignoring the within-dog effects. From this analysis, there is a significant between-dog effect for Depleted ( $p$ -value=0.0229). The interaction and the main effect for Drug are not significant ( $p$ -values=0.1734 and 0.1281, respectively).

Univariate analyses for within-subject (within-dog) effects and related interactions are displayed in [Output 42.7.6](#). The results for this example are the same as for the multivariate analyses; this is not always the case. In addition, before the univariate analyses are used to make conclusions about the data, the result of the sphericity test (requested with the `PRINTE` option in the `REPEATED` statement and displayed in [Output 42.7.5](#)) should be examined. If the sphericity test is rejected, consider using the adjusted G-G or H-F-L probabilities. See the section “[Repeated Measures Analysis of Variance](#)” on page 3367 for more information.

[Output 42.7.7](#) is produced by the `SUMMARY` option in the `REPEATED` statement. If the `POLYNOMIAL` option is not used, a similar table is displayed using the default `CONTRAST` transformation. The linear, quadratic, and cubic trends for Time, labeled as ‘Time\_1’, ‘Time\_2’, and ‘Time\_3’, are displayed, and in each case, the Source labeled ‘Mean’ gives a test for the respective trend.

**Output 42.7.7** Tests of Between-Subject Effects for Transformed Variables

**Example 42.8: Mixed Model Analysis of Variance with the RANDOM Statement**

Milliken and Johnson (1984) present an example of an unbalanced mixed model. Three machines, which are considered as a fixed effect, and six employees, which are considered a random effect, are studied. Each employee operates each machine for either one, two, or three different times. The dependent variable is an overall rating, which takes into account the number and quality of components produced.

The following statements form the data set and perform a mixed model analysis of variance by requesting the **TEST** option in the **RANDOM** statement. Note that the machine\*person interaction is declared as a

random effect; in general, when an interaction involves a random effect, it too should be declared as random. The results of the analysis are shown in [Output 42.8.1](#) through [Output 42.8.4](#).

```

data machine;
 input machine person rating @@;
 datalines;
1 1 52.0 1 2 51.8 1 2 52.8 1 3 60.0 1 4 51.1 1 4 52.3 1 5 50.9
1 5 51.8 1 5 51.4 1 6 46.4 1 6 44.8 1 6 49.2 2 1 64.0 2 2 59.7
2 2 60.0 2 2 59.0 2 3 68.6 2 3 65.8 2 4 63.2 2 4 62.8 2 4 62.2
2 5 64.8 2 5 65.0 2 6 43.7 2 6 44.2 2 6 43.0 3 1 67.5 3 1 67.2
3 1 66.9 3 2 61.5 3 2 61.7 3 2 62.3 3 3 70.8 3 3 70.6 3 3 71.0
3 4 64.1 3 4 66.2 3 4 64.0 3 5 72.1 3 5 72.0 3 5 71.1 3 6 62.0
3 6 61.4 3 6 60.5
;

proc glm data=machine;
 class machine person;
 model rating=machine person machine*person;
 random person machine*person / test;
run;

```

The **TEST** option in the **RANDOM** statement requests that PROC GLM determine the appropriate *F* tests based on **person** and **machine\*person** being treated as random effects. As you can see in [Output 42.8.4](#), this requires that a linear combination of mean squares be constructed to test both the machine and person hypotheses; thus, *F* tests that use Satterthwaite approximations are needed.

Note that you can also use the MIXED procedure to analyze mixed models. The following statements use PROC MIXED to reproduce the mixed model analysis of variance; the relevant part of the PROC MIXED results is shown in [Output 42.8.5](#).

```
proc mixed data=machine method=type3;
 class machine person;
 model rating = machine;
 random person machine*person;
run;
```

**Output 42.8.5** PROC MIXED Mixed Model Analysis of Variance (Partial Output)

| Residual                    | .                                                  | .      | .       | .      |

The advantage of PROC MIXED is that it offers more versatility for mixed models; the disadvantage is that it can be less computationally efficient for large data sets. See Chapter 59, “The MIXED Procedure,” for more details.

### Example 42.9: Analyzing a Doubly Multivariate Repeated Measures Design

This example shows how to analyze a doubly multivariate repeated measures design by using PROC GLM with an IDENTITY factor in the REPEATED statement. Note that this differs from previous releases of PROC GLM, in which you had to use a MANOVA statement to get a doubly repeated measures analysis.

Two responses, Y1 and Y2, are each measured three times for each subject (pretreatment, posttreatment, and in a later follow-up). Each subject receives one of three treatments; A, B, or the control. In PROC GLM, you use a REPEATED factor of type IDENTITY to identify the different responses and another repeated factor to identify the different measurement times. The repeated measures analysis includes multivariate tests for time and treatment main effects, as well as their interactions, across responses. The following statements produce Output 42.9.1 through Output 42.9.3.

```

options ls=96;
data Trial;
 input Treatment $ Repetition PreY1 PostY1 FollowY1
 PreY2 PostY2 FollowY2;
 datalines;
A 1 3 13 9 0 0 9
A 2 0 14 10 6 6 3
A 3 4 6 17 8 2 6
A 4 7 7 13 7 6 4
A 5 3 12 11 6 12 6
A 6 10 14 8 13 3 8
B 1 9 11 17 8 11 27
B 2 4 16 13 9 3 26
B 3 8 10 9 12 0 18
B 4 5 9 13 3 0 14
B 5 0 15 11 3 0 25
B 6 4 11 14 4 2 9
Control 1 10 12 15 4 3 7
Control 2 2 8 12 8 7 20
Control 3 4 9 10 2 0 10
Control 4 10 8 8 5 8 14
Control 5 11 11 11 1 0 11
Control 6 1 5 15 8 9 10
;

proc glm data=Trial;
 class Treatment;
 model PreY1 PostY1 FollowY1
 PreY2 PostY2 FollowY2 = Treatment / nouni;
 repeated Response 2 identity, Time 3;
run;

```

**Output 42.9.1** A Doubly Multivariate Repeated Measures Design

| The GLM Procedure           |        |             |
|-----------------------------|--------|-------------|
| Class Level Information     |        |             |
| Class                       | Levels | Values      |
| Treatment                   | 3      | A B Control |
| Number of Observations Read |        | 18          |
| Number of Observations Used |        | 18          |

The levels of the repeated factors are displayed in [Output 42.9.2](#). Note that RESPONSE is 1 for all the Y1 measurements and 2 for all the Y2 measurements, while the three levels of Time identify the pretreatment, posttreatment, and follow-up measurements within each response. The multivariate tests for within-subject effects are displayed in [Output 42.9.3](#).

**Output 42.9.2** Repeated Factor Levels

NOTE: F Statistic for Roy's Greatest Root is an upper bound.  
NOTE: F Statistic for Wilks' Lambda is exact.

The table for Response\*Treatment tests for an overall treatment effect across the two responses; likewise, the tables for Response\*Time and Response\*Treatment\*Time test for time and the treatment-by-time interaction, respectively. In this case, there is a strong main effect for time and possibly for the interaction, but not for treatment.

In previous releases (before the IDENTITY transformation was introduced), in order to perform a doubly repeated measures analysis, you had to use a MANOVA statement with a customized transformation matrix M. You might still want to use this approach to see details of the analysis, such as the univariate ANOVA for each transformed variate. The following statements demonstrate this approach by using the MANOVA statement to test for the overall main effect of time and specifying the SUMMARY option.

```
proc glm data=Trials;
 class Treatment;
 model PreY1 PostY1 FollowY1
 PreY2 PostY2 FollowY2 = Treatment / nouni;
 manova h=intercept m=prey1 - posty1,
 prey1 - followy1,
 prey2 - posty2,
 prey2 - followy2 / summary;
run;
```

The M matrix used to perform the test for time effects is displayed in [Output 42.9.4](#), while the results of the multivariate test are given in [Output 42.9.5](#). Note that the test results are the same as for the Response\*Time effect in [Output 42.9.3](#).

**Output 42.9.4** M Matrix to Test for Time Effect (Repeated Measure)

The **SUMMARY** option in the **MANOVA** statement creates an ANOVA table for each transformed variable as defined by the M matrix. MVAR1 and MVAR2 contrast the pretreatment measurement for Y1 with

the posttreatment and follow-up measurements for Y1, respectively; MVAR3 and MVAR4 are the same contrasts for Y2. [Output 42.9.6](#) displays these univariate ANOVA tables and shows that the contrasts are all strongly significant except for the pre-versus-post difference for Y2.

**Output 42.9.6** Summary Output for the Test for Time Effect

## Example 42.10: Testing for Equal Group Variances

This example demonstrates how you can test for equal group variances in a one-way design. The data come from the University of Pennsylvania Smell Identification Test (UPSIT), reported in O'Brien and Heft (1995). The study is undertaken to explore how age and gender are related to sense of smell. A total of 180 subjects

20 to 89 years old are exposed to 40 different odors: for each odor, subjects are asked to choose which of four words best describes the odor. The Freeman-Tukey modified arcsine transformation (Bishop, Fienberg, and Holland 1975) is applied to the proportion of correctly identified odors to arrive at an olfactory index. For the following analysis, subjects are divided into five age groups:

$$\text{agegroup} = \begin{cases} 1 & \text{if } \text{age} \leq 25 \\ 2 & \text{if } 25 < \text{age} \leq 40 \\ 3 & \text{if } 40 < \text{age} \leq 55 \\ 4 & \text{if } 55 < \text{age} \leq 70 \\ 5 & \text{if } 70 < \text{age} \end{cases}$$

The following statements create a data set named `upsit`, containing the age group and olfactory index for each subject.

```
data upsit;
 input agegroup smell @@;

Older people are more at risk for problems with their sense of smell, and this should be reflected in significant differences in the mean of the olfactory index across the different age groups. However, many older people also have an excellent sense of smell, which implies that the older age groups should have greater variability. In order to test this hypothesis and to compute a one-way ANOVA for the olfactory index that is

robust to the possibility of unequal group variances, you can use the **HOVTEST** and **WELCH** options in the **MEANS** statement for the GLM procedure, as shown in the following statements.

```
proc glm data=upsit;
 class agegroup;
 model smell = agegroup;
 means agegroup / hovtest welch;
run;
```

Output 42.10.1, Output 42.10.2, and Output 42.10.3 display the usual ANOVA test for equal age group means, Levene's test for equal age group variances, and Welch's test for equal age group means, respectively. The hypotheses of age effects for mean and variance of the olfactory index are both confirmed.

As discussed in “Homogeneity of Variance in One-Way Models” on page 3362, Levene’s test or any other test for homogeneity of variance should not be used as a diagnostic for the assumption of equal group variances that underlies the usual analysis of variance. However, graphical diagnostics can be a useful informal tool for monitoring whether your data meet the assumptions of a GLM analysis. The following statements perform a one-way ANOVA as before, but with ODS Graphics enabled. In addition to the box plot that is produced by default, the `PLOTS=DIAGNOSTICS` option requests a panel of summary diagnostics for the fit. These additional plots are shown in [Output 42.10.4](#) and [Output 42.10.5](#).

```
ods graphics on;
proc glm data=upsit plot=diagnostics;
 class agegroup;
 model smell = agegroup;
run;
ods graphics off;
```

**Output 42.10.4** Box Plot of Olfactory Index by Age Group

**Output 42.10.5** Diagnostics for One-Way ANOVA of Olfactory Index by Age Group

Output 42.10.4 clearly shows different degrees of variability for olfactory index within different age groups, with the variability generally rising with age. Likewise, several of the plots in the diagnostics panel shown in Output 42.10.5 indicate a relationship between olfactory variability and mean olfactory index. Also, note that the plot of Cook's  $D$  statistic indicates that observations in the higher, more variable age groups are overly influential on the analysis of group means. The overall inference from these plots is that an assumption of equal group variances is probably untenable and that the analysis of the group means should thus take this into account.

## Example 42.11: Analysis of a Screening Design

Yin and Jillie (1987) describe an experiment performed on a nitride etch process for a single wafer plasma etcher. The experiment is run using four factors: cathode power (`power`), gas flow (`flow`), reactor chamber pressure (`pressure`), and electrode gap (`gap`). Of interest are the main effects and interaction effects of the factors on the nitride etch rate (`rate`). The following statements create a SAS data set named `HalfFraction`, containing the factor settings and the observed etch rate for each of eight experimental runs.

```
data HalfFraction;
 input power flow pressure gap rate;
 datalines;
0.8 4.5 125 275 550
0.8 4.5 200 325 650
0.8 550.0 125 325 642
0.8 550.0 200 275 601
1.2 4.5 125 325 749
1.2 4.5 200 275 1052
1.2 550.0 125 275 1075
1.2 550.0 200 325 729
;
```

Notice that each of the factors has just two values. This is a common experimental design when the intent is to screen from the many factors that *might* affect the response the few that actually *do*. Since there are  $2^4 = 16$  different possible settings of four two-level factors, this design with only eight runs is called a “half fraction.” The eight runs are chosen specifically to provide unambiguous information on main effects at the cost of confounding interaction effects with each other.

One way to analyze these data is simply to use PROC GLM to compute an analysis of variance, including both main effects and interactions in the model. The following statements demonstrate this approach.

```
proc glm data=HalfFraction;
 class power flow pressure gap;
 model rate=power|flow|pressure|gap@2;
run;
```

The “@2” notation in the `MODEL` statement includes all main effects and two-factor interactions between the factors. The output is shown in [Output 42.11.1](#).

**Output 42.11.1** Analysis of Variance for Nitride Etch Process Half Fraction

| The GLM Procedure       |        |         |
|-------------------------|--------|---------|
| Class Level Information |        |         |
| Class                   | Levels | Values  |
| power                   | 2      | 0.8 1.2 |
| flow                    | 2      | 4.5 550 |
| pressure                | 2      | 125 200 |
| gap                     | 2      | 275 325 |

| pressure*gap                | 0        | 0.0000         | .           | .         | .      |

Notice that there are no error degrees of freedom. This is because there are 10 effects in the model (4 main effects plus 6 interactions) but only 8 observations in the data set. This is another cost of using a fractional design: not only is it impossible to estimate all the main effects and interactions, but there is also no information left to estimate the underlying error rate in order to measure the significance of the effects that are estimable.

Another thing to notice in [Output 42.11.1](#) is the difference between the Type I and Type III ANOVA tables. The rows corresponding to main effects in each are the same, but no Type III interaction tests are estimable, while some Type I interaction tests are estimable. This indicates that there is *aliasing* in the design: some interactions are completely confounded with each other.

In order to analyze this confounding, you should examine the aliasing structure of the design by using the **ALIASING** option in the **MODEL** statement. Before doing so, however, it is advisable to *code* the design, replacing low and high levels of each factor with the values  $-1$  and  $+1$ , respectively. This puts each factor on an equal footing in the model and makes the aliasing structure much more interpretable. The following statements code the data, creating a new data set named Coded.

```
data Coded; set HalfFraction;
 power = -1*(power =0.80) + 1*(power =1.20);
 flow = -1*(flow =4.50) + 1*(flow =550);
 pressure = -1*(pressure=125) + 1*(pressure=200);
 gap = -1*(gap =275) + 1*(gap =325);
run;
```

The following statements use the GLM procedure to reanalyze the coded design, displaying the parameter estimates as well as the functions of the parameters that they each estimate.

```
proc glm data=Coded;
 model rate=power|flow|pressure|gap@2 / solution aliasing;
run;
```

The parameter estimates table is shown in [Output 42.11.2](#).

**Output 42.11.2** Parameter Estimates and Aliases for Nitride Etch Process Half Fraction

| The GLM Procedure        |              |                |         |         |                           |
|--------------------------|--------------|----------------|---------|---------|---------------------------|

| pressure                 | 2.000000     | .              | .       | .       | pressure                  |
| power*pressure           | -12.750000 B | .              | .       | .       | power*pressure + flow*gap |
| flow*pressure            | -98.750000 B | .              | .       | .       | flow*pressure + power*gap |
| gap                      | -63.500000   | .              | .       | .       | gap                       |
| power*gap                | 0.000000 B   | .              | .       | .       |                           |
| flow*gap                 | 0.000000 B   | .              | .       | .       |                           |
| pressure*gap             | 0.000000 B   | .              | .       | .       |                           |

In the “Expected Value” column, notice that, while each of the main effects is unambiguously estimated by its associated term in the model, the expected values of the interaction estimates are more complicated. For example, the relatively large effect ( $-98.75$ ) corresponding to `flow*pressure` actually estimates the combined effect of `flow*pressure` and `power*gap`. Without further information, it is impossible to disentangle these

aliased interactions; however, since the main effects of both power and gap are large and those for flow and pressure are small, it is reasonable to suspect that power\*gap is the more “active” of the two interactions.

Fortunately, eight more runs are available for this experiment (the other half fraction). The following statements create a data set containing these extra runs and add it to the previous eight, resulting in a full  $2^4 = 16$  run replicate. Then PROC GLM displays the analysis of variance again.

```
data OtherHalf;
 input power flow pressure gap rate;
 datalines;
0.8 4.5 125 325 669
0.8 4.5 200 275 604
0.8 550.0 125 275 633
0.8 550.0 200 325 635
1.2 4.5 125 275 1037
1.2 4.5 200 325 868
1.2 550.0 125 325 860
1.2 550.0 200 275 1063
;
data FullRep;
 set HalfFraction OtherHalf;
run;

proc glm data=FullRep;
 class power flow pressure gap;
 model rate=power|flow|pressure|gap@2;
run;
```

The results are displayed in [Output 42.11.3](#).

With 16 runs, the analysis of variance tells the whole story: all effects are estimable and there are five degrees of freedom left over to estimate the underlying error. The main effects of **power** and **gap** and their interaction are all significant, and no other effects are. Notice that the Type I and Type III ANOVA tables are the same; this is because the design is orthogonal and all effects are estimable.

This example illustrates the use of the GLM procedure for the model analysis of a screening experiment. Typically, there is much more involved in performing an experiment of this type, from selecting the design points to be studied to graphically assessing significant effects, optimizing the final model, and performing

subsequent experimentation. Specialized tools for this are available in SAS/QC software, in particular the ADX Interface and the FACTEX and OPTEx procedures. See *SAS/QC User's Guide* for more information.

### Overview: GLMMOD Procedure

The GLMMOD procedure constructs the design matrix for a general linear model; it essentially constitutes the model-building front end for the GLM procedure. You can use the GLMMOD procedure in conjunction with other SAS/STAT software regression procedures or with SAS/IML software to obtain specialized analyses for general linear models that you cannot obtain with the GLM procedure.

While some of the regression procedures in SAS/STAT software provide for general linear effects modeling with classification variables and interaction or polynomial effects, many others do not. For such procedures, you must specify the model directly in terms of distinct variables. For example, if you want to use the REG procedure to fit a polynomial model, you must first create the crossproduct and power terms as new variables, usually in a DATA step. Alternatively, you can use the GLMMOD procedure to create a data set that contains the design matrix for a model as specified using the effects modeling facilities of the GLM procedure.

Note that the TRANSREG procedure provides alternative methods to construct design matrices for full-rank and less-than-full-rank models, polynomials, and splines. See Chapter 97, “The TRANSREG Procedure,” for more information.

## Getting Started: GLMMOD Procedure

---

### A One-Way Design

A one-way analysis of variance considers one treatment factor with two or more treatment levels. This example employs PROC GLMMOD together with PROC REG to perform a one-way analysis of variance to study the effect of bacteria on the nitrogen content of red clover plants. The treatment factor is bacteria strain, and it has six levels. Red clover plants are inoculated with the treatments, and nitrogen content is later measured in milligrams. The data are derived from an experiment by Erdman (1946) and are analyzed in Chapters 7 and 8 of Steel and Torrie (1980). PROC GLMMOD is used to create the design matrix. The following DATA step creates the SAS data set Clover.

```

title 'Nitrogen Content of Red Clover Plants';
data Clover;
 input Strain $ Nitrogen @@;
 datalines;
3DOK1 19.4 3DOK1 32.6 3DOK1 27.0 3DOK1 32.1 3DOK1 33.0
3DOK5 17.7 3DOK5 24.8 3DOK5 27.9 3DOK5 25.2 3DOK5 24.3
3DOK4 17.0 3DOK4 19.4 3DOK4 9.1 3DOK4 11.9 3DOK4 15.8
3DOK7 20.7 3DOK7 21.0 3DOK7 20.5 3DOK7 18.8 3DOK7 18.6
3DOK13 14.3 3DOK13 14.4 3DOK13 11.8 3DOK13 11.6 3DOK13 14.2
COMPOS 17.3 COMPOS 19.4 COMPOS 19.1 COMPOS 16.9 COMPOS 20.8
;

```

The variable Strain contains the treatment levels, and the variable Nitrogen contains the response. The following statements produce the design matrix:

```

proc glmmod data=Clover;
 class Strain;
 model Nitrogen = Strain;
run;

```

The classification variable, or treatment factor, is specified in the CLASS statement. The MODEL statement defines the response and independent variables. The design matrix produced corresponds to the model

$$Y_{i,j} = \mu + \alpha_i + \epsilon_{i,j}$$

where  $i = 1, \dots, 6$  and  $j = 1, \dots, 5$ .

Figure 43.1 and Figure 43.2 display the output produced by these statements. Figure 43.1 displays information about the data set, which is useful for checking your data.

The design matrix, shown in Figure 43.2, consists of seven columns: one for the mean and six for the treatment levels. The vector of responses, Nitrogen, is also displayed.

Figure 43.2 Design Matrix

| Observation<br>Number | Nitrogen | Design Points |   |   |   |   |   |   |

| 30                    | 20.8     | 1             | 0 | 0 | 0 | 0 | 0 | 1 |

Usually, you will find PROC GLMMOD most useful for the data sets it can create rather than for its displayed output. For example, the following statements use PROC GLMMOD to save the design matrix for the clover study to the data set CloverDesign instead of displaying it.

```
proc glmmmod data=Clover outdesign=CloverDesign noprint;
 class Strain;
 model Nitrogen = Strain;
run;
```

Now you can use the REG procedure to analyze the data, as the following statements demonstrate:

```
proc reg data=CloverDesign;
 model Nitrogen = Col2-Col7;
run;
```

The results are shown in Figure 43.3.

## Syntax: GLMMOD Procedure

The following statements are available in the GLMMOD procedure.

```

PROC GLMMOD < options > ;
 BY variables ;
 CLASS variables ;
 FREQ variable ;
 MODEL dependents = independents < / options > ;
 WEIGHT variable ;

```

The PROC GLMMOD and MODEL statements are required. If classification effects are used, the classification variables must be declared in a CLASS statement, and the CLASS statement must appear before the MODEL statement.

## PROC GLMMOD Statement

```

PROC GLMMOD < options > ;

```

The PROC GLMMOD statement invokes the GLMMOD procedure. [Table 43.1](#) summarizes the options available in the PROC GLMMOD statement.

**Table 43.1** PROC GLMMOD Statement Options

| Statement  | Description                                                          |
|------------|----------------------------------------------------------------------|
| DATA=      | Specifies the SAS data set to be used                                |
| NAMELEN=   | Specifies the maximum length for an effect name                      |
| NOPRINT    | Suppresses the normal display of results                             |
| OUTPARM=   | Names an output data set describing the design matrix columns        |
| OUTDESIGN= | Names an output data set to contain the columns of the design matrix |
| PREFIX=    | Specifies a prefix to use in naming the columns of the design matrix |
| ZEROBASED  | Modifies the numbering for the columns of the design matrix          |

It has the following options:

### **DATA=SAS-data-set**

specifies the SAS data set to be used by the GLMMOD procedure. If you do not specify the DATA= option, the most recently created SAS data set is used.

### **NAMELEN=*n***

specifies the maximum length for an effect name. Effect names are listed in the table of parameter definitions and stored in the EFFNAME variable in the OUTPARM= data set. By default,  $n = 20$ . You can specify  $20 < n \leq 200$  if 20 characters are not enough to distinguish between effects, which might be the case if the model includes a high-order interaction between variables with relatively long, similar names.

**NOPRINT**

suppresses the normal display of results. This option is generally useful only when one or more output data sets are being produced by the GLMMOD procedure. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “Using the Output Delivery System,” for more information.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of the classification variables (which are specified in the **CLASS** statement). This option applies to the levels for all classification variables, except when you use the (default) **ORDER=FORMATTED** option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The **ORDER=** option can take the following values:

| Value of <b>ORDER=</b> | Levels Sorted By                                                                                                                       |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DATA</b>            | Order of appearance in the input data set                                                                                              |
| <b>FORMATTED</b>       | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| <b>FREQ</b>            | Descending frequency count; levels with the most observations come first in the order                                                  |
| <b>INTERNAL</b>        | Unformatted value                                                                                                                      |

By default, **ORDER=FORMATTED**. For **ORDER=FORMATTED** and **ORDER=INTERNAL**, the sort order is machine-dependent. For more information about sort order, see the chapter on the **SORT** procedure in the *Base SAS Procedures Guide* and the discussion of **BY**-group processing in *SAS Language Reference: Concepts*.

**OUTPARM=SAS-data-set**

names an output data set to contain the information regarding the association between model effects and design matrix columns.

**OUTDESIGN=SAS-data-set**

names an output data set to contain the columns of the design matrix.

**PREFIX=name**

specifies a prefix to use in naming the columns of the design matrix in the **OUTDESIGN=** data set. The default prefix is **Col** and the column name is formed by appending the column number to the prefix, so that by default the columns are named **Col1**, **Col2**, and so on. If you specify the **ZEROBASED** option, the column numbering starts at zero, so that with the default value of **PREFIX=** the columns of the design matrix in the **OUTDESIGN=** data set are named **Col0**, **Col1**, and so on.

**ZEROBASED**

specifies that the numbering for the columns of the design matrix in the **OUTDESIGN=** data set begin at 0. By default it begins at 1, so that with the default value of **PREFIX=** the columns of the design matrix in the **OUTDESIGN=** data set are named **Col1**, **Col2**, and so on. If you use the **ZEROBASED** option, the column names are instead **Col0**, **Col1**, and so on.

---

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC GLMMOD to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the GLMMOD procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

**CLASS** *variables* </ TRUNCATE > ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

**NOTE:** Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the ORDER= option in the PROC GLMMOD statement. You can specify the following option in the CLASS statement after a slash (/):

### TRUNCATE

specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

---

## FREQ and WEIGHT Statements

**FREQ** *variable* ;

**WEIGHT** *variable* ;

FREQ and WEIGHT variables are transferred to the output data sets without change.

---

## MODEL Statement

**MODEL** *dependents = independents </ options >* ;

The MODEL statement names the dependent variables and independent effects. For the syntax of effects, see the section “Specification of Effects” on page 3324 in Chapter 42, “The GLM Procedure.”

You can specify the following option in the MODEL statement after a slash (/):

### **NOINT**

requests that the intercept parameter not be included in the model.

---

## Details: GLMMOD Procedure

---

### Displayed Output

For each pass of the data (that is, for each BY group and for each pass required by the pattern of missing values for the dependent variables), the GLMMOD procedure displays the definitions of the columns of the design matrix along with the following:

- the number of the column
- the name of the associated effect
- the values that the classification variables take for this level of the effect

The design matrix itself is also displayed, along with the following:

- the observation number
- the dependent variable values
- the FREQ and WEIGHT values, if any
- the columns of the design matrix

---

## Missing Values

If some variables have missing values for some observations, then PROC GLMMOD handles missing values in the same way as PROC GLM; see the section “Missing Values” on page 3379 in Chapter 42, “The GLM Procedure,” for further details.

---

## OUTPARM= Data Set

An output data set containing information regarding the association between model effects and design matrix columns is created whenever you specify the OUTPARM= option in the PROC GLMMOD statement. The OUTPARM= data set contains an observation for each column of the design matrix with the following variables:

- a numeric variable, `_COLNUM_`, identifying the number of the column of the design matrix corresponding to this observation
- a character variable, `EFFNAME`, containing the name of the effect that generates the column of the design matrix corresponding to this observation
- the CLASS variables, with the values they have for the column corresponding to this observation, or blanks if they are not involved with the effect associated with this column

If there are BY-group variables or if the pattern of missing values for the dependent variables requires it, the single data set defines several design matrices. In this case, for each of these design matrices, the OUTPARM= data set also contains the following:

- the current values of the BY variables, if you specify a BY statement
- a numeric variable, `_YPASS_`, containing the current pass of the data, if the pattern of missing values for the dependent variables requires multiple passes

---

## OUTDESIGN= Data Set

An output data set containing the design matrix is created whenever you specify the OUTDESIGN= option in the PROC GLMMOD statement. The OUTDESIGN= data set contains an observation for each observation in the DATA= data set, with the following variables:

- the dependent variables
- the FREQ variable, if any
- the WEIGHT variable, if any
- a variable for each column of the design matrix, with names COL1, COL2, and so forth

If there are BY-group variables or if the pattern of missing values for the dependent variables requires it, the single data set contains several design matrices. In this case, for each of these, the OUTDESIGN= data set also contains the following:

- the current values of the BY variables, if you specify a BY statement
- a numeric variable, `_YPASS_`, containing the current pass of the data, if the pattern of missing values for the dependent variables requires multiple passes

---

## ODS Table Names

PROC GLMMOD assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 43.2** ODS Tables Produced by PROC GLMMOD

| ODS Table Name | Description                                 | Statement                                           |
|----------------|---------------------------------------------|-----------------------------------------------------|
| ClassLevels    | Table of class levels                       | CLASS statement                                     |
| DependentInfo  | Simultaneously analyzed dependent variables | default when there are multiple dependent variables |
| DesignPoints   | Design matrix                               | default                                             |
| NObs           | Number of observations                      | default                                             |
| Parameters     | Parameters and associated column numbers    | default                                             |

---

## Examples: GLMMOD Procedure

---

### Example 43.1: A Two-Way Design

The following program uses the GLMMOD procedure to produce the design matrix for a two-way design. The two classification factors have seven and three levels, respectively, so the design matrix contains  $1 + 7 + 3 + 21 = 32$  columns in all. Output 43.1.1, Output 43.1.2, and Output 43.1.3 display the output produced by the following statements.

```
data Plants;
 input Type $ @;
 do Block=1 to 3;
 input StemLength @;
 output;
 end;
 datalines;
Clarion 32.7 32.3 31.5
Clinton 32.1 29.7 29.1
Knox 35.7 35.9 33.1
O'Neill 36.0 34.2 31.2
Compost 31.8 28.0 29.2
Wabash 38.2 37.8 31.9

## Example 43.2: Factorial Screening

Screening experiments are undertaken to select from among the many possible factors that might affect a response the few that actually do, either simply (main effects) or in conjunction with other factors (interactions). One method of selecting significant factors is forward model selection, in which the model is built by successively adding the most statistically significant effects. Forward selection is an option in the REG procedure, but the REG procedure does not allow you to specify interactions directly (as the GLM procedure does, for example). You can use the GLMMOD procedure to create the screening model for a design and then use the REG procedure on the results to perform the screening.

The following statements create the SAS data set `Screening`, which contains the results of a screening experiment:

```

title 'PROC GLMMOD and PROC REG for Forward Selection Screening';
data Screening;
 input a b c d e y;
 datalines;
-1 -1 -1 -1 1 -6.688
-1 -1 -1 1 -1 -10.664
-1 -1 1 -1 -1 -1.459
-1 -1 1 1 1 2.042
-1 1 -1 -1 -1 -8.561
-1 1 -1 1 1 -7.095
-1 1 1 -1 1 0.553
-1 1 1 1 -1 -2.352
 1 -1 -1 -1 -1 -4.802
 1 -1 -1 1 1 5.705
 1 -1 1 -1 1 14.639
 1 -1 1 1 -1 2.151
 1 1 -1 -1 1 5.884
 1 1 -1 1 -1 -3.317
 1 1 1 -1 -1 4.048
 1 1 1 1 1 15.248
;

```

The data set contains a single dependent variable (`y`) and five independent factors (`a`, `b`, `c`, `d`, and `e`). The design is a half-fraction of the full  $2^5$  factorial, the precise half-fraction having been chosen to provide uncorrelated estimates of all main effects and two-factor interactions.

The following statements use the GLMMOD procedure to create a design matrix data set containing all the main effects and two-factor interactions for the preceding screening design.

```

ods output DesignPoints = DesignMatrix;
proc glmmod data=Screening;
 model y = a|b|c|d|e@2;
run;

```

Notice that the preceding statements use ODS to create the design matrix data set, instead of the OUTDESIGN= option in the PROC GLMMOD statement. The results are equivalent, but the columns of the data set produced by ODS have names that are directly related to the names of their corresponding effects.

Finally, the following statements use the REG procedure to perform forward model selection for the screening design. Two MODEL statements are used, one without the selection options (which produces the regression analysis for the full model) and one with the selection options. [Output 43.2.1](#) and [Output 43.2.2](#) show the results of the PROC REG analysis.

```
proc reg data=DesignMatrix;
 model y = a--d_e;
 model y = a--d_e / selection = forward
 details = summary
 slentry = 0.05;
run;
```

| 4                            | a_e              | a*e   | 4              | 0.0722           | 0.9895         | .    | 75.66   | <.0001 |

The full model has 16 parameters (the intercept + 5 main effects + 10 interactions). These are all estimable, but since there are only 16 observations in the design, there are no degrees of freedom left to estimate error; consequently, there is no way to use the full model to test for the statistical significance of effects. However, the forward selection method chooses only four effects for the model: the main effects of factors a, c, and e, and the interaction between a and e. Using this reduced model enables you to estimate the underlying level of noise, although note that the selection method biases this estimate somewhat.

### Overview: GLMPOWER Procedure

Power and sample size analysis optimizes the resource usage and design of a study, improving chances of conclusive results with maximum efficiency. The GLMPOWER procedure performs prospective power and sample size analysis for linear models, with a variety of goals:

- determining the sample size required to get a significant result with adequate probability (power)
- characterizing the power of a study to detect a meaningful effect
- conducting what-if analyses to assess sensitivity of the power or required sample size to other factors

Here *prospective* indicates that the analysis pertains to planning for a future study. This is in contrast to *retrospective* analysis for a past study, which is not supported by this procedure.

The statistical analyses that are covered include Type III tests and contrasts of fixed effects in univariate linear models, optionally with covariates. The covariates can be continuous or categorical. Tests and contrasts involving random effects are not supported. For power and sample size analyses in a variety of other statistical situations, see Chapter 71, “[The POWER Procedure](#).”

Input for PROC GLMPOWER includes the components considered in study planning:

- design (including subject profiles and their allocation weights)
- statistical model
- contrasts of class effects
- significance level (alpha)
- surmised response means for subject profiles (often called “cell means”)
- surmised variability
- power
- sample size

In order to identify power or sample size as the result parameter, you designate it by a missing value in the input. The procedure calculates this result value over one or more scenarios of input values for all other components.

You specify the design and the cell means by using an *exemplary data set*, a data set of artificial values constructed to represent the intended sampling design and the surmised response means in the underlying population. You specify the model and contrasts by using [MODEL](#) and [CONTRAST](#) statements similar to those in the GLM, ANOVA, and MIXED procedures. You specify the remaining parameters with the [POWER](#) statement, which is similar to analysis statements in the POWER procedure.

In addition to tabular results, PROC GLMPOWER produces graphs. You can produce the most common types of plots easily with default settings and use a variety of options for more customized graphics. For example, you can control the choice of axis variables, axis ranges, number of plotted points, mapping of graphical features (such as color, line style, symbol, and panel) to analysis parameters, and legend appearance.

If ODS Graphics is enabled, then PROC GLMPOWER uses ODS Graphics to create graphs; otherwise, traditional graphs are produced.

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

For specific information about the statistical graphics and options available with the GLMPOWER procedure, see the [PLOT](#) statement and the section “[ODS Graphics](#)” on page 3500.

The GLMPOWER procedure is one of several tools available in SAS/STAT software for power and sample size analysis. PROC POWER covers a variety of other analyses such as  $t$  tests, equivalence tests, confidence intervals, binomial proportions, multiple regression, one-way ANOVA, survival analysis, logistic regression, and the Wilcoxon rank-sum test. The Power and Sample Size application provides a user interface and implements many of the analyses supported in the procedures. See Chapter 71, “[The POWER Procedure](#),” and Chapter 72, “[The Power and Sample Size Application](#),” for details.

The following sections of this chapter describe how to use PROC GLMPOWER and discuss the underlying statistical methodology. The section “[Getting Started: GLMPOWER Procedure](#)” on page 3477 introduces PROC GLMPOWER with examples of power computation for a two-way analysis of variance. The section “[Syntax: GLMPOWER Procedure](#)” on page 3483 describes the syntax of the procedure. The section “[Details: GLMPOWER Procedure](#)” on page 3495 summarizes the methods employed by PROC GLMPOWER and provides details on several special topics. The section “[Examples: GLMPOWER Procedure](#)” on page 3501 illustrates the use of the GLMPOWER procedure with several applications.

For an overview of methodology and SAS tools for power and sample size analysis, see Chapter 18, “[Introduction to Power and Sample Size Analysis](#).” For more discussion and examples for linear models, see Castelloe and O’Brien (2001); O’Brien and Shieh (1992); Muller et al. (1992); O’Brien and Muller (1993). For additional discussion of general power and sample size concepts, see O’Brien and Castelloe (2007); Castelloe (2000); Muller and Benignus (1992); Lenth (2001).

## Getting Started: GLMPOWER Procedure

---

### Simple Two-Way ANOVA

This example demonstrates how to use PROC GLMPOWER to compute and plot power for each effect test in a two-way analysis of variance (ANOVA).

Suppose you are planning an experiment to study the effect of light exposure at three levels on the growth of two varieties of flowers. The planned data analysis is a two-way ANOVA with flower height (measured at two weeks) as the response and a model consisting of the effects of light exposure, flower variety, and their interaction. You want to calculate the power of each effect test for a balanced design with a total of 60 specimens (10 for each combination of exposure and variety) with  $\alpha = 0.05$  for each test.

As a first step, create an *exemplary data set* describing your conjectures about the underlying population means. You believe that the mean flower height for each combination of variety and exposure level (that is, for each design profile, or for each *cell* in the design) roughly follows [Table 44.1](#).

**Table 44.1** Mean Flower Height (in cm) by Variety and Exposure

| Variety | Exposure |    |    |
|---------|----------|----|----|
|         | 1        | 2  | 3  |
| 1       | 14       | 16 | 21 |
| 2       | 10       | 15 | 16 |

The following statements create a data set named Exemplary containing these cell means.

```
data Exemplary;
 do Variety = 1 to 2;
 do Exposure = 1 to 3;
 input Height @@;
 output;
 end;
 end;
datalines;
 14 16 21
 10 15 16
;
```

You also conjecture that the error standard deviation is about 5 cm.

Use the `DATA=` option in the `PROC GLMPOWER` statement to specify Exemplary as the exemplary data set. Identify the classification variables (Variety and Exposure) by using the `CLASS` statement. Specify the model by using the `MODEL` statement. Use the `POWER` statement to specify power as the result parameter and provide values for the other analysis parameters, error standard deviation and total sample size. The following SAS statements perform the power analysis:

```
proc glmpower data=Exemplary;
 class Variety Exposure;
 model Height = Variety | Exposure;
 power
 stddev = 5
 ntotal = 60
 power = .;
run;
```

The `MODEL` statement defines the full model including both main effects and the interaction. The `POWER=` option in the `POWER` statement identifies power as the result parameter with a missing value (`POWER=.`). The `STDDEV=` option specifies an error standard deviation of 5, and the `NTOTAL=` option specifies a total sample size of 60. The default value for the `ALPHA=` option sets the significance level to  $\alpha = 0.05$ .

Figure 44.1 shows the output.

**Figure 44.1** Sample Size Analysis for Two-Way ANOVA

| The GLMPOWER Procedure   |        |
|--------------------------|--------|
| Fixed Scenario Elements  |        |
| Dependent Variable       | Height |
| Error Standard Deviation | 5      |
| Total Sample Size        | 60     |
| Alpha                    | 0.05   |
| Error Degrees of Freedom | 54     |

Figure 44.1 *continued*

| Computed Power |                  |            |       |
|----------------|------------------|------------|-------|
| Index          | Source           | Test<br>DF | Power |
| 1              | Variety          | 1          | 0.718 |
| 2              | Exposure         | 2          | 0.957 |
| 3              | Variety*Exposure | 2          | 0.191 |

The power is about 0.72 for the test of the Variety effect. In other words, there is a probability of 0.72 that the test of the Variety effect will produce a significant result (given the assumptions for the means and error standard deviation). The power is 0.96 for the test of the Exposure effect and 0.19 for the interaction test.

Now, suppose you want to account for some of your uncertainty in conjecturing the true error standard deviation by evaluating the power at reasonable low and high values, 4 and 6.5. You also want to plot power for sample sizes between 30 and 90. The following statements perform the analysis:

```
ods listing style=htmlbluecml;
ods graphics on;

proc glmpower data=Exemplary;
 class Variety Exposure;
 model Height = Variety | Exposure;
 power
 stddev = 4 6.5
 ntotal = 60
 power = .;
 plot x=n min=30 max=90;
run;

ods graphics off;
```

The **PLOT** statement with the **X=N** option requests a plot with sample size on the X axis. (The result parameter—in this case, power—is always plotted on the other axis.) The **MIN=** and **MAX=** options in the **PLOT** statement specify the sample size range. The **ODS GRAPHICS ON** statement enables ODS Graphics. The **ODS LISTING STYLE=HTMLBLUECML** statement specifies the HTMLBLUECML style, which is suitable for use with PROC GLMPOWER because it allows both marker symbols and line styles to vary. See the section “ODS Styles Suitable for Use with PROC GLMPOWER” on page 3501 for more information.

Figure 44.2 shows the output, and Figure 44.3 shows the plot.

**Figure 44.2** Sample Size Analysis for Two-Way ANOVA with Input Ranges

| The GLMPOWER Procedure   |                  |         |         |       |
|--------------------------|------------------|---------|---------|-------|

| 5                        | Variety*Exposure | 4.0     | 2       | 0.280 |
| 6                        | Variety*Exposure | 6.5     | 2       | 0.130 |

Figure 44.2 reveals that the power ranges from about 0.130 to 0.996 for the different effect tests and scenarios for standard deviation, with a sample size of 60. In Figure 44.3, the line style identifies the effect test, and the plotting symbol identifies the standard deviation. The locations of the plotting symbols identify actual computed powers; the curves are linear interpolations of these points. Note that the computed points in the plot occur at sample size multiples of 6, because there are 6 cells in the design (and by default, sample sizes are rounded to produce integer cell sizes).

**Figure 44.3** Plot of Power versus Sample Size for Two-Way ANOVA with Input Ranges

## Incorporating Contrasts, Unbalanced Designs, and Multiple Means Scenarios

Suppose you want to compute power for the two-way ANOVA described in the section “Simple Two-Way ANOVA” on page 3477, but you want to additionally perform the following tasks:

- try an unbalanced sample size allocation with respect to Exposure, using twice as many samples for levels 2 and 3 as for level 1
- consider an additional, less optimistic scenario for the cell means, shown in Table 44.2
- test a contrast of Exposure comparing levels 1 and 3

**Table 44.2** Additional Cell Means Scenario

| Variety | Exposure |    |    |
|---------|----------|----|----|
|         | 1        | 2  | 3  |
| 1       | 15       | 16 | 20 |
| 2       | 11       | 14 | 15 |

To specify the unbalanced design and the additional cell means scenario, you can add two new variables to the exemplary data set (Weight for the sample size weights, and HeightNew for the new cell means scenario). Change the name of the original cell means scenario to HeightOrig. The following statements define the exemplary data set:

```
data Exemplary;
 input Variety $ Exposure $ HeightOrig HeightNew Weight;
 datalines;
 1 1 14 15 1
 1 2 16 16 2
 1 3 21 20 2
 2 1 10 11 1
 2 2 15 14 2
 2 3 16 15 2
 ;
```

In PROC GLMPOWER, specify the name of the weight variable by using the **WEIGHT** statement, and specify the name of the cell means variables as dependent variables in the **MODEL** statement. Use the **CONTRAST** statement to specify the contrast as you would in PROC GLM. The following statements perform the sample size analysis.

```
proc glmpower data=Exemplary;
 class Variety Exposure;
 model HeightOrig HeightNew = Variety | Exposure;
 weight Weight;
 contrast 'Exposure=1 vs Exposure=3' Exposure 1 0 -1;
 power
 stddev = 5
 ntotal = 60
 power = .;
run;
```

Figure 44.4 shows the output.

**Figure 44.4** Sample Size Analysis for More Complex Two-Way ANOVA

| The GLMPOWER Procedure  |            |                          |                          |      |        |       |
|-------------------------|------------|--------------------------|--------------------------|------|--------|-------|
| Fixed Scenario Elements |            |                          |                          |      |        |       |
|                         |            | Weight Variable          |                          |      | Weight |       |
|                         |            | Error Standard Deviation |                          |      | 5      |       |
|                         |            | Total Sample Size        |                          |      | 60     |       |
|                         |            | Alpha                    |                          |      | 0.05   |       |
|                         |            | Error Degrees of Freedom |                          |      | 54     |       |
| Computed Power          |            |                          |                          |      |        |       |
| Index                   | Dependent  | Type                     | Source                   | Test | DF     | Power |
| 1                       | HeightOrig | Effect                   | Variety                  |      | 1      | 0.672 |
| 2                       | HeightOrig | Effect                   | Exposure                 |      | 2      | 0.911 |
| 3                       | HeightOrig | Effect                   | Variety*Exposure         |      | 2      | 0.217 |
| 4                       | HeightOrig | Contrast                 | Exposure=1 vs Exposure=3 |      | 1      | 0.951 |
| 5                       | HeightNew  | Effect                   | Variety                  |      | 1      | 0.754 |
| 6                       | HeightNew  | Effect                   | Exposure                 |      | 2      | 0.633 |
| 7                       | HeightNew  | Effect                   | Variety*Exposure         |      | 2      | 0.137 |
| 8                       | HeightNew  | Contrast                 | Exposure=1 vs Exposure=3 |      | 1      | 0.705 |

The power of the contrast of Exposure levels 1 and 3 is about 0.95 for the original cell means scenario (HeightOrig) and only 0.71 for the new one (HeightNew). The power is higher for the test of Variety, but lower for the tests of Exposure and of Variety\*Exposure for the new cell means scenario compared to the original one. Note also for the HeightOrig scenario that the power for the unbalanced design (Figure 44.4) compared to the balanced design (Figure 44.1) is slightly lower for the tests of Variety and Exposure, but slightly higher for the test of Variety\*Exposure.

## Syntax: GLMPOWER Procedure

The following statements are available in the GLMPOWER procedure:

```

PROC GLMPOWER < options > ;
 BY variables ;
 CLASS variables ;
 CONTRAST 'label' effect values < ... effect values > < / options > ;
 MODEL dependents = independents ;
 PLOT < plot-options > < / graph-options > ;
 POWER < options > ;
 WEIGHT variable ;

```

The **PROC GLMPOWER** statement, the **MODEL** statement, and the **POWER** statement are required. If your model contains classification effects, the classification variables must be listed in a **CLASS** statement, and the **CLASS** statement must appear before the **MODEL** statement. In addition, **CONTRAST** and **POWER** statements must appear after the **MODEL** statement. **PLOT** statements must appear after the **POWER** statement that defines the analysis for the plot.

You can use multiple **CONTRAST**, **POWER**, and **PLOT** statements. Each **CONTRAST** statement defines a separate contrast. Each **POWER** statement produces a separate analysis and uses the information contained in the **CLASS**, **MODEL**, **WEIGHT**, and all **CONTRAST** statements. Each **PLOT** statement refers to the previous **POWER** statement and generates a separate graph (or set of graphs).

Table 44.3 summarizes the basic functions of each statement in PROC GLMPOWER. The syntax of each statement in Table 44.3 is described in the following pages.

**Table 44.3** Statements in the GLMPOWER Procedure

| Statement            | Description                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------|
| <b>PROC GLMPOWER</b> | Invokes procedure and specifies exemplary data set                                                           |
| <b>BY</b>            | Specifies variables to define subgroups for the analysis                                                     |
| <b>CLASS</b>         | Declares classification variables                                                                            |
| <b>CONTRAST</b>      | Defines linear tests of model parameters                                                                     |
| <b>MODEL</b>         | Defines model and specifies dependent variable(s) used for cell means scenarios                              |
| <b>PLOT</b>          | Displays graphs for preceding <b>POWER</b> statement                                                         |
| <b>POWER</b>         | Identifies parameter to solve for and provides one or more scenarios for values of other analysis parameters |
| <b>WEIGHT</b>        | Specifies variable for allocating sample sizes to different subject profiles                                 |

## PROC GLMPOWER Statement

**PROC GLMPOWER** < options > ;

The **PROC GLMPOWER** statement invokes the GLMPOWER procedure. You can specify the following options.

**DATA=SAS-data-set**

names a SAS data set to be used as the exemplary data set, which is an artificial data set constructed to represent the intended sampling design and the conjectured response means for the underlying population.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of the classification variables (which are specified in the **CLASS** statement).

This option applies to the levels for all classification variables, except when you use the (default) **ORDER=FORMATTED** option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The **ORDER=** option can take the following values:

| Value of <b>ORDER=</b> | Levels Sorted By                                                                                                                       |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DATA</b>            | Order of appearance in the input data set                                                                                              |
| <b>FORMATTED</b>       | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| <b>FREQ</b>            | Descending frequency count; levels with the most observations come first in the order                                                  |
| <b>INTERNAL</b>        | Unformatted value                                                                                                                      |

By default, **ORDER=FORMATTED**. For **ORDER=FORMATTED** and **ORDER=INTERNAL**, the sort order is machine-dependent.

For more information about sort order, see the chapter on the **SORT** procedure in the *Base SAS Procedures Guide* and the discussion of **BY**-group processing in *SAS Language Reference: Concepts*.

**PLOTONLY**

specifies that only graphical results from the **PLOT** statement be produced.

---

**BY Statement**

**BY** variables ;

You can specify a **BY** statement with **PROC GLMPOWER** to obtain separate analyses of observations in groups that are defined by the **BY** variables. When a **BY** statement appears, the procedure expects the input data set to be sorted in order of the **BY** variables. If you specify more than one **BY** statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the **SORT** procedure with a similar **BY** statement.
- Specify the **NOTSORTED** or **DESCENDING** option in the **BY** statement for the **GLMPOWER** procedure. The **NOTSORTED** option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the **BY** variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the **BY** variables by using the **DATASETS** procedure (in Base SAS software).

Because sorting the data changes the order in which PROC GLMPOWER reads observations, the sort order for the levels of the classification variables might be affected if you have also specified **ORDER=DATA** in the PROC GLMPOWER statement. This, in turn, affects specifications in **CONTRAST** statements.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

## CLASS Statement

**CLASS** *variables* ;

The **CLASS** statement names the classification variables to be used in the analysis. If you use the **CLASS** statement, it must appear before the **MODEL** statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the **CLASS** variables.

## CONTRAST Statement

**CONTRAST** *'label'* *effect values* < . . . *effect values* > < / *options* > ;

The **CONTRAST** statement enables you to define custom hypothesis tests by specifying an **L** vector or matrix for testing the hypothesis  $L\beta = 0$ . Thus, to use this feature you must be familiar with the details of the model parameterization used in PROC GLM. For more information, see the section “**Parameterization of PROC GLM Models**” on page 3327 of Chapter 42, “**The GLM Procedure**.” All of the elements of the **L** vector can be given, or if only certain portions of the **L** vector are given, the remaining elements are constructed by PROC GLMPOWER from the context (in a manner similar to rule 4 discussed in the section “**Construction of Least Squares Means**” on page 3363 of Chapter 42, “**The GLM Procedure**”).

There is no limit to the number of **CONTRAST** statements you can specify. Each sample size analysis includes tests for all **CONTRAST** statements.

In the **CONTRAST** statement,

- label* identifies the contrast on the output. A label is required for every contrast specified. Labels must be enclosed in quotes.
- effect* identifies an effect that appears in the **MODEL** statement, or the INTERCEPT effect. You do not need to include all effects that are in the **MODEL** statement.
- values* are constants that are elements of the **L** vector associated with the effect.

You can specify the following option in the **CONTRAST** statement after a slash (/):

**SINGULAR=***number*

tunes the estimability checking. If  $ABS(L - LH) > C \times \text{number}$  for any row in the contrast, then **L** is declared nonestimable. **H** is the  $(X'X)^{-1}X'X$  matrix, and **C** is  $ABS(L)$  except for rows where **L** is zero, and then it is 1. The default value for the **SINGULAR=** option is  $10^{-4}$ . Values for the **SINGULAR=** option must be between 0 and 1.

The **CONTRAST** statement enables you to perform custom hypothesis tests. If the hypothesis is estimable, then the sum of squares due to it,  $SS(H_0: \mathbf{L}\boldsymbol{\beta} = 0)$ , is computed as

$$(\mathbf{Lb})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{Lb})$$

where  $\mathbf{b} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y}$  is the estimated solution vector.

The degrees of freedom associated with the hypothesis are equal to the row rank of  $\mathbf{L}$ . The sum of squares computed in this situation is equivalent to the sum of squares computed using an  $\mathbf{L}$  matrix with any row deleted that is a linear combination of previous rows.

Multiple-degrees-of-freedom hypotheses can be specified by separating the rows of the  $\mathbf{L}$  matrix with commas.

## MODEL Statement

**MODEL** *dependents* = *independents* ;

The **MODEL** statement serves two basic purposes:

- The *dependents* specify scenarios for the cell means.
- The *independents* specify the independent effects.

The *independents* can involve classification variables, continuous variables, or both. You can include main effects and interactions by using the effects notation of PROC GLM; see the section “[Specification of Effects](#)” on page 3324 in Chapter 42, “[The GLM Procedure](#)” for further details. For any model effect involving classification variables (interactions as well as main effects), the number of levels cannot exceed 32,767. If no independent effects are specified, only an intercept term is fit. The **MODEL** statement must appear before the **POWER** statement if the **EFFECTS** option is used in the **POWER** statement.

You can account for covariates in the model by using the **NCOVARIATES=** option and either the **CORRXY=** or **PROPVARREDUCTION=** option in the **POWER** statement.

Each dependent variable refers to a set of surmised cell means in the exemplary data set (named by the **DATA=** option in the **PROC GLMPOWER** statement). These cell means are response means for all of the subject profiles. Multiple dependent variables correspond to multiple scenarios for these cell means. All models are univariate; the GLMPOWER procedure currently does not support multivariate analyses.

The **MODEL** statement is required. You can specify only one **MODEL** statement.

## PLOT Statement

**PLOT** *plot-options* < / *graph-options* > ;

The **PLOT** statement produces a graph or set of graphs for the sample size analysis defined by the previous **POWER** statement. The *plot-options* define the plot characteristics, and the *graph-options* are like those in SAS/GRAPH software. If ODS Graphics is enabled, then the **PLOT** statement uses ODS Graphics to create graphs. For example:

```
ods listing style=htmlbluecml;
ods graphics on;

proc glmpower data=Exemplary;
 class Variety Exposure;
 model Height = Variety | Exposure;
 power
 stddev = 4 6.5
 ntotal = 60
 power = .;
 plot x=n min=30 max=90;
run;

ods graphics off;
```

Otherwise, traditional graphics are produced. For example:

```
ods graphics off;

proc glmpower data=Exemplary;
 class Variety Exposure;
 model Height = Variety | Exposure;
 power
 stddev = 4 6.5
 ntotal = 60
 power = .;
 plot x=n min=30 max=90;
run;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The ODS LISTING STYLE=HTMLBLUECML statement specifies the HTMLBLUECML style, which is suitable for use with PROC GLMPOWER because it allows both marker symbols and line styles to vary. See the section “[ODS Styles Suitable for Use with PROC GLMPOWER](#)” on page 3501 for more information.

Table 44.4 summarizes the options available in the PLOT statement.

**Table 44.4** PLOT Statement Options

| Option              | Description                                                                 |
|---------------------|-----------------------------------------------------------------------------|
| <b>Plot Options</b> |                                                                             |
| INTERPOL=           | Specifies the type of curve to draw                                         |
| KEY=                | Specifies the style of key for the plot                                     |
| MARKERS=            | Specifies the locations for plotting symbols                                |
| MAX=                | Specifies the maximum of the range of values                                |
| MIN=                | Specifies the minimum of the range of values                                |
| NPOINTS=            | Specifies the number of values                                              |
| STEP=               | Specifies the increment between values                                      |
| VARY                | Specifies how plot features should be linked to varying analysis parameters |
| X=                  | Specifies a plot with the requested type of parameter on the X axis         |
| XOPTS=              | Specifies plot characteristics pertaining to the X axis                     |

Table 44.4 *continued*

| Option               | Description                                                         |
|----------------------|---------------------------------------------------------------------|
| Y=                   | Specifies a plot with the requested type of parameter on the Y axis |
| YOPTS=               | Specifies plot characteristics pertaining to the Y axis             |
| <b>Graph Options</b> |                                                                     |
| DESCRIPTION=         | Specifies a descriptive string                                      |
| NAME=                | Specifies a name for the catalog entry for the plot                 |

## Options

You can specify the following *plot-options* in the **PLOT** statement.

### **INTERPOL=JOIN | NONE**

specifies the type of curve to draw through the computed points. The **INTERPOL=JOIN** option connects computed points with straight lines. The **INTERPOL=NONE** option leaves computed points unconnected.

### **KEY=BYCURVE** < (*bycurve-options*) >

### **KEY=BYFEATURE** < (*byfeature-options*) >

### **KEY=ONCURVES**

specifies the style of key (or “legend”) for the plot. The default is **KEY=BYFEATURE**, which specifies a key with a column of entries for each plot feature (line style, color, and/or symbol). Each entry shows the mapping between a value of the feature and the value(s) of the analysis parameter(s) linked to that feature. The **KEY=BYCURVE** option specifies a key with each row identifying a distinct curve in the plot. The **KEY=ONCURVES** option places a curve-specific label adjacent to each curve.

You can specify the following *byfeature-options* in parentheses after the **KEY=BYCURVE** option.

### **NUMBERS=OFF | ON**

specifies how the key should identify curves. If **NUMBERS=OFF**, then the key includes symbol, color, and line style samples to identify the curves. If **NUMBERS=ON**, then the key includes numbers matching numeric labels placed adjacent to the curves. The default is **NUMBERS=ON**.

### **POS=BOTTOM | INSET**

specifies the position of the key. The **POS=BOTTOM** option places the key below the X axis. The **POS=INSET** option places the key inside the plotting region and attempts to choose the least crowded corner. The default is **POS=BOTTOM**.

You can specify the following *byfeature-options* in parentheses after **KEY=BYFEATURE** option.

### **POS=BOTTOM | INSET**

specifies the position of the key. The **POS=BOTTOM** option places the key below the X axis. The **POS=INSET** option places the key inside the plotting region and attempts to choose the least crowded corner. The default is **POS=BOTTOM**.

**MARKERS=ANALYSIS | COMPUTED | NICE | NONE**

specifies the locations for plotting symbols.

The **MARKERS=ANALYSIS** option places plotting symbols at locations corresponding to the values of the relevant input parameter from the **POWER** statement preceding the **PLOT** statement.

The **MARKERS=COMPUTED** option (the default) places plotting symbols at the locations of actual computed points from the sample size analysis.

The **MARKERS=NICE** option places plotting symbols at tick mark locations (corresponding to the argument axis).

The **MARKERS=NONE** option disables plotting symbols.

**MAX=number | DATAMAX**

specifies the maximum of the range of values for the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). The default is **DATAMAX**, which specifies the maximum value that occurs for this parameter in the **POWER** statement that precedes the **PLOT** statement.

**MIN=number | DATAMIN**

specifies the minimum of the range of values for the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). The default is **DATAMIN**, which specifies the minimum value that occurs for this parameter in the **POWER** statement that precedes the **PLOT** statement.

**NPOINTS=number****NPTS=number**

specifies the number of values for the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). You cannot use the **NPOINTS=** and **STEP=** options simultaneously. The default value for typical situations is 20.

**STEP=number**

specifies the increment between values of the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). You cannot use the **STEP=** and **NPOINTS=** options simultaneously. By default, the **NPOINTS=** option is used instead of the **STEP=** option.

**VARY ( feature <BY parameter-list> <, ..., feature <BY parameter-list>> )**

specifies how plot features should be linked to varying analysis parameters. Available *features* are **COLOR**, **LINestyle**, **PANEL**, and **SYMBOL**. A “panel” refers to a separate plot with a heading identifying the subset of values represented in the plot.

The *parameter-list* is a list of one or more names separated by spaces. Each name must match the name of an analysis option used in the **POWER** statement preceding the **PLOT** statement, *or* one of the following keywords: **SOURCE** (for the tests) and **DEPENDENT** (for the cell means scenarios). Also, the name must be the *primary* name for the analysis option—that is, the one listed first in the syntax description.

If you omit the < **BY parameter-list** > portion for a feature, then one or more multivalued parameters from the analysis will be automatically selected for you.

**X=N | POWER**

specifies a plot with the requested type of parameter on the X axis and the parameter being solved for on the Y axis. When **X=N**, sample size is assigned to the X axis. When **X=POWER**, power is assigned to the X axis. You cannot use the **X=** and **Y=** options simultaneously. The default is **X=POWER**, unless the result parameter is power, in which case the default is **X=N**.

**XOPTS= ( *x-options* )**

specifies plot characteristics pertaining to the X axis.

You can specify the following *x-options* in parentheses.

**CROSSREF=NO | YES**

specifies whether the reference lines defined by the **REF= *x-option*** should be crossed with a reference line on the Y axis that indicates the solution point on the curve.

**REF=number-list**

specifies locations for reference lines extending from the X axis across the entire plotting region. See the section “[Specifying Value Lists in the POWER Statement](#)” on page 3495 for information about specifying the *number-list*.

**Y=N | POWER**

specifies a plot with the requested type of parameter on the Y axis and the parameter being solved for on the X axis. When **Y=N**, sample size is assigned to the Y axis. When **Y=POWER**, power is assigned to the Y axis. You cannot use the **Y=** and **X=** options simultaneously. By default, the **X=** option is used instead of the **Y=** option.

**YOPTS= ( *y-options* )**

specifies plot characteristics pertaining to the Y axis.

You can specify the following *y-options* in parentheses.

**CROSSREF=NO | YES**

specifies whether the reference lines defined by the **REF= *y-option*** should be crossed with a reference line on the X axis that indicates the solution point on the curve.

**REF=number-list**

specifies locations for reference lines extending from the Y axis across the entire plotting region. See the section “[Specifying Value Lists in the POWER Statement](#)” on page 3495 for information about specifying the *number-list*.

You can specify the following *graph-options* in the **PLOT** statement after a slash (/).

**DESCRIPTION='string'**

specifies a descriptive string of up to 40 characters that appears in the “Description” field of the graphics catalog. The description does not appear on the plots. By default, PROC GLMPOWER assigns a description either of the form “Y versus X” (for a single-panel plot) or of the form “Y versus X (S),” where Y is the parameter on the Y axis, X is the parameter on the X axis, and S is a description of the subset represented on the current panel of a multipanel plot.

**NAME='string'**

specifies a name of up to eight characters for the catalog entry for the plot. The default name is PLOT $n$ , where  $n$  is the number of the plot statement within the current invocation of PROC GLMPOWER. If the name duplicates the name of an existing entry, SAS/GRAPH software adds a number to the duplicate name to create a unique entry—for example, PLOT11 and PLOT12 for the second and third panels of a multipanel plot generated in the first PLOT statement in an invocation of PROC GLMPOWER.

---

## POWER Statement

**POWER** < options > ;

The **POWER** statement performs power and sample size analyses for the Type III test of each effect in the model defined by the **MODEL** statements and for the contrasts defined by all **CONTRAST** statements. The **MODEL** statement must appear before the **POWER** statement if the **EFFECTS** option is used in the **POWER** statement.

### Summary of Options

Table 44.5 summarizes the options available in the **POWER** statement.

**Table 44.5** POWER Statement Options

| Option            | Description                                                               |
|-------------------|---------------------------------------------------------------------------|
| ALPHA=            | Specifies the level of significance of each test                          |
| CORRXY=           | Specifies multiple correlation ( $\rho$ ) between covariates and response |
| DEPENDENT         | Specifies the location of the Dependent column in the output              |
| EFFECTS           | Specifies the model effects                                               |
| NCOVARIATES=      | Specifies additional degrees of freedom due to covariates                 |
| NFRACTIONAL       | Enables fractional input and output for sample sizes                      |
| NTOTAL=           | Specifies the sample size                                                 |
| OUTPUTORDER=      | Controls ordering in output                                               |
| POWER=            | Specifies Power                                                           |
| PROPVARREDUCTION= | Specifies proportional variance reduction ( $r$ ) due to covariates       |
| STDDEV=           | Specifies error standard deviation                                        |

Table 44.6 summarizes the valid result parameters.

**Table 44.6** Summary of Result Parameters in the POWER Statement

| Solve for   | Syntax     |
|-------------|------------|
| Power       | POWER = .  |
| Sample size | NTOTAL = . |

## Dictionary of Options

### **ALPHA=***number-list*

specifies the level of significance of each test. The default is 0.05, corresponding to the usual  $0.05 \times 100\% = 5\%$  level of significance. Note that this is a test-wise significance level with the same value for all tests, not incorporating any corrections for multiple testing. See the section “[Specifying Value Lists in the POWER Statement](#)” on page 3495 for information about specifying the *number-list*.

### **CORRXY=***number-list*

specifies the multiple correlation ( $\rho$ ) between all covariates and the response. The error standard deviation given by the **STDDEV=** option is consequently reduced by multiplying it by a factor of  $(1 - \rho^2)^{\frac{1}{2}}$ , provided that the number of covariates (as determined by the **NCOVARIATES=** option) is greater than zero. You cannot use the **CORRXY=** and the **PROPVARREDUCTION=** options simultaneously. See the section “[Specifying Value Lists in the POWER Statement](#)” on page 3495 for information about specifying the *number-list*.

### **DEPENDENT**

specifies the location of the Dependent column in the output when the **OUTPUTORDER=REVERSE** option or **OUTPUTORDER=SYNTAX** option is used, according to its relative position in the **POWER** statement.

### **EFFECTS** <= <( effect ... effect ) >>

specifies the model effects to include in the power analysis. By default, or if the **EFFECTS** keyword is specified without the equal sign (=), all model effects are included. Specify **EFFECTS=()** to exclude all model effect tests from the power analysis. You can include main effects and interactions by using the effects notation of PROC GLM; see the section “[Specification of Effects](#)” on page 3324 in Chapter 42, “[The GLM Procedure](#)” for further details. The **MODEL** statement must appear before the **POWER** statement if the **EFFECTS** option is used.

### **NCOVARIATES=***number-list*

### **NCOVARIATE=***number-list*

### **NCOVS=***number-list*

### **NCOV=***number-list*

specifies the number of additional degrees of freedom to accommodate covariate effects—both class and continuous—not listed in the **MODEL** statement. The error degrees of freedom are consequently reduced by the value of the **NCOVARIATES=** option, and the error standard deviation (whose unadjusted value is provided with the **STDDEV=** option) is reduced according to the value of the **CORRXY=** or **PROPVARREDUCTION=** option. See the section “[Specifying Value Lists in the POWER Statement](#)” on page 3495 for information about specifying the *number-list*.

### **NFRACTIONAL**

#### **NFRAC**

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 3495 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

### **NTOTAL=***number-list*

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). Values for the sample size must be no smaller than the model degrees of freedom (counting the

covariates). See the section “Specifying Value Lists in the POWER Statement” on page 3495 for information about specifying the *number-list*.

### **OUTPUTORDER=INTERNAL | REVERSE | SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **DEPENDENT**
- **EFFECTS**
- weight variable (from the **WEIGHT** statement)
- **ALPHA=**
- **NCOVARIATES=**
- **CORRXY=**
- **PROPVARREDUCTION=**
- **STDDEV=**
- **NTOTAL=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **POWER** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **POWER** statement.

### **POWER=number-list**

specifies the desired power of each test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability (for example, 0.9) rather than a percentage. Note that this is a test-wise power with the same value for all tests, without any correction for multiple testing. See the section “Specifying Value Lists in the POWER Statement” on page 3495 for information about specifying the *number-list*.

### **PROPVARREDUCTION=number-list**

#### **PVRED=number-list**

specifies the proportional reduction ( $r$ ) in total R square incurred by the covariates—in other words, the amount of additional variation explained by the covariates. The error standard deviation given by the **STDDEV=** option is consequently reduced by multiplying it by a factor of  $(1 - r)^{\frac{1}{2}}$ , provided that the number of covariates (as determined by the **NCOVARIATES=** option) is greater than zero. You cannot use the **PROPVARREDUCTION=** and the **CORRXY=** options simultaneously. See the section “Specifying Value Lists in the POWER Statement” on page 3495 for information about specifying the *number-list*.

### **STDDEV=number-list**

specifies the error standard deviation, or root MSE. If covariates are specified using the **NCOVARIATES=** option, then the **STDDEV=** option denotes the error standard deviation before accounting for these covariates. See the section “Specifying Value Lists in the POWER Statement” on page 3495 for information about specifying the *number-list*.

## Restrictions on Option Combinations

For the relationship between covariates and response, specify either the multiple correlation (by using the `CORRXY=` option) or the proportional reduction in total R square (by using the `PROPVARREDUCTION=` option).

---

## WEIGHT Statement

**WEIGHT** *variable* ;

The **WEIGHT** statement names a variable that provides a profile weight (“cell weight”) for each observation in the exemplary data set specified by the `DATA=` option in the **PROC GLMPOWER** statement.

If the **WEIGHT** statement is not used, then a balanced design is assumed with default cell weights of 1.

---

## Details: GLMPOWER Procedure

---

### Specifying Value Lists in the POWER Statement

To specify one or more scenarios for an analysis parameter (or set of parameters) in the **POWER** statement, you provide a list of values for the option that corresponds to the parameter(s). To identify the parameter you want to solve for, you place a missing value in the appropriate list.

Scenarios for scalar-valued parameters, such as power, are represented by a *number-list*.

#### Number-Lists

A *number-list* can be one of two things: a series of one or more numbers expressed in the form of one or more DOLISTS, or a missing value indicator ( . ).

The DOLIST format is the same as in the **DATA** step. For example, you can specify four scenarios (30, 50, 70, and 100) for a total sample size in either of the following ways:

```
NTOTAL = 30 50 70 100
NTOTAL = 30 to 70 by 20 100
```

A missing value identifies a parameter as the result parameter; it is valid only with options representing parameters you can solve for in a given analysis. For example, you can request a solution for **NTOTAL**:

```
NTOTAL = .
```

---

### Sample Size Adjustment Options

By default, **PROC GLMPOWER** rounds sample sizes conservatively (down in the input, up in the output) so that all total sizes *and* sample sizes for individual design profiles are integers. This is generally considered conservative because it selects the closest realistic design providing *at most* the power of the (possibly fractional) input or mathematically optimized design. In addition, all design profile sizes are adjusted to be multiples of their corresponding weights. If a design profile is present more than once in the exemplary

data set, then the weights for that design profile are summed. For example, if a particular design profile is present twice in the exemplary data set with weight values 2 and 6, then all sample sizes for this design profile become multiples of  $2 + 6 = 8$ .

With the `NFRACTIONAL` option, sample size input is not rounded, and sample size output is reported in two versions, a raw “fractional” version and a “ceiling” version rounded up to the nearest integer.

Whenever an input sample size is adjusted, both the original (“nominal”) and adjusted (“actual”) sample sizes are reported. Whenever computed output sample sizes are adjusted, both the original input (“nominal”) power and the achieved (“actual”) power at the adjusted sample size are reported.

---

## Error and Information Output

The Error column in the main output table explains reasons for missing results and flags numerical results that are bounds rather than exact answers.

The Info column provides further information about Error entries, warnings about any boundary conditions detected, and notes about any adjustments to input. Note that the Info column is hidden by default in the main output. You can view it by using the `ODS OUTPUT` statement to save the output as a data set and the `PRINT` procedure. For example, the following SAS statements print both the Error and Info columns for a power computation in a one-way ANOVA:

```
data MyExemp;
 input A $ Y1 Y2;
 datalines;
 1 10 11
 2 12 11
 3 15 11
 ;

proc glmpower data=MyExemp;
 class A;
 model Y1 Y2 = A;
 power
 stddev = 2
 ntotal = 3 10
 power = .;
 ods output output=Power;
run;

proc print noobs data=Power;
 var NominalNTotal NTotal Dependent Power Error Info;
run;
```

The output is shown in [Figure 44.5](#).

**Figure 44.5** Error and Information Columns

| Nominal |        | Dependent | Power | Error         | Info                         |
|---------|--------|-----------|-------|---------------|------------------------------|
| NTotal  | NTotal |           |       |               |                              |
| 3       | 3      | Y1        | .     | Invalid input | Error DF=0                   |
| 10      | 9      | Y1        | 0.557 |               | Input N adjusted             |
| 3       | 3      | Y2        | .     | Invalid input | Error DF=0 / No effect       |
| 10      | 9      | Y2        | 0.050 |               | Input N adjusted / No effect |

The sample size of 3 specified with the `NTOTAL=` option causes an “Invalid input” message in the Error column and an “Error DF=0” message in the Info column, because a sample size of 3 is so small that there are no degrees of freedom left for the error term. The sample size of 10 causes an “Input N adjusted” message in the Info column, because it is rounded down to 9 to produce integer group sizes of 3 per cell. The cell means scenario represented by the dependent variable Y2 causes a “No effect” message to appear in the Info column, because the means in this scenario are all equal.

## Displayed Output

If you use the `PLOTONLY` option in the `PROC GLMPOWER` statement, the procedure displays only graphical output. Otherwise, the displayed output of the `GLMPOWER` procedure includes the following:

- the “Fixed Scenario Elements” table, which shows all applicable single-valued analysis parameters, in the following order: the dependent variable representing the cell means, the source of the test, the weight variable, parameters input explicitly, parameters supplied with defaults, and ancillary results
- an output table showing the following when applicable (in order): the index of the scenario, the dependent variable representing the cell means, the type of the test, the source of the test, all multivalued input, ancillary results, the primary computed result, and error descriptions
- plots (if requested)

The exception to these ordering conventions is that the `DEPENDENT` and `EFFECTS` options may be used along with the `OUTPUTORDER=SYNTAX` or `OUTPUTORDER=REVERSE` option in the `POWER` statement to specify the relative location of the output for dependent variable and type and source of test.

Ancillary results include the following:

- Actual Power, the achieved power, if it differs from the input (Nominal) power value
- fractional sample size, if the `NFRACTIONAL` option is used in the `POWER` statement

If sample size is the result parameter and the `NFRACTIONAL` option is used in the `POWER` statement, then both “Fractional” and “Ceiling” sample size results are displayed. Fractional sample sizes correspond to the “Nominal” values of power. Ceiling sample sizes are simply the fractional sample sizes rounded up to the nearest integer; they correspond to “Actual” values of power.

The noncentrality parameter is computed and stored in a hidden column called Noncentrality in the “Output” table.

## ODS Table Names

PROC GLMPOWER assigns a name to each table that it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 44.7. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 44.7** ODS Tables Produced by PROC GLMPOWER

| ODS Table Name | Description                                                                                                                                                                        | Statement |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| FixedElements  | Factoid with single-valued analysis parameters                                                                                                                                     | Default   |
| Output         | All input and computed analysis parameters, error messages, and information messages for each scenario                                                                             | Default   |
| PlotContent    | Data contained in plots, including analysis parameters and indices identifying plot features. (NOTE: This table is saved as a data set and not displayed in PROC GLMPOWER output.) | PLOT      |

## Computational Methods and Formulas

This section describes the approaches used in PROC GLMPOWER to compute power and sample size.

### Contrasts in Fixed-Effect Univariate Models

The univariate linear model has the form

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where  $\mathbf{y}$  is the  $N \times 1$  vector of responses,  $\mathbf{X}$  is the  $N \times p$  design matrix,  $\boldsymbol{\beta}$  is the  $p \times 1$  vector of model parameters corresponding to the columns of  $\mathbf{X}$ , and  $\boldsymbol{\epsilon}$  is an  $N \times 1$  vector of errors with

$$\epsilon_1, \dots, \epsilon_N \sim N(0, \sigma^2) \quad (\text{i.i.d.})$$

In PROC GLMPOWER, the model parameters  $\boldsymbol{\beta}$  are not specified directly, but rather indirectly as  $\mathbf{y}^*$ , which represents either conjectured response means or typical response values for each design profile. The  $\mathbf{y}^*$  values are manifested as the dependent variable in the MODEL statement. The vector  $\boldsymbol{\beta}$  is obtained from  $\mathbf{y}^*$  according to the least squares equation,

$$\boldsymbol{\beta} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y}^*$$

Note that, in general, there is not a 1-to-1 mapping between  $\mathbf{y}^*$  and  $\boldsymbol{\beta}$ . Many different scenarios for  $\mathbf{y}^*$  might lead to the same  $\boldsymbol{\beta}$ . If you specify  $\mathbf{y}^*$  with the intention of representing cell means, keep in mind that PROC GLMPOWER allows scenarios that are *not* valid cell means according to the model specified in the MODEL statement. For example, if  $\mathbf{y}^*$  exhibits an interaction effect but the corresponding interaction term is left out of the model, then the cell means ( $\mathbf{X}\boldsymbol{\beta}$ ) derived from  $\boldsymbol{\beta}$  differ from  $\mathbf{y}^*$ . In particular, the cell means thus derived are the projection of  $\mathbf{y}^*$  onto the model space.

It is convenient in power analysis to parameterize the design matrix  $\mathbf{X}$  in three parts,  $\{\ddot{\mathbf{X}}, \mathbf{w}, N\}$ , defined as follows:

1. The  $q \times p$  essence design matrix  $\ddot{\mathbf{X}}$  is the collection of unique rows of  $\mathbf{X}$ . Its rows are sometimes referred to as “design profiles.” Here,  $q \leq N$  is defined simply as the number of unique rows of  $\mathbf{X}$ .
2. The  $q \times 1$  weight vector  $\mathbf{w}$  reveals the relative proportions of design profiles. Row  $i$  of  $\ddot{\mathbf{X}}$  is to be included in the design  $w_i$  times for every  $w_j$  times row  $j$  is included. The weights are assumed to be standardized (that is, sum up to 1).
3. The total sample size is  $N$ . This is the number of rows in  $\mathbf{X}$ . If you gather  $Nw_i = n_i$  copies of the  $i$ th row of  $\ddot{\mathbf{X}}$ , for  $i = 1, \dots, q$ , then you end up with  $\mathbf{X}$ .

It is useful to express the crossproduct matrix  $\mathbf{X}'\mathbf{X}$  in terms of these three parts,

$$\mathbf{X}'\mathbf{X} = N \ddot{\mathbf{X}}' \text{diag}(\mathbf{w}) \ddot{\mathbf{X}}$$

since this factors out the portion ( $N$ ) depending on sample size and the portion ( $\ddot{\mathbf{X}}' \text{diag}(\mathbf{w}) \ddot{\mathbf{X}}$ ) depending only on the design structure.

A general linear hypothesis for the univariate model has the form

$$H_0: \mathbf{L}\boldsymbol{\beta} = \boldsymbol{\theta}_0$$

$$H_A: \mathbf{L}\boldsymbol{\beta} \neq \boldsymbol{\theta}_0$$

where  $\mathbf{L}$  is an  $r_L \times p$  contrast matrix (assumed to be full rank) and  $\boldsymbol{\theta}_0$  is the null value (usually just a vector of zeros). Note that effect tests are just contrasts that use special forms of  $\mathbf{L}$ . Thus, this scheme covers both effect tests and custom contrasts.

The test statistic is

$$F = \frac{\left(\frac{SS_H}{r_L}\right)}{\hat{\sigma}^2}$$

where

$$SS_H = \frac{1}{N} (\mathbf{L}\hat{\boldsymbol{\beta}} - \boldsymbol{\theta}_0)' (\mathbf{L} (\mathbf{X}'\mathbf{X})^{-1} \mathbf{L}')^{-1} (\mathbf{L}\hat{\boldsymbol{\beta}} - \boldsymbol{\theta}_0)$$

$$\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{X})^{-1} \mathbf{X}'\mathbf{y}$$

$$\hat{\sigma}^2 = \frac{1}{DF_E} (\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}})' (\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}})$$

where  $DF_E = N - \text{rank}(\mathbf{X})$ . Note that  $DF_E = N - p$  if  $\mathbf{X}$  has full rank.

Under  $H_0$ ,  $F \sim F(r_L, DF_E)$ . Under  $H_A$ ,  $F$  is distributed as  $F(r_L, DF_E, \lambda)$  with noncentrality

$$\lambda = N (\mathbf{L}\boldsymbol{\beta} - \boldsymbol{\theta}_0)' \left( \mathbf{L} \left( \ddot{\mathbf{X}}' \text{diag}(\mathbf{w}) \ddot{\mathbf{X}} \right)^{-1} \mathbf{L}' \right)^{-1} (\mathbf{L}\boldsymbol{\beta} - \boldsymbol{\theta}_0) \sigma^{-2}$$

Muller and Peterson (1984) give the exact power of the test as

$$\text{power} = P(F(r_L, DF_E, \lambda) \geq F_{1-\alpha}(r_L, DF_E))$$

Sample size is computed by inverting the power equation.

See Muller et al. (1992) and O'Brien and Shieh (1992) for additional discussion.

## Adjustments for Covariates

If you specify covariates in the model (whether continuous or categorical), then two adjustments are made in order to compute approximate power in the presence of the covariates. Let  $n_v$  denote the number of covariates (counting dummy variables for categorical covariates individually). In other words,  $n_v$  is the total degrees of freedom used by the covariates. The adjustments are as follows:

1. The error degrees of freedom decrease by  $n_v$ .
2. The error standard deviation  $\sigma$  shrinks by a factor of  $(1 - \rho^2)^{\frac{1}{2}}$  (if the **CORRXY=** option to specify the correlation  $\rho$  between covariates and response) or  $(1 - r)^{\frac{1}{2}}$  (if the **PROPVARRREDUCTION=** option is used to specify the proportional reduction in total  $R^2$  incurred by the covariates). Let  $\sigma^*$  represent the updated value of  $\sigma$ .

As a result of these changes, the power is computed as

$$\text{power} = P(F(r_L, DF_E - n_v, \lambda^*) \geq F_{1-\alpha}(r_L, N - r_x - n_v))$$

where  $\lambda^*$  is calculated using  $\sigma^*$  rather than  $\sigma$ :

$$\lambda^* = N (\mathbf{L}\boldsymbol{\beta} - \boldsymbol{\theta}_0)' \left( \mathbf{L} \left( \ddot{\mathbf{X}}' \text{diag}(\mathbf{w}) \ddot{\mathbf{X}} \right)^{-1} \mathbf{L}' \right)^{-1} (\mathbf{L}\boldsymbol{\beta} - \boldsymbol{\theta}_0) (\sigma^*)^{-2}$$

---

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

If ODS Graphics is not enabled, then PROC GLMPOWER creates traditional graphics.

You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC GLMPOWER generates are listed in Table 44.8, along with the required statements and options.

**Table 44.8** Graphs Produced by PROC GLMPOWER

| ODS Graph Name | Plot Description                                                         | Option      |
|----------------|--------------------------------------------------------------------------|-------------|
| PowerPlot      | Plot with power and sample size on the axes                              | <b>PLOT</b> |
| PowerAbort     | Empty plot that shows an error message when a plot could not be produced | <b>PLOT</b> |

---

## ODS Styles Suitable for Use with PROC GLMPOWER

ODS styles control the appearance of graphs produced by PROC GLMPOWER. ODS provides over 50 styles, but most are not suitable for use in PROC GLMPOWER. PROC GLMPOWER requires a style that distinguishes curves based on a combination of color, line style, and symbol marker. Styles that are well-suited for use in PROC GLMPOWER include: STATISTICAL, ANALYSIS, DEFAULT, LISTING, and HTMLBLUECML. The HTMLBLUE and PLATEAU styles are commonly used, but they are not well-suited for use with PROC GLMPOWER because they rely primarily on color to distinguish curves rather than a combination of color, line style, and symbol marker.

In this chapter, a style is explicitly specified at the start of each example that uses ODS Graphics to remind you to use one of the suitable styles. Styles are specified in an ODS destination statement. Destinations include LISTING, HTML, RTF, PDF, and many others. You can set the style and the destination as follows:

```
ods html style=htmlbluecml;
ods graphics on;

proc glmpower data=Exemplary;
 class Variety Exposure;
 model Height = Variety | Exposure;
 power
 stddev = 4 6.5
 ntotal = 60
 power = .;
 plot x=n min=30 max=90;
run;

ods graphics off;
ods html close;
```

For more information about ODS and ODS destinations, see Chapter 20, “Using the Output Delivery System.” For more information ODS styles, see Chapter 21, “Statistical Graphics Using ODS.”

---

## Examples: GLMPOWER Procedure

---

### Example 44.1: One-Way ANOVA

This example deals with the same situation as in [Example 71.1](#) in Chapter 71, “The POWER Procedure.”

Hocking (1985, p. 109) describes a study of the effectiveness of electrolytes in reducing lactic acid buildup for long-distance runners. You are planning a similar study in which you will allocate five different fluids to runners on a 10-mile course and measure lactic acid buildup immediately after the race. The fluids consist of water and two commercial electrolyte drinks, EZDure and LactoZap, each prepared at two concentrations, low (EZD1 and LZ1) and high (EZD2 and LZ2).

You conjecture that the standard deviation of lactic acid measurements given any particular fluid is about 3.75, and that the expected lactic acid values will correspond roughly to [Table 44.9](#). You are least familiar with the LZ1 drink and hence decide to consider a range of reasonable values for that mean.

**Table 44.9** Mean Lactic Acid Buildup by Fluid

| Water | EZD1 | EZD2 | LZ1      | LZ2  |
|-------|------|------|----------|------|
| 35.6  | 33.7 | 30.2 | 29 or 28 | 25.9 |

You are interested in four different comparisons, shown in [Table 44.10](#) with appropriate contrast coefficients.

**Table 44.10** Planned Comparisons

| Comparison                | Contrast Coefficients |      |      |     |     |
|---------------------------|-----------------------|------|------|-----|-----|
|                           | Water                 | EZD1 | EZD2 | LZ1 | LZ2 |
| Water versus electrolytes | 4                     | -1   | -1   | -1  | -1  |
| EZD versus LZ             | 0                     | 1    | 1    | -1  | -1  |
| EZD1 versus EZD2          | 0                     | 1    | -1   | 0   | 0   |
| LZ1 versus LZ2            | 0                     | 0    | 0    | 1   | -1  |

For each of these contrasts you want to determine the sample size required to achieve a power of 0.9 for detecting an effect with magnitude in accord with [Table 44.9](#). You are not yet attempting to choose a single sample size for the study, but rather checking the range of sample sizes needed for individual contrasts. You plan to test each contrast at  $\alpha = 0.025$ . In the interests of reducing costs, you will provide twice as many runners with water as with any of the electrolytes; that is, you will use a sample size weighting scheme of 2:1:1:1:1.

Before calling PROC GLMPOWER, you need to create the *exemplary data set* to specify means and weights for the design profiles:

```
data Fluids;
 input Fluid $ LacticAcid1 LacticAcid2 CellWgt;
 datalines;
 Water 35.6 35.6 2
 EZD1 33.7 33.7 1
 EZD2 30.2 30.2 1
 LZ1 29 28 1
 LZ2 25.9 25.9 1
 ;
```

The variable LacticAcid1 represents the cell means scenario with the larger LZ1 mean (29), and LacticAcid2 represents the scenario with the smaller LZ1 mean (28). The variable CellWgt contains the sample size allocation weights.

Use the `DATA=` option in the PROC GLMPOWER statement to specify Fluids as the exemplary data set. The following statements perform the sample size analysis:

```
proc glmpower data=Fluids;
 class Fluid;
 model LacticAcid1 LacticAcid2 = Fluid;
 weight CellWgt;
 contrast "Water vs. others" Fluid -1 -1 -1 -1 4;
 contrast "EZD vs. LZ" Fluid 1 1 -1 -1 0;
 contrast "EZD1 vs. EZD2" Fluid 1 -1 0 0 0;
```

```

contrast "LZ1 vs. LZ2" Fluid 0 0 1 -1 0;
power
 stddev = 3.75
 alpha = 0.025
 ntotal = .
 power = 0.9;
run;

```

The **CLASS** statement identifies Fluid as a classification variable. The **MODEL** statement specifies the model and the two cell means scenarios LacticAcid1 and LacticAcid2. The **WEIGHT** statement identifies CellWgt as the weight variable. The **CONTRAST** statement specifies the contrasts. Since PROC GLMPOWER by default processes class levels in order of formatted values, the contrast coefficients correspond to the following order: EZD1, EZD2, LZ1, LZ2, Water. (**NOTE:** You could use the **ORDER=DATA** option in the **PROC GLMPOWER** statement to achieve the same ordering as in Table 44.10 instead.) The **POWER** statement specifies total sample size as the result parameter and provides values for the other analysis parameters (error standard deviation, alpha, and power).

Output 44.1.1 displays the results.

**Output 44.1.1** Sample Sizes for One-Way ANOVA Contrasts

| The GLMPOWER Procedure   |             |          |                  |         |          |              |         |
|--------------------------|-------------|----------|------------------|---------|----------|--------------|---------|
| Fixed Scenario Elements  |             |          |                  |         |          |              |         |
| Weight Variable          |             |          |                  | CellWgt |          |              |         |
| Alpha                    |             |          |                  | 0.025   |          |              |         |
| Error Standard Deviation |             |          |                  | 3.75    |          |              |         |
| Nominal Power            |             |          |                  | 0.9     |          |              |         |
| Computed N Total         |             |          |                  |         |          |              |         |
| Index                    | Dependent   | Type     | Source           | Test DF | Error DF | Actual Power | N Total |
| 1                        | LacticAcid1 | Effect   | Fluid            | 4       | 25       | 0.958        | 30      |
| 2                        | LacticAcid1 | Contrast | Water vs. others | 1       | 25       | 0.947        | 30      |
| 3                        | LacticAcid1 | Contrast | EZD vs. LZ       | 1       | 55       | 0.929        | 60      |
| 4                        | LacticAcid1 | Contrast | EZD1 vs. EZD2    | 1       | 169      | 0.901        | 174     |
| 5                        | LacticAcid1 | Contrast | LZ1 vs. LZ2      | 1       | 217      | 0.902        | 222     |
| 6                        | LacticAcid2 | Effect   | Fluid            | 4       | 25       | 0.972        | 30      |
| 7                        | LacticAcid2 | Contrast | Water vs. others | 1       | 19       | 0.901        | 24      |
| 8                        | LacticAcid2 | Contrast | EZD vs. LZ       | 1       | 43       | 0.922        | 48      |
| 9                        | LacticAcid2 | Contrast | EZD1 vs. EZD2    | 1       | 169      | 0.901        | 174     |
| 10                       | LacticAcid2 | Contrast | LZ1 vs. LZ2      | 1       | 475      | 0.902        | 480     |

The sample sizes range from 24 for the comparison of water versus electrolytes to 480 for the comparison of LZ1 versus LZ2, both assuming the smaller LZ1 mean. The sample size for the latter comparison is relatively large because the small mean difference of  $28 - 25.9 = 2.1$  is hard to detect. PROC GLMPOWER also includes the effect test for Fluid. Note that, in this case, it is equivalent to **TEST=OVERALL\_F** in the **ONEWAYANOVA** statement of PROC POWER, since there is only one effect in the model.

The Nominal Power of 0.9 in the “Fixed Scenario Elements” table in [Output 44.1.1](#) represents the input target power, and the Actual Power column in the “Computed N Total” table is the power at the sample size (N Total) adjusted to achieve the specified sample weighting. Note that all of the sample sizes are rounded up to multiples of 6 to preserve integer group sizes (since the group weights add up to 6). You can use the `NFRACTIONAL` option in the `POWER` statement to compute raw fractional sample sizes.

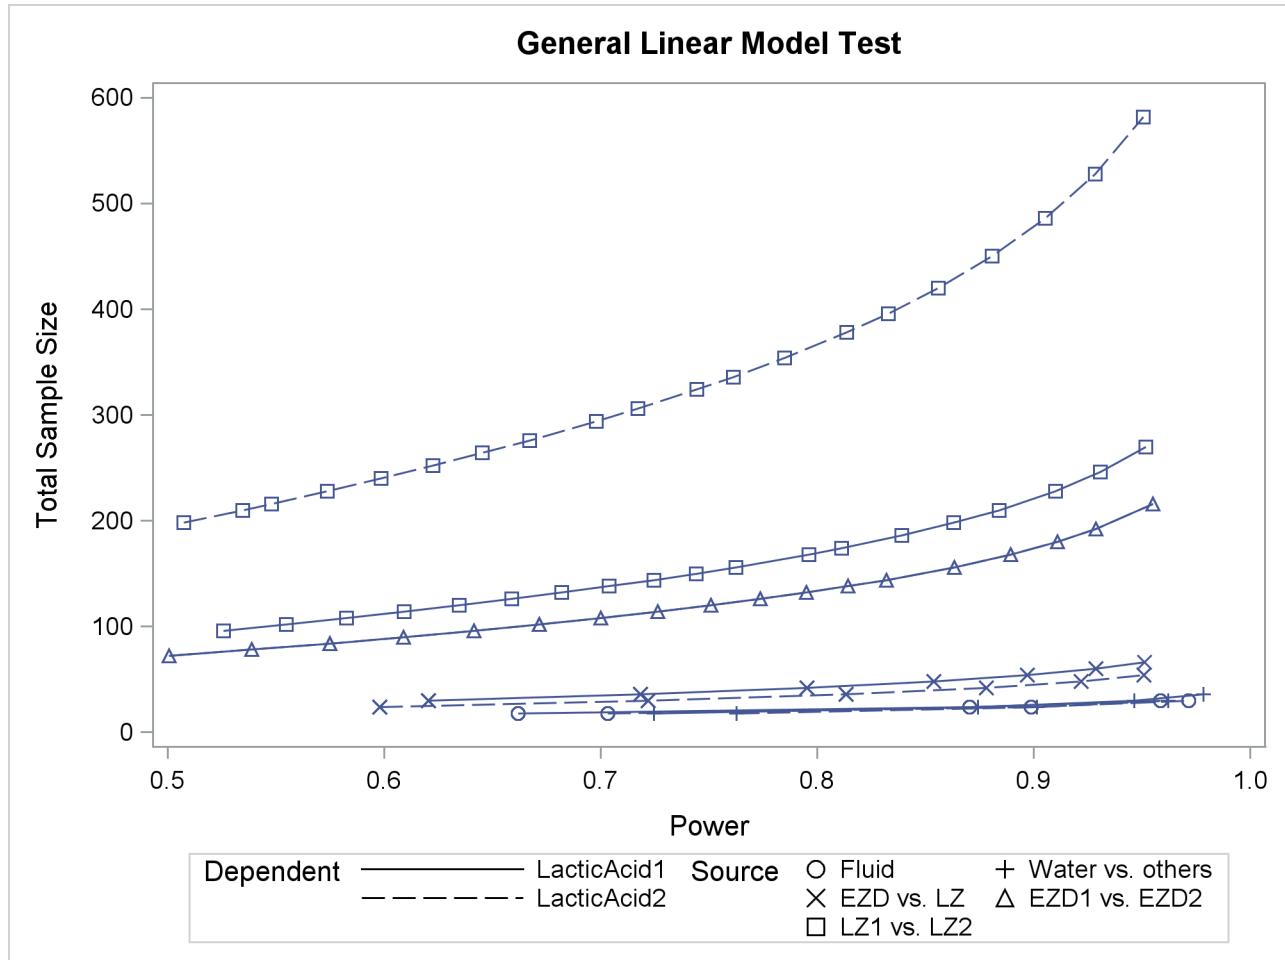

Suppose you want to plot the required sample size for the range of power values from 0.5 to 0.95. First, define the analysis by specifying the same statements as before, but add the `PLOTONLY` option to the `PROC GLMPOWER` statement to disable the nongraphical results. Next, specify the `PLOT` statement with `X=POWER` to request a plot with power on the X axis. (The result parameter—here sample size—is always plotted on the other axis.) Use the `MIN=` and `MAX=` options in the `PLOT` statement to specify the power range. The following statements produce the plot:

```
ods listing style=htmlbluecml;
ods graphics on;

proc glmpower data=Fluids plotonly;
 class Fluid;
 model LacticAcid1 LacticAcid2 = Fluid;
 weight CellWgt;
 contrast "Water vs. others" Fluid -1 -1 -1 -1 4;
 contrast "EZD vs. LZ" Fluid 1 1 -1 -1 0;
 contrast "EZD1 vs. EZD2" Fluid 1 -1 0 0 0;
 contrast "LZ1 vs. LZ2" Fluid 0 0 1 -1 0;
 power
 stddev = 3.75
 alpha = 0.025
 ntotal = .
 power = 0.9;
 plot x=power min=.5 max=.95;
run;
```

The `ODS LISTING STYLE=HTMLBLUECML` statement specifies the `HTMLBLUECML` style, which is suitable for use with `PROC GLMPOWER` because it allows both marker symbols and line styles to vary. See the section “[ODS Styles Suitable for Use with PROC GLMPOWER](#)” on page 3501 for more information. See [Output 44.1.2](#) for the resulting plot.

**Output 44.1.2** Plot of Sample Size versus Power for One-Way ANOVA Contrasts

In Output 44.1.2, the line style identifies the cell means scenario, and the plotting symbol identifies the test. The plotting symbol locations identify actual computed powers; the curves are linear interpolations of these points. The plot shows that the required sample size is highest for the test of LZ1 versus LZ2, which was previously found to require the most resources.

Note that some of the plotted points in [Output 44.1.2](#) are unevenly spaced. This is because the plotted points are the *rounded* sample size results at their corresponding *actual* power levels. The range specified with the `MIN=` and `MAX=` values in the `PLOT` statement corresponds to *nominal* power levels. In some cases, actual power is substantially higher than nominal power. To obtain plots with evenly spaced points (but with *fractional* sample sizes at the computed points), you can use the `NFRACTIONAL` option in the `POWER` statement preceding the `PLOT` statement.

Finally, suppose you want to plot the power for the range of sample sizes you will likely consider for the study (the range of 24 to 480 that achieves 0.9 power for different comparisons). In the `POWER` statement, identify power as the result (`POWER=.`), and specify any total sample size value (say, `NTOTAL=100`). Specify the `PLOT` statement with `X=N` to request a plot with sample size on the X axis.

The following statements produce the plot:

```
proc glmpower data=Fluids plotonly;
 class Fluid;
 model LacticAcid1 LacticAcid2 = Fluid;
 weight CellWgt;
 contrast "Water vs. others" Fluid -1 -1 -1 -1 4;
 contrast "EZD vs. LZ" Fluid 1 1 -1 -1 0;
 contrast "EZD1 vs. EZD2" Fluid 1 -1 0 0 0;
 contrast "LZ1 vs. LZ2" Fluid 0 0 1 -1 0;
 power
 stddev = 3.75
 alpha = 0.025
 ntotal = 24
 power = .;
 plot x=n min=24 max=480;
run;

ods graphics off;
```

Note that the value 100 specified with the `NTOTAL=100` option is not used. It is overridden in the plot by the `MIN=` and `MAX=` options in the `PLOT` statement, and the `PLOTONLY` option in the `PROC GLMPOWER` statement disables nongraphical results. But the `NTOTAL=` option (along with a value) is still needed in the `POWER` statement as a placeholder, to identify the desired parameterization for sample size.

See [Output 44.1.3](#) for the plot.

**Output 44.1.3** Plot of Power versus Sample Size for One-Way ANOVA Contrasts

Although [Output 44.1.2](#) and [Output 44.1.3](#) surface essentially the same computations for practical power ranges, they each provide a different quick visual assessment. [Output 44.1.2](#) reveals the range of required sample sizes for powers of interest, and [Output 44.1.3](#) reveals the range of achieved powers for sample sizes of interest.

## Example 44.2: Two-Way ANOVA with Covariate

Suppose you can enhance the planned study discussed in [Example 44.1](#) in two ways:

- incorporate results from races at two different altitudes (“high” and “low”)
- measure the body mass index of each runner before the race

This is equivalent to adding a second fixed effect and a continuous covariate to your model.

Since lactic acid buildup is more pronounced at higher altitudes, you will include altitude as a factor in the model along with fluid, extending the one-way ANOVA to a two-way ANOVA. In doing so, you expect to lower the residual standard deviation from about 3.75 to 3.5 (in addition to generalizing the study results). You assume there is negligible interaction between fluid and altitude and plan to use a main-effects-only model. You conjecture that the mean lactic acid buildup follows [Table 44.11](#).

**Table 44.11** Mean Lactic Acid Buildup by Fluid and Altitude

| Altitude | Water | Fluid |      |     |      |
|----------|-------|-------|------|-----|------|
|          |       | EZD1  | EZD2 | LZ1 | LZ2  |
| High     | 36.9  | 35.0  | 31.5 | 30  | 27.1 |
| Low      | 34.3  | 32.4  | 28.9 | 27  | 24.7 |

By including a measurement of body mass index as a covariate in the study, you hope to further reduce the error variability. The extent of this reduction in variability is commonly expressed in two alternative ways: (1) the correlation between the covariates and the response or (2) the proportional reduction in total R square incurred by the covariates. You prefer the former and guess that the correlation between body mass index and lactic acid buildup is between 0.2 and 0.3. You specify these estimates with the `NCOVARIATES=` and `CORRXY=` options in the `POWER` statement. The covariate is not included in the `MODEL` statement.

You are interested in the same four fluid comparisons as in [Example 44.1](#), shown in [Table 44.10](#), except this time you want to marginalize over the effect of altitude.

For each of these contrasts, you want to determine the sample size required to achieve a power of 0.9 to detect an effect with magnitude according to [Table 44.11](#). You are not yet attempting to choose a single sample size for the study, but rather checking the range of sample sizes needed by individual contrasts. You plan to test each contrast at  $\alpha = 0.025$ . You will provide twice as many runners with water as with any of the electrolytes, and you predict that you can study approximately two-thirds as many runners at high altitude than at low altitude. The resulting planned sample size weighting scheme is shown in [Table 44.12](#). Since the scheme is only approximate, you use the `NFRACTIONAL` option in the `POWER` statement to disable the rounding of sample sizes up to integers satisfying the weights exactly.

**Table 44.12** Approximate Sample Size Allocation Weights

| Altitude | Fluid |      |      |     |     |
|----------|-------|------|------|-----|-----|
|          | Water | EZD1 | EZD2 | LZ1 | LZ2 |
| High     | 4     | 2    | 2    | 2   | 2   |
| Low      | 6     | 3    | 3    | 3   | 3   |

First, you create the exemplary data set to specify means and weights for the design profiles:

```
data Fluids2;
 input Altitude $ Fluid $ LacticAcid CellWgt;
 datalines;
 High Water 36.9 4
 High EZD1 35.0 2
 High EZD2 31.5 2
 High LZ1 30 2
 High LZ2 27.1 2
 Low Water 34.3 6
 Low EZD1 32.4 3
 Low EZD2 28.9 3
 Low LZ1 27 3
 Low LZ2 24.7 3
 ;
```

The variables `Altitude`, `Fluid`, and `LacticAcid` specify the factors and cell means in [Table 44.11](#). The variable `CellWgt` contains the sample size allocation weights in [Table 44.12](#).

Use the `DATA=` option in the `PROC GLMPOWER` statement to specify `Fluids2` as the exemplary data set. The following statements perform the sample size analysis:

```
proc glmpower data=Fluids2;
 class Altitude Fluid;
 model LacticAcid = Altitude Fluid;
 weight CellWgt;
 contrast "Water vs. others" Fluid -1 -1 -1 -1 4;
 contrast "EZD vs. LZ" Fluid 1 1 -1 -1 0;
 contrast "EZD1 vs. EZD2" Fluid 1 -1 0 0 0;
 contrast "LZ1 vs. LZ2" Fluid 0 0 1 -1 0;
 power
 nfractional
 stddev = 3.5
 ncovariates = 1
 corrxy = 0.2 0.3 0
 alpha = 0.025
 ntotal = .
 power = 0.9;
run;
```

The `CLASS` statement identifies `Altitude` and `Fluid` as classification variables. The `MODEL` statement specifies the model, and the `WEIGHT` statement identifies `CellWgt` as the weight variable. The `CONTRAST` statement specifies the contrasts in [Table 44.10](#). As in [Example 44.1](#), the order of the contrast coefficients corresponds to the formatted class levels (`EZD1`, `EZD2`, `LZ1`, `LZ2`, `Water`). The `POWER` statement specifies total sample size as the result parameter and provides values for the other analysis parameters. The `NCOVARIATES=` option specifies the single covariate (body mass index), and the `CORRXY=` option specifies the two scenarios for its correlation with lactic acid buildup (0.2 and 0.3). [Output 44.2.1](#) displays the results.

#### Output 44.2.1 Sample Sizes for Two-Way ANOVA Contrasts

| The GLMPOWER Procedure               |            |
|--------------------------------------|------------|
| Fixed Scenario Elements              |            |
| Dependent Variable                   | LacticAcid |
| Weight Variable                      | CellWgt    |
| Alpha                                | 0.025      |
| Number of Covariates                 | 1          |
| Std Dev Without Covariate Adjustment | 3.5        |
| Nominal Power                        | 0.9        |

| 12                       | 0.906        | 44              |
| 13                       | 0.901        | 146             |
| 14                       | 0.902        | 139             |
| 15                       | 0.901        | 152             |
| 16                       | 0.901        | 275             |
| 17                       | 0.900        | 260             |
| 18                       | 0.901        | 286             |

The sample sizes in [Output 44.2.1](#) range from 21 for the comparison of water versus electrolytes (assuming a correlation of 0.3 between body mass and lactic acid buildup) to 275 for the comparison of LZ1 versus LZ2 (assuming a correlation of 0.2). PROC GLMPower also includes the effect tests for Altitude and Fluid. Note that the required sample sizes for this study are lower than those for the study in [Example 44.1](#).

Note that the error standard deviation has been reduced from 3.5 to 3.43 (when correlation is 0.2) or 3.34 (when correlation is 0.3) in the approximation of the effect of the body mass index covariate. The error degrees of freedom has also been automatically adjusted, lowered by 1 (the number of covariates).

Suppose you want to plot the required sample size for the range of power values from 0.5 to 0.95. First, define the analysis by specifying the same statements as before, but add the **PLOTONLY** option to the **PROC GLMPOWER** statement to disable the nongraphical results. Next, specify the **PLOT** statement with **X=POWER** to request a plot with power on the X axis. Sample size is automatically placed on the Y axis. Use the **MIN=** and **MAX=** options in the **PLOT** statement to specify the power range. The following statements produce the plot:

```
ods listing style=htmlbluecml;
ods graphics on;

proc glmpower data=Fluids2 plotonly;
 class Altitude Fluid;
 model LacticAcid = Altitude Fluid;
 weight CellWgt;
 contrast "Water vs. others" Fluid -1 -1 -1 -1 4;
 contrast "EZD vs. LZ" Fluid 1 1 -1 -1 0;
 contrast "EZD1 vs. EZD2" Fluid 1 -1 0 0 0;
 contrast "LZ1 vs. LZ2" Fluid 0 0 1 -1 0;
 power
 nfractional
 stddev = 3.5
 ncovariates = 1
 corrxxy = 0.2 0.3 0
 alpha = 0.025
 ntotal = .
 power = 0.9;
 plot x=power min=.5 max=.95;
run;
```

The **ODS LISTING STYLE=HTMLBLUECML** statement specifies the **HTMLBLUECML** style, which is suitable for use with **PROC GLMPOWER** because it allows both marker symbols and line styles to vary. See the section “[ODS Styles Suitable for Use with PROC GLMPOWER](#)” on page 3501 for more information. See [Output 44.2.2](#) for the resulting plot.

**Output 44.2.2** Plot of Sample Size versus Power for Two-Way ANOVA Contrasts

In [Output 44.1.2](#), the line style identifies the test, and the plotting symbol identifies the scenario for the correlation between covariate and response. The plotting symbol locations identify actual computed powers; the curves are linear interpolations of these points. As in [Example 44.1](#), the required sample size is highest for the test of LZ1 versus LZ2.

Finally, suppose you want to plot the power for the range of sample sizes you will likely consider for the study (the range of 21 to 275 that achieves 0.9 power for different comparisons). In the **POWER** statement, identify power as the result (**POWER=.**), and specify **NTOTAL=21**. Specify the **PLOT** statement with **X=N** to request a plot with sample size on the X axis.

The following statements produce the plot:

```
proc glmpower data=Fluids2 plotonly;
 class Altitude Fluid;
 model LacticAcid = Altitude Fluid;
 weight CellWgt;
 contrast "Water vs. others" Fluid -1 -1 -1 -1 4;
 contrast "EZD vs. LZ" Fluid 1 1 -1 -1 0;
 contrast "EZD1 vs. EZD2" Fluid 1 -1 0 0 0;
 contrast "LZ1 vs. LZ2" Fluid 0 0 1 -1 0;
 power
 nfractional
 stddev = 3.5
 ncovariates = 1
 corrxxy = 0.2 0.3 0
 alpha = 0.025
 ntotal = 21
 power = .;
 plot x=n min=21 max=275;
run;

ods graphics off;
```

The **MAX=275** option in the **PLOT** statement sets the maximum sample size value. The **MIN=** option automatically defaults to the value of 21 from the **NTOTAL=** option in the **POWER** statement.

See [Output 44.2.3](#) for the plot.

**Output 44.2.3** Plot of Power versus Sample Size for Two-Way ANOVA Contrasts

Although [Output 44.2.2](#) and [Output 44.2.3](#) surface essentially the same computations for practical power ranges, they each provide a different quick visual assessment. [Output 44.2.2](#) reveals the range of required sample sizes for powers of interest, and [Output 44.2.3](#) reveals the range of powers achieved for sample sizes of interest.

## Overview: GLMSELECT Procedure

The GLMSELECT procedure performs effect selection in the framework of general linear models. A variety of model selection methods are available, including the LASSO method of Tibshirani (1996) and the related LAR method of Efron et al. (2004). The procedure offers extensive capabilities for customizing the selection with a wide variety of selection and stopping criteria, from traditional and computationally efficient significance-level-based criteria to more computationally intensive validation-based criteria. The procedure also provides graphical summaries of the selection search.

The GLMSELECT procedure compares most closely to REG and GLM. The REG procedure supports a variety of model-selection methods but does not support a CLASS statement. The GLM procedure supports a CLASS statement but does not include effect selection methods. The GLMSELECT procedure fills this gap. GLMSELECT focuses on the standard independently and identically distributed general linear model for univariate responses and offers great flexibility for and insight into the model selection algorithm. GLMSELECT provides results (displayed tables, output data sets, and macro variables) that make it easy to take the selected model and explore it in more detail in a subsequent procedure such as REG or GLM.

## Features

The main features of the GLMSELECT procedure are as follows:

- **Model Specification**
  - supports different parameterizations for classification effects
  - supports any degree of interaction (crossed effects) and nested effects
  - supports hierarchy among effects
  - supports partitioning of data into training, validation, and testing roles
  - supports constructed effects including spline and multimember effects

- **Selection Control**

- provides multiple effect selection methods
- enables selection from a very large number of effects (tens of thousands)
- offers selection of individual levels of classification effects
- provides effect selection based on a variety of selection criteria
- provides stopping rules based on a variety of model evaluation criteria
- provides leave-one-out and  $k$ -fold cross validation
- supports data resampling and model averaging

- **Display and Output**

- produces graphical representation of selection process
- produces output data sets containing predicted values and residuals
- produces an output data set containing the design matrix
- produces macro variables containing selected models
- supports parallel processing of BY groups
- supports multiple SCORE statements

The GLMSELECT procedure supports the following effect selection methods. These methods are explained in detail in the section “[Model-Selection Methods](#)” on page 3559.

|          |                                                                                                                                                                                                                                 |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FORWARD  | Forward selection. This method starts with no effects in the model and adds effects.                                                                                                                                            |
| BACKWARD | Backward elimination. This method starts with all effects in the model and deletes effects.                                                                                                                                     |
| STEPWISE | Stepwise regression. This is similar to the FORWARD method except that effects already in the model do not necessarily stay there.                                                                                              |
| LAR      | Least angle regression. This method, like forward selection, starts with no effects in the model and adds effects. The parameter estimates at any step are “shrunk” when compared to the corresponding least squares estimates. |
| LASSO    | This method adds and deletes parameters based on a version of ordinary least squares where the sum of the absolute regression coefficients is constrained.                                                                      |

Hybrid versions of LAR and LASSO are also supported. They use LAR or LASSO to select the model, but then estimate the regression coefficients by ordinary weighted least squares.

The GLMSELECT procedure is intended primarily as a model selection procedure and does not include regression diagnostics or other postselection facilities such as hypothesis testing, testing of contrasts, and LS-means analyses. The intention is that you use PROC GLMSELECT to select a model or a set of candidate models. Further investigation of these models can be done by using these models in existing regression procedures.

## Getting Started: GLMSELECT Procedure

The following data set contains salary and performance information for Major League Baseball players who played at least one game in both the 1986 and 1987 seasons, excluding pitchers. The salaries (*Sports Illustrated*, April 20, 1987) are for the 1987 season and the performance measures are from 1986 (Collier Books, *The 1987 Baseball Encyclopedia Update*).

```

data baseball;
 length name $ 18;
 length team $ 12;
 input name $ 1-18 nAtBat nHits nHome nRuns nRBI nBB

```

Suppose you want to investigate whether you can model the players' salaries for the 1987 season based on performance measures for the previous season. The aim is to obtain a parsimonious model that does not overfit this particular data, making it useful for prediction. This example shows how you can use PROC GLMSELECT as a starting point for such an analysis. Since the variation of salaries is much greater for the higher salaries, it is appropriate to apply a log transformation to the salaries before doing the model selection.

The following code selects a model with the default settings:

```
ods graphics on;
proc glmselect data=baseball plots=all;
 class league division;
 model logSalary = nAtBat nHits nHome nRuns nRBI nBB
 yrMajor crAtBat crHits crHome crRuns crRbi
 crBB league division nOuts nAssts nError
 / details=all stats=all;
run;
ods graphics off;
```

PROC GLMSELECT performs effect selection where effects can contain classification variables that you specify in a **CLASS** statement. The “Class Level Information” table shown in [Figure 45.1](#) lists the levels of the classification variables division and league.

**Figure 45.1** Class Level Information

| The GLMSELECT Procedure |        |                   |
|-------------------------|--------|-------------------|
| Class Level Information |        |                   |
| Class                   | Levels | Values            |
| league                  | 2      | American National |
| division                | 2      | East West         |

When you specify effects that contain classification variables, the number of parameters is usually larger than the number of effects. The “Dimensions” table in [Figure 45.2](#) shows the number of effects and the number of parameters considered.

**Figure 45.2** Dimensions

| Dimensions           |    |
|----------------------|----|
| Number of Effects    | 19 |
| Number of Parameters | 21 |

**Figure 45.3** Model Information

| The GLMSELECT Procedure   |               |
|---------------------------|---------------|
| Data Set                  | WORK.BASEBALL |
| Dependent Variable        | logSalary     |
| Selection Method          | Stepwise      |
| Select Criterion          | SBC           |
| Stop Criterion            | SBC           |
| Effect Hierarchy Enforced | None          |

You find details of the default search settings in the “Model Information” table shown in [Figure 45.3](#). The default selection method is a variant of the traditional stepwise selection where the decisions about what effects to add or drop at any step and when to terminate the selection are both based on the Schwarz Bayesian information criterion (SBC). The effect in the current model whose removal yields the maximal decrease in the SBC statistic is dropped provided this lowers the SBC value. Once no decrease in the SBC value can be obtained by dropping an effect in the model, the effect whose addition to the model yields the lowest SBC statistic is added and the whole process is repeated. The method terminates when dropping or adding any effect increases the SBC statistic.

**Figure 45.4** Candidates for Entry at Step Two

| Best 10 Entry Candidates |          |           |
|--------------------------|----------|-----------|
| Rank                     | Effect   | SBC       |
| 1                        | nHits    | -252.5794 |
| 2                        | nAtBat   | -241.5789 |
| 3                        | nRuns    | -240.1010 |
| 4                        | nRBI     | -232.2880 |
| 5                        | nBB      | -223.3741 |
| 6                        | nHome    | -208.0565 |
| 7                        | nOuts    | -205.8107 |
| 8                        | division | -194.4688 |
| 9                        | crBB     | -191.5141 |
| 10                       | nAssts   | -190.9425 |

The `DETAILS=ALL` option requests details of each step of the selection process. The “Best 10 Entry Candidates” table at each step shows the candidates for inclusion or removal at that step ranked from best to worst in terms of the selection criterion, which in this example is the SBC statistic. By default only the 10 best candidates are shown. [Figure 45.4](#) shows the candidate table at step two.

To help in the interpretation of the selection process, you can use graphics supported by PROC GLMSELECT. ODS Graphics must be enabled before requesting plots. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS.](#)” With ODS Graphics enabled, the `PLOTS=ALL` option together with the `DETAILS=STEPS` option in the `MODEL` statement produces a needle plot view of the “Candidates” tables. The plot corresponding to the “Candidates” table at step two is shown in [Figure 45.5](#). You can see that adding the effect 'nHits' yields the smallest SBC value, and so this effect is added at step two.

Figure 45.5 Needle Plot of Entry Candidates at Step Two

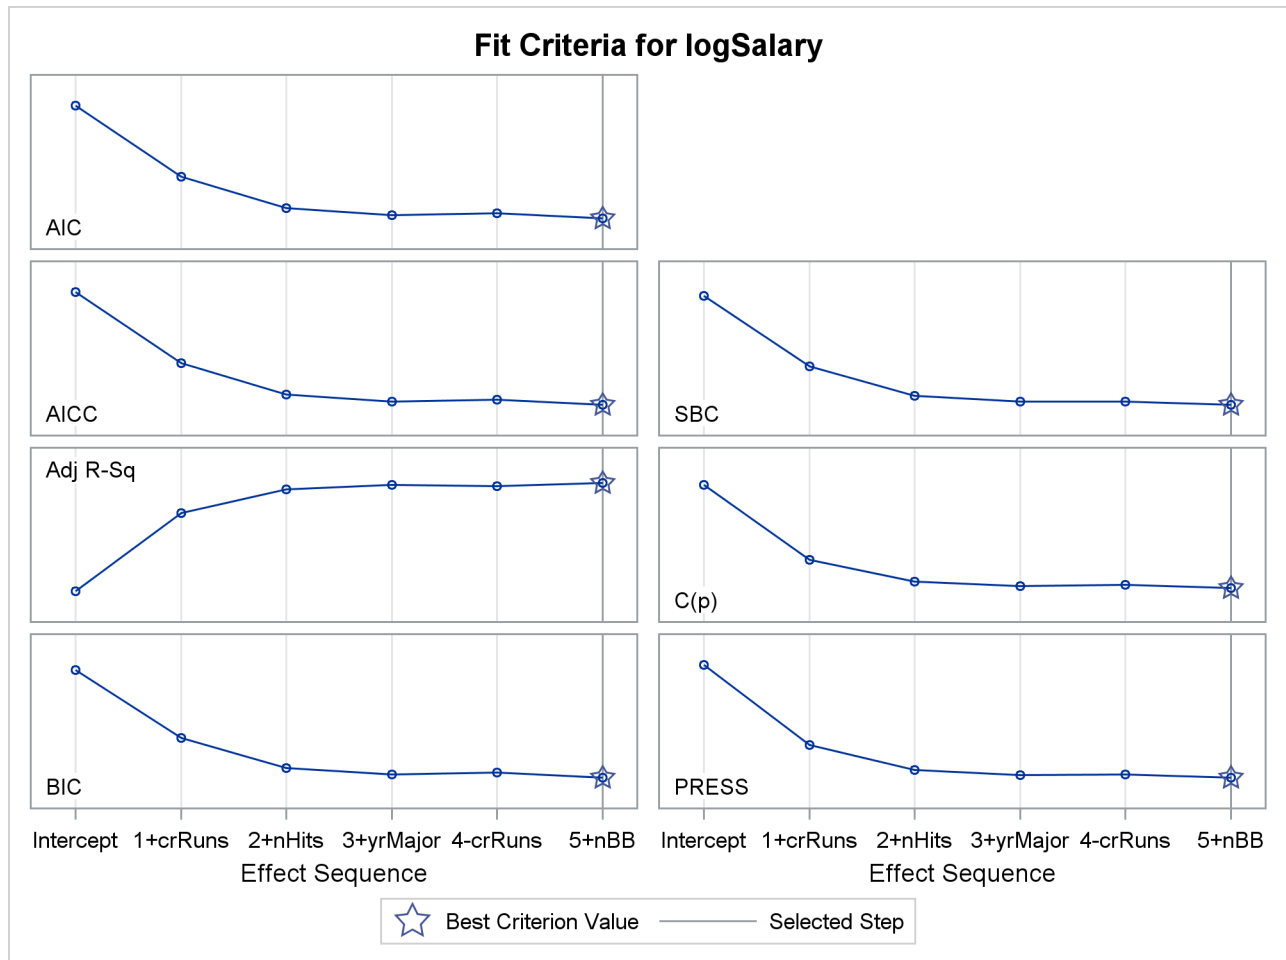

The “Stepwise Selection Summary” table in Figure 45.6 shows the effect that was added or dropped at each step of the selection process together with fit statistics for the model at each step. The `STATS=ALL` option in the `MODEL` statement requests that all the available fit statistics are displayed. See the section “Criteria Used in Model Selection Methods” on page 3568 for descriptions and formulas. The criterion panel in Figure 45.7 provides a graphical view of the progression of these fit criteria as the selection process evolves. Note that none of these criteria has a local optimum before step five.

Figure 45.7 Criterion Panel

The stop reason and stop details tables in Figure 45.8 gives details of why the selection process terminated. This table shows that at step five the best add candidate, 'division', and the best drop candidate, 'nBB', yield models with SBC values of  $-268.6094$  and  $-262.8353$ , respectively. Both of these values are larger than the current SBC value of  $-269.7804$ , and so the selection process stops at the model at step five.

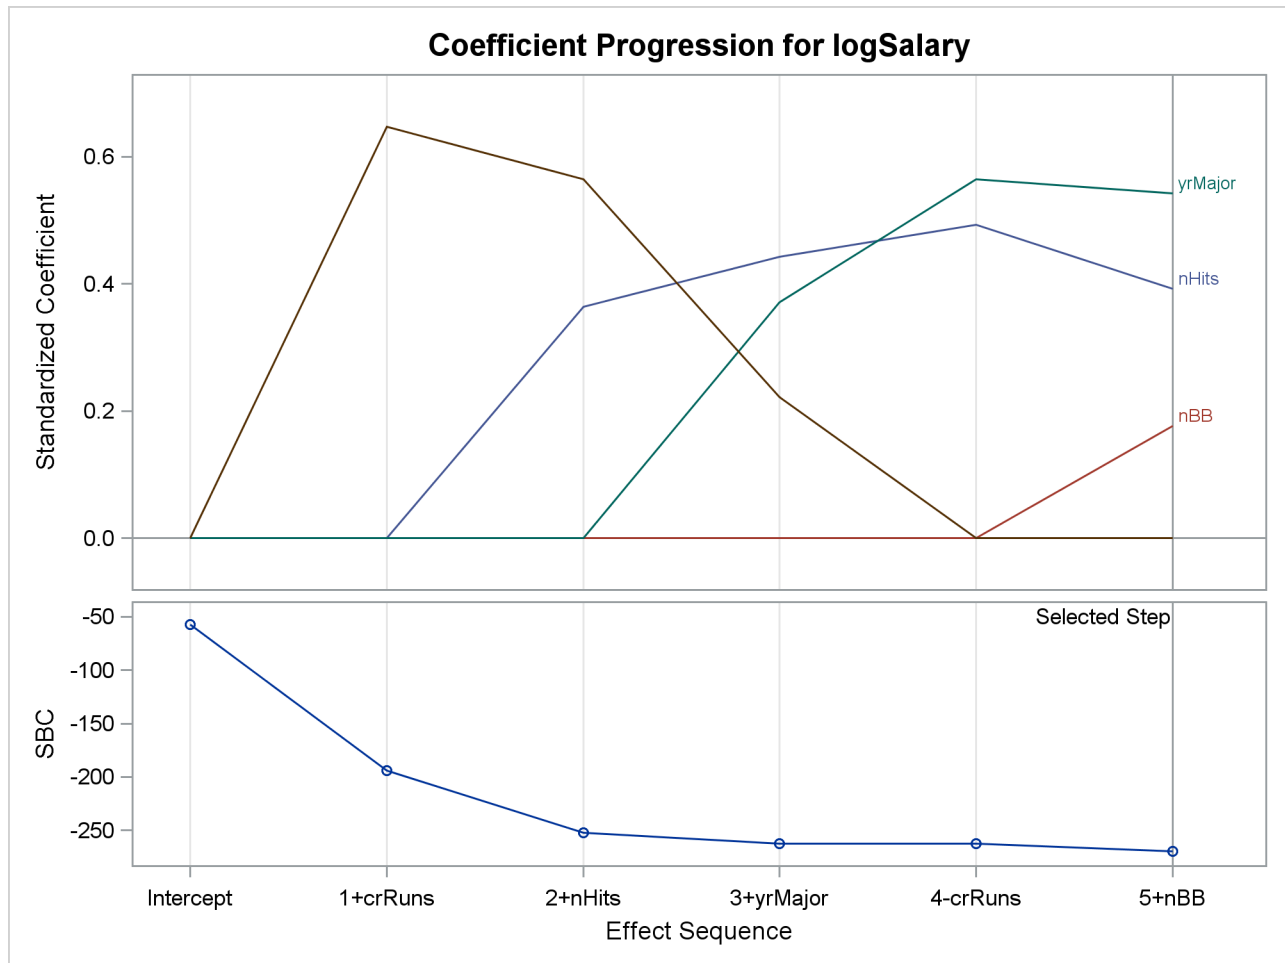

Figure 45.8 Stopping Details

| Selection stopped at a local minimum of the SBC criterion. |          |               |             |
|------------------------------------------------------------|----------|---------------|-------------|
| Stop Details                                               |          |               |             |
| Candidate For                                              | Effect   | Candidate SBC | Compare SBC |
| Entry                                                      | division | -268.6094     | > -269.7804 |
| Removal                                                    | nBB      | -262.8353     | > -269.7804 |

The coefficient panel in [Figure 45.9](#) enables you to visualize the selection process. In this plot, standardized coefficients of all the effects selected at some step of the stepwise method are plotted as a function of the step number. This enables you to assess the relative importance of the effects selected at any step of the selection process as well as providing information as to when effects entered the model. The lower plot in the panel shows how the criterion used to choose the selected model changes as effects enter or leave the model.

**Figure 45.9** Coefficient Progression

The selected effects, analysis of variance, fit statistics, and parameter estimates tables shown in [Figure 45.10](#) give details of the selected model.

PROC GLMSELECT provides you with the flexibility to use several selection methods and many fit criteria for selecting effects that enter or leave the model. You can also specify criteria to determine when to stop the selection process and to choose among the models at each step of the selection process. You can find continued exploration of the baseball data that uses a variety of these methods in [Example 45.1](#).

---

## Syntax: GLMSELECT Procedure

The following statements are available in the GLMSELECT procedure:

```

PROC GLMSELECT < options > ;
 BY variables ;
 CLASS variable < (v-options) > < variable < (v-options ...) > > < / v-options > < options > ;
 CODE < options > ;
 EFFECT name = effect-type (variables < / options >) ;
 FREQ variable ;
 MODEL variable = < effects > < / options > ;
 MODELAVERAGE < options > ;
 OUTPUT < OUT=SAS-data-set > < keyword< =name > > < ... keyword< =name > > ;
 PARTITION < options > ;
 PERFORMANCE < options > ;
 SCORE < DATA=SAS-data-set > < OUT=SAS-data-set > ;
 STORE < OUT= > item-store-name < / LABEL='label' > ;
 WEIGHT variable ;

```

All statements other than the **MODEL** statement are optional and multiple **SCORE** statements can be used. **CLASS** and **EFFECT** statements, if present, must precede the **MODEL** statement.

The **STORE** and **CODE** statements are also used by many other procedures. A summary description of functionality and syntax for these statements is also shown after the **PROC GLMSELECT** statement in alphabetical order, but you can find full documentation about them in the section “**STORE Statement**” on page 501 of Chapter 19, “Shared Concepts and Topics.”

---

## PROC GLMSELECT Statement

```

PROC GLMSELECT < options > ;

```

The **PROC GLMSELECT** statement invokes the GLMSELECT procedure. Table 45.1 summarizes the options available in the **PROC GLMSELECT** statement.

**Table 45.1** PROC GLMSELECT Statement Options

| Option                  | Description                                         |
|-------------------------|-----------------------------------------------------|
| <b>Data Set Options</b> |                                                     |
| <b>DATA=</b>            | Names a data set to use for the regression          |
| <b>MAXMACRO=</b>        | Sets the maximum number of macro variables produced |
| <b>TESTDATA=</b>        | Names a data set that contains test data            |
| <b>VALDATA=</b>         | Names a data set that contains validation data      |

Table 45.1 *continued*

| Option                      | Description                                                    |
|-----------------------------|----------------------------------------------------------------|
| <b>ODS Graphics Options</b> |                                                                |
| PLOTS=                      | Produces ODS graphical displays                                |
| <b>Other Options</b>        |                                                                |
| OUTDESIGN=                  | Requests a data set that contains the design matrix            |
| NAMELEN=                    | Sets the length of effect names in tables and output data sets |
| NOPRINT                     | Suppresses displayed output including plots                    |
| SEED=                       | Sets the seed used for pseudo-random number generation         |

Following are explanations of the options that you can specify in the PROC GLMSELECT statement (in alphabetical order).

**DATA=SAS-data-set**

names the SAS data set to be used by PROC GLMSELECT. If the DATA= option is not specified, PROC GLMSELECT uses the most recently created SAS data set. If the named data set contains a variable named `_ROLE_`, then this variable is used to assign observations for training, validation, and testing roles. See the section “Using Validation and Test Data” on page 3577 for details on using the `_ROLE_` variable.

**MAXMACRO=*n***

specifies the maximum number of macro variables with selected effects to create. By default, MAXMACRO=100. PROC GLMSELECT saves the list of selected effects in a macro variable, `&_GLSIND`. Say your input effect list consists of `x1-x10`. Then `&_GLSIND` would be set to `x1 x3 x4 x10` if, for example, the first, third, fourth, and tenth effects were selected for the model. This list can be used, for example, in the model statement of a subsequent procedure. If you specify the OUTDESIGN= option in the PROC GLMSELECT statement, then PROC GLMSELECT saves the list of columns in the design matrix in a macro variable named `&_GLSMOD`.

With BY processing, one macro variable is created for each BY group, and the macro variables are indexed by the BY group number. The MAXMACRO= option can be used to either limit or increase the number of these macro variables when you are processing data sets with many BY groups.

With no BY processing, PROC GLMSELECT creates the following:

|                              |                                                                          |
|------------------------------|--------------------------------------------------------------------------|
| <code>_GLSIND</code>         | selected effects                                                         |
| <code>_GLSIND1</code>        | selected effects                                                         |
| <code>_GLSMOD</code>         | design matrix columns                                                    |
| <code>_GLSMOD1</code>        | design matrix columns                                                    |
| <code>_GLSNUMBYS</code>      | number of BY groups                                                      |
| <code>_GLSNUMMACROBYS</code> | number of <code>_GLSIND<sub>i</sub></code> macro variables actually made |

With BY processing, PROC GLMSELECT creates the following:

|                                    |                                                                                                                                                                                                                              |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_GLSIND</code>               | selected effects for BY group 1                                                                                                                                                                                              |
| <code>_GLSIND1</code>              | selected effects for BY group 1                                                                                                                                                                                              |
| <code>_GLSIND2</code>              | selected effects for BY group 2                                                                                                                                                                                              |
| .                                  |                                                                                                                                                                                                                              |
| .                                  |                                                                                                                                                                                                                              |
| .                                  |                                                                                                                                                                                                                              |
| <code>_GLSIND<math>m</math></code> | selected effects for BY group $m$ , where a number is substituted for $m$                                                                                                                                                    |
| <code>_GLSMOD</code>               | design matrix columns for BY group 1                                                                                                                                                                                         |
| <code>_GLSMOD1</code>              | design matrix columns for BY group 1                                                                                                                                                                                         |
| <code>_GLSMOD2</code>              | design matrix columns for BY group 2                                                                                                                                                                                         |
| .                                  |                                                                                                                                                                                                                              |
| .                                  |                                                                                                                                                                                                                              |
| .                                  |                                                                                                                                                                                                                              |
| <code>_GLSMOD<math>m</math></code> | design matrix columns for BY group $m$ , where a number is substituted for $m$                                                                                                                                               |
| <code>_GLSNUMBYS</code>            | $n$ , the number of BY groups                                                                                                                                                                                                |
| <code>_GLSNUMMACROBYS</code>       | the number $m$ of <code>_GLSIND<math>i</math></code> macro variables actually made. This value can be less than <code>_GLSNUMBYS = <math>n</math></code> , and it is less than or equal to the <code>MAXMACRO=</code> value. |

See the section “[Macro Variables Containing Selected Models](#)” on page 3572 for further details.

#### **NOPRINT**

suppresses all displayed output including plots.

#### **NAMELEN= $n$**

specifies the length of effect names in tables and output data sets to be  $n$  characters long, where  $n$  is a value between 20 and 200 characters. The default length is 20 characters.

#### **OUTDESIGN < (*options*) >< =SAS-data-set >**

creates a data set that contains the design matrix. By default, the GLMSELECT procedure includes in the OUTDESIGN data set the X matrix corresponding to the parameters in the selected model. Two schemes for naming the columns of the design matrix are available. In the first scheme, names of the parameters are constructed from the parameter labels that appear in the ParameterEstimates table. This naming scheme is the default when you do not request BY processing and is not available when you do use BY processing. In the second scheme, the design matrix column names consist of a prefix followed by an index. The default naming prefix is `_X`.

You can specify the following *options* in parentheses to control the contents of the OUTDESIGN data set:

#### **ADDINPUTVARS**

requests that all variables in the input data set be included in the OUTDESIGN= data set.

#### **FULLMODEL**

specifies that parameters corresponding to all the effects specified in the MODEL statement be included in the OUTDESIGN= data set. By default, only parameters corresponding to the selected model are included.

**NAMES**

produces a table associating columns in the OUTDESIGN data set with the labels of the parameters they represent.

**PREFIX=<prefix>**

requests that the design matrix column names consist of a prefix followed by an index. The default naming prefix is `_X`. You can optionally specify a different prefix.

**PARMLABELSTYLE=options**

specifies how parameter names and labels are constructed for nested and crossed effects.

The following *options* are available:

**INTERLACED <(SEPARATOR=quoted string)>**

forms parameter names and labels by positioning levels of classification variables and constructed effects adjacent to the associated variable or constructed effect name and using “ \* ” as the delimiter for both crossed and nested effects. This style of naming parameters and labels is used in the TRANSREG procedure. You can request truncation of the classification variable names used in forming the parameter names and labels by using the CPREFIX= and LPREFIX= options in the CLASS statement. You can use the SEPARATOR= suboption to change the delimiter between the crossed variables in the effect. PARMLABELSTYLE=INTERLACED is not supported if you specify the SPLIT option in an EFFECT statement or a CLASS statement. The following are examples of the parameter labels in this style (Age is a continuous variable, Gender and City are classification variables):

```
Age
Gender male * City Beijing
City London * Age
```

**SEPARATE**

specifies that in forming parameter names and labels, the effect name appears before the levels associated with the classification variables and constructed effects in the effect. You can control the length of the effect name by using the NAMELEN= option in the PROC GLMSELECT statement. In forming parameter labels, the first level that is displayed is positioned so that it starts at the same offset in every parameter label—this enables you to easily distinguish the effect name from the levels when the parameter labels are displayed in a column in the “Parameter Estimates” table. This style of labeling is used in the GLM procedure and is the default if you do not specify the PARMLABELSTYLE option. The following are examples of the parameter labels in this style (Age is a continuous variable, Gender and City are classification variables):

```
Age
Gender*City male Beijing
Age*City London
```

**SEPARATECOMPACT**

requests the same parameter naming and labeling scheme as PARMLABELSTYLE=SEPARATE except that the first level in the parameter label is separated from the effect name by a single blank. This style of labeling is used in the PLS procedure. The following are examples of the parameter labels in this style (Age is a continuous variable, Gender and City are classification variables):

```

Age
Gender*City male Beijing
Age*City London

```

**PLOTS** <(global-plot-options)> <= plot-request <(options)>>

**PLOTS** <(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>>

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```

plots=all
plots=coefficients(unpack)
plots(unpack)=(criteria candidates)

```

ODS Graphics must be enabled before plots can be requested. For example:

```

ods graphics on;

proc glmselect plots=all;
 model y = x1-x100;
run;

ods graphics off;

```

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

### Global Plot Options

The *global-options* apply to all plots generated by the GLMSELECT procedure, unless it is altered by a *specific-plot-option*.

#### ENDSTEP=*n*

specifies that the step ranges shown on the horizontal axes of plots terminates at specified step. By default, the step range shown terminates at the final step of the selection process. If you specify the ENDSTEP= option as both a global plot option and a specific plot option, then the ENDSTEP= value on the specific plot is used.

#### LOGP | LOGPVALUE

displays the natural logarithm of the entry and removal significance levels when the **SELECT=SL** option is specified.

#### MAXSTEPLABEL=*n*

specifies the maximum number of characters beyond which labels of effects on plots are truncated.

**MAXPARMLABEL= *n***

specifies the maximum number of characters beyond which parameter labels on plots are truncated.

**STARTSTEP=*n***

specifies that the step ranges shown on the horizontal axes of plots start at the specified step. By default, the step range shown starts at the initial step of the selection process. If you specify the STARTSTEP= option both as a global plot option and a specific plot option, then the STARTSTEP= value on the specific plot is used.

**STEPAXIS=EFFECT | NORMB | NUMBER**

specifies the horizontal axis to be used on the plots, where this axis represents the sequence of entering or departing effects.

**STEPAXIS=EFFECT**

requests that each step be labeled by a prefix followed by the name of the effect that enters or leaves at that step. The prefix consists of the step number followed by a “+” sign or a “-” sign depending on whether the effect enters or leaves at that step.

**STEPAXIS=NORMB**

is valid only with LAR and LASSO selection methods and requests that the horizontal axis value at step *i* be the L1 norm of the parameters at step *i*, normalized by the L1 norm of the parameters at the final step.

**STEPAXIS=NUMBER**

requests that each step be labeled by the step number.

**UNPACK**

suppresses paneling. By default, multiple plots can appear in some output panels. Specify UNPACK to get each plot individually. You can also specify UNPACK as a suboption with CRITERIA and COEFFICIENTS.

**Specific Plot Options**

The following listing describes the specific plots and their options.

**ALL**

requests that all default plots be produced. Note that candidate plots are produced only if you specify **DETAILS=STEPS** or **DETAILS=ALL** in the **MODEL** statement.

**ASE | ASEPLOT <(aseplot-option)>**

plots the progression of the average square error on the training data, and the test and validation data whenever these data are provided with the **TESTDATA=** and **VALDATA=** options or are produced by using a **PARTITION** statement. The following *aseplot-option* option is available:

**STEPAXIS=EFFECT | NORMB | NUMBER**

specifies the horizontal axis to be used.

**CANDIDATES | CANDIDATESPLOT** <(candidatesplot-options)>

produces a needle plot of the SELECT= criterion values for the candidates for entry or removal at each step of the selection process, ordered from best to worst. Candidates plots are not available if you specify **SELECTION=NONE**, **SELECTION=LAR**, or **SELECTION=LASSO** in the **MODEL** statement, or if you have not specified **DETAILS=ALL** or **DETAILS=STEPS** in the **MODEL** statement. The following *candidatesplot-options* are available:

**LOGP | LOGPVALUE**

displays the natural logarithm of the entry and removal significance levels when the **SELECT=SL** option is specified.

**SHOW=number**

specifies the maximum number of candidates displayed at each step. The default is **SHOW=10**.

**COEFFICIENTS | COEFFICIENTPANEL** <(coefficientPanel-options)>

plots a panel of two plots. The upper plot shows the progression of the parameter values as the selection process proceeds. The lower plot shows the progression of the **CHOOSE=** criterion. If no **CHOOSE=** criterion is in effect, then the AICC criterion is displayed. The following *coefficientPanel-options* are available:

**LABELGAP=percentage**

specifies the percentage of the vertical axis range that forms the minimum gap between successive parameter labels at the final step of the coefficient progression plot. If the values of more than one parameter at the final step are closer than this gap, then the labels on all but one of these parameters is suppressed. The default value is **LABELGAP=5**. Planned enhancements to the automatic label collision avoidance algorithm will obviate the need for this option in future releases of the GLMSELECT procedure.

**LOGP | LOGPVALUE**

displays the natural logarithm of the entry and removal significance levels when the **SELECT=SL** option is specified.

**STEPAXIS=EFFECT | NORMB | NUMBER**

specifies the horizontal axis to be used.

**UNPACK | UNPACKPANEL**

displays the coefficient progression and the **CHOOSE=** criterion progression in separate plots.

**CRITERIA | CRITERIONPANEL** <(criterionPanel-options)>

plots a panel of model fit criteria. The criteria that are displayed are ADJRSQ, AIC, AICC, and SBC, as well as any other criteria that are named in the **CHOOSE=**, **SELECT=**, **STOP=**, or **STATS=** option in the **MODEL** statement. The following *criterionPanel-options* are available:

**STEPAXIS=EFFECT | NORMB | NUMBER**

specifies the horizontal axis to be used.

**UNPACK | UNPACKPANEL**

displays each criterion progression on a separate plot.

**EFFECTSELECTPCT** <(effectSelectPct-options)>

requests a bar chart whose bars correspond to effects that are selected in at least one sample when you use the **MODEL AVERAGE** statement. The length of a bar corresponds to the percentage of samples where the selected model contains the effect the bar represents. The **EFFECTSELECTPCT** option is ignored if you do not specify a **MODEL AVERAGE** statement. The following *effectSelectPct-options* are available:

**MINPCT=percent**

specifies that effects that appear in fewer than the specified percentage of the sample selected models not be included in the plot. By default, effects that are shown in the EffectSelectPct table are displayed.

**ORDER=ASCENDING | DESCENDING | MODEL**

specifies the ordering of the effects in the bar chart. **ORDER=MODEL** specifies that effects appear in the order in which they appear in the **MODEL** statement. **ORDER=ASCENDING | DESCENDING** specifies that the effects are shown in ascending or descending order of the number of samples in which the effects appear in the selected model. The default is **ORDER=DESCENDING**.

**NONE**

suppresses all plots.

**PARMDIST** <(parmDist-options)>

produces a panel that shows histograms and box plots of the parameter estimate values across samples when you use a **MODEL AVERAGE** statement. There is a histogram and box plot for each parameter that appears in the AvgParmEst table. The **PARMDIST** option is ignored if you do not specify a **MODEL AVERAGE** statement. The following *parmDist-options* are available:

**MINPCT=percent**

specifies that distributions be shown only for parameters whose estimates are nonzero in at least the specified percentage of the selected models. By default, distributions are shown for the all parameters that appear in the AvgParmEst table.

**ORDER=ASCENDING | DESCENDING | MODEL**

specifies the ordering of the parameters in the panels. **ORDER=MODEL** specifies that parameters be shown in the order in which the corresponding effects appear in the **MODEL** statement. **ORDER=ASCENDING | DESCENDING** specifies that the parameters be shown in an ascending or descending order of the number of samples in which the parameter estimate is nonzero. The default is **ORDER=DESCENDING**.

**NOBOXPLOTS**

suppress the box plots.

**PLOTSPERPANEL=number**

specifies the maximum number of parameter distributions that appear in a panel. If the number of relevant parameters is greater than *number*, then multiple panels are produced. Valid values are 1–16 with 9 as the default.

**UNPACK**

specifies that the distribution for each relevant parameter be shown in a separate plot.

**SEED=number**

specifies an integer used to start the pseudo-random number generator for resampling the data, random cross validation, and random partitioning of data for training, testing, and validation. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer's clock.

**TESTDATA=SAS-data-set**

names a SAS data set containing test data. This data set must contain all the variables specified in the **MODEL** statement. Furthermore, when a **BY** statement is used and the **TESTDATA=data set** contains any of the **BY** variables, then the **TESTDATA=** data set must also contain all the **BY** variables sorted in the order of the **BY** variables. In this case, only the test data for a specific **BY** group is used with the corresponding **BY** group in the analysis data. If the **TESTDATA=** data set contains none of the **BY** variables, then the entire **TESTDATA =** data set is used with each **BY** group of the analysis data.

If you specify a **TESTDATA=data set**, then you cannot also reserve observations for testing by using a **PARTITION** statement.

**VALDATA=SAS-data-set**

names a SAS data set containing validation data. This data set must contain all the variables specified in the **MODEL** statement. Furthermore, when a **BY** statement is used and the **VALDATA=data set** contains any of the **BY** variables, then the **VALDATA=** data set must also contain all the **BY** variables sorted in the order of the **BY** variables. In this case, only the validation data for a specific **BY** group are used with the corresponding **BY** group in the analysis data. If the **VALDATA=** data set contains none of the **BY** variables, then the entire **VALDATA =** data set is used with each **BY** group of the analysis data.

If you specify a **VALDATA=data set**, then you cannot also reserve observations for validation by using a **PARTITION** statement.

---

## BY Statement

**BY variables ;**

You can specify a **BY** statement with **PROC GLMSELECT** to obtain separate analyses of observations in groups that are defined by the **BY** variables. When a **BY** statement appears, the procedure expects the input data set to be sorted in order of the **BY** variables. If you specify more than one **BY** statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the **SORT** procedure with a similar **BY** statement.
- Specify the **NOTSORTED** or **DESCENDING** option in the **BY** statement for the **GLMSELECT** procedure. The **NOTSORTED** option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the **BY** variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

**CLASS** *variable* <(v-options)> . . . <*variable* <(v-options)>> </options> ;

The CLASS statement names the classification variables to be used in the analysis. The CLASS statement must precede the MODEL statement.

Table 45.2 summarizes the options available in the CLASS statement.

**Table 45.2** CLASS Statement Options

| Option     | Description                                                |
|------------|------------------------------------------------------------|
| CPREFIX=   | Specifies maximum number of CLASS variable name characters |
| DELIMITER= | Specifies the delimiter                                    |
| DESCENDING | Reverses the sort order                                    |
| LPREFIX=   | Labels design variables                                    |
| MISSING    | Allows for missing values                                  |
| ORDER=     | Specifies the sort order                                   |
| PARAM=     | Specifies the parameterization method                      |
| REF=       | Specifies the reference level                              |
| SHOW       | Requests a table for each CLASS variable                   |
| SPLIT      | Splits CLASS variables into independent effects            |

The following options can be specified after a slash (/):

### **DELIMITER=***quoted character*

specifies the delimiter that is used between levels of classification variables in building parameter names and lists of class level values. The default if you do not specify DELIMITER= is a space. This option is useful if the levels of a classification variable contain embedded blanks.

### **SHOW | SHOWCODING**

requests a table for each classification variable that shows the coding used for that variable.

You can specify various *v-options* for each variable by enclosing them in parentheses after the variable name. You can also specify global *v-options* for the CLASS statement by placing them after a slash (/). Global *v-options* are applied to all the variables specified in the CLASS statement. If you specify more than one CLASS statement, the global *v-options* specified in any one CLASS statement apply to all CLASS statements. However, individual CLASS variable *v-options* override the global *v-options*.

The following *v-options* are available:

**CPREFIX=*n***

specifies that, at most, the first *n* characters of a CLASS variable name be used in creating names for the corresponding design variables. The default is  $32 - \min(32, \max(2, f))$ , where *f* is the formatted length of the CLASS variable. The CPREFIX= applies only when you specify the PARMLABELSTYLE=INTERLACED option in the PROC GLMSELECT statement.

**DESCENDING****DESC**

reverses the sort order of the classification variable.

**LPREFIX=*n***

specifies that, at most, the first *n* characters of a CLASS variable label be used in creating labels for the corresponding design variables. The default is  $256 - \min(256, \max(2, f))$ , where *f* is the formatted length of the CLASS variable. The LPREFIX= applies only when you specify the PARM-LABELSTYLE=INTERLACED option in the PROC GLMSELECT statement.

**MISSING**

allows missing value (‘.’ for a numeric variable and blanks for a character variables) as a valid value for the CLASS variable.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of classification variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option might be useful when you use the CONTRAST or ESTIMATE statement. If ORDER=FORMATTED for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values. Note that this represents a change from previous releases for how class levels are ordered. Before SAS 8, numeric class levels with no explicit format were ordered by their BEST12. formatted values, and in order to revert to the previous ordering you can specify this format explicitly for the affected classification variables. The change was implemented because the former default behavior for ORDER=FORMATTED often resulted in levels not being ordered numerically and usually required the user to intervene with an explicit format or ORDER=INTERNAL to get the more natural ordering. The following table shows how PROC GLMSELECT interprets values of the ORDER= option.

| Value of ORDER=  | Levels Sorted By                                                                                                                       |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DATA</b>      | Order of appearance in the input data set                                                                                              |
| <b>FORMATTED</b> | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| <b>FREQ</b>      | Descending frequency count; levels with the most observations come first in the order                                                  |
| <b>INTERNAL</b>  | Unformatted value                                                                                                                      |

By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent.

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**PARAM=keyword**

specifies the parameterization method for the classification variable or variables. Design matrix columns are created from CLASS variables according to the following coding schemes. The default is PARAM=GLM. If PARAM=ORTHOPOLY or PARAM=POLY, and the CLASS levels are numeric, then the ORDER= option in the CLASS statement is ignored, and the internal, unformatted values are used. See the section “CLASS Variable Parameterization and the SPLIT Option” on page 3570 for further details.

|                    |                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------|
| <b>EFFECT</b>      | specifies effect coding.                                                                               |
| <b>GLM</b>         | specifies less-than-full-rank, reference-cell coding; this option can be used only as a global option. |
| <b>ORDINAL</b>     |                                                                                                        |
| <b>THERMOMETER</b> | specifies the cumulative parameterization for an ordinal CLASS variable.                               |
| <b>POLYNOMIAL</b>  |                                                                                                        |
| <b>POLY</b>        | specifies polynomial coding.                                                                           |
| <b>REFERENCE</b>   |                                                                                                        |
| <b>REF</b>         | specifies reference-cell coding.                                                                       |
| <b>ORTHEFFECT</b>  | orthogonalizes PARAM=EFFECT.                                                                           |
| <b>ORTHORDINAL</b> |                                                                                                        |
| <b>ORTHOTHERM</b>  | orthogonalizes PARAM=ORDINAL.                                                                          |
| <b>ORTHOPOLY</b>   | orthogonalizes PARAM=POLYNOMIAL.                                                                       |
| <b>ORTHREF</b>     | orthogonalizes PARAM=REFERENCE.                                                                        |

The EFFECT, POLYNOMIAL, REFERENCE, and ORDINAL schemes and their orthogonal parameterizations are full rank. The REF= option in the CLASS statement determines the reference level for the EFFECT and REFERENCE schemes and their orthogonal parameterizations.

**REF='level' | keyword**

specifies the reference level for PARAM=EFFECT, PARAM=REFERENCE, and their orthogonalizations. For an individual (but not a global) variable REF= option, you can specify the *level* of the variable to use as the reference level. For a global or individual variable REF= option, you can use one of the following keywords. The default is REF=LAST.

|              |                                                  |
|--------------|--------------------------------------------------|
| <b>FIRST</b> | designates the first-ordered level as reference. |
| <b>LAST</b>  | designates the last-ordered level as reference.  |

**SPLIT**

splits the columns of the design matrix that correspond to any effect that contains a split classification variable so that they can enter or leave a model independently of the other design columns for that effect. For example, suppose a variable named `temp` has three levels with values 'hot', 'warm', and 'cold', and a variable named `sex` has two levels with values 'M' and 'F' are used in a PROC GLMSELECT job as follows:

```
proc glmselect;
 class temp sex/split;
 model depVar = sex sex*temp;
run;
```

The two effects named in the **MODEL** statement are split into eight independent effects. The effect 'sex' is split into two effects labeled 'sex\_M' and 'sex\_F'. The effect 'sex\*temp' is split into six effects labeled 'sex\_M\*temp\_hot', 'sex\_F\*temp\_hot', 'sex\_M\*temp\_warm', 'sex\_F\*temp\_warm', 'sex\_M\*temp\_cold', and 'sex\_F\*temp\_cold'. Thus the previous PROC GLMSELECT step is equivalent to the following step:

```
proc glmselect;
 model depVar = sex_M sex_F sex_M*temp_hot sex_F*temp_hot
 sex_M*temp_warm sex_F*temp_warm
 sex_M*temp_cold sex_F*temp_cold;
run;
```

The split option can be used on individual classification variables. For example, consider the following PROC GLMSELECT step:

```
proc glmselect;
 class temp(split) sex;
 model depVar = sex sex*temp;
run;
```

In this case the effect 'sex' is not split and the effect 'sex\*temp' is split into three effects labeled 'sex\*temp\_hot', 'sex\*temp\_warm', and 'sex\*temp\_cold'. Furthermore each of these three split effects now has two parameters that correspond to the two levels of 'sex', and the PROC GLMSELECT step is equivalent to the following:

```
proc glmselect;
 class sex;
 model depVar = sex sex*temp_hot sex*temp_warm sex*temp_cold;
run;
```

---

## CODE Statement

**CODE** < options > ;

The CODE statement enables you to write SAS DATA step code for computing predicted values of the fitted model either to a file or to a catalog entry. This code can then be included in a DATA step to score new data.

Table 45.3 summarizes the *options* available in the CODE statement.

**Table 45.3** CODE Statement Options

| Option    | Description                                                                  |
|-----------|------------------------------------------------------------------------------|
| CATALOG=  | Names the catalog entry where the generated code is saved                    |
| DUMMIES   | Retains the dummy variables in the data set                                  |
| ERROR     | Computes the error function                                                  |
| FILE=     | Names the file where the generated code is saved                             |
| FORMAT=   | Specifies the numeric format for the regression coefficients                 |
| GROUP=    | Specifies the group identifier for array names and statement labels          |
| IMPUTE    | Imputes predicted values for observations with missing or invalid covariates |
| LINESIZE= | Specifies the line size of the generated code                                |
| LOOKUP=   | Specifies the algorithm for looking up CLASS levels                          |
| RESIDUAL  | Computes residuals                                                           |

For details about the syntax of the CODE statement, see the section “CODE Statement” on page 390 in Chapter 19, “Shared Concepts and Topics.”

---

## EFFECT Statement

**EFFECT** *name=effect-type (variables < / options >)* ;

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “GLM Parameterization of Classification Variables and Effects” on page 383 in Chapter 19, “Shared Concepts and Topics.”

You can specify the following *effect-types*:

|                          |                                                                                                                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>COLLECTION</b>        | is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference. |
| <b>LAG</b>               | is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.                                                                     |
| <b>MULTIMEMBER   MM</b>  | is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.                                                                       |
| <b>POLYNOMIAL   POLY</b> | is a multivariate polynomial effect in the specified numeric variables.                                                                                                                             |

**SPLINE** is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 45.4 summarizes the *options* available in the EFFECT statement.

**Table 45.4** EFFECT Statement Options

| Option                             | Description                                                                                                                                           |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Collection Effects Options</b>  |                                                                                                                                                       |
| DETAILS                            | Displays the constituents of the collection effect                                                                                                    |
| <b>Lag Effects Options</b>         |                                                                                                                                                       |
| DESIGNROLE=                        | Names a variable that controls to which lag design an observation is assigned                                                                         |
| DETAILS                            | Displays the lag design of the lag effect                                                                                                             |
| NLAG=                              | Specifies the number of periods in the lag                                                                                                            |
| PERIOD=                            | Names the variable that defines the period                                                                                                            |
| WITHIN=                            | Names the variable or variables that define the group within which each period is defined                                                             |
| <b>Multimember Effects Options</b> |                                                                                                                                                       |
| NOEFFECT                           | Specifies that observations with all missing levels for the multi-member variables should have zero values in the corresponding design matrix columns |
| WEIGHT=                            | Specifies the weight variable for the contributions of each of the classification effects                                                             |
| <b>Polynomial Effects Options</b>  |                                                                                                                                                       |
| DEGREE=                            | Specifies the degree of the polynomial                                                                                                                |
| MDEGREE=                           | Specifies the maximum degree of any variable in a term of the polynomial                                                                              |
| STANDARDIZE=                       | Specifies centering and scaling suboptions for the variables that define the polynomial                                                               |
| <b>Spline Effects Options</b>      |                                                                                                                                                       |
| BASIS=                             | Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion                                               |
| DEGREE=                            | Specifies the degree of the spline transformation                                                                                                     |
| KNOTMETHOD=                        | Specifies how to construct the knots for spline effects                                                                                               |

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “EFFECT Statement” on page 393 in Chapter 19, “Shared Concepts and Topics.”

---

## FREQ Statement

**FREQ** *variable* ;

The variable specified in the FREQ statement identifies a variable in the input data set containing the frequency of occurrence of each observation. PROC GLMSELECT treats each observation as if it appears  $n$  times, where  $n$  is the value of the FREQ variable for the observation. If it is not an integer, the frequency value is truncated to an integer. If it is less than 1 or if it is missing, the observation is not used.

---

## MODEL Statement

**MODEL** *dependent* = < *effects* > / < *options* > ;

The MODEL statement names the dependent variable and the explanatory effects, including covariates, main effects, constructed effects, interactions, and nested effects; see the section “Specification of Effects” on page 3324 in Chapter 42, “The GLM Procedure,” for more information. If you omit the explanatory effects, the procedure fits an intercept-only model.

After the keyword MODEL, the dependent (response) variable is specified, followed by an equal sign. The explanatory effects follow the equal sign.

Table 45.5 summarizes the options available in the MODEL statement.

**Table 45.5** MODEL Statement Options

| Option      | Description                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------|
| CVDETAILS=  | Requests details when cross validation is used                                                              |
| CVMETHOD=   | Specifies how subsets for cross validation are formed                                                       |
| DETAILS=    | Specifies details to be displayed                                                                           |
| HIERARCHY=  | Specifies the hierarchy of effects to impose                                                                |
| NOINT       | Specifies models without an explicit intercept                                                              |
| ORDERSELECT | Requests that parameter estimates be displayed in the order in which the parameters first entered the model |
| SELECTION=  | Specifies the model selection method                                                                        |
| STATS=      | Specifies additional statistics to be displayed                                                             |
| SHOWPVALUES | Requests $p$ -values in “ANOVA” and “Parameter Estimates” tables                                            |
| STB         | Adds standardized coefficients to “Parameter Estimates” tables                                              |

You can specify the following options in the MODEL statement after a slash (/):

**CVDETAILS=ALL**

**CVDETAILS=COEFFS**

**CVDETAILS=CVPRESS**

specifies the details produced when cross validation is requested as the **CHOOSE=**, **SELECT=**, or **STOP=** criterion in the MODEL statement. If  $n$ -fold cross validation is being used, then the training data are subdivided into  $n$  parts, and at each step of the selection process, models are obtained on

each of the  $n$  subsets of the data obtained by omitting one of these parts. `CVDETAILS=COEFFS` requests that the parameter estimates obtained for each of these  $n$  subsets be included in the parameter estimates table. `CVDETAILS=CVPRESS` requests a table containing the predicted residual sum of squares of each of these models scored on the omitted subset. `CVDETAILS=ALL` requests both `CVDETAILS=COEFFS` and `CVDETAILS=CVPRESS`. If `DETAILS=STEPS` or `DETAILS=ALL` has been specified in the `MODEL` statement, then the requested `CVDETAILS` are produced for every step of the selection process.

**CVMETHOD=BLOCK**  $\langle (n) \rangle$

**CVMETHOD=RANDOM**  $\langle (n) \rangle$

**CVMETHOD=SPLIT**  $\langle (n) \rangle$

**CVMETHOD=INDEX** (*variable*)

specifies how the training data are subdivided into  $n$  parts when you request  $n$ -fold cross validation by using any of the `CHOOSE=CV`, `SELECT=CV`, and `STOP=CV` suboptions of the `SELECTION=` option in the `MODEL` statement.

- `CVMETHOD=BLOCK` requests that parts be formed of  $n$  blocks of consecutive training observations.
- `CVMETHOD=SPLIT` requests that the  $i$ th part consist of training observations  $i, i + n, i + 2n, \dots$
- `CVMETHOD=RANDOM` assigns each training observation randomly to one of the  $n$  parts.
- `CVMETHOD=INDEX(variable)` assigns observations to parts based on the formatted value of the named variable. This input data set variable is treated as a classification variable and the number of parts  $n$  is the number of distinct levels of this variable. By optionally naming this variable in a `CLASS` statement you can use the `CLASS` statement options `ORDER=` and `MISSING` to control how the levelization of this variable is done.

$n$  defaults to 5 with `CVMETHOD=BLOCK`, `CVMETHOD=SPLIT`, or `CVMETHOD=RANDOM`. If you do not specify the `CVMETHOD=` option, then the `CVMETHOD` defaults to `CVMETHOD=RANDOM(5)`.

**DETAILS=level**

**DETAILS=STEPS**  $\langle (step\ options) \rangle$

specifies the level of detail produced, where *level* can be `ALL`, `STEPS`, or `SUMMARY`. The default if the `DETAILS=` option is omitted is `DETAILS=SUMMARY`. The `DETAILS=ALL` option produces the following:

- entry and removal statistics for each variable selected in the model building process
- ANOVA, fit statistics, and parameter estimates
- entry and removal statistics for the top 10 candidates for inclusion or exclusion at each step
- a selection summary table

The `DETAILS=SUMMARY` option produces only the selection summary table.

The option `DETAILS=STEPS`  $\langle (step\ options) \rangle$  provides the step information and the selection summary table. The following options can be specified within parentheses after the `DETAILS=STEPS` option:

**ALL**

requests ANOVA, fit statistics, parameter estimates, and entry or removal statistics for the top 10 candidates for inclusion or exclusion at each selection step.

**ANOVA**

requests ANOVA at each selection step.

**FITSTATISTICS | FITSTATS | FIT**

requests fit statistics at each selection step. The default set of statistics includes all of the statistics named in the **CHOOSE=**, **SELECT=**, and **STOP=** suboptions specified in the **MODEL** statement **SELECTION=** option, but additional statistics can be requested with the **STATS=** option in the **MODEL** statement.

**PARAMETERESTIMATES | PARMEST**

requests parameter estimates at each selection step.

**CANDIDATES <(SHOW= ALL | n)>**

requests entry or removal statistics for the best  $n$  candidate effects for inclusion or exclusion at each step. If you specify **SHOW=ALL**, then all candidates are shown. If **SHOW=** is not specified, then the best 10 candidates are shown. The entry or removal statistic is the statistic named in the **SELECT=** option that is specified in the **MODEL** statement **SELECTION=** option.

**HIERARCHY=keyword****HIER=keyword**

specifies whether and how the model hierarchy requirement is applied. This option also controls whether a single effect or multiple effects are allowed to enter or leave the model in one step. You can specify that only classification effects, or both classification and continuous effects, be subject to the hierarchy requirement. The **HIERARCHY=** option is ignored unless you also specify one of the following options: **SELECTION=FORWARD**, **SELECTION=BACKWARD**, or **SELECTION=STEPWISE**.

Model hierarchy refers to the requirement that for any term to be in the model, all model effects contained in the term must be present in the model. For example, in order for the interaction  $A*B$  to enter the model, the main effects  $A$  and  $B$  must be in the model. Likewise, neither effect  $A$  nor effect  $B$  can leave the model while the interaction  $A*B$  is in the model.

The keywords you can specify in the **HIERARCHY=** option are as follows:

**NONE**

specifies that model hierarchy not be maintained. Any single effect can enter or leave the model at any given step of the selection process.

**SINGLE**

specifies that only one effect enter or leave the model at one time, subject to the model hierarchy requirement. For example, suppose that the model contains the main effects  $A$  and  $B$  and the interaction  $A*B$ . In the first step of the selection process, either  $A$  or  $B$  can enter the model. In the second step, the other main effect can enter the model. The interaction effect can enter the model only when both main effects have already entered. Also, before  $A$  or  $B$  can be removed from the model, the  $A*B$  interaction must first be removed. All effects (**CLASS** and **interval**) are subject to the hierarchy requirement.

**SINGLECLASS**

is the same as HIERARCHY=SINGLE except that only CLASS effects are subject to the hierarchy requirement.

The default value is HIERARCHY=NONE.

**NOINT**

suppresses the intercept term that is otherwise included in the model.

**ORDERSELECT**

specifies that for the selected model, effects be displayed in the order in which they first entered the model. If you do not specify the ORDERSELECT option, then effects in the selected model are displayed in the order in which they appeared in the MODEL statement.

**SELECTION=method <(method options)>**

specifies the method used to select the model, optionally followed by parentheses enclosing options applicable to the specified method. The default if the SELECTION= option is omitted is SELECTION=STEPWISE.

The following methods are available and are explained in detail in the section “[Model-Selection Methods](#)” on page 3559.

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NONE</b>     | no model selection                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>FORWARD</b>  | forward selection. This method starts with no effects in the model and adds effects.                                                                                                                                                                                                                                                                                                                                    |
| <b>BACKWARD</b> | backward elimination. This method starts with all effects in the model and deletes effects.                                                                                                                                                                                                                                                                                                                             |
| <b>STEPWISE</b> | stepwise regression. This is similar to the FORWARD method except that effects already in the model do not necessarily stay there.                                                                                                                                                                                                                                                                                      |
| <b>LAR</b>      | least angle regression. This method, like forward selection, starts with no effects in the model and adds effects. The parameter estimates at any step are “shrunk” when compared to the corresponding least squares estimates. If the model contains classification variables, then these classification variables are split. See the <a href="#">SPLIT</a> option in the <a href="#">CLASS</a> statement for details. |
| <b>LASSO</b>    | This method adds and deletes parameters based on a version of ordinary least squares where the sum of the absolute regression coefficients is constrained. If the model contains classification variables, then these classification variables are split. See the <a href="#">SPLIT</a> option in the <a href="#">CLASS</a> statement for details.                                                                      |

[Table 45.6](#) lists the applicable suboptions for each of these methods.

**Table 45.6** Applicable SELECTION= Options by Method

| Option     | FORWARD | BACKWARD | STEPWISE | LAR LASSO |
|------------|---------|----------|----------|-----------|
| STOP =     | x       | x        | x        | x         |
| CHOOSE =   | x       | x        | x        | x         |
| STEPS =    | x       | x        | x        | x         |
| MAXSTEPS = | x       | x        | x        | x         |
| SELECT =   | x       | x        | x        |           |
| INCLUDE =  | x       | x        | x        |           |
| SLENTRY =  | x       |          | x        |           |
| SLSTAY =   |         | x        | x        |           |
| DROP =     |         |          | x        |           |
| ADAPTIVE   |         |          |          | x         |
| LSCOEFFS   |         |          |          | x         |

The syntax of the suboptions that you can specify in parentheses after the SELECTION= option method follows. Note that, as described in Table 45.6, not all selection suboptions are applicable to every SELECTION= method.

**ADAPTIVE** <(< **GAMMA**=*non-negative number* > < **INEST**=*SAS-data-set* > )>

requests that adaptive weights be applied to each of the coefficients in the LAR and LASSO methods. You use the optional INEST= option to name the SAS data set that contains estimates which are used to form the adaptive weights for all the parameters in the model. If you do not specify an INEST= data set, then ordinary least squares estimates of the parameters in the model are used in forming the adaptive weights. You use the GAMMA= option to specify the power transformation that is applied to the parameters in forming the adaptive weights. The default value is GAMMA=1.

**CHOOSE**=*criterion*

specifies the criterion for choosing the model. The specified *criterion* is evaluated at each step of the selection process, and the model that yields the best value of the criterion is chosen. If the optimal value of the criterion occurs for models at more than one step, then the model with the smallest number of parameters is chosen. If you do not specify the CHOOSE= option, then the model at the final step in the selection process is selected.

The criteria that you can specify in the CHOOSE= option are shown in Table 45.7. See the section “Criteria Used in Model Selection Methods” on page 3568 for more detailed descriptions of these criteria.

**Table 45.7** Criteria for the CHOOSE= Option

| <i>Criterion</i> | <b>Criterion</b>                                                      |
|------------------|-----------------------------------------------------------------------|
| <b>ADJRSQ</b>    | Adjusted R-square statistic                                           |
| <b>AIC</b>       | Akaike's information criterion                                        |
| <b>AICC</b>      | Corrected Akaike's information criterion                              |
| <b>BIC</b>       | Sawa Bayesian information criterion                                   |
| <b>CP</b>        | Mallows' C(p) statistic                                               |
| <b>CV</b>        | Predicted residual sum of square with <i>k</i> -fold cross validation |
| <b>PRESS</b>     | Predicted residual sum of squares                                     |
| <b>SBC</b>       | Schwarz Bayesian information criterion                                |
| <b>VALIDATE</b>  | Average square error for the validation data                          |

For ADJRSQ the chosen value is the largest one; for all other criteria, the smallest value is chosen. You can use the CHOOSE=VALIDATE option only if you have specified a VALDATA= data set in the PROC GLMSELECT statement or if you have reserved part of the input data for validation by using either a PARTITION statement or a \_ROLE\_ variable in the input data.

**DROP=*policy***

specifies when effects are eligible to be dropped in the STEPWISE method. Valid values for policy are BEFOREADD and COMPETITIVE.

If you specify DROP=BEFOREADD, then effects currently in the model are examined to see if any meet the requirements to be removed from the model. If so, the effect that gives the best value of the removal criterion is dropped from the model and the stepwise method proceeds to the next step. Only when no effect currently in the model meets the requirement to be removed from the model are any effects added to the model.

DROP=COMPETITIVE can be specified only if the SELECT= criterion is not SL. If you specify DROP=COMPETITIVE, then the SELECT= criterion is evaluated for all models where an effect currently in the model is dropped or an effect not yet in the model is added. The effect whose removal or addition to the model yields the maximum improvement to the SELECT= criterion is dropped or added.

The default if you do not specify DROP= suboption with the STEPWISE method is DROP=BEFOREADD. If SELECT=SL, then this yields the traditional stepwise method as implemented in PROC REG.

**INCLUDE=*n***

forces the first *n* effects listed in the MODEL statement to be included in all models. The selection methods are performed on the other effects in the MODEL statement. The INCLUDE= option is available only with SELECTION=FORWARD, SELECTION=STEPWISE, and SELECTION=BACKWARD.

**LSCOEFFS**

requests a hybrid version of the LAR and LASSO methods, where the sequence of models is determined by the LAR or LASSO algorithm but the coefficients of the parameters for the model at any step are determined by using ordinary least squares.

**MAXSTEP=*n***

specifies the maximum number of selection steps that are done. The default value of *n* is the number of effects in the model statement for the FORWARD, BACKWARD, and LAR methods and is three times the number of effects for the STEPWISE and LASSO methods.

**SELECT=*criterion***

specifies the criterion that PROC GLMSELECT uses to determine the order in which effects enter and/or leave at each step of the specified selection method. The SELECT= option is not valid with the LAR and LASSO methods. The criteria that you can specify with the SELECT= option are ADJRSQ, AIC, AICC, BIC, CP, CV, PRESS, RSQUARE, SBC, SL, and VALIDATE. See the section “Criteria Used in Model Selection Methods” on page 3568 for a description of these criteria. The default value of the SELECT= criterion is SELECT=SBC. You can use SELECT=SL to request the traditional approach where effects enter and leave the model based on the significance level. With other SELECT= criteria, the effect that is selected to enter or leave at a step of the selection process is the effect whose addition to or removal from the current model gives the maximum improvement in the specified criterion.

**SLENTRY=*value*****SLE=*value***

specifies the significance level for entry, used when the STOP=SL or SELECT=SL option is in effect. The defaults are 0.50 for FORWARD and 0.15 for STEPWISE.

**SLSTAY=*value*****SLS=*value***

specifies the significance level for staying in the model, used when the STOP=SL or SELECT=SL option is in effect. The defaults are 0.10 for BACKWARD and 0.15 for STEPWISE.

**STEPS=*n***

specifies the number of selection steps to be done. If the STEPS= option is specified, the STOP= and MAXSTEP= options are ignored.

**STOP=*n*****STOP=*criterion***

specifies when PROC GLMSELECT stops the selection process. If the STEPS= option is specified, then the STOP= option is ignored. If the STOP=option does not cause the selection process to stop before the maximum number of steps for the selection method, then the selection process terminates at the maximum number of steps.

If you do not specify the STOP= option but do specify the SELECT= option, then the criterion named in the SELECT=option is also used as the STOP= criterion. If you do not specify either the STOP= or SELECT= option, then the default is STOP=SBC.

If STOP=*n* is specified, then PROC GLMSELECT stops selection at the first step for which the selected model has *n* effects.

The nonnumeric arguments that you can specify in the STOP= option are shown in Table 45.8. See the section “Criteria Used in Model Selection Methods” on page 3568 for more detailed descriptions of these criteria.

**Table 45.8** Nonnumeric Criteria for the STOP= Option

| Option          | Criteria                                                              |
|-----------------|-----------------------------------------------------------------------|
| <b>NONE</b>     |                                                                       |
| <b>ADJRSQ</b>   | Adjusted R-square statistic                                           |
| <b>AIC</b>      | Akaike's information criterion                                        |
| <b>AICC</b>     | Corrected Akaike's information criterion                              |
| <b>BIC</b>      | Sawa Bayesian information criterion                                   |
| <b>CP</b>       | Mallows' C(p) statistic                                               |
| <b>CV</b>       | Predicted residual sum of square with <i>k</i> -fold cross validation |
| <b>PRESS</b>    | Predicted residual sum of squares                                     |
| <b>SBC</b>      | Schwarz Bayesian information criterion                                |
| <b>SL</b>       | Significance level                                                    |
| <b>VALIDATE</b> | Average square error for the validation data                          |

With the SL criterion, selection stops at the step where the significance level for entry of all the effects not yet in the model is greater than the SLE= value for addition steps in the FORWARDS and STEPWISE methods and where the significance level for removal of any effect in the current model is greater than the SLS= value in the BACKWARD and STEPWISE methods. With the ADJRSQ criterion, selection stops at the step where the next step would yield a model with a smaller value of the Adjusted R-square statistic; for all other criteria, selection stops at the step where the next step would yield a model with a larger value of the criteria. You can use the VALIDATE option only if you have specified a VALDATA= data set in the PROC GLMSELECT statement or if you have reserved part of the input data for validation by using either a PARTITION statement or a \_ROLE\_ variable in the input data.

**STAT|STATS=***name*

**STATS=**(*names*)

specifies which model fit statistics are displayed in the fit summary table and fit statistics tables. If you omit the STATS= option, the default set of statistics that are displayed in these tables includes all the criteria specified in any of the CHOOSE=, SELECT=, and STOP= options specified in the MODEL statement SELECTION= option.

The statistics that you can specify follow:

|               |                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ADJRSQ</b> | the adjusted R-square statistic                                                                                                                                                                                                                                                                                                                                                          |
| <b>AIC</b>    | Akaike's information criterion                                                                                                                                                                                                                                                                                                                                                           |
| <b>AICC</b>   | corrected Akaike's information criterion                                                                                                                                                                                                                                                                                                                                                 |
| <b>ASE</b>    | the average square errors for the training, test, and validation data. The ASE statistics for the test and validation data are reported only if you have specified TEST-DATA= and/or VALDATA= in the PROC GLMSELECT statement or if you have reserved part of the input data for testing and/or validation by using either a PARTITION statement or a _ROLE_ variable in the input data. |
| <b>BIC</b>    | the Sawa Bayesian information criterion                                                                                                                                                                                                                                                                                                                                                  |
| <b>CP</b>     | the Mallows' C(p) statistic                                                                                                                                                                                                                                                                                                                                                              |

- FVALUE**            the  $F$  statistic for entering or departing effects
- PRESS**             the predicted residual sum of squares statistic
- RSQUARE**         the R-square statistic
- SBC**                the Schwarz Bayesian information criterion
- SL**                 the significance level of the  $F$  statistic for entering or departing effects

The statistics ADJRSQ, AIC, AICC, FVALUE, RSQUARE, SBC, and SL can be computed with little computation cost. However, computing BIC, CP, CVPRESS, PRESS, and ASE for test and validation data when these are not used in any of the **CHOOSE=**, **SELECT=**, and **STOP=** options specified in the MODEL statement **SELECTION=** option can hurt performance.

**SHOWPVALUES**

**SHOWPVALS**

displays  $p$ -values in the “ANOVA” and “Parameter Estimates” tables. These  $p$ -values are generally liberal because they are not adjusted for the fact that the terms in the model have been selected.

**STB**

produces standardized regression coefficients. A standardized regression coefficient is computed by dividing a parameter estimate by the ratio of the sample standard deviation of the dependent variable to the sample standard deviation of the regressor.

**MODEL AVERAGE Statement (Experimental)**

**MODEL AVERAGE** < options > ;

The experimental MODEL AVERAGE statement requests that model selection be repeated on resampled subsets of the input data. An average model is produced by averaging the parameter estimates of the selected models that are obtained for each resampled subset of the input data.

Table 45.9 summarizes the options available in the MODEL AVERAGE statement.

**Table 45.9** MODEL AVERAGE Statement Options

| <b>Option</b>    | <b>Description</b>                                                     |
|------------------|------------------------------------------------------------------------|
| <b>ALPHA=</b>    | Specifies lower and upper quantiles of the sample parameter            |
| <b>DETAILS</b>   | Displays model selection details                                       |
| <b>NSAMPLES=</b> | Specifies the number of samples used for the refit averaging           |
| <b>REFIT</b>     | Performs a second round of model averaging                             |
| <b>SAMPLING=</b> | Specifies how to generate the samples taken from the training data     |
| <b>SUBSET</b>    | Uses only a subset of the selected models in forming the average model |
| <b>TABLES</b>    | Controls the displayed tables                                          |

The following *options* are available:

**ALPHA= $\alpha$**

controls which lower and upper quantiles of the sample parameter estimates are displayed. The ALPHA= option also controls which quantiles of the predicted values are added to the output data set when the LOWER= and UPPER= options are specified in the OUTPUT statement. The lower and upper quantiles used are  $\alpha/2$  and  $1 - \alpha/2$ , respectively. The value specified must lie in the interval  $[0, 1]$ . The default value is ALPHA=0.5.

**DETAILS**

requests that model selection details be displayed for each sample of the data. The level of detail shown is controlled by the DETAILS= option in the MODEL statement.

**NSAMPLES= $n$**

specifies the number of samples to be used. The default value is NSAMPLES=100.

**REFIT <(refit-options)>**

requests that a second round of model averaging, referred to as the refit averaging, be performed. Usually, the initial round of model averaging produces a model that contains a large number of effects. You can use the refit option to obtain a more parsimonious model. For each data sample in the refit, a least squares model is fit with no effect selection. The effects that are used in the refit depend on the results of the initial round of model averaging. If you do not specify any *refit-options*, then effects that are selected in at least twenty percent of the samples in the initial round of model averaging are used in the refit model average. The following *refit-options* are available:

**BEST= $n$**

specifies that the  $n$  most frequently selected effects in the initial round of model averaging be used in the refit averaging.

**MINPCT=*percent***

specifies that the effects that are selected at least the specified percentage of times in the initial round of model averaging be used in the refit averaging.

**NSAMPLES= $n$**

specifies the number of samples to be used for the refit averaging. The default value is the number of samples used in the initial round of model averaging.

**SAMPLING=SRS | URS <(sampling-options)>**

specifies how the samples of the usable observations in the training data are generated. SAMPLING=SRS specifies simple random sampling in which samples are generated by randomly drawing without replacement. SAMPLING=URS specifies unrestricted random sampling in which samples are generated by randomly drawing with replacement. Model averaging with samples drawn without replacement corresponds to the bootstrap methodology. The default is SAMPLING=URS. If you specify a frequency variable by using a FREQ statement, then the  $i$ th observation is sampled  $f_i$  times, where  $f_i$  is the frequency of the  $i$ th observation.

You can specify one of the following *sampling-options*:

**PERCENT=percent**

specifies the percentage of the training data that is used in each sample. The default value is 75% for SAMPLING=SRS and 100% for SAMPLING=URS.

**SIZE=n**

specifies the sum of frequencies in each sample.

**SUBSET(subset-options)**

specifies that only a subset of the selected models be used in forming the average model and producing predicted values. The following *subset-options* are available:

**BEST=n**

specifies that only the best *n* models be used, where the model ranking criterion used is the frequency score. See the section “Model Selection Frequencies and Frequency Scores” on page 3577 for the definition of the frequency score. If multiple models with the same frequency score correspond to the *n*th best model, then all these tied models are used in forming the average model and producing predicted values.

**MINMODELFREQ=freq**

specifies that only models that are selected at least *freq* times be used in forming the average model and producing predicted values.

**TABLES <(ONLY)> <=table-request <(options)>>**

**TABLES <(ONLY)> <= (table-request <(options)> <... table-request <(options)>>>**

controls the displayed output that is produced in the initial round of model averaging. By default, the following tables are produced:

**EFFECTSELECTPCT** displays the percentage of times that effects appear in the selected models.

**MODELSELECTFREQ** displays the frequency with which models are selected.

**AVGPAREST** displays the mean, standard deviation, and quantiles of the parameter estimates of the parameters that appear in the selected models.

When you specify only one *table-request*, you can omit the outer parentheses. Here are some examples:

```
tables=none
tables=(all parmest (minpct=10))
tables(only)=effectselectpct (order=model minpct=15)
```

The following *table-request* options are available:

**ALL**

requests that all model averaging output tables be produced. You can specify other options with ALL; for example, to request all tables and to require that effects are displayed in decreasing order of selection frequency in the EffectSelectPct table, specify TABLES=(ALL EFFECTSELECTPCT(ORDER=DESCENDING)).

**EFFECTSELECTPCT** < (*effectSelectPct-options*) >

specifies how the effects in the EffectSelectPct table are displayed. The following *effectSelectPct-options* are available:

**ALL**

specifies that effects that appear in the selected model for any sample be displayed.

**MINPCT=percent**

specifies that the effects displayed must appear in the selected model for at least the specified percentage of the samples. By default, this table includes effects that appear in at least twenty percent of the selected models. The MINPCT= option is ignored if you also specify the ALL option as a *effectSelectPct* option.

**ORDER=ASCENDING | DESCENDING | MODEL**

specifies the order in which the effects are displayed. ORDER=MODEL specifies that effects be displayed in the order in which they appear in the **MODEL** statement. ORDER=ASCENDING | DESCENDING specifies that the effects be displayed in ascending or descending order of their selection frequency.

**MODELSELECTFREQ** < (*modelSelectFreq-options*) >

specifies how the models in the ModelSelectFreq table are displayed. The following *modelSelectFreq-options* are available:

**ALL**

specifies that all selected models be displayed in the ModelSelectFreq table.

**BEST=*n***

specifies that only the best *n* models be displayed, where the model ranking criterion used is the frequency score. See the section “[Model Selection Frequencies and Frequency Scores](#)” on page 3577 for the definition of the frequency score. The default value is BEST=20. The BEST= option is ignored if you also specify the ALL option as a *modelSelectFreq-option*.

**ONLY**

suppresses the default output. If you specify the ONLY option within parentheses after the TABLES option, then only the tables specifically requested are produced.

**PARMEST** < (*parmEst-options*) >

specifies how the parameters in the AvgParmEst table are displayed. The following *parmEst-options* are available:

**ALL**

specifies that parameters that are nonzero in the selected model for any sample be displayed.

**MINPCT=percent**

specifies that the parameters displayed must have nonzero estimates in the selected model for at least the specified percentage of the samples. By default, this table includes parameters that appear in at least twenty percent of the selected models. The MINPCT= option is ignored if you also specify the ALL option as a *parmEst* option.

**NONZEROPARMS**

specifies that for each parameter, the sample that is used to compute the estimate mean, standard deviation, and quantiles consist of just the nonzero values of that parameter in the selected models. If you do not specify the NONZEROPARMS option, then parameters that do not appear in a selected model are assigned the value zero in that model and these zero values are retained when computing the estimate means, standard deviations, and quantiles.

**ORDER=ASCENDING | DESCENDING | MODEL**

specifies the order in which the effects are displayed. ORDER=MODEL specifies that effects are displayed in the order in which they appear in the MODEL statement. ORDER=ASCENDING | DESCENDING specifies that the effects are displayed in ascending or descending order of their selection frequency.

---

## OUTPUT Statement

**OUTPUT** < **OUT=SAS-data-set** > < *keyword* < =*name* > > ... < *keyword* < =*name* > > ;

The OUTPUT statement creates a new SAS data set that saves diagnostic measures calculated for the selected model. If you do not specify a *keyword*, then the only diagnostic included is the predicted response.

All the variables in the original data set are included in the new data set, along with variables created in the OUTPUT statement. These new variables contain the values of a variety of statistics and diagnostic measures that are calculated for each observation in the data set. If you specify a BY statement, then a variable `_BY_` that indexes the BY groups is included. For each observation, the value of `_BY_` is the index of the BY group to which this observation belongs. This variable is useful for matching BY groups with macro variables that PROC GLMSELECT creates. See the section “[Macro Variables Containing Selected Models](#)” on page 3572 for details.

If you have requested *n*-fold cross validation by requesting **CHOOSE=CV**, **SELECT=CV**, or **STOP=CV** in the MODEL statement, then a variable `_CVINDEX_` is included in the output data set. For each observation used for model training the value of `_CVINDEX_` is *i* if that observation is omitted in forming the *i*th subset of the training data. See the **CVMETHOD=** for additional details. The value of `_CVINDEX_` is 0 for all observations in the input data set that are not used for model training.

If you have partitioned the input data with a **PARTITION** statement, then a character variable `_ROLE_` is included in the output data set. For each observation the value of `_ROLE_` is as follows:

|                     |                  |
|---------------------|------------------|
| <code>_ROLE_</code> | Observation Role |
| TEST                | testing          |
| TRAIN               | training         |
| VALIDATE            | validation       |

If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

Details on the specifications in the OUTPUT statement follow.

*keyword* < =*name* >

specifies the statistics to include in the output data set and optionally names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), followed optionally by an equal sign, and a variable to contain the statistic.

If you specify *keyword=name*, the new variable that contains the requested statistic has the specified name. If you omit the optional *=name* after a *keyword*, then the new variable name is formed by using a prefix of one or more characters that identify the statistic. For residuals and predicted values, the prefix is followed by an underscore ( ), followed by the dependent variable name.

The keywords allowed and the statistics they represent are as follows:

**PREDICTED | PRED | P** predicted values. The prefix for the default name is *p*.

**RESIDUAL | RESID | R** residual, calculated as ACTUAL – PREDICTED. The prefix for the default name is *r*.

When you also use the **MODEL AVERAGE** statement, the following keywords and the statistics that they represent are also available:

**LOWER**  $\alpha/2$  percentile of the sample predicted values. By default,  $\alpha = 0.5$ , which yields the 25th percentile. You can change the value of  $\alpha$  by using the ALPHA= option in the **MODEL AVERAGE** statement. The default name is *LOWER*.

**MEDIAN** median of the sample predicted values. The default name is *median*.

**SAMPLEFREQ | SF** sample frequencies. For the *i*th sample, a column that contains the frequencies used for that sample is added. The name of this column is formed by appending an index *i* to the name that you specify. If you do not specify a name, then the default prefix is *sf*.

**SAMPLEPRED | SP** sample predictions. For the *i*th sample, a column that contains the predicted values produced by the model selected for that sample is added. The name of this column is formed by appending an index *i* to the name that you specify. If you do not specify a name, then the default prefix is *sp*.

**STANDARDDEVIATION | STDDEV** standard deviation of the sample predicted values. The default name is *stdDev*.

**UPPER**  $1 - \alpha/2$  percentile of the sample predicted values. By default,  $\alpha = 0.5$ , which yields the 75th percentile. You can change the value of  $\alpha$  by using the ALPHA= option in the **MODEL AVERAGE** statement. The default name is *UPPER*.

**OUT=SAS data set**

specifies the name of the new data set. By default, the procedure uses the *DATA*n** convention to name the new data set.

---

## PARTITION Statement

The **PARTITION** statement specifies how observations in the input data set are logically partitioned into disjoint subsets for model training, validation, and testing. Either you can designate a variable in the input data set and a set of formatted values of that variable to determine the role of each observation, or you can specify proportions to use for random assignment of observations for each role.

An alternative to using a **PARTITION** statement is to provide a variable named `_ROLE_` in the input data set to define roles of observations in the input data. If you specify a **PARTITION** statement then the `_ROLE_`

variable if present in the input data set is ignored. If you do not use a PARTITION statement and the input data do not contain a variable named `_ROLE_`, then all observations in the input data set are assigned to model training.

The following mutually exclusive options are available:

**ROLEVAR | ROLE=variable(< TEST='value' > < TRAIN='value' > < VALIDATE='value' >)**

names the variable in the input data set whose values are used to assign roles to each observation. The formatted values of this variable that are used to assign observations roles are specified in the TEST=, TRAIN=, and VALIDATE= suboptions. If you do not specify the TRAIN= suboption, then all observations whose role is not determined by the TEST= or VALIDATE= suboptions are assigned to training. If you specify a TESTDATA= data set in the PROC GLMSELECT statement, then you cannot also specify the TEST= suboption in the PARTITION statement. If you specify a VALDATA= data set in the PROC GLMSELECT statement, then you cannot also specify the VALIDATE= suboption in the PARTITION statement.

**FRACTION(< TEST=fraction > < VALIDATE=fraction >)**

requests that specified proportions of the observations in the input data set be randomly assigned training and validation roles. You specify the proportions for testing and validation by using the TEST= and VALIDATE= suboptions. If you specify both the TEST= and the VALIDATE= suboptions, then the sum of the specified fractions must be less than one and the remaining fraction of the observations are assigned to the training role. If you specify a TESTDATA= data set in the PROC GLMSELECT statement, then you cannot also specify the TEST= suboption in the PARTITION statement. If you specify a VALDATA= data set in the PROC GLMSELECT statement, then you cannot also specify the VALIDATE= suboption in the PARTITION statement.

---

## PERFORMANCE Statement

**PERFORMANCE** < options > ;

The PERFORMANCE statement is used to change default options that affect the performance of PROC GLMSELECT and to request tables that show the performance options in effect and timing details.

The following options are available:

**DETAILS**

requests the PerfSettings table that shows the performance settings in effect and the Timing table that provides a broad timing breakdown of the PROC GLMSELECT step.

**BUILDSSCP=FULL**

**BUILDSSCP=INCREMENTAL**

specifies whether the SSCP matrix is built incrementally as the selection process progresses or whether the SSCP matrix for the full model is built at the outset. Building the SSCP matrix incrementally can significantly reduce the memory required and the time taken to perform model selection in cases where the number of parameters in the selected model is much smaller than the number of parameters in the full model, but it can hurt performance in other cases since it requires at least one pass through the model training data at each step. If you use backward selection or no selection, or if the BIC or CP statistics are required in the selection process, then the BUILDSSCP=INCREMENTAL option is ignored. In other cases, BUILDSSCP=INCREMENTAL is used by default if the number

of effects is greater than 100. See the section “Building the SSCP Matrix” on page 3575 for further details.

---

## SCORE Statement

```
SCORE < DATA=SAS-data-set > < OUT=SAS-data-set > < keyword< =name > > ... < keyword< =name > >
 ;
```

The SCORE statement creates a new SAS data set containing predicted values and optionally residuals for data in a new data set that you name. If you do not specify a DATA= data set, then the input data are scored. If you have multiple data sets to predict, you can specify multiple SCORE statements. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

When a BY statement is used, the score data set must either contain all the BY variables sorted in the order of the BY variables or contain none of the BY variables. If the score data set contains all of the BY variables, then the model selected for a given BY group is used to score just the matching observations in the score data set. If the score data set contains none of the BY variables, then the entire score data set is scored for each BY group.

All observations in the score data set are retained in the output data set. However, only those observations that contain nonmissing values for all the continuous regressors in the selected model and whose levels of the class variables appearing in effects of the selected model are represented in the corresponding class variable in the procedure’s input data set are scored. All the variables in the input data set are included in the output data set, along with variables containing predicted values and optionally residuals.

Details on the specifications in the SCORE statement follow:

### DATA=SAS data set

names the data set to be scored. If you omit this option, then the input data set named in the DATA= option in the PROC GLMSELECT statement is scored.

### keyword< =name >

specifies the statistics to include in the output data set and optionally names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), followed optionally by an equal sign, and a variable to contain the statistic.

If you specify *keyword=name*, the new variable that contains the requested statistic has the specified name. If you omit the optional *=name* after a *keyword*, then the new variable name is formed by using a prefix of one or more characters that identify the statistic, followed by an underscore (\_), followed by the dependent variable name.

The keywords allowed and the statistics they represent are as follows:

**PREDICTED | PRED | P** predicted values. The prefix for the default name is *p*.

**RESIDUAL | RESID | R** residual, calculated as ACTUAL – PREDICTED. The prefix for the default name is *r*.

**OUT=SAS data set**

gives the name of the new output data set. By default, the procedure uses the *DATA*n** convention to name the new data set.

## STORE Statement

**STORE** < **OUT=** > *item-store-name* < / **LABEL=** 'label' > ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “STORE Statement” on page 501 in Chapter 19, “Shared Concepts and Topics.”

## WEIGHT Statement

**WEIGHT** *variable* ;

A WEIGHT statement names a variable in the input data set with values that are relative weights for a weighted least squares fit. If the weight value is proportional to the reciprocal of the variance for each observation, then the weighted estimates are the best linear unbiased estimates (BLUE).

Values of the weight variable must be nonnegative. If an observation’s weight is zero, the observation is deleted from the analysis. If a weight is negative or missing, it is set to zero, and the observation is excluded from the analysis. A more complete description of the WEIGHT statement can be found in Chapter 42, “The GLM Procedure.”

## Details: GLMSELECT Procedure

### Model-Selection Methods

The model selection methods implemented in PROC GLMSELECT are specified with the **SELECTION=** option in the **MODEL** statement.

#### Full Model Fitted (NONE)

The complete model specified in the **MODEL** statement is used to fit the model and no effect selection is done. You request this by specifying **SELECTION=NONE** in the **MODEL** statement.

#### Forward Selection (FORWARD)

The forward selection technique begins with just the intercept and then sequentially adds the effect that most improves the fit. The process terminates when no significant improvement can be obtained by adding any effect.

In the traditional implementation of forward selection, the statistic used to gauge improvement in fit is an  $F$  statistic that reflects an effect's contribution to the model if it is included. At each step, the effect that yields the most significant  $F$  statistic is added. Note that because effects can contribute different degrees of freedom to the model, it is necessary to compare the  $p$ -values corresponding to these  $F$  statistics.

More precisely, if the current model has  $p$  parameters excluding the intercept, and if you denote its residual sum of squares by  $RSS_p$  and you add an effect with  $k$  degrees of freedom and denote the residual sum of squares of the resulting model by  $RSS_{p+k}$ , then the  $F$  statistic for entry with  $k$  numerator degrees of freedom and  $n - (p + k) - 1$  denominator degrees of freedom is given by

$$F = \frac{(RSS_p - RSS_{p+k})/k}{RSS_{p+k}/(n - (p + k) - 1)}$$

where  $n$  is number of observations used in the analysis.

The process stops when the significance level for adding any effect is greater than some specified entry significance level. A well-known problem with this methodology is that these  $F$  statistics do not follow an  $F$  distribution (Draper, Guttman, and Kanemasu 1971). Hence these  $p$ -values cannot reliably be interpreted as probabilities. Various ways to approximate this distribution are described by Miller (2002). Another issue when you use significance levels of entering effects as a stopping criterion arises because the entry significance level is an a priori specification that does not depend on the data. Thus, the same entry significance level can result in overfitting for some data and underfitting for other data.

One approach to address the critical problem of when to stop the selection process is to assess the quality of the models produced by the forward selection method and choose the model from this sequence that “best” balances goodness of fit against model complexity. PROC GLMSELECT supports several criteria that you can use for this purpose. These criteria fall into two groups—information criteria and criteria based on out-of-sample prediction performance.

You use the **CHOOSE=** option of forward selection to specify the criterion for selecting one model from the sequence of models produced. If you do not specify a **CHOOSE=** criterion, then the model at the final step is the selected model.

For example, if you specify

```
selection=forward(select=SL choose=AIC SLE=0.2)
```

then forward selection terminates at the step where no effect can be added at the 0.2 significance level. However, the selected model is the first one with the minimal value of Akaike's information criterion. Note that in some cases this minimal value might occur at a step much earlier than the final step, while in other cases the AIC criterion might start increasing only if more steps are done (that is, a larger value of SLE is used). If what you are interested in is minimizing AIC, then too many steps are done in the former case and too few in the latter case. To address this issue, PROC GLMSELECT enables you to specify a stopping criterion with the **STOP=** option. With a stopping criterion specified, forward selection continues until a local extremum of the stopping criterion in the sequence of models generated is reached. You can also specify **STOP=** number, which causes forward selection to continue until there are the specified number of effects in the model.

For example, if you specify

```
selection=forward(select=SL stop=AIC)
```

then forward selection terminates at the step where the effect to be added at the next step would produce a model with an AIC statistic larger than the AIC statistic of the current model. Note that in most cases, provided that the entry significance level is large enough that the local extremum of the named criterion occurs before the final step, specifying

```
selection=forward(select=SL choose=CRITERION)
```

or

```
selection=forward(select=SL stop=CRITERION)
```

selects the same model, but more steps are done in the former case. In some cases there might be a better local extremum that cannot be reached if you specify the **STOP=** option but can be found if you use the **CHOOSE=** option. Also, you can use the **CHOOSE=** option in preference to the **STOP=** option if you want examine how the named criterion behaves as you move beyond the step where the first local minimum of this criterion occurs.

Note that you can specify both the **CHOOSE=** and **STOP=** options. You might want to consider models generated by forward selection that have at most some fixed number of effects but select from within this set based on a criterion you specify. For example, specifying

```
selection=forward(stop=20 choose=ADJRSQ)
```

requests that forward selection continue until there are 20 effects in the final model and chooses among the sequence of models the one that has the largest value of the adjusted R-square statistic. You can also combine these options to select a model where one of two conditions is met. For example,

```
selection=forward(stop=AICC choose=PRESS)
```

chooses whatever occurs first between a local minimum of the predicted residual sum of squares (PRESS) and a local minimum of corrected Akaike's information criterion (AICC).

It is important to keep in mind that forward selection bases the decision about what effect to add at any step by considering models that differ by one effect from the current model. This search paradigm cannot guarantee reaching a "best" subset model. Furthermore, the add decision is greedy in the sense that the effect deemed most significant is the effect that is added. However, if your goal is to find a model that is best in terms of some selection criterion other than the significance level of the entering effect, then even this one step choice might not be optimal. For example, the effect you would add to get a model with the smallest value of the PRESS statistic at the next step is not necessarily the same effect that has the most significant entry  $F$  statistic. PROC GLMSELECT enables you to specify the criterion to optimize at each step by using the **SELECT=** option. For example,

```
selection=forward(select=CP)
```

requests that at each step the effect that is added be the one that gives a model with the smallest value of the Mallows'  $C(p)$  statistic. Note that in the case where all effects are variables (that is, effects with one degree of freedom and no hierarchy), using ADJRSQ, AIC, AICC, BIC, CP, RSQUARE, or SBC as the selection criterion for forward selection produces the same sequence of additions. However, if the degrees of freedom contributed by different effects are not constant, or if an out-of-sample prediction-based criterion is used, then different sequences of additions might be obtained.

You can use **SELECT=** together with **CHOOSE=** and **STOP=**. If you specify only the **SELECT=** criterion, then this criterion is also used as the stopping criterion. In the previous example where only the selection criterion is specified, not only do effects enter based on the Mallows'  $C(p)$  statistic, but the selection terminates when the  $C(p)$  statistic first increases.

You can find discussion and references to studies about criteria for variable selection in Burnham and Anderson (2002), along with some cautions and recommendations.

**Examples of Forward Selection Specifications****selection=forward**

adds effects that at each step give the lowest value of the SBC statistic and stops at the step where adding any effect would increase the SBC statistic.

**selection=forward(select=SL)**

adds effects based on significance level and stops when all candidate effects for entry at a step have a significance level greater than the default entry significance level of 0.15.

**selection=forward(select=SL stop=validation)**

adds effects based on significance level and stops at a step where adding any effect increases the error sum of squares computed on the validation data.

**selection=forward(select=AIC)**

adds effects that at each step give the lowest value of the AIC statistic and stops at the step where adding any effect would increase the AIC statistic.

**selection=forward(select=ADJRSQ stop=SL SLE=0.2)**

adds effects that at each step give the largest value of the adjusted R-square statistic and stops at the step where the significance level corresponding to the addition of this effect is greater than 0.2.

**Backward Elimination (BACKWARD)**

The backward elimination technique starts from the full model including all independent effects. Then effects are deleted one by one until a stopping condition is satisfied. At each step, the effect showing the smallest contribution to the model is deleted. In traditional implementations of backward elimination, the contribution of an effect to the model is assessed by using an  $F$  statistic. At any step, the predictor producing the least significant  $F$  statistic is dropped and the process continues until all effects remaining in the model have  $F$  statistics significant at a stay significance level (SLS).

More precisely, if the current model has  $p$  parameters excluding the intercept, and if you denote its residual sum of squares by  $RSS_p$  and you drop an effect with  $k$  degrees of freedom and denote the residual sum of squares of the resulting model by  $RSS_{p-k}$ , then the  $F$  statistic for removal with  $k$  numerator degrees of freedom and  $n - p - k$  denominator degrees of freedom is given by

$$F = \frac{(RSS_{p-k} - RSS_p)/k}{RSS_p/(n - p - k)}$$

where  $n$  is number of observations used in the analysis.

Just as with forward selection, you can change the criterion used to assess effect contributions with the **SELECT=** option. You can also specify a stopping criterion with the **STOP=** option and use a **CHOOSE=** option to provide a criterion used to select among the sequence of models produced. See the discussion in the section “Forward Selection (FORWARD)” on page 3559 for additional details.

### Examples of Backward Selection Specifications

`selection=backward`

removes effects that at each step produce the largest value of the Schwarz Bayesian information criterion (SBC) statistic and stops at the step where removing any effect increases the SBC statistic.

`selection=backward(stop=press)`

removes effects based on the SBC statistic and stops at the step where removing any effect increases the predicted residual sum of squares (PRESS).

`selection=backward(select=SL)`

removes effects based on significance level and stops when all candidate effects for removal at a step have a significance level less than the default stay significance level of 0.15.

`selection=backward(select=SL choose=validate SLS=0.1)`

removes effects based on significance level and stops when all effects in the model are significant at the 0.1 level. Finally, from the sequence of models generated, choose the one that gives the smallest average square error when scored on the validation data.

### Stepwise Selection(STEPWISE)

The stepwise method is a modification of the forward selection technique that differs in that effects already in the model do not necessarily stay there.

In the traditional implementation of stepwise selection method, the same entry and removal  $F$  statistics for the forward selection and backward elimination methods are used to assess contributions of effects as they are added to or removed from a model. If at a step of the stepwise method, any effect in the model is not significant at the `SLSTAY=` level, then the least significant of these effects is removed from the model and the algorithm proceeds to the next step. This ensures that no effect can be added to a model while some effect currently in the model is not deemed significant. Only after all necessary deletions have been accomplished can another effect be added to the model. In this case the effect whose addition yields the most significant  $F$  value is added to the model and the algorithm proceeds to the next step. The stepwise process ends when none of the effects outside the model has an  $F$  statistic significant at the `SLENTRY=` level and every effect in the model is significant at the `SLSTAY=` level. In some cases, neither of these two conditions for stopping is met and the sequence of models cycles. In this case, the stepwise method terminates at the end of the second cycle.

Just as with forward selection and backward elimination, you can change the criterion used to assess effect contributions, with the `SELECT=` option. You can also specify a stopping criterion with the `STOP=` option and use a `CHOOSE=` option to provide a criterion used to select among the sequence of models produced. See the discussion in the section “[Forward Selection \(FORWARD\)](#)” on page 3559 for additional details.

For selection criteria other than significance level, PROC GLMSELECT optionally supports a further modification in the stepwise method. In the standard stepwise method, no effect can enter the model if removing any effect currently in the model would yield an improved value of the selection criterion. In the modification, you can use the `DROP=COMPETITIVE` option to specify that addition and deletion of effects should be treated competitively. The selection criterion is evaluated for all models obtained by deleting an effect from the current model or by adding an effect to this model. The action that most improves the selection criterion is the action taken.

**Examples of Stepwise Selection Specifications**

```
selection=stepwise
```

requests stepwise selection based on the SBC criterion. First, if removing any effect yields a model with a lower SBC statistic than the current model, then the effect producing the smallest SBC statistic is removed. When removing any effect increases the SBC statistic, then provided that adding some effect lowers the SBC statistic, the effect producing the model with the lowest SBC is added.

```
selection=stepwise(select=SL)
```

requests the traditional stepwise method. First, if the removal of any effect yields an  $F$  statistic that is not significant at the default stay level of 0.15, then the effect whose removal produces the least significant  $F$  statistic is removed and the algorithm proceeds to the next step. Otherwise the effect whose addition yields the most significant  $F$  statistic is added, provided that it is significant at the default entry level of 0.15.

```
selection=stepwise(select=SL stop=SBC)
```

is the traditional stepwise method, where effects enter and leave based on significance levels, but with the following extra check: If any effect to be added or removed yields a model whose SBC statistic is greater than the SBC statistic of the current model, then the stepwise method terminates at the current model. Note that in this case, the entry and stay significance levels still play a role as they determine whether an effect is deleted from or added to the model. This might result in the selection terminating before a local minimum of the SBC criterion is found.

```
selection=stepwise(select=SL SLE=0.1 SLS=0.08 choose=AIC)
```

selects effects to enter or drop as in the previous example except that the significance level for entry is now 0.1 and the significance level to stay is 0.08. From the sequence of models produced, the selected model is chosen to yield the minimum AIC statistic.

```
selection=stepwise(select=AICC drop=COMPETITIVE)
```

requests stepwise selection based on the AICC criterion with steps treated competitively. At any step, evaluate the AICC statistics corresponding to the removal of any effect in the current model or the addition of any effect to the current model. Choose the addition or removal that produced this minimum value, provided that this minimum is lower than the AICC statistic of the current model.

```
selection=stepwise(select=SBC drop=COMPETITIVE stop=VALIDATE)
```

requests stepwise selection based on the SBC criterion with steps treated competitively and where stopping is based on the average square error over the validation data. At any step, SBC statistics corresponding to the removal of any effect from the current model or the addition of any effect to the current model are evaluated. The addition or removal that produces the minimum SBC value is made. The average square error on the validation data for the model with this addition or removal is evaluated. If this average square error is greater than the average square error on the validation data prior to this addition or deletion, then the algorithm terminates at this prior model.

**Least Angle Regression (LAR)**

Least angle regression was introduced by Efron et al. (2004). Not only does this algorithm provide a selection method in its own right, but with one additional modification it can be used to efficiently produce LASSO solutions. Just like the forward selection method, the LAR algorithm produces a sequence of

regression models where one parameter is added at each step, terminating at the full least squares solution when all parameters have entered the model.

The algorithm starts by centering the covariates and response, and scaling the covariates so that they all have the same corrected sum of squares. Initially all coefficients are zero, as is the predicted response. The predictor that is most correlated with the current residual is determined and a step is taken in the direction of this predictor. The length of this step determines the coefficient of this predictor and is chosen so that some other predictor and the current predicted response have the same correlation with the current residual. At this point, the predicted response moves in the direction that is equiangular between these two predictors. Moving in this direction ensures that these two predictors continue to have a common correlation with the current residual. The predicted response moves in this direction until a third predictor has the same correlation with the current residual as the two predictors already in the model. A new direction is determined that is equiangular between these three predictors and the predicted response moves in this direction until a fourth predictor joins the set having the same correlation with the current residual. This process continues until all predictors are in the model.

As with other selection methods, the issue of when to stop the selection process is crucial. You can specify a criterion to use to choose among the models at each step with the `CHOOSE=` option. You can also specify a stopping criterion with the `STOP=` option. See the section “Criteria Used in Model Selection Methods” on page 3568 for details and Table 45.10 for the formulas for evaluating these criteria. These formulas use the approximation that at step  $k$  of the LAR algorithm, the model has  $k$  degrees of freedom. See Efron et al. (2004) for a detailed discussion of this so-called simple approximation.

A modification of LAR selection suggested in Efron et al. (2004) uses the LAR algorithm to select the set of covariates in the model at any step, but uses ordinary least squares regression with just these covariates to obtain the regression coefficients. You can request this hybrid method by specifying the `LSCOEFFS` suboption of `SELECTION=LAR`.

## Lasso Selection (LASSO)

LASSO (least absolute shrinkage and selection operator) selection arises from a constrained form of ordinary least squares regression where the sum of the absolute values of the regression coefficients is constrained to be smaller than a specified parameter. More precisely let  $\mathbf{X} = (x_1, x_2, \dots, x_m)$  denote the matrix of covariates and let  $\mathbf{y}$  denote the response, where the  $x_j$ s have been centered and scaled to have unit standard deviation and mean zero, and  $\mathbf{y}$  has mean zero. Then for a given parameter  $t$ , the LASSO regression coefficients  $\boldsymbol{\beta} = (\beta_1, \beta_2, \dots, \beta_m)$  are the solution to the constrained optimization problem

$$\text{minimize } \|\mathbf{y} - \mathbf{X}\boldsymbol{\beta}\|^2 \quad \text{subject to } \sum_{j=1}^m |\beta_j| \leq t$$

Provided that the LASSO parameter  $t$  is small enough, some of the regression coefficients will be exactly zero. Hence, you can view the LASSO as selecting a subset of the regression coefficients for each LASSO parameter. By increasing the LASSO parameter in discrete steps, you obtain a sequence of regression coefficients where the nonzero coefficients at each step correspond to selected parameters.

Early implementations (Tibshirani 1996) of LASSO selection used quadratic programming techniques to solve the constrained least squares problem for each LASSO parameter of interest. Later Osborne, Presnell, and Turlach (2000) developed a “homotopy method” that generates the LASSO solutions for all values of

*t.* Efron et al. (2004) derived a variant of their algorithm for least angle regression that can be used to obtain a sequence of LASSO solutions from which all other LASSO solutions can be obtained by linear interpolation. This algorithm for `SELECTION=LASSO` is used in PROC GLMSELECT. It can be viewed as a stepwise procedure with a single addition to or deletion from the set of nonzero regression coefficients at any step.

As with the other selection methods supported by PROC GLMSELECT, you can specify a criterion to choose among the models at each step of the LASSO algorithm with the `CHOOSE=` option. You can also specify a stopping criterion with the `STOP=` option. See the discussion in the section “**Forward Selection (FORWARD)**” on page 3559 for additional details. The model degrees of freedom PROC GLMSELECT uses at any step of the LASSO are simply the number of nonzero regression coefficients in the model at that step. Efron et al. (2004) cite empirical evidence for doing this but do not give any mathematical justification for this choice.

A modification of LASSO selection suggested in Efron et al. (2004) uses the LASSO algorithm to select the set of covariates in the model at any step, but uses ordinary least squares regression with just these covariates to obtain the regression coefficients. You can request this hybrid method by specifying the `LSCOEFFS` suboption of `SELECTION=LASSO`.

## Adaptive Lasso Selection

Adaptive lasso selection is a modification of lasso selection; in adaptive lasso selection weights are applied to each of the parameters in forming the lasso constraint (Zou 2006). More precisely, suppose that the response  $y$  has mean zero and the regressors  $x$  are scaled to have mean zero and common standard deviation. Furthermore, suppose that you can find a suitable estimator  $\hat{\beta}$  of the parameters in the true model and you define a weight vector by  $w = 1/|\hat{\beta}|^\gamma$ , where  $\gamma \geq 0$ . Then the adaptive lasso regression coefficients  $\beta = (\beta_1, \beta_2, \dots, \beta_m)$  are the solution to the constrained optimization problem

$$\text{minimize } \|y - \mathbf{X}\beta\|^2 \quad \text{subject to } \sum_{j=1}^m |w_j \beta_j| \leq t$$

You can specify  $\hat{\beta}$  by using the `INEST=` suboption of the `SELECTION=LASSO` option in the `MODEL` statement. The `INEST=` data set has the same structure as the `OUTEST=` data set that is produced by several SAS/STAT procedures including the `REG` and `LOGISTIC` procedures. The `INEST=` data set must contain all explanatory variables in the `MODEL` statement. It must also contain an intercept variable named `Intercept` unless the `NOINT` option is specified in the `MODEL` statement. If `BY` processing is used, the `INEST=` data set must also include the `BY` variables, and there must be one observation for each `BY` group. If the `INEST=` data set also contains the `_TYPE_` variable, only observations with `_TYPE_` value 'PARMS' are used.

If you do not specify an `INEST=` data set, then PROC GLMSELECT uses the solution to the unconstrained least squares problem as the estimator  $\hat{\beta}$ . This is appropriate unless collinearity is a concern. If the regressors are collinear or nearly collinear, then Zou (2006) suggests using a ridge regression estimate to form the adaptive weights.

---

## Model Selection Issues

Many authors caution against the use of “automatic variable selection” methods and describe pitfalls that plague many such methods. For example, Harrell (2001) states that “stepwise variable selection has been a very popular technique for many years, but if this procedure had just been proposed as a statistical method, it would most likely be rejected because it violates every principle of statistical estimation and hypothesis testing.” He lists and discusses several of these issues and cites a variety of studies that highlight these problems. He also notes that many of these issues are not restricted to stepwise selection, but affect forward selection and backward elimination, as well as methods based on all-subset selection.

In their introductory chapter, Burnham and Anderson (2002) discuss many issues involved in model selection. They also strongly warn against “data dredging,” which they describe as “the process of analyzing data with few or no a priori questions, by subjectively and iteratively searching the data for patterns and ‘significance’.” However, Burnham and Anderson also discuss the desirability of finding parsimonious models. They note that using “full models” that contain many insignificant predictors might avoid some of the inferential problems arising in models with automatically selected variables but will lead to overfitting the particular sample data and produce a model that performs poorly in predicting data not used in training the model.

One problem in the traditional implementations of forward, backward, and stepwise selection methods is that they are based on sequential testing with specified entry (SLE) and stay (SLS) significance levels. However, it is known that the “ $F$ -to-enter” and “ $F$ -to-delete” statistics do not follow an  $F$  distribution (Draper, Guttman, and Kanemasu 1971). Hence the SLE and SLS values cannot reliably be viewed as probabilities. One way to address this difficulty is to replace hypothesis testing as a means of selecting a model with information criteria or out-of-sample prediction criteria. While Harrell (2001) points out that information criteria were developed for comparing only prespecified models, Burnham and Anderson (2002) note that AIC criteria have routinely been used for several decades for performing model selection in time series analysis.

Problems also arise when the selected model is interpreted as if it were prespecified. There is a “selection bias” in the parameter estimates that is discussed in detail in Miller (2002). This bias occurs because a parameter is more likely to be selected if it is above its expected value than if it is below its expected value. Furthermore, because multiple comparisons are made in obtaining the selected model, the  $p$ -values obtained for the selected model are not valid. When a single best model is selected, inference is conditional on that model.

Model averaging approaches provide a way to make more stable inferences based on a set of models. PROC GLMSELECT provides support for model averaging by averaging models that are selected on resampled data. Other approaches for performing model averaging are presented in Burnham and Anderson (2002), and Bayesian approaches are discussed in Raftery, Madigan, and Hoeting (1997).

Despite these difficulties, careful and informed use of variable selection methods still has its place in modern data analysis. For example, Foster and Stine (2004) use a modified version of stepwise selection to build a predictive model for bankruptcy from over 67,000 possible predictors and show that this yields a model whose predictions compare favorably with other recently developed data mining tools. In particular, when the goal is prediction rather than estimation or hypothesis testing, variable selection with careful use of validation to limit both under and over fitting is often a useful starting point of model development.

## Criteria Used in Model Selection Methods

PROC GLMSELECT supports a variety of fit statistics that you can specify as criteria for the **CHOOSE=**, **SELECT=**, and **STOP=** options in the **MODEL** statement. The following statistics are available:

|          |                                                                                                                                        |
|----------|----------------------------------------------------------------------------------------------------------------------------------------|
| ADJRSQ   | adjusted R-square statistic (Darlington 1968; Judge et al. 1985)                                                                       |
| AIC      | Akaike's information criterion (Darlington 1968; Judge et al. 1985)                                                                    |
| AICC     | corrected Akaike's information criterion (Hurvich and Tsai 1989)                                                                       |
| BIC      | Sawa Bayesian information criterion (Sawa 1978; Judge et al. 1985)                                                                     |
| CP       | Mallows' $C_p$ statistic (Mallows 1973; Hocking 1976)                                                                                  |
| PRESS    | predicted residual sum of squares statistic                                                                                            |
| SBC      | Schwarz Bayesian information criterion (Schwarz 1978; Judge et al. 1985)                                                               |
| SL       | significance level of the $F$ statistic used to assess an effect's contribution to the fit when it is added to or removed from a model |
| VALIDATE | average square error over the validation data                                                                                          |

Table 45.10 provides formulas and definitions for the fit statistics.

**Table 45.10** Formulas and Definitions for Model Fit Summary Statistics

| Statistic        | Definition or Formula                                                                         |
|------------------|-----------------------------------------------------------------------------------------------|
| $n$              | Number of observations                                                                        |
| $p$              | Number of parameters including the intercept                                                  |
| $\hat{\sigma}^2$ | Estimate of pure error variance from fitting the full model                                   |
| SST              | Total sum of squares corrected for the mean for the dependent variable                        |
| SSE              | Error sum of squares                                                                          |
| ASE              | $\frac{SSE}{n}$                                                                               |
| MSE              | $\frac{SSE}{n-p}$                                                                             |
| $R^2$            | $1 - \frac{SSE}{SST}$                                                                         |
| ADJRSQ           | $1 - \frac{(n-1)(1-R^2)}{n-p}$                                                                |
| AIC              | $n \ln \left( \frac{SSE}{n} \right) + 2p + n + 2$                                             |
| AICC             | $1 + \ln \left( \frac{SSE}{n} \right) + \frac{2(p+1)}{n-p-2}$                                 |
| BIC              | $n \ln \left( \frac{SSE}{n} \right) + 2(p+2)q - 2q^2$ where $q = \frac{n\hat{\sigma}^2}{SSE}$ |
| CP ( $C_p$ )     | $\frac{SSE}{\hat{\sigma}^2} + 2p - n$                                                         |

Table 45.10 continued

### Formulas for AIC and AICC

There is some inconsistency in the literature on the precise definitions for the AIC and AICC statistics. The definitions used in PROC GLMSELECT changed between the experimental and the production release of the procedure in SAS 9.2. The definitions now used in PROC GLMSELECT yield the same final models as before, but PROC GLMSELECT makes the connection between the AIC statistic and the AICC statistic more transparent.

In the context of linear regression, several different versions of the formulas for AIC and AICC appear in the statistics literature. However, for a fixed number of observations, these different versions differ by additive and positive multiplicative constants. Because the model selected to yield a minimum of a criterion is not affected if the criterion is changed by additive and positive multiplicative constants, these changes in the formula for AIC and AICC do not affect the selection process.

The following section provides details about these changes. Formulas used in the experimental download release are denoted with a superscript of ( $d$ ) and  $n$ ,  $p$  and SSE are defined in Table 45.10.

The experimental download release of PROC GLMSELECT used the following formulas for AIC (Darlington 1968; Judge et al. 1985) and AICC (Hurvich, Simonoff, and Tsai 1998):

$$\text{AIC}^{(d)} = n \log\left(\frac{\text{SSE}}{n}\right) + 2p$$

and

$$\text{AICC}^{(d)} = \log\left(\frac{\text{SSE}}{n}\right) + 1 + \frac{2(p+1)}{n-p-2}$$

PROC GLMSLECT now uses the definitions of AIC and AICC found in Hurvich and Tsai (1989):

$$\text{AIC} = n \log\left(\frac{\text{SSE}}{n}\right) + 2p + n + 2$$

and

$$\text{AICC} = \text{AIC} + \frac{2(p+1)(p+2)}{n-p-2}$$

Hurvich and Tsai (1989) show that the formula for AICC can also be written as

$$\text{AICC} = n \log \left( \frac{\text{SSE}}{n} \right) + \frac{n(n+p)}{n-p-2}$$

The relationships between the alternative forms of the formulas are

$$\text{AIC} = \text{AIC}^{(d)} + n + 2$$

$$\text{AICC} = n \text{AICC}^{(d)}$$

---

## CLASS Variable Parameterization and the SPLIT Option

The GLMSELECT procedure supports nonsingular parameterizations for classification effects. A variety of these nonsingular parameterizations are available. You use the PARAM= option in the CLASS statement to specify the parameterization. See the section “Other Parameterizations” on page 387 in Chapter 19, “Shared Concepts and Topics,” for details.

PROC GLMSELECT also supports the ability to split classification effects. You can use the SPLIT option in the CLASS statement to request that the columns of the design matrix that correspond to any effect that contains a split classification variable can be selected to enter or leave a model independently of the other design columns of that effect. The following statements illustrate the use of SPLIT option together with other features of the CLASS statement:

```
data codingExample;
 drop i;
 do i=1 to 1000;
 c1 = 1 + mod(i,6);
 if i < 50 then c2 = 'very low ';
 else if i < 250 then c2 = 'low';
 else if i < 500 then c2 = 'medium';
 else if i < 800 then c2 = 'high';
 else c2 = 'very high';
 x1 = ranuni(1);
 x2 = ranuni(1);
 y = x1 + 10*(c1=3) +5*(c1=5) +rannor(1);
 output;
 end;
run;
proc glmselect data=codingExample;
 class c1(param=ref split) c2(param=ordinal order=data) /
 delimiter = ',' showcoding;
 model y = c1 c2 x1 x2/orderselect;
run;
```

The “Class Level Information” table shown in Figure 45.11 is produced by default whenever you specify a CLASS statement.

**Figure 45.11** Class Level Information

| The GLMSELECT Procedure |        |                                        |
|-------------------------|--------|----------------------------------------|
| Class Level Information |        |                                        |
| Class                   | Levels | Values                                 |
| c1                      | 6 *    | 1, 2, 3, 4, 5, 6                       |
| c2                      | 5      | very low, low, medium, high, very high |

\* Associated Parameters Split

Note that because the levels of the variable c2 contain embedded blanks, the DELIMITER="," option has been specified. The SHOWCODING option requests the display of the “Class Level Coding” table shown in Figure 45.12. An ordinal parameterization is used for c2 because its levels have a natural order. Furthermore, because these levels appear in their natural order in the data, you can preserve this order by specifying the ORDER=DATA option.

**Figure 45.12** Class Level Coding

| Class Level Coding |                  |   |   |   |   |  |
|--------------------|------------------|---|---|---|---|--|
| c1<br>Level        | Design Variables |   |   |   |   |  |
|                    | 1                | 2 | 3 | 4 | 5 |  |
| 1                  | 1                | 0 | 0 | 0 | 0 |  |
| 2                  | 0                | 1 | 0 | 0 | 0 |  |
| 3                  | 0                | 0 | 1 | 0 | 0 |  |
| 4                  | 0                | 0 | 0 | 1 | 0 |  |
| 5                  | 0                | 0 | 0 | 0 | 1 |  |
| 6                  | 0                | 0 | 0 | 0 | 0 |  |

The SPLIT option has been specified for the classification variable c1. This permits the parameters associated with the effect c1 to enter or leave the model individually. The “Parameter Estimates” table in Figure 45.13 shows that for this example the parameters that correspond to only levels 3 and 5 of c1 are in the selected model. Finally, note that the ORDERSELECT option in the MODEL statement specifies that the parameters are displayed in the order in which they first entered the model.

**Figure 45.13** Parameter Estimates

| Parameter Estimates |    |           |                |         |
|---------------------|----|-----------|----------------|---------|
| Parameter           | DF | Estimate  | Standard Error | t Value |
| Intercept           | 1  | -0.216680 | 0.068650       | -3.16   |
| c1_3                | 1  | 10.160900 | 0.087898       | 115.60  |
| c1_5                | 1  | 5.018015  | 0.087885       | 57.10   |
| x1                  | 1  | 1.315468  | 0.109772       | 11.98   |

## Macro Variables Containing Selected Models

Often you might want to perform postselection analysis by using other SAS procedures. To facilitate this, PROC GLMSELECT saves the list of selected effects in a macro variable. This list does not explicitly include the intercept so that you can use it in the **MODEL** statement of other SAS/STAT regression procedures.

The following table describes the macro variables that PROC GLMSELECT creates. Note that when BY processing is used, one macro variable, indexed by the BY group number, is created for each BY group.

| Macro Variable          | Description                   |
|-------------------------|-------------------------------|
| <b>No BY processing</b> |                               |
| _GLSIND1                | Selected model                |
| <b>BY processing</b>    |                               |
| _GLSNUMBYS              | Number of BY groups           |
| _GLSIND1                | Selected model for BY group 1 |
| _GLSIND2                | Selected model for BY group 2 |
| ...                     |                               |

You can use the macro variable `_GLSIND` as a synonym for `_GLSIND1`. If you do not use BY processing, `_GLSNUMBYS` is still defined and has the value 1.

To aid in associating indexed macro variables with the appropriate observations when BY processing is used, PROC GLMSELECT creates a variable `_BY_` in the output data set specified in an **OUTPUT** statement (see the section “**OUTPUT Statement**” on page 3555) that tags observations with an index that matches the index of the appropriate macro variable.

The following statements create a data set with two BY groups and run PROC GLMSELECT to select a model for each BY group.

```
data one(drop=i j);
 array x{5} x1-x5;
 do i=1 to 1000;
 classVar = mod(i,4)+1;
 do j=1 to 5;
 x{j} = ranuni(1);
 end;
 if i<400 then do;
 byVar = 'group 1';
 y = 3*classVar+7*x2+5*x2*x5+rannor(1);
 end;
 else do;
 byVar = 'group 2';
 y = 2*classVar+x5+rannor(1);
 end;
 output;
 end;
run;
```

```

proc glmselect data=one;
 by byVar;
 class classVar;
 model y = classVar x1|x2|x3|x4|x5 @2 /
 selection=stepwise(stop=aicc);
 output out=glmselectOutput;
run;

```

The preceding PROC GLMSELECT step produces three macro variables:

| Macro Variable | Value             | Description                            |
|----------------|-------------------|----------------------------------------|
| _GLSNUMBYS     | 2                 | Number of BY groups                    |
| _GLSIND1       | classVar x2 x2*x5 | Selected model for the first BY group  |
| _GLSIND2       | classVar x5       | Selected model for the second BY group |

You can now leverage these macro variables and the output data set created by PROC GLMSELECT to perform postselection analyses that match the selected models with the appropriate BY-group observations. For example, the following statements create and run a macro that uses PROC GLM to perform LSMeans analyses.

```

%macro LSMeansAnalysis;
 %do i=1 %to &_GLSNUMBYS;
 title1 "Analysis Using the Selected Model for BY group number &i";
 title2 "Selected Effects: &&_GLSIND&i";

 ods select LSMeans;
 proc glm data=glmselectOutput(where = (_BY_ = &i));
 class classVar;
 model y = &&_GLSIND&i;
 lsmeans classVar;
 run;quit;
 %end;
%mend;
%LSMeansAnalysis;

```

The LSMeans analysis output from PROC GLM is shown in [Output 45.14](#).

**Figure 45.14** LS-Means Analyses for Selected Models

## Using the STORE Statement

The preceding section shows how you can use macro variables to facilitate performing postselection analysis by using other SAS procedures. An alternative approach is to use the STORE statement to save the results of the PROC GLMSELECT step in an *item store*. You can then use the PLM procedure to obtain a rich set of postselection analyses. The following statements show how you can use this approach to obtain the same LSMeans analyses as shown in section “[Macro Variables Containing Selected Models](#)” on page 3572:

```
proc glmselect data=one;
 by byVar;
 class classVar;
 model y = classVar x1|x2|x3|x4|x5 @2 /
 selection=stepwise(stop=aicc);
 store out=glmselectStore;
run;

proc plm source=glmselectStore;
 lsmeans classVar;
run;
```

The LSMeans analysis output for the first BY group is shown in Figure 45.15.

**Figure 45.15** LS-Means Analysis Produced by PROC PLM

| The PLM Procedure            |          |                   |     |         |         |
|------------------------------|----------|-------------------|-----|---------|---------|

## Building the SSCP Matrix

Traditional implementations of FORWARD and STEPWISE selection methods start by computing the augmented crossproduct matrix for all the specified effects. This initial crossproduct matrix is updated as effects enter or leave the current model by sweeping the columns corresponding to the parameters of the entering or departing effects. Building the starting crossproduct matrix can be done with a single pass through the data and requires  $O(m^2)$  storage and  $O(nm^2)$  work, where  $n$  is the number of observations and  $m$  is the number of parameters. If  $k$  selection steps are done, then the total work sweeping effects in and out of the model is  $O(km^2)$ . When  $n \gg m$ , the work required is dominated by the time spent forming the crossproduct matrix. However, when  $m$  is large (tens of thousands), just storing the crossproduct matrix becomes intractable even though the number of selected parameters might be small. Note also that when interactions of classification effects are considered, the number of parameters considered can be large, even though the number of effects considered is much smaller.

When the number of selected parameters is smaller than the total number of parameters, it turns out that many of the crossproducts are not needed in the selection process. Let  $y$  denote the dependent variable, and suppose at some step of the selection process that  $\mathbf{X}$  denotes the  $n \times p$  design matrix columns corresponding to the currently selected model. Let  $\mathbf{Z} = \mathbf{z}_1, \mathbf{z}_2, \dots, \mathbf{z}_{m-p}$  denote the design matrix columns corresponding to the  $m - p$  effects not yet in the model. Then in order to compute the reduction in the residual sum of squares when  $\mathbf{z}_j$  is added to the model, the only additional crossproducts needed are  $\mathbf{z}'_j y$ ,  $\mathbf{z}'_j \mathbf{X}$ , and  $\mathbf{z}'_j \mathbf{z}_j$ . Note that it is not necessary to compute any of  $\mathbf{z}'_j \mathbf{z}_i$  with  $i \neq j$  and if  $p \ll m$ , and this yields a substantial saving in both memory required and computational work. Note, however, that this strategy does require a pass through the data at any step where adding an effect to the model is considered.

PROC GLMSELECT supports both of these strategies for building the crossproduct matrix. You can choose which of these strategies to use by specifying the `BUILDSSCP=FULL` or `BUILDSSCP=INCREMENTAL` option in the `PERFORMANCE` statement. If you request BACKWARD selection, then the full SSCP matrix is required. Similarly, if you request the BIC or CP criterion as the `SELECT=`, `CHOOSE=`, or `STOP=` criterion, or if you request the display of one or both of these criteria with the `STATS=BIC`, `STATS=CP`, or `STATS=ALL` option, then the full model needs to be computed. If you do not specify the `BUILDSSCP=` option, then PROC GLMSELECT switches to the incremental strategy if the number of effects is greater than one hundred. This default strategy is designed to give good performance when the number of selected

parameters is less than about 20% of the total number of parameters. Hence if you choose options that you know will cause the selected model to contain a significantly higher percentage of the total number of candidate parameters, then you should consider specifying `BUILDSSCP=FULL`. Conversely, if you specify fewer than 100 effects in the `MODEL` statement but many of these effects have a large number of associated parameters, then specifying `BUILDSSCP=INCREMENTAL` might result in improved performance.

## Model Averaging

As discussed in the section “[Model Selection Issues](#)” on page 3567, some well-known issues arise in performing model selection for inference and prediction. One approach to address these issues is to use resampled data as a proxy for multiple samples that are drawn from some conceptual probability distribution. A model is selected for each resampled set of data, and a predictive model is built by averaging the predictions of these selected models. You can perform this method of model averaging by using the `MODEL AVERAGE` statement. Resampling-based methods, in which samples are obtained by drawing with replacement from your data, fall under the umbrella of the widely studied methodology known as the bootstrap (Efron and Tibshirani 1993). For use of the bootstrap in the context of variable selection, see Breiman (1992).

By default, when the average is formed, models that are selected in multiple samples receive more weight than infrequently selected models. Alternatively, you can start by fitting a prespecified set of models on your data, then use information-theoretic approaches to assign a weight to each model in building a weighted average model. You can find a detailed discussion of this methodology in Burnham and Anderson (2002), in addition to some comparisons of this approach with bootstrap-based methods.

In the linear model context, the average prediction that you obtain from a set of models is the same as the prediction that you obtain with the single model whose parameter estimates are the averages of the corresponding estimates of the set of models. Hence, you can regard model averaging as a selection method that selects this average model. To show this, denote by  $\beta^{(i)}$  the parameter estimates for the sample  $i$  where  $\beta_j^{(i)} = 0$  if parameter  $j$  is not in the selected model for sample  $i$ . Then the predicted values  $\hat{y}^{(i)}$  for average model  $i$  are given by

$$\hat{y}^{(i)} = \mathbf{X}\boldsymbol{\beta}^{(i)}$$

where  $\mathbf{X}$  is the design matrix of the data to be scored. Forming averages gives

$$\hat{y}^{(*)} = \frac{1}{N} \sum_{i=1}^N \hat{y}^{(i)} = \frac{1}{N} \sum_{i=1}^N \mathbf{X}\boldsymbol{\beta}^{(i)} = \mathbf{X} \left( \frac{1}{N} \sum_{i=1}^N \boldsymbol{\beta}^{(i)} \right) = \mathbf{X}\boldsymbol{\beta}^{(*)}$$

where for parameter  $j$ ,  $\beta_j^{(*)} = \frac{1}{N} \sum_{i=1}^N \beta_j^{(i)}$ .

You can see that if a parameter estimate is nonzero for just a few of the sample models, then averaging the estimates for this parameter shrinks this estimate towards zero. It is this shrinkage that ameliorates the bias that a parameter is more likely to be selected if it is above its expected value rather than below it. This reduction in bias often produces improved predictions on new data that you obtain with the average model. However, the average model is not parsimonious since it has nonzero estimates for any parameter that is selected in any sample.

One resampling-based approach for obtaining a parsimonious model is to use the number of times that regressors are selected as an indication of importance and then to fit a new model that uses just the regressors that you deem to be most important. This approach is not without risk. One possible problem is that you

might have several regressors that, for purposes of prediction, can be used as surrogates for one another. In this case it is possible that none of these regressors individually appears in a large enough percentage of the sample models to be deemed important, even though every model contains at least one of them. Despite such potential problems, this strategy is often successful. You can implement this approach by using the REFIT option in the `MODEL AVERAGE` statement. By default, the REFIT option performs a second round of model averaging, where a fixed model that consists of the effects that are selected in a least twenty percent of the samples in the initial round of model averaging is used. The average model is obtained by averaging the ordinary least squares estimates obtained for each sample in the refit. Note that the default selection frequency cutoff of twenty percent is merely a heuristic guideline that often produces reasonable models.

Another approach to obtaining a parsimonious average model is to form the average of just the frequently selected models. You can implement this strategy by using the SUBSET option in the `MODEL AVERAGE` statement. However, in situations where there are many irrelevant regressors, it is often the case that most of the selected models are selected just once. In such situations, having a way to order the models that are selected with the same frequency is desirable. The following section discusses a way to do this.

### Model Selection Frequencies and Frequency Scores

The model frequency score orders models by their selection frequency, but also uses effect selection frequencies to order different models that are selected with the same frequency. Let  $\mathbf{x}_i$  denote the  $i$ th effect and let  $f_i$  denote the selection fraction for this effect.  $f_i$  is computed as the number of samples whose selected model contains effect  $\mathbf{x}_i$  divided by the number of samples. Suppose the  $j$ th model that consists of the  $K$  effects  $\mathbf{x}_{j_1}, \mathbf{x}_{j_2}, \dots, \mathbf{x}_{j_K}$  is selected  $m_j$  times. Then the model *frequency score*,  $s_j$ , for this model is computed as the sum of the model selection frequency and the average selection fraction for this model; that is,

$$s_j = m_j + \frac{\sum_{k=1}^K f_{j_k}}{K}$$

When you use the `BEST= $b$`  suboption of the SUBSET option in the `MODEL AVERAGE` statement, then the average model is formed from the  $b$  models with the largest model frequency scores.

---

## Using Validation and Test Data

When you have sufficient data, you can subdivide your data into three parts called the training, validation, and test data. During the selection process, models are fit on the training data, and the prediction error for the models so obtained is found by using the validation data. This prediction error on the validation data can be used to decide when to terminate the selection process or to decide what effects to include as the selection process proceeds. Finally, once a selected model has been obtained, the test set can be used to assess how the selected model generalizes on data that played no role in selecting the model.

In some cases you might want to use only training and test data. For example, you might decide to use an information criterion to decide what effects to include and when to terminate the selection process. In this case no validation data are required, but test data can still be useful in assessing the predictive performance of the selected model. In other cases you might decide to use validation data during the selection process but forgo assessing the selected model on test data. Hastie, Tibshirani, and Friedman (2001) note that it is difficult to give a general rule on how many observations you should assign to each role. They note that a typical split might be 50% for training and 25% each for validation and testing.

PROC GLMSELECT provides several methods for partitioning data into training, validation, and test data. You can provide data for each role in separate data sets that you specify with the `DATA=`, `TESTDATA=`, and `VALDATA=` options in the PROC GLMSELECT procedure. An alternative method is to use a `PARTITION` statement to logically subdivide the `DATA=` data set into separate roles. You can name the fractions of the data that you want to reserve as test data and validation data. For example, specifying

```
proc glmselect data=inData;
 partition fraction(test=0.25 validate=0.25);
 ...
run;
```

randomly subdivides the `inData` data set, reserving 50% for training and 25% each for validation and testing.

In some cases you might need to exercise more control over the partitioning of the input data set. You can do this by naming a variable in the input data set as well as a formatted value of that variable that correspond to each role. For example, specifying

```
proc glmselect data=inData;
 partition roleVar=group(test='group 1' train='group 2');
 ...
run;
```

assigns all roles observations in the `inData` data set based on the value of the variable named `group` in that data set. Observations where the value of `group` is 'group 1' are assigned for testing, and those with value 'group 2' are assigned to training. All other observations are ignored.

You can also combine the use of the `PARTITION` statement with named data sets for specifying data roles. For example,

```
proc glmselect data=inData testData=inTest;
 partition fraction(validate=0.4);
 ...
run;
```

reserves 40% of the `inData` data set for validation and uses the remaining 60% for training. Data for testing is supplied in the `inTest` data set. Note that in this case, because you have supplied a `TESTDATA=` data set, you cannot reserve additional observations for testing with the `PARTITION` statement.

When you use a `PARTITION` statement, the output data set created with an `OUTPUT` statement contains a character variable `_ROLE_` whose values 'TRAIN', 'TEST', and 'VALIDATE' indicate the role of each observation. `_ROLE_` is blank for observations that were not assigned to any of these three roles. When the input data set specified in the `DATA=` option in the PROC GLMSELECT statement contains an `_ROLE_` variable and no `PARTITION` statement is used, and `TESTDATA=` and `VALDATA=` are not specified, then the `_ROLE_` variable is used to define the roles of each observation. This is useful when you want to rerun PROC GLMSELECT but use the same data partitioning as in a previous PROC GLMSELECT step. For example, the following statements use the same data for testing and training in both PROC GLMSELECT steps:

```
proc glmselect data=inData;
 partition fraction(test=0.5);
 model y=x1-x10/selection=forward;
 output out=outDataForward;
run;
```

```
proc glmselect data=outDataForward;
 model y=x1-x10/selection=backward;
run;
```

When you have reserved observations for training, validation, and testing, a model fit on the training data is scored on the validation and test data, and the average squared error, denoted by ASE, is computed separately for each of these subsets. The ASE for each data role is the error sum of squares for observations in that role divided by the number of observations in that role.

### Using the Validation ASE as the STOP= Criterion

If you have provided observations for validation, then you can specify `STOP=VALIDATE` as a suboption of the `SELECTION=` option in the `MODEL` statement. At step  $k$  of the selection process, the best candidate effect to enter or leave the current model is determined. Note that here “best candidate” means the effect that gives the best value of the `SELECT=` criterion that need not be based on the validation data. The validation ASE for the model with this candidate effect added is computed. If this validation ASE is greater than the validation ASE for the model at step  $k$ , then the selection process terminates at step  $k$ .

### Using the Validation ASE as the CHOOSE= Criterion

When you specify the `CHOOSE=VALIDATE` suboption of the `SELECTION=` option in the `MODEL` statement, the validation ASE is computed for the models at each step of the selection process. The model at the first step yielding the smallest validation ASE is selected.

### Using the Validation ASE as the SELECT= Criterion

You request the validation ASE as the selection criterion by specifying the `SELECT=VALIDATE` suboption of the `SELECTION=` option in the `MODEL` statement. At step  $k$  of the selection process, the validation ASE is computed for each model where a candidate for entry is added or candidate for removal is dropped. The selected candidate for entry or removal is the one that yields a model with the minimal validation ASE.

---

## Cross Validation

Deciding when to stop a selection method is a crucial issue in performing effect selection. Predictive performance of candidate models on data not used in fitting the model is one approach supported by PROC GLMSELECT for addressing this problem (see the section “Using Validation and Test Data” on page 3577). However, in some cases, you might not have sufficient data to create a sizable training set and a validation set that represent the predictive population well. In these cases, cross validation is an attractive alternative for estimating prediction error.

In  $k$ -fold cross validation, the data are split into  $k$  roughly equal-sized parts. One of these parts is held out for validation, and the model is fit on the remaining  $k - 1$  parts. This fitted model is used to compute the predicted residual sum of squares on the omitted part, and this process is repeated for each of  $k$  parts. The sum of the  $k$  predicted residual sum of squares so obtained is the estimate of the prediction error that is denoted by `CVPRESS`. Note that computing the `CVPRESS` statistic for  $k$ -fold cross validation requires fitting  $k$  different models, and so the work and memory requirements increase linearly with the number of cross validation folds.

You can use the `CVMETHOD=` option in the `MODEL` statement to specify the method for splitting the data into  $k$  parts. `CVMETHOD=BLOCK( $k$ )` requests that the  $k$  parts be made of blocks of  $\text{floor}(n/k)$  or  $\text{floor}(n/k) + 1$  successive observations, where  $n$  is the number of observations. `CVMETHOD=SPLIT( $k$ )` requests that parts consist of observations  $\{1, k + 1, 2k + 1, 3k + 1, \dots\}$ ,  $\{2, k + 2, 2k + 2, 3k + 2, \dots\}$ , . . . ,  $\{k, 2k, 3k, \dots\}$ . `CVMETHOD=RANDOM( $k$ )` partitions the data into random subsets each with roughly  $\text{floor}(n/k)$  observations. Finally, you can use the formatted value of an input data set variable to define the parts by specifying `CVMETHOD=variable`. This last partitioning method is useful in cases where you need to exercise extra control over how the data are partitioned by taking into account factors such as important but rare observations that you want to “spread out” across the various parts.

You can request details of the CVPRESS computations by specifying the `CVDETAILS=` option in the `MODEL` statement. When you use cross validation, the output data set created with an `OUTPUT` statement contains an integer-valued variable, `_CVINDEX_`, whose values indicate the subset to which an observation is assigned.

The widely used special case of  $n$ -fold cross validation when you have  $n$  observations is known as *leave-one-out* cross validation. In this case, each omitted part consists of one observation, and CVPRESS statistic can be efficiently obtained without refitting the model  $n$  times. In this case, the CVPRESS statistic is denoted simply by PRESS and is given by

$$\text{PRESS} = \sum_{i=1}^n \left( \frac{r_i}{1 - h_i} \right)^2$$

where  $r_i$  is the residual and  $h_i$  is the leverage of the  $i$ th observation. You can request *leave-one-out* cross validation by specifying PRESS instead of CV with the options `SELECT=`, `CHOOSE=`, and `STOP=` in the `MODEL` statement. For example, if the number of observations in the data set is 100, then the following two PROC GLMSELECT steps are mathematically equivalent, but the second step is computed much more efficiently:

```
proc glmselect;
 model y=x1-x10/selection=forward(stop=CV) cvMethod=split(100);
run;

proc glmselect;
 model y=x1-x10/selection=forward(stop=PRESS);
run;
```

Hastie, Tibshirani, and Friedman (2001) include a discussion about choosing the cross validation fold. They note that as an estimator of true prediction error, cross validation tends to have decreasing bias but increasing variance as the number of folds increases. They recommend five- or tenfold cross validation as a good compromise. By default, PROC GLMSELECT uses `CVMETHOD=RANDOM(5)` for cross validation.

## Using Cross Validation as the STOP= Criterion

You request cross validation as the stopping criterion by specifying the `STOP=CV` suboption of the `SELECTION=` option in the `MODEL` statement. At step  $k$  of the selection process, the best candidate effect to enter or leave the current model is determined. Note that here “best candidate” means the effect that gives the best value of the `SELECT=` criterion that need not be the CV criterion. The CVPRESS score for the model with this candidate effect added or removed is determined. If this CVPRESS score is greater than the CVPRESS score for the model at step  $k$ , then the selection process terminates at step  $k$ .

## Using Cross Validation as the CHOOSE= Criterion

When you specify the `CHOOSE=CV` suboption of the `SELECTION=` option in the `MODEL` statement, the CVPRESS score is computed for the models at each step of the selection process. The model at the first step yielding the smallest CVPRESS score is selected.

## Using Cross Validation as the SELECT= Criterion

You request cross validation as the selection criterion by specifying the `SELECT=CV` suboption of the `SELECTION=` option in the `MODEL` statement. At step  $k$  of the selection process, the CVPRESS score is computed for each model where a candidate for entry is added or a candidate for removal is dropped. The selected candidate for entry or removal is the one that yields a model with the minimal CVPRESS score. Note that at each step of the selection process, this requires forming the CVPRESS statistic for all possible candidate models at the next step. Since forming the CVPRESS statistic for  $k$ -fold requires fitting  $k$  models, using cross validation as the selection criterion is computationally very demanding compared to using other selection criteria.

---

## Displayed Output

The following sections describe the displayed output produced by PROC GLMSELECT. The output is organized into various tables, which are discussed in the order of appearance. Note that the contents of a table might change depending on the options you specify.

### Model Information

The “Model Information” table displays basic information about the data sets and the settings used to control effect selection. These settings include the following:

- the selection method
- the criteria used to select effects, stop the selection, and choose the selected model
- the effect hierarchy enforced

The ODS name of the “Model Information” table is ModelInfo.

### Performance Settings

The “Performance Settings” table displays settings that affect performance. These settings include whether threading is enabled and the number of CPUs available as well as the method used to build the crossproduct matrices. This table is displayed only if you specify the `DETAILS` option in the `PERFORMANCE` statement. The ODS name of the “Performance Settings” table is PerfSettings.

### Number of Observations

The “Number of Observations” table displays the number of observations read from the input data set and the number of observations used in the analysis. If you specify a `FREQ` statement, the table also displays the sum of frequencies read and used. If you use a `PARTITION` statement, the table also displays the number

of observations used for each data role. If you specify `TESTDATA=` or `VALDATA=` data sets in the PROC GLMSELECT statement, then “Number of Observations” tables are also produced for these data sets. The ODS name of the “Number of Observations” table is `NObs`.

### Class Level Information

The “Class Level Information” table lists the levels of every variable specified in the `CLASS` statement. The ODS name of the “Class Level Information” table is `ClassLevelInfo`.

### Class Level Coding

The “Class Level Coding” table shows the coding used for variables specified in the `CLASS` statement. The ODS name of the “Class Level Coding” table is `ClassLevelCoding`.

### Dimensions

The “Dimensions” table displays information about the number of effects and the number of parameters from which the selected model is chosen. If you use split classification variables, then this table also includes the number of effects after splitting is taken into account. The ODS name of the “Dimensions” table is `Dimensions`.

### Candidates

The “Candidates” table displays the effect names and values of the criterion used to select entering or departing effects at each step of the selection process. The effects are displayed in sorted order from best to worst of the selection criterion. You request this table with the `DETAILS=` option in the `MODEL` statement. The ODS name of the “Candidates” table is `Candidates`.

### Selection Summary

The “Selection Summary” table displays details about the sequence of steps of the selection process. For each step, the effect that was entered or dropped is displayed along with the statistics used to select the effect, stop the selection, and choose the selected model. You can request that additional statistics be displayed with the `STATS=` option in the `MODEL` statement. For all criteria that you can use for model selection, the steps at which the optimal values of these criteria occur are also indicated. The ODS name of the “Selection Summary” table is `SelectionSummary`.

### Stop Reason

The “Stop Reason” table displays the reason why the selection stopped. To facilitate programmatic use of this table, an integer code is assigned to each reason and is included if you output this table by using an ODS `OUTPUT` statement. The reasons and their associated codes follow:

## Code Stop Reason

|    |                                                                        |
|----|------------------------------------------------------------------------|
| 1  | maximum number of steps done                                           |
| 2  | specified number of steps done                                         |
| 3  | specified number of effects in model                                   |
| 4  | stopping criterion at local optimum                                    |
| 5  | model is an exact fit                                                  |
| 6  | all entering effects are linearly dependent on those in the model      |
| 7  | all effects are in the model                                           |
| 8  | all effects have been dropped                                          |
| 9  | requested full least squares fit completed                             |
| 10 | stepwise selection is cycling                                          |
| 11 | dropping any effect does not improve the selection criterion           |
| 12 | no effects are significant at the specified SLE or SLS levels          |
| 13 | adding or dropping any effect does not improve the selection criterion |
| 14 | all remaining effects are required                                     |

The ODS name of the “Stop Reason” table is StopReason.

## Stop Details

The “Stop Details” table compares the optimal value of the stopping criterion at the final model with how it would change if the best candidate effect were to enter or leave the model. The ODS name of the “Stop Details” table is StopDetails.

## Selected Effects

The “Selected Effects” table displays a string containing the list of effects in the selected model. The ODS name of the “Selected Effects” table is SelectedEffects.

## ANOVA

The “ANOVA” table displays an analysis of variance for the selected model. This table includes the following:

- the Source of the variation, Model for the fitted regression, Error for the residual error, and C Total for the total variation after correcting for the mean. The Uncorrected Total Variation is produced when the **NOINT** option is used.
- the degrees of freedom (DF) associated with the source
- the Sum of Squares for the term
- the Mean Square, the sum of squares divided by the degrees of freedom
- the *F* Value for testing the hypothesis that all parameters are zero except for the intercept. This is formed by dividing the mean square for Model by the mean square for Error.

- the  $\text{Prob}>F$ , the probability of getting a greater  $F$  statistic than that observed if the hypothesis is true. Note that these  $p$ -values are displayed only if you specify the “SHOWPVALUES” option in the **MODEL** statement. These  $p$ -values are generally liberal because they are not adjusted for the fact that the terms in the model have been selected.

You can request “ANOVA” tables for the models at each step of the selection process with the **DETAILS=** option in the **MODEL** statement. The ODS name of the “ANOVA” table is ANOVA.

## Fit Statistics

The “Fit Statistics” table displays fit statistics for the selected model. The statistics displayed include the following:

- Root MSE, an estimate of the standard deviation of the error term. It is calculated as the square root of the mean square error.
- Dep Mean, the sample mean of the dependent variable
- R-square, a measure between 0 and 1 that indicates the portion of the (corrected) total variation attributed to the fit rather than left to residual error. It is calculated as  $\text{SS}(\text{Model})$  divided by  $\text{SS}(\text{Total})$ . It is also called the *coefficient of determination*. It is the square of the multiple correlation—in other words, the square of the correlation between the dependent variable and the predicted values.
- Adj R-Sq, the adjusted  $R^2$ , a version of  $R^2$  that has been adjusted for degrees of freedom. It is calculated as

$$\bar{R}^2 = 1 - \frac{(n - i)(1 - R^2)}{n - p}$$

where  $i$  is equal to 1 if there is an intercept and 0 otherwise,  $n$  is the number of observations used to fit the model, and  $p$  is the number of parameters in the model.

- fit criteria AIC, AICC, BIC, CP, and PRESS if they are used in the selection process or are requested with the **STATS=** option. See the section “Criteria Used in Model Selection Methods” on page 3568 for details and [Table 45.10](#) for the formulas for evaluating these criteria.
- the CVPRESS statistic when cross validation is used in the selection process. See the section “Cross Validation” on page 3579 for details.
- the average square errors (ASE) on the training, validation, and test data. See the section “Using Validation and Test Data” on page 3577 for details.

You can request “Fit Statistics” tables for the models at each step of the selection process with the **DETAILS=** option in the **MODEL** statement. The ODS name of the “Fit Statistics” table is FitStatistics.

## Cross Validation Details

The “Cross Validation Details” table displays the following:

- the fold number
- the number of observations used for fitting

- the number of observations omitted
- the predicted residual sum of squares on the omitted observations

You can request this table with the `CVDETAILS=` option in the `MODEL` statement whenever cross validation is used in the selection process. This table is displayed for the selected model, but you can request this table at each step of the selection process by using the `DETAILS=` option in the `MODEL` statement. The ODS name of the “Cross Validation Details” table is `CVDetails`.

## Parameter Estimates

The “Parameter Estimates” table displays the parameters in the selected model and their estimates. The information displayed for each parameter in the selected model includes the following:

- the parameter label that includes the effect name and level information for effects containing classification variables
- the degrees of freedom (DF) for the parameter. There is one degree of freedom unless the model is not full rank.
- the parameter estimate
- the standard error, which is the estimate of the standard deviation of the parameter estimate
- T for H0: Parameter=0, the  $t$  test that the parameter is zero. This is computed as the parameter estimate divided by the standard error.
- the Prob > |T|, the probability that a  $t$  statistic would obtain a greater absolute value than that observed given that the true parameter is zero. This is the two-tailed significance probability. Note that these  $p$ -values are displayed only if you specify the `SHOWPVALUES` option in the `MODEL` statement. These  $p$ -values are generally liberal because they are not adjusted for the fact that the terms in the model have been selected.

If cross validation is used in the selection process, then you can request that estimates of the parameters for each cross validation fold be included in the “Parameter Estimates” table by using the `CVDETAILS=` option in the `MODEL` statement. You can request “Parameter Estimates” tables for the models at each step of the selection process with the `DETAILS=` option in the `MODEL` statement. The ODS name of the “Parameter Estimates” table is `ParameterEstimates`.

## Score Information

For each `SCORE` statement, the “Score Information” table displays the names of the score input and output data sets, and the number of observations that were read and successfully scored. The ODS name of the “Score Information” table is `ScoreInfo`.

## Timing Breakdown

The “Timing Breakdown” table displays a broad breakdown of where time was spent in the `PROC GLM-SELECT` step. This table is displayed only if you specify the `DETAILS` option in the `PERFORMANCE` statement. The ODS name of the “Timing Breakdown” table is `Timing`.

## ODS Table Names

PROC GLMSELECT assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 45.11.

For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 45.11** ODS Tables Produced by PROC GLMSELECT

| ODS Table Name      | Description                                   | Statement     | Option           |
|---------------------|-----------------------------------------------|---------------|------------------|
| ANOVA               | Selected model ANOVA table                    | MODEL         | Default          |
| AvgParmEst          | Average parameter estimates                   | MODEL AVERAGE | Default          |
| BSplineDetails      | B-spline basis details                        | EFFECT        | DETAILS          |
| Candidates          | Entry/removal effect ranking                  | MODEL         | DETAILS=         |
| ClassLevelCoding    | Classification variable coding                | CLASS         | SHOWCODING       |
| ClassLevelInfo      | Classification variable levels                | CLASS         | Default          |
| CollectionLevelInfo | Levels of collection effects                  | EFFECT        | DETAILS          |
| CVDetails           | Cross validation PRESS by fold                | MODEL         | CVDETAILS=       |
| Dimensions          | Number of effects and parameters              | MODEL         | Default          |
| EffectSelectPct     | Effect selection percentages                  | MODEL AVERAGE | Default          |
| FitStatistics       | Selected model fit statistics                 | MODEL         | Default          |
| MMLevelInfo         | Levels of multimember effects                 | EFFECT        | DETAILS          |
| ModelAvgInfo        | Model averaging information                   | MODEL AVERAGE | Default          |
| ModelInfo           | Model information                             | MODEL         | Default          |
| ModelSelectFreq     | Model selection frequencies                   | MODEL AVERAGE | Default          |
| NObs                | Number of observations                        | MODEL         | Default          |
| ParameterNames      | Labels for column names in the design matrix  | PROC          | OUTDESIGN(names) |
| ParameterEstimates  | Selected model parameter estimates            | MODEL         | Default          |
| PerfSettings        | Performance settings                          | PERFORMANCE   | DETAILS          |
| PolynomialDetails   | Polynomial details                            | EFFECT        | DETAILS          |
| PolynomialScaling   | Polynomial scaling                            | EFFECT        | DETAILS          |
| RefitAvgParmEst     | Refit average parameter estimates             | MODEL AVERAGE | REFIT            |
| ScoreInfo           | Score request information                     | SCORE         | Default          |
| SelectedEffects     | List of selected effects                      | MODEL         | Default          |
| SelectionSummary    | Selection summary                             | MODEL         | Default          |
| StopDetails         | Stopping criterion details                    | MODEL         | Default          |
| StopReason          | Reason why selection stopped                  | MODEL         | Default          |
| Timing              | Timing details                                | PERFORMANCE   | DETAILS          |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

You must also specify the PLOTS= option in the PROC GLMSELECT statement.

The following sections describe the ODS graphical displays produced by PROC GLMSELECT. The examples use the Baseball data set that is described in the section “Getting Started: GLMSELECT Procedure” on page 3520.

## ODS Graph Names

PROC GLMSELECT assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 45.12.

**Table 45.12** Graphs Produced by PROC GLMSELECT

| ODS Graph Name      | Plot Description                                 | PLOTS Option         |
|---------------------|--------------------------------------------------|----------------------|
| AdjRSqPlot          | Adjusted R-square by step                        | CRITERIA(UNPACK)     |
| AICCPLOT            | Corrected Akaike’s information criterion by step | CRITERIA(UNPACK)     |
| AICPlot             | Akaike’s information criterion by step           | CRITERIA(UNPACK)     |
| ASEPlot             | Average square errors by step                    | ASE                  |
| BICPlot             | Sawa’s Bayesian information criterion by step    | CRITERIA(UNPACK)     |
| CandidatesPlot      | SELECT= criterion by effect                      | CANDIDATES           |
| ChooseCriterionPlot | CHOOSE= criterion by step                        | COEFFICIENTS(UNPACK) |
| CoefficientPanel    | Coefficients and CHOOSE= criterion by step       | COEFFICIENTS         |
| CoefficientPlot     | Coefficients by step                             | COEFFICIENTS(UNPACK) |
| CPPlot              | Mallows’ $C_p$ by step                           | CRITERIA(UNPACK)     |
| CriterionPanel      | Fit criteria by step                             | CRITERIA             |
| CVPRESSPlot         | Cross validation predicted RSS by step           | CRITERIA(UNPACK)     |
| EffectSelectPctPlot | Resampling effect selection percentages          | EFFECTSELECTPCT      |

Table 45.12 continued

| ODS Graph Name  | Plot Description                                | PLOTS= Option    |
|-----------------|-------------------------------------------------|------------------|
| ParmDistPanel   | Resampling parameter estimate distributions     | PARMDIST         |
| PRESSPlot       | Predicted RSS by step                           | CRITERIA(UNPACK) |
| SBCPlot         | Schwarz Bayesian information criterion by step  | CRITERIA(UNPACK) |
| ValidateASEPlot | Average square error on validation data by step | CRITERIA(UNPACK) |

### Candidates Plot

You request the “Candidates Plot” by specifying the PLOTS=CANDIDATES option in the PROC GLMSELECT statement and the DETAILS=STEPS option in the MODEL statement. This plot shows the values of selection criterion for the candidate effects for entry or removal, sorted from best to worst from left to right across the plot. The leftmost candidate displayed is the effect selected for entry or removal at that step. You can use this plot to see at what steps the decision about which effect to add or drop is clear-cut. See Figure 45.5 for an example.

### Coefficient Panel

When you specify the PLOTS=COEFFICIENTS option in the PROC GLMSELECT statement, PROC GLMSELECT produces a panel of two plots showing how the standardized coefficients and the criterion used to choose the final model evolve as the selection progresses. The following statements provide an example:

```
ods graphics on;

proc glmselect data=baseball plots=coefficients;
 class league division;
 model logSalary = nAtBat nHits nHome nRuns nRBI nBB
 yrMajor|yrMajor crAtBat|crAtBat crHits|crHits
 crHome|crHome crRuns|crRuns crRbi|crRbi
 crBB|crBB league division nOuts nAssts nError /
 selection=forward(stop=AICC CHOOSE=SBC);
run;
```

Figure 45.16 shows the requested graphic. The upper plot in the panel displays the standardized coefficients as a function of the step number. You can request standardized coefficients in the parameter estimates tables by specifying the STB option in the MODEL statement, but this option is not required to produce this plot. To help in tracing the changes in a parameter, the standardized coefficients for each parameter are connected by lines. Coefficients corresponding to effects that are not in the selected model at a step are zero and hence not observable. For example, consider the parameter crAtBat\*crAtBat in Output 45.16. Because crAtBat\*crAtBat enters the model at step 2, the line that represents this parameter starts rising from zero at step 1 when crRuns enters the model. Parameters that are nonzero at the final step of the selection are labeled if their magnitudes are greater than 1% of the range of the magnitudes of all the nonzero parameters at this step. To avoid collision, labels corresponding to parameters with similar values at the final step might get suppressed. You can control when this label collision avoidance occurs by using the LABELGAP=

suboption of the PLOTS=COEFFICIENTS option. Planned enhancements to the automatic label collision avoidance algorithm will obviate the need for this option in future releases of the GLMSELECT procedure.

**Figure 45.16** Coefficient Panel

The lower plot in the panel shows how the criterion used to choose among the examined models progresses. The selected step occurs at the optimal value of this criterion. In this example, this criterion is the SBC criterion and it achieves its minimal value at step 9 of the forward selection.

In some cases, particularly when the final step contains a large number of parameters, you might be interested in using this plot only to discern if and when the parameters in the model are essential unchanged beyond a certain step. In such cases, you might want to suppress the labeling of the parameters and use a numeric axis on the horizontal axis of the plot. You can do this using the STEPAXIS= and MAXPARMLABEL= suboptions of the PLOTS=CRITERIA option. The following statements provide an example:

```
proc glmselect data=baseball
 plots(unpack maxparmlabel=0 stepaxis=number)=coefficients;

 class league division;
 model logSalary = nAtBat nHits nHome nRuns nRBI nBB
 yrMajor|yrMajor crAtBat|crAtBat crHits|crHits
 crHome|crHome crRuns|crRuns crRbi|crRbi
```

```

crBB|crBB league division nOuts nAssts nError /
selection=forward(stop=none);

run;

```

The UNPACK = option requests that the plots of the coefficients and CHOOSE= criterion be shown in separate plots. The STEPAXIS=NUMBER option requests a numeric horizontal axis showing step number, and the MAXPAMLABEL=0 option suppresses the labels for the parameters. The “Coefficient Plot” is shown in Figure 45.17. You can see that the standardized coefficients do not vary greatly after step 16.

**Figure 45.17** Coefficient Plot

### Criterion Panel

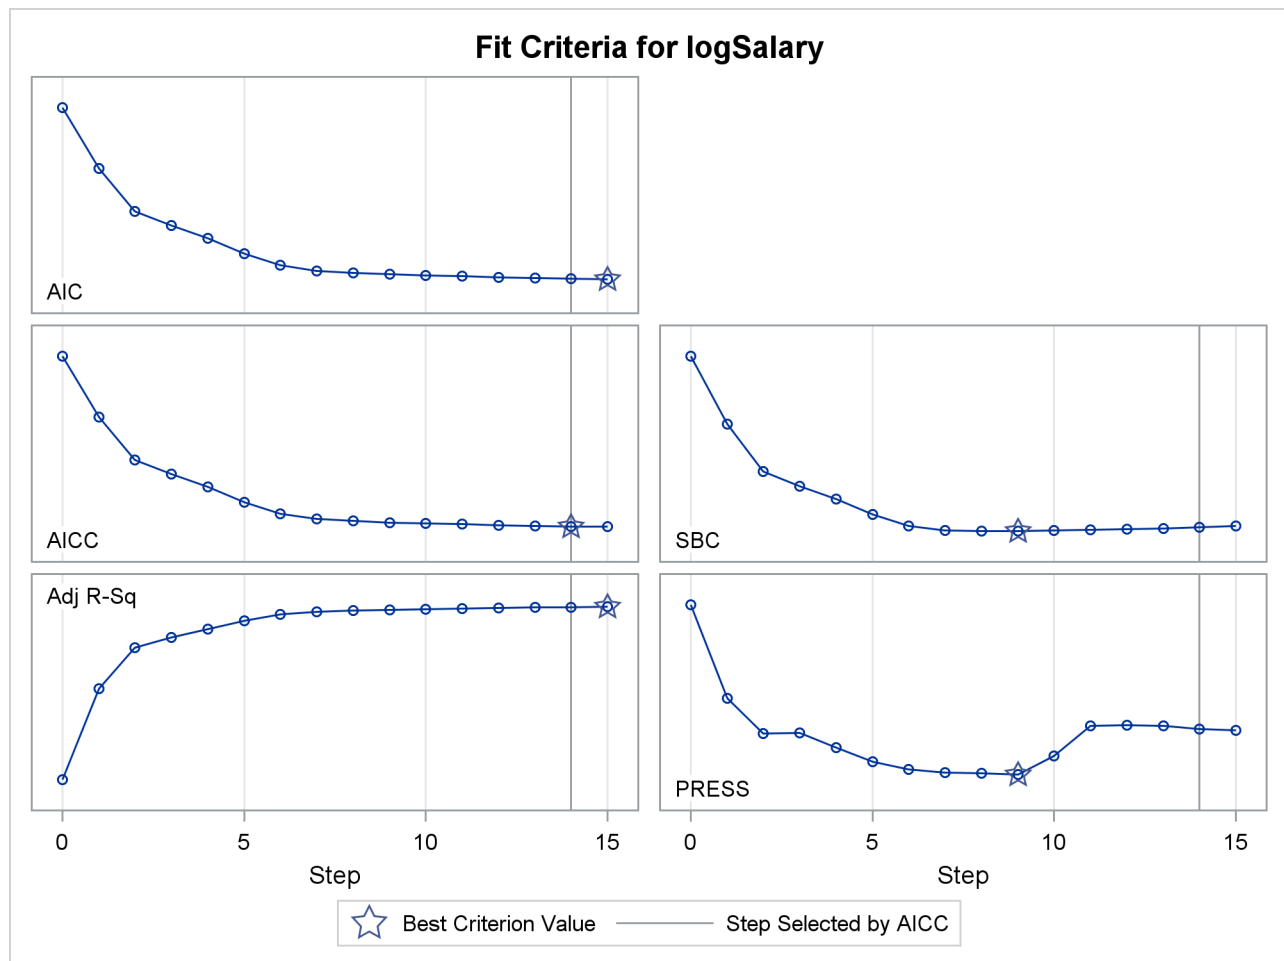

You request the criterion panel by specifying the PLOTS=CRITERIA option in the PROC GLMSELECT statement. This panel displays the progression of the ADJRSQ, AIC, AICC, and SBC criteria, as well as any other criteria that are named in the CHOOSE=, SELECT=, STOP=, or STATS= option in the MODEL statement.

The following statements provide an example:

```
proc glmselect data=baseball plots=criteria;
 class league division;
 model logSalary = nAtBat nHits nHome nRuns nRBI nBB
 yrMajor|yrMajor crAtBat|crAtBat crHits|crHits
 crHome|crHome crRuns|crRuns crRbi|crRbi
 crBB|crBB league division nOuts nAssts nError /
 selection=forward(steps=15 choose=AICC)
 stats=PRESS;
run;
```

Figure 45.18 shows the requested criterion panel. Note that the PRESS criterion is included in the panel because it is named in the `STATS=` option in the `MODEL` statement. The selected step is displayed as a vertical reference line on the plot of each criterion, and the legend indicates which of these criteria is used to make the selection. If the selection terminates for a reason other than optimizing a criterion displayed on this plot, then the legend will not report a reason for the selected step. The optimal value of each criterion is indicated with the “Star” marker. Note that it is possible that a better value of a criterion might have been reached had more steps of the selection process been done.

Figure 45.18 Criterion Panel

## Average Square Error Plot

You request the average square error plot by specifying the `PLOTS=ASE` option in the `PROC GLMSELECT` statement. This plot shows the progression of the average square error (ASE) evaluated separately on the training data, and the test and validation data whenever these data are provided with the `TESTDATA=` and `VALDATA=` options or are produced by using a `PARTITION` statement. You use the plot to detect when overfitting the training data occurs. The ASE decreases monotonically on the training data as parameters are added to a model. However, the average square error on test and validation data typically starts increasing when overfitting occurs. See [Output 45.1.9](#) and [Output 45.2.6](#) for examples.

## Examining Specific Step Ranges

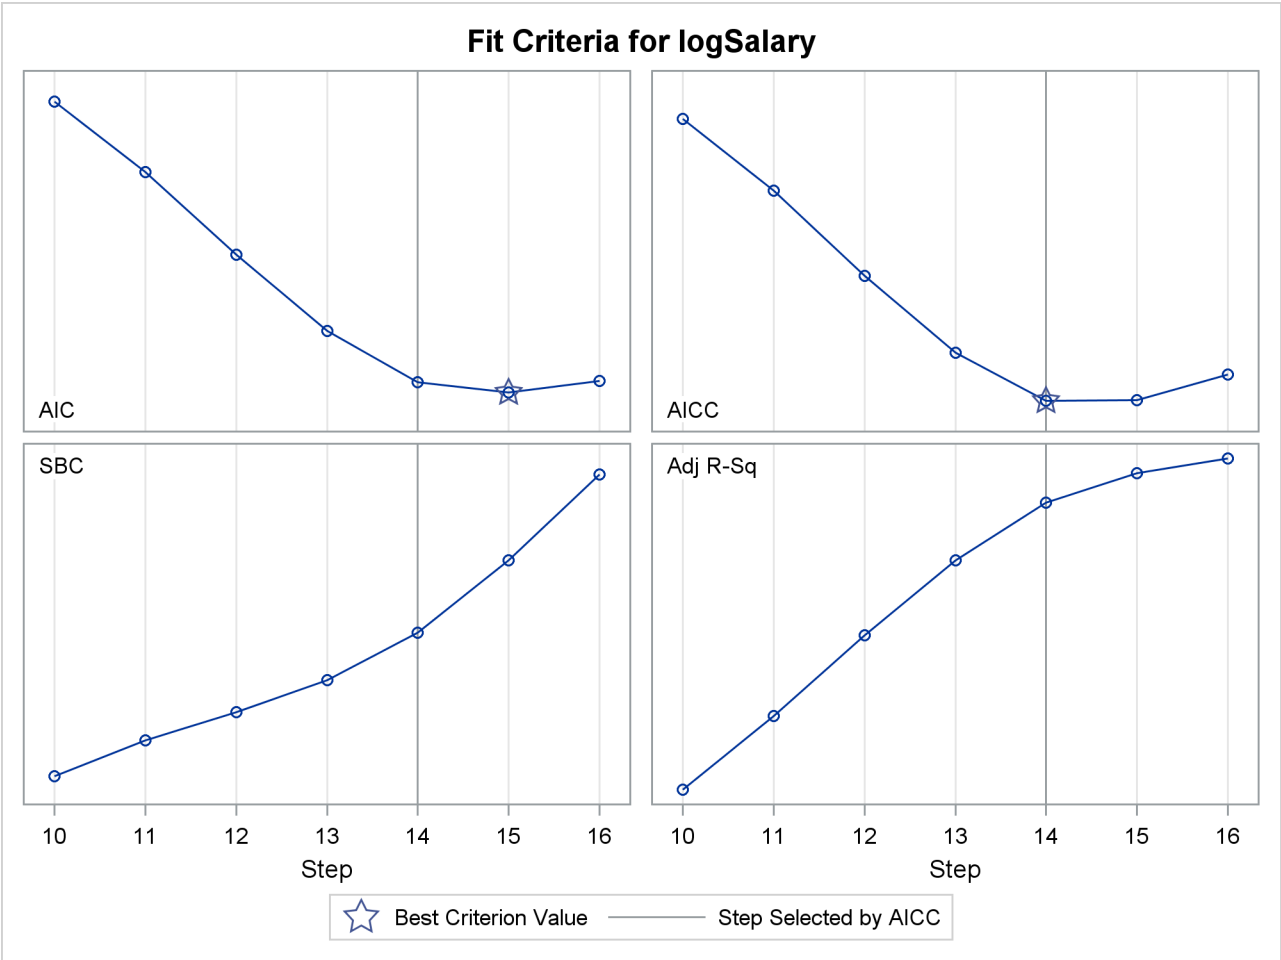

The coefficient panel, criterion panel, and average square error plot display information for all the steps examined in the selection process. In some cases, you might want to focus attention on just a particular step range. For example, it is hard to discern the variation in the criteria displayed in [Figure 45.18](#) near the selected step because the variation in these criteria in the steps close to the selected step is small relative to the variation across all steps. You can request a range of steps to display using the `STARTSTEP=` and `ENDSTEP=` suboptions of the `PLOTS=` option. You can specify these options as both global and specific plot options, with the specific options taking precedence if both are specified. The following statements provide an example:

```
proc glmselect data=baseball plots=criteria(startstep=10 endstep=16);
 class league division;
 model logSalary = nAtBat nHits nHome nRuns nRBI nBB
 yrMajor|yrMajor crAtBat|crAtBat crHits|crHits
 crHome|crHome crRuns|crRuns crRbi|crRbi
 crBB|crBB league division nOuts nAssts nError /
 selection=forward(stop=none choose=AICC);
run;

ods graphics off;
```

[Figure 45.19](#) shows the progression of the fit criteria between steps 10 and 16. Note that if the optimal value of a criterion does not occur in this specified step range, then no optimal marker appears for that criterion. The plot of the SBC criterion in [Figure 45.19](#) is one such case.

Figure 45.19 Criterion Panel for Specified Step Range

---

## Examples: GLMSELECT Procedure

---

### Example 45.1: Modeling Baseball Salaries Using Performance Statistics

This example continues the investigation of the baseball data set introduced in the section “Getting Started: GLMSELECT Procedure” on page 3520. In that example, the default stepwise selection method based on the SBC criterion was used to select a model. In this example, model selection that uses other information criteria and out-of-sample prediction criteria is explored.

PROC GLMSELECT provides several selection algorithms that you can customize by specifying criteria for selecting effects, stopping the selection process, and choosing a model from the sequence of models at each step. For more details on the criteria available, see the section “Criteria Used in Model Selection Methods” on page 3568. The `SELECT=SL` suboption of the `SELECTION=` option in the `MODEL` statement in the following code requests the traditional hypothesis test-based stepwise selection approach, where effects in the model that are not significant at the stay significance level (SLS) are candidates for removal and effects not yet in the model whose addition is significant at the entry significance level (SLE) are candidates for addition to the model.

```
ods graphics on;

proc glmselect data=baseball plot=CriterionPanel;
 class league division;
 model logSalary = nAtBat nHits nHome nRuns nRBI nBB
 yrMajor crAtBat crHits crHome crRuns crRbi
 crBB league division nOuts nAssts nError
 / selection=stepwise(select=SL) stats=all;
run;
```

The default SLE and SLS values of 0.15 might not be appropriate for these data. One way to investigate alternative ways to stop the selection process is to assess the sequence of models in terms of model fit statistics. The `STATS=ALL` option in the `MODEL` statement requests that all model fit statistics for assessing the sequence of models of the selection process be displayed. To help in the interpretation of the selection process, you can use graphics supported by PROC GLMSELECT. ODS Graphics must be enabled before requesting plots. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” With ODS Graphics enabled, the `PLOTS=CRITERIONPANEL` option in the PROC GLMSELECT statement produces the criterion panel shown in [Output 45.1.1](#).

Output 45.1.1 Criterion Panel

You can see in [Output 45.1.1](#) that this stepwise selection process would stop at an earlier step if you use the Schwarz Bayesian information criterion (SBC) or predicted residual sum of squares (PRESS) to assess the selected models as stepwise selection progresses. You can use the `CHOOSE=` suboption of the `SELECTION=` option in the `MODEL` statement to specify the criterion you want to use to select among the evaluated models. The following statements use the PRESS statistic to choose among the models evaluated during the stepwise selection.

```
proc glmselect data=baseball;
 class league division;
 model logSalary = nAtBat nHits nHome nRuns nRBI nBB
 yrMajor crAtBat crHits crHome crRuns crRbi
 crBB league division nOuts nAssts nError
 / selection=stepwise(select=SL choose=PRESS);
run;
```

Note that the selected model is the model at step 9. By default, PROC GLMSELECT displays the selected model, ANOVA and fit statistics, and parameter estimates for the selected model. These are shown in [Output 45.1.2](#).

## Output 45.1.2 Details of Selected Model

| yrMajor                                                           | 1   | 0.070056       | 0.018911       | 3.70    |
| crHits                                                            | 1   | 0.000247       | 0.000143       | 1.72    |
| division East                                                     | 1   | 0.143082       | 0.070972       | 2.02    |
| division West                                                     | 0   | 0              | .              | .       |
| nOuts                                                             | 1   | 0.000241       | 0.000134       | 1.81    |

Even though the model that is chosen to give the smallest value of the PRESS statistic is the model at step 9, the stepwise selection process continues to the step where the stopping condition based on entry and stay significance levels is met. If you use the PRESS statistic as the stopping criterion, the stepwise selection process stops at step 9. This ability to stop at the first extremum of the criterion you specify can significantly reduce the amount of computation done, especially in the cases where you are selecting from a large number of effects. The following statements request stopping based on the PRESS statistic. The stop reason and stop details tables are shown in [Output 45.1.3](#).

```
proc glmselect data=baseball plot=Coefficients;
 class league division;
 model logSalary = nAtBat nHits nHome nRuns nRBI nBB
 yrMajor crAtBat crHits crHome crRuns crRbi
 crBB league division nOuts nAssts nError
 / selection=stepwise(select=SL stop=PRESS);
run;
```

**Output 45.1.3** Stopping Based on PRESS Statistic

| The GLMSELECT Procedure                                      |        |                 |         |         |
|--------------------------------------------------------------|--------|-----------------|---------|---------|
| Selection stopped at a local minimum of the PRESS criterion. |        |                 |         |         |
| Stop Details                                                 |        |                 |         |         |
| Candidate For                                                | Effect | Candidate PRESS | Compare | PRESS   |
| Entry                                                        | crBB   | 88.6321         | >       | 88.5528 |
| Removal                                                      | nAtBat | 88.6866         | >       | 88.5528 |

The `PLOTS=COEFFICIENTS` specification in the PROC GLMSELECT statement requests a plot that enables you to visualize the selection process.

Output 45.1.4 Coefficient Progression Plot

Output 45.1.4 shows the standardized coefficients of all the effects selected at some step of the stepwise method plotted as a function of the step number. This enables you to assess the relative importance of the effects selected at any step of the selection process as well as providing information as to when effects entered the model. The lower plot in the panel shows how the criterion used to choose the selected model changes as effects enter or leave the model.

Model selection is often done in order to obtain a parsimonious model that can be used for prediction on new data. An ever-present danger is that of selecting a model that overfits the “training” data used in the fitting process, yielding a model with poor predictive performance. Using cross validation is one way to assess the predictive performance of the model. Using  $k$ -fold cross validation, the training data are subdivided into  $k$  parts, and at each step of the selection process, models are obtained on each of the  $k$  subsets of the data obtained by omitting one of these parts. The cross validation predicted residual sum of squares, denoted CV PRESS, is obtained by summing the squares of the residuals when each of these submodels is scored on the data omitted in fitting the submodel. Note that the PRESS statistic corresponds to the special case of “leave-one-out” cross validation.

In the preceding example, the PRESS statistic was used to choose among models that were chosen based on entry and stay significance levels. In the following statements, the `SELECT=CVPRESS` suboption of the `SELECTION=` option in the `MODEL` statement requests that the CV PRESS statistic itself be used

as the selection criterion. The `DROP=COMPETITIVE` suboption requests that additions and deletions be considered simultaneously when deciding whether to add or remove an effect. At any step, the CV PRESS statistic for all models obtained by deleting one effect from the model or adding one effect to the model is computed. Among these models, the one yielding the smallest value of the CV PRESS statistic is selected and the process is repeated from this model. The stepwise selection terminates if all additions or deletions increase the CV PRESS statistic. The `CVMETHOD=SPLIT(5)` option requests five-fold cross validation with the five subsets consisting of observations {1, 6, 11, ...}, {2, 7, 12, ...}, and so on.

```
proc glmselect data=baseball plot=Candidates;
 class league division;
 model logSalary = nAtBat nHits nHome nRuns nRBI nBB
 yrMajor crAtBat crHits crHome crRuns crRbi
 crBB league division nOuts nAssts nError
 / selection=stepwise(select=CV drop=competitive)
 cvMethod=split(5);
run;
```

The selection summary table is shown in [Output 45.1.5](#). By comparing [Output 45.1.5](#) and [Output 45.6](#) you can see that the sequence of models produced is different from the sequence when the stepwise selection is based on the SBC statistic.

**Output 45.1.5** Stepwise Selection Based on Cross Validation

\* Optimal Value Of Criterion

If you have sufficient data, another way you can assess the predictive performance of your model is to reserve part of your data for testing your model. You score the model obtained using the training data on the test data and assess the predictive performance on these data that had no role in the selection process. You can also reserve part of your data to validate the model you obtain in the training process. Note that the validation data are not used in obtaining the coefficients of the model, but they are used to decide when to stop the selection process to limit overfitting.

PROC GLMSELECT enables you to partition your data into disjoint subsets for training validation and testing roles. This partitioning can be done by using random proportions of the data, or you can designate a variable in your data set that defines which observations to use for each role. See the section “[PARTITION Statement](#)” on page 3556 for more details.

The following statements randomly partition the baseball data set, using 50% for training, 30% for validation, and 20% for testing. The model selected at each step is scored on the validation data, and the average residual sums of squares (ASE) is evaluated. The model yielding the lowest ASE on the validation data is selected. The ASE on the test data is also evaluated, but these data play no role in the selection process. Note that a seed for the pseudo-random number generator is specified in the PROC GLMSELECT statement.

```
proc glmselect data=baseball plots=(CriterionPanel ASE) seed=1;
 partition fraction(validate=0.3 test=0.2);
 class league division;
 model logSalary = nAtBat nHits nHome nRuns nRBI nBB
 yrMajor crAtBat crHits crHome crRuns crRbi
 crBB league division nOuts nAssts nError
 / selection=forward(choose=validate stop=10);
run;
```

**Output 45.1.6** Number of Observations Table

| The GLMSELECT Procedure                    |     |
|--------------------------------------------|-----|
| Number of Observations Read                | 322 |
| Number of Observations Used                | 263 |
| Number of Observations Used for Training   | 132 |
| Number of Observations Used for Validation | 80  |
| Number of Observations Used for Testing    | 51  |

Output 45.1.6 shows the number of observation table. You can see that of the 263 observations that were used in the analysis, 132 (50.2%) observations were used for model training, 80 (30.4%) for model validation, and 51 (19.4%) for model testing.

**Output 45.1.7** Selection Summary and Stop Reason

```

9 nAtBat 0.3337 0.4580

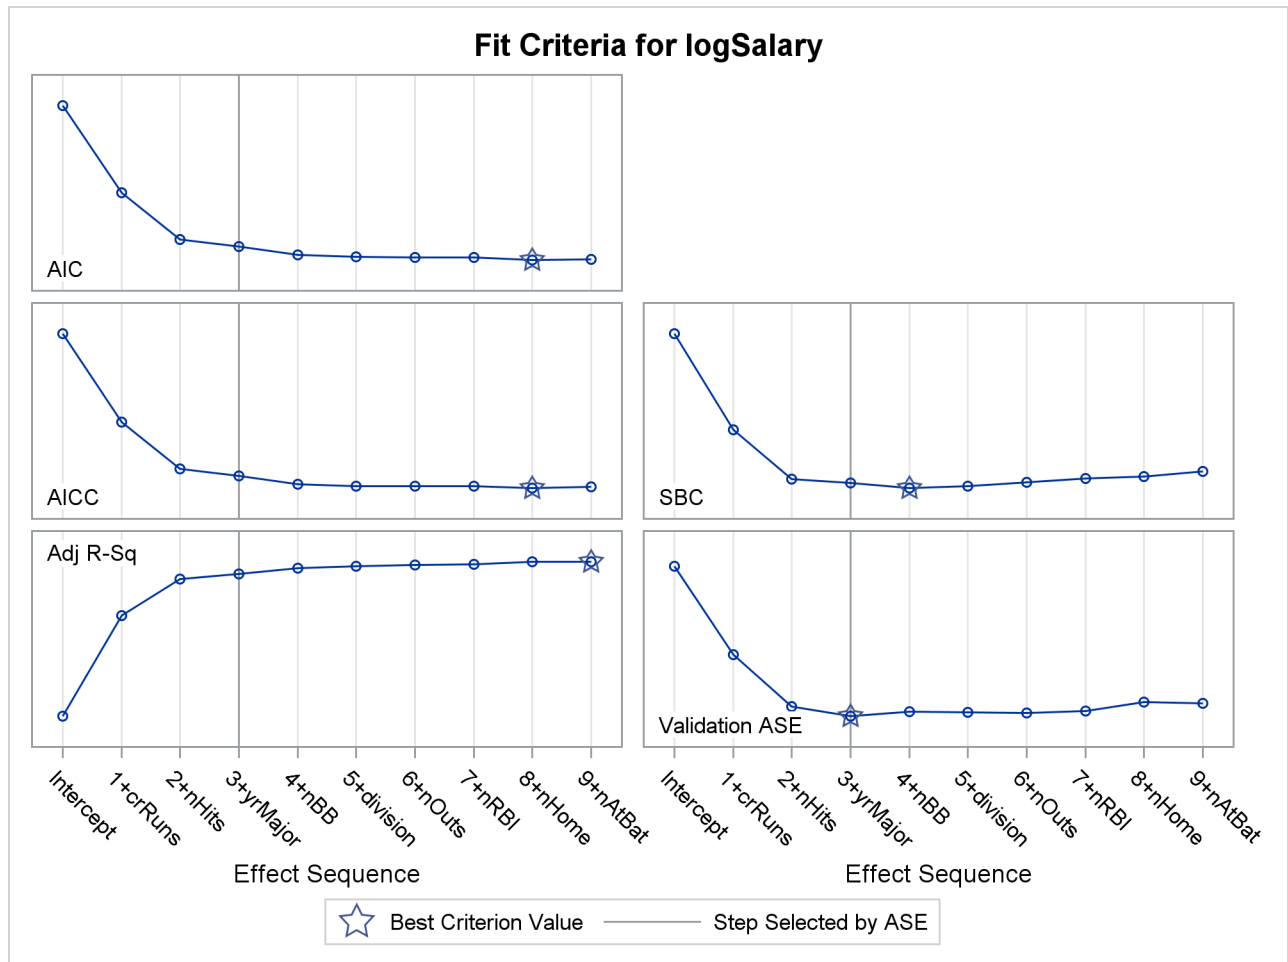

* Optimal Value Of Criterion

Selection stopped at the first model containing the specified number of effects
(10) .

```

Output 45.1.7 shows the selection summary table and the stop reason. The forward selection stops at step 9 since the model at this step contains 10 effects, and so it satisfies the stopping criterion requested with the STOP=10 suboption. However, the selected model is the model at step 3, where the validation ASE, the CHOOSE= criterion, achieves its minimum.

Output 45.1.8 Criterion Panel

The criterion panel in [Output 45.1.8](#) shows how the various criteria evolved as the stepwise selection method proceeded. Note that other than the ASE evaluated on the validation data, these criteria are evaluated on the training data.

Output 45.1.9 Average Square Errors by Role

Finally, the ASE plot in [Output 45.1.9](#) shows how the average square error evolves on the training, validation, and test data. Note that while the ASE on the training data continued decreasing as the selection steps proceeded, the ASE on the test and validation data behave more erratically.

LASSO selection, pioneered by Tibshirani (1996), is a constrained least squares method that can be viewed as a stepwise-like method where effects enter and leave the model sequentially. You can find additional details about the LASSO method in the section “[Lasso Selection \(LASSO\)](#)” on page 3565. Note that when classification effects are used with LASSO, the design matrix columns for all effects containing classification variables can enter or leave the model individually. The following statements perform LASSO selection for the baseball data. The LASSO selection summary table is shown in [Output 45.1.10](#).

```
proc glmselect data=baseball plot=CriterionPanel ;
 class league division;
 model logSalary = nAtBat nHits nHome nRuns nRBI nBB
 yrMajor crAtBat crHits crHome crRuns crRbi
 crBB league division nOuts nAssts nError
 / selection=lasso(choose=CP steps=20);
run;

ods graphics off;
```

**Example 45.2: Using Validation and Cross Validation**

This example shows how you can use both test set and cross validation to monitor and control variable selection. It also demonstrates the use of split classification variables.

The following statements produce analysis and test data sets. Note that the same statements are used to generate the observations that are randomly assigned for analysis and test roles in the ratio of approximately two to one.

```

data analysisData testData;
 drop i j c3Num;
 length c3$ 7;

 array x{20} x1-x20;

 do i=1 to 1500;
 do j=1 to 20;
 x{j} = ranuni(1);
 end;

 c1 = 1 + mod(i,8);
 c2 = ranbin(1,3,.6);

 if i < 50 then do; c3 = 'tiny'; c3Num=1;end;
 else if i < 250 then do; c3 = 'small'; c3Num=1;end;
 else if i < 600 then do; c3 = 'average'; c3Num=2;end;
 else if i < 1200 then do; c3 = 'big'; c3Num=3;end;
 else do; c3 = 'huge'; c3Num=5;end;

 y = 10 + x1 + 2*x5 + 3*x10 + 4*x20 + 3*x1*x7 + 8*x6*x7
 + 5*(c1=3)*c3Num + 8*(c1=7) + 5*rannor(1);

 if ranuni(1) < 2/3 then output analysisData;
 else output testData;
 end;
run;

```

Suppose you suspect that the dependent variable depends on both main effects and two-way interactions. You can use the following statements to select a model:

```

ods graphics on;

proc glmselect data=analysisData testdata=testData
 seed=1 plots(stepAxis=number)=(criterionPanel ASEPlot);
 partition fraction(validate=0.5);
 class c1 c2 c3(order=data);
 model y = c1|c2|c3|x1|x2|x3|x4|x5|x5|x6|x7|x8|x9|x10
 |x11|x12|x13|x14|x15|x16|x17|x18|x19|x20 @2
 / selection=stepwise(choose = validate
 select = s1)
 hierarchy=single stb;
run;

```

Note that a `TESTDATA=` data set is named in the PROC GLMSELECT statement and that a `PARTITION` statement is used to randomly assign half the observations in the analysis data set for model validation and the rest for model training. You find details about the number of observations used for each role in the number of observations tables shown in [Output 45.2.1](#).

**Output 45.2.1** Number of Observations Tables

| The GLMSELECT Procedure                    |      |
|--------------------------------------------|------|
| Observation Profile for Analysis Data      |      |
| Number of Observations Read                | 1010 |
| Number of Observations Used                | 1010 |
| Number of Observations Used for Training   | 510  |
| Number of Observations Used for Validation | 500  |

The “Class Level Information” and “Dimensions” tables are shown in [Output 45.2.2](#). The “Dimensions” table shows that at each step of the selection process, 278 effects are considered as candidates for entry or removal. Since several of these effects have multilevel classification variables as members, there are 661 parameters.

**Output 45.2.2** Class Level Information and Problem Dimensions

| Class Level Information |        |                             |
|-------------------------|--------|-----------------------------|
| Class                   | Levels | Values                      |
| c1                      | 8      | 1 2 3 4 5 6 7 8             |
| c2                      | 4      | 0 1 2 3                     |
| c3                      | 5      | tiny small average big huge |

| Dimensions           |     |
|----------------------|-----|
| Number of Effects    | 278 |
| Number of Parameters | 661 |

The model statement options request stepwise selection with the default entry and stay significance levels used for both selecting entering and departing effects and stopping the selection method. The **CHOOSE=VALIDATE** suboption specifies that the selected model is chosen to minimize the predicted residual sum of squares when the models at each step are scored on the observations reserved for validation. The **HIERARCHY=SINGLE** option specifies that interactions can enter the model only if the corresponding main effects are already in the model, and that main effects cannot be dropped from the model if an interaction with such an effect is in the model. These settings are listed in the model information table shown in [Output 45.2.3](#).

**Output 45.2.3** Model Information

| The GLMSELECT Procedure        |                    |
|--------------------------------|--------------------|
| Data Set                       | WORK.ANALYSISDATA  |
| Test Data Set                  | WORK.TESTDATA      |
| Dependent Variable             | Y                  |
| Selection Method               | Stepwise           |
| Select Criterion               | Significance Level |
| Stop Criterion                 | Significance Level |
| Choose Criterion               | Validation ASE     |
| Entry Significance Level (SLE) | 0.15               |
| Stay Significance Level (SLS)  | 0.15               |
| Effect Hierarchy Enforced      | Single             |
| Random Number Seed             | 1                  |

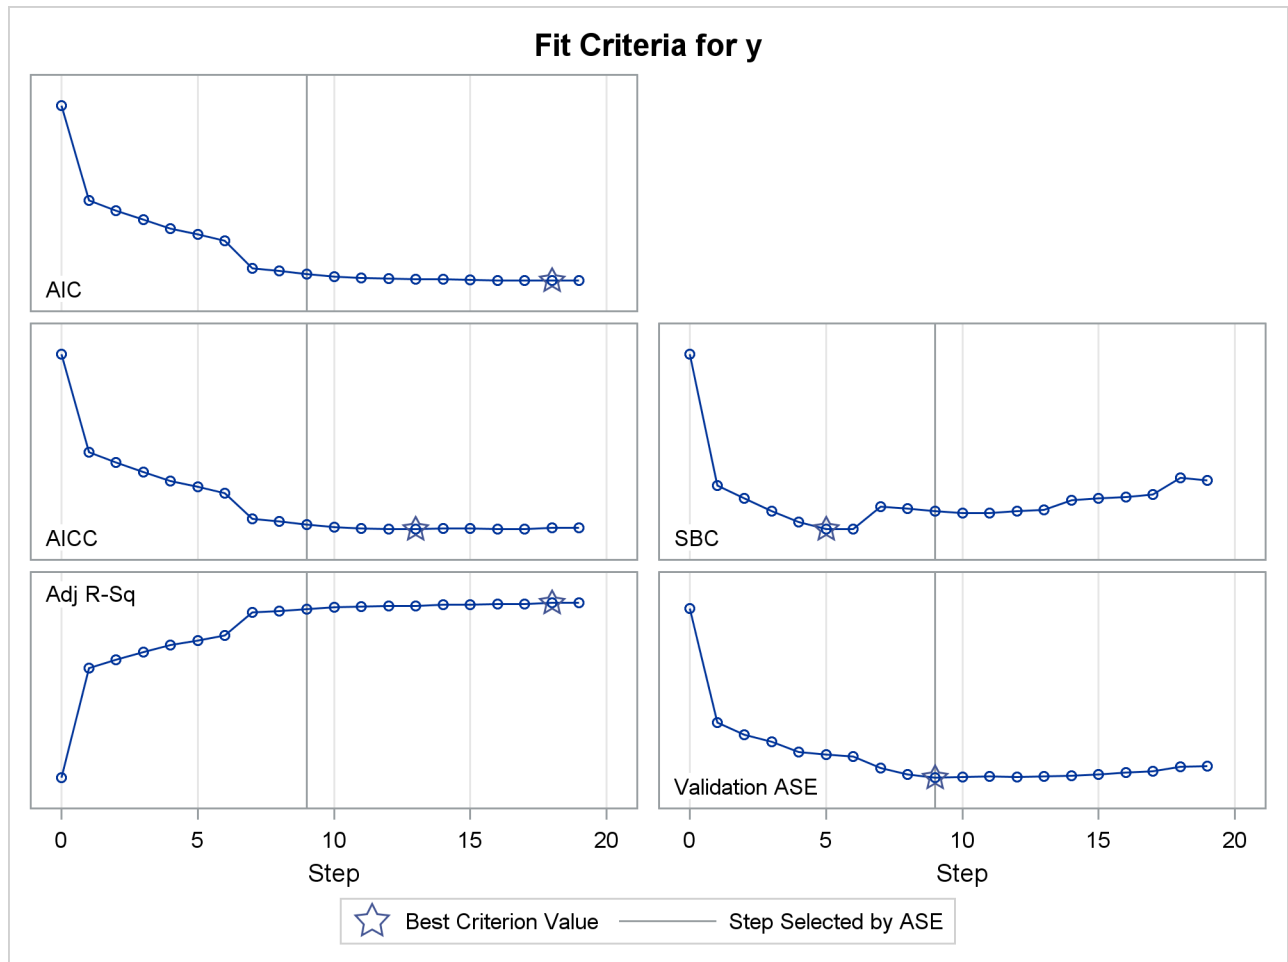

The stop reason and stop details tables are shown in [Output 45.2.4](#). Note that because the `STOP=` suboption of the `SELECTION=` option was not explicitly specified, the stopping criterion used is the selection criterion, namely significance level.

**Output 45.2.4** Stop Details

| Selection stopped because the candidate for entry has SLE > 0.15 and the candidate for removal has SLS < 0.15. |        |                        |         |              |       |
|----------------------------------------------------------------------------------------------------------------|--------|------------------------|---------|--------------|-------|
| Stop Details                                                                                                   |        |                        |         |              |       |
| Candidate For                                                                                                  | Effect | Candidate Significance | Compare | Significance |       |
| Entry                                                                                                          | x2*x5  | 0.1742                 | >       | 0.1500       | (SLE) |
| Removal                                                                                                        | x5*x10 | 0.0534                 | <       | 0.1500       | (SLS) |

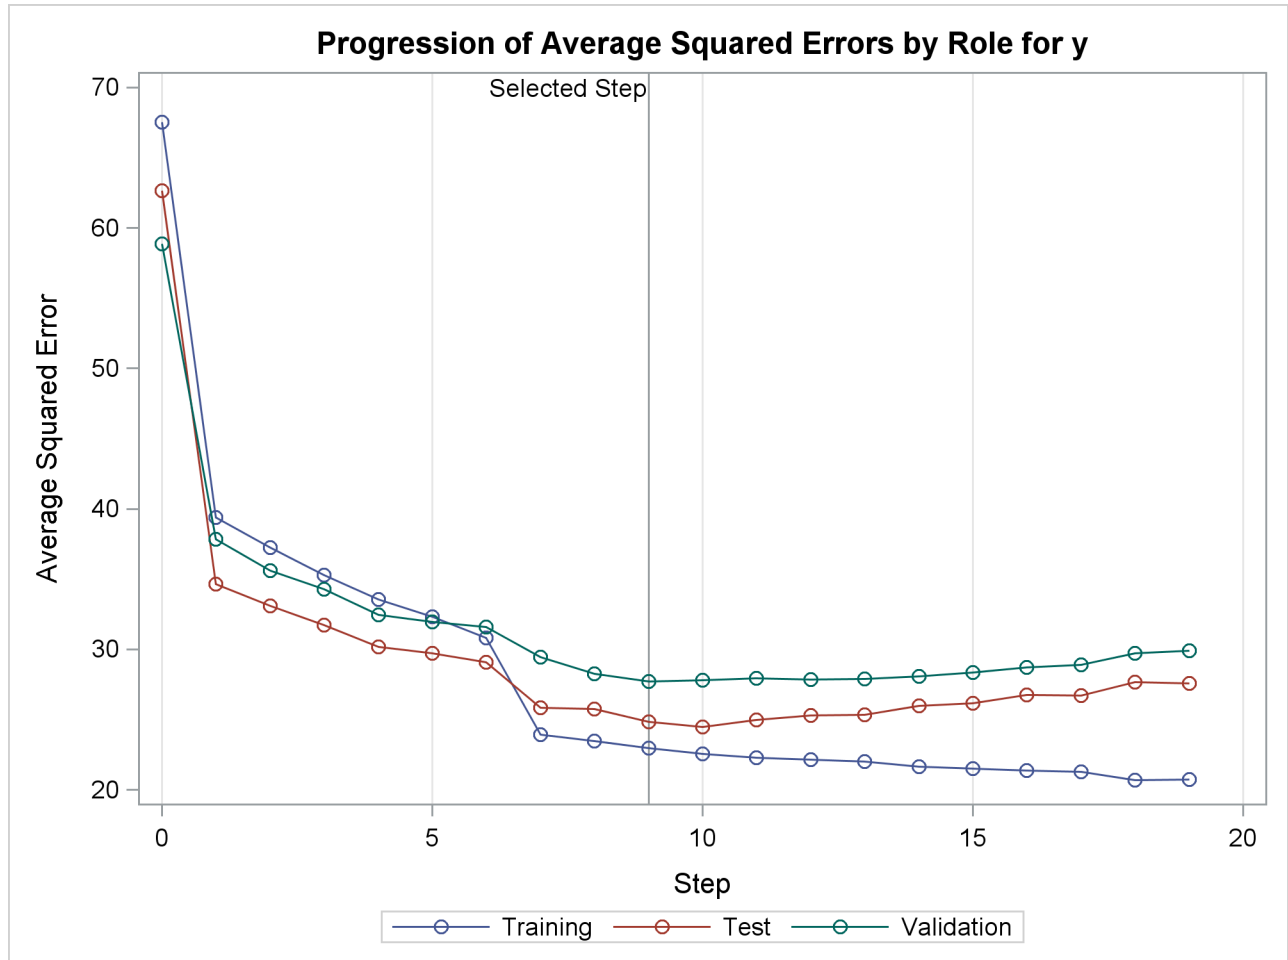

The criterion panel in [Output 45.2.5](#) shows how the various fit criteria evolved as the stepwise selection method proceeded. Note that other than the ASE evaluated on the validation data, these criteria are evaluated on the training data. You see that the minimum of the validation ASE occurs at step 9, and hence the model at this step is selected.

Output 45.2.5 Criterion Panel

Output 45.2.6 shows how the average squared error (ASE) evolved on the training, validation, and test data. Note that while the ASE on the training data decreases monotonically, the errors on both the validation and test data start increasing beyond step 9. This indicates that models after step 9 are beginning to overfit the training data.

**Output 45.2.6** Average Squared Errors

Output 45.2.7 shows the selected effects, analysis of variance, and fit statistics tables for the selected model. Output 45.2.8 shows the parameter estimates table.

**Output 45.2.7** Selected Model Details

The magnitudes of the standardized estimates and the  $t$  statistics of the parameters of the effect 'c1' reveal that only levels '3' and '7' of this effect contribute appreciably to the model. This suggests that a more parsimonious model with similar or better predictive power might be obtained if parameters corresponding to the levels of 'c1' are allowed to enter or leave the model independently. You request this with the SPLIT option in the CLASS statement as shown in the following statements:

```
proc glmselect data=analysisData testdata=testData
 seed=1 plots(stepAxis=number)=all;
 partition fraction(validate=0.5);
 class c1(split) c2 c3(order=data);
 model y = c1|c2|c3|x1|x2|x3|x4|x5|x5|x6|x7|x8|x9|x10
 |x11|x12|x13|x14|x15|x16|x17|x18|x19|x20 @2
 / selection=stepwise(stop = validate
 select = s1)
 hierarchy=single;
 output out=outData;
run;
```

The “Class Level Information” and “Dimensions” tables are shown in Output 45.2.9. The “Dimensions” table shows that while the model statement specifies 278 effects, after splitting the parameters corresponding to the levels of c1, there are 439 split effects that are considered for entry or removal at each step of the selection process. Note that the total number of parameters considered is not affected by the split option.

**Output 45.2.9** Class Level Information and Problem Dimensions

```

The GLMSELECT Procedure

Class Level Information

Class Levels Values
c1 8 * 1 2 3 4 5 6 7 8
c2 4 0 1 2 3
c3 5 tiny small average big huge

* Associated Parameters Split

Dimensions

Number of Effects 278
Number of Effects after Splits 439
Number of Parameters 661

```

The stop reason and stop details tables are shown in [Output 45.2.10](#). Since the validation ASE is specified as the stopping criterion, the selection stops at step 11, where the validation ASE achieves a local minimum and the model at this step is the selected model.

**Output 45.2.10** Stop Details

```

Selection stopped at a local minimum of the residual sum of squares of the
validation data.

Stop Details

Candidate Candidate Compare
For Effect Validation ASE Validation ASE
Entry x18 25.9851 > 25.7462
Removal x6*x7 25.7611 > 25.7462

```

You find details of the selected model in [Output 45.2.11](#). The list of selected effects confirms that parameters corresponding to levels '3' and '7' only of c1 are in the selected model. Notice that the selected model with classification variable c1 split contains 18 parameters, whereas the selected model without splitting c1 has 45 parameters. Furthermore, by comparing the fit statistics in [Output 45.2.7](#) and [Output 45.2.11](#), you see that this more parsimonious model has smaller prediction errors on both the validation and test data.

**Output 45.2.11** Details of the Selected Model

When you use a **PARTITION** statement to subdivide the analysis data set, an output data set created with the **OUTPUT** statement contains a variable named `_ROLE_` that shows the role each observation was assigned to. See the section “**OUTPUT Statement**” on page 3555 and the section “**Using Validation and Test Data**” on page 3577 for additional details.

The following statements use **PROC PRINT** to produce **Output 45.2.12**, which shows the first five observations of the `outData` data set.

```
proc print data=outData(obs=5);
run;
```

Cross validation is often used to assess the predictive performance of a model, especially for when you do not have enough observations for test set validation. See the section “[Cross Validation](#)” on page 3579 for further details. The following statements provide an example where cross validation is used as the `CHOOSE=` criterion.

```
proc glmselect data=analysisData testdata=testData
 plots(stepAxis=number)=(criterionPanel ASEPlot);
 class c1(split) c2 c3(order=data);
 model y = c1|c2|c3|x1|x2|x3|x4|x5|x5|x6|x7|x8|x9|x10
 |x11|x12|x13|x14|x15|x16|x17|x18|x19|x20 @2
 / selection = stepwise(choose = cv
 select = s1)

 stats = press
 cvMethod = split(5)
 cvDetails = all
 hierarchy = single;
 output out=outData;
run;
```

The `CVMETHOD=SPLIT(5)` option in the `MODEL` statement requests five-fold cross validation with the five subsets consisting of observations  $\{1, 6, 11, \dots\}$ ,  $\{2, 7, 12, \dots\}$ , and so on. The `STATS=PRESS` option requests that the leave-one-out cross validation predicted residual sum of squares (PRESS) also be computed and displayed at each step, even though this statistic is not used in the selection process.

Output 45.2.13 shows how several fit statistics evolved as the selection process progressed. The five-fold CV PRESS statistic achieves its minimum at step 19. Note that this gives a larger model than was selected when the stopping criterion was determined using validation data. Furthermore, you see that the PRESS statistic has not achieved its minimum within 25 steps, so an even larger model would have been selected based on leave-one-out cross validation.

**Output 45.2.13** Criterion Panel

Output 45.2.14 shows how the average squared error compares on the test and training data. Note that the ASE error on the test data achieves a local minimum at step 11 and is already slowly increasing at step 19, which corresponds to the selected model.

Output 45.2.14 Average Squared Error Plot

The `CVDETAILS=ALL` option in the `MODEL` statement requests the “Cross Validation Details” table in [Output 45.2.15](#) and the cross validation parameter estimates that are included in the “Parameter Estimates” table in [Output 45.2.16](#). For each cross validation index, the predicted residual sum of squares on the observations omitted is shown in the “Cross Validation Details” table and the parameter estimates of the corresponding model are included in the “Parameter Estimates” table. By default, these details are shown for the selected model, but you can request this information at every step with the `DETAILS=` option in the `MODEL` statement. You use the `_CVINDEX_` variable in the output data set shown in [Output 45.2.17](#) to find out which observations in the analysis data are omitted for each cross validation fold.

**Output 45.2.15** Breakdown of CV Press Statistic by Fold

| Cross Validation Details |                    |          |            |
|--------------------------|--------------------|----------|------------|
| Index                    | ---Observations--- |          | CV PRESS   |

This example demonstrates the usefulness of effect selection when you suspect that interactions of effects are needed to explain the variation in your dependent variable. Ideally, a priori knowledge should be used to decide what interactions to allow, but in some cases this information might not be available. Simply fitting a least squares model allowing all interactions produces a model that overfits your data and generalizes very poorly.

The following statements use forward selection with selection based on the SBC criterion, which is the default selection criterion. At each step, the effect whose addition to the model yields the smallest SBC value is added. The `STOP=NONE` suboption specifies that this process continue even when the SBC statistic grows whenever an effect is added, and so it terminates at a full least squares model. The `BUILDSSCP=FULL` option is specified in a `PERFORMANCE` statement, since building the SSCP matrix incrementally is counterproductive in this case. See the section “`BUILDSSCP=FULL`” on page 3557 for details. Note that if all you are interested in is a full least squares model, then it is much more efficient to simply specify `SELECTION=NONE` in the `MODEL` statement. However, in this example the aim is to add effects in roughly increasing order of explanatory power.

```

proc glmselect data=analysisData testdata=testData plots=ASEPlot;
 class c1 c2 c3(order=data);
 model y = c1|c2|c3|x1|x2|x3|x4|x5|x5|x6|x7|x8|x9|x10
 |x11|x12|x13|x14|x15|x16|x17|x18|x19|x20 @2
 / selection=forward(stop=none)
 hierarchy=single;
 performance buildSSCP = full;
run;

ods graphics off;

```

The ASE plot shown in [Output 45.2.18](#) clearly demonstrates the danger in overfitting the training data. As more insignificant effects are added to the model, the growth in test set ASE shows how the predictions produced by the resulting models worsen. This decline is particularly rapid in the latter stages of the forward selection, because the use of the SBC criterion results in insignificant effects with lots of parameters being added after insignificant effects with fewer parameters.

**Output 45.2.18** Average Squared Error Plot

### Example 45.3: Scatter Plot Smoothing by Selecting Spline Functions

This example shows how you can use model selection to perform scatter plot smoothing. It illustrates how you can use the experimental EFFECT statement to generate a large collection of B-spline basis functions from which a subset is selected to fit scatter plot data.

The data for this example come from a set of benchmarks developed by Donoho and Johnstone (1994) that have become popular in the statistics literature. The particular benchmark used is the “Bumps” functions to which random noise has been added to create the test data. The following DATA step, extracted from Sarle (2001), creates the data. The constants are chosen so that the noise-free data have a standard deviation of 7. The standard deviation of the noise is  $\sqrt{5}$ , yielding bumpsNoise with a signal-to-noise ratio of 3.13 ( $7/\sqrt{5}$ ).

```
%let random=12345;

data DoJoBumps;
 keep x bumps bumpsWithNoise;

 pi = arcos(-1);

 do n=1 to 2048;
 x=(2*n-1)/4096;
 link compute;
 bumpsWithNoise=bumps+rannor(&random)*sqrt(5);
 output;
 end;
stop;

compute:
 array t(11) _temporary_ (.1 .13 .15 .23 .25 .4 .44 .65 .76 .78 .81);
 array b(11) _temporary_ (4 5 3 4 5 4.2 2.1 4.3 3.1 5.1 4.2);
 array w(11) _temporary_ (.005 .005 .006 .01 .01 .03 .01 .01 .005 .008 .005);

 bumps=0;
 do i=1 to 11;
 bumps=bumps+b[i]*(1+abs((x-t[i])/w[i]))**4;
 end;
 bumps=bumps*10.528514619;
 return;
run;
```

The following statements use the SGPLOT procedure to produce the plot in [Output 45.3.1](#). The plot shows the bumps function superimposed on the function with added noise.

```
proc sgplot data=DoJoBumps;
 yaxis display=(nolabel);
 series x=x y=bumpsWithNoise/lineattrs=(color=black);
 series x=x y=bumps/lineattrs=(color=red);
run;
```

**Output 45.3.1** Donoho-Johnstone Bumps Function

Suppose you want to smooth the noisy data to recover the underlying function. This problem is studied by Sarle (2001), who shows how neural nets can be used to perform the smoothing. The following statements use the LOESS statement in the SGPLOT procedure to show a loess fit superimposed on the noisy data (Output 45.3.2). (See Chapter 53, “The LOESS Procedure,” for information about the loess method.)

```
proc sgplot data=DoJoBumps;
 yaxis display=(nolabel);
 series x=x y=bumps;
 loess x=x y=bumpsWithNoise / lineattrs=(color=red) nomarkers;
run;
```

The algorithm selects a smoothing parameter that is small enough to enable bumps to be resolved. Because there is a single smoothing parameter that controls the number of points for all local fits, the loess method undersmooths the function in the intervals between the bumps.

Output 45.3.2 Loess Fit

Another approach to doing nonparametric fitting is to approximate the unknown underlying function as a linear combination of a set of basis functions. Once you specify the basis functions, then you can use least squares regression to obtain the coefficients of the linear combination. A problem with this approach is that for most data, you do not know a priori what set of basis functions to use. You need to supply a sufficiently rich set to enable the features in the data to be approximated. However, if you use too rich a set of functions, then this approach yields a fit that undersmooths the data and captures spurious features in the noise.

The penalized B-spline method (Eilers and Marx 1996) uses a basis of B-splines (see the section “**EFFECT Statement**” on page 393 of Chapter 19, “**Shared Concepts and Topics**”) corresponding to a large number of equally spaced knots as the set of approximating functions. To control the potential overfitting, their algorithm modifies the least squares objective function to include a penalty term that grows with the complexity of the fit.

The following statements use the PBSPLINE statement in the SGPLOT procedure to show a penalized B-spline fit superimposed on the noisy data (Output 45.3.3). See Chapter 97, “**The TRANSREG Procedure**,” for details about the implementation of the penalized B-spline method.

```

proc sgplot data=DoJoBumps;
 yaxis display=(nolabel);
 series x=x y=bumps;
 pbspline x=x y=bumpsWithNoise /
 lineattrs=(color=red) nomarkers;
run;

```

As in the case of loess fitting, you see undersmoothing in the intervals between the bumps because there is only a single smoothing parameter that controls the overall smoothness of the fit.

### Output 45.3.3 Penalized B-spline Fit

An alternative to using a smoothness penalty to control the overfitting is to use variable selection to obtain an appropriate subset of the basis functions. In order to be able to represent features in the data that occur at multiple scales, it is useful to select from B-spline functions defined on just a few knots to capture large scale features of the data as well as B-spline functions defined on many knots to capture fine details of the data. The following statements show how you can use PROC GLMSELECT to implement this strategy:

```

proc glmselect data=dojoBumps;
 effect spl = spline(x / knotmethod=multiscale(endscale=8)
 split details);
 model bumpsWithNoise=spl;
 output out=out1 p=pBumps;
run;

proc sgplot data=out1;
 yaxis display=(nolabel);
 series x=x y=bumps;
 series x=x y=pBumps / lineattrs=(color=red);
run;

```

The `KNOTMETHOD=MULTISCALE` suboption of the `EFFECT spl = SPLINE` statement provides a convenient way to generate B-spline basis functions at multiple scales. The `ENDSCALE=8` option requests that the finest scale use B-splines defined on  $2^8$  equally spaced knots in the interval  $[0, 1]$ . Because the cubic B-splines are nonzero over five adjacent knots, at the finest scale, the support of each B-spline basis function is an interval of length about 0.02 ( $5/256$ ), enabling the bumps in the underlying data to be resolved. The default value is `ENDSCALE=7`. At this scale you will still be able to capture the bumps, but with less sharp resolution. For these data, using a value of `ENDSCALE=` greater than eight provides unneeded resolution, making it more likely that basis functions that fit spurious features in the noise are selected.

[Output 45.3.4](#) shows the model information table. Since no options are specified in the `MODEL` statement, `PROC GLMSELECT` uses the stepwise method with selection and stopping based on the SBC criterion.

#### Output 45.3.4 Model Settings

| The GLMSELECT Procedure   |                |
|---------------------------|----------------|
| Data Set                  | WORK.DOJOBUMPS |
| Dependent Variable        | bumpsWithNoise |
| Selection Method          | Stepwise       |
| Select Criterion          | SBC            |
| Stop Criterion            | SBC            |
| Effect Hierarchy Enforced | None           |

The `DETAILS` suboption in the `EFFECT` statement requests the display of spline knots and spline basis tables. These tables contain information about knots and basis functions at all scales. The results for scale four are shown in [Output 45.3.5](#) and [Output 45.3.6](#).

**Output 45.3.5** Spline Knots

| Knots for Spline Effect spl |       |                         |          |            |
|-----------------------------|-------|-------------------------|----------|------------|
| Knot<br>Number              | Scale | Scale<br>Knot<br>Number | Boundary | x          |
| 40                          | 4     | 1                       | *        | -0.11735   |
| 41                          | 4     | 2                       | *        | -0.05855   |

| 51                                  | 4     | 20     | 0.94096           | 1.11735 | 19-22         |

The Dimensions table in [Output 45.3.7](#) shows that at each step of the selection process, 548 effects are considered as candidates for entry or removal. Note that although the MODEL statement specifies a single constructed effect spl, the SPLIT suboption causes each of the parameters in this constructed effect to be treated as an individual effect.

**Output 45.3.7** Dimensions

| Dimensions           |     |
|----------------------|-----|
| Number of Effects    | 548 |
| Number of Parameters | 548 |

[Output 45.3.8](#) shows the parameter estimates for the selected model. You can see that the selected model contains 31 B-spline basis functions and that all the selected B-spline basis functions are from scales four through eight. For example, the first basis function listed in the parameter estimates table is spl\_S4:9—the ninth B-spline function at scale 4. You see from [Output 45.3.6](#) that this function is nonzero on the interval (0.29, 0.52).

**Output 45.3.8** Parameter Estimates

| Parameter Estimates |    |            |                |         |
|---------------------|----|------------|----------------|---------|

The OUTPUT statement captures the predicted values in a data set named out1, and [Output 45.3.9](#) shows a fit plot produced by PROC SGPLOT.

**Output 45.3.9** Fit by Selecting B-splines

### Example 45.4: Multimember Effects and the Design Matrix

This example shows how you can use multimember effects to build predictive models. It also demonstrates several features of the OUTDESIGN= option in the PROC GLMSELECT statement.

The simulated data for this example describe a two-week summer tennis camp. The tennis ability of each camper was assessed and ratings were assigned at the beginning and end of the camp. The camp consisted of supervised group instruction in the mornings with a number of different options in the afternoons. Campers could elect to participate in unsupervised practice and play. Some campers paid for one or more individual lessons from 30 to 90 minutes in length, focusing on forehand and backhand strokes and volleying. The aim of this example is to build a predictive model for the rating improvement of each camper based on the times the camper spent doing each activity and several other variables, including the age, gender, and initial rating of the camper.

The following statements produce the TennisCamp data set:

```

data TennisCamp;
 length forehandCoach $6 backhandCoach $6 volleyCoach $6 gender $1;
 input forehandCoach backhandCoach volleyCoach tLessons tPractice tPlay
 gender inRating nPastCamps age tForehand tBackhand tVolley
 improvement;
 label forehandCoach = "Forehand lesson coach"
 backhandCoach = "Backhand lesson coach"
 volleyCoach = "Volley lesson coach"
 tForehand = "time (1/2 hours) of forehand lesson"
 tBackhand = "time (1/2 hours) of backhand lesson"
 tVolley = "time (1/2 hours) of volley lesson"
 tLessons = "time (1/2 hours) of all lessons"
 tPractice = "total practice time (hours)"
 tPlay = "total play time (hours)"
 nPastCamps = "Number of previous camps attended"
 age = "age (years)"
 inRating = "Rating at camp start"
 improvement = "Rating improvement at end of camp";
 datalines;
. . Tom 1 30 19 f 44 0 13 0 0 1 6
Greg . . 2 12 33 f 48 2 15 2 0 0 14

;

```

A multimember effect (see the section “EFFECT Statement” on page 393 of Chapter 19, “Shared Concepts and Topics”) is appropriate for modeling the effect of coaches on the campers’ improvement, because campers might have worked with multiple coaches. Furthermore, since the time a coach spent with each camper varies, it is appropriate to use these times to weight each coach’s contribution in the multimember effect. It is also important not to exclude campers from the analysis if they did not receive any individual instruction. You can accomplish all these goals by using a multimember effect defined as follows:

```

class forehandCoach backhandCoach volleyCoach;
effect coach = MM(forehandCoach backhandCoach volleyCoach/ noeffect
 weight=(tForehand tBackhand tVolley));

```

Based on similar previous studies, it is known that the time spent practicing should not be included linearly, because there are diminishing returns and perhaps even counterproductive effects beyond about 25 hours. A spline effect with a single knot at 25 provides flexibility in modeling effect of practice time.

The following statements use PROC GLMSELECT to select effects for the model.

```
proc glmselect data=TennisCamp outdesign=designCamp;
 class forehandCoach backhandCoach volleyCoach gender;

 effect coach = mm(forehandCoach backhandCoach volleyCoach / noeffect
 details weight=(tForehand tBackhand tVolley));
 effect practice = spline(tPractice/knotmethod=list(25) details);

 model improvement = coach practice tLessons tPlay age gender
 inRating nPastCamps;

run;
```

Output 45.4.1 shows the class level and MM level information. The levels of the constructed MM effect are the union of the levels of its constituent classification variables. The MM level information is not displayed by default—you request this table by specifying the DETAILS suboption in the relevant **EFFECT** statement.

**Output 45.4.1** Levels of MM EFFECT Coach

| 6                                 | Andy Brunna Elaine Greg Mike Tom |

Output 45.4.2 shows the parameter estimates for the selected model. You can see that the constructed multimember effect coach and the spline effect practice are both included in the selected model. All coaches provided benefit (all the parameters of the multimember effect coach are positive), with Greg and Mike being the most effective.

**Output 45.4.2** Parameter Estimates

| Parameter Estimates |        |    |           |                |         |

Suppose you want to examine regression diagnostics for the selected model. PROC GLMSELECT does not support such diagnostics, so you might want to use the REG procedure to produce these diagnostics. You can overcome the difficulty that PROC REG does not support CLASS and EFFECT statements by using the OUTDESIGN= option in the PROC GLMSELECT statement to obtain the design matrix that you can use as an input data set for further analysis with other SAS procedures.

The following statements use PROC PRINT to produce Output 45.4.3, which shows the first five observations of the design matrix designCamp.

```
proc print data=designCamp(obs=5);
run;
```

**Output 45.4.3** First Five Observations of the designCamp Data Set

|   | c<br>o<br>a<br>c<br>c                                         |                                           |                                                                    |                                                                         |                                                                         |                                                                         |                                                                         |                                                                         | p<br>r<br>r<br>r<br>r<br>r |         |         |         |         | i<br>m<br>p<br>r<br>o<br>v<br>e<br>m<br>e<br>n<br>t |         |         |         |         |   |

| 5 | 1                                                             | 0                                         | 2                                                                  | 0                                                                       | 0                                                                       | 0                                                                       | 0                                                                       | 34                                                                      | 0.16228                    | 0.49279 | 0.29088 | 0.05405 | 0.00000 | 12                                                  |         |         |         |         |   |

To facilitate specifying the columns of the design matrix corresponding to the selected model, you can use the macro variable named `_GLSMOD` that PROC GLMSELECT creates whenever you specify the `OUT-DESIGN=` option. The following statements use PROC REG to produce a panel of regression diagnostics corresponding to the model selected by PROC GLMSELECT.

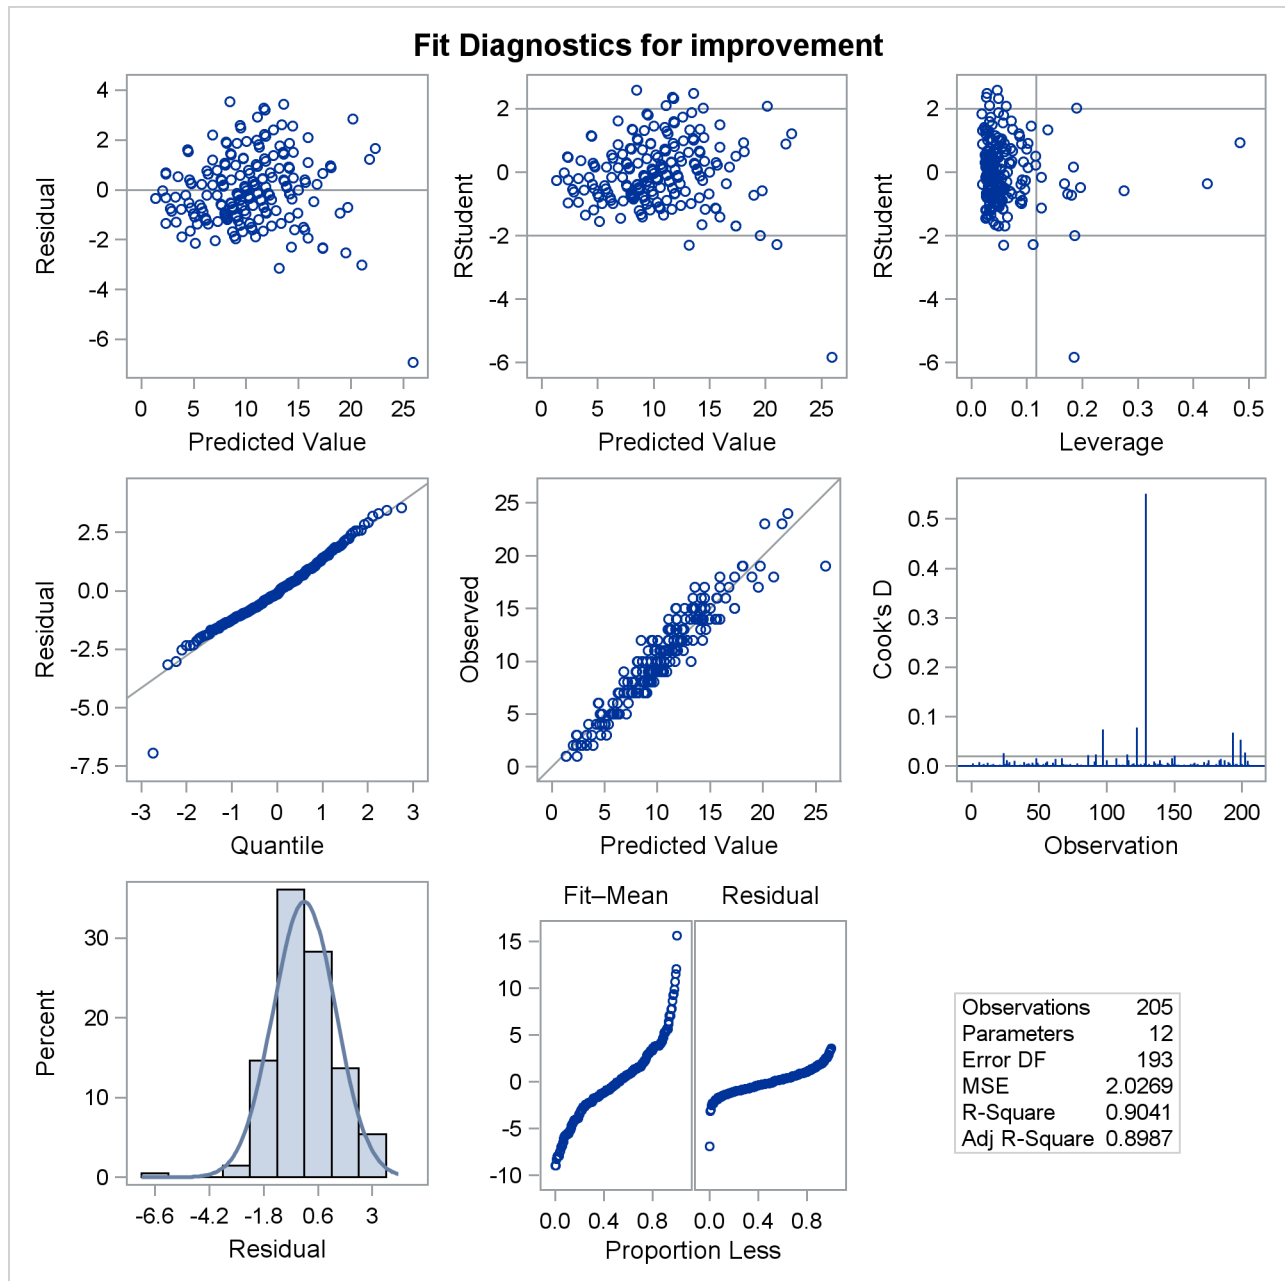

```
ods graphics on;

proc reg data=designCamp;
 model improvement = &_GLSMOD;
quit;

ods graphics off;
```

The regression diagnostics shown in [Output 45.4.4](#) indicate a reasonable model. However, they also reveal the presence of one large outlier and several influential observations that you might want to investigate.

Output 45.4.4 Fit Diagnostics

Sometimes you might want to use subsets of the columns of the design matrix. In such cases, it might be convenient to produce a design matrix with generic names for the columns. You might also want a design matrix containing the columns corresponding to the full model that you specify in the `MODEL` statement. By default, the design matrix includes only the columns that correspond to effects in the selected model. The following statements show how to do this.

```

proc glmselect data=TennisCamp
 outdesign(fullmodel prefix=parm names)=designCampGeneric;
 class forehandCoach backhandCoach volleyCoach gender;

 effect coach = mm(forehandCoach backhandCoach volleyCoach / noeffect
 details weight=(tForehand tBackhand tVolley));
 effect practice = spline(tPractice/knotmethod=list(25) details);

 model improvement = coach practice tLessons tPlay age gender
 inRating nPastCamps;

run;

```

The PREFIX=parm suboption of the OUTDESIGN= option specifies that columns in the design matrix be given the prefix parm with a trailing index. The NAMES suboption requests the table in [Output 45.4.5](#) that associates descriptive labels with the names of columns in the design matrix. Finally, the FULLMODEL suboption specifies that the design matrix include columns corresponding to all effects specified in the MODEL statement.

**Output 45.4.5** Descriptive Names of Design Matrix Columns

| The GLMSELECT Procedure |              |
|-------------------------|--------------|
| Selected Model          |              |
| Parameter Names         |              |

### Example 45.5: Model Averaging

This example shows how you can combine variable selection methods with model averaging to build parsimonious predictive models. This example uses simulated data that consist of observations from the model

$$y = \mathbf{X}\boldsymbol{\beta} + N(0, \sigma^2)$$

where  $\mathbf{X}$  is drawn from a multivariate normal distribution  $N(0, \mathbf{V})$  with  $V_{i,j} = \rho^{|i-j|}$  where  $0 < \rho < 1$ . This setup has been widely studied in investigations of variable selection methods. For examples, see Breiman (1992); Tibshirani (1996); Zou (2006).

The following statements define a macro that uses the SIMNORMAL procedure to generate the regressors. This macro prepares a TYPE=CORR data set that specifies the desired pairwise correlations. This data set is used as the input data for PROC SIMNORMAL which produces the sampled regressors in an output data set named Regressors.

```
%macro makeRegressorData (nObs=100, nVars=8, rho=0.5, seed=1);
data varCorr;
drop i j;
array x{&nVars};
length _NAME_ $8 _TYPE_ $8;
NAME = '';

TYPE = 'MEAN';
do j=1 to &nVars; x{j}=0; end;
output;

TYPE = 'STD';
```

```

do j=1 to &nVars; x{j}=1;end;
output;

__TYPE_ = 'N';
do j=1 to &nVars; x{j}=10000;end;
output;

__TYPE_ = 'CORR';
do i=1 to &nVars;
 __NAME_="x" || trim(left(i));
 do j= 1 to &nVars;
 x{j}=&rho**(abs(i-j));
 end;
 output;
end;
run;

proc simnormal data=varCorr(type=corr) out=Regressors
 numReal=&nObs seed=&seed;
 var x1-x&nVars;
run;
%mend;

```

The following statements use the %makeRegressorData macro to generate a sample of 100 observations with 10 regressors, where  $E(\mathbf{X}_i \mathbf{X}_j) = 0.5^{|i-j|}$ , the true coefficients are  $\boldsymbol{\beta}' = (3, 1.5, 0, 0, 2, 0, 0, 0, 0, 0)$ , and  $\sigma = 3$ .

```

%makeRegressorData (nObs=100, nVars=10, rho=0.5);

data simData;
 set regressors;
 yTrue = 3*x1 + 1.5*x2 + 2*x5;
 y = yTrue + 3*rannor(2);
run;

```

The adaptive lasso algorithm (see “Adaptive Lasso Selection” on page 3566) is a modification of the standard lasso algorithm in which weights are applied to each of the parameters in forming the lasso constraint. Zou (2006) shows that the adaptive lasso has theoretical advantages over the standard lasso. Furthermore, simulation studies show that the adaptive lasso tends to perform better than the standard lasso in selecting the correct regressors, particularly in high signal-to-noise ratio cases. The following statements fit an adaptive lasso model to the simData data:

```

proc glmselect data=simData;
 model y=x1-x10/selection=LASSO(adaptive stop=none choose=svc);
run;

```

The selected model and parameter estimates are shown in [Output 45.5.1](#)

#### Output 45.5.1 Model Selected by Adaptive Lasso

|                                                                                      |
|--------------------------------------------------------------------------------------|
| <p>The GLMSELECT Procedure<br/>Selected Model</p> <p>Effects: Intercept x1 x2 x5</p> |
|--------------------------------------------------------------------------------------|

**Output 45.5.1** *continued*

| Parameter Estimates |    |           |
|---------------------|----|-----------|
| Parameter           | DF | Estimate  |
| Intercept           | 1  | -0.243219 |
| x1                  | 1  | 3.246129  |
| x2                  | 1  | 1.310514  |
| x5                  | 1  | 2.132416  |

You see that the selected model contains only the relevant regressors x1, x2, and x5. You might want to investigate how frequently the adaptive lasso method selects just the relevant regressors and how stable the corresponding parameter estimates are. In a simulation study, you can do this by drawing new samples and repeating this process many times. What can you do when you only have a single sample of the data available? One approach is to repeatedly draw subsamples from the data that you have, and to fit models for each of these samples. You can then form the average model and use this model for prediction. You can also examine how frequently models are selected, and you can use the frequency of effect selection as a measure of effect importance.

The following statements show how you can use the **MODEL AVERAGE** statement to perform such an analysis:

```
ods graphics on;

proc glmselect data=simData seed=3 plots=(EffectSelectPct ParmDistribution);
 model y=x1-x10/selection=LASSO(adaptive stop=none choose=SBC);
 modelAverage tables=(EffectSelectPct(all) ParmEst(all));
run;
```

The ModelAverageInfo table in **Output 45.5.2** shows that the default sampling method is the bootstrap approach of drawing 100 samples with replacement, where the sampling percentage of 100 means that each sample has the same sum of frequencies as the input data. You can use the **SAMPLING=** and **NSAMPLES=** options in the **MODEL AVERAGE** statement to modify the sampling method and the number of samples used.

**Output 45.5.2** Model Averaging Information

| The GLMSELECT Procedure     |                                 |
|-----------------------------|---------------------------------|
| Model Averaging Information |                                 |
| Sampling Method             | Unrestricted (with replacement) |
| Sample Percentage           | 100                             |
| Number of Samples           | 100                             |

Output 45.5.3 shows the percentage of samples where each effect is in the selected model. The ALL option of the EFFECTSELECTPCT request in the TABLES= option specifies that effects that appear in any selected model are shown. (By default, the “Effect Selection Percentage” table displays only those effects that are selected at least 20 percent of the time.)

**Output 45.5.3** Effect Selection Percentages

| Effect Selection Percentage |                      |
|-----------------------------|----------------------|
| Effect                      | Selection Percentage |
| x1                          | 100.0                |
| x2                          | 99.00                |
| x3                          | 33.00                |
| x4                          | 7.00                 |
| x5                          | 100.0                |
| x6                          | 14.00                |
| x7                          | 25.00                |
| x8                          | 9.00                 |
| x9                          | 7.00                 |
| x10                         | 16.00                |

The EFFECTSELECTPCT request in the PLOTS= option in the PROC GLMSELECT statement produces the bar chart shown in Output 45.5.4, which graphically displays the information in the EffectSelectPct table.

**Output 45.5.4** Effect Selection Percentages

Output 45.5.5 shows the frequencies with which models get selected. By default, only the “best” 20 models are shown. See the section “Model Selection Frequencies and Frequency Scores” on page 3577 for details about how these models are ordered.

**Output 45.5.5** Model Selection Frequency

| Model Selection Frequency |                      |                   |                 |                              |
|---------------------------|----------------------|-------------------|-----------------|------------------------------|
| Times Selected            | Selection Percentage | Number of Effects | Frequency Score | Effects in Model             |
| 44                        | 44.00                | 4                 | 45.00           | Intercept x1 x2 x5           |
| 9                         | 9.00                 | 5                 | 9.86            | Intercept x1 x2 x3 x5        |
| 8                         | 8.00                 | 6                 | 8.76            | Intercept x1 x2 x3 x5 x7     |
| 4                         | 4.00                 | 5                 | 4.82            | Intercept x1 x2 x5 x8        |
| 4                         | 4.00                 | 7                 | 4.67            | Intercept x1 x2 x3 x5 x6 x7  |
| 3                         | 3.00                 | 5                 | 3.85            | Intercept x1 x2 x5 x7        |
| 2                         | 2.00                 | 5                 | 2.83            | Intercept x1 x2 x5 x10       |
| 2                         | 2.00                 | 5                 | 2.81            | Intercept x1 x2 x4 x5        |
| 2                         | 2.00                 | 6                 | 2.74            | Intercept x1 x2 x3 x5 x6     |
| 2                         | 2.00                 | 7                 | 2.66            | Intercept x1 x2 x3 x5 x6 x10 |
| 1                         | 1.00                 | 5                 | 1.83            | Intercept x1 x2 x5 x6        |
| 1                         | 1.00                 | 4                 | 1.81            | Intercept x1 x5 x7           |
| 1                         | 1.00                 | 5                 | 1.81            | Intercept x1 x2 x5 x9        |
| 1                         | 1.00                 | 6                 | 1.75            | Intercept x1 x2 x3 x5 x10    |
| 1                         | 1.00                 | 6                 | 1.74            | Intercept x1 x2 x3 x5 x8     |
| 1                         | 1.00                 | 6                 | 1.73            | Intercept x1 x2 x5 x6 x7     |
| 1                         | 1.00                 | 6                 | 1.72            | Intercept x1 x2 x5 x7 x9     |
| 1                         | 1.00                 | 6                 | 1.71            | Intercept x1 x2 x5 x8 x10    |
| 1                         | 1.00                 | 6                 | 1.70            | Intercept x1 x2 x4 x5 x10    |
| 1                         | 1.00                 | 7                 | 1.68            | Intercept x1 x2 x3 x5 x7 x10 |

You can see that the most frequently selected model is the model that contains just the true underlying regressors. Although this model is selected in 44% of the samples, most of the selected models contain at least one irrelevant regressor. This is not surprising because even though the true model has just a few large effects in this example, the regressors have nontrivial pairwise correlations.

When your goal is simply to obtain a predictive model, then a good strategy is to average the predictions that you get from all the selected models. In the linear model context, this corresponds to using the model whose parameter estimates are the averages of the estimates that you get for each sample, where if a parameter is not in a selected model, the corresponding estimate is defined to be zero. This has the effect of shrinking the estimates of infrequently selected parameters towards zero.

Output 45.5.6 shows the average parameter estimates. The ALL option of the PARMEST request in the TABLES= option specifies that all parameters that are nonzero in any selected model are shown. (By default, the “Average Parameter Estimates” table displays only those parameters that are nonzero in at least 20 percent of the selected models.)

**Output 45.5.6** Average Parameter Estimates

| Average Parameter Estimates |                    |                        |                  |                       |

The average estimate for a parameter is computed by dividing the sum of the estimate values for that parameter in each sample by the total number of samples. This corresponds to using zero as the estimate value for the parameter in those samples where the parameter does not appear in the selected model. Similarly, these zero estimates are included in the computation of the estimated standard deviation and quantiles that are displayed in the AvgParmEst table. If you want see the estimates that you get if you do not use zero for nonselected parameters, you can specify the NONZEROPARMS suboption of the PARMEST request in the TABLES=option.

The PARMDISTRIBUTION request in the PLOTS= option in the PROC GLMSELECT statement requests the panel in [Output 45.5.7](#), which shows the distribution of the estimates for each parameter in the average model. For each parameter in the average model, a histogram and box plot of the nonzero values of the estimates are shown. You can use this plot to assess how the selected estimates vary across the samples.

## Output 45.5.7 Effect Selection Percentages

You can obtain details about the model selection for each sample by specifying the **DETAILS** option in the **MODEL AVERAGE** statement. You can use an **OUTPUT** statement to output the mean predicted value and standard deviation, quantiles of the predicted values, as well as the individual sample frequencies and predicted values for each sample. The following statements show how you do this:

```
proc glmselect data=simData seed=3;
 model y=x1-x10/selection=LASSO(adaptive stop=none choose=SBC);
 modelAverage details;
 output out=simOut sampleFreq=sf samplePred=sp
 p=p stddev=stddev lower=q25 upper=q75 median;
run;
```

Output 45.5.8 shows the selection summary and parameter estimates for sample 1 of the model averaging. Note that you can obtain all the model selection output, including graphs, for each sample.

**Output 45.5.8** Selection Details for Sample 1

By default, the LOWER and UPPER options in the OUTPUT statement produce the lower and upper quartiles of the sample predicted values. You can change the quantiles produced by using the ALPHA= option in the MODEL AVERAGE statement. The variables sf1–sf100 contain the sample frequencies used for each sample, and the variables sp1–sp100 hold the corresponding predicted values. Even if you do not specify the DETAILS option in the MODEL AVERAGE statement, you can use the sample frequencies in the output data set to reproduce the selection results for any particular sample. For example, the following statements recover the selection for sample 1:

```
proc glmselect data=simOut;
 freq sf1;
 model y=x1-x10/selection=LASSO(adaptive stop=none choose=SBC);
run;
```

The average model is not parsimonious—it includes shrunken estimates of infrequently selected parameters which often correspond to irrelevant regressors. It is tempting to ignore the estimates of infrequently selected parameters by setting their estimate values to zero in the average model. However, this can lead to a poorly performing model. Even though a parameter might occur in only one selected model, it might be a very important term in that model. Ignoring its estimate but including some of the estimates of the other parameters in this model leads to biased predictions. One scenario where this might occur is when the data contains two highly correlated regressors which are both strongly correlated with the response.

You can obtain a parsimonious model by using the frequency of effect selection as a measure of effect importance and refitting a model that contains just the effects that you deem important. In this example, Output 45.5.3 shows that the effects x1, x2, and x5 all get selected at least 99 percent of the time, whereas all other effects get selected less than 34 percent of the time. This large gap suggests that using 35% as the selection cutoff for this data will produce a parsimonious model that retains good predictive performance. You can use the REFIT option to implement this strategy. The REFIT option requests a second round of model averaging, where you use the MINPCT= suboption to specify the minimum percentage of times an effect must be selected in the initial set of samples to be included in the second round of model averaging. The average model is obtained by averaging the ordinary least squares estimates obtained for each sample. The following statements show how you do this:

```
proc glmselect data=simData seed=3 plots=(ParmDistribution);
 model y=x1-x10/selection=LASSO(adaptive stop=none choose=SBC);
 modelAverage refit(minpct=35 nsamples=1000) alpha=0.1;
run;
```

```
ods graphics off;
```

The NSAMPLES=1000 suboption of the REFIT option specifies that 1,000 samples be used in the refit, and the MINPCT=35 suboption specifies the cutoff for inclusion in the refit. The ALPHA=0.1 option specifies that the fifth and 95th percentiles of the estimates be displayed. [Output 45.5.10](#) shows the effects that are used in performing the refit and the resulting average parameter estimates.

**Output 45.5.10** Refit Average Parameter Estimates

| The GLMSELECT Procedure       |           |           |                              |           |          |
|-------------------------------|-----------|-----------|------------------------------|-----------|----------|
| Refit Model Averaging Results |           |           |                              |           |          |
| Effects: Intercept x1 x2 x5   |           |           |                              |           |          |
| Average Parameter Estimates   |           |           |                              |           |          |
| Parameter                     | Mean      | Standard  | -----Estimate Quantiles----- |           |          |
|                               | Estimate  | Deviation | 5%                           | Median    | 95%      |
| Intercept                     | -0.243514 | 0.315207  | -0.762462                    | -0.230630 | 0.271510 |
| x1                            | 3.226252  | 0.299443  | 2.737843                     | 3.226758  | 3.708131 |
| x2                            | 1.453584  | 0.308062  | 0.947059                     | 1.454635  | 1.968231 |
| x5                            | 2.226044  | 0.345185  | 1.627491                     | 2.228189  | 2.780034 |

[Output 45.5.11](#) displays the distributions of the estimates that are obtained for each parameter in the refit model. Because the distributions are approximately normal and a large number of samples are used, it is reasonable to interpret the range between the fifth and 95th percentiles of each estimate as an approximate 90% confidence interval for that estimate.

**Output 45.5.11** Effect Selection Percentages

## Overview: HPMIXED Procedure

The HPMIXED procedure uses a number of specialized high-performance techniques to fit linear mixed models with variance component structure. The HPMIXED procedure is specifically designed to cope with estimation problems involving a large number of fixed effects, a large number of random effects, or a large number of observations.

The HPMIXED procedure complements the MIXED procedure and other SAS/STAT procedures for mixed modeling. On the one hand, the models supported by the HPMIXED procedure are a subset of the models that you can fit with the MIXED procedure, and the confirmatory inferences available in the HPMIXED procedure are also a subset of the general analyses available with the MIXED procedure. On the other hand, the HPMIXED procedure can have considerably better performance than other SAS/STAT mixed modeling tools, in terms of memory requirements and computational speed.

A mixed model can be large in a number of ways, not all of which are suited for the specialized algorithms and storage techniques implemented in the HPMIXED procedure. The following are examples of linear mixed modeling problems for which the HPMIXED procedure has been specifically designed:

- linear mixed models with thousands of levels for the fixed and/or random effects
- linear mixed models with hierarchically nested fixed and/or random effects, possibly with hundreds or thousands of levels at each level of the hierarchy

---

## Basic Features

The HPMIXED procedure enables you to specify a linear mixed model with variance component structure, to estimate the covariance parameters by restricted maximum likelihood, and to perform confirmatory inference in such models. The HPMIXED procedure fits the specified linear mixed model and produces appropriate statistics.

The following are some of the basic features of the HPMIXED procedure:

- capacity to handle large linear mixed model problems for balanced or unbalanced data
- MIXED-type **MODEL** and **RANDOM** statements for model specification and **CONTRAST**, **ESTIMATE**, **LSMEANS**, and **TEST** statements for inferences
- estimate covariance parameters by restricted maximum likelihood (REML)
- output statistics by using the **OUTPUT** statement

- computation of appropriate standard errors for all specified estimable linear combinations of fixed and random effects, and corresponding  $t$  and  $F$  tests
- subject and group effects that enable blocking and heterogeneity, respectively
- **NLOPTIONS** statement, which enables you to exercise control over the numerical optimization

The HPMIXED procedure uses the Output Delivery System (ODS), a SAS subsystem that provides capabilities for displaying and controlling the output from SAS procedures. ODS enables you to convert any of the output from the HPMIXED procedure into a SAS data set. See the section “ODS Table Names” on page 3699 and Chapter 20, “Using the Output Delivery System,” for further information about using ODS with the HPMIXED procedure.

---

## Assumptions and Notation

The linear mixed models fit by the HPMIXED procedure can be represented as linear statistical models in the following form:

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$$

$$\boldsymbol{\gamma} \sim N(\mathbf{0}, \mathbf{G})$$

$$\boldsymbol{\epsilon} \sim N(\mathbf{0}, \sigma^2\mathbf{I})$$

$$\text{Cov}[\boldsymbol{\gamma}, \boldsymbol{\epsilon}] = \mathbf{0}$$

The symbols in these expressions denote the following:

- $\mathbf{y}$  the  $(n \times 1)$  vector of responses
- $\mathbf{X}$  the  $(n \times k)$  design matrix for the fixed effects
- $\boldsymbol{\beta}$  the  $(k \times 1)$  vector of fixed-effects parameters
- $\mathbf{Z}$  the  $(n \times q)$  design matrix for the random effects
- $\boldsymbol{\gamma}$  the  $(q \times 1)$  vector of random effects
- $\boldsymbol{\epsilon}$  the  $(n \times 1)$  vector of unobservable residual errors

As is customary for statistical models in the linear mixed model family, the random effects are assumed normally distributed. The same holds for the residual errors and these are furthermore distributed independently of the random effects. As a consequence, these assumptions imply that the response vector  $\mathbf{y}$  has a multivariate normal distribution.

Further assumptions, implicit in the preceding expression, are as follows:

- The conditional mean of the data—given the random effects—is linear in the fixed effects and the random effects.
- The marginal mean of the data is linear in the fixed-effects parameters.

## Computational Approach

The computational methods to efficiently solve large mixed model problems with the HPMIXED procedure rely on a combination of several techniques, including sparse matrix storage, specialized solving of sparse linear systems, and dedicated nonlinear optimization.

### Sparse Storage and Computation

One of the fundamental computational tasks in analyzing a linear mixed model is solving the mixed model equations

$$\begin{bmatrix} \mathbf{X}'\mathbf{X} & \mathbf{X}'\mathbf{Z} \\ \mathbf{Z}'\mathbf{X} & \mathbf{Z}'\mathbf{Z} + \sigma^2\mathbf{G}^{-1} \end{bmatrix} \begin{bmatrix} \boldsymbol{\beta} \\ \boldsymbol{\gamma} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\mathbf{y} \\ \mathbf{Z}'\mathbf{y} \end{bmatrix}$$

where  $\mathbf{G}$  denotes the variance matrix of the random effects. The mixed model crossproduct matrix

$$\begin{bmatrix} \mathbf{X}'\mathbf{X} & \mathbf{X}'\mathbf{Z} \\ \mathbf{Z}'\mathbf{X} & \mathbf{Z}'\mathbf{Z} + \sigma^2\mathbf{G}^{-1} \end{bmatrix}$$

is a key component of these equations, and it often has many zero values (George and Liu 1981). Sparse storage techniques can result in significant savings in both memory and CPU resources. The HPMIXED procedure draws on sparse matrix representation and storage where appropriate or necessary.

### Conjugate Gradient Algorithm and Iteration-on-Data Technology

Solving the mixed model equations is a critical component of linear mixed model analysis. The two main components of the preconditioned conjugate gradient (PCCG) algorithm are preconditioning and matrix-vector product computing (Shewchuk 1994). The algorithm is guaranteed to converge to the solution within  $n_e$  iterations, where  $n_e$  is equal to the number of distinct eigenvalues of the mixed model equations. This simple yet powerful algorithm can be easily implemented with an iteration-on-data (IOD) technique (Tsuruta, Misztal, and Strandén 2001) that can yield significant savings of memory resources.

The combination of the PCCG algorithm and iteration on data makes it possible to efficiently compute best linear unbiased predictors (BLUPs) for the random effects in mixed models with large mixed model equations.

### Average Information Algorithm

The HPMIXED procedure estimates covariance parameters by restricted maximum likelihood. The default optimization method is a quasi-Newton algorithm. When the Hessian or information matrix is required, the HPMIXED procedure takes advantage of the computational simplifications that are available by *averaging information* (AI). The AI algorithm (Johnson and Thompson 1995; Gilmour, Thompson, and Cullis 1995) replaces the second derivative matrix with the average of the observed and expected information matrices. The computationally intensive trace terms in these information matrices cancel upon averaging. Coarsely, the AI algorithm can be viewed as a hybrid of a Newton-Raphson approach and Fisher scoring.

---

## The HPMIXED Procedure Contrasted with the MIXED Procedure

The HPMIXED procedure is designed to solve large mixed model problems by using sparse matrix techniques. A mixed model can be large in many ways: a large number of observations, a large number of columns in the  $\mathbf{X}$  matrix, a large number of columns in the  $\mathbf{Z}$  matrix, and a large number of covariance parameters. The aim of the HPMIXED procedure is parameter estimation, inference, and prediction in linear mixed models with large  $\mathbf{X}$  and/or  $\mathbf{Z}$  matrices and many observations, but with relatively few covariance parameters.

The models that you can fit with the HPMIXED procedure and the available postprocessing analyses are a subset of the models and analyses available with the MIXED procedure. With the HPMIXED procedure you can model only G-side random effects with variance component structure or an unstructured covariance matrix in a Cholesky parameterization. R-side random effects and direct modeling of their covariance structures are not supported.

The MIXED and HPMIXED procedures offer different balances for computing performance and statistical generality. To some extent the generality of the MIXED procedure means that it cannot serve as a high-performance computing tool for all of the model-data scenarios that it can potentially handle. For example, although efficient sparse algorithms are available to estimate variance components in large linear mixed models, the computational configuration changes profoundly when, for example, Kenward-Roger degree-of-freedom adjustments are requested.

On the other hand, the HPMIXED procedure can handle only a small subset of the models that PROC MIXED can fit. Invariably, some features of high-performance sparse computing methods might be surprising at first. For example, the best computational path depends on the model and the data, so that in models with a singular  $\mathbf{X}'\mathbf{X}$  matrix, the order in which singularities are detected and accounted for can change from one data set to the next.

The following is a list of features available in the MIXED procedure, but *not* available in the HPMIXED procedure:

- a variety of covariance structures by using the TYPE= option in the RANDOM statement
- automatic Type III tests of fixed effects. You request tests of fixed effects in the HPMIXED procedure with the TEST statement.
- ODS statistical graphics
- advanced degree-of-freedom adjustments available by using the DDFM= option
- maximum likelihood or method-of-moments estimation for the covariance parameters
- a PRIOR statement for a sampling-based Bayesian analysis

## Getting Started: HPMIXED Procedure

### Mixed Model with Large Number of Fixed and Random Effects

In animal breeding, it is common to model genetic and environmental effects with a random effect for the animal. When there are many animals being studied, this can lead to very large mixed model equations to be solved. In this example we present an analysis of simulated data with this structure.

Suppose you have 3000 animals from five different genetic species raised on 100 different farms. The following DATA step simulates 40000 observations of milk yield (Yield) from a linear mixed model with variables Species and Farm in the fixed-effect model and Animal as a random effect. The random effect due to Animal is simulated with a variance of 4.0, while the residual error variance is 8.0. These variance component values reflect the fact that variation in milk yield is typically genetically controlled to be no more than 33% ( $4/(4+8)$ ).

```
data Sim;
 keep Species Farm Animal Yield;
 array AnimalEffect{3000};
 array AnimalFarm{3000};
 array AnimalSpecies{3000};
 do i = 1 to dim(AnimalEffect);
 AnimalEffect{i} = sqrt(4.0)*rannor(12345);
 AnimalFarm{i} = 1 + int(100*ranuni(12345));
 AnimalSpecies{i} = 1 + int(5*ranuni(12345));
 end;
 do i = 1 to 40000;
 Animal = 1 + int(3000*ranuni(12345));
 Species = AnimalSpecies{Animal};
 Farm = AnimalFarm{Animal};
 Yield = 1 + Species + Farm/10 + AnimalEffect{Animal}
 + sqrt(8.0)*rannor(12345);
 output;
 end;
run;
```

A simple linear mixed model analysis is performed by using the following SAS statements:

```
proc hpmixed data=Sim;
 class Species Farm Animal;
 model Yield = Species Species*Farm;
 random Animal;
 test Species*Farm;
 contrast 'Species1 = Species2 = Species3'
 Species 1 0 -1,
 Species 0 1 -1;
run;
```

Selected results from the preceding SAS statements are shown in [Figure 46.1](#) through [Figure 46.4](#).

The “Class Level Information” table in [Figure 46.1](#) shows that the three model effects have 5, 100, and 3000 levels, respectively. Only a portion of the levels are displayed by default. The “Dimensions” table shows

that the model contains a single G-side covariance parameter and a single R-side covariance parameter. R-side covariance parameters are those associated with the covariance matrix  $\mathbf{R}$  in the conditional distribution, given the random effects. In the case of the HPMIXED procedure this matrix is simply  $\mathbf{R} = \sigma^2\mathbf{I}$  and the single R-side covariance parameter corresponds to the residual variance. The G-side parameter is the variance of the random Animal effect; the  $\mathbf{G}$  matrix is a diagonal ( $3000 \times 3000$ ) matrix with the common variance on the diagonal.

**Figure 46.1** Class Levels and Dimensions

| The HPMIXED Procedure   |        |                                                           |
|-------------------------|--------|-----------------------------------------------------------|
| Class Level Information |        |                                                           |
| Class                   | Levels | Values                                                    |
| Species                 | 5      | 1 2 3 4 5                                                 |
| Farm                    | 100    | 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18<br>19 20 ... |
| Animal                  | 3000   | 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18<br>19 20 ... |
| Dimensions              |        |                                                           |
| G-side Cov. Parameters  |        | 1                                                         |
| R-side Cov. Parameters  |        | 1                                                         |
| Columns in X            |        | 506                                                       |
| Columns in Z            |        | 3000                                                      |
| Subjects (Blocks in V)  |        | 1                                                         |

Taking into account the intercept as well as the number of levels of the Species and Species\*Farm effects, the  $\mathbf{X}$  matrix for this problem has 506 columns, so that the mixed model equations

$$\begin{bmatrix} \mathbf{X}'\mathbf{X} & \mathbf{X}'\mathbf{Z} \\ \mathbf{Z}'\mathbf{X} & \mathbf{Z}'\mathbf{Z} + \sigma^2\mathbf{G}^{-1} \end{bmatrix} \begin{bmatrix} \boldsymbol{\beta} \\ \boldsymbol{\gamma} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\mathbf{y} \\ \mathbf{Z}'\mathbf{y} \end{bmatrix}$$

have 3506 rows and columns. This is a substantial computational problem: simply storing a single copy of this matrix in dense format requires nearly 50 megabytes of memory. The sparse matrix techniques of PROC HPMIXED use a small fraction of this amount of memory and a similarly small fraction of the CPU time required to solve the equations with dense techniques. For more information about sparse versus dense techniques, see the section “[Sparse Matrix Techniques](#)” on page 3696.

Figure 46.2 displays the covariance parameter estimates at convergence of the REML algorithm. The variance component estimate for animal effect is  $\hat{\sigma}_a^2 = 3.9889$  and for residual  $\hat{\sigma}^2 = 7.9623$ . These estimates are close to the simulated values (4.0 and 8.0).

**Figure 46.2** Estimates of Variance Components

| Covariance Parameter Estimates |          |
|--------------------------------|----------|
| Cov Parm                       | Estimate |
| Animal                         | 3.9889   |
| Residual                       | 7.9623   |

The **TEST** statement requests a Type III test of the fixed effect in the model. By default, the HPMIXED procedure does not compute Type III tests, because they can be computationally demanding. The tests of the **Species\*Farm** effect is highly significant. That indicates animals of a genetic species perform differently in different environments.

**Figure 46.3** Type III Tests of Fixed Effect

| Type III Tests of Fixed Effects |           |           |         |        |
|---------------------------------|-----------|-----------|---------|--------|
| Effect                          | Num<br>DF | Den<br>DF | F Value | Pr > F |
| Species*Farm                    | 495       | 39500     | 11.72   | <.0001 |

You can use the **CONTRAST** or **ESTIMATE** statement to test custom linear hypotheses involving the fixed and/or random effects. The **CONTRAST** statement in the preceding program tests the null hypothesis that there are no differences among the first three genetic species. Results from this analysis are shown in **Figure 46.4**. The small *p*-value indicates that there are significant differences among the first three genetics species.

**Figure 46.4** Result of CONTRAST Statement

| Contrasts                      |           |           |         |        |
|--------------------------------|-----------|-----------|---------|--------|
| Label                          | Num<br>DF | Den<br>DF | F Value | Pr > F |
| Species1 = Species2 = Species3 | 2         | 39500     | 92.93   | <.0001 |

## Syntax: HPMIXED Procedure

The following statements are available in the HPMIXED procedure:

```

PROC HPMIXED < options > ;
 BY variables ;
 CLASS variable < (REF= option) > ... < variable < (REF= option) > > < / global-options > ;
 EFFECT name=effect-type (variables < / options >) ;
 ID variables ;
 MODEL dependent = < fixed-effects > < / options > ;
 RANDOM random-effects < / options > ;
 REPEATED repeated-effect < / options > ;
 PARMS < (value-list) ... > < / options > ;
 TEST fixed-effects < / options > ;
 CONTRAST 'label' contrast-specification < , contrast-specification > < , ... > < / options > ;
 ESTIMATE 'label' contrast-specification < (divisor=n) >
 < , 'label' contrast-specification < (divisor=n) > > < , ... > < / options > ;
 LSMEANS fixed-effects < / options > ;
 NLOPTIONS < options > ;
 OUTPUT < OUT=SAS-data-set >
 < keyword < (keyword-options) > < =name > > ...
 < keyword < (keyword-options) > < =name > > < / options > ;
 WEIGHT variable ;

```

Items within angle brackets ( < > ) are optional. The CONTRAST, ESTIMATE, LSMEANS, RANDOM, and TEST statements can appear multiple times; all other statements can appear only once.

The PROC HPMIXED and MODEL statements are required, and the MODEL statement must appear after the CLASS statement if these statements are included. The BY, CLASS, MODEL, ID, OUTPUT, TEST, RANDOM, REPEATED and WEIGHT statements are described in full after the PROC HPMIXED statement in alphabetical order. The EFFECT, is shared with many other procedures. Summary descriptions of functionality and syntax for this statement is also given after the PROC HPMIXED statement in alphabetical order, but you can find full documentation on it in Chapter 19, “Shared Concepts and Topics.”

Table 46.1 summarizes the basic functions and important options of each PROC HPMIXED statement.

**Table 46.1** Summary of PROC HPMIXED Statements

| Statement    | Description                                                                       | Options                                                             |
|--------------|-----------------------------------------------------------------------------------|---------------------------------------------------------------------|
| PROC HPMIXED | Invokes the procedure                                                             | DATA= specifies input data set, METHOD= specifies estimation method |
| BY           | Performs multiple PROC HPMIXED analyses in one invocation                         | None                                                                |
| CLASS        | Declares qualitative variables that create indicator variables in design matrices | None                                                                |

Table 46.1 *continued*

| Statement | Description                                                          | Options                                                                                                                                                                                       |
|-----------|----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID        | Lists additional variables to be included in predicted values tables | None                                                                                                                                                                                          |
| MODEL     | Specifies dependent variable and fixed effects, setting up <b>X</b>  | <b>S</b> requests solution for fixed-effects parameters, <b>DDFM=</b> specifies denominator degrees of freedom method                                                                         |
| RANDOM    | Specifies random effects, setting up <b>Z</b> and <b>G</b>           | <b>SUBJECT=</b> creates block-diagonality, <b>TYPE=</b> specifies covariance structure, <b>S</b> requests solution for random-effects parameters                                              |
| REPEATED  | Sets up <b>R</b>                                                     | <b>SUBJECT=</b> creates block-diagonality, <b>TYPE=</b> specifies covariance structure, <b>R=</b> displays estimated blocks of <b>R</b> , <b>GROUP=</b> enables between-subject heterogeneity |
| PARMS     | Specifies a grid of initial values for the covariance parameters     | <b>HOLD=</b> and <b>NOITER</b> hold the covariance parameters or their ratios constant, <b>PARMS-DATA=</b> reads the initial values from a SAS data set                                       |
| CONTRAST  | Constructs custom hypothesis tests                                   | <b>E</b> displays the <b>L</b> matrix coefficients                                                                                                                                            |
| ESTIMATE  | Constructs custom scalar estimates                                   | <b>CL</b> produces confidence limits                                                                                                                                                          |
| LSMEANS   | Computes least squares means for classification fixed effects        | <b>DIFF</b> computes differences of the least squares means, <b>CL</b> produces confidence limits, <b>SLICE=</b> tests simple effects                                                         |
| WEIGHT    | Specifies a variable by which to weight <b>R</b>                     | None                                                                                                                                                                                          |

## PROC HPMIXED Statement

**PROC HPMIXED** < options > ;

The PROC HPMIXED statement invokes the HPMIXED procedure. Table 46.2 summarizes the options available in the PROC HPMIXED statement. These and other options in the PROC HPMIXED statement are then described fully in alphabetical order.

Table 46.2 PROC HPMIXED Statement Options

| Option               | Description                                         |
|----------------------|-----------------------------------------------------|
| <b>Basic Options</b> |                                                     |
| <b>DATA=</b>         | Specifies input data set                            |
| <b>METHOD=</b>       | Specifies the estimation method                     |
| <b>NOPROFILE</b>     | Includes scale parameter in optimization            |
| <b>ORDER=</b>        | Determines the sort order of <b>CLASS</b> variables |

Table 46.2 *continued*

| Option                        | Description                                                   |
|-------------------------------|---------------------------------------------------------------|
| BLUP                          | Computes BLUP/BLUE only                                       |
| <b>Displayed Output</b>       |                                                               |
| IC=                           | Displays a table of information criteria                      |
| ITDETAILS                     | Displays estimates and gradients added to “Iteration History” |
| MAXCLPRINT=                   | Specifies the maximum levels of CLASS variables to print      |
| LOGNOTE                       | Writes periodic status notes to the log                       |
| MMEQ                          | Displays mixed model equations                                |
| NOCLPRINT                     | Suppresses “Class Level Information” completely or in parts   |
| NOITPRINT                     | Suppresses “Iteration History” table                          |
| SIMPLE                        | Displays “Descriptive Statistics” table                       |
| <b>Singularity Tolerances</b> |                                                               |
| SINGCHOL=                     | Tunes singularity for Cholesky decompositions                 |
| SINGRES=                      | Tunes singularity for the residual variance                   |
| SINGULAR=                     | Tunes general singularity criterion                           |

You can specify the following *options*.

**BLUP**< (*suboptions*) >=*SAS-data-set*

creates a data set that contains the BLUE and BLUP solutions. The covariance parameters are assumed to be known and given by PARMs statement. All hypothesis testing is ignored. The statements TEST, ESTIMATE, CONTRAST, LSMEANS, and OUTPUT are all ignored. This option is designed for users who need BLUP solutions for random effects with many levels, up to tens of millions.

You can specify the following suboptions:

ITPRINT=*number* specifies that the iteration history be displayed after every *number* of iterations. This suboption applies only for iterative solving methods (IOC or IOD). The default value is 10, which means the procedure displays the iteration history for every 10 iterations.

MAXITER=*number* specifies the maximum number of iterations allowed. This applies only for iterative solving methods (IOC or IOD). The default value is the number of parameters in the BLUE/BLUP plus two.

METHOD=DIRECT|IOC|IOD specifies the method used to solve for BLUP solutions. METHOD=DIRECT requires storing mixed model equations (MMEQ) in memory and computing the Cholesky decomposition of MMEQ. This method is the most accurate, but it is the most inefficient in terms of speed and memory. METHOD=IOD does not build mixed model equations; instead it iterates on data to solve for the solutions. This method is most efficient in terms of memory. METHOD=IOC requires storing mixed model equations in memory and iterates on MMEQ to solve for the solutions. This method is the most efficient in terms of speed. The default method is IOC.

TOL=*number* specifies the tolerance value. This suboption applies only for iterative solving methods (IOC or IOD). The default value is the square root of machine precision.

**DATA=SAS-data-set**

names the SAS data set to be used by PROC HPMIXED. The default is the most recently created data set.

**INFOCRIT=NONE | PQ | Q****IC=NONE | PQ | Q**

determines the computation of information criteria in the “Fit Statistics” table. The criteria are all in smaller-is-better form, and are described in Table 46.3.

**Table 46.3** Information Criteria

| Criteria | Formula                                                                                       | Reference                                                  |
|----------|-----------------------------------------------------------------------------------------------|------------------------------------------------------------|
| AIC      | $-2\ell + 2d$                                                                                 | Akaike (1974)                                              |
| AICC     | $-2\ell + 2dn^*/(n^* - d - 1)$ for $n^* \geq d + 2$<br>$-2\ell + 2d(d + 2)$ for $n^* < d + 2$ | Hurvich and Tsai (1989) and<br>Burnham and Anderson (1998) |
| HQIC     | $-2\ell + 2d \log(\log(n))$ for $n > 1$                                                       | Hannan and Quinn (1979)                                    |
| BIC      | $-2\ell + d \log(n)$ for $n > 0$                                                              | Schwarz (1978)                                             |
| CAIC     | $-2\ell + d(\log(n) + 1)$ for $n > 0$                                                         | Bozdogan (1987)                                            |

Here  $\ell$  denotes the maximum value of the restricted log likelihood,  $d$  is the dimension of the model, and  $n, n^*$  reflect the size of the data. When  $n \leq 1$ , the value of the HQIC criterion is  $-2\ell$ . When  $n=0$ , the values of the BIC and CAIC criteria are undefined.

The quantities  $d, n$ , and  $n^*$  depend on the model and IC= option.

- models without random effects:
  - The IC=Q and IC=PQ options have no effect on the computation.
  - $d$  equals the number of parameters in the optimization whose solutions do not fall on the boundary or are otherwise constrained.
  - $n$  equals the number of used observations minus  $\text{rank}(\mathbf{X})$ .
  - $n^*$  equals  $n$ , unless  $n < d + 2$ , in which case  $n^* = d + 2$ .
- models with random effects:
  - $d$  equals the number of parameters in the optimization whose solutions do not fall on the boundary or are otherwise constrained. If IC=PQ, this value is incremented by  $\text{rank}(\mathbf{X})$ .
  - $n$  equals the effective number of subjects as displayed in the “Dimensions” table, unless this value equals 1, in which case  $n$  equals the number of levels of the first random effect specified. The IC=Q and IC=PQ options have no effect.
  - $n^*$  equals  $n$ , unless  $n < d + 2$ , in which case  $n^* = d + 2$ . The IC=Q and IC=PQ options have no effect.

The IC=NONE option suppresses the “Fit Statistics” table. IC=Q is the default.

**ITDETAILS**

displays the parameter values at each iteration and enables the writing of notes to the SAS log pertaining to “infinite likelihood” and “singularities” during optimization iterations.

**LOGNOTE**

writes to the log periodic notes that describe the current status of computations. This option is designed for use with analyses that require extensive CPU resources.

**MAXCLPRINT=number**

specifies the maximum levels of CLASS variables to print in the ODS table “ClassLevels.” The default value is 20. MAXCLPRINT=0 enables you to print all levels of each CLASS variable. However, the option **NOCLPRINT** takes precedence over MAXCLPRINT.

**METHOD=**

specifies the estimation method for the covariance parameters. The REML specification performs residual (restricted) maximum likelihood, and it is currently the only available method. This option is therefore currently redundant for PROC HPMIXED, but it is included for consistency with other mixed model procedures in SAS/STAT software.

**MMEQ**

displays coefficients of the mixed model equations. These are

$$\begin{bmatrix} \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{Z} \\ \mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{Z} + \widehat{\mathbf{G}}^{-1} \end{bmatrix} \begin{bmatrix} \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{y} \\ \mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{y} \end{bmatrix}$$

assuming  $\widehat{\mathbf{G}}$  is nonsingular. If  $\widehat{\mathbf{G}}$  is singular, PROC HPMIXED produces the following coefficients

$$\begin{bmatrix} \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{Z}\widehat{\mathbf{G}} \\ \widehat{\mathbf{G}}\mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{X} & \widehat{\mathbf{G}}\mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{Z}\widehat{\mathbf{G}} + \widehat{\mathbf{G}} \end{bmatrix} \begin{bmatrix} \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{y} \\ \widehat{\mathbf{G}}\mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{y} \end{bmatrix}$$

See the section “Model and Assumptions” on page 3693 for further information about these equations.

**NAMELEN=number**

specifies the length to which long effect names are shortened. The default and minimum value is 20.

**NLPRINT**

requests that optimization-related output options specified in the NLOPTIONS statement override corresponding options in the PROC HPMIXED statement. When you specify NLPRINT, the ITDE-  
TAILS and NOITPRINT options in the PROC HPMIXED statement are ignored and the following six options in the NLOPTIONS statement are enabled: NOPRINT, PHISTORY, PSUMMARY, PALL, PLONG, and PHISTPARMS.

The syntax and options of the NLOPTIONS statement are described in the section “NLOPTIONS Statement” on page 482 in Chapter 19, “Shared Concepts and Topics.”

**NOCLPRINT<=number>**

suppresses the display of the “Class Level Information” table if you do not specify *number*. If you do specify *number*, only levels with totals that are less than *number* are listed in the table.

**NOFIT**

suppresses fitting of the model. When the NOFIT option is in effect, PROC HPMIXED produces the “Model Information,” “Class Level Information,” “Number of Observations,” “Dimensions,” and “Descriptive Statistics” tables. These can be helpful in gauging the computational effort required to fit the model.

**NOINFO**

suppresses the display of the “Model Information,” “Number of Observations,” and “Dimensions” tables.

**NOITPRINT**

suppresses the display of the “Iteration History” table.

**NOPRINT**

suppresses the normal display of results. The NOPRINT option is useful when you want only to create one or more output data sets with the procedure by using the **OUTPUT** statement. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “Using the Output Delivery System,” for more information.

**NOPROFILE**

includes the residual variance as one of the covariance parameters in the optimization iterations. This option applies only to models that have a residual variance parameter. By default, this parameter is profiled out of the optimization iterations, except when you have specified the **HOLD=** option in the **PARMS** statement.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of the classification variables (which are specified in the **CLASS** statement). This option applies to the levels for all classification variables, except when you use the (default) **ORDER=FORMATTED** option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The **ORDER=** option can take the following values:

| Value of <b>ORDER=</b> | Levels Sorted By                                                                                                                       |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DATA</b>            | Order of appearance in the input data set                                                                                              |
| <b>FORMATTED</b>       | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| <b>FREQ</b>            | Descending frequency count; levels with the most observations come first in the order                                                  |
| <b>INTERNAL</b>        | Unformatted value                                                                                                                      |

By default, **ORDER=FORMATTED**. For **ORDER=FORMATTED** and **ORDER=INTERNAL**, the sort order is machine-dependent. For more information about sort order, see the chapter on the **SORT** procedure in the *Base SAS Procedures Guide* and the discussion of **BY**-group processing in *SAS Language Reference: Concepts*.

**SIMPLE**

displays the mean, standard deviation, coefficient of variation, minimum, and maximum for each variable used in **PROC HPMIXED** that is not a classification variable.

**SINGCHOL=number**

tunes the singularity criterion in Cholesky decompositions. The default is 1E6 times the machine epsilon; this product is approximately 1E–10 on most computers.

**SINGRES=number**

sets the tolerance for which the residual variance is considered to be zero. The default is 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

**SINGULAR=number**

tunes the general singularity criterion applied by the HPMIXED procedure in divisions and inversions. The default is 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

**UPDATE**

is an alias for the [LOGNOTE](#) option.

## BY Statement

**BY variables ;**

You can specify a BY statement with PROC HPMIXED to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the HPMIXED procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

Since sorting the data changes the order in which PROC HPMIXED reads observations, the sort order for the levels of the [CLASS](#) variable might be affected if you have specified [ORDER=DATA](#) in the [PROC HPMIXED](#) statement. This, in turn, affects specifications in the [CONTRAST](#) and [ESTIMATE](#) statements.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

## CLASS Statement

**CLASS** *variable* <(REF= option)> ... <*variable* <(REF= option)>> </global-options> ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

**NOTE:** Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the ORDER= option in the PROC HPMIXED statement.

You can specify the following REF= option to indicate how the levels of an individual classification variable are to be ordered by enclosing it in parentheses after the variable name:

**REF= 'level' | FIRST | LAST**

specifies a level of the classification variable to be put at the end of the list of levels. (In procedures that solve mixed model equations by sequentially sweeping rows and columns, this level thus corresponds to the reference level in the usual interpretation of the estimates of a singular parameterization. However, since PROC HPMIXED does not necessarily solve mixed model equations in the original order, this interpretation of the specified REF= level does not apply for this procedure.) You can specify the *level* of the variable to use as the reference level; specify a value that corresponds to the formatted value of the variable if a format is assigned. Alternatively, you can specify REF=FIRST to designate that the first ordered level serve as the reference, or REF=LAST to designate that the last ordered level serve as the reference. To specify that REF=FIRST or REF=LAST be used for all classification variables, use the REF= *global-option* after the slash (/) in the CLASS statement.

You can specify the following *global-options* in the CLASS statement after a slash (/):

**REF=FIRST | LAST**

specifies a level of all classification variables to be put at the end of the list of levels. (In procedures that solve mixed model equations by sequentially sweeping rows and columns, this level thus corresponds to the reference level in the usual interpretation of the estimates of a singular parameterization. However, since PROC HPMIXED does not necessarily solve mixed model equations in the original order, this interpretation of the specified REF= level does not apply for this procedure.) Specify REF=FIRST to designate that the first ordered level for each classification variable serve as the reference. Specify REF=LAST to designate that the last ordered level serve as the reference. This option applies to all the variables specified in the CLASS statement. To specify different reference levels for different classification variables, use REF= options for individual variables.

**TRUNCATE**

specifies that class levels be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

## CONTRAST Statement

**CONTRAST** *label* *contrast-specification* < , *contrast-specification* > < , ... > < / *options* > ;

The CONTRAST statement provides a mechanism for obtaining custom hypothesis tests. It is patterned after the CONTRAST statement in PROC MIXED and enables you to select an appropriate inference space (McLean, Sanders, and Stroup 1991).

You can test the hypothesis  $\mathbf{L}'\boldsymbol{\phi} = \mathbf{0}$ , where  $\mathbf{L}' = [\mathbf{K}' \mathbf{M}']$  and  $\boldsymbol{\phi}' = [\boldsymbol{\beta}' \boldsymbol{\gamma}']$ , in several inference spaces. The inference space corresponds to the choice of  $\mathbf{M}$ . When  $\mathbf{M} = \mathbf{0}$ , your inferences apply to the entire population from which the random effects are sampled; this is known as the *broad* inference space. When all elements of  $\mathbf{M}$  are nonzero, your inferences apply only to the observed levels of the random effects. This is known as the *narrow* inference space, and you can also choose it by specifying all of the random effects as fixed. The GLM procedure uses the narrow inference space. Finally, by zeroing portions of  $\mathbf{M}$  corresponding to selected main effects and interactions, you can choose *intermediate* inference spaces. The broad inference space is usually the most appropriate, and it is used when you do not specify any random effects in the CONTRAST statement.

In the CONTRAST statement,

|                               |                                                                                                                                                                                                                                                 |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>label</i>                  | identifies the contrast in the table. A label is required for every contrast specified. Labels can be up to 20 characters and must be enclosed in single quotes.                                                                                |
| <i>contrast-specification</i> | identifies the fixed effects and random effects and their coefficients from which the $\mathbf{L}$ matrix is formed. The syntax representation of a <i>contrast-specification</i> is < fixed-effect values ... > <   random-effect values ... > |
| <i>fixed-effect</i>           | identifies an effect that appears in the <b>MODEL</b> statement. The keyword INTERCEPT can be used as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the <b>MODEL</b> statement.        |
| <i>random-effect</i>          | identifies an effect that appears in the <b>RANDOM</b> statement. The first random effect must follow a vertical bar ( ); however, random effects do not have to be specified.                                                                  |
| <i>values</i>                 | are constants that are elements of the $\mathbf{L}$ matrix associated with the fixed and random effects.                                                                                                                                        |

The rows of  $\mathbf{L}'$  are specified in order and are separated by commas. The rows of the  $\mathbf{K}'$  component of  $\mathbf{L}'$  are specified on the left side of the vertical bars (|). These rows test the fixed effects and are, therefore, checked for estimability. The rows of the  $\mathbf{M}'$  component of  $\mathbf{L}'$  are specified on the right side of the vertical bars. They test the random effects, and no estimability checking is necessary.

If PROC HP MIXED finds the fixed-effects portion of the specified contrast to be nonestimable (see the **SINGULAR=** option on page 3671), then it displays missing values for the test statistics and a note in the log.

If the elements of  $\mathbf{L}$  are not specified for an effect that contains a specified effect, then the elements of the specified effect are automatically “filled in” over the levels of the higher-order effect. This feature is designed to preserve estimability for cases where there are complex higher-order effects. The coefficients for the higher-order effect are determined by equitably distributing the coefficients of the lower-level effect as in the construction of least squares means. In addition, if the intercept is specified, it is distributed over all classification effects that are not contained by any other specified effect. If an effect is not specified and

does not contain any specified effects, then all of its coefficients in **L** are set to 0. You can override this behavior by specifying coefficients for the higher-order effect.
